PDLy (y=0-5)	5*y+4:5*y	rw	**Payload Data Length** PDL determines the number of data bits per frame that the PSI5 channel x is setup for in slot y. PDL does not include the start bits and the Parity/CRC bits. PDL includes the Messaging bits, the Frame Control bits and the Status bits. 00_H 0 bit data 01_H 1 bit data 02_H 2 bit data 03_H 3 bit data … $1C_H$ 28 bit data $1D_H$ 0 bit data … $1F_H$ 0 bit data

Field	Bits	Type	Description
ASYN	30	rw	**Asynchronous Mode** If set, • the watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled • If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0 • Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. • No Sync Pulses generated, TX path is inactive 0_B off (default) 1_B on
AVBS	31	rw	**Verbose Mode for Asynchronous Mode** If set, and ASYN is set and WDL0 is > 0 an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watch dog timer for the PSI5 channel x without reception of a frame. 0_B off (default) 1_B on

Receiver Control Register B x

The Receiver Control Registers RCRBx contains control bits/bit fields that are related to the PSI5 receiver operation. It configures up to 6 frame types in the up to 6 slots.

RCRBx (x=0-3)
Receiver Control Register B x **(038_H+x*90_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SD	15:0	r	**Serial Data** of last serial data frame on channel x slot z. SD0 is on bit position 0. If SDS.CON is not set, bits [15:12] are zero.
MID	23:16	r	**Message ID** of last serial data frame. ID0 is on bit position 16. If SDS.CON is set, bits [23:20] are zero.
SCRC	29:24	r	**SCRC** CRC of last serial data frame. CRC0 is on position 24.

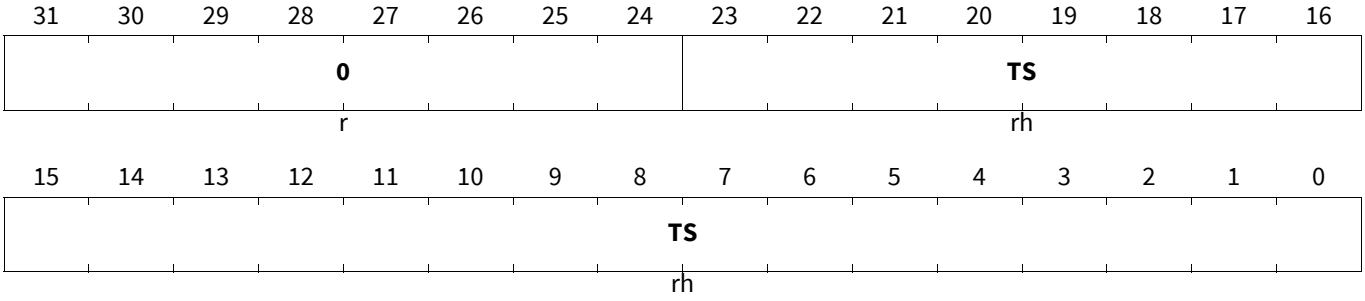
Field	Bits	Type	Description
SCRI	30	r	**CRC of Serial Message failed Interrupt Flag.** This bit is set if the CRC of the serial message fails. This includes a check of the Messaging bit field for correct 0 values of bit 1 in frames 7, 13 and 18. See INTSTATx.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID

Start of Pulse Time Stamp Capture Register x

Each time a sync pulse is sent on channel x, the time stamp is captured in this register. RCRC.TSP selects, if TSRA, B or C is used. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SPTSCx (x=0-3)

Start of Pulse Time Stamp Capture Register x(078_H+x*90_H) **Application Reset Value: 0000 0000_H**



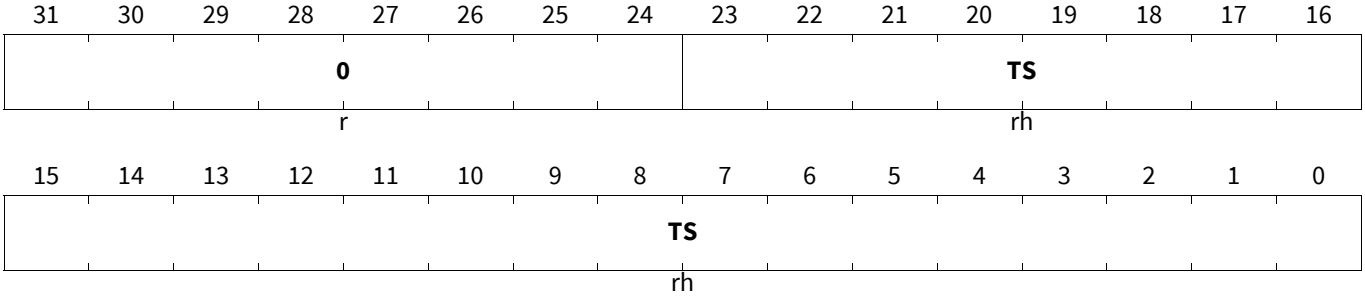
Field	Bits	Type	Description
TS	23:0	rh	**Time Stamp** of the last sync pulse sent on channel x. The Time Stamp is taken at the rising edge of the pulse.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

Start of Frame Time Stamp Capture Register x

Each time a start of frame is received on channel x, the time stamp is captured in this register. The first rising edge of the first start bit is captured. Note that a preceding “Idle Time” is required for start bit detection. In case the two start bits should not be received successfully (i.e. without manchester coding errors) the frame is completely dropped and the latest captured value is overwritten with the next SOF or at the referring WDLy for “empty messages” if configured in RCRBx.VBSy. RCRC.TSF selects, if TSRA, B or C is used. RCRCx.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SFTSCx (x=0-3)

Start of Frame Time Stamp Capture Register x($07C_H$+x*90_H) **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TS	23:0	rh	**Time Stamp** of the last frame received on channel x. The Time Stamp is taken at the rising edge of the first start bit S1 that was qualified by the receiver.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

Receive Data Register Low x

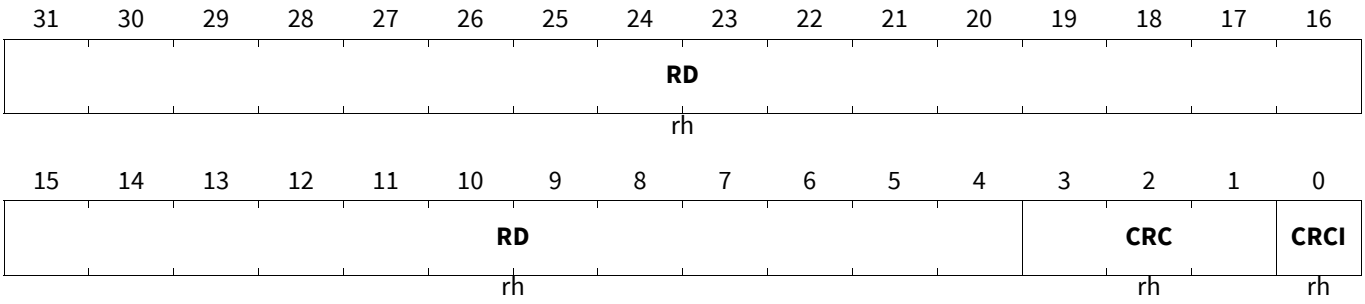
The Receive Data Register RDRLx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

The bit CRCI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRLx (x=0-3)

Receive Data Register Low x **(080_H+x*90_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CRCI	0	rh	**CRC Error Flag** This bit is set if the CRC or Parity check fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) 0_B correct CRC/Parity 1_B wrong CRC/Parity

Field	Bits	Type	Description
CRC	3:1	rh	**CRC** CRC/parity bit of last PSI5 frame. CRC0 or Parity bit is on bit position 1. In case of NFI, this field is cleared.
RD	31:4	rh	**RD** Receive data of last PSI5 frame. D0 is on bit position 4. In case of NFI, this field is cleared.

Receive Data Register High x

The Receive Data Register RDRHx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

The bits RBI, RMI, RSI, NBI and TEI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRHx (x=0-3)

Receive Data Register High x **(084_H+x*90_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RBI	**NFI**	**MEI**	**NBI**	**TEI**	**SC**			**TS**							
rh	rh	rh	rh	rh		rh		rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS															
rh															

Field	Bits	Type	Description
TS	23:0	rh	**Time Stamp** of the last received PSI5 frame. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx. (It can be selected if the time stamp of the last sync pulse is stored or the time stamp for the start of frame).
SC	26:24	rh	**Slot Counter** In Synchronous Mode (RCRAx.ASYN=0): Number of the slot the SOF of the frame was received in. In Asynchronous Mode (RCRAx.ASYN=1): revolving frame number between 1 and 6. 000_B not valid (SOF too early) 001_B Slot 1 … 110_B Slot 6 111_B not valid

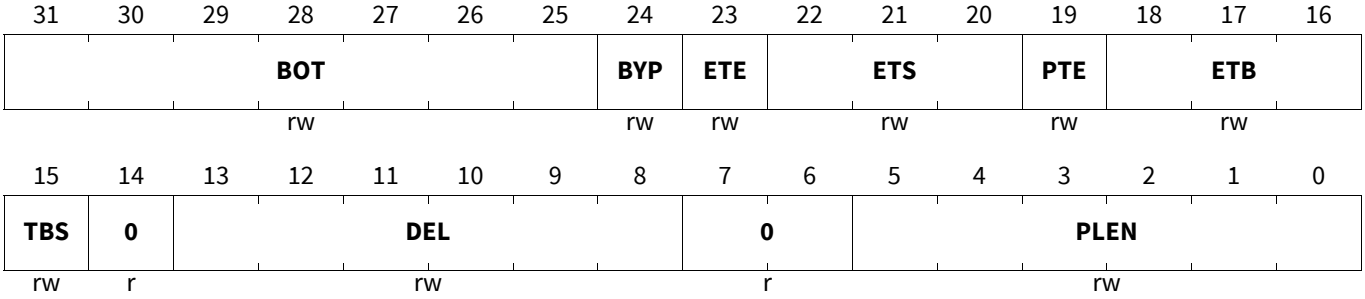
Field	Bits	Type	Description
TEI	27	rh	**Time Slot Error Flag** In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy). In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. 0_B no error 1_B error
NBI	28	rh	**Number of bits Error Flag** This bit is set if the last frame received less bits than expected but no manchester coding error occurred until S1, S2, M0 and M1 where received. Note that the frame after the error might be completely wrong. 0_B all bits received 1_B not all bits received
MEI	29	rh	**Error in Message Bits Flag** This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG) Note that the frame after the error might be completely wrong. 0_B frame is correct 1_B frame is not correct
NFI	30	rh	**No Frame Received Flag** This bit is set when the NFI condition as described in the first paragraph of INTSTATA.NFI occurs. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If RCRBx.VBS is set, an empty frame is stored anyhow and RDIx is issued as well. The content of RDRL/Hx / RDML/Hx is valid for SC and for this bit (NFI). Bit fields RD and CRC are cleared (all zero). If RCRC.VBSx is 0 then TS is cleared. If RCRC.VBSx is 1 then TS is set to either SPTSCx.TS or SFTSCx.TS depending on the value of RCRC.TSR. 0_B no error 1_B error
RBI	31	rh	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow

Pulse Generation Control Register x

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

PGCx (x=0-3)

Pulse Generation Control Register x **(088_H+x*90_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PLEN	5:0	rw	**Pulse Length** Defines the length of the pulse in TTS times (defined by FDRT). This is the standard pulse width without data coding into the pulse width or for coding a ‘0’. 00_H Pulse length is 0 TTS 01_H Pulse length is 1 TTS … $3F_H$ Pulse length is 63 TTS
DEL	13:8	rw	**Delay Length** In case data is coded into the pulse length, this defines the ADDITONAL length of the pulse in TTS times. The resulting sum length is the pulse width for coding a ‘1’ into the pulse width. 00_H Pulse length is 0 TTS 01_H Pulse length is 1 TTS … $3F_H$ Pulse length is 63 TTS
TBS	15	rw	**Time Base Select** This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{GTM}
ETB	18:16	rw	**External Time Base Select** Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
PTE	19	rw	**Periodic Trigger Enable** Periodic trigger is defined by CTVx. Should be 0 if ETE or BYP is set. 0_B disabled 1_B enabled

Field	Bits	Type	Description
ETS	22:20	rw	**External Trigger Select** Selects the external trigger line for pulse generation (e.g. angle synchronous). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
ETE	23	rw	**External Trigger Enable** “Angle sync. trigger”, external line is selected by ETS. Should be 0 if PTE or BYP is set. 0_B disabled 1_B enabled
BYP	24	rw	**Bypass Enable** An external signal, selected by ETS directly drives the output of channel x. Should be 0 if PTE or ETE is set. 0_B disabled 1_B enabled
BOT	31:25	rw	**Blank Out Time** BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver. 00_H Blank Out Time is 0 TTS 01_H Blank Out Time is 1 TTS … $7F_H$ Blank Out Time is 127 TTS
0	7:6, 14	r	**Reserved** Read as 0; should be written with 0.

Channel Trigger Value Register x

The Channel Trigger Value Register x contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

CTVx (x=0-3)

Channel Trigger Value Register x **($08C_H$+x*90_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CTC															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTV															
rw															

Field	Bits	Type	Description
CTV	15:0	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse is generated.
CTC	31:16	rwh	**Channel Trigger Counter** This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Send Control Register x

The Send Control Register SCR contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

SCRx (x=0-3)
Send Control Register x **(090_H+x*90_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TRQ	**0**		**TOF**	**TSF**	**TPF**	**GO**	**INH**	**STA**	**CRC**	**SOL**					
r	r		r	r	r	w	rw	rw	rw	rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLUO	**FLUS**	**SSL**						**BSC**	**EPS**	**PLL**					
w	w	rw						rw	rw	rw					

Field	Bits	Type	Description
PLL	5:0	rw	**Pay Load Length of Registers SDRL/H** If PLL > 31, SDRH needs to be written to trigger the HW for automatic STA, BSC or CRC generation or just moving data to SSRL/H. Else writing to SDRL is sufficient. PLL needs to written before SDRL/H is used for proper operation. If insertion of STA, BSC and CRC results in more than 64 bits, the MSBs are truncated in SSR. Defines the length that is taken into account: 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
EPS	6	rw	**Enhanced Protocol Selection** 0_B PSI5 V1.3. No Pulse length extension 1_B Enhanced Protocol with Pulse length extension.

Field	Bits	Type	Description
BSC	7	rw	**Bit Stuffing Control** Depending from bit EPS after 3 bits a '1' is inserted (V1.3) or after 6 bits a '0' is inserted (enhanced Power Train Mode) Note that this makes the frame longer. 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled.
SSL	13:8	rw	**Pay Load Length of Registers SSRL/H** If SSL > 31, SSRH needs to be written to trigger the HW for automatic moving data to SORL/H. Else writing to SSRL is sufficient. SSL needs to be written before SSRL/H is used for proper operation. Defines the length that is taken into account. Start Sequence, BSC and CRC need to be added to PLL by SW if SSL is calculated based on PLL. 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
FLUS	14	w	**Flush SSRH/Lx** Setting this bit stops the shifting process and flushes (clears) SSRH/Lx and TSF. TPIx is issued at the end of successful flushing. Reads always as zero.
FLUO	15	w	**Flush SORH/Lx** Setting this bit stops the sending process and flushes (clears) SORH/Lx and TOF. TSIx is issued at the end of successful flushing. Reads always as zero.
SOL	21:16	rw	**Pay Load Length of Registers SORL/H** If SOL > 31, SORH needs to be written to trigger the HW for automatic moving data to the pulse generator. Else writing to SORL is sufficient. SOL needs to written before SORL/H is used for proper operation. Defines the length that is taken into account. Start Sequence, CRC and Stuffing needs to be added by SW to PLL if SOL is calculated based on PLL. 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically. 1_B CRC is automatically generated and added to the frame by HW (according to EPS). Note that this makes the frame longer. CRC calculation is not performed, if at least 1 CRC bit does not fit into 64 bit, e.g. due to STA or BSC. In this case, one or two zero bits are inserted.

Field	Bits	Type	Description
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, payload starts at bit 0! 1_B automatically generated and added to the frame by HW (according to EPS) payload starts at bit 3/9 (EPS = 0/1). Note that this makes the frame longer.
INH	24	rw	**Inhibit Transfer** This inhibits the automatic transfer from the shift registers SSRL/H to SORL/H after the preparation of all automatic bit fields (STA, BSC, CRC). After a write access to SDRL/Hx, the automatic preparation is done by HW if selected. If automatic preparation of the start sequence is not selected, data is moved by HW without change to SSRL/H. When the HW is done with the transfer to the internal shift registers, interrupt TPI is activated, flag TSF is set and flag TPF is cleared automatically. Depending on INH, GO must be set after TPI before transfer to SORL/H takes place: After the transfer to SORL/H, TSI is activated, TOF is set and and TSF is cleared automatically. . INH defines the start mode: 0_B automatic transfer 1_B GO bit must be set before transfer
GO	25	w	**Release prepared Send data** This is only relevant if INH is set It allows for manual control of the transfer from SSRH/L to SORL/H. It is always read as zero and is automatically cleared. 0_B no transfer 1_B start transfer
TPF	26	r	**Transmit Preparation Flag** If set, preparation is in progress: start sequence and/ or CRC and/or stuffing and/or at least copying data from SDRL/H. If set, write access to SDRL/H will not change any data and issue TPOI. It is cleared automatically after preparation is finished.
TSF	27	r	**Transmit Shift Flag** If set, data in SSRL/H is waiting to be shifted to SORL/H. This can be caused by an automatic transfer from SDRL/H or from a CPU write access to SSRL/H. If SSL < 32 it is sufficient to write SSRL. Else, only writing SSRH will set TSF. If set, write access to SSRL/H will not change any data and issue TSOI. It is cleared automatically after data was shifted to SORL/H or after flushing the register by setting bit FLUS.
TOF	28	r	**Transmit Output Flag** If set, data in SORL/H is waiting to be transmitted to the sensor. This can be caused by an automatic transfer from SSRL/H or from a CPU write access to SORL/H. If SOL < 32 it is sufficient to write SORL. Else, only writing SDRH will set TSF. If set, write access to SORL/H will not change any data and issue TOOI. It is cleared automatically after data was transmitted to the sensor or after flushing the register by setting bit FLUO.

Field	Bits	Type	Description
TRQ	31	r	**Transfer Request in Progress** While a transfer is being sent this bit is set. Write access is ignored.
0	30:29	r	**Reserved** Read as 0; should be written with 0.

Send Data Register Low x

The Send Data Register SDRLx for channel x shows the data content of a data frame to be sent.

Data to be sent must be written while the channel is enabled (GCR.CEN is set). While CEN is cleared the HW can not detect the write access as all state machines are stopped.

SDRLx (x=0-3)

Send Data Register Low x **(094_H+x*90_H)** **Application Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SDy (y=32-63)	y-32	rw	**SDy** Send data of next ECU to Sensor frame. The unused MSBs (bit position SCRx.PLL and higher) must be written with '0'. If PLL is < 32, SDRHx must not be written.

Send Shift Register Low x

The Send Shift Register SSRLx for channel x shows the data that will be shifted to the Send Output Register SORL. It contains as well the stuff bits as specified in PSI5 V1.3 or in PSI5 V2.1 frame formats 1-3. During transmission, all bits are shifted to LSB with each sync pulse. MSB is filled up with zero.

SSRLx (x=0-3)

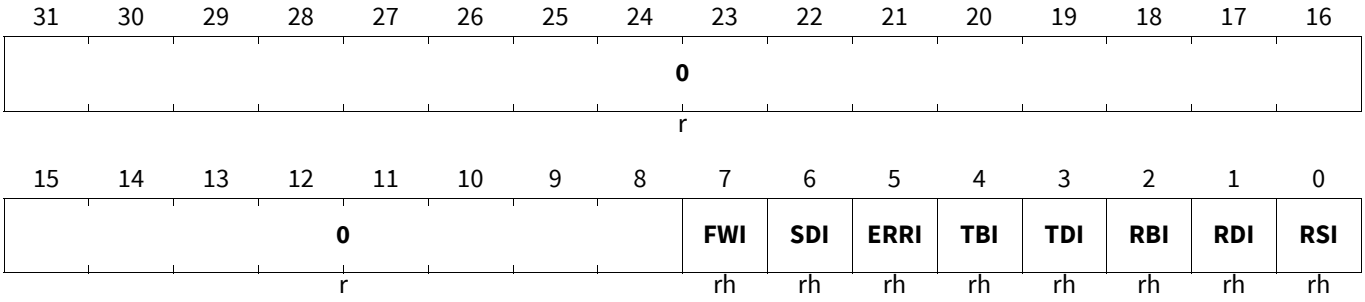
Interrupt Overview Register

INTOV
Interrupt Overview Register **($2F8_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RSI	0	rh	**Interrupt Pending on any Node Pointer RSI** If any interrupt requested flag is set for any Node Pointer RSI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RSI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RDI	1	rh	**Interrupt Pending on any Node Pointer RDI** If any interrupt requested flag is set for any Node Pointer RDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RBI	2	rh	**Interrupt Pending on any Node Pointer RBI** If any interrupt requested flag is set for any Node Pointer RBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
TDI	3	rh	**Interrupt Pending on any Node Pointer TDI** If any interrupt requested flag is set for any Node Pointer TDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
TBI	4	rh	**Interrupt Pending on any Node Pointer TBI** If any interrupt requested flag is set for any Node Pointer TBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
ERRI	5	rh	**Interrupt Pending on any Node Pointer ERRI** If any interrupt requested flag is set for any Node Pointer ERRI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.ERRI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.

Field	Bits	Type	Description
SDI	6	rh	**Interrupt Pending on any Node Pointer SDI** If any interrupt requested flag is set for any Node Pointer SDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.SDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
FWI	7	rh	**Interrupt Pending on any Node Pointer FWI** If any interrupt requested flag is set for any Node Pointer FWI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.FWI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
0	31:8	r	**Reserved** Read as 0.

Interrupt Node Pointer Register x

The Interrupt Node Pointer Register INPx contains the node pointers of PSI5 channel x.

Node Pointer ERRI is one single node pointer for the following interrupts:

- TEI
- NFI
- NBI
- MEI
- CRCI
- RUI
- RMI
- WSIy
- SOIy
- SCRIy

Node Pointer TBI is one single node pointer for the following interrupts:

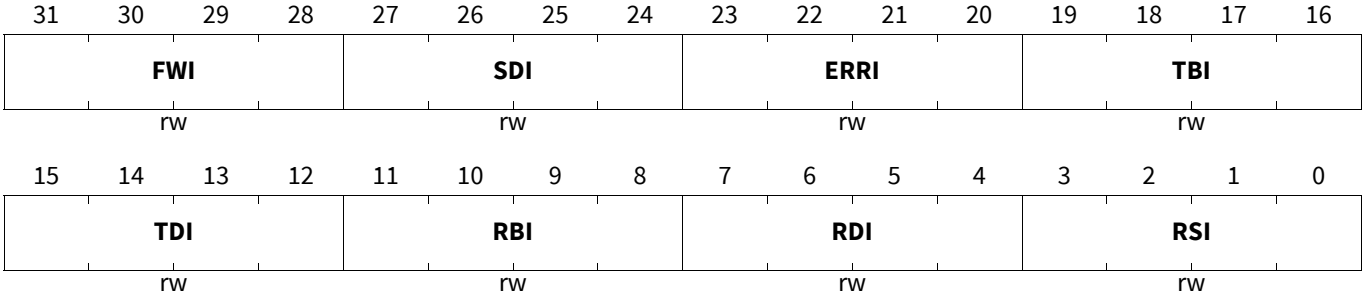
- TPOI
- TSOI
- TOOI

Node Pointer TDI is one single node pointer for the following interrupts:

- TPI
- TSI
- TOI

INPx (x=0-3)

Interrupt Node Pointer Register x **($2FC_H$+x*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RSI	3:0	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RSI (if enabled by bit INTENAx.RSI). 0_H Trigger Output TRIGO 0 is selected 1_H Trigger Output TRIGO 1 is selected … 7_H Trigger Output TRIGO 7 is selected 8_H reserved … F_H reserved
RDI	7:4	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RDI (if enabled by bit INTENAx.RDI). For bit field definition, see RSI.
RBI	11:8	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RBI (if enabled by bit INTENAx.RBI). For bit field definition, see RSI.
TDI	15:12	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPI, TSI, TOI (if enabled by bit INTENAx.TPI, TSI, TOI). For bit field definition, see RSI.
TBI	19:16	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPOI, TSOI, TOOI (if enabled by bit INTENAx.TPOI, TSOI, TOOI). For bit field definition, see RSI.
ERRI	23:20	rw	**Interrupt Node Pointer for Interrupt ERRI** This bit field defines the interrupt node, that is requested due to the set condition for bit TEI, NFI, NBI, MEI, CRCI, RUI, RMI, CRCIy, WSIy, SOIy, SCRIy. For bit field definition, see RSI.

Field	Bits	Type	Description
SDI	27:24	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
FWI	31:28	rw	**Interrupt Node Pointer for FWI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FWI. For bit field definition, see RSI.

Interrupt Status Register A x

The Interrupt Status Registers INTSTATA/Bx contains status bits that show the status of any interrupt of PSI5 channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATAx (x=0-3)
Interrupt Status Register A x **(310_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															NFI

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors NFI, TEI, NBI, MEI, CRCI if selected to be taken into account in register GCR. This bit can be cleared by bit INTCLRAx.RSI. This bit can be set by bit INTSETAx.RSI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDRL/Hx. Both RDI and RSI will be issued together at correct reception. This bit can be cleared by bit INTCLRAx.RDI. This bit can be set by bit INTSETAx.RDI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. Thus, RBI can be ignored if the receive memory is used. This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRAx.RBI. This bit can be set by bit INTSETAx.RBI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TEI	3	rh	**Time Slot Error Interrupt Request Flag** In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy). In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. This bit can be cleared by bit INTCLRAx.TEI. This bit can be set by bit INTSETAx.TEI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NBI	4	rh	**Number of Bits Wrong Request Flag** This bit is set if the last frame received less bits than expected but no Manchester coding error occurred until S1, S2, M0 and M1 where received. Note that the frame after the error might be completely wrong. This bit can be cleared by bit INTCLRAx.NBI. This bit can be set by bit INTSETAx.NBI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
MEI	5	rh	**Error in Message Bits Flag** This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG) Note that the frame after the error might be completely wrong. This bit can be cleared by bit INTCLRAx.MEI. This bit can be set by bit INTSETAx.MEI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
CRCI	6	rh	**CRC Error Request Flag** This bit is set if the CRC fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) This bit can be cleared by bit INTCLRAx.CRCI. This bit can be set by bit INTSETAx.CRCI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
FWI	7	rh	**FIFO Warning Level Request Flag** This bit is set after if the configured warning level of the FIFOx was reached. (See RFCx) This bit can be cleared by bit INTCLRAx.FWI. This bit can be set by bit INTSETAx.FWI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RUI	8	rh	**Receive Memory Underrun Interrupt Request Flag** This bit is set after a SPB master reads from FIFO while no new data was available. (See RFCx) This bit can be cleared by bit INTCLRAx.RUI. This bit can be set by bit INTSETAx.RUI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RMI	9	rh	**Receive Memory Overflow Flag** This bit is set after a frame has been received while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag RDIxWRP and finds this flag already set. The old data is overwritten by the new data in the buffer memory. This bit can be cleared by bit INTCLRAx.RMIx. This bit can be set by bit INTSETAx.RMIx. This bit is set independently from INTENAx. 0_B No overflow 1_B Overflow
TPI	10	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved from SDRL/H to SSRL/H. Thus a new value can be written to SDRL/Hx and the prepared data can be checked and modified by SW. This bit is automatically cleared by writing SDRx. This is an exception! It allows for DMA transfers without CPU activity. This bit can be cleared by bit INTCLRAx.TDI. This bit can be set by bit INTSETAx.TDI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
TPOI	11	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set after if SDRL/H is written while TPF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TPOI. This bit can be set by bit INTSETAx.TPOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TSI	12	rh	**Transfer Shift Interrupt Request Flag** This bit is set after data to be transferred has been moved from SSRL/H to SORL/H. Thus a new value can be written to SSRL/Hx. This bit is NOT cleared by writing SSRL/Hx. This bit can be cleared by bit INTCLRAx.TSI. This bit can be set by bit INTSETAx.TSI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TSOI	13	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after if SSRL/H is written while TSF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TSOI. This bit can be set by bit INTSETAx.TSOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TOI	14	rh	**Transfer Output Interrupt Request Flag** This bit is set after last bit to be transferred has been moved from SORL/H to the pulse generator. Thus a new value can be written to SORL/Hx. This bit is NOT cleared by writing SORL/Hx. This bit can be cleared by bit INTCLRAx.TOI. This bit can be set by bit INTSETAx.TOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TOOI	15	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after if SORL/H is written while TOF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TOOI. This bit can be set by bit INTSETAx.TOOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
NFI	16	rh	**No Frame Received Interrupt Flag** This bit is set at the end of a slot if a frame is expected in the slot and SOF was not received in the slot. A special case is where an SOF is received in slot 0. In this scenario, the NFI bit is only set at the end of slot 1 if a frame is expected in slot 1 and an EOF was not received in slot 1. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If the “SOF only frame” crosses the WDL, NFI occurs after WDL and EOF detection. If RCRBx.VBS is set, an empty frame is stored anyhow. In this case RDIx is issued as well. The only valid information is SC, TS (captured at the end of the slot) and this bit (NFI). This bit can be cleared by bit INTCLRAx.NFI. This bit can be set by bit INTSETAx.NFI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
0	31:17	r	**Reserved** Read as 0.

Interrupt Status Register B x

Field	Bits	Type	Description
RSI	0	w	**Set Interrupt Request Flag RSI** Setting this bit set bit INTSTATx.RSI. Clearing this bit has no effect. Reading this bit returns always zero.
RDI	1	w	**Set Interrupt Request Flag RDI** Setting this bit set bit INTSTATx.RDI. Clearing this bit has no effect. Reading this bit returns always zero.
RBI	2	w	**Set Interrupt Request Flag RBI** Setting this bit set bit INTSTATx.RBI. Clearing this bit has no effect. Reading this bit returns always zero.
TEI	3	w	**Set Interrupt Request Flag TEI** Setting this bit set bit INTSTATx.TEI. Clearing this bit has no effect. Reading this bit returns always zero.
NBI	4	w	**Set Interrupt Request Flag NBI** Setting this bit set bit INTSTATx.NBI. Clearing this bit has no effect. Reading this bit returns always zero.
MEI	5	w	**Set Interrupt Request Flag MEI** Setting this bit set bit INTSTATx.MEI. Clearing this bit has no effect. Reading this bit returns always zero.
CRCI	6	w	**Set Interrupt Request Flag CRCI** Setting this bit set bit INTSTATx.CRCI. Clearing this bit has no effect. Reading this bit returns always zero.
FWI	7	w	**Set Interrupt Request Flag FWI** Setting this bit set bit INTSTATx.FWI. Clearing this bit has no effect. Reading this bit returns always zero.
RUI	8	w	**Set Interrupt Request Flag RUI** Setting this bit set bit INTSTATx.RUI. Clearing this bit has no effect. Reading this bit returns always zero.
RMI	9	w	**Set Interrupt Request Flag RMI** Setting this bit set bit INTSTATx.RMI. Clearing this bit has no effect. Reading this bit returns always zero.
TPI	10	w	**Set Interrupt Request Flag TPI** Setting this bit set bit INTSTATx.TPI. Clearing this bit has no effect. Reading this bit returns always zero.

Field	Bits	Type	Description
TPOI	11	w	**Set Interrupt Request Flag TPOI** Setting this bit set bit INTSTATx.TPOI. Clearing this bit has no effect. Reading this bit returns always zero.
TSI	12	w	**Set Interrupt Request Flag TSI** Setting this bit set bit INTSTATx.TSI. Clearing this bit has no effect. Reading this bit returns always zero.
TSOI	13	w	**Set Interrupt Request Flag TSOI** Setting this bit set bit INTSTATx.TSOI. Clearing this bit has no effect. Reading this bit returns always zero.
TOI	14	w	**Set Interrupt Request Flag TOI** Setting this bit set bit INTSTATx.TOI. Clearing this bit has no effect. Reading this bit returns always zero.
TOOI	15	w	**Set Interrupt Request Flag TOOI** Setting this bit set bit INTSTATx.TOOI. Clearing this bit has no effect. Reading this bit returns always zero.
NFI	16	w	**Set Interrupt Request Flag NFI** Setting this bit set bit INTSTATx.NFI. Clearing this bit has no effect. Reading this bit returns always zero.
0	31:17	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status **($3CC_H$)** **Debug Reset Value: $0000\ 0000_H$**

SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. The kernel continues when hard suspend is left. 2_H Soft suspend option A (Suspends after end of current send or receive transfers, if any are ongoing) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B…EN31 -> TAG ID 011111B.

ACCEN0

Access Enable Register 0 ($3D0_H$) Application Reset Value: FFFF FFFF$_H$

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

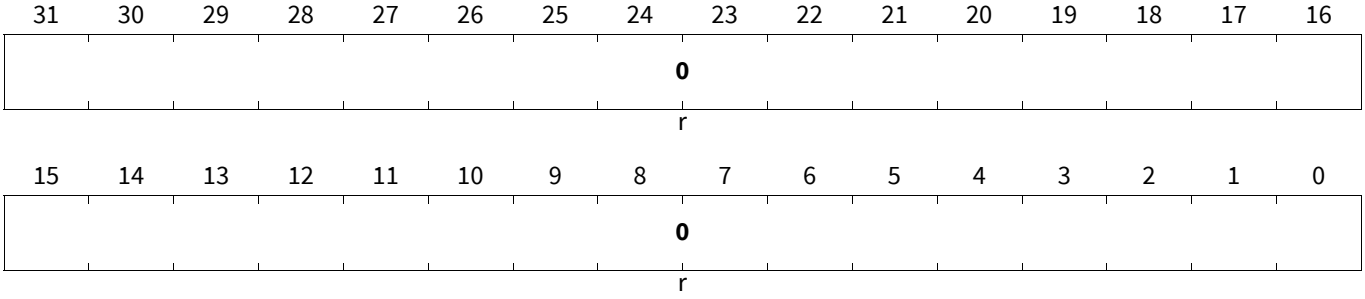
The Access Enable Register 1 controls write access[1] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B…EN31 -> TAG ID 111111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ACCEN1

Access Enable Register 1 **(3D4$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0

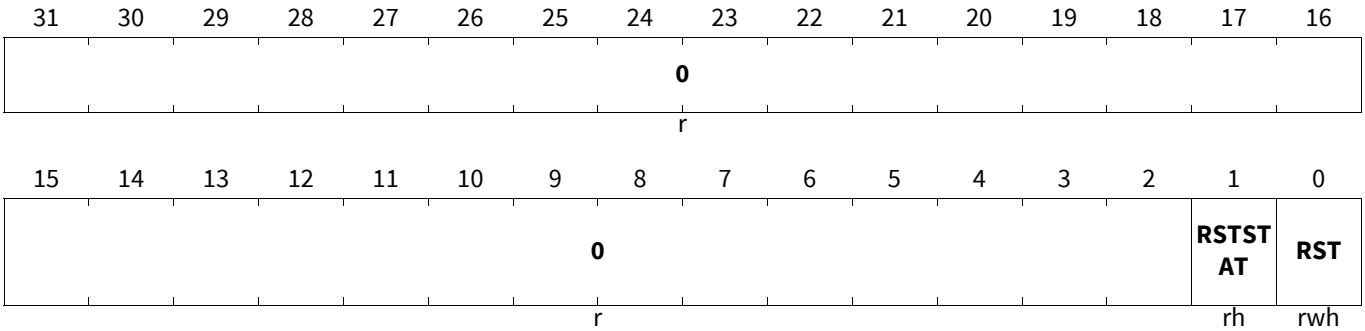
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 **(3D8$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($3DC_H$)** **Application Reset Value: $0000\ 0000_H$**

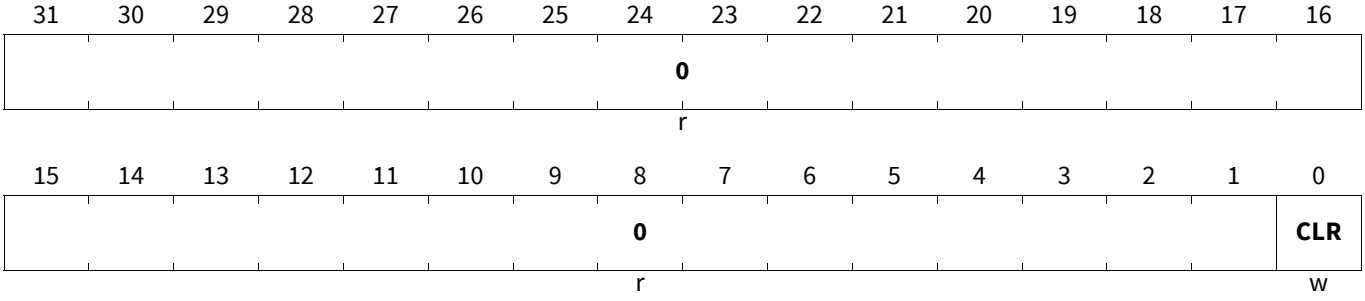
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (3E0$_H$) Application Reset Value: 0000 0000$_H$



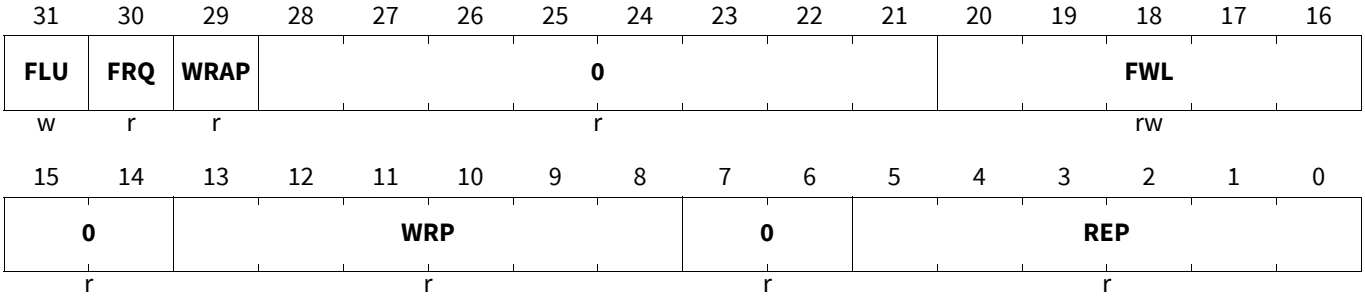
Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Receive FIFO Control Register x

RFCx contains control bits for the FIFO and Ring Buffer operation.

RFCx (x=0-3)

Receive FIFO Control Register x (3E4$_H$+x*4) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
REP	5:0	r	**FIFO Read Pointer** points to the buffer to be read next. Incremented after read. The last bit bit indicates if RDMxH or RDMxL is read. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI)
WRP	13:8	r	**FIFO/Ring Buffer Write Pointer** points to the buffer written last. Incremented before write. The last bit indicates if RDMxH or RDMxL is written. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI).

Field	Bits	Type	Description
FWL	20:16	rw	**FIFO Warning Level** Number of new entries at which the FIFO Warning Interrupt FWIx is set automatically. For calculation WRP and REP are used. I.e. only if the memory is read via RDFx, this works properly.
WRAP	29	r	**Write Pointer WRAP Indicator** If set, the Write Pointer is one wrap around ahead of the Read Pointer. It is cleared, if the Read Pointer wraps around too or when FLU is set by SW.
FRQ	30	r	**Flush Request** if set, FIFO read and write pointers are not incremented any more due to excessive RMI. (Too many overrun conditions). This bit is cleared when FLU is set.
FLU	31	w	**Flush** if set, FIFO read and write pointers are cleared. Bits and WRAP are cleared. SW needs to clear interrupts as needed. This bit can only be set and is cleared by HW. Always read as 0.
0	7:6, 15:14, 28:21	r	**Reserved** Read as 0; should be written with 0.

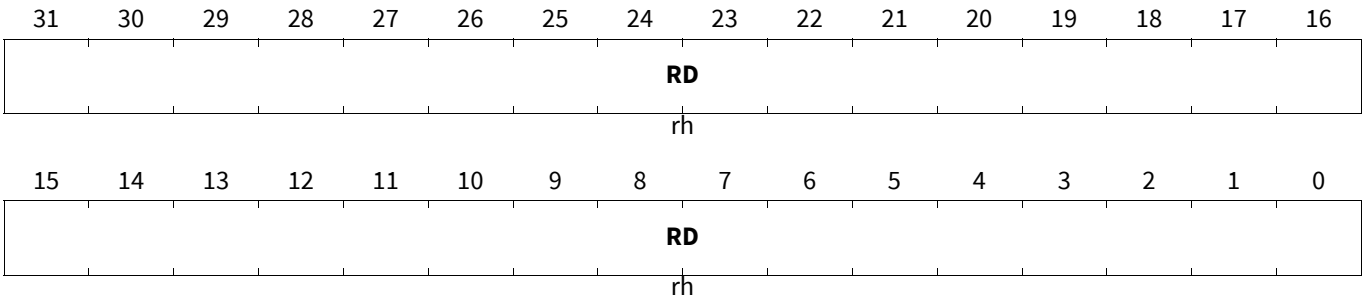
Receive Data FIFO x

The Receive Data FIFO RDFx for channel x shows the oldest data content of up to 32 received data frames. I.e. RFCx.REP is pointing at the buffer presented.

Do not set a debugger watch point on this register as any read access will issue a hard ware request for new data (move read pointer REP and present referring memory content in RDFx). A debugger watch point can be set on the RDML/Hx and RFCx to monitor the FIFO behavior.

RDFx (x=0-3)

Receive Data FIFO x **($3F8_H$+x*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RD	31:0	rh	**RD** Shows the content of RDML/Hxy; y = RFCx.REP[5:1]; L/H = RFCx.REP[0]. Reading this register triggers incrementation of REP and presentation of next FIFO value at next read access! Once a complete buffer is read (64 bit, 2 accesses to RDF) all overview flags for this very buffer are cleared automatically.

RSI Overview Register x

The RSI Overview Register RSIOVx contains flags to manage the receive memory of PSI5 channel x.

RSIOVx (x=0-3)

RSI Overview Register x **($40C_H$+x*4)** **Application Reset Value: 0000 0000_H**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSIy (y=0-31)	y	rh	**RSI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RSICLRx.RSIy. This bit can be set by bit RSISETx.RSIy.

RMI Overview Register x

The RMI Overview Register RMIOVx contains flags to manage the receive memory of PSI5 channel x.

RMIOVx (x=0-3)

RMI Overview Register x **(420_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RMI31	**RMI30**	**RMI29**	**RMI28**	**RMI27**	**RMI26**	**RMI25**	**RMI24**	**RMI23**	**RMI22**	**RMI21**	**RMI20**	**RMI19**	**RMI18**	**RMI17**	**RMI16**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMI15	**RMI14**	**RMI13**	**RMI12**	**RMI11**	**RMI10**	**RMI9**	**RMI8**	**RMI7**	**RMI6**	**RMI5**	**RMI4**	**RMI3**	**RMI2**	**RMI1**	**RMI0**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RMIy (y=0-31)	y	rh	**RMI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RMICLRx.RMIy. This bit can be set by bit RMISETx.RMIy.

NBI Overview Register x

The NBI Overview Register NBIOVx contains flags to manage the receive memory of PSI5 channel x.

NBIOVx (x=0-3)
NBI Overview Register x **(434_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NBI31	**NBI30**	**NBI29**	**NBI28**	**NBI27**	**NBI26**	**NBI25**	**NBI24**	**NBI23**	**NBI22**	**NBI21**	**NBI20**	**NBI19**	**NBI18**	**NBI17**	**NBI16**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBI15	**NBI14**	**NBI13**	**NBI12**	**NBI11**	**NBI10**	**NBI9**	**NBI8**	**NBI7**	**NBI6**	**NBI5**	**NBI4**	**NBI3**	**NBI2**	**NBI1**	**NBI0**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
NBIy (y=0-31)	y	rh	**NBI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit NBICLRx.NBIy. This bit can be set by bit NBISETx.NBIy.

TEI Overview Register x

The TEI Overview Register TEIOVx contains flags to manage the receive memory of PSI5 channel x.

TEIOVx (x=0-3)
TEI Overview Register x **(448_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEI31	**TEI30**	**TEI29**	**TEI28**	**TEI27**	**TEI26**	**TEI25**	**TEI24**	**TEI23**	**TEI22**	**TEI21**	**TEI20**	**TEI19**	**TEI18**	**TEI17**	**TEI16**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RDIy (y=0-31)	y	rh	**RDI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RDICLRx.RDIy. This bit can be set by bit RDISETx.RDIy.

NFI Overview Register x

The NFI Overview Register NFIOVx contains flags to manage the receive memory of PSI5 channel x.

NFIOVx (x=0-3)

NFI Overview Register x **(484_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NFI31	**NFI30**	**NFI29**	**NFI28**	**NFI27**	**NFI26**	**NFI25**	**NFI24**	**NFI23**	**NFI22**	**NFI21**	**NFI20**	**NFI19**	**NFI18**	**NFI17**	**NFI16**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NFI15	**NFI14**	**NFI13**	**NFI12**	**NFI11**	**NFI10**	**NFI9**	**NFI8**	**NFI7**	**NFI6**	**NFI5**	**NFI4**	**NFI3**	**NFI2**	**NFI1**	**NFI0**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
NFIy (y=0-31)	y	rh	**NFI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit NFICLRx.NFIy. This bit can be set by bit NFISETx.NFIy.

MEI Overview Register x

The MEI Overview Register MEIOVx contains flags to manage the receive memory of PSI5 channel x.

MEIOVx (x=0-3)

MEI Overview Register x **(498_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEI31	**MEI30**	**MEI29**	**MEI28**	**MEI27**	**MEI26**	**MEI25**	**MEI24**	**MEI23**	**MEI22**	**MEI21**	**MEI20**	**MEI19**	**MEI18**	**MEI17**	**MEI16**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEI15	**MEI14**	**MEI13**	**MEI12**	**MEI11**	**MEI10**	**MEI9**	**MEI8**	**MEI7**	**MEI6**	**MEI5**	**MEI4**	**MEI3**	**MEI2**	**MEI1**	**MEI0**
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
MEIy (y=0-31)	y	rh	**MEI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit MEICLRx.MEIy. This bit can be set by bit MEISETx.MEIy.

RSI Overview Set Register x

The RSI Overview Set Register RSISETx contains bits to set the status flags of RSIOVx.

RSISETx (x=0-3)

RSI Overview Set Register x **($4AC_H$+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSI31	RSI30	RSI29	RSI28	RSI27	RSI26	RSI25	RSI24	RSI23	RSI22	RSI21	RSI20	RSI19	RSI18	RSI17	RSI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSI15	RSI14	RSI13	RSI12	RSI11	RSI10	RSI9	RSI8	RSI7	RSI6	RSI5	RSI4	RSI3	RSI2	RSI1	RSI0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RSIy (y=0-31)	y	w	**Set RSI Flag of Buffer y** Setting this bit sets bit RSIOVx.RSIy Clearing this bit has no effect. Reading this bit returns always zero.

RMI Overview Set Register x

The RMI Overview Set Register RMISETx contains bits to set the status flags of RMIOVx.

RMISETx (x=0-3)

RMI Overview Set Register x **($4C0_H$+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RMI31	RMI30	RMI29	RMI28	RMI27	RMI26	RMI25	RMI24	RMI23	RMI22	RMI21	RMI20	RMI19	RMI18	RMI17	RMI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RMI15	RMI14	RMI13	RMI12	RMI11	RMI10	RMI9	RMI8	RMI7	RMI6	RMI5	RMI4	RMI3	RMI2	RMI1	RMI0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RMIy (y=0-31)	y	w	**Set RMI Flag of Buffer y** Setting this bit sets bit RMIOVx.RMIy Clearing this bit has no effect. Reading this bit returns always zero.

NBI Overview Set Register x

The NBI Overview Set Register NBISETx contains bits to set the status flags of NBIOVx.

NBISETx (x=0-3)

NBI Overview Set Register x **($4D4_H$+x*4)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NBI31	**NBI30**	**NBI29**	**NBI28**	**NBI27**	**NBI26**	**NBI25**	**NBI24**	**NBI23**	**NBI22**	**NBI21**	**NBI20**	**NBI19**	**NBI18**	**NBI17**	**NBI16**
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
CRCIy (y=0-31)	y	w	**Set CRCI Flag of Buffer y** Setting this bit sets bit CRCIOVx.CRCIy Clearing this bit has no effect. Reading this bit returns always zero.

RDI Overview Set Register x

The RDI Overview Set Register RDISETx contains bits to set the status flags of RDIOVx.

RDISETx (x=0-3)

RDI Overview Set Register x **(510_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDI31	**RDI30**	**RDI29**	**RDI28**	**RDI27**	**RDI26**	**RDI25**	**RDI24**	**RDI23**	**RDI22**	**RDI21**	**RDI20**	**RDI19**	**RDI18**	**RDI17**	**RDI16**
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDI15	**RDI14**	**RDI13**	**RDI12**	**RDI11**	**RDI10**	**RDI9**	**RDI8**	**RDI7**	**RDI6**	**RDI5**	**RDI4**	**RDI3**	**RDI2**	**RDI1**	**RDI0**
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RDIy (y=0-31)	y	w	**Set RDI Flag of Buffer y** Setting this bit sets bit RDIOVx.RDIy Clearing this bit has no effect. Reading this bit returns always zero.

NFI Overview Set Register x

The NFI Overview Set Register NFISETx contains bits to set the status flags of NFIOVx.

NFISETx (x=0-3)

NFI Overview Set Register x **(524_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NFI31	**NFI30**	**NFI29**	**NFI28**	**NFI27**	**NFI26**	**NFI25**	**NFI24**	**NFI23**	**NFI22**	**NFI21**	**NFI20**	**NFI19**	**NFI18**	**NFI17**	**NFI16**
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

43 Peripheral Sensor Interface with Serial PHY Connection (PSI5-S)

The PSI5-S IP-module performs communication according to the PSI5 specification. It communicates with the external world via one ASC interface for all channels. This ASC is built into the PSI5-S module. If the optional bidirectional mode is used, the commands to the external Physical Layer Interface (PHY) are transmitted via this ASC.

Figure 657 shows a global view of the PSI5-S interface.

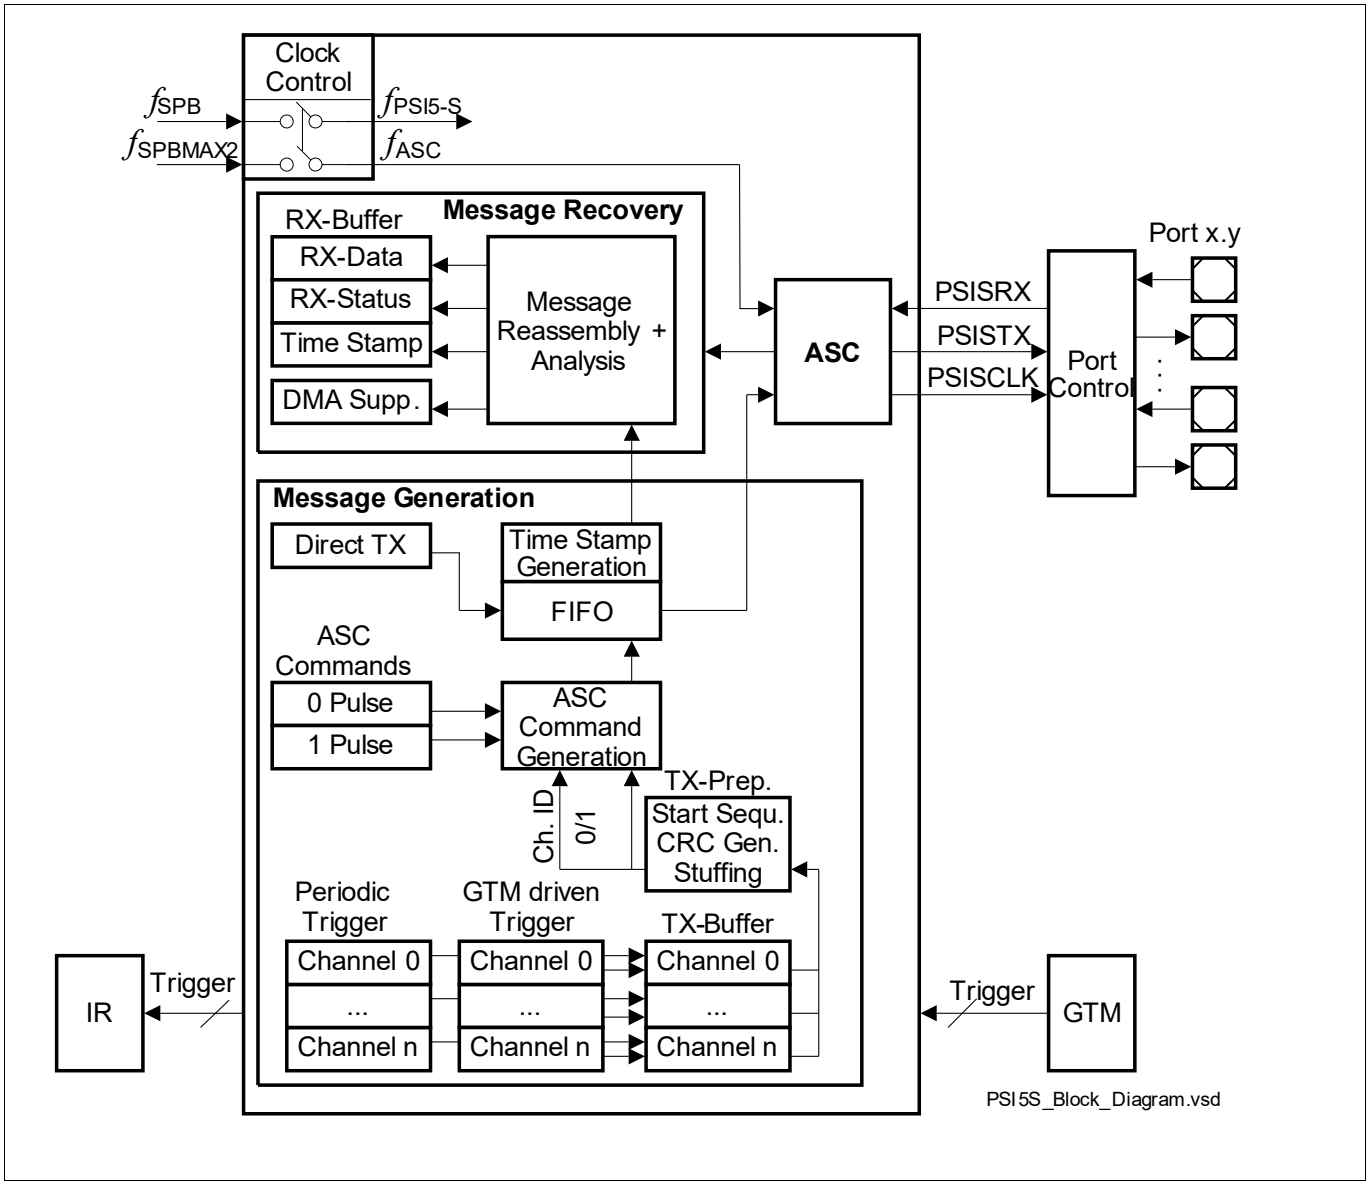

Figure 657 General Block Diagram of the PSI5-S Interface

43.1 Feature List

General Features

- ASC based communication with compatible PSI5-S PHY
- Baud rate Generator (up to 12,5) MBaud (@ 200 MHz ASC Sub Module Clock)
- Clock out generator to supply external PHY
- Conformance with PSI5 protocol specification
- Data rates of 125 kbit/s and 189 kbit/s supported (by external PHY already)
- 8 PSI5-S channels sharing one common ASC (inc. channel 0 frame 1 special use)
- Supports 6 sensor slots per channel
- Asynchronous and synchronous PSI5 data transmission modes
- 8 Interrupt or DMA triggers

Features of Message Recovery Block

- ASC format 10 Bit: 1 Start Bit, 8 Data bits, 1 Stop Bit (Up Stream)
- Each PSI5 Frame is transported in a Packet Frame consisting of 3 to 6 UART Frames transmitted back to back, i.e. with exactly one stop bit - no additional delay.
- Packet Frames are separated by a programmable idle time (1 … 16 idle bits)
- Assembly and decoding of Packet frames (envelope)
- Routing of PSI5 Frames to their referring channel receive buffer in system memory by hardware DMA support
- Checking CRC of Packet Frames (XCRC)
- Frames with XCRC NOK will be routed to channel 0 frame 1
- The external PHY sends all Frames of an Asynchronous Channel with FID = 1, all frames of this channel have the same length and structure as defined for FID 1. Thus it is sufficient to configure frame 1 for asynchronous channels.
- Configurable data length 8 … 28 bit + 3 bit PSI5 CRC or 1 bit PSI5 Parity
- CRC check of received PSI5 sensor data, CRC code still transparent
- No HW Support of extended serial data messaging according to SENT SAE J2716 JAN 2010. Messaging bits are transported fully transparent for SW decoding
- 24-Bit time stamp on sync pulse request via ASC (resolution: 1µs)
- Two independent time bases for Time Stamp: clocked by GTM (1 out of n GTM signals is selectable) or internal periodic trigger generator
- PHY answers to CPU commands with standard frames of fixed predefined length in channel 0 frame 0.
- Error bits in Packet Frame are presented fully transparent and an interrupt is issued.
- One Interrupt for error free Packet Frame, relevant errors are selectable
- One Interrupt for Packet Frame reception disregarding any error.

Features of Message Generation Block

- Support of ECU to Sensor communication
- One 32-bit send data register per channel for downstream data input
- Data is shifted out LSB first, MSB is filled with ‘0’ or ‘1’ with each shift (depending on bit coding method: Tooth Gap or Pulse Width)
- ASC format 11 Bit: 1 Start Bit, 8 Data bits, 1 Parity, 1 Stop Bit (Down Stream)

- Downstream commands of fixed format (3 MSB = Channel ID, 5 LSB = Command)
- All commands are randomly programmable and thus not interpreted by PSI5-S
- Downstream data transmission by 2 different ASC commands (short/no and long pulse)
- 8 common lines of FIFO for all channels, writable by
- PSI5 Message Generation
- Sync Pulse Generation (pre programmed Bytes for ‘0’ and ‘1’)
- CPU Commands
- Direct CPU Write Registers allow for insertion of commands into the FIFO for configuration and debugging
- 8 GTM inputs for Sync Pulse Triggering
- SW configurable staggering of Sync Pulse generation
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence generator for downstream data (can be switched off)
- Bit stuffing generator for downstream data (can be switched off)
- CRC generator for downstream data (can be switched off)
- Internal Loop Back mode for check of CRC generator and SW development

43.2 Overview

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

PSI5 defines a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages communication with this PHY and the presentation of the data to the application. Note that there is no on chip PHY, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5-S channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a set of 3 32-bit registers for all channels: one PSI5-S Message Receive Data Register containing the received sensor data, one time stamp register containing the 24-bit value and one additional register containing status bits.

For synchronous communication mode, the module can consume sync pulses from the external GTM or generate periodic sync pulses by itself. It supports as well ECU to sensor communication by offering a 32-bit register, where messages can be set up by the CPU. All kinds of sync pulses are translated into a referring, programmable Byte to be sent via ASC.

The register set of the PSI5-S module can be accessed directly by the CPU for configuration, data read out and status query.

43.2.1 Definitions

SENT: Single Edge Nibble Transmission

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

PHY: Physical Layer Interface

ECU: Electronic Control Unit

FSM: Finite State Machine

ASIC: Application Specific Integrated Circuit

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SOF: Start of Frame

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

UART: Universal Asynchronous Receiver Transmitter

43.3 Functional Description

PSI5-S is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 658 shows a typical application in which a PSI5-S interface reads a sensor device.

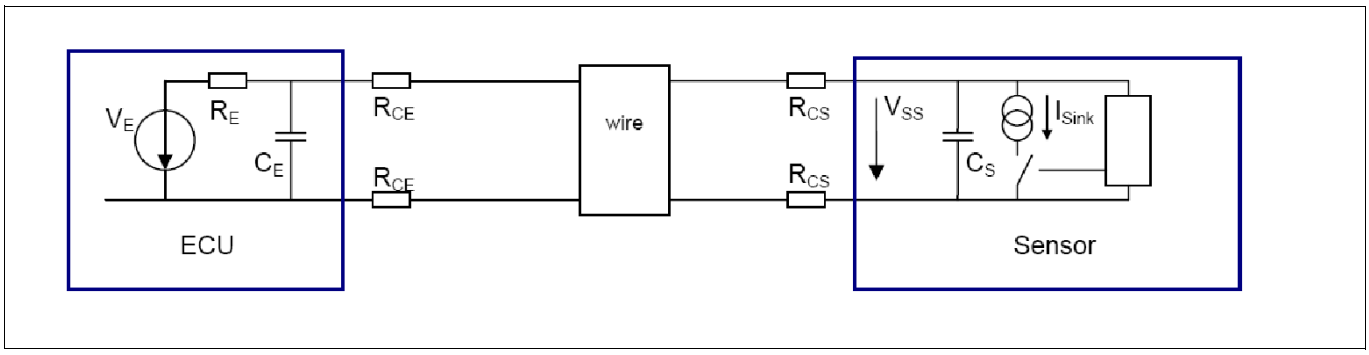

Figure 658 PSI5 to External Device Connection

PSI5-S communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage of the current loop.

Figure 659 shows a typical application in which a PSI5 ECU reads multiple PSI sensor devices on a bus.

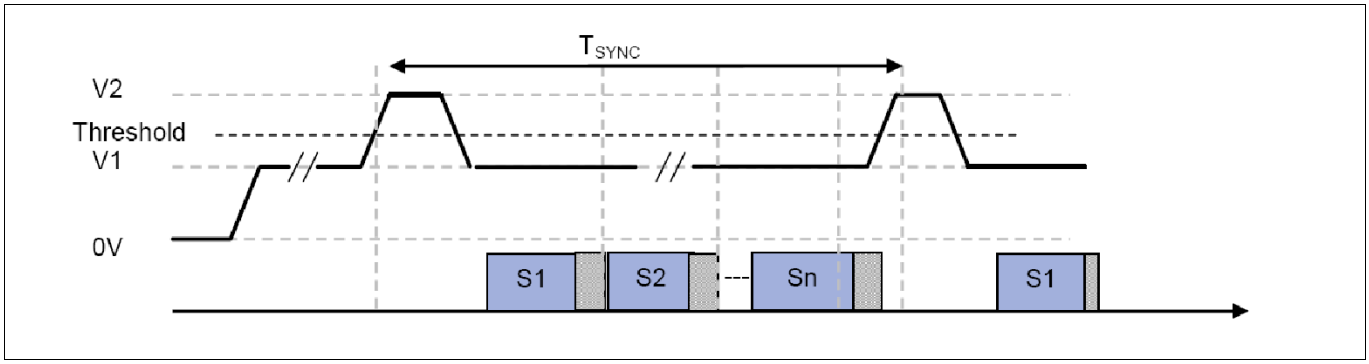

Figure 659 PSI5 Frames with Sync pulses

43.3.1 PSI5 ECU to Sensor Operation

ECU to Sensor communication is defined in PSI5 V2.0 2011-06. Data transmission and configuration of the sensor can be done by modulation of the Sync Pulses.

The Module supports two modes:

- Tooth Gap Method
- Pulse Width Method

With the Tooth Gap Method, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for PSI5 Frames but are interpreted as data for the sensor. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

With the Pulse Width Method a standard length pulse represents a 0, a longer pulse a 1. This way continuos data transmission can be achieved. The pulses can be non isochronous, e.g. dependent from the angle position of a rotating axis.

43.3.2 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5-S protocol.

43.3.2.1 Communication between PSI5-S and PHY via UART

This chapter treats the communication on the UART connection.

43.3.2.1.1 “Packet Frames” received from PHY

Figure 660 and **Figure 661** show the layout and definitions of the “Packet Frames”. Packet Frames are 3 to 6 “UART Frames” carrying one “PSI5 Frame”. The format accepted by PSI5-S is explained here. A UART frame is one transmission unit on the ASC. On the receive path it consists of one Start Bit, 8 Data Bits and one Stop bit. Parity can be chosen optionally, e.g. for loop back tests.The figures show the minimum and maximum Packet Frame population with data. Where the figures show ‘Res0’ bits, these bits can be crowded by more data bits if configured so.

Detection of Frame Boundaries and Packet Frame Processing

- SOF (Start of Frame) is defined by a start bit detected after idle on ASC.
- Idle equals at least 2 Stop Bits.
  - The required idle time can be configured between 1 and 16 additional Stop Bits.
  - An idle state signal is provided internally by the ASC to the reassembly unit.

  - The idle signal starts on detection of the first stop bit and ends when the first slope of the next start bit has passed the 2 out of 3 majority vote input filter.
- If idle is detected before the minimum of 3 UART Frames was received, these UART Frames are copied to channel 0 frame 1 (non recoverable frames).
- Based on the ChID and FID received in the first UART frame, the module checks
  - If the referring channel is enabled and
  - If the FID is valid and configured (PDL > 0) and
  - What the number is of expected UART frames configured in UFC
  - If at least this number of UART frames is received without idle and
  - If the XCRC is correct
- If these checks pass
  - EOF is detected after the correct number of UART frames
  - Data is copied to RDR, interrupts, and the status are updated in RDS. In particular CRC/P check is executed. Time Stamp (TSM) and Target address (TAR) are updated. Depending from bit RCRAx.FIDS the FID might be manipulated.
  - The message recovery unit does not wait for idle to execute the steps above.
- If these checks fail (“non recoverable frames”)
  - EOF is detected after idle or a maximum of 6 UART Frames
  - The 1 to 6 UART Frames are stored in channel 0 frame 1.
- If more UART frames follow a passing or failing Packet Frame without idle,
  - EOF is detected after idle or a maximum of 6 UART Frames
  - The 1 to 6 UART Frames are stored in channel 0 frame 1
  - Reception is stopped
  - The next UART Frames following without idle time are ignored
  - Reception starts only after the idle time programmed in GCR.IDT is detected (“bubbling idiot” protection)

Non Recoverable Frame Presentation in RDR and RDS

- RDS.FID and ChID are derived from the first UART Frame received.
- RDR.RD[27:0] contains all bits of each UART Frame received after the header. I.e. 0 bits for 1 UART Frame,
  8 bits for 2 UART Frames,
  16 bits for 3 UART Frames,
  24 bits for 4 UART Frames,
  28 bits for 5 and 6 UART Frames.
- RDS.CRC is determined as follows:
  - If 6 UART Frames were received: bits [6:4] of the 5th UART Frame.
  - If 1 … 5 UART Frames where received: determined by PDL
  - PDL may not be reliable, but this way all data is covered either in the data field or in the XCRC field. In case PDL was correct, CRC is shown correctly.
- RDS.XCRC contains always the bits [7:2] of the last UART Frame received. Also if only 1 UART Frame was received.
- Note that XCRCI is always set as either XCRC was wrong or the number of UART frames received was wrong or it could not be determined.

Loop Back support

- Parity and number of stop bits need to be configured the same for sender and receiver in loop back mode. Parity control and polarity of parity can be configured separately each for TX and RX. This can be done before switching on loop back mode. Alternatively the parity control can be adjusted as well in one single register access together with switching the ASC part to loop back mode.
- Both ways are supported: add Parity bit to the receiver or use the transmitter without parity. (Standard use case is to use transmitter with parity)
- Data to be transmitted can be written directly to register CDW
- This way a synthetic Packet Frame can be sent to the reassembly unit for test purposes.
- The received loop back data is treated in the same way as the normal receive data. Good frames are received in their referring channel and slot. Frames with wrong XCRC, idle time or UFC are stored in channel 0 frame 1.

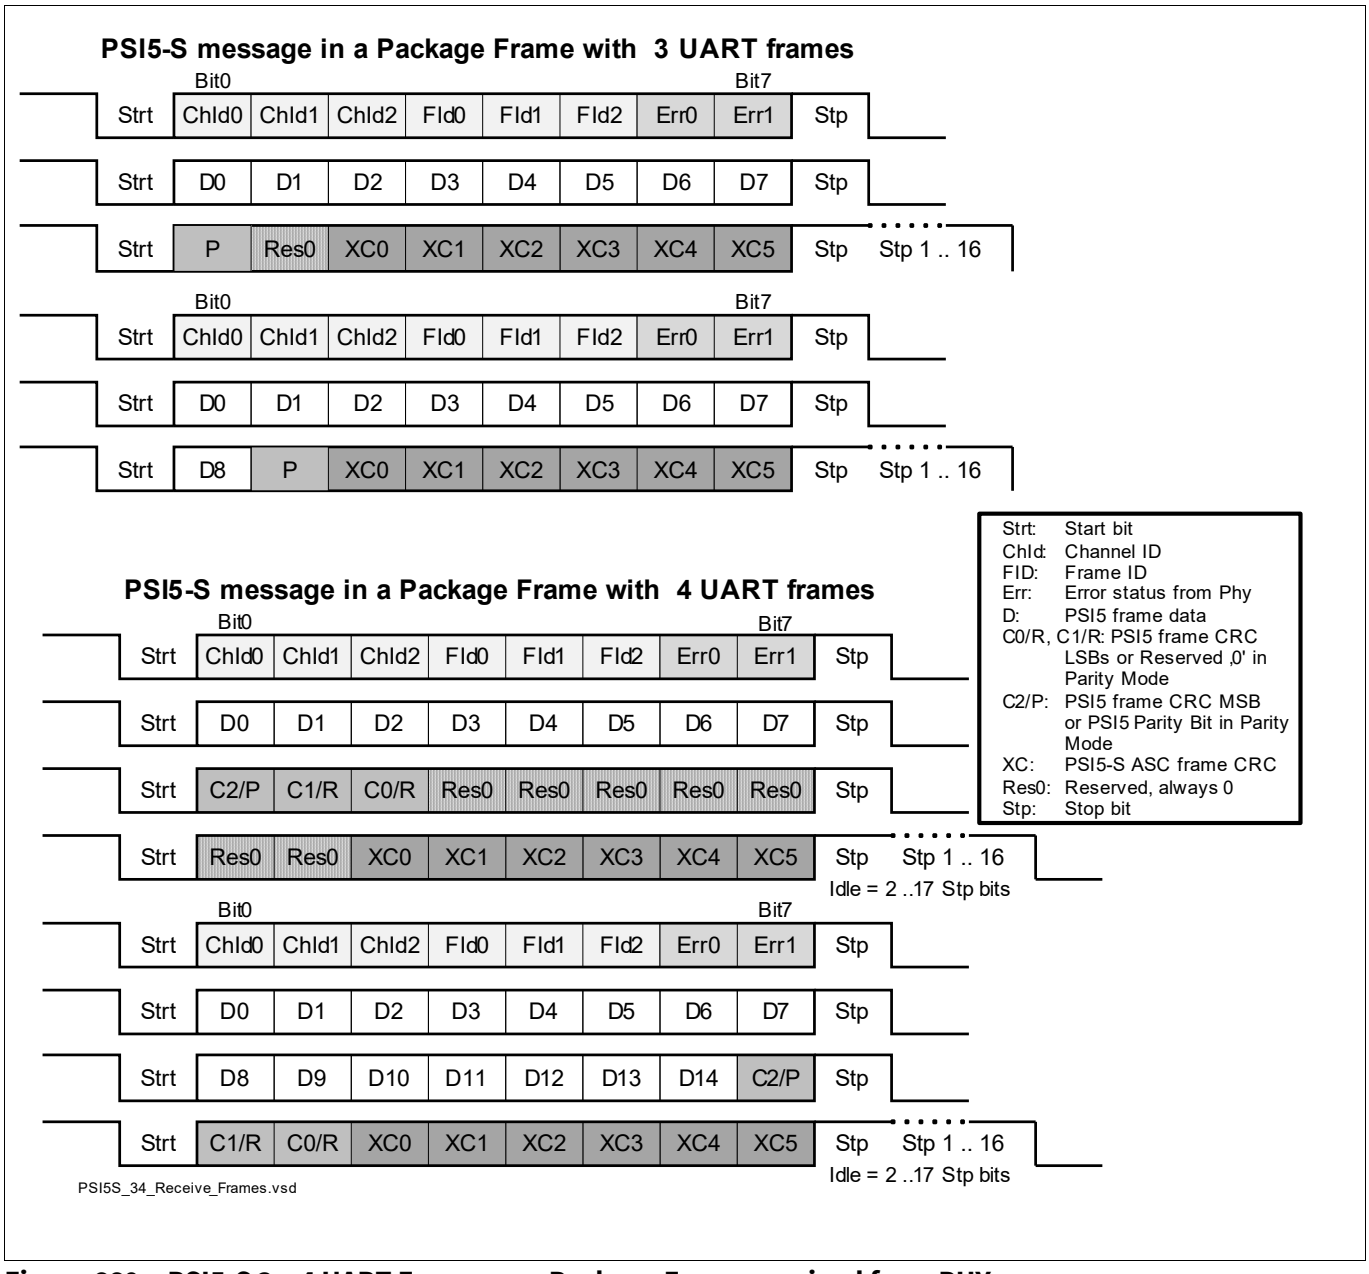

Figure 660 PSI5-S 3 + 4 UART Frames per Package Frame received from PHY

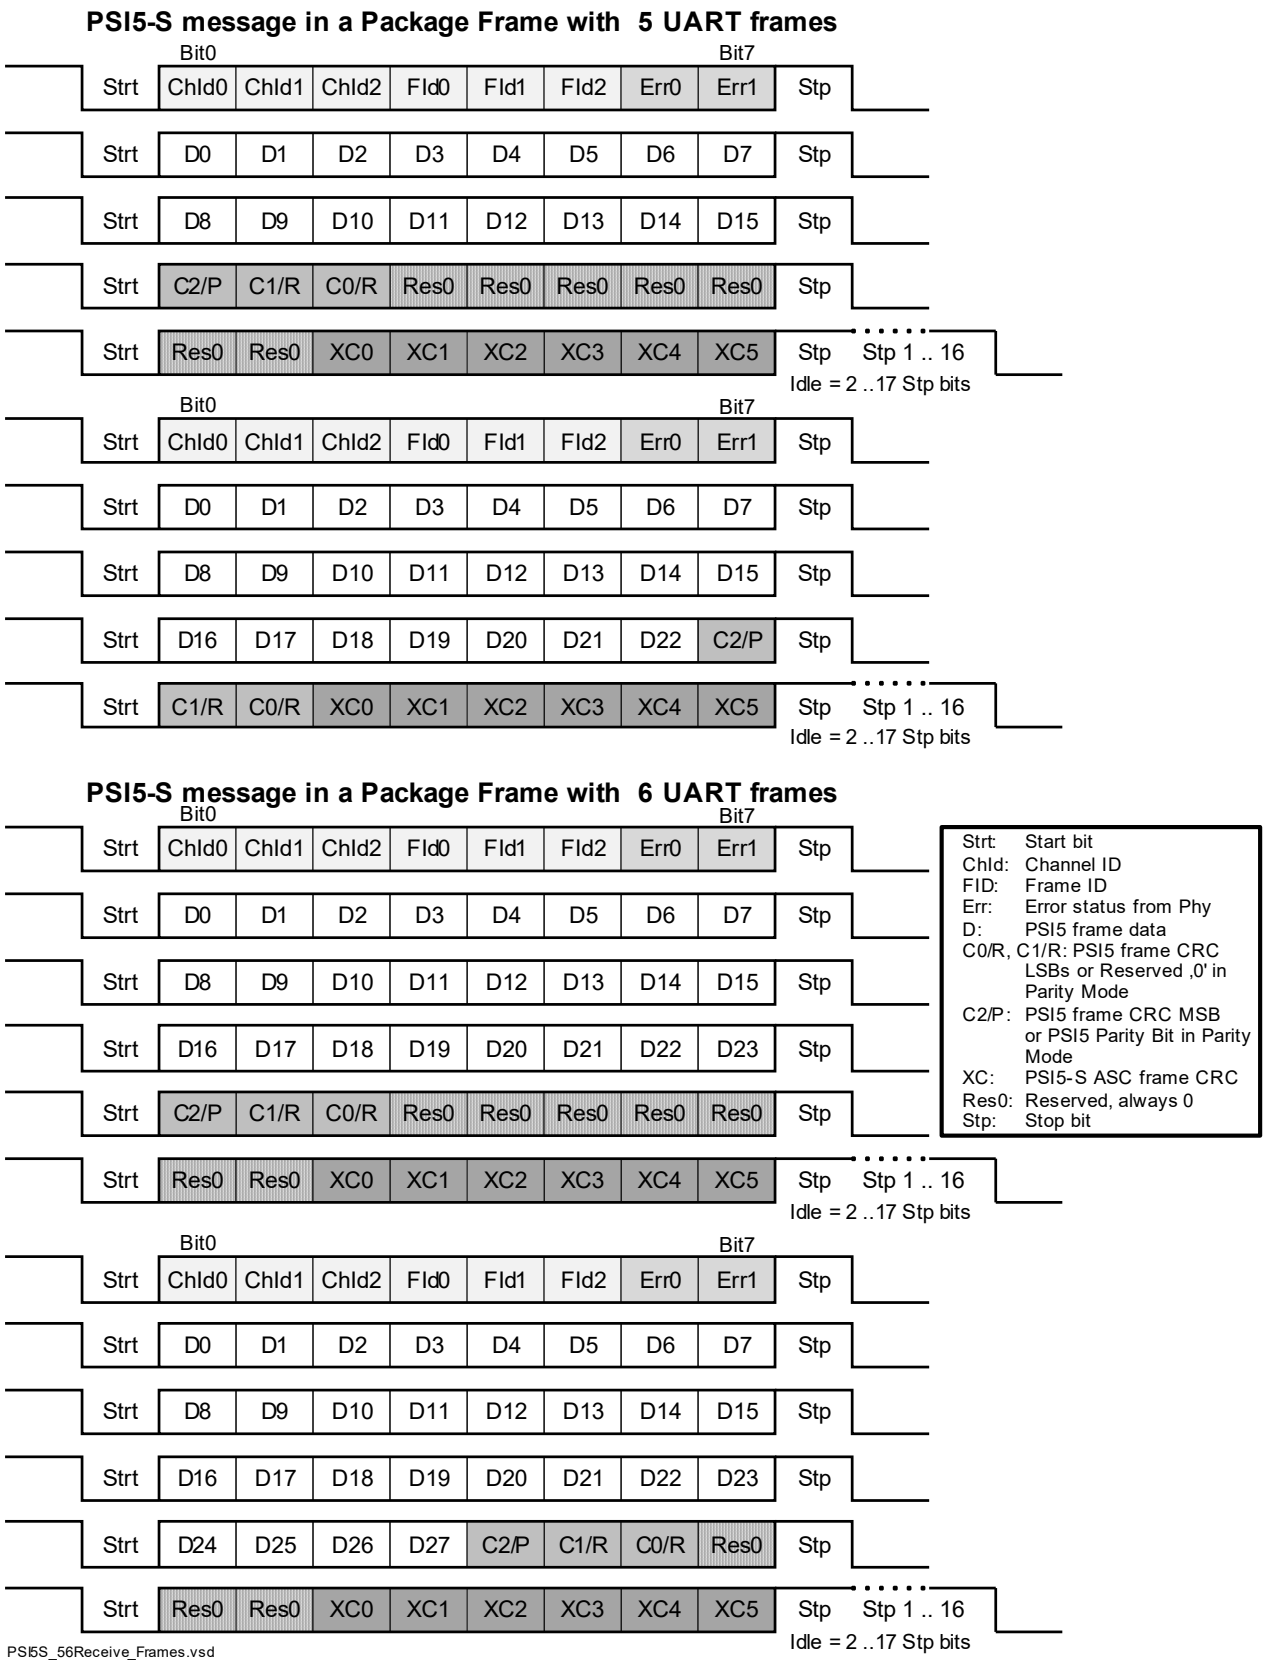

Figure 661 PSI5-S 5 + 6 UART Frames per Package Frame received from PHY

XCRC Content

XCRC is always sent at the end of the last UART Packet. For XCRC calculation, all bits of the preceding UART Frames that belong to the Packet Frame are relevant including potential stuffing bits (Res0). UART Start / Stop bits are excluded.

In detail the XCRC shall contain the header (ChID, FID, Err0, Err1), PSI5 frame data (D0 … Dx, PSI5 frame Parity Bit or CRC bits) and potential stuffing bits (Res0) between P/CRC and XCRC. Not included are start and stop bits of the UART packets and the 2 start bits (S0, S1) of the PSI5 frame.

The LSB of the first byte (ChId0) is fed first into the XCRC polynomial.

XCRC Calculation Method

XCRC equals the CRC defined in PSI5 Standard 2.0 “Frame format 4 ECU to Sensor Message CRC”, see **“ECU to Sensor Communication” on Page 11**.

43.3.2.1.2 PSI5-S UART Frames transmitted to PHY

Figure 662 shows the layout and definitions of the UART Frames sent by PSI5-S.

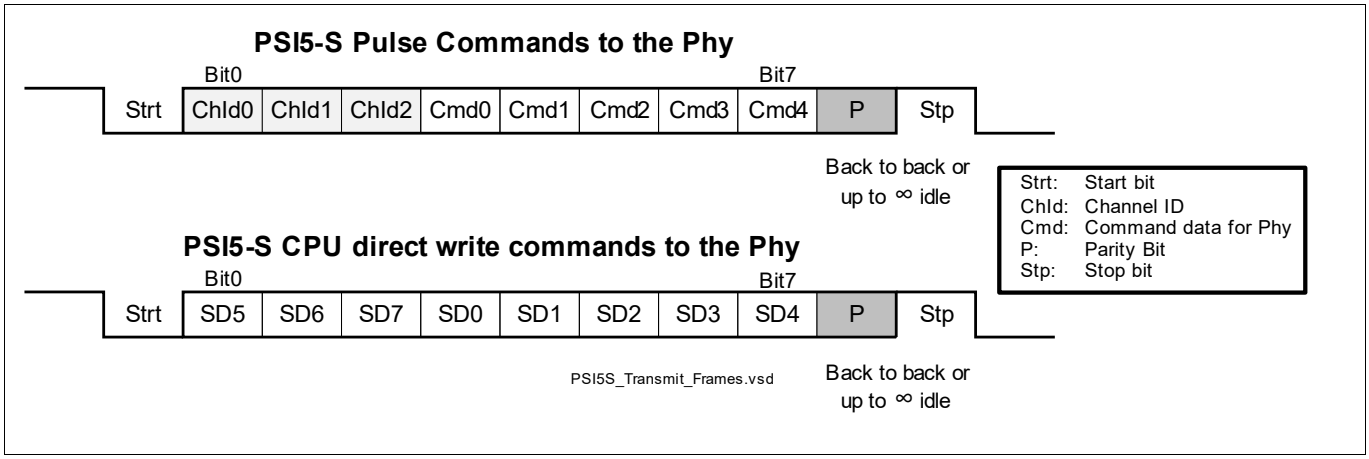

Figure 662 PSI5-S UART Frames transmitted to the PHY

43.3.2.2 Communication between PHY and Sensor (PSI5 Standard)

This chapter treats the frame formats on the PSI5 bus as short reference.

43.3.2.2.1 PSI5 Standard Frame Format

Figure 663 shows the principal layout and definitions of a PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

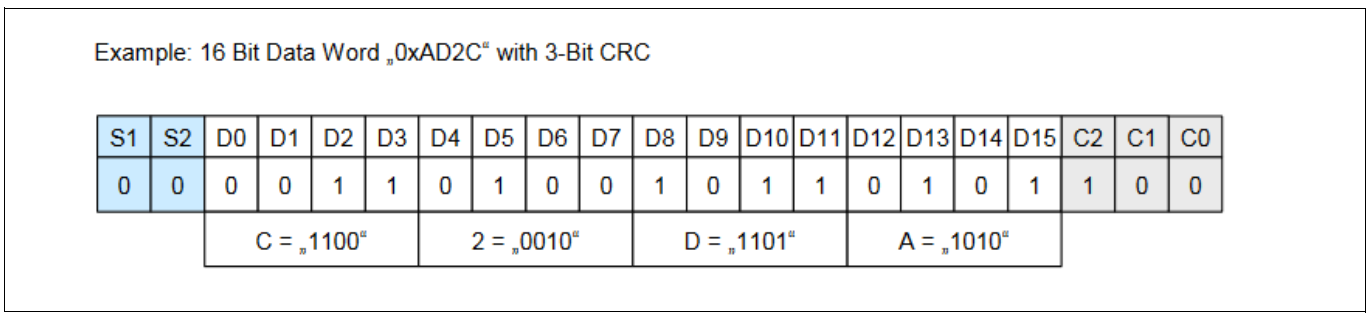

Figure 663 Standard PSI5 Frame Format

43.3.2.2.2 PSI5 Extended Frame Format

Figure 664 shows the layout and definitions of an Extended PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first.

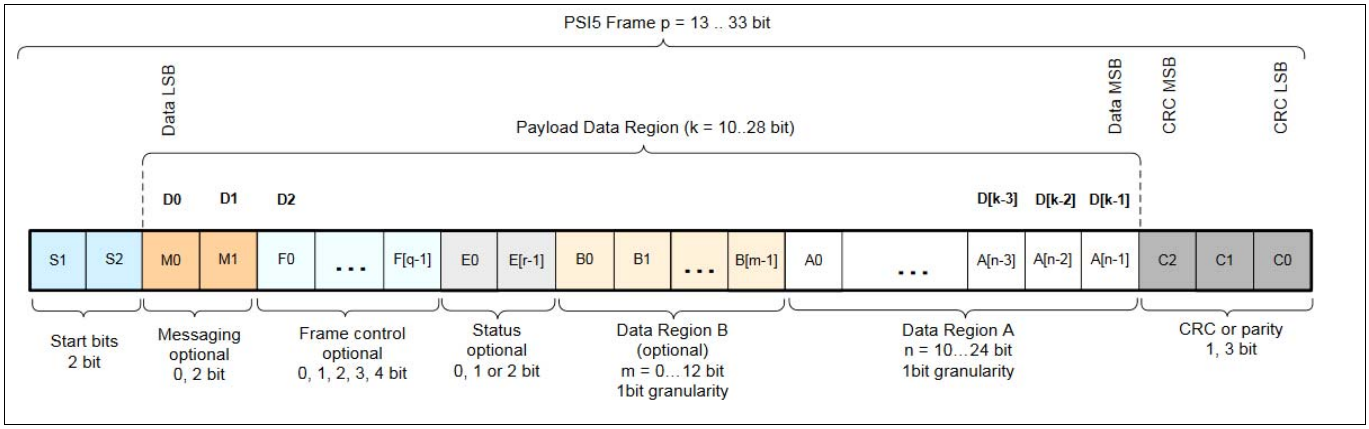

Figure 664 PSI5 Extended Frame Format

PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1) 1-bit even parity

2) 3-bit CRC

The applied generator polynomial of the CRC is g(x) = 1 + x + x3 with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

43.3.2.2.3 Sync Pulses

Sync Pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is transmitted via ASC to the external PHY. The external PHY translates this ASC command into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 Frame, starting with the 2 start bits, data and Parity or CRC. The timing diagram in **Figure 665** visualizes a synchronous transmission

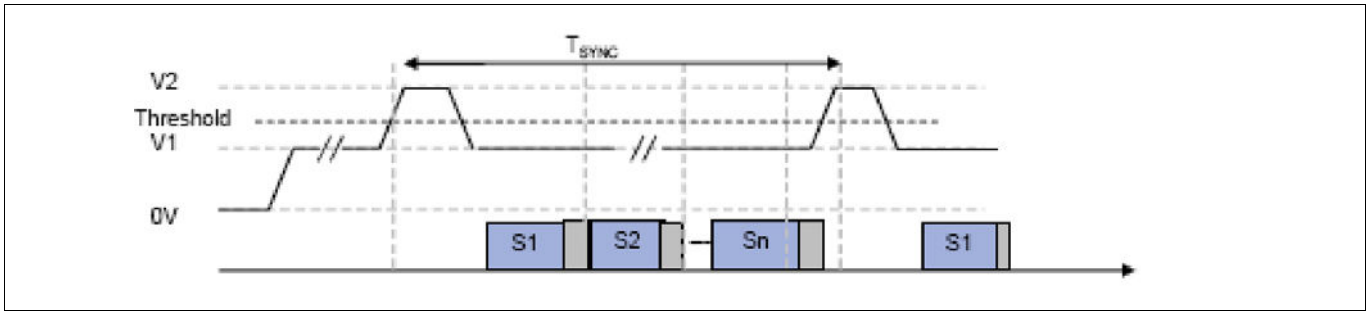

Figure 665 Synchronous Transmission

ECU to Sensor Communication

PSI5 V2.0 2011-06 defines 4 principle frame formats. Please refer to this standard document for more details. As the main target application is power train, only frame format 4 is cited here. This is the format for the power train sub standard.

Two methods for the ECU to Sensor Communication are supported:
Tooth Gap Method (see **Figure 666**) and
Pulse Width Method (see **Figure 667** and **Figure 668**) .

Tooth Gap Method

uses usually 31 sync pulses as start condition and start bits (0 1 0) to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

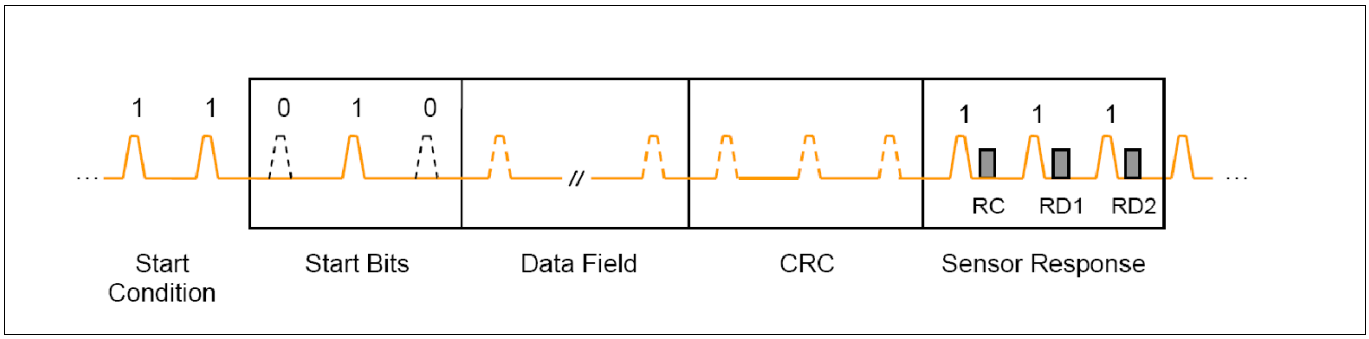

Figure 666 ECU to Sensor (Tooth Gap Method)

Pulse Width Method

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously.

Sync Bits of frame format 4

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted after every six bits of the sensor address and the payload data. With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

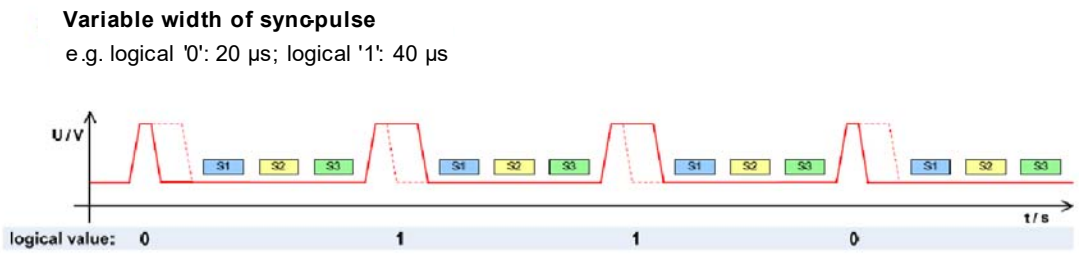

Figure 667 ECU to Sensor, Bit transmission (Pulse Width Method)

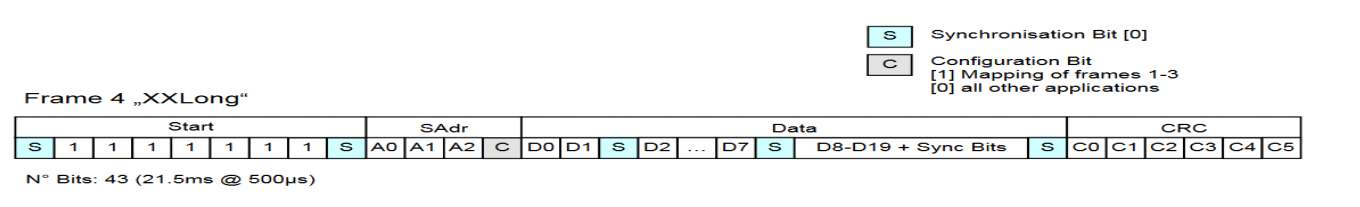

Figure 668 ECU to Sensor, Frame format 4 (power train)

Frame format 4 ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.
The generator polynomial of the CRC is
g(x)=x6 + x4 +x3 +1
with a binary CRC initialization value “010101”.
The transmitter extends the data bits by six zeros (as MSBs).
This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1 … C5].This CRC value is computed as a function of the contents of all address and data bits and Sync bits (“0” bits). For purposes of the CRC calculation, the bits shall be ordered: m = [A0 A1 … A3 D0 D1 0 D2 … D19 0].

In this implementation the number of elements is configurable. While the standard is 4 address and 20 data bits, the module allows longer or shorter messages too.

43.3.3 Clock Generation

The PSI5-S module provides 2 central Time Stamp Counters and the central Time Stamp Clock f_{TS} to each channel. See **Figure 669**. The clock of each Time Stamp Counter is individually selectable: either f_{TS} or any of the GTM inputs can be selected to drive them.

This chapter shows in detail how f_{TS} is adjusted.

For details on the principles of a fractional divider, please refer to the SCU chapter of section “Clock Control”.

The PSI5-S module provides 2 internal clock signals centrally

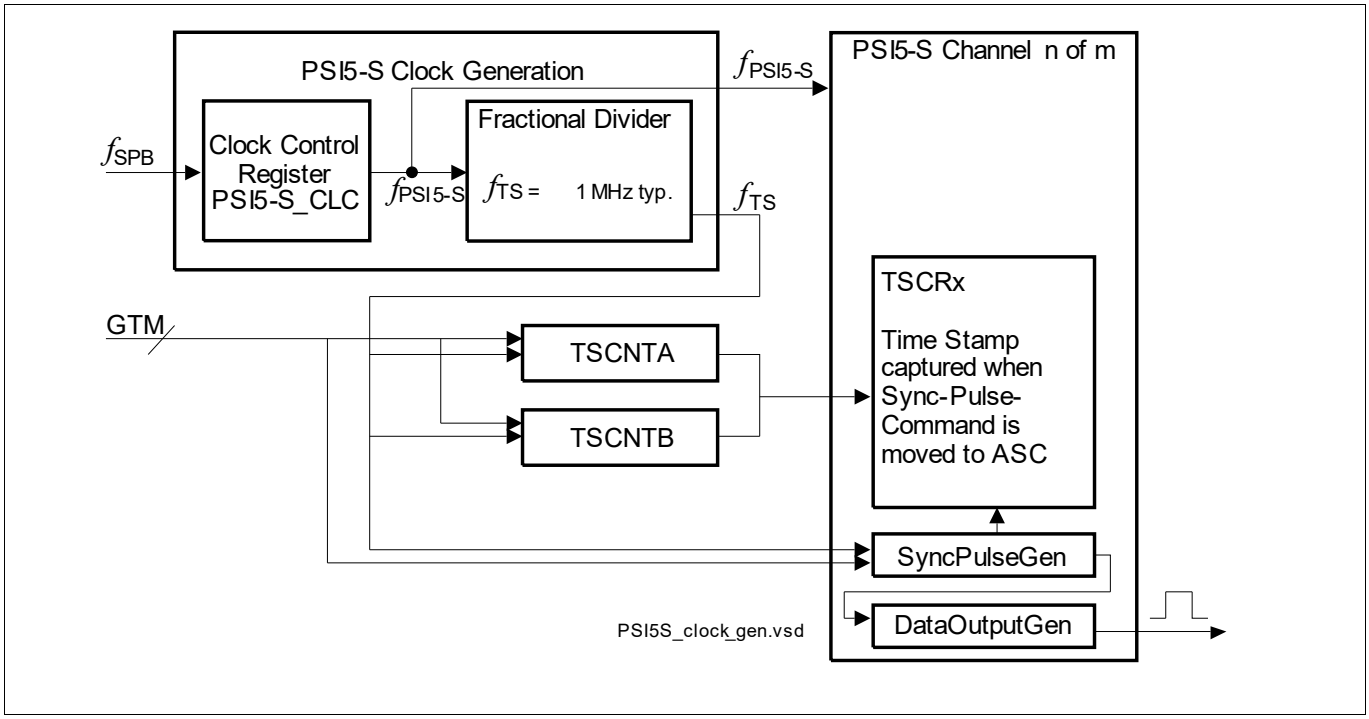

Figure 669 PSI5-S Module Clock Generation

- f_{PSI5-S}
  This is the module clock that is used inside the PSI5-S kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5-S} is controlled by register FDR and derived from the system clock frequency f_{SPB}. The clock control register CLC makes it possible to enable/disable f_{PSI5-S} under certain conditions.

The following two formulas define the frequency of f_{PSI5-S}:

$f_{PSI5-S} = f_{SPB} / (1024 - PSI5\text{-}S\_FDR.STEP)$; FDR.DM = 01B (43.1)

$f_{PSI5-S} = f_{SPB} \times PSI5\text{-}S\_FDR.STEP / 1024$ with STEP = 0 … 1023; FDRT.DM = 10B (43.2)

- f_{TS}
  This clock is usually used to drive the central Time Stamp Counters.
  It can be selected to drive the global sync pulse time base and
  inside the PSI5-S channels to drive the local sync pulse generators and watch dog timers. The fractional divider register FDRT controls the frequency of f_{TS}.This is usually adjusted to 1 MHz / 1 µs period time.

The following two formulas define the frequency of f_{TS}:

$f_{TS} = f_{PSI5-S} / (1024 - PSI5\text{-}S\_FDRT.STEP)$; FDRT.DM = 01B (43.3)

$f_{TS} = f_{PSI5-S} \times PSI5\text{-}S\_FDRT.STEP / 1024$ with STEP = 0 … 1023; FDRT.DM = 10B (43.4)

43.3.3.1 Overview on Clocks in the System

To reduce system cost, the external PHY can be supplied with a clock from this device. EXTCLK1/2 (SCU), CMU_ECK (GTM) or by PSISCLK (PSI5-S). The range is limited to 20 … 25 MHz maximum for proper clock transmission. The PHY needs to provide 3 clocks from this: Sample clock for 189 kHz, and 125 kHz and the ASC oversampling clock.

A divider by 2 is added between the actual fractional divider block and the output signal $f_{PSISCLK}$ in order to achieve a duty cycle of 50% (plus tolerances due to fractional divider jitter). This is why the formulas contain the division by 2 at the end.

- $f_{PSISCLK}$
  This clock is used to drive the external PHY.
  The fractional divider register **FDO** controls the frequency of $f_{PSISCLK}$.

The following formula defines the frequency of $f_{PSISCLK}$:

$$f_{PSISCLK} = f_{ASC} / (2048 - PSI5\text{-}S\_FDO.STEP) / 2; DM = 01B \quad (43.5)$$

$$f_{PSISCLK} = f_{ASC} \times PSI5\text{-}S\_FDO.STEP / 2048 / 2 \text{ with } STEP = 0 \ldots 2047; DM = 10B \quad (43.6)$$

In order to relax the requirements with respect to ASC communication while allowing for high bit rates, some additional provisions have been made. The ASC Sub Module is supplied with a higher frequency (f_{ASC}) to allow for very high precision at high baud rates (4 - 12,5 M). As a second measure to achieve this, the fractional divider in ASC is longer than in the standard module. **Figure 670** illustrates the situation on PCB. Refer to the ASC sub chapter for baud rate calculations.

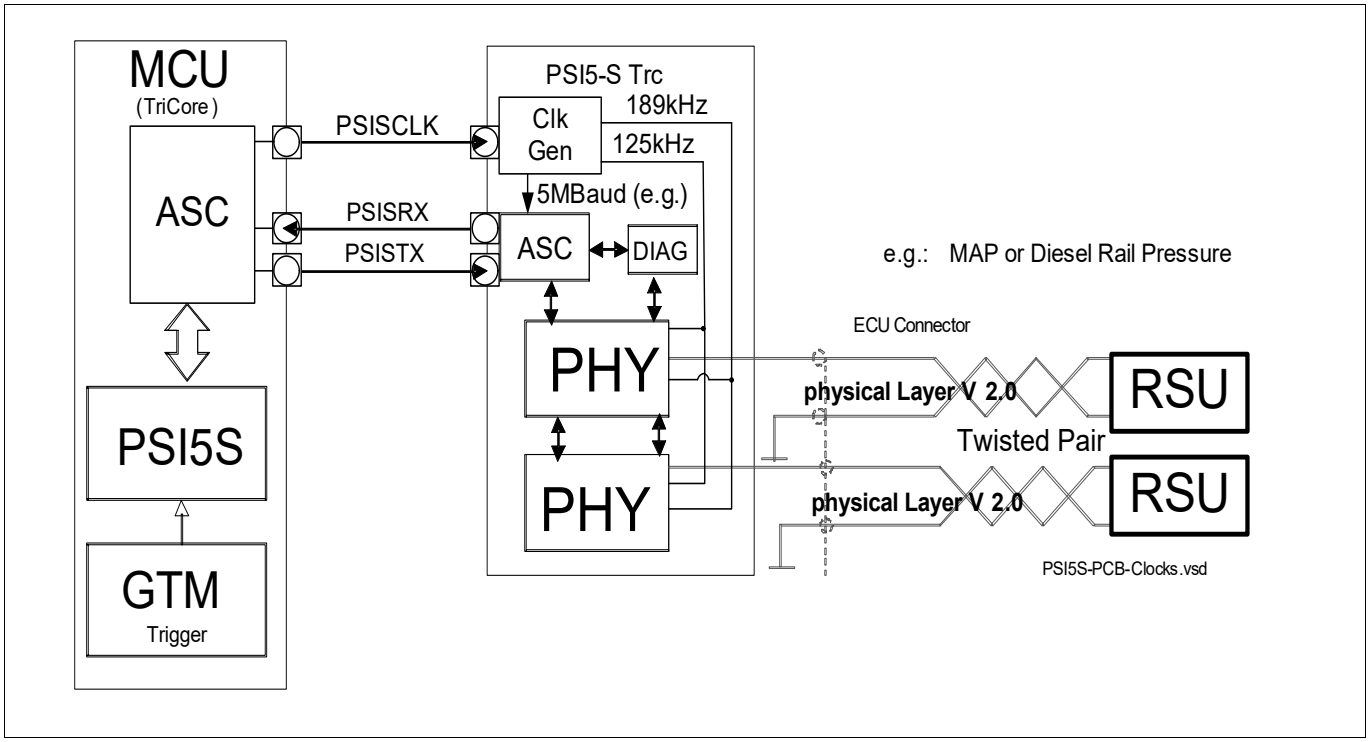

Figure 670 PSI5-S Clock Requirements of PHY

43.3.4 Time Stamp Generation

Two time bases can be selected for Time Stamping:

Any of TSCNTA and TSCNTB provide one Time Stamp Counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by SW single or synchronously.

The last sync pulse sent on a channel is stored in the sync pulse time stamp capture register TSCRx. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture. Non recoverable Packet Frames will be stored with the current value of TSCNTA/B directly copied to TSM. See RCRAx on **Page 60** and on for more details.

For each channel the capture time (TSCRx) is stored.

Figure 671 shows the time stamp generation:

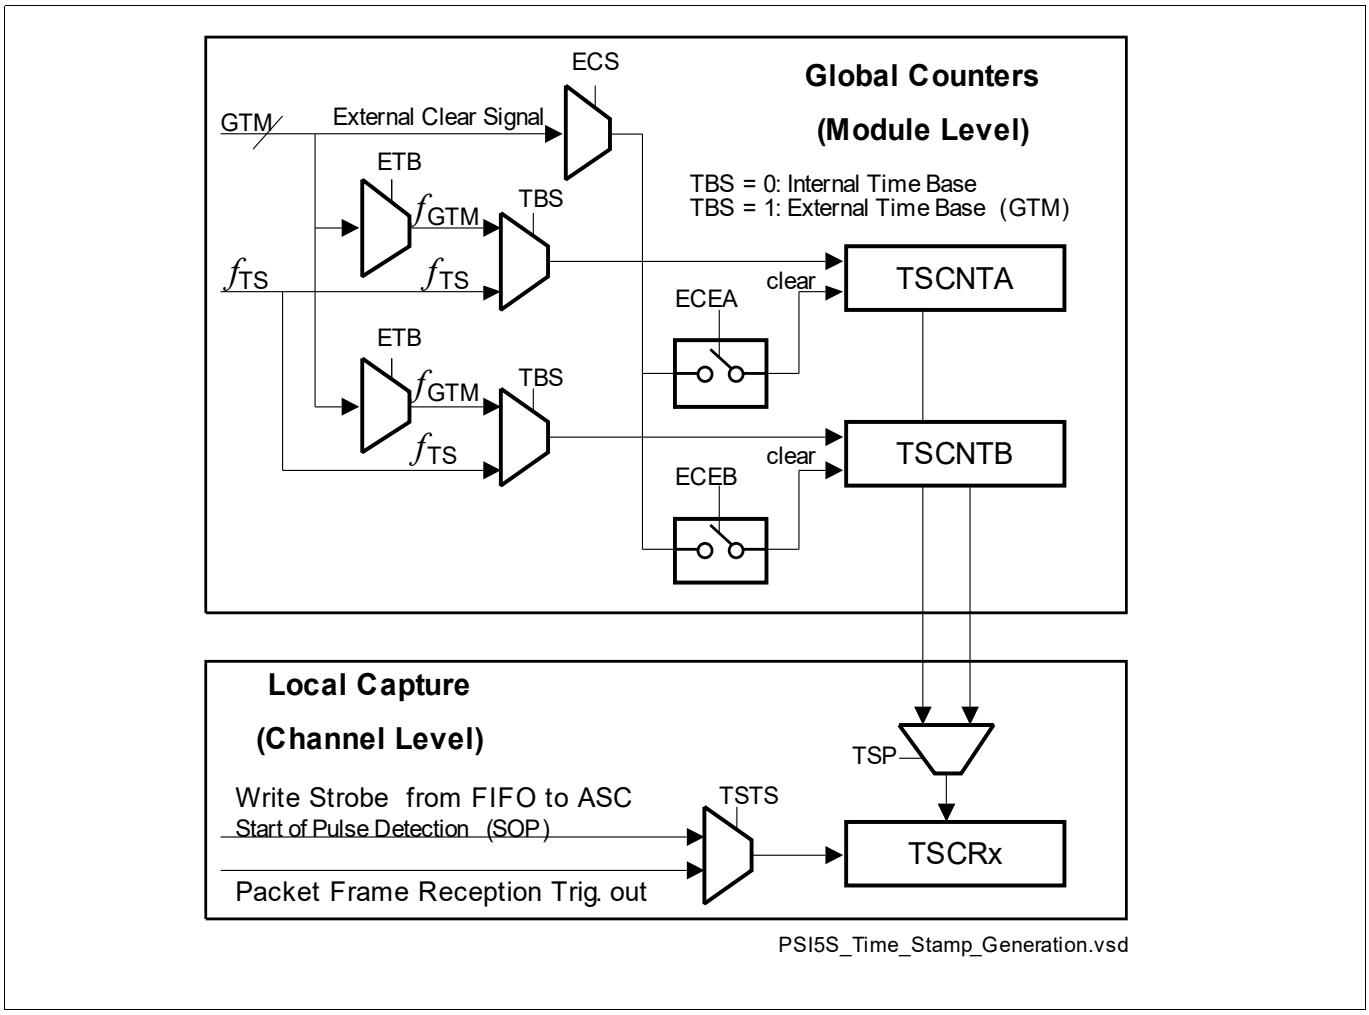

Figure 671 Time Stamp Generation

43.3.5 Watch Dog Timers

The value entered in WDTx.WDL defines the time in multiples of TTS (defined in FDRT) until expiry of the watch dog.

There are two modes of operation that can be selected with bit RCRAx.WDMS.

In normal operation an interrupt (TEI) is issued if the distance between two RDIs is longer than specified in WDL. In this mode, The internal watch dog timer is started automatically when the channel is enabled.

In synchronous mode, TEI is issued if the watch dog timer expires without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long.

In both modes, only completely and correctly received Packet Frames on channel x can qualify, i.e. Packet Frames with XCRC checked ok. Otherwise the channel number can not be determined - the referring WDLx not be selected.

The internal watch dog timer is compared to WDL. A match

- triggers a TEI.
- restarts the watch dog timer. I.e. it clears the internal watch dog timer and it counts on from zero. TEI is repeated if no recoverable frames are received.

If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed.

Asynchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is cleared the internal watch dog timer y is restarted on reception of a new recoverable frame (RDIx) for the referring channel. It is not restarted by a sync pulse and not stopped by a certain number of received Packet Frames.

The example below shows the use of the watch dog. The sync pulse is completely ignored by the watch dog system.

F2 is the only frame coming too late. All others start before the expiry of the watch dog.

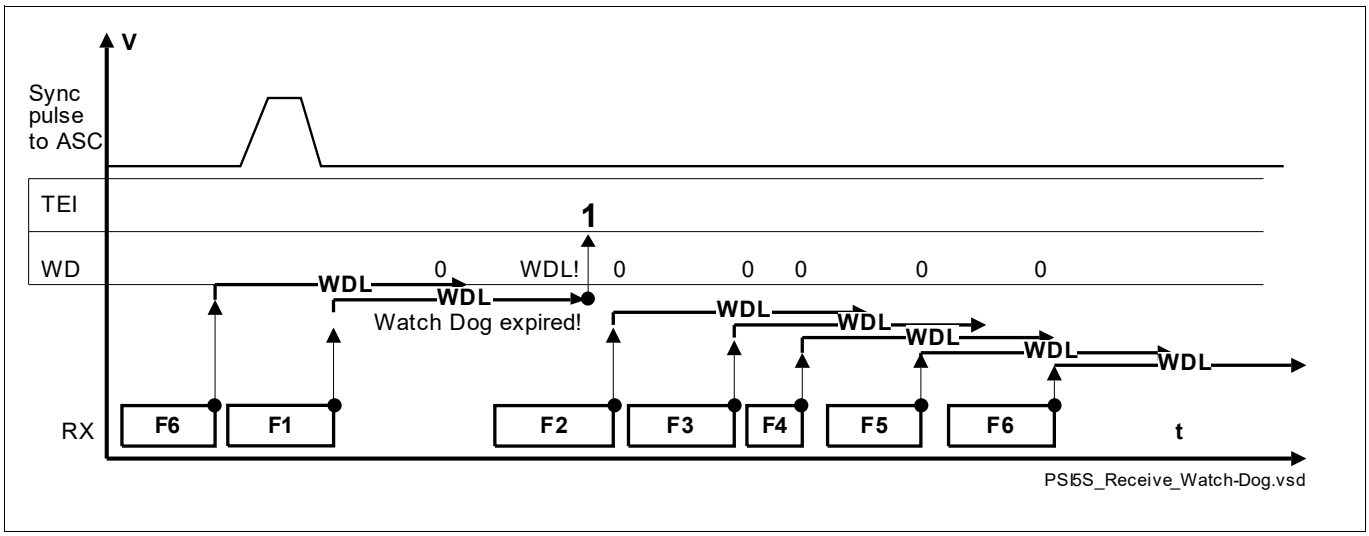

Figure 672 Watch Dog Timers

Synchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is set the WDT is restarted on sync pulse and stopped at reception of the last frame configured in NFx. Register NFCx contains the bit fields NFx which configure the number of Packet Frames expected after the sync pulse. FCNT.FCx is the counter that is compared with NFx.

The Watch Dog Timer is restarted (cleared and set to run), each time a Sync Pulse is transferred for the referring channel from FIFO to ASC. The Watch Dog Timer of this channel is forced to stop if the number of a received Packet Frames (counted in FCNT.FCx matches the number configured in NFC.NFx. This supports in particular angle synchronous channels where the distance of packets can vary strongly with e.g. the roundings per minute of an axis.

The WDT can not stop in time if a non recoverable (and thus not countable) Packet Frame is received! If more than the configured number of Packet Frames are received, no dedicated interrupt is issued for this but the frame is still received correctly.

RCRAx.WDMS should be 0 on asynchronous channels. Otherwise, the internal Watch Dog Timer will be stopped after reception of the number of configured frames but never be restarted due to the lack of a Sync Pulse!

If a sensor is not present in a special configuration, NFx must be reduced accordingly! E.g. if out of F1 … F6 the F2 is missing, only 5 frames are configured.

Please refer to register **“NFC” on Page 58** for detailed description.

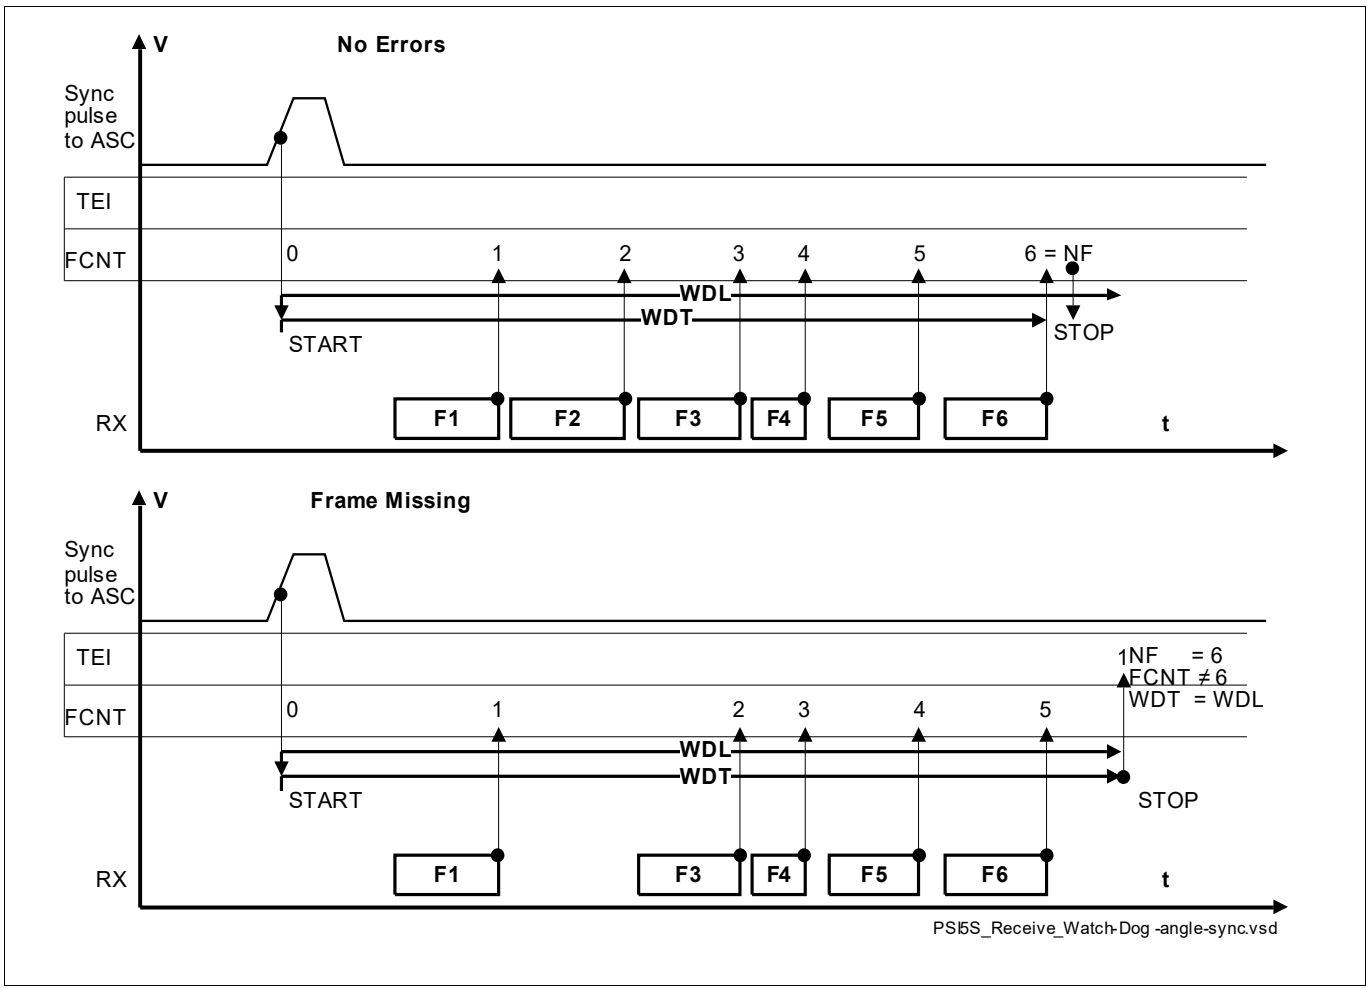

Figure 673 Watch Dog Timers in synchronous mode

43.3.6 Send Data

This chapter contains the details of how data to be sent is prepared. The scope extends to:

- Periodic Triggers
- Angle Synchronous Triggers
- ECU to Sensor communication

43.3.6.1 Channel Trigger

The Channel Trigger Value Register CTVx contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

The Channel Trigger Value CTV is the compare value which restarts the counter CTC on equality and only on equality. At exactly this time, a sync pulse is triggered.
The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - “CTC preset value”

I.e. CTC preset is > CTV so that the the time to roll over is the offset.

Of course CTC preset can be < CTV so that this CTC has some advance.

Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external PHYs can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.

For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 … 7 can be used.

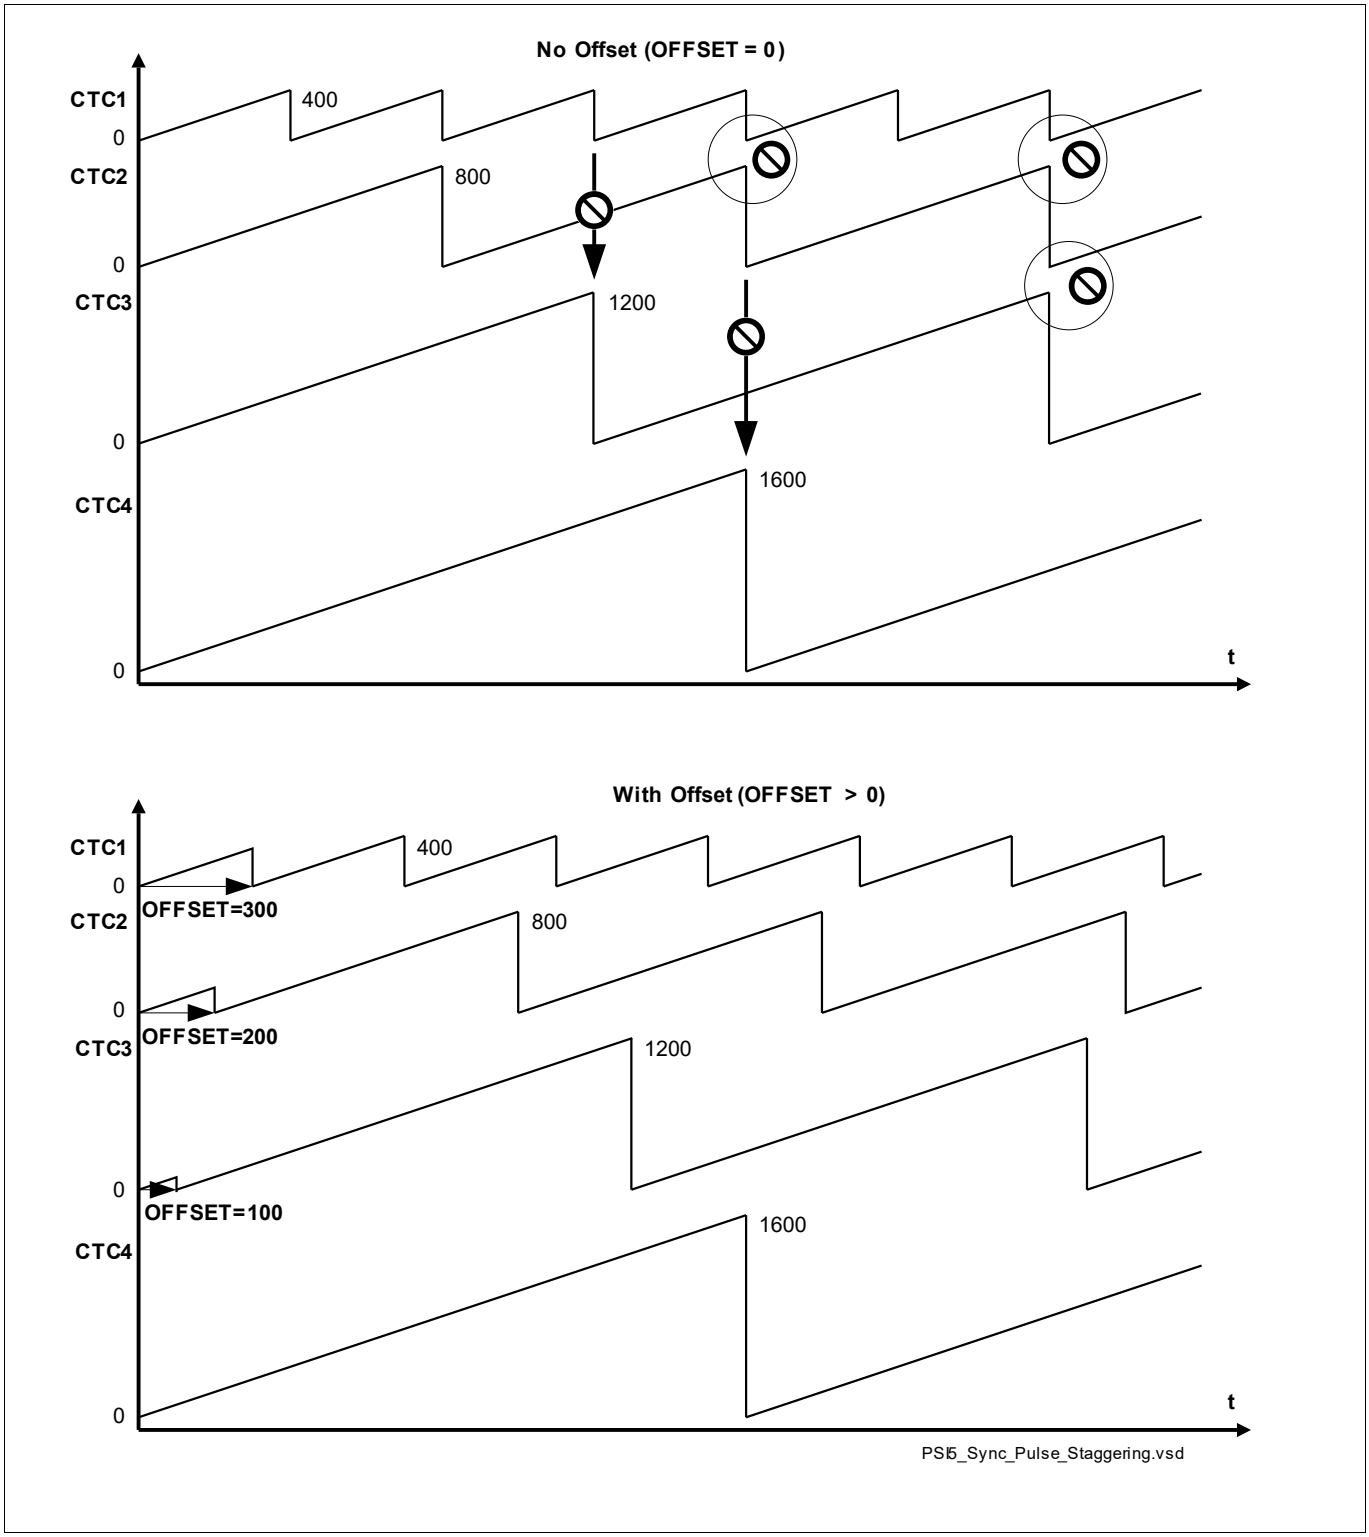

Figure 674 PSI5-S Pulse Staggering

43.3.6.2 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (Tooth Gap Method, EPS[0]=0)
- sync pulses for ECU to Sensor communication (PWM Method, EPS[0]=1)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. The pulses will be modulated according to the selected standard. EPS selects between PWM method and Tooth Gap Method with pulse dropping.

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TPF.

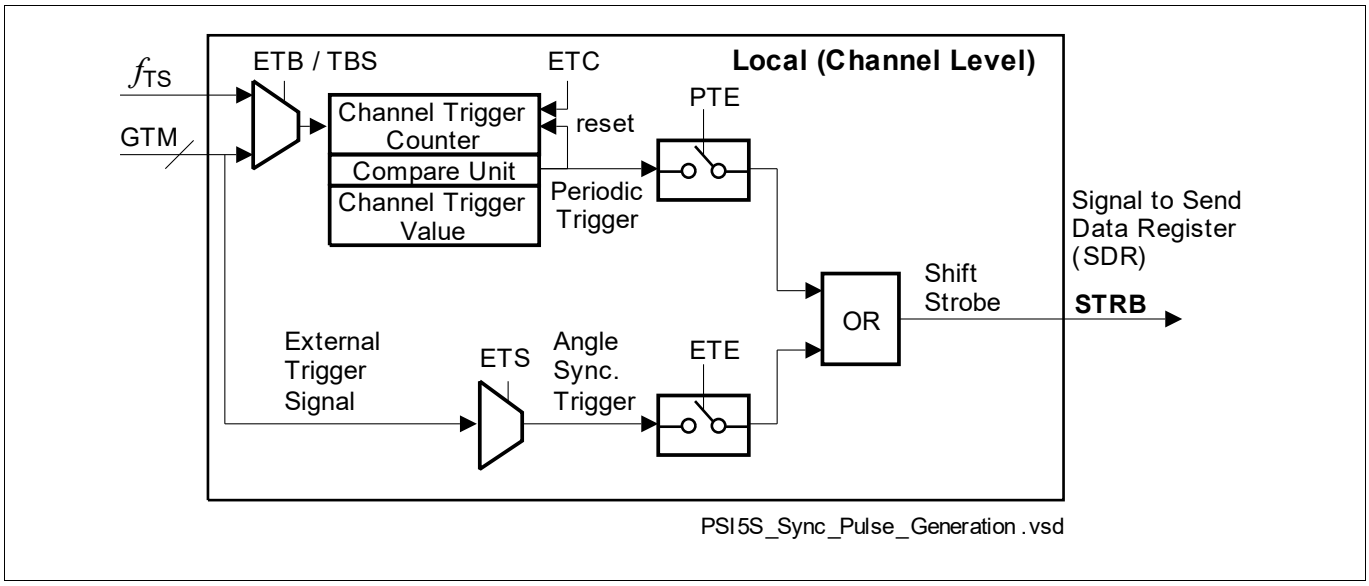

Figure 675 PSI5-S Sync Pulse Generation

43.3.6.3 Send Data Preparation

Figure 676 shows the mechanisms how ECU to sensor communication data is treated:

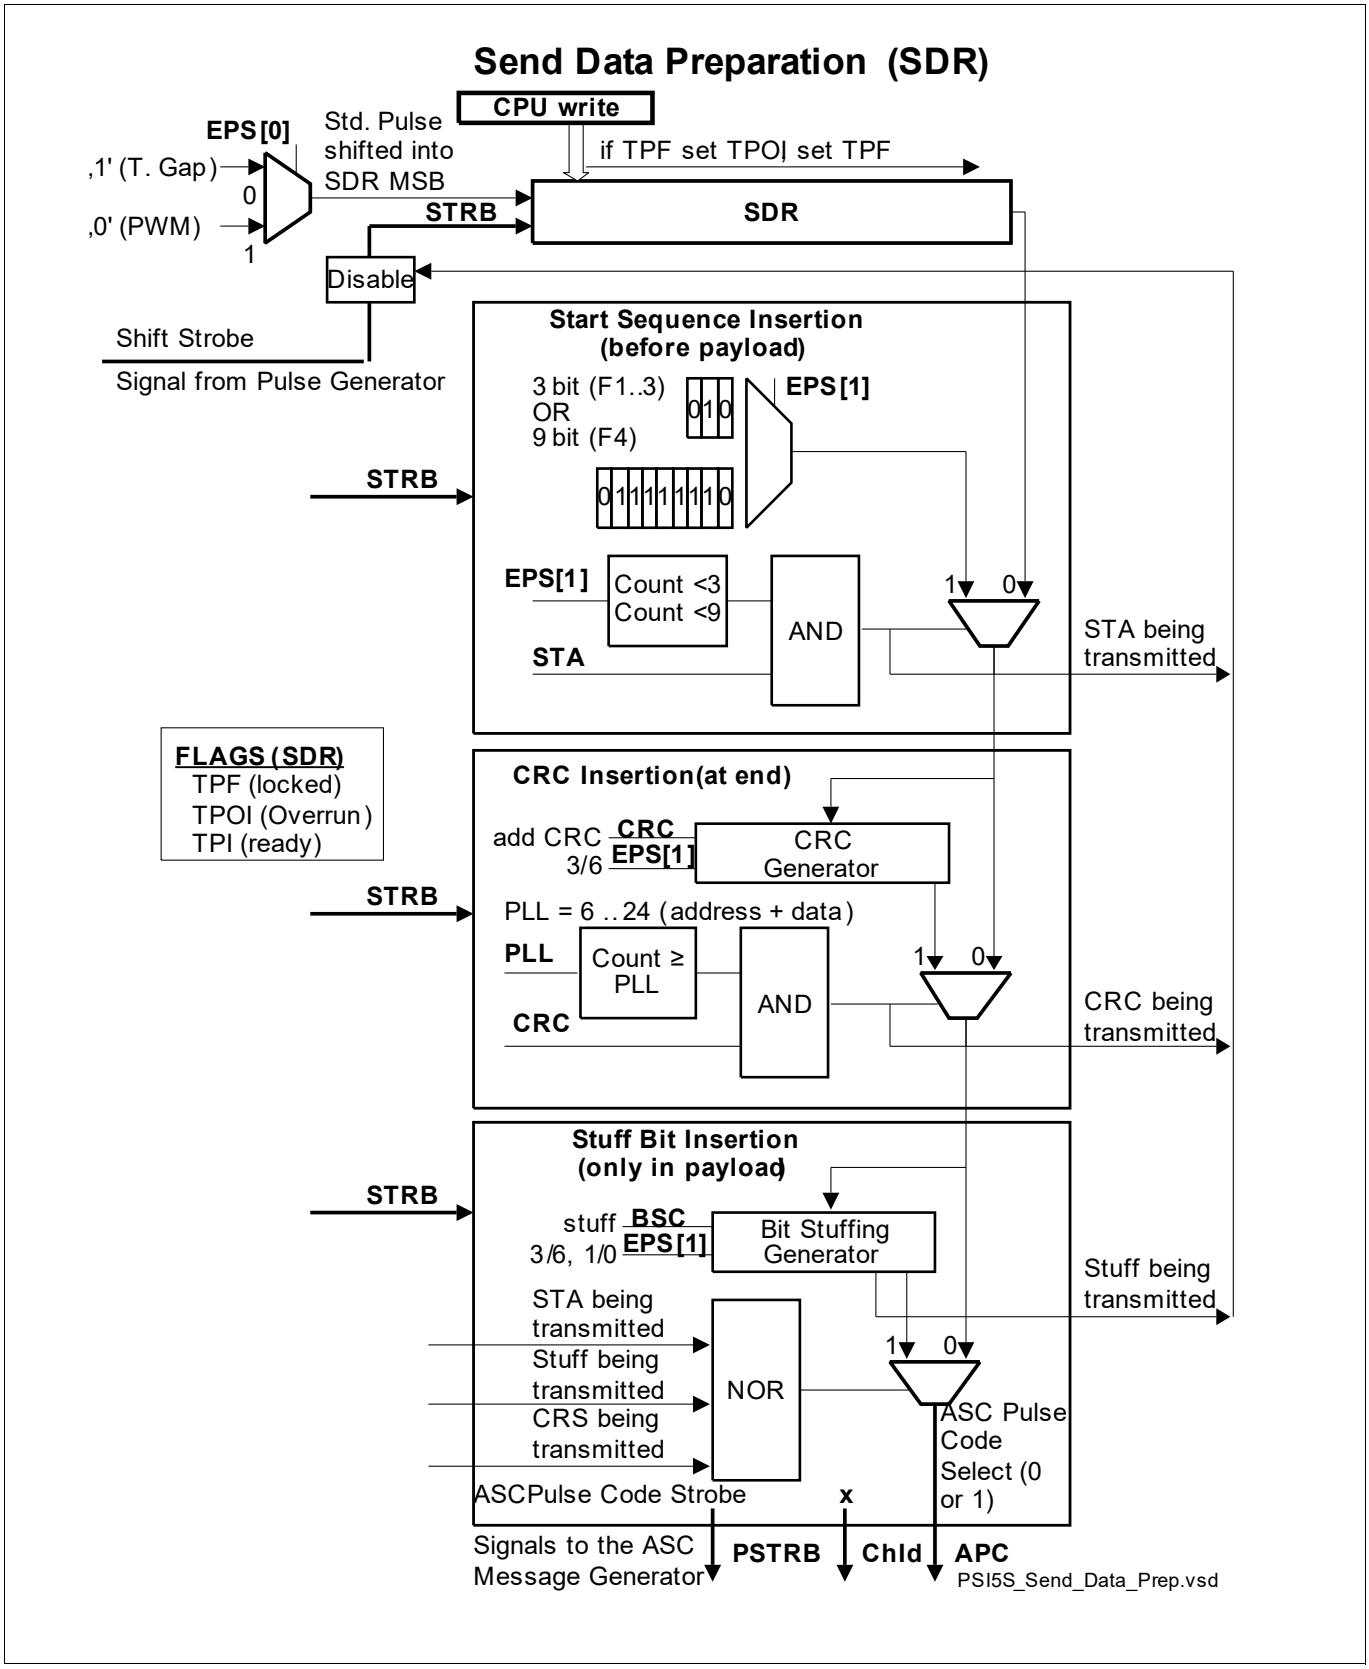

Figure 676 PSI5-S Send Data Preparation

43.3.7 Message Generation

Figure 677 shows the message generation logic. The generated ASC commands are sorted into an internal FIFO of 8 entries of 9 bits width. The MSB stores the information, if a command is generated from the sync pulse generation (ASC Pulse Code Strobe issued the write into FIFO) or if the CPU wrote a command. This is important for the Time Stamp generation. Usually the Time Stamp is captured when a Sync Pulse Command leaves the FIFO i.e. is copied to the ASC TX buffer. Commands stored in the FIFO can only trigger a Time Stamp capture if they are marked as Sync Pulse in bit 8. Nevertheless, the CPU can set MSB (bit 8) in Register CDW if the command is to be treated like a Sync Pulse Command and a Time Stamp should be captured. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture and bit 9 is ignored.
There is no further arbitration of the CPU and Message Generation Unit. The PHY answers CPU commands with standard frames of fixed predefined length in channel 0 frame 0.

Interrupt FOI is issued if a transfer to the FIFO was generated by the message generation unit or by CDW (CPU direct write register) while the FIFO was full. In a correct setup, this will never be the case as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays. In most cases too many write accesses to CDW will be the root cause. This exceptional condition can be handled either by waiting until the FIFO has transferred at least one command or by a module reset by SW. It should not occur in the application but FOI should help SW generation and debugging.

The transfer path of a command to the ASC could add jitter to sync pulses.

In case several channels request a pulse at exactly the same time, the channel with the lower channel number is served first and CDW has highest priority.

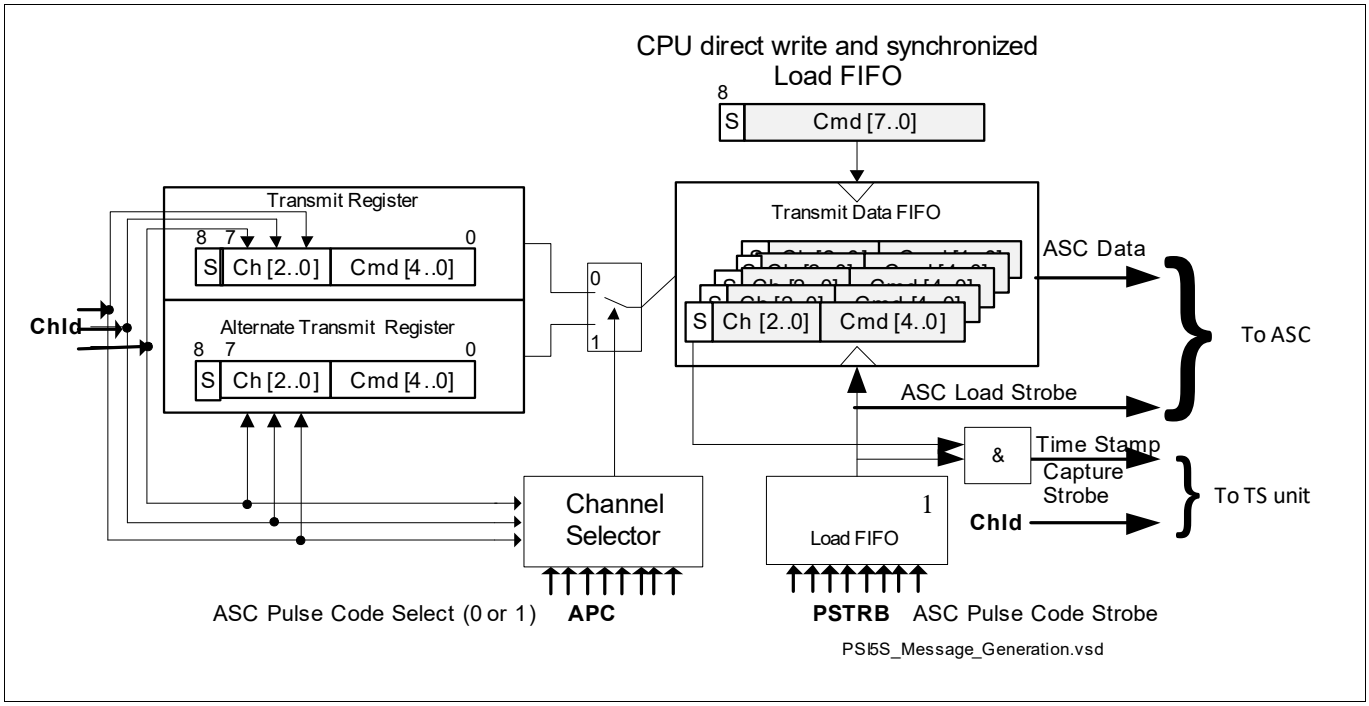

Figure 677 PSI5-S Message Generation Logic

43.3.8 DMA Support

The received frames come in sequentially and are XCRC checked. The complete reassembled frame including Channel Id (ChId), Frame ID (FId) and status are available at RDR and RDS. TSM shows the latest time stamp of the currently received channel.

RDR, RDS and TSM are located in 3 sequentially addressed registers. This way, they are easily readable by DMA. See **Figure 678**.

43.3.8.1 Single DMA, 8 dedicated DMAs

With one single DMA channel, one common frame buffer in the system memory can be build up. All frames can be collected from RDR, RDS and TSM. The DMA source address is programmed to be always RDS, block transfer is set to 3 words with auto address increment. The target is set to be automatically incremented. This results in one buffer in system memory with all frames from all channels.

Individual buffers for each channel can be build up if more DMA channels are used. Each channel can generate its own receive triggers RDI and RSI. Thus individual DMAs can be set up for each channel similarly to the single DMA use case but with individual target addresses for each channel.

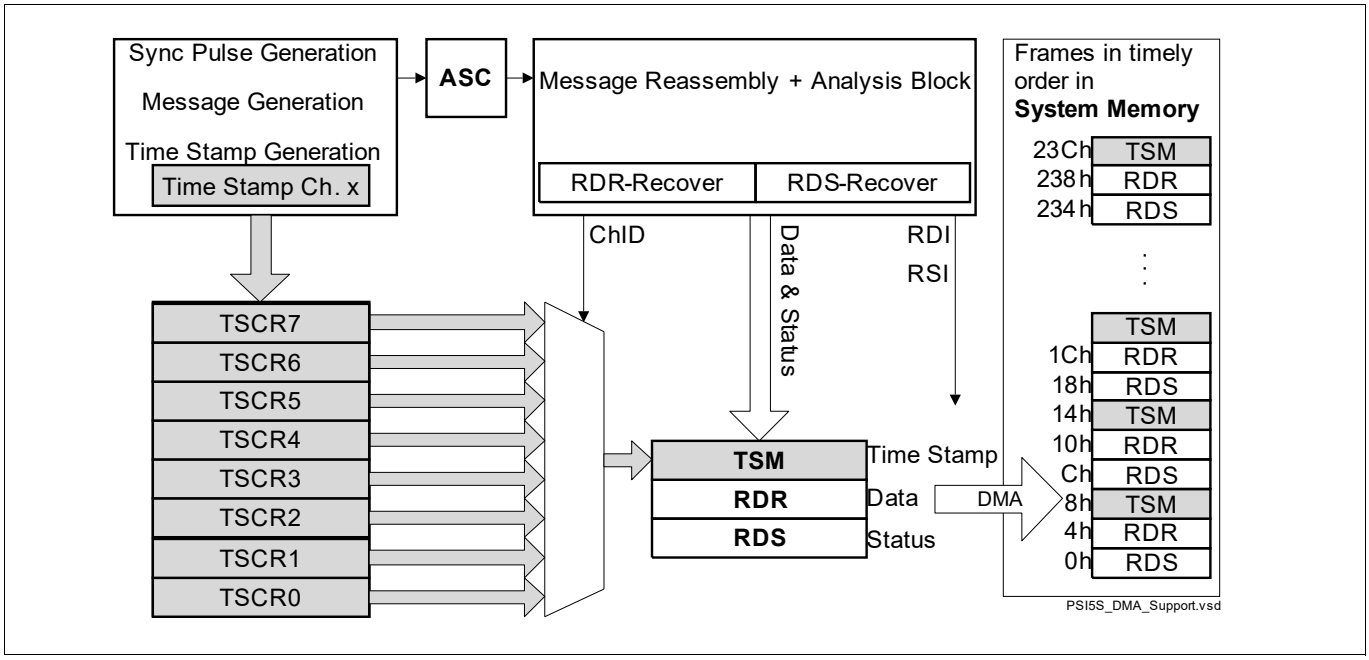

Figure 678 PSI5-S Single DMA Support

43.3.8.2 Two daisy chained DMAs

The PSI5-S supports sorting by channel with only two DMA channels. Register TAR contains the target address that is to be copied by the first DMA into the target address register of the second DMA. Source and target of the first DMA are fixed (DMA register SADR and DADR). The target address offered in TAR is calculated by PSI5-S by adding an offset value to the programmable base address defined in BAR. This allows for locating the channel buffers at any location in system memory.

The resulting base + offset is presented in TAR. The target address depends on:

- BAR (base address)
- ChID: offset of channel number currently received (channel number x 6 (buffer lines) x 3 (words per frame) x 4 Bytes per word = 72 Bytes x channel number. This allows to receive 6 frames per channel which equals the maximum number of PSI5 Frames per Sync Pulse.
- FID: offset of frame ID currently received. (3 words i.e. 12 Bytes per frame)
  Note that the frame ID used for this sorting depends from RCRAx.FIDS! In particular in asynchronous mode, FIDS needs to be set so that the FID from the Packet Frame is replaced by a rolling number.
- Note that the message reassembly unit forces non recoverable messages to be stored at the address for ChID = 0, FID = 1 but with original ChID and FID! I.e. RDS contains the CHID and FID as received in the first UART Frame for better debugging!
- The source address of the second DMA needs to be programmed to be fixed to the address of RDS. Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).
  Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see DMA chapter, DMA_MExCHCR.BLKM) 32 bit (the data width is defined in DMA_MExCHCR.CHDW) accesses.
  Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).

The second DMA must be of the next lower priority than the first. Selecting hardware request input via CHCRxz.PRSEL allows for daisy chaining the two DMA channels. See **Figure 679**.

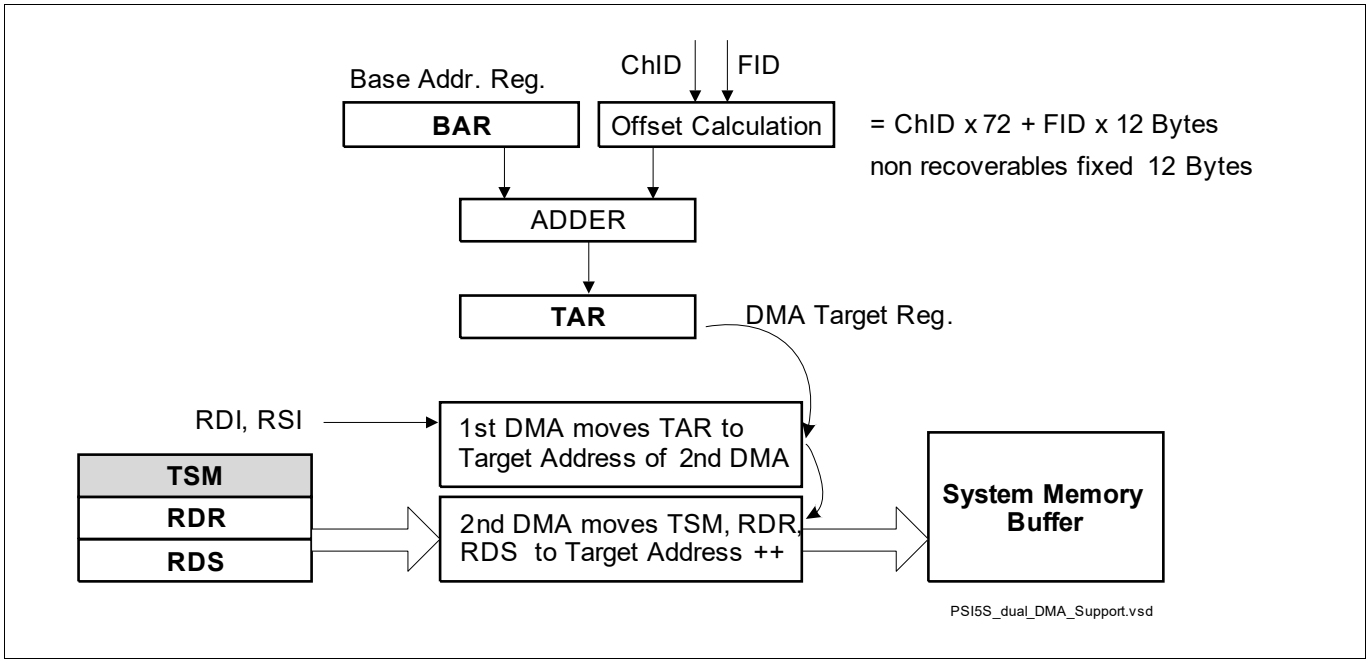

Figure 679 PSI5-S Dual DMA Support (daisy chained)

Table 430 shows the detailed mapping of the received frames resulting from the described calculation rules:

43.3.8.3 Interrupts for DMA support

Interrupts for Single DMA usage

Interrupts RDI or RSI can be used as trigger for the DMA transfer from TSM/RDS/RDR.

Interrupts for two daisy chained DMA usage

If one of the buffers is full, this is signalled to SW by interrupt CHCI. The "status buffer full" is defined as follows: current number of received frames counted in FCNT.FCx equals the number of expected frames configured in NFC.NFx. In synchronous mode this is the case, if all expected PSI5 frames after a Sync Pulse are received by PSI5-S. The number of expected frames is looked up in register NFC.NFx for channel x. In Asynchronous mode, NFC.NFx should be programmed to 6 while RCRAx.FIDS is set. This way the FID for an asynchronous channel is a rolling number 0 … 5 and the 6 buffer locations are used completely before CHCI is issued. See **Figure 680**.

There is a delay between CHCI and the completion of the DMA transfer of the last set of RDS, RDR and TSM to the system memory! SW needs special checks to grant data consistency, e.g. evaluating the DMA interrupts or comparison of the Time Stamps in the System Memory!

CHCI is not granting that all data is completely moved to system memory by DMA!

Improved Data Consistency with Packet Frame Count (PFC)

For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

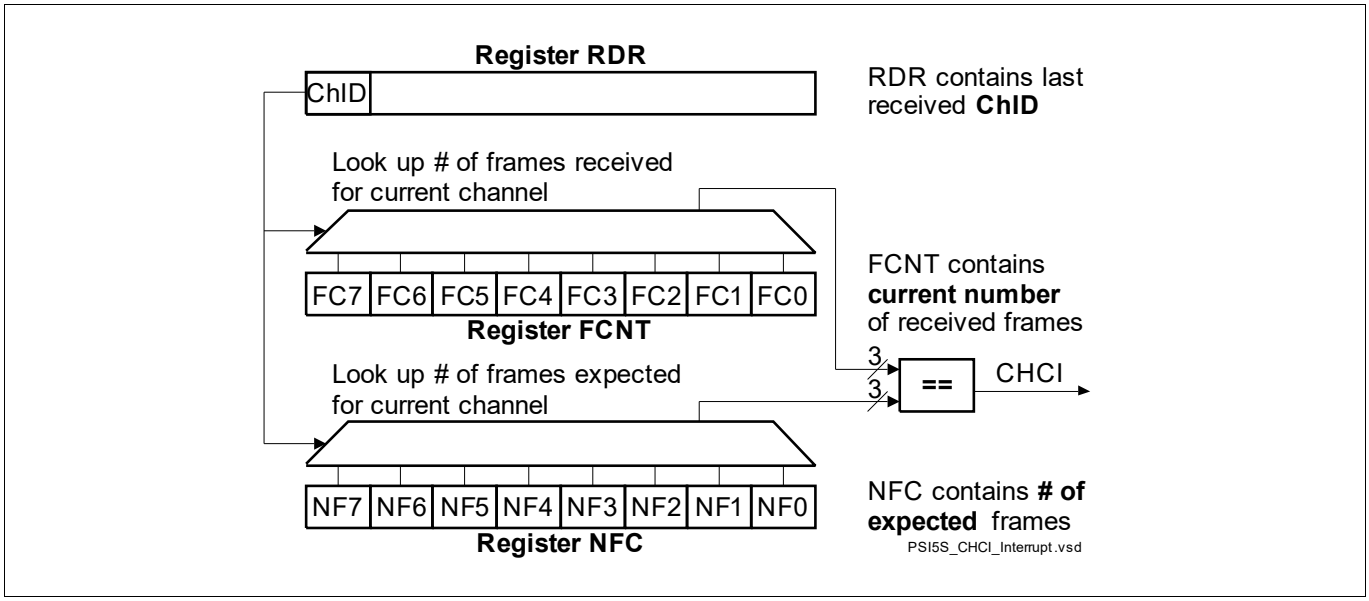

Figure 680 PSI5-S Generation of Interrupt CHCI

43.3.9 Error Detection Capabilities

Each PSI5-S channel can detect and signal the following error conditions:

Protocol Level:

- Packet Frame CRC Error (XCRC)
- PSI5 Frame Checksum error (CRCI)
- Frame not sent in time / UART Frames missing (TEI)
- Error Bits Set in Packet Frame (HDI)
- Errors Signalled by ASC Sub Module (i.e. PE, FE, OE)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- ECU to Sensor Data Buffer Underrun (TBI)

43.3.10 Special use of Channel 0

Note that data that is received in incomplete or too long Packet Frames is always copied - as is - to Channel 0 Frame ID 1. This can happen, if UART Frames are lost, the PHY sends non allowed data or idle before the actual end of the Packet Frame. See **““Packet Frames” received from PHY” on Page 5**.

This is the only actual reservation / limitation in functionality of Channel 0. I.e. all frames can be received and sorted correctly in Channel 0 as long as the Packet Frame is configured with: ChID = 0. It is recommended not to use ChID = 0 AND FID = 1 for normal sensor frames but to keep FID = {2, 3 ,4 ,5}.

The target application assumes, that the PHY sends messages for its own house keeping with ChID = 0, FID = 0. This is assumed in this document and e.g. shown in **Table 430 “Frame Mapping” on Page 25**. Nevertheless, a different application may not have this functionality or may use a different ChID / FID configuration.

43.3.11 ASC Kernel Description

Figure 681 shows a global view of the ASC interface. The ASC is fully integrated into the PSI5-S module. It can be switched to dedicated internal use of the PSI5-S module or to ASC only mode where all PSI5 functionality is disabled. In the last case, the whole PSI5-S module represents one additional ASC in the system.

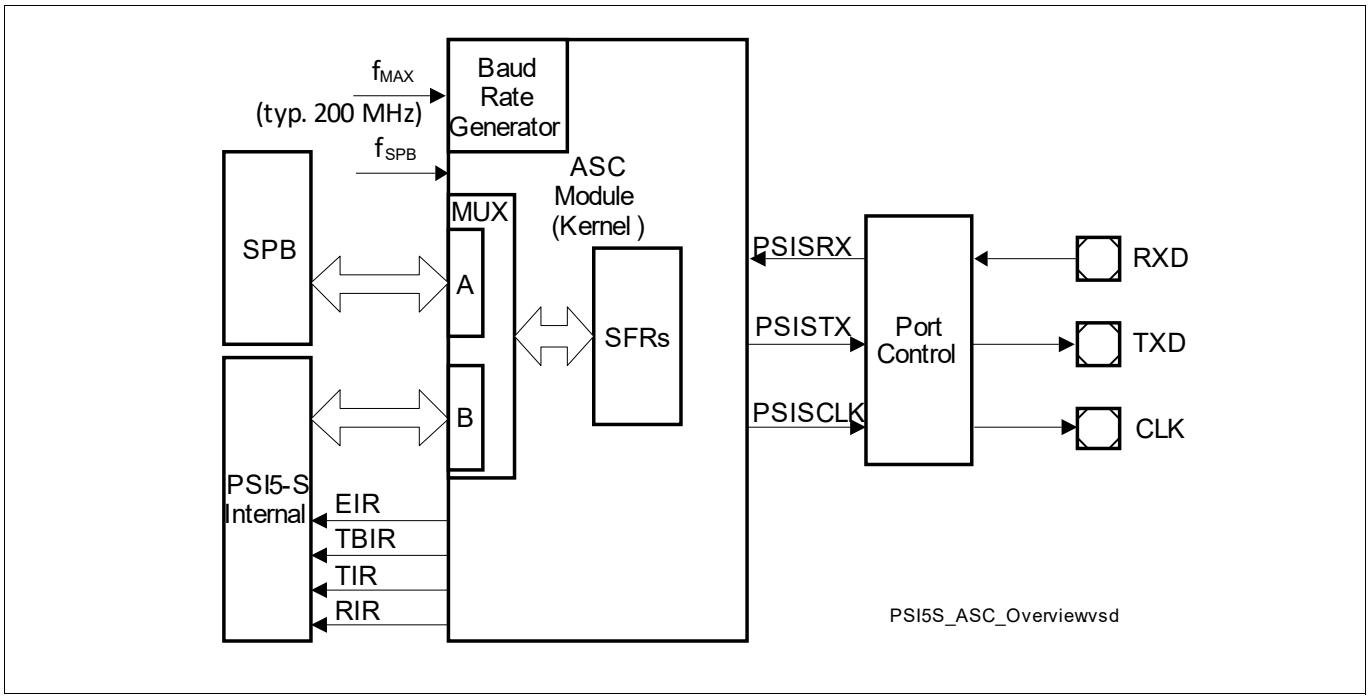

Figure 681 General Block Diagram of the ASC Interface

The ASC module communicates with the external world via two I/O lines. The RXD line is the receive data input signal (and also output signal in Synchronous Mode), and TXD is the transmit output signal.

Clock control, address decoding, and interrupt service request control are managed outside the ASC module kernel.

43.3.11.1 Overview

The ASC provides serial communication between this device and other micro controllers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered in ASC only mode. During internal PSI5-S mode, double-buffering is switched off for the transmitter. The receiver stays double buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

Peripheral Sensor Interface with Serial PHY Connection (PSI5-S)

Features

- Full-duplex asynchronous operating modes
  - 8-bit or 9-bit data frames, LSB first
  - Parity-bit generation/checking
  - Separate Parity control for receive and transmit
  - One or two stop bits
  - Baud rate from 12,5 Mbit/s to 3 bit/s (@ 200 MHz module clock)
  - Multiprocessor mode for automatic address/data Byte detection
  - Loop-back capability
- Half-duplex 8-bit synchronous operating mode
  - Baud rate from 25 Mbit/s to 2034,5 bit/s (@ 200 MHz module clock)
- Double-buffered transmitter (in ASC-only mode)/receiver
- Interrupt generation
  - On a transmit buffer empty condition
  - On a transmit last bit of a frame condition
  - On a receive buffer full condition
  - On an error condition (frame, parity, overrun error)
- Implementation features
  - Connections to DMA Controller
  - Connections from GTM

43.3.11.2 General Operation

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronously to a shift clock generated by the microcontroller. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data are double-buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

A transmission is started by writing to the Transmit Buffer Register, TBUF. Only the number of data bits determined by the selected operating mode will actually be transmitted; that is, bits written to positions 9 through 15 of register TBUF are always insignificant. Data transmission is double-buffered, so a new character may be written to TBUF before the transmission of the previous character is complete. This allows a back-to-back transmission of characters to take place without gaps.

Data reception is enabled by the receiver enable bit CON.REN. After a reception has been completed, the received data and, if provided by the selected operating mode, the received parity bit can be read from the (read-only) receive buffer register RBUF. Unused bits in the upper half of RBUF that are not required in the selected operating mode will be read as zeros.

Data reception is double-buffered, so that reception of a second character may already begin before the previously received character has been read out of the receive buffer register. During the exclusive use by the PSI5-S, double buffering is switched off. The PSI5-S internal output FIFO is used instead. As commands for sync pulses are time stamped inside PSI5-S as they leave the internal FIFO, the double buffering would add unwanted jitter. In all modes, receive buffer overrun error detection can be selected through bit CON.OEN. When enabled, the overrun error status flag CON.OE and the error interrupt request line EIR will be activated when the receive buffer register has not been read by the time reception of a second character is complete. In this case, the previously received character in the receive buffer is overwritten.

The loop-back option (selected by bit CON.LB) allows the data currently being transmitted to be received simultaneously in the receive buffer. This may be used to test serial communication routines at an early stage without having to provide an external network. In loop-back mode, the alternate input/output function of port pins is not required.

43.3.11.3 Asynchronous Operation

Asynchronous Mode supports full-duplex communication, in which both transmitter and receiver use the same data frame format and have the same baud rate. Data is transmitted on pin TXD and received on pin RXD. **Figure 682** shows the block diagram of the ASC when operating in Asynchronous Mode.

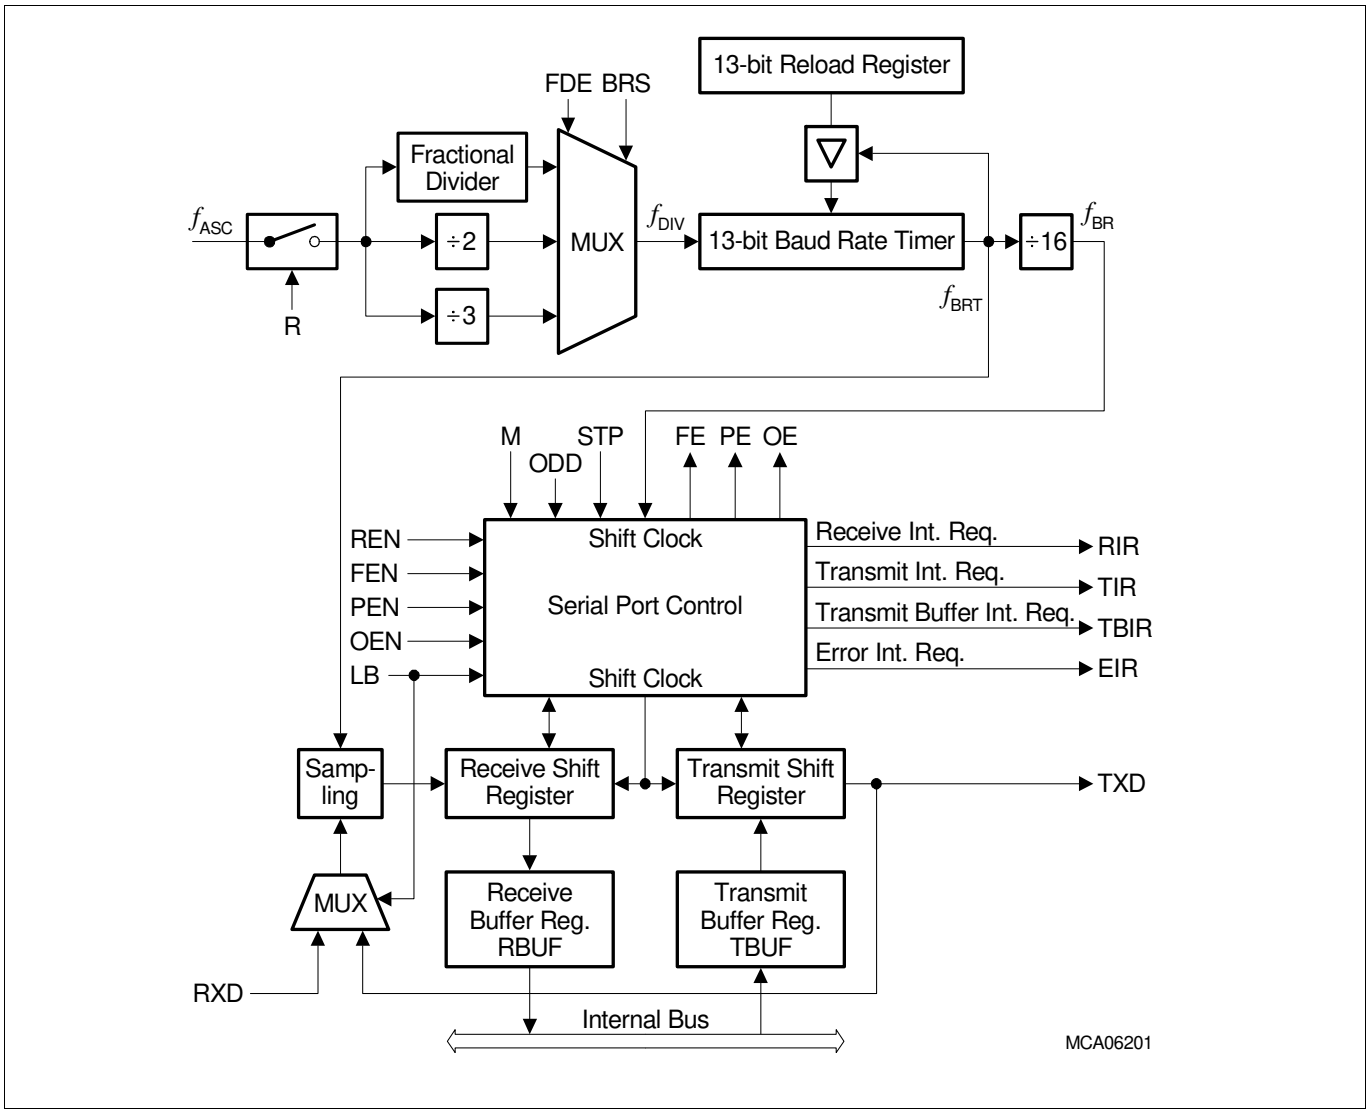

Figure 682 Asynchronous Mode of the ASC

43.3.11.3.1 Asynchronous Data Frames

Asynchronous data frames can consist of 8-bit or 9-bit data frames.

8-bit Data Frames

The 8-bit data frames consist of either eight data bits D7 … D0 (CON.M = 001_B), or of seven data bits D6 … D0 plus an automatically generated parity bit (CON.M = 011_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2 sum of the seven data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 8-bit data mode). The parity error flag CON.PE will be set, along with the error interrupt request flag, if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

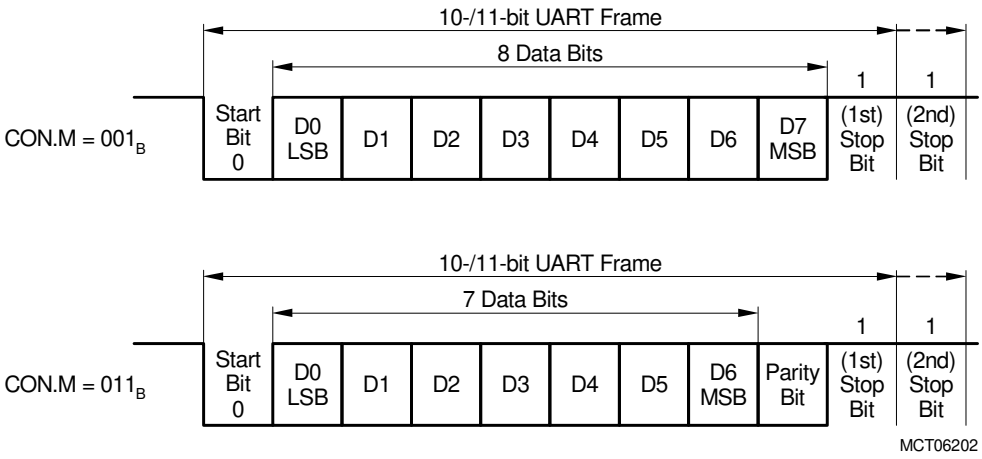

Figure 683 Asynchronous 8-bit Frames

9-bit Data Frames

The 9-bit data frames consist of nine data bits D8 … D0 (CON.M = 100_B), or of eight data bits D7 … D0 plus an automatically generated parity bit (CON.M = 111_B) or of eight data bits D7 … D0 plus wake-up bit (CON.M = 101_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2-sum of the eight data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 9-bit data and wake-up mode). The parity error flag CON.PE will be set along with the error interrupt request flag if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

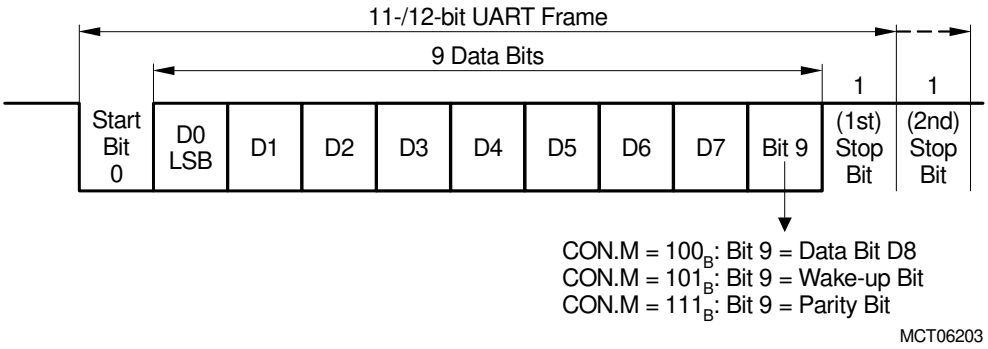

Figure 684 Asynchronous 9-bit Frames

In Wake-up Mode (CON.M = 101_B), received frames are transferred to the receive buffer register only if the 9^{th} bit (the wake-up bit) of the frame is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

This feature can be used to control communication in multi-processor systems, for example:
When the master processor aims to transmit a block of data to one of several slaves, it first sends out an address ‘Byte’ (in this case, a ‘Byte’ consists of nine bits) that identifies the target slave. An address ‘Byte’ differs from a data ‘Byte’ in that the additional 9^{th} bit is a 1 for an address ‘Byte’ but is a 0 for a data ‘Byte’, so, no slave will be interrupted by a data ‘Byte’. An address ‘Byte’ will interrupt all slaves (operating in 8-bit data + wake-up bit mode), so each slave can examine the eight LSBs of the received character (the address). The addressed slave will switch to 9-bit data mode (for example, by clearing bit CON.M[0]), which enables it to also receive the data Bytes

that will be coming (having the wake-up bit cleared). The slaves that were not being addressed remain in 8-bit data + wake-up bit mode, ignoring the following data ‘Bytes’.

43.3.11.3.2 Asynchronous Transmission

Asynchronous transmission begins when the next overflow of the divide-by-16 baud rate timer (transition of the baud rate clock f_{BR}) occurs, if bit CON.R is set and data has been loaded into TBUF. The transmitted data frame consists of three elements:

1. The start bit
2. The data field (8 or 9 bits, LSB first, including a parity bit, if selected)
3. The delimiter (1 or 2 stop bits)

Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register; thus, freeing TBUF for the next transmit data to be loaded. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may then be loaded with the next transmit data while transmission of the previous one continues.

The Transmit Interrupt Request line TIR will be activated before the last bit of a frame is transmitted, that is, before the first or the second stop bit is shifted out of the transmit shift register.

Note: A dedicated GPIO device pin which is connected to the module output pin TXD must be configured by software as alternate data output for asynchronous transmission.

43.3.11.3.3 Asynchronous Reception

Asynchronous reception is initiated by a falling edge (1-to-0 transition) on pin RXD, on the condition that bits CON.R and CON.REN are set. The receive data input pin RXD is sampled at sixteen times the rate of the selected baud rate. A majority decision of the 7^{th}, 8^{th} and 9^{th} sample determines the effective sampled bit value. This avoids erroneous results that may be caused by noise.

If the detected value is not a 0 when the start bit is sampled, the receive circuit is reset and waits for the next 1-to-0 transition at pin RXD. If the start bit proves valid, the receive circuit continues sampling and shifts the incoming data frame into the receive shift register.

When the last stop bit has been received, the contents of the receive shift register are transferred to the Receive Data Buffer Register RBUF. Simultaneously, the receive interrupt request line RIR is activated after the 9^{th} sample in the last stop bit time-slot (as programmed), regardless whether valid stop bits have been received or not. The receive circuit then waits for the next start bit (1-to-0 transition) at the receive data input line.

Note: A dedicated GPIO pin that is connected to the module input pin RXD must be configured by software as input for asynchronous reception.

Asynchronous reception is stopped by clearing bit CON.REN. A currently received frame is completed including generation of the receive interrupt request and an error interrupt request, if appropriate. Start bits that follow this frame will not be recognized.

Note: In wake-up mode, received frames are transferred to the receive buffer register only if the 9^{th} bit (the wake-up bit) is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

43.3.11.3.4 RXD/TXD Data Path Selection in Asynchronous Modes

The data paths for the serial input and output data in Asynchronous Modes are affected by control bit CON.LB (loop-back) as shown in **Figure 685**.

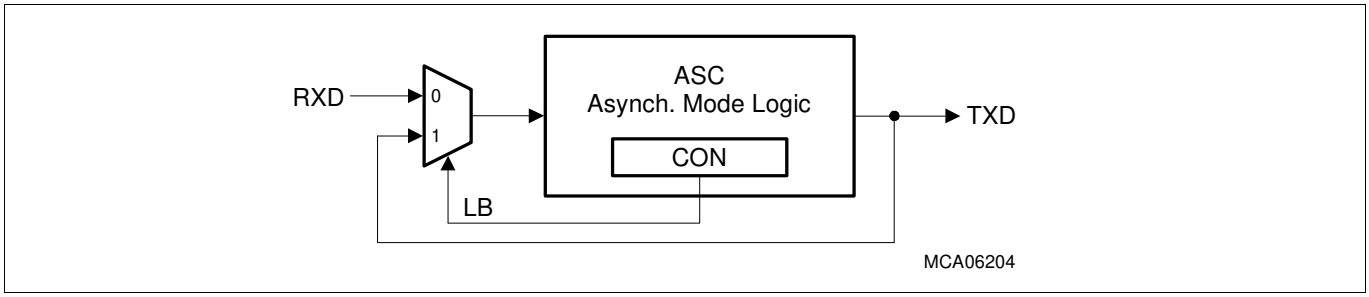

Figure 685 RXD/TXD Data Path Selection in Asynchronous Modes

43.3.11.4 Synchronous Operation

Synchronous Mode supports half-duplex communication, usable for simple I/O expansion via shift registers. Data is transmitted and received via pin RXD while pin TXD outputs the shift clock. These signals are typically connected as alternate functions with GPIO port pins. Synchronous Mode is selected with CON.M = 000_B.

Eight data bits are transmitted or received synchronous to a shift clock generated by the internal baud rate generator. The shift clock is active only as long as data bits are transmitted or received.

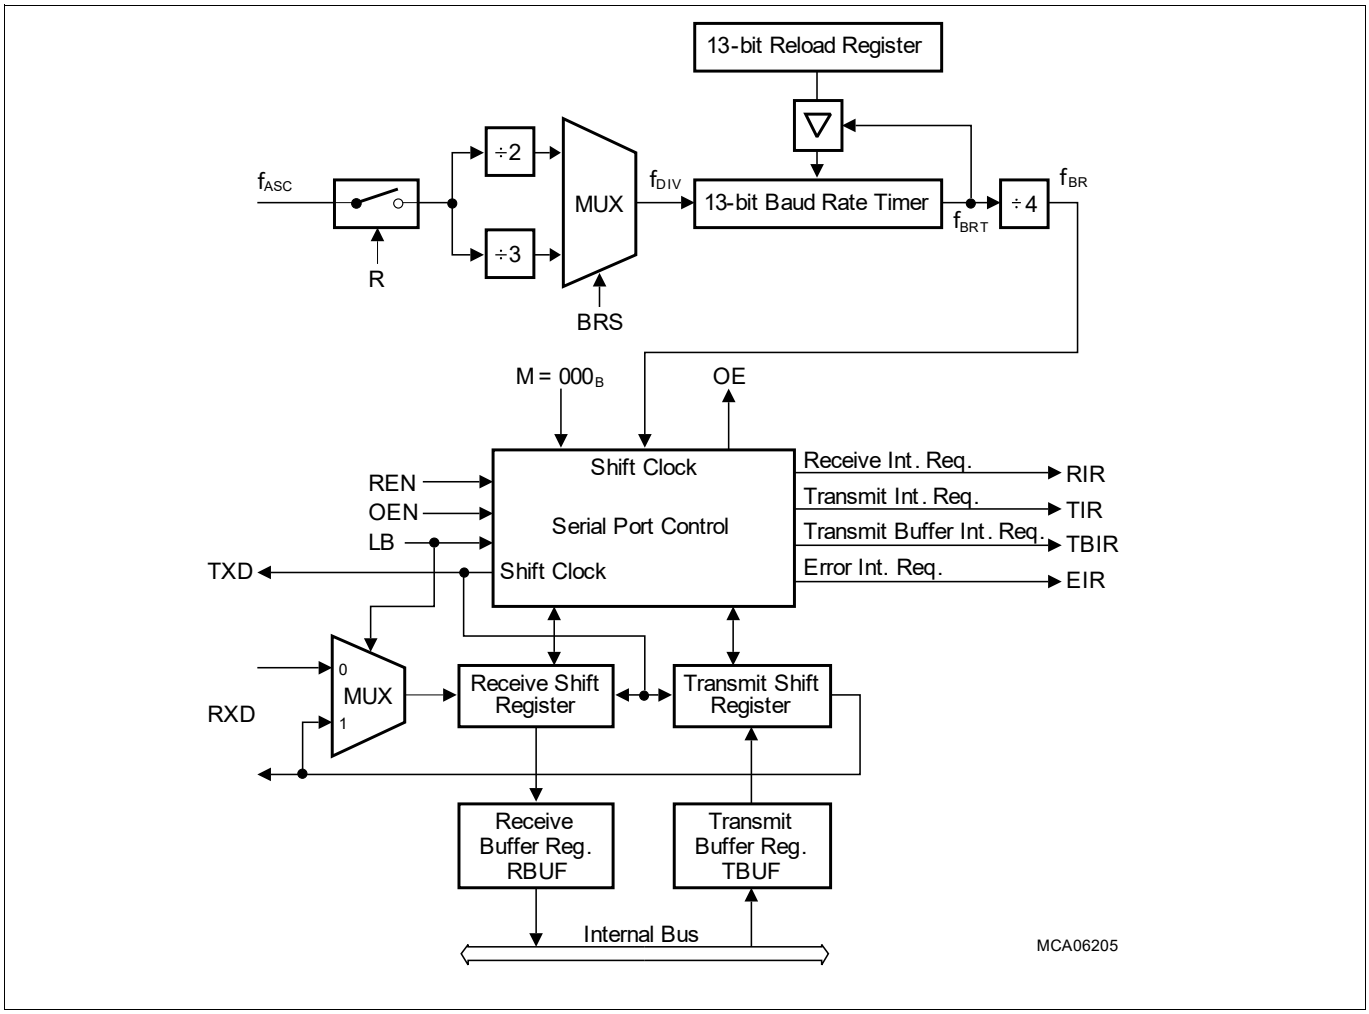

Figure 686 Synchronous Mode of Serial Channel ASC

43.3.11.4.1 Synchronous Transmission

Synchronous transmission begins after data has been loaded into TBUF, provided that CON.R is set and CON.REN = 0 (half-duplex, no reception), with one exception: in asynchronous Loop-back Mode (bit CON.LB set), CON.REN must be set for reception of the transmitted Byte. In synchronous Loop-back Mode, the transmitted Byte can still be received if CON.REN=0. Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register, thus freeing TBUF for the next data to be sent. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may now be loaded with the next data, while transmission of the previous one continues. The data bits are transmitted synchronously with the shift clock. After the bit time for the 8^{th} data bit, both TXD and RXD will be set to high level, the transmit interrupt request line TIR is activated, and serial data transmission stops.

Note: The dedicated GPIO device pins that are connected to TXD and RXD must be configured by software as alternate data outputs in order to provide the shift clock and the output data during synchronous transmission.

43.3.11.4.2 Synchronous Reception

Synchronous reception is initiated by setting bit CON.REN = 1. If bit CON.R = 1, the data applied at RXD is clocked into the receive shift register synchronously to the clock which is output at TXD. After the 8^{th} bit has been shifted in, the contents of the receive shift register are transferred to the receive data buffer RBUF, the receive interrupt request line RIR is activated, the receiver enable bit CON.REN is reset, and serial data reception stops.

Synchronous reception is stopped by clearing bit CON.REN. Any Byte that is currently being received is completed, including the generation of the receive interrupt request and an error interrupt request, if appropriate. Writing to the transmit buffer register while a reception is in progress has no effect on reception and will not start a transmission.

If a previously received Byte has not been read out of the receive buffer register by the time the reception of the next Byte is complete, both the error interrupt request line EIR and the overrun error status flag CON.OE will be activated/set, provided that the overrun check has been enabled by bit CON.OEN.

Note: The dedicated GPIO device pin that is connected to TXD must be configured by software as alternate data output in order to provide the shift clock. The dedicated GPIO device pin that is connected to RXD must be configured by software as input during synchronous reception.

43.3.11.4.3 Synchronous Timing

Figure 687 shows timing diagrams of the ASC Synchronous Mode data reception and data transmission. In idle state, the shift clock is at high level. With the beginning of a synchronous transmission of a data Byte, the data is shifted out at RXD with the falling edge of the shift clock. If a data Byte is received through RXD, data is latched with the rising edge of the shift clock.

One shift clock cycle (f_{BR}) delay is inserted between two consecutive receive or transmit data Bytes.

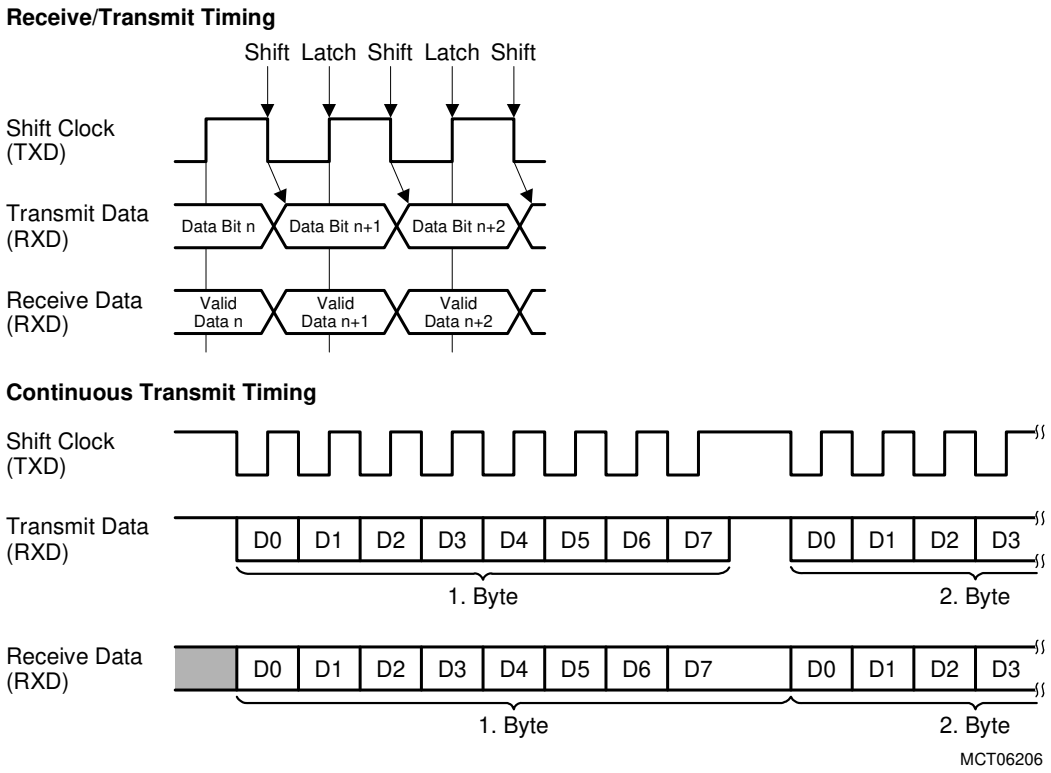

Figure 687 ASC Synchronous Mode Waveforms

43.3.11.5 Baud Rate Generation

The ASC has its own dedicated 13-bit baud rate generator with 13-bit reload capability, allowing baud rate generation independent of other timers.

The baud rate generator is clocked with a clock (f_{DIV}) which is derived via a prescaler from the ASC module clock f_{ASC}. The baud rate timer is counting downwards and can be started or stopped through the baud rate generator run bit CON.R. Each underflow of the timer generates one clock pulse to the serial channel. The timer is reloaded with the value stored in its 13-bit reload register at each underflow. The resulting clock f_{BRT} is again divided by a factor for the baud rate clock (÷ 16 in asynchronous operating modes and ÷ 4 in synchronous operating mode). The prescaler is selected by the bits CON.BRS and CON.FDE. In the asynchronous operating modes, a fractional divider prescaler unit is available (in addition to the two fixed dividers) that allows selection of prescaler divider ratios of n/2048 with n = 0-2047. Therefore, the baud rate of ASC is determined by the module clock, the content of register FDV, the reload value in register BG, and the operating mode (asynchronous or synchronous).

Register BG is the dual-function baud rate generator/reload register. Reading BG returns the contents of the timer in bit field BR_VALUE (bits 31:13 return zero), while writing to BG always updates the reload register (bits 31:13 are insignificant).

An auto-reload of the timer with the contents of the reload register is performed each time BG is written to. However, if CON.R = 0 at the time the write operation to BG is performed, the timer will not be reloaded until the first instruction cycle after CON.R = 1. For a clean baud rate initialization, BG should only be written if CON.R = 0. If BG is written with CON.R = 1, an unpredictable behavior of the ASC may occur during running transmit or receive operations.

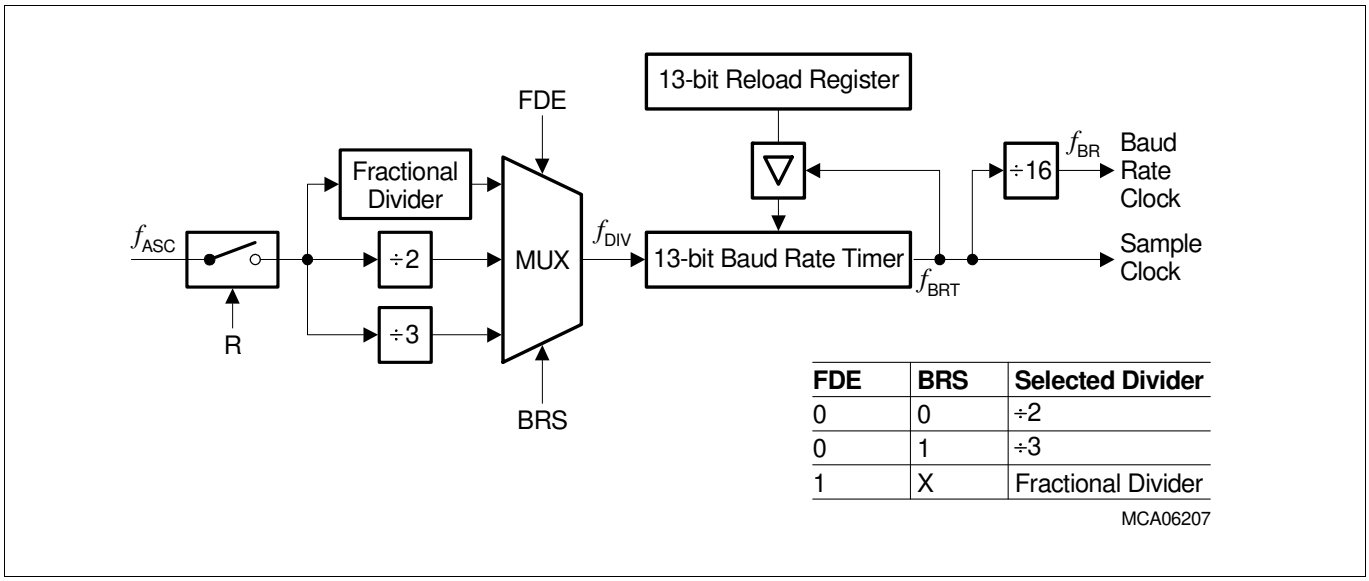
43.3.11.5.1 Baud Rates in Asynchronous Mode

For asynchronous operation, the baud rate generator provides a clock f_{BRT} with sixteen times the rate of the established baud rate. Every received bit is sampled on the 7th, 8th and 9th cycle of this clock. The clock divider circuitry, which generates the input clock f_{DIV} for the 13-bit baud rate timer, is extended by a fractional divider circuitry that allows the adjustment of more accurate baud rates and the extension of the baud rate range.

The baud rate of the baud rate generator depends on the settings of the following bits and register values:

- Input clock f_{ASC}
- Selection of the baud rate timer input clock f_{DIV} by bits CON.FDE and CON.BRS
- If bit CON.FDE = 1 (fractional divider): value of register FDV
- Value of the 13-bit reload register BG

The output clock of the baud rate timer with the reload register is the sample clock in the asynchronous operating modes of the ASC. For baud rate calculations, this baud rate clock f_{BR} is derived from the sample clock f_{BRT} by a division of sixteen.



FDE	BRS	Selected Divider
0	0	÷2
0	1	÷3
1	X	Fractional Divider

Figure 688 ASC Baud Rate Generator Circuitry in Asynchronous Modes

Using the Fixed Input Clock Divider

The baud rate for asynchronous operation of the serial channel ASC when using the fixed input clock divider ratios (CON.FDE = 0) and the required BG reload value for a given baud rate can be determined by the following formulas:

Table 431 Asynchronous Baud Rate Formulas using the Fixed Input Clock Dividers

FDE	BRS	BG	Formula
0	0	0 … 8191	Baud rate = f_{ASC} / (32 x (BG + 1)) BG = f_{ASC} / (32 x Baud rate) - 1
	1		Baud rate = f_{ASC} / (48 x (BG + 1)) BG = f_{ASC} / (48 x Baud rate) - 1

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved for the asynchronous operating modes when using the two fixed clock dividers and a module clock of 200 MHz is 6.25 Mbit/s.

Using the Fractional Divider

When the fractional divider is selected, the input clock f_{DIV} for the baud rate timer is derived from the module clock f_{ASC} by a programmable fractional divider. If CON.FDE = 1, the fractional divider is activated. It divides f_{ASC} by a fraction of n/2048 for any value of n from 0 to 2047. If n = 0, the divider ratio is 1, which means that $f_{DIV} = f_{ASC}$. In general, the fractional divider allows the baud rate to be programmed with much better accuracy than with the two fixed prescaler divider stages.

Note: In fractional divider mode, the clock f_{DIV} can have a maximum period jitter of one f_{ASC} clock period.

Table 432 Asynchronous Baud Rate Formulas using the Fractional Input Clock Divider

FDE	BRS	BG	FDV	Formula
1	–	0 … 8191	1 … 2047	Baud rate = (FDV / 2048) x (f_{ASC} / (16 x (BG + 1)))
			0	Baud rate = f_{ASC} / (16 x (BG + 1))

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer. FDV represents the contents of the fractional divider register bit field FDV.FD_VALUE, taken as an unsigned 11-bit integer.

43.3.11.5.2 Baud Rates in Synchronous Mode

For synchronous operation, the baud rate generator provides a clock f_{BRT} that runs with four times the established baud rate (see **Figure 689**).

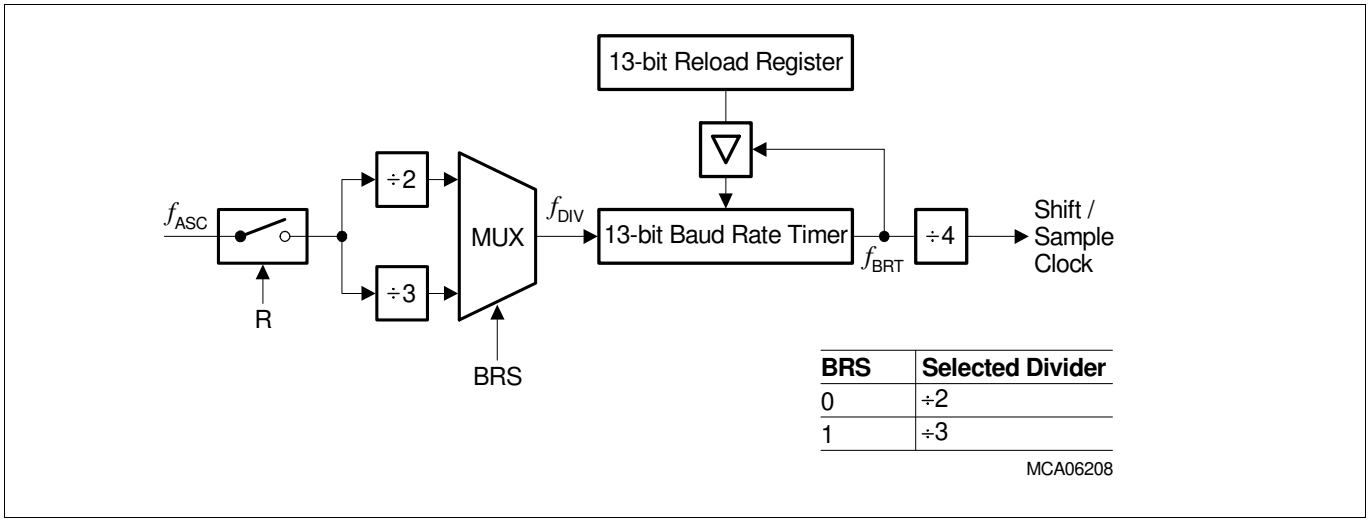


Figure 689 ASC Baud Rate Generator Circuitry in Synchronous Mode

The baud rate for synchronous operation of the serial channel ASC can be determined by the formulas as shown in **Table 433**.

Table 433 Synchronous Baud Rate Formulas

BRS	BG	Formula
0	0 … 8191	Baud rate = f_{ASC} / (8 x (BG + 1)) BG = f_{ASC} / (8 x Baud rate) - 1
1		Baud rate = f_{ASC} / (12 x (BG + 1)) BG = f_{ASC} / (12 x Baud rate) - 1

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

43.3.11.6 Hardware Error Detection Capabilities

To improve the reliability of serial data exchange, the serial channel ASC provides an error interrupt request flag that indicates the presence of an error and three (selectable) error status flags in register CON that indicate which error has been detected during reception. Upon completion of a reception, the error interrupt request line EIR will be activated simultaneously with the receive interrupt request line RIR, if one or more of the following conditions are met:

- If the framing error detection enable bit CON.FEN is set and any of the expected stop bits is not high, the framing error flag CON.FE is set, indicating that the error interrupt request is due to a framing error (asynchronous operating modes only).
- If the parity error detection enable bit CON.PEN is set in the modes where a parity bit is received and the parity check on the received data bits proves false, the parity error flag CON.PE is set, indicating that the error interrupt request is due to a parity error (asynchronous operating modes only).
- If the overrun error detection enable bit CON.OEN is set and the last character received was not read out of the receive buffer by software or DMA transfer at the time the reception of a new frame is complete, the overrun error flag CON.OE is set indicating that the error interrupt request is due to an overrun error (Asynchronous and Synchronous Modes).

43.3.11.7 Interrupts

Four interrupt sources are provided for serial channel ASC. Line TIR indicates a transmit interrupt, TBIR indicates a transmit buffer interrupt, RIR indicates a receive interrupt, and EIR indicates an error interrupt of the serial channel. The interrupt output lines TBIR, TIR, RIR, and EIR are synchronized to the PSI5-S kernel and routed by the INPs to the trigger output lines.

The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE.

Note: By contrast to the error interrupt request line EIR, the error status flags CON.FE/CON.PE/CON.OE are not reset automatically but must be cleared by software.

For normal operation (that is, other than error interrupt), the ASC provides three interrupt requests to control data exchange via this serial channel:

- TBIR is activated when data is moved from TBUF to the transmit shift register.
- TIR is activated before the last bit of an asynchronous frame is transmitted, or after the last bit of a synchronous frame has been transmitted.
- RIR is activated when the received frame is moved to RBUF.

While the task of the receive interrupt handler is quite clear, the transmitter is serviced by two interrupt handlers. This provides advantages for the servicing software.

For single transfers, it is sufficient to use the transmitter interrupt (TIR), which indicates that the previously loaded data has been transmitted, except for the last bit of an asynchronous frame.

For multiple back-to-back transfers, it is necessary to load the following piece of data at least before the last bit of the previous frame has been transmitted. In Asynchronous Mode, this leaves just one bit-time for the handler to respond to the transmitter interrupt request; in Synchronous Mode, it is entirely impossible.

Using the Transmit Buffer Interrupt (TBIR) to reload transmit data provides the time necessary to transmit a complete frame for the service routine, as TBUF may be reloaded while the previous data is still being transmitted.

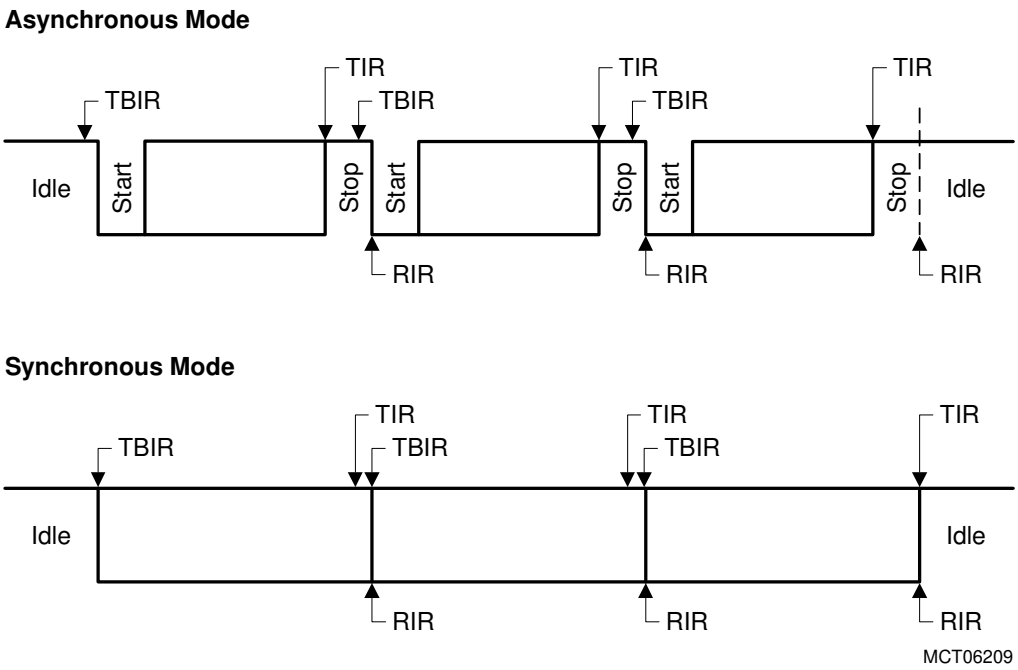

Figure 690 ASC Interrupt Generation

As shown in **Figure 690**, TBIR is an early trigger for the reload routine, while TIR indicates the completed transmission. Software using handshake should, therefore, rely on TIR at the end of a data block to ensure that all data has been transmitted.

43.3.12 Interrupts

8 Interrupt sources are available for the PSI5-S module. For each trigger source of a channel x one interrupt can be selected in register INPx.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to Receive Data Register RDR.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts/errors XCRCI, CRCI, TEI, PE, FE, OE, RBI or HDI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set interrupt RDI and finds RDI already set.

TPI indicates a transmit interrupt. It is activated when data is completely moved from a SDR to ASC (TPI). Thus it can be used to trigger the next write access to SDR.

TPOI indicates a transfer (send) register (SDR) overrun interrupt. It is set if data is written to SDR while the referring register is locked (occupied), signalled by TPF. The data written is ignored in this case. FOI indicates that the output FIFO was overrun.

In addition the protocol error interrupts are available:

CRCI, XCRC. If CRC interrupt is activated, data is to be treated as invalid according to standard V2.0 2011-06. Note that the wrong data is still available in all buffers. For XCRCI, these frames are always stored in Channel 0 Frame 1.

TEI is issued by the watch dog timer if the timely distance between two frames is too long.

CHCI indicates that the last frame expected for a channel is received.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.

If more than one interrupt source is connected to the same interrupt node pointer (in register INPx all node pointer point to the same line), the requests are combined to one common line.

43.3.13 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router.

43.4 Registers

This section describes the kernel registers of the PSI5-S module. All PSI5-S kernel register names described in this section will be referenced in other parts of this User's Manual by the module name prefix "PSI5S_" for the PSI5-S interface.

All registers in the PSI5-S address spaces are reset with the application reset with one exception: OCS is reset with debug reset only. (Definition see SCU section "Reset Operation").

The complete and detailed address map of the PSI5-S module is described below.

x can take the values 0 … 7 (PSI5-S channels)

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

43.4.1 Module Control

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

Note: After a hardware reset operation, the clocks $f_{PSI5\text{-}S}$ and the ASC clock f_{ASC} are switched off and the PSI5-S module and the included ASC module are disabled (DISS set).

CLC
Clock Control Register (0000_H) Application Reset Value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

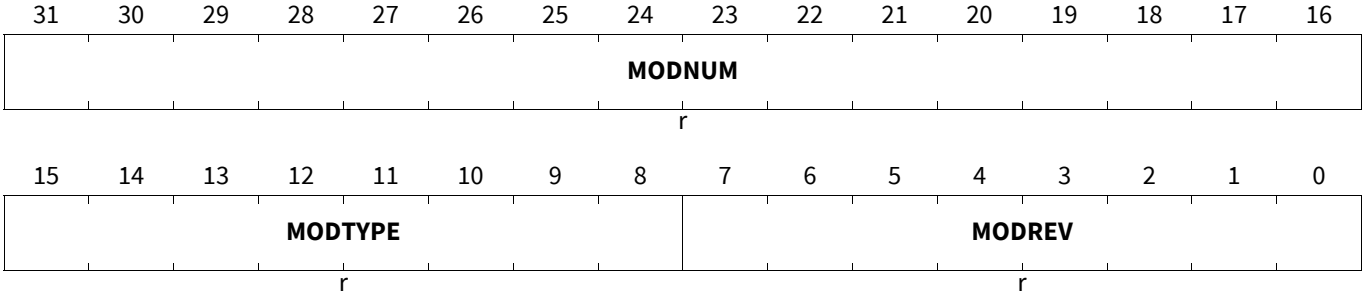
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. *Note: This bit disables the kernel clocks $f_{PSI5\text{-}S}$ and the ASC clock f_{ASC}.*
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**External Sleep Mode Request Disable Bit** Used to control module's sleep mode. *Note: If this bit is cleared the kernel clocks $f_{PSI5\text{-}S}$ and the ASC clock f_{ASC} are disabled during System Sleep Mode.*
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The PSI5-S Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(0008$_H$)** **Application Reset Value: 00D3 C0XX$_H$**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the PSI5-S: $00D3_H$

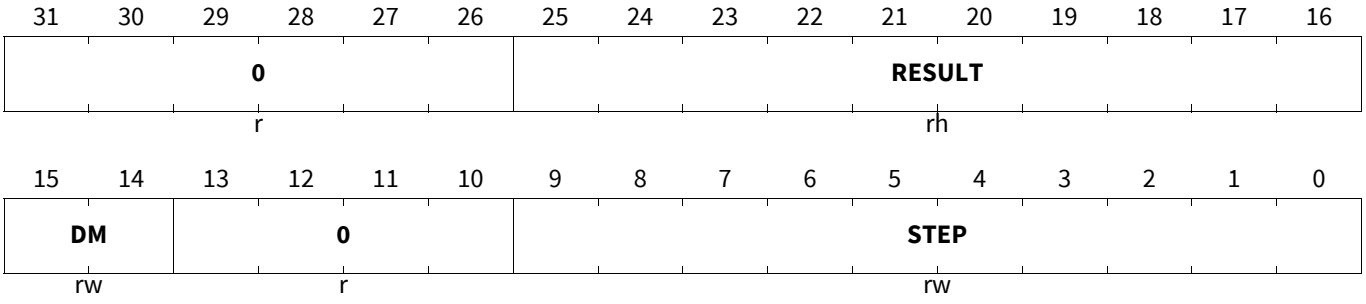
PSI5-S Fractional Divider Register

The Fractional Divider Register controls the clock $f_{PS5\text{-}S}$.

This bit field only controls the kernel clock $f_{PSI5\text{-}S}$ and not the sampling clock f_{ASC}.

FDR

PSI5-S Fractional Divider Register **(000C$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.

Field	Bits	Type	Description
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Time Stamp

The PSI5-S Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of the Time Stamp Registers TSCNTA/B and the Sync Pulse Time Base Counter SBC. It divides $f_{PSI5\text{-}S}$ by a factor as given in **Equation (43.3)** and **Equation (43.4)**. It contains as well the bits for reset control of the Time Stamp Counters.

FDRT

Fractional Divider Register for Time Stamp (0010_H) Application Reset Value: $0000\ 0000_H$

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.

Field	Bits	Type	Description
ECS	28:26	rw	**External Time Stamp Clear Source Select** Selects the external trigger line that clears the global Time Stamp Counters TSCNTA/B.CTS if this is enabled by ECEA/ECEB. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7
ECEA	29	rw	**External Time Stamp Clear Enable A** Enables the external trigger line selected by ECS to clear the global Time Stamp Counter TSCNTA.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEB	30	rw	**External Time Stamp Clear Enable B** Enables the external trigger line selected by ECS to clear the global Time Stamp Counter TSCNTB.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
0	13:10, 31	r	**Reserved** Read as 0; should be written with 0.

Time Stamp Count Register A

This PSI5-S Module Time Stamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{TRIGx} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTA

Time Stamp Count Register A **(0014_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CTS															
r															

Field	Bits	Type	Description
CTS	23:0	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS if TBS is set. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7

Field	Bits	Type	Description
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
TBEA	28	rw	**Time Base Enable TSCNTA** This bit starts/stops TSCNTA.CTS 0_B CTS stopped (w/o clear of CTS) 1_B CTS started (w/o clear of CTS)
TBEB	29	rw	**Time Base Enable TSCNTB** This bit starts/stops TSCNTB.CTS 0_B CTS stopped (w/o clear of CTS) 1_B CTS started (w/o clear of CTS)
CLRA	30	w	**Clear Time Stamp Counter A** This bit clears TSCNTA.CTS. TSCNTA.CTS counts on, starting from 0.
CLRB	31	w	**Clear Time Stamp Counter B** This bit clears TSCNTB.CTS. TSCNTB.CTS counts on, starting from 0.

Time Stamp Count Register B

This PSI5-S Module Time Stamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{TRIGx} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTB

Time Stamp Count Register B **(0018_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7

Field	Bits	Type	Description
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
0	31:28	r	**Reserved** Read as 0; should be written with 0.

Global Control Register

The Global Control Register defines module wide settings.

The first 8 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI.

GCR
Global Control Register **($001C_H$)** **Application Reset Value: $0000\ 001F_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		r			rw			rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETC7	**ETC6**	**ETC5**	**ETC4**	**ETC3**	**ETC2**	**ETC1**	**ETC0**	**HDI**	**RBI**	**OE**	**FE**	**PE**	**TEI**	**XCRCI**	**CRCI**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCI	0	rw	**CRCI** is selected if bit is set.
XCRCI	1	rw	**XCRCI** is selected if bit is set.
TEI	2	rw	**TEI** is selected if bit is set.
PE	3	rw	**PE** is selected if bit is set.
FE	4	rw	**FE** is selected if bit is set.
OE	5	rw	**OE** is selected if bit is set.
RBI	6	rw	**RBI** is selected if bit is set.
HDI	7	rw	**HDI** is selected if bit is set.

Field	Bits	Type	Description
ETCx (x=0-7)	x+8	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0 … x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTCx counts on, starting from its current value. CTCx can be written only if ETCx is cleared (stopped).
CENx (x=0-7)	x+16	rw	**Enable Channel x** This bit enables PSI5-S Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. Frames received for a disabled channel are copied to ChID 0, FID 1 with original IDs.
IDT	27:24	rw	**Idle Time (GLOBAL VALUE FOR ALL CHANNELS)** determines the number of stop bits in addition to the stop bit of the last UART Frame that is required for SOF detection. (IDT-1) idle bit times are allowed/tolerated within one Packet Frame. Default is IDT = 0, i.e. back to back transfer. 0_H 1 bit time idle … F_H 16 bit time idle
ASC	31	rw	**ASC only Mode** is selected if bit is set. The ASC registers are fully controllable by SW via SPB. If cleared, the ASC is controlled by the message reassembly unit and the message generation unit. RBUF and TBUF are no longer writable by SW and interrupts are handled by the message reassembly block automatically.
0	30:28	r	**Reserved** Read as 0; should be written with 0.

Number of Frames Control Register

This register contains the number of Packet Frames expected after a Sync Pulse.

It stores the compare values for the counters in register FCNT.

See **“FCNT” on Page 59**.

NFC

Number of Frames Control Register (0020$_H$) Application Reset Value: 0024 9249$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								NF7			NF6			NF5	
r								rw			rw			rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NF5		NF4		NF3			NF2			NF1			NF0		
rw		rw		rw			rw			rw			rw		

Field	Bits	Type	Description
NFx (x=0-7)	3*x+2:3*x	rw	**Number of expected Frames on Channel x** 000_B reserved, do not use! Reads back 1. 001_B 1 … 110_B 6 111_B reserved, do not use! Reads back 6.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

Frame Counter Register

This register contains the number of Packet Frames actually received after the last Sync Pulse. A Sync Pulse on channel x will clear FCx.

If FCNT.FCx equals NFC.NFx interrupt CHCI is issued and FCNT.FCx will roll over to '1' with the reception of the next recoverable message on channel x. The roll over happens in any case, even if no Sync Pulse clears FCx after CHCI.

If RCRAx.WDMS is set, NFC and FCNT affect the operation of the watch dog timer. See **"Watch Dog Timers" on Page 15**.

NFC and FCNT also affect the generation of interrupt CHCI. See **"Interrupts for DMA support" on Page 29**.

FCNT
Frame Counter Register **(0024_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NFCLR7	**NFCLR6**	**NFCLR5**	**NFCLR4**	**NFCLR3**	**NFCLR2**	**NFCLR1**	**NFCLR0**	**FC7**			**FC6**			**FC5**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FC5	**FC4**			**FC3**			**FC2**			**FC1**			**FC0**		
rh	rh			rh			rh			rh			rh		

Field	Bits	Type	Description
FCx (x=0-7)	3*x+2:3*x	rh	**Frame Counter for Channel x** Contains the number of received frames on Channel x. Copied to RDR.FID if RCRAx.FIDS is set. 000_B 0 (after reset, Sync (if WDMS is set only) or setting NFCLRx) 001_B 1 … 110_B 6 111_B not valid

Field	Bits	Type	Description
NFCLRx (x=0-7)	x+24	w	**Clear Number of Frame Counter for Channel x** Clears the referring counter FCNT.FCx. Intended for use during recovery from TEI. If set while a frame is being received, this action results in FCx = '1'. Thus FCx will never be '0' when RDI/RSI signal a new receive frame. Use with care!

Input and Output Control Register

The Input and Output Control Register IOCR determines for the PSI5-S:

- the alternate input for the receiver

IOCR

Input and Output Control Register (0028$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														ALTI	
r														rw	

Field	Bits	Type	Description
ALTI	1:0	rw	**Alternate Input Select** Selects the alternate input for RX of the ASC: 00_B Alternate Input 0 selected … 11_B Alternate Input 3 selected
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Receiver Control Register Ax

The Receiver Control Registers RCRAx contain control bits/bit fields that are related to the PSI5-S receiver operation. It enables the channel and determines the use of CRC or parity. CENx must be clear for write access.

RCRAx (x=0-7)

Receiver Control Register Ax (0030$_H$+x*4) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				UFC5		UFC4		UFC3		UFC2		UFC1		UFC0	
r				rw		rw		rw		rw		rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					WDMS	FIDS	TSTS	TSP	TSEN	CRC5	CRC4	CRC3	CRC2	CRC1	CRC0
r					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCy (y=0-5)	y	rw	**CRC or Parity Selection** If set, a 3 bit CRC checksum is expected for the PSI5-S channel x in slot y. Else, 1 bit Parity is assumed. This bit field is looked up before potential modification of FID according to FIDS. 0_B 1 Parity Bit is configured (default) 1_B 3 CRC bits are configured
TSEN	6	rw	**Time Stamp Enable** Enables the time stamping for channel x 0_B off (default) TSCRx and thus TSM are forced to 0x0000 0000! 1_B on, see TSP and TSTS
TSP	7	rw	**Time Stamp Select** For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCNTA is captured in TSM and not in TSCR0 (independent from TSP). 0_B TSCNTA.CTS is captured in TSCRx 1_B TSCNTB.CTS is captured in TSCRx
TSTS	8	rw	**Time Stamp Trigger Select** 0_B On Sync Pulse. TSCRx is updated on Sync Pulse. TSM is updated from TSCRx on Packet Frame reception after ChID extraction. For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCR0 is not updated and TSM is updated with the current value of TSCNTA (independent from TSP). This happens at the time the FSM assumes the Packet Frame to be non recoverable. This allows following good packets to be time stamped correctly. 1_B On any Frame. TSCRx and TSM are updated simultaneously with the current value of TSCNTA/B depending from RCRAx.TSP on Packet Frame reception after ChID extraction. (RDI) This allows SW to read the time of reception on the referring channel from TSCRx. For non recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs), TSM is updated with the current value of TSCNTA (independent from TSP and TSEN). This happens at the time the FSM assumes the Packet Frame to be non recoverable. TSCR0 is updated only if RCRA0.TSTS is set (‘1’)
FIDS	9	rw	**Frame ID Select** 0_B Frame ID is updated from Packet Frame Header (sync mode). Channel 0 should have FIDS cleared. This avoids that the module overwrites non recoverable messages with Transceiver Messages. Note that non recoverable messages are always stored in ChID ‘0’, FID ’1’ with original IDs. 1_B Frame ID is a rolling number 0 … 5 copied from FCNT.(FCx-1) (async mode) Non recoverable messages are still stored in ChID ‘0’, FID ’1’ with original IDs.
WDMS	10	rw	**Watch Dog Timer Mode Select** 0_B Watch Dog Timer is restarted on reception of each recoverable frame on Channel x (async mode). 1_B Watch Dog Timer is restarted on Sync Pulse and stopped at reception of the last frame configured in NFC.NFx.(sync mode)

Field	Bits	Type	Description
UFCy (y=0-5)	2*y+17:2*y+16	rw	**UART Frame Count per Packet Frame in Slot y** This bit field defines the number of UART Frames per Packet Frame that are expected for Slot y. This bit field is looked up before potential modification of FID according to FIDS. 00_B 3 UART Frames 01_B 4 UART Frames 10_B 5 UART Frames 11_B 6 UART Frames
0	15:11, 31:28	r	**Reserved** Read as 0; should be written with 0.

Receiver Control Register Bx

The Receiver Control Registers RCRBx configures the number of payload bits and implicitly the number of UART Frames (Bytes) each of the up to 6 slots in channel x. CENx must be clear for write access.

RCRBx (x=0-7)

Receiver Control Register Bx **(0050_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		**PDL5**					**PDL4**					**PDL3**			
r		rw					rw					rw			

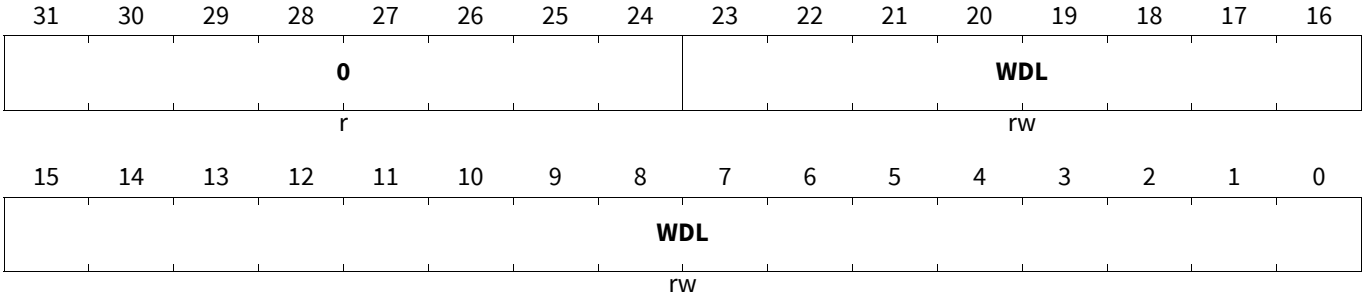
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PDL3		**PDL2**				**PDL1**					**PDL0**				
rw		rw				rw					rw				

Field	Bits	Type	Description
PDLy (y=0-5)	5*y+4:5*y	rw	**Payload Data Length** PDL determines the number of bits in a Packet Frame frame for Slot y. It also determines the position of the CRC/Parity bit. E.g. 8 defines 8 data bits on position [7:0]. On bit position 8 the CRC/Parity is located. See **Figure 660**. If PDLy is cleared (‘0’) no frame is expected for this slot. Packet Frames received for a slot with PDL = ‘0’ are copied to ChID 0, FID 1 with original IDs without further processing. This bit field is looked up before potential modification of FID according to RCRAx.FIDS 00_H No Frame expected! 01_H 8 bits … 08_H 8 bits 09_H 9 bits … $1B_H$ 27 bits $1C_H$ 28 bits … $1F_H$ 28 bits

Field	Bits	Type	Description
0	31:30	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register x

WDTx (x=0-7)
Watch Dog Timer Register x **(0070_H+x*4)** **Application Reset Value: 0000 0000_H**

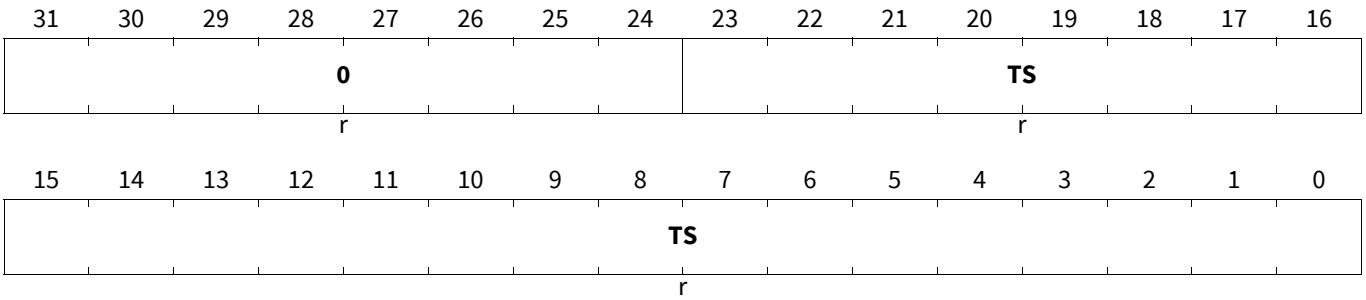


Field	Bits	Type	Description
WDL	23:0	rw	**Watch Dog Timer Limit** for channel x. If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed. CENx must be clear for write access.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

Capture Register TSCRx

If RCRAx.TSEN is set, the time stamp is captured in this register each time a sync pulse is sent from the ASC FIFO to the ASC TX buffer for channel x. RCRAx.TSP selects, if TSCNTA or B is used.

TSCRx (x=0-7)
Capture Register TSCRx **(0090_H+x*4)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TS	23:0	r	**Time Stamp** of the last sync pulse sent for channel x.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

Receive Status Register

The Receive Status Register RDS shows the status of a received data frame.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

The bits CRCI, XCRCI, HDI, PE, FE, OE, TEI and RBI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTAT or CON (ASC sub module) for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTAT or CON before latest frame reception.

RDS

Receive Status Register (00B0$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FE	PE	HDI	ERR1	ERR0	CRCI	CRC2	CRC1	CRC0	XCRCI	XCRC5	XCRC4	XCRC3	XCRC2	XCRC1	XCRC0
rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
XCRCy (y=0-5)	y	rh	**XCRC** CRC of last Packet Frame. XCRC0 is on bit position 0.
XCRCI	6	rh	**XCRC Error Flag** This bit is set if the CRC check on the enveloping Packet Frame fails including the case where XCRC check can not be performed (non recoverable frames) see **Chapter 43.3.2.1.1**. 0_B correct XCRC 1_B wrong XCRC
CRCy (y=0-2)	y+7	rh	**CRC** of last frame. CRC0 / Parity is on bit position 7. If Parity is used, CRC1/2 are always 0.
CRCI	10	rh	**CRC Error Flag** This bit is set if the CRC or Parity check on the transported PSI5 frame fails. 0_B correct CRC/Parity 1_B wrong CRC/Parity
ERR0	11	rh	**Error signalling Flag 0** This bit represents the status of the error signalling flag Err0 in the enveloping Packet Frame.
ERR1	12	rh	**Error signalling Flag 1** This bit represents the status of the error signalling flag Err1 in the enveloping Packet Frame.

Field	Bits	Type	Description
HDI	13	rh	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
PE	14	rh	**ASC Parity Error Flag** This bit is set if the error flag signalling a parity error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
FE	15	rh	**ASC Framing Error Flag** This bit is set if the error flag signaling a framing error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
OE	16	rh	**ASC Overrun Error Flag** This bit is set if the error flag signaling an overrun error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
TEI	17	rh	**Time Error Flag** This bit is set if the watch dog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. If WDMS is in synchronous mode, all frames after TEI have TEI set in RDS until either CHCI is issued or INSTATx.TEI is cleared by SW. RDS.TEI flag is independently from INTENx.TEI. 0_B no error 1_B error
RBI	18	rh	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds RDI already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow
FID	21:19	rh	**Frame ID (Frame Number)** See bit RCRAx.FIDS for actual content. 000_B Slot0 … 101_B Slot5 110_B not valid, frame is copied to ChID 0, FID 1 with original IDs 111_B not valid, frame is copied to ChID 0, FID 1 with original IDs
CID	24:22	rh	**Channel ID (Channel Number)** 000_B channel 0 001_B channel 1 … 111_B channel 7

Field	Bits	Type	Description
AFC	27:25	rh	**Actual UART Frame Count** This bit field shows the number of UART frames actually received. This is used to further analyze non recoverable frames by SW or during debugging.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Receive Data Register

The Receive Data Register RDR shows the data content of a received data frame. If Messaging bits are used, they are located on bit position [1:0].

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

RDR
Receive Data Register **($00B4_H$)** **Application Reset Value: $0000\ 0000_H$**

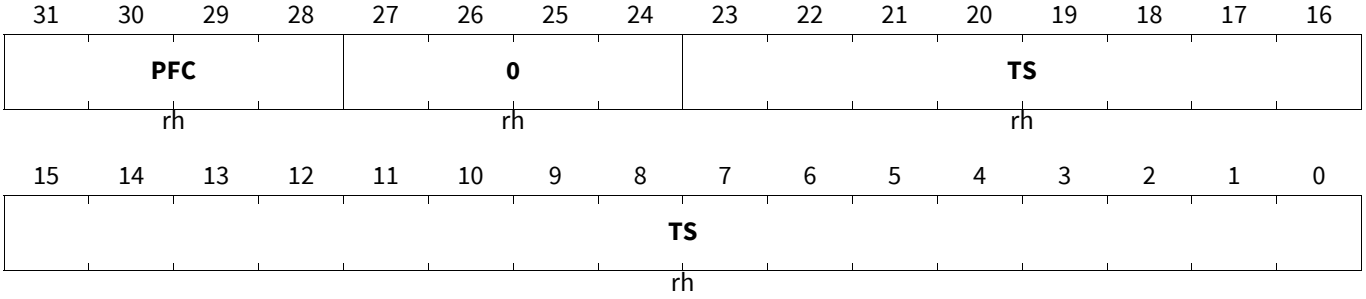
Field	Bits	Type	Description
RDy (y=0-27)	y	rh	**PSI5 Receive Data** of last frame. D0 is on bit position 0.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Time Stamp Mirror Register

Each time a new frame is received, the value from TSCRx for the referring channel is mirrored here. This register is updated, after XCRC was checked ok, as the referring channel number can not be securely determined before.

TSM
Time Stamp Mirror Register **($00B8_H$)** **Application Reset Value: $0000\ 0000_H$**

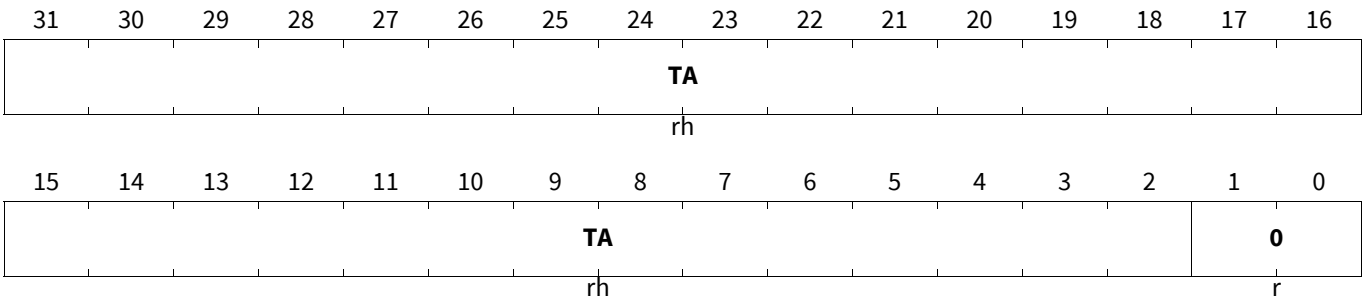


Field	Bits	Type	Description
TS	23:0	rh	**Time Stamp** of the last sync pulse sent on channel x.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.
0	27:24	rh	**Reserved** Read as 0; should be written with 0.

Target Address Register

TAR contains the address that is to be copied by the first DMA into the target address register of the second DMA. This is required for the use case with 2 DMAs. See **"DMA Support" on Page 23**

TAR
Target Address Register **($00D0_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TA	31:2	rh	**Target Address** Contains the upper 30 bit of the target address for the next DMA transfer. The 32 bit target address must be word aligned. Thus the 2 LSBs are fixed to 0. It is updated each time a new Packet Frame is received completely.

Field	Bits	Type	Description
0	1:0	r	**Reserved** Read as 0; should be written with 0.

Base Address Register

BAR contains the address in the system memory where the PSI5-S buffer for all channels is built up.

BAR must be configured by the application for an address space that is big enough for all channels that are enabled. TAR will wrap around after the upper limit (0xFFFF FFFF) if adding the offsets (based on ChID and FID) exceeds this limit.

BAR
Base Address Register **($00D4_H$)** **Application Reset Value: $0000\ 0000_H$**

TBS	0		ATXCMD					0			TXCMD				
rw	r		rw					r			rw				

Field	Bits	Type	Description
TXCMD	4:0	rw	**TX Command** Defines the value that is copied to the ASC FIFO for coding a '0'.
ATXCMD	12:8	rw	**Alternate TX Command** Defines the value that is copied to the ASC FIFO for the alternate pulse width i.e. for coding a '1'.
TBS	15	rw	**Time Base Select** This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{TRIGx} according to the setting of bit ETB.
ETB	18:16	rw	**External Time Base Select** Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7
PTE	19	rw	**Periodic Trigger Enable** Periodic trigger is defined by CTVx. Should be 0 if ETE is set. 0_B disabled 1_B enabled
ETS	22:20	rw	**External Trigger Select** Selects the external trigger line for pulse generation (e.g. angle synchronous). 000_B TRIG0 001_B TRIG1 … 111_B TRIG7
ETE	23	rw	**External Trigger Enable** "Angle sync. trigger", external line is selected by ETS. Should be 0 if PTE is set. 0_B disabled 1_B enabled
0	7:5, 14:13, 31:24	r	**Reserved** Read as 0; should be written with 0.

Channel Trigger Value Register x

CTV contains the value that determines the period of periodic triggers for each channel. It contains as well the counter that can be initialized with an offset so that the phase of harmonic trigger frequencies on different channels can be staggered.

CTVx (x=0-7)

Channel Trigger Value Register x **(0110_H+x*4)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CTC															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTV															
rw															

Field	Bits	Type	Description
CTV	15:0	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse triggered.
CTC	31:16	rwh	**Channel Trigger Counter** This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Send Control Register x

The Send Control Register SCRx contains control data bits required for sending data from the PSI5-S module to the sensor / external PHY.

Data is collected in SDRx and the control bits are collected in SCRx.

The send control unit is build to transmit complete ECU to sensor frames.

SCRx (x=0-7)

Send Control Register x **(0130_H+x*4)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					TPF	0		STA	CRC	0					
r					r	r		rw	rw	r					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	FLUS	0					BSC	EPS		0	PLL				
r	w	r					rw	rw		r	rw				

Field	Bits	Type	Description
PLL	4:0	rw	**Pay Load Length of Registers SDRx** Defines the length that is taken into account. PLL needs to written before SDRx is used for proper operation. 00_H length is 6 … 06_H length is 6 07_H length is 7 … 17_H length is 23 18_H length is 24 … $1F_H$ length is 24
EPS	7:6	rw	**Enhanced Protocol Selection** EPS[0] controls the Bit Format and MSB Fill bit. (0: Tooth Gap, MSB Fill 1) (1: PWM, MSB Fill 0) EPS[1] controls the Frame Format (0: Frame Format 1 - 3) (1: Frame Format 4) 00_B Tooth Gap Method, '1' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 01_B Pulse Width Method, '0' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 10_B reserved, do not use! 11_B Pulse Width Method, '0' for filling the shift register from MSB; Frame Format 4 (9 bit start sequence, 6 bit stuffing distance, '0' for stuffing, 6 bit CRC).
BSC	8	rw	**Bit Stuffing Control** Depending from bit EPS[1] after 3 bits a '1' is inserted (Frame Format 1 - 3) or after 6 bits a '0' is inserted (Frame Format 4) 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled.
FLUS	14	w	**Flush SDRx** Setting this bit stops shifting out the data in SDRx, the start sequence or CRC if any and clears the referring FSMs and counters, if EPS[0]=0 SDRx is flushed by setting all bits if EPS[0]=1 SDRx is flushed by clearing all bits clears TPF TPIx is issued at the end of successful flushing. Reads always as zero.
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically, it still can be written by SW together with the data (e.g. to test the remote CRC) 1_B CRC is automatically generated by HW (according to EPS[1])
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, shifting out payload starts at bit 0! 1_B automatically generated by HW (according to EPS[1]) shifting out payload starts after 3/9 bits (EPS[1] = 0/1)

Field	Bits	Type	Description
TPF	26	r	**Transmit in Progress Flag** If set, data preparation and transmission is in progress: start sequence or CRC or stuffing bits or data from SDRx are being transferred. It is cleared automatically after preparation and transmitting is finished. If set, write access to SDRx will not change any data and issue TPOI.
0	5, 13:9, 21:15, 25:24, 31:27	r	**Reserved** Read as 0; should be written with 0.

Send Data Register x

The Send Data Register SDRx shows the data content of a data frame to be sent.

CENx must be set for write access. For initialization SCRx.FLUS can be used.

SDRx (x=0-7)
Send Data Register x **(0150_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SDy (y=0-23)	y	rwh	**SDy** Send data of next ECU to Sensor frame. Each time a bit is shifted out, the whole content is shifted right by 1 position and the MSB is filled with ‘1’ or ‘0’ depending from EPS[0]. This allows to read back SDR and determine the status of the shift process by SW. The unused MSBs (bit position SCRx.PLL and higher) must be written with ‘0’ if EPS[0] is set (PWM Method) and with ‘1’ if EPS[0] is cleared (Tooth Gap Method). This is required, as the respective standard value is shifted into the register from MSB during shift out operation. SDRx will be filled with this value after shift out process.
0	31:24	r	**Reserved** Read as 0.

CPU Direct Write Register

The CPU Direct Write Register CDW allows the CPU to insert a command into the ASC FIFO. Note that Bits SD[7:5] select the channel for which the time stamp is captured. These bits are copied to the UART Frame Bit positions [2:0] (ChID) while SD[4:0] are copied to UART Frame Bit positions [7:3] (Command). See **Figure 662**.

CDW
CPU Direct Write Register **(0170_H)** **Application Reset Value: $0000\ 0000_H$**

MTX	18:16	rw	**Mode Selection TX direction** While bit field M controls the RX path, MTX controls the mode for the TX path. 000_B 8-bit data Synchronous Mode. M needs to be cleared as well for proper operation. 001_B 8-bit data Asynchronous Mode 010_B Reserved. Do not use this combination. 011_B 7-bit data + parity Asynchronous Mode 100_B 9-bit dataAsynchronous Mode 101_B 8-bit data + wake up bit Asynchronous Mode 110_B Reserved. Do not use this combination. 111_B 8-bit data + parity Asynchronous Mode
ODDTX	28	rw	**Parity Selection TX direction** While bit field ODD controls the RX path, ODDTX controls the mode for the TX path. 0_B Even parity selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data) 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
0	27:19, 31:29	r	**Reserved** Read as 0; should be written with 0.

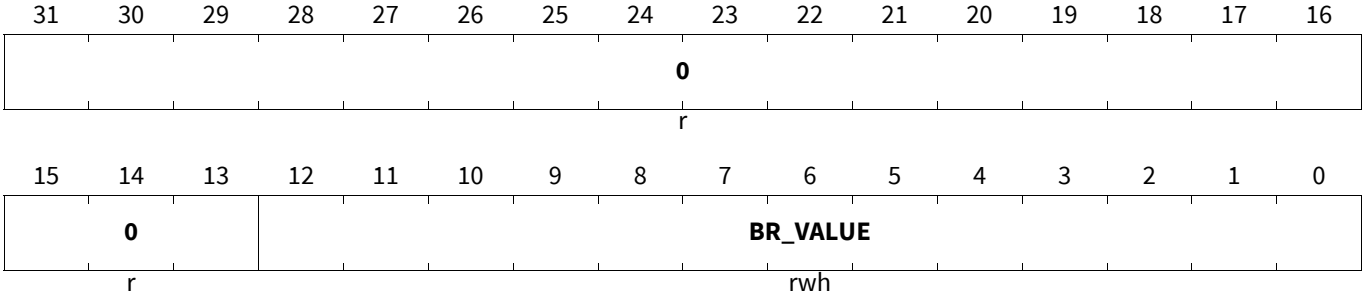
Serial data transmission or reception is possible only when the run bit CON.R is set to 1. Otherwise, the serial interface is idle. To avoid unpredictable behavior of the serial interface, do not program the mode control field CON.M to one of the reserved combinations.

Baud Rate Timer/Reload Register

The Baud Rate Timer Reload Register BG of the ASC module contains the 13-bit reload value for the baud rate timer in Asynchronous and Synchronous Modes.

BG

Baud Rate Timer/Reload Register (0214$_H$) Application Reset Value: 0000 0000$_H$



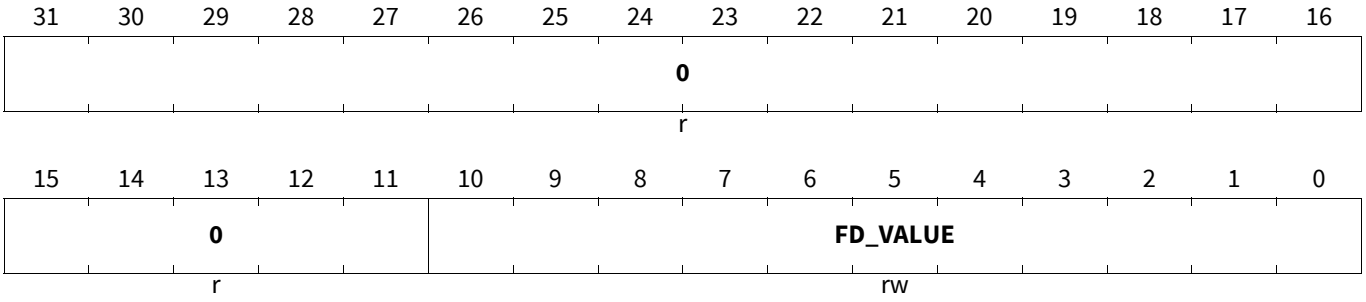
Field	Bits	Type	Description
BR_VALUE	12:0	rwh	**Baud Rate Timer/Reload Register Value** Reading BR_VALUE returns the 13-bit content of the baud rate timer. Writing BR_VALUE loads the baud rate timer reload register. BG should only be written if CON.R = 0.
0	31:13	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register

The Fractional Divider Register FDV of the ASC module contains the 11-bit divider value for the fractional divider (asynchronous mode only).

FDV

Fractional Divider Register (0218$_H$) Application Reset Value: 0000 0000$_H$



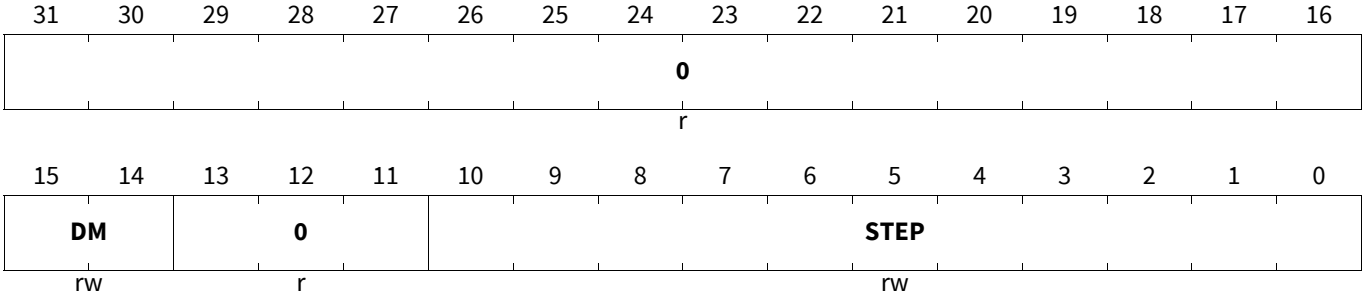
Field	Bits	Type	Description
FD_VALUE	10:0	rw	**Fractional Divider Register Value** FD_VALUE contains the 11-bit value n of the fractional divider which determines the fractional divider ratio n/2048 (n = 0-2047). With n = 0, the fractional divider is switched off (divider ratio = 1).
0	31:11	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider for Output CLK Register

The Fractional Divider Register FDO contains the 11-bit divider value for the fractional divider that is generating $f_{PSISCLK}$ from f_{ASC}. PSISCLK is a clock that can be used on a pin to drive the external PHY.

FDO

Fractional Divider for Output CLK Register (021C$_H$) Application Reset Value: 0000 0000$_H$



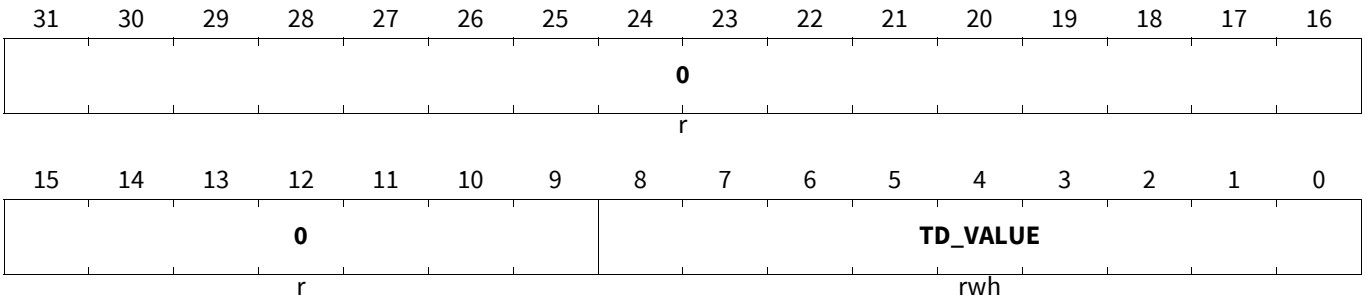
Field	Bits	Type	Description
STEP	10:0	rw	**Step Value** Reload or addition value for internal accumulator.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated.
0	13:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

Transmit Buffer Register

The Transmit Buffer Register TBUF of the ASC module contains the transmit data value in Asynchronous And Synchronous Modes. If GCR.ASC is cleared, TBUF is no longer writable by SW and interrupts are handled by the message reassembly block automatically.

TBUF

Transmit Buffer Register (0220$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TD_VALUE	8:0	rwh	**Transmit Data Register Value** TBUF contains the data to be transmitted in the asynchronous and synchronous operating modes of the ASC. Data transmission is double-buffered; therefore, a new value can be written to TBUF before the transmission of the previous value is complete.

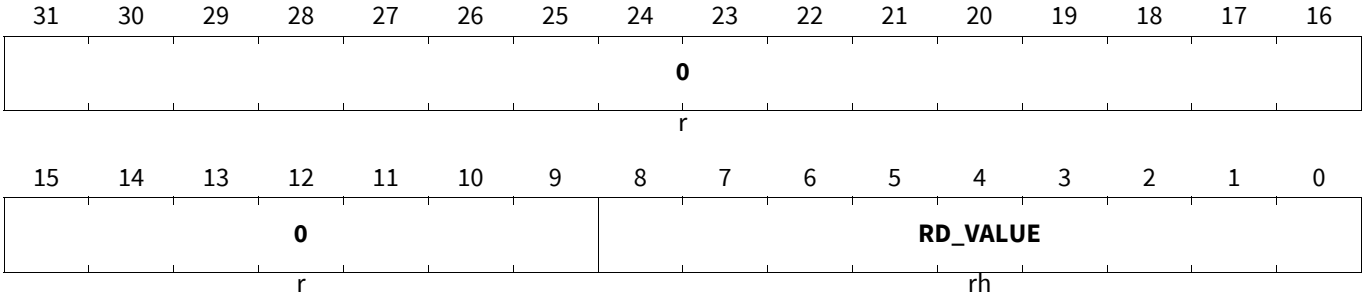
Field	Bits	Type	Description
0	31:9	r	**Reserved** Read as 0; should be written with 0.

Receive Buffer Register

The receive buffer register RBUF of the ASC module contains the receive data value in Asynchronous and Synchronous Modes.

RBUF

Receive Buffer Register **(0224_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RD_VALUE	8:0	rh	**Receive Data Register Value** RBUF contains the received data bits and, depending on the selected mode, the parity bit in the asynchronous and synchronous operating modes of the ASC. In Asynchronous Mode, with CON.M = 011_B (7-bit data + parity), the received parity bit is written into RBUF.7. In Asynchronous Mode, with CON.M = 111_B (8-bit data + parity), the received parity bit is written into RBUF.8.
0	31:9	r	**Reserved** Read as 0.

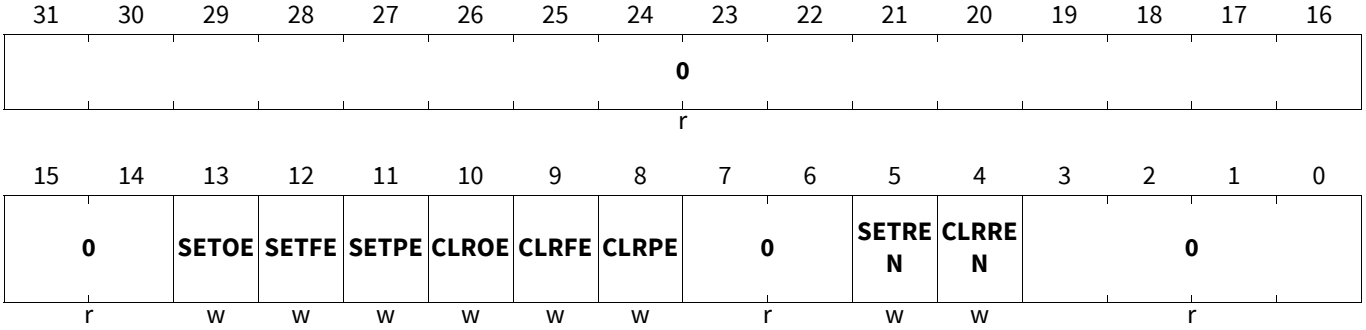
Write Hardware Bits Control Register

The three error flags in register CON and the REN bit can be set or cleared by software via register WHBCON. WHBCON is a write-only register. Reading WHBCON always returns $0000\ 0000_H$.

Note: When the set and clear bits for an error flag are set at the same time during a WHBCON write operation (e.g SETPE = CLRPE = 1), the error flag in CON is not affected.

WHBCON

Write Hardware Bits Control Register (0250$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
CLRREN	4	w	**Clear Receiver Enable Bit** Bit is always read as 0. 0_B No effect 1_B Bit CON.REN is cleared.
SETREN	5	w	**Set Receiver Enable Bit** Bit is always read as 0. 0_B No effect 1_B Bit CON.REN is set.
CLRPE	8	w	**Clear Parity Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.PE is cleared.
CLRFE	9	w	**Clear Framing Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.FE is cleared.
CLROE	10	w	**Clear Overrun Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.OE is cleared.
SETPE	11	w	**Set Parity Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.PE is set.
SETFE	12	w	**Set Framing Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.FE is set.
SETOE	13	w	**Set Overrun Error Flag** Bit is always read as 0. 0_B No effect 1_B Bit CON.OE is set.

Field	Bits	Type	Description
0	3:0, 7:6, 31:14	r	**Reserved** Read as 0; should be written with 0.

Interrupt Status Register x

The Interrupt Status Registers INTSTATx contains status bits that show the status of any interrupt of PSI5-S channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x=0-7)

Interrupt Status Register x **(0260_H+x*4)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0							**HDI**	**TPOI**	**TPI**	**CRCI**	**CHCI**	**TEI**	**RBI**	**RDI**	**RSI**
r							rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI if selected to be taken into account in register GCR. This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together at correct reception. This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds this interrupt already set. The old data is overwritten by the new data. This bit is NOT cleared by reading RDR. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TEI	3	rh	**Timing Error Interrupt Request Flag** This bit is set if the watch dog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. Note that the root cause might be a non recoverable frame! This bit can be cleared by bit INTCLRx.TEI. This bit can be set by bit INTSETx.TEI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
CHCI	4	rh	**Channel Completed Interrupt Request Flag** This bit is set if FCNT.FCx equals NFC.NFx. This bit can be cleared by bit INTCLRx.CHCI. This bit can be set by bit INTSETx.CHCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
CRCI	5	rh	**CRC Error Request Flag** This bit is set if the CRC fails. This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TPI	6	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved completely. Thus a new value can be written to SDRx. This bit can be cleared by bit INTCLRx.TPI. This bit can be set by bit INTSETx.TPI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
TPOI	7	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set if SDR is written while TPF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRx.TPOI. This bit can be set by bit INTSETx.TPOI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
HDI	8	rh	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. Up 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
0	31:9	r	**Reserved** Read as 0.

Interrupt Set Register x

The Interrupt Set Registers INTSETx contain control bits that trigger an interrupt pulse for any interrupt of PSI5-S channel x.

INTSETx (x=0-7)

Interrupt Set Register x **(0280_H+x*4)** **Application Reset Value: $0000\ 0000_H$**

Interrupt Status Register Global

The Interrupt Status Registers INTSTATG contains status bits that show the status of any global interrupt, i.e. of the ASC inside PSI5-S and XCRCI indicating a non recoverable message is received. On XCRCI, the non recoverable message is stored in ChID ‘0’, FID ’1’ with original IDs. INTSTATG contains as well FOI indicating a FIFO overrun condition. In a correct setup, this will never be set as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays.

The bits are set independently from the referring Interrupt Enable in Register INTENG. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATG

Interrupt Status Register Global **(0304_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TIR	2:0	rw	**Interrupt Node Pointer for Interrupt TIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.TIR (if enabled by bit INTENG.TIR). 000_B Trigger Output TRIGO 0 is selected … 111_B Trigger Output TRIGO 7 is selected
RIR	5:3	rw	**Interrupt Node Pointer for Interrupt RIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.RIR (if enabled by bit INTENG.RIR). For bit field definition, see TIR.
EIR	8:6	rw	**Interrupt Node Pointer for Interrupt EIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.EIR (if enabled by bit INTENG.EIR). For bit field definition, see TIR.
TBIR	11:9	rw	**Interrupt Node Pointer for Interrupt TBIR** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.TBIR (if enabled by bit INTENG.TBIR). For bit field definition, see TIR.
XCRCI	14:12	rw	**Interrupt Node Pointer for Interrupt XCRCI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.XCRCI (if enabled by bit INTENG.XCRCI). For bit field definition, see TIR.
FOI	17:15	rw	**Interrupt Node Pointer for Interrupt FOI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATG.FOI (if enabled by bit INTENG.FOI). For bit field definition, see TIR.
0	31:18	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status (03CC$_H$) Debug Reset Value: 0000 0000$_H$

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B.

ACCEN0

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

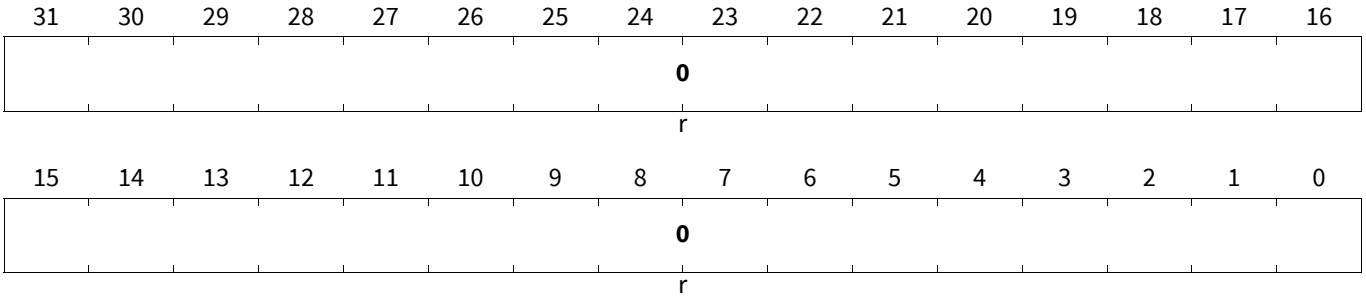
Access Enable Register 1

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

ACCEN1

Access Enable Register 1 **($03D4_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

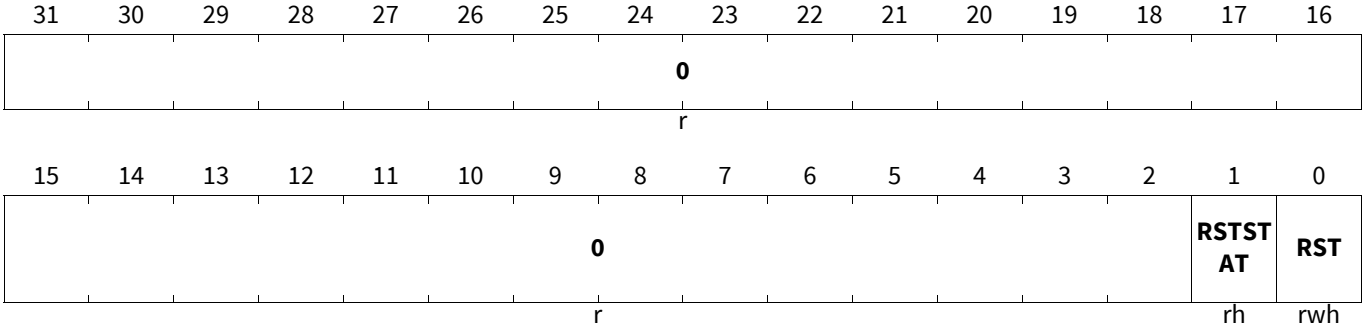
Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCL.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(03D8$_H$)** **Application Reset Value: 0000 0000$_H$**

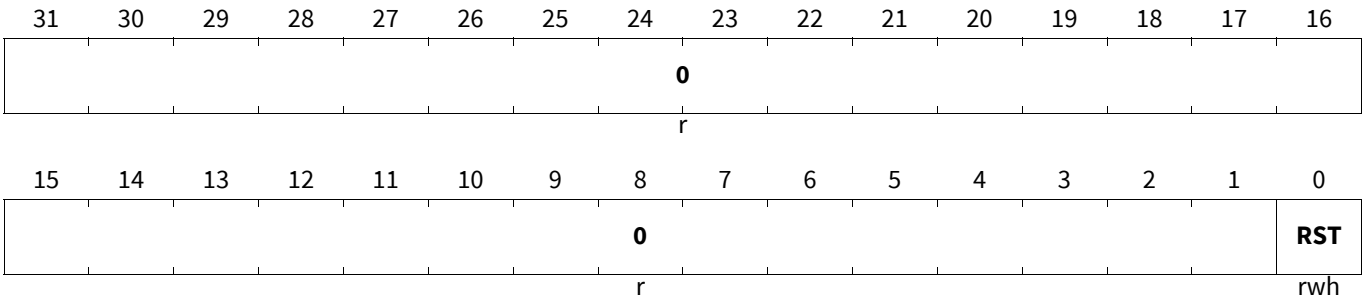


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **(03DC$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

44 Gigabit Ethernet MAC (GETH)

This chapter describes the Ethernet MAC [1)2)].

1) Excerpted portions are Synopsys Proprietary. Used with permission.

2) Module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed.

44.1 Feature List

The detailes feature list can be found in **Chapter 44.2.4**.

44.1.1 Delta to AURIX™ TC2xx

GETH was not implemented in AURIX™ TC2xx.

44.2 Overview

44.2.1 Basic Structure Diagram

Figure 691 shows the basic structure of the module:

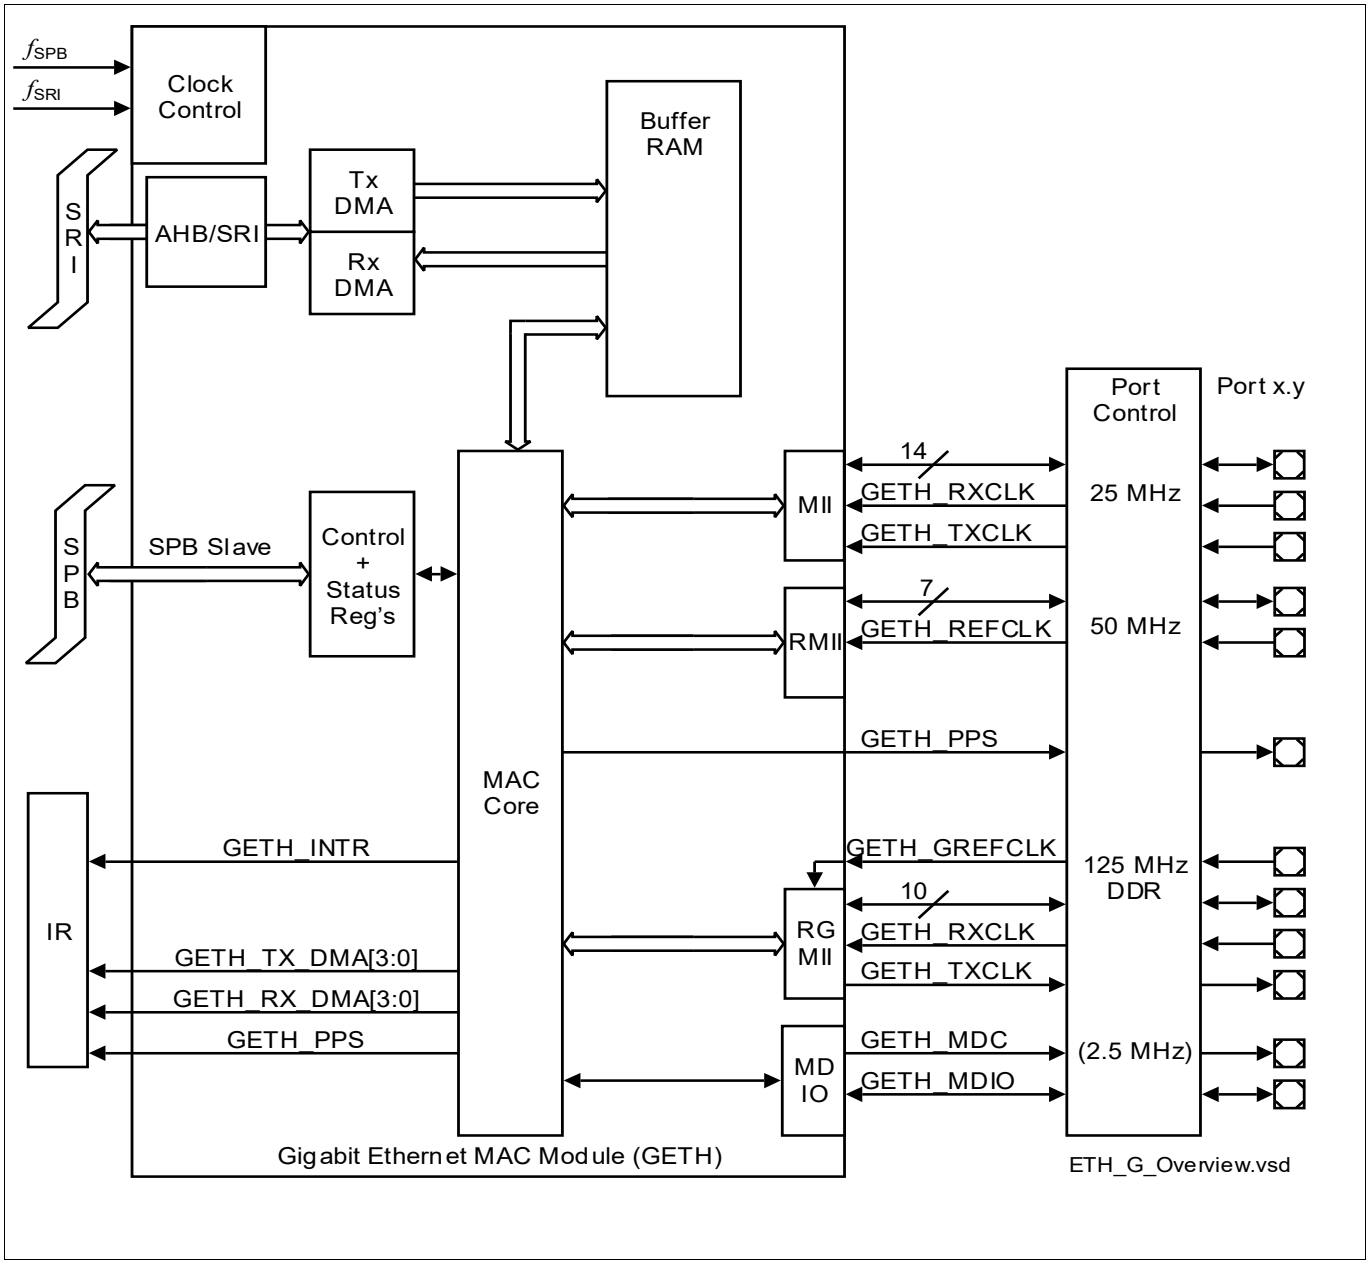

Figure 691 Ethernet MAC Module Overview

44.2.2 DWC_ether_qos General Product Description

The DWC_ether_qos enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008.

As shown in **Figure 692**, one AHB or AXI Master interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all the paths (Transmit and Receive) in all channels. Each channel has a separate set of Control

and Status registers (CSR) for managing the Transmit and Receive functions, descriptor handling, and interrupt handling.

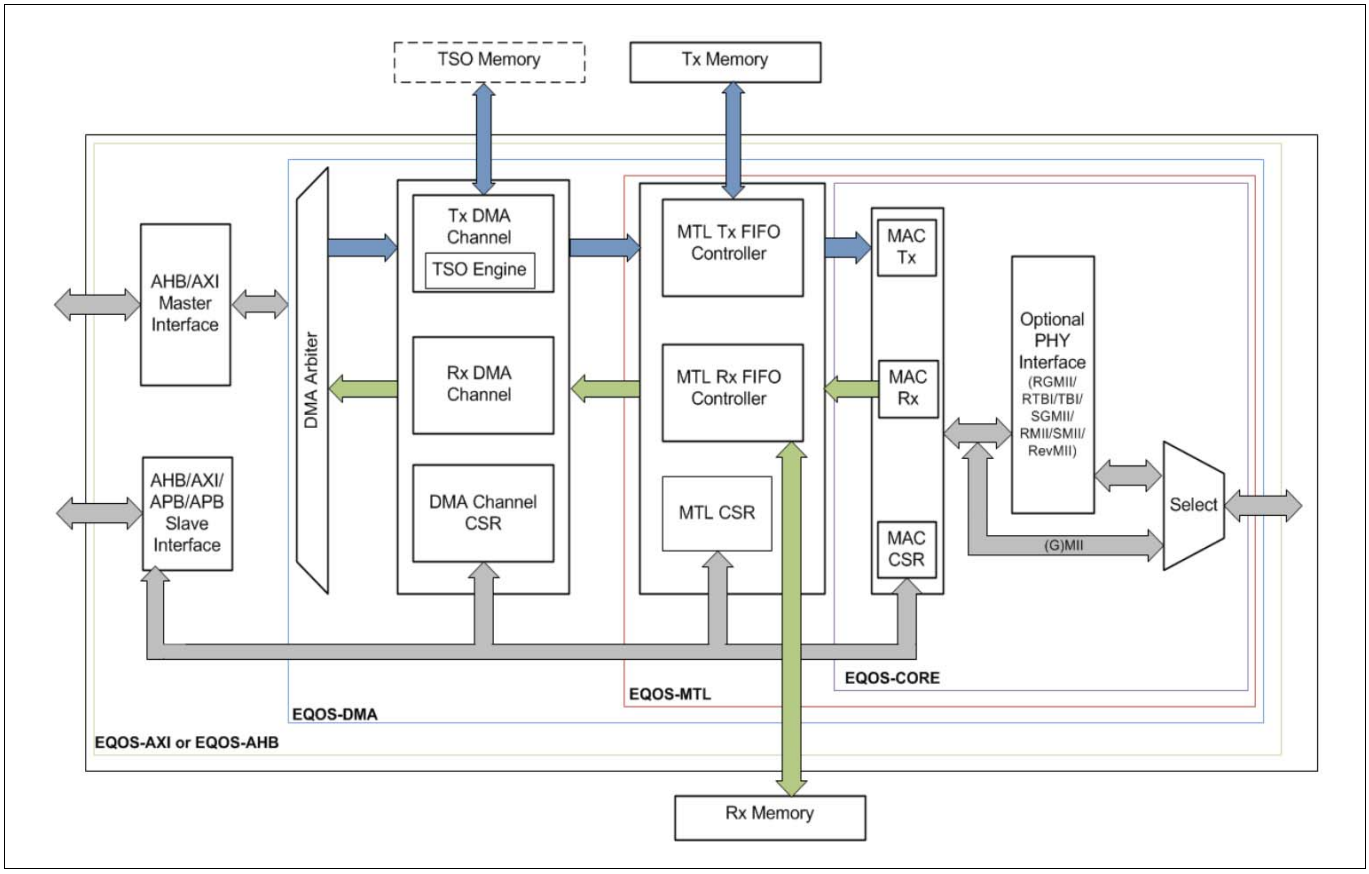

Figure 692 System-Level Block Diagram

Note: When you configure the MAC for a single PHY interface, the MUX logic is removed and the corresponding PHY interface is directly connected to the ports.

44.2.3 DWC_ether_qos Interfaces

The DWC_ether_qos supports several options to interface to the application: to the MAC through native CORE, MTL, or DMA interfaces; or through AHB or AXI interfaces. The DWC_ether_qos also supports a variety of PHY interfaces, as well.

The DWC_ether_qos controller supports the following interfaces:

- **AHB Interface**
  The AHB interface is designed to integrate with AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through the AHB master interface. When the AHB interface is selected, the host CPU uses the default 32-bit AHB slave interface to access the Control and Status registers (CSRs) of the DWC_ether_qos subsystem.
- **PHY Interfaces**
  The DWC_ether_qos supports any one or a combination of the following PHY interfaces:
  - Media Independent Interface (MII) [Default]
  - Reduced GMII (RGMII)
  - Reduced MII (RMII)

44.2.4 DWC_ether_qos Features

44.2.4.1 Standard Compliance

The DWC_ether_qos supports defaults interfaces defined in the IEEE 802.3 specifications and several industry standard to the PHY.

In addition to the default interfaces defined in the IEEE 802.3 specifications, the DWC_ether_qos supports several industry standard interfaces to the PHY. The DWC_ether_qos is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC, Media Independent Interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization
- IEEE 802.1AS-2011 and 802.1-Qav-2009 for Audio Video (AV) traffic
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master, AHB slave, and APB slave ports
- RGMII/RTBI specification version 2.6 from HP/Marvell
- RMII specification version 1.2 from RMII consortium

44.2.4.2 MAC Features

44.2.4.2.1 MAC Tx and Rx Common Features

The DWC_ether_qos controller supports a number common features of the MAC Tx and Rx.

The DWC_ether_qos controller supports the following features common to both MAC Tx and Rx:

- Separate transmission, reception, and control interfaces to the application
- Configurable big-endian and little-endian mode for Transmit and Receive paths
- 10, 100, and 1000 Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant interface to communicate with an external Gigabit or Fast Ethernet PHY
  - RGMII interface (optional) to communicate with an external gigabit PHY
  - RMII interface (optional) to communicate with an external Fast Ethernet PHY
- Half-duplex operation:
  - CSMA/CD Protocol support
  - Flow control using backpressure support (based on implementation-specific white papers and UNH Ethernet Clause 4 MAC Test Suite - Annex D)
  - Packet bursting and packet extension in 1000 Mbps half-duplex operation
- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in (G)MII and Reduced Gigabit Media Independent Interface (RGMII) PHYs.
- 64-bit data transfer interface on the application side
- Data center bridging (DCB) is not supported
- Full-duplex flow control operations (IEEE 802.3x Pause packets, Priority flow control (PFC) is not supported)
- Network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Module to support Ethernet packet timestamping as described in IEEE 1588-2002 and IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in TX direction.

- Flexibility to control the Pulse-Per-Second (PPS) output signal (ptp_pps_o)
- Optional MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management
- Programmable control to clear interrupt status bits on writing 1 to it
- Programmable control to provide Slave error response for accesses to the reserved registers within the CSR address space

44.2.4.2.2 MAC Tx Features

The DWC_ether_qos controller supports a number of MAC Tx features.

The DWC_ether_qos supports the following MAC Tx features

- Preamble and start of packet data (SFD) insertion
- Separate 32-bit status for each packet transmitted from the application
- Automatic CRC and pad generation controllable on a per-packet basis
- Programmable packet length to support Standard or Jumbo Ethernet packets with up to 9 KB of size
- Programmable Inter Packet Gap (40–96 bit times in steps of 8)
- IEEE 802.3x Flow Control automatic transmission of zero-quanta Pause packet when flow control input transitions from assertion to de-assertion (in full-duplex mode)
- Option to transmit packets with reduced preamble size in full-duplex mode
- Insert, replace, or delete queue/channel-based VLAN tags

44.2.4.2.3 MAC Rx Features

The DWC_ether_qos controller supports a number of MAC Rx features.

The DWC_ether_qos controller supports the following MAC Rx features:

- Automatic Pad and CRC Stripping options
- Option to disable Automatic CRC checking
- Preamble and SFD deletion
- Separate 112-bit or 128-bit status
- Programmable watchdog timeout limit
- Flexible address filtering modes:
  - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 31 48-bit SA address comparison check with masks for each byte
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based (optional) filtering. Filtering based on either outer or inner VLAN tag is possible.
  - Extended VLAN tag based filtering 8 filter selection
- IEEE 802.1Q VLAN tag detection and option to delete the VLAN tags in received packets
- Optional module to detect remote wake-up packets and AMD magic packets
- Optional forwarding of received Pause packets to the application (in full-duplex mode)
- Optional Receive module for Layer 3/Layer 4 checksum offload for received packets
- Optional stripping of up to two VLAN Tags and providing the tags in the status.

44.2.4.3 Transaction Layer (MTL) Features

The DWC_ether_qos supports a number of Tx and Rx Transaction Layer (MTL) features.

The MTL block consists of the following FIFOs: Tx FIFO and Rx FIFO. The FIFO size is 4kB for Tx and 8 kB for Rx . The FIFO space is shared by multiple queues (up to 4 Tx and up to 4 Rx queues). You can configure the buffer size for each queue in multiples of 256 bytes. The MTL block supports the following features:

The MTL includes the following feature groups:

- MTL Tx and Rx Common Features
- MTL Tx Features
- MTL Rx Features

44.2.4.3.1 MTL Tx and Rx Common Features

The DWC_ether_qos supports a number of common features of the Tx and Rx Transaction Layer (MTL).

The DWC_ether_qos controller supports the following common features of the MTL Tx and Rx:

- 32-bitTransaction Layer block (bridges the application and the MAC)
- Data transfers executed using simple FIFO protocol
- Synchronization for all clocks in the design (Transmit, Receive, and Application clocks)
- Optimization for packet-oriented transfers with packets delimiters
- Two dual-port RAM-based synchronous FIFO controllers
- RAM memory instantiation outside the top-level module to facilitate memory testing or instantiation
- Programmable burst length, up to half the size of the MTL Rx queue or Tx queue size, to support burst data transfer in the EQOS-MTL configuration
- Programmable threshold capability for each queue (default of 64 bytes)
- Optional Debug and slave mode operation on Queue 0 (default queue)

44.2.4.3.2 MTL Tx Features

The DWC_ether_qos supports a number of Tx Transaction Layer (MTL) features.

The DWC_ether_qos controller supports the following MTL Tx features:

- Following FIFO sizes on transmission: 256 byte, 512 byte, 1 KB, 2 KB, 4 KB
- Multiple queues (up to 4) on the Transmit path with a common memory for all Tx queues
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable queue size in configurations with multiple queues. Each queue size can be programmed in terms of 256 bytes
- Automatic retransmission of collision packets in half-duplex mode
- Discard packets on late collision, excessive collisions, excessive deferral, and under-run conditions with appropriate status
- Disabling of Data Memory RAM chip-select when inactive to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum
- Programmable interrupt options for different operational conditions
- Statistics by generating pulses for packets dropped (because of underflow) in the Tx FIFO
- Optional statistics related to bandwidth consumption by each queue of up to 16 blocks over a 125 µ's period
- Optional packet-level control for
  - VLAN tag insertion or replacement

  - Ethernet source address insertion
  - Layer3/Layer4 Checksum insertion control
  - One-step timestamp
  - Timestamp control
  - CRC and pad control
- Following scheduling algorithms in configurations with multiple queues:
  - Weighted Round Robin (WRR)
  - Strict Priority (SP)
- Option to support dropping of Tx Status to improve the Transmit throughput

44.2.4.3.3 MTL Rx Features

The DWC_ether_qos supports a number of Rx Transaction Layer (MTL) features.

The DWC_ether_qos controller supports the following Rx MTL features:

- Following Rx queue sizes in the Receive path: 256 byte, 512 byte, 1 KB, 2 KB, 4 KB, 8 KB
- Multiple queues (up to 4) on the Receive path with a common memory for all Rx queues
- Programmable Rx queue threshold (default fixed at 64 bytes) in Threshold (or cut-through) mode
- Option to filter all error packets on reception and not forward them to the application in the store-and-forward mode
- Option to forward the undersized good packets
- Statistics by generating pulses for packets dropped (because of overflow) in the Rx FIFO
- Automatic generation of Pause packet control or backpressure signal to the MAC based on the Rx Queue fill level
- Arbitration among queues when multiple queues are present. The following arbitration schemes are supported:
  - Weighted Round Robin (WRR)
  - Weighted Strict priority (WSP)
  - Strict Priority (SP)

44.2.4.4 DMA Block Features

The DWC_ether_qos controller support a variety of DMA block features.

The DMA block exchanges data between the MTL block and system memory. The well defined descriptors structure acts as a software and hardware interface. The application can use a set of registers (DMA CSR) to control the DMA operations. The DMA block supports the following features:

- 32-bit data transfers
- Multi-channel Transmit and Receive engines (up to 4 Transmit channels; up to 4 Receive channels)
- Separate DMA channel in the Transmit path for each queue in MTL
- Single or multiple DMA channels for any number of queues in MTL Receive path
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 KB of data)

- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host CSR access and host data interface
- Routing of received packets to the DMA channels based on the DA or VLAN Priority in multi-channel DMA configurations
- Option to split the packet header (Layer 3 and Layer 4) and payload in a different buffers
- Time-sensitive conditional packet transmission by comparing the Slot Time information provided in the descriptor (useful for AV applications)
- Programmable control for Transmit Descriptor posted writes to improve the throughput

44.2.4.5 AHB Interface Features

44.2.4.5.1 AHB Master Interface Features

The DWC_ether_qos controller supports the AHB Master interface as the application interface.

The AHB master interface supports the following features:

- Interfaces with the application through AHB
- Little-endian and big-endian modes
- 32-bitdata on the AHB master port
- Option to select address-aligned bursts from AHB master port
- Split, Retry, and Error AHB responses
- AHB 1K boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)

The AHB master interface does not generate the following:

- Wrap burst
- Locked or Protected transfers

44.2.4.5.2 AHB Slave Interface Features

The DWC_ether_qos controller supports the AHB Slave interface as the CSR interface.

The AHB slave interface supports the following features:

- Interfaces with the application through AHB
- Little-endian and big-endian modes
- AHB slave interface (32-bit) for CSR access in which only 32-bit or less (byte, half-word) accesses are possible
- All AHB burst types

The AHB slave interface does not generate the following responses:

- Split
- Retry
- Error

44.2.4.6 Audio and Video Features

DWC_ether_qos can be used in Audio Video (AV) mode, and the supported features are compliant to the industry standards for AV traffic.

Note: Data center bridging (DCB) and Priority Flow Control (PFC) are not supported.

DWC_ether_qos supports the following Audio Video (AV) features:

- Separate channels or queues for AV data transfer in 100 Mbps and 1000 Mbps modes
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for Transmit channels
- Single Tx FIFO and Rx FIFO (MTL) for all selected queues (system-side interface [AHB] remains the same)
- Programmable Slot Interval with range from 1µ to 4096µs and granularity of 1µs.

44.2.4.7 Generic Queuing Support

- Programmable control for routing Receive packets with Multicast/Broadcast destination address to a programmable Receive Queue. Support routing of Untagged Receive packets to a programmable Receive Queue. Programmable control for routing VLAN tagged and untagged IEEE 1588 PTP over Ethernet Receive packets to a same or separate programmable Receive Queue. Programmable control for routing Unicast/Multicast Receive packets that fail the destination address filter to a separate programmable Receive Queues.

44.2.4.8 Monitor, Testing, and Debugging Features

The monitoring, testing, and debugging mechanism in DWC_ether_qos help in effective analysis of the configured features.

DWC_ether_qos supports the following features for monitoring, testing, and debugging:

- Internal loopback from Tx to Rx on the GMII or MII for debugging
- DMA states (Tx and Rx) as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data paths and FIFO fill-levels
- Application Abort status bits
- MMC (RMON) module
- Current Tx or Rx Buffer pointer as status registers
- Current Tx or Rx Descriptor pointer as status registers
- Statistical counters to calculate the bandwidth served by each Transmit channel when AV or DCB support is enabled
- Tx or Rx Queues memory accessible through Slave port for debug

44.3 Functional Description

44.3.1 Architecture

This chapter describes the DWC_ether_qos interfaces, protocols, functionality, and implementation.

44.3.1.1 CSR Slave Interface

The CSR slave interface provides access to the CSR space.

By default, all the slave interface will provide OKAY response to all CSR accesses. If SEEN bit ofMAC_CSR_SW_Ctrl register is programmed to 1, DWC_ether_qos will provide error response whenreserved registers within the CSR space are accessed.

44.3.1.1.1 AHB Slave Interface

The AHB slave interface communicates with an application using the AHB interface. When the AHB interface is selected, the host CPU uses the default 32-bit AHB slave interface to access the Control and Status Registers (CSRs) of the DWC_ether_qos subsystem.

The 32-bit AHB slave interface provides access to the DMA, MTL, and MAC CSR space. The AHB slave interface supports the following features:

- Fully AMBA 2.0 Compliant AHB slave—no restrictions
- Single and all burst transfers
- Busy and early terminations
- 32-bit, 16-bit, and 8-bit write or read transfers to the CSRThe 32-bit CSR access is recommended to avoid any software synchronization problems.
- OKAY response:
  The SPLIT, RETRY, or ERROR responses are not supported. When a reserved address is read in MAC register space, it gives all zeros data and generates an OKAY response (When SEEN bit is set, MAC generates ERROR response). Similarly, when a reserved address is written, the ignores the write request and generates an OKAY response (When SEEN bit is set, MAC generates ERROR response).

44.3.1.2 Application Master Interface

44.3.1.2.1 AHB Master Interface

The AHB interface is designed to integrate with AMBA High-Performance Bus (AHB) on the application side. The AHB interface transfers the data to and from system memory through AHB master interface.

In the EQOS-AHB configuration, the DMA controller interfaces with the application through the AMBA AHB interface. The AHB master interface controls the data transfers and the AHB slave interface accesses the CSR space.

AHB Master Interface Features

The AHB master interface supports several features.

The AHB master interface converts the internal DMA request cycles into AHB cycles. The AHB master interface has the following features:

- The AHB master interface is AMBA 2.0-compliant AHB master with no restrictions
- The AHB master interface supports the following burst length modes: fixed, unspecified, and mixed. These modes are explained in the Burst Length Modes section.
- The AHB slaves interfacing with the AHB master support the SINGLE and INCR transfers.

- The AHB master interface can handle the AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response halts all further transactions for that DMA and indicates the error as fatal through CSR and interrupt. The application can choose to give a hard or soft reset to the module to restart the operation.
- The AHB master interface can handle the AHB 1K boundary breaking.
- The AHB master interface can align all AHB burst transfers to an address value. For more information, see Aligning AHB Burst Transfers to An Address Value.
- The DMA requests an AHB Burst Read transfer only when it can completely accept the received burst data. The data read from the AHB is always pushed into the DMA without any delay or Busy cycles. However, when multiple channels are selected, there may be some delay and Busy cycles may be inserted because of the shared-memory architecture for the channels.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to completely transfer the burst. The AHB interface always assumes that it has the data available to push into the AHB bus. However, the DMA can prematurely indicate end-of-valid data (because of the transfer of EOP of an Ethernet packet) during the burst.
  In Fixed Burst Length mode, the AHB master interface continues the burst with dummy data until the specified length is completed. In INCR mode, it ends the burst transfer prematurely.

Burst Length Modes

The AHB master interface supports the following burst length modes:

- Fixed Burst Length
  In fixed burst length mode, the AHB master always initiates a burst with SINGLE, INCR4, INCR8, or INCR16 type. However, when such a burst is responded with SPLIT, RETRY, or Early Burst Termination (EBT), by default, the AHB master again initiates the pending transfers of the burst with INCR or SINGLE burst length type. When only one beat is remaining, the AHB master performs a SINGLE transfer. If more than one beat is remaining, the AHB master performs an INCR transfer. The AHB master terminates such INCR bursts when remaining beats of the original requested fixed burst are transferred.
  To ensure that the AHB master always performs the INCRx and SINGLE transfers even when a part of the burst is initiated again after a SPLIT, RETRY, or EBT response, use the RIB bit of the DMA_Mode register. However, when you enable this mode, the pending burst may further get split into multiple transfers as per the following rules before any new transfer is initiated:
  - If the DMA requests a burst transfer that is not equal to INCR4, INCR8, or INCR16, the AHB application interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4, and three SINGLE transactions.
  - If the burst length is more than 16, the AHB master interface splits it into multiple burst transfers. For example, if the burst length is 32 and the DMA starts a 32-beat transfer, the AHB master splits the burst into two INCR16.
- Unspecified Burst Length
  In unspecified burst mode, the AHB master always initiates a transfer with INCR and completes the DMA requested burst in one transfer.
- Mixed Burst Mode
  In mixed burst mode, the AHB master always initiates the bursts with fixed-size (INCRx) when the DMA requests transfers of size less than or equal to 16 beats. When the DMA requests bursts of length more than 16, the AHB master initiates such transfers with INCR and completes the request in one transfer.
  To ensure that the pending burst of a transfer is rebuilt only with INCRx transfers when an INCRx transfer is interrupted by RETRY, SPLIT, or EBT response, use the RB bit of the DMA_SysBus_Mode register. However, if an INCR burst initiated in this mode is interrupted, the AHB master rebuilds the burst only with INCR transfers.
  You can choose the burst modes by programming the FB bit in the DMA_SysBus_Mode register.

Note: The AHB master does not generate the WRAP bursts, and locked or protected transfers. Therefore, the DWC_ether_qos does not have the HLOCK or HPROT output signals.

Aligning AHB Burst Transfers to An Address Value

The AHB master interface can align all AHB burst transfers to an address value.

You can enable aligning all AHB burst transfers to an address value, by using the AAL bit in the DMA_SysBus_Mode register. If Bit 0 and Bit 12 of DMA_SysBus_Mode register are set to1, the AHB interface and the DMA ensure that all initiated beats are aligned to the address, completing the packet transfer in the minimum number of required beats.

44.3.1.3 DMA Controller

The DMA controller transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The DWC_ether_controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal and error conditions.

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The DMA supports up to 4 Tx and 4 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. You can control the offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The DWC_ether_qos supports the ring structure for the DMA descriptor. For more information on the descriptor, see “Descriptors” that describes the descriptor structure and how the DMA accesses the descriptors.

44.3.1.3.1 DMA Arbiter (EQOS-DMA and EQOS-AHB Configurations)

The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface.

The arbiter inside the DMA module performs the arbitration between the Tx and Rx channel accesses to the AHB master interface. The following two types of arbitrations are supported:

- Round-Robin Arbitration
  When Bit 1 of the DMA_Mode register is reset and both Tx and Rx DMAs are simultaneously requesting for access, the arbiter allocates the data bus in ratio set by Bits[14:12] of DMA_Mode register.
- Fixed-Priority Arbitration
  When Bit 1 of the DMA_Mode register is set, the Rx DMA always gets priority over the Tx DMA for data access by default. When Bit 11 of DMA_Mode Register is also set, the Tx DMA gets priority over the Rx DMA as explained in the following table.

Note: The Rx DMA places the next request only after the earlier request is complete. There is delay to find data availability in the MTL queue (ari_rdy and ari_pbl is enabled, if data equal to PBL is available; MTL asserts ari_rxwatermark which indicates required data availability) and place the request. So, there is no overlap of Rx DMA request with Tx DMA request when operating in single DMA mode. However, this is possible with multiple Rx DMA enabled.

Table 437 Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 1	Priority Scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests.
0	0	1	0	0	Rx has priority over Tx in ratio 2:1.
0	1	0	0	0	Rx has priority over Tx in ratio 3:1.
0	1	1	0	0	Rx has priority over Tx in ratio 4:1.
1	0	0	0	0	Rx has priority over Tx in ratio 5:1.
1	0	1	0	0	Rx has priority over Tx in ratio 6:1.
1	1	0	0	0	Rx has priority over Tx in ratio 7:1.
1	1	1	0	0	Rx has priority over Tx in ratio 8:1.
x	x	x	1	1	Tx always has priority over Rx.
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests.
0	0	1	1	0	Tx has priority over Rx in ratio 2:1.
0	1	0	1	0	Tx has priority over Rx in ratio 3:1.
0	1	1	1	0	Tx has priority over Rx in ratio 4:1.
1	0	0	1	0	Tx has priority over Rx in ratio 5:1.
1	0	1	1	0	Tx has priority over Rx in ratio 6:1.
1	1	0	1	0	Tx has priority over Rx in ratio 7:1.
1	1	1	1	0	Tx has priority over Rx in ratio 8:1.

44.3.1.3.2 DMA Transmit Operation

DMA Transmit Operation: Default (Non-OSP) Mode

When the Transmit (Tx) DMA engine transfers data from the system memory to the device port (MTL), it can operate in the default (non-OSP) mode.

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES3[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application advances the Descriptor Tail pointer offset value of the Transmit Channel.
3. While in the Run state, the DMA runs an Arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed.
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and Bit 2 and Bit 16 of Status Register of corresponding DMA channel are set and the Tx Engine proceeds to step 11:
   a) The descriptor is flagged as owned by the application (TDES3 [31] = 1'b0)
   b) The Descriptor Tail pointer is equal to the Current Descriptor pointer in Ring Descriptor list Mode
   c) An error condition occurs
6. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1’b1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
7. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.
8. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end of- Ethernet-packet data is transferred to the MTL.
9. When packet transmission is complete, if IEEE 1588 Timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step.If timestamp feature is not enabled for this packet, the DMA does not alter the contents of TDES0 and TDES1.
10. Bit 0 of Status Register of corresponding channel is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.
11. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the DMA_CH0_TxDesc_Tail_Pointer when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.

The Tx DMA transmission flow in default mode is shown in **Figure 693**.

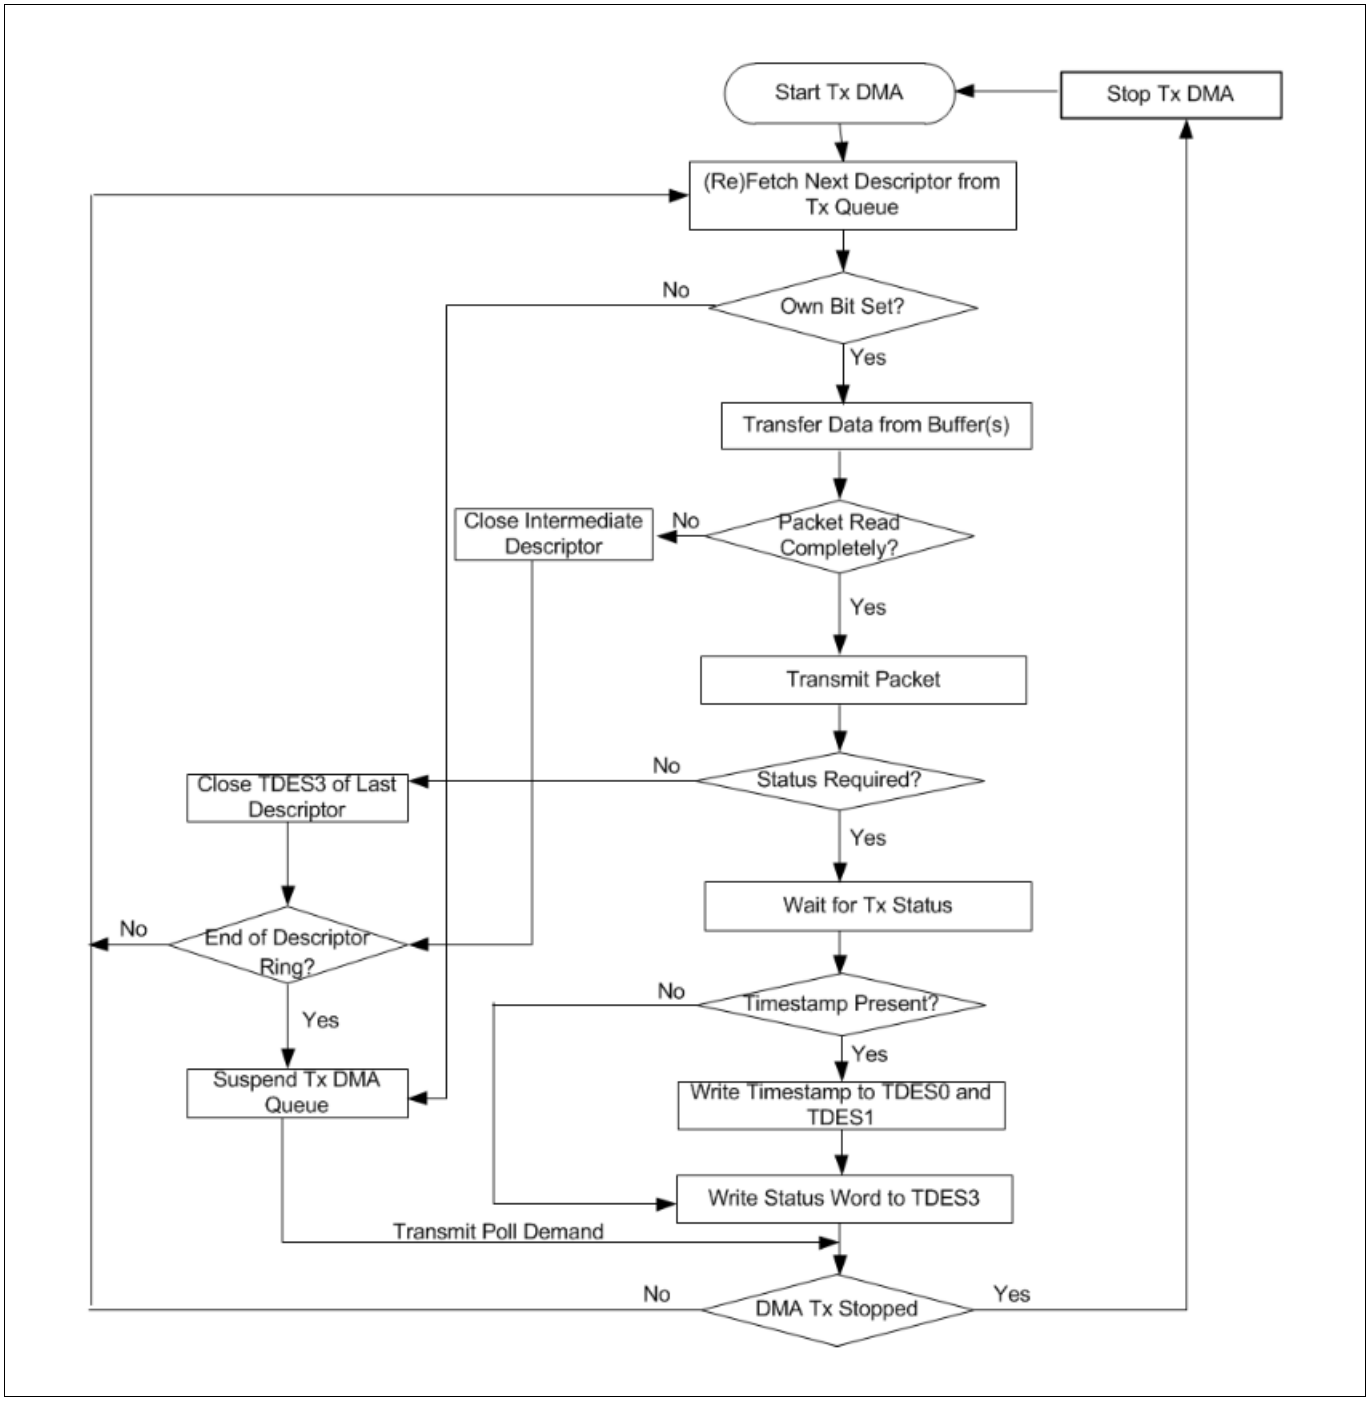

Figure 693 Tx DMA Operation in Default Mode

DMA Transmit Operation: OSP Mode

When the Transmit (Tx) DMA engine transfers data from the system memory to the device port (MTL), it can operate in the OSP mode.

In the Run state, if Bit 4 is set in the Transmit Control Register of corresponding DMA channel, the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. As the Transmit process finishes transferring the first packet, it immediately polls the Transmit Descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.

In OSP mode, the Run state Tx DMA operates in the following sequence:

1. The DMA operates as described in step 1 - step 7 of the Tx DMA (default mode).
2. The DMA fetches the next descriptor without closing the last descriptor of previous packet.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES1, thus closing the descriptor.
   If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA does the following:If no status is pending and the application stopped the DMA by clearing Bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
   a) Writes the timestamp (if enabled for the current packet) to TDES0 and TDES1
   b) Writes the status to the corresponding TDES1
   c) Sets relevant interrupts and returns to Suspend mode

   Note: If no status is pending and the application stopped the DMA by clearing Bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.

8. The DMA can exit Suspend mode and enter the Run state (goes to step 1 or step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

   Note: The DMA fetches the next descriptor before closing the current descriptor. Therefore, the descriptor ring length must be more than two. Synopsys recommends having a minimum descriptor length of four.

The basic flow is described in **Figure 694**.

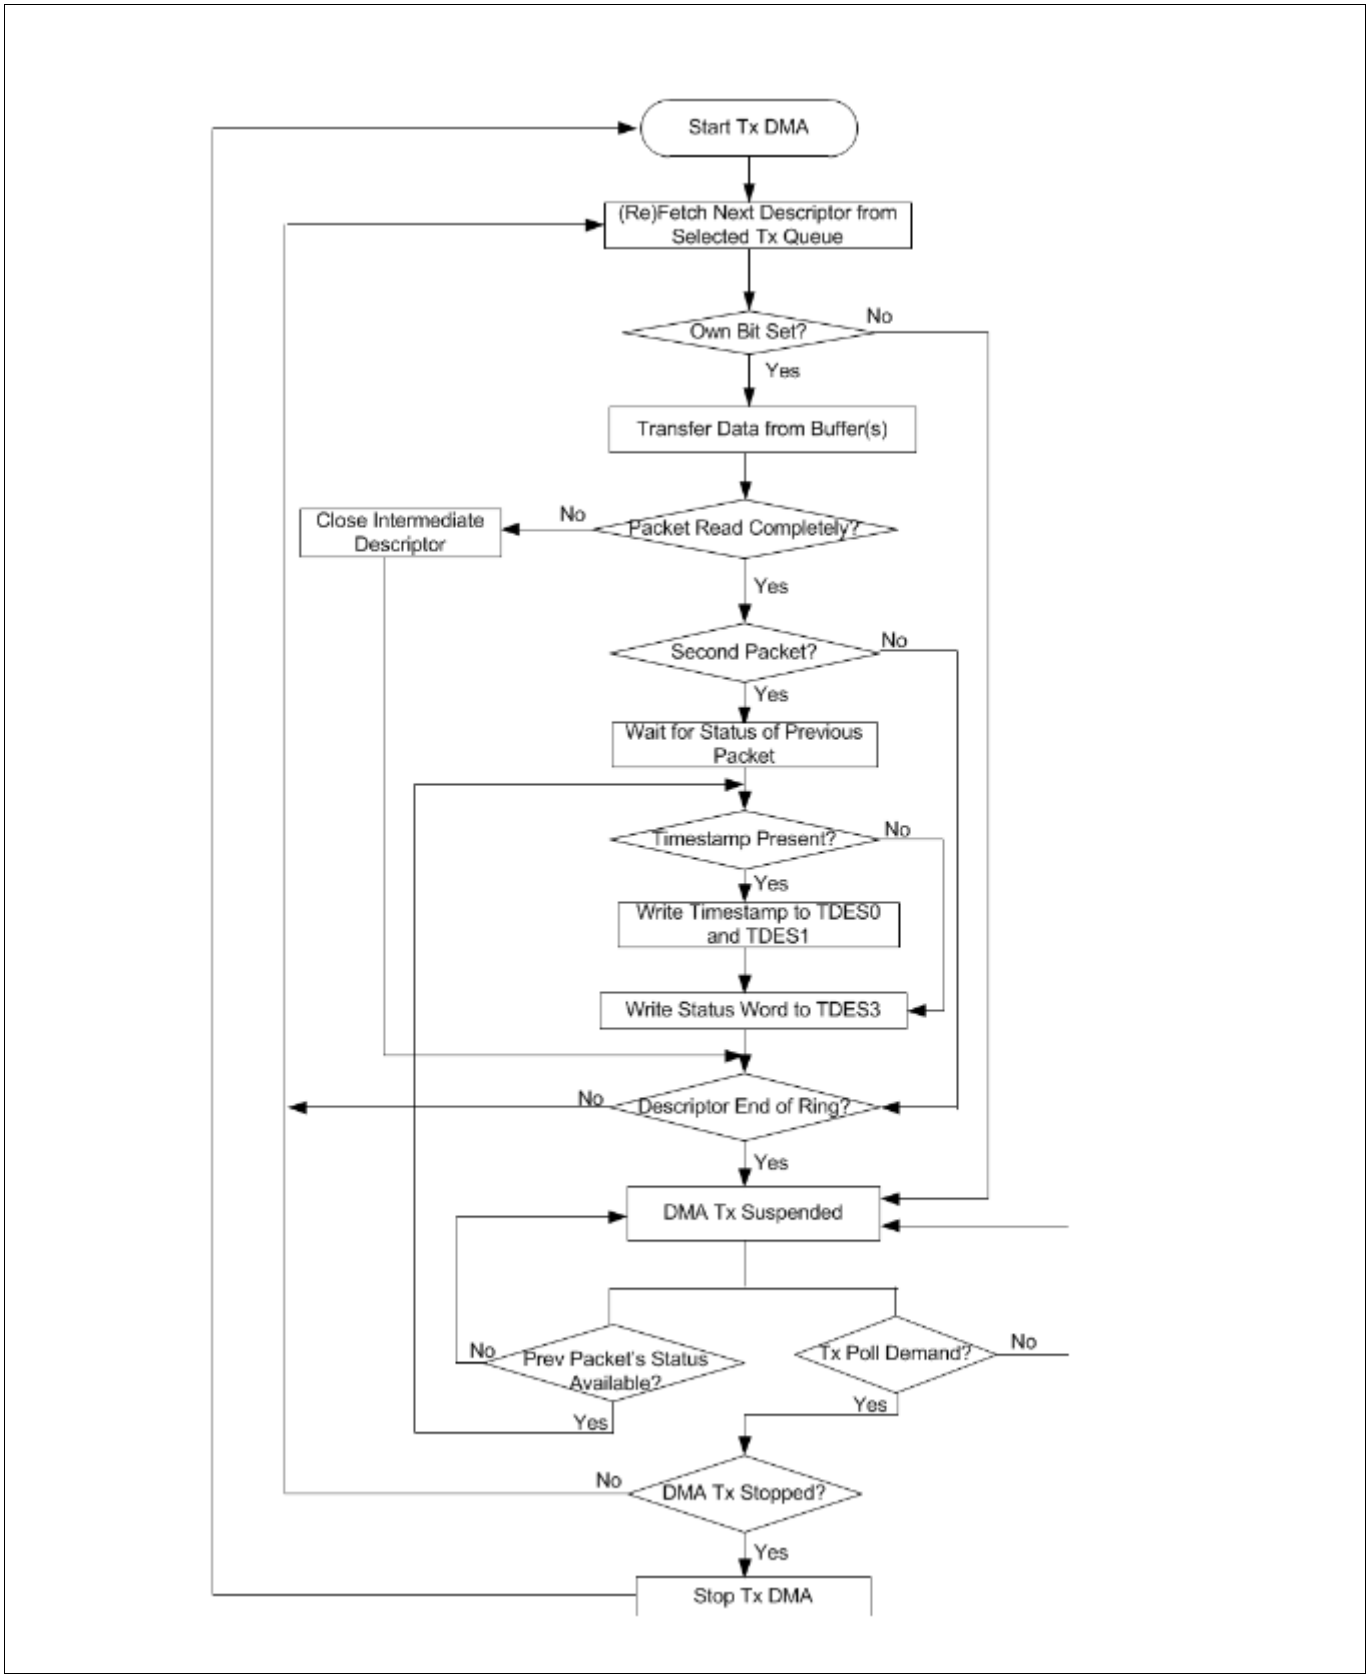

Figure 694 Tx DMA Operation in OSP Mode

Transmit Packet Processing

It is important to understand how the Tx DMA processes packets.

The Tx DMA expects that the data buffers contain complete Ethernet packets, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Length fields contain valid data. If the Tx Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet packets (excluding preamble), including the CRC bytes.

Packets can be data-chained and can span several buffers. Packets must be delimited by the First Descriptor (TDES3[29]) and the Last Descriptor (TDES3[28]). As transmission starts, the First Descriptor must have TDES3[29] set. When this occurs, the packet data is transferred from the application buffer to the MTL Tx Queue. Concurrently, if the current packet has the Last Descriptor (TDES3[28]) clear, the Tx Process attempts to acquire the Next Descriptor. The Tx Process expects this descriptor to have TDES3[29] clear. If TDES3[28] is clear, it indicates an intermediary buffer. If TDES3[28] is set, it indicates the last buffer of the packet.

After the last buffer of the packet has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 3 (TDES3) word of the descriptor that has the Last Descriptor Bit set in Transmit Descriptor 3 (TDES3[28]). At this time, if Interrupt on Completion (TDES2[31]) is set, Bit 0 of Status Register of corresponding DMA channel is set, the Next Descriptor is fetched, and the process repeats. The actual packet transmission begins after either of the following:

- The MTL Tx Queue has reached a programmable Transmit threshold (Bits[6:4] of Transmit Operation Mode register of corresponding MTL Transmit Queue)
- A full packet is contained in the FIFO

You can also use the store-and-forward mode (Bit 1 of MTL Transmit Operation Mode Register of a queue). In this mode, descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the packet.

Note: To ensure proper transmission of a packet and the next packet, you must specify a non-zero buffer size for the Transmit descriptor that has the Last Descriptor (TDES3[28]) set.

Transmit Polling Suspended

It is important to understand how the Tx DMA suspends polling during the DMA Transmit operation.

Transmit polling can be suspended by any of the following conditions:

- The DMA detects a descriptor owned by the application (TDES3[31]=0).
  To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command by writing the Tail Pointer register. If the DMA goes into SUSPEND state because of this condition, Bit 15 and Bit 2 of Status Register of corresponding DMA channel are set.
- A packet transmission is aborted when a Transmit error is detected because of underflow.The appropriate Transmit Descriptor 3 (TDES3) bit is set. When this condition occurs, the following bits are set and the information is written to Transmit Descriptor 0, causing the suspension:
  - Bit 14 of Status Register of corresponding DMA channel
  - Transmit Underflow bit of corresponding queue in MTL_Interrupt_Status
- The DMA detects that the Tail Pointer is equal to the Current descriptor closed by the it.To resume, the software driver must modify the Tail Pointer register.

In all conditions, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

DMA Transmit Channel Arbitration

It is important to understand how the Tx DMA handles channel arbitration during the DMA Transmit operation.

An arbiter provides access to multiple DMAs trying to access the Bus Interface Unit (BIU). **Figure 695** shows the arbitration process.

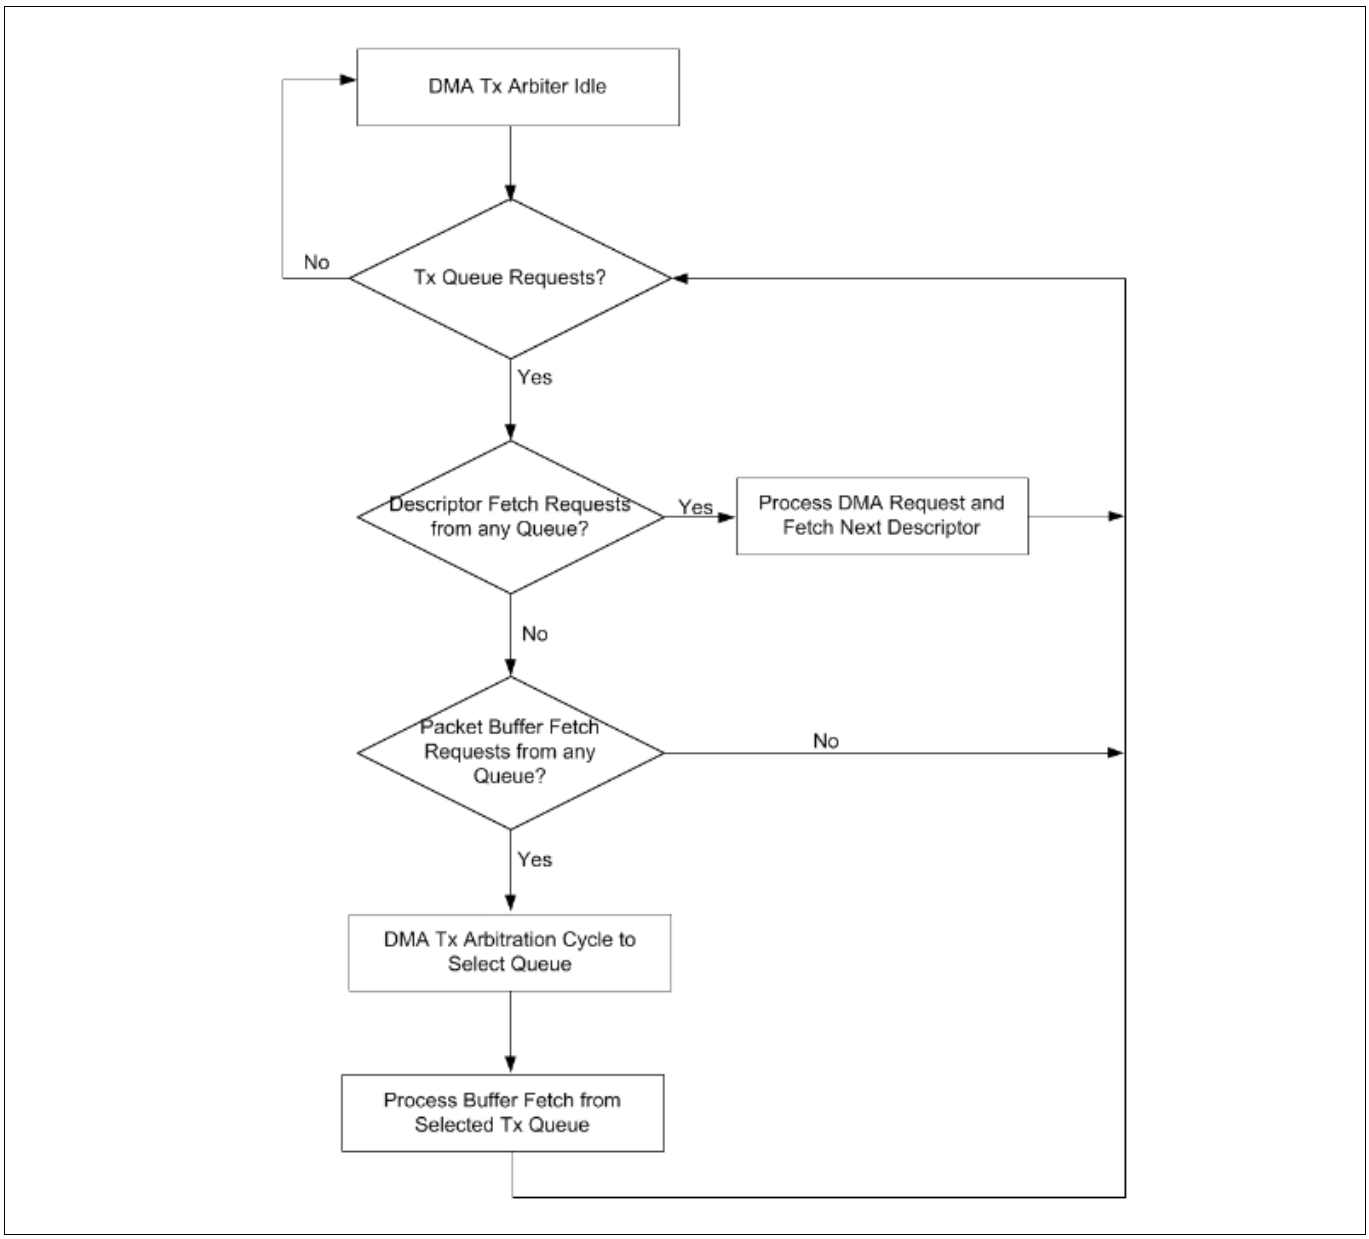

Figure 695 DMA Tx Channel Arbitration Process

When there is any request in the Tx queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests.Therefore, when there is a descriptor fetch request, the DMA arbiter acknowledges the DMA channel that is requesting for a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (Channel 1 having priority over Channel 0, Channel 2 having priority over Channel 1 and so on). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted Strict Priority (WSP): In WSP arbitration mode, the arbiter first processes Channel 7 (or the last enabled channel) and then Channel 6, Channel 5, and so on. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to Channel7 (or last enabled channel). If Channel 7 has no frames to transmit, the remaining weight is assigned to Channel 6 and so on.
- Weighted Round Robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit.
- Fixed priority (FP): In Fixed priority mode, Channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the Transmit Control register of a channel is ignored.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

44.3.1.3.3 DMA Receive Operation

The Receive (Rx) DMA engine transfers data from the device port to the system memory.

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel. The ARI data at the start of the frame indicates the channel number to which the current frame must be written. If only one DMA channel is selected, this information is not provided.

Figure 696 shows the reception sequence for Rx DMA engine. The following list describes this sequence:

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]).
   The application must set the correct value in the Receive Descriptor Tail Pointer register of corresponding DMA channel.
2. When Bit 0 of Receive Control register of corresponding DMA channel is set, the DMA enters the Run state. The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor Tail Pointer register values. If there are no free descriptors, the DMA Channel enters the suspend state and goes to step 11.
3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).
5. The DMA processes the incoming packets and places these in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.
7. The DMA takes the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last Descriptor bit set.
8. The DMA writes the Frame Length to RDES3 and VLAN Tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 Timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the Rx DMA Descriptor Ring, go to step 3; otherwise, go to the Suspend state (step 11).
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application advances the Receive Tail Pointer register of a channel.
    The engine proceeds to step 2 and refetches the next descriptor.

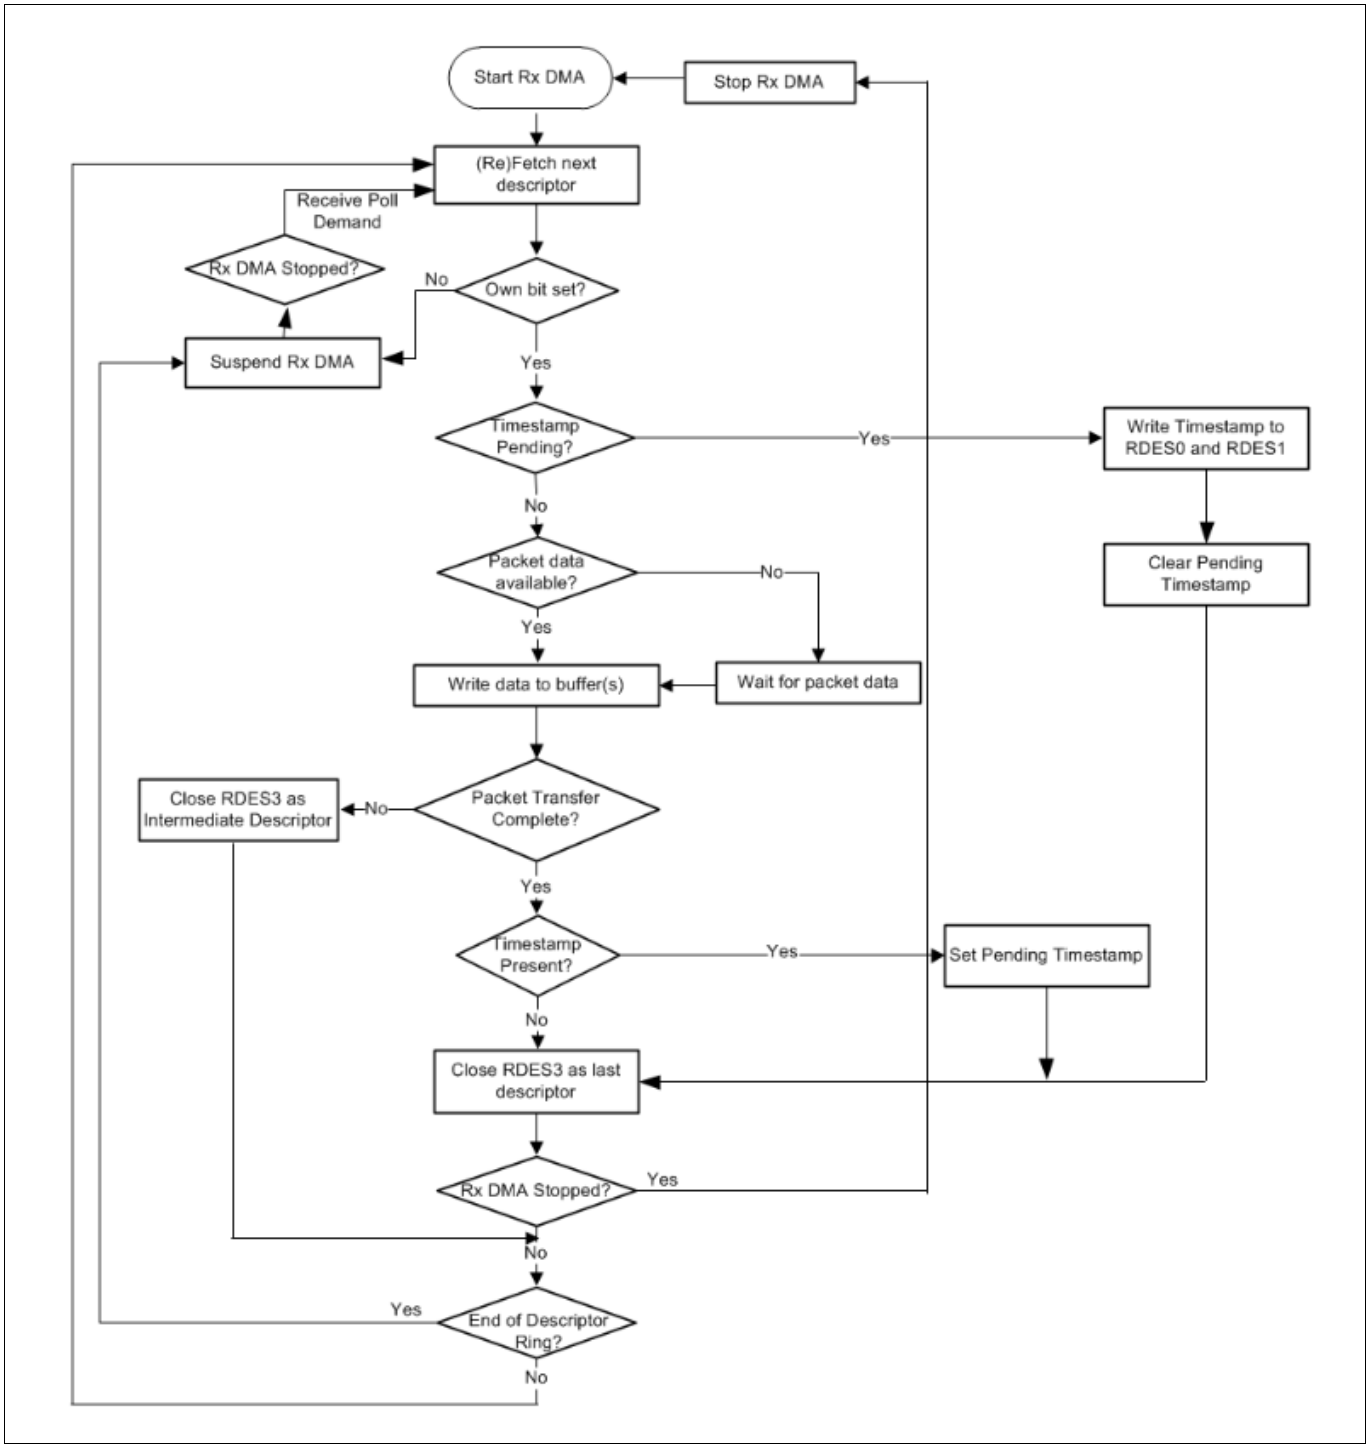

Figure 696 Receive DMA Operation

Receive Descriptor Acquisition

Under certain conditions, DWC_ether_qos attempts to acquire an extra descriptor in the anticipation of an incoming packet.

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming packet. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- Bit 0 of Receive Control Register of corresponding DMA channel is set immediately after being placed in the Run state.
- The Descriptor Tail pointer register value is ahead of the Current Descriptor acquired by the Rx DMA.
- The controller has completed packet reception, but the current Receive Descriptor is not yet closed.
- A Receive poll demand is issued (update of the Tail Pointer register).

Receive Packet Processing

During operation, the Rx engine tries to acquire an extra descriptor before it receives a packet and processes.

The sequence for processing a Receive packet is as follows:

1. The MAC transfers the received packets to the MTL memory only if the packet passes the address filter. If the packet fails the address filtering, it is dropped in the MAC block (unless Bit 31 of MAC_Packet_Filter register is set).
2. If packet size is greater than or equal to configurable threshold bytes set for Rx Queue of MTL, or when the complete packet is written to the queue in the store-and-forward mode, the MTL block requests the DMA block to begin transferring the packet data to the Receive Buffer pointed by the current descriptor.
   Packets smaller than 64 bytes, because of collision or premature termination, are removed from the MTL Receive Queue.
3. When the DMA application Interface (AHB/AXI or MDC) becomes ready, it transfers the data and sets the following:
   a) If the packet fits in a single descriptor, the DMA sets both Last Descriptor (RDES3[28]) and First Descriptor (RDES3[29]).
   b) If the packets fits into more than one descriptor, the DMA sets the First Descriptor (RDES3[29]) to delimit the packet.
4. The DMA releases the descriptors by resetting the Own (RDES3[31]) bit to 1’b0, either because the Receive buffer filled up or the last segment of the packet is transferred to the Receive buffer. The received packets status is updated in the last descriptor.
5. If Interrupt Enabled on Completion (RDES3[30]) bit is set in any of the Descriptors between the First and Last Descriptor of the Packet and Bit 6 of Interrupt Enable Register of corresponding DMA channel is set, the DMA sets Bit 6 of Status register of corresponding DMA channel.
   The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if Bit 7 of Interrupt Enable Register of corresponding DMA channel is set, the Receive Process sets Bit 7 of Status register of corresponding DMA channel and then enters the Suspend state. The position in the receive list is retained.

44.3.1.3.4 Error Response to DMA

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to DWC_ether_qos or re-initialize the DMA descriptor list and start again. The rest of the DMA channels are not affected by such errors.

44.3.1.3.5 DMA Interrupts

There are two groups of interrupts that occur in the DMA Rx and Tx channel pair: Normal and Abnormal interrupts. Normal interrupts happen during packet transfers and abnormal interrupts indicate error events.

Interrupts can be generated as a result of various events in the DWC_ether_qos controller. These events are captured in status registers, and interrupt enables are provided for each source of an interrupt such that the interrupt signal (sbd_intr_o) is asserted for an event only when the corresponding interrupt enable is set.

In EQOS-AXI configuration, the interrupt status and corresponding enable registers are organized in an hierarchical manner so that it is easier for software to traverse and identify the source of an interrupt event quickly. When sbd_intr_o is asserted, the DMA_Interrupt_Status register is the first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX and RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH(#i)_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register
- MTL_Interrupt_Status register
- MAC_Interrupt_Status register

The sbd_intr_o interrupt is a level signal and will get de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH[n]_Status register captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CH[n]_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of DMA_CH[n]_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1’b1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in DMA_Interrupt_Status register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[6] of DMA_CH[n]_Status register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the DMA_Interrupt_Status register for the cause of the interrupt and clear the source in the respective Status register. The sbd_intr_o is cleared only when all the bits of DMA_Interrupt_Status register are cleared.

Periodic Scheduling of Transmit and Receive Interrupt

To improve the throughput and performance, DWC_ether_qos supports interrupt timer and transmit descriptor to generate interrupts periodically, instead of every DMA transfer.

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The DWC_ether_qos gives the flexibility to schedule the interrupt at regular intervals using two methods:

- Set Interrupt on Completion bit in Transmit descriptor (TDES2[31]) once for every “required” number of packets to be transmitted.
- Similarly, set the IOC (RDES3[30]) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.

In addition to above, an interrupt timer (DMA_CH[n]_Rx_Interrupt_Watchdog_Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30]) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH[n]_Interrupt_Enable register.The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor's IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

Per Channel Transfer Complete Interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CH[n]_Status register.

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in DMA_CH[n]_Status register. The TI bit is set whenever the Tx DMA channel closes the a descriptor in which the IOC (Interrupt On Completion - TDES2[31]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[30]) bit is set.

The common sbd_intr_o output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH[n]_Interrupt_Enable register.

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[17:16] in DMA_Mode. **Table 438** explains the Transfer Complete Interrupt behavior.

Table 438 DWC_ether_qos Transfer Complete Interrupt Behavior

Sl No	Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
1.	INTRM=0	A pulse is asserted on these output signals when corresponding TX/RX transfercomplete event (for which IOC descriptor bits are enabled) is detected.	The TI/RI status signals are set whenever the "Transfer complete" event is detected. The bits get cleared whenever the software driver writes'1' to these bits. The sbd_intr_o is asserted when ever the corresponding interrupts are also enabled in DMA_CH[n]_Interrupt_Enable register.

Table 438 DWC_ether_qos Transfer Complete Interrupt Behavior (cont'd)

Sl No	Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
2.	INTM=1	These signals reflect the value ofcorresponding TI/RI bits inDMA_CH[n]_Status register when thecorresponding interrupt enable is set. Hence they are level signals and are cleared by the application by writing 1'b1 to the RI/TI status bits. This signal will not be asserted when the corresponding interrupt enable bit is not set.	The TI/RI is set as explained above.However, the sbd_intr_o signal is not asserted for any RI/TI events.
3.	INTM=2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits inDMA_CH[n]_Status register when thecorresponding interrupt enable is set. They are level signals and cleared by software by writing 1'b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared forthe previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then DWC_ether_qos automatically set these status bits again.However, the sbd_intr_o signal is not generated based on TI/RI

44.3.1.4 MAC Transaction Layer

44.3.1.4.1 SPRAM Interface

The MAC supports the Single Port RAM Interface. In the DPRAM, each transmit and Receive FIFO memory is split into two SPRAM blocks.

Figure 697 shows the high level architectural approach for supporting single port RAM interface. It describes the data flow, clock domains and memory interfaces in EQOS-MTL configuration with GMII/MII PHY interface.

As compared to a single DPRAM instance (with application clock on 1 port and GMII/MII clock on the other port), each Transmit and Receive FIFO memory is split into two SPRAM blocks (Odd and Even) and operates with the application clock. Each SPRAM block will have the same width as earlier (DPRAM) but will have half the depth of the total FIFO memory selected in the configuration. Thus the total memory space will be retained as configured.

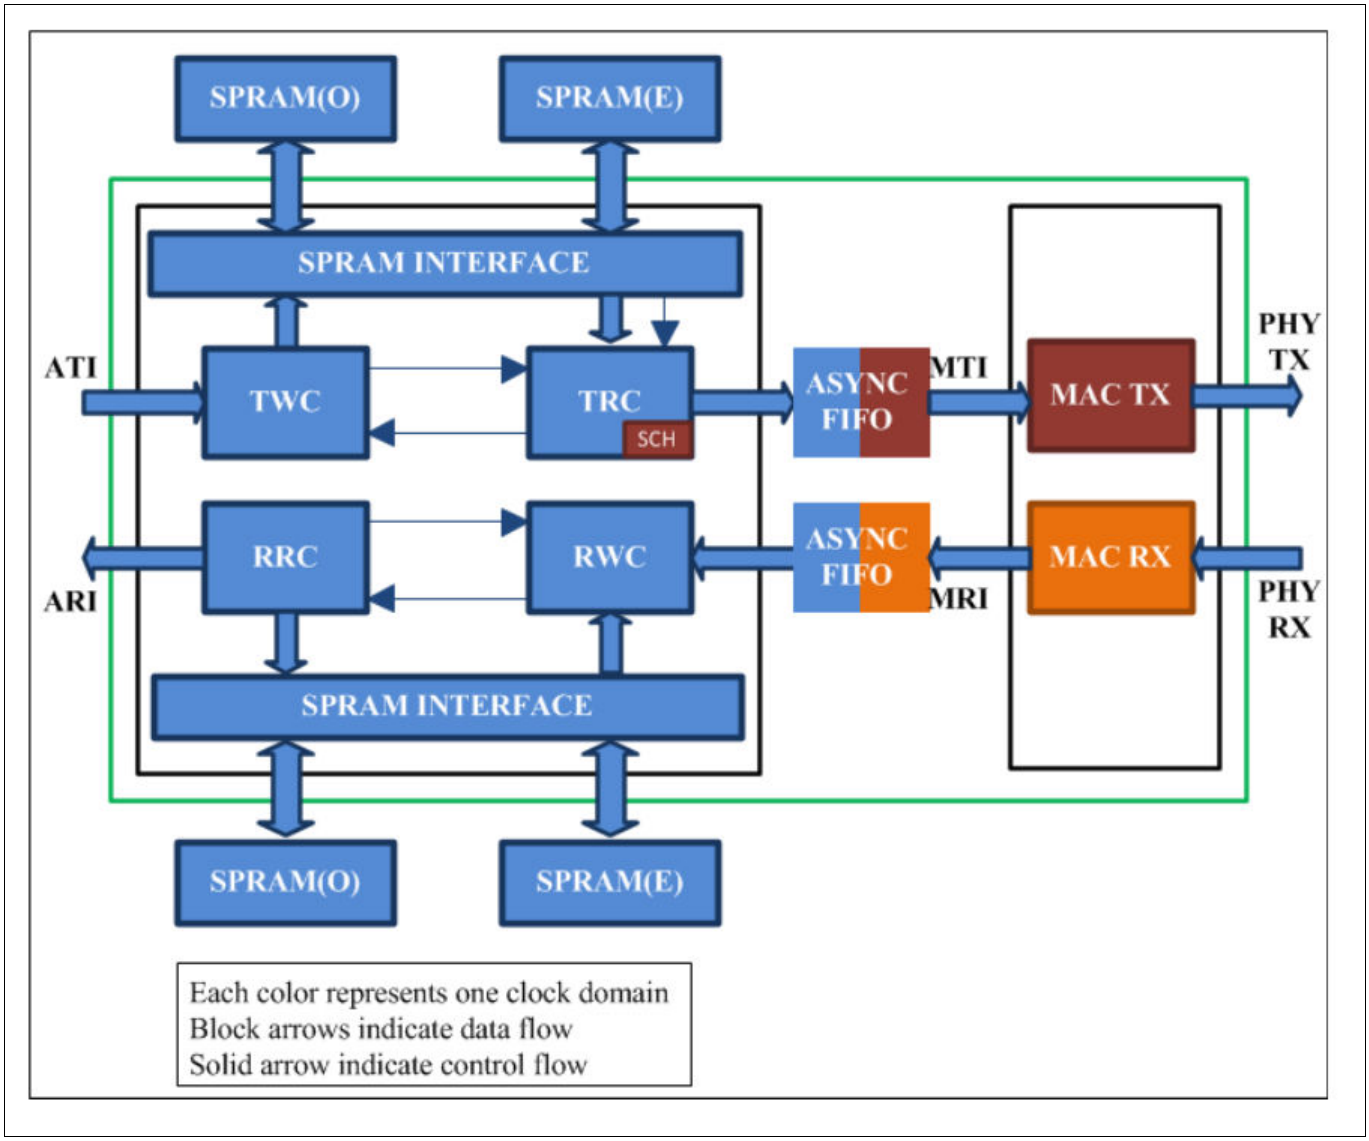

Figure 697 SPRAM Architecture Block Diagram

Application Clock Frequency Requirements for Memory Transfers

The application clock frequency must be such that the data transfer bandwidth of memory must be at least twice the bandwidth as that of the line.

Due to the requirement of simultaneous read and write transfers from the FIFO memories, the application clock frequency should be such that the data transfer bandwidth of memory must be at least twice the bandwidth as that of the line.

In addition to the previous requirement, additional bandwidth is required to allow delays due to contention between read and writes to a single memory block (Odd or Even). The probability of contention increases with multiple Queues (in Tx Side) especially in EQOS-AXI and EQOS-MTL configurations. These are mainly due to

- Possibility of receiving and writing interleaved data of different queues, all of which are to the same (odd or even) memory clocks in consecutive clock cycles.
- Non-sequential reads & writes of control words for each packet by scheduler in TX side
- Non-sequential writes of status words for each packet in RX side.

Considering the above, the minimum application clock frequency estimate in the various modes/speeds/configurations to avoid underflow in the "Async FIFO" in TX path is given in **Table 439**.

Table 439 Application Clock Frequency Estimate in Various Modes/Speeds

Configuration	No of Tx Queues	DW = 32
EQOS-AHB, EQOS-DMA	Any	62.5 MHz

When the speed is 100Mbps (MII mode), the minimum application clock frequency is reduced by factor of 10.

In the RX side, contention can happen if the slave memory does not accept data continuously and in the worst case there can be a contention for every memory access if the slave memory introduces one busy cycle after every transfer. However, status word writes steal cycles during the IPG (Inter-packet Gap) of received packets. The number of status words to be written depends on the configuration (for example, IEEE 1588 requires 64-bit timestamps, VLAN stripping requires 32-bit VLAN tags, etc). The depth (or area) of the register Asynchronous FIFO has to be larger to avoid overflows.

However, the minimum application clock frequency will be the same in all configurations in 1 Gbps speed as shown in **Table 440**.

Table 440 Minimum Application Clock Frequency in Various Configurations

Configuration	No of Rx Queues	DW = 32
Any	Any	69 MHz

For 100Mbps operating mode, the application clock frequency can be reduced by a factor of 10.

Notes

1. *The previous tables are pessimistic and estimated with a worst case scenario assumptions. These will be validated in simulation and updated later.*
2. *To handle valid frames of size < 64 bytes received in the line, increase the application clock frequency further, as the overhead due to status is considerably large on Rx side.*
3. *The previous computation assumes 12 bytes of IPG and 8 bytes of preamble+SFD. To handle reduced IPG and preamble, increase the application clock frequency further, to transfer the status in the available gaps between packets on the application interface (MRI).*

44.3.1.5 MAC

The MAC communicates with the MTI, MRI, and MCI interfaces of the DWC_ether_controller.

The MAC supports many interfaces towards the PHY chip. The PHY interface can be selected only once after reset. The MAC communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI), and MAC Control Interface (MCI).

44.3.1.5.1 MAC Transmission

The following six modules constitute the transmission function of the MAC:

- Transmit Bus Interface Module
- Transmit Packet Controller Module
- Transmit Protocol Engine Module
- Transmit Scheduler Module
- Transmit CRC Generator Module
- Transmit Flow Control Module

MAC Transmit Bus Interface Module

The MAC Transmit Bus Interface (TBU) accepts data in 32, 64, or 128-bit wide bus and runs on the clk_tx_i clock of GMII interface.

The Transmit Bus Interface (TBU) module connects the Transmit path of the MAC with an external packet through a FIFO interface.

MAC Transmit Packet Controller Module

The MAC Transmit Packet Controller (TPC) module consists of eight registers to hold the data and the last data control received from the TBU.

The Transmit Packet Controller (TPC) module consists of eight registers to hold the data and the last data control received from the TBU.

MAC Transmit Protocol Engine Module

The MAC Transmit Protocol Engine (TPE) module consists of a Transmit State Machine that controls the operation of Ethernet packet transmission.

The Transmit Protocol Engine (TPE) module consists of a Transmit State Machine that controls the operation of Ethernet packet transmission.

The Transmit State Machine of this module contains the following features to meet the IEEE 802.3/802.3z specification:

- Generates preamble and SFD
- Generates jam pattern in the half-duplex mode after normal collision
- Generates carrier extension in the half-duplex (only in the GMII) mode when packet is smaller than 512 bytes
- Supports packet bursting in the half-duplex (only in the GMII) mode
- Supports jabber timeout
- Supports flow control for the half-duplex mode (backpressure)
- Generates Transmit packet status
- Contains timestamp snapshot logic for IEEE 1588 support

When the TPC module requests the TPE module for a new packet transmission, the Transmit State Machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 8’b10101010 pattern and the SFD is defined as 1 byte of 8b’10101011 pattern.

The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps Ethernet and 4,096 bit times for 1,000 Mbps Ethernet). The jam pattern generation is applicable only to half-duplex mode, not to full duplex mode. In full-duplex mode, the Transmit State Machine ignores the phy_col_i signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the packet to the end of the CRC field, the Transmit State Machine sends a 32-bit jam pattern of 32’h55555555 on MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the Transmit state machine completes the transmission of preamble and SFD, and then sends the jam pattern.

In GMII mode, if a collision occurs any time between the beginning of the packet and the end of the extension field, the Transmit State Machine sends a 32-bit jam pattern of 32’h55555555 on GMII to inform all other stations of the collision. If the collision is seen during the preamble transmission phase, the Transmit State Machine completes the transmission of preamble and SFD, and then sends the jam pattern. If a collision occurs during the extension field, the Transmit State Machine sends a 32-bit jam pattern of 32'h1F1F1F1F.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Packet Burst mode is enabled), the Transmit State Machine sends a 32-bit jam pattern and sets the late collision bit in the Transmit packet status.

Note: At the GMII or MII interface, the collision signal (phy_col_i) being asynchronous is checked by the transmitter after it is double-synchronized to clk_tx domain. This additional latency delays the recognition of collision or late-collision event. When the output of phy_col_i synchronizer is asserted after the complete packet is transmitted, it is not recognized as collision even if the COL signal is high at the GMII interface before the end of transmission. Similarly, an assertion of COL signal at the GMII input at the last byte of normal collision window might be identified as late collision because of the synchronizer delay.

In GMII half-duplex mode (1000 Mbps), the Transmit State Machine ensures that all valid carrier events exceed a slot time of 4,096 bit times. To accomplish this, any Transmit packet shorter than 512 bytes from the TFC module is extended using a carrier extension. On GMII, this is signaled to the PHY by asserting phy_txer_o, de-asserting phy_txen_o, and setting phy_txd_o[7:0] to 8h'0F.

When the Packet Burst mode is enabled, only the first packet of the burst is carrier extended if it is shorter than 512 bytes. The carrier extension is not applicable for MII half-duplex and GMII or MII full-duplex modes. When the Packet Burst mode is enabled, the Transmit State Machine transmits a burst of packets (as long as packets are available from the TFC module) without releasing the carrier of the PHY. To accomplish this, the state machine inserts the carrier extension for a minimum IPG period (96 bit times) between the packets. The Transmit State Machine continues to burst packets as long as additional packets are available from the TPC module and a burst limit of 8,192 byte times has not been exceeded. If an additional packet is not available at the end of the IPG period in the middle of the burst, the Transmit State Machine releases the carrier by de-asserting the phy_txer_o and phy_txen_o signals on GMII.

The TPE module maintains a jabber timer to stop the transmission of Ethernet packets if the TFC module transfers more than 2,048 (default) bytes. The timeout is changed to 10,240 bytes when the Jumbo packet is enabled.

The Transmit State Machine uses the deferral mechanism for flow control (backpressure) in the half-duplex mode. When the application requests to stop receiving packets, the Transmit State Machine sends a JAM pattern of (8'h55) 32 bytes whenever it senses a reception of a packet, provided the Transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests the flow control through a sideband signal mti_flowctrl_i (or by setting BPA bit of the Flow Control Register of corresponding MTL queue). If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamp is enabled for the Transmit packet, this block takes a snapshot of the system time when the SFD is put onto the Transmit GMII or MII bus. The system time source is either an external input or it is internally generated according to the configuration selected.

Transmit Module

The MAC Transmit Scheduler (STX) module is responsible for scheduling the packet transmission on GMII or MII.

The Transmit Scheduler (STX) module is responsible for scheduling the packet transmission on GMII or MII. It provides an enable signal to the TPE module after satisfying the IPG and back-off delays.

The STX module performs the following functions:

- Maintains the inter-packet gap between two transmitted packetsThe STX module maintains an idle period of the configured inter-packet gap (IPG bits of MAC_Configuration register) between any two transmitted packets. If packets from the TPC arrive at the TPE module sooner than the configured IPG time, the TPE module waits for the enable signal from the STX module before starting the transmission on GMII or MII. The STX module starts its IPG counter as soon as the carrier signal of GMII or MII goes inactive. At the end of programmed IPG value, the module issues an enable signal to the TPE module in the full-duplex mode.

- Implements the Truncated Binary Exponential Back-off algorithm
  The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in the half-duplex mode.

MAC Transmit CRC Generator Module

The MAC Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet packet.

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet packet.

The TPC module sends the packet data and any necessary padding to the CTX module through an 8-bit interface.

The CTX module calculates the 32-bit CRC for the FCS field of the Ethernet packet. The encoding is defined by the following generating polynomial:

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The CTX module gets the byte data of Ethernet packet from the TPC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TPC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming packet. The TPC module issues the start command before sending the new packet data for calculation. The calculated CRC is valid on the next clock after the data is received.

In GMII mode, the Data Valid signal is valid for every clock, from the first data byte through the last data byte. In MII mode, this signal is valid every alternate clock.

MAC Transmit Flow Control Module

The MAC Transmit Flow Control (FTX) module generates and transmits the Pause packets to the TFC module based on the flow control triggers in full-duplex mode.

The Transmit Flow Control (FTX) module generates and transmits the Pause packets to the TFC module based on the flow control triggers in full-duplex mode.

The TFC module receives the Pause packet from the FTX module, appends the calculated CRC, and sends the packet to the TPE module.

44.3.1.5.2 MAC Reception

A receive operation is initiated when the MAC detects an SFD on GMII or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

The following are the functional blocks in the Receive path of the MAC.

- Receive Protocol Engine Module
- Receive CRC Module
- Receive Packet Controller Module
- Receive Flow Control Module
- Receive Bus Interface Unit Module
- Address Filtering Module

MAC Receive Protocol Engine Module

The MAC Receive Protocol Engine (RPE) consists of the Receive State Machine which strips the preamble, SFD, and carrier extension of the received Ethernet packet (in half-duplex 1000-Mbps mode).

The Receive Protocol Engine (RPE) consists of the Receive State Machine which strips the preamble, SFD, and carrier extension of the received Ethernet packet (in half-duplex 1000-Mbps mode).

MAC Receive CRC Module

The MAC Receive CRC (CRX) interfaces with the RPE module to check any CRC error in the packet being received.

The Receive CRC (CRX) interfaces with the RPE module to check any CRC error in the packet being received. This module calculates the 32-bit CRC for received packet that includes the Destination address field through the FCS field.

MAC Receive Packet Controller Module

The MAC Receive Packet Controller (RPC) receives the Ethernet packet data and status from the RPE module.

The Receive Packet Controller (RPC) receives the Ethernet packet data and status from the RPE module.

MAC Receive Bus Interface Unit Module

The MAC Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RPC module into a 32-bit, 64-bit, or 128-bit FIFO protocol on the Application side.

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RPC module into a 32-bit, 64-bit, or 128-bit FIFO protocol on the Application side.

Address Filtering Module

The MAC Address Filtering (AFM) module performs the destination and source address checking function on all received packets and reports the address filtering status to the RPC module.

The Address Filtering (AFM) module performs the destination and source address checking function on all received packets and reports the address filtering status to the RPC module.

44.3.2 Processing Double VLAN

44.3.2.1 Introduction to Double VLAN Processing

The DWC_ether_qos supports the double VLAN tagging feature, in which the MAC can process up to two VLAN tags.

DWC_ether_qos supports two VLAN tags, namely inner and outer, for processing double VLANs. This feature is referred as the double VLAN tagging feature in which the MAC can process two VLAN tags. With this feature, the DWC_ether_qos supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

44.3.2.2 Description to Double VLAN Processing

DWC_ether_qos supports the double VLAN tagging feature to enable the MAC layer to support up to two VLAN tags. The MAC layer supports various features on the transmit and receive side to support the double VLAN tagging feature.

Table 441 describes the features supported by the MAC on the Transmit side.

Table 442 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 441 Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_Incl and MAC_Inner_VLAN_Incl registers. The DWC_ether_qos supports processing of any sequence of outer and inner VLAN tags. Note: The DWC_ether_qos does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

Table 442 Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

44.3.3 Source Address and VLAN Insertion, Replacement, or Deletion

44.3.3.1 Introduction to SA and VLAN Insertion, Replacement, or Deletion

DWC_ether_qos supports the feature to insert, replace, or delete the source address (SA) and VLAN fields that are part of transmit packets.

The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through ATI interfaces. DWC_ether_qos supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. You can enable the SA insertion or replacement feature for all Transmit packets or selective packets. Similarly, you can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets.

44.3.3.2 Programming Source Address Insertion or Replacement

DWC_ether_qos supports the feature to insert or replace the source address (SA) with information in the SA field of the MAC Address register.

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- Enabling SA insertion or replacement for all packets
  To enable this feature for all packets, program the SARC field of the MAC_Configuration register.
- Enabling SA insertion or replacement for selective packets
  To enable this feature for selective packets, use the following method depending on the configuration:
  - EQOS-AHB, , or :
    Program the SA Insertion Control field (Bits[25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

44.3.3.3 Programming VLAN Insertion, Replacement, or Deletion

DWC_ether_qos supports the feature to insert, replace or delete the VLAN fields (VLAN type and VLAN tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register.

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields

- Insert or replace the VLAN Type and VLAN Tag fields
  Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described **Table 443**

Table 443 VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with one of the following depending upon the configuration: – EQOS-AHB, , or : Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- Enabling VLAN insertion, replacement, or deletion for all packets
  To enable this feature for all packets, program the VLC and VLP fields of MAC_VLAN_Incl register.
- Enabling VLAN insertion, replacement, or deletion for selective packets
  To enable this feature for selective packets, use the following method depending upon the configuration:In addition, the VLP (VLAN Priority control) bit must be reset in Register 24 (for outer VLAN) and Register 25 (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.
  – EQOS-AHB, , or : Program the VTIR field of TDES2 Normal Descriptor).

In addition, the VLP (VLAN Priority control) bit must be reset in Register 24 (for outer VLAN) and Register 25 (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

44.3.4 Queue Channel Based VLAN Tag Insertion

44.3.4.1 Introduction to Queue/Channel Based VLAN Tag Insertion on Tx

DW_ether_qos supports insertion of VLAN tags in Transmit packets and these VLAN tags can be based on a queue or channel.

DWC_ether_qos supports channel/queue based VLAN tag insertion on all transmitted packets.

44.3.4.2 Accessing Queue/Channel Specific VLAN Tag Registers

You can access VLAN tags specific to a queue/channel using the MAC_VLAN_Incl register.

Queue/Channel specific VLAN tag registers are accessed using indirect addressing via the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

44.3.5 Managing Buffers and Memories

44.3.5.1 Introduction to Transmit and Receive FIFOs

DWC_ether_qos provides transmit and receive FIFOs to buffer data while transmitting and receiving information from an application.

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application . Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are required to be two-ported RAM of 35-bit or 68-bit or 133-bit width for 32, 64 or 128 data bus widths, respectively. The extra bits are used for storing the byte-enable information.

When multiple queues are selected, all Tx queue share the Tx FIFO memory and all Rx queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx queue.

44.3.5.2 Transmit and Receive FIFO-Related Registers

The Transmit (Tx) and Receive (Rx) registers are used as buffers while sending and receiving information from an application.

Following are the Transmit and Receive FIFO-related registers:

- MTL_TxQ0_Operation_Mode
- MTL_RxQ0_Operation_Mode

44.3.6 Using PHY Interface

The DWC_ether_qos supports a number of interfaces that can be enabled as the Line interface to the PHY.

The following topics are discussed:

- Station Management Agent
- Reduced Gigabit Media Indepent Interface
- Reduced Media Independent Interface

44.3.6.1 Station Management Agent

44.3.6.1.1 Introduction to Station Management Agent

The application can access the PHY registers through the Station Management Agent (SMA) module. SMAis a two-wire Station Management interface (MIM).

44.3.6.1.2 Functional Description of Station Management Agent

For MIM accesses, the maximum operating frequency of the MDC (gmii_mdc_o) is 2.5 MHz, as specified inthe IEEE 802.3. In the DWC_ether_qos core, the gmii_mdc_o clock is derived from the application clock orclk_csr_i , using a divider-counter. The divide factor depends on the clock range setting (CR field) in theMAC_MDIO_Address register.Select the clock divide factor as mentioned in the description of CR field of MAC_MDIO_Address register,to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIMinterface, there is a provision to select a different divider.

The MDIO frame structure is as follows:

Table 444 MDIO Clause 45 Frame Structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2’00
OPCODE	2’b09, 2’b01, 2’b10, 2’b11
PHY ADDR	5-bit address select for one of 32 PHYs
DEV ADDR	5-bit address select for one of 32 devices
TA	Turnaround is 2’bZ0 for Read and post-read increment address and 2’b10 for Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value. For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. In address and data write cycles, the DWC_ether_qos drives the MDIO line during the transfer of these 16 bits.In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits.

The frame structure for Clause 22 frames is also supported. The C45E bit in the MAC_MDIO_Addressregister can be programmed to enable Clause 22 or Clause 45 mode of operation. The following table showsthe Clause 22 frame format.

Table 445 MDIO Clause 22 Frame Structure

Field	Description
IDLE	The mdio line is three-state; there is no clock on gmii_mdc_o.
PREAMBLE	32 continuous bits of value 1
START	Start of packet is 2’01
OPCODE	2’b10 for Read and 2’b01 for Write
PHY ADDR	5-bit address select for one of 32 PHYs
REG ADDR	5-bit address to select the register within each MMD
TA	Turnaround is 2’bZ0 for Read and 2’b10 for Write Where Z is the tri-state level
DATA/ADDRESS	Any 16-bit value. In a Write operation, the MAC drives mdio. In a Read operation, the PHY drives it.

In addition to normal read and write operations, the SMA also supports post-read increment address whileoperating in Clause 45 mode.

GMII/MII Management Write Operation

After the Station Management Agent receives the PHY address and the write data from the MAC CSR module, the SMA starts a Write operation to the PHY registers.

Figure 698 illustrates the flow for a write operation from the SMA module to the PHY registers.

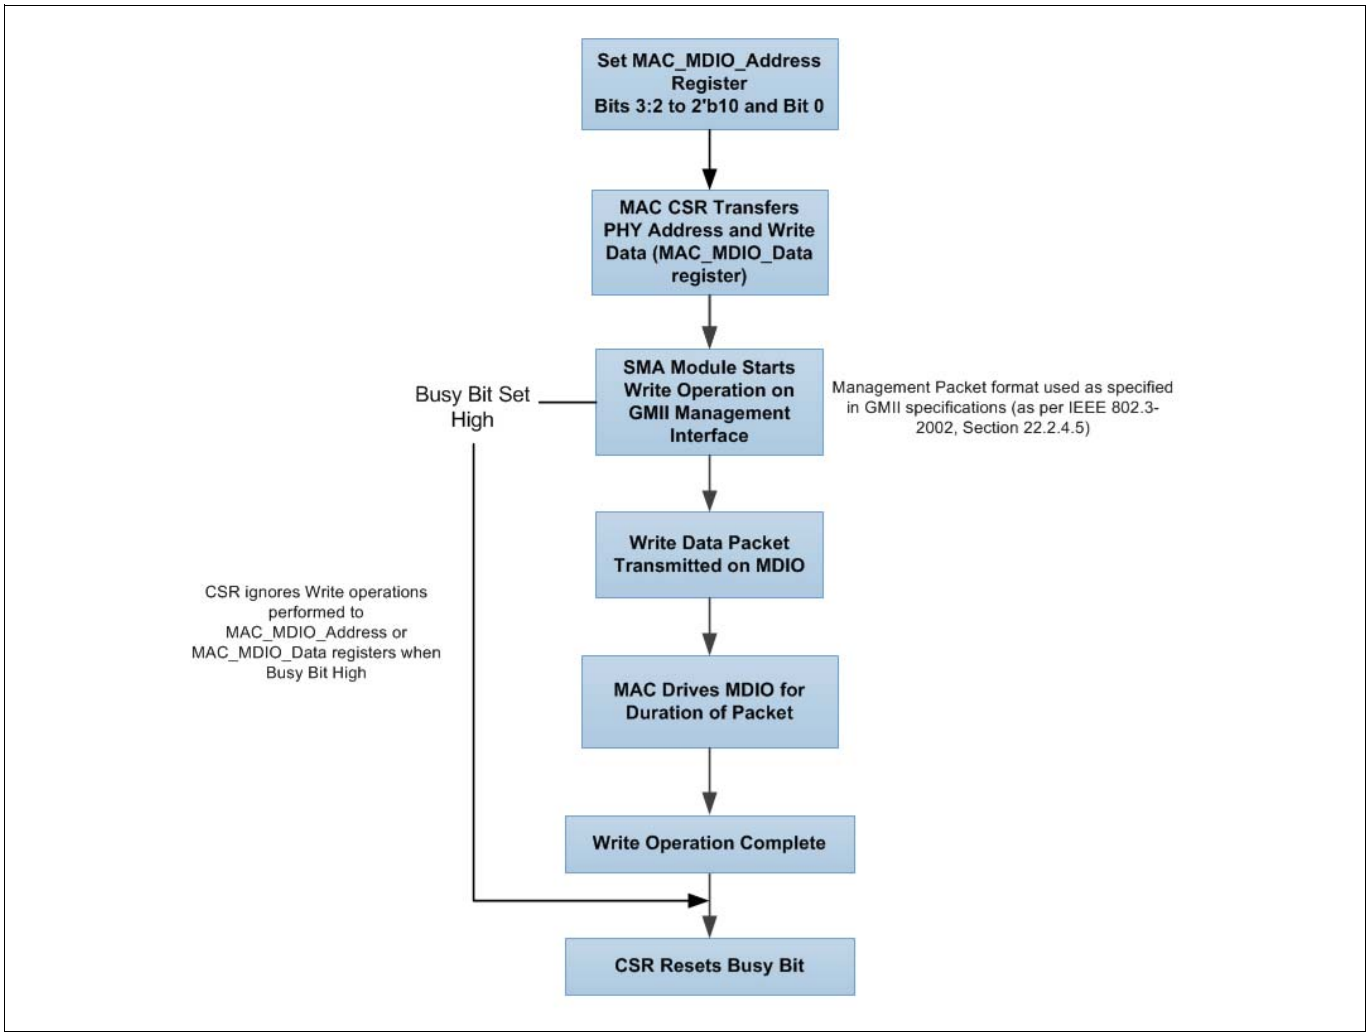

Figure 698 SMA Write Operation Flow

GMII/MII Management Read Operation

After the Station Management Agent receives the PHY address and the register address in the PHY from the MAC CSR module, the SMA initiates a Read operation to the PHY registers.

The flow of a Management read operation is as follows:

1. Set Bit[3:2] to 2'b11 and Bit 0 in the MAC_MDIO_Address register
2. The MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers
3. The SMA module starts a Read operation on the GMII Management Interface using the Management Packet Format specified in the GMII specifications (as per IEEE 802.3-2002, Section 22.2.4.5).
4. When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MAC_MDIO_Address or MAC_MDIO_Data register during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface.
5. When the Read operation is complete, the SMA indicates this to the CSR.
6. The CSR resets the Busy bit and updates the MAC_MDIO_Data register with the data read from the PHY.

44.3.6.1.3 Preamble Suppression

The IEEE standard specifies 32-bit preamble (all-ones) for the MDIO frames. The DWC_ether_qos providescontrols to support preamble suppression, it will transmit MDIO frames with only 1 preamble bit. Thepreamble suppression can be enabled by setting PSE bit of MAC_MDIO_Address register.

44.3.6.1.4 Trailing Clocks and Back to Back transactions

The DWC_ether_qos drives MDC clock on the gmii_mdc_o port for duration of the MDIO frame. There isno clock driven during the idle period. The trailing clocks feature can be used if the PHY needs the MDCclock to be active for some cycles after the MDIO frame. The NTC field in MAC_MDIO_Address registerallows programming of trailing clocks from 0 to 7.

The DWC_ether_qos supports Back to Back transactions which allows start of next MDIO frame even beforethe trailing clocks are completed for previous MDIO frame. This feature can be enabled by setting BTB bit inMAC_MDIO_Address register when trailing clocks feature is also enabled. When Back to Back transactionsis enabled, the GMII Busy will be cleared immediately after MDIO frame completion allowing SW to issuenext command, which will be executed by DWC_ether_qos while trailing clocks are still on for previousMDIO frame. When Back to Back transactions is not enabled, the GMII Busy will be cleared after the trailingclocks are completed for MDIO frame.

44.3.6.1.5 Interrupt for MDIO transaction completion

The MDIO interface generates an interrupt on completion of MDIO read or write transactions. The application can avoid polling the GMII Busy bit of MAC_MDIO_Address register and know the completion of MDIO commands based on the interrupt generated. The interrupt is generated only if the MDIO Interrupt Enable bit of MAC Interrupt Enable bit is set.

44.3.6.2 Reduced Gigabit Media Independent Interface

44.3.6.2.1 Introduction to Reduced Gigabit Media Independent Interface (RGMII)

The Reduced Gigabit Media Independent Interface (RGMII) module is implemented in DWC_ether_qos to reduce the pin count as mentioned in the RGMII specification.

The Reduced Gigabit Media Independent Interface (RGMII) specification reduces the pin count of the interconnection between the MAC and the PHY for GMII and MII interfaces. To achieve this, the data path and control signals are reduced and multiplexed together with both edges of the Transmit and Receive clocks. For Gigabit operation, the clocks operate at 125 MHz; for 10/100 operation, the clock rates are 2.5 MHz/25 MHz.

The RGMII module is instantiated between the GMII of the MAC and the PHY to translate the control and data signals between the GMII and RGMII protocols.

The RGMII block has the following characteristics:

- Supports 10 Mbps, 100 Mbps, and 1000 Mbps operation rates
- Requires no extra clock because both edges of the incoming clocks are used. To simplify back-end implementation of the MAC, there are separate clock inputs (180 degrees out-of-phase with the associated transmit/receive clocks) for logic that uses the falling edges. For guidelines for clock connections when the MAC operates with an RGMII, see DesignWare Cores Ethernet Quality-of-Service User Guide.
- Extracts the in-band (link speed, link status, and duplex mode) status signals from the PHY and provides them to the MAC for link detection

44.3.6.3 Reduced Media Independent Interface

44.3.6.3.1 Introduction to Reduced Media Independent Interface

The Reduced Media Independent Interface is instantiated between the MAC and the PHY. The RMII helps to translate the MII signals (to/from the MAC) to RMII signals (to/from the PHY).

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count

The RMII module is instantiated between the MAC and the PHY. This helps in translating the MII of the MAC into the RMII. The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation
- Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock references externally.

44.3.7 Packet Filtering

44.3.7.1 Packet Filtering Sequence

The receive packet passes through various filters such as source/destination address filter, VLAN filter, before being delivered to the host or being discard.

Figure 699 shows the filtering sequence for Rx packets.

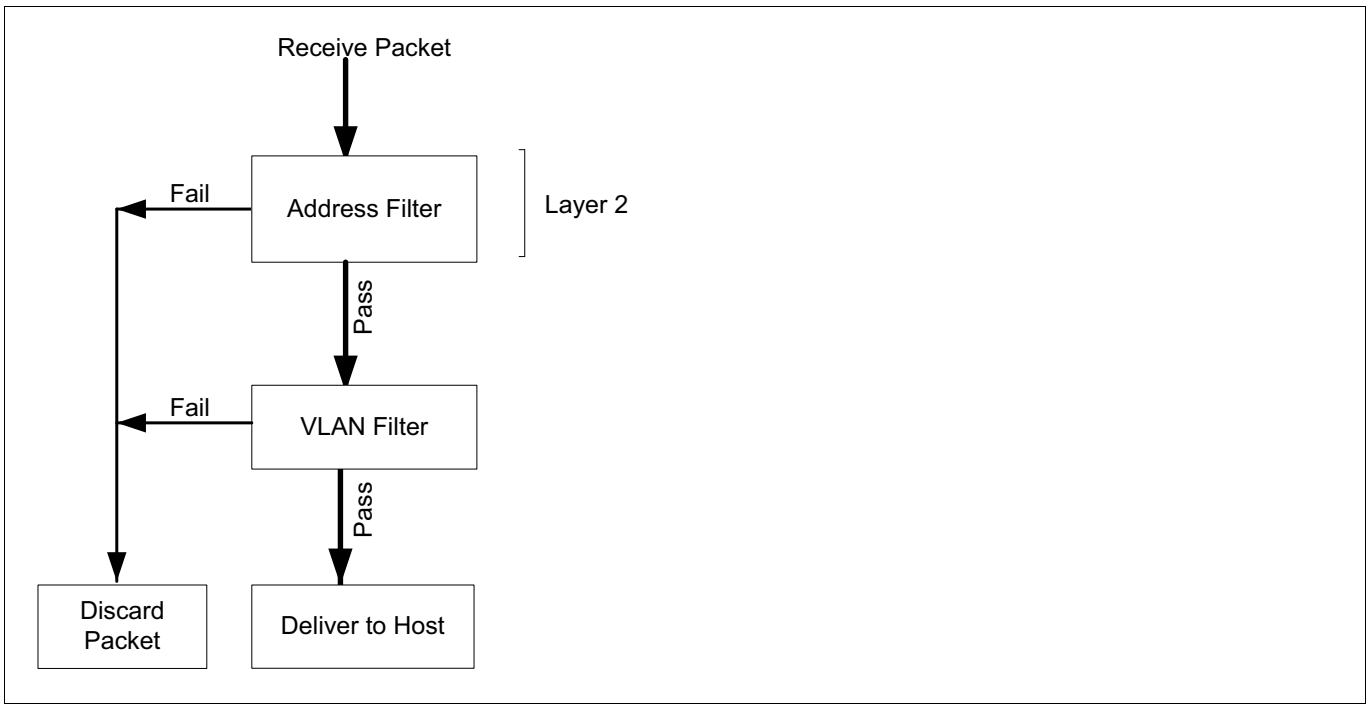

Figure 699 Packet Filtering Sequence

44.3.7.2 Source Address or Destination Address Filtering

44.3.7.2.1 Introduction to Source or Destination Address Filtering

DWC_ether_qos supports the address filtering module that checks the source and destination address of incoming packets.

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

44.3.7.2.2 Programming Different Types of Address Filtering

The different types of address filtering that you can program are unicast destination, multicast destination, hash and perfect address, broadcast address, unicast source address and inverse filtering.

Unicast Destination Address Filtering

The MAC supports up to 128 MAC addresses for unicast perfect filtering. MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr127 addresses are selected with an individual enable bit. For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA. The MacAddr32 to MacAddr127 addresses do not have mask control and all 6-bytes of the MAC address are compared with the received 6-bytes of DA.

Multicast Destination Address Filtering

To program the MAC to pass all multicast packets, set the PM bit in MAC_Packet_Filter register.

The multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

Broadcast Address Filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in MAC_Packet_Filter register.

Unicast Source Address Filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers[1–31] to use SA instead of DA for comparison by setting Bit 30 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

Inverse Filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of

the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 446 summarizes the DA and SA filtering based on the type of packets received.

Note: When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

Table 446 Destination Address Filtering

Packet Type	PR	DAIF	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	Pass
	0	X	X	0	Pass
	0	X	X	1	Fail
Unicast	1	X	X	X	Pass all packets
	0	0	X	X	Pass on Perfect/Group filter match
	0	1	X	X	Fail on Perfect/Group filter match
Multicast	1	X	X	X	Pass all packets
	X	X	1	X	Pass all packets
	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	1	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

44.3.7.3 VLAN Filtering

44.3.7.3.1 VLAN Tag Perfect Filtering

The VLAN tag perfect filtering in DWC_ether_qos enables the MAC to forward VLAN-tagged packets along with VLAN tag match status and to drop the VLAN packets that do not match.

In VLAN tag perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of MAC_VLAN_Tag register. In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of MAC_VLAN_Tag register. The VLAN packet status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

Note: The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based perfect filter is available in all configurations.

44.3.7.3.2 Introduction to VLAN Tag Hash Filtering

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table.

44.3.7.3.3 VLAN Tag Hash Filtering

The 16-bit VLAN Hash Table is used for group address filtering based on the VLAN tag. The VLAN Tag Hash Filtering feature can be enabled using the VTHM (VLAN Tag Hash Table Match Enable) bit of the MAC_VLAN_Tag register.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table.

The MAC performs the VLAN hash matching based on the VTHM of the MAC_VLAN_Tag register. If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

Notes

1. *The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in MAC_VLAN_TAG register.*
2. *When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register.*
3. *When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of MAC_VLAN_Hash_Table register.*

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table 447 shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in

MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail. In the following table, value X means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 447 VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In **Table 447**, X represents any value.

44.3.7.4 Extended Rx VLAN Filtering and Routing

44.3.7.4.1 Introduction to Extended Receive VLAN Filtering

The Extended Receive VLAN Filtering feature enables both Perfect and Hash filtering in an application. The filter result is based on the perfect filter result and the Hash Filter result, and the result is passed to the application as part of the status bits.

Perfect filtering is done for the VLAN Tag Filters. For each VLAN Tag Filter, the VLAN Tag ID is compared. The combined result of all the enabled VLAN Tag Filters determines the overall VLAN Tag Filter result. The filter result is passed to the application as part of the status bits.

When the VLAN Tag Filter gives a pass result, the frame is considered to have passed the VLAN Tag Filters. If the frame fails all the filters, the frame is considered to have failed the VLAN filter.

In addition to Perfect Filtering, Hash Filtering can also be enabled. In Hash Filtering, the overall VLAN Filter result is determined by the Hash Filter result and the perfect filter result. The overall filter result determines if the frame will be dropped or forwarded to the application based on the programming on the VTFE and RA bits of the MAC Filter Register.

44.3.7.4.2 Comparision Modes

An application has several comparison options for each VLAN Tag Filter, and a pass or fail result can be obtained for the comparison.

For each VLAN Tag Filter, the application has the following comparison options:

- It can program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID.
- It can choose if 12 or 16 bits of the VID field need to be compared.
- Type check can be disabled or enabled for each filter; if enabled, the application can choose if the VID comparison is for SVLAN or CVLAN type frames only.For example, if a filter is enabled for 16 bit comparison, SVLAN Type, and Outer VLAN Tag, any single or double VLAN Tagged frames with Outer SVLAN Tags are compared with this filter, and a pass or fail result is obtained.

Note: The inner VLAN Tag comparison is applicable only if Double VLAN Tag processing is enabled through the parameter and the MAC VLAN Control Register bit.

44.3.7.4.3 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled (by setting the VTFE bit), the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Receive All (RA) is enabled and the enable bit (VFFQE) for the queue is set.

RA and VTFE bits are implemented in the MAC_Packet_Filter register.

VFFQ and VFFQE fields are implemented in the MAC_RxQ_Ctrl4 register.

The packets that pass the VLAN filtering are routed based on the VLAN TAG priority field. The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The packets that fail the VLAN filtering are expected to be dropped, however when RA bit is set the VLAN filter fails are forwarded to the application. If the VLAN Filter Fails and Queue Enable (VFFQE) bit is selected then the VLAN filter fail packets are forwarded to the queue number programmed in VFFQ field, and if VFFQE is not enabled, the queue number is determined by the VLAN tag priority.

Rx Queue routing table for Unicast tagged packets:

Table 448 OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

RA	VTFE	SA/DA Filter Result	VLANFilter Result	VFFQE	Queue Routing
X	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ*/PSRQ
1	X	FAIL	X	1	UFFQ*/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

X : Don’t care condition

UFFQ* : When UFFQE is enabled

44.3.7.4.4 Filter Status

The Extended Receive VLAN Filtering & Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

Currently the MAC indicates the VLAN Filter Status through one bit in the status – VF in RDES2. When Extended RX VLAN Filtering & Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions in various configurations. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15 – Outer VLAN Tag Filter Status
  - Bit 14 – Inner VLAN Tag FilterStatus

In ARI status: MAC Filter Status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Bit 46 – Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filtersprogrammed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Table 449 and **Table 450** show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the **Table 449**

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison . bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).

- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
  OTS – Outer VLAN Tag Filter Status
  ITS – Inner VLAN Tag Filter Status

Table 449 OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 450 shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 450 OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 1-1 indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of Table 1-1 indicates that Inverse Filtering is enabled, Hash Filter and atleast one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tagmismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bitset to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

44.3.7.4.5 Stripping

DWC_ether_qos supports the stripping feature in which the stripping operation is enabled on Inner VLAN Tags in received packets. This field indicates the stripping operation on inner VLAN Tag in received packet:

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.

As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If the application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if Stripping is enabled for any of the tags, the tag can be put in the status. For this the application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

44.3.8 Using IEEE 1588 Timestamp Support

44.3.8.1 Using IEEE 1588 Timestamp Support

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects.

The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

44.3.8.1.1 Introduction to IEEE 1588 Timestamp Support

The IEEE 1588-2002 supports PTP transported over UDP/IP and IEEE 1588-2008 supports PTP transported over Ethernet.

The supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP and IEEE 1588-2008 supports PTP transported over Ethernet. The ; provides programmable support for both standards.

The controller supports the following features:

- Supports both timestamp formats
- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

44.3.8.1.2 Description of IEEE 1588 Timestamp Support

Clock Types

 supports different clock types defined in IEEE 1588-2008.

The ; supports the following clock types:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

Ordinary Clock

The ordinary clock has a single PTP state and a single physical port. In a domain, an ordinary clock supports a single copy of the protocol.

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in MAC_Timestamp_Control.
- Maintains the data sets such as timestamp values

Table 451 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 451 Ordinary Clock: PTP messages for Snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in MAC_Timestamp_Control.

Boundary Clock

A boundary clock, typically has several physical ports communicating with the network.

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

End-to-End Transparent Clock

End-to-End transparent clock supports end-to-end delay measurement mechanism between the slave clocks and the master clock.

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot must be taken at both Ingress and Egress ports only for the messages mentioned in **Table 452**. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the MAC_Timestamp_Control register.

Table 452 End to end Transparent Clock: PTP messages for Snapshot

PTP Messages
SYNC
Delay_Req

Peer-to-Peer Transparent Clock

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer.

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in **Table 453**.

Table 453 Peer-to-Peer Transparent Clock: PTP Messages for Snapshot

PTP Messages
SYNC
Pdelay_req
Pdelay_Resp

You can take the snapshot by setting the SNAPTYPESEL bit to 11 in MAC_Timestamp_Control register.

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages.

Figure 700 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

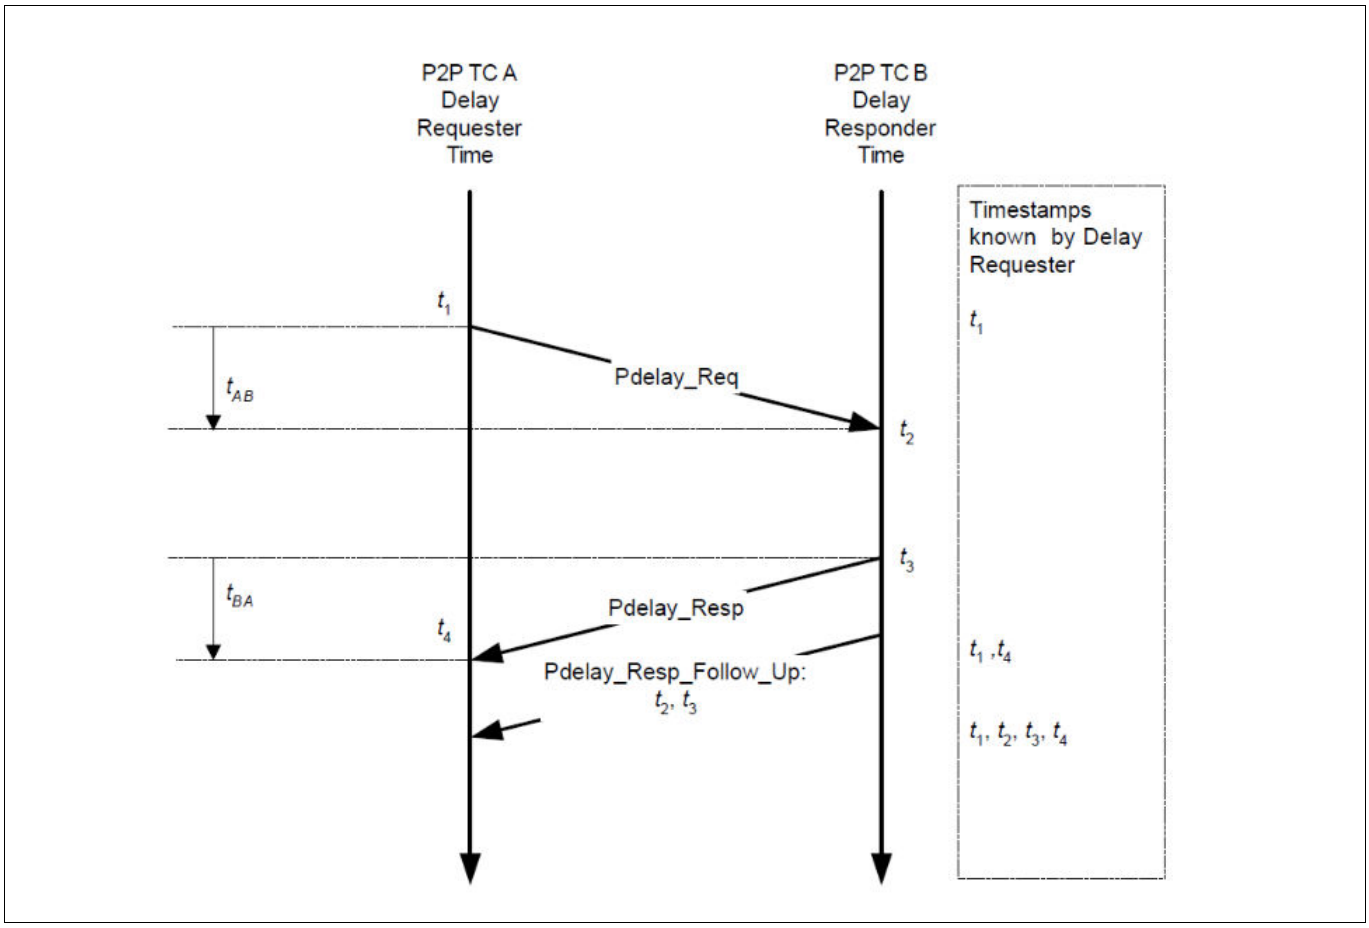

Figure 700 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in **Figure 700**, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.
   To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   a) Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   b) Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   c) Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network.

Because the reference timing source (the PTP clock clk_ptp_ref_i) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programmed in the Ingress Correction register.

The value that needs to be programmed in the ingress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value as follows:

```
INGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp as follows:

```
Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY
```

Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

It is represented by setting bit 31 to 1 and bits 30:0 containing 10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programmed value is 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 31 to 1 and bits 30:0 containing 2^31 - <ingress_correction_value> represented in binary.

Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value) programmed in the Egress Correction register.

The value to be programmed in the egress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value as follows:

When Enable one step timestamp feature is selected,

```
EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)
```

Otherwise,

```
EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)
```

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp as follows:

```
Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY
```

Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form as follows:

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <egress_correction_value> represented in binary. The value must not exceed 0x 3B9A_C9FF. If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programmed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <egress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 2^31 - <egress_correction_value> represented in binary.

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application clock domain.

Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of GMII or MII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

Maximum PTP Clock Frequency

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock.

In addition, the resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

Minimum PTP Clock Frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the GMII or MII clock domain.

This relationship is given in the following equation:

```
3 * PTP clock period + 4 * GMII/MII clock period <= Minimum gap between two SFDs
```

The GMII or MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in **Table 454**.

Notes

1. *It is recommended that you use a clock that has constant frequency, preferably a divided application clock.*
2. *When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit MAC_Sub_Second_Increment register limits the minimum PTP frequency that can be used to ~4 MHz.*

Table 454 Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with External Timestamp Input	Minimum PTP Frequency with Internal Timestamp
10 Mbps full duplex	168 MII clocks(128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	~45 KHz	5 MHz
10 Mbps half duplex	48 MII clocks(8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	170 KHz	5 MHz
100 Mbps full duplex	168 MII clocks(128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	~0.5 MHz	5 MHz
100 Mbps half duplex	48 MII clocks(8 clocks for a JAM pattern sent just after SFD because of collision + 24 IFG + 16 preamble)	4.55 MHz	5 MHz
1000 Mbps full duplex	84 GMII clocks(64 clocks for a 64-byte packet + 12 clocks of min IFG + 8 clocks of preamble)	~4.7 MHz	5 MHz
1000 Mbps half duplex	24 GMII clocks(4 clocks for a JAM pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	18.75 MHz	18.75 MHz

PTP Processing and Control

The IEEE 1588-2008 specification supports peer-to-peer (PTP) messages in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. This topic discuses the common message header format as defined in IEEE 1588-2008.

Table 455 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 455 Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset

(*) – control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets over IPv4
- PTP Packets over IPv6
- PTP Packets over Ethernet

PTP Packets over IPv4

The Ethernet payload contains certain fields that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for PTO packets over IPv4 and ethernet, and framers over IPv6 packets. This topic discusses fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2.

Table 456 provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4.

Table 456 IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81(or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: • 224.0.1.129 • 224.0.1.130 • 224.0.1.131 • 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex)0xE0, 0x00, 0x00, 0x6B (Hex)	• PTP Primary multicast address: 224.0.1.129 • PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	• 0x013F: PTP event messages • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

Table 456 IPv4-UDP PTP Packet Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

a. PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only)

This is based on the IEEE 1588-2008, Annex D and the message format defined in the following table.

Table 457 Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0

PTP Packets over IPv6

The Ethernet payload contains certain fields that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for PTO packets over IPv4 and ethernet, and framers over IPv6 packets. This topic discusses fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2.

Table 458 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4.

Table 458 IPv6-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [7:4])	0x6	IP version is IPv6
Layer 4 Protocol	20[1] (*)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	• PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) • PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57a	0x013F, 0x140	• 0x013F: PTP event message • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94a	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management (version1)
PTP Message Type Field (IEEE 1588 version 2)	62a (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1) The Extension Header is not defined for PTP packets.

This is based on the IEEE 1588-2008, Annex D and the message format defined in the following table.

Table 459 Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset

PTP Packets over Ethernet

The Ethernet payload contains certain fields that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for PTO packets over IPv4 and ethernet, and framers over IPv6 packets. This topic discusses fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2.

Table 460 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 460 Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1)]	0–5	01-1B-19-00-00-0001-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2)]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3)]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field(IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

Table 460 Ethernet PTP Packet Fields Required for Control And Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1) The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2) IEEE 1588-2008, Annex F
3) The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the GMII or MII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis.

Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can do this by using the following method based on your configuration:

- EQOS-AHB, EQOS-AXI, and EQOS-DMA Configurations
  You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet.
  The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the GMII or MII interface or to process packets to identify the valid PTP messages.

Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)

- Enable the node to be a master or slave and select the snapshot typeThis feature controls the type of messages for which snapshots are taken.

Note: The DWC_ether_qos also supports the PTP messages over VLAN packets.

Table 461 Ethernet PTP Packet Fields Required for Control And Status

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp,Pdelay_Req, Pdelay_Resp,Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The following list describes how the timestamp is provided, depending on the configuration:

- EQOS-AHB, EQOS-AXI, and EQOS-DMA Configurations
  The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

44.3.8.2 Using IEEE 1588 System Time Source

44.3.8.2.1 Introduction to IEEE 1588 Time Source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008).

The internal reference time provides the following options for using the reference timing source in a node:

- External Timestamp Input
  This option takes an external 64-bit timing reference and its clock as input. The clock input is used to synchronize the timing reference to the MAC clock domain.
- Internal Reference Time (80-bit)
  This option takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

44.3.8.2.2 Description of IEEE 1588 Time Source

External Timestamp Input

External timestamp input option takes an external 64-bit timing reference and its clock as input. The clock input is used to synchronize the timing reference to the MAC clock domain.

The 64-bit timing reference is split into the following two 32-bit signals:

- Upper 32-bits providing the time in seconds
- Lower 32-bits providing the time in nanoseconds

This timing reference is used to timestamp the packets.

Internal Reference Time

Internal reference time option takes the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.

The timestamp has the following fields:

- UInteger48 seconds Field
  The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.
- UInteger32 nanosecondsField
  The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001.
  The nanoseconds field supports the following two modes:
  - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
  - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

System Time Register Module

The system time generator module is an optional module. It is not available if external time updating is enabled.

The 64-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the GMII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in **Figure 701**. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This algorithm is shown in **Figure 701**.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.

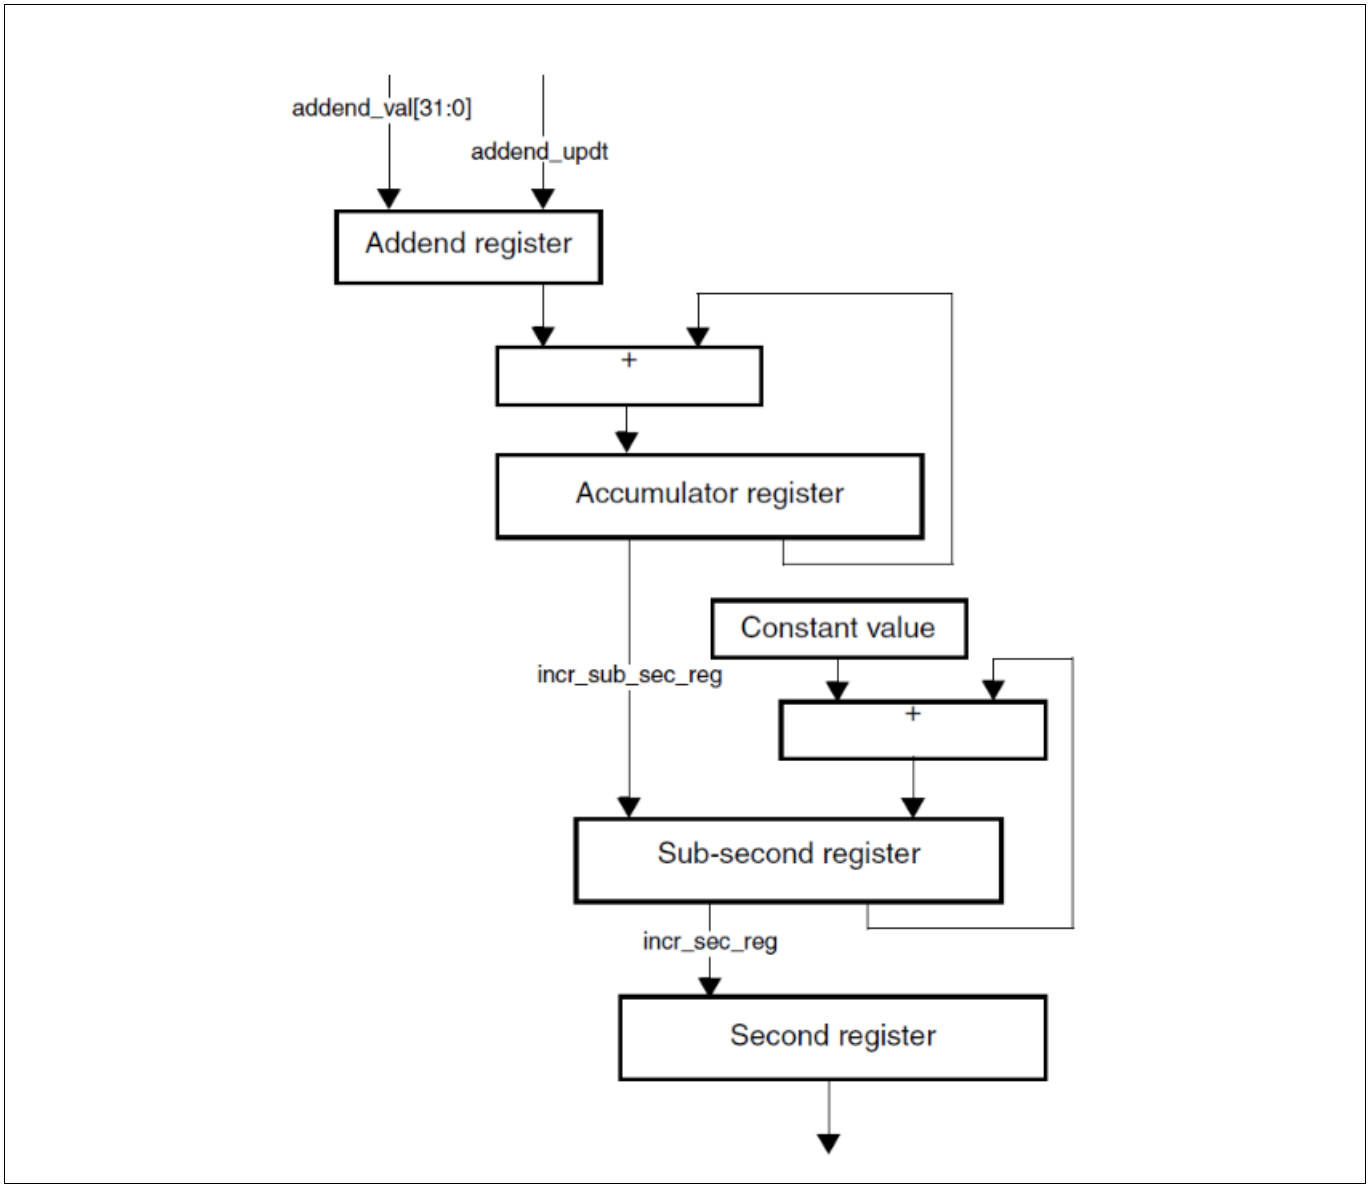

Figure 701 System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Therefore, the default addend value to be set in the register is 2^32 / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^32 / 1.30, or 0xC4EC4EC4. If the clock drifts higher, for example, to 67 MHz, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (2^32 / 1.32) must be programmed.

In **Figure 701**, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). When External Time Update is enabled, the optional System Time module is not available. Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

FreqCompensationValue0 = 2^32 / FreqDivisionRatio

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time MasterSyncTimen the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTimen and computes MasterClockTimen as
  - $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, MasterClockCountn is
  - $MasterClockCount_n = MasterClockTime_n – MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  - $SlaveClockCount_n = SlaveClockTime_n – SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  - $ClockDiffCount_n = MasterClockTime_n – SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  - $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  - $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

44.3.8.3 Using IEEE 1588 Higher Word Register

44.3.8.3.1 Introduction to IEEE 1588 Higher Word Register

The timestamp maintained in the MAC is 64-bit wide. The overflow to upper 16-bits of seconds register happens once in 130 years. The values of the upper 16-bits of the seconds field can be read from the CSR register.

This optional feature is provided to invoke an additional Higher Word Register.

44.3.8.4 Using Flexible Pulse-Per-Second Output

44.3.8.4.1 Introduction to Flexible Pulse-Per-Second Output

The GETH provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output.

Notes

1. *By default, is in the “Fixed Pulse-Per-Second Output” mode and indicates 1 second interval.*
2. *The frequency of the PPS output can be changed by setting the PPSCTRL0 field in the MAC_PPS_Control register.*

44.3.8.4.2 Description of Flexible Pulse-Per-Second Output

GETH provides features such as programming the start or stop time, with the flexible PPS output option.

GETH supports the following features with the flexible PPS output option:

- Programming the start or stop time in terms of system time.
- Programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time.
- Programming the stop time in advance, that is, you can program the stop time before the actual start time has elapsed.
- Programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programmed in the MAC_Sub_Second_Increment register. You can program the width of pulse from 1 to 2^32-1 units of sub-second increment value.
- Programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^32-1 units of sub-second increment value.
- Option to cancel the programmed PPS start or stop request.
- Error if the start or stop time being programmed has already elapsed.

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the TSCFUPDT bit of MAC_Timestamp_Control register is set to 0, this clock is similar to

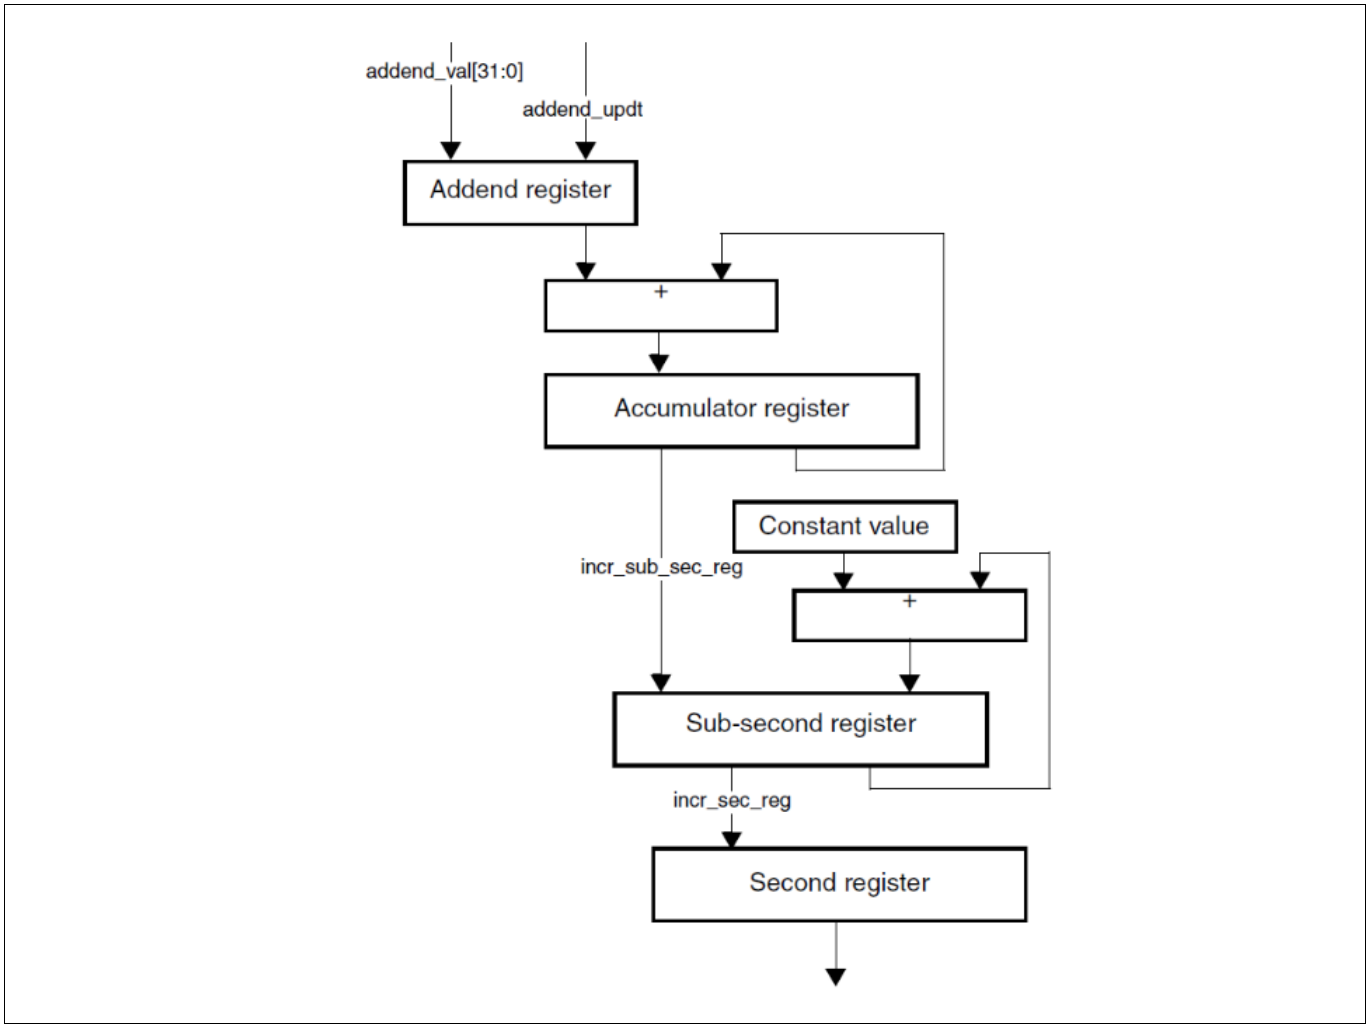

Figure 702 System Time Update Using Fine Method

PPS Start or Stop Time

The start time in the Target Time registers can be programmed initially.

You can initially program the start time in the Target Time registers. If you have enabled additional flexible PPS outputs, you need to program the following registers corresponding to an enabled flexible PPS output:

- MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers for second Flexible PPS output
- MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers for third Flexible PPS output
- MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers for fourth Flexible PPS output

If required, you can again program the start or stop time but you can do it only after the earlier programmed value is synchronized to the PTP clock domain. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can

cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value.

For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

44.3.8.5 Using One-Step Timestamp Feature

44.3.8.5.1 MAC Transmit PTP Mode

MAC updates different fields of the Transmit PTP packets.

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

Table 462 shows how the PTP mode is selected based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the MAC_Timestamp_Control register and the fields that are updated for the incoming PTP packets based on the message type in that mode, during the one-step timestamping operation.

Table 462 MAC_Transmit_PTP_Mode_and_One-Step_Timestamping_Operation

Programming			Mode	Per Packet Control 1)			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE 2)	OSTC 3)	TTS 4)	
X	X	X	N/A	1	X	X	Timestamp is captured and returned to application
X	X	X	N/A	X	0	X	OST operation is not performed (PTP packet is not modified)
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)

Table 462 MAC_Transmit_PTP_Mode_and_One-Step_Timestamping_Operation (cont'd)

Programming			Mode	Per Packet Control 1)			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE 2)	OSTC 3)	TTS 4)	
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field)Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field)Sync (correction field for sub-nanosecond cor)
2'b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)
2'b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanismorPeer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)(applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field)Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field)Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

Table 462 MAC_Transmit_PTP_Mode_and_One-Step_Timestamping_Operation (cont'd)

Programming			Mode	Per Packet Control 1)			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE 2)	OSTC 3)	TTS 4)	
2'b01	1	1	Ordinary or Boundary Master with support for peer delay mechanism	0	1	X	Sync (originTimestamp field)Sync (correction field for sub-nanosecond cor)
				1	1	X	Pdelay_Req (originTimestamp field)Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field)Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)

1) The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.

2) TTSE represents TTSE bit of transmit descriptor in EQOS-AXI configuration, TTSE bit in TX control word in EQOS-MTL configuration, mti_ena_timestamp_i signal in EQOS-CORE configuration. The TTSE function is independent of the OST function and the programmed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.

3) OSTC represents OSTC bit of transmit descriptor in EQOS-AXI configuration, OSTC bit in TX control word in EQOS-MTL configuration, mti_ost_en_i signal in EQOS-CORE configuration.

4) TTS represents the timestamp value provided in the TTSH, TTSL fields of transmit descriptor in EQOS-AXI configuration, timestamp provided in the TTSH, TTSL fields in the TX control word in EQOS-MTL configuration, mti_ost_i signal in EQOS-CORE configuration.

Note: Residence time/ turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp.When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy.Clocks supporting peer delay mechanism do not use delay request or response, but it is included in OST for flexibility.

44.3.8.6 One-Step Time Stamping for PTP Over UDP

44.3.8.6.1 Introduction to One-Step Timestamping for PTP Over UDP Feature

One step timestamping for PTP over UDP feature is available in configuration where IEEE 1588 Timestamp Support option is selected. DWC_ether_qos supports one-step timestamp operation for PTP messages sent over UDP/IPv4 and UPD/IPv6. DWC_ether_qos supports the one step timestamp operation for PTP messages sent over UDP/IPv4 and UDP/IPv6. Because origin timestamp and/or correction field (based on the PTP message type and the programmed PTP mode) in the PTP message are updated as part of the one step timestamp operation, it also requires update to the checksum field of the PTP message sent over UDP/IP.

44.3.8.6.2 Checksum Update for One-Step Timestamping for PTP

DWC_ether_qos, updates checksum for a packet, in the MTL before the packet is sent to the MACwhere the PTP message is updated for one step timestamp operation.

In DWC_ether_qos, checksum is updated for a packet, in the MTL before the packet is sent to the MAC where the PTP message is updated for one step timestamp operation. PTP requires the timestamp to be captured while the packet (SFD of the packet) is on the line and one step timestamp requires the origin timestamp and/or correction field to be updated in the PTP header while the packet is being transmitted on the line. Because the PTP message is present in the UDP payload, it is not possible to update the checksum field in the UDP header for modifications made to the PTP message, because it is already transmitted by then. Instead, the following options are supported that are in line with specification mentioned in Annex D & E of IEEE 1588-2008:

- When PTP message is sent over UDP/IPv4, the UDP checksum may be set to 0. The application must set the UDP checksum to 0 and set CIC to 0 or 1 while providing the packet to the MAC and the MAC does not update checksum for changes in origin timestamp or correction field.
- When PTP message is sent over UDP/IPv6, a transmitting node extends the UDP payload of all PTP messages by 2 octets beyond the end of the PTP message. The contents of the UDP checksum field or the final 2 octets of the UDP payload might be modified to ensure that the UDP checksum remains intact after modification of PTP fields. The application must add the two extra bytes at the end of the PTP message while providing the packet to the MAC and the MAC updates these two bytes to keep the checksum correct.

A programmable option (CSC field in MAC_Timestamp_Control register) supports UDP with non-zero checksum for IPv4. When set, the two bytes at the end of the PTP message are updated to keep the UDP checksum correct, similar to PTP over UDP/IPv6. So, the application must add two bytes at the end of the PTP message sent to the DWC_ether_qos and DWC_ether_qos updates these two bytes to keep the checksum correct.

Updating the pad bytes to keep the checksum correct requires the old value of correction field and/or origin timestamp in the packet. To get better latency and area, the application can set the origin timestamp field to zero, for PTP message in particular modes in which DWC_ether_qos overwrites the origin timestamp. For example, DWC_ether_qos operating in Ordinary/Boundary master mode overwrites the origin timestamp field of the sync message, when OSTC is set. Because the sync message is originated by the port operating in Ordinary/Boundary master mode, it is possible for the application generating the message to set the origin timestamp field to zero.

Notes

1. *For PTP over UPD/IPv6 and PTP over UDP/IPv4 with CSC set, the DWC_ether_qos does not verify the presence of the two pad bytes, instead it overwrites the two bytes after the PTP. message*
2. *When Enable One step timestamp for PTP over UDP/IP feature is selected, Enable Transmit TCP/IP Checksum offload feature is automatically enabled and this is enabled only for Queue 0 in multiple transmit queue configurations. If the application requires OST support for PTP messages sent over UDP/IP for packets sent from queues other than 0, transmit checksum engine must be manually enabled for those transmit queues. If checksum engine is not enabled, no updates will be done for PTP messages sent overUDP/IP even though OSTC is set.*
3. *One-Step timestamp operation is not supported for tunneled packets*

44.3.8.7 Using IEEE 1588 Sub Nanoseconds Timestamp Support

The ingress and egress correction can have sub-nanoseconds accuracy.

44.3.8.7.1 Description of IEEE 1588 Sub Nanoseconds Timestamp Support

The sub-nanosecond part of the ingress and egress correction is programmed in the TSICSNS and TSECSNSfields of the MAC Timestamp Ingress Correction Subnanosecond and MAC Timestamp Egress CorrectionSubnanosecond registers, respectively.

In this case, the correction has an unit of nanosecond, multiplied by 2^8. The least significant 8 bits of thevalue should be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and TSCTRLSSR bit is set, then TSEC must be 0x3and TSECSNS must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS andTSCTRLSSR bit is set, then TSIC must be 0xBB9A_C9FC and TSICSNS must be 0x66 (fractional part of (10^9- 3.6) * 256).

44.3.9 Multiple Channels and Queues Support

44.3.9.1 Block Diagram of DWC_ether_qos Multiple Channels and Queues

The DWC_ether_qos supports up to eight queues and channels on Tx and Rx paths.

Figure 703 shows the architecture of DWC_ether_qos with multiple queues and channels.

Note: In multi queue/channel configurations, enable only Q0/CH0 on Tx and Rx for half-duplex operation. If you want to enable single queue/channel in full-duplex operation, any queue/channel can be enabled.

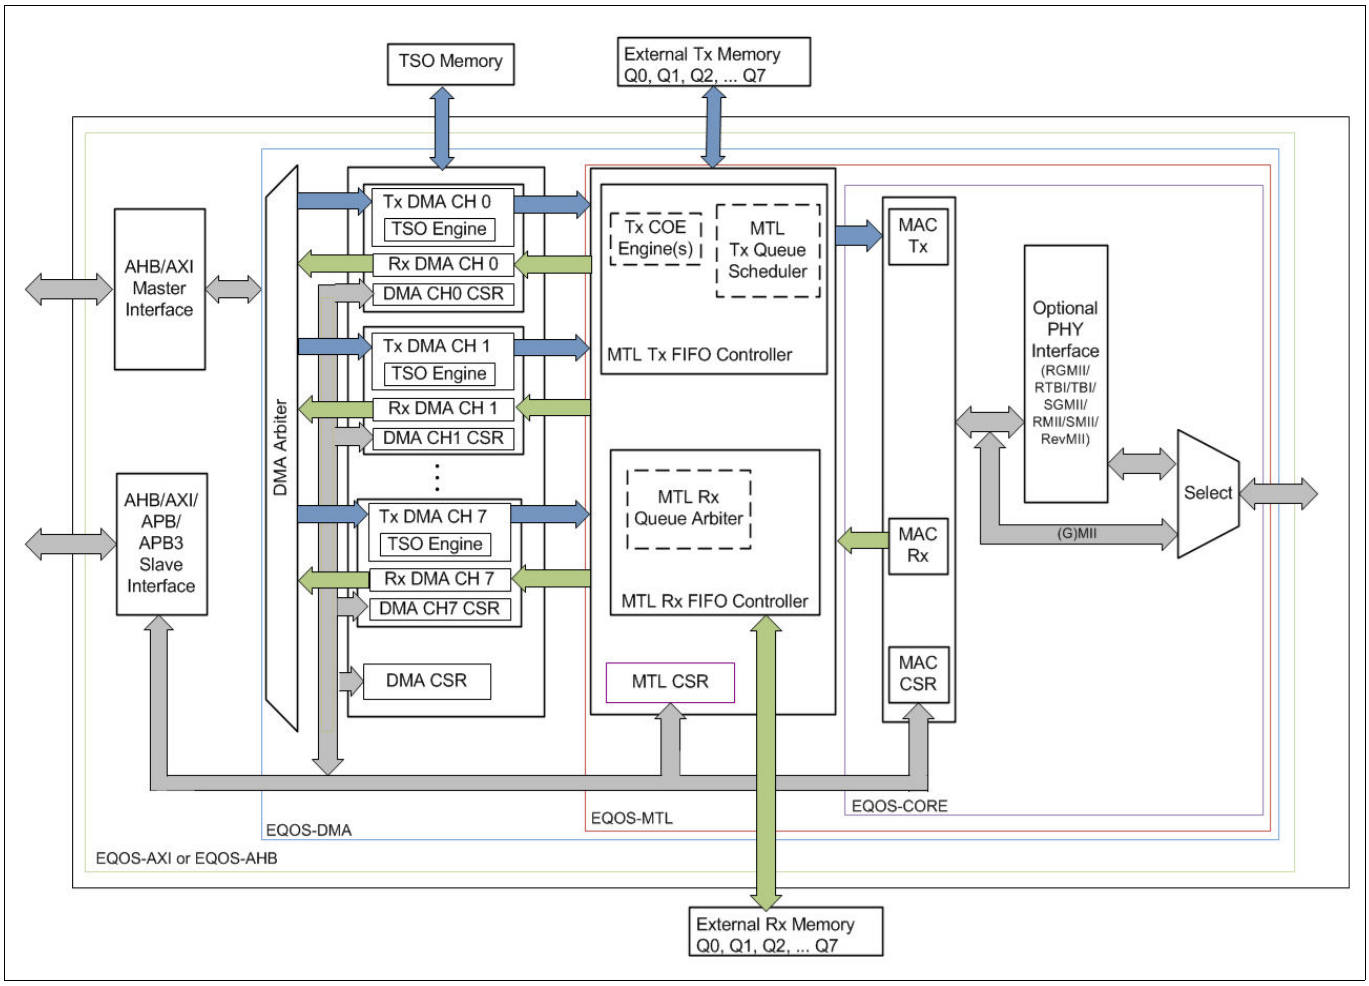

Figure 703 DWC_ether_qos with Multiple Channels and Queues Block Diagram

44.3.9.2 Multiple Queues and Channels Support in Transmit Path

The DWC_ether_qos supports up to eight Transmit queues.

The number of Tx channels is equal to the number of Tx queues. Depending on how the DWC_ether_qos is configured, the controller supports the following methods for handling transfers in the transmit path.

The following topics are discussed:

- Description of Fixed Priority Scheme in EQOS-AHB and EQOS-DMA
- Description of Weighted Strict Priority in EQOS-AHB and EQOS-DMA
- Description of Weighted Round Robin in EQOS-AHB and EQOS-DMA

44.3.9.2.1 Description of Fixed Priority Scheme in EQOS-AHB and EQOS-DMA

For AHB and DMA configurations, the fixed priority scheme is the default scheme.

The fixed priority scheme is the default priority scheme for the DMA channels. In fixed priority scheme, the channel with highest priority always wins the arbitration when it requests the bus. **Table 463** provides information about the priority levels of DMA channels.

Table 463 Fixed Priority Scheme for DMA Channels

Priority Level	Channel
0 (low)	Channel 0
1	Channel 1
2	Channel 2
3	Channel 3
4	Channel 4
5	Channel 5
6	Channel 6
7 (high)	Channel 7

44.3.9.2.2 Description of Weighted Strict Priority in EQOS-AHB and EQOS-DMA

You can use a Weighted Strict Priority (WSP) scheme for EQOS-AHB and EQOS-DMA configurations, where the weight corresponds to the number of burst transactions given to a channel in one arbitration cycle.

In Weighted Strict Priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with highest priority gets the unused burst transfer time before it is allocated to a channel with next highest priority.

The channel priorities are fixed. Channel 7 has the highest priority and Channel 0 has the lowest priority. When a channel uses the allocated burst transfers, the channel with next lower priority is processed. After processing the allocated bandwidth of all channels that had packets to transmit, any unused burst transfer time is allocated to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

44.3.9.2.3 Description of Weighted Round Robing in EQOS-AHB and EQOS-DMA

EQOS-AHB and EQOS-DMA configurations support a Weighted Round Robin (WRR) priority scheme, in which the weight can be programmed through the DMA_CH#_Tx_Control register.

In Weighted Round Robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the DMA_CH#_Tx_Control register provides the weight for each Transmit channel as shown in **Table 464**.

Table 464 Weight for DMA Channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5

Table 464 Weight for DMA Channels (cont'd)

TCW Field	Transmit Channel Weight
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

44.3.9.3 Multiple Queues in Receive Path

The DWC_ether_qos supports up to eight Receive channels; the number of Rx channels is independent of the Rx queues.

The DWC_ether_qos supports up to eight Receive channels in EQOS-AHB, EQOS-AXI, and EQOS-DMA configurations. The number of Rx channels is independent of the Rx queues.

In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

44.3.9.3.1 Priority Scheme for Tx DMA and Rx DMA

The DWC_ether_qos DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin.

The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If you have enabled the Tx DMA and Rx DMA of a channel, you can specify which DMA gets the bus when the channel gets the control of the bus. You can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the DMA_Mode register. For round-robin arbitration, you can use the PR field of the DMA_Mode register to specify the weighted priority between the Tx DMA and Rx DMA. The following table provides information about the priority scheme between Tx DMA and Rx DMA.

Table 465 Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests.
0	0	1	0	0	Rx has priority over Tx in ratio 2:1.
0	1	0	0	0	Rx has priority over Tx in ratio 3:1.
0	1	1	0	0	Rx has priority over Tx in ratio 4:1.
1	0	0	0	0	Rx has priority over Tx in ratio 5:1.
1	0	1	0	0	Rx has priority over Tx in ratio 6:1.
1	1	0	0	0	Rx has priority over Tx in ratio 7:1.

Table 465 Priority Scheme for Tx DMA and Rx DMA (cont'd)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Scheme
1	1	1	0	0	Rx has priority over Tx in ratio 8:1.
x	x	x	1	1	Tx always has priority over Rx.
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests.
0	0	1	1	0	Tx has priority over Rx in ratio 2:1.
0	1	0	1	0	Tx has priority over Rx in ratio 3:1.
0	1	1	1	0	Tx has priority over Rx in ratio 4:1.
1	0	0	1	0	Tx has priority over Rx in ratio 5:1.
1	0	1	1	0	Tx has priority over Rx in ratio 6:1.
1	1	0	1	0	Tx has priority over Rx in ratio 7:1.
1	1	1	1	0	Tx has priority over Rx in ratio 8:1.

Note: Bits 14, 13, 12, 11, and 10 are not valid if one of the paths (Transmit or Receive) is not present in a channel. The Transmit and Receive paths are always present in Channel 0.

44.3.9.4 Multiple Queues and Channels Support in EQOS-MTL

For EQOS-MTL configurations, queues are controlled through the MTL_TxQ#_Operation_Mode and MTL_rxQ#_Operation_Mode registers.

The DWC_ether_qos supports up to eight Tx and Rx queues. This section describes how multiple queues and channels are supported in MTL.

You can control a Tx queue through the MTL_TxQ#_Operation_Mode register. You can control an Rx queue through the MTL_RxQ#_Operation_Mode register.

44.3.9.4.1 Queue Memory

The DWC_ether_qos MTL Tx queues share one Tx memory while Rx queues share one Rx memory; individual queue sizes can be programmed in blocks of 256 bytes.

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of MTL_TxQ#_Operation_Mode register and the Rx queue size in the RQS field of the MTL_RxQ#_Operation_Mode register.

The DWC_ether_qos supports the total Tx memory size of 128 KB (16 KB * 8) and total Rx memory size of 256 KB (32 KB * 8). The total memory size can be selected in powers of 2, that is, 1 KB, 2 KB, 4 KB, 8 KB, 16 KB, 32 KB, 64 KB, 128 KB, and 256 KB. In configurations with a single queue, the maximum Tx memory size is 32 KB and the maximum Rx memory size is 64 KB. In configurations with a single queue, the FIFOs size of 128 bytes, 256 bytes, and 512 bytes is also supported.

44.3.9.5 Rx Queue to DMA Mapping

The DWC_ether_qos controller supports two types of Rx queue to DMA mapping: Static Mapping and Dynamic (Per Packet) Mapping.

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the following registers:

- MTL_RxQ_DMA_Map0 Register (for queues 0, 1, 2 and 3)
- MTL_RxQ_DMA_Map1 Register (for queues 4, 5, 6 and 7)

The following types of Rx Queue to DMA mapping is possible through programming:

- Static Mapping
- Dynamic (Per Packet) Mapping

44.3.9.5.1 Static Mapping

In Static Mapping mode, all packets of an Rx Queue are connected to a specific DMA channel.

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

44.3.9.5.2 Dynamic (Per Packet) Mapping

In Dynamic (per packet) Mapping mode, the destination DMA channel is decide by the MAC core receiver for each packet.

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, depending on the following in decreasing order of priority:

1. Extended VLAN Based DMA Selection
   Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set.The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to 0. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled.If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
2. Ethernet DA-Based DMA Selection
   The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

44.3.9.6 Selection of Tag Priorities Assigned to Tx and Rx Queues

The DWC_ether_qos controller supports assigning tag priorities to Tx and Rx Queues through programming registers.

The VLAN Tag priorities can be assigned to Tx Queues by programming the corresponding PSTQ# field in the following registers:

- MAC_TxQ_Prty_Map0 (for Tx Queues 0 to 3)
- MAC_TxQ_Prty_Map1 (for Tx Queues 4 to 7)

The bit corresponding to the VLAN Tag priority can be set in the PSTQ# field for assigning that priority to the Tx Queue. For example, if you want to assign VLAN Tag priority of 3 to Tx Queue 0, set bit [3] in PSTQ0 field.

The same VLAN Tag priority can be set for multiple Tx queues. The Tx packet association to particular Tx Queue is governed by the application, so the MAC does not route the packet based on Tx Queue priority mapping; it is only used for Pause Flow Control (PFC). The settings in the PSTQ# field determines the Tx Queues blocked for transmission when the PFC packet is received with corresponding VLAN Tag priorities enabled.

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 register. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

44.3.9.7 Rx Side Routing from MAC to Queues

The MAC routes the Rx packets to the Rx Queues based on following packet types in that order:

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register and the corresponding Rx Queue is enabled for DCB/generic through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 register or the Rx Queue number specified in the PTPQ field inMAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

44.3.9.8 Rx Side Arbitration Between DMA and MTL

The DWC_ether_qos controller supports Rx side arbitration between the DMA and the MTL.

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

44.3.9.9 Tx Side Arbitration between DMA and MTL

The DWC_ether_qos support Tx side arbitration between the DMA and the MTL.

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX Checksum Engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

44.3.9.10 Audio Video Bridging

44.3.9.10.1 Introduction to AV Feature

The DWC_ether_qos supports the AV data transfer in 100 Mbps and 1000 Mbps modes. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
- IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

Note: In EQOS-CORE configurations, the AV feature is limited to identifying the AV Type payloads in the Ethernet packet and indicating it on the MAC Receive Interface (MRI) through mri_q_sel_o signal along with the SOP. For more information, see "Receive Path Functions".

44.3.9.10.2 Transmit Path Functions

When the DWC_ether_qos controller supports the AV Bridging feature, you can enable and disable certain functions associated with the transmit path.

When you select the AV feature, the Transmit paths of Queue 0 and the highest enabled queue are enabled by default.

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.

You can disable the credit-based shaper algorithm for all queues or lower-priority queues. For example, you can either disable the credit-based shaper algorithm for Queue 1 and Queue 2 or only for Queue 1. You should not disable the credit-based shaper algorithm for Queue 2 and enable it for Queue 1. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict priority algorithm.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit.
- If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in the following table.

Table 466 Weight for DMA Channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

44.3.9.10.3 Receive Path Functions

When the DWC_ether_qos controller supports the AV Bridging feature, you can enable and disable certain functions associated with the receive path.

When you select the AV feature, the Receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the Receive paths of additional queues. By enabling the Receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor as explained in "Receive Descriptor". All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program Bits[15:8] in the Transmit Flow Control Register of the corresponding queue.
- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these packets on any other queue, you can program Bits[2:0] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[6:4] of the MAC_RxQ_Ctrl1 register.

44.3.9.10.4 Credit-Based Sharper Algorithm

When the DWC_ether_qos supports the AV feature, the MTL Queue Scheduler uses the credit-based sharper algorithm. You can program additional queues to use this algorithm.

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

- Credit Value
- idleSlopeCredit and sendSlopeCredit Values
- Bandwidth Status

Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL Queue Scheduler.

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in **Table 467**.

Table 467 Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	• portTransmitRate = 100 Mbps • idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) • sendSlope = 30 Mbps	• credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. • credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The DWC_ether_qos supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 1 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The idleSlopeCredit and sendSlopeCredit values are programmable.

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[6:4] of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

44.3.9.10.5 Slot Number Function with Audio Video Bridging

Introduction to Slot Number Function

When the DWC_ether_qos controller supports the AV feature, you can program the slot number where the DMA fetches data from system memory in the Transmit Descriptor 3 (TDES3).

When the AV feature is enabled, you can use the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals.

You can program the slot number at which the DMA should fetch the data from system memory in the Transmit Descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels.

Description of Slot Number Function

You can enable the DMA to fetch data only if it matches the current slot or next two slots.

When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot number. The reference slot number is updated every time the interval programmed in SIV field of DMA_CH[n]_Slot_Function_Control_Status register in terms of microseconds of the IEEE 1588 system time elapses. In addition, the slot interval counter is initialized to zero when the seconds field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state until there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program Bit 1 of the Slot Function Control and Status register of the corresponding DMA channel.

Note: If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

You can enable the check for slot number by setting Bit 0 of the Slot Function Control and Status register of corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, Bits [19:16] indicate the value of the reference slot number in DMA.

44.3.9.11 Queue Modes

You can specify queue modes depending on the type of feature supported.

You can enable a Tx queue for generic/DCB, AV, or all types of traffic. When you select multiple Tx queues without selecting the DCB feature, the queues are enabled for generic queuing using WRR or WSP algorithms.

To enable a Tx queue for AV, you need to select the Enable Audio Video Bridging option and then the Enable Support for AV in Tx Queue # option. The queuing is based on the CBS or SP algorithms.

You can enable an Rx queue for generic, DCB, AV, or all types of traffic. A particular queue enabled for generic/DCB or AV based routing is determined by the RXQ#EN field of corresponding queue. The following list explains how Rx queues are enabled based on the selected features:

- Multiple Rx queues without the DCB feature
  When you select multiple Rx queues without selecting DCB feature, all queues are enabled for generic queuing based on the VLAN Tag priority. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. By default untagged packets are routed to Receive queue specified in UPQ field of MAC_RxQ_Ctrl1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.
- Multiple Rx queues with AV feature
  When you select the Enable Audio Video Bridging option, AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority for DCB data packets. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 register. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register.

44.3.9.12 Programming Guidelines for Disabling Flow Control in AV Queues

The DWC_ether_qos supports programming of same priorities for AV and DCB enabled Rx queues, when both coexist. For example, priority 1 can be programmed in PSRQ[n] field corresponding to Rx Queue enabled for AV in MAC_RxQ_Ctrl2 register and same priority 1 can be programmed in PSRQ[n] field corresponding to Rx Queue enabled for DCB in MAC_RxQ_Ctrl2 register, at the same time. When AV and DCB operation coexists, it requires that the Flow Control is disabled for AV enabled queues. See, “Disabling Flow Control for AV Enabled Queues”.

44.3.9.13 Queue Priorities

The Tx queue priorities can be programmed through the MAC_TxQ_Prty_Map0 and MAC_TxQ_Prty_Map1 registers. The Rx queue priorities are programmed through the Rx Flow Control register.

You can program the priority of a Tx queue in the MAC_TxQ_Prty_Map0 and MAC_TxQ_Prty_Map1 registers. You can program the priority of an Rx queue corresponding field of MAC_RxQ_Ctrl2 register. The priority should be assigned in the following order:

1. AV queue (high priority)
2. Best-effort queue (low priority)

The software should put packets with correct priorities in the respective programmed queue on Tx side. The MAC uses the programmed priorities for blocking the Tx queues when a PFC packet is received. If a single queue is selected for multiple priorities and PFC is enabled, the entire queue is paused if one or more priorities in the queue are paused.

44.3.10 Using TCP/IP Offloading Features

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has an optional Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, and error detection in the Receive path.

By using the Checksum Offload features, the software can offload the task of checksum insertion and checking to the hardware. This feature helps in improving the throughput.

In the transmit path MAC calculates the checksum and inserts it in the Tx packet. In the receive path, MAC verifies the received checksum with the internally calculated checksum and provides the status.

It is possible to split the received packet such that the header and the payload are stored in different buffers in system memory.

44.3.10.1 Using Transmit Checksum Offload Engine

44.3.10.1.1 Introduction to the Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in improving the throughput.

44.3.10.2 Description of the Transmit Checksum Offload Engine

The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if the DWC_ether_qos is configured for Threshold (cut-through) mode.

You must make sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. When reading starts, the COE fails and consequently all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the number of bytes, given by the following equation:

```
Packet size < TxQSize - ((PBL + 7) * 4)
```

Where:

- TxQSize is indicated by TQS field of MTL_TxQ#_Operation_Mode register
- PBL = TxPBL field in the DMA_CH#_TX_Control register in all DMA configurations

See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

44.3.10.2.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 of TDES3 Normal Descriptor (Write-Back Format). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
- For IPv46datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

44.3.10.2.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector. This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and

no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 468 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Table 468 Transmit Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum insertiion	Hardware TCP/UDP/ICMP checksum insertion
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	 • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	 • Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	 • Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	 • No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	 • Not Applicable • Not Applicable	 • No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes

Table 468 Transmit Checksum Offload Engine Functions for Different Packet Types (cont'd)

Packet type	Hardware IP header checksum insertiion	Hardware TCP/UDP/ICMP checksum insertion
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

44.3.10.3 Using Receive Checksum Offload Engine

44.3.10.3.1 Introduction to the Receive Checksum Offload Engine

DWC_ether_qos provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path.

The MAC has a Checksum Offload Engine (COE) to support packet error detection in the Receive path. In the receive path, MAC verifies the received checksum with the internally calculated checksum and provides the status.

44.3.10.3.2 Description of the Receive Checksum Offload Engine

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 469 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status, as described in Table 3-13 on page 174.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 469 Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes

Table 469 Receive Checksum Offload Engine Functions for Different Packet Types (cont'd)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

44.3.11 Splitting Header on Receive

Optionally, the incoming receive packet header can be split such that the header and the payload are stored in different buffers in the system memory. Header splitting is also useful for non-IP packets such as AVB traffic which are generally multicast type. This enables the application to store the packet header of AVB streams and payload for AVTP (Audio Video Transport Protocol) packets and the DMA can process the header and payload of the received packets separately. The table below shows how DMA processes a packet depending upon its type and the value of the SPLM bit.

Table 470 Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	SPLM	Description
TCP or UDP Packet	00 (L3/L4 Split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (notTCP/UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload
IP packet and non IP packet	01 (L2 Split)	The DMA writes the Ethernet header based on split offset (SPLOFST) into the header buffer.
IP packet	10 (Combination of L2 or L3/L4Split)	L3/L4 split
Non-IP packet		L2 split
NA	11	Reserved

Note: L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped.

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames.

44.3.12 Implementing Low-Power Modes

44.3.12.1 Implementing Energy Efficient Ethernet

44.3.12.1.1 Introduction to Energy Efficient Ethernet (EEE)

EEE is an operational mode that allows a controller to operate in low-power mode.

This topic provides an overview of power management through EEE.

EEE is an operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps. The DWC_ether_qos supports the IEEE 802.3az-2010 for EEE.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionalities to save power during the periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

44.3.12.1.2 Description of EEE

Transmit Path Functions

The transmit path functions include tasks that the MAC must perform to make the PHY to enter the LPI state.To enter this state, the software must set the MAC_LPI_Control_Status.LPIEN bit to initiate the LPI protocol.

In the transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER field of MAC_LPI_Control_Status register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

Note: According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the TxCLK clock during the LPI state in the MII (10 or 100) mode. However, the MAC can stop the GTX_CLK clock during the LPI state in the GMII (1000) code.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts TX_EN
2. Asserts TX_ER
3. Sets TXD[3:0] to 0x1 (for 100 Mbps) or TXD[7:0] to 0x01 (for 1,000 Mbps)

   Note: The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.

4. Updates the status (TLPIEN bit of MAC_LPI_Control_Status register) and generates an interrupt

To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMERThe MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC_LPI_Timers_Control register.
3. Updates the LPI exit status (TLPIEX bit of the MAC_LPI_Control_Status register) and generates an interrupt

Figure 704 shows the behavior of TX_EN, TX_ER, and TXD[3:0] signals during the LPI mode transitions.

Notes

1. *The MAC does not stop the TX_CLK clock. You can stop this clock (as shown in **Figure 704**) if your PHY supports it and when the MAC sets the sbd_tx_clk_gating_ctrl_o signal to 1. The sbd_tx_clk_gating_ctrl_o signal is asserted after nine Tx Clock Cycles, one Pulse Synchronizer delay (BCM22), and one CSR clock cycle. The assertion of the sbd_tx_clk_gating_ctrl_o signal is dependent on the LPITCSE bit of the MAC_LPI_Control_Status register.*
2. *If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern and so the Tx Clock cannot be gated.*
3. *In the EQOS-CORE configuration, when the Tx clock gating is done during the LPI mode, you cannot use the LPITXA bit of the MAC_LPI_Control_Status register.*
4. *If the MAC is in the Tx LPI mode and the Tx clock is stopped, the application should not write to CSR registers that are synchronized to Tx clock domain.*
5. *If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC transmitter comes out of the LPI mode.*

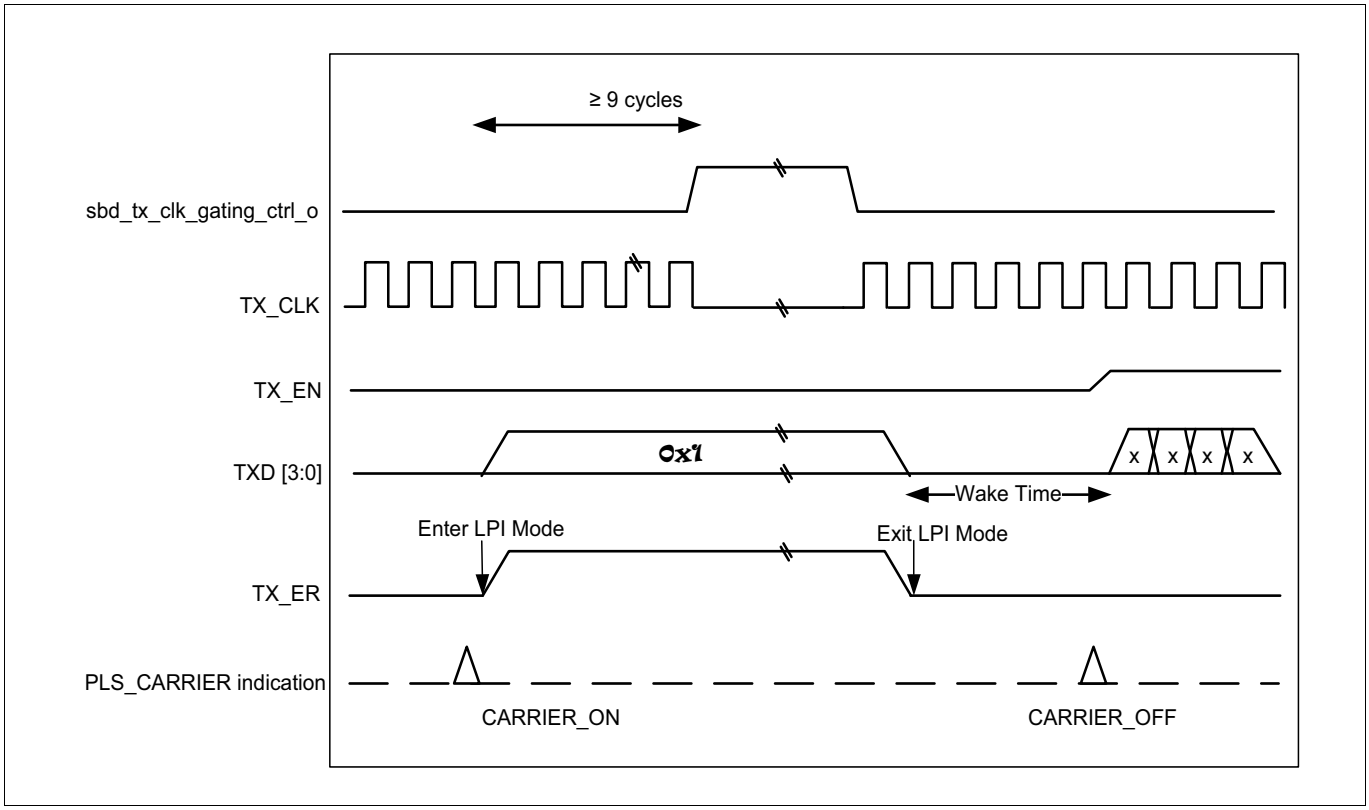

Figure 704 LPI Transitions (Transmit)

Automated Entry/Exit of LPI mode in TX Path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by MAC_LPI_Control_Status register.

When LPITXA (Bit[19]) and LPITXEN (Bit[16]) of MAC_LPI_Control_Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[20] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in MAC_LPI_Entry_Timer. In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

Receive Path Functions

The receive path functions include the tasks that the PHY and MAC must perform when the PHY receives signals from the link partner to exit the LPI state.

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER
2. The PHY sets RXD[7:0] to 0x01
3. The PHY de-asserts RX_DV

   Note: The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and immediately generates an interrupt

Notes

1. *If the LPI pattern is detected for a very short duration (that is, less than two cycles of Rx clock), the MAC does not enter the Rx LPI mode.*
2. *If the duration between end of the current Rx LPI pattern and start of the next Rx LPI pattern, is very short (that is, less than two cycles of Rx clock), then the MAC exits and again enters the Rx LPI mode. The MAC does not give the Rx LPI Exit and Entry interrupts.*

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates an interrupt immediately. The sideband signal lpi_intr_o (synchronous to Rx clock) is also asserted.

Figure 705 shows the behavior of RX_ER, RX_DV, and RXD[3:0] signals during the LPI mode transitions.

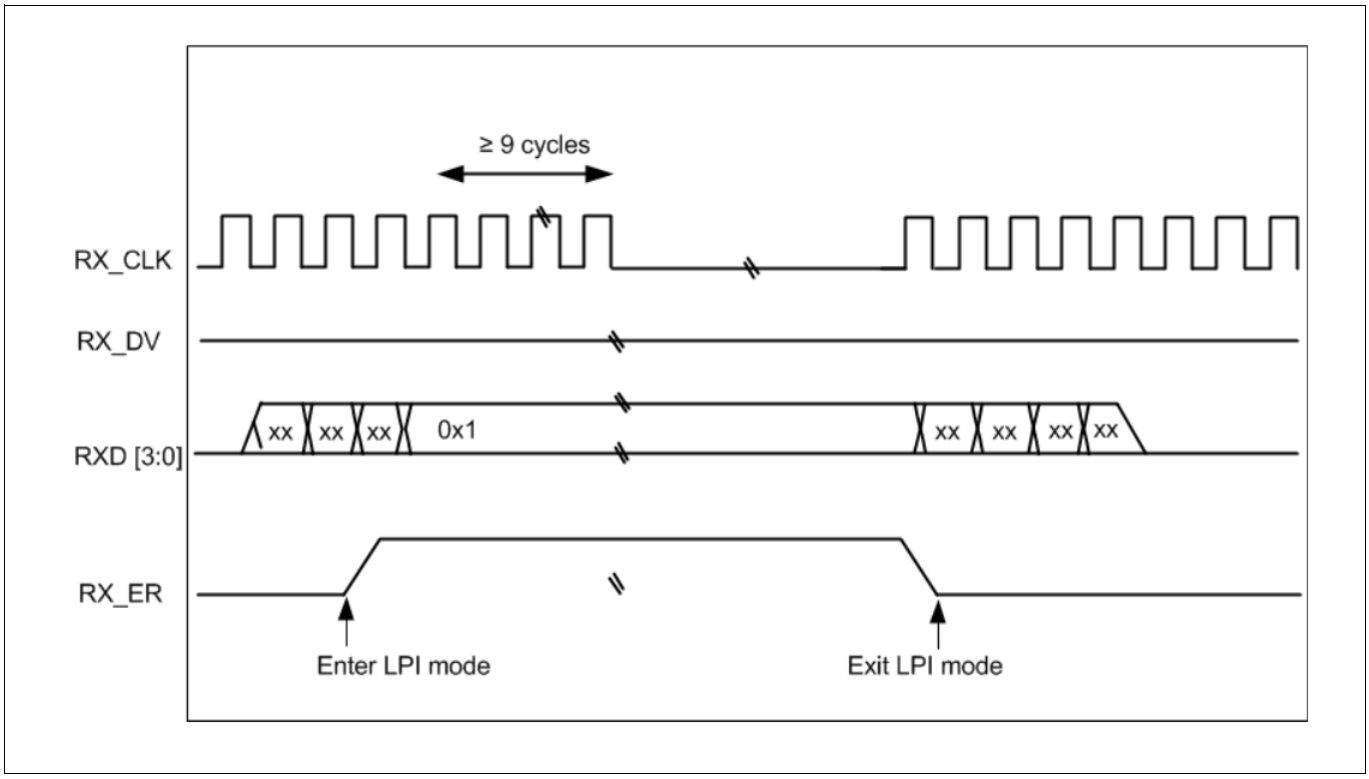

Figure 705 LPI Transitions (Receive)

Notes

1. *If the RX_CLK_stoppable bit (in the PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than nine clock cycles after the start of the LPI state as shown in **Figure 705**.*
2. *If the MAC is in the LPI mode and the application issues a soft reset or hard reset, the MAC receiver comes out of the LPI mode during reset. If the LPI pattern is still received after the reset is de-asserted, the MAC receiver again enters the LPI state.*
3. *If the RX clock is stopped in the RX LPI mode, the application should not write to the CSR registers that are being synchronized to the RX clock domain.*
4. *When the PHY sends the LPI pattern, if EEE feature is enabled, the MAC automatically enters the LPI state. There is no software control to prevent the MAC from entering the LPI state.*

44.3.12.1.3 LPI Timers

The transmitter maintains the LPI LS TIMER, LPI TW TIMER, and LPI AUTO ENTRY TIMER timers.

Following are the LPI timers that are loaded with the respective values from the MAC_LPI_Timers_Control and MAC_LPI_Entry_Timer registers:

- LPI LS TIMER
  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of MAC_LPI_Control_Status register.
  The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit.
  This timer is cleared every time the link goes down. It starts to increment when the link is up again and

continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in Bits[25:16] of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.

- LPI TW TIMER
  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in Bit[15:0] of MAC Register 53 (LPI Timers Control Register). The terminal count of the timer is the value of resolved Transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count.
  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µ s.
- LPI AUTO ENTRY TIMER
  This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPITE bit in MAC_LPI_Control_Status register is set.

Note: Program the PLS bit of MAC_LPI_Control_Status to 1'b0 before switching between the GMII and MII modes. This resets the internal timers. If the mode is changed after the LPI LS TIMER or LPI TW TIMER starts, the change in the Tx clock frequency can result in incorrect timeout.

44.3.12.1.4 LPI Interrupt

This topic describes the low-power idle (LPI) mode interrupt signal that MAC generates when it enters or exits the LPI state.

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The interrupt mci_intr_o (sbd_intr_o in EQOS-DMA configurations) is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC_LPI_Control_Status register.

When the MAC exits the Rx LPI state, then in addition to the mci_intr_o (sbd_intr_o in EQOS-DMA configurations), the sideband signal lpi_intr_o (synchronous to Rx clock) is asserted. You can use the lpi_intr_o signal to trigger the external clock-gating circuitry to restore the application clock to the MAC. The lpi_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the LPI state. If you do not want to gate-off the application clock during the Rx LPI state, you can leave the lpi_intr_o signal unconnected and use the mci_intr_o (sbd_intr_o in EQOSDMA configurations) signal to detect Rx LPI exit.

The lpi_intr_o signal is generated in the Rx clock domain. It may not be cleared immediately afterthe MAC_LPI_Control_Status register is read. This is because the clear signal, generated in CSRclock domain, has to cross the Rx clock domain, and then clear the interrupt source. This delay is atleast four clock cycles of Rx clock and can be significant when the DWC_ether_qos is operating in the 10Mbps mode.

44.3.12.2 Implementing Power Management Through Magic Packet Detection

44.3.12.2.1 Power Management (PMT) Through Magic Packet Detection

You can configure a controller to function in low-power mode and power it on only when it receives a magic packet addressed to it from the network.

This section provides an overview of power management through magic packet detection.

The PMT block supports the reception of magic packets as wake up packets. Power can be saved by gating off the CSR clock and the Tx Clock during power-down mode. The PMT block does not perform the clock gate function, but generates interrupts for magic packets that the MAC receives.

Note: The magic packet feature is implemented based on the Magic Packet Technology white paper.

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wake-up packet data format of six bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wake-up by writing 1 to the MGKPKTEN bit of the MAC_PMT_Control_Status register. The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48’hFF_FF_FF_FF_FF_FF pattern following the destination address, source address, and Length/Type fields. The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48’hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48’hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than six, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

```
Destination Address Source Address Length/Type..... FF FF FF FF FF FF00 11 22
33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44
55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44 55 00
11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 5500 11 22 33 44 55 00 11 22
33 44 55 00 11 22 33 44 55 00 11 22 33 44 55…CRC
```

DWC_ether_qos checks the remote wake-up packet only for length error, FCS error, dribble bit error, GMII error, collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, DWC_ether_qos considers it a valid packet.

The magic packet detection is updated in the MAC_PMT_Control_Status register for the received magic packet. A PMT interrupt to the Application triggers a read to the MAC_PMT_Control_Status register to determine whether a magic packet has been received.

Notes

1. *The watchdog timeout limit for a magic packet is 2,048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.*
2. *The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a magic packet only when Enable IPv4 ARP Offload is selected in the configuration.*

PMT Block Registers

Use the MGKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

44.3.12.3 Implementing Power Managemetn Through Remote Wake-Up Packet Detection

44.3.12.3.1 Power Management (PMT) Throught Remote Wake-Up Packet Detection

You can configure a controller to function in low-power mode and power it on only when it receives a remote wake-up packet addressed to it from the network.

This topic provides an overview of power management through remote wake-up packet detection.

The power management block supports the reception of network (remote) wake-up packets as wake up packets. Power can be saved by gating off the CSR clock and the Tx Clock during power down mode. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up packets that the MAC receives.

More number of Remote Wake-up Filters facilitate a wider range of packets being detected as remote wake-up packets.

Note: The remote wake-up packet feature is implemented based on the Device Class Power Management Reference Specification and various implementation-specific white papers.

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status, the normal operation is resumed after a remote wake-up packet is received. The application writes all eight wake-up filter registers, by performing a sequential Write to address (00C4H). The application enables remote wake-up by writing 1 to the RWKPKTEN bit of the MAC_PMT_Control_Status register.

The PMT block supports 16 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wake-up packet.

The Filter Offset (see Filter i Offset) determines the offset from which the packet is to be examined. The Filter Byte Mask (see Filter i Byte Mask) determines which bytes of the packet must be examined. The 31st bit of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up packet is checked only for length error, FCS error, dribble bit error, GMII error, collision. In addition, the remote wake-up packet is checked to ensure that it is not a runt packet. Even if the remote wake-up packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wake-up packet detection is updated in the PMT Control and Status register for every remote wakeup packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wake-up packet.

Notes

1. *The watchdog timeout limit for a remote wake-up frame is 2,048 bytes irrespective of the value programmed in WD bit of MAC_Configuration register and PWE bit in MAC_Watchdog_Timeout register.*
2. *The value programmed in DCRCC bit of MAC_Ext_Configuration register is applicable to a remote wake-up frame only when Enable IPv4 ARP Offload is selected in the configuration.*

PMT Block Registers

Use the RWKPKTEN bits of the MAC_PMT_Control_Status register to generate power management events. The application should program these bits. You can access the PMT registers in the similar manner as you access the MAC CSR registers.

Figure 706 Remote Wake-Up Packet Filter Register

44.3.12.3.2 PMT Interrupt Signals

This topic describes the power management (PMT) interrupt signal that MAC generates when it enters or exits the power-down mode.

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. In addition to the mci_intr_o (sbd_intr_o in EQOS-DMA configurations), the pmt_intr_o (synchronous to Rx clock) signal is asserted. The pmt_intr_o signal, synchronous to the Rx clock domain, is provided so that you can stop the application clock when the MAC is in the power-down mode.

The pmt_intr_o signal is generated in the Rx clock domain. It is not cleared immediately when the PMT Control and Status register is read. This is because the resultant clear signal has to cross to the Rx clock domain, and then clear the interrupt source. This delay is at least four clock cycles of Rx clock and can be significant when the DWC_ether_qos is operating in the 10 Mbps mode.

When software resets the PWRDWN bit in Remote Wake-Up Packet Detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

44.3.12.4 System Considerations During Power Down

This topic describes the recommended power-down and wake-up sequence when the controller is running in low-power mode.

The DWC_ether_qos neither gates nor stops clocks when the power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during the power-down mode, because it is involved in the magic packet or remote wake-up packet detection. However, the application path clock can be gated during the power-down mode. The transmit path clock must be gated during the power-down mode only if ARP Offload is not enabled.

The recommended power-down and wake-up sequence is as follows:

1. Disable the Transmit DMA (if applicable) and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt [Bit 0 of the DMA_CH0_Status register] is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC Configuration register.
3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. You can do this by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter the Power-Down mode.
6. Gate the application and transmit clock (transmit clock must be gated only if ARP Offload is not enabled) inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.

   Note: On receiving a valid remote wake-up packet, the DWC_ether_qos asserts the pmt_intr_o signal and exits the Power-Down mode.

   Note: On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.

7. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

44.3.13 Using MAC Management Counters

44.3.13.1 Introduction to MAC Management Counters

The DWC_ether_qos supports storing the statistics about the received and transmitted packets in registers that are accessible through the application.

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32-bits wide. The write data is qualified with the corresponding mci_be_i signals. Therefore, non-32-bit accesses are allowed as long as the address is word-aligned. The MMCs are accessed using transactions, in the same way the CSR address space is accessed.

The MMC counters are free running. There is no separate enable for the counters to start. If a particular MMC counter is present in the RTL, it starts counting when corresponding packet is received or transmitted. The Receive MMC counters are updated for packets that are passed by the Address Filter (AFM) block. The statistics of packets, dropped by the AFM module, are not updated unless they are runt packets of less than 6 bytes (DA bytes are not received fully). To get statistics of all packets, set Bit 0 in the “MAC_Packet_Filter” register.

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet packets. This gathering is only enabled when you select the Full Checksum Offload Engine in coreConsultant.

You can select the MMC counters individually during configuration. The addresses for counters that are not selected become reserved. The width of each MMC counter is 32-bit, by default. You can individually change the width to 16-bit for each selected MMC counter during configuration.

For MMC register details, see registers “MMC_Control” to “RxICMP_Error_Octets”.

44.3.13.2 Address Assignments

The MMC registers follow a certain naming convention and their descriptions use certain terminologies that you should know.

The MMC register naming conventions are as follows.

- “tx” as a prefix or suffix indicates counters associated with transmission
- “rx” as a prefix or suffix indicates counters associated with reception
- “_g” as a suffix indicates registers that count only good packets
- “_gb” as a suffix indicates registers that count packets regardless of whether they are good or bad.

The following definitions define the terminology used in MMC register descriptions.

- Transmitted packets are considered “good” if transmitted successfully. In other words, a transmitted packet is good if the packets transmission is not aborted because of any of the following errors:
  - Jabber Timeout
  - No Carrier or Loss of Carrier
  - Late Collision
  - Packet Underflow
  - Excessive Deferral
  - Excessive Collision
- Received packets are considered “good” if none of the following errors exists:

  - CRC error
  - Runt packet (shorter than 64 bytes)
  - Alignment error (in 10/100 Mbps only)
  - Length error (non-Type packet only)
  - Out of Range (non-Type packet only, longer than 1518 bytes)
  - GMII_RXER Input error
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN Frame maxsize = 1,522
  - Jumbo Frame maxsize = 9,018
  - JumboVLAN Frame maxsize = 9,022
- The maximum receive packet size depends on the packet type and control bits (JE, S2KP, GPSLCE and EDVLP), as shown in the **Table 471** table.

Table 471 Size of the Maximum Receive Packet

JE	S2KP	GPSLCE	EDVLP	Untagged Frame maxsize in bytes	Single VLAN Frame maxsize in bytes	Double VLAN Frame maxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

Notes

1. *The MMC counters registers at the following offset addresses are of type Read-Only and have the default value of 0:*
   0x0714 to 0x0778
   0x0780 to 0x07E4
   0x0810 to 0x0844
   0x0850 to 0x0884
2. *The RX MMC counters and RX IPC MMC counters are updated only for packets that pass the Destination Address filter except when the UCDBC bit is set for broadcast packets in the MMC_Control register.*

44.3.14 Flow Control

This chapter describes the flow control for Transmit and Receive paths.

Note: Priority Flow Control (PFC) is not supported.

44.3.14.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

44.3.14.1.1 Flow Control in Full-Duplex Mode

DWC_ether_qos supports full-duplex flow control operations. In full-duplex mode, the DWC_ether_qos uses one of the following packet types for flow control:

- IEEE 802.3x Pause packets
- Priority flow control (PFC) packets

The PFC packets are used only when the Enable Data Center Bridging option is selected. The PFCE bit ofMAC_Rx_Flow_Ctrl register determines whether PFC packets or IEEE 802.3x Pause Control packets are used for flow control. If the PFCE bit is set, the MAC sends the PFC packets.

Pause Packet Structure

The table below describes the fields of a Pause packet.

Table 472 Size of the Maximum Receive Packet

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrlregister

Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Similarly, when the mti_flowctrl_i signal is asserted, the MAC generates and transmits a single Pause packet. If the mti_flowctrl_i signal remains asserted at a configurable number of slot times before the Pause time runs out, the MAC transmits a second Pause packet. This process is repeated as long as the mti_flowctrl_i signal remains active. If the mti_flowctrl_i signal goes inactive prior to the sampling time, the MAC transmits a Pause packet with zero Pause time (if the DZPQ bit in MAC_Q#_Tx_Flow_Ctrl register is set to 0) to indicate to the remote end that the Receive buffer is ready to receive new data packets.

For PFC packets, you can specify the priority, pause time, and other controls for a queue in MAC_Q#_Tx_Flow_Ctrl register. The MAC supports independent flow control for each Rx queue. There is one trigger input for each Rx queue. Therefore, when multiple triggers come simultaneously, the MAC sends one PFC packet for each trigger. Based on the hardware trigger or software trigger through respective queues, the MAC sends a PFC packet with programmed Pause Time and priority. If multiple priorities are programmed in same Rx queue, multiple priorities are set for the PFC packet with same Pause Time values. A separate pause timer is available for each Rx queue.

44.3.14.1.2 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

The table below describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 473 Size of the Maximum Receive Packet

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

44.3.14.2 Triggering Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end. The application can request the MAC to send a Pause packet or initiate back-pressure by using either of the following method:

The application sets the FCB_BPA bit in the corresponding MAC_Q#_Tx_Flow_Ctrl register.

The flow control is triggered based on the following:

Rx Queue Threshold: The flow control operation of the MAC is enabled when the EHFC bit of corresponding MTL_RxQ#_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in RFA field of MTL_RxQ#_Operation_ Mode register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field.

The hardware flow control generated based on the Rx Queue threshold crossing condition is applicable only when the Rx queue size is 4,096 bytes or more.

Note: The RFS sets the threshold at which the flow control is triggered and the MAC schedules to send a PAUSE frame to be sent by the local transmitter. The remote transmitter can continue to send packets until it receives this PAUSE packet. So the RXQ needs space to take in this data even after the flow-control is triggered, to avoid overflow and loss of packets. The max-space required that is calculated theoretically can be 2 max-sized packets + a little more assuming that the read from the RXFIFO is not occurring during this whole time. Theoretically, this makes RFA=4 or more, which implies that RxQ must have at the least 4KB size. Practically, the system works with RFA=2 (Full – 2KB, with very little probability of overflow). If you have FIFO size of less than 4K, then with RFA=2, the flow control will be triggered with just 1000B in the RxQ which is even less than max packet size. The RFA field MTL_RxQ[n]_Operation_Mode register is used for activating the Flow Control. These bits control the threshold (fill-level of Rx queue) at which the flow control is activated. For Example: If your RXQ size is

2K and you set the RFA to 1K; as soon as you receive 1K, the Flow Control is activated. If you are sending a packet of 1500 bytes (which is allowed as per spec), you will be triggering flow-control even before you receive a complete packet. This will reduce the throughput considerably. If your RXQ size is 4K, you can set the RFA to 2K, so that you are able to receive the whole packet.

44.3.14.3 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

Note: Receive pause packets should have a frame size of 64 bytes.

44.3.14.3.1 Description of Receive Flow Control

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

The table below describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 474 Size of the Maximum Receive Packet

TFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets butrecognizes such packets as Control packets.
1	0	The MAC receiver detects or processes the Pause packets andresponds to such packets by stopping the MAC transmitter.

You can enable the PFC packet detection by setting the PFCE bit in the MAC_Rx_Flow_Ctrl register. If PFC packet detection is enabled, the MTL Tx queue corresponding to the received priority is blocked when the PFC packet is received. If PFC packet detection is not enabled in configurations with multiple queues and RFE bit is enabled, the MAC transmitter is blocked when the 802.3x Pause packet is received.

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:
   a) Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001).
   b) Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of MAC_Rx_Flow_Ctrl register is set. If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address.
2. The MAC decodes the following fields of the received packet:
   a) Type field: This field is checked for 16'h8808.
   b) Opcode field: This field is checked for 16'h0001 (Pause packet) or 16'h0101 (PFC packet).
   c) Pause Time or Pause Time Vector field: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked. The Pause Time Vector field (for PFC packet) is captured to determine the time for which the MTL Tx queue corresponding to the received priority needs to be blocked.Priority Enable Vector field: This field is valid only for PFC packets. It is captured to determine the MTL Tx queue corresponding to the received priority.

3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter does one of the following:
   a) For 802.3x Pause packets, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).
   b) For PFC packets, the MAC blocks the Tx queues corresponding to the priority. Based on the priorities assigned to the Tx queues in MAC_TxQ_Prty_Map0 and MAC_TxQ_Prty_Map1 registers, the MAC asserts the respective bit in the mti_disable_txq_o signal and loads the Pause timer corresponding to the priority. The Tx queue corresponding to the priority is blocked till the Pause timer expires. In addition to the PFC-based flow control operation, when PFCE bit is set, all bits of the mti_disable_txq_o signal are asserted while in LPI mode so that the ETS or CBS scheduler start over again after exiting the LPI mode.
4. The MAC transfers the received control packet to the application based on the setting of the PCF field in MAC_Packet_Filter register.

If subsequent Pause or PFC packets are received before the earlier Pause Time expires, the MAC updates thePause Timer with new value.

44.3.14.4 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

44.3.15 Using Loopback Mode

44.3.15.1 Guidelines for Using Loopback Mode

You need to follow certain guidelines to use the loopback feature of the DWC_ether_qos controller.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.

The Transmit and Receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the phy_txd_o data to the Receive path. The asynchronous FIFO is 10-bits (6-bits in 10/100 Mbps mode) wide to accommodate phy_txd_o, phy_txen_o, and phy_txer_o. The depth of FIFO is five in 1000 Mbps mode and nine in 10/100 Mbps mode. The FIFO is free-running to write on the write clock (clk_tx_i) and read on every read clock (clk_rx_i).

At the start of each packet read out of the FIFO, the Write and Read pointers get re-initialized to have an offset of 2 (4 in 10/100 Mbps mode). This avoids overflow or underflow during a packet transfer. This also ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption for packet sizes up to 9,022 bytes with a difference of 200 ppm between (G)MII Transmit and Receive clock frequencies. Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO.

At the end of every received packet, the Receive Protocol Engine module generates received packet status and sends it to the Receive Packet Controller module. The control, missed packet, and filter fail status are added to the Receive status in the Receive Packet Controller module.

The MAC does not process ARP or PMT packets that are looped back.

44.3.15.2 Enabling Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back on the MII or GMII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block.

44.3.16 Interrupts from the MAC

Various events in optional modules of the MAC can generate interrupts.

Interrupts can be generated from the MAC as a result of various events in the optional modules.

In EQOS-DMA and EQOS-AHB configurations, these interrupt events are combined with the events in the DMA on the sbd_intr_o signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The MAC_Interrupt_Status register describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the mci_intr_o or sbd_intr_o signals by setting the corresponding mask bits in the MAC_Interrupt_Enable register.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, when set high, Bit 0 of the MAC_Interrupt_Status register indicates that the link status on the RGMII, SGMII, or SMII interface has changed. You must read the MAC_PHYIF_Control_Status register to clear this interrupt event.

The interrupts from the RGMII, and PCS blocks and the optional General Purpose Inputs are combined (OR’ed) and given as the GLI bit in the DMA_Interrupt_Status register.

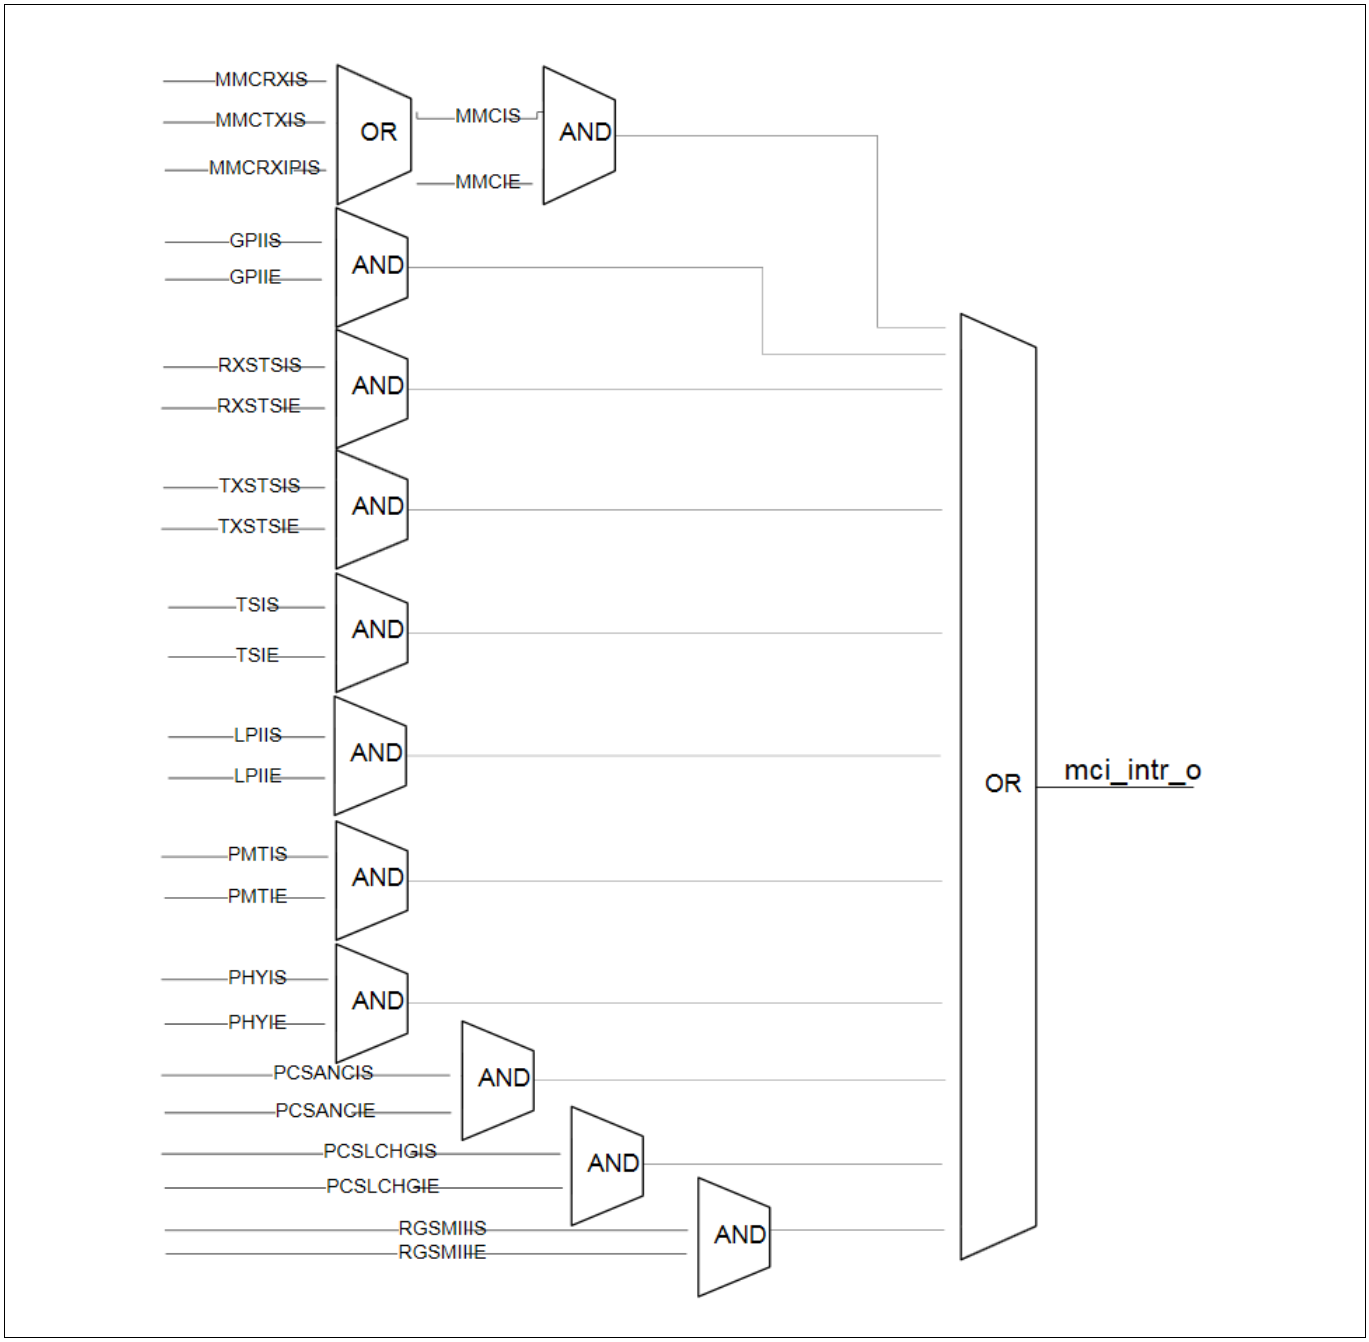

Figure 707 MAC Interrupt Enabling Scheme

Note: By default, the MAC interrupt status bits are cleared when the register that contains the source of the interrupt is read. If RCWE bit in MAC_CSR_SW_Ctrl register is programmed to 1, the MAC interrupt status bits are cleared when the bit that contains the source of the interrupt is explicitly written to 1.

44.3.17 Descriptors

44.3.17.1 Overview of Descriptors

The DWC_ether_qos controller support two types of descriptors: Norma and Context.

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The DWC_ether_qos supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

Note: There is no limit for the number of descriptors that can be used for a single packet.

44.3.17.2 Descriptor Structure

The DWC_ether_qos supports the ring structure for a DMA descriptor, which separates descriptors by the Word, DWord, or LWord number programmed in the DMA_CH#_Control.DSL register field.

The DWC_ether_qos supports the ring structure for DMA descriptor as shown in **Figure 708**.

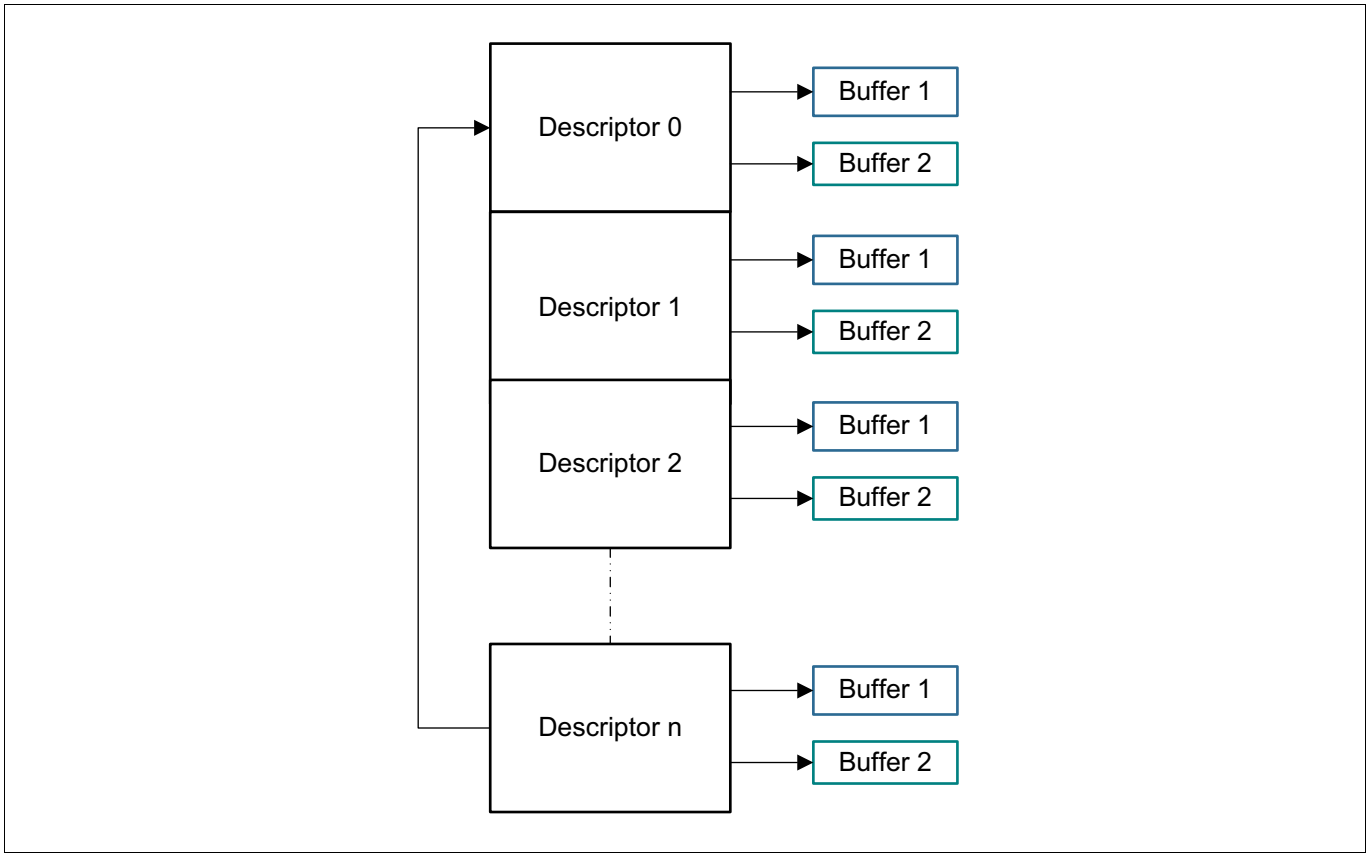

Figure 708 Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

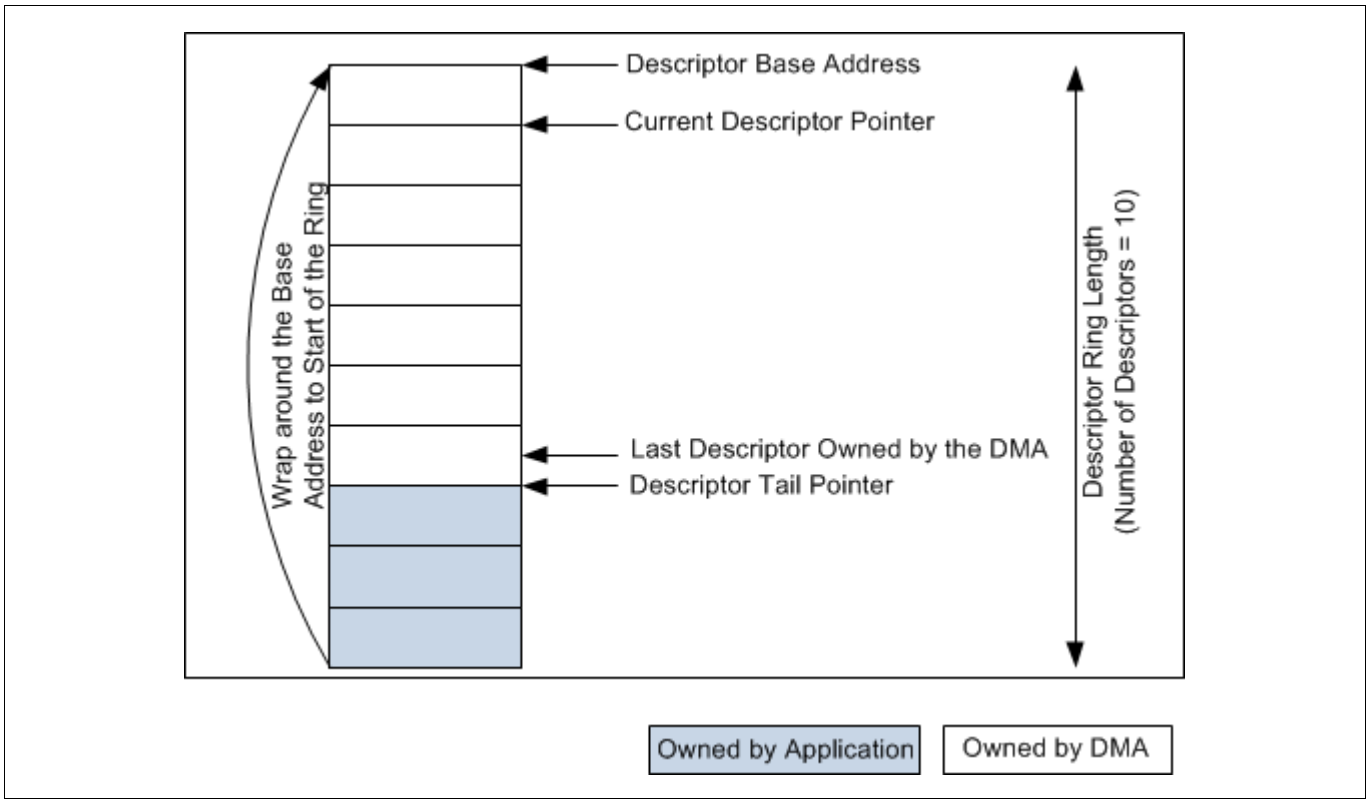

Figure 709 DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

44.3.17.3 Split Header Support

You can enable the optional split header support by programming the DMA_CH#_Control.SPH register bit, which allows the DMA to process the header and payload of a received packet separately.

Split Header support is an optional feature. You can enable the split header feature by selecting the Enable Split Header Feature option and setting the SPH bit in the DMA_CH#_Control register.

The DMA can process the header and payload of received packets separately.

Table 475 shows how DMA processes a packet depending upon its type.

Table 475 Header Split Points

Packet Type	Description
TCP or UDP Packet	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer
IP packet (not TCP/UDP)	The DMA writes the Ethernet header + IP header into the header buffer
Non-IP packet	The DMA does not split the header and payload

The IP header includes IPv4 options in case of a IPv4 packet, and IPv6 extension headers in case of IPv6 frames. The points at which the header is split are shown in **Figure 710**.

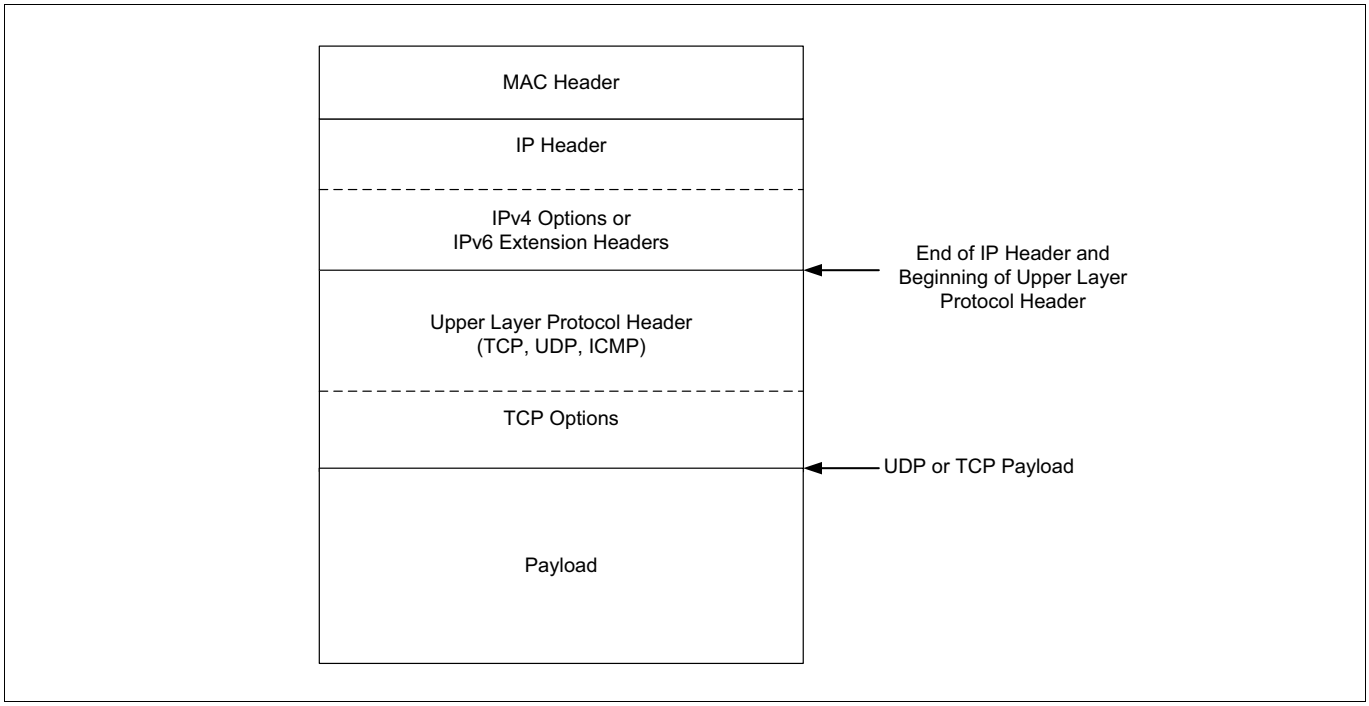

Figure 710 Header Split Points

44.3.17.3.1 Descriptor Structure with Split Header Feature

The DWC_ether_qos supports the split header structure for descriptors.

Figure 711 shows the descriptor structure without the Split Header feature.

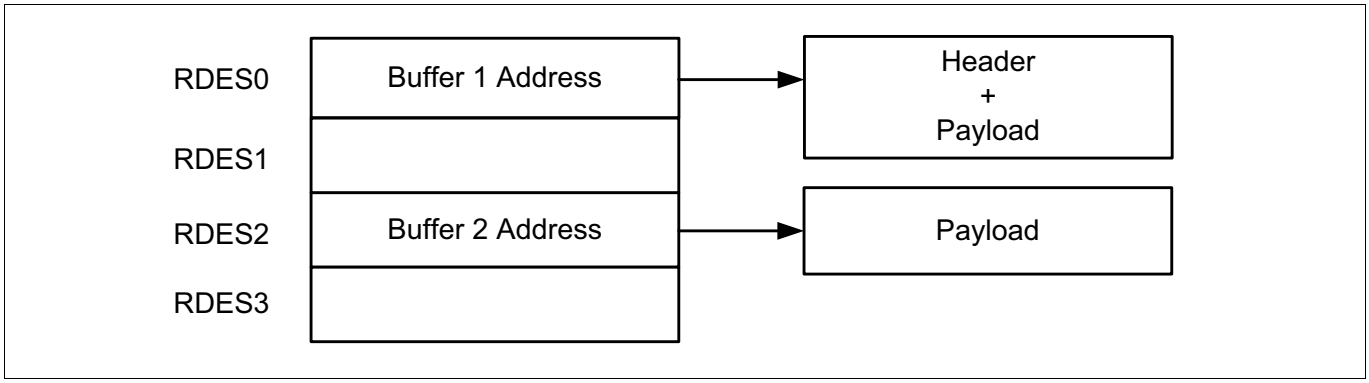

Figure 711 Descriptors without Split Header Feature

Figure 712 shows the descriptor structure with the Split Header feature.

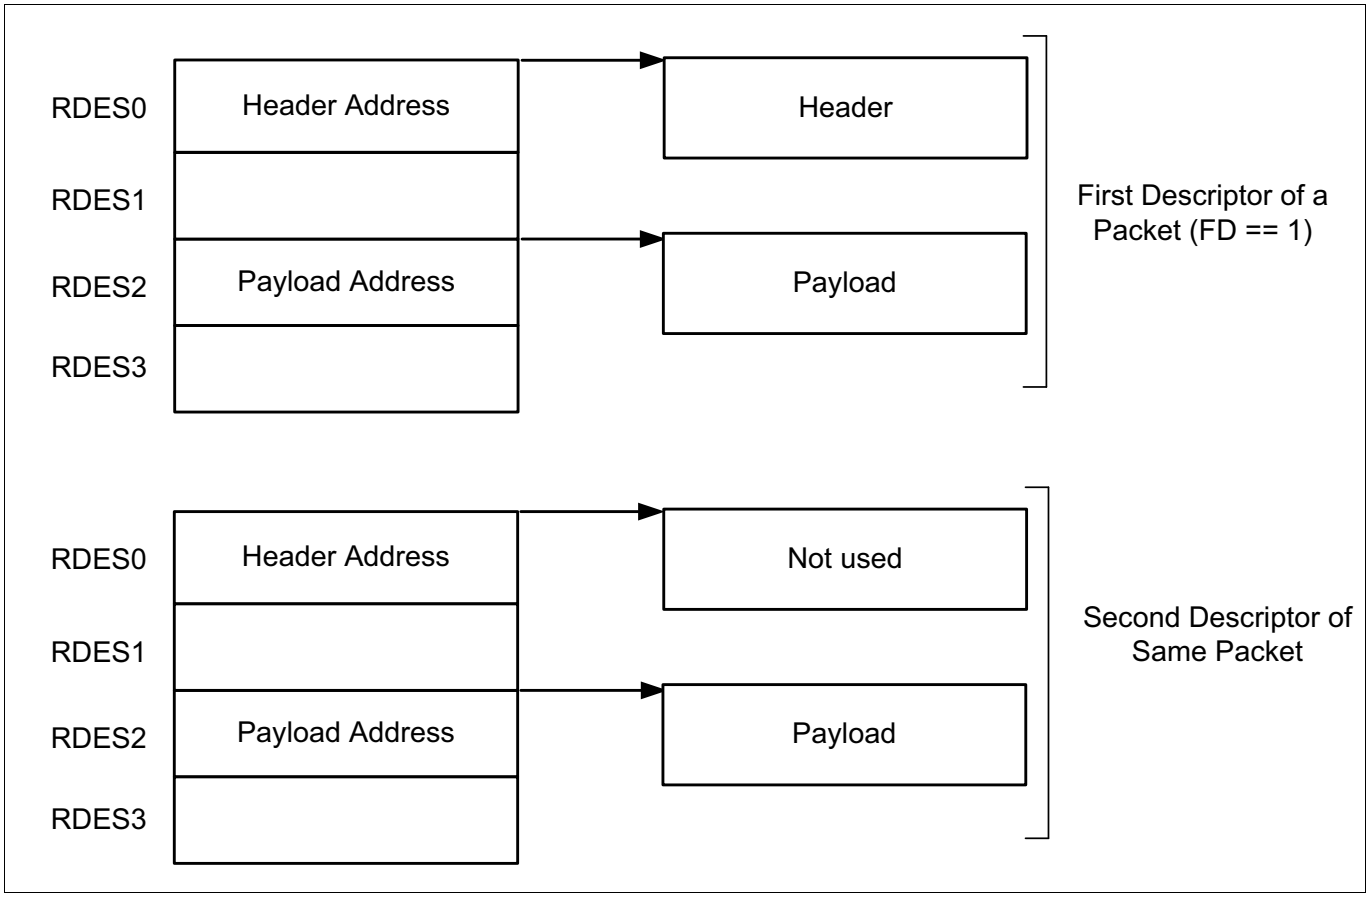

Figure 712 Descriptors with Split Header Feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[29] (FD Bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[28] (LD Bit) set). The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA Channel Register 2 (Receive Control Register). The DMA fills receive buffers fully in all except the last descriptor. The header length is taken to

be the value based on the bits programmed in the MAC Extended Configuration Register HDSMS field (Bits [22:20]).

44.3.17.4 Descriptor Endianness

You must align the descriptor address to the configured bus width in terms of endianness.

Figure 713 shows the normal Receive and Transmit descriptors for 32-bit data bus when the endian mode of data bus and descriptors is little-endian.

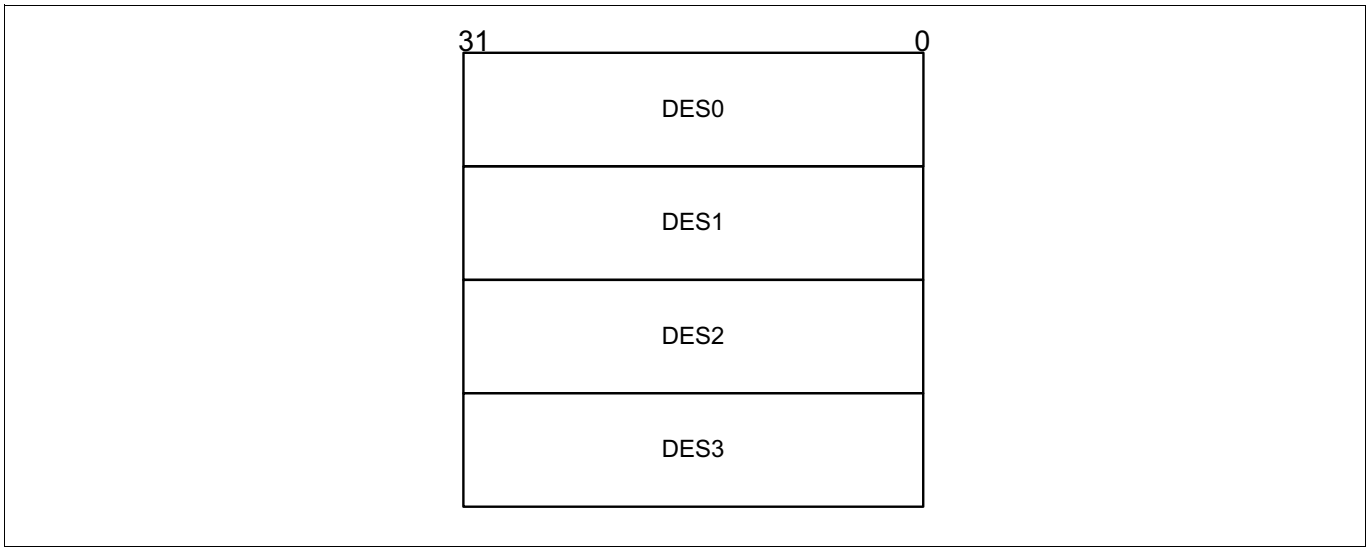

Figure 713 Rx/Tx Descriptors in Same-Endian Mode for 32-Bit Little-Endian or Reverse Endian Mode for 32-Bit Big-Endian Data Bus

44.3.17.5 Transmit Descriptor

The DWC_ether_qos support two types of Transmit Descriptor formats: Read and Write-back.

The DMA in DWC_ether_qos requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

44.3.17.5.1 Transmit Norma Descriptor (Read Format)

Figure 714 shows the Read Format for a Transmit normal descriptor. **Table 476** through **Table 479** describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

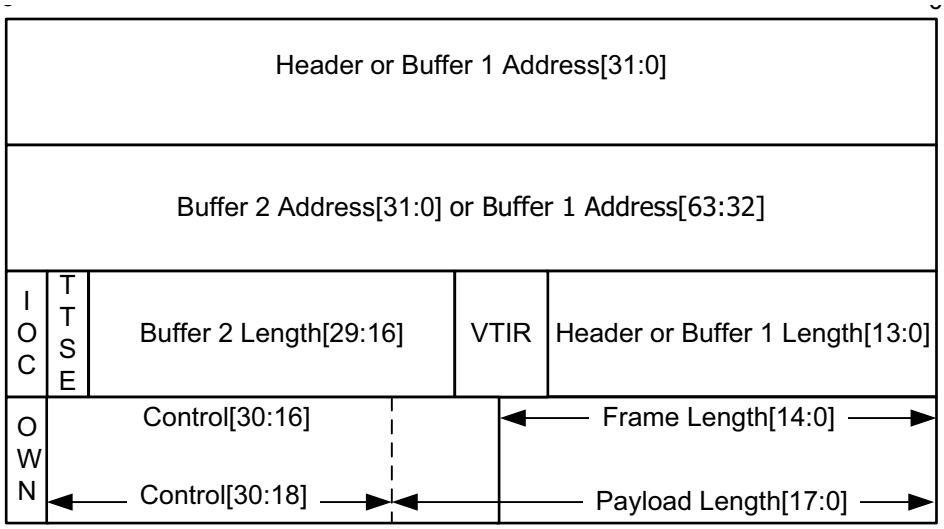

Figure 714 Transmit Descriptor Read Format

Table 476 TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1.

Table 477 TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

Table 478 TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CH#_Status register after the present packet has been transmitted.
30	TTSE/TMWD	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.

Table 478 TDES2 Normal Descriptor (Read Format) (cont'd)

Bits	Name	Description
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	B1L	Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length.

Table 479 TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context TypeThis bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.

Table 479 TDES3 Normal Descriptor (Read Format) (cont'd)

Bits	Name	Description
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.

Table 479 TDES3 Normal Descriptor (Read Format) (cont'd)

Bits	Name	Description
22:19	SLOTNUMorTHL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP header. The minimum value of this field must be 5. This field is valid only for the first descriptor.
18	RES_18	Reseved
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload LengthThese bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload length. This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Packet Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: `Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length` When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length. This length does not include Ethernet header or TCP/IP header length.

44.3.17.5.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Figure 715 illustrates the write-back format of the Transmit Descriptor.

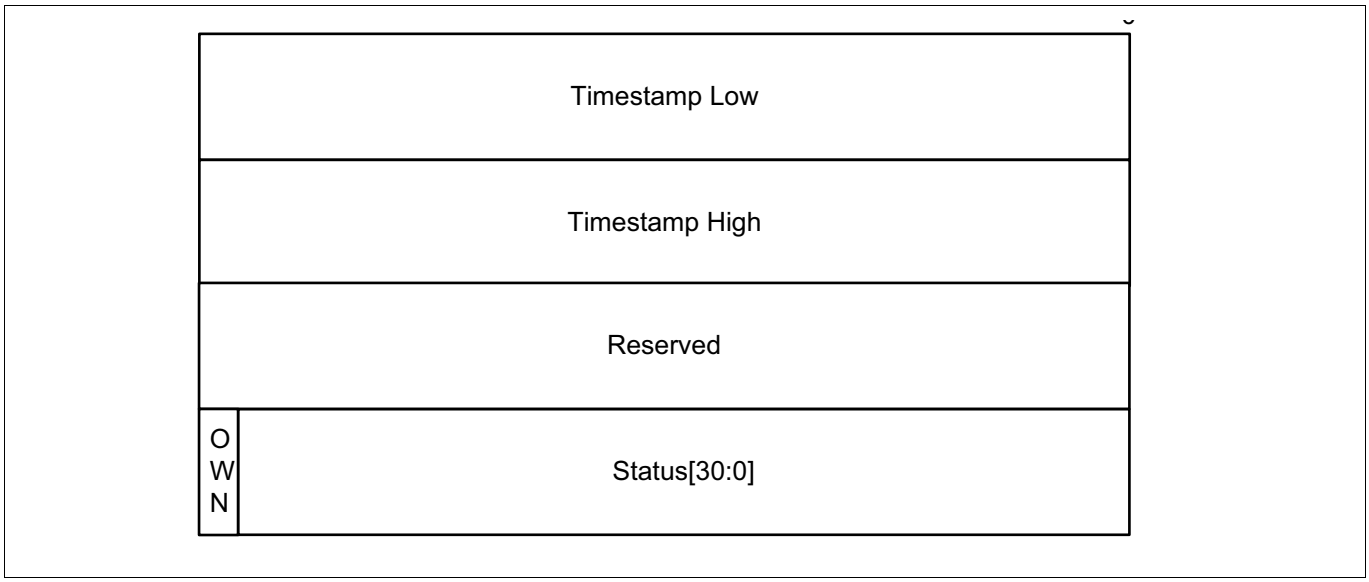

Figure 715 Transmit Descriptor Write-Back Format

As described in Table 480, this format is only applicable to the last descriptor of a packet.

Table 480 TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and the Timestamp status (TTSS) bit is set.

As provided in Table 481, this format is only applicable to the last descriptor of a packet.

Table 481 TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding Transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set.

As given in Table 482, this format is applicable only to the last descriptor of a packet.

Table 482 TDES2 Normal Descriptor (Write-Back Format)

Bit	Description
31:0	Reserved

As provided in Table 483, this format is applicable only to the last descriptor of a packet.

Table 483 TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DWC_ether_qos DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
30	CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status registerNote 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	Rsvd	Reserved

Table 483 TDES3 Normal Descriptor (Write-Back Format) (cont'd)

Bit	Name	Description
15	ES	Error Summary This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum ErrorThis bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.

Table 483 TDES3 Normal Descriptor (Write-Back Format) (cont'd)

Bit	Name	Description
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

44.3.17.5.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

Note: The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet. The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

Figure 716 shows the format of the Transmit Context descriptor.

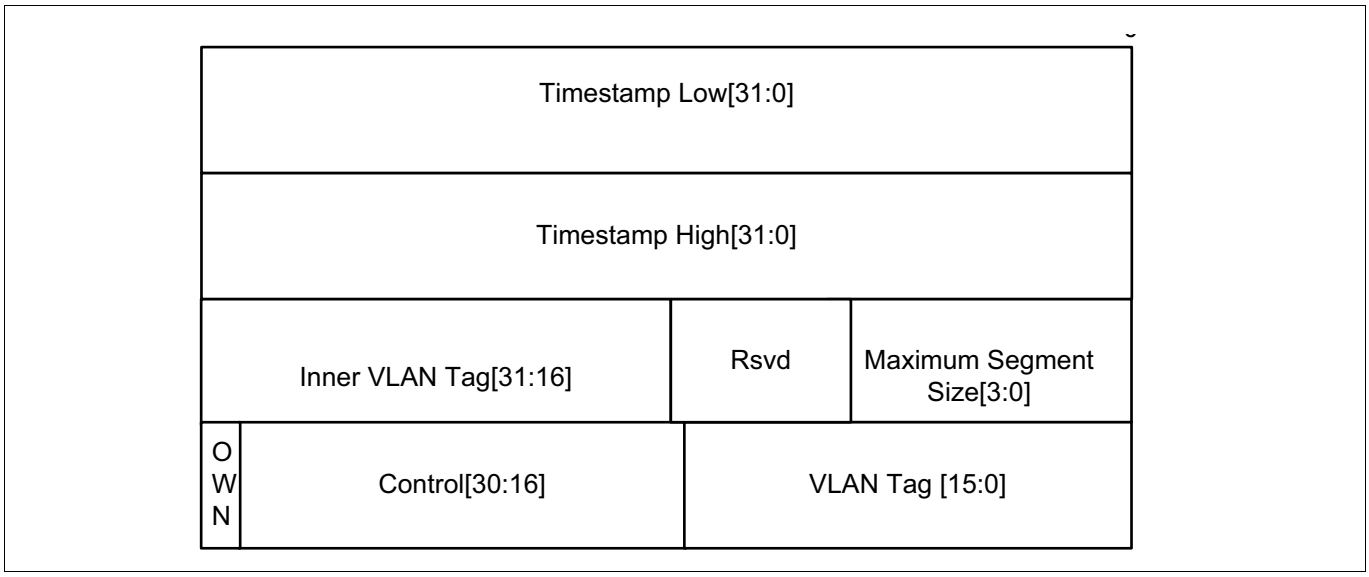

Figure 716 Transmit Context Descriptor Format

Table 484 describes the format of the TDES0 Context descriptor.

Table 484 TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 485 provides the format of the TDES1 Context descriptor.

Table 485 TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

Table 486 explains the format of the TDES2 Context descriptor.

Table 486 TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.

Table 486 TDES2 Context Descriptor (cont'd)

Bit	Name	Description
15:14	Rsvd	Reserved
13:0	MSS	Maximum Segment Size When the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected, the driver can provide maximum segment size in this field. This segment size is used while segmenting the TCP/IP payload. This field is valid only if the TCMSSV bit of TDES3 context descriptor is set and the OSTC bit of the TDES3 context descriptor is reset.

Table 487 details the format of the TDES3 Context descriptor.

Table 487 TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DWC_ether_qos DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid.When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status registerNote 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Rsvd	Reserved

Table 487 TDES3 Context Descriptor (cont'd)

Bit	Name	Description
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

44.3.17.6 Receive Descriptor

The DWC_ether_qos controller supports two receive descriptors: normal and context.

The DMA in DWC_ether_qos attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA will write the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in "Receive Context Descriptor".

44.3.17.6.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Figure 717 shows the Read Format for a Receive Normal Descriptor.

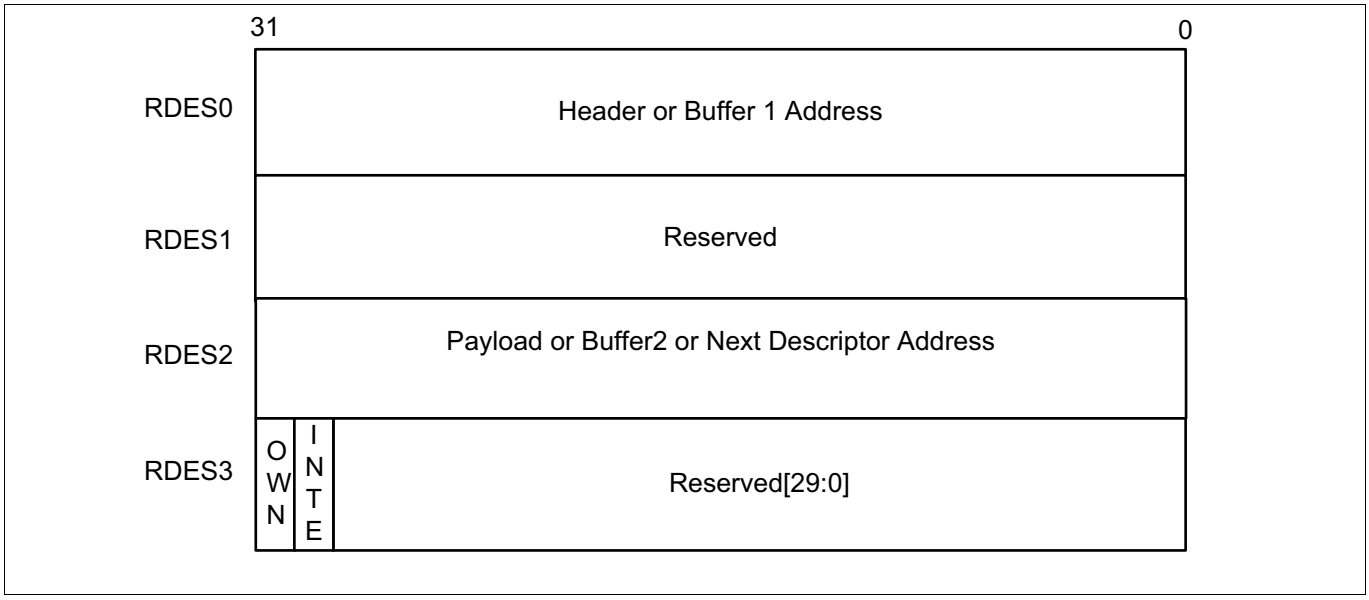

Figure 717 Receive Normal Descriptor Read Format

Note: In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, DWC_ether_qos does not transfer data to that buffer and skips to the next buffer or next descriptor.

Table 488 explains the read format of the RDES0 Normal Descriptor.

Table 488 RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet.The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer.If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

Table 489 describes the read format of the RDES1 Normal Descriptor.

Table 489 RDES1 Normal Descriptor (Read Format)

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 490 provides the read format of the RDES2 Normal Descriptor.

Table 490 RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2.When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

Table 491 describes the read format of the RDES3 Normal Descriptor.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 491 RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DWC_ether_qos DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid.The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid.The application must set this value if the address pointed to by Buffer 1 address in RDES1 canbe used by the DMA to write received packet data.
23:0	Rsvd	Reserved

44.3.17.6.2 Receive Normal Descriptor (Write-Back Format)

Figure 718 illustrates the write-back format for a Receive Normal descriptor.

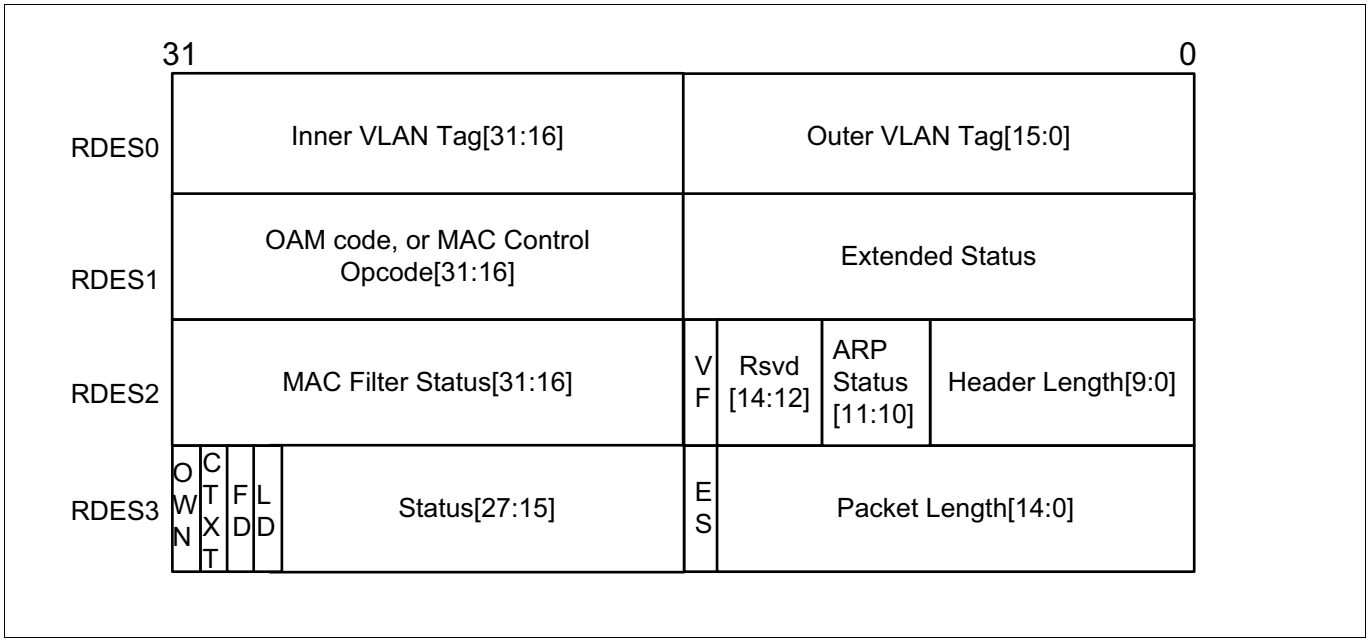

Figure 718 Receive Normal Descriptor (Write-Back Format)

Table 492 describes the write-back format for the RDES0 Normal Descriptor.

Table 492 RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN TagThis field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set.This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN TagThis field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set). **Table 493** provides the details of the write-back format for RDES1 Normal Descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 493 RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type CodeIf Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode If Bits[18:16] of RDES3 are set to 3'b110, this field contains the MAC Control packet opcode field.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.

Table 493 RDES1 Normal Descriptor (Write-Back Format) (cont'd)

Bit	Name	Description
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

Rsvd	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 494 RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:27	Rsvd	Reserved
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value.
17	DAF	Destination Address Filter Fail When this bit is set, it indicates that the packet failed the DA Filter in the MAC.
16	SAF	SA Address Filter Fail When this bit is set, it indicates that the packet failed the SA Filter in the MAC.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter.This bit is valid only when DWC_EQOS_ERVFE is not enabled.If DWC_EQOS_ERVFE is enabled, the bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only when DWC_EQOS_ERVFE is enabled. This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see the Filter Status topic.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

Table 495 describes the write-back format for the RDES3 Normal Descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 495 RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DWC_ether_qos DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 00: Intermediate Descriptor • 01: First Descriptor • 10: Reserved • 11: Descriptor Error (due to all 1s) *Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.*
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.

Table 495 RDES3 Normal Descriptor (Write-Back Format) (cont'd)

Bit	Name	Description
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set).Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO.Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved

Table 495 RDES3 Normal Descriptor (Write-Back Format) (cont'd)

Bit	Name	Description
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

44.3.17.6.3 Receive Context Descriptor

The DMA can write to Receive Context Descriptor, which provices extended status related to he last receive packet. The descriptor is read only for the application.

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

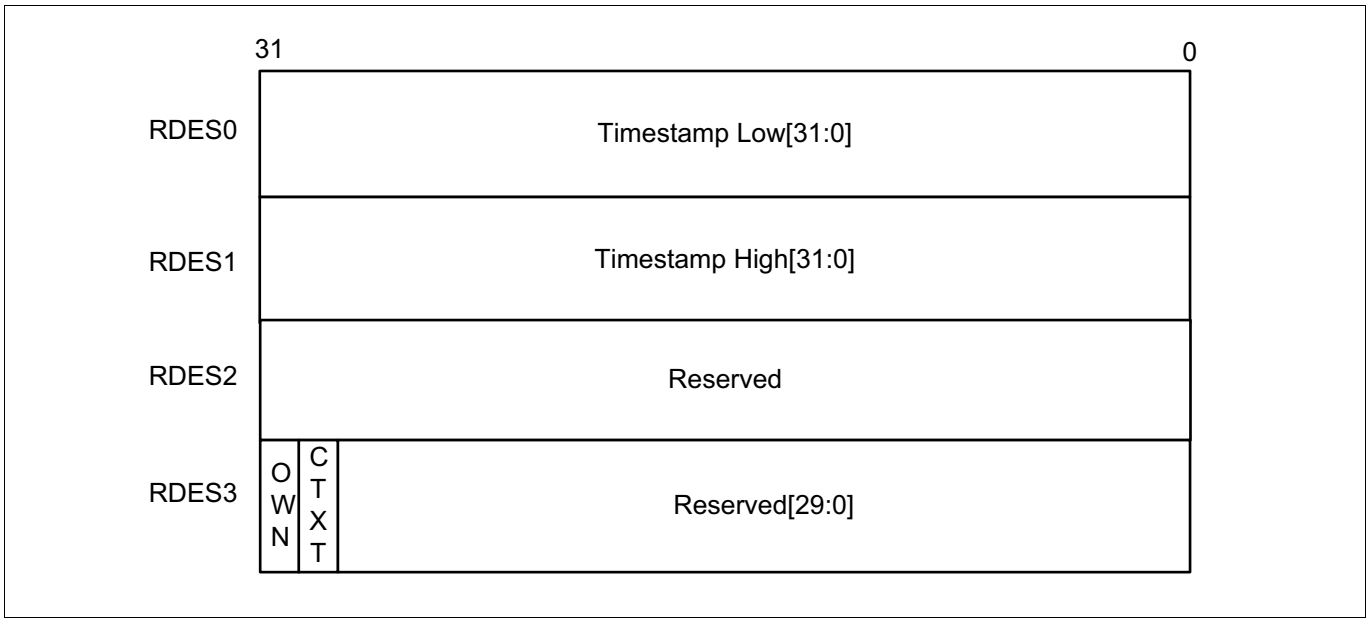

Figure 719 Receive Context Descriptor Format

Table 496 RDES0 Context Descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

Table 497 RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

28:0	Rsvd	Reserved

44.3.18 Programming Sequences

Depending on the DWC_ether_qos configuration, the controller must be initialized in the proper sequence. Additionally, it is recommended that you follow programming guidelines for the supported features.

The DWC_ether_qos is programmed through the software registers.

Note: After a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 6 cycles of the destination clock (PHY receive clock or PHY transmit clock).

44.3.18.1 Initializing DMA

You must perform a number of steps to initialize the DMA.

Complete the following steps to initialize the DMA:

Steps

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SysBus_Mode register:
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
   d) If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3).
5. Note: The descriptor address from the start to the end of the ring must not cross the 4GB boundary.
   Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
7. Note: For 40- or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).
   Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

44.3.18.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

Steps

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   c) Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a) Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d) Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

44.3.18.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

Steps

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled in your configuration (during configuration in the coreConsultant), program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_Packet_Filter register:
   a) Receive All
   b) Promiscuous mode
   c) Hash or Perfect Filter
   d) Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_Tx_Flow_Ctrl register:
   a) Pause time and other Pause frame control bits
   b) Transmit Flow control bits
   c) Flow Control Busy
4. Program the MAC_Interrupt_Enable register, as required, and if applicable, for your configuration.

5. Program the appropriate fields in the MAC_Configuration register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_Configuration registers to start the MAC transmitter and receiver.

44.3.18.4 Performing Normal Receive and Transmit Operation

During normal operation of the DWC_ether_qos, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

Steps

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Current_App_RxBuffer).

44.3.18.5 Stopping and Starting Transmission

You can pause transmission by disabling the Transmit DMA, waiting for previous frame transmissions to complete, disabling the MAC transmitter and receiver, and disabling the Receive DMA.

Notes

1. *Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.*
2. *Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.*

Complete the following steps to pause the transmission for some time. The steps are provided for Channel 0.

Steps

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Configuration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_RxQ0_Debug Register, PRXQ=0 and RXQSTS=00).

5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug Register and RXQSTS is 0 in MTL_RxQ0_Debug Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

44.3.18.6 Programming Guidelines for Switching to New Descriptor List in RxDMA

If you want to switch to a new descriptor list is allowed when the RxDMA is in the SUSPEND state, however, make sure you understand the guidelines before the switch.

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

44.3.18.7 Programming Guidelines for Multi-Channel, Multi-Queuing

44.3.18.7.1 Programming Guidelines for Multi-Channel Multi-Queuing - Transmit

You can program several aspects of a Transmit queue, such as specifying queue size, enabling a queue, and programming the scheduling method.

Complete the following steps:

Steps

1. Program the Transmit queue size in the TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in the TQS field, the size of the queue is determined.
2. For a queue to be used, the queue needs to be enabled in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode Register. In DMA configurations, the ST bit of DMA_CH[n]_Tx_Control Register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_Operation_Mode register.
4. Program the MTL_TxQ[n]_Quantum_Weight for generic or DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit and MTL_TxQ[n]_LoCredit registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TxQ_Prty_Map0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

44.3.18.7.2 Programming Guidelines for Multi-Channel Multi-Queuing - Receive

You can program several aspects of a Receive queue, such as specifying queue size, enabling a queue for AV or DCB, setting the packet types (so they can be routed to Receive queues), and defining arbitration and mapping if multiple DMA channels enabled.

Complete the following steps:

Steps

1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_Rx_Control Register and corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a) AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
   b) AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 Register.
   c) Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 Register to indicate to MAC which queue should get the DCB packets.
   d) VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 7.
   e) The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 register.
4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a) Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b) Program the MTL_RxQ[n]_Control to decide the weights and the packet arbitration for each RxQ.
   c) If static mapping is programmed in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d) Set RXQ[n]DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue.
   e) In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.
   Note: The priorities set in PSRQ7-0 should be unique.

44.3.18.8 Programming Guidelines for GMII Link State Transitions

There are two programming tasks with regards to GMII Link State Transitions when transmit and receive clocks are either running or stopped when the Link is down.

When the Link is down, there are two types of scenarios where you must perform programming steps:

- When transmit and receive clocks are running
- When transmit and receive clocks are stopped

44.3.18.8.1 Transmit and Receive Clocks Running when Link Down

When the Link is down but the Transmit and Receive clocks are still running, you need to need to disable the Transmit DMA and the MAC receiver, wait for previous frame transmissions to complete, disable the MAC transmitter, verify both Tx and Rx queues are empty, read PHY registers to determine latest configuration and then program MAC registers, and restart the Tx DMA, and then enable the MAC Transmit and Receiver.

The following steps explains how to program DWC_ether_qos when the link is down but the Transmit and Receive clocks are running:

Note: The steps are provided for Channel 0.

Steps

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Disable the MAC receiver by clearing Bit 2 (RE) of MAC_Configuration Register.
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TxQ0_Debug Register (TRCSTS is not 01).Or, Flush the Tx FIFO for faster empty operation.
4. Disable the MAC transmitter by clearing Bit 1(TE) of the MAC_Configuration Register.
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TxQ0_Debug Register and RXQSTS is 0 in MTL_RxQ0_Debug Register).
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers.
7. Restart the operation by starting the Tx DMA, and then enabling the MAC Transmitter and Receiver.

44.3.18.8.2 Transmit and Receive Clocks Stopped when Link Down

When the Link is down and the clocks are stopped, you need to disable the MAC Transmitter and Receiver, wait until clocks are restored, wait for completion of transfer (in progress when clocks stopped), read PHY registers to determine latest operation mode and program the MAC registers, and then restart MAC Transmitter and Receiver.

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

Note: The steps are provided for Channel 0.

Steps

1. Disable the MAC Transmitter and Receiver by clearing bits RE and TE of MAC_Configuration Register. This does not take effect immediately as the clocks are absent.
2. Wait until the link is up and the clocks are restored.
3. Wait for the completion of the transfer of any partial frame, if any, at time of stopping of Transmit/Receive clock. This can be checked by reading the MAC_Debug Register (should be all-zero). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

44.3.18.9 Programming Guidelines for IEEE 1588 Timestamping

There are several programming tasks that can be performed after you enable the IEEE 1588 Timestamping feature: initializing timestamp counter, synchronizing or updating system time in one process, and synchronizing or updating system time to reduce system-time jitter.

There are three programming tasks that can be performed after you have enabled the IEEE 1588 Timestamping feature:

- Initializing the timestamp counter
- Synchronizing or updating the system time in one process (coarse correction method)
- Synchronizing or updating the system time to reduce system-time jitter (fine correction method)

44.3.18.9.1 Initialization Guidelines for System Time Generation

During the initialization of the DWC_ether_qos controller, you can enable the timestamp feature.

You can enable the timestamp feature by setting Bit 0 of the MAC_Timestamp_Control Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during initialization:

Steps

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_Interrupt_Enable Register.
2. Set Bit 0 of MAC_Timestamp_Control Register to enable timestamping.
3. Program MAC_Sub_Second_Increment Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_Timestamp_Control Register.
5. Poll the MAC_Timestamp_Control Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_Timestamp_Control Register to select the Fine Update method (if required).
7. Program MAC_System_Time_Seconds_Update Register and MAC_System_Time_Nanoseconds_Update Register with the appropriate time value.
8. Set Bit 2 in MAC_Timestamp_Control Register.
   The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers.
   If one-step timestamping is enabled
   a) To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b) Program registers MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
9. Enable the MAC receiver and transmitter for proper timestamping.

Example

Note: If timestamp operation is disabled by clearing Bit 0 of MAC_Timestamp_Control Register, you need to repeat all these steps to restart the timestamp operation.

44.3.18.9.2 Updating System Time in One Process

You can synchronize or updated the system time in one process by programmiing the Timestamp Update registers.

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

Steps

1. Set the offset (positive or negative) in the Timestamp Update registers (MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update).
2. Set Bit 3 (TSUPDT) of the MAC_Timestamp_Control Register.
   The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

44.3.18.9.3 Updating System Time to Reduce System-Time Jitter

You can program the DWC_ether_qos controller to synchronize or update the system time to reduce system-time jitter, which is known as fine correction method).

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

Steps

1. With the help of the algorithm explained in the “System Time Register Module” section, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_Timestamp_Addend with the new value and set Bit 5 of the MAC_Timestamp_Control Register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds Register and MAC_PPS[n]_Target_Time_Nanoseconds Register.
5. Enable the Timestamp interrupt in bit 12 of MAC_Interrupt_Enable register.
6. Set bit 4 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_Interrupt_Status Register.
8. Reprogram MAC_Timestamp_Addend Register with the old value and set bit 5 again.

44.3.18.10Programming Guidelines for AV Feature

There are several programming tasks you can perform after you enable the AV Feature: initializing the DMA (QOS-AHB configuration only), enabling slot number checking, enabling average bits per slot reporting, and disabling flow control for AV-enabld queues.

After you enable the AV feature in the DWC_ether_qos controller, there are several programming tasks to be followed:

- Initialzing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

44.3.18.10.1 Initializing the DMA

The first step in programming the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence only for QOS-AHB configuration with AV feature.

Steps

1. Provide a software reset to reset all QOS internal registers and logic (bit 0 in DMA_Mode register).
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_Mode register), which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_Mode register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.
5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).
8. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register:
   a) Transmit Store And Forward (TSF)
   b) Transmit Threshold Control (TTC)
   c) Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queu
   d) Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register and bit 0 of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register.

44.3.18.10.2 Enabling Slot Number Checking

You can enable slot number checking feature if you want to specify the intervals at which the DMA channels mapped to AV Queues fetch the frames from the AHB/AXI system bus.

Before you begin

These steps should be completed after step 11 and before step 12 of “Initializing DMA”.

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AHB/AXI system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable timestamping and program the MAC_Sub_Second_Increment register. Complete the following steps to enable the slot number checking:

Steps

1. Enable timestamping by following the steps described in “Initialization Guideline for System Time Generation”.
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).
3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

44.3.18.10.3 Enabling Average Bits Per Slot Reporting

You can enable the ability to report the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

Steps

1. Enable timestamping by following the steps described in the “Initialization Guideline for System Time Generation” section.
2. Program Bits [6:4], SLC, of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

   Note: The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.

   Note: When not required, you can disable this interrupt to stop the interrupt flooding.
4. Read Bits [16:0], ABS, from the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

   Note: The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register indicates that a new value is updated in the ABS field.

44.3.18.10.4 Disabling Transmit Flow Control for AV Enabled Queues

You can disable the transmit flow control for the AV-enabled queue.

You can disable the transmit flow control for the AV-enabled queues, as follows:

- Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RxQ[n]_Operation_Mode register to 0.

44.3.18.10.5 Disabling Receive Flow Control for AV Enabled Queues

You can disable the receive flow control for the AV-enabled queue.

You can disable the receive flow control for the AV-enabled queues, as follows:

- Program the PSTQ[n] field corresponding to AV enabled Tx Queue in MAC_TxQ_Prty_Map0/1 register to 0.

44.3.18.11Programming Guidelines for Energy Efficient Ethernet

There are several programming tasks you can perform for the Energy Efficient Ethernet (EEE) feature: entering and exiting Tx LPI mode, and gating off CSR clock in LPI mode.

After you enable the Energy Efficient Ethernet (EEE) in the DWC_ether_qos controller, you can program the following:

- Entering and Exiting Tx LPI mode during the QoS initialization
- Gating off the CSR clock in the Rx LPI mode
- Gating off the CSR clock in the Tx LPI mode

44.3.18.11.1 Entering and Exiting the Tx LPI Mode

Energy Efficient Ethernet (EEE) enables the IEEE 802.3 Media Access Control (MAC) sub layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. In the Transmit path, the software must set the LPIEN bit of the MAC_LPI_Control_Status register to indicate to the MAC to stop transmission and initiate the LPI protocol. You can configure the Energy Efficient Ethernet (EEE) feature in coreConsultant while initializing the core.

Before you begin

Complete the following steps during QoS core initialization:

Steps

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode.)
3. Program Bits[25:16] and Bits[15:0] in MAC_LPI_Timers_Control Register.
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 of MAC_LPI_Control_Status accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Program the MAC_1US_Tic_Counter as per the frequency of the clock used for accessing the CSR slave port.
9. Program the MAC_LPI_Entry_Timer register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
10. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_Control_Status register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
11. Set Bit 16 of MAC_LPI_Control_Status Register to make the MAC Transmitter enter the LPI state.
12. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.
13. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
14. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.

Example

Notes

1. *To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the Tx FIFO, you should set Bit 19 in MAC_LPI_Control_Status Register.*
2. *To switch off the GMII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.*
3. *To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of MAC_LPI_Control_Status Register to be generated. Restore the clocks before performing step 6 when you want to come out of the LPI state.*

44.3.18.11.2 Gating Off the CSR Clock in the Rx LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode. In the Rx LPI mode, the MAC RX enters the LPI mode and the RX LPI interrupt is set. The interrupt pin is asserted and cleared when the host reads the MAC LPI Control Status register.

Before you begin

The following operations are performed when the MAC receives the LPI pattern from the PHY:

Steps

1. The MAC RX enters the LPI mode and the Rx LPI entry interrupt status [RLPIEN interrupt of MAC_LPI_Control_Status Register] is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the MAC_LPI_Control_Status Register.

Example

After the sbd_intr_o interrupt is asserted and the MAC Tx is also in the LPI mode, you can gate-off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR.

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when MAC_LPI_Control_Status Register is read.

44.3.18.11.3 Gating Off the CSR Clock in the Tx LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode. To gate off the CSR Clock in the Tx LPI mode, the Transmit LPI Entry interrupt is set and the interrupt pin is asserted.

Before you begin

The following operations are performed when Bit 16 (LPIEN) of MAC_LPI_Control_Status is set:

Steps

1. The Transmit LPI Entry interrupt (TLPIEN bit of MAC_LPI_Control_Status Register) is set.
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the MAC_LPI_Control_Status Register.

Example

After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR.

For restoring the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. After the CSR clock is resumed, reset Bit 16 (LPIEN) of MAC_LPI_Control_Status Register to bring the MAC out of the LPI mode.

44.3.18.12Programming Guidelines for Flexible Pulse-Per-Second Output

There are several programming tasks related to the Flexible Pulse-Per-Second (PPS) Output: generating single pulse on PPS, generating pulse train on PPS, and generating an interrupt without affecting PPS.

After you enable the Flexible Pulse-Per-Second Output feature in the DWC_ether_qos controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS, see **Note on Page 155**
- Generating a Pulse Train on PPS

- Generating an Interrupt without Affecting the PPS

44.3.18.12.1 Generating Single Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To generate a single pulse on PPS, program the MAC_PPS_Control and Target Time registers, and also program the start time value and the width of the PPS signal output. Finally, set the MAC_PPS_Control register to generte a single pulse on the PPS signal output.

Complete the following steps to generate single pulse on PPS:

Steps

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers (register MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (register MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the width of the PPS signal output in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_Control to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

44.3.18.12.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse, following is the procedure:

Steps

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1).
3. Program Bits [3:0], PPSCMD, of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.
   If you give this command before the previous pulse becomes low, then the new command overwrites theprevious command and the QOS may generate only 1 extended pulse.

44.3.18.12.3 Generating a Pulse Train on PPS

The DWC_ether_qos provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. To generate a pulse train on the pulse per second (PPS), program the MAC_PPS_Contro and Target Time l register, set the interval between the train of pulses on the PPS signal output. Further, program the width of the PPS signal output, set the MAC_PPS_Control register and program the stop value in the Target Time register. Finally, program the stop value in the Target Time registers.

Complete the following steps to generate a pulse train on PPS:

Steps

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers (register 736 and 737) for start time of the PPS signal output.
2. Program the start time value in the Target Time registers (register 736 and 737).
3. Program the interval value between the train of pulses on the PPS signal output inMAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program the width of the PPS signal output in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_Control Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.
   By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands.
6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 3:0) of MAC_PPS_Control to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

Example

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

44.3.18.12.4 Generating an Interrupt without Affecting the PPS

The MAC_PPS_Control register enable you to set the Target Time registers to generate interrupts, to generate interrupts and the ppps start and stop time, or to generate only the pps start and stop time. This topic discusses the procedure to generate only an interrupt event.

The Bits [6:5], TRGTMODSEL, of the MAC_PPS_Control Register enable you to program the Target Time registers (register 736 and 737) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Complete the following steps to program the Target Time registers to generate only interrupt event:

Steps

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.
   If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is over-written with the new mode and new programmed Target Time register value.

44.3.18.13Programming Guidelines for Split Header on Receive

Split Header support is an optional feature that you can enable by selecting the Enable Split Header Feature option and by setting the SPH bit in the DMA_CH#_Control register. The DMA can process the header and payload of received packets separately.

When split header support is enabled, the buffer 1 (RDES0) of the descriptors is used only for the header. Therefore the DMA writes the header of the received packet in buffer 1 when FD bit of RDES3 is set. The payload of the received packet is directed to the buffer2 (RDES2).

For subsequent descriptors (FD is set to 0), buffer1 is not used and the payload is written only to buffer 2. When the host enables split header structure by setting the SPH Bit[24] of register DMA_CH[n]_Control_register, the host must ensure that Buffer1 is always valid in all descriptors by creating Buffer1 and indicating this by setting Bit[24] (BUF1V) of RDES3 for all descriptors.

44.3.18.14Programming Guidelines for VLAN filtering on Receive

In VLAN tag filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

Complete the following steps to program VLAN filtering on receive:

Steps

1. Program MAC_VLAN_Tag register for the following bit to select the filtering method:
   a) ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   b) VTHM: VLAN Tag Hash Table Match Enable.
   c) ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   d) ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   e) DOVLTC: Ignores VLAN Type for Tag Match
   f) VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching
2. Program VL of MAC_VLAN_Tag Register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_Hash_Table Register. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. To help you program the hash table, a sample C routine that generates a VLAN tag's 4-bit hash is included in resources/sample_codes/ directory of your workspace.

44.3.18.15Programming Guidelines for Extended VLAN Filtering and Routing on Receive

44.3.18.15.1 Programming Guidelines for Extended VLAN Filtering and Routing on Receive - Write

In the extended VLAN filtering, perfect filtering is done for the VLAN Tag Filters and for each VLAN Tag Filter, the VLAN Tag ID is compared. The combined result of all the enabled VLAN Tag Filters determines the overall VLAN Tag Filter result. The filter result is passed to the application as part of the status bits.

For the indirect access of the per VLAN Tag registers, follow these steps to write into the registers:

Steps

1. Write the required data into the MAC VLAN Tag Data register.
2. Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
3. Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.

44.3.18.15.2 Programming Guidelines for Extended VLAN Filtering and Routing on Receive - Read

In the extended VLAN filtering, perfect filtering is done for the VLAN Tag Filters and for each VLAN Tag Filter, the VLAN Tag ID is compared. The combined result of all the enabled VLAN Tag Filters determines the overall VLAN Tag Filter result. The filter result is passed to the application as part of the status bits. To read from each VLAN Tag register, set the OFS field in the VLAN Tag Control Register and set the OB field.

For the indirect access of the per VLAN Tag registers, follow these steps to read from the registers:

Steps

1. Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
2. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

44.3.18.16Programming sequence for Queue/Channel Based VLAN Inclusion Register

To program the queue/channel-based VLAN inclusion register, complete the following steps:

Note: Indirect VLAN include registers are not accessed while setting the CBTI bit.

Steps

1. Set the CBTI bit of MAC_VLAN_Incl register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_Incl(#i) register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_Incl register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl register initiates access to indirect access MAC_VLAN_Incl(#i) register.
3. The BUSY bit of MAC_VLAN_Incl register is set by DWC_ether_qos to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. On completion of the access, the BUSY bit is cleared. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

44.3.19 Definition of the PHY Interfaces MII, RMII and RGMII

The module has up to 3 PHY interfaces. Some products may contain less.

Table 500 PHY Interfaces of Gigabit Ethernet MAC

IF	Signal Name in Standard	GETH Signal Name	I/O
MII	TX_EN	TXEN	O
	TXD[3:0]	TXD[3:0]	O
	TX_ER	TXER	O
	TX_CLK	TXCLK	I
	COL	COL	I
	CRS	CRS	I
	RX_DV	RXDV	I
	RXD[3:0]	RXD[3:0]	I
	RX_ER	RXER	I
	RX_CLK	RXCLK	I

Table 500 PHY Interfaces of Gigabit Ethernet MAC (cont'd)

IF	Signal Name in Standard	GETH Signal Name	I/O
RMII	TX_EN	TXEN	O
	TXD[1:0]	TXD[1:0]	O
	CRS_DV	CRSDV	I
	RXD[1:0]	RXD[1:0]	I
	REF_CLK	REFCLK	I
RGMII	TD[3:0]	TXD[3:0]	O
	TX_CTL	TCTL	O

44.4 Functional Specifications for Flexible Header Feature (FHE)

44.4.1 Overview of Feature

- Programmable control to enabled/disable Flexible Header Feature
- The Flexible Header position is fixed within the Ethernet packet
  - After 12 bytes from the start of packet data (After MAC SA field in the Ethernet packet)
  - This Header Length is fixed to 4 bytes .
- All the packets (from Application on Tx path and from Line on the Rx path) will have this Flexible Header
  - The Pause/PFC frames are sent/received without this Flexible Header as Pause/PFC is link to link communication generated and consumed at MAC Layer.
- All the existing offload features of the QOS IP like COE, IEEE 1588 PTP, VLAN tagging, Packet filtering and queueing based on L2/L3/L4 headers, etc. will be transparently supported when the FH is present.
- PTP Offload (Automatic generation of SYNC, Delay_Resp, Pdelay_Req, and Pdelay_Resp PTP packets in the Transmit path) features will not be supported when Flexible Header feature is enabled.

44.4.1.1 Trasmit Path Features

- The application/software will insert the Header inside the packet to be transmitted at the correct location
- The Hardware parser logic in TxCOE is modified to be aware of the presence of this additional header
- The VLAN/SA Insertion/Replacement/Deletion features are supported in the presence of Flexible Header
- The IEEE 1588 based One-step timestamping (OST) feature supported in the presence of Flexible Header
- The application/host software must ensure that the minimum and maximum Ethernet packet size rules are not violated after the insertion of the FH field. The MAC Transmitted will include every packet byte (including FH) in the updation of RMON counters
- The Ethernet CRC computation must include the FH field for all the frames that have the FH field after SA.

44.4.1.2 Receive Path Features

- In this mode, the MAC Receiver will always strip the 4 Bytes of Flexible Header present after the MAC SA field and provides the 4B Flexible Header as a packet status for all incoming Rx packets (except Pause/PFC frames)
- For Pause/PFC frames, DUT checks for the presence of MAC DA to be 01:80:C2:00:00:01 else it will be considered as non-pause/non-PFC frame for which Flexible header after MAC SA will always be stripped. This means that “Unicast” PAUSE/PFC will not be supported in this mode.
- The hardware parser logic in RxCOE (L2/VLAN/L3/L4 filter) is aware of the Flexible Header.
- Double VLAN tagging mode will be supported even when FH field is present. The 4B of FH will be provided in the Descriptor Status field by the Receive DMA after transferring the packet to the host memory.
- The RMON counters in the MAC Receiver will count the FH bytes as part of the Ethernet packet received.
- The MAC Receiver will continue to check for the same min/max packet size rules, irrespective of the presence of the FH bytes.
- The Ethernet CRC received on the line must include the FH field for all the frames that have FH field.

NOTE: VLAN Tag in Rx Status feature is not supported when Flexible Header feature is used, as the corresponding Rx Packet status field is used to give the 4B of FH instead of the VLAN Tags. VLAN stripping feature is supported, for use cases where the VLAN fields can be used for routing and subsequently stripped.

44.4.2 Functional Description of the FHE Functionality

The flexible header functionality is enabled in both Transmit and Receive directions when bit[31] (FHE) of the MAC_Ext_Configuration register is set to 1. When this is enabled, all the incoming packets (from Application on Tx path and from Line on the Rx path) must have this Flexible Header. Hence this bit must be set only once during initialization, before any Transmit DMA is started or MAC Receiver is enabled. Otherwise, a mix of packets with and without FH will be present in the data-paths.

44.4.2.1 Transmit Checksum Offload Engine (TxCOE)

When the Flexible Header functionality is enabled, the TxCOE engine will consider the 4B Flexible header as a part of Ethernet Header (6 DA + 6 SA + 4 FH = 16 bytes total) and look for Type/Length/VLAN fields from Byte 17 onwards in the Ethernet packet.

44.4.2.2 Transmit SA/VLAN Insertion/Replacment

The Flexible Header is assumed to be present after MAC SA (incase of SA Insertion is not enabled) and after the MAC DA (in case SA Insertion is enabled).

The VLAN Insertion/Replacement/Deletion point will be after the Flexible Header field.

44.4.2.3 PTP One_Step Processing

When the Flexible Header functionality is enabled , the PTP Type is decoded assuming the EtherType/Tag starts after the Flexible Header (Flexible header is assumed to be after MAC SA). So, determining the PTP Type (without Tag, with Single Tag or Double Tag) is done accordingly.

When PTP Over UDP/IP is enabled, the Correction field offset is determined by TxCOE engine which parses the Tx packet and offset determination is based on presence of the Flexible header.

44.4.2.4 Transmit Pad Insertion

When Flexible Header functionality is enabled then Padding is appended only when total packet size is less than 60B including Flexible header. Note that padding is done only when CPC[1:0] (Pad CRC Control is set to 2'b00).

44.4.2.5 Transmit Packet Length implication

When Flexible Header functionality is enabled then the following limits are determined by including Flexible header as part of packet data

- Jabber Limit
- Carrier Extension
- Collision Window

All the management (RMON/MMC) counters consider Flexible header as part of packet data.

There is no impact of the FH in any of the other Transmit functions like TX Scheduler (CBS, DWRR, WFQ algorithms). These functions use only the total length of Ethernet packet for their calculations for which the FH is taken as part of the total packet.

The Transmit PAUSE/PFC packet generator will operate as usual and will not insert any FH in the generated PAUSE/PFC packet.

44.4.2.6 Receive Status

When the Flexible Header feature is enabled, the VLAN status in the Rx Descriptor in DMA configurations and VLAN Status in MTL configurations will not be provided and instead the 4B stripped Flexible header of the received packets will be provided in those fields.

As VLAN Status in the Rx Status is not be supported when Flexible Header feature is enabled, the EIVLRXS and EVLRXS fields of MAC_VLAN _Tag_Ctrl will be ignored and treated as always "0".

44.4.2.7 MAC Receiver functions and offloads

When the Flexible Header functionality is enabled, the MAC Receiver will consider the 4B Flexible Header as a part of Ethernet Header. Hence it will look for the Ethernet Type/VLAN Tag from Byte 17 of the received packet instead of Byte 13.

Hence all offload functions like Type/VLAN-/L3-/L4-header based filtering and queueing, PTP/AVTP/OAM packet processing, will look for their corresponding header fields at an offset of 4 Bytes as compared to the normal mode (FH mode is disabled).

The only exception is when the DA field = 01:80:C2:00:00:01 (Special multicast address) in the received packet. Such packets will be parsed for PFC/PAUSE control fields in the usual position assuming that FH field is absent even when FH mode is enabled.

Note that the RMON Octet counters (MAC layer) will count the FH as part of the packet length. Similarly, the maximum packet size rule checks will consider FH as part of the Ethernet packet for consideration.

44.4.3 High Level Microarchitecture

44.4.3.1 Tx Side

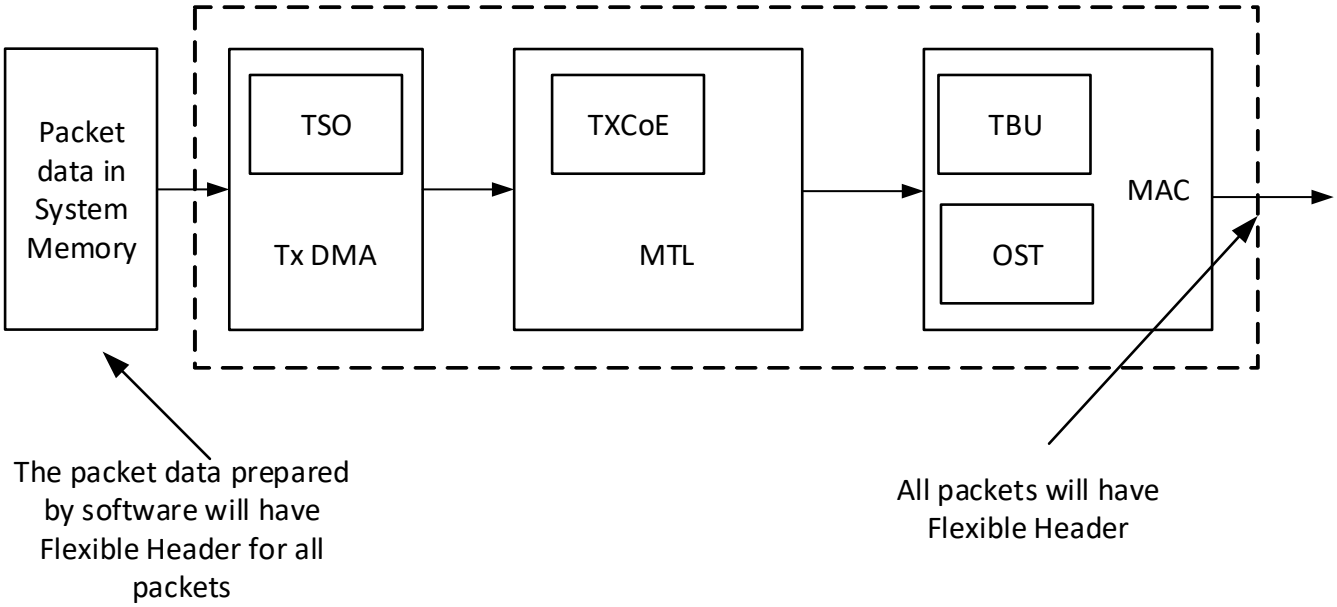

Figure 720 Tx Flow

On Tx side, all the packets initiated by the software will have Flexible Header when the FHE bit in MAC_Ext_Configuration register is set. The TxCOE engines assume 4B flexible header after MAC SA as a part of Ethernet header. The TBU block in the MAC takes are of SA/VLAN insertion/replacement in the presence of the Flexible Header. It also identifies the start of the PTP Header for PTPover Ethernet packet during One-step Timestamping.

Hence the RTL Design changes are limited to these blocks – TxCOE, OST & TBU.

44.4.3.2 Rx Side

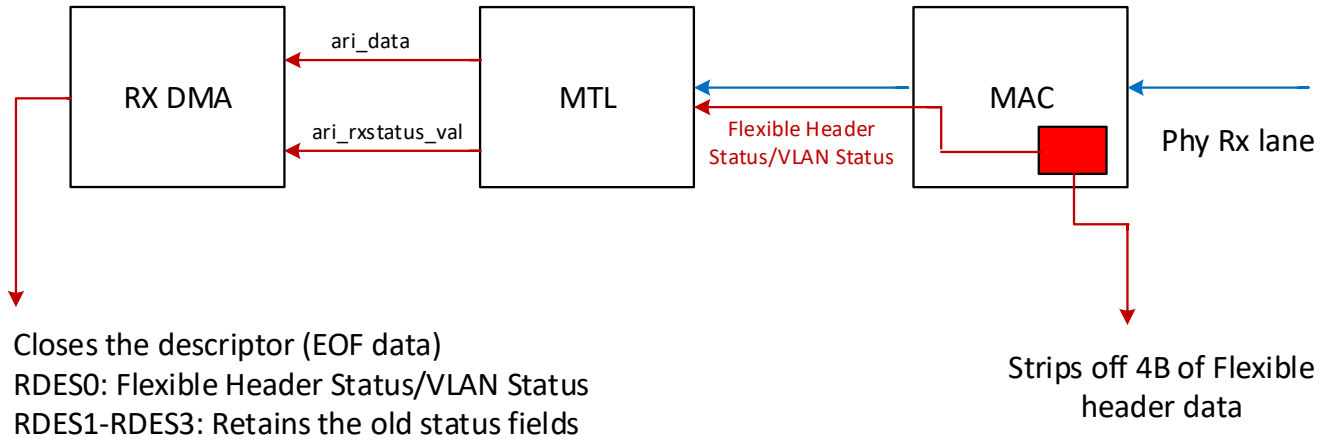

Figure 721 Rx Flow

For the incoming Rx packets, the 4B Flexible header after SA is stripped in the MAC if the FHE field of MAC_Ext_Configuration register is set. Pause/PFC packets are assumed not to have a Flexible header and hence no stripping is done. The stripped data is provided as one of the Status word to MTL.

Hence, the main RTL/Design changes are restricted to RPE and RRPE blocks.

- In the RRPE module the FH is stripped and the rest of packet given to all the other functions.
- In the RPE module the stripped/extracted FH is made part of the Rx Status.

44.4.4 DMA Descriptors / MTL Status

44.4.4.1 Receive Descriptor (DMA Configuration)

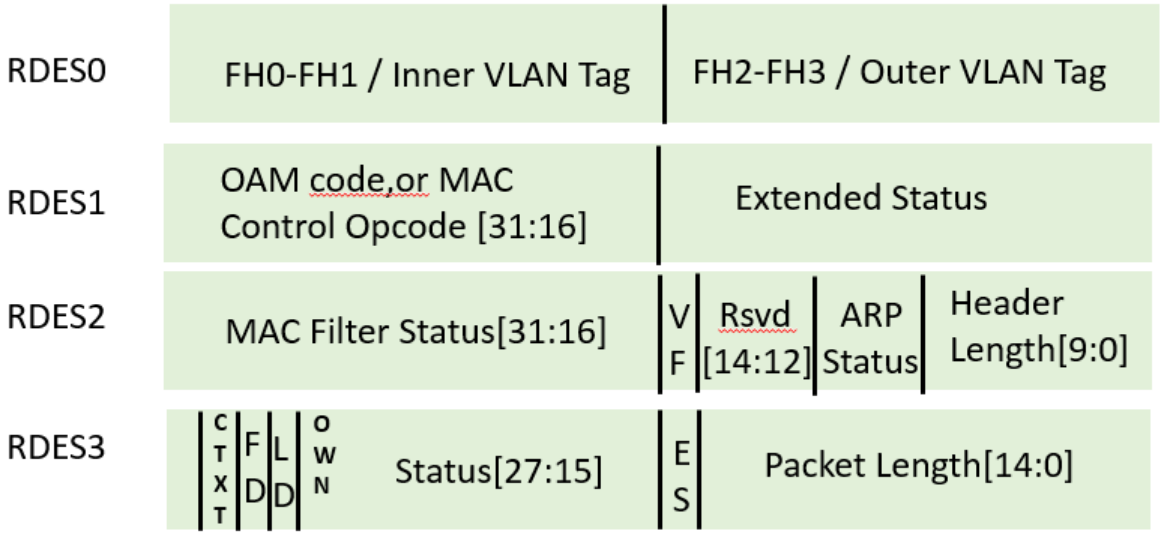

Figure 722 Receive Descriptor (DMA Configuration)

When FHE bit of MAC_Ext_Configuration register is set, then the stripped 4B Flexible header data (FH0,FH1,FH2,FH3 in the order the header bytes arrive at the Rx lane) will be provided in the RDES0 during Rx descriptor write back.

44.4.4.2 ARI Status (MTL Configuration)

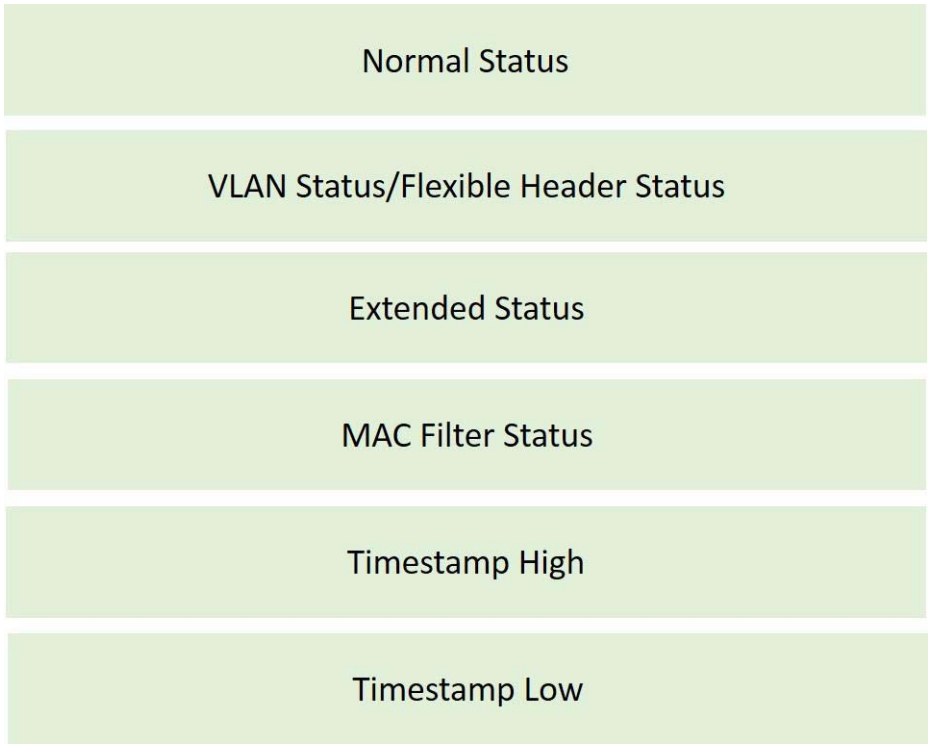

Figure 723 ARI Status (MTL Configuration)

When FHE bit is enabled in the configuration then the stripped 4B Flexible header data is provided in the second status word in the place of VLAN status.

Flexible Header Status:

If FHE bit of MAC_Ext_Configuration register is set then 4B of Flexible header after SA is stripped from the incoming Rx packets and provided in this status word.

Table 501

Field	Description
31:00	Flexible Header
	This field indicates the stripped Flexible Header data.
	Data presented as {FH0,FH1,FH2,FH3} in the same order the header bytes arrive on the line.

44.4.5 Software Initialization and Guidelines

The FHE bit in the MAC_Ext_Configuration should be enabled/disabled only when the MAC Transmitter and Receiver, all Transmit DMA are disabled and no packets are in the pipeline.

The MAC Tx and Rx can be disabled by setting 0 on bit[0] (RE) and bit[1] (TE) of the MAC_Configuration register.

The packets not being in the design pipeline can be checked by monitoring the

- MTL_TXQn_Debug register(s)
- MTL_RXQn_Debug register(s)
- DMA_Debug_Status0/1/2 registers

44.5 Registers

General notes on registers:

- All CSRs are implemented as 32-bit registers and can be accessed in 1 read/write cycle with a 32-bit MCI interface (or 32-bit AHB slave port). If you initiate a non-32-bit register access, the byte enable signals (mci_be_i[3:0]) qualify the corresponding register bytes. Only write operations are qualified with byte enables, while read operations are always 32-bit, unless the register is affected by a read operation. Byte enable signals qualify reads to such registers as, for example, the MMC counter registers.
- The transfer of particular register contents (e.g., MAC DA address register) to the Transmit or Receive clock domains are initiated when a particular byte is written. This is indicated in the register descriptions, where applicable.
- After a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 6 cycles of the destination clock (PHY receive clock or PHY transmit clock).

44.5.1 Register Description

Accesses to reserved addresses (part of the address space but no register defined) will generate a bus error (BE).

All registers in the DMA and MAC Registers map (offset 0000_H - $1FFC_H$) are P = ACCEN protected. The DMA registers for additional Module Control are ACCEN protected according to separate table below.

All registers in the GETH address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

Register Overview Tables of GETH

44.5.1.1 GMAC Registers

MAC Configuration Register

The MAC Configuration Register establishes the operating mode of the MAC.

MAC_CONFIGURATION
MAC Configuration Register **(0000_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES_31		SARC		IPC		IPG		GPSLCE	S2KP	CST	ACS	WD	BE	JD	JE
r		rw		rw		rw		rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PS	FES	DM	LM	ECRSFD	DO	DCRS	DR	RES_7	BL		DC	PRELEN		TE	RE
rw	rw	rw	rw	rw	rw	rw	rw	r	rw		rw	rw		rw	rw

Field	Bits	Type	Description
RE	0	rw	**Receiver Enable** When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. Value After Reset: 0x0
TE	1	rw	**Transmitter Enable** When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. Value After Reset: 0x0
PRELEN	3:2	rw	**Preamble Length for Transmit packets** These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. Value After Reset: 0x0 00_B 7 bytes of preamble 01_B 5 bytes of preamble 10_B 3 bytes of preamble 11_B Reserved

Field	Bits	Type	Description
DC	4	rw	**Deferral Check** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. Value After Reset: 0x0
BL	6:5	rw	**Back-Off Limit** The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. where n = retransmission attempt The random integer r takes the value in the range 0 <= r < 2^k Value After Reset: 0x0 00_B 01_B k = min (n, 8) 10_B k = min (n, 4) 11_B k = min (n, 1)
RES_7	7	r	**Reserved** Value After Reset: 0x0
DR	8	rw	**Disable Retry** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. Value After Reset: 0x0

Field	Bits	Type	Description
DCRS	9	rw	**Disable Carrier Sense During Transmission** When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. Value After Reset: 0x0
DO	10	rw	**Disable Receive Own** When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. Value After Reset: 0x0
ECRSFD	11	rw	**Enable Carrier Sense Before Transmission in Full-Duplex Mode** When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. Value After Reset: 0x0
LM	12	rw	**Loopback Mode** When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. Value After Reset: 0x0
DM	13	rw	**Duplex Mode** When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. Value After Reset: 0x0
FES	14	rw	**Speed** This bit selects the speed mode: The mac_speed_o[0] signal reflects the value of this bit. Value After Reset: 0x0 0_B 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1_B 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
PS	15	rw	**Port Select** This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. Value After Reset: 0x0 0_B For 1000 Mbps operations or 2500 Mbps operations$_B$ 1_B For 10 or 100 Mbps operations $_B$

Field	Bits	Type	Description
JE	16	rw	**Jumbo Packet Enable** When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. Value After Reset: 0x0
JD	17	rw	**Jabber Disable** When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. Value After Reset: 0x0
BE	18	rw	**Packet Burst Enable** When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. Value After Reset: 0x0
WD	19	rw	**Watchdog Disable** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. Value After Reset: 0x0
ACS	20	rw	**Automatic Pad or CRC Stripping** When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. **Note**: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . Value After Reset: 0x0
CST	21	rw	**CRC stripping for Type packets** When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. **Note**: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. Value After Reset: 0x0

Field	Bits	Type	Description
S2KP	22	rw	**IEEE 802.3as Support for 2K Packets** When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the table, Giant Packet Status based on S2KP and JE Bits. **Note**: When the JE bit is set, setting this bit has no effect on the giant packet status. Value After Reset: 0x0
GPSLCE	23	rw	**Giant Packet Size Limit Control Enable** When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. Value After Reset: 0x0
IPG	26:24	rw	**Inter-Packet Gap** These bits control the minimum IPG between packets during transmission. LOST SEQUENCE DEFINITION This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_Ext_Configuration register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. Value After Reset: 0x0 000_B 96 bit times 001_B 88 bit times 010_B 80 bit times 111_B 40 bit times

Field	Bits	Type	Description
IPC	27	rw	**Checksum Offload** When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. Value After Reset: 0x0
SARC	30:28	rw	**Source Address Insertion or Replacement Control** This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: **Note**: • Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. Value After Reset: 0x0 000_B The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 001_B The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 010_B If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets.If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets. 011_B If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets.If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets.
RES_31	31	r	**Reserved for future use.**

MAC Extended Configuration Register

The MAC Extended Configuration Register establishes the operating mode of the MAC.

MAC_EXT_CONFIGURATION

MAC Extended Configuration Register **(0004_H)** **Application Reset Value: $0000\ 0000_H$**

RES_15_14		GPSL													
r		rw													

Field	Bits	Type	Description
GPSL	13:0	rw	**Giant Packet Size Limit** If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_Configuration register. Value After Reset: 0x0
RES_15_14	15:14	r	**Reserved** Value After Reset: 0x0
DCRCC	16	rw	**Disable CRC Checking for Received Packets** When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. Value After Reset: 0x0
SPEN	17	rw	**Slow Protocol Detection Enable** When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. Value After Reset: 0x0

Field	Bits	Type	Description
USP	18	rw	**Unicast Slow Protocol Packet Detect** When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5. Value After Reset: 0x0
RES_19	19	r	**Reserved** Value After Reset: 0x0
HDSMS	22:20	rw	**Maximum Size for Splitting the Header Data** These bits indicate the maximum header size allowed for splitting the header data in the received packet: 101_B-111_B Reserved If the Enable Split Header Structure option is not selected, these bits are reserved and read-only (RO). Value After Reset: 0x0 000_B 64 bytes 001_B 128 bytes 010_B 256 bytes 011_B 512 bytes 100_B 1024 bytes
RES_23	23	r	**Reserved** Value After Reset: 0x0
EIPGEN	24	rw	**Extended Inter-Packet Gap Enable** When this bit is set, the MAC interprets EIPG field and IPG field in MAC_Configuration register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in MAC_Configuration register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. Value After Reset: 0x0

Field	Bits	Type	Description
EIPG	29:25	rw	**Extended Inter-Packet Gap** The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in MAC_Configuration register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times Value After Reset: 0x0
RES_30	30	r	**Reserved** Value After Reset: 0x0
FHE	31	rw	**Flexible Header Enable** When this is set then it is expected that all the incoming packets from the Line to have 4B Flexible Header in the Rx path (except for the pause and PFC packets). Similarly, in the Tx path all the packets from application are expected to have 4B Flexible header. The position of the Flexible Header is always fixed at 12Bytes from the beginning of the packet (after MAC DA/SA).

MAC Packet Filter Register

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

MAC_PACKET_FILTER
MAC Packet Filter Register **(0008_H)** **Application Reset Value: $0000\ 0000_H$**

r					r	rw	rw	rw		rw	rw	rw	r		rw

Field	Bits	Type	Description
PR	0	rw	**Promiscuous Mode** When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. Value After Reset: 0x0

Field	Bits	Type	Description
RES_2_1	2:1	r	**Reserved**
DAIF	3	rw	**DA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. Value After Reset: 0x0
PM	4	rw	**Pass All Multicast** When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. Value After Reset: 0x0
DBF	5	rw	**Disable Broadcast Packets** When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. Value After Reset: 0x0
PCF	7:6	rw	**Pass Control Packets** These bits control the forwarding of all control packets (including unicast and multicast Pause packets). Value After Reset: 0x0 00_B The MAC filters all control packets from reaching the application. 01_B The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. 10_B The MAC forwards all control packets to the application even if they fail the Address filter. 11_B The MAC forwards the control packets that pass the Address filter.
SAIF	8	rw	**SA Inverse Filtering** When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. Value After Reset: 0x0

Field	Bits	Type	Description
SAF	9	rw	**Source Address Filter Enable** When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. **Note**: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. Value After Reset: 0x0
RES_10	10	r	**Reserved**
RES_15_11	15:11	r	**Reserved** Value After Reset: 0x0
VTFE	16	rw	**VLAN Tag Filter Enable** When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. Value After Reset: 0x0
RES_19_17	19:17	r	**Reserved** Value After Reset: 0x0
RES_21_20	21:20	r	**Reserved**

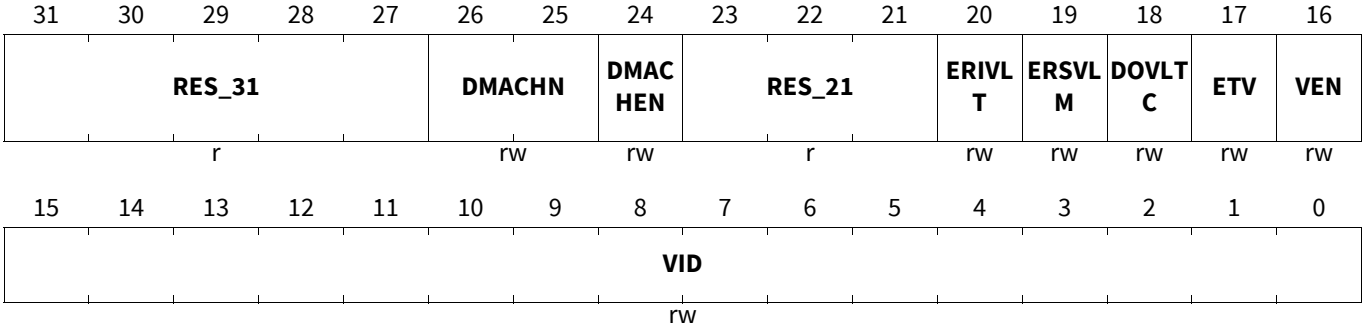
RES_19_20	20:19	r	**Reserved** Value After Reset: 0x0
EVLS	22:21	rw	**Enable VLAN Tag Stripping on Receive** This field indicates the stripping operation on the outer VLAN Tag in received packet: Value After Reset: 0x0 00_B Do not strip 01_B Strip if VLAN filter passes 10_B Strip if VLAN filter fails 11_B Always strip
RES_23	23	r	**Reserved** Value After Reset: 0x0
EVLRXS	24	rw	**Enable VLAN Tag in Rx status** When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. Value After Reset: 0x0
VTHM	25	rw	**VLAN Tag Hash Table Match Enable** When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. Value After Reset: 0x0
EDVLP	26	rw	**Enable Double VLAN Processing** When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). Value After Reset: 0x0
RES_27	27	rw	**Reserved** Value After Reset: 0x0
EIVLS	29:28	rw	**Enable Inner VLAN Tag Stripping on Receive** This field indicates the stripping operation on inner VLAN Tag in received packet: Value After Reset: 0x0 00_B Do not strip 01_B Strip if VLAN filter passes 10_B Strip if VLAN filter fails 11_B Always strip
RES_30	30	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
EIVLRXS	31	rw	**Enable Inner VLAN Tag in Rx Status** When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. Value After Reset: 0x0

MAC VLAN Tag Data Register

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

MAC_VLAN_TAG_DATA
MAC VLAN Tag Data Register **(0054_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
VID	15:0	rw	**VLAN Tag ID** This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set. Value After Reset: 0x0
VEN	16	rw	**VLAN Tag Enable** This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. Value After Reset: 0x0
ETV	17	rw	**12bits or 16bits VLAN comparison** This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Value After Reset: 0x0

Field	Bits	Type	Description
DOVLTC	18	rw	**Disable VLAN Type Comparison** This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. Value After Reset: 0x0
ERSVLM	19	rw	**Enable S-VLAN Match for received Frames** This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. Value After Reset: 0x0
ERIVLT	20	rw	**Enable Inner VLAN Tag Comparison** This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). Value After Reset: 0x0

DMACHN	26:25	rw	**DMA Channel Number** The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed. Value After Reset: 0x0
RES_31	31:27	r	**Reserved** Value After Reset: 0x0

MAC VLAN Hash Table Register

When the VTHM bit of the MAC_VLAN_Tag register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag Register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

Perform bitwise reversal for the value obtained in step 1.

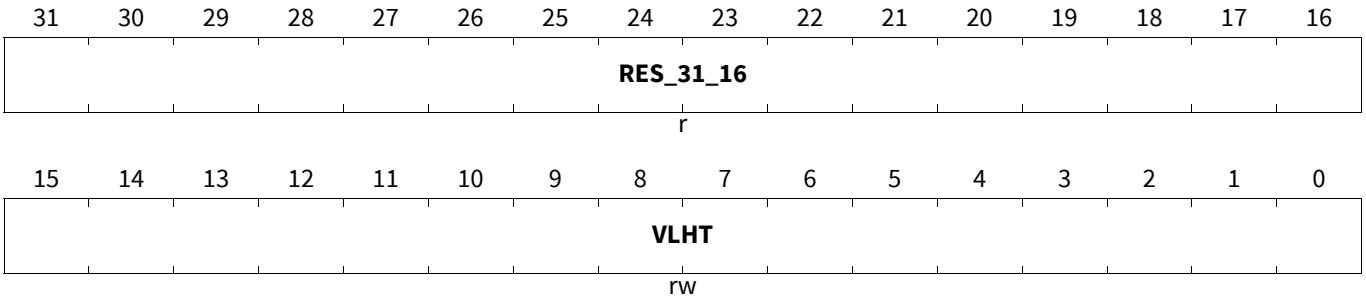
Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

MAC_VLAN_HASH_TABLE

MAC VLAN Hash Table Register (0058$_H$) Application Reset Value: 0000 0000$_H$



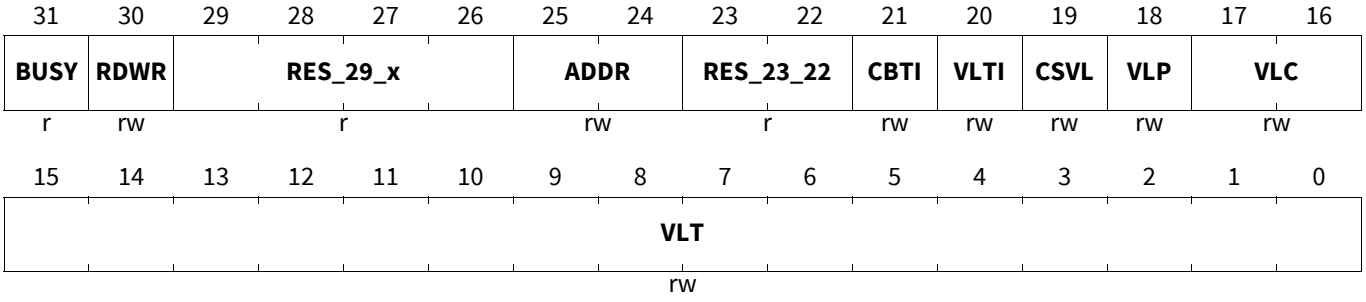
Field	Bits	Type	Description
VLHT	15:0	rw	**VLAN Hash Table** This field contains the 16-bit VLAN Hash Table. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MAC VLAN Tag Inclusion or Replacement Register

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

MAC_VLAN_INCL

MAC VLAN Tag Inclusion or Replacement Register(0060$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
VLT	15:0	rw	**VLAN Tag for Transmit Packets** This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: • Bits[15:13]: User Priority • Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • Bits[11:0]: VLAN Identifier (VID) field of VLAN tag Value After Reset: 0x0
VLC	17:16	rw	**VLAN Tag Control in Transmit Packets** **Note**: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. Value After Reset: 0x0 00_B No VLAN tag deletion, insertion, or replacement 01_B VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. 10_B VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 11_B VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8).
VLP	18	rw	**VLAN Priority Control** When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. Value After Reset: 0x0
CSVL	19	rw	**C-VLAN or S-VLAN** When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. Value After Reset: 0x0
VLTI	20	rw	**VLAN Tag Input** When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: • The Tx descriptor Value After Reset: 0x0

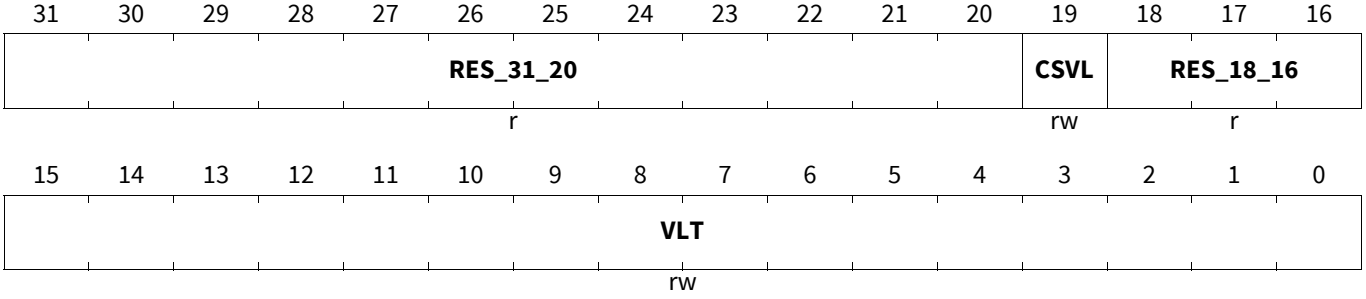
Field	Bits	Type	Description
CBTI	21	rw	**Channel based tag insertion** When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register Value After Reset: 0x0
RES_23_22	23:22	r	**Reserved** Value After Reset: 0x0
ADDR	25:24	rw	**Address** This field selects one of the queue/channel specific VLAN Inclusion register for read/write access This doesn't have any effect when CBTI is reset Value After Reset: 0x0
RES_29_x	29:26	r	**Reserved** Value After Reset: 0x0
RDWR	30	rw	**Read write control** This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation This doesn't have any effect when CBTI is reset Value After Reset: 0x0
BUSY	31	r	**Busy** Value After Reset: 0x0

MAC VLAN Tag Inclusion or Replacement Register per Queue

The Tx Queue x VLAN Tag Inclusion register contains the VLAN tag for insertion in the Transmit packets from Tx Queue x. It also contains the VLAN tag insertion controls.

MAC_VLAN_INCL_Q_i (i=0-3)

MAC VLAN Tag Inclusion or Replacement Register per Queue(0060_H) Application Reset Value: $0000\ 0000_H$



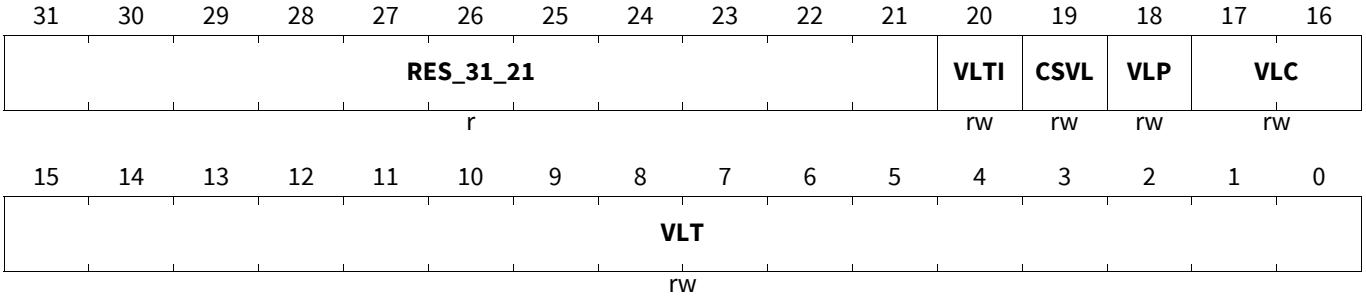
Field	Bits	Type	Description
VLT	15:0	rw	**VLAN Tag for Transmit Packets** This field contains the value of the VLAN tag to be inserted. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: • Bits[15:13]: User Priority • Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • Bits[11:0]: VLAN Identifier (VID) field of VLAN tag Value After Reset: 0x0
RES_18_16	18:16	r	**Reserved** Value After Reset: 0x0
CSVL	19	rw	**C-VLAN or S-VLAN** When this bit is set, S-VLAN type (0x88A8) is inserted in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted in the 13th and 14th bytes of transmitted packets. Value After Reset: 0x0
RES_31_20	31:20	r	**Reserved** Value After Reset: 0x0

MAC Inner VLAN Tag Inclusion or Replacement Register

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

MAC_INNER_VLAN_INCL_i (i=0-3)

MAC Inner VLAN Tag Inclusion or Replacement Register(0064_H) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
VLT	15:0	rw	**VLAN Tag for Transmit Packets** This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: • Bits[15:13]: User Priority • Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • Bits[11:0]: VLAN Identifier (VID) field of VLAN tag Value After Reset: 0x0
VLC	17:16	rw	**VLAN Tag Control in Transmit Packets** The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). **Note**: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. Value After Reset: 0x0 00_B No VLAN tag deletion, insertion, or replacement 01_B VLAN tag deletion 10_B VLAN tag insertion 11_B VLAN tag replacement
VLP	18	rw	**VLAN Priority Control** When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and the VLC field is ignored. Value After Reset: 0x0
CSVL	19	rw	**C-VLAN or S-VLAN** When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. Value After Reset: 0x0

Field	Bits	Type	Description
VLTI	20	rw	**VLAN Tag Input** When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: • The Tx descriptor Value After Reset: 0x0
RES_31_21	31:21	r	**Reserved** Value After Reset: 0x0

MAC Queue 0 TX Flow Control Register

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Rx_Flow_Ctrl register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_RxQ_Ctrl2 register.

MAC_Q0_TX_FLOW_CTRL

MAC Queue 0 TX Flow Control Register (0070_H) Application Reset Value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES_15_8								DZPQ	PLT			RES_3_2		TFE	FCB_BPA
r								rw	rw			r		rw	rw

Field	Bits	Type	Description
FCB_BPA	0	rw	**Flow Control Busy or Backpressure Activate** This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. **Full-Duplex Mode:** In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. **Half--Duplex Mode:** When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
TFE	1	rw	**Transmit Flow Control Enable** **Full-Duplex Mode:** In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. **Half--Duplex Mode:** In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. Value After Reset: 0x0
RES_3_2	3:2	r	**Reserved** Value After Reset: 0x0

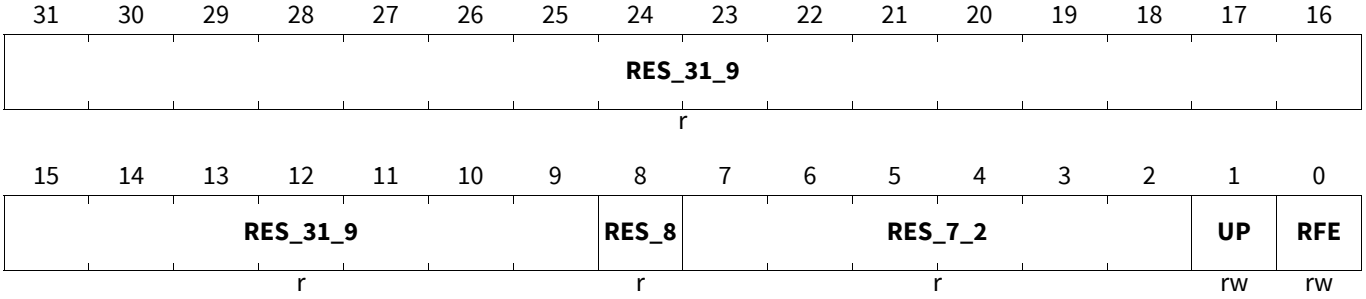
Field	Bits	Type	Description
PLT	6:4	rw	**Pause Low Threshold** This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: 110_B-111_B Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. Value After Reset: 0x0 000_B Pause Time minus 4 Slot Times (PT -4 slot times) 001_B Pause Time minus 28 Slot Times (PT -28 slot times) 010_B Pause Time minus 36 Slot Times (PT -36 slot times) 011_B Pause Time minus 144 Slot Times (PT -144 slot times) 100_B Pause Time minus 256 Slot Times (PT -256 slot times) 101_B Pause Time minus 512 Slot Times (PT -512 slot times)
DZPQ	7	rw	**Disable Zero-Quanta Pause** When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. Value After Reset: 0x0
RES_15_8	15:8	r	**Reserved** Value After Reset: 0x0
PT	31:16	rw	**Pause Time** This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain. Value After Reset: 0x0

MAC Receive Flow Control Register

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

MAC_RX_FLOW_CTRL

MAC Receive Flow Control Register (0090$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RFE	0	rw	**Receive Flow Control Enable** When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. Value After Reset: 0x0
UP	1	rw	**Unicast Pause Packet Detect** A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. **Note**: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. Value After Reset: 0x0

Field	Bits	Type	Description
RGSMIIIS	0	r	**RGMII or SMII Interrupt Status** This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_Control_Status register). This bit is cleared when the MAC_PHYIF_Control_Status register is read (or LNKSTS bit of MAC_PHYIF_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0
RES_2_1	2:1	r	**Reserved for future use.**
PHYIS	3	r	**PHY Interrupt** This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is writtento 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).Value After Reset: 0x0
PMTIS	4	r	**PMT Interrupt Status** This bit is set when a Magic packet or Wake-on-LAN packet is received in the powerdown mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_Control_Status register (or corresponding interrupt source bit of MAC_PMT_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0
LPIIS	5	r	**LPI Interrupt Status** When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0
RES_7_6	7:6	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
MMCIS	8	r	**MMC Interrupt Status** This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. Value After Reset: 0x0
MMCRXIS	9	r	**MMC Receive Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. Value After Reset: 0x0
MMCTXIS	10	r	**MMC Transmit Interrupt Status** This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. Value After Reset: 0x0
MMCRXIPIS	11	r	**MMC Receive Checksum Offload Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. Value After Reset: 0x0
TSIS	12	r	**Timestamp Interrupt Status** If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: • The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. • There is an overflow in the Seconds register. • The Target Time Error occurred, that is, programmed target time already elapsed. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and Mac_TxTimestamp_Status_Seconds registers. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register. Value After Reset: 0x0

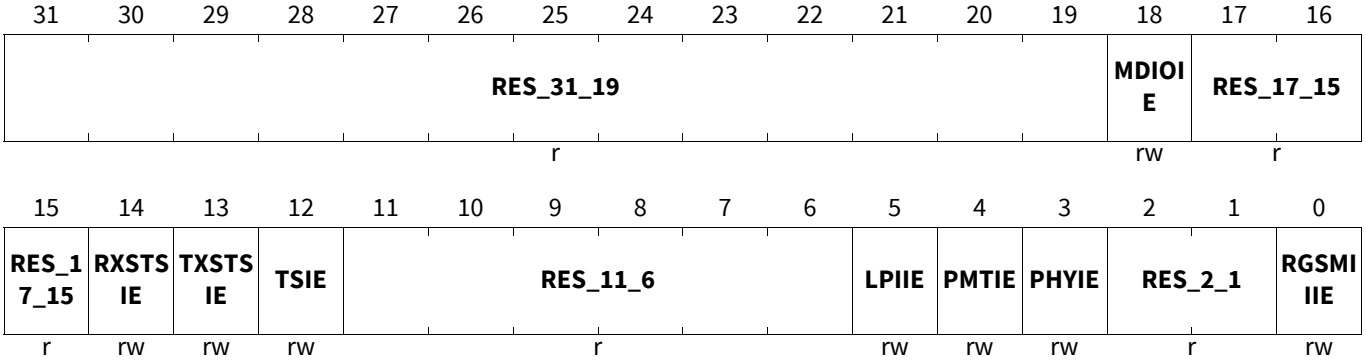
Field	Bits	Type	Description
TXSTSIS	13	r	**Transmit Status Interrupt** This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status register: • Excessive Collision (EXCOL) • Late Collision (LCOL) • Excessive Deferral (EXDEF) • Loss of Carrier (LCARR) • No Carrier (NCARR) • Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. Value After Reset: 0x0
RXSTSIS	14	r	**Receive Status Interrupt** This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_Rx_Tx_Status register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register. Value After Reset: 0x0
RES_17_15	17:15	r	**Reserved for future use.**
MDIOIS	18	r	**MDIO Interrupt Status** This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of MAC_CSR_SW_Ctrl register is set.Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_19	31:19	r	**Reserved** Value After Reset: 0x0

MAC Interrupt Enable Register

The Interrupt Enable register contains the masks for generating the interrupts.

MAC_INTERRUPT_ENABLE

MAC Interrupt Enable Register **($00B4_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RGSMIIIE	0	rw	**RGMII or SMII Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of RGSMIIIS bit in MAC_Interrupt_Status register. Value After Reset: 0x0
RES_2_1	2:1	r	**Reserved for future use.**
PHYIE	3	rw	**PHY Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in MAC_Interrupt_Status register. Value After Reset: 0x0
PMTIE	4	rw	**PMT Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in MAC_Interrupt_Status register. Value After Reset: 0x0
LPIIE	5	rw	**LPI Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in MAC_Interrupt_Status register. Value After Reset: 0x0
RES_11_6	11:6	r	**Reserved** Value After Reset: 0x0
TSIE	12	rw	**Timestamp Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in MAC_Interrupt_Status register. Value After Reset: 0x0
TXSTSIE	13	rw	**Transmit Status Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the MAC_Interrupt_Status register. Value After Reset: 0x0

Field	Bits	Type	Description
RXSTSIE	14	rw	**Receive Status Interrupt Enable** When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the MAC_Interrupt_Status register. Value After Reset: 0x0
RES_17_15	17:15	r	**Reserved for future use.**
MDIOIE	18	rw	**MDIO Interrupt Enable** MDIO Interrupt Enable: When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_Interrupt_Status register. Value After Reset: 0x0
RES_31_19	31:19	r	**Reserved** Value After Reset: 0x0

MAC Receive Transmit Status Register

The Receive Transmit Status register contains the Receive and Transmit Error status.

MAC_RX_TX_STATUS

MAC Receive Transmit Status Register (00B8$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RES_31_9							RWT	RES_7_6		EXCOL	LCOL	EXDEF	LCARR	NCARR	TJT
r							r	r		r	r	r	r	r	r

Field	Bits	Type	Description
TJT	0	r	**Transmit Jabber Timeout** This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
NCARR	1	r	**No Carrier** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0

Field	Bits	Type	Description
LCARR	2	r	**Loss of Carrier** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
EXDEF	3	r	**Excessive Deferral** When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
LCOL	4	r	**Late Collision** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. This bit is reserved in the EQOS-CORE configurations and also in configurations with full-duplex mode. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
EXCOL	5	r	**Excessive Collisions** When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_7_6	7:6	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
RWT	8	r	**Receive Watchdog Timeout** This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_9	31:9	r	**Reserved** Value After Reset: 0x0

MAC PMT Control and Status Register

The PMT Control and Status Register.

MAC_PMT_CONTROL_STATUS

MAC PMT Control and Status Register (00C0$_H$) Application Reset Value: 0000 0000$_H$

r					rw	rw	r		r	r	r		rw	rw	rw

Field	Bits	Type	Description
PWRDWN	0	rw	**Power Down** When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. **Note**: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0

Field	Bits	Type	Description
MGKPKTEN	1	rw	**Magic Packet Enable** When this bit is set, a power management event is generated when the MAC receives a magic packet. Value After Reset: 0x0
RWKPKTEN	2	rw	**Remote Wake-Up Packet Enable** When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. Value After Reset: 0x0
RES_4_3	4:3	r	**Reserved** Value After Reset: 0x0
MGKPRCVD	5	r	**Magic Packet Received** When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RWKPRCVD	6	r	**Remote Wake-Up Packet Received** When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_8_7	8:7	r	**Reserved** Value After Reset: 0x0
GLBLUCAST	9	rw	**Global Unicast** When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. Value After Reset: 0x0

Field	Bits	Type	Description
RWKPFE	10	rw	**Remote Wake-up Packet Forwarding Enable** When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
RES_23_11	23:11	r	**Reserved** Value After Reset: 0x0
RWKPTR	28:24	r	**Remote Wake-up FIFO Pointer** This field gives the current value (0 to 7) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register. Value After Reset: 0x0
RES_30_29	30:29	r	**Reserved** Value After Reset: 0x0
RWKFILTRST	31	rw	**Remote Wake-Up Packet Filter Register Pointer Reset** When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0

MAC Wake-up Packet Filter Register

The wkuppktfilter_reg register at address 0C4H loads the Wake-up Packet Filter register.

To load values in a Wake-up Packet Filter register, the entire register (wkuppktfilter_reg) must be written. The wkuppktfilter_reg register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0C4H) for wkuppktfilter_reg0, wkuppktfilter_reg1, - wkuppktfilter_reg31, respectively. The wkuppktfilter_reg register is read in a similar way. The DWC_ether_qos updates the wkuppktfilter_reg register current pointer value in Bits[26:24] of MAC_PMT_Control_Status register.

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, …,15) to determine whether or not a packet is a wake-up packet.

The MSB (31st bit) must be zero.

Bit j[30:0] is the byte mask.

If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value.

Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as “Pattern 1 AND NOT Pattern 2".

Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.

Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

The minimum allowed offset is 12, which refers to the 13th byte of the packet.

The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wake-up filter register block.

The 16-bit CRC calculation uses the following polynomial:

G(x) = x^16 + x^15 + x^2 + 1

Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.

8-bit Offset Pointer: Specifies the byte to start the CRC16 computation.

The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.

Note: If you are accessing these registers in byte or half-word mode, the internal counter to access the appropriate wkuppktfilter_reg is incremented when CPU accesses Lane 3 (or Lane 0 in big-endian mode).

Note: After a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 6 cycles of the destination clock (PHY receive clock or PHY transmit clock).

Notes on And_Previous bit setting

The And_Previous bit setting is applicable within a set of 4 filters.

Setting of And_Previous bit of filter that is not enabled has no effect. In other words, setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example:

If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set) but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 1 is not enabled (bit 0 of in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered.

If Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 of Filter 3 command is set), but Filter 2 is not enabled (bit 0 of in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. - If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 of Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 of Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 of Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Field	Bits	Type	Description
TLPIEN	0	r	**Transmit LPI Entry** When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0

Field	Bits	Type	Description
TLPIEX	1	r	**Transmit LPI Exit** When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0
RLPIEN	2	r	**Receive LPI Entry** When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note**: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. Value After Reset: 0x0
RLPIEX	3	r	**Receive LPI Exit** When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). **Note**: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. Value After Reset: 0x0
RES_7_4	7:4	r	**Reserved** Value After Reset: 0x0
TLPIST	8	r	**Transmit LPI State** When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. Value After Reset: 0x0
RLPIST	9	r	**Receive LPI State** When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. Value After Reset: 0x0
RES_15_10	15:10	r	**Reserved** Value After Reset: 0x0
LPIEN	16	rw	**LPI Enable** When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. Value After Reset: 0x0

Field	Bits	Type	Description
PLS	17	rw	**PHY Link Status** This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. Value After Reset: 0x0
PLSEN	18	rw	**PHY Link Status Enable** This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_Control_Status register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_Control_Status register and takes only the PLS bit. Value After Reset: 0x0
LPITXA	19	rw	**LPI Tx Automate** This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. Value After Reset: 0x0
LPIATE	20	rw	**LPI Timer Enable** This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. Value After Reset: 0x0

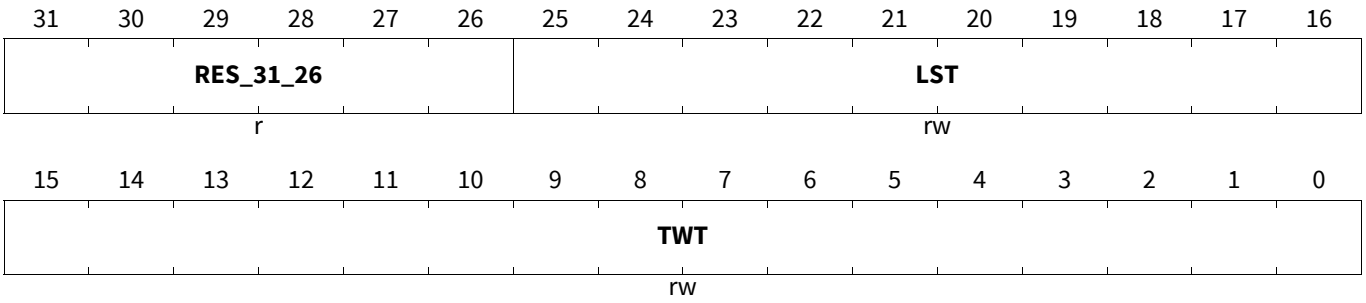
Field	Bits	Type	Description
LPITCSE	21	rw	**LPI Tx Clock Stop Enable** When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. Value After Reset: 0x0
RES_31_22	31:22	r	**Reserved** Value After Reset: 0x0

MAC LPI Timers Control Register

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

MAC_LPI_TIMERS_CONTROL

MAC LPI Timers Control Register **(00D4$_H$)** **Application Reset Value: 03E8 0000$_H$**

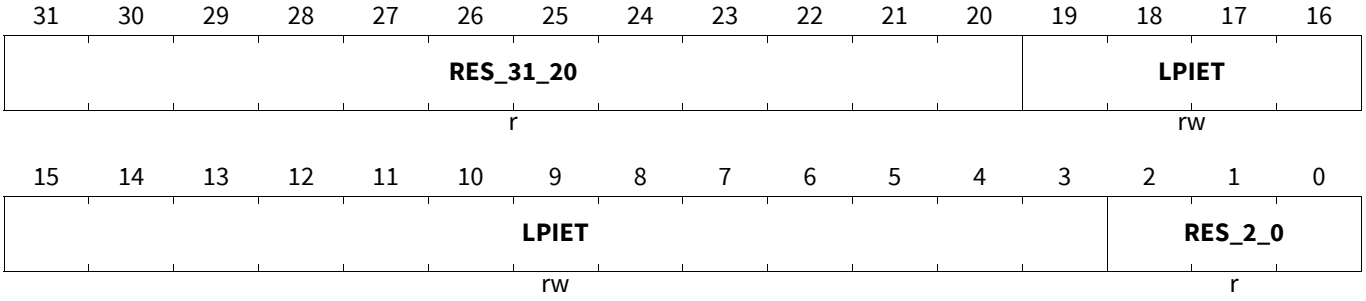


Field	Bits	Type	Description
TWT	15:0	rw	**LPI TW Timer** This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer. Value After Reset: 0x0
LST	25:16	rw	**LPI LS Timer** This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard. Value After Reset 0x3e8
RES_31_26	31:26	r	**Reserved** Value After Reset: 0x0

MAC LPI Entry Timer Register

This register controls the Tx LPI entry timer. This counter is enabled only when bit[20](LPITE) bit of MAC_LPI_Control_Status is set to 1. This register is present only when you select the Energy Efficient Ethernet feature in coreConsultant.

MAC_LPI_ENTRY_TIMER
MAC LPI Entry Timer Register **(00D8$_H$)** **Application Reset Value: 0000 0000$_H$**

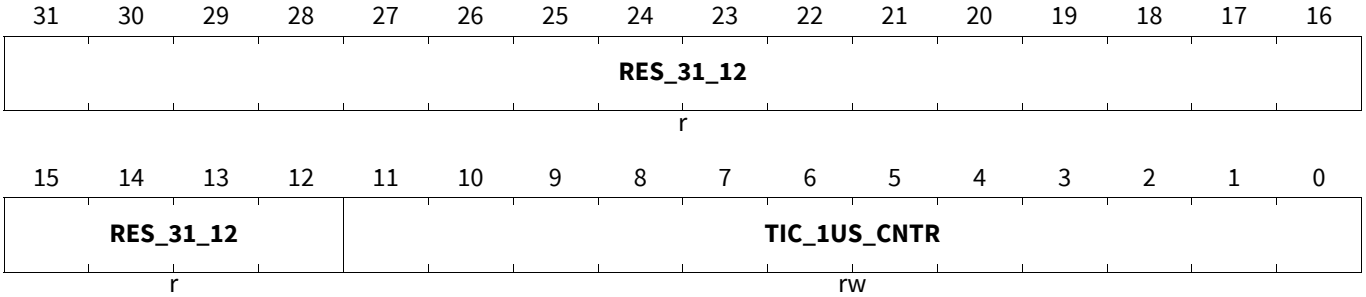


Field	Bits	Type	Description
RES_2_0	2:0	r	**Reserved** Value After Reset: 0x0
LPIET	19:3	rw	**LPI Entry Timer** This field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds. Value After Reset: 0x0
RES_31_20	31:20	r	**Reserved** Value After Reset: 0x0

MAC One Microsecond Tic Counter Register

This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

MAC_1US_TIC_COUNTER
MAC One Microsecond Tic Counter Register **(00DC$_H$)** **Application Reset Value: 0000 0063$_H$**



Field	Bits	Type	Description
TIC_1US_CNTR	11:0	rw	**1US TIC Counter** The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters. Value After Reset: 0x63
RES_31_12	31:12	r	**Reserved** Value After Reset: 0x0

MAC PHY Interface Control and Status Register

The PHY Interface Control and Status register indicates the status signals received by the SGMII, RGMII, or SMII interface (selected at reset) from the PHY. This register is optional. It is present only when the MAC is configured for the SGMII, RGMII, or SMII PHY interface.

MAC_PHYIF_CONTROL_STATUS

MAC PHY Interface Control and Status Register (00F8$_H$) **Application Reset Value: 0000 0000$_H$**

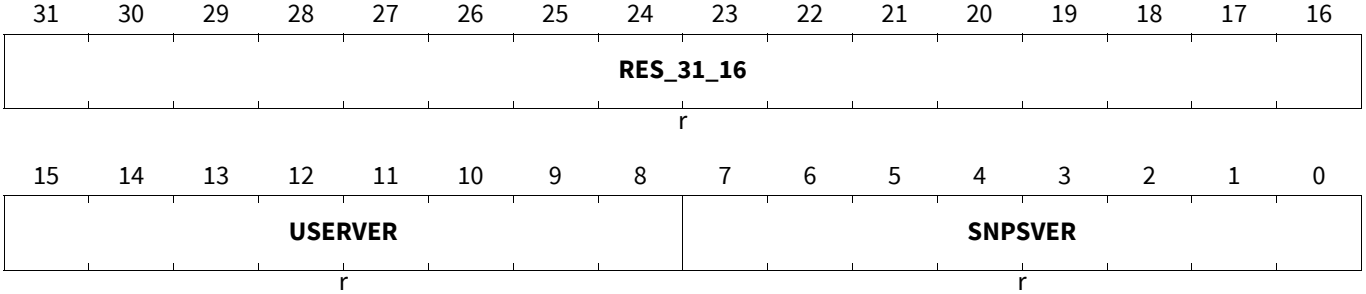
LNKSPEED	18:17	r	**Link Speed** This bit indicates the current speed of the link: Value After Reset: 0x0 00_B 2.5 MHz 01_B 25 MHz 10_B 125 MHz
LNKSTS	19	r	**Link Status** This bit indicates whether the link is up (1'b1) or down (1'b0). Value After Reset: 0x0
RES_31_20	29:20	r	**Reserved** Value After Reset: 0x0

MAC Version Register

The version register identifies the version of the DWC_ether_qos. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set while configuring the core.

MAC_VERSION

MAC Version Register **(0110_H)** **Application Reset Value: $0000\ 1050_H$**

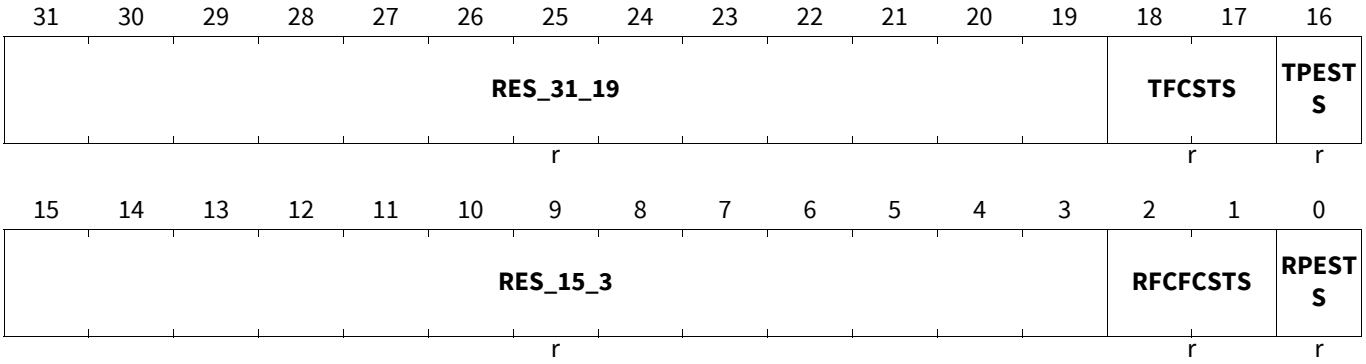


Field	Bits	Type	Description
SNPSVER	7:0	r	**Synopsys-defined Version** IP Version
USERVER	15:8	r	**User-defined Version (configured with coreConsultant)** Value After Reset: 0x10
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MAC Debug Register

The Debug register provides the debug status of various MAC blocks.

MAC_DEBUG
MAC Debug Register **(0114_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RPESTS	0	r	**MAC GMII or MII Receive Protocol Engine Status** When this bit is set, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data, and it is not in the Idle state. Value After Reset: 0x0
RFCFCSTS	2:1	r	**MAC Receive Packet Controller FIFO Status** When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module. Value After Reset: 0x0
RES_15_3	15:3	r	**Reserved** Value After Reset: 0x0
TPESTS	16	r	**MAC GMII or MII Transmit Protocol Engine Status** When this bit is set, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data, and it is not in the Idle state. Value After Reset: 0x0

Field	Bits	Type	Description
TFCSTS	18:17	r	**MAC Transmit Packet Controller Status** This field indicates the state of the MAC Transmit Packet Controller module: Status of the previous packet OR IPG or backoff period to be over Value After Reset: 0x0 00_B Idle state 01_B Waiting for one of the following: 10_B Generating and transmitting a Pause control packet (in full-duplex mode) 11_B Transferring input packet for transmission
RES_31_19	31:19	r	**Reserved** Value After Reset: 0x0

MAC Hardware Feature Register 0

This register indicates the presence of first set of the optional features or functions of the DWC_ether_qos. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

All bits are set or reset according to the features selected while configuring the core in coreConsultant.

MAC_HW_FEATURE0

RES_15	NTC			CR				RES_7_5			SKAP	GOC_1	GOC_0	C45E	GB
r	rw			rw				r			rw	rw	rw	rw	rw

Field	Bits	Type	Description
GB	0	rw	**GMII Busy** The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDl field (and also RA field when C45E is set) in MAC_MDIO_Data register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. **Note**: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
C45E	1	rw	**Clause 45 PHY Enable** When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. Value After Reset: 0x0
GOC_0	2	rw	**GMII Operation Command 0** This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. Value After Reset: 0x0

Field	Bits	Type	Description
GOC_1	3	rw	**GMII Operation Command 1** This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: 00_BReserved 01_BWrite 10_BPost Read Increment Address for Clause 45 PHY 11_BRead When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. Value After Reset: 0x0
SKAP	4	rw	**Skip Address Packet** When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. Value After Reset: 0x0
RES_7_5	7:5	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
CR	11:8	rw	**CSR Clock Range** The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0110_B, 0111_B Reserved The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface. Value After Reset: 0x0 0_H CSR clock = 60-100 MHz; MDC clock = CSR clock/42 1_H CSR clock = 100-150 MHz; MDC clock = CSR clock/62 2_H CSR clock = 20-35 MHz; MDC clock = CSR clock/16 3_H CSR clock = 35-60 MHz; MDC clock = CSR clock/26 4_H CSR clock = 150-250 MHz; MDC clock = CSR clock/102 5_H CSR clock = 250-300 MHz; MDC clock = CSR clock/124 6_H CSR clock = 300-500 MHz; MDC clock = CSR clock/204 7_H CSR clock = 500-800 MHz; MDC clock = CSR clock/324 8_H CSR clock/4 9_H CSR clock/6 A_H CSR clock/8 B_H CSR clock/10 C_H CSR clock/12 D_H CSR clock/14 E_H CSR clock/16 F_H CSR clock/18
NTC	14:12	rw	**Number of Trailing Clocks** This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer. Value After Reset: 0x0
RES_15	15	r	**Reserved** Value After Reset: 0x0
RDA	20:16	rw	**Register/Device Address** These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY. Value After Reset: 0x0

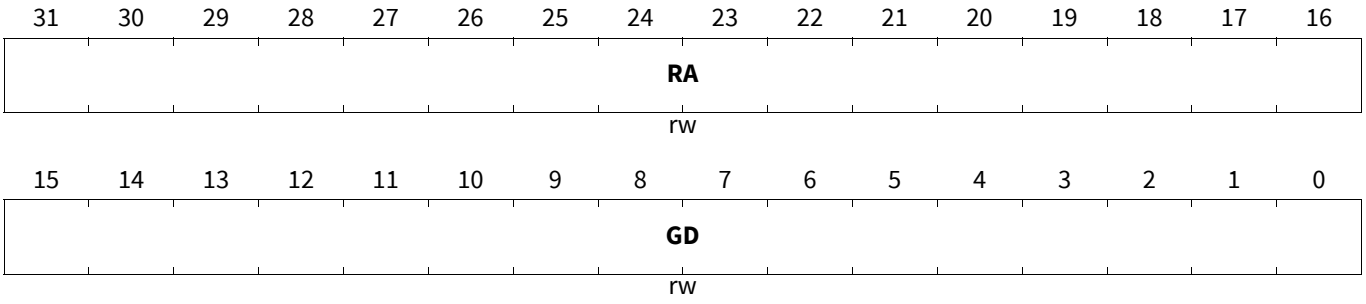
Field	Bits	Type	Description
PA	25:21	rw	**Physical Layer Address** This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing. Value After Reset: 0x0
BTB	26	rw	**Back to Back transactions** When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. Value After Reset: 0x0
PSE	27	rw	**Preamble Suppression Enable** When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. Value After Reset: 0x0
RES_31_28	31:28	r	**Reserved** Value After Reset: 0x0

MAC MDIO Data Register

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

MAC_MDIO_DATA

MAC MDIO Data Register **(0204_H)** **Application Reset Value: $0000\ 0000_H$**



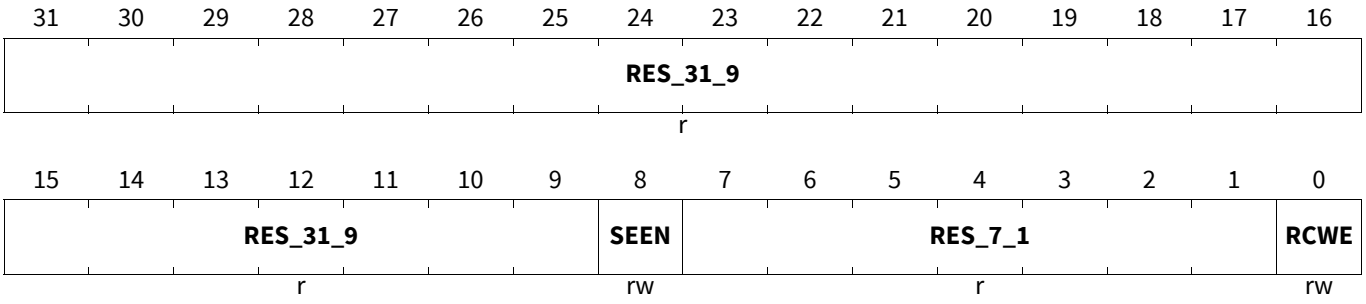
Field	Bits	Type	Description
GD	15:0	rw	**GMII Data** This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation. Value After Reset: 0x0
RA	31:16	rw	**Register Address** This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for. Value After Reset: 0x0

MAC CSR Software Controls Register

This register contains SW programmable controls for changing the CSR access response and status bits clearing.

MAC_CSR_SW_CTRL

MAC CSR Software Controls Register (0230$_H$) Application Reset Value: 0000 0000$_H$



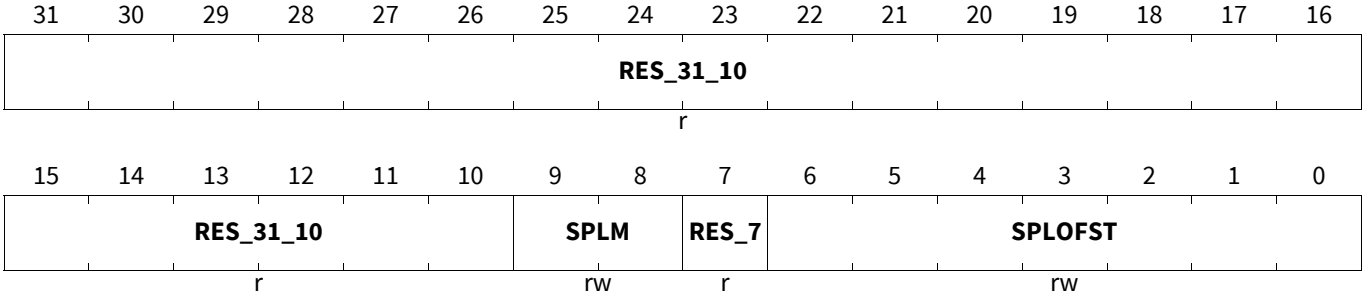
Field	Bits	Type	Description
RCWE	0	rw	**Register Clear on Write 1 Enable - RCWE** When this bit is set, the access mode of some register fields changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it. When this bit is reset, the access mode of these register fields remain as Clear on Read. Value After Reset: 0x0
RES_7_1	7:1	r	**Reserved** Value After Reset: 0x0
SEEN	8	rw	**Slave Error Response Enable** When this bit is set, the MAC responds with Slave Error for accesses to reserved registers in CSR space. When this bit is reset, the MAC responds with Okay response to any register accessed from CSR space. Value After Reset: 0x0
RES_31_9	31:9	r	**Reserved** Value After Reset: 0x0

MAC Extended Configuration Register 1

MAC Extended Configuration Register 1 contains Split mode control field and offset field for Split Header feature.

MAC_EXT_CFG1

MAC Extended Configuration Register 1 (0238_H) Application Reset Value: $0000\ 0002_H$



Field	Bits	Type	Description
SPLOFST	6:0	rw	**Split Offset** These bits indicate the value of offset from the beginning of Length/Type field at which header split should take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms ofbytes.
RES_7	7	r	**Reserved** Value After Reset: 0x0
SPLM	9:8	rw	**Split Mode** These bits indicate the mode of splitting the incoming Rx packets. They are 00_B Split at L3/L4 header 01_B Split at L2 header with an offset. Always Split atSPLOFST bytes from the beginning of Length/Type field ofthe Frame 10_B Combination mode: Split similar to SPLM=00 for IPpackets that are untagged or tagged and VLAN stripped 11_B Reserved
RES_31_10	31:10	r	**Reserved** Value After Reset: 0x0

MAC Address 0 High Register

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

MAC_ADDRESS0_HIGH

MAC Address 0 High Register **(0300_H)** **Application Reset Value: 8000 FFFF$_H$**

RES_23_x	23:18	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
MBC	29:24	rw	**Mask Byte Control** These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: • Bit 29: Register 194[15:8] • Bit 28: Register 194[7:0] • Bit 27: Register 195[31:24] • … • Bit 24: Register 195[7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. Value After Reset: 0x0
SA	30	rw	**Source Address** When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received packet. Value After Reset: 0x0
AE	31	rw	**Address Enable** When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. Value After Reset: 0x0

MAC Address i Low Register

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

MAC_ADDRESSi_LOW (i=1-31)
MAC Address i Low Register **($030C_H$+(i-1)*8)** **Application Reset Value: FFFF FFFF$_H$**

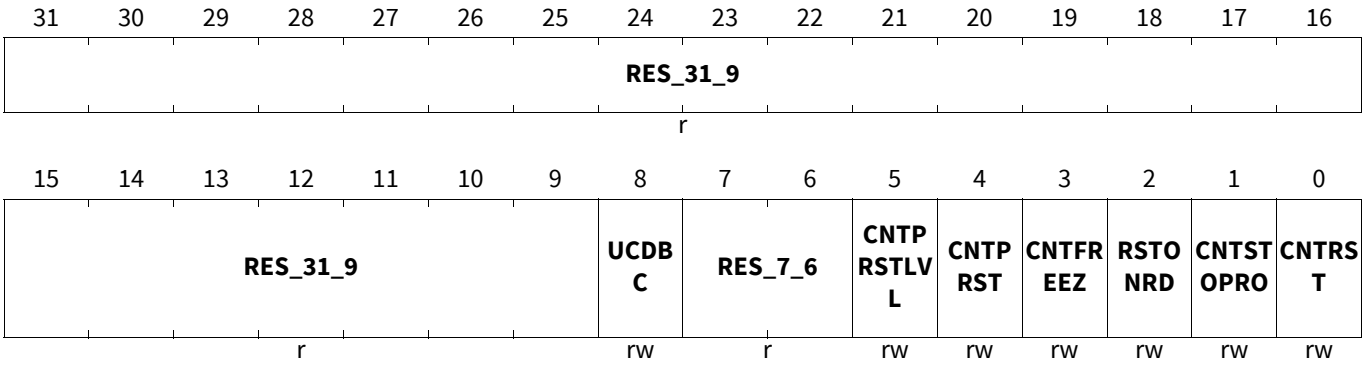
Field	Bits	Type	Description
ADDRLO	31:0	rw	**MAC Address1 [31:0]** This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process. Value After Reset: 0xffffffff

MMC Control Register

This register establishes the operating mode of MMC.

MMC_CONTROL
MMC Control Register **(0700_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CNTRST	0	rw	**Counters Reset** When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Value After Reset: 0x0
CNTSTOPRO	1	rw	**Counter Stop Rollover** When this bit is set, the counter does not roll over to zero after reaching the maximum value. Value After Reset: 0x0
RSTONRD	2	rw	**Reset on Read** When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. Value After Reset: 0x0
CNTFREEZ	3	rw	**MMC Counter Freeze** When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. Value After Reset: 0x0
CNTPRST	4	rw	**Counters Preset** When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. Value After Reset: 0x0

Field	Bits	Type	Description
CNTPRSTLVL	5	rw	**Full-Half Preset** When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. Value After Reset: 0x0
RES_7_6	7:6	r	**Reserved** Value After Reset: 0x0
UCDBC	8	rw	**Update MMC Counters for Dropped Broadcast Packets** When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. Value After Reset: 0x0
RES_31_9	31:9	r	**Reserved** Value After Reset: 0x0

MMC Receive Interrupts Register

This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).

Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

MMC_RX_INTERRUPT

MMC Receive Interrupts Register **(0704_H)** **Application Reset Value: $0000\ 0000_H$**

MMC Transmit Interrupts Register

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values

(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

MMC_TX_INTERRUPT

MMC Transmit Interrupts Register **(0708_H)** **Application Reset Value: $0000\ 0000_H$**

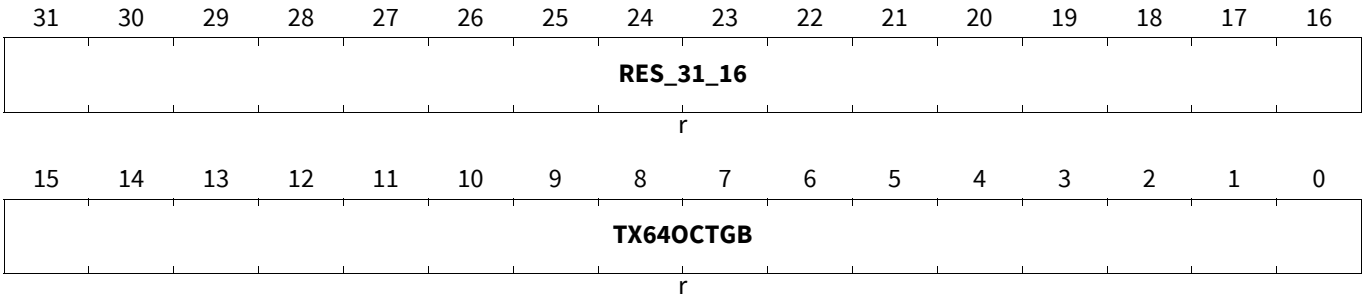
Good And Bad 64 Octets Packets Transmitted Count Register(0724_H) **Application Reset Value: $0000\ 0000_H$**



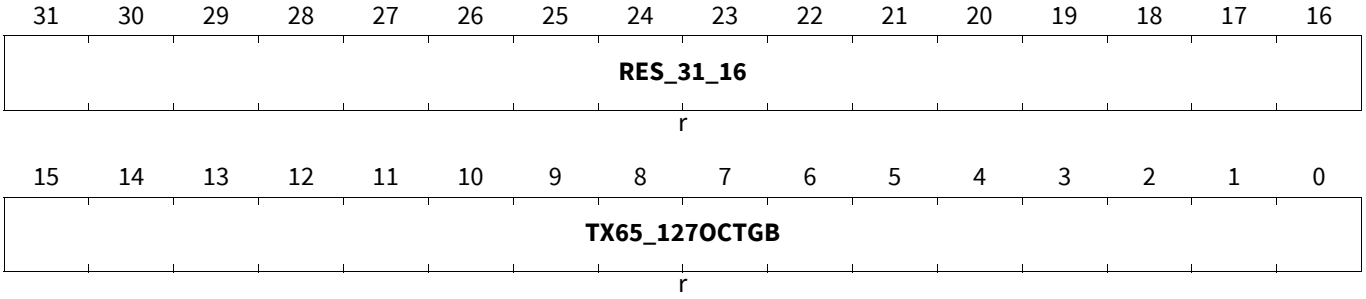
Field	Bits	Type	Description
TX64OCTGB	15:0	r	**Tx 64Octets Packets Good_Bad** This field indicates the number of good and bad packets transmitted with length 64 bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad 65to127 Octets Packets Transmitted Count Register

This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets.

TX_65TO127OCTETS_PACKETS_GOOD_BAD

Good And Bad 65to127 Octets Packets Transmitted Count Register(0728_H) Application Reset Value: $0000\ 0000_H$



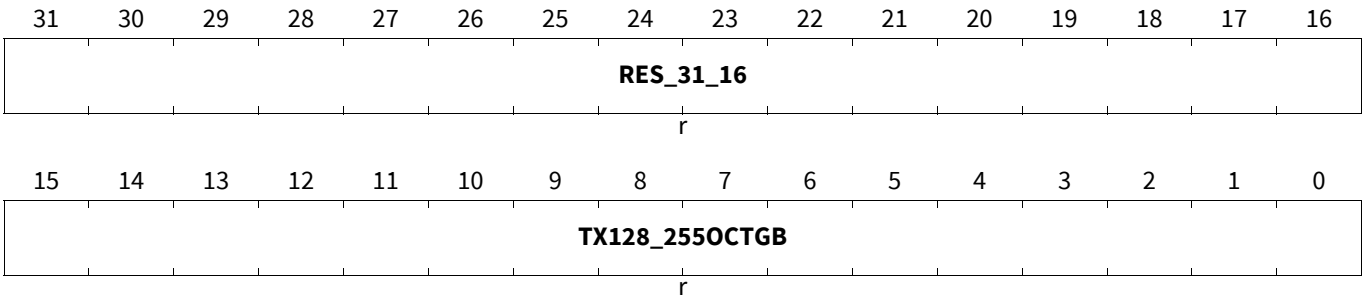
Field	Bits	Type	Description
TX65_127OCTGB	15:0	r	**Tx 65To127Octets Packets Good Bad** This field indicates the number of good and bad packets transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad 128to255 Octets Packets Transmitted Count Register

This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 128 to 255 (inclusive) bytes, exclusive of preamble and retried packets.

TX_128TO255OCTETS_PACKETS_GOOD_BAD

Good And Bad 128to255 Octets Packets Transmitted Count Register($072C_H$) Application Reset Value: $0000\ 0000_H$

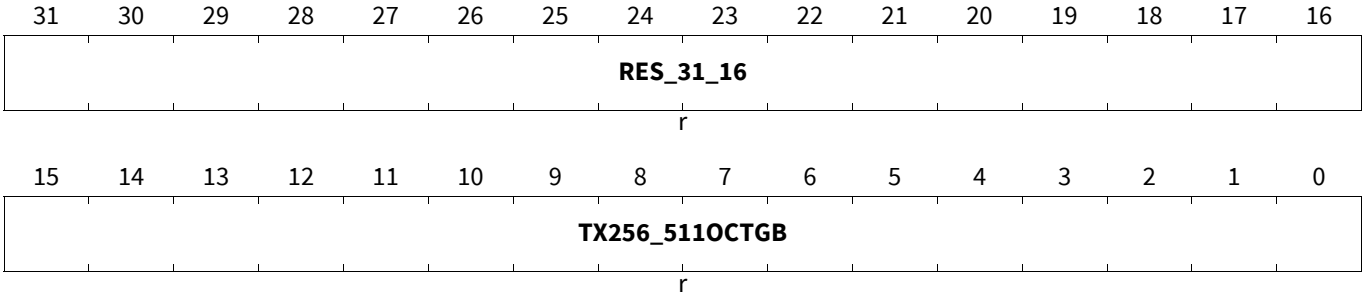


Field	Bits	Type	Description
TX128_255OCTGB	15:0	r	**Tx 128To255Octets Packets Good Bad** This field indicates the number of good and bad packets transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad 256to511 Octets Packets Transmitted Count Register

This register provides the number of good and bad packets transmitted by DWC_ether_qos with length between 256 to 511 (inclusive) bytes, exclusive of preamble and retried packets.

TX_256TO511OCTETS_PACKETS_GOOD_BAD
Good And Bad 256to511 Octets Packets Transmitted Count Register(0730_H) Application Reset Value: $0000\ 0000_H$

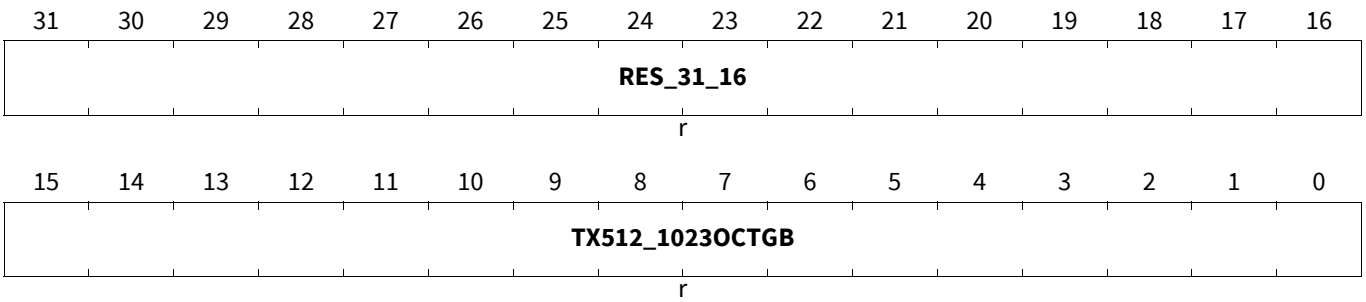


Field	Bits	Type	Description
TX256_511OCTGB	15:0	r	**Tx 256To511Octets Packets Good Bad** This field indicates the number of good and bad packets transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad 512to1023 Octets Packets Transmitted Count Register

This register provides the number of good and bad packets transmitted by DWC_ether_qos with length 512 to 1023 (inclusive) bytes, exclusive of preamble and retried packets.

TX_512TO1023OCTETS_PACKETS_GOOD_BAD
Good And Bad 512to1023 Octets Packets Transmitted Count Register(0734_H)Application Reset Value: $0000\ 0000_H$

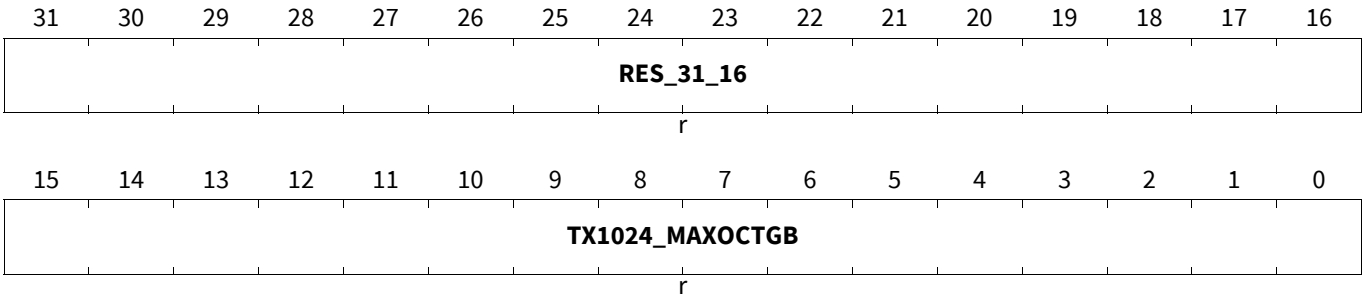


Field	Bits	Type	Description
TX512_1023OCTGB	15:0	r	**Tx 512To1023Octets Packets Good Bad** This field indicates the number of good and bad packets transmitted with length between 512 and 1023 (inclusive) bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad 1024toMax Octets Packets Transmitted Count Register

This register provides the number of good and bad packets transmitted by DWC_ether_qos with length 1024 to maxsize (inclusive) bytes, exclusive of preamble and retried packets.

TX_1024TOMAXOCTETS_PACKETS_GOOD_BAD
Good And Bad 1024toMax Octets Packets Transmitted Count Register(0738_H) Application Reset Value: $0000\ 0000_H$



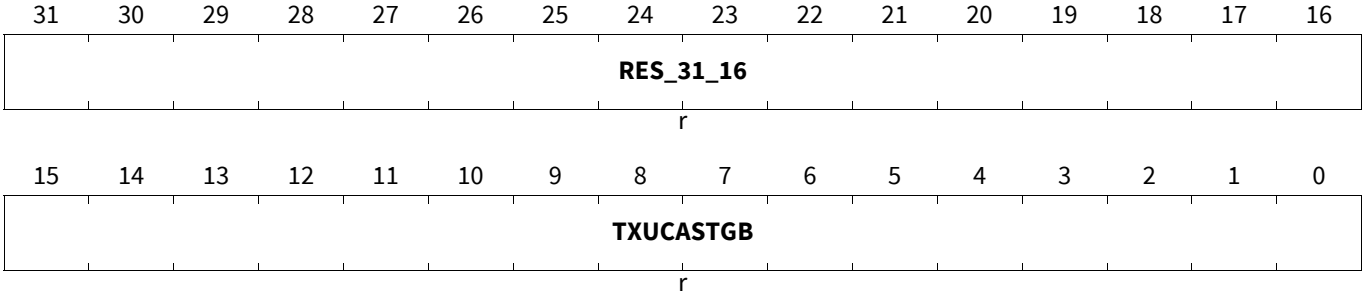
Field	Bits	Type	Description
TX1024_MAXOCTGB	15:0	r	**Tx 1024ToMaxOctets Packets Good Bad** This field indicates the number of good and bad packets transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried packets. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Transmitted Unicat Packets Count Register

This register provides the number of good and bad unicast packets transmitted by DWC_ether_qos.

TX_UNICAST_PACKETS_GOOD_BAD

Good Transmitted Unicat Packets Count Register($073C_H$) **Application Reset Value: $0000\ 0000_H$**



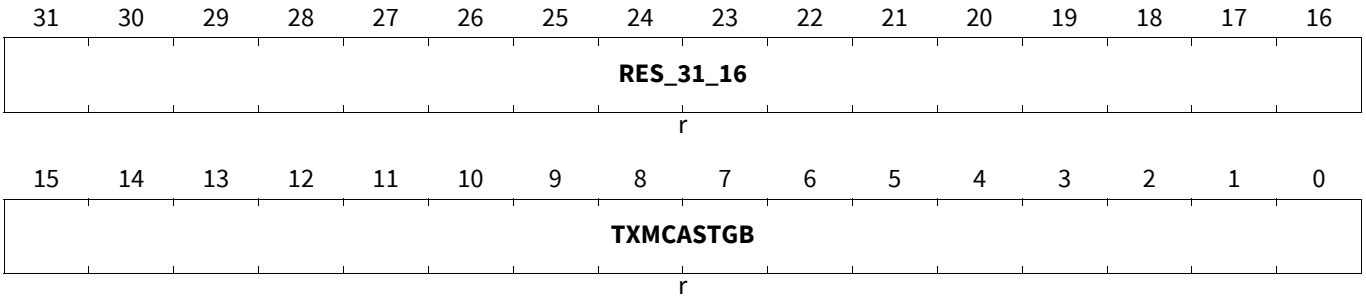
Field	Bits	Type	Description
TXUCASTGB	15:0	r	**Tx Unicast Packets Good Bad** This field indicates the number of good and bad unicast packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad Transmitted Multicast Packets Count Register

This register provides the number of good and bad multicast packets transmitted by DWC_ether_qos.

TX_MULTICAST_PACKETS_GOOD_BAD

Good And Bad Transmitted Multicast Packets Count Register(0740_H) **Application Reset Value: $0000\ 0000_H$**



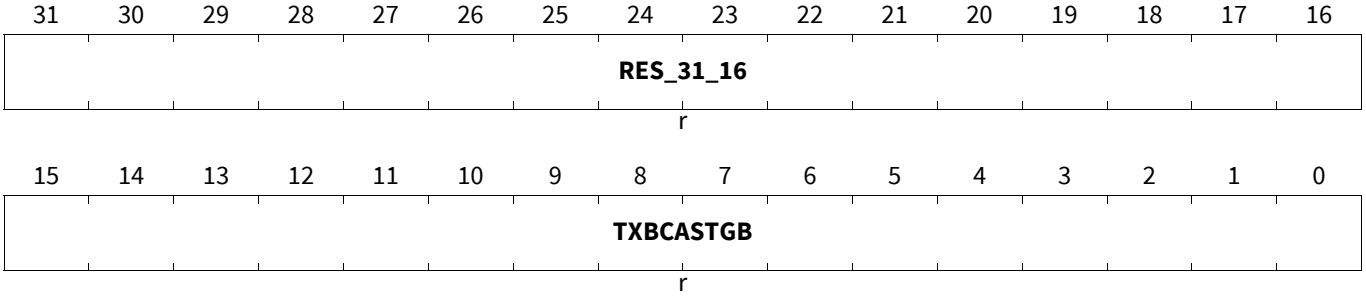
Field	Bits	Type	Description
TXMCASTGB	15:0	r	**Tx Multicast Packets Good Bad** This field indicates the number of good and bad multicast packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad Transmitted Broadcast Packets Count Register

This register provides the number of good and bad broadcast packets transmitted by DWC_ether_qos.

TX_BROADCAST_PACKETS_GOOD_BAD

Good And Bad Transmitted Broadcast Packets Count Register(0744_H) Application Reset Value: $0000\ 0000_H$



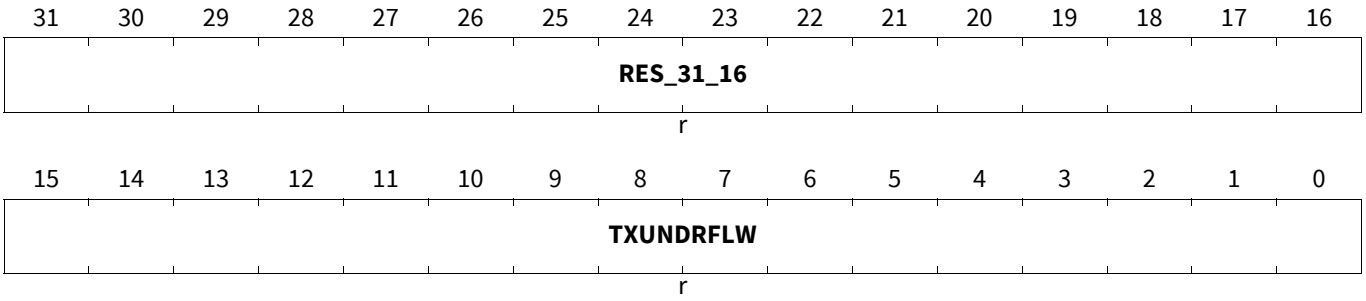
Field	Bits	Type	Description
TXBCASTGB	15:0	r	**Tx Broadcast Packets Good Bad** This field indicates the number of good and bad broadcast packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Underflow Error Packets Count Register

This register provides the number of packets aborted by DWC_ether_qos because of packets underflow error.

TX_UNDERFLOW_ERROR_PACKETS

Transmitted Underflow Error Packets Count Register(0748_H) Application Reset Value: $0000\ 0000_H$



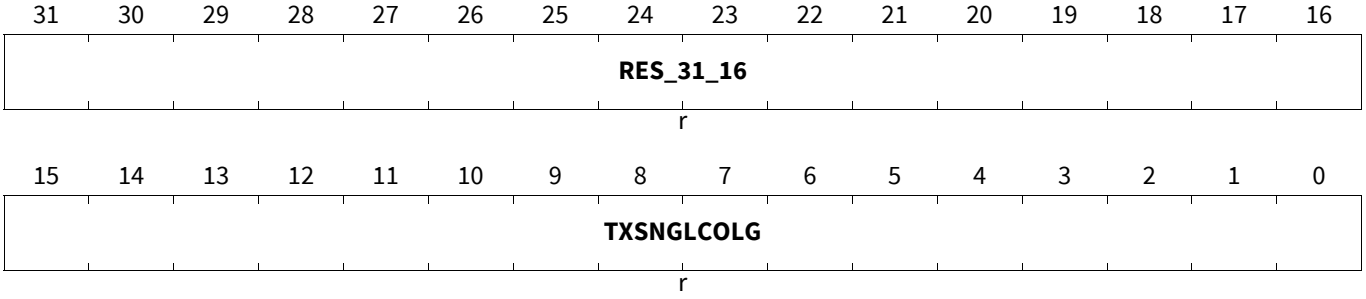
Field	Bits	Type	Description
TXUNDRFLW	15:0	r	**Tx Underflow Error Packets** This field indicates the number of packets aborted because of packets underflow error. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Transmitted Single Collision Count Register

This register provides the number of successfully transmitted packets by DWC_ether_qos after a single collision in the half-duplex mode.

TX_SINGLE_COLLISION_GOOD_PACKETS

Good Transmitted Single Collision Count Register(074C$_H$) **Application Reset Value: 0000 0000$_H$**



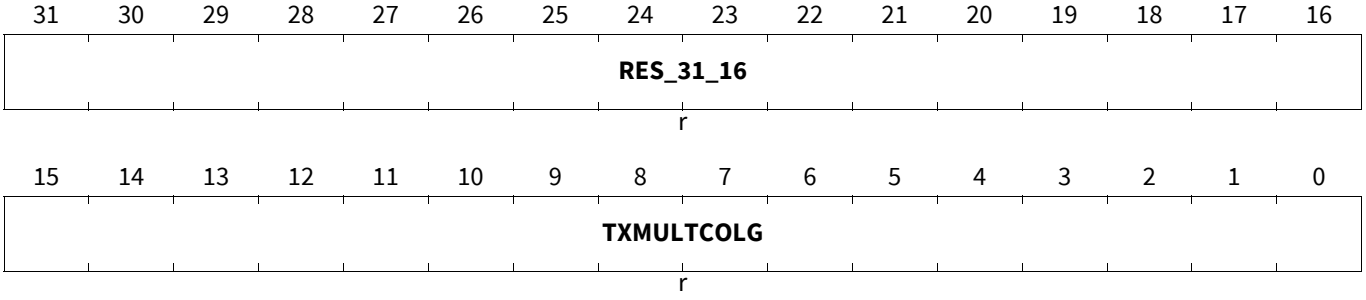
Field	Bits	Type	Description
TXSNGLCOLG	15:0	r	**Tx Single Collision Good Packets** This field indicates the number of successfully transmitted packets after a single collision in the half-duplex mode. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Multiple Collision Count Register

This register provides the number of successfully transmitted packets by DWC_ether_qos after multiple collisions in the half-duplex mode.

TX_MULTIPLE_COLLISION_GOOD_PACKETS

Transmitted Multiple Collision Count Register (0750$_H$) **Application Reset Value: 0000 0000$_H$**



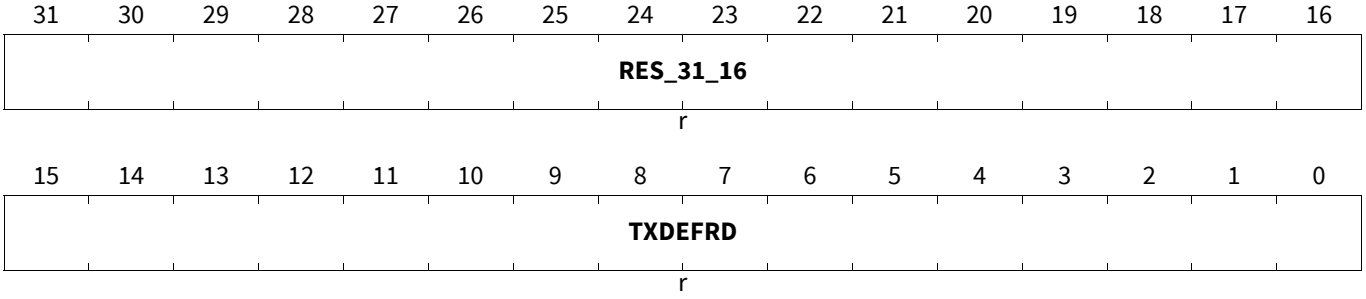
Field	Bits	Type	Description
TXMULTCOLG	15:0	r	**Tx Multiple Collision Good Packets** This field indicates the number of successfully transmitted packets after multiple collisions in the half-duplex mode. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Deferred Packets Count Register

This register provides the number of successfully transmitted by DWC_ether_qos after a deferral in the half-duplex mode.

TX_DEFERRED_PACKETS

Transmitted Deferred Packets Count Register (0754$_H$) **Application Reset Value: 0000 0000$_H$**



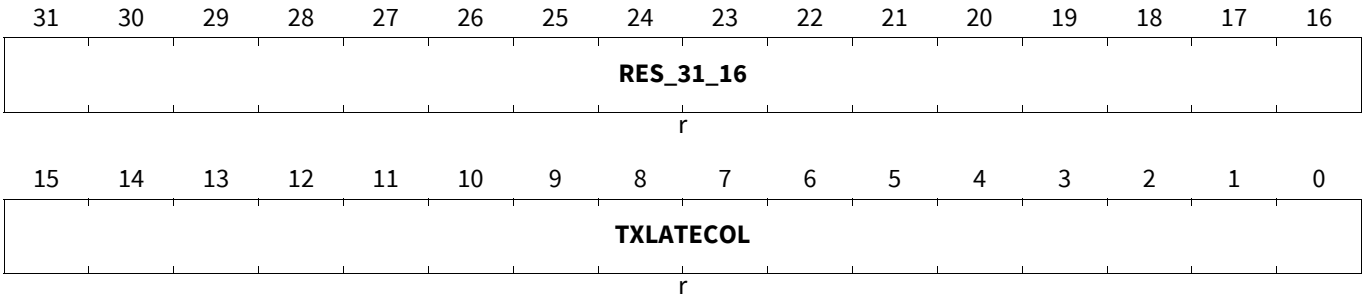
Field	Bits	Type	Description
TXDEFRD	15:0	r	**Tx Deferred Packets** This field indicates the number of successfully transmitted after a deferral in the half-duplex mode. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Late Collision Packets Count Register

This register provides the number of packets aborted by DWC_ether_qos because of late collision error.

TX_LATE_COLLISION_PACKETS

Transmitted Late Collision Packets Count Register(0758$_H$) **Application Reset Value: 0000 0000$_H$**



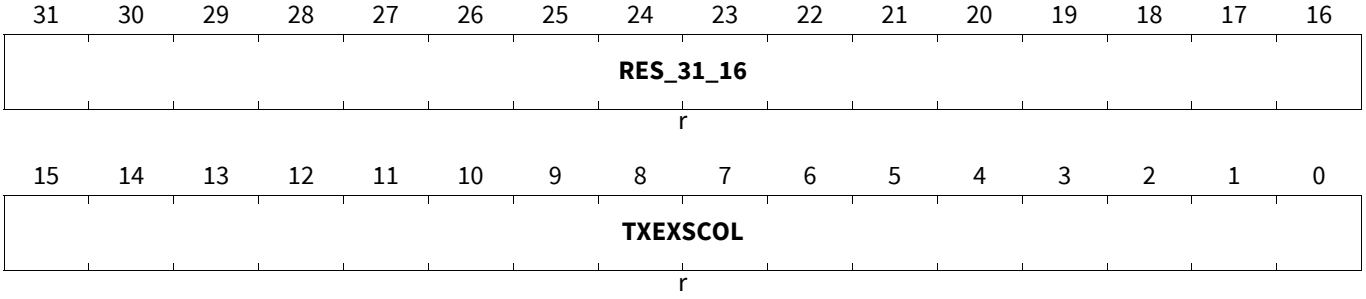
Field	Bits	Type	Description
TXLATECOL	15:0	r	**Tx Late Collision Packets** This field indicates the number of packets aborted because of late collision error. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Excessive Collision Packets Count Register

This register provides the number of packets aborted by DWC_ether_qos because of excessive (16) collision errors.

TX_EXCESSIVE_COLLISION_PACKETS

Transmitted Excessive Collision Packets Count Register(075C$_H$) **Application Reset Value: 0000 0000$_H$**



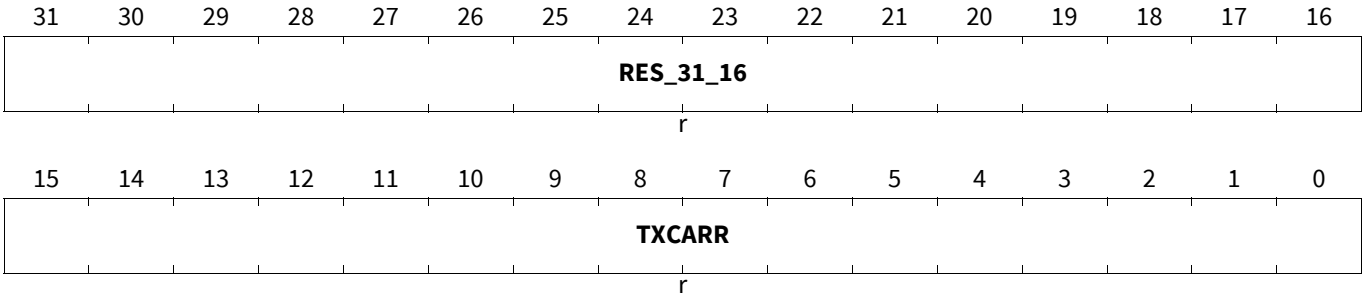
Field	Bits	Type	Description
TXEXSCOL	15:0	r	**Tx Excessive Collision Packets** This field indicates the number of packets aborted because of excessive (16) collision errors. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Carrier Error Packets Count Register

This register provides the number of packets aborted by DWC_ether_qos because of carrier sense error (no carrier or loss of carrier).

TX_CARRIER_ERROR_PACKETS

Transmitted Carrier Error Packets Count Register(0760$_H$) **Application Reset Value: 0000 0000$_H$**



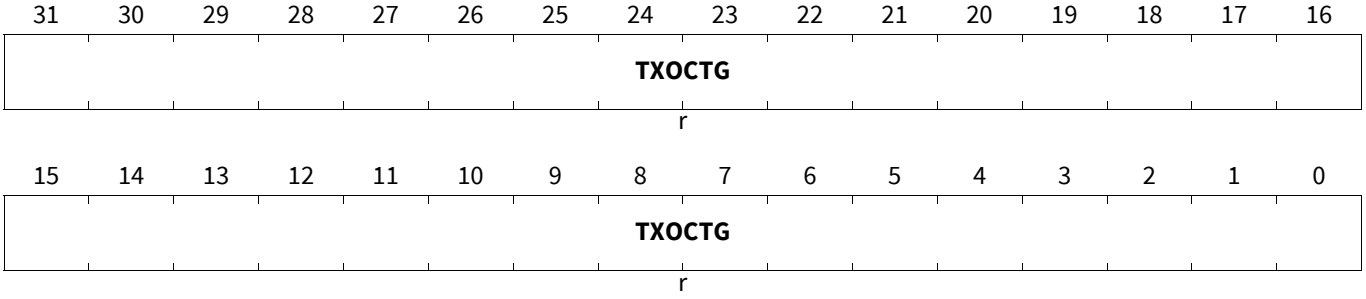
Field	Bits	Type	Description
TXCARR	15:0	r	**Tx Carrier Error Packets** This field indicates the number of packets aborted because of carrier sense error (no carrier or loss of carrier). Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Transmitted Octet Count Register

This register provides the number of bytes transmitted by DWC_ether_qos, exclusive of preamble, only in good packets.

TX_OCTET_COUNT_GOOD

Good Transmitted Octet Count Register (0764$_H$) Application Reset Value: 0000 0000$_H$



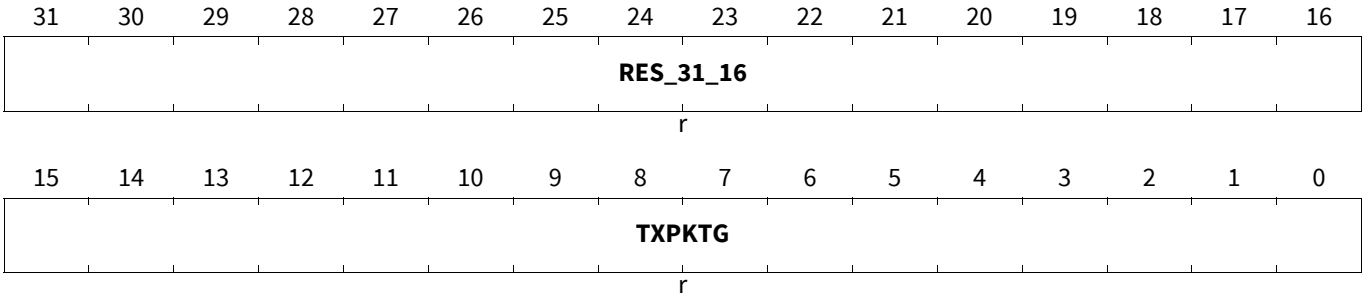
Field	Bits	Type	Description
TXOCTG	31:0	r	**Tx Octet Count Good** This field indicates the number of bytes transmitted, exclusive of preamble, only in good packets. Value After Reset: 0x0

Good Transmitted Packet Count Register

This register provides the number of good packets transmitted by DWC_ether_qos.

TX_PACKET_COUNT_GOOD

Good Transmitted Packet Count Register (0768$_H$) Application Reset Value: 0000 0000$_H$



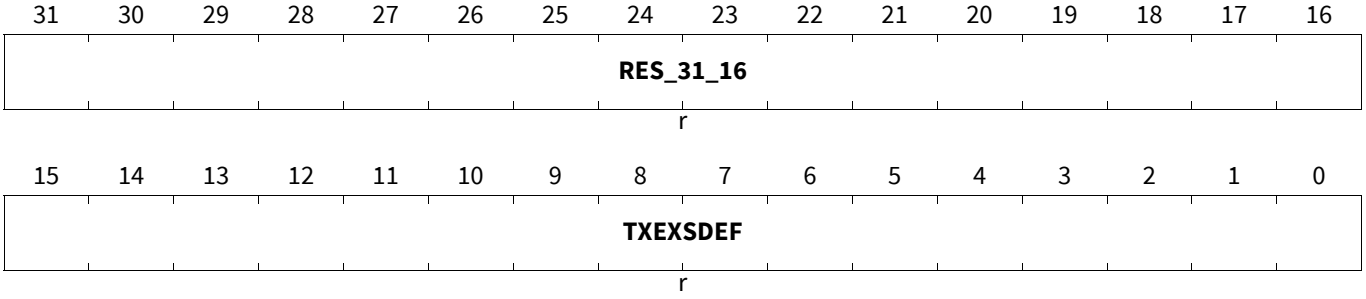
Field	Bits	Type	Description
TXPKTG	15:0	r	**Tx Packet Count Good** This field indicates the number of good packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Excessive Deferral Error Count Register

This register provides the number of packets aborted by DWC_ether_qos because of excessive deferral error (deferred for more than two max-sized packet times).

TX_EXCESSIVE_DEFERRAL_ERROR

Transmitted Excessive Deferral Error Count Register(076C$_H$) **Application Reset Value: 0000 0000$_H$**



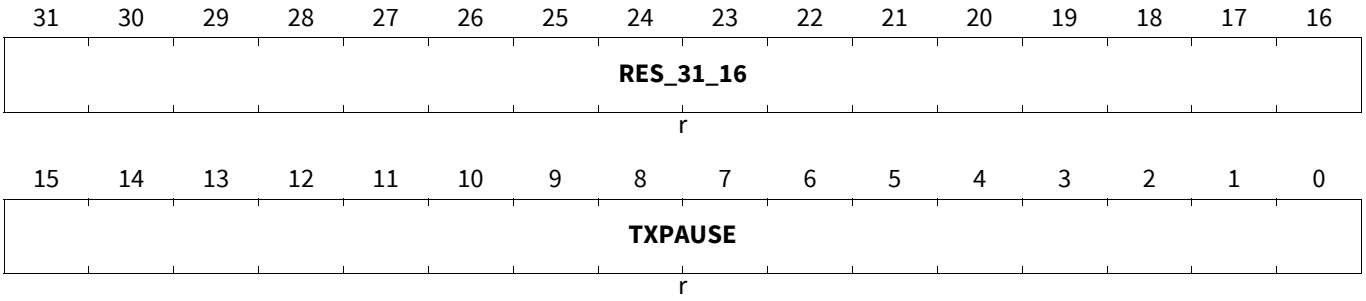
Field	Bits	Type	Description
TXEXSDEF	15:0	r	**Tx Excessive Deferral Error** This field indicates the number of packets aborted because of excessive deferral error (deferred for more than two max-sized packet times). Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted Pause Packets Count Register

This register provides the number of good Pause packets transmitted by DWC_ether_qos.

TX_PAUSE_PACKETS

Transmitted Pause Packets Count Register (0770$_H$) **Application Reset Value: 0000 0000$_H$**



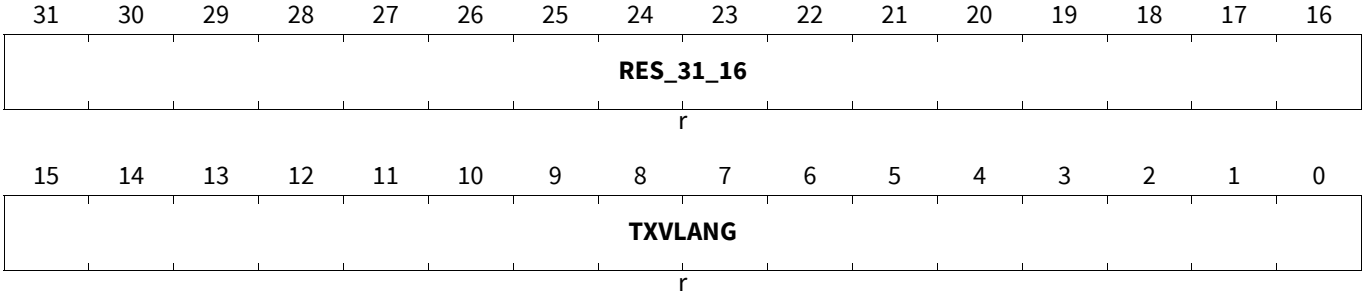
Field	Bits	Type	Description
TXPAUSE	15:0	r	**Tx Pause Packets** This field indicates the number of good Pause packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Transmitted VLAN Packets Count Register

This register provides the number of good VLAN packets transmitted by DWC_ether_qos.

TX_VLAN_PACKETS_GOOD

Good Transmitted VLAN Packets Count Register(0774_H) **Application Reset Value: $0000\ 0000_H$**



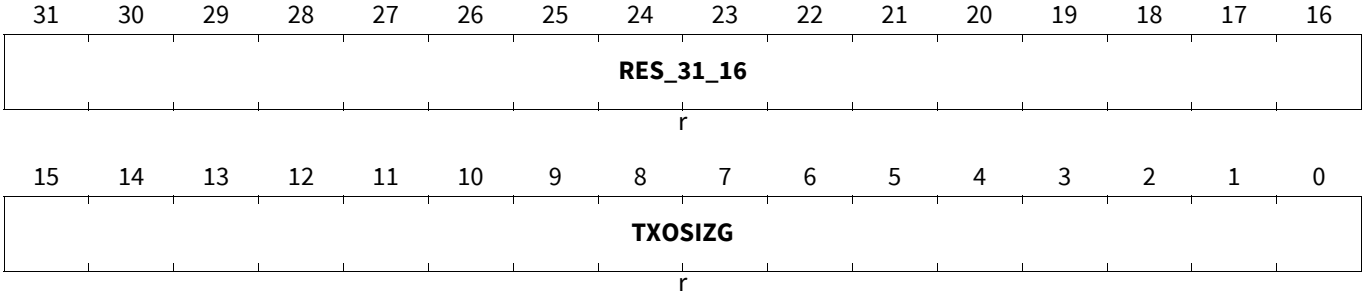
Field	Bits	Type	Description
TXVLANG	15:0	r	**Tx VLAN Packets Good** This field provides the number of good VLAN packets transmitted. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Transmitted Osize Packets Count Register

This register provides the number of packets transmitted by DWC_ether_qos without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register).

TX_OSIZE_PACKETS_GOOD

Good Transmitted Osize Packets Count Register(0778_H) **Application Reset Value: $0000\ 0000_H$**



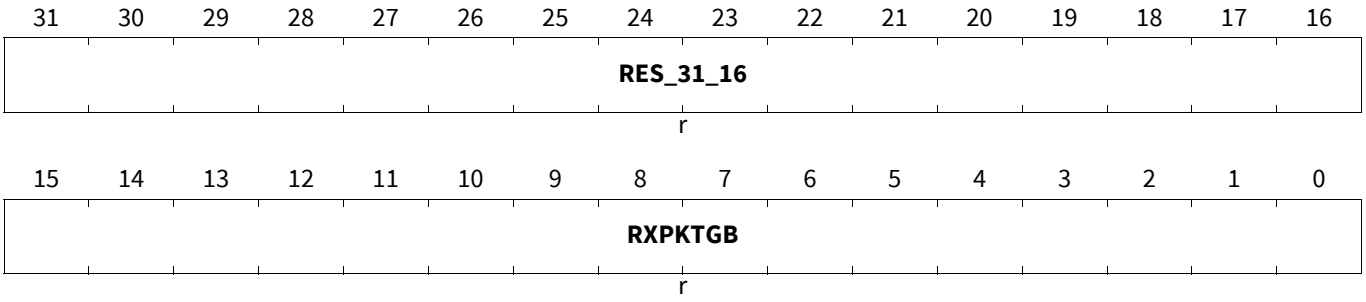
Field	Bits	Type	Description
TXOSIZG	15:0	r	**Tx OSize Packets Good** This field indicates the number of packets transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged packets; 2000 bytes if enabled in S2KP bit of the MAC_Configuration register). Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad Received Packets Count Register

This register provides the number of good and bad packets received by DWC_ether_qos.

RX_PACKETS_COUNT_GOOD_BAD

Good And Bad Received Packets Count Register (0780_H) **Application Reset Value: $0000\ 0000_H$**



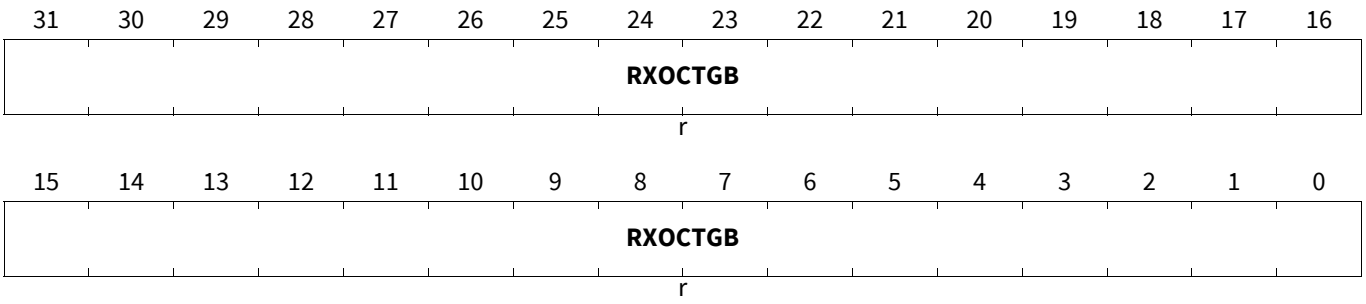
Field	Bits	Type	Description
RXPKTGB	15:0	r	**Rx Packets Count Good Bad** This field indicates the number of good and bad packets received. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good And Bad Received Octet Count Register

This register provides the number of bytes received by DWC_ther_qos, exclusive of preamble, in good and bad packets.

RX_OCTET_COUNT_GOOD_BAD

Good And Bad Received Octet Count Register (0784_H) **Application Reset Value: $0000\ 0000_H$**



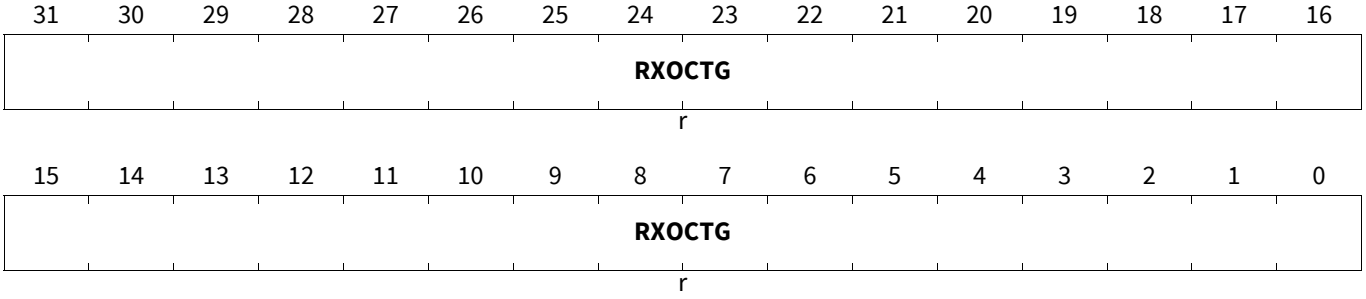
Field	Bits	Type	Description
RXOCTGB	31:0	r	**Rx Octet Count Good Bad** This field indicates the number of bytes received, exclusive of preamble, in good and bad packets. Value After Reset: 0x0

Good Received Octet Count Register

This register provides the number of bytes received by DWC_ether_qos, exclusive of preamble, only in good packets.

RX_OCTET_COUNT_GOOD

Good Received Octet Count Register (0788$_H$) Application Reset Value: 0000 0000$_H$



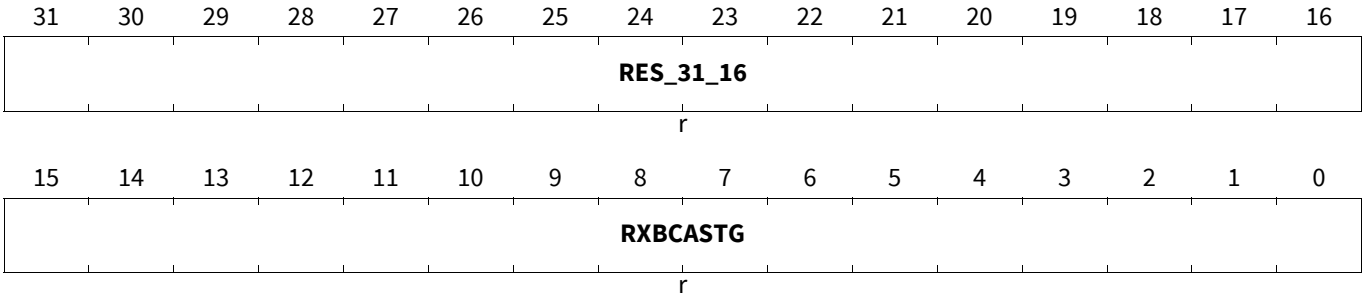
Field	Bits	Type	Description
RXOCTG	31:0	r	**Rx Octet Count Good** This field indicates the number of bytes received, exclusive of preamble, only in good packets. Value After Reset: 0x0

Good Received Broadcast Packets Count Register

This register provides the number of good broadcast packets received by DWC_ether_qos.

RX_BROADCAST_PACKETS_GOOD

Good Received Broadcast Packets Count Register(078C$_H$) Application Reset Value: 0000 0000$_H$



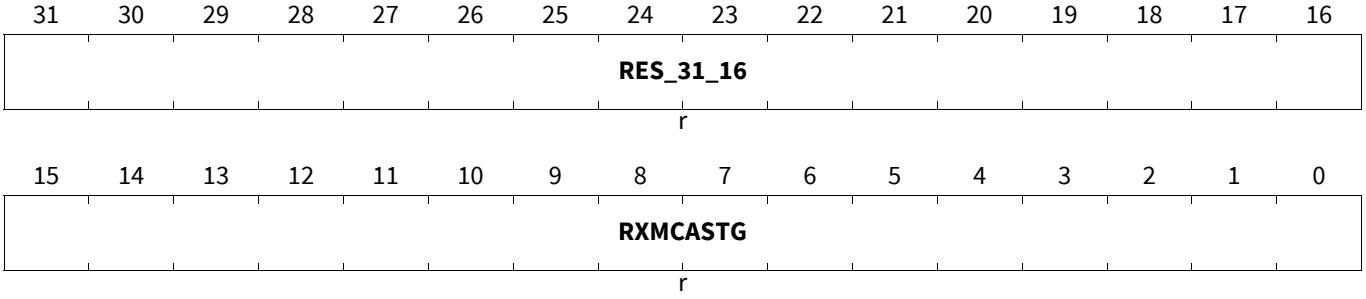
Field	Bits	Type	Description
RXBCASTG	15:0	r	**Rx Broadcast Packets Good** This field indicates the number of good broadcast packets received. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Good Received Multicast Packets Count Register

This register provides the number of good multicast packets received by DWC_ether_qos.

RX_MULTICAST_PACKETS_GOOD

Good Received Multicast Packets Count Register(0790$_H$) **Application Reset Value: 0000 0000$_H$**



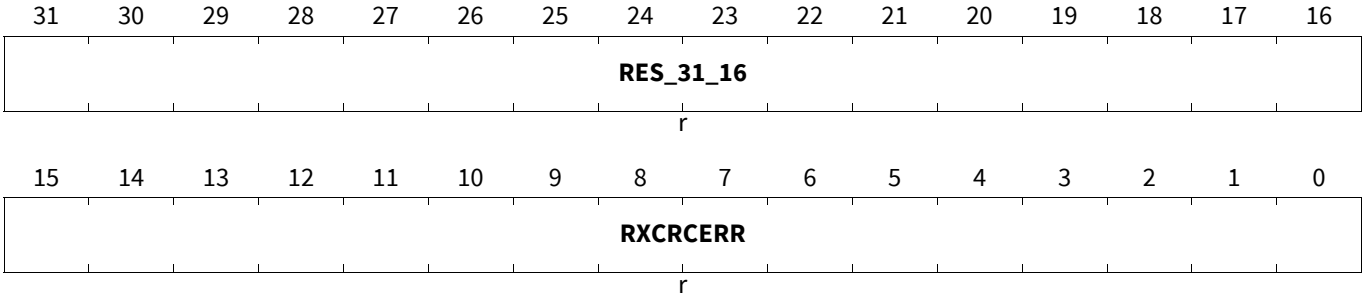
Field	Bits	Type	Description
RXMCASTG	15:0	r	**Rx Multicast Packets Good** This field indicates the number of good multicast packets received. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received CRC Error Packets Count Register

This register provides the number of packets received by DWC_ether_qos with CRC error.

RX_CRC_ERROR_PACKETS

Received CRC Error Packets Count Register (0794$_H$) **Application Reset Value: 0000 0000$_H$**



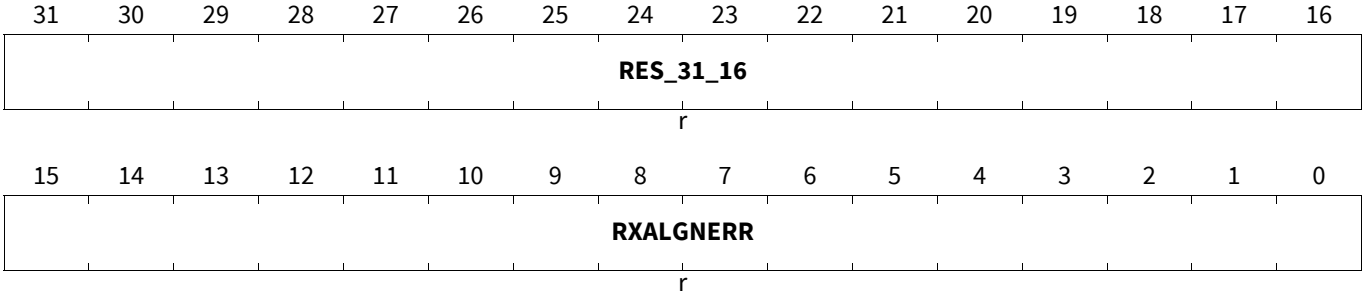
Field	Bits	Type	Description
RXCRCERR	15:0	r	**Rx CRC Error Packets** This field indicates the number of packets received with CRC error. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received Alignment Error Count Register

This register provides the number of packets received by DWC_ether_qos with alignment (dribble) error. It is valid only in 10/100 mode.

RX_ALIGNMENT_ERROR_PACKETS

Received Alignment Error Count Register (0798$_H$) Application Reset Value: 0000 0000$_H$



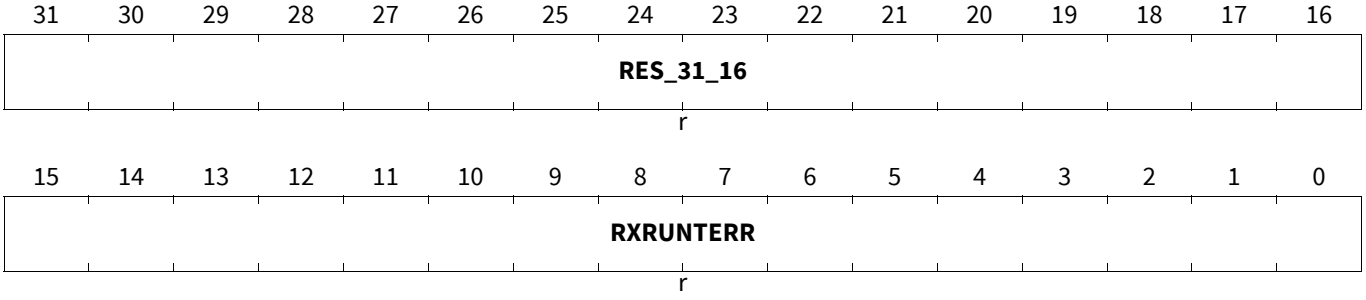
Field	Bits	Type	Description
RXALGNERR	15:0	r	**Rx Alignment Error Packets** This field indicates the number of packets received with alignment (dribble) error. It is valid only in 10/100 mode. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received Runtime Error Count Register

This register provides the number of packets received by DWC_ether_qos with runt (length less than 64 bytes and CRC error) error.

RX_RUNT_ERROR_PACKETS

Received Runtime Error Count Register (079C$_H$) Application Reset Value: 0000 0000$_H$

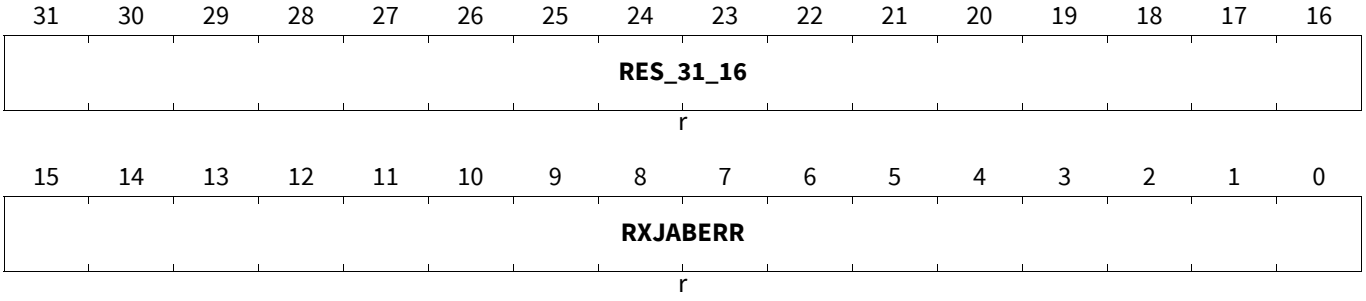


Field	Bits	Type	Description
RXRUNTERR	15:0	r	**Rx Runt Error Packets** This field indicates the number of packets received with runt (length less than 64 bytes and CRC error) error. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received Jabber Error Count Register

This register provides the number of giant packets received by DWC_ether_qos with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN tagged) are considered as giant packets.

RX_JABBER_ERROR_PACKETS
Received Jabber Error Count Register (07A0$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RXJABERR	15:0	r	**Rx Jabber Error Packets** This field indicates the number of giant packets received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. Transmitted LPI Microseconds Count Register

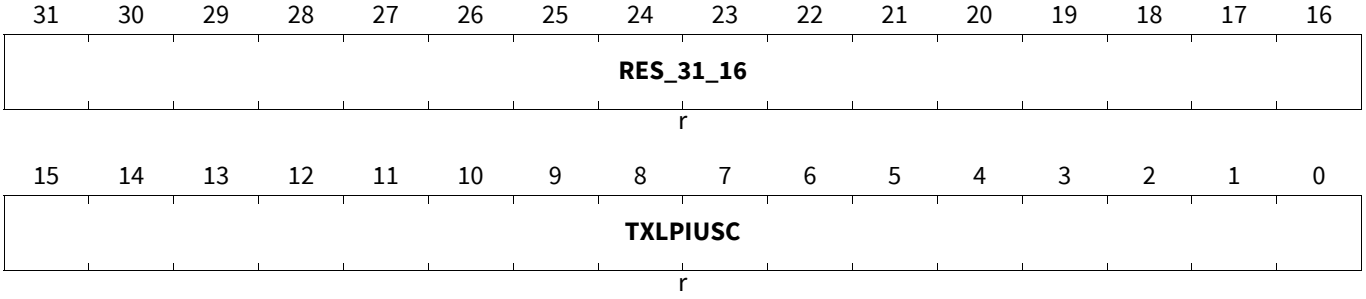
This register provides the number of microseconds Tx LPI is asserted by DWC_ether_qos.

TX_LPI_USEC_CNTR

Transmitted LPI Microseconds Count Register (07EC$_H$) Application Reset Value: 0000 0000$_H$



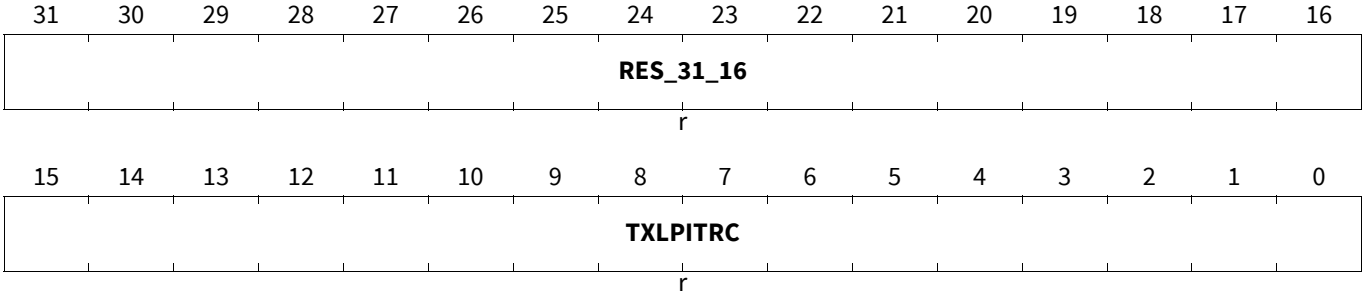
Field	Bits	Type	Description
TXLPIUSC	15:0	r	**Tx LPI Microseconds Counter** This field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Transmitted LPI Transition Count Register

This register provides the number of times DWC_ether_qos has entered Tx LPI.

TX_LPI_TRAN_CNTR

Transmitted LPI Transition Count Register (07F0$_H$) Application Reset Value: 0000 0000$_H$



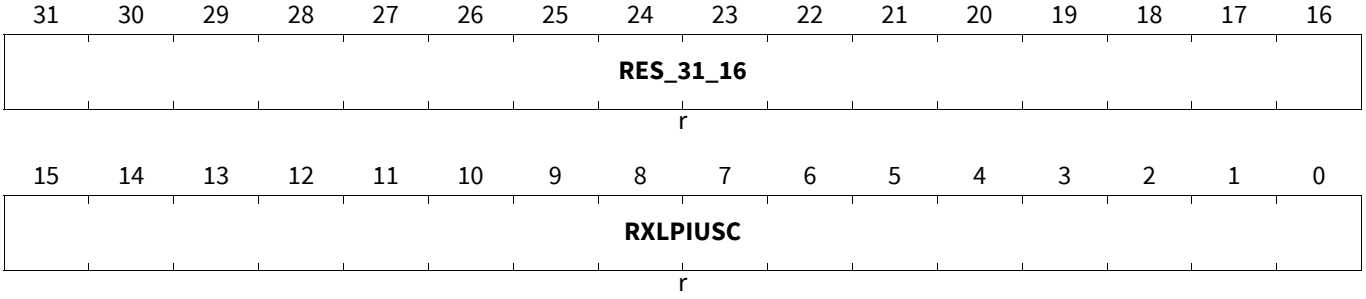
Field	Bits	Type	Description
TXLPITRC	15:0	r	**Tx LPI Transition counter** This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate Mode (because of LPITXA bit set in the LPI Control and Status register), the counter will increment. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received Microseconds LPI Count Register

This register provides the number of microseconds Rx LPI is sampled by DWC_ether_qos.

RX_LPI_USEC_CNTR

Received Microseconds LPI Count Register (07F4$_H$) Application Reset Value: 0000 0000$_H$



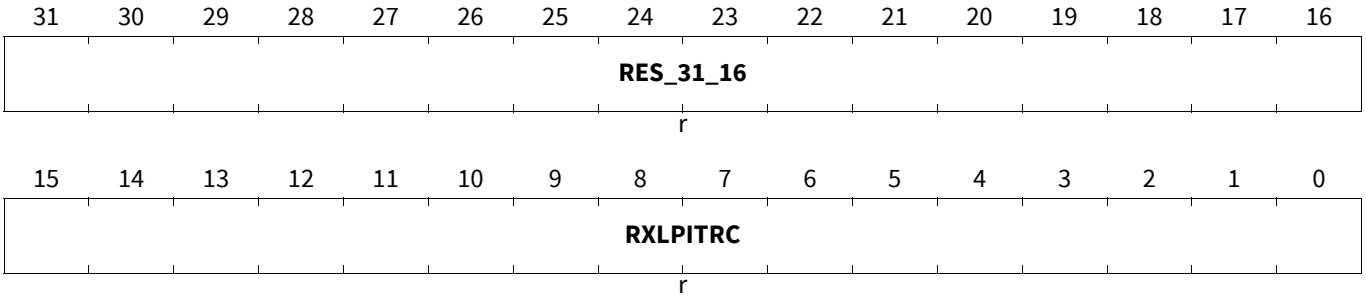
Field	Bits	Type	Description
RXLPIUSC	15:0	r	**Rx LPI Microseconds Counter** This field indicates the number of microseconds Rx LPI is asserted. For every Rx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

Received LPI Transition Count Register

This register provides the number of times DWC_ether_qos has entered Rx LPI.

RX_LPI_TRAN_CNTR

Received LPI Transition Count Register (07F8$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RXLPITRC	15:0	r	**Rx LPI Transition counter** This field indicates the number of times Rx LPI Entry has occurred. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MMC IPC Receive Interrupts Mask Register

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

MMC_IPC_RX_INTERRUPT_MASK
MMC IPC Receive Interrupts Mask Register (0800_H) Application Reset Value: $0000\ 0000_H$

MMC IPC Receive Interrupts Register

This register maintains the interrupt that the receive IPC statistic counters generate.

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

MMC_IPC_RX_INTERRUPT
MMC IPC Receive Interrupts Register **(0808_H)** **Application Reset Value: $0000\ 0000_H$**

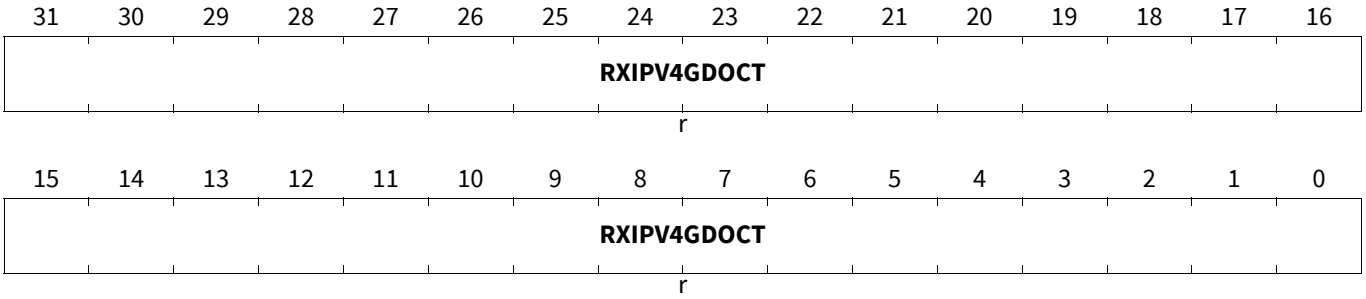
Good Received IPV4 Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV4_GOOD_OCTETS

Good Received IPV4 Octets Count Register (0850$_H$) Application Reset Value: 0000 0000$_H$



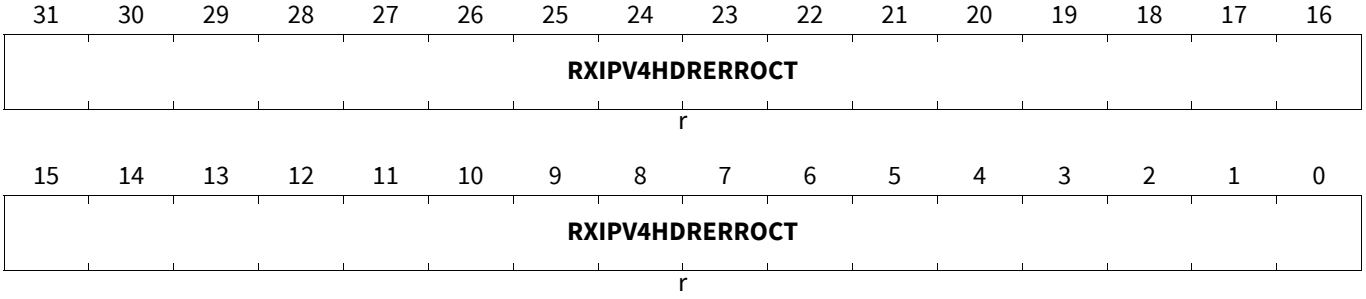
Field	Bits	Type	Description
RXIPV4GDOCT	31:0	r	**RxIPv4 Good Octets** This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. Value After Reset: 0x0

Received IPV4 Header Error Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV4_HEADER_ERROR_OCTETS

Received IPV4 Header Error Octets Count Register(0854_H) **Application Reset Value: $0000\ 0000_H$**



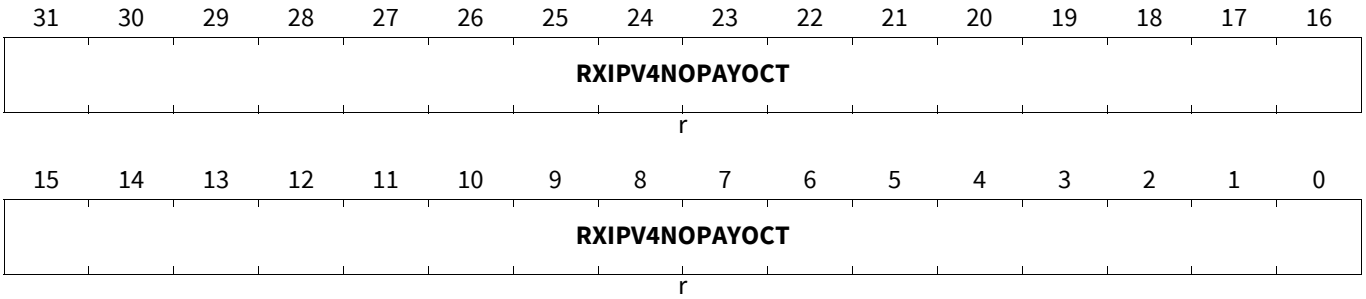
Field	Bits	Type	Description
RXIPV4HDRERROCT	31:0	r	**RxIPv4 Header Error Octets** This field indicates the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. Value After Reset: 0x0

Received IPV4 No Payload Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV4_NO_PAYLOAD_OCTETS

Received IPV4 No Payload Octets Count Register(0858_H) **Application Reset Value: $0000\ 0000_H$**



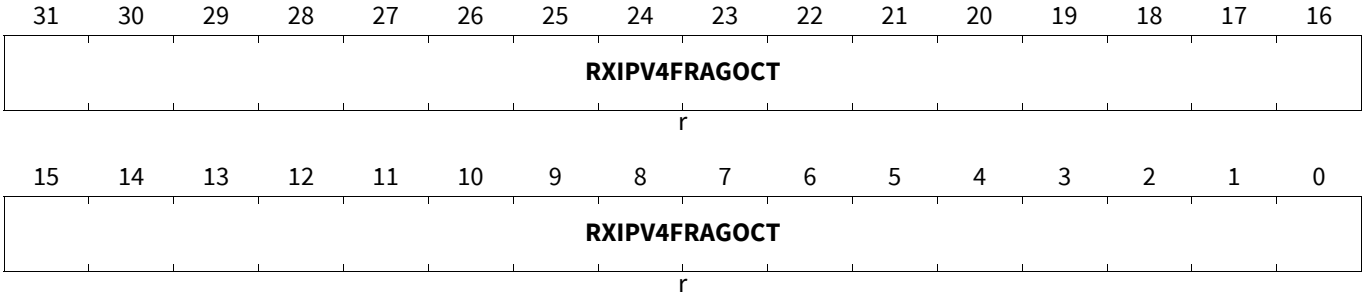
Field	Bits	Type	Description
RXIPV4NOPAYOCT	31:0	r	**RxIPv4 Payload Octets** This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. Value After Reset: 0x0

Received IPV4 Fragmented Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV4_FRAGMENTED_OCTETS

Received IPV4 Fragmented Octets Count Register(085C$_H$) **Application Reset Value: 0000 0000$_H$**



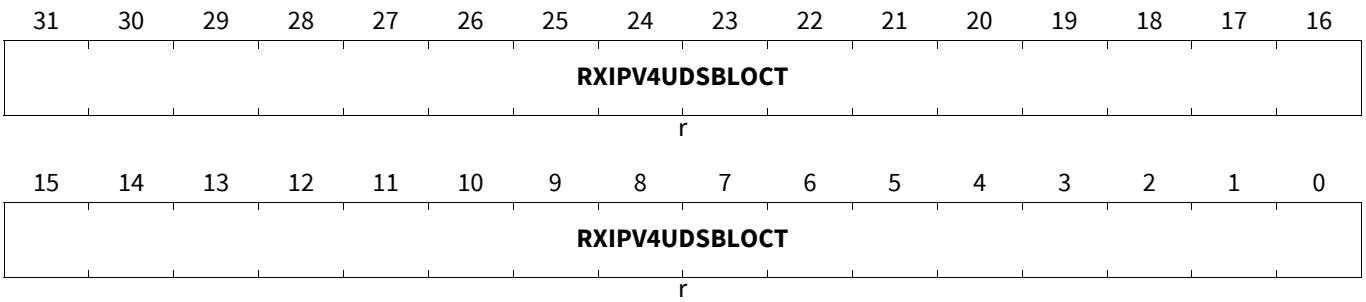
Field	Bits	Type	Description
RXIPV4FRAGOCT	31:0	r	**RxIPv4 Fragmented Octets** This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the Length field of IPv4 header is used to update this counter. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. Value After Reset: 0x0

Received IPV4 UPD Checksum Disabled Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS

Received IPV4 UPD Checksum Disabled Octets Count Register(0860$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RXIPV4UDSBLOCT	31:0	r	**RxIPv4 UDP Checksum Disable Octets** This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. Value After Reset: 0x0

Good Received IPV6 Octets Count Register

This register provides the number of bytes received by DWC_ether_qos in good IPv6 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

RXIPV6_GOOD_OCTETS
Good Received IPV6 Octets Count Register (0864$_H$) Application Reset Value: 0000 0000$_H$

MAC Timestamp Control Register

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

MAC_TIMESTAMP_CONTROL
MAC Timestamp Control Register **($0B00_H$)** **Application Reset Value: $0000\ 2000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES_31_29			AV8021ASMEN	RES_27_25			TXTSSTSM	RES_23_21			RES_20	CSC	TSENMACADDR	SNAPTYPSEL	
r			rw	r			rw	r			r	rw	rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSMSTRENA	TSEVNTENA	TSIPV4ENA	TSIPV6ENA	TSIPENA	TSVER2ENA	TSCTRLSSR	TSENALL	RES_7_6		TSADDREG	RES_4	TSUPDT	TSINIT	TSCFUPDT	TSENA
rw	rw	rw	rw	rw	rw	rw	rw	r		rw	r	rw	rw	rw	rw

Field	Bits	Type	Description
TSENA	0	rw	**Enable Timestamp** When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. Value After Reset: 0x0
TSCFUPDT	1	rw	**Fine or Coarse Timestamp Update** When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. Value After Reset: 0x0
TSINIT	2	rw	**Initialize Timestamp** When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register). This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
TSUPDT	3	rw	**Update Timestamp** When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
RES_4	4	r	**Reserved for future use.**
TSADDREG	5	rw	**Update Addend Register** When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
RES_7_6	7:6	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
TSENALL	8	rw	**Enable Timestamp for All Packets** When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. Value After Reset: 0x0
TSCTRLSSR	9	rw	**Timestamp Digital or Binary Rollover Control** When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. Value After Reset: 0x0
TSVER2ENA	10	rw	**Enable PTP Packet Processing for Version 2 Format** When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. Value After Reset: 0x0
TSIPENA	11	rw	**Enable Processing of PTP over Ethernet Packets** When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. Value After Reset: 0x0
TSIPV6ENA	12	rw	**Enable Processing of PTP Packets Sent over IPv6-UDP** When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. Value After Reset: 0x0
TSIPV4ENA	13	rw	**Enable Processing of PTP Packets Sent over IPv4-UDP** When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. Value After Reset: 0x1
TSEVNTENA	14	rw	**Enable Timestamp Snapshot for Event Messages** When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. Value After Reset: 0x0
TSMSTRENA	15	rw	**Enable Snapshot for Messages Relevant to Master** When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. Value After Reset: 0x0

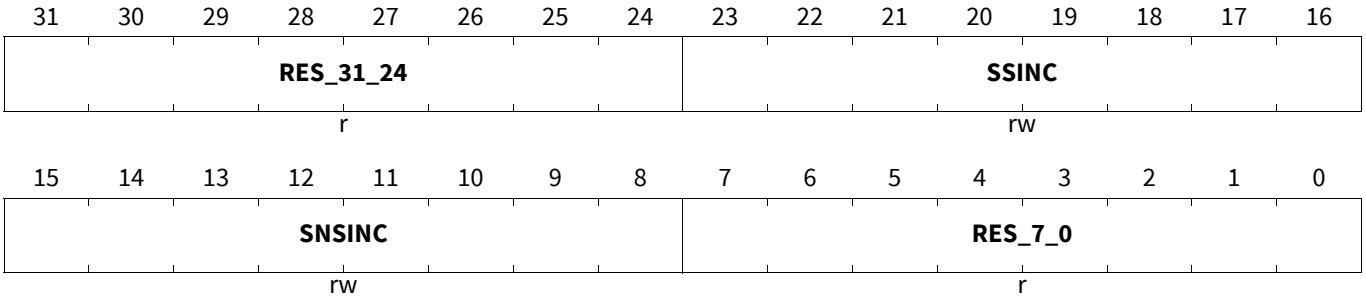
Field	Bits	Type	Description
SNAPTYPSEL	17:16	rw	**Select PTP packets for Taking Snapshots** These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table. Value After Reset: 0x0
TSENMACADDR	18	rw	**Enable MAC Address for PTP Packet Filtering** When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. Value After Reset: 0x0
CSC	19	rw	**Enable checksum correction during OST for PTP over UDP/IPv4 packets** When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application shall form the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application shall form the packet with UDP checksum set to 0. Value After Reset: 0x0
RES_20	20	r	**Reserved for future use.**
RES_23_21	23:21	r	**Reserved** Value After Reset: 0x0
TXTSSTSM	24	rw	**Transmit Timestamp Status Mode** When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. Value After Reset: 0x0
RES_27_25	27:25	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
AV8021ASMEN	28	rw	**AV 802.1AS Mode Enable** When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. Value After Reset: 0x0
RES_31_29	31:29	r	**Reserved** Value After Reset: 0x0

MAC Sub-Second Increment Register

This register specifies the value to be added to the internal system time every cycle of clk_ptp_ref_i clock.

MAC_SUB_SECOND_INCREMENT
MAC Sub-Second Increment Register **($0B04_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RES_7_0	7:0	r	**Reserved** Value After Reset: 0x0
SNSINC	15:8	rw	**Sub-nanosecond Increment Value** This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set. and if the required increment is 5.3ns, then SSINC should be 0x05 and SNSINC should be 0x4C. Value After Reset: 0x0

Field	Bits	Type	Description
SSINC	23:16	rw	**Sub-second Increment Value** The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465. Value After Reset: 0x0
RES_31_24	31:24	r	**Reserved** Value After Reset: 0x0

MAC System Time Seconds Register

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

MAC_SYSTEM_TIME_SECONDS

MAC System Time Seconds Register (0B08$_H$) Application Reset Value: 0000 0000$_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSSS															
rw															

Field	Bits	Type	Description
TSSS	30:0	rw	**Timestamp Sub Seconds** The value in this field is the sub seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_Timestamp_Control is set, the programmed value must be 10^9 - <sub-second_value>. When TSCTRLSSR bit in MAC_Timestamp_Control is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set. Value After Reset: 0x0
ADDSUB	31	rw	**Add or Subtract Time** When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. Value After Reset: 0x0

MAC Timestamp Addend Register

The Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

MAC_TIMESTAMP_ADDEND

MAC Timestamp Addend Register **($0B18_H$)** **Application Reset Value: $0000\ 0000_H$**

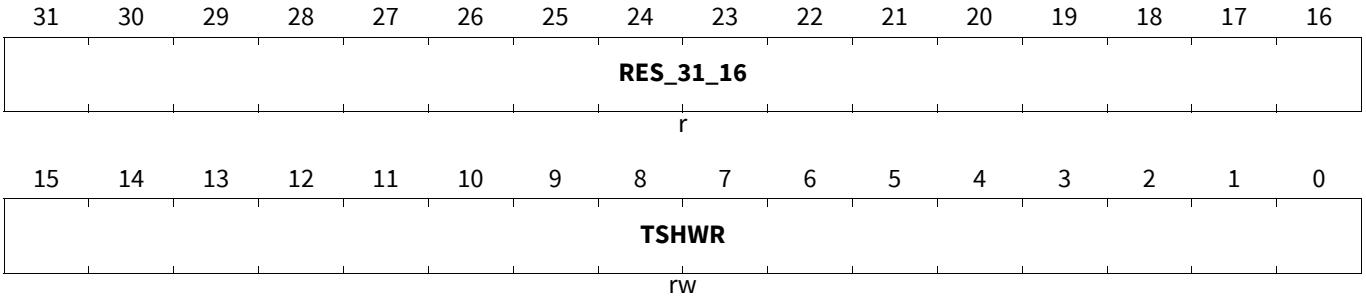
MAC System Time Higher Word Seconds Register

The System Time - Higher Word Seconds register.

MAC_SYSTEM_TIME_HIGHER_WORD_SECONDS

MAC System Time Higher Word Seconds Register($0B1C_H$) **Application Reset Value: $0000\ 0000_H$**



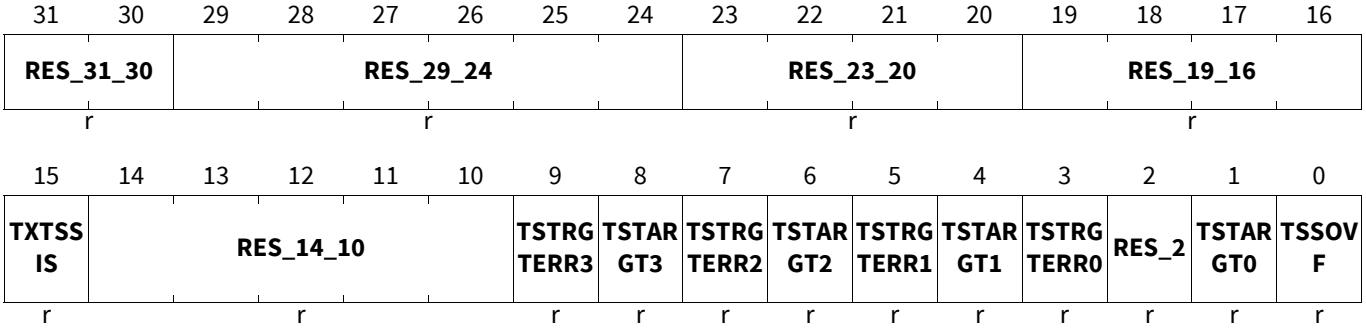
Field	Bits	Type	Description
TSHWR	15:0	rw	**Timestamp Higher Word Register** This field contains the most-significant 16-bits of timestamp seconds value. This register is optional. You can add this register by selecting the Add IEEE 1588 Higher Word Register option. This register is directly written to initialize the value and it is incremented when there is an overflow from 32-bits of the System Time Seconds register. Access restriction applies. Updated based on the event. Setting 1 sets. Setting 0 clears. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MAC Timestamp Status Register

The Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register.

MAC_TIMESTAMP_STATUS

MAC Timestamp Status Register **(0B20$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TSSOVF	0	r	**Timestamp Seconds Overflow** When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTARGT0	1	r	**Timestamp Target Time Reached** When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_2	2	r	**Reserved for future use.**
TSTRGTERR0	3	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTARGT1	4	r	**Timestamp Target Time Reached for Target Time PPS1** When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0

Field	Bits	Type	Description
TSTRGTERR1	5	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTARGT2	6	r	**Timestamp Target Time Reached for Target Time PPS2** When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTRGTERR2	7	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTARGT3	8	r	**Timestamp Target Time Reached for Target Time PPS3** When this bit is set, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
TSTRGTERR3	9	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Value After Reset: 0x0
RES_14_10	14:10	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
TXTSSIS	15	r	**Tx Timestamp Status Interrupt Status** When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_Tx_Timestamp_Status_Nanoseconds and MAC_Tx_Timestamp_Status_Seconds registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the MAC_Tx_Timestamp_Status_Seconds register is read (or write to MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set). Value After Reset: 0x0
RES_19_16	19:16	r	**Reserved for future use.**
RES_23_20	23:20	r	**Reserved** Value After Reset: 0x0
RES_29_24	29:24	r	**Reserved for future use.**
RES_31_30	31:30	r	**Reserved** Value After Reset: 0x0

MAC Transmit Timestamp Nanoseconds Status Register

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [15] in MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

MAC_TX_TIMESTAMP_STATUS_NANOSECONDS

MAC Transmit Timestamp Nanoseconds Status Register($0B30_H$) **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXTSSMIS	**TXTSSLO**														
r	r														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TXTSSLO															
r															

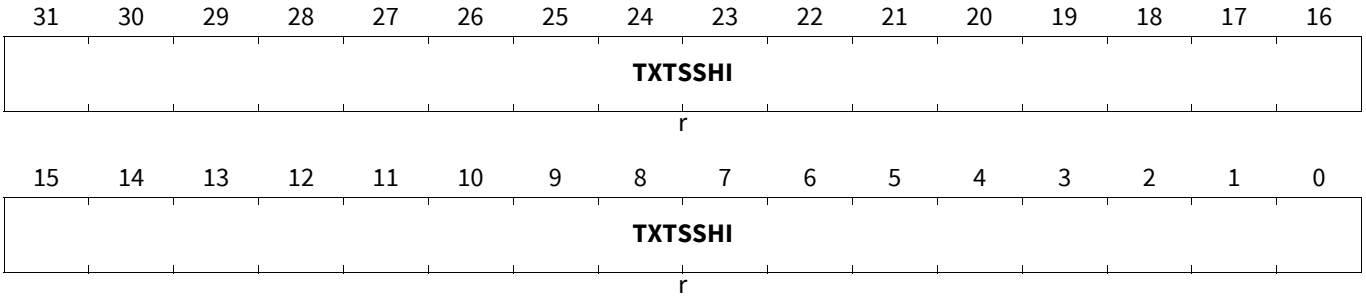
Field	Bits	Type	Description
TXTSSLO	30:0	r	**Transmit Timestamp Status Low** This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp. Value After Reset: 0x0
TXTSSMIS	31	r	**Transmit Timestamp Status Missed** When this bit is set, it indicates one of the following: • The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset • The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0

MAC Transmit Timestamp Seconds Status Register

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

MAC_TX_TIMESTAMP_STATUS_SECONDS

MAC Transmit Timestamp Seconds Status Register($0B34_H$) **Application Reset Value: $0000\ 0000_H$**



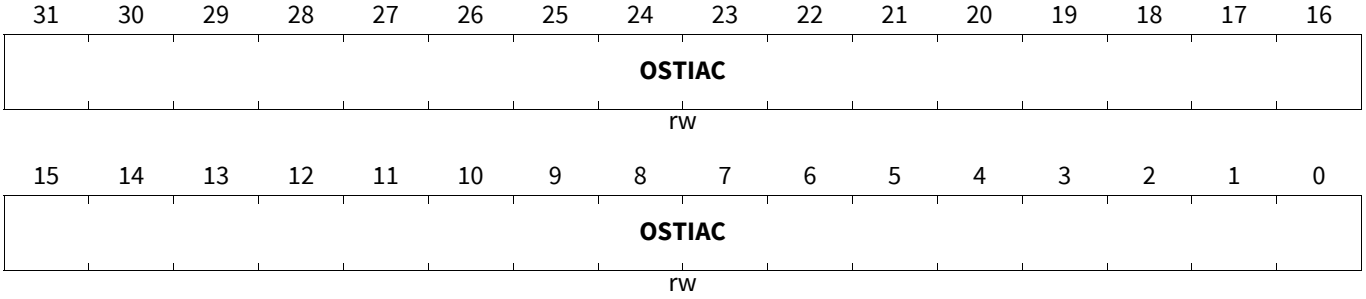
Field	Bits	Type	Description
TXTSSHI	31:0	r	**Transmit Timestamp Status High** This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp. Value After Reset: 0x0

MAC Timestamp Ingress Asymmetry Correction Register

The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in PDelay_Resp PTP messages.

MAC_TIMESTAMP_INGRESS_ASYM_CORR

MAC Timestamp Ingress Asymmetry Correction Register(0B50$_H$) **Application Reset Value: 0000 0000$_H$**



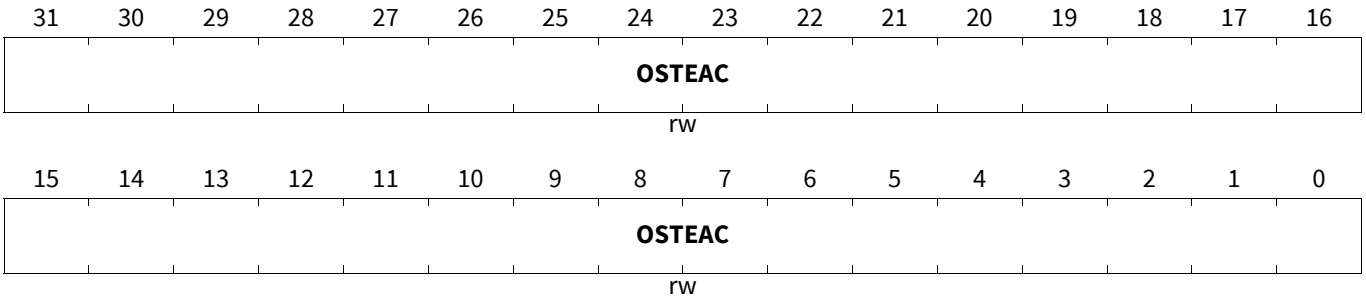
Field	Bits	Type	Description
OSTIAC	31:0	rw	**One-Step Timestamp Ingress Asymmetry Correction** This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit. Value After Reset: 0x0

MAC Timestamp Egress Asymmetry Correction Register

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

MAC_TIMESTAMP_EGRESS_ASYM_CORR

MAC Timestamp Egress Asymmetry Correction Register(0B54$_H$) **Application Reset Value: 0000 0000$_H$**



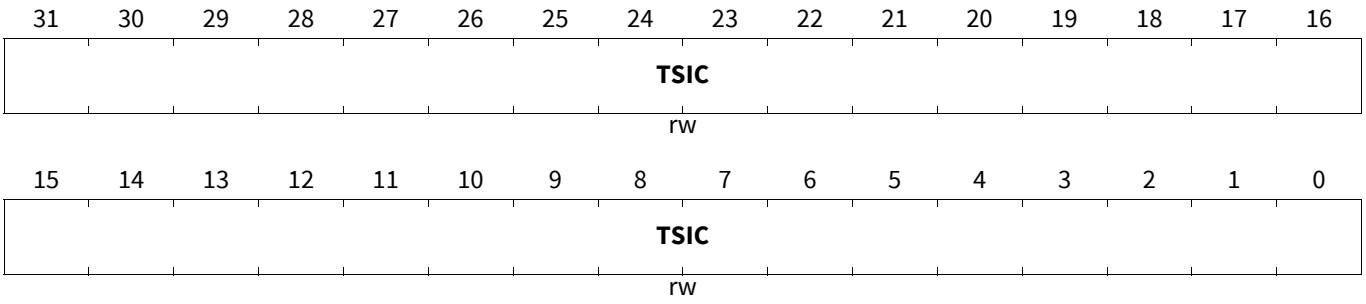
Field	Bits	Type	Description
OSTEAC	31:0	rw	**One-Step Timestamp Egress Asymmetry Correction** This field contains the egress path asymmetry value to be subtracted from correctionField of Pdelay_Resp PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, the programmed value must be 0xFFFD_8000, which is the 2's complement of 0x0002_8000(2.5 * 216). Similarly, if the required correction is -3.3 ns, the programmed value is 0x0003_4CCC (3.3 * 216). Value After Reset: 0x0

MAC Timestamp Ingress Correction Nanoseconds Register

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND

MAC Timestamp Ingress Correction Nanoseconds Register($0B58_H$) **Application Reset Value: $0000\ 0000_H$**



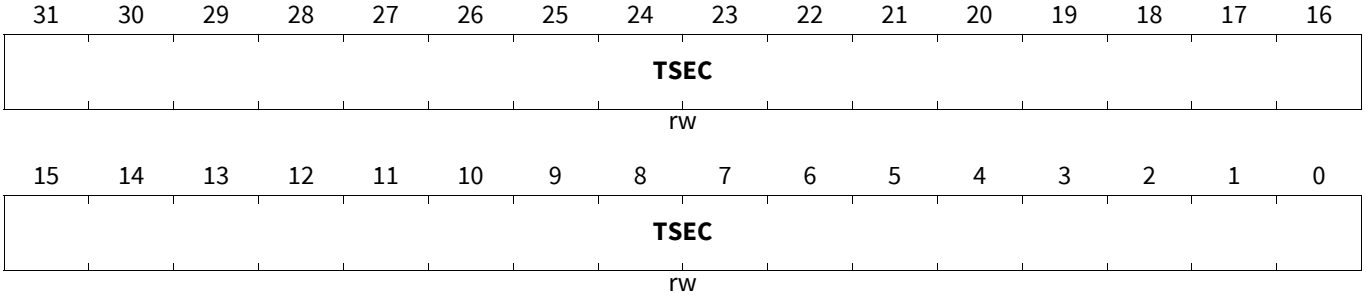
Field	Bits	Type	Description
TSIC	31:0	rw	**Timestamp Ingress Correction** This field contains the ingress path correction value as defined by the Ingress Correction expression. Value After Reset: 0x0

MAC Timestamp Egress Correction Nanoseconds Register

This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND

MAC Timestamp Egress Correction Nanoseconds Register(0B5C$_H$) Application Reset Value: 0000 0000$_H$



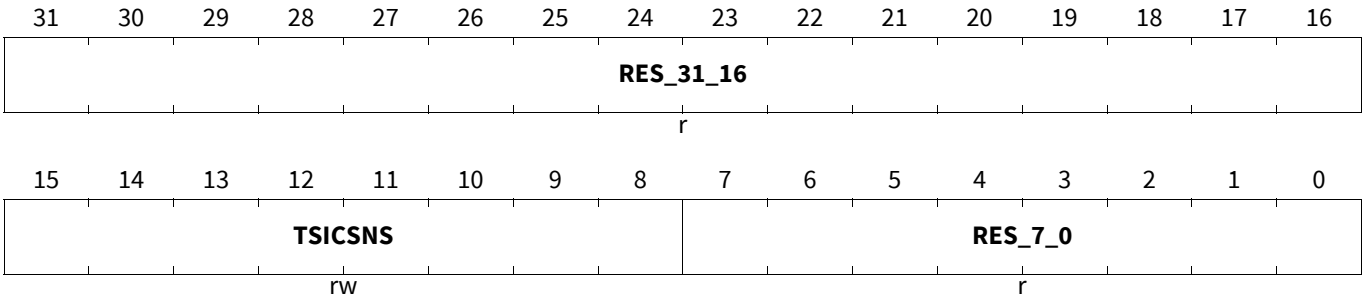
Field	Bits	Type	Description
TSEC	31:0	rw	**Timestamp Egress Correction** This field contains the nanoseconds part of the egress path correction value as defined by the Egress Correction expression. Value After Reset: 0x0

MAC Timestamp Ingress Correction Subnanoseconds Register

This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for ingress direction.

MAC_TIMESTAMP_INGRESS_CORR_SUBNANOSEC

MAC Timestamp Ingress Correction Subnanoseconds Register(0B60$_H$) Application Reset Value: 0000 0000$_H$



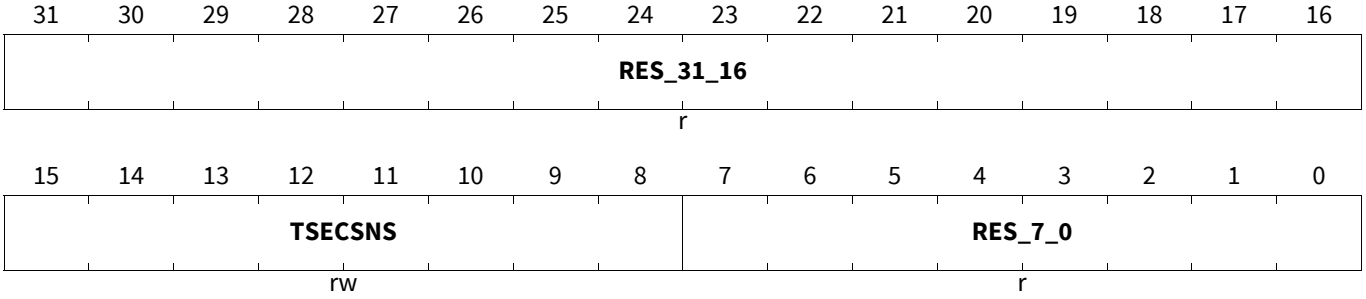
Field	Bits	Type	Description
RES_7_0	7:0	r	**Reserved** Value After Reset: 0x0
TSICSNS	15:8	rw	**Timestamp Ingress Correction, sub-nanoseconds** This field contains the sub-nanoseconds part of the ingress path correction value as defined by the “Ingress Correction” expression. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MAC Timestamp Egress Correction Subnanoseconds Register

This register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for egress direction.

MAC_TIMESTAMP_EGRESS_CORR_SUBNANOSEC

MAC Timestamp Egress Correction Subnanoseconds Register($0B64_H$) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RES_7_0	7:0	r	**Reserved** Value After Reset: 0x0
TSECSNS	15:8	rw	**Timestamp Egress Correction, sub-nanoseconds** This field contains the sub-nanoseconds part of the egress path correction value as defined by the “Egress Correction” expression. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

MAC PPS Control Register

PPS Control register.

Bits[30:24] of this register are valid only when four Flexible PPS outputs are selected. Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. Bits[6:4] are valid only when Flexible PPS feature is selected.

Notes on Bits [3:0] in the binary rollover mode, PPSEN0 = 0

The PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:

When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.

When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and 537 ms period and a second clock of 463 ms period (268 ms low and 195 ms high)

When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and 268 ms period and a fourth clock of 195 ms period (134 ms low and 61 ms high)

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.

Notes on Bits [3:0]: In the mode “Flexible PPS Output (ptp_pps_o[0]) Control”, PPSEN0 = 1

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0:

0000: No Command

0001: START Single Pulse

This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register.

0010: START Pulse Train

This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands.

0011: Cancel START

This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time.

0100: STOP Pulse train at time

This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses.

0101: STOP Pulse Train immediately

This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010).

0110: Cancel STOP Pulse train

This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.

0111-1111: Reserved

MAC_PPS_CONTROL
MAC PPS Control Register **($0B70_H$)** **Application Reset Value: $0000\ 0000_H$**

r	r	r	r	r	rw	rw	rw

Field	Bits	Type	Description
PPSCTRL_PPSCMD	3:0	rw	**Flexible PPS Output (ptp_pps_o[0]) Control** This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: LOST SEQUENCE DEFINITION Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0 1_H The binary rollover is 2 Hz, and the digital rollover is 1 Hz. 2_H The binary rollover is 4 Hz, and the digital rollover is 2 Hz. 3_H The binary rollover is 8 Hz, and the digital rollover is 4 Hz. 4_H The binary rollover is 16 Hz, and the digital rollover is 8 Hz. F_H The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.
PPSEN0	4	rw	**Flexible PPS Output Mode Enable** When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode). Value After Reset: 0x0
TRGTMODSEL0	6:5	rw	**Target Time Register Mode for PPS0 Output** This field indicates the Target Time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) mode for PPS0 output signal: Value After Reset: 0x0 00_B Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port. 01_B Reserved 10_B Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation. 11_B Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted.

MAC PPS 0 Target Time Seconds Register

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

MAC_PPS0_TARGET_TIME_SECONDS
MAC PPS 0 Target Time Seconds Register (0B80$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSTRH0															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSTRH0															
rw															

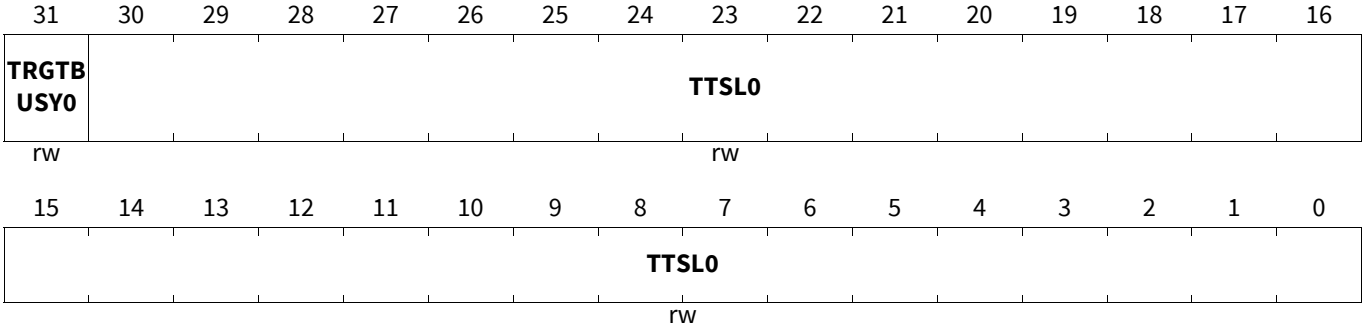
Field	Bits	Type	Description
TSTRH0	31:0	rw	**PPS Target Time Seconds Register** This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register. Value After Reset: 0x0

MAC PPS 0 Target Time Nanoeconds Register

PPS0 Target Time Nanoseconds register.

MAC_PPS0_TARGET_TIME_NANOSECONDS

MAC PPS 0 Target Time Nanoeconds Register (0B84$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TTSL0	30:0	rw	**Target Time Low for PPS Register** This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
TRGTBUSY0	31	rw	**PPS Target Time Register Busy** The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. Value After Reset: 0x0

MAC PPS 0 Interval Register

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

MAC_PPS0_INTERVAL

MAC PPS 0 Interval Register **(0B88$_H$)** **Application Reset Value: 0000 0000$_H$**

PPSINT0															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPSINT0															
rw															

Field	Bits	Type	Description
PPSINT0	31:0	rw	**PPS Output Signal Interval** These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register. Value After Reset: 0x0

MAC PPS 0 Width Register

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

MAC_PPS0_WIDTH

MAC PPS 0 Width Register **(0B8C$_H$)** **Application Reset Value: 0000 0000$_H$**

PPSWIDTH0															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPSWIDTH0															
rw															

Field	Bits	Type	Description
PPSWIDTH0	31:0	rw	**PPS Output Signal Width** These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. **Note**: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval. Value After Reset: 0x0

MTL Operation Mode Register

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

MTL_OPERATION_MODE
MTL Operation Mode Register **($0C00_H$)** **Application Reset Value: $0000\ 0000_H$**

RES_15_7									TTC			TXQEN		TSF	FTQ
r									rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note**: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0

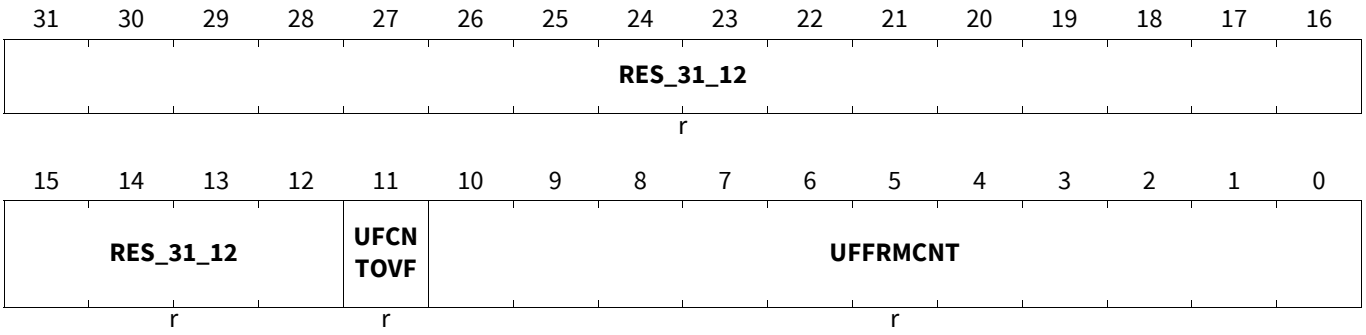
Field	Bits	Type	Description
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. Value After Reset: 0x0
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue 0. This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. **Note**: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. Value After Reset: 0x0 00_B Not enabled 01_B Reserved 10_B Enabled 11_B Reserved
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. Value After Reset: 0x0 000_B 32 001_B 64 010_B 96 011_B 128 100_B 192 101_B 256 110_B 384 111_B 512
RES_15_7	15:7	r	**Reserved** Value After Reset: 0x0
TQS	19:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits Value After Reset: 0x0
RES_31_x	31:20	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Transmit Underflow Counter Register

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

MTL_TXQ0_UNDERFLOW

MTL Queue 0 Transmit Underflow Counter Register(0D04$_H$) **Application Reset Value: 0000 0000$_H$**



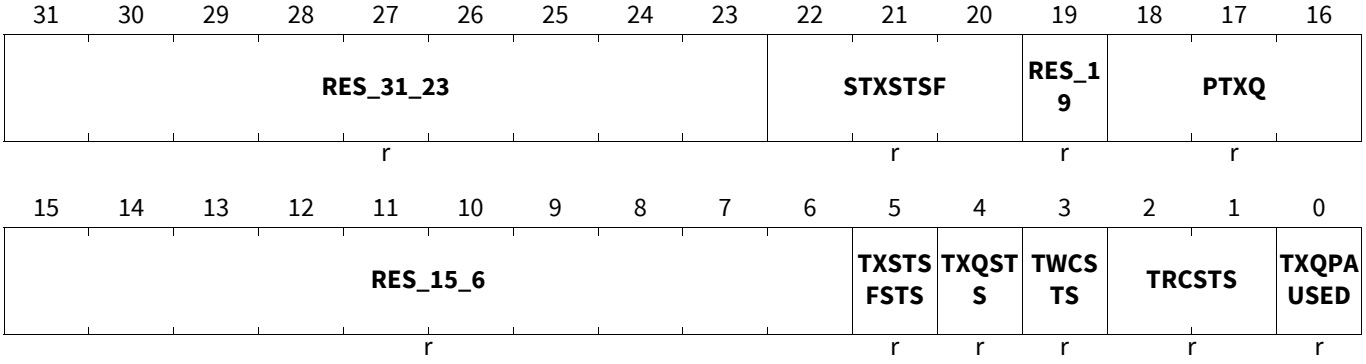
Field	Bits	Type	Description
UFFRMCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
UFCNTOVF	11	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_12	31:12	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Transmit Debug Register

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

MTL_TXQ0_DEBUG

MTL Queue 0 Transmit Debug Register (0D08$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TXQPAUSED	0	r	**Transmit Queue in Pause** When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: • Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled • Reception of 802.3x Pause packet when PFC is disabled Value After Reset: 0x0
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: Value After Reset: 0x0 00_B Idle state 01_B Read state (transferring data to the MAC transmitter) 10_B Waiting for pending Tx Status from the MAC transmitter 11_B Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. Value After Reset: 0x0
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. Value After Reset: 0x0
TXSTSFSTS	5	r	**MTL Tx Status FIFO Full Status** When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. Value After Reset: 0x0
RES_15_6	15:6	r	**Reserved** Value After Reset: 0x0

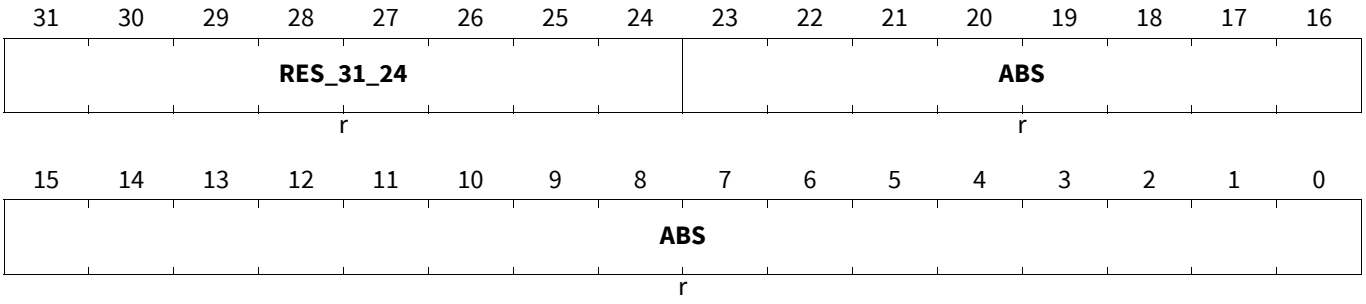
Field	Bits	Type	Description
PTXQ	18:16	r	**Number of Packets in the Transmit Queue** This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue. Value After Reset: 0x0
RES_19	19	r	**Reserved** Value After Reset: 0x0
STXSTSF	22:20	r	**Number of Status Words in Tx Status FIFO of Queue** This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO. Value After Reset: 0x0
RES_31_23	31:23	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Transmit Status Register

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

MTL_TXQ0_ETS_STATUS

MTL Queue 0 Transmit Status Register (0D14$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ABS	23:0	r	**Average Bits per Slot This field contains the average transmitted bits per slot.** When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680. Value After Reset: 0x0
RES_31_24	31:24	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Transmit Quantum or Weights Register

The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.

MTL_TXQ0_QUANTUM_WEIGHT

MTL Queue 0 Transmit Quantum or Weights Register(0D18$_H$) **Application Reset Value: 0000 0000$_H$**

ISCQW															
rw															

Field	Bits	Type	Description
ISCQW	20:0	rw	**Quantum or Weights** When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queueing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. Value After Reset: 0x0
RES_31_21	31:21	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Interrupt Control Status Register

This register contains the interrupt enable and status bits for the queue 0 interrupts.

MTL_Q0_INTERRUPT_CONTROL_STATUS

MTL Queue 0 Interrupt Control Status Register (0D2C$_H$) **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES_31_25							RXOIE	RES_23_17							RXOVFIS
r							rw	r							rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES_15_10						ABPSIE	TXUIE	RES_7_2						ABPSIS	TXUNFIS
r						rw	rw	r						rw	rw

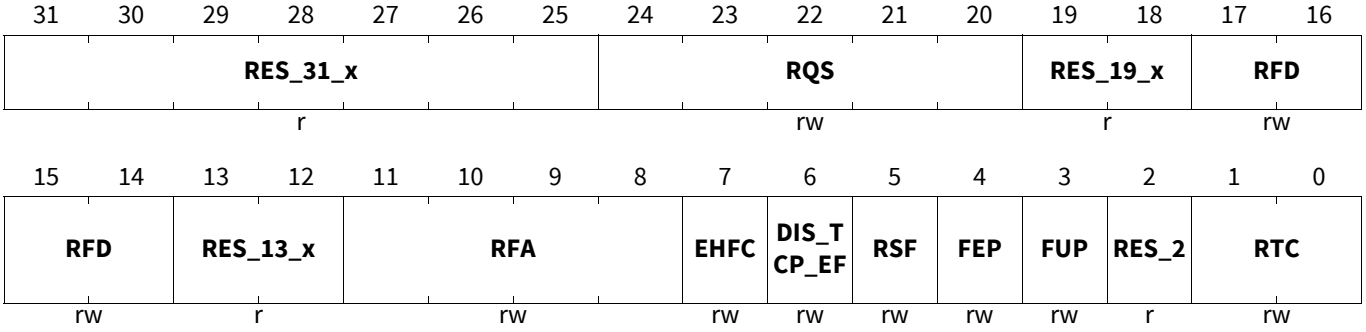
Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RES_7_2	7:2	r	**Reserved** Value After Reset: 0x0
TXUIE	8	rw	**Transmit Queue Underflow Interrupt Enable** When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. Value After Reset: 0x0
ABPSIE	9	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. **When this bit is cleared, the interrupt is not asserted for such an event.** Value After Reset: 0x0
RES_15_10	15:10	r	**Reserved** Value After Reset: 0x0
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RES_23_17	23:17	r	**Reserved** Value After Reset: 0x0
RXOIE	24	rw	**Receive Queue Overflow Interrupt Enable** When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. Value After Reset: 0x0
RES_31_25	31:25	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Receive Operation Mode Register

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

MTL_RXQ0_OPERATION_MODE

MTL Queue 0 Receive Operation Mode Register (0D30$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. Value After Reset: 0x0 00_B 64 01_B 32 10_B 96 11_B 128
RES_2	2	r	**Reserved** Value After Reset: 0x0
FUP	3	rw	**Forward Undersized Good Packets** When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. Value After Reset: 0x0

Field	Bits	Type	Description
FEP	4	rw	**Forward Error Packets** When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. Value After Reset: 0x0
RSF	5	rw	**Receive Queue Store and Forward** When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. Value After Reset: 0x0
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. Value After Reset: 0x0
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. Value After Reset: 0x0
RFA	11:8	rw	**Threshold for Activating Flow Control (in half-duplex and full-duplex** These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD. Value After Reset: 0x0
RES_13_x	13:12	r	**Reserved** Value After Reset: 0x0

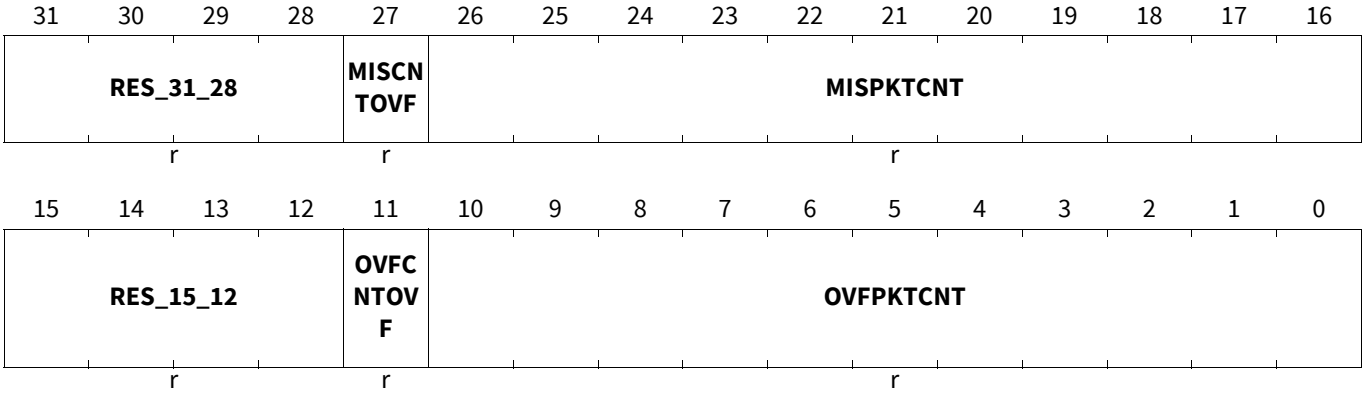
Field	Bits	Type	Description
RFD	17:14	rw	**Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)** These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: LOST SEQUENCE DEFINITION The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only. Value After Reset: 0x0 0_H Full minus 1 KB, that is, FULL 1 KB 1_H Full minus 1.5 KB, that is, FULL 1.5 KB 2_H Full minus 2 KB, that is, FULL 2 KB 3_H Full minus 2.5 KB, that is, FULL 2.5 KB E_H Full minus 8 KB, that is, FULL 8 KB F_H Full minus 8.5 KB, that is, FULL 8.5 KB
RES_19_x	19:18	r	**Reserved** Value After Reset: 0x0
RQS	24:20	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits Value After Reset: 0x0
RES_31_x	31:25	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Receive Missed Packet and Overflow Counter Register

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT

MTL Queue 0 Receive Missed Packet and Overflow Counter Register($0D34_H$) Application Reset Value: $0000\ 0000_H$

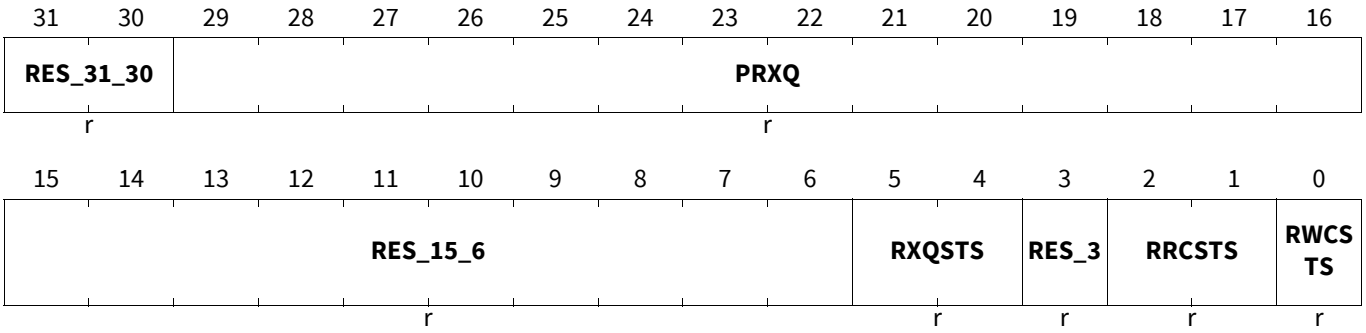


Field	Bits	Type	Description
OVFPKTCNT	10:0	r	**Overflow Packet Counter** This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
OVFCNTOVF	11	r	**Overflow Counter Overflow Bit** When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_15_12	15:12	r	**Reserved** Value After Reset: 0x0
MISPKTCNT	26:16	r	**Missed Packet Counter** This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
MISCNTOVF	27	r	**Missed Packet Counter Overflow Bit** When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_28	31:28	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Receive Debug Register

The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.

MTL_RXQ0_DEBUG
MTL Queue 0 Receive Debug Register (0D38$_H$) Application Reset Value: 0000 0000$_H$



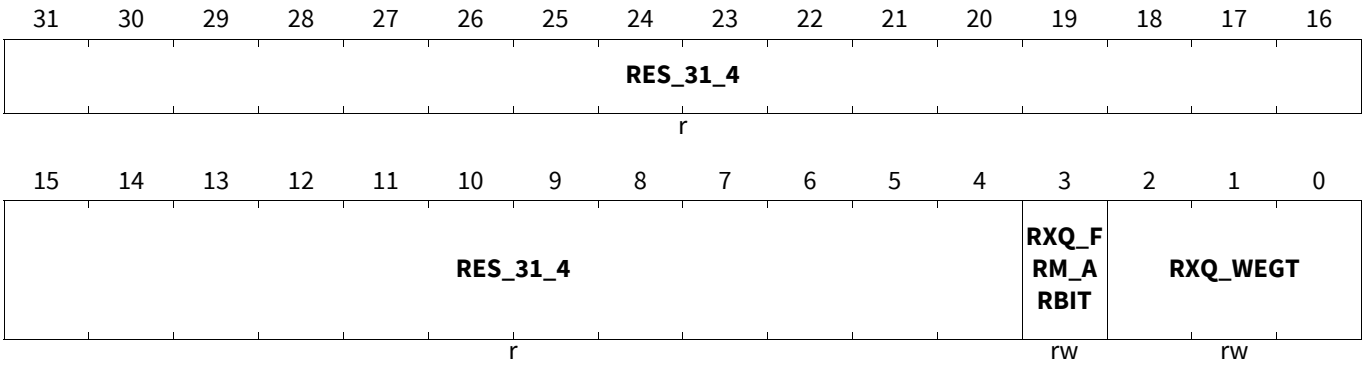
Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. Value After Reset: 0x0
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: Value After Reset: 0x0 00_B Idle state 01_B Reading packet data 10_B Reading packet status (or timestamp) 11_B Flushing the packet data and status
RES_3	3	r	**Reserved** Value After Reset: 0x0
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: Value After Reset: 0x0 00_B Rx Queue empty 01_B Rx Queue fill-level below flow-control deactivate threshold 10_B Rx Queue fill-level above flow-control activate threshold 11_B Rx Queue full
RES_15_6	15:6	r	**Reserved** Value After Reset: 0x0
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size. Value After Reset: 0x0
RES_31_30	31:30	r	**Reserved** Value After Reset: 0x0

MTL Queue 0 Receive Control Register

The Queue Receive Control register controls the receive arbitration and passing of received packets to the application.

MTL_RXQ0_CONTROL

MTL Queue 0 Receive Control Register (0D3C$_H$) Application Reset Value: 0000 0000$_H$



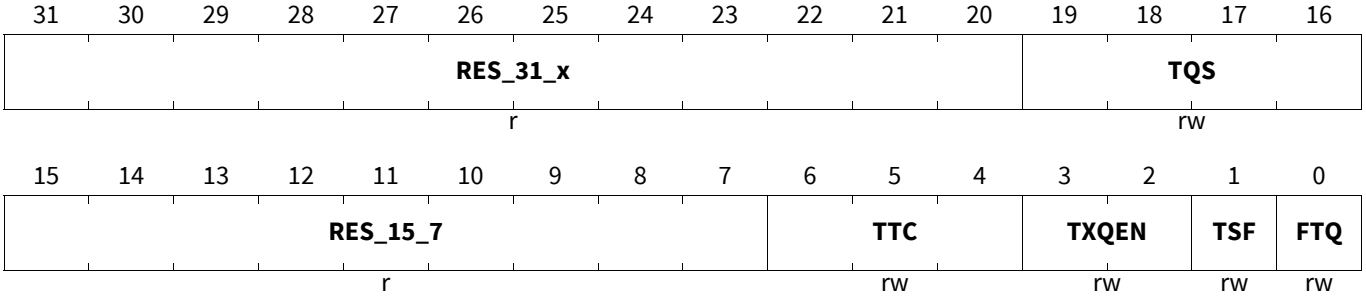
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Value After Reset: 0x0
RXQ_FRM_ARBIT	3	rw	**Receive Queue Packet Arbitration** When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: • PBL amount of data (indicated by ari_qN_pbl_i[]) or • Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). Value After Reset: 0x0
RES_31_4	31:4	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit Operation Mode Register

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

MTL_TXQi_OPERATION_MODE (i=1-3)

MTL Queue i Transmit Operation Mode Register($0D40_H$+(i-1)*40_H) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. **Note**: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. Value After Reset: 0x0
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue 0. **Note**: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. Value After Reset: 0x0 00_B Not enabled 01_B Enable in AV mode 10_B Enabled 11_B Reserved

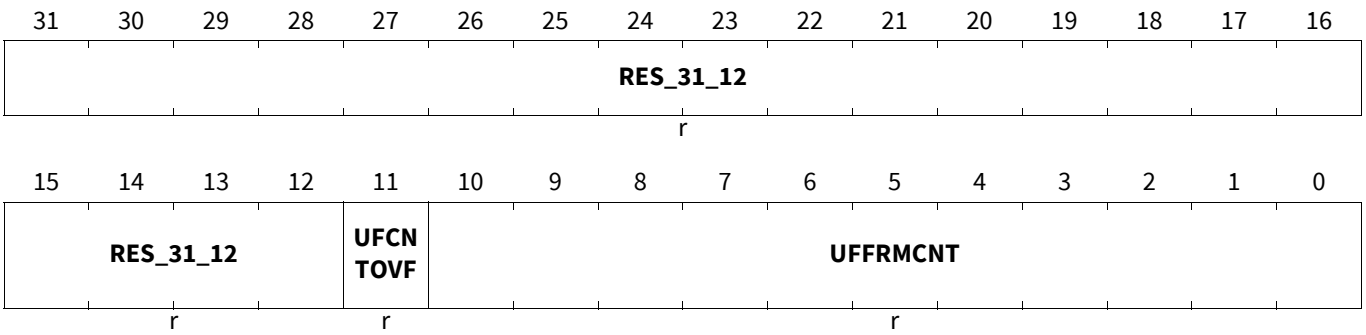
Field	Bits	Type	Description
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. Value After Reset: 0x0 000_B 32 001_B 64 010_B 96 011_B 128 100_B 192 101_B 256 110_B 384 111_B 512
RES_15_7	15:7	r	**Reserved** Value After Reset: 0x0
TQS	19:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits Value After Reset: 0x0
RES_31_x	31:20	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit Underflow Counter Register

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

MTL_TXQi_UNDERFLOW (i=1-3)

MTL Queue i Transmit Underflow Counter Register($0D44_H$+(i-1)*40_H) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
UFFRMCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
UFCNTOVF	11	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_12	31:12	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit Debug Register

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

MTL_TXQi_DEBUG (i=1-3)

MTL Queue i Transmit Debug Register **($0D48_H+(i-1)*40_H$)** **Application Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
TXQPAUSED	0	r	**Transmit Queue in Pause** When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: • Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled • Reception of 802.3x Pause packet when PFC is disabled Value After Reset: 0x0

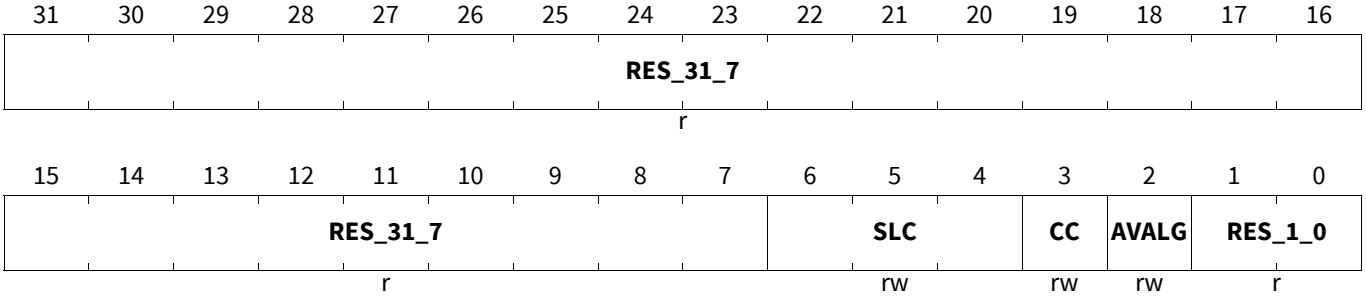
Field	Bits	Type	Description
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: Value After Reset: 0x0 00_B Idle state 01_B Read state (transferring data to the MAC transmitter) 10_B Waiting for pending Tx Status from the MAC transmitter 11_B Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. Value After Reset: 0x0
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. Value After Reset: 0x0
TXSTSFSTS	5	r	**MTL Tx Status FIFO Full Status** When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. Value After Reset: 0x0
RES_15_6	15:6	r	**Reserved** Value After Reset: 0x0
PTXQ	18:16	r	**Number of Packets in the Transmit Queue** This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue. Value After Reset: 0x0
RES_19	19	r	**Reserved** Value After Reset: 0x0
STXSTSF	22:20	r	**Number of Status Words in Tx Status FIFO of Queue** This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO. Value After Reset: 0x0
RES_31_23	31:23	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit ETS Control Register

The Queue ETS Control register controls the enhanced transmission selection operation.

MTL_TXQi_ETS_CONTROL (i=1-3)

MTL Queue i Transmit ETS Control Register($0D50_H$+(i-1)*40_H) **Application Reset Value: $0000\ 0000_H$**



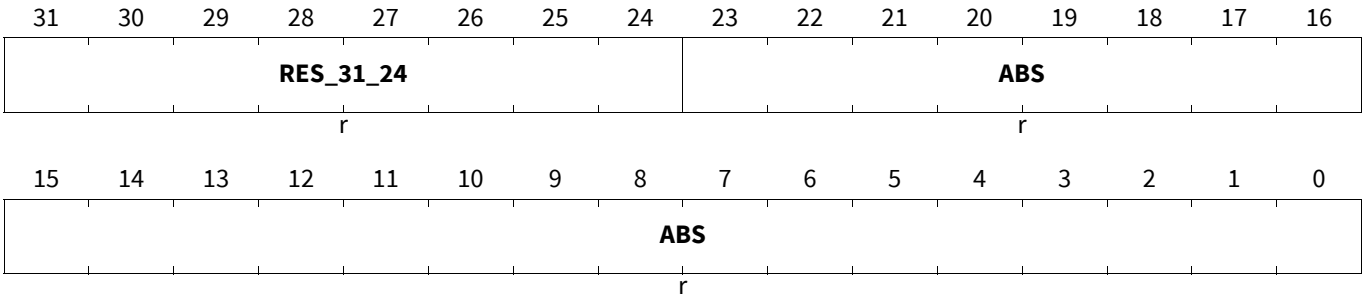
Field	Bits	Type	Description
RES_1_0	1:0	r	**Reserved** Value After Reset: 0x0
AVALG	2	rw	**AV Algorithm** When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected. Value After Reset: 0x0
CC	3	rw	**Credit Control** When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated. Value After Reset: 0x0
SLC	6:4	rw	**Slot Count** If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CH[n]_Slot_Interval register if present or 125us) over which the average transmitted bits per slot, provided in the MTL_TxQ[n]_ETS_Status register, need to be computed for Queue. The encoding is as follows: 101_B-111_B Reserved Value After Reset: 0x0 000_B 1 Slot 001_B 2 Slots 010_B 4 Slots 011_B 8 Slots 100_B 16 Slots
RES_31_7	31:7	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit ETS Status Register

The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

MTL_TXQi_ETS_STATUS (i=1-3)

MTL Queue i Transmit ETS Status Register (0D54$_H$+(i-1)*40$_H$) Application Reset Value: 0000 0000$_H$



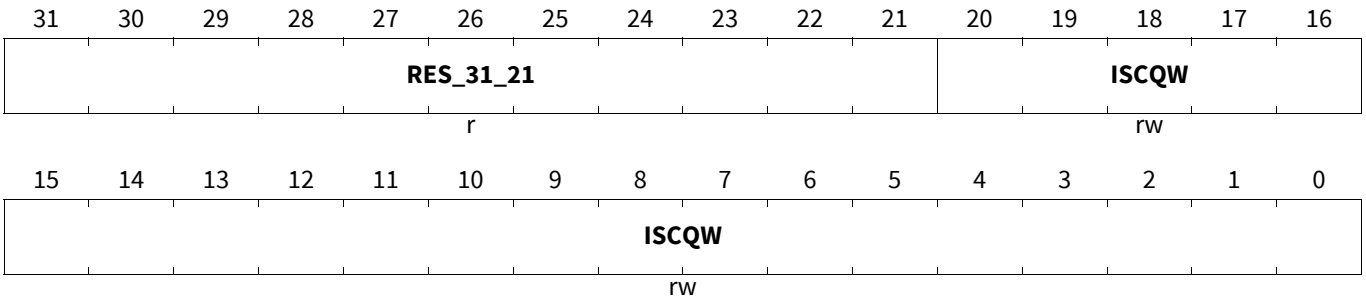
Field	Bits	Type	Description
ABS	23:0	r	**Average Bits per Slot** This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ[n]_ETS_CONTROL register. When Enable Slot Interval feature is selected, the maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. Otherwise, the maximum value of this field is 0x30D4 in 100 Mbs, 0x1E848 in 1000 Mbps and 0x4C4B4 in 2500 Mbps respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680. This field is reserved in configurations with only one transmit queue. Value After Reset: 0x0
RES_31_24	31:24	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit Quantum or Weights Register

The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

MTL_TXQi_QUANTUM_WEIGHT (i=1-3)

MTL Queue i Transmit Quantum or Weights Register(0D58$_H$+(i-1)*40$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ISCQW	20:0	rw	**idleSlopeCredit, Quantum or Weights** **idleSlopeCredit** When AV feature is enabled, this field contains the idleSlopeCredit value required for the creditbased shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. **Quantum** When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. **Weights** When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights*packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queueing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register. Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time. Value After Reset: 0x0
RES_31_21	31:21	r	**Reserved** Value After Reset: 0x0

MTL Queue i Transmit SendSlopeCredit Register

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

MTL_TXQi_SENDSLOPECREDIT (i=1-3)

MTL Queue i Transmit SendSlopeCredit Register($0D5C_H$+(i-1)*40_H) **Application Reset Value: $0000\ 0000_H$**

LC															
rw															

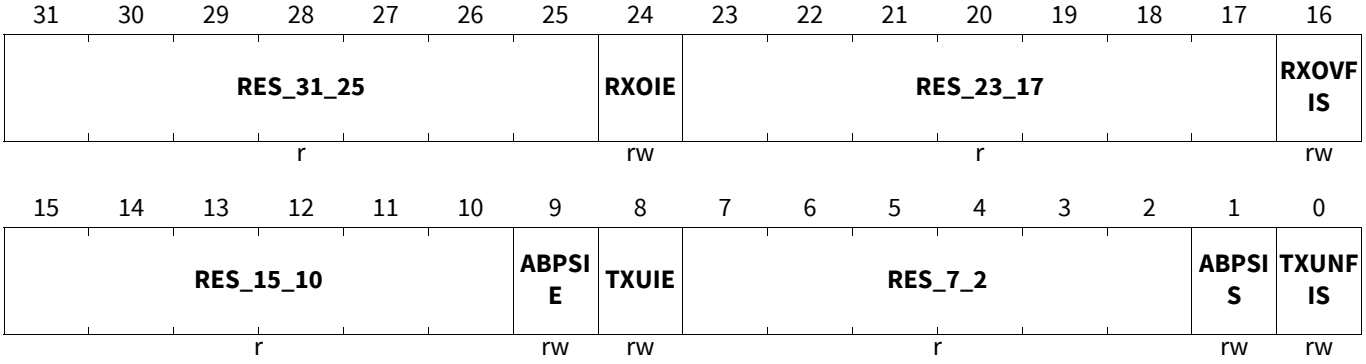
Field	Bits	Type	Description
LC	28:0	rw	**loCredit Value** When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000. Value After Reset: 0x0
RES_31_29	31:29	r	**Reserved** Value After Reset: 0x0

MTL Queue i Interrupt Status Register

This register contains the interrupt enable and status bits for the queue 1 interrupts.

MTL_Qi_INTERRUPT_CONTROL_STATUS (i=1-3)

MTL Queue i Interrupt Status Register **($0D6C_H$+(i-1)*40_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RES_7_2	7:2	r	**Reserved** Value After Reset: 0x0
TXUIE	8	rw	**Transmit Queue Underflow Interrupt Enable** When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. Value After Reset: 0x0
ABPSIE	9	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. Value After Reset: 0x0
RES_15_10	15:10	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RES_23_17	23:17	r	**Reserved** Value After Reset: 0x0
RXOIE	24	rw	**Receive Queue Overflow Interrupt Enable** When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. Value After Reset: 0x0
RES_31_25	31:25	r	**Reserved** Value After Reset: 0x0

MTL Queue i Receive Operation Mode Register

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command. The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

MTL_RXQi_OPERATION_MODE (i=1-3)

MTL Queue i Receive Operation Mode Register($0D70_H$+(i-1)*40_H) **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES_31_x							RQS					RES_19_x		RFD	
r							rw					r		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RFD		RES_13_x		RFA				EHFC	DIS_TCP_EF	RSF	FEP	FUP	RES_2	RTC	
rw		r		rw				rw	rw	rw	rw	rw	r	rw	

Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. Value After Reset: 0x0 00_B 64 01_B 32 10_B 96 11_B 128
RES_2	2	r	**Reserved** Value After Reset: 0x0
FUP	3	rw	**Forward Undersized Good Packets** When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. Value After Reset: 0x0
FEP	4	rw	**Forward Error Packets** When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. Value After Reset: 0x0
RSF	5	rw	**Receive Queue Store and Forward** When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. Value After Reset: 0x0

Field	Bits	Type	Description
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. Value After Reset: 0x0
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. This bit is not used (reserved and always reset) when the Rx queue is less than 4 KB. Value After Reset: 0x0
RFA	11:8	rw	**Threshold for Activating Flow Control (in half-duplex and full-duplex** These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD. Value After Reset: 0x0
RES_13_x	13:12	r	**Reserved** Value After Reset: 0x0
RFD	17:14	rw	**Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)** These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: LOST SEQUENCE DEFINITION The de-assertion is effective only after flow control is asserted. **Note:** The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only. Value After Reset: 0x0 0_H Full minus 1 KB, that is, FULL 1 KB 1_H Full minus 1.5 KB, that is, FULL 1.5 KB 2_H Full minus 2 KB, that is, FULL 2 KB 3_H Full minus 2.5 KB, that is, FULL 2.5 KB E_H Full minus 8 KB, that is, FULL 8 KB F_H Full minus 8.5 KB, that is, FULL 8.5 KB
RES_19_x	19:18	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
RQS	24:20	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one and the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits Value After Reset: 0x0
RES_31_x	31:25	r	**Reserved** Value After Reset: 0x0

MTL Queue i Receive Missed Packet and Overflow Counter Register

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

MTL_RXQi_MISSED_PACKET_OVERFLOW_CNT (i=1-3)
MTL Queue i Receive Missed Packet and Overflow Counter Register($0D74_H+(i-1)*40_H$) Application Reset Value: 0000 0000_H

RES_15	PR			TXPR	RES_10	ARBC	RES_8_5				TAA			DA	SWR
r	rw			rw	r	rw	r				rw			rw	rw

Field	Bits	Type	Description
SWR	0	rw	**Software Reset** When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all DWC_ether_qos clock domains. Before reprogramming any DWC_ether_qos register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. **Note**: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. Value After Reset: 0x0
DA	1	rw	**DMA Tx or Rx Arbitration Scheme** This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit. The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path. Value After Reset: 0x0 0_B Weighted Round-Robin with Rx:Tx or Tx:Rx 1_B Fixed Priority
TAA	4:2	rw	**Transmit Arbitration Algorithm** This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. $011\text{-}111_B$ Reserved Value After Reset: 0x0 000_B Fixed priority. In fixed priority, Channel 0 has the lowest priority and the last channel has the highest priority. 001_B Weighted Strict Priority (WSP) 010_B Weighted Round-Robin (WRR)
RES_8_5	8:5	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
ARBC	9	rw	**Arbitration Control** When this bit is reset to 0, the DMA arbitrates as soon as the current burst transaction is completed. So, in this mode, the arbiter will miss the next/subsequent request from the same DMA since there are inherent delays between the completion of 1 transfer request and the next transaction request generated from the same DMA. Consequently, the WRR ratio becomes 1:1 irrespective of the programmed ratio. When this bit is set to 1, the DMA arbitration is delayed for a few clock cycles after the completion of current transaction so that the next request from the same DMA can be considered. This allows the arbiter to maintain WRR ratio as programmed.
RES_10	10	r	**Reserved** Value After Reset: 0x0
TXPR	11	rw	**Transmit Priority** When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus. Value After Reset: 0x0
PR	14:12	rw	**Priority Ratio** These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set. Value After Reset: 0x0 000_B The priority ratio is 1:1 001_B The priority ratio is 2:1 010_B The priority ratio is 3:1 011_B The priority ratio is 4:1 100_B The priority ratio is 5:1 101_B The priority ratio is 6:1 110_B The priority ratio is 7:1 111_B The priority ratio is 8:1
RES_15	15	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
INTM	17:16	rw	**Interrupt Mode** This field defines the interrupt mode of DWC_ether_qos. The behavior of the following outputs changes depending on the following settings: • sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) • sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) • sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the DMA_CH0_Status. For more details please refer Table "DWC_ether_qos Transfer Complete Interrupt Behavior". Value After Reset: 0x0 00_B sbd_perch_* are pulse signals for each completion events. sbd_intr_o is also asserted and cleared only when software clears the corresponding RI/TI status bits 01_B sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these packet transfer completion events. 10_B sbd_perch_* are level signals asserted on corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these packet transfer completion events. 11_B Reserved
RES_18_31	31:18	r	**Reserved** Value After Reset: 0x0

DMA System Bus Mode Register

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

DMA_SYSBUS_MODE

r	r		r	r							rw	rw			rw

Field	Bits	Type	Description
ST	0	rw	**Start or Stop Transmission Command** When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: • The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. • The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. Value After Reset: 0x0
TCW	3:1	rw	**Transmit Channel Weight** This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels. Value After Reset: 0x0
OSF	4	rw	**Operate on Second Packet** When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. Value After Reset: 0x0
RES_11_5	11:5	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
TxPBL	21:16	rw	**Transmit Programmable Burst Length** These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32. Value After Reset: 0x0
RES_23_22	23:22	r	**Reserved** Value After Reset: 0x0

RES_15	**RBSZ_13_y**												**RBSZ_x_0**		**SR**
r	rw												r		rw

Field	Bits	Type	Description
SR	0	rw	**Start or Stop Receive** When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: • The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. • The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. Value After Reset: 0x0
RBSZ_x_0	2:1	r	**Receive Buffer size Low** RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO). Value After Reset: 0x0
RBSZ_13_y	14:3	rw	**Receive Buffer size High** RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. **Note**: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as allzero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width). Value After Reset: 0x0
RES_15	15	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
RxPBL	21:16	rw	**Receive Programmable Burst Length** These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQ[n]_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32. Value After Reset: 0x0
RES_23_22	23:22	r	**Reserved** Value After Reset: 0x0
RES_27_24	27:24	r	**Reserved for future use.**
RES_30_28	30:28	r	**Reserved** Value After Reset: 0x0
RPF	31	rw	**DMA Rx Channel0 Packet Flush** When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. Value After Reset: 0x0

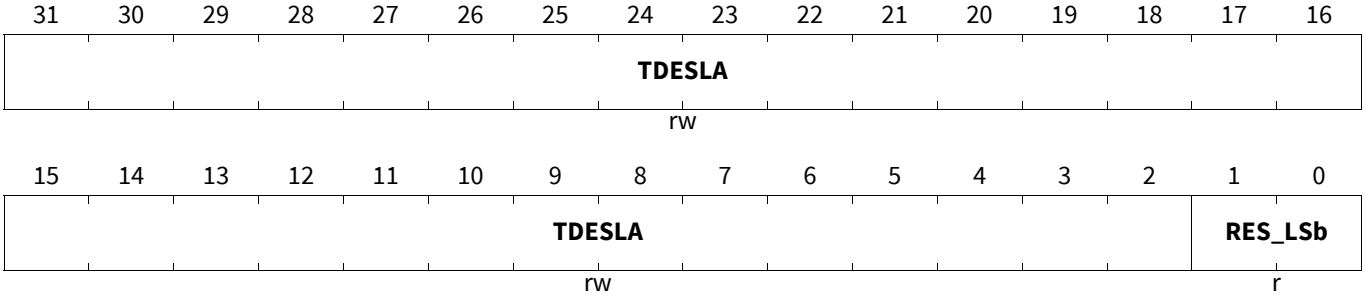
DMA Channel i Transmit Descriptor List Address Register

The DMA Channel i Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

DMA_CHi_TXDESC_LIST_ADDRESS (i=0-3)

DMA Channel i Transmit Descriptor List Address Register(1114_H+i*80_H)Application Reset Value: 0000 0000_H



Field	Bits	Type	Description
RES_LSb	1:0	r	**Reserved** Value After Reset: 0x0
TDESLA	31:2	rw	**Start of Transmit List** This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: • 31:2 for 32-bit configuration • 31:3 for 64-bit configuration • 31:4 for 128-bit configuration Value After Reset: 0x0

DMA Channel i Receive Descriptor List Address Register

The DMA Channel i Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

DMA_CHi_RXDESC_LIST_ADDRESS (i=0-3)

DMA Channel i Receive Descriptor List Address Register($111C_H$+i*80_H) Application Reset Value: 0000 0000_H

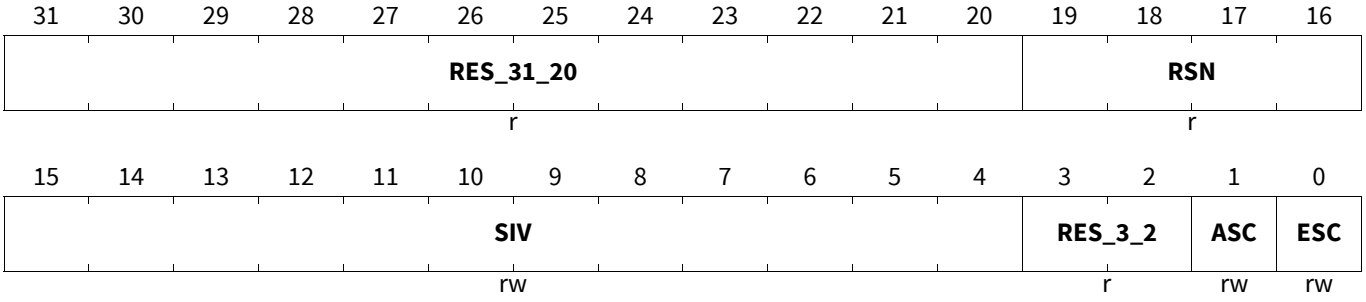
DMA Channel i Slot Function Control and Status Register

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

DMA_CHi_SLOT_FUNCTION_CONTROL_STATUS (i=0-3)

DMA Channel i Slot Function Control and Status Register($113C_H$+i*80_H) **Application Reset Value: 0000 $07C0_H$**



Field	Bits	Type	Description
ESC	0	rw	**Enable Slot Comparison** When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is • equal to the reference slot number or • ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Value After Reset: 0x0
ASC	1	rw	**Advance Slot Check** When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is • equal to the reference slot number given in the RSN field or • ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. Value After Reset: 0x0
RES_3_2	3:2	r	**Reserved** Value After Reset: 0x0

Field	Bits	Type	Description
SIV	15:4	rw	**Slot Interval Value** This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/ reset value is 0x07C which corresponds to slot interval of 125us. Value After Reset: 0x7c
RSN	19:16	r	**Reference Slot Number** This field gives the current value of the reference slot number in the DMA. It is used for slot comparison. Value After Reset: 0x0
RES_31_20	31:20	r	**Reserved** Value After Reset: 0x0

DMA Channel i Current Application Transmit Descriptor Register

The DMA Channel i Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

DMA_CHi_CURRENT_APP_TXDESC (i=0-3)
DMA Channel i Current Application Transmit Descriptor Register(1144_H+i*80_H) Application Reset Value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NIS	AIS	CDE	FBE	ERI	ETI	RWT	RPS	RBU	RI	RES_5_3			TBU	TPS	TI
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r			rw	rw	rw

Field	Bits	Type	Description
TI	0	rw	**Transmit Interrupt** This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
TPS	1	rw	**Transmit Process Stopped** This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0

Field	Bits	Type	Description
TBU	2	rw	**Transmit Buffer Unavailable** This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RES_5_3	5:3	r	**Reserved** Value After Reset: 0x0
RI	6	rw	**Receive Interrupt** This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RBU	7	rw	**Receive Buffer Unavailable** This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RPS	8	rw	**Receive Process Stopped** This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
RWT	9	rw	**Receive Watchdog Timeout** This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. Value After Reset: 0x0

Field	Bits	Type	Description
ETI	10	rw	**Early Transmit Interrupt** This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
ERI	11	rw	**Early Receive Interrupt** This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
FBE	12	rw	**Fatal Bus Error** This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
CDE	13	rw	**Context Descriptor Error** This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid.Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
AIS	14	rw	**Abnormal Interrupt Summary** Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: • Bit 1: Transmit Process Stopped • Bit 7: Receive Buffer Unavailable • Bit 8: Receive Process Stopped • Bit 10: Early Transmit Interrupt • Bit 12: Fatal Bus Error • Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0

Field	Bits	Type	Description
NIS	15	rw	**Normal Interrupt Summary** Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: • Bit 0: Transmit Interrupt • Bit 2: Transmit Buffer Unavailable • Bit 6: Receive Interrupt • Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. Value After Reset: 0x0
TEB	18:16	r	**Tx DMA Error Bits** This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 18 1_B Error during data transfer by Tx DMA 0_B No Error during data transfer by Tx DMA Bit 17 1_B Error during descriptor access 0_B Error during data buffer access Bit 16 1_B Error during read transfer 0_B Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt. Value After Reset: 0x0
REB	21:19	r	**Rx DMA Error Bits** This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 21 1_B Error during data transfer by Rx DMA 0_B No Error during data transfer by Rx DMA Bit 20 1_B Error during descriptor access 0_B Error during data buffer access Bit 19 1_B Error during read transfer 0_B Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt. Value After Reset: 0x0

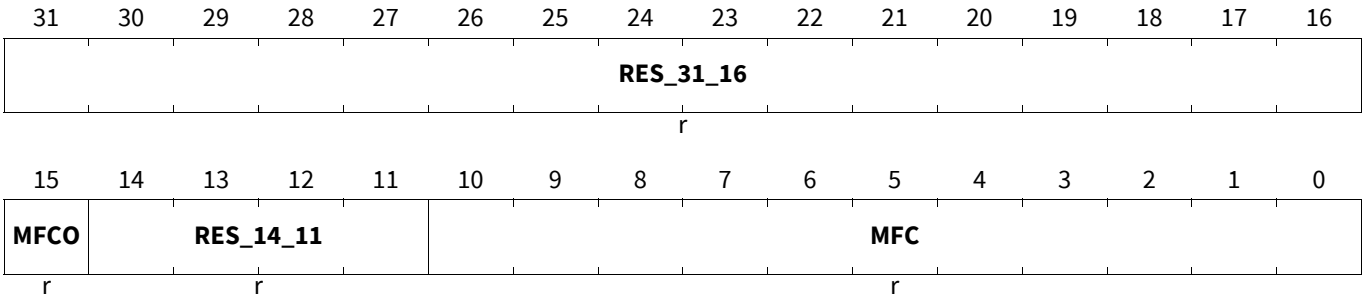
Field	Bits	Type	Description
RES_31_22	31:22	r	**Reserved** Value After Reset: 0x0

DMA Channel i Missed Frames Count Register

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CHx_RX_CONTROL register.

DMA_CHi_MISS_FRAME_CNT (i=0-3)

DMA Channel i Missed Frames Count Register(1164_H+i*80_H) **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MFC	10:0	r	**Dropped Packet Counters** This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CHx_RX_CONTROL register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_14_11	14:11	r	**Reserved** Value After Reset: 0x0
MFCO	15	r	**Overflow status of the MFC Counter** When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. Value After Reset: 0x0
RES_31_16	31:16	r	**Reserved** Value After Reset: 0x0

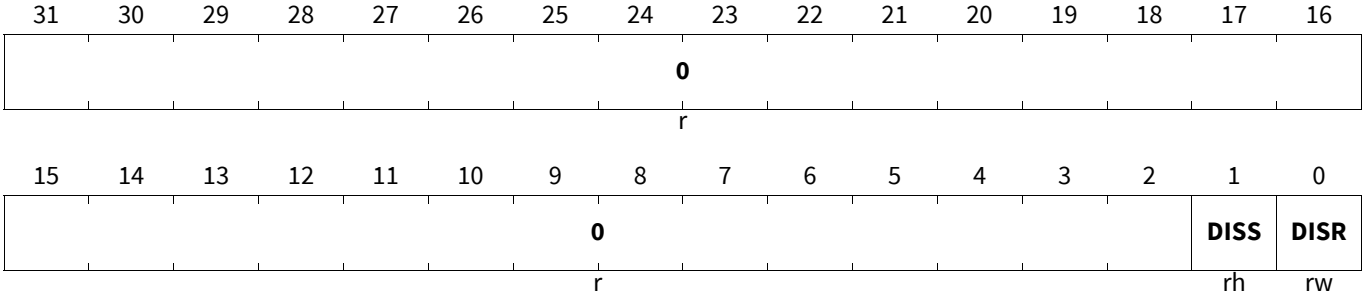
Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock for the module.

Note: After a power on or application reset, the input clocks are switched off inside the module and the GETHmodule is disabled (DISS set).

CLC

Clock Control Register **(2000_H)** **Application Reset Value: $0000\ 0003_H$**



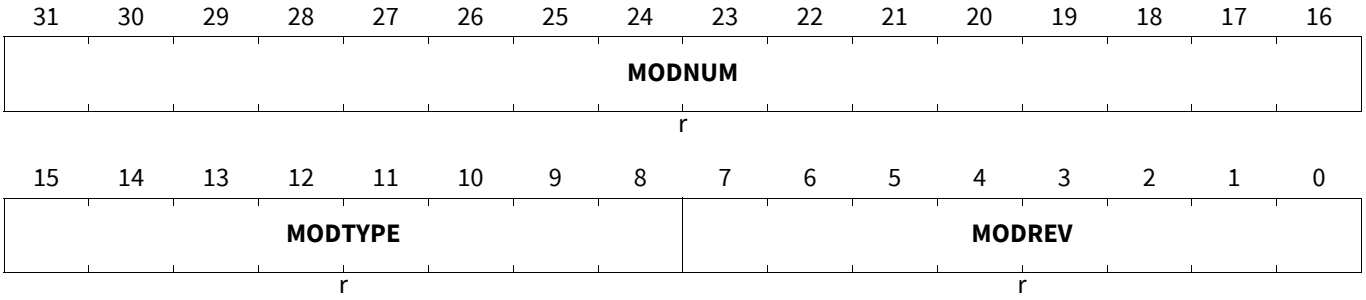
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The disable request is delayed internally until all pending transactions on the master (SRI) and slave (SPB) interface are completed.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The GETHModule Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(2004_H)** **Application Reset Value: $00E9\ C0XX_H$**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision). To be incremented eg. 2 for GMAC QoS
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the GETH: $00E9_H$

General Purpose Control Register

The Input and Output Control Register GPCTL determines which alternate input is to be used and selects the phy interface.

This register is not affected by the local module reset.

GPCTL

General Purpose Control Register (2008$_H$) Application Reset Value: 0000 0000$_H$

Field	Bits	Type	Description
ALTIy (y=0-10)	2*y+1:2*y	rw	**Alternate Input Select** Selects the alternate input for channel y. If no signal is connected to an alternate input, it is connected to GND. Map of signals demultiplexed by ALTI bit fields: ALTI0: MDIO ALTI1: RXCLK, REFCLK ALTI2: CRS ALTI3: COL ALTI4: RXDV, CRSDV, RCTL ALTI5: RXER ALTI6: RXD0 ALTI7: RXD1 ALTI8: RXD2 ALTI9: RXD3 ALTI10: TXCLK 00_B Alternate Input 0 selected 01_B Alternate Input 1 selected 10_B Alternate Input 2 selected 11_B Alternate Input 3 selected

Field	Bits	Type	Description
EPR	24:22	rw	**External Phy Interface RMII Mode Bit** Used to select the phy interface during module reset of MAC triggered by setting SWR bit of DMA_Mode Register. Note that the status of this bit is latched in during module reset only. 000_B MII is selected and the divider (see 100B)is not active but the clock signals clk_tx_i and clk_rx_i are connected directly to the referring port pins 001_B RGMII is selected. The clock signals are connected directly to the referring port pins 010_B do not use! 011_B do not use! 100_B RMII is selected and an internal predivider divides the clock clk_rmii_i from pin ETHRXC by 2 or 20 and provides it to the internal signals clk_tx_i and clk_rx_i. The division factor depends from the signal mac_speed_o, controlled by bit FES in Register 0 (MAC Configuration Register) 101_B do not use! … 111_B do not use!
0	30:25, 31	r	**Reserved** Read as 0; should be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B.

Attention: The DMA control registers are NOT protected by ACCEN0! They have separate (GETH_ACCEN0Dx) registers. See below.

ACCEN0
Access Enable Register 0 **($200C_H$)** **Application Reset Value: $FFFF\ FFFF_H$**

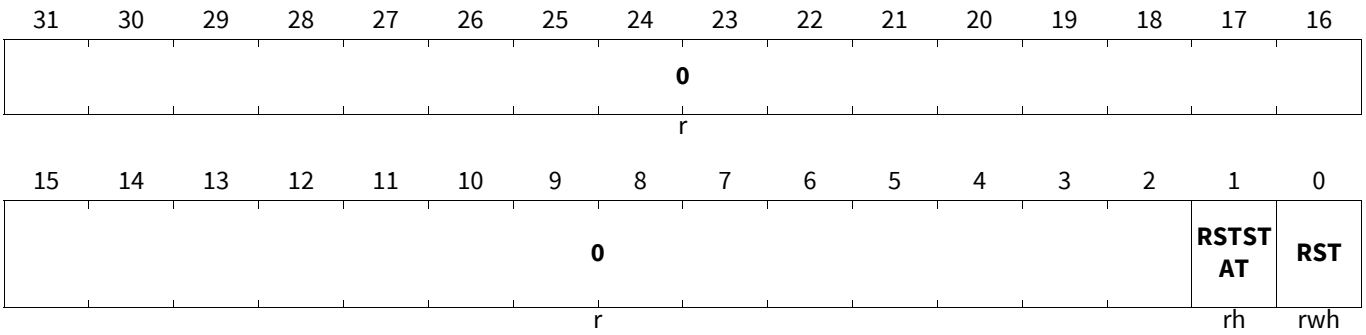
Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **(2014_H)** **Application Reset Value: 0000 0000_H**

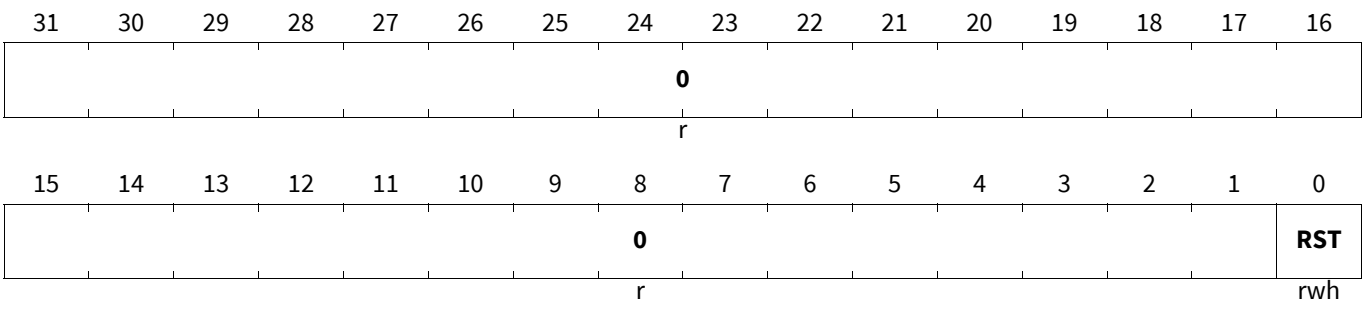


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set and both: master and slave interface are idle. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **(2018_H)** **Application Reset Value: 0000 0000_H**

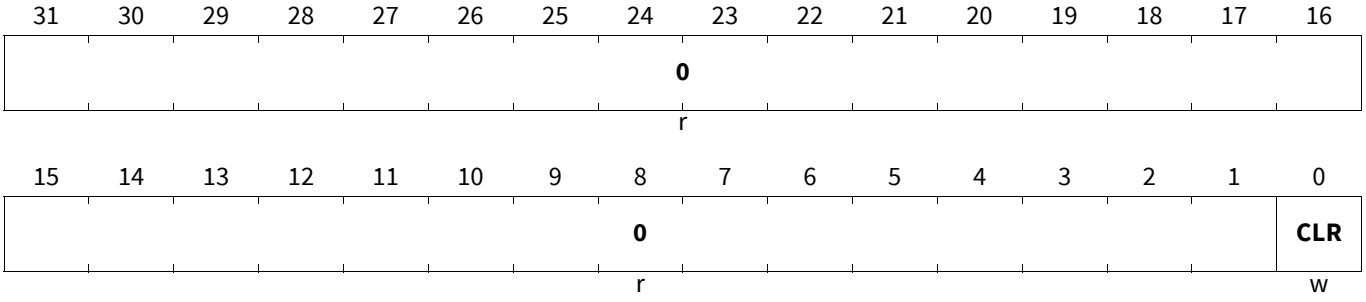


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set and both: master and slave interface are idle. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register **($201C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Access Enable Register 0 for DMAx

The Access Enable Register 0 for DMA x controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0Dx / ACCEN1Dx are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0Dx.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the registers needed to configure DMAx. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in these registers

These registers (0 …x) protect the address space (size: 80H for each DMA) occupied by the control registers that are available for each DMA. E.g. DMA_CHx_Control, DMA_CH0_Tx_Control, DMA_CH0_Rx_Control, DMA_CH0_TxDesc_List_HAddress … and so on. (Offset 0x1100H + x * 80H … 0x117CH + x * 80H)

ACCEN0Dx (x=0-3)

Skew Control Register

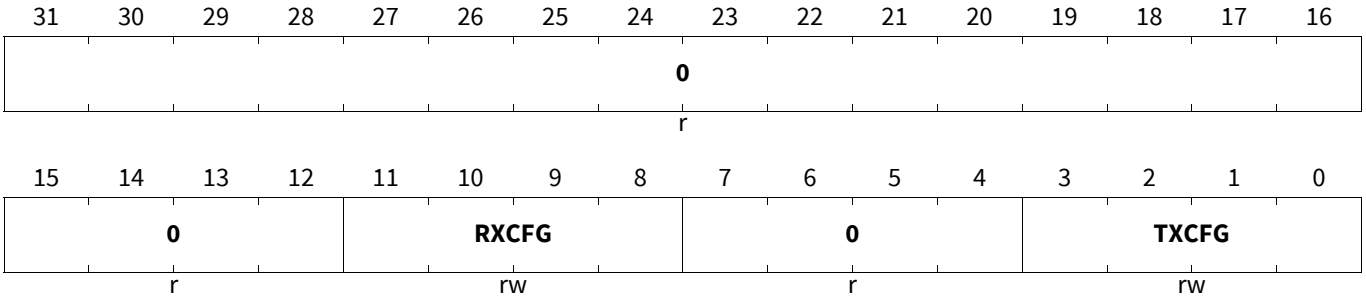
This register controlls the operation of the delay block.

This register is not affected by the local module reset

NOTE: Intended for configuration phase only. Do not change during frame transmission! Data might be lost.

SKEWCTL

Skew Control Register **(2040_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TXCFG	3:0	rw	**TX Clock delay control for RGMII Mode** Used to specify the receive timing skew in RGMII mode using integrated delay generation on TXCLK. In MII and RMII mode, this is not active. Skew is (TXCFG * 222,22) ps. If cleared, skew is 0 (default, skew generation switched off).
RXCFG	11:8	rw	**RX Clock delay control for RGMII Mode** Used to specify the receive timing skew in RGMII mode using integrated delay generation on RXCLK. In MII and RMII mode, this is not active. Skew is (RXCFG * 222,22) ps. If cleared, skew is 0 (default, skew generation switched off).
0	7:4, 31:12	r	**Reserved** Read as 0; should be written with 0.

44.6 IO Interfaces

The GETH is connected to general purpose I/O lines. Each line is connected to up to four different general purpose I/O lines that can be chosen alternatively. The selection from one of these alternatives is done by application SW by programming GETH_GPCTL.ALTIx respectively.

For MDIO, ALTIx selects the direction control signal (“HW_OUT control”) gmii_mdo_o_e_[x] as well. The signals gmii_mdo_o_e_[n] that are not selected are forced passive.

The following port control operations and selections must be executed for these I/O lines:

- GETH_GPCTL.ALTIx to select alternate inputs. If RGMII is selcted ALTI is not needed to be programmed. The input ports are selected automatically. For RGMII there is only one alternative input per signal available.
- Pad driver characteristics selection for the outputs (Port PDR registers)
- Port Pin Controller Select Register PCSR (Set bit SELx for TXER, TXCLK, TXD[3:0], TXEN, TCTL if used for GETH)
- Input/output function selection (Port IOCR registers)

Some PHYs provide an interrupt output, signalling e.g. line activity. It might be useful to connect this to an interrupt input on system level. This signal is not connected to the GETH itself!

If for one product no signal is connected to an alternate input, it is connected to GND internally at module entity level. This allows to leave some signals unconnected in the application (i.e. RXER, CRS, COL) and save pins and external connection to GND.

45 SRI External Bus Unit (EBU)

The External Bus Unit (EBU), controls the transactions between external memories or peripheral units, and the internal memories and peripheral units. The basic interfaces of the EBU are shown in **Figure 724**.

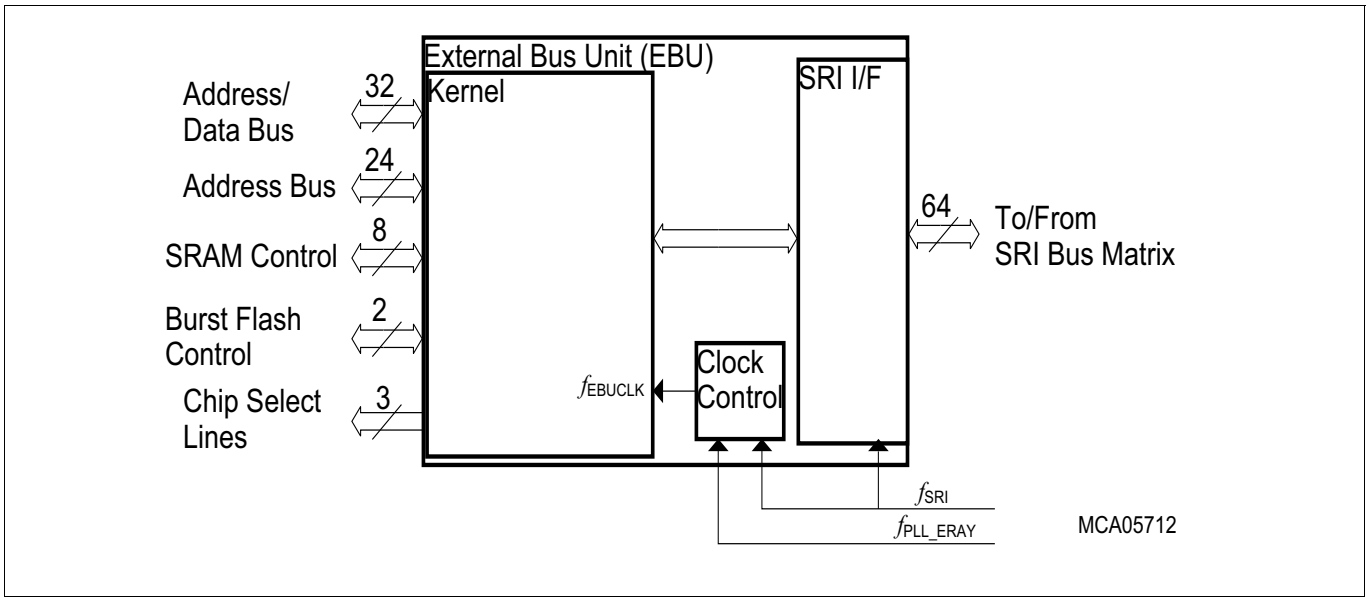

Figure 724 EBU Interface Diagram

The EBU is internally connected to the SRI by a single slave interface.

45.1 Feature List

Features supported in the Memory Controller:-

- Highly programmable access parameters.
- Intel-style peripheral/device support.
- Burst FLASH support (see **Section 45.3.14** for specific device types).
- Synchronous SRAM support (see **Section 45.3.14** for specific device types).
- NAND flash
- Multiplexed access (address & data on the same bus)
- Data Buffering: Two read buffers. Single write buffer in the SRI interface.
- Three programmable address regions.
- External bus frequency: Module frequency:flash clock = 1:1, 1:2, 1:3 or 1:4.

45.2 Overview

The Memory Controller module for SRI-based systems connects on-chip controller cores (e.g. Tricore CPU, DMA Controller) to external resources such as memories and peripherals. **Figure 725** shows Memory Controller within a typical system.

Any SRI master can (in conjunction with an SRI Matrix) access external memories through the Memory Controller.

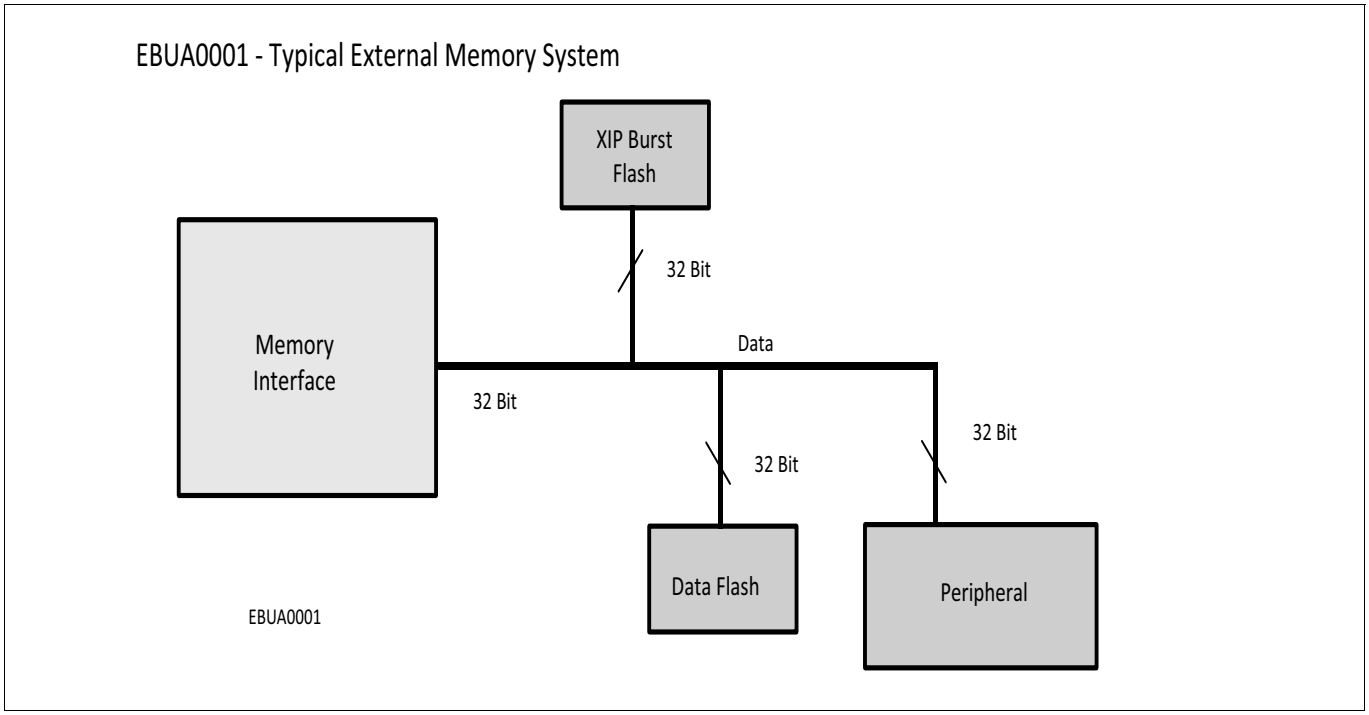

Figure 725 Typical External Memory System

45.3 Functional Description

45.3.1 References

The EBU complies with the requirements of Open NAND Flash Interface Specification (Revision 2.0, 27-February-2008) when generating accesses to external memories.

45.3.2 Product Specific Core Customisation

A pin multiplexing scheme has been implemented to allow the use of low power, 5 volt compatible pads for the 32 bit databus. This has the effect of imposing the following limitations on EBU configuration

- Some programming of the Ports logic is needed to ensure that the correct pads are available for EBU to operate
- SDRAM is not supported
- Use of byte control lines limits the available external address bus to A(19:0).
- Region 2 cannot be used if external bus arbitration is enabled, External bus arbitration is not supported so no advantage is gained by enabling it.
- The use of slower pads for the main databus means that extra setup time may be needed for asynchronous writes and that the clock frequency for synchronous writes may have to be reduced.
- The combined CS signal described in **Section 45.3.10.7** is not available as a device I/O for the TC39x.

It is possible to programme the EBU ignoring these restrictions but doing so will result in unpredictable operation and possible lockups of the system.

45.3.3 Allocation of Unused Signals as GPIO

The EBU will allow pins not required for its programmed configuration to be allocated for use as GPIO.

For some signals, the EBU is unable to determine automatically whether or not the signals are required for a particular configuration. These signals can be manually made available for GPIO or alternate EBU functions by writing to the **USERCON** register.

Additionally some EBU signals are routed through the normal output multiplexer of the Ports logic. These signals have to be configured for EBU operation using the control registers in the relevant Ports instance.

45.3.4 Memory Controller Structure

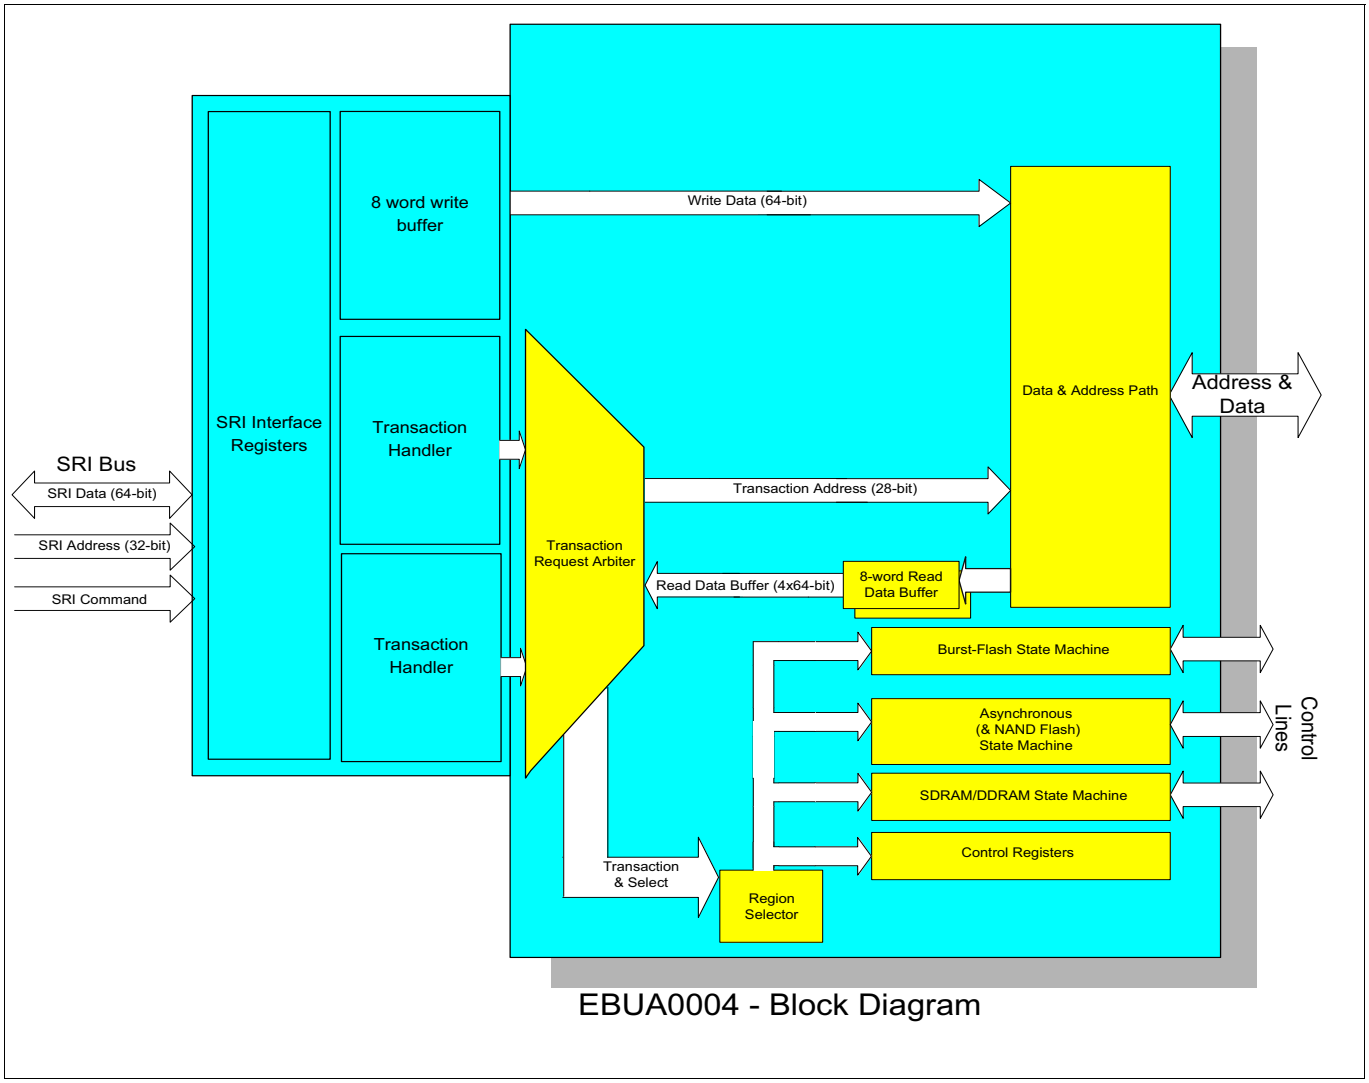

Figure 726 Memory Controller Block Diagram

The SRI interface translates SRI transactions from the ports into appropriate transaction requests which can be transferred to the arbiter. The interface can handle two transactions simultaneously as required by the SRI protocol which has a two deep, command pipeline. The interface will also generate an ECC code for all read data returned and will check ECC codes received along with each SRI transaction. In the event of a transaction failing the ECC check, an error will be flagged to the system for further processing and the transaction will be terminated with an SRI error.

The arbiter looks at the transaction requests and schedules corresponding requests to the relevant state machine. Only one state machine can be active at any time and the arbiter is designed to prevent out-of-order

execution. The dedicated state machines are used to sequence control signals and to co-ordinate accesses to each of the different external memory/device types and also the internal registers.

If two consecutive accesses are to the same state machine, the second access can be queued before the first has completed. This allows accesses to run “back-to-back” on the external bus and maximises bandwidth utilisation.

45.3.5 Memory Controller Read Architecture

The memory controller contains two, identical read buffers each with a capacity of 4, 64 bit words. A read access will be allowed to proceed if one of the buffers is flagged as available. The data read from the external memory will be stored in the read buffer and the outputs from the read buffer will be multiplexed to the SRI port. Once the SRI port signals that all data has been returned to the requesting SRI master, the read buffer will again be flagged as available.

This architecture allows reads to be in progress simultaneously, as a second read can be running while the first read is still waiting for data to be returned to the SRI master.

45.3.6 Access Arbitration

Arbitration of SRI accesses is handled by the SRI itself. The EBU will only ensure that accesses are processed in the order that they arrive at the SRI interface.

45.3.6.1 Programming Sequence Locking

Programming sequences for some Burst Flash devices require that the source of the programming transactions has exclusive access to the external memory device for the duration of the write sequence. If such devices are used and can be accessed by multiple transaction sources then the “Locked Programming Sequence” feature can be enabled via register bit EBU_BUSWCONx.LOCKCS.

The fail-safe timeout timer defaults to a count of 255 and is decremented at a frequency of SRI_CLK/16. It commences counting from the preload value every time a write completes. The default value can be changed by writing to the EBU_MODCON.LOCKTIMEOUT register field.

45.3.6.2 Access Enable

Write accesses from any specific bus master can be temporarily denied access to the EBU registers by setting the relevant bit in the ACCEN register. See the register description in **“Access Enable Registers, ACCEN0 and ACCEN1” on Page 85** for a full description of the operation of this feature.

45.3.7 Clocking Strategy and Local Clock Generation

The Memory Controller can be configured to operate from several possible clock sources. The clock generation logic is used to select between these clock sources and generate the internal clock used for the memory controller, EBU_CLK.

45.3.7.1 Clocking Modes

The bridges can be operated in one of two modes using one of two clocks:-

- Asynchronous mode: The SRI clock and Memory Controller internal clock (EBU_CLK) are assumed to be asynchronous. EBU_CLK is derived from the Flexray PLL output.
- Synchronous mode: The is derived from the controller (SRI) clock. The EBU_CLK and SRI interface clocks have aligned edges (although pulse swallowing can be used on the EBU_CLK clock, so that the EBU core can run at a lower frequency than the SRI bus matrix).

- Synchronous or Asynchronous mode at half of SRI clock: The EBU clock is running at half the frequency of the processor clock. The EBU clock is edge aligned with the processor and SRI interface clocks.

The clock for the SRI interface of the memory controller, is always be derived from the same synchronous source (the processor clock, .

The mode of operation of the bridge is controlled by the **CLC.SYNC** register field. The **CLC.SYNCACK** field will be updated to report the current operating mode.

The **CLC.SYNC** register field can be used (dynamically) to switch between these two modes.

If **CLC.DIV2** is set to 0_B, then **CLC.SYNC** also controls the clock input and switches it between the processor clock and the Flexray PLL output.

However, if **CLC.DIV2** is set to 1_B, then EBU clock source is forced to be half the frequency of the processor clock and **CLC.SYNC** serves no useful purpose. The value of **DIV2** in use by the memory controller is stored in the **CLC.DIV2ACK** field.

45.3.7.2 Standby Mode

The Memory Controller can be configured to disable its internal clock and enter standby mode by writing a logic '1' to the **EBU_CLC.DISR** register field.

45.3.7.3 External Bus Clock Generation

The memory controller can generate two external bus clocks.

One of these is intended for use with SDRAM type devices controlled by the SDRAM state machine[1)] and is output on SDCLKO.

The other is intended for use with other synchronous memories such as burst flash and is output on BFCLKO. See **"Burst Flash Clock" on Page 46**

Clock feedback is used to correct for pad output and PCB track delays and each clock output therefore has an equivalent clock input. These are SDCLKI and BFCLKI respectively.

The clocking mode will be determined by the **AGEN** fields of the configured memory regions.

Setting the **CLK_COMB** bit in the **MODCON** register will cause the same clock to be generated on both the SDCLKO and BFCLKO pins. It is recommended that only one region is configured for a continuously running clock if this option is selected and that all synchronous regions have the same clock divide ratio programmed.

45.3.8 External Bus Arbitration

External bus arbitration is provided to allow the EBU to share its external bus with other master devices. This capability allows other external master devices to obtain ownership of the external bus, and to use the bus to access external devices connected to this bus. The scheme provided by the EBU is compatible with other TriCore and XC2XXX devices and therefore allows the use of such devices as (external bus) masters together with the .

*Note: In this section, the term "external master" is used to denote a device which is located on the **external** bus and is capable of generating accesses across the external bus (i.e. is capable of driving the external bus). An external master is not able to access units that are located inside the .*

45.3.8.1 External Bus Modes

The EBU can be in one of two bus states on the external bus:

- Owner State
- Hold State

When in Owner State, the EBU operates as the master of the external bus. In other words, the EBU drives the external bus as required in order to access devices located on the external bus. While the EBU is in Owner State it is not possible for any other master to perform any accesses on the external bus. When the EBU is in Owner State, **MODCON.BUSSTATE** is set to 1_B.

In Hold State, the EBU tri-states the appropriate signal on the external bus in order to allow another external bus master to perform accesses on the external bus (i.e. to allow another master to drive the various external bus signals without contention with EBU). When the EBU is in Hold State, **MODCON.BUSSTATE** is set to 0_B.

45.3.8.2 Arbitration Signals and Parameters

The arbitration scheme consists of an external bus master that is responsible for controlling the allocation of the external bus. This master is referred to as the "Arbiter" within this document. The other external bus master

1) See **"Programmable Device Types" on Page 21** for the device types supported by the EBU and the state machines used to control them

(termed Participant within this document) requests ownership of the bus, and when necessary, from the Arbiter. The EBU can be programmed to operate either as an Arbiter or as a Participant (see **Page 8**). The following three lines are used by the EBU to arbitrate the external bus.

Table 505 EBU External Bus Arbitration Signals

Signal	Direction	Function
$\overline{\text{HOLD}}$	In	$\overline{\text{HOLD}}$ is asserted (low) by an external bus master when the external bus master requests to obtain ownership of the external bus from the EBU.
$\overline{\text{HLDA}}$	In/Out[1)]	$\overline{\text{HLDA}}$ is asserted (low) by the Arbiter to signal that the external bus is available for use by the Participant (i.e. the bus is not being used by the Arbiter). $\overline{\text{HLDA}}$ is sampled by the Participant to detect when it may use the external bus.
$\overline{\text{BREQ}}$	Out	$\overline{\text{BREQ}}$ is asserted (low) by the EBU when the EBU requests to obtain ownership of the external bus.

1) The direction of this signal depends upon the mode in which the EBU is operating (see **Page 8**).

Two components that are equipped with the EBU arbitration protocol can be directly connected together (without additional external logic) as shown below:

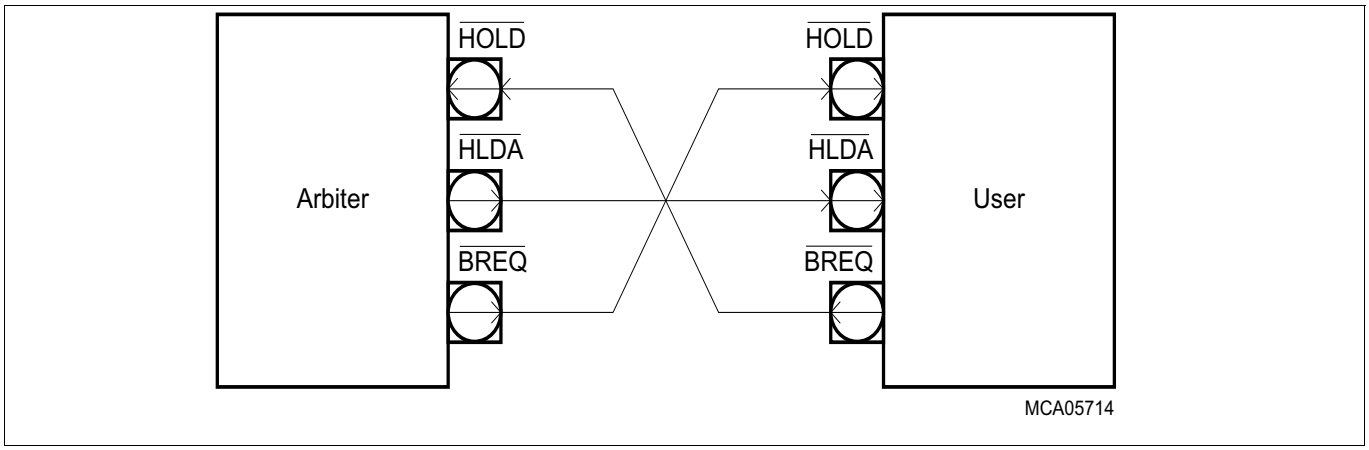

Figure 727 Connection of Bus Arbitration Signals

*Note: In the example of **Figure 727**, it is possible for the EBU to perform the function or either Arbiter or Participant (or indeed both the Arbiter and Participant may be the EBU).*

Table 506 lists the programmable parameters for the external bus arbitration.

Table 506 External Bus Arbitration Programmable Parameters

Parameter	Function	Description See
EBU_MODCON.ARBMODE	Arbitration mode selection	**Page 8**
EBU_MODCON.ARBSYNC	Arbitration input signal sampling control	
EBU_MODCON.EXTLOCK	External bus ownership locking control	
EBU_MODCON.TIMEOUTC	External bus time-out control	

45.3.8.3 Arbitration Modes

The arbitration mode of the EBU can be selected through configuration pins during reset or by programming the EBU_MODCON.ARBMODE bit field (see **Page 8**) after reset. Four different modes are available:

- No Bus Mode
- Sole Master Mode
- Arbiter Mode
- Participant Mode

45.3.8.3.1 No Bus Arbitration Mode

All accesses of the EBU to devices on the external bus are prohibited and will generate an SRI bus error. The EBU is in hold state all the time. The $\overline{\text{HOLD}}$ and $\overline{\text{HLDA}}$ arbitration inputs are ignored and $\overline{\text{BREQ}}$ arbitration output remains at high (inactive) level.

No Bus Mode is selected by EBU_MODCON.ARBMODE = 00_B.

45.3.8.3.2 Sole Master Arbitration Mode

The EBU is the only master on the external bus; therefore no arbitration is necessary and the EBU has access to the external bus at any time. The EBU is in owner state all the time. The $\overline{\text{HOLD}}$ arbitration input is ignored, and the $\overline{\text{HLDA}}$ and $\overline{\text{BREQ}}$ arbitration outputs remain at high (inactive) level.

Sole Master Mode is selected by EBU_MODCON.ARBMODE = 11_B.

45.3.8.3.3 Arbiter Mode Arbitration Mode

The EBU is the default owner of the external bus (e.g. applicable when operating from external memory). Arbitration is performed if an external master (e.g. second TriCore) needs to access the external bus.

The EBU is cooperative in relinquishing ownership of the external bus while operating in Arbiter Mode. When the $\overline{\text{HOLD}}$ input is active, the EBU will generate delay any attempt to access the external bus from the internal SRI. However, the EBU is aggressive in regaining ownership of the external bus while operating in Arbiter Mode. The EBU, having yielded ownership of the bus, will always request return of ownership even if there is no EBU external bus access pending.

Arbiter Mode is selected by EBU_MODCON.ARBMODE = 01_B.

Table 507 and **Figure 728** show the functionality of the arbitration signals in Arbiter Mode.

Table 507 Function of Arbitration Pins in Arbiter Mode

Pin	Type	Pin Function in Arbiter Mode
$\overline{\text{HOLD}}$	In	In owner state (EBU is the owner of the external bus), a low level at $\overline{\text{HOLD}}$ indicates a request for bus ownership from the external master. In hold state (EBU is not the owner of the external bus), a high level at $\overline{\text{HOLD}}$ indicates that the external master has relinquished bus ownership, which causes the EBU to exit hold state.
$\overline{\text{HLDA}}$	Out	While $\overline{\text{HLDA}}$ is high, the EBU is operating in owner state. A high-to-low transition indicates that the EBU has entered hold state and that the external bus is available to the external master. While $\overline{\text{HLDA}}$ is low, the EBU is operating in hold state. A low-to-high transition indicates that the EBU has exited hold state, and has retaken ownership of the external bus.
$\overline{\text{BREQ}}$	Out	$\overline{\text{BREQ}}$ is high during normal operation. The EBU drives $\overline{\text{BREQ}}$ low two EBU clock cycles after entering hold state (after asserting $\overline{\text{HLDA}}$ low). $\overline{\text{BREQ}}$ returns high one clock cycle after the EBU has exited hold state (after driving $\overline{\text{HLDA}}$ high).

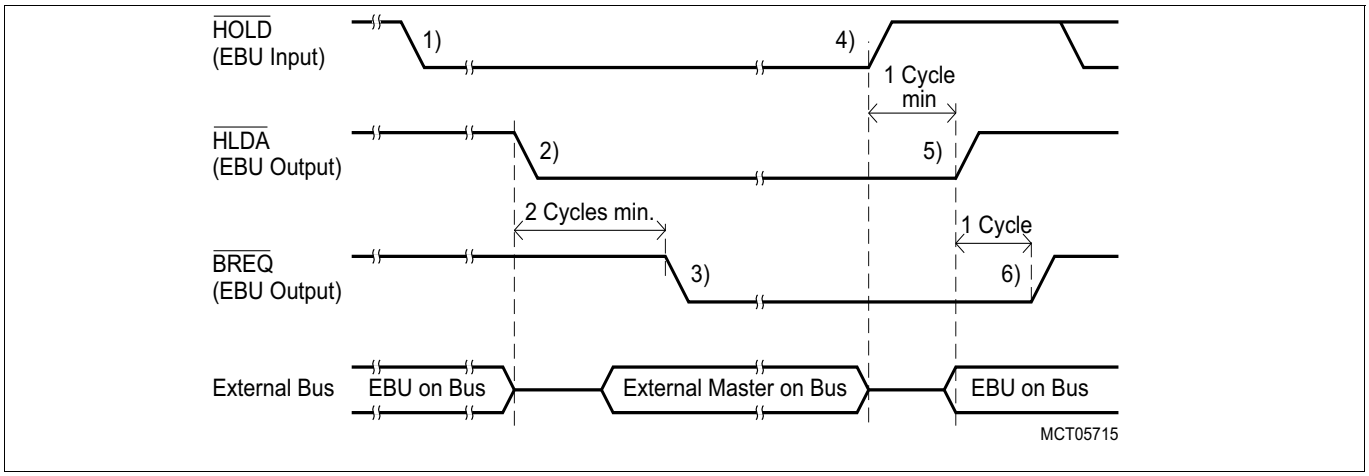

Figure 728 Arbitration Sequence with the EBU in Arbiter Mode

In Arbiter Mode, the arbitration sequence starts with the EBU as owner of the external bus.

1. The external master wants to perform an external bus access by asserting a low signal on the $\overline{\text{HOLD}}$ input.
2. When the EBU is able to release bus ownership, it enters hold state by tri-stating its bus interface lines and drives $\overline{\text{HLDA}}$ = 0 to indicate that it has released the bus. At this point, the external master ia allowed to drive the bus.
3. Two clock (EBU_CLK) cycles minimum after issuing $\overline{\text{HLDA}}$ low, the EBU drives $\overline{\text{BREQ}}$ low in order to regain bus ownership. This bus request is issued whether or not the EBU has a pending external bus access. However, the external master will ignore this signal until it has finished its bus access. This scheme assures that the external master can perform at least one complete external bus access.
4. When the external master has completed its access, it tri-states its bus interface and sets $\overline{\text{HOLD}}$ to inactive (high) level to signal that it has released the bus back to the EBU.
5. When the EBU detects that the bus has been released, it returns $\overline{\text{HLDA}}$ to high level and returns to owner state by actively driving the bus interface lines. There is always at least one clock (EBU_CLK) cycle delay from the release of the $\overline{\text{HOLD}}$ input to the EBU driving the bus.

6. Finally, the EBU deactivates the $\overline{\text{BREQ}}$ signal a minimum of one clock (EBU_CLK) cycle after deactivation of $\overline{\text{HLDA}}$. Now (and not earlier) the external master can generate a new hold request to the EBU.

This sequence assures that the EBU can perform at least one complete bus cycle before it re-enters hold state as a result of a request from the external master.

The conditions that cause change of bus ownership when the EBU is operating in Arbiter Mode are shown in **Figure 729**.

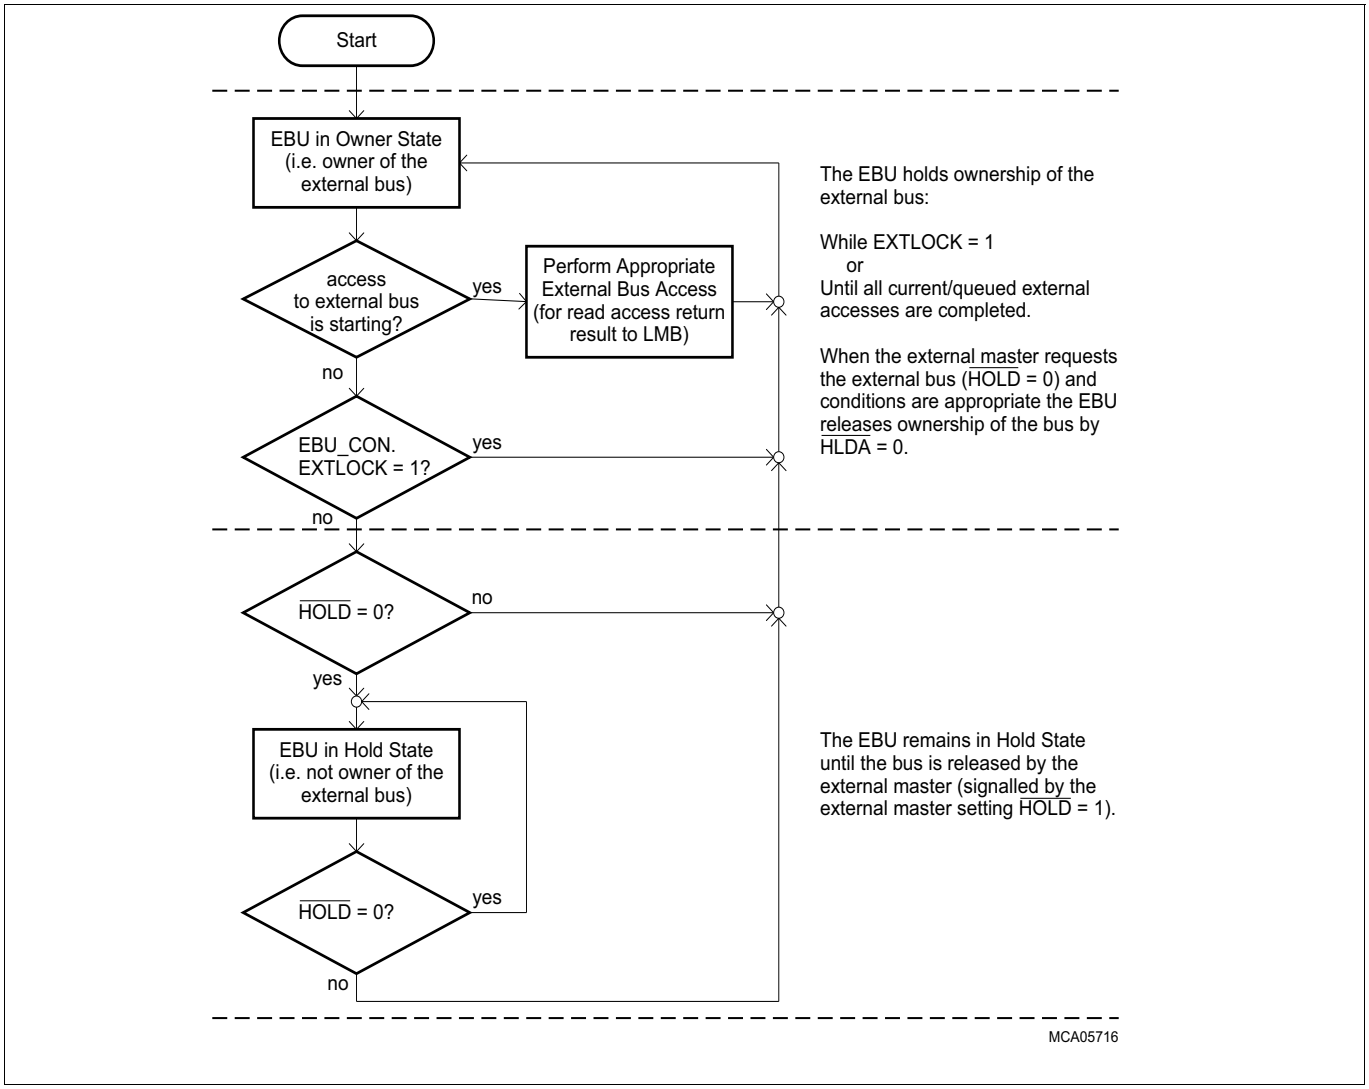

Figure 729 Bus Ownership Control in Arbiter Mode

45.3.8.3.4 “Participant Mode” Arbitration Mode

The EBU tries to gain bus ownership only in case of pending transfers (e.g. when operating from internal memory and performing stores to external memory). While the EBU is not the owner of the external bus (default state), any SRI access to the external bus will be delayed by the EBU. Any such access will cause the EBU to arbitrate for ownership of the external bus.

Once the access has been completed, the EBU will continue to accept requests from the SRI bus until the external master asserts $\overline{HOLD}$ = 0. After the external master has asserted $\overline{HOLD}$ = 0, the EBU will respond by delaying subsequent SRI accesses to external memory and will return ownership of the bus to the external master once any ongoing transaction is complete.

The use of the arbitration signals in Participant Mode is:

Table 508 Function of Arbitration Pins in Participant Mode

Pin	Type	Pin Function in Participant Mode
$\overline{HOLD}$	In	When the EBU is not in hold state ($\overline{HLDA}$ = 0) and has completely taken over control of the external bus, a low level at $\overline{HOLD}$ requests the EBU to return to hold state.
$\overline{HLDA}$	In	When the $\overline{HLDA}$ signal is high, the EBU is in hold state. When the EBU has requested ownership of the bus, the EBU is released from hold state by a high-to-low transition at $\overline{HLDA}$.
$\overline{BREQ}$	Out	$\overline{BREQ}$ remains high as long as the EBU does not need to access the external bus. When the EBU detects that an external access is required, it sets $\overline{BREQ}$ = 0 and waits for signal $\overline{HLDA}$ to become low. When the EBU has completed the external bus access (and has re-entered hold state), it will set $\overline{BREQ}$ = 1 to signal that it has relinquished ownership of the external bus.

Participant Mode arbitration mode is selected by EBU_CON.ARBMODE = 10_B.

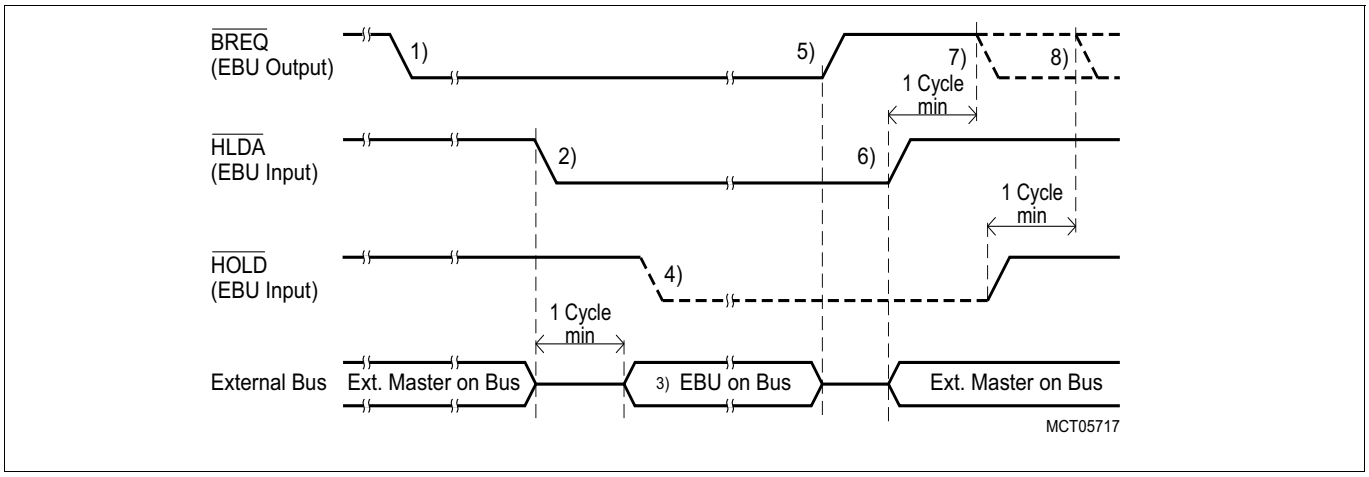

Figure 730 Arbitration Sequence with the EBU in Participant Mode

In Participant Mode, the arbitration sequence starts with the EBU in hold state.

1. The EBU detects that it has to perform an external bus access by asserting a low signal on the $\overline{BREQ}$ output.
2. When the external master is able to release bus ownership, the external master releases the external bus by tri-stating its bus interface lines and drives the $\overline{HLDA}$ = 0.
3. At least one clock (EBU_CLK) cycle after detecting $\overline{HLDA}$ = 0, the EBU will start to drive the external bus.

4. When the EBU is in owner state, the external master may optionally drive $\overline{HOLD}$ = 0 to signal that it wants to regain ownership of the external bus.
5. When the criterias are met for the EBU to release the bus ownership, the EBU enters hold state and drives $\overline{BREQ}$ = 1 output high to signal that it has released the bus.
6. When the external master detects that the EBU has released the bus ($\overline{BREQ}$ = 1), it returns $\overline{HLDA}$ to high level and takes ownership of the external bus.
7. The EBU will not request ownership of the external bus again ($\overline{BREQ}$ = 0) at least one clock (EBU_CLK) cycle after $\overline{HLDA}$ has been driven high).
8. In owner state, the EBU will not request ownership of the external bus $\overline{BREQ}$ = 0) for at least one clock (EBU_CLK) cycle after its $\overline{HOLD}$ input has been driven high.

The conditions that cause change of bus ownership when the EBU is operating in Participant Mode is shown in **Figure 729**.

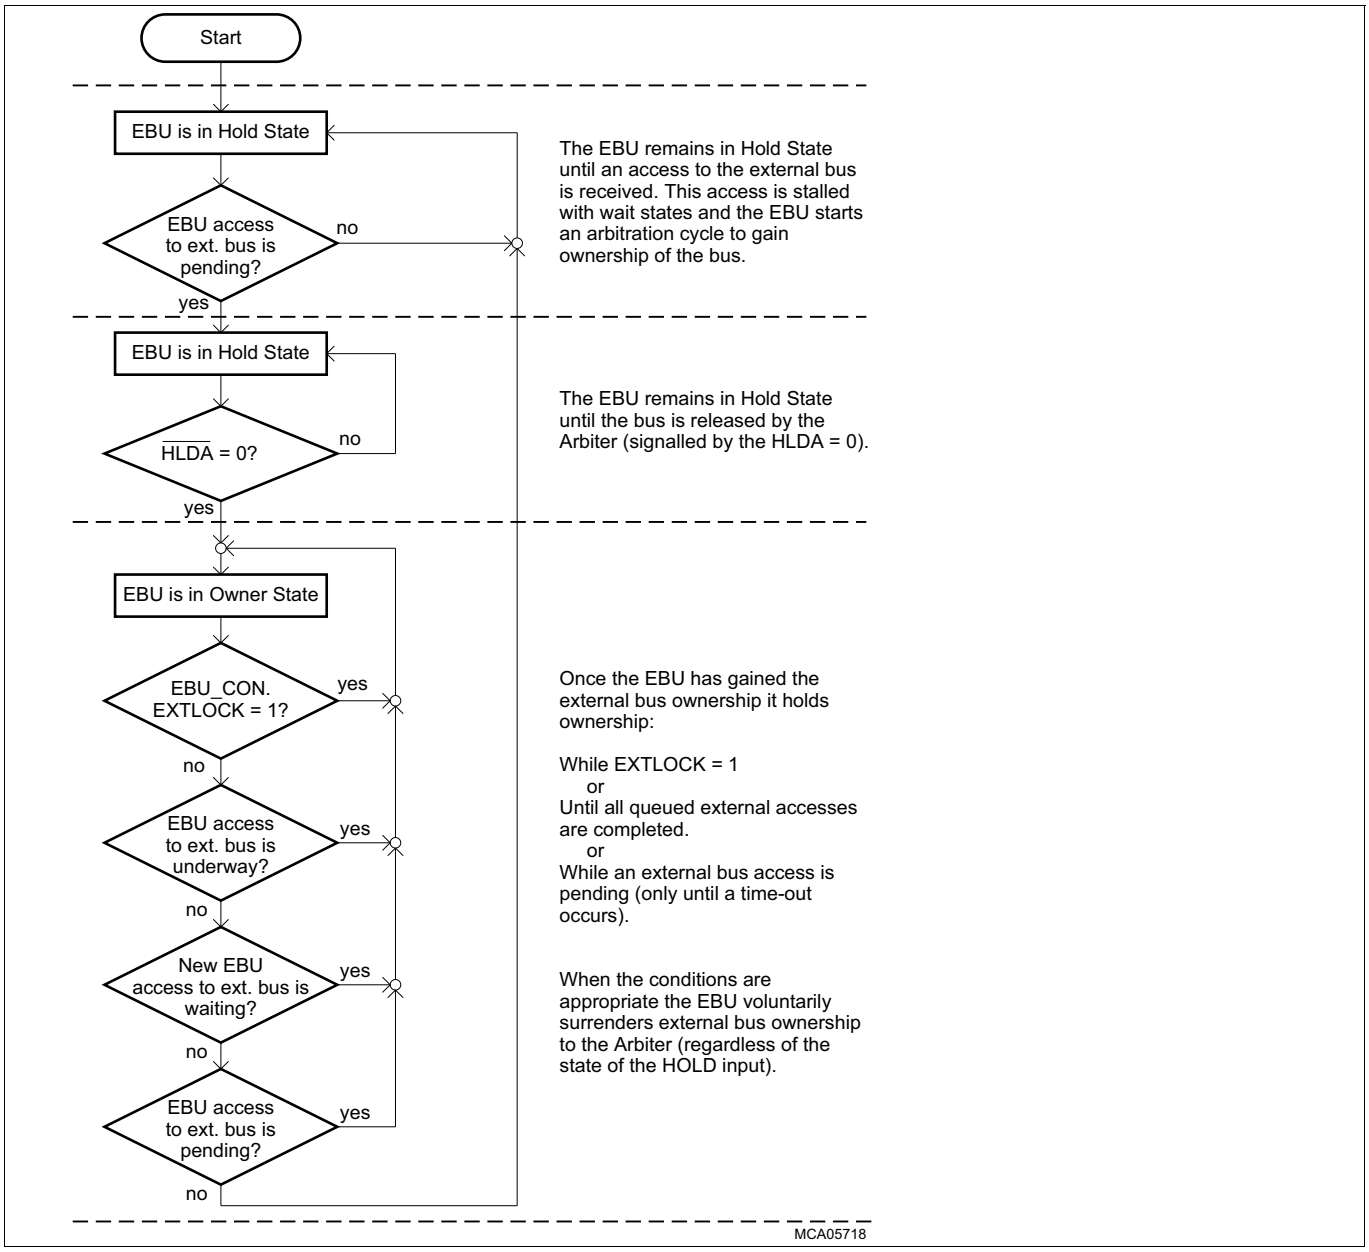

Figure 731 Bus Ownership Control with the EBU in Participant Mode

45.3.8.4 Switching Arbitration Modes

The arbitration logic will allow arbitration modes to be switched “on-the-fly” and will switch between modes as described in the following sections. However it is recommended that the arbitration mode is set as soon as possible after power on and that it is then not modified.

If this is not possible, then changes in arbitration mode should use “no bus” mode as an intermediate state with the arbiter in participant mode being placed in no bus mode first. Once both arbiters are in no bus mode, then the new modes can be set.

Note: It should be remembered that the arbitration logic drives the HLDA pin in arbiter or sole master modes and that having both sets of logic in one of these modes should be avoided to prevent contention on the signal.

45.3.8.5 Arbitration Input Signal Sampling

The sampling of the arbitration inputs can be programmed for two modes:

- Synchronous Arbitration
- Asynchronous Arbitration

When synchronous arbitration signal sampling is selected (ARBSYNC = 0), the arbitration input signals are sampled and evaluated in the same clock cycle. This mode provides the least overhead during arbitration (i.e. when changing bus ownership). The disadvantage is that the input signals must adhere to setup and hold times with respect to EBU_CLK to prevent the propagation of meta-stable signals in the EBU.

When asynchronous arbitration signal sampling is selected (ARBSYNC = 1), the arbitration signals are sampled and then fed to an additional register to be evaluated in the cycle following that in which they were sampled. This provides the EBU with good immunity to signals changing state at or around the time at which they are sampled. The disadvantage is the introduction of additional latency during arbitration (i.e. when changing bus ownership).

45.3.8.6 Locking the External Bus

The external bus can be locked to allow the EBU to perform uninterrupted sequences of external bus accesses. The EBU allows two methods of locking the external bus:

- Locked SRI accesses (i.e Read-Modify-Write)
- Lock bit EXTLOCK

When the EBU has ownership of the external bus and is performing external bus accesses in response to a locked SRI access sequence, the ownership of the external bus will not be relinquished until the locked SRI access sequence has been completed.

When lock bit EXTLOCK = 1, the EBU will hold the ownership of the external bus until EXTLOCK is subsequently cleared. If EXTLOCK is written to 1 while the EBU is the owner of the external bus, the EBU is immediately prevented from responding to requests for the external bus until EXTLOCK is cleared[1)]. If EXTLOCK is written to 1 while the EBU is not the owner of the external bus, the EBU will immediately attempt to gain ownership. When the EBU gains the ownership of the external bus the next time, the external master is prevented from regaining ownership of the external bus until EXTLOCK is again cleared.

Note: There is no time-out mechanism available for the EXTLOCK bit. When the EBU is owner of the external bus with EXTLOCK bit set, the external master will remain locked off the bus until the EXTLOCK bit is cleared by software.

1) Requests for the external bus already pending when EXTLOCK is set will not be cancelled so the EBU can give up control of the external bus after EXTLOCK is set provided that the request occurs before the EXTLOCK bit is set.

45.3.8.7 Interaction with Debug System

The EBU monitors the OCDS suspend signal used to freeze peripheral state when the system receives a break command. If the EBU detects a break it will request the external bus (if it is not the current owner). Once the EBU owns the bus, it will refuse any further arbitration requests until the suspend is released. This allows the external memories to be read by the attached debugger.

If this behaviour is not required, setting the **MODCON.OCDS_SUSP_DIS** bitfield will cause external bus arbitration to continue to operate normally during a break.

45.3.8.8 Arbitrating SDRAM control signals

Normally, the memory controller will not surrender control of a connected SDRAM type device[1)] when arbitrating the external bus. This is because the memory controller needs to keep track of which pages are open in the SDRAM and also because of restrictions on the SDRAM clock.

However, the memory controller can be programmed to tri-state the SDRAM control signals SDCLKO, CKE, $\overline{RAS}$ and $\overline{CAS}$ by setting the EBU_MODCON.SDTRI bit to 1_B. When this bit is set, SDRAM can be shared with another controller provided certain conditions are met by both memory controllers.

- The SDRAM must be in self refresh mode with the clock safely stopped before ownership of the external bus is transferred. This ensures that all pages in the SDRAM are closed and that the CKE signal is at logic zero. This can be achieved for the memory controller by setting the **SDRMREF.AUTOSELFR** to 1_B.
- The SDRAM CKE input must have a pull down sufficient to ensure that there is a guaranteed logic zero on the input while bus ownership is being transferred.

45.3.9 Start-Up/Boot Process

During reset, the EBU will be in “nobus” mode and all pins will be controlled by the Port I/O logic. After reset is removed, the EXTBOOT.EBU_CFG register filed can be written to request an external boot. If external boot is required, then the EBU will set the BUSCONx.PORTW and BUSRCONx.AGEN fields to the appropriate values and enable the necessary pins for use by the EBU. If external boot is not requested then the EBU will remain in “nobus” mode until configured by software.

45.3.9.1 Disabled (arbitration mode is “nobus”)

The EBU will come up with access to the external bus disabled after reset (i.e. no access from SRI to external memory is possible without EBU re-configuration).

45.3.9.2 External Boot Mode

The External Boot Mode of the EBU allows the EBU to boot (i.e. run all start-up code) from external memory. Immediately after reset a system may have no knowledge as to the type of memory connected to the external bus. When external boot mode is selected, the EBU will exit system firmware with the registers configures to allow slow (safe) accesses to both muxed and non-muxed asynchronous memories.

When External Boot Mode is selected, the EBU can be configured to automatically read a 32-bit Boot Configuration Value from an external memory (connected to $\overline{CS0}$, chip select region 0). The Boot Configuration Value in the external boot memory makes it possible to initialize the EBU with more appropriate configuration values for the external boot memory. These configuration values will, in turn, be used for the subsequent read accesses from the external boot memory (i.e. instruction fetches).

1) SDRAM, DDRAM & LPDDR-NVM devices

The boot configuration fetch is triggered by writing 1_B to the EBU_EXTBOOT.EBUCFG bit before the end of system boot[1]. In this case the EBU_EXTBOOT.CFGEND bit should be polled to determine when the fetch has ended and the registers updated.

The EBU_EXTBOOT.CFGERR bit will be set if the configuration word fetch fails to retrieve valid data. See **"Configuration Word Fetch Process" on Page 15** for a full description of the configuration process.

Note: External boot cannot be used if an SDRAM is connected. This is because these devices do not have an external reset input and will therefore be in an indeterminate state after a reset of the EBU. This state could cause the memory device to drive the databus and, as the SDCLKO output is disabled after reset, the memory device will remain in this state during the external boot process and interfere with the reads from the boot memory.

45.3.9.2.1 Configuration Word Fetch Process

If an External Boot configuration fetch is enabled, the EBU will perform one external bus read access to external bus address 000004_H of the memory device attached to chip select line $\overline{CS0}$. As it is assumed by the that the attached memory device has a 32 bit data bus, this is equivalent to a SRI or byte address of 000010_H because of the address translation implemented in the EBU (see **Chapter 45.3.10.4 on Page 20**).

The data read by this read access is used to configure the EBU with parameters (see **Page 17**). The boot read access itself is performed as an asynchronous access cycle with all timing parameters set to their maximum values. This access scheme supports ROMs, EPROMs or Flash memories with both separate address and data connections and also multiplexed address and data connections. **Figure 732** shows a timing example of booting from a standard demultiplexed asynchronous memory device.

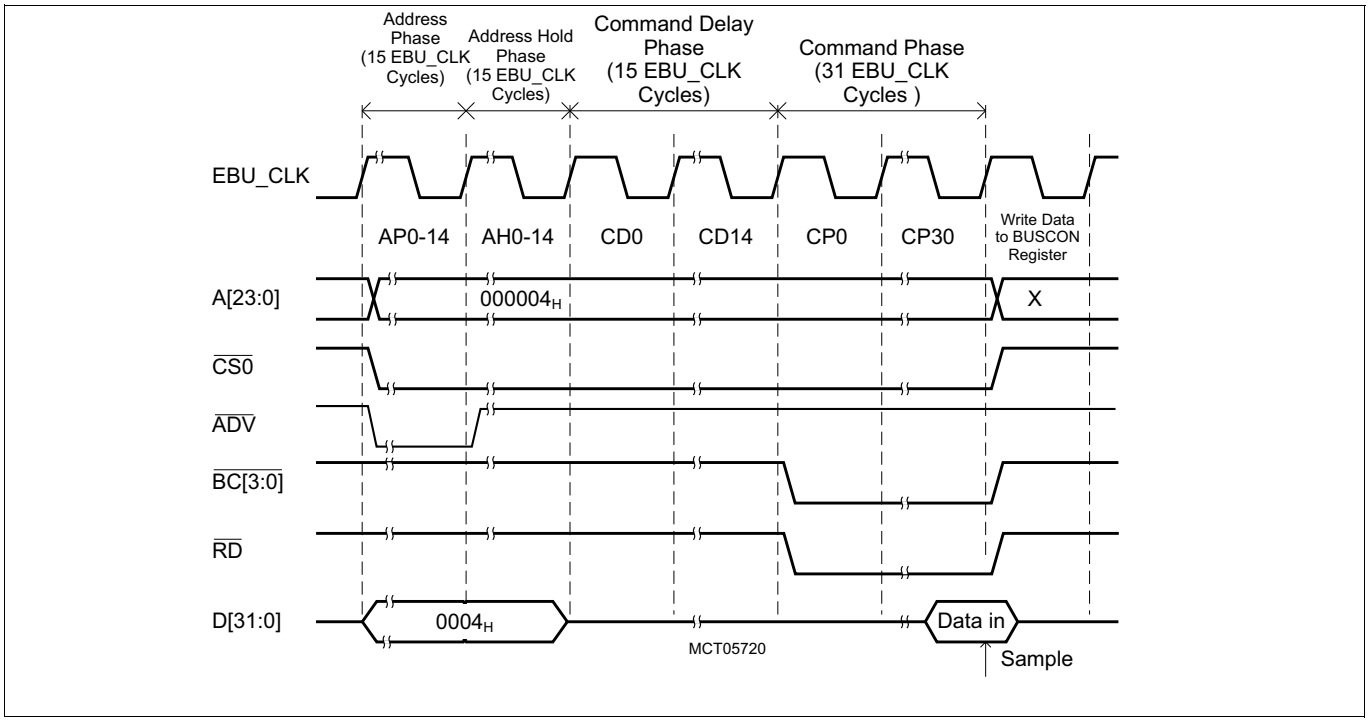

Figure 732 Boot Read Access Cycle

When a configuration fetch is triggered, the EBU waits 256 EBU_CLK clock cycles until the access is initiated, as shown in **Figure 732**. This gap is inserted to fulfill the recovery times needed by external synchronous devices

1) This is determined by the state of the BOOT_ACTIVE flag generated by the SCU.

such as Flash ROMs. During the read access, the maximum number of programmable EBU_CLK cycles is inserted (WAITRDC = 31), and the evaluation of the $\overline{WAIT}$ signal is inhibited.

Note: The boot memory must be connected to chip select line $\overline{CS0}$. The EBU assumes that the boot memory is 32-bits wide and, therefore, always reads a 32-bit configuration word at the "Data in" point shown above.

*Note: If $FFFF_H$ is returned as on bits 15 downto 0 of the configuration word during the boot read cycle (e.g. by reading the configuration word from an erased external boot memory device), the arbitration mode is set to No Bus Mode (ARBMODE = 00_B, see **"No Bus Arbitration Mode" on Page 8**). However since a value for the BCGEN field of 11_B is not legal for boot, at least one bit of the fetched word will be 0_B for valid data*

45.3.9.2.2 Boot Configuration Value

The EBU supports boot operation from 32-bit wide memories. The format of the Boot Configuration Value is as follows (Bits 31 to 16 are reserved for future expansion):

Boot Configuration Value **Reset Value:**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCGEN		WAIT		WAITINV	ADDRC				WAITRDC					PORTW	

Field	Bits	Type	Description
PORTW	1:0		**Port Width** 00_B external memory is 8 bit 01_B external memory is 16 bit 10_B external memory is two 16 bit memories in parallel to make a 32 bit memory 11_B external memory is 32 bit
WAITRDC	[6:2]		**Number of Wait States for Read Accesses** Loaded into EBU_BUSRAP0.WAITRDC.
ADDRC	[10:7]		**Number of Cycles in the Address Phase** Loaded into EBU_BUSRAP0.ADDRC.
WAITINV	11		**WAIT Input Polarity Control** Loaded into EBU_BUSRCON0.WAITINV.
WAIT	[13:12]		**External Wait State Control** Loaded into EBU_BUSRCON0.WAIT.
BCGEN	[15:14]		**Byte Control Signal Control** Loaded into EBU_BUSRCON0.BCGEN.
RES	[31:16]		**Reserved** This bit field is reserved for future use. In the , RES should always be set to 0_H.

45.3.10 Accessing the External Bus

Each internal SRI master can access external devices via the EBU. The SRI address range occupied by the EBU is defined in the system address map. In addition, the EBU provides three user-programmable external memory regions which can be mapped into the SRI address space using the EBU_ADDRSELx registers. The EBU_ADDRSELs register allows the base address and size of the region to be defined.

Each of these regions is provided with a set of registers that determine the parameters of the external bus transaction as defined in **Section 45.3.10.1**. As can be seen from the table **Section 45.3.10.1**, each register set corresponds directly to a chip select signal for an external memory device. in An SRI transaction that matches one of these user-programmable external memory regions is translated by the EBU to the appropriate external access(es).

45.3.10.1 External Memory Regions

Each of the external memory regions has its own associated chip select output $\overline{CS}[2:0]$ and a set of control registers to specify the type of memory/peripheral device and the access parameters.

The access parameters for each of the regions can be programmed individually to accommodate different types of external devices. Separate control registers are available to control read and write accesses. This allows optimal access types, speeds and parameters to be chosen. Access type is configured via BUSRCONx and BUSWCONx. Access parameters are configured via BUSRAPx and BUWAPx.

Throughout this document the generic term EBU_BUSCONx is used when either of BUSRCONx or BUSWCONx is applicable and EBU_BUSAPx is used when either of BUSRAPx or BUSWAPx is applicable.

Table 509 EBU Address Regions, Registers and Chip Selects

Region	Associated Chip Select	Address Select Registers	Bus Configuration Registers	Bus Access Parameters Registers
Region 0	$\overline{CS0}$	EBU_ADDRSEL0	EBU_BUSRCON0 EBU_BUSWCON0	EBU_BUSRAP0 EBU_BUSWAP0
Region 1	$\overline{CS1}$	EBU_ADDRSEL1	EBU_BUSRCON1 EBU_BUSWCON1	EBU_BUSRAP1 EBU_BUSWAP1
Region 2	$\overline{CS2}$	EBU_ADDRSEL2	EBU_BUSRCON2 EBU_BUSWCON2	EBU_BUSRAP2 EBU_BUSWAP2

Table 510 lists the programmable parameters that are available for the three external regions (regions 0 to 2) independent of the attached memory device.

Table 510 Programmable Parameters of Regions

Register	Parameter (Bit/Bit field)	Function
EBU_ADDRSELx	ALTSEG	Alternate segment of region to be compared to SRI address bits [31:28].
	BASE	Region base address to be compared with SRI address in conjunction with the MASK parameter.
	MASK	Address mask for each external region. Specifies the number of right-most bits in the base address starting from bit 26.
	WPROT	Write Protect bit for each region.
	ALTENAB	Alternate segment enable of a region. Determines whether or not parameter ALTSEG is always compared to SRI address.
	REGENAB	Enable bit for each region. A disabled region will always generate a miss during address comparison.
EBU_BUSCONx	AGEN	Region access type: See **Section 45.3.11.1**

45.3.10.2 Address Comparison

Address Comparison is implemented in addition to the address decoding in the SRI bus matrix and is used to map SRI addresses to the EBU regions. The address comparison operation will, by default, take two clock cycles. If the frequency of the SRI bus is set to be less than or equal to 180 MHz, then the SRI interface of the EBU can be set to use single cycle decode. This is controlled by the **MODCON.FAST_SRI** bitfield. When set to 1_B, the SRI interface will use a single cycle for address decode.

Note: As the FAST_SRI bit modifies the SRI interface behaviour dynamically, some care is needed when changing the mode of operation. When setting or clearing the bit, time should be allowed after writing the register for the setting to take effect before attempting a read from the EBU. To ensure the new setting has taken effect, it is suggested that the EBU_MODCON register is written twice with the new setting. This is because internal architecture constraints mean that the data from the first write must have been transferred to the register before the second write can proceed.

45.3.10.2.1 Operation Address Comparison

Each of the three EBU regions can be programmed for independent base addresses and lengths by bits and bit fields in registers EBU_ADDRSELx.

- Bit REGEN is the enable control of a region. If the region is disabled (REGEN = 0), no address comparison will take place for the region.
- Bit field BASE specifies address bits A[31:12] of region x, where A[31:28] must only point to segments 8, 10, 13, and 14. [1)]
- Bit field MASK determines the length of a region. It specifies how many bits of anSRI SRI address must match the contents of the BASE(x) bit field (to a maximum of 15, starting with A[26]). Note that address bits A[31:27] must always match.
- Bit WPROT write protects a region. If the region is protected (WPROT = 1), no address comparison will take place for that region on a write access[2)]

1) There is no hardware lockout preventing other values being written to A[31:28], but in most cases this will result in an inaccessible memory. Enabling a memory region at segment $F8_H$ will result in the memory region conflicting with the registers. The EBU will not work correctly if this is done.

- Bit field ALTSEG determines the number of an alternate segment that can be used for address comparison with A[31:28] (if enabled by ALTENAB = 1).
- Bit ALTENAB determines whether an additional alternate segment number as defined by ALTSEG is used for address comparison.

When defining mirrored segments, the user is responsible for ensuring that there is no collision. There is no checking mechanism in hardware that ensures that each segment defined (either in BASE[31:28] or ALTSEG[11:8] or both) is exclusive. Therefore, the user must ensure that each mapping from region 0 to 3 does not interfere with any other; otherwise, only the mapping with the highest priority will take effect.

45.3.10.3 SRI Bus Width Translation

If the SRI access size is wider than the external bus width specified for the selected external region, the internal access is split in the EBU into several external accesses. For example, if the SRI requests to read a 64-bit word and the external device is only 16-bit wide, the EBU will automatically perform four external 16-bit accesses. When multiple accesses are generated in this way, external bus arbitration is blocked until the multiple access is complete. This means that the EBU remains the owner of the external bus for the duration of the access sequence. The external accesses are performed in ascending SRI address order.

45.3.10.4 Address Alignment During Bus Accesses

During an external bus access, the EBU will align the internal byte address to generate the appropriate external word or half-word address aligned to the external address pins. The address alignment will be done as follows:

- For 8 bit memory accesses
  - AD[15:0] will be driven with the value from A_{SRI}[15:0] (mutiplexed accesses only)
  - A[23:0] will be driven with the value from A_{SRI}[23:0]
- For 16 bit memory accesses
  - AD[15:0] will be driven with the value from A_{SRI}[16:1] (mutiplexed accesses only)
  - A[23:0] will be driven with the value from A_{SRI}[24:1]
- For 32 bit memory accesses
  - AD[15:0] and AD[31:16] will both be driven with the value from A_{SRI}[17:2] (accesses to paired 16-bit multiplexed devices only)
  - AD[31:0] will be driven with the right-justified and zero-padded value from A_{SRI}[31:2] (accesses to paired 32-bit multiplexed devices only)
  - A[23:0] will be driven with the value from A_{SRI}[25:2]

45.3.10.5 SRI Data Buffering

The data for all SRI writes are “posted” into a buffer in the SRI interface before the access is passed to the state machine blocks for execution. This means that all the write data is available to the state machine before the access starts independent of the relative clock frequencies of the internal and external buses and that the write completes at the initiating master before the data is written to the external memory.

2) The WPROT bit also appiles to the read phase of a read modify write, SRI transaction. This is to prevent two possible error conditions. The first would be where the read phase was accepted and the write phase errored. This is an SRI protocol violation. The second would be where the read and write accesses occurred to different memory addresses (if the read took place to a write protected region and there was an unprotected, lower priority, region mapped to the same address space).

45.3.10.6 Chip Select Control

The EBU generates three chip select signals, $\overline{CSx}$, which are all available at dedicated chip select outputs. Each chip select is associated exclusively with an EBU region. See **"External Memory Regions" on Page 18** for a complete description.

45.3.10.7 Combined Chip Select ($\overline{CSCOMB}$)

The EBU can also generate a combined, global chip select. This is controlled using the EBU_ADDRSELx.GLOBALCS register fields. If this is set to 1_B in a register, then the $\overline{CSCOMB}$ chip select is asserted whenever the associated normal chip select is asserted. Multiple GLOBALCS fields can be set simultaneously.

45.3.11 Connecting External Memories

The EBU supports interconnection to a wide variety of memory/peripheral devices with flexible programming of the access parameters. In the following sections, the basic features for these access modes are described. The types of external access cycles provided by the EBU are:

- Asynchronous accesses with multiplexed or demultiplexed address and data bus
  - ROMs, EPROMs
  - NOR flash devices
  - NAND flash devices
  - Static RAMs and PSRAMs
- Synchronous accesses with multiplexed or demultiplexed address and data bus
  - NOR flash devices (operating in burst mode)
  - PSRAMs
  - Page mode flash[1)]
- Accesses using SDRAM Type Command Protocol
  - Mobile SDRAM

Note: Not all memory types supported by the memory controller are known to be available in all quality grades and temperature ranges.

Each type of access is controlled by a state machine in the EBU kernel. See **Table 511** for a list of the access types supported and the controlling state machine.

SDRAM type accesses comply with the relevant protocol and have limited programmability. Asynchronous and Synchronous accesses use the concept of access phases of programmable duration and are more fully described in **"Phases for Asynchronous and Synchronous Accesses" on Page 24**

45.3.11.1 Programmable Device Types

Each CS region (0 to) can be individually configured using the BUSCONx.AGEN register field, to be connected to one of the following external memory/device types:

1) Page mode flash devices are not synchronous but have in common with synchronous devices the ability to return multiple data words for each supplied address. They are therefore handled by the synchronous state machine of the EBU

Table 511 agen description

agen value	Device Type	State Machine
0	Muxed Asynchronous Type (default after reset)	Asynchronous
1	Muxed Burst Type	Synchronous
2	NAND flash (page optimised)	Asynchronous
3	Muxed Cellular RAM	Synchronous
4	Demuxed Asynchronous Type	Asynchronous
5	Demuxed Burst Type	Synchronous
6	Demuxed Page Mode	Synchronous
7	Demuxed Cellular RAM	Synchronous
8	SDRAM	SDRAM
9	Reserved	Synchronous
10	Reserved	SDRAM
11	Reserved	-
12	Reserved	SDRAM
13	Reserved	Synchronous
14	Reserved	-
15	Reserved	-

The AGEN fields for the BUSRCONx and BUSWCONx can, in most cases, be set independently. This allows devices such as burst flash, which require synchronous reads and asynchronous writes to be supported efficiently.

There are device types where this capability does not confer any advantage. In these cases, writing to the BUSRCONx.AGEN field will also update the BUSWCONx.AGEN field.

The AGEN values which trigger the automatic BUSWCONx.AGEN update are:

- SDRAM: 8_D

While the BUSRCONx.AGEN field is set to one of these values, any attempt to set the value of the related BUSWCONx.AGEN field will be ignored.

45.3.11.2 Support for Multiplexed Device Configurations

Memory Controller supports a number of configurations of Multiplexed memory/peripheral devices using different values of the EBU_BUSRCONx.PORTW bit-field. The EBU_BUSWCONx registers also contain the PORTW field but in this case the field is read only and reflects the value set in the related one of the EBU_BUSRCONx registers. The values set in the EBU_BUSRCONx registers are used for both read and write accesses.

Note: When using multiplexed devices a non-zero recovery phase is mandatory for all devices to prevent read data from one access conflicting with the address for the next access to the multiplexed memory.

Table 512 Pins used to connect Multiplexed Devices to Memory Controller

Memory Device Configuration	Memory Controller Pins		
	A(23:0)[1)]	**AD(31:16)**	**AD(15:0)**
8-bit MUX	A(23:0)	-	A(7:0)/ D(7:0)
16-bit MUX	A(23:0)	-	A(15:0)/ D(15:0)
Twin 16-bit MUX	A(23:0)	A(15:0)/ D(31:16)	A(15:0)/ D(15:0)
32-bit MUX	-	A(31:16)/ D(31:16)	A(15:0)/ D(15:0)

1) These pins are always outputs which are connected to address pins on the Multiplexed device(s)

Table 513 Selection of Multiplexed Device Configuration

PORTW value	
00_B	8-bit multiplexed (deprecated)[1)]
01_B	16-bit multiplexed[2)]
10_B	Twin, 16-bit Multiplexed[3)]
11_B	32 bit multiplexed[4)]

1) 8-bit port width is only intended for NAND flash and ONFI devices which do not require particular values on the address bus. Correct operation of multiplexed addressing is not verified or guaranteed.
2) Address will only be driven onto AD(15:0) during the address and address hold phases. A(15:0) will be driven with address for duration of access
3) Lower 16 bits of address will be driven onto both A(15:0) and AD(15:0) during the address and address hold phases
4) Full address will be driven onto A(15:0) and AD(15:0) during the address and address hold phases

45.3.11.3 Support for Non-Multiplexed Device Configurations

The Memory Controller supports 16-bit and 32-bit non-multiplexed memory devices.

Table 514 Pins used to connect non-multiplexed Devices to Memory Controller

Memory Device Configuration	Memory Controller Pins		
	A(23:0)	**AD(31:16)**	**AD(15:0)**
8-bit non-MUX	A(23:0)	-	D(7:0)
16-bit non-MUX	A(23:0)	-	D(15:0)

Table 514 Pins used to connect non-multiplexed Devices to Memory Controller (cont'd)

Memory Device Configuration	Memory Controller Pins		
	A(23:0)	**AD(31:16)**	**AD(15:0)**
twin, 16-bit non-MUX	A(23:0)	D(31:16)	D(15:0)
32-bit non-MUX	A(23:0)	D(31:16)	D(15:0)

Table 515 Selection of non-Multiplexed Device Configuration

PORTW value	
00_B	8-bit[1)]
01_B	16-bit
10_B	Twin 16-bit
11_B	32-bit

1) 8-bit port width is only intended for NAND flash and ONFI devices which do not require particular values on the address bus. Correct operation of addressing for other device types is not verified or guaranteed

45.3.12 Phases for Asynchronous and Synchronous Accesses

Accesses to asynchronous and synchronous devices are composed of a number of standard access phases (according to the type of device and the type of access). Each output signal for the EBU is active in defined phases. The length of the phases can be programmed to adjust the pulse width and timing relationships of the output signals

There are six access phases defined:

- Address Phase AP (mandatory for read and write cycles of both device types)
- Command Delay Phase CD (optional)
- Command Phase CP (mandatory)
- Burst Phase BP (Synchronous Accesses only)
- Data Hold Phase DH (optional, only applies to write cycles)
- Recovery Phase RP (optional)

Throughout the remainder of this document, a short-hand notation is adopted to represent any clock cycle in any phase. This notation consists of two or three letters followed by a number. The letters identify the access phase within which the clock cycle is located (e.g. AP for Address Phase). The number denotes the number of EBU_CLK clock cycles within the phase (i.e. 1 = first, etc.). In the case of delays that can be extended by external control inputs the lower case letters "e" and "i" are inserted following the two letter phase identifier to differentiate between internally ("i") and externally ("e") generated delays. For example, AP2 identifies the second clock in the Address Phase. CPe3 identifies the third clock in the Command Phase which is being extended by external wait-states.

45.3.12.1 Address Phase (AP)

The Address Phase is mandatory. It always consists of at least one or more EBU_CLK cycles. The phase can be optionally extended to accommodate slower devices.

At the start of the Address Phase, the EBU:

- Selects the device to be accessed by asserting the appropriate $\overline{CSx}$ signal,
- Issues the address which is to be accessed on the address bus,
- For multiplexed devices, drives the address onto the muliplexed address/data bus,

- Asserts the $\overline{ADV}$ signal low,[1)]
- Asserts the appropriate $\overline{BCx}$ signals if these are programmed to be asserted with the $\overline{CSx}$ signal,
- At the end of the Address Phase the EBU returns the $\overline{ADV}$ signal to high.

The length (number of EBU_CLK cycles) of the Address Phase is programmed via the EBU_BUSAPx.ADDRC bit field parameter.

45.3.12.2 Address Hold Phase (AH)

The Address Hold Phase is optional. It consists of zero or more EBU_CLK cycles. It is intended to provide hold time for the multiplexed address bits after the $\overline{ADV}$ signal has returned to the inactive state.

At the end of the address hold phase, the multiplexed address will be removed from the bus:

- During a read access, the multiplexed address/data bus will return to the high impedance condition to allow the read data to be driven by the external memory
- During a write access, the write data will be driven onto the multiplexed address/data bus

45.3.12.3 Command Delay Phase (CD)

The Command Delay phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. The CD phase allows for the insertion of a delay between Address Phase (or optional Address Hold phase) and Command Phase(s). This phase accommodates devices that are not fast enough to receive commands immediately after getting the address or multiplexed devices which require a bus turnaround delay on reads.

The length (number of EBU_CLK cycles) of the Command Delay phase is programmed via the EBU_BUSAPx.CMDDELAY bit field. This parameter makes it possible to select between zero to seven Command Delay phases.

1) If an active high, ALE, signal is required, the polarity of the $\overline{ADV}$ output can be inverted by setting the ALE field of the EBU_MODCON register.

45.3.12.4 Command Phase (CP)

The Command Phase is mandatory for asynchronous devices. It always consists of at least one or more EBU_CLK cycles. The phase can optionally be extended to accommodate slower devices.

The length (number of EBU_CLK cycles) of the Command Phase is separately programmable for read and write accesses. Bit field EBU_BUSAPx.WAITRDC determines the basic length of Command Phases during read cycles and bit field EBU_BUSAPx.WAITWRC determines the basic length of Command Phases during write cycles.

Additionally, when accessing asynchronous devices, a Command Phase can also be extended externally using the $\overline{\text{WAIT}}$ signal when the region being accessed is programmed for external command delay control via bit EBU_BUSCONx.WAIT.

The Command Phase is further subdivided into:

- CPi (= internally-programmed Command Phase)
- CPe (= externally-prolonged Command Phase, i.e. prolonged by the assertion of the $\overline{\text{WAIT}}$ signal).

At the start of the Command Phase, the EBU:

- Asserts the appropriate control signal $\overline{\text{RD}}$ or RD/$\overline{\text{WR}}$ low according to the access type (read or write),
- Issues the data to be written on the data bus AD[15:0] (in the case of a write cycle),
- Asserts the appropriate $\overline{\text{BCx}}$ low (in the case where $\overline{\text{BCx}}$ is programmed to be asserted with the $\overline{\text{RD}}$ or RD/$\overline{\text{WR}}$ signals).

At the end of the Command Phase during an asynchronous access, the EBU:

- Returns the appropriate control signal $\overline{\text{RD}}$ or RD/$\overline{\text{WR}}$ high according to the type of access type (read or write),
- Latches the data from the data bus AD[15:0] (in the case of a read cycle),
- Returns the appropriate $\overline{\text{BCx}}$ high (in the case where $\overline{\text{BCx}}$ is programmed to be asserted with the $\overline{\text{RD}}$ or RD/$\overline{\text{WR}}$ signals).

At the end of the Command Phase during a synchronous access, the $\overline{\text{RD}}$ or RD/$\overline{\text{WR}}$ signals hold their state and the state machine transfers to the Burst Phase. Transition to Burst Phase will always occur synchrnously with a rising edge of BFCLKO. If necessary, the Command Phase will be extended to ensure that this happens.

45.3.12.5 Data Hold Phase (DH)

The Data Hold phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. Furthermore, it is only available for asynchronous write accesses (with two exceptions, see below). The Data Hold phase extends the amount of time for which data is still held on the bus after the rising edge of the RD/$\overline{\text{WR}}$ signal occurred. The Data Hold phase is used to accommodate external devices that require a data hold time after the rising edge of the RD/$\overline{\text{WR}}$ signal. The length (number of EBU_CLK cycles) of the Data Hold phase is programmed via the EBU_BUSAPx.DATAC bit field.

45.3.12.5.1 Exceptional use of Data Hold

In two cases, signals other than the data bus may need to have a hold time maintained relative to RD/$\overline{\text{WR}}$ or $\overline{\text{RD}}$. These cases occur when $\overline{\text{ADV}}$ and $\overline{\text{BAA}}$ are being used as NAND flash control signals which happens for AGEN settings of 2_D or 13_D. For these two settings, the Data Hold Phase will apply to both reads and writes.

45.3.12.6 Burst Phase (BP)

The Burst Phase is mandatory during burst accesses. At the end of the Burst Phase the EBU reads data from the data bus or updates the write data. During a burst access, Burst Phases are repeated as many times as required in order to read or write the required amount of data from or to the external memory device.

At the start of the first Burst Phase during a burst read access, the EBU:

- Drives the $\overline{BAA}$ signal low to cause the Burst Flash device to advance the address with each subsequent BFCLKO positive edge.

The first burst phase of an access will always start on arising edge of BFCLKO. If necessary, the length of the previous phase will be extended to ensure that this happens.

At the end of the last Burst Phase during a burst access, the EBU:

- Returns the $\overline{BAA}$ signal high,
- Returns the $\overline{CSx}$ signal high,
- Returns the $\overline{RD}$ signal high.
- Returns the RD/$\overline{WR}$ signal high

provided that a Control Hold phase has not been programmed.

During accesses to Burst Flash devices the length of the Burst Phase will be programmed such that the end of the Burst Phase always coincides with a positive edge of the appropriate BFCLKO (Burst Flash Clock) signal.

A Burst Phase is always at least one clock cycle in length. The length of each Burst Phase (i.e. the number of cycles) is derived from the value of the EXTCLOCK and EXTDATA fields in the EBU_BUSAPx register. The length of the burst phase will be either be:

- one period of BFCLKO if EXTDATA is 00_B,
- two periods of BFCLKO if EXTDATA is 01_B.
- four periods of BFCLKO if EXTDATA is 10_B.
- eight periods of BFCLKO if EXTDATA is 11_B.

45.3.12.7 Recovery Phase (RP)

The Recovery Phase is optional (although for access types which would cause a bus contention a single cycle of recovery is normally forced by the memory controller logic). This means that it can also be programmed for a length of zero EBU_CLK clock cycles. This phase allows the insertion of a delay following an external bus access that delays the start of the Address Phase for the next external bus access. This permits flexible adjustment of the delay between accesses to the various external devices. The following individually programmable delays are provided on a region by region basis for the following conditions:

- Bit fields EBU_BUSAPx.RDRECOVC determine the basic length of the Recovery Phase after a read access.
- Bit fields EBU_BUSAPx.WRRECOVC determine the basic length of the Recovery Phase after a write access.
- Bit fields EBU_BUSAPx.DTACS determine the length (basic number of EBU_CLK clock cycles) of the Recovery Phase after a read/write access of one region that is followed by a read/write access of another region or a read to one region is followed by a write to the same region (BUSRAPx.DTACS) or a write to one region is followed by a read to the same region (BUSWAPx.DTACS).

The EBU implements a “highest wins” algorithm to ensure that the longest applicable recovery delay is always used between consecutive accesses to the external bus. **Table 516** shows the scheme for determining this delay for all possible circumstances. For example, if a read access to a region associated with $\overline{CS1}$ is followed by a write to a region associated with $\overline{CS2}$, the delay will be the highest of BUSRAP1.DTACS and BUSRAP1.RDRECOVC. In this case, if BUSRAP1.DTACS is greater than BUSRAP1.RDRECOVC, then the number of recovery cycles between the two accesses is BUSRAP1.DTACS clock cycles (minimum).

Table 516 Parameters for Recovery Phase

Case			Parameter(s) used to calculate "Highest Wins" Recovery Phase
Region	Current Access	Next Access	
Same $\overline{CSn}$	Read	Read	RDRECOVC
	Write	Write	WRRECOVC
	Read	Write	BUSRAPx.DTACS
	Write	Read	BUSWAPx.DTACS
Different $\overline{CSn}$	Read	Read	BUSRAPx.DTACS, RDRECOVC
	Write	Write	BUSWAPx.DTACS, WRRECOVC
	Read	Write	BUSRAPx.DTACS, RDRECOVC
	Write	Read	BUSWAPx.DTACS, WRRECOVC

45.3.13 Asynchronous Read/Write Accesses

Asynchronous read/write access of the EBU support the following features:

- EBU_CLK clock-synchronous signal generation
- Support for 8-bit, 16-bit and 32-bit bus width
  Performing an SRI access with a data size greater than that of the external device automatically triggers a sequence of the appropriate number of external accesses to match the SRI access width.
- Demultiplexed address/data lines
- Programmable access parameters
  - Internal control of command delay cycles
  - External and/or internal control of wait states
  - Variable data hold cycles for write operation (to allow flexible hold time adjustment)
  - Variable inactive/recovery cycles when:
    Switching between different memory regions (CS),
    Switching between read and write operations,
    After each read cycle,
    After each write cycle.

Software driver routines are required in order to support Nand Flash devices using asynchronous device accesses. A single Nand Flash access sequence is performed by generating the appropriate sequence of discrete asynchronous device accesses in software.

45.3.13.1 Signal List

The following signals of the EBU are used for asynchronous accesses:

Table 517 Asynchronous Mode Signal List

Signal/Pin	Type	Function
AD[31:0]	O	Address/Data bus lines 0-31
A[23:0]	O	Address bus lines 0-23
$\overline{\text{CS}}$[2:0]	O	Chip select 0-3
$\overline{\text{RD}}$	O	Read control line
RD/$\overline{\text{WR}}$	O	Write control line
$\overline{\text{BC}}$[3:0]	O	Byte control lines 0-3
$\overline{\text{WAIT}}$	I	Wait input

45.3.13.2 Standard Asynchronous Access Phases

Accesses to asynchronous devices are composed of a subset of the standard access phases which are detailed in **Section 45.3.12**. The standard access phases for asynchronous devices are:

- AP: Address Phase (compulsory - see **Page 24**)
- AH: Address Hold Phase (Optional - see **Page 25**)
- CD: Command Delay Phase (optional - see **Page 25**)
- CP: Command Phase (compulsory - see **Page 26**)
- DH: Data Hold Phase (optional - see **Page 26**)
- RP: Recovery Phase (optional - see **Page 27**)

Figure 733 above shows an example of an access to a non-multiplexed device and **Figure 734** an example of an access to a multiplexed device.

45.3.13.3 Example Waveforms

The following figures show example waveforms for asynchronous accesses

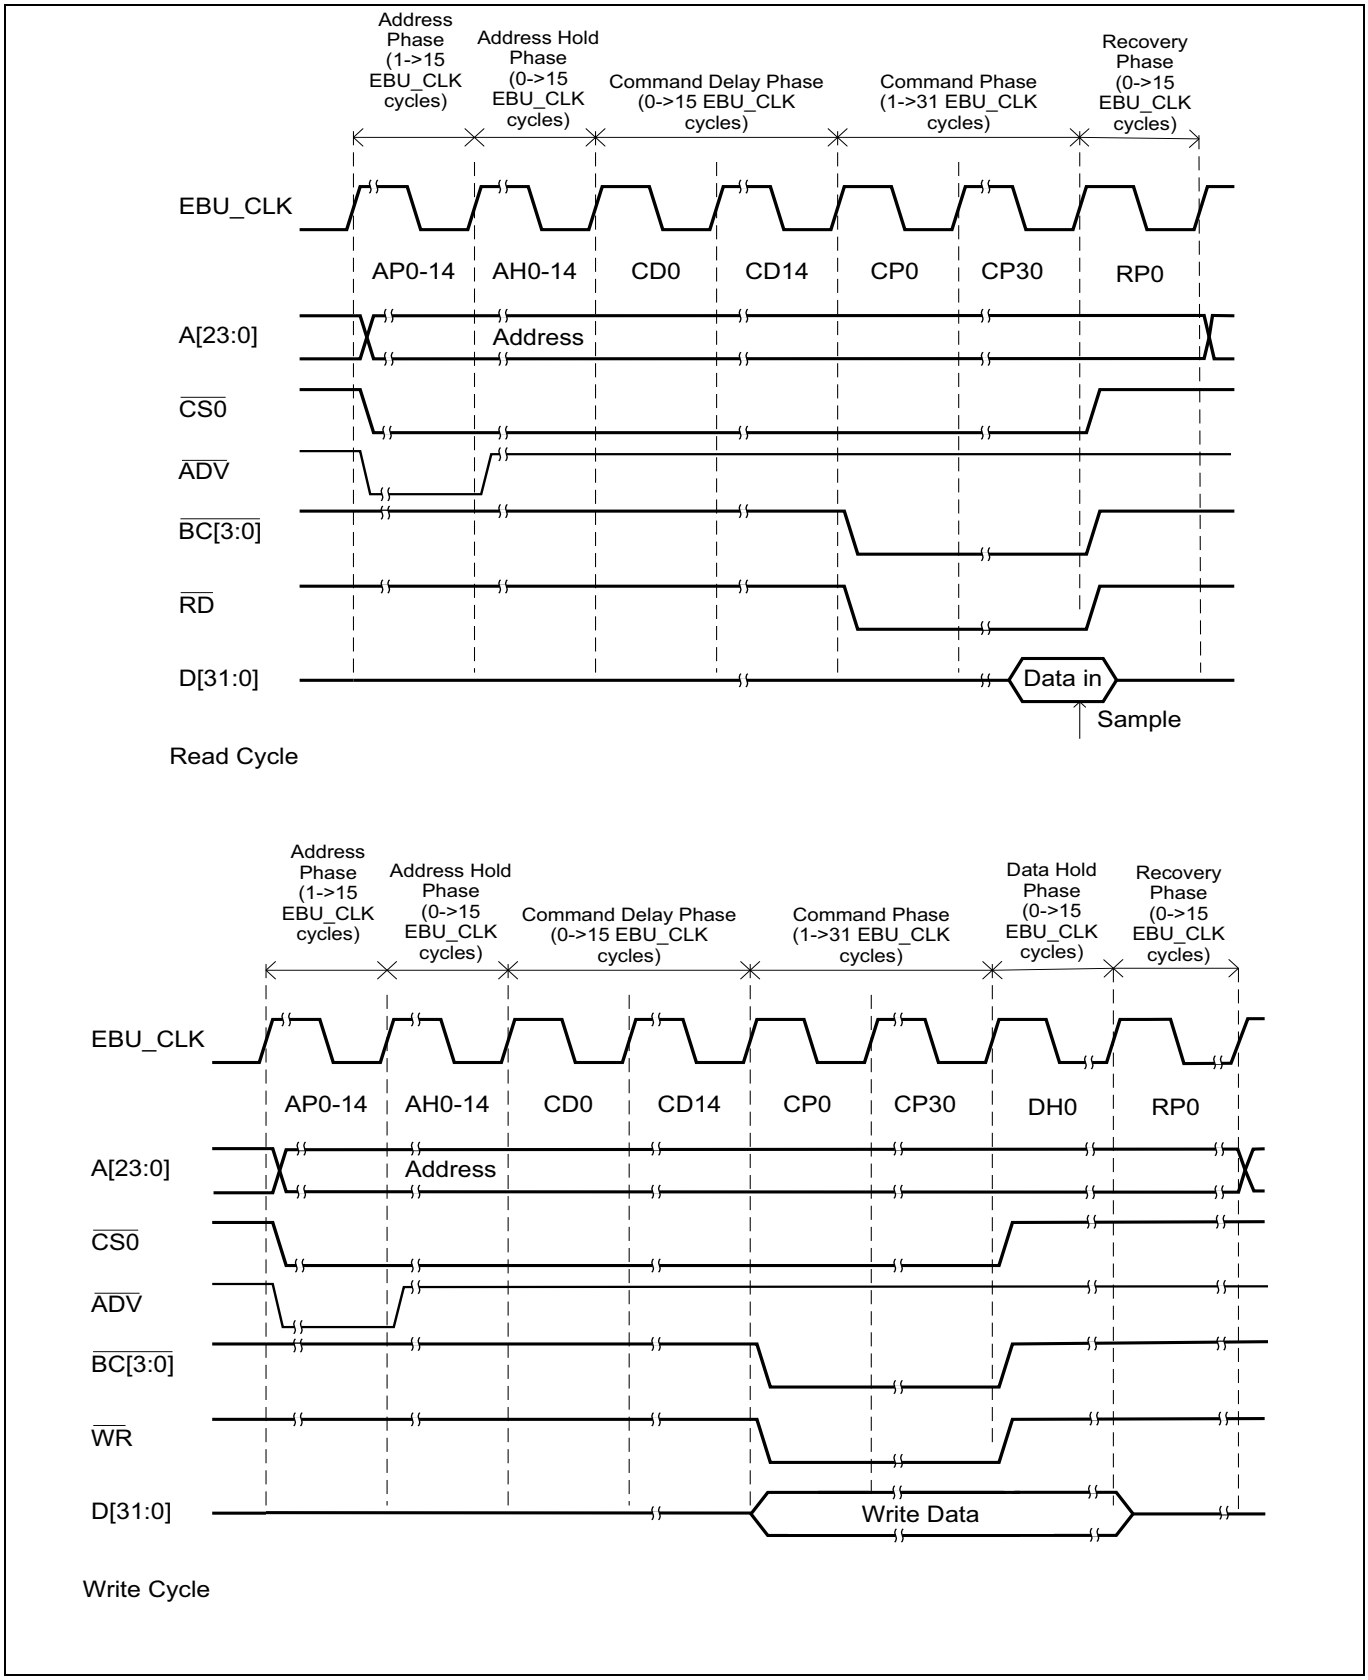

Figure 733 Asynchronous non-muxed Access

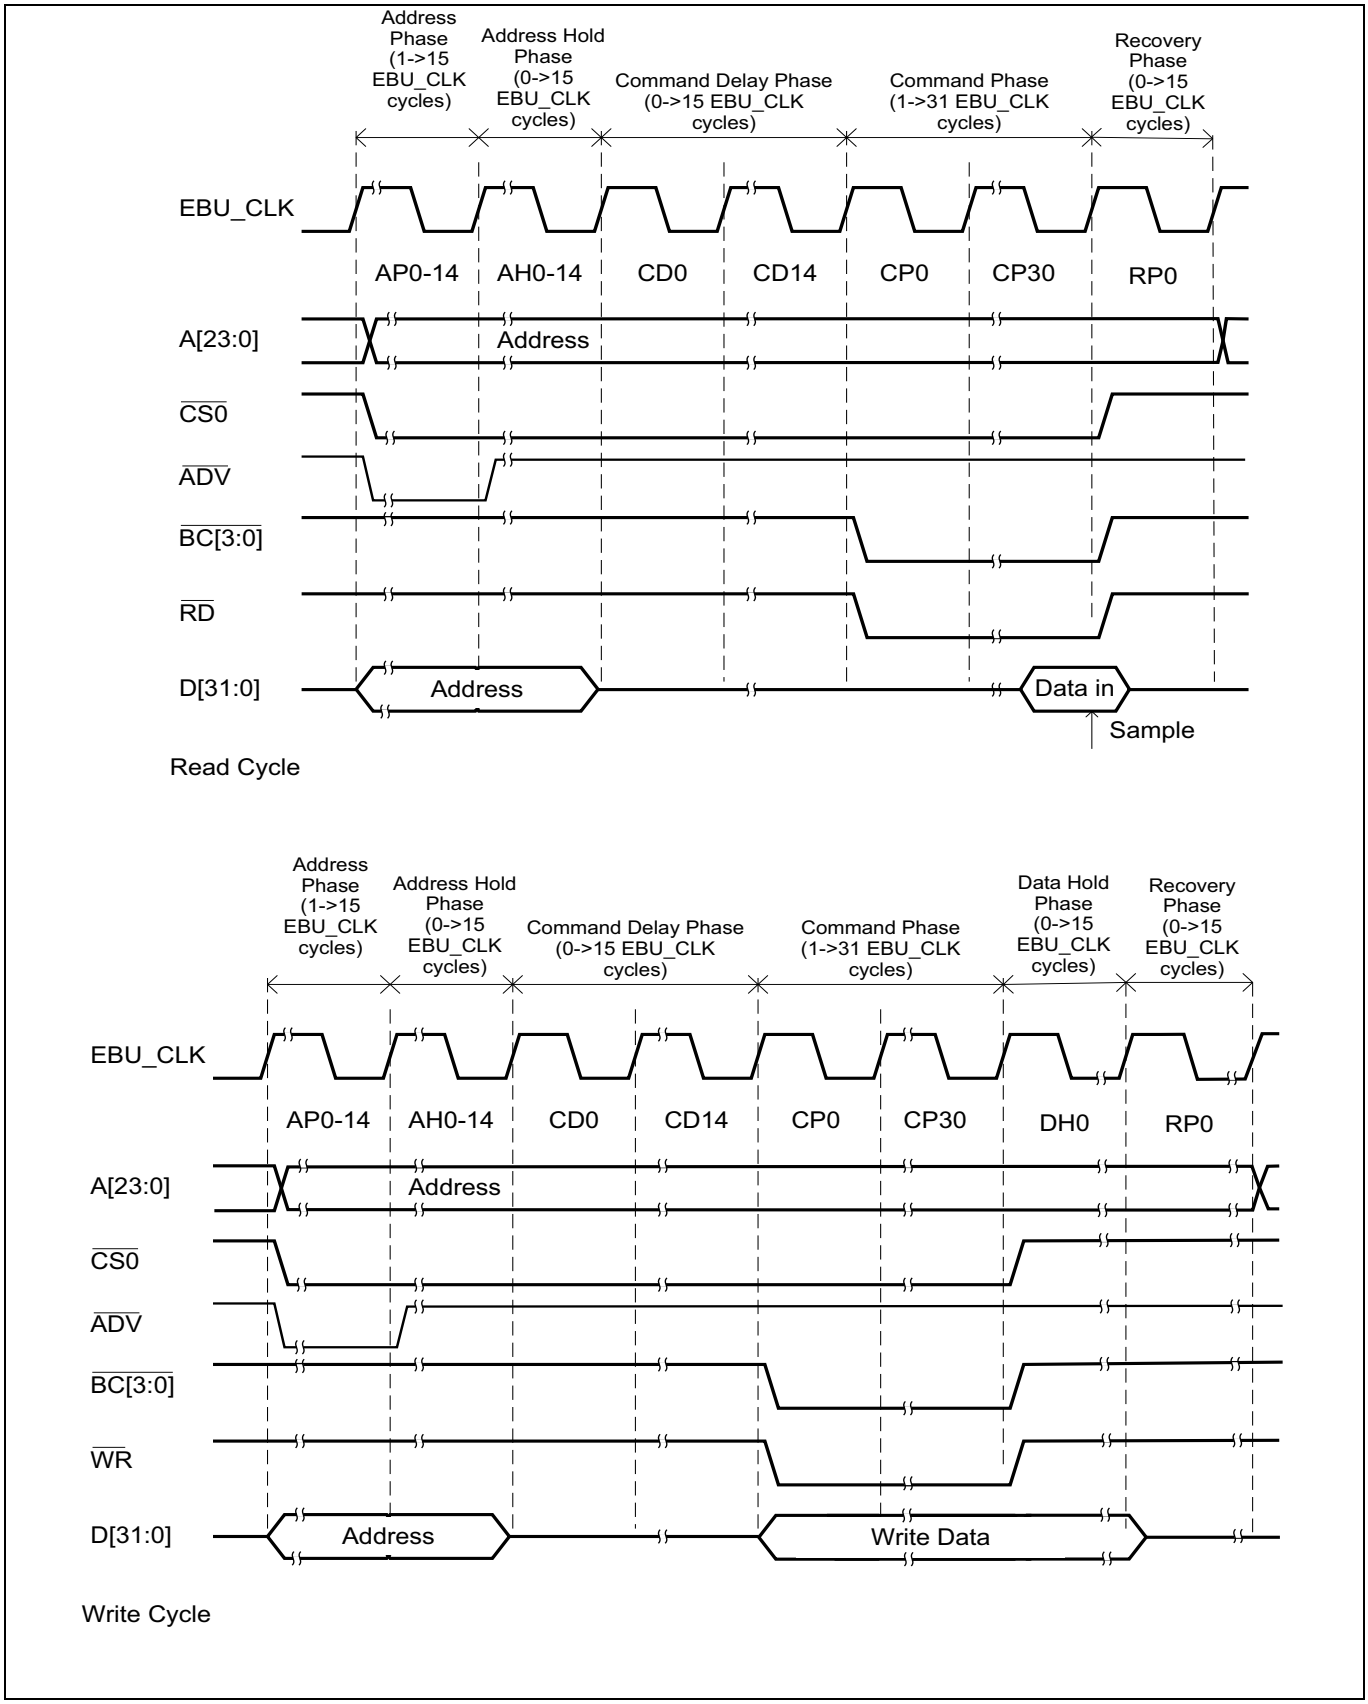

Figure 734 Asynchronous muxed Access

45.3.13.4 Control of $\overline{ADV}$ & Other Signal Delays During Asynchronous Accesses

For asynchronous accesses, the Memory Controller output signals: $\overline{ADV}$, $\overline{CS}$, $\overline{RD}$, RD/$\overline{WR}$, and $\overline{BC}$ signals can be delayed with respect to the start of the access phases they are asserted in. The amount by which the signal is delayed depends on the setting of the EBU_BUSRAPx.EXTCLOCK field of the region being addressed for read accesses and the EBU_BUSWAPx.EXTCLOCK field of the region being addressed for writes:-

- When EXTCLOCK is set to 00_B, control signals are asserted on the negative edge of . i.e. they are in effect delayed by an EBU_CLK high pulse width (T_{PH})with respect to the other signals.
- When EXTCLOCK is not set to 00_B, control signals are asserted on the next positive edge of . i.e. they are in effect delayed by an cycle (T_{CLK}) with respect to the other signals.

The Memory Controller allows these delays to be enabled and disabled independently via the register bits EBU_BUSCONx.EBSE for $\overline{ADV}$ and EBU_BUSCONCx.ECSE for the other control signals. The default setting after reset has the delay disabled.

Table 518 $\overline{ADV}$ Signal Timing

EXTCLOCK is set to	ADV Falling Edge Position		ADV Rising Edge Position	
	Delay Disabled[1]	Delay Enabled	Delay Disabled[1]	Delay Enabled
00_B	Start of AP1	Start of AP1 + T_{PH}	Start of AP1	Start of AP1 + T_{PH}
01_B, 10_B, 11_B	Start of AP1	End of AP1	Start of AP1	End of AP1

1) See **Figure 733** for details of this signal positioning.

Table 519 $\overline{RD}$ and RD/$\overline{WR}$ Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1]	Delay Enabled	Delay Disabled[1]	Delay Enabled
00_B	Start of CP1	Start of CP1 + T_{PH}	End of CPn[2]	End of CPn + T_{PH}
01_B, 10_B, 11_B	Start of CP1	End of CP1	End of CPn	End of CPn + T_{CLK}

1) See **Figure 733** for details of this signal positioning.

2) CPn indicates the final Command Phase.

Table 520 $\overline{CS}$ Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1]	Delay Enabled	Delay Disabled[1]	Delay Enabled
00_B	Start of AP1	Start of AP1 + T_{PH}	End of DHn[2]	End of DHn + T_{PH}
01_B, 10_B, 11_B	Start of AP1	End of AP1	End of DHn	End of DHn + T_{CLK}

1) See **Figure 733** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn, the final Command Phase, if the programmed Data Hold phase length is zero clocks.

The byte control signals, $\overline{BC}$x, can either use the timing in **Table 519** if EBU_BUSCONx.BCGEN is set to 01_B or 10_B or the timing in **Table 520** if EBU_BUSCONx.BCGEN is set to 00_B. A EBU_BUSCONx.BCGEN value of 11_B is not valid for asynchronous accesses.

Write data is handled differently to the other signals. Delays are never applied to the write data.

Note: If the control signals are delayed a recovery phase must be used to prevent conflicts between accesses as the rising edge of the control signals will be delayed past the end of the command phase. If a

multiplexed access is used without a recovery phase, the address for the next access will be delayed by one clock cycle to enforce a bus turnaround time on the data bus, resulting in the valid address being driven one clock after ADV is asserted.

45.3.13.5 Programmable Parameters

Table 521 lists the programmable parameters for asynchronous accesses.

Table 521 Asynchronous Access Programmable Parameters

Register	Parameter (Bit/Bit field)	Function
EBU_BUSAPx	ADDRC	Number of cycles in address phase
	CMDDELAY	Number of programmed command delay cycles[1].
	AHOLD	Number of Cycles in Address Hold Phase[1]
	WAITRDC	Number of programmed wait states for read accesses.
	WAITWRC	Number of programmed wait states for write accesses.
	DATAC	Number of Data Hold cycles.
EBU_BUSAPx	RDRECOVC	Number of minimum recovery cycles after a read access.
	WRRECOVC	Number of minimum recovery cycles after a write access.
	DTARDWR	Number of minimum recovery cycles between a read access and a write access.
	DTACS	Number of minimum recovery cycles when the next access going to a different memory region.
EBU_BUSCONx	WAIT	External Wait State control (OFF, asynchronous, synchronous)
	WAITINV	Reversed polarity at WAIT: active low or active high

1) This phase can be programmed for devices without multiplexed address and data busses but serves no purpose other than extending the access

45.3.13.6 Asynchronous Access Control

In general, there are only two critical phase during accesses to asynchronous devices with separate address and data buses. These phases are:

- **Command Phase** (see Page 26) which is used to control the widths of the Output Enable and Write Enable pulses. The length of the Command Phase is set by the bit fields EBU_BUSRAPx.WAITRDC and EBU_BUSWAPx.WAITWRC.
- **Data Hold Phase** (see Page 26) which is used to ensure that the write data is stable long enough to allow it to be successfully latched into the device. The length of the Command Phase is set by the bit field EBU_BUSWAPx.DATAC

As the “address to data valid” and the “chip select to data” valid parameters of asynchronous devices are usually greater than “output enable to data valid” parameter, the lengths of the “Address”, “Address Hold” and “Command Delay” phases can be used to extend the time between the start of the access when the address and chip select are driven and the end of the Command Phase when the read or write event occurs.

For devices with a multiplexed address and data buses two additional phases control the latching of the address into the device and also critical:

- **Address Phase** (see Page 24) which is used to control the width of the ADV pulse. The length of the Address Phase is available via bit fields EBU_BUSAPx.**ADDRC**

- **Address Hold Phase** (see **Page 25**) which is used to ensure that the address is stable long enough to allow it to be successfully latched into the device. The length of the Address Phase is available via bit fields EBU_BUSAPx.**AHOLDC**

45.3.13.6.1 External Extension of the Command Phase by WAIT

The $\overline{\text{WAIT}}$ input can be used to cause the EBU to extend the Command Phase by inserting additional cycles prior to deactivation of the $\overline{\text{RD}}$ and RD/$\overline{\text{WR}}$ lines. This signal can be programmed separately for each region to be ignored or sampled either synchronously or asynchronously (selected via the EBU_BUSCONx.WAIT bit field). Additionally, the polarity of $\overline{\text{WAIT}}$ can be programmed for active low (default after reset) or active high function via bit EBU_BUSCONx.WAITINV. The signal will only take effect after the programmed number of Command Phase cycles has passed. This means that the signal can only be used to extend the phase, not to shorten it.

Table 522 Operation of WAIT input

Value of BUSCONx.WAIT	Mode of the $\overline{\text{WAIT}}$ input
0_D	OFF (default after reset).
1_D	Asynchronous input at WAIT.
2_D	Synchronous input at WAIT.
3_D	reserved

When programmed for synchronous operation, $\overline{\text{WAIT}}$ is sampled on every rising edge of EBU_CLK during the Command Phase. The sampled value is then used on the next rising edge of EBU_CLK to decide whether to prolong the Command Phase or to start the next phase. **Figure 735** shows an example of $\overline{\text{WAIT}}$ used in Synchronous Mode.

Note: Due to the one-cycle delay in Synchronous Mode between the sampling of the $\overline{\text{WAIT}}$ input and its evaluation by the EBU, the Command Phase must always be programmed to be at least one EBU_CLK cycle (via EBU_BUSAPx.WAITRDC or EBU_BUSAPx.WAITWRC) in this mode.

When programmed for asynchronous operation, $\overline{\text{WAIT}}$ is also sampled at each rising edge of EBU_CLK during the Command Phase. However, an extra synchronization cycle is inserted prior to the use of the sampled value. This means that the sampled value is not used until the second following rising edge of EBU_CLK. **Figure 736** shows an example of $\overline{\text{WAIT}}$ used in Asynchronous Mode.

Note: Due to the two-cycle delay in Asynchronous Mode between the sampling of the $\overline{\text{WAIT}}$ input and its evaluation by the EBU, the Command Phase must always be programmed to be at least two EBU_CLK cycles (via EBU_BUSAPx.WAITRDC or EBU_BUSAP.WAITWRC) in this mode.

Figure 735 shows an example of the extension of the Command Phase through the $\overline{\text{WAIT}}$ input in synchronous mode:

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the $\overline{\text{WAIT}}$ input as low and starts the first cycle of the Command Phase (CPi1 - internally programmed).
- At EBU_CLK edge 2, the EBU samples the $\overline{\text{WAIT}}$ input as low and starts an additional Command Phase cycle (CPe2 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 3, the EBU samples the $\overline{\text{WAIT}}$ input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 4, as a result of the $\overline{\text{WAIT}}$ input sampled as high at point 3, the EBU terminates the Command Phase, reads the input data from D[31:0] and starts the Recovery Phase.

Note: Synchronous operation means that even though access to the device may be asynchronous, the control logic generating the control signals must meet setup and hold time requirements with respect to EBU_CLK.

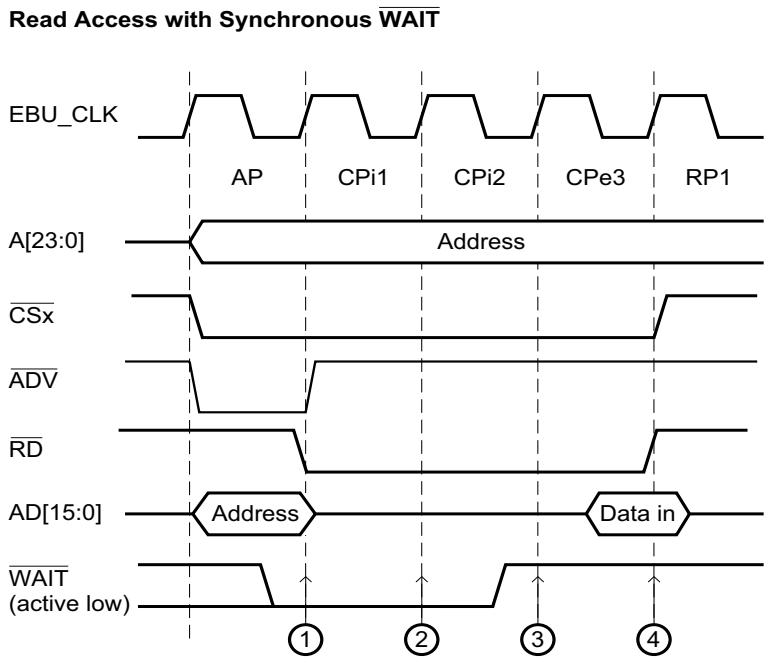

Figure 735 External Wait Insertion (Synchronous Mode)

Figure 736 shows an example of the extension of the Command Phase through the WAIT input in asynchronous mode:

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the WAIT input as low and starts the first cycle of the Command Phase (CPi1 - internally programmed).
- At EBU_CLK edge 2, the EBU samples the WAIT input as low and starts the second cycle of the Command Phase (CPi2 - internally programmed).
- At EBU_CLK edge 3, the EBU samples the WAIT input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the WAIT input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 4, the EBU starts an additional Command Phase cycle (CPe4 - externally generated) as a result of the WAIT input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 5, as a result of the WAIT input sampled as high at EBU_CLK edge 3, the EBU terminates the Command Phase, reads the input data from AD[15:0],and starts the Recovery Phase.

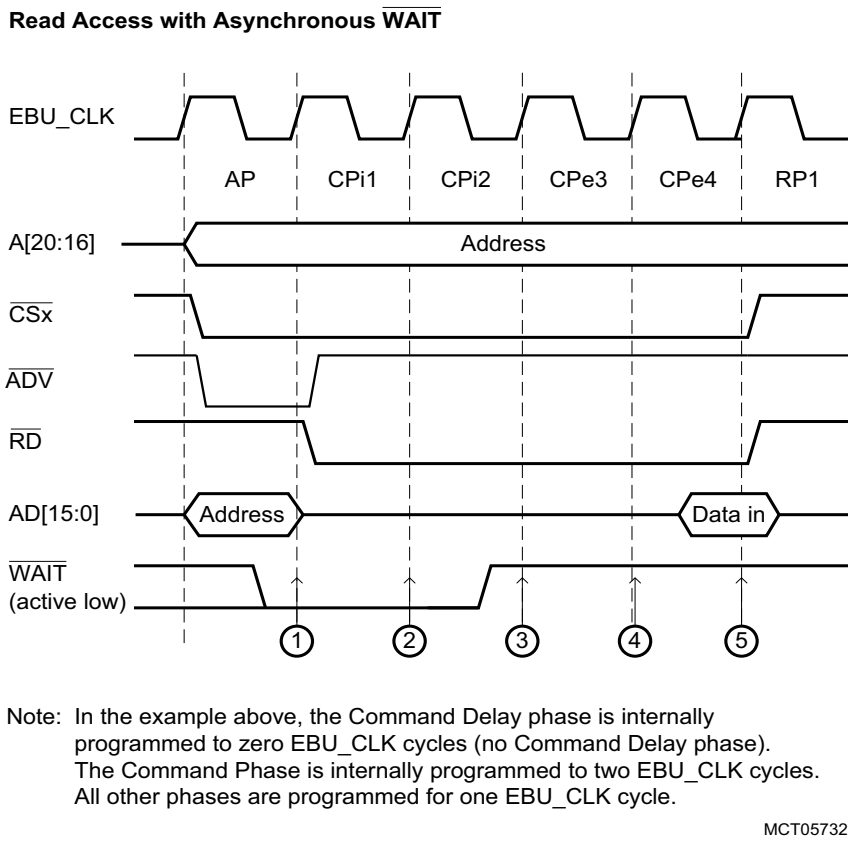

Figure 736 External Wait Insertion (Asynchronous Mode)

45.3.13.7 Interfacing to Asynchronous Nand Flash Devices

The memory controller provides support for specific Nand Flash devices. The required access sequences (read or write) are generated by connecting the Nand Flash device as an Asynchronous Device and using appropriate processor generated access sequences to emulate the NAND flash commands. **Figure 737** Shows an example of Memory Controller connected to a Nand Flash device:-

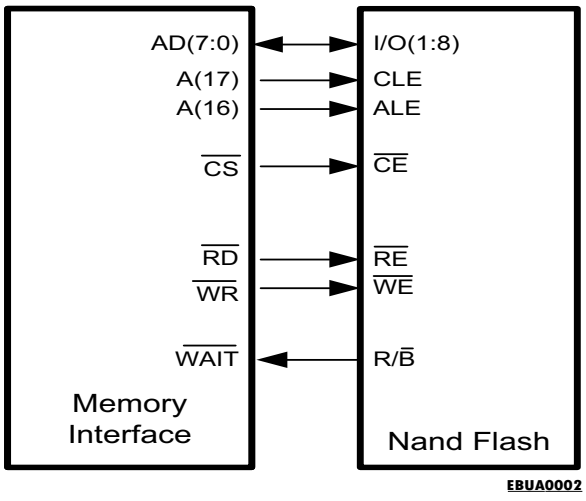

Figure 737 Example of interfacing a Nand Flash device to the Memory Controller

The R/$\overline{B}$ input from the NAND flash is connected to the memory controller $\overline{WAIT}$ input and is available as the EBU_MODCON.STS. This enables a NAND flash to be driven by software from the processor.

In the instance shown above two address lines are connected to the Nand Flash, and rather than being connected to address inputs, they are connected to control inputs. This allows access to three “registers” in the Nand Flash as follows:-

Table 523 Nand Flash “Registers” (8 bit device)

SRI Address	“Register”	Comment
Base + 00000_H	Data Register	Read/Write: Used to read data from and write data to the device.
Base + 10000_H	Address Register	Write only: Used to write the required access address to the device.
Base + 20000_H	Command Register	Write only: Used to write the required command to the device.

Note: SRI addresses are byte addresses and addresses on the external bus are word addresses. The SRI address of the virtual register will depend on the port width. of the addressed memory region. See ***“SRI Bus Width Translation” on Page 20***

45.3.13.7.1 NAND flash page mode

NAND flash memories are page oriented devices capable of extended read operations with a single setup phase for command signals at the beginning of the access. The asynchronous controller of the Memory Controller will split a large transfer into multiple accesses to external memory but each of these accesses will have the overhead of the initial setup phase. Enabling page mode, by setting the agen field in EBU_BUSCONx to 2_D, will cause the standard flow of the controller to be modified as follows:

- For a read, if data remains to be fetched at the end of a command phase, the controller will start a new command delay phase, instead of a new address phase or recovery phase and the address will not be incremented. If EBU_BUSRAPx.cmddelay is set to zero, the command delay phase will have a duration of one clock cycle but in this case the command delay phase is mandatory to ensure that the $\overline{RD}$ and RD/$\overline{WR}$ signals return to the high state.
- For a write, if data remains to be written at the end of a data hold phase (or command phase if the length of data hold is zero), the controller will start a new command phase, instead of a new address phase or recovery phase and the address will not be incremented. If EBU_BUSWAPx.datac is set to zero, the data hold phase will have a duration of one clock cycle as in this case the data hold phase is mandatory to ensure that the $\overline{RD}$ and RD/$\overline{WR}$ signals return to the high state. The command phase will be forced to have a minimum length of two clocks.

Enabling NAND flash page mode will also reconfigure the EBU signals used for ALE and CLE. While A(17:16) can still be used directly, the same values will also be output on $\overline{ADV}$ and $\overline{BAA}$.

- $\overline{ADV}$ will be used as ALE and will output the value of A(16).
- $\overline{BAA}$ will be used as CRE and will output the value of A(17).

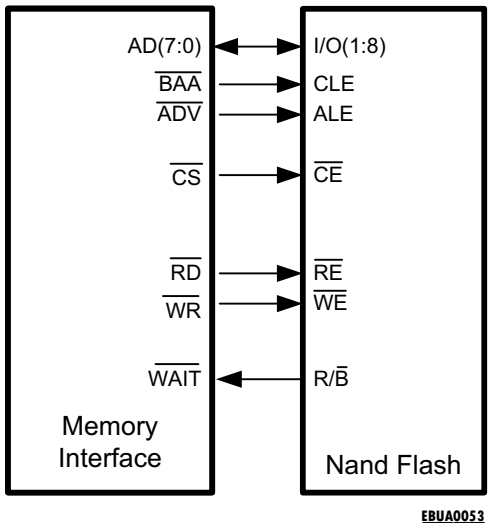

Figure 738 NAND Flash Connection for AGEN=3_D

To allow accesses to run consecutively without violating $\overline{\text{ADV}}$ and $\overline{\text{BAA}}$ timing restrictions, both signals will be set inactive (1_B) at the beginning of the recovery phase of the access.

See **Figure 739** for example waveforms.

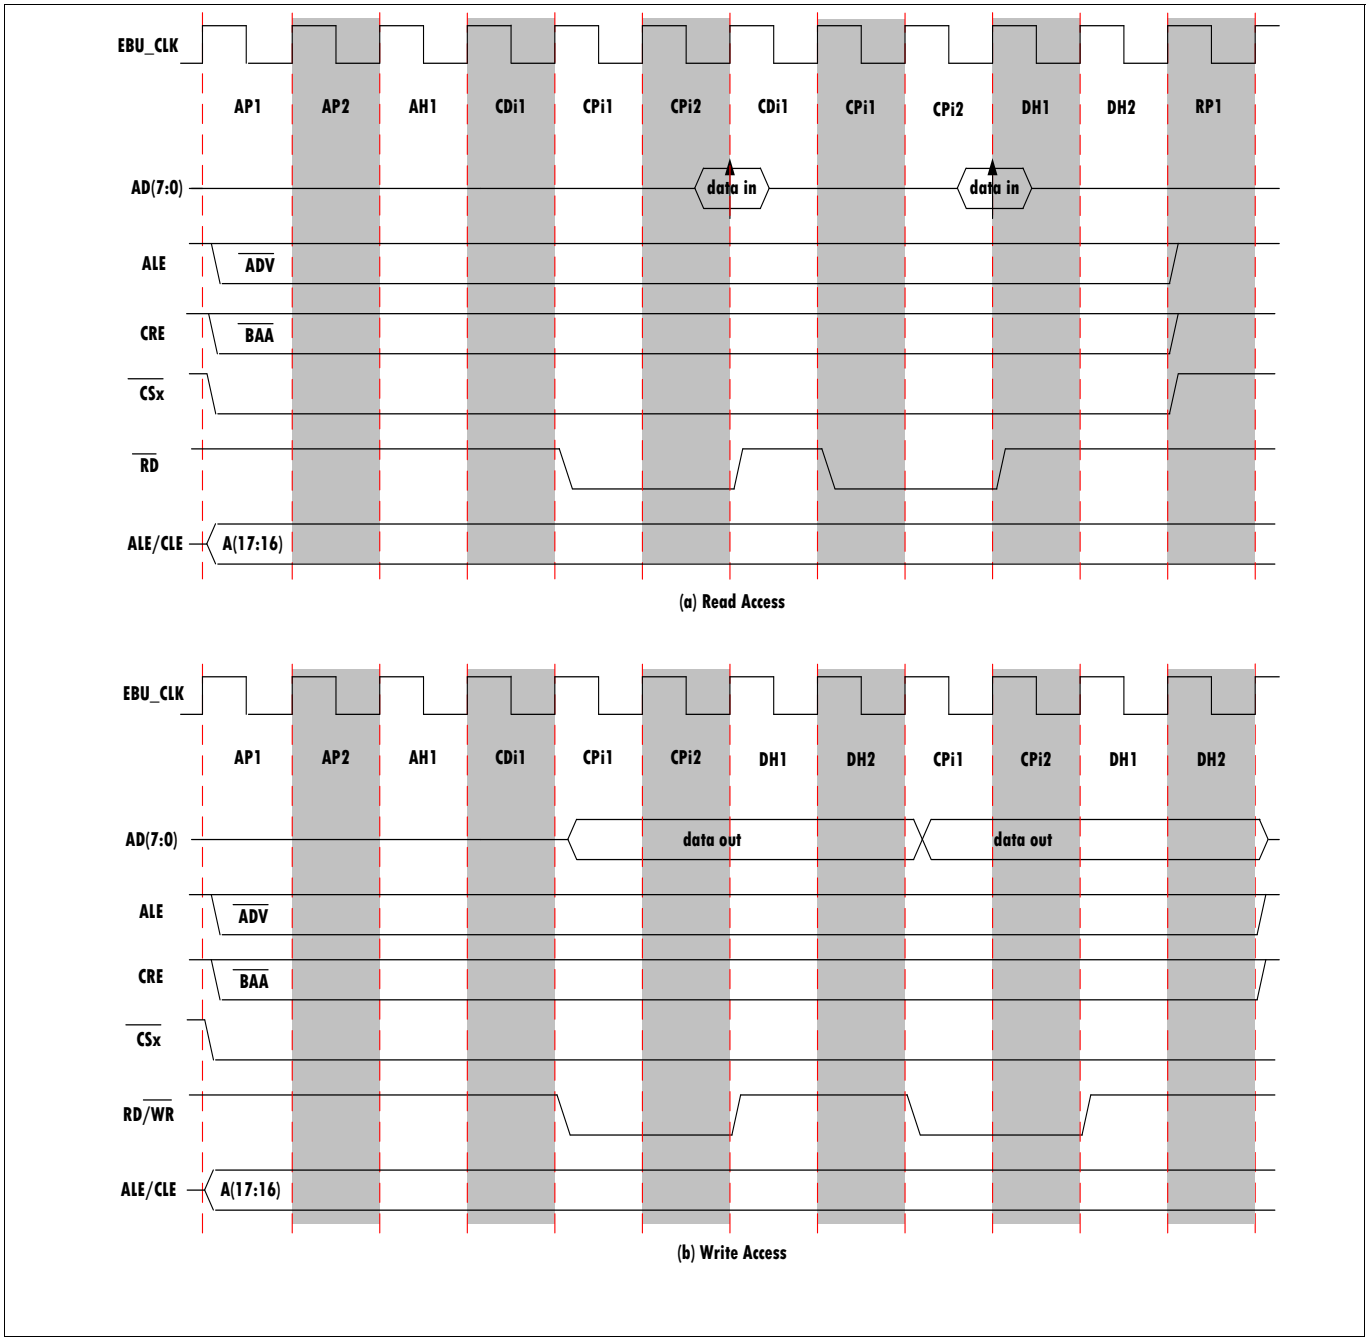

Figure 739 NAND Flash Page Mode Accesses

Example Nand Flash Read Sequence

Figure 740 shows an example of how the processor can generate a Nand Flash read access sequence given this configuration:-

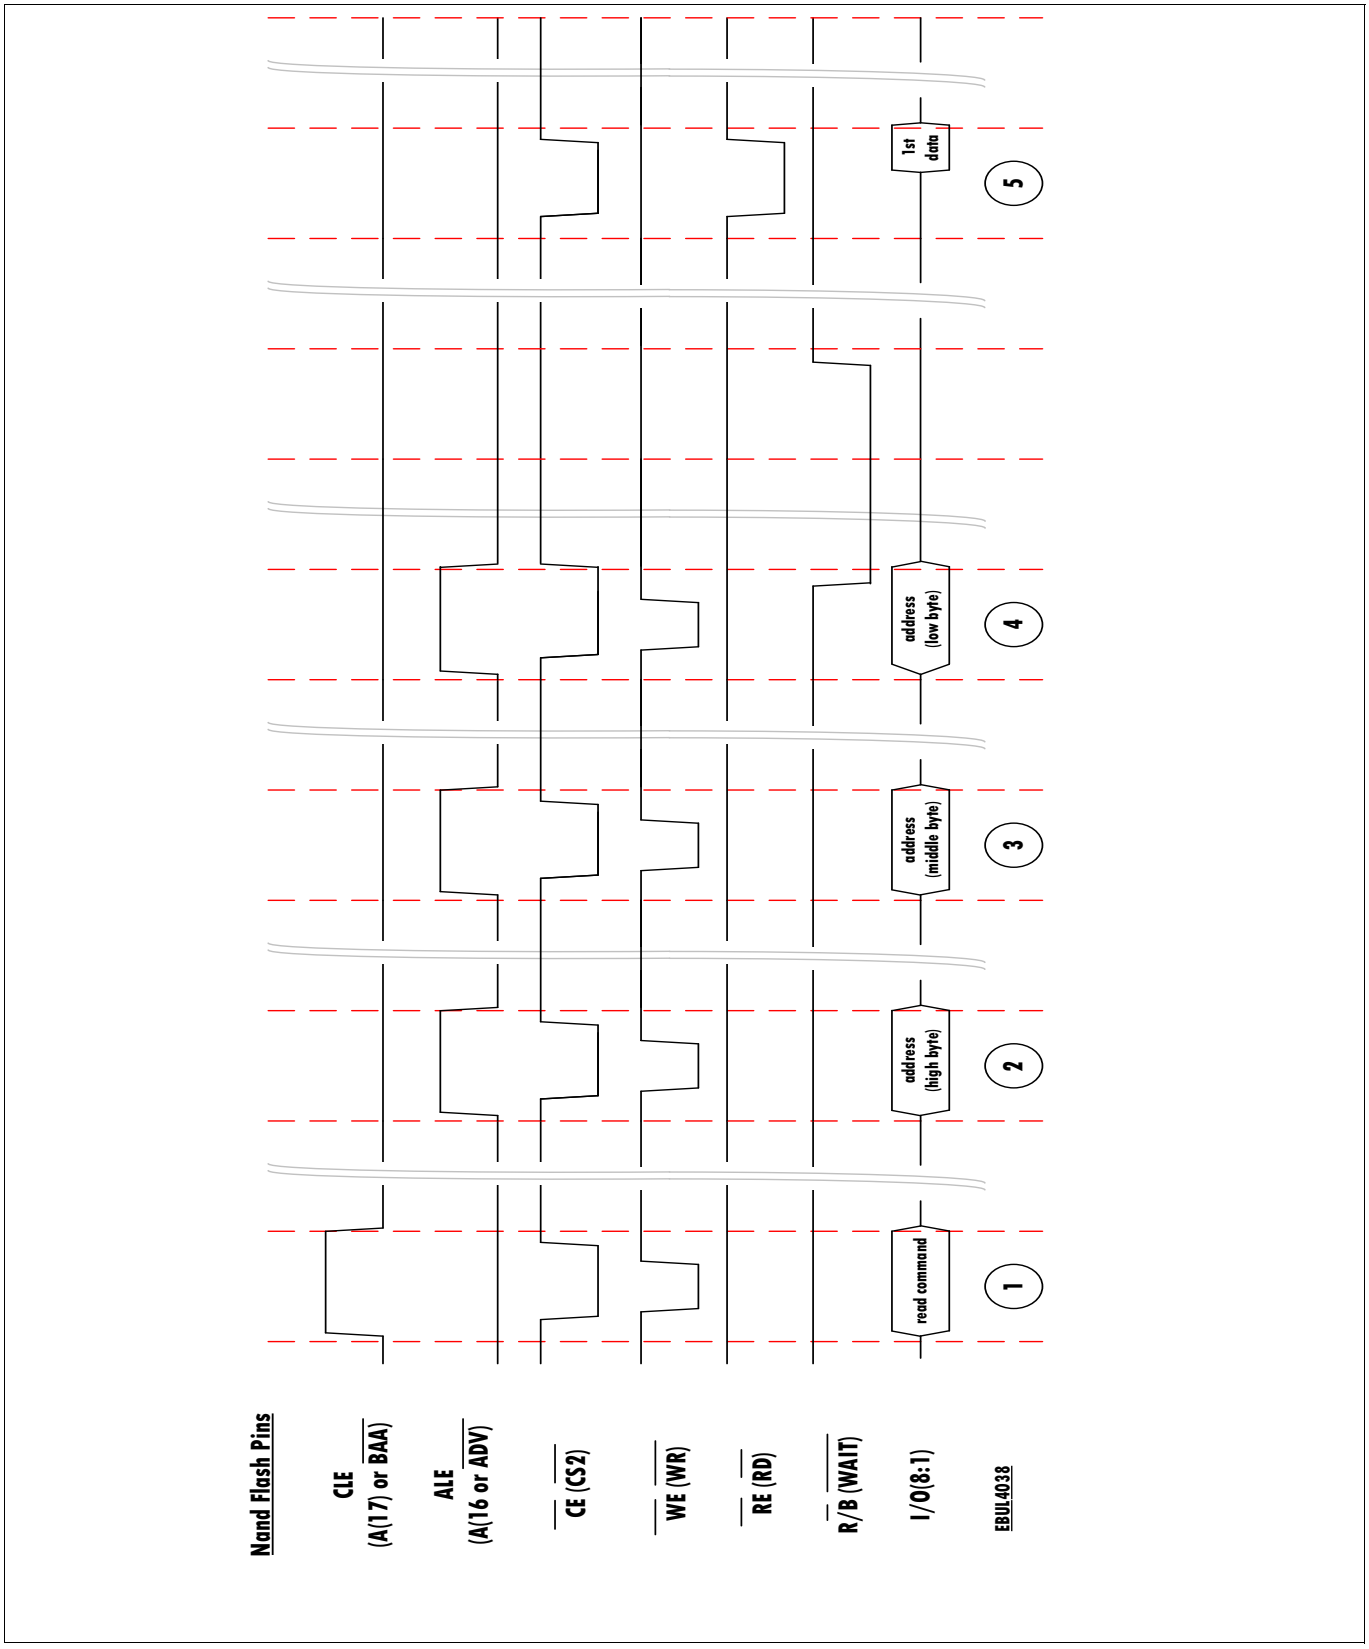

Figure 740 Example of an Memory Controller Nand Flash access sequence (read)

1. In the cycle marked ‘1’ in **Figure 740** the processor initiates a read sequence by writing the “Read Command” value to address “NAND_FLASH_BASE + 0x20000”. This generates a write sequence with CLE (A(17)) driven high and ALE (A(16)) driven low.
2. In the cycle marked ‘2’ the processor loads the most significant byte of the read address by writing to address “NAND_FLASH_BASE + 0x10000”. This generates a write sequence with CLE (A(17)) driven low and ALE (A(16)) driven high.
3. In the cycle marked ‘3’ the processor loads the middle significant byte of the read address by repeating the access specified in ‘2’ above.
4. In the cycle marked ‘4’ the processor loads the least significant byte of the read address by repeating the access specified in ‘2’ above. The Nand Flash responds to this final address byte by driving it’s R/$\overline{B}$ output low. The processor monitors this pin (using the EBU_MODCON.sts bit) until the Nand Flash has completed it’s internal data fetch.
5. In the cycle marked ‘5’ the processor reads the first byte of data by reading address “NAND_FLASH_BASE + 0x00000”. The processor can subsequently read any additionally required (sequential) data bytes by repeating cycle ‘5’.

Note: A similar scheme can be used to generate write access sequences.

45.3.14 Synchronous Read/Write Accesses

The Memory Controller is designed to generate waveforms compatible with the burst modes of:

1. INTEL and compatible burst flash devices
2. SPANSION and compatible burst flash devices
3. INFINEON and MICRON cellular RAM
4. Fujitsu and Compatible FCRAM/uTRAM/CosmoRAM
5. Samsung OneNAND burst capable NAND flash and compatible devices
6. M-Systems DiskOnchipG3 and compatible devices
7. GSI/ISSI/IDT SSRAM

Note: Not all of the supported synchronous memory types are known to be available in automotive grade or with I/O voltages compatible with the TC29x I/O pads.

Features

The Synchronous Access Controller is primarily designed to perform burst mode read and write cycles for an external instruction memories, external Cellular RAM and FCRAM data memories. In general, the features are:-

- Fully synchronous timing with flexible programmable timing parameters (address cycles, read wait cycles, data cycles).
- Programmable $\overline{WAIT}$ function.
- Programmable burst (mode and length)
- 8-bit device width.
- 16-bit device width.
- 32-bit device width
- Page mode read accesses.
- Resynchronisation of read data to a feedback clock to maximise the frequency of operation (optional).

45.3.14.1 Signals

The following signals are used for the Burst FLASH interface:-

Table 524 Burst Flash Signal List

Signal	Type	Function
	I/O	Multiplexed Address/Data bus
$\overline{RD}$	O	Read control
$\overline{WR}$	O	Write control
A(:0)	O	Address bus
$\overline{ADV}$	O	Address valid strobe
$\overline{WAIT}$	I	Wait/terminate burst control
$\overline{CS}$	O	Chip select
BFCLKO	O	Burst FLASH Clock, running equal to, 1/2, 1/3 or 1/4 of the frequency of the EBU core logic.
BFCLKI	I	Burst FLASH Clock Feedback.
$\overline{BAA}$	O	Advance Burst Address
STS	I	Burst FLASH Status Input (Optional, value of $\overline{WAIT}$ pin available through status register)

45.3.14.2 Support for Burst FLASH device types

Support is provided for a maximum of different Burst FLASH configurations on the external bus - i.e. one on each external chip select.

Bit-fields EBU_BUSCONx.EBSE, EBU_BUSCONx.ECSE, EBU_BUSCONx.wait, EBU_BUSCONx.FBBMSEL, EBU_BUSCONx.BFCMSEL and EBU_BUSCONx.FETBLEN are used to configure specific characteristics for burst access cycles.

45.3.14.3 Typical Burst Flash Connection

The figure below shows a typical burst flash connection.

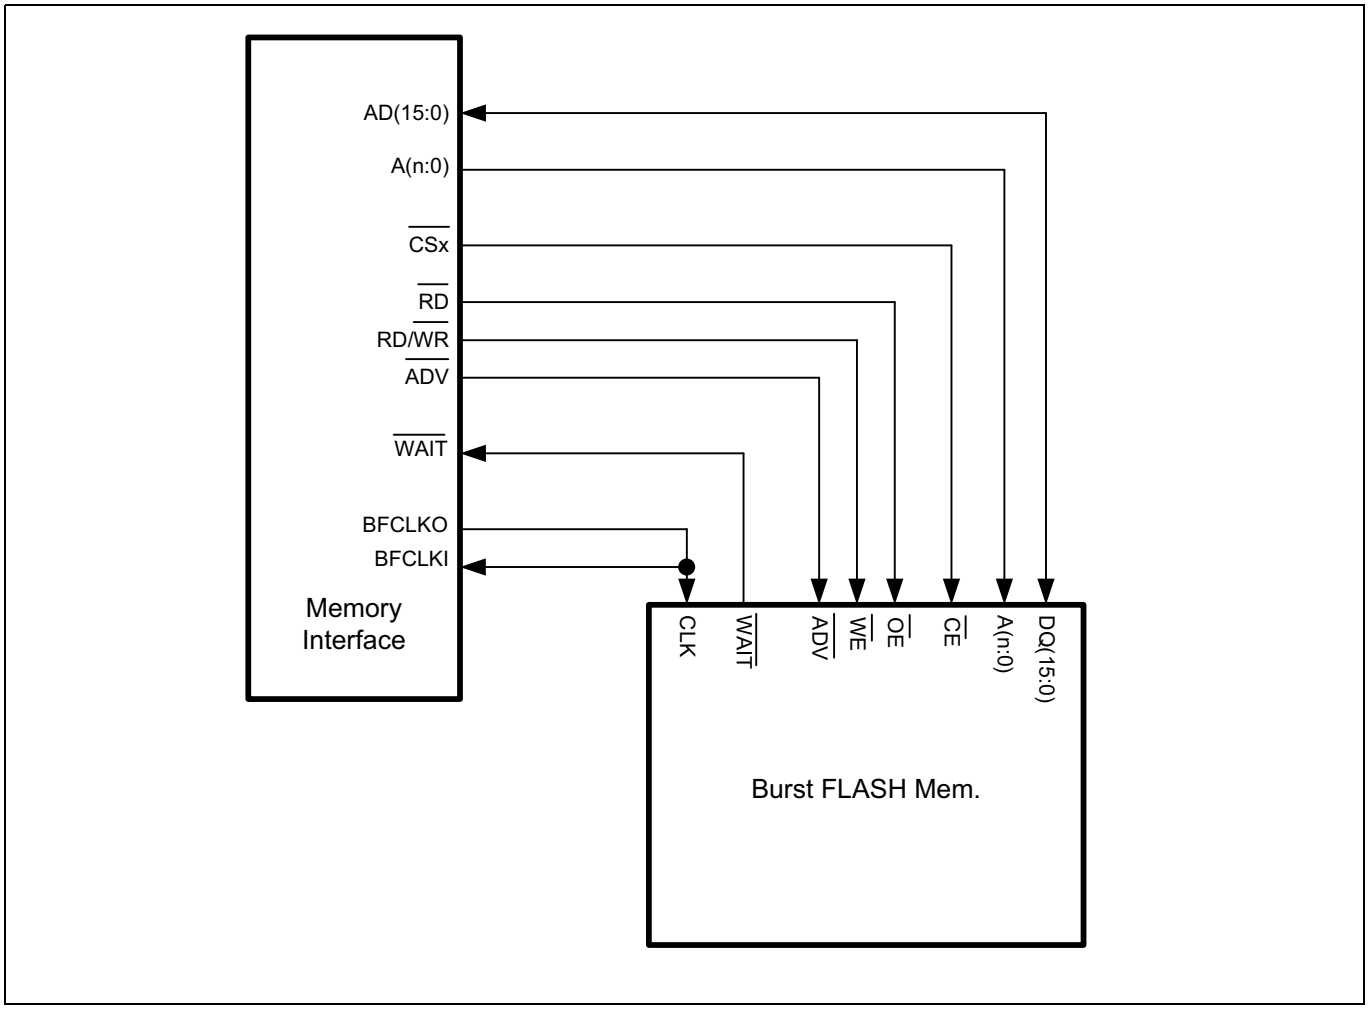

Figure 741 Typical Burst Flash Connection

45.3.14.4 Standard Access Phases

Accesses to burst FLASH devices are composed of a number of “Standard Access Phases” (which are detailed in **Section 45.3.12**). The Standard Access Phases for Burst FLASH devices are:-

- AP: Address Phase (compulsory - see **“Address Phase (AP)” on Page 24**).
- AH: Address Hold Phase (optional see **“Address Hold Phase (AH)” on Page 25**).
- CD: Command Delay Phase (optional - see **“Command Delay Phase (CD)” on Page 25**).
- CP: Command Phase (optional - see **“Command Phase (CP)” on Page 26**).
- BP: Burst Phase (compulsory - see **“Burst Phase (BP)” on Page 26**).
- RP: Recovery Phase (optional - see **“Recovery Phase (RP)” on Page 27**).

Note: During a burst access the Burst Phase (BP) is repeated the required number of times to complete the burst length.

See **Figure 742** for an example synchronous access to a non-multiplexed device and **Figure 743** for an example synchronous access to a multiplexed device.

45.3.14.5 Example Waveforms

The following figures show example waveforms for synchronous accesses

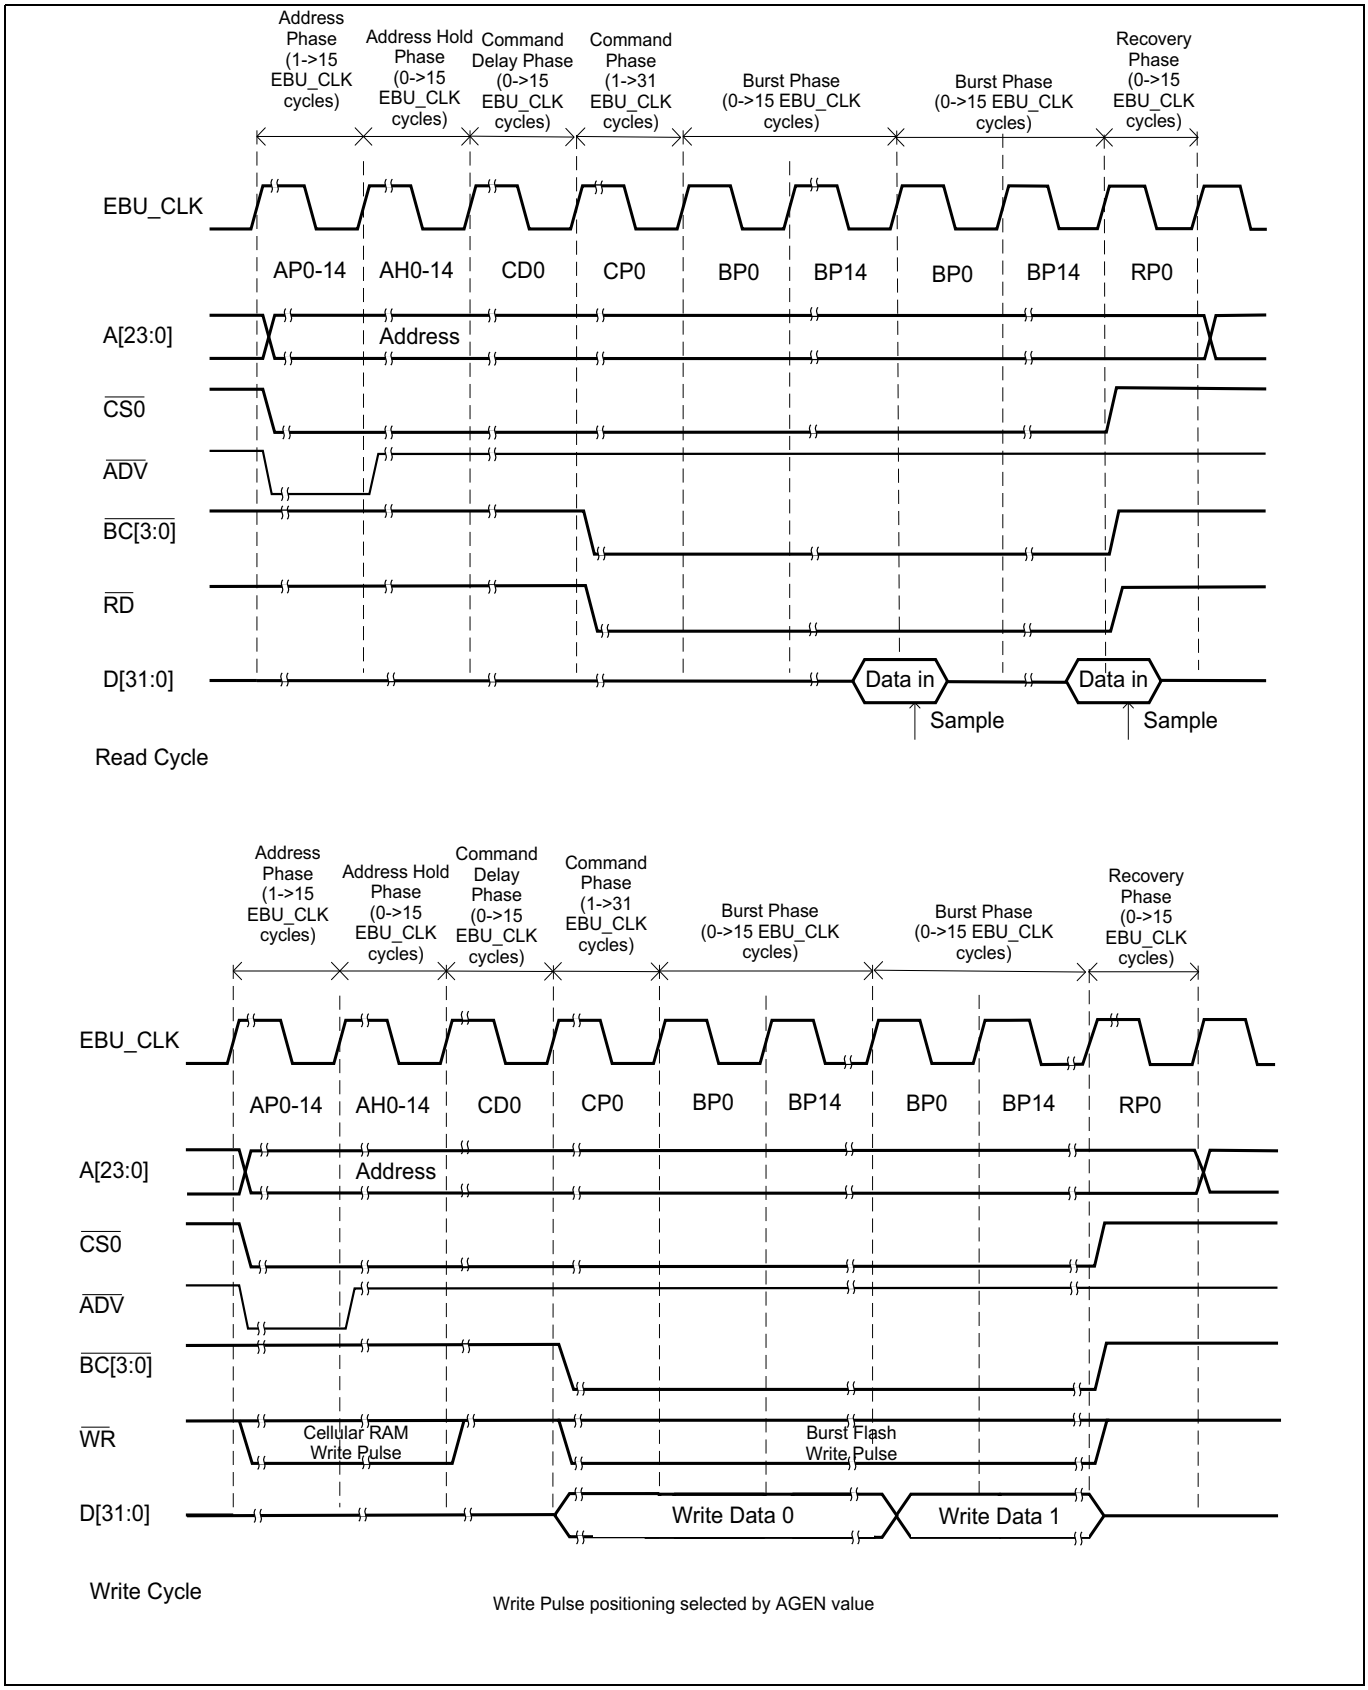

Figure 742 Synchronous non-muxed Access

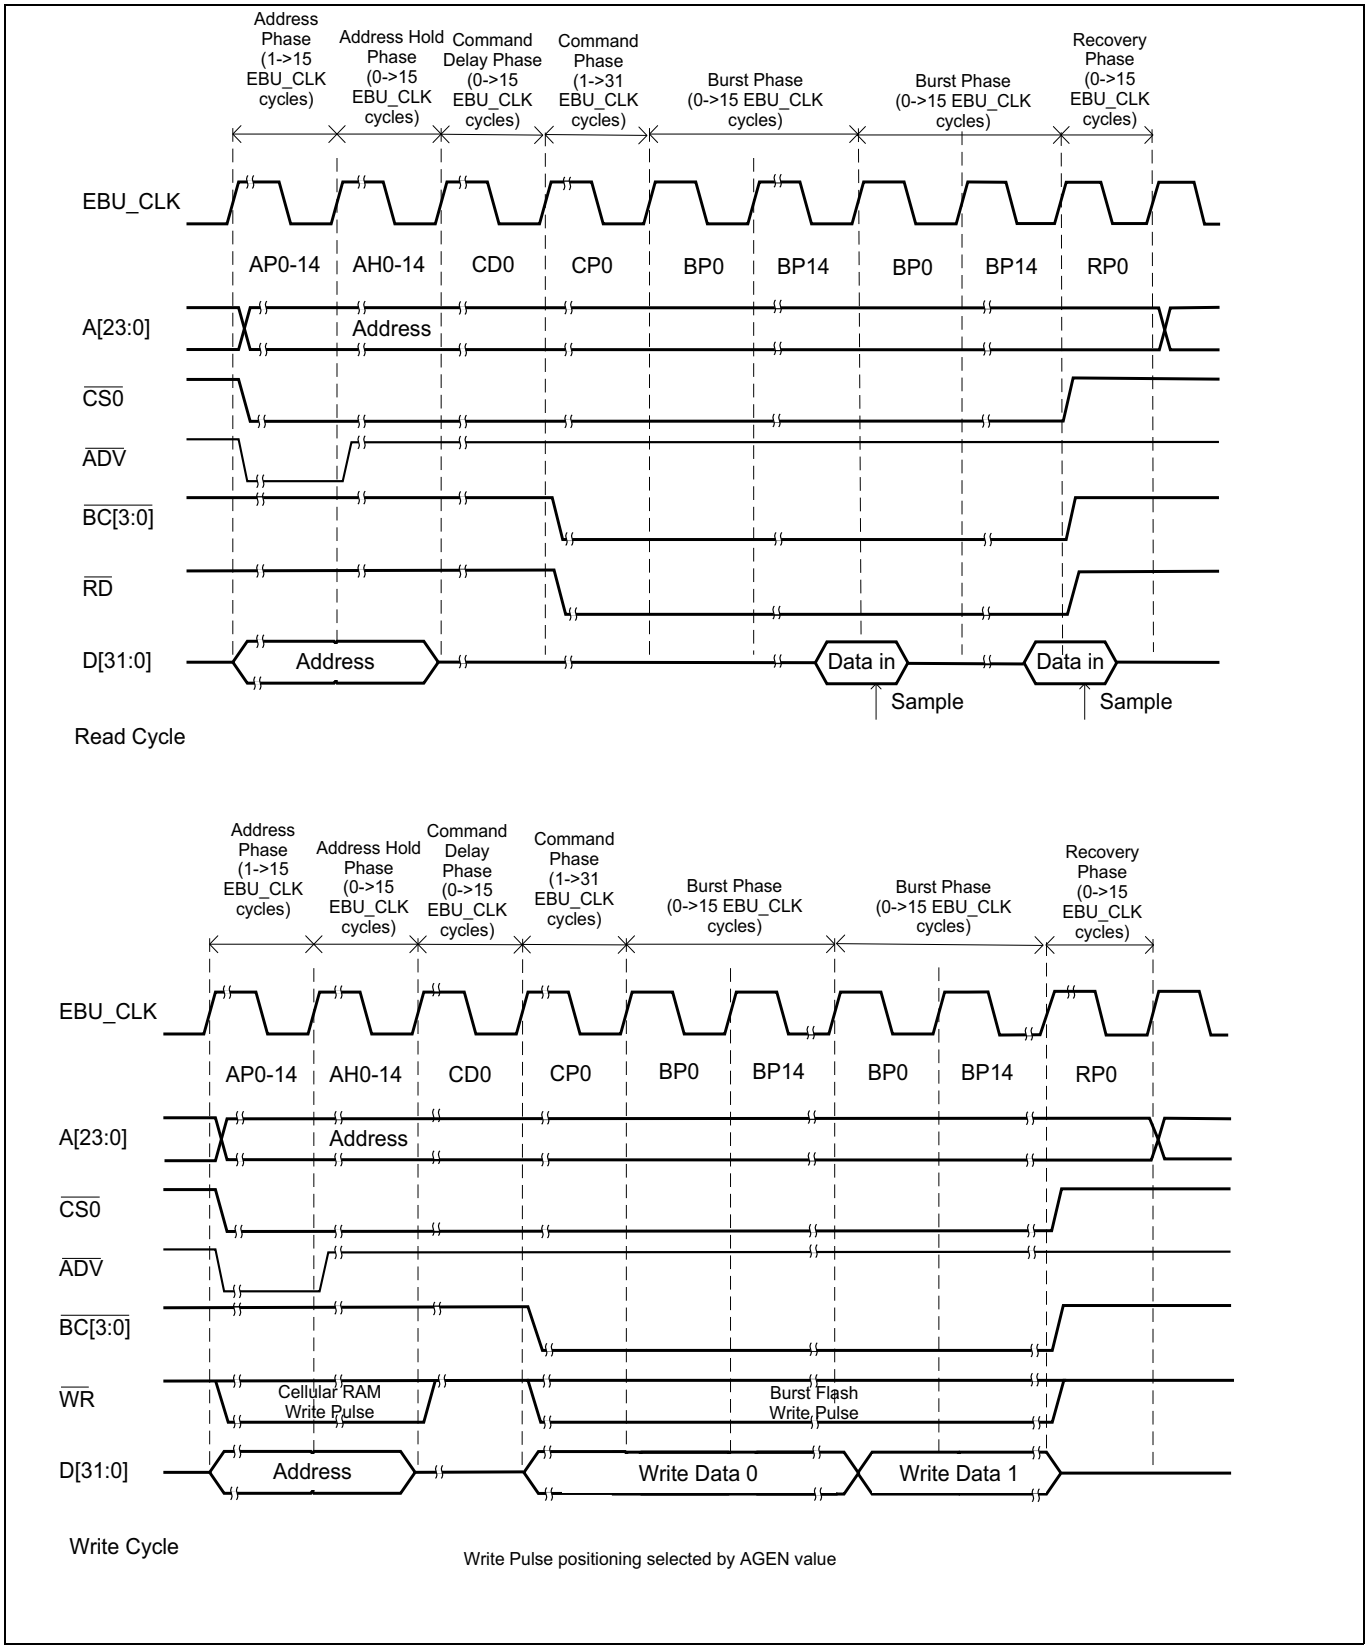

Figure 743 Synchronous muxed Access

45.3.14.6 Burst Length Control

The maximum number of valid data samples that can be generated by a flash device in a single read access is set by the EBU_BUSCONx.FBBMSEL bit and the EBU_BUSCONx.FETBLEN bit field.

The EBU_BUSCONx.FBBMSEL bit is used to select Continuous Burst Mode where there is no limit to the number of data samples in a burst read access.

The EBU_BUSCONx.FBBMSEL and EBU_BUSCONx.FETBLEN bit-fields are used to select the maximum number of data samples in a single access. Where an SRI request exceeds the amount of data that can be fetched or stored by the programmed number of data samples, the EBU will automatically generate the appropriate number of burst accesses to transfer the required amount of data.

Note: Selection of Continuous Burst Mode (by use of the 'FBBMSEL' bit) overrides the maximum burst setting (specified by the FETBLEN bit-field).

45.3.14.7 Burst Flash Clock

Since the can run too fast for clocking Burst FLASH devices, the Memory Controller provides an additional clock source (BFCLKO). This signal is generated by a programmable clock divider driven by and allows to BFCLKO ratios of 1:1, 2:1, 3:1 and 4:1 to be selected. The frequency of the signal is determined by bit-field EBU_BUSRP.EXTCLOCK. Note that it is possible to set a different clock rate for synchronous writes to the same device by programming EBU_BUSWP.EXTCLOCK to a different value.

If a continuously running BFCLKO is required, then the BUSRCONx.BFCMSEL field can be used to enable an ungated flash clock. This bit is normally set to 1_B in all the BUSRCONx registers after reset. If cleared, the related BUSRAPx.EXTCLOCK field will be used to generate a stable BFCLKO. If multiple BUSRCONx.BFCMSEL fields are set to 0_B, then the highest priority (lowest index) BUSRAPx.EXTCLOCK field will be used.

During a burst access to a synchronous device, BFCLKO will generate correctly aligned clock edges as shown in **Figure 744**. The BFCLKO signal is gated to ensure that it is low (zero) at all other times (including asynchronous read/writes of/to synchronous devices). This provides power savings and ensures correct asynchronous accesses to Burst FLASH device(s).

The start of the address and burst phases are synchronised, by hardware, to the rising edge of BFCLKO. Exiting from a phase extended by the WAIT input will also be synchronised to the rising edge of BFCLKO.

Note: The length of the standard accesses phases during Burst FLASH accesses are programmed as a multiple of independent of the BFCLKO frequency. It is the users responsibility to program the access phases to ensure that the sampling of data by Memory Controller guarantees valid sampling of the data from the Burst FLASH device.

The EBU uses the clock to generate all external bus access sequences.

Table 525 EXTCLOCK to clock ratio mapping

EXTCLOCK value	BFCLKO divide ratio
00	1:1
01	1:2
10	1:3
11	1:4

Unless documented elsewhere, all outputs to the external bus are generated of the rising edge of .

The BFCLKO phase is controlled so that control signal changes will normally occur at the rising edge of BFCLKO unless configured otherwise by register settings.

45.3.14.8 Control of $\overline{ADV}$ & Control Signal Delays During Synchronous Accesses

The Memory Controller output signals: $\overline{ADV}$, $\overline{CS}$, $\overline{RD}$, RD/$\overline{WR}$, $\overline{BC}$ and AD signals can be delayed with respect to the BFCLKO clock signal.

The delays can be enabled and disabled by the register bits EBU_BUSCONx.EBSE for the $\overline{ADV}$ signal and by EBU_BUSCON.ECSE for the $\overline{CS}$, $\overline{RD}$, RD/$\overline{WR}$, $\overline{BAA}$ and write data signals

The amount by which the signal is delayed depends on the ratio of to the Burst FLASH clock as follows:-

- When the ratio of to BFCLKO is 1:1, signals are asserted on the negative edge of . i.e. it is in effect delayed by an EBU_CLK high pulse width (T_{PH}) with respect to BFCLKO.
- When the ratio of to BFCLKO is 1:2 or 1:3, control signals are asserted on the next positive edge of . i.e. it is in effect delayed by an cycle (T_{CLK}) with respect to BFCLKO.
- When the ratio of to BFCLKO is 1:4, control signals are asserted on the negative edge of BFCLKO. i.e. it is in effect delayed by two cycles ($2*T_{CLK}$) with respect to BFCLKO.
- If the access is to a Cellular RAM (BUSWCONx.AGEN=3_D or 7_D), then the RD/$\overline{WR}$ signal is treated as a qualifier to the address and its timing will therefore not be affected by the setting of EBU.BUSWCON.ECSE.

For read accesses the EXTCLOCK field used will be from the BUSRAPx register of the region being accessed. For write accesses the EXTCLOCK field used will be from the BUSWAPx register of the region being accessed. However if a continuous BFCLKO is being generated (BUSRCONx.BFCMSEL=0_B), for all accesses, the EXTCLOCK value from the register with BFCMSEL set to 0_B will be used when calculating delays. This ensures that the signals are always delayed correclty relative to the clock on the BFLCKO output.

The default setting after reset has the delays disabled.

If the delay is disabled, then the signals will not be delayed in 1:1 mode (except for ADV which will be guaranteed to be after the edge of BFCLKO). In 2:1, 3:1 and 4:1 mode, the signals will be delayed by an EBU_CLK high pulse width (T_{PH}) from the start of the cycle in which they are asserted.

Table 526 $\overline{ADV}$ Signal Timing

EXTCLOCK is set to	$\overline{ADV}$ Falling Edge position		$\overline{ADV}$ Rising Edge position	
	Delay Disabled[1]	Delay Enabled	Delay Disabled[1]	Delay Enabled
00_B	Start of AP1	Start of AP1+T_{PH}	End of APn	End of APn+T_{PH}
01_B, 10_B	Start of AP1+T_{PH}	End of AP1	End of APn+T_{PH}	End of APn+ T_{CLK}
11_B	Start of AP1+T_{PH}	End of AP1 + T_{CLK}	End of APn+T_{PH}	End of APn + $2*T_{CLK}$

1) See **Figure 742** for details of this signal positioning.

Table 527 $\overline{RD}$ and RD/$\overline{WR}$ Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1]	Delay Enabled	Delay Disabled	Delay Enabled
00_B	Start of CP1	Start of CP1 + T_{PH}	End of CPn[2]	End of CPn + T_{PH}
01_B, 10_B	Start of CP1 + T_{PH}	End of CP1	End of CPn + T_{PH}	End of CPn + T_{CLK}
11_B	Start of CP1 + T_{PH}	End of CP1 + T_{CLK}	End of CPn + T_{PH}	End of CPn + $2*T_{CLK}$

1) See **Figure 742** for details of this signal positioning.

2) CPn indicates the final Command Phase.

Table 528 $\overline{CS}$ Data Signal Timing

EXTCLOCK is set to	Set at:		Cleared at:	
	Delay Disabled[1]	Delay Enabled	Delay Disabled	Delay Enabled
00_B	Start of AP1	Start of AP1 + T_{PH}	End of DHn[2]	End of DHn + T_{PH}
01_B, 10_B	Start of AP1 + T_{PH}	End of AP1	End of DHn + T_{PH}	End of DHn + T_{CLK}
11_B	Start of AP1 + T_{PH}	End of AP1 + T_{CLK}	End of DHn + T_{PH}	End of DHn + 2*T_{CLK}

1) See **Figure 742** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn if the programmed Data Hold phase length is zero clocks.

The byte control signals, $\overline{BC}$x, can either use the timing in **Table 527** if EBU_BUSCONx.BCGEN is set to 01_B or 10_B or the timing in **Table 528** if EBU_BUSCONx.BCGEN is set to 00_B. A EBU_BUSCONx.BCGEN value of 11_B is not valid for synchronous accesses.

Table 529 Write Data Signal Timing

EXTCLOCK is set to	Data Driven at:		Data Cleared at:		Data Changes at:	
	Delay Disabled[1]	Delay Enabled	Delay Disabled	Delay Enabled	Delay Disabled	Delay Enabled
00_B	Start of CP1	Start of CP1 + T_{PH}	End of DHn[2]	End of DHn + T_{PH}	Start of BP1	Start of BP1 + T_{PH}
01_B, 10_B	Start of CP1 + T_{PH}[3]	End of CP1[3]	End of DHn + T_{PH}	End of DHn + T_{CLK}	Start of BP1 + T_{PH}	End of BP1
11_B	Start of CP1 + T_{PH}[3]	End of CP1 + T_{CLK}[3]	End of DHn + T_{PH}	End of DHn + 2*T_{CLK}	Start of BP1 + T_{PH}	End of BP1 + T_{CLK}

1) See **Figure 742** for details of this signal positioning.

2) DHn indicates the final Data Hold Phase. This is replaced by CPn if the programmed Data Hold phase length is zero clocks.

3) Data bus will be enabled at the start of CP1

These delay options apply to write data only. Addresses which are output on the data bus to support devices with multiplexed address and data connections are not delayed.

Note: If the control signals are delayed a recovery phase must be used to prevent conflicts between accesses as the rising edge of the control signals will be delayed past the end of the command phase. If a multiplexed access is used without a recovery phase, the address for the next access will be delayed by one clock cycle to enforce a bus turnaround time on the data bus, resulting in the valid address being driven one clock after $\overline{ADV}$ is asserted.

45.3.14.9 Burst Flash Clock Feedback

The Memory Controller can be configured to use clock feedback to optimise the operating frequency for a given flash device. This is enabled by setting the EBU_BUSCONx.FDBKEN bit to one. With this bit enabled the first sampling stage for read data has its own clock (PD_BFCLKFEEDBK_I). This will be derived from the BFCLKO output by using a second pad (BFCLKI) to monitor the BFCLKO signal after the output pad delay.

Clock feedback should be used whenever possible as it allows the best possible performance

A side effect of using this mode is an increase in data latency by one BFCLKO cycle compared with not using clock feedback.

Note: Clock feedback will be automatically disabled for burst writes as the additional latency on the $\overline{WAIT}$ input would prevent correct operation of the memory controller.

45.3.14.10Asynchronous Address Phase

As operating frequency increases, it becomes increasingly hard to avoid violating some timing parameters. The asynchronous address phase allows the address to be latched into the flash memory using the ADV signal before the clock is enabled. This is only possible if explicitly allowed by the flash data sheet.

If the EBU_BUSCONx.AAP is set, then the clock will not start until the end of the address hold phase of the access. The rising edge of the clock will always be co-incident with the transition from the address hold phase. If the address hold phase has zero length then the first rising edge of the clock will coincide with the tranistion from the address phase. If this mode is enabled a recovery phase of one BFCLK period will be enforced at the end of the previous transaction to ensure that the clock has time to turn off before the start of the next access.

Setting this mode for any region will force the clocks on all synchronous accesses to be disabled in the recovery phase. Only one clock pulse will occur during the recovery phase.

AAP mode is incompatible with the continuous clock mode and will be disabled automatically if continuous clocking is enabled by setting any BUSRCONx.BFCMSEL bit to 0_B.

45.3.14.11 Critical Word First Read Accesses

In the default case, the memory controller will always start a burst at the lowest address possible and wrapping of the burst data is handled internally to the memory controller. However, some burst devices implement a wrapping feature which is compatible with the wrapped bursts used by the processor cache fill requests. If this is the case, there is an advantage to using the wrapping mode in the device as the instruction required by the processor (the critical word) can be fetched first from the external memory.

The mode is enabled by setting the EBU_BUSCONx.dba bit for the appropriate region. Once enabled, the memory controller will not align the start address for the burst and the device will be relied on to return data in the correct order. The memory controller must fetch all the data in a single burst. If the transaction is split into multiple accesses on the external bus by use of the FETBLEN field, the issued addresses will be incorrect.

Note: The cache line fill will use an SRI, BTR4 transfer. This translates to a 16 word burst for a 16 bit device. The device must therefore support a 16 word wrap setting. A 32 bit memory must support a 8 word wrap setting. The memory controller supports a 16 word burst using the continuous burst setting for FBBMSEL. Other burst opcodes must not be generated for accesses to the external memory by the system if this mode is enabled, otherwise data corruption will occur.

45.3.14.12Example Burst Flash Access Cycle

The figure below shows an example burst flash access without clock feedback configured.

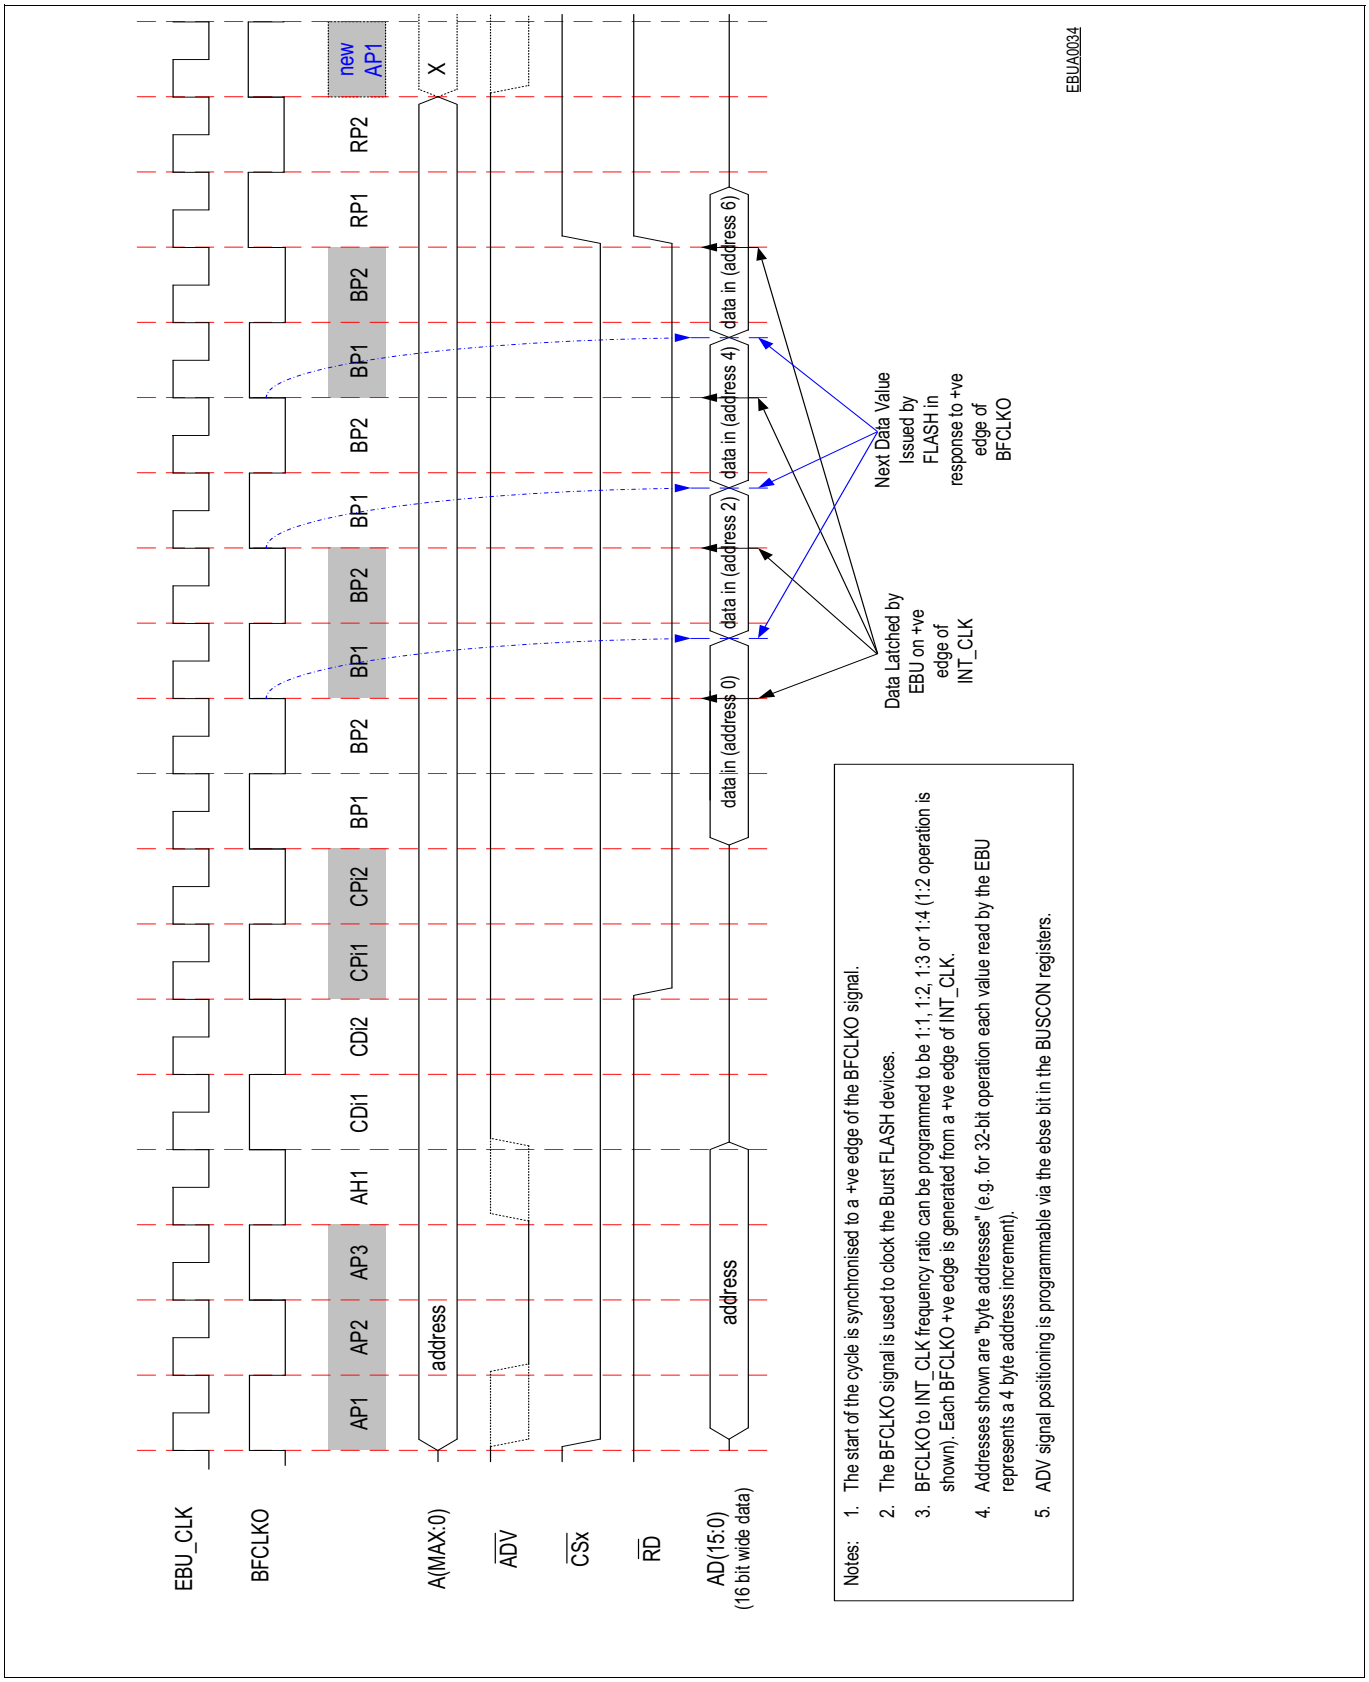

Figure 744 Burst FLASH Read without Clock Feedback (burst length of 4)

Figure 744 shows an example of a burst read access (burst length of four) to a Burst FLASH device with $\overline{\text{WAIT}}$ and clock feedback functions disabled.

Programmability of the length of the Address, Command Delay and Command phases allows flexible configuration to meet the initial read access time of a Burst FLASH device.

Data is sampled at the end of each Burst Phase cycle. The Burst Phase is repeated the appropriate number of times for the programmed burst length (programmable for lengths of 1, 2, 4 or 8 via the EBU_BUSCONx.FETBLEN bit-field).

Figure 744 shows an access cycle with the following settings:-

- Clock Feedback disabled.
- Address Phase length = 3 cycles (see ADDRC and **“Address Phase (AP)” on Page 24**).
- Command Delay Phase length = 3 cycles (see CMDDELAY and **“Command Delay Phase (CD)” on Page 25**).
- Command Phase length = 2 cycles (see WAITRDC and **“Command Phase (CP)” on Page 26**).
- Burst Phase length = 2 cycles (see EXTCLOCK, EXTDATA and **“Burst Phase (BP)” on Page 26**).
- Recovery Phase length = 2 cycles (see **“Recovery Phase (RP)” on Page 27**).
- Burst Length = 4 (see FETBLEN).
- BFCLKO frequency = 1/2 of frequency (see EXTCLOCK).

45.3.14.13External Cycle Control via the $\overline{\text{WAIT}}$ Input

Memory Controller provides control of the Burst FLASH device via the $\overline{\text{WAIT}}$ input. This allows Memory Controller to support operation of Burst FLASH while crossing Burst FLASH page boundaries. During a Burst FLASH access the $\overline{\text{WAIT}}$ input operates in one of four modes:-

- Disabled
- Early Wait for Page Load.
- Wait for Page Load.
- Abort and Retry Access.

Selection of the mode in which the $\overline{\text{WAIT}}$ input operates during Burst FLASH reads is selected via the EBU_BUSCONx.WAIT bits.

Table 530 Operation of WAIT input

Value of BUSCONx.WAIT	Mode of the $\overline{\text{WAIT}}$ input
0_D	OFF (default after reset).
1_D	Wait for page load (Early WAIT).
2_D	Wait for page load (WAIT with data).
3_D	reserved

Note: Selection of “Disabled” via the wait bit-field prevents the $\overline{\text{WAIT}}$ input having any effect on a Burst FLASH access cycle

Wait for Page Load Mode

This mode supports devices which assert a $\overline{WAIT}$ output for the duration of clock cycles in which the data output by the device is invalid or, alternatively, one clock cycle earlier than the data output is invalid. This includes Intel and AMD Burst FLASH devices (and compatibles) configured for Early Wait Generation Mode (EBU_BUSCONX.wait=01_B) and standard wait generation (EBU_BUSCONx.wait=10_B).

In operation, the burst flash controller loads a counter with the required number of samples at the start of each burst. At the end of each burst phase, the burst flash controller samples the $\overline{WAIT}$ input and the data bus at the end of each Burst phase. If $\overline{WAIT}$ is inactive, the sample is valid, the sample counter is decremented and the sampled data is passed to the datapath of the Memory Controller. This synchronous sampling means that the validity of the sample can not be determined until the clock cycle after the end of the burst phase. The Burst Flash controller will therefore overrun and generate extra burst phases until the sample counter is decremented to zero. Extra data samples returned after the sample counter is zero will be discarded.

The only difference if early wait is used is that the validity of data in burst phase "n" is determined by the value of $\overline{WAIT}$ in burst phase "n-1".

This mode of operation is compatible with the use of clock feedback as, with feedback enabled, $\overline{WAIT}$ is fed through the same resynchronisation signals as the data bus. The only effect on operation is that the number of overrun cycles will increase as the decrementing of the sample counter will be lagged by the resynchronisation stages.

During the initial phases of an access, $\overline{WAIT}$ is sampled on every edge of . This is so the first burst phase is working with an accurate value for the $\overline{WAIT}$ signal. To ensure this is the case, the command phase should be of sufficient length to allow the device to drive $\overline{WAIT}$ and for the signal to propagate to the controller.

Abort and Retry Access

In this mode, the $\overline{WAIT}$ input is polled during the address and address hold phases only. If an active state on $\overline{WAIT}$ is detected, the address phase of the access will be restarted after the end of the address hold phase.

In this mode $\overline{WAIT}$ cannot be used to extend the command phase of an access.

45.3.14.14Flash Non-Array Access Support

Several types of flash memories will assert $\overline{WAIT}$ permanently during an access which is not directed to the memory array. An example of this would be polling the status register to check if a programming operation has completed. If the BUSRCON[3:0].NAA field is set, then an access to the region with SRI A(26) set will proceed as if the appropriate wait field in BUSRCON[3:0] or BUSWCON[3:0] was set to 00_B and $\overline{WAIT}$ was disabled. When set, this field affects both read and write accesses.

45.3.14.15Termination of a Burst Access

A burst read operation is terminated by de-asserting $\overline{CSx}$ signal followed by the appropriate length Recovery Phase. **Figure 745** shows an example of termination of a burst access following the read of two locations (i.e. two Burst Phases) from a 16-bit non-multiplexed Burst FLASH device.

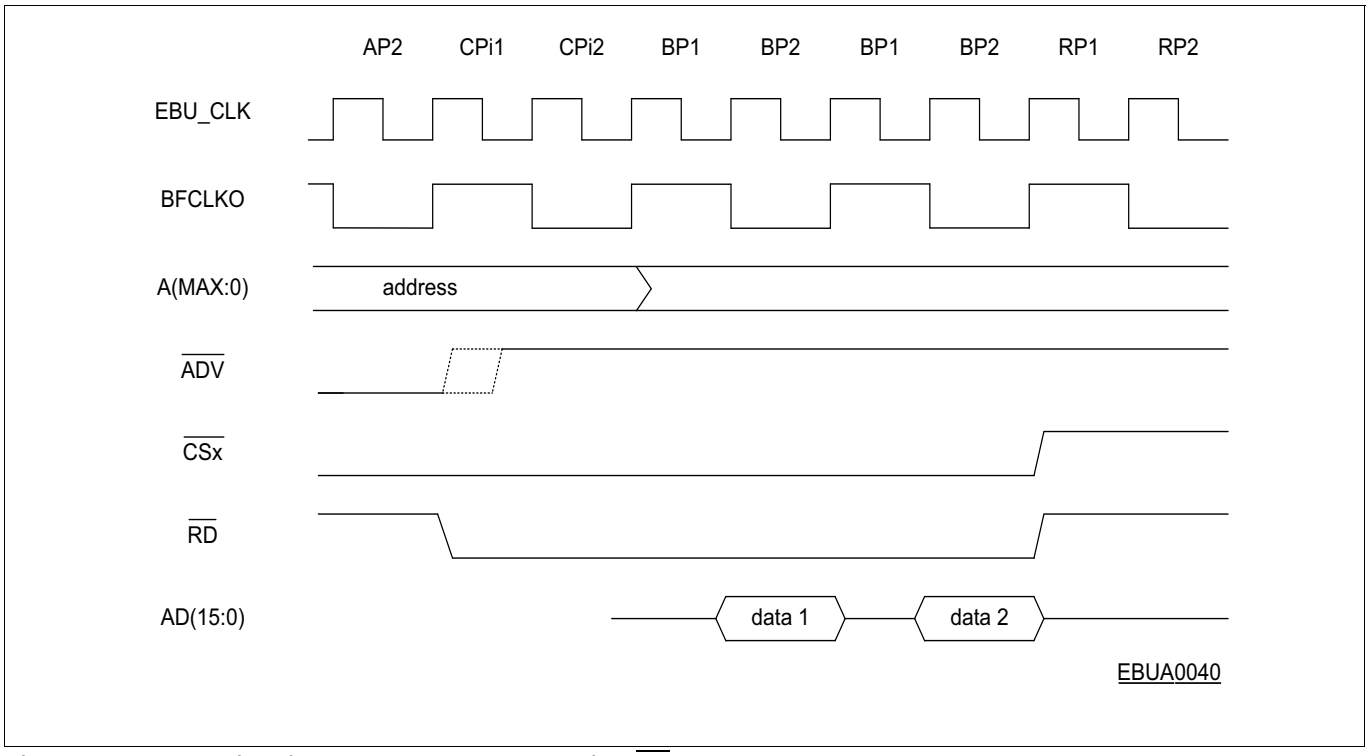

Figure 745 Terminating a Burst by de-asserting $\overline{CS}$

45.3.14.16Burst Flash Device Programming Sequences

Programming sequences for some Burst Flash devices must not be interrupted by other read/write operations to the same device. There is an optional hardware lock feature to guarantee that programming sequences are not interrupted. See **Section 45.3.6.1** for details.

45.3.14.17Cellular RAM

Cellular RAM devices have been designed to meet the growing memory and bandwidth demands of modern cellular phone designs. The devices have been designed with a “multi-protocol” interface to allow use of the devices with existing memory interfaces (i.e. by re-use of existing memory protocols). The supported interface protocols supported by Cellular RAM devices are:-

1. SRAM (Asynchronous Read and Write).
2. NOR Flash (Synchronous Burst Read, Asynchronous Write).
3. Synchronous (Synchronous Burst Read and Write).

In principle, when using previous versions of Memory Controller, the first two of the above modes (1 and 2 above) provided Cellular RAM support. For maximum performance, the Memory Controller now supports Synchronous Mode (3 above) for Cellular RAM (Synchronous Burst Read and Write).

As Cellular RAM Synchronous Mode consists of a Burst FLASH compatible Burst Read access, Cellular RAM support has been provided by enhancing the Burst FLASH interface by the inclusion of a Burst Write capability. For this reason Cellular RAM is treated as a special type of Burst FLASH device.

Cellular RAM support is selected by programming the desired region as cellular RAM via the EBU_BUSCONx.AGEN bit-field.

Synchronous Read Access

A Synchronous Cellular RAM Burst Read Access is compatible with a Burst FLASH Burst Read Access. As a result preceding sections applying to Burst FLASH devices apply and should be consulted for details of Cellular RAM Burst Read Accesses.

45.3.14.17.1 Synchronous Write Access

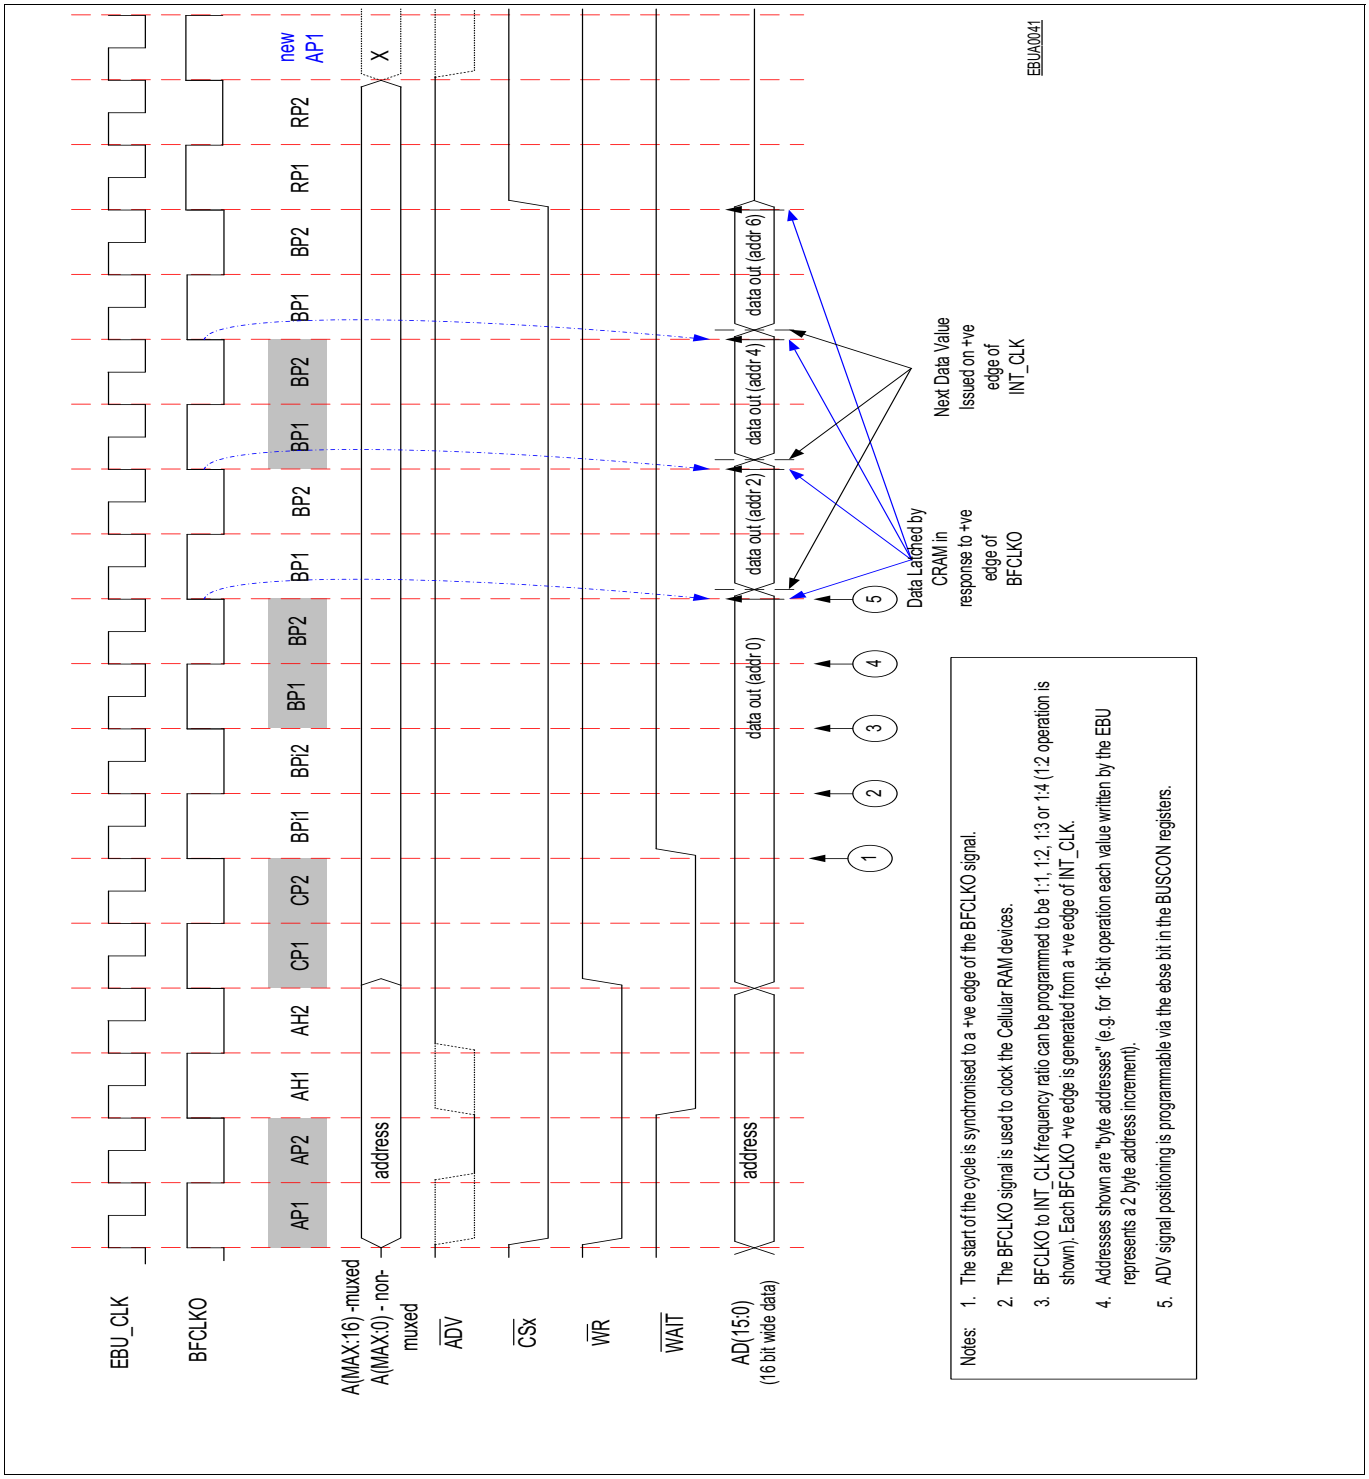

Figure 746 Burst Cellular RAM Burst Write Access (burst length of 4)

Figure 746 shows an example of a Cellular RAM burst write access.

*Note: **Figure 746** shows operation with a BFCLKO to ratio of 1:2.*

The Start of the access cycle is the same as for a Synchronous Read access (see **Figure 744**) except that the $\overline{WR}$ signal is treated as an address phase signal (i.e. it is asserted active during the Address Phase and Address Hold Phase and is then deasserted). See **"Fujitsu FCRAM Support (burst write with WR active during data phase)" on Page 56** for alternative $\overline{WR}$ timing during burst write.

The remaining sequence is as follows (with reference to the figure above):-

1. At the positive edge of labelled as '1' above the first Burst Phase starts. As the state machine is currently in the command phase, the interface samples the $\overline{\text{WAIT}}$ input. This is sampled as "active". By coincidence, in this example, the Cellular RAM also deasserts it's $\overline{\text{WAIT}}$ output as a response to this clock edge to signal that it will start to take the data from the data bus on the BFCLKO rising clock edge after the next (i.e. the rising edge of BFCLKO labelled as '5' above) - this need not be the case.
2. At the positive edge of labelled as '2' above the second programmed period of the Burst Phase begins.
3. At the positive edge of labelled as '3' above the Burst FLASH evaluates the $\overline{\text{WAIT}}$ sample from '1' above. As this sample was "active" the write data is not updated. As this clock edge is coincident with the end of a burst phase the $\overline{\text{WAIT}}$ input is resampled. The value of this new $\overline{\text{WAIT}}$ sample is "inactive".
4. At the positive edge of labelled as '5' above the Burst FLASH again evaluates the $\overline{\text{WAIT}}$ sample from '3' above. As this sample was "in-active", and the edge is coincident with the end of a burst phase, the next data value is issued to the pins and the next Burst Phase is started.

This process continues until all the data is written.

45.3.14.17.2 Fujitsu FCRAM Support (burst write with $\overline{\text{WR}}$ active during data phase)

The FCRAM device type can be supported in two ways. Later FCRAMs have a compatibility bit in the device configuration register which programmes the device to expect the $\overline{\text{WR}}$ signal to be active with the address and to be latched with the $\overline{\text{ADV}}$ signal. In this mode, FCRAM can be treated as an Infineon/Micron cellular RAM.

Alternatively, if a write is attempted to a region configured as a burst flash, the memory controller will generate a burst write with the $\overline{\text{WR}}$ signal asserted with the write data. This should be directly compatible with an FCRAM operating in its native mode.

45.3.14.18Programmable Parameters

The following table lists the programmable parameters for burst flash accesses. These parameters only apply when the EBU_BUSCONx.agen parameter for a particular memory region is set for access to synchronous burst devices (page mode or otherwise).

Table 531 Burst Flash Access Programmable Parameters

Parameter	Function	Register
ADDRC	Number of cycles in Address Phase.	EBU_BUSAPx
AHOLDC	Number of cycles in Address Hold.	EBU_BUSAPx
CMDDELAY	Number of programmed Command Delay cycles.	EBU_BUSAPx
WAITRDC	Number of programmed wait states for read accesses.	EBU_BUSAPx
WAITWRC	Number of programmed wait states for write accesses.	EBU_BUSWAPx
EXTDATA	Extended data	EBU_BUSAPx
RDRECOVC	Number of minimum recovery cycles after a read access when the next access is to the same region.	EBU_BUSRAPx
WRRECOVC	Number of minimum recovery cycles after a write access when the next access is to the same region.	EBU_BUSWAPx
RDDTACS	Number of minimum recovery cycles after a read access when the next access is to a different region.	EBU_BUSRAPx
WRDTACS	Number of minimum recovery cycles after a write access when the next access is to a different region.	EBU_BUSWAPx

Table 531 Burst Flash Access Programmable Parameters (cont'd)

Parameter	Function	Register
WAIT	Sampling of $\overline{\text{WAIT}}$ input: OFF, SYNCHRONOUS, ASYNCHRONOUS or WAIT_CELLULAR_RAM	EBU_BUSCONx
FBBMSEL	Flash synchronous burst mode: CONTINUOUS or DEFINED (as in FETBLEN)	EBU_BUSCONX
FETBLEN	Synchronous burst length: SINGLE, BURST2, BURST4 or BURST8	EBU_BUSCONx
BFCMSEL	Flash Clock Mode, continuous or gated	EBU_BUSRCONx
EXTCLOCK	Frequency of external clock at pin BFCLKO: equal, 1/2, 1/3 or 1/4 of	EBU_BUSAPx
EBSE	delay $\overline{\text{ADV}}$ output to improve hold margin	EBU_BUSCONx
ECSE	delay $\overline{\text{CS}}$, $\overline{\text{WR}}$ and write data outputs to improve hold margin	EBU_BUSCONx
LOCKCS	enable locked write sequences for this region	EBU_BUSWCONx
FDBKEN	enable clock feedback to improve read data margins	EBU_BUSRCONx
DBA	disable alignment of read bursts on external bus	EBU_BUSRCONx
AAP	enable the "asynchronous address phase" mode.	EBU_BUSCONx
PORTW	memory port width	EBU_BUSRCONx

Note: datac is not used for burst write accesses

45.4 Registers

This section describes the registers and programmable parameters of the EBU. All these registers can be read in User Mode, but can only be written in Supervisor Mode.

All registers are reset by the application reset.

SDRAM is not supported and therefore the registers **SDRMCON**, **SDRMOD**, **SDRMREF** and **SDRSTAT** are not useful.

Table 532 Register Address Space - EBU

Module	Base Address	End Address	Note
(EBU)	82000000_H	$87FFFFFF_H$	Access to External Memory via cached address range
	$A2000000_H$	$A7FFFFFF_H$	Access to external memory via non-cached address range
EBU	$F8400000_H$	$F840FFFF_H$	sri slave interface

Table 533 Register Overview - EBU (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	EBU Clock Control Register	0000000 H	U,SV,32, 64	SV,P,E,32,6 4	Application Reset	60

SDRMOD	EBU SDRAM Mode Register	000006C H	U,SV,32, 64	SV,P,32,64	Application Reset	79
SDRMREF	EBU SDRAM Refresh Control Register	0000070 H	U,SV,32, 64	SV,P,32,64	Application Reset	81

Table 533 Register Overview - EBU (ascending Offset Address) (cont'd)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
SDRSTAT	EBU SDRAM Status Register	0000074 H	U,SV,32, 64	SV,P,32,64	Application Reset	83
ACCEN0	EBU Access Enable Register 0	00000B0 H	U,SV,32, 64	SV,SE,32,64	Application Reset	85
ACCEN1	EBU Access Enable Register 1	00000B4 H	U,SV,32, 64	SV,SE,32,64	Application Reset	85

Access Restrictions

Note: The EBU registers are accessible only through word or double-word accesses. Half-word and byte accesses on EBU registers will generate a bus error. Accesses to a 64bit word only partially populated with accessible registers will cause a bus error. Writes to unused address space, or writes to the endinit protected CLC register will also cause an error .

45.4.1 Clock Control Register, CLC

EBU Clock Control Register

CLC

EBU Clock Control Register **(0000000_H)** **Application Reset Value: $0055\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
STS	0	r	**Memory Status Bit** Software access to the $\overline{WAIT}$ input pin to the EBU.
LCKABRT	1	rwh	**Lock Abort** This is a status bit which is set when a chip select lock has been cancelled by a program fetch or data read. The flag is cleared by writing 1_B to the field. See **Section 45.3.6.1** 0_B Lock function is operating normally 1_B Lock function has been aborted by processor instruction read from locked device
SDTRI	2	rw	**SDRAM Tristate** 0_B SDRAM control signals are driven by the EBU when the EBU does not own the external bus. SDRAM cannot be shared. 1_B SDRAM control signals are tri-stated by the EBU when the EBU does not own the external bus. The SDRAM can be shared. *Note: The signals affected by this setting are CKE, SDCLKO, CAS and RAS*
CLK_COMB	3	rw	**Combined External Bus Clock** Burst flash protocol and SDRAM protocol devices use the same external clock when set. 0_B The SDRAM and synchronous state machines use clocks on separate pins 1_B Both state machines use the clock on BFCLKO when accessing external memories
EXTLOCK	4	rw	**External Bus Lock Control** Allows the external bus arbitration to be locked with the EBU owning the bus. 0_B External bus is not locked after the EBU gains ownership 1_B External bus is locked after the EBU gains ownership

Field	Bits	Type	Description
ARBSYNC	5	rw	**Arbitration Signal Synchronization Control** Assumed status of the arbitration control signals, $\overline{BREQ}$ and $\overline{HLDA}$ 0_B Arbitration inputs are synchronous 1_B Arbitration inputs are asynchronous, use two resynchronisation flip-flops.
ARBMODE	7:6	rw	**Arbitration Mode Selection** Operating mode of the external bus arbitration 00_B No Bus arbitration mode selected 01_B Arbiter Mode arbitration mode selected 10_B Participant arbitration mode selected 11_B Sole Master arbitration mode selected
TIMEOUTC	15:8	rw	**Bus Time-out Control** This bit field determines the number of inactive cycles after the EBU gains ownership of the external bus before an arbitration time-out occurs and re-arbitration can occur. 00_H Time-out is disabled. 01_H Time-out is generated after 1 x 8 clock cycles. FF_H Time-out is generated after 255 x 8 clock cycles.
LOCKTIMEOUT	23:16	rw	**Lock Timeout Counter Preload** Value to be preloaded into the timeout counter for the arbitration lock. *Note: (see **Section 45.3.6.1**)*
FIFO_BYPASS	24	rw	**Reserved** Must be set to 0_B for correct operation of the SDRAM
FAST_SRI	25	rw	**Clock Cycles used for SRI Address Decode** 0_B Use two clock cycles for address decode (default after reset) 1_B Use one clock cycle for address decode. See **"Address Comparison" on Page 19** for a detailed description.
OCDS_SUSP_DIS	26	rw	**OCDS SUSPEND Disable** The EBU external arbitration will normally be disabled with the EBU owning the external bus while OCDS is active. Setting this bit will allow external bus arbitration to continue operation. See **Section 45.3.8.7**
RES	29:27	r	**Reserved** write with 0_H
BUSSTATE	30	rh	**External Bus State** Status bit controlled by the arbitration logic (See **"External Bus Arbitration" on Page 6**) reflecting the ownership of the external memory bus. 0_B The EBU does not own the external bus and attached memories cannot be accessed. 1_B The EBU owns the external bus.
ALE	31	rw	**ALE Mode** Switch the $\overline{ADV}$ output to be an active high ALE signal instead of active low $\overline{ADV}$. 0_B Output is $\overline{ADV}$ 1_B Output is ALE

w	r														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES														CFGERR	CFGEND
r														rh	rh

Field	Bits	Type	Description
CFGEND	0	rh	**Configuration End** 0_B Configuration fetch is running 1_B Configuration fetch has completed or not started

Field	Bits	Type	Description
CFGERR	1	rh	**Configuration Fetch Error** 0_B No error 1_B The configuration fetch has returned a word with all bits set. This indicates an unprogrammed or missing flash
RES	30:2	r	**Reserved** Read as 0; must be written with 0.
EBUCFG	31	w	**Configuration Word Fetch** Write 1_B to trigger automatically set the EBU to sole master arbitration mode and fetch a configuration word from external memory. Always reads 0_B

45.4.4 Address Select Register, ADDRSELx (x=0-2)

EBU Address Select Register x

ADDRSELx (x=0-2)
EBU Address Select Register x **(0000018_H+x*4)** **Reset Value: Table 535**

BASE				ALTSEG				MASK				GLOBALCS	WPROT	ALTENAB	REGENAB
rw				rw				rw				rw	rw	rw	rw

Field	Bits	Type	Description
REGENAB	0	rw	**Memory Region Enable** 0_B Memory region is disabled (default after reset[1)]). 1_B Memory region is enabled.
ALTENAB	1	rw	**Alternate Segment Comparison Enable** 0_B ALTSEG is never compared to SRI address (default after reset). 1_B ALTSEG is always compared to SRI address.
WPROT	2	rw	**Memory Region Write Protect** 0_B Region is enabled for write accesses 1_B Region is write protected.
GLOBALCS	3	rw	**Combined Chip Select Control** Controls whether the $\overline{\text{CSCOMB}}$ output should be asserted for valid accesses to this region. 0_B $\overline{\text{CSCOMB}}$ not asserted 1_B $\overline{\text{CSCOMB}}$ asserted
MASK	7:4	rw	**Memory Region Address Mask** Specifies the number of right-most bits in the base address starting at bit 26, which should be included in the address comparison. Bits [31:27] will always be part of the comparison.
ALTSEG	11:8	rw	**Memory Region Alternate Segment** Alternate segment to be compared to SRI address bit [31:28].
BASE	31:12	rw	**Memory Region Base Address** Base address to be compared to SRI address in conjunction with the mask control.

1) except for ADDRSEL0, REGENAB in register ADDRSEL0 is 1_B after reset.

Table 535 Reset Values of ADDRSELx (x=0-2)

Reset Type	Reset Value	Note
Application Reset	$A000\ 0001_H$	Value for ADDRSEL0
Application Reset	$0000\ 0000_H$	Value for other ADDRSEL registers

45.4.5 Bus Read Configuration Register, BUSRCONx (x=0-2)

EBU Bus Configuration Register

*Note: When in external boot mode (see **Page 14**) the reset value of BUSCON0 is overwritten automatically (subsequent to the release of reset) as a result of the external Boot Configuration Value fetch.*

BUSRCONx (x=0-2)

RES1								NAA	BFCMSEL	FDBKEN	RESERVED	FBBMSEL	FETBLEN		
r								rw	rw	rw	r	rw	rw		

Field	Bits	Type	Description
FETBLEN	2:0	rw	**Burst Length for Synchronous Burst** Defines maximum number of burst data cycles which are executed by Memory Controller during a burst access to a Synchronous Burst device. 000_B 1 data access (default after reset). 001_B 2 data accesses. 010_B 4 data accesses. 011_B 8 data accesses. 100_B reserved. … 111_B reserved.
FBBMSEL	3	rw	**Synchronous burst buffer mode select** 0_B Burst buffer length defined by value in fetblen (default after reset). 1_B Continuous mode. All data required for transaction is transferred in a single burst.
RESERVED	4	r	**Reserved** 0_B Reserved bit always reads ‘0’.
FDBKEN	5	rw	**Burst FLASH Clock Feedback Enable** 0_B BFCLK feedback not used. 1_B Incoming data and control signals (from the Burst FLASH device) are re-synchronised to the BFCLKI input.
BFCMSEL	6	rw	**Burst Flash Clock Mode Select** 0_B Burst Flash Clock runs continously with values selected by this register 1_B Burst Flash Clock is disabled between accesses

Field	Bits	Type	Description
NAA	7	rw	**Enable flash non-array access workaround** set to logic one to enable workaround when region is accessed with address bit 28 set. See **"Flash Non-Array Access Support" on Page 52**
RES1	15:8	r	**Reserved** 00_H Reserved Value
ECSE	16	rw	**Early Chip Select for Synchronous Burst** 0_B CS is delayed. 1_B CS is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*
EBSE	17	rw	**Early Burst Signal Enable for Synchronous Burst** 0_B ADV is delayed. 1_B ADV is not delayed. *Note: (see **Control of ADV & Other Signal Delays During Asynchronous Accesses** and **Control of ADV & Control Signal Delays During Synchronous Accesses**)*
DBA	18	rw	**Disable Burst Address Wrapping** 0_B Memory Controller automatically re-aligns any non-aligned synchronous burst access so that data can be fetched from the device in a single burst transaction. 1_B Memory Controller always starts any burst access to a synchronous burst device at the address specified by the SRI request. Any required address wrapping must be automatically provided by the Burst FLASH device. *Note: Care must be taken with the use of this feature. The Burst capable device must be programmed to wrap at the appropriate address boundary prior to selection of this mode. **"Critical Word First Read Accesses" on Page 49***
WAITINV	19	rw	**Reversed polarity at WAIT** 0_B **OFF**, input at WAIT pin is active low (default after reset). 1_B **Polarity_reversed**, input at WAIT pin is active high.
BCGEN	21:20	rw	**Byte Control Signal Control** This bit field selects the timing mode of the byte control signals. 00_B Byte control signals follow chip select timing. 01_B Byte control signals follow control signal timing ($\overline{RD}$, RD/$\overline{WR}$) (default after reset). 10_B Byte control signals follow write enable signal timing (RD/$\overline{WR}$ only). 11_B SDRAM access type. Signals used for DQM.
PORTW	23:22	rw	**Device Addressing Mode** See **Table 513** and **Table 515**

Field	Bits	Type	Description
WAIT	25:24	rw	**External Wait Control** Function of the WAIT input. This is specific to the device type (i.e. the agen field). For Asynchronous Devices, see **"External Extension of the Command Phase by WAIT" on Page 34** For Synchronous Burst Devices, see **"External Cycle Control via the WAIT Input" on Page 51**
AAP	26	rw	**Asynchronous Address phase:** Enables an access mode for synchronous memories where the clock is not started until after the address hold phase. 0_B Clock is enabled at beginning of access. 1_B Clock is enabled at after address phase.
LCKABRT	27	rwh	**Lock Abort** This is a status bit which is set when the chip select lock has been cancelled by a program fetch or data read. The flag is cleared by writing 1_B to the field. See **Section 45.3.6.1** 0_B Lock function is operating normally 1_B Lock function has been aborted by processor instruction read from locked device
AGEN	31:28	rw	**Device Type for Region** See **Section 45.3.11.1Programmable Device Types**

45.4.6 Bus Write Configuration Register, BUSWCONx (x=0-2)

EBU Bus Write Configuration Register

CRCD		AWIDTH		CRP		CRSC		CRFSH				CRAS			
rw		rw		rw		rw		rw				rw			

Field	Bits	Type	Description
CRAS	3:0	rw	**Row to precharge delay counter** Number of clock cycles between row activate command and a precharge command. 0-15$_H$: Minimum Cras + 1 clock cycles (default after reset Cras is 0)
CRFSH	7:4	rw	**Initialization refresh commands counter** Number of refresh commands issued during power-up initialization sequence. 0-15$_H$: Perform Crfsh + 1 refresh cycles (default after reset Crfsh is 0)
CRSC	9:8	rw	**Mode register set-up time** Number of NOP cycles after a mode register set command. 0-3$_H$: Insert Crsc + 1 NOP cycles (default after reset Crsc is 0)
CRP	11:10	rw	**Row precharge time counter** Number of NOP cycles inserted after a precharge command. The actual number performed can be greater due to CAS latency and burst length. 0-3$_H$: Insert Crsc + 1 NOP cycles (default after reset Crp is 0)
AWIDTH	13:12	rw	**Width of column address** Number of address bits from bit 0 to be used for column address. e.g. for 16 bit DRAMs 00_B **reserved**, do not use 01_B Address(8:0) 10_B Address(9:0) 11_B Address(10:0)
CRCD	15:14	rw	**Row to column delay counter** Number of NOP cycles between a row address and a column address. 0-3$_H$: Insert Crcd + 1 NOP cycles (default after reset Crcd is 0).
CRC	21:16	rw	**Refresh cycle time counter** Number of NOP cycles following a refresh command before another command (other than a NOP) can be issued to the SDRAM. Combined with the Crce bit as follows:- 0-3F$_H$: Insert Crc + 1 NOP cycles.

Field	Bits	Type	Description
BANKM	24:22	rw	**Mask for bank tag** SRI address bits to be used for determining bank number. 000_B Reserved; (default after reset) 001_B Address bit 21 to 20 010_B Address bit 22 to 21 011_B Address bit 23 to 22 100_B Address bit 24 to 23 101_B Address bit 25 to 24 110_B Address bit 26 to 25 111_B Address bit 26
RES	27:25	r	**Reserved**
CLKDIS	28	rw	**Disable SDRAM clock output** 0_B clock enabled 1_B clock disabled
PWR_MODE	30:29	rw	**Power Save Mode used for gated clock mode** 00_B precharge before clock stop (default after reset) 01_B auto-precharge before clock stop 10_B active power down (stop clock without precharge) 11_B clock stop power down
SDCMSEL	31	rw	**SDRAM clock mode select** 0_B clock continuously runs 1_B clock disabled between accesses

w	r	rw							rw			rw	rw		

Field	Bits	Type	Description
BURSTL	2:0	rw	**Burst length** Number of locations can be accessed with a single command. 000_B 1 (default after reset) 001_B 2 010_B 4 011_B 8 100_B 16 *Note: Other values reserved*
BTYP	3	rw	**Burst type** Memory Controller only supports sequential burst. 0_B Only this value should be written (default after reset) 1_B Reserved
CASLAT	6:4	rw	**CAS latency** Number of clocks between a READ command and the availability of data. 010_B Two clocks (default after reset) 011_B Three clocks *Note: Other values reserved*
OPMODE	13:7	rw	**Operation Mode** Memory Controller only supports burst write standard operation. 00_H Only this value should be written (default after reset) *Note: Other values reserved*
RES	14	r	**Reserved** 0_B Fixed Value
COLDSTART	15	w	**SDRAM coldstart** This bit will always read 0. If a write to the **SDRMOD** register takes place with this bit set, the SDRAM device mode register will be updated to match the data written to the register.

Field	Bits	Type	Description
XOPM	29:16	rw	**Extended Operation Mode** Value to be written to the extended mode register of a “Mobile” SDRAM device. This value is issued to the SDRAM via it’s address inputs during an extended mode register write. This field is wider than current extended mode registers to allow support of future enhanced “Mobile” SDRAM devices. *Note: Consult the appropriate SDRAM documentation for the function of these bits.*
XBA	31:30	rw	**Extended Operation Bank Select** Value to be written to the bank select pins of a “Mobile” SDRAM device during an extended mode register write operation. Control of these bits is provided to allow support of future enhanced “Mobile” SDRAM devices. *Note: Care must be taken when programming these bits to ensure that a valid extended mode register access occurs (e.g. it is possible to generate an extra unwanted standard mode register write by incorrect programming of these bits).* *4. Consult the appropriate SDRAM documentation for the function of these bits.*

45.4.11 SDRAM Refresh Control Register, SDRMREF

EBU SDRAM Refresh Control Register

SDRMREF
EBU SDRAM Refresh Control Register (0000070$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES				RES_DLY			ARFSH	SELFREX_DLY							
r				rw			rw	rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERFSHC		AUTO SELFR	SELFR EN	SELFR ENST	SELFR EX	SELFR EXST	REFRESHR			REFRESHC					
rw		rw	rw	rh	rw	rh	rw			rw					

Field	Bits	Type	Description
REFRESHC	5:0	rw	**Refresh counter period** Number of clock cycles between refresh operations. Uses ((erfshc x 64) +refreshc) as a single counter value where 0_D means that no refresh is needed an the refresh generator is disable. This is the default setting after reset. For all other vales, the refresh period is ((erfshc x 64) + refreshc) x 64 clock cycles
REFRESHR	8:6	rw	**Number of refresh commands** The number of additional refresh commands issued to SDRAM each time a refresh is due. 000_B 1 refresh command is issued (default after reset). 001_B 1 additional refresh command is issued. 110_B 6 additional refresh commands are issued. 111_B 7 additional refresh commands are issued.
SELFREXST	9	rh	**Self Refresh Exit Status.** If this bit is set to ’1’, it means the Self Refresh Exit command has been successfully issued. This bit is reset when bit selfren is set to ’1’ or a reset takes place.
SELFREX	10	rw	**Self Refresh Exit (Power Up).** When this bit is written with ’1’ the Self Refresh Exit command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1. This is also used after power is applied to drive CKE high
SELFRENST	11	rh	**Self Refresh Entry Status.** If this bit is set to ’1’, it means the Self Refresh Entry command has been successfully issued. This bit is reset when bit selfrex is set to ’1’ or a reset takes place.
SELFREN	12	rw	**Self Refresh Entry** When this bit is written with ’1’ the Self Refresh Entry command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1.

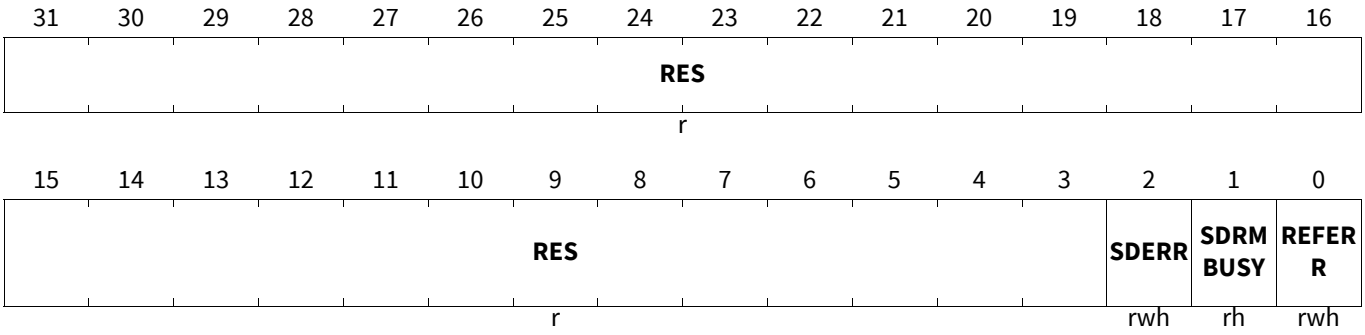
Field	Bits	Type	Description
AUTOSELFR	13	rw	**Automatic Self Refresh** When this bit is set to '1', Memory Controller will automatically issue the Self Refresh Entry command to all SDRAM devices when it gives up control of the external bus, and will automatically issue Self Refresh Exit when it regains control of the bus.
ERFSHC	15:14	rw	**Extended Refresh Counter Period** This field is used to increase the range of the refreshc field from 6 bits to 8 bits with erfshc being used as bits 7 and 6 of the extended field and refreshc as bit 5 to 0.
SELFREX_DLY	23:16	rw	**Self Refresh Exit Delay** Number of NOP cycles inserted after a self refresh exit before a command is permitted to the SDRAM/DDRAM.
ARFSH	24	rw	**Auto Refresh on Self refresh Exit** If set to one, an auto refresh cycle will be performed on exiting self refresh before the self refresh exit delay. If set to zero, no refresh will be performed.
RES_DLY	27:25	rw	**Delay on Power Down Exit** Number of NOPs after the SDRAM controller exits power down before an active command is permitted.
RES	31:28	r	**Reserved** 0_H Reserved Value

45.4.12 SDRAM Status Register, SDRSTAT

EBU SDRAM Status Register

SDRSTAT

EBU SDRAM Status Register (0000074$_H$) Application Reset Value: 0000 0000$_H$



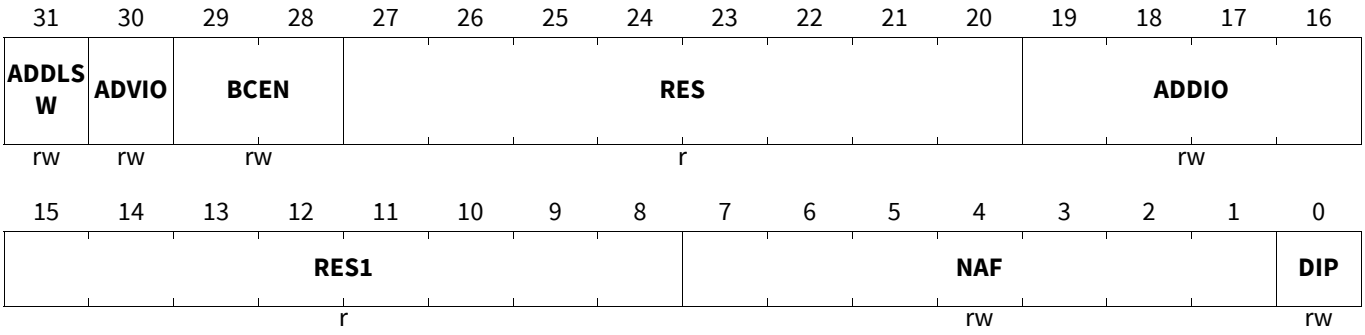
Field	Bits	Type	Description
REFERR	0	rwh	**SDRAM Refresh Error** Unsuccessful previous refresh request collides with a new request. This bit latches at 1_B and is reset by writing 0_B. 0_B No refresh error. 1_B Refresh error occurred.
SDRMBUSY	1	rh	**SDRAM Busy** The status of power-up initialization sequence. 0_B Power-up initialization sequence is not running 1_B Power-up initialization sequence is running
SDERR	2	rwh	**SDRAM read error** SDRAM controller has detected an error when returning read data. 0_B Reads running successfully 1_B Read error condition has been detected *Note: This bit latches at 1_B and is reset by writing 0_B.*
RES	31:3	r	**Reserved** 00000000_HReserved Value

45.4.13 Test/Control Configuration Register, USERCON

EBU Test/Control Configuration Register

USERCON

EBU Test/Control Configuration Register (000000C$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
DIP	0	rw	**Disable Internal Pipelining**
NAF	7:1	rw	**No Assigned Function** Reserved for future requirements
RES1	15:8	r	**Reserved** Read as 0; should be written with 0.
ADDIO	19:16	rw	**Address Pins to GPIO Mode** Individual Control Bits for Address Bus Bits 19 downto 16 respectively. 0_H Address Bit is required for addressing memory 1_H Address Bit switched to GPIO function
RES	27:20	r	**Reserved**
BCEN	29:28	rw	**Byte Control Enable** 00_B Byte control off. Pins available for address or GPIO as set by Ports logic 01_B 8 bit byte control. Byte control 0 only. A(22:20) available for address or GPIO as set by Ports logic 10_B 16 bit byte control. $\overline{BC}$(1:0) available. A(21:20) available for address or GPIO as set by Ports logic 11_B 32 bit byte control. $\overline{BC}$(3:0) available.
ADVIO	30	rw	**ADV Pin to GPIO Mode** Control Bit for the $\overline{ADV}$/ALE output 0_B $\overline{ADV}$ pin is required for controlling memory 1_B $\overline{ADV}$ pin is switched to GPIO function
ADDLSW	31	rw	**Enable Address LSW, A(15:0) for GPIO** Switch the least significant 16 bits of the address bus to GPIO mode. 0_B A(15:0) in use by EBU 1_B A(15:0) used as GPIO.

45.4.14 Access Enable Registers, ACCEN0 and ACCEN1

EBU Access Enable Register 0

The Access Enable Register 0 controls write access for transactions to registers with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding. Write accesses not permitted by the setting of the register will be errored.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … ,EN31 -> TAG ID 011111B.

ACCEN0

EBU Access Enable Register 0 **($00000B0_H$)** **Application Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BREQ	out	**Bus Request**
DQ(15:0)	out	**Data Line**
A(23:0)	out	**Address Output**

45.5.1 Bus State During Reset

The state of the various bus signals is controlled by Memory Controller during reset as follows:-

Table 537 Memory Controller External Bus pin states during reset

Pin Name	State during Reset[1)]	State during Idle[2)]	State during "no bus" mode
	GPIO	High Impedance - pull ups enabled to pull to '1'.	GPIO
	High impedance pull to '1' (high).	High Impedance - pull ups enabled to pull to '1'.	High Impedance - pull ups enabled to pull to '1' (High).
A(:19)	GPIO	Driven to '0' after reset, otherwise last used address	GPIO
A(:0)	High impedance pull to '1' (high).	Driven to '1' (High) at reset, last used address when idle	High impedance pull to '1' (high).
$\overline{CS}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{CS}$	GPIO	Driven to '1' (High).	GPIO
$\overline{RD}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{WR}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{CAS}$	GPIO	Driven to '1' (High).	GPIO
$\overline{RAS}$	GPIO	Driven to '1' (High).	GPIO
CKE	GPIO	Dependant on SDRAM clocking/power save mode	GPIO
$\overline{ADV}$	GPIO	Driven to '1' (High).	GPIO
SDCLKO	GPIO	Driven to '0' (Low).	GPIO
SDCLKI	GPIO	High Impedance	GPIO
BFCLKI	GPIO	High Impedance	GPIO
BFCLKO	GPIO	Driven to '0' (Low).	GPIO
$\overline{BC}$	GPIO	Driven to '1' (High).	GPIO
$\overline{BC}$	High impedance pull to '1' (high).	Driven to '1' (High).	High impedance pull to '1' (high).
$\overline{WAIT}$	GPIO	Always an input (must have a pull-resistor to inactive state).	GPIO
$\overline{HOLD}$	GPIO	depends on state of bus arbitration logic	GPIO
$\overline{HLDA}$	GPIO		GPIO
$\overline{BREQ}$	GPIO		GPIO
$\overline{BAA}$	GPIO	Driven to '1' (High).	GPIO

1) GPIO controlled pins should be high impedance with pull up during reset.

2) Assuming that the pins have not been made available as GPIO.

Applicable reset is cgu_con_clk_rst_n_i.

46 SD- and eMMC Interface (SDMMC)

The purpose of the SDMMC module is to enable communication to external managed NAND Flashes using the SD- or eMMC interface. The focus of the module is set to the communication with a single embedded (eMMC) memory device or a single SD-card.

46.1 Feature List

This section describes the features of the SDMMC module.

- Communication to eMMC memories
  - Communication using 1-, 4- or 8-data lines
  - Legacy MMC card- and High-speed SDR mode supported
- Communication to SD-cards
  - Communication using 1- or 4-data lines
  - Default- and High Speed Mode supported
  - Communication to SDIO cards
- Communication support using different levels of DMA support
  - Programmed Input Output (PIO) - Operation without DMA
  - Single Operation DMA (SDMA)
  - Advanced DMA-2 (ADMA2)
  - Advanced DMA-3 (ADMA3)
- Block buffer of 2x512 Bytes
- Compliant to “Embedded Multi-Media Card (eMMC) Standard (5.1)”with the following exceptions:
  - no dual voltage eMMC support, only high voltage (3.3V)
  - no high clock frequencies for HS200/HS400, only 0-50MHz
  - no large 4kB sector device support, only 512B sectors
  - no DDR signaling only SDR signaling
  - no data strobe support
  - no high speed DDR, HS200 or HS400 speed mode support, only Legacy MMC card and High Speed SDR
  - no “Interrupt” mode, only “device identification”, “data transfer” and “inactive” mode
  - no clock tuning support
  - no multi device support
- Compliant to “SD Specifications Part A2 SD Host Controller Standard Specification v4.10” with the following exceptions:
  - no Multi Slot Support , only single cards
  - no suspend and resume functionality
  - no Sampling Clock Tuning supported, only Default Speed Mode and High Speed Mode supported
  - no Suspend/Resume operation in an SDIO card
- Compliant to “SD Specifications Part 1 Physical Layer Specification v4.2” with the following exceptions
  - no UHS-II voltages, only high voltage SD Memory Card
  - no UHS-I and UHS-II speed modes, only Default Speed Mode and High Speed Mode
  - no physical write protection switch support
  - no card insertion detection, only sensing of pull-up on DAT line

– no SPI card support

46.2 Functional Description

46.2.1 Architecture

46.2.1.1 System Description

The DWC_mshc controller supports master bus interface and the slave bus interface. It also contains a DMA for data transfer, a registers unit and a FIFO controller.

Figure 747 describes the main functional building blocks of the DWC_mshc core.

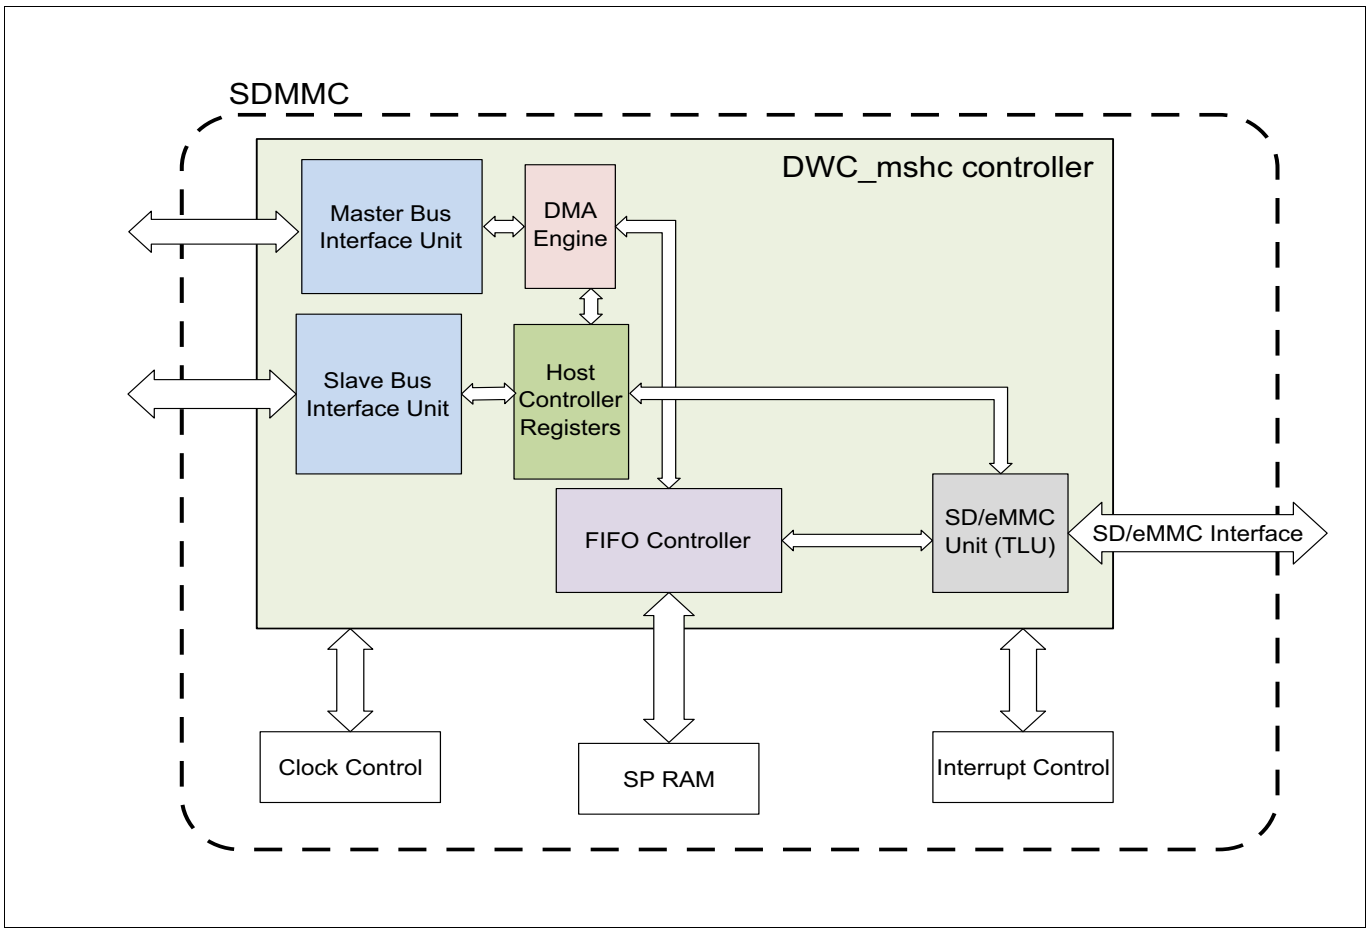

Figure 747 System-Level Block Diagram

Following are various modules in the Mobile Storage Host Controller:

- **The Master Bus Interface Unit** on **Page 4**
- **The Slave Bus Interface (SBI) Module** on **Page 4**
- **DMA Engine** on **Page 4**
- **DWC_mshc Registers** on **Page 4**
- **FIFO Controller** on **Page 4**
- **SD/eMMC Unit** on **Page 4**
- **SPRAM (single port RAM)** on **Page 5**
- **Interrupts** on **Page 5**

The Master Bus Interface Unit

This Master Bus Interface Unit (MBIU) implements the logic to transfer data on the AMBA High-Performance bus. The AHB interface transfers data to and from the system memory through the AHB master bus interface.

The Slave Bus Interface (SBI) Module

The AHB slave bus interface (SBI) module implements the logic to primarily access the DWC_mshc registers by using an external AMBA high-performance (AHB) bus. This module supports only the little endian scheme for register accesses.

DMA Engine

The DMA Engine unit handles data transfer between DWC_mshc and system memory. The key features of this unit are as follows.

- Support SDMA/ADMA2/ADMA3 modes
- Write back the received data packets to the system memory
- All bus accesses by the DMA engine are executed in user mode
- Support of SINGLE and burst (INCR4 and INCR8) transfers
  - In order of achieving optimal performance with burst transfers, data should be aligned to 256-bit for INCR8 and 128-bit for INCR4. E.g. in case of INCR8 and non 256-bit aligned data, the DMA engine will use SINGLE and INCR4 transfers until 256-bit alignment is achieved.
- 32-bit addressing support
- 32-bit data width

DWC_mshc Registers

The host controller register unit comprises of the standard SD host controller registers as specified in the SD Specifications Part A2 SD Host Controller Standard Specification Version 4.20a.

For the following registers the internal clock controlled by CLK_CTRL.INTERNAL_CLK_EN must be enabled before accessing them:

- BLOCKSIZE
- BLOCKCOUNT
- ARGUMENT
- XFER_MODE
- CMD

FIFO Controller

The data FIFO controller interfaces the internal FIFO of the host and the transaction controller unit.

SD/eMMC Unit

SD/eMMC unit is responsible for managing SD/eMMC interface protocols. The key features of this unit are to:

- Generate DS/HS command and data packets
- Generate CRC and check for command and data packets
- Handle packet timeouts
- Support 1-bit DAT, 4-bit DAT, and 8-bit DAT modes
- SD/eMMC interface signals
  - SDMMC_DAT0-7: data lines

- SDMMC_CMD: command line
- SDMMC_CLK: clock line

For the different data widths 1-, 4- and 8-wire communication different enable signals for the corresponding Data Pins are required to activate and deactivate these lines according to the output width selection.

SPRAM (single port RAM)

The SPRAM is used for the storage of data blocks. This RAM has twice the size of the SD/eMMC blocksize of 512bytes. This results in a 1kbyte buffer.

The single port RAM is not initialized after reset. Reading the RAM should only be done after the uninitialized values got overwritten (either data was received by the card, or the RAM was written by application software to prepare a write to the card). This is to avoid checksum errors (safety alerts) when the software accesses uninitialized RAM cells.

Interrupts

The DWC_mshc_controller supports two types of interrupts:

- Status Interrupts (corresponding to register NORMAL_INT_STAT_R) and
- Error Interrupts (corresponding to register ERROR_INT_STAT_R)

46.2.1.2 Error Handling

DWC_mshc is capable of detecting different types of error in SD and eMMC. Error is detected in either command or data portion of the transaction. When an error is detected, the Error interrupt in Normal interrupt status register (NORMAL_INT_STAT_R) is set.

DWC_mshc supports Error Interrupt Status register (ERROR_INT_STAT_R) to capture the interrupt status. When error occurs in the SD and eMMC mode, one of the bits is set in the Error Interrupt Status register. command is used to recover from error detected during data transfer. In addition to these two registers, there are two more error status registers, namely Auto CMD Error Status register and ADMA Error Status registers that are supported in both SD and eMMC modes.

Table 539 lists error types and categories into which they can be grouped for SD/eMMC mode.

Table 539 Error Types and Categories for SD/eMMC Mode

Error Type	Categories
Command Errors	• Command Timeout Error • Command CRC Error • Command End Bit Error • Command Index Error • Command Conflict Error • Response Error
Auto Command Errors	• Command not issued by Auto CMD12 Error • Auto Command Timeout Error • Auto Command CRC Error • Auto Command End Bit Error • Auto Command Index Error • Auto Command Conflict Error • Auto CMD response Error

Table 539 Error Types and Categories for SD/eMMC Mode (cont'd)

Error Type	Categories
Data Errors	• Data Timeout Error • Data CRC Error • Data End bit Error • ADMA Error
Command Errors	• Timeout for CMD_RES • TID Error • Framing Error • CRC Error • RES Packet Error • EBSY Error • Header Error
Data Errors	• Timeout for Deadlock • ADMA Error • Unrecoverable Error • TID Error • Framing Error • CRC Error • Retry Expired Error • Header Error • EBSY Error

46.2.1.3 OCDS Suspend

The SDMMC module has the following behaviour for OCDS hard and soft suspend on TC39x.

- During OCDS suspend the SDMMC registers are not readable and writable with the exception of the registers starting from offset 0x300.
- The DMA master interface is stopped in operation.
  - If the suspend is asserted during an ongoing DMA transfer, then this transfer is ed and an error interrupt is generated if this is interrupt is enabled.

On all devices other than TC39x the OCDS suspend signal has no effect.

46.2.2 DWC_mshc Programming Sequences

46.2.2.1 Pin enabling

When using the SDMMC module the direction registers of the corresponding ports need to be configured to input. Other pin configurations (such as pulls and driver strength) need to be selected according to the application needs.

46.2.2.2 Programming Overview

A certain programming sequence is required for DWC_mshc and the card subsystem before starting data transfer with a connected card. Initially, both the host controller and the card needs to be initialized.

Following is the programming sequence required before starting the data transfer with the card:

1. Start providing hclk to DWC_mshc and apply its reset hresetn. This clock is required for card detection logic and for accessing most of the registers in DWC_mshc.
2. Check if the card is already inserted by reading Present State Register (PSTATE_REG). This step is required for a removable card. If the card is already inserted, then goto Step 4.
3. Wait for the card insertion interrupt. This step is required for removable card. Card detection sequence is described in the “Card Detection” programming sequence.
4. Set up basic settings for DWC_mshc as described in “Host Controller Setup Sequence”. It involves settings such as the bus power voltage level for the card, timeout counter value, setting clock generation parameters. Different setup sequences for SD card (“SD Interface”) and eMMC card (“eMMC Device”) are provided. This step can also be executed immediately after Step 1.
5. Enable input clocks (other than hclk) that are available in DWC_mshc. Internal clocks (bclk and tmclk) are enabled followed by the card clocks (cclk_tx/cclk_rx) as discussed in the programming sequence in “Host Controller Clock Setup Sequence”. At this stage, DWC_mshc is ready to communicate with the card.
6. Identify the type of card that is connected to DWC_mshc as explained in the programming sequence in “SD Card Interface Detection”. If DWC_mshc is connected to an eMMC card, then programming sequence described in “eMMC Card Interface Setup” must be executed. This is a simplified sequence especially for an eMMC card as the type of card is always known. Both the programming sequences provide power and clock to the card.
7. After powering up the card, the card is initialized. Appropriate sequence as shown below must to be executed based on type of the connected card.

   Card Initialization Sequence for Different Cards

Type of Card	Card Initialization Sequence
SD	SD Card Initialization and Identification
eMMC	Initializing and Identifying an eMMC Card

8. As both host controller and card are initialized, the host can start sending commands to the card to perform the data transfer. Control and data commands are two types of commands that can be issued to the card. The control command is used to read or write any register in the card. The data command is used for writing or reading data to or from the card. The table below lists the control and data command sequences for SD and eMMC cards.

   a) Data transfer can be ed using command.

   b) If errors are detected during the transfer, recovery should be done using the Error Recovery sequence.

   Command Sequence for Different Cards

Type of Card	Command Sequence	
SD/eMMC	Control CMD	Issuing CMD without Data Transfer
	Data CMD	Issuing CMD with Data Transfer

46.2.2.3 Card Detection

Figure 748 shows the sequence for detecting a card. The procedure outlined in **Figure 748** applies to both SD and SDIO cards. This programming sequence is not required for an eMMC device as it is non-removable.

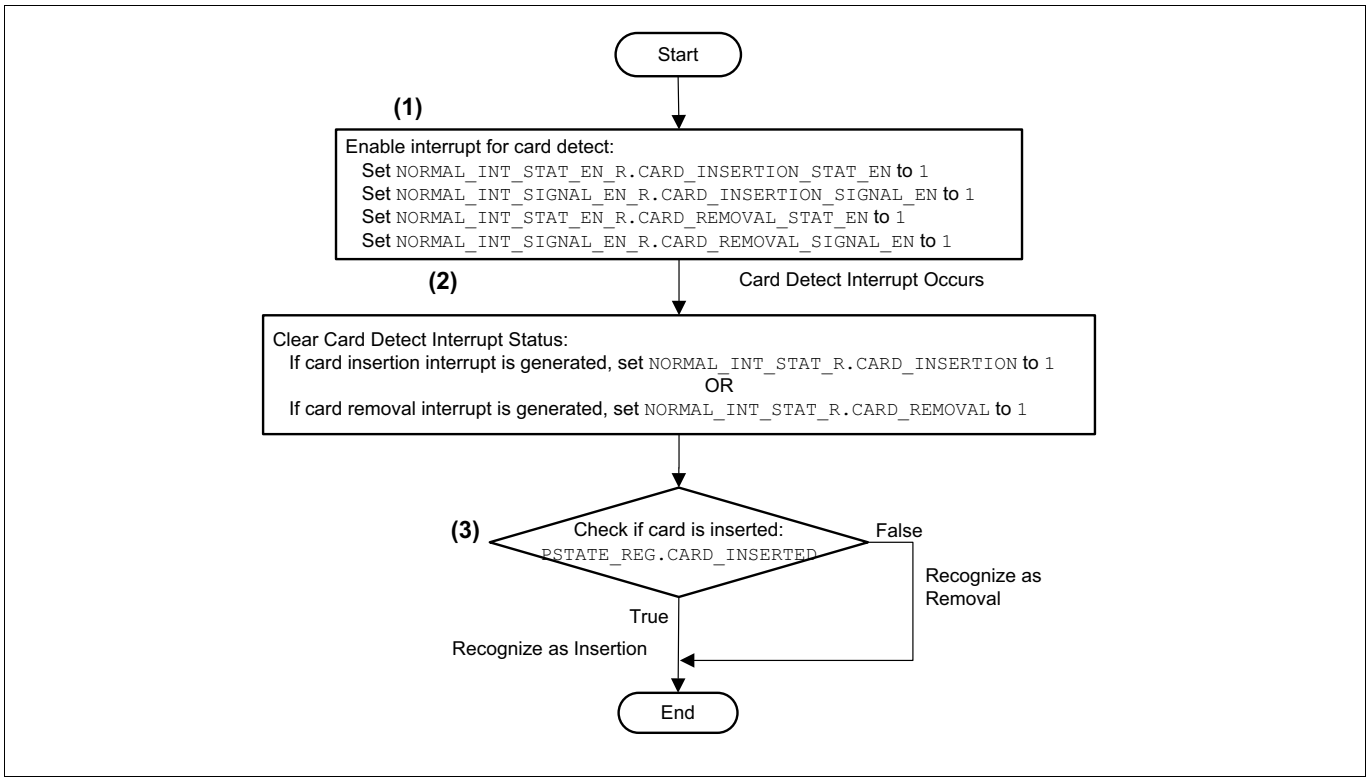

Figure 748 Card Detection

46.2.2.4 Host Controller Setup Sequence

This section discusses the host controller setup sequence for SD and an eMMC device. This section discusses the following sequences:

- **Host Controller Setup Sequence for an SD Interface** on page **Page 9**
- **Host Controller Setup Sequence for an eMMC Device** on page **Page 10**

46.2.2.4.1 Host Controller Setup Sequence for an SD Interface

The host controller setup sequence for an SD interface involves basic settings for DWC_mshc. The procedure involves settings such as the bus power voltage level for the card, timeout counter value, setting clock generation parameters.

Figure 749 shows the host controller setup sequence. The register parameters set in this sequence retain their values irrespective of bus speed mode changes.

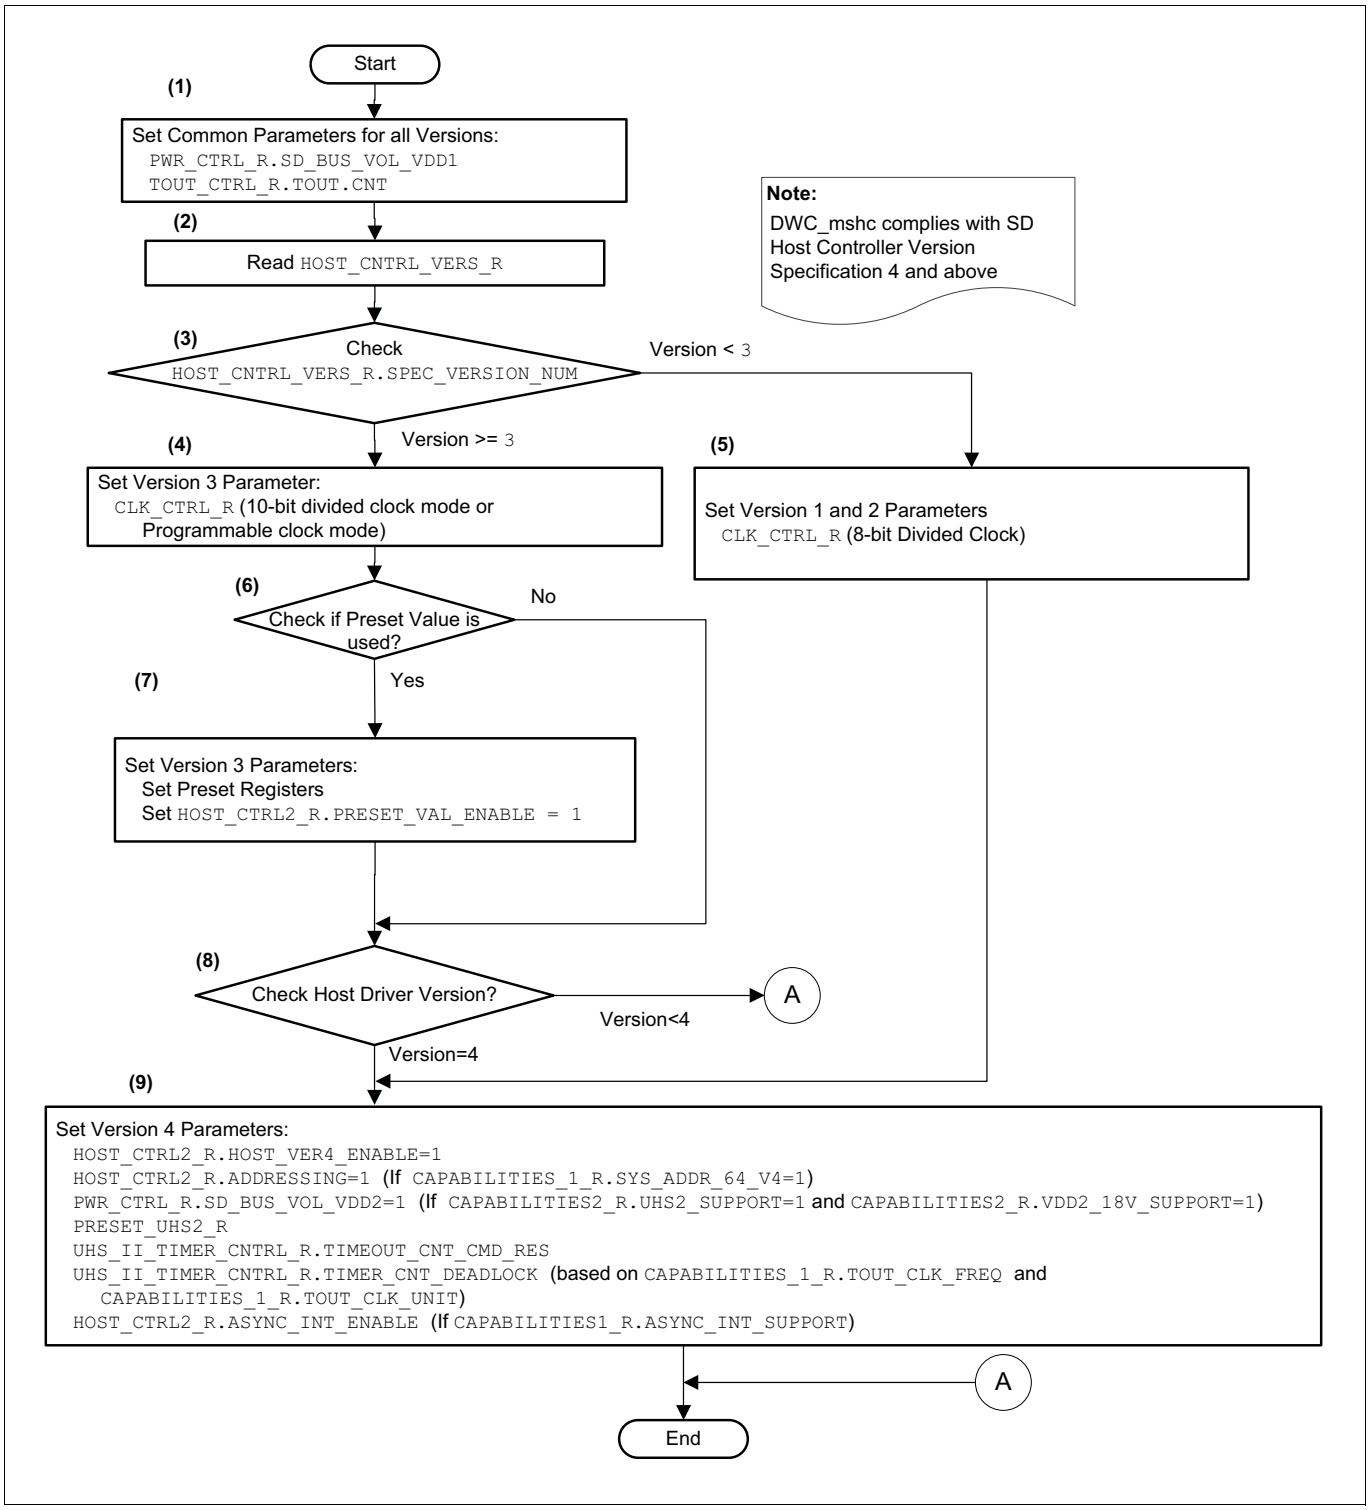

Figure 749 Host Controller Setup Sequence for SD Interface

46.2.2.4.2 Host Controller Setup Sequence for an eMMC Device

The host controller setup sequence for an eMMC device involves basic settings for DWC_mshc. The procedure involves setting certain parameters common to both version 3 and 4, clock control register, and version 4 parameters.

Figure 750 shows the host controller setup sequence for an eMMC device. In addition to completing the programming sequence in Figure 4-3, you must set the parameter EMMC_CRTL_R.CARD_IS_EMMC = 1.

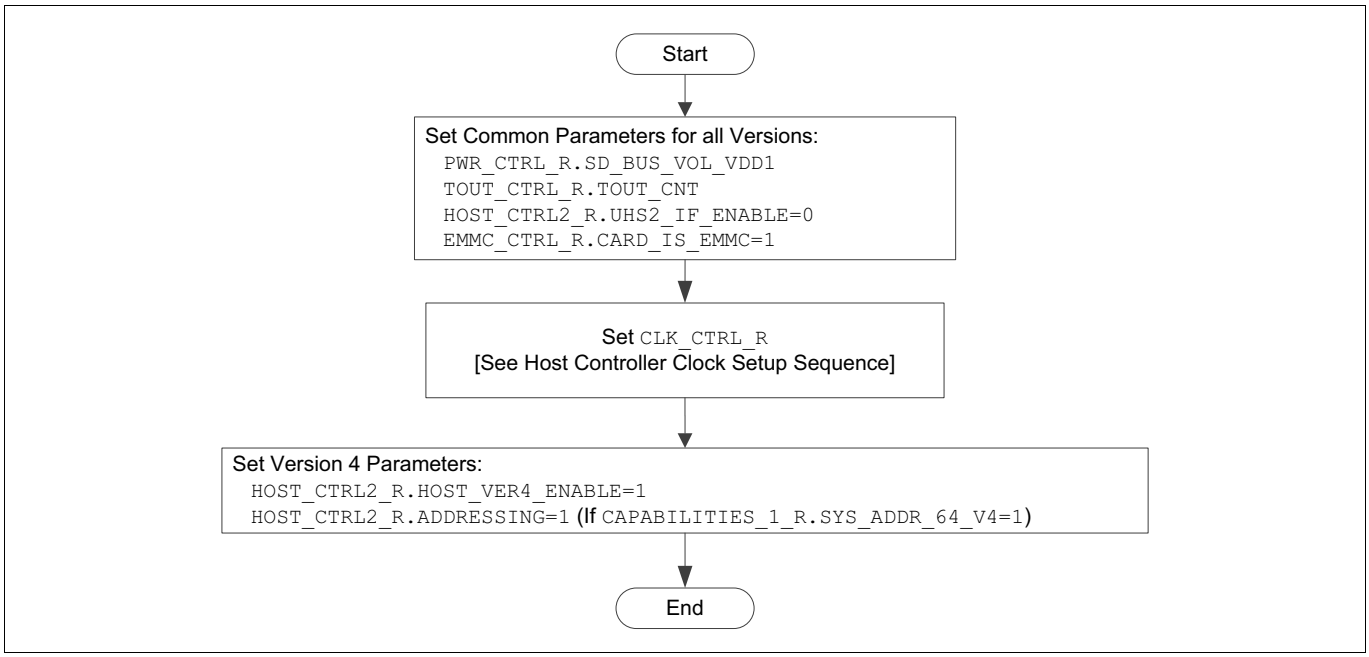

Figure 750 Host Controller Setup Sequence for eMMC Interface

46.2.2.5 Clock Control

This section discusses the programming sequence for setting up internal clocks and card clock provided to DWC_mshc and for supplying and setting up a clock provided to the card, and for changing the card clock frequency.

This section includes the following sequences:

- **Host Controller Clock Setup Sequence** on page **Page 11**
- **Card Clock Supply and Stop Sequence** on page **Page 12**
- **SD Clock Frequency Change Sequence** on page **Page 12**

46.2.2.5.1 Host Controller Clock Setup Sequence

The DWC_mshc requires number of clock signals from the system. All the input clocks are asynchronous to each other. Based on controls available for enabling clocks required for DWC_mshc, they are categorized into two types, namely Internal clock and Card clock.

Figure 751 shows the sequence for setting up clocks for DWC_mshc.

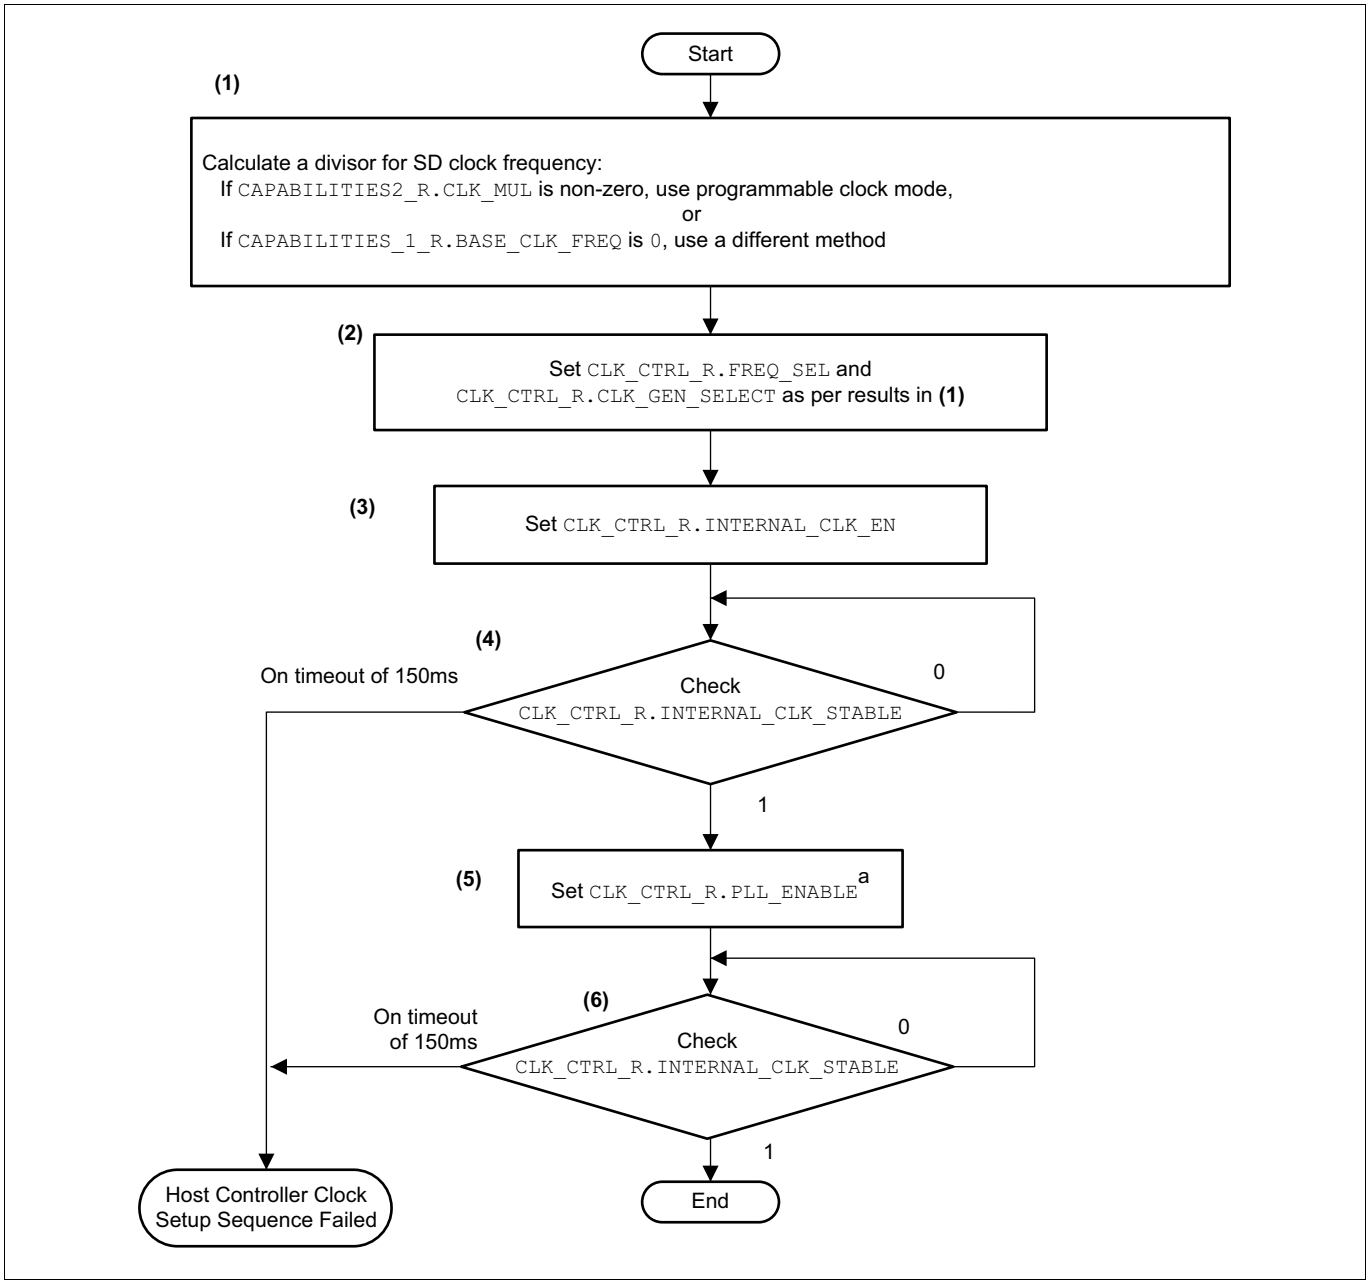

Figure 751 Host Controller Clock Setup Sequence

[a] Step to be ignored as there is no PLL.

46.2.2.5.2 Card Clock Supply and Stop Sequence

A clock Supply and Stop Sequence can be initiated, only when there is no active data transfer between the DWC_mshc and the card.

Figure 752 shows the flow chart for stopping the clock to card. The procedure outlined in Figure 4-5 applies to both SD and eMMC cards.

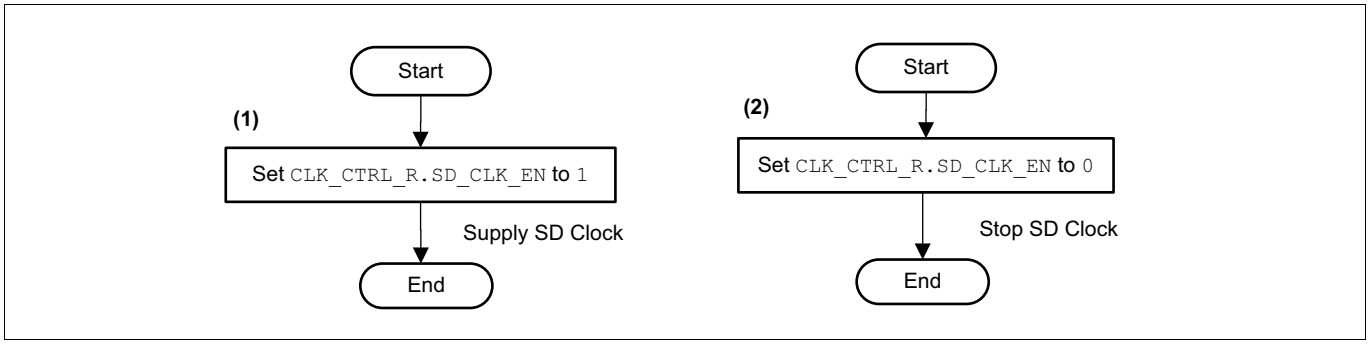

Figure 752 Card Clock Supply and Stop Sequence

46.2.2.5.3 SD Clock Frequency Change Sequence

The method used to change the SD clock frequency can either be a clock multiplier of programmable clock generator, or any different mode (if the Base Clock Frequency bit in the Capabilities register is 0).

Figure 753 shows the sequence for changing SD clock frequency.

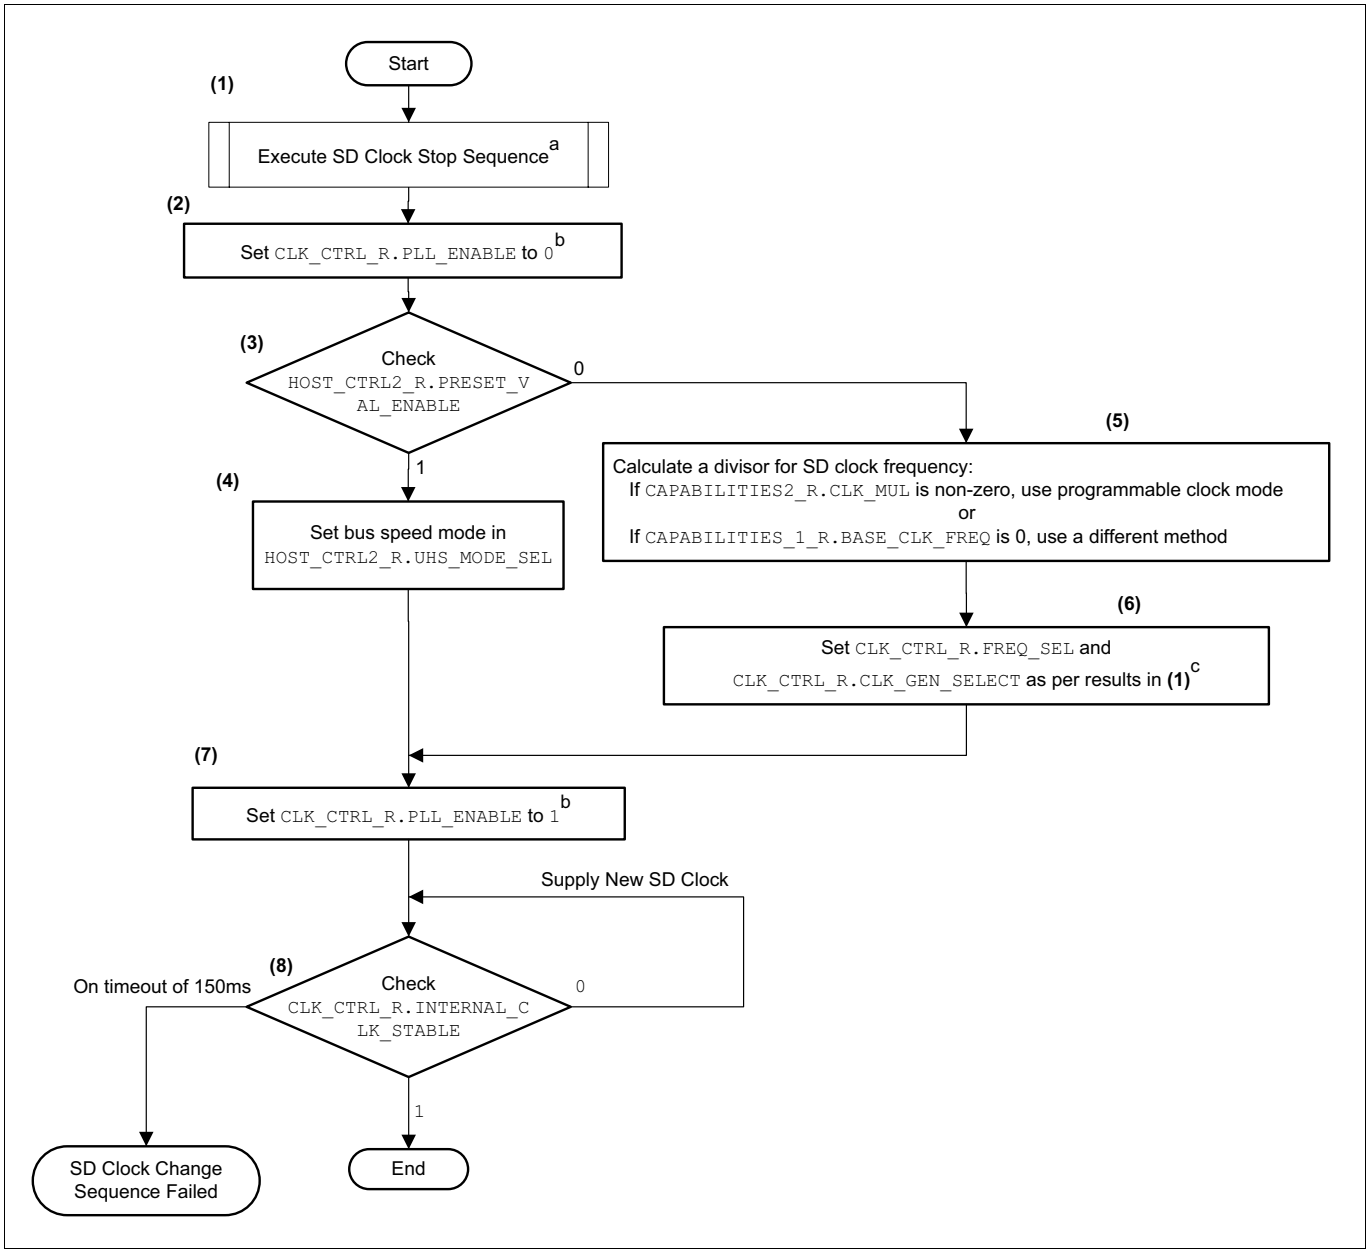

Figure 753 SD Interface Clock Frequency Change Sequence

[a] Refer "**Card Clock Supply and Stop Sequence**" on **Page 12**.

[b] Step to be ignored as there is no PLL.

[c] Step to be ignored as Clock Multiplier option is not supported.

46.2.2.6 Card Interface Setup Sequence

This section discusses the programming sequence for setting up the card interface for an SD, UHS-II and eMMC cards.

This section discusses the following topics:

46.2.2.6.1 SD Card Interface Setup Sequence

The SD card interface setup sequence involves the procedure to detect the SD card, set the necessary SD register bits, change the SD clock frequency, supply the SD clock and perform SD 4-bit mode initialization.

Figure 754 shows the programming sequence for detecting and setting up the SD card interface.

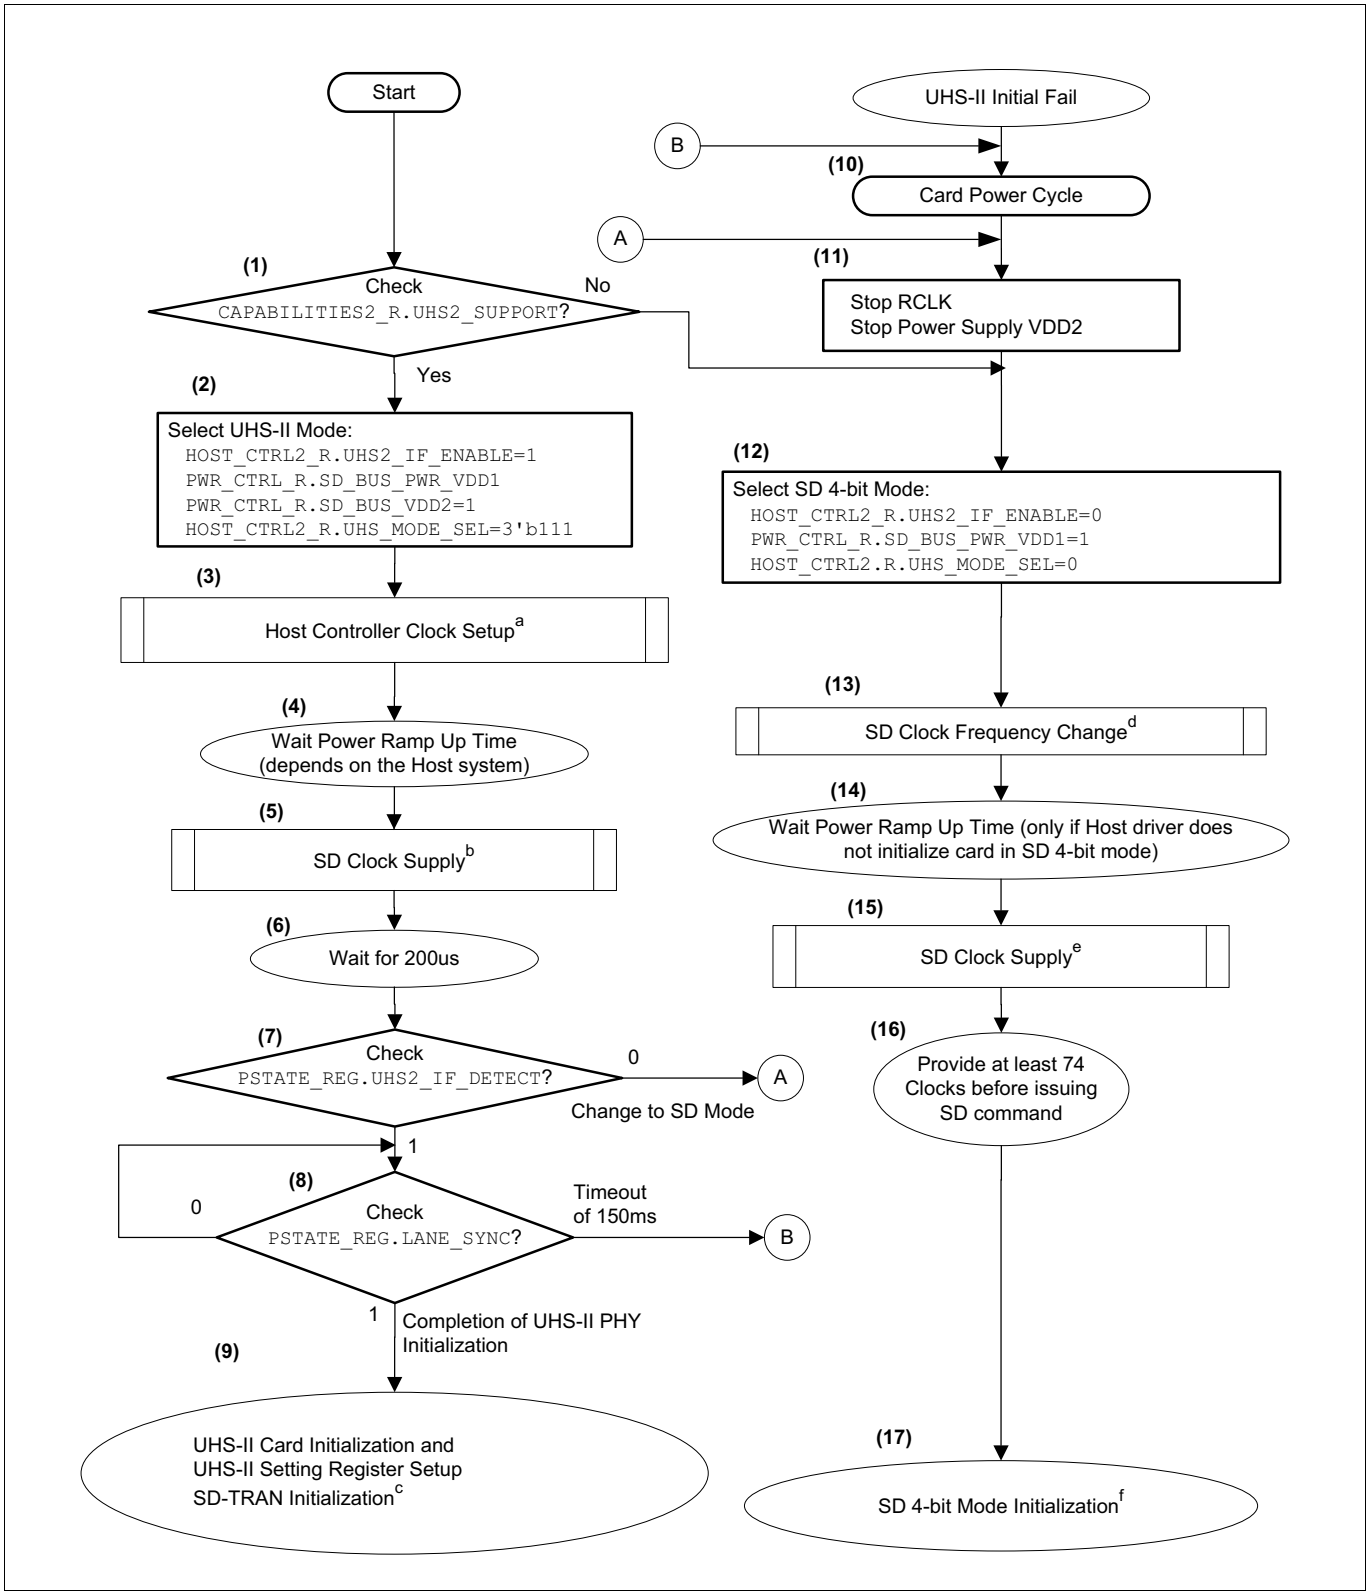

Figure 754 SD Card Interface Detection Sequence

[a] Refer "**Host Controller Clock Setup Sequence**" on **Page 11**.

[b e] Refer "**Card Clock Supply and Stop Sequence**" on **Page 12**.

[c f] Refer "**SD Card Initialization and Identification**" on **Page 21**.

[d] Refer "**SD Changing Bus Speed Mode**" on **Page 32**.

46.2.2.6.2 eMMC Card Interface Setup

The eMMC card interface setup sequence involves the procedure to apply the power to the bus, change the eMMC clock frequency, supply the SD clock and finally, perform the card initialization.

Figure 755 shows the programming sequence to set up an eMMC device.

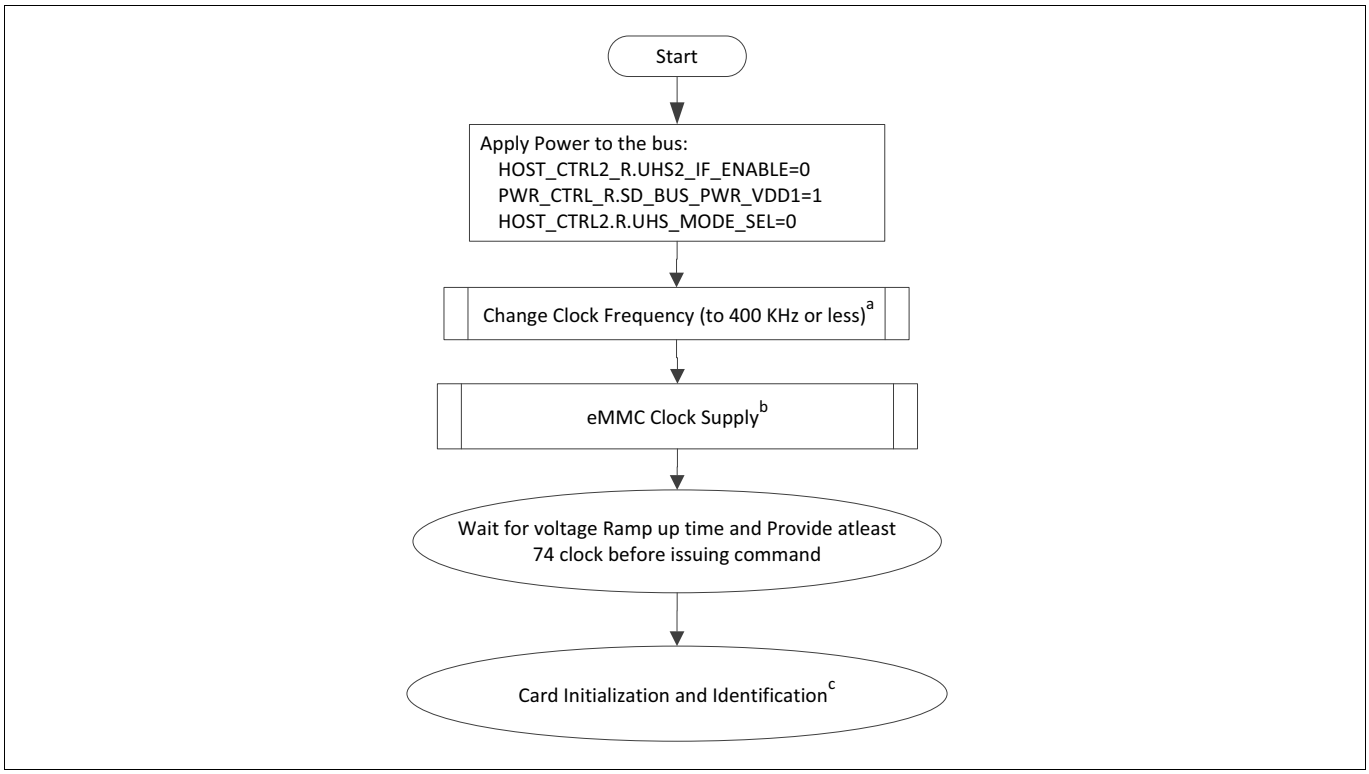

Figure 755 eMMC Card Interrupt Setup Sequence

[a] Refer the programming sequence "**SD Changing Bus Speed Mode**" on **Page 32**.

[b] Refer the programming sequence "Refer "**Card Clock Supply and Stop Sequence**" on **Page 12**."

[c] Refer the programming sequence **SD Card Initialization and Identification**" on **Page 21**.

46.2.2.7 Timeout Setting for an SD/eMMC Bus

To detect timeout errors, DWC_mshc must calculate a divisor using the Capabilities register, and as per the divisor value, set the data timeout counter value.

Figure 756 shows the timeout setting for an SD/eMMC bus.

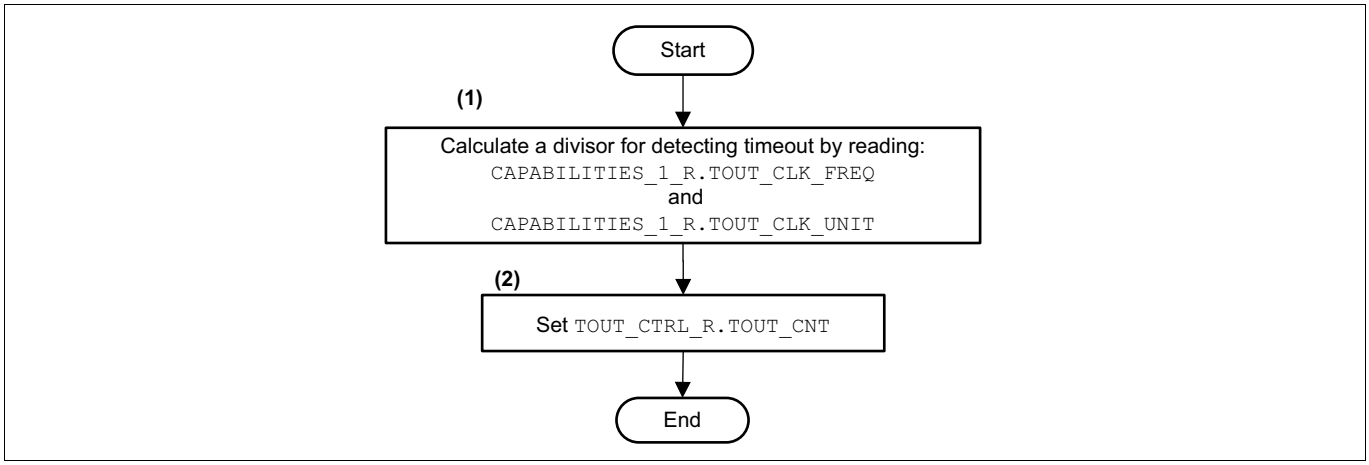

Figure 756 Timeout Setting Sequence for an SD/eMMC Bus

46.2.2.8 Abort Transaction

An abort command to the card is issued to abort an ongoing data transaction. To abort a transaction on an SD or eMMC card, CMD12 is issued, whereas to abort a transaction on an SDIO card, CMD52 is issued.

Following are the instances when an abort command must be issued:

- To stop an infinite block transfer
- To stop transfer due to a request from an application
- To stop a transfer due to an error detection

The sequence to issue an abort command is shown in “Abort Command Sequence”. An abort command can be issued synchronously or asynchronously during data transfer. In asynchronous abort, abort command is issued at any time irrespective of the state of data transfer as a subcommand.

Synchronous abort ensures that the data transfer is stopped (at block gap) before issuing an abort command. Both methods are explained in “Asynchronous Abort” and “Synchronous Abort” respectively.

This section discusses the following sequences:

- **Abort Command Sequence** on page **Page 17**
- **Asynchronous Abort** on page **Page 18**
- **Synchronous Abort** on page **Page 19**

46.2.2.8.1 Abort Command Sequence

Figure 757 shows the abort command sequence.

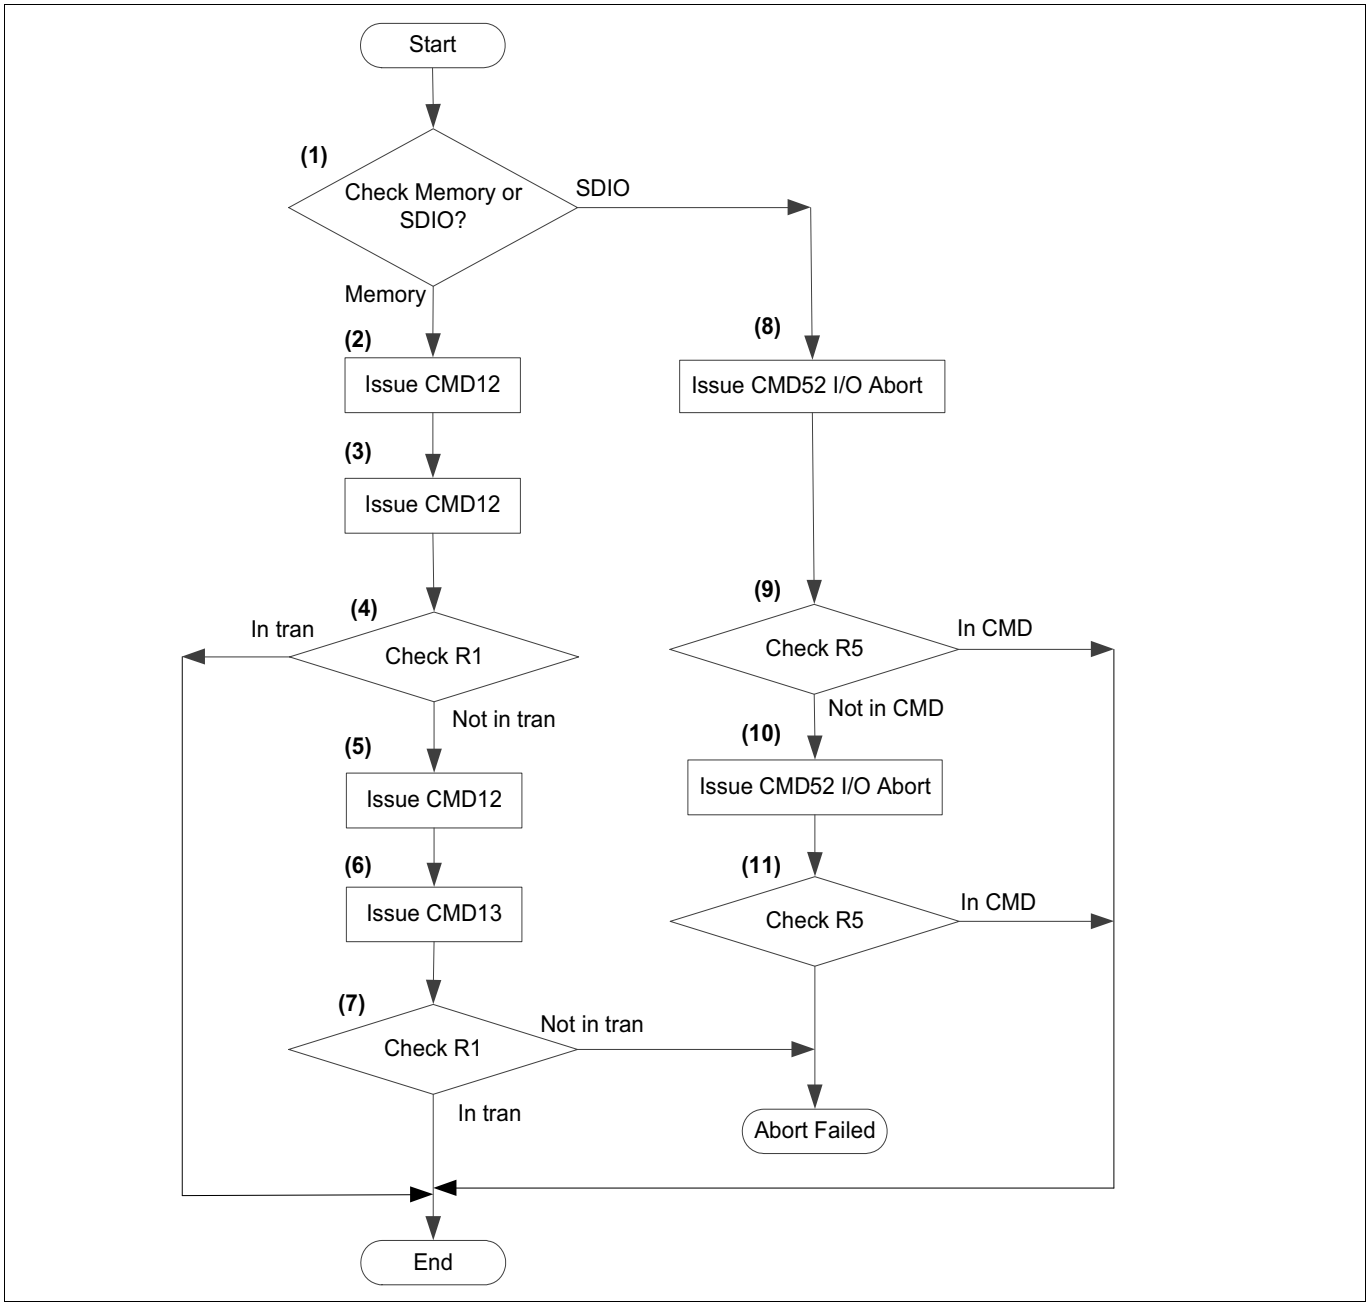

Figure 757 Abort Command Sequence

46.2.2.8.2 Asynchronous Abort

Figure 758 shows the asynchronous abort.

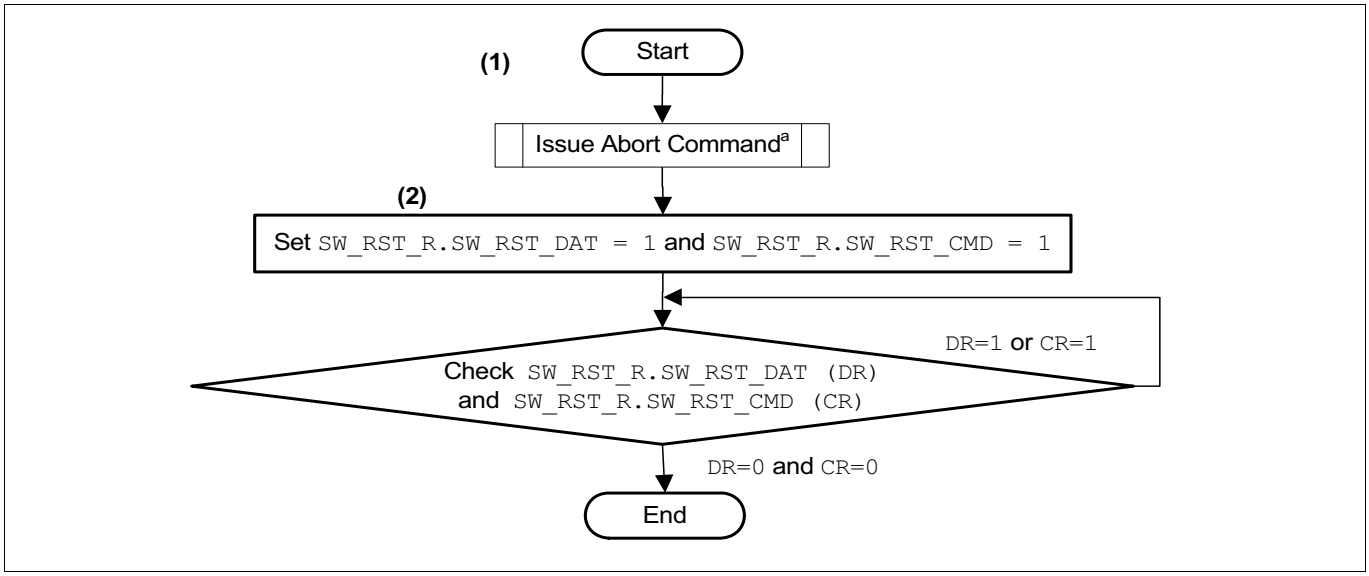

Figure 758 Asynchronous Abort Sequence

[a] Refer "**Abort Command Sequence**" on **Page 17**.

46.2.2.8.3 Synchronous Abort

Figure 759 shows the synchronous abort.

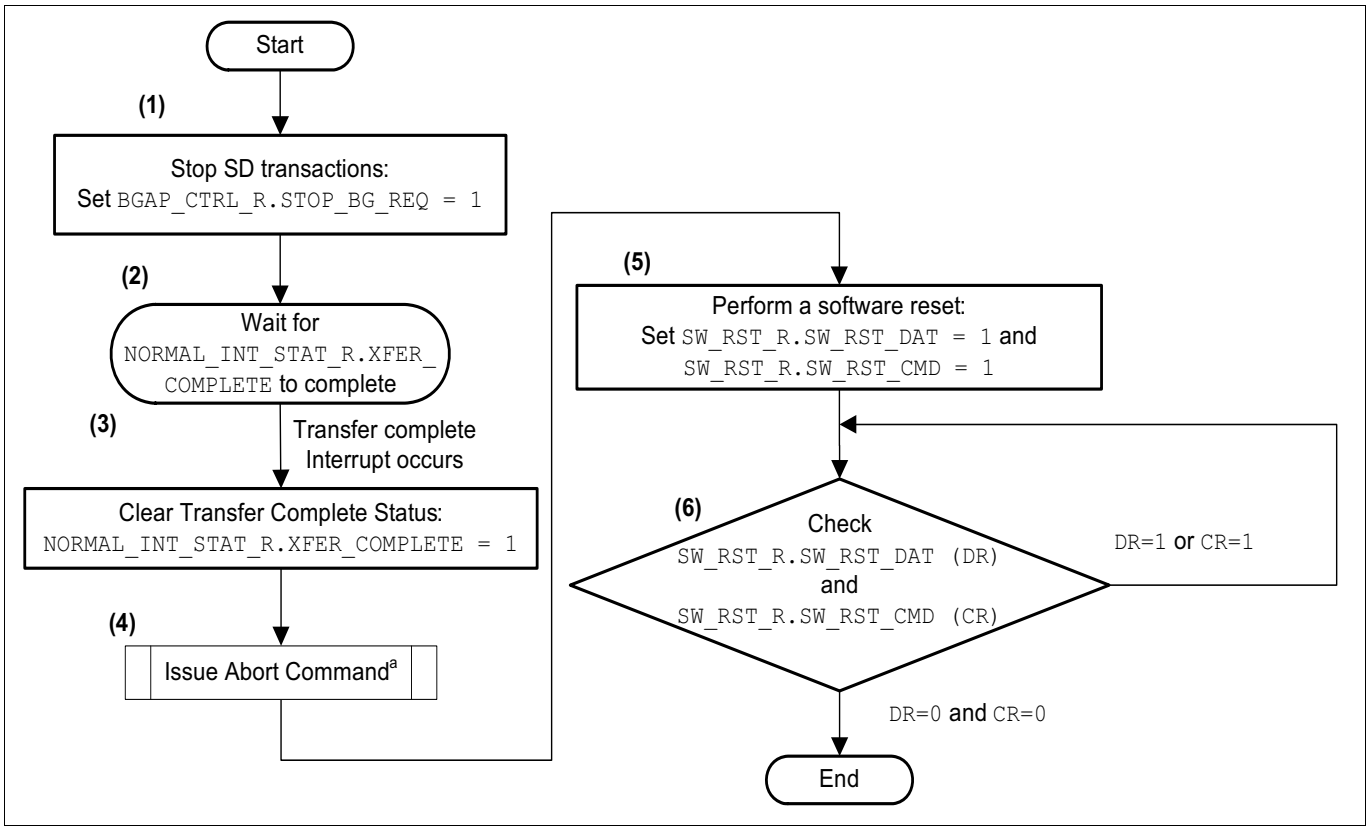

Figure 759 Synchronous Abort Sequence

[a] Refer "**Abort Command Sequence**" on **Page 17**.

46.2.2.9 SD/SDIO Transaction Mode

This section includes the sequences to generate and control different types of SD/SDIO transactions.

This section discusses the following programming sequences:

46.2.2.9.1 SD Card Initialization and Identification

After powering up the SD card, it must be initialized so that the host can start sending commands to the card to perform the data transfer.

Figure 760 and **Figure 761** show the sequence for SD card initialization and identification.

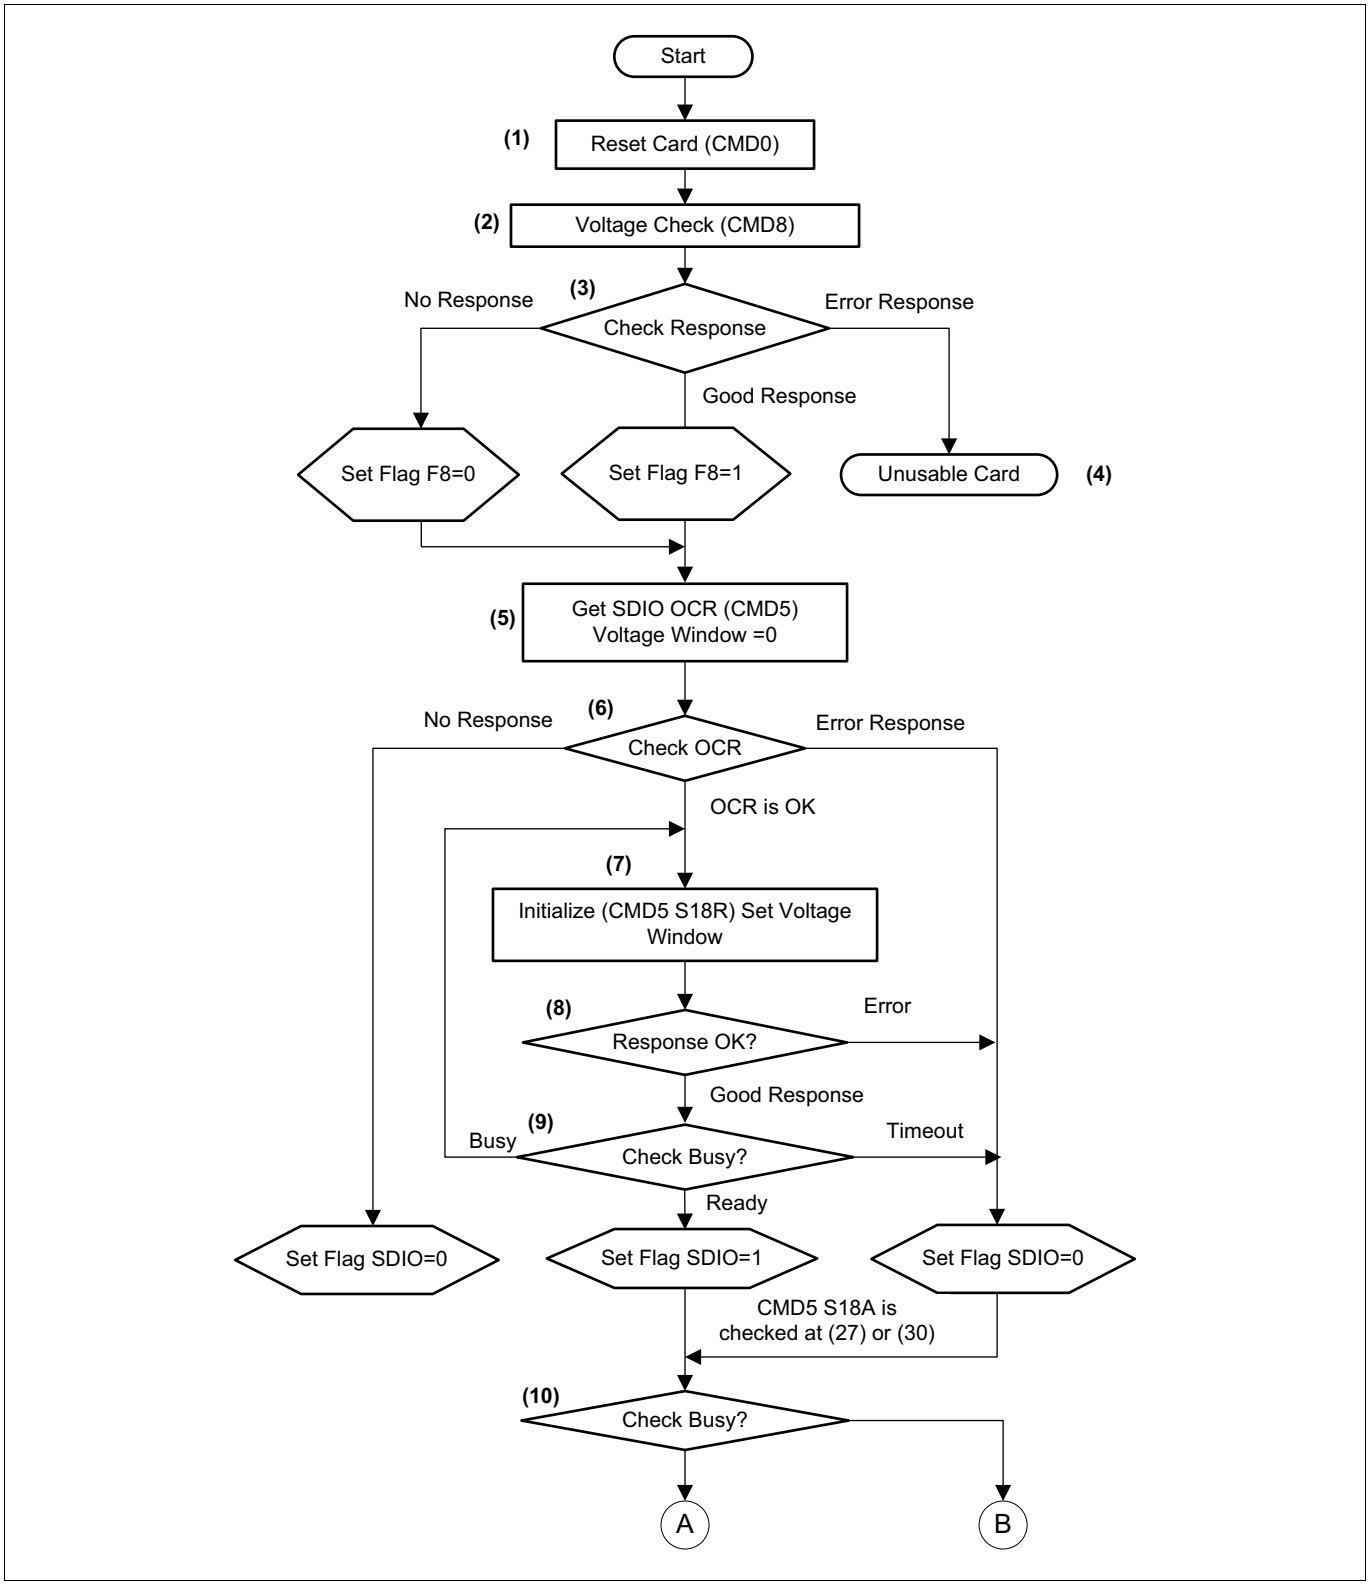

Figure 760 SD Card Initialization and Identification Part 1

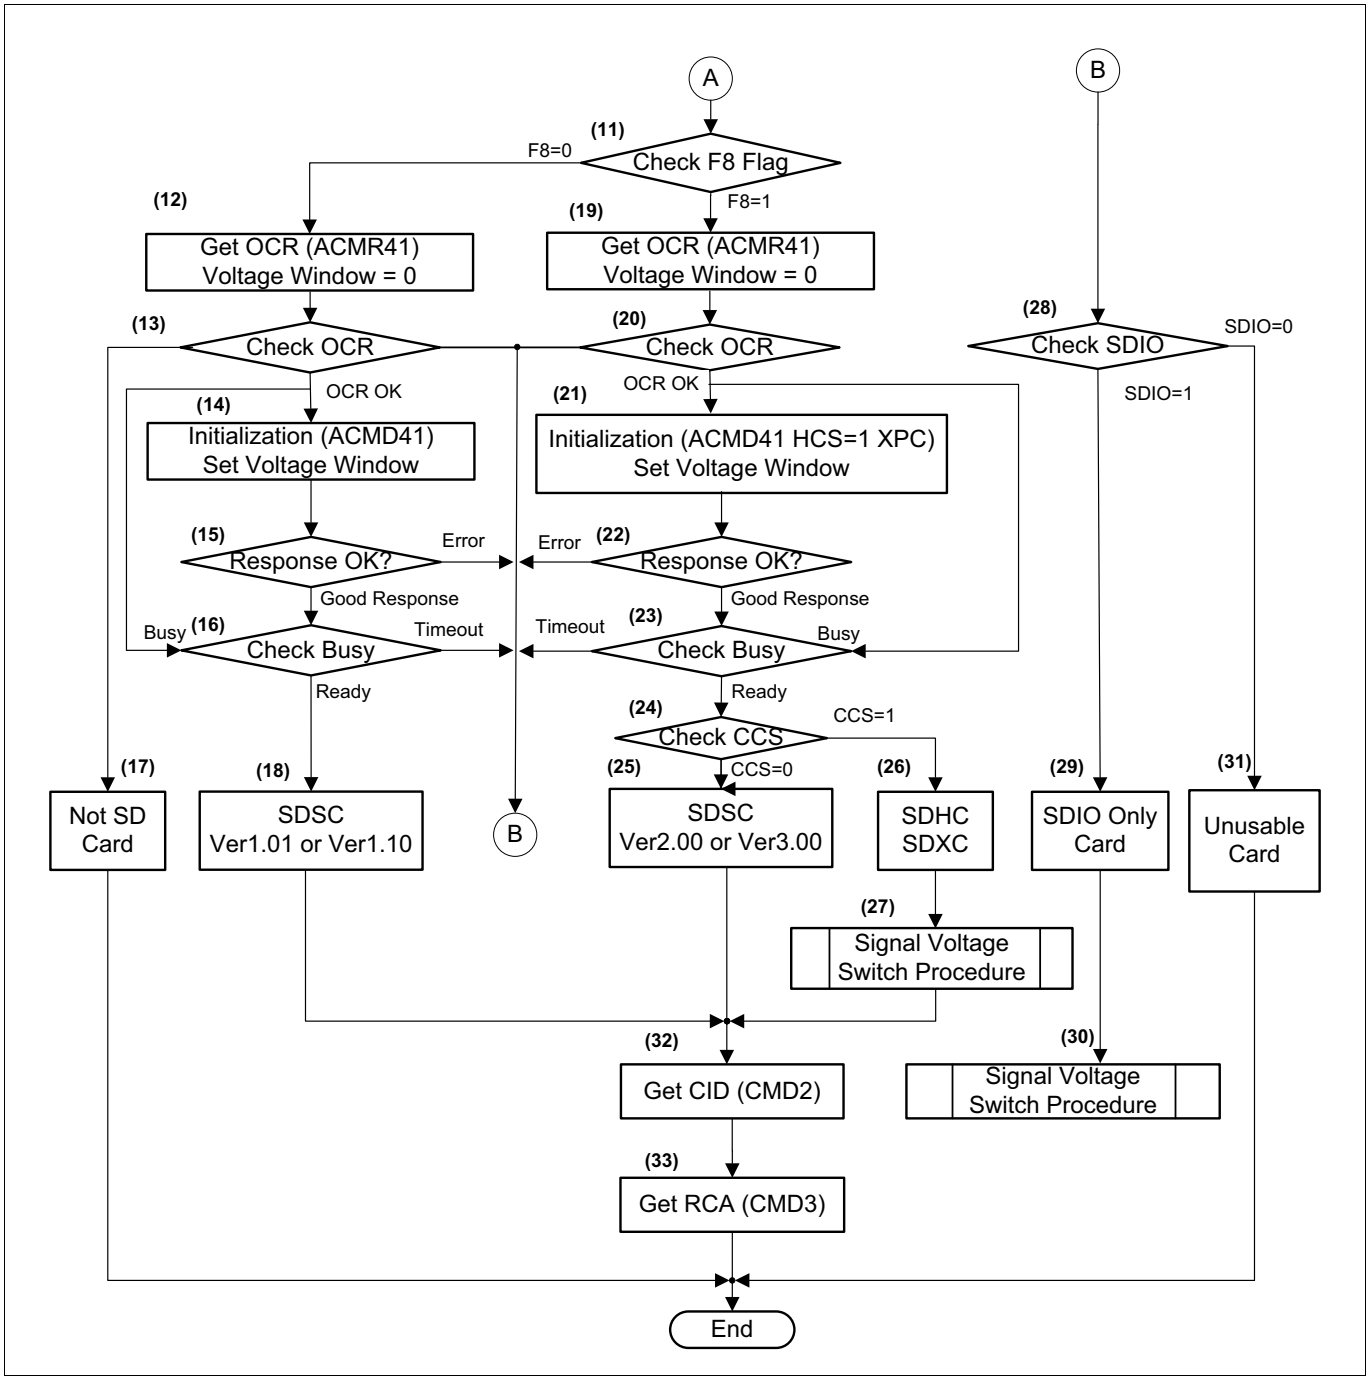

Figure 761 SD Card Initialization and Identification Part 2

Note: During the initialization sequence if the card supports the Read Wait feature, it is recommended that the Read Wait feature be enabled in DWC_mshc by programming the RD_WAIT_CTRL field in BGAP_CTRL_R register.

46.2.2.9.2 Changing SD Bus Width

Based on the data width of the SD card, the host driver must change the data width of the Host controller to 1-bit or 4-bit.

Figure 762 shows the sequence for changing data bus bit mode on an SD Bus.

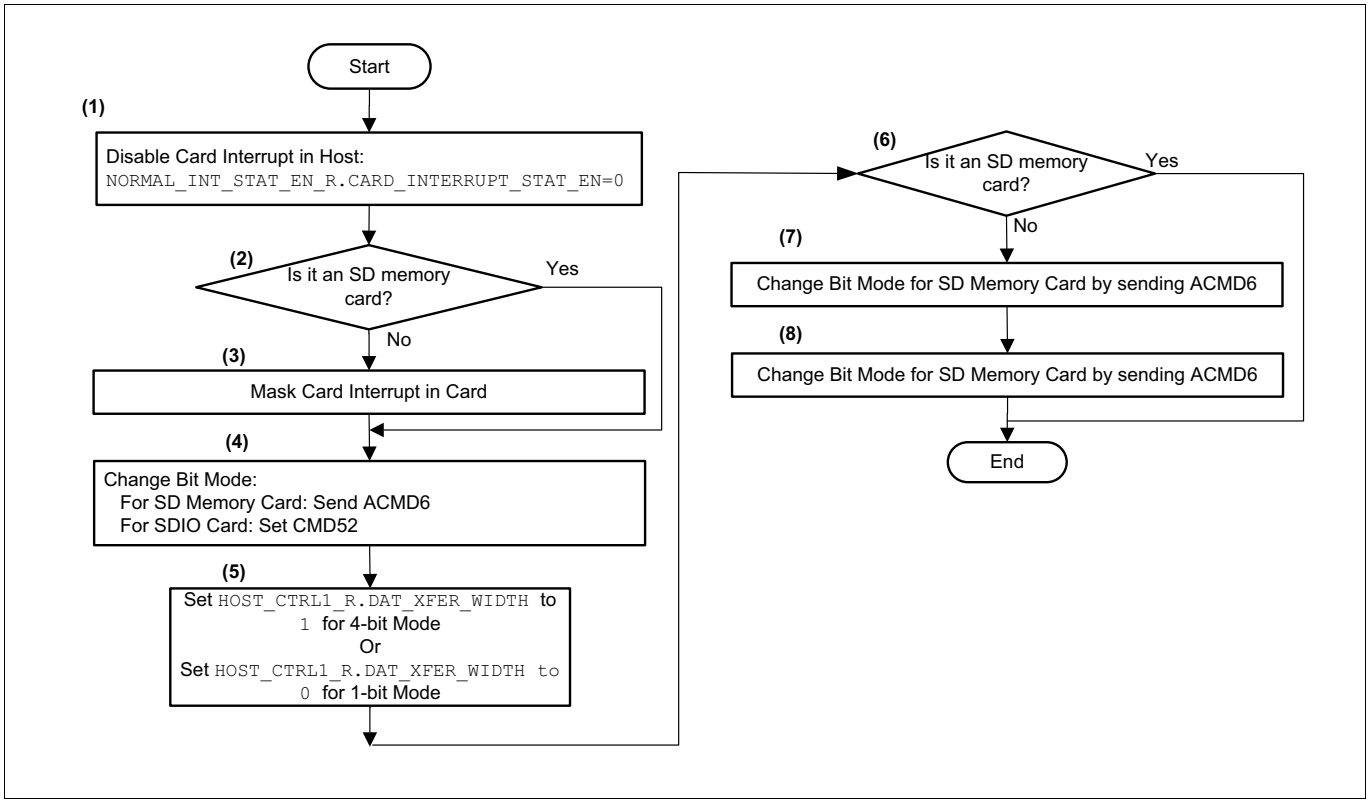

Figure 762 Changing SD Bus Width Sequence

46.2.2.9.3 SD Bus Power Control

In order to control the bus power of the card, the maximum voltage that the Host controller supports must be set and this voltage is selected by the host driver for an SD card.

Figure 763 shows the sequence for controlling the SD Bus Power.

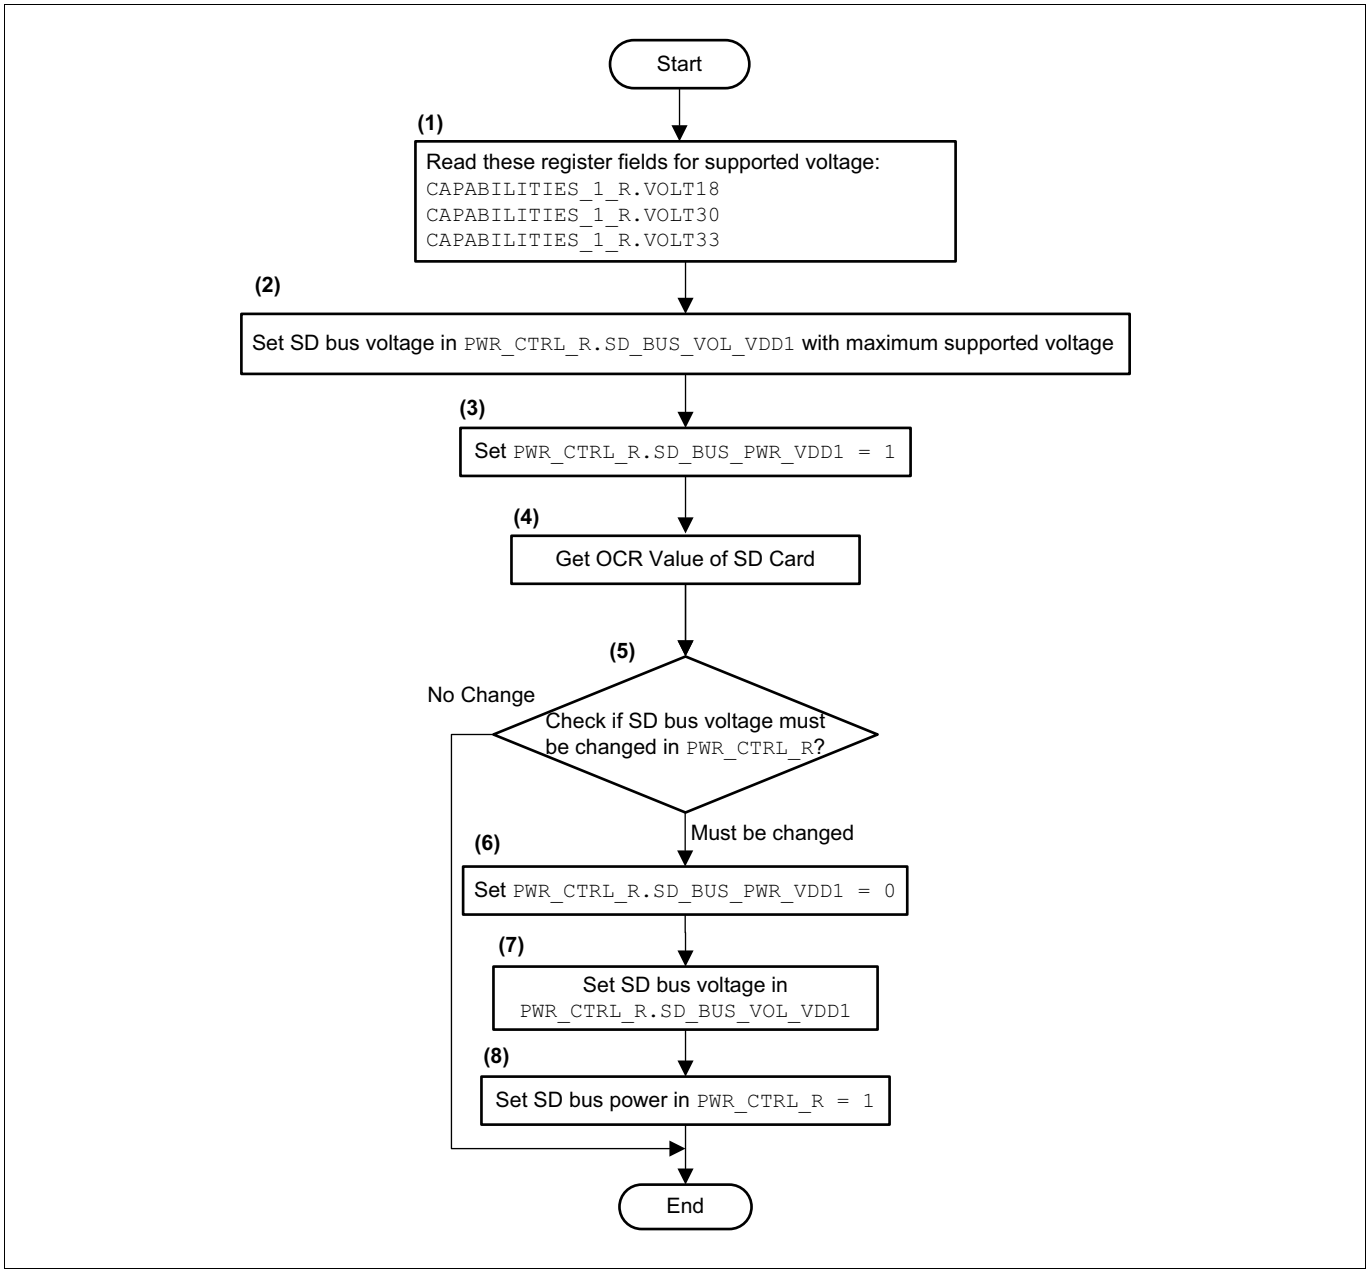

Figure 763 SD Bus Power Control Sequence

46.2.2.9.4 Issuing CMD Without Data Transfer

An SD command may or may not use the data line (DAT) for data transfer.

Figure 764 shows the sequence on how to issue and complete an SD command using the data line and without transferring any data.

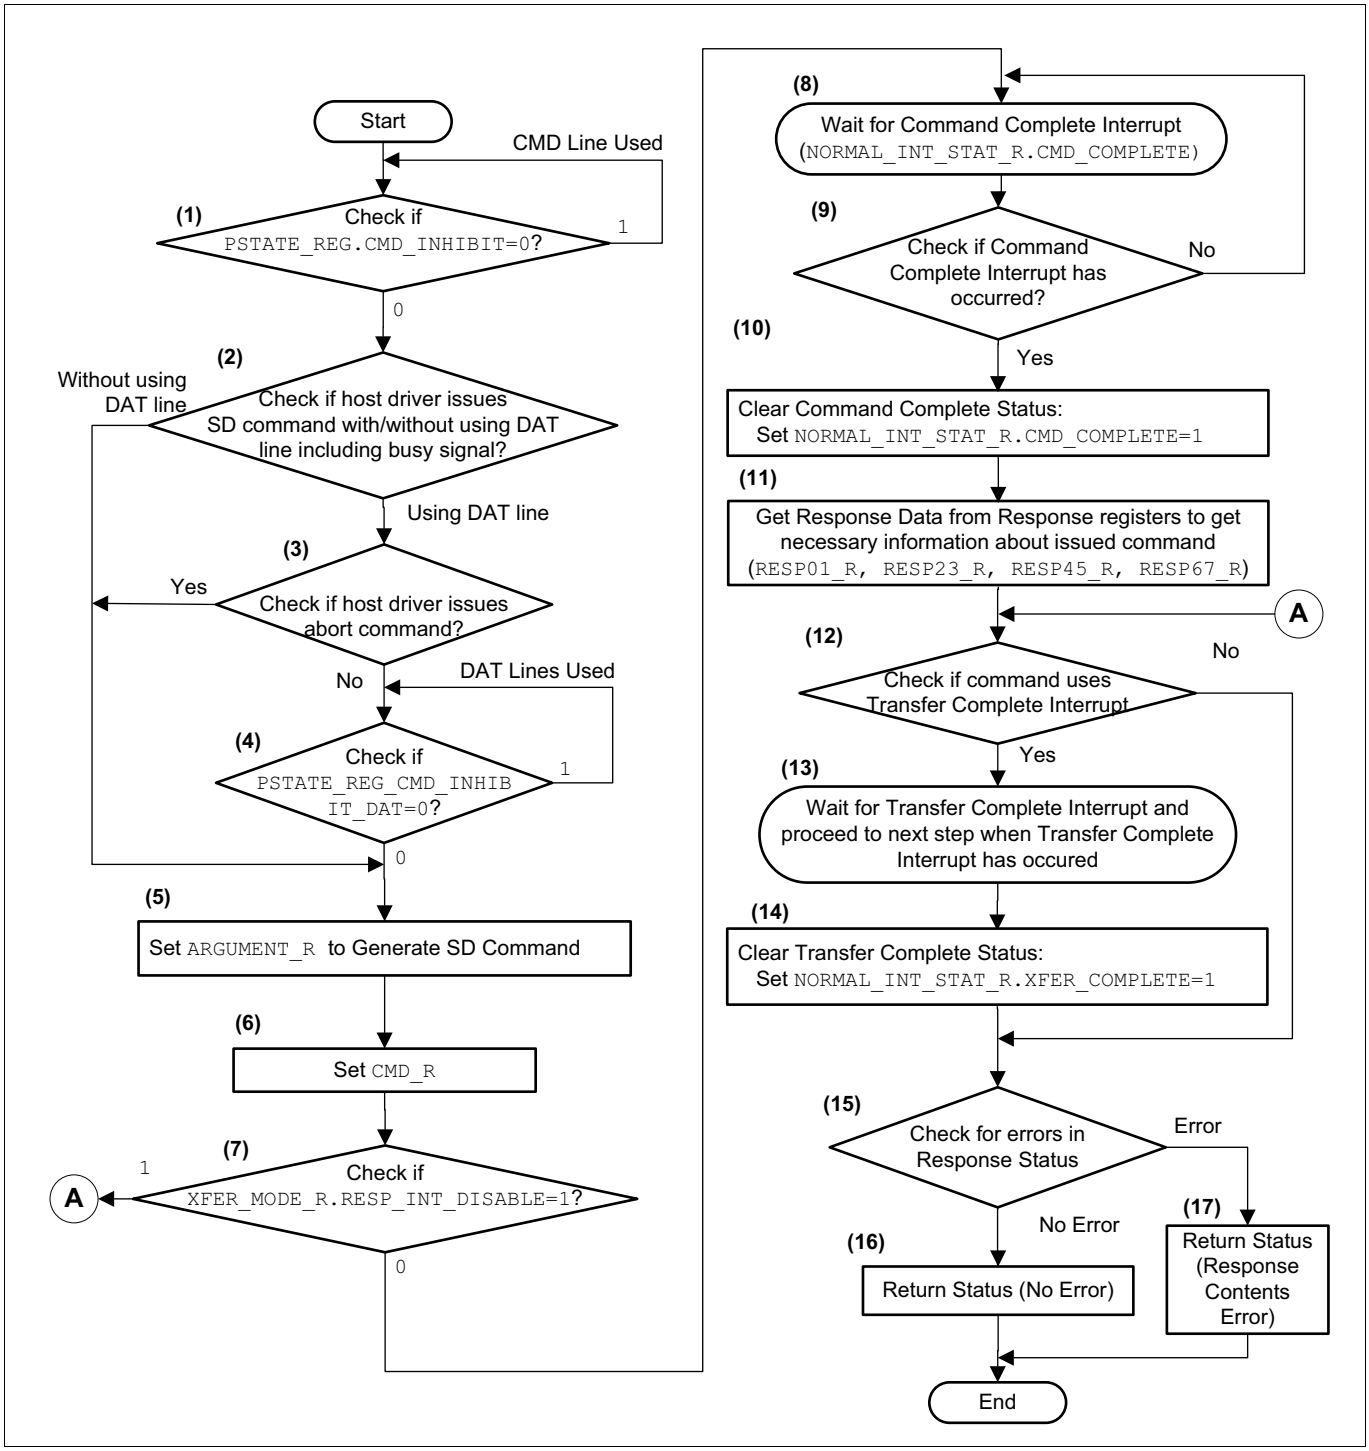

Figure 764 SD Command Issue and Complete

46.2.2.9.5 Issuing CMD with Data Transfer (Not Using DMA/PIO)

An SD command can perform data transfer on a DAT line with or without using DMA/PIO method.

Figure 765 and **Figure 766** show the transaction that does not use DMA or Programmed Input/Output (PIO) method for data transfer using the DAT line.

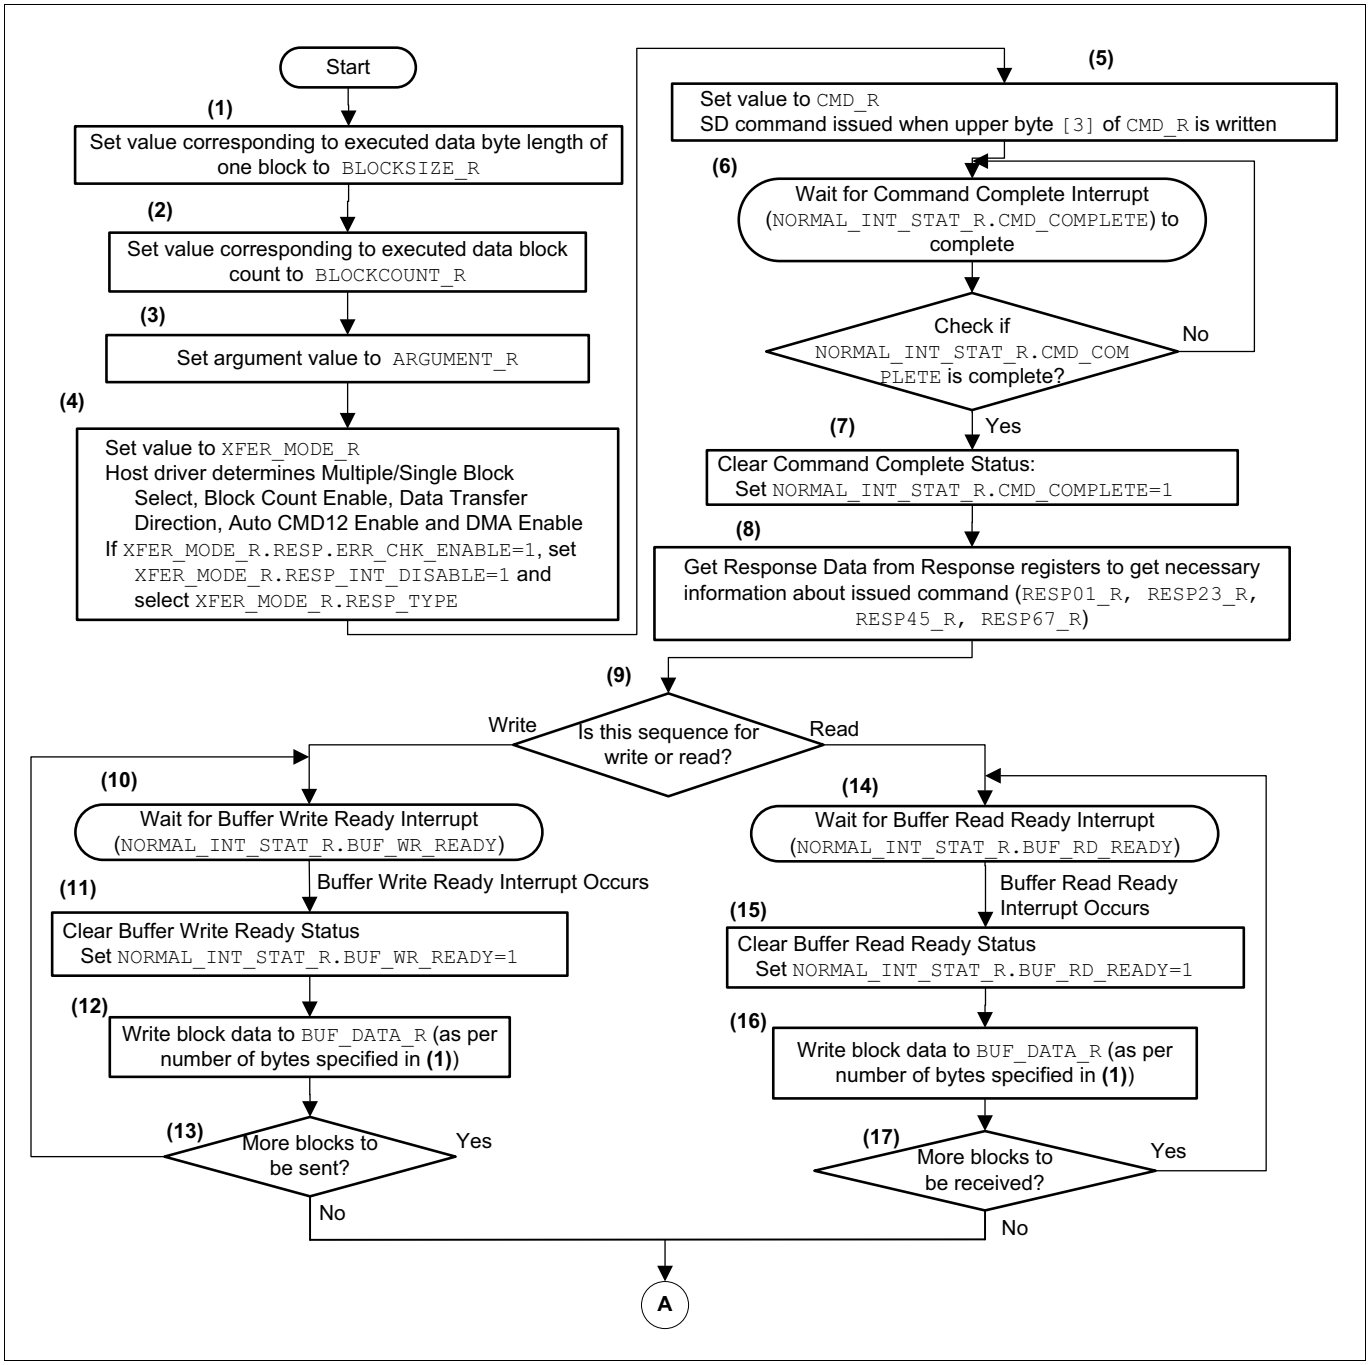

Figure 765 Transaction Control with Data Transfer Using DAT Line (Not Using DMA/PIO) Part 1

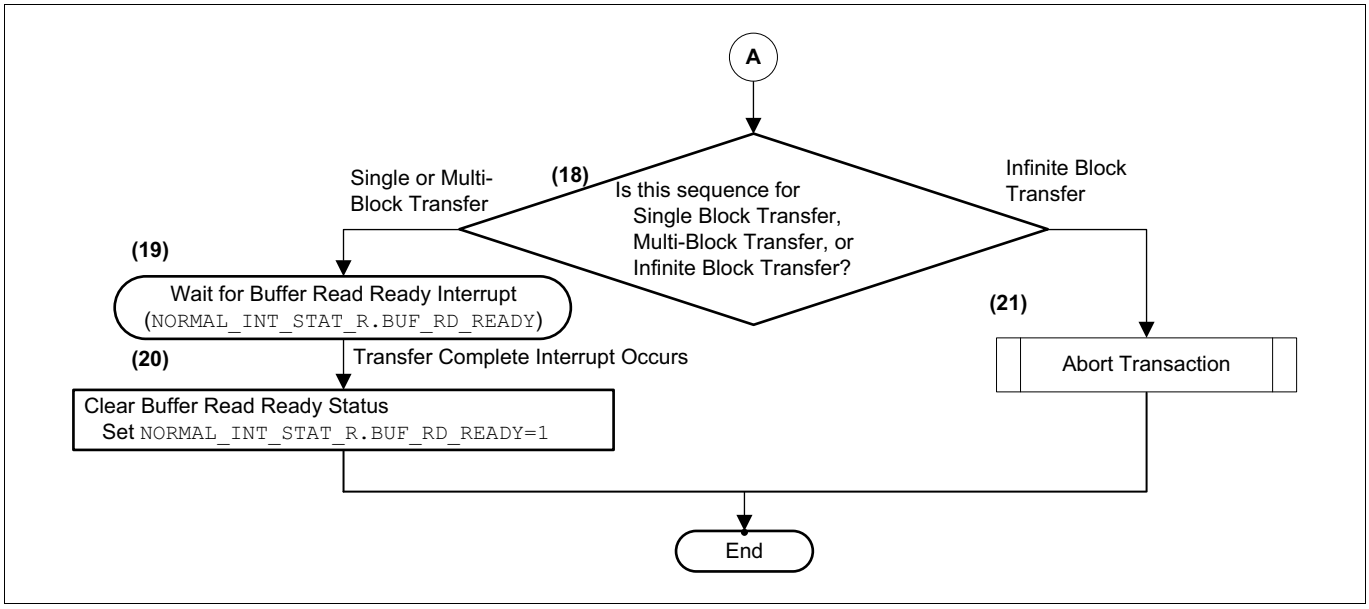

Figure 766 Transaction Control with Data Transfer Using DAT Line (Not Using DMA/PIO) Part 2

46.2.2.9.6 Issuing CMD with Data Transfer (Using SDMA)

When an SD command uses Single operation DMA (SDMA) for data transfer using the DATA line, only single SD command transaction can be executed for each SDMA operation. SDMA is appropriate for short data transfer.

Figure 767 shows the transaction that uses SDMA for data transfer using the DAT line.

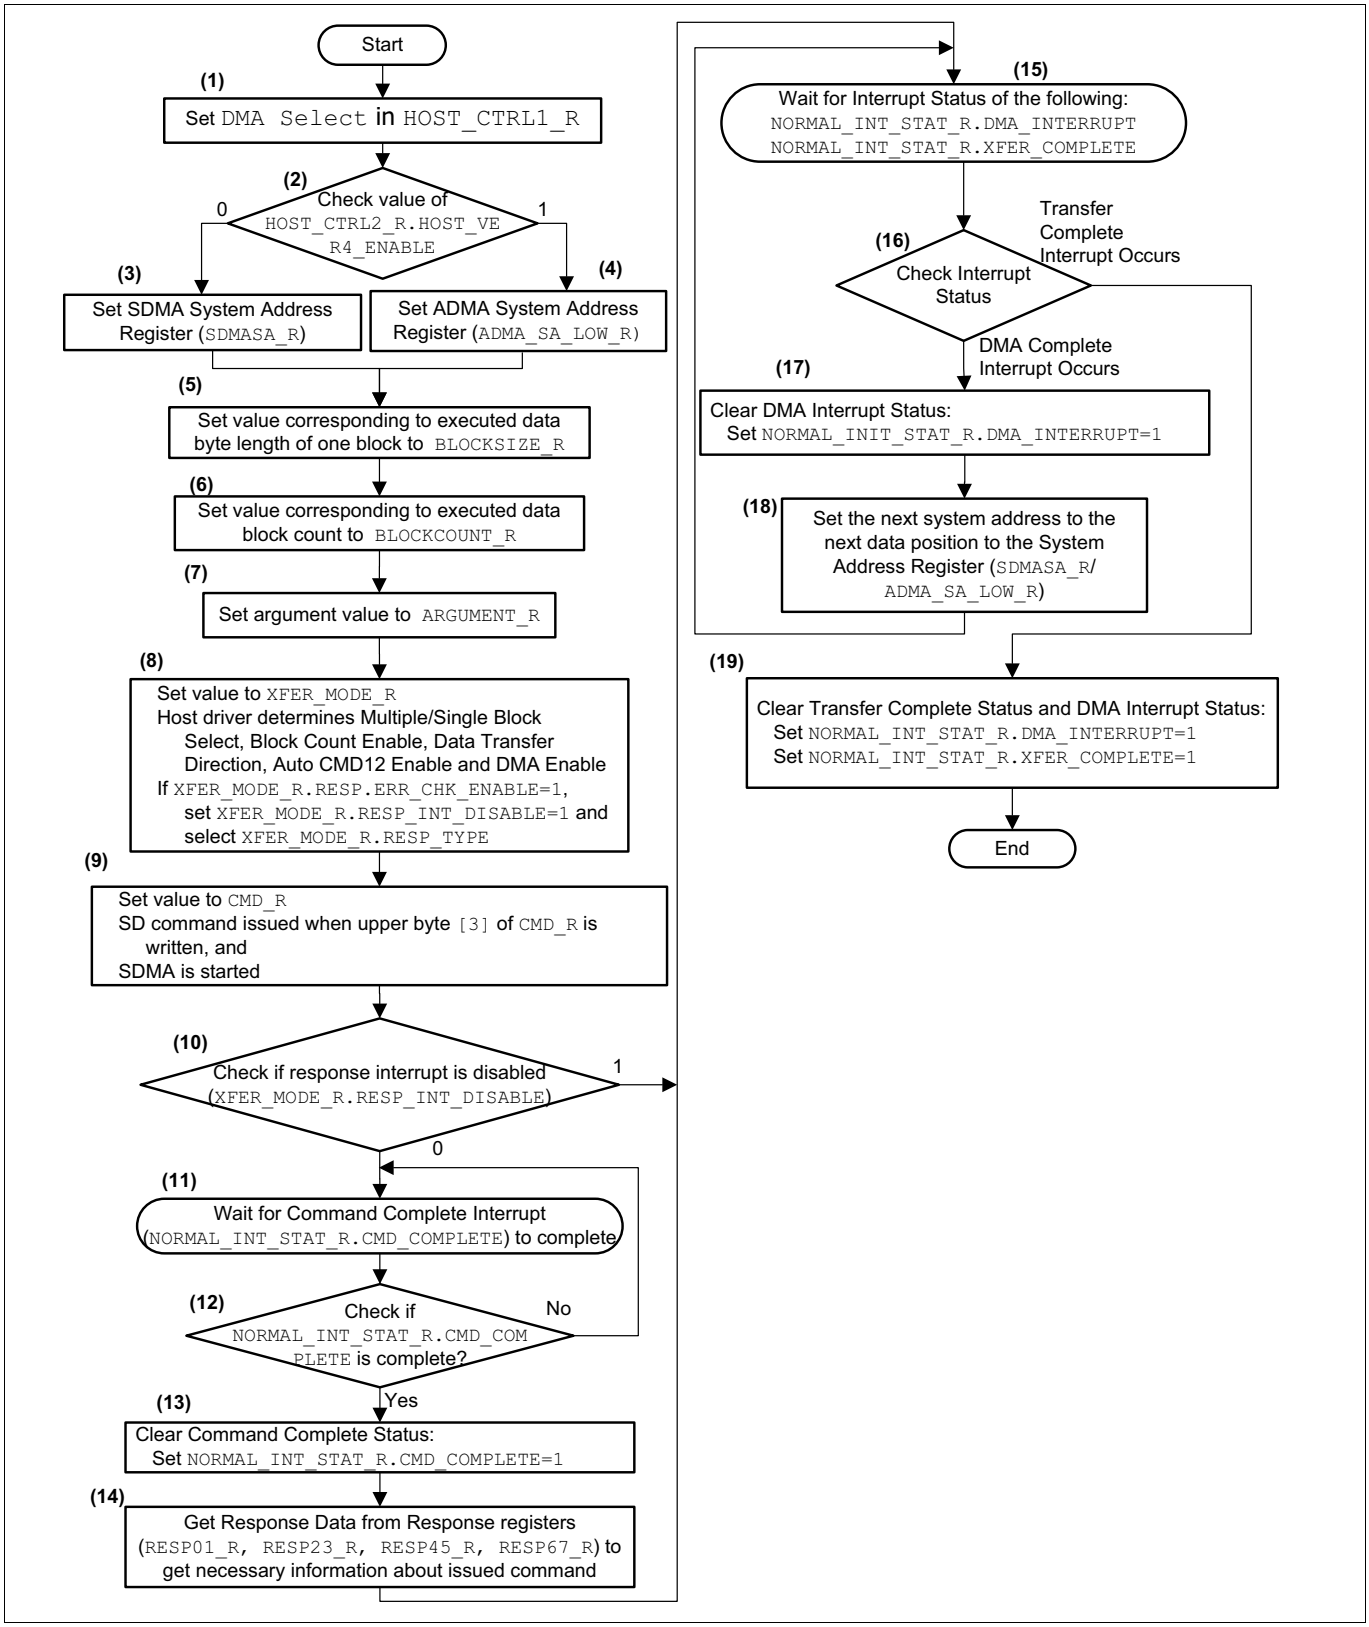

Figure 767 Transaction Control with Data Transfer using SDMA

46.2.2.9.7 Issuing CMD with Data Transfer (Using ADMA2)

ADMA2 is one of the DMA transfer types that can be used for lengthy data transfers. DWC_mshc supports the ADMA2 algorithm for data transfer between the system memory and the SD card without interrupting CPU operation. Therefore, ADMA is appropriate for lengthy data transfers. ADMA2 uses the scatter gather DMA algorithm to obtain high data transfer speed.

Figure 768 and **Figure 769** show the transaction that uses ADMA2 for data transfer using the DAT line.

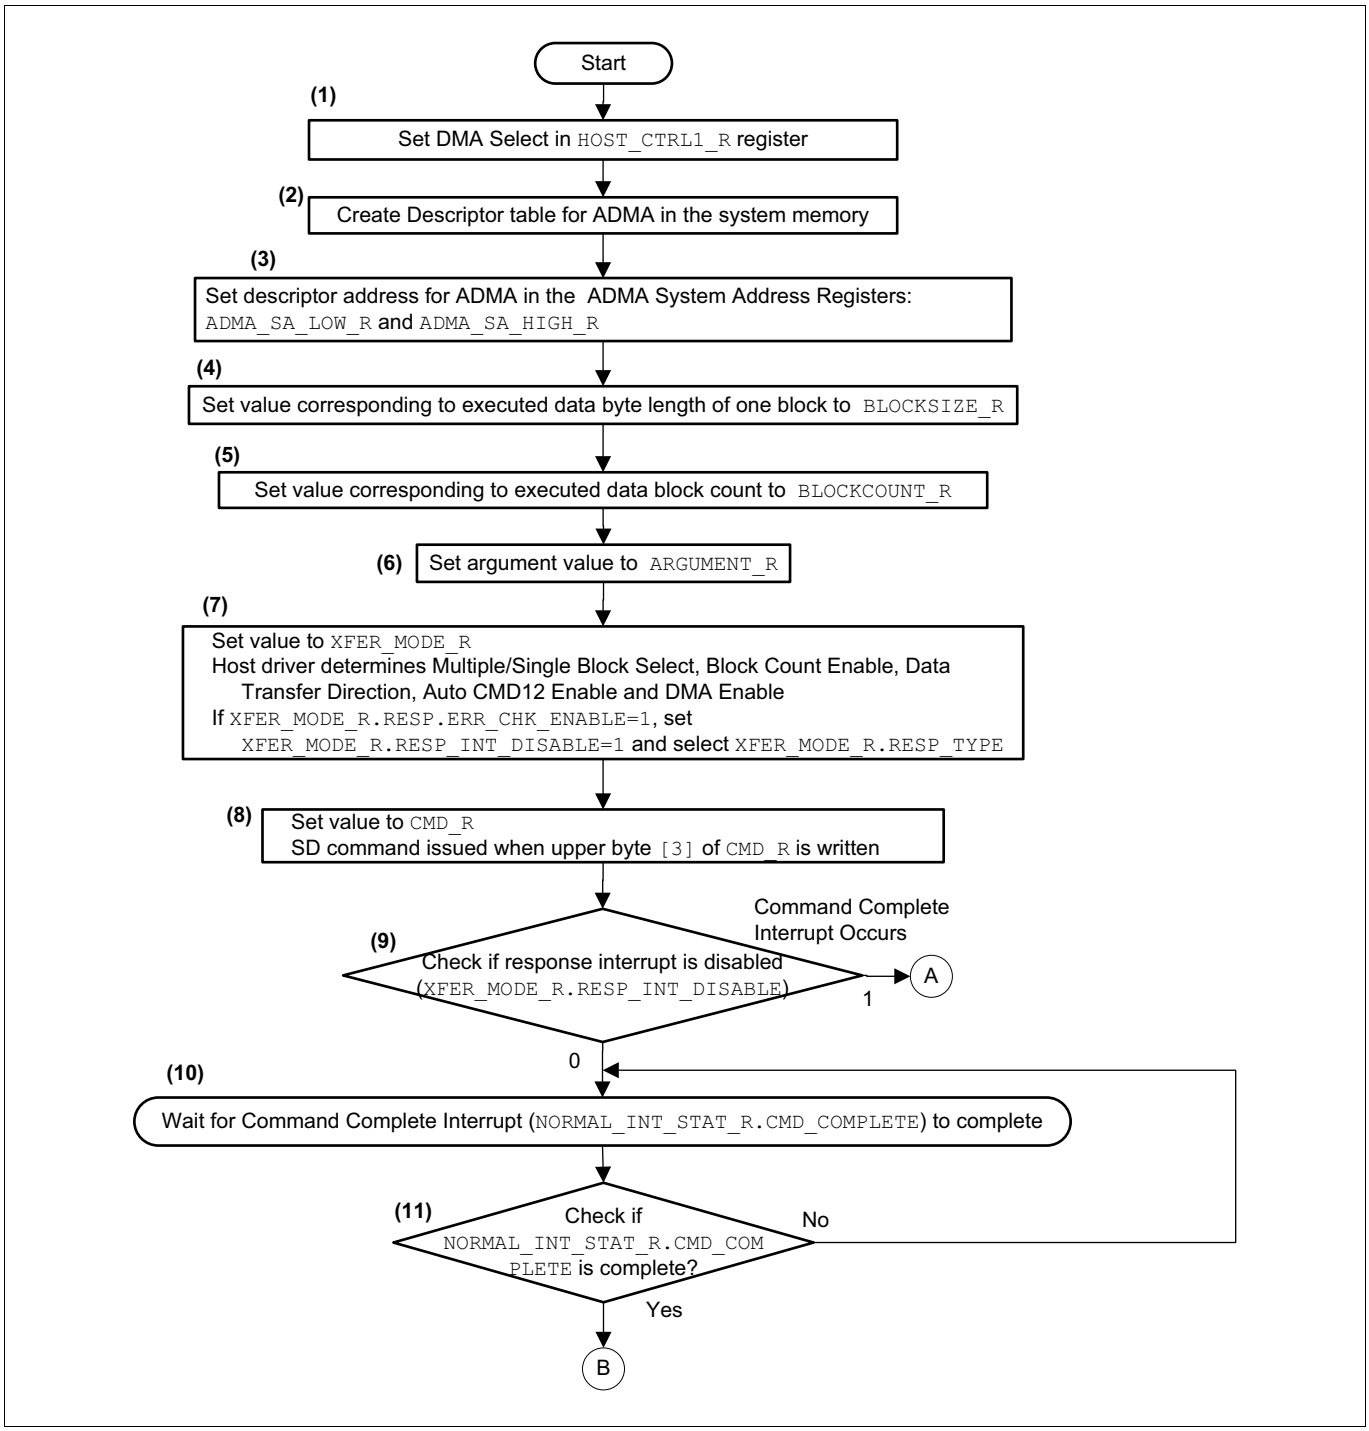

Figure 768 Transaction Control with Data Transfer Using DAT Line (Using ADMA2) Part 1

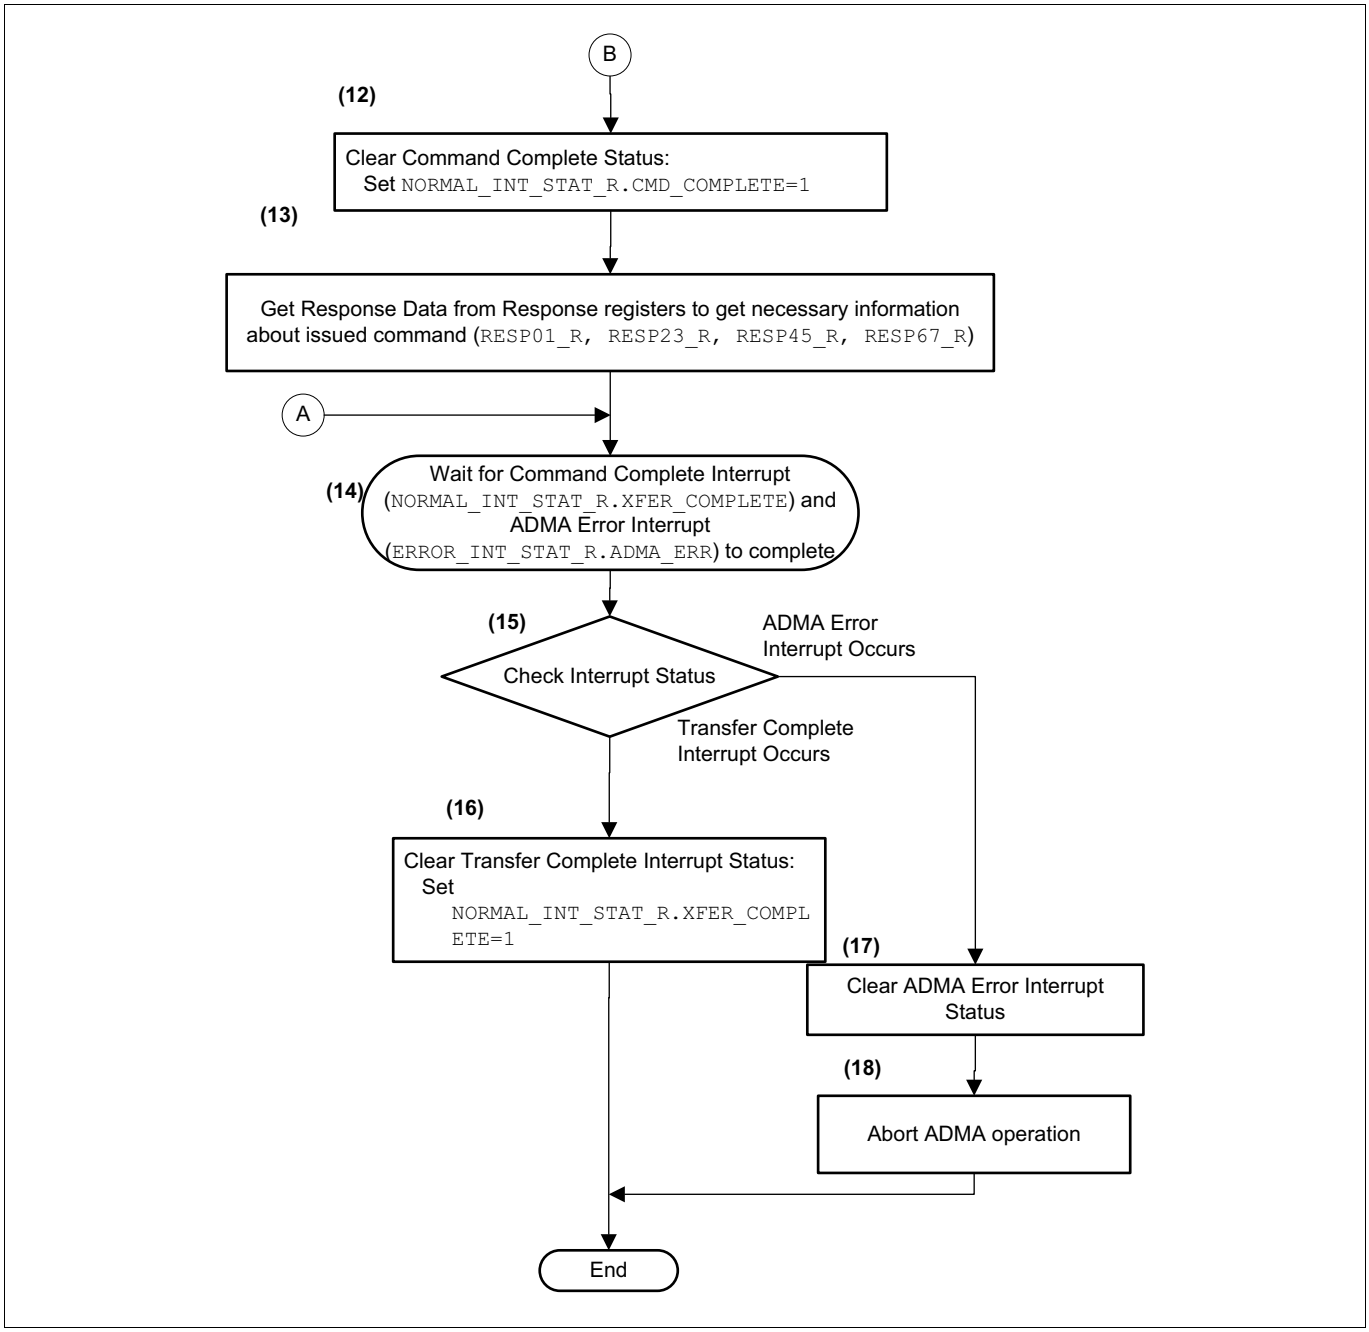

Figure 769 Transaction Control with Data Transfer Using DAT Line (Using ADMA) Part 2

46.2.2.9.8 Issuing CMD with Data Transfer (Using ADMA3)

ADMA3 is one of the DMA transfer types that can be used for very lengthy data transfers. ADMA3 performs multiple read/write SD command operations at a time and uses the scatter gather DMA algorithm to obtain high data transfer speed.

Figure 770 shows the transaction that uses ADMA3 for data transfer using the DAT line.

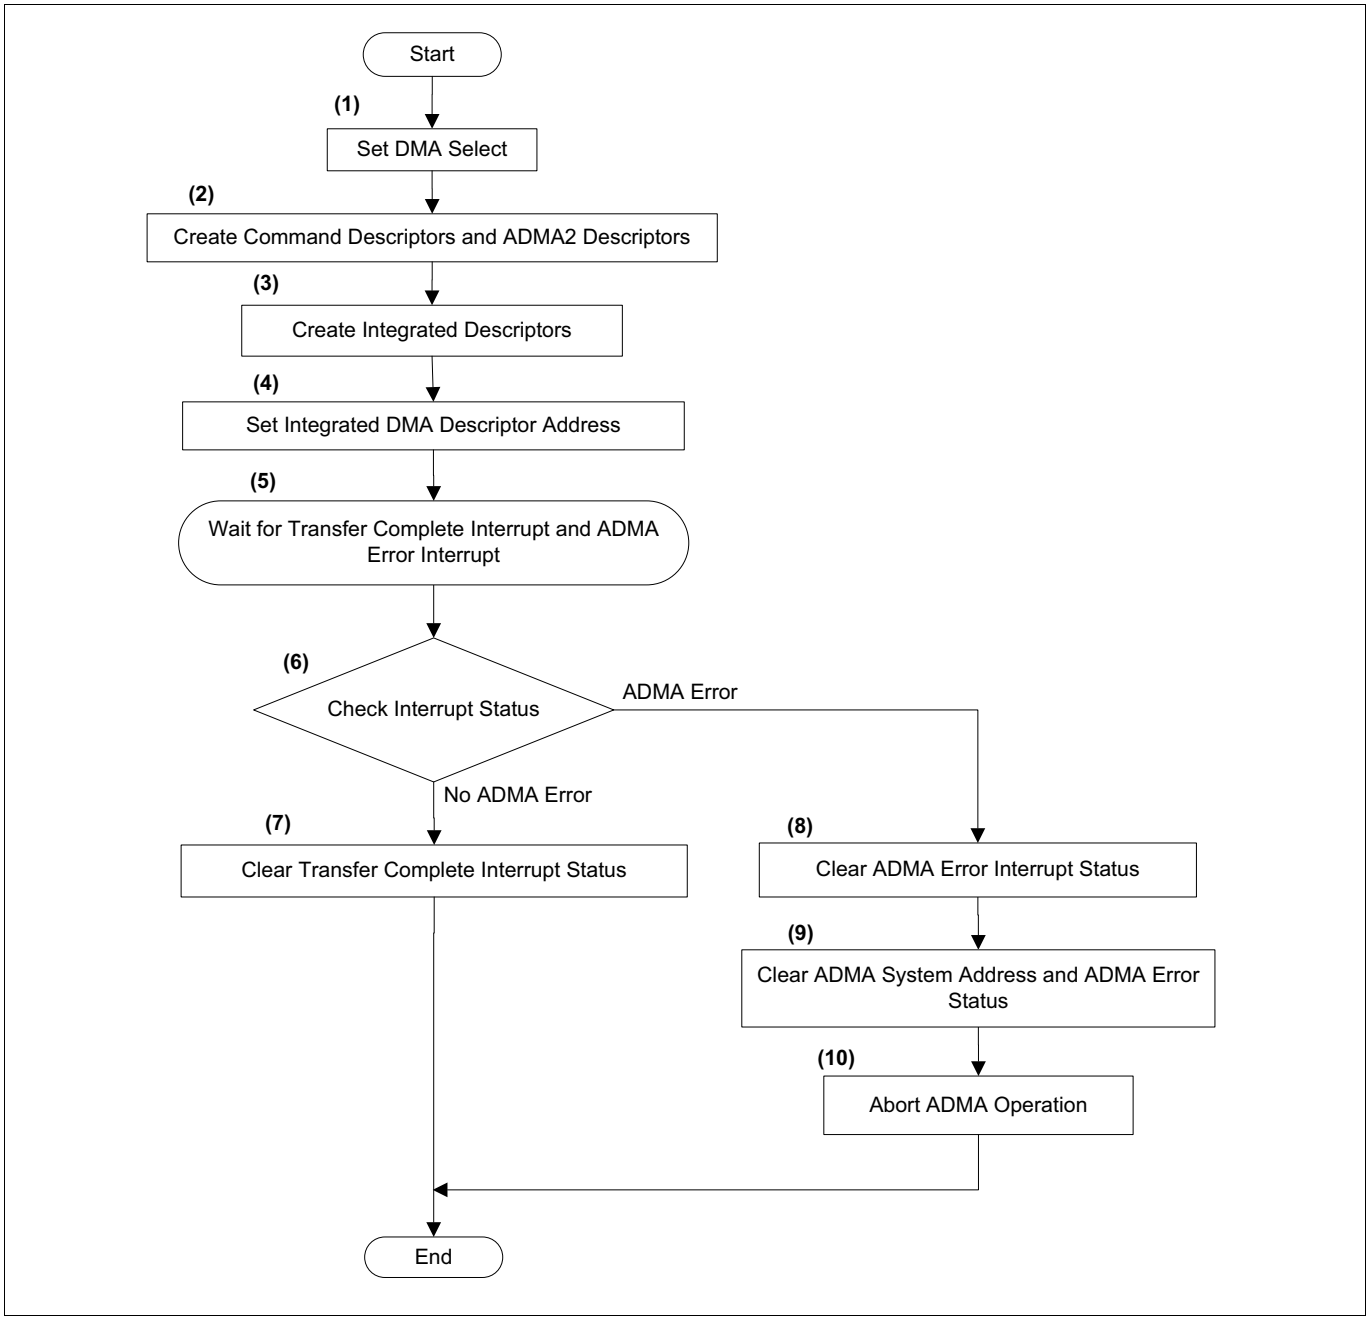

Figure 770 Transaction Control with Data Transfer Using DAT Line (Using ADMA3)

46.2.2.9.9 SD Changing Bus Speed Mode

The SD bus speed mode of the controller must be changed to match the host driver speed mode. The switch command (CMD6) is used to change the bus speed mode. The different bus speed modes are default speed (DS) mode and high speed (HS) mode.

Figure 771 shows the procedure to change the bus speed mode for an SD card.

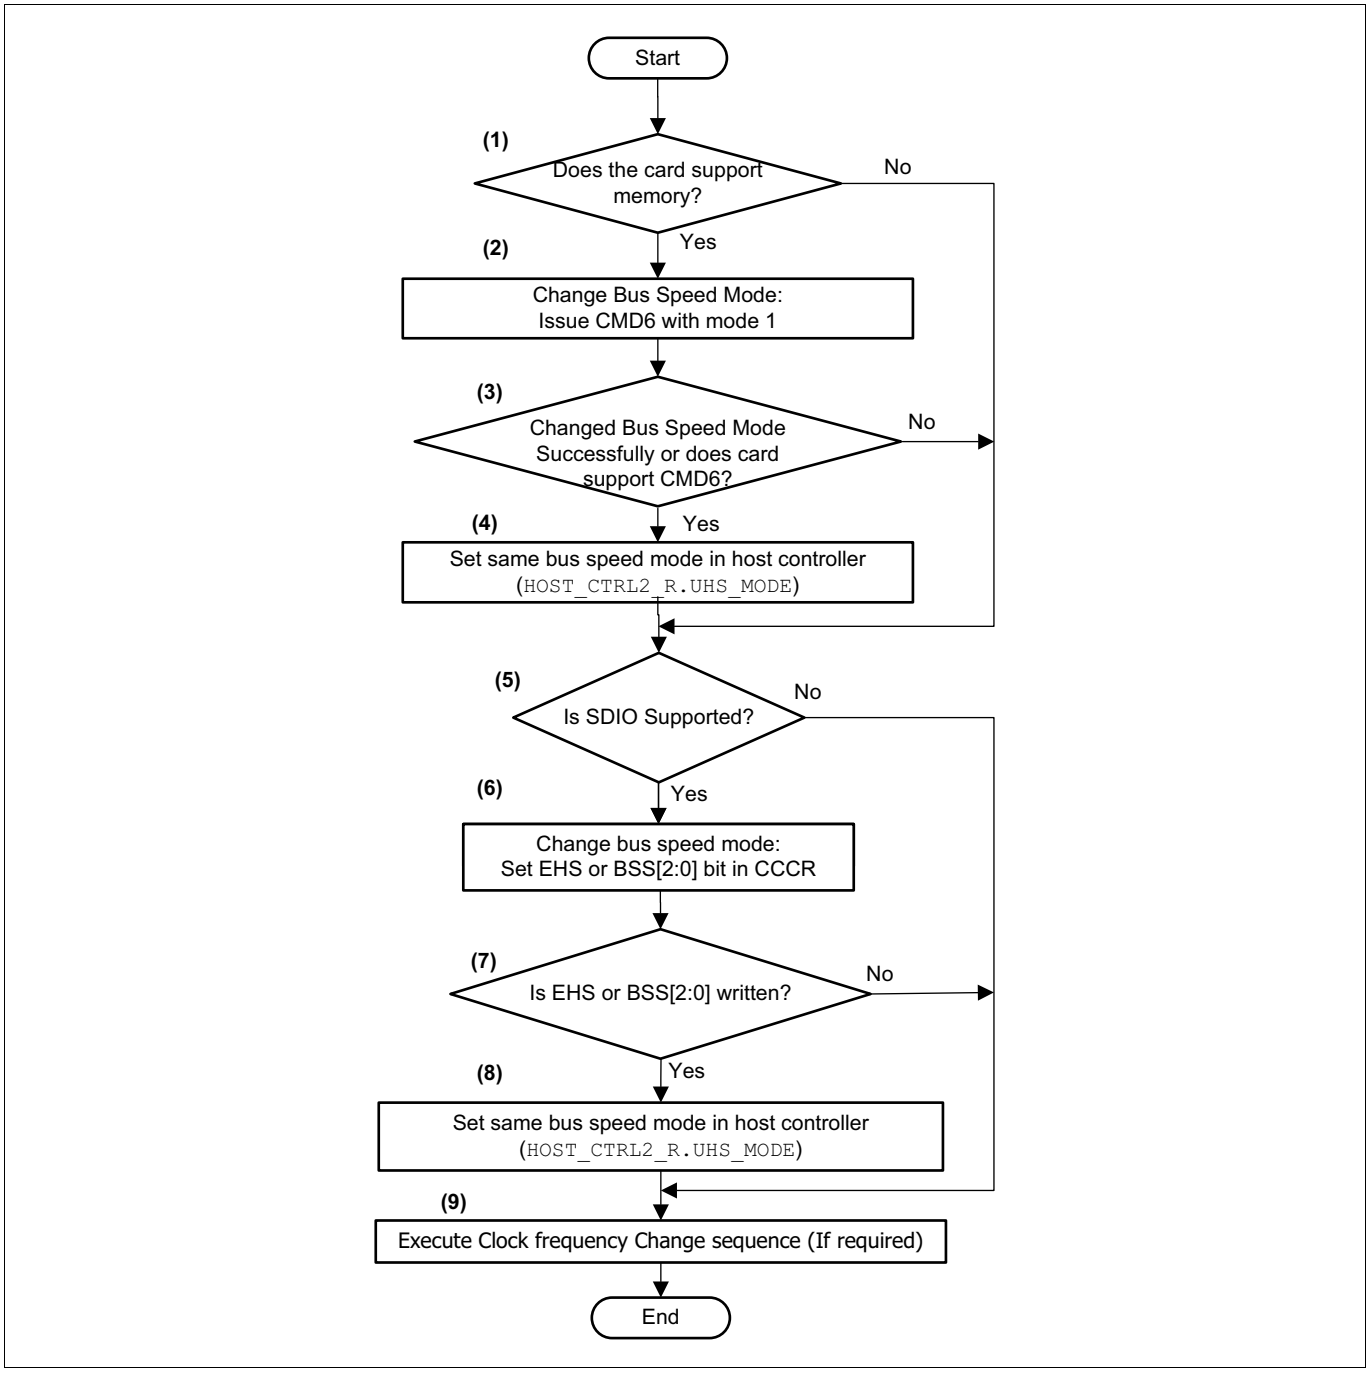

Figure 771 Changing Bus Speed Mode for SD Card

46.2.2.9.10 SDIO Card Interrupt

This section discusses the sequence for including an SDIO card interrupt.

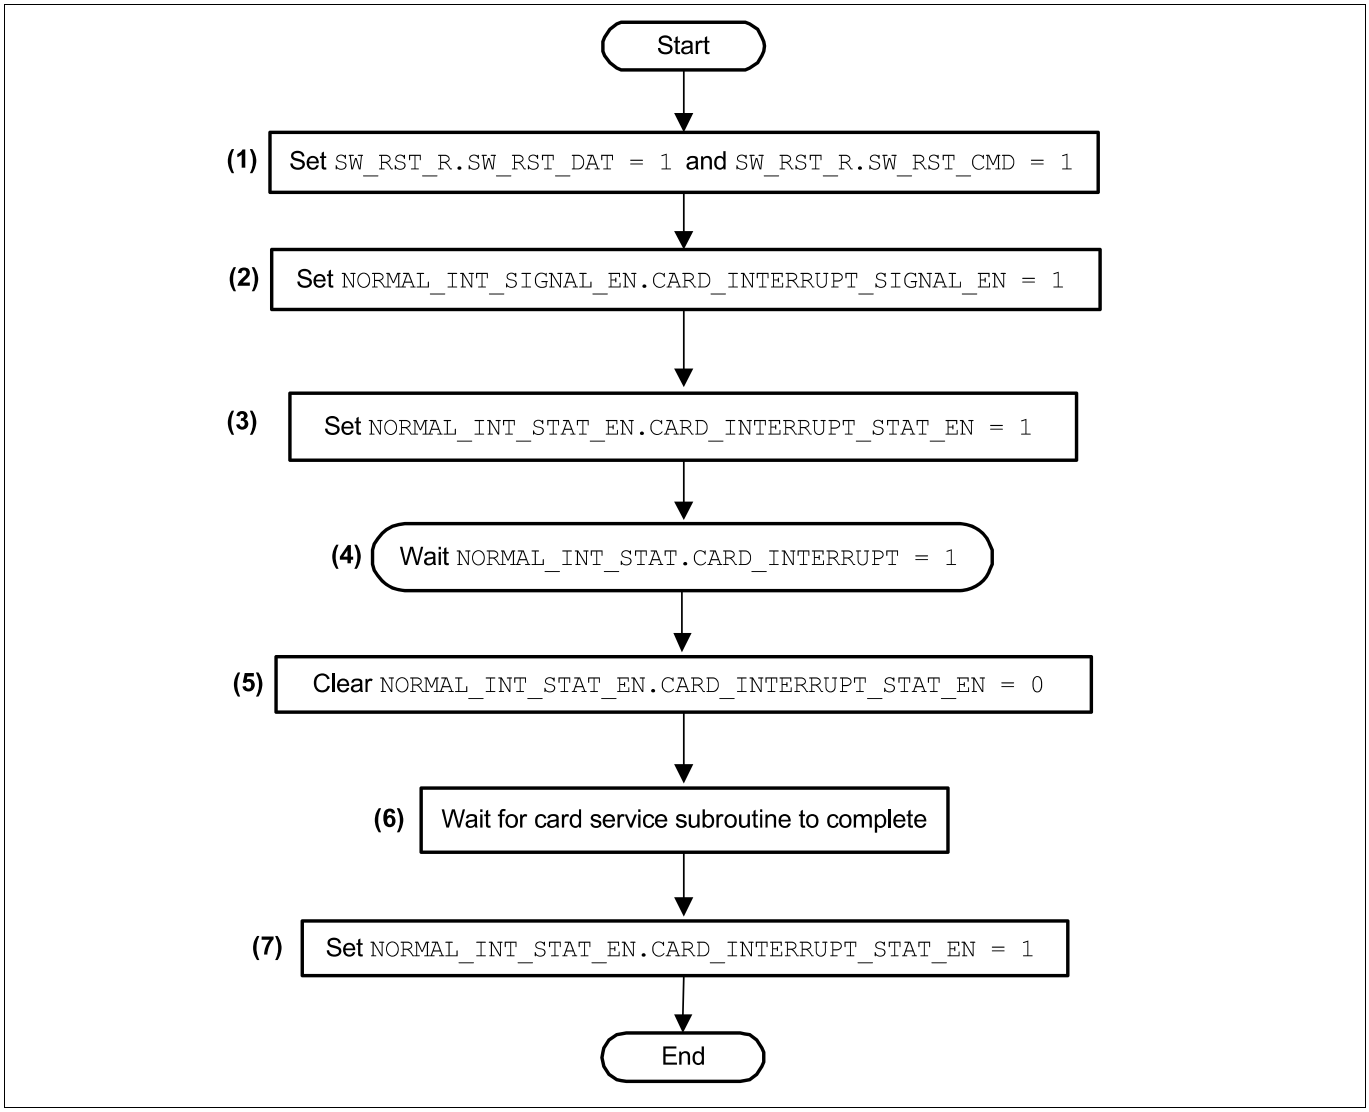

Figure 772 SDIO Card Interrupt Sequence

46.2.2.10 eMMC Transaction Mode

This section discusses the programming sequence for setting the host controller for an eMMC interface.

This section discusses the following programming sequences:

- **Initializing and Identifying an eMMC Device** on page **Page 34**
- **Issue CMD without Data Transfer for an eMMC Device** on page **Page 35**
- **Issue CMD with Data Transfer for an eMMC Device** on page **Page 35**
- **Switch to Various Speed Modes in an eMMC Device** on page **Page 35**
- **Changing the Data Bus Width for an eMMC Device** on page **Page 36**

46.2.2.10.1 Initializing and Identifying an eMMC Device

After powering up the eMMC device, it must be initialized so that the host can start sending commands to the device to perform the data transfer.

Figure 773 shows the programming sequence to initialize and identify an eMMC device.

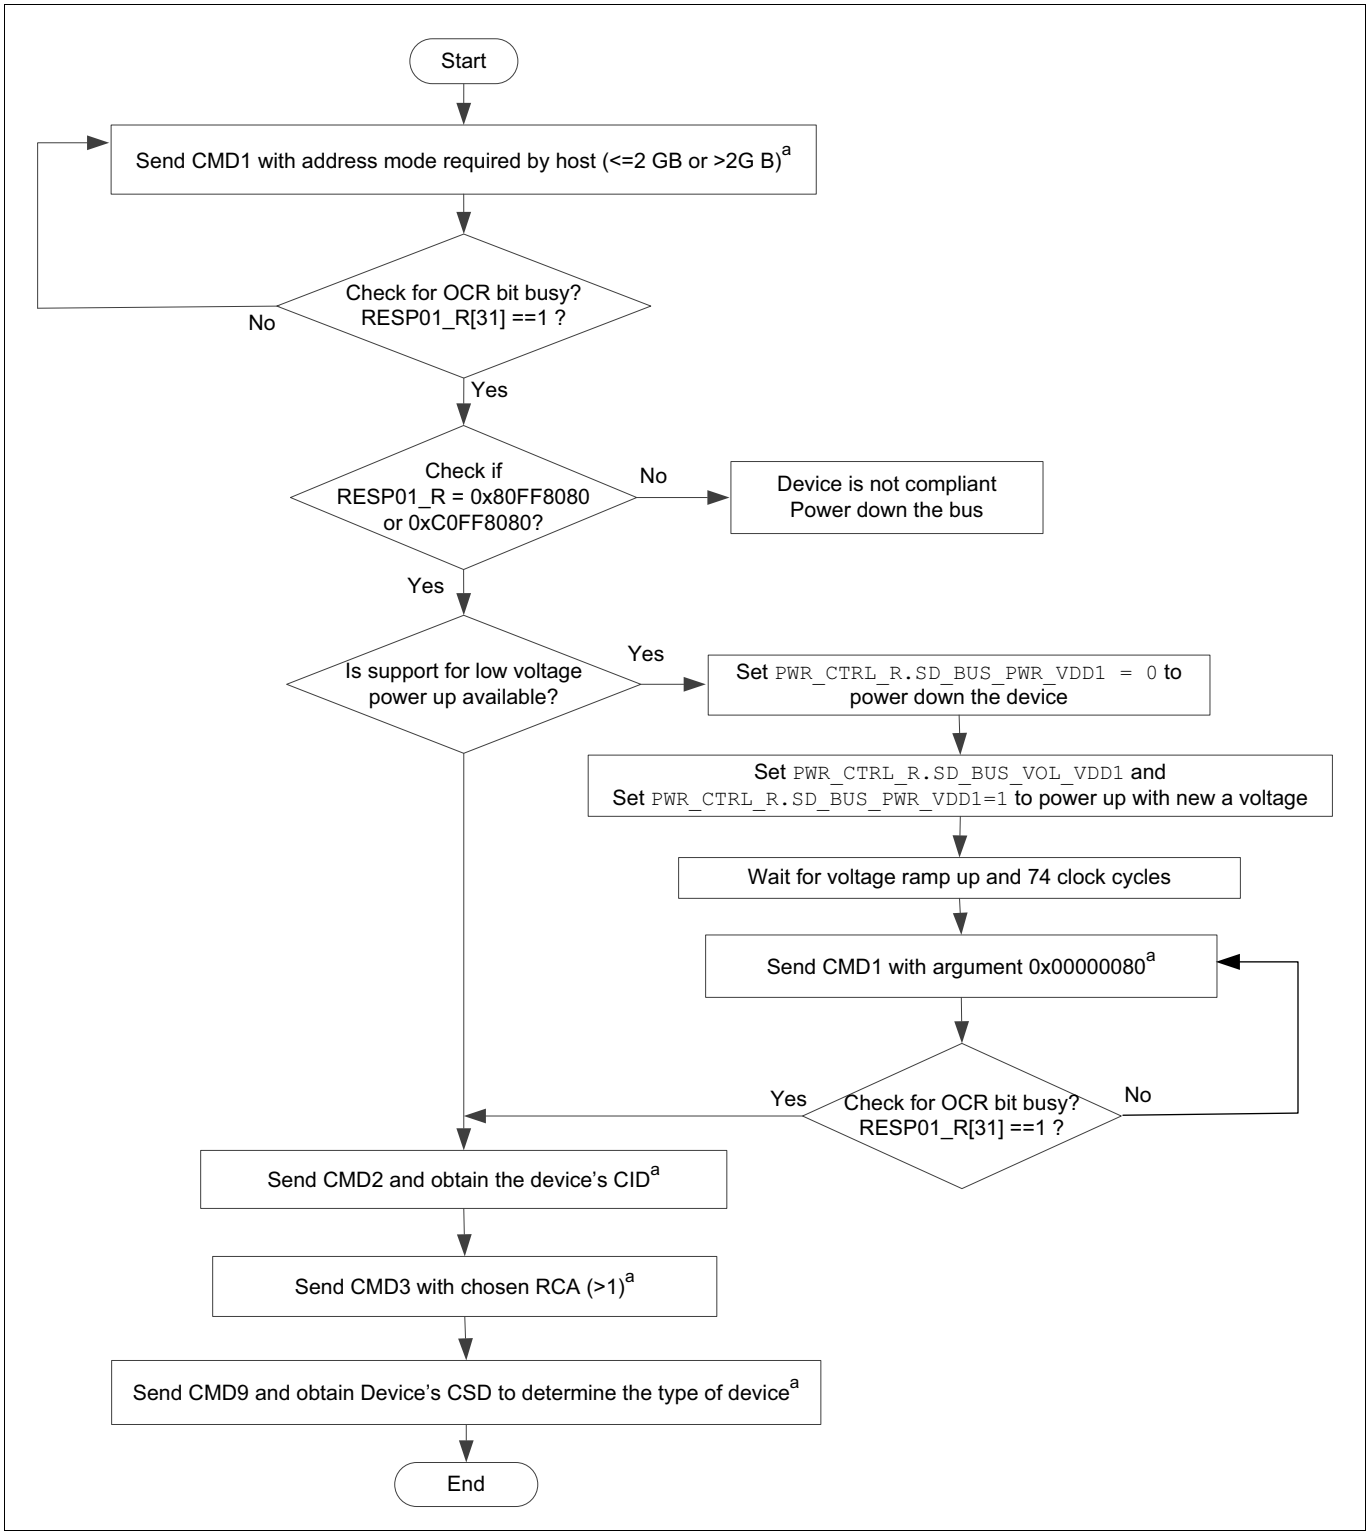

Figure 773 Card Initialization and Identification Programming Sequence

[a] Refer programming sequence for "**Issuing CMD Without Data Transfer**" on **Page 25**.

46.2.2.10.2 Issue CMD without Data Transfer for an eMMC Device

An eMMC device may or may not use the data line (DAT) for data transfer.

The programming sequence for issuing a command without data transfer for an eMMC device is similar to the sequence mentioned in **Issuing CMD Without Data Transfer** on **Page 25**.

46.2.2.10.3 Issue CMD with Data Transfer for an eMMC Device

For an eMMC device, data transfer can occur on the DAT line with or without using DMA/PIO method, and while using DMA, data can be transfer using SDMA, ADMA2, or ADMA3 algorithms.

The programming sequence for issuing a command with data transfer for an eMMC device is similar to the programming sequence mentioned in **Issuing CMD with Data Transfer (Not Using DMA/PIO)** on **Page 26**, **Issuing CMD with Data Transfer (Using SDMA)** on **Page 28**, **Issuing CMD with Data Transfer (Using ADMA2)** on **Page 29** Data transfer can be done with or without using DMA. The supported DMA modes are SDMA, ADMA2, and ADMA3.

46.2.2.10.4 Switch to Various Speed Modes in an eMMC Device

The eMMC bus speed mode of the controller must be changed to match the host driver speed mode. During this process, DWC_mshc must sample the CMD line using data strobe. The switch command (CMD6) is used to change the bus speed mode, and this command is effective only during transfer mode.

Figure 774 shows the programming sequence to switch to various speed modes in an eMMC device. In **Figure 774**, note that CMD6 is effective only during the transfer state.

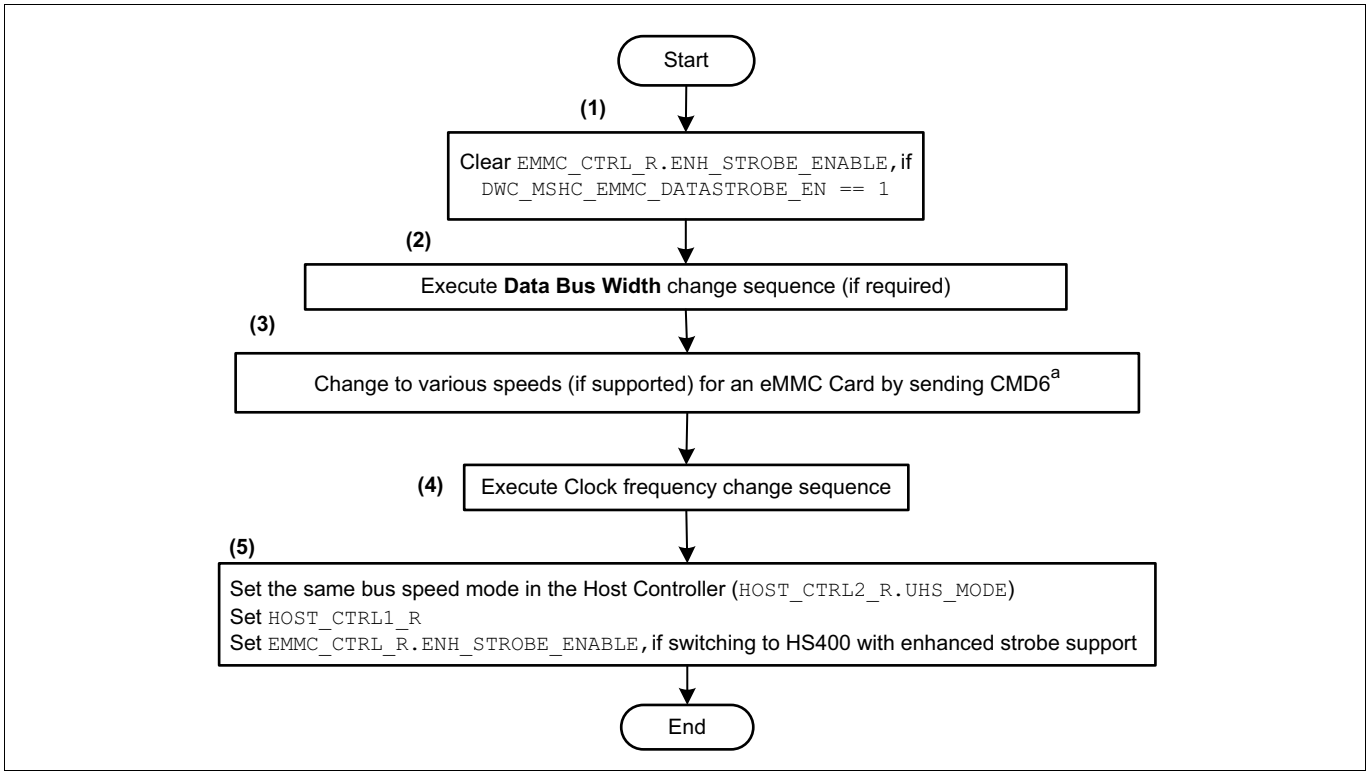

Figure 774 Programming Sequence to Switch to Various Speed Modes in an eMMC Device

[a] Refer programming sequence for "**Issuing CMD Without Data Transfer**" on **Page 25**.

46.2.2.10.5 Changing the Data Bus Width for an eMMC Device

Based on the data bus width of the eMMC device, the host driver must change the data bus width of the Host controller to 1-bit, 4-bit, or 8-bit using CMD6.

Figure 775 shows the programming sequence to change the data bus width for an eMMC device. In **Figure 775**, note that CMD6 is effective only during transfer state.

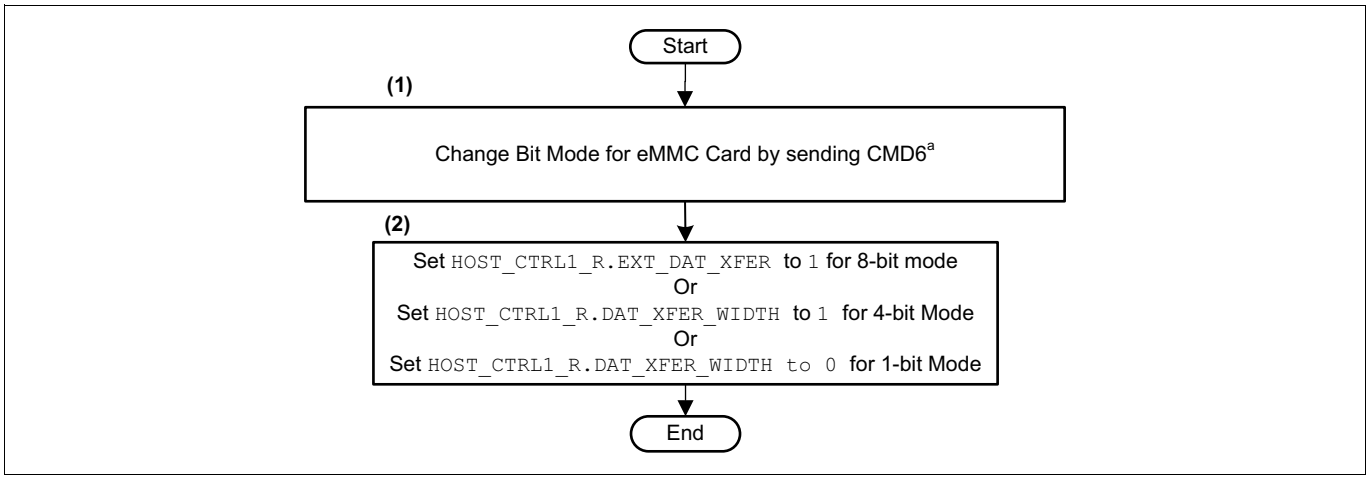

Figure 775 Programming Sequence to Change Data Bus Width for an eMMC Device

46.2.2.11 Boot and Abort Programming Sequences for eMMC

This section discusses the following programming sequences for booting:

- **Preparing for a Boot** on page **Page 37**
- **Initiating a Mandatory Boot in Non-DMA Mode** on page **Page 38**
- **Initiating a Mandatory Boot in SDMA Mode** on page **Page 39**
- **Initiating a Mandatory Boot in ADMA2 Mode** on page **Page 40**
- **Abort Mandatory Boot** on page **Page 41**
- **Initiating Alternate Boot** on page **Page 42**
- **Alternate Boot** on page **Page 43**

46.2.2.11.1 Preparing for a Boot

Before a device can be booted, necessary register bits must be set so that values such as signally level, bus speed mode, bus width, DMA mode are set.

Figure 776 shows the programming sequence to prepare for a boot.

Note: The Host Controller does not support boot in ADMA3 mode.

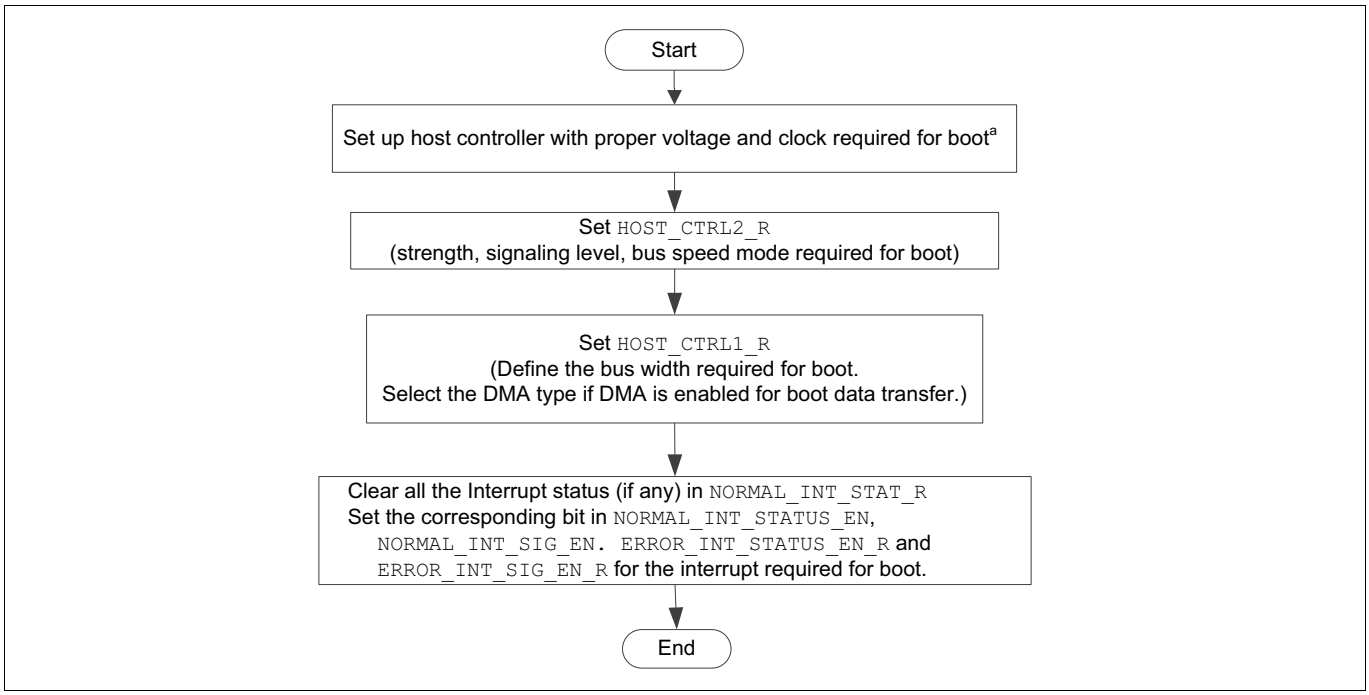

Figure 776 Programming Sequence to Prepare for a Boot

[a] Refer the programming sequence for **Host Controller Clock Setup Sequence**

46.2.2.11.2 Initiating a Mandatory Boot in Non-DMA Mode

While initiating a mandatory boot, the boot is initiated after setting the mandatory boot enable bit in Boot Control Register. In this case, the CMD line is held low for entire boot operation. It is considered that the device is in pre-boot state when boot is initiated. In a non-DMA mode, the process is slower compared to that of a process in a DMA mode.

Figure 777 shows the programming flow to initiate a mandatory boot in non-DMA mode.

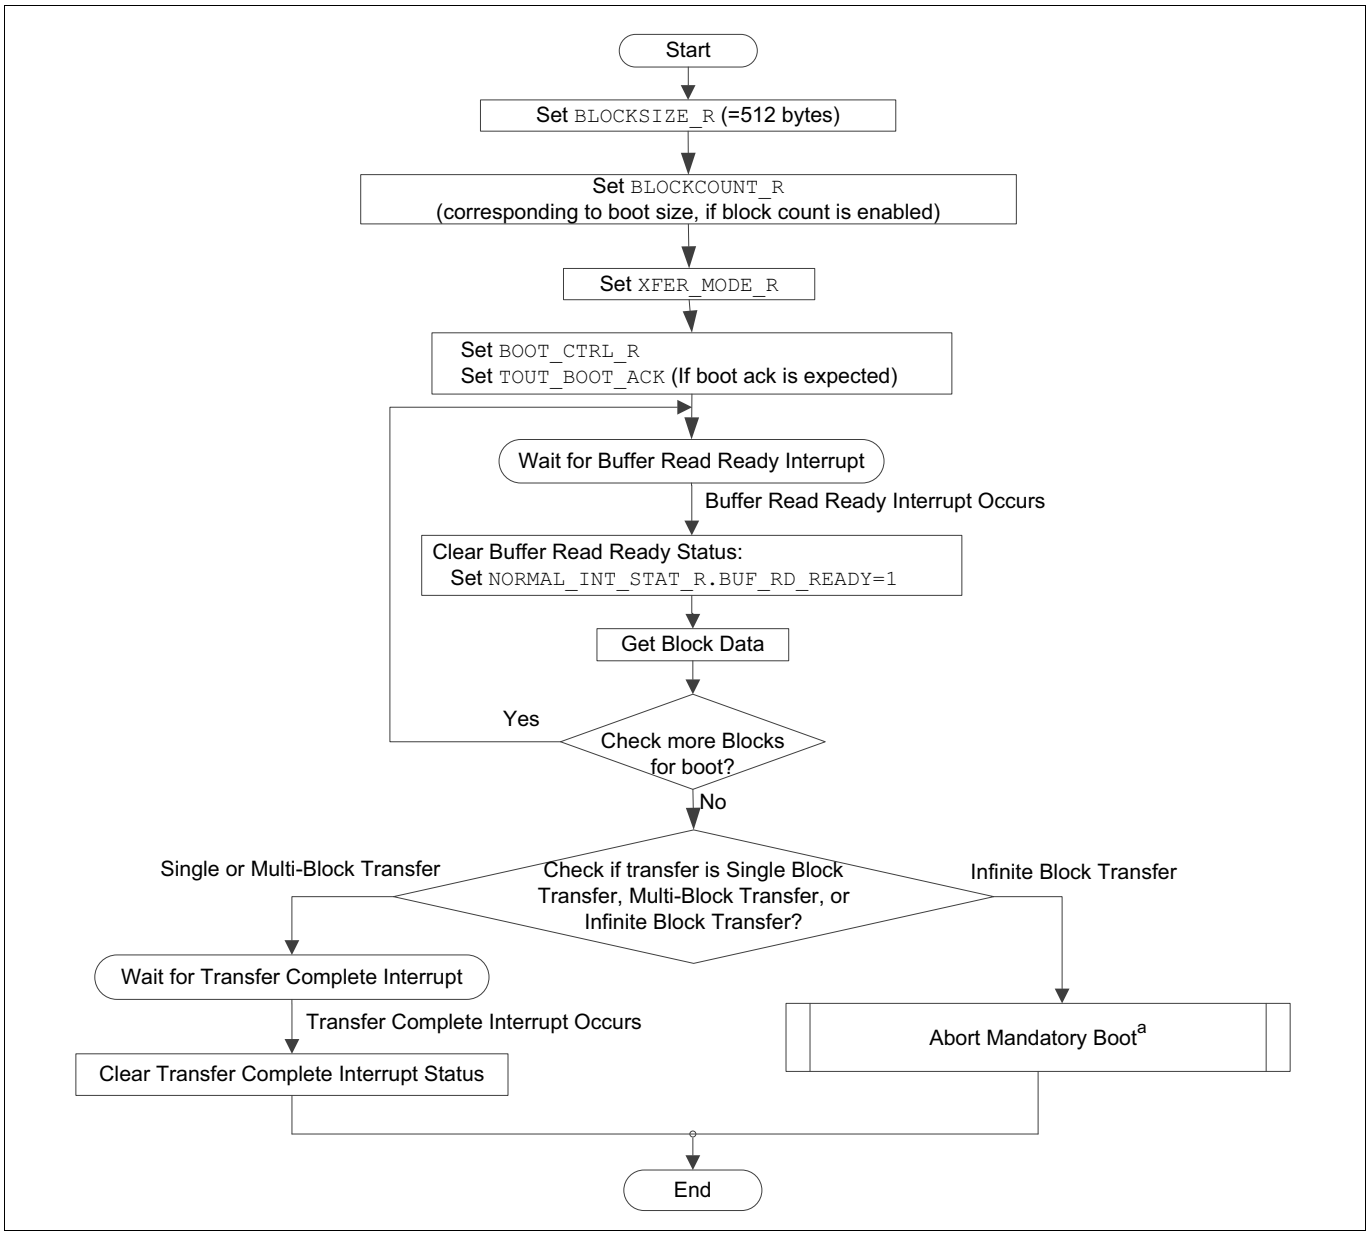

Figure 777 Programming Sequence for Initiating a Mandatory Boot in Non-DMA Mode

[a] Refer programming sequence for "**Abort Mandatory Boot**" on **Page 41**.

46.2.2.11.3 Initiating a Mandatory Boot in SDMA Mode

The procedure to initiate a mandatory boot in SDMA mode involves setting SDMA setting address register and other values related to data transfer.

Figure 778 shows the programming sequence to initiate a mandatory boot in SDMA mode.

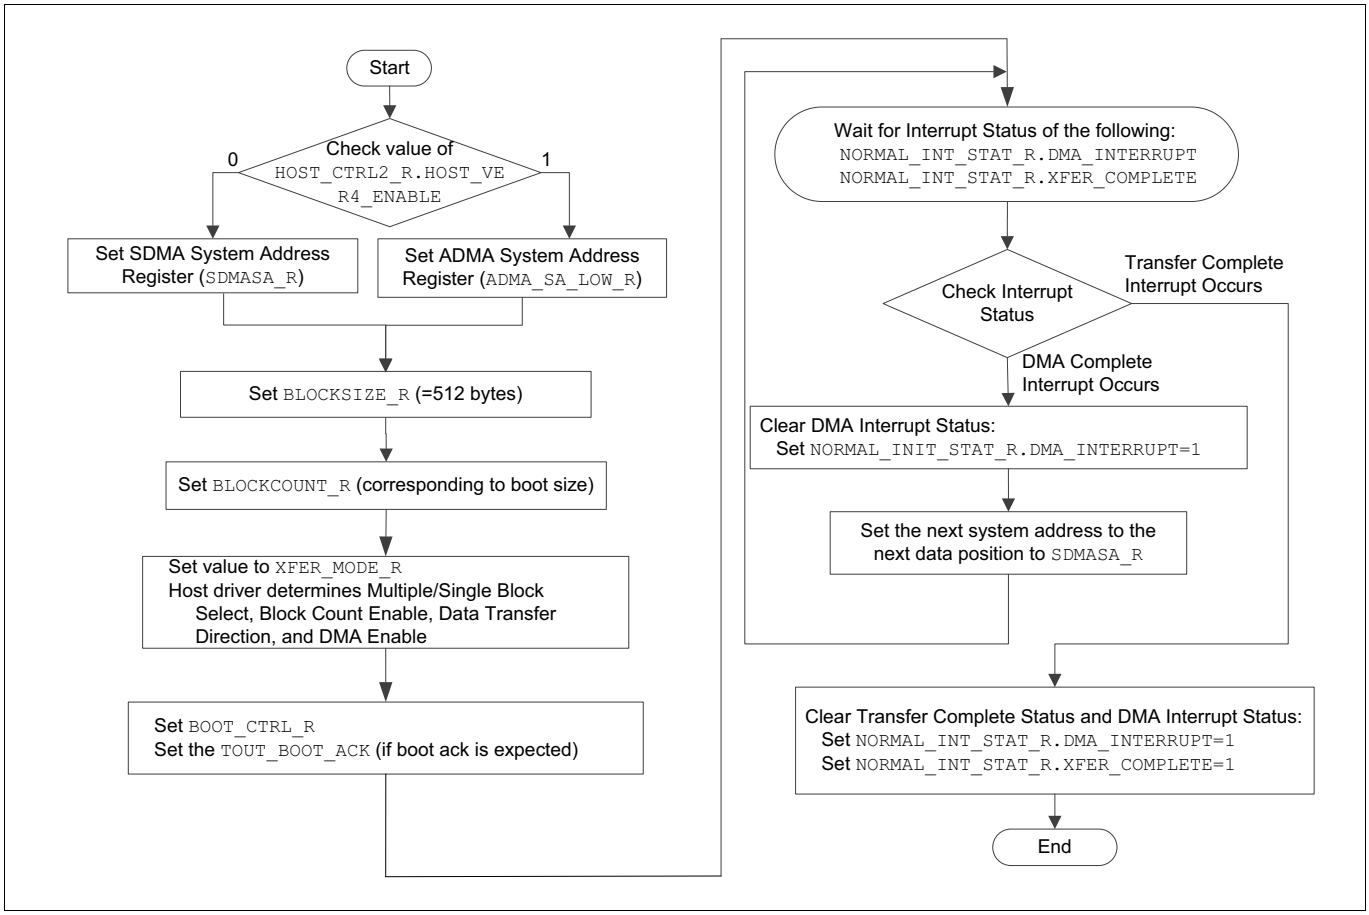

Figure 778 Programming Sequence to Initiate a Mandatory Boot in SDMA Mode

46.2.2.11.4 Initiating a Mandatory Boot in ADMA2 Mode

The procedure to initiate a mandatory boot in ADMA2 mode involves setting ADMA setting address register and other values related to data transfer.

Figure 779 shows the programming sequence for initiating a mandatory boot in ADMA2 mode.

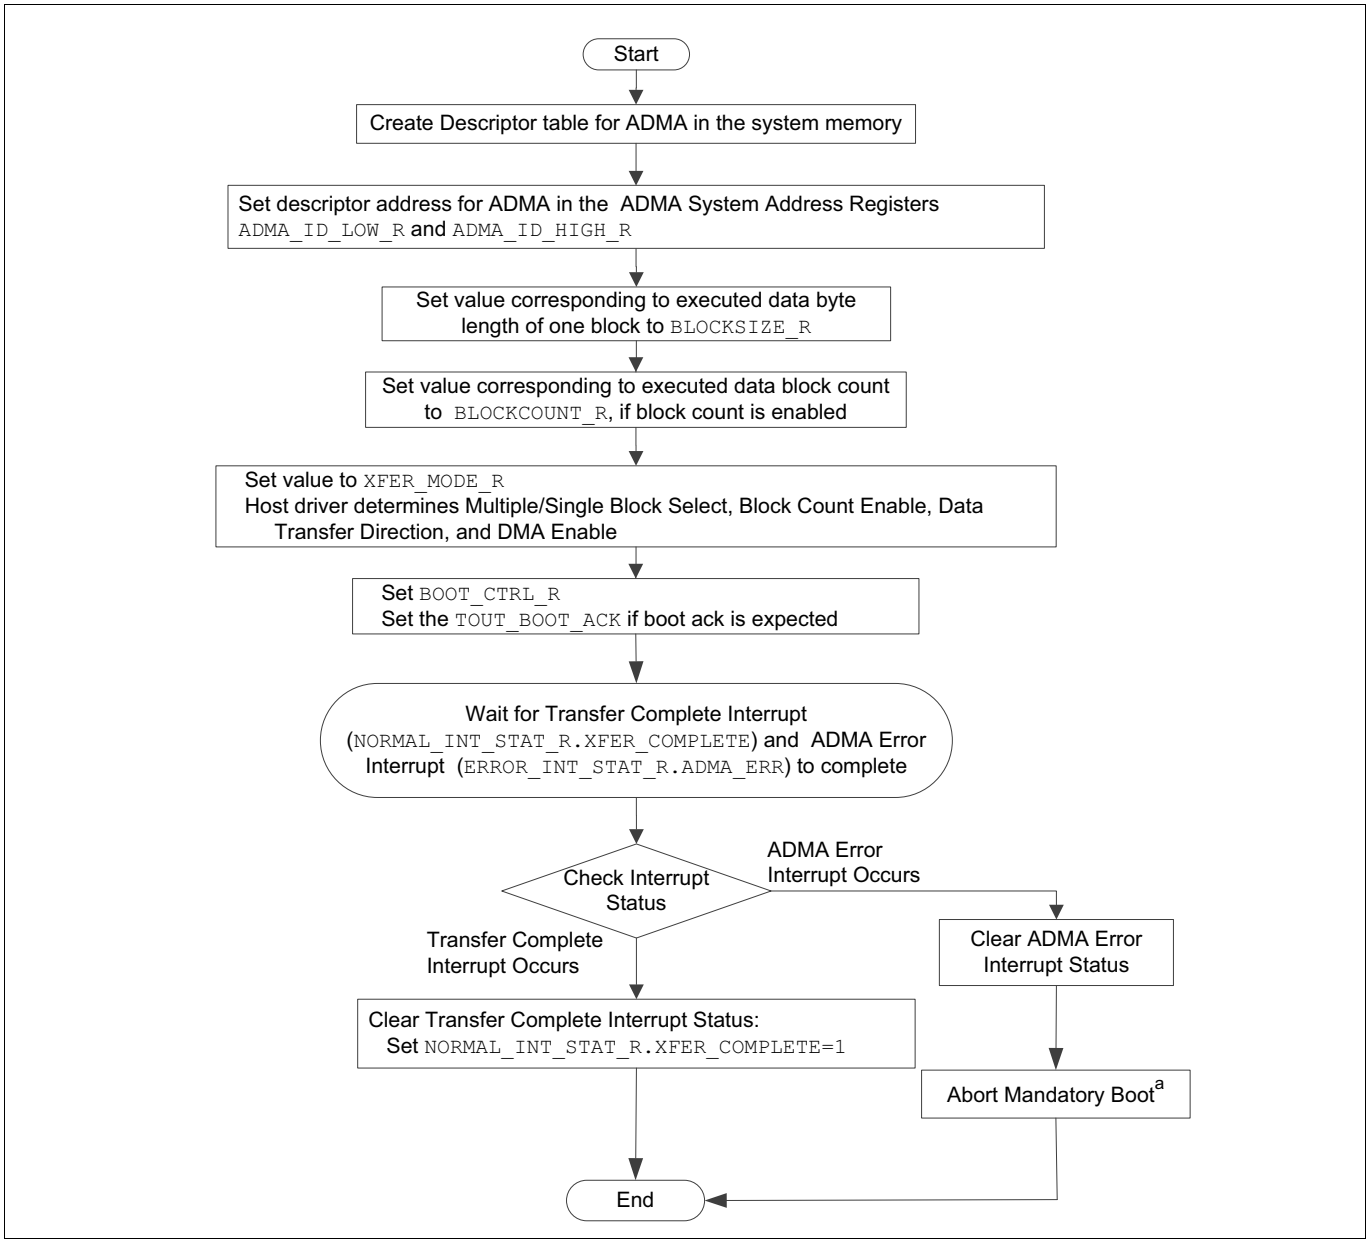

Figure 779 Programming Sequence to Initiate a Mandatory Boot in ADMA2 Mode

[a] Refer programming sequence for "**Abort Mandatory Boot**" on **Page 41**.

46.2.2.11.5 Abort Mandatory Boot

A mandatory boot is executed when an application wants to exit the boot prematurely due to an error or due to receipt of sufficient boot data.

Figure 780 shows the programming sequence for ing a mandatory boot. A mandatory boot is usually exited by pulling up the CMD line to high automatically by DWC_mshc if the boot data is successfully transmitted to the system memory and if the transfer complete interrupt is generated. Note that in **Figure 780**, command inhibit shall be asserted while the CMD line is pulled low and command complete interrupt shall be generated while exiting the mandatory boot.

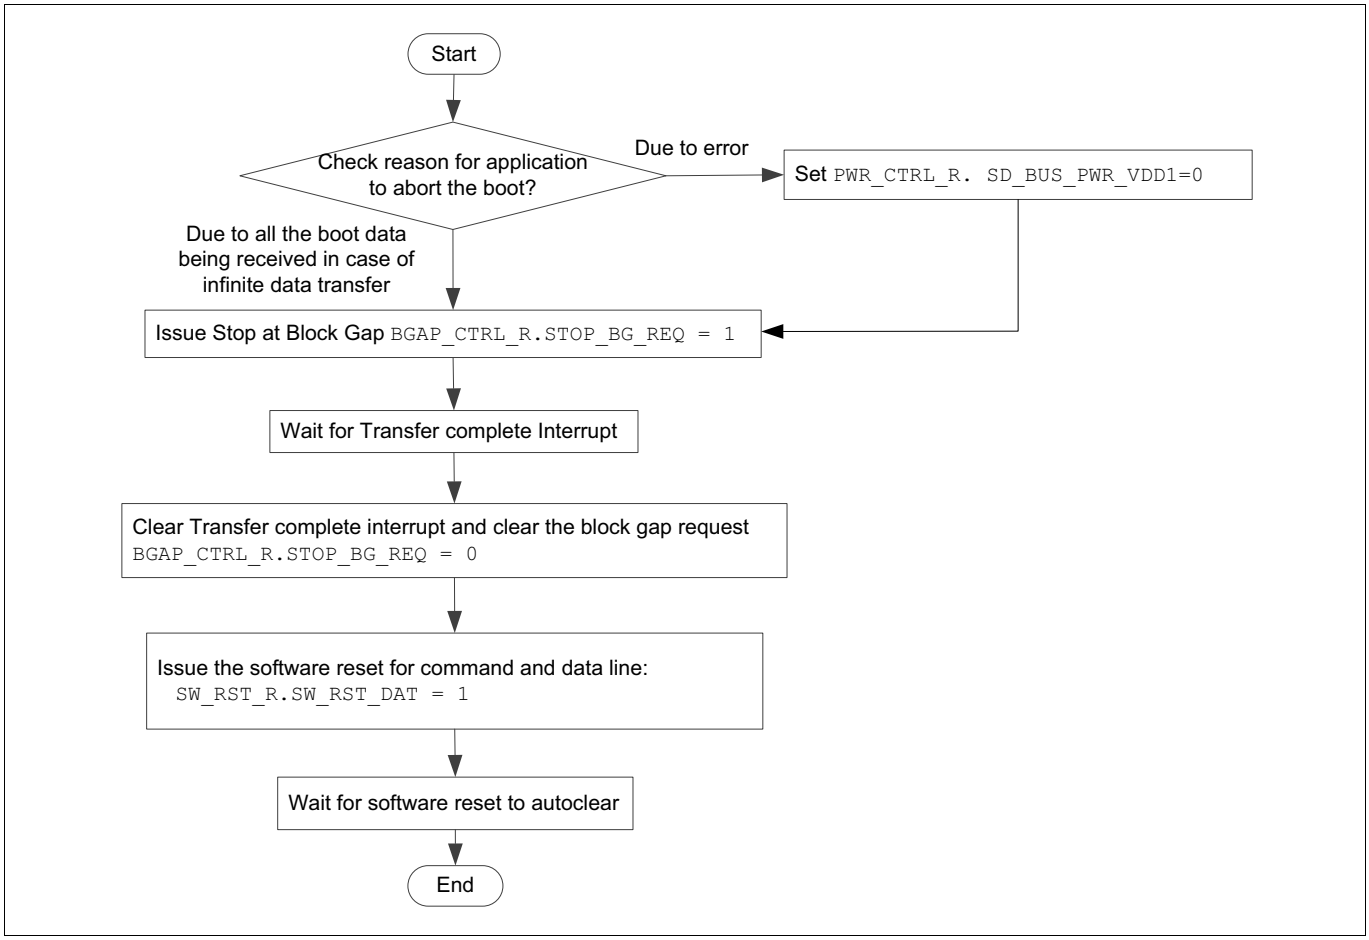

Figure 780 Programming Sequence to a Abort Mandatory Boot

46.2.2.11.6 Initiating Alternate Boot

Alternate Boot is a command-based boot operation and can be initiated by issuing CMD0.

For the programming sequence for initiating an alternate book, refer programming sequences for “Issuing CMD with Data Transfer”, “Issuing CMD with Data Transfer (Using SDMA)”, and “Issuing CMD with Data Transfer (Using ADMA2)” with the following exceptions:

- If boot acknowledgment is expected, BOOT_CTRL_R shall be programmed to set the timeout counter for boot acknowledgment before setting the CMD_R register.
- Response check cannot be performed as CMD0 has no response.
- ing the alternate boot operation follows the “ Alternate Boot” programming sequence instead of CMD12 for other data transfer operation.

When the boot is initiated, device state is assumed to be in pre-boot state and 74 clock cycles has expired after power is stable before issuing CMD0.

46.2.2.11.7 Alternate Boot

An alternate boot is ed if an application wants to exit the boot prematurely due to error or sufficient boot data has been received. However, an alternate boot can only be exited by the application by issuing CMD0/reset. The application exits the boot after transfer compete interrupt is received.

Figure 781 shows the programming sequence for ing an alternate boot.

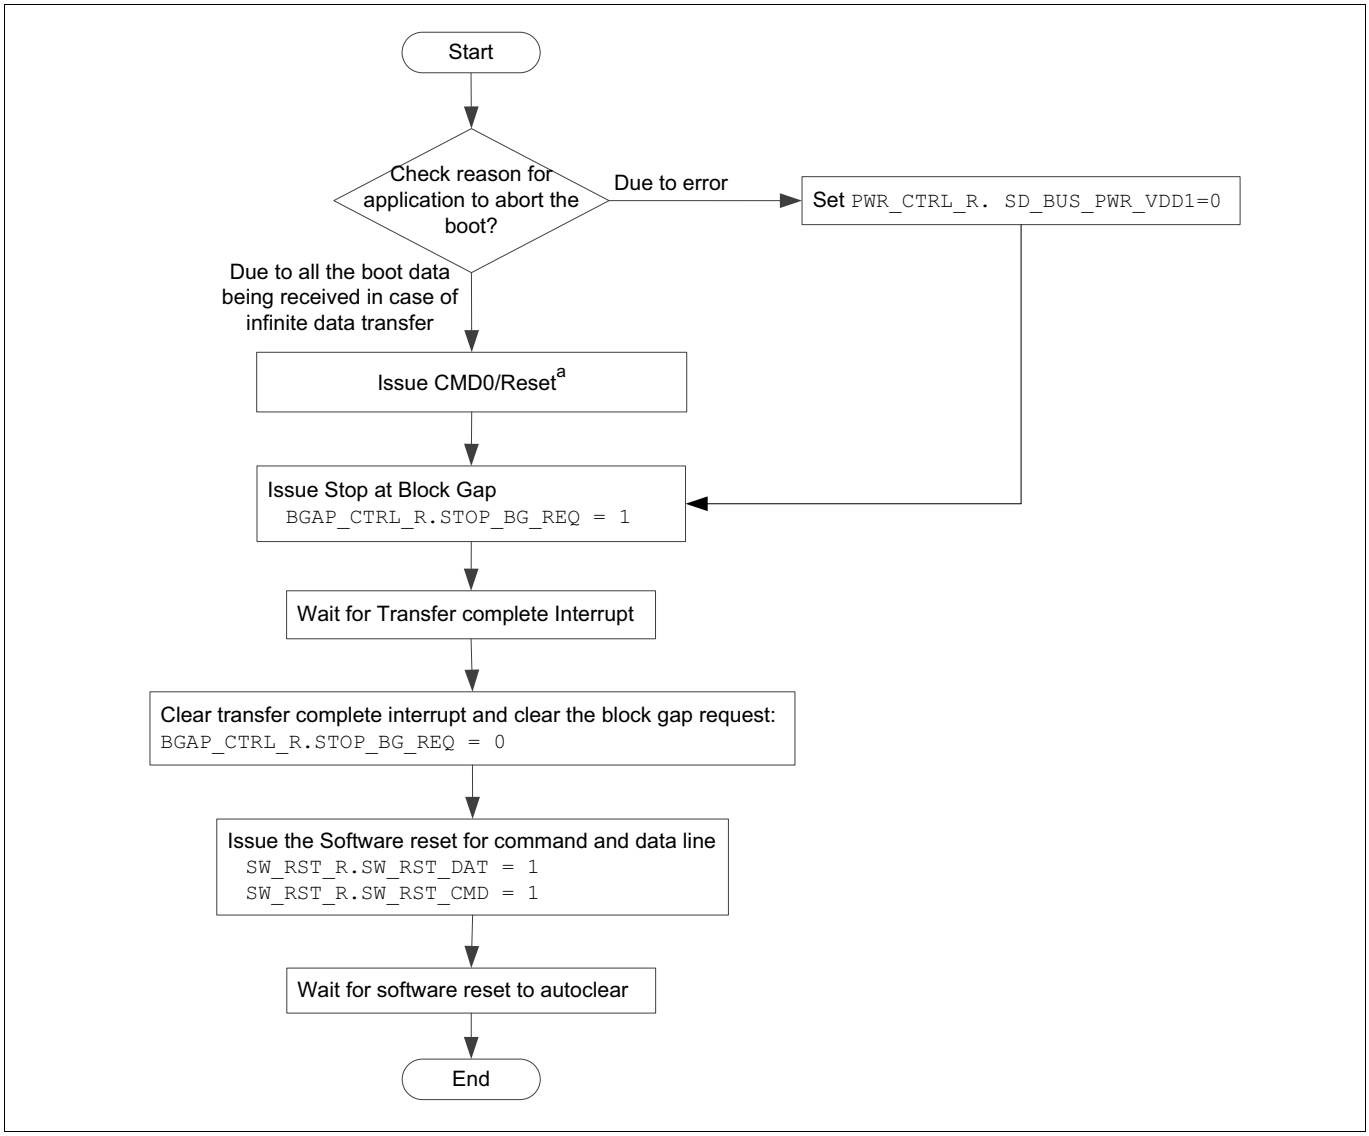

Figure 781 Programming Sequence for ing an Alternate Boot

[a] Refer programming sequence for "**Initializing and Identifying an eMMC Device**" on **Page 34**.

46.2.2.12 Error Recovery in SD/eMMC Mode

An error recovery procedure is required when an error interrupt is indicated by the Error Interrupt Status register and when errors exist in Auto CMD12.

Figure 782 and **Figure 783** show the error recovery sequence for SD/eMMC mode.

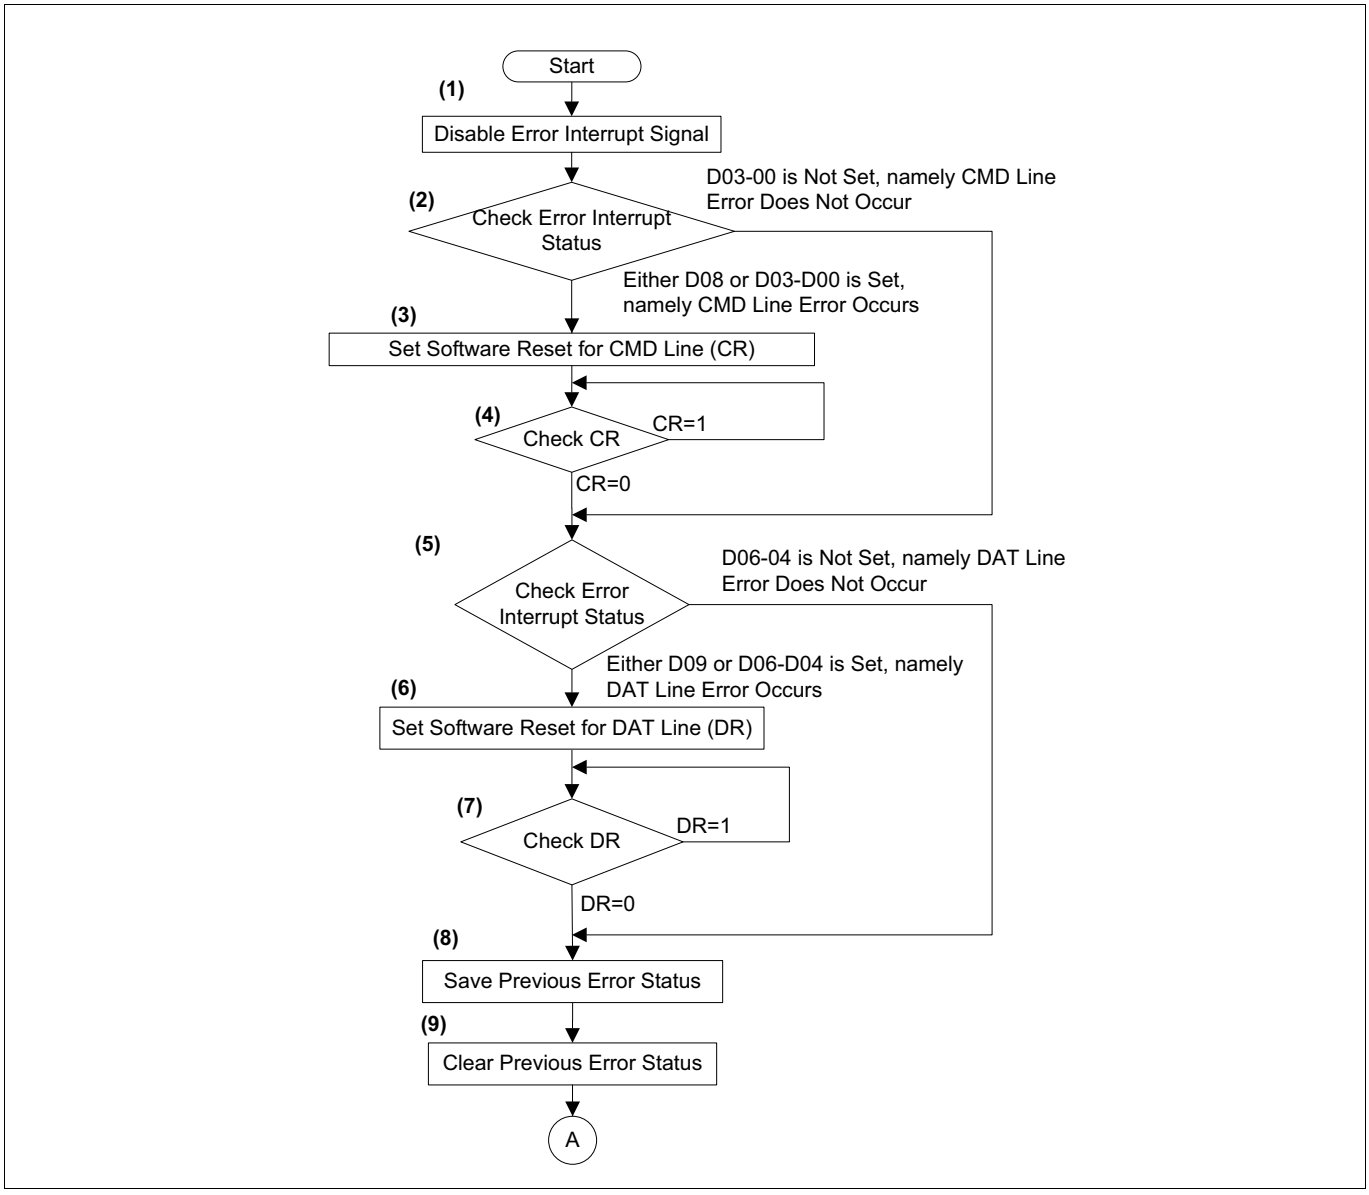

Figure 782 Programming Sequence for Error Recovery in SD/eMMC Mode Part 1

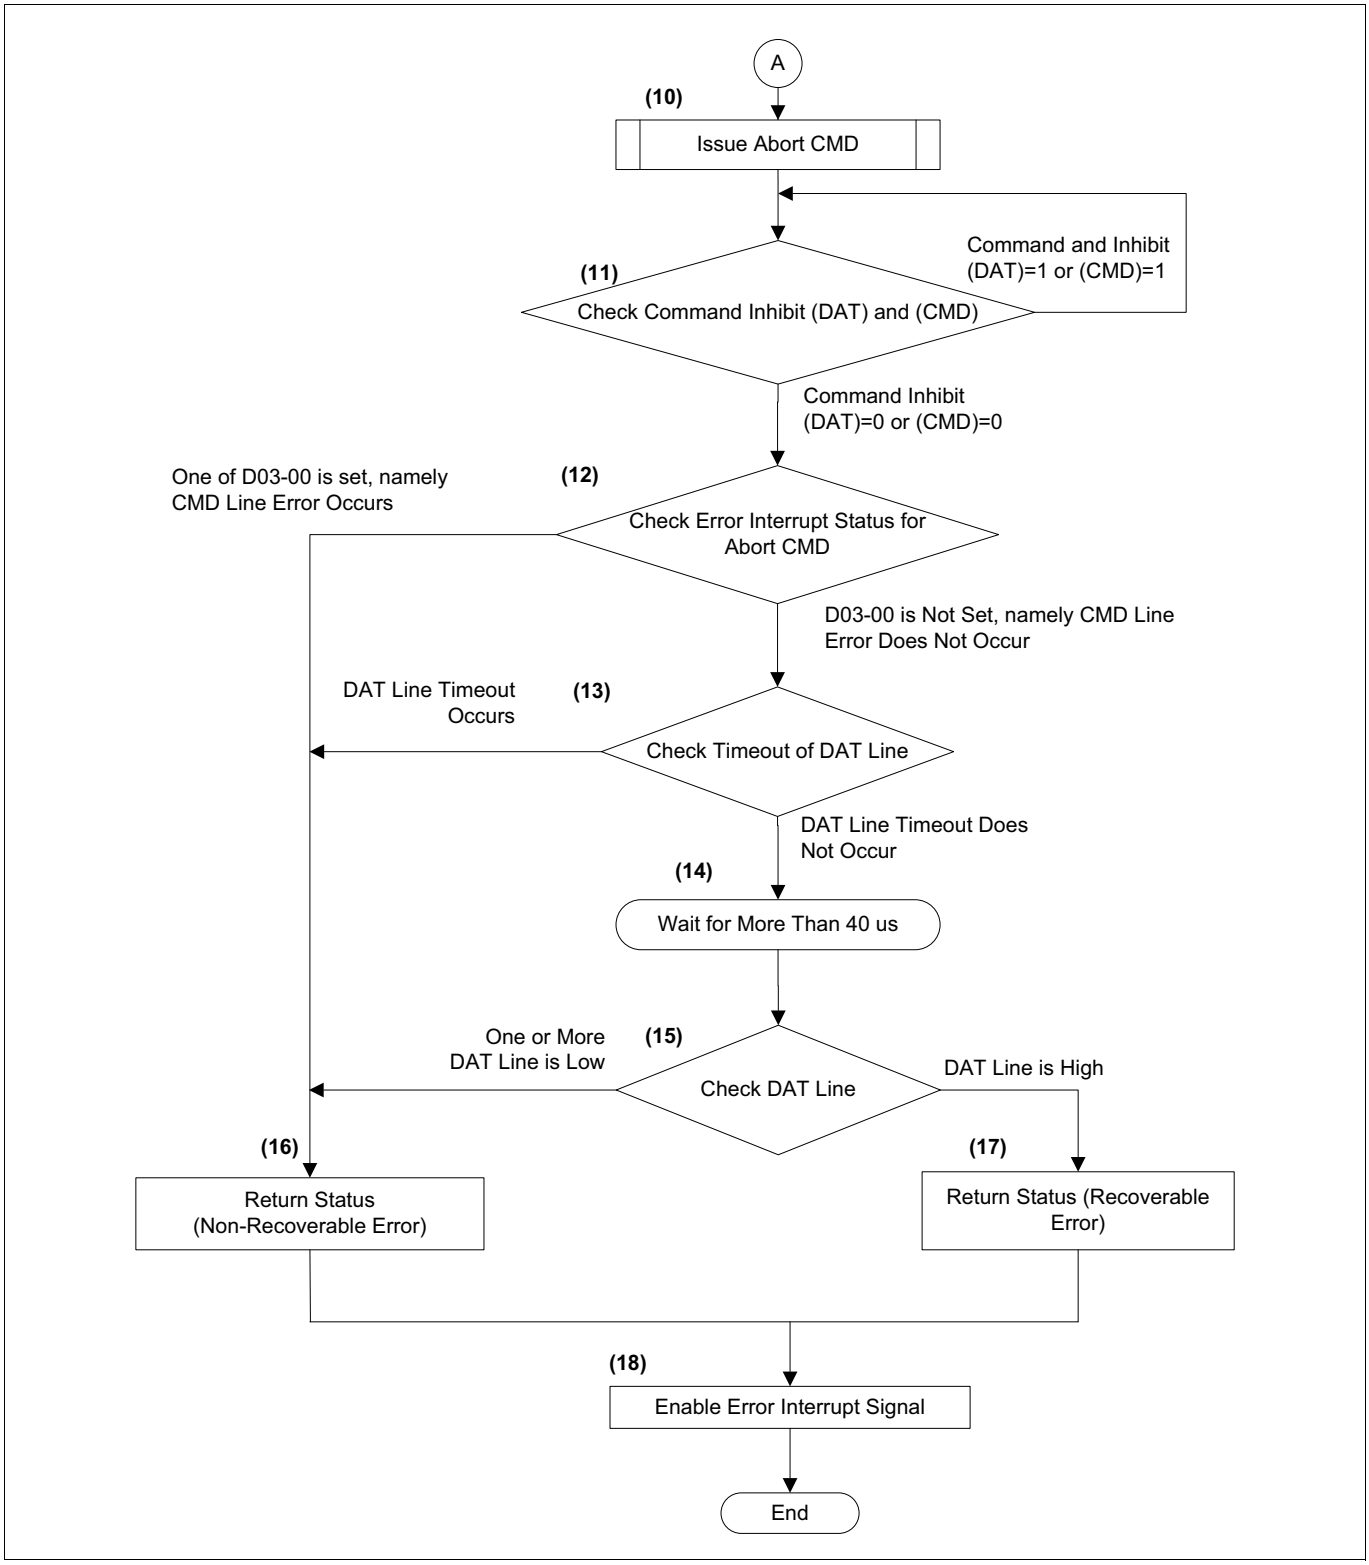

Figure 783 Programming Sequence for Error Recovery in SD/eMMC Mode Part 2

46.3 Registers

Accessing non-listed addresses will result in an bus error.

Table 540 Register Overview - SDMMC (ascending Offset Address)

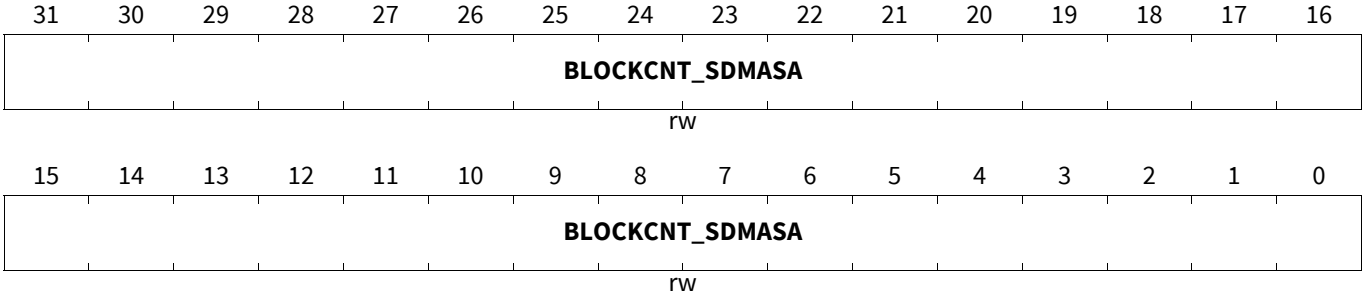
SDMA System Address register

This register is used to configure 32-bit Block Count or SDMA System Address based on the Host Version 4 Enable bit in the Host Control 2 register. This register is applicable for both SD and eMMC modes.

SDMASA

SDMA System Address register **(000_H)** **Application Reset Value: 0000 0000_H**

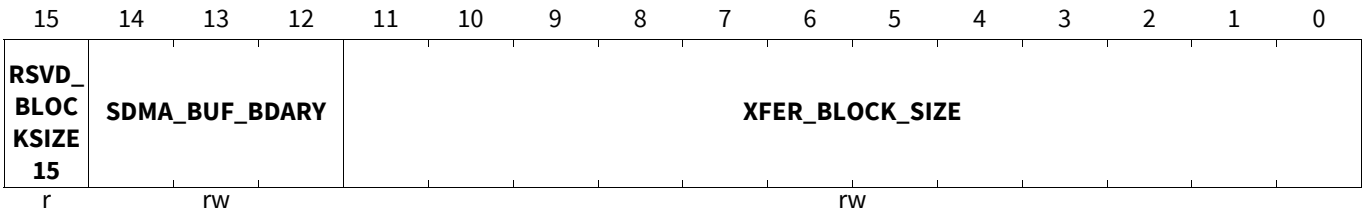


Field	Bits	Type	Description
BLOCKCNT_SDMASA	31:0	rw	**32-bit Block Count (SDMA System Address)** • SDMA System Address (Host Version 4 Enable = 0) - This register contains the system memory address for SDMA transfer in the 32-bit addressing mode. When the Host Controller stops an SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing. Reading this register during data transfers may return invalid value. • 32-bit Block Count (Host Version 4 Enable = 1) - From Host Controller Version 4.10, this register is redefined as 32-bit Block Count. The Host Controller decrements the block count of this register for every block transfer and the data transfer stops when the count reaches zero. This register should be accessed when no transaction is executing. Reading this register during data transfers may return invalid value. • FFFF_FFFFh - 4G - 1 block • ... - ... • 0000_0002h - 2 blocks • 0000_0001h - 1 block • 0000_0000h - Stop Count *Note: For Host Version 4 Enable = 0, Host driver shall not program system address in this register while operating in ADMA mode. It should be programmed in ADMA System Address register.* *Note: For Host Version 4 Enable = 0, Host driver shall program 32-bit block count in this register when Auto CMD23 is enabled for non-DMA and ADMA mode.* **Volatile:** true

Block Size register

This register is used to configure SDMA buffer boundary and number of bytes in a data block. This register is applicable for both SD and eMMC modes.

BLOCKSIZE
Block Size register **(004_H)** **Application Reset Value: 0000_H**



Field	Bits	Type	Description
XFER_BLOCK_SIZE	11:0	rw	**Transfer Block Size** This register specifies the block size of data transfers. In case of memory, it shall be set up to 512 bytes. It can be accessed only if no transaction is executing. Read operations during transfers may return an invalid value, and write operations shall be ignored. 000_H No Data Transfer 001_H 1 Byte 002_H 2 Bytes … 200_H 512 Bytes 201_H reserved … FFF_H reserved
SDMA_BUF_BDARY	14:12	rw	**SDMA Buffer Boundary** These bits specify the size of contiguous buffer in system memory. The SDMA transfer shall wait at every boundary specified by these fields and the Host Controller generates the DMA interrupt to request the Host Driver to update the SDMA System Address register. 000_B 4K Bytes 001_B 8K Bytes 010_B 16K Bytes 011_B 32K Bytes 100_B 64K Bytes 101_B 128K Bytes 110_B 256K Bytes 111_B 512K Bytes
RSVD_BLOCKSIZE15	15	r	**Reserved** This bit is reserved. It will always return 0.

16-bit Block Count register

This register is used to configure the number of data blocks. This register is applicable for both SD and eMMC modes.

BLOCKCOUNT
16-bit Block Count register **(006_H)** **Application Reset Value: 0000_H**

Field	Bits	Type	Description
ARGUMENT	31:0	rw	**Command Argument** The SD/eMMC command argument is specified as bit 39-8 of the command format.

Transfer Mode register

This register is used to control the operation of data transfers for an SD/eMMC mode. The Host driver shall set this register before issuing a command that transfers data.

XFER_MODE

Transfer Mode register **($00C_H$)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD							RESP_INT_DISABLE	RESP_ERR_CHK_ENABLE	RESP_TYPE	MULTI_BLK_SEL	DATA_XFER_DIR	AUTO_CMD_ENABLE		BLOCK_COUNT_ENABLE	DMA_ENABLE
r							rw	rw	rw	rw	rw	rw		rw	rw

Field	Bits	Type	Description
DMA_ENABLE	0	rw	**DMA Enable** This bit enables the DMA functionality. If this bit is set to 1, a DMA operation begins when Host Driver writes to Command register. You can select one of the DMA modes by using DMA Select in the Host Control 1 register. The DMA supports only transfers of 32bit data. The addresses have to be 32bit aligned for 32bit addressing. 0_B No data transfer or Non DMA data transfer 1_B DMA Data transfer
BLOCK_COUNT_ENABLE	1	rw	**Block Count Enable** This bit is used to enable the Block Count register, which is relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. Host Driver should set this bit to 0 when ADMA is used. 0_B Disable 1_B Enable

Field	Bits	Type	Description
AUTO_CMD_ENABLE	3:2	rw	**Auto Command Enable** This field determines use of auto command functions. *Note: In SDIO, this field should be set as 00b (Auto Command Disabled).* 00_B Auto Command Disabled 01_B Auto CMD12 Enable 10_B Auto CMD23 Enable 11_B Auto CMD Auto Select
DATA_XFER_DIR	4	rw	**Data Transfer Direction Select** This bit defines the direction of DAT line data transfers. This bit is set to 1 by the Host Driver to transfer data from the SD/eMMC card to the Host Controller and it is set to 0 for all other commands. 0_B Write (Host to Card) 1_B Read (Card to Host)
MULTI_BLK_SEL	5	rw	**Multi/Single Block Select** This bit is set when issuing multiple-block transfer commands using DAT line. If this bit is set to 0, it is not necessary to set Block Count register. 0_B Write (Single Block) 1_B Read (Multiple Block)

Field	Bits	Type	Description
RESP_TYPE	6	rw	**Response Type R1/R5** When response error check is enabled, this bit selects either R1 or R5 response types. Error statuses checked in R1: • OUT_OF_RANGE • ADDRESS_ERROR • BLOCK_LEN_ERROR • WP_VIOLATION • CARD_IS_LOCKED • COM_CRC_ERROR • CARD_ECC_FAILED • CC_ERROR • ERROR Response Flags checked in R5: • COM_CRC_ERROR • ERROR • FUNCTION_NUMBER • OUT_OF_RANGE 0_B R1 (Memory) 1_B R5 (SDIO)
RESP_ERR_CHK_ENABLE	7	rw	**Response Error Check Enable** Host Controller supports response check function to avoid overhead of response error check by Host driver. Only R1 and R5 can be checked by the controller. If Host Controller checks the response error, set this bit to 1 and set Response Interrupt Disable to 1. If an error is detected, Response Error interrupt is generated in the Error Interrupt Status register. *Note: Response error check should not be enabled for any reponse type other than R1 and R5.* *Note: Response check should not be enabled for tuning command.* 0_B Response Error Check is disabled 1_B Response Error Check is enabled

Field	Bits	Type	Description
RESP_INT_DISABLE	8	rw	**Response Interrupt Disable** Host Controller supports response check function to avoid overhead of response error check by Host driver. Only R1 and R5 can be checked by the controller. If Host Driver checks response error, set this bit to 0 and wait for Command Complete Interrupt and then check the response register. If Host Controller checks response error, set this bit to 1 and set Response Error Check Enable to 1. Command Complete Interrupt is disabled by this bit regardless of Command Complete Signal Enable. *Note: While carrying out tuning (When Execute Tuning bit in Host Control2 register is set), command complete interrupt is not generated irrespective of Response Interrupt Disable setting.* 0_B Response Interrupt enabled 1_B Response Interrupt is disabled
RSVD	15:9	r	**Reserved** These bits are reserved. They will always return 0.

Command register

This register is used to provide the information related to command and response packet. This register is applicable for an SD/eMMC mode.

CMD
Command register **($00E_H$)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD		CMD_INDEX						CMD_TYPE		DATA_PRESENT_SEL	CMD_IDX_CHK_ENABLE	CMD_CRC_CHK_ENABLE	SUB_CMD_FLAG	RESP_TYPE_SELECT	
r		rw						rw		rw	rw	rw	rw	rw	

Field	Bits	Type	Description
RESP_TYPE_SELECT	1:0	rw	**Response Type Select** These bits indicate the type of response expected from the card. 00_B No Response 01_B Response Length 136 10_B Response Length 48 11_B Response Length 48 (check Busy after response)
SUB_CMD_FLAG	2	rw	**Sub Command Flag** This bit distinguishes a main command or a sub command. 0_B Main Command 1_B Sub Command

Field	Bits	Type	Description
CMD_CRC_CHK_ENABLE	3	rw	**Command CRC Check Enable** If this bit is set, Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC error. *Note: CRC Check enable should be set to 0 for the command with no response, R3 response and R4 response.* 0_B Disable 1_B Enable
CMD_IDX_CHK_ENABLE	4	rw	**Command Index Check Enable** If this bit is set, Host Controller shall check the index field in the response to verify if it has the same value as the command index. If it is not, it is reported as a Command Index error. *Note: Index Check enable should be set to 0 for the command with no response, R2 response, R3 response and R4 response.* 0_B Disable 1_B Enable
DATA_PRESENT_SEL	5	rw	**Data Present Select** This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. This bit is set to 0 in the following instances: • Command using CMD line • Command with no data transfer but using busy signal on DAT[0] line • Resume Command 0_B No Data Present 1_B Data Present
CMD_TYPE	7:6	rw	**Command Type** These bits indicate the command type. 00_B Normal Command 01_B Suspend Command 10_B Resume Command 11_B Abort Command
CMD_INDEX	13:8	rw	**Command Index** These bits shall be set to the command number that is specified in bits 45-40 of the Command Format.
RSVD	15:14	r	**Reserved** These bits are reserved. They will always return 0.

Response Register 01

This register is used to store the response from the cards. The response can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers: RESP01_R, RESP23_R, RESP45_R and RESP67_R.

RESP01_R stores 39-08 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP01

Response Register 01 **(010_H)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESP01															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESP01															
r															

Field	Bits	Type	Description
RESP01	31:0	r	**Command Response** These bits reflect bits 39-8 of the Response Field. *Note: For Auto CMD, the 32-bit response (bits 39-8 of the Response Field) is updated in RESP67_R register.* **Volatile:** true

Response Register 23

This register is used to store the response from the cards. The response can be of maximum 128 bits. These 128 bits are segregated into four 32-bit registers RESP01_R, RESP23_R, RESP45_R and RESP67_R.

RESP23_R stores 71-40 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP23

Response Register 23 **(014_H)** **Application Reset Value: 0000 0000$_H$**

r				r	r	r	r	r				r	r	r	r

Field	Bits	Type	Description
CMD_INHIBIT	0	r	**Command Inhibit (CMD)** In an SD/eMMC mode, if this bit is 0, it indicates that the CMD line is not in use and the Host controller can issue an SD/eMMC command using the CMD line. This bit is set when the command register is written. This bit is cleared when the command response is received. This bit is not cleared by the response of auto CMD12/23 but cleared by the response of read/write command. **Volatile:** true 0_B Host Controller is not ready to issue a command 1_B Host Controller is ready to issue a command
CMD_INHIBIT_DAT	1	r	**Command Inhibit (DAT)(SD/eMMC Mode only)** This status bit is generated if either DAT line active or Read transfer active is set to 1. If this bit is 0, it indicates that Host Controller can issue subsequent SD/eMMC commands. **Volatile:** true 0_B Can issue command which used DAT line 1_B Cannot issue command which used DAT line
DAT_LINE_ACTIVE	2	r	**DAT Line Active (SD/eMMC Mode only)** This bit indicates whether one of the DAT lines on the SD/eMMC bus is in use. In the case of read transactions, this status indicates whether a read transfer is executing on the SD/eMMC bus. In the case of write transactions, this status indicates whether a write transfer is executing on the SD/eMMC bus. For command with busy, this status indicates whether command executing busy is executing on the SD/eMMC bus. **Volatile:** true 0_B DAT Line Inactive 1_B DAT Line Active
RE_TUNE_REQ	3	r	**Re-Tuning Request** This bit can be ignored.
DAT_7_4	7:4	r	**DAT[7:4] Line Signal Level (Embedded only)** This status is used to check the DAT line level to recover from errors and for debugging. **Volatile:** true
WR_XFER_ACTIVE	8	r	**Write Transfer Active (SD/eMMC Mode only)** This status indicates whether a write transfer is active. **Volatile:** true 0_B No valid data 1_B Transferring data

Field	Bits	Type	Description
RD_XFER_ACTIVE	9	r	**Read Transfer Active (SD/eMMC Mode only)** This status indicates whether a read transfer is active. **Volatile:** true 0_B No valid data 1_B Transferring data
BUF_WR_ENABLE	10	r	**Buffer Write Enable** This status is used for non-DMA transfers. This bit is set if space is available for writing data. **Volatile:** true 0_B Write disable 1_B Write enable
BUF_RD_ENABLE	11	r	**Buffer Read Enable** This status is used for non-DMA transfers. This bit is set if valid data exists in Host buffer. **Volatile:** true 0_B Read disable 1_B Read enable
RSVD_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true
CARD_INSERTED	16	r	**Card Inserted** This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that Host Driver will not need to wait for it to stabilize. **Volatile:** true 0_B Reset or Debouncing or No card 1_B Card Inserted
CARD_STABLE	17	r	**Card Stable** If this bit is set, it means the Card Detect Level is stable. No card is detected if this bit is set to 1 and card inserted is 0 **Volatile:** true 0_B Reset or Debouncing 1_B No Card or Inserted
CARD_DETECT_LEVEL	18	r	**Card Detect Pin Level - CARD_DETECT_PIN_LEVEL** This bit reflects the card detect stats. **Volatile:** true 0_B No card present 1_B Card Present

Field	Bits	Type	Description
WR_PROTECT_SW_LVL	19	r	**Write Protect Switch Pin Level** The write Protect Switch is supported only for memory and combo card. **Volatile:** true 0_B Write protected 1_B Write enabled
DAT_3_0	23:20	r	**DAT[3:0] Line Signal Level (SD/eMMC Mode only)** This status is used to check the DAT line level to recover from errors and for debugging. **Volatile:** true
CMD_LINE_LVL	24	r	**Command Line Signal Level (SD/eMMC Mode only)** This status is used to check the CMD line level to recover from errors and for debugging. **Volatile:** true
HOST_REG_VOL	25	r	**Host Regulator Voltage Stable** This bit can be ignored. **Volatile:** true
RSVD_26	26	r	**Reserved** This bit is reserved. It will always return 0. **Volatile:** true
CMD_ISSUE_ERR	27	r	**Command Not Issued by Error** This bit is set if a command cannot be issued after setting the command register due to error except Auto CMD12 error **Volatile:** true 0_B No error for issuing a command 1_B Command cannot be issued
SUB_CMD_STAT	28	r	**Sub Command Status** This status is used to distinguish main command and sub command status. **Volatile:** true 0_B Main Command Status 1_B Sub Command Status
IN_DORMANT_ST	29	r	**In Dormant Status** This bit can be ignored. **Volatile:** true
LANE_SYNC	30	r	**Lane Synchronization** This bit can be ignored. **Volatile:** true
UHS2_IF_DETECT	31	r	**UHS-II IF Detection** This bit can be ignored. **Volatile:** true

Host Control 1 Register

This register is used to control the operation of Host Controller. This register is applicable for an SD/eMMC mode.

HOST_CTRL1
Host Control 1 Register **(028$_H$)** **Application Reset Value: 00$_H$**

7	6	5	4	3	2	1	0
CARD_DETECT_SIG_LVL	CARD_DETECT_TEST_LVL	EXT_DAT_XFER	DMA_SEL		HIGH_SPEED_EN	DAT_XFER_WIDTH	LED_CTRL
rw	rw	rw	rw		rw	rw	rw

Field	Bits	Type	Description
LED_CTRL	0	rw	**LED Control** This bit can be ignored. Must be written with '0'. 0_B LED off 1_B LED on
DAT_XFER_WIDTH	1	rw	**Data Transfer Width (SD/eMMC Mode only)** This bit selects the data width of the Host Controller. The Host Driver shall set it to match the data width of the SD/eMMC card. 0_B 1-bit mode 1_B 4-bit mode
HIGH_SPEED_EN	2	rw	**High Speed Enable (SD/eMMC Mode only)** Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. This bit is used to determine the selection of preset value for High Speed mode. *Note: DWC_MSHC always outputs the **sd_cmd_out and sd_dat_out** lines at the rising edge of **cclk_tx** clock irrespective of this bit.* 0_B Normal Speed mode 1_B High Speed mode

Field	Bits	Type	Description
DMA_SEL	4:3	rw	**DMA Select** This field is used to select the DMA type. When Host Version 4 Enable is 1 in Host Control 2 register: • 00b - SDMA is selected • 01b - Reserved • 10b - ADMA2 is selected • 11b - ADMA2 or ADMA3 is selected When Host Version 4 Enable is 0 in Host Control 2 register: • 00b - SDMA is selected • 01b - Reserved • 10b - 32-bit Address ADMA2 is selected • 11b - Reserved 00_B SDMA is selected 01_B Reserved 10_B ADMA2 is selected (+32 bit address if Host Version 4 enable is 1 in Host Control 2 register) 11_B ADMA2 or ADMA3 is selected
EXT_DAT_XFER	5	rw	**Extended Data Transfer Width (Embedded and an SD/eMMC Mode only)** This bit controls 8-bit bus width mode of embedded device. 0_B Bus Width is selected by Data Transfer Width 1_B 8-bit Bus Width
CARD_DETECT_TEST_LVL	6	rw	**Card Detect Test Level** This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not 0_B No Card 1_B Card Inserted
CARD_DETECT_SIG_LVL	7	rw	**Card Detect Signal Selection** This bit selects source for card detection 0_B SDCD# is selected (for normal use) 1_B The Card Detect Test Level is selected (for test purpose)

Power Control Register

Control the bus power for the Card. This register is applicable for an SD/eMMC mode.

PWR_CTRL
Power Control Register **(029$_H$)** **Application Reset Value: 00$_H$**

7	6	5	4	3	2	1	0
SD_BUS_VOL_VDD2			SD_BUS_PWR_VDD2	SD_BUS_VOL_VDD1			SD_BUS_PWR_VDD1
rw			rw	rw			rw

Field	Bits	Type	Description
SD_BUS_PWR_VDD1	0	rw	**SD Bus Power for VDD1** Before setting this bit, the SD Host Driver shall set SD Bus Voltage Select. If the Host Controller detects the No Card state, this bit shall be cleared. In SD mode, if this bit is cleared, the Host Controller shall stop SD Clock by clearing SD_CLK_IN bit in CLK_CTRL_R register. 0_B Power off 1_B Power on
SD_BUS_VOL_VDD1	3:1	rw	**SD Bus Voltage Select for VDD1/eMMC Bus Voltage Select for VDD.** By setting these bits, the Host Driver selects the voltage level for the SD/eMMC card. Before setting this register, the Host Driver shall check the Voltage Support bits in the capabilities register. If an unsupported voltage is selected, the Host System shall not supply SD Bus voltage. The value set in this field is available on the DWC_mshc output signal (sd_vdd1_sel), which will be used by the voltage switching circuitry. 000_B Reserved … 110_B Reserved 111_B SD 3.3 V (Typ.) / eMMC 3.0 V (Typ.)
SD_BUS_PWR_VDD2	4	rw	**SD Bus Power for VDD2.** This bit needs to be written with '1'
SD_BUS_VOL_VDD2	7:5	rw	**SD Bus Voltage Select for VDD2.** This field needs to be written with 0b000 000_B VDD2 Not Supported 001_B Reserved … 101_B Reserved 110_B Not used 111_B Not used

Block Gap Control Register

The host driver shall use this register to control any operation related to Block Gap. This register is applicable for an SD/eMMC mode.

BGAP_CTRL
Block Gap Control Register **(02A$_H$)** **Application Reset Value: 00$_H$**

7	6	5	4	3	2	1	0
RSVD_7_4				INT_AT_BGAP	RD_WAIT_CTRL	CONTINUE_REQ	STOP_BG_REQ
r				rw	rw	rw	rw

Field	Bits	Type	Description
STOP_BG_REQ	0	rw	**Stop At Block Gap Request** This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. 0_B Transfer 1_B Stop
CONTINUE_REQ	1	rw	**Continue Request** This bit is used to restart the transaction, which was stopped using the Stop At Block Gap Request. The Host Controller automatically clears this bit when the transaction re-starts. If stop at block gap request is set to 1, any write to this bit is ignored. **Volatile:** true 0_B Not Affected 1_B Restart
RD_WAIT_CTRL	2	rw	**Read Wait Control (SD Mode only)** This bit is used to enable the read wait protocol to stop read data using DAT[2] line if the card supports read wait. Otherwise, the Host Controller has to stop the card clock to hold the read data. 0_B Disable Read Wait Control 1_B Enable Read Wait Control
INT_AT_BGAP	3	rw	**Interrupt At Block Gap (SD Mode only)** This bit is valid only in 4-bit mode of SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. 0_B Disabled 1_B Enabled
RSVD_7_4	7:4	r	**Reserved** These bits of Block Gap Control register are reserved. They will always return 0.

Wakeup Control Register

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control Register, when wakeup event through Card Interrupt is desired.

WUP_CTRL
Wakeup Control Register **(02B$_H$)** **Application Reset Value: 00$_H$**

7	6	5	4	3	2	1	0
RSVD_7_3					CARD_REMOVAL	CARD_INSERT	CARD_INT
r					rw	rw	rw

Field	Bits	Type	Description
CARD_INT	0	rw	**Wakeup Event Enable on Card Interrupt** This bit enables wakeup event through Card Interrupt assertion in the Normal Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. 0_B Disable 1_B Enable
CARD_INSERT	1	rw	**Wakeup Event Enable on SD Card Insertion** This bit enables wakeup event through Card Insertion assertion in the Normal Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not affect this bit. 0_B Disable 1_B Enable
CARD_REMOVAL	2	rw	**Wakeup Event Enable on SD Card Removal** This bit enables wakeup event through Card Removal assertion in the Normal Interrupt Status register.FN_WUS (Wake Up Support) in CIS does not affect this bit. 0_B Disable 1_B Enable
RSVD_7_3	7:3	r	**Reserved** These bits are reserved. They will always return 0.

Clock Control Register

This register controls SDCLK (card clock) in an SD/eMMC mode. This register is applicable for an SD/eMMC mode.

CLK_CTRL
Clock Control Register **(02C$_H$)** **Application Reset Value: 0000$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FREQ_SEL								UPPER_FREQ_SEL		CLK_GEN_SELECT	RSVD_4	PLL_ENABLE	SD_CLK_EN	INTERNAL_CLK_STABLE	INTERNAL_CLK_EN
rw								rw		rw	r	rw	rw	r	rw

Field	Bits	Type	Description
INTERNAL_CLK_EN	0	rw	**Internal Clock Enable** This bit is set to 0 when the Host Driver is not using the Host Controller or the Host Controller awaits a wakeup interrupt. The Host Controller should stop its internal clock to go to a very low power state. However, registers can still be able read and written to. 0_B Stop 1_B Oscillate
INTERNAL_CLK_STABLE	1	r	**Internal Clock Stable** Host Driver checks clock stability by this status twice after Internal Clock Enable is set and after PLL Enable is set. **Volatile:** true 0_B Not Ready 1_B Ready
SD_CLK_EN	2	rw	**SD/eMMC Clock Enable** This bit stops the SDCLK or RCLK when this bit is set to 0. SDCLK/RCLK Frequency Select can be changed when this bit is 0. 0_B Disable 1_B Enable
PLL_ENABLE	3	rw	**PLL Enable** This bit can be ignored. Must be written with '0'. 0_B PLL is in low power mode 1_B PLL is enabled
RSVD_4	4	r	**Reserved** This bit is reserved. It will always return 0.
CLK_GEN_SELECT	5	rw	**Clock Generator Select** This bit is used to select the clock generator mode in SDCLK/RCLK Frequency Select. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set to a value specified in one of the Preset Value registers. **Volatile:** true 0_B Divided Clock Mode 1_B Programmable Clock Mode
UPPER_FREQ_SEL	7:6	rw	**SDCLK/RCLK Frequency Select - FREQ_SEL** These bits together with FREQ_SEL are used to select the frequency of the SDCLK pin. This field depends on setting of Preset Value Enable in Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set to a value specified in one of the Preset Value register. SPB clock frequency is calculated with the formula =fSPB * 1/((N+1)*2). **Volatile:** true

Field	Bits	Type	Description
FREQ_SEL	15:8	rw	**SDCLK/RCLK Frequency Select** These bits together with UPPER_FREQ_SEL are used to select the frequency of the SDCLK pin. This field depends on setting of Preset Value Enable in Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set to a value specified in one of the Preset Value register. SPB clock frequency is calculated with the formula =fSPB * 1/((N+1)*2). **Volatile:** true **10-bit Divided Clock Mode:** • 3FFh - 1/2048 SPB Clock • ... - ... • N - 1/2(N+1) SPB Clock • ... - ... • 002h - 1/6 SPB Clock • 001h - 1/4 SPB Clock • 000h - 1/2 SPB Clock

Timeout Control Register

At the initialization of the Host Controller, the Host Driver shall set the Data Timeout Counter value for an SD/eMMC mode according to the timer clock defined in the Capabilities register.

TOUT_CTRL

Timeout Control Register **($02E_H$)** **Application Reset Value: 00_H**

7	6	5	4	3	2	1	0
RSVD_7_4				TOUT_CNT			
r				rw			

Field	Bits	Type	Description
TOUT_CNT	3:0	rw	**Data Timeout Counter Value.** This value determines the interval by which DAT line timeouts are detected. The Timeout is based on the base clock TMCLK, which is fSPB devided by 32. Timeout clock frequency will be generated by dividing the base clock TMCLK value by this value. When setting this register, prevent inadvertent timeout events by clearing the Data Timeout Error Status Enable (in the Error Interrupt Status Enable register) *Note: During a boot operating in an eMMC mode, an application should configure the boot data timeout value (approximately 1 sec) in this field.* 0_H TMCLK * 2^13 1_H TMCLK * 2^14 2_H TMCLK * 2^15 … E_H TMCLK * 2^27 F_H Reserved
RSVD_7_4	7:4	r	**Reserved** These bits are reserved. They will always return 0.

Software Reset Register

A reset pulse is generated when writing 1 to each bit of this register. After completing the reset, the Host Controller shall clear each bit. As it takes some time to complete software reset, the Host Driver shall confirm that these bits are 0. This register is applicable for an SD/eMMC mode.

SW_RST
Software Reset Register **($02F_H$)** **Application Reset Value: 00_H**

7	6	5	4	3	2	1	0
RSVD_7_3					SW_RST_DAT	SW_RST_CMD	SW_RST_ALL
r					rw	rw	rw

Field	Bits	Type	Description
SW_RST_ALL	0	rw	**Software Reset For All** This reset affects the entire Host Controller except for the card detection circuit. During its initialization, the Host Driver shall set this bit to 1 to reset the Host Controller. All registers are reset except the capabilities register. If this bit is set to 1, the Host Driver should issue reset command and reinitialize the SD/eMMC card. **Volatile:** true 0_B Work 1_B Reset

Field	Bits	Type	Description
SW_RST_CMD	1	rw	**Software Reset For CMD line** Only part of command circuit is reset to be able to issue a command. This reset is effective only for a command issuing circuit (including response error statuses related to Command Inhibit (CMD) control) and does not affect the data transfer circuit. Host Controller can continue data transfer even after this reset is executed during handling of subcommand response errors. The following registers and bits are cleared by this bit: - Present State register Command Inhibit (CMD) - Normal Interrupt Status register Command Complete - Error Interrupt Status Response error statuses related to Command Inhibit (CMD) **Volatile:** true 0_B Work 1_B Reset

Field	Bits	Type	Description
SW_RST_DAT	2	rw	**Software Reset For DAT line (SD/eMMC Mode only)** This bit resets only a part of the data circuit and the DMA circuit is also reset. The following registers and bits are cleared by this bit: • Buffer Data Port register Buffer is cleared and initialized. – Buffer is cleared and initialized. • Present state register Buffer Read Enable Buffer Write Enable Read Transfer Active Write Transfer Active DAT Line Active Command Inhibit (DAT) – Buffer Read Enable – Buffer Write Enable – Read Transfer Active – Write Transfer Active – DAT Line Active – Command Inhibit (DAT) • Block Gap Control register Continue Request Stop At Block Gap Request – Continue Request – Stop At Block Gap Request • Normal Interrupt status register Buffer Read Ready Buffer Write Ready DMA Interrupt Block Gap Event Transfer Complete – Buffer Read Ready – Buffer Write Ready – DMA Interrupt – Block Gap Event – Transfer Complete **Volatile:** true 0_B Work 1_B Reset
RSVD_7_3	7:3	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true

Normal Interrupt Status Register

This register reflects the status of Normal Interrupt. This register is applicable for an SD/eMMC mode.

NORMAL_INT_STAT

Normal Interrupt Status Register **(030_H)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	rwh	r	r	r	r	r	r	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
CMD_COMPLETE	0	rwh	**Command Complete** In an SD/eMMC Mode, this bit is set when the end bit of a response except for Auto CMD12 and Auto CMD23. This interrupt is not generated when the Response Interrupt Disable in Transfer Mode Register is set to 1. A write of 1 clears this register field. **Volatile:** true 0_B No command complete 1_B Command Complete
XFER_COMPLETE	1	rwh	**Transfer Complete** This bit is set when a read/write transfer and a command with status busy is completed. A write of 1 clears this register field. **Volatile:** true 0_B Not complete 1_B Command execution is completed
BGAP_EVENT	2	rwh	**Block Gap Event** This bit is set when both read/write transaction is stopped at block gap due to Stop at Block Gap Request. A write of 1 clears this register field. **Volatile:** true 0_B No Block Gap Event 1_B Transaction stopped
DMA_INTERRUPT	3	rwh	**DMA Interrupt** This bit is set if the Host Controller detects the SDMA Buffer Boundary during transfer. In case of ADMA, by setting Int field in the descriptor table, Host controller generates this interrupt. This interrupt shall not be generated after Transfer Complete. A write of 1 clears this register field. **Volatile:** true 0_B No DMA Interrupt 1_B DMA Interrupt is generated

Field	Bits	Type	Description
BUF_WR_READY	4	rwh	**Buffer Write Ready** This bit is set if the Buffer Write Enable changes from 0 to 1. A write of 1 clears this register field. **Volatile:** true 0_B Not ready to write buffer 1_B Ready to write buffer
BUF_RD_READY	5	rwh	**Buffer Read Ready** This bit is set if the Buffer Read Enable changes from 0 to 1. A write of 1 clears this register field. **Volatile:** true 0_B Not ready to read buffer 1_B Ready to read buffer
CARD_INSERTION	6	rwh	**Card Insertion** This bit is set if the Card Inserted in the Present State register changes from 0 to 1. A write of 1 clears this register field. **Volatile:** true 0_B Card state stable or Debouncing 1_B Card Inserted
CARD_REMOVAL	7	rwh	**Card Removal** This bit is set if the Card Inserted in the Present State register changes from 1 to 0. A write of 1 clears this register field. **Volatile:** true 0_B Card state stable or Debouncing 1_B Card Removed
CARD_INTERRUPT	8	r	**Card Interrupt** This bit reflects the synchronized value of: DAT[1]. *Note: This reflection changes after the interrupt ocurred. Clearing the interrupt is only possible by clearing it inside the card while the CARD_INTERRUPT is disabled inside SDMMC.* **Volatile:** true 0_B No Card Interrupt 1_B Generate Card Interrupt
INT_A	9	r	**INT_A (Embedded)** This bit is set if INT_A is enabled. **Volatile:** true 0_B No Interrupt is detected 1_B INT_A is detected

Field	Bits	Type	Description
INT_B	10	r	**INT_B (Embedded)** This bit is set if INT_B is enabled. **Volatile:** true 0_B No Interrupt is detected 1_B INT_B is detected
INT_C	11	r	**INT_C (Embedded)** This bit is set if INT_C is enabled. **Volatile:** true 0_B No Interrupt is detected 1_B INT_C is detected
RE_TUNE_EVENT	12	r	**Re-tuning Event** This bit can be ignored. **Volatile:** true
FX_EVENT	13	r	**FX Event** This status is set when r[14] of response register is set to 1 and Response Type R1/R5 is set to 0 in Transfer Mode register. This interrupt is used with response check function. **Volatile:** true 0_B No Event 1_B FX Event is detected
CQE_EVENT	14	rwh	**Command Queuing Event** This bit can be ignored. 0_B No Event 1_B Command Queuing Event is detected
ERR_INTERRUPT	15	r	**Error Interrupt** If any of the bits in the Error Interrupt Status register are set, then this bit is set. **Volatile:** true 0_B No Error 1_B Error

Error Interrupt Status Register

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Status Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit and writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. This register is applicable for an SD/eMMC mode.

ERROR_INT_STAT

Error Interrupt Status Register **(032_H)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_ERR3	VENDOR_ERR2	VENDOR_ERR1	BOOT_ACK_ERR	RESP_ERR	TUNING_ERR	ADMA_ERR	AUTO_CMD_ERR	CUR_LMT_ERR	DATA_END_BIT_ERR	DATA_CRC_ERR	DATA_TOUT_ERR	CMD_IDX_ERR	CMD_END_BIT_ERR	CMD_CRC_ERR	CMD_TOUT_ERR
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CMD_TOUT_ERR	0	rw	**Command Timeout Error (SD/eMMC Mode only)** This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command. If the Host Controller detects a CMD line conflict, clock cycles. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Time out
CMD_CRC_ERR	1	rw	**Command CRC Error (SD/eMMC Mode only)** Command CRC Error is generated in two cases. If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B CRC Error Generated
CMD_END_BIT_ERR	2	rw	**Command End Bit Error (SD/eMMC Mode only)** This bit is set when detecting that the end bit of a command response is 0. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B End Bit Error Generated
CMD_IDX_ERR	3	rw	**Command Index Error (SD/eMMC Mode only)** This bit is set if a Command Index error occurs in the commandresponse. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error

Field	Bits	Type	Description
DATA_TOUT_ERR	4	rw	**Data Timeout Error (SD/eMMC Mode only)** This bit is set when detecting one of the following timeout conditions: - Busy timeout for R1b, R5b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Time out
DATA_CRC_ERR	5	rw	**Data CRC Error (SD/eMMC Mode only).** This error occurs when detecting CRC error when transferring read data which uses the DAT line, when detecting the Write CRC status having a value of other than 010 or when write CRC status timeout. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error
DATA_END_BIT_ERR	6	rw	**Data End Bit Error (SD/eMMC Mode only)** This error occurs either when detecting 0 at the end bit position of read data that uses the DAT line or at the end bit position of the CRC status. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error
CUR_LMT_ERR	7	rw	**Current Limit Error** By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. A reading of 1 for this bit means that the Host Controller is not supplying power to the SD card due to some failure. A reading of 0 for this bit means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Power Fail

Field	Bits	Type	Description
AUTO_CMD_ERR	8	rw	**Auto CMD Error (SD/eMMC Mode only)** This error status is used by Auto CMD12 and Auto CMD23. This bit is set when detecting that any of the bits D00 to D05 in Auto CMD Error Status register has changed from 0 to 1. D07 is effective in case of Auto CMD12. Auto CMD Error Status register is valid while this bit is set to 1 and may be cleared by clearing of this bit (another implementation is also allowed). A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error
ADMA_ERR	9	rw	**ADMA Error** This bit is set when the Host Controller detects error during ADMA-based data transfer. The error could be due to following reasons: • Error response received from System bus (Master I/F) • ADMA3,ADMA2 Descriptors invalid • CQE Task or Transfer descriptors invalid When the error occurs, the state of the ADMA is saved in the ADMA Error Status register. In eMMC CQE mode: The Host Controller generates this Interrupt when it detects an invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error has occurred in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error
TUNING_ERR	10	rw	**Tuning Error** This bit can be ignored and needs to be written to with '0'. **Volatile:** true
RESP_ERR	11	rw	**Response Error (SD Mode only)** Host Controller Version 4.00 supports response error check function to avoid overhead of response error check by Host Driver during DMA execution. If Response Error Check Enable is set to 1 in the Transfer Mode register, Host Controller Checks R1 or R5 response. If an error is detected in a response, this bit is set to 1. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error

Field	Bits	Type	Description
BOOT_ACK_ERR	12	rw	**Boot Acknowledgement Error (eMMC Mode only)** This bit is set when there is a timeout for boot acknowledgement or when detecting boot ack status having a value other than 010. This is applicable only when boot acknowledgement is expected and boot feature in DWC_mshc is enabled with DWC_MSHC_EMMC_BOOT_EN = 1. A write of 1 clears this register field. **Volatile:** true 0_B No Error 1_B Error
VENDOR_ERR1	13	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error
VENDOR_ERR2	14	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error
VENDOR_ERR3	15	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error

Normal Interrupt Status Enable Register

This register enables the Interrupt Status for Normal Interrupt Status register (NORMAL_INT_STAT_R) when NORMAL_INT_STAT_R is set to 1. This register is applicable for an SD/eMMC mode.

NORMAL_INT_STAT_EN
Normal Interrupt Status Enable Register **(034_H)** **Application Reset Value: 0000_H**

VENDOR_ERR_SIGNAL_EN1	13	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B Masked 1_B Enabled
VENDOR_ERR_SIGNAL_EN2	14	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B Masked 1_B Enabled
VENDOR_ERR_SIGNAL_EN3	15	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B Masked 1_B Enabled

Auto CMD Status Register

This register is used to indicate the CMD12 response error of Auto CMD12, and the CMD23 response error of Auto CMD23. The Host driver can determine the kind of Auto CMD12/CMD23 errors that can occur in this register. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when Auto CMD Error is set. This register is applicable for an SD/eMMC mode. Writing this register has no effect.

AUTO_CMD_STAT
Auto CMD Status Register **($03C_H$)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_15_8								CMD_NOT_ISSUED_AUTO	RSVD_6	AUTO_CMD_RESP_ERR	AUTO_CMD_IDX_ERR	AUTO_CMD_EBIT_ERR	AUTO_CMD_CRC_ERR	AUTO_CMD_TOUT_ERR	AUTO_CMD12_NOT_EXEC
r								r	r	r	r	r	r	r	r

Field	Bits	Type	Description
AUTO_CMD12_NOT_EXEC	0	r	**Auto CMD12 Not Executed** If multiple memory block data transfer is not started due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means that the Host Controller cannot issue Auto CMD12 to stop multiple memory block data transfer, due to some error. If this bit is set to 1, error status bits (D04-D01) is meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. **Volatile:** true 0_B Executed 1_B Not Executed
AUTO_CMD_TOUT_ERR	1	r	**Auto CMD Timeout Error** This bit is set if no response is returned with 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, error status bits (D04 - D01) are meaningless. **Volatile:** true 0_B No Error 1_B Time out
AUTO_CMD_CRC_ERR	2	r	**Auto CMD CRC Error** This bit is set when detecting a CRC error in the command response. **Volatile:** true 0_B No Error 1_B CRC Error Generated
AUTO_CMD_EBIT_ERR	3	r	**Auto CMD End Bit Error** This bit is set when detecting that the end bit of command response is 0. **Volatile:** true 0_B No Error 1_B End Bit Error Generated

Field	Bits	Type	Description
AUTO_CMD_IDX_ERR	4	r	**Auto CMD Index Error** This bit is set if the command index error occurs in response to a command. **Volatile:** true 0_B No Error 1_B Error
AUTO_CMD_RESP_ERR	5	r	**Auto CMD Response Error** This bit is set when Response Error Check Enable in the Transfer Mode register is set to 1 and an error is detected in R1 response of either Auto CMD12 or CMD13. This status is ignored if any bit between D00 to D04 is set to 1. **Volatile:** true 0_B No Error 1_B Error
RSVD_6	6	r	**Reserved** This bit is reserved. It will always return 0. **Volatile:** true
CMD_NOT_ISSUED_AUTO_CMD12	7	r	**Command Not Issued By Auto CMD12 Error** If this bit is set to 1, CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. **Volatile:** true 0_B No Error 1_B Not Issued
RSVD_15_8	15:8	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true

Host Control 2 Register

This register is used to control how the Host Controller operates. This register is applicable for an SD/eMMC mode.

HOST_CTRL2
Host Control 2 Register **($03E_H$)** **Application Reset Value: 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRESET_VAL_ENABLE	ASYNC_INT_ENABLE	ADDRESSING	HOST_VER4_ENABLE	CMD23_ENABLE	ADMA2_LEN_MODE	RSVD_9	UHS2_IF_ENABLE	SAMPLE_CLK_SEL	EXEC_TUNING	DRV_STRENGTH_SEL		SIGNALING_EN	UHS_MODE_SEL		
rw	rw	rw	rw	rw	rw	r	rw	rw	rw	rw		rw	rw		

Field	Bits	Type	Description
UHS_MODE_SEL	2:0	rw	**eMMC Speed Mode Select - MODE_SEL** This field is reserved and needs to be written to with '000'. 000_B Standard setting 001_B reserved 010_B Reserved … 111_B Reserved
SIGNALING_EN	3	rw	**1.8 V Signaling Enable** This bit must remain '0'.
DRV_STRENGTH_SEL	5:4	rw	**Driver Strength Select** This bitfield can be ignored.
EXEC_TUNING	6	rw	**Execute Tuning** This bit must remain '0'.
SAMPLE_CLK_SEL	7	rw	**Sampling Clock Select** This bit must remain '0'.
UHS2_IF_ENABLE	8	rw	**UHS-II Interface Enable** This bit must remain '0'.
RSVD_9	9	r	**Reserved** This bit is reserved. It will always return 0.
ADMA2_LEN_MODE	10	rw	**ADMA2 Length Mode** This bit selects ADMA2 Length mode to be either 16-bit or 26-bit. 0_B 16-bit Data Length Mode 1_B 26-bit Data Length Mode
CMD23_ENABLE	11	rw	**CMD23 Enable** If the card supports CMD23, this bit is set to 1. This bit is used to select Auto CMD23 or Auto CMD12 for ADMA3 data transfer. 0_B Auto CMD23 is disabled 1_B Auto CMD23 is enabled

Field	Bits	Type	Description
HOST_VER4_ENABLE	12	rw	**Host Version 4 Enable** This bit selects either Version 3.00 compatible mode or Version 4 mode. Functions of following fields are modified for Host Version 4 mode: • SDMA Address: SDMA uses ADMA System Address ($05F_H$-058_H) instead of SDMA System Address register (003_H-000_H) • ADMA2/ADMA3 selection: ADMA3 is selected by DMA select in Host Control 1 register • 32-bit Block Count: SDMA System Address register (003_H-000_H) is modified to 32-bit Block Count register *Note: It is recommended not to program ADMA3 Integrated Descriptor Address registers while operating in Host version less than 4 mode (Host Version 4 Enable = 0).* 0_B Version 3.00 compatible mode 1_B Version 4 mode
ADDRESSING	13	rw	**64-bit Addressing** This bit is effective when Host Version 4 Enable is set to 1. 0_B 32 bits addressing 1_B Reserved
ASYNC_INT_ENABLE	14	rw	**Asynchronous Interrupt Enable** This bit can be set if a card supports asynchronous interrupts and Asynchronous Interrupt Support is set to 1 in the Capabilities register. 0_B Disabled 1_B Enabled
PRESET_VAL_ENABLE	15	rw	**Preset Value Enable** This bit enables automatic selection of SDCLK frequency and Driver strength Preset Value registers. When Preset Value Enable is set, SDCLK frequency generation (Frequency Select and Clock Generator Select) amd driver strength selection is performed by the controller. These values are selected from set of Preset Value registers based on selected speed mode. During initialization, the host driver needs to manually set the clock preset value to SDCLK/Rclk frequency select. Preset value enable can be set after intialization completed, in accordance with PartA2_SD Host_controller_simplified_specification. 0_B SDCLK and Driver Strength are controlled by Host Driver 1_B Automatic Selection of SDCLK frequency and Driver Strength as Preset Values are Enabled

Capabilities 1 Register 0 to 31

This register provides the Host Driver with information specific to the Host Controller implementation. The host controller implements these values as fixed. Capabilities register is segregated into two 32-bit registers:

CAPABILITIES1_R and CAPABILITIES2_R. The CAPABILITIES1_R register is the lower part of Capabilities register. Writing this register has no effect.

CAPABILITIES1

Capabilities 1 Register 0 to 31 **(040_H)** **Application Reset Value: 216C 6483$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE_CLK_FREQ								TOUT_CLK_UNIT	RSVD_6	TOUT_CLK_FREQ					
r								r	r	r					

Field	Bits	Type	Description
TOUT_CLK_FREQ	5:0	r	**Timeout Clock Frequency** This bit shows the base clock frequency used to detect Data Timeout Error. The Timeout Clock unit defines the unit of the field value: • Timeout Clock Unit = 0 [KHz] unit: 1 KHz to 63 KHz • Timeout Clock Unit = 1 [MHz] unit: 1 MHz to 63 MHz • Not 0 unit: 1 KHz to 63 KHz or 1 MHz to 63 MHz • 00 0000b - Get information through another method
RSVD_6	6	r	**Reserved** This bit is reserved. It will always return 0.
TOUT_CLK_UNIT	7	r	**Timeout Clock Unit** This bit shows the unit of base clock frequency used to detect Data TImeout Error. 0_B kHz 1_B MHz

Field	Bits	Type	Description
BASE_CLK_FREQ	15:8	r	**Base Clock Frequency for SD clock** This value indicates the base (maximum) clock frequency for SD Clock. The definition of this field depends on Host Controller Version. • 6-Bit Base Clock Frequency: This mode is supported by the Host Controller version 1.00 and 2.00. The upper 2 bits are not effective and are always 0. The unit values are 1 MHz. The supported clock range is 10 MHz to 63 MHz. 11xx xxxb - Not Supported 0011 1111b - 63 MHz ..... - ..... 0000 0010 - 2 MHz 0000 001b - 1 MHz 0000 0000 - Get information through another method • 8-Bit Base Clock Frequency: This mode is supported by the Host Controller version 3.00. The unit values are 1 MHz. The supported clock range is 10 MHz to 255 MHz. FFh - 255 MHz ..... - ..... 02h - 2 MHz 01h - 1 MHz 00h - Get information through another method If the frequency is 16.5 MHz, the larger value shall be set to 0001001b (17 MHz) because the Host Driver uses this value to calculate the clock divider value and it shall not exceed the upper limit of the SD Clock frequency. If these bits are all 0, the Host system has to get information using a different method.
MAX_BLK_LEN	17:16	r	**Maximum Block Length** This bit indicates the maximum block size that the Host driver can read and write to the buffer in the Host Controller. The buffer transfers this block size without wait cycles. The transfer block length is always 512 bytes for the SD Memory irrespective of this bit. 00_B 512 Byte 01_B 1024 Byte 10_B 2048 Byte 11_B Reserved
Embedded_8_BIT	18	r	**8-bit Support for Embedded Device** This bit indicates whether the Host Controller is capable of using an 8-bit bus width mode. This bit is not effective when the Slot Type is set to 10b. 0_B 8-bit Bus Width not Supported 1_B 8-bit Bus Width Supported

Field	Bits	Type	Description
ADMA2_SUPPORT	19	r	**ADMA2 Support** This bit indicates whether the Host Controller is capable of using ADMA2. 0_B ADMA2 not Supported 1_B ADMA2 Supported
RSVD_20	20	r	**Reserved** This bit is reserved. It will always return 0.
HIGH_SPEED_SUPPORT	21	r	**High Speed Support** This bit indicates whether the Host Controller and the Host System supports High Speed mode and they can supply the SD Clock frequency from 25 MHz to 50 MHz. 0_B High Speed not Supported 1_B High Speed Supported
SDMA_SUPPORT	22	r	**SDMA Support** This bit indicates whether the Host Controller is capable of using SDMA to transfer data between the system memory and the Host Controller directly. 0_B SDMA not Supported 1_B SDMA Supported
SUS_RES_SUPPORT	23	r	**Suspense/Resume Support** This bit indicates whether the Host Controller supports Suspend/Resume functionality. If this bit is 0, the Host Driver shall not issue either Suspend or Resume commands because the Suspend and Resume mechanism is not supported. 0_B Not Supported 1_B Supported
VOLT_33	24	r	**Voltage Support 3.3 V** 0_B 3.3 V Not Supported 1_B 3.3 V Supported
VOLT_30	25	r	**Voltage Support 3.0 V** 0_B 3.0 V Not Supported 1_B 3.0 V Supported
VOLT_18	26	r	**Voltage Support 1.8 V** 0_B 1.8 V Not Supported 1_B 1.8 V Supported

Field	Bits	Type	Description
SYS_ADDR_64_V4	27	r	**64-bit System Address Support for V4** This bit sets the Host Controller to support 64-bit System Addressing of V4 mode. 0_B 64-bit System Address for V4 is Not Supported 1_B 64-bit System Address for V4 is Supported
SYS_ADDR_64_V3	28	r	**64-bit System Address Support for V3** This bit sets Host Controller to support 64-bit System Addressing of V3 mode. SDMA cannot be used in 64-bit Addressing in Version 3 Mode. 0_B 64-bit System Address for V3 is Not Supported 1_B 64-bit System Address for V3 is Supported
ASYNC_INT_SUPPORT	29	r	**Asynchronous Interrupt Support (SD Mode only)** 0_B Asynchronous Interrupt Not Supported 1_B Asynchronous Interrupt Supported
SLOT_TYPE	31:30	r	**Slot Type** This field indicates usage of a slot by a specific Host System. 00_B Removable Card Slot 01_B Embedded Slot for one Device 10_B Shared Bus Slot (SD mode) 11_B Reserved

Capabilities Register 32 to 63

This register provides the Host Driver with information specific to the Host Controller implementation. The host controller implements these values as fixed. Capabilities register is segregated into two 32-bit registers, namely CAPABILITIES1_R and CAPABILITIES2_R. The CAPABILITIES2_R register is upper part of Capabilities register. Writing this register has no effect.

CAPABILITIES2
Capabilities Register 32 to 63 **(044_H)** **Application Reset Value: $0800\ 0007_H$**

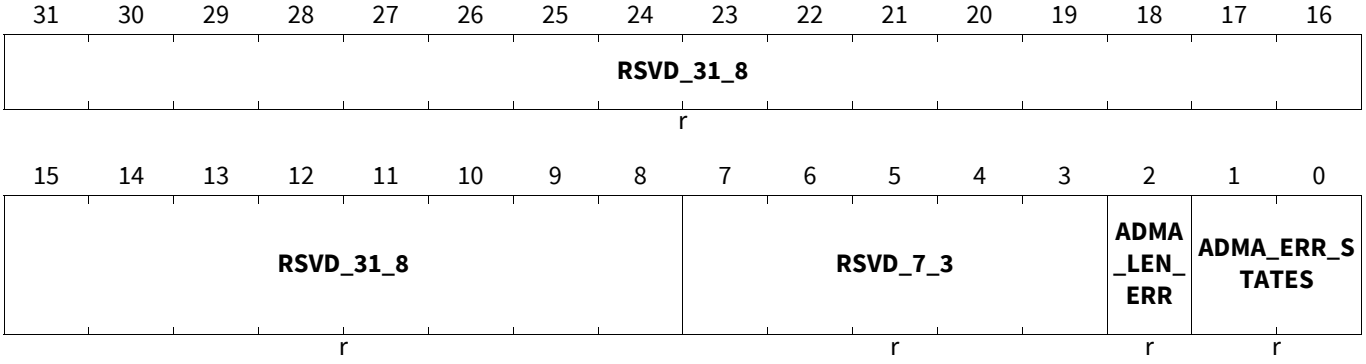
ADMA Error Status Register

This register holds the ADMA state during ADMA error. This register is applicable for an SD/eMMC mode. Writing this register has no effect.

ADMA_ERR_STAT

ADMA Error Status Register **(054_H)** **Application Reset Value: $0000\ 0000_H$**



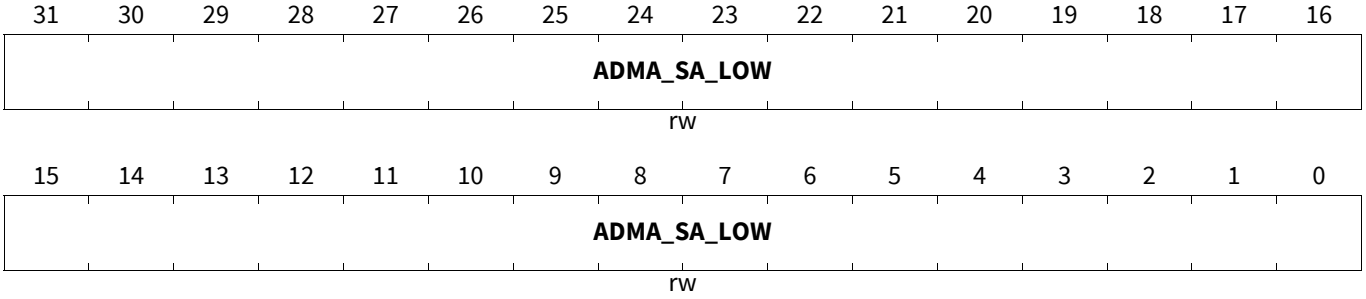
Field	Bits	Type	Description
ADMA_ERR_STATES	1:0	r	**ADMA Error States** These bits indicate the state of ADMA when an error occurs during ADMA data transfer. **Volatile:** true 00_B Stop DMA (SYS_ADR register points to a location next to the error descriptor) 01_B Fetch Descriptor (SYS_ADR register points to the error descriptor) 10_B Never set this state (Not used) 11_B Transfer Data (SYS_ADR register points to a location next to the error descriptor)
ADMA_LEN_ERR	2	r	**ADMA Length Mismatch Error States** This error occurs in the following instances: • While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length • Total data length cannot be divided by the block length **Volatile:** true 0_B No Error 1_B Error
RSVD_7_3	7:3	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true
RSVD_31_8	31:8	r	**Reserved** These bits are reserved. They will always return 0. Volatile: true

ADMA System Address Register Low

This register holds the lower 32-bit system address for DMA transfer. This register is applicable for an SD/eMMC mode.

ADMA_SA_LOW

ADMA System Address Register Low **(058_H)** **Application Reset Value: 0000 0000_H**



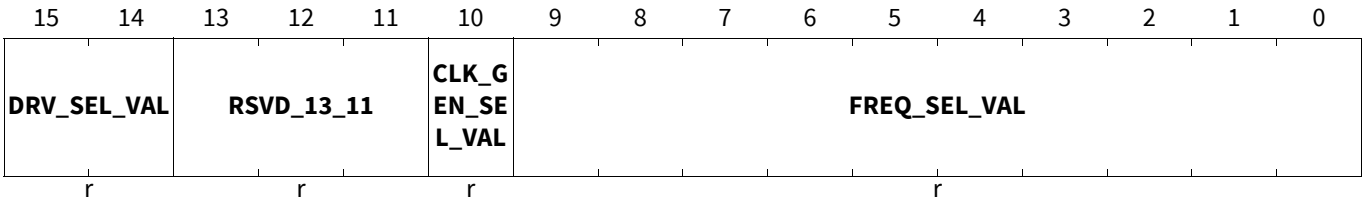
Field	Bits	Type	Description
ADMA_SA_LOW	31:0	rw	**ADMA System Address** These bits indicate the lower 32 bits of the ADMA system address. • SDMA If Host Version 4 Enable is set to 1, this register holds the system address of the data location • ADMA2 This register holds byte address of executing command of the descriptor table • ADMA3 This register is set by ADMA3. ADMA2 increments the address of this register that points to the next line, every time a Descriptor line is fetched. **Volatile:** true

Preset Value for Initialization

This register defines Preset Value for Initialization in SD/eMMC mode. Writing this register has no effect.

PRESET_INIT

Preset Value for Initialization **(060_H)** **Application Reset Value: $007F_H$**



Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK Frequency Select field of the Clock Control register described by a Host System.

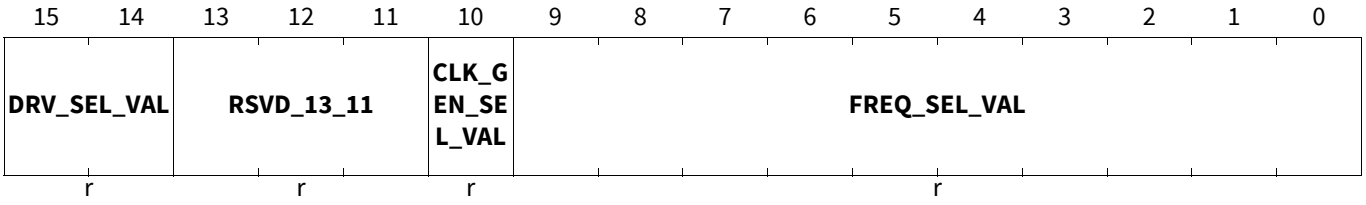
Field	Bits	Type	Description
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when the Host Controller supports a programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8V signaling bus speed modes. This field is meaningless for 3.3V signaling. 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected

Preset Value for Default Speed

This register defines Preset Value for Default Speed mode in SD mode. Writing this register has no effect.

PRESET_DS

Preset Value for Default Speed **(062_H)** **Application Reset Value: 0001_H**



Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK Frequency Select field of the Clock Control register described by a Host System.
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when Host Controller supports programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.

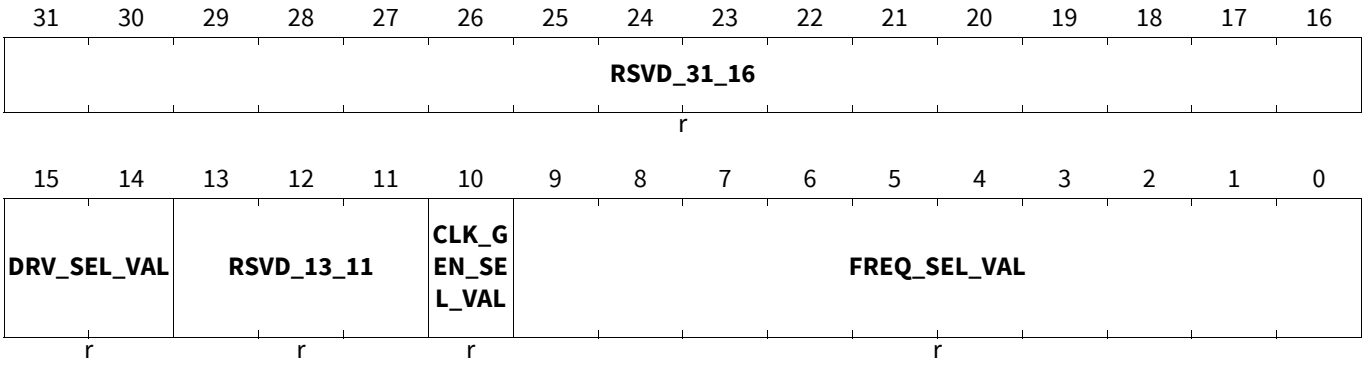
Field	Bits	Type	Description
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8 V signaling bus speed modes. This field is meaningless for 3.3 V signaling. **Value After Reset:** 0_H 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected

Preset Value for High Speed

This register defines Preset Value for High Speed mode in SD mode. Writing this register has no effect.

PRESET_HS

Preset Value for High Speed **(064_H)** **Application Reset Value: 0000 0000$_H$**



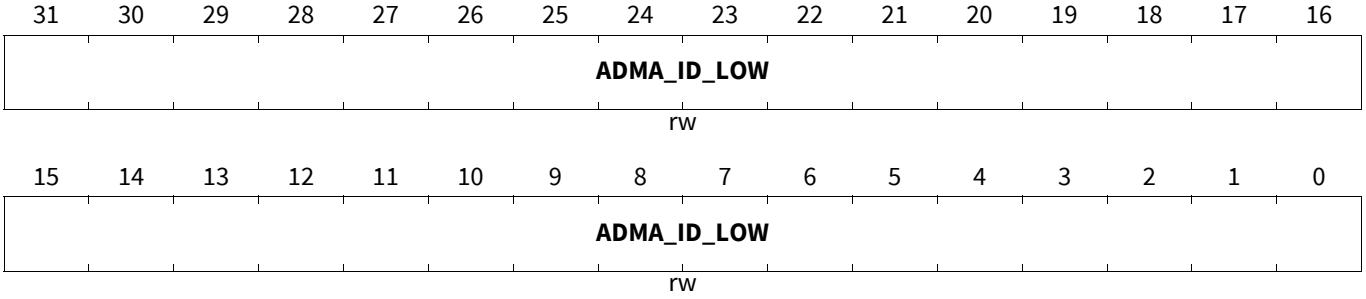
Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK Frequency Select field of the Clock Control register described by a Host System.
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when Host Controller supports programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8 V signaling bus speed modes. This field is meaningless for 3.3 V signaling. 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected
RSVD_31_16	31:16	r	**Reserved** These bits are reserved. They will always return 0.

ADMA3 Integrated Descriptor Address Register - Low

This register holds the lower 32-bit Integrated Descriptor address.This register is applicable for an SD/eMMC mode.

ADMA_ID_LOW

ADMA3 Integrated Descriptor Address Register - Low(078_H) **Application Reset Value: $0000\ 0000_H$**



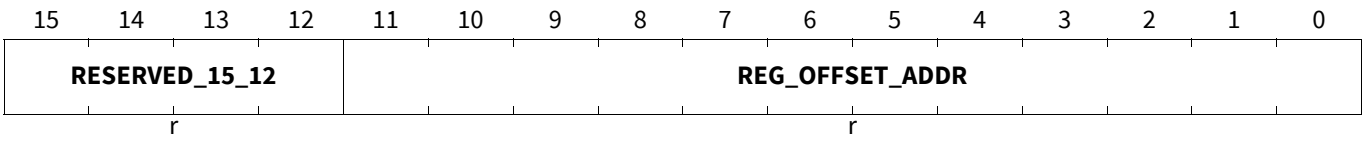
Field	Bits	Type	Description
ADMA_ID_LOW	31:0	rw	**ADMA Integrated Descriptor Address** This bit indicates the lower 32-bit of the ADMA Integrated Descriptor address. The start address of Integrated Descriptor is set to this register. The ADMA3 fetches one Descriptor Address and increments this field to indicate the next Descriptor address. **Volatile:** true

Pointer for Vendor Specific Area 1

This register used as a pointer for the Vendor Specific Area 1. Writing this register has no effect.

P_VENDOR_SPECIFIC_AREA

Pointer for Vendor Specific Area 1 **($0E8_H$)** **Application Reset Value: 0180_H**

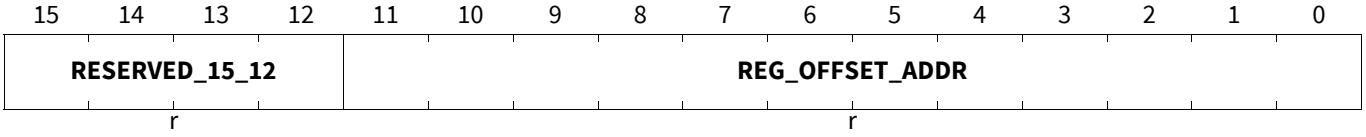


Field	Bits	Type	Description
REG_OFFSET_ADDR	11:0	r	**Base offset Address for Vendor Specific registers.**
RESERVED_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0.

Pointer for Vendor Specific Area 2

This register is used as a pointer for the Vendor Specific Area 2. Writing this register has no effect.

P_VENDOR2_SPECIFIC_AREA
Pointer for Vendor Specific Area 2 **($0EA_H$)** **Application Reset Value: 0300_H**

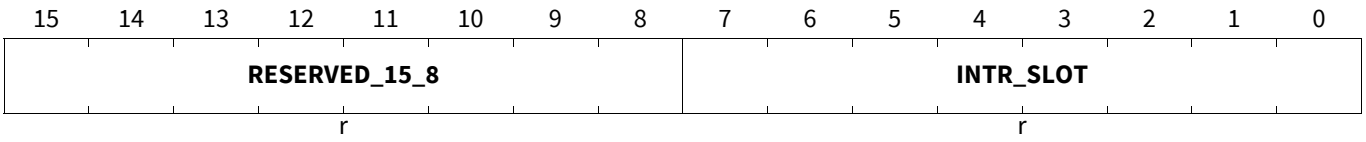


Field	Bits	Type	Description
REG_OFFSET_ADDR	11:0	r	**Base offset Address for Command Queuing registers.**
RESERVED_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0.

Slot Interrupt Status Register

This register indicate the Interrupt status of each slot. Writing this register has no effect.

SLOT_INTR_STATUS
Slot Interrupt Status Register **($0FC_H$)** **Application Reset Value: 0000_H**



Field	Bits	Type	Description
INTR_SLOT	7:0	r	**Interrupt signal for each Slot** These status bits indicate the logical OR of Interrupt signal and Wakeup signal for each slot. A maximum of 8 slots can be defined. If one interrupt signal is associated with multiple slots, the Host Driver can know which interrupt is generated by reading these status bits. By a power on reset or by setting Software Reset For All, the interrupt signal are de-asserted and this status reads 00h. **Volatile:** true 01_H Bit 0 - Slot 1 02_H Bit 1 - Slot 2 04_H Bit 2 - Slot 3 08_H Bit 3 - Slot 4 10_H Bit 4 - Slot 5 20_H Bit 5 - Slot 6 40_H Bit 6 - Slot 7 80_H Bit 7 - Slot 8
RESERVED_15_8	15:8	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true

Host Controller Version

This register is used to indicate the Host Controller Version number. Writing this register has no effect.

HOST_CNTRL_VERS
Host Controller Version **($0FE_H$)** **Application Reset Value: 1005_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_VERSION_NUM								SPEC_VERSION_NUM							
r								r							

Field	Bits	Type	Description
SPEC_VERSION_NUM	7:0	r	**Specification Version Number** This field indicates Host controller specification version. The upper and lower 4-bits indicate the version. 00_H SD Host Controller Specification Version 1.00 01_H SD Host Controller Specification Version 2.00 02_H SD Host Controller Specification Version 3.00 03_H SD Host Controller Specification Version 4.00 04_H SD Host Controller Specification Version 4.10 05_H SD Host Controller Specification Version 4.20 **others**, Reserved
VENDOR_VERSION_NUM	15:8	r	**Vendor Version Number** This field is reserved for the vendor version number. Host Driver should not use this status.

MSHC version

This register reflects the current release number of DWC_mshc/DWC_mshc_lite.

MSHC_VER_ID
MSHC version **(180_H)** **Application Reset Value: $3135\ 302A_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSHC_VER_ID															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSHC_VER_ID															
r															

Field	Bits	Type	Description
MSHC_VER_ID	31:0	r	**Current release number** This field indicates the Synopsys DesignWare Cores DWC_mshc/DWC_mshc_lite current release number that is read by an application. Current release is 1.50a which is represented in ASCII as 0x313530. Lower 8 bits read from this register can be ignored by the application. Application reading this register in conjunction with MSHC_VER_TYPE_R will gather details of the current release.

MSHC version type

This register reflects the current release type of DWC_mshc/DWC_mshc_lite.

MSHC_VER_TYPE
MSHC version type **(184_H)** **Application Reset Value: $6C70\ 3032_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSHC_VER_TYPE															
r															

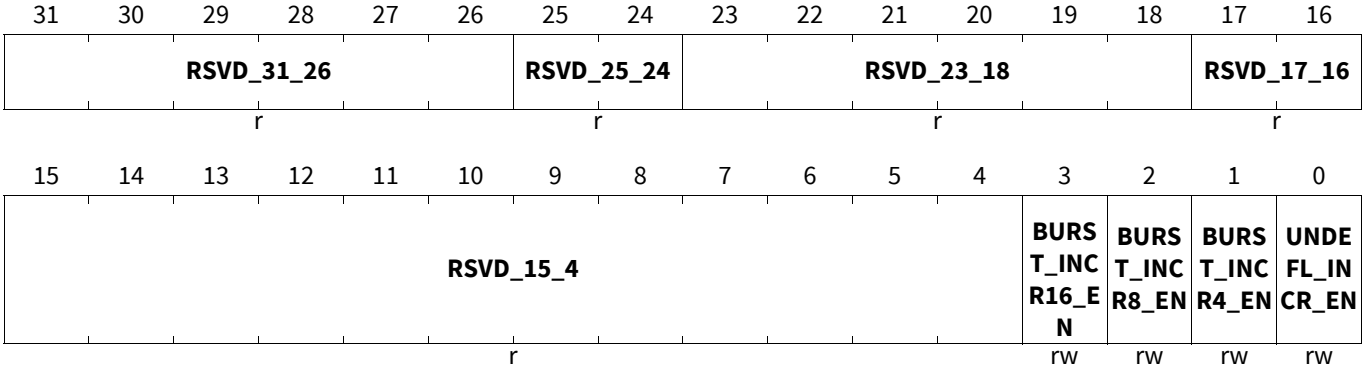
Field	Bits	Type	Description
MSHC_VER_TYPE	31:0	r	**Current release type** This field indicates the Synopsys DesignWare Cores DWC_mshc/DWC_mshc_lite current release type that is read by an application. Current release is of type "ga", which is represented in ASCII as 0x6761. Lower 16 bits read from this register can be ignored by the application. Application reading this register in conjunction with MSHC_VER_ID_R will gather details of the current release.

DMA burst control register

This register is used to control the Master bus interface.

MBIU_CTRL

DMA burst control register **(190_H)** **Application Reset Value: $0303\ 0006_H$**



Field	Bits	Type	Description
UNDEFL_INCR_EN	0	rw	**Controls the generation of undefined length INCR transfer on master interface** Must be disabled for usage of INCR4 and INCR8 bursts. 0_B INCR type bursts are not preferrend on AHB Master interface 1_B INCR type bursts are preferrend on AHB Master interface
BURST_INCR4_EN	1	rw	**Controls generation of INCR4 transfers on master interface** 0_B INCR bursts of length 4 are not generated on the master interface 1_B INCR bursts of length 4 can be generated on the master interface
BURST_INCR8_EN	2	rw	**Controls generation of INCR8 transfers on master interface** 0_B INCR bursts of length 8 are not generated on the master interface 1_B INCR bursts of length 8 can be generated on the master interface
BURST_INCR16_EN	3	rw	**Controls generation of INCR16 transfers on master interface** Not supported. Must be disabled. 0_B INCR bursts of length 16 are not generated on the master interface 1_B INCR bursts of length 16 can be generated on the master interface
RSVD_15_4	15:4	r	**Reserved - RSVD_7_4** These bits are reserved. They will always return 0.
RSVD_17_16	17:16	r	**Reserved** Write '1' to read '1'.
RSVD_23_18	23:18	r	**Reserved - RSVD_31_8** These bits are reserved. They will always return 0.
RSVD_25_24	25:24	r	**Reserved - RSVD_7_4** Write '1' to read '1'.
RSVD_31_26	31:26	r	**Reserved - RSVD_31_8** These bits are reserved. They will always return 0.

eMMC Control register

This register is used to control the eMMC operation.

EMMC_CTRL
eMMC Control register **(1AC$_H$)** **Application Reset Value: 0000$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD						CQE_ALGO_SEL	ENH_STROBE_ENABLE	RSVD_7_2						DISABLE_DATA_CRC_CHK	CARD_IS_EMMC
r						rw	rw	r						rw	rw

Field	Bits	Type	Description
CARD_IS_EMMC	0	rw	**eMMC Card present** This bit indicates the type of card connected. An application program this bit based on the card connected to MSHC. 0_B Card connected to MSHC is non eMMC card 1_B Card connected to MSHC is eMMC card
DISABLE_DATA_CRC_CHK	1	rw	**Disable Data CRC Check** This bit controls masking of CRC16 error for Card Write in eMMC mode. This is useful in bus testing (CMD19) for an eMMC device. In bus testing, an eMMC card does not send CRC status for a block, which may generate CRC error. This CRC error can be masked using this bit during bus testing. 0_B DATA CRC check is enabled 1_B DATA CRC check is disabled
RSVD_7_2	7:2	r	**Reserved** These bits are reserved. They will always return 0.
ENH_STROBE_ENABLE	8	rw	**Enhanced Strobe Enable** This bit will be ignored.
CQE_ALGO_SEL	9	rw	**Scheduler algorithm selected for execution** This bit will be ignored.
RSVD	15:10	r	**Reserved** These bits are reserved. They will always return zero.

eMMC Boot Control register

This register is used to control the eMMC Boot operation.

BOOT_CTRL
eMMC Boot Control register **(1AE$_H$)** **Application Reset Value: 0000$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT_TOUT_CNT				RSVD_11_9			BOOT_ACK_ENABLE	VALIDATE_BOOT	RSVD_6_1						MAN_BOOT_EN
rw				r			rw	w	r						rw

Field	Bits	Type	Description
MAN_BOOT_EN	0	rw	**Mandatory Boot Enable** This bit is used to initiate the mandatory boot operation. The application shall set this bit along with VALIDATE_BOOT bit. Writing 0 is ignored. The DWC_mshc clears this bit after the boot transfer is completed or terminated. **Testable:** readOnly 0_B Mandatory boot disable 1_B Mandatory boot enable
RSVD_6_1	6:1	r	**Reserved** These bits are reserved. They will always return 0.
VALIDATE_BOOT	7	w	**Validate Mandatory Boot Enable bit** This bit is used to validate the MAN_BOOT_EN bit. 0_B Ignore Mandatory boot Enable bit 1_B Validate Mandatory boot enable bit
BOOT_ACK_ENABLE	8	rw	**Boot Acknowledge Enable** When this bit set, DWC_mshc checks for boot acknowledge start pattern of 0-1-0 during boot operation. This bit is applicable for both mandatory and alternate boot mode. 0_B Boot Ack disable 1_B Boot Ack enable
RSVD_11_9	11:9	r	**Reserved** These bits are reserved. They will always return 0.
BOOT_TOUT_CNT	15:12	rw	**Boot Ack Timeout Counter Value.** This value determines the interval by which boot ack timeout (50 ms) is detected when boot ack is expected during boot operation. 0_H TMCLK * 2^13 1_H TMCLK * 2^14 2_H TMCLK * 2^15 … E_H TMCLK * 2^27 F_H Reserved

Embedded Control register

This register is control embedded device. When host controller is connected to removable device this register is not used.

EMBEDDED_CTRL
Embedded Control register **(280_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVD_31	BACK_END_PWR_CTRL							RSVD_23	INT_PIN_SEL			RSVD_19	CLK_PIN_SEL		
r	rw							r	rw			r	rw		

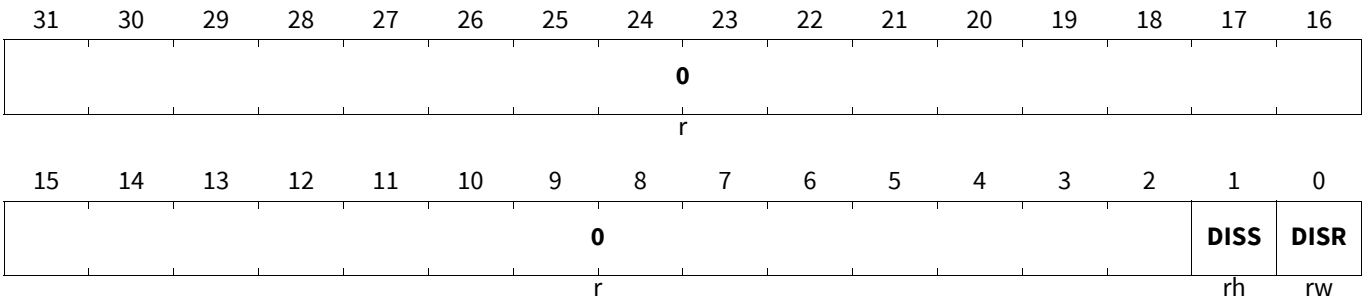
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_15	BUS_WIDTH_PRESET							RSVD_7_6		NUM_INT_PIN		RSVD_3	NUM_CLK_PIN		
r	r							r		r		r	r		

Field	Bits	Type	Description
NUM_CLK_PIN	2:0	r	**Number of Clock Pins (SD Mode)** This field is not used and can be ignored.
RSVD_3	3	r	**Reserved** This bit is reserved. It will always return 0.
NUM_INT_PIN	5:4	r	**Number of Interrupt Input Pins** This field is not used and can be ignored.
RSVD_7_6	7:6	r	**Reserved** These bits are reserved. They will always return 0.
BUS_WIDTH_PRESET	14:8	r	**Bus Width Preset (SD Mode)** This field is not used and can be ignored.
RSVD_15	15	r	**Reserved** This bit is reserved. It will always return 0.
CLK_PIN_SEL	18:16	rw	**Clock Pin Select (SD Mode)** This field is not used and should not be changed.
RSVD_19	19	r	**Reserved** This bit is reserved. It will always return 0.
INT_PIN_SEL	22:20	rw	**Interrupt Pin Select** This field is not used and should not be changed.
RSVD_23	23	r	**Reserved** This bit is reserved. It will always return 0.
BACK_END_PWR_CTRL	30:24	rw	**Back-End Power Control (SD Mode)** This field is not used and should not be changed.
RSVD_31	31	r	**Reserved** This bit is reserved. It will always return 0.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock for the module.

CLC
Clock Control Register **(300_H)** **Application Reset Value: 0000 0003$_H$**

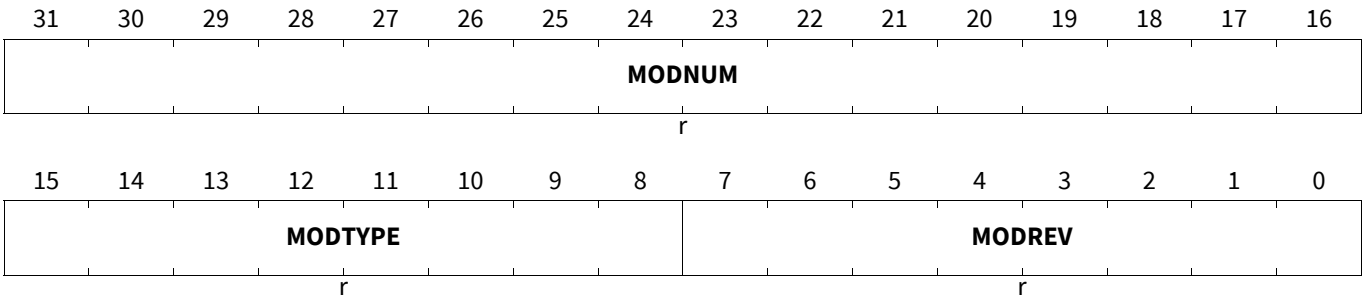


Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The disable request is delayed internally until all pending transactions on the master and slave interface are completed.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The SDMMC Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(304_H)** **Application Reset Value: 00E9 C0XX$_H$**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).

Field	Bits	Type	Description
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bitfield defines the module identification number for the SDMMC Module: $00E9_H$

Access Enable Register 0

The Access Enable Register 0 controls write access[1)]for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B.

ACCEN0

Access Enable Register 0 **($30C_H$)** **Application Reset Value: $FFFF\ FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

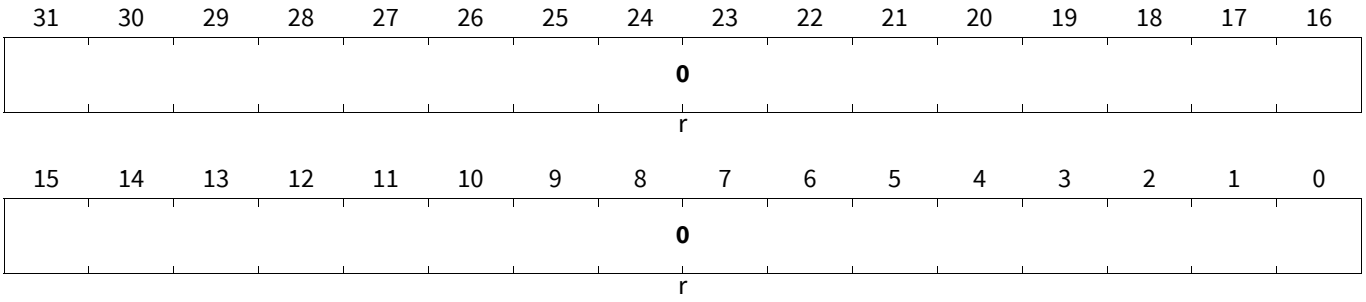
The Access Enable Register 1 controls write access1) for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the device.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, … , EN31 -> TAG ID 111111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ACCEN1

Access Enable Register 1 **(310_H)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0

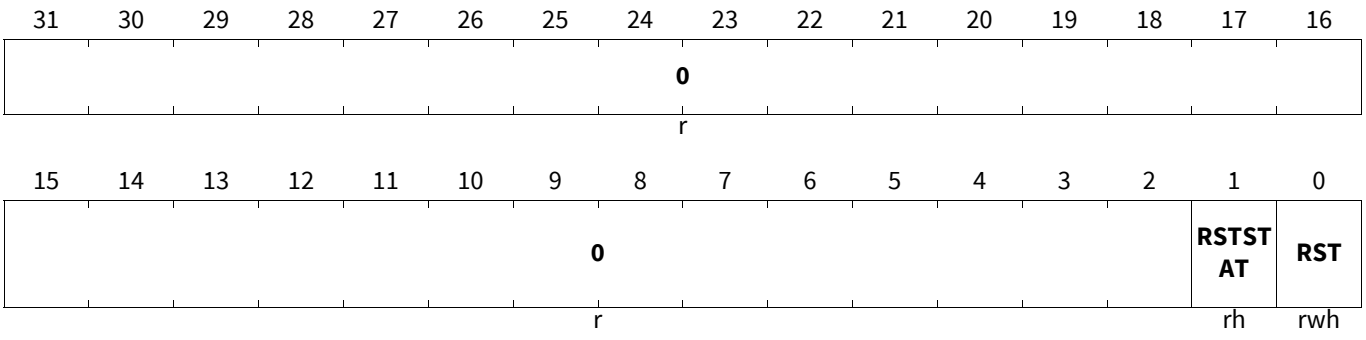
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 **(314_H)** **Application Reset Value: 0000 0000$_H$**

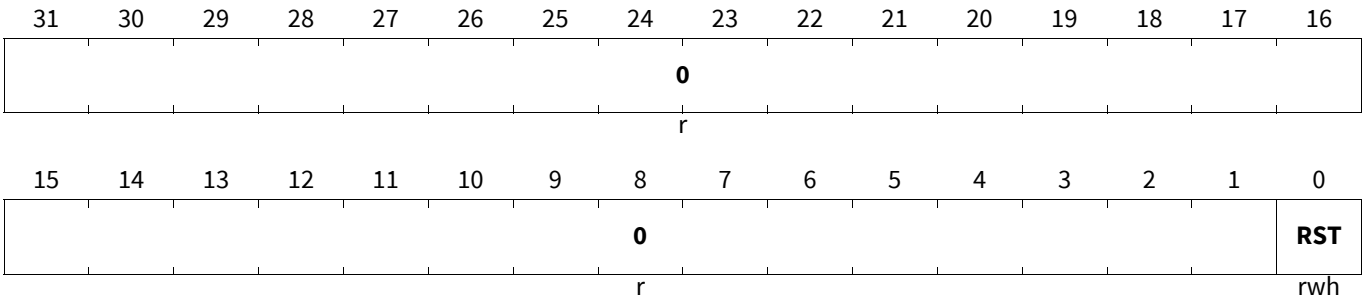


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set and both: master and slave interface are idle. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **(318_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set and both: master and slave interface are idle. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested

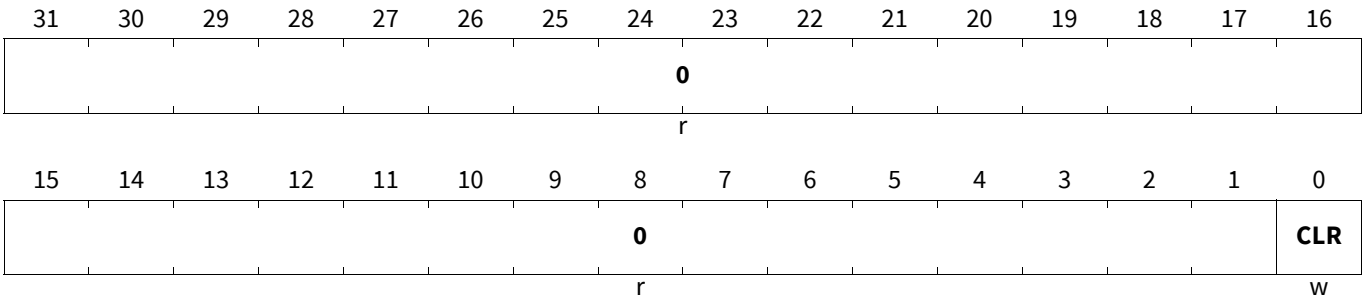
Field	Bits	Type	Description
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **($31C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

46.4 IO Interfaces

The table below lists all the interfaces of the SDMMC to other modules.

Table 541 List of SDMMC Interface Signals

Interface Signals	I/O	Description
CMD_IN	in	**command in** This signal reflects the read input from the command line pad.
CMD	out	**command out** This signal reflects the write output to the command line pad.
DAT0_IN	in	**read data in** This signal reflects the read input from the data line pads.
DAT1_IN		
DAT2_IN		
DAT3_IN		
DAT4_IN

47 Hardware Security Module (HSM)

The HSM is a separate processor subsystem dedicated for security tasks. It is connected as master and slave to the SPB bus.

For security reasons this module is described in a separate documentation. Please contact your Infineon representative for further information.

48 Input Output Monitor (IOM)

Description of the IOM (Input Output Monitor) block and its function within the system.

48.1 Feature List

- 16 Filter & Prescaler Channels, each connected to a specific pad (PIN), the output of which to serve as a monitor or reference signal.
- 16 Logic Analyzer Modules (LAMs), with each channel comprising a multiplexer to independently select monitor and reference signal inputs, with which to undertake the compare. A local event (i.e. internal to IOM) is generated when timing relationships between selected monitor and reference signals are violated. Configurable via register settings.
- 1 EXOR combiner, configurable (via register) to select a range of up to 8 GTM inputs in order to generate a combined signal to serve as a reference.
- Event Combiner Module (ECM), that takes the 16 local event signals (1 from each of the LAM modules) and generates a system event signal (connecting to system Safety Management Unit) from a single, combination or multiple local event(s). Configurable via register settings.
- System Peripheral Bus (SPB) interface for configuration and status register interaction.

48.2 Overview

The Input Output Monitor (IOM) module serves as a smart I/O comparison unit, observing and checking for the correct operation of system peripheral outputs that may serve and/or control externally-attached hardware, as well as the correct operation of the hardware itself, including any sensors whose signals may serve as an input to the monitoring function.

The monitoring function may be achieved in a number of configurable ways depending upon the application and the type of safety measure to be deployed. (Examples of such measures are included later-on within this chapter).

Monitor and reference signals (where needed) are taken from applicable system peripherals (i.e. Capture/Compare Units and General Purpose Timer Units) where they connect to internal pad logic (that feeds/controls I/O Ports), which may or may not be driven to the pads (configuration dependent). In this manner connectivity can be made to a signal that is to be driven externally, and to another signal that may serve as a reference, although may not be driven off-chip. A driven signal may also serve as a reference in order to compare against another that may be provided via a GPIO input, e.g. from a sensor external to the device.

Up to 16 monitoring points can be configured, with the capability to generate a system event that may be driven from one individual, several individual or multiple occurrences of a monitored condition, or a combination of several depending upon configuration.

48.3 Functional Description

48.3.1 Interfaces

The IOM features the following interfaces:

- System Peripheral Bus (SPB) - for the configuration of constituent parts of the IOM and the interrogation of associated status registers/bitfields.
- Multiple port logic/module connectivity, serving as reference or monitor signals.
- Safety Management Unit (SMU) - a single global event signal used to inform the SMU of a generated event within the IOM.

Note: The functionality of the IOM is independent from system debug, and no connectivity or mode of operation exists for this purpose.

48.3.2 Kernel Description

In addition to the Logic Analyzer Modules, Filter & Prescaler Blocks and Event Combiner Module, the IOM also features a System Peripheral Bus (SPB) interface for configuration and status register access. Note: All the configuration registers are protected by the register access protection mechanism (global definition).

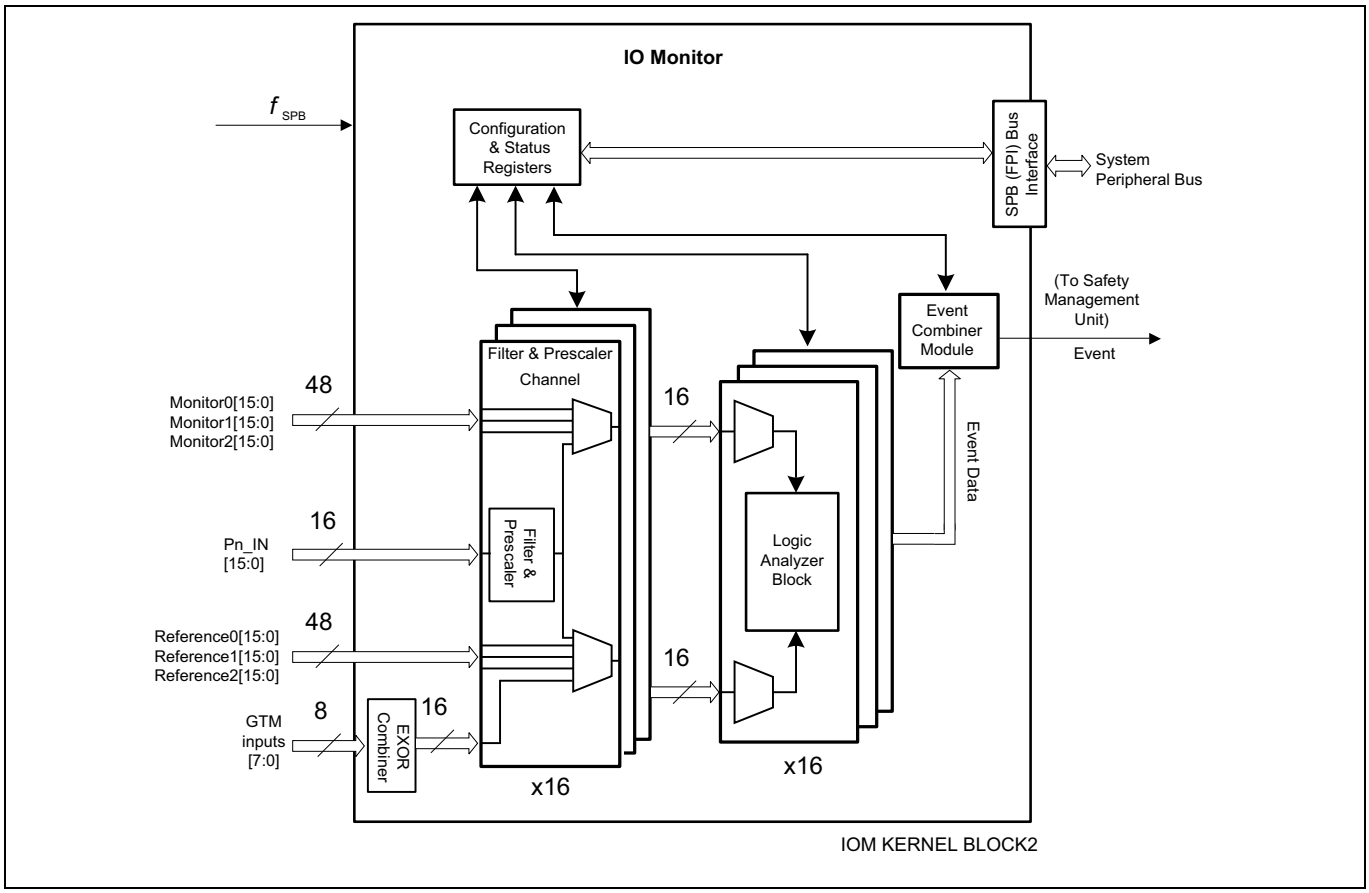

Figure 784 IO Monitor Block Diagram

The operational clock for the IOM (f_{IOM}) is derived form the SPB clock after applying the divider configurable in CLC.RMC bitfield.

48.3.3 Filter & Prescaler Channel (FPC) Description

The IOM instances 16 Filter & Prescaler Channels (FPC's) for the purposes of preconditioning and filtering the signals received from the pads (Pn_IN inputs) that may be used as a reference or monitor.

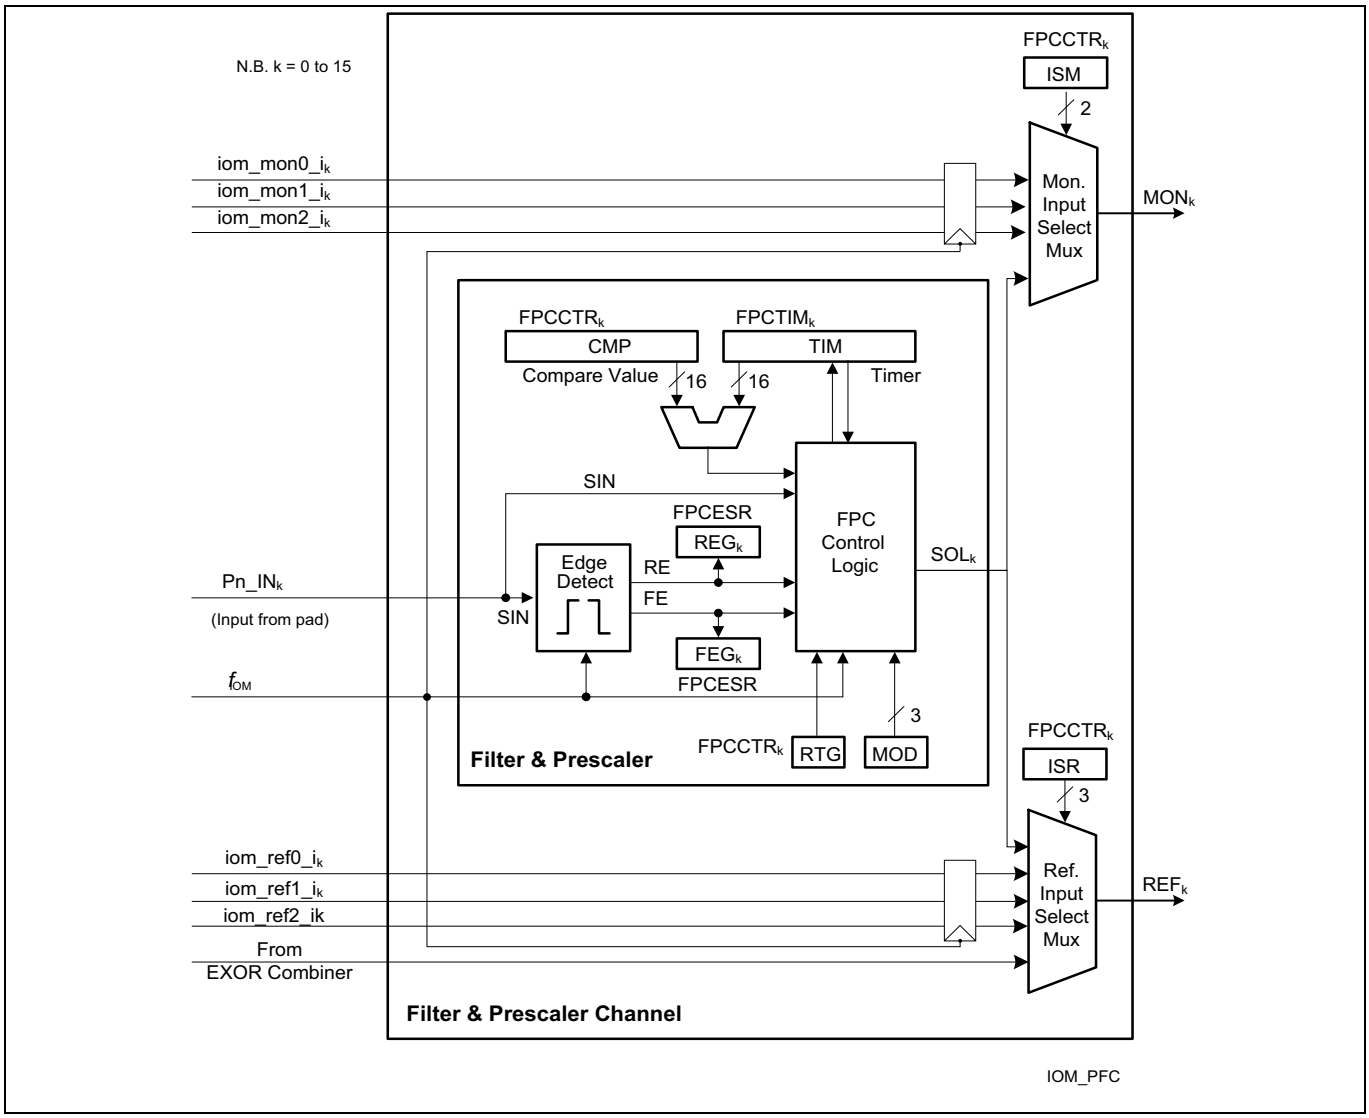

Figure 785 Monitor & Reference Selection logic incorporating Filter and Prescaler channel

As shown in **Figure 785**, each FPC is equipped with a signal input multiplexer, an edge detection circuitry, a 16-bit timer, a 16-bit compare register, a 16-bit comparator, and a FPC control circuitry. The edge detection circuitry detects respective edges for the prescaler modes and detects glitches in all other modes.

FPC Registers

The following registers are assigned to the Filter and Prescaler Channels FPCk (k = 0-15):

- FPCESR = Filter and Prescaler Channels Rising and Falling Edge Status Register.
- FPCCTRk = Filter and Prescaler Channel Control Register k
- FPCTIMk = Filter and Prescaler Channel Timer Register k

FPC Operating Modes

Each filter and prescaler channel can be individually configured to operate in one of the following operating modes:

- Delayed Debounce Filter Mode on both edges
- Immediate Debounce Filter Mode on both edges
- Rising edge: Immediate Debounce Filter Mode, falling edge: No filtering
- Rising edge: No filtering, falling edge: Immediate Debounce Filter Mode
- Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode
- Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode
- Prescaler Mode (triggered by edge detection circuitry on rising edge)
- Prescaler Mode (triggered by edge detection circuitry on falling edge)

The operation mode is selected by bit field FPCCTRk.MOD.

FPC Input Signal notes

The FPC input signal sampling frequency is f_{IOM}.

FPC Output Signal notes

A level output, representative signal SOLk, indicating the direction of the detected signal transition, that can be configured to connect to the Logic Analyzer Module.

Delayed Debounce Filter Mode

In Delayed Debounce Filter Mode, the signal input SIN is filtered from all signal transitions and glitches with a width smaller than f_{IOM} multiplied by the compare register value (FPCCTRk.CMP).

The input signal SIN is analyzed at the selected filter clock rate of f_{IOM}. If the state of the input sample differs from the current output signal value, the 16-bit timer is increased by one. When the timer register FPCTIMk is not in its idle state (0000_H) and the state of the input sample matches the current output signal value, the 16-bit timer is decremented by one (see **Figure 786**); if bit FPCCTRk.RTG is set, the timer will be set to idle state again (see **Figure 787**). A rising or falling edge, occurring on the signal input line SIN when the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCESR.REG (on rising edge glitch) or FPCESR.FEG (on falling edge glitch). When the timer matches the 16-bit compare value stored in FPCCTRk.CMP (timer threshold), the level output signal line SOLk is inverted, and the timer is reset to 0000_H. The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value FPCCTRk.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal.

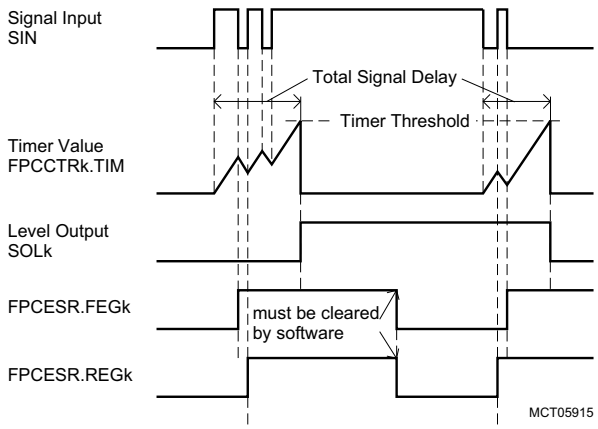

Figure 786 FPC Delayed Debounce Filter Algorithm with Timer Decrement

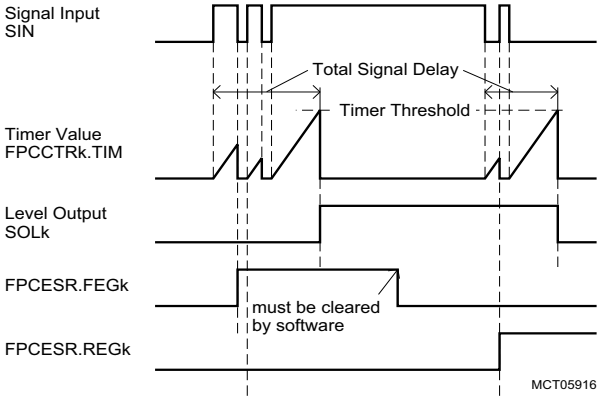

Figure 787 FPC Delayed Debounce Filter Algorithm with Timer Reset

The total signal delay from input to output depends on the programmed compare register value, the number of high-frequency pulses (glitches) during the filter operating time, and the timer behavior in case of a glitch (decrement or reset).

The FPC Delayed Debounce Filter Mode is selected by:

- FPCCTRk.MOD = 000_B

Immediate Debounce Filter Mode

In Immediate Debounce Filter Mode, the input signal is filtered from signal transitions and glitches arriving a programmable time after an input signal edge detection (see **Figure 788**).

The input signal (SIN) is sampled with f_{IOM} and the input signal SIN edge detection is also performed with f_{IOM}. The further analysis (e.g. filter timer increment, glitch detection) is also achieved with f_{IOM}.

As long as the timer is reset, the FPC control circuitry copies the sampled input value directly to the level output signal line SOLk. When a rising or falling edge occurs on SIN and the 16-bit compare value (FPCCTRk.CMP) is not zero, the timer is enabled to be increased by the selected clock and the copy mechanism is disabled. When the timer value FPCTIMk.TIM matches the compare value FPCCTRk.CMP, the timer is reset and the copy mechanism is enabled again. A rising or falling edge, occurring on SIN while the timer is greater than zero but less than the compare value, sets the corresponding glitch flag FPCESR.REG (on rising edge glitch) or FPCESR.FEG (on falling edge glitch). The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value FPCCTRk.CMP is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal without any disable periods.

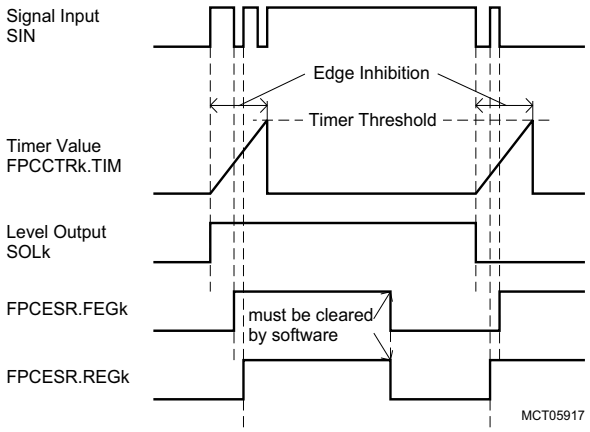

Figure 788 FPC Immediate Debounce Filter Algorithm on Both Edges

Note: During the last clock cycle of edge inhibition time (where timer value is equal to the compare value) an input signal glitch will be filtered but the corresponding glitch status flag in register FPCESR.REG/FPCESR.FEG is not set.

The Immediate Debounce Filter can be enabled for both edges. The signal output follows the signal input value immediately after the timer threshold of the filtered edge is reached (see **Figure 789**).

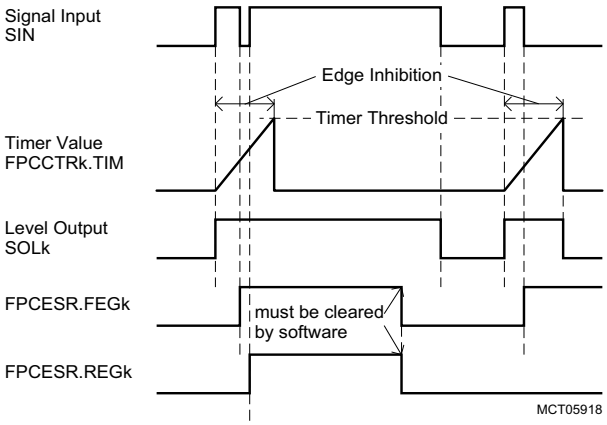

Figure 789 FPC Immediate Debounce Filter Algorithm on Rising Edge only

The FPC Immediate Debounce Filter Modes are selected by:

- FPCCTRk.MOD = 001_B: Immediate Debounce Filter Mode on both edges
- FPCCTRk.MOD = 010_B: Immediate Debounce Filter Mode on rising edge only, no filtering on falling edge.
- FPCCTRk.MOD = 011_B: Immediate Debounce Filter Mode on falling edge only, no filtering on rising edge.

Mixed Filter Modes

In the Mixed Filter Modes, one edge of a signal is filtered in the Delayed Debounce Mode, and the other edge is filtered in the Immediate Debounce Mode. The Debounce Mode is switched when the timer threshold is reached. Note that both filter modes use the same timer threshold in this case (see **Figure 790**, demonstrating Delayed Debounce Mode with Timer Decrement on Rising Edge and Immediate Debounce of on Falling Edge).

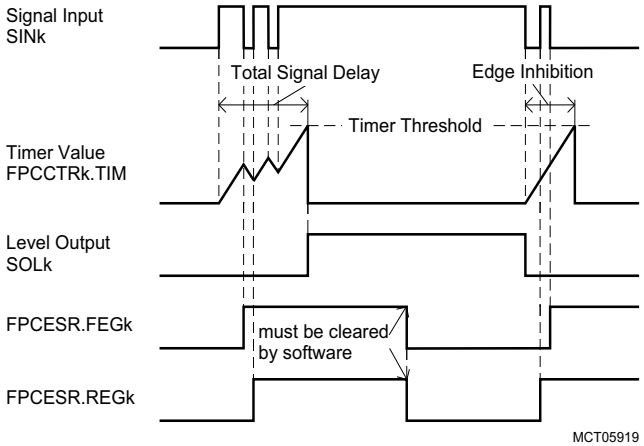

Figure 790 FPC Mixed Filter Algorithm

The FPC Mixed Filter Modes are selected by:

- FPCCTRk.MOD = 100_B: Delayed Debounce Filter Mode on rising edge, Immediate Debounce Filter Mode on falling edge
- FPCCTRk.MOD = 101_B: Immediate Debounce Filter Mode on rising edge, Delayed Debounce Filter Mode on falling edge

Prescaler Mode

In Prescaler Mode, the input signal is sampled and analyzed with f_{IOM}. The FPC control circuitry counts each rising (or falling) edge of the input signal. When the timer value matches the compare value:

- one IOM module clock pulse is generated at the level output signal SOLk
- the timer FPCTIMk.TIM is reset to 0000_H

Figure 791 shows a divide-by-6 operation using the FPC in Prescaler Mode with trigger on rising edge selected.

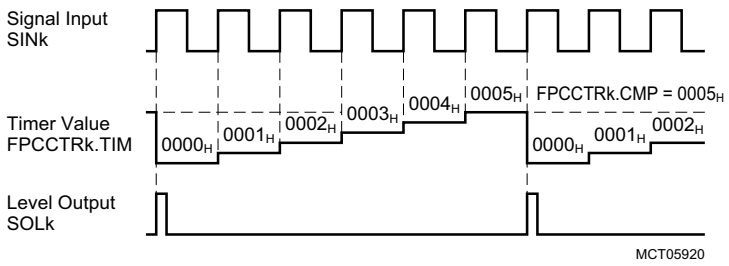

Figure 791 FPC Prescaler Mode

For a divide-by-n operation, the compare value FPCCTRk.CMP must be set to n - 1.

The FPC Prescaler Modes are selected by:

- FPCCTRk.MOD = 110_B: Prescaler Mode triggered by edge detection circuitry on rising edge
- FPCCTRk.MOD = 111_B: Prescaler Mode triggered by edge detection circuitry on falling edge

48.3.4 EXOR Combiner Description

The EXOR Combiner can be configured to accepts up to 8 external inputs from GTM module outputs.The output from which can then be used as a reference to the Logic Analyzer Module.

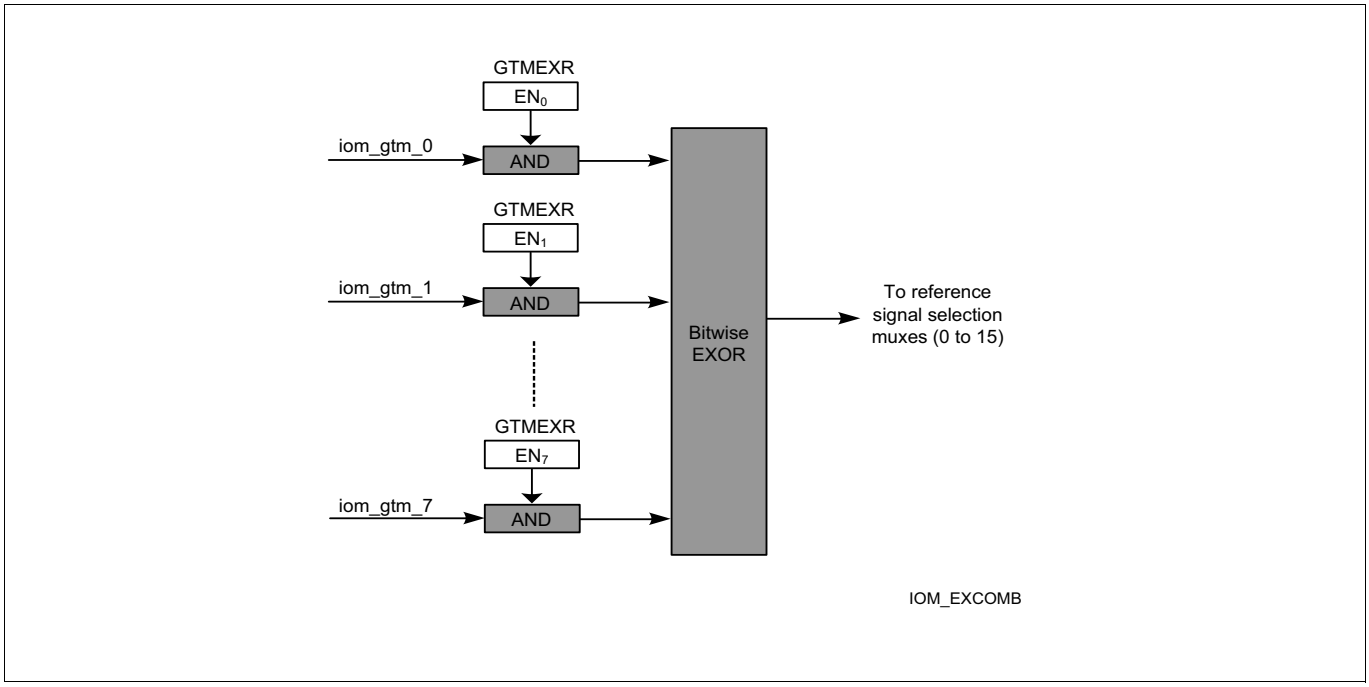

Figure 792 EXOR Combiner block diagram

EXOR Combiner Registers

The following registers are assigned to the block:

- GTMEXR = GTM Input EXOR Combiner Selection Configuration Register.

EXOR Combiner Input Signals

- 8 inputs from the GTM module(s).

EXOR Combiner Output Signals

- 1 output signal reflecting the combined logical EXOR function on the associated (and enabled input(s)).

48.3.5 Logic Analyzer Module (LAM) Description

The IOM instances 16 Logic Analyzer Modules (LAM's) for the purposes of monitor and reference signal comparison. Each block accepts one monitor and one reference level signal from the 16 monitor & 16 reference signals available, from the FPC/Input selection block. The behavior of each LAM is set by configuring the associated register settings. All sub-blocks of every LAM run at IOM frequency (f_{IOM}), for instance this is the frequency of the event window counter.

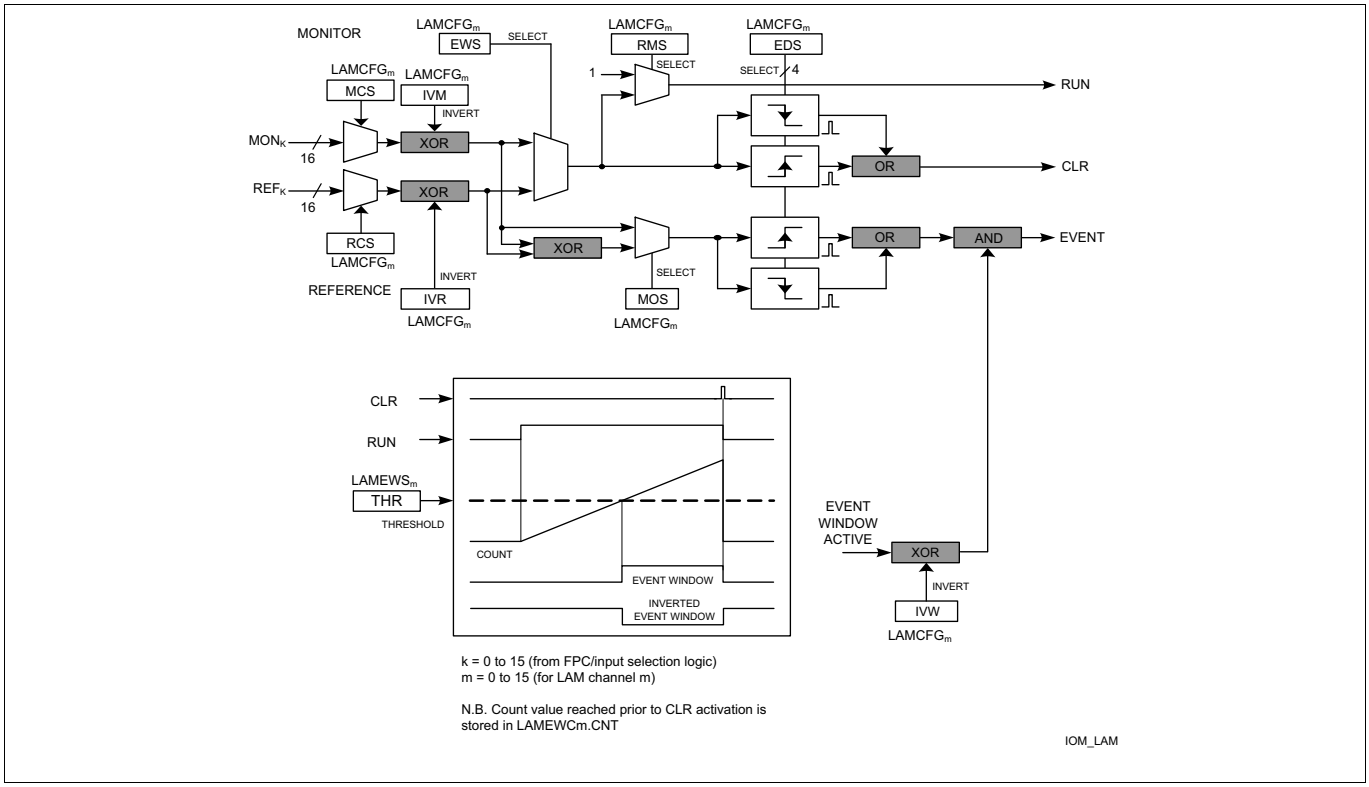

Figure 793 Logic Analyzer Module (LAM) block diagram

As shown in **Figure 793**, each Logic Analyzer Module features inputs for the Reference & Monitor points, fed from the requisite Filter & Prescaler block. Depending upon the Logic Analyzer Module configuration register (LAMCFG), and the event window settings register (LAMEWS), the block may be configured to monitor a particular type of signal behavior, input from sensors external to the device in order to monitor, govern and/or control external application behavior with particular regard to any given safety requirements.

If the 24-bit event window counter reaches its maximum value ($FFFFFF_H$), it will keep the maximum value until a clear condition arrives. This counter status (counter frozen at $FFFFFF_H$) will be notified by the LAMEWCm.CNTO flag.

LAM Registers

The following registers are assigned to the Logic Analyzer Module LAM m (m = 0-15):

- LAMCFGm = Logic Analyzer Module Configuration Register m
- LAMEWSm = Logic Analyzer Module Event Window Settings Register m
- LAMEWCm = Logic Analyzer Module Event Window Count Status Register m

After reset the counter for channel 'm' will be kept constant until a write operation to one of the 3 LAM registers: LAMCFGm, LAMEWSm or LAMEWCm.

Writing to one of the 3 LAM registers clears the LAMEWCm register and resets the internal counter for channel m.

LAM Input Signals

Two inputs exist for each LAM:

- Reference signal input, fed from the requisite Filter & Prescaler block.
- Monitor signal input, fed from the requisite Filter & Prescaler block.

Depending upon the required function, both inputs or just the Monitor input may be utilized.

LAM Output Signals

One output is provided by each LAM:

- Event trigger output, configured to be active when a monitored signal falls outside the intended timed and/or periodic behavior. When LAMCFGm.DISEV is set to 1, the LAM will suppress alarm outputs to the ECM. Except for sending alarms to the ECM, all other effects of an alarm condition being detected (for instance, setting LAMEWCm.CNT to the value of the counter) will still take place inside the LAM.

48.3.6 Event Combiner Module (ECM) Description

The IOM instances one Event Combiner Module, which takes the event outputs from each of the 16 Logic Analyzer Modules (LAM's). Some or all of these events can then be combined in a variety of configurable ways in order to generate a single system event.

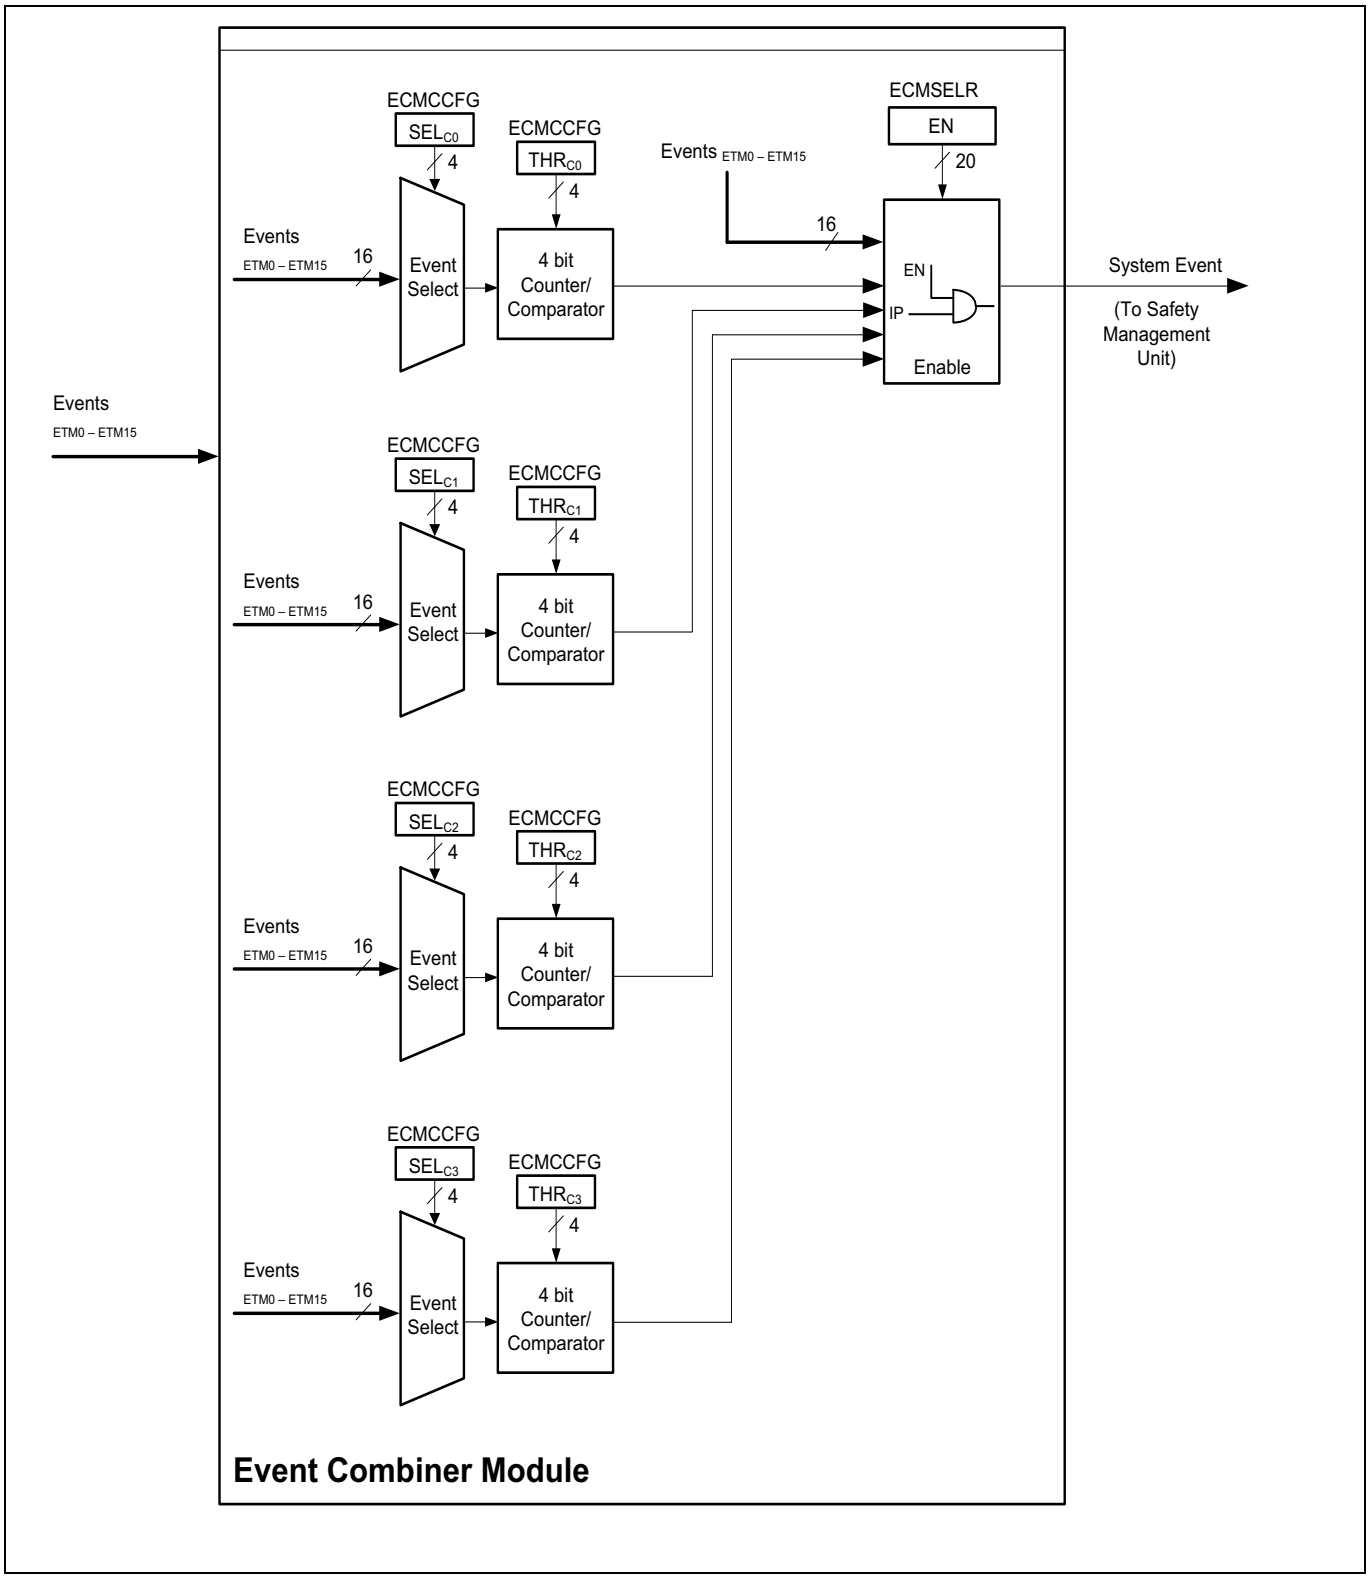

Figure 794 Event Combiner Module (ECM) block diagram

Four separate 4bit counters with configurable thresholds are also available to be assigned to count multiple occurring events from any of the 16 available LAM's. The output of these counter units (active once a count threshold has been met/surpassed) can also be included (via configuration) within the generation of the system event.

The ECM also includes two Event Trigger History (ETMETH0/1) registers, updated with each system event, used to record the status of the 16 LAM event outputs, thereby identifying which triggers were responsible.

All sub-blocks of the ECM run at IOM frequency (f_{IOM}). The IOM ensures that the System Event generated last as least one SPB clock cycle. (Note: the alarm output adapted to the f_{SPB} will be connected to the Safety Management Unit, SMU.EMM).

ECM Registers

The following registers are assigned to the ECM:

- ECMCCFG = ECM Counter Configuration Register (for the four 4bit local event counters).
- ECMSELR = ECM Global Event Selection Register (for the selection of local events, or multiples thereof, required to generate the global event signal).
- ECMETH0/1 =ECM Event Trigger History Register.

ECM Input Signals

- From Logic Analyzer Modules (LAM's)
  - Local event triggers from LAM blocks (0 to 15).

ECM Output Signals

- Global event trigger output, intended to be connected to the Safety Management Unit.

48.3.7 Configuration Sequence

In order to avoid undefined behavior due to the initialization order of the IOM submodules, the configuration sequence for an application that is using the IOM should be the following:

1st Step: Configure SMU reaction for the IOM as no alarm.

2nd Step: Enable the IOM and its clock by setting CLC.DISR to 0 and CLC.RMC to 1.

3rd Step: Configure the EXOR Combiner if required.

4th Step: If needed, configure each FPC:

- Configure each channel "m" (with "m" form 0 to 15) using the FPCCTRm register.
- Clear the existing rising and falling edge status flags by writing to the FPCESR register.

5th Step: Configure each LAM block "m" (with "m" form 0 to 15) :

- Set the desired event window count threshold by writing to LAMEWSm.THR.
- Configure the application specific settings for each LAM block in LAMCFGm register.

6th Step: Configure the ECM:

- Select the different events from the LAM to be combined in the ECMSELR register.
- Configure each of the four event counter submodules in ECMCCFG register.
- Write to ECMETH0 or ECMETH1 to clear all event trigger active flags.

7th Step: If required, configure the desired clock divider in CLC.RMC.

8th Step: Configure SMU reaction for the IOM to a specific alarm reaction.

48.3.8 Example Monitor/Safety Measures

For each channel the following measurements shall be possible:

- Duty cycle measurement
- Set-up and/or hold time measurement
- Delay window (min,max) with respect to rising or falling edge

The following waveforms provide more examples of typical signal monitoring functionality that could be deployed using the IOM. Some typical configuration settings are also provided on some of the examples.

48.3.8.1 Example 1 - Pulse or duty cycle too short

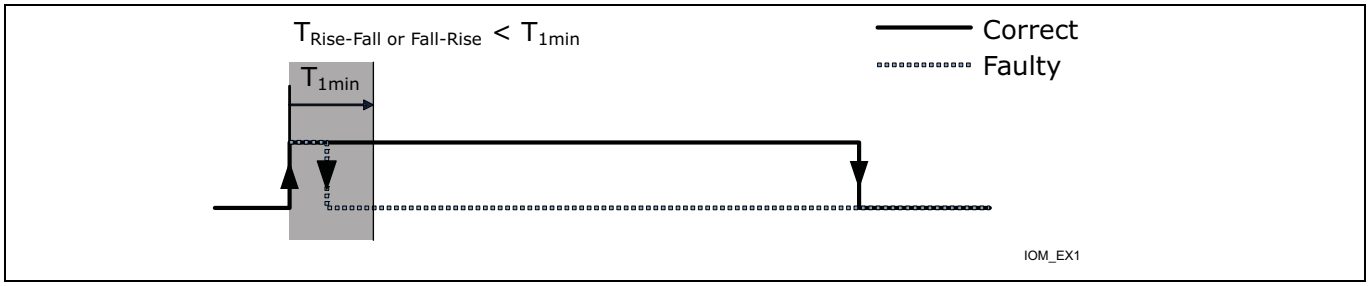

Figure 795 example 1 - pulse or duty cycle too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don’t care

LAMCFG.IVM: 0x0 ; don’t invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW: 0x1 ; invert window, capture events when the counter is below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum pulse width forbidden. If pulse width is shorter or equal to this value then an event will be triggered)

48.3.8.2 Example 2 - Pulse or duty cycle too long

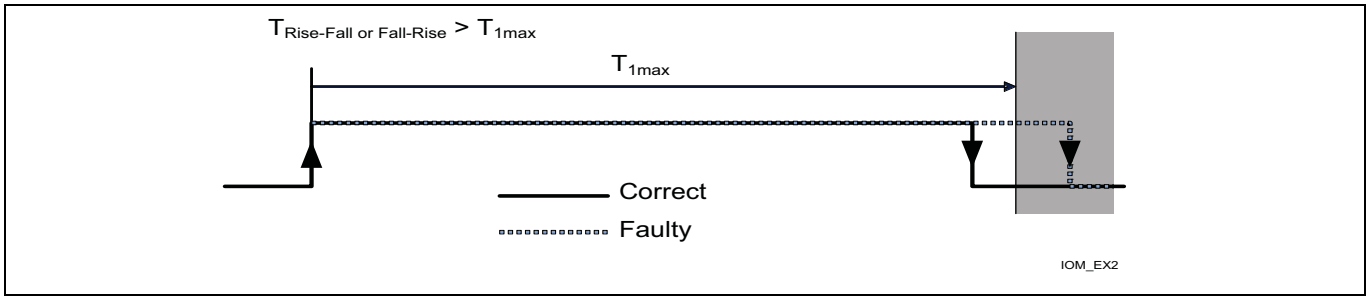

Figure 796 example 2 - pulse or duty cycle too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don’t care

LAMCFG.IVM: 0x0 ; don’t invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW: 0x0 ; do not invert window, capture events when the counter is equal or above the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum pulse width accepted. If pulse width is longer than this value then an event will be triggered)

48.3.8.3 Example 3 - Period too short

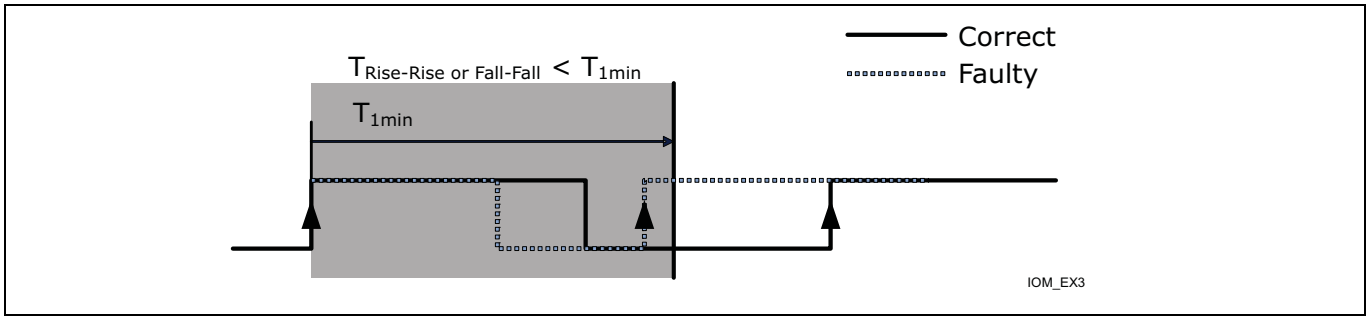

Figure 797 example 3 - period too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don’t care

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW: 0x1 ; invert window, capture events when the counter is below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum period length forbidden. If period is shorter or equal than this value then an event will be triggered)

48.3.8.4 Example 4 - Period too long

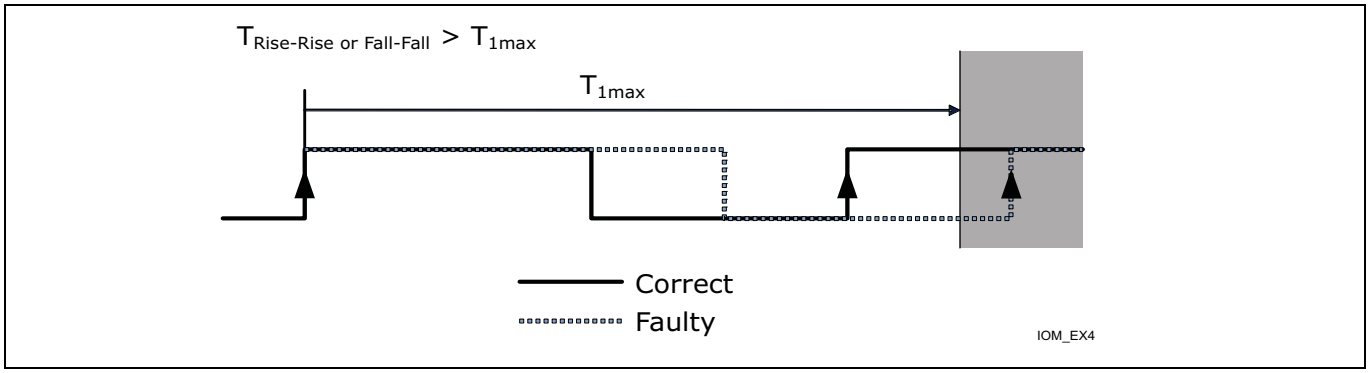

Figure 798 example 4 - period too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don’t care

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW: 0x0 ; do not invert window, capture events when the counter is equal or above the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum period length required. If period is longer than this value then an event will be triggered)

48.3.8.5 Example 5 - Diagnosis of Command and Feedback - acceptable propagation window and/or signal consistency check

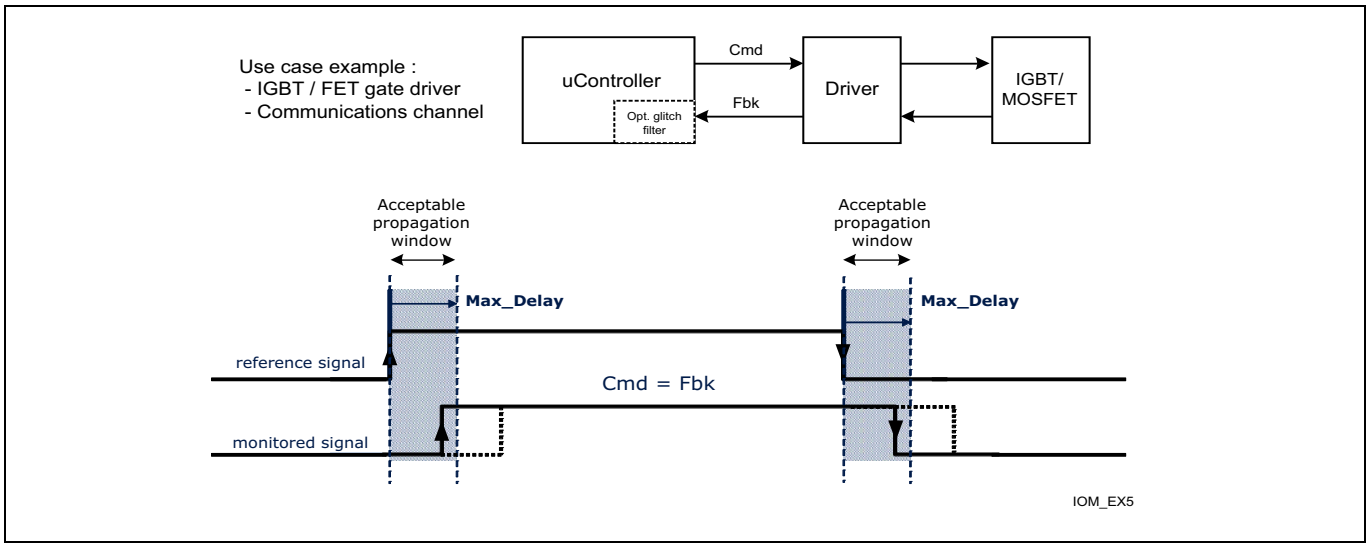

Figure 799 example 5 - Diagnosis of Command & Feedback

Using the driven signal (off-chip) as a reference, using a feedback signal (input to device) as the monitor. Checking that the monitored signal shows activity within an acceptable propagation window, and/or that the feedback signal shows the same behavior as the reference (Command = Feedback).

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don’t invert reference signal

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x1 ; (MON xor REF) signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xB ; CLR on both edges of REF, EVT on falling edge (of xor’d signal)

LAMCFG.IVW: 0x0 ; do not invert window, capture events when the counter is equal or above the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; set to max delay allowed (if the delay between corresponding edges of reference and monitor signals is longer than this value, the event will be triggered)

Note: For proper diagnosis in example 5, the edges of the reference and monitor signals must arrive to the IOM in the following order: first leading edge of reference signal, second leading edge of monitor signal, third trailing edge of reference signal and fourth trailing edge of monitor signal.

48.3.8.6 Example 6 - Diagnosis of Set-up and Hold times

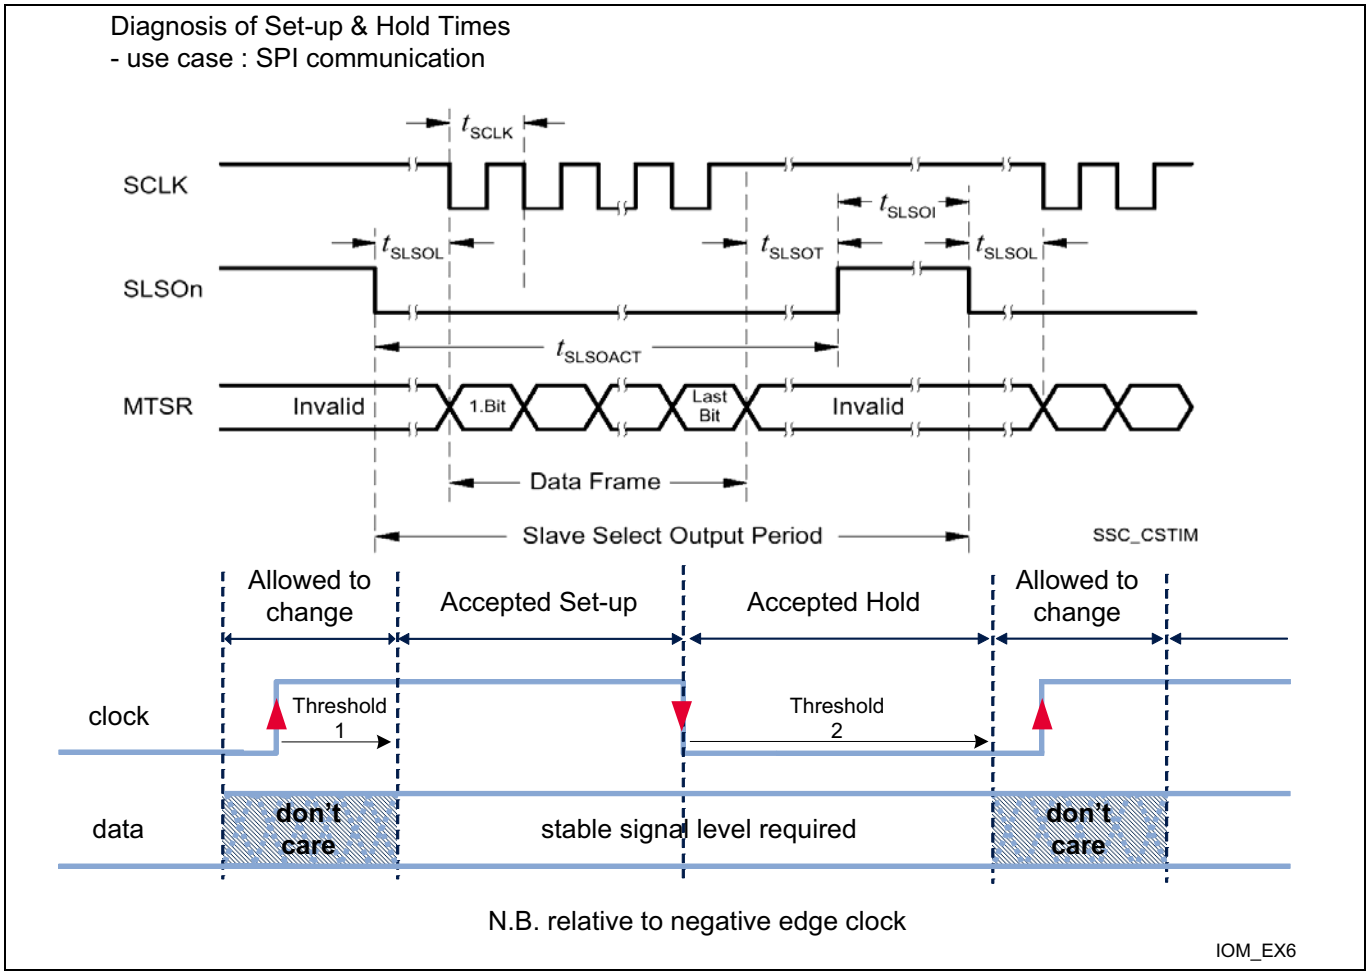

Figure 800 example 6 - Diagnosis of Set-up & Hold times

Ensuring that data remains stable within the Set-up and Hold windows, generating an event otherwise, and/or ensuring that data only changes within the specified windows.

Note: 2 LAM channels will be required for this purpose, one for set-up, one for hold.

Example settings for LAM block registers for Set-up

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; run is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xF ; CLR on both edges, EVT on both edges

LAMCFG.IVW: 0x0 ; do not invert window, capture events when the counter is equal or above the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Set-up (ref Threshold 1 on waveforms shown, changes in monitor signal will be accepted for “THR” cycles after a raising edge in the reference signal. After that, a change in the monitor signal while the reference signal is “1”, will generate an alarm).

Example settings for LAM block registers for Hold

LAMCFG.IVR: 0x1 ; invert reference signal (use for gating)

LAMCFG.IVM: 0x0 ; don’t invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; event window is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xD ; CLR on positive edge (inverted neg. edge), EVT on both edges

LAMCFG.IVW: 0x1 ; invert window, capture events when the counter is below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Hold (ref Threshold 2 on waveforms shown, changes in monitor signal will generate an alarm if they occur inside the “THR” cycles after a falling edge in the reference signal).

48.4 Registers

This section describes the kernel registers of the IOM unit.

All read and write accesses to an undefined address location within the IOM address space will result in a bus error on the System Peripheral Bus (SPB).

Table 543 Register Overview - IOM (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	IOM Clock Control Register	000_H	U,SV	SV,E,P	Application Reset	39

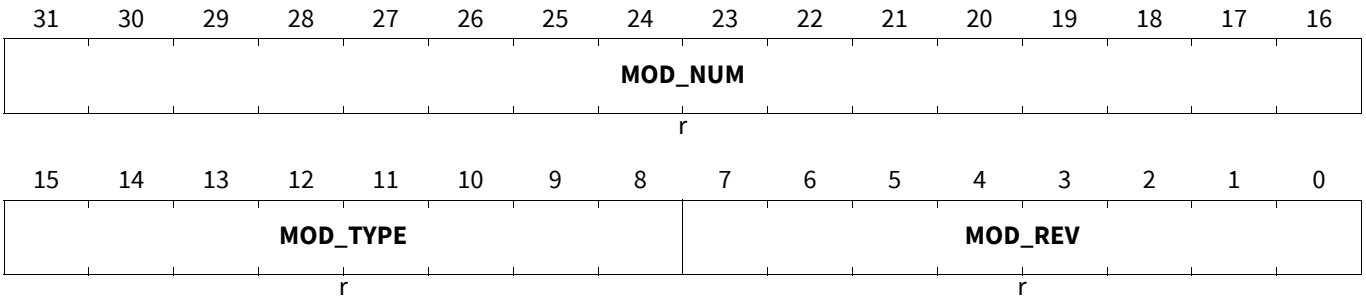
48.4.1 IOM Identification Register (IOM_ID)

IOM Identification Register

The IOM Identification Register ID contains read-only information about the module version.

ID
IOM Identification Register **(008_H)** **Application Reset Value: $00CC\ C002_H$**



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** MOD_REV defines the Module revision number.
MOD_TYPE	15:8	r	**Module Number Value** This bit field defines the module as a 32 bit module: $C0_H$
MOD_NUM	31:16	r	**Module Number Value** This bit field defines the identification number for the IOM.

48.4.2 Filter & Prescaler Channel (FPC) Registers

IOM Filter and Prescaler Channels Rising & Falling Edge Status Register

The Filter and Prescaler Edge Status Register stores the state of detected rising and falling edges from each of the FPC.

FPCESR.FEGk and FPCESR.REGk are written disregarding the filter configuration FPCCTRk.MOD.

The register can be used to selectively clear individual bits by writing a 0 in the respective bitfield.

Individual bits are also cleared with a write to the control register (FPCCTRk) or timer register (FPCTIMk).

NOTE: LDMST or SWAPMSK.W should be used only with bit mask enabled for all ´rwh´ bits in the addressed register.

FPCESR

IOM Filter and Prescaler Channels Rising & Falling Edge Status Register(078_H) Application Reset Value: $0000\ 0000_H$

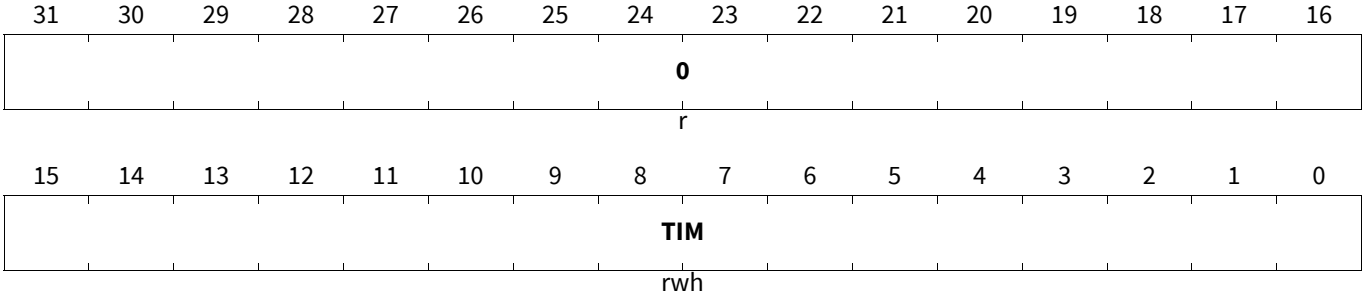
IOM Filter and Prescaler Channel Timer Register k

The IOM Filter & Prescaler Channel Timer Register is used to reset the value of the timer for the required application. A write to this register will result in its contents being set to the reset value. This is also undertaken whenever the FPCCTRk register is written with a new value. Writing FPCTIMk also clears the relevant fields of FPCESR.

FPCTIMk (k=0-15)

IOM Filter and Prescaler Channel Timer Register k ($0C0_H$+k*4) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TIM	15:0	rwh	**Timer Value of Filter and Prescaler Channel k** This bit bitfield shows the values of the timer of the Filter and Prescaler Channel. Writing to TIM will result in its content being set to its reset value.
0	31:16	r	**Reserved** Read as 0; shall be written with 0.

48.4.3 GTM Input Related Registers

IOM GTM Input EXOR Combiner Selection Register

Enables the incoming GTM-connected input signals for inclusion within a combined EXOR function.

GTMEXR

IOM GTM Input EXOR Combiner Selection Register(040_H) **Application Reset Value: $0000\ 0000_H$**

48.4.4 Logic Analyzer Module (LAM) Registers

IOM Logic Analyzer Module Event Window Count Status Register m

Used to store the window count value reached in the LAM block once an event has been generated. If the edge which triggered the event also clears the counter, the value stored here is taken before clearing takes place. It also provides a bitfield for signaling the counter overflow. Any write command to one of the LAM registers (LAMEWCm, LAMCFGm and LAMEWSm) will clear this register.

LAMEWCm (m=0-15)
IOM Logic Analyzer Module Event Window Count Status Register m(100_H+m*4) Application Reset Value: $0000\ 0000_H$

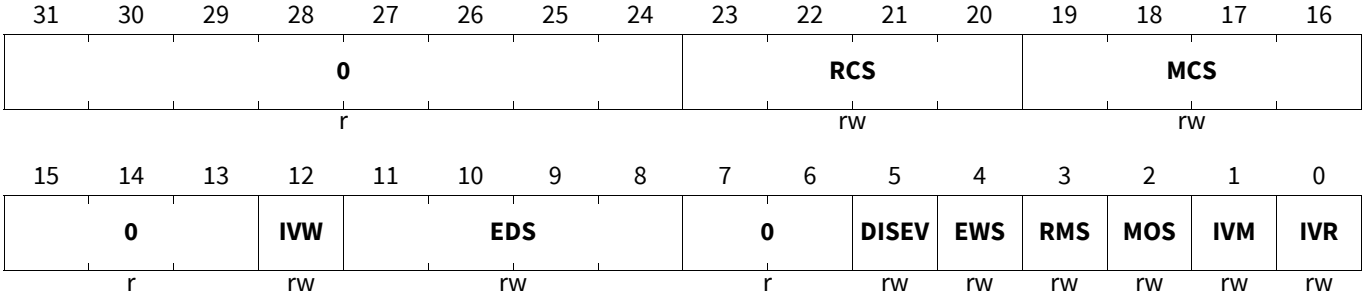
Field	Bits	Type	Description
CNT	23:0	rwh	**Event Window Count Value LAM block m** The count value of the event window attained coincident with an event occurring.
CNTO	31	rwh	**Count Overflow Flag LAM block m** This bit field provides the information wether the count has reached its maximum value. 0_B The count value has not reached its maximum value since the previous count clear. 1_B The count value has reached its maximum value since the previous count clear.
0	30:24	r	**Reserved** Read as 0; shall be written with 0.

IOM Logic Analyzer Module Configuration Register m

Used to configure the application-specific settings for each LAM block, including signal selection multiplexers at the block inputs.

LAMCFGm (m=0-15)

IOM Logic Analyzer Module Configuration Register m(180_H+m*4) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
IVR	0	rw	**Invert Reference LAM block m** This bit field determines whether the reference signal from the FPC (reference channel) is inverted or not. 0_B Don't invert reference signal from FPC. 1_B Invert reference signal from FPC.
IVM	1	rw	**Invert Monitor LAM block m** This bit field determines whether the monitor signal from the FPC (monitor channel) is inverted or not. 0_B Don't invert monitor signal from FPC. 1_B Invert monitor signal from FPC.
MOS	2	rw	**Monitor Source Select LAM block m** This bit field determines whether the monitor signal from the FPC (monitor channel) is sourced directly or compared (EXOR'd) with the reference signal from the FPC(reference channel) for the event compare. 0_B Monitor signal is sourced directly from FPC(monitor channel). 1_B Monitor signal is EXOR'd with FPC(reference channel).
RMS	3	rw	**Runmode Select LAM block m** This bit field determines whether the event window generation is free-running or gated with the monitor or reference. 0_B Event window generation is free-running. 1_B Event window generation is gated with the monitor or reference signal.
EWS	4	rw	**Event Window Select LAM block m** This bit field determines whether the event window generation is from the monitor or reference signal. 0_B Event window generation is determined from the reference signal. 1_B Event window generation is determined from the monitor signal.

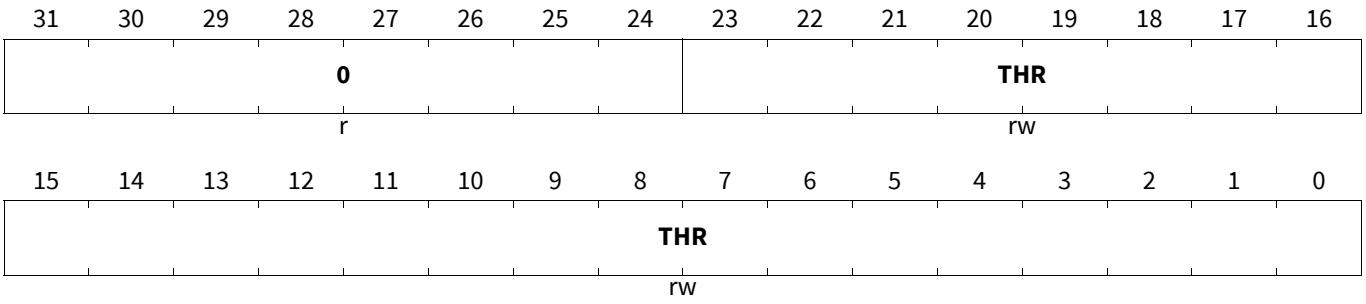
Field	Bits	Type	Description
DISEV	5	rw	**Disable Events LAM block m** This bit field allows to suppress alarm outputs from LAM block m to the ECM. Except for sending alarms to the ECM, all other effects of an alarm condition being detected (for instance, setting LAMEWCm.CNT to the value of the counter) will still take place inside LAM block m. 0_B Events will be generated. 1_B No events will be sent form LAM to ECM. Except for sending alarms to the ECM, all other effects of an alarm condition being detected (for instance, setting LAMEWCm.CNT to the value of the counter) will still take place inside LAM block m.
EDS	11:8	rw	**Event Window Active Edge Selection LAM block m** This bit field determines which active edges of the monitor and reference signals are used for the event window generation. 0_H Neither edge used to clear event window counter. Neither edge used to gate event generation. 1_H Positive edge used to clear event window counter. Neither edge used to gate event generation. 2_H Negative edge used to clear event window counter. Neither edge used to gate event generation. 3_H Either edge used to clear event window counter. Neither edge used to gate event generation. 4_H Neither edge used to clear event window counter. Positive edge used to gate event generation. 5_H Positive edge used to clear event window counter. Positive edge used to gate event generation. 6_H Negative edge used to clear event window counter. Positive edge used to gate event generation. 7_H Either edge used to clear event window counter. Positive edge used to gate event generation. 8_H Neither edge used to clear event window counter. Negative edge used to gate event generation. 9_H Positive edge used to clear event window counter. Negative edge used to gate event generation. A_H Negative edge used to clear event window counter. Negative edge used to gate event generation. B_H Either edge used to clear event window counter. Negative edge used to gate event generation. C_H Neither edge used to clear event window counter. Either edge used to gate event generation. D_H Positive edge used to clear event window counter. Either edge used to gate event generation. E_H Negative edge used to clear event window counter. Either edge used to gate event generation. F_H Either edge used to clear event window counter. Either edge used to gate event generation.

Field	Bits	Type	Description
IVW	12	rw	**Invert Event Window LAM block m** This bit field determines whether the event window polarity is inverted or not. 0_B Event window non-inverted. 1_B Event window inverted.
MCS	19:16	rw	**Monitor Input Signal Selection LAM block m** This bit field determines which FPC/mux block k monitor output signal is to be used for LAM block m. 0_H Monitor signal provided by FPC/mux block 0. 1_H Monitor signal provided by FPC/mux block 1. 2_H Monitor signal provided by FPC/mux block 2. 3_H Monitor signal provided by FPC/mux block 3. 4_H Monitor signal provided by FPC/mux block 4. 5_H Monitor signal provided by FPC/mux block 5. 6_H Monitor signal provided by FPC/mux block 6. 7_H Monitor signal provided by FPC/mux block 7. 8_H Monitor signal provided by FPC/mux block 8. 9_H Monitor signal provided by FPC/mux block 9. A_H Monitor signal provided by FPC/mux block 10. B_H Monitor signal provided by FPC/mux block 11. C_H Monitor signal provided by FPC/mux block 12. D_H Monitor signal provided by FPC/mux block 13. E_H Monitor signal provided by FPC/mux block 14. F_H Monitor signal provided by FPC/mux block 15.
RCS	23:20	rw	**Reference Input Signal Selection LAM block m** This bit field determines which FPC/mux block k reference output signal is to be used for LAM block m. 0_H Reference signal provided by FPC/mux block 0. 1_H Reference signal provided by FPC/mux block 1. 2_H Reference signal provided by FPC/mux block 2. 3_H Reference signal provided by FPC/mux block 3. 4_H Reference signal provided by FPC/mux block 4. 5_H Reference signal provided by FPC/mux block 5. 6_H Reference signal provided by FPC/mux block 6. 7_H Reference signal provided by FPC/mux block 7. 8_H Reference signal provided by FPC/mux block 8. 9_H Reference signal provided by FPC/mux block 9. A_H Reference signal provided by FPC/mux block 10. B_H Reference signal provided by FPC/mux block 11. C_H Reference signal provided by FPC/mux block 12. D_H Reference signal provided by FPC/mux block 13. E_H Reference signal provided by FPC/mux block 14. F_H Reference signal provided by FPC/mux block 15.
0	7:6, 15:13, 31:24	r	**Reserved** Read as 0; shall be written with 0.

IOM Logic Analyzer Module Event Window Configuration Register m

Used to set the threshold value for the event window counter.

LAMEWSm (m=0-15)
IOM Logic Analyzer Module Event Window Configuration Register m(1C0$_H$+m*4)Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
THR	23:0	rw	**Event Window Count Threshold** This bit field contains the value of the counter at which the event window becomes active (before optional inversion).
0	31:24	r	**Reserved** Read as 0; shall be written with 0.

48.4.5 Event Combiner Module (ECM) Registers

IOM Event Combiner Module Counter Configuration Register

The Event Combiner Configuration register is used to configure each of the four event counter submodules, enabling multiple events from one selected LAM block (for each event counter submodule) to be counted in the generation of a system event. Writing to this register will clear the internal ECM counters.

ECMCCFG

IOM Event Combiner Module Counter Configuration Register(030_H) Application Reset Value: $0000\ 0000_H$

IOM Event Combiner Module Event Trigger History Register 0

One of two registers (IOM_ECMETH0 and IOM_ECMETH1) that record the status of LAM's 0 to 15 event outputs for the generated system events.

The generation of a system event will cause the status of the event outputs from LAM blocks 0 to 15 that generated the system event to be recorded in ETA0-15, respectively. Just prior to this happening, the previous status held in ETA0-15 is moved to ETB0-15. Similarly, the previous content of ETB0-15 is moved to ETC0-15. In addition, the previous content of the ETC0-15 is OR'ed with the current value of ETD15-0 and placed in ETD15-0. The contents of ETD15-0 will be maintained until the application explicitly clears the ETD15-0 bits.

At reset (or a register write to either IOM_ECMETH0 or IOM_ECMETH1), all Event Trigger Active flags (ETA, ETB, ETC, ETD) will be cleared.

ECMETH0

48.4.6 System Registers

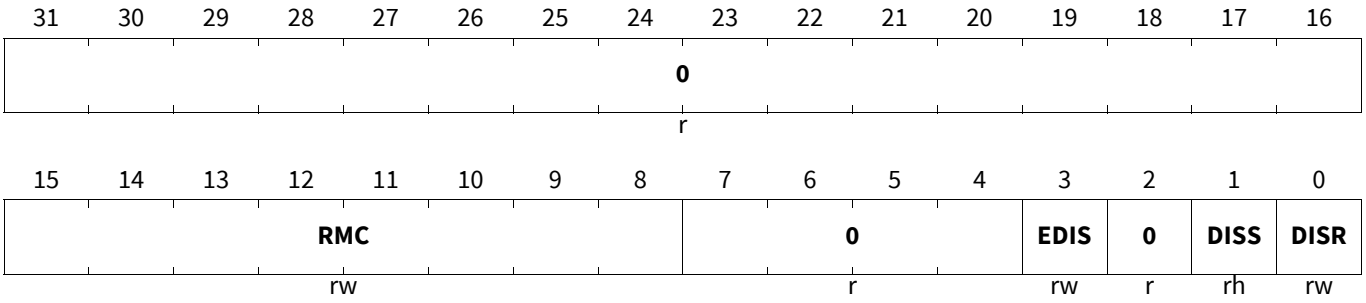
IOM Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{IOM} module clock signal, sleep mode and disable mode for the module.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

CLC

IOM Clock Control Register (000_H) Application Reset Value: 0000 0003$_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested 1_B Module disable is requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled 1_B Module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep mode request is regarded. Module is enabled to go to into Sleep Mode. 1_B Sleep mode request is disregarded. Sleep Mode cannot be entered upon a request.
RMC	15:8	rw	**8-bit Clock Divider Value in RUN Mode** 00_H No clock signal fIOM generated (default after reset) 01_H Clock fIOM equal to the input clock frequency selected 02_H fIOM = (input clock frequency)/2 selected … FF_H fIOM = (input clock frequency)/255 selected
0	2, 7:4, 31:16	r	**Reserved** Read as 0; shall be written with 0.

IOM Access Enable Register 0

The Access Enable Register 0 controls write access[1] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B.

ACCEN0

ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

IOM Access Enable Register 1

The Access Enable Register 1 controls write access[1] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in this family of devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, … , EN31 -> TAG ID 111111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; shall be written with 0.

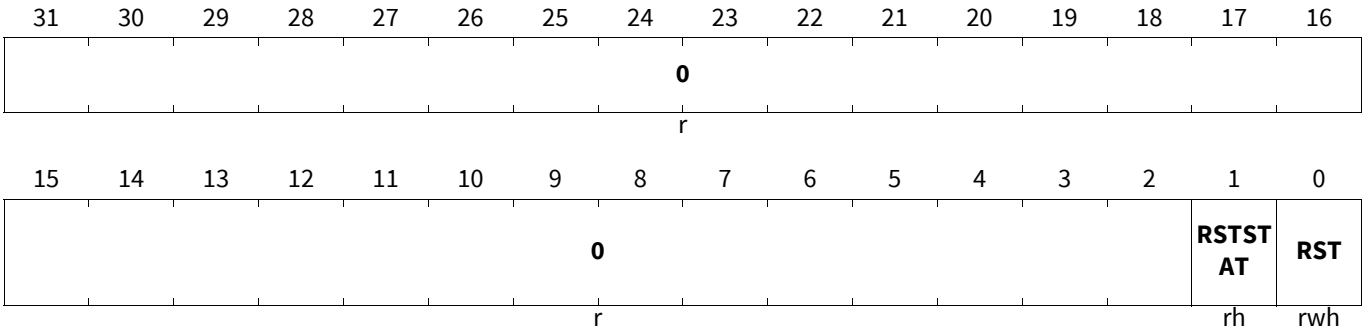
IOM Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
IOM Kernel Reset Register 0 **(024_H)** **Application Reset Value: $0000\ 0000_H$**

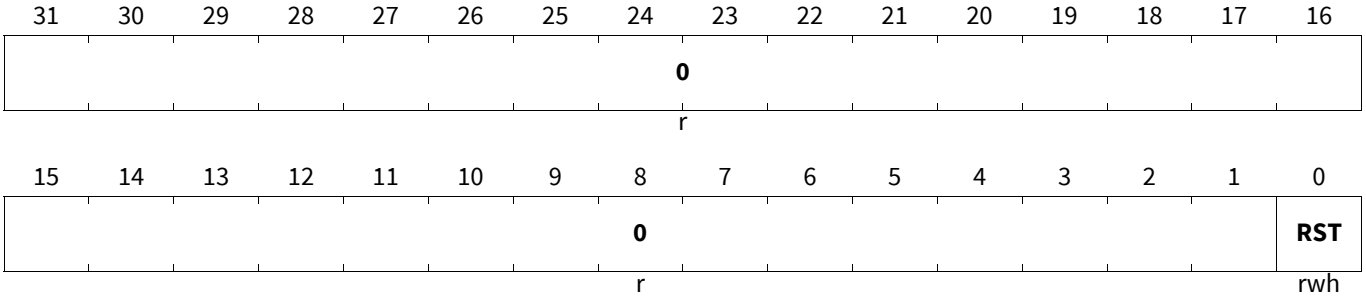


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

IOM Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
IOM Kernel Reset Register 1 **(020_H)** **Application Reset Value: 0000 0000_H**

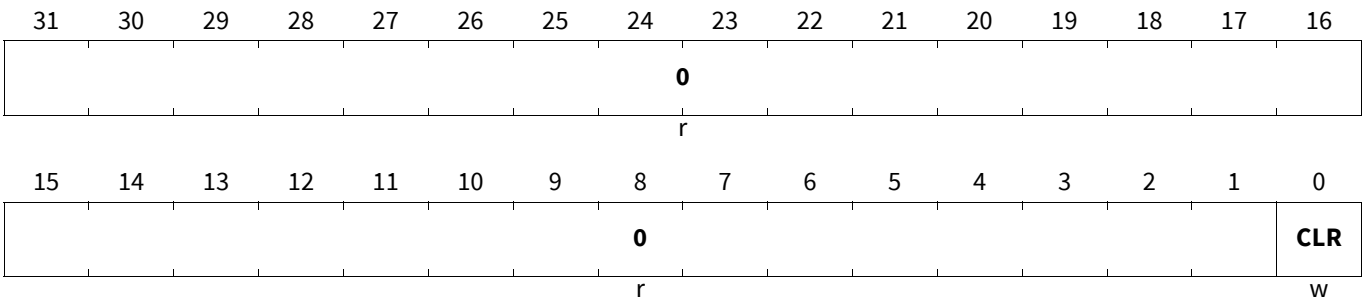


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; shall be written with 0.

IOM Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
IOM Kernel Reset Status Clear Register **($01C_H$)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT

Field	Bits	Type	Description
0	31:1	r	**Reserved** Read as 0; shall be written with 0.

48.5 IO Interfaces

The table below lists all the interfaces of the IOM to other modules.

Table 544 List of IOM Interface Signals

Interface Signals	I/O	Description
MON0(15:0)	in	**Monitor input 0** One bit per channel.
MON1(15:0)	in	**Monitor input 1** One bit per channel.
MON2(15:0)	in	**Monitor input 2** One bit per channel.
REF0(15:0)	in	**Reference input 0** One bit per channel.
REF1(15:0)	in	**Reference input 1** One bit per channel.
REF2(15:0)	in	**Reference input 2** One bit per channel.
PIN(15:0)	in	**GPIO pad input to FPC** One bit per channel.
GTM(7:0)	in	**GTM-provided inputs to EXOR combiner**
alarm	out	**Event for SMU** This signal is set to 1 if IOM mismatch is detected.

49 8-Bit Standby Controller (SCR)

The SCR is an 8-bit microcontroller that can continue to run during the standby mode. It is based on the XC800 Core that is compatible with the industry standard 8051 processor. There is an embedded 8 KB XRAM for program code and data.

Key features include a 16-bit general purpose timer with a capture/compare unit (T2CCU) for digital signal generation like pulse generation, pulse width modulation and pulse width measuring. It also includes a Real Time Clock (RTC) to support periodic wake-up in standby mode and an On-Chip Debug Support (OCDS) unit for software development and debugging of XC800-based systems. Local Interconnect Network (LIN) applications are also supported through extended UART features and the provision of LIN low level drivers for the AURIX™ TC3xx Platform. For low power applications, various power saving techniques are available for selection by the user. Control of the numerous on-chip peripheral functionalities is achieved by extending the Special Function Register (SFR) address range with an intelligent paging mechanism optimized for interrupt handling.

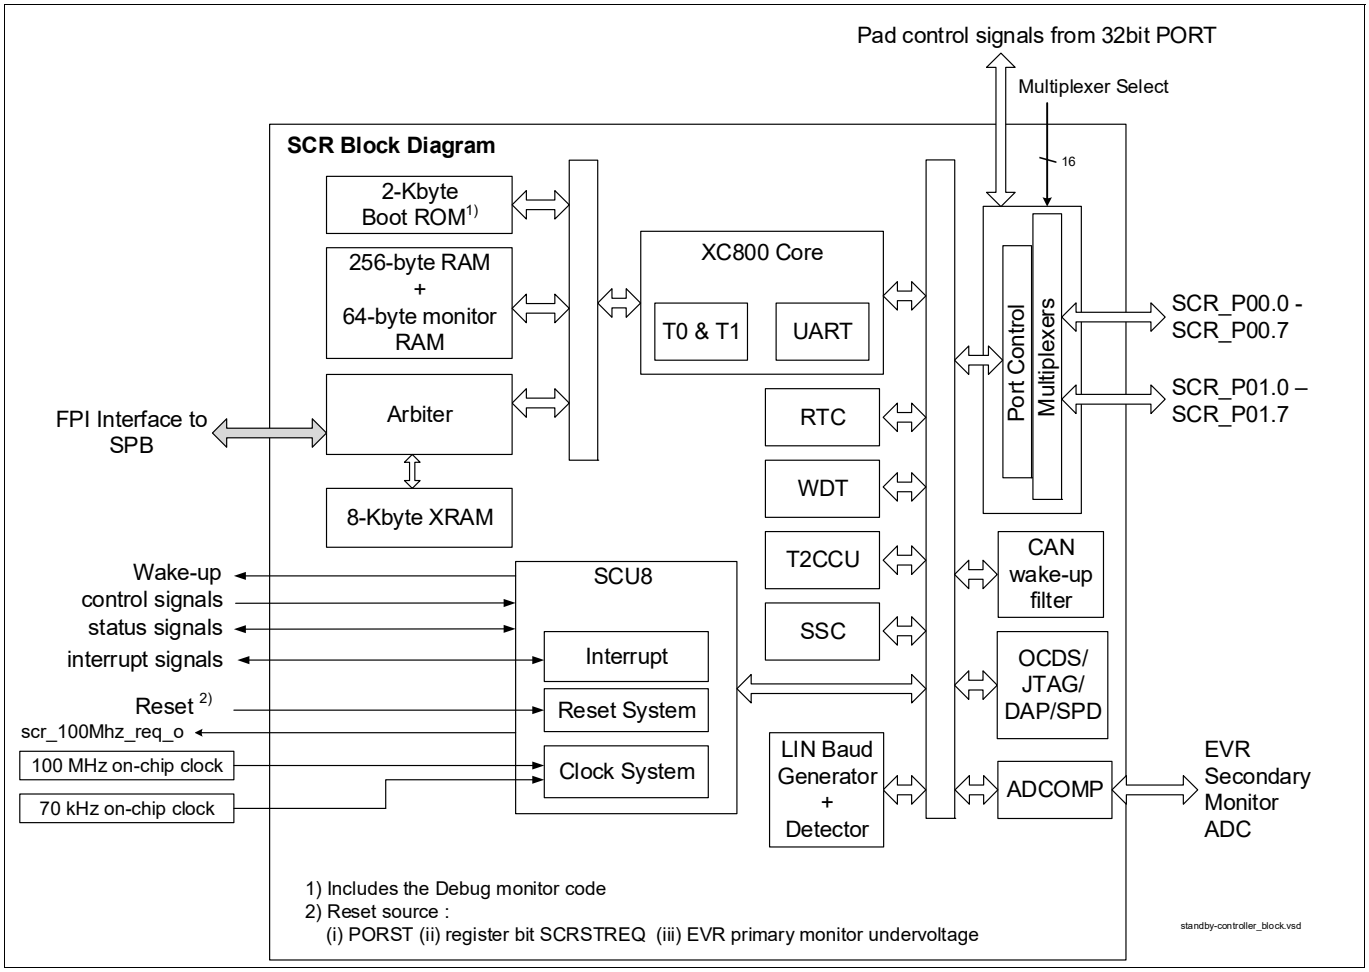

Figure 801 SCR Block Diagram

Note: Regarding the version numbers in the bottom line of the pages in this SCR chapter, please note that the 1st number represents the AURIX-SCR-sub-chapter version, and the 2nd number represents the SCR chapter version.
Note that if there are changes in the SCR sub-chapters, one or both version numbers will change.

49.1 Features of the SCR

The following list summarizes the main features of the SCR:

- High performance XC800 Core
  - compatible to standard 8051 Core
  - two clocks per CPU cycle architecture (for memory access without wait state)
  - two data pointers
  - maximum 20 MHz of core frequency
- On-chip Memory
  - 2-Kbyte Boot ROM for startup firmware
  - 256-byte RAM; plus 64-byte Monitor RAM
  - 8-Kbyte XRAM for program code and data; accessible by CPUx via the main SPB bus.
- Power saving modes
  - idle mode
  - clock gating control to each peripheral
- Watchdog Timer (WDT) with programmable window feature for refresh operation and warning prior to overflow
- Two general purpose I/O ports
  - able to control the shared pins in SCR Ports P00 and P01 (P33 and P34 of TriCore)
- Three 16-bit timers - Timer 0, Timer 1, Timer 2 of T2CCU
- Capture/compare unit of T2CCU for digital signal generation
- Real-time clock with on-chip oscillator to support periodic wake-up in standby mode
- Full duplex serial interface (UART)
- Synchronous serial channel (SSC)
- ADCOMP unit which provides ADC compare functionality.
- Interrupt supported from SCR to TriCore and vice versa.
- XRAM Programmable via the System Peripheral Bus.
- On-chip Debug Support via single pin DAP interface (SPD)
  - 1.5-Kbyte monitor ROM (part of the Boot ROM)
  - 64-byte monitor RAM

49.3 XC800 CPU

This chapter describes the XC800 CPU.

49.3.1 SFRs of the CPU

The XC800 CPU registers occupy direct Internal Data Memory space locations in the range 80_H to FF_H.

49.3.1.1 Stack Pointer (SP, $D4_H$)

The SP register contains the Stack Pointer. The Stack Pointer is used to load the program counter into internal data memory during LCALL and ACALL instructions and to retrieve the program counter from memory during RET and RETI instructions. Data may also be saved on or retrieved from the stack using PUSH and POP instructions. Instructions that use the stack automatically pre-increment or post-decrement the stack pointer so that the stack pointer always points to the last byte written to the stack, i.e. the top of the stack. On reset, the Stack Pointer is reset to 07_H. This causes the stack to begin at a location = 08_H above register bank zero. The SP can be read or written under software control. The programmer must ensure that the location and size of the stack in internal data memory do not overlap with other application data.

49.3.1.2 Data Pointer (DPTR, D5-6_H)

The Data Pointer (DPTR) is stored in registers DPL (Data Pointer Low byte) and DPH (Data Pointer High byte) to form 16-bit addresses for External Data Memory accesses (MOVX A,@DPTR and MOVX @DPTR,A), for program byte moves (MOVC A,@A+DPTR) and for indirect program jumps (JMP @A+DPTR).

Two true 16-bit operations are allowed on the Data Pointer: load immediate (MOV DPTR, #data) and increment (INC DPTR).

49.3.1.3 Accumulator (ACC, $E0_H$)

This register provides one of the operands for most ALU operations. ACC is the symbol for the accumulator register. The mnemonics for accumulator-specific instructions, however, refer to the accumulator simply as “A”.

49.3.1.4 B Register (DA_H)

The B register is used during multiply and divide operations to provide the second operand. For other instructions, it can be treated as another scratch pad register.

49.3.1.5 Program Status Word (PSW, $D0_H$)

The PSW contains several status bits that reflect the current state of the core.

Program Status Word Register

PSW
Program Status Word Register **($0D0_H$)** **Reset Value: Table 547**

Reset Type	Reset Value	Note
Generated Reset	00_H	
LVD Reset	00_H	

49.3.1.6 Extended Operation Register (EO, $D7_H$)

The instruction set includes an additional instruction MOVC @(DPTR++),A which writes to program memory implemented as RAM. This instruction may be used both to download code into the program memory when the CPU is initialized and subsequently, to provide software updates. The instruction copies the contents of the accumulator to the code memory at the location pointed to by the current data pointer, then increments the data pointer.

The instruction uses the opcode $A5_H$, which is the same as the software break instruction TRAP (see **Table 550**). Bit TRAP_EN in the Extended Operation (EO) register is used to select the instruction executed by the opcode $A5_H$. When bit TRAP_EN is 0 (default), the $A5_H$ opcode executes the MOVC instruction. When bit TRAP_EN is 1, the $A5_H$ opcode executes the software break instruction TRAP, which switches the CPU to debug mode for breakpoint processing.

Register EO is also used to select the current data pointer.

Extended Operation Register

49.3.1.7 Power Control Register (PCON, D9$_H$)

The PCON register provides control for entering idle mode, baud rate control for UART in mode 2, as well as two general purpose flags.

The XC800 CPU has two power-saving modes: idle mode and power-down mode. The idle mode can be entered via the PCON register. In idle mode, the clock to the core is disabled while the timers, serial port and interrupt controller continue to run. In power-down mode 1, the clock to the entire core is stopped.

Note: Power down mode is not available in SCR.

Power Control Register

PCON
Power Control Register (0D9$_H$) Reset Value: Table 549

49.3.1.8 Interrupt Registers

One non-maskable and fourteen maskable interrupt nodes are available.

Refer to Interrupt chapter for details of the interrupt registers.

49.3.2 SFRs of The Core Peripherals

49.3.2.1 Timer Registers

Two 16-bit timers are provided - Timer 0 (T0) and Timer 1 (T1).

Refer to Timer 0 and Timer 1 chapter for details of the timer registers.

49.3.2.2 UART Registers

The UART uses three SFRs - PCON, SCON and SBUF.

Refer to **Section 49.3.1.7** and UART chapter for details of the UART registers.

49.3.3 Instruction Timing

A CPU cycle comprises two input clock periods, referred to as Phase 1 (P1) and Phase 2 (P2), that correspond to two different CPU states. A CPU state within an instruction is referenced by the CPU cycle and state number, e.g., C2P1 means the first clock period within CPU cycle 2. Memory access takes place during one or both phases of the CPU cycle. SFR writes occur only at the end of P2. Instructions are 1, 2, or 3 bytes long and can take 1, 2 or 4 CPU cycles to execute. Registers are generally updated and the next opcode pre-fetched at the end of P2 of the last CPU cycle for the current instruction.

The XC800 CPU supports access to slow memory by using wait cycle(s). Each wait cycle lasts one CPU cycle, i.e. two clock periods. For example, in case of a memory requiring one/two wait state(s), the access time is increased by one CPU cycle for every byte of opcode/operand fetched.

Figure 802 shows the fetch/execute timing related to the internal states and phases. Execution of an instruction occurs at C1P1. For a 2-byte instruction, the second reading starts at C1P1.

Figure 802 (a) shows two timing diagrams for a 1-byte, 1-cycle (1 x CPU cycle) instruction. The first diagram shows the instruction being executed within one CPU cycle since the opcode (C1P2) is fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over two CPU cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the flash memory.

Figure 802 (b) shows two timing diagrams for a 2-byte, 1-cycle (1 x CPU cycle) instruction. The first diagram shows the instruction being executed within one CPU cycle since the second byte (C1P1) and the opcode (C1P2) are fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three CPU cycles (instruction time extended), with one wait cycle inserted for each access to the flash memory. In this case, two wait cycles are inserted in total.

Figure 802 (c) shows two timing diagrams of a 1-byte, 2-cycle (2 x CPU cycle) instruction. The first diagram shows the instruction being executed over two CPU cycles with the opcode (C2P2) fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three CPU cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the slow memory requiring one/two wait state(s).

Note: For instructions that are executed over two or more CPU cycles, execution cycle may or may not be extended in case of access to slow memory with one/two wait states. The execution cycle is,

nonetheless, guaranteed consistent for each instruction when accessed from slow memory with defined wait state(s). Reference: ***Table 550****.*

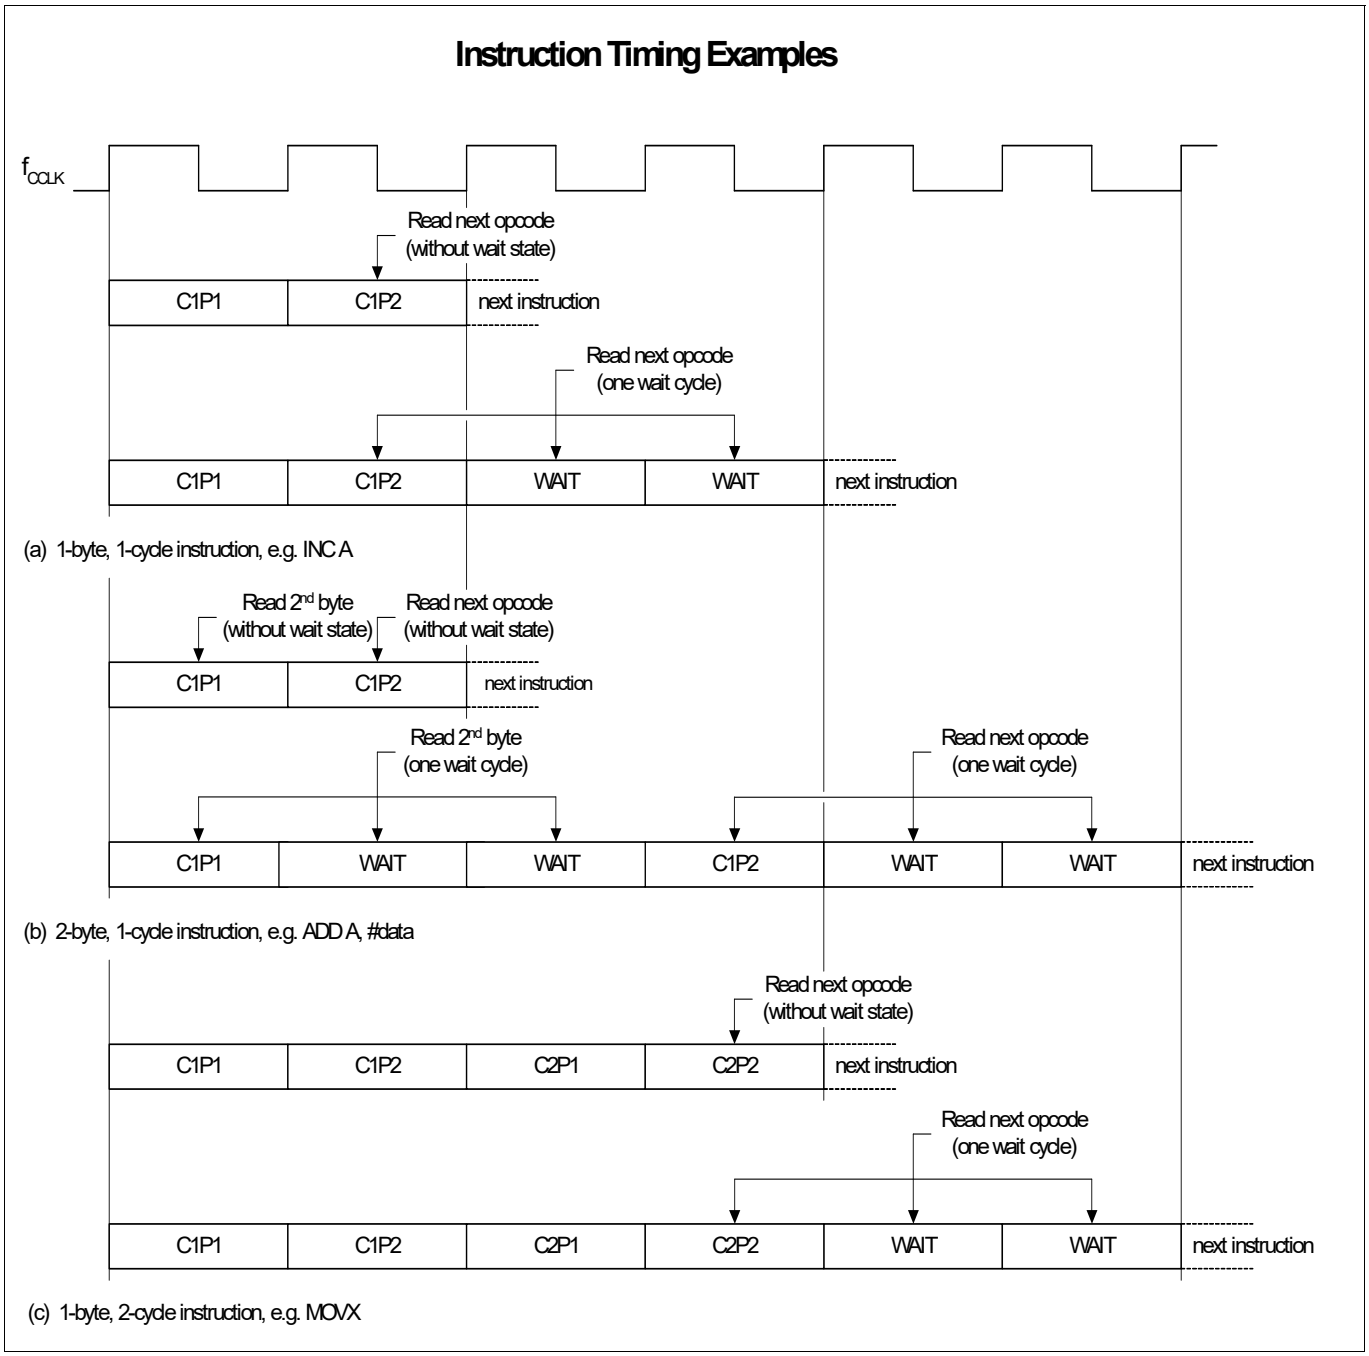

Figure 802 CPU Instruction Timing

The time taken for each instruction includes:

- decoding/executing the fetched opcode
- fetching the operand/s (for instructions > 1 byte)
- fetching the first byte (opcode) of the next instruction (due to CPU pipeline)

Note: The XC800 CPU fetches the opcode of the next instruction while executing the current instruction.

Table 550 lists all the instructions supported by the XC800 CPU. Instructions are 1, 2 or 3 bytes long as indicted in the 'Bytes' column. Each instruction takes 1, 2 or 4 CPU cycles to execute (with no wait cycle). The table gives two values for the number of CPU cycles required by each instruction. The first value applies to fetching operand/s and opcode from fast memory (e.g. Boot ROM and XRAM) without wait state. The second value applies to fetching operand/s and opcode (and in some cases accessing data) from slow memory (e.g. Flash) with wait cycles inserted due to memory requiring one/two wait state(s). One CPU cycle comprises two CCLK clock cycles.

TRAP	A5	1	1	–

1) In case of fetch from slow memory requiring only 1 wait state, no wait cycle may be required per the instruction fetched (normally for opcodes that do not require fetch in the next cycle).
2) Depending on whether the operation is accessing memory with zero or one/two wait state.
3) For branch instructions, the instruction time may vary depending on jump destination.

49.3.4 XRAM Addressing Modes

External Data Memory (XRAM) is accessed using MOVX instructions only. These use either 8-bit or 16-bit indirect address. The DPTR register is used for 16-bit addressing and either register R0 or R1 is used to form the 8-bit address.

49.3.4.1 Access to XRAM Using the DPTR (16-bit addressing Mode)

The external memory can be accessed by two read/write instructions, which use the 16-bit DPTR for indirect addressing. These instructions are:

- MOVX A, @DPTR (Read)
- MOVX @DPTR, A (Write)

49.3.4.2 Access to XRAM Using the Register R0/R1 (8-bit addressing Mode)

The SCR provides also instructions for accesses to XRAM using the 8-bit address (indirect addressing with registers R0 or R1). These instructions are:

- MOVX A, @Ri (Read)
- MOVX @Ri, A (Write)

To access the XRAM properly, higher order address must be put in SFR XADDRH . And this write instruction must be preceding the MOVX instructions.

49.4 Memory Organization

The SCR CPU operates in the following four address spaces:

- 2 Kbyte of Boot ROM program memory, ECC protected.
- 256 byte of internal RAM data memory, ECC protected.
- 8 Kbyte of XRAM memory (32-bit memory, accessible to TriCore via the System Peripheral Bus):
  - ECC protected;
  - XRAM can be read/written as program memory or external data memory;
- a 128-byte Special Function Register area.

Figure 803 illustrates the memory address spaces of the SCR.

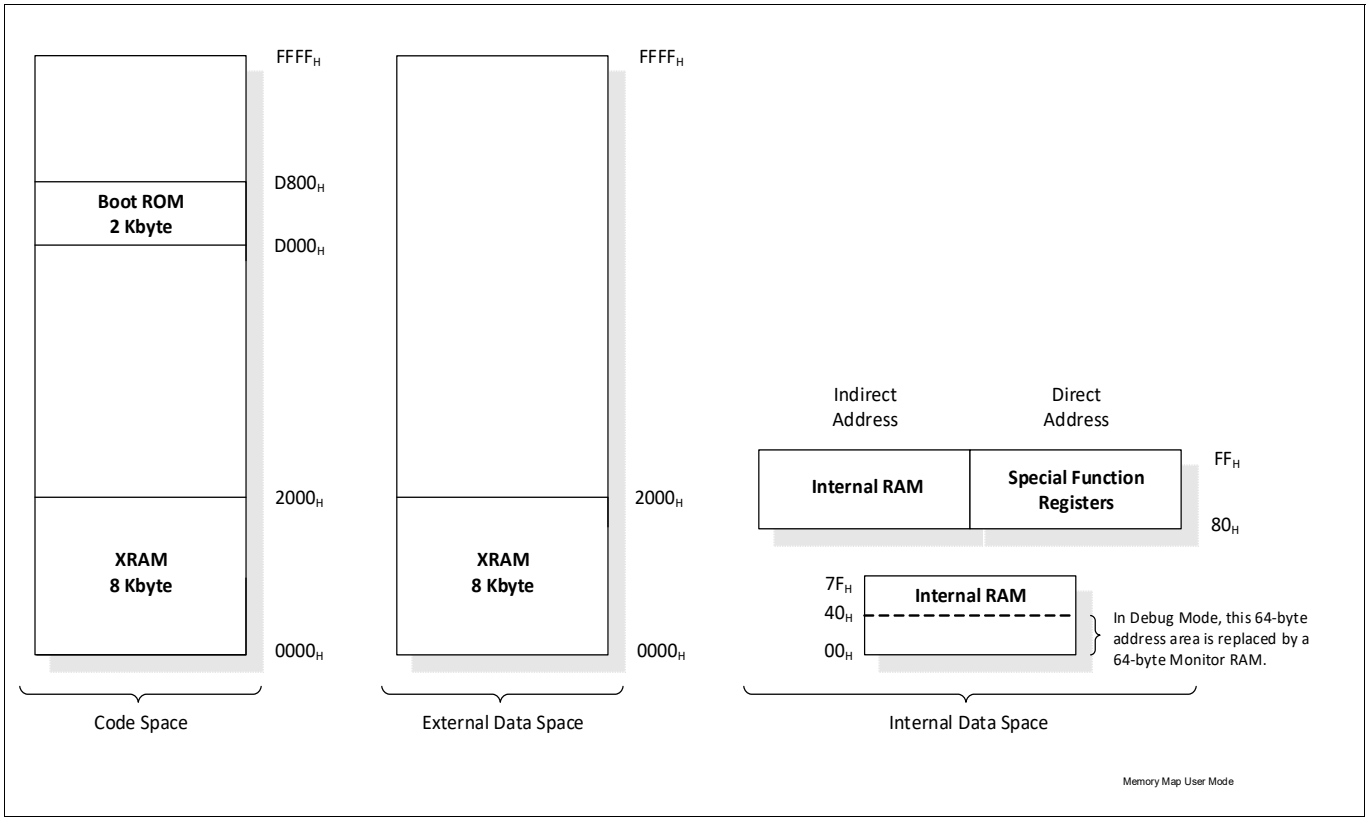

Figure 803 Memory Map of the SCR

49.4.1 Program Memory

The code space is theoretically 64 Kbytes. However, only access to defined program memory (as shown in memory map figure) is supported. For the MemOrg, defined code space is occupied by on-chip memories.

49.4.2 Data Memory

The data space consists of an internal and external data space. Access to internal and external data space are distinguished by different sets of instruction opcodes. In the SCR, the on-chip XRAM is located in external data space and accessed by MOVX instructions. SCR does not support access to external (off-chip) memory. Internal data space is occupied by Internal RAM (IRAM) and Special Function Registers (SFRs), distinguished by direct or indirect addressing.

49.4.2.1 Internal Data Memory

The internal data memory is divided into two physically separate and distinct blocks: the 256-byte RAM and the 128-byte Special Function Register (SFR) area. While the upper 128 bytes of RAM and the SFR area share the same address locations, they are accessed through different addressing modes. The lower 128 bytes of RAM can be accessed through either direct or register indirect addressing, while the upper 128 bytes of RAM can be accessed through register indirect addressing only. The SFRs are accessible through direct addressing.

The 16 bytes of RAM that occupy addresses from 20_H to $2F_H$ are bit-addressable. RAM occupying direct addresses from 30_H to $7F_H$ can be used as scratch pad registers or used for the stack.

49.4.2.2 External Data Memory

The 8-Kbyte XRAM is mapped to both the external data memory area and the program memory area. The SCR XRAM can be accessed by both the SCR's XC800 core and the main Tricore CPU. The arbiter module determines which CPU has control of the XRAM at any one time. The Tricore CPU accesses the XRAM via the peripheral bus. An FPI slave interface is provided to the SCR to interface to the SPB bus. The arbiter module is responsible for arbitrating between the SCR core and the Tricore accesses to the XRAM via the SPB.

SCR core accesses the XRAM using either the 'MOVX' or 'MOVC' instructions. The 'MOVX' instructions for XRAM access use either 8-bit or 16-bit indirect addresses, as shown in **Table 553**.

Table 553 Instructions for External Data Memory Access

Type of Access	16-bit Addressing Mode	8-bit Addressing Mode
Read	MOVX A, @DPTR	MOVX A, @Ri
Write	MOVX @DPTR, A	MOVX @Ri, A

While the DPTR register is used for 16-bit addressing, either register R0 or R1 is used to form the 8-bit address. The upper byte of the XRAM address during execution of the 8-bit accesses is defined by the value stored in register XADDRH. Hence, the write instruction for setting the higher order XRAM address in register XADDRH must precede the 'MOVX' instruction.

A write access to a undefined external data memory address has no effect while a read access returns undefined data.

XADDRH is specified in the core part of the manual.

49.4.3 Special Function Registers

The Special Function Registers (SFRs) occupy direct internal data memory space in the range 80_H to FF_H. All registers, except the program counter, reside in the SFR area. The SFRs include pointers and registers that provide an interface between the CPU and the on-chip peripherals. As the 128-SFR range is less than the total number of registers required, address extension mechanisms are required to increase the number of addressable SFRs. The address extension mechanisms include:

- Mapping
- Paging

49.4.3.1 Address Extension by Mapping

Address extension is performed at the system level by mapping. The SFR area is extended into two portions: the standard (non-mapped) SFR area and the mapped SFR area. Each portion supports the same address range 80_H to FF_H, bringing the number of addressable SFRs to 256. The extended address range is not directly controlled by the CPU instruction itself, but is derived from bit RMAP in the system control register SYSCON0 at address $8F_H$. To access SFRs in the mapped area, bit RMAP in SFR SYSCON0 must be set. However, the SFRs in the standard area can be accessed by clearing bit RMAP. **Figure 804** shows how the SFR area can be selected.

As long as bit RMAP is set, the mapped SFR area can be accessed. This bit is not cleared automatically by hardware. Thus, before standard/mapped registers are accessed, bit RMAP must be cleared/set, respectively, by software.

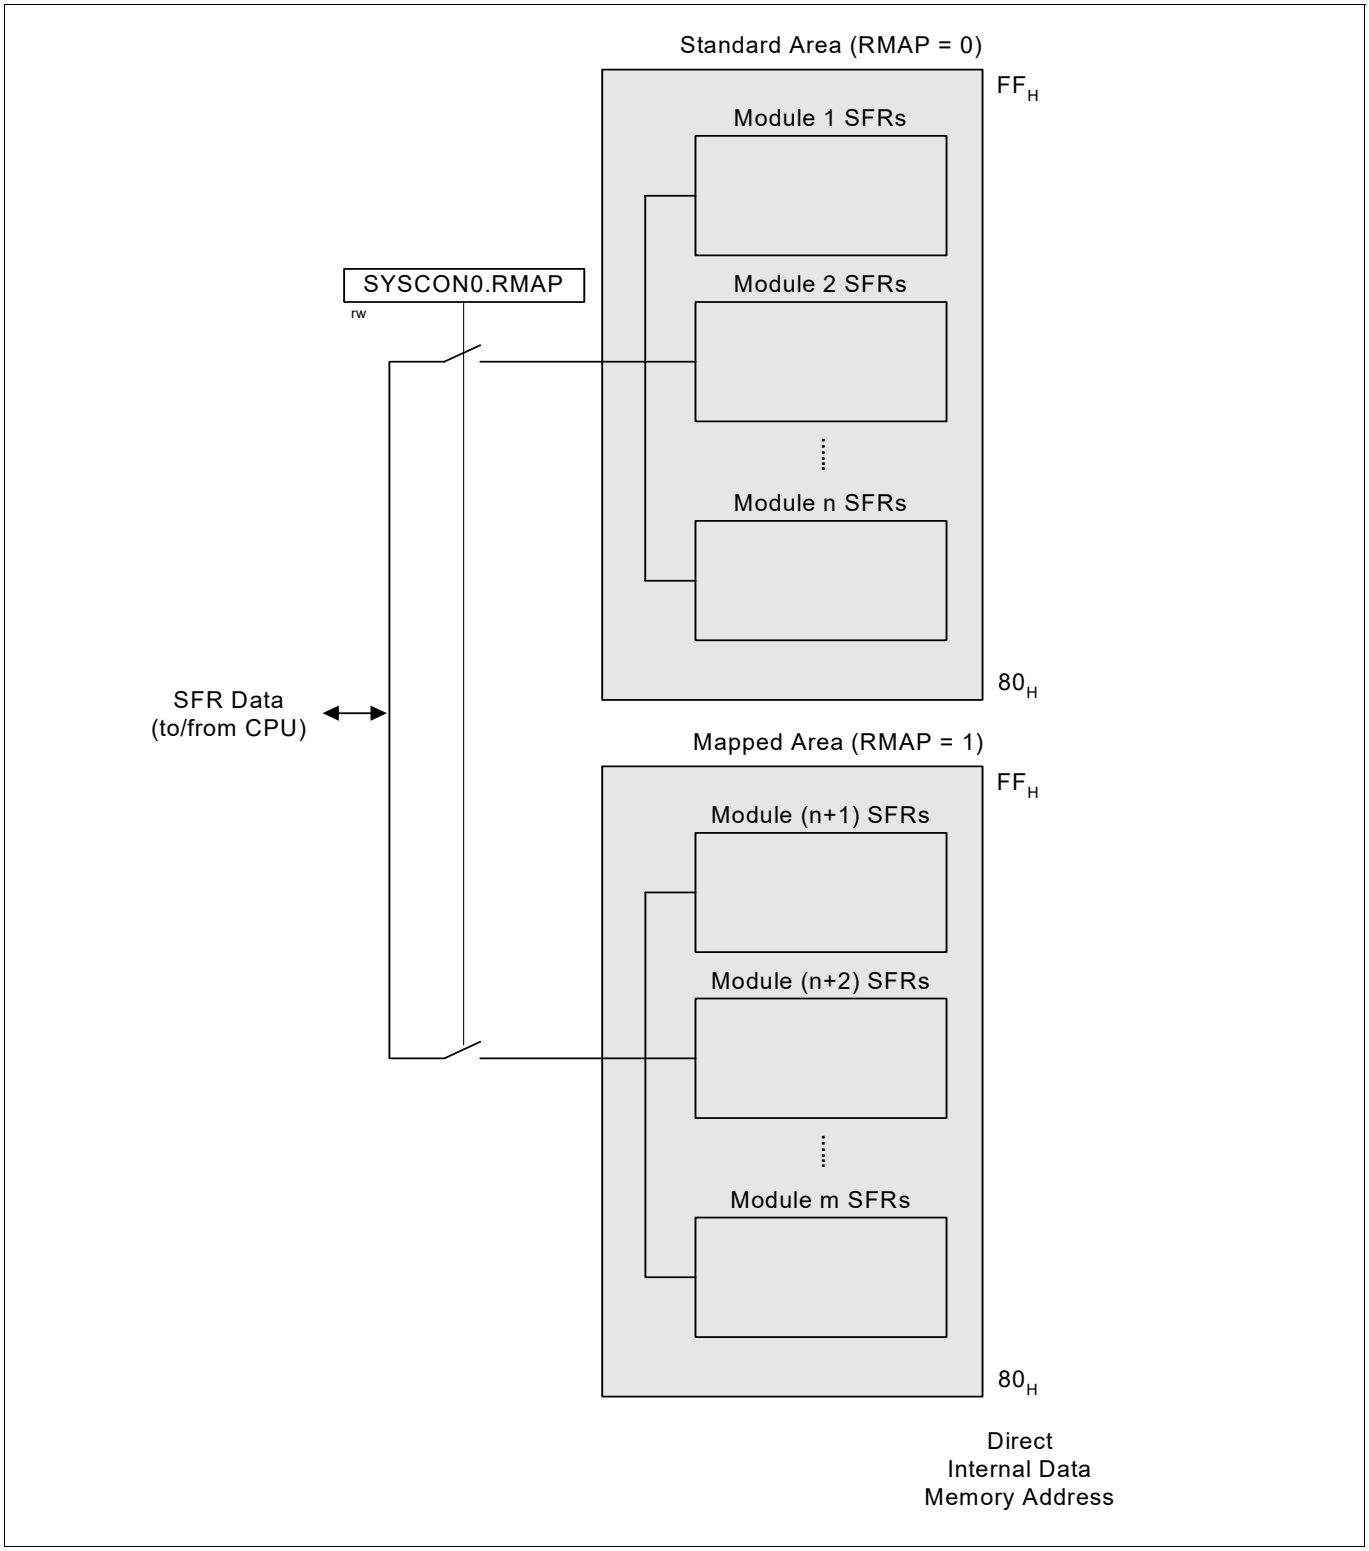

Figure 804 Address Extension by Mapping

49.4.3.2 System Control Register 0

The SYSCON0 register contains the bit to select the SFR mapping.

System Control Register 0

SYSCON0
System Control Register 0 **(088_H)** **Reset Value: Table 554**

AMSEL	2	rw	**Active Memory Map Select** 0_B Active memory map 0: Boot ROM is only mapped from 0xD000 1_B Active memory map 1: Last 512 bytes of Boot ROM are mapped to both, 0x0000 and 0xD600
0	1, 7:3	r	**Reserved** Returns 0 when read; shall be written with 0.

Table 554 Reset Values of SYSCON0

Reset Type	Reset Value	Note
LVD Reset	XXXX X1X0_B	
Generated Reset	---- -1-0_B	

49.4.3.3 Address Extension by Paging

Address extension is further performed at the module level by paging. Certain peripherals have a built-in local address extension mechanism for increasing the number of addressable SFRs. The extended address range is not directly controlled by the CPU instruction itself, but is derived from bit field PAGE in the module page register MOD_PAGE. Hence, the bit field PAGE must be programmed before accessing the SFRs of the target module. Each module may contain a different number of pages and a different number of SFRs per page, depending on the specific requirement. Besides setting the correct RMAP bit value to select the SFR area, the user must also ensure that a valid PAGE is selected to target the desired SFRs.

Figure 805 shows how a page inside the extended address range can be selected.

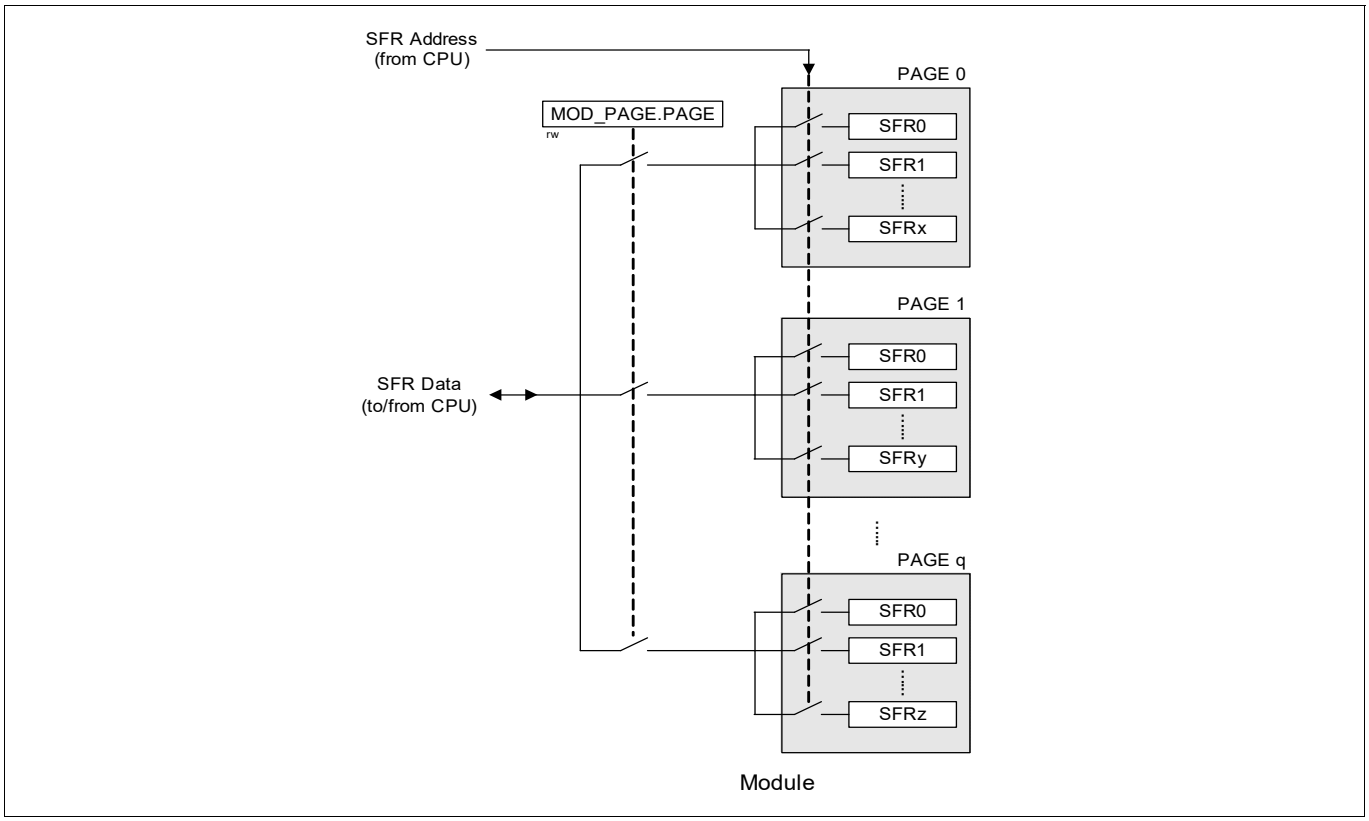

Figure 805 Address Extension by Paging

In order to access a register located in a page other than the current one, the current page must be exited. This is done by reprogramming the bit field PAGE in the page register. Only then can the desired access be performed.

If an interrupt routine is initiated between the page register access and the module register access, and the interrupt needs to access a register located in another page, the current page setting can be saved, the new one programmed, and the old page setting restored. This is possible with the storage fields MOD_STx (x = 0 - 3) for the save and restore action of the current page setting. By indicating which storage bit field should be used in parallel with the new page value, a single write operation can:

- Save the contents of PAGE in MOD_STx before overwriting with the new value
  (this is done at the beginning of the interrupt routine to save the current page setting and program the new page number); or
- Overwrite the contents of PAGE with the contents of MOD_STx, ignoring the value written to the bit positions of PAGE
  (this is done at the end of the interrupt routine to restore the previous page setting before the interrupt occurred)

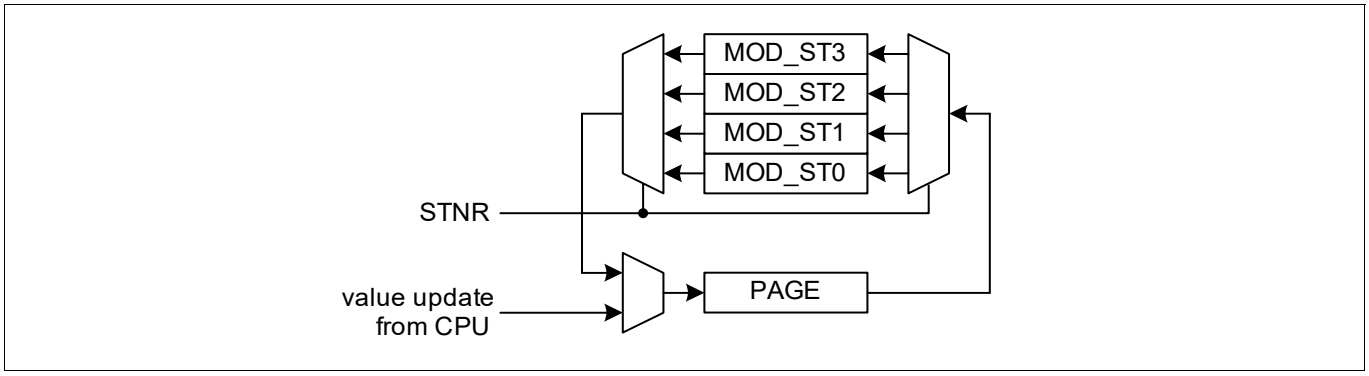

Figure 806 Storage Elements for Paging

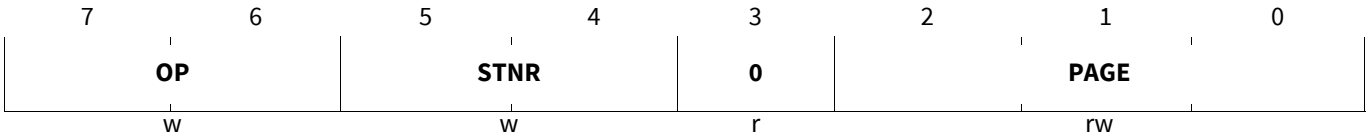
With this mechanism, a certain number of interrupt routines (or other routines) can perform page changes without reading and storing the previously used page information. The use of only write operations makes the system simpler and faster. Consequently, this mechanism significantly improves the performance of short interrupt routines.

49.4.3.4 Page Register

The page register has the following definition:

Page Register for module MOD

MOD_PAGE
Page Register for module MOD **Reset Value: 00_H**



Field	Bits	Type	Description
PAGE	[2:0]	rw	**Page Bits** When written, the value indicates the new page. When read, the value indicates the currently active page.
STNR	[5:4]	w	**Storage Number** This number indicates which storage bit field is the target of the operation defined by bit field OP. If OP = 10_B, the contents of PAGE are saved in MOD_STx before being overwritten with the new value. If OP = 11_B, the contents of PAGE are overwritten by the contents of MOD_STx. The value written to the bit positions of PAGE is ignored. 00_B MOD_ST0 is selected. 01_B MOD_ST1 is selected. 10_B MOD_ST2 is selected. 11_B MOD_ST3 is selected.
OP	[7:6]	w	**Operation** $0X_B$ Manual page mode. The value of STNR is ignored and PAGE is directly written. 10_B New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the previous contents of PAGE are saved in the storage bit field STx indicated by STNR. 11_B Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit field STx indicated by STNR.
0	3	r	**Reserved** Returns 0 if read; shall be written with 0.

49.4.3.5 Bit-Addressing

SFRs that have addresses in the form of $1XXXX000_B$ (e.g., 80_H, 88_H, 90_H,..., $F0_H$, $F8_H$) are bit addressable.

49.4.3.6 Bit Protection Scheme

The bit protection scheme prevents direct software writing of selected bits (i.e., protected bits) using the PASSWD register. When the bit field MODE is 11_B, writing 10011_B to the bit field PASS opens access to writing of all protected bits, and writing 10101_B to the bit field PASS closes access to writing of all protected bits. In both cases, the value of the bit field MODE is not changed even if PASSWD register is written with 98H or A8H. It can only be changed when bit field PASS is written with 11000_B, for example, writing C0H to PASSWD register disables the bit protection scheme.

Note that access is opened for maximum 34 CCLKs if the “close access” password is not written. If “open access” password is written again before the end of 34 CCLK cycles, there will be a recount of 34 CCLK cycles.

Password Register

PASSWD
Password Register **(086_H)** **Reset Value: Table 555**
RMAP: X, PAGE: X

7	6	5	4	3	2	1	0
PASS					PROTECT_S	MODE	
w					rh	rw	

Field	Bits	Type	Description
MODE	1:0	rw	**Bit-Protection Scheme Control Bit** These two bits cannot be written directly. To change the value between 11_B and 00_B, the bitfield PASS must be written with 11000_B, only then the MODE[1:0] will be registered. 00_B **SCHEME_DIS**, Scheme Disabled 11_B **SCHEME_EN3**, Scheme Enabled **others**, Reserved; do not use
PROTECT_S	2	rh	**Bit-Protection Signal Status Bit** This bit shows the status of the protection. 0_B Software is able to write to all protected bits 1_B Software is unable to write to any protected bits (default)
PASS	7:3	w	**Password Bits** The Bit-Protection Scheme only recognizes three patterns. 13_H **PROT_OPEN**, Opens access to writing of all protected bits 15_H **PROT_CLOSE**, Closes access to writing of all protected bits 18_H **MODE_EN**, Enables writing of the bit field MODE

49.4.4 Memory Control Unit

The Memory Control Unit (MCU Module) is the interface between the CPU and the memories, providing three functions to the MemOrg:

- Active memory map selection
- Allows one physical memory (i.e. XRAM) to be accessed as both program and data memory at the same time
- Memory protection

49.4.4.1 Memory Protection Unit

The SCR consists of the following memory blocks:

- Boot ROM
- XRAM

The target of the memory protection scheme is to prevent unauthorized read out of critical data from the Boot ROM.

The memory protection scheme is hardware-based and is used to protect the Boot ROM;MOVC read instructions executed out of the “unsafe” program memory address range (e.g. XRAM) that target the Boot ROM are blocked when protection is enabled.

49.4.5 Arbiter

The arbiter serves the following purposes:

- Provides access to the XRAM via the SoC System Peripheral Bus (SPB), using an FPI slave interface.
- Arbitrates the XRAM access between SCR core and Tricore CPU (access via the peripheral bus). SCR is given higher priority to access the XRAM.

49.4.5.1 Arbiter Logic

The Arbiter is clocked by SCR f_{sys} clock (i.e., either undivided 100MHz clock, or the 70kHz clock).

The arbiter always grants the SCR higher priority when accessing the XRAM. During a read from the XC800 core, the output from the XRAM is latched until the value is used by the XC800 core. During a write, the data is simply written to the XRAM at the next f_{sys} clock edge.

49.5 SCR Firmware

This chapter describes the BootROM firmware for the SCR. It contains the following sections:

- BootROM Overview
- Startup Procedure
- On-Chip Debug Support (OCDS)

49.5.1 Overview

The SCR BootROM firmware provides the following features:

- Startup procedure for stable operation of the SCR
- Basic debugging capability via OCDS mode

Startup procedure initializes the SCR to a known state to ensure stable operation. The startup procedure consists of all the settings and initialization to be done after SCR reset, before branching to various boot modes. On-Chip Debug Support provides basic debugging capability to the user.

Please refer to the relevant sections for more details.

49.5.1.1 BootROM location

The size of the BootROM is 2 Kbyte, and it operates in two different memory maps:

- In Active Memory Map 1 (AMSEL=1), BootROM is mapped to two address spaces, 0000_H - $01FF_H$ and $D600_H$ - $D7FF_H$
- In Active Memory Map 0 (AMSEL=0), BootROM is mapped to address space $D000_H$ -$D7FF_H$

Upon reset, the active memory map is 1 and the BootROM code is executed from address 0000_H. At the beginning of the BootROM code, a jump instruction to address $D60x_H$ is executed, followed by an instruction to clear the AMSEL bit. This is to switch the active memory map to 0. All other BootROM instructions will be executed in active memory map 0.

49.5.1.2 Boot Mode Option

Entry to various boot modes such as User Mode 0, User Mode 1 and debug mode (OCDS Mode) are done in the startup code of the BootROM. The startup code will depend on the SCR configuration value in the SFR SCR_HWCFG, to enter each mode. **Table 557** shows the Boot Modes configuration value.

Table 557 SCR Boot Mode

Boot Mode[1)]	SCRCFG Value
User Mode 0, XRAM is not programmed	00_H
User Mode 1, XRAM is programmed and will be executed	01_H
OCDS Mode, SCR DAP interface	02_H - 03_H
OCDS Mode, SCR SPD interface	04_H- 07_H
OCDS Mode, SOC DAP interface	$0A_H$- $0B_H$
OCDS Mode, SOC SPD interface	$0C_H$- $0F_H$

1) SPD : Single Pin DAP; DPD: Dual Pin DAP

49.5.2 OCDS Mode

This section describes the On Chip Debug System (OCDS) module and the interaction with the Monitor ROM and external debugger.The OCDS provides basic functionality to support development without the need to purchase expensive In Circuit Emulator (ICE) device which is the traditional way of debugging the embedded systems. The interface that can used to support this function is DAP.

The TRAP_EN bit in Extended Operation register (EO.4) need to enable for OCDS functionality to work properly.

When entering OCDS mode, the firmware configures the debug ports.

49.5.2.1 Features

List of features supported:

- Set breakpoints on instruction address and within a specified range
- Set breakpoints on internal RAM address for read and write
- Support unlimited software breakpoint in RAM code region
- Processing External breaks
- Stepping through the program code

In summary, up to four hardware breakpoints can be set for the current implementation. It can be used for detection specific Instruction Pointer (IP), a range of IP and specific range of read/write of internal RAM, unlimited software breakpoint (only possible in writable region) and external break. When any of the above is encountered, that corresponds to a debug event which will then trigger the execution of Monitor ROM.

49.5.2.2 OCDS Basic Understanding

For a complete understanding of the OCDS concept, its description can be found in the OCDS chapter.

49.5.2.2.1 Introduction of the XC800 Core Debug mode

The Program Counter will freeze when the core entered the debug mode and it will enter this mode when the TRAP instruction is executed and with the TRAP_EN = '1'. It will also enter upon DebugReq activation for IRAM and External Breaks. For hardware breakpoint, the TRAP instruction is actually supplied by the Monitor Mode Control (MMC) hardware block.

49.5.2.2.2 Minimum hardware and overhead are added

OCDS hardware consists of the MMC, additional internal RAM and JTAG and additional ROM memory.

The OCDS is built on top of debug mode together with minimum hardware overhead, Monitor ROM and additional 64 bytes of RAM to perform the breakpoint debugging functionality.

Monitor is resident in the BootROM region and it will make use of the additional 64 bytes of internal RAM termed Monitor RAM and together with the hardware to realize the OCDS functionality. The Monitor RAM which occupied the same memory location as the standard 8051 internal RAM, and it is selected through the MRAMS bit (MMCR).

49.5.2.2.3 Implementation of OCDS with the debug mode of XC800 Core

Some combination logic together with the support of the Monitor ROM to coordinate the processes. In this document, the tasks of the Monitor ROM will be explained in details in the next section.

49.5.2.3 OCDS Monitor Firmware

This section will describe the Monitor firmware interaction between the Monitor ROM with the OCDS hardware and the debugger software in host PC.

49.5.2.3.1 OCDS mode entry

OCDS mode is entered if:

- OCDS Boot option for SCR DAP interface, SFR SCR_HWCFG = 02_H - 03_H;
- OCDS Boot option for SCR SPD interface, SFR SCR_HWCFG = 04_H - 07_H;
- OCDS Boot option for SOC DAP interface, SFR SCR_HWCFG = $0A_H$ - $0B_H$;
- OCDS Boot option for SOC SPD interface, SFR SCR_HWCFG = $0C_H$ - $0F_H$;

IP hardware breakpoint at XRAM address 0x0000 is set before it exits OCDS mode.

Note: Due to a sideeffect, the first instruction in Wait for Debug Event needs to be HMONITOR, otherwise debugging will not work.

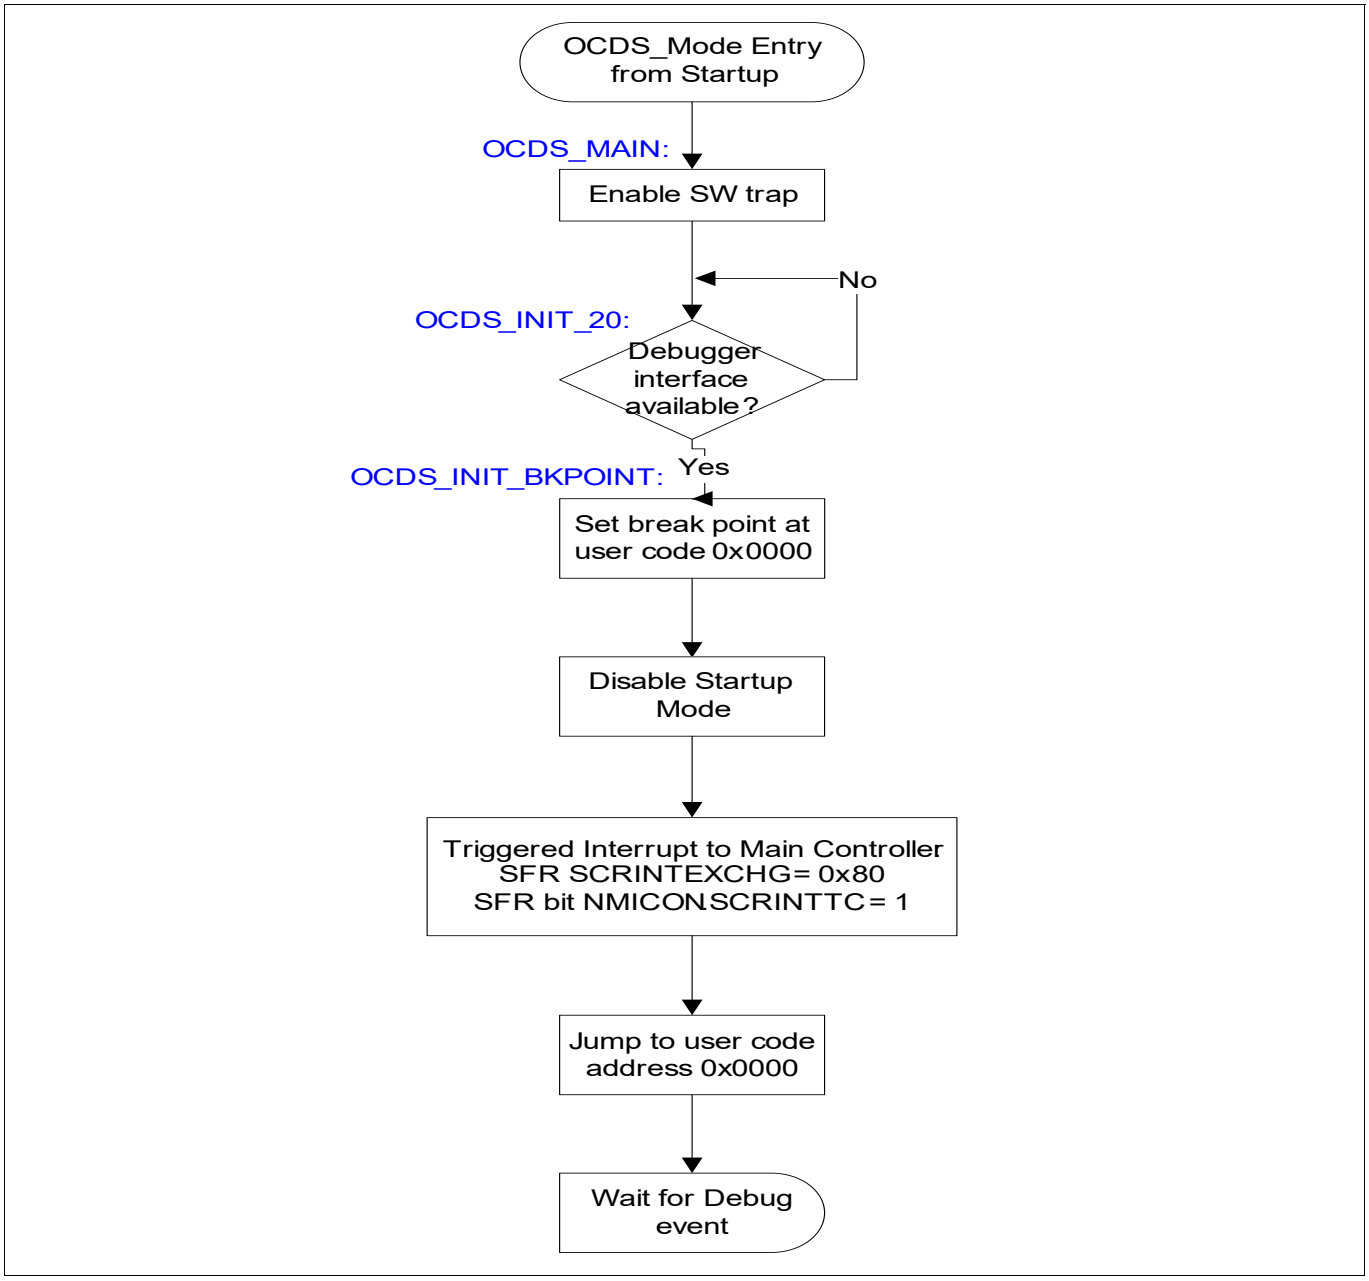

Figure 807 OCDS Initialisation

49.5.2.3.2 Communication between the Debugger and Monitor

The debugger will be the master and it will control all the read and write transactions. A virtual memory map is defined as followed.

Virtual Address Translation

To facilitate the debugger to get an insight of the memory map and all the registers in the system, a set of virtual address is defined to relate them to the physical address of the program memory, external memory and all of the other memories and registers within the system. In this way, the debugger will read or write to the virtual address and the actual reading and writing to the correct memory segment and register are controlled by the Monitor program.

Table 558 Translation of Virtual Memory to Physical Memory

Description	Physical address	Valid Virtual Address for SCR	Virtual Address (2.5 bytes)
Program memory	0000_H - $1FFF_H$	00000_H - $01FFF_H$ (8K)	00000_H - $0FFFF_H$ (64K)
External memory	0000_H - $1FFF_H$	10000_H - $11FFF_H$ (8K)	10000_H - $1FFF_H$ (64K)
Internal memory	00_H - FF_H	20000_H - $200FF_H$ (256)	20000_H - $2FFF_H$ (64K)
Indirectly accessible OCDS register	HWBPxH/L 08_H - $0F_H$	22208_H - $2220F_H$ (8)	22200_H - $222FF_H$ (256)
Monitor Virtual Registers	22300_H - $2233F_H$	22300_H - $2233F_H$ (up to 64 bytes but not all contain the valid data)	22300_H - $223FF_H$
Reserved			30000_H -$3FFFF_H$
SFR registers and page number. (Including standard, mapped and paged)	80_H-FF_H	40000_H - $7FFFF_H$ (Always BIT18=1) BIT17:15 Page number BIT14:8 SFR page address BIT7: SFR standard (RMAP=0), mapped (RMAP=1) BIT6:0 SFR address	40000_H - $7FFF_H$

For the XRAM program memory, the virtual translated address is the same as their address. For external memory and internal IRAM, the upper nibble of the virtual address is 1_H and 2_H respectively.

There are 8 indirect OCDS registers. They are the OCDS hardware breakpoint (HWBPxH/L). These registers are only accessible by setting HWBPSR first to select the relevant registers. To simplify the debugger task of setting breakpoint, the registers are mapped to the virtual address. The monitor program will base on the virtual address and write to these registers appropriately.

Table 559 Indirectly Accessible OCDS Registers

Register name	Virtual translated Address	Description
HWBP0L	22208_H	Set the address for breakpoint 0
HWBP0H	22209_H	
HWBP1L	$2220A_H$	Set the address for breakpoint 1
HWBP1H	$2220B_H$	

Table 559 Indirectly Accessible OCDS Registers (cont'd)

Register name	Virtual translated Address	Description
HWBP2L	$2220C_H$	Set the address for breakpoint 2
HWBP2H	$2220D_H$	
HWBP3L	$2220E_H$	Set the address for breakpoint 3
HWBP3H	$2220F_H$	

In order to optimize the amount of virtual address allocated to the SFR. A scheme has been devised to cope with all the SFR type i.e. standard, mapped, paged type.In order to access all the SFR, the following fields are required and defined below.

Table 560 Distribution of the Bit Definition

Field	Bit definition	Description
RMAP	BIT7	To indicate which region of SFR to access. '0' - standard registers and '1' - (R)mapped
SFR_ADDRESS	BIT 6:0	SFR to be accessed. The value of the SFR is always 80_H or above. Thus it is represented by 7bit omitting the most significant bit.
SFR_PAGE_ ADDRESS	BIT14:8	For accessing paged SFR, there is a need to write the page number to the SFR PAGE address first. Once again, it is represented by 7 bit. For non-paged SFR, this field must be written with 00_H.
PAGE_NUMBER	BIT17:15	For non-paged SFR, the PAGE_NUMBER must be set to $0F_H$. For paged SFR, this field can be used to specify page number from 0 to 07_H.
BIT18	BIT18	According to **Chapter 558** always 1.

The standard SFR refers to those SFR that required SYSCON0.RMAP=0 before they can be accessed and the mapped SFR refer to those SFR that can be accessed only when SYSCON0.RMAP=1. As for paged SFR, in additional to the standard or mapped properties, they also required the page number to be set, and it is written to the corresponding SFR_PAGE_ADDRESS. If the SFR does not paging, then SFR_PAGE_ADDRESS field must set to zero.

Bit17-Bit15 will represent the page number from 0x0-0x7, if the value equal to 0x07 and it is a non-paged SFR, then it is not necessary to set the SFR_PAGE_ADDRESS and BIT14-8 can be clear to zero.Otherwise, Bit14-8 will indicate the address (7bit only) for that SFR page. Bit7 = 0 will represent standard and 1 if mapped SFR. Bit6-0 will indicate the address (7bit only) for that desired SFR to be read out. The SFR is represented by 7 bit as its address is always above 80H and the MSB is not required and automatically handled by the firmware.

The list of registers that are used in the monitor program need to be preserved, thus to access these few SFR, the corresponding virtual address should be supplied instead of following the format given in **Table 560**

Table 561 Monitor Virtual Registers

Monitor Virtual Register Name	Virtual Translated Address	Description
mons_SCU_PAGE	$2231A_H$	Current SCU_PAGE register

mons_RETL	22334_H	Return address low byte
mons_SP	22335_H	Current Stack Pointer

Protocol Definition between the Debugger and Monitor ROM

There are 5 Monitor processed commands that are defined and described as follows.

Table 562 Monitor Processed Commands

Command	Value	Description
READ_BYTE	$1X_H$	Read a byte.
READ_BLOCK	$2X_H$	Read a block of data and return byte by byte to the host.
WRITE_BYTE	$3X_H$	Write a byte to memory location.
WRITE_BLOCK	$4X_H$	Write a block of data starting from memory location.
WRITE_PROTECTED_SFR	$5X_H$	Write a byte to the password protected bit SFR

Note: In the command field, only the upper nibble will indicate the command type, the lower nibble is used to store the 4 MSB bit of the virtual address and is not part of the command.

Some assumptions are made:

- Instead of 12 bit, it is round up to 16 bit for easy handling. Thus some are dummy bits that are not used but need to be there for data padding purpose to ensure the proper operation.
- Debugger send commands and data to Monitor, the Monitor ROM will acknowledge all bytes that are the command, parameters and data field that have been received. This is to ensure all the bytes from the debugger is received correctly.
- All commands (read or write) will be issued with a unique command_ID, since there are only five commands defined.
- A new command 50_H is introduced to support the password protected bit SFR write operation.

Monitor Processed Commands

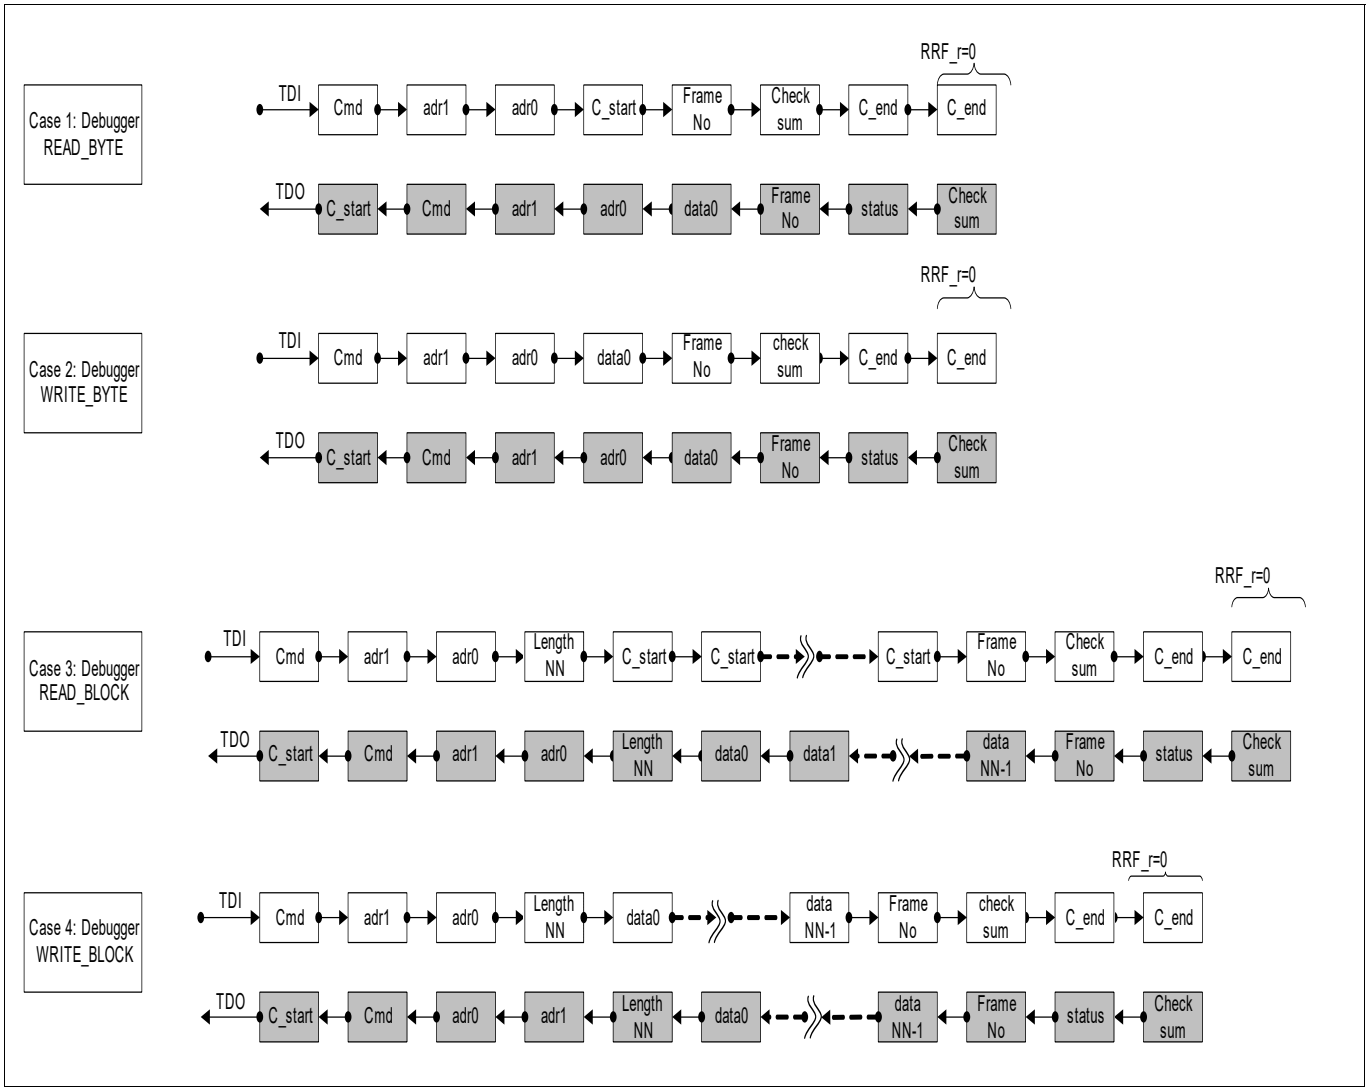

Figure 808 Monitor Processed Commands

The following is a list of the Monitor processed commands that are supported by the Monitor firmware.

Monitor processed command: READ_BYTE ($1X_H$)

The debugger will send 1 byte of command and 2 bytes of address.Next C_START, Frame No and Checksum are sent. Lastly followed by the C_end and C_end with RRF_r =0. The corresponding fields and the status byte are then checked by the debugger.

Monitor processed command: READ_BLOCK ($2X_H$)

The debugger will send 1 byte of command, 2 bytes of address and 1 byte of length. Next the C_START is send one after other until all the data are being transferred.Next the Frame No and Checksum are send followed by the C_end and C_end with RRF_r =0.

Monitor processed command: WRITE_BYTE ($3X_H$)

This command flow is very similar to the READ_BYTE command except that the C_START is not send out by debugger. Instead the data byte is written there.

Monitor processed command: WRITE_BLOCK ($4X_H$)

This command flow is similar to the READ_BLOCK except the C_START is not send out by the debugger. Instead all the data fields are send.Next the Frame No and checksum are also being sent out followed by the C_end and C_end with RRF_r=0.

Refer to the flow chart **Figure 808** that describe the commands flow.

Monitor processed command: WRITE_PROTECTED_SFR ($5X_H$)

This command is added to support writing to the password protected SFR and its functionality is similar to the WRITE_BYTE.

Note: For all the 5 commands being described, the upper 4 bit MSB of the address field is embedded inside the lower nibble of command byte. The Frame No is a 1 byte field wide, it just a sequence number that increment itself and warp around when it is overflows.

Description of the various fields use in the protocol

Various fields are define to establish the communication link between the debugger and Monitor ROM. They are outlined in **Table 563**.

Table 563 Different fields that are defined

Description (byte)	Value	Description
C_START (1)	01_H	To indicate start or ongoing event
C_END (1)	02_H	To indicate ending event
FRAMENO (1)		The debugger will send a 00_H first and sequentially increase it by 1 and wraps around if the value exceeds the single byte length. This value must reset and start from 00_H when Monitor Mode is (re-)entered or when COMRST has been activated.
CHECKSUM (1)		The checksum for the debugger and Monitor side are calculated by XORing all the fields except its checksum.
STATUS(1)		The following bit will set to indicate an error condition. BIT0 - Debugger CHECKSUM and the calculated value does not match. Read/Write operation to the memory is executed. BIT1 - Frame number out of sequence. Read/Write operation to the memory is executed. BIT2 - Control bytes, C_START not received correctly. Read/Write operation to the memory is executed. BIT3 - Invalid Range of the memory location. Read/Write operation to the memory is not executed.
ADR0 (1)		This represent the least significant 8 bit of the virtual address.
ADR1 (1)		This represent the next higher 8 bit of the virtual address.

Table 563 Different fields that are defined (cont'd)

Description (byte)	Value	Description
CMD (1)		The upper nibble contains the command as specified in **Figure 808**. The other nibble represent the most significant 4 bit of the virtual address. Thus together, they made up the 20 bits address.
Length (1)		This field is used in the read block command and write block command. It indicates the number of data bytes to be read or written into the memory. Valid range of this field is from 1 to 255.

JTAG communication and controlling the OCDS hardware control bits

Table 564 list the monitor hardware related commands.

Table 564 Monitor hardware related command

Mode/ Command	Data	Jena_r	RRF_r	MMODE_r	MBCON_r	COMRST_r	Description
HSTATE	XX_H	0	0	0	0	0	Get the status of the OCDS status bits.
HCONFIG	$A5_H$	1	0	0	0	0	Debug interface enabled by MMCR2.JENA = 1
HDEBUG	DATA	0	1	0	0	0	Data read and write
HMONITOR	$A5_H$	0	0	1	0	0	Enter the Monitor mode
HMBCOUT	XX_H	1	0	0	X	0	Jena_r must be set together with the MBCON_r state to control the MBC output. To activate it,MBCON_r=1 and to disable it MBCON_r=0.
HCOMRST	$A5_H$	0	0	0	0	1	Reset the transaction and start with a new command.
HRESET	$5A_H$	1	1	1	1	1	Reset the complete the SCR (main reset) including OCDS, but not DAP.

The prefix with H indicate that it is a OCDS hardware related commands.

The HDEBUG command/mode is use for any data read and write transaction and it is actually being used to support the five Monitor processed commands.

49.5.2.3.3 Activate the Monitor ROM

When a debug event occurred, the debug mode will be entered and instruction will be fetched from MM_START that represent the upper 8 bit of the program code address bus.MMCR.MMODE is set by the hardware to signal that the Monitor mode is entered.

The following need to be taken care. (Extract from OCDS specification)

- Save user Interrupt Enable (IEN0) and disable the global interrupt.
- Save current (user) Stack Pointer (SP) into Monitor RAM.
- Initiate the stack to dedicate area in Monitor RAM
- Save the SYSCON0 into the Monitor RAM, to preserve the user value of RMAP control bit.

- Clear the RMAP bit in SYSCON0.
- Save the current (user) PSW,A,B,DPH and DPL to Monitor IRAM.
- Set RMAP bit in the SYSCON0, to access MMICR.
- Clear the MMICR.DRETR
- Perform a LCALL to MON_START_ST (or MON_NORMAL_ST), so the break address is saved and debug mode is exited and continue to run in Monitor ROM mode.
- NOP instruction is required here for proper functioning.
- Communication between the debugger and Monitor through the selected interface.

Figure 809 shows the flow diagram when the debug event occurred. Debugging a BootROM startup code will cause the device to enter endless loop. A reset of the device is needed to exit the endless loop.

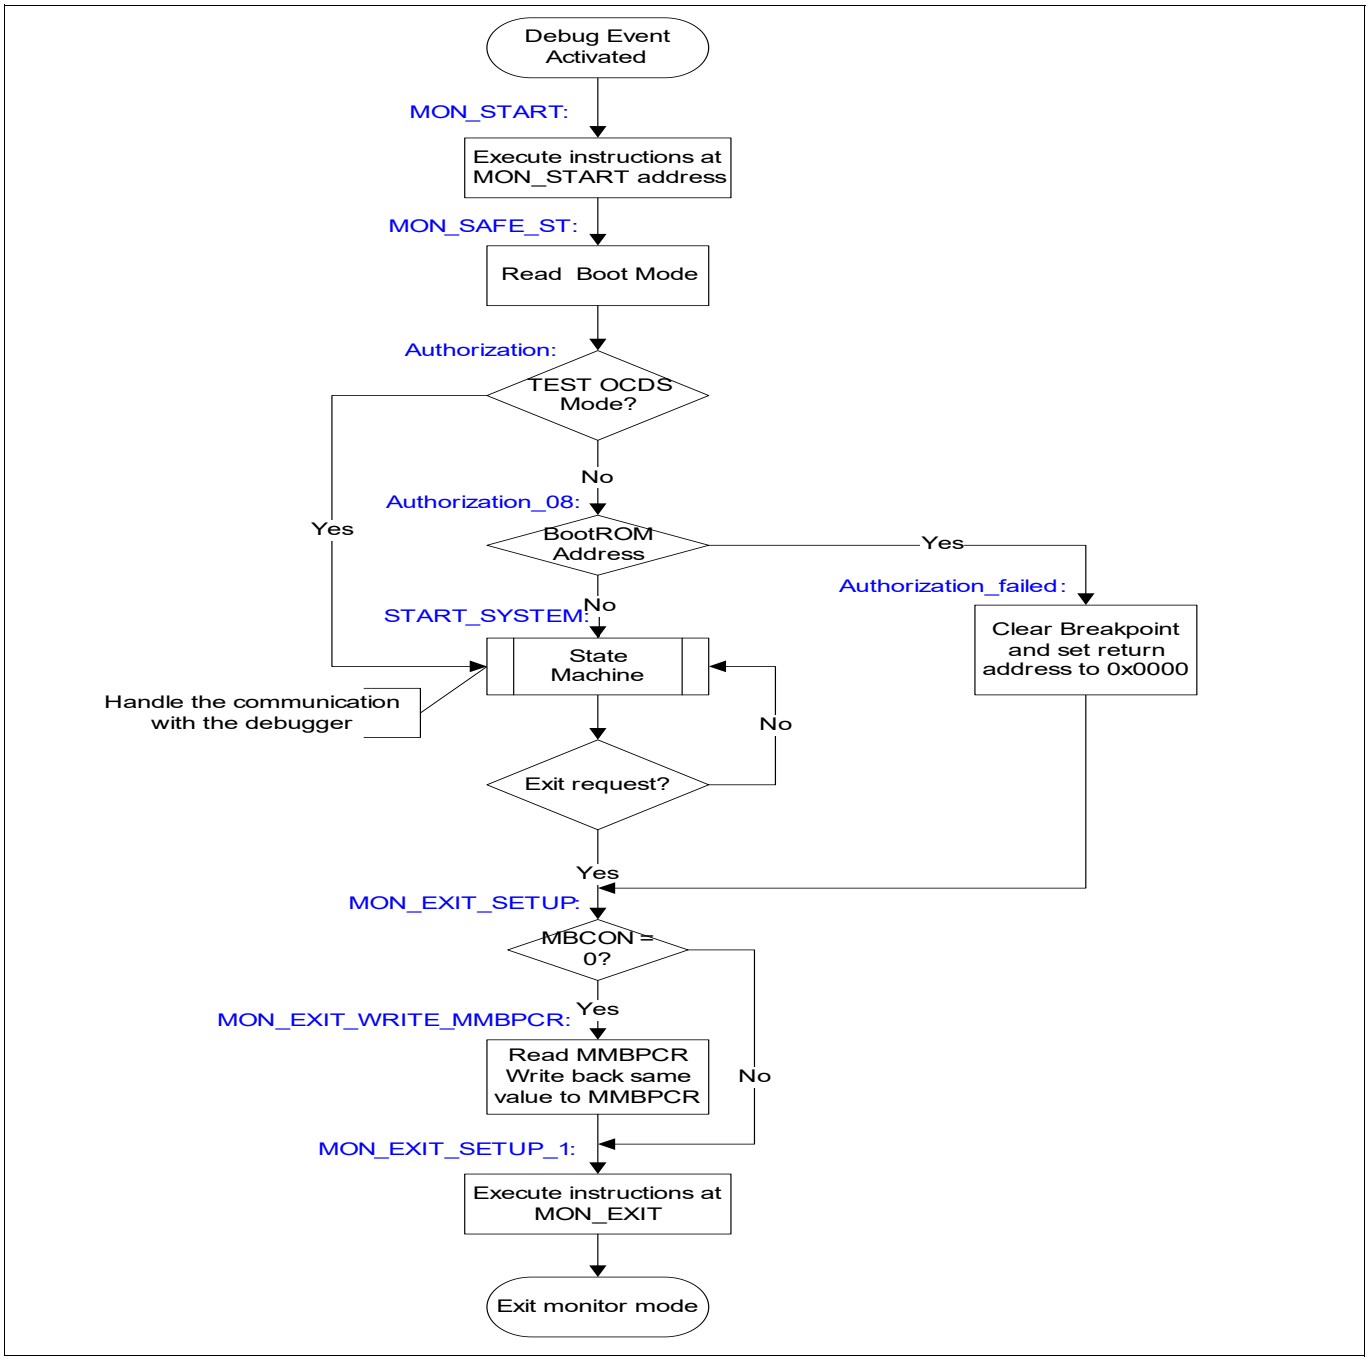

Figure 809 Debug mode Flow Diagram

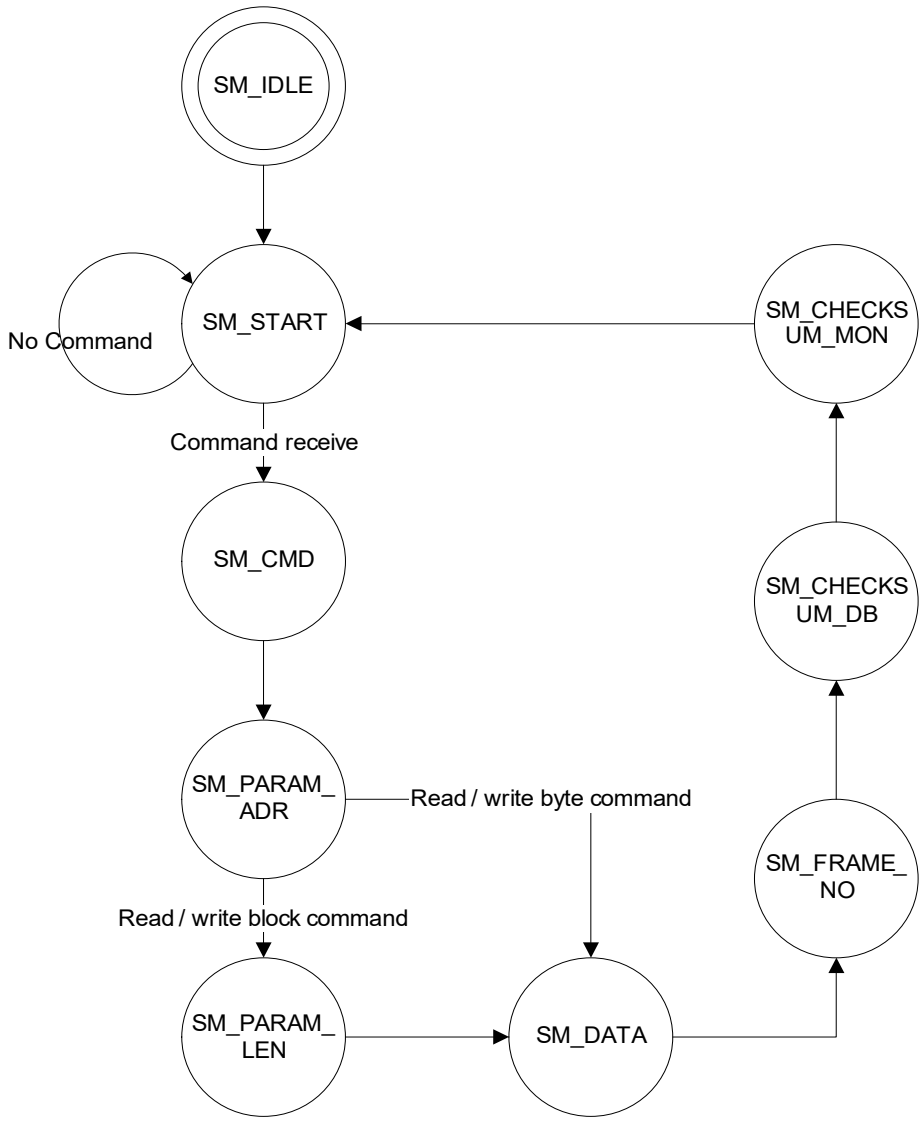
Figure 810 shows the state-machine flow diagram in the monitor program. The detailed descriptions and flow diagrams of each state can be found in **Chapter 49.5.2.4.8**.



State	Description
SM_IDLE	Idle state
SM_START	Clear variables used in the state machine, waiting for new command
SM_CMD	Receive Command
SM_PARAM_ADR	Receive 20bits virtual address
SM_PARAM_LEN	Receive data length parameter for read/write block commands
SM_DATA	Receive data for write / write block commands, Execute command. For read command, output data to host. For write command, update the data into memory (SFR, XRAM)
SM_FRAME_NO	Keep track on number of frame send by the debugger
SM_CHECKSUM_DB	Calculate the debugger checksum
SM_CHECKSUM_MON	Calculate the monitor checksum

Figure 810 State Machine - To handle monitor processed commands from host

49.5.2.3.4 Exit the Monitor ROM to return to user mode

To exit monitor mode and return to the user code, the following steps are needed to restore the user status and return to the proper user address.

The steps needed to return to user mode.

- After writing to the MMCR.EXIT=1 followed by NOP, this will trigger the debug mode to be entered.
- Mons_SYSCON0 and mons_RETH are temporary stored into the 2 OCDS scratch registers.
- SYSCON.RMAP is cleared and set the SCU_PAGE=0 to restore back the saved mons_SCU_PAGE.
- IEN0,DPH,DPL,B,A,PSW and SP are restored back respectively from the Monitor IRAM.
- The return addresses which are contained in the mons_RETL and MMWR2 are pushed to the stack.
- The SYSCON0 is updated with the value stored in the MMWR1
- RET is performed, i.e jump to address that are stored in the stack which transfer the control back to the user program.
- NOP is followed to ensure proper operation.

49.5.2.3.5 Single step execution

Single step execution:

- Current instruction in the user mode is executed and a new debug event will automatically be triggered and the Monitor mode is entered again.
- The return address is calculated by minus 1 of the break address.
- In the event when other break event happened due to single step or others, then step will always take the higher priority and consider first for the calculation of the return address.

49.5.2.3.6 Software breakpoint implementation

It is only possible if the original opcode can be replaced by the TRAP opcode. And this implies that the code memory must be writable.Thus for the XRAM, the XRAM content must be saved by the debugger and modified with the TRAP opcode $A5_H$. After the break has occurred, the debugger should program back the original user code, so that the normal flow of the program is not affected.

49.5.2.4 Important information for Debugger

This section will describe the additional tasks that are required by the debugger to produce seamless integration and synchronization flow between the monitor firmware. The debugger is the master for all transaction and it must keep track of the flow and always in sync with the current MCU resources changed. The OCDS capabilities will be disabled for BootROM region.

49.5.2.4.1 Specific Infineon DAP instruction to configure DUT

The debugger on the host side act as the master and is responsible for initiating and controlling all JTAG transactions.

From the BootROM perspective, it is only concern with the JTAG communication between the JTAG module and the OCDS module. The communication can begin once the JTAG Instruction Register (IR) is set with **JTAG_IO_INSTRUCTION1 (IOINSTR1)** ($C1_H$). This will effectively connect the external JTAG pins to the OCDS JTAG Interface module thus enabling communication between the debugger and the OCDS module.

49.5.2.4.2 Initial entry to the monitor mode

There is only one possible initial entry into the monitor mode.

Upon a reset, with boot mode configured for OCDS by the SOC, it will enter OCDS mode. The IP break point is configured at address 0000_H and execution begin at that specific address and a break event is generated and monitor mode will be entered.

49.5.2.4.3 Implementation of the debugger

Upon the entry of the monitor, the PC value are saved into the mons_RETH and mons_RETL.

The 16 bytes from $1FE8_H$ to $1FF7_H$ of the XRAM is been used by the Monitor ROM to perform reading and writing the SFR. Thus the contents at these location must be saved by the debugger when the Monitor mode is entered and restored them before exiting the Monitor mode.

IP and IRAM breakpoints are supported and modified by writing to the OCDS registers. Likewise, the debugger can view and modified any SFR according based on the virtual address translation.

For every transaction, a status byte will be returned. A non-zero value will indicate that there is error, refer to the table for the STATUS byte field definition **Table 563**.

49.5.2.4.4 Calculation of the return address upon a break event

The break address is stored in mons_RETH (33_H) and mons_RETL (34_H) upon a break and enter the monitor mode. Thus the debugger must check what type of break has occurred and calculate the return address accordingly.

For IP and IRAM breakpoint, the return address = **break address - 2**. For any other break, the return address = **break address -1**.

The debugger will need to update the return address into the mons_RETH and mons_RETL before exiting the monitor mode. To implement the “Go address” function, the debugger should modify the mons_RETH and mons_RETL directly before exiting.

49.5.2.4.5 Limitation of the monitor mode

Interrupt handling, if an external interrupt has occurred. The monitor will not be able to service it. For IRAM read and write break, only the return address can be calculated but the break address might not be known.

49.5.2.4.6 Exit sequence of the monitor mode

To exit the Monitor mode, the debugger will need to write to the MMCR.MEXIT = 1 together with the MMCR.MEXIT_P = 1. Upon writing to these bits, the Monitor mode is automatically exited. Prior to this, the starting 16 bytes from ($1FE8_H$ - $1FF7_H$) of the XRAM must be restored.

49.5.2.4.7 An example of a Debugging session

Here is an example of a debugging session:

- Initial entry of the monitor mode through OCDS mode.
- The PC is saved to the stack by the monitor firmware. The debugger will buffer the 16bytes of XRAM at address $1FE8_H$ - $1FF7_H$, into its memories.
- Load a user hex file into the XRAM memory.
- Set the IP and IRAM breakpoints.
- Modify the mons_RETH and RETL to the starting address for execution.
- Clear all the breakpoint flag.
- Follow the exit sequence.
- The break will occur and once again the monitor mode is entered and PC is saved.
- Debugger will once again buffer the 16 bytes of data into the its memories.

- All the memories and SFR can be read and modified.
- The return address is calculated based on the break address and the breakpoint flags.
- The return address is updated.
- Restore back the 16 bytes of XRAM content back to its original location.
- Follow the exit sequence.
- This process will repeat as long as there is a break event.

49.5.2.4.8 Detailed description of Monitor Program State Machine

This session described the flow of the major states:

- Start state - start of the state machine
- Command state - Received OCDS command and the upper 4bits of the virtual address.
- Parameter Address state - Received the lower 16-bits virtual address.
- Parameter Data Length state - Received the frame Length
- Data state - For read command, this state will perform the read commands and send out the data. For write command, this state will receive the data and perform the write operation to the respective memory.

Start and Command States

Figure 811 shows the flow of start state and command state. The lower nibble of the command byte contains the uppermost 4 bits of the virtual address.

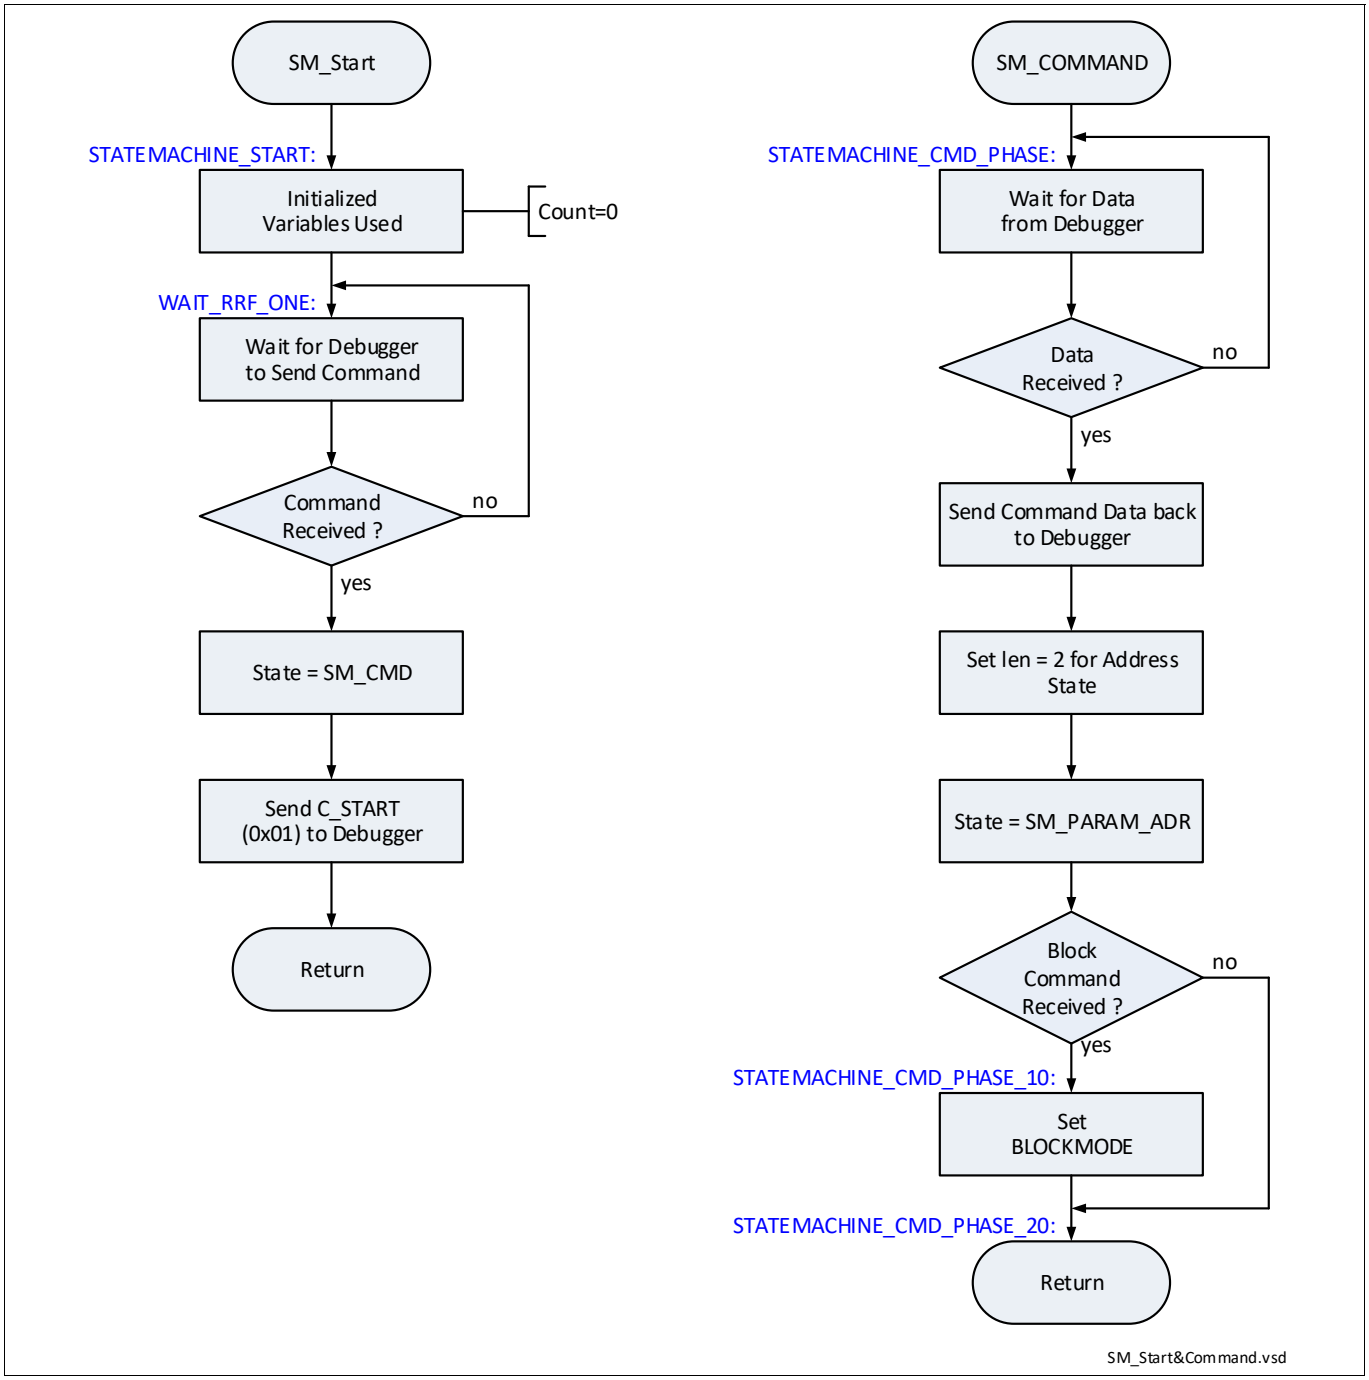


Figure 811 Start State and Command State

Parameter Address State

In this state, the next 16 bits of the virtual address are received. The 20-bits virtual address indicates which memory or SFR is to be accessed.

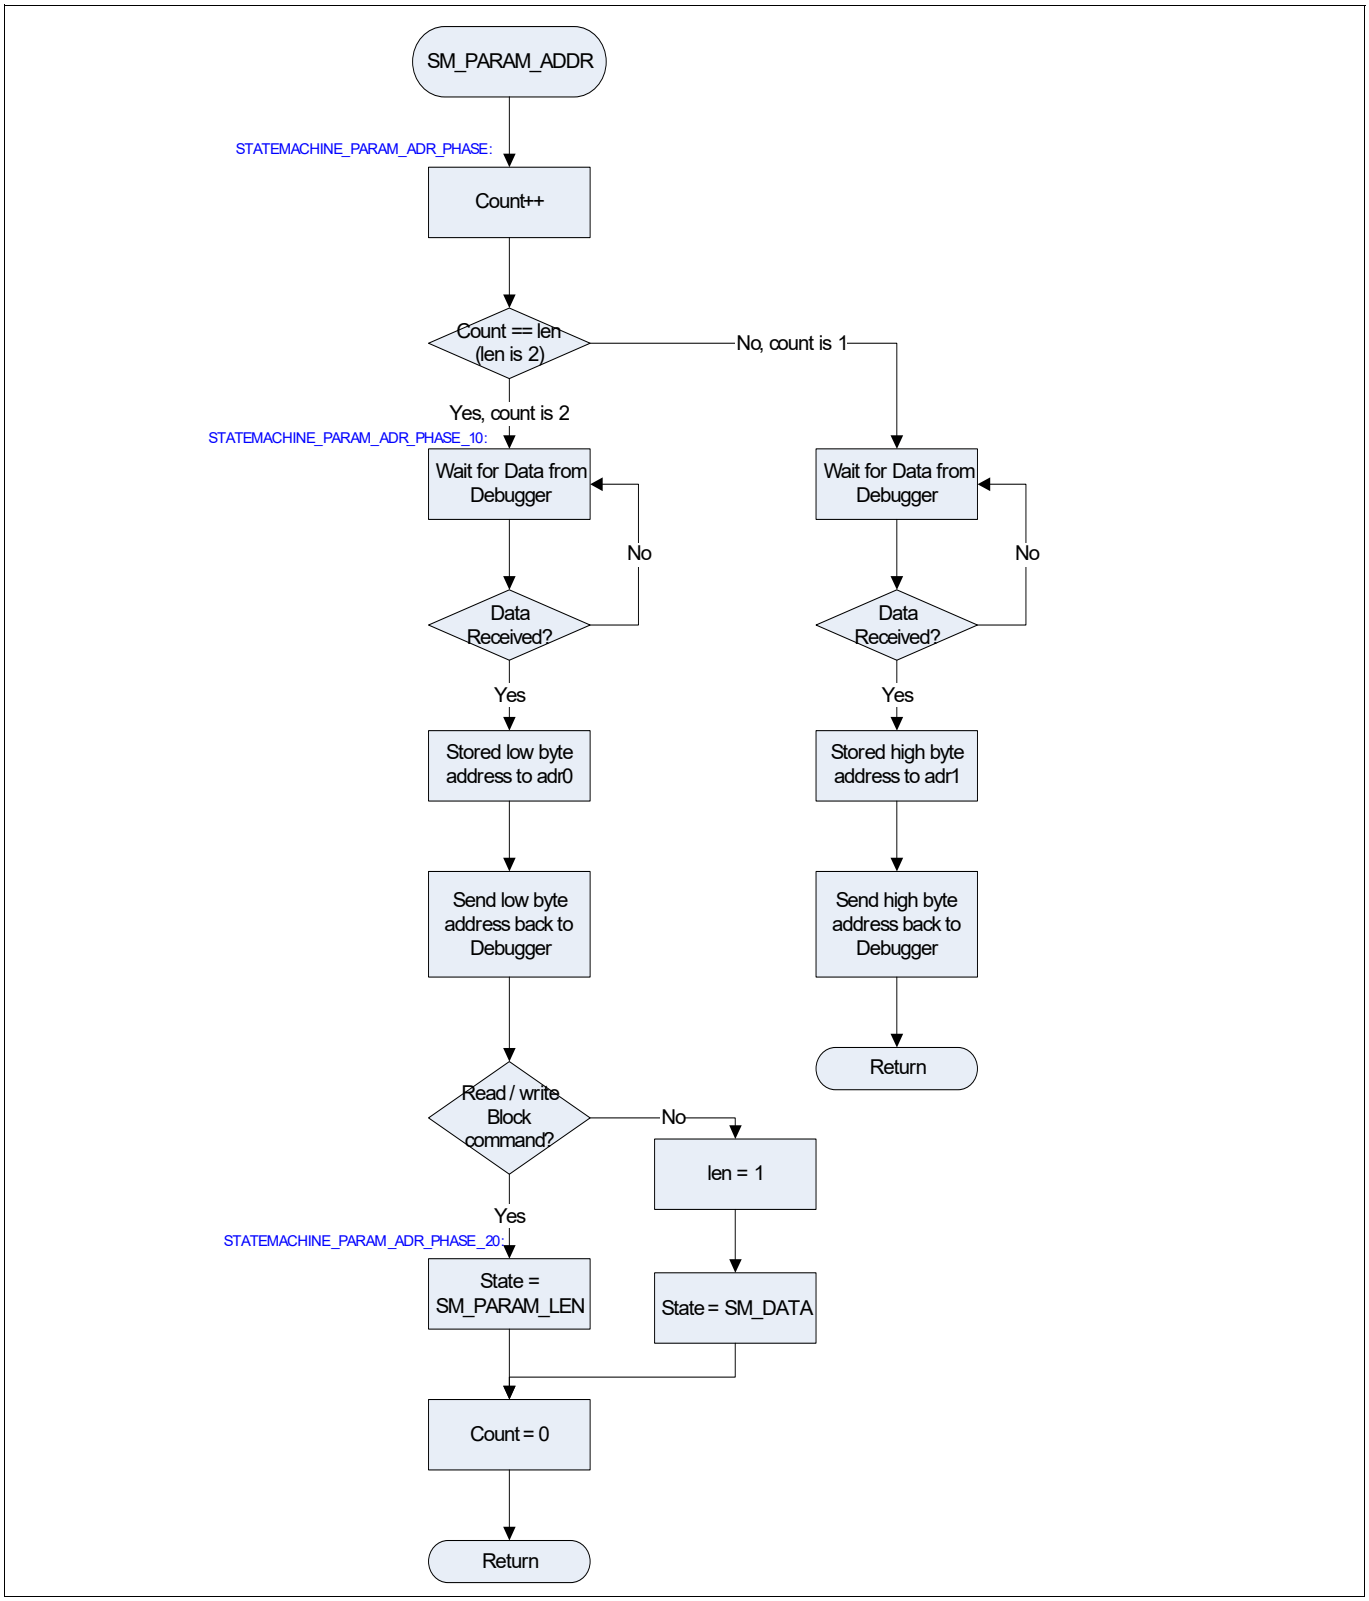

Figure 812 Parameter Address State

Parameter Length State

This state is entered if the command is read block command or write block command. The data received indicates the number of data bytes to be received or sent.

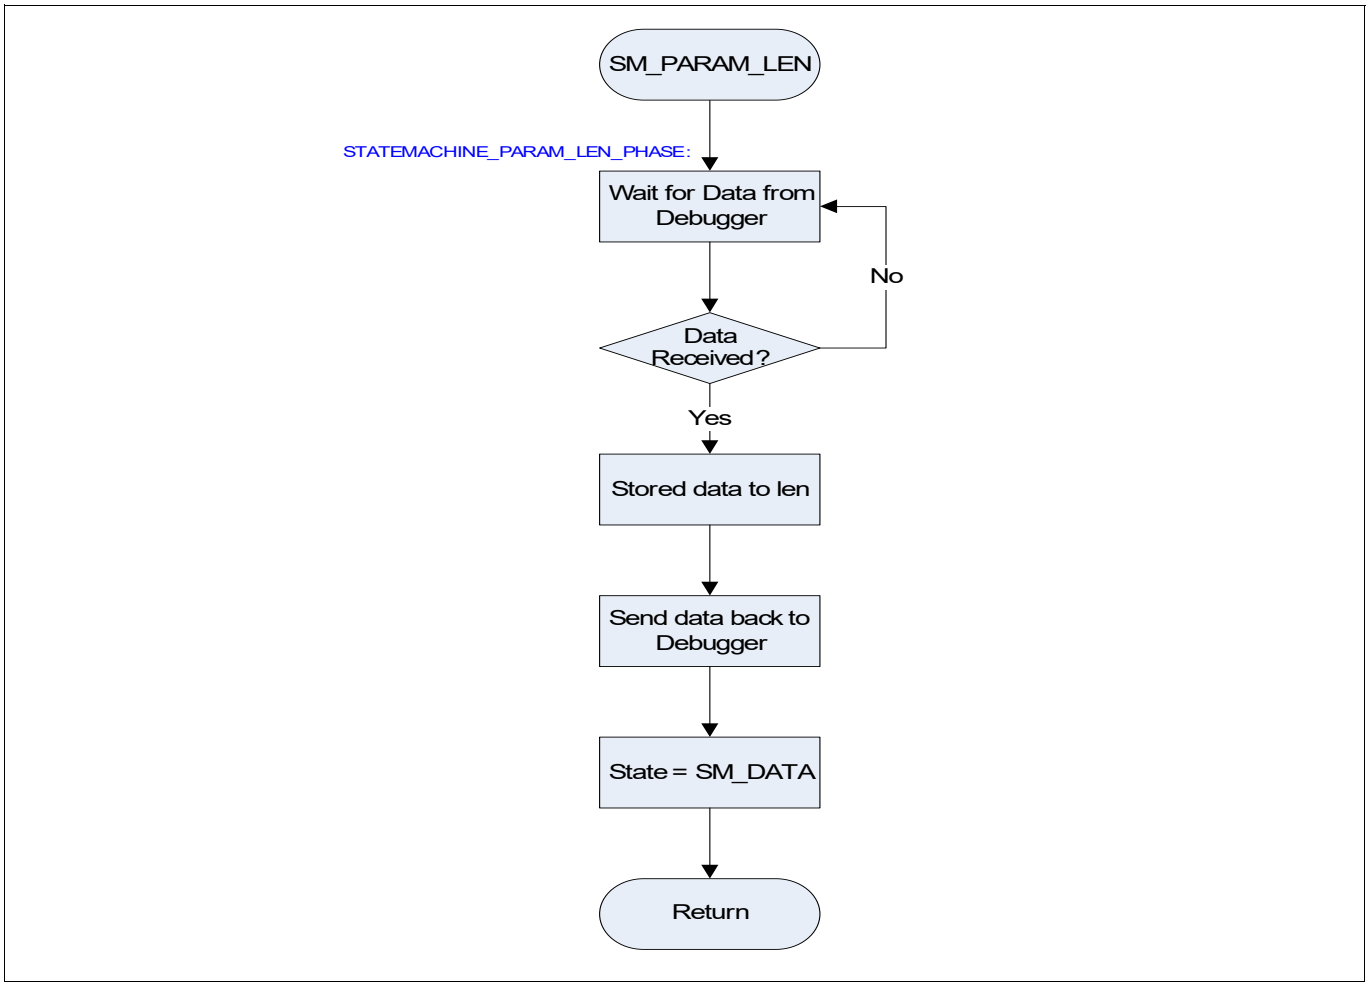

Figure 813 Parameter Length State

Data State

For Read_BYTE and READ_BLOCK commands, data is read from the respective memory or SFR and send to the debugger. For the other 3 commands, data is received from the debugger and written to the memory or SFR.

49.6 Special Function Register (SFR) Block

The SFR Block implements all of the special function registers.

The registers in the SFR Block are described and referred to in the relevant chapters (e.g. Interrupt chapter/SCU chapter/Ports chapter etc).

The SFR block supports the local address extension mechanism, and the SFRs in the SFR block are organized into 6 pages.

The page register, SFR SCU_PAGE, at address $F1_H$, contains the page value and the page control information.

49.6.1 Registers in the SFR Block

Page Register for SFRs

SCU_PAGE
Page Register for SFRs **($0F1_H$)** **Reset Value: Table 566**
RMAP: 0, PAGE: X

7	6	5	4	3	2	1	0
OP		**STNR**		**0**	**PAGE**		
w		w		r	rw		

Field	Bits	Type	Description
PAGE	2:0	rw	**Page Bits** When written, the value indicates the new page address. When read, the value indicates the currently active page = addr[y:x+1]. 000_B **PAGE0**, Selection is PAGE0 001_B **PAGE1**, Selection is PAGE1 010_B **PAGE2**, Selection is PAGE2 011_B **PAGE3**, Selection is PAGE3 100_B **PAGE4**, Selection is PAGE4 101_B **PAGE5**, Selection is PAGE5 110_B **PAGE6**, Selection is PAGE6 111_B **PAGE7**, Selection is PAGE7
STNR	5:4	w	**Storage Number** This number indicates which storage bitfield is the target of the operation defined by bit OP. If OP = 10_B, the contents of PAGE are saved in STx before being overwritten with the new value. If OP = 11_B, the contents of PAGE are overwritten by the contents of STx. The value written to bitfield PAGE is ignored. 00_B **MOD_ST0**, ST0 is selected 01_B **MOD_ST1**, ST1 is selected 10_B **MOD_ST2**, ST2 is selected 11_B **MOD_ST3**, ST3 is selected
OP	7:6	w	**Operation** 00_B **PAGE_MANUAL0**, Manual page mode. The value of STNR is ignored and PAGE is directly written. 01_B **PAGE_MANUAL1**, Manual page mode. The value of STNR is ignored and PAGE is directly written 10_B **PAGE_SAVE**, New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the former contents of PAGE are saved in the storage bit field STx indicated by STNR. 11_B **PAGE_RESTORE**, Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit field STx indicated by STNR.

Field	Bits	Type	Description
0	3	r	**Reserved** Returns 0 when read; shall be written with 0.

49.7 System Control Unit (SCU)

The System Control Unit (SCU) supports all central control tasks in the SCR. The SCU includes the following functional modules:

- Clock System and Control
- Reset Control
- Boot and Startup
- Power Management
- General Port Control
- Kernel SFR

49.7.1 Clock System and Control

Figure 818 shows the block diagram of the clock system in the SCR. It consists of two internal oscillators and a clock control unit (CCU). The two oscillators, a 100 MHz oscillator and a 70 kHz oscillator, are supplied from inside the PMS. These two clock sources to SCR are gated with bit PMSWCR4.SCREN in both normal and standby mode. If this bit is set to “0”, SCR is disabled and the clock inputs would be gated off. The system clock f_{SYS} is generated either by the 100 MHz or 70 kHz internal oscillator.

The selection between 70 kHz and 100 MHz clock is as follows: the 70 kHz clock is selected for SCR operation (f_{sys}) only during standby. During normal run mode, always the 100 MHz is selected.

In standby mode, the 100 MHz oscillator may be powered down as configured in PMSWCR4.SCRCLKSEL. When necessary, the 100 MHz oscillator can be powered up using bit CMCON.OSCPD. Whenever 100 MHz is powered up, the SCR f_{sys} runs on 100 MHz.

The CCU generates all necessary clock signals within the microcontroller from the system clock. It consists of:

- Clock source selection in active mode
- Centralized enable/disable circuit for clock control

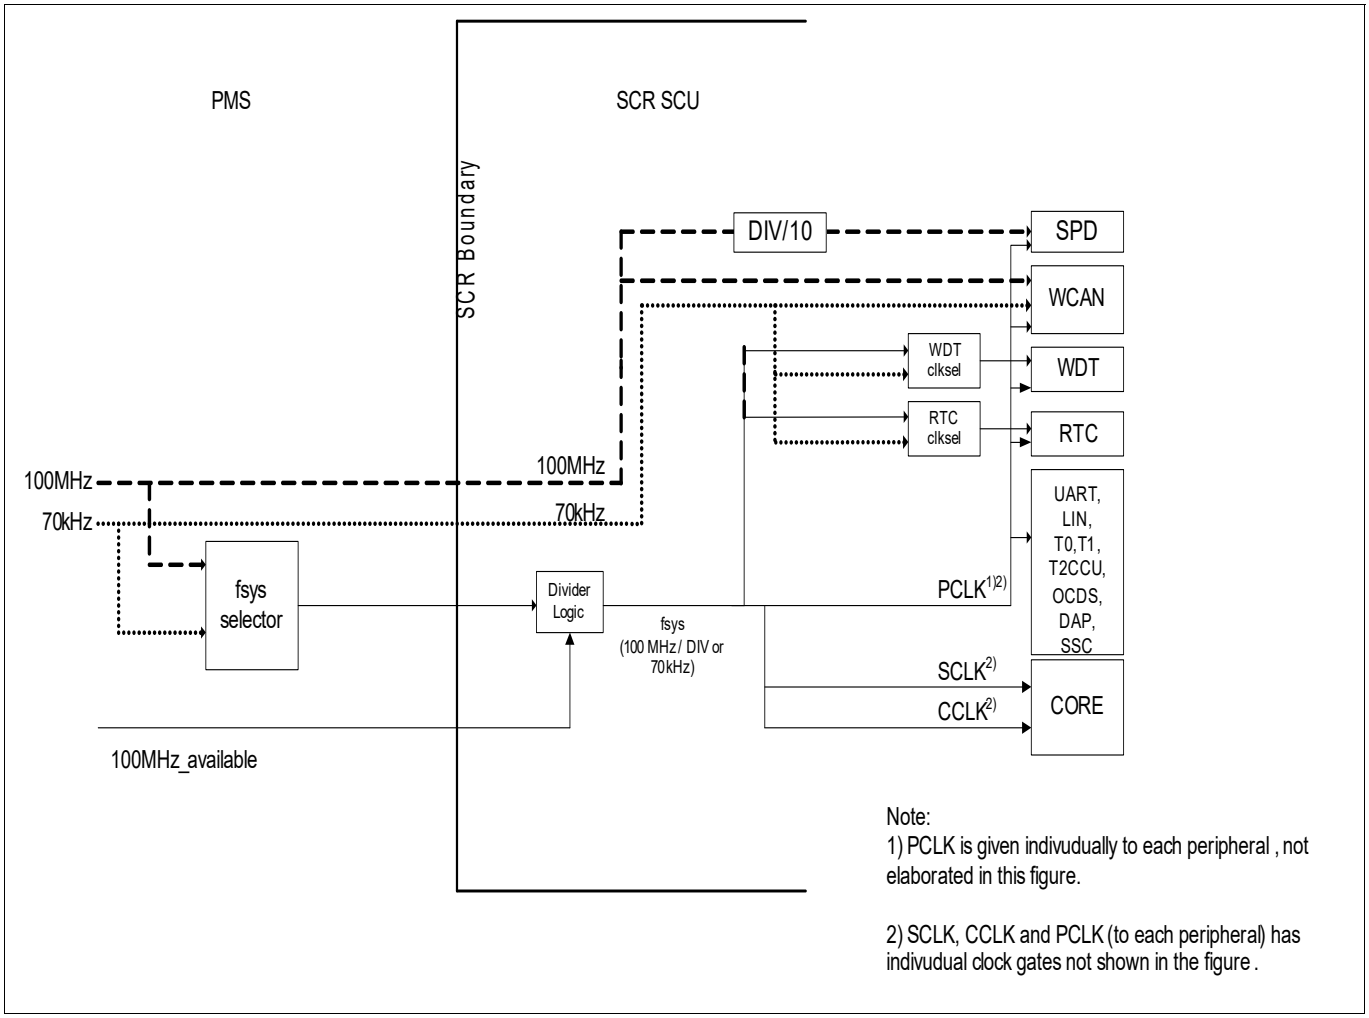

Figure 818 Clock System Block Diagram

In active mode, the main module frequencies (synchronous unless otherwise stated) are as follows:

- CPU clock (CCLK, SCLK) = 70 kHz or 100 MHz / DIV (default)
- Peripheral clock (PCLK) = CPU clock

When 100 MHz clock source is selected, the clock to the CPU and peripherals will be divided by the programmable factor DIV that is selectable by the bit field CMCON.DIV.

Peripherals that are running in PCLK frequency are e.g. UART/LIN, T0, T1, T2CCU, etc.

Note: SPD Debug interface can only be supported when the 100 MHz oscillator is available.

Note: WDT and RTC clock running faster than PCLK frequency is not supported.

49.7.1.2 Module Suspend Control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (MMCR2.MMODE = 1) and the Debug-Suspend signal is active (MMCR2.DSUSP = 1), timers in certain modules in the SCR can be suspended based on the settings of their corresponding module suspend bits in register MODSUSP. When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

Module Suspend Control Register

Table 572 Reset Values of DBG_MODSUSP

Reset Type	Reset Value	Note
LVD Reset	$X1_H$	
Generated Reset	-1_H	

49.7.2 Reset Control

The SCR has three types of resets:

- Power reset caused by an LVD reset,
- Reset from Main Controller via PMSWCR4.SCRSTREQ and PORST,
- and generated resets.

The SCR Watchdog Timer Reset, the RAM double bit ECC Reset and the Soft Reset which have the source within the SCR are called Generated Resets.

Combination of reset via PMSWCR4.SCRSTREQ and an SCRPORST (trigger on SCR PORST pin) is known as Main Reset.

When the SCR is first powered up, the SCR enters User Mode 0 and start operation with the release of the system reset via the LVD reset. The CPU then starts to execute from the Boot ROM firmware. User Mode 0 is used by CPUx to program the user code to the SCR internal XRAM. Once the XRAM is programmed, a new boot mode must be selected via PMSWCR4.SCRCFG. A reset must be issued by CPUx via bit PMSWCR4.SCRSTREQ to start running SCR in the new boot mode.

In User Mode 0, the 8-bit CPU starts to execute an infinite loop from the Boot ROM firmware and user code will not be executed in User Mode 0 once the system reset is released. Please refer to “Boot mode” section for detailed information about the other boot modes.

For the generated resets the following applies:

- The Watchdog Timer (WDT) module is capable of resetting the device if it detects a malfunction in the system.
- A double bit ECC event in the SRAM can also trigger a reset.
- As for Soft reset, it can be triggered by application software where applicable.

49.7.2.1 Types of Reset

The following reset types affect the SCR.

External resets (reset sources not within the SCR):

- LVD reset, caused by an undervoltage detection
  - Triggered asynchronously during power failure (undervoltage),
  - OCDS/Debug-system is reset only when the LVD reset occurs.
- Main reset
  - SCRPORST triggered by the PORST pin , if enabled using PMSWCR4.PORSTREQ triggering a main reset.
  - This is a combined reset, consisting of all the Power reset sources and synchronous reset by the main controller CPUx via bit PMSWCR4.SCRSTREQ.
  - Main reset also activates the Generated reset
  - Resets all registers including the reset indication bits.

Generated Resets (i.e., reset with sources within the SCR):

- SCU Watchdog Timer (WDT) reset
  - Requested by WDT overflow or out of boundary refresh event if it is enabled via RSTCON.WDTRSTEN.
  - Resets all registers except the reset indication bits.
  - If this reset is enabled, it can also trigger an interrupt to the Tricore.
- RAM Double Bit ECC Reset
  - Requested by ECC event if it is enabled via RSTCON.ECCRSTEN.
  - Resets all registers except the reset indication bits.
  - If this reset is enabled, it can also trigger an interrupt to the Tricore.
- Soft reset (generated reset)
  - Requested by soft reset event
  - Resets all registers except the reset indication bits.

This section describes the definition and controls depending on the reset source. **Figure 819** shows a simplified overview of the reset signals.

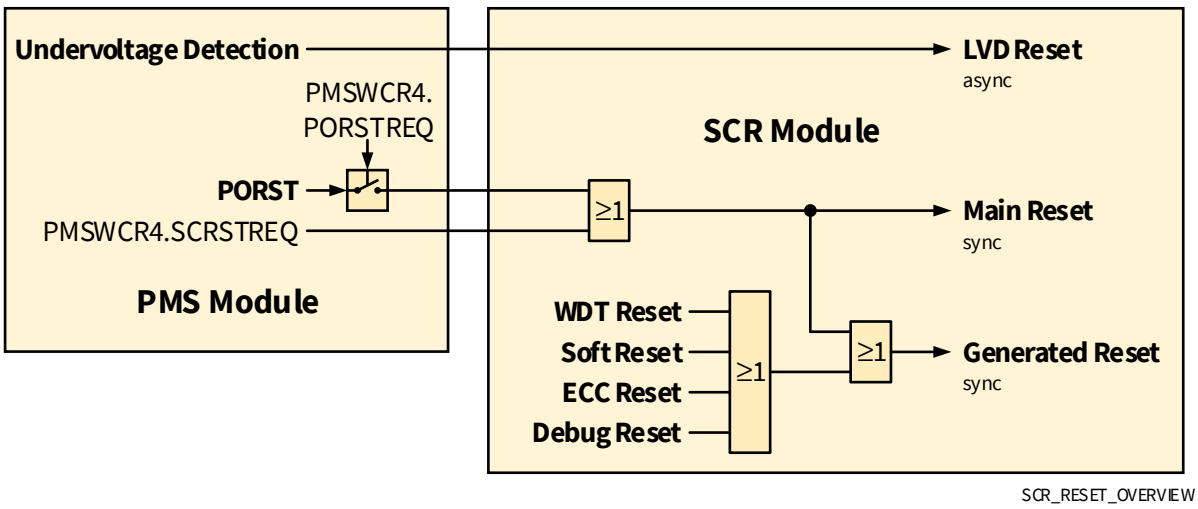

Figure 819 Simplified Reset Overview

Note: In the TC38x and TC39x, triggering of the PORST would reset the ports of the PMS. Some of them are shared with the SCR, meaning the communication of the SCR with the external world would be broken. In the TC35x and TC37x, the PORST does not reset any of the PMS pads, meaning the communication will be maintained.

49.7.2.1.1 LVD Reset (Undervoltage Reset)

The LVD reset, resets the SCR including the OCDS, and starts the correction in case of an ECC error.

An LVD reset will also trigger the Main and Generated Reset.

49.7.2.1.2 Main Reset (External Reset)

Main reset includes PORST and reset from Tricore via the PMSWCR4.SCRSTREQ bit.

A Main reset also triggers the Generated reset.

When the SCR is first powered up, the SCR enters User Mode 0 and start operation with the release of the system reset via the LVD Reset. User Mode 0 is used by CPUx to program the user code to the SCR internal XRAM. Once the XRAM is programmed, a new boot mode must be selected via PMSWCR4.SCRCFG. The Main Reset must then be issued as triggered by CPUx via bit PMSWCR4.SCRSTREQ to start running SCR in the new boot mode.

In User Mode 0, the 8-bit CPU starts to execute an infinite loop from the Boot ROM firmware and user code will not be executed. For more information on the other boot modes (User Mode 1 and Debug mode), refer to “Boot mode” section.

Note: Resetting SCR to enter a new boot mode is only possible via the reset that is triggered by bit PMSWCR4.SCRSTREQ from the main controller.

49.7.2.1.3 Generated Resets

Generated Reset is activated together with Main reset, and on a Watchdog Timer Reset, an ECC Reset, a Soft Reset or a Debug Reset.

Watchdog Timer Reset

The watchdog timer reset is an internal reset and can be disabled by bit RSTCON.WDTRSTEN. The Watchdog Timer (WDT) maintains a counter that must be refreshed or cleared periodically. If the WDT is not serviced correctly and in time, it will generate an NMI request to the CPU and then reset the device (WDT_RST) after a predefined time-out period if this reset type is enabled. When the reset is disabled, no reset will be triggered when the overflow event or out of boundary refresh event happens.

Bit RSTST.WDTRST is used to indicate the watchdog timer reset status.

Note: The event signal can be cleared by main reset.

Double Bit ECC Reset

The double bit ECC reset is an internal reset and can be disabled by bit RSTCON.ECCRSTEN (not adviced). The 8-bit data from the CPU is encoded with an Error Correction Code (ECC) before being stored in the XRAM memory. During a read access, data is retrieved from the memory and decoded for dynamic error detection and correction. If a double bit error is detected, it will generate a reset if this reset type is enabled. When the reset is disabled, no reset will be triggered when the ECC event happens.

Bit RSTST.ECCRST is used to indicate the ECC reset status.

Note: The event signal can be cleared by main reset.

Soft Reset

Soft reset is an internal reset that is caused by a software set of the soft reset request bit, SWRQ, in RSTCON register. It can be triggered by application software where necessary.

Bit RSTST.SOFTRST is used to indicate the soft reset status.

Note: The event signal can be cleared by main reset.

Debug Reset

A debug reset is a generated reset that is caused by debugger reset commands.

49.7.2.2 Module Reset Behavior

Table 573 gives an overview on how the various modules or functions of the SCR are affected with respect to the reset type. An “X” means that the module/function is reset to its default state.

Table 573 Effect of Reset on Modules/Functions

Module/ Function	LVD Reset	Main Reset	Generated Reset
CPU Core	X	X	X
SCU	X	X	X except reset indication bits
Peripherals	X	X	X
Debug System	X	Not affected	Not affected
Port Control	X	X	X
On-Chip Static RAM	Affected, unreliable	Not affected, reliable	Not affected, reliable
Clock System	X	X	X

49.7.2.3 Reset Register Description

RSTST register consist of the reset indication bits of a ECC reset, WDT reset and soft reset. **Table 575** shows the reset value of RSTST register after these events.

49.7.3 Boot and Startup

This section describes the boot mode for SCR. After the first power-up, SCR will enter User Mode 0. Subsequently, bitfield PMSWCR4.SCRCFG is used to change the boot mode that SCR will enter after a reset is deasserted. A reset to the SCR can be triggered by a PMSWCR4.SCRSTREQ reset request to start it off in the chosen mode. If an internal reset happens after a change of PMSWCR4.SCRCFG, the SCR will also start in the mode specified by the SCRCFG value. **Table 579** shows the various boot modes available in SCR.

Table 579 Boot Modes

SCRCFG Value	Boot Mode	Descriptions
00_H	User Mode 0	Default mode after LVD reset with no user code in XRAM and CPUx can download code using this mode. User code in XRAM will not be executed
01_H	User Mode 1	User Code in XRAM at address 0000_H will be executed
02_H	OCDS Mode	Debug mode using SCR DAP0_0 pin and DAP1_0 pin
03_H		Debug mode using SCR DAP0_1 pin and DAP1_1 pin
04_H - 05_H		Debug mode using SCR SPD_0 pin
06_H - 07_H		Debug mode using SCR SPD_1 pin
$0A_H$ - $0B_H$		Debug mode using SOC DAP interface
$0C_H$ - $0F_H$		Debug mode using SOC SPD interface

At end of the startup routine, an interrupt is triggered to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 80_H in SCRINTEXCHG register depending on the boot mode. This is used to indicate that SCR has finished executing the startup code and is ready for CPUx to download code to XRAM in User Mode 0 or jump to user code in User Mode 1 or jump to debug monitor code in OCDS mode.

Note: To change the boot mode, SCR has to be enabled first. Changing of boot mode when SCR is disabled will have no effect.

49.7.3.1 Boot ROM Operating Mode

After a reset, the CPU will always start by executing the Boot ROM code which occupies the program memory address space 0000_H – $07FF_H$. The Boot ROM start-up procedure will first switch the address space for the Boot ROM to $D000_H$ – $D7FF_H$. The remaining Boot ROM start-up procedure will be executed from $D60X_H$. The memory organization of the SCR shown in this document is after the Boot ROM address switch where the different operating modes are executed.

49.7.3.1.1 User Mode 0

User Mode 0 is the default boot mode after an LVD reset where XRAM memory is not programmed. This mode allows the downloading of code to SC internal XRAM memory. In this mode, the CPU will only executed start-up code in Boot ROM. At the end of start-up code, an interrupt would be triggered to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 80_H in SCRINTEXCHG register. This is used to indicate that SCR is ready for CPUx to download code to XRAM.

No application software can be exectuted in User Mode 0

49.7.3.1.2 User Mode 1

If the User Mode 1 is selected, the Boot ROM will jump to program memory address 0000_H to execute the user code in the XRAM memory. To use this mode, the XRAM must be pre-loaded with user code. This is the normal operating mode of the SCR.

For the last 8 bytes of XRAM starting at address $1FF8_H$, user need to program 4 sets of pre-fixed bytes with each set containing 55_H followed by AA_H. User code will not be executed and SCR will enter an endless loop if the memory content does not match these data sequence. It is used to avoid an unintentional entry to User Mode 1. Before entering the endless loop, the start-up code will trigger an interrupt to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 81_H in SCRINTEXCHG register. If there is a match, the same interrupt is triggered to the main controller with a value of 80_H in SCRINTEXCHG register to indicate the execution of user code.

49.7.3.1.3 OCDS Mode with SCR DAP/SPD pin

If the OCDS mode with SCR DAP/SPD pin is selected, the debug mode will be entered for debugging program code. The OCDS hardware is initialized and a jump to program memory address 0000_H is performed next. The user code in the XRAM memory is executed and the debugging process may be started.

Note: The DAP/SPD pin must be directly accessible by SCR. The control of these pins must be given to SCR using bit Pn_PCSR.SELx enabling this boot mode.

49.7.3.1.4 OCDS Mode with SOC DAP/SPD pin

If the OCDS mode with SOC DAP/SPD pin is selected, the debug mode will be entered for debugging program code using the SOC DAP/SPD pins that are also used by the main debug system. The OCDS hardware is initialized and a jump to program memory address 0000_H is performed next. The user code in the XRAM memory is executed and the debugging process may be started.

49.7.4 Power Management

This section describes the features and functionality provided for power management of the SCR. In addition, the exiting of standby mode via SCR will be described in this section. Standby mode is one of the power saving mode in the SCR.

49.7.4.1 Overview

The SCR power-management system allows software to configure the various processing units so that they automatically adjust to draw the minimum necessary power for the application.

There are generally two power modes: Active Mode and Idle Mode. The operation of the system components in each of these states can be configured by software. The power modes provide flexible reduction of power consumption through a combination of techniques, including:

- Stopping the CPU clock
- Stopping the clocks of other system components individually
- Clock-speed reduction of some peripheral components

In Active mode, the CPU and peripherals is running in system frequency.

In Idle mode, the Core is stopped with its clock disabled. Peripherals, with respective input clocks not disabled, are still functional. The watchdog timer, however, must be disabled by user before the system enters into an idle

mode; otherwise, it may generate an internal reset when an overflow occurs and this will disrupt the idle mode. The idle mode is terminated automatically when any enabled interrupt signal is detected.

49.7.4.2 Functional Description

This section describes the power-save modes, their operations, and entry and exit. It also describes the respective behavior of the SCR system components.

49.7.4.2.1 Idle Mode

Software requests Idle Mode by setting the bit PCON.IDLE to 1.

The power management state machine (PMSM) posts an idle request signal to the CPU. The CPU finishes its current operation, sends an acknowledge signal back to the PMSM, and then enters into an inactive state in which the CPU clock (CCLK) is disabled.

The system returns to either active mode when there is an incoming interrupt request to an enabled interrupt node.

Interrupt to the CPU causes the CCLK to recover. Upon RETI instruction, the CPU will return to execute the next instruction following the instruction which sets the IDLE bit to 1.

Note: The user is advised to disable watchdog timer prior to entering the Idle Mode.

49.7.4.2.2 Peripheral Management

It is possible to disable the clock for some peripherals separately in order to save power. Refer to **“Peripheral Management Register” on Page 74**. Each bit in the register can be set to disable the clock to that module.

49.7.4.3 Exit Standby Mode via SCR

In standby mode of the system, SCR could be operating in either active mode or idle mode. Hence, SCR could be one of the wake-up source to exit standby mode. Before entering standby mode, the followings steps related to SCR need to be setup before issuing the standby request:

- Configure the wake-up signals related to SCR that would trigger the exit from standby mode via PMSWCR4 register
- Configure the clock selection for SCR in standby mode via SCRCLKSEL bit.

To exit from standby mode, one of the following wake-up sources from SCR could be used:

- WDT event
- SRAM ECC double bit error
- Software request
- WCAN WUF event
- RTC compare match event

Besides the specified events such as WDT overflow event, SRAM ECC error, WCAN event or RTC compare match event, other types of events from SSC, T0, T1, T2CCU and UART could issue a wake-up request via the bit SCRWKP in STDBYWKP register.

49.7.4.4.1 Peripheral Management Register

Each register bit controls one peripheral. When this bit is set, the request signal to gate off the clock to the respective module is asserted. The SCU will then synchronize the gating off of the clock to the peripheral. In SCR, the clock inputs of all peripherals as specified in the PMCON1 register are gated off upon power on reset (LVD reset).

49.7.5 Miscellaneous Control

There are certain miscellaneous functions supported such as the bit protection scheme.

49.7.5.1 Bit Protection Register

The Bit-Protection Scheme disallows direct software writing of selected bits (i.e. Protected bits) by the SFR PASSWD. When the bit field MODE is 11_B, writing 10011_B to the bit field PASS opens access to writing of all protected bits and writing 10101_B to the bit field PASS closes access to writing of all protected bits. Note that access is opened for maximum 34 CCLKs if the “close access” password is not written. If “open access” password is written again before the end of 34 CCLK cycles, there will be a recount of 34 CCLK cycles.

Password Register

PASSWD
Password Register **(086_H)** **Reset Value: Table 584**

49.8 Watchdog Timer (WDT)

49.8.1 Overview

The Watchdog Timer (WDT) provides a highly reliable and secure way to detect and recover from software or hardware failures. The WDT is reset at a regular interval that is predefined by the user. The CPU must service the WDT within this interval to prevent the WDT from causing generated reset. Hence, routine service of the WDT confirms that the system is functioning properly. This ensures that an accidental malfunction of the SCR will be aborted in a user-specified time period. The WDT reset is default enabled. It can also be disabled via RSTCON register.

The WDT is by default disabled.

In debug mode, the WDT is default suspended and stops counting (its debug suspend bit is default set i.e., MODSUSP.WDTSUSP = 1. Therefore during debugging, there is no need to refresh the WDT.

Features

- 16-bit Watchdog Timer
- Programmable reload value for upper 8 bits of timer
- Programmable window boundary
- Clock source from either the 70 kHz clock or the 100 MHz/DIV clock
- Selectable input frequency of $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$

49.8.2 System Information

This section consist of the system information required to use the WDT.

49.8.2.1 Reset Effects

The Watchdog Timer maintains a counter which must be refreshed or cleared periodically. Otherwise, the counter will overflow and the watchdog reset will be asserted. The assertion of the reset could be disabled by setting bit RSTCON.WDTRSTEN. The occurrence of a WDT reset is indicated by the bit WDTRST in RSTST register.

49.8.2.2 Clocking Configuration

The WDT runs on either the 70 kHz clock or the 100 MHz/DIV clock. Bit WDT_CON.WDTCLK is used to select the WDT clock source, f_{WDTCLK}.

49.8.2.3 Interrupt Events and Assignment

Table 587 shows the non-maskable interrupt node assignment of the WDT interrupt source.

Table 587 WDT Events' Non-maskable Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
WDT Overflow	NMICON.NMIWDT	NMISR.FNMIWDT	73_H

49.8.2.4 Module Suspend Control

The timer in the WDT is by default suspended on entering debug mode. The WDT can be allowed to run in debug mode by clearing the bit WDTSUSP in SFR MODSUSP to 0. Refer to the definition of register MODSUSP.

49.8.3 Functional Description

The Watchdog Timer (WDT) is a 16-bit timer, which is incremented by a count rate of $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$. The f_{WDTCLK} clock input is selectable between the 70 kHz clock or the 100 MHz/DIV clock using the WDTCLK bit. This 16-bit timer is realized as two concatenated 8-bit timers. The upper 8 bits of the WDT can be preset to a user-programmable value via a watchdog service access in order to vary the watchdog expire time. The lower 8 bits are reset on each service access. **Figure 820** shows the block diagram of the WDT unit.

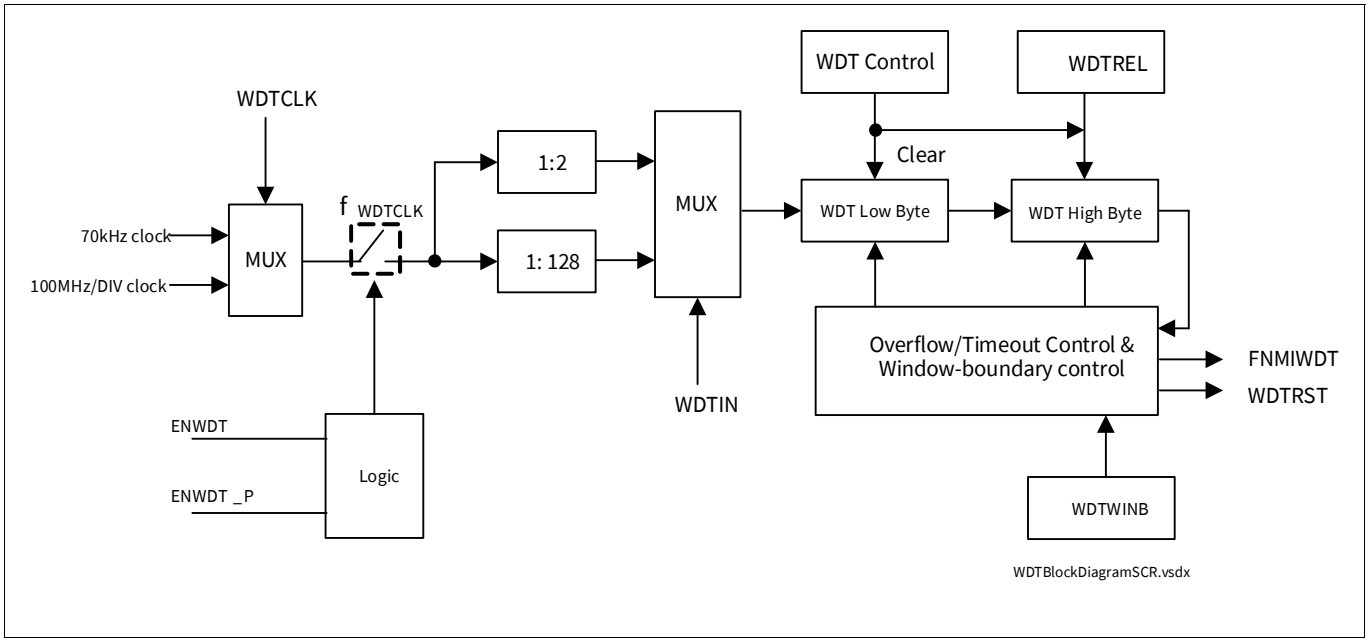

Figure 820 WDT Block Diagram

If the WDT is enabled by setting WDTEN to 1, the timer is set to a user-defined start value and begins counting up. It must be serviced before the counter overflows. Servicing is performed through refresh operation (setting bit WDTRS to 1). This reloads the timer with the start value, and normal operation continues.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed and normal mode is terminated. A WDT NMI request (FNMIWDT) is then asserted and pre-warning is entered. The pre-warning lasts for 30_H count. During the pre-warning period, refreshing of the WDT is ignored and the WDT cannot be disabled. The user software shall not refresh the WDT upon entering the pre-warning period. A reset (WDTRST) of the SCR is imminent (if it is enabled by bit RSTCON.WDTRSTEN) and can no longer be avoided. The occurrence of a WDT reset is indicated by the bit WDTRST in RSTST register. If refresh happens at the same time an overflow occurs, WDT will not go into pre-warning period.

Note: In the SCR, it is possible to wake-up the main controller from standby mode when the WDT overflow event happened by setting bit STDBYWKP.WDTWKSEL to 1.

The WDT must be serviced periodically so that its count value will not overflow. Servicing the WDT clears the low byte and reloads the high byte with the preset value in bit field WDTREL. Servicing the WDT also clears the bit WDTRS.

The WDT has a “programmable window boundary”, which disallows any refresh during the WDT’s count-up. A refresh during this window-boundary constitutes an invalid access to the WDT and causes the WDT to activate WDTRST, although no NMI request is generated in this instance. The window boundary is from 0000_H to the value obtained from the concatenation of WDTWINB and 00_H. This feature can be enabled by WINBEN.

After being serviced, the WDT continues counting up from the value (<WDTREL> * 2^8). The time period for an overflow of the WDT is programmable in two ways:

- The input frequency to the WDT can be selected via bit WDTIN in register WDT_CON to be either $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$.
- The reload value WDTREL for the high byte of WDT can be programmed in register WDT_REL.

The period P_{WDT} between servicing the WDT and the next overflow can be determined by the following formula:

$$P_{WDT} = \frac{2^{(1+<WDTIN>*6)} * (2^{16} - WDTREL * 2^{8})}{f_{PCLK}} \quad (49.1)$$

PWDT_formula.vsd

If the Window-Boundary Refresh feature of the WDT is enabled, the period during which a refresh is allowed is shortened if WDTWINB is greater than WDTREL. See also **Figure 821**. This period can be calculated by the same formula by replacing WDTREL with WDTWINB. In order for this feature to be useful, WDTWINB cannot be smaller than WDTREL.

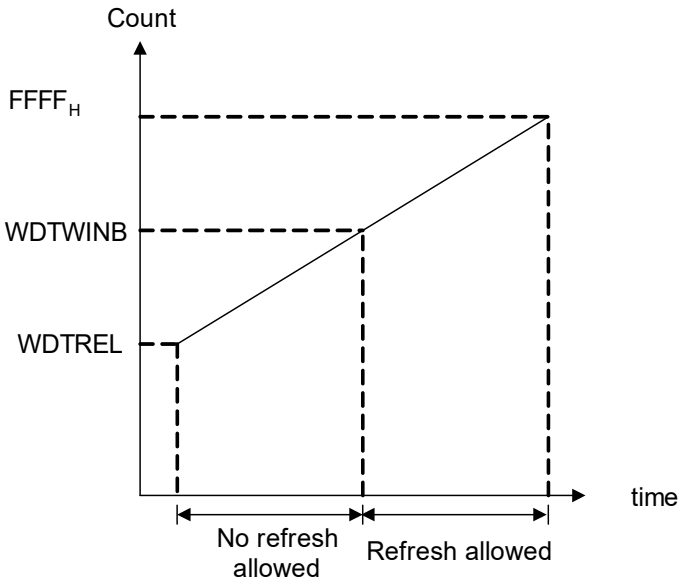

Figure 821 WDT Timing Diagram

Table 588 lists the possible ranges for the watchdog time which can be achieved using a certain module clock. Some numbers are rounded to 3 significant digits.

Table 588 Watchdog Time Ranges

Reload value in WDTREL	Prescaler for f_{WDT}					
	2 (WDTIN = 0)			128 (WDTIN = 1)		
	20 MHz	16 MHz	12 MHz	20 MHz	16 MHz	12 MHz
FF_H	25.5 µs	32.0 µs	42.67 µs	1.63 ms	2.05 ms	2.73 ms
$7F_H$	3.3 ms	4.13 ms	5.5 ms	211 ms	264 ms	352 ms
00_H	6.55 ms	8.19 ms	10.92 ms	419 ms	524 ms	699 ms

Note: For safety reasons, the user is advised to rewrite WDT_CON each time before the WDT is serviced.

Note: The Watchdog Timer can be suspended when OCDS enters Monitor Mode and has the Debug-Suspend signal activated, provided the respective suspend bit, WDTSUSP in SFR MODSUSP, is set. See Module Suspend Control section.

49.8.4 Registers Description

Five SFRs control the operations of the WDT. **Table 589** lists the addresses of these SFRs.

Table 589 Register Overview - WDT (sorted by Name)

Short Name	Description	RMAP	PAGE	Offset Address	Page Number
WDT_CON	Watchdog Timer Control Register	0	X	081_H	83
WDT_H	Watchdog Timer High Byte	0	X	085_H	86
WDT_L	Watchdog Timer Low Byte	0	X	084_H	85
WDT_REL	Watchdog Timer Reload Register	0	X	082_H	85
WDT_WINB	Watchdog Window-Boundary Register	0	X	083_H	86

49.8.4.1 Watchdog Timer Registers

The Watchdog Timer Current Count Value is contained in the Watchdog Timer Register WDT_H and WDT_L, which are non-bitaddressable read-only register. The operation of the WDT is controlled by its bitaddressable WDT Control Register WDT_CON. This register also selects the input clock prescaling factor. The register WDT_REL specifies the reload value for the high byte of the timer. WDT_WINB specifies Watchdog Window-Boundary count value.

v2.3		
	First Official Release of completely reworked SCR chapter	
	No change	

49.9 Interrupt System

The XC800 Core supports one non-maskable interrupt (NMI) and 14 maskable interrupt requests. In addition to the standard interrupt functions supported by the core, e.g., configurable interrupt priority and interrupt masking, the SCR interrupt system provides extended interrupt support capabilities such as the mapping of each interrupt vector to several interrupt sources to increase the number of interrupt sources supported, and additional status registers for detecting and identifying the interrupt source.

49.9.1 Interrupt Sources

The SCR supports 14 interrupt vectors with four priority levels. These interrupt vectors are assigned to the on-chip peripherals: Timer 0, Timer 1, UART, RTC, WCAN, and SSC are each assigned one dedicated interrupt vector. T2CCU and LIN interrupts has to share an interrupt vector. External interrupt 0, 1 and 2 are each assigned one dedicated interrupt vector. The remaining 13 external interrupts are shared among 4 interrupt vectors.

A non-maskable interrupt (NMI) with the highest priority is shared by the following:

- Watchdog Timer, warning before overflow
- OCDS, on user IRAM event
- RAM ECC error
- External NMI (via rising edge on EXTNMI pin)
- Main controller - This interrupt is triggered either when software sets PMSWCR2.TCINTREQ or when PMSWCR2.SMURST or PMSWCR2.RST are set.
- Wake-up interrupt: This interrupt is triggered when any of the wakeup inputs were triggered, and the VEXT supply did not ramp up even after the blanking time interval. Please see PMS chapter for additional details

Figure 822, **Figure 823**, and **Figure 824** give a general overview of the interrupt sources and nodes, and their corresponding control and status flags. **Figure 825** gives the corresponding overview for the NMI sources.

The details of the peripheral interrupt sources are described in the respective peripheral chapters, while the details of the external interrupt sources can be found in **Figure 835** through **Figure 838** in this chapter.

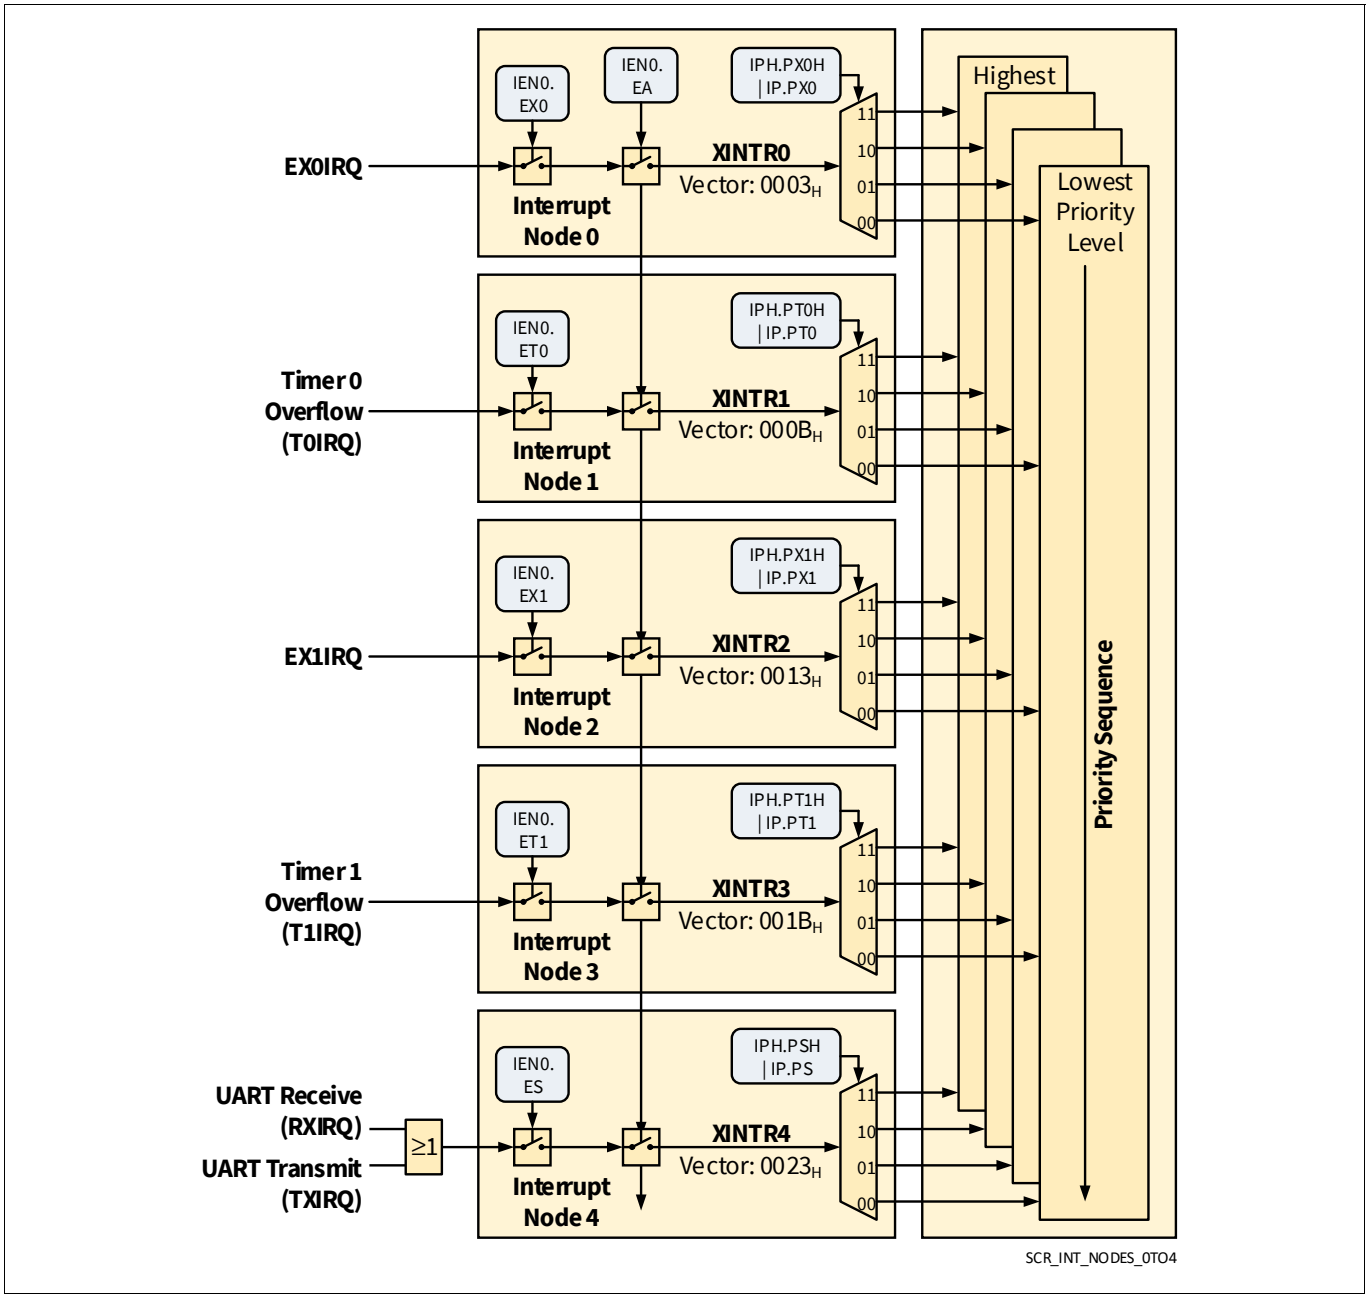

Figure 822 Interrupt Request Sources and Interrupt Nodes 0 through 4

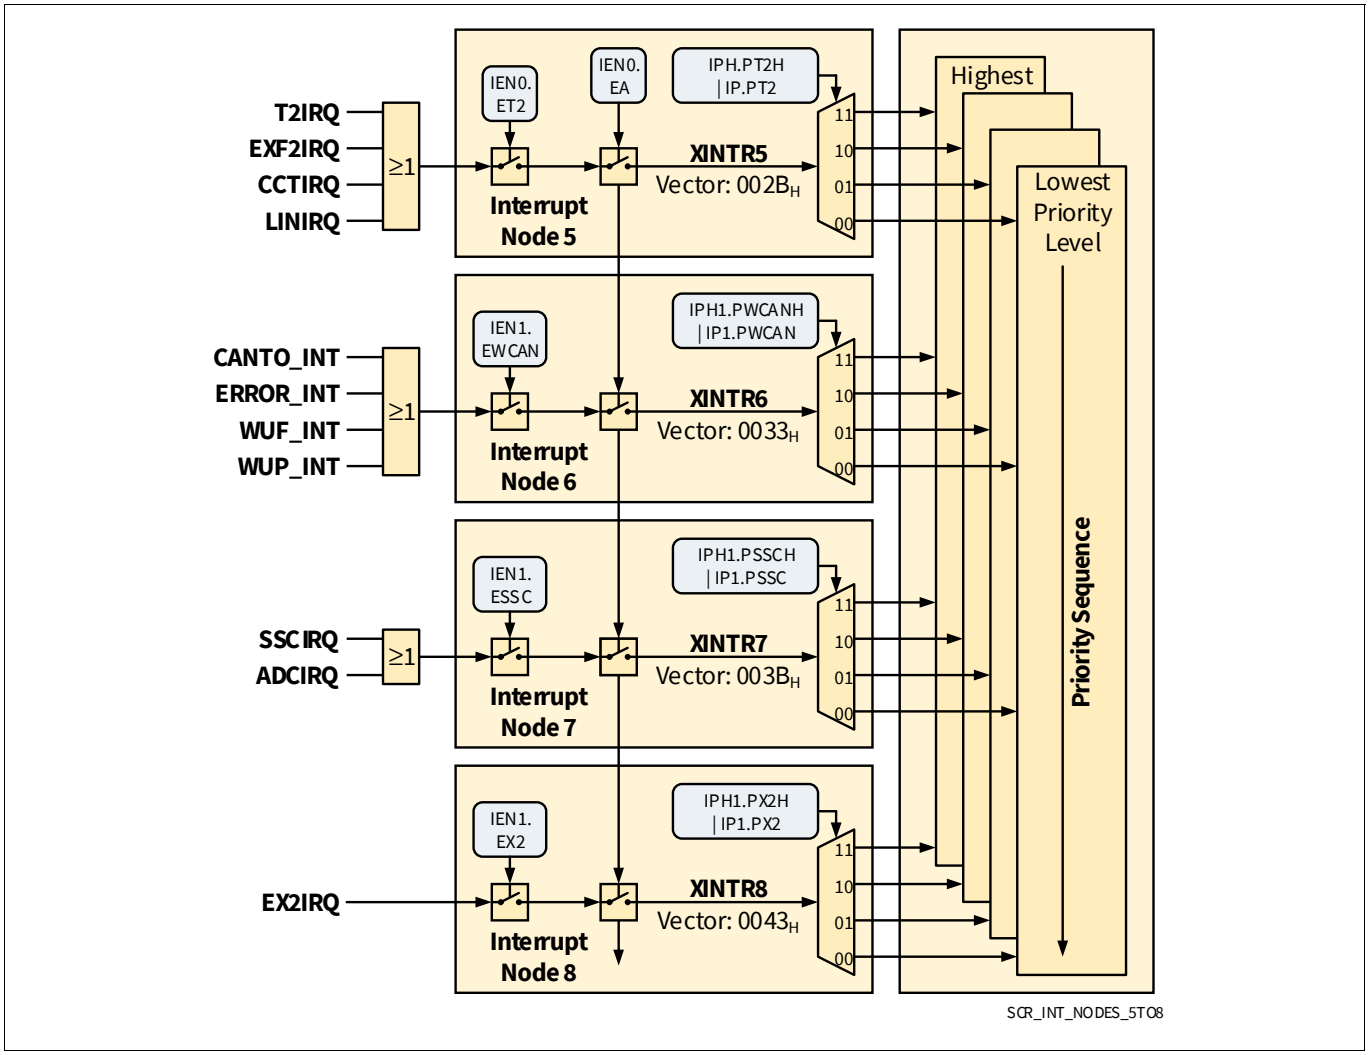

Figure 823 Interrupt Request and Interrupt Nodes 5 through 8

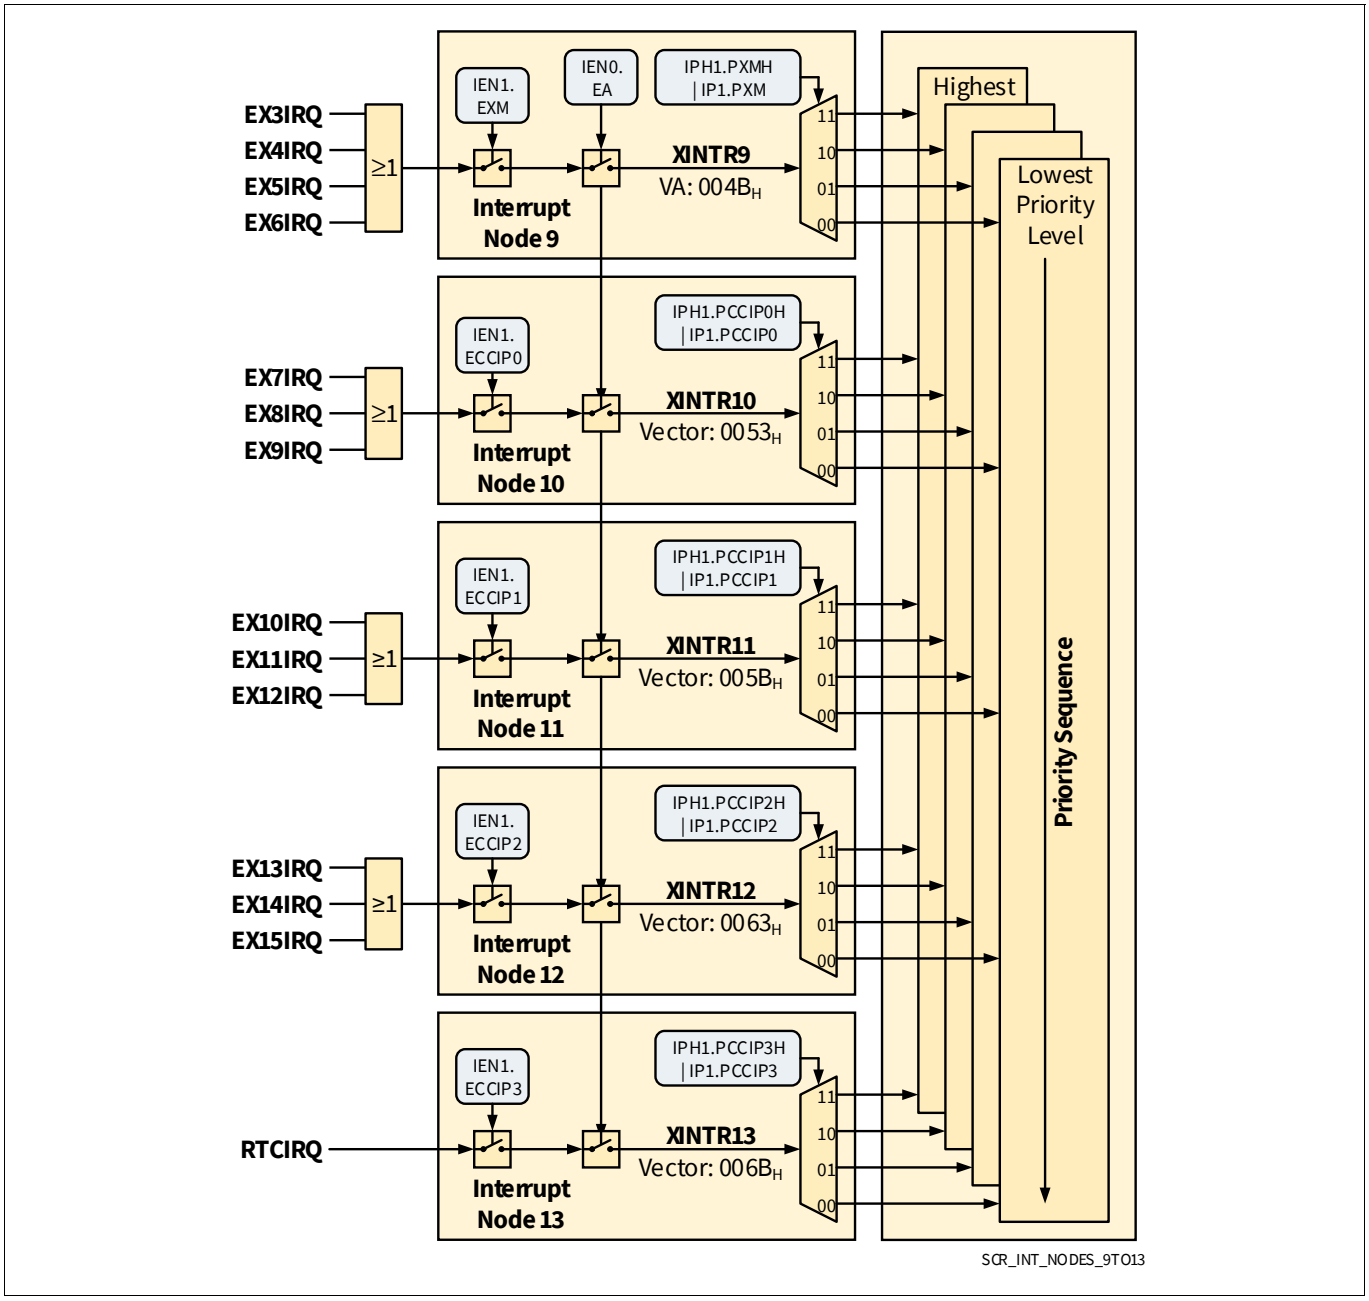

Figure 824 Interrupt Request and Interrupt Nodes 9 through 13

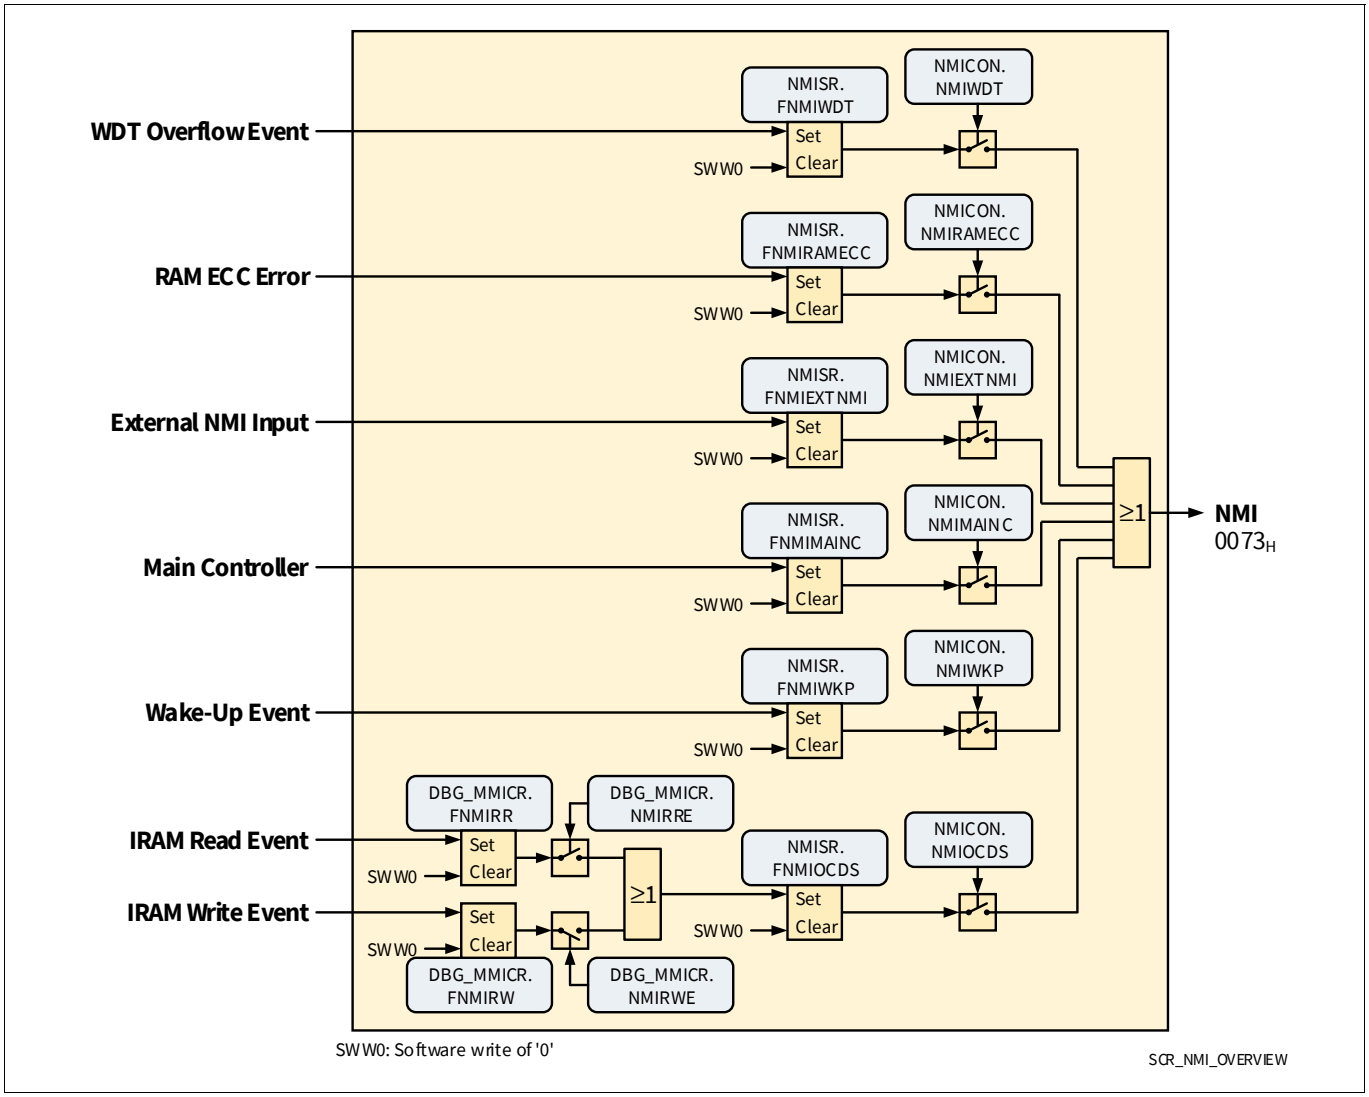

Figure 825 Non-Maskable Interrupt (NMI) Request Sources

49.9.1.1 Interrupt Source and Vector

Each interrupt event source has an associated interrupt vector address for the interrupt node it belongs to. This vector is accessed to service the corresponding interrupt node request. The interrupt service of each interrupt node can be individually enabled or disabled via an enable bit. The assignment of the SCR interrupt sources to the interrupt vector address and the corresponding interrupt node enable bits are summarized in **Table 597**.

Table 597 Interrupt Vector Address

Level	Interrupt Node	Vector Address	Assignment for SCR	Enable Bit	SFR
0	NMI	0073_H	Watchdog Timer NMI	NMIWDT	NMICON

49.9.1.2 Interrupt Source and Priority

An interrupt that is currently being serviced can only be interrupted by a higher priority interrupt, but not by another interrupt of the same or lower priority. Hence, an interrupt of the highest priority cannot be interrupted by any other interrupt request.

If two or more requests of different priority levels are received simultaneously, the request with the highest priority is serviced first. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced first. Thus, within each priority level, there is a second priority structure determined by the polling sequence as shown in **Table 598**.

Table 598 Priority Structure within Interrupt Level

Source	Level
Non-Maskable Interrupt (NMI)	(highest)
External Interrupt 0	1
Timer 0	2
External Interrupt 1	3
Timer 1	4
UART	5
T2CCU / LIN	6
Wake-Up CAN Filter	7
A/D Converter	8
SSC	8
External Interrupt 2	9
External Interrupt [6:3]	10
External Interrupt [9:7]	11
External Interrupt [12:10]	12
External Interrupt [15:13]	13
Real-Time Clock	14

49.9.2 Interrupt Structure

An interrupt event source may be generated from the on-chip peripherals or from external. Detection of interrupt events is controlled by the respective on-chip peripherals. Interrupt status flags are available for determining which interrupt event has occurred, especially useful for an interrupt node which is shared by several event sources. Each interrupt node (except NMI) has a global enable/disable bit. In most cases, additional enable bits are provided for enabling/disabling particular interrupt events (provided for NMI events). No interrupt will be requested for any occurred event that has its interrupt enable bit disabled.

The SCR has, in general, two interrupt structures distinguished mainly by the manner in which the pending interrupt request (one per interrupt vector/node going directly to the core) is generated (due to the events) and cleared.

Common among these two interrupt structures is the interrupt masking bit, EA, which is used to globally enable or disable all interrupt requests (except NMI) to the core. Resetting bit EA to 0 only masks the pending interrupt requests from the core, but does not block the capture of incoming interrupt requests.

Note: The NMI node is similar to the other interrupt nodes, except for the exclusion of EA bit. Effectively, NMI node is non-maskable.

49.9.2.1 Interrupt Structure 1

For interrupt structure 1 (see **Figure 826**), the interrupt event will set the interrupt status flag which doubles as a pending interrupt request to the core. An active pending interrupt request will interrupt the core only if its corresponding interrupt node is enabled. Once an interrupt node is serviced (interrupt acknowledged), its pending interrupt request (represented by the interrupt status flag) may be automatically cleared by hardware (the core).

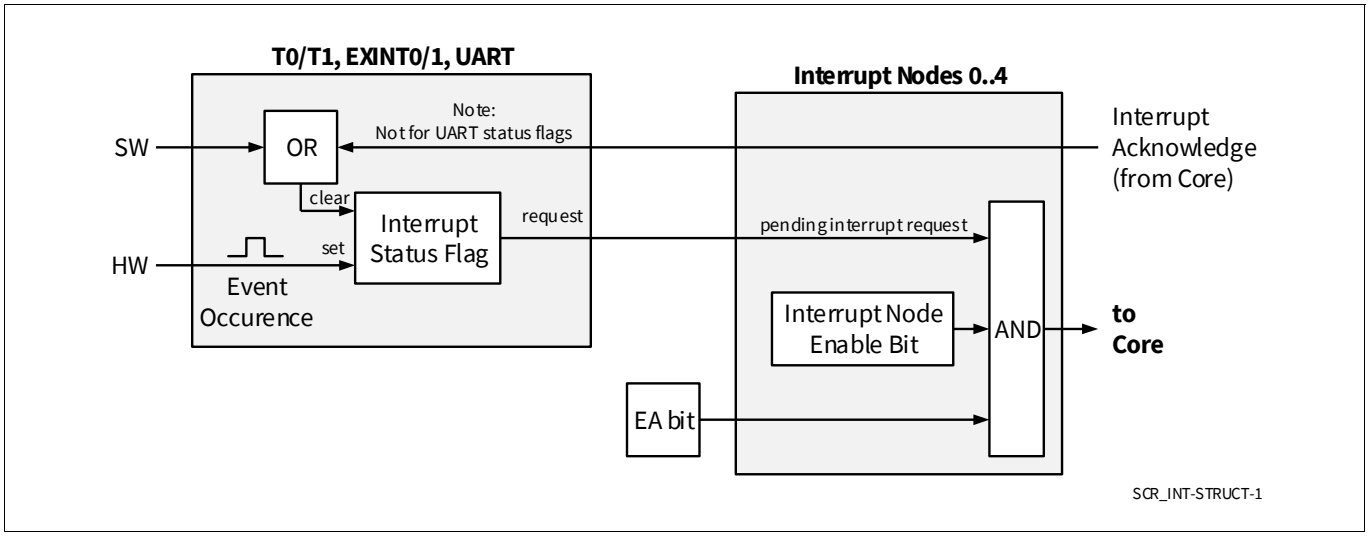

Figure 826 Interrupt Structure 1

For the SCR, interrupt sources of Timer 0, Timer 1, external interrupt 0 and external interrupt 1 (each having a dedicated interrupt node) will have their respective interrupt status flags TF0, TF1, IE0 and IE1 in register T01_TCON cleared by the core, once their corresponding pending interrupt request is serviced. In the case that an interrupt node is disabled (e.g. software polling is used), its interrupt status flag must be cleared by software, since the core will not be interrupted (and therefore the interrupt acknowledge is not generated).

For the UART which has its dedicated interrupt node, interrupt status flags RI and TI in register SCON will NOT be cleared by the core, even when its pending interrupt request is serviced. The UART interrupt status flags (and hence the pending interrupt request) can only be cleared by software.

49.9.2.2 Interrupt Structure 2

Interrupt structure 2 is implemented for interrupt nodes 5 through 13, relevant for the T2CCU, LIN, external interrupts 2 to 15, WCAN, SSC and RTC interrupt sources. For interrupt structure 2, the interrupt status flag does not directly drive the pending interrupt request. Instead, the interrupt nodes have a separate internal pending flag (FF).

An event generated by an associated interrupt source will set the internal pending flag. When the node is enabled, and the CPU is ready to service that interrupt request, the pending flag is automatically cleared by hardware (interrupt acknowledged) on entry into the service routine.

However, the status flag of the associated interrupt source is not automatically cleared; it must be cleared by software (preferably in the service routine).

Most of the interrupt nodes 5 through 13 have more than one associated interrupt source. The request signals of the sources are ORed for the set input of the pending flag. The clear input of the pending flag is either activated by the interrupt acknowledge, or when the status flags of ALL associated interrupt sources are cleared (inactive).

If one wants to clear the internal pending flag in an interrupt node with structure 2, special considerations need to be taken into account, depending on the associated interrupt source(s).

The interrupt sources differ slightly in the configuration of the request and the status lines. This is detailed in the following.

Interrupt Nodes 8 through 12

Figure 827 illustrates the configuration (indicated as Type a) for interrupt nodes 8 through 12, which are connected to the external interrupts EXINT2 through EXINT15. All interrupt sources connected to these nodes have the same configuration (Type a). These external interrupts do not have a separate interrupt enable control; instead, an event is disabled by selecting the '0'-input of its edge-detection multiplexer (see **Figure 836** through **Figure 838**).

Thus, in order to clear the pending FF in the interrupt node, all associated status flags connected to that node must be cleared by software.

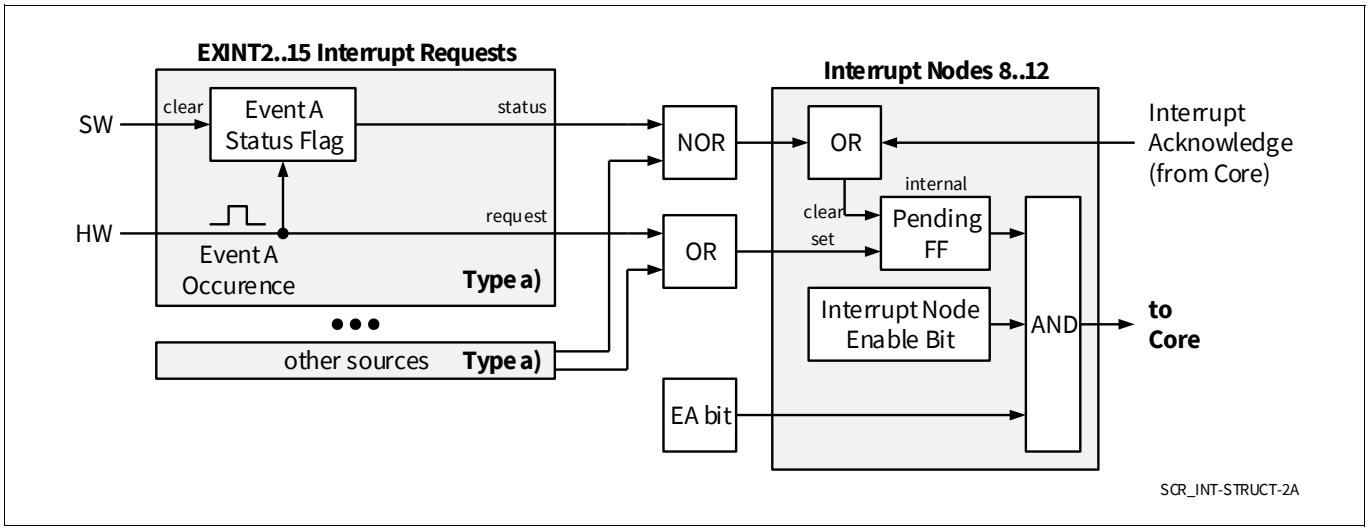

Figure 827 Interrupt Structure 2 for Nodes 8 through 12

Interrupt Node 5

Figure 828 illustrates the configurations for interrupt node 5. Here, two different types of interrupt source configurations (indicated as Type b and Type c) are connected to the same node.

- For the LIN and the CCTIRQ (of T2CCU) interrupt sources, the request line as well as the status line are enabled/disabled via the associated interrupt enable bit. Thus, when disabling the interrupt source, also the status line to the clear input of the interrupt node's pending flag FF is deactivated.
- For the two interrupt sources T2IRQ and EXF2IRQ of the T2CCU, only the request line is enabled/disabled via the associated interrupt enable bit. Thus, when disabling the interrupt source, the status bit needs to be cleared by software in order to be able to clear the pending flag in the interrupt node.

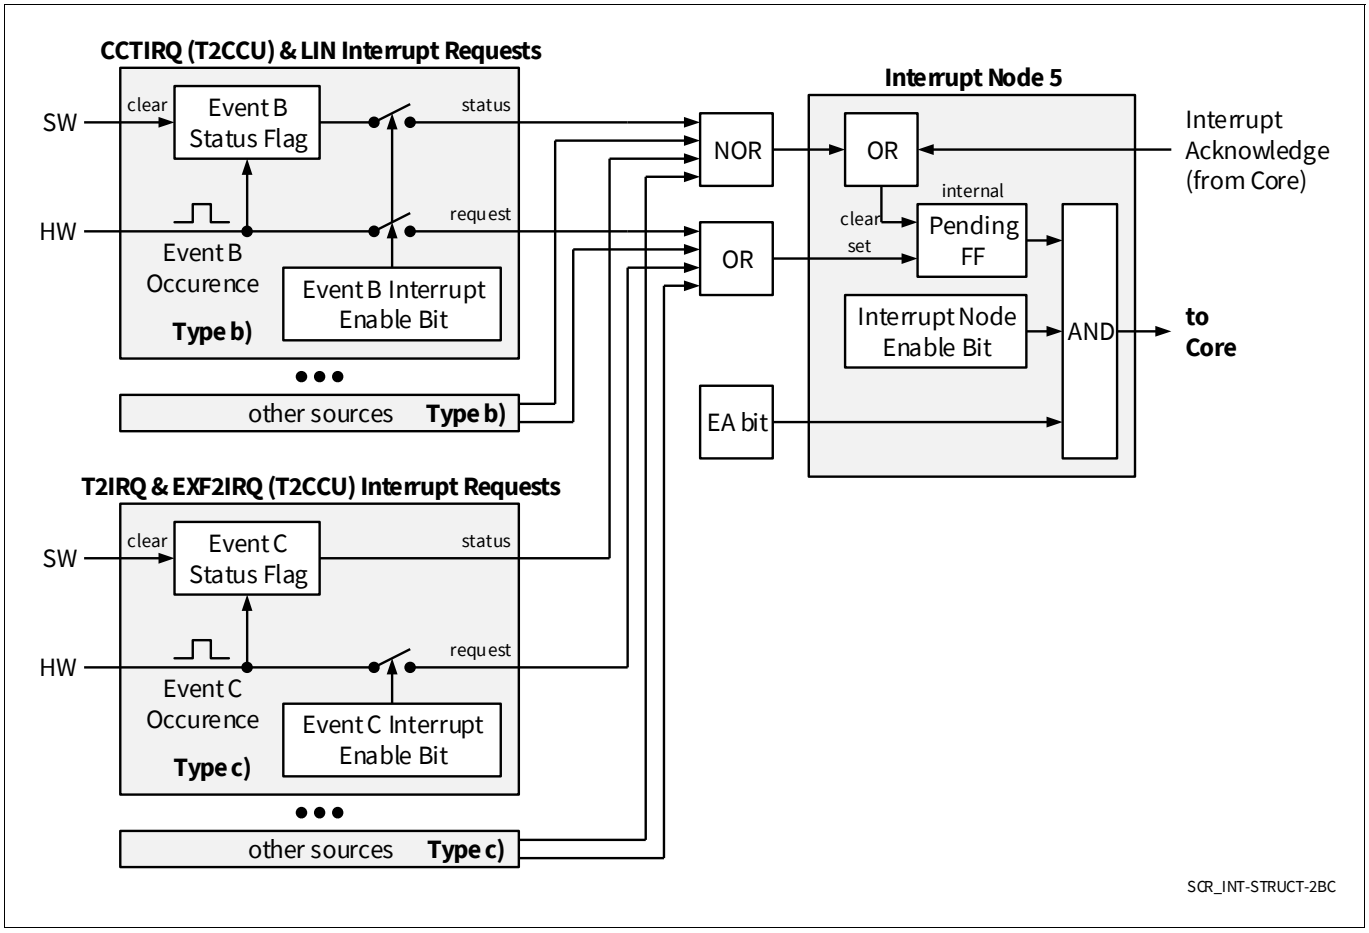

Figure 828 Interrupt Structure 2 for Node 5

Interrupt Node 6

Figure 829 illustrates the configuration for interrupt node 6, which is connected to the WCAN interrupt sources. Only the request line is enabled/disabled via the associated interrupt enable bit. Thus, when disabling the interrupt source, all active status bits of the WCAN module need to be cleared by software in order to be able to clear the pending flag in the interrupt node.

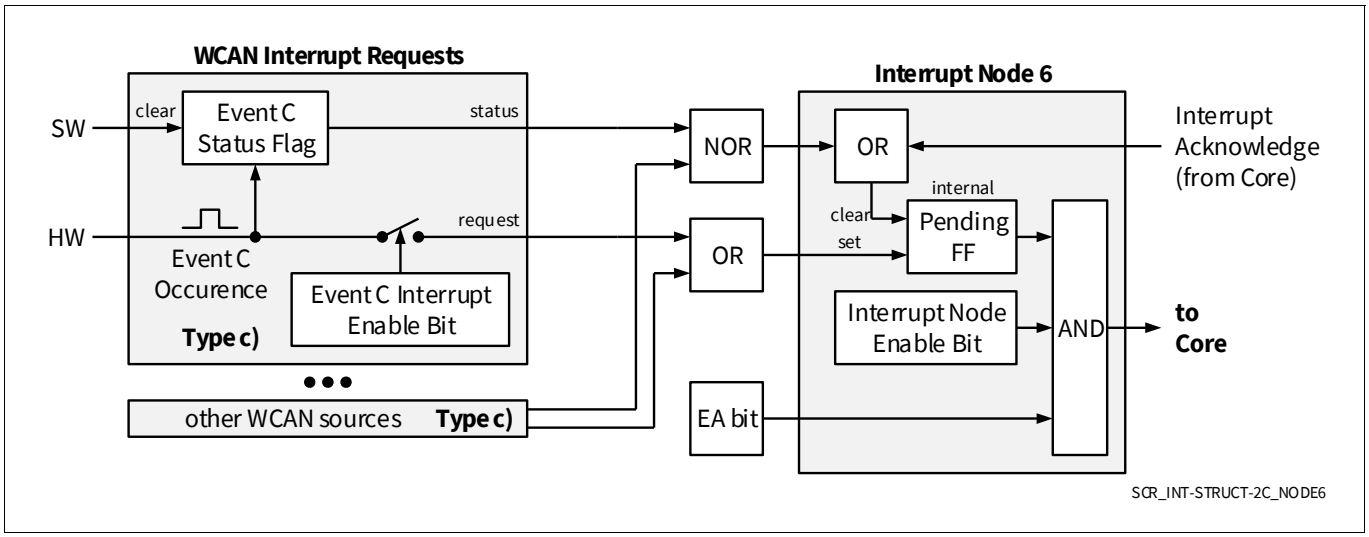

Figure 829 Interrupt Structure 2 for Node 6

Interrupt Node 13

Figure 830 illustrates the configuration for interrupt node 13, which is solely connected to the RTC interrupt source. Only the request line is enabled/disabled via the associated interrupt enable bit. Thus, when disabling the interrupt source, the status bit needs to be cleared by software in order to be able to clear the pending flag in the interrupt node.

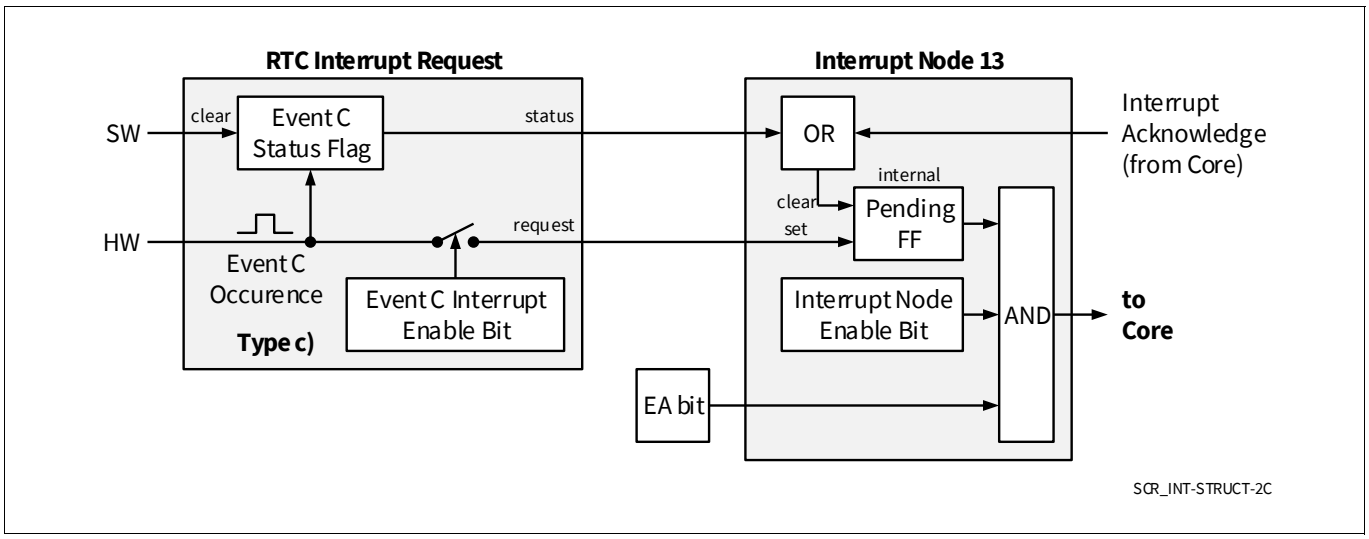

Figure 830 Interrupt Structure 2 for Node 13

Interrupt Node 7

Figure 831 illustrates the configuration for interrupt node 7, which is connected to the SSC and ADCOMP interrupt sources. These interrupt sources are handled by a separate block in the interrupt module, controlled by registers SCU_MODIEN, IRCON1, and IEN1. Here, the status flag is only set when the interrupt event is enabled.

In order to clear the pending FF in the interrupt node, all associated status flags connected to that node must be cleared by software.

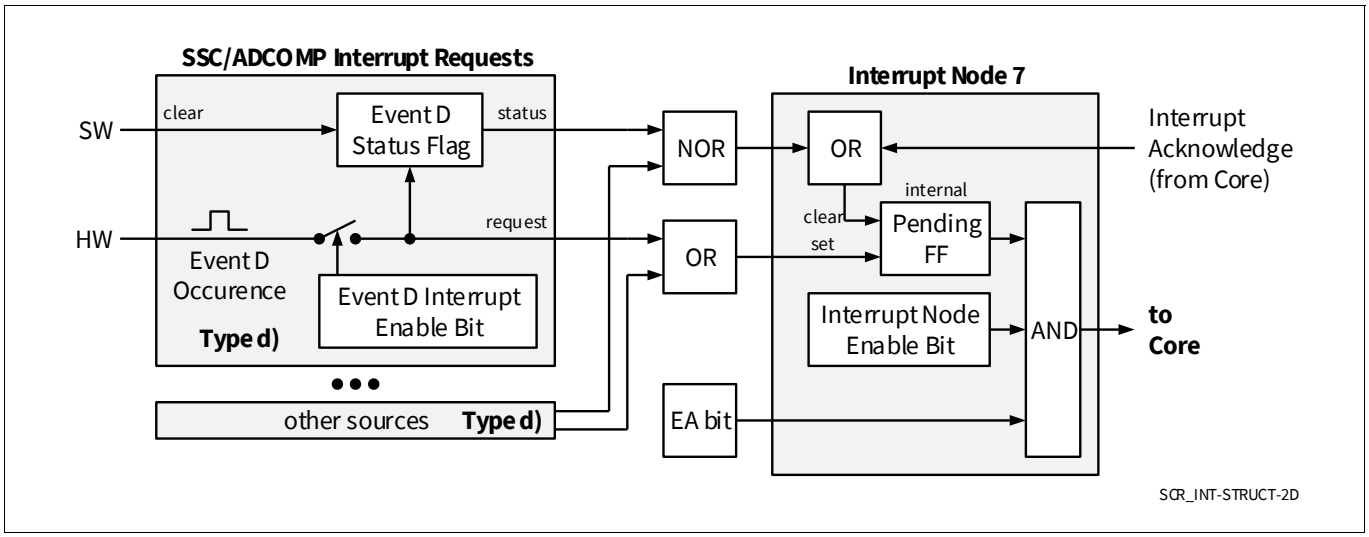

Figure 831 Interrupt Structure 2 for Node 7

49.9.3 Interrupt Handling

The interrupt request signals are sampled at phase 2 in each CPU cycle. The sampled requests are then polled during the following CPU cycle. If one interrupt node request was active at phase 2 of the preceding cycle, the

polling cycle will find it and the interrupt system will generate a LCALL to the node's service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of equal or higher priority is already in progress.
2. The current (polling) cycle is not in the final cycle of the instruction in progress.
3. The instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP/IPH or IP1/IPH1.

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress is completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP/IPH or IP1/IPH1, then at least one more instruction will be executed before any interrupt is vectored to; this delay guarantees that changes of the interrupt status can be observed by the CPU.

The polling cycle is repeated with each CPU cycle, and the values polled are the values that were present at phase 2 of the previous CPU cycle. Note that if any interrupt flag is active but its node interrupt request was not responded to for one of the conditions already mentioned, and if the flag is no longer active at a later time when servicing the interrupt node, the corresponding interrupt source will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle interrogates only the pending interrupt requests.

The processor acknowledges an interrupt request by executing a hardware generated LCALL to the corresponding service routine. In some cases, hardware also clears the flag that generated the interrupt, while in other cases, the flag must be cleared by the user's software. The hardware-generated LCALL pushes the contents of the Program Counter (PC) onto the stack (but it does not save the PSW) and reloads the PC with an address that depends on the interrupt node being vectored to, as shown in the **Table 597**.

Program execution returns to the next instruction after calling the interrupt when the RETI instruction is encountered. The RETI instruction informs the processor that the interrupt routine is no longer in progress, then pops the two top bytes from the stack and reloads the PC. Execution of the interrupted program continues from the point where it was stopped. Note that the RETI instruction is important because it informs the processor that the program has left the current interrupt priority level. A simple RET instruction would also have returned execution to the interrupted program, but it would have left the interrupt control system on the assumption that an interrupt was still in progress. In this case, no interrupt of the same or lower priority level would be acknowledged.

49.9.4 Interrupt Response Time

Due to an interrupt event of (the various sources of) an interrupt node, its corresponding request signal will be sampled active at phase 2 in every CPU cycle. The value is not polled by the circuitry until the next CPU cycle. If the request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two CPU cycles. Thus, a minimum of three complete CPU cycles will elapse from activation of the interrupt request to the beginning of execution of the first instruction of the service routine as shown in **Figure 832**.

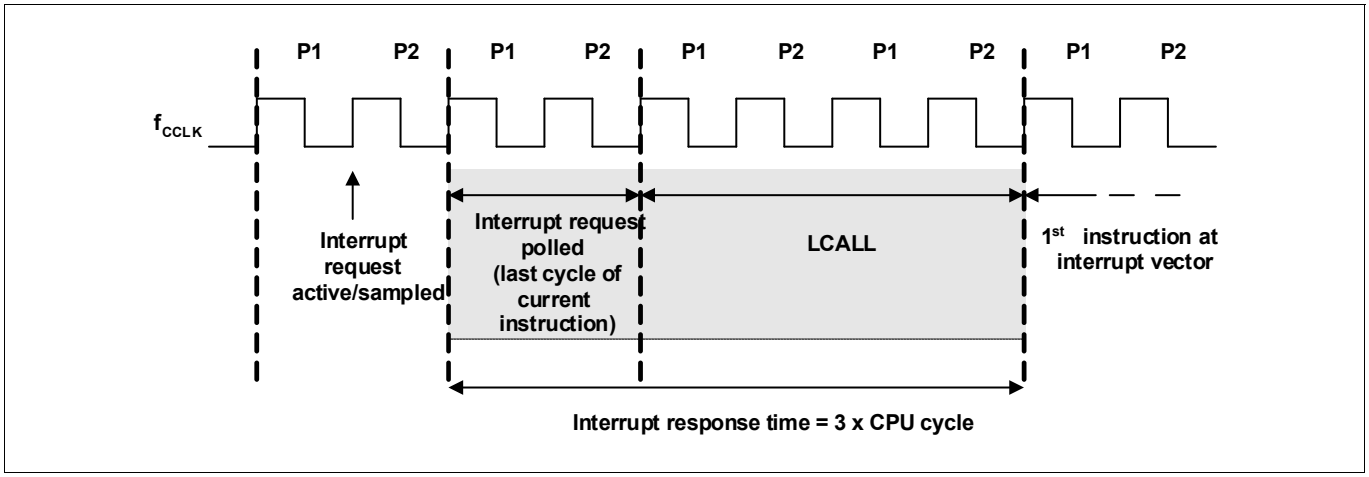

Figure 832 Minimum Interrupt Response Time

A longer response time would be obtained if the request is blocked by one of the three previously listed conditions:

1. If an interrupt of equal or higher priority is already in progress, the additional wait time will depend on the nature of the other interrupt's service routine.
2. If the instruction in progress is not in its final cycle, the additional wait time cannot be more than three CPU cycles since the longest instructions (MUL and DIV) are only four CPU cycles long. See **Figure 833**.
3. If the instruction in progress is RETI or a write access to registers IEN0, IEN1 or IP(H), IP1(H), the additional wait time cannot be more than five cycles (a maximum of one more CPU cycle to complete the instruction in progress, plus four CPU cycles to complete the next instruction, if the instruction is MUL or DIV). See **Figure 834**.

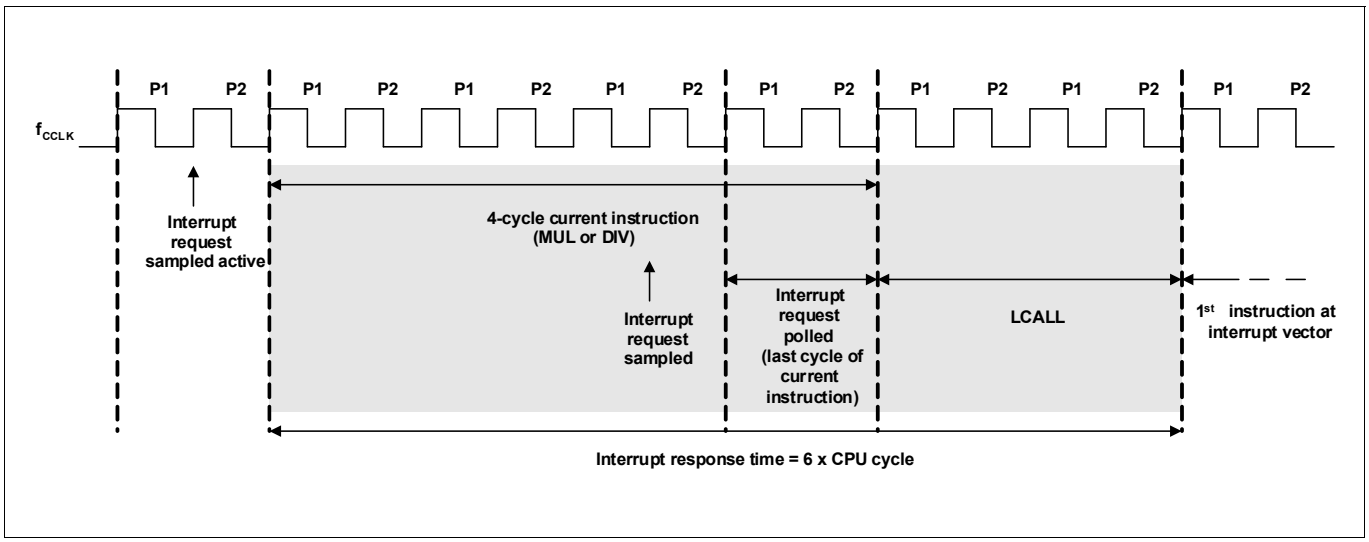

Figure 833 Interrupt Response Time for Condition 2

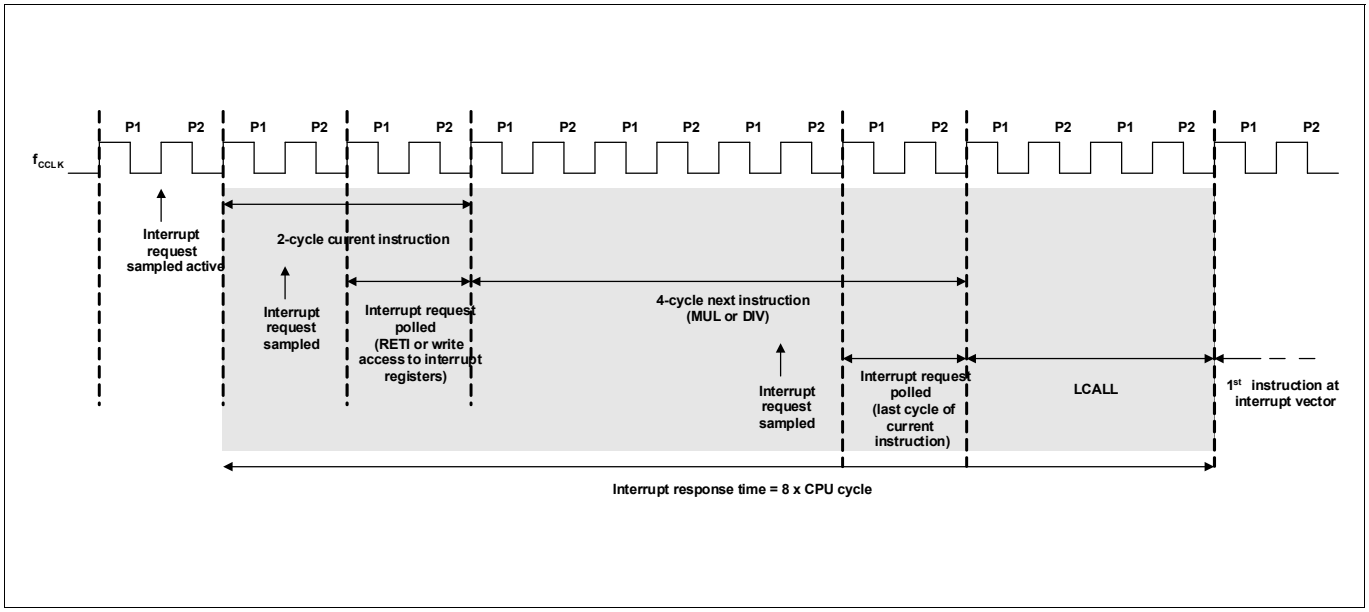

Figure 834 Interrupt Response Time for Condition 3

Thus in a single interrupt system, the response time is always more than three CPU cycles and less than nine CPU cycles (wait states are not considered). When considering wait states, the interrupt response time will be extended depending on the user instructions (also the hardware generated LCALL) being executed during the interrupt response time (shaded region in **Figure 833** and **Figure 834**).

49.9.5 Interrupt from/to TriCore CPUx

There is an interrupt signal from main SoC TriCore CPUx to trigger an 8-bit NMI event. It is triggered by setting a bit in register (PMSWCR2.TCINTREQ) that is located in the main SCU. The interrupt data exchange register, TCINTEXCHG, is used to indicate the type of SOC events that causes this interrupt.

In SCR, there is also an interface to trigger an interrupt to CPUx. This is done via bit NMICON.SCRINTTC. The type of SCR events that causes this interrupt to CPUx can be stored in register SCRINTEXCHG.

49.9.6 Registers Description

Interrupt Special Function Registers or bits are used for interrupt configuration such as node enable, external interrupt control, interrupt flags and interrupt priority setting.

Table 599 lists the SFRs and corresponding addresses.

49.9.6.1 Interrupt Node Enable Registers

Each interrupt node can be individually enabled or disabled by setting or clearing the corresponding bit in the interrupt enable registers IEN0 and IEN1. Register IEN0 also contains the global interrupt masking bit (EA), which can be cleared to block all pending interrupt requests at once.

The NMI interrupt vector is shared by a number of sources, each of which can be enabled or disabled individually via register NMICON.

After reset, the enable bits in IEN0, IEN1 and NMICON are cleared to 0. This implies that all interrupt nodes are disabled by default.

49.9.6.2 External Interrupt Control Registers

The 16 external interrupts, EXINT[15:0], are driven into the SCR from the ports. The external interrupt pin assignment for SCR is shown in **Table 603**. External interrupts can be positive, negative, or double-edge triggered. Registers EXICON0 through EXICON3 specify the active edge for an external interrupt. Among the external interrupts, external interrupt 0 and external interrupt 1 can be selected to bypass edge detection in the SCU, for direct feed-through to the core. The signal to the core can be further programmed to either low-level or negative transition activated, by bits IT0 and IT1 in the TCON register. However, for edge detection in SCU, T01_TCON.IT0/1 must be set to falling edge triggered. A detected active edge event will generate internally two CCLK cycle low pulse for detection by the core.

If the external interrupt is positive (negative) edge triggered, the external source must hold the request pin low (high) for at least one CCLK cycle, and then hold it high (low) for at least one CCLK cycle to ensure that the transition is recognized. If edge detection is bypassed for external interrupt 0 and/or external interrupt 1, the external source must hold the request pin “high” or “low” for at least two CCLK cycles.

External interrupts 3 to 15 share 4 interrupt nodes. Therefore, in addition to the corresponding interrupt node enable, each external interrupt 3 to 15 may be disabled individually; they are disabled by default after reset.

1) The pad control of this pin is in the 32-bit Ports module (via PMS). The input function is available after reset, this pin can be used as external interrupt input.

Note: Several external interrupts support alternative input signals. When switching inputs, the active edge/level trigger select and the level on the associated pins should be considered to prevent unintentional interrupt generation.

The following figures show block diagrams and connection overviews of External Interrupts 0 through 15.

Note: NMISR register can only be cleared by software or reset to the default value after the Main Reset. Its value is retained on any other resets. This allows the cause of the previous NMI to be checked.

49.9.6.4 Interrupt Priority Registers

Each interrupt node can be individually programmed to one of the four priority levels available. Two pairs of Interrupt Priority Registers are available to program the priority level of the each interrupt vector. The first pair of Interrupt Priority Registers are SFRs IP and IPH. The second pair of Interrupt Priority Registers are SFRs IP1 and IPH1.

The corresponding bits in each pair of Interrupt Priority Registers select one of the four priority levels as shown in **Table 614**.

Table 614 Interrupt Priority Level Selection

IPH.x / IPH1.x	IP.x / IP1.x	Priority Level
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

*Note: NMI always has the highest priority (above Level 3); it does not use the priority level selection shown in **Table 614**.*

49.9.7 Interrupt Events Related Registers

There are some interrupt events related registers, which can be used to enable specific interrupts, or to exchange data to and from the main controller. These are described here.

49.9.7.1 Interrupt Event Enable Control

The five interrupt events of SSC module are of interrupt structure 2. As there is no enable/disable bit(s) for these interrupt events within the module, bits are defined in the SCU register SCU_MODIEN to provide for this purpose.

49.10 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The SCR has a maximum of 16 general purpose I/O ports with 8-bit peripheral I/O lines that are shared with the 32-bit peripherals I/O lines. It is organized into two parallel ports. Internally within the SCR, these ports are always referred to as SCR_P00 and SCR_P01. Here, within the SCR, the terms SCR_P00 and SCR_P01 do not refer to the main-SoC ports P00 and P01. Instead, they are actually mapped to pins in ports P33 and P34.1 in this platform. This particular pin assignment of these functions is shown in **Table 624**.

Upon reset, the 32-bit Ports module has the full control of all the pads. During run mode, the control of these 16 pins can be switched to SCR if necessary via the 32-bit Ports register Pn_PCSR.

A separate set of pad control registers as shown in **Table 625** are available in SCR to control these ports.

In **Table 624**, the transfer from a TC26x device to a TC3xx device is shown.

Table 624 Pin assignment for Ports in SCR

SCR Ports	Main SoC Ports / Pins
SCR_P00.0 - SCR_P00.7	P33.0 - P33.7
SCR_P01.0	P34.1
SCR_P01.1 - SCR_P01.7	P33.9 - P33.15

Note: Not all pins described in this chapter might be available for a specific device.

49.10.1 Basic Port Operation

Figure 839 is a general block diagram of an SCR GPIO port slice.

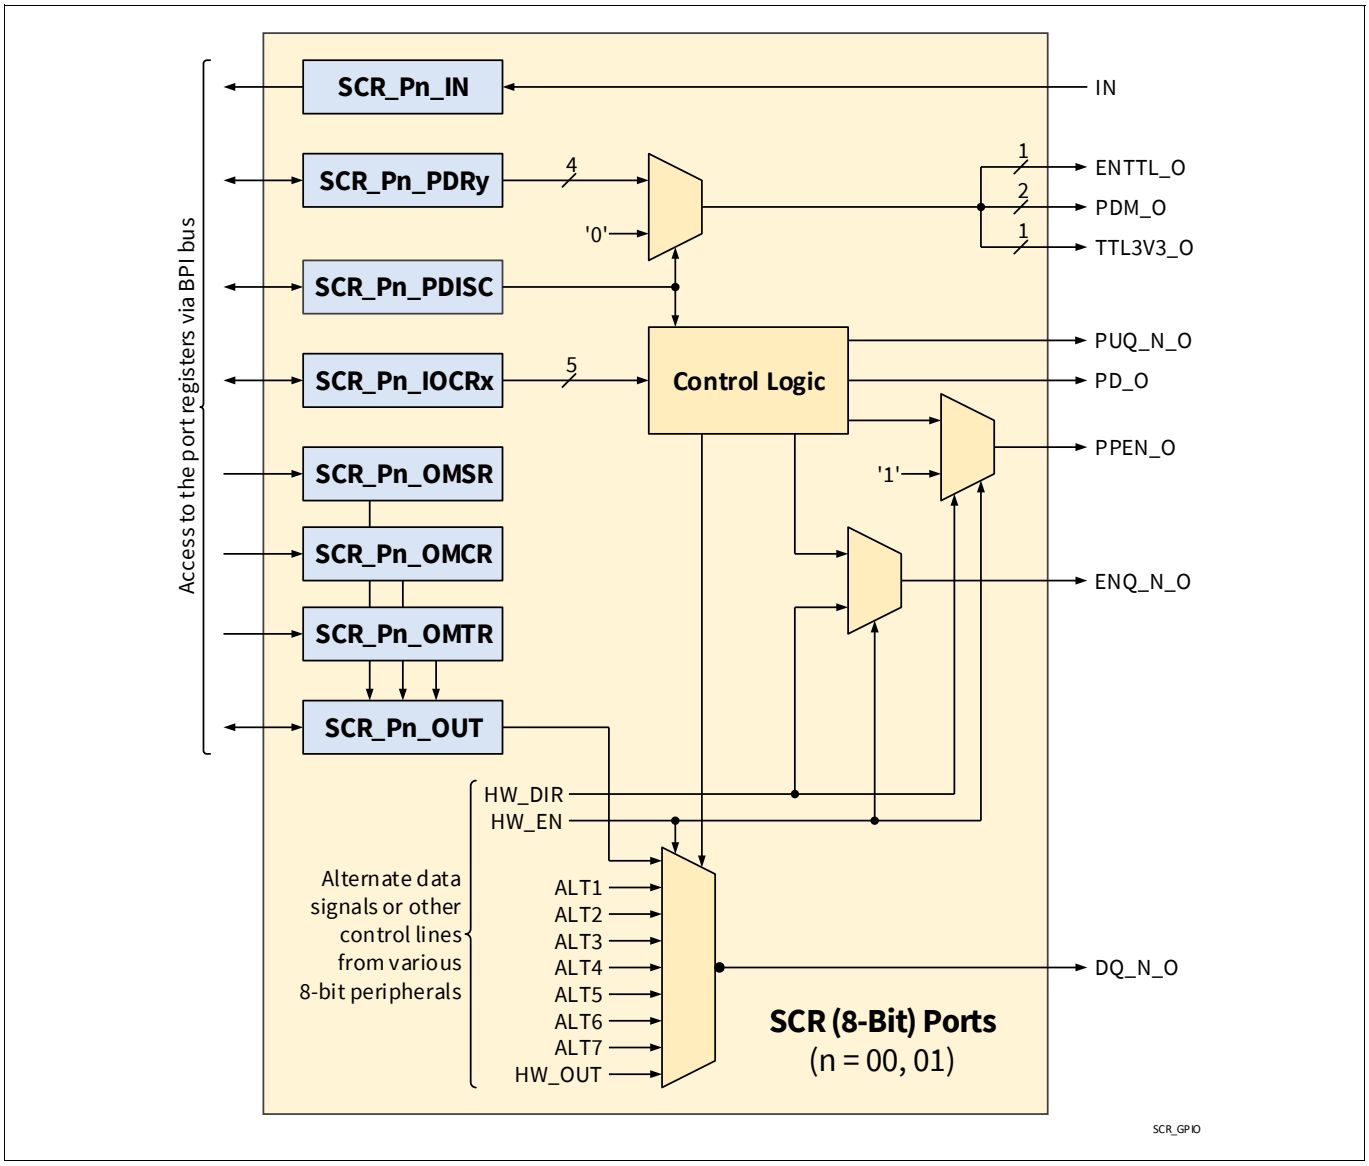

Figure 839 General Structure of a Port Pin

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register SCR_Pn_IN (n=00, 01). Input signals are connected directly to the various inputs of the peripheral units (AltDataIn). The function of the input line from the pin to the input register SCR_Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output.

This means that when the port is in output mode, the level of the pin can be read by software via SCR_Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the SCR_Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register SCR_Pn_IOCR has to be written for input or output selection. The SCR_Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input

pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (SCR_Pn_IOCR register) to the Output Data Register SCR_Pn_OUT. Software can set, clear, or toggle the bit in SCR_Pn_OUT through separate SCR_Pn_OMSR, SCR_Pn_OMCR, or SCR_Pn_OMTR registers. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register SCR_Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register SCR_Pn_OMSR, Output Modification Clear Register SCR_Pn_OMCR, or the Output Modification Toggle Register SCR_Pn_OMTR.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied through software via the output register SCR_Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register SCR_Pn_IN.

49.10.2 Port Register Overview

The individual control and data bits of each parallel port are implemented in a number of 8-bit registers. Bits with the same meaning and function are assembled together in the same register. The registers configure and use the port as general purpose I/O or alternate function input/output. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described separately. The definition of these registers are similar to the 32-bit format.

The registers are shown in **Figure 840**.

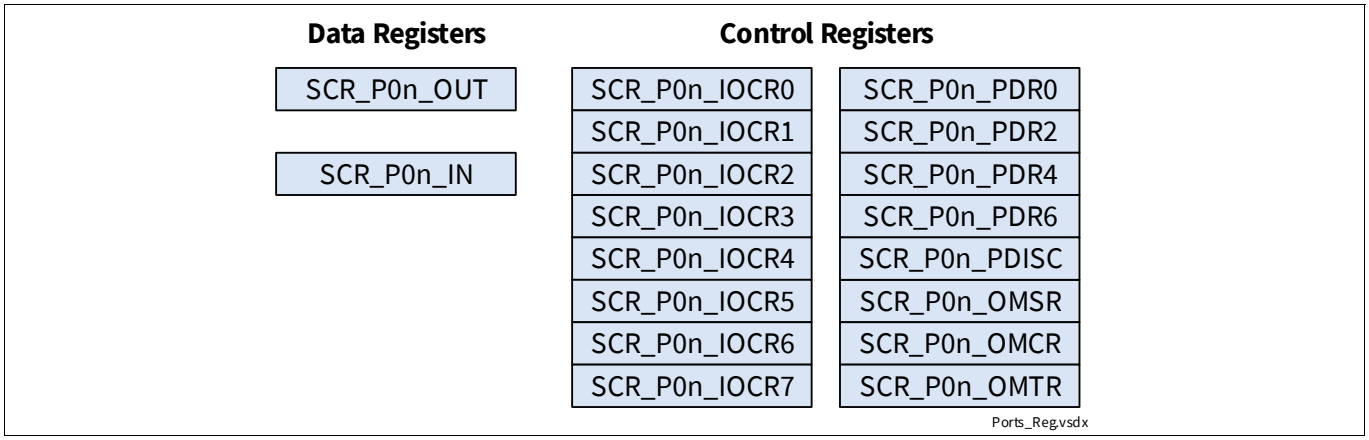

Figure 840 SCR Port Registers

The Port SFRs are located in the standard memory area (RMAP = 0) and the addresses are listed in **Table 625**.

Table 625 Register Overview - PORTS (sorted by Name)

49.10.2.2 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit field PC.

Each 8-bit wide port input/output control register controls one GPIO port line:

- Register SCR_P00_IOCR0 controls the SCR_P00.0 (P33.0) port line, register SCR_P01_IOCR0 controls the SCR_P01.0 port line (P34.1).
- Registers SCR_P00/01_IOCR1 control the SCR_P00.1 (P33.1) and SCR_P01.1 (P33.9) port lines.
- Accordingly, the other registers control the port lines SCR_P00.2 through SCR_P00.7 (P33L), and SCR_P01.2 through SCR_P01.7 (P33H), respectively.

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

Note: The reset values of 10_H and 00_H for SCR_Pn_IOCRx registers represents input pull-up and no input pull device (tri-state mode) being activated, respectively. The switching of the intended mode of the device is controlled by HWCFG6. When a cold reset is activated and HWCFG6=1, the pins are set to input pull-up mode as long as PORST is activated. If HWCFG6=0, the pins have the default state of tri-state mode. The pad state can also be configured by software through PMSWCR5.TRISTREQ bit. In the event of a warm reset or wake-up from standby mode, PMSWCR5.TRISTREQ is not affected by reset, hence SCR_Pn_IOCRx registers have the reset values configured as per the last state of the TRISTREQ bit.

49.10.2.3 Pad Driver Mode Register

Overview

The pad structure of the SCR GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the PDx bit fields in the pad driver mode registers SCR_Pn_PDRy (y=0, 2, 4, 6), independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. SCR_Pn_PDRy registers are assigned to each port.

The assignment of each port pin to one of these pad classes is shown in the port configuration figures. Further details about pad driver classes that are available in the AURIX™ TC3xx Platform are summarized in the Target Data Sheet/Data Sheet.

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDx in the pad driver mode registers SCR_Pn_PDRy make it possible to select the port line functionality as shown in the tables below.

Table 629 Pad Driver Mode Selection- RFast Pads

PDx.1	PDx.0	Speed Grade	Driver Setting
0	0	1	Strong Driver, Sharp Edge (“ss”)
0	1	2	Strong Driver, Medium Edge (“sm”)
1	0	3	Medium Driver (“m”)
1	1	4	RGMII Driver

Table 630 Pad Driver Mode Selection- Fast Pads

PDx.1	PDx.0	Speed Grade	Driver Setting
0	0	1	Strong Driver, Sharp Edge (“ss”)
0	1	2	Strong Driver, Medium Edge (“sm”)
1	X	3	Medium Driver (“m”)

Table 631 Pad Driver Mode Selection- Slow Pads

PDx.1	PDx.0	Speed Grade	Driver Setting
X	0	1	Medium Driver, Sharp Edge (“sm”)
X	1	2	Medium Driver (“m”)

Note: AURIX™ TC3xx Platform Data Sheet describes the DC characteristics of all pad classes.

TTL/Automotive Input Selection

The input function can operate with different VIH and VIL levels depending on the pad supply voltage and the selection done by the PLx bits of the Pn_PDRx registers, as shown in **Table 632**.

PLx.1 additionally also changes the pull-up and pull-down resistors.

Table 632 Pad Level Selection

PLx.1	PLx.0	Input Levels
0	X	Automotive level “AL”
1	0	TTL level for 5 V supply
1	1	TTL level for 3.3 V supply

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDRy (y=0, 2, 4, 6) registers, respectively. Each PDx field controls one pin. For coding of PDx, see **Table 629**, **Table 630** and **Table 631**. Similarly, each PLx bit controls one pin. For coding of PLx, see **Table 632**.

49.10.2.4 Pin Function Decision Control Register

The pad structure of the SCR GPIO lines offers the possibility to disable/enable port pad or select digital input. For the selection of digital input, the parameters defined for Class S pads must be met. This feature can be controlled by individual bits in the SCR_Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the SCR_Pn_IOCR register. One SCR_Pn_PDISC register is assigned to each port.

Note: After reset, all SCR_P0n_PDISC registers have the reset value of FF_H.

49.10.2.5 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by SCR_P0n_IOCRx as output. Writing a 0 to a SCR_P0n_OUT.Px (x = 0-7) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of SCR_P0n_OUT.Px can be individually set, cleared, or toggled by writing appropriate values into the port output modification set register SCR_P0n_OMSR, or port output modification clear register SCR_P0n_OMCR, or the port output toggle register SCR_P0n_OMTR, respectively.

Note: SCR_P01_OUT.P0 is connected to P34.1 instead of P33.8

49.10.3 SCR Functions in Port SCR_P00 (P33L)

This section describes the SCR functions of Port SCR_P00, which is mapped on P33L.

49.10.3.1 SCR Port SCR_P00 Configuration

The SCR has functions on Port lines SCR_P00.0 - SCR_P00.7 (P33.0 - P33.7). It can be alternatively used for UART, WCAN, SSC, T0/T1, T2CCU and External Interrupt input and output functions.

49.10.3.2 Port SCR_P00 Function Table

Table 643 summarizes the SCR I/O control selection functions of the 8 Port SCR_P00 lines, while **Figure 841** provides an overview of the SCR_P00 connections to other modules.

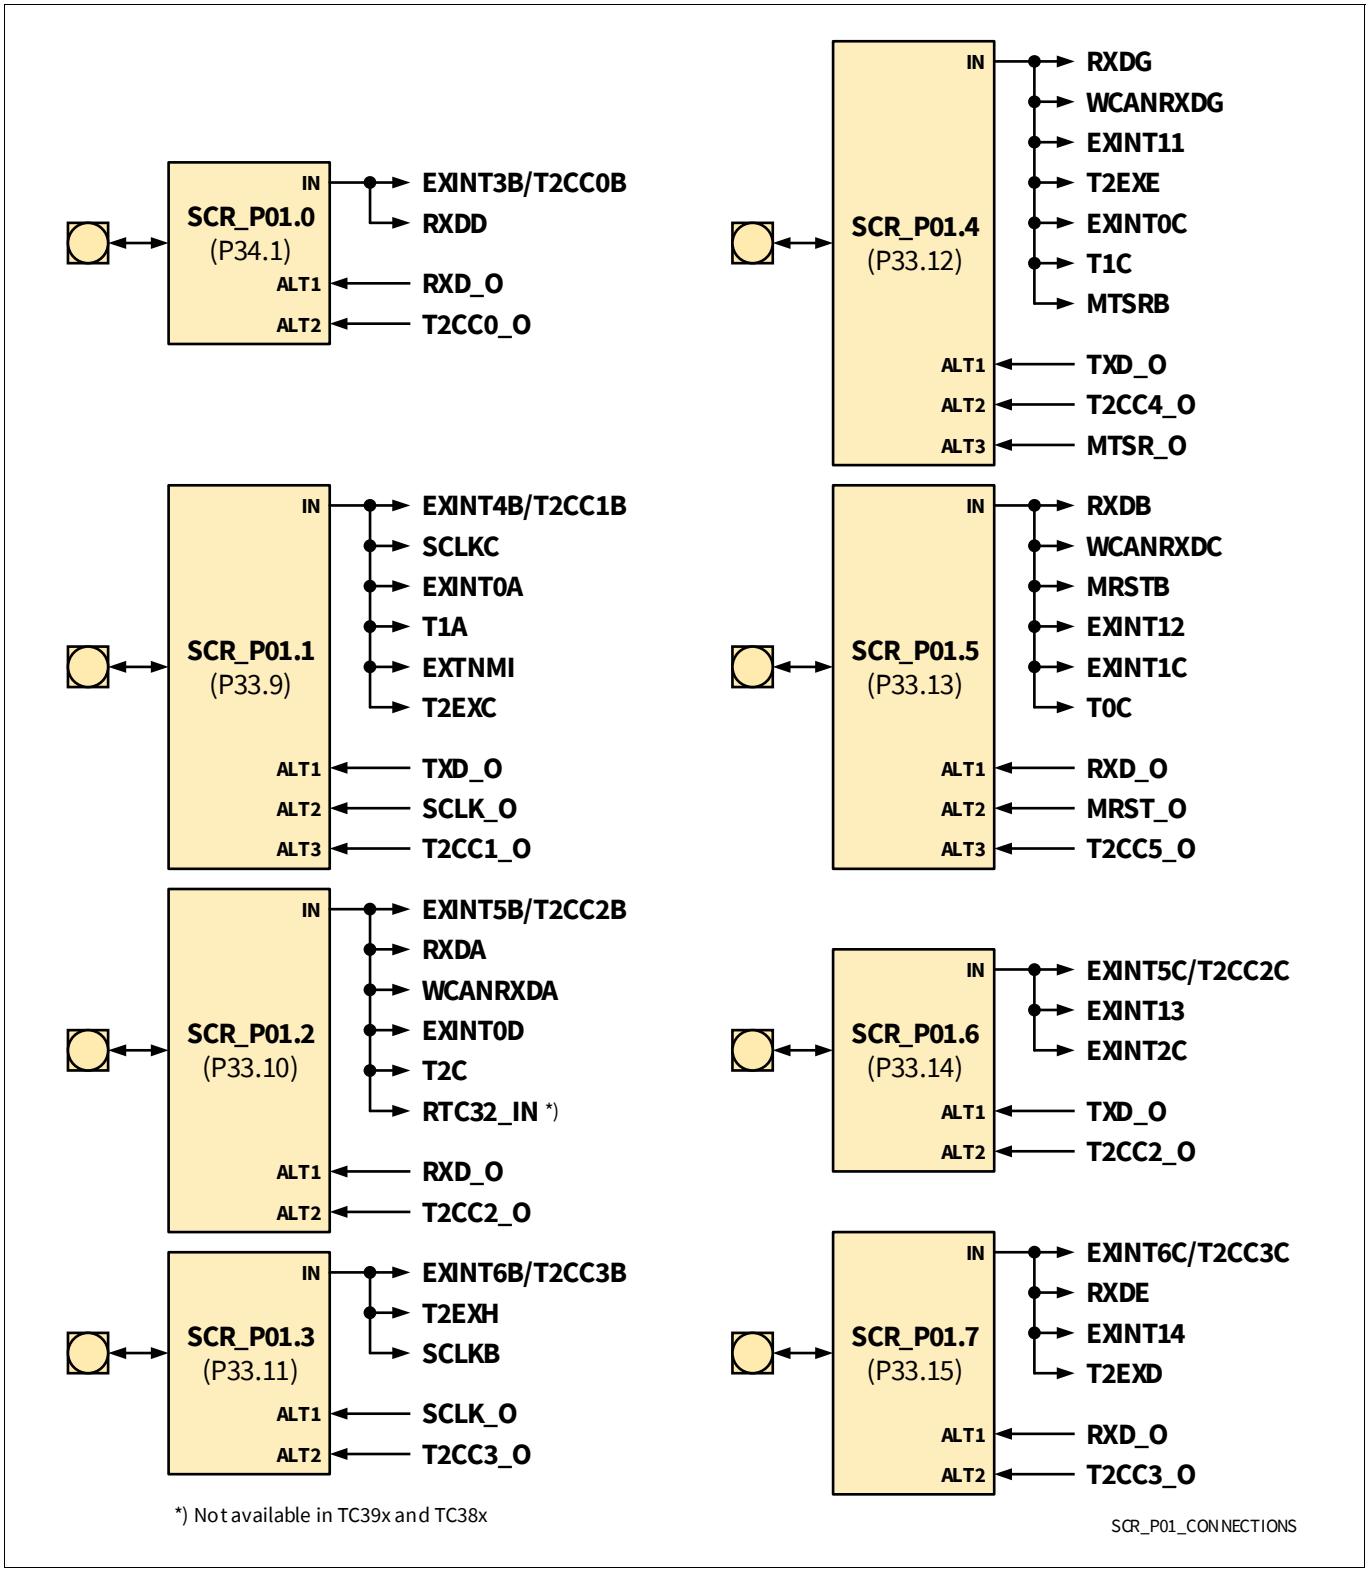

Figure 842 SCR_P01 Connection Overview

49.10.4.3 Port SCR_P01 Registers

The following registers are available on Port SCR_P01 (P34.1 and P33H).

The Port SFRs are located in the standard memory area (RMAP = 0).

Note: P34.1 is used instead of P33.8.

49.10.6 General Port Control

There are a number of control registers for input pin selection of SSC, UART, External interrupts [15:0], T0, T1, T2CCU and WCAN modules. These registers are implemented within the SFR block. **Table 648** provides an overview of these registers.

49.11 Real-Time Clock (RTC)

49.11.1 Overview

One of the SCR's peripherals is the Real-Time Clock (RTC) that, once started, can work independently of the state of the rest of the microcontroller.

Features

- Periodic Wake-up Mode using either the 70 kHz clock or the 100 MHz/DIV clock
- Wake-up source during standby mode, e.g. operating system timer

49.11.2 System Information

This section provides system information relevant to the Real-Time Clock.

49.11.2.1 Interrupt Events and Assignment

Table 656 lists the interrupt event sources from the RTC, and the corresponding event interrupt enable bit and flag bit.

Table 656 RTC Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit
RTC compare/wake-up	RTC_CON.ECRTC	RTC_CON.CFRTC

Table 657 shows the interrupt node assignment for each RTC interrupt source.

Table 657 RTC Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
RTC compare/wake-up	IEN1.ECCIP3	–	$6B_H$

49.11.2.2 Module Suspend Control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (MMCR2.MMODE = 1) and the Debug-Suspend signal is active (MMCR2.DSUSP = 1), the timer/counter in RTC module in the SCR can be suspended based on the settings of their corresponding module suspend bits in register MODSUSP.

When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

49.11.3 Clock Source

RTC clock, f_{RTC}, is selectable between the 70 kHz clock or the 100 MHz/DIV clock via bit RTCCLKSEL in RTC_CON register, or an external 32 kHz / 32.768 kHz oscillator signal supplied via pin SCR_P01.2 (P33.10) can be used, selected via bit RTC32SEL.

Note: The external input option via pin SCR_P01.2 (P33.10) is NOT available in the TC39x, TC38x and TC35x devices. (EXT devices have this clock input.)

Once powered up, these clocks can operate irrespective of the state of the microcontroller. That is, it keeps running even when the SCR has entered idle or the device has entered standby mode.

In case of clock failure, the RTC stops counting.

49.11.4 Real Time Clock Operation

The real-time clock consists of a 41-bit timer (including 9-bit prescaler) which count up. It contains a set of 4 count registers, collectively know at RTC_CNT register, that shows the current count value or the current time of the real-time clock. Before starting the real-time clock, RTC_CNT register can be written with any value. The value written is used as an initial value for the real-time clock when it is started. Another set of registers, RTC_CR register, that consists of 4 registers can be used for interrupt generation. It can also be used to wake-up device from standby mode. The RTC_CR register is also used to store the capture value when a capture event is triggered. The real-time clock is started by setting bit RTCC in the RTC_CON register to 1. This enables the input clock into the real-time clock timer.

The RTC starts counting after 1 PCLK + 4 RTC Clock cycles after the RTCC is set.

Note: Before starting the RTC counter, the compare value in registers RTC_CRn should be set to a value <> 0 (e.g. 0xFFFF). Otherwise, the RTC will not start if it is initially 0, or stop after an overflow to 0.

49.11.4.1 Periodic Wake-up Mode

Figure 843 shows the real-time clock. It consists of a 41-bit general purposes timer. The PCLK is the input clock to the timer.

Before the real-time clock starts to run, RTC_CNT register of the real-time clock can be written with any values. The value written is used as an initial value for the real-time clock timer, when it is started by setting bit RTCC in the RTC_CON register to 1. This bit also enables the input clock into the real-time clock timer. RTC_CNT register is protected by the bit protection scheme as described in the SCU chapter. The initial count value can only be updated when the protection scheme is being disabled in the stop mode (RTCC = 0). The real-time clock's lower 9 bits, which serve as a prescaler into the 32-bit counters, RTC_CNT, are set to an initial value of 000000000_B when the RTC starts to run. The prescaler can be bypassed by setting bit RTPBYP in the RTC_CON register to 1.

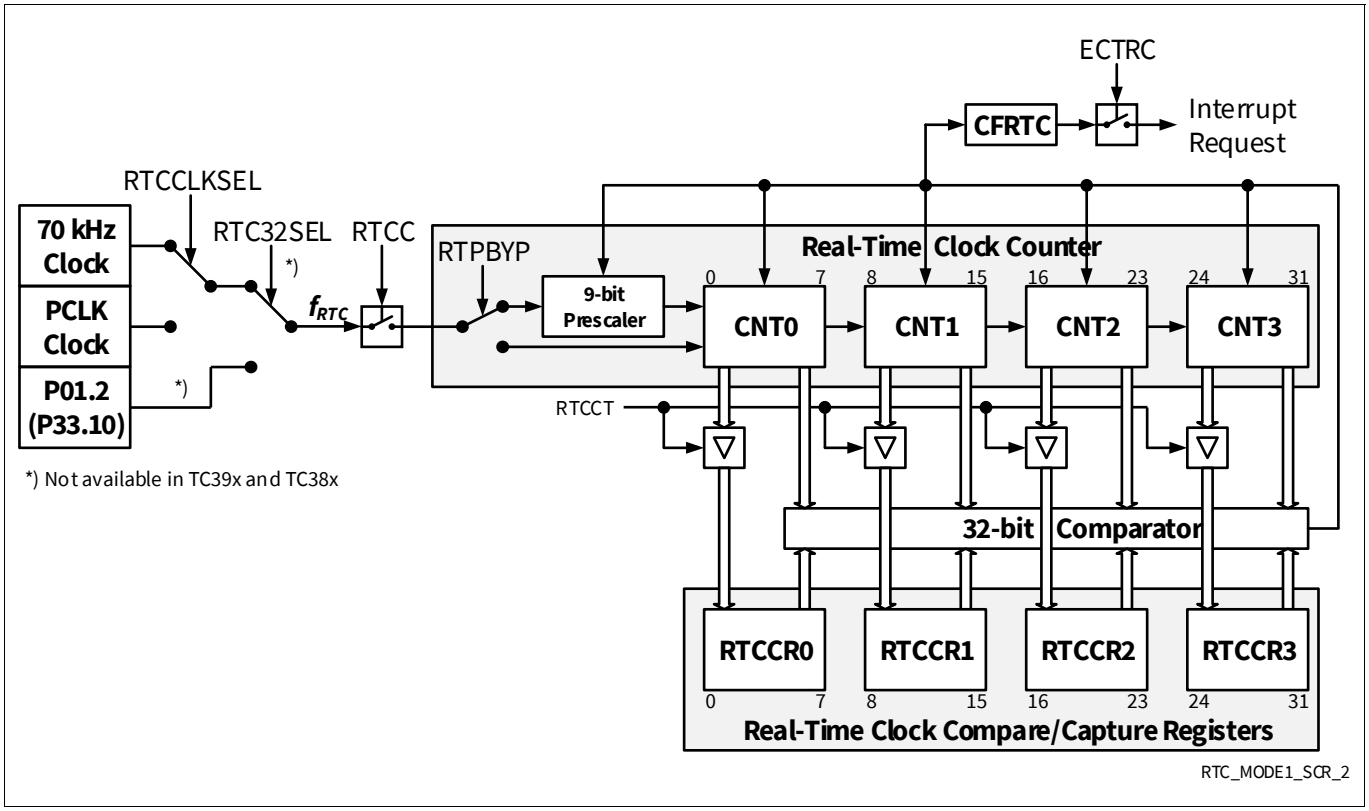

Figure 843 Real-Time Clock Periodic Wake-up Mode with 9-bit Prescaler

While the real-time clock is in operation, the contents of RTC_CR register will be compared to the real-time clock counter (RTC_CNT). An interrupt will be generated when the contents are equal if ECRTC is set to 1; bit CFRTC in register RTC_CON will be set. The CFRTC flag can be monitored for the real-time clock wake-up request, but the flag has to be cleared to 0 by user software. In such situation, the real-time clock counter is reset and starts counting from zero again.

Note: Before starting the RTC counter, the compare value in registers RTC_CRn should be set to a value <> 0 (e.g. 0xFFFF). Otherwise, the RTC will not start if it is initially 0, or stop after an overflow to 0.

With RTC still running in standby mode, it is able to wake-up at a fixed time by programming the number of count value that is equivalent to the length of time to wake-up in the RTC_CR register. The real-time clock can generate a wake-up request to the main controller if bit STDBYWKP.RTCWKSEL is set to 1.

A capture event could be triggered by setting RTCCT bit in RTC_CON register to 1. The previous content in the RTC_CR register will be overwritten with the captured RTC_CNT values after a maximum of 9 f_{RTC} cycles. An update of the actual compared value is necessary once a captured event is triggered. In SCR, it is recommended to trigger a capture event to read the value of the RTC counter (RTC_CNT). There is the potential of reading a wrong 32-bit real-time value while the RTC is in running mode as only 8 bit of data could be fetched at one time.

The real-time clock stops counting and RTC_CNT register holds the last value when the RTCC bit is set to 0. Setting this bit subsequently will start a new counting sequence which begin with the stop count.

Note: For the capture event to complete, up to 9 f_{RTC} cycles are required. During this time window, the compare event is temporarily disabled and no compare match happens. Once the capture is complete and the RTC_CR is updated, the compare event is enabled again. In both cases- i.e.- prescaler bypassed or not bypassed - it is ensured that the next compare match happens only after the next overflow.

49.11.4.2 RTC Access Delays and Restrictions

When accessing the RTC registers, the following delays and restrictions need to be obeyed:

- When the SCR is running and the clock is stable, RTC_CON.RTCC is allowed to be set/cleared.
- When the RTC clock is changed between available clocks, the waiting time of four old/current clock cycles and four clocks of the new/selected clock cycles need to be inserted before setting RTC_CON.RTCC.
  Moreover, upon each clock selection change, it is required to insert up to 9 RTC Clock cycles to the waiting time mentioned in the previous sentence.
- When an SCR reset is triggered, the RTC clock is set to 70 kHz per default. After triggering the reset, software has to wait 2 PCLK + 3 RTC clock cycles, before bit PMCON1.RTC_DIS may be cleared.
- When bit PMCON1.RTC_DIS is cleared, a waiting time of four RTC clock cycles needs to be inserted before any write access to RTC registers may be performed.

When the 9-bit prescaler is bypassed (RTPBYP = 1), then when consecutively reading the RTC count registers, the folowing delays, due to synchronization, need to be taken into account:

- When the RTC is running with PCLK, a delay of 6 PCLK cycles is present between the read accesses; thus, the RTC count value between two read operations may differ by 6 counts.
- When the RTC is running with 70 kHz, a delay of 5 RTC clock cycles is present between the read accesses; thus, the RTC count value between two read operations will differ by 5 counts.

49.11.5 Power Saving Mode Option

Once started, the real-time clock continues counting until the bit RTC_CON.RTCC is cleared. The real-time clock is not affected by the idle mode of the SCR, and continues counting in standby mode provided the PCLK clock is available. In addition, the real-time clock will not automatically disable the operation when there is a clock failure.

49.11.6 RTC Interrupt Request

The following figure illustrates the RTC interrupt request. Note that the flag must be cleared by software. See also the section on “Interrupt Structure 2” in chapter “Interrupt System”.

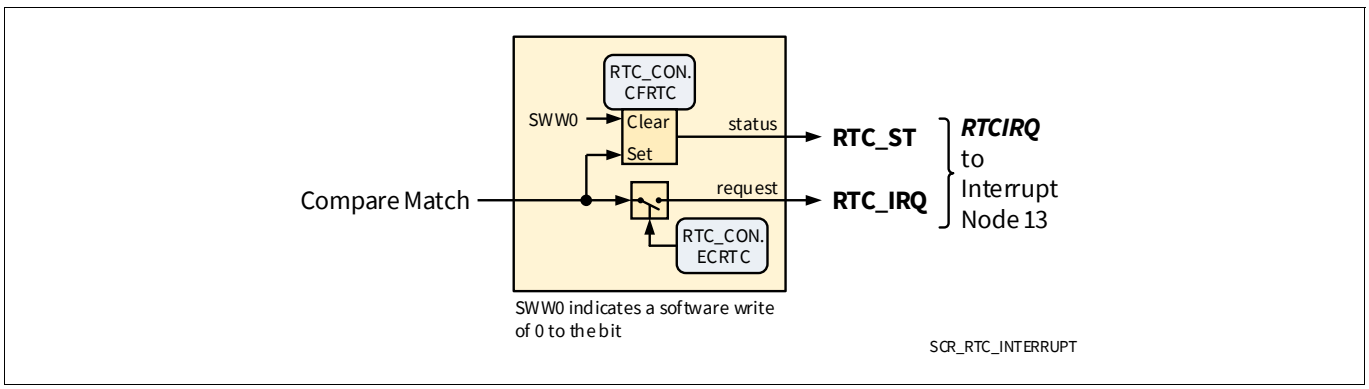

Figure 844 RTC Interrupt Request

49.11.7 Real-Time Clock Register

49.11.7.1 Register Mapping

9 SFRs are used to control the operation of real-time clock. They can be accessed from the standard (non-mapped) SFR area. The registers are described in the following.

Table 658 lists the addresses of these SFRs.

Table 658 Register Overview - RTC (sorted by Name)

Table 660 Reset Values of RTC_CON

Reset Type	Reset Value	Note
LVD Reset	00_H	
Generated Reset	00_H	

Note: The external input option via pin SCR_P01.2 (P33.10) is NOT available in the TC39x. TC38x and TC35x devices. Thus, bits RTC32SEL and INIT32 in register RTC_CON are also not available in these devices, and the respective bit positions are read-only. EXT devices will have the clock input.

Note: If the application changes back from external RTC oscillator to PCLK AND at the same time, the SCR is waking up (from 70kHz to PCLK), then the RTC clock is for 3 cycles at 70kHz, before changing to PCLK.

Count Clock Register n

4 count registers, RTC_CNT0 - RTC_CNT3, are used to represent the most significant 32 bits of the 41-bit real-time clock timer.

Note: When RTC_CNTn is written, a minimum delay of 8 RTC clock cycles is required, until the next write access to the register is allowed. Otherwise, the second write access will be lost.

Real-Time Clock Compare/Capture Register n

4 compare and capture registers, RTC_CR0 - RTC_CR3, are used to represent 32 bits of compare value,which will generate a compare event when it matches the counter value as specified in the RTC_CNT register.

When a capture event is triggered by setting RTCCT bit to 1, the content in the RTC_CRn register will be overwritten with the captured RTC_CNT value after a maximum of 8 f_{RTC} clock cycles. In order to take effect of the

new capture value inside RTC_CRn, another delay of 9 RTC clock cycles is required. During this time, the compare interrupt is disabled.

If the prescaler is bypassed, then the captured value inside the register is 2 or 3 clock cycles higher in relation to the point in time of the trigger set in RTCCT. Otherwise, the value is exact or 1 clock cycle higher than the point in time of the trigger.

Note: When RTC_CRn is written, a minimum delay of 8 RTC clock cycles is required, until the next write access to the register is allowed. Otherwise, the second write access is not guaranteed.

Note: Before starting the RTC counter, the compare value in registers RTC_CRn should be set to a value different to 0 (e.g. 0xFFFF). Otherwise, the RTC will not start if it is initially 0, or stop after an overflow to 0.

49.12 Timer 0 and Timer 1

49.12.1 Overview

Timer 0 and Timer 1 can function as both, timers or counters. When functioning as a timer, Timer 0 and Timer 1 are incremented at $f_{PCLK}/2$ (i.e. every 2 PCLKs). When functioning as a counter, Timer 0 and Timer 1 are incremented in response to a 1-to-0 transition (falling edge) at their respective external input pins, T0 or T1.

They are useful in many timing applications such as measuring the time interval between events, counting events and generating signals at regular intervals. In particular, Timer 1 can be used as the baudrate generator for the on-chip serial port.

Features:

- Four operational modes:
  - Mode 0: 13-bit timer/counter
  - Mode 1: 16-bit timer/counter
  - Mode 2: 8-bit timer/counter with auto-reload
  - Mode 3: Two 8-bit timers/counters

49.12.2 System Information

This section provides system information relevant to the Timer 0 and 1.

49.12.2.1 Pinning

This section describes the GPIO connections of timers 0 and 1. Please see also the GPIO chapter.

Peripheral Input Select Register 1

The MODPISEL1 register is used for input pin selection of the External Interrupt Inputs 0, 1 and 2. The register is on SCU_PAGE.

Timer 0/1 Inputs Overview

The following figures shows the connections and selections for the inputs to timers 0 and 1.

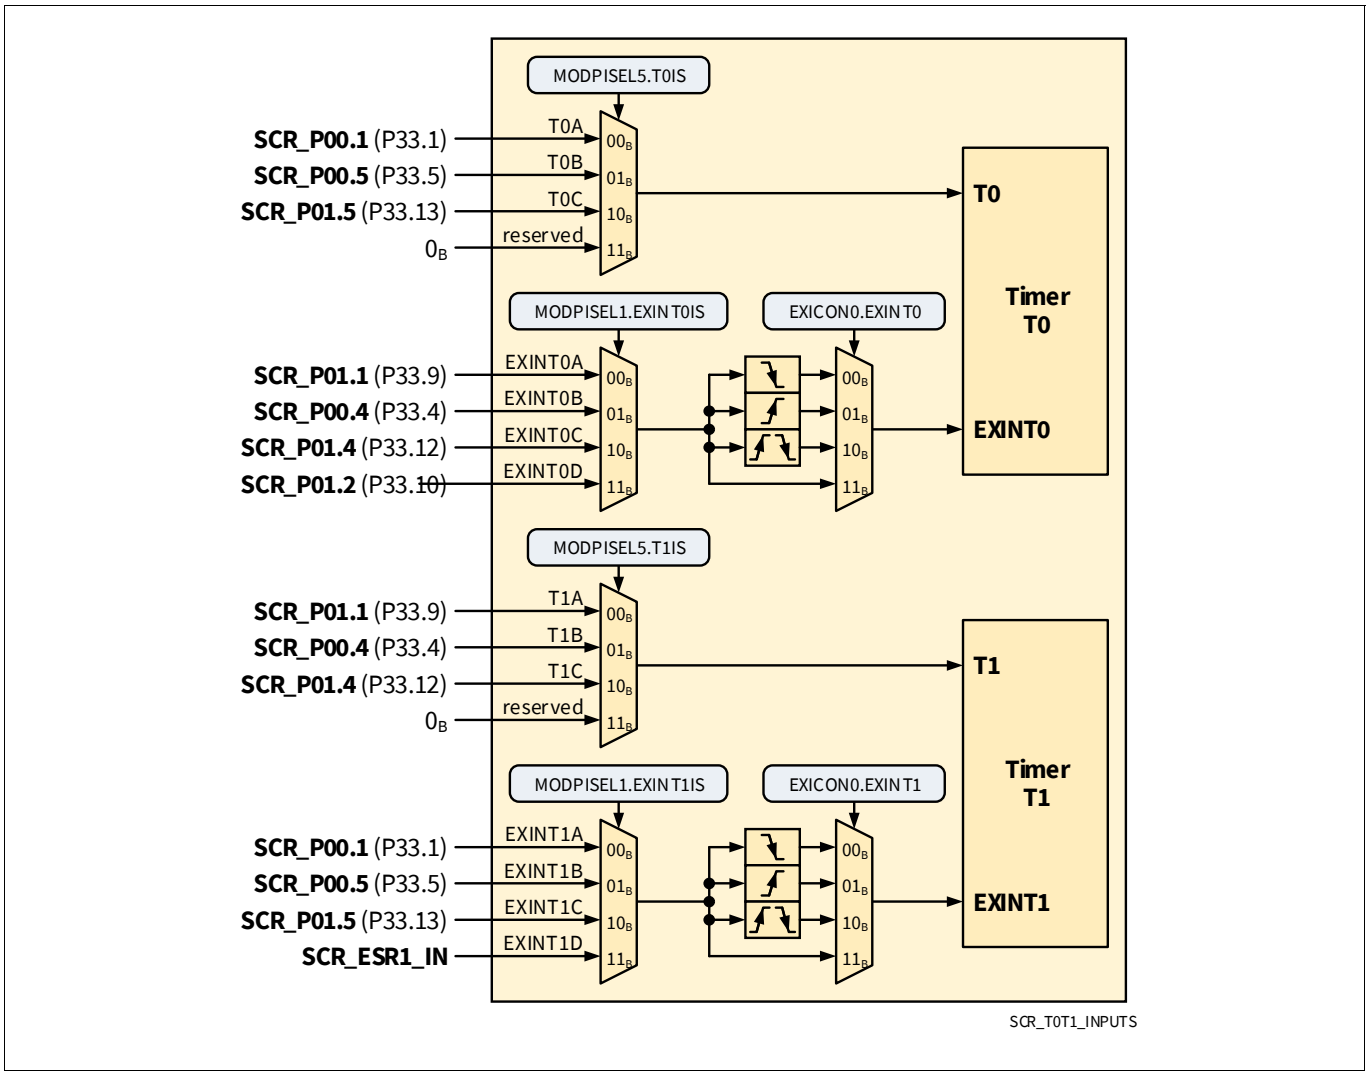

Figure 845 Timer 0 and 1 Modules Input Signals

49.12.2.2 Clocking Configuration

The Timer 0 and 1 run on the PCLK.

49.12.2.3 Interrupt Events and Assignment

Table 667 lists the interrupt event sources from Timer 0 and 1, and the interrupt node assignment for each Timer 0 and 1 interrupt source.

Table 667 Timer 0 and 1 Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
External Interrupt 0	IEN0.EX0	T01_TCON.IE0	03_H
Timer 0 Overflow	IEN0.ET0	T01_TCON.TF0	$0B_H$
External Interrupt 1	IEN0.EX1	T01_TCON.IE1	13_H
Timer 1 Overflow	IEN0.ET1	T01_TCON.TF1	$1B_H$

49.12.3 Basic Timer Operations

The operations of the two timers are controlled using the Special Function Registers (SFRs) T01_TCON and T01_TMOD. To enable a timer, i.e., allow the timer to run, its control bit T01_TCON.TRx is set. To select the timer input to be either from internal system clock or external pin, the input selector bit T01_TMOD.TxS is used.

Note: The "x" (e.g., T01_TCON.TRx) in this chapter denotes either 0 or 1.

Each timer consists of two 8-bit registers - T01_TLx (low byte) and T01_THx (high byte) which defaults to 00_H on reset. Setting or clearing T01_TCON.TRx does not affect the timer registers.

The timers 0 and 1 can be used as a counter, where the timer register is incremented in response to a 1-to-0 transition (falling edge) at the corresponding external input pin (T0 or T1). When the samples show a high for two PCLKs and a low in the next two PCLKs, the count is incremented. Since it takes four PCLKs to recognize a 1-to-0 transition, the maximum count rate is 1/4 of the PCLK frequency. There are no restrictions on the duty cycle of the external input signal, but it must be held at least two full PCLKs to ensure that a given level is sampled at least once before it changes.

Timer Overflow

When a timer overflow occurs, the timer overflow flag, T01_TCON.TFx, is set, and an interrupt may be raised if the interrupt enable control bit, IEN0.ETx, is set. The overflow flag is automatically cleared when the interrupt service routine is entered. See also **Section 49.12.5**.

When Timer 0 operates in mode 3, the Timer 1 control bits, TR1, TF1 and ET1 are reserved for TH0, see **Section 49.12.4.4**.

External Control

In addition to pure software control, the timers can also be enabled or disabled through external port control. When external port control is used, SFR EXICON0 must first be configured to bypass the edge detection circuitry for EXINTx to allow direct feed-through. When the timer is enabled (T01_TCON.TRx = 1) and T01_TMOD.GATEx is set, the respective timer will only run if the core external interrupt EXINTx = 1. This facilitates pulse width measurements. However, this is not applicable for Timer 1 in mode 3.

If T01_TMOD.GATEx is cleared, the timer reverts to pure software control.

49.12.4 Timer Modes

Timers 0 and 1 are fully compatible and can be configured in four different operating modes, as shown in **Table 668**. The bit field TxM in register T01_TMOD selects the operating mode to be used for each timer.

In modes 0, 1 and 2, the two timers operate independently, but in mode 3, their functions are specialized.

Table 668 Timer 0 and Timer 1 Modes

Mode	Operation
0	**13-bit timer/counter** The timer is essentially an 8-bit counter with a divide-by-32 prescaler. This mode is included solely for compatibility with Intel 8048 devices.
1	**16-bit timer/counter** The timer registers, T01_TLx and T01_THx, are concatenated to form a 16-bit timer/ counter.
2	**8-bit timer/counter with auto-reload** The timer register T01_TLx is reloaded with a user-defined 8-bit value in T01_THx upon overflow.
3	**Timer 0 operates as two 8-bit timers/counters** The timer registers, T01_TL0 and T01_TH0, operate as two separate 8-bit counters. Timer 1 is halted and retains its count even if enabled.

49.12.4.1 Mode 0

Putting either Timer 0 or Timer 1 into mode 0 configures it as an 8-bit timer/counter with a divide-by-32 prescaler. **Figure 846** shows the mode 0 operation.

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1s to all 0s, it sets the timer overflow flag TFx (see exception below). The overflow flag TFx can then be used to request an interrupt (see **Section 49.12.5**). The count input is enabled for the timer when TRx = 1 and either GATEx = 0 or EXINTx = 1 (setting GATEx = 1 allows the timer to be controlled by external input EXINTx to facilitate pulse width measurements). TRx is a control bit in the register TCON; bit GATEx is in register T01_TMOD.

The 13-bit register consists of all the 8 bits of T01_THx and the lower 5 bits of T01_TLx. The upper 3 bits of T01_TLx are indeterminate and should be ignored. Setting the run flag (TRx) does not clear the registers.

Mode 0 operation is the same for Timer 0 and Timer 1 (exception see below)

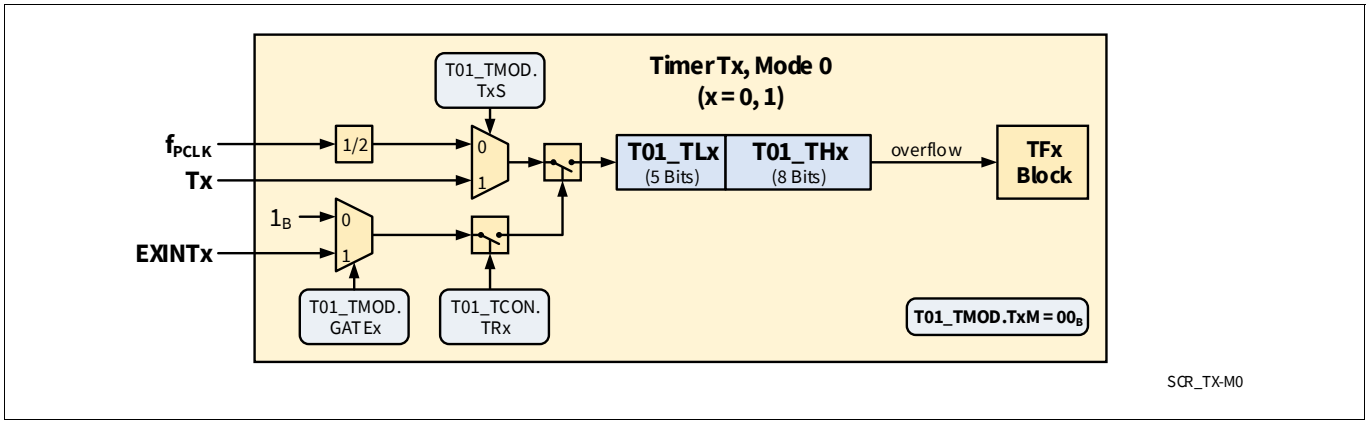

Figure 846 Timer x, Mode 0: 13-Bit Timer/Counter

The configuration shown in **Figure 846** above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; thus, the mode 0 configuration of Timer 1 in this case is shown in **Figure 847**.

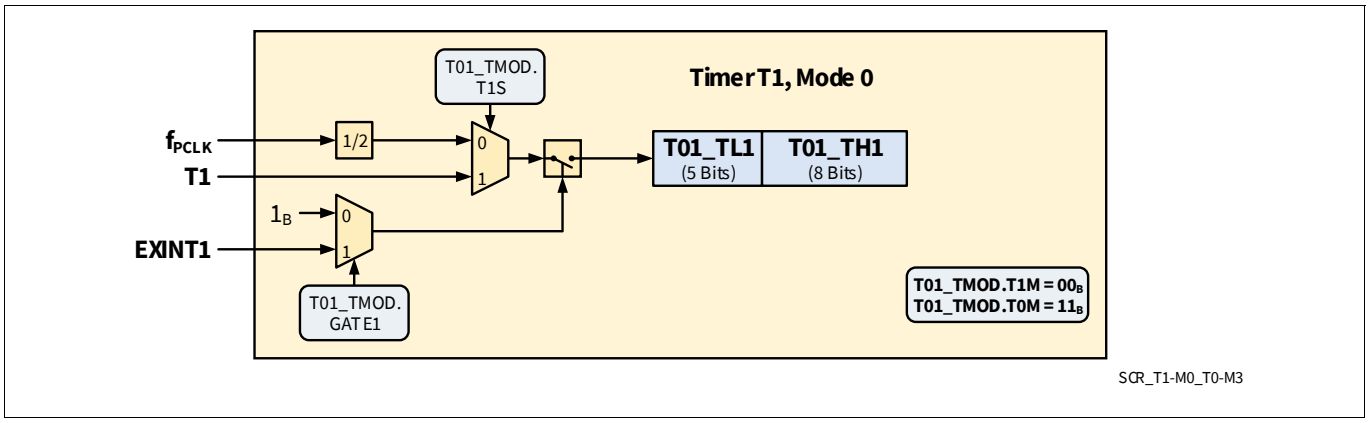

Figure 847 Timer 1 in Mode 0 while Timer 0 is in Mode 3: 13-bit Timer/Counter

49.12.4.2 Mode 1

Mode 1 operation is similar to that of mode 0, except that the timer register runs with all 16 bits. Mode 1 operation for Timer x is shown in **Figure 848**.

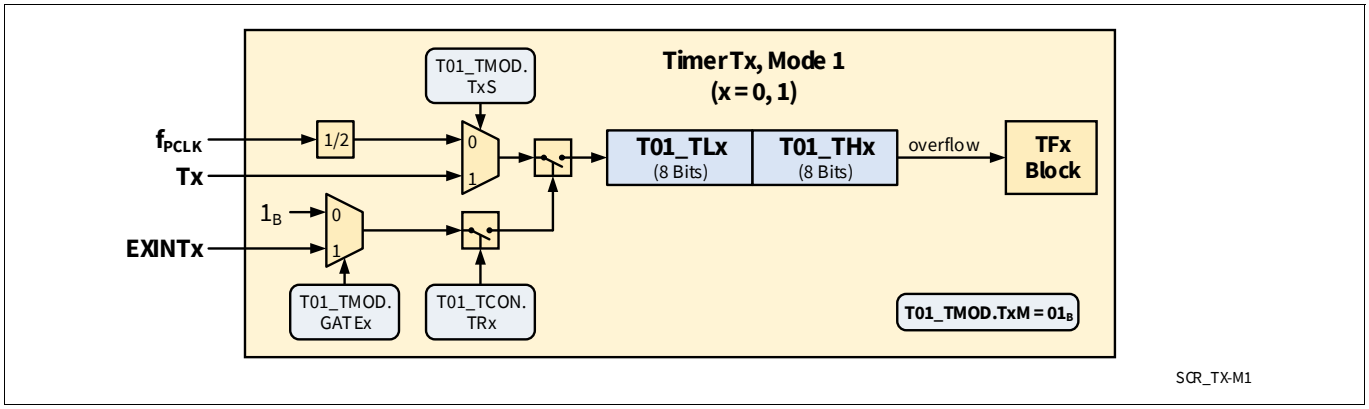

Figure 848 Timer x, Mode 1: 16-Bit Timer/Counter

The configuration shown in **Figure 848** above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; thus, the mode 1 configuration of Timer 1 in this case is shown in **Figure 849**.

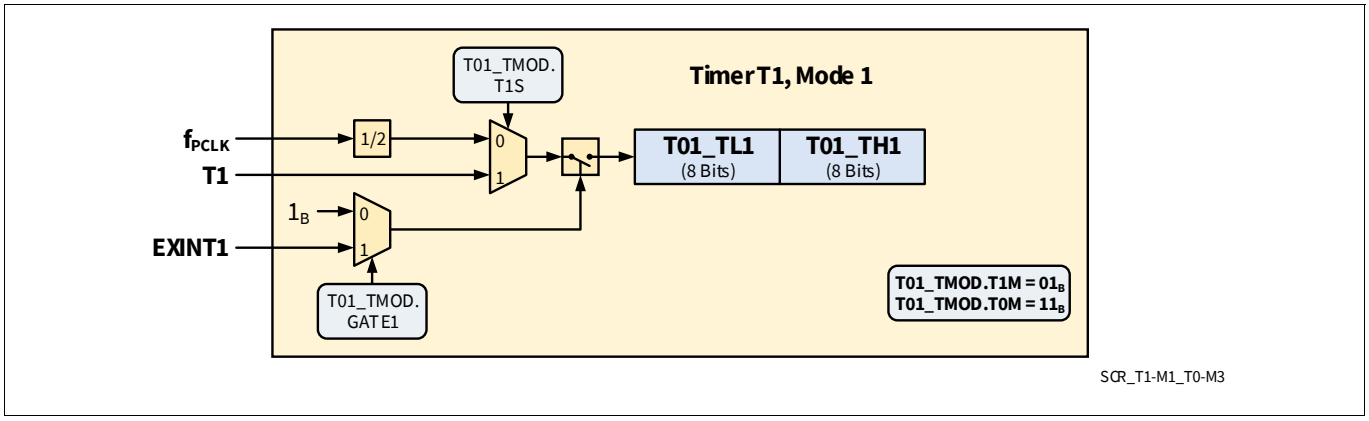

Figure 849 Timer 1 in Mode 1 while Timer 0 is in Mode 3: 16-bit Timer/Counter

49.12.4.3 Mode 2

In Mode 2 operation, the timer is configured as an 8-bit counter (TLx) with automatic reload, as shown in **Figure 850**.

An overflow from TLx not only sets TFx, but also reloads TLx with the contents of THx that has been preset by software. The reload leaves THx unchanged.

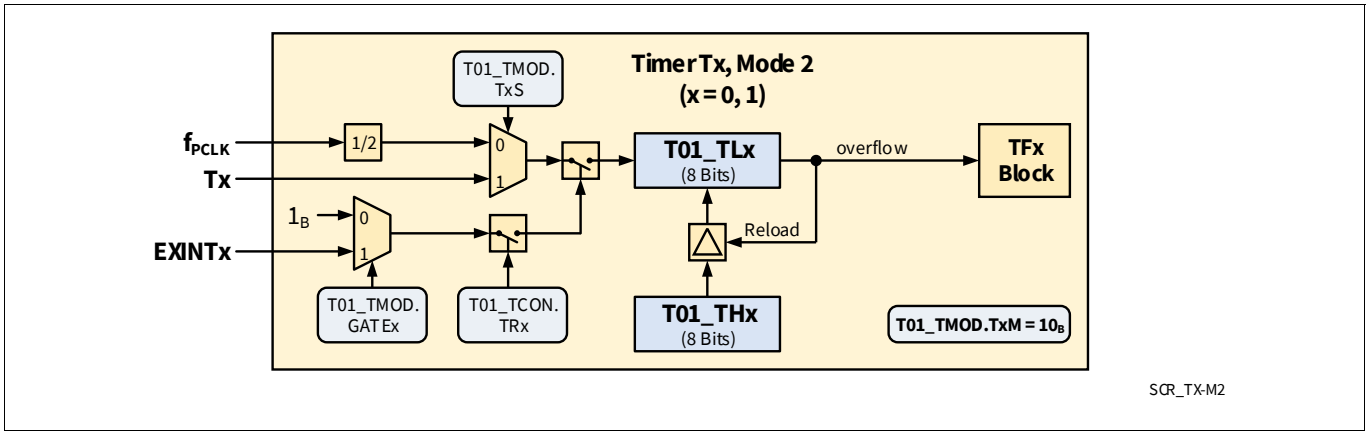

Figure 850 Timer x, Mode 2: 8-Bit Timer/Counter with Auto-Reload

The configuration shown in **Figure 850** above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; thus, the mode 2 configuration of Timer 1 in this case is shown in **Figure 851**.

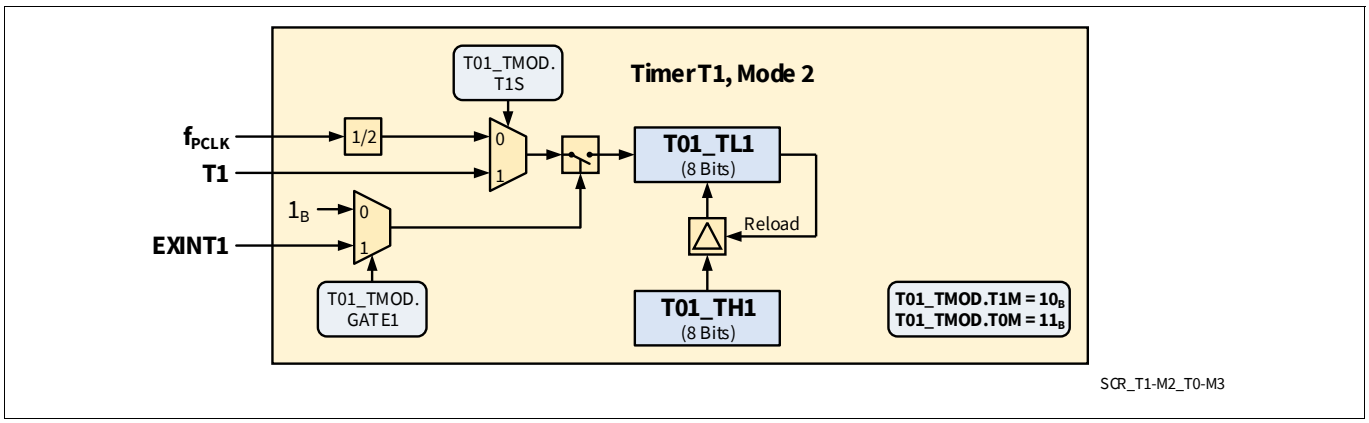

Figure 851 Timer 1 in Mode 2 while Timer 0 is in Mode 3: 8-bit Timer/Counter

49.12.4.4 Mode 3

In mode 3, Timer 0 and Timer 1 behave differently. Timer 0 in mode 3 establishes TL0 and TH0 as two separate counters. Timer 1 in mode 3 simply holds its count. The effect is the same as setting TR1 = 0.

The logic for mode 3 operation for Timer 0 is shown in **Figure 852**. TL0 uses the Timer 0 control bits GATE0, TR0 and TF0, while TH0 is locked into a timer function (counting $f_{PCLK}/2$) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now sets TF1 upon overflow and generates an interrupt if ET1 is set (see also **Section 49.12.5**).

Mode 3 is provided for applications requiring an extra 8-bit timer. When Timer 0 is in mode 3 and TR1 is set, Timer 1 can be turned on by switching it to any of the other modes and turned off by switching it into mode 3.

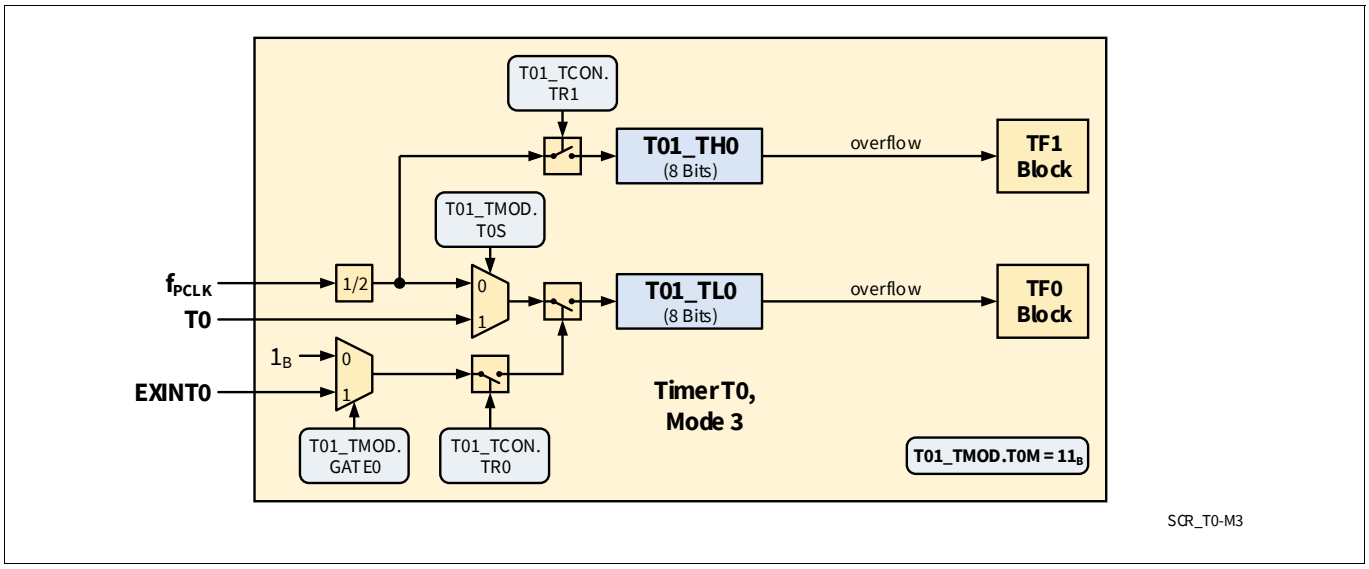

Figure 852 Timer 0, Mode 3: Two 8-Bit Timers/Counters

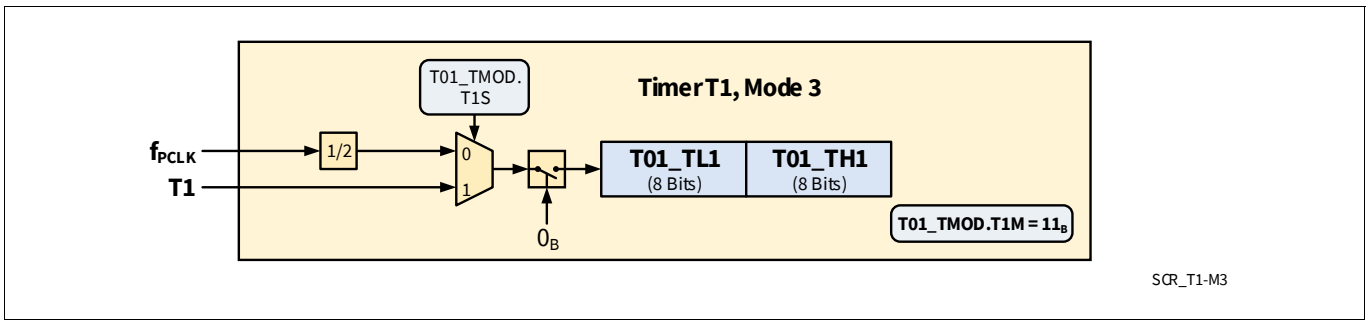

Figure 853 Timer 1 in Mode 3: Timer stops

49.12.5 T0/T1 Interrupt Flags and Requests

The following figure illustrates the T0/T1 interrupt requests. Besides the overflow interrupts, the T0/T1 module also handles the control for the two external interrupts EXINT0 and EXINT1.

Note that when timer T0 operates in Mode 3, flag TF0 is set by an overflow of the 8-bit timer part TL0, while flag TF1 is set by an overflow of the 8-bit timer part TH0. Besides being set by hardware, the flags can also be set by software (triggering an interrupt request).

The interrupt flags are automatically cleared by the CPU on entry into the respective service routine. They can also be cleared by software. See also the section on “Interrupt Structure 1” in chapter “Interrupt System”.

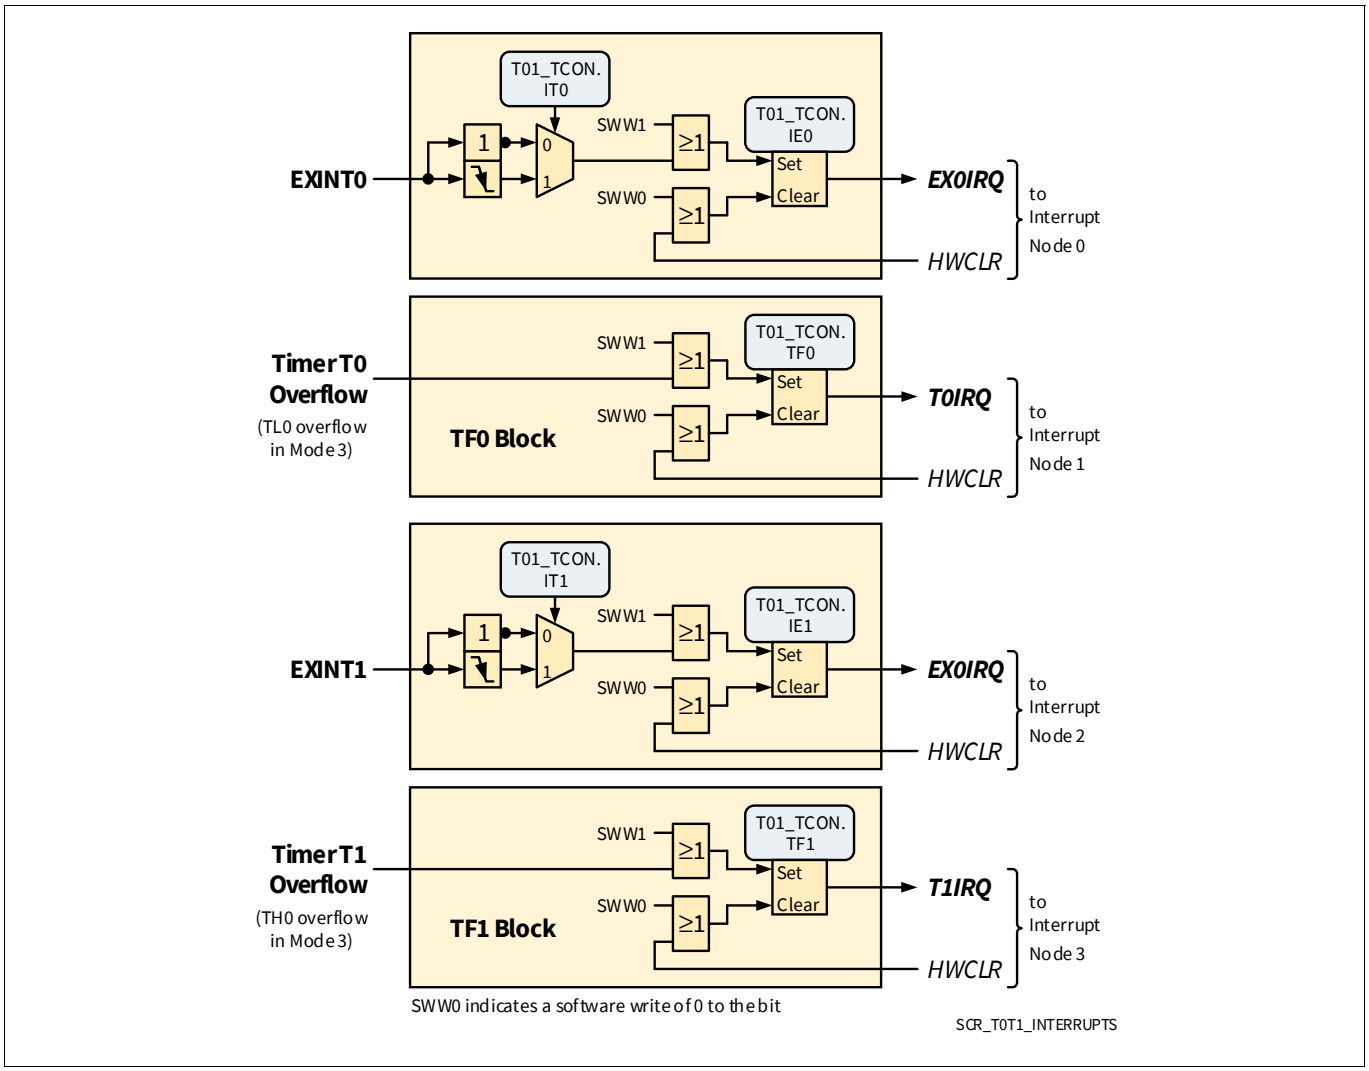

Figure 854 T0/T1 Interrupt Requests

49.12.6 Register Map

Seven SFRs control the operations of Timer 0 and Timer 1. They can be accessed from both the standard (non-mapped) and mapped SFR area.

Table 669 lists the addresses of these SFRs.

Table 669 Register Overview - T0 / T1 (sorted by Name)

Short Name	Description	RMAP	PAGE	Offset Address	Page Number

49.12.7 Register Description

The low bytes (TL0, TL1) and high bytes (TH0, TH1) of both Timer 0 and Timer 1 can be combined to a one-timer configuration depending on the mode used. Register T01_TCON controls the operations of Timer 0 and Timer 1. The operating modes of both timers are selected using register T01_TMOD. Register IEN0 contains bits that enable interrupt operations in Timer 0 and Timer 1.

49.13 T2CCU Module

The T2CCU module is a flexible timing unit with two 16-bit timers and a 6-channel Capture/Compare Unit (CCU).

49.13.1 Overview

The block diagram of the T2CCU module is shown in **Figure 855**. It consists of the Timer 2, the Capture/Compare Timer (CCT), and a Capture/Compare Unit (CCU). Control is available in the CCU, for each of its 16-bit capture/compare channels, to individually select either Timer 2 or the Capture/Compare Timer (CCT) as the time base. Both timers have a resolution of 16 bits. The clock frequency of T2CCU, f_{T2CCU}, is set at PCLK frequency.

The T2CCU can be used for various digital signal generation and event capturing like pulse generation, pulse width modulation, pulse width measuring etc. Target applications include various automotive control as well as industrial applications (frequency generation, digital-to-analog conversion, process control etc.).

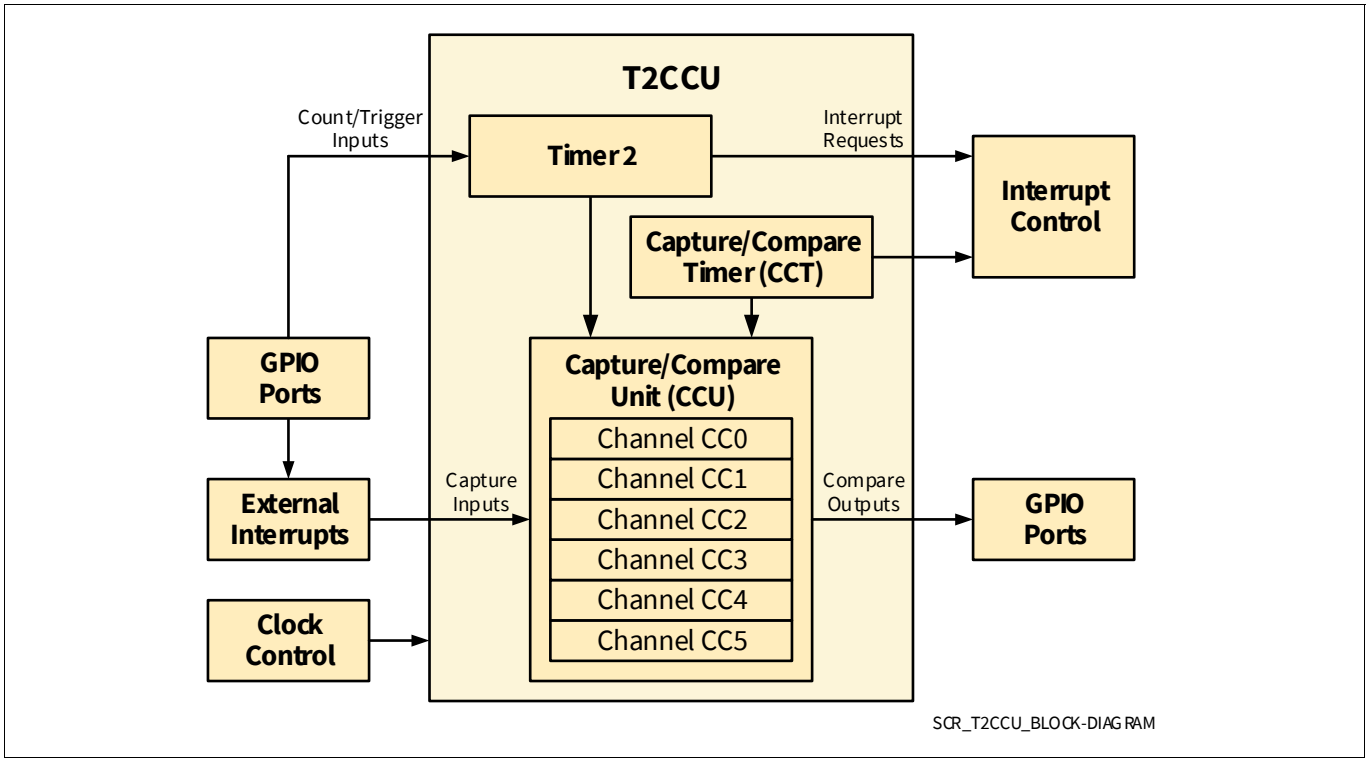

Figure 855 T2CCU Module Block Diagram

The T2CCU has the following features:

Timer 2

- 16-bit resolution
- Timer or counter operation
- 16-bit auto-reload mode
- Selectable up or down counting
- One channel, 16-bit capture mode
- Baudrate generator for U(S)ART
- Usable as base timer for the CCU

Capture/Compare Timer (CCT)

- 16-bit resolution
- Timer operation
- 16-bit reload mode
- Extremely flexible Capture/Compare Timer count rate by cascading with Timer 2
- Capture/Compare Timer may be ‘reset’ immediately by triggering overflow event

Capture/Compare Unit (CCU)

- 16-bit resolution
- Option to individually select either Timer 2 or the CCT as base timer for a channel
- Six compare channels in total
  - Shadow register for each compare register: Transfer via software control or on timer overflow
  - Compare Mode 0: Compare output signal changes from the inactive level to active level on compare match. Returns to inactive level on timer overflow.
    Compare Mode 0 can be configured with or without dead-time generation.
    Active level can be defined by register bit for channel groups A and B.
    Support of 0% to 100% duty cycle in compare mode 0.
  - Compare Mode 1: Full control of the software on the compare output signal level, for the next compare match.
  - Concurrent Compare Mode with channel 0
- Four capture channels, shared with the compare channels
  - Capture Mode 0: Capture on any external event (rising/falling/both edge) at the 4 pins T2CC0 to T2CC3.
  - Capture Mode 1: Capture upon writing to the low byte of the corresponding channel capture register.
  - Capture mode 0 or 1 can be established independently on the 4 capture channels.

49.13.2 Timer 2

The Timer 2 of the T2CCU has the following features:

- 16-bit auto-reload mode
- selectable up or down counting
- One channel, 16-bit capture mode
- Timer 2 can be used as a stand-alone timer, aside of the CCU, or can be used as a base timer for the CCU

49.13.2.1 Basic Timer 2 Operations

The following sections describe the basic functions of Timer 2.

49.13.2.1.1 Timer 2 Start/Stop and Count Control

The count input to Timer 2 is controlled by the run bit TR2, located in register T2_CON. Timer 2 can be started by setting run bit TR2 either through hardware or software. The timer can only be stopped via software by clearing bit TR2.

The run bit TR2 can be set by various events:

- By software: Write ’1’ to bit T2CON.TR2.
- By hardware:
  - A selectable transition at input T2EX. This input is enabled/disabled via bit T2_MOD.T2RHEN. The active transition of the input, either a rising or a falling edge, is selected via bit T2_MOD.REGS.
    Please note that input T2EX can also be used for the capture/reload control of Timer 2 (see following sections).
  - Via the synchronous start signal from the capture/compare timer CCT. This event is enabled/disabled via bit TIMSYN in register T2CCU_CCTCON. This option can be used to trigger a synchronous start of both timers, timer 2 and timer CCT. See **Synchronized Start of Timer 2 and CCT Timer** for details on this option.

All of these actions set the run bit TR2 to 1. Its output controls the count input to the Timer 2. The state of the run bit can be read by software. To stop the timer, clear the run bit TR2 by writing a ‘0’ to it.

Figure 856 illustrates the start/stop and count control of timer 2. The count input selection is described in the next section. In the further diagrams of Timer 2, the start/stop control is shown as a block, together with the count input control. For the details, please refer to **Figure 856**.

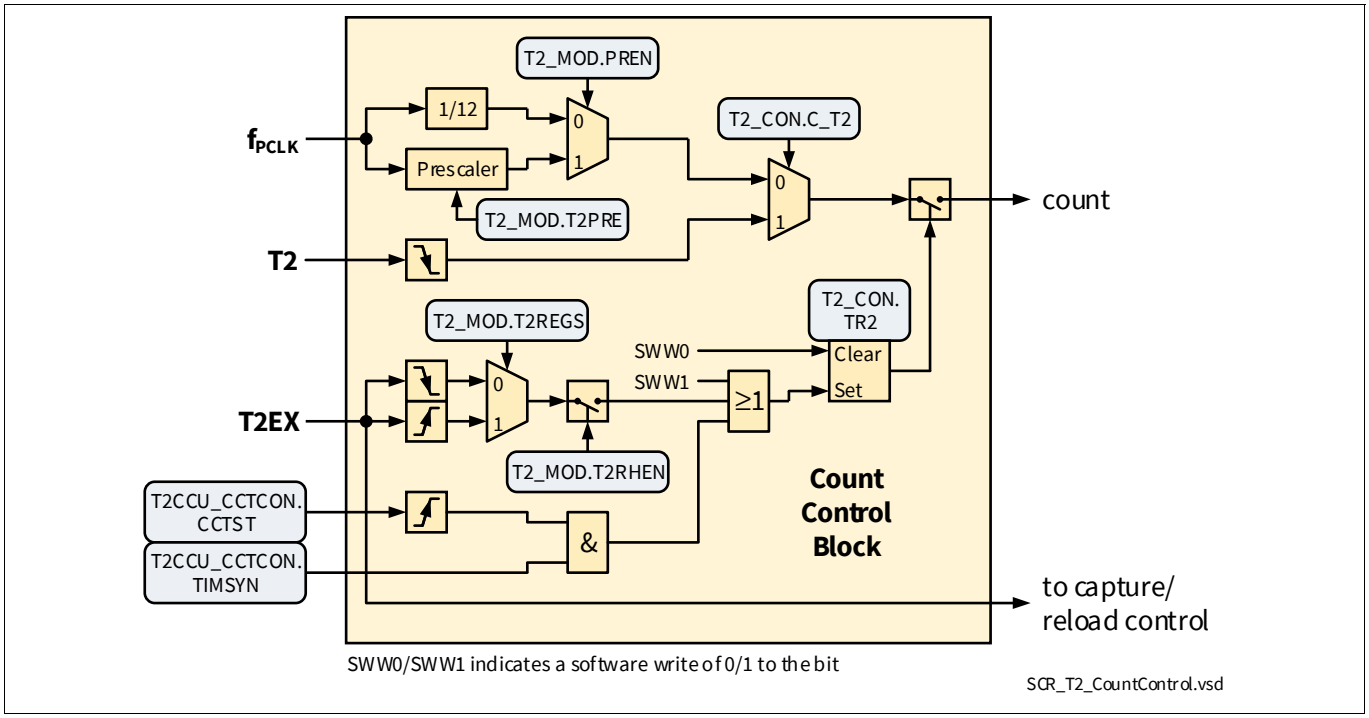

Figure 856 Timer 2 Start/Stop and Count Control

49.13.2.1.2 Count Clock Options

Timer 2 can either operate as a timer or as a counter. The selection is made via bit C_T2 in register T2_CON.

- Timer mode (C_T2 = 0):
  Either $f_{PCLK}/12$ or f_{PCLK} divided by a programmable prescaler can be selected as input clock to Timer 2. The selection is made via bit PREN in register T2_MOD.
  The divide factor for the programmable prescaler is chosen via bitfield T2_MOD.T2PRE.
- Counter mode ((C_T2 = 1):
  Timer 2 counts in response to a 1-to-0 transition at input T2. Input T2 is sampled over 2 PCLK clock cycles. If a 1 was detected during the first clock and a 0 was detected in the following clock, then a count clock for Timer 2 is generated. Therefore, the input levels should be stable for at least 1 PCLK clock cycle.

49.13.2.2 Timer 2 Operating Modes

The following sections describe the various operating modes of Timer 2.

Note: In order to simplify the diagrams, the connection of the Timer 2 contents to the Capture/Compare Unit (CCU) is not shown in the following figures.

49.13.2.2.1 Reload Mode of Timer 2

In reload mode of Timer 2 (bit CP_RL2 in register T2_CON is 0), the RC2 register (register pair T2_RC2H | T2_RC2L) is used to hold a reload/trigger value for Timer 2:

- When down-counting is disabled, the value in RC2 is loaded into Timer 2 either on overflow or in response to an external signal transition.
- When down-counting is enabled, the value in RC2 is used as a trigger value to load $FFFF_H$ into Timer 2.

In the following sections, these operations are described in detail.

*Note: For a description of the interrupt request and flag logic "TF2 Block" and "EXF2 Block", please see **Section 49.13.2.3, Timer 2 Interrupt Requests**.*

Reload Operation in Up-Counting Mode

When bit DCEN in register T2_MOD is 0, Timer 2 can only count up, and the RC2 register is used to hold a reload value. **Figure 857** shows an operational block diagram of Timer 2 in this configuration.

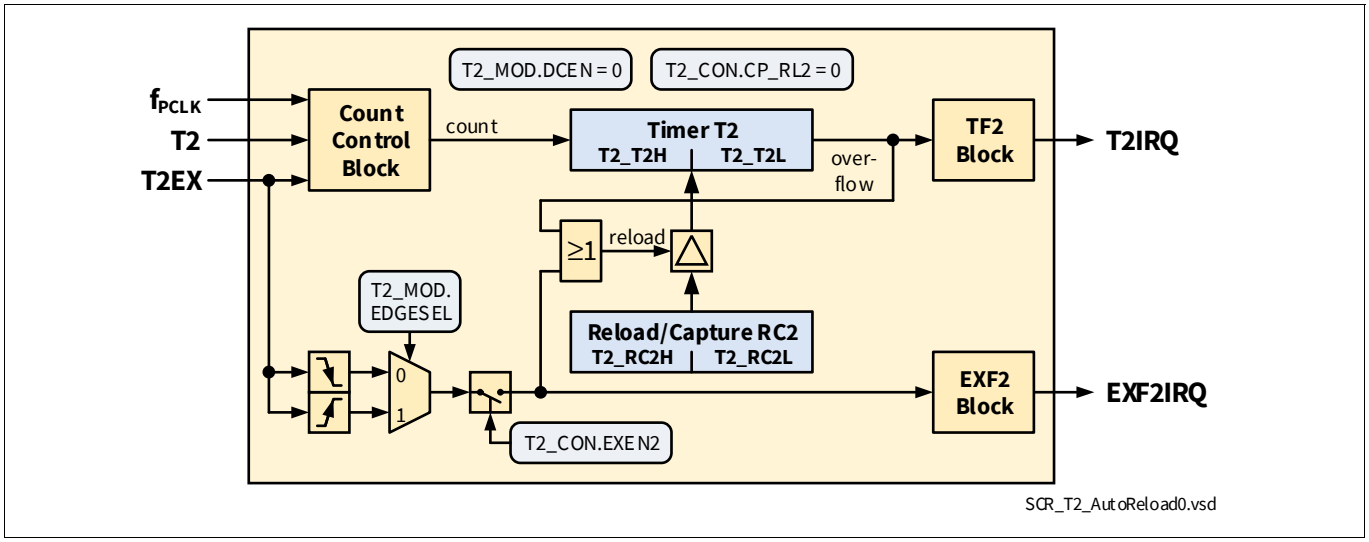

Figure 857 Reload Operation in Up-Counting Mode (T2_MOD.DCEN = 0)

Depending on bit EXEN2 in register T2_CON, two options exist:

- EXEN2 = 0: Reload on overflow only (auto-reload):
  - Once the timer is started, it counts up to its maximum value $FFFF_H$.
  - The next count clock pulse leads to an overflow condition: Timer 2 is loaded with the contents of register RC2, and flag TF2 in register T2_CON is set to 1 (can be used to generate an interrupt request).
  - With the next count clock pulse(s), the timer continues to count up from the reloaded value.
- EXEN2 = 1: Reload on overflow or on external signal edge:
  - Once the timer is started, it counts up.
  - A reload of Timer 2 is performed either on an overflow condition (auto-reload, see above) or by a selected signal edge on input T2EX (external reload). With the next count clock pulse(s), the timer continues to count up from the reloaded value.
  - The signal edge can either be a positive (0-to-1), or a negative (1-to-0) transition at input T2EX. The selection is done via bit EDGESEL in register T2_MOD.
  - The selected signal transition also sets flag EXF2 in register T2_CON to 1 (can be used to generate an interrupt request).

Note that the input signal T2EX can be used for both, the timer count control and the external reload function.

When bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The reload will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

Note: In counter mode, if the reload via T2EX and the count clock T2 are detected simultaneously, the reload takes precedence over the count. The counter increments its value with the following T2 count clock.

Reload Operation in Up/Down-Counting Mode

When bit DCEN in register T2_MOD is set to 1, the up/down count selection is enabled for Timer 2. The count direction is determined by the level at input pin T2EX. **Figure 858** shows an operational block diagram of Timer 2 in this configuration.

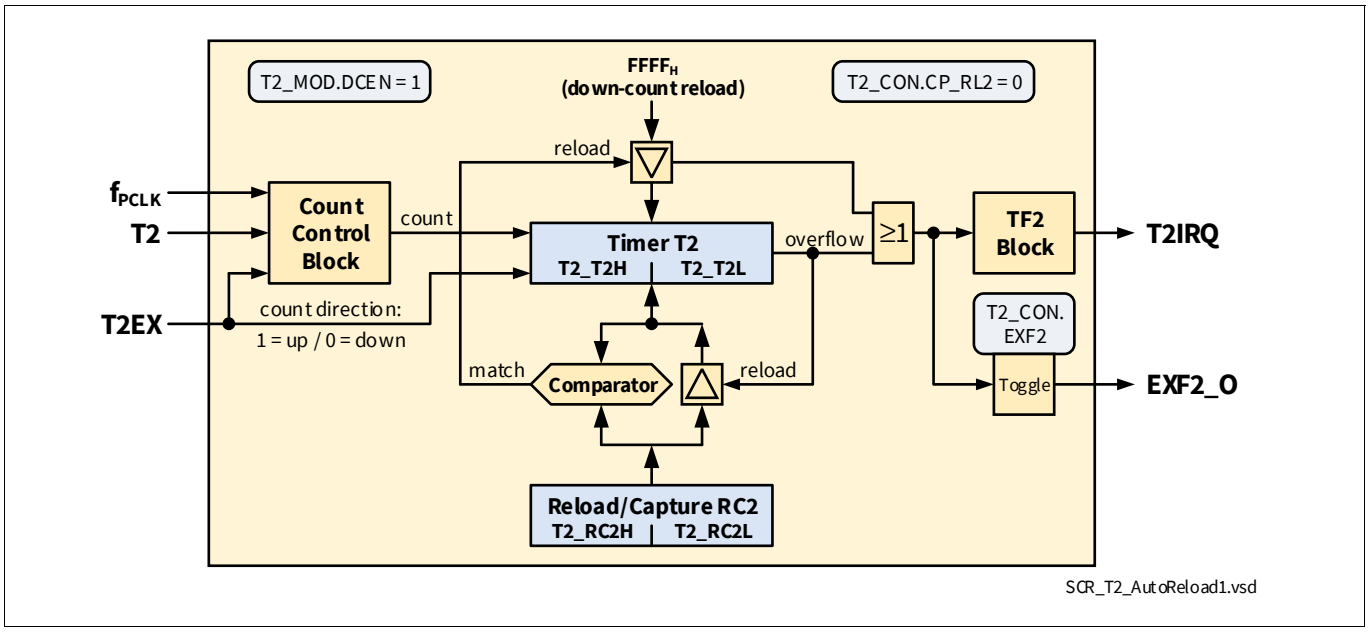

Figure 858 Reload Operation in Up/Down-Counting Mode (T2_MOD.DCEN = 1)

The operation in this mode is as follows:

- A logic 1 at pin T2EX sets the Timer 2 to up-counting mode:
  - Once the timer is started, it counts up to its maximum value FFFF$_H$.
  - The next count clock pulse leads to an overflow condition: Timer 2 is loaded with the contents of register RC2, and flag TF2 in register T2_CON is set to 1 (can be used to generate an interrupt request).
  - With the next count clock pulse(s), the timer continues to count up from the reloaded value.
- A logic 0 at pin T2EX sets the Timer 2 to down-counting mode:
  - Once the timer is started, it counts down.
  - When the timer contents match the value stored in register RC2, an “underflow” condition is generated. Timer 2 is loaded with the value FFFF$_H$, and flag TF2 in register T2_CON is set to 1 (can be used to generate an interrupt request).
  - With the next count clock pulse(s), the timer continues to count down from FFFF$_H$.

If bit T2RHEN is set, Timer 2 can be started either by rising edge (T2REGS = 1) at pin T2EX and then proceed with the up counting, or be started by falling edge (T2REGS = 0) at pin T2EX and then proceed with the down counting.

In this mode, bit EXF2 toggles whenever an overflow or an underflow condition is detected. This flag, however, does not generate an interrupt request.

49.13.2.2.2 Capture Mode of Timer 2

In capture mode of Timer 2 (bit T2_CON.CP_RL2 is 1), the RC2 register (register pair T2_RC2H | T2_RC2L) is used to latch the current contents of the timer in response to an external event.

Figure 859 shows an operational block diagram of Timer 2 in this configuration.

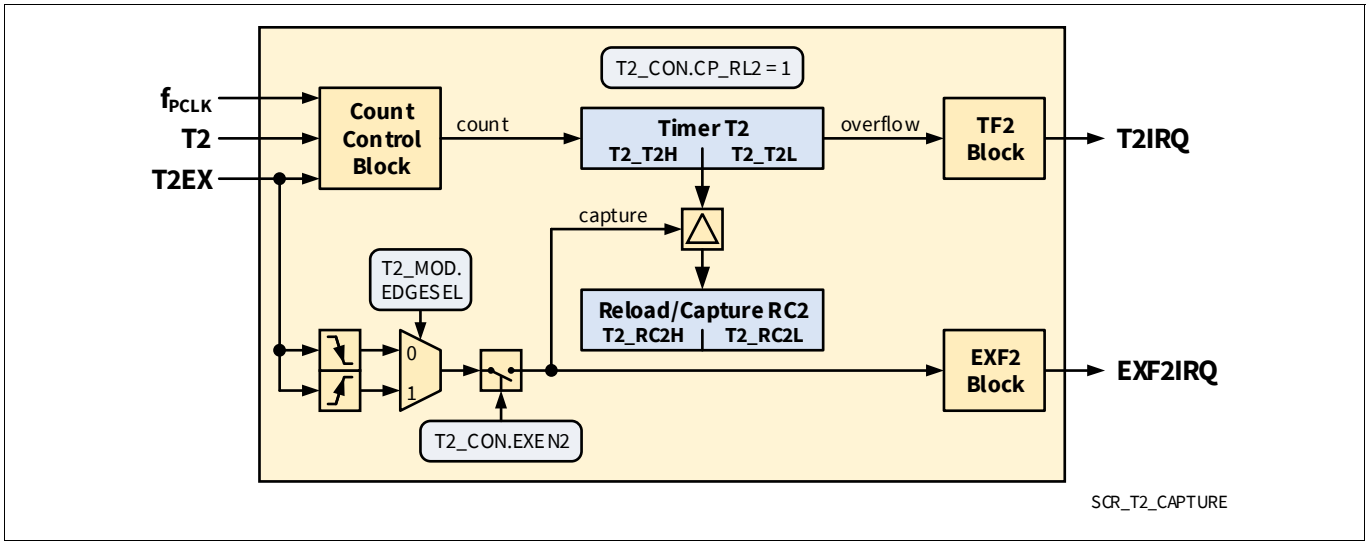

Figure 859 Capture Mode of Timer 2

To operate the timer in capture mode, the following settings must be made:

- Enable capture mode: Set bit CP_RL2 in register T2_CON to 1.
- Disable the down-count function: Clear bit DCEN in register T2_MOD to 0.
- Enable the external input T2EX: Set bit EXEN2 in register T2_CON to 1.

The timer functions as a 16-bit timer and always counts up to $FFFF_H$. With the next clock pulse, an overflow condition occurs; bit TF2 is set (which can generate an interrupt request), and the timer registers are loaded with 0000_H. The counting continues with the next clock pulse(s).

With a falling or rising edge (chosen by T2_MOD.EDGESEL) at input T2EX, the contents of the timer register are captured into the RC2 register. At the same time, bit EXF2 in register T2_CON is set to 1.
The external input is sampled in every PCLK clock cycle. When a sample shows a low (high) level in one PCLK clock cycle, and a high (low) in the next PCLK clock cycle, a transition is recognized. If the capture signal is detected while the timer is being incremented, the timer is first incremented before the capture operation is performed. This ensures that always the latest value of the timer register is captured.

Note that the input signal T2EX can be used for both, the timer count control and the external capture function.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The capture will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

49.13.2.3 Timer 2 Interrupt Requests

Timer 2 can generate two different interrupt requests to the CPU:

- An interrupt request on timer overflow, and
- an interrupt request on an external transition at input T2EX.

These interrupt requests are detailed in the following sections.

49.13.2.3.1 Timer Overflow Interrupt Request

Figure 860 shows a functional diagram of the overflow interrupt request generation. The flag TF2 in register T2_CON is set on an overflow of the timer (in certain modes), or it can be set by software. When enabled via bit TF2EN in register T2_CON1, the signal which sets the TF2 flag will generate an interrupt request to the CPU.

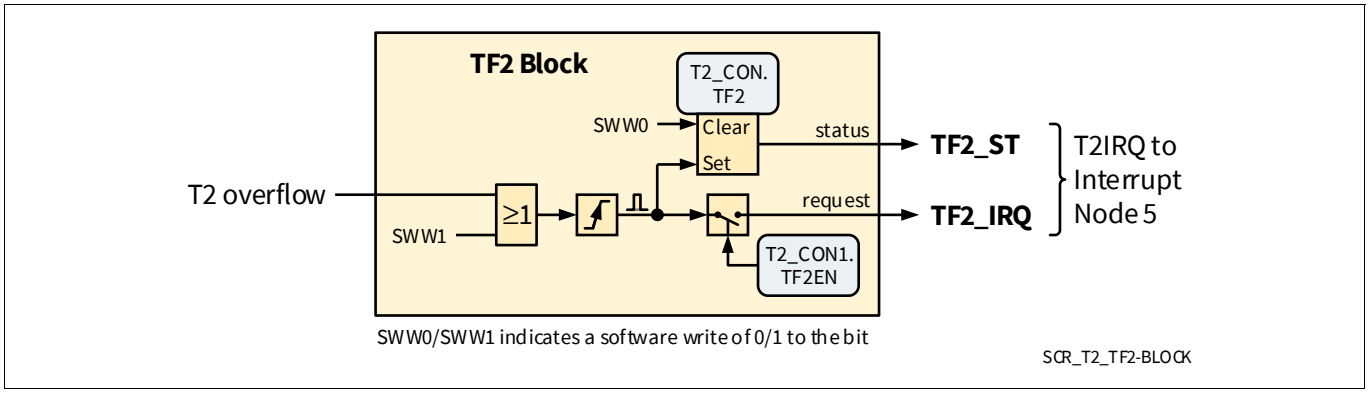

Figure 860 TF2 Flag Block

The overflow flag and the corresponding overflow interrupt request (if enabled) will be set/generated in the following cases:

- By software:
  By writing a 1 to flag T2_CON.TF2, the flag will be set and an interrupt request (if enabled) will be generated.
- Reload Operation in Up-Counting Mode (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 0):
  When an overflow of Timer 2 occurs.
- Reload Operation in Up/Down-Counting Mode (T2_MOD.DCEN = 1, T2_CON.CP_RL2 = 0):
  When an overflow of Timer 2 occurs, or when an “underflow” (timer contents match the value stored in register RC2) occurs.
- Capture Mode of Timer 2 (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 1):
  When an overflow of Timer 2 occurs.

Flag TF2 must be cleared by software.

Note: The overflow interrupt request logic of Timer 2 is basically of type “interrupt structure 2” (see section “Interrupt Structure” in chapter “Interrupt System”), however, the status signal does not have an individual enable control. Thus, in order to clear the pending request flag in the interrupt system, it is necessary to clear all status flags assigned to that interrupt node, even if the respective interrupt request is not enabled.

Note: Although two signals, TF2_IRQ and TF2_ST are connected to the respective interrupt node, the general signal name T2IRQ is used to represent both signals (interrupt structure 2).

49.13.2.3.2 Timer External Interrupt Request

Figure 861 shows a functional diagram of the external interrupt request generation. The flag EXF2 in register T2_CON is set on an external transition at input T2EX (in certain modes), or it can be set by software. When enabled via bit EXF2EN in register T2_CON1, the signal which sets the EXF2 flag will generate an interrupt request to the CPU.

The output of flag EXF2 is also connected to certain GPIO port lines.

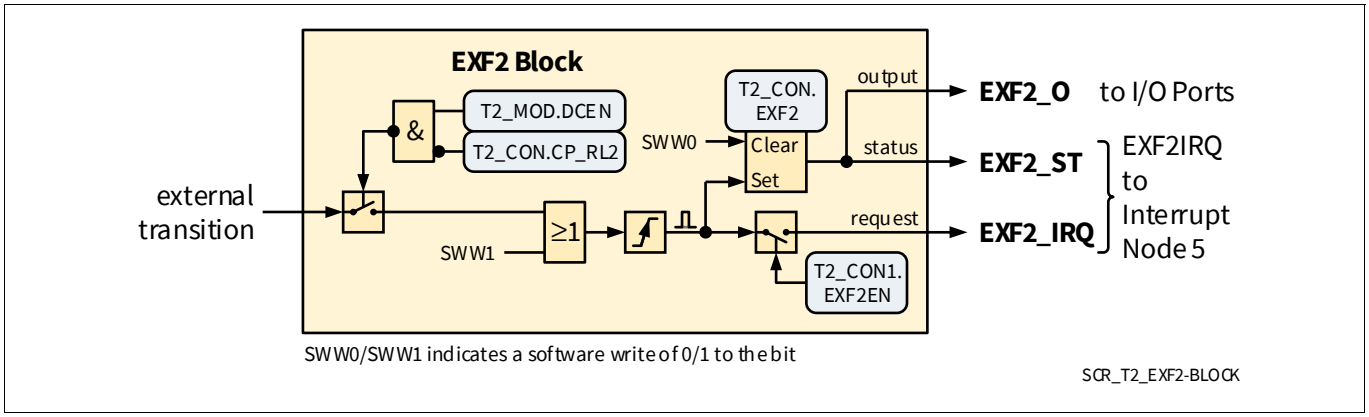

Figure 861 EXF2 Flag Block

The external transition flag EXF2 and the corresponding external interrupt request (if enabled) will be set/generated in the following cases:

- By software:
  By writing a 1 to flag T2_CON.EXF2, the flag will be set and an interrupt request (if enabled) will be generated.
- Reload Operation in Up-Counting Mode (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 0):
  When bit T2_CON.EXEN2 is set and the selected transition at input T2EX occurs.
- Reload Operation in Up/Down-Counting Mode (T2_MOD.DCEN = 1, T2_CON.CP_RL2 = 0):
  In this mode, flag EXF2 will toggle on each overflow or “underflow” (timer contents match the value stored in register RC2) of Timer 2. No interrupt request will be generated (this is not shown in **Figure 861**).
- Capture Mode of Timer 2 (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 1):
  When bit T2_CON.EXEN2 is set and the selected transition at input T2EX occurs.

Flag EXF2 must be cleared by software.

Note that while the timer/counter function is disabled (TR2 = 0), it is still possible to generate a Timer 2 interrupt to the core via an external event at input T2EX, as long as Timer 2 remains enabled (PMCON1.T2CCU_DIS = 0). To achieve this, bit EXEN2 in register T2_CON must be set. As a result, any transition on T2EX will cause either a dummy reload or a dummy capture, depending on the CP_RL2 bit selection.

Note: The external interrupt request logic of Timer 2 is basically of type “interrupt structure 2” (see section “Interrupt Structure” in chapter “Interrupt System”), however, the status signal does not have an individual enable control. Thus, in order to clear the pending request flag in the interrupt system, it is necessary to clear all status flags assigned to that interrupt node, even if the respective interrupt request is not enabled.

Note: Although two signals, EXF2_IRQ and EXF2_ST are connected to the respective interrupt node, the general signal name EXF2IRQ is used to represent both signals (interrupt structure 2).

49.13.2.4 Input Selection for Timer 2

Timer 2 can be used as an event counter which counts 1-to-0 transitions at the external input T2. This input is selected from three different sources, T2A, T2B and T2C. The selection is performed by the SFR bits MODPISEL3.T2IS. In addition, there are eight sources for the input T2EX for Timer 2. They can be selected by MODPISEL3.T2EXIS.

The pin assignment for the T2CCU is shown in the GPIO chapter of the SCR.

The bitfield PAGE of SCU_PAGE register must be programmed before accessing the MODPISEL3 register.

Peripheral Input Select Register 3

The MODPISEL3 register is used for input pin selection of the T2CCU and SSC modules. The register is on SCU_PAGE. The connections of Timer 2 T2EXF and T2EXG are available via PMS.

49.13.2.5 Timer 2 Register Map

All Timer 2 register names described in the following sections are referenced in other chapters of this document with the module name prefix “T2_”, e.g., T2_CON.

The Timer 2 SFRs are located in the standard (non-mapped) SFR area. **Table 679** lists these addresses.

Table 679 Register Overview - Timer 2 (sorted by Name)

49.13.3 Capture/Compare Timer of T2CCU

The Capture/Compare Timer (CCT) is part of the T2CCU, and is a dedicated time base for the CCU capture/compare operations. **Figure 862** shows a block diagram of the CCT timer.

Note: In order to simplify the diagrams, the connection of the CCT contents to the Capture/Compare Unit (CCU) is not shown in the following figures.

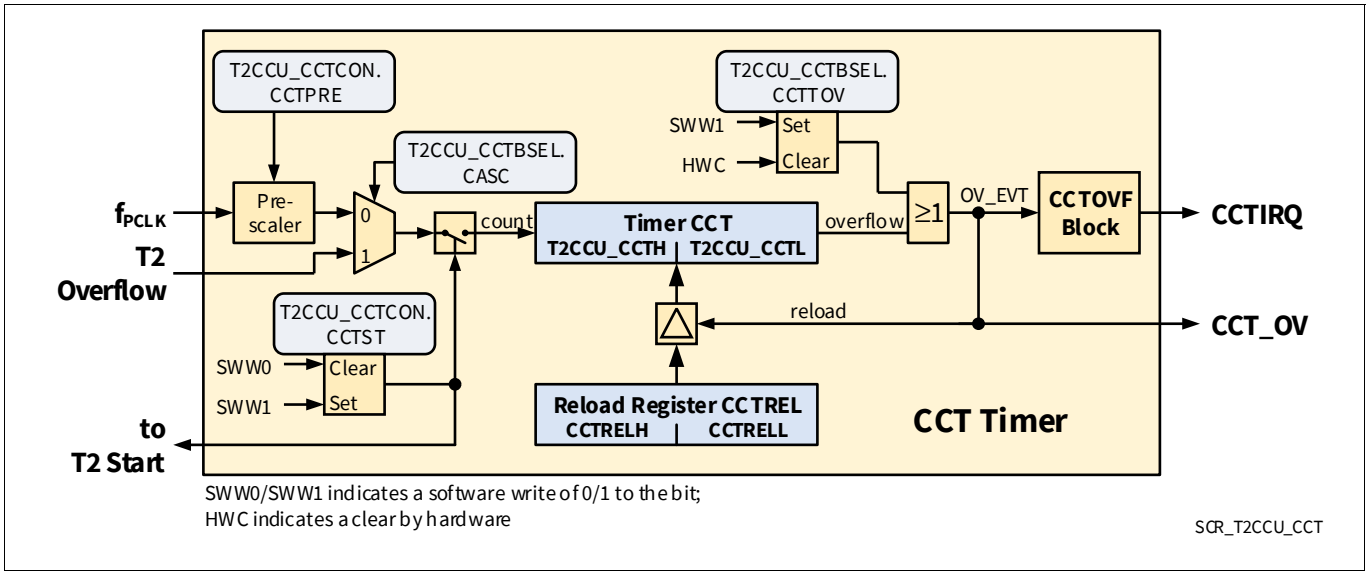

Figure 862 CCT Timer Block Diagram

49.13.3.1 CCT Timer Basic Operation

The features of the CCT are:

- 16-bit timer, comprised of register pair T2CCU_CCTH | T2CCU_CCTL (in the following simply called CCT).
- 16-bit reload register, comprised of register pair T2CCU_CCTRELH | T2CCU_CCTRELL (in the following simply called CCTREL).
- Start or stop controlled by software.
- Input clock prescaler with 12 selectable stages (input clock range from f_{PCLK} to $f_{PCLK}/2048$).
- Once started, the CCT counts up from the initial value stored in its count register to $FFFF_H$. With the next clock pulse, it overflows, and gets loaded with the value stored in register CCTREL. The counting up continues from this value with the following clock pulse(s).
- CCT can be concatenated with Timer 2.
- Optional synchronous start of CCT and Timer 2 possible.
- CCT overflow event is generated either on CCT timer overflow or triggered by software. CCT overflow event performs the following:
  - Reloads CCT with contents of register CCTREL.
  - Sets flag CCTOVF to 1 (can generate an interrupt request).
  - Pulses output line CCT_OV.

When writing to the CCT timer register pair T2CCU_CCTH | T2CCU_CCTL, the following rules have to be obeyed:

- When the CCT is not running (CCTCON.CCTST = 0), a write to the byte registers T2CCU_CCTH/T2CCU_CCTL updates the corresponding byte of the CCT timer.

- When the CCT is running (CCTCON.CCTST = 1), register T2CCU_CCTH has to be written first (this value is held in a shadow register). With the following write to register T2CCU_CCTL, both actual timer registers are updated, and the timer continues counting up from the written value.

The CCT may be stopped at any time by clearing bit CCTST to 0. The timer registers will hold the last count value.

49.13.3.2 Software-Triggered CCT Timer Overflow

A special feature of the CCT timer is the possibility to 'reset' the timer immediately by a Software-Triggered Timer Overflow event. By 'reset', the CCT timer is reloaded and starts counting from the value from the reload registers, while all actions associated with the operation mode of the timer channels on base timer overflow will be executed. When setting bit T2CCU_CCTBSEL.CCTTOV by software, the CCT timer overflow event is triggered asynchronously to the timer count operation. Bit CCTTOV is held at 1 for one PCLK cycle, then it is automatically cleared by hardware.

An example usage for a channel operating in compare mode 0 is illustrated in **Figure 863**. For more details on compare mode 0, refer to **Section 49.13.4.2**.

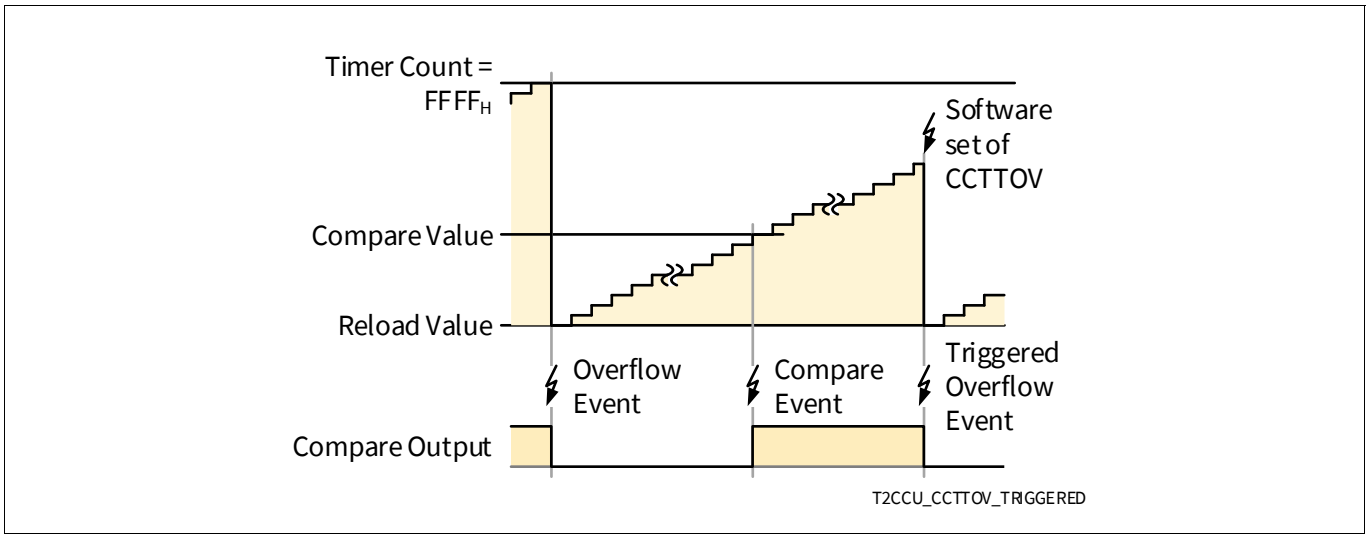

Figure 863 Example of Channel in Compare Mode 0 on 'Triggered Timer Overflow' Event

49.13.3.3 Synchronized Start of Timer 2 and CCT Timer

As described in the previous sections, the two timers of the T2CCU are usually started or stopped individually: Timer 2 via bit TR2, and the CCT via bit CCTST.
However, it is also possible to start both timers synchronously. The procedure required to perform this is listed below:

1. Ensure CCT timer is not already running;
2. Clear bit TR2 (stop Timer 2) and ensure timers are properly initialized;
3. Set bit TIMSYN in register CCTCON to enable synchronized timer starts;
4. Set bit CCTST; this will also set bit TR2.

Steps 3 and 4 can be combined in a single write operation to SFR T2CCU_CCTCON.

To stop the timers, the respective timer bits need to be cleared independently.

49.13.3.4 Cascading Timer 2 and CCT Timer for Flexible Count Rate

Especially for applications requiring the base timer to run at a flexible count rate, it is possible to cascade Timer 2 with the CCT timer. When bit T2CCU_CCTBSEL.CASC is set, the CCT timer will increment its count with every

overflow of Timer 2. In this mode, Timer 2 acts as a prescaler for timer CCT. See **Figure 864** for a block diagram of this option.

Note: Timer 2 may be configured in timer mode or as an external event counter via input T2.

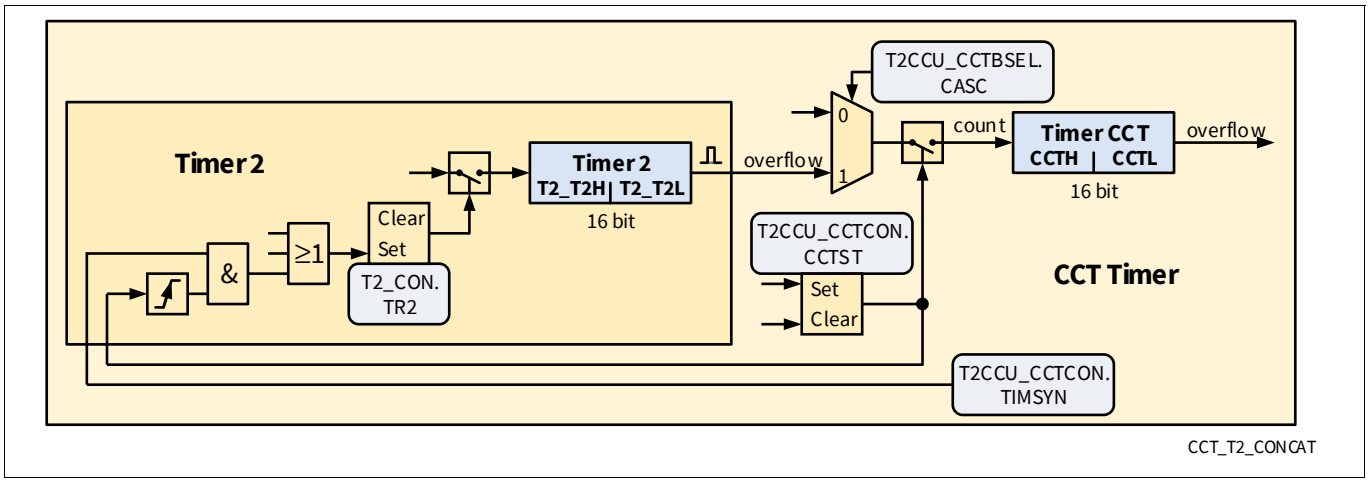

Figure 864 Cascading Timer 2 with the CCT Timer

49.13.3.5 CCT Overflow Flag and Interrupt Request

The overflow flag and the corresponding overflow interrupt request (if enabled) will be set/generated in the following cases:

- By software:
  - By writing a 1 to flag T2CCU_CCTCON.CCTOVF.
  - By writing a 1 to bit T2CCU_CCTBSEL.CCTTOV (Software-Triggered Timer Overflow, see **Section 49.13.3.2**).
- By hardware, when an overflow of the CCT timer occurs.

An interrupt request to the CPU is enabled when the enable bit T2CCU_CCTCON.CCTOVEN is set to 1.

Note that flag CCTOVF must be cleared by software.

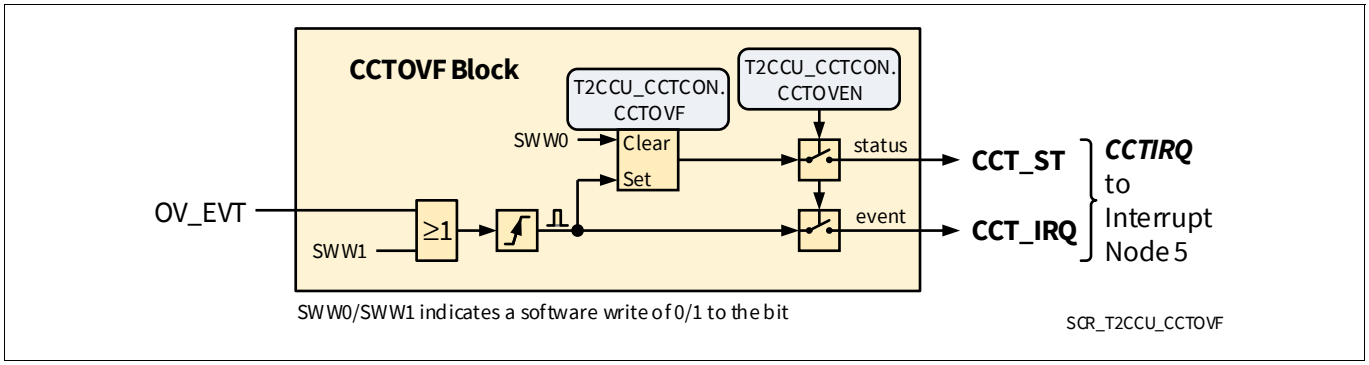

Figure 865 CCT Overflow Flag Block

Note: Although two signals, CCT_IRQ and CCT_ST are connected to the respective interrupt node, the general signal name CCTIRQ is used to represent both signals (interrupt structure 2).

49.13.4 Capture/Compare Unit (CCU) of the T2CCU

The Capture/Compare Unit (CCU) of the T2CCU consists of four 16-bit capture/compare channels (CC0 - CC3) and two 16-bit compare-only channels (CC4 - CC5), illustrated in **Figure 866**.

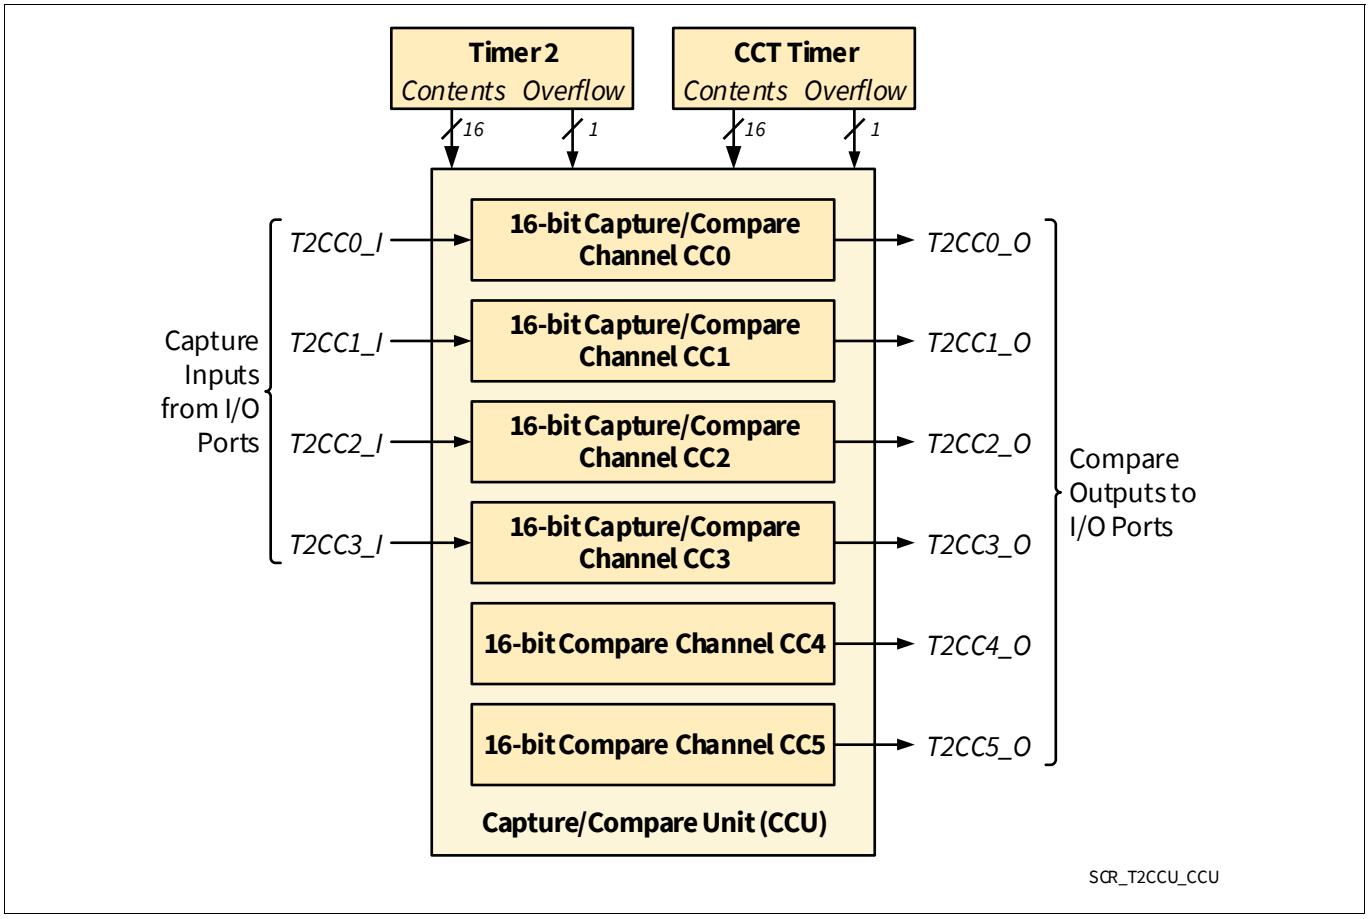

Figure 866 T2CCU Capture/Compare Unit (CCU) Overview

The main features of the CCU are:

- 4 channels (CC0 - CC3), which can be used for capture or compare operation.
- 2 channels (CC4 - CC5), which can be used for compare operation.
- Each capture channel (CC0 - CC3) has a capture input T2CCx_I, coming from the I/O pins.
- Each compare channel (CC0 - CC5) has a compare output signal T2CCx_O, leading to the I/O pins.
- Each channel can individually select either Timer 2 or the CCT as a base timer (using the contents and the overflow signal of the selected timer). The capture/compare resolution for a channel is determined by the operating frequency of the selected base timer.
- Compare Operation: Various compare modes are available:
  - Compare Mode 0 without dead-time generation.
  - Compare Mode 0 with dead-time generation.
  - Compare Mode 1.
  - Concurrent Compare Mode.
- Capture Operation: Two modes are available:
  - Hardware-triggered capture.
  - Software-triggered capture.

The input/output signals of the CCU are assigned as alternate functions of general-purpose I/O ports. The compare outputs share the same pins as the capture inputs, and the ports are (partly) shared with External Interrupt Inputs, see **Table 687**. The corresponding external interrupt request flags are set for the capture/compare function. See also **Section 49.13.4.4**.

Table 687 Input/Output Signals of the CCU

Output/Input	Function
T2CC0_O / T2CC0_I / EXINT3	Compare output/Capture input for channel 0
T2CC1_O / T2CC1_I / EXINT4	Compare output/Capture input for channel 1
T2CC2_O / T2CC2_I / EXINT5	Compare output/Capture input for channel 2
T2CC3_O / T2CC3_I / EXINT6	Compare output/Capture input for channel 3
T2CC4_O	Compare output for channel 4
T2CC5_O	Compare output for channel 5

49.13.4.1 Capture/Compare Operation

The following sections describe the compare and capture operations of the CCU in detail.

Note: For defined behavior, it is required of the user to initialize properly all the T2CCU related SFRs before enabling any T2CCU capture or compare mode.

49.13.4.2 Compare Operation

In compare operation, the contents of a compare register can be regarded as a “time stamp”, at which the corresponding output reacts in a predefined way (with either a positive or negative transition). Variation of this “time stamp” changes the waveform of a rectangular output signal at the pin. As a variation of the duty cycle of a periodic signal, this may be used for pulse width modulation as well as for a continually controlled generation of any kind of square waveforms. Various compare modes are available to cover a wide range of possible applications.

The value stored in a compare register is constantly compared to the current value of the selected base timer. When the timer value is equal to or higher than the compare value, a “compare match” is detected, and appropriate actions are taken.

Figure 867 illustrates the configuration of the CCU for compare operation. The following items are important for the compare operation:

- Each 16-bit compare registers CCx (x = 0..5) is represented by two 8-bit registers, named T2CCU_CCxH (high-byte register) and T2CCU_CCxL (low-byte register).
- The desired compare mode is selected by bit T2CCU_COCON.COMOD, and applies to all enabled compare channels.
- For output polarity control and the dead-time generation, the channels are organized into two groups. Group A comprises channels CC0, CC2, and CC4, while Group B comprises channels CC1, CC3, and CC5.
- In all compare modes, the new output value arrives at the port pin within the same PCLK cycle in which the internal compare signal is activated.
- The compare output is only actively driven when the compare function is enabled. When the compare function is enabled by writing to a channel’s CCMx bits, the respective compare output is latched (as initial value) based on the settings of the channel’s registers and bit.
- The rising edge of the compare match signal is the active edge for all compare match operations.

- Each compare register has a shadow transfer mechanism which allows glitch-free pulse width modulation; see detailed description below.

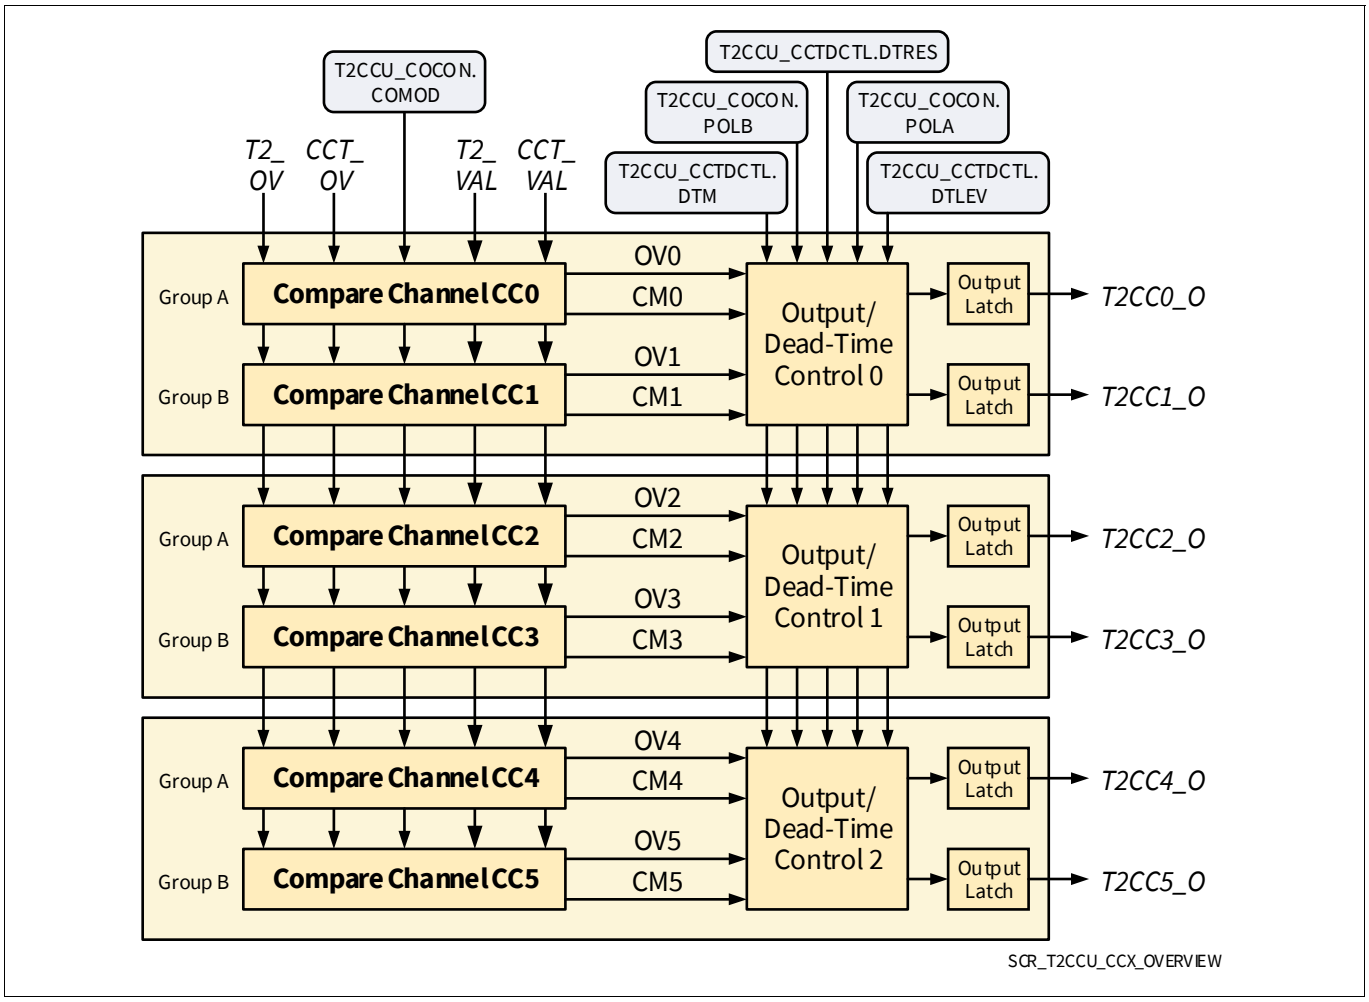

Figure 867 CCU Compare Channel Configuration Overview

Shadow Registers for Compare Registers

To update a 16-bit compare value, two write accesses are required because of the two 8-bit registers of a compare channel. To allow for a glitch free update of a compare value without an intermediate “wrong” value, shadow registers are implemented. Software write accesses do not target the actual compare register, but the respective shadow register. After the write access, the value is transferred from the shadow register into the actual compare register via one of two options:

1. Hardware Control: The transfer from the shadow register into the compare register is triggered by the overflow signal of the selected base timer. In this case, the update of the compare registers is controlled by hardware and is therefore independent from any service delay.
   This option is selected by setting bit T2CCU_COSHDW.TXOV to 1.
2. Software Control: The transfer from the shadow register into the compare register is triggered by setting the corresponding bit T2CCU_COSHDW.COOUTx via software. Bit COOUTx will be cleared automatically by hardware at the next PCLK, after being set.
   This option is selected by setting bit T2CCU_COSHDW.ENSHDW to 1.

In both cases, the rising edge of the event pulse signal is the active edge for the transfer from shadow register to compare register.

Note that it is not allowed to set both bits, TXOV and ENSHDW, at the same time. If bit TXOV is set to enable shadow transfer on timer overflow, bit ENSHDW will be cleared by internal hardware to disable shadow transfer by software.

Figure 868 illustrates the shadow transfer mechanism.

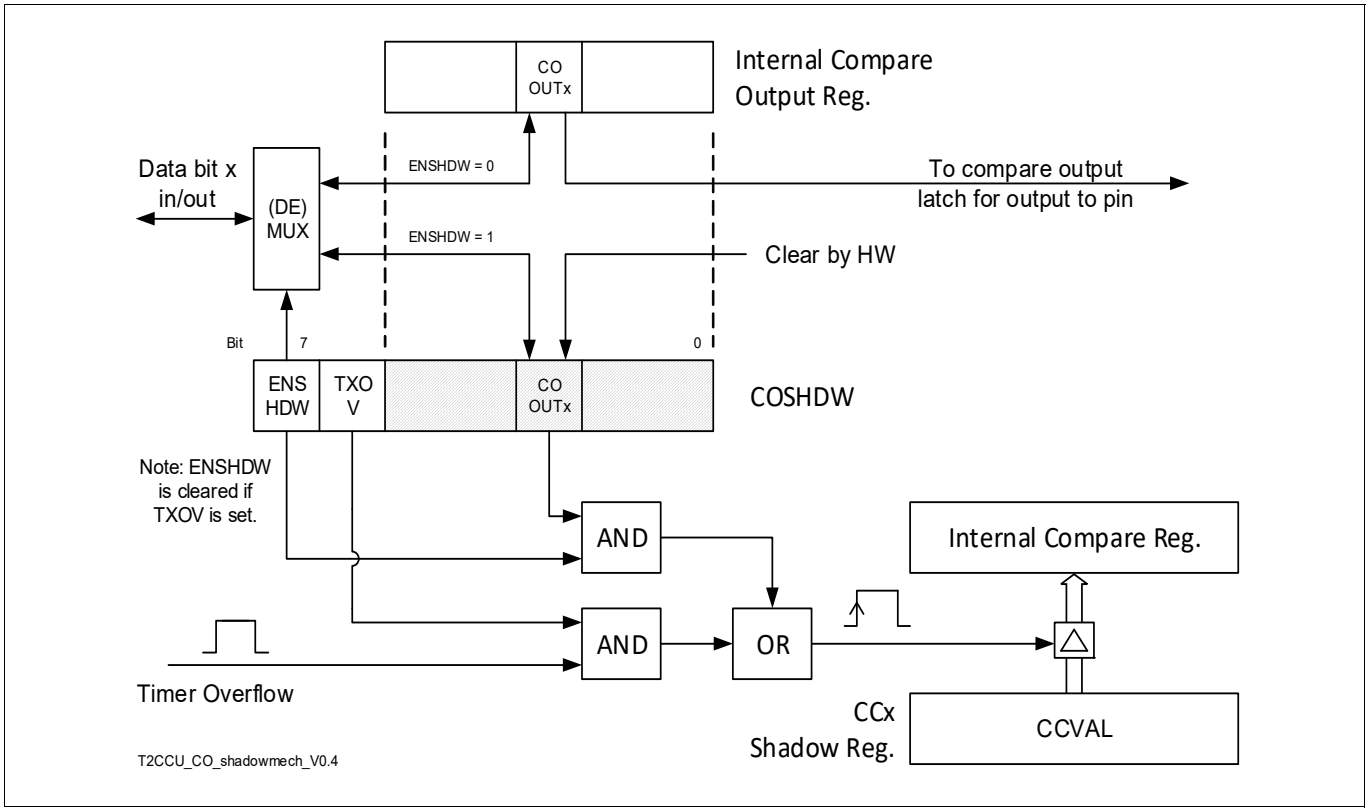

Figure 868 Compare Value Shadow Transfer Mechanism and the Dual Function of Bits COOUTx

Mapped Compare Output Bits

In Compare Mode 1 and Concurrent Compare Mode, bits COOUTx in register T2CCU_COSHDW are used to set the polarity of the respective compare output. To select between the two functions of the COOUTx bits (shadow transfer vs. output polarity), the state of bit ENSHDW in register T2CCU_COSHDW is used (see **Figure 868**):

- When ENSHDW = 1, bits COOUTx can be directly accessed to trigger the shadow transfer of the compare value.
- When ENSHDW = 0, writing or reading to the COOUTx bits actually accesses an internal compare output register instead of the COOUTx bits in register T2CCU_COSHDW.

The following compare modes are available, described in detail in the following sections:

- **Compare Mode 0 (without dead-time control)**.
- **Compare Mode 0 with Dead-Time Control**.
- **Compare Mode 1**.
- **Concurrent Compare Mode**.

49.13.4.2.1 Compare Mode 0 (without dead-time control)

In Compare Mode 0 without dead-time control, the output signal is affected by a compare match and by the overflow of the associated timer. A compare match sets the output to active level, while the timer overflow resets the output to the inactive level.

Compare Mode 0 is ideal for generating pulse width modulated output signals, which in turn can be used for digital-to-analog conversion via a filter network or by the controlled device (e.g. the inductance of a DC or AC motor). Compare Mode 0 may also be used for providing output clocks with initially defined period and duty cycle. This usage needs the least CPU time. Once set up, the output goes on oscillating without any CPU intervention.

Figure 869 shows a timing diagram example of Compare Mode 0, while **Figure 870** provides a functional diagram of this mode. Please see **Figure 871** for the output control.

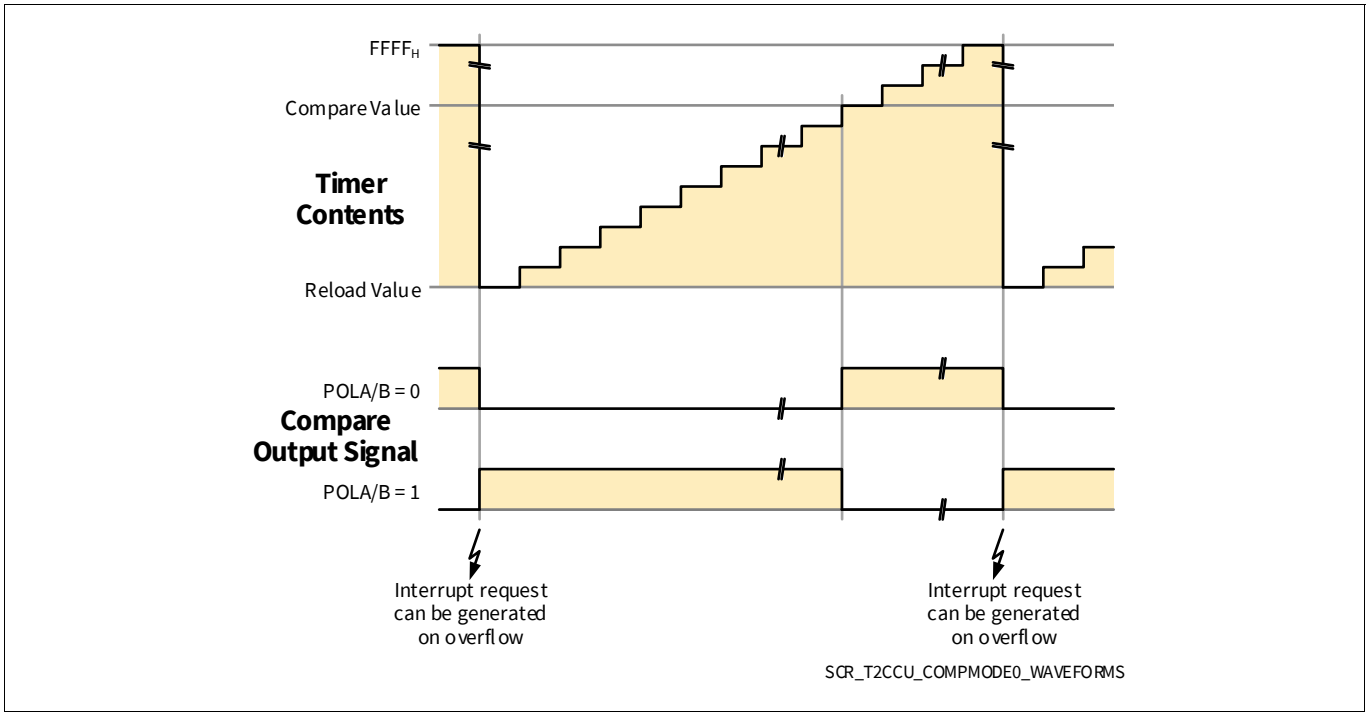

Figure 869 Channel Output Example in Compare Mode 0 (without dead-time control)

To configure Compare Mode 0, the following steps need to be done:

- Set bitfield COMOD in register T2CCU_COCON to 00_B to select Compare Mode 0.
- Set bit TXOV in register T2CCU_COSHDW to 1_B (the usual way to perform the compare shadow value transfer in Compare Mode 0 is via the timer overflow).
- Configure the desired output polarity of the compare outputs via bits POLA and POLB in register T2CCU_COCON. Bit POLA applies to channels 0, 2, and 4 (channel group A), while POLB applies to channels 1, 3, and 5 (channel group B).

Note: The two steps listed above can be done in one write access to register T2CCU_COCON. However, the enabling of compare channels 4 and 5 (see following step) must be done in a separate write access to register COCON, to ensure a glich-free compare output level.

- For compare channels 0 through 3, individually enable the compare mode for the desired compare registers by setting bitfield CCMx in register T2CCU_CCEN to 10_B.
  For compare channels 4 and 5, individually enable the compare mode for the desired compare registers by setting bit CCMx in register T2CCU_COCON to 1_B.

The compare output is immediately set to the appropriate level when the associated compare register is enabled via bit/bitfield CCMx:

- To the active level if the base timer contents are equal to or greater than the compare register contents.

- To the inactive level if the base timer contents are less than the compare register contents.

Either Timer 2 or the CCT timer can be used as base timer in Compare Mode 0. The shadow transfer of a new compare value is usually triggered by the overflow of the selected base timer (set bit TXOV in register T2CCU_COSHDW to 1_B).

Note that no interrupt is generated when a compare match occurs. See **Section 49.13.4.4** for further information.

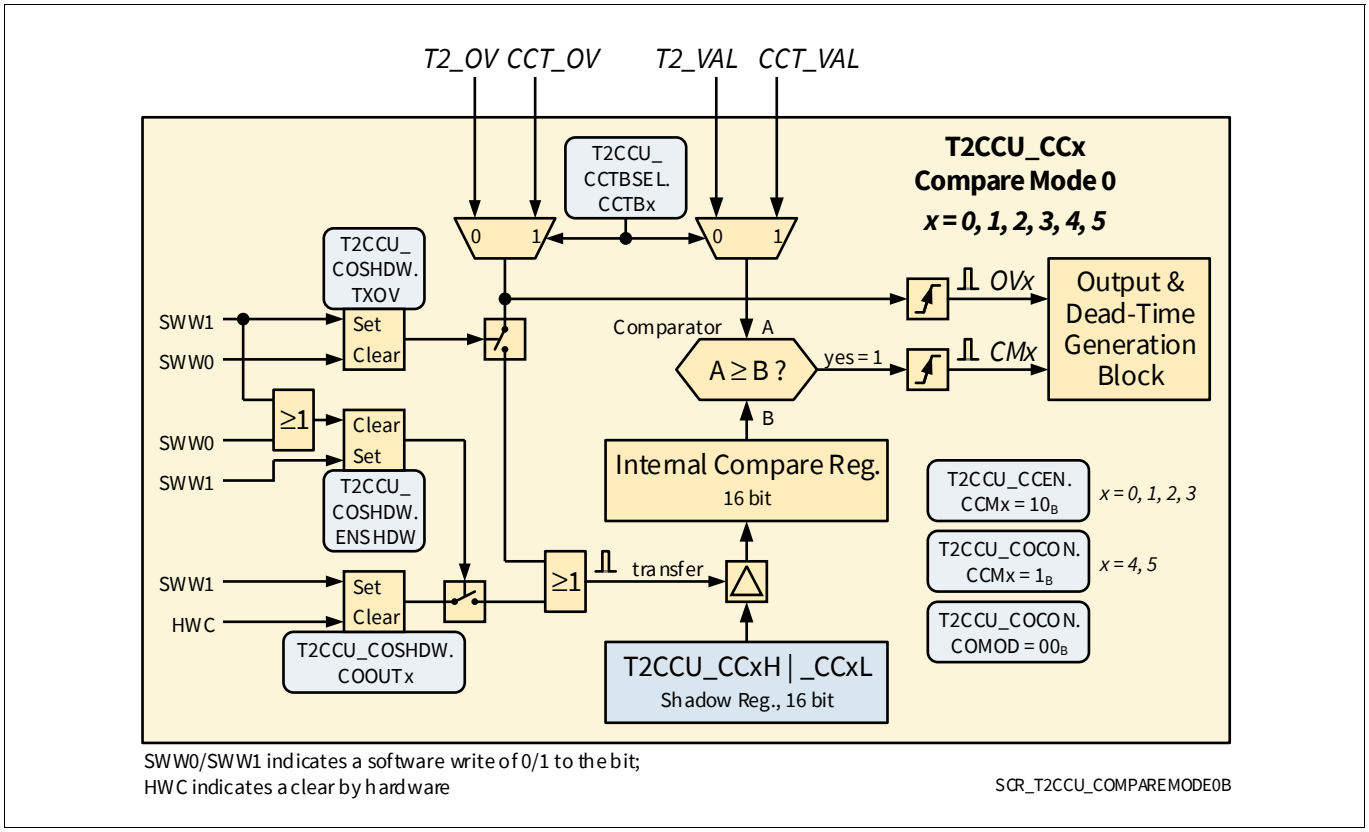

Figure 870 Functional Diagram of Compare Mode 0 (without dead-time control)

Operation in the first timer period after initialization

The following needs to be regarded concerning the compare output level for the first timer period after initialization:

- Although a compare value might have been written to the compare shadow register before enabling the compare operation, the actual compare register will contain 0000_H (if no transfer from the shadow register to the actual compare register has been forced via software, see below).
- In this case, the value of the timer will be greater than or equal to the value in the compare register (in any case - whether the timer contains the initial value of 0x0 or has been programmed to another value).
- Thus, the condition of a “compare match” is true (timer ≥ compare value), and the compare output level will be set to the active level.
- On the following timer overflow, the first compare value shadow transfer takes place (bit T2CCU_COSHDW.TXOV = 1_B), and the output will go to its inactive level if the programmed compare value is > 0000_H.
- From this second timer period on, the output will switch from inactive to active level on compare match and vice versa on timer overflow.

In order to get a proper compare operation already during the first timer period, a compare value shadow transfer must be forced by software. This can only be done after compare mode is enabled.

- After enabling the compare mode and before starting the timer, a compare value shadow transfer must be forced by software.
- Write a value greater than the timer value to the compare shadow register.
- Set bit T2CCU_COSHDW.ENSHDW to 1_B (clear bit T2CCU_COSHDW.TXOV to 0_B with the same write access), and set T2CCU_COSHDW.COOUTx to 1_B.
- After this, clear bit T2CCU_COSHDW.ENSHDW to 0_B and set bit T2CCU_COSHDW.TXOV to 1_B with the same write access (bit T2CCU_COSHDW.COOUTx is cleared automatically by hardware).
- Now the actual compare register contains the programmed value (> timer value), and the compare output goes to inactive level.
- The timer can now be started for its first period.

PWM Signal from 0% to 100% Duty Cycle in Compare Mode 0

The active level of a PWM signal refers to the compare output signal level from the time of compare match until the next timer overflow. To generate signals with duty cycles of 100% or 0%, the following methods can be used:

- To support a 100% duty cycle for a compare channel with T2CCU_COCON.POLA/B = 0 (active level = high), the compare value must be set equal to the timer reload value. In this case, the internal hardware will not cause the compare output signal to the inactive level on timer overflow, and the output stays at the active level until the next timer overflow, when the compare value is no more equal to the timer reload value.
- To support a 0% duty cycle for a compare channel with T2CCU_COCON.POLA/B = 0, the compare value must be smaller than the timer overflow reload value. In this case, the timer reload value must not be zero. The compare match event will not happen, and the compare output stays at the inactive level (low).

The mechanisms described above apply correspondingly for the case that the chosen active level = low (T2CCU_COCON.POLA/B = 1).

49.13.4.2.2 Compare Mode 0 with Dead-Time Control

Compare Mode 0 offers an additional feature for the generation of complementary signals with a so-called dead-time between the deactivation of one signal and the activation of the other signal.

The generation of (complementary) signals with dead-time for the high-side and the low-side switches of a power inverter phase is based on twin grouping of the consecutive compare channels – one from group A and the other from group B. The three compare channel pairs therefore are comprised of channel 0 with 1, channel 2 with 3, and channel 4 with 5.

The Compare Mode 0 with dead-time generation can be used under the following conditions:

- All involved compare channels must use the CCT timer.
- Both channels of a channel pair must have the same compare value (CC0=CC1; CC2=CC3; CC4=CC5).
- All used channels must have the dead-time generation enabled (bit DTEy in register T2CCU_CCTDCTH = 1).
- All high-side and low-side switches must have the same active polarity. E.g., if the high-side switch should be active while the CCT timer value is above the compare value, then the low-side switch should be active while the CCT timer value is below the compare value.
- The active signal polarity is controlled by the bits T2CCU_COCON.POLA (for compare channel group A) and T2CCU_COCON.POLB (for compare channel group B). POLA and POLB must be set to complementary values.

Figure 871 illustrates the dead-time generation. This logic is implemented three times, one for each compare channel pair. It mainly consists of an 8-bit down-counter (dead-time counter, clocked with the CCT count rate), and a logic to manipulate the output signals.

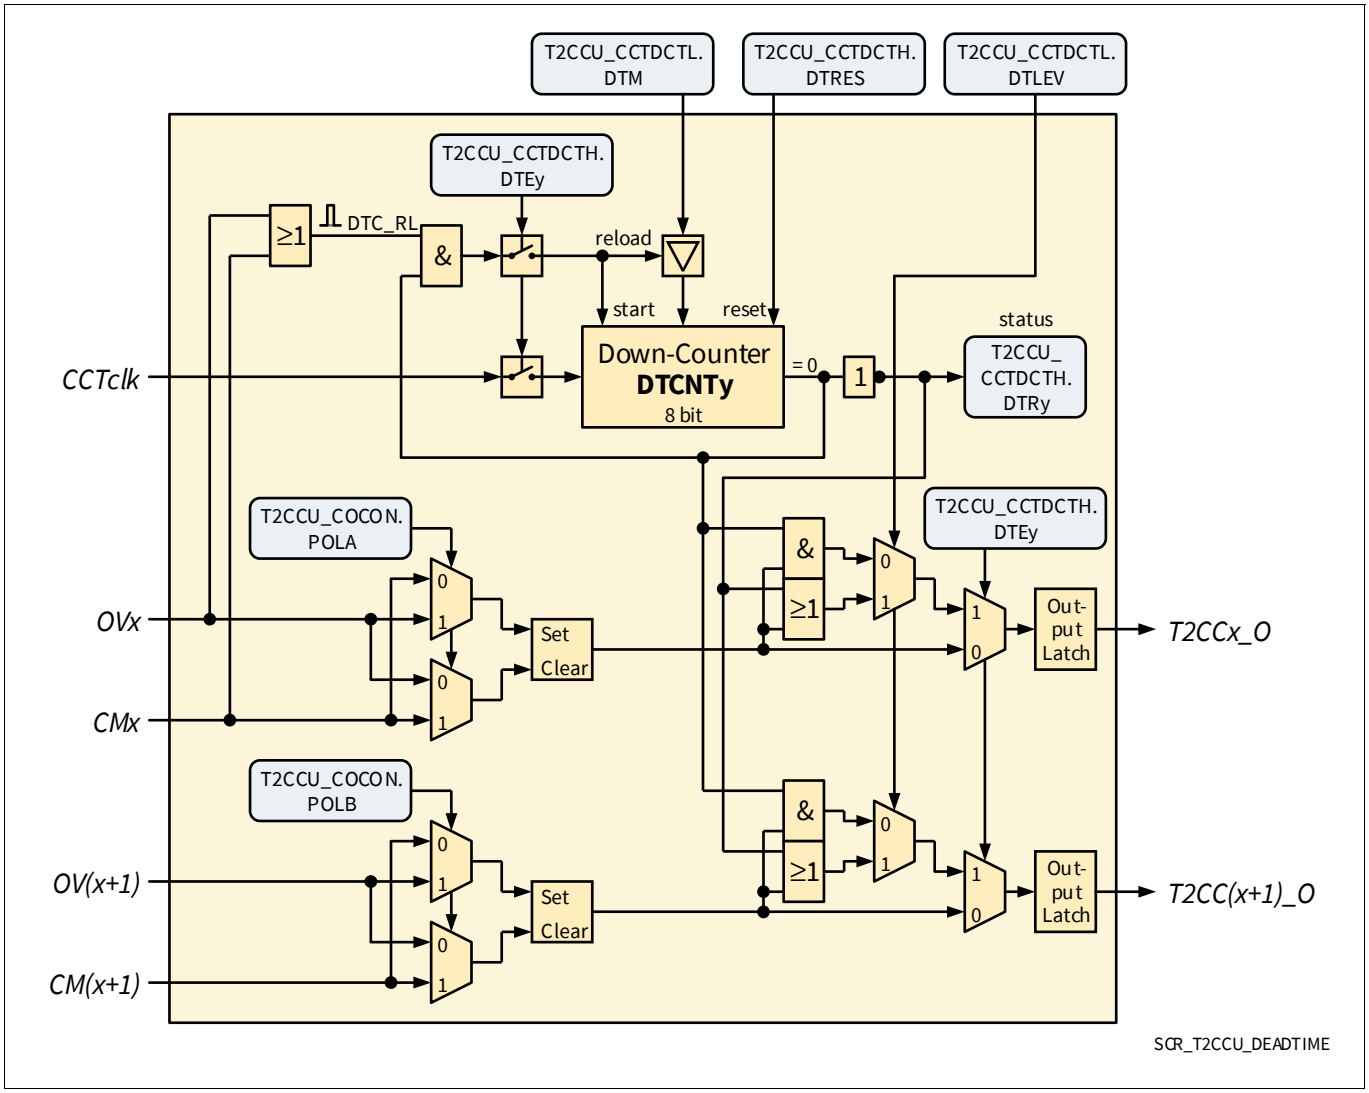

Figure 871 Output & Dead-Time Generation Block

The detailled operation is as follows:

- If dead-time is not enabled for a channel (bit DTEy in register T2CCU_CCTDCTH = 0), the output signal polarity is solely controlled by bits POLA/POLB.
- If dead-time is enabled for a channel (bit DTEy in register T2CCU_CCTDCTH = 1), the output signal polarity is controlled by bits POLA/POLB and the dead-time control logic:
  - As long as the dead-time counter is not running (signal '= 0' is active, status flag T2CCU_CCTDCTH.DTRy = 0), the output signals are determined by bits POLA/POLB.
  - Each instance of the CCT timer overflow or a compare match event (of channel from group A, rising edge) triggers the corresponding dead-time counter.
    The trigger pulse (DTC_RL) reloads the dead-time counter with the value programmed in bitfield T2CCU_CCTDTCL.DTM, and starts it. This can only take place if the dead-time feature is enabled by bit T2CCU_CCTDTCH.DTEx and while the counter is zero.
  - Once started, the dead-time counter counts down until it reaches 0. Then it stops counting.
  - As long as the dead-time counter is running, the output signals are forced to their programmed dead-time level. This level is determined by bit DTLEV in register T2CCU_CCTDCTL. DTLEV must be set such that the outputs a forced to the inactive level during the dead-time.

Please see also the section **Operation in the first timer period after initialization** on **Page 221**, which applies in a similar manner for the dead-time operation.

Figure 872 illustrates the resulting signal waveforms for the dead-time operation (example with POLA = 0 and POLB = 1).

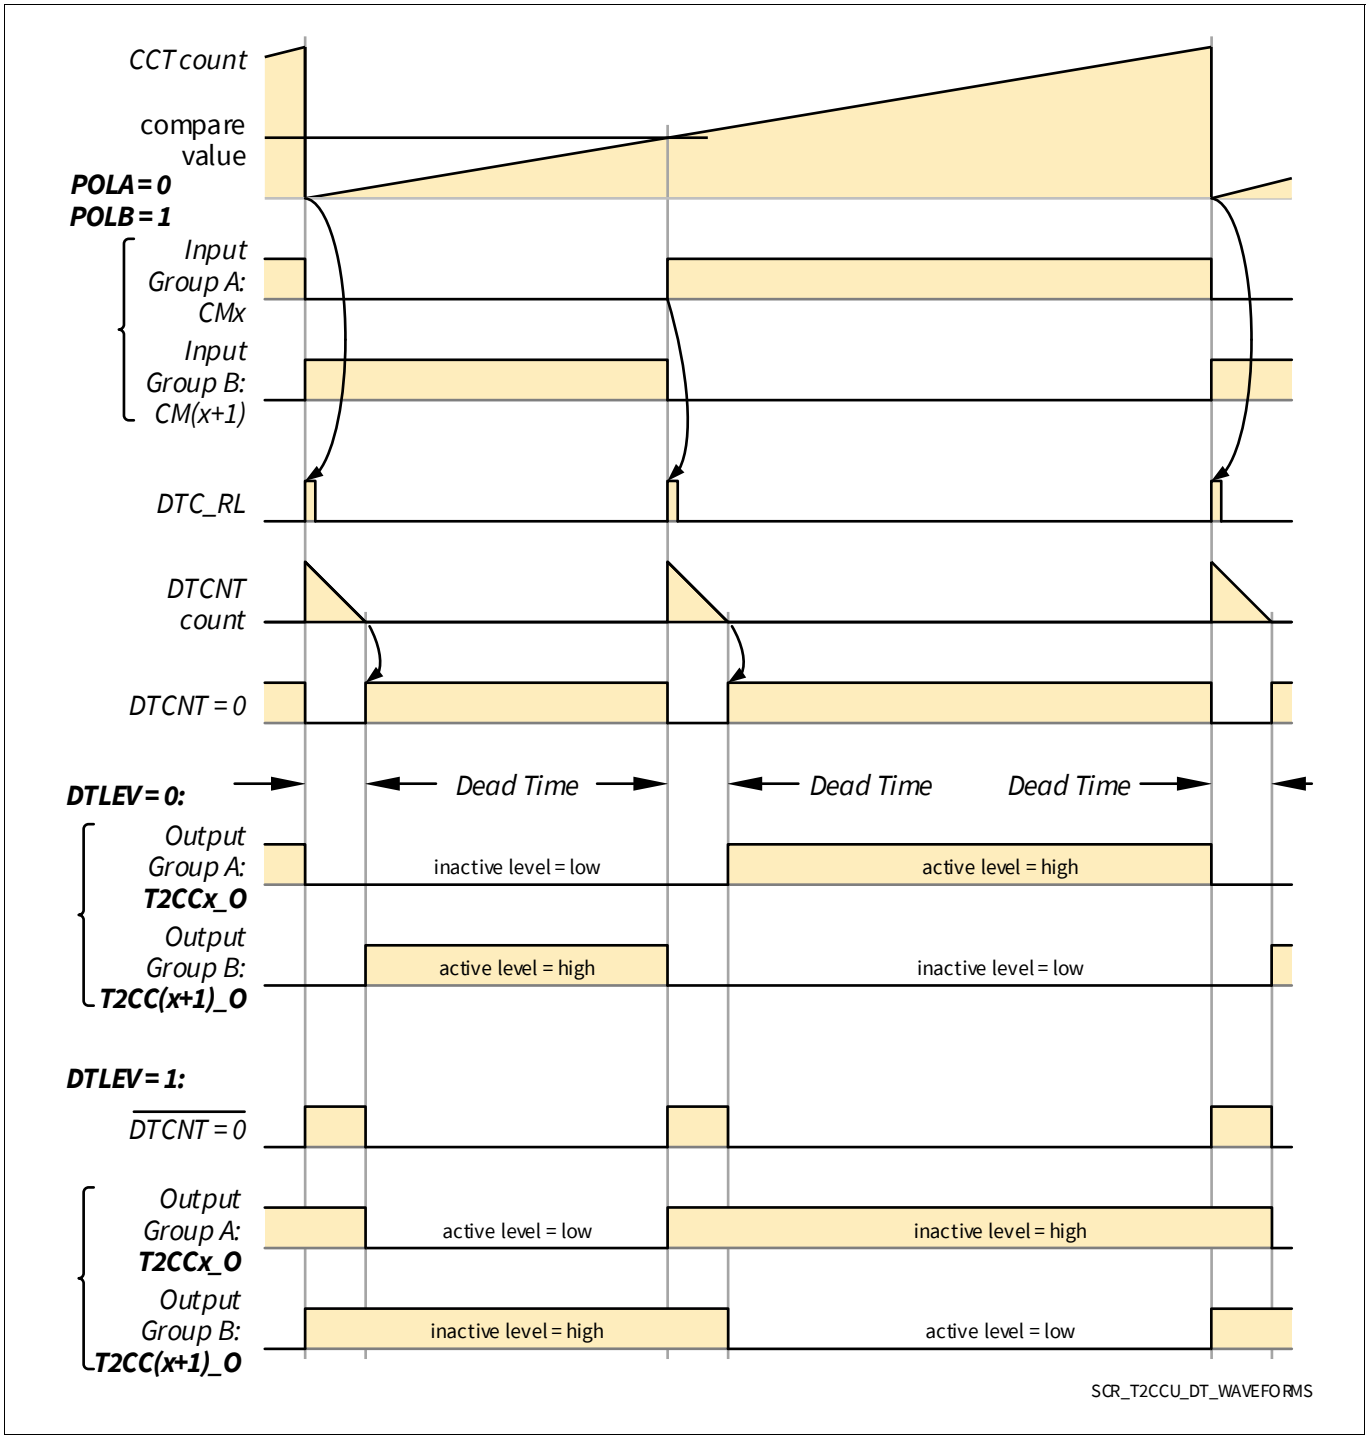

Figure 872 PWM-Signals with Dead-Time Generation (illustrated for one channel pair)

Note: While the channels pairs can be individually enabled or disabled for dead-time generation via their DTEy bits, the dead-time (DTM) and the dead-time level (DTLEV) apply to all channels. In addition, the reset control (DTRES) applies to all three dead-time counters.

Note: The dead-time logic is designed for the application case in which one and only one compare event is generated within one timer period. If more than one compare event happens within one timer period or if two or more timer overflows happen without a compare event in between, proper functionality of the dead-time logic is not assured.
In addition, the timer must not be disabled while the dead-time is in progress or between a timer overflow and a compare match.

Note: When the dead-time DTM in register T2CCU_CCTDTCL is set to 0_H, no dead-time will be generated. This is equivalent as if the dead-time function is not enabled (e.g. DTEy = 0_B).

49.13.4.2.3 Compare Mode 1

In Compare Mode 1, the output signal is only updated on a compare match, but not by the respective timer overflow (as in Compare Mode 0). In Compare Mode 1, the software adaptively determines the transition of the output signal. It is commonly used when output signals are not related to a constant signal period (as in a standard PWM Generation), but must be controlled very precisely with high resolution and without jitter. In Compare Mode 1, the compare output signal level is under the full control of the software.

Figure 873 shows a functional diagram of Compare Mode 1.

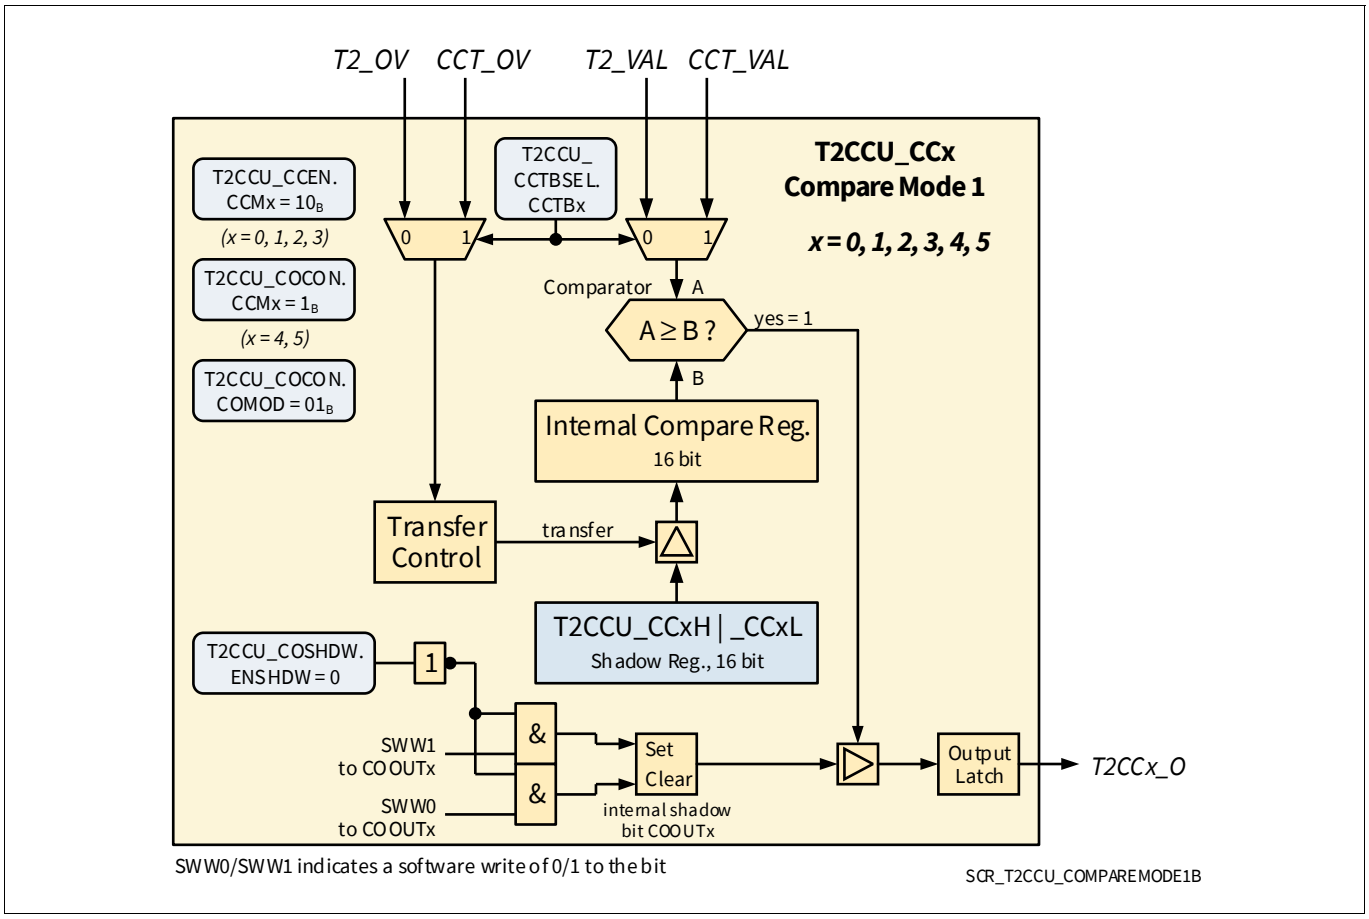

Figure 873 Functional Diagram of Compare Mode 1

To configure Compare Mode 1, the following steps need to be done:

- Set bitfield COMOD in register T2CCU_COCON to 01_B to select Compare Mode 1.
- For compare channels 0 through 3, individually enable the compare mode for the desired compare registers by setting bitfield CCMx in register T2CCU_CCEN to 10_B.

For compare channels 4 and 5, individually enable the compare mode for the desired compare registers by setting bit CCMx in register T2CCU_COCON to 1_B.

- The shadow transfer of a new compare value is triggered by the overflow of the selected base timer (T2CCU_COSHDW.TXOV = 1).
- The software writes the desired output level for the next compare match to the COOUTx bit(s) of the internal compare output register (in this case, bit T2CCU_COSHDW.ENSHDW must be cleared to 0). This new value will not appear at the output until the next compare match occurs.
  Thus, one can choose, independently for each compare channel, whether the output signal is to toggle (1-to-0 or 0-to-1) or to remain at the same level, when a compare match occurs.

The compare output is immediately set to the value initialized to bit COOUTx (of the internal compare output register), when the associated compare register is enabled via bit/bitfield CCMx.

Either Timer 2 or the CCT timer can be used as base timer in Compare Mode 0. The shadow transfer of a new compare value must be triggered by the overflow of the selected base timer.

Note that no interrupt is generated when a compare match occurs. See **Section 49.13.4.4** for further information.

49.13.4.2.4 Concurrent Compare Mode

Concurrent Compare Mode allows to manipulate more than one output with the same compare event. Up to all six compare outputs can be updated concurrently when a compare channel 0 event occurs.

Concurrent compare is an ideal and effective mode for applications where more than one synchronous output signal is to be generated. Such applications could include, e.g., a multiple-phase stepper motor control, or control of ignition coils of a car engine. These applications generally require predefined bit-patterns to be put to an output port at precisely predefined moments.

Figure 874 illustrates the function of Concurrent Compare Mode.

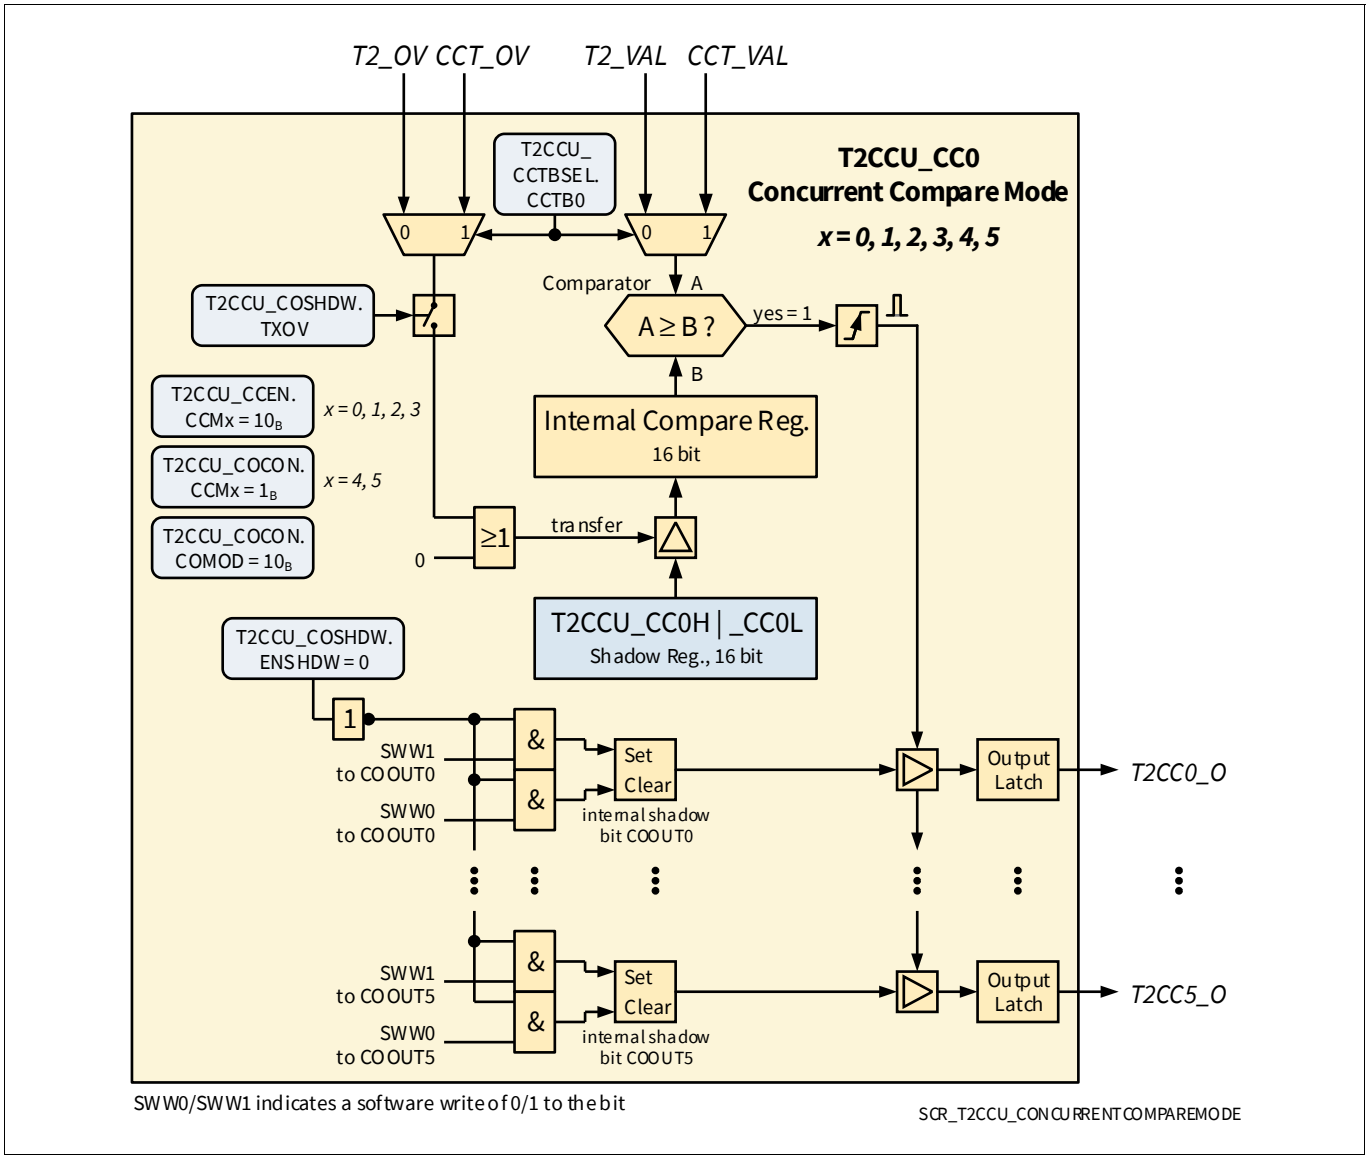

Figure 874 Functional Diagram of Concurrent Compare Mode

To operate the CCU in Concurrent Compare Mode, the following configurations must be made:

- Bit T2CCU_COSHDW.ENSHDW must be cleared to 0.
- The shadow transfer is triggered by the overflow of the selected base timer; set bit T2CCU_COSHDW.TXOV to 1_B.
- Set the compare mode to Concurrent Compare Mode, by setting bitfield T2CCU_COCON.COMOD to 10_B.
- Write the initial output values to the internal compare output bits T2CCU_COSHDW.COOUTx of the desired outputs.
- Only Compare Channel 0 is used for the outputs. Write the required compare value to T2CCU_CC0H and T2CCU_CC0L.
- Enable the desired output signals via their individual enable bits (for channels 0 to 3: Set bitfield T2CCU_CCEN.CCMx to 10_B; for channels 4 and 5: Set bit T2CCU_COCON.CCMx to 1_B).

Note: The compare outputs are latched with the corresponding values initialized to the COOUTx bits of the internal compare output register when setting the CCMx enable control for the desired outputs (make

sure to first select Concurrent Compare Mode via T2CCU_COCON.COMOD, and to program the desired values into the COOUTx bits).

- During steady operation, write the new compare value to register pair T2CCU_CC0H and T2CCU_CC0L, and the new output values to bits T2CCU_COSHDW.COOUTx.
- With the following timer overflow, the new compare value will be used during the new timer period, and the new output values will appear at the outputs when the compare match occurs.

Figure 875 illustrates two examples of how four rectangular waveforms can be generated at the port using a pattern table. The patterns are written to the internal compare output register (with T2CCU_COSHDW.ENSHDW = 0) before the corresponding timer count is reached. The (future) timer count at which the pattern shall be available at the port must be loaded to the compare shadow registers T2CCU_CC0H and T2CCU_CC0L, and transferred to the internal compare registers. To manage the waveform generation, one example uses a time schedule table with list of compare values, the other example makes use of a fixed compare value (such as $FFF0_H$) with shorter timer period. In these ways, each channel can be controlled at predefined time(s) by the user on whether to toggle or not.

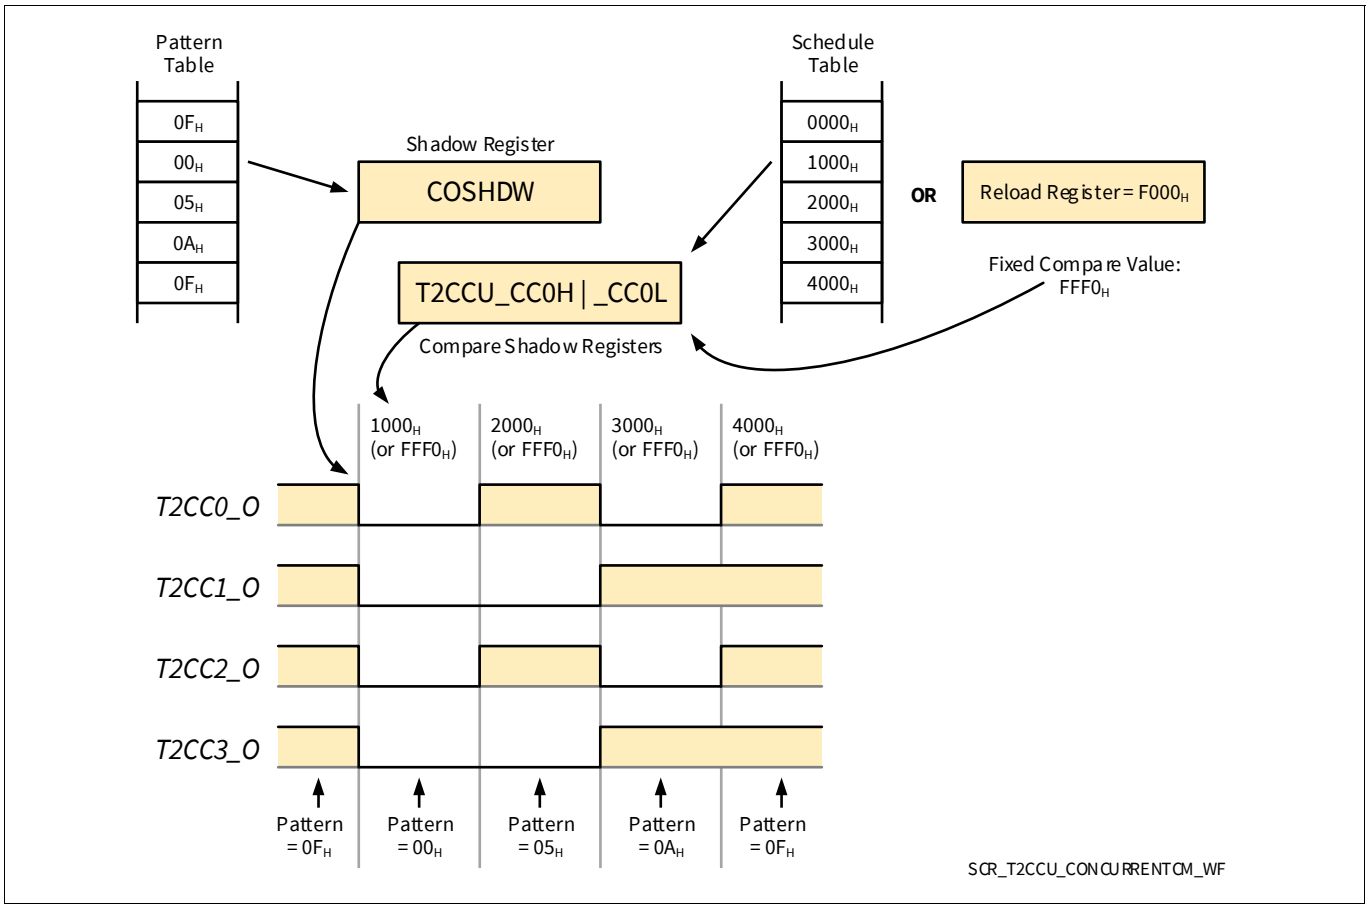

Figure 875 Two Examples of Waveform Generation in Concurrent Compare Mode (by Schedule Table of Compare Values or Fixed Compare Value)

49.13.4.2.5 Using Interrupts in Combination with the Compare Function

There are no interrupt requests generated within the CCU on a compare match. Thus, it is not possible to directly trigger an interrupt service routine on a compare match to handle the programming of new compare and/or output values.

However, there are two options to overcome this:

- In many cases, the overflow interrupt request of the associated base timer can be used.
- Since the compare outputs are connected to the same pins which serve as external interrupt inputs (and CCU capture inputs), these interrupts can be used.

These options offer the following possibilities:

- Compare Mode 0 (with or without dead-time):
  In this mode, a compare match will always show a defined signal edge at the compare output. This signal edge will also appear on the associated input line for the external interrupt input. By appropriately programming the external interrupt configuration, an interrupt request to the CPU can be generated. In the associated service routine, the next compare value can be written to the compare shadow register.
- Compare Mode 1 and Concurrent Compare Mode:
  In these modes, the shadow transfer of compare and output value is always triggered with the overflow of the selected base timer. Thus, the associated overflow interrupt of the timer is the right trigger for a respective service routine to set up new compare and output values.

See also **Section 49.13.4.3.3** for more information for configuring the external interrupt input.

49.13.4.3 Capture Function

The capture modes of the CCU allow the measurement of external signal pulse widths or the latching of time-stamps via the capture/compare registers CC0 through CC3. Each of the 16-bit registers can be used to latch the current 16-bit count value of the selected base timer. Two capture modes are provided for this function, a hardware- and a software-triggered capture:

- In Capture Mode 0, an external event at input T2CCUx_I latches the contents of the selected base timer into the associated capture register.
- In Capture Mode 1, a software write to the low byte of a capture register latches the contents of the selected base timer into the associated capture register.

The two capture modes can be established individually for each capture channel. That means, in contrast to the compare modes, it is possible to simultaneously select Mode 0 for one capture channel and Mode 1 for another channel. **Figure 876** shows the capture operation a capture/compare channel.

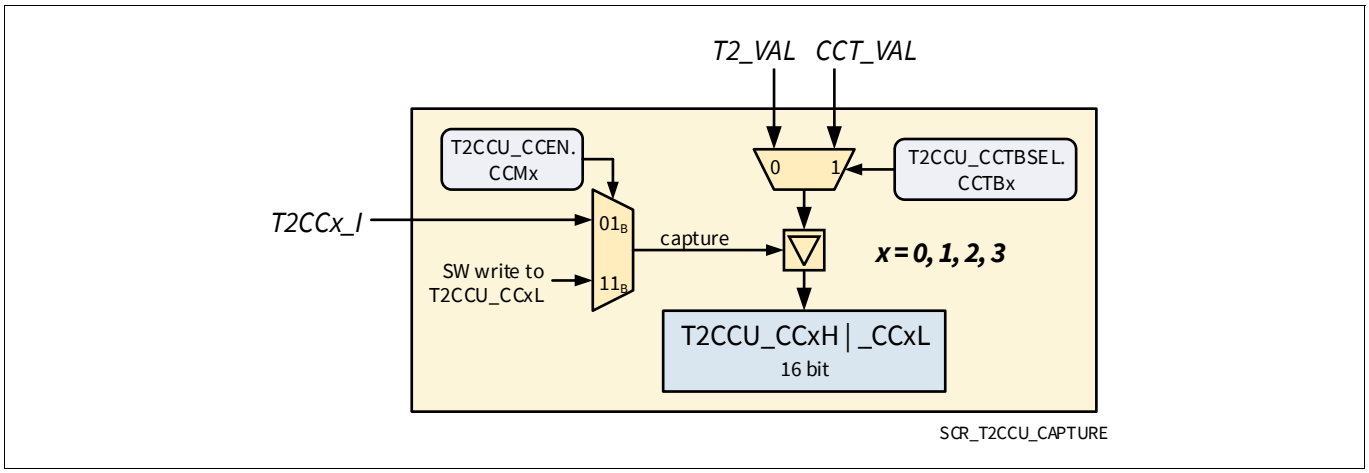

Figure 876 Functional Diagram of Capture Mode

49.13.4.3.1 Capture Mode 0

In Capture Mode 0, any selected external event (rising/falling/both edge) at the associated input (T2CC0_I through T2CC3_I) latches the channel timer contents to the corresponding channel capture register. The capture edge is defined by the corresponding external interrupt set up (each capture input shares the same pin with an external interrupt). The timer contents are latched into the corresponding capture register in the PCLK cycle following the one in which the external transition was recognized.

To configure Capture Mode 0, the following steps need to be done:

- Configure the external input signal (and interrupt request) associated with the desired capture channel (see **Section 49.13.4.3.3**).
- Select the base timer for the desired capture register via T2CCU_CCTBSEL.CCTBx.
- Set bitfield T2CCU_CCEN.CCMx to 01_B (capture mode 0).

49.13.4.3.2 Capture Mode 1

In Capture Mode 1, a capture will occur upon writing to the low byte of the corresponding channel capture register. Thus, the software is able to read the contents of the channel timer “on-the-fly”. The value written to the capture register is irrelevant for this function. The timer contents will be latched into the channel capture register following the write instruction. In this mode, no interrupt request will be generated.

To configure Capture Mode 1, the following steps need to be done:

- Select the base timer for the desired capture register via T2CCU_CCTBSEL.CCTBx.
- Set bitfield T2CCU_CCEN.CCMx to 11_B (capture mode 1).
- Write any value to the low-byte register T2CCU_CCxL to trigger the capture operation.

49.13.4.3.3 Configuring the External Capture Input

Each capture input shares the same pin with an external interrupt. In fact, the capture input T2CCUx_I is derived from the external interrupt input such that it is connected from the edge selection multiplexer for the external interrupt to the CCU of the T2CCU. This is exemplary illustrated in **Figure 877** for capture input T2CC0_I.

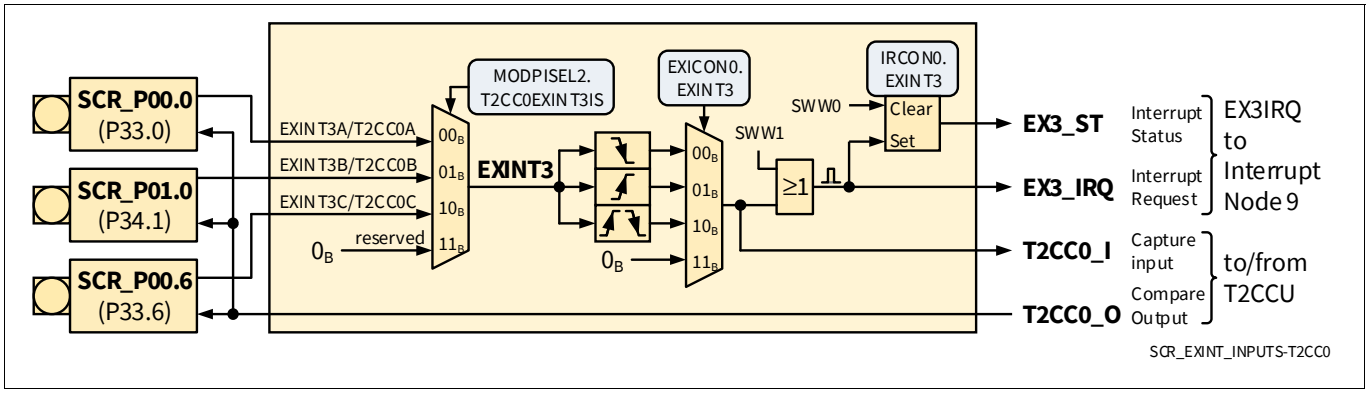

Figure 877 Capture Input Configuration

An external interrupt input is sampled in every PCLK cycle. When a sample shows a low (high) level in one PCLK cycle and a high (low) in the next PCLK cycle, a transition is recognized. The corresponding external interrupt request flag(s) (EXINT3 to EXINT6) is set. If the interrupt(s) is enabled, the CPU will vector to the appropriate interrupt service routine.

When a hardware capture mode is programmed for a CCU capture channel, the edge selected for the associated external interrupt input is also used as the relevant capture trigger. The timer contents are latched to the corresponding capture register in the PCLK cycle following the one in which the transition was identified.

When configuring an external capture input, the following points are relevant:

- The desired input pin is selected via bitfield T2CCxEXINTyIS in register MODPISEL2.
- The external interrupt inputs EXINT3 through EXINT6, which are shared with the capture inputs T2CC0 through T2CC3, all share one interrupt node, XINTR9.
- The common enable bit for this interrupt node is IEN1.EXM.
- The active edge is selected via bitfields EXINTx (x = 3 to 6) in registers EXICON0 resp. EXICON1.
- The interrupt status flags are EXINT3 through EXINT6 in register IRCON0.

Compare Match Interrupts

Since a compare match does not directly generate an interrupt request, the external interrupt inputs, which are shared with the compare outputs, can be used to generate an appropriate interrupt request, if required.

For this, the measures described in the section above for the capture inputs are taken. Since the channel is programmed for one of the compare modes, the capture input line has no effect.

The change of the compare output signal on a compare match is then used to trigger the associated interrupt request.

The main advantage in using compare match interrupts is to avoid unintentional overwriting of compare/compare output registers before a match has been reached. This could happen when the CPU writes to the compare registers without knowing about the actual timer count.

Note: As an alternative, the timer overflow interrupt may be used in place of the compare match interrupt.

49.13.4.4 CCU Interrupt and I/O Connections

This section describes the connections of the capture/compare channels to interrupts, as well as to the I/O ports (and other modules).

Usually, the interrupt request blocks are used which also provide the respective capture input T2CCx_I. However, since the capture/compare I/O lines are connected to more than on port pin, alternative interrupt requests can be used. In addition, the connection to other SCR modules is shown.

49.13.4.4.1 Capture/Compare Channel 0

Figure 878 illustrates the connections of capture/compare channel 0 to the ports, interrupt request blocks, and other SCR modules.

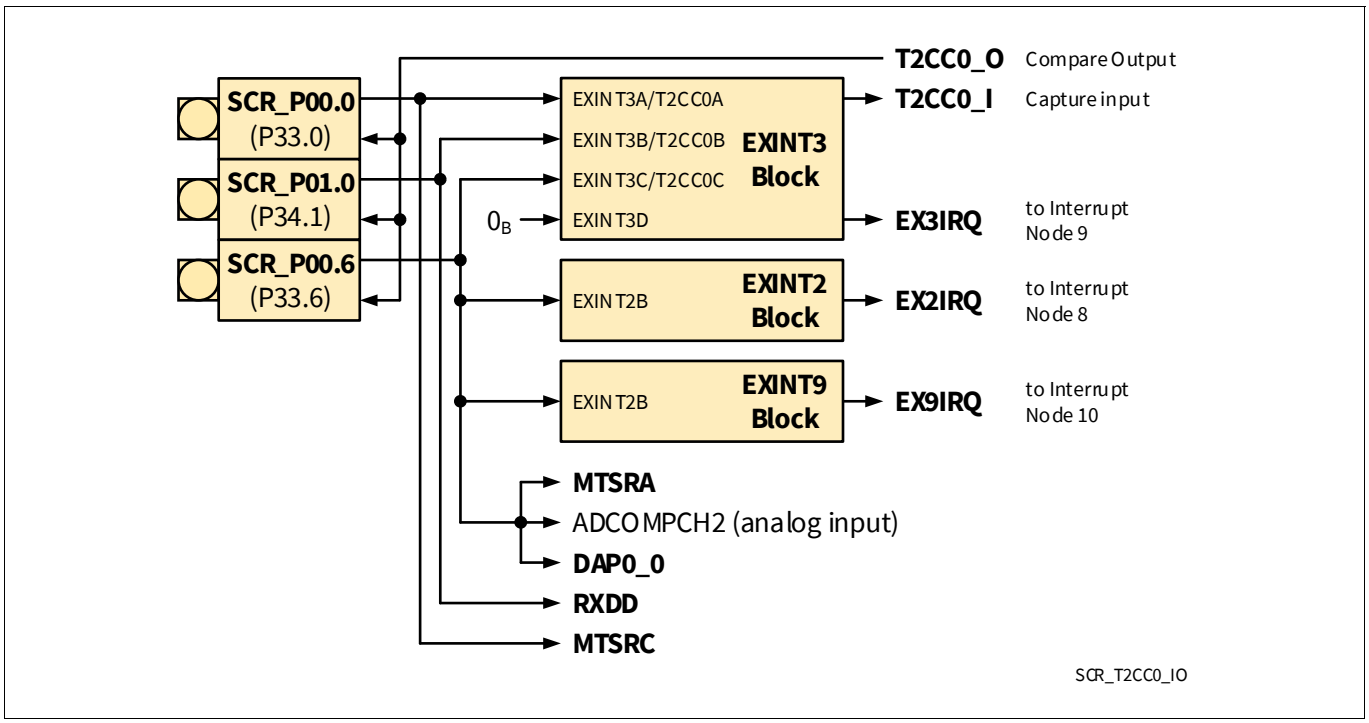

Figure 878 Interrupt and I/O Connections for Capture/Compare Channel 0

49.13.4.4.2 Capture/Compare Channel 1

Figure 879 illustrates the connections of capture/compare channel 1 to the ports, interrupt request blocks, and other SCR modules.

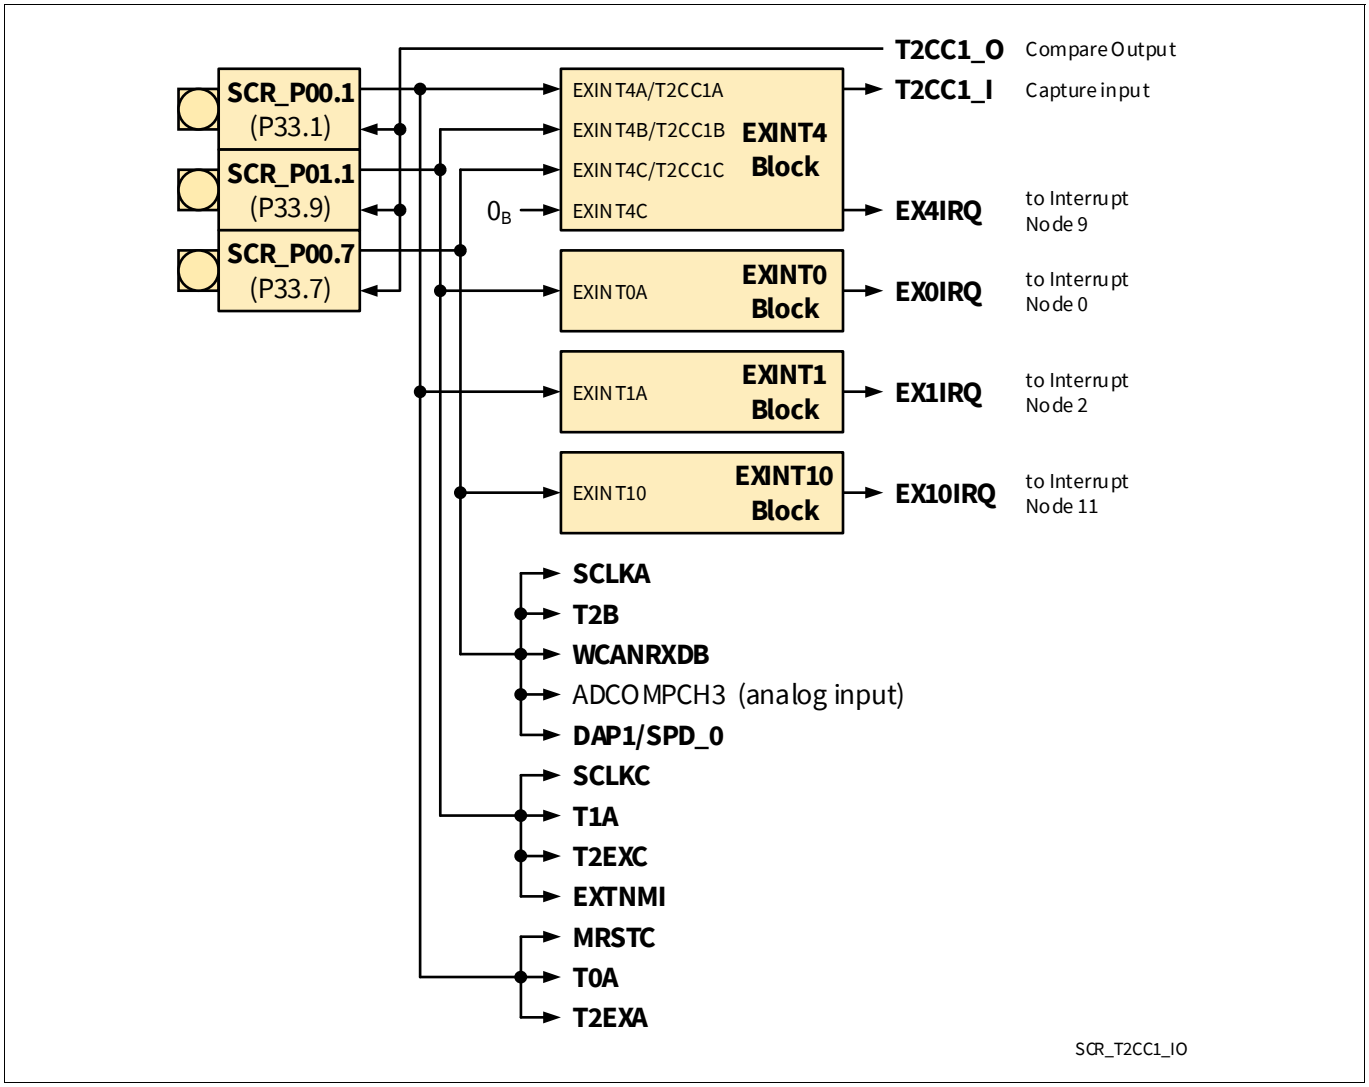

Figure 879 Interrupt and I/O Connections for Capture/Compare Channel 1

49.13.4.4.3 Capture/Compare Channel 2

Figure 880 illustrates the connections of capture/compare channel 2 to the ports, interrupt request blocks, and other SCR modules.

49.13.7 Implementation Details of T2CCU

This section describes the implementation details of the T2CCU module.

49.13.7.1 Interfaces of the T2CCU

Figure 884 gives an overview of the interconnections of the T2CCU.

The interrupt lines of the T2CCU are connected to the CPU interrupt controller.

The General Purpose IO (GPIO) Ports provide the interface from the T2CCU to the external world.

The T2CCU timers can be suspendedwhen OCDS enters Monitor Mode and has the Debug-Suspend signal activated, provided the respective timer suspend bits, T2SUSP and CCTSUSP (in register DBG_MODSUSP), are set. Refer to the OCDS chapter.

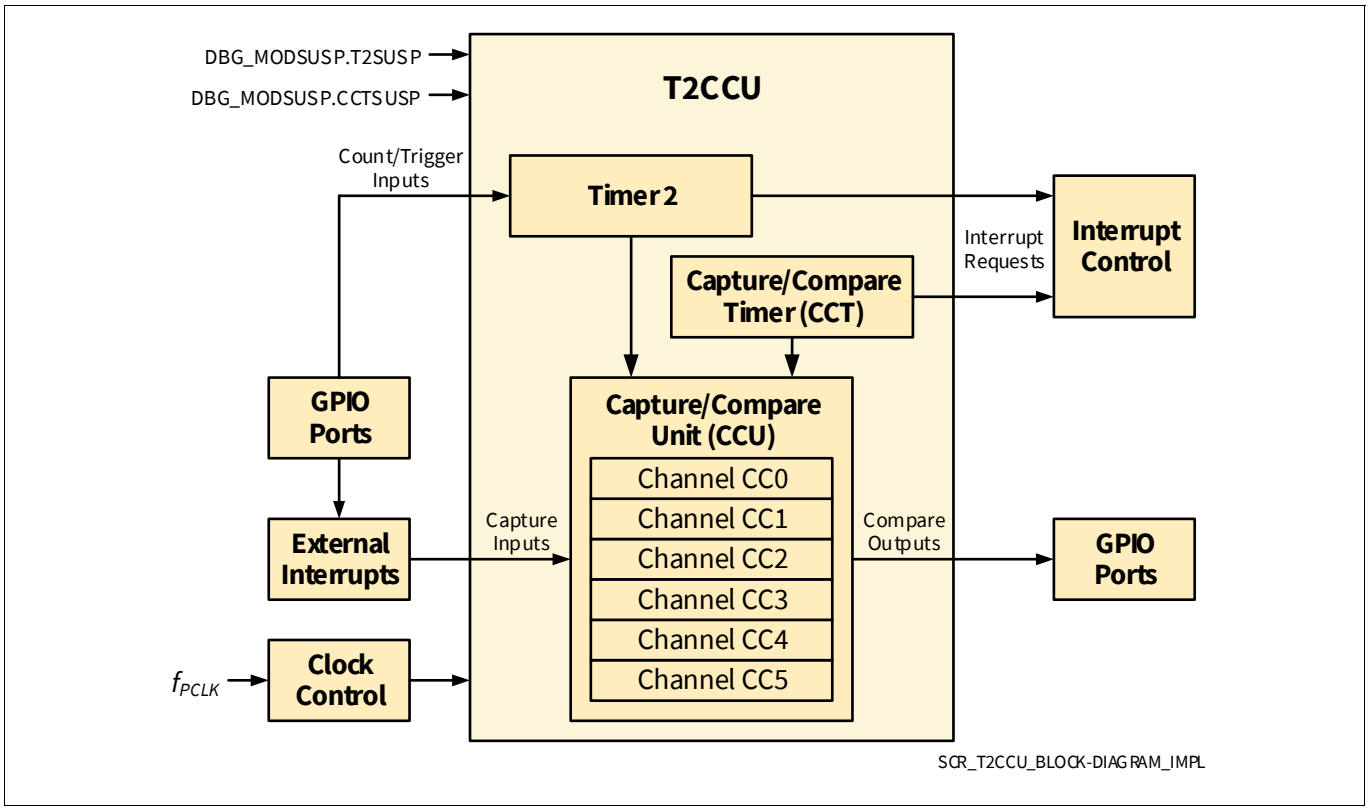

Figure 884 Interconnections of T2CCU

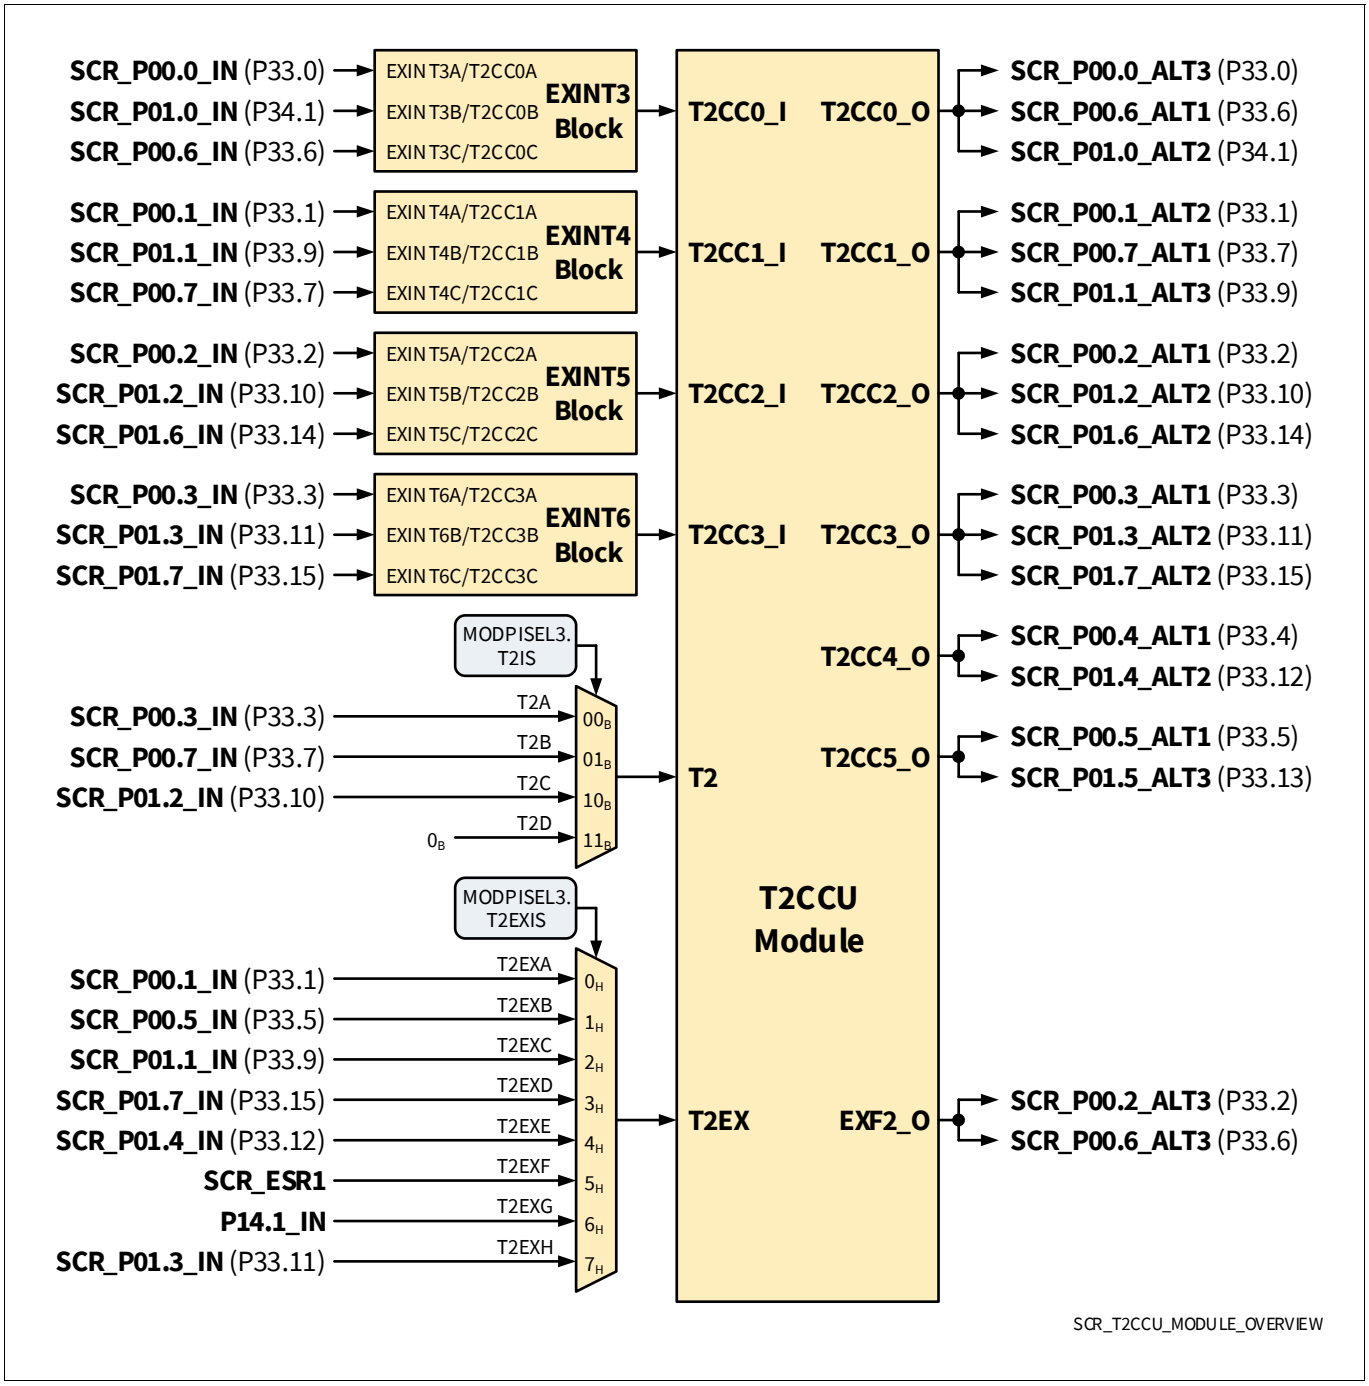

Figure 885 T2CCU Connections to the GPIO Ports

49.13.7.1.1 Interrupt Events and Assignment

Table 706 lists the interrupt event sources from the T2CCU, and the corresponding event interrupt enable bit and flag bit.

Table 706 T2CCU Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit

CCT Timer Overflow	T2CCU_CCTCON.CCTOVEN	T2CCU_CCTCON.CCTOVF

Table 707 shows the interrupt node assignment for each T2CCU interrupt source.

Table 707 T2CCU Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
Timer 2 Overflow	IEN0.ET2	–	$2B_H$
Timer 2 External Input			
CCT Timer Overflow			

49.13.7.1.2 Module Suspend Control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (DBG_MMCR2.MMODE = 1) and the Debug-Suspend signal is active (DBG_MMCR2.DSUSP = 1), the timers in the T2CCU module can be suspended based on the settings of their corresponding module suspend bits in register DBG_MODSUSP. When suspended, only the timer stops counting, since the counter input clock is gated off. The module is still clocked, so that module registers are accessible.

49.14 Universal Asynchronous Receiver/Transmitter (UART)

49.14.1 Overview

The UART provides a full-duplex asynchronous receiver/transmitter, i.e., it can transmit and receive simultaneously. It is also receive-buffered, i.e., it can commence reception of a second byte before a previously received byte has been read from the receive register. However, if the first byte still has not been read by the time reception of the second byte is complete, one of the bytes will be lost.

Note: A module cycle of the UART consists of 2 PCLK cycles.

Note: In this chapter, the input and output signals from/to the GPIO ports are referred to with their generic name, such as TXD and RXD. However, the actual input and output signals use separate lines from/to the GPIO, since they are connected in different ways to the pin logic (pin input line; alternate data output line). Only where explicitly applicable, the generic signal names are extended with an "_I" (input line) or "_O" (output line) identifier.

UART Features:

- Full-duplex asynchronous modes
  - 8-bit or 9-bit data frames, LSB first
  - fixed or variable baudrate
- Receive buffered
- Multiprocessor communication
- Interrupt generation on the completion of a data transmission or reception

49.14.2 UART Modes

The UART can be used in four different modes. In mode 0, it operates as an 8-bit shift register. In mode 1, it operates as an 8-bit serial port. In modes 2 and 3, it operates as a 9-bit serial port. The only difference between mode 2 and mode 3 is the baudrate, which is fixed in mode 2 but variable in mode 3. The variable baudrate is set by the underflow rate on the dedicated baudrate generator.

The different modes are selected by setting bits SM0 and SM1 to their corresponding values, as shown in **Table 709**.

Table 709 UART Modes

SM0	SM1	Operating Mode	Baudrate
0	0	Mode 0: 8-bit shift register	$f_{PCLK}/2$
0	1	Mode 1: 8-bit shift UART	Variable
1	0	Mode 2: 9-bit shift UART	$f_{PCLK}/64$ or $f_{PCLK}/32$
1	1	Mode 3: 9-bit shift UART	Variable

49.14.2.1 Mode 0, 8-Bit Shift Register, Fixed Baudrate

In mode 0, the serial port behaves as an 8-bit shift register. Data is shifted in through RXD, and out through RXDO, while the TXD line is used to provide a shift clock which can be used by external devices to clock data in and out.

The transmission cycle is activated by a write to SBUF. One module cycle later, the data has been written to the transmit shift register with a 1 at the 9th bit position. For the next seven module cycles, the contents of the

transmit shift register are shifted right one position and a zero shifted in from the left so that when the MSB of the data byte is at the output position, it has a 1 and a sequence of zeros to its left. The control block then executes one last shift beforesetting the TI bit. If SCON.TI is set, the next data can be written to SBUF, without destroying the ongoing transmission. If SCON.TI is not set, the ongoing transmission maybe corrupted.

Reception is started by the condition REN = 1 and RI = 0. At the start of the reception cycle, 11111110_B is written to the receive shift register. In each module cycle that follows, the contents of the shift register are shifted left one position and the value sampled on the RXD line in the same module cycle is shifted in from the right. When the 0 of the initial byte reaches the leftmost position, the control block executes one last shift, loads SBUF and sets the RI bit.

The baudrate for the transfer is fixed at $f_{PCLK}/2$, where f_{PCLK} is the input clock frequency, i.e. one bit per module cycle.

Note: The bit SCON.RI is set at the beginning of the 8th bit.

49.14.2.2 Mode 1, 8-Bit UART, Variable Baudrate

In mode 1, the UART behaves as an 8-bit serial port. A start bit (0), 8 data bits, and a stop bit (1) are transmitted on TXD or received on RXD at a variable baudrate.

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and a 1 is loaded to the 9th bit position (as in mode 0). At phase 1 of the module cycle after the next rollover in the divide-by-16 counter, the start bit is copied to TXD, and data is activated one bit time later. One bit time after the data is activated, the data starts getting shifted right with zeros shifted in from the left. When the MSB gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baudrate). The divide-by-16 counter is then reset and $1111\ 1111_B$ is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the stop bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see **Section 49.14.3**) or the received stop bit = 1. If none of these conditions is met, the received byte is lost.

The associated timings for transmit/receive in mode 1 are illustrated in **Figure 886**.

Note: The bit SCON.RI is set at the end of the 8th bit.

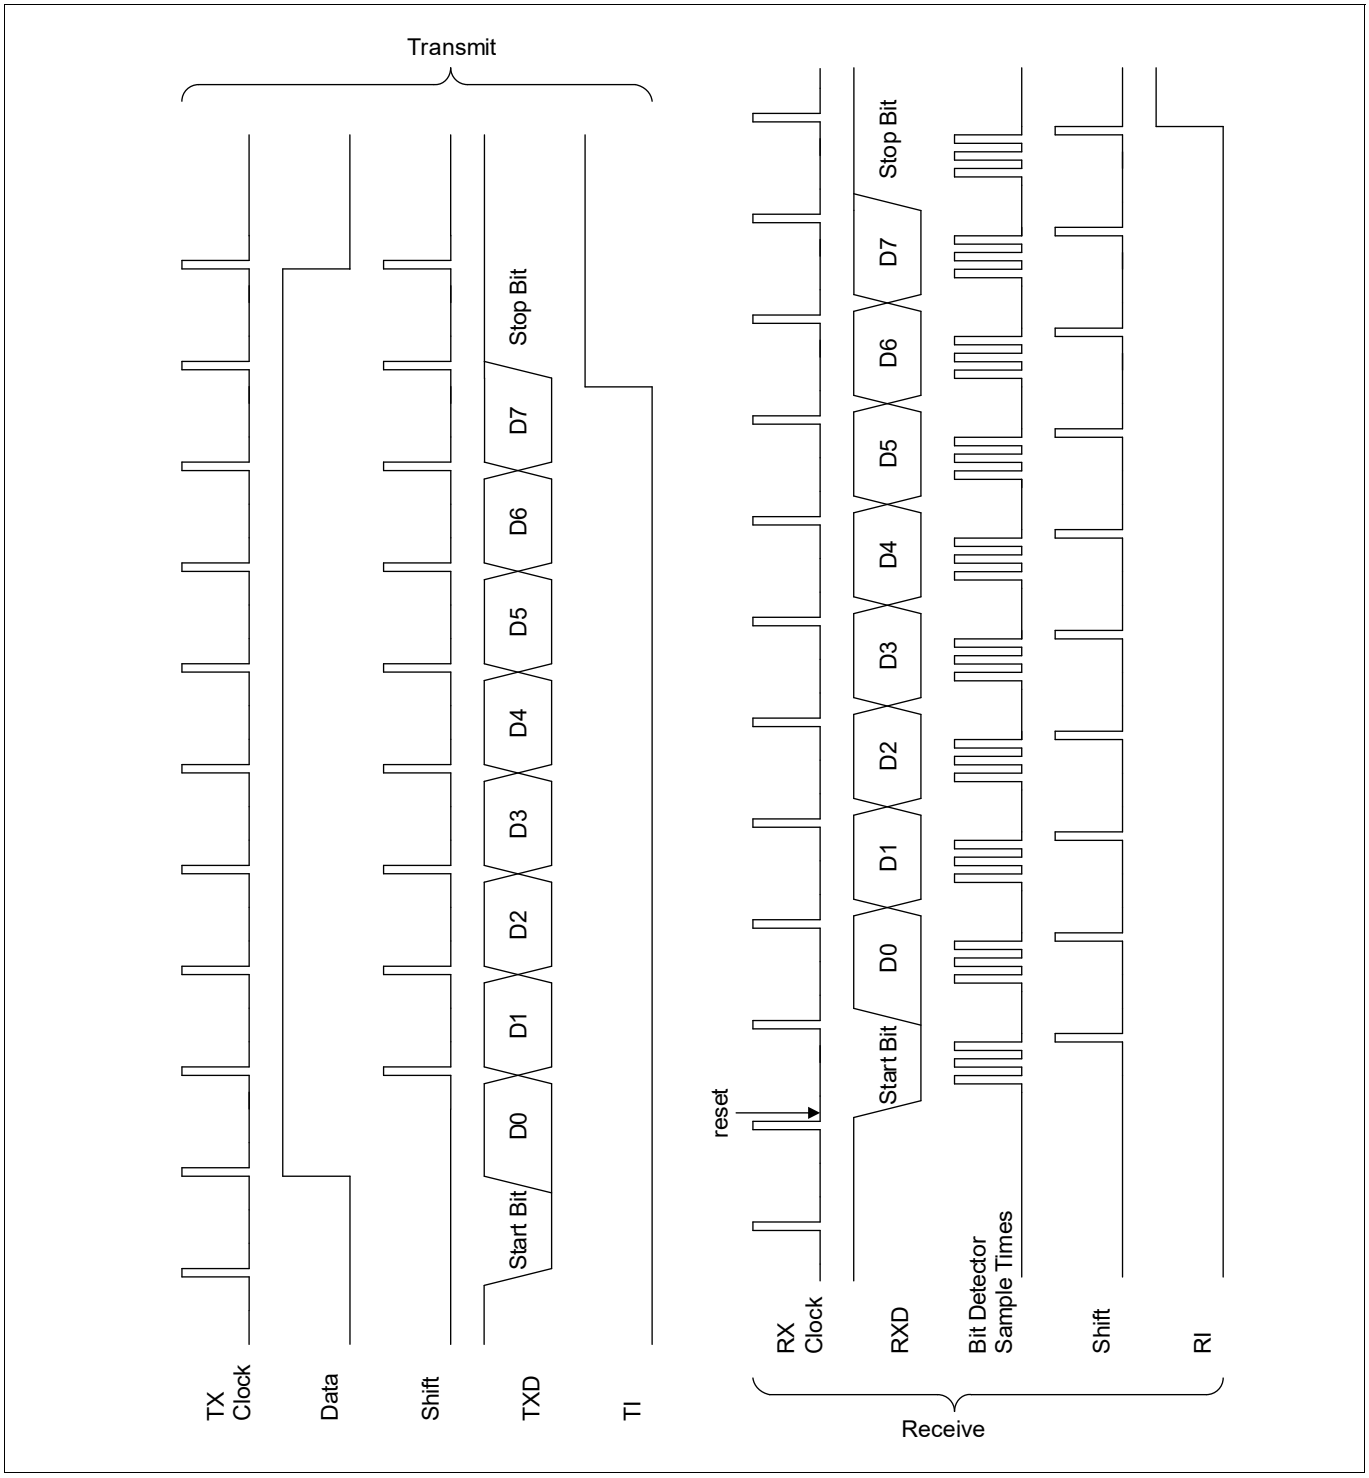

Figure 886 Serial Interface, Mode 1, Timing Diagram

49.14.2.3 Mode 2, 9-Bit UART, Fixed Baudrate

In mode 2, the UART behaves as a 9-bit serial port. A start bit (0), 8 data bits plus a programmable 9th bit and a stop bit (1) are transmitted on TXD or received on RXD. The 9th bit for transmission is taken from TB8 (SCON.3) while for reception, the 9th bit received is placed in RB8 (SCON.2).

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and TB8 is copied into the 9th bit position. At phase 1 of the module cycle following the next rollover in the divide-by-16 counter, the start bit is copied to TXD and data is activated one bit time later. One bit time after the data is activated, the data starts shifting right. For the first shift, a stop bit (1) is shifted in from the left and for subsequent shifts, zeros are shifted in. When the TB8 bit gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baudrate). The divide-by-16 counter is then reset and $1111\ 1111_B$ is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the 9th data bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see **Section 49.14.3**) or the 9th bit = 1. If none of these conditions is met, the received byte is lost.

The baudrate for the transfer is either $f_{PCLK}/64$ or $f_{PCLK}/32$, depending on the setting of the top bit (SMOD) of the PCON (Power Control) register, which acts as a Double Baudrate selector.

Note: The bit SCON.RI is set at the end of the 9th bit.

49.14.2.4 Mode 3, 9-Bit UART, Variable Baudrate

Mode 3 is the same as mode 2 in all respects except that the baudrate is variable.

In all modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in the modes by the incoming start bit if REN = 1.

The serial interface also provides interrupt requests when transmission or reception of the frames has been completed. The corresponding interrupt request flags are TI or RI, respectively. If the serial interrupt is not used (i.e., serial interrupt not enabled), TI and RI can also be used for polling the serial interface.

The associated timings for transmit/receive in modes 2 and 3 are illustrated in **Figure 887**.

Note: The bit SCON.RI is set at the end of the 9th bit.

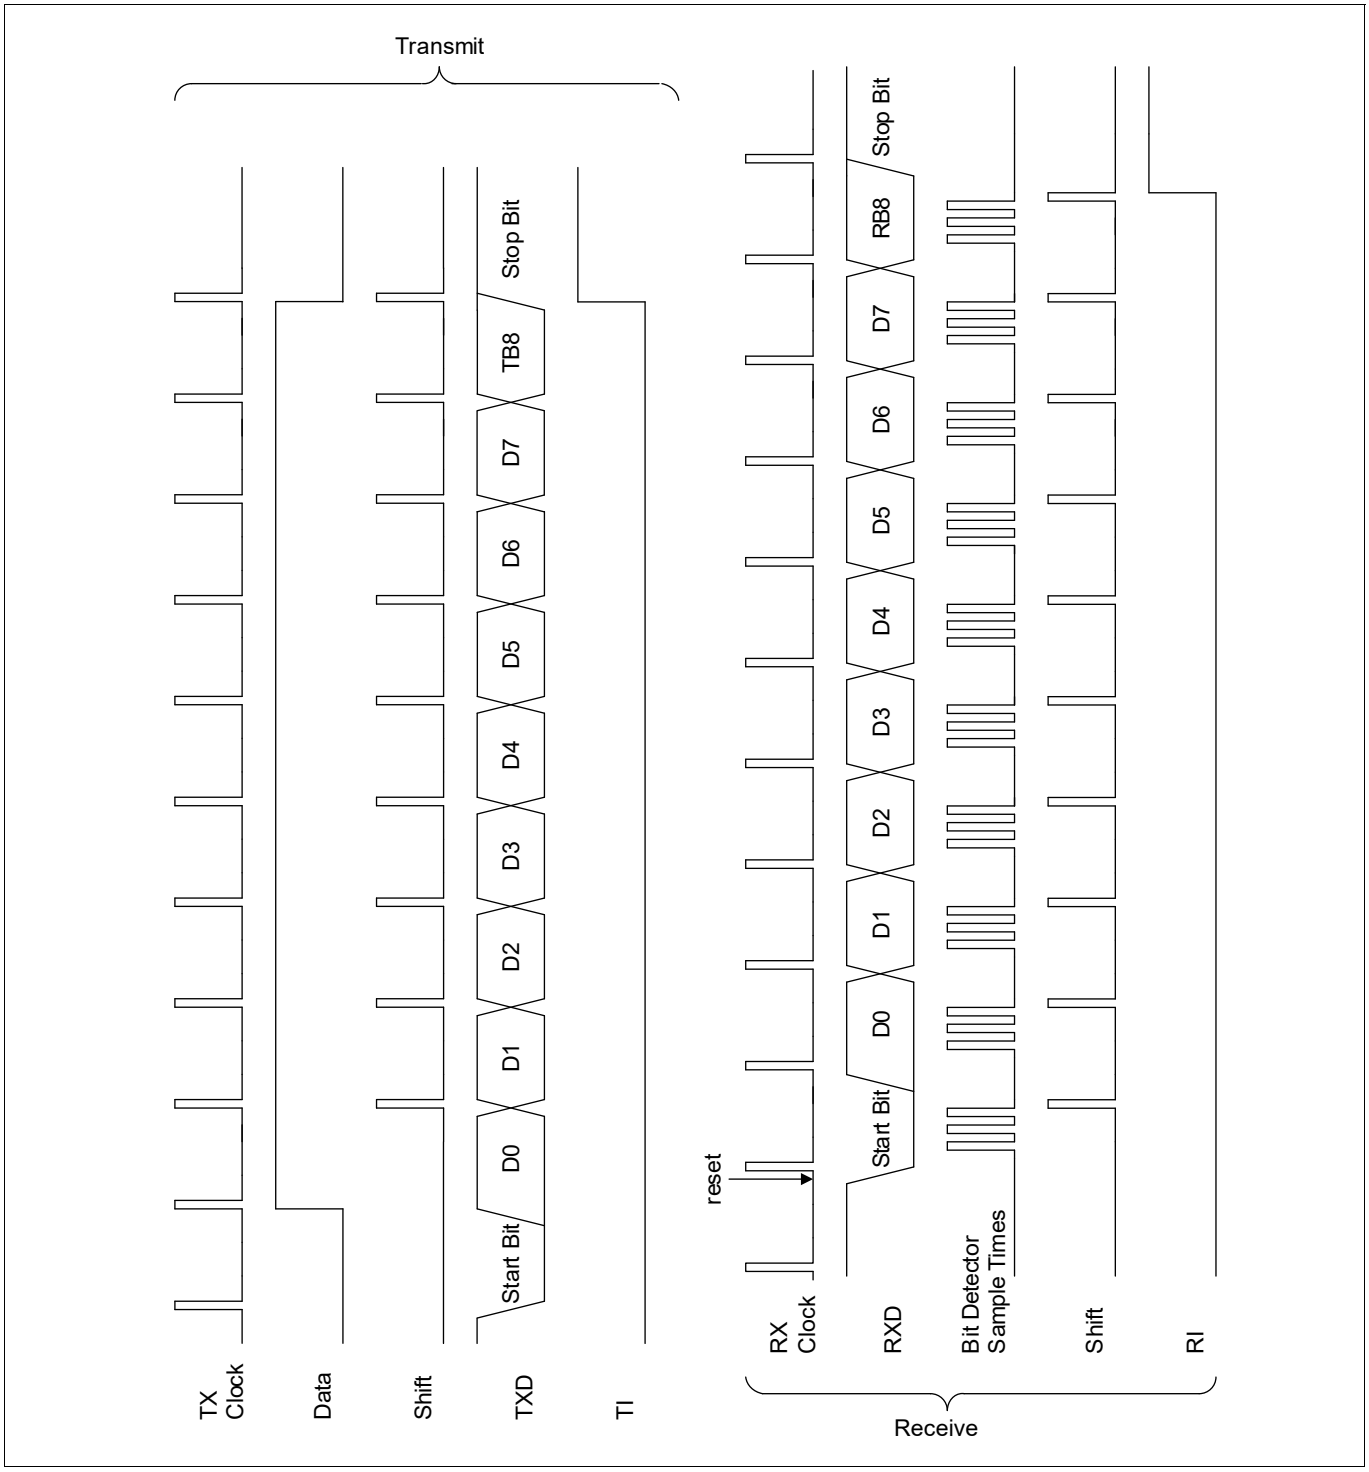

Figure 887 Serial Interface, Modes 2 and 3, Timing Diagram

49.14.3 Multiprocessor Communication

Modes 2 and 3 have a special provision for multiprocessor communication using a system of address bytes with bit 9 = 1 and data bytes with bit 9 = 0. In these modes, 9 data bits are received. The 9th data bit goes into RB8. The communication always ends with one stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1.

This feature is enabled by setting bit SM2 in SCON. One of the ways to use this feature in multiprocessor systems is described in the following paragraph.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte that identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that were not being addressed retain their SM2s as set and ignore the incoming data bytes.

Bit SM2 has no effect in mode 0. SM2 can be used in mode 1 to check the validity of the stop bit. In a mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

49.14.4 Baudrate Generation

There are several ways to generate the baudrate clock for the serial ports, depending on the mode in which they are operating.

The baudrates in modes 0 and 2 are fixed, so they use the fixed clock, (see **Section 49.14.4.1**). In modes 1 and 3, the variable baudrate is generated using the UART baudrate generator (see **Section 49.14.4.2**).

“Baudrate clock” and “baudrate” must be distinguished from each other. The serial interface requires a clock rate that is 16 times the baudrate, to accommodate for the 16-times oversampling on reception. Therefore, the UART baudrate generator must provide a “baudrate clock” to the serial interface, where it is divided by 16 to obtain the actual “baudrate”. The abbreviation f_{PCLK} refers to the input clock frequency.

49.14.4.1 Fixed Clock

The baudrates in modes 0 and 2 are fixed. However, while the baudrate in mode 0 can only be $f_{PCLK}/2$, the baudrate in mode 2 can be selected as either $f_{PCLK}/64$ or $f_{PCLK}/32$ depending on bit SMOD in the PCON register.

Bit SMOD acts as a double baudrate selector, as shown in **Figure 888**. If SMOD = 0 (value after reset), the baudrate is 1/64 of the input clock frequency f_{PCLK}. If SMOD = 1, the baudrate is 1/32 of f_{PCLK}.

$$\text{Mode 2 Baudrate} = \frac{2^{SMOD}}{64} \times f_{PCLK}$$

uart_baudrate_formula_fixed.vsd

Figure 888 Mode 2 Baudrate

49.14.4.2 UART Baudrate Generator

The UART baudrate generator is used to generate the variable baudrate for the UART in modes 1 and 3. It has programmable 11-bit reload value, 3-bit prescaler, and 5-bit fractional divider.

The baudrate generator is clocked derived via a prescaler (f_{DIV}) from the input clock f_{PCLK}. The baudrate timer counts downwards and can be started or stopped through the baudrate control run bit BCON.R. Each underflow of the timer provides one clock pulse to the serial channel. The timer is reloaded with the 11-bit BR_VALUE stored in its reload register BGH/BGL each time it underflow. The duration between underflows depends on the ‘n’ value in the fractional divider, which can be selected by the bits BGL.FD_SEL. ‘n’ times out of 32, the timer counts one cycle more than specified by BR_VALUE. The prescaler is selected by the bits BCON.BRPRE.

Register BGH/BGL is the dual-function Baudrate Generator/Reload register. Reading BGH/BGL returns the contents of the timer, while writing to BGH/BGL always updates the reload register.

Registers BGH/BGL may be written only when BCON.R is 0. An auto-reload of the timer with the contents of the reload register is performed one instruction cycle after the next time BCON.R is set. Any write to BGH/BGL, while BCON.R is set, is not allowed.

The baudrate of the baudrate generator depends on the following bits and register values:

- Input clock f_{PCLK}.

- Value of bit field BCON.BRPRE.
- Value of bit field BG.FD_SEL.
- Value of the 11-bit reload value BR_VALUE in registers BGH/BGL.

Figure 889 shows a simplified block diagram of the baudrate generator. Note that f_{BR} is 16 times the configured baudrate, due to synchronization and oversampling needs.

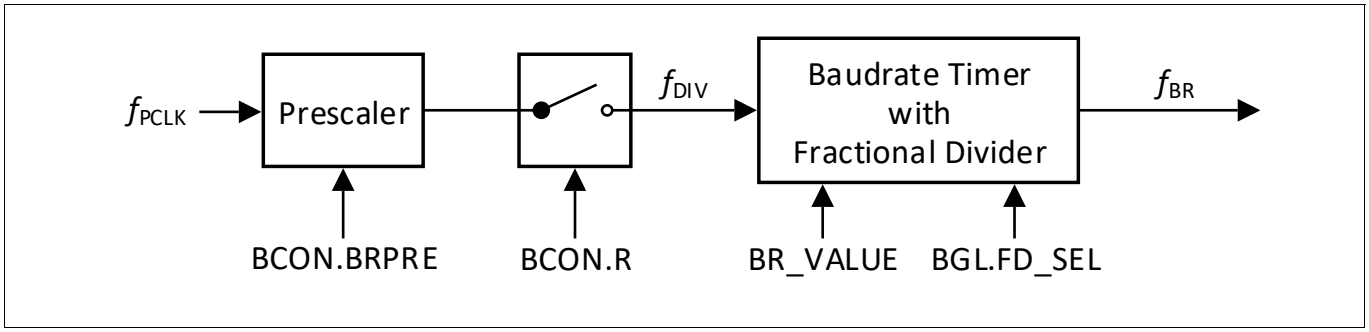

Figure 889 Simplified Baudrate Generator Block Diagram

The formula shown in **Figure 890** calculates the final baudrate.

$$\text{Baudrate} = \frac{f_{BR}}{16} = \frac{f_{PCLK}}{16 \times \text{Prescaler} \times (\text{BR\_VALUE} + n/32)} = \frac{f_{PCLK}}{16 \times (2^{\text{BCON.BRPRE}}) \times (\text{BR\_VALUE} + (\text{BGL.FD\_SEL}/32))}$$

uart_baudrate_formula.vsd

Figure 890 Baudrate Calculation

The value of the prescaler is chosen by the bit field BCON.BRPRE. BR_VALUE represents the contents of the reload value, taken as unsigned 11-bit integer from the two bit fields BR_VALUE in registers BGH and BGL. n/32 is defined by the fractional divider selection in bit field BGL.FD_SEL.

Note that the maximum baudrate that can be generated in this implementation is limited to $f_{PCLK}/48$. Hence, for a module clock of 20 MHz, the maximum achievable baudrate is 416.67 kBaud.

Table 710 lists various commonly used baudrates together with their corresponding parameter settings and the deviation errors compared to the intended baudrate.

Table 710 Typical Baudrates of UART (f_{PCLK} = 20 MHz)

Baudrate (f_{PCLK} = 20 MHz)	BCON.BRPRE	Reload Value (BR_VALUE)	Numerator of Fractional Value (BGL.FD_SEL)	BG Value[1]	Deviation Error
115.2 kBaud	000_B (prescaler = 1)	10 ($0A_H$)	27 ($1B_H$)	$015B_H$	+0.06%
20 kBaud	000_B (prescaler = 1)	62 ($3E_H$)	16 (10_H)	$07D0_H$	+0.00%
19.2 kBaud	000_B (prescaler = 1)	65 (41_H)	3 (03_H)	0823_H	+0.02%
9600 Baud	001_B (prescaler = 2)	65 (41_H)	3 (03_H)	0823_H	+0.02%
4800 Baud	010_B (prescaler = 4)	65 (41_H)	3 (03_H)	0823_H	+0.02%
2400 Baud	011_B (prescaler = 8)	65 (41_H)	3 (03_H)	0823_H	+0.02%

1) The BG value is obtained by concatenating the 11-bit BR_VALUE and 5-bit FD_SEL value to a 16-bit value, which represents the contents of the register pair BGH|BGL.

49.14.5 UART Interrupt Requests

The following figure illustrates the UART receive and transmit interrupt requests. Note that the RI/TI flags are not automatically cleared by the CPU on entry into the respective service routine. They must be cleared by software. See also the section on “Interrupt Structure 1” in chapter “Interrupt System”.

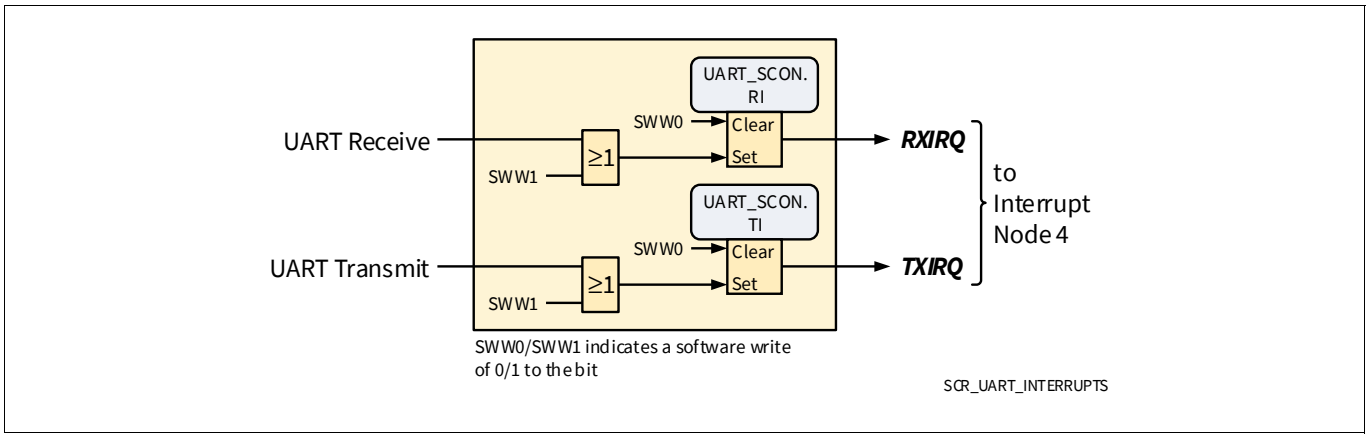

Figure 891 UART Receive and Transmit Interrupt Requests

49.14.6 LIN Support in UART

The UART module can be used to support the Local Interconnect Network (LIN) protocol for both master and slave operations. The LIN baudrate detection feature, which consists of the hardware logic for Break and Synch Field detection, provides the capability to detect the baudrate within LIN protocol using Timer 2. This allows the UART module to be synchronized to the LIN baudrate for data transmission and reception. Timer 2 will be used for BREAK detection and generation.

49.14.6.1 LIN Protocol

LIN is a holistic communication concept for local interconnected networks in vehicles. The communication is based on the SCI (UART) data format, a single-master/multiple-slave concept, a clock synchronization for nodes without stabilized time base. An attractive feature of LIN is self-synchronization of the slave nodes without a crystal or ceramic resonator, which significantly reduces the cost of hardware platform. Hence, the baudrate must be calculated and returned with every message frame.

The structure of a LIN frame is shown in **Figure 892**. The frame consists of the:

- header, which comprises a Break (13-bit time low), Synch Byte (55_H), and ID field
- response time
- data bytes (according to UART protocol)
- checksum

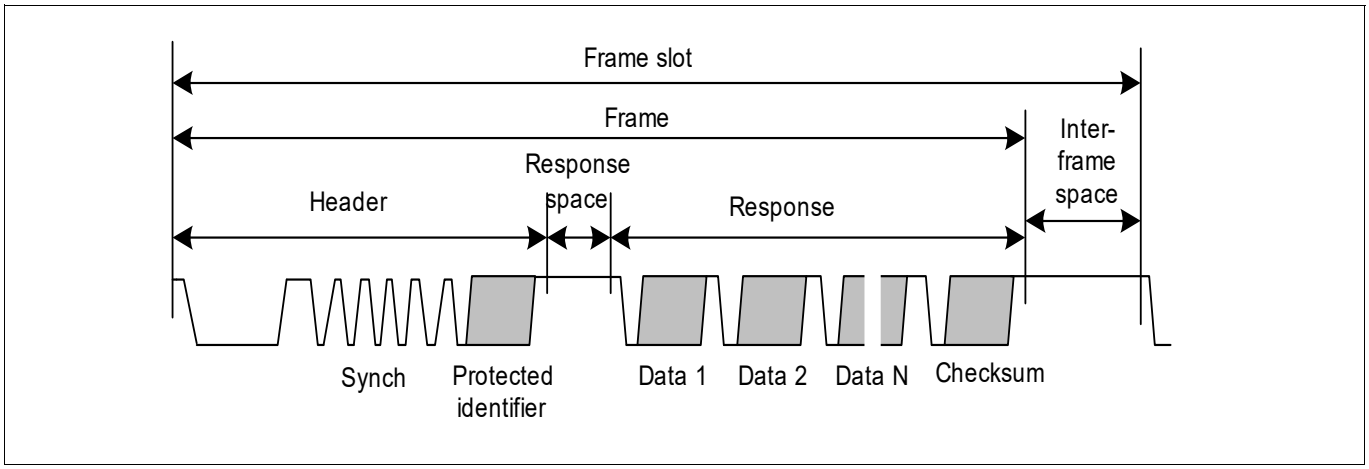

Figure 892 The Structure of LIN Frame

Each byte field is transmitted as a serial byte, as shown in **Figure 893**. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and the stop bit is encoded as a bit with value one (recessive).

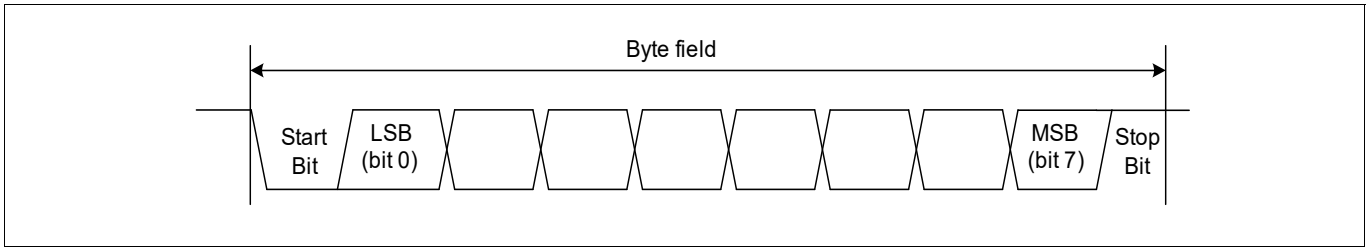

Figure 893 The Structure of Byte Field

The break is used to signal the beginning of a new frame. It is the only field that does not comply with **Figure 893**. A break is always generated by the master task (in the master mode) and it must be at least 13 bits of dominant value, including the start bit, followed by a break delimiter, as shown in **Figure 894**. The maximum length is 26.6 bit times. The break delimiter will be at least one nominal bit time long.

A slave node will use a break detection threshold of 11 nominal bit times.

Figure 894 The Break Field

Synch Byte is a specific pattern for determination of time base. The byte field is with the data value 55_H, as shown in **Figure 895**.

A slave task is always able to detect the Break/Synch sequence, even if it expects a byte field (assuming the byte fields are separated from each other). If this happens, detection of the Break/Synch sequence will abort the transfer in progress and processing of the new frame will commence.

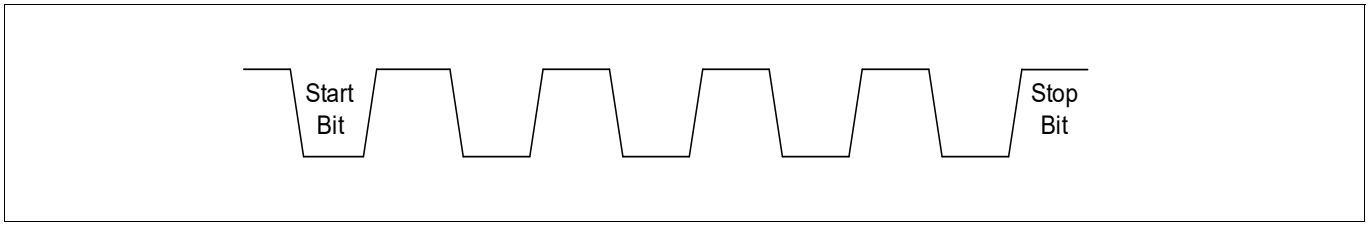

Figure 895 The Synch Byte Field

The slave task will receive and transmit data when an appropriate ID is sent by the master:

1. Slave waits for Synch Break
2. Slave synchronizes on Synch Byte
3. Slave snoops for ID
4. According to ID, slave determines whether to receive or transmit data, or do nothing
5. When transmitting, the slave sends 2, 4 or 8 data bytes, followed by check byte

49.14.6.2 LIN Header Transmission

LIN header transmission is only applicable in master mode. In the LIN communication, a master task decides when and which frame is to be transferred on the bus. It also identifies a slave task to provide the data transported by each frame. The information needed for the handshaking between the master and slave tasks is provided by the master task through the header portion of the frame.

The header consists of a break and synch pattern followed by an identifier. Among these three fields, only the break pattern cannot be transmitted as a normal 8-bit UART data. The break must contain a dominant value of 13 bits or more to ensure proper synchronization of slave nodes.

In the LIN communication, a slave task is required to be synchronized at the beginning of the protected identifier field of frame. For this purpose, every frame starts with a sequence consisting of a break field followed by a synch byte field. This sequence is unique and provides enough information for any slave task to detect the beginning of a new frame and be synchronized at the start of the identifier field.

49.14.6.3 Automatic Synchronization to the Host

Upon entering LIN communication, a connection is established and the transfer speed (baudrate) of the serial communication partner (host) is automatically synchronized in the following steps that are to be included in user software:

STEP 1: Initialize interface for reception and timer for baudrate measurement

STEP 2: Wait for an incoming LIN frame from host

STEP 3: Synchronize the baudrate to the host

STEP 4: Enter for Master Request Frame or for Slave Response Frame

The next section, **Section 49.14.6.4**, provides some hints on setting up the microcontroller for baudrate detection of LIN.

*Note: Re-synchronization and setup of baudrate are always done for **every** Master Request Header or Slave Response Header LIN frame.*

49.14.6.4 Initialization of Break/Synch Field Detection Logic

The LIN baudrate detection feature provides measures to detect the baudrate within the LIN protocol using Timer 2 within the LIN software. Initialization consists of:

- Serial port of the microcontroller set to Mode 1 (8-bit UART, variable baudrate) for communication.
- Provide the baudrate range via bit field BCON.BGSEL.
- Toggle BCON.BRDIS bit (set the bit to 1 before clearing it back to 0) to initialize the Break/Synch detection logic.
- Clear all status flags LINST.BRK, LINST.EOFSYN and LINST.ERRSYN to 0.
- Timer 2 is set to capture mode with falling edge trigger at input T2EX. Bit T2_MOD.EDGESEL is set to 0 by default, and bit T2_CON.CP_RL2 is set to 1.
- Timer 2 external events are enabled. T2_CON. EXEN2 is set to 1 (EXF2 flag is set when a negative transition occurs at input T2EX).
- f_{T2} can be configured by bit field T2_MOD.T2PRE.

Note: It is also recommended to toggle the BCON.BRDIS bit after the reception of each LIN frame (complete or erroneous frame) to avoid a wrong Break field detection in noisy environments (i.e. spikes on the LIN bus).

49.14.6.5 Break Detection

The Break/Synch Field detection logic supports a maximum number of bits in the Break field as defined by the conformance test 26.6 bits.

49.14.6.6 Baudrate Range Selection

If the maximum number of bits in the Break field is exceeded, the internal counter will overflow, which results in a baudrate detection error. Therefore, an appropriate BGSEL value has to be selected for the required baudrate detection range.

The baudrate range defined by different BGSEL settings is shown in **Table 711**.

Each BGSEL setting supports a range of baudrate for detection. If the baudrate used is outside the defined range, the baudrate may not be detected correctly.

Table 711 BGSEL Bit Field Definition for Different Input Frequencies

f_{PCLK}	BGSEL	Baudrate Selection for Detection $f_{PCLK}/(2184*2^{BGSEL})$ to $f_{PCLK}/(74*2^{BGSEL})$
20 MHz	00_B	9.2 kHz to 270.2 kHz
	01_B	4.6 kHz to 135.1 kHz
	10_B	2.3 kHz to 67.5 kHz
	11_B	1.1 kHz to 33.7 kHz

When f_{PCLK} = 20 MHz, the baudrate range between 1.1 kHz to 270.2 kHz can be detected. The following examples serve as a guide to select the BGSEL value:

- If the baudrate falls in the range of 1.2 kHz to 2.3 kHz, the selected BGSEL value is 11_B.
- If the baudrate falls in the range of 2.3 kHz to 4.6 kHz, the selected BGSEL value is 10_B.
- If the baudrate falls in the range of 4.6 kHz to 9.2 kHz, the selected BGSEL value is 01_B.
- If the baudrate falls in the range of 9.2 kHz to 270.2 kHz, the selected BGSEL value is 00_B. If the baudrate is 20 kHz, the possible values of BGSEL that can be selected are 00_B, 01_B, 10_B, and 11_B. However, it is advisable to select 00_B for better detection accuracy.

49.14.6.7 LIN Baudrate Detection

The configuration has to take place in software. The baudrate detection for LIN is shown in **Figure 896**, the Header LIN frame consists of the:

- SYN Break (13 bit times low)
- SYN byte (55_H)
- Protected ID field

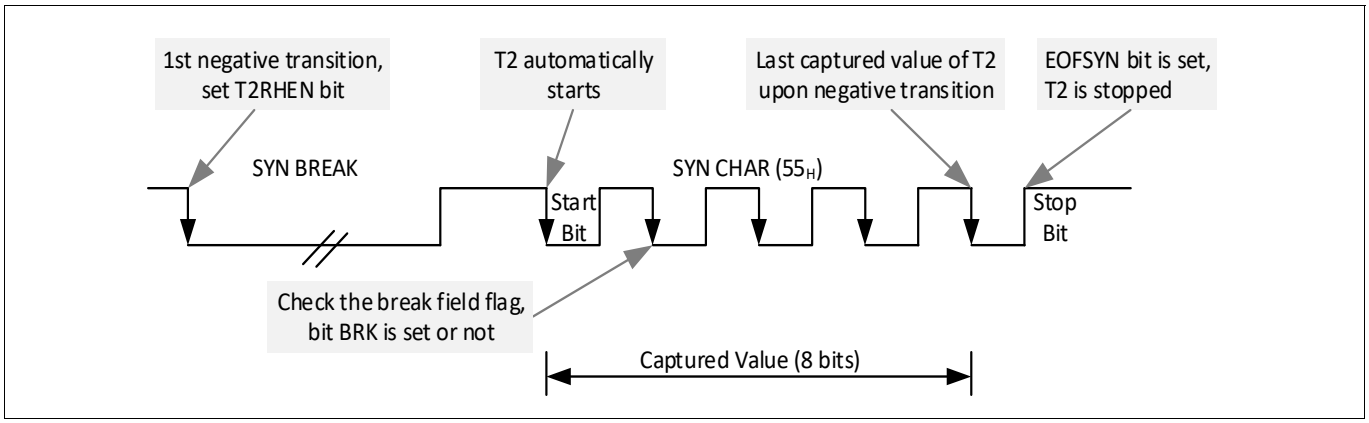

Figure 896 LIN Auto Baudrate Detection

With the first falling edge:

- The Timer 2 External Start Enable bit (T2_MOD.T2RHEN) is set. The falling edge at input T2EX is selected by default for Timer 2 External Start (bit T2_MOD.T2REGS is 0).

With the second falling edge:

- Start Timer 2 by the hardware.

With the third falling edge:

- Timer 2 captures the timing of 2 bits of SYN byte.
- Check the Break Field Flag bit LINST.BRK.

If the Break Field Flag LINST.BRK is set, software may continue to capture 4/6/8 bits of SYN byte. Finally, the End of SYN Byte Flag (LINST.EOFSYN) is set, Timer 2 is stopped. T2 Reload/Capture register (T2_RC2H/L) is the time taken for 2/4/6/8 bits according to the implementation. Then the LIN routine calculates the actual baudrate, sets the PRE and BG values if the UART module uses the baudrate generator for baudrate generation.

After the third falling edge, the software may discard the current operation and continue to detect the next header LIN frame if the following conditions were detected:

- The Break Field Flag LINST.BRK is not set, or
- The SYN Byte Error Flag LINST.ERRSYN is set, or
- The Break Field Flag LINST.BRK is set, but the End of SYN Byte Flag LINST.EOFSYN and the SYN Byte Error Flag LINST.ERRSYN are not set.

49.14.6.8 LIN Interrupt Requests

The following figure illustrates the LIN interrupt requests. Note that the flags must be cleared by software. See also the section on “Interrupt Structure 2” in chapter “Interrupt System”.

49.14.8.1 UART Registers

UART contains the two Special Function Registers (SFRs), SCON and SBUF. SCON is the control register and SBUF is the data register. On reset, both SCON and SBUF return 00_H. The serial port control and status register is the SFR SCON. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8) and the serial port interrupt bits (TI and RI).

SBUF is the receive and transmit buffer of the serial interface. Writing to SBUF loads the transmit register and initiates transmission. This register is used for both transmit and receive data. Transmit data is written to this location and receive data is read from this location, but the two paths are independent.

Reading out SBUF accesses a physically separate receive register.

Serial Data Buffer

Note: Register UART_SBUF may only be written to when no transmission is in progress (a previously commenced transmission is finished when bit UART_SCON.TI is set to 1). Otherwise, an ongoing transmission may be corrupted.

49.14.8.3 Baudrate Generator Timer/Reload Registers

The low and high bytes of the baudrate timer/reload register BG contain the 11-bit reload value for the baudrate timer and the 5-bit fractional divider selection.

Reading the low byte of register BG returns the content of the lower three bits of the baudrate timer and the FD_SEL setting, while reading the high byte returns the content of the upper 8 bits of the baudrate timer.

Writing to register BG loads the baudrate timer with the reload and fractional divider values from the BG register, the first instruction cycle after UART_BCON.R is set.

BG may only be written if R = 0.

49.15 Synchronous Serial Channel

This chapter describes the Synchronous Serial Channel (SSC).

49.15.1 Overview

The Synchronous Serial Channel (SSC) supports both full-duplex and half-duplex serial synchronous communication. The serial clock signal can be generated by the SSC itself (Master Mode) through its own 16-bit baud-rate generator, or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices using other synchronous serial channel. Transmission and reception of data is double-buffered. In slave mode, the SSC is limited to 1 MBaud/s.

Features

- Master and Slave Mode operation
  - Full-duplex or half-duplex operation
- Transmit and receive buffered; four-stage FIFO for receive
- Flexible data format
  - Programmable number of data bits: 4 to 8 bits (1, 2 and 3 bit transfers are programmable, but forbidden)
  - Programmable shift direction: Least Significant Bit (LSB) or Most Significant Bit (MSB) shift first
  - Programmable clock polarity: idle low or high state for the shift clock
  - Programmable clock/data phase: data shift with leading or trailing edge of the shift clock
- Variable baud-rate
- Compatible with Serial Peripheral Interface (SPI)
- Interrupt generation
  - On a transmitter empty condition
  - On a receive condition
  - On a receiver FIFO full and empty condition.
  - On an error condition (receive, baud-rate, transmit error)

Figure 899 shows the block diagram of the SSC.

Note: In this chapter, the input and output signals from/to the GPIO ports are referred to with their generic name, such as MTSR, MRST, or SCLK. However, the actual input and output signals use separate lines from/to the GPIO, since they are connected in different ways to the pin logic (pin input line; alternate data output line). Only where explicitly applicable, the generic signal names are extended with an "_I" (input line) or "_O" (output line) identifier.

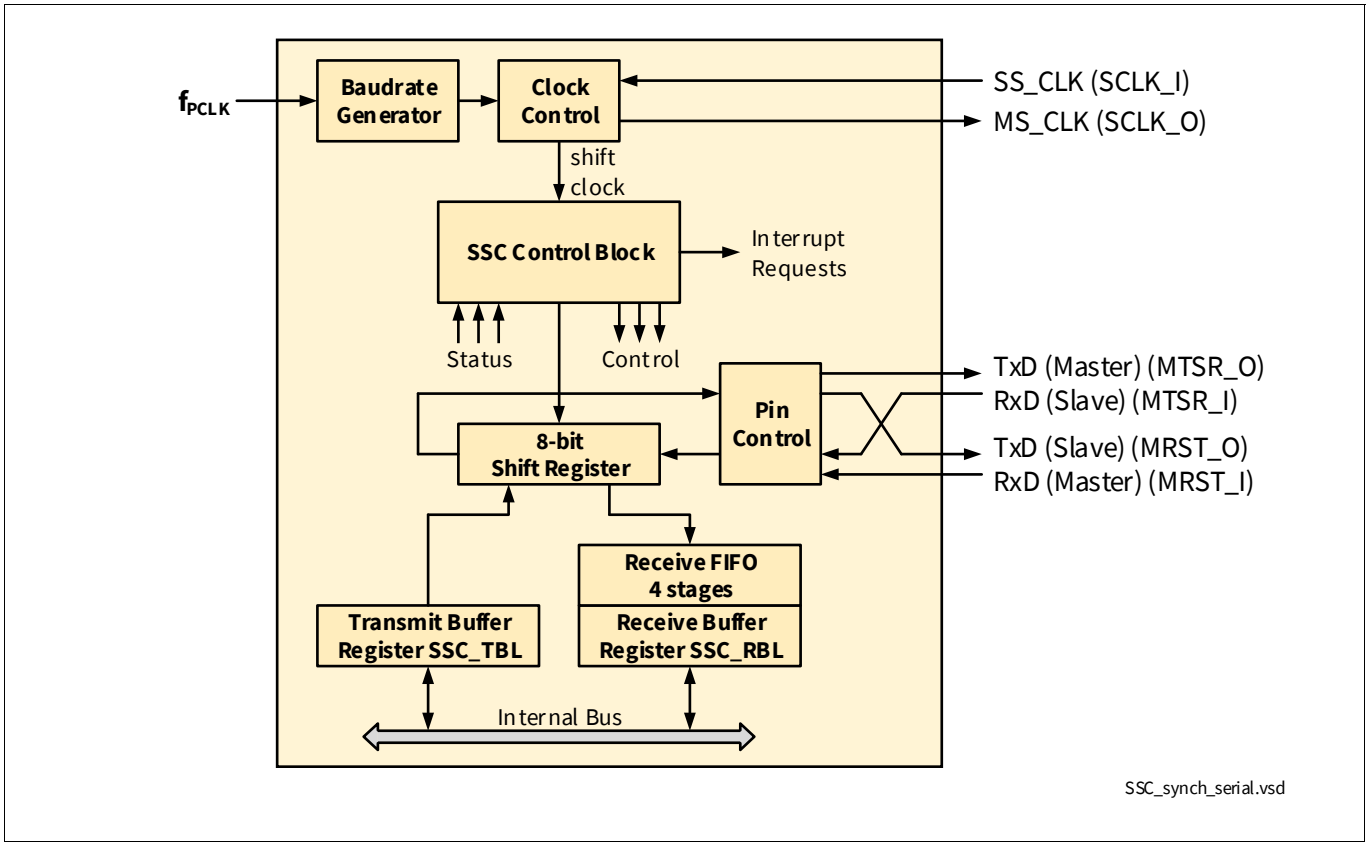

Figure 899 SSC Block Diagram

49.15.2 General Operation

The SSC supports full-duplex and half-duplex synchronous communication up to 3.33 MBaud (@ 20 MHz module clock). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit baud-rate generator provides the SSC with a separate serial clock signal.

The SSC can be configured in a very flexible way, so it can be used with other synchronous serial channels, can serve for master/slave or multimaster interconnections, or can operate compatible with the popular SPI interface. Thus, the SSC can be used to communicate with shift registers (I/O expansion), peripherals (e.g. EEPROMs, etc.) or other controllers (networking). The SSC supports half-duplex and full-duplex communication. Data is transmitted or received on lines TXD and RXD, normally connected with pins MTSR (Master Transmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output via line MS_CLK (Master Serial Shift Clock) or input via line SS_CLK (Slave Serial Shift Clock). Both lines are normally connected to pin SCLK.

49.15.2.1 Operating Mode Selection

The operating mode of the serial channel SSC is controlled by two register pairs, sharing the same addresses:

- During programming (SSC disabled; SSC_CONPH.EN = 0), access to register pair SSC_CONPH/SSC_CONPL is available, providing access to a set of control bits.
- During operation (SSC enabled; SSC_CONOH.EN = 1), access to register pair SSC_CONOH/SSC_CONOL is available, providing access to a set of control/status flags.

The two register pairs share the same two addresses. The selection between the registers is depending on the state of the enable bit EN prior to an access to the register pairs.

The shift register of the SSC is connected to both the transmit lines and the receive lines via the pin control logic. Transmission and reception of serial data are synchronized and take place at the same time, i.e. the same number of transmitted bits is also received. Transmit data is written into the Transmit Buffer (SSC_TBL) and it is moved, on the next shifting edge, to the shift register as soon as this is empty. An SSC master (SSC_CONOH.MS = 1) immediately begins transmitting, while an SSC slave (SSC_CONOH.MS = 0) will wait for an active shift clock. When the transfer starts, the busy flag SSC_CONOH.BSY is set and the Transmit Interrupt Request line TIR will be activated within the timeframe of the first bit to indicate that register SSC_TBL may be reloaded again. When the programmed number of bits (4…8) has been transferred, the contents of the shift register are moved to the Receive FIFO and the Receive Interrupt Request line RIR will be activated for the first received frame. If no further transfer is to take place (SSC_TBL is empty), SSC_CONOH.BSY will be cleared (Master Mode). In Slave Mode, SSC_CONOH.BSY will always be cleared after a single transfer. Software shall not modify SSC_CONOH.BSY, as this flag is hardware controlled.

Note: The SSC starts transmission and sets SSC_CONOH.BSY minimum two clock cycles after transmit data is written into SSC_TBL. Therefore, it is not recommended to poll SSC_CONOH.BSY to check for the start and end of a single transmission. Instead, interrupt service routines should be used if interrupts are enabled, or the interrupt flags IRCON1.TIR and IRCON1.RIR should be polled if interrupts are disabled.

Note: Only one serial interface can be master at a given time.

The transfer of serial data bits can be programmed in many respects:

- The data width can be specified from 4 bits to 8 bits
- A transfer may start with either the LSB or the MSB
- The shift clock may be idle low or idle high
- The data bits may be shifted with the leading edge or the trailing edge of the shift clock signal
- The baud-rate may be set from 152.59 Baud up to 3.33 MBaud (@ 20 MHz module clock)
- The shift clock can be generated (MS_CLK) or can be received (SS_CLK)

These features allow the adaptation of the SSC to a wide range of applications requiring serial data transfer.

The Data Width Selection supports the transfer of frames of any data length, from 4-bit “characters” up to 8-bit “characters”. Starting with the LSB (SSC_CONPL.HB = 0) allows communication with SSC devices in Synchronous Mode or with 8051-like serial interfaces, for example. Starting with the MSB (SSC_CONPL.HB = 1) allows operation compatible with the SPI interface.

Regardless of the data width selected and whether the MSB or the LSB is transmitted first, the transfer data is always right-aligned in registers SSC_TBL and SSC_RBL, with the LSB of the transfer data in bit 0 of these registers. The data bits are rearranged for transfer by the internal shift register logic. The unselected bits of SSC_TBL are ignored; the unselected bits of SSC_RBL will not be valid and should be ignored by the receiver service routine.

The Clock Control allows the adaptation of transmit and receive behavior of the SSC to a variety of serial interfaces. A specific shift clock edge (rising or falling) is used to shift out transmit data, while the other shift clock edge is used to latch in receive data. Bit SSC_CONPL.PH selects the leading edge or the trailing edge for each function. Bit SSC_CONPL.PO selects the level of the shift clock line in the idle state. Thus, for an idle-high clock, the leading edge is a falling one, a 1-to-0 transition (see **Figure 900**).

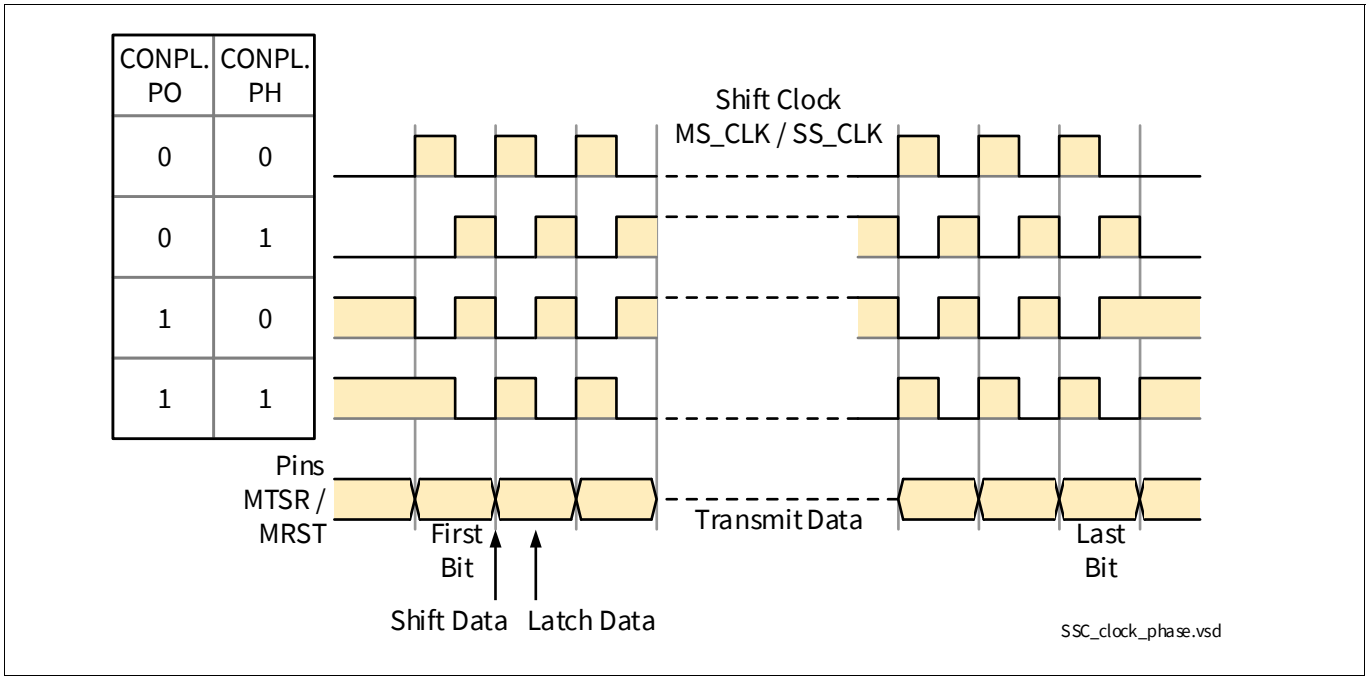

Figure 900 Serial Clock Phase and Polarity Options

49.15.2.2 Full-Duplex Operation

The various devices are connected through three lines. The definition of these lines is always determined by the master: the line connected to the master's data output line TXD is the transmit line; the receive line is connected to its data input line RXD; the shift clock line is either MS_CLK or SS_CLK. Only the device selected for master operation generates and outputs the shift clock on line MS_CLK. Since all slaves receive this clock, their pin SCLK must be switched to input mode. The output of the master's shift register is connected to the external transmit line, which in turn is connected to the slaves' shift register input. The output of the slaves' shift register is connected to the external receive line in order to enable the master to receive the data shifted out of the slave. The external connections are hard-wired, the function and direction of these pins is determined by the master or slave operation of the individual device.

Note: The shift direction shown in the figure applies for MSB-first operation as well as for LSB-first operation.

When initializing the devices in this configuration, one device must be selected for master operation while all other devices must be programmed for slave operation. Initialization includes the operating mode of the device's SSC and also the function of the respective port lines.

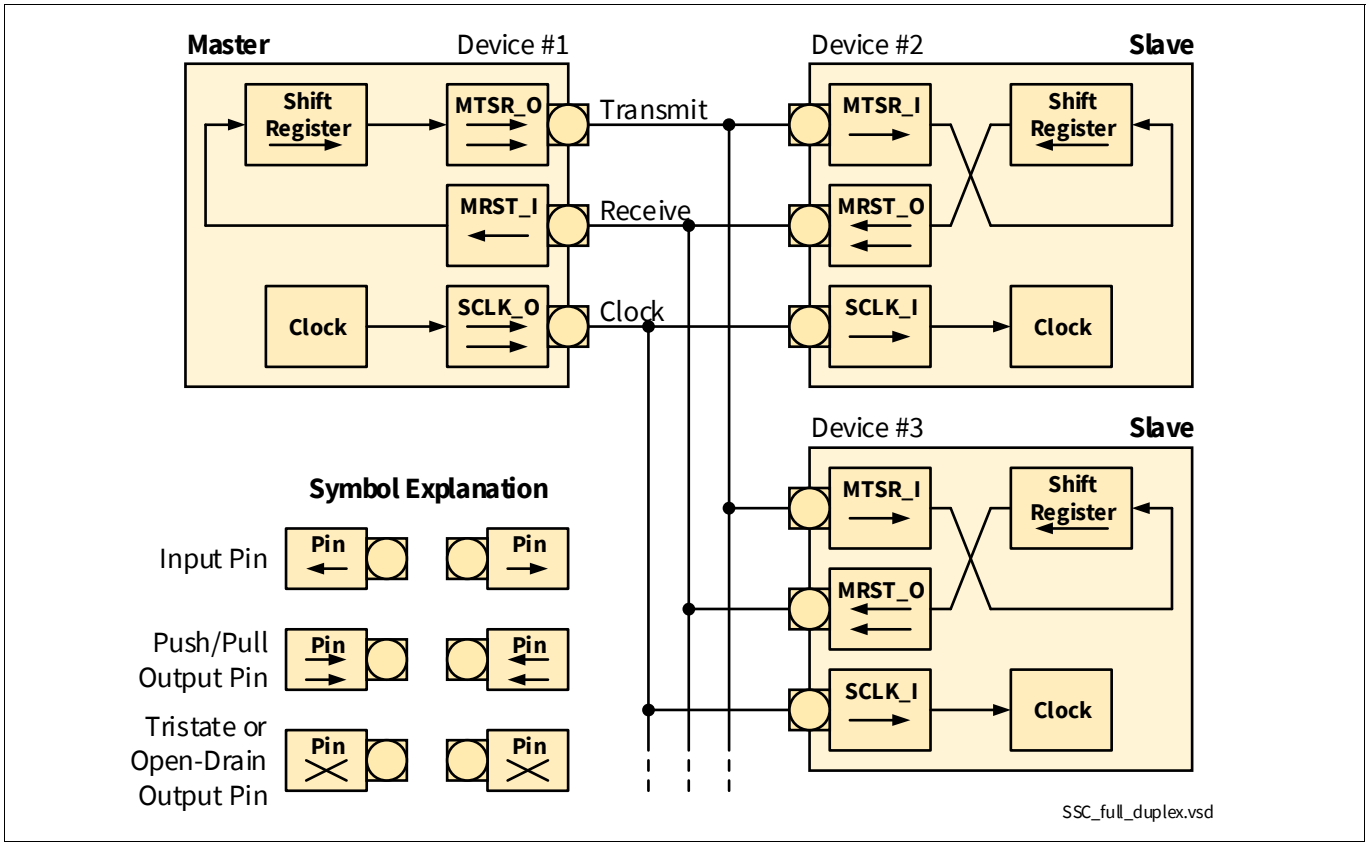

Figure 901 SSC Full-Duplex Configuration

The data output pins MRST of all slave devices are connected together onto the one receive line in the configuration shown in **Figure 901**. During a transfer, each slave shifts out data from its shift register. There are two ways to avoid collisions on the receive line due to different slave data:

- Only one slave drives the line, i.e. enables the driver of its MRST pin. All the other slaves must have their MRST pins programmed as input so only one slave can put its data onto the master's receive line. Only receiving data from the master is possible. The master selects the slave device from which it expects data either by separate select lines, or by sending a special command to this slave. The selected slave then switches its MRST line to output until it gets a de-selection signal or command. This option is applicable only if the pin has output driver disabling capability.
- The slaves use open-drain output on MRST. This forms a wired-AND connection. The receive line needs an external pull-up in this case. Corruption of the data on the receive line sent by the selected slave is avoided when all slaves not selected for transmission to the master only send ones (1s). Because this high level is not actively driven onto the line, but only held through the pull-up device, the selected slave can pull this line actively to a low-level when transmitting a zero bit. The master selects the slave device from which it expects data either by separate select lines or by sending a special command to this slave.

After performing the necessary initialization of the SSC, the serial interfaces can be enabled. For a master device, the alternate clock line will now go to its programmed polarity. The alternate data line will go to either 0 or 1 until the first transfer starts.

When the serial interfaces are enabled, the master device can initiate the first data transfer by writing the transmit data into register SSC_TBL. This value is copied into the shift register (assumed to be empty at this time), and the selected first bit of the transmit data will be placed onto the TXD line before the next clock from the baud-rate generator (transmission starts only if SSC_CONPH.EN = 1).

Depending on the selected clock phase, a clock pulse will also be generated on the MS_CLK line. At the same time, with the opposite clock edge, the master latches and shifts in the data detected at its input line RXD. This “exchanges” the transmit data with the receive data. Because the clock line is connected to all slaves, their shift registers will be shifted synchronously with the master’s shift register — shifting out the data contained in the registers, and shifting in the data detected at the input line. After the pre-programmed number of clock pulses (via the data width selection), the data transmitted by the master is contained in all the slaves’ shift registers, while the master’s shift register holds the data of the selected slave. In the master and all slaves, the contents of the shift register are copied into the receive FIFO and the receive interrupt line RIR is activated for the first received frame.

When a slave device is transmitting its data, the bit SSC_CONOH.BSY is not set until the first clock edge at SS_CLK appears. The slave device will not wait for the next clock from the baud-rate generator, as the master does. The reason for this is that, depending on the selected clock phase, the first clock edge generated by the master may already be used to clock in the first data bit. Thus, the slave’s first data bit must already be valid at this time.

Note: For Master and Slave Mode the following applies: In the case SSC_CONPL.PH = 1, the value is placed immediately on the bus, while for SSC_CONPL.PH = 0, it is placed on the output with the first shifting edge. Besides, the value is not immediately copied into the shift register, but with the first shifting edge.

Note: On the SSC, a transmission and a reception takes place at the same time, regardless of whether valid data has been transmitted or received.

Note: The initialization of the SCLK pin on the master requires some attention in order to avoid undesired clock transitions, which may disturb the other devices. Before the clock pin is switched to output mode, the clock output level should be selected in the control register SSC_CONPL, and the alternate output be prepared via the appropriate GPIO register, or the output latch must be loaded with the clock idle level.

49.15.2.3 Half-Duplex Operation

In a Half-Duplex Mode, only one data line is necessary for both receiving **and** transmitting of data (see **Figure 902**).

The master device controls the data transfer by generating the shift clock, while the slave devices receive it. Due to the fact that all transmit and receive pins are connected to the one data exchange line, serial data may be moved between arbitrary stations.

Similar to Full-Duplex Mode, there are two ways to avoid collisions on the data exchange line:

- Only the transmitting device may enable its transmit pin driver. This option is applicable only if the pin has output driver disabling capability.
- The non-transmitting devices use open-drain output and send only ones.

Because the data inputs and outputs are connected together, a transmitting device will clock in its own data at the input pin (MRST for a master device, MTSR for a slave). By this method, any corruptions on the common data exchange line are detected if the received data is not equal to the transmitted data.

The Half-Duplex Mode port configuration using three pins is shown in **Figure 902**.

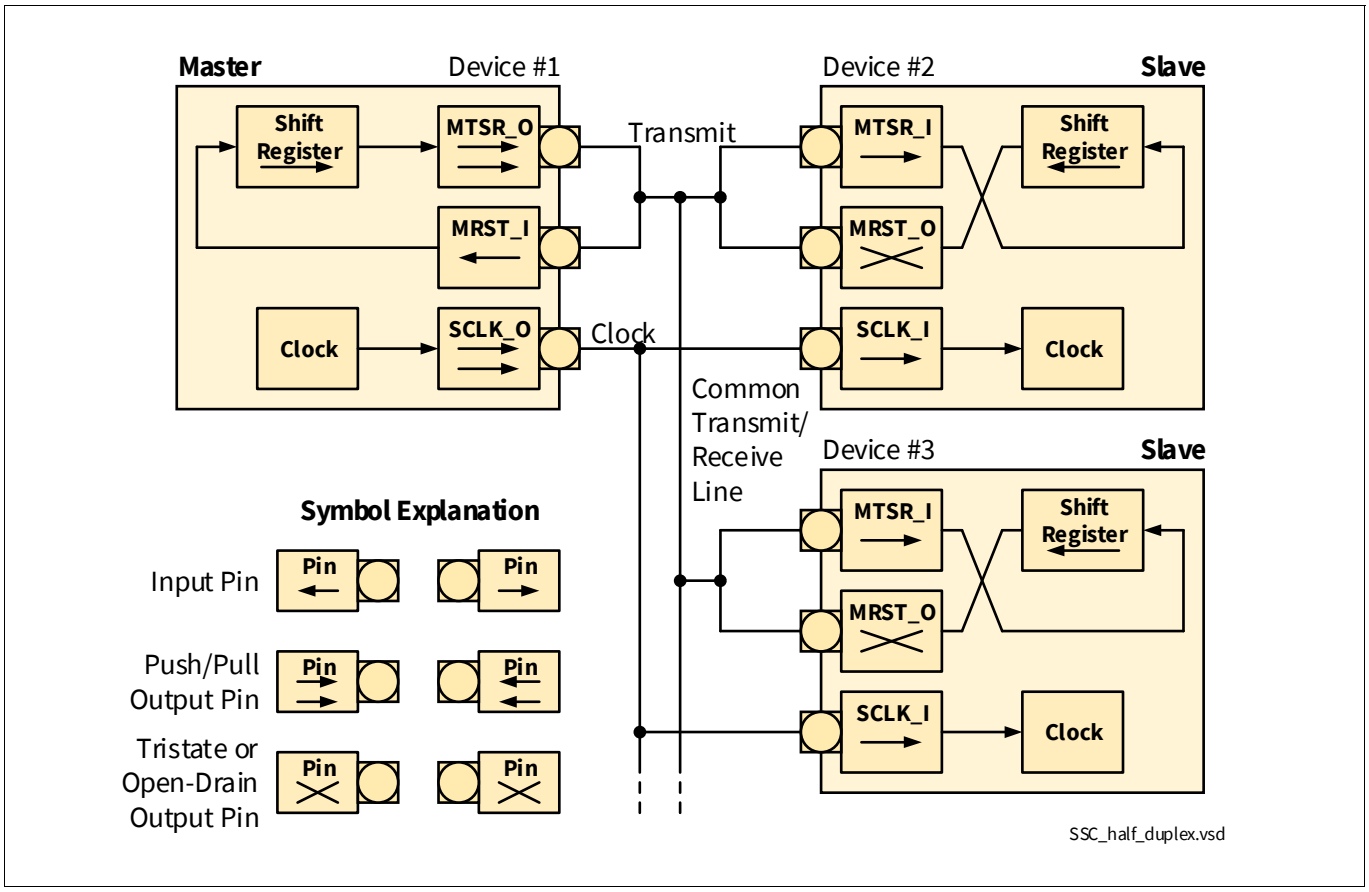

Figure 902 SSC Half-Duplex Configuration

49.15.2.4 Loop Back Mode

To aid debugging, it is useful to receive back the data which is sent out. When SSC_CONPL.LB is set, the receive input is connected to the transmit output. Hence, the data which is sent out is automatically received back. Loop-back mode is supported only in master mode.

49.15.2.5 Continuous Transfers (Master Mode only)

When the transmit interrupt request flag is set, it indicates that the transmit buffer SSC_TBL is empty and ready to be loaded with the next transmit data. If SSC_TBL has been reloaded by the time the current transmission is finished (at least 2 PCLK cycles before the last latching edge), the data is immediately transferred to the shift register and the next transmission will start without any additional delay. In such a case, there is no gap between the two successive frames on the data line. For example, two byte transfers would look the same as one word transfer. This feature can be used to interface with devices that can operate with or require more than 8 data bits per transfer. It is just a matter of software, how long a total data frame length can be. This option can also be used to interface to byte-wide and word-wide devices on the same serial bus, for instance.

Note: Of course, this can happen only in multiples of the selected basic data width, because it would require disabling/enabling of the SSC to reprogram the basic data width on-the-fly. Additionally, if the next data is now written any time after 2 PCLK cycles before the last latching edge, then there may be up to a half SCLK clock delay to start transmission of the new word.

Note: In slave mode, when SSC_CONPL.PH = 0, if the data is written into the transmit buffer at least 4 PCLK cycles before the first SS_CLK edge of the next transfer (whether shifting or latching), then continuous transfer occurs and no transmit error is generated. Otherwise, a transmit error is generated. If SSC_CONPL.PH = 1, then the data has to be provided 7 PCLK cycles before the first SS_CLK edge of the next transfer. Otherwise, a transmit error is generated.

49.15.2.6 Baud-Rate Generation

The serial channel SSC has its own dedicated 16-bit baud-rate generator with 16-bit reload capability, allowing baud-rate generation independent of the timers. **Figure 903** shows the baud-rate generator.

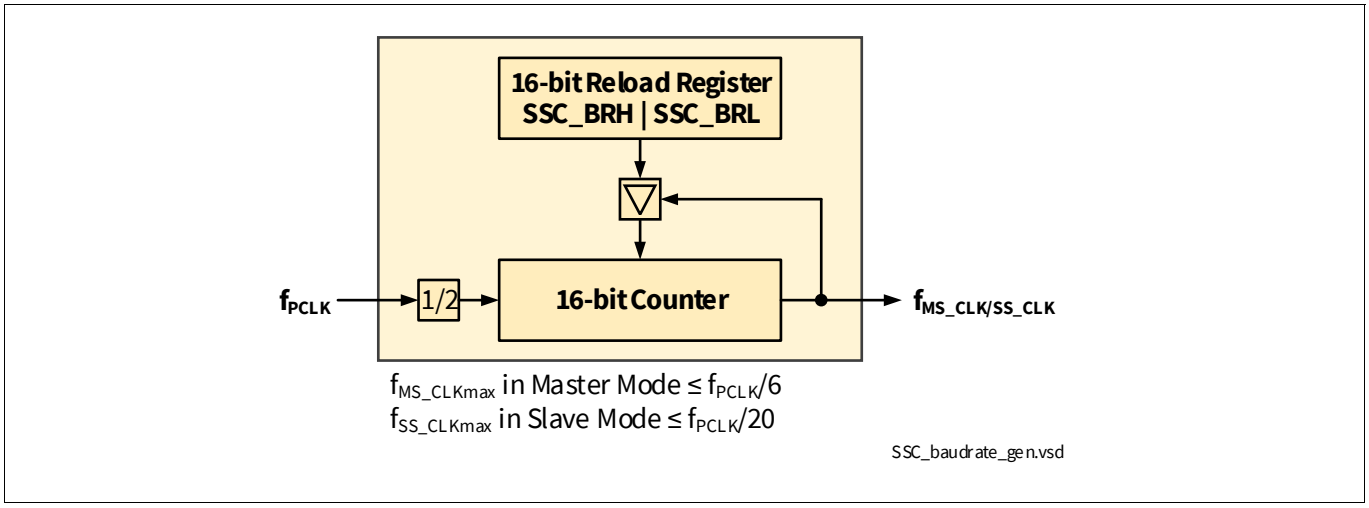

Figure 903 SSC Baud-Rate Generator

The baud-rate generator is clocked with the module clock f_{hw_clk} (which is the PCLK (fPCLK)). The timer counts downwards. On underflow, it is reloaded with the 16-bit value BR contained in register pair SSC_BRH|SSC_BRL.

Note: Never write to BR while the SSC is enabled. The desired value shall be written to BR only when SSC is disabled.

The formulas below calculate either the resulting baud-rate for a given reload value, or the required reload value for a given baud-rate:

Note: For the SSC module in the SCR, f_{hw_clk} is the PCLK (f_{PCLK}).

$$\text{Baudrate} = \frac{f_{hw\_clk}}{2 \times (
 + 1)} \qquad BR = \frac{f_{hw\_clk}}{2 \times \text{Baudrate}} - 1$$

SSC_baudrate_formula.vsd

Figure 904 SSC Baud-Rate Calculation

BR represents the contents of the reload register pair, taken as an unsigned 16-bit integer, while baud-rate is equal to f_{MS_CLK/SS_CLK} as shown in **Figure 903**.

The maximum baud-rate that can be achieved when using a module clock of 20 MHz is 3.33 MBaud in Master Mode (with BR = 0002_H) (the theoretical value is 10 MBaud, but not guaranteed) or 1 MBaud (the theoretical value is 5 MBaud, but this value is not guaranteed) in Slave Mode (with BR = 0009_H).

Table 722 lists some possible baud-rates together with the required reload values and the resulting bit times, assuming a module clock of 20 MHz.

Table 722 Typical Baud-Rates of the SSC (f_{hw_clk} = 20 MHz)

Reload Value	Baud-Rate (= f_{MS_CLK/SS_CLK})	Deviation
0000_H	not allowed	0.0%
0001_H	not allowed	0.0%
0004_H	2 MBaud (only in Master Mode)	0.0%
0009_H	1 MBaud	0.0%
0013_H	500 kBaud	0.0%
0063_H	100 kBaud	0.0%
$FFFF_H$	152.59 Baud	0.0%

49.15.2.7 Error Detection Mechanisms

The SSC is able to detect three different error conditions. Receive Error is detected in all modes; Transmit Error and Baud-Rate Error apply only to Slave Mode. When an error is detected, the respective error flag is/can be set and an error interrupt request will be generated if enabled (see Figure 905). The error interrupt handler may then check the error flags to determine the cause of the error interrupt. The error flags are not reset automatically, but must be cleared by software after servicing. This allows servicing of some error conditions via interrupt, while the others may be polled by software.

Note: The error interrupt handler must clear the associated (enabled) error flag(s) to prevent repeated interrupt requests.

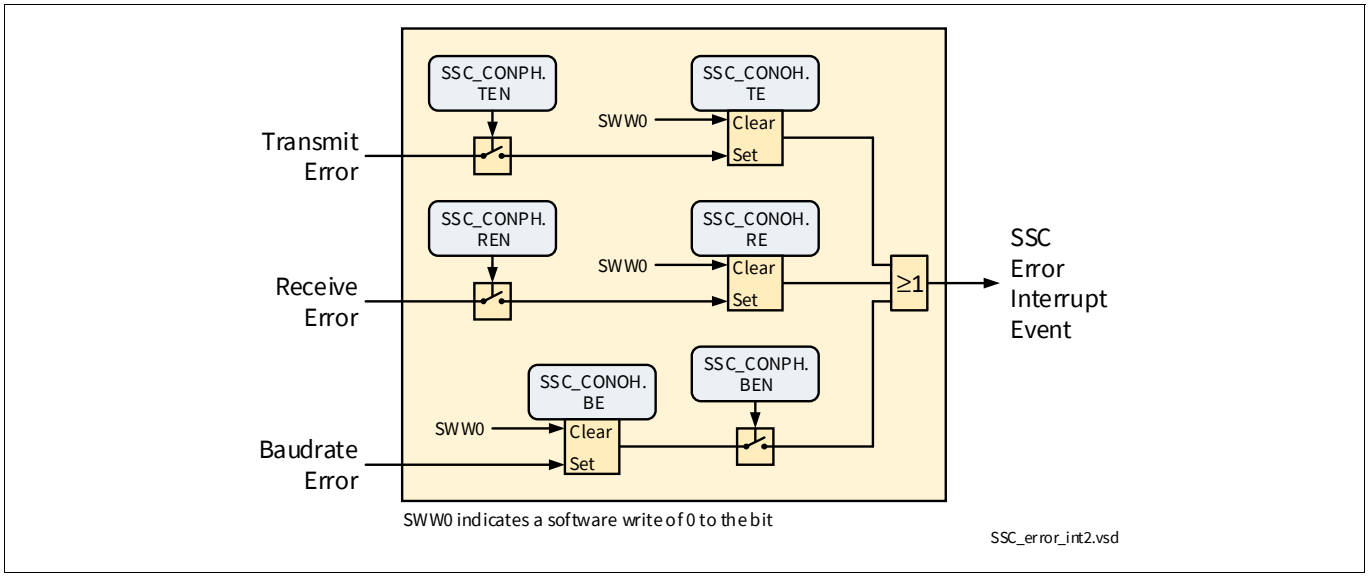

Figure 905 SSC Error Interrupt Control (interrupt pulse no signal)

A **Receive Error** (Master or Slave Mode) is detected when the FIFO is full (FIFO full already set) and another frame is completely received, but the previous data was not read out of the receive FIFO. This condition sets the error flag SSC_CONOH.RE and the error interrupt request line, when enabled via SSC_CONPH.REN. The FIFO has four elements, afterwards, the reception is stopped. FIFO full will be raised. When Receive Error is raised, an additional reception was intended, but as the FIFO is full it is lost.

A **Baud-Rate Error** (Slave Mode) is detected when the incoming clock signal deviates from the programmed baud-rate by more than 100%, i.e. it is either more than double or less than half the expected baud-rate. This condition sets the error flag SSC_CONOH.BE and, when enabled via SSC_CONPH.BEN , the error interrupt request line. Using this error detection capability requires that the slave's baud-rate generator is programmed to the same baud-rate as the master device. This feature detects false additional, or missing pulses on the clock line (within a certain frame).

A **Transmit Error** (Slave Mode) is detected when a transfer was initiated by the master (SS_CLK gets active) but the transmit buffer SSC_TBL of the slave was not updated since the last transfer. This condition sets the error flag SSC_CONOH.TE and the error interrupt request line, when enabled via SSC_CONPH.TEN. If a transfer starts while the transmit buffer is not updated, the slave may shift out invalid data. This may lead to corruption of the data on the transmit/receive line in half-duplex mode (open-drain configuration) if this slave is not selected for transmission. This mode requires that slaves not selected for transmission only shift out ones; that is, their transmit buffers must be loaded with '$FFFF_H$' prior to any transfer.

Note: In order to avoid possible conflicts or misinterpretations, it is recommended to always load the slave's transmit buffer prior to any transfer.

The cause of an error interrupt request (receive, baud-rate, transmit error) can be identified by the error status flags in control register SSC_CONOH.

Note: The error status flags SSC_CONOH.TE , SSC_CONOH.RE, and SSC_CONOH.BE are not reset automatically upon entry into the error interrupt service routine, but must be cleared by software.

49.15.3 SSC Interrupts

The five SSC interrupts can be separately enabled or disabled by setting or clearing their corresponding enable bits in SFR SCU_MODIEN.

For a detailed description of the various interrupts see **Section 49.15.2**. An overview is given in **Table 723**.

Table 723 SSC Interrupt Sources

Interrupt	Signal	Description
Transmission starts	TIR	Indicates that the transmit buffer can be reloaded with new data.
Transmission ends	RIR	The configured number of bits has been transmitted and shifted to the receive buffer. This is only the case for the first reception after FIFO empty.
Receive FIFO full	RFI	The receive FIFO is full and will stop reception. Further information is lost.
Receive FIFO empty	REI	The receive FIFO is empty, further access will provide junk data.
Receive Error	EIR	This interrupt occurs if a new data frame is completely received while the FIFO is full.
Baud-Rate Error (Slave Mode only)	EIR	This interrupt is generated when the incoming clock signal deviates from the programmed baud-rate by more than 100%.
Transmit Error (Slave Mode only)	EIR	TE is generated in case corrupted data is sent. This can be an empty transmit buffer or corrupted data on the serial bus (in case the transmit buffer is overwritten round about transmission start).

Figure 906 shows a diagram of the interrupt request handling of the SSC.

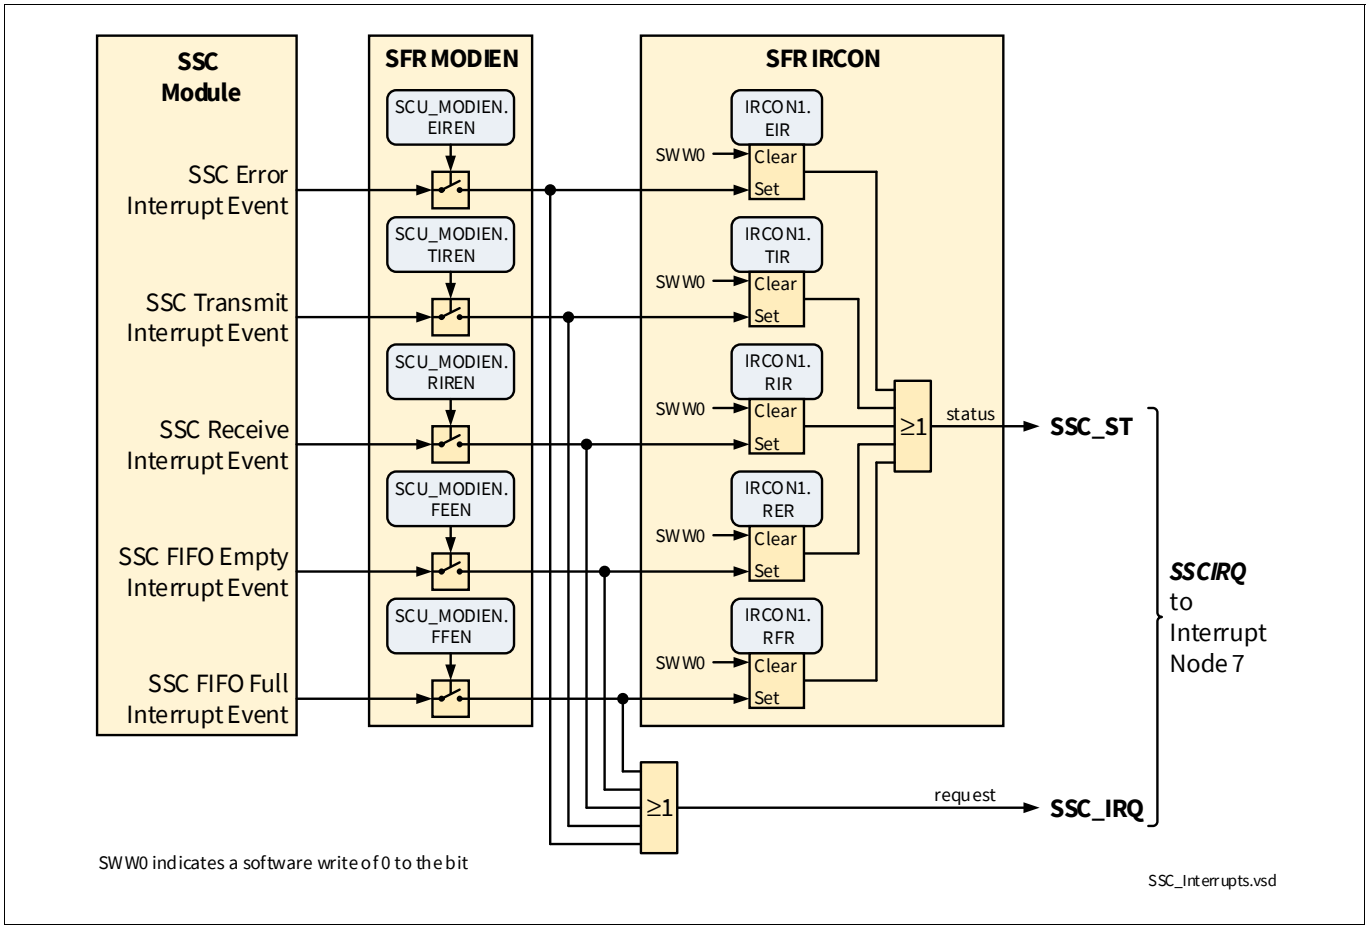

Figure 906 SSC Interrupt Request Overview

49.15.4 SSC Connections to GPIO

The following figure illustrates the signal connections of the SSC to the GPIO ports.

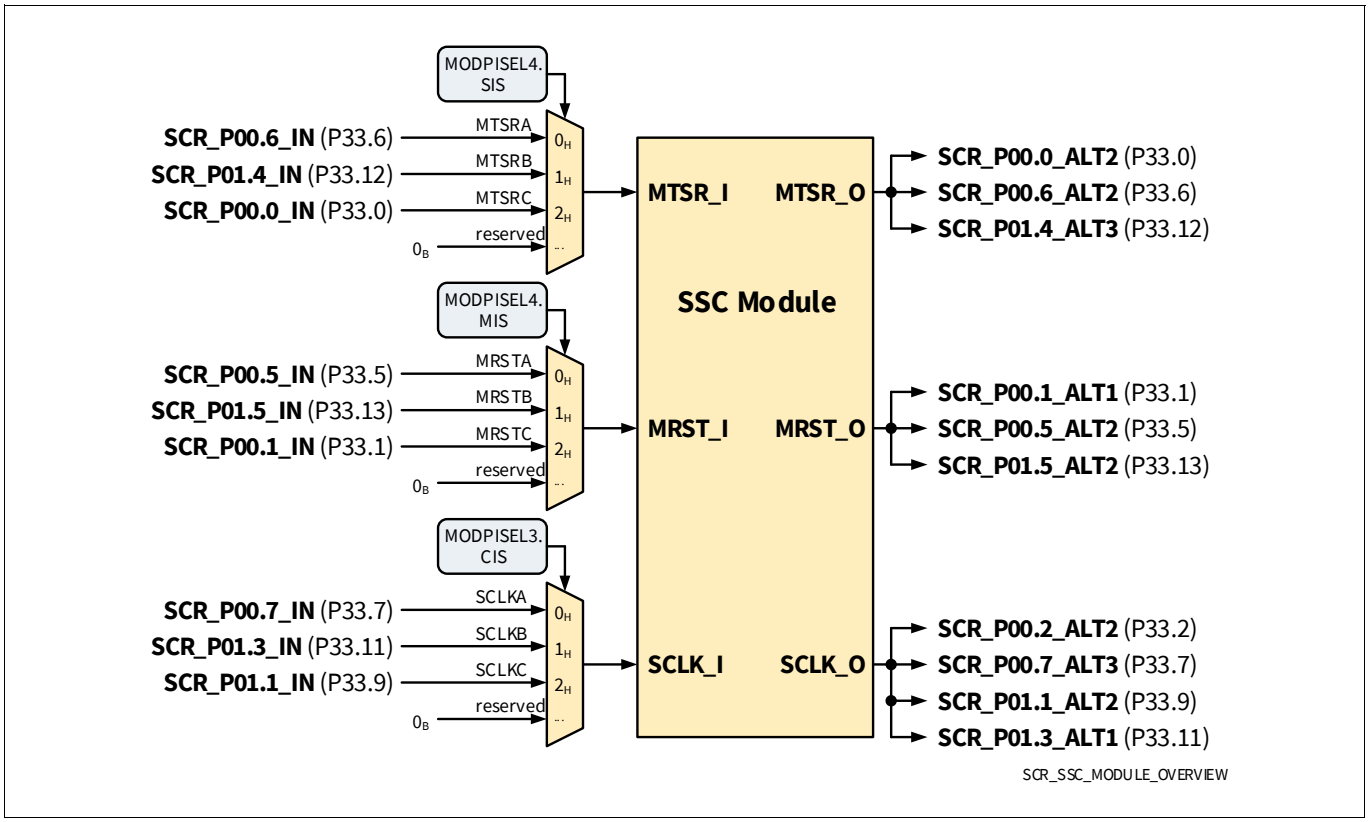

Figure 907 SSC Connections to GPIO Ports

49.15.5 Register Description

The SSCSpecial Function Registers are accessed from the standard (non-mapped) SFR area. The addresses of the SFRs are listed in **Table 724**.

Table 724 Register Overview - SSC (sorted by Name)

Short Name	Description	RMAP	PAGE	Offset Address	Page Number
SSC_BRH	Baud Rate Timer Reload Register High	0	X	$08E_H$	**303**
SSC_BRL	Baud Rate Timer Reload Register Low	0	X	$08D_H$	**303**
SSC_CONOH	Control Register High [Operation Mode]	0	X	$08A_H$	**301**
SSC_CONOL	Control Register Low [Operation Mode]	0	X	089_H	**300**

SSC_CONPL	Control Register Low [Programming Mode]	0	X	089_H	**298**
SSC_RBL	Receiver Buffer Register	0	X	$08C_H$	**304**
SSC_TBL	Transmitter Buffer Register	0	X	$08B_H$	**304**

49.15.5.1 Configuration Register

The operating mode of the serial channel SSC is controlled by two register pairs, sharing the two same addresses:

- Register pair SSC_CONPH/SSC_CONPL provides access to a set of control bits, and is accessible in Programming Mode.
- Register pair SSC_CONOH/SSC_CONOL provides access to a set of control/status flags, and is accessible in Operating Mode.

The selection between the register pairs is depending on the state of the enable bit EN prior to an access to the register. This bit is available at the MSB position in both registers, SSC_CONPH and SSC_CONOH:

- When EN = 0 (Programming Mode), registers SSC_CONPH and SSC_CONPL are accessible.
- When EN = 1 (Operating Mode), registers SSC_CONOH and SSC_CONOL are accessible.

Since the selection is dependent on the state of the EN bit prior to an access, writing, for example, $1100\ 0000_B$ to SSC_CONPH in programming mode (SSC_CONPH.EN = 0) will initialize the SSC (SSC_CONPH.EN was 0) and then turn it on. Then, register pair SSC_CONOH | SSC_CONOL is accessible, with SSC_CONOH.EN = 1.

Control Register Low [Programming Mode]

Note: When initializing the SSC, register SSC_CONPL must be written first, before writing to register SSC_CONPH and setting bit SSC_CONPH.EN to 1.

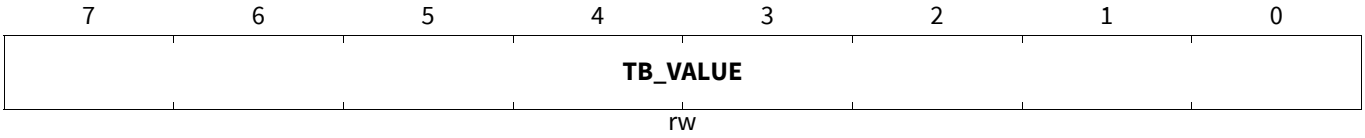
Transmitter Buffer Register **($08B_H$)** **Reset Value: Table 731**
RMAP: 0, PAGE: X



Field	Bits	Type	Description
TB_VALUE	7:0	rw	**Transmit Data Register Value** TB_VALUE is the data value to be transmitted. Unselected bits of TB_VALUE are ignored during transmission.

Table 731 Reset Values of SSC_TBL

Reset Type	Reset Value	Note
LVD Reset	00_H	
Generated Reset	00_H	

Note on programming SSC_TBL

Note: Before writing to SSC_TBL a minimum delay of 4 PCLK cycles has to be regarded after writing SSC_CONPH.EN=1.
e.g. SSC_CON_PH.EN=1;
for (i=0;i<4;i++) nop();
SSC_TBL=Byte to be transfered
Instead of nop() more usefull code can be used, as long as a delay of 4 cycles is guaranteed.

Recommendation in case of continuous transfer

It is recommended to use the the transmit interrupt as signal to write the next piece of information to the transmit buffer register. This way, it is guaranteed, that the module has the information on time (in slave mode) to guarantee the transmission.

49.15.5.4 Receive Buffer Register

The SSC receive buffer register SSC_RBL contains the received data value. It is the access point to the FIFO. The FIFO depth is 4 bytes. The FIFO stops receiving, when full. Warning flags for FIFO full (RFF) and FIFO empty (RFE) exist in SSC_CONOH.

Receiver Buffer Register

Note: Before disabling the SSC by clearing bit SSC_CONOH.EN during operation, received data has to be read out of the FIFO, as otherwise the software can read corrupted data.

SSC_RBL
Receiver Buffer Register **($08C_H$)** **Reset Value: Table 732**
RMAP: 0, PAGE: X

49.16 ADC Comparator Unit (ADCOMP)

The ADCOMP constitutes an 8-bit successive approximation Analog-to-Digital converter, supporting up to 4 channels. The ADCOMP unit is periodically activated during STANDBY mode to measure certain analog inputs, and is characterized by short activation periods after which the unit is powered off to keep the overall STANDBY current to the minimum. The conversion control involves enabling the ADC Comparator unit, selecting the channel, and subsequently issuing start of conversion via software with the support of a timer unit. After conversion is completed, end of conversion event is indicated and an interrupt may be generated.

49.16.1 Features

The ADCOMP has the following features:

- 8-bit resolution. LSB = 23.077 mV. Range = 0 - 5861.54 mV. VIN = [LSB * (ADCRES-1)]
- Accuracy / TUE = +-4 LSB
- Periodic monitoring of up to 4 ADC channels (CH0: SCR_P00.4, CH1: SCR_P00.5, CH2: SCR_P00.6 and CH3: SCR_P00.7). For the actual mapping of these SCR Ports to the ports of the device, please refer to the SCR GPIO chapter.
- Minimum 200 ns sampling time + 400 ns conversion time. Higher sampling time to be realized using timer (maximum sampling time is limited to 800 ns).

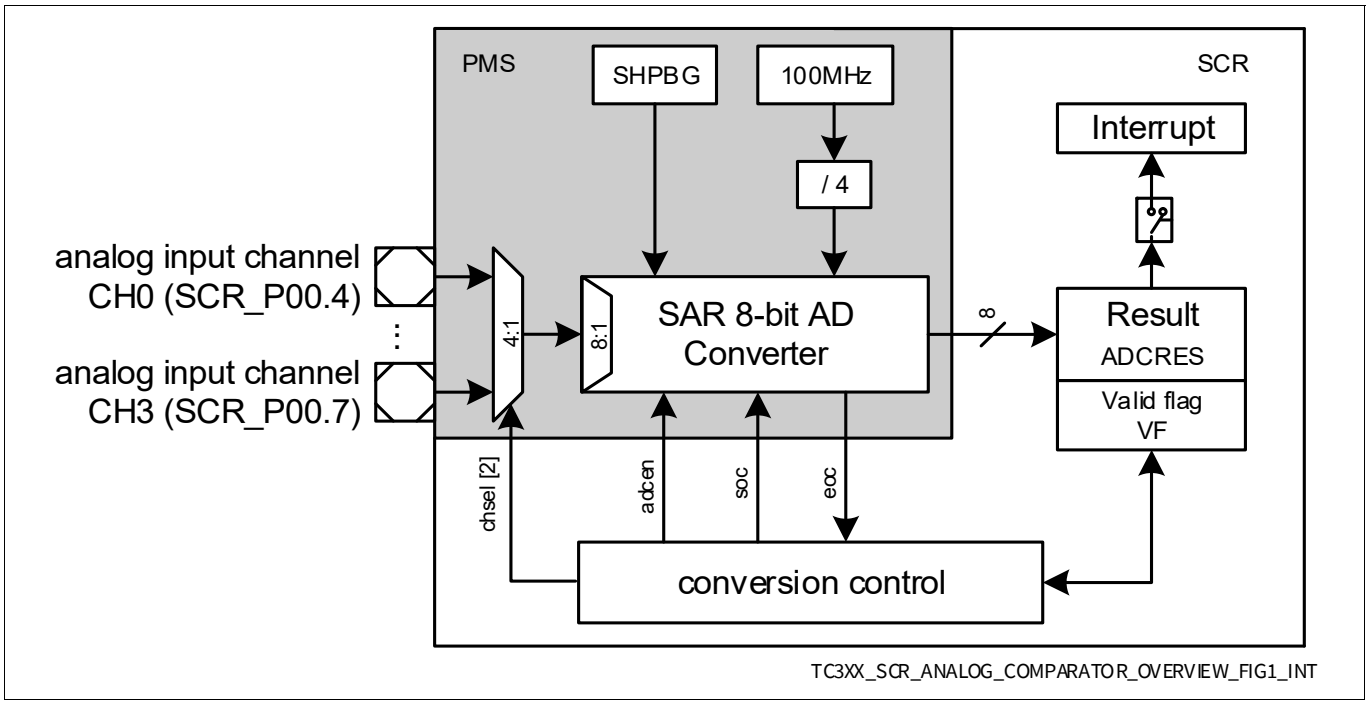

Figure 908 ADC Comparator Overview

49.16.2 Overview

The ADC unit is clocked with 25 MHz clock derived from the 100 MHz back-up clock. The reference voltage for the conversion is derived from the secondary high-precision bandgap. The analog channels are selected via a 4:1 multiplexer. The AD converter is primarily used as a secondary voltage monitor during normal RUN operation of TC3xx, and therefore has an inherent 8:1 multiplexer to route the various supply inputs. During RUN mode, the ADCOMP unit cannot be activated in SCR, and ADCENREQ is ignored. The ADCOMP unit may be enabled via ADCENREQ bit only during STANDBY mode, as during normal operation the unit is used for voltage monitoring. In normal mode, the ADCOMP channels may be converted using the main VADC unit. The conversion control and

result handling part is encapsulated in the SCR digital domain, and is clocked via the PCLK clock derived from the 100 MHz back-up clock. Requests from the SCR during RUN mode of the device will be ignored.

49.16.3 ADC Comparator Operation

In STANDBY mode, the Bandgap and the ADC unit are switched off by default. Before an ADC conversion is triggered, SHPBG Bandgap, ADC unit and 100 MHz back-up clock need to be started. The ADC needs to be enabled via bit ADCOMP_CON.ADCENREQ. The activation of the ADCOMP unit will in turn start the Bandgap, the 100 MHz clock and the SAR ADC unit for the time of conversion and a certain stabilization time need to be waited. In case the PMS is not in STANDBY mode, ADCENREQ is ignored. Once the sub-units are in operational state, ADCOMP_CON.ADCEN and ADCOMP_CON.EOCSAMPLE bits are set to indicate that a start of conversion may be triggered. The conversion and sampling phases are carried out back to back, as shown in **Figure 909**. Foremost, the required channel is selected via ADCOMP_CON.ADCCHSEL. The sample time is defined by the time between End of Conversion (EOCSAMPLE) and the Start of Conversion (SOC). The first conversion is a dummy conversion and is triggered by setting ADCOMP_CON.SOC start of conversion bit. The conversion phase is subsequently started, which takes 10 (EVR) clock cycles resulting into 400 ns in case of a trimmed EVR oscillator. After the conversion phase is completed, bit ADCOMP_CON.EOCSAMPLE is set. EOCSAMPLE triggers an interrupt if activated via ADCOMP_CON.ADCIEN enable bit. The converted result is transferred to ADCOMP_RES result register, and the valid flag ADCOMP_CON.VF is set. This valid flag indicates that a “new” valid data has been stored in the corresponding result register, and can be read out. The valid flag is automatically cleared when the next SOC is given.

The previous end of conversion automatically triggers the next sampling phase. The start of the sampling phase is not under the control of the software, but only the end of the sampling phase can be controlled via the SOC bit. Adequate time need to be waited after EOCSAMPLE to provide the required sample time. The sample time may be realized by using one of the SCR timers. A minimum sample time of 200 ns is required, and may extend up to 800 ns, depending on the external sensor. The sample phase is indicated by bit ADCOMP_CON.EOCSAMPLE. It is intended that the result is read before the subsequent SOC conversion event. When the SOC is given, the result may no longer be valid, and hence the ADCOMP_CON.VF is cleared.

SOC request is not taken if EOCSAMPLE flag is currently not set. Once the sample time has elapsed, a new start of conversion request can be triggered by software. After the conversion is completed, ADCOMP unit may be disabled by clearing ADCOMP_CON.ADCENREQ register bit.

In case ADCENREQ is cleared during ongoing conversion, then the ADC is disabled only after the currently running conversion is ended.

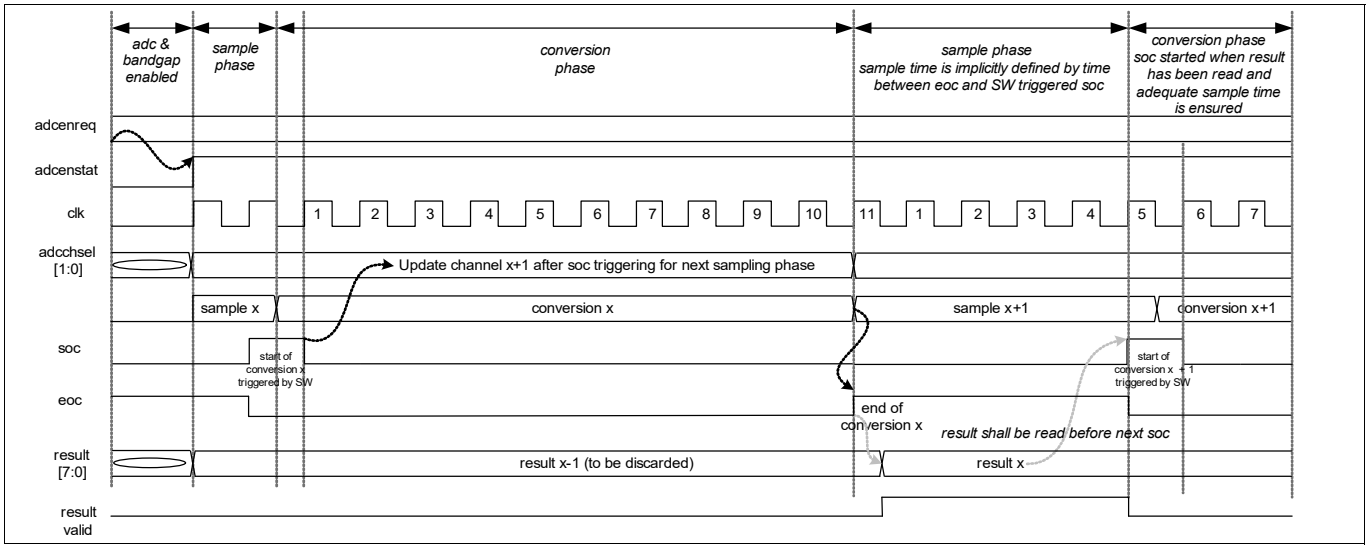

Figure 909 ADC comparator signal diagram

In case of a STANDBY wake-up request, an ongoing conversion of ADCOMP is completed. Consequently, as a wakeup request has been raised, the PMS is woken up, and the control of AD converter is given over to the PMS. This inherently results into a worst case delay of 400 ns (10 EVR clock cycles).

In case of a reset event during STANDBY, the ADCOMP operation is aborted. Consequently, the control is transferred to the PMS on re-start after reset. In case of an SCR reset, the ADCOMP is disabled.

49.16.4 ADCOMP Interrupt Request

Figure 910 shows a diagram of the interrupt request handling of the ADCOMP module.

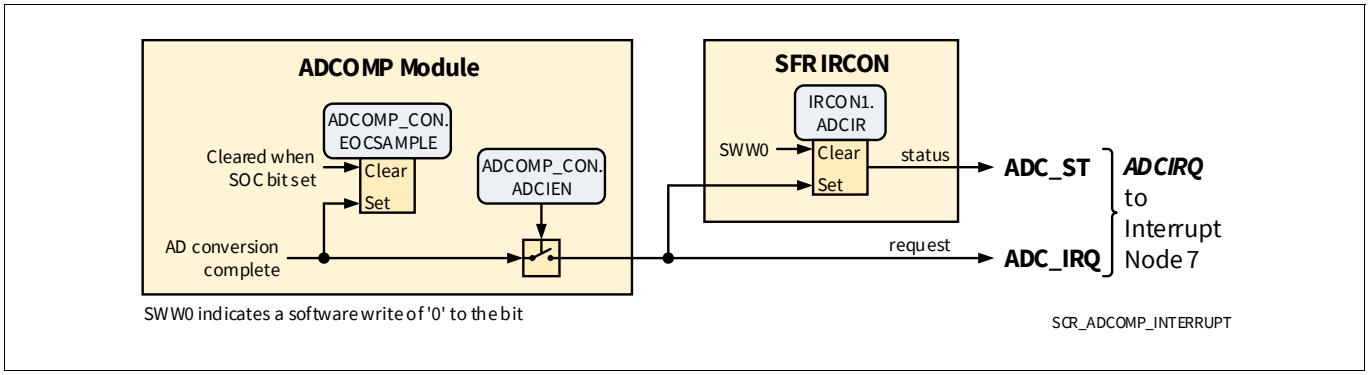

Figure 910 ADCOMP Interrupt Request Overview

49.16.5 ADCOMP Connections to GPIO

The following figure illustrates the signal connections of the ADCOMP module to the GPIO inputs.

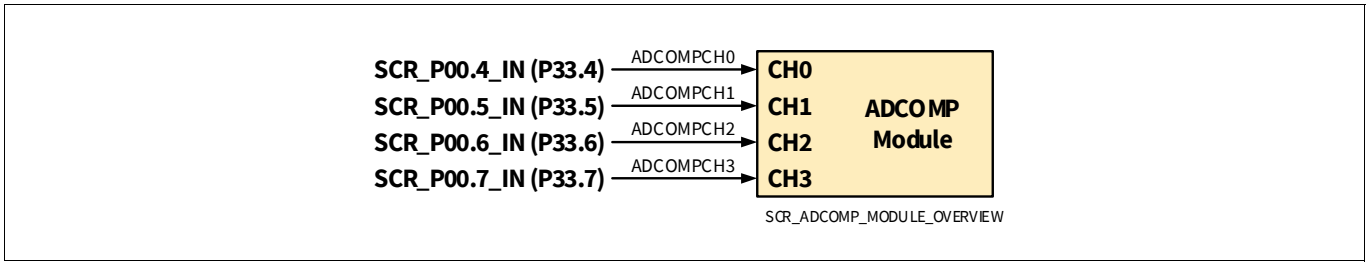

Figure 911 ADCOMP to GPIO Connection Overview

49.16.6 ADCOMP Registers

This section describes all ADCOMP special function registers. The ADCOMP and interrupt related SFRs are also listed, as shown in **Table 734**.

Note: All ADCOMP register names shall be referenced fully with the module name prefix “ADCOMP_”.

Note: The ADCOMP SFRs must be accessed via the paging mechanism at SCU Page 0.

Table 734 Register Overview - ADCOMP (sorted by Name)

Short Name	Description	RMAP	PAGE	Offset Address	Page Number
ADCOMP_CON	ADCOMP Control Register	0	0	$0FB_H$	311
ADCOMP_RES	ADCOMP Result Register	0	0	$0FA_H$	312

49.16.6.1 ADCOMP Registers Description

The following describes the Special Function Registers of the ADCOMP kernel.

ADCOMP Control Register

ADCOMP_CON
ADCOMP Control Register **($0FB_H$)** **Reset Value: Table 735**
RMAP: 0, PAGE: SCU_PAGE=0

7	6	5	4	3	2	1	0
SOC	**EOCSAMPLE**	**VF**	**ADCCHSEL**		**ADCIEN**	**ADCEN**	**ADCENREQ**
rwh	rh	rh	rw		rw	rh	rw

Field	Bits	Type	Description
ADCENREQ	0	rw	**ADC Comparator Enable Request** This bit activates the ADC unit, the associated bandgap and clock required for the ADC unit. It is required to wait some time for the units to start after the request. In case ADCENREQ is cleared during ongoing conversion, then the ADC is disabled when the currently running conversion is ended. 0_B ADCOMP unit is disabled 1_B ADCOMP unit is enabled
ADCEN	1	rh	**ADC Comparator Enable Status** This bit indicates that the ADC unit, the associated bandgap, and the clock required for the ADC unit are active, and a subsequent conversion can be triggered. It is set after some time after ADCOMP_CON.ANCENREQ is set. 0_B ADCOMP unit is disabled 1_B ADCOMP unit is enabled
ADCIEN	2	rw	**ADC Comparator Interrupt Enable** Software can read this bit to get the status whether the interrupt is currently enabled or disabled. 0_B No interrupt is generated 1_B Interrupt is generated after conversion
ADCCHSEL	4:3	rw	**ADC Channel Select** This bitfield selects the channel and configures the 4:1 ADC multiplexer before a conversion is triggered. After a channel is selected, adequate time needs to be provided for sampling before a conversion is started. 00_B **CH0**, CH0 is selected 01_B **CH1**, CH1 is selected 10_B **CH2**, CH2 is selected 11_B **CH3**, CH3 is selected
VF	5	rh	**ADC Valid Flag for Result Register** Indicates a new result in ADCOMP_RES register. 0_B There is no valid result 1_B A new result is available in the ADCOMP_RES result register. The valid flag is automatically cleared when bit SOC is set.

Field	Bits	Type	Description
EOCSAMPLE	6	rh	**ADC End of Conversion / Sampling Indication** This bit indicates that a conversion is completed and the result can be read. A new conversion via SOC can be started only when the EOC from the previous conversion has been set. This bit is automatically cleared when SOC is set. 0_B ADC conversion is currently going on 1_B ADC conversion is completed. ADC is currently sampling.
SOC	7	rwh	**ADC Start of Conversion Request** This bit activates a new conversion. Setting this bit has effect only when both, ADCEN and EOC, are set. This bit is automatically cleared by hardware once the conversion has started. If VF is set, setting SOC to 1 clears VF. 0_B ADC conversion is not started 1_B ADC conversion is started

49.17 Wake-Up CAN (WCAN) Filter

This chapter describes the WCAN controller of the SCR. It contains the following sections:

- Overview on the Wake-Up capabilities (see **Page 314**)
- Functional description of the WCAN kernel (see **Page 317**)
- WCAN Kernel register description (see **Page 318**)
- Functional description on the CAN based kernel (see **Page 340**)
- SCR implementation specific details and registers of the WCAN (port connections and control, interrupt control, address decoding, clock control (see **Page 356**)

Note: The WCAN kernel register names described in this chapter will be referenced in the Standby Domain Internal Target Specification by the module name prefix “WCAN_”.

49.17.1 Definitions and Abbreviations

- WUF - Wake-Up Frame
- WUP - Wake-Up Pattern; Wake-Up Pattern detection has to be supported by external CAN transceiver and WUP detection has to be notified by transceiver to WCAN by a falling edge on RXD. To keep the context simple, the term Wake-Up Pattern is used in WCAN specification.

49.17.2 Wake-Up CAN Filter Implementation

49.17.2.1 Overview

This section describes the 11898-6 datalink layer. The Wake-Up CAN module contains 1 CAN node, representing only the receive part of the communication interface. Furthermore, the Wake-Up CAN filter functionality and interfaces in AURIX™ TC3xx Platform.

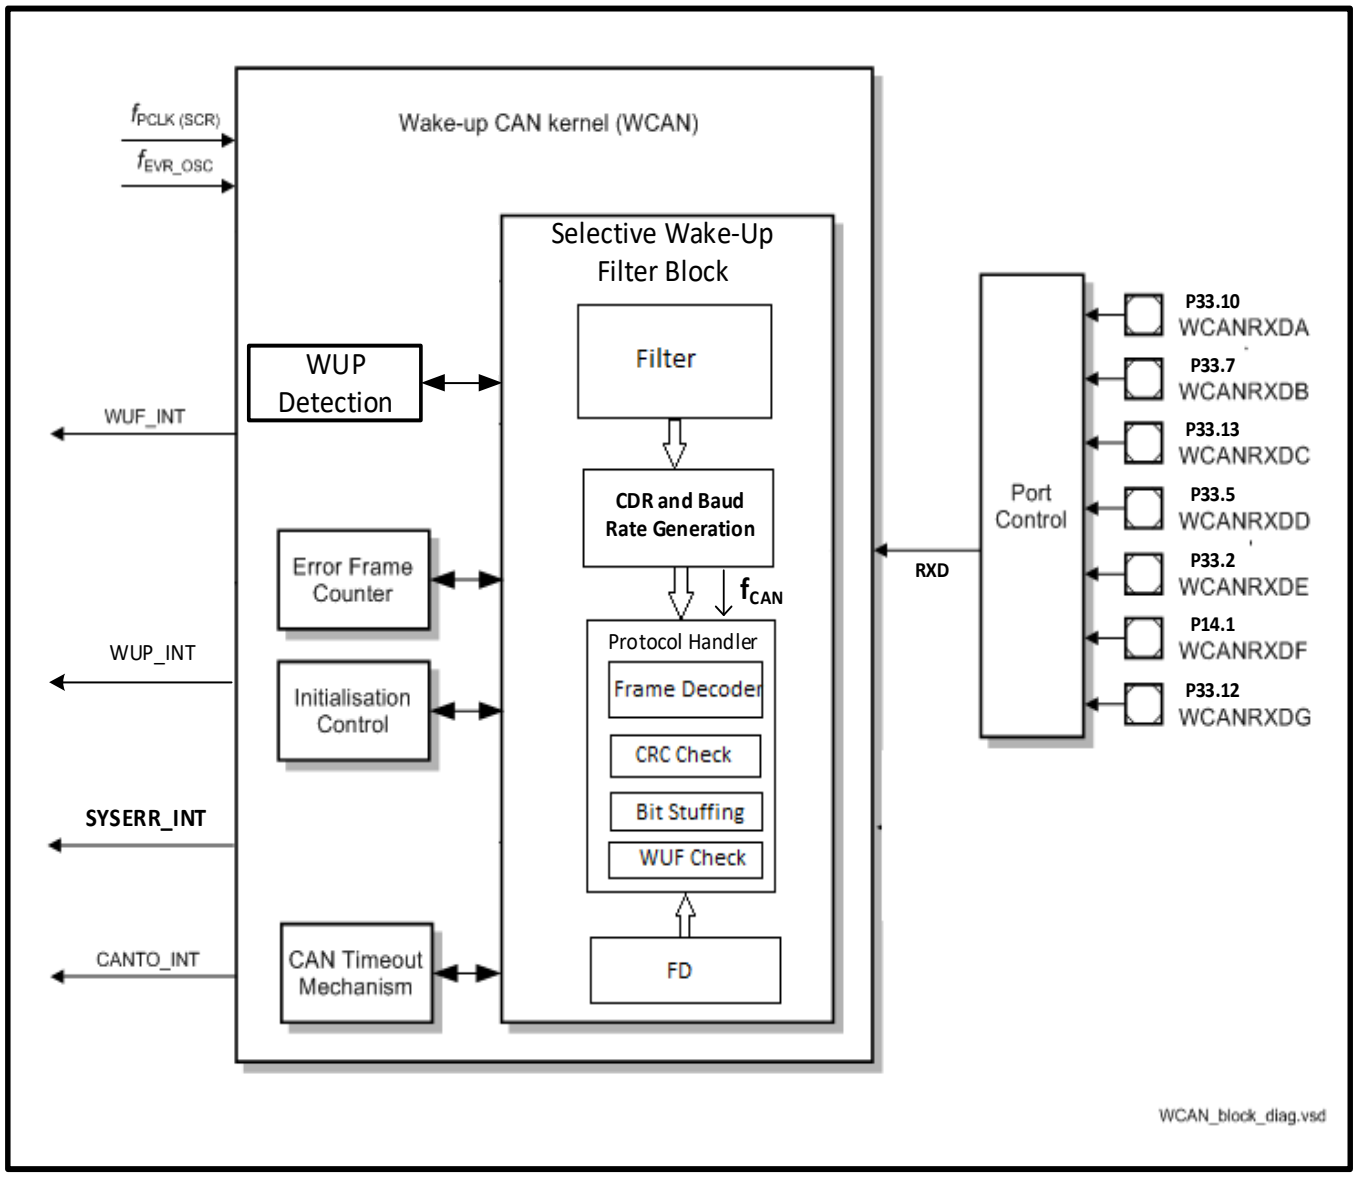

Figure 912 Wake-Up CAN Filter Interfaces

49.17.2.2 WCAN Filter Features

The following are the feature list for WCAN module in SCR:

- Wake-Up CAN functionality in conformance to ISO 11898-6
- 1 Wake-Up CAN node
- Guaranteed data transfer rate up to 500 kBaud, baudrates higher are dependent on customer settings. Default settings for 125 kBaud, 250 kBaud and 500 kBaud are according to the given propagation delays of German OEMs.
- Oscillator tolerance requirement (+/- 4%) improved with Clock and Data Recovery (CDR)
- 1 Wake-up frame configuration registers to the wake-up node
  - Set up to handle frames with 11-bit and/or 29-bit identifiers
  - Programmable acceptance mask register for filtering
  - Programmable wake-up message ID, DLC and Data
- Wake-Up CAN message Time-out feature
- Power saving through Standby mode on CAN message Time-out
- WUP detection by monitoring falling edge on RXD when in standby mode
- Tolerant to CAN FD frames
- Error counter to debounce CAN protocol and wake-up function errors
- Interrupt generation on
  - Successful Wake-up message frame reception
  - Error recognition
  - Wake-Up CAN timeout
  - WUP (falling edge on RXD) detection

49.17.2.3 Introduction

49.17.2.3.1 Feature Overview

Reception and evaluation of CAN frames is handled in accordance to CAN specification ISO 11898-6 data link layer. The received messages will be compared against the programmed wake-up pattern and in case of pattern match, a wake-up will be issued. In case of an erroneous understanding or errors on the bus, the receive error counter can also reach a wake-up threshold. The node will be purely listening to the bus and will not communicate to the outside.The CAN node has Wake-Up Frame (WUF) configuration registers. In these WUF registers, the identifier including a bitwise mask, the corresponding DLC as well as a data mask is included. Only (outside the erroneous case), if all criteria match, a wake-up will be initiated.The bit timings for the CAN nodes are derived from the CAN clock (fCAN) and are programmable up to a data rate of 1 MBaud, nonetheless guaranteed wake-up is only given for special configurations according to the propagation delay defined by the German OEMs.

Features

- Compliant to ISO 11898-6.
- Receive operation according to 11898-6.
- Tolerant to CAN FD frames
- Dedicated control registers for the CAN node.Data transfer rates are guaranteed until 500 kBaud, in case of higher baudrates more wake-up frames might be needed.Transmitter tolerances up to 0.4% are calculated and guaranteed with CDR enabled. Higher transmitter tolerances are not pretested.
  - The message buffer can be configured to accept only standard or only extended Classical frames as valid Wake-Up frame.
- Four interrupt sources do exist, wake-up frame found, tSILENCE expired, error overflow and WUP detected.

49.17.2.4 WCAN Module Control Registers

Wake-Up CAN Configuration Register

WCAN_CFG
Wake-Up CAN Configuration Register **($0B0_H$)** **Reset Value: Table 738**
RMAP: 0, PAGE: WCAN_PAGE=0

7	6	5	4	3	2	1	0
0				**CCE**	**SELWK_EN**	**0**	**WCAN_EN**
r				rw	rwh	r	rw

Field	Bits	Type	Description
WCAN_EN	0	rw	**WCAN Enable** This bit enables or disables the clock to WCAN Selective Wake-Up filter block. 0_B Disable Clock to WCAN Selective Wake-Up filter block 1_B Enable Clock to WCAN Selective Wake-Up filter block
SELWK_EN	2	rwh	**Selective Wake-Up Enable** The Selective Wake-up Enable function enables the protocol handler. The status of the protocol handler is also acknowledged through INTESTAT0.SWACK. The status of the Selective Wakeup Active is given in INTESTAT1.SWKSET. It also serves several functions when enabled. 1. Allows Wake-up source WUF to generate WUF_INT (see Figure "Wake-up Frame Detection"). 2. Allows error counter to generate ERROR_INT (see Figure "Error Counter"), indicated by INTESTAT0.ECOFL. 3. Triggers ERROR_INT and wake-up if there are any changes to the message object registers, indicated by INTESTAT0.MORC. 4. If a SYSERR occurs while SELWK_EN is enabled, then the Selective Wake-up function shall be disabled (ie., this bit field will be reset to 0). It is also indicated by INTESTAT0.ERSEL. 0_B Selective wake disabled 1_B Selective wake enabled
CCE	3	rw	**Configuration Change Enable** This bit field enables the configuration of the Bit Timing Registers. It also acts as soft-reset to the Selective Wake-up filter block. It has to be set back to '0' once the bit timing registers are modified for desired baudrate. 0_B The Bit Timing Registers (BTLn_CTRL), CDR Configuration registers (CDR_CTRL, CDR_UPPER_CTRL, CDR_LOWER_CTRL) and CAN_FD_CTRL may only be read. All attempts to modify them will be ignored. 1_B The Bit Timing Registers and CDR Configuration registers may be read and written
0	1, 7:4	r	**Reserved** Returns 0 when read; shall be written with 0.

WUP	**ERSEL**	**MORC**	**ECOFL**	**CANTO**	**SYSERR**	**MODE**	**SWACK**
rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
SWACK	0	rh	**Selective Wake-Up Enable Acknowledge** This bit field indicates the acknowledgement of protocol handler enabled/disabled. 0_B Protocol Handler is disabled and configuration of WUF is possible 1_B Protocol Handler is enabled and configuration of WUF should not be done
MODE	1	rh	**WCAN Mode of Operation** This bitfield indicates the WCAN mode of operation. 0_B Normal Mode 1_B Standby Mode
SYSERR	2	rh	**CAN Wake-Up System Error** The SYSERR indicates a configuration error (MORC), and an error counter overflow condition (ECOFL). 0_B Selective Wake Mode is possible 1_B System Error detected, WCAN enabling not possible. It also leads to SYSERR_INT interrupt trigger if enabled through ERRMASK.
CANTO	3	rh	**CAN Time-Out Detection** This bit indicates that there was an inactive CAN bus on RXDCO pin within tSILENCE of 750 ms. See section "CAN Message Timeout". A software write to INTESTATCLR0.CANTOCLR is required to reset this bit. 0_B Normal operation 1_B CAN Time-Out detected. It also leads to CANTO_INT interrupt if enabled through CANTOMASK.
ECOFL	4	rh	**Error Counter Overflow** This bit field shows occurrence of Error Counter overflow. A set condition of this flag by hardware has higher priority than a clear through ECOFLCLR. 0_B Error Counter has not overflowed (<= 31) 1_B Error Counter overflowed (> 31)
MORC	5	rh	**Message Object Register Changed** A set condition of this flag by hardware has higher priority than a clear through MORCCLR. 0_B Message object registers not modified after SELWK_EN is set 1_B Message object registers was modified after SELWK_EN is set

Field	Bits	Type	Description
ERSEL	6	rh	**Error Select** A set condition of this flag by hardware has higher priority than a clear through ERSELCLR. 0_B SYSERR is not set while SELWK_EN is enabled 1_B SYSERR is set while SELWK_EN is enabled
WUP	7	rh	**Wake-Up Pattern Detected** This bit field is set when a falling edge on RXD (or WUP) is detected, when WCAN is in Standby mode. A software write to INTESTATCLR0.WUPCLR is required to clear this bit field. 0_B WUP not detected 1_B WUP detected. It also triggers WUP_INT interrupt when enabled through INTMRSLT.WUPMASK

WUF	0	rh	**Wake-Up Frame Detection (acc. ISO 11898-6)** This bit shows the status whether a Wake-up Frame has been detected. 0_B No Wake-Up Frame detected 1_B Wake-Up Frame detected. It also leads to WUF_INT interrupt trigger if enabled through WUFMASK.
SYNC	1	rh	**Synchronisation (at least one CAN frame without fail must have been received)** This bit is set when a valid Classical CAN frame is detected and is updatedafter every received Classical CAN frame. This flag is not updated when aCAN FD frame is received. Clearing this flag through SYNCCLR has higherpriority than a set condition by hardware. 0_B WCAN function not working or not synchronous to CAN bus 1_B Valid CAN frame received, WCAN function is synchronous to CAN bus

Field	Bits	Type	Description
SWKSET	2	rh	**Selective Wake Activity** 0_B Selective Wake is not active 1_B Selective Wake is activated
CANSIL	3	rh	**CAN Bus Silent Time during Selective Wake Operation** This bit is set if there is no activity on RXDC0 pin on the CAN bus after tSILENCE of 750 ms expired. If any activity is detected on the bus, this bit is reset automatically. tSILENCE is fixed at 750 ms. This bit can also be cleared through bit WCAN_INTESCLR.CANSILCLR. A set condition of this bit has higher priority than a clear through CANSILCLR. 0_B tSILENCE not exceeded 1_B tSILENCE is exceeded
FDF	4	rh	**FD Frame Reception** This bit indicates reception of CAN FD frame. After reception of the CAN FD frame is completed, this bit is cleared to '0'. 0_B No action 1_B FD Frame is being received
RXDF	5	rh	**Filtered Receive Data Input** This bit shows the logic state of the filtered received data input signal (RXD_filt). 0_B Dominant 1_B Recessive
RXDS	6	rh	**Sampled Receive Data Input** This bit shows the logic state of the sampled received data input signal by the protocol handler. 0_B Dominant 1_B Recessive
0	7	r	**Reserved** Returns 0 when read; shall be written with 0.

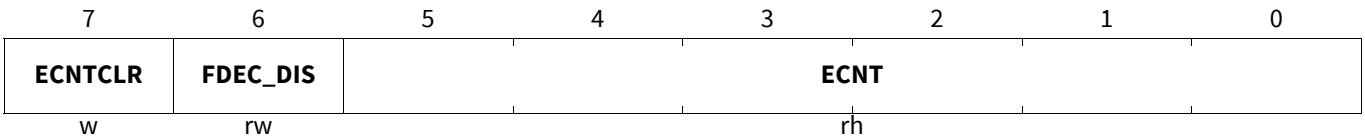
Wake-Up CAN Error Counter Register

WCAN_FRMERRCNT
Wake-Up CAN Error Counter Register **($0B2_H$)** **Reset Value: Table 742**
RMAP: 0, PAGE: WCAN_PAGE=1



Field	Bits	Type	Description
ECNT	5:0	rh	**SWK CAN Frame Error Counter** If WCAN_FD_CTRL.FDEN = 0, the CAN Frame Error Counter is incremented when an error message or CAN FD frame is received, and decremented on a reception of a correct classical CAN frame, if ECNT>0. If FDEN = 1, the behaviour of the error counter is based on FDEC_DIS bit configuration. See section "Error Counter".
FDEC_DIS	6	rw	**Error Count Disable on CAN FD Frame** This bit is used to describe the behaviour of the Error Counter for FD frames. The value of this bit has no effect if WCAN_FD_CTRL.FDEN = 0. *Note: When an FD frame is detected, the error is checked only until the FDF bit of the FD frame.* 0_B Error counter is incremented or decremented based on correctness of the bitfields in arbitration phase of the FD frame 1_B Error counter is active only for Classical CAN frames, and it is frozen for CAN FD frames
ECNTCLR	7	w	**Error Counter Clear Bit** Writing a 1 to this bit clears the error counter FRMERRCNT.ECNT.

49.17.2.5 WCAN Initialization Sequence

Inorder to initialize the WCAN module, the following sequence has to be performed.

- Set **WCAN_CFG**.WCAN_EN = 1b
- Set **WCAN_CFG**.CCE = 1b
- Configure CDR,CAN FD and Baud Rate Configuration registers
- Reset **WCAN_CFG**.CCE = 0b
- Reset **WCAN_CFG**.SELWK_EN = 0b
- Configure WUF Configuration registers
- Set **WCAN_CFG**.SELWK_EN = 1b
- Wait until **WCAN_INTESTAT0**.SWACK = 1b

In order to perform only reconfiguration of the WUF Configuration registers, the following sequence has to be performed

- Set **WCAN_CFG**.WCAN_EN = 1b
- Reset **WCAN_CFG**.SELWK_EN = 0b
- Wait until **WCAN_INTESTAT0**.SWACK =0b
- Configure WUF Configuration registers
- Set **WCAN_CFG**.SELWK_EN = 1b
- Wait until **WCAN_INTESTAT0**.SWACK = 1b

After the initialization/WUF reconfiguration sequence is performed, the application software has to check the **WCAN_INTESTAT1**.SWKSET bit field to verify if the Selective Wake-Up feature is successfully enabled or not. The SWKSET bit field is set to '1' if all of the below mentioned conditions are true, and it is cleared if any of the conditions is not met

- **WCAN_CFG**.WCAN_EN = 1b
- **WCAN_CFG**.CCE = 0b
- **WCAN_INTESTAT0**.SWACK = 1b
- **WCAN_INTESTAT0**.MODE = 0b
- f_{BACK} is switched on

*Note: If application software writes either **WCAN_CFG**.CCE = 1 or **WCAN_CFG**.SELWK_EN = 0b when WCAN is already active, then any ongoing reception will be lost. If **WCAN_CFG**.WCAN_EN = 0 when WCAN is already active, then the selective wake-Up filter block will be in halt state and the application software has to perform re-initialization based on the sequence given above.*

49.17.2.6 Wake-Up Frame Configuration and Detection

The received frame is compared to the configured wake-up frame and incase a match is detected a wake-up request is issued. The wake-up request sets the **WCAN_INTESTAT1**.WUF flag and issues WUF_INT interrupt if not masked by **WCAN_INTMRSLT**.WUFMASK. Only a matched Classical CAN frame can lead to WUF detection.

*Note: In addition to the message object configuration registers (i.e **WCAN_DLC_CTRL**, IDn_CTRL(n=0-3), MASK_IDn_CTRL(n=0-3), **WCAN_DATAn_CTRL (n=0-7)**) the node bit timing configuration is configured in the BTLn_CTRL(n=1-2) register.*

49.17.2.6.1 Configuration of Wake-Up Frame Filter

The message object configuration of the wake-up frame is done in the following registers

- Register IDn_CTRL (n=0-3) contains the CAN identifier filter bits.
- Register MASK_IDn_CTRL (n=0-3) contains the ID mask bits.
- Register **WCAN_DLC_CTRL** are the data length code filter bits.
- Register **WCAN_DATAn_CTRL (n=0-7)** are the data filter bits.

49.17.2.6.2 Detection of Wake-Up Frame Filter

The compare mechanisms are different according to the information field inside the CAN frame.

- The identifier programmed inside IDn_CTRL (n=0-3) and MASK_IDn_CTRL (n=0-3) has to match the data in the received frame and the logic seen in **Figure 913**, a wake-up condition is detected.
- The DLC programmed in **WCAN_DLC_CTRL** together with the data filter bits in **WCAN_DATAn_CTRL (n=0-7)** will be compared to the DLC and data inside the received frame, in case a single '1' match in **WCAN_DATAn_CTRL (n=0-7)**, a wake-up condition within the data is detected. DLC values greater than 8 will be treated as 8. See **Figure 913**.

If and only if, identifier and masking, the **WCAN_DLC_CTRL** and the **WCAN_DATAn_CTRL (n=0-7)** will lead to a match, a valid wake-up Frame (WUF) is detected and a wake-up interrupt will be issued if **WCAN_CFG**.SELWK_EN is enabled.

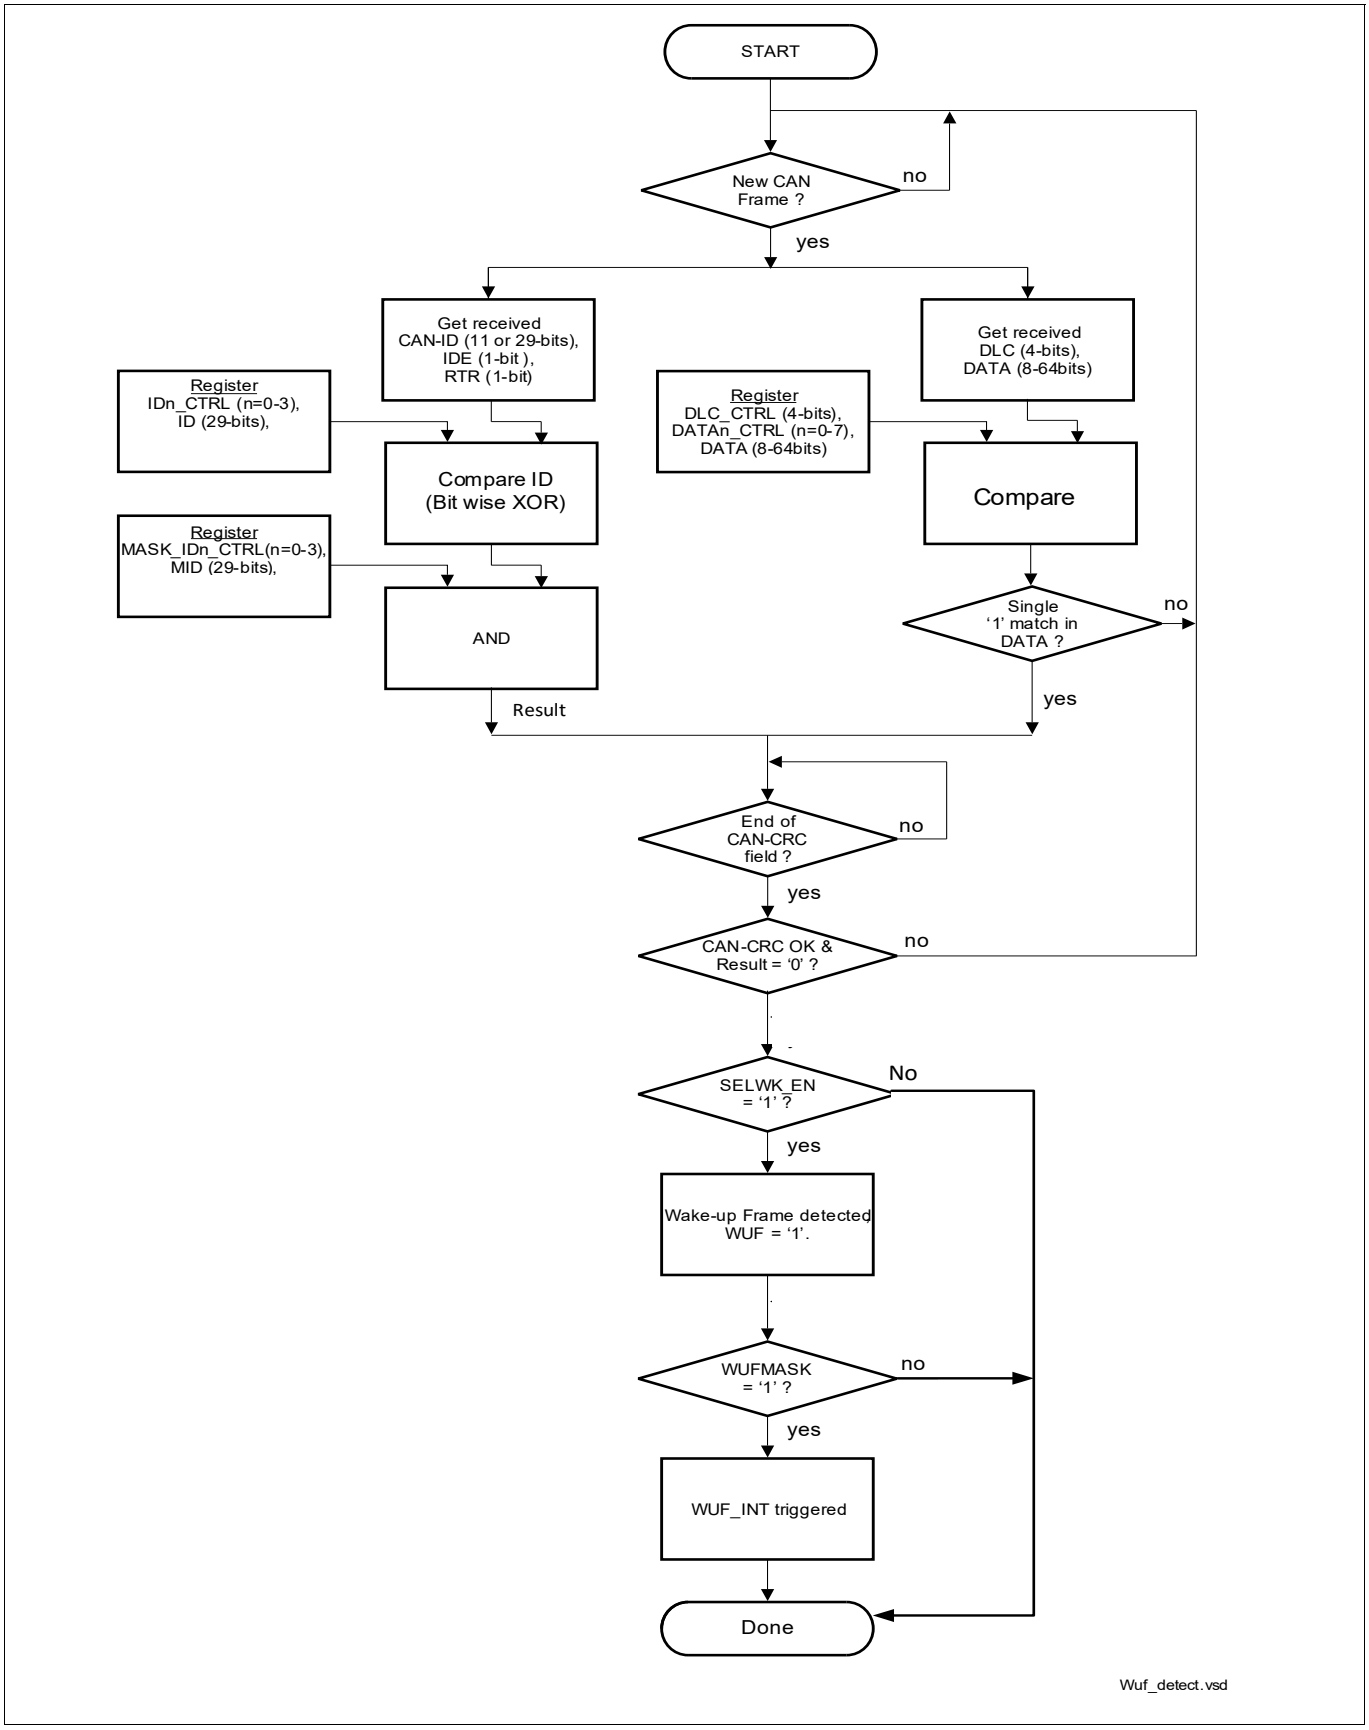

Figure 913 Wake-Up Frame Detection

49.17.2.7 CAN Message Timeout

A timeout mechanism to monitor CAN bus activity is available on the WCAN. The timeout mechanism monitors the RXDC0 pin. When the RXDC0 pin is inactive for a tSILENCE time of 750 ms, both CAN bus silent bit (**WCAN_INTESTAT1**.CANSIL) and if selective Wake-Up is enabled, CAN timeout bit (**WCAN_INTESTAT0**.CANTO) will be set with a CAN time out interrupt (CANTO_INT). An occurrence of CAN Timeout will clear the error counter.

The CAN bus silent bit (**WCAN_INTESTAT1**.CANSIL) is reset when there is activity on the CAN bus where else the CAN timeout bit can be reset by setting CAN time out clear bit (**WCAN_INTESCLR0**.CANTOCLR). When WCAN_EN = 0, the timeout counter remains in the reset state. The **WCAN_INTESTAT1**.CANSIL can also be cleared by setting **WCAN_INTESCLR1**.CANSILCLR.

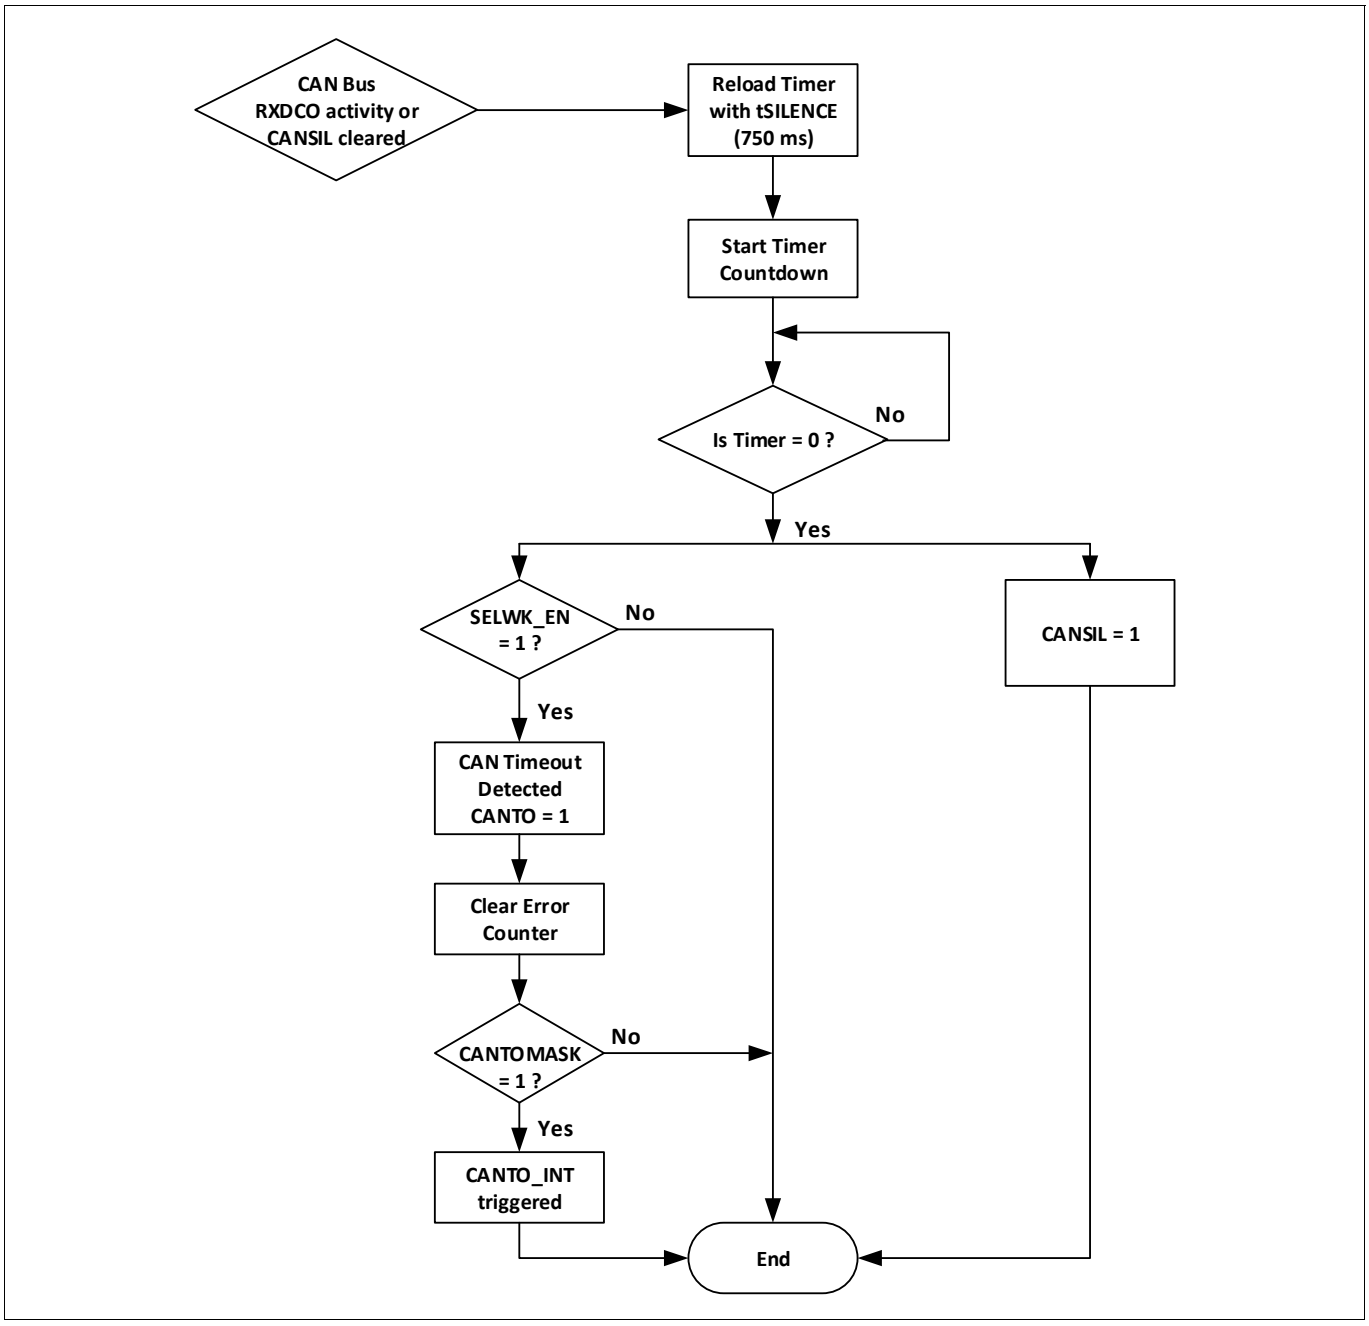

Figure 914 CAN Timeout

49.17.2.8 Error Counter

The error counting mechanism in ISO 11898-6 is different to ISO 11898-1. As the device is only receiving messages and never transmitting it could never get into a bus-off situation. Therefore an ISO11898-6 implementation is incrementing its error counter on a Form, Stuff and a CRC error. In case of a correct message, the error counter will be decremented, if it is greater than 0. In case the error counter is greater than 31 an overflow occurs and a wake-up will be initiated. This shall enable the software to correct the situation. In case of overflow the **WCAN_INTESTAT0**.SYSERR and **WCAN_INTESTAT0**.ECOFL flags are set. The error counter is cleared when timeout has occurred or when **WCAN_CFG**.SELWK_EN is re-enabled (from '0' to '1'). If the CAN FD tolerance feature is enabled and a CAN FD frame is received, the error monitoring is done only until FDF bit field. The behavior of the error counter for CAN FD frames is based on **WCAN_FRMERRCNT**.FDEC_DIS bit field. The conditions at which error counter is incremented or decremented is given in the table below. The **WCAN_INTESTAT0**.ECOFL flags can be cleared by writing **WCAN_INTESCLR0**.ECOFLCLR to '1'.

Note: If ECNTCLR is written to '1' and at the same time an error in received frame has occurred, the error counter will remain cleared and it will not be incremented.

Table 745 Error Counter Conditions

WCAN_FD_CTRL.FDEN	**WCAN_FRMERRCNT.FDEC_DIS**	**Behavior of Error Counter**
0	X	Decrement on: • Valid Classical CAN frame Increment on: • Corrupt Classical CAN frame • CAN FD Frame
1	0	Decrement on: • Valid Classical or CAN FD frame Increment on: • Corrupt CAN FD Frame • Corrupt Classical CAN frame
1	1	Decrement on: • Valid Classical CAN frame Increment on: • Corrupt Classical CAN frame No Action: • CAN FD Frame

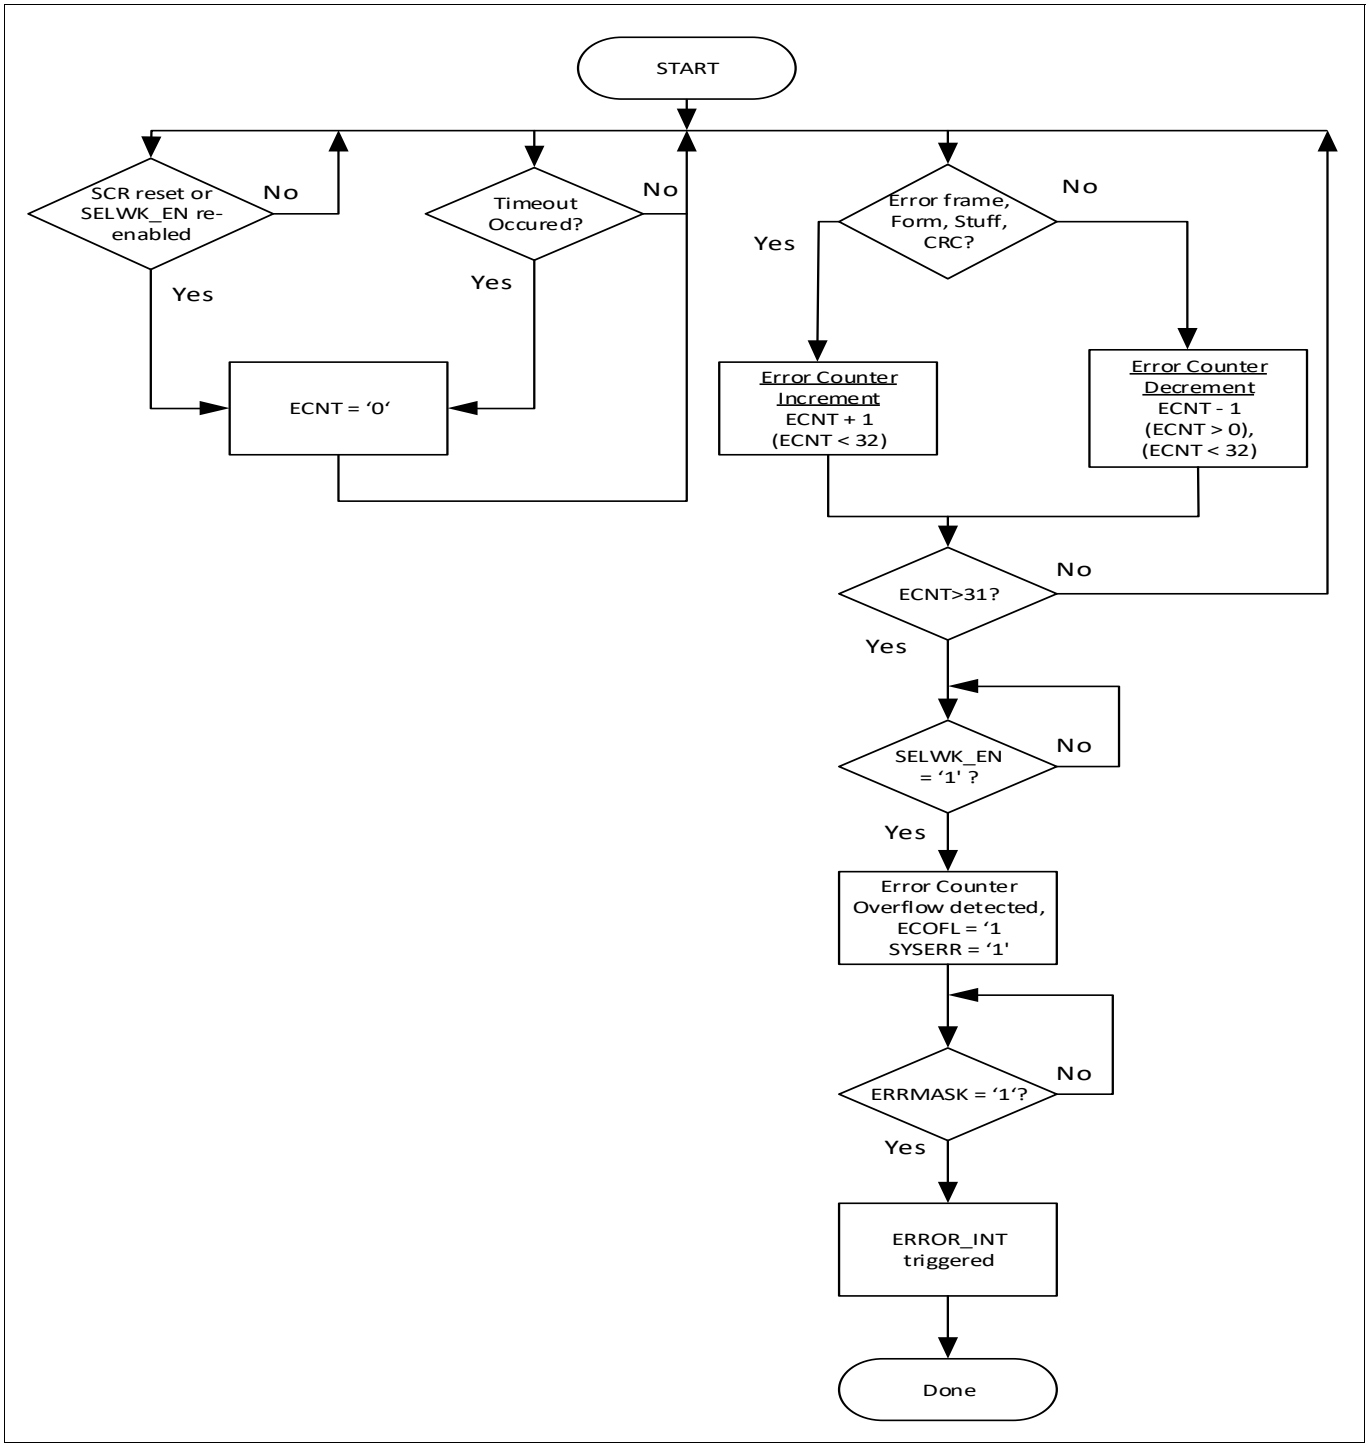

Figure 915 Error Counter

49.17.3 WUP Detection

WCAN supports WUP detection by receiving a falling edge of RXD when a Wake-Up Pattern is detected by the CAN Transceiver. In case the CAN Transceiver doesn't support Wake-Up Pattern detection, then WCAN considers any falling edge on RXD as WUP. In WCAN, the WUP detection is active only when the Selective Wake-Up feature is enabled and CAN timeout has occurred. On occurrence of CAN Timeout, WCAN enters into a Standby mode. When WCAN is in Standby mode,

- the protocol Handler is reset and Selective Wake-Up feature is disabled;
- the Clock to the Protocol Handler is switched off to save power;
- WUP detection is active - waiting for a falling edge on RXD (decoding of the WUP itself should be done by the CAN Transceiver);
- **WCAN_INTESTAT0**.MODE = 1 and **WCAN_INTESTAT1**.SWKSET = 0.

Note: In WCAN Standby mode, the WUP detection is active even when 100 MHz f_{BACK} is switched-off. In such a case, the WUP detection will be performed with 70 kHz clock. In-order to save power when WCAN in standby mode, the application software may disable 100 MHz f_{BACK}, and only 70 kHz clock can be provided. The 100 MHz f_{BACK} is automatically turned-on when WUP is detected.

When WUP is detected in Standby Mode, the WCAN enters into the Normal Mode where,

- selective Wake-Up feature is re-enabled;
- the clock to the protocol handler is active;
- Error Counter is reset to '0';
- 100 MHz f_{BACK} enable is requested (CMCON.OSCPD = '0' when CMCON.OSCWAKE = '1'), when 100 MHz f_{BACK} is disabled in Standby Mode;
- **WCAN_INTESTAT0**.MODE = 0, **WCAN_INTESTAT1**.SWKSET = 1 and **WCAN_INTESTAT0**.WUP = 1;
- WUP_INT is triggered when it is not masked through **WCAN_INTMRSLT**.WUPMASK.

The application software can make WCAN to leave the Standby Mode by SCR Reset or by disabling WCAN (WCAN_EN = 0). The figure below shows the state diagram on transition of WCAN between different modes of operation.

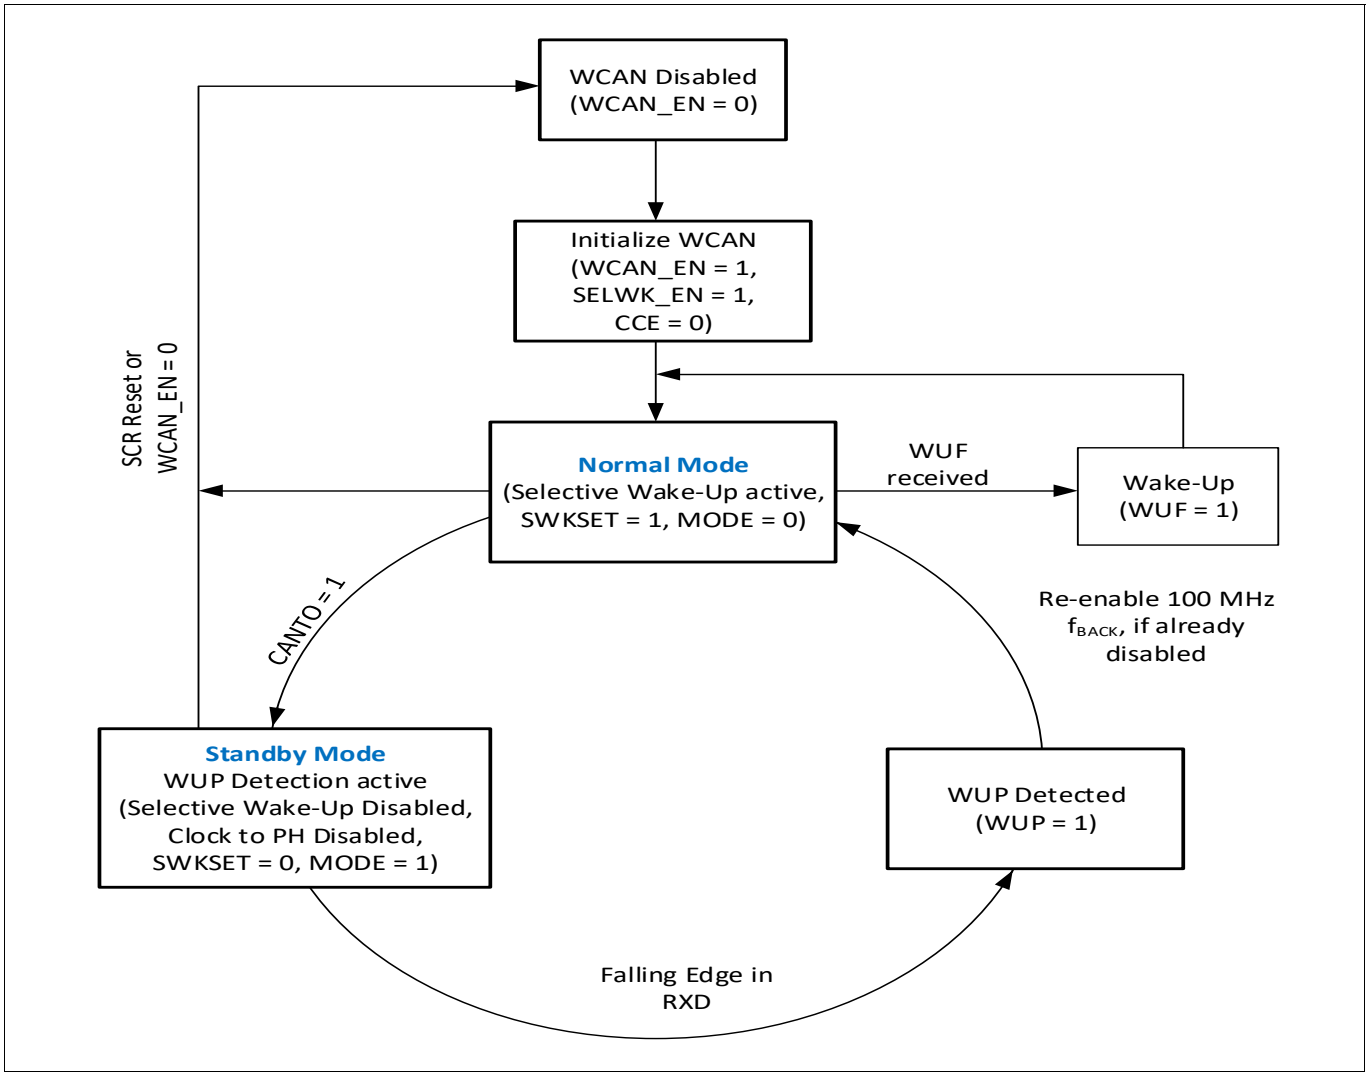

Figure 916 WCAN Modes of Operation

49.17.4 CAN Functional Description

49.17.4.1 CAN Node Control

The CAN node is equipped with an individual set of SFR registers to control and to monitor the CAN node.

49.17.4.1.1 Baud Rate Prescaler

The WCAN has an integer divider with a scaling factor defined by the BRP bit field. The f_{BACK} is the input frequency and the fCAN is the scaled output frequency of the integer divider. The BRP bit field is recommended to be configured based on the baud rates required as shown in **Table 747**, because BRP values influences the receive input filter time and CAN FD filter time. The fCAN frequency is fed to the Receive Input Filter and CDR (to measure the sample point). When 100 MHz f_{BACK} is switched off, the Selective Wake-Up filter block will be reset and then f_{CAN} is also switched off. Hence, the Selective wake-up feature cannot be used ie., **WCAN_INTESTAT1**.SWKSET = 0.

49.17.4.1.2 Receive Input Filter

The RXD signal coming from the transceiver, is filtered to eliminate the jitter effects from the CAN bus, The filter time is dependent on the recommended baud rate configuration and the BRP values (**Table 747**). The filtering is done based on fCAN frequency. The filtering time T_filt is based on the END COUNT value for different BRP as shown in **Table 747**. The filter has an asymmetrical behavior as shown in **Figure 917**.

The first recessive to dominant edge is detected asynchronously, and the event is used for the starting of the filter counter. Once the counter reaches the END COUNT value, the RXD is checked again if it is still '0', then the synchronization edge is considered valid. Hence the filter introduces a delay of T_filt.

At dominant to recessive edge, RXD is checked at each fCAN clock cycle. The RXD_FILT output is '1' only if the input signal is a stable recessive for entire filtering time (T_filt). The recessive bits shorter than t_glitch are filtered out and only recessive bits longer that t-detect are considered valid.

When CAN FD tolerance is enable, the received input signal RXD is used directly without filtering for the data phase, to avoid the additional filter delay.

The logic level of the filtered input RXD_FILT is shown in **WCAN_INTESTAT1**.RXDF.

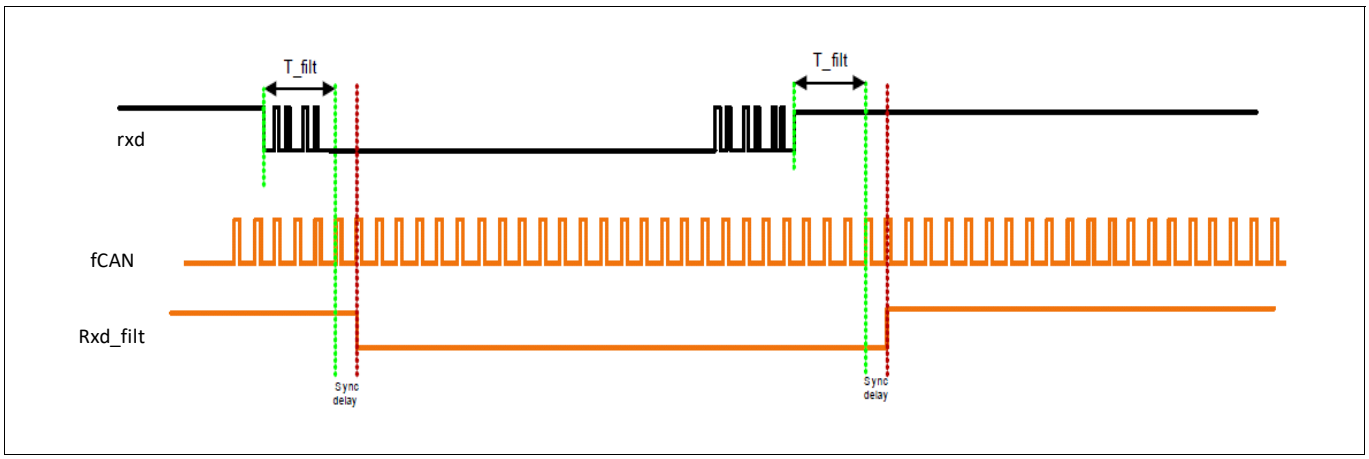

Figure 917 RXD Filtering

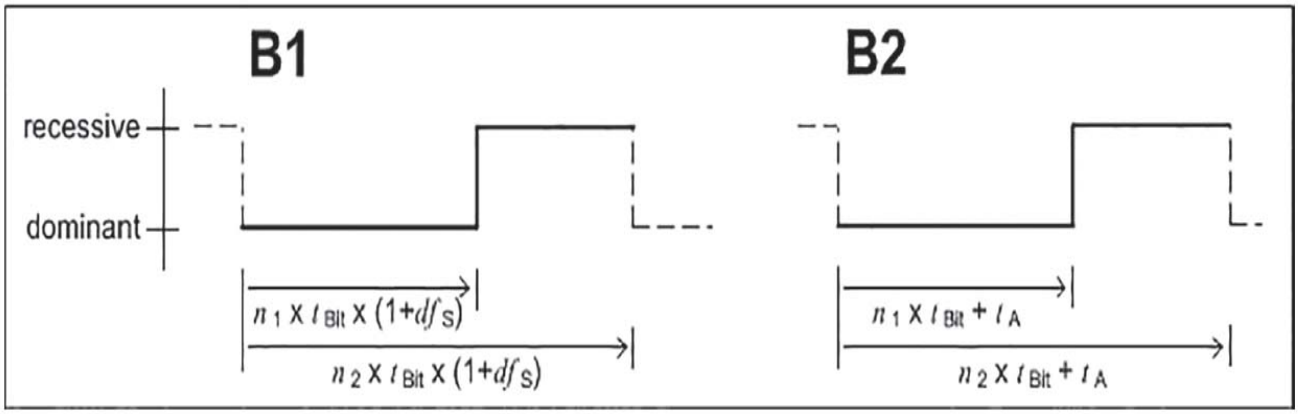
49.17.4.1.3 Bit Timing

According to ISO 11898-2 standard, a received classical CAN frame can be decoded correctly when the timing of the CAN bit fields complies with multiple instances of signal shape B1 and one instance of signal shape B2 (to

handle the sender clock tolerance and loss of arbitration). In order to compensate possible deviations of the CAN oscillator frequency, integrated clock and data recovery is used (CDR). The CDR can be optionally enabled or disabled using CDR_EN bit field. It is recommended to always enable the CDR feature. If CDR is disabled, the required oscillator tolerance is 1% or else it is 4%. When CDR is disabled, the sample point position is calculated directly based on BTLn_CTRL (n=1,2) values. Before enabling the CDR, the bit timings parameters have to be properly configured as shown in **Table 747**. When CAN FD tolerance is enabled **WCAN_FD_CTRL**.FDEN = 1, the CDR is stopped during CAN FD frame reception, in order to avoid calculation based on high baud-rate data phase. The CDR is kept at last calculated value before CAN FD has been detected.



Key

n_1 number of consecutive dominant bits {1, 2, 3, 4, 5}

n_2 number of bits between two falling edges {2, 3, ..., 10}; n2 > n1

t_A $0 \le t_A \le 55$ % of t_{Bit} (product specific higher maximum values for t_A are allowed)

t_B $0 \le t_B \le 5$ % of t_{Bit} (product specific higher maximum values for t_B are allowed)

t_{Bit} nominal bit time (Note: often used values for t_{Bit} are 2 µs, 4 µs and 8 µs)

df_S transceivers according to this document shall tolerate sender clock frequency deviations up to at least 0,5 %

Figure 918 CAN Bit Timing Signal Shape

Clock and Data Recovery (CDR)

The CDR consists of three building blocks as shown in **Figure 919**. The CDR uses the fCAN clock. This clock period defines the duration of one time quanta tq. For ISO 11898-6 some settings are guaranteed to be working according to the given propagation delay times (see **Section 49.17.4.1.4**). Working settings for 125k, 250k and 500k will be provided. The acquisition counter of CDR measures the CAN bit timings in terms of number of tq. The sample point calculation evaluates the new sample point based on the computed CAN bit length and the sample point position configured in **WCAN_BTL2_CTRL**. The filter block is used to compensate the error introduced during internal measurement of number of tq in one bit time.

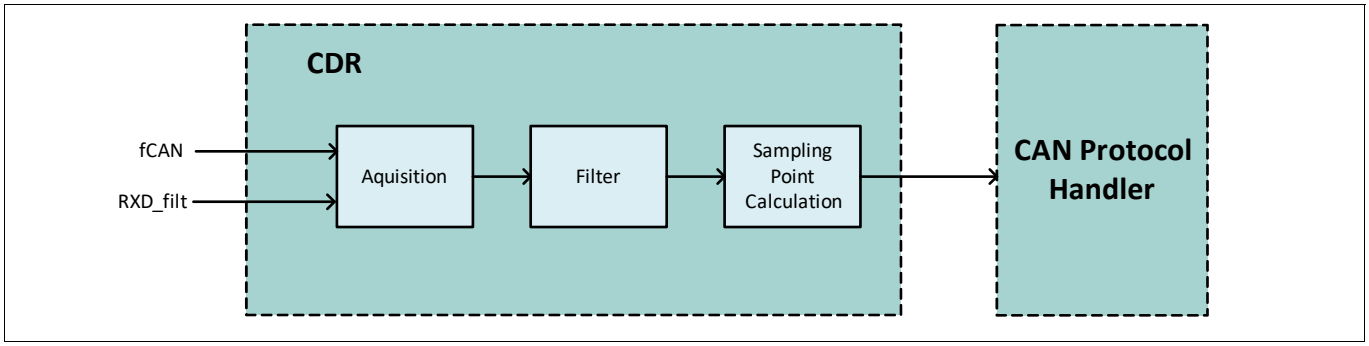


Figure 919 CDR Block Diagram

The configuration change enable, **WCAN_CFG**.CCE has to be enabled before a valid CAN bit timing can be written to the CAN Node Bit Timing Register, BTLn_CTRL (n=1-2). This is then followed by resetting **WCAN_CFG**.CCE bit before enabling the operation of the CAN node.

Note: The proposed sample point is at 80% of the bit time.

Acquisition Counter

The acquisition counter measures the bit timing based on the number of tq between two synchronization events (i.e., recessive to dominant transition of the filtered RX signal). The counter is active only if CDR_EN=1 and enabled by the protocol handler. The protocol handler enables the acquisition outside the arbitration phase, where CAN bit shortenings and extension are likely to occur. The only exception to that scenario is when an error is detected in the arbitration phase. In that case, the acquisition is enabled for preventing deadlock situation when the oscillator is outside the range and error occurs during Arbitration. The synchronization edges occurring within an error frame are cancelled by the windowing of acquisition. Based on the counter value, the number of CAN bits received between two synchronization events can be determined. This value is between 2 and 10, in accordance to the bit-stuffing rule.

Filter and Sample Point Calculation

The sample point calculation block evaluates the sampling position of the CAN bus bit based on the information from the Acquisition Counter and from the CDR configuration registers. Depending on the selected frequency and the baud rate, the default number of actual clock pulses expected during a CAN bus bit time is configured in **WCAN_BTL1_CTRL** register. The sampling position of the CAN bit is defined in BTL2_CTRL.SP bit field. It can be calculated as follows

BTL2_CTRL.SP = (64*sampling point)/100

*Note: For Example: A sampling point at 80% of bit time corresponds to **WCAN_BTL2_CTRL**.SP = 33_H.*

The number of tqs in one CAN bit time (tbit_calc) is measured internally based on the output from the acquisition counter and the expected number of tqs in one CAN bit time as provided by **WCAN_BTL1_CTRL**. This measured value can be read from the **WCAN_CDR_MEAS_HIGH** and **WCAN_CDR_MEAS_LOW**. The error introduced during the measurement is compensated using the Error scaling factor. During successive CDR measurements, the new bit timing value is evaluated by an averaging algorithm:

tbit_new = tbit_calc + error / SEL_FILT

where SEL_FILT is the error scaling factor (ie., the value over how many acquisition cycles the average will be built) as described in Table below.

Table 746 Number of acquisitions based on ESF

ESF	SEL_FILT
00_B	8
01_B	16 (recommended)
10_B	32
11_B	Adaptive averaging (based on number of bits between two consecutive synchronization edges) 2, 3 or 4 CAN bits = 32 5 or 6 CAN bits = 16 7, 8 or 9 CAN bits = 8

The sample point is then calculated based on **WCAN_BTL2_CTRL** and tbit_new. The sampling point is calculated only when tbit_new falls within the range defined by **WCAN_CDR_LOWER_CTRL**.LOWER and **WCAN_CDR_UPPER_CTRL**.UPPER. If not, the sample point is calculated directly based on the tbit value defined in **WCAN_BTL1_CTRL**.

Table 747 Bit Timing and RXD Filter configuration - Recommended

Baud Rate (kbits/s)	BRP	BTL1_CTRL	RXD Filter END COUNT	t_glitch (ns)	t-detect (ns)
1000	00_B	64_H	24	200	400
500	01_B	64_H	16	250	500
250	10_B	64_H	8	250	500
125	11_B	64_H	8	400	1400

49.17.4.1.4 Network Propagation Delays

The “worst case” network propagation delay is the network propagation delay after the 5th bit for the dominant to recessive edge on the bus. (See **Figure 920**)

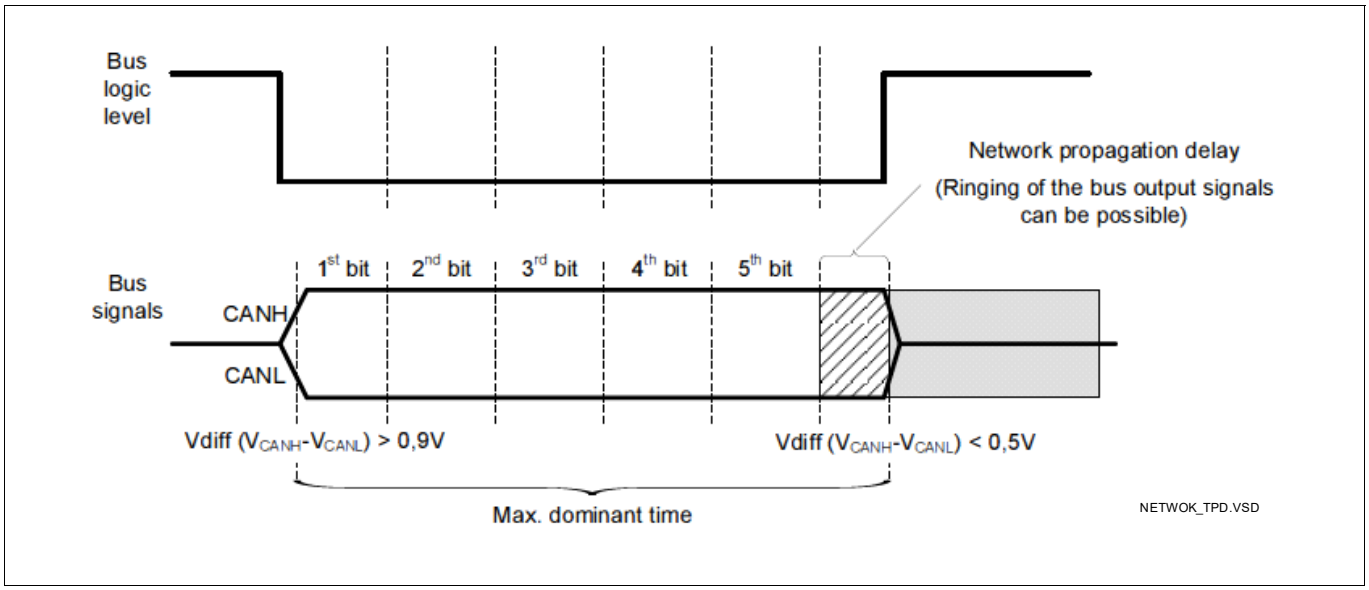

Figure 920 Network Propagation Delay after 5th Bit

The WCANmodule will be capable of sampling the recessive stuff bit after 5 consecutive dominant bits to ensure a safe wake-up, even if the dominant to recessive edge is delayed for the value of the network propagation delay shown in **Table 748**. The network propagation delay describes the maximal occurrence propagation delay which can be seen on the bus. This maximum network propagation delay does not include any EMC jitter. (i.e no HF injection)

Table 748 Network propagation delay

Baud Rate (Baud)	Network Propagation Delay (ns)	Maximum Dominant time (ns) (sender oscillator tolerance included)
1 MBaud	550	5550
500 kBaud	1350	11350
250 kBaud	2675	22675
125 kBaud	5450	45450

For HF injection the WCAN module is able to handle EMC network propagation delay as shown in **Table 749**.

Table 749 EMC Network propagation delay

Baud Rate (Baud)	Network Propagation Delay (ns)	Maximum Dominant time (ns) (sender oscillator tolerance included)
1 MBaud	450	5450
500 kBaud	1250	11250
250 kBaud	2575	22575
125 kBaud	5350	45350

Also the WCAN module is able to decode frames that contain sequences of 5 consecutive dominant bits followed by 5 consecutive recessive bits as shown in **Figure 920**.

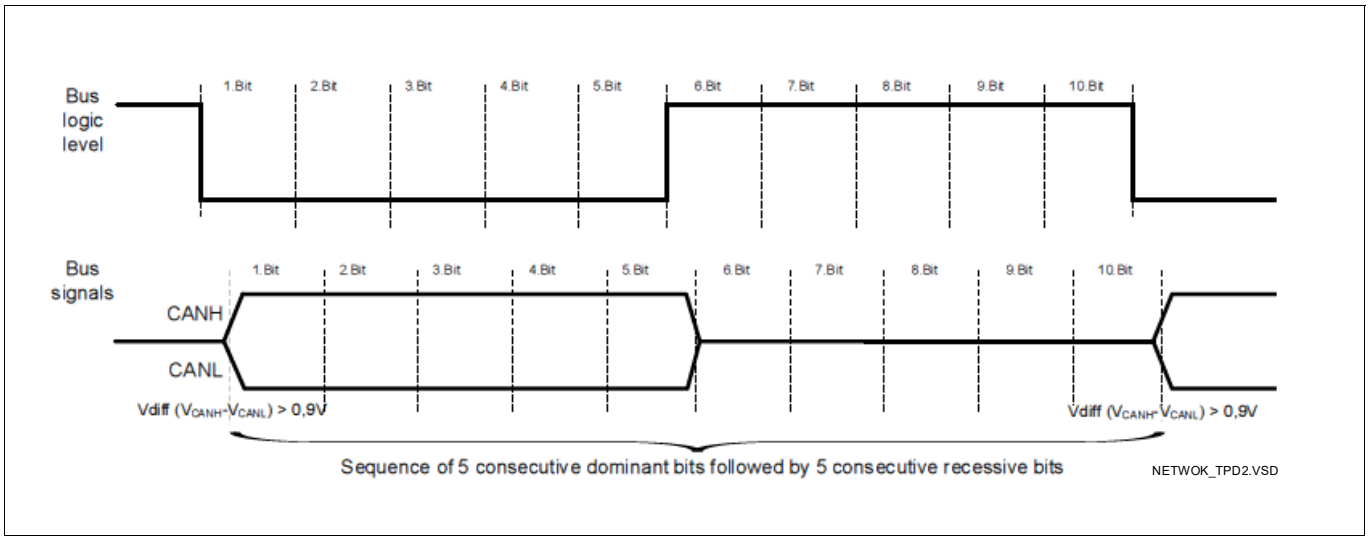

Figure 921 Network Propagation Delay after 10th Bit

The transmitting CAN node on the bus has to guarantee a maximum baud rate tolerance of +/- 0.4% for correct detection of the CAN frames (See **Table 750**)

Table 750 Worst Case length of 10 bits

Baud Rate (Baud)	Worst Case time for length of 10 bits by sender oscillator tolerance (-0.4%)	Worst Case time for length of 10 bits by sender oscillator tolerance (+0.4%)
1 MBaud	9960 ns	10040 ns
500 kBaud	19920 ns	20080 ns
250 kBaud	39840 ns	40160 ns
125 kBaud	79680 ns	80320 ns

49.17.4.1.5 CAN FD Tolerance

The WCAN can be configured as CAN FD tolerant (FDEN = 1), which means that protocol handler doesn't consider received CAN FD frames as error condition. When FDF bit is found dominant, the decoding phase is stopped and the protocol handler goes to the bus integration state waiting for 5 consecutive recessive bits. The protocol handler has an End Of Frame (EOF) bit counter to detect 5 consecutive recessive bits. The FD block generates a reset signal (active low) for the EOF bit counter, when a dominant bit in the high bit-rate phase is detected. The FD block directly uses the RXD signal and operates at f_{BACK} to avoid losing a dominant bit during the high bit-rate phase. Consequently a filter to suppress the dominant glitches is introduced in FD block. Since only dominant detection acts as the reset for EOF bit counter, the filter is an up-counter incremented when the RXD signal is dominant and reset when the RXD is recessive. So the filtered RXD is considered dominant when the counter end value (FD End Count) is reached. The glitch length (t_FD_glitch) to filter out and the minimum dominant pulse to detect (t_FD_detect) are based on the Baud rate and the FD factor as shown in **Table 751** below.

Table 751 CAN FD dominant bit filter time

Arbitration Baud Rate (kBaud)	FD Factor	FD_FILT	FD End Count	t_FD_glitch (ns)	t_FD_detect (ns)
125	4	011	90	400	1400
250	4	010	48	200	700
500	4	001	25	100	350
125	10	010	48	200	700
250	10	001	25	100	350
500	10	000	13	50	175

49.17.4.2 WCAN Kernel Registers

49.17.4.2.1 Register Address Map

The register set of the WCAN module consists of the below distinct subsets:

1. The Configuration, Miscellaneous Registers exist in one instance and apply for the entire WCAN module.
2. The Wake-Up CAN registers consist of the following:
   a) CAN Node Registers (**WCAN_BTL1_CTRL**, **WCAN_BTL2_CTRL**, **WCAN_CDR_CTRL**, **WCAN_CDR_UPPER_CTRL**, **WCAN_CDR_LOWER_CTRL**, **WCAN_CDR_MEAS_HIGH**, **WCAN_CDR_MEAS_LOW** and **WCAN_FD_CTRL**), which applies to a single CAN node.
   b) WUF configuration registers (DLC_CTRL, IDx_CTRL, MASK_IDx_CTRL, DATAx_CTRL) are defined for a single message object, and thus exist once for each message object.

Configuration and Status Registers

The configuration and status registers of a WCAN node are accessed from standard (non-mapped) SFR area. **Table 752** shows the address as seen on the Standby Controller (SCR).

Table 752 WCAN Configuration and Status Registers Address Map

Register	Addr.	Page	SCR Reset Value	Full Name of Register
WCAN_CFG	$B0_H$	0	00_H	Configuration Register
WCAN_INTMRSLT	$B1_H$	0	00_H	Interrupt Mask and Reference Select Register
WCAN_INTESTAT0	$B0_H$	1	00_H	Interrupt and Event Status 0 Register
WCAN_INTESTAT1	$B1_H$	1	60_H	Interrupt and Event Status 1 Register
WCAN_FRMERRCNT	$B2_H$	1	00_H	Frame Error Counter Register
WCAN_INTESCLR0	$B3_H$	1	00_H	Interrupt and Event Status Clear Register 0
WCAN_INTESCLR1	$B4_H$	1	00_H	Interrupt and Event Status Clear Register 1

CAN Node Registers

The registers of a WCAN node are accessed from standard (non-mapped) SFR area. **Table 753** shows the address of registers as seen on the Standby Controller (SCR).

Table 753 CAN Node Registers Address Map

Register	Addr.	Page	SCR Reset Value	Full Name of Register

49.17.4.2.2 CAN Node Registers

The CAN node specific registers contain information that is directly related to the operation of the CAN node.The Node Control Register contains basic settings that define the bit timing for the operation of the CAN node.

Bit Timing Logic Control Register

The Bit Timing Logic Control Registers contain all parameters to setup the bit timing for the CAN transfer.

*Note: The startup-software (SSW) overwrites the BTL1_CTRL register with 64_H and BTL2_CTRL register with 73_H after reset, to obtain a 500 Kbits/s baud rate. Please use the values specified in **Table 747** for 1 Mbits/s (BTL1_CTRL1, BTL2_CTRL), 250 Kbits/s (BTL1_CTRL, BTL2_CTRL) and 125 Kbits/s (BTL1_CTRL, BTL2_CTRL) baud rate.*
*The Configuration Change Enable, **WCAN_CFG**.CCE has to be enabled before the BTLn_CTRL register can be written.*

49.17.5.2 Port and Interrupt Control

The interconnections between the Wake-Up CAN module and the port I/O lines are controlled in the port control logic for Port 13. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (SCR_IOCR registers (SCR module) and IOCR registers (GPIO module))

49.17.5.2.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that selects the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the WCAN module are controlled by the port input/output control registers shown below (see MODPISEL0 register in SCU chapter).

Table 781 shows how bits and bit fields must be programmed for the required I/O functionality of the CAN I/O lines.

Table 781 WCAN I/O Control Selection and Setup

Module	Port Lines	Input/Output Control Register Bits	I/O
CAN	CAN0		
	P33.10 / WCANRXDA	SCR_P01_IOCR2.PC2 = 0XXXXB	Input
	P33.7 / WCANRXDB	SCR_P00_IOCR7.PC7 = 0XXXXB	Input
	P33.13 / WCANRXDC	SCR_P01_IOCR5.PC5 = 0XXXXB	Input
	P33.5 / WCANRXDD	SCR_P00_IOCR5.PC5 = 0XXXXB	Input
	P33.2 / WCANRXDE	SCR_P00_IOCR2.PC2 = 0XXXXB	Input
	P14.1 / WCANRXDF [1)]	P14_IOCR1.PC1 = 0XXXXB	Input
	P33.12 / WCANRXDG	SCR_P01_IOCR4.PC4 = 0XXXXB	Input

Note: *[1)] The pad control of this pin is in the 32-bit GPIO module. This port can be used only when VDDEXT is supplied.*

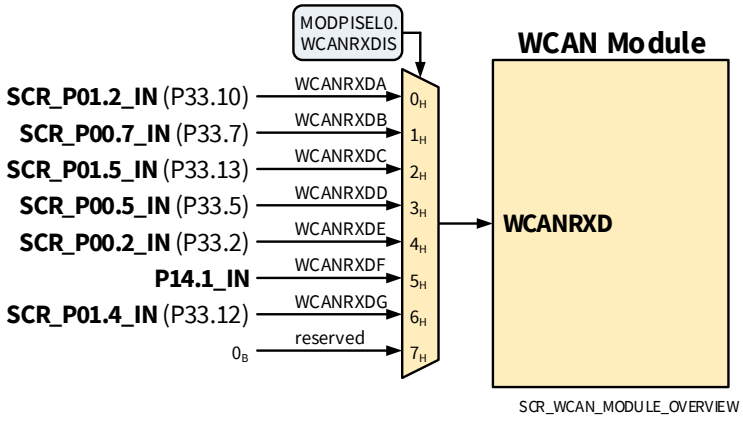

Figure 923 Wake-Up CAN Connections to GPIO Ports

49.17.5.2.2 Interrupt Control

The interrupt control logic in the Wake-Up CAN module consists of the following interrupts shown in **Table 782** and **Figure 924**.

Table 782 WCAN Interrupt Outputs

Interrupt inputs	Connected to WCAN Interrupt Output

49.18 Debug System

This chapter describes the XC800/SCR debug system, in particular focus on the OCDS unit which provides the hardware to support debug functionality.

49.18.1 Overview

The debug system comprises of the On-Chip Debug Support (OCDS) unit and Debug-Monitor in ROM which provides basic debug functionality for XC800/SCR-based systems, controlled directly by an external tool via debug interface pin(s).

49.18.1.1 Features

The main debug functionality supported are:

- Set breakpoints on instruction address and on address range within the Program Memory
- Set breakpoints on Internal RAM address range
- Support unlimited software breakpoints in Flash/RAM code region
- Process external breaks via debug interface
- Step through the program code
- User handling of OCDS NMI in case of IRAM read/write breakpoint

49.18.1.2 Components of the Debug System

The components of the debug system are briefly described here.

49.18.1.2.1 Debug Interface

The debug interface allows to access the device, such as for data read or write. The debug interface supports:

- 2-pin Device Access Port (DAP)
- Single-pin DAP (SPD)

The DAP interface refers to the dual-pin Device Access Port standardized for the Infineon microcontrollers. It offers high noise immunity and robustness, and utilizes only two pins DAP0 (clock), DAP1 (serial data in/out).

The SPD interface refers to the single-pin Device Access Port standardized for the Infineon microcontrollers. It utilizes only one pin DAP1 for serial data in/out.

49.18.1.2.2 Monitor Program

Part of the Boot ROM is occupied by the OCDS Monitor program (or OCDS firmware). On the command from the debugger, the Monitor program executes the actual instructions for accessing the addressable locations such as memories, sfrs of the device.

49.18.1.2.3 On-Chip Debug System Unit (OCDS)

The OCDS hardware is the core of the debug system, controlling the debugging with interfaces to the XC800 CPU.

49.18.2 Product Specific Information

This section provides product specific information relevant to the OCDS.

49.18.2.1 Pinning

Table 784 describes the OCDS pin function.

Table 784 OCDS Pin Functions

Function	Description
DAP0_1	Dual-pin debug access port: clock
DAP0_0	
DAP1/SPD_1	Single-pin debug access port: data
DAP1/SPD_0	

The pin will be set up via hardware once the OCDS mode is selected. Detailed pinout is given in the GPIO chapter.

49.18.2.2 Clocking Configuration

The OCDS runs at the peripheral frequency, PCLK.

49.18.2.3 JTAG ID

The following assignment of JTAG ID are used for SCR:

VERSION = 1_H, PART_NUMBER = $01EC_H$, i.e. JTAG ID Register = $101EC083_H$

49.18.3 Revision History

Table 785 Revision History

49.19 Device Access Port (DAP2)

In addition to the pins functionally used by the application some pins are needed to communicate with tools during development. Tools commonly used are board tester, debugger, emulator, calibration tools and performance analyzers. On the other hand the cost inferred by each non-functional pin is a strong argument to reduce the tool access port to as few pins as possible.

The standardized device access port (DAP2) of all current micro controllers offers a convenient method to get the required functionality at the least possible cost: Depending on configuration, one, two of the device's pins are reserved for tooling until the next reset. The different modes are detailed in this chapter.

DAP2 is used for debugging purposes together with the OCDS module, supported by the startup firmware for halt-after-reset on user code start address or by appropriate DAP telegram for "hot-attach" after reset (HMONITOR command to the SCR).

For SCR, the DAP kernel interfaces with the SPD unit with in-direct control of DAP port via the SPD. The addition of the SPD unit supports single-pin-DAP in addition to the standard dual-pin DAP. In this chapter, 'DAP[x]' generally refers to the 'SD_DAP[x]' which is the signal interfacing between DAP and SPD units.

This chapter also refers to the POSD reset event. The debug system of SCR is reset in case of an LVD reset. Therefore POSD in this chapter complies to LVD Reset.

TRST is inside the SCR attached to the PORST pin. The device is capable of pure JTAG only. No IO_Client is implemented.

DAP Features

Please note that the following list party represents the combination of DAP and IOClient functionality.

- Generic protocol with minimum overhead
- High-speed due to synchronous clocking
- Low pin-count
  - DAP0 clock pin
  - DAP1 data pin
- Robust interface
  - Telegrams protected by 6-bit CRC (CRC6). Optional 32-bit CRC (CRC32) checks for critical communication sequences
  - Interface enabling pattern with 50 relevant bits
  - Tool can automatically detect and recover from any kind of reset
  - Electrically robust by using standard pads with full ESD protection
- Optimized random memory accesses
  - Combined read data and set next address telegram hides internal access latency
  - Optional usage of short 16-bit offset address instead of 32 bit
  - 8/16 bit data is transferred with 8/16 bit width instead of 32 bit
  - Results in ca. 0.5 us for a random read of arbitrary data size at 160 MHz
- Effective DAP block access bandwidth for 160 MHz clocking:
  - 15 MByte/s for block read or write
- Device to tool triggering mode with minimum overhead
- On-chip JTAG infrastructure can be controlled
- Very cost effective tool hardware possible

Please note that the block access bandwidth scales linear with the DAP clock frequency. The maximum DAP frequency is product specific and can be lower than 160 MHz. It is assumed that the internal bus clock frequency is high enough.

49.20 Single Pin DAP (SPD)

The SPD module converts between the single pin and the two pin DAP protocol (**Figure 925**).

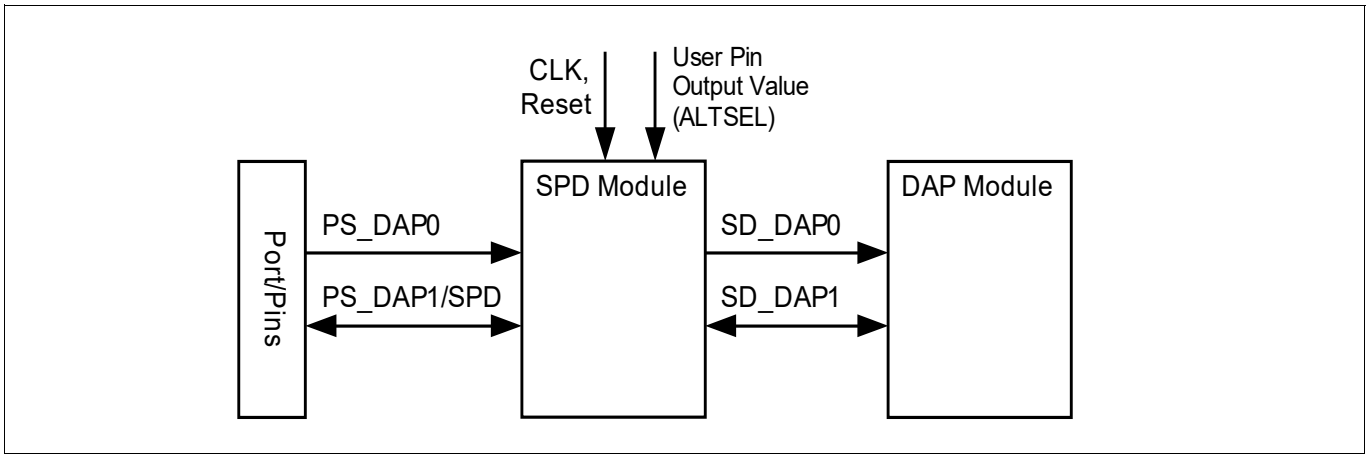

Figure 925 SPD System Integration

Features

- 2 MHz bit frequency (effective 1.3 Mbits/s for DAP telegrams)
- Digital and small implementation
- Very robust against clock deviations between tool and device

IMPORTANT NOTICE

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics ("Beschaffenheitsgarantie").

With respect to any examples, hints or any typical values stated herein and/or any information regarding the application of the product, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation warranties of non-infringement of intellectual property rights of any third party.

In addition, any information given in this document is subject to customer's compliance with its obligations stated in this document and any applicable legal requirements, norms and standards concerning customer's products and any use of the product of Infineon Technologies in customer's applications.

The data contained in this document is exclusively intended for technically trained staff. It is the responsibility of customer's technical departments to evaluate the suitability of the product for the intended application and the completeness of the product information given in this document with respect to such application.

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (**www.infineon.com**).

WARNINGS

Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies' products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.
