AURIX™ TC3xx

About this document

Scope and purpose

This User's Manual describes the Infineon AURIX™ TC3xx Platform family, a range of 32-bit multicore microcontrollers based on the Infineon TriCore™ Architecture.

This family document covers the superset functionality. It is supplemented by a separate device specific document "Appendix" that covers differences of a particular device to this family superset.

Table of Contents

27 System Timer (STM)

This chapter describes the System Timer (STM). The STM is designed for global system timing applications requiring both high precision and long period.

27.1 Feature List

The STM has the following features:

- Free-running 64-bit counter
- All 64 bits can be read synchronously
- Different 32-bit portions of the 64-bit counter can be read synchronously
- Flexible service request generation based on compare match with partial STM content
- Counting starts automatically after an Application Reset
- STM registers are reset by an Application Reset if bit ARSTDIS.STMxDIS is cleared. If bit ARSTDIS.STMxDIS is set, the STM registers are not reset by application reset, and are reset by system reset instead.

Special STM register semantics provide synchronous views of the entire 64-bit counter, or 32-bit subsets at different levels of resolution.

27.2 Overview

Figure 1 provides an overview on the STM module. It shows the options for reading parts of the STM content.

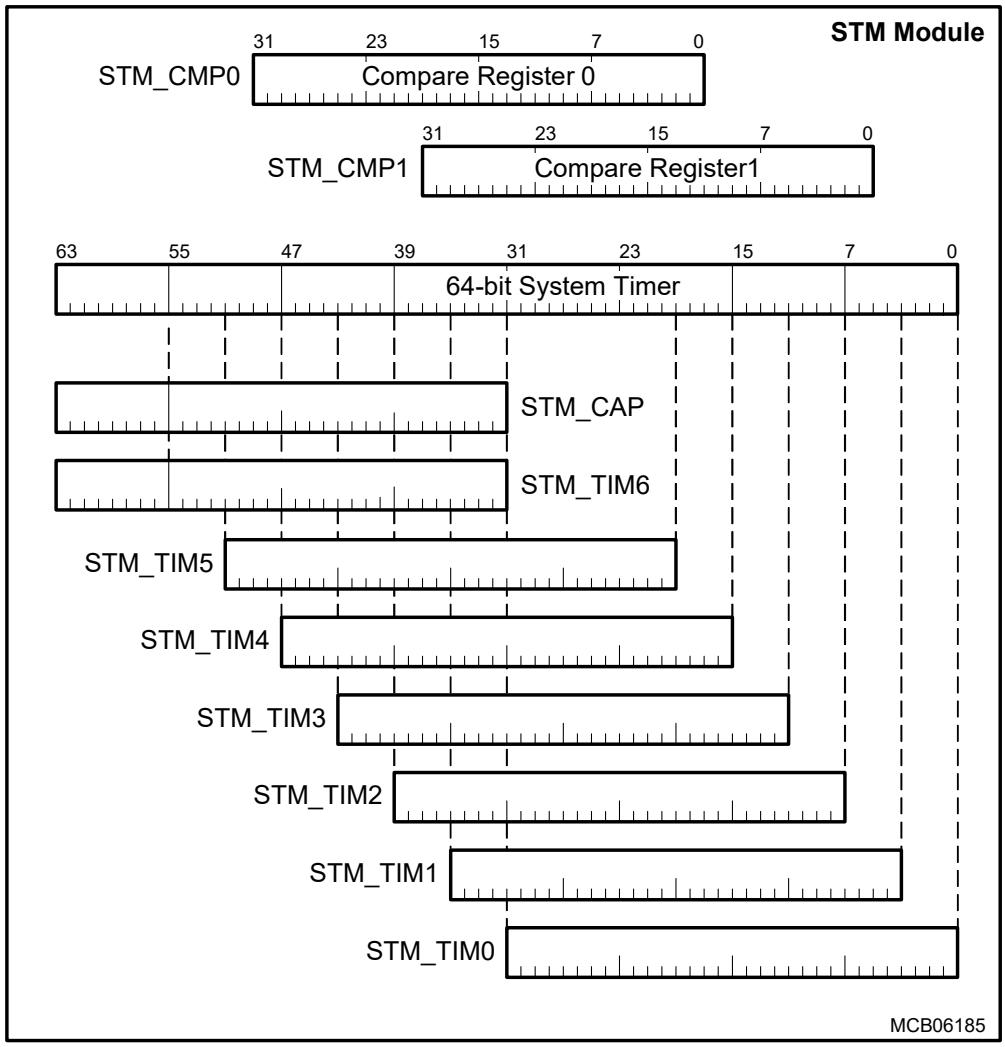

Figure 1 General Block Diagram of the STM Module

27.3 Functional Description

The STM is an upward counter, running at frequency f_{STM}. In case of an Application Reset, the STM is reset if bit SCU_ARSTDIS.STMxDIS is cleared. After reset, the STM is enabled and immediately starts counting up. It is not possible to affect the content of the timer during normal operation. The timer registers can only be read but not written to.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes. In suspend mode, the STM clock is stopped but all registers are still readable.

Due to the 64-bit width of the STM, it is not possible to read its entire content with one instruction. It needs to be read with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to possible overflow from the low part of the timer to the high part between the two read operations). To enable a synchronous and consistent reading of the STM content, a capture register (CAP) is implemented. It latches the content of the high part of the STM each time

when one of the registers TIM0 to TIM5 is read. Thus, CAP holds the upper value of the timer at exactly the same time when the lower part is read. The second read operation would then read the content of the CAP to get the complete timer value.

The STM can also be read in sections from seven registers, TIM0 through TIM6, that select increasingly higher-order 32-bit ranges of the STM. These can be viewed as individual 32-bit timers, each with a different resolution and timing range.

The content of the 64-bit System Timer can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

27.3.1 Compare Register Operation

The content of the 64-bit STM can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

Two parameters are programmable for the compare operation:

1. The width of the relevant bits in registers CMP0/CMP1 (compare width MSIZEx) that is taken for the compare operation can be programmed from 0 to 31.
2. The first bit location in the 64-bit STM that is taken for the compare operation can be programmed from 0 to 31.

These programming capabilities make compare functionality very flexible. It even makes it possible to detect bit transitions of a single bit n (n = 0 to 31) within the 64-bit STM by setting MSIZE = 0 and MSTART = n.

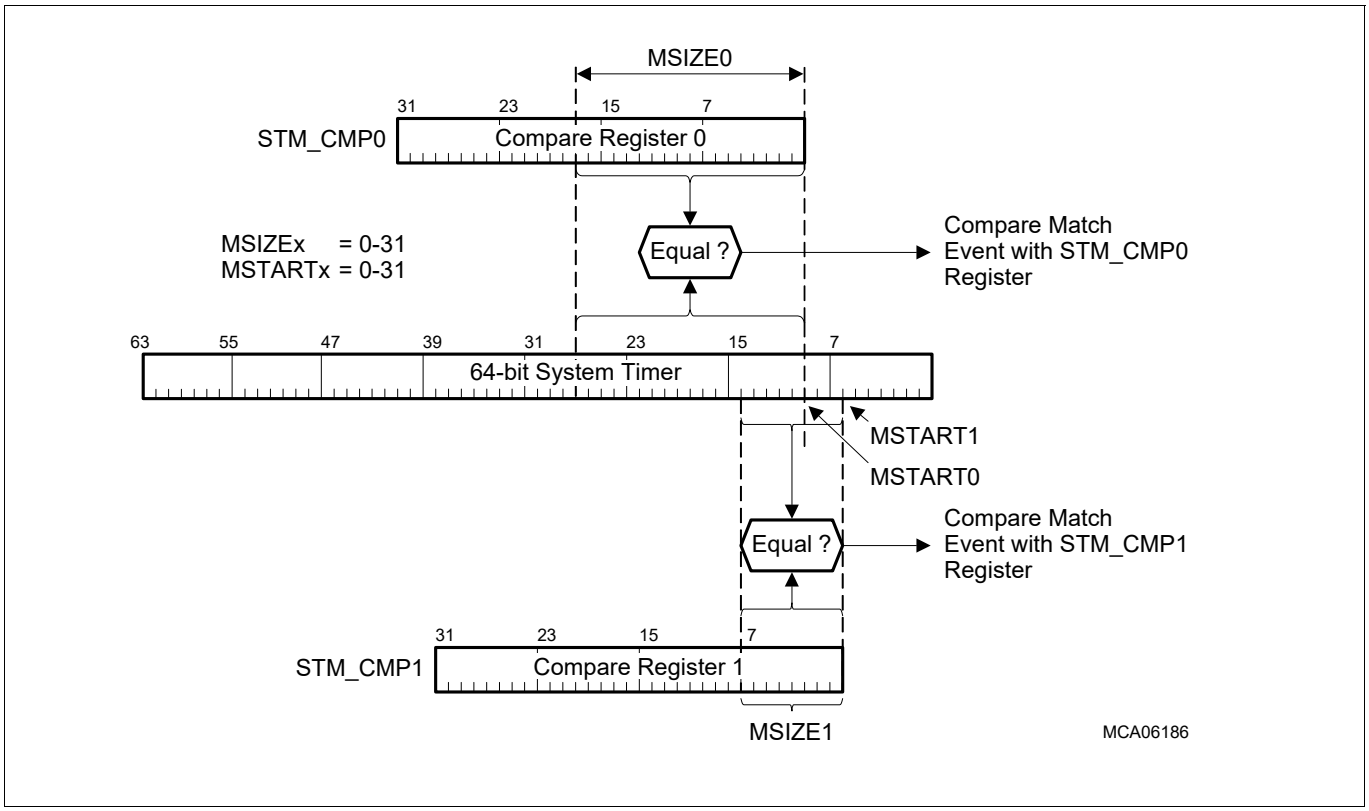

Figure 2 Compare Mode Operation

Figure 2 shows an example of the compare operation. In this example the following parameters are programmed:

- MSIZE0 = $10001_B = 17_D$; MSTART0 = $01010_B = 10_D$
- MSIZE1 = $00111_B = 7_D$; MSTART1 = $00111_B = 7_D$

A compare operation with MSIZE not equal 11111_B always implies that the compared value as stored in the CMP register is right-extended with zeros. This means that in the example of Figure 2, the compare register content CMP0[17:0] plus ten zero bits right-extended is compared with STM[27:0] with STM[9:0] = 000_H. In case of register CMP1, STM[14:0] with STM[6:0] = 00_H are compared with CMP1[9:0] plus seven zero bits right-extended.

27.3.2 Compare Match Interrupt Control

The compare match interrupt control logic is shown in **Figure 3**. Each CMPx register has its compare match interrupt request flag (ICR.CMPxIR) that is set by hardware on a compare match event. The interrupt request flags can be set (ISCR.CMPxIRS) or cleared (ISCR.CMPxIRR) by software. Note that setting ICR.CMPxIR by writing a 1 into ISSR.CMPxIRS does not generate an interrupt at STMIRx. The compare match interrupts from CMP0 and CMP1 can be further directed by ICR.CMPxOS to either output signal STMIR0 or STMIR1.

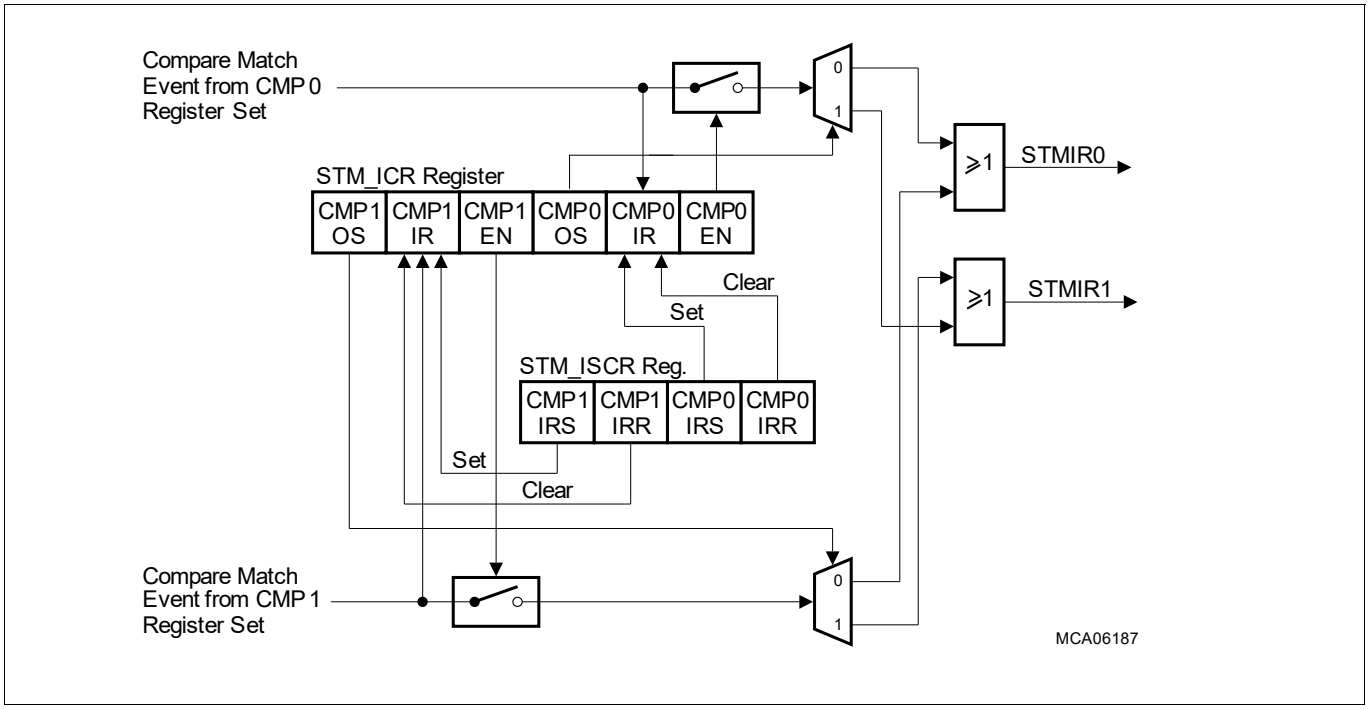

Figure 3 STM Interrupt Control

The compare match interrupt flags ICR.CMPxIR are immediately set after an STM reset operation, caused by a compare match event with the reset values of the STM and the compare registers CMPx. This does not directly generate compare match interrupts because the compare match interrupts are automatically disabled after an STM reset operation (ICR.CMPxEN = 0). Therefore, before enabling a compare match interrupt after an STM Application Reset, the software should configure the STM and modify the reset values of the compare registers. Otherwise, undesired compare match interrupt events are triggered. The CMPxIR flags which are set after an STM reset can be cleared by writing register ISCR with CMPxIRR set.

27.3.3 Using Multiple STMs

For systems that include multiple CPUs there are also multiple STMs available. Each STM is aimed to serve as time base for one individual CPU operating system main scheduler clock trigger. This is done by the usage of one compare register and the associated interrupt generating the trigger.

All STM modules are connected and controlled by f_{STM} and can therefore operate on the same frequency if desired.

27.3.4 STM as Reset Trigger

A compare match triggered by an CMP0 event can generate a reset in the system. The reset has to be enabled for each STM module individually in register SCU_RSTCON.

27.4 Registers

This section describes the registers of the STM.

Table 1 Register Overview - STM (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control Register	0000_H	U,SV	SV,E,P	Application Reset	7
ID	Module Identification Register	0008_H	U,SV	BE	Application Reset	8

27.4.1 Clock Control Register

Clock Control Register

The STM clock control register is used to switch the STM on or off and to control its input clock rate. After reset, the STM is always enabled and starts counting. The STM can be disabled by setting bit DISR to 1.

CLC

Clock Control Register (0000_H) Application Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	rw	r	rw

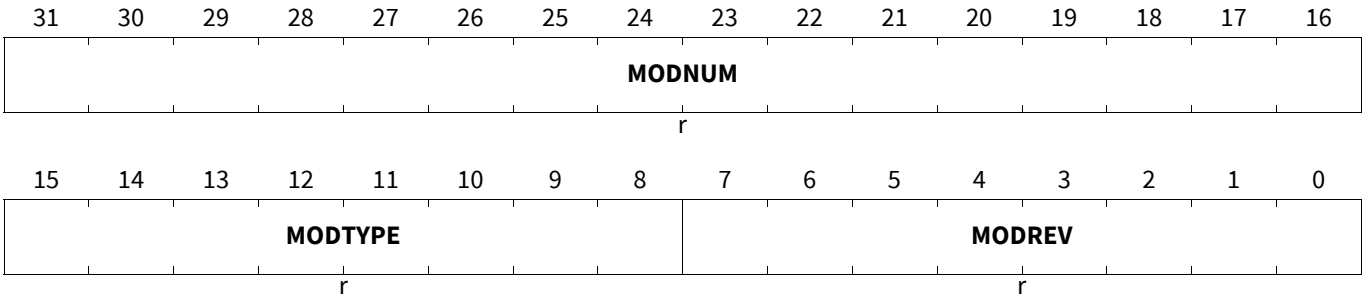
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the STM module. *Note: f_{STM} is generated by the CCU.* 0_B No disable requested 1_B Disable requested
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the STM module. 0_B STM module is enabled 1_B STM module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used for module sleep mode control.
0	2	rw	**Reserved** Read as 0; shall be written with 0.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The STM Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(0008_H)** **Application Reset Value: $0000\ C007_H$**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision). Current revision is 0x7.
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the STM: 0068_H

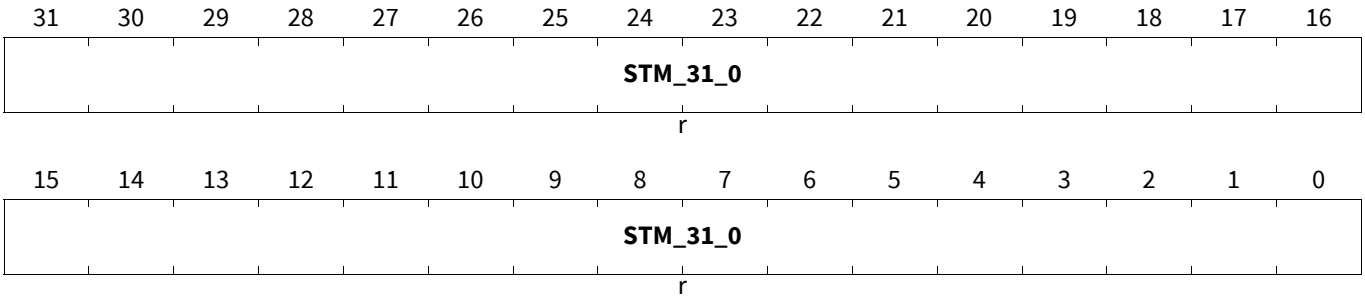
27.4.2 Timer/Capture Registers

Registers TIM0 to TIM6 provide 32-bit views at varying resolutions of the underlying STM counter.

Timer Register 0

Register TIM0SV address the STM[31:0] bits at a second optional address as TIM0.

TIM0
Timer Register 0 **(0010_H)** **Application Reset Value: $0000\ 0000_H$**

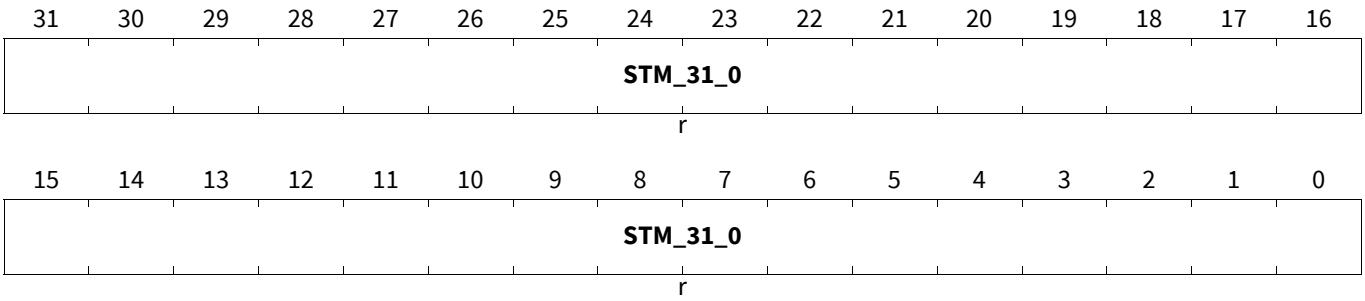


Field	Bits	Type	Description
STM_31_0	31:0	r	**System Timer Bits [31:0] - STM[31:0]** This bit field contains bits [31:0] of the 64-bit STM.

Timer Register 0 Second View

Register TIM0SV address the STM[31:0] bits at a second optional address as TIM0.

TIM0SV
Timer Register 0 Second View **(0050_H)** **Application Reset Value: $0000\ 0000_H$**

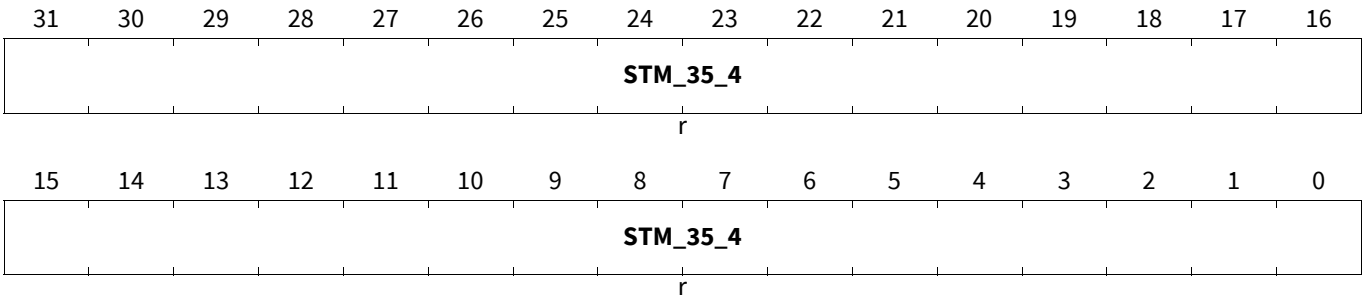


Field	Bits	Type	Description
STM_31_0	31:0	r	**System Timer Bits [31:0] - STM[31:0]** This bit field contains bits [31:0] of the 64-bit STM.

Timer Register 1

TIM1

Timer Register 1 **(0014_H)** **Application Reset Value: $0000\ 0000_H$**

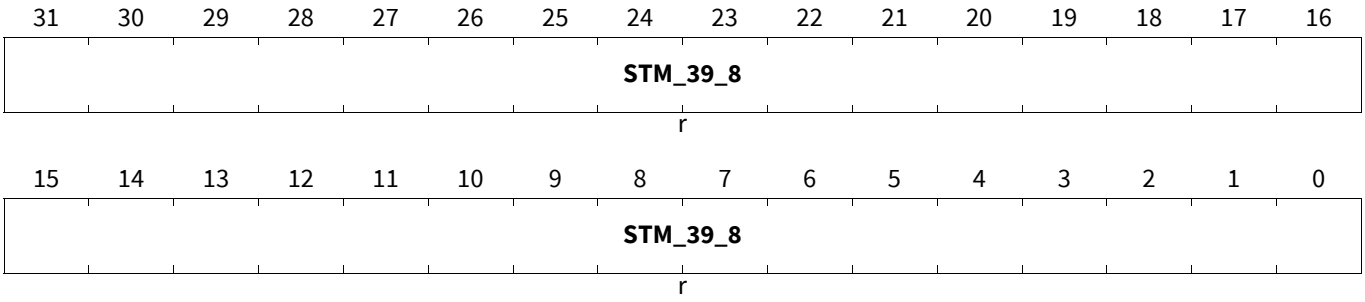


Field	Bits	Type	Description
STM_35_4	31:0	r	**System Timer Bits [35:4] - STM[35:4]** This bit field contains bits [35:4] of the 64-bit STM.

Timer Register 2

TIM2

Timer Register 2 **(0018_H)** **Application Reset Value: $0000\ 0000_H$**

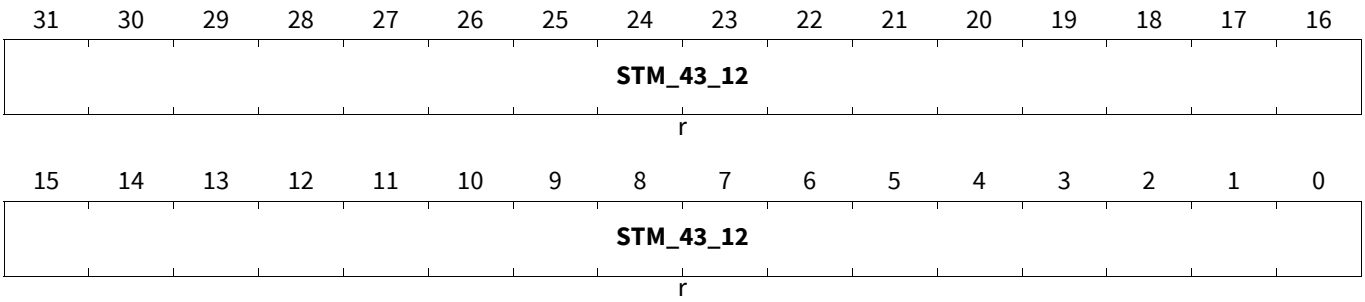


Field	Bits	Type	Description
STM_39_8	31:0	r	**System Timer Bits [39:8] - STM[39:8]** This bit field contains bits [39:8] of the 64-bit STM.

Timer Register 3

TIM3

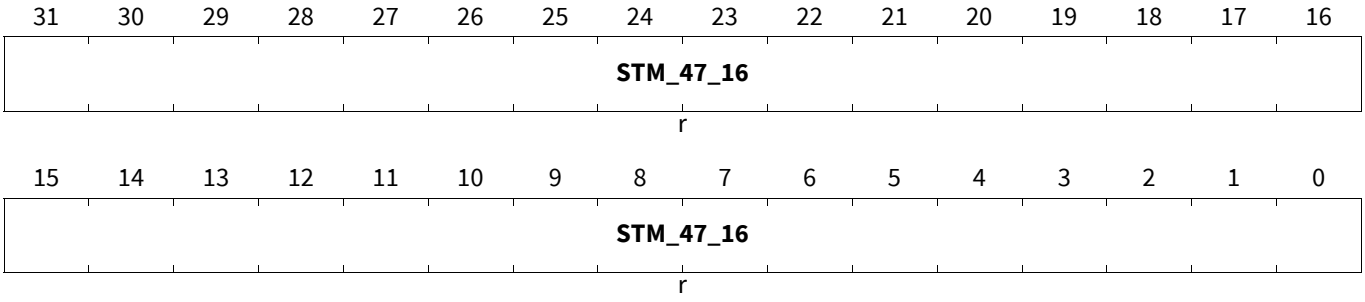
Timer Register 3 **($001C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STM_43_12	31:0	r	**System Timer Bits [43:12] - STM[43:12]** This bit field contains bits [43:12] of the 64-bit STM.

Timer Register 4

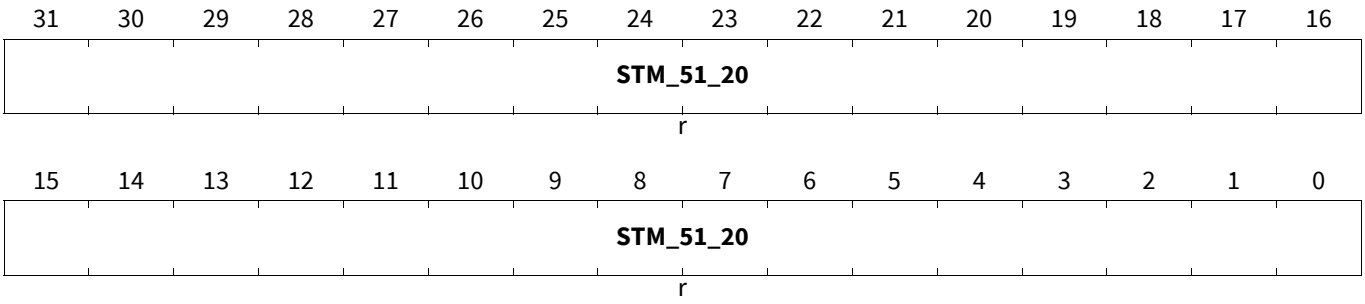
TIM4
Timer Register 4 **(0020_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STM_47_16	31:0	r	**System Timer Bits [47:16] - STM[47:16]** This bit field contains bits [47:16] of the 64-bit STM.

Timer Register 5

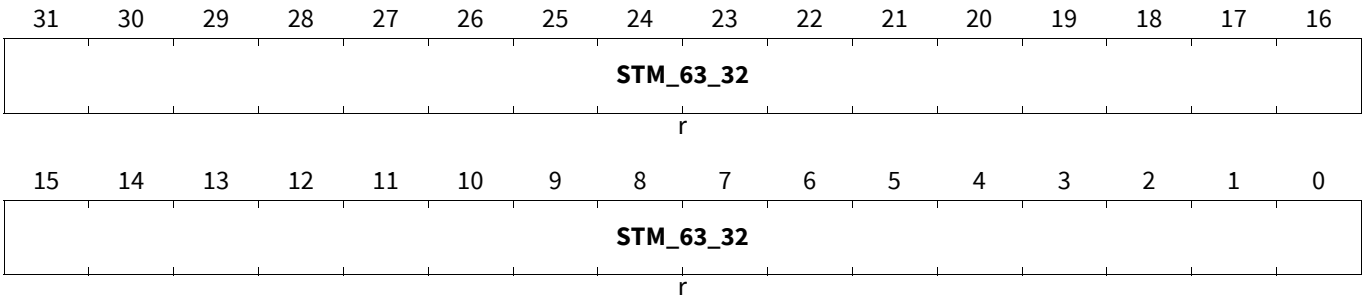
TIM5
Timer Register 5 **(0024_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STM_51_20	31:0	r	**System Timer Bits [51:20] - STM[51:20]** This bit field contains bits [51:20] of the 64-bit STM.

Timer Register 6

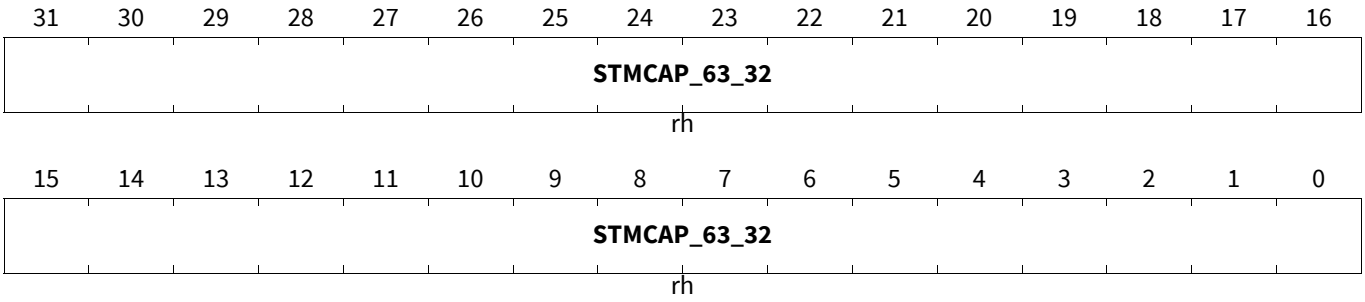
TIM6
Timer Register 6 **(0028_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STM_63_32	31:0	r	**System Timer Bits [63:32] - STM[63:32]** This bit field contains bits [63:32] of the 64-bit STM.

Timer Capture Register

CAP
Timer Capture Register **($002C_H$)** **Application Reset Value: $0000\ 0000_H$**

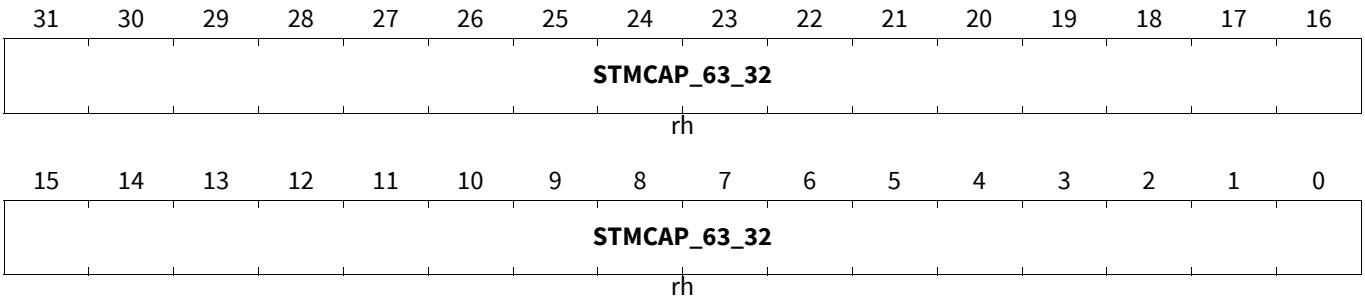


Field	Bits	Type	Description
STMCAP_63_32	31:0	rh	**Captured System Timer Bits [63:32] - STMCAP[63:32]** The capture register STMCAP always captures the STM bits [63:32] when one of the registers TIM0 to TIM6 or TIM0SV is read. This capture operation is performed in order to enable software to operate with a coherent value of all the 64 STM bits at one time stamp.This bit field contains bits [63:32] of the 64-bit STM. *Note: Reading register TIM0SV captures also the read value for register TIM6. In this way reading TIM0SV followed by CAPSV delivers the timer values for the first read request.*

Timer Capture Register Second View

CAPSV

Timer Capture Register Second View **(0054_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
STMCAP_63_32	31:0	rh	**Captured System Timer Bits [63:32] - STMCAP[63:32]** The capture register STMCAP always captures the STM bits [63:32] when one of the registers TIM0 to TIM6 or TIM0SV is read. This capture operation is performed in order to enable software to operate with a coherent value of all the 64 STM bits at one time stamp.This bit field contains bits [63:32] of the 64-bit STM. *Note: Reading register TIM0SV captures also the read value for register TIM6. In this way reading TIM0SV followed by CAPSV delivers the timer values for the first read request.*

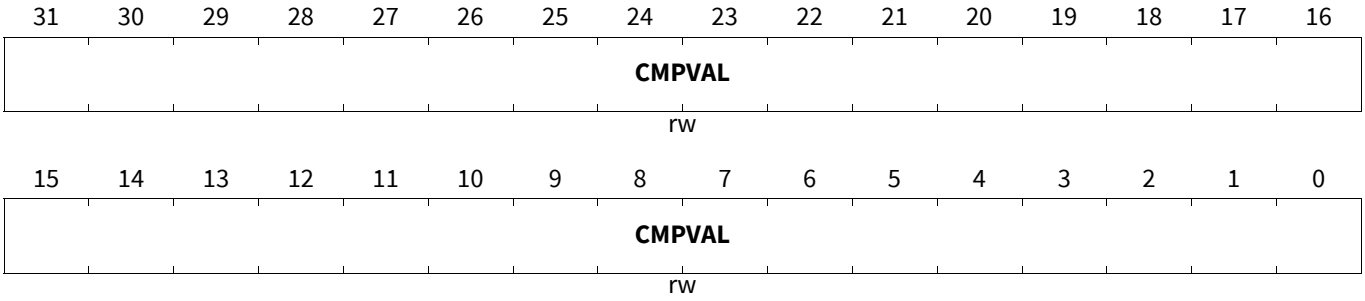
27.4.3 Compare Registers

The compare register CMPx holds up to 32-bits; its value is compared to the value of the STM.

Compare Register x

CMPx (x=0-1)

Compare Register x **(0030_H+x*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CMPVAL	31:0	rw	**Compare Value of Compare Register x** This bit field holds up to 32 bits of the compare value (right-adjusted).

Compare Match Control Register

The STM Compare Match Control Register controls the parameters of the compare logic.

CMCON

Compare Match Control Register **(0038_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r			rw					r			rw				

Field	Bits	Type	Description
MSIZE0	4:0	rw	**Compare Register Size for CMP0** This bit field determines the number of bits in register CMP0 (starting from bit 0) that are used for the compare operation with the System Timer. ... 00_H CMP0[0] used for compare operation 01_H CMP0[1:0] used for compare operation $1E_H$ CMP0[30:0] used for compare operation $1F_H$ CMP0[31:0] used for compare operation
MSTART0	12:8	rw	**Start Bit Location for CMP0** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP0 bit 0. The number of bits to be compared is defined by bit field MSIZE0. ... 00_H STM[0] is the lowest bit number 01_H STM[1] is the lowest bit number $1E_H$ STM[30] is the lowest bit number $1F_H$ STM[31] is the lowest bit number
MSIZE1	20:16	rw	**Compare Register Size for CMP1** This bit field determines the number of bits in register CMP1 (starting from bit 0) that are used for the compare operation with the System Timer. ... 00_H CMP1[0] used for compare operation 01_H CMP1[1:0] used for compare operation $1E_H$ CMP1[30:0] used for compare operation $1F_H$ CMP1[31:0] used for compare operation

Field	Bits	Type	Description
MSTART1	28:24	rw	**Start Bit Location for CMP1** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP1 bit 0. The number of bits to be compared is defined by bit field MSIZE1. ... 00_H STM[0] is the lowest bit number 01_H STM[1] is the lowest bit number $1E_H$ STM[30] is the lowest bit number $1F_H$ STM[31] is the lowest bit number
0	7:5, 15:13, 23:21, 31:29	r	**Reserved** Read as 0; should be written with 0.

27.4.4 Interrupt Registers

Interrupt Control Register

The two compare match interrupts of the STM are controlled by the STM Interrupt Control Register.

ICR
Interrupt Control Register **(003C$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0									CMP1OS	CMP1IR	CMP1EN	0	CMP0OS	CMP0IR	CMP0EN
r									rw	rh	rw	r	rw	rh	rw

Field	Bits	Type	Description
CMP0EN	0	rw	**Compare Register CMP0 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP0. 0_B Interrupt on compare match with CMP0 disabled 1_B Interrupt on compare match with CMP0 enabled
CMP0IR	1	rh	**Compare Register CMP0 Interrupt Request Flag** This bit indicates whether or not a compare match event of compare register CMP0 has occured. CMP0IR can be cleared by software and can be set by software, too (see ISCR register). After a STM reset operation, CMP0IR is immediately set as a result of a compare match event with the reset values of the STM and the compare registers CMP0. *Note: This flag does not gate the interrupt generation. i.e., even if this flag is not cleared, compare match event interrupts are forwarded if CMPxEN is set.* 0_B A compare match event has not been detected since the bit was last cleared. 1_B A compare match event has been detected.
CMP0OS	2	rw	**Compare Register CMP0 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP0. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected

Field	Bits	Type	Description
CMP1EN	4	rw	**Compare Register CMP1 Interrupt Enable Control** This bit enables the compare match interrupt with compare register CMP1. 0_B Interrupt on compare match with CMP1 disabled 1_B Interrupt on compare match with CMP1 enabled
CMP1IR	5	rh	**Compare Register CMP1 Interrupt Request Flag** This bit indicates whether or not a compare match event of compare register CMP1 has occured. CMP1IR can be cleared by software and can be set by software, too (see ISCR register). After a STM reset operation, CMP1IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP1. *Note: This flag does not gate the interrupt generation. i.e., even if this flag is not cleared, compare match event interrupts are forwarded if CMPxEN is set.* 0_B A compare match event has not been detected since the bit was last cleared. 1_B A compare match event has been detected.
CMP1OS	6	rw	**Compare Register CMP1 Interrupt Output Selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP1. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
0	3, 31:7	r	**Reserved** Read as 0; should be written with 0.

Interrupt Set/Clear Register

The bits in the STM Interrupt Set/Clear Register make it possible to set or cleared the compare match interrupt request status flags of register ICR.

Note: Reading register ISCR always returns 0000 0000$_H$.

ISCR

Interrupt Set/Clear Register (0040$_H$) Application Reset Value: 0000 0000$_H$

CMP0IRS	1	w	**Set Compare Register CMP0 Interrupt Flag** 0_B Bit ICR.CMP0IR is not changed. 1_B Bit ICR.CMP0IR is set. The state of bit CMP0IRR is “don’t care” in this case.
CMP1IRR	2	w	**Reset Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is cleared.
CMP1IRS	3	w	**Set Compare Register CMP1 Interrupt Flag** 0_B Bit ICR.CMP1IR is not changed. 1_B Bit ICR.CMP1IR is set. The state of bit CMP1IRR is “don’t care” in this case.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

27.4.5 Interface Registers

OCDS Control and Status Register

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.When OCDS is disabled the OCS suspend control is ineffective.

OCS

OCDS Control and Status Register (00E8$_H$) Debug Reset Value: 0000 0000$_H$

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

KRST0

Kernel Reset Register 0 **(00F4$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0														RSTSTAT	RST
r														rh	rwh

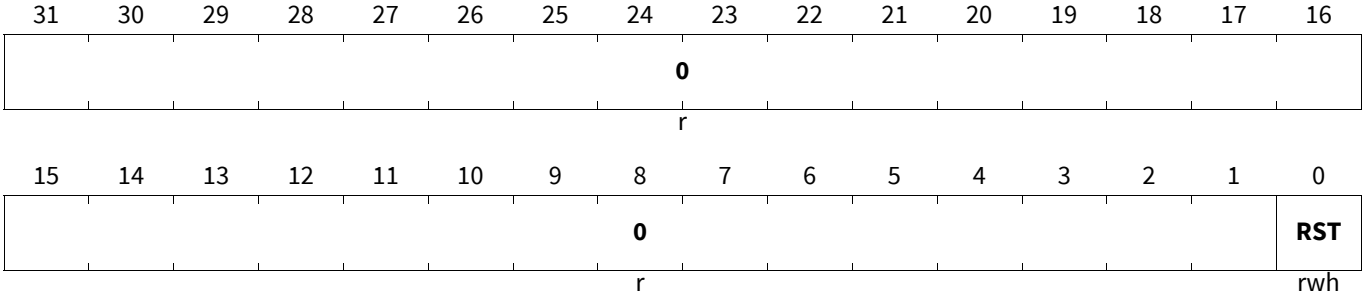
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the STM kernel. STM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the STM kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **(00F0$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **(00EC$_H$)** **Application Reset Value: 0000 0000$_H$**

28 Generic Timer Module (GTM)

GTM general Architecture

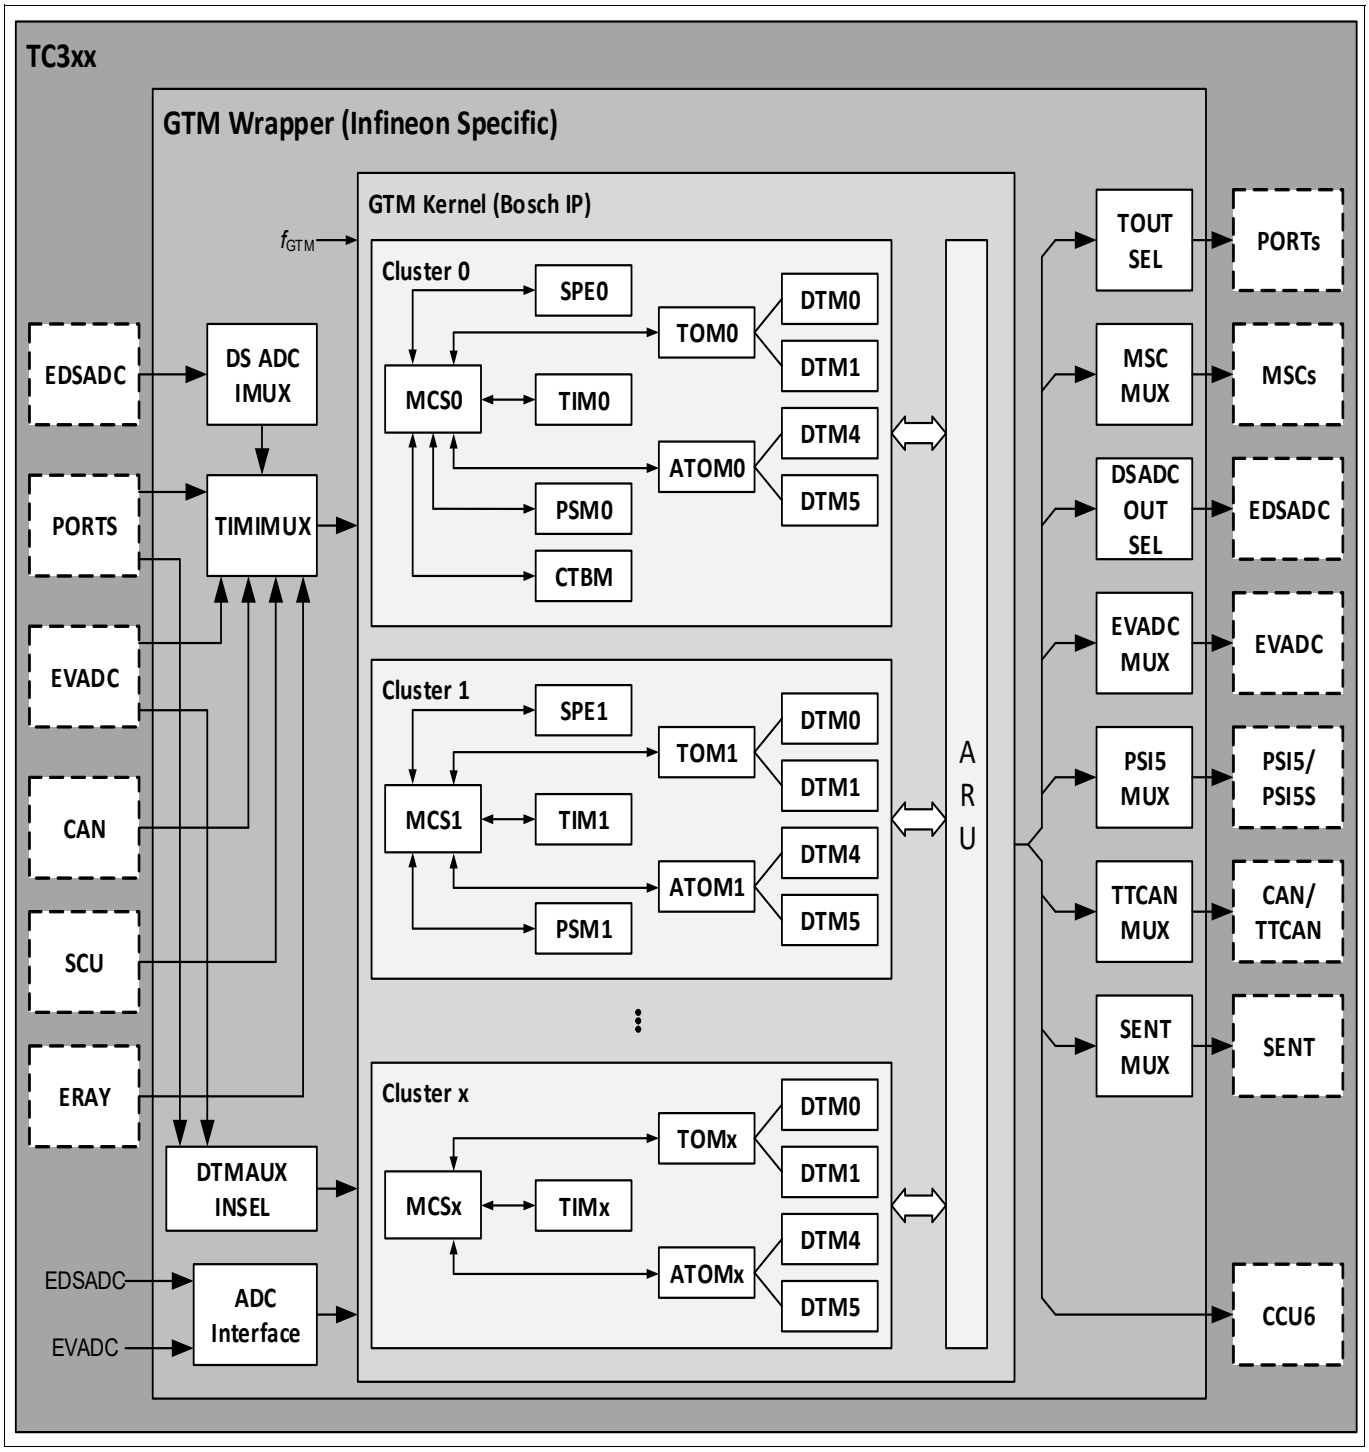

Figure 4 GTM Architecture block diagram

Note: The GTM system runs with the GTM global clock f_{GTM} (referred in this chapter as SYS_CLK)

28.1 Feature List

FEATURE LIST

The GTM module is comprised of two main parts:

- the GTM IP v3.1.5.1, designed by Bosch
  - The GTM IP consists of many different sub-modules, offering a wide-variety of functionality to address all the most common applications that are relevant for a timer module
- the GTM Wrapper[1] designed by Infineon

The following is a list of some of the most important GTM IP features found in the sub-modules:

- Central/Edge aligned PWM Generation (TOM/ATOM)
- Dedicated module for asymmetric dead time generation (DTM)
- Dedicated support for DC-DC phase shift operation (DTM)
- Logical combination of digital signals (DTM)
- Provide common time base for system (TBU)
- Multiple capture/compare of external signals and combination with time stamps (TIM/ATOM/TBU)
- Complex digital signals generation (PSM, ATOM, MCS)
- Digital signals filtering and characterization (TIM)
- Input signal measurement and timeout detection (TIM)
- BLDC motor control using Block Commutation Mode (SPE, TIM, TOM)
- Engine angle clock for engine management applications (DPLL, TIM, MAP, TBU)
- Injection/Ignition pulses generation with dedicated HW support (DPLL, ATOM, MCS)
- Programmable RISC-like cores to offload the CPU (MCS)
- Automatic data sharing between GTM modules without CPU/DMA (ARU,BRC)
- Configurable operating frequency up to 200MHz (CCM,CMU)

28.1.1 Delta to AURIX

Backward compatibility

- The GTM IP v3.1.5.1 is fully backward compatible with previous generations
- The GTM wrapper is not fully backward compatible
  - Some parts of the wrapper has been changed to increase the GTM flexibility and to address the higher number of connectivities required by the AURIX second generation

GTM IP differences

The main differences between GTM2.x and GTM3.1.x are the following:

- Maximum operation frequency extended up to 200MHz[2]
- GTM architecture divided in clusters
- Enhanced the MCS RISC-like processor enhanced with new instructions (i.e. MUL,DIV)

1) For the GTM Wrapper details, please refer to the GTM Implementation chapter
2) Only for the first five clusters

- Every MCS can access all the other GTM modules' registers inside the same cluster
- Every MCS can get interrupts from all the other GTM modules inside the same cluster
- MCS memory write protection against CPU/DMA accesses and other MCS
- Added new configurable scheduling schemes to the ARU
- Added the emergency switch off feature to the DTM modules
- Improved the DPLL ticks generation and the bi-directional sensors support
- Added new ADC Interface to the MCS
- Added new TBU modulo counter (engine angle clock)
- Added new up-down counter mode to (A)TOM modules
- Added new scheduling schemes to the MCS

GTM Wrapper differences

With the TC3xx devices, there are significant changes with the Wrapper:

- Increased the number of selectable GTM output resources connected to each Port (from 4 to 12)
- Added three more triggers towards ADC (from 2 to 5)
- Implemented a new multiplexer to connect Port and ADC signals to DTM
- Created a new interface to connect all the EVADC and EDSADC result registers to the MCS

28.2 Overview

GTM Kernel Architecture

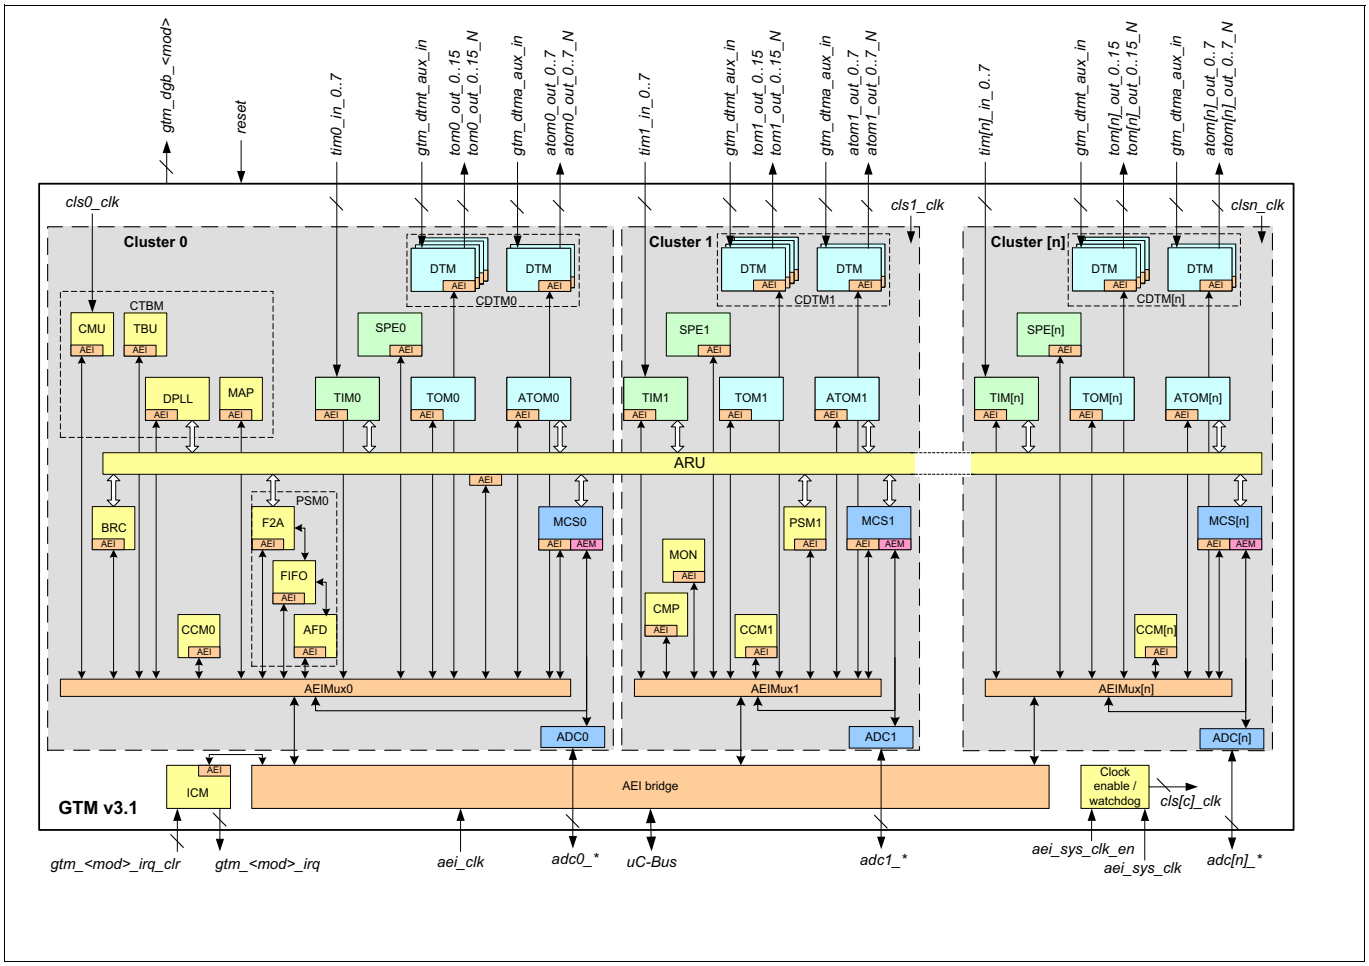

Figure 5 GTM Architecture Block Diagram

28.3 Generic Timer Module (GTM)

This document is based on the following GTM specification of the Robert Bosch GmbH:

- Version: release-v3.1.5.1-2016.03.24
- Date: 24 March 2016

28.3.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with sub-modules of different functionality. These sub-modules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The scalability and configurability is reached with an architecture philosophy where dedicated hardware sub-modules are located around a central routing unit (called Advanced Routing Unit (ARU)). The ARU can connect the sub-modules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM can run -once setup by an external CPU- independent and in parallel to the software. There

may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.

The hardware sub-modules have dedicated functionality's, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several sub-modules through the ARU complex functions can be established. E.g. the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called *infrastructure components* further on. These components are present in all GTM variants. However, the number of these components may vary from device to device.

Other sub-modules have a more general architecture and can fulfill typical timer functions, e.g. there are PWM generation units. The third classes of sub-modules are those fulfilling a dedicated functionality for a certain application domain, e.g. the DPLL serves engine management applications. A fourth group of sub-modules is responsible for supporting the implementation of safety functions to fulfill a defined safety level. The module ICM is responsible for interrupt services and defines the fifth group.

Each GTM is build up therefore with sub-modules coming from those four groups. The application class is defined by the amount of components of those sub-modules integrated into the implemented GTM.

28.3.2 Document Structure

The structure of this document is motivated out of the aforementioned sub-module classes. **Section 28.4** describes the dedicated GTM implementation this specification is written for. It gives an overview about the implemented sub-modules.

The following sections **Section 28.5** up to **Section 28.12** deals with the so called infrastructure components for routing, clock management and common time base functions. Sections **Section 28.13** to **Section 28.16** describe the signal input and output modules while the following **Section 28.17** explains the signal processing and generation sub-module with **Section 28.18** its memory configuration. The next sections **Section 28.19** to **Section 28.21** provides a detailed description of application specific modules like the MAP, DPLL and SPE. The last sections **Section 28.23** to **Section 28.24** provide to safety related modules (not part of the Infineon safety manual) like CMP and MON sub-modules. **Section 28.22** describes a module that bundles several interrupts coming from the other sub-modules and connect them to the outside world.

Note: Infineon: CMP and MON are not part of the safety manual. As safety measure the IOM is provided in combination with GTP1/2 or CCU6.

Table 5 Sub-module groups

Chapter	Sub-module	Group

Section 28.23	Output Compare Unit (CMP)	Safety features (not part of the Infineon safety manual)
Section 28.24	Monitoring Unit (MON)	Safety features (not part of the Infineon safety manual)

28.4 GTM Architecture

28.4.1 Overview

As already mentioned in the Introduction the GTM forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different number of sub-modules (i.e. ATOM, BRC, MCS, PSM, SPE, TIM, TOM, DTM) and different number of channel per sub-module (if applicable) are possible.The device dependent configuration (i.e. the number of sub-modules) is listed in the device specific appendix. The Parameter Storage Module (PSM) is only a virtual hierarchy and consists of the sub-module F2A, FIFO and AFD.The Cluster Dead Time Module (CDTM) is also a virtual hierarchy and consists of up to six DTM modules. It depends on the GTM device configuration which of the six DTM instances are available. Please refer to device specific appendix for list of available DTM instances. In general, the first four DTM modules inside a CDTM[n] hierarchy are connected to the outputs of the TOM instance [n] of the cluster [n], the other two DTM instances are connected to the outputs of the ATOM instance [n] of this cluster [n].

The cluster view of a GTM_IP architecture is depicted in **Figure 6**. This is a generic figure which shows a possible GTM-IP device configuration.

The device dependent configuration (i.e. the count of sub-modules and channels per sub-module) is listed in the device specific appendix.

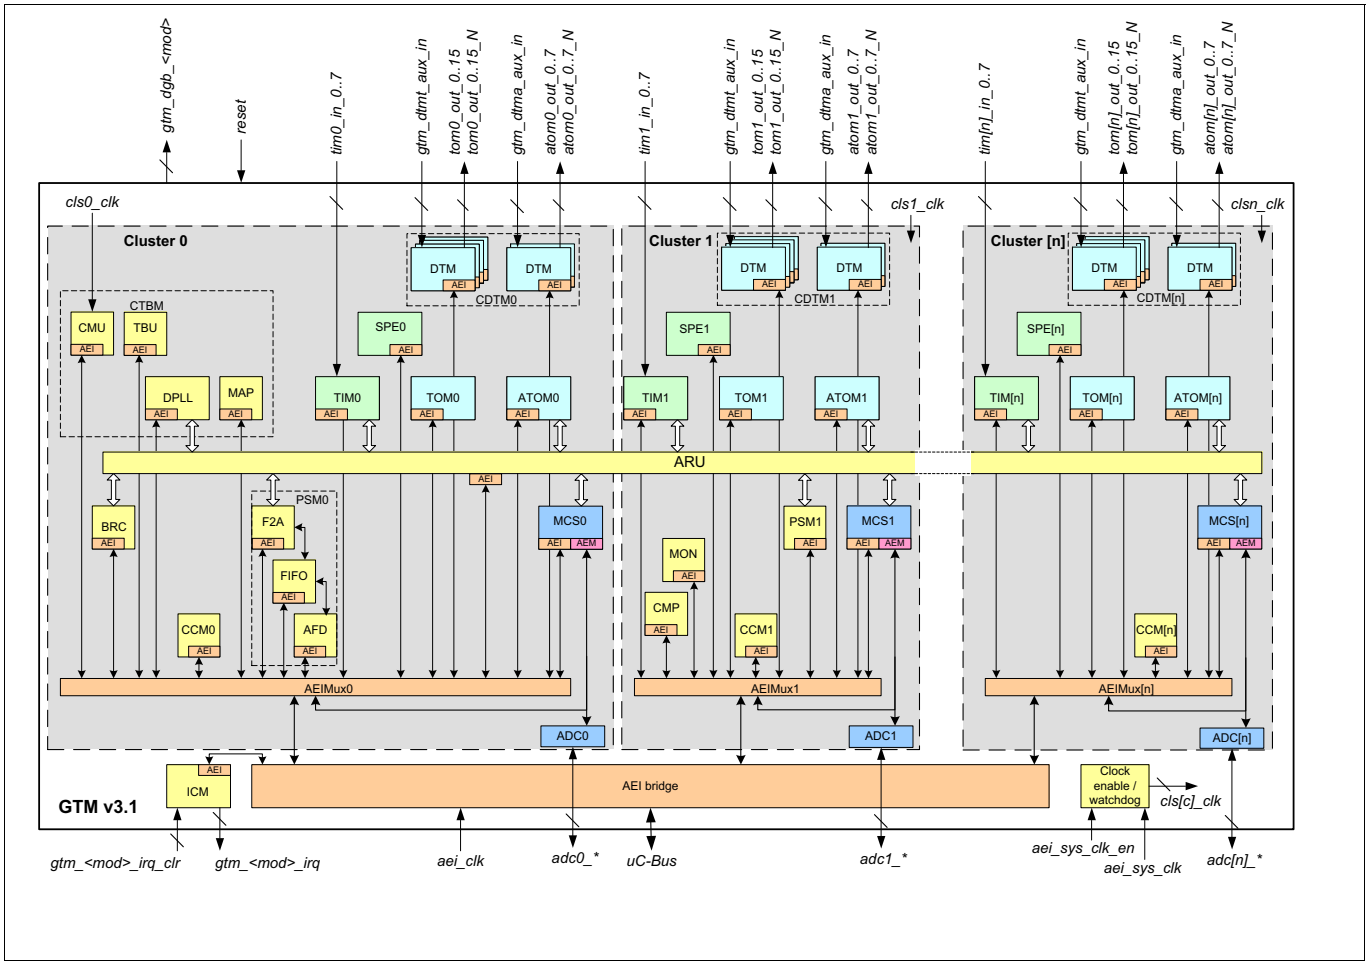

Figure 6 GTM Architecture Block Diagram

The GTM is divided in multiple clusters 0…n. A certain amount of modules exist in each cluster. The operating frequency of a cluster can be configured to OFF, aei_sys_clk or aei_sys_clk/2. The clock enable generation can be implemented internal to the GTM_IP or external. In case of an external enable generation aei_sys_clk_en is used to generate the internal clocks. In addition an enable watchdog is implemented to monitor the correctness of the external applied enable signals aei_sys_clk_en.

The central component of the GTM is the Advanced Routing Unit (ARU) where most of the sub-modules are located around and connected to. This ARU forms together with the Broadcast (BRC) and the Parameter Storage Module (PSM) the infrastructure part of the GTM. The ARU is able to route data from a connected source sub-module to a connected destination sub-module. The routing is done in a deterministic manner with a round-robin scheduling scheme of connected channels which receive data from ARU and with a worst case round-trip time.

The routed data word size of the ARU is 53 bit. The data word can logically be split into three parts. These parts are shown in **Figure 7**. Bits 0 to 23 and bits 24 to 47 typically hold data for the operation registers of the GTM. This can be, for example, the duty cycle and period duration of a measured PWM input signal or the output characteristic of an output PWM to be generated. Another possible content of Data0 and Data1 can be two 24 bit values of the GTM time bases TBU_TS0, TBU_TS1 and TBU_TS2. Bits 48 to 52 can contain control bits to send control information from one sub-module to another. These ARU Control Bits (ACB) can have a different meaning for different sub-modules.It is also possible to route data from a source to a destination and the destination can act later on as source for another destination. These routes through the GTM are further on called *data streams*. For a detailed description of the ARU sub-module please refer to the ARU chapter.

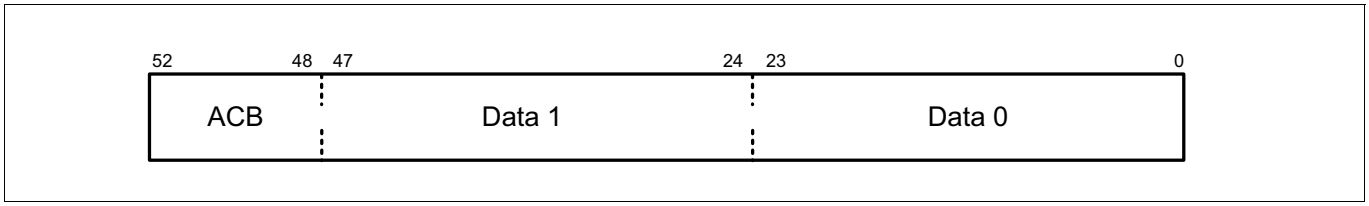

Figure 7 ARU Data Word Description

The BRC is able to distribute data from one source module to more than one destination modules connected to the ARU. The PSM sub-module consists of three sub-units, the AEI-to-FIFO Data Interface (AFD), FIFO-to-ARU Interface (F2A) and the FIFO itself. The PSM can serve as a data storage for incoming data characteristics or as parameter storage for outgoing data. This data is stored in a RAM that is logically located inside the FIFO sub-unit, but physically the RAM is implemented and integrated by the silicon vendor with his RAM implementation technology. Therefore, the GTM provides the interface to the RAM at its module boundary. The AFD sub-unit is the interface between the FIFO and the GTM SoC system bus interface AEI (see **Section 28.4.2.1** for detailed discussion). The F2A sub-unit is the interface between the FIFO sub-unit and the ARU.

Signals are transferred into the GTM at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in parallel and route the values to ARU for further processing. The internal operation registers of the TIM sub-module are 24 bits wide.

The Clock Management Unit (CMU) serves up to 13 different clocks for the GTM and up to three external clock pins *GTM_ECLK0…2*. It acts as a clock divider for the system clock. The counters implemented inside other sub-modules are typically driven from this sub-module. Please note, that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock *SYS_CLK*.[1)] This global clock typically corresponds to the micro controller bus clock the GTM-IP is connected to and should not exceed 100MHz because of the power dissipation of the used transistors where the GTM is implemented with.

The TBU provides up to three independent common time bases for the GTM. In general, the number of time bases depends on the implemented device. If three time bases are implemented, two of these time bases can also be clocked with the digital PLL (DPLL) *sub_inc1*c and *sub_inc2c* outputs. The DPLL generates the higher frequent clock signals *sub_inc1*, *sub_inc2*, *sub_inc1c* and *sub_inc2c* on behalf of the frequencies of up to two input signals. These two input signals can be selected out of six incoming signals from the TIM0 sub-module. In this sub-module the incoming signals are filtered and transferred to the MAP sub-module where two of these six signals are selected for further processing inside the DPLL.

Signal outputs are generated with the Dead Time Module (DTM), Timer Output Modules (TOM) and the ARU-connected TOMs (ATOM). Each TOM channel is able to generate a PWM signal at its output. Because of the integrated shadow register even the generation of complex PWM outputs is possible with the TOM channels by serving the parameters with the CPU. It is possible to trigger TOM channels for a successor TOM sub-module through a trigger line between TOM(x)_CH(15) and TOM(x+1)_CH(0). But to avoid long trigger paths the GTM integrator can configure after which TOM sub-module instance a register is placed into the trigger signal chain. Each register results in one SYS_CLK cycle delay of the trigger signal. Please refer to device specification of silicon vendor for unregistered trigger chain length.

In addition, each TOM sub-module can integrate functions to drive one BLDC engine. This BLDC support is established together with the TIM and Sensor Pattern Evaluation (SPE) sub-module.

The ATOMs offer the additional functionality to generate complex output signals without CPU interaction by serving these complex waveform characteristics by other sub-modules that are connected to the ARU like the PSM or Multi Channel Sequencer (MCS). While the internal operation and shadow registers of the TOM channels

1) SYS_CLK = f_{GTM} clock provided by the GTM wrapper. f_{GTM} max value is $2xf_{SPB}$ = 200MHz

are 16 bit wide, the operation and shadow registers of the ATOM channels are 24 bit wide to have a higher resolution and to have the opportunity to compare against time base values coming from the TBU.

It is possible to trigger ATOM channels for a successor ATOM sub-module through a trigger line between ATOM(x)_CH(7) and ATOM(x+1)_CH(0). But to avoid long trigger paths the GTM integrator can configure after which ATOM sub-module instance a register is placed into the trigger signal chain. Each register results in one SYS_CLK cycle delay of the trigger signal. Please refer to device specification of silicon vendor for unregistered trigger chain length.

Together with the MCS the ATOM is able to generate an arbitrary predefined output sequence at the GTM output pins. The output sequence is defined by instructions located in RAM connected to the MCS sub-module. The instructions define the points were an output signal should change or to react on other signal inputs. The output points can be one or two time stamps (or even angle stamp in case of an engine management system) provided by the TBU. Since the MCS is able to read data from the ARU it is also able to operate on incoming data routed from the TIM. Additionally, the MCS can process data that is located in its connected RAMs. The MCS RAM is located logically inside the MCS while the silicon vendor has to implement its own RAM technology there.

The two modules Compare Module (CMP) and Monitor Module (MON) implement safety related features. The CMP compares two output channels of the DTM and sends the result to the MON sub-module were the error is signaled to the CPU. The MON module is also able to monitor the ARU and CMU activities.

In the described implementation the sub-modules of the GTM have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier manageable bunch of interrupts that are visible outside of the GTM.

On the GTM top level there are some configurable signal connections from the signal output of the DTM modules to the input signals of the TIM modules.

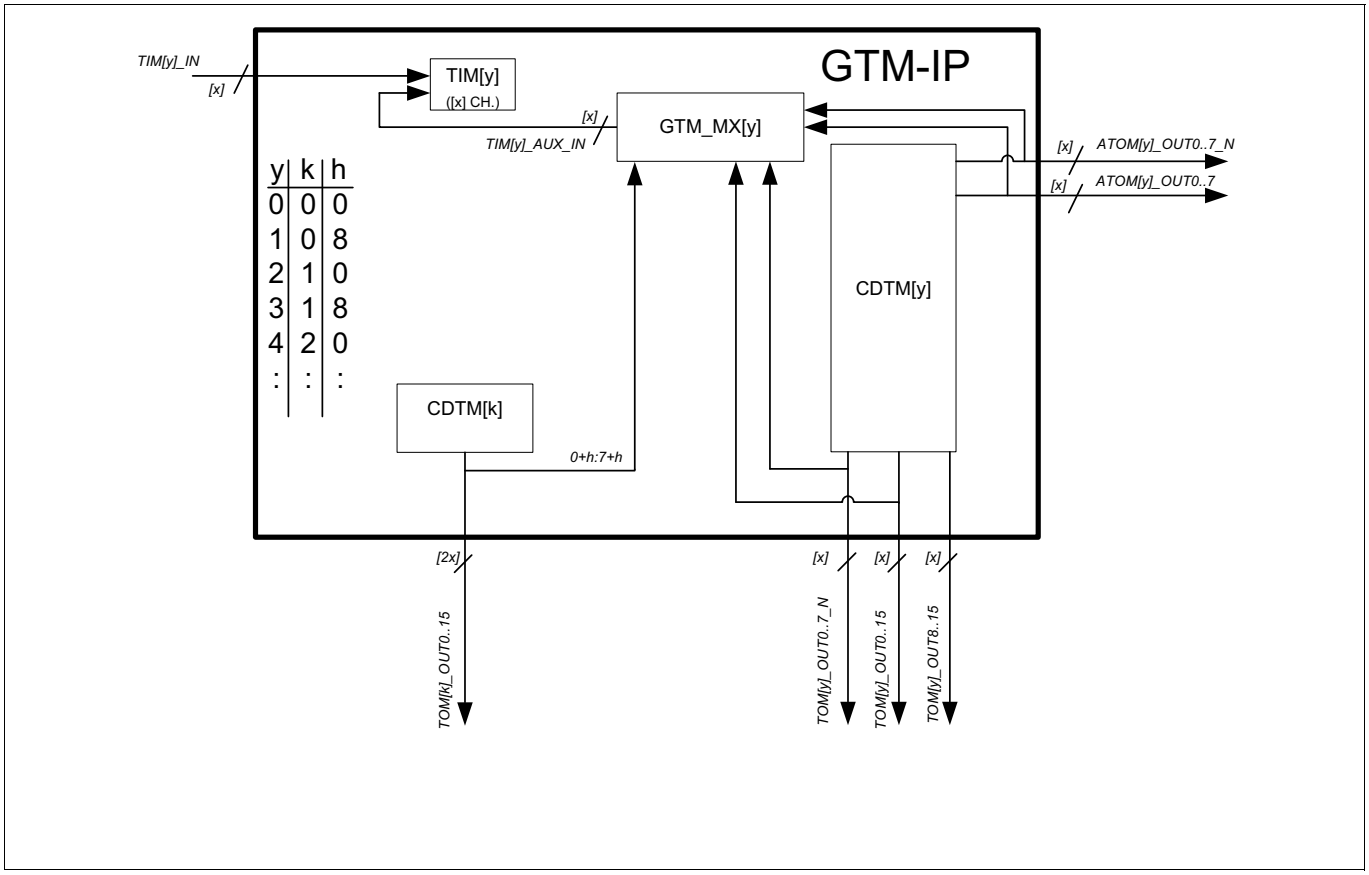

Figure 8 GTM signal multiplex

The next diagram gives an overview of the connectivity for different configuration of GTM global bit **SRC_IN_MUX** of register **GTM_CFG** and the cluster configuration register **CCM[y]_TIM_AUX_IN_SRC**. The source selection is defined per channel with the bit **SRC_CH[x]** and **SEL_OUT_N_CH[x]** in the register **CCM[y]_TIM_AUX_IN_SRC**.

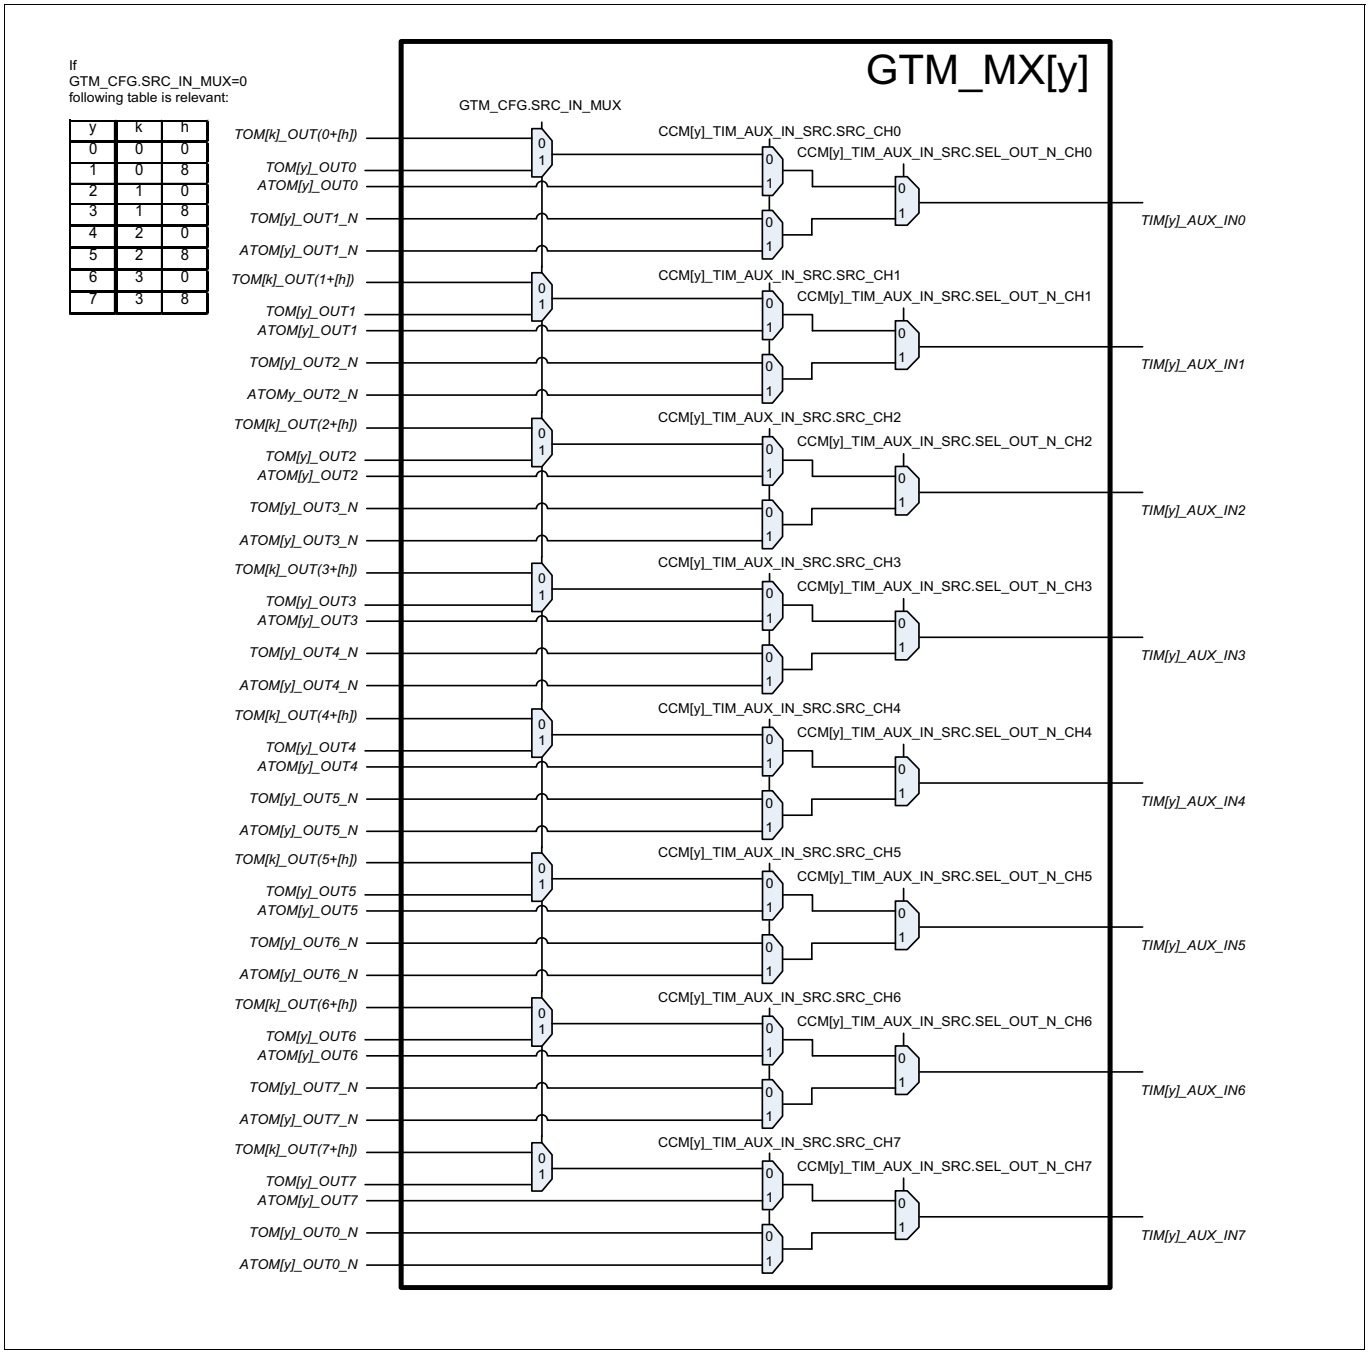

Figure 9 TIM auxiliary input multiplexing

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are routed to ATOM instance [i] and TOM instance [i] with i=0…cITIM-1 (cITIM defines the number of available TIM instances, please refer to device specific device specific appendix).This TIM trigger can be used to trigger inside the ATOM or TOM instance either a channel or the global control register of AGC or TGC0/TGC1 unit.

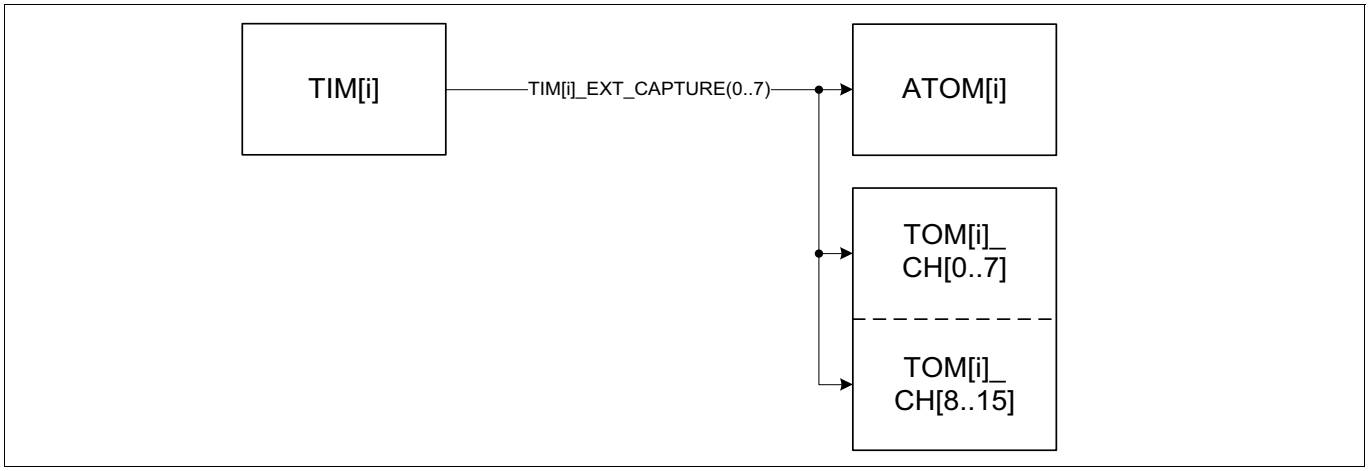

Figure 10 TIM external capture forwarding to TOM and ATOM

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are additionally routed to the MCS instance [i]. This trigger forwarding can be enabled by register CCM[i]_EXT_CAP_EN.

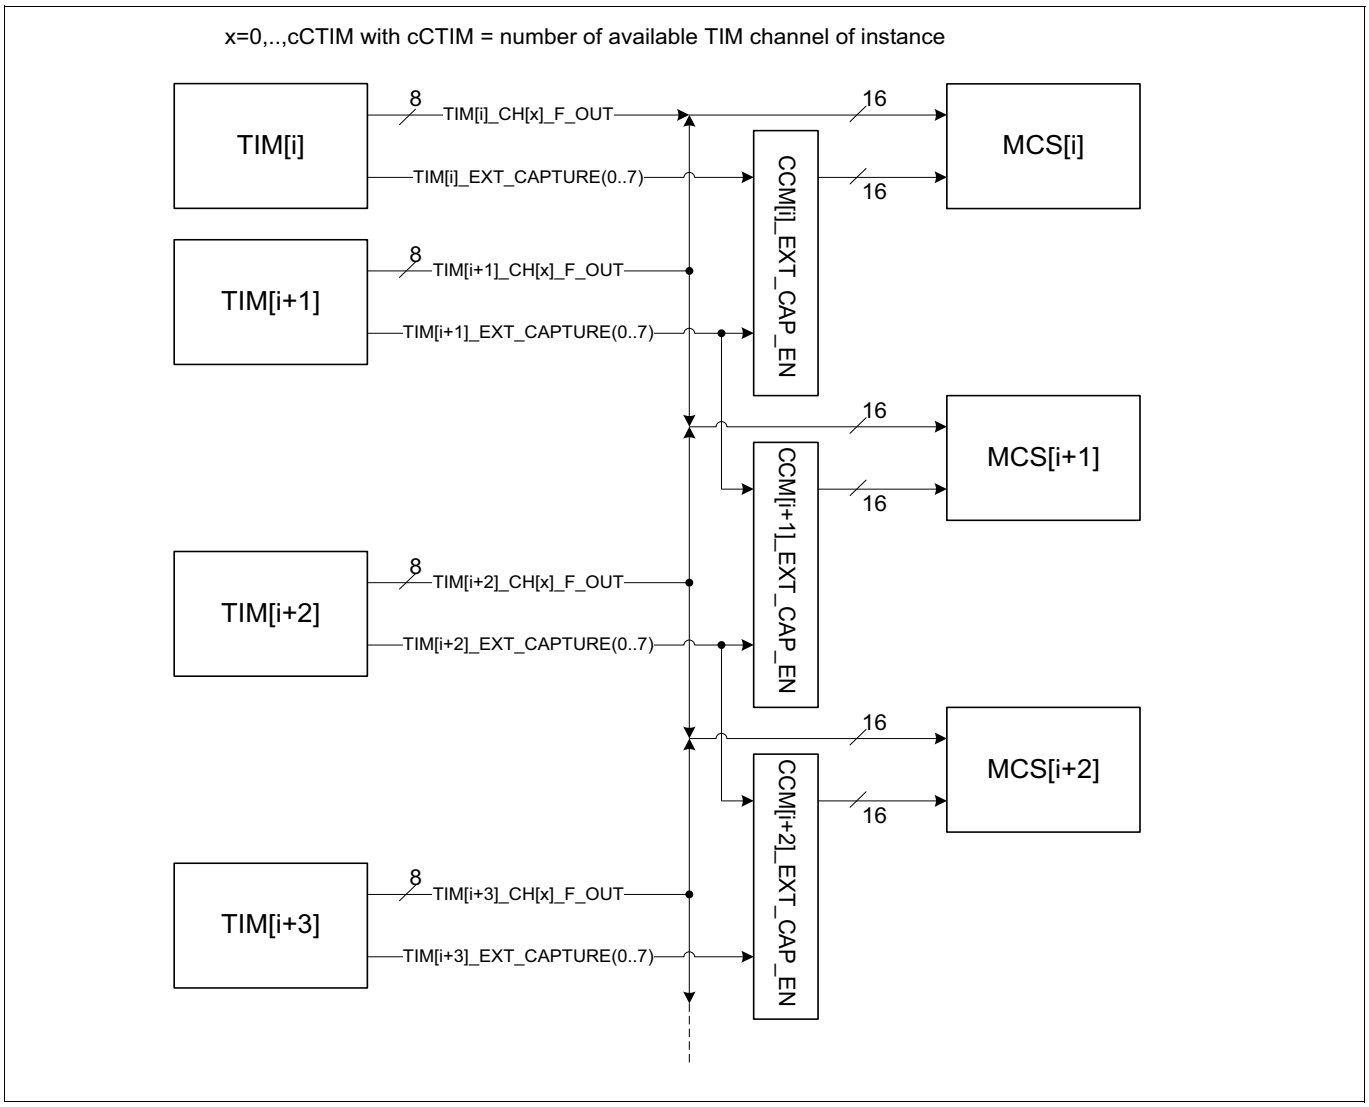

Figure 11 TIM to MCS signal forwarding

28.4.2 GTM Interfaces

In general the GTM can be divided into four interface groups. Two interface groups represent the ports of the GTM where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM input sub-module TIM and to the GTM output sub-modules DTM.

Another interface is the bus interface where the GTM can be connected to the SoC system bus. This generic bus interface is described in more detail in **Section 28.4.2.1**. The last interface is the interrupt controller interface. The GTM provides several interrupt lines coming from the various sub-modules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated micro controller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **Section 28.4.5**.

28.4.2.1 GTM Generic Bus Interface (AEI)

The GTM is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is typically done with a bridge module translating the AEI signals to the SoC bus signals of the silicon vendor. The AEI bus signals are depicted in the following table:

Table 6 AEI bus signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM select line	1
AEI_ADDR	I	GTM address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive one of the following values:

Table 7 AEI Status Signal

AEI_STATUS	Description
0b00	No Error
0b01	Illegal Byte Addressing
0b10	Illegal Address Access
0b11	Unsupported Address

The signal value 0b00 is returned if no error occurred during AEI access.

The signal value 0b01 is returned if the bus address is not an integer multiple of 4 (byte addressing).

The signal value 0b11 is returned if the address is not handled in the GTM.

The signal value 0b10 is returned if the written register is a protected register (e.g. protected by bit RF_PROT) or if the register is temporarily not writable because of sub-module internal state or the clock of the relevant cluster is disabled.

In case of an illegal write access signaled by status 0b10 the register will not be modified.

Reading registers will never return status 0b10.

Note: Exception for register CMU_CLK_CTRL. In case of write access signalled by aei_status 0b10 the register will be modified each completely disabled bit.

The detailed list of register addresses with return status 0b10 can be found in the appendix.

28.4.2.2 GTM Multi-master and multitasking support

To support multi-master and multi-task access to the registers of the GTM a dedicated write-access scheme is used for critical control bits inside the IP that need such a mechanism. This can be for example a shared register where more than one channel can be controlled globally by one register write access. Such register bits are implemented inside the GTM with a double bit mechanism, where the writing of 0b00 and 0b11 has no effect on the register bit and where 0b01 sets the bit and 0b10 resets the bit. If the CPU wants to read the status of the bit it always gets a 0b00 if the bit is reset and it gets an 0b11 if the bit is set.

28.4.3 ARU Routing Concept

One central concept of the GTM is the routing mechanism of the ARU sub-module for data streams. Each data word transferred between the ARU and its connected sub-module is 53 bit wide. It is important to understand this concept in order to use the resources of the GTM effectively. Each module that is connected to the ARU may provide an arbitrary number of ARU write channels and an arbitrary number of ARU read channels. In the following, the ARU write channels are named data sources and the ARU read channels are named data destinations.

The concept of the ARU intends to provide a flexible and resource efficient way for connecting any data source to an arbitrary data destination. In order to save resource costs, the ARU does not implement a switch matrix, but it implements a data router with serialized connectivity providing the same interconnection flexibility. **Figure 12** shows the ARU data routing principle. Data sources are marked with a green rectangle and the data destinations are marked with yellow rectangles. The dashed lines in the ARU depict the configurable connections between data sources and data destinations. A connection between a data source and a data destination is also called a data stream.

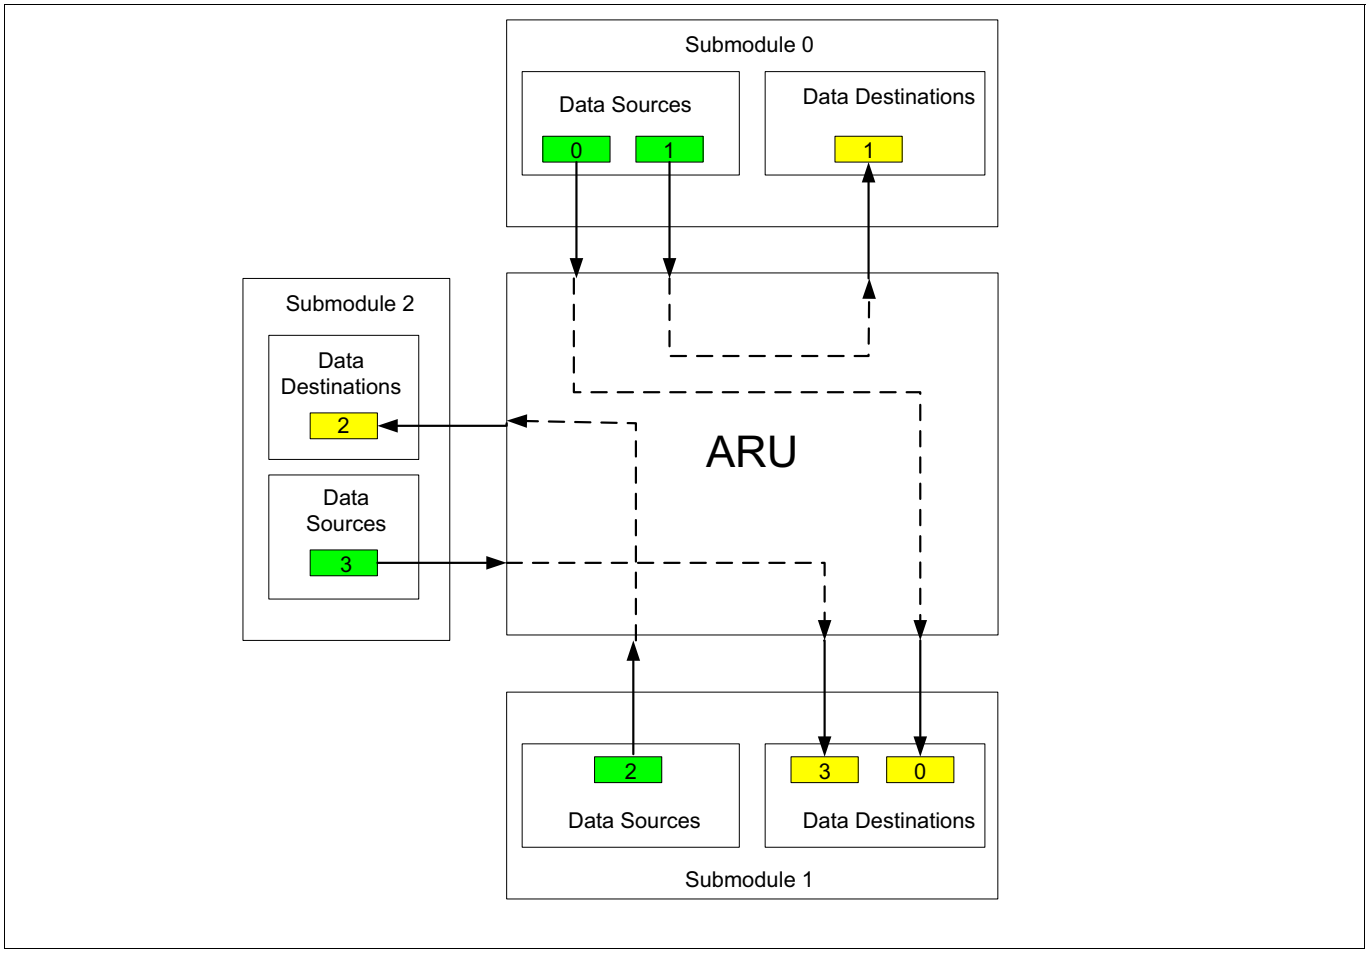

Figure 12 Principle of data routing using ARU

The configuration of the data streams is realized according to the following manner: Each data source has its fixed and unique source address: The ARU read ID.The fixed address of each data source is pointed out by the numbers in the green boxes of **Figure 12**. The address definitions of all available data sources in the GTM can be obtained from the product specific appendix. The connection from a specific data source to a specific data destination is defined by configuring the corresponding address of a data source (i.e. the ARU read ID) in the desired data destination. The configured address of each data destination is pointed out by the numbers in the yellow boxes of **Figure 12**.

Normally, the destination is idle and waits for data from the source. If the source offers new data, the destination does a destructive read, processes the data and goes idle again. The same data is never read twice.

There is one sub-module for which this destructive read access does not hold. This is the BRC sub-module configured in Maximum Throughput Mode (MTM). For a detailed description of this module please refer to chapter “Broadcast Module (BRC)”.

The functionality of the ARU is as follows: The ARU sequentially polls the data destinations of the connected modules in a round-robin order. If a data destination requests new data from its configured data source and the data source has data available, the ARU delivers the data to the destination and it informs both, the data source and destination that the data is transferred. The data source marks the delivered ARU data as invalid which means that the destination consumed the data.

It should be noted that each data source should only be connected to a single data destination. This is because the destinations consume the data. If two destinations would reference the same source one destination would consume the data before the other destination could consume it. Since the data transfers are blocking, the second destination would block until it receives new data from the source. If a data source should be connected

to more than one data destination the sub-module Broadcast (BRC) has to be used. On the other hand, the transfer from a data source to the ARU is also blocking, which means that the source channel can only provide new data to the ARU when an old data word is consumed by a destination. In order to speed up the process of data transfers, the ARU handles two different data destinations in parallel.

Following table gives an overview about the number of data destinations and data sources of each GTM instance type.

Table 8 ARU source and destination address count per instance

Sub-module	Number of data sources per instance	Number of data destinations per instance
ARU	1	0
DPLL	24	24
TIM	8	0
MCS	24	8
BRC	22	12
TOM	0	0
ATOM	8	8
DTM	0	0
PSM	8	8
ICM	0	0
CMP	0	0
MON	0	0
CCM	0	0

28.4.3.1 ARU Round Trip Time

The ARU uses a round-robin arbitration scheme with a fixed round trip time for all connected data destinations. This means that the time between two adjacent read requests resulting from a data destination channel always takes the round trip time, independently if the read request succeeds or fails.

28.4.3.2 ARU Blocking Mechanism

Another important concept of the ARU is its blocking mechanism that is implemented for transferring data from a data source to a data destination. This mechanism is used by ARU connected sub-modules to synchronize the sub-modules to the routed data streams. **Figure 13** explains the blocking mechanism.

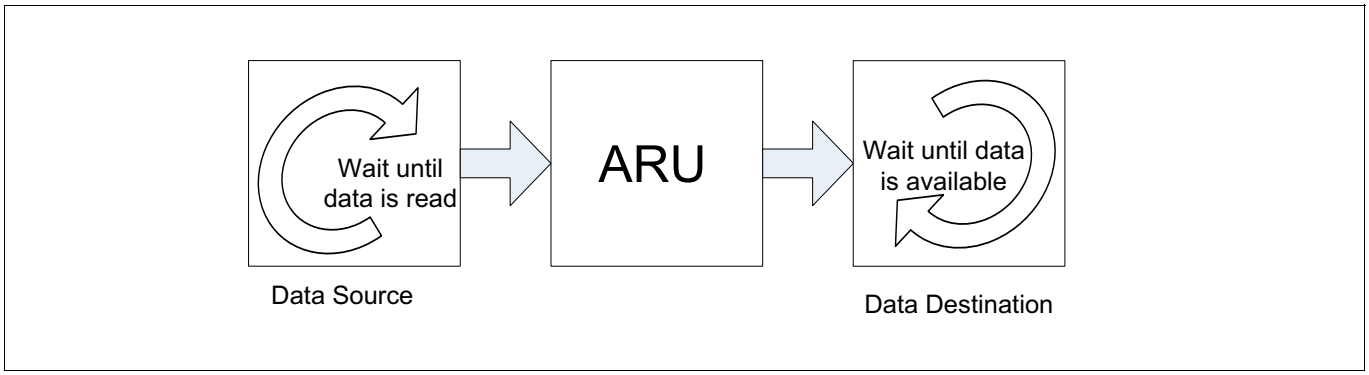

Figure 13 Graphical representation of ARU blocking mechanism

If a data destination requests data from a data source over the ARU but the data source does not have any data yet, it has to wait until the data source provides new data. In this case the sub-module that owns the data destination may perform other tasks. When a data source produces new data faster than a data destination can consume the data the source raises an error interrupt and signals that the data could not be delivered in time. The new data is marked as valid for further transfers and the old data is overwritten.

In any case the round trip time for the ARU has a fixed reset value for a specific device configuration. The end value of the round-trip counter can be changed with a configuration register **ARU_CADDR_END** inside the ARU. For more details see the ARU specific chapter.

It is possible to reset the ARU round-trip counter **ARU_CADDR** manually synchronous to CMU clock enable from configuration register inside CMU module. Please refer to CMU specific chapter for more details.

One exception is the BRC sub-module when configured in Maximal Throughput Mode. Please refer to Broadcast Module chapter for a detailed description.

28.4.4 GTM Clock and Time Base Management (CTBM)

Inside the GTM several sub-units are involved in the clock and time base management of the whole GTM. **Section 28.4.4.1** shows the connections and sub blocks involved in these tasks. The sub blocks involved are called Clock and Time Base Management (CTBM) modules further on.

28.4.4.1 GTM Clock and time base management architecture

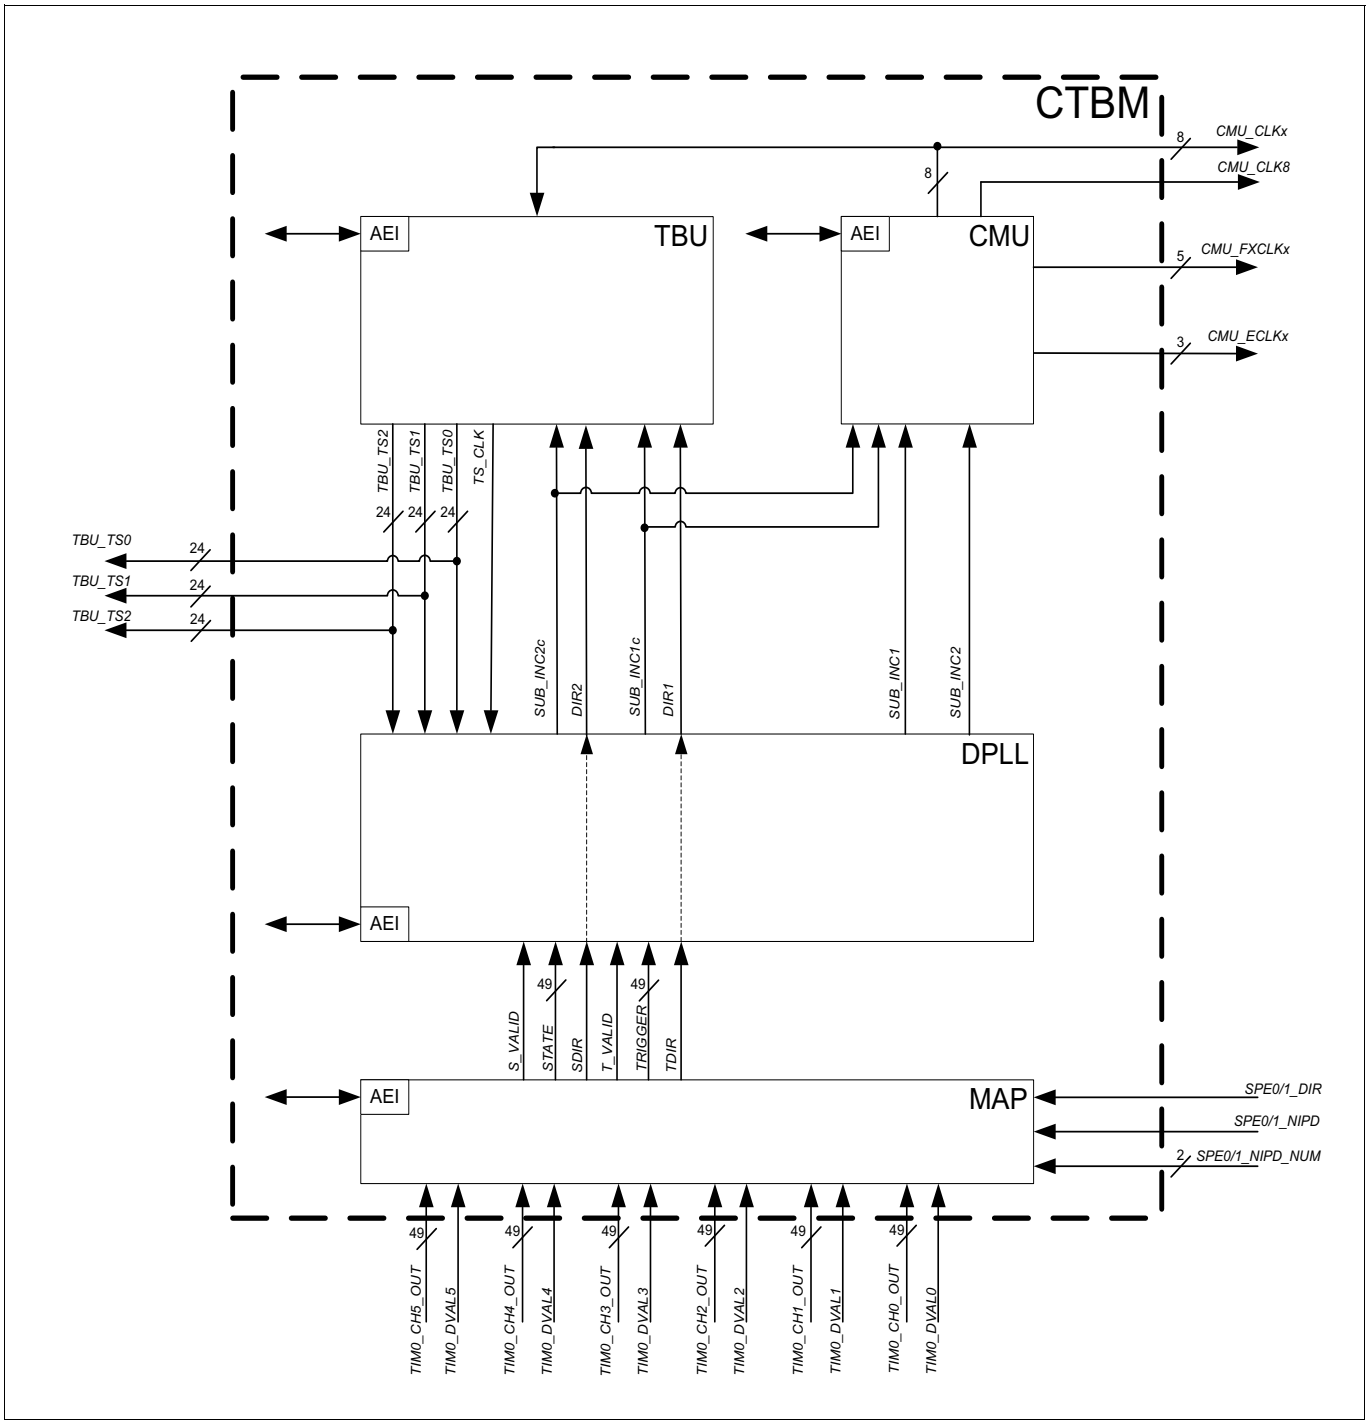

Figure 14 CTBM architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates up to 14 clocks for the sub-modules of the GTM and up to three GTM external clocks *CMU_ECLK[z]* (z: 0…2). For a detailed description of the CMU functionality and clocks please refer to Clock Management Unit chapter.

The five (5) *CMU_FXCLK[y]* (y: 0…4) clocks are used by the TOM sub-module for PWM generation.

A maximum of nine (9) *CMU_CLK[x]* (x: 0…8) clocks are used by other sub-modules of the GTM for signal generation.

Inside the Time Base Unit (TBU) one of *CMU_CLK[x]* (x: 0…7) clocks is used per channel to generate a common time base for the GTM. Besides the *CMU_CLK[x]* signals, the TBU can use the compensated *SUB_INC[i]c* (i: 1,2) signals coming from the DPLL sub-module for time base generation. This time base then typically represents an angle clock for an engine management system. For the meaning of compensated (*SUB_INC[i]c*) and uncompensated (*SUB_INC[i]*) DPLL signals please refer to the DPLL chapter. The *SUB_INC[i]c* signals in combination with the two direction signal lines *DIR[i]* the TBU time base can be controlled to run forwards or backwards. The TBU functionality is described in chapter “Time Base Unit (TBU)”.

The TBU sub-module generates the three time base signals *TBU_TS0*, *TBU_TS1* and *TBU_TS2* which are widely used inside the GTM as common time bases for signal characterization and generation.

Besides the time base 1 and 2 which may represent a relative angle clock for an engine management system it is helpful to have an absolute angle clock for CPU/MCS internal angle algorithm calculations. This absolute angle clock is represented by the TBU base 3. The TBU channel 0 up to 2 are widely used inside the GTM as common time (channel 0, 1 and/or 2) or angle (channel 1 and/or 2) bases for signal characterization and generation. The TBU channel 3 is only configurable and readable by MCS0 or CPU.

As stated before, the DPLL sub-module provides the four clock signals *SUB_INC[i]* and *SUB_INC[i]c* which can be seen as a clock multiplier generated out of the two input signal vectors *TRIGGER* and *STATE* coming from the MAP sub-module. For a detailed description of the DPLL functionality please refer to chapter “Digital PLL Module (DPLL)”.

The MAP sub-module is used to select the *TRIGGER* and *STATE* signals for the DPLL out of six input signals coming from TIM0 sub-module. Besides this, the MAP sub-module is able to generate a *TDIR* (TRIGGER Direction) and *SDIR* (STATE Direction) signal for the DPLL and TBU coming from the SPE0 and SPE1 signal lines. The direction signals are generated out of a defined input pattern. For a detailed description of the MAP sub-module please refer to chapter “TIM0 Input Mapping Module (MAP)”.

28.4.4.2 Cyclic Event Compare

With the time base module (TBU) the GTM provides three counters, where the counter of TBU_CH0 represents a time and the counter TBU_CH1 and TBU_CH2 may represent a time (if clock source is CMU_CLK generated inside CMU) or an angle (if clock source is a DPLL sub_inc signal provided via CMU).

From application point of view it is necessary to divide the cyclic event counter representing time or angle into two parts, the past and the future.The border of past/future is a moving border depending on current time or angle value.The cyclic event counting and the moving border of past/future is depicted in the figure below.

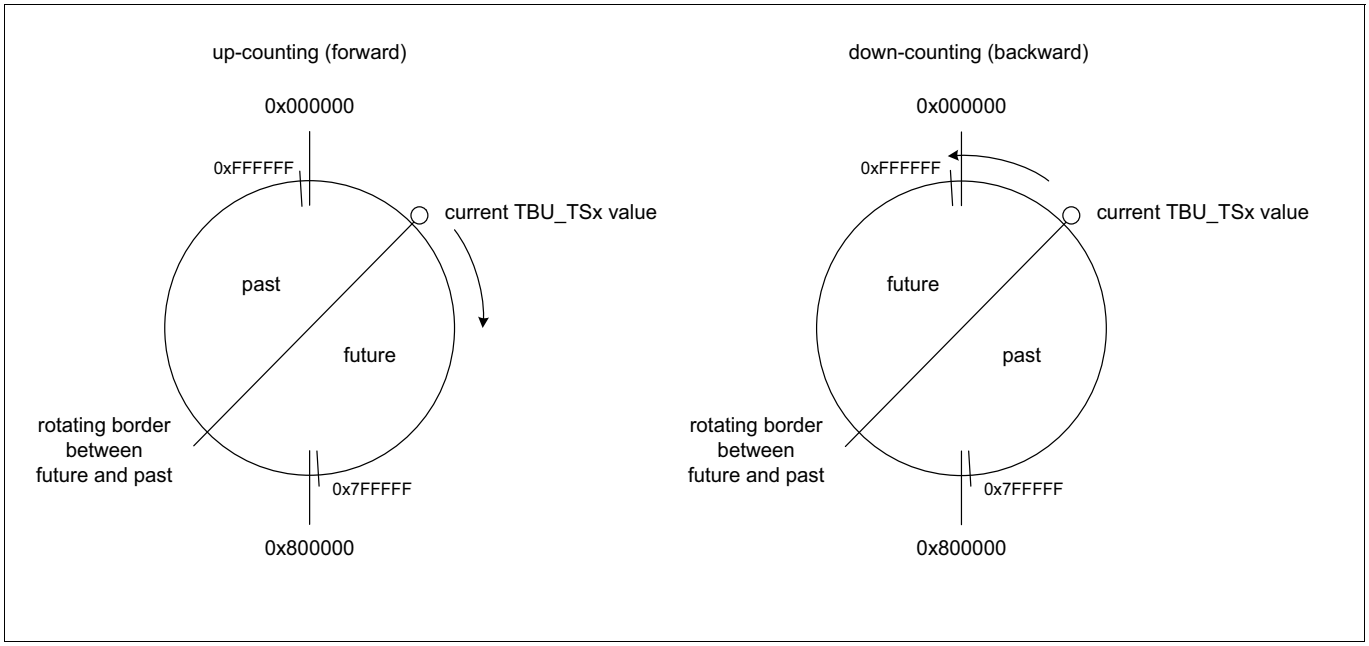

Figure 15 Cyclic event counter representing time or angle

Inside different submodules of GTM a grater-equal compare (in case of up-counting) or a less-equal compare (in case of down-counting) against a TBU base value (representing time or angle) always means that it is checked if the reference value is in relation to the current TBU value in the future or in the past.

28.4.5 GTM Interrupt Concept

The sub-modules of the GTM can generate thousands of interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In these interrupt groups the GTM sub-module interrupt signals are bundled to a smaller set of interrupts. From these interrupt sets, a smaller amount of interrupt signals is created and signaled outside of the GTM as a signal *GTM_<MOD>_IRQ,* where <MOD> identifies the name of the corresponding GTM sub-module.

Moreover, each output signal *GTM_<MOD>_IRQ* has a corresponding input signal *GTM_<MOD>_IRQ_CLR* that can be used for clearing the interrupts. These input signals can be used by the surrounding micro controller system as:

- acknowledge signal from a DMA controller
- validation signal from ADC
- clear signal from a GTM-external interrupt controller to do an atomic clear while entering an ISR routine

The controlling of the individual interrupts is done inside the sub-modules. If a sub-module consists of several sub-module channels that are most likely to work independent from each other (like TIM, PSM, MCS, TOM, and ATOM), each sub-module channel has its own interrupt control and status register set, named as interrupt set in the following. Other sub-modules (SPE, ARU, DPLL, BRC, CMP and global GTM functionality) have a common interrupt set for the whole sub-module.

The interrupt set consists of four registers: The **IRQ_EN** register, the **IRQ_NOTIFY** register, the **IRQ_FORCINT** register, and the **IRQ_MODE** register. While the registers **IRQ_EN**, **IRQ_NOTIFY,** and **IRQ_FORCINT** signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register **IRQ_MODE** configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of micro controller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

- Level mode,

- Pulse mode,
- Pulse-Notify mode,
- Single-Pulse mode.

These interrupt modes are described in more details in the following subsections.

The register **IRQ_EN** allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal *GTM_<MOD>_IRQ*.

The register **IRQ_NOTIFY** collects the occurrence of interrupt events. The behavior for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write access with value '1' to a bit in the register **IRQ_NOTIFY** always clears the corresponding **IRQ_NOTIFY** bit.

Moreover, the enabling of a disabled interrupt source with a write access to the register **IRQ_EN** also clears the corresponding bit in the **IRQ_NOTIFY** register but only if the error interrupt source **EIRQ_EN** is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register **IRQ_NOTIFY** is not cleared.

Additionally, each write access to the register **IRQ_MODE**, clears all bits in the **IRQ_NOTIFY** register. It should be notified that the clearing of **IRQ_NOTIFY** is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register **IRQ_EN**, define the new interrupt mode by writing register **IRQ_MODE**, followed by enabling the desired interrupts with the register **IRQ_EN**.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register **EIRQ_EN**, define the new interrupt mode by writing register **IRQ_MODE**, followed by enabling the desired error interrupts with the register **EIRQ_EN**.

The register **IRQ_FORCINT** is used by software for triggering individual interrupts with a write access with value '1'. Since a write access to **IRQ_FORCINT** only generates a single pulse, **IRQ_FORCINT** is not implemented as a true register and thus any read access to **IRQ_FORCINT** always results with a value of '0'.

The mechanism for triggering interrupts with **IRQ_FORCINT** is globally disabled after reset. It has to be explicitly enabled by clearing the bit **RF_PROT** in the register **GTM_CTRL** (see **Chapter 28.4.9.3**)

For the modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE and CMP each interrupt may configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register **EIRQ_EN**.It is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because both interrupt clear signals could reset the notify bit this is expected to cause problems in a system and therefore it is strongly recommended to not enable both interrupt types at the same point in time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register **EIRQ_EN** also clears the corresponding bit in the **IRQ_NOTIFY** register only if the interrupt source **IRQ_EN** is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register **IRQ_NOTIFY** is not cleared.

All enabled error interrupts are OR-combined inside the ICM and assigned to the dedicated GTM port *gtm_err_irq*. A corresponding input *gtm_err_irq_clr* allows the reset of this error interrupt from outside the GTM (hardware clear).

To be able to detect the module source of the error interrupt the ICM provides the register **ICM_IRQG_MEI**.

The error interrupt causing channel can be determined for the module FIFO by evaluating the ICM register **ICM_IRQG_CEI0**.

The error interrupt causing channel can be determined for the modules TIM by evaluating the ICM register **ICM_IRQG_CEI1...2**.

The error interrupt causing channel can be determined for the modules MCS with all possible channel by evaluating the ICM register **ICM_IRQG_MCS[i]_CEI**. In case of usage only the first 8 channels of each MCS the error interrupt causing channel can be determined by evaluating the ICM register **ICM_IRQG_CEI3...4**.

28.4.5.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register **IRQ_NOTIFY**, independent of the corresponding enable bit of register **IRQ_EN** and **EIRQ_EN**.

An interrupt event, which is defined as a pulse on the signal *Int_out* of **Figure 16**, may be triggered by the interrupt source of the sub-module or by software performing a write access to the corresponding register **IRQ_FORCINT**, with a disabled bit **RF_PROT** in register **GTM_CTRL**.

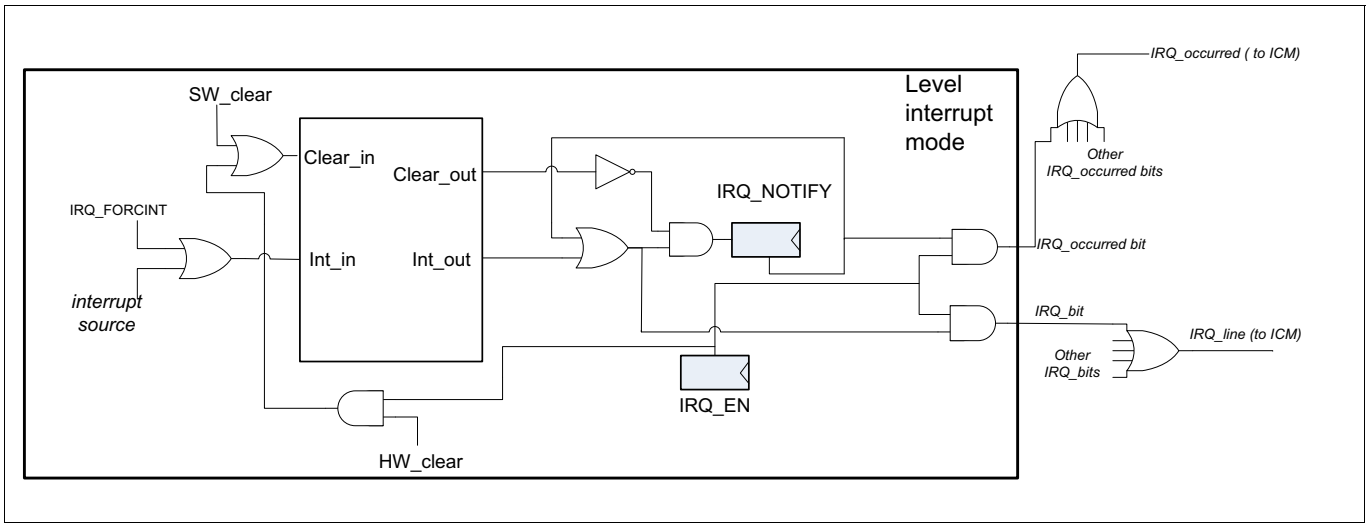

Figure 16 Level interrupt mode scheme

A collected interrupt bit in register **IRQ_NOTIFY** may be cleared by a clear event, which is defined as a pulse on signal *Clear_out* of **Figure 16**. A clear event can be performed by writing '1' to the corresponding bit in the register **IRQ_NOTIFY** leading to a pulse on signals *SW_clear*. A clear event may also result from an externally connected signal *GTM_<MOD>_IRQ_CLR*, which is routed to the signal *HW_clear* of **Figure 16**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register **IRQ_EN**.

As **Table 9** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 9 Priority of Interrupt Events and Clear Events

Int_in	Clear_in	Int_out	Clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

As shown in **Figure 16** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal *IRQ_bit*, if the corresponding interrupt is enabled in register **IRQ_EN**.

With exception of the sub-modules ARU and DPLL, the signal *IRQ_bit* is OR-combined with the neighboring *IRQ_bit* signals of the same interrupt set and they are routed as a signal *IRQ_line* to the interrupt concentrator module (ICM). The interrupt signals *IRQ_bit* of the sub-modules DPLL and ARU are routed directly as a signal *IRQ_line* to the sub-module ICM. In some cases (sub-modules TOM and ATOM) the ICM may further OR-combine

several *IRQ_line* signals to an outgoing interrupt signal *GTM_<MOD>_IRQ*. In the other cases the *IRQ_line* signals are directly connected to the outgoing signals *GTM_<MOD>_IRQ,* within the sub-module ICM.

The signal *IRQ_occurred* is connected in a similar way as the signal *IRQ_line*, however this signal is used for monitoring the interrupt state of the register **IRQ_NOTIFY** in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown below.

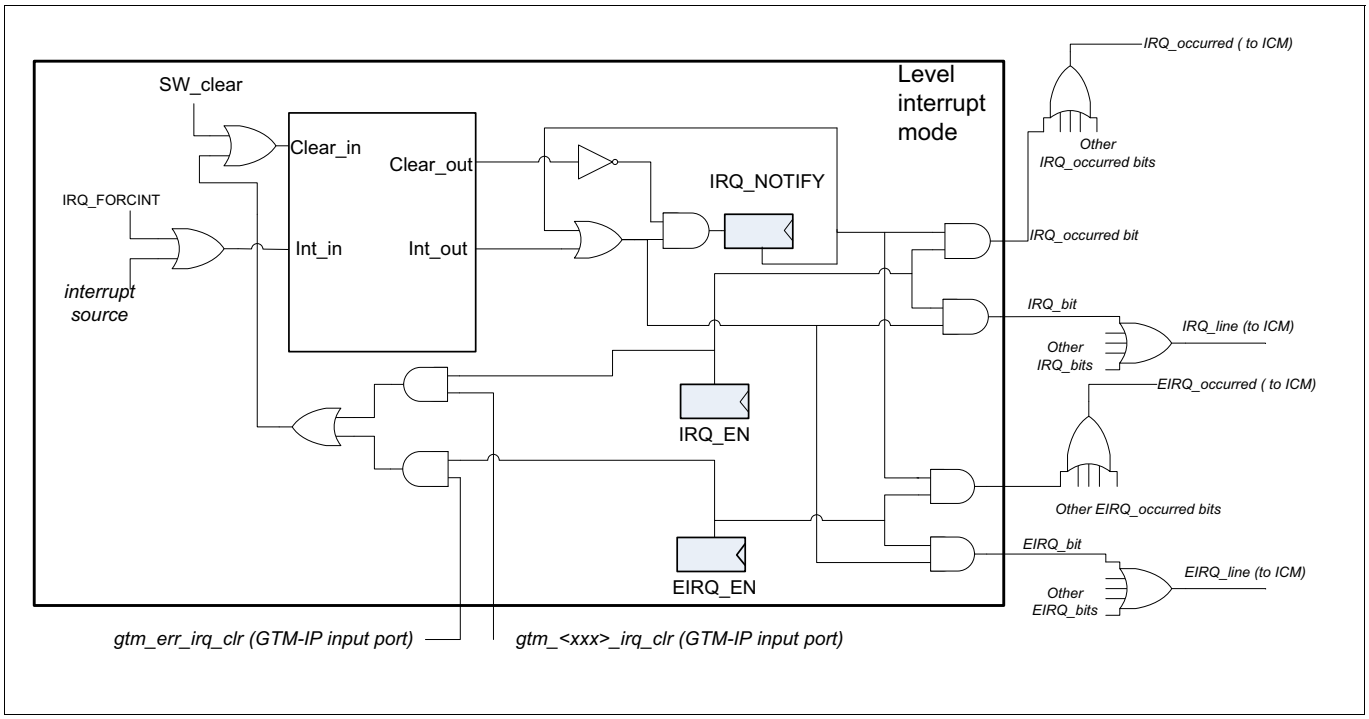

Figure 17 Level interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

A collected interrupt bit in register **IRQ_NOTIFY** may be cleared by a clear event, which is defined as a pulse on signal *Clear_out* of **Figure 17**. A clear event can be performed by writing '1' to the corresponding bit in the register **IRQ_NOTIFY** leading to a pulse on signals *SW_clear*. A clear event may also result from the externally connected signal *gtm_<MOD>_irq_clr* or *gtm_err_irq_clr*, which is routed as an *HW_clear* to *Clear_in* of **Figure 17**. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register **IRQ_EN** or **EIRQ_EN**.

As it can be seen from the **Figure 17** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal *IRQ_bit*, if the corresponding interrupt is enabled in register **IRQ_EN**.

28.4.5.2 Pulse interrupt mode

The Pulse interrupt mode behavior can be observed from **Figure 18**.

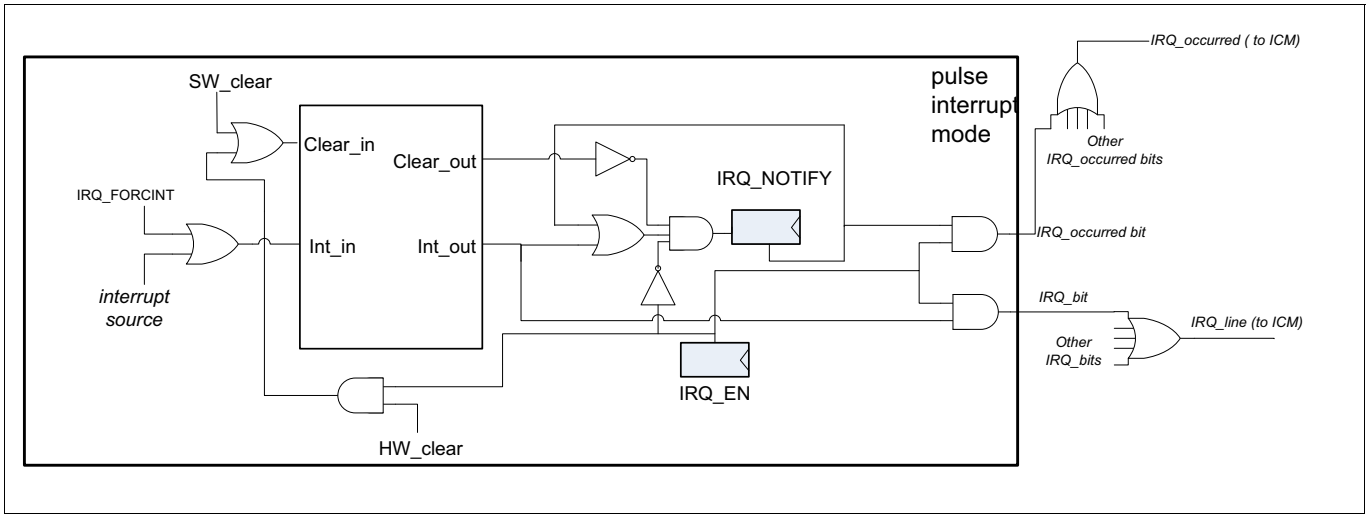

Figure 18 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the *IRQ_bit* signal if **IRQ_EN** is enabled.

As it can be seen from the figure, the interrupt bit in **IRQ_NOTIFY** register is always cleared if **IRQ_EN** is enabled.

However, if an interrupt is disabled in the register **IRQ_EN**, an occurred interrupt event is captured in the register **IRQ_NOTIFY**, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

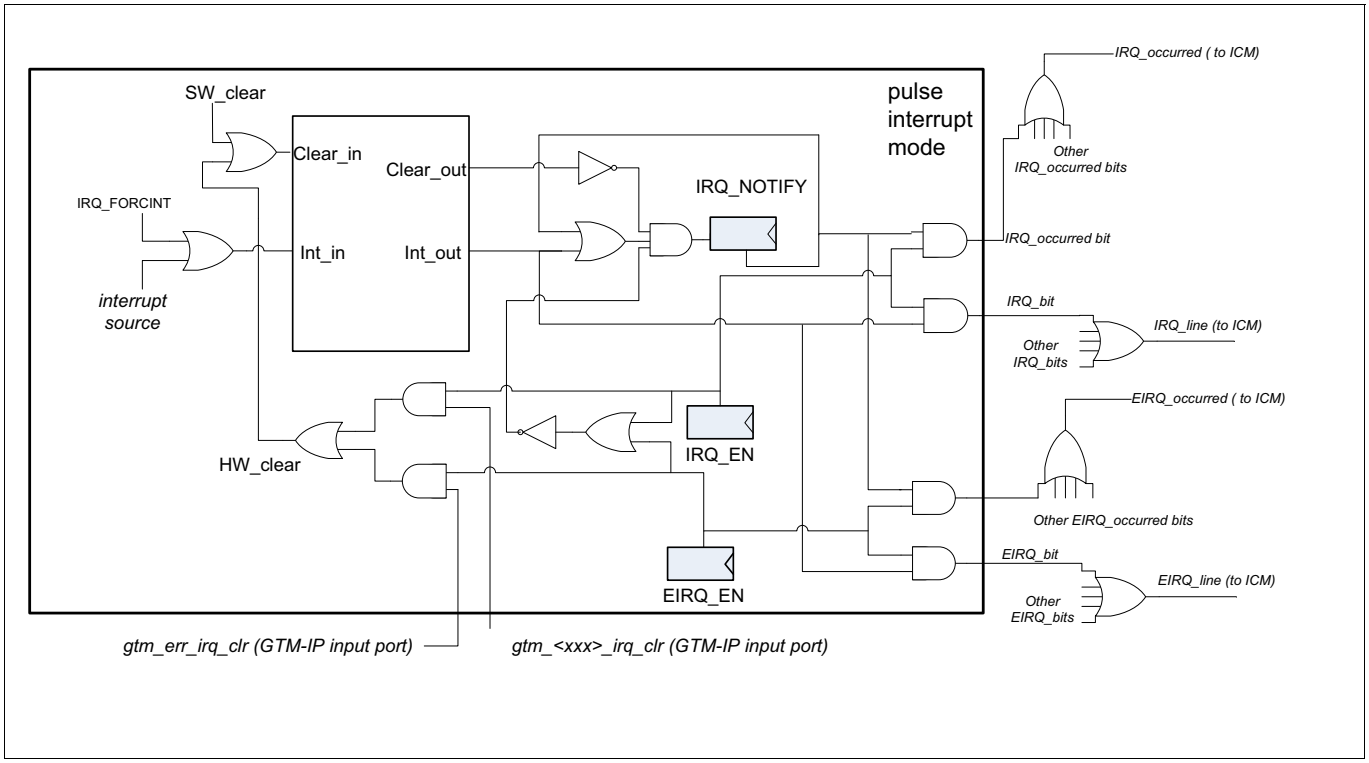

Figure 19 Pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the *EIRQ_bit* signal if **EIRQ_EN** is enabled.

As it can be seen from the figure, the interrupt bit in **IRQ_NOTIFY** register is always cleared if **EIRQ_EN** or **IRQ_EN** are enabled.

However, if an error interrupt is disabled in the register **EIRQ_EN**, an occurred error interrupt event is captured in the register **IRQ_NOTIFY**, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

28.4.5.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register **IRQ_NOTIFY**. If an interrupt is enabled by the register **IRQ_EN**, each interrupt event will also generate a pulse on the *IRQ_bit* signal. The signal *IRQ_occurred* will be high if interrupt is enabled in register **IRQ_EN** and the corresponding bit of register **IRQ_NOTIFY** is set. The Pulse-notify interrupt mode is shown in **Figure 20**.

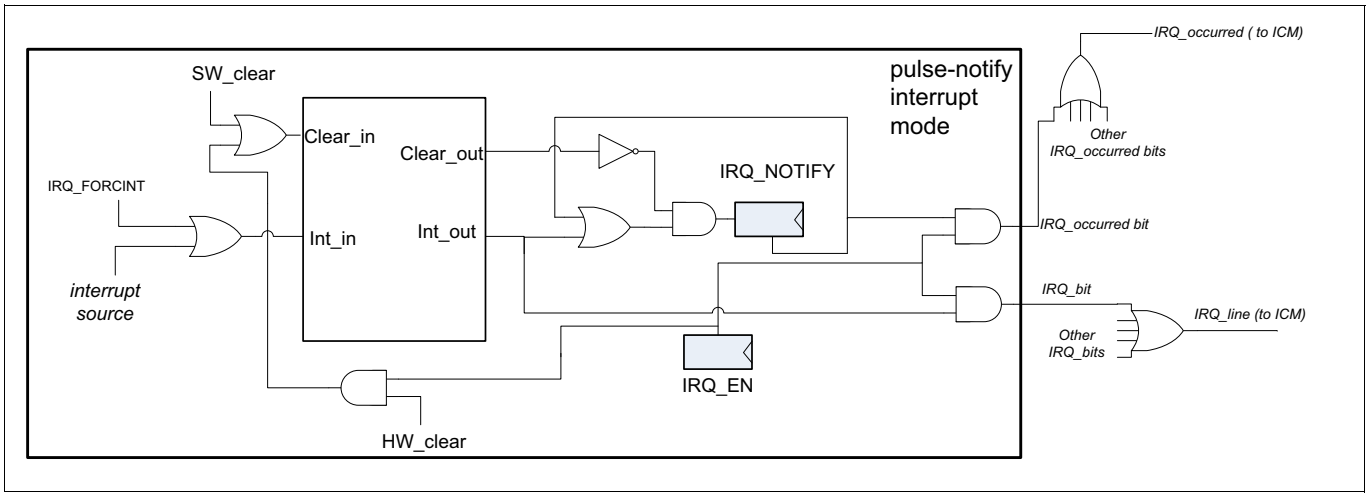

Figure 20 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

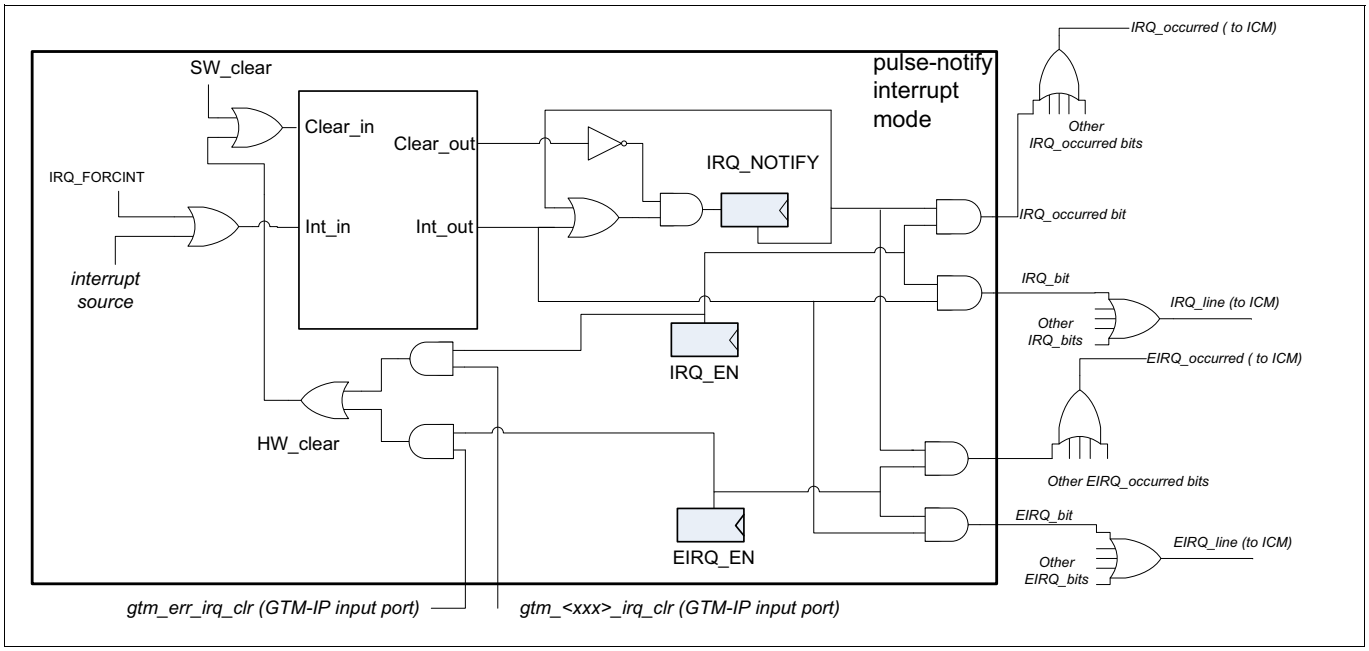

Figure 21 Pulse-notify interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register **IRQ_NOTIFY**. If an error interrupt is enabled by the register **EIRQ_EN**, each error interrupt event will also generate a pulse on the *EIRQ_bit* signal. The signal *EIRQ_occurred* will be high if error interrupt is enabled in register **EIRQ_EN** and the corresponding bit of register **IRQ_NOTIFY** is set. The Pulse-notify interrupt mode for error interrupts is shown in **Figure 21**.

28.4.5.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register **IRQ_NOTIFY**, independent of the state of **IRQ_EN**. However, only the first interrupt event of an enabled interrupt within a common interrupt set is forwarded to signal *IRQ_line.* Additional interrupt events of the same interrupt set cannot generate pulses on the signal *IRQ_line*, until the corresponding bits in register **IRQ_NOTIFY** of enabled interrupts are cleared by a clear event. The *IRQ_occurred* signal line will be high, if the **IRQ_EN** and the **IRQ_NOTIFY** register bits are set. The Single-pulse interrupt mode is shown in **Figure 22**.

The only exceptions are the modules ARU and DPLL. In these modules the *IRQ_occurred* bit of each interrupt is directly connected (without OR-conjunction of neighboring *IRQ_occurred* bits) to the inverter for suppressing further interrupt pulses.

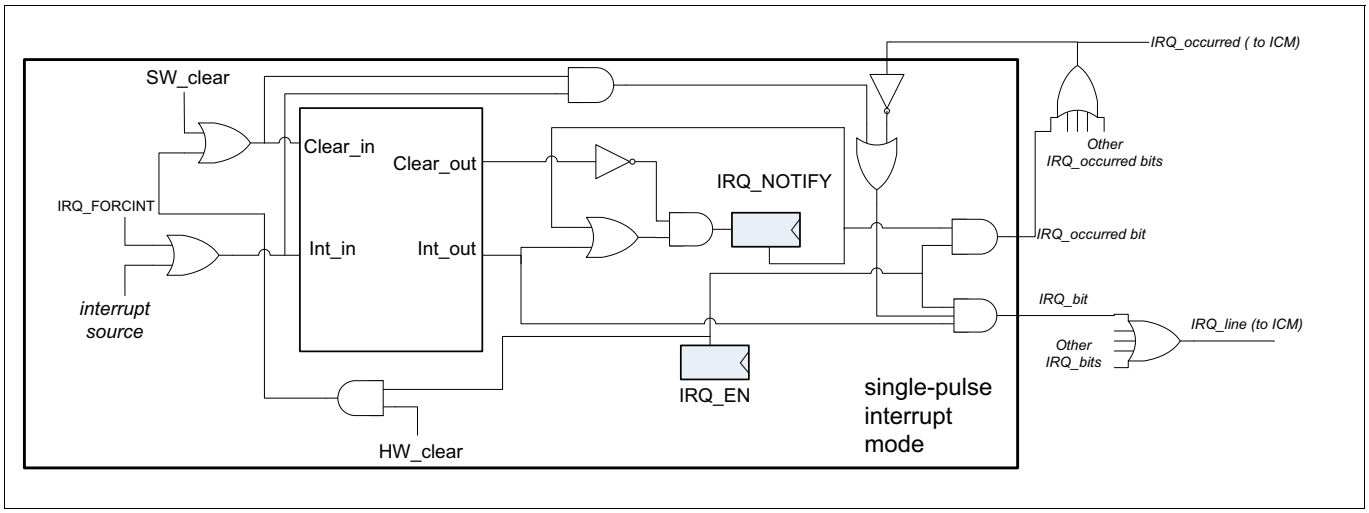

Figure 22 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behavior in the single pulse mode, all desired interrupt sources should be enabled by a single write access to **IRQ_EN** and the notification bits should be cleared by a single write access to the register **IRQ_NOTIFY**.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below.

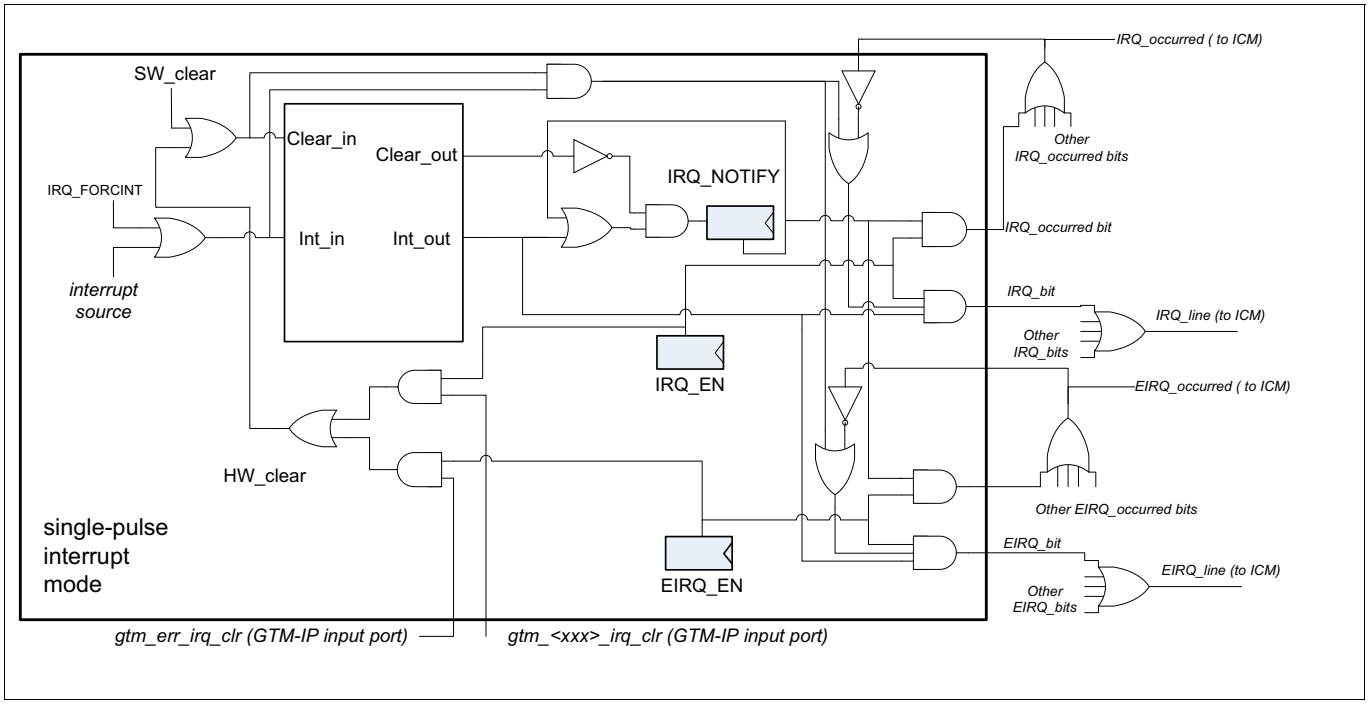

Figure 23 Single-pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register **IRQ_NOTIFY**, independent of the state of **EIRQ_EN**. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal *EIRQ_line.* Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal *EIRQ_line*, until the corresponding bits in register **IRQ_NOTIFY** of enabled error interrupts are cleared by a clear event. The *EIRQ_occurred* signal line will be high, if the **EIRQ_EN** and the **IRQ_NOTIFY** register bits are set. The Single-pulse interrupt mode for error interrupts is shown in **Figure 23**.

To avoid unexpected EIRQ behavior in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to **EIRQ_EN** and the notification bits should be cleared by a single write access to the register **IRQ_NOTIFY**.

The only exceptions are the modules ARU and DPLL. In these modules the *EIRQ_occurred* bit of each error interrupt is directly connected (without OR-conjunction of neighboring *EIRQ_occurred* bits) to the inverter for suppressing further error interrupt pulses.

28.4.5.5 GTM Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM sub-module first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register **IRQ_NOTIFY** is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register **IRQ_NOTIFY** afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM sub-module please refer to chapter “Interrupt Concentrator Module (ICM)”.

28.4.6 GTM Software Debugger Support

For software debugger support the GTM comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behavior to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

Table 10 describes the behavior of some GTM registers with special functionality on behalf of read accesses from the AEI bus interface.

Table 10 Register behavior in case of Software Debugger accesses

Module	Register	Description
AFD	AFD[i]_CH[x]_BUFFACC	The FIFO read access pointers are not altered on behalf of a Debugger read access to this register.
TIM	TIM[i]_CH[x]_GPR0/1	The overflow bit is not altered in case of a Debugger read access to this registers.
ATOM	ATOM[i]_CH[x]_SR0/1	In SOMC mode a read access to this register by the Debugger does not release the channel for a new compare/match event.

Further on, some important states inside the GTM sub-module have to be signaled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signaling please refer to the GTM module integration guide.

The GTM provides an external signal *gtm_halt*, which disables clock signal *SYS_CLK* for debugging purposes. If *SYS_CLK* is disabled, a connected debugger can read any GTM related register and the GTM internal RAMs using AEI. Moreover, the debugger can also perform write accesses to the internal RAMs and to all GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

28.4.7 GTM Programming conventions

To serve different application domains the GTM is a highly configurable module with many configuration modes. In principle the sub-modules of the GTM are intended to be configured at system startup to fulfill certain functionality for the application domain the micro controller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behavior.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM sub-modules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behavior of the GTM.

28.4.8 GTM TOP-Level Configuration Register Overview

Table 11 GTM TOP-Level Configuration Register Overview

Register name	Description	see Page
GTM_REV	GTM Version control register	30
GTM_RST	GTM Global reset register	31
GTM_CTRL	GTM Global control register	31
GTM_AEI_ADDR_XPT	GTM AEI Timeout exception address register	32
GTM_AEI_STA_XPT	GTM AEI Non zero status register	33
GTM_IRQ_NOTIFY	GTM Interrupt notification register	34
GTM_IRQ_EN	GTM Interrupt enable register	36
GTM_EIRQ_EN	GTM Error interrupt enable register	44

Table 11 GTM TOP-Level Configuration Register Overview (cont'd)

Register name	Description	see Page
GTM_IRQ_FORCINT	GTM Software interrupt generation register	37
GTM_IRQ_MODE	GTM top level interrupts mode selection	39
GTM_BRIDGE_MODE	GTM AEI bridge mode register	39
GTM_BRIDGE_PTR1	GTM AEI bridge pointer 1 register	41
GTM_BRIDGE_PTR2	GTM AEI bridge pointer 2 register	42
GTM_MCS_AEM_DIS	GTM MCS master port disable register	43
GTM_CLS_CLK_CFG	GTM Cluster Clock Configuration	45
GTM_CFG	GTM Configuration register	46

28.4.9 GTM TOP-Level Configuration Registers Description

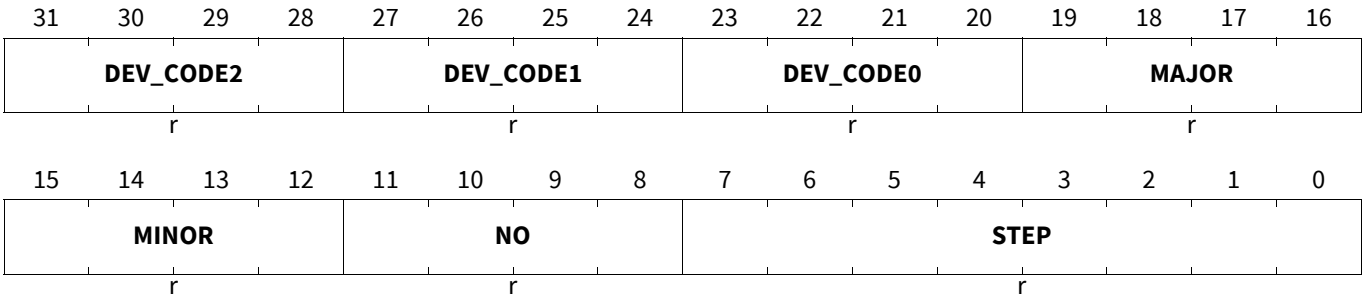
28.4.9.1 Register GTM_REV

Please keep in mind, that the actual Revision number is the reset value. This reset value is dependent on the delivery done by Bosch AE for the actual device. In case of Infineon's decision to change via metal fix for a different version, the reset value contains the initial version.

GTM Version Control Register

Note: The numbers are encoded in BCD. Values "A" - "F" are characters.

REV
GTM Version Control Register **(000000_H)** **Application Reset Value: $3153\ 15B6_H$**



Field	Bits	Type	Description
STEP	7:0	r	**Release step** GTM Release step
NO	11:8	r	**Delivery number** Define delivery number of GTM specification.
MINOR	15:12	r	**Minor version number** Define minor version number of GTM specification.
MAJOR	19:16	r	**Major version number** Define major version number of GTM specification.
DEV_CODE0	23:20	r	**Device encoding digit 0** Device encoding digit 0.
DEV_CODE1	27:24	r	**Device encoding digit 1** Device encoding digit 1.
DEV_CODE2	31:28	r	**Device encoding digit 2** Device encoding digit 2.

28.4.9.2 Register GTM_RST

GTM Global Reset Register

RST

GTM Global Reset Register **(000004$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				BRIDGE_MODE_WRDIS	0										
r				rw	r										

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															0
r															r

Field	Bits	Type	Description
BRIDGE_MODE_WRDIS	27	rw	**GTM_BRIDGE_MODE write disable** This bit is write protected by bit RF_PROT 0_B Writing of GTM_BRIDGE_MODE register is enabled 1_B Writing of GTM_BRIDGE_MODE register is disabled
0	0, 26:1, 31:28	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.3 Register GTM_CTRL

GTM Global Control Register

CTRL

GTM Global Control Register **(000008$_H$)** **Application Reset Value: 0000 0001$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AEIM_CLUSTER				0			TO_VAL					0		TO_MODE	RF_PROT
r				r			rw					r		rw	rw

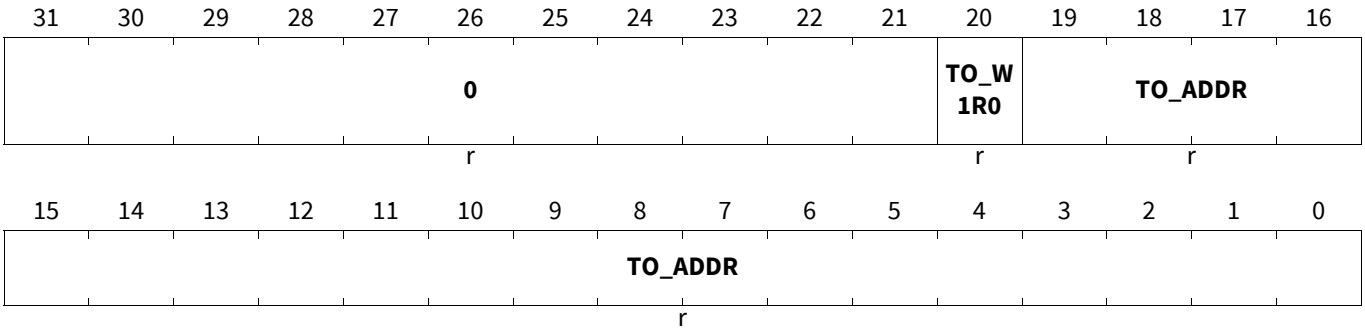
Field	Bits	Type	Description
RF_PROT	0	rw	**RST and FORCINT protection** 0_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled
TO_MODE	1	rw	**AEI timeout mode** 0_B Observe: If timeout_counter=0 the address and rw signal in addition with timeout flag will be stored to the GTM_AEI_ADDR_XPT register. Following timeout_counter=0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenable the storing of a next faulty access. 1_B Abort: In addition to observe mode, the pending access will be aborted by signaling an illegal module access on aei_status and sending ready. In case of a read, deliver as data 0 by serving of next AEI accesses.
TO_VAL	8:4	rw	**AEI timeout value** These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
AEIM_CLUSTER	15:12	r	**AEIM cluster number** These bits show the number of the AEI master port cluster which throws the interrupts *AEIM_USP_ADDR, AEIM_IM_ADDR* and *AEIM_USP_BE* depending on the AEI master port access status.Note: If one of the corresponding irq notify bits (6:4) is set, this bit field will be frozen until the interrupt notify bits (6:4) are cleared.
0	3:2, 11:9, 31:16	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.4 Register GTM_AEI_ADDR_XPT

GTM AEI Timeout Exception Address Register

AEI_ADDR_XPT

GTM AEI Timeout Exception Address Register (00000C$_H$) **Application Reset Value: 0000 0000$_H$**

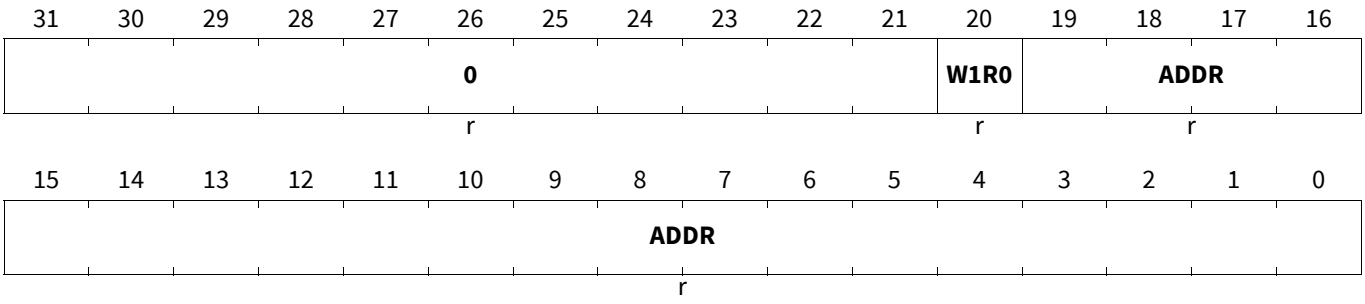


Field	Bits	Type	Description
TO_ADDR	19:0	r	**AEI timeout address** This bit field defines the AEI address for which the AEI timeout event occurred.
TO_W1R0	20	r	**AEI timeout Read/Write flag** This bit defines the AEI Read/Write flag for which the AEI timeout event occurred.
0	31:21	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.5 Register GTM_AEI_STA_XPT

GTM AEI Non Zero Status Register

AEI_STA_XPT
GTM AEI Non Zero Status Register **(00002C$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ADDR	19:0	r	**AEI exception address** This bit field captures the address of the first AEI access resulting with a non-zero AEI status signal. The bit field can be cleared by clearing the interrupt flags AEI_USP_ADDR,AEI_USP_BE, and AEI_IM_ADDR in the register GTM_IRQ_NOTIFY.
W1R0	20	r	**AEI exception Read/Write flag** This bit defines the AEI Read/Write flag for which the AEI non-zero event occurred. This bit field captures the address of the first AEI access resulting with a non-zero AEI status signal. The bit field can be cleared by clearing the interrupt flags AEI_USP_ADDR, AEI_USP_BE, and AEI_IM_ADDR in the register GTM_IRQ_NOTIFY.
0	31:21	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.6 Register GTM_IRQ_NOTIFY

GTM Interrupt Notification Register

IRQ_NOTIFY

GTM Interrupt Notification Register (000010$_H$) Application Reset Value: 0000 0000$_H$

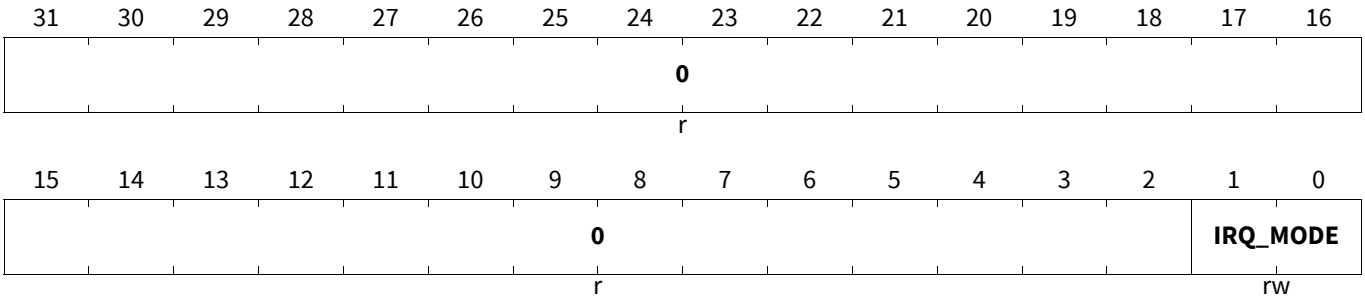
TRG_CLK_PER_ERR	8	rw	**Trigger CLK_PER_ERR_IRQ interrupt by software** This bit is cleared automatically after write. This bit is write protected by bit RF_PROT of **CTRL** Read as zero in case of INT_CLK_EN_GEN = 0b1. 0_B No interrupt triggering 1_B Assert CLK_PER_ERR_IRQ interrupt for one clock cycle
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.9 Register GTM_IRQ_MODE

GTM Top Level Interrupts Mode Selection Register

IRQ_MODE

GTM Top Level Interrupts Mode Selection Register(00001C$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
IRQ_MODE	1:0	rw	**Interrupt strategy mode selection for the AEI timeout and address monitoring interrupts** The interrupt modes are described in **Section 28.4.5**.Note: This mode selection is only valid for the six interrupts described in section **Register GTM_IRQ_NOTIFY** 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode
0	31:2	r	**Reserved** Read as zero, shall be written as zero.

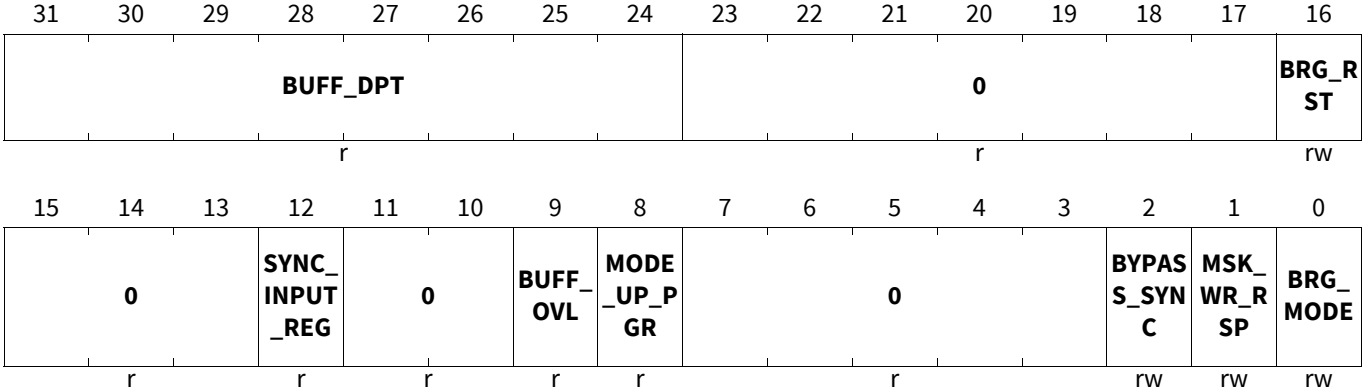
28.4.9.10 Register GTM_BRIDGE_MODE

GTM AEI Bridge Mode Register

Note: *All writable bits are write protected by bit BRIDGE_MODE_WRDIS*

BRIDGE_MODE

GTM AEI Bridge Mode Register **(000030$_H$)** **Application Reset Value: 0200 1001$_H$**



Field	Bits	Type	Description
BRG_MODE	0	rw	**Defines the operation mode for the AEI bridge** Reset value depends on the hardware configuration chosen by silicon vendor. BRG_MODE shall not be written with 0. 0_B AEI bridge operates in sync_bridge mode 1_B AEI bridge operates in async_bridge mode
MSK_WR_RSP	1	rw	**Mask write response** With active write buffer MSK_WR_RSP=1, execution of actions can be delayed due to previous inserted write actions in the transaction buffer which wait to be serviced. This can lead to the fact that an access on the bus to a different peripheral than the GTM might be executed earlier in time than the write access buffered in the GTM. Applications must be setup up with this in mind otherwise unexpected operation can happen. 0_B Do not mask the write response. Depending on the selected address the latency for execution can vary due to GTM internal arbitration. After this time the status of the access will be signaled by the signal AEI_STATUS to the bus interface. 1_B Mask write response. The write buffer of the bridge is activated, the actual access will be stored to the write buffer, and without latency on the bus interface; the acceptance of the access is signaled. AEI_STATUS=0b00 will be signaled. In case of a full write buffer, the actual access will be postponed until the next write buffer entry becomes free. Note: The status of the executed write accesses can be observed by using the notify bits AEI_USP_ADDR ,AEI_IM_ADDR, AEI_USP_BE in the register GTM_IRQ_NOTIFY.
BYPASS_SYNC	2	rw	**Bypass synchronizer flipflops** Function only available with BRG_MODE=1 0_B Synchronizer flip-flops in use, latency increase due to synchronization (aei_clk -> aei_sys_clk and back aei_sys_clk -> aei_clk). This setting must be used if aei_clk and aei_sys_clk operate fully asynchronous by independent clock sources. 1_B Synchronizer flip-flops are bypassed. No additional latency due to synchronization. This setting can be used if aei_clk and aei_sys_clk are generated by clock gating or clock division out of a common clock source. Clock edges on aei_clk and aei_sys_clk generated out of the same clock edge of the common clock source must have zero skew.
MODE_UP_PGR	8	r	**Mode update in progress** 0_B No update in progress 1_B Update in progress
BUFF_OVL	9	r	**Buffer overflow register** A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see GTM_BRIDGE_PTR1 register). 0_B No buffer overflow occurred 1_B Buffer overflow occurred

Field	Bits	Type	Description
SYNC_INPUT_REG	12	r	**Additional pipelined stage in synchronous bridge mode** Reset value depends on the hardware configuration chosen by silicon vendor. 0_B No additional pipelined stage implemented 1_B Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
BRG_RST	16	rw	**Bridge software reset** This bit is cleared automatically after write. 0_B No bridge reset request 1_B Bridge reset request
BUFF_DPT	31:24	r	**Buffer depth of AEI bridge** Signals the buffer depth of the GTM AEI bridge implementation. Reset value depends on the hardware configuration chosen by silicon vendor.
0	7:3, 11:10, 15:13, 23:17	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.11 Register GTM_BRIDGE_PTR1

GTM AEI Bridge Pointer 1 Register

Note: This register operates on the AEI_CLK domain.

Note: This register holds diagnosis information about the AEI bus bridge. Each access to the GTM_IP will update the defined pointer bit fields. Depending on the mode of GTM_MODE_BRIDGE (BRG_MODE, MSK_WR_RESP), the AEI protocol and operating frequency which is use, the 4 pointer bit fields will change at different clock cycles relative to the start of the transaction. This leads to the fact that reading the register can show values not equal to the defined Initial Value, even directly after a write to GTM_BRIDGE_MODE with BRG_RST=1 was done.

BRIDGE_PTR1
GTM AEI Bridge Pointer 1 Register **(000034_H)** **Application Reset Value: $0020\ 0000_H$**

r	r					r					r				

Field	Bits	Type	Description
NEW_TRAN_PTR	4:0	r	**New transaction pointer** Signals the actual value of the new transaction pointer.

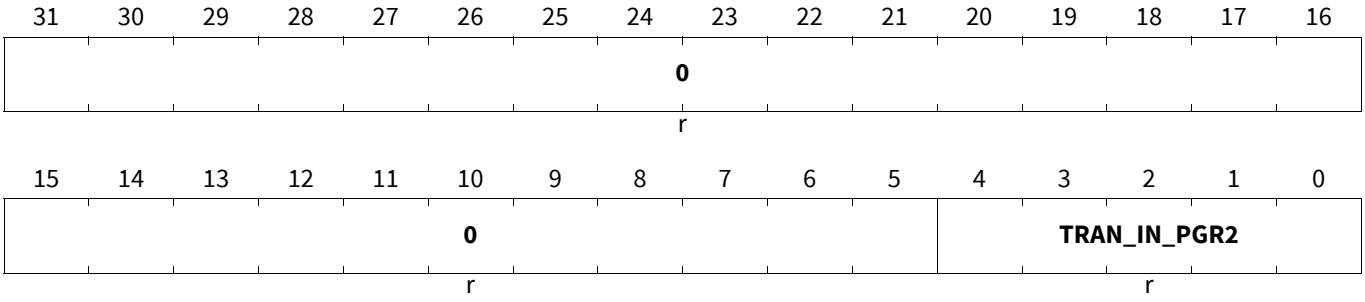
Field	Bits	Type	Description
FIRST_RSP_PTR	9:5	r	**First response pointer** Signals the actual value of first response pointer.
TRAN_IN_PGR	14:10	r	**Transaction in progress pointer (acquire)** Transaction in progress pointer.
ABT_TRAN_PGR	19:15	r	**Aborted transaction in progress pointer** Aborted transaction in progress pointer.
FBC	25:20	r	**Free buffer count** Number of free buffer entries. Initial value depends on the hardware configuration chosen by silicon vendor. (see BUFF_DPT in GTM_BRIDGE_MODE register).
RSP_TRAN_RDY	31:26	r	**Response transactions ready.** Amount of ready response transactions.

28.4.9.12 Register GTM_BRIDGE_PTR2

GTM AEI Bridge Pointer 2 Register

Note: This register operates on the GTM_CLK domain.

BRIDGE_PTR2
GTM AEI Bridge Pointer 2 Register **(000038_H)** **Application Reset Value: $0000\ 0000_H$**

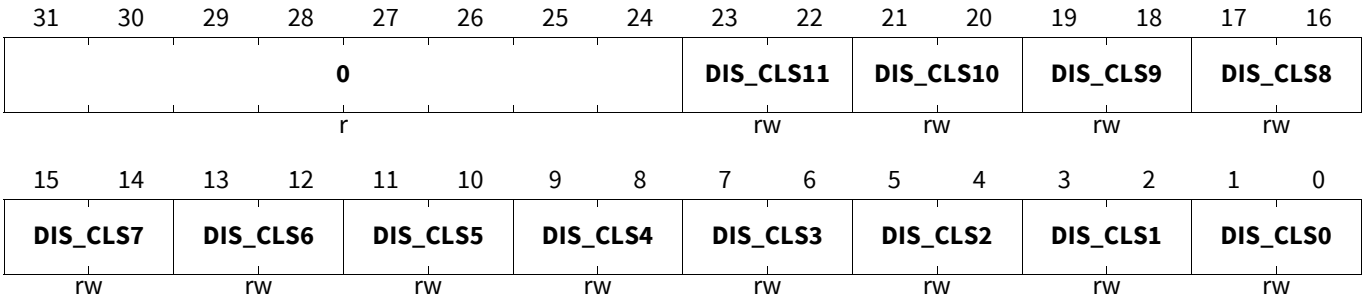


Field	Bits	Type	Description
TRAN_IN_PGR2	4:0	r	**Transaction in progress pointer (aquire2)** Transaction in progress pointer 2.
0	31:5	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.13 Register GTM_MCS_AEM_DIS

GTM MCS Master Port Disable Register

MCS_AEM_DIS
GTM MCS Master Port Disable Register (00003C$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
DIS_CLS0	1:0	rw	**Disable MCS AEIM access in cluster 0** Multicore encoding in use (**DIS_CLSx(1)** defines the state of the signal) Any read access to a **DIS_CLSx** bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored. 00_B State is 0; MCS AEM access in cluster x enabled (ignore write access) 01_B Change state to 0 10_B Change state to 1 11_B State is 1; MCS AEM access in cluster x disabled (ignore write access)
DIS_CLS1	3:2	rw	**Disable MCS AEIM access in cluster 1, see bit DIS_CLS0**
DIS_CLS2	5:4	rw	**Disable MCS AEIM access in cluster 2, see bit DIS_CLS0**
DIS_CLS3	7:6	rw	**Disable MCS AEIM access in cluster 3, see bit DIS_CLS0**
DIS_CLS4	9:8	rw	**Disable MCS AEIM access in cluster 4, see bit DIS_CLS0**
DIS_CLS5	11:10	rw	**Disable MCS AEIM access in cluster 5, see bit DIS_CLS0**
DIS_CLS6	13:12	rw	**Disable MCS AEIM access in cluster 6, see bit DIS_CLS0**
DIS_CLS7	15:14	rw	**Disable MCS AEIM access in cluster 7, see bit DIS_CLS0**
DIS_CLS8	17:16	rw	**Disable MCS AEIM access in cluster 8, see bit DIS_CLS0**
DIS_CLS9	19:18	rw	**Disable MCS AEIM access in cluster 9, see bit DIS_CLS0**
DIS_CLS10	21:20	rw	**Disable MCS AEIM access in cluster 10, see bit DIS_CLS0**
DIS_CLS11	23:22	rw	**Disable MCS AEIM access in cluster 11, see bit DIS_CLS0**
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.14 Register GTM_EIRQ_EN

Field	Bits	Type	Description
CLK_PER_ERR_EIRQ_EN	8	rw	**CLK_PER_ERR_EIRQ interrupt enable** Read as zero in case of INT_CLK_EN_GEN = 0b1. Read as zero, shall be written as zero. 0_B Disable error interrupt, interrupt is not visible outside GTM 1_B Enable error interrupt, interrupt is visible outside GTM
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.15 Register GTM_CLS_CLK_CFG

GTM Cluster Clock Configuration

Note: For clusters greater than 4 (only MAX 100 MHz capable), the allowed setting for the CLS_CLK_DIV are 00_B and 10_B (clock divider 2). For clusters < 5, 200 MHz is available. In case a device has a single 100 MHz cluster, the ARU will run with 100 MHz.

Note: Writing a value to a bit field CLS[c]_CLK_DIV that is not available in the device, an AEI status 10_B is returned.

Note: The availability of configuration bits is indicated by value of bit CFG_CLOCK_RATE in register CCM[c]_HW_CFG. If CFG_CLOCK_RATE=0, only the values 00_B and 01_B are valid for bit fields CLS[c]_CLK_DIV.

CLS_CLK_CFG
GTM Cluster Clock Configuration **($0000B0_H$)** **Application Reset Value: $00AA\ AAAA_H$**

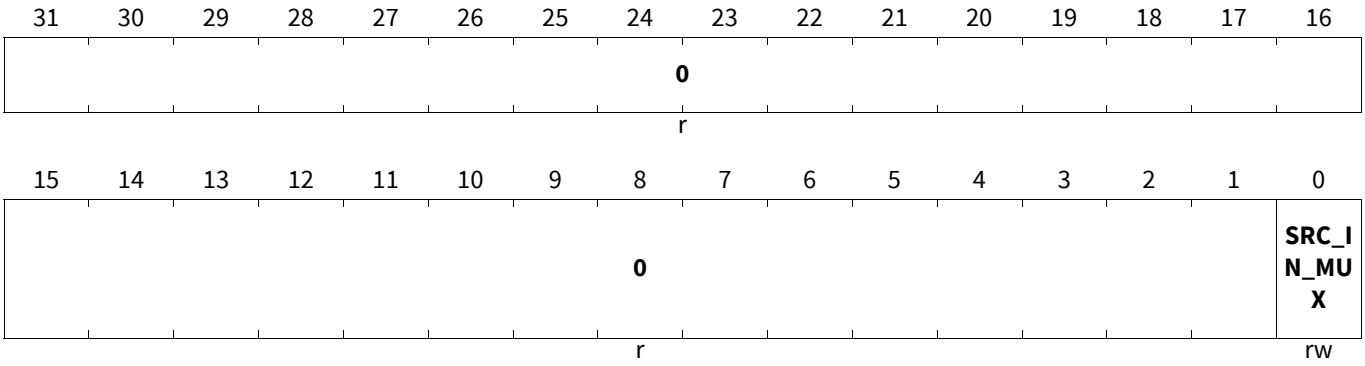
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.4.9.16 Register GTM_CFG

GTM Configuration Register

CFG

GTM Configuration Register **(000028_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SRC_IN_MUX	0	rw	**GTM_TIM[i]_AUX_IN input source selection** See **Figure 9** for details. 0_B Use for TIM[i] output of TOM[n] 1_B Use for TIM[i] output of TOM[i] (same cluster)
0	31:1	r	**Reserved** Read as zero, shall be written as zero.

28.5 Advanced Routing Unit (ARU)

28.5.1 Overview

The Advanced Routing Unit (ARU) is a flexible infrastructure component for transferring 53 bit wide data (five control bits and two 24 bit values) between several sub-modules of the GTM core in a configurable manner.

Since the concept of the ARU has already been described in the paragraph “ARU routing concept”, this section only describes additional ARU features that can be used by the software for configuring and debugging ARU related data streams.Also the definition of 'streams' and 'channels' in the ARU context is done in “ARU routing concept”.

The principle of ARU data routing is described in “ARU Write Address Overview”. In the real GTM implementation the ARU serves in parallel per clock period two individual data destinations, one destination at port ARU-0 and at port ARU-1. Both ARU ports ARU-0 and ARU-1 are running by default in parallel but can be configured in dynamic routing mode (see below) to run in an individual mode.

As already defined in the “ARU routing concept”, the ARU read ID is the address of the data source that is configured in the data destination module. These ARU read ID's are selected by the individual counter of ARU ports ARU-0 and ARU-1.

Via the ARU ports ARU-0 and ARU-1 with each ARU read ID two independent GTM sub-modules are addressed and served. The combination of ARU port (ARU-0 or ARU-1) and the ARU read ID addresses one ARU wdata source (i.e. the ARU write port of a GTM sub-module).

The assignment of ARU write ports of GTM sub-modules to the ARU ports ARU-0 and ARU-1 and the ARU read ID's is device depending and can be found in the corresponding sub-chapter.

28.5.2 Special Data Sources

Besides the addresses of the sub-module related data sources as described in product specific appendix, the ARU provides two special data sources that can be used for the configuration of data streams. These data sources are defined as follows:

Address 0x1FF: Data source that provides always a 53 bit data word with zeros. A read access to this memory location will never block a requesting data destination.

Address 0x1FE: Data source that never provides a data word. A read access to this memory location will always block a requesting data destination. This is the reset value of the read registers inside the data destinations.

Address 0x000: This address is reserved and can be used to bring data through the ARU registers **ARU_DATA_H** and **ARU_DATA_L** into the system by writing the write address 0x000 into the **ARU_ACCESS** register. This means that software test data can be brought into the GTM by the CPU.

28.5.3 ARU Access via AEI

Besides the data transfer between the connected sub-modules, there are two possibilities to access ARU data via the AEI.

28.5.3.1 Default ARU Access

The default ARU access incorporates the registers **ARU_ACCESS**, which is used for initiation of a read or write request and the registers **ARU_DATA_H** and **ARU_DATA_L** that provide the ARU data word to be transferred.

The status of a read or write transfer can be determined by polling specific bits in register **ARU_ACCESS**. Furthermore the *acc_ack* bit in the interrupt notify register is set after the read or write access is performed to avoid data loss e.g. on access cancelation.

A pending read or write request may also be canceled by clearing the associated bit.

In the case of a read request, the AEI access behaves as a read request initiated by a data destination of a module. The read request is served by the ARU immediately when no other destination has a pending read request. This means, that an AEI read access does not take part in the scheduling of the destination channels and that the time between two consecutive read accesses is not limited by the round trip time.

On the other hand, the AEI access has the lowest priority behind the ARU scheduler that serves the destination channels. Thus, in worst case, the read request is served after one round trip of the ARU, when all destination channels would request data at the same point in time.

In the case of the write request, the ARU provides the write data at the address defined by the ADDR bit field inside the **ARU_ACCESS** register.

To avoid data loss, the reserved ARU address 0x0 has to be used to bring data into the system. Otherwise, in case the address specified inside the ADDR bit field is defined for another sub-module that acts as a source at the ARU data loss may occur and no deterministic behavior is guaranteed.

This is because the regular source sub-module is not aware that its address is used by the ARU itself to provide data to a destination.

It is guaranteed that the ARU write data is send to the destination in case of both modules want to provide data at the same time.

Configuring both read and write request bits results in a read request, if the write request bit inside the register isn't already set. The read request bit will be set but not the write request bit. The following table describes the important cases of the bit 12 (RREQ) and bit 13 (WREQ) of the **ARU_ACCESS** register:

Table 12 WREQ and RREQ in ARU_ACCESS register

AEI write access: aei_wdata (13:12)	actual value of ARU_ACCESS(13:12)	next value of ARU_ACCESS(13:12)	comment
0 0	0 1	0 0	cancel read request
0 0	1 0	0 0	cancel write request
0 1	1 0	1 0	unchanged register
1 0	0 1	0 1	unchanged register
1 1	0 0	0 1	both read and write request results in a read request
1 1	1 0	1 0	as before but WREQ bit is already set -> unchanged register

28.5.3.2 Debug Access

The debug access mode enables to inspect routed data of configured data streams during runtime.

The ARU provides two independent debug channels, whereas each is configured by a dedicated ARU read address in register **ARU_DBG_ACCESS0** and **ARU_DBG_ACCESS1** respectively.

The registers **ARU_DBG_DATA0_H** and **ARU_DBG_DATA0_L** (**ARU_DBG_DATA1_H** and **ARU_DBG_DATA1_L**) provide read access to the latest data word that the corresponding data source sent through the ARU.

Any time when data is transferred through the ARU from a data source to the destination requesting the data the interrupt signal *ARU_NEW_DATA0*_IRQ (*ARU_NEW_DATA1*_IRQ) is raised.

For advanced debugging purposes, the interrupt signal can also be triggered by software using the register **ARU_IRQ_FORCINT**.

Please note, that the debug mechanism should not be used by the application, when a HW-Debugger is used to trace the ARU communication. In that case, the debug registers are used by the HW-Debugger to specify the ARU streams that should be traced.

28.5.4 ARU dynamic routing

A dynamic routing feature of the ARU is implemented and can be configured using the additional AEI registers**:**,

- **ARU_CTRL**
- **ARU_[x]_DYN_CTRL**
- **ARU_[x]_DYN_RDADDR**
- **ARU_[x]_DYN_ROUTE_LOW**
- **ARU_[x]_DYN_ROUTE_HIGH**
- **ARU_[x]_DYN_ROUTE_SR_LOW**
- **ARU_[x]_DYN_ROUTE_SR_HIGH**

For further information see the register part of this chapter.

28.5.4.1 Dynamic routing - CPU controlled

The dynamic routing feature can be enabled separately for ARU-0 and ARU-1 by setting the corresponding bit fields of the register **ARU_CTRL**.

The enabling of the dynamic routing feature is synchronized to the normal routing scheme if ARU master ID-0 is addressed. The dynamic route will started with additional ARU master DYN_READ_ID0.

With the dynamic routing feature it is possible to insert additional ARU master ID's, DYN_READ_IDy (y:0-5), in a defined manner into the normal ARU routing scheme.

While inserting additional ARU master ID's the normal ARU routing scheme is paused. Therefore please consider that inserting additional ARU master ID's will lengthen the normal routing scheme.

It is possible to configure 6 additional ARU master ID's in the **ARU_[x]_DYN_ROUTE_LOW/_HIGH** registers for both ARU-0 and ARU-1.

In the bit field **DYN_CLK_WAIT** of **ARU_[x]_DYN_ROUTE_HIGH** register the number of clock cycles has to be configured, after which one of the additional ARU master ID's will be inserted.

After each configured number of clock cycles the defined ARU master ID's will be inserted cyclic one after each other in the following manner:
… -> DYN_READ_ID0 -> DYN_READ_ID1 -> DYN_READ_ID2 -> DYN_READ_ID3 -> DYN_READ_ID4 -> DYN_READ_ID5 -> DYN_READ_ID0 -> ….

In the shadow registers **ARU_[x]_DYN_ROUTE_SR_LOW/_HIGH** further 6 ARU master, DYN_READ_IDy (y:6-11), can be configured.

The bit DYN_UPDATE_EN in the **ARU_[x]_DYN_ROUTE_SR_HIGH** register controls whether the **ARU_[x]_DYN_ROUTE_LOW/_HIGH** registers are updated from its shadow registers except DYN_UPDATE_EN, it is not updated. The update is executed once after writing **ARU_[x]_DYN_ROUTE_SR_HIGH**. If update started DYN_UPDATE_EN is reset.

With the DYN_ROUTE_SWAP option in the **ARU_[x]_DYN_CTRL** register it is possible to swap the registers **ARU_[x]_DYN_ROUTE_LOW/HIGH** with its shadow registers **ARU_[x]_DYN_ROUTE_SR_LOW/HIGH**. The swapping is executed always after the 6 ARU master DYN_READ_ID's are inserted. So it is possible to insert a maximum of 12 ARU master DYN_READ_ID's cyclic after each configured number of clock cycles. If swap started DYN_UPDATE_EN is reset.

Setting the bit field **DYN_CLK_WAIT** of **ARU_[x]_DYN_ROUTE_HIGH** register to zero, only the defined ARU master DYN_READ_ID's will be executed. The normal ARU routing scheme is stopped.

Setting the bit field **DYN_CLK_WAIT** of **ARU_[x]_DYN_ROUTE_HIGH** register to 15, only the normal ARU routing scheme is executed. Inserting of additional ID's is stopped.

To reset the ARU caddr counter and ARU dynamic route counter set bit ARU_ADDR_RSTGLB of **CMU_GLB_CTRL** following by a write access to register **CMU_CLK_EN**.

28.5.4.1.1 Dynamic routing ring mode

In dynamic routing ring mode it is possible to use all 24 DYN_READ_ID's from both ARU-0 and ARU-1 by setting bit field ARU_DYN_RING_MODE in **ARU_CTRL** register to 1. In this mode all 4 registers **ARU_[x]_DYN_ROUTE_LOW/_HIGH** and **ARU_[x]_DYN_ROUTE_SR_LOW/_HIGH** are connected as a ring, so all 24 DYN_READ_ID's can be used from both ARU's. The ring structure is shown in **Figure 24**. The data register shift direction is shown by the arrows in the ring.

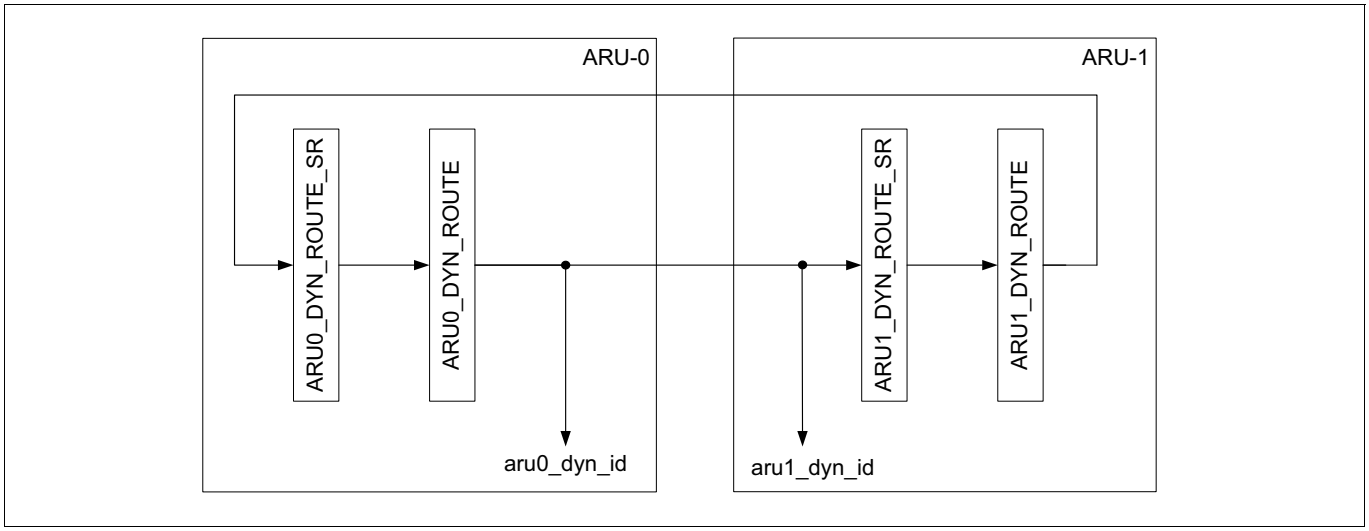


Figure 24 ARU dynamic routing - ring mode

Enabling the dynamic routing ring mode will automatically reset the caddr counter of both ARU-0 and ARU-1. This is necessary to synchronize both ARU's in this mode.

Enabling the dynamic routing ring mode will ignored DYN_ROUTE_SWAP and DYN_UPDATE_EN.

Note: DYN_ARU_UPDATE_EN should be disabled in dynamic routing ring mode.

It is possible to enable the dynamic routing ring mode for both ARU-0 and ARU-1 or only for one of the ARU's by setting the corresponding bit field ARU_0_DYN_EN/ARU_1_DYN_EN of the register **ARU_CTRL.**

Because of the fact that to each ARU port ARU-0 and ARU-1 with the same ARU read ID two different GTM sub-modules are served it may make sense to enable ARU dynamic routing only for one port ARU-0 or ARU-1 if configured to ring-mode. The other port is then served in the default round robin manner.

In dynamic routing ring mode **ARU_[x]_DYN_ROUTE_LOW/_HIGH** and **ARU_[x]_DYN_ROUTE_SR_LOW/_HIGH** are not write-protected. NOTE: Avoid modification of **ARU_[x]_DYN_ROUTE_LOW/_HIGH** and **ARU_[x]_DYN_ROUTE_SR_LOW/_HIGH** in active dynamic routing ring mode.

28.5.4.2 Dynamic routing - ARU controlled

Furthermore it is possible to reload the **ARU_[x]_DYN_ROUTE_SR_LOW/_HIGH** registers by ARU itself.

Therefore the ARU has its own master port which will be served in the normal ARU routing scheme. The ARU read address for this master port has to be configured in the register **ARU_[x]_DYN_RDADDR.**

This feature can be enabled by setting bit DYN_ARU_UPDATE_EN of **ARU_[x]_DYN_CTRL** register.

The following mapping of the ARU word to the **ARU_[x]_DYN_ROUTE_LOW/_HIGH** registers is implemented:

- **ARU_[x]_DYN_ROUTE_SR_LOW(23:0) = aru_data(23:0)**
- **ARU_[x]_DYN_ROUTE_SR_HIGH(28:0) = aru_data(52:24)**

The bit field aru_data(51:48) controls the configuration bits DYN_CLK_WAIT and the bit aru_data(52) controls the configuration bit DYN_UPDATE_EN. Both functions are described in **Section 28.5.4.1**.

In opposite to the dynamic routing scheme controlled from CPU/AEI (only the 6 additional ARU master DYN_REA_ID's are inserted) two additional ID's are served. One is the ARU master ID itself for reloading and the other is the default ID-0. The ID-0 is only added to the inserted routing scheme if bit field **DYN_CLK_WAIT** of **ARU_[x]_DYN_ROUTE_HIGH** is set to zero (only the inserted routing scheme is executed). This ensures that a debug access can take place even if only the inserted routing scheme is executed.

The following dynamic routing scheme is executed for 15 > **DYN_CLK_WAIT** > 0:
… -> ARU-master_ID -> DYN_READ_ID0 ->DYN_READ_ID1 -> DYN_READ_ID2 -> DYN_READ_ID3 -> DYN_READ_ID4 -> DYN_READ_ID5 -> ARU-master_ID -> …

The following dynamic routing scheme is executed for **DYN_CLK_WAIT** = 0:
… -> ARU-master_ID -> DYN_READ_ID0 -> DYN_READ_ID1 -> DYN_READ_ID2 -> DYN_READ_ID3 -> DYN_READ_ID4 -> DYN_READ_ID5 -> default_ID0 -> ARU-master_ID -> …

With the possibility of reloading the dynamic routing scheme over ARU, a FIFO or MCS is able to deliver the dynamic routing scheme data.

28.5.5 ARU Interrupt Signals

Table 13 ARU Interrupt Signals

Signal	Description
ARU_NEW_DATA0_IRQ	Indicates that data is transferred through the ARU using debug channel **ARU_DBG_ACCESS0**.
ARU_NEW_DATA1_IRQ	Indicates that data is transferred through the ARU using debug channel **ARU_DBG_ACCESS1**.
ARU_ACC_ACK_IRQ	ARU access acknowledge IRQ.

28.5.6 ARU Configuration Register Overview

Table 14 ARU Configuration Register Overview

Register name	Description	see Page
ARU_ACCESS	ARU access register	53
ARU_DATA_H	ARU access register upper data word	54
ARU_DATA_L	ARU access register lower data word	55
ARU_DBG_ACCESS0	ARU debug access channel 0	55
ARU_DBG_DATA0_H	ARU debug access 0 transfer register upper data word	57
ARU_DBG_DATA0_L	ARU debug access 0 transfer register lower data word	57
ARU_DBG_ACCESS1	ARU debug access channel 0	58
ARU_DBG_DATA1_H	ARU debug access 1 transfer register upper data word	59
ARU_DBG_DATA1_L	ARU debug access 1 transfer register lower data word	60
ARU_IRQ_NOTIFY	ARU interrupt notification register	60
ARU_IRQ_EN	ARU interrupt enable register	61
ARU_IRQ_FORCINT	ARU force interrupt register	62
ARU_IRQ_MODE	ARU interrupt mode register	63
ARU_CADDR_END	ARU caddr counter end value	63
ARU_CADDR	ARU caddr counter value	64
ARU_CTRL	ARU enable dynamic routing	65
ARU_[z]_DYN_CTRL	ARU z dynamic routing control register	66
ARU_[z]_DYN_RDADDR	ARU z read ID for dynamic routing	66
ARU_[z]_DYN_ROUTE_LOW	ARU z lower bits of DYN_ROUTE register	67
ARU_[z]_DYN_ROUTE_HIGH	ARU z higher bits of DYN_ROUTE register	68
ARU_[z]_DYN_ROUTE_SR_LOW	ARU z shadow register for ARU_[z]_DYN_ROUTE_LOW	68
ARU_[z]_DYN_ROUTE_SR_HIGH	ARU z shadow register for ARU_[z]_DYN_ROUTE_HIGH	69

28.5.7 ARU Configuration Register Description

28.5.7.1 Register ARU_ACCESS

ARU Access Register

Note: The register ARU_ACCESS can be used either for reading or for writing at the same point in time.

ARU_ACCESS
ARU Access Register **(000280$_H$)** **Application Reset Value: 0000 01FE$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		WREQ	RREQ	0			ADDR								
r		rw	rw	r			rw								

Field	Bits	Type	Description
ADDR	8:0	rw	**ARU address** Define the ARU address used for transferring data. For an ARU write request, the preferred address 0x0 have to be used. A write request to the address 0x1FF (always full address) or 0x1FE (always empty address) are ignored and doesn't have any effect. ARU address bits ADDR are only writable if RREQ and WREQ bits are zero.
RREQ	12	rw	**Initiate read request** This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a read request. RREQ bit is only writable if WREQ bit is zero, so to switch from RREQ to WREQ a cancel request has to be performed before. Configuring both RREQ and WREQ bits results in a read request, so RREQ bit will be set if the WREQ bit of the register isn't already set. The ARU read request on address ADDR is served immediately when no other destination has actually a read request when the RREQ bit is set by CPU. In a worst case scenario, the read request is served after one round trip of the ARU, but this is only the case when every destination channel issues a read request at consecutive points in time. 0_B No read request is pending 1_B Set read request to source channel addressed by ADDR

Field	Bits	Type	Description
WREQ	13	rw	**Initiate write request** This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a write request. WREQ bit is only writable if RREQ bit is zero, so to switch from WREQ to RREQ a cancel request has to be performed before. Configuring both RREQ and WREQ bits results in a read request, so WREQ bit will not be set The data is provided at address ADDR. This address has to be programmed as the source address in the destination sub-module channel. In worst case, the data is provided after one full ARU round trip. 0_B No write request is pending 1_B Mark data in registers ARU_DATA_H and ARU_DATA_L as valid
0	11:9, 31:14	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.2 Register ARU_DATA_H

ARU Access Register Upper Data Word

ARU_DATA_H
ARU Access Register Upper Data Word **(000284_H)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			**DATA**												
r			rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA															
rw															

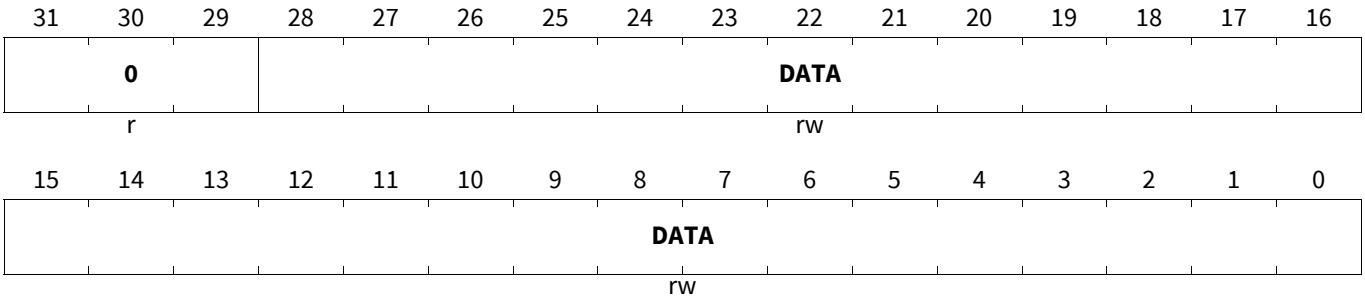
Field	Bits	Type	Description
DATA	28:0	rw	**Upper ARU data word** Transfer upper ARU data word addressed by ADDR. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register.
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.3 Register ARU_DATA_L

ARU Access Register Lower Data Word

ARU_DATA_L

ARU Access Register Lower Data Word **(000288$_H$)** **Application Reset Value: 0000 0000$_H$**



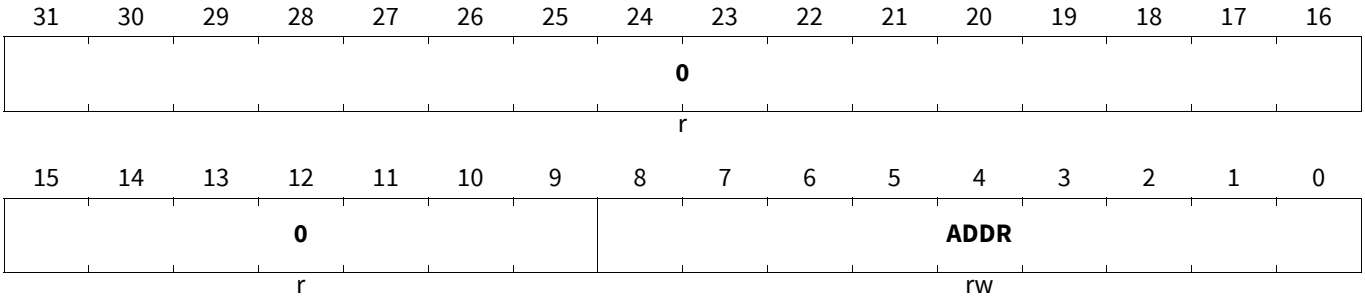
Field	Bits	Type	Description
DATA	28:0	rw	**Lower ARU data word** Transfer lower ARU data word addressed by ADDR. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word are mapped to the data bits 24 to 28 of this register when data is read by the CPU. For writing data into the ARU by the CPU the bits 24 to 28 are **not** transferred to bit 48 to 52 of the ARU word. Only bits 0 to 23 are written to bits 0 to 23 of the ARU word.
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.4 Register ARU_DBG_ACCESS0

ARU Debug Access Channel 0

ARU_DBG_ACCESS0

ARU Debug Access Channel 0 **(00028C$_H$)** **Application Reset Value: 0000 01FE$_H$**



Field	Bits	Type	Description
ADDR	8:0	rw	**ARU debugging address** Define address of ARU debugging channel 0.

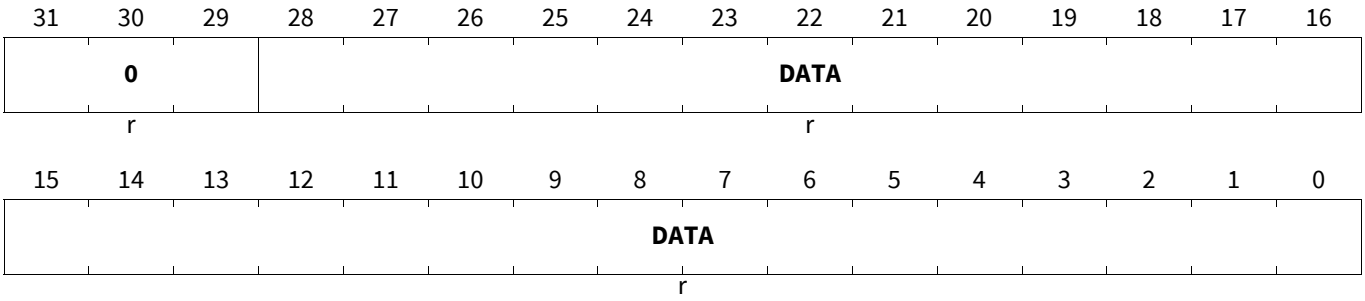
Field	Bits	Type	Description
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.5 Register ARU_DBG_DATA0_H

ARU Debug Access 0 Transfer Register Upper Data Word

ARU_DBG_DATA0_H

ARU Debug Access 0 Transfer Register Upper Data Word(000290$_H$) **Application Reset Value: 0000 0000$_H$**



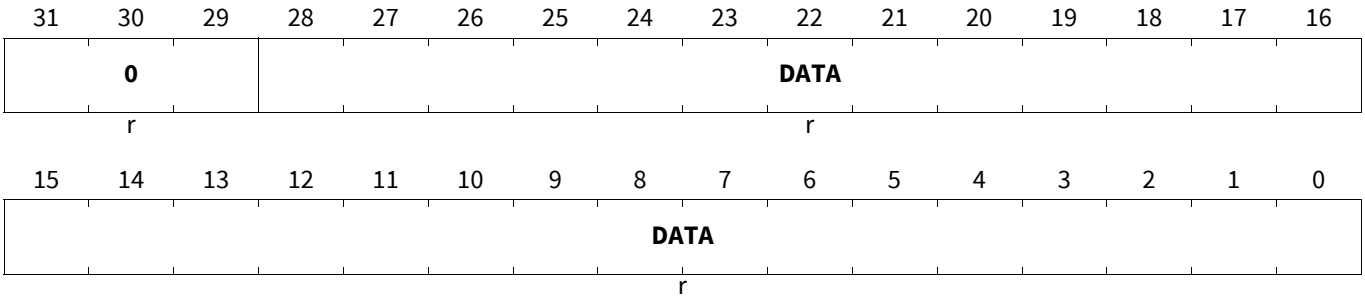
Field	Bits	Type	Description
DATA	28:0	r	**Upper debug data word** Transfer upper ARU data word addressed by register **DBG_ACCESS0**. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register The interrupt *ARU_NEW_DATA0_IRQ* is raised if a new data word is available.
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.6 Register ARU_DBG_DATA0_L

ARU Debug Access 0 Transfer Register Lower Data Word

ARU_DBG_DATA0_L

ARU Debug Access 0 Transfer Register Lower Data Word(000294$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
DATA	28:0	r	**Lower debug data word** Transfer lower ARU data word addressed by register **DBG_ACCESS0**. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register. The interrupt *ARU_NEW_DATA0_IRQ* is raised if a new data word is available.
0	31:29	r	**Reserved** Read as zero, shall be written as zero

28.5.7.7 Register ARU_DBG_ACCESS1

ARU Debug Access Channel 1

ARU_DBG_ACCESS1
ARU Debug Access Channel 1 **(000298_H)** **Application Reset Value: 0000 01FE$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							**ADDR**								
r							rw								

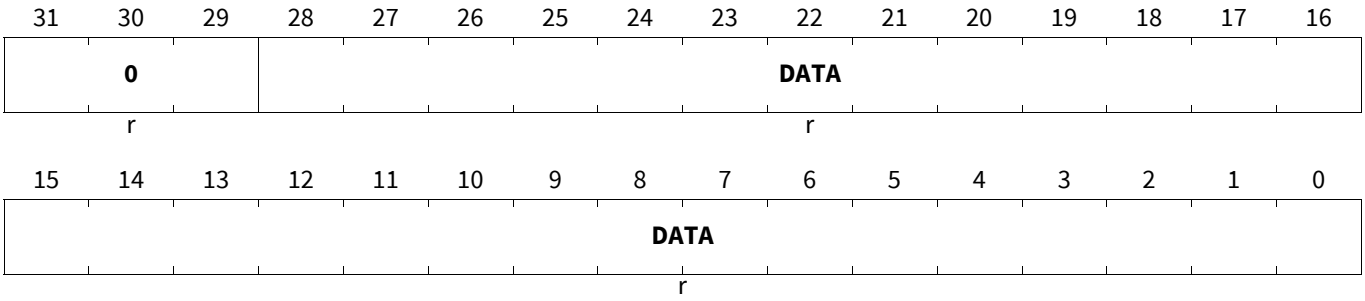
Field	Bits	Type	Description
ADDR	8:0	rw	**ARU debugging address** Define address of ARU debugging channel 1.
0	31:9	r	**Reserved** Read as zero, shall be written as zero

28.5.7.8 Register ARU_DBG_DATA1_H

ARU Debug Access 1 Transfer Register Upper Data Word

ARU_DBG_DATA1_H

ARU Debug Access 1 Transfer Register Upper Data Word(00029C$_H$) **Application Reset Value: 0000 0000$_H$**



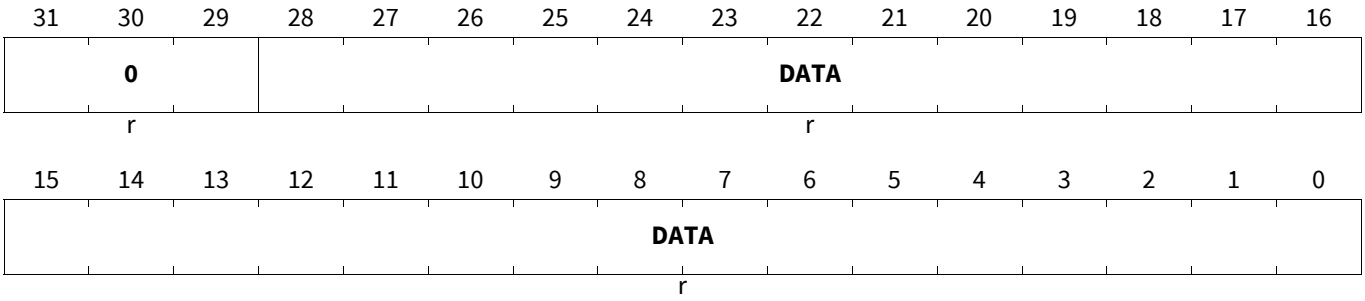
Field	Bits	Type	Description
DATA	28:0	r	**Upper debug data word** Transfer upper ARU data word addressed by register **DBG_ACCESS1**. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register. The interrupt *ARU_NEW_DATA1_IRQ* is raised if a new data word is available.
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.9 Register ARU_DBG_DATA1_L

ARU Debug Access 1 Transfer Register Lower Data Word

ARU_DBG_DATA1_L

ARU Debug Access 1 Transfer Register Lower Data Word(0002A0$_H$) **Application Reset Value: 0000 0000$_H$**



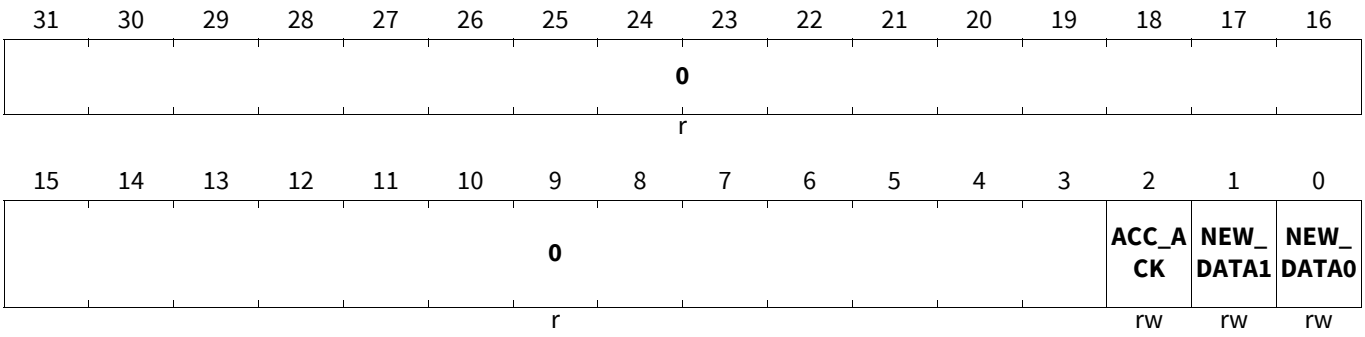
Field	Bits	Type	Description
DATA	28:0	r	**Lower debug data word** Transfer lower ARU data word addressed by register **DBG_ACCESS1**. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register. The interrupt *ARU_NEW_DATA1_IRQ* is raised if a new data word is available.
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.10 Register ARU_IRQ_NOTIFY

ARU Interrupt Notification Register

ARU_IRQ_NOTIFY

ARU Interrupt Notification Register **(0002A4$_H$)** **Application Reset Value: 0000 0000$_H$**

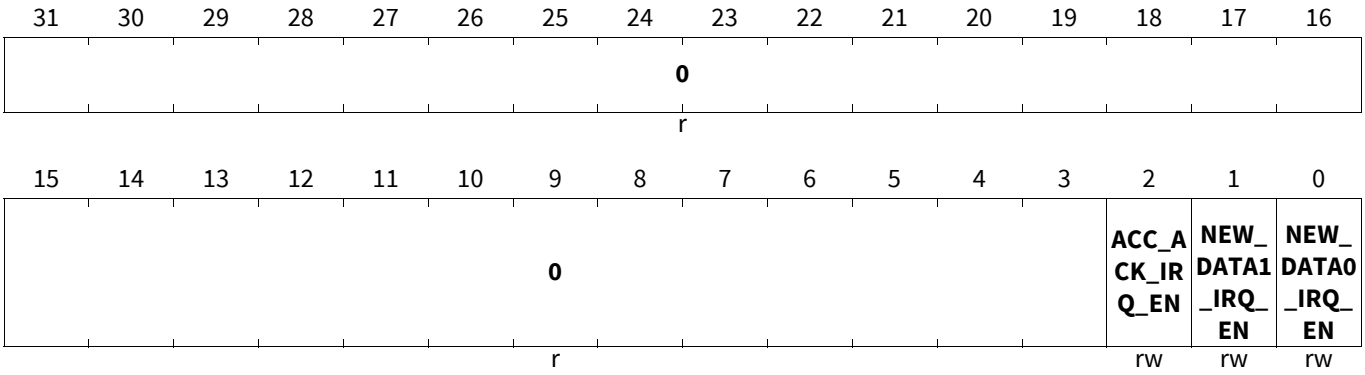


Field	Bits	Type	Description
NEW_DATA0	0	rw	**Data was transferred for addr ARU_DBG_ACCESS0** This bit will be cleared on a CPU write access of value '1'. (As the bit is rw, otherwise no clear.) A read access leaves the bit unchanged. 0_B No interrupt occurred 1_B ARU_NEW_DATA0_IRQ interrupt was raised by the ARU
NEW_DATA1	1	rw	**Data was transferred for addr ARU_DBG_ACCESS1** This bit will be cleared on a CPU write access of value '1'. (As the bit is rw, otherwise no clear.) A read access leaves the bit unchanged. 0_B No interrupt occurred 1_B ARU_NEW_DATA1_IRQ interrupt was raised by the ARU
ACC_ACK	2	rw	**AEI to ARU access finished, on read access data are valid** This bit will be cleared on a CPU write access of value '1'. (As the bit is rw, otherwise no clear.) A read access leaves the bit unchanged.
0	31:3	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.11 Register ARU_IRQ_EN

ARU Interrupt Enable Register

ARU_IRQ_EN
ARU Interrupt Enable Register **($0002A8_H$)** **Application Reset Value: $0000\ 0000_H$**



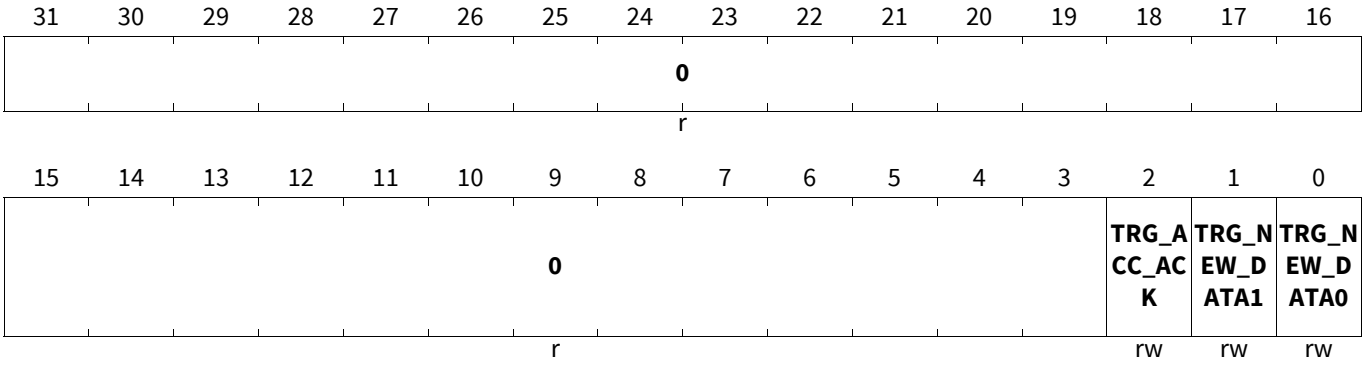
Field	Bits	Type	Description
NEW_DATA0_IRQ_EN	0	rw	**ARU_NEW_DATA0_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
NEW_DATA1_IRQ_EN	1	rw	**ARU_NEW_DATA1_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM
ACC_ACK_IRQ_EN	2	rw	**ACC_ACK_IRQ interrupt enable** 0_B Disable interrupt, interrupt is not visible outside GTM 1_B Enable interrupt, interrupt is visible outside GTM

Field	Bits	Type	Description
0	31:3	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.12 Register ARU_IRQ_FORCINT

ARU Force Interrupt Register

ARU_IRQ_FORCINT
ARU Force Interrupt Register **(0002AC$_H$)** **Application Reset Value: 0000 0000$_H$**

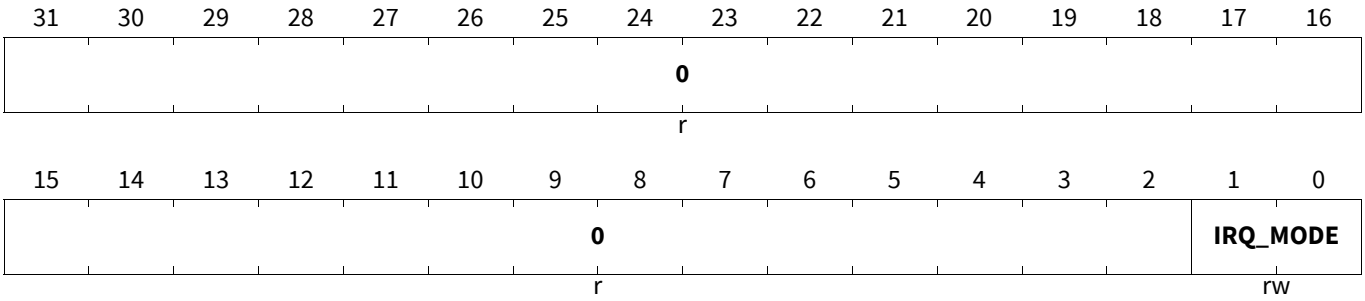


Field	Bits	Type	Description
TRG_NEW_DATA0	0	rw	**Trigger new data 0 interrupt** Note: This bit is cleared automatically after write. This bit is write protected by bit RF_PROT of register GTM_CTRL. 0_B Corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register
TRG_NEW_DATA1	1	rw	**Trigger new data 1 interrupt** Note: This bit is cleared automatically after write. This bit is write protected by bit RF_PROT of register GTM_CTRL. 0_B Corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register
TRG_ACC_ACK	2	rw	**Trigger ACC_ACK interrupt** Note: This bit is cleared automatically after write. This bit is write protected by bit RF_PROT of register GTM_CTRL. 0_B Corresponding bit in status register will not be forced 1_B Assert corresponding field in ARU_IRQ_NOTIFY register
0	31:3	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.13 Register ARU_IRQ_MODE

ARU Interrupt Mode Register

ARU_IRQ_MODE
ARU Interrupt Mode Register **(0002B0$_H$)** **Application Reset Value: 0000 0000$_H$**

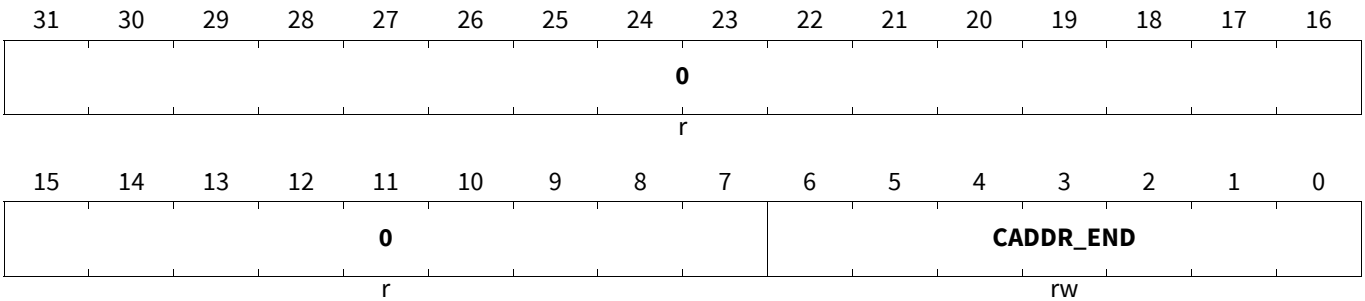


Field	Bits	Type	Description
IRQ_MODE	1:0	rw	**IRQ mode selection** The interrupt modes are described in **Section 28.4.5**. 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode
0	31:2	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.14 Register ARU_CADDR_END

ARU caddr Counter End Value Register

ARU_CADDR_END
ARU caddr Counter End Value Register **(0002B4$_H$)** **Application Reset Value: 0000 007F$_H$**



Field	Bits	Type	Description
CADDR_END	6:0	rw	**Set end value of ARU caddr counter** The ARU roundtrip counter aru_caddr runs from zero to caddr_end value. Shorten the ARU roundtrip cycle by setting a smaller number than the defined reset value will cause that not all ARU-connected modules will be served. Making the roundtrip cycle longer than the reset value would cause longer ARU roundtrip time and as a result some ARU-connected modules will not be served as fast as possible for this device. This bit is write protected by bit RF_PROT of register GTM_CTRL
0	31:7	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.15 Register ARU_CADDR

ARU caddr Counter Value

Note: The registers CADDR_0 and CADDR_1 start incrementing with each clock cycle just after reset. Due to this the initial reset value cannot be read back.

ARU_CADDR

ARU caddr Counter Value **(0002FC$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									**CADDR_1**						
r									r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

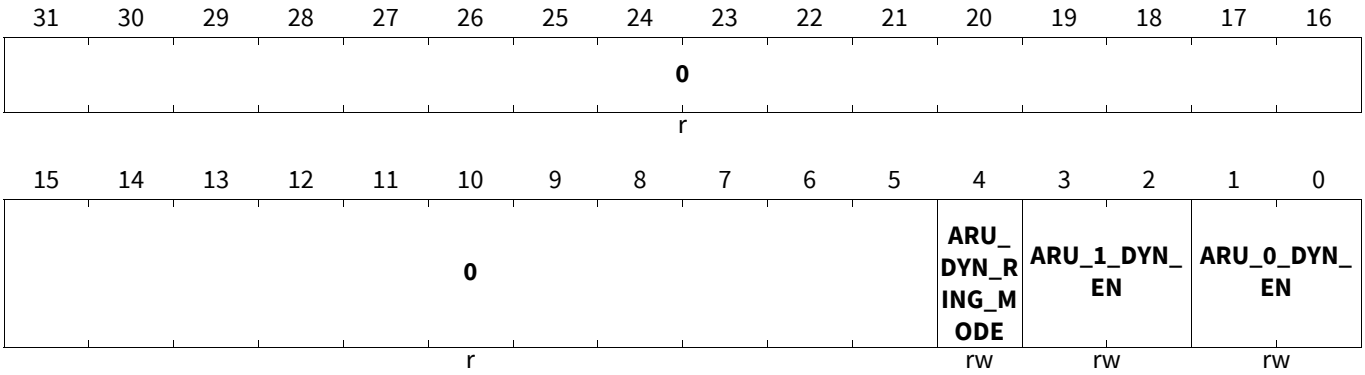
r									r						

Field	Bits	Type	Description
CADDR_0	6:0	r	**Value of ARU-0 caddr counter**
CADDR_1	22:16	r	**Value of ARU-1 caddr counter**
0	15:7, 31:23	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.16 Register ARU_CTRL

ARU Enable Dynamic Routing Register

ARU_CTRL
ARU Enable Dynamic Routing Register (0002BC$_H$) Application Reset Value: 0000 0000$_H$

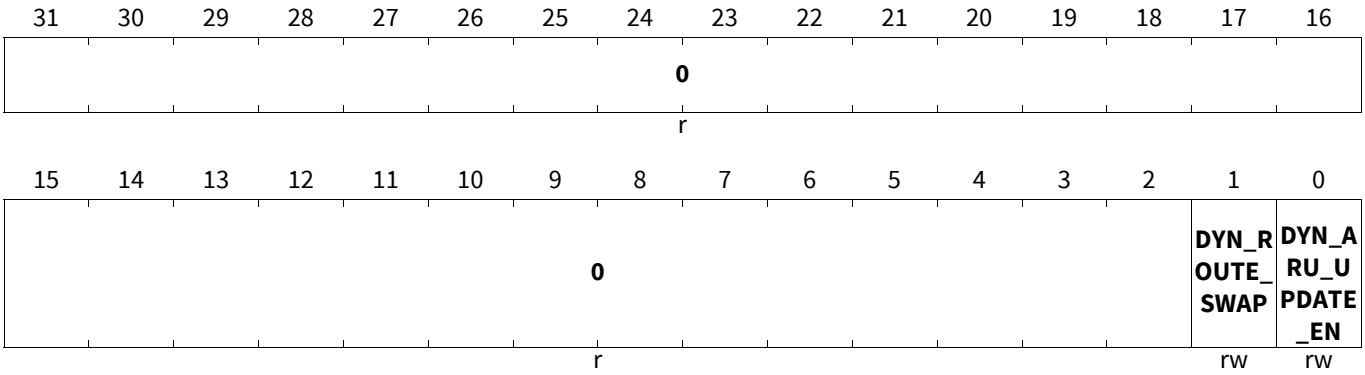


Field	Bits	Type	Description
ARU_0_DYN_EN	1:0	rw	**Enable dynamic routing for ARU-0** Dynamic routing enable of ARU-0. Write of following double bit values is possible: If dynamic routing is disabled, the normal ARU routing scheme for ARU-0 is executed. 00_B no change 01_B Disable dynamic routing 10_B Enable dynamic routing 11_B no change
ARU_1_DYN_EN	3:2	rw	**Enable dynamic routing for ARU-1** Dynamic routing enable of ARU-1. Write of following double bit values is possible: If dynamic routing is disabled, the normal ARU routing scheme for ARU-1 is executed. 00_B no change 01_B Disable dynamic routing 10_B Enable dynamic routing 11_B no change
ARU_DYN_RING_MODE	4	rw	**Enable dynamic routing ring mode** Dynamic routing ring mode for both ARU-0 and ARU-1. 0_B Different dynamic routing scheme for ARU-0 and ARU-11 1_B Same dynamic routing scheme for ARU-0 and ARU-1 with 24 possible read-ID's (dynamic routing ring mode)
0	31:5	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.17 Register ARU_[z]_DYN_CTRL

ARU z Dynamic Routing Control Register

ARU_z_DYN_CTRL (z=0-1)
ARU z Dynamic Routing Control Register (0002C0$_H$+z*4) Application Reset Value: 0000 0000$_H$

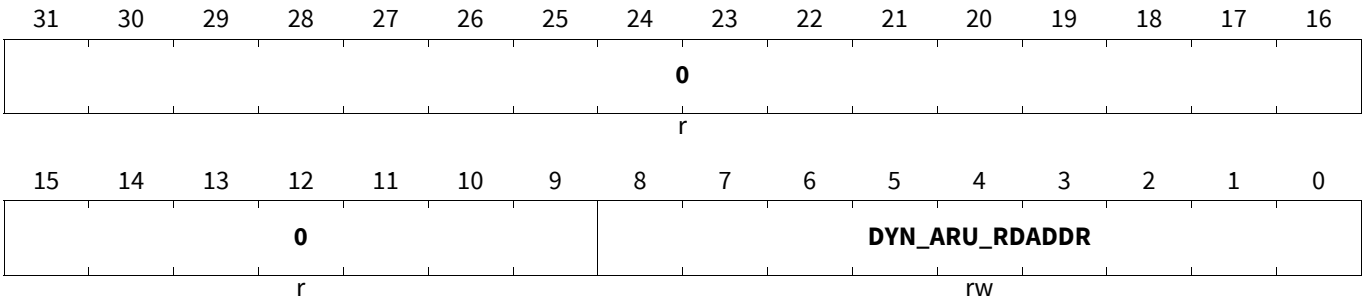


Field	Bits	Type	Description
DYN_ARU_UPDATE_EN	0	rw	**Enable reload of DYN_ROUTE register from ARU itself** Enable reload of DYN_ROUTE register from ARU itself.
DYN_ROUTE_SWAP	1	rw	**Enable swapping DYN_ROUTE_SR with DYN_ROUTE register** Enable swapping **DYN_ROUTE_SR** with **DYN_ROUTE** register.
0	31:2	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.18 Register ARU_[z]_DYN_RDADDR

ARU z Read ID for Dynamic Routing

ARU_z_DYN_RDADDR (z=0-1)
ARU z Read ID for Dynamic Routing (0002E8$_H$+z*4) Application Reset Value: 0000 0000$_H$



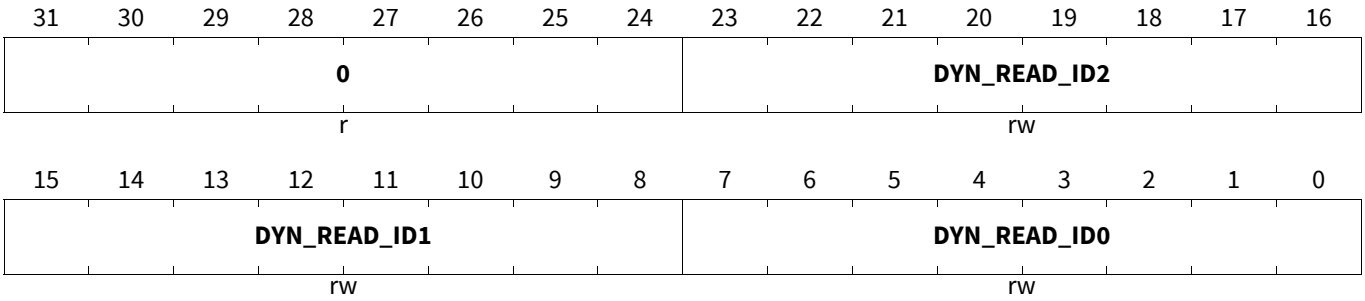
Field	Bits	Type	Description
DYN_ARU_RDADDR	8:0	rw	**ARU read address ID to reload the DYN_ROUTE register** ARU read address ID to reload the DYN_ROUTE register from ARU itself.
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.19 Register ARU_[z]_DYN_ROUTE_LOW

ARU z Lower Bits of DYN_ROUTE Register

ARU_z_DYN_ROUTE_LOW (z=0-1)

ARU z Lower Bits of DYN_ROUTE Register (0002C8$_H$+z*4) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
DYN_READ_ID0	7:0	rw	**ARU read ID 0** ARU read ID 0 for dynamic routing.
DYN_READ_ID1	15:8	rw	**ARU read ID 2** ARU read ID 1 for dynamic routing.
DYN_READ_ID2	23:16	rw	**ARU read ID 2** ARU read ID 2 for dynamic routing.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.5.7.20 Register ARU_[z]_DYN_ROUTE_HIGH

ARU z Higher Bits of DYN_ROUTE Register

ARU_z_DYN_ROUTE_HIGH (z=0-1)

ARU z Higher Bits of DYN_ROUTE Register (0002D0$_H$+z*4) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rw				rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DYN_READ_ID4								DYN_READ_ID3							
rw								rw							

Field	Bits	Type	Description
DYN_READ_ID3	7:0	rw	**ARU read ID 3** ARU read ID 3 for dynamic routing.
DYN_READ_ID4	15:8	rw	**ARU read ID 4** ARU read ID 4 for dynamic routing.
DYN_READ_ID5	23:16	rw	**ARU read ID 5** ARU read ID 5 for dynamic routing.
DYN_CLK_WAIT	27:24	rw	**Number of clk cycles for dynamic routing** Defines the number of clk cycles between each dynamic routing ID.
0	31:28	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.21 Register ARU_[z]_DYN_ROUTE_SR_LOW

ARU z Shadow Register for ARU_z_DYN_ROUTE_LOW

NOTE : This is the shadow register for register **ARU_[z]_DYN_ROUTE_LOW**

ARU_z_DYN_ROUTE_SR_LOW (z=0-1)

ARU z Shadow Register for ARU_z_DYN_ROUTE_LOW(0002D8$_H$+z*4) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DYN_READ_ID7								DYN_READ_ID6							
rw								rw							

Field	Bits	Type	Description
DYN_READ_ID6	7:0	rw	**ARU read ID 6** ARU read ID 6 for dynamic routing. These bits are mapped to ARU data bits aru_data(7:0).
DYN_READ_ID7	15:8	rw	**ARU read ID 7** ARU read ID 7 for dynamic routing. These bits are mapped to ARU data bits aru_data(15:8).
DYN_READ_ID8	23:16	rw	**ARU read ID 8** ARU read ID 8 for dynamic routing. These bits are mapped to ARU data bits aru_data(23:16).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.5.7.22 Register ARU_[z]_DYN_ROUTE_SR_HIGH

ARU z Shadow Register for ARU_z_DYN_ROUTE_HIGH

NOTE : This is the shadow register for register **ARU_[z]_DYN_ROUTE_HIGH**

ARU_z_DYN_ROUTE_SR_HIGH (z=0-1)

ARU z Shadow Register for ARU_z_DYN_ROUTE_HIGH(0002E0$_H$+z*4) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			DYN_UPDATE_EN	DYN_CLK_WAIT				DYN_READ_ID11							
r			rw	rw				rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DYN_READ_ID10								DYN_READ_ID9							
rw								rw							

Field	Bits	Type	Description
DYN_READ_ID9	7:0	rw	**ARU read ID 9** ARU read ID 9 for dynamic routing. These bits are mapped to ARU data bits aru_data(31:24).
DYN_READ_ID10	15:8	rw	**ARU read ID 10** ARU read ID 10 for dynamic routing. These bits are mapped to ARU data bits aru_data(39:32).
DYN_READ_ID11	23:16	rw	**ARU read ID 11** ARU read ID 11 for dynamic routing. These bits are mapped to ARU data bits aru_data(47:40).
DYN_CLK_WAIT	27:24	rw	**Number of clk cycles for dynamic routing** Defines the number of clk cycles between each dynamic routing ID. These bits are mapped to ARU data bits aru_data(51:48).

Field	Bits	Type	Description
DYN_UPDATE_EN	28	rw	**Update enable from shadow register** Enable update **ARU_[z]_DYN_ROUTE_LOW/_HIGH** registers from shadow registers **ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH**. This bit is mapped to ARU data bit aru_data(52).
0	31:29	r	**Reserved** Read as zero, shall be written as zero.

28.6 Broadcast Module (BRC)

28.6.1 Overview

Since each write address for the sub-module channels of the GTM that are able to write to the ARU can only be read by a single module, it is impossible to provide a data stream to different modules in parallel (This statement holds not for sources, which do not invalidate their data after the data were read by any consumer, e.g. DPLL).

To overcome this issue for regular modules, the sub-module Broadcast (BRC) enables to duplicate data streams multiple times.

The BRC sub-module provides 12 input channels as well as 22 output channels.

In order to clone an incoming data stream, the corresponding input channel can be mapped to zero or more output channels.

When mapped to zero no channel is read.

To destroy an incoming data stream, the **EN_TRASHBIN** bit inside the **BRC_SRC_[x]_DEST** register has to be set.

The total number of output channels that are assigned to a single input channel is variable. However, the total number of assigned output channels must be less than or equal to 22.

28.6.2 BRC Configuration

As it is the case with all other sub-modules connected to the ARU, the input channels can read arbitrary ARU address locations and the output channels provide the broadcast data to fixed ARU write address locations.

The associated write addresses for the BRC sub-module are fixed and can be obtained from the product specific appendix.

The read address for each input channel is defined by the corresponding register **BRC_SRC_[x]_ADDR** (x: 0…11).

The mapping of an input channel to several output channels is defined by setting the appropriate bits in the register **BRC_SRC_[x]_DEST** (x: 0…11). Each output channel is represented by a single bit in the register **BRC_SRC_[x]_DEST**.

If no output channel bit is set within a register **BRC_SRC_[x]_DEST**, no data is provided to the corresponding ARU write address location from the defined read input specified by **BRC_SRC_[x]_ADDR**. This means that the channel does not broadcast any data and is disabled (reset state).

Besides the possibility of mapping an input channel to several output channels, the bit **EN_TRASHBIN** of register **BRC_SRC_[x]_DEST** may be set, which results in dropping an incoming data stream. In this case the data of an input channel defined by **BRC_SRC_[x]_ADDR** is consumed by the BRC module and not routed to any succeeding sub-module. In consequence, the output channels defined in the register **BRC_SRC_[x]_DEST** are ignored. Therefore, the bits 0 to 21 are set to zero (0) when trash bin functionality is enabled.

In general, the BRC sub-module can work in two independent operation modes. In the first operation mode the data consistency is guaranteed since a BRC channel requests only new data from a source when all destination channels for the BRC have consumed the old data value. This mode is called *Data Consistency Mode* (DCM).

In a second operation mode the BRC channel always requests data from a source and distributes this data to the destination regardless whether all destinations have already consumed the old data. This mode is called *Maximum Throughput Mode* (MTM).

MTM ensures that always the newest available data is routed through the system, while it is not guaranteed data consistency since some of the destination channels can be provided with the old data while some other destination channels are provided with the new data. If this is the case, the Data Inconsistency Detected Interrupt *BRC_DID_IRQ[x]* is raised but the channel continues to work.

Furthermore in MTM mode it is guaranteed that it is not possible to read a data twice by a read channel. This is blocked.

The channel mode can be configured inside the **BRC_SRC_[x]_ADDR** register.

To avoid invalid configurations of the registers **BRC_SRC_[x]_DEST**, the BRC also implements a plausibility check for these configurations. If the software assigns an already used output channel to a second input channel, BRC performs an auto correction of the lastly configured register **BRC_SRC_[x]_DEST** and it triggers the interrupt *BRC_DEST_ERR*.

Consider the following example for clarification of the auto correction mechanism. Assume that the following configuration of the 22 lower significant bits for the registers **BRC_SRC_[x]_DEST**:

BRC_SRC_0_DEST: 00 0000 0000 1000 1000 0000 (binary)

BRC_SRC_1_DEST: 00 0000 0000 0100 0000 0100 (binary)

BRC_SRC_2_DEST: 00 0000 0000 0001 0100 0010 (binary)

BRC_SRC_3_DEST: 00 0000 0000 0010 0001 1001 (binary)

If the software overwrites the value for register **BRC_SRC_2_DEST** with

BRC_SRC_2_DEST: 00 0000 0000 1001 0010 0010 (binary)

(changed bits are underlined), then the BRC releases a *BRC_DEST_ERR* interrupt since bit 11 is already assigned in register **BRC_SRC_0_DEST**. The auto correction forces bit 11 to be cleared. The modifications of the bits 5 and 6 are accepted, since there is no violation with previous configurations. So the result of the write access mentioned above results in the following modified register configuration:

BRC_SRC_2_DEST: 00 0000 0000 0001 0010 0010 (binary)

For debug purposes, the interrupt *BRC_DEST_ERR* can also be released by writing to register **BRC_IRQ_FORCINT**. Nevertheless, the interrupt has to be enabled to be visible outside of the GTM.

28.6.3 BRC Interrupt Signals

Table 15 BRC Interrupt Signals

Signal	Description
BRC_DEST_ERR_IRQ	Indicating configuration errors for BRC module
BRC_DID_IRQ[x]	Data inconsistency occurred in MTM mode (x:0…11)

28.6.4 BRC Configuration Register Overview

Table 16 BRC Configuration Register Overview

Register Name	Description	see Page

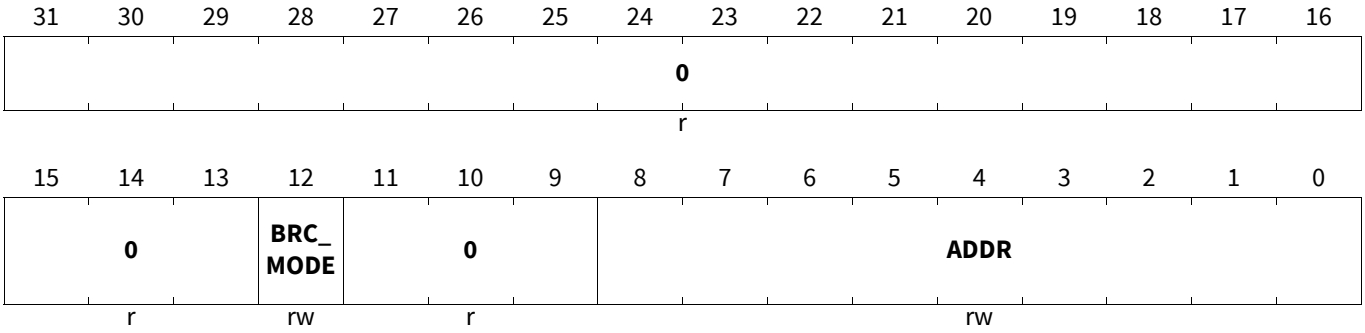
28.6.5 BRC Configuration Register Description

28.6.5.1 Register BRC_SRC_[z]_ADDR

BRC Read Address for Input Channel z

BRC_SRC_z_ADDR (z=0-11)
BRC Read Address for Input Channel z **(000400_H+z*8)** **Application Reset Value: 0000 $01FE_H$**



Field	Bits	Type	Description
ADDR	8:0	rw	**Source ARU address. Defines an ARU read address used as data source for input channel z** This bit field is only writable if channel is disabled.
BRC_MODE	12	rw	**BRC_MODE: BRC Operation mode select** This bit field is only writable if channel is disabled. 0_B Consistency Mode (DCM) selected 1_B Maximum Throughput Mode (MTM) selected
0	11:9, 31:13	r	**Reserved** Read as zero, shall be written as zero.

28.6.5.2 Register BRC_SRC_[z]_DEST

BRC Destination Channels for Input Channel z

BRC_SRC_z_DEST (z=0-11)

BRC Destination Channels for Input Channel z(000404_H+z*8) **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

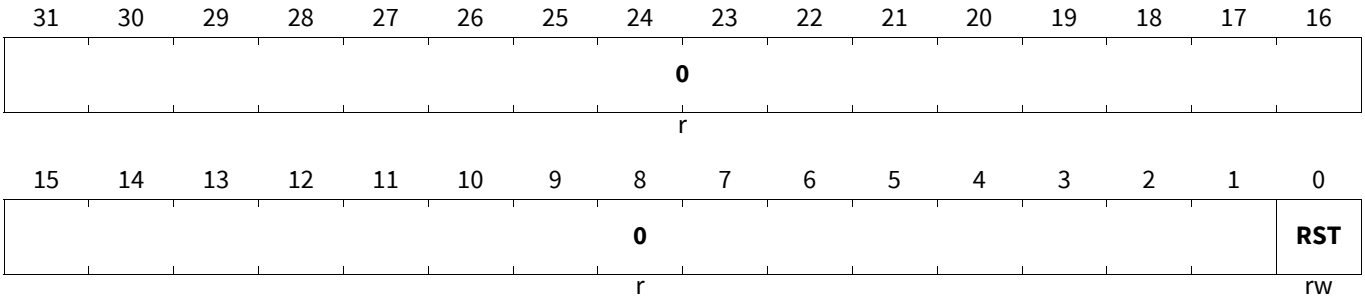
DID_EIRQ_ENx (x=0-11)	x+1	rw	**Enable DID interrupt for channel x** 0_B Disable error interrupt, error interrupt is not visible outside GTM 1_B Enable error interrupt, error interrupt is visible outside GTM
0	31:13	r	**Reserved** Read as zero, shall be written as zero.

28.6.5.8 Register BRC_RST

BRC Software Reset Register

BRC_RST

BRC Software Reset Register **(000470_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RST	0	rw	**Software reset** This bit is cleared automatically after write by CPU. The channel registers are set to their reset values and channel operation is stopped immediately. 0_B No action 1_B Reset BRC
0	31:1	r	**Reserved** Read as zero, shall be written as zero

28.7 First In First Out Module (FIFO)

28.7.1 Overview

The FIFO unit is the storage part of the FIFO sub-module. The F2A described in (FIFO to ARU Unit) and the AFD described in chapter “AEI to FIFO Data Interface” implement the interface part of the FIFO sub-module to the ARU and the AEI bus. Each FIFO unit embeds eight logical FIFOs. These logical FIFOs are configurable in the following manner:

- FIFO size (defines start and end address)
- FIFO operation modes (normal mode or ring buffer operation mode)
- Fill level control / memory region read protection

Each logical FIFO represents a data stream between the sub-modules of the GTM and the microcontroller connected to AFD sub-module (see chapter AEI to FIFO Data Interface). The FIFO RAM counts 1K words, where the word size is 29 bit. This gives the freedom to program or receive 24 bit of data together with the five control bits inside an ARU data word.

The FIFO unit provides three ports for accessing its content. One port is connected to the F2A interface, one port is connected to the AFD interface and one port has its own AEI bus interface.

The AFD interface has always the highest priority. Accesses to the FIFO from AFD interface and direct AEI interface in parallel - which means at the same time - is not possible, because both interfaces are driven from the same AEI bus interface of the GTM.

The priority between F2A and direct AEI interface can be defined by software. This can be done by using the register **FIFO[i]_CH[x]_CTRL** for all FIFO channels of the sub-module.

The FIFO is organized as a single RAM that is also accessible through the FIFO AEI interface connected to one of the FIFO ports. To provide the direct RAM access, the RAM is mapped into the address space of the microcontroller. The addresses for accessing the RAM via AEI can be found in [1].

After reset, the FIFO RAM isn't initialized by hardware.

The FIFO channels can be flushed individually. Each of the eight FIFO channels can be used whether in normal FIFO operation mode or in ring buffer operation mode.

Beside the possibility of flushing each FIFO channel directly, a write access to FIFO[i]_CH[x]_END_ADDR or to FIFO[i]_CH[x]_START_ADDR will also flush the regarding channel which means that the read and write pointer and also the fill level of the regarding channel will be reset. In consequence of this existing data in the concerned FIFO channel are not longer valid- thereafter the channel is empty.

28.7.2 Operation Modes

28.7.2.1 FIFO Operation Mode

In normal FIFO operation mode the content of the FIFO is written and read in first-in first-out order, where the data is destroyed after it is delivered to the system bus or the F2A sub-module (see chapter “FIFO to ARU Unit ”).

The upper and lower watermark registers (registers **FIFO[i]_CH[x]_UPPER_WM** and **FIFO[i]_CH[x]_LOWER_WM**) are used for controlling the FIFO’s fill level. If the fill level falls below the lower watermark or it exceeds the upper watermark, an interrupt signal is triggered by the FIFO sub-module if enabled inside the **FIFO[i]_IRQ_EN**.

The interrupt signals are sent to the Interrupt Concentrator Module (ICM) (see chapter “Interrupt Concentrator Module”). The ICM can also initiate specific DMA transfers.

28.7.2.2 Ring Buffer Operation Mode

The ring buffer mode can be used to provide a continuous data or configuration stream to the other GTM sub-modules without CPU interaction. In ring buffer mode the FIFO provides a continuous data stream to the F2A sub-module. The first word of the FIFO is delivered first and after the last word is provided by the FIFO to the ARU, the first word can be obtained again.

If in ring buffer mode the read pointer reaches the write pointer it will be set again to the configured start address. So the read pointer always rotates cyclic between the configured start address of the regarding FIFO channel (first written data) and the write pointer which points to the last written data of the channel.

It is possible to add data to the FIFO channel via the AEI to FIFO interface (AFD) using the register AFD[i]_CH[x]_BUF_ACC while running in ring buffer mode. The new written data will be added in the next ring buffer cycle.

However, the register AFD[i]_CH[x]_BUF_ACC should not be read in read buffer mode.

It is recommended to fill the FIFO channel first before enabling the data stream in the FIFO to ARU interface (F2A).

Modifications of the continuous data stream can be achieved by using direct memory access which is provided by the FIFO AEI interface.

28.7.2.3 DMA Hysteresis Mode

The DMA hysteresis mode can be enabled by setting bit DMA_HYSTERESIS=1 in the **FIFO[i]_CH[x]_IRQ_MODE** register.

In the DMA hysteresis mode the lower and upper watermark will be masked to generate the DMA request (=*fifo_irq*) in the following manner.

If a DMA is writing data to a FIFO (configured by setting bit DMA_HYST_DIR=1 in register **FIFO[i]_CH[x]_IRQ_MODE)**, the DMA request will be generated by the lower watermark. The upper watermark does not generate a DMA request. The next DMA request will be generated by the next lower watermark until the upper watermark was reached.

If a DMA is reading data from a FIFO (configured by setting bit DMA_HYST_DIR=0 in register **FIFO[i]_CH[x]_IRQ_MODE)**, the DMA request will be generated by the upper watermark. The lower watermark does not generate a DMA request. The next DMA request will be generated by the next upper watermark until the lower watermark was reached.

Note that the watermarks have to achieve the following condition depending on the irq mode

- IRQ_MODE = Level / Pulse / Pulse-Notify mode:
  - Upper watermark > Lower watermark
- IRQ_MODE = Single-Pulse mode:
  - Upper watermark > Lower watermark + 1

28.7.3 FIFO Interrupt

Table 17 FIFO Interrupt Signals

Signal	Description
FIFO[i]_CH[x]_EMPTY	Indicating empty FIFO x (x:0…7) was reached
FIFO[i]_CH[x]_FULL	Indicating full FIFO x (x:0…7) was reached

Table 17 FIFO Interrupt Signals (cont'd)

Signal	Description
FIFO[i]_CH[x]_LOWER_WM	Indicating FIFO x (x:0…7) reached lower watermark.
FIFO[i]_CH[x]_UPPER_WM	Indicating FIFO x (x:0…7) reached upper watermark.

28.7.4 FIFO Configuration Register Overview

Table 18 FIFO Configuration Register Overview

Register Name	Description	see Page
FIFO[i]_CH[z]_CTR	FIFOi channel z control register	84
FIFO[i]_CH[z]_END_ADDR	FIFOi channel z end address register	85
FIFO[i]_CH[z]_START_ADDR	FIFOi channel z start address register	85
FIFO[i]_CH[z]_UPPER_WM	FIFOi channel z upper watermark register	86
FIFO[i]_CH[z]_LOWER_WM	FIFOi channel z lower watermark register	86
FIFO[i]_CH[z]_STATUS	FIFOi channel z status register	87
FIFO[i]_CH[z]_FILL_LEVEL	FIFOi channel z fill level register	88
FIFO[i]_CH[z]_WR_PTR	FIFOi channel z write pointer register	88
FIFO[i]_CH[z]_RD_PTR	FIFOi channel z read pointer register	89
FIFO[i]_CH[z]_IRQ_NOTIFY	FIFOi channel z interrupt notification register	90
FIFO[i]_CH[z]_IRQ_EN	FIFOi channel z interrupt enable register	91

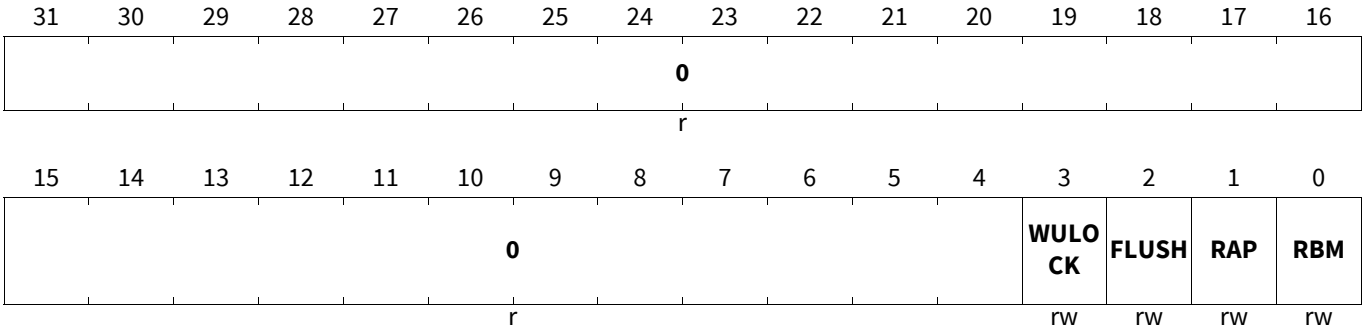
28.7.5 FIFO Configuration Registers Description

28.7.5.1 Register FIFO[i]_CH[z]_CTRL

FIFOi Channel z Control Register

FIFOi_CHz_CTRL (i=0-2;z=0-7)
FIFOi Channel z Control Register **(018400_H+i*4000_H+z*40_H)** **Application Reset Value: 0000 0000_H**



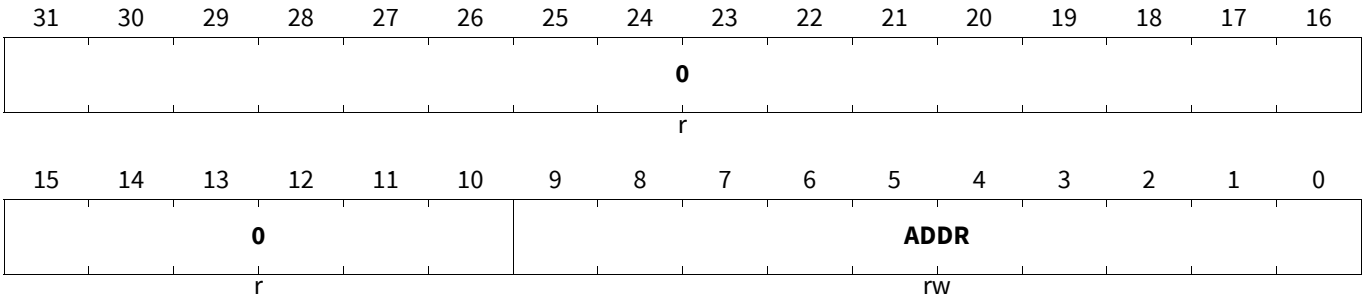
Field	Bits	Type	Description
RBM	0	rw	**Ring buffer mode enable** 0_B Normal FIFO operation mode 1_B Ring buffer mode
RAP	1	rw	**RAM access priority** RAP bit is only functional in register FIFO_0_CTRL. The priority is defined for all FIFO channels there. 0_B FIFO ports have higher access priority than AEI-IF 1_B AEI-IF has higher access priority than FIFO ports
FLUSH	2	rw	**FIFO Flush control** A FIFO Flush operation resets the **FIFO[i]_CH[z]_FILL_LEVEL**, **FIFO[i]_CH[z]_WR_PTR** and **FIFO[i]_CH[z]_RD_PTR** registers to their initial values. 0_B Normal operation 1_B Execute FIFO flush (bit is automatically cleared after flush)
WULOCK	3	rw	**RAM write unlock** Enable/disable direct RAM write access to the memory mapped FIFO region. Only the bit WULOCK of register FIFO[i]_CH0_CTRL enables/disables the direct RAM write access for all FIFO channel (whole FIFO RAM). The WULOCK bits of the other channels are writeable but have no effect. 0_B Direct RAM write access disabled 1_B Direct RAM write access enabled
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.7.5.2 Register FIFO[i]_CH[z]_END_ADDR

FIFOi Channel z End Address Register

FIFOi_CHz_END_ADDR (i=0-2;z=0-7)

FIFOi Channel z End Address Register (018404_H+i*4000_H+z*40_H) **Reset Value: Table 19**



Field	Bits	Type	Description
ADDR	9:0	rw	**End address for FIFO channel z** value for ADDR is calculated as ADDR = 128*(x+1)-1 A write access will flush the regarding channel
0	31:10	r	**Reserved** Read as zero, shall be written as zero.

Table 19 Reset Values of FIFOi_CHz_END_ADDR (i=0-2;z=0-7)

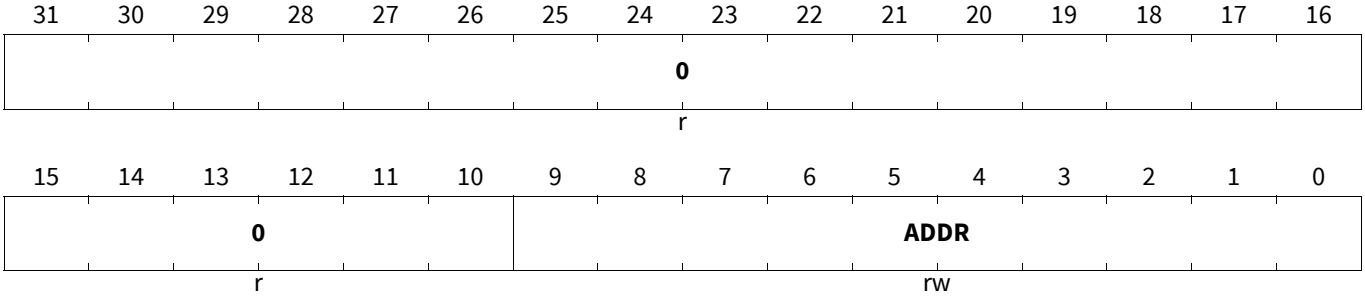
Reset Type	Reset Value	Note
Application Reset	0x80 * (z + 1) - 1	

28.7.5.3 Register FIFO[i]_CH[z]_START_ADDR

FIFOi Channel z Start Address Register

FIFOi_CHz_START_ADDR (i=0-2;z=0-7)

FIFOi Channel z Start Address Register (018408_H+i*4000_H+z*40_H) **Reset Value: Table 20**



Field	Bits	Type	Description
ADDR	9:0	rw	**Start address for FIFO channel z** Initial value for ADDR is calculated as ADDR = 128*z. A write access will flush the regarding channel.

Field	Bits	Type	Description
0	31:10	r	**Reserved** Read as zero, shall be written as zero.

Table 20 Reset Values of FIFOi_CHz_START_ADDR (i=0-2;z=0-7)

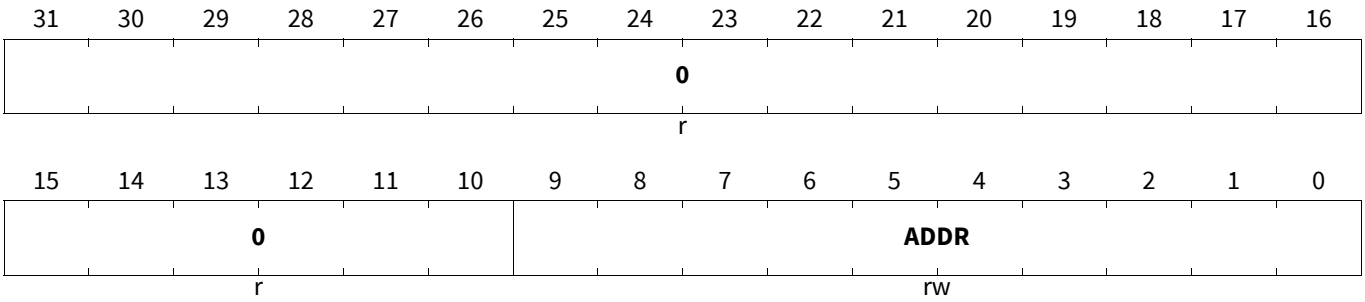
Reset Type	Reset Value	Note
Application Reset	0x80 * z	

28.7.5.4 Register FIFO[i]_CH[z]_UPPER_WM

FIFOi Channel z Upper Watermark Register

FIFOi_CHz_UPPER_WM (i=0-2;z=0-7)

FIFOi Channel z Upper Watermark Register($01840C_H$+i*4000_H+z*40_H) Application Reset Value: 0000 0060_H



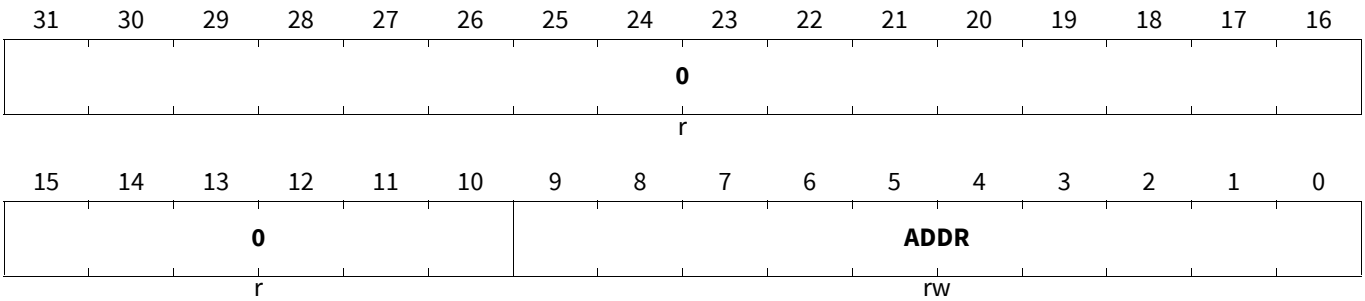
Field	Bits	Type	Description
ADDR	9:0	rw	**Upper watermark address for channel z** The upper watermark is configured as a relative fill level of the FIFO. ADDR must be in range: 0 <= ADDR <= **FIFO[i]_CH[x]_END_ADDR** - **FIFO[i]_CH[x]_START_ADDR**. Initial value for ADDR is defined as ADDR = 0x60.
0	31:10	r	**Reserved** Read as zero, shall be written as zero.

28.7.5.5 Register FIFO[i]_CH[z]_LOWER_WM

FIFOi Channel z Lower Watermark Register

FIFOi_CHz_LOWER_WM (i=0-2;z=0-7)

FIFOi Channel z Lower Watermark Register(018410_H+i*4000_H+z*40_H) Application Reset Value: 0000 0020_H



Field	Bits	Type	Description
ADDR	9:0	rw	**Lower watermark address for channel z** The lower watermark is configured as a relative fill level of the FIFO. ADDR must be in range: 0 <= ADDR <= **FIFO[i]_CH[z]_END_ADDR** - **FIFO[i]_CH[z]_START_ADDR**. Initial value for ADDR is defined as ADDR = 0x20.
0	31:10	r	**Reserved** Read as zero, shall be written as zero.

28.7.5.6 Register FIFO[i]_CH[z]_STATUS

FIFOi Channel z Status Register

FIFOi_CHz_STATUS (i=0-2;z=0-7)
FIFOi Channel z Status Register **(018414_H+i*4000_H+z*40_H)** **Application Reset Value: 0000 0005_H**

FIFO_UWM_EIRQ_EN	3	rw	**FIFO Upper Watermark error interrupt enable** 0_B Disable error interrupt, error interrupt is not visible outside GTM 1_B Enable error interrupt, error interrupt is visible outside GTM
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.8 AEI to FIFO Data Interface (AFD)

28.8.1 Overview

The AFD sub-module implements a data interface between the AEI bus and the FIFO sub-module, which consists of eight logical FIFO channels.

The AFD sub-module provides one buffer registers that are dedicated to the logical channels of the FIFO. Access to the corresponding FIFO channel is given by reading or writing this buffer registers **AFD[i]_CH[x]_BUF_ACC**.

An AEI write access to the buffer register where the corresponding FIFO channel is full will be ignored. The data will be lost.

An AEI read access to the buffer register where the corresponding FIFO channel is empty will be served with zero data.

28.8.2 AFD Register overview

28.9 FIFO to ARU Unit (F2A)

28.9.1 Overview

The F2A is the interface between the ARU and the FIFO sub-module. Since the data width of the ARU (ARU word) is 53 bit (two 24 bit values and five control bits) and the data width of the FIFO is only 29 bit, the F2A has to distribute the data from and to the FIFO channels in a configurable manner.

The data transfer between FIFO and ARU is organized with eight different streams that are connected to the eight different channels of the corresponding FIFO module. A stream represents a data flow from/to ARU to/from the FIFO via the F2A.

The general definition of 'channels' and 'streams' in the ARU context is done in the subparagraph “ARU routing concept”.

Each FIFO channel can act as a write stream (data flow from FIFO to ARU) or as a read stream (data flow from ARU to FIFO).

Within these streams the F2A can transmit/receive the lower, the upper or both 24 bit values of the ARU together with the ARU control bits according to the configured transfer modes as described in **Section 28.9.2**.

Each stream can be enabled/disabled separately within the register **F2A[i]_ENABLE**. If a stream will be disabled, the stream data which are stored inside the F2A will be deleted. This is necessary to ensure, that no old data are transferred after enabling a stream.

28.9.2 Transfer modes

The F2A unit provides several transfer modes to map 29 bit data of the FIFO from/to 53 bit data of the ARU. E.g. it is configurable that the 24 bit FIFO data is written to the lower ARU data entry (means bits 0 to 23) or to the higher 24 bit ARU data entry (means bits 24 to 47). Bits 24 to 28 of the FIFO data entry (the five control bits) are written/read in both cases to/from bits 48 to 52 of the ARU entry.

When both values of the ARU have to be stored in the FIFO the values are stored behind each other inside the FIFO if the FIFO is not full.

If there is only space for one 24 bit data word plus the five control bits, the F2A transfers one part of the 53 bits first and then waits for transferring the second part before new data is requested from the ARU.

When two values from the FIFO have to be written to one ARU location the words have to be located behind each other inside the FIFO.

The transfer to ARU is only established when both parts could be read out of the FIFO otherwise if only one 29 bit word was provided by the FIFO the F2A waits until the second part is available before the data is made available at the ARU.

Figure 25 shows the data ordering of the FIFO when both ARU values must be transferred between ARU and FIFO.

When reading from the ARU the F2A first writes the lower word to the FIFO.

In case of writing to the ARU the F2A reads the lower word first from the FIFO, thus the lower word must be written first to the FIFO through the AFD interface.

Please note, that the five control bits (bits 48 to 52 of the ARU data word) are duplicated as bit 24 to 28 of both FIFO words in case of reading from ARU.

In the case of writing to the ARU, bits 24 to 28 of the last written FIFO word (the higher ARU word) are copied to bits 48 to 52 of the corresponding ARU location.

The transfer modes can be configured with the **TMODE** bits of registers **F2A[i]_CH[x]_STR_CFG**.

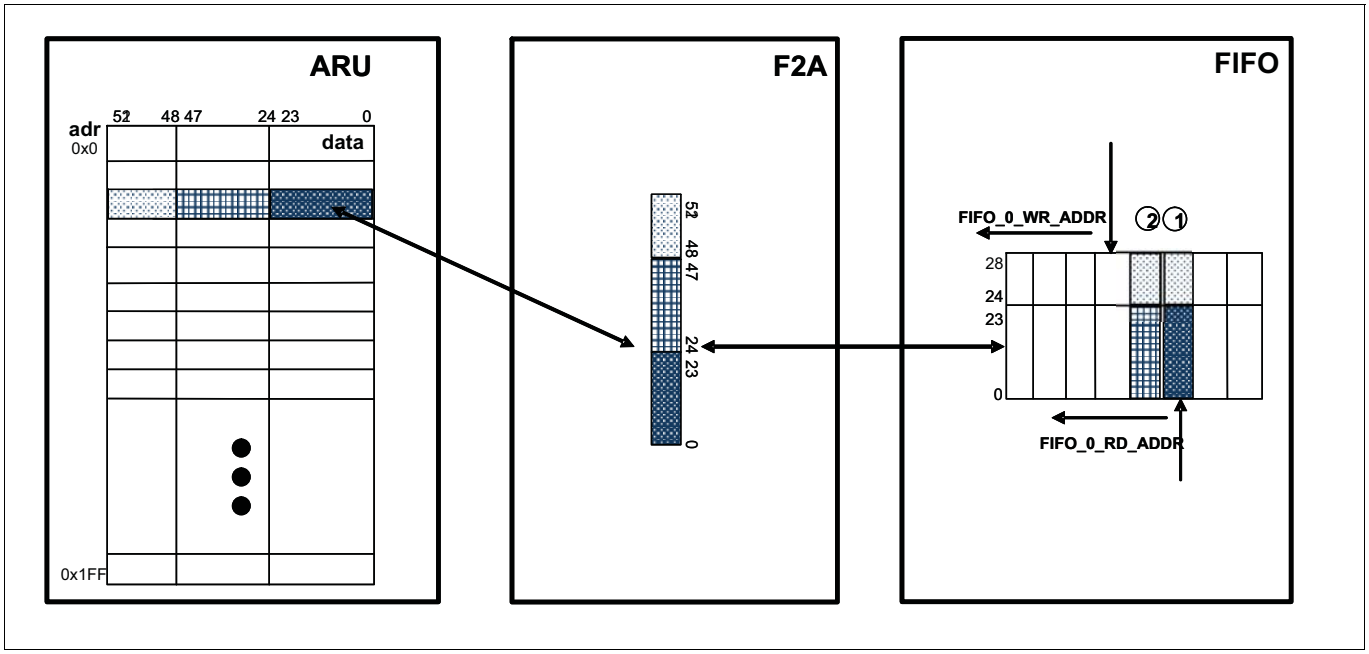

Figure 25 Data transfer of both ARU words between ARU and FIFO

28.9.3 Internal buffer mode

It is possible to use a FIFO channel as a buffer which is accessed only internally from ARU side. To do this, a read and a write stream of the F2A to one FIFO channel are needed. Therefore it is possible to reconfigure the upper 4 F2A streams 4…7 to the lower 4 FIFO channels 0…3 in the following manner:

- F2A stream 4 (+ F2A stream 0) -> FIFO channel 0
- F2A stream 5 (+ F2A stream 1) -> FIFO channel 1
- F2A stream 6 (+ F2A stream 2) -> FIFO channel 2
- F2A stream 7 (+ F2A stream 3) -> FIFO channel 3

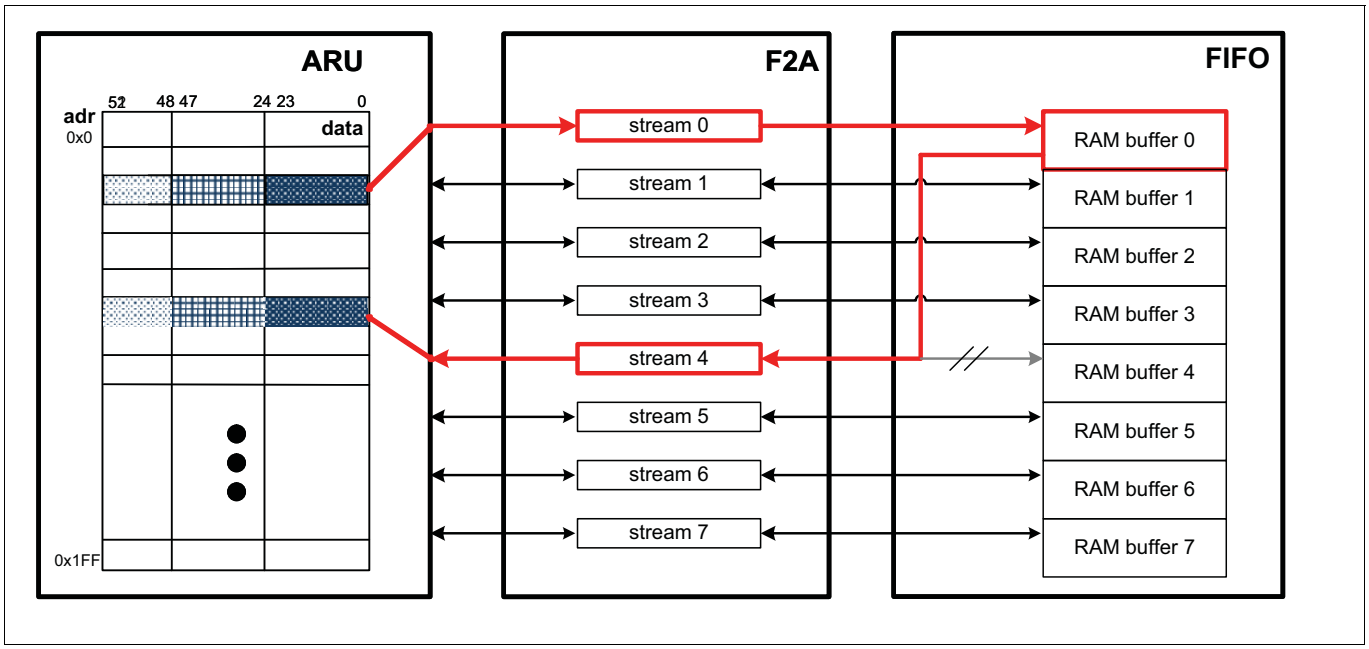

Figure 26 Re-configuration of F2A stream 4 to FIFO channel 0

The configuration of each 4 upper F2A streams can be done separately for each stream in the configuration register **F2A[i]_CTRL**.

Note that the corresponding upper FIFO channel (4…7) cannot be used in this configuration.

28.9.4 F2A Configuration Register Overview

Table 24 F2A Configuration Register Overview

Register name	Description	see Page
F2A[i]_ENABLE	F2Ai stream activation register	99

0	31:8	r	**Reserved** Read as zero, shall be written as zero.

28.10 Clock Management Unit (CMU)

28.10.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM. The CMU consists of three sub-units that generate different clock sources for the whole GTM. The primary clock source for this sub-module is the cluster 0 clock signal cls0_clk which is defined by the value of bit field CLS0_CLK_DIV in the register GTM_CLS_CLK_CFG. **Figure 27** shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) sub-unit provides eight dedicated clock sources for the following GTM modules: TIM, ATOM, TBU, and MON. Each instance of such a module can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The Fixed Clock Generation (FXU) sub-unit generates predefined non-configurable clocks *CMU_FXCLK[y]* (y: 0…4) for the TOM modules and the MON module. The *CMU_FXCLK[y]* signals are derived from the *CMU_GCLK_EN* signal generated by the Global Clock Divider. The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}.

The External Clock Generation (EGU) sub-unit is able to generate up to three chip external clock signals visible at *CMU_ECLK[z]* (z: 0…2) with a duty cycle of about 50%.

The External Clock Generation (EGU) sub-unit is able to generate clock *CMU_CLK8* for module CCM to manage 2 clock domains.

The clock source signals *CMU_CLK[x]* (x: 0…7) and *CMU_FXCLK[y]* are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the *CLS0_CLK* signal.

The four configurable clock signals *CMU_CLK0*, *CMU_CLK1*, *CMU_CLK6* and *CMU_CLK7* are used for the TIM filter counters.

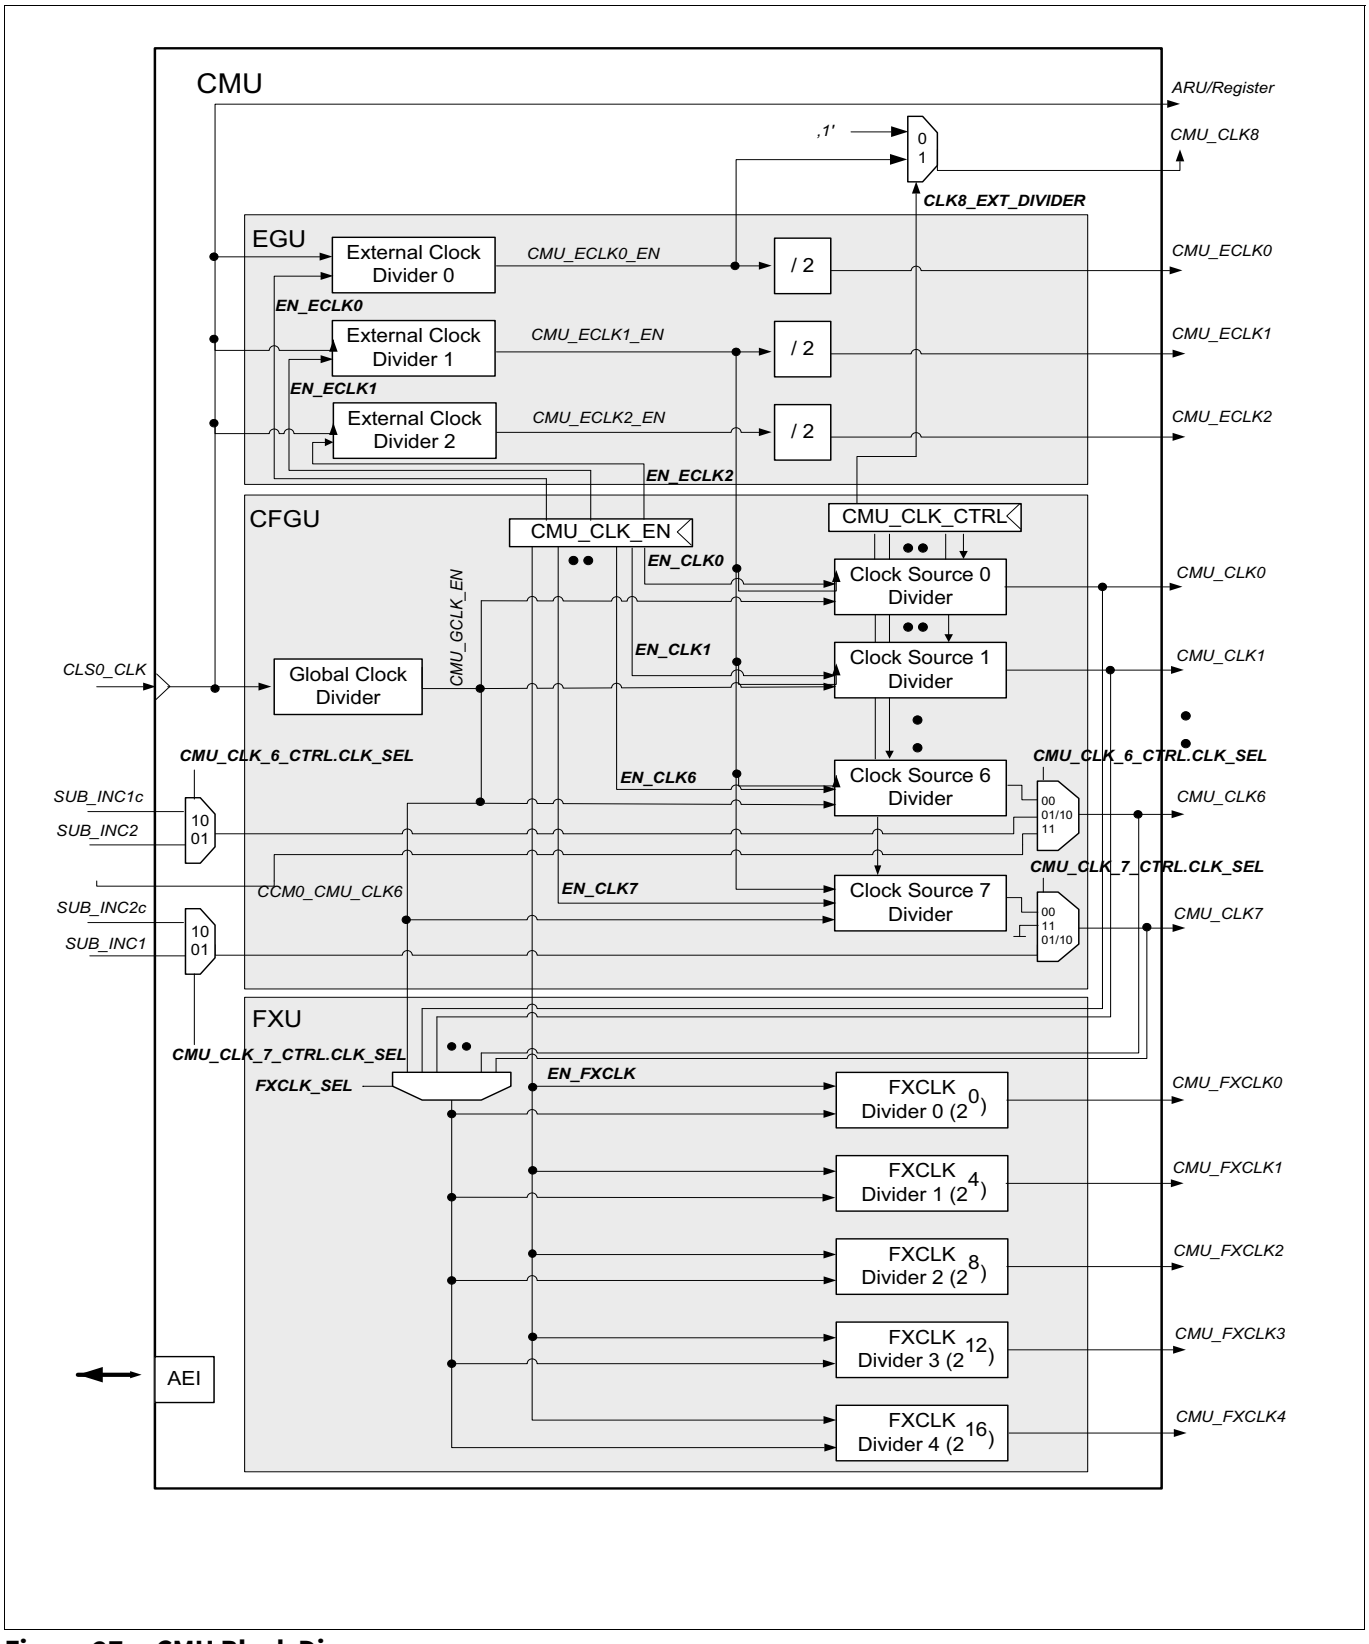

Figure 27 CMU Block Diagram

28.10.2 Global Clock Divider

The sub block Global Clock Divider can be used to divide the CMU primary source signal CLS0_CLK into a common subdivided clock signal.

The divided clock signal of the sub block Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the *CLS0_CLK* signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

$$T_{CMU\_GCLK\_EN}=(Z/N)*T_{CLS0\_CLK}$$

is implemented according the following algorithm

(*Z*: *CMU_GCLK_NUM(23:0)*; *N*: *CMU_GCLK_DEN(23:0)*; *Z,N* >0)

(1) Set remainder (*R*), operand1 (*OP1*) and operand2 (*OP2*) register during INIT-phase (with implicit conversion to signed):

R=Z, OP1=N, OP2=N-Z;

(2) After leaving INIT-phase (at least one *CMU_CLK[x]* has been enabled) the sign of remainder R for each CLS0_*CLK* cycle will be checked:

(3) If *R>0* keep updating remainder and keep *CMU_GCLK_EN='0'*:

R=R-OP1;

(4) If *R<0* update remainder and set *CMU_GCLK_EN='1'*:

R=R-OP2

After at most (*Z/N*+1) subtractions (3) there will be a negative *R* and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder *R* is a measure for the distance to a real *Z/N* clock and will be regarded for the next generated clock enable cycle phase. The new *R* value will be *R=R+(Z-N)*. In the worst case the remainder *R* will sum up to an additional cycle in the generated clock enable period after *Z*-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If *Z* is an integer multiple of *N* no additional cycles will be included for the generated clock enable at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder *R* uses the complement of (*Z-N*).

28.10.3 Configurable Clock Generation sub-unit (CFGU)

The CMU sub-unit CFGU provides up to eight configurable clock divider blocks that divide the common C*MU_GCLK_EN* signal into dedicated enable signals for the GTM sub blocks.

The configuration of the eight different clock signals *CMU_CLK[x]* (x: 0…7) always depends on the configuration of the global clock enable signal *CMU_GCLK_EN*. Additionally, each clock source has its own configuration data, provided by the control register **CMU_CLK_[x]_CTRL (x=0..7)**.

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field **CLK_CNT[x]** of the register **CMU_CLK_[x]_CTRL**.

The frequency *fx = 1/Tx* of the corresponding clock enable signal *CMU_CLK[x]* can be determined by the unsigned representation of **CLK_CNT[x]** of the register **CMU_CLK_[x]_CTRL** in the following way:

$$T_{CMU\_CLK}[x]=(CLK\_CNT[x]+1)*T_{CMU\_GCLK\_EN}$$

The corresponding wave form is shown in **Figure 28**.

Each clock signal *CMU_CLK[x]* can be enabled individually by setting the appropriate bit field **EN_CLK[x]** in the register **CMU_CLK_EN**. Except for *CMU_CLK6* and *CMU_CLK7* individual enabling and disabling is active only if **CLK_SEL** is reset.

Alternatively, clock source six and seven (*CMU_CLK6* and *CMU_CLK7*) may provide the signal *SUB_INC1* and *SUB_INC2* coming from module DPLL as clock enable signal depending on the bit field **CLK_SEL(1:0)** of the register **CMU_CLK_6_CTRL** and on the bit field **CLK_SEL(1:0)** of the register **CMU_CLK_7_CTRL**.

CMU_CLK8 is switched by **CLK8_EXT_DIVIDER** of the register **CMU_CLK_CTRL** between *CLS0_CLK* and *CMU_ECLK0*.

To switch the clock reference CMU_GCLK_EN with *CMU_ECLK1*_EN an input selector are used in all Clock Source Divider. The *CMU_ECLK1*_EN source is enabled by setting the appropriate bit field **CMU[x]_EXT_DIVIDER** in the register **CMU_CLK_CTRL**.

To avoid unexpected behavior of the hardware, the configuration of register **CMU_CLK_[x]_CTRL** and **CMU_CLK_CTRL** can only be changed, when the corresponding clock signal *CMU_CLK[x]* and *CMU_ECLK[1]* is disabled.

Further, any changes to the registers **CMU_GCLK_NUM** and **CMU_GCLK_DEN** can only be performed, when all clock enable signals *CMU_CLK[x]* and the **EN_FXCLK** bit inside the **CMU_CLK_EN** register are disabled.

The clock source signals *CMU_CLK[x]* (x: 0…7) and *CMU_FXCLK[y]* are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the *CLS0_CLK* signal.

The hardware guarantees that all clock signals *CMU_CLK[x]* (x: 0…7), which were enabled simultaneous, are synchronized to each other. Simultaneous enabling does mean that the bits **EN_CLK[x]** in the register **CMU_CLK_EN** are set by the same write access.

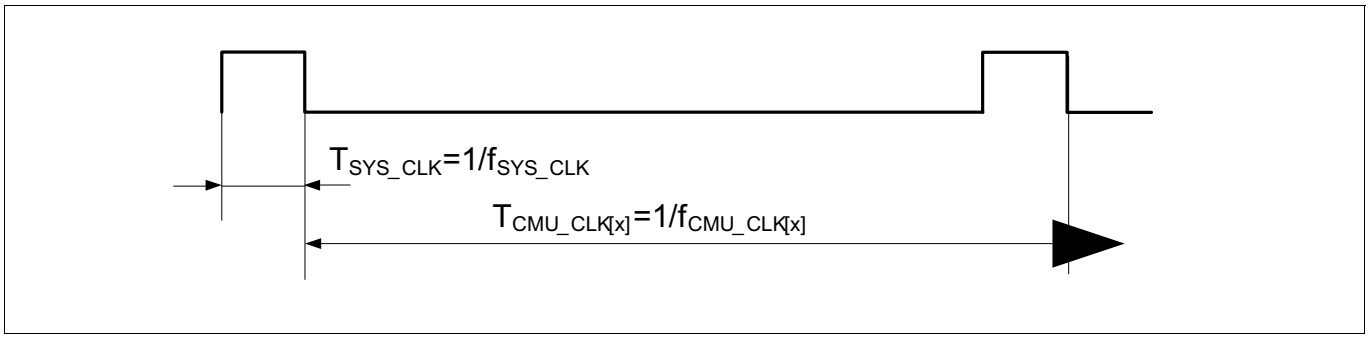

Figure 28 Wave Form of Generated Clock Signal CMU_CLK[x]

28.10.4 Fixed Clock Generation (FXU)

The FXU sub-unit generates fixed clock enables out of the *CMU_GCLK_EN* or one of the eight *CMU_CLK[x]* enable signal depending on the **FXCLK_SEL** bit field of the **CMU_FXCLK_CTRL** register. These clock enables are used for the PWM generation inside the TOM modules.

All clock enables *CMU_FXCLK[y]* can be enabled or disabled simultaneous by setting the appropriate bit field **EN_FXCLK** in the register **CMU_CLK_EN**.

The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}. The signals *CMU_FXCLK[y]* are implemented in form of enable signals for the corresponding registers (see also **Figure 28**)

28.10.5 External Generation Unit (EGU)

The EGU sub-unit generate up to three separate clock output signals *CMU_ECLK[z]* (z: 0…2).

Each of these clock signals is derived from the corresponding External Clock Divider z sub block, which generates a clock signal derived from the GTM input clock *CLS0_CLK*.

In contrast to the signals *CMU_CLK[x]* and *CMU_FXCLK[y]*, which are treated as simple enable signals for the registers, the signals *CMU_ECLK[z]* have a duty cycle of about 50% that is used as a true clock signal for external peripheral components.

To manage a second global frequency CMU_GCLK_EN could be replaced by ECLK[1]_EN for CMU_CLK[x](x:0..7). Also the all-time enabled CMU_CLK8 could be replaced by ECLK[0]_EN.

Each of the external clocks dividers are enabled and disabled by setting the appropriate bit field **EN_ECLK[z]** in the register **CMU_CLK_EN**.

The clock frequencies $f_{CMU\_ECLK[z]} = 1/T_{CMU\_ECLK[z]}$ of the external clocks are controlled with the registers **CMU_ECLK_[z]_NUM** and **CMU_ECLK_[z]_DEN** as follows:

$$T_{CMU\_ECLK}[z] = (ECLK[z]\_NUM / ECLK[z]\_DEN) * T_{CLS0\_CLK}$$

and is implemented according the following algorithm

(*Z:CMU_ECLK_[z]_NUM(23:0); N: CMU_ECLK_[z]_DEN(23:0*); *Z,N >0*; *Z>=N; CMU_ECLK[z]*='0'):

(1) Set remainder (*R*), operand1 (*OP1*) and operand2 (*OP2*) register during INIT-phase (with implicit conversion to signed): *R=Z, OP1=N, OP2=N-Z;*

(2) After leaving INIT-phase (*CMU_ECLK[z]* has been enabled) the sign of remainder R for each *CLS0_CLK* cycle will be checked:

(3) If *R>0* keep updating remainder and keep *CMU_ECLK[z]*: *R=R-OP1;*

(4) If *R<0* update remainder and toggle *CMU_ECLK[z]*: *R=R-OP2*;

After at most (*Z/N*+1) subtractions (3) there will be a negative *R* and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder *R* is a measure for the distance to a real *Z/N* clock and will be regarded for the next generated clock toggle phase. The new *R* value will be *R=R+(Z-N)*. In the worst case the remainder *R* will sum up to an additional cycle in the generated clock toggle period after *Z*-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock toggle. If *Z* is an integer multiple of *N* no additional cycles will be included for the generated clock toggle at all. Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder *R* uses the complement of (*Z-N*).

The default value of the *CMU_ECLK[z]* output is low.

28.10.6 CMU Configuration Register Overview

Table 25 CMU Configuration Register Overview

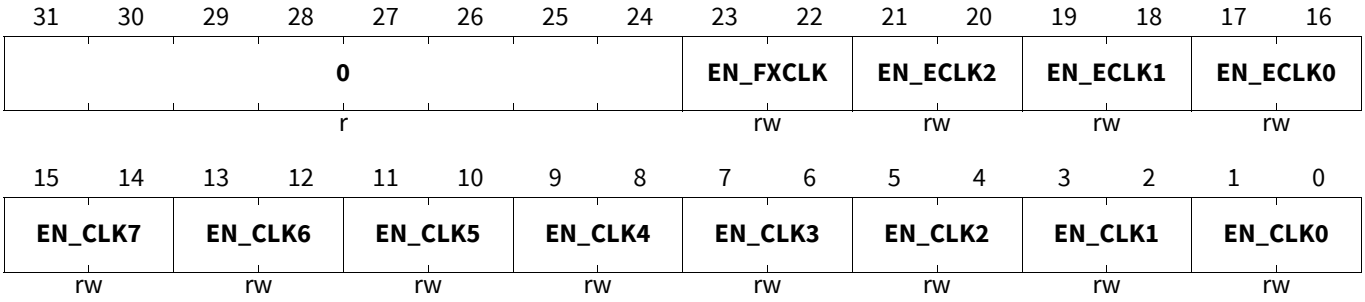
Register Name	Description	see Page
CMU_CLK_EN	CMU clock enable	107
CMU_GCLK_NUM	CMU global clock control numerator	108
CMU_GCLK_DEN	CMU global clock control denominator	108
CMU_CLK_[z]_CTRL	CMU control for clock source z	109
CMU_ECLK_[z]_NUM	CMU external clock z control numerator	110
CMU_ECLK_[z]_DEN	CMU external clock z control denominator	110
CMU_FXCLK_CTRL	CMU control FXCLK sub-unit input clock	111
CMU_GLB_CTRL	CMU synchronizing ARU and clock source	112
CMU_CLK_CTRL	CMU control for clock source selection	113

28.10.7 CMU Configuration Register Description

28.10.7.1 Register CMU_CLK_EN

CMU Clock Enable Register

CMU_CLK_EN
CMU Clock Enable Register **(000300_H)** **Application Reset Value: $0000\ 0000_H$**

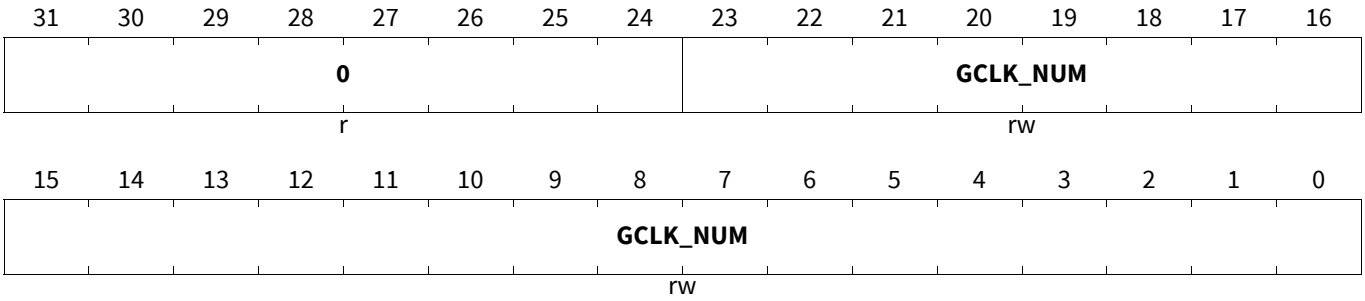


Field	Bits	Type	Description
EN_CLKx (x=0-7)	2*x+1:2*x	rw	**Enable clock source x** Any read access to an **EN_CLK[x]**, **EN_ECLK[z]** or **EN_FXCLK** bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored. Any disabling to **EN_CLK[x]** will be reset internal counters for configurable clocks. 00_B Clock source is disabled (ignore write access) 01_B Disable clock signal and reset internal states 10_B Enable clock signal 11_B Clock signal enabled (ignore write access)
EN_ECLKx (x=0-2)	2*x+17:2*x +16	rw	**Enable ECLK x generation sub-unit** Coding see bit EN_CLKx.
EN_FXCLK	23:22	rw	**Enable all CMU_FXCLK, see bits 1:0** An enable to **EN_FXCLK** from disable state will be reset internal fixed clock counters.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.10.7.2 Register CMU_GCLK_NUM

CMU Global Clock Control Numerator

CMU_GCLK_NUM
CMU Global Clock Control Numerator **(000304_H)** **Application Reset Value: $0000\ 0001_H$**



Field	Bits	Type	Description
GCLK_NUM	23:0	rw	**GCLK_NUM** Value can only be modified when all clock enables **EN_CLK[x]** and the **EN_FXCLK** are disabled. The CMU hardware alters the content of **CMU_GCLK_NUM** and **CMU_GCLK_DEN** automatically to 0x1, if **CMU_GCLK_NUM** is specified less than **CMU_GCLK_DEN** or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register **CMU_GCLK_NUM** followed by a single write to register **CMU_GCLK_DEN**.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.10.7.3 Register CMU_GCLK_DEN

CMU Global Clock Control Denominator

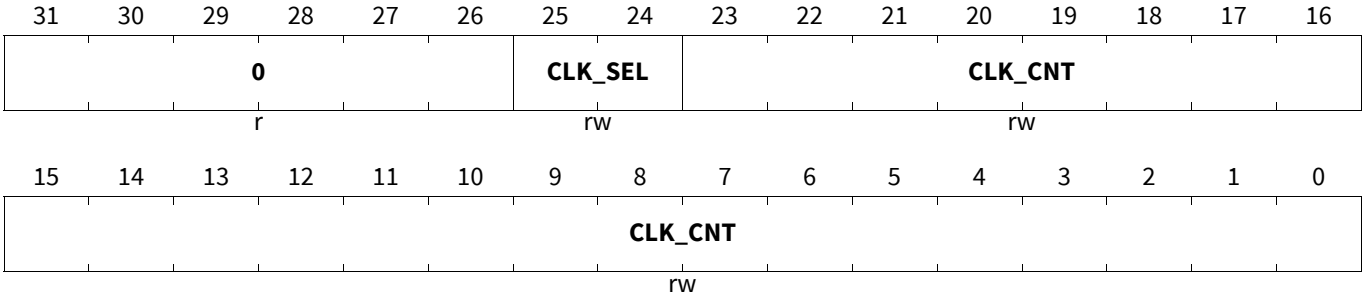
CMU_GCLK_DEN
CMU Global Clock Control Denominator **(000308_H)** **Application Reset Value: $0000\ 0001_H$**

Field	Bits	Type	Description
GCLK_DEN	23:0	rw	**GCLK_DEN** Value can only be modified when all clock enables **EN_CLK[x]** and the **EN_FXCLK** are disabled. The CMU hardware alters the content of **CMU_GCLK_NUM** and **CMU_GCLK_DEN** automatically to 0x1, if **CMU_GCLK_NUM** is specified less than **CMU_GCLK_DEN** or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register **CMU_GCLK_NUM** followed by a single write to register **CMU_GCLK_DEN**.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.10.7.4 Register CMU_CLK_[z]_CTRL

CMU Control for Clock Source z

CMU_CLK_z_CTRL (z=0-7)
CMU Control for Clock Source z **($00030C_H$+z*4)** **Application Reset Value: 0000 0000_H**

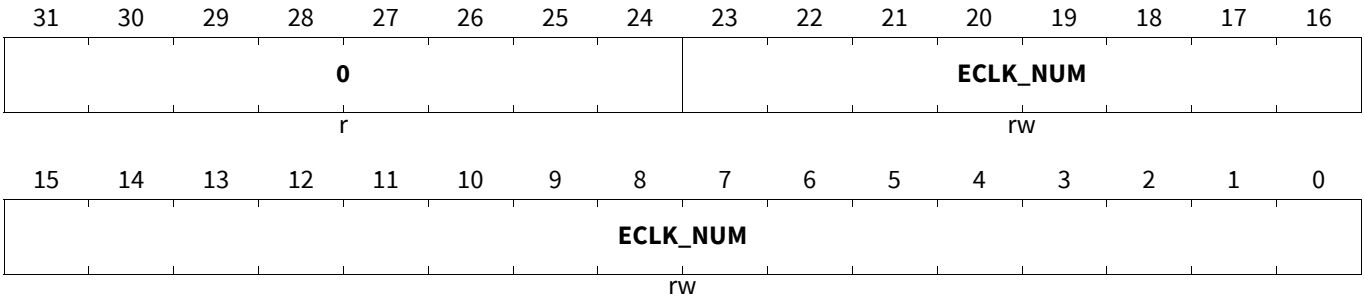


Field	Bits	Type	Description
CLK_CNT	23:0	rw	**Clock count** Defines count value for the clock divider. Value can only be modified when clock enable **EN_CLKz** and **EN_ECLK1** are disabled.
CLK_SEL	25:24	rw	**Clock source selection for CMU_CLKz** Value can only be modified when clock enable **EN_CLKz** and **EN_ECLK1** are disabled. *Note: The existence and interpretation of this bit field depends on z. z>5*
0	31:26	r	**Reserved** Read as zero, shall be written as zero.

28.10.7.5 Register CMU_ECLK_[z]_NUM

CMU External Clock z Control Numerator

CMU_ECLK_z_NUM (z=0-2)
CMU External Clock z Control Numerator (00032C$_H$+z*8) Application Reset Value: 0000 0001$_H$



Field	Bits	Type	Description
ECLK_NUM	23:0	rw	**ECLK_NUM** Numerator for external clock divider. Defines numerator of the fractional divider. *Note: Value can only be modified when clock enable **EN_ECLK[z]** disabled.* *Note: The CMU hardware alters the content of **CMU_ECLK_[z]_NUM** and **CMU_ECLK_[z]_DEN** automatically to 0x1, if **CMU_ECLK_[z]_NUM** is specified less than **CMU_ECLK_[z]_DEN** or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register **CMU_ECLK_[z]_NUM** followed by a single write to register **CMU_ECLK_[z]_DEN**.*
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.10.7.6 Register CMU_ECLK_[z]_DEN

CMU External Clock z Control Denominator

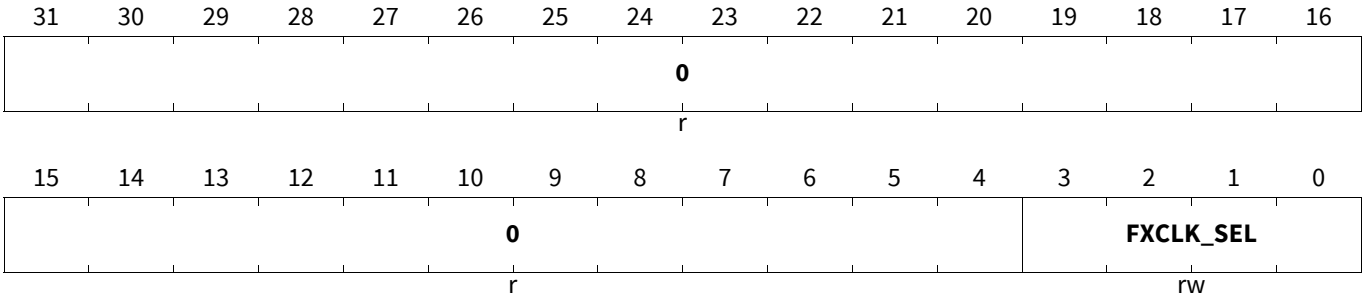
CMU_ECLK_z_DEN (z=0-2)
CMU External Clock z Control Denominator (000330$_H$+z*8) Application Reset Value: 0000 0001$_H$

Field	Bits	Type	Description
ECLK_DEN	23:0	rw	**ECLK_DEN** Denominator for external clock divider. Defines denominator of the fractional divider *Note: Value can only be modified when clock enable **EN_ECLK[z]** disabled.* *Note: The CMU hardware alters the content of **CMU_ECLK_[z]_NUM** and **CMU_ECLK_[z]_DEN** automatically to 0x1, if **CMU_ECLK_[z]_NUM** is specified less than **CMU_ECLK_[z]_DEN** or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register **CMU_ECLK_[z]_NUM** followed by a single write to register **CMU_ECLK_[z]_DEN**.*
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.10.7.7 Register CMU_FXCLK_CTRL

CMU Control FXCLK Sub-Unit Input Clock

CMU_FXCLK_CTRL
CMU Control FXCLK Sub-Unit Input Clock (000344$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
FXCLK_SEL	3:0	rw	**Input clock selection for EN_FXCLK line** This value can only be written when the CMU_FXCLK generation is disabled. See bits 23..22 in register **CMU_CLK_EN**. Other values for FXCLK_SEL are reserved and should not be used, but they behave like FXCLK_SEL = 0. 0_H CMU_GCLK_EN selected 1_H CMU_CLK0 selected 2_H CMU_CLK1 selected 3_H CMU_CLK2 selected 4_H CMU_CLK3 selected 5_H CMU_CLK4 selected 6_H CMU_CLK5 selected 7_H CMU_CLK6 selected 8_H CMU_CLK7 selected CMU_CLK7 selected
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.10.7.8 Register CMU_GLB_CTRL

CMU Synchronizing ARU and Clock Source

CMU_GLB_CTRL
CMU Synchronizing ARU and Clock Source (000348$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															ARU_ADDR_RSTGLB
r															rw

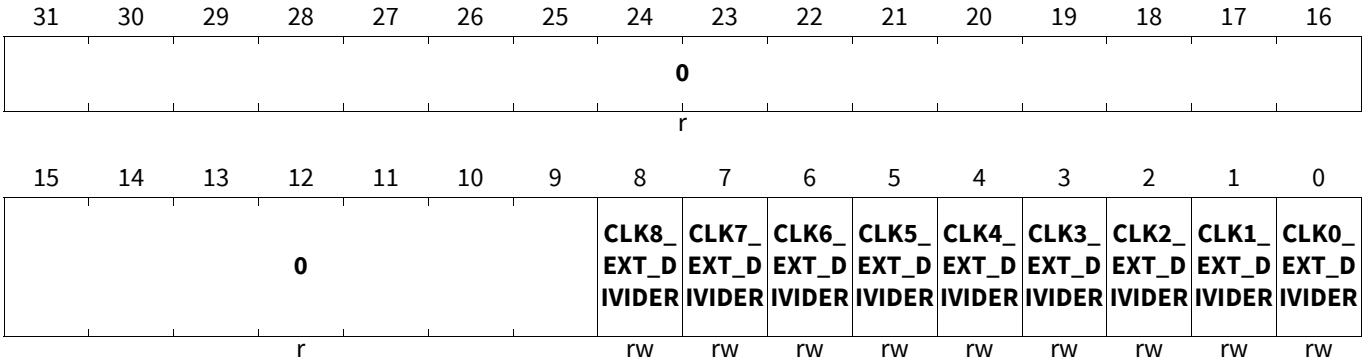
Field	Bits	Type	Description
ARU_ADDR_RSTGLB	0	rw	**Reset ARU caddr counter and ARU dynamic route counter** Writing value 1 to this bit field results in a request to reset the ARU caddr counter and ARU dynamic route counter. The next following write access to register **CMU_CLK_EN** applies the ARU caddr counter reset, ARU dynamic route counter reset and resets this bit. This feature can be used to synchronize the ARU round trip time to the CMU clocks. This bit is write protected. Before writing to this bit set bit RF_PROT of register **GTM_CTRL** to 0.

Field	Bits	Type	Description
0	31:1	r	**Reserved** Read as zero, shall be written as zero

28.10.7.9 Register CMU_CLK_CTRL

CMU Control for Clock Source Selection

CMU_CLK_CTRL
CMU Control for Clock Source Selection **(00034C$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLK0_EXT_DIVIDER	0	rw	**Clock source selection for CMU_CLK_0_CTRL** Value can only be modified when clock enable **EN_CLK0** and **EN_ECLK1** are disabled. 0_B Use Clock Source CMU_GCLK_EN 1_B Use Clock Source CMU_ECLK1
CLK1_EXT_DIVIDER	1	rw	**Clock source selection for CMU_CLK_1_CTRL** Value can only be modified when clock enable **EN_CLK1** and **EN_ECLK1** are disabled.
CLK2_EXT_DIVIDER	2	rw	**Clock source selection for CMU_CLK_2_CTRL** Value can only be modified when clock enable **EN_CLK2** and **EN_ECLK1** are disabled.
CLK3_EXT_DIVIDER	3	rw	**Clock source selection for CMU_CLK_3_CTRL** Value can only be modified when clock enable **EN_CLK3** and **EN_ECLK1** are disabled.
CLK4_EXT_DIVIDER	4	rw	**Clock source selection for CMU_CLK_4_CTRL** Value can only be modified when clock enable **EN_CLK4** and **EN_ECLK1** are disabled.
CLK5_EXT_DIVIDER	5	rw	**Clock source selection for CMU_CLK_5_CTRL** Value can only be modified when clock enable **EN_CLK5** and **EN_ECLK1** are disabled.
CLK6_EXT_DIVIDER	6	rw	**Clock source selection for CMU_CLK_6_CTRL** Value can only be modified when clock enable **EN_CLK6** and **EN_ECLK1** are disabled.

Field	Bits	Type	Description
CLK7_EXT_DIVIDER	7	rw	**Clock source selection for CMU_CLK_7_CTRL** Value can only be modified when clock enable **EN_CLK7** and **EN_ECLK1** are disabled.
CLK8_EXT_DIVIDER	8	rw	**Clock source selection for CMU_CLK8** Value can only be modified when **EN_ECLK0** is disabled. 0_B Use Clock Source CLS0_CLK 1_B Use Clock Source CMU_ECLK0
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

28.11 Cluster Configuration Module (CCM)

28.11.1 Overview

As already mentioned in the chapter “GTM architecture”, each submodule of the GTM is aligned explicitly to a cluster. The Cluster Configuration Module (CCM) enables the configuration of several cluster specific options namely

- cluster's clock frequency,
- module clock gating,
- Status observation of the cluster's MCS bus master (AEM),
- address range protection, and
- global architecture configuration.

The register **CCM[i]_CFG** allows disabling the system clock signal for unused sub modules of the i-th cluster. The registers **CCM[i]_CMU_CLK_CFG** and **CCM[i]_CMU_FXCLK_CFG** allows the configuration of various cluster clock frequencies.

Figure 29 shows important details about the wiring of the cluster's local clock signals.

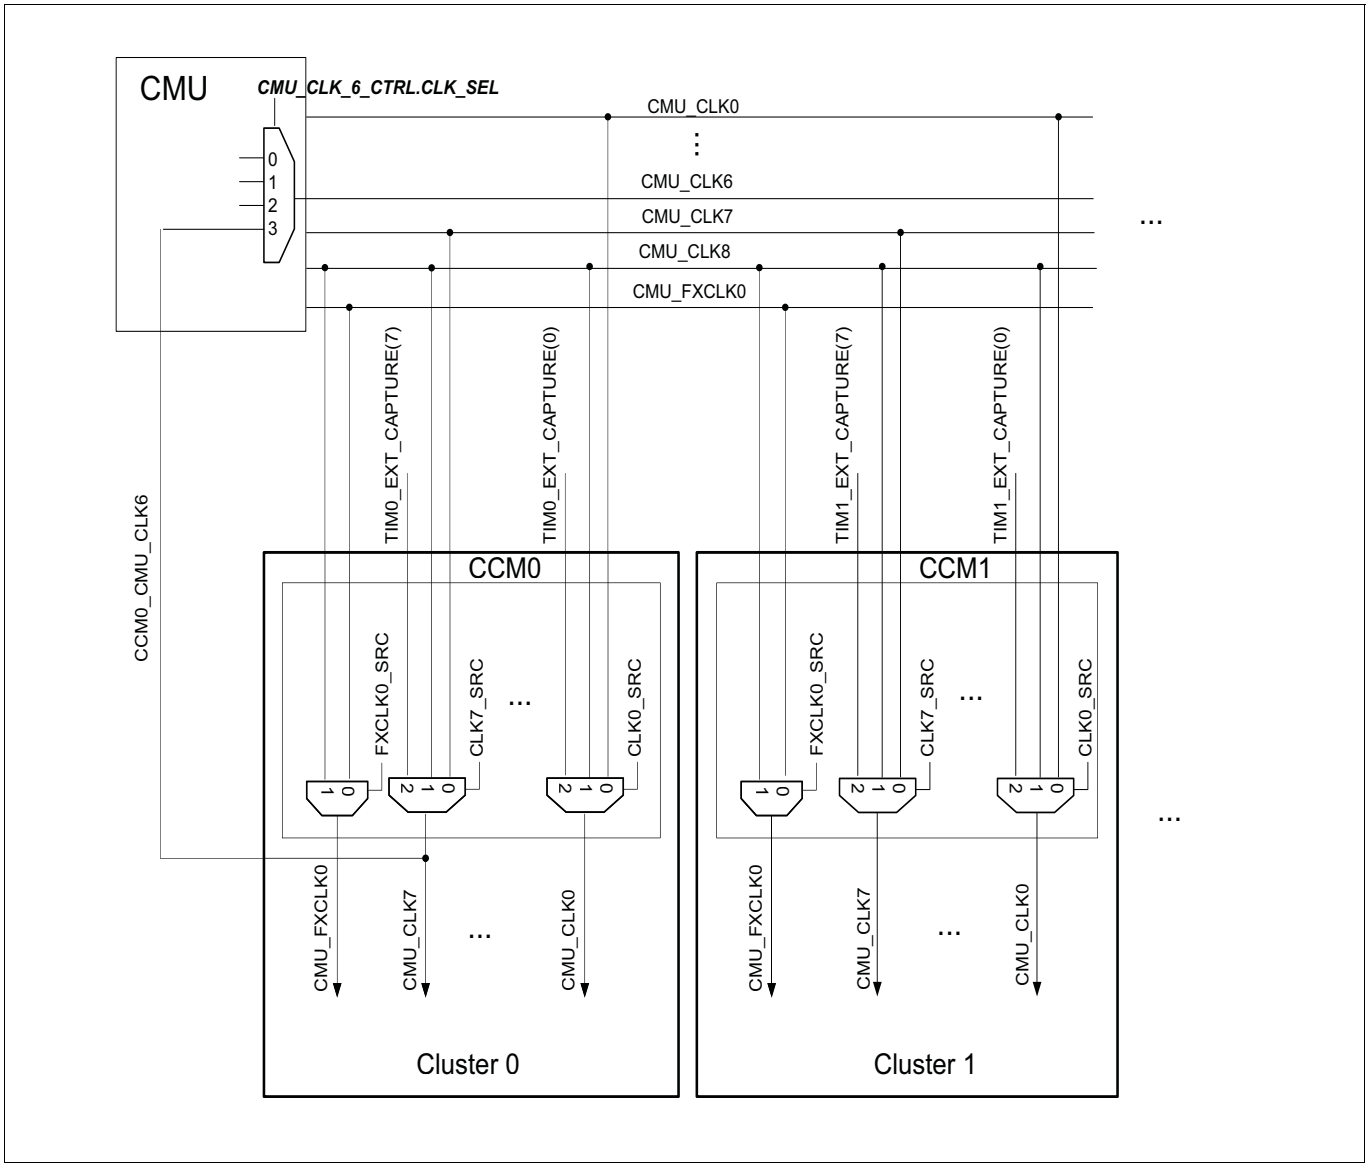


Figure 29 Cluster Clock Signal Wiring

The register **CCM[i]_AEIM_STA** captures the address and the reason of the first invalid AEIM bus master access of the cluster's MCS module.

The registers **CCM[i]_HW_CONF**, **CCM[i]_AUX_IN_SRC**, **CCM[i]_EXT_CAP_EN**, **CCM[i]_TOM_OUT**, and **CCM[i]_ATOM_OUT** are global status and configuration registers that are mirrored from the group of TOP-Level registers. The intention of these registers is to bring up cluster specific configuration registers into the address space of the bus master of the cluster's MCS module.

28.11.2 Address Range Protection

The CCM also provides up to NARP so called address range protectors (ARPs), where the number NARP depends on the actual device configuration (defined in device specific appendix). An ARP can be used to define a configurable write protected address range in order to support enhanced safety features. The address width of and ARP is also device dependent and it is determined by the parameter AAW as defined in device specific appendix.

The protected address range is mapped to the address range of the cluster's MCS RAM port.

Each ARP z (with z = 0…NARP-1) can be configured by the registers **CCM[i]_ARP[z]_CTRL** and **CCM[i]_ARP[z]_PROT**, where the register **CCM[i]_ARP[z]_CTRL** enables to configure the size and base address offset for an ARP and the register **CCM[i]_ARP[z]_PROT** configures, that an MCS channel x with a set bit field **WPROTx** cannot write to the corresponding z-th ARP. Whenever an MCS channel x is writing to an ARP that does not allow a write access from channel x by the configuration register **CCM[i]_ARP[z]_PROT**, the write access is discard. The bit field **WPROT_AEI** of register **CCM[i]_ARP[z]_CTRL** allows to configure if a CPU write access (via AEI slave interface) to the z-th ARP is protected. If the CPU wants to write to the z-th ARP while **WPROT_AEI** is set, the write access will be discard and the AEI status signal will signalize an invalid module access.

Considering the size and base address of an ARP, it should be noted that the configuration possibilities are limited. Details about the configuration can be found in the register description of **MCS[i]_ARP[z]_CTRL**.

The bit field **DIS_PROT** of register **CCM[i]_ARP[z]_CTRL** changes the meaning of an ARP configuration in a way that it explicitly allows an MCS channel x with a set bit field **WPROTx** to write to the z-th ARP. Accordingly, if the bit **DIS_PROT** is set while the bit **WPROT_AEI** is also set in the register **CCM[i]_ARP[z]_CTRL**, the z-th ARP explicitly allows a write access from the CPU to the z-th ARP. A meaningful application of an ARP z with a set bit field **DIS_PROT** for an MCS channel x has another ARP with a surrounding wider address range that is defining a write protection for MCS channel x and some other MCS channels.

Since the address range of an ARP can surround another ARP it is possible to configure contradictory conditions for MCS channels or the CPU within the overlapping area (e.g. if ARP y surrounds ARP z and ARP y allows a write access for an MCS channel x but ARP z prohibits a write access for MCS channel x). In order to resolve this ambiguity, the following rule is defined: A write protection for a specific address c concerning MCS channel x (the CPU) is active, if and only if, address c is covered by at least one ARP with a cleared bit **DIS_PROT** and a set bit **WPROTx** (**WPROT_AEI**) and there exists no ARP covering address c with a set bit field **DIS_PROT** and a set bit field **WPROTx** (**WPROT_AEI**).

28.11.3 CCM Configuration Register Overview

Table 26 CCM Configuration Register Overview

Register name	Description	see Page
CCM[i]_PROT	CCMi Protection Register	119
CCM[i]_CFG	CCMi Configuration Register	119

CLS_PROT	0	rw	**Cluster Protection** 0_B Write protection of cluster configuration registers is disabled 1_B Write protection of cluster configuration registers is enabled
0	31:1	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.2 Register CCM[i]_CFG

CCMi Configuration Register

NOTE: The module specific clock enable registers (bit field **EN_***) are only implemented if the corresponding module is available in the i-th cluster.

NOTE: For the Clusters greater than 4, (only 100MHz capable), the only allowed settings for the CLS_CLK_DIV are 00 and 10 (clock divider 2).

CCMi_CFG (i=0-11)
CCMi Configuration Register **($0E21F8_H$+i*200_H)** **Application Reset Value: XXXX $XXXX_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
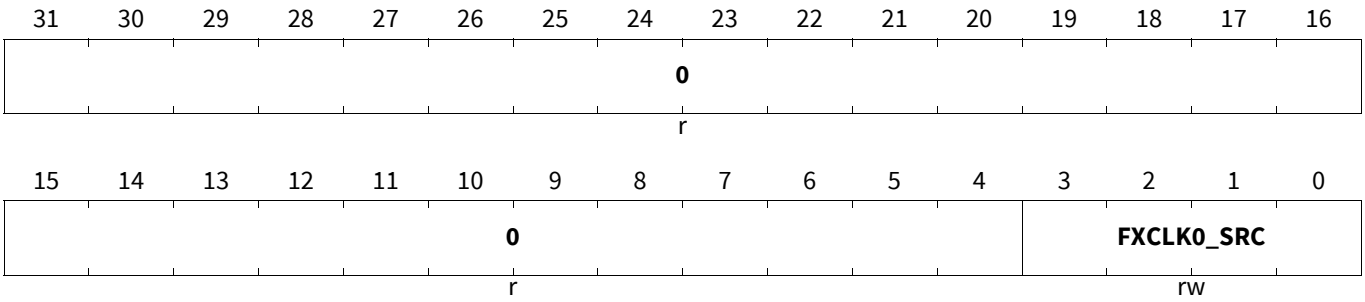
0	31:30, 27:26, 23:22, 19:18, 15:14, 11:10, 7:6, 3:2	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.4 Register CCM[i]_CMU_FXCLK_CFG

CCMi CMU Fixed Clock Configuration Register

CCMi_CMU_FXCLK_CFG (i=0-11)

CCMi CMU Fixed Clock Configuration Register(0E21F4$_H$+i*200$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
FXCLK0_SRC	3:0	rw	**Fixed clock 0 source signal selector** Bit field values that are not mentioned above are reserved. These bits are only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared. 0_H Use CMU_FXCLK0 signal of CMU as CMU_FXCLK0 signal within cluster 1_H Use CMU_CLK8 signal of CMU as CMU_FXCLK0 signal within cluster
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.5 Register CCM[i]_AEIM_STA

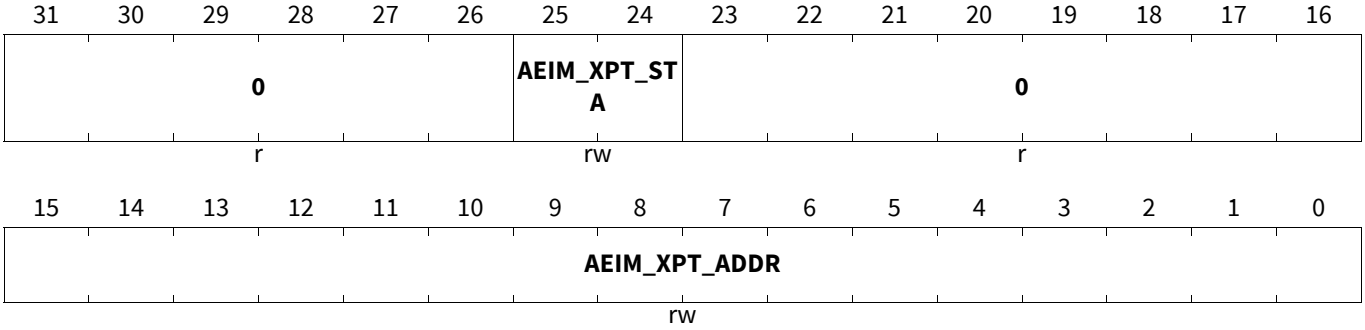
CCMi MCS Bus Master Status Register

Note: Only the first invalid AEIM bus master access of the MCS is updating this register with the invalid AEIM address (bit field AEIM_XPT_ADDR) and the reason of the invalid access (bit field AEIM_XPT_STA). A write access to this register (independent of the written data) always resets the bit fields AEIM_XPT_STA and AEIM_XPT_ADDR, and the next invalid AEIM access is captured by this register, again.

Note: If the i-th cluster does not provide an MCS module, this register is not available.

CCMi_AEIM_STA (i=0-11)

CCMi MCS Bus Master Status Register (0E21D8$_H$+i*200$_H$) Application Reset Value: 0000 0000$_H$



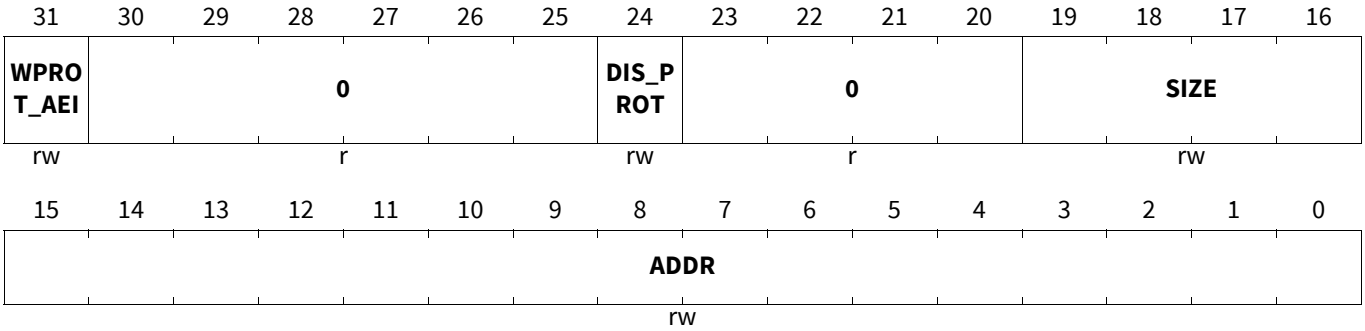
Field	Bits	Type	Description
AEIM_XPT_ADDR	15:0	rw	**Exception Address** Invalid bus master (AEIM) address of MCS module.
AEIM_XPT_STA	25:24	rw	**AEIM exception status** 00_B No invalid MCS bus master access occurred 01_B Invalid byte addressing of MCS bus master access 10_B Illegal module access of MCS bus master access 11_B Invalid MCS bus master access to an unsupported address
0	23:16, 31:26	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.6 Register CCM[i]_ARP[z]_CTRL

CCM0 Address Range Protector z Control Register

CCMi_ARPz_CTRL (i=0-9;z=0-9)

CCMi Address Range Protector z Control Register(0E2000$_H$+i*200$_H$+z*8) Application Reset Value: 0003 0000$_H$



Field	Bits	Type	Description
ADDR	15:0	rw	**ARP base address** Base address for address range protector z. Only the bits 5 to AAW-1 of this bit field are implemented as registers. The bits AAW to 15 are reserved bits and always read and written as zeros. The bits 0 and 1 are functionally used for the definition of an ARP but they are always read and written as zeros. The actual base address for a protected address range is only defined by the upper AAW-(**SIZE**+2) bits (bit position 2+**SIZE** to bit position AAW-1) of bit field **ADDR**. The lower **SIZE**+2 bits (bit 0 to **SIZE**+1) are ignored for the address calculation and assumed as zeros. This bit field is only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared.
SIZE	19:16	rw	**Size of ARP** Size of memory range protector z. The actual size of a protected memory range is defined as 2^{SIZE} address locations, whereas the bit field **SIZE** is interpreted as an unsigned integer number. This bit field is only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared.
DIS_PROT	24	rw	**Disable ARP protection** This bit field is only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared. 0_B Bit WPROTx (WPROT_AEI) defines write protection for selected address range 1_B Bit WPROTx (WPROT_AEI) explicitly allows write access to selected address range
WPROT_AEI	31	rw	**AEI slave write protection** The address range interval that is protected by this ARP can be calculated as [(**ADDR** AND NOT 4*(2^{SIZE}-1)); (**ADDR** AND NOT 4*(2^{SIZE}-1)) + 4*(2^{SIZE}-1)], assuming a byte-wise addressing, an unsigned integer representation for the bit fields **SIZE** and **ADDR**. NOT and AND are bitwise logical operators. The incrementation interval for neighboring memory locations is always 4. This bit field is only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared. 0_B Write protection to address range from AEI slave is disabled 1_B Write protection to address range from AEI slave is enabled
0	23:20, 30:25	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.7 Register CCM[i]_ARP[z]_PROT

CCM0 Address Range Protector z Protection Register

Only the first T bits of this register (bit 0 to T-1) are functionally implemented. The other bits (bit T to 31) are reserved bits. Parameter T reflects the number of available MCS channels in the cluster's MCS module.
These bit fields of this register are only writable if bit field **CLS_PROT** of register **CCM[i]_PROT** is cleared.

The meaning of the bit fields **WPROTx** can be changed by the bit field **DIS_PROT** of register **CCM[i]_ARP[z]_CTRL**.

CCMi_ARPz_PROT (i=0-9;z=0-9)
CCMi Address Range Protector z Protection Register($0E2004_H$+i*200_H+z*8) Application Reset Value: 0000 0000_H

r	r	r	r	r			r	r			r	r	r	r	r

Field	Bits	Type	Description
GRSTEN	0	r	**Global Reset Enable** 0_B Global GTM reset register disabled 1_B Global GTM reset register enabled
BRIDGE_MODE_RST	1	r	**Bridge mode after reset** 0_B Bridge starts in synchronous mode after reset 1_B Bridge starts in asynchronous mode after reset
SYNC_INPUT_REG	2	r	**Additional pipelined stage in synchronous bridge mode** *Note: this register is only relevant (if existing) for synchronous bridge mode* 0_B No additional pipelined stage implemented. 1_B Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
CFG_CLOCK_RATE	3	r	**Clocks per ARU transfer** *Note: This value defines also the availability of configuration bits in register GTM_CLS_CLK_CFG.* If CFG_CLOCK_RATE=0, only the values 00_B and 01_B are valid for bit fields CLS[x]x_CLK_DIV. If CFG_CLOCK_RATE=1, only the values 00_B, 01_B and 10_B are valid for bit fields CLS[x]x_CLK_DIV. 0_B Each system clock an ARU transfer is scheduled 1_B Each second system clock an ARU transfer is scheduled. ARU transfer rate is half the system clock frequency.
ATOM_OUT_RST	4	r	**ATOM_OUT reset level** *Note: This value represents the ATOM output level after reset. The inverse value of this bit is the reset value of bit SL in all ATOM channels.* 0_B ATOM_OUT reset level is '0' 1_B ATOM_OUT reset level is '1'
ATOM_TRIG_CHAIN	7:5	r	**ATOM trigger chain length without synchronization register** It defines after which ATOM instance count a synchronization register is introduced into trigger chain (after ATOM_TRIG_<i> output if instance i and ATOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance, a synchronization register is placed.
TOM_OUT_RST	8	r	**TOM_OUT reset level** *Note: This value represents the TOM output level after reset. The inverse value of this bit is the reset value of bit SL in all TOM channels.* 0_B TOM_OUT reset level is '0' 1_B TOM_OUT reset level is '1'

Field	Bits	Type	Description
TOM_TRIG_CHAIN	11:9	r	**TOM trigger chain length without synchronization register** It defines after which TOM instance count a synchronization register is introduced into trigger chain (after TOM_TRIG_<i> output if instance i and TOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance, a synchronization register is placed.
RAM_INIT_RST	12	r	**RAM initialization from reset** 0_B RAM is not initialized after reset 1_B RAM is initialized after reset
ERM	13	r	**Enable RAM1 MSB for available MCS modules** *Note: The bit reflects the state of the configuration parameter ERM mentioned in the specification of MCFG.* 0_B MSB of MCS RAM1 address not used 1_B MSB of MCS RAM1 address used
ARU_CONNECT_CONFIG	14	r	**Defines number of parallel ARU ports** 0_B Two ARU ports available (two independent counter) 1_B One ARU port available
IRQ_MODE_LEVEL	16	r	**IRQ_MODE_LEVEL** 0_B Level mode not available 1_B Level mode available
IRQ_MODE_PULSE	17	r	**IRQ_MODE_PULSE** 0_B Pulse mode not available 1_B Pulse mode available
IRQ_MODE_PULSE_NOTIFY	18	r	**IRQ_MODE_PULSE_NOTIFY** 0_B Pulse notify mode not available 1_B Pulse notify mode available
IRQ_MODE_SINGLE_PULSE	19	r	**IRQ_MODE_SINGLE_PULSE** 0_B Single pulse mode not available 1_B Single pulse mode available
ATOM_TRIG_INTCHAIN	23:20	r	**ATOM internal trigger chain length without synchronization register** ATOM internal trigger chain length without synchronization register It defines after which ATOM channel count a synchronization register is introduced into trigger chain. Valid values are 1 to 8. 4 means that in channel 4 of the atom instances a synchronization register is placed.
TOM_TRIG_INTCHAIN	28:24	r	**TOM internal trigger chain length without synchronization register** It defines after which TOM channel count a synchronization register is introduced into trigger chain. Valid values are 1 to 16. 8 means that in channel 8 of the TOM instances, a synchronization register is placed.
INT_CLK_EN_GEN	29	r	**Internal clock enable generation** 0_B GTM external clock enable signals in use 1_B GTM internal clock enable signals in use

Field	Bits	Type	Description
0	15, 31:30	r	**Reserved** Read as zero, shall be written as zero.

28.11.4.9 Register CCM[i]_TIM_AUX_IN_SRC

CCMi TIM Module AUX_IN Source Selection Register

CCMi_TIM_AUX_IN_SRC (i=0-11)

28.12 Time Base Unit (TBU)

28.12.1 Overview

The Time Base Unit TBU provides common time bases for the GTM. The TBU sub-module is organized in channels, where the number of channels is device dependent. There are up to four channels implemented inside the TBU. The time base register **TBU_CH0_BASE** of TBU channel 0 is 27 bits wide and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signal *TBU_TS0*. The two TBU channels 1 and 2 have a time base register **TBU_CH[y]_BASE** (y: 1, 2) of 24 bit length. The time base register value *TBU_TS[y]* is provided to subsequent sub-modules of the GTM.

The time base register of TBU channel 3 **TBU_CH3_BASE** is 24 bit wide. It used as a modulo counter by **TBU_CH3_BASE_MARK** to get a relative angle clock to **TBU_CH[y]_BASE**. The absolute angle clock value for the current **TBU_CH3_BASE** is captured in **TBU_CH3_BASE_CAPTURE**.

TBU_CH[y]_BASE = TBU_CH3_BASE_CAPTURE + **... + TBU_CH3_BASE*TBU_CH3_BASE_MARK**

DIRy: direction value for time base y (y:1…2)

0 up counter

1 down counter

Note: The right-hand sum is limited to 24 bit.

The *TBU_UP[y]* (y: 1…2) signals are set to high for a single SYS_CLK period, whenever the corresponding signal *TBU_TS[y]* (y: 1…2) is getting updated. The signal *TBU_UP0_L* is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS0x is getting updated and *TBU_UP0_H* is set to high for a single SYS_CLK period, whenever the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register **TBU_CHEN**. **Figure 30** shows a block diagram of the Time Base Unit.

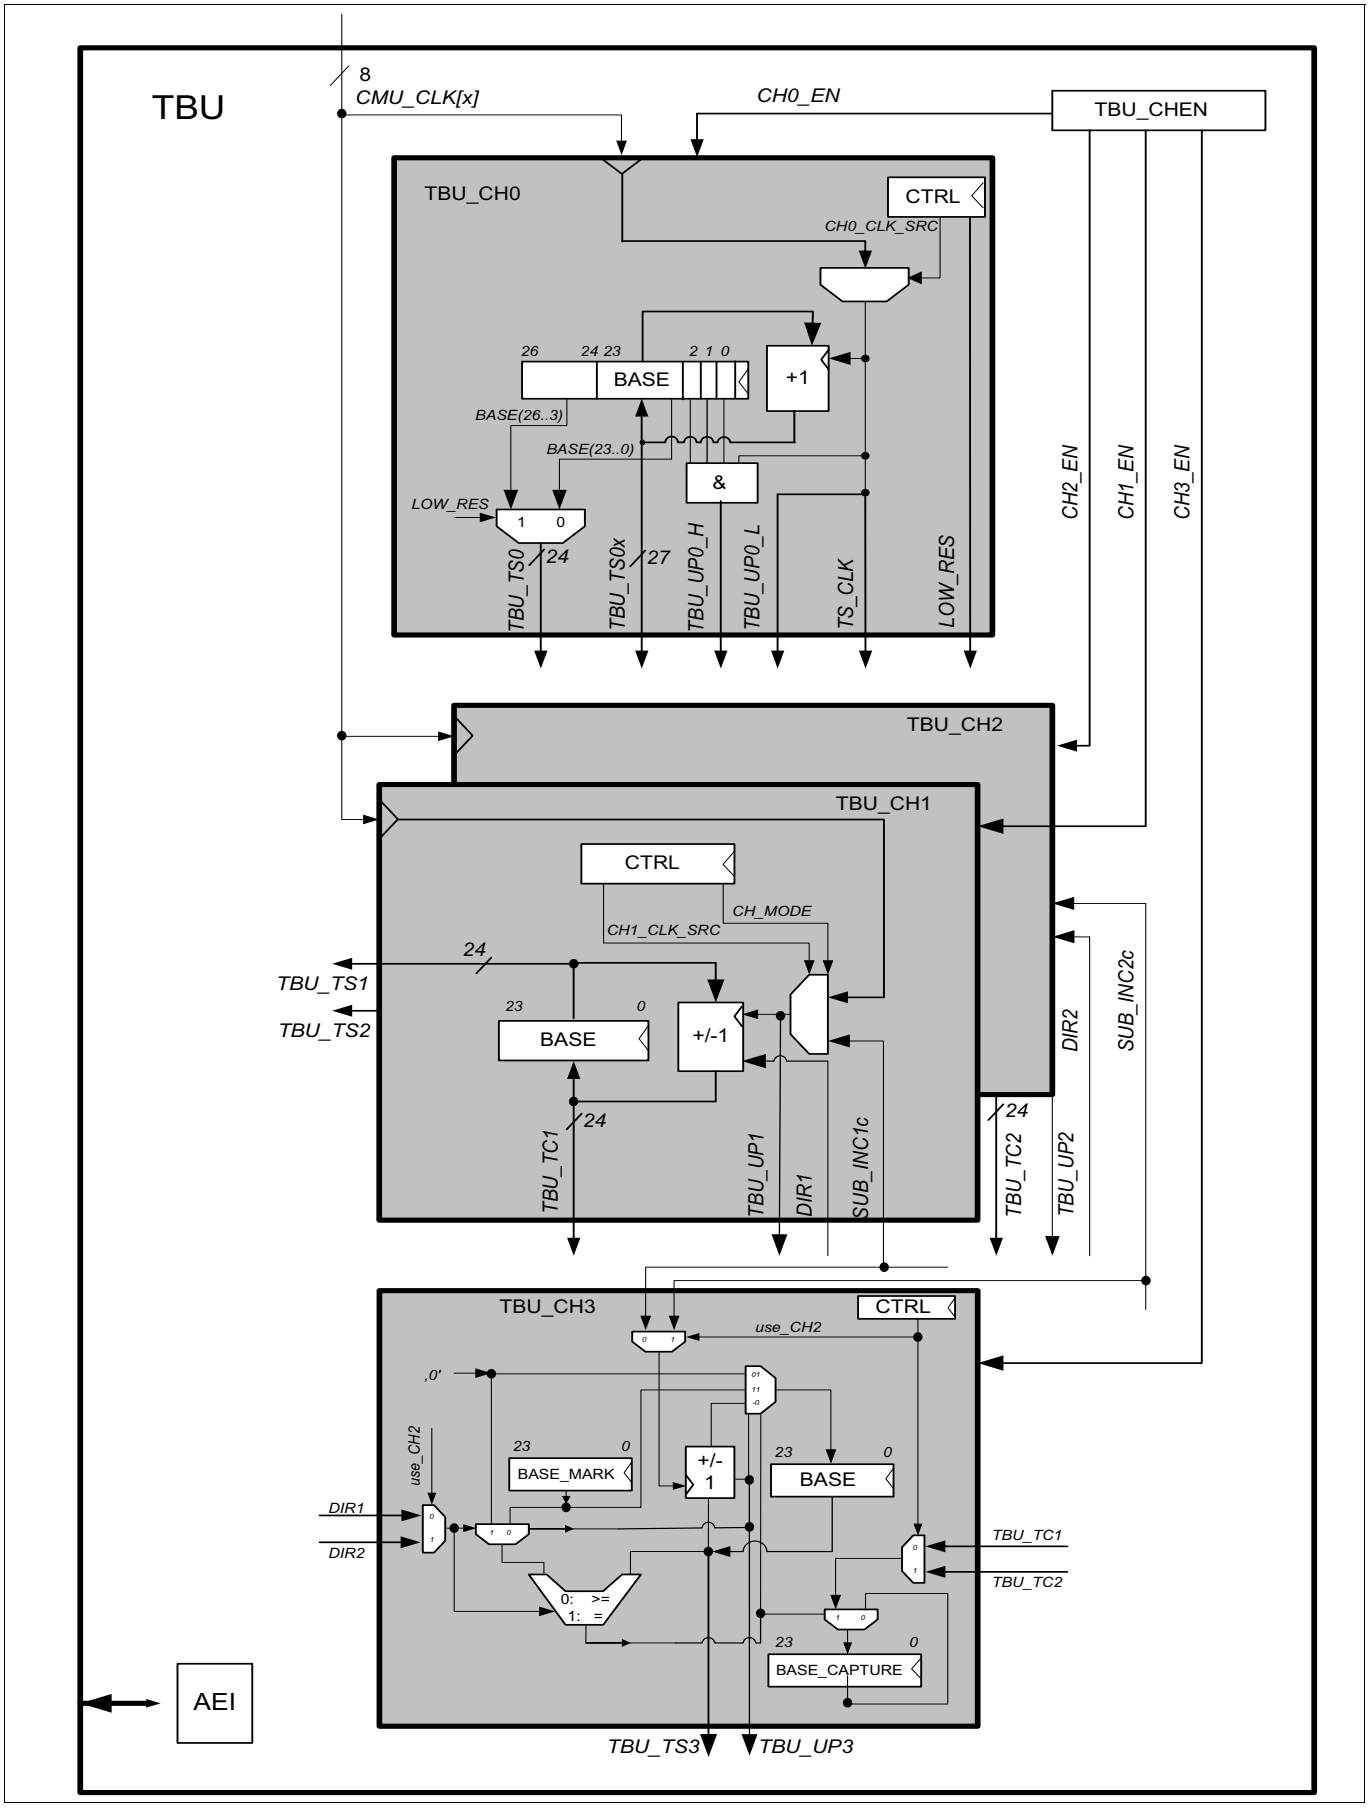

Figure 30 TBU Block Diagram

Dependent on the device a third TBU channel exists which offers the same functionality as time base channel 1.

The configuration of the independent time base channels TBU_CH[z]_BASE is done via the AEI interface. The TBU channel 0 to 2 may select one of the eight *CMU_CLK[x]* (x: 0…7) signals coming from the CMU sub-module.

For TBU channels 1 and 2 an additional clock signal *SUB_INC[y]c* (y: 1, 2) coming from the DPLL can be selected as input clock for the TBU_CH[y]_BASE. This clock in combination with the *DIR[y]* signals determines the counter direction of the TBU_CH[y]_BASE.

The selected time stamp clock signal for the TBU_CH0 sub-unit is served via the *TS_CLK* signal line to the DPLL sub-module. The *TS_CLK* signal equals the signal *TBU_UP0*.

28.12.2 TBU Channels

The time base values are generated within the TBU time base channels in two independent and one dependent operation modes.

In all modes, the time base register **TBU_CH[z]_BASE** (z: 0…3) can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register **TBU_CH[z]_BASE** (z: 0…3) can always be read in order to determine the actual value of the counter.

28.12.2.1 Independent Modes

28.12.2.1.1 Free Running Counter Mode

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field **LOW_RES** of register **TBU_CH0_CTRL,** the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM sub-modules.

TBU channel 1 and 2 provides a 24 bit counter in a free running counter mode enabled by reset CH_MODE of register **TBU_CH[y]_CTRL** (y:1…2).

In TBU Free running counter mode, the time base register **TBU_CH[v]_BASE** (v:0…2) is updated on every specified incoming clock event by the selected signal *CMU_CLK[x]* (x: 0…8) (dependent on **TBU_CH[v]_CTRL** (v:0…2) register). In general the time base register **TBU_CH[v]_BASE** is incremented on every *CMU_CLK[x]* clock tick.

28.12.2.1.2 Forward/Backward Counter Mode

TBU channel 1 and 2 provides a 24 bit forward/backward counter enabled by set CH_MODE of register **TBU_CH[y]_CTRL** (y:1…2). In this mode the *DIR[y]* signal provided by the DPLL is taken into account.

The value of the time base register **TBU_CH[y]_BASE** is incremented in case when the *DIR[y]* signal equals ‘0’ and decremented in case when the *DIR[y]* signal is ‘1’.

28.12.2.2 Dependent Mode

28.12.2.2.1 Modulo Counter Mode

TBU channel 3 provides a 24 bit forward/backward modulo counter. The clock SUB_INC[y]c and counter direction DIR[y] provided by DPLL is selected by use_CH2 of register TBU_CH3_CTRL.

The modulo value is defined in TBU_CH3_BASE_MARK. In forward counter mode if TBU_CH3_BASE value is reaching TBU_CH3_BASE_MARK TBU_CH3_BASE is reset and TBU_TS[y] is captured in TBU_CH3_BASE_CAPTURE. In backward counter mode if TBU_CH3_BASE value is reaching '0' TBU_CH3_BASE is set to TBU_CH3_BASE_MARK and TBU_TS[y] is captured in TBU_CH3_BASE_CAPTURE.

28.12.3 TBU Configuration Register Overview

Table 27 TBU Configuration Register Overview

Register Name	Description	see Page
TBU_CHEN	TBU global channel enable	135
TBU_CH0_CTRL	TBU channel 0 control	135
TBU_CH0_BASE	TBU channel 0 base	136
TBU_CH1_CTRL	TBU channel 1 control	137
TBU_CH[y]_BASE	TBU channel y base	139
TBU_CH2_CTRL	TBU channel 2 control	138
TBU_CH3_CTRL	TBU channel 3 control	140
TBU_CH3_BASE	TBU channel 3 base	140
TBU_CH3_BASE_MARK	TBU channel 3 modulo value	141
TBU_CH3_BASE_CAPTURE	TBU channel 3 base captured	141

In a typical application the Time Base Unit (TBU) considers channels 0, 1 and 3 only. In this case register addresses 0x20…0x2C are reserved and shall be read as zero. Channel 2 can be additionally implemented on special high-end application requirements.

28.12.4 TBU Register description

28.12.4.1 Register TBU_CHEN

TBU Global Channel Enable

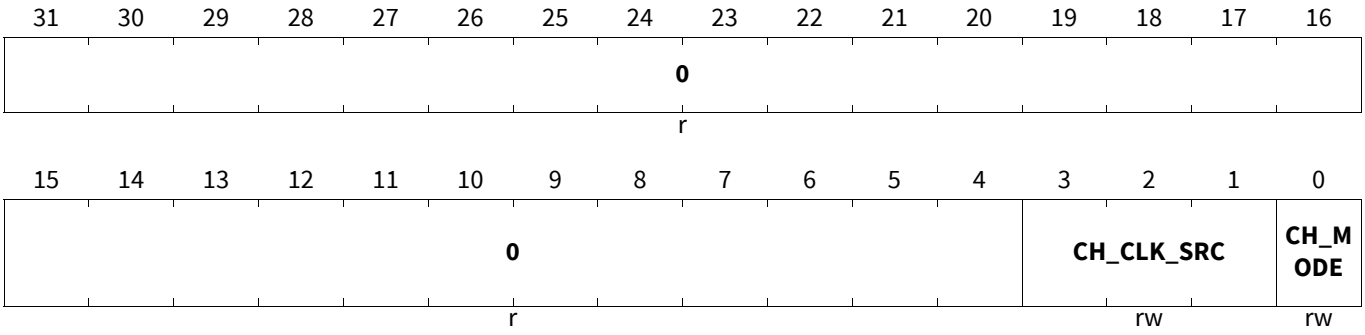
BASE															
rw															

Field	Bits	Type	Description
BASE	26:0	rw	**Time base value for channel 0** The value of **BASE** can only be written if the TBU channel 0 is disabled. If channel 0 is enabled, a read access to this register provides the current value of the underlying 27 bit counter.
0	31:27	r	**Reserved** Read as zero, shall be written as zero

28.12.4.4 Register TBU_CH1_CTRL

TBU Channel 1 Control Register

TBU_CH1_CTRL
TBU Channel 1 Control Register **(00010C$_H$)** **Application Reset Value: 0000 0000$_H$**

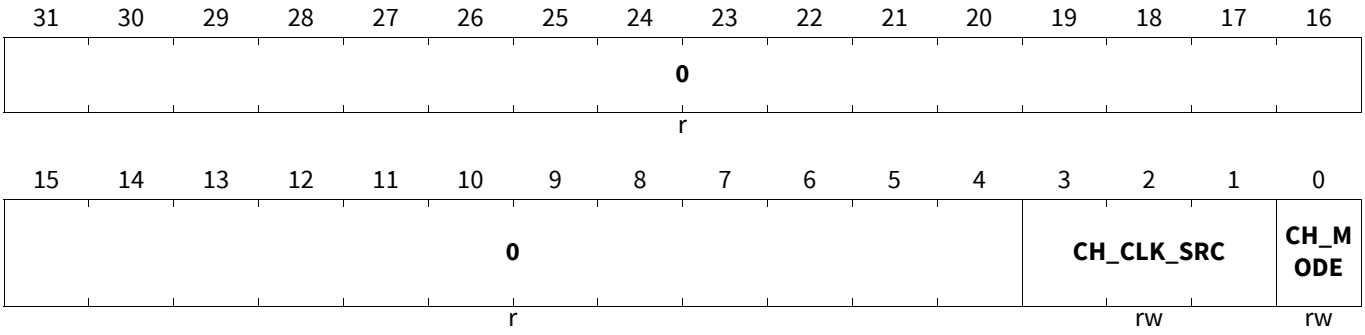


Field	Bits	Type	Description
CH_MODE	0	rw	**Channel mode** This value can only be modified if channel 1 is disabled. In Free running counter mode the CMU clock source specified by **CH_CLK_SRC** is used for the counter. In Forward/Backward counter mode the *SUB_INC1c* clock signal in combination with the *DIR1* input signal is used to determine the counter direction and clock frequency. 0_B Free running counter mode 1_B Forward/backward counter mode
CH_CLK_SRC	3:1	rw	**Clock source for channel 1 time base counter** This value can only be modified if channel 1 was disabled 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.12.4.5 Register TBU_CH2_CTRL

TBU Channel 2 Control Register

TBU_CH2_CTRL
TBU Channel 2 Control Register **(000114_H)** **Application Reset Value: $0000\ 0000_H$**



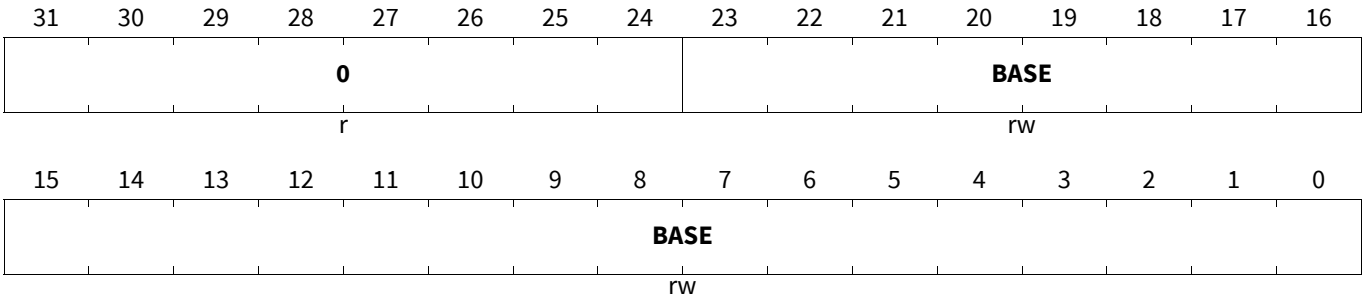
Field	Bits	Type	Description
CH_MODE	0	rw	**Channel mode** This value can only be modified if channel 2 is disabled. In Free running counter mode the CMU clock source specified by **CH_CLK_SRC** is used for the counter. In Forward/Backward counter mode the *SUB_INC2c* clock signal in combination with the *DIR2* input signal is used to determine the counter direction and clock frequency. 0_B Free running counter mode 1_B Forward/backward counter mode
CH_CLK_SRC	3:1	rw	**Clock source for channel 2 time base counter** This value can only be modified if channel 2 was disabled 000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected
0	31:4	r	**Reserved** Read as zero, shall be written as zero.

28.12.4.6 Register TBU_CH[y]_BASE

TBU Channel 1 Base Register

TBU_CH1_BASE

TBU Channel 1 Base Register **(000110_H)** **Application Reset Value: $0000\ 0000_H$**

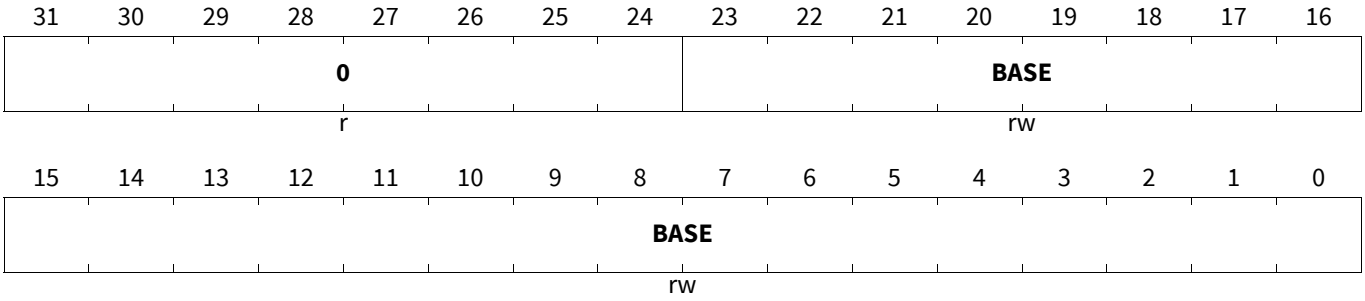


Field	Bits	Type	Description
BASE	23:0	rw	**Time base value for channel y (y: 1, 2)** The value of **BASE** can only be written if the corresponding TBU channel y is disabled. If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

TBU Channel 2 Base Register

TBU_CH2_BASE

TBU Channel 2 Base Register **(000118_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
BASE	23:0	rw	**Time base value for channel y (y: 1, 2)** The value of **BASE** can only be written if the corresponding TBU channel y is disabled. If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.12.4.7 Register TBU_CH3_CTRL

TBU Channel 3 Control Register

TBU_CH3_CTRL
TBU Channel 3 Control Register **(00011C$_H$)** **Application Reset Value: 0000 0001$_H$**

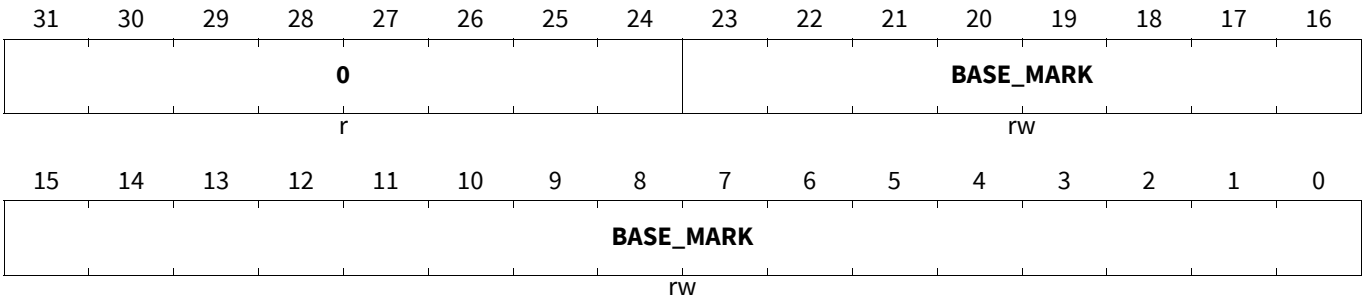
BASE															
rw															

Field	Bits	Type	Description
BASE	23:0	rw	**Time base value for channel 3** The value of **BASE** can only be written if the corresponding TBU channel 3 is disabled. If the corresponding channel 3 is enabled, a read access to this register provides the current value of the underlying counter.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.12.4.9 Register TBU_CH3_BASE_MARK

TBU Channel 3 Modulo Value Register

TBU_CH3_BASE_MARK
TBU Channel 3 Modulo Value Register **(000124_H)** **Application Reset Value: 0000 0000$_H$**

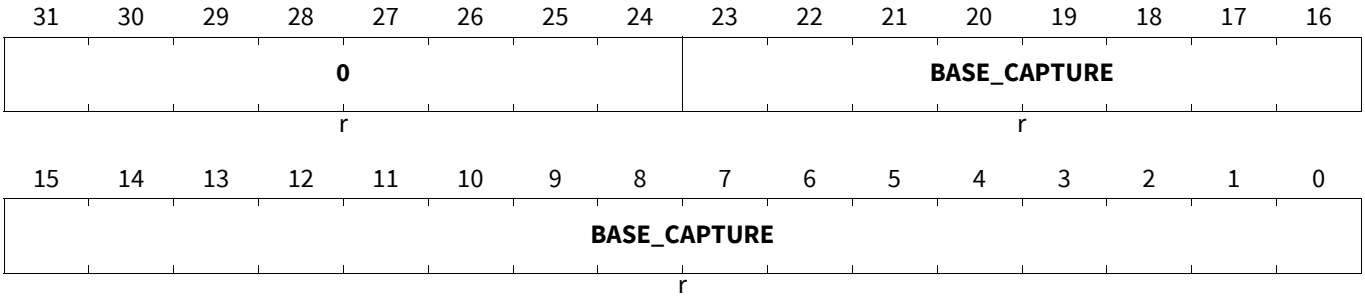


Field	Bits	Type	Description
BASE_MARK	23:0	rw	**Modulo value for channel 3** The value of **BASE_MARK** can only be written if the corresponding TBU channel 3 is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.12.4.10Register TBU_CH3_BASE_CAPTURE

TBU Channel 3 Base Captured Register

TBU_CH3_BASE_CAPTURE
TBU Channel 3 Base Captured Register **(000128_H)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BASE_CAPTURE	23:0	r	**Captured value of time base channel 1 or 2** When USE_CH2=0, TBU_TS1 is captured, and if USE_CH2 is set TBU_TS2 is captured.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.13 Timer Input Module (TIM)

28.13.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels. For advanced data processing the detected input characteristics of the TIM module can be routed through the ARU to subsequent processing units of the GTM.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal duration for a whole PWM period.

The architecture of TIM is shown in **Figure 31**.

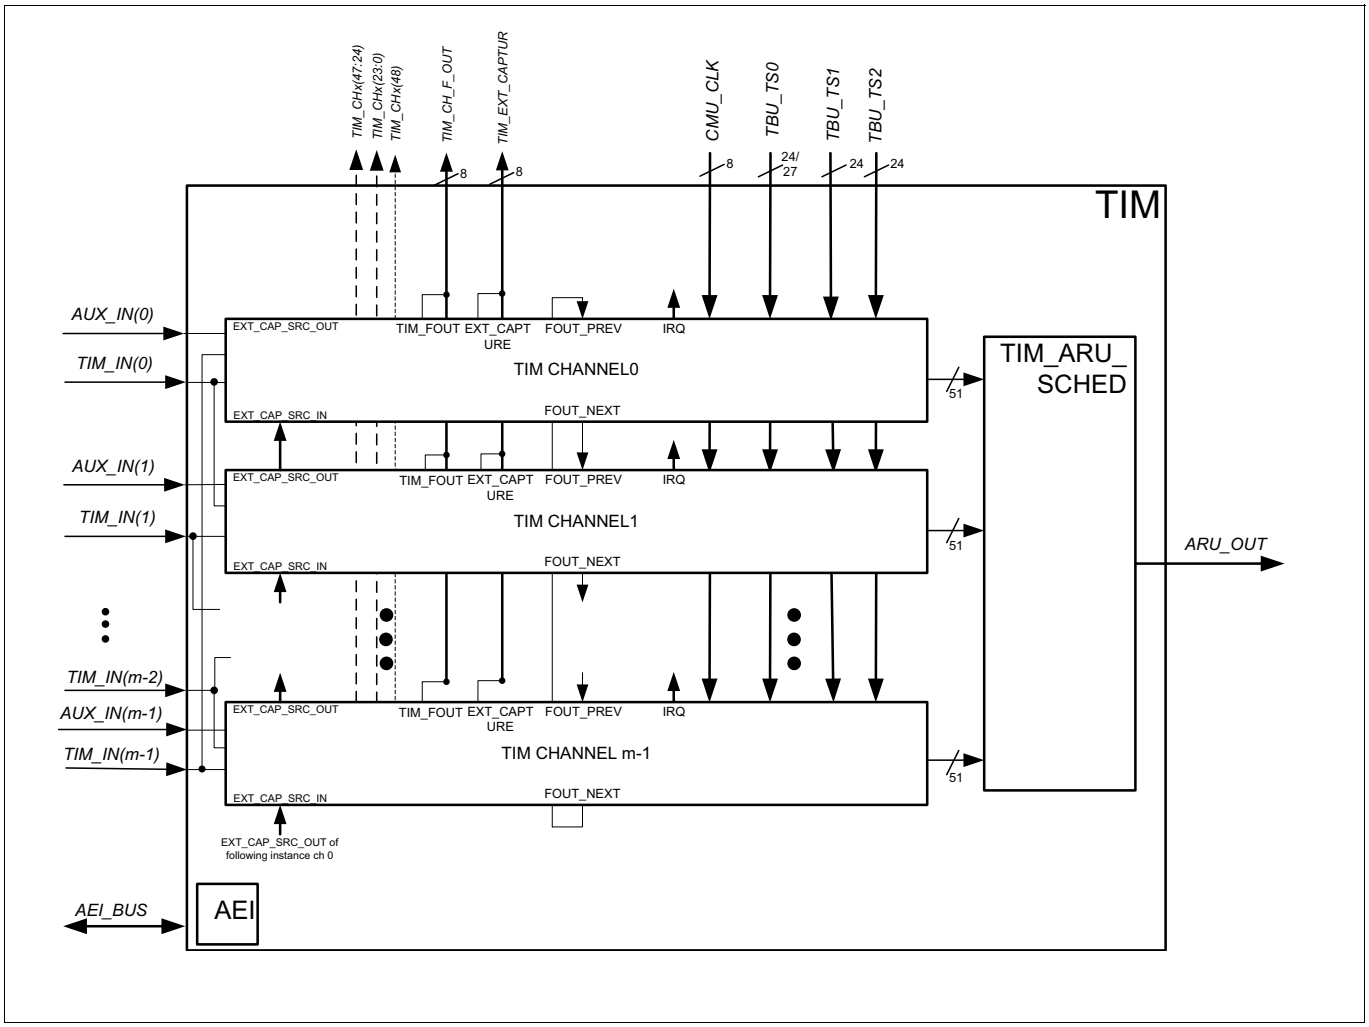


Figure 31 TIM Block Diagram

The number of channels *m* inside a TIM sub-module depends on the device.

Each of the *m* dedicated input signals are filtered inside the FLTx sub-unit of the TIM Module. It should be noted that the incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The measurement values can be read by the CPU directly via the AEI-Bus or they can be routed through the ARU to other sub-modules of the GTM.

For the GTM TIM0 sub-module only, the dashed signal outputs *TIM[i]_CH[x](23:0)*, *TIM[i]_CH[x](47:24)* and *TIM[i]_CH[x](48)* come from the TIM0 sub-module channels zero (0) to five (5) and are connected to MAP sub-module. There, they are used for further processing and for routing to the DPLL.

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (*TBU_TS0(23…0)*) or the higher 24 bits (*TBU_TS0(26…3)*) are stored inside the **GPR0** and **GPR1** registers.

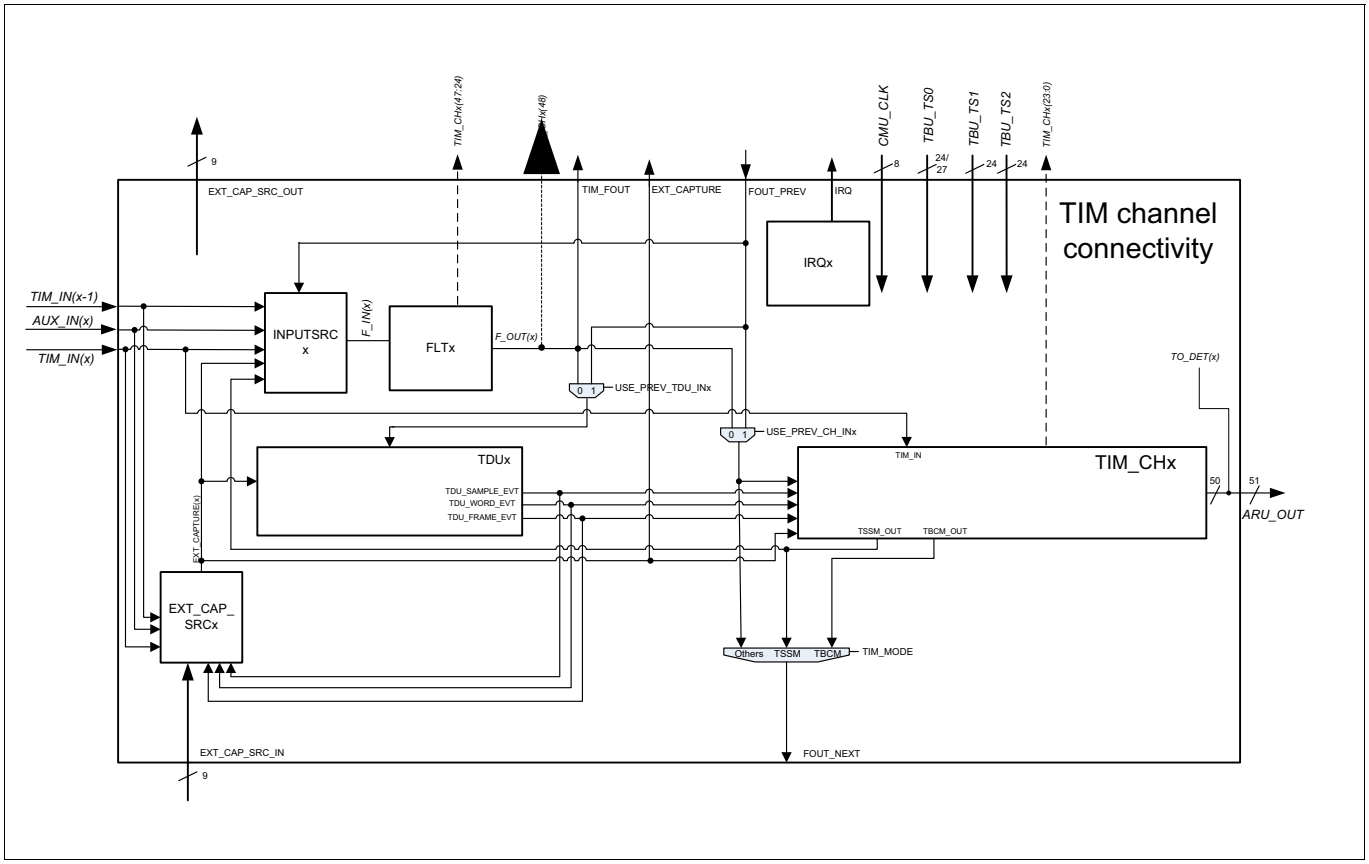

Figure 32 TIM channel internal connectivity

Above figure gives an overview of the channel internal connectivity of the sub units. The sub units with the major functionality are listed next:

- INPUT_SRCx: Select signal for processing by the Filter unit FLTx
- FLTx: The filter unit provides different filter mechanisms described in more detail in **Section 28.13.2**.
- TDUx: Timeout detection unit (no subsequent edge detected during a specified duration
- TIM_CHx: Measurement unit; different measurements strategies configurable on the filtered signal
- IRQx: Local interrupt controller (enabling, status, …)
- EXT_CAP_SRCx: Selects a local signal ext_capture(x) which is needed by certain functions

Details are given in the next chapters.

Depending on the values of the configuration bit fields **USE_PREV_TDU_INx**, **USE_PREV_CH_INx** it is possible to operate on the signal of the local channel x or the previous channel x-1.

Depending on the value of the configuration bit field **TIM_MODEx** it is possible to provide different signals (via FOUT_NEXT) to the next channel.

In TBCM mode each capture event selected by the sensitive edges (CNTS) will be forwarded with the value of ECNT[0] to the following channel (via FOUT_NEXT).

28.13.1.1 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT,TDU,TIM_CH units. It can be selected by the bit fields **CICTRL** and **MODE_x**, **VAL_x** in the register **TIM[i]_IN_SRC** which source is in use.

Alternatively the signal **F_IN(x)** can be generated by a 8 bit lookup table, which allows to define any function of 3 input sources.

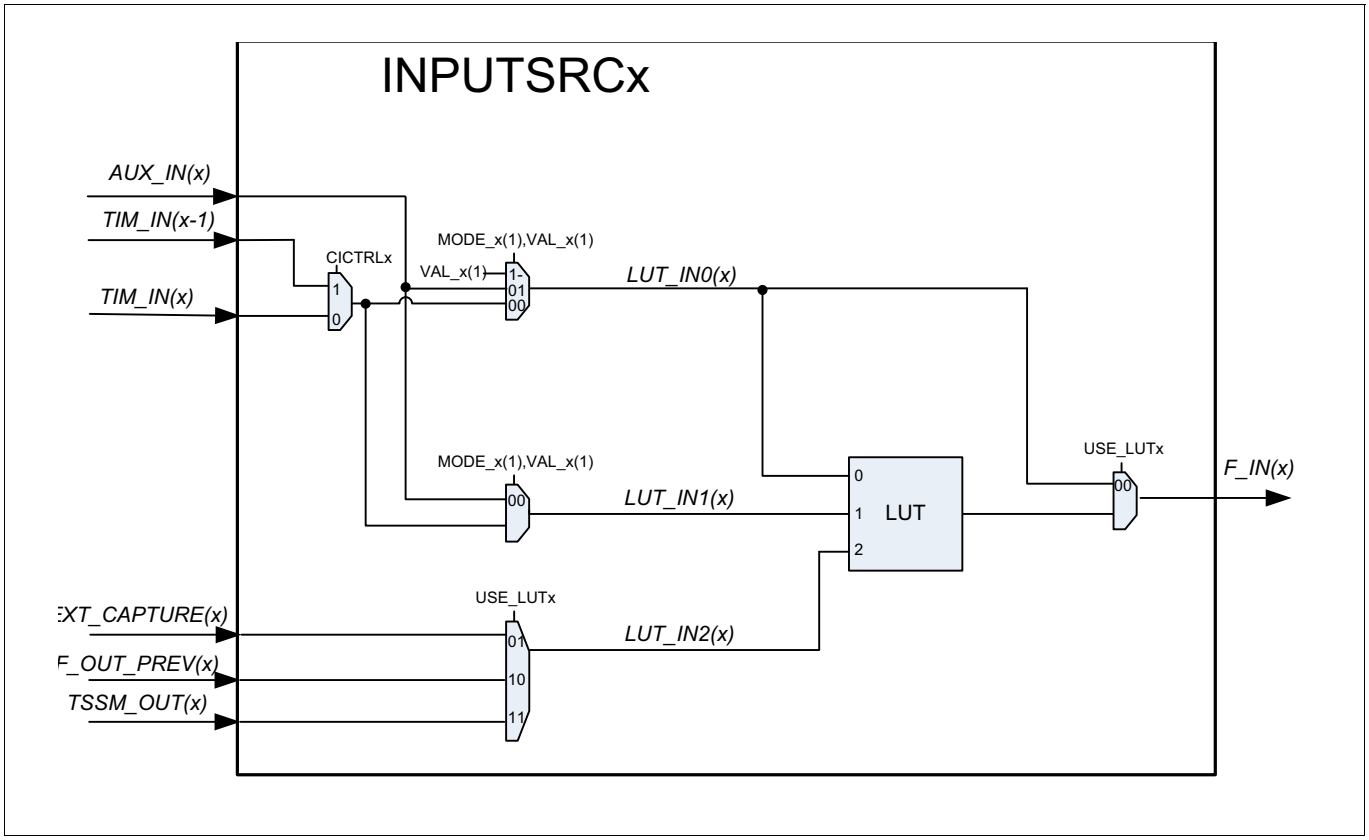

Figure 33 INPUTSRC Block Diagram

If **USE_LUT**=b00 is set the lookup table signal generation is bypassed and the signal selection is performed as follows:

In a certain **MODE_x**, **VAL_x** combination the input signal *F_IN(x)* can be driven by **VAL_x(1)** with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register **TIM[i]_IN_SRC** a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the **CICTRL** bit field in the corresponding **TIM[i]_CH[x]_CTRL** register. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional signal **AUX_IN[x]** can be selected as an input signal. The source of this signal is defined in the subchapter “TIM auxiliary input multiplexing”.

If **USE_LUT** !=0b00 is set, the lookup table signal generation with following inputs is in use. See **Figure 33**:

Input **LUT_INO(x)** selection:

TIM_IN(x) if **CICTRLx**=0 and **MODE_x**(1)=0 and **VAL_x**(1)=0
TIM_IN(x-1) if **CICTRLx**=1 and MODE_x(1)=0 and VAL_x(1)=0

AUX_IN(x) if MODE_x(1)=0 and VAL_x(1)=1
VAL_x(1) if MODE_x(1)=1

Input **LUT_IN1(x)** selection:

AUX_IN(x) if **MODE_x**(1)=0 and **VAL_x**(1)=0
TIM_IN(x) if **CICTRLx**=0
TIM_IN(x-1) if **CICTRLx**=1

Input **LUT_IN2(x)** selection:
EXT_CAPTURE(x) if **USE_LUT**=0b01
FOUT_PREV(x) if **USE_LUT**=0b10
TSSM_OUT(x) if **USE_LUT**=0b11

The lookup table is defined by the contents of the bit field **TO_CNT2x**. The lookup_table_index is defined by **LUT_IN2**(x) & **LUT_IN1**(x) & **LUT_IN0**(x). The signal **F_IN**(x) is generated by **TO_CNT2x**[lookup_table_index].

If **USE_LUT** !=0b00 is set, only limited functionality is available in the TDU. See bit field Slicing (**SLICING**) in the register TIM[i]_CH[x]_TDUV.

28.13.1.2 Input observation

It is possible to observe for all channels of one instance by reading **TIM_INP_VAL** the actual signal values of the following processing stages:

- TIM_IN(7:0) signals after TIM input synchronization
- TIM F_IN(7:0) signals after TIM INPUTSRC selection (input to TIM_FLT)
- TIM F_OUT(7:0) signals after TIM filter functionality (output of TIM_FLT)

28.13.1.3 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal **EXT_CAPTURE**. The source to use for this signal can be configured by the bit field **EXT_CAP_SRCx** in the register TIM[i]_CH[x]_ECTRL

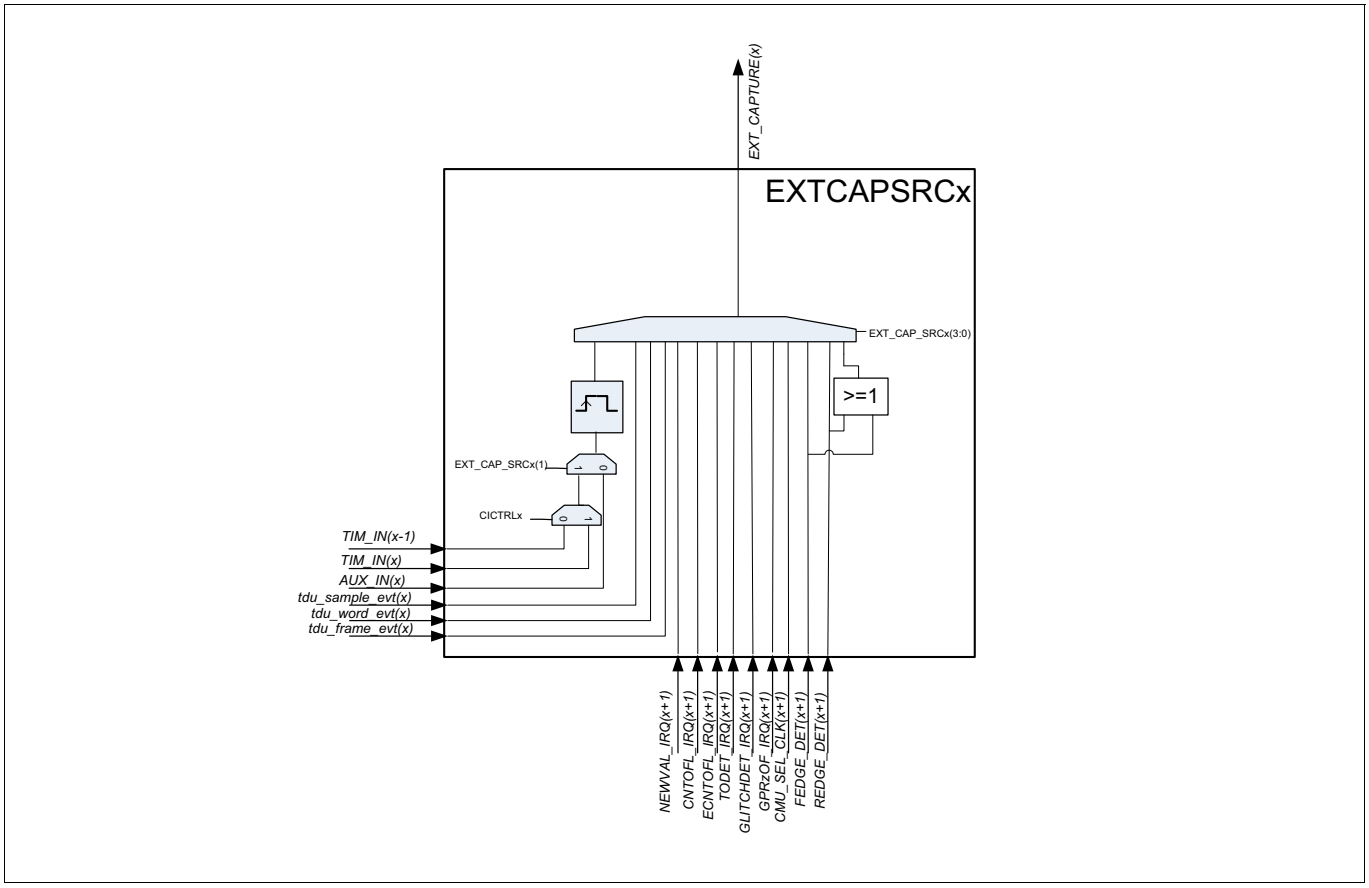

Figure 34 EXTCAPSRC Block Diagram

The external capture functionality can be enabled for the TIM channel **x** with the bit **EXT_CAP_EN** in the register **TIM[i]_CH[x]_CTRL**, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal **TIM_IN[x]** and **AUX_IN[x]** is applied.

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register **TIM[i]_CH[x+1]_FORCINT**.

28.13.2 TIM Filter Functionality (FLT)

28.13.2.1 Overview

The TIM sub-module provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT sub-unit. The FLT architecture is shown in **Figure 35**.

The filter includes a clock synchronization unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal *F_IN* to the selected filter clock frequency, which is controlled with the bit field **FLT_CNT_FRQ** of register **TIM[i]_CH[x]_CTRL**.

The synchronized input signal *F_IN_SYNC* is used for further processing within the filter.

It should be noted that glitches with a duration go less than the selected CMU clock period is lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- immediate edge propagation mode,
- individual de-glitch time mode (up/down counter), and
- individual de-glitch time mode (hold counter).
- individual de-glitch time mode (reset counter).

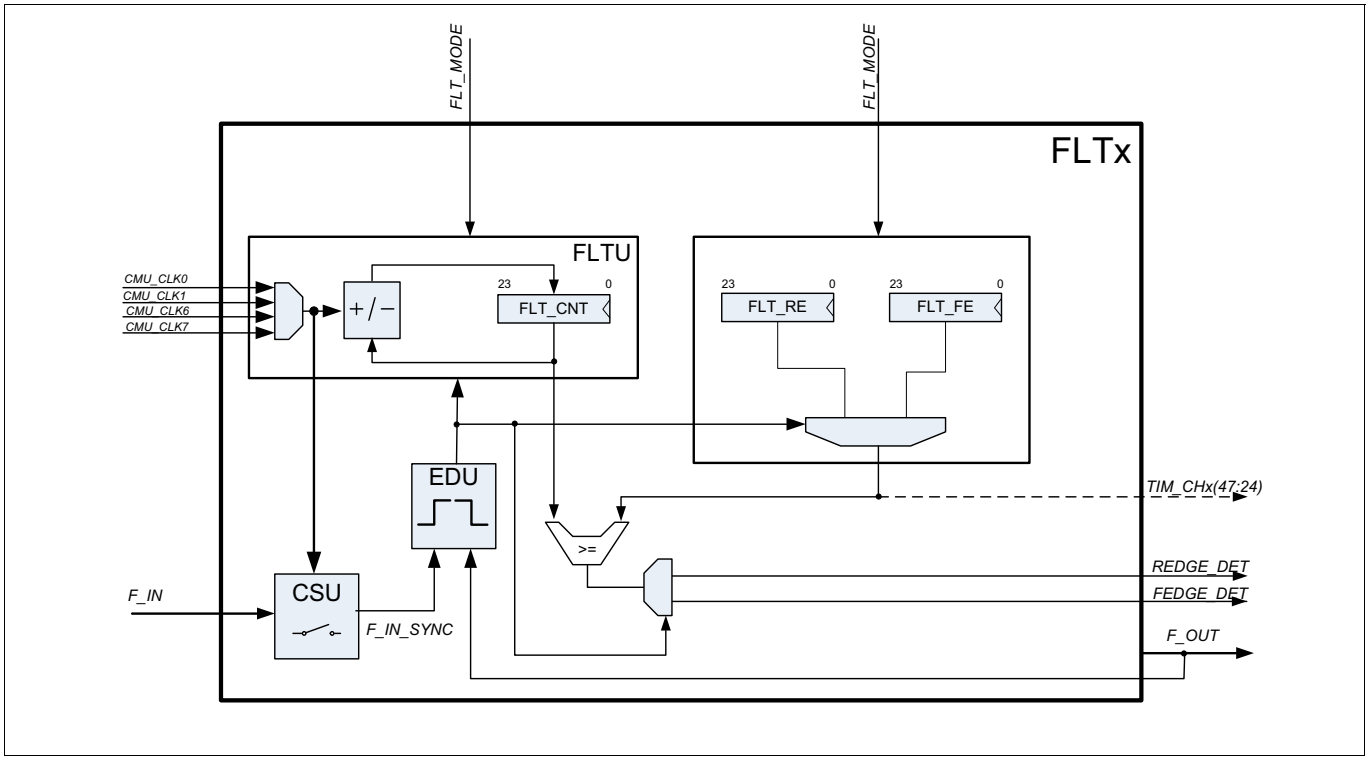

Figure 35 FLT Architecture

The filter parameters (deglitching and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers **FLT_RE** (rising edge) and **FLT_FE** (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters **FLT_xE** can always be determined by:

T=(FLT_xE+1)*T_{FLT_CLK},

When a glitch is detected on an input signal a status flag **GLITCHDET** is set inside the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

Table 28 gives an overview about the meanings for the registers **FLT_RE** and **FLT_FE**. In the individual deglitching time modes, the actual filter threshold for a detected regular edge is provided on the *TIM[i]_CH[x](47:24)* output line. In the case of immediate edge propagation mode, a value of zero is provided on the *TIM[i]_CH[x](47:24)* output line.

The *TIM[i]_CH[x](47:24)* output line is used by the MAP sub-module for further processing (please see chapter “TIM0 Input Mapping Module (MAP)”).

Table 28 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/down counter)	De-glitch time for rising edge	De-glitch time for falling edge

Table 28 Filter Parameter summary for the different Filter Modes (cont'd)

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (reset counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter **FLT_CNT** is used to measure the glitch and acceptance times.

The frequency of the **FLT_CNT** counter is configurable in bit field **FLT_CNT_FRQ** of register **TIM[i]_CH[x]_CTRL**.

The counter **FLT_CNT** can either be clock with the *CMU_CLK0, CMU_CLK1, CMU_CLK6* or the *CMU_CLK7* signal. These signals are coming from the CMU sub-module.

The **FLT_CNT**, **FLT_FE** and **FLT_RE** registers are 24-bit width. For example, when the resolution of the *CMU_CLK0* signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

28.13.2.2 TIM Filter Modes

28.13.2.2.1 Immediate Edge Propagation Mode

In immediate edge propagation mode after detection of an edge the new signal level on *F_IN_SYNC* is propagated to *F_OUT* with a delay of one T_{period} and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the **FLT_RE** and **FLT_FE** registers.

Each signal change on the input *F_IN_SYNC* during the duration of the acceptance time has no effect on the output signal level *F_OUT* of the filter but it sets the glitch **GLITCHDET** bit in the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

After it expires an acceptance time the input signal *F_IN_SYNC* is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to *F_OUT*.

Independent of a signal level change the value of *F_OUT* is always set to *F_IN_SYNC,* when the acceptance time expires (see also **Figure 37**).

Figure 36 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (*F_IN*) and after filtering (*F_OUT*) are shown. The acceptance time *at1* is specified in the register **FLT_RE**.

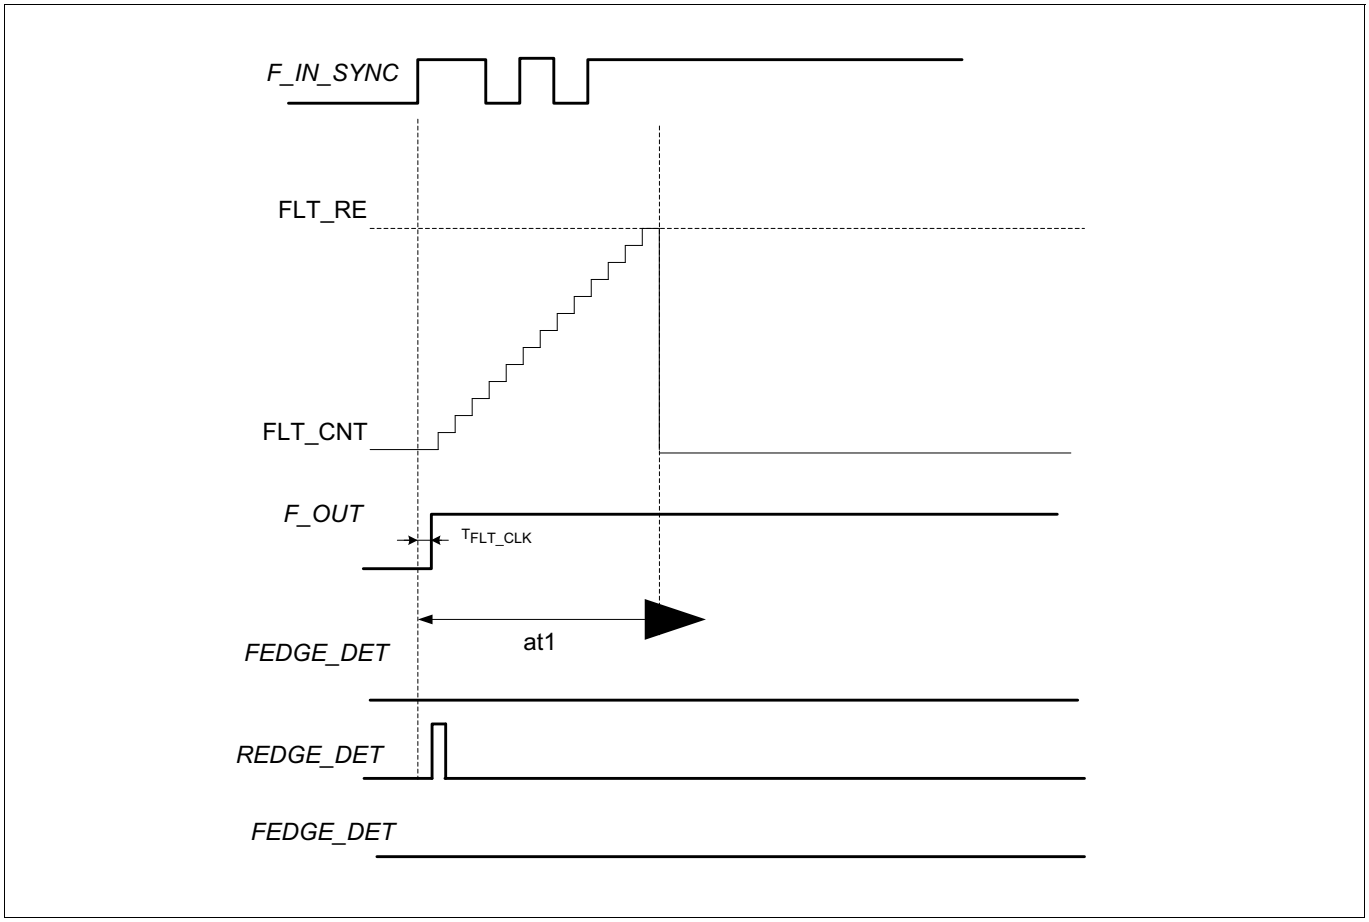

Figure 36 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on *F_IN_SYNC* are transferred directly to *F_OUT*.

The counter **FLT_CNT** is incremented until acceptance time threshold is reached.

Figure 37 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

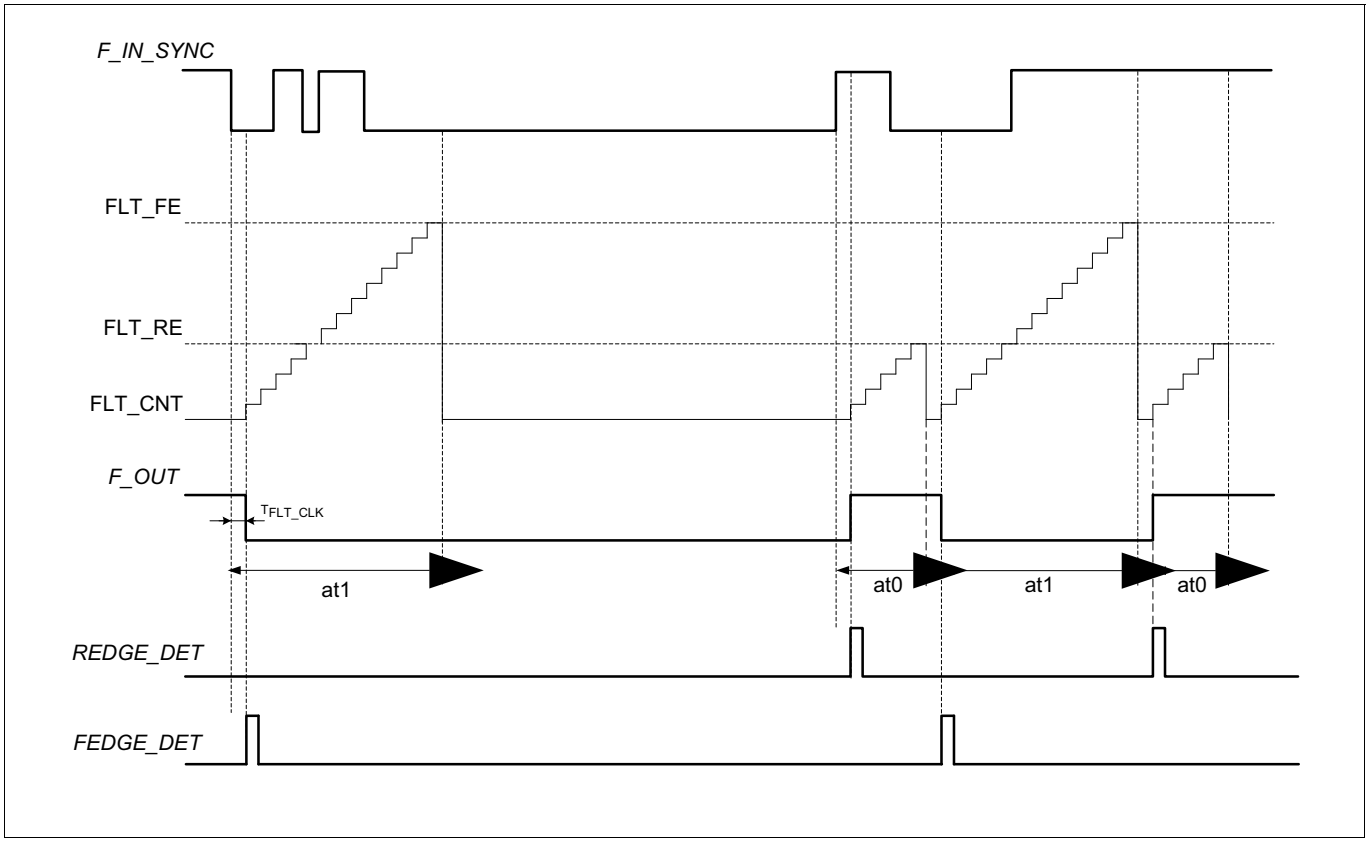

Figure 37 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the **FLT_CNT** has reached the acceptance time for a specific signal edge and the signal *F_IN_SYNC* has already changed to the opposite level of *F_OUT*, the opposite signal level is set to *F_OUT* and the acceptance time measurement is started immediately. **Figure 37** shows this scenario at the detection of the first rising edge and the second falling edge.

28.13.2.2.2 Individual De-glitch Time Mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers **FLT_RE** and **FLT_FE,** respectively.

The filter counter register **FLT_CNT** is incremented when the signal level on *F_IN_SYNC* is unequal to the signal level on *F_OUT* and decremented if *F_IN_SYNC* equals *F_OUT*.

After **FLT_CNT** has reached a value of zero during decrementing the counter is stopped immediately.

If a glitch is detected a glitch detection bit **GLITCHDET** is set in the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

The detected edge signal together with the new signal level is propagated to *F_OUT* after the individual de-glitch threshold is reached. **Figure 38** shows the behavior of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

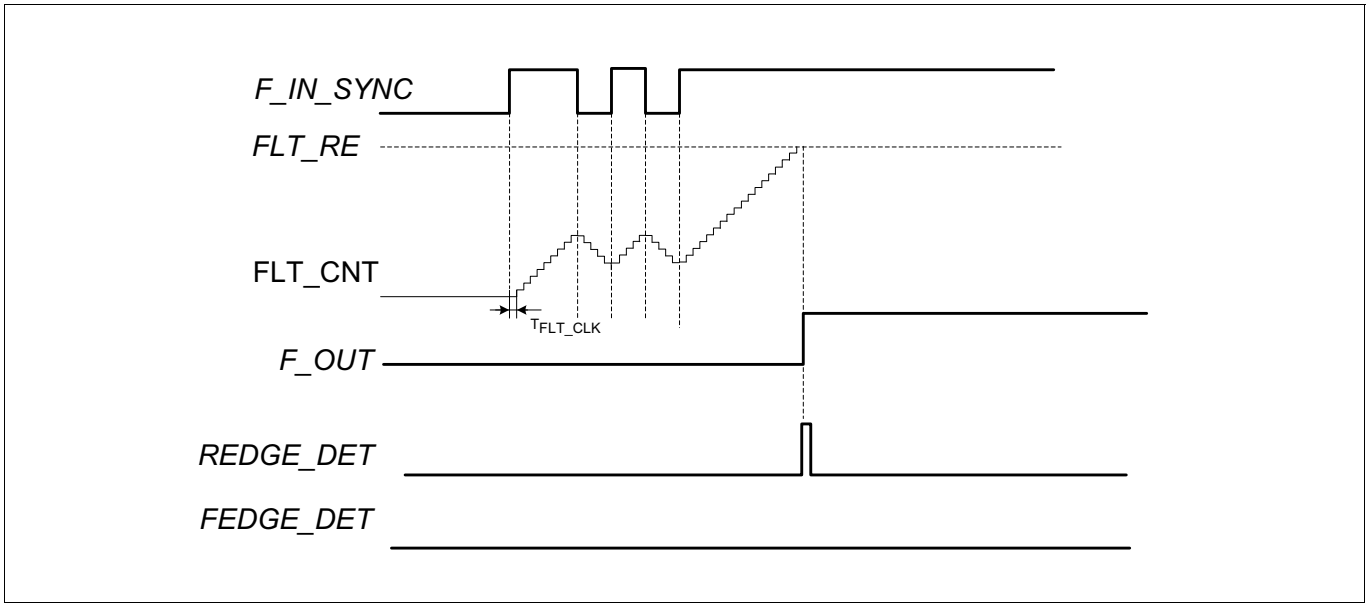

Figure 38 Individual De-glitch Time Mode (up/down counter) in the case of a rising edge

28.13.2.2.3 Individual De-glitch Time Mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers **FLT_RE** and **FLT_FE,** respectively.

The filter counter register **FLT_CNT** is incremented when the signal level on *F_IN_SYNC* is unequal to the signal level on *F_OUT* and the counter value of **FLT_CNT** is hold if *F_IN* equals *F_OUT*.

If a glitch is detected the glitch detection bit **GLITCHDET** is set in the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

The detected edge signal together with the new signal level is propagated to *F_OUT* after the individual de-glitch threshold is reached. **Figure 39** shows the behavior of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

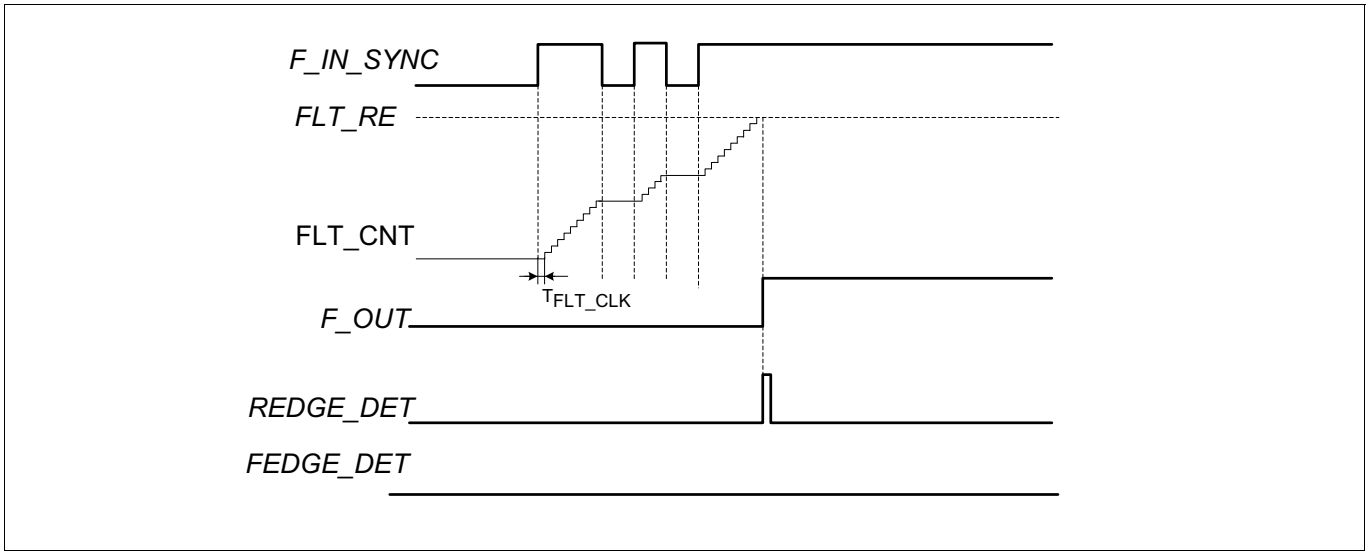

Figure 39 Individual De-glitch Time Mode (hold counter) in the case of a rising edge

28.13.2.2.4 Individual De-glitch Time Mode (reset counter)

In individual de-glitch time mode (reset counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers **FLT_RE** and **FLT_FE,** respectively.

The filter counter register **FLT_CNT** is incremented when the signal level on *F_IN_SYNC* is unequal to the signal level on *F_OUT* and the counter value of **FLT_CNT** is reset to 0x000000 if *F_IN* equals *F_OUT*.

If a glitch is detected the glitch detection bit **GLITCHDET** is set in the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

The detected edge signal together with the new signal level is propagated to *F_OUT* after the individual de-glitch threshold is reached. **Figure 40** shows the behavior of the filter in individual de-glitch time (reset counter) mode in the case of the rising edge detection.

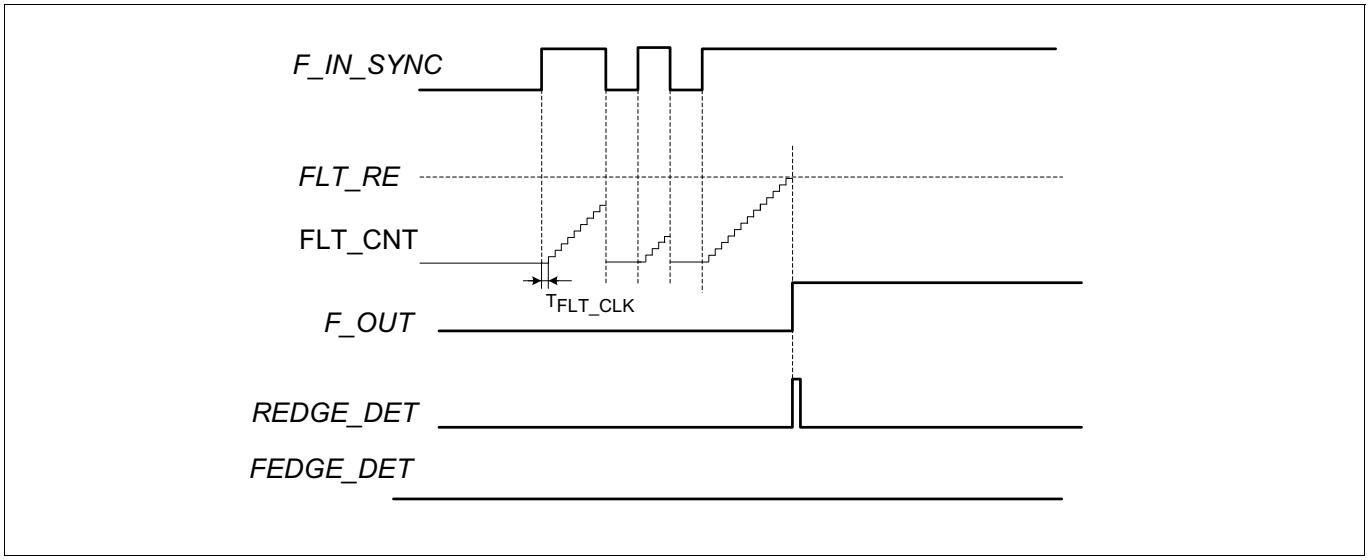

Figure 40 Individual De-glitch Time Mode (reset counter) in the case of a rising edge

28.13.2.2.5 Immediate Edge Propagation and Individual De-glitch Mode

As already mentioned, the four different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitching mode (whether up/down counter, hold counter or reset counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitching mode (up/down counter) as shown in **Figure 41**.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitching time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitching counter cannot measure the time T_{ERROR}, as shown in **Figure 41**.

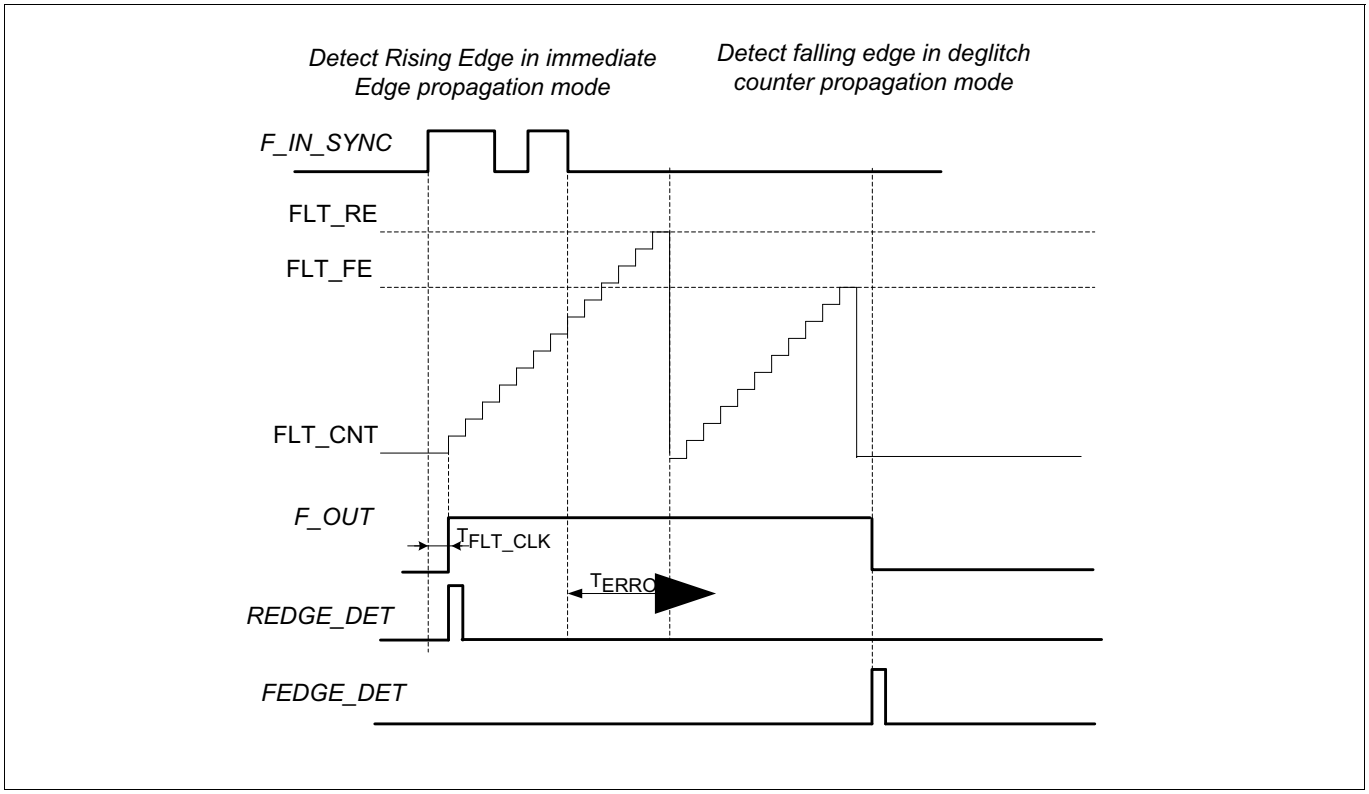

Figure 41 Mixed mode measurement

28.13.2.3 TIM Filter re-configuration

If **FLT_EN**=1 a change of or **FLT_FE** will take place immediately.

If **FLT_EN**=1 a change of **FLT_MODE_RE** or **FLT_MODE_FE** will be used with the next occurring corresponding edge. If the mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If **FLT_EN**=1 a change of **FLT_CTR_RE**, **FLT_CTR_FE**, **EFLT_CTR_RE** or **EFLT_CTR_FE** will take place immediately.

28.13.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM sub-module has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

In each timeout unit exist 3 8 bit counter/comparator slices. A counter/comparator slice is shown below. The counter TO_CNT will increment by signal *INC*. The counter can be loaded with the value *LOAD_VAL* if *LOAD_VAL*= 1. GT_EVT will be 1 if TO_CNT > TOV is fulfilled. EQ_EVT will be 1 if TO_CNT = TOV is fulfilled.

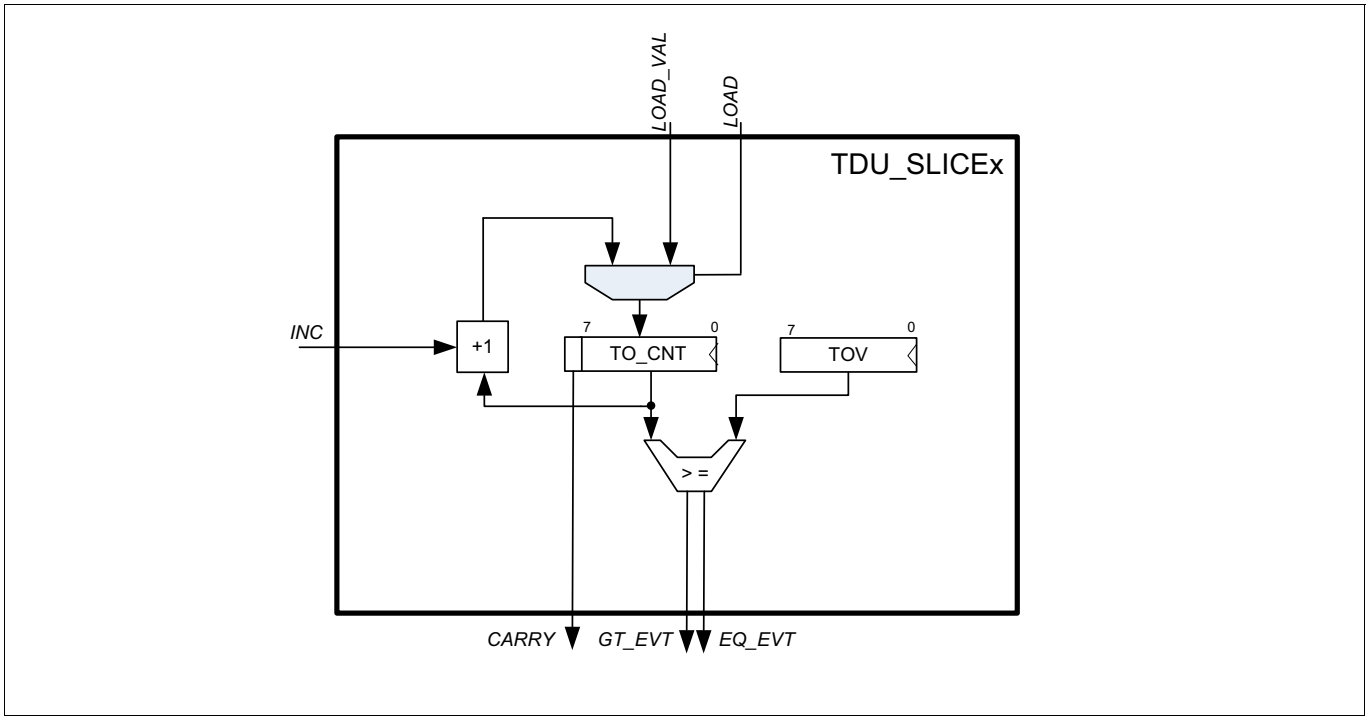

Figure 42 Counter/comparator slice

The counter/comparator slices can be cascaded depending on the application needs to operate as:

- 3x 8-bit counter
- 1x 16-bit counter and 1x 8-bit counter
- 1x 24-bit counter
- 2x 8-bit counter

This allows the user to use the functions:

- timeout on input signals
- local CMU clock prescaler 8 bit
- trigger event generation 8-bit (external capture, todet_irq)

in parallel.

With usage of the 3x 8-bit counter it is possible to define different timeout values for the 2 signal levels.

Following table shows which functions can be used in parallel.

28.13.3.1 Used parallel functions

Table 29 Used parallel functions)

Counter type	Timeout functionality	Generate local TIM CMU clk	Source for external capture to previous channel	Source for TODET_IRQ
24 bit	24 bit	no	tdu_timeout_evt tdu_sample_evt	tdu_timeout_evt tdu_sample_evt
1 x 8 bit 1 x 16 bit	16 bit local clk tdu_sample_evt usable	yes	tdu_timeout_evt, tdu_frame_evt, tdu_sample_evt	tdu_timeout_evt, tdu_frame_evt, tdu_sample_evt
3x 8 bit	8 bit local clk tdu_sample_evt usable	yes	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt
3x 8 bit	no	yes	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt
2x 8 bit	no	no	tdu_timeout_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_word_evt, tdu_frame_evt

Next table shows which of the available 8 bit resources are cascaded with a chosen **SLICING**.

28.13.3.2 Which of the available 8 bit resources are cascaded with a chosen SLICING

Table 30 Which of the available 8 bit resources are cascaded with a chosen SLICING

Based on a chosen counter configuration by **SLICING** it is possible to control the start behavior of the counters by **TDU_START** in multiple ways. In addition the stopping of the counters can be controlled by **TDU_STOP**. Depending on the application needs it can be decided how the individual counter slices can be reset/reloaded by the configuration field **TDU_RESYNC**.

Depending on the counter configuration, up to 4 internal compare events tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt out of the 3 comparator slices can be generated. It can be chosen by **TODET_IRQ_SRC** which shall be used as *TIM_TODETx_IRQ* signal which will be accessible by the **TODET** bit inside the **TIM[i]_CH[x]_IRQ_NOTIFY** register

The TDU architecture is shown in **Figure 43**.

28.13.3.3 Architecture of the TDU Sub-unit

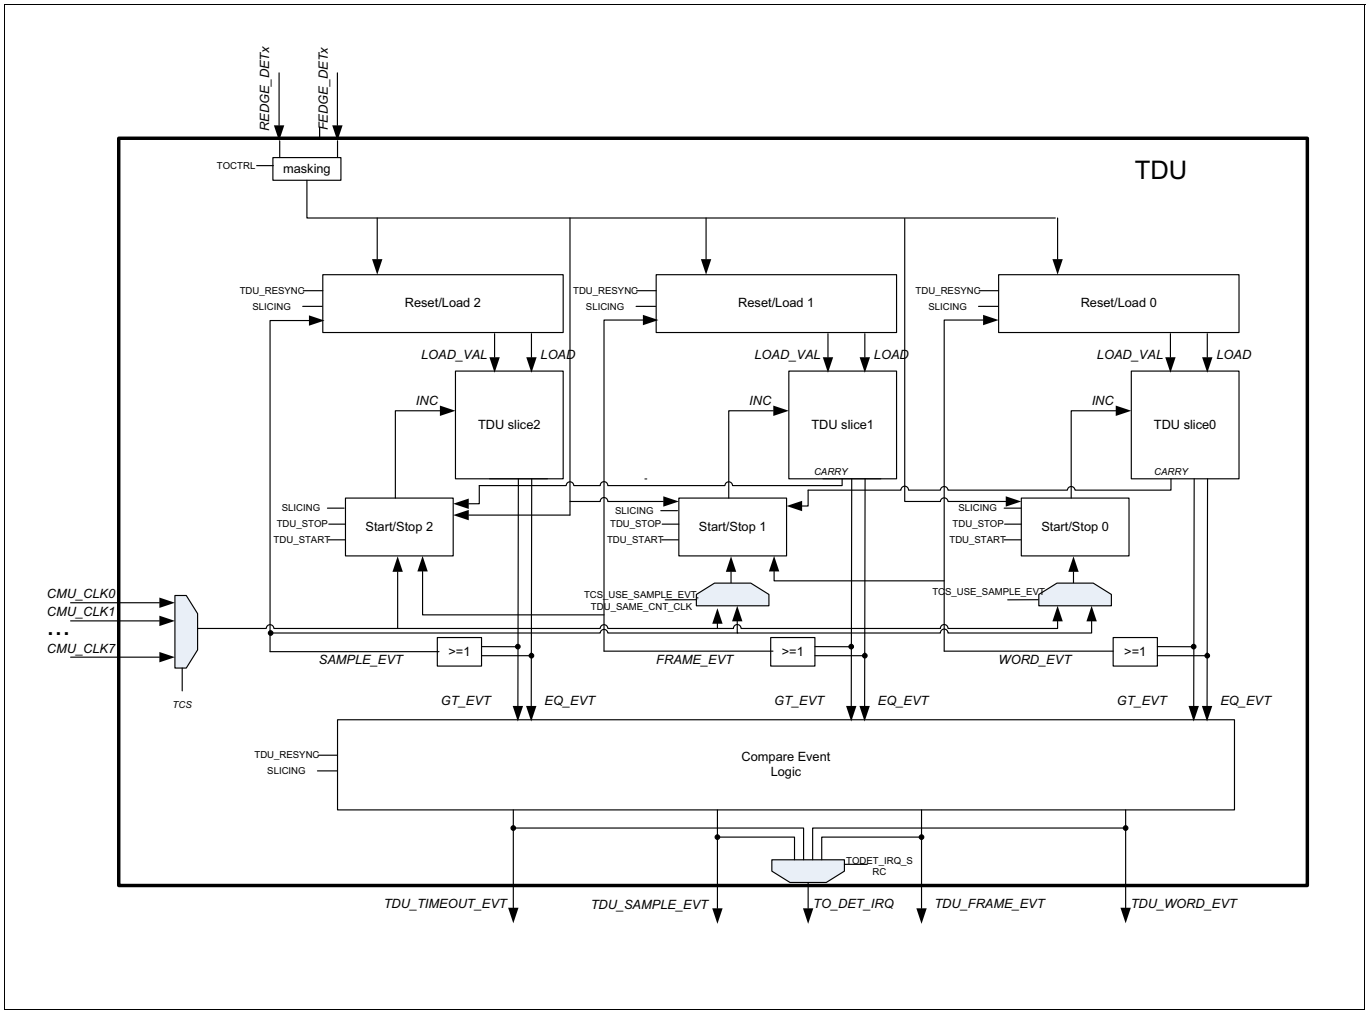

Figure 43 Architecture of the TDU Sub-unit

Each TDU_slice has its own start/stop control, based on the chosen configuration it will decide if the counter inside the TDU slice will increment on the resolution of the applied clock/event. The reset/load control decides based on the configuration settings and the compare result of the TDU slices those the counters **TO_CNT**,**TO_CNT1**,**TO_CNT2** have to be reloaded. Depending on the chosen counter/compare configuration the compare event logic will generate based on the compare results of the 3 TDU slices and the chosen resolution the events *tdu_sample_evt*, *tdu_word_evt*, *tdu_frame_evt*.

The primary resolution on which the TDU is working can be specified with the bit field **TCS** of the register **TIM[i]_CH[x]_TDUV**. The corresponding input signal *CMU_CLKx* will be used to clock the TDU. The individual timeout/counter values have to be specified in number of ticks of the selected input clock signal in the fields **TOV**, **TOV1**, **TOV2** of the timeout value register **TIM[i]_CH[x]_TDUV** of the TIM channel x.

In case of cascading the bit slices by usage of **SLICING** and **TCS_USE_SAMPLE_EVT** and **TDU_SAME_CLK** the resolution for counting can be switched to the events tdu_sample_evt or tdu_word_evt. More details see table above.

The counter compare units start operation on occurrence of the first "start event" configured by **TDU_START**. They continue their operation until the first "stop event" configured by **TDU_STOP** occurs.

In case of occurrence of a start event and a compare/count resolution event in the same clock cycle, the counters will increment or reload/reset based on **TDU_RESYNC** immediately. No *tdu_sample_evt*, *tdu_word_evt*, *tdu_frame_evt* will be generated.

In case of occurrence of a stop event the counters will not change their values. In case of occurrence of a stop event and a compare/count resolution event in the same clock cycle the corresponding events *tdu_sample_evt*, *tdu_word_evt*, *tdu_frame_evt* will be generated.

In case of occurrence of a start event and a stop event in the same clock cycle the counters will not change their values. No *tdu_sample_evt*, *tdu_word_evt*, *tdu_frame_evt* will be generated.

The function of the timeout unit (configured to **TDU_RESYNC**=0000,**TDU_START**=000) can be started or stopped inside the **TIM[i]_CH[x]_CTRL** register by setting/resetting the **TOCTRL** bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field **TOCTRL**.

The TDU generates an interrupt signal *TIM_TODETx_IRQ* whenever a timeout is detected for an individual input signal, and the **TODET** bit is set inside the **TIM[i]_CH[x]_IRQ_NOTIFY** register.

In addition, when the ARU access is enabled with the **ARU_EN** bit inside the **TIM[i]_CH[x]_CTRL** register, the actual values stored inside the registers **TIM[i]_CH[x]_GPR0** and **TIM[i]_CH[x]_GPR1** are sent together with the last stored signal level to the ARU if a timeout event *TDU_TIMEOUT_EVT* occurs.

To signal that a timeout occurred, the ARU_OUT(50) bit (ACB(2)) is set. The bit ACB(0) will be updated with the timeout event to the signal level on which the timeout was detected. Timeout signaling with ACB(2) is only possible with **TODET_IRQ_SRC**= 0000.

Thus, a destination could determine if a timeout occurred at the TIM input by evaluating ACB bit 2.

Since the TIM channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid at the ARU. In that case, the new edge associated data is stored inside the registers **TIM[i]_CH[x]_GPR0** and **TIM[i]_CH[x]_GPR1**, the GPR overflow detected bit is set together in the ACB field (ACB(1)) with the timeout bit (ACB(2)) and the values are marked as valid to the ARU.

The ACB bit 2 is cleared, when a successful ARU write access by the TIM channel took place.

The ACB bit 1 is cleared, when a successful ARU write access by the TIM channel took place.

When a valid edge initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is set. The bit ACB(0) will be updated to the level on which the timeout occurred.

When a timeout occurred and initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is not set.

The following table clarifies the meaning of the ACB Bits for valid data provided by a TIM channel:

Table 31 ACB Bits for valid data provided by a TIM channel

ACB4/3	ACB2	ACB1	ACB0	Description
dc	0	0	SL	Valid edge detected
dc	0	1	SL	Input edge overwritten by subsequent edge
dc	1	0	SL	Timeout detected without valid edge
dc	1	1	SL	Timeout detected with subsequent valid edge detected

28.13.4 TIM Channel Architecture

28.13.4.1 Overview

Each TIM channel consist of an input edge counter **ECNT**, a Signal Measurement Unit (SMU) with a counter **CNT**, a counter shadow register **CNTS** for SMU counter and two general purpose registers **GPR0** and **GPR1** for value storage.

The value **TOV** of the timeout register **TIM[i]_CH[x]_TDU** is provided to TDU sub-unit of each individual channel for timeout measurement. The architecture of the TIM channel is depicted in **Figure 44**.

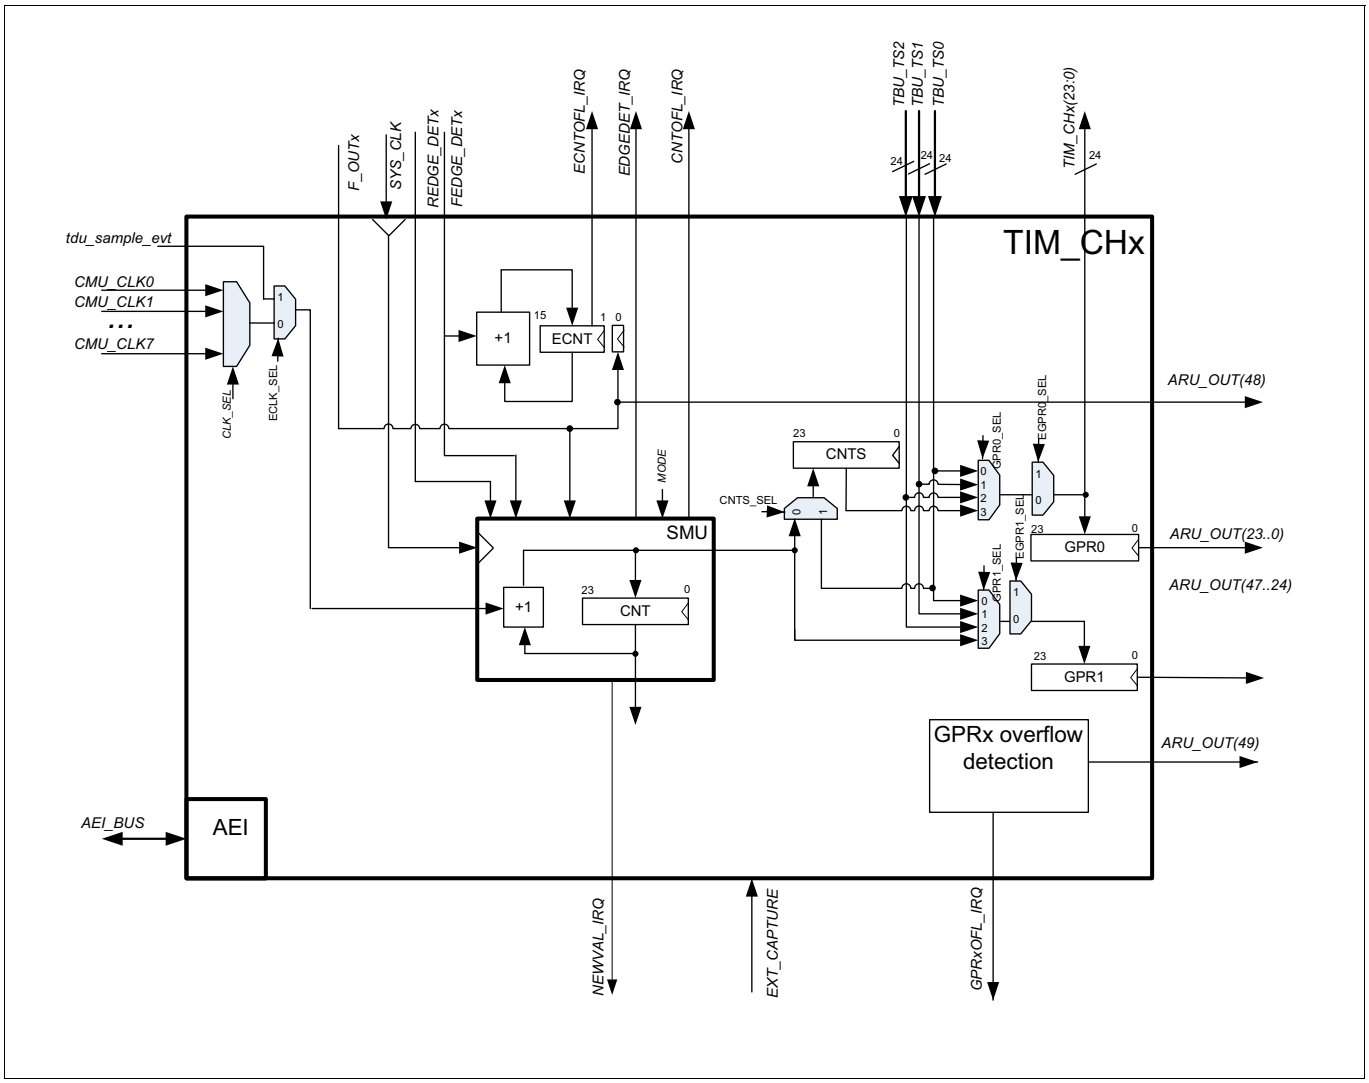

Figure 44 TIM Channel Architecture

Each TIM channel receives both input trigger signals *REDGE_DETx* and *FEDGE_DETx,* generated by the corresponding filter module in order to signalize a detected echo of the input signal *F_INx*. The signal *F_OUTx* shows the filtered signal of the channel's input signal *F_INx*.

The edge counter **ECNT** counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of **ECNT**. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates **ECNT** by composing the ECNT[n:1] bits with F_OUTx as bit 0).

Thus, the whole ECNT counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current **ECNT[7:0]** register content is made visible on the bits 31 down to 24 of the registers **GPR0**, **GPR1,** and **CNTS**. This allows the software to detect inconsistent read accesses to registers **GPR0**, **GPR1**, and **CNTS**. However, the update strategy of these registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field **FR_ECNT_OFL** when an **ECNT** overflow is signaled on **ECNTOFL**. An ECNT overflow can be signaled on 8 bit or full range resolution.

While reading the register **TIM[i]_CH[x]_ECNT** the bit **ECNT[0]** shows the input signal value F_OUTx independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of **TIM[i]_CH[x]_ECNT** will be frozen until a read of the register takes place. This read will reset the **ECNT** counter. Continuing reads will show the input signal value in bit **ECNT[0]** again.

When new data is written into **GPR0** and **GPR1** the **NEWVAL** bit is set in **TIM[i]_CH[x]_IRQ_NOTIFY** register and depending on corresponding enable bit value the *NEWVALx_IRQ* interrupt is raised.

Each TIM input channel has an ARU connection for providing data via the ARU to the other GTM sub-modules. The data provided to the ARU depends on the TIM channel mode and its corresponding adjustments (e.g. multiplexer configuration).

The bit **ARU_EN** of register **TIM[i]_CH[x]_CTRL** decides, whether the measurement results of registers **GPR0** and **GPR1** are consumed by another sub-module via ARU (**ARU_EN** = 1) or the CPU via AEI (**ARU_EN** = 0).

To guarantee a consistent delivery of data from the **GPR0** and **GPR1** registers to the ARU or the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit **NEWVAL** is set inside **TIM[i]_CH[x]_IRQ_NOTIFY** register) while the old data is not consumed by the ARU (**ARU_EN** = 1) or CPU (**ARU_EN** = 0), the TIM channel sets the **GPROFL** bit inside the status register **TIM[i]_CH[x]_IRQ_NOTIFY** and it overwrites the data inside the registers **GPR0** and **GPR1**. In addition when **ARU_EN**=1 the bit ACB(1) is set to 1 to indicate the overflow in the ARU data.

If the CPU is selected as consumer for the registers **GPR0** and **GPR1** (**ARU_EN** = 0), the acknowledge for reading out data is performed by a read access to the register **GPR0**. Thus, register **GPR1** should be read always before **GPR0**.

If the ARU is selected as consumer for the registers **GPR0** and **GPR1** (**ARU_EN** = 1), the acknowledge for reading out data is performed by the ARU itself. However, the registers **GPR0** and **GPR1** could be read by CPU without giving an acknowledge.

28.13.4.2 TIM Channel Modes

The TIM provides seven different measurement modes that can be configured with the bit field **TIM_MODE** of register **TIM[i]_CH[x]_CTRL**. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register **TIM[i]_CH[x]_CTRL** for a more detailed controlling of each mode. The meanings of these bits are as follows:

- **DSL**: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured.
- **EGPR0_SEL, GPR0_SEL** and **EGPR1_SEL, GPR1_SEL**: control the actual content of the registers **GPR0** and **GPR1** after a measurement has finished.
- **CNTS_SEL**: control the content of the registers **CNTS.** The actual time for updating the **CNTS** register is mode dependent.
- **OSM**: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.
- **NEWVAL**: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signaling that the registers GPR0 and GPR1 are updated.
- **ARU_EN**: enables sending of the registers **GPR0** and **GPR1** together with the actual signal level (in bit 48) and the overflow signal GPROFL (in bit 49), and the timeout status information (bit 50) to the ARU.
- **EXT_CAP_EN**: forces an update of the registers **GPR0** and **GPR1** and **CNTS** (TIM channel mode dependent) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields **EXT_CAP_SRC** in the register **TIM[i]_CH[x]_ECTRL.**

28.13.4.2.1 TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The **DSL** bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, **DSL**=1) and **IMM_START**=0, the channel starts measuring after the first rising edge is detected by the filter.

If **IMM_START**=1 the measurement starts immediately after activating the channel by **TIM_EN**=1.

Measurement is done with the **CNT** register counting with the configured clock coming from **CMU_CLKx** until a falling edge is detected.

Assume: **SWAP_CAPTURE**=0, **ECNT_RESET**=0

Then the counter value is stored inside the shadow register **CNTS** (if **CNTS_SEL** = 0) and the counter **CNT** counts continuously until the next rising edge is reached.

On this following rising edge the content of the **CNTS** register is transferred to **GPR0** and the content of **CNT** register is transferred to **GPR1**, assuming settings for the selectors **EGPR0_SEL**=0,**GPR0_SEL**=11 and **EGPR1_SEL**=0,**GPR1_SEL**=11. By this, **GPR0** contains the duty cycle length and **GPR1** contains the period. It should be noted, that the bits 1 to 7 of the **ECNT** may be used to check data consistency of the registers **GPR0** and **GPR1**.

In addition the **CNT** register is cleared **NEWVAL** status bit inside of **TIM[i]_CH[x]_IRQ_NOTIFY** status register and depending on corresponding interrupt enable condition *TIM_NEWVALx_IRQ* interrupt is raised.

The CNTS register update is not performed until the measurement is started. Afterwards each edge leaving the level defined by DSL is performing a CNTS register update.

If a PWM with a low level duty cycle should be measured (**DSL** = 0) and **IMM_START**=0, the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in **CNTS** and then finally in **GPR0** and the period is stored in **GPR1**.

When a PWM period was successfully measured, the data in the registers **GPR0** and **GPR1** is marked as valid for reading by the ARU when the **ARU_EN** bit is set inside **TIM[i]_CH[x]_CTRL** register, the **NEWVAL** bit is set inside the **TIM[i]_CH[x]_IRQ_NOTIFY** register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader attached to the ARU (**ARU_EN** bit enabled) or by the CPU the TIM channel set **GPROFL** status bit in **TIM[i]_CH[x]_IRQ_NOTIFY** and depending on corresponding interrupt enable bit value raises a *GPROFL_IRQ* and overwrites the old values in **GPR0** and **GPR1**. A new measurement is started afterwards.

If the register **CNT** produces an overflow during the measurement, the bit **CNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_CNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

If the register **ECNT** produces an overflow during the measurement, the bit **ECNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_ECNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

If **ECNT_RESET**=0 the counter **CNT** will be reset to 0 on active edge (defined by **DSL**) of the input signal. If **ECNT_RESET**=1 the counter **CNT** will be reset to 0 on each edge of the input signal.

Assume **EXT_CAP_EN**=0 and **SWAP_CAPTURE**=0:On every input edge to the active level defined by **DSL** will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**. Every edge to the inactive level will capture the data selected by **CNTS_SEL** to the registers **CNTS**.

Assume **EXT_CAP_EN**=0 and **SWAP_CAPTURE**=1:On every input edge to the inactive level defined by **DSL** will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**. Every edge to the active level will capture the data selected by **CNTS_SEL** to the registers **CNTS**.

External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled **EXT_CAP_EN**=1, the PWM measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

On every external capture event the data selected by **CNTS_SEL, EGPR0_SEL**, **GPR0_SEL** will be captured to the registers **CNTS, GPR0.**

If **SWAP_CAPTURE**=0 every external capture event will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**. Every input edge to the level != **DSL** will capture the data selected by **CNTS_SEL** to the registers **CNTS**.

If **SWAP_CAPTURE**=1 every input edge to the inactive level != **DSL** will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**.

Assume **SWAP_CAPTURE**=0:

Operation is done depending on CMU clock, **ISL, DSL** bit and the input signal value defined in next table (Assume CNTS_SEL= 0):

Table 32 Operation depending on CMU clock, ISL, DSL and the input signal value (Assume CNTS_SEL= 0)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
rising edge	-	0	0	0	capture CNT value in CNTS
falling edge	-	0	0	0	CNT=0
rising edge	-	0	1	0	no
falling edge	-	0	1	0	capture CNT value in CNTS; CNT=0
1	1	0	-	1	CNT++
0	1	0	-	1	no
falling edge	-	0	0	1	capture CNT value in CNTS
rising edge	-	0	0	1	CNT=0
falling edge	-	0	1	1	no
rising edge	-	0	1	1	capture CNT value in CNTS; CNT=0
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

The CNTS register update is not performed until the measurement is started (first edge defined by DSL is detected). Afterwards the update of the CNTS register is defined by ISL,DSL combinations in the table above.

28.13.4.2.2 TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit **DSL** of register **TIM[i]_CH[x]_CTRL** register.

If **IMM_START**=0 the pulse integration measurement is started with occurrence of the first edge defined by DSL on the input signal. If **IMM_START**=1 the measurement starts immediately after activating the channel by **TIM_EN**=1.

The pulse times are measured by incrementing the TIM channel counter **CNT** until the counter is stopped with occurrence of a input signal edge to the opposite signal level defined by **DSL**.

The counter **CNT** counts with the *CMU_CLKx* clock specified by the *CLK_SEL* bit field of the **TIM[i]_CH[x]_CTRL** register.

The **CNT** register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Assume **EXT_CAP_EN**=0 and **SWAP_CAPTURE**=0:After measurement is started, every falling(DSL=1) or rising(DSL=0) input edge will issue a *TIM_NEWVALx_IRQ* interrupt, and the registers **CNTS**, **GPR0** and **GPR1** are updated according to settings of its corresponding input multiplexers, using the bits **EGPR0_SEL**, **EGPR1_SEL**, **GPR0_SEL**, **GPR1_SEL** and **CNTS_SEL**. It should be noted, that the bits 1 to 7 of the **ECNT** may be used to check data consistency of the registers **GPR0** and **GPR1**.

Assume **EXT_CAP_EN**=0 and **SWAP_CAPTURE**=1:After measurement is started, every falling(DSL=1) or rising(DSL=0) input edge will issue a *TIM_NEWVALx_IRQ* interrupt, and the registers **CNTS**, **GPR0** are updated according to settings of its corresponding input multiplexers, using the bits **EGPR0_SEL**, **GPR0_SEL** and **CNTS_SEL**.

Every input edge to active level defined by **DSL** (rising DSL=1;falling DSL=0) will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**.

When the **ARU_EN** bit is set inside the **TIM[i]_CH[x]_CTRL** register the measurement results of the registers **GPR0** and **GPR1** can be send to subsequent sub-modules attached to the ARU.

External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled **EXT_CAP_EN**=1, the pulse integration is done until next external capture event occurs.

On every external capture event the data selected by **CNTS_SEL, EGPR0_SEL**, **GPR0_SEL** will be captured to the registers **CNTS, GPR0.**

If **SWAP_CAPTURE**=0 every external capture event will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**.

If **SWAP_CAPTURE**=1 every input edge to the inactive level != **DSL** will capture the data selected by **EGPR1_SEL**, **GPR1_SEL** to the registers **GPR1**.

Assume **SWAP_CAPTURE**=0; **IMM_START**=0:

Operation is done depending on CMU clock, **DSL** bit and the input signal value defined in next table (inc_cnt = false if TIM channel is enabled):

Table 33 Operation depending on CMU clock, DSL and the input signal value (inc_cnt = false if TIM channel is enabled)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
falling edge	-	0	-	0	inc_cnt = true
rising edge	-	0	-	0	if inc_cnt == true then {do capture GPRx, CNTS; issue NEWVAL_IRQ} inc_cnt = false
rising edge	-	0	-	1	inc_cnt = true
falling edge	-	0	-	1	if inc_cnt == true then {do capture GPRx, CNTS; issue NEWVAL_IRQ} inc_cnt = false

Table 33 Operation depending on CMU clock, DSL and the input signal value (inc_cnt = false if TIM channel is enabled) (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	-	-	if inc_cnt == true then CNT++;
-	-	rising edge	-	-	do capture GPRx, CNTS; issue NEWVAL_IRQ; CNT=0
-	0	0	-	-	no

28.13.4.2.3 TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields **DSL** and **ISL** in **TIM[i]_CH[x]_CTRL** register.

In addition, a *TIM[i]_NEWVAL[x]_IRQ* interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register **CNT** is used to count the number of edges, and the bit fields **EGPR0_SE**L, **EGPR1_SE**L,**GPR0_SEL**, **GPR1_SEL**, and **CNTS_SEL** can be used to configure the desired update values for the registers **GPR0**, **GPR1** and **CNTS**. These register are updated whenever the edge counter **CNT** is incremented due to the arrival of a desired edge.

If the preceding data was not consumed by a reader attached to the ARU or by the CPU the TIM channel sets **GPROFL** status bit and raises a *GPROFL[x]_IRQ* if it was enabled in **TIM[i]_CH[x]_IRQ_EN** register and overwrites the old values in **GPR0** and **GPR1** with the new ones.

If the register **CNT** produces an overflow during the measurement, the bit **CNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_CNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

If the register **ECNT** produces an overflow during the measurement, the bit **ECNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_ECNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

The TIM Input Event Mode does not depend on the bit field **CLK_SEL** of register **TIM[i]_CH[x]_CTRL**.

External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on the **DSL**, **ISL** bit and the input signal value defined in next table:

Table 34 Capturing depended on the DSL, ISL and the input signal value, if external capture is enabled

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	1	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

28.13.4.2.4 TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a *TIM[i]_NEWVAL[x]_IRQ* is raised is programmable. In this mode it must be specified in the **CNTS** register after how many edges the interrupt has to be raised.

A value of 0 in **CNTS** means that after one edge an interrupt is raised and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields **DSL** and **ISL** of register **TIM[i]_CH[x]_CTRL**.

With each triggered interrupt, the registers **GPR0** and **GPR1** are updated according to bits **EGPR0_SE**L, **EGPR1_SE**L,**GPR0_SEL** and **GPR1_SEL**.

If the register **ECNT** produces an overflow during the measurement, the bit **ECNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_ECNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field **CLK_SEL** of register **TIM[i]_CH[x]_CTRL**.

External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on the external capture signal, **DSL**, **ISL** bit and the input signal value defined in next table:

Table 35 Operation depending on the external capture signal, DSL, ISL and the input signal value

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	if CNT >= CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
-	0	1	-	no
1	rising edge	0	1	if CNT >= CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	-	0	1	no
0	rising edge	0	0	if CNT >= CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
1	-	0	0	no

28.13.4.2.5 TIM Bit Compression Mode (TBCM)

The TIM Bit Compression Mode can be used to combine all filtered input signals of a TIM sub-module to a parallel *m* bit data word, which can be routed to the ARU, where *m* is the number of channels available in the TIM sub-module.

Figure 45 gives an overview of the TIM bit compression mode.

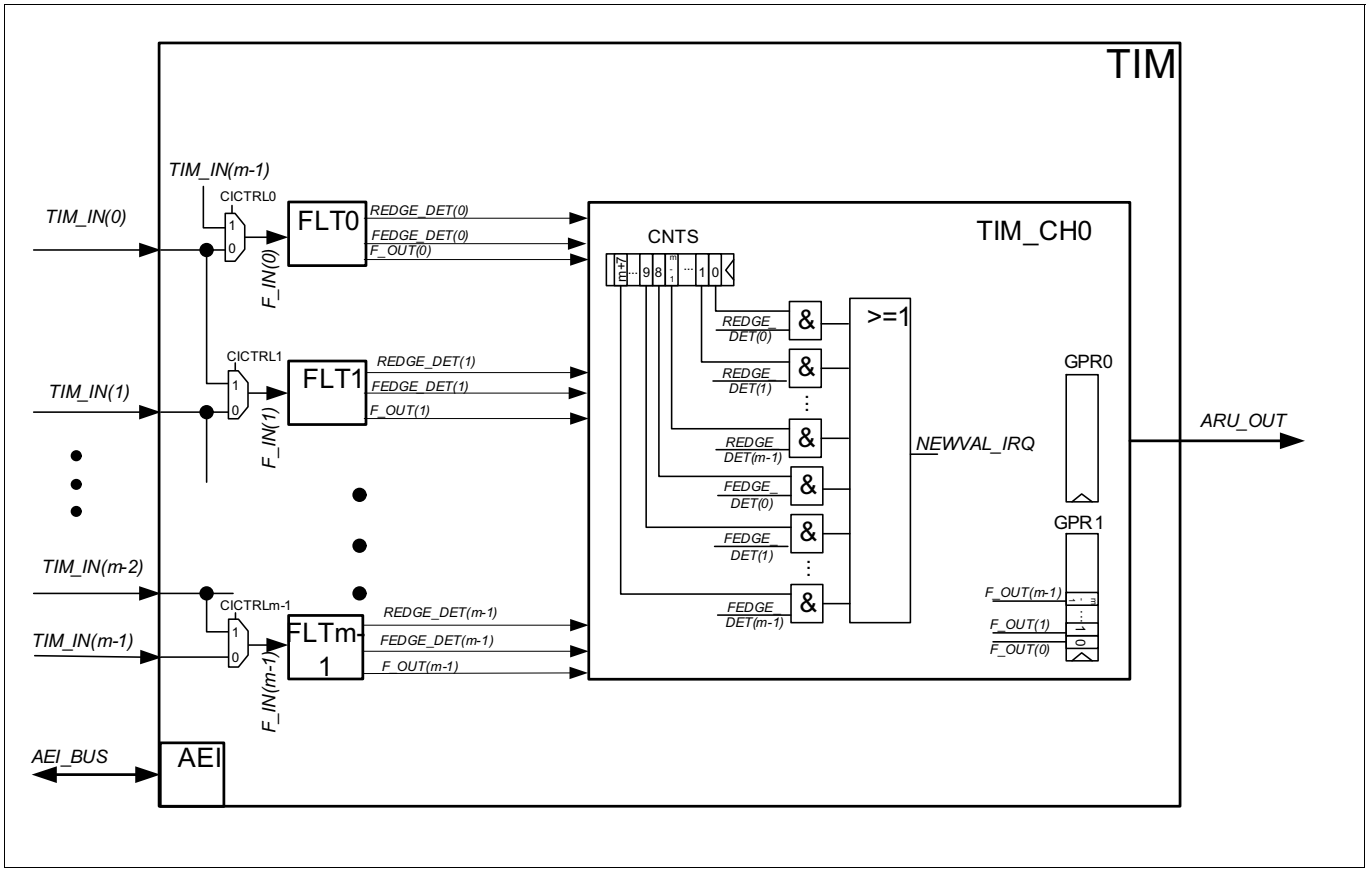

Figure 45 TIM Bit Compression Mode

The register **CNTS** of a channel is used to configure the event that releases the *NEWVAL_IRQ* and samples the input signals F_IN(0) to F_IN(*m*-1) in ascending order as a parallel data word in **GPR1**.

The bits 0 to *m-1* of the **CNTS** register are used to select the *REDGE_DET* signals of the TIM filters 0 to *m-1* as a sampling event, and the bits 8 to (7+*m*) are used to select the *FEDGE_DET* signals of the TIM filters 0 to *m-1*, respectively. If multiple events are selected, the events are OR-combined (see also **Figure 45**).

EGPR0_SEL,**GPR0_SEL** selects the timestamp value, which is routed through the ARU. **GPR1_SEL** is not applicable in TBCM mode.

If the bit **ARU_EN** of register **TIM[i]_CH[x]_CTRL** is set, the sampled data of register **GPR1** is routed together with a time stamp of register **GPR0** to the ARU, whenever the NEWVAL_IRQ is released.

In TIM Bit compression mode, the register **ECNT** increments with each *NEWVAL_IRQ*, which means that the value of ECNT may depend on all *m* input signals. Consequently, the LSB of **ECNT** does not reflect the actual level of the input signal TIM_IN(x).

If the register **ECNT** produces an overflow during the measurement, the bit **ECNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_ECNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

The TIM Bit Compression Mode does not depend on the bit field **CLK_SEL** of register **TIM[i]_CH[x]_CTRL**.

External capture Bit Compression Mode (TBCM)

If external capture is enabled, capturing is done depending on the **DSL**, **ISL** bit and the input signal value defined in next table:

Table 36 Capturing depended on the DSL, ISL and the input signal value, if external capture is enabled

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	1	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

28.13.4.2.6 TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and raising *TIM[i]_NEWVAL[x]_IRQ* is programmable. In this mode it must be specified in the **CNTS** register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in **TIM[i]_CH[x]_CNTS** means that after one **CLK_SEL** edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the **TIM[i]_CH[x]_CNT** register the elapsed cycles were incremented and compared against **TIM[i]_CH[x]_CNTS**. If **TIM[i]_CH[x]_CNT** is greater or equal to **TIM[i]_CH[x]_CNTS** a trigger will be raised. This allows by writing a value to **TIM[i]_CH[x]_CNTS** that the actual period time can be changed on the fly.

Operation is done depending on CMU clock, **DSL**, **ISL** bit and the input signal value defined in next table:

Table 37 Operation depending on CMU clock, DSL, ISL and the input signal value

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description

-	1	0	1	-	if CNT >= CNTS then do capture
					  issue NEWVAL_IRQ;
					  CNT=0
					else
					  CNT++
					endif

0	0	0	0	1	no

1	1	0	0	1	if CNT >= CNTS then do capture;
					  issue NEWVAL_IRQ;
					  CNT=0
					else
					  CNT++
					endif

0	0	-	0	1	no

0	1	0	0	0	if CNT >= CNTS then do capture;
					  issue NEWVAL_IRQ;
					  CNT=0
					else
					  CNT++
					endif

Table 37 Operation depending on CMU clock, DSL, ISL and the input signal value (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
1	0	0	0	0	no
-	0	0	-	-	no

In this mode the **TIM[i]_CH[x]_GPR1** operates as a shadow register for **TIM[i]_CH[x]_CNTS**. This would allow that the period for the next sampling period could be specified. The update of **TIM[i]_CH[x]_CNTS** will only take place once on a trigger if the **TIM[i]_CH[x]_GPR1** was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from **TIM[i]_CH[x]_GPR1** and afterwards the new sampling period for the next sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers **GPR0** and **GPR1** are updated according to bits **GPR0_SEL**, **GPR1_SEL, EGPR0_SEL** and **EGPR1_SEL**.

When selecting **ECNT** as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture. Selecting **GPR0_SEL** = '11' and **EGPR0_SEL** = '0' for TIM channel 0 all 8 TIM input signals will be captured to **GPR0[7:0]**.

In the TGPS Mode the bit field **CLK_SEL** of register **TIM[i]_CH[x]_CTRL** will define the selected CMU clock which will be used.

The behavior of the **ECNT** counter is configurable by **ECNT_RESET**. If set to 1 on each interrupt (period expired) the **ECNT** will be reset. Otherwise it operates in wrap around mode.

If the register **ECNT** produces an overflow during the measurement, the bit **ECNTOFL** is set inside the register **TIM[i]_CH[x]_IRQ_NOTIFY** and interrupt *TIM_ECNTOFL[x]_IRQ* is raised depending on corresponding interrupt enable condition.

External capture TIM Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter **CNT** and issue a *NEWVAL_IRQ*.

Operation is done depending on the CMU clock, external capture signal, **DSL**, **ISL** bit and the input signal value defined in next table:

Table 38 Operation depending on the CMU clock, external capture signal, DSL, ISL and the input signal value

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description

-	1	0	1	-	if CNT >= CNTS then do
					capture;
					issue NEWVAL_IRQ;
					CNT=0
					else
					CNT++
					endif

0	0	0	0	1	no

Table 38 Operation depending on the CMU clock, external capture signal, DSL, ISL and the input signal value (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description

1	1	0	0	1	if CNT >= CNTS then do
					capture;
					issue NEWVAL_IRQ;
					CNT=0
					else
					CNT++
					endif

0	0	-	0	1	no

0	1	0	0	0	if CNT >= CNTS then do
					capture;
					issue NEWVAL_IRQ;
					CNT=0
					else
					CNT++
					endif

1	0	0	0	0	no
-	0	0	-	-	no
-	-	rising edge	-	-	do capture; issue NEWVAL_IRQ; CNT =0

28.13.4.2.7 TIM Serial Shift Mode (TSSM)

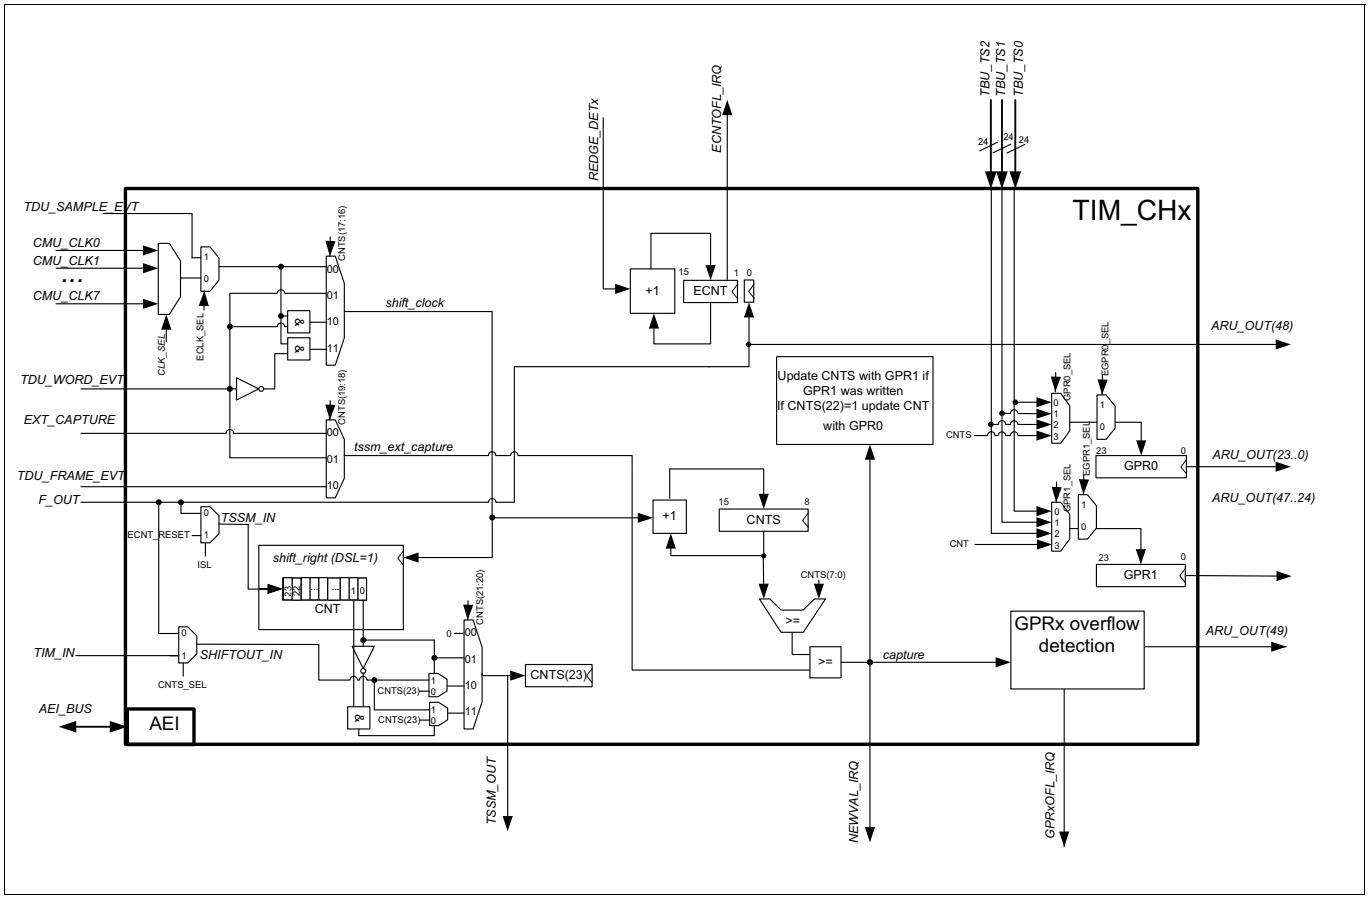

Figure 46 TIM Serial Shift Mode (TSSM)

In the TIM Serial Shift Mode on each shift clock event the actual value of the input signal **TSSM_INx** will be registered in dependence of **DSL** n the register **TIM[i]_CH[x]_CNT**.

If **ISL**=0 is set **FOUTx** will be used as shift in value **TSSM_INx**, with **ISL**=1 the bit field **ECNT_RESET** defines the value for **TSSM_INx**.

With **DSL**=0 **TSSM_INx** will be stored in **TIM[i]_CH[x]_CNT[0]** and **TIM[i]_CH[x]_CNT[22:0]** will be shifted left. With **DSL**</ b>=1 **TSSM_OUTx** will be stored in **TIM[i]_CH[x]_CNT[23]** and **TIM[i]_CH[x]_CNT[23:1]** will be shifted right.

Operation is done depending on the shift clock, external capture signal, **DSL**, **ISL** bit and the input signal value defined in next table:

Table 39 Operation depending on the shift clock, external capture signal, DSL, ISL and the input signal value

Input signal TSSM_INx	shift clock	tssm_ext_capture	ISL	DSL	Action description
-	0	0	-	-	no
-	-	1	-	-	if EXT_CAP_EN=1 then see function table in next chapter else no endif

Table 39 Operation depending on the shift clock, external capture signal, DSL, ISL and the input signal value (cont'd)

Input signal TSSM_INx	shift clock	tssm_ext_capture	ISL	DSL	Action description

value	1	0	0	0	CNT[23:1]= CNT[22:0];
					CNT[0]= value
					if CNTS[15:8] >= CNTS[7:0]
					then
					do capture;
					issue NEWVAL_IRQ;
					CNTS[15:8]=0
					else
					CNTS[15:8]++
					endif

value	1	0	0	1	CNT[22:0]= CNT[23:1];
					CNT[23]= value
					if CNTS[15:8] >= CNTS[7:0]
					then
					do capture;
					issue NEWVAL_IRQ;
					CNTS[15:8]=0
					else
					CNTS[15:8]++
					endif

value	1	0	1	0	CNT[23:1]= CNT[22:0]; CNT[0]= value if CNTS[15:8] >= CNTS[7:0] then do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET else CNTS[15:8]++ endif

value	1	0	1	1	CNT[22:0]= CNT[23:1];
					CNT[23]= value
					if CNTS[15:8] >= CNTS[7:0]
					then
					do capture;
					issue NEWVAL_IRQ;
					CNTS[15:8]=0
					CNT[23:0]=ECNT_RESET
					else
					CNTS[15:8]++
					endif

The register **TIM[i]_CH[x]_CNTS[7:0]** define the amount of bits which will be stored inside **TIM[i]_CH[x]_CNT.**

Each shift clock will increment the register **TIM[i]_CH[x]_CNTS[15:8].** If the condition **TIM[i]_CH[x]_CNTS[15:8] >= TIM[i]_CH[x]_CNTS[7:0]** is met a capture event is raised and *TIM[i]_NEWVAL[x]_IRQ* is asserted.

With each capture event the registers **GPR0** and **GPR1** are updated according to bits **GPR0_SEL**, **GPR1_SEL, EGPR0_SEL** and **EGPR1_SEL**.

If the bit field **ISL** is set to 1 the register bits **TIM[i]_CH[x]_CNT** are set to the value defined by **ECNT_RESET** in case of a capture event.

In this mode the **TIM[i]_CH[x]_GPR1** operates as a shadow register for **TIM[i]_CH[x]_CNTS**. This allows that the amount of bits to sample can be specified. The update of **TIM[i]_CH[x]_CNTS** will only take place once on a trigger if the **TIM[i]_CH[x]_GPR1** was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from **TIM[i]_CH[x]_GPR1** and afterwards the new amount of bits to sample for the next sampling period (the one after the actual sampling period) could be written.

The shift clock which will be in use is selectable by **TIM[i]_CH[x]_CNTS[17:16]**:

$\mathbf{00_B}$: source selection by **USE_TDU_CLK_SRC** is in use. It can be set to any CMU_CLK source or to the local TDU sample clock tdu_sample_evt.

$\mathbf{01_B}$: the tdu_word_evt signal will be used as shift clock source.

$\mathbf{10_B}$: the clk source selected by **USE_TDU_CLK_SRC** is used and gated with tdu_word_evt. If tdu_word_evt=0 then shift clock will be 0.

$\mathbf{11_B}$: the clk source selected by **USE_TDU_CLK_SRC** is used and gated with tdu_word_evt. If tdu_word_evt=1 then shift clock will be 0.

Signal Generation with TIM Serial Shift Mode

If **TIM[i]_CH[x]_CNTS[22]** is 1 the **TIM[i]_CH[x]_GPR0** operates as a shadow register for **TIM[i]_CH[x]_CNT**. This allows that the bits for shifting out can be specified. The update of **TIM[i]_CH[x]_CNT** will only take place once on a trigger if the **TIM[i]_CH[x]_GPR0** was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from **TIM[i]_CH[x]_GPR0** and afterwards the new bits to shift out could be written.

In addition the TIM Serial Shift Mode is able to generate a signal **TSSM_OUT** which can be used internally to the TIM channel.

On each system clock the value for **TSSM_OUT** is generated as defined next. The actual value can be read by the register bit **TIM[i]_CH[x]_CNTS[23]**.

Following functionality for **TSSM_OUTx** is selectable by **TIM[i]_CH[x]_CNTS[21:20]:**

$\mathbf{00_B}$: Constant output; **TSSM_OUTx** = 0.

$\mathbf{10_B}$:Shift output; If **DSL**=0 (shift left) then **TSSM_OUTx** = **TIM[i]_CH[x]_CNT[23]** else (shift right) **TSSM_OUTx** = **TIM[i]_CH[x]_CNT[0]**.

$\mathbf{10_B}$: Latched output; If **DSL**=0 and **TIM[i]_CH[x]_CNT[23]**=1 then **TSSM_OUTx** = **SHIFTOUT_INx** elsif **DSL**=1 and **TIM[i]_CH[x]_CNT[0]**=1 then **TSSM_OUTx** = **SHIFTOUT_INx**.

$\mathbf{11_B}$: Registered output; If **DSL**=0 and **TIM[i]_CH[x]_CNT[23:22]**=b01 then **TSSM_OUTx** = **SHIFTOUT_INx** elsif **DSL**=1 and **TIM[i]_CH[x]_CNT[1:0]**=b10 then **TSSM_OUTx** = **SHIFTOUT_INx**.

In case of registered or latched output mode the signal **SHIFTOUT_INx** is selectable by **CNTS_SEL**.

If **CNTS_SEL**=0 is set **FOUTx** will be used for **SHIFTOUT_INx**, with **CNTS_SEL**=1 the signal **TIM_INx** is in us for **SHIFTOUT_INx**.

External capture TIM Serial Shift Mode (TSSM)

If external capture is enabled (**EXT_CAP_EN**=1), the external capture events will capture the GPRx, reset the counter **CNT** depending on ISL and issue a *NEWVAL_IRQ*. Functionality from previous table will be applied.

The source which will be used as external capture event for TSSM mode is selectable by **TIM[i]_CH[x]_CNTS[19:18]**:

00_B: source selection by **EXT_CAP_SRC** is in use.

01_B: tdu_word_evt signal will be used as source.

10_B: tdu_frame_evt signal will be used as source.

11_B: reserved

Operation is done depending on the shift clock, external capture signal, **DSL**, **ISL** bit and the input signal value defined in next table:

Table 40 Operation depending on the shift clock, external capture signal, DSL, ISL and the input signal value

Input signal F_OUTx	shift clock	tssm_ext_capture	ISL	DSL	Action description
-	0	1	1	-	do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET

value	1	1	0	0	CNT[23:1]= CNT[22:0]; CNT[0]= value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0
value	1	1	0	1	CNT[22:0]= CNT[23:1]; CNT[23]= value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0

28.13.5 MAP Submodule Interface

The GTM provides one dedicated TIM sub-module TIM0 where channels zero (0) to five (5) are connected to the MAP sub-module described in chapter “TIM0 Input Mapping Module ”. There, the TIM0 sub-module channels provide the input signal level together with the actual filter value and the annotated time stamp for the edge

together in a 49 bit wide signal to the MAP sub-module. This 49 bit wide data signal is marked as valid with a separate valid signal tim0_map_dval[x] (x: 0…5).

28.13.5.1 Structure of map data

Table 41 MAP Submodule Interface

tim0_map_data[x](48)	Signal level bit from tim0_ch[x]
tim0_map_data[x](47:24)	actual filter value TIM0_CH[x]_FLT_RE/ TIM0_CH[x]_FLT_FE if corresponding channel x bit field FLT_MODE_RE/ FLT_MODE_FE is 1 else 0 is assigned.
tim0_map_data[x](23:0)	time stamp value selected by TBU0_SEL, GRP0_SEL, EGPR0_SEL, CNTS_SEL of channel x if bit field TIM_EN= 1
tim0_map_dval[x]	mark tim0_map_data[x] valid for one clock cycle

*Note: With **TIM_EN**=1 the MAP interface starts operation, it is not dependent on the setting of the bit fields **TIM_MODE, ISL, DSL**.*

Note: While the MAP interface is in use the following guidelines have to be fulfilled, otherwise inconsistent filter values can be transferred.

Change **TIM0_CH[x]_FLT_RE** only between occurrence of rising and falling edge.

Change **TIM0_CH[x]_FLT_FE** only between occurrence of falling and rising edge.

28.13.6 TIM Interrupt Signals

Table 42 TIM Interrupt Signals

Signal	Description
TIM[i]_NEWVAL[x]_IRQ	New measurement value detected by SMU of channel x (x: 0…m-1)
TIM[i]_ECNTOFL[x]_IRQ	ECNT counter overflow of channel x (x: 0…m-1)
TIM[i]_CNTOFL[x]_IRQ	SMU CNT counter overflow of channel x (x: 0…m-1)
TIM[i]_GPROFL[x]_IRQ	GPR0 and GPR1 data overflow, old data was not read out before new data has arrived at input pin of channel x (x: 0…m-1)
TIM[i]_TODET[x]_IRQ	Time out reached for input signal of channel x (x: 0…m-1)
TIM[i]_GLITCHDET[x]_IRQ	A glitch was detected by the TIM filter of channel x (x: 0…m-1)

28.13.7 TIM Configuration Register Overview

Table 43 TIM Configuration Register Overview

Register Name	Description	see Page
TIM[i]_CH[x]_CTRL	TIMi channel x control register	178
TIM[i]_CH[x]_ECTRL	TIMi channel x extended control register	194
TIM[i]_CH[x]_FLT_RE	TIMi channel x filter parameter 0 register	182

TIM[i]_CH[x]_TDUC	TIMi channel x TDU counter register	193
TIM[i]_CH[x]_GPR0	TIMi channel x general purpose 0 register	183
TIM[i]_CH[x]_GPR1	TIMi channel x general purpose 1 register	184
TIM[i]_CH[x]_CNT	TIMi channel x SMU counter register	185
TIM[i]_CH[x]_ECNT	TIMi channel x SMU edge counter register	194
TIM[i]_CH[x]_CNTS	TIMi channel x SMU shadow counter register	185
TIM[i]_CH[x]_IRQ_NOTIFY	TIMi channel x interrupt notification register	186
TIM[i]_CH[x]_IRQ_EN	TIMi channel x interrupt enable register	187
TIM[i]_CH[x]_EIRQ_EN	TIMi channel x error interrupt enable register	191
TIM[i]_CH[x]_IRQ_FORCINT	TIMi channel x force interrupt register	188
TIM[i]_CH[x]_IRQ_MODE	TIMi interrupt mode configuration register	189
TIM[i]_RST	TIMi global software reset register	188
TIM[i]_IN_SRC	TIMi AUX IN source selection register	190
TIM[i]_INP_VAL	TIMi input value observation register	198

28.13.8 TIM Configuration Registers Description

28.13.8.1 Register TIM[i]_CH[x]_CTRL

TIMi Channel x Control Register

Table 44 Filter Modes for Rising Edge

FLT_MODE_RE		EFLT_CTR_RE[1)]	FLT_CTR_RE	Coding
0	Immediate edge propagation mode for rising edge	0	0	Immediate edge propagation mode
		0	1	Immediate edge propagation mode
		1	0	Reserved
		1	1	Reserved
1	Individual de-glitch mode for rising edge	0	0	Up-Down Counter individual de-glitch mode
		0	1	Hold Counter individual de-glitch mode
		1	0	Reset Counter individual de-glitch mode
		1	1	Reserved

1) Bit is located in register TIM[i]_CH[x]_ECTRL.

Table 45 Filter Modes for Falling Edge

FLT_MODE_FE		EFLT_CTR_FE[1)]	FLT_CTR_FE	Coding
0	Immediate edge propagation mode for rising edge	0	0	Immediate edge propagation mode
		0	1	Immediate edge propagation mode
		1	0	Reserved
		1	1	Reserved
1	Individual de-glitch mode for rising edge	0	0	Up-Down Counter individual de-glitch mode
		0	1	Hold Counter individual de-glitch mode
		1	0	Reset Counter individual de-glitch mode
		1	1	Reserved

1) Bit is located in register TIM[i]_CH[x]_ECTRL.

TIMi_CHx_CTRL (i=0-7;x=0-7)

TIMi Channel x Control Register **($001024_H+i*800_H+x*80_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TOCTRL		EGPR1_SEL	EGPR0_SEL	FR_ECNT_OFL		CLK_SEL		FLT_CTR_FE	FLT_MODE_FE	FLT_CTR_RE	FLT_MODE_RE	EXT_CAP_EN	FLT_CNT_FRQ		FLT_EN

ECNT_RESET	ISL	DSL	CNTS_SEL	GPR1_SEL		GPR0_SEL		TBU0_SEL	CICTRL	ARU_EN	OSM	TIM_MODE			TIM_EN
rw	rw	rw	rw	rw		rw		rw	rw	rw	rw	rw			rw

Field	Bits	Type	Description
TIM_EN	0	rw	**TIM channel x enable** Enabling of the channel resets the registers **ECNT, TIM[i]_CH[x]_CNT, TIM[i]_CH[x]_GPR0,** and **TIM[i]_CH[x]_GPR1** to their reset values. After finishing the action in one-shot mode the **TIM_EN** bit is cleared automatically. Otherwise, the bit must be cleared manually. 0_B Channel disabled 1_B Channel enabled
TIM_MODE	3:1	rw	**TIM channel x mode** If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 0b000 (TPWM mode). The TIM_MODE register should not be changed while the TIM channel is enabled. If the TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL,ISL,TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM channel by setting TIM_EN= 0 and reenabling with TIM_EN= 1 will change the channel operation mode. 000_B PWM Measurement Mode (TPWM) 001_B Pulse Integration Mode (TPIM) 010_B Input Event Mode (TIEM) 011_B Input Prescaler Mode (TIPM) 100_B Bit Compression Mode (TBCM) 101_B Gated Periodic Sampling Mode (TGPS) 110_B Serial Shift Mode (TSSM)
OSM	4	rw	**One-shot mode** After finishing the action in one-shot mode the **TIM_EN** bit is cleared automatically. 0_B Continuous operation mode 1_B One-shot mode
ARU_EN	5	rw	**GPR0 and GPR1 register values routed to ARU** 0_B Registers content not routed 1_B Registers content routed
CICTRL	6	rw	**Channel Input Control** 0_B Use signal TIM_IN(x) as input for channel x 1_B Use signal TIM_IN(x-1) as input for channel x (or TIM_IN(m-1) if x is 0)
TBU0_SEL	7	rw	**TBU_TS0 bits input select for TIM0_CH[x]_GPRz (z: 0, 1)** This bit is only applicable for TIM0. 0_B Use TBU_TS0(23..0) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1 1_B Use TBU_TS0(26..3) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1

Field	Bits	Type	Description
GPR0_SEL	9:8	rw	**Selection for GPR0 register** If EGPR0_SEL =0 / EGPR0_SEL =1 : If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input. 00_B Use TBU_TS0 as input / use ECNT as input 01_B Use TBU_TS1 as input / use TIM_INP_VAL as input 10_B Use TBU_TS2 as input / reserved 11_B Use CNTS as input; if TGPS mode in channel = 0 is selected, use TIM Filter F_OUT as input / reserved
GPR1_SEL	11:10	rw	**Selection for GPR1 register** If EGPR1_SEL =0 / EGPR1_SEL =1: If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input. Note: In TBCM mode: EGPR1_SEL=1, GPR1_SEL=01 selects TIM_INP_VAL as input; in all other cases, TIM Filter F_OUT is used. 00_B Use TBU_TS0 as input / use ECNT as input 01_B Use TBU_TS1 as input / use TIM_INP_VAL as input 10_B Use TBU_TS2 as input / reserved 11_B Use CNT as input / reserved
CNTS_SEL	12	rw	**Selection for CNTS register** The functionality of the **CNTS_SEL** is disabled in the modes TIPM,TGPS and TBCM. **CNTS_SEL** in TSSM mode selects the source signal for registered or latched shift out operation. 0_B use F_OUTx 1_B use TIM_INx 0_B Use CNT register as input 1_B Use TBU_TS0 as input
DSL	13	rw	**Signal level control** In TIM_MODE=0b110 (TSSM), the bit field DSL defines the shift direction. 0_B Shift left 1_B Shift right 0_B Measurement starts with falling edge (low level measurement) 1_B Measurement starts with rising edge (high level measurement)
ISL	14	rw	**Ignore signal level** This bit is mode dependent and will have different meanings (see details in the TIM Channel mode description). 0_B Use DSL bit for selecting active signal level (TIEM) 1_B Ignore DSL and treat both edges as active edge (TIEM)

Field	Bits	Type	Description
ECNT_RESET	15	rw	**Enables resetting of counter in certain modes** If TIM_MODE=0b101 (TGPS) / TIM_MODE=0b000 (TPWM) else ECNT counter operating in wrap around mode; In TIM_MODE=0b110 (TSSM), the bit field ECNT_RESET defines the initial polarity for the shift register. 0_B ECNT counter operating in wrap around mode / ECNT counter operating in wrap around mode, CNT is reset on active input edge defined by DSL 1_B ECNT counter is reset with periodic sampling / ECNT counter operating in wrap around mode, CNT is reset on active and inactive input edge
FLT_EN	16	rw	**Filter enable for channel x** If the filter is disabled, all filter related units (including CSU) are bypassed, which means that the signal *F_IN* is directly routed to signal *F_OUT*. 0_B Filter disabled and internal states are reset 1_B Filter enabled
FLT_CNT_FRQ	18:17	rw	**Filter counter frequency select** 00_B FLT_CNT counts with CMU_CLK0 01_B FLT_CNT counts with CMU_CLK1 10_B FLT_CNT counts with CMU_CLK6 11_B FLT_CNT counts with CMU_CLK7
EXT_CAP_EN	19	rw	**Enables external capture mode** The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored. 0_B External capture disabled 1_B External capture enabled
FLT_MODE_RE	20	rw	**Filter mode for rising edge** Coding see **Table 44**.
FLT_CTR_RE	21	rw	**Filter counter mode for rising edge** Coding see **Table 44**.
FLT_MODE_FE	22	rw	**Filter mode for falling edge** Coding see **Table 45**.
FLT_CTR_FE	23	rw	**Filter counter mode for falling edge** Coding see **Table 45**.
CLK_SEL	26:24	rw	**CMU clock source select for channel** If ECLK_SEL =0 / ECLK_SEL =1: 000_B CMU_CLK0 selected / tdu_sample_evt of TDU selected 001_B CMU_CLK1 selected / reserved 010_B CMU_CLK2 selected / reserved 011_B CMU_CLK3 selected / reserved 100_B CMU_CLK4 selected / reserved 101_B CMU_CLK5 selected / reserved 110_B CMU_CLK6 selected / reserved 111_B CMU_CLK7 selected / reserved

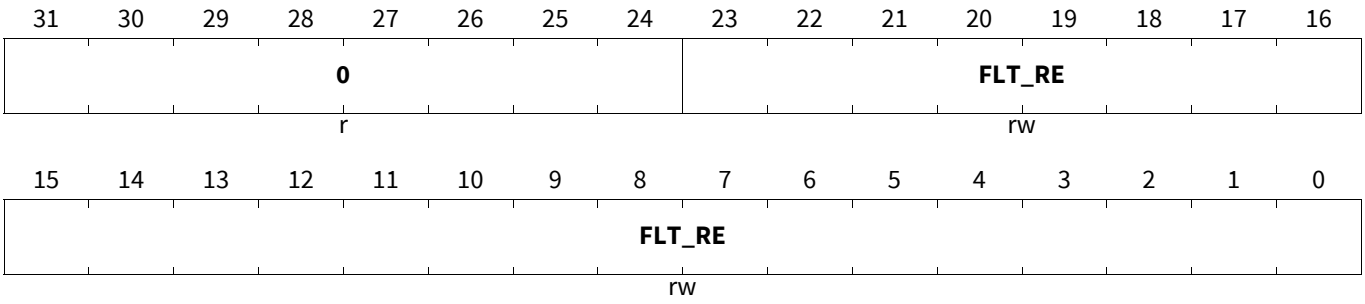
Field	Bits	Type	Description
FR_ECNT_OFL	27	rw	**Extended Edge counter overflow behavior** 0_B Overflow will be signaled on ECNT bit width = 8 1_B Overflow will be signaled on EECNT bit width (full range)
EGPR0_SEL	28	rw	**Extension of GPR0_SEL bit field** Details described in GPR0_SEL bit field.
EGPR1_SEL	29	rw	**Extension of GPR1_SEL bit field** Details described in GPR1_SEL bit field.
TOCTRL	31:30	rw	**Timeout control** It has to be mentioned that writing of TOCTRL= 0 will every time stop the TDU, independent of the previous state of TOCTRL. 00_B Timeout feature disabled 01_B Timeout feature enabled for rising edge only 10_B Timeout feature enabled for falling edge only 11_B Timeout feature enabled for both edges

28.13.8.2 Register TIM[i]_CH[x]_FLT_RE

TIMi Channel x Filter Parameter 0 Register

TIMi_CHx_FLT_RE (i=0-7;x=0-7)

TIMi Channel x Filter Parameter 0 Register($00101C_H$+i*800_H+x*80_H) Application Reset Value: 0000 0000_H



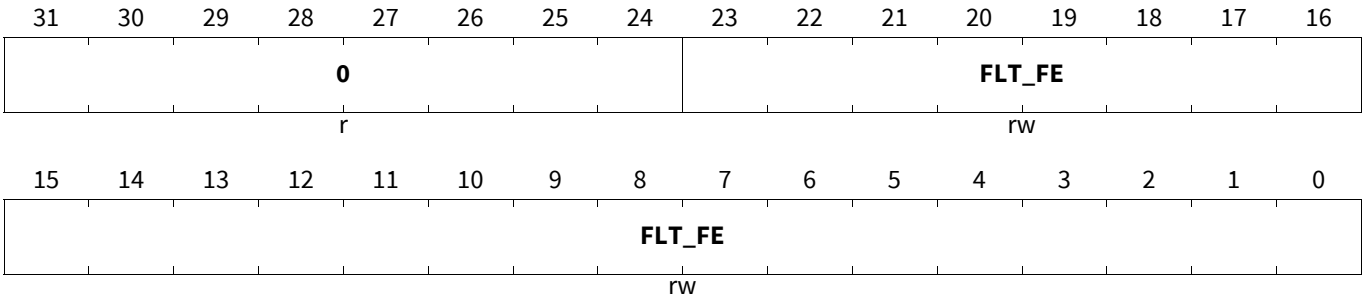
Field	Bits	Type	Description
FLT_RE	23:0	rw	**Filter parameter for rising edge** FLT_RE has different meanings in the various filter modes.Immediate edge propagation mode = acceptance time for rising edgeIndividual deglitch time mode = deglitch time for rising edge.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

28.13.8.3 Register TIM[i]_CH[x]_FLT_FE

TIMi Channel x Filter Parameter 1 Register

TIMi_CHx_FLT_FE (i=0-7;x=0-7)

TIMi Channel x Filter Parameter 1 Register(001020_H+i*800_H+x*80_H) Application Reset Value: 0000 0000_H



Field	Bits	Type	Description
FLT_FE	23:0	rw	**Filter parameter for falling edge** FLT_FE has different meanings in the various filter modes.Immediate edge propagation mode = acceptance time for falling edge Individual deglitch time mode = deglitch time for falling edge.
0	31:24	r	**Reserved** Read as zero, shall be written as zero

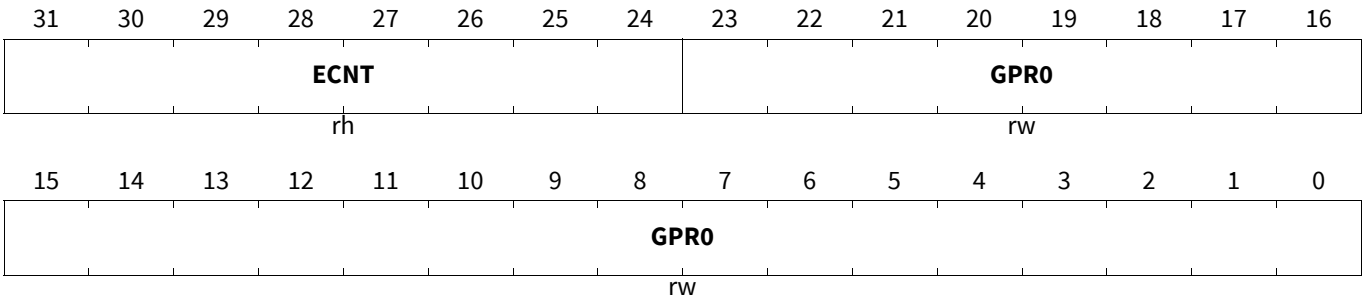
28.13.8.4 Register TIM[i]_CH[x]_GPR0

TIMi Channel x General Purpose 0 Register

Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

TIMi_CHx_GPR0 (i=0-7;x=0-7)

TIMi Channel x General Purpose 0 Register(001000_H+i*800_H+x*80_H) Application Reset Value: 0000 0000_H



Field	Bits	Type	Description
GPR0	23:0	rw	**Input signal characteristic parameter 0** The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields **EGPR0_SEL**, **GPR0_SEL** of register **TIM[i]_CH[x]_CTRL**. **Note:** The content of this register can only be written in TIM channel mode TSSM.
ECNT	31:24	rh	**Edge counter** The **ECNT** counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of **ECNT**.

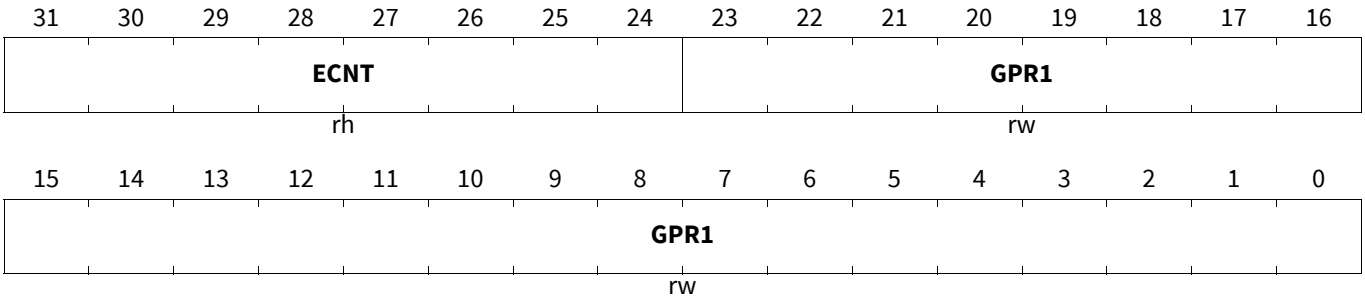
28.13.8.5 Register TIM[i]_CH[x]_GPR1

TIMi Channel x General Purpose 1 Register

Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

TIMi_CHx_GPR1 (i=0-7;x=0-7)

TIMi Channel x General Purpose 1 Register(001004_H+i*800_H+x*80_H) Application Reset Value: 0000 0000_H

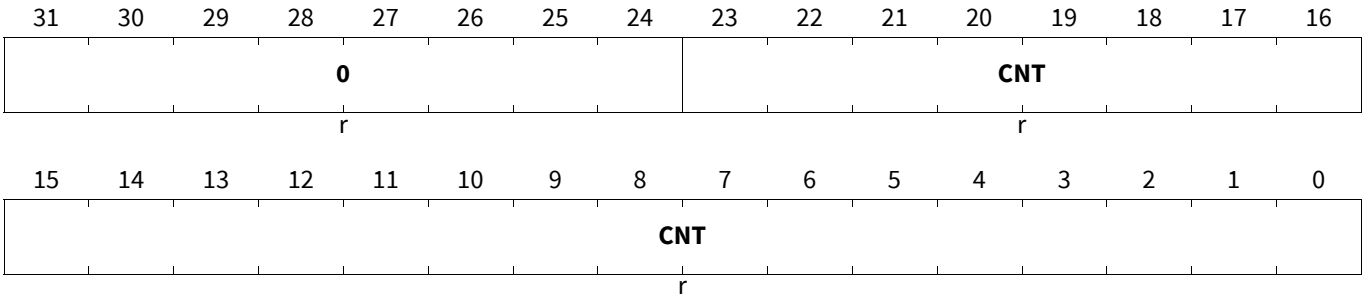


Field	Bits	Type	Description
GPR1	23:0	rw	**Input signal characteristic parameter 1** The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields **EGPR1_SEL**, **GPR1_SEL** of register **TIM[i]_CH[x]_CTRL**. In TBCM mode if EGPR1_SEL=1, GPR1_SEL=01 then TIM_INP_VAL is used as input in all other cases TIM Filter F_OUT is used as input and Bits GPR1(23:8) = 0 The content of this register can only be written in TIM channel mode TGPS and TSSM.
ECNT	31:24	rh	**Edge counter** The **ECNT** counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of **ECNT**.

28.13.8.6 Register TIM[i]_CH[x]_CNT

TIMi Channel x SMU Counter Register

TIMi_CHx_CNT (i=0-7;x=0-7)
TIMi Channel x SMU Counter Register (001008_H+i*800_H+x*80_H) Application Reset Value: 0000 0000_H



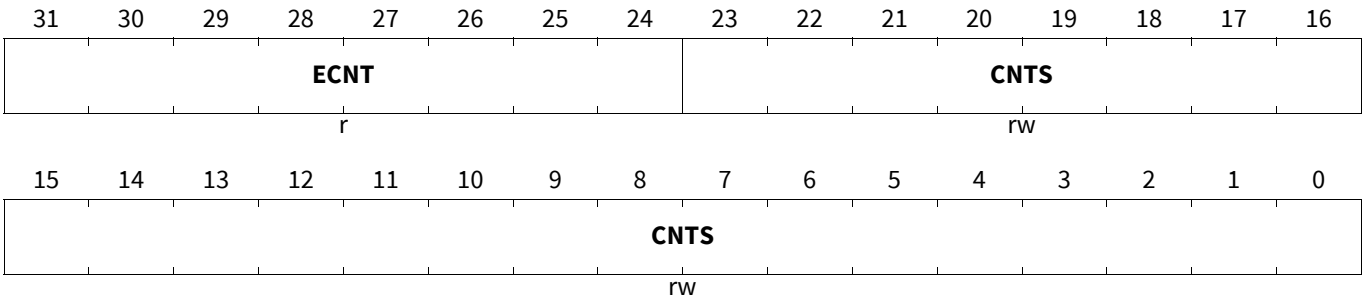
Field	Bits	Type	Description
CNT	23:0	r	**Actual SMU counter value** The meaning of this value depends on the configured mode: TPWM = actual duration of PWM signal.TPIM = actual duration of all pulses (sum of pulses).TIEM = actual number of received edges.TIPM = actual number of received edges.TGPS = elapsed time for periodic sampling.TSSM = shift data.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.13.8.7 Register TIM[i]_CH[x]_CNTS

TIMi Channel x SMU Shadow Counter Register

Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.

TIMi_CHx_CNTS (i=0-7;x=0-7)
TIMi Channel x SMU Shadow Counter Register(001010_H+i*800_H+x*80_H)Application Reset Value: 0000 0000_H



Field	Bits	Type	Description
CNTS	23:0	rw	**Counter shadow register** The content of this register has different meaning for the TIM channels modes. The content depends directly on the bit field **CNTS_SEL** of register **TIM[i]_CH[x]_CTRL**. The register **TIM[i]_CH[x]_CNTS** is only writable in TIPM,TBCM ,TGPS and TSSM mode.
ECNT	31:24	r	**Edge counter** The **ECNT** counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of **ECNT**.

28.13.8.8 Register TIM[i]_CH[x]_IRQ_NOTIFY

TIMi Channel x Interrupt Notification Register

TIMi_CHx_IRQ_NOTIFY (i=0-7;x=0-7)
TIMi Channel x Interrupt Notification Register($00102C_H$+i*800_H+x*80_H)Application Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r										rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
NEWVAL	0	rw	**New measurement value detected by in channel x** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. 0_B No event has occurred 1_B NEWVAL has occurred on the TIM channel
ECNTOFL	1	rw	**counter overflow of channel x** See bit 0.
CNTOFL	2	rw	**SMU CNT counter overflow of channel x** See bit 0.
GPROFL	3	rw	**GPR0 and GPR1 data overflow** Old data not read out before new data has arrived at input pin. See bit 0.
TODET	4	rw	**Timeout reached for input signal of channel x** See bit 0.

Field	Bits	Type	Description
GLITCHDET	5	rw	**Glitch detected on channel x, (x:0...m-1)** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. 0_B No glitch detected for last edge 1_B Glitch detected for last edge
0	31:6	r	**Reserved** Read as zero, shall be written as zero.

28.13.8.9 Register TIM[i]_CH[x]_IRQ_EN

TIMi Channel x Interrupt Enable Register

TIMi_CHx_IRQ_EN (i=0-7;x=0-7)

TIMi Channel x Interrupt Enable Register(001030_H+i*800_H+x*80_H) **Application Reset Value: 0000 0000_H**

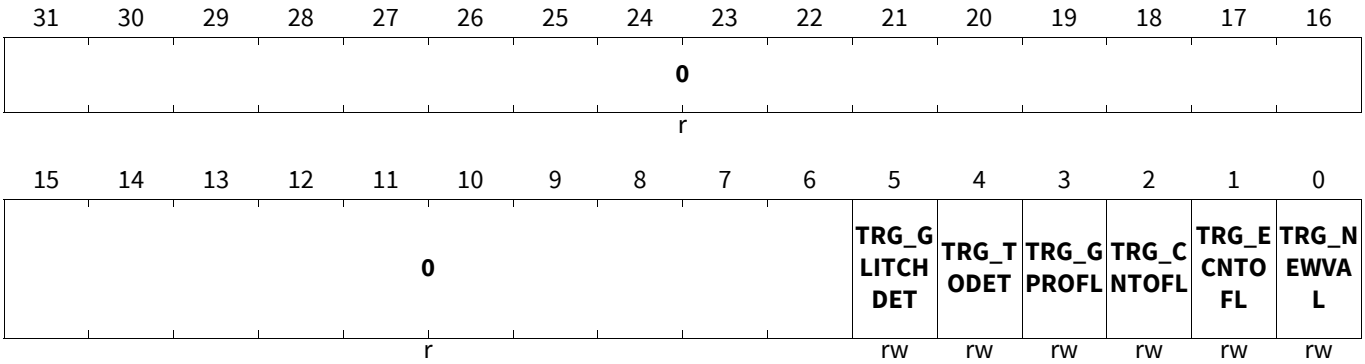
0	31:6	r	**Reserved** Read as zero, shall be written as zero.

28.13.8.10Register TIM[i]_CH[x]_IRQ_FORCINT

TIMi Channel x Force Interrupt Register

TIMi_CHx_IRQ_FORCINT (i=0-7;x=0-7)

TIMi Channel x Force Interrupt Register(001034_H+i*800_H+x*80_H) **Application Reset Value: 0000 0000_H**

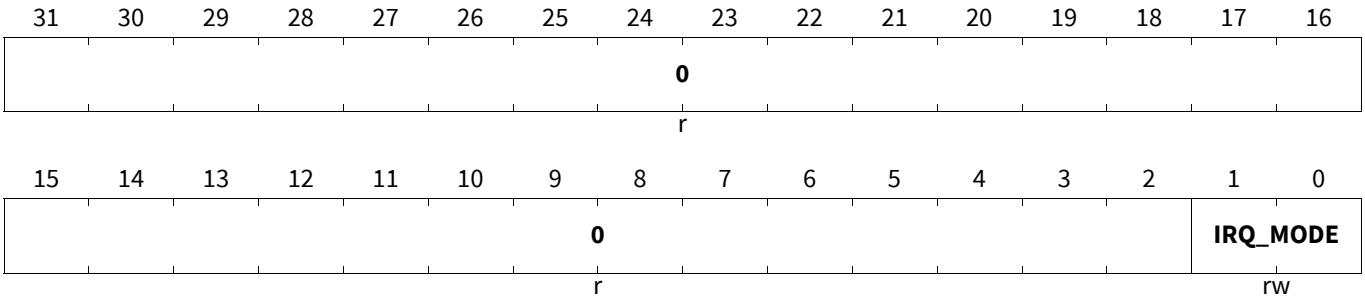


Field	Bits	Type	Description
TRG_NEWVAL	0	rw	**Trigger NEWVAL bit in TIM_CHx_IRQ_NOTIFY register by software** This bit is cleared automatically after write. This bit is write protected by bit RF_PROT of register GTM_CTRL. 0_B No interrupt triggering 1_B Assert corresponding field in TIM[i]_CH[x]_IRQ_NOTIFY register
TRG_ECNTOFL	1	rw	**Trigger ECNTOFL bit in TIM_CHx_IRQ_NOTIFY register by software** Coding see bit 0.
TRG_CNTOFL	2	rw	**Trigger CNTOFL bit in TIM_CHx_IRQ_NOTIFY register by software** Coding see bit 0.
TRG_GPROFL	3	rw	**Trigger GPROFL bit in TIM_CHx_IRQ_NOTIFY register by software** Coding see bit 0.
TRG_TODET	4	rw	**Trigger TODET bit in TIM_CHx_IRQ_NOTIFY register by software** Coding see bit 0.
TRG_GLITCHDET	5	rw	**Trigger GLITCHDET bit in TIM_CHx_IRQ_NOTIFY register by software** Coding see bit 0.
0	31:6	r	**Reserved** Read as zero, shall be written as zero.

28.13.8.11Register TIM[i]_CH[x]_IRQ_MODE

TIMi Channel x Interrupt Mode Configuration Register

TIMi_CHx_IRQ_MODE (i=0-7;x=0-7)
TIMi Channel x Interrupt Mode Configuration Register(001038_H+i*800_H+x*80_H) Application Reset Value: $0000\ 0000_H$

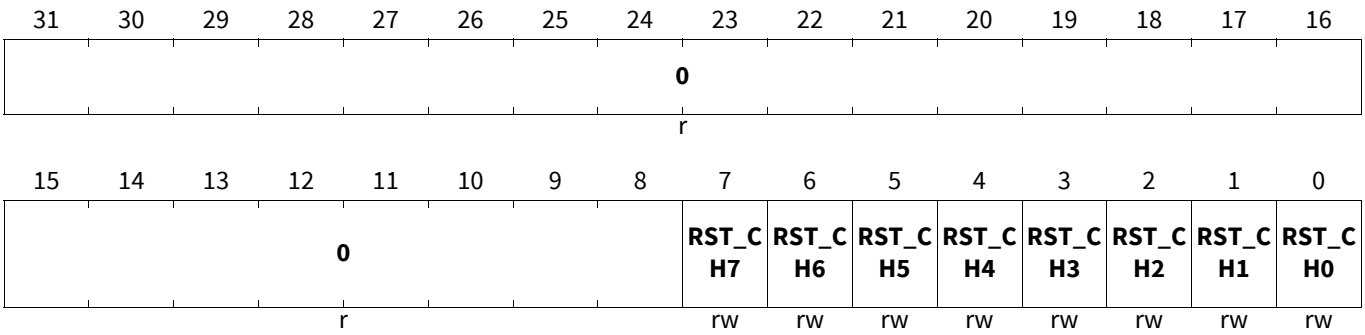


Field	Bits	Type	Description
IRQ_MODE	1:0	rw	**IRQ mode selection** The interrupt modes are described in **Section 28.4.5**. 00_B Level mode 01_B Pulse mode 10_B Pulse-Notify mode 11_B Single-Pulse mode
0	31:2	r	**Reserved** Read as zero, shall be written as zero

28.13.8.12Register TIM[i]_RST

TIMi Global Software Reset Register

TIMi_RST (i=0-7)
TIMi Global Software Reset Register ($00107C_H$+i*800_H) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RST_CHx (x=0-7)	x	rw	**Software reset of channel x** This bit is cleared automatically after write by CPU. The channel registers are set to their reset values and channel operation is stopped immediately. Please note, that the RST field width of this register depends on the number of implemented channels m within this sub-module. This register description represents a register layout for m = 8. 0_B No action 1_B Reset channel x
0	31:8	r	**Reserved** Read as zero, shall be written as zero.

28.13.8.13Register TIM[i]_IN_SRC

TIMi AUX IN Source Selection Register

TIMi_IN_SRC (i=0-7)
TIMi AUX IN Source Selection Register **(001078_H+i*800_H)** **Application Reset Value: 0000 0000_H**

rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
VAL_x (x=0-7)	4*x+1:4*x	rw	**Value to be fed to Channel x** Multicore encoding in use (**VAL_x(1)** defines the state of the signal). Function depends on the combination of VAL_x(1) and MODE_x(1) see MODE_0 description. Any read access to a **VAL_x** bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored. 00_B State is 0 (ignore write access) 01_B Change state to 0 10_B Change state to 1 11_B State is 1 (ignore write access)

Field	Bits	Type	Description
MODE_x (x=0-7)	4*x+3:4*x+2	rw	**Input source to Channel x** Multicore encoding in use (**MODE_x(1)** defines the state of the signal). Function table: **MODE_x(1)=0** , **VAL_x(1)**=0: The input signal defined by bit field **CICTRL** of the TIM channel is used as input source. **MODE_x(1)=0** , **VAL_x(1)**=1: The signal TIM_AUX_IN of the TIM channel is used as input source. **MODE_x(1)=1** : The state **VAL_x(1)** defines the input level for the TIM channel. Any read access to a **MODE_x** bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored. 00_B State is 0 (ignore write access) 01_B Change state to 0 10_B Change state to 1 11_B State is 1 (ignore write access)

28.14 Timer Output Module (TOM)

28.14.1 Overview

The Timer Output Module (TOM) offers up to 16 independent channels (index x) to generate simple PWM signals at each output pin *TOM[i]_CH[x]_OUT*.

Additionally, at TOM output *TOM[i]_CH15_OUT* a pulse count modulated signal can be generated.

The architecture of the TOM sub-module is depicted in **Figure 47**.

Indices and their range as used inside this chapter are:

y=0,1

z=0…7

The following design variables are used inside this chapter. Please refer to AURIX device specific appendix for correct value.

cCTO: TOM channel count; number of channels per instance - 1.

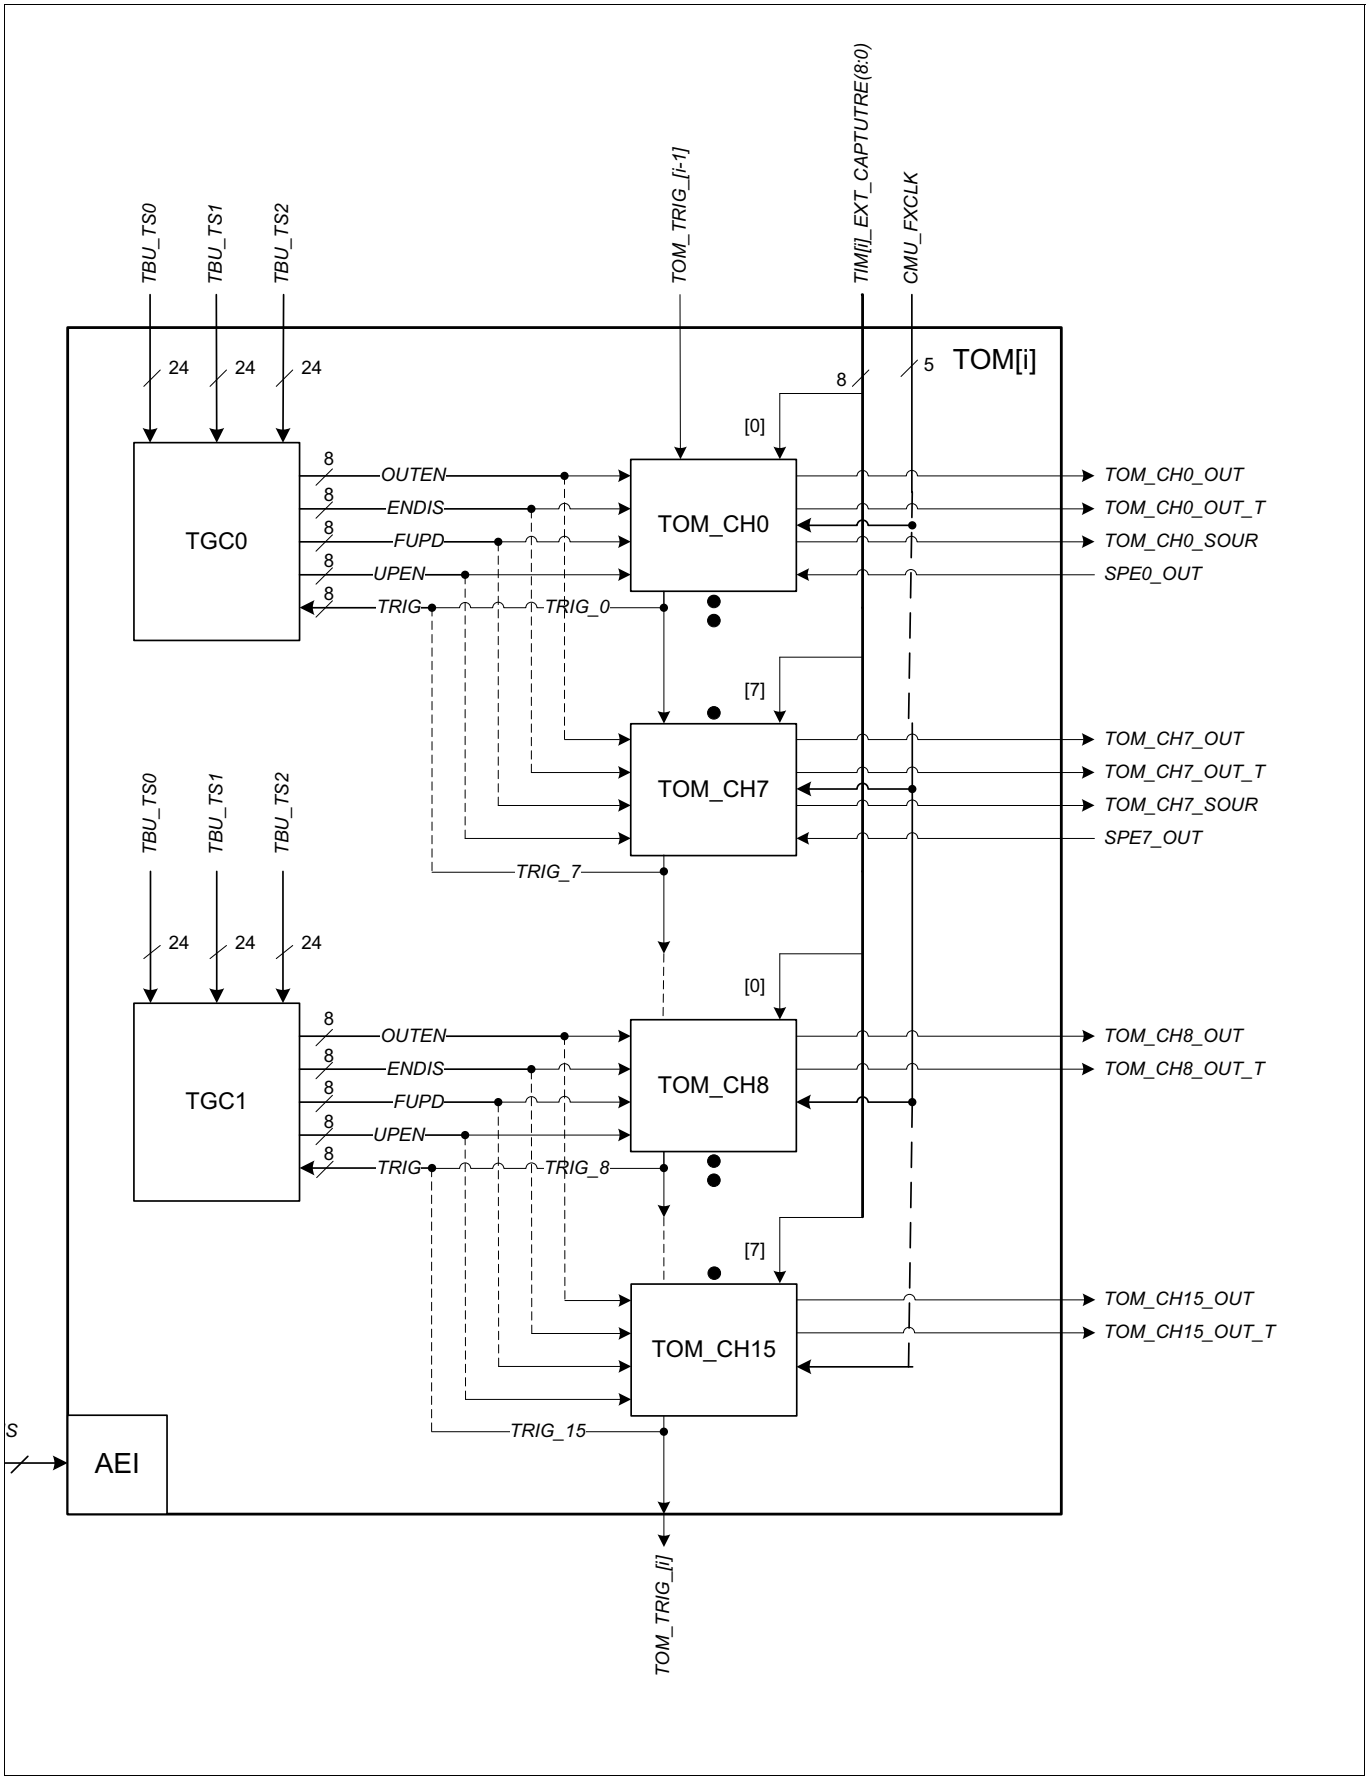

Figure 47 TOM block diagram

The two sub-modules TGC0 and TGC1 are global channel control units that control the enabling/disabling of the channels and their outputs as well as the update of their period and duty cycle register.

The module TOM receives two (three) timestamp values *TBU_TS0*, *TBU_TS1* (and *TBU_TS2*) in order to realize synchronized output behavior on behalf of a common time base.

The 5 dedicated clock line inputs *CMU_FXCLK* are providing divided clocks that can be selected to clock the output pins.

The trigger signal *TOM_TRIG_[i-1]* of TOM instance i comes from the preceding instance i-1, the trigger *TOM_TRIG_[i]* is routed to succeeding instance i+1.Note, TOM0 is connected to its own output *TOM_TRIG_0*, i.e. the last channel of TOM instance 0 can trigger the first channel of TOM instance 0 (this path is registered, which means delayed by one SYS_CLK period).

28.14.2 TOM Global Channel Control (TGC0, TGC1)

28.14.2.1 Overview

There exist two global channel control units (TGC0 and TGC1) to drive a number of individual TOM channels synchronously by external or internal events.

Each TGC[y] can drive up to eight TOM channels where TGC0 controls TOM channels 0 to 7 and TGC1 controls TOM channels 8 to 15.

The TOM sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each TOM channel with control register **TOM[i]_TGC[y]_ENDIS_CTRL** and status register **TOM[i]_TGC[y]_ENDIS_STAT**
- Global output enable mechanism for each TOM channel with control register **TOM[i]_TGC[y]_OUTEN_CTRL** and status register **TOM[i]_TGC[y]_OUTEN_STAT**
- Global force update mechanism for each TOM channel with control register **TOM[i]_TGC[y]_FUPD_CTRL**
- Update enable of the register **CM0**, **CM1** and **CLK_SRC** for each TOM channel with the control bit field **UPEN_CTRL[z]** of **TOM[i]_TGC[y]_GLB_CTRL**

28.14.2.2 TGC Sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources. The three trigger sources are:

- the host CPU (bit **HOST_TRIG** of register **TOM[i]_TGC[y]_GLB_CTRL**)
- the TBU time stamp (signal *TBU_TS0, TBU_TS1, TBU_TS2* if available)
- the internal trigger signal *TRIG* (bunch of trigger signals *TRIG_[x]* which can be either the trigger *TRIG_CCU0* of channel x, the trigger of preceding channel x-1 (i.e. signal *TRIG_[x-1]*) or the external trigger *TIM_EXT_CAPTURE(t)* of assigned TIM channel t.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit **HOST_TRIG** of register **TOM[i]_TGC[y]_GLB_CTRL**).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits **TBU_SEL**) and the time stamp compare value defined in the bit field **ACT_TB** of register **TOM[i]_TGC[y]_ACT_TB**.Note, a signed compare of **ACT_TB** and selected *TBU_TS*[*x*] with x=0,1,2 is performed.

The third possibility is the input *TRIG* (bunch of trigger signals *TRIG_[x]*) coming from the TOM channels 0 to 7 / 8 to 15.

The corresponding trigger signal *TRIG_[x]* coming from channel [x] can be masked by the register **TOM[i]_TGC[y]_INT_TRIG**.

To enable or disable each individual TOM channel, the register **TOM[i]_TGC[y]_ENDIS_CTRL** and/or **TOM[i]_TGC[y]_ENDIS_STAT** have to be used.

The register **TOM[i]_TGC[y]_ENDIS_STAT** controls directly the signal *ENDIS*. A write access to this register is possible.

The register **TOM[i]_TGC[y]_ENDIS_CTRL** is a shadow register that overwrites the value of register **TOM[i]_TGC[y]_ENDIS_STAT** if one of the three trigger conditions matches.

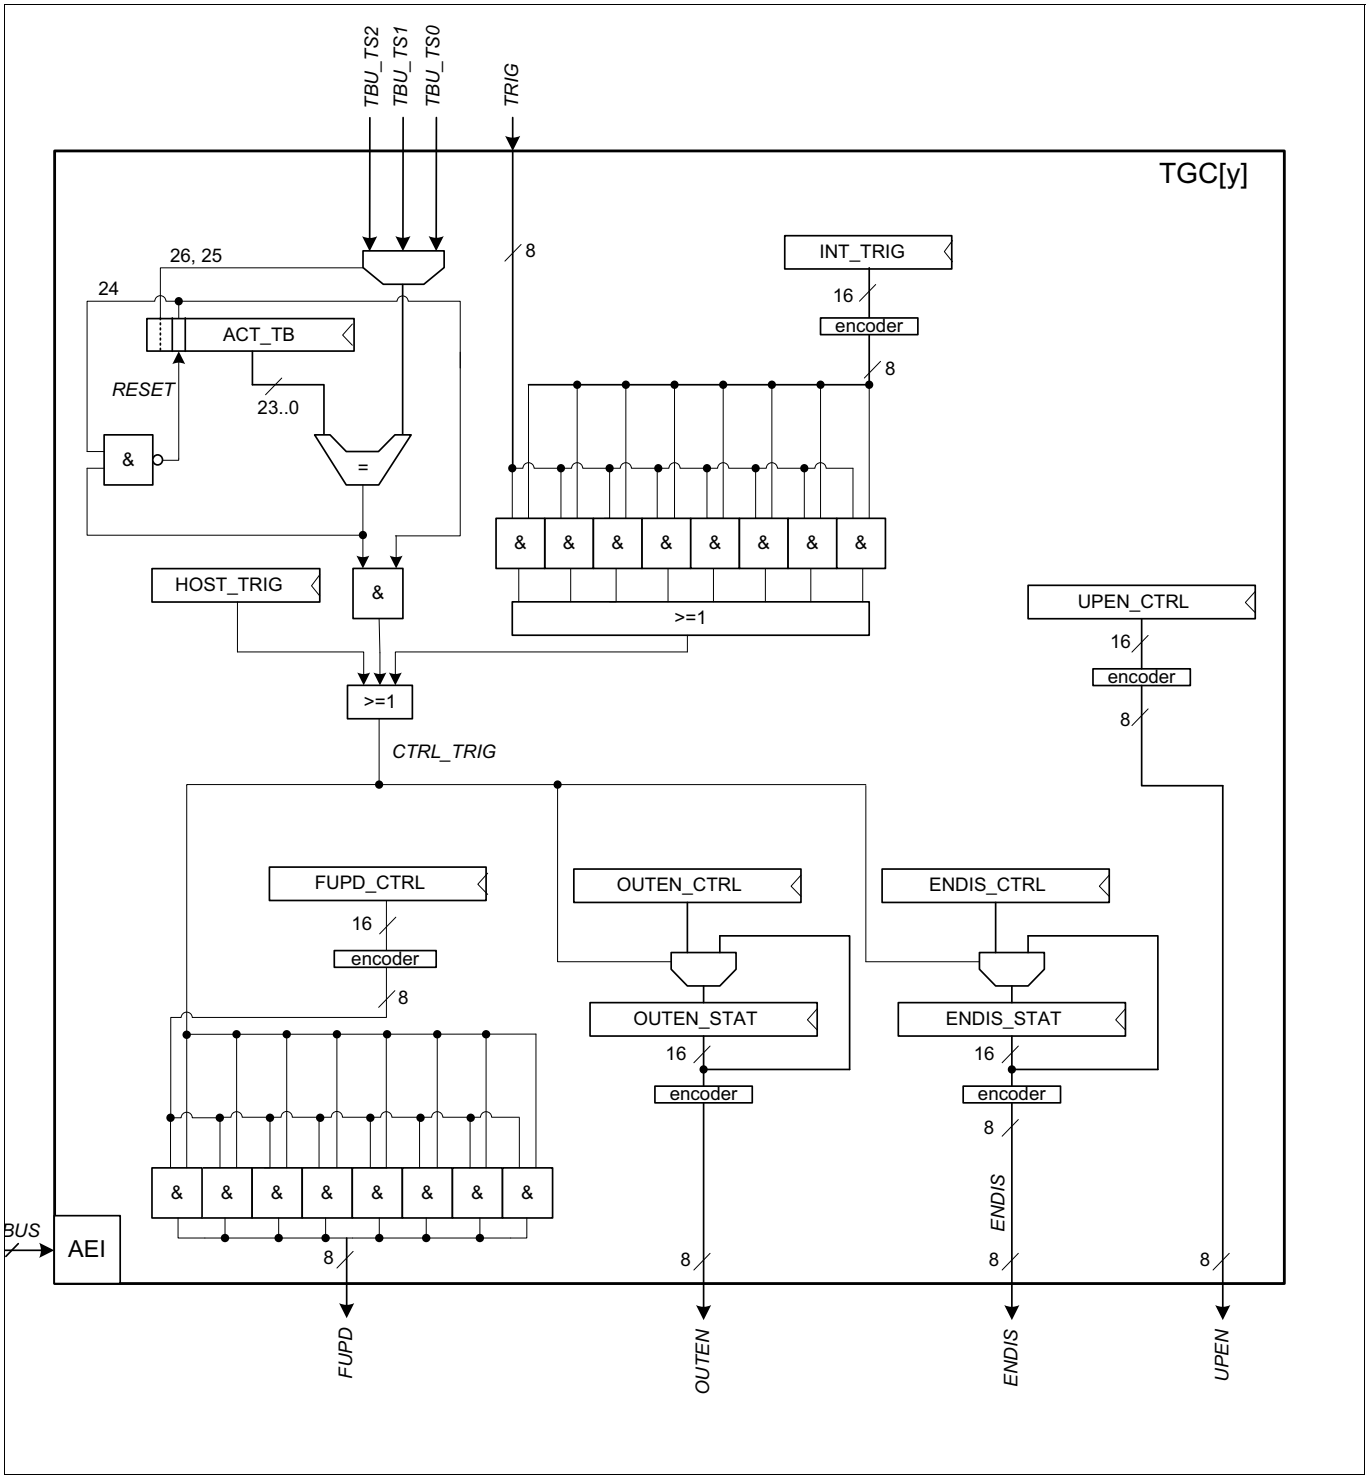

Figure 48 TOM Global channel control mechanism

The output of the individual TOM channels can be controlled using the register **TOM[i]_TGC[y]_OUTEN_CTRL** and **TOM[i]_TGC[y]_OUTEN_STAT**.

The register **TOM[i]_TGC[y]_OUTEN_STAT** controls directly the signal *OUTEN*. A write access to this register is possible.

The register **TOM[i]_TGC[y]_OUTEN_CTRL** is a shadow register that overwrites the value of register **TOM[i]_TGC[y]_OUTEN_STAT** if one of the three trigger conditions matches.

If a TOM channel is disabled by the register **TOM[i]_TGC[y]_OUTEN_STAT**, the actual value of the channel output at *TOM_CH[x]_OUT* is defined by the signal level bit (**SL**) defined in the channel control register **TOM[i]_CH[x]_CTRL**.If the output is enabled, the output at *TOM_CH[x]_OUT* depends on value of flip-flop **SOUR**.

The register **TOM[i]_TGC[y]_FUPD_CTRL** defines which of the TOM channels receive a *FORCE_UPDATE* event if the trigger signal *CTRL_TRIG* is raised.

Note: The force update request is stored and executed synchronized to the selected CMU_FXCLK.

The register bits **UPEN_CTRL[z]** defines for which TOM channel the update of the working register **CM0**, **CM1** and **CLK_SRC** by the corresponding shadow register **SR0**, **SR1** and **CLK_SRC_SR** is enabled. If update is enabled, the register **CM0**, **CM1** and **CLK_SRC** will be updated on reset of counter register **CN0** (see **Figure 49** and **Figure 50**). An exception is the configuration of SR0_TRIG=1 which enable the trigger generation defined by **SR0**. Then **CM0** is not updated with **SR0**.

28.14.3 TOM Channel

Each individual TOM channel comprises a Counter Compare Unit 0 (CCU0) which contains the counter register **CN0** and the period register **CM0**, a Counter Compare Unit 1 (CCU1) which contains the duty cycle register **CM1** and the Signal Output Generation Unit (SOU) which contains the output register **SOUR**. The architecture is depicted in **Figure 49** for channels 0 to 7 and in **Figure 50** for channels 8 to 15.

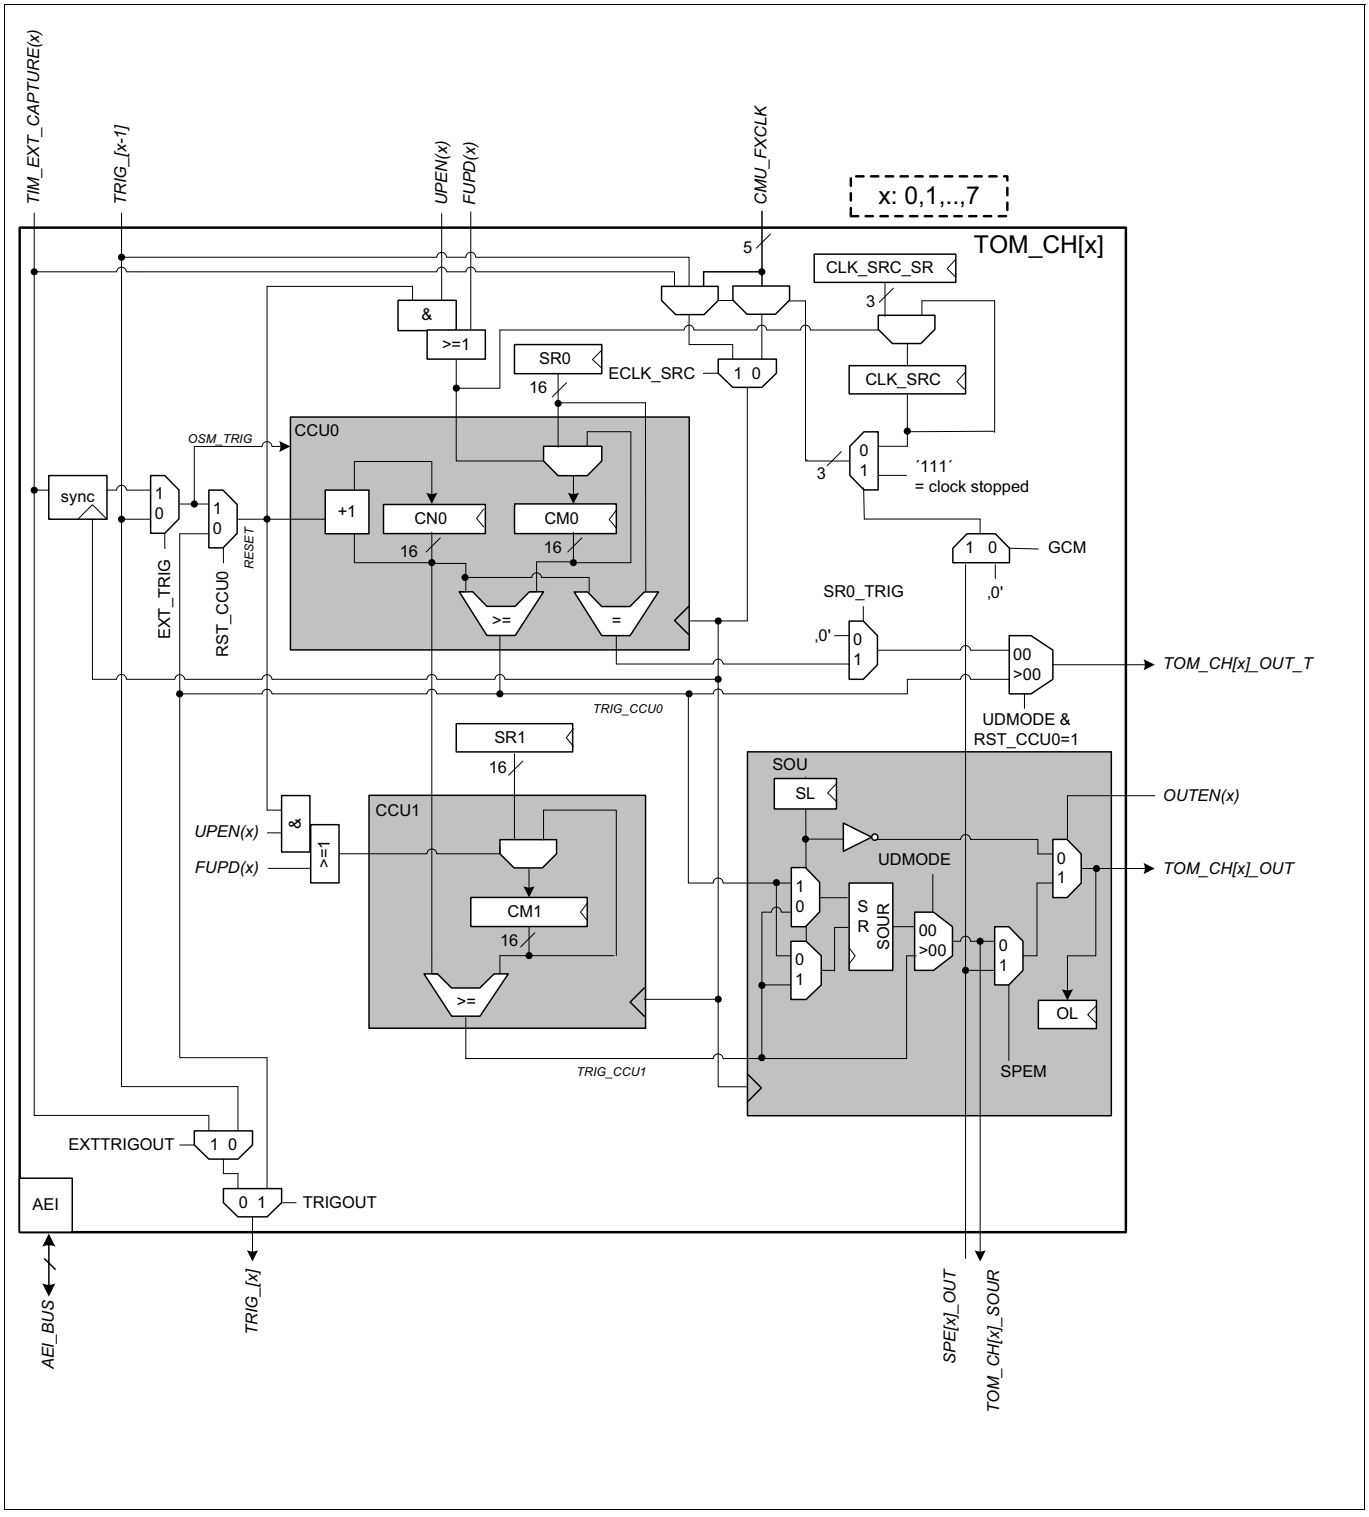

Figure 49 TOM Channel 0…7 architecture

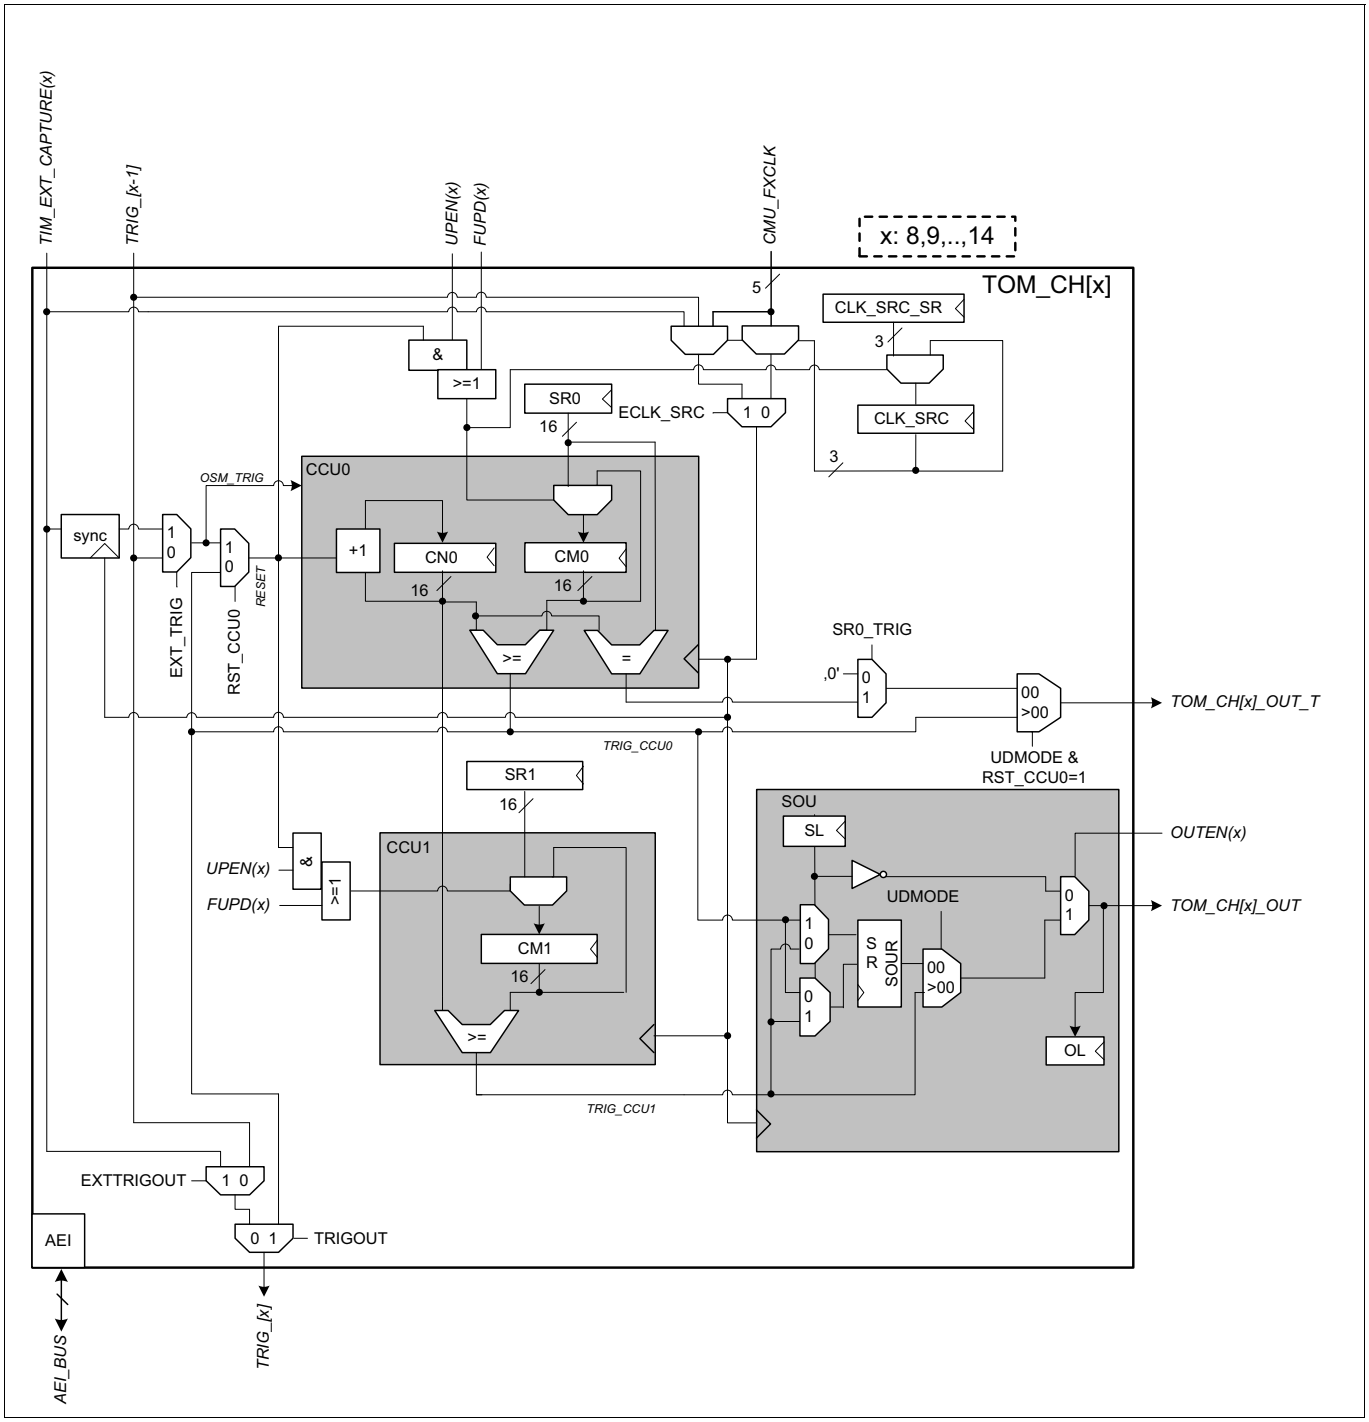

Figure 50 TOM Channel 8...14 architecture

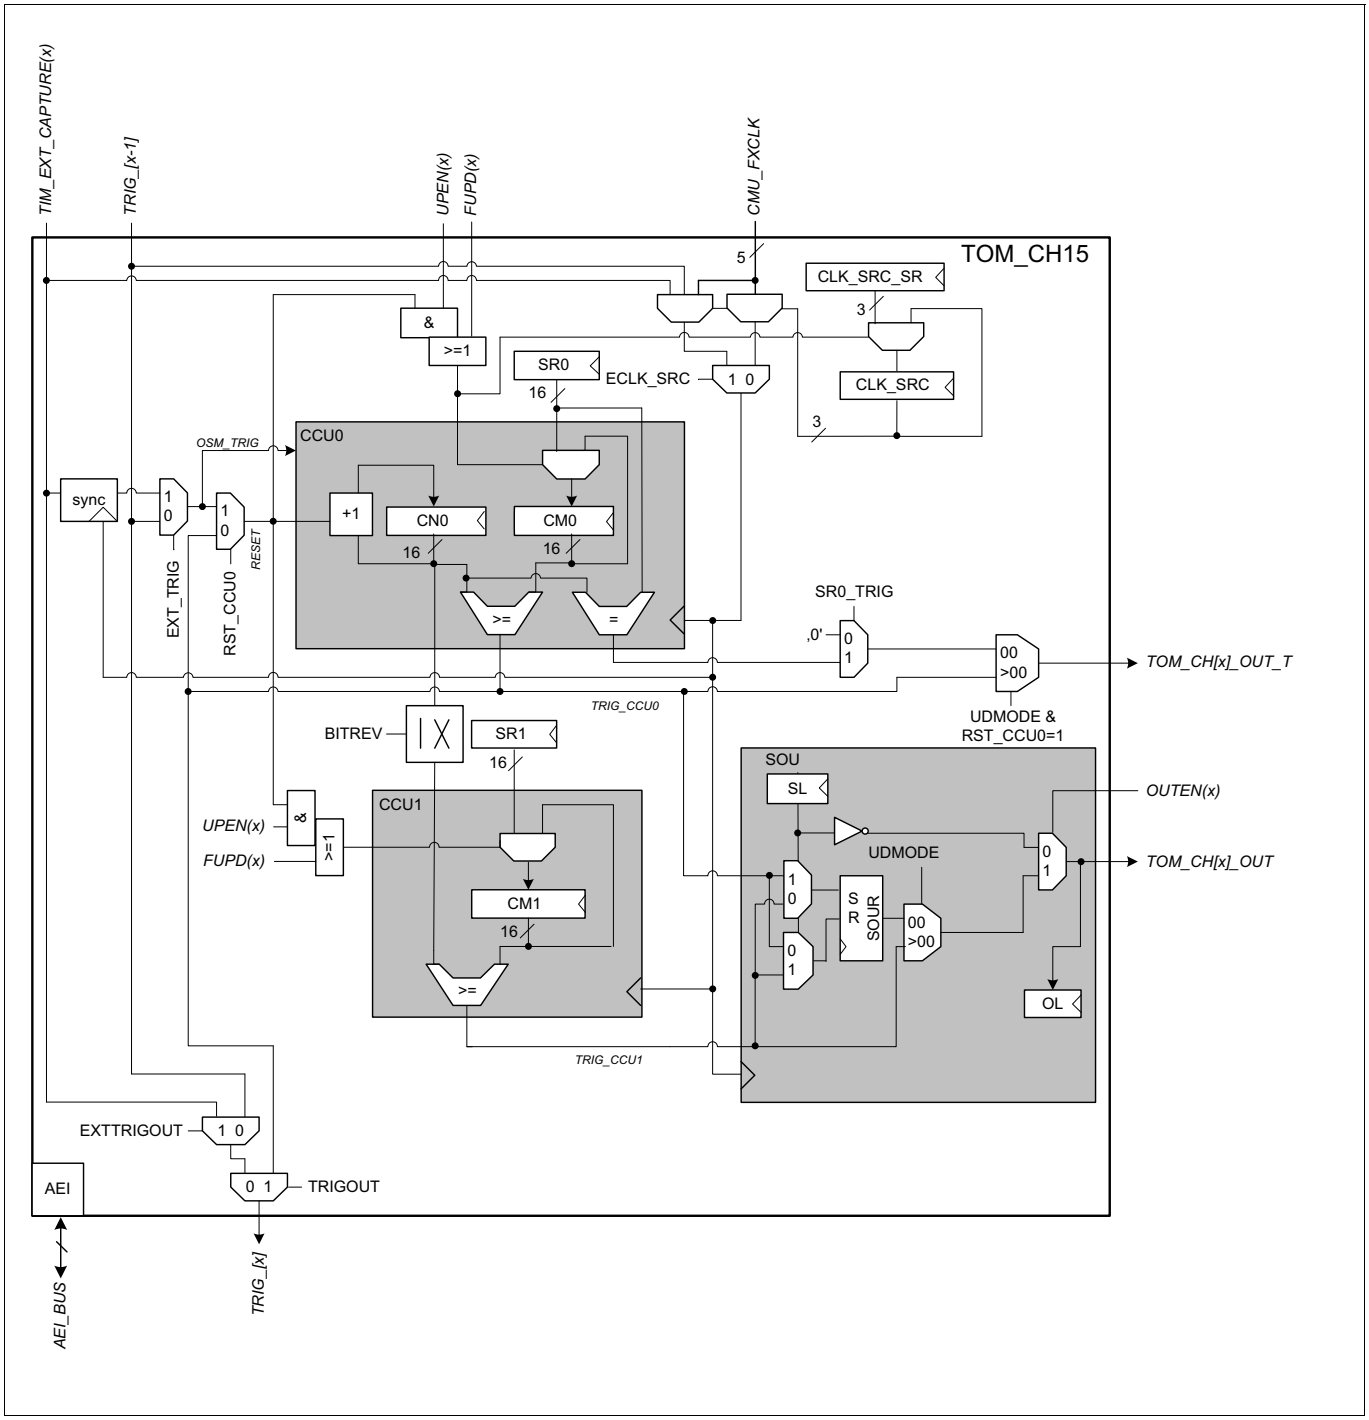

Figure 51 TOM Channel 15 architecture

The CCU0 contains a counter **CN0** which is clocked with one of the selected input frequencies (*CMU_FXCLK*) provided from outside of the sub-module.

Depending on configuration bits RST_CCU0 of register **TOM[i]_CH[x]_CTRL** the counter register **CN0** can be reset either when the counter value is equal to the compare value **CM0** (i.e. CN0 counts only 0 to CM0-1 and is then reset to 0) or when signaled by the TOM[i] trigger signal *TRIG_[x-1]* of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal *TIM_EXT_CAPTURE(x)* of the assigned TIM channel [x].

Note: As an exception, the input *TRIG_[0]* of instance TOM0 is triggered by its own last channel cCTO via signal *TRIG_[cCTO]*.

When the counter register **CN0** is greater or equal than the value **CM0** (in fact CM0-1) the sub-unit CCU0 triggers the SOU sub-unit and the succeeding TOM sub-module channel (signal *TRIG_CCU0*).

In the sub-unit CCU1 the counter register **CN0** is compared with the value of register **CM1**. If **CN0** is greater or equal than **CM1** the sub-unit CCU1 triggers the SOU sub-unit (signal *TRIG_CCU1*).

If counter register **CN0** of channel x is reset by its own CCU0 unit (i.e. the compare match of **CN0**>=**CM0**-1 configured by RST_CCU0=0), following statements are valid:

- **CN0** counts from 0 to **CM0**-1 and is then reset to 0.
- When CN0 is reset from CM0 to 0, an edge to SL is generated
- When CN0 is incrementing and reaches CN0 > CM1, an edge to !SL is generated.
- if **CM0**=0 or **CM0**=1, the counter **CN0** is constant 0.
- if **CM1**=0, the output is !SL = 0% duty cycle
- if **CM1** >= **CM0** and **CM0**>1, the output is SL = 100% duty cycle

If the counter register **CN0** of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0=1), following statements are valid:

- **CN0** counts from 0 to MAX-1 and is then reset to 0 by trigger signal
- **CM0** defines the edge to SL value, **CM1** defines the edge to !SL value.
- if **CM0**=**CM1**, the output switches to SL if **CN0**=**CM0**=**CM1** (**CM0** has higher priority)
- if **CM0**=0 and **CM1**=MAX, the output is SL = 100% duty cycle
- if **CM0** > MAX, the output is !SL = 0% duty cycle, independent of **CM1**.

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the TOM channel.

The SOU sub-unit is responsible for output signal generation. On a trigger *TRIG_CCU0* from sub-unit CCU0 or *TRIG_CCU1* from sub-unit CCU1 an SR flip-flop of sub-unit SOU is either set or reset. If it is set or reset depends on the configuration bit **SL** of the control register **TOM[i]_CH[x]_CTRL**. The initial signal output level for the channel is the reverse value of the bit **SL**.

Figure 54 clarifies the PWM output behavior with respect to the **SL** bit definition. The output level on the TOM channel output pin *TOM[i]_CH[x]_OUT* is captured in bit **OL** of register **TOM[i]_CH[x]_STAT**.

28.14.3.1 Duty cycle, Period and Clock Frequency Update Mechanisms

The two action register **CM0** and **CM1** can be reloaded with the content of the shadow register **SR0** and **SR1**. The register **CLK_SRC** that determines the clock frequency of the counter register **CN0** can be reloaded with its shadow register **CLK_SRC_SR** (bit field in register **TOM[i]_CH[x]_CTRL**).

The update of the register **CM0**, **CM1** and **CLK_SRC** with the content of its shadow register is done when the reset of the counter register **CN0** is requested (via signal *RESET*). This reset of **CN0** is done if the comparison of **CN0** greater or equal than **CM0** is true or when the reset is triggered by another TOM channel [x-1] via the signal *TRIG_[x-1]* or when signaled via the signal *TIM_EXT_CAPTURE(x)* of the assigned TIM channel [x].

With the update of the register **CLK_SRC** at the end of a period a new counter **CN0** clock frequency can easily be adjusted.

In case of RST_CCU0=1 and update enabled by UPEN_CTRL[z] the register CM0, CM1 and CLK_SRC will be updated when CN0 is reset.

An update of duty cycle, period and counter **CN0** clock frequency becoming effective synchronously with start of a new period can easily be reached by performing following steps:

1. disable the update of the action register with the content of the corresponding shadow register by setting the channel specific configuration bit **UPEN_CTRL[z]** of register **TOM[i]_TGC[y]_GLB_CTRL** to '0'.
2. write new desired values to **SR0**, **SR1**, **CLK_SRC_SR**

3. enable update of the action register by setting the channel specific configuration bit **UPEN_CTRL[z]** of register **TOM[i]_TGC[y]_GLB_CTRL** to '1'.

28.14.3.1.1 Synchronous Update Of Duty Cycle Only

A synchronous update of only the duty cycle can be done by simply writing the desired new value to register **SR1** without preceding disable of the update mechanism (as described in the chapter above). The new duty cycle is then applied in the period following the period where the update of register **SR1** was done.

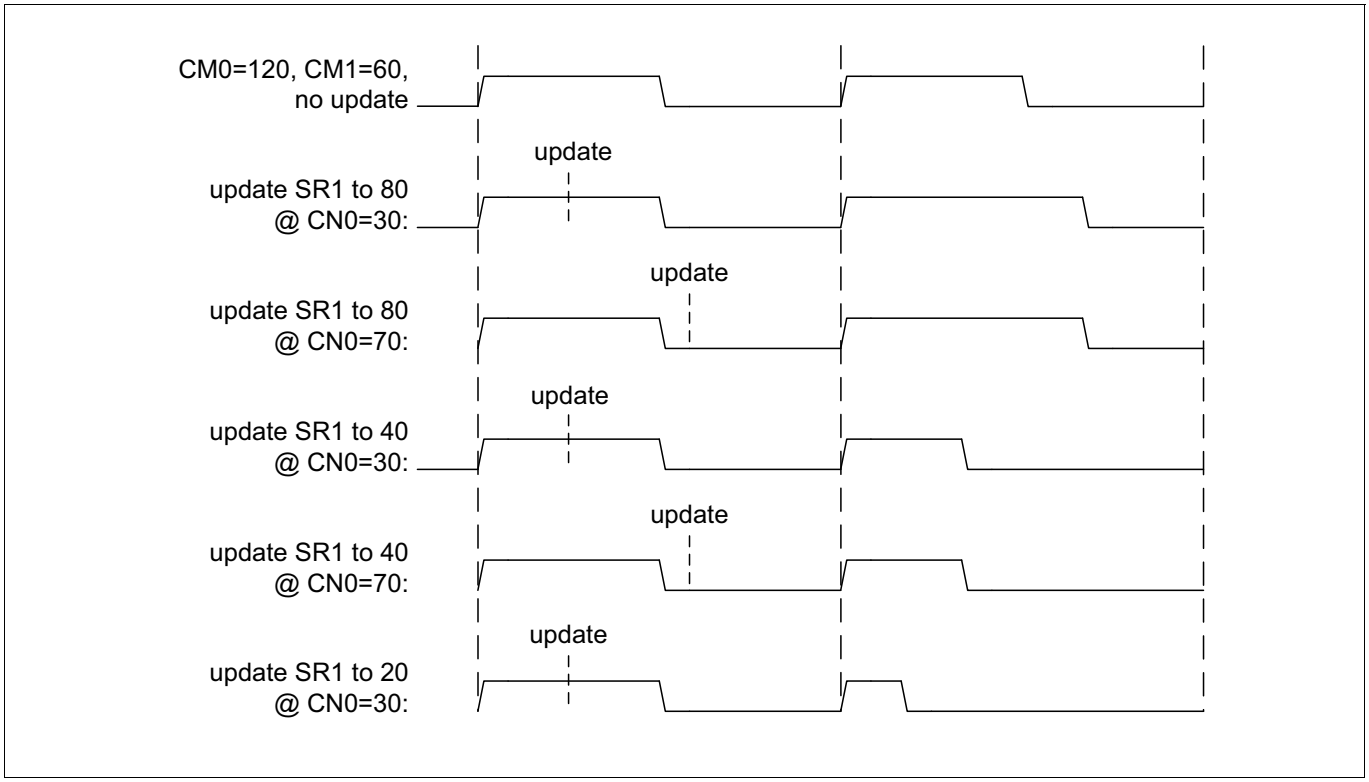

Figure 52 Synchronous update of duty cycle

28.14.3.1.2 Asynchronous Update Of Duty Cycle Only

If the update of the duty cycle should be performed independent of the start of a new period (asynchronous), the desired new value can be written directly to register **CM1**. In this case it is recommended to additionally either disable the synchronous update mechanism as a whole (i.e. clearing bits **UPEN_CTRL[z]** of corresponding channel [x] in register **TOM[i]_TGX[y]_GLB_CTRL**) or updating **SR1** with the same value as **CM1** before writing to **CM1**.

Depending on the point of time of the update of **CM1** in relation to the actual value of **CN0** and **CM1**, the new duty cycle is applied in the current period or the following period (see **Figure 53**). In any case the creation of glitches are avoided. The new duty cycle may jitter from update to update by a maximum of one period (given by **CM0**). However, the period remains unchanged.

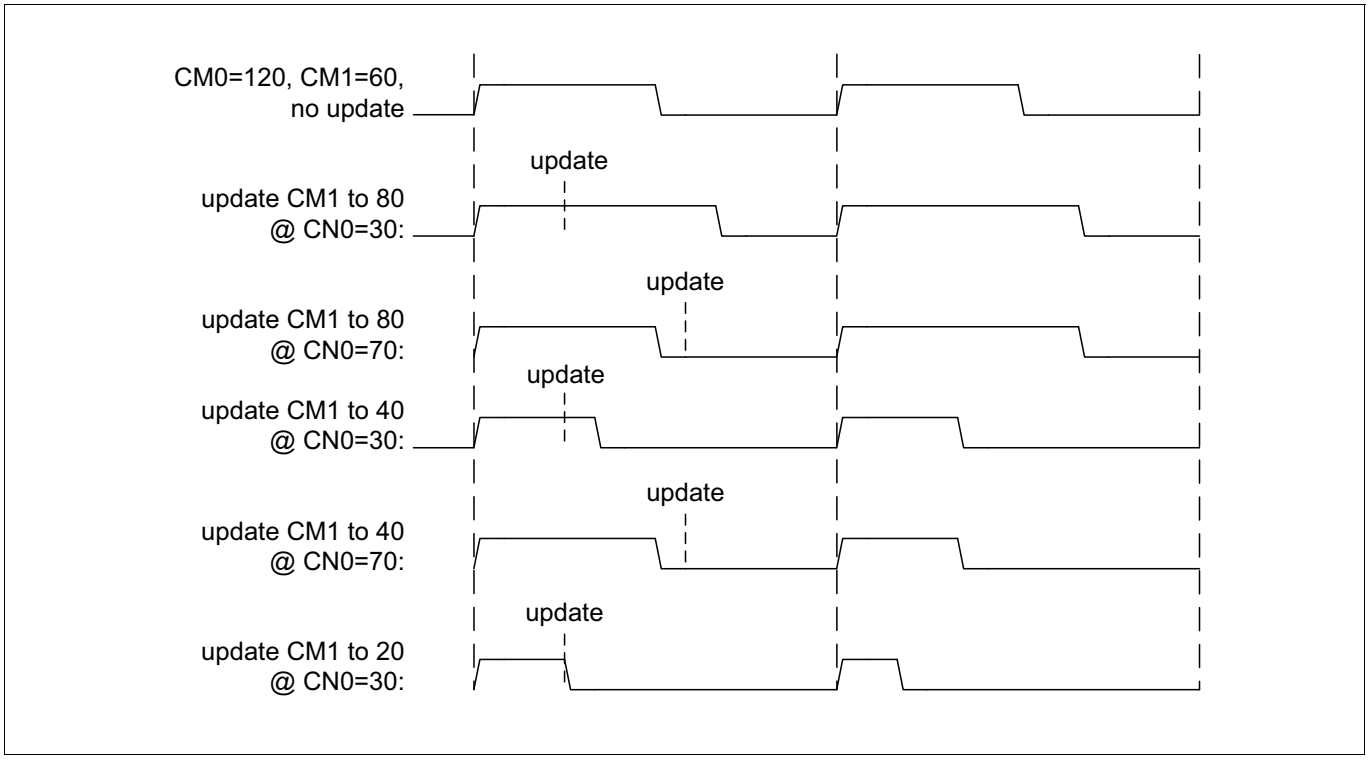

Figure 53 Asynchronous update of duty cycle

28.14.3.2 Continuous Counting Up Mode

In continuous mode the TOM channel starts incrementing the counter register **CN0** once it is enabled by setting the corresponding bits in register **TOM[i]_TGC[y]_ENDIS_STAT** (refer to **Section 28.14.2.2** for details of enabling a TOM channel).

The signal level of the generated output signal can be configured with the configuration bit **SL** of the channel configuration register **TOM[i]_CH[x]_CTRL**.

If the counter **CN0** is reset from **CM0** back to zero, the first edge of a period is generated at *TOM[i]_CH[x]_OUT*.

The second edge of the period is generated if **CN0** has reached **CM1**.

Every time the counter **CN0** has reached the value of **CM0** it is reset back to zero and proceeds with incrementing.

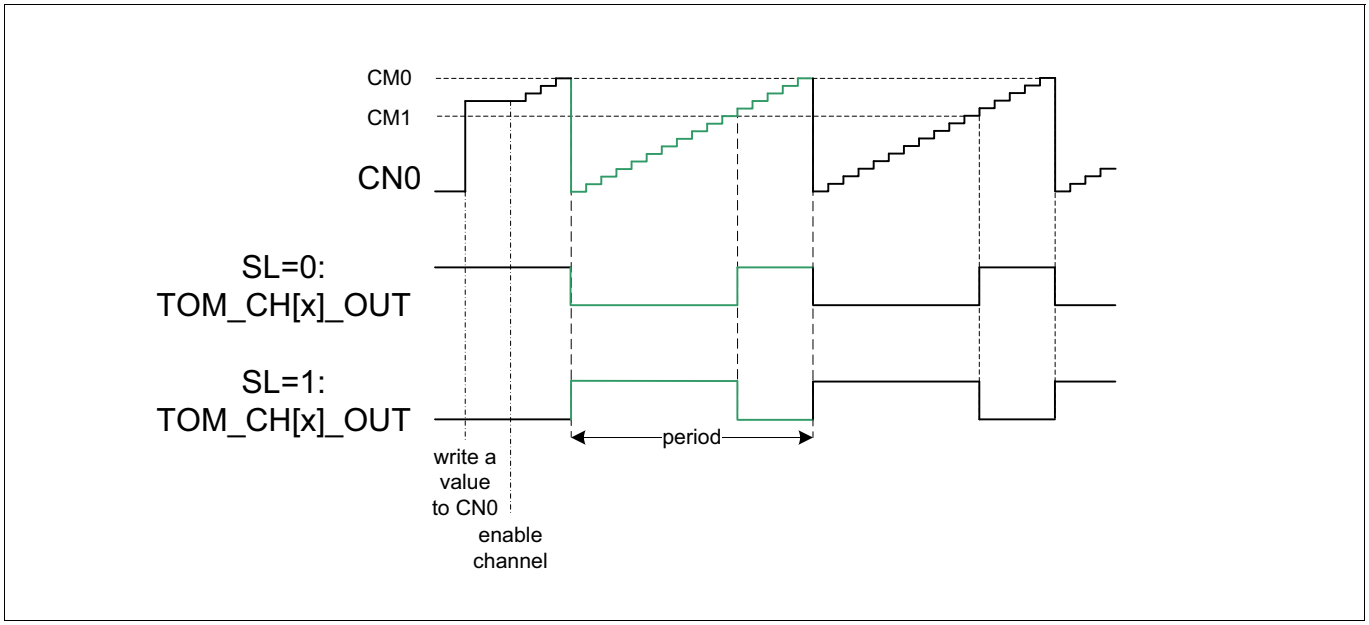

Figure 54 PWM Output with respect to configuration bit SL in continuous mode

28.14.3.3 Continuous Counting Up-Down Mode

In continuous mode, if **CN0** counts up and down (UDMODE != 0b00), depending on configuration bits RST_CCU0 of register **TOM[i]_CH[x]_CTRL** the counter register **CN0** changes direction either when the counter value is equal to the compare value **CM0,** has counted down to 0 or when triggered by the TOM[i] trigger signal *TRIG_[x-1]* of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal *TIM_EXT_CAPTURE(x)* of the assigned TIM channel [x].

In this case, if UPEN_CTRL[x]=1, also the working register **CM0**, **CM1** and **CLK_SRC** are updated depending on UDMODE.

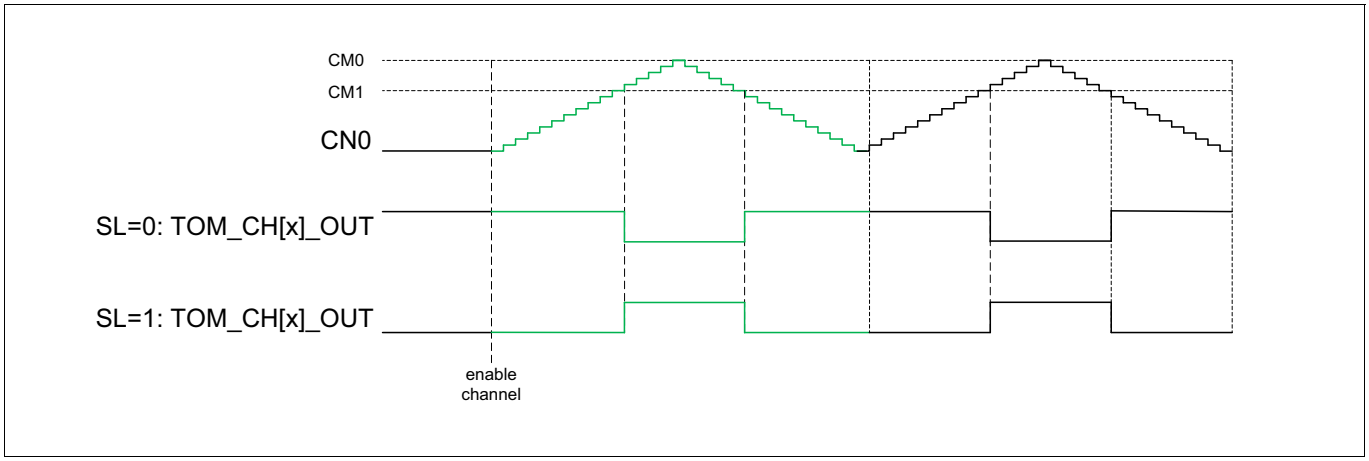

Figure 55 PWM Output behavior with respect to the SL bit in the ATOM[i]_CH[x]_CTRL register if UDMODE != 0b00

The clock of the counter register **CN0** can be one of the CMU clocks CMU_FXCLKx.The clock for **CN0** is defined by CLK_SRC_SR value in register **TOM[i]_CH[x]_CTRL.**The duration of a period in multiples of selected **CN0** counter clock ticks is defined by the **CM0** configuration value (i.e. **CM0** defines half of period in up-down mode).**CM1** defines the duty cycle value in clock ticks of selected **CN0** counter clock **CM0** defines half of duty cycle in up-down mode).

If counter register **CN0** of channel x is reset by its own CCU0 unit (i.e. the compare match of **CN0**>=**CM0** configured by RST_CCU0=0), following statements are valid:

- **CN0** counts continuously first up from 0 to **CM0**-1 and then down to 0.
- if **CN0** >= **CM1**, the output is set to SL
- if **CM1**=0, the output is SL (i.e. 100% duty cycle)
- if **CM1**>= **CM0**, the output is !SL (i.e. 0% duty cycle)
- On output *TOM[i]_CHx]_OUT* a PWM signal is generated. The period is defined by **CM0**, the duty cycle is defined by **CM1**.

This behavior is depicted in **Figure 55**.

If the counter register **CN0** of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0=1), following statements are valid:

- **CN0** counts continuously first up. On a trigger signal the counter switches to count down mode. If <**CN0** has reached 0, it switches to count up mode.
- if **CN0** >= **CM1**, the output is set to SL
- if **CM1**=0, the output is SL (i.e. 100% duty cycle)
- if **CM1** >= **CM0**, the output is !SL (i.e. 0% duty cycle)
- On output **TOM[i]_CHx]_OUT** a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by **CM1**.
- On output **TOM[i]_CHx]_OUT** a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by **CM0**.

This behavior is depicted in figure **Figure 56**.

Note that in case of up-down counter mode and RST_CCU0=1 it is recommended that:

- the triggering channel and the triggered channel are both running in up-down mode,
- the time between two trigger signals is equal to the time needed for CN0 of triggered to count back to 0 and again up to the same upper value.

The second recommendation can be reached by synchronizing the start of triggering channel and triggered channel,i.e. let both channels start with CN0 value 0. Note that if there is a synchronization register in the trigger chain (indicated by value TOM_TRIG_CHAIN in register CCM[i]_HW_CONF), the additional delay of the trigger by one clock period has to be taken into account by starting at triggering channel with a CN0 value 1 (+1 compared to CN0 of triggered channel).

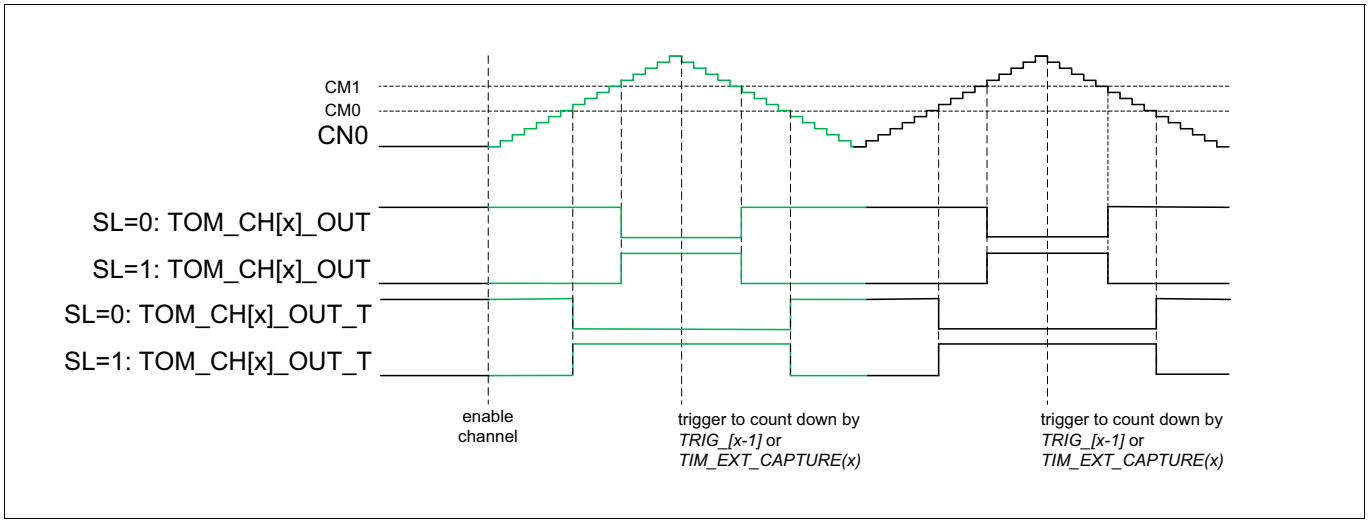

Figure 56 PWM Output behavior in case of RST_CCU0=1 and UDMODE != 0b00

28.14.3.4 One-shot Counting Up Mode

In one-shot mode, the TOM channel generates one pulse with a signal level specified by the configuration bit **SL** in the channel [x] configuration register **TOM[i]_CH[x]_CTRL**.

First the channel has to be enabled by setting the corresponding **TOM[i]_TGC[y]_ENDIS_STAT** value and the one-shot mode has to be enabled by setting bit **OSM** in register **TOM[i]_CH[x]_CTRL**.

In one-shot mode the counter **CN0** will not be incremented once the channel is enabled.

A write access to the register **CN0** triggers the start of pulse generation (i.e. the increment of the counter register **CN0**).

If SPE mode of TOM[i] channel 2 is enabled (set bit **SPEM** of register **TOM[i]_CH2_CTRL**), also the trigger signal *SPE[i]_NIPD* can trigger the reset of register **CN0** to zero and a start of the pulse generation.

The new value of **CN0** determines the start delay of the first edge. The delay time of the first edge is given by (**CM0-CN0**) multiplied with period defined by current value of **CLK_SRC**.

If the counter **CN0** is reset from **CM0** back to zero, the first edge at *TOM[i]_CH[x]_OUT* is generated.

To avoid an update of **CMx** register with content of **SRx** register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 00 (in register **TOM[i]_TGC[y]_GLB_CTRL**)

The second edge is generated if **CN0** is greater or equal than **CM1** (i.e. **CN0** was incremented until it has reached **CM1** or **CN0** is greater than **CM1** after an update of **CM1**).

If the counter **CN0** has reached the value of **CM0** a second time, the counter stops.

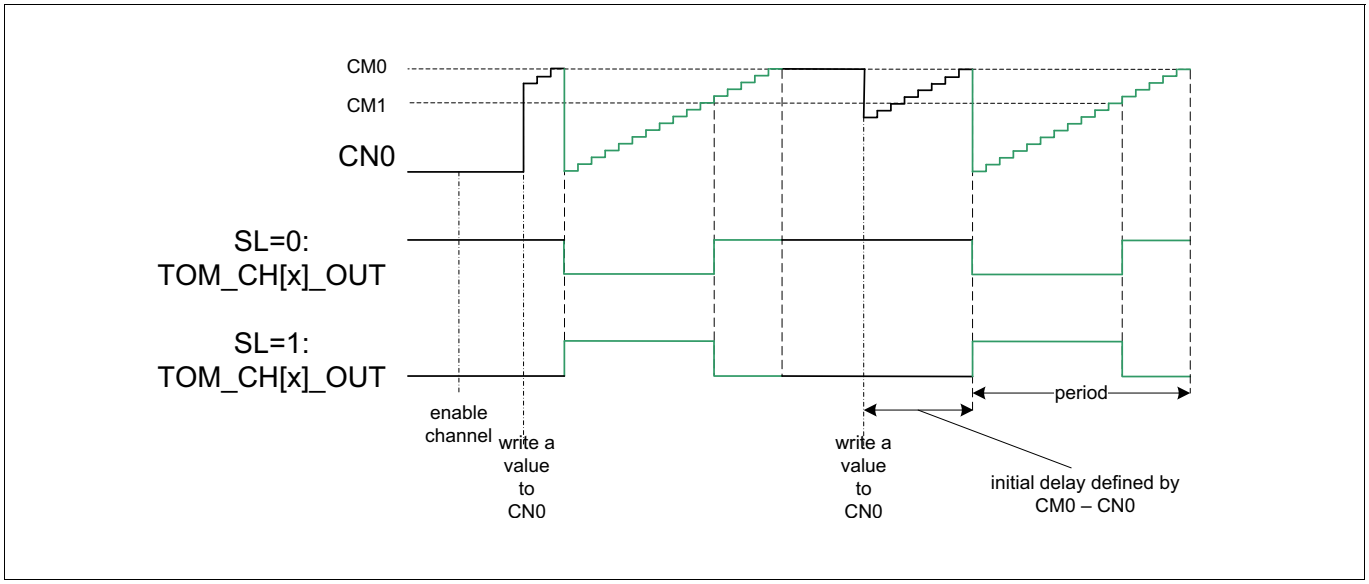

Figure 57 PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

Further output of single periods can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the affect of a second write access to CN0 depends on the phase of CN0:

phase 1: update of CN0 before CN0 reaches first time CM0

phase 2: update of CN0 after CN0 has reached first time CM0 but is less than CM1

phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value CN0new < CM0 leads to a shift of first edge (generated if CN0 reaches CM0 first time) by the time CM0-CN0new.

In phase 2: writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: Writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

If a channel is configured to one-shot mode and configuration bit OSM_TRIG is set to 1, the trigger signal *OSM_TRIG* (i.e. *TRIG_[x-1]* or *TIM_EXT_CAPTURE(x)*) triggers start of one pulse generation.

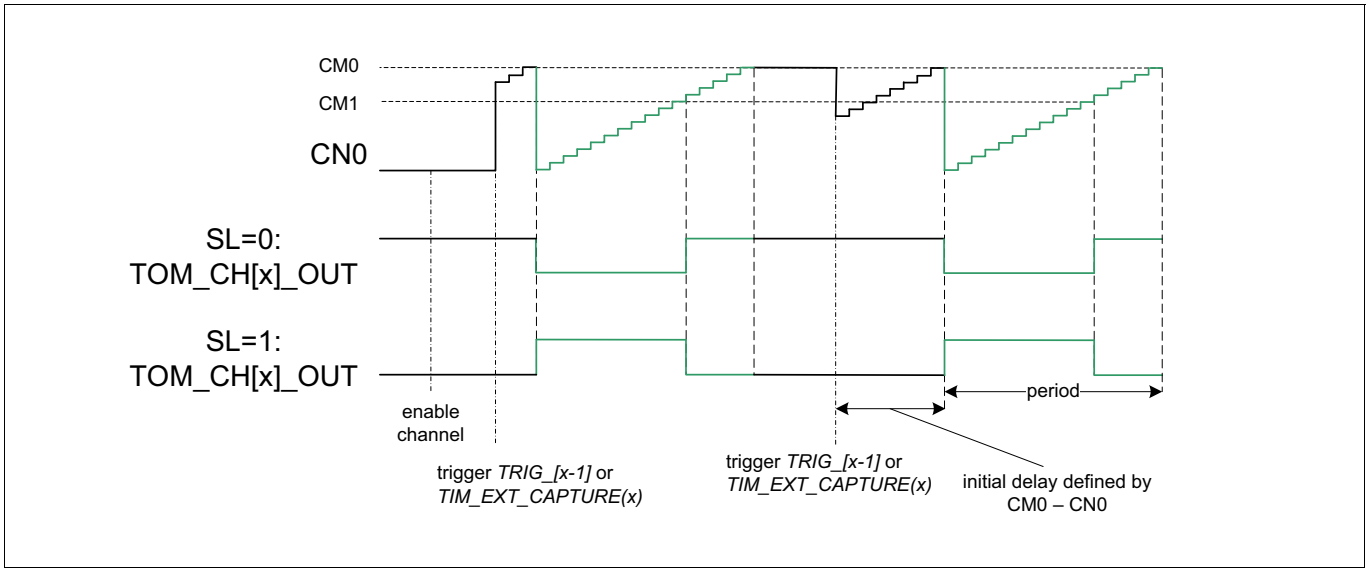

Figure 58 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIG_[x-1] or TIM_EXT_CAPTURE(x)

28.14.3.5 One-shot Counting Up-Down Mode

The TOM channel can operate in one-shot counting up-down mode when the bit OSM = 1 and the UDMODE != 0b00. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding **ENDIS_STAT** value.

In One-shot mode the counter **CN0** will not be incremented once the channel is enabled.

A write access to the register **CN0** triggers the start of pulse generation (i.e. the increment of the counter register **CN0**).

To avoid an update of **CMx** register with content of **SRx** register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 0b00 (in register **TOM[i]_CH[x]_CTRL**)

If the counter **CN0** is greater or equal than **CM1**, the output *TOM[i]_CH[x]_OUT* is set to SL value.

If the counter **CN0** is less than **CM1**, the output *TOM[i]_CH[x]_OUT* is set to !SL value.

If the counter **CN0** has reached the value 0 (by counting down), it stops.

The new value of **CN0** determines the start delay of the first edge. The delay time of the first edge is given by (**CM1-CN0**) multiplied with period defined by current value of **CLK_SRC**.

Figure 59 depicts the pulse generation in one-shot mode.

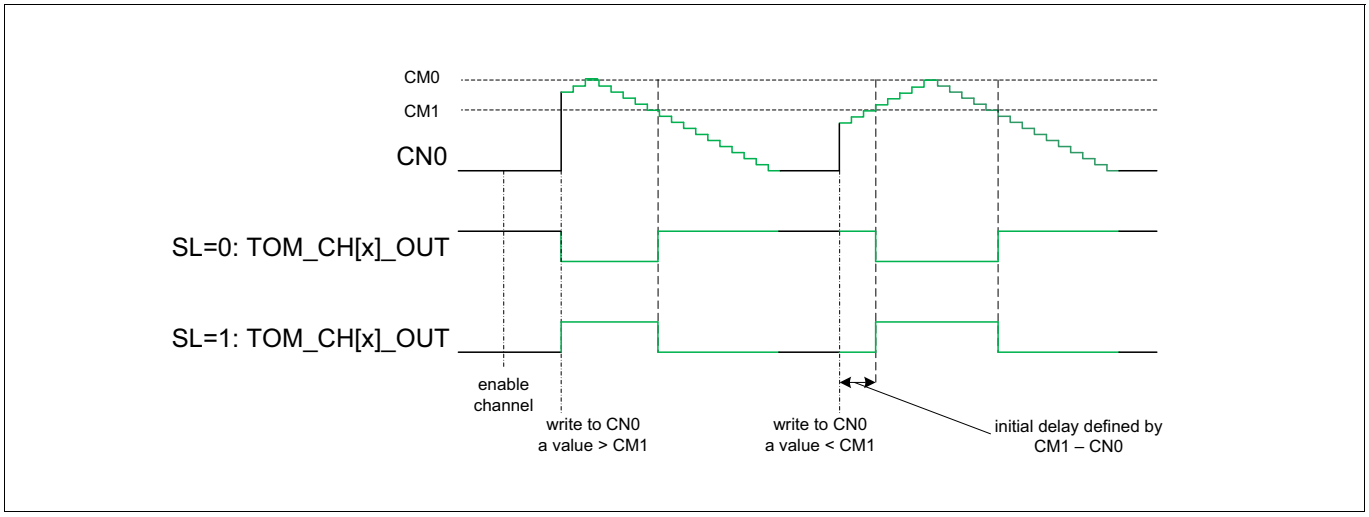

Figure 59 PWM Output with respect to configuration bit SL in one-shot counting up-down mode and UDMODE != 0b00: trigger by writing to CN0

Further output of single pulses can be started by writing to register **CN0**.

If a channel is configured to one-shot counting up-down mode and configuration bit OSM_TRIG is set to 1, the trigger signal *OSM_TRIG* (i.e. *TRIG_[x-1]* or *TIM_EXT_CAPTURE(x)*) triggers start of one pulse generation.

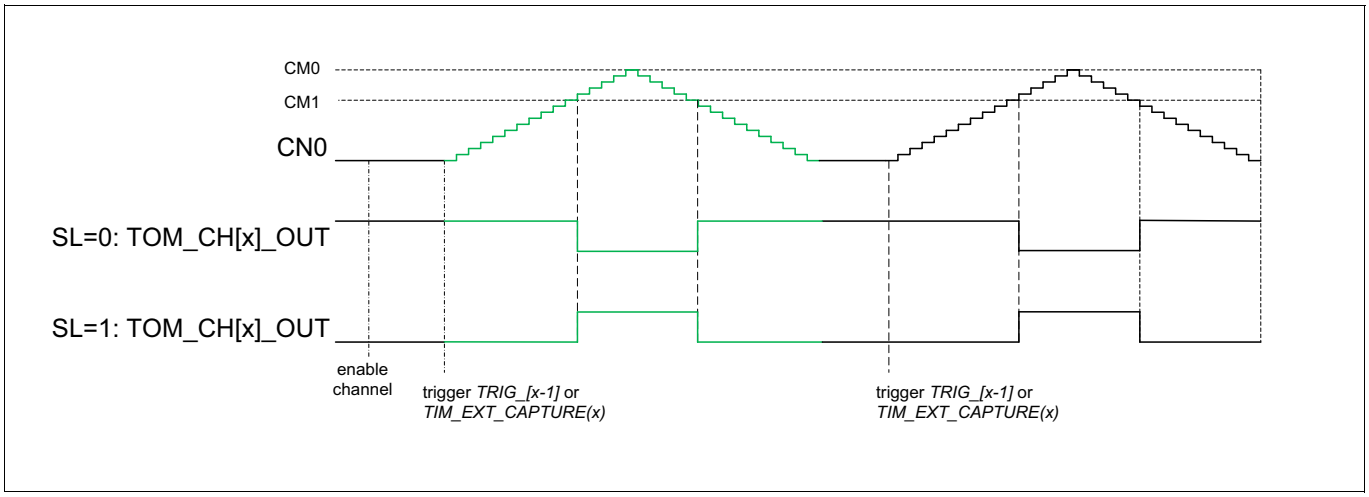

Figure 60 PWM Output with respect to configuration bit SL in one-shot counting up-down mode and UDMODE != 0b00: trigger by TRIG_[x-1] or TIM_EXT_CAPTURE(x)

28.14.3.6 Pulse Count Modulation Mode

At the output *TOM[i]_CH15_OUT* a pulse count modulated signal can be generated instead of the simple PWM output signal.

Figure **Figure 51** outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit **BITREV** to 1.

With the configuration bit **BITREV**=1 a bit-reversing of the counter output **CN0** is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the **CN0** register value is shown in the following **Figure 61**.

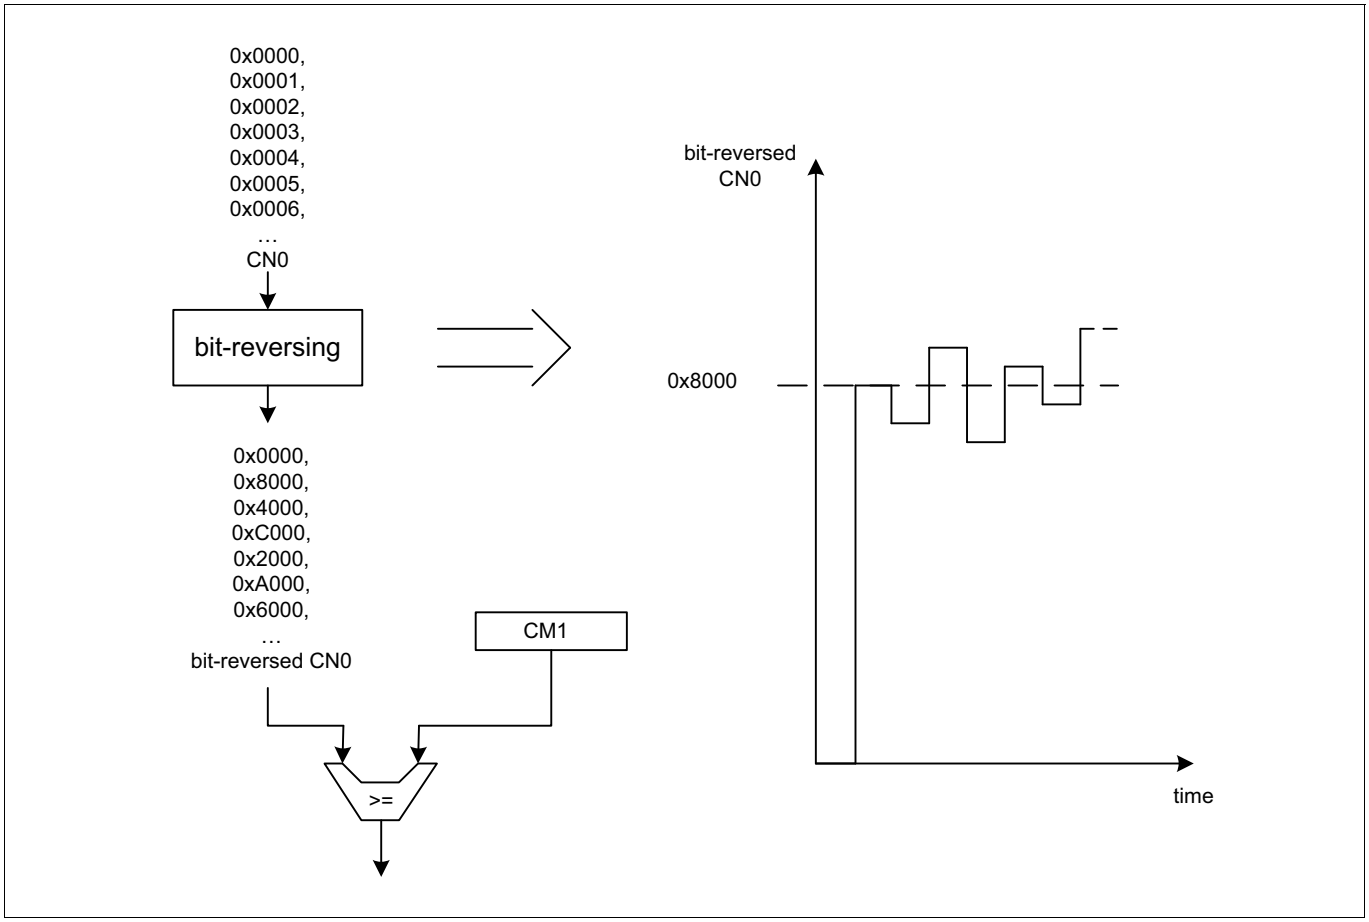

Figure 61 Bit reversing of counter CN0 output

In the PCM mode the counter register **CN0** is incremented by every clock tick depending on configured CMU clock (*CMU_FXCLK*).

The output of counter register **CN0** is first bit-reversed and then compared with the configured register value **CM1**.

If the bit-reversed value of register **CN0** is greater than **CM1**, the SR flip-flop of sub-module SOU is set (depending on configuration register **SL**) otherwise the SR flip-flop is reset. This generates at the output *TOM[i]_CH15_OUT* a pulse count modulated signal.

In PCM mode the **CM0** register - in which the period is defined - normally has to be set to its maximum value 0xFFFF.

To reduce time period of updating duty cycle value in **CM1** register, it is additionally possible to setup period value in **CM0** register to smaller values than maximum value as described before.

Possible values for **CM0** register are each even numbered values to the power of 2 e.g. 0x8000, 0x4000, 0x2000 ….

In this case the duty cycle has to be configured in the following manner.

Depending on how much the period in CM0 register is decreased - means shifted right starting from 0x10000 - the duty cycle in CM1 register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g.

period CM0 = 0x0100 -> shifted 8 bits right from 0x10000

--> so duty cycle has to be shifted left 8 bit:

e.g. 50% duty cycle = 0x00080 -> shift 8 bits left -> CM1 = 0x8000

More examples:

period CM0	-->	duty cycle	-->	no shift	-->	CM1
0xFFFF	-->	0x8000	-->	no shift	-->	0x8000
0x8000	-->	0x4000	-->	shift 1 bit left	-->	0x8000
0x4000	-->	0x1000	-->	shift 2 bits left	-->	0x4000
0x2000	-->	0x0FFF	-->	shift 3 bits left	-->	0x7FF8
0x1000	-->	0x0333	-->	shift 4 bits left	-->	0x3330
0x0800	-->	0x0055	-->	shift 5 bits left	-->	0x0AA0
…						
0x0020	-->	0x0008	-->	shift 19 bits left	-->	0x4000
0x0010	-->	0x0005	-->	shift 20 bits left	-->	0x5000
…						

Note: In this mode the interrupt CCU1TC (see register **TOM[i]_CH[x]_IRQ_NOTIFY**) is set every time if bit reverse value of **CN0** is greater or equal than **CM1** which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

28.14.3.7 Trigger Generation

For applications with constant PWM period defined by CM0, it is not necessary to update regularly the **CM0** register with **SR0** register. For these applications the **SR0** register can be used to define an additional output signal and interrupt trigger event.

If bit SR0_TRIG in register **TOM[i]_CH[x]_CTRL** is set, the register **SR0** is no longer used as a shadow register for register **CM0**. Instead, **SR0** is compared against **CN0** and if both are equal, a pulse of signal level '1' is generated at the output *TOM[i]_CH[x]_OUT_T*.The bit SR0_TRIG should only be set if bit RST_CCU0 of this channel is 0.

If bit SR0_TRIG is set the interrupt notify flag CCU1TC is no longer set on a compare match of **CM1** and **CN0**. Instead, the CCU1TC interrupt notify flag is set in case of a compare equal match of **SR0** and **CN0**.

With configuration bit TRIG_PULSE one can select if the output *TOM[i]_CH[x]_OUT_T* is high as long as CN0=SR0 (TRIG_PULSE=0) or if there will be only one pulse of length one SYS_CLK period when CN0 becomes SR0 (TRIG_PULSE=1).

The TOM output signal routing to DTM or GTM top level is described in subchapter “DTM connections on GTM-IP top level”

28.14.4 TOM BLDC Support

The TOM sub-module offers in combination with the SPE sub-module a BLDC support. To drive a BLDC engine TOM channels 0 to 7 can be used.

The BLDC support can be configured by setting the **SPEM** bit inside the **TOM[i]_CH[z]_CTRL** register. When this bit is set the TOM channel output is controlled through the SPE_OUT(z) signal coming from the SPE sub-module (see **Figure 49**). Please refer to chapter “Sensor Pattern Evaluation” for a detailed description of the SPE sub-module.

The TOM[i]_CH2,6,7,8 or 9 can be used together with the SPE module to trigger a delayed update of the **SPE_OUT_CTRL** register (i.e. commutation delay) after new input pattern detected by SPE (signaled by *SPE[i]_NIPD*). This feature is configured on TOM[i]_CH2,6,7,8 or 9 by setting SPE_TRIG=1 and OSM=1. With this configuration the TOM channel i generates one single PWM pulse on trigger by signal *SPE_NIPD*.

For details please refer to chapter of SPE sub-module description.

28.14.5 TOM Gated Counter Mode

Each TOM - SPE module combination provides also the feature of a gated counter mode. This is reached by using the *FSOI* input of a TIM module to gate the clock of a CCU0 sub-module.

To configure this mode, registers of module SPE should be set as following:

- the SPE should be enabled (bit **SPE_EN** = 1),
- all three TIM inputs should be disabled **SIE0** = **SIE1** = **SIE2** = 0),
- **SPE[i]_OUT_CTRL** should be set to 00005555h (set **SPE_OUT()** to '0'),
- mode FSOM should be enabled (**FSOM**=1),
- set in bit field **FSOL** bit c if channel c of module TOM is chosen for gated counter mode
- Additionally in module TOM
  - mode should be disabled (**SPEM**=0) and
  - the gated counter mode should be enabled (**GCM**=1)

As a result of this configuration, the counter **CN0** in sub-module CCU0 of TOM channel c counts as long as input *FSOI* is '0'.

28.15 ARU-connected Timer Output Module (ATOM)

28.15.1 Overview

The ARU-connected Timer Output Module (ATOM) is able to generate complex output signals without CPU interaction due to its connectivity to the ARU. Typically, output signal characteristics are provided over the ARU connection through sub-modules connected to ARU like e.g. the MCS, DPLL or PSM. Each ATOM sub-module contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the ATOM sub-module is depicted in **Figure 62**.

The following design variables are used inside this chapter. Please refer to device specific appendix for correct value.

cCATO: ATOM channel count; number of channels per instance - 1

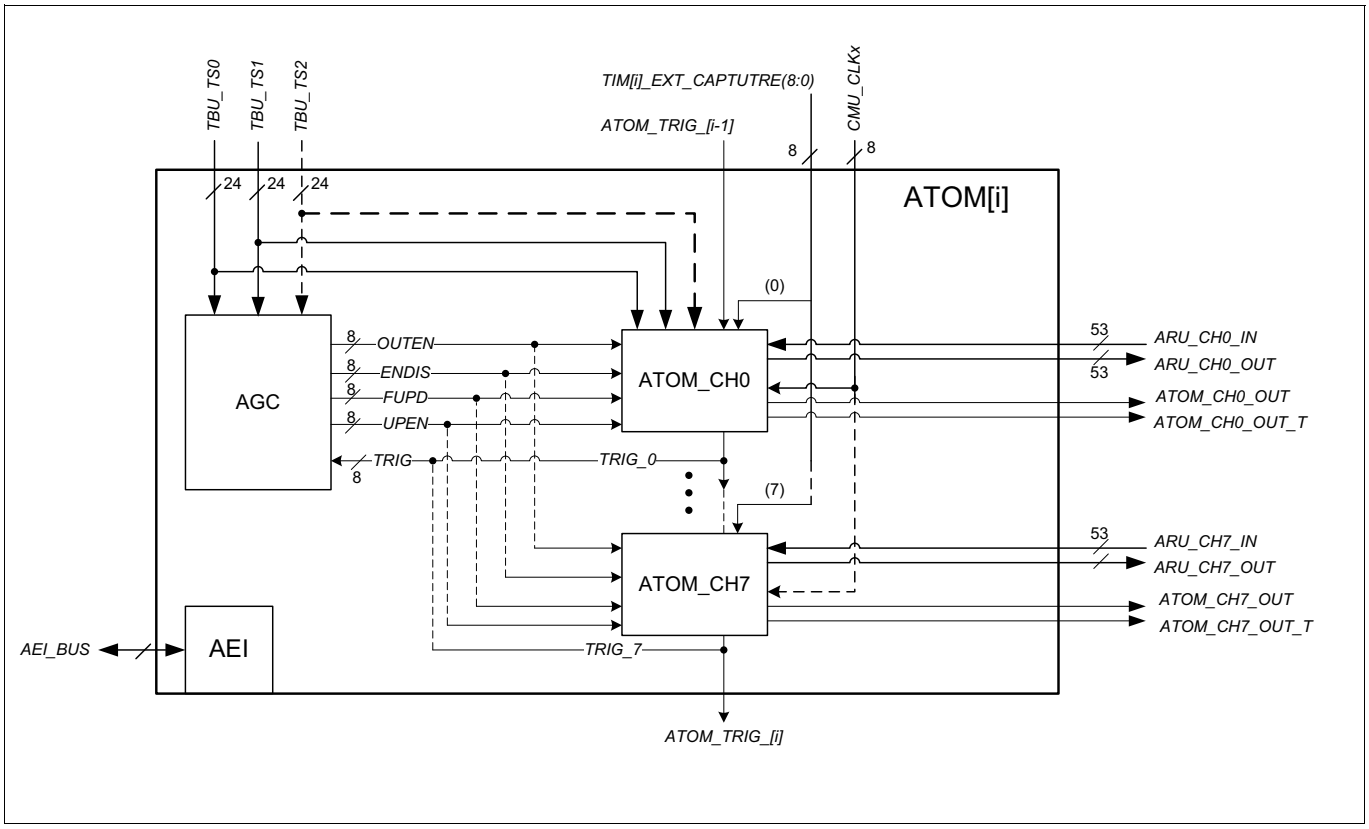

Figure 62 ATOM block diagram

The architecture of the ATOM sub-module is similar to the TOM sub-module, but there are some differences. First, the ATOM integrates only eight output channels. Hence, there exists one ATOM Global Control sub-unit (AGC) for the ATOM channels. The ATOM is connected to the ARU and can set up individual read requests from the ARU and write requests to the ARU. Furthermore, the ATOM channels are able to generate signals on behalf of time stamps and the ATOM channels are able to generate a serial output signal on behalf of an internal shift register.

Each ATOM channel provides five modes of operation:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)

- ATOM Signal Output Mode Buffered Compare (SOMB)

These modes are described in more detail in **Section 28.15.3**.

The ATOM channels' operation registers (e.g. counter, compare registers) are 24 bit wide. Moreover, the input clocks for the ATOM channels come from the configurable *CMU_CLKx* signals of the CMU sub-module. This gives the freedom to select a programmable input clock for the ATOM channel counters. The ATOM channel is able to generate a serial bit stream, which is shifted out at the *ATOM[i]_CH[x]_OUT* output. When configured in this serial shift mode (SOMS) the selected CMU clock defines the shift frequency.

Each ATOM channel provides a so called *operation* and *shadow* register set. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over CPU and/or ARU.

When update via ARU is selected, it is possible to configure for ATOM SOMP mode if both shadow registers are updated via ARU or only one of the shadow registers is updated.

On the other hand, the shadow registers can be used to provide data to the ARU when one or both of the compare units inside an ATOM channel match. This feature is only applicable in SOMC mode.

In TOM channels it is possible to reload the content of the operation registers with the content of the corresponding shadow registers and change the clock input signal for the counter register simultaneously. This simultaneous change of the input clock frequency together with reloading the operation registers is also implemented in the ATOM channels.

In addition to the feature that the CPU can select another *CMU_CLKx* during operation (i.e. updating the shadow register bit field CLK_SRC_SR of the **ATOM[i]_CH[x]_CTRL** register), the selection can also be changed via the ARU. Then, for the clock source update, the ACBI register bits of the **ATOM[i]_CH[x]_STAT** register are used as a shadow register for the new clock source.

In general, the behavior of the compare units CCU0 and CCU1 and the output signal behavior is controlled with the ACB bit field inside the **ATOM[i]_CH[x]_CTRL** register when the ARU connection is disabled and the behavior is controlled via ARU through the ACBI bit field of the **ATOM[i]_CH[x]_STAT** register, when the ARU is enabled.

Since the ATOM is connected to the ARU, the shadow registers of an ATOM channel can be reloaded via the ARU connection or via CPU over its AEI interface. When loaded via the ARU interface, the shadow registers act as a buffer between the ARU and the channel operation registers. Thus, a new parameter set for a PWM can be reloaded via ARU into the shadow registers, while the operation registers work on the actual parameter set.

The trigger signal *ATOM_TRIG_[i-1]* of ATOM instance i comes from the preceding instance i-1, the trigger *ATOM_TRIG_[i]* is routed to succeeding instance i+1. Note, ATOM0 is connected to its own output ATOM_TRIG_0, i.e. the last channel of ATOM instance 0 can trigger the first channel of ATOM instance 0 (this path is registered, which means delayed by one SYS_CLK period).

28.15.1.1 ATOM Global Control (AGC)

Synchronous start, stop and update of work register of up to 8 channels is possible with the AGC sub-unit. This sub-unit has the same functionality as the TGC sub-unit of the TOM sub-module.

28.15.1.1.1 Overview

There exists one global channel control unit (AGC) to drive a number of individual ATOM channels synchronously by external or internal events.

An AGC can drive up to eight ATOM channels.

The ATOM sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each ATOM channel with control register **ATOM[i]_AGC_ENDIS_CTRL** and status register **ATOM[i]_AGC_ENDIS_STAT**

- Global output enable mechanism for each ATOM channel with control register **ATOM[i]_AGC_OUTEN_CTRL** and status register **ATOM[i]_AGC_OUTEN_STAT**
- Global force update mechanism for each ATOM channel with control register **ATOM[i]_AGC_FUPD_CTRL**
- Update enable of the register **CM0**, **CM1** and **CLK_SRC** for each ATOM channel with the control bit field **UPEN_CTRL[z]** of **ATOM[i]_AGC_GLB_CTRL**

28.15.1.1.2 AGC Sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources. The three trigger sources are:

- the host CPU (bit **HOST_TRIG** of register **ATOM[i]_AGC_GLB_CTRL**)
- the TBU time stamp (signal *TBU_TS0…2* if available)
- the internal trigger signal *TRIG* (bunch of trigger signals *TRIG_[x]* which can be either the trigger *TRIG_CCU0* of channel x, the trigger of preceding channel x-1 (i.e. signal *TRIG_[x-1]*) or the external trigger *TIM_EXT_CAPTURE(x)* of assigned TIM channel x.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit **HOST_TRIG** of register **AOM[i]_AGC_GLB_CTRL**).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits **TBU_SEL**) and the time stamp compare value defined in the bit field **ACT_TB** of register **ATOM[i]_AGC_ACT_TB**. Note, a cyclic event compare of **ACT_TB** and selected *TBU_TS*[*x*] is performed.

The third possibility is the input *TRIG* (bunch of trigger signals *TRIG_[x]*) coming from the ATOM channels 0 to 7.

The corresponding trigger signal *TRIG_[x]* coming from channel [x] can be masked by the register **ATOM[i]_AGC_INT_TRIG**.

To enable or disable each individual ATOM channel, the registers **ATOM[i]_AGC_ENDIS_CTRL** and/or **ATOM[i]_AGC_ENDIS_STAT** have to be used.

The register **ATOM[i]_AGC_ENDIS_STAT** controls directly the signal *ENDIS*. A write access to this register is possible.

The register **ATOM[i]_AGC_ENDIS_CTRL** is a shadow register that overwrites the value of register **AOM[i]_AGC_ENDIS_STAT** if one of the three trigger conditions matches.

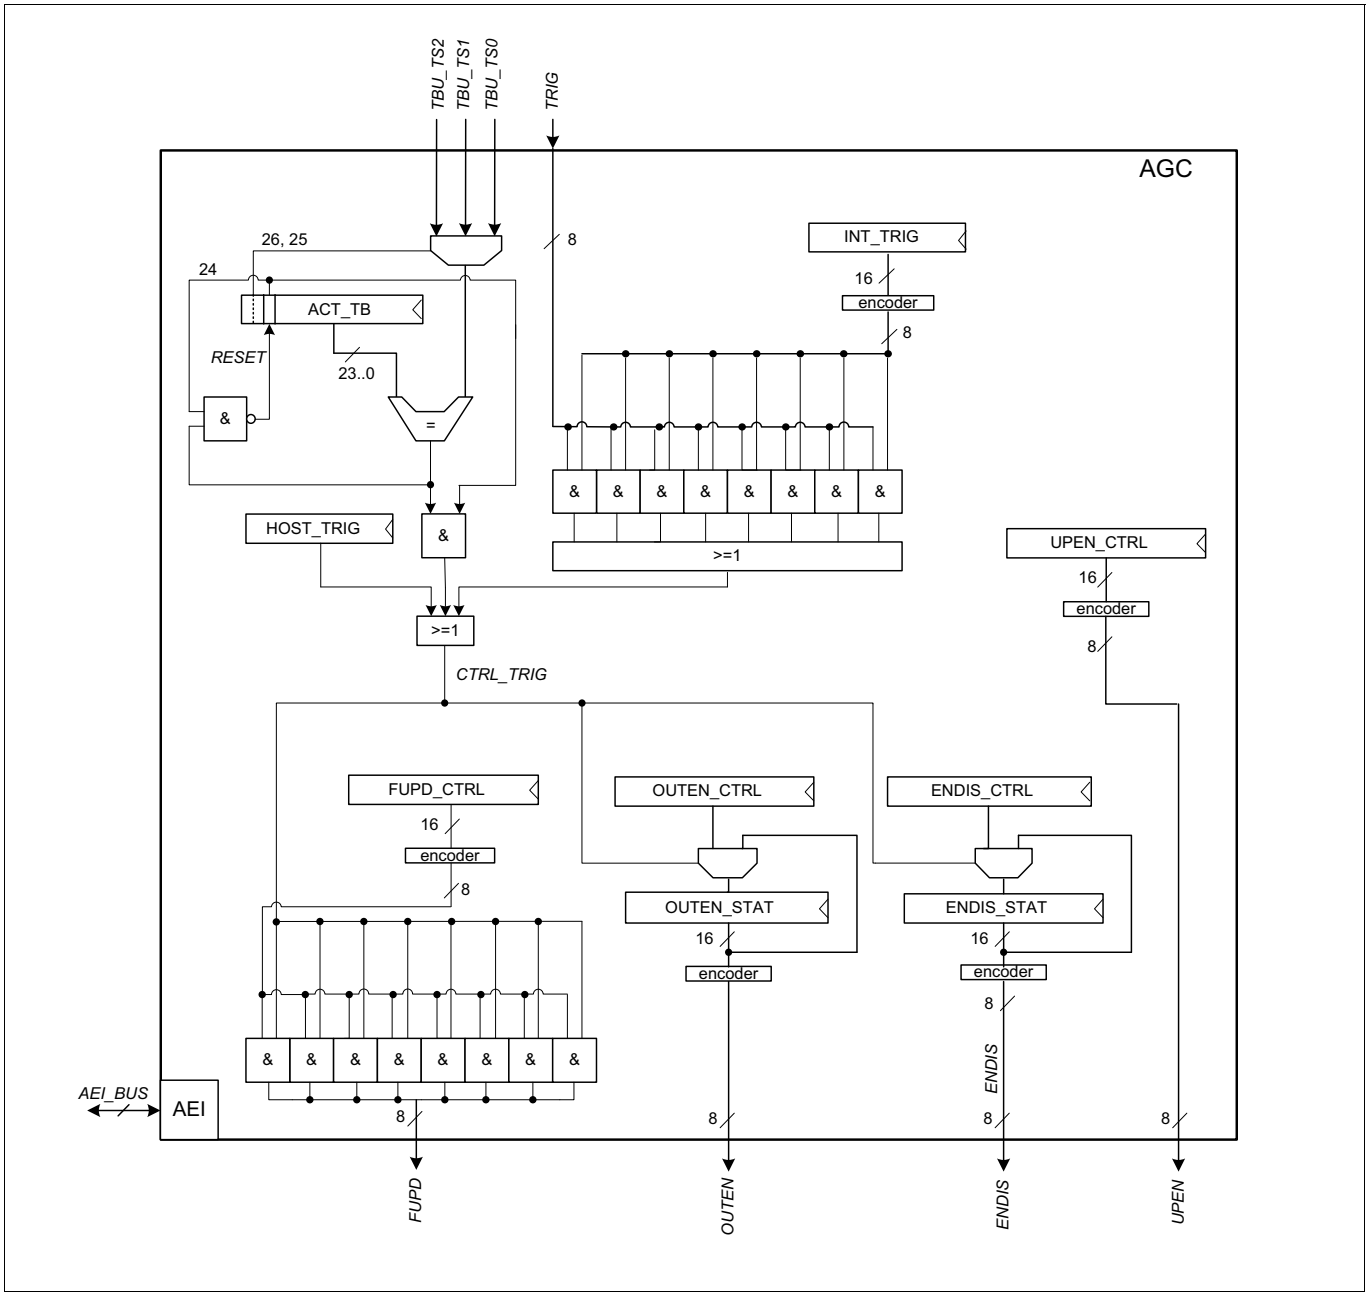

Figure 63 ATOM Global channel control mechanism

The output of the individual ATOM channels can be controlled using the register **ATOM[i]_AGC_OUTEN_CTRL** and **ATOM[i]_AGC_OUTEN_STAT**.

The register **ATOM[i]_AGC_OUTEN_STAT** controls directly the signal *OUTEN*. A write access to this register is possible.

The register **ATOM[i]_AGC_OUTEN_CTRL** is a shadow register that overwrites the value of register **ATOM[i]_AGC_OUTEN_STAT** if one of the three trigger conditions matches.

If an ATOM channel is disabled by the register **ATOM[i]_AGC_OUTEN_STAT**, the actual value of the channel output at *ATOM_CH[x]_OUT* is defined by the signal level bit (**SL**) defined in the channel control register **ATOM[i]_CH[x]_CTRL**.If the output is enabled, the output at *ATOM_CH[x]_OUT* depends on value of FlipFlop **SOUR**.

The register **ATOM[i]_AGC_FUPD_CTRL** defines which of the ATOM channels receive a *FORCE_UPDATE* event if the trigger signal *CTRL_TRIG* is raised. Note: In SOMP mode the force update request is stored and executed synchronized to the selected CMU_CLK. In all other modes the force update request is executed immediately.

The register bits **UPEN_CTRL[x]** defines for which ATOM channel the update of the working register **CM0**, **CM1** and **CLK_SRC** by the corresponding shadow register **SR0**, **SR1** and **CLK_SRC_SR** is enabled. If update is enabled, the register **CM0**, **CM1** and **CLK_SRC** will be updated on reset of counter register **CN0** (see **Figure 64**).

28.15.1.2 ATOM Channel Mode Overview

Each ATOM channel offers the following different operation modes:

In ATOM Signal Output Mode Immediate (**SOMI**), the ATOM channels generate an output signal immediately after receiving an ARU word according to the two signal level output bits of the ARU word received through the ACBI bit field. Due to the fact, that the ARU destination channels are served in a round robin order, the output signal can jitter in this mode with a jitter of the ARU round trip time.

In ATOM Signal Output Mode Compare (**SOMC**), the ATOM channel generates an output signal on behalf of time stamps that are located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new time stamps either by CPU or via the ARU. The new time stamps are directly loaded into the channels operation register. The shadow registers are used as capture registers for two time base values, when a compare match of the channels operation registers occurs.

In ATOM Signal Output Mode PWM (**SOMP**), the ATOM channel is able to generate simple and complex PWM output signals like the TOM sub-module by comparing its operation registers with a sub-module internal counter. In difference to the TOM, the ATOM shadow registers can be reloaded by the CPU and by the ARU in the background, while the channel operates on the operation registers.

In ATOM Signal Output Mode Serial (**SOMS**), the ATOM channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the *CMU_CLKx* clock signals. Please refer to **Section 28.15.3.4** for further details.

In ATOM Signal Output Buffered Compare (**SOMB**), the ATOM channel generates an output signal on behalf of time stamps that located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new compare values either by CPU or via the ARU. The new compare values received via ARU are stored first in the shadow register and only if previous compare match is occurred, the operation register are updated with the content of the shadow register.

28.15.2 ATOM Channel Architecture

Each ATOM channel is able to generate output signals according to five operation modes. The architecture of the ATOM channels is similar to the architecture of the TOM channels. The general architecture of an ATOM channel is depicted in **Figure 64**.

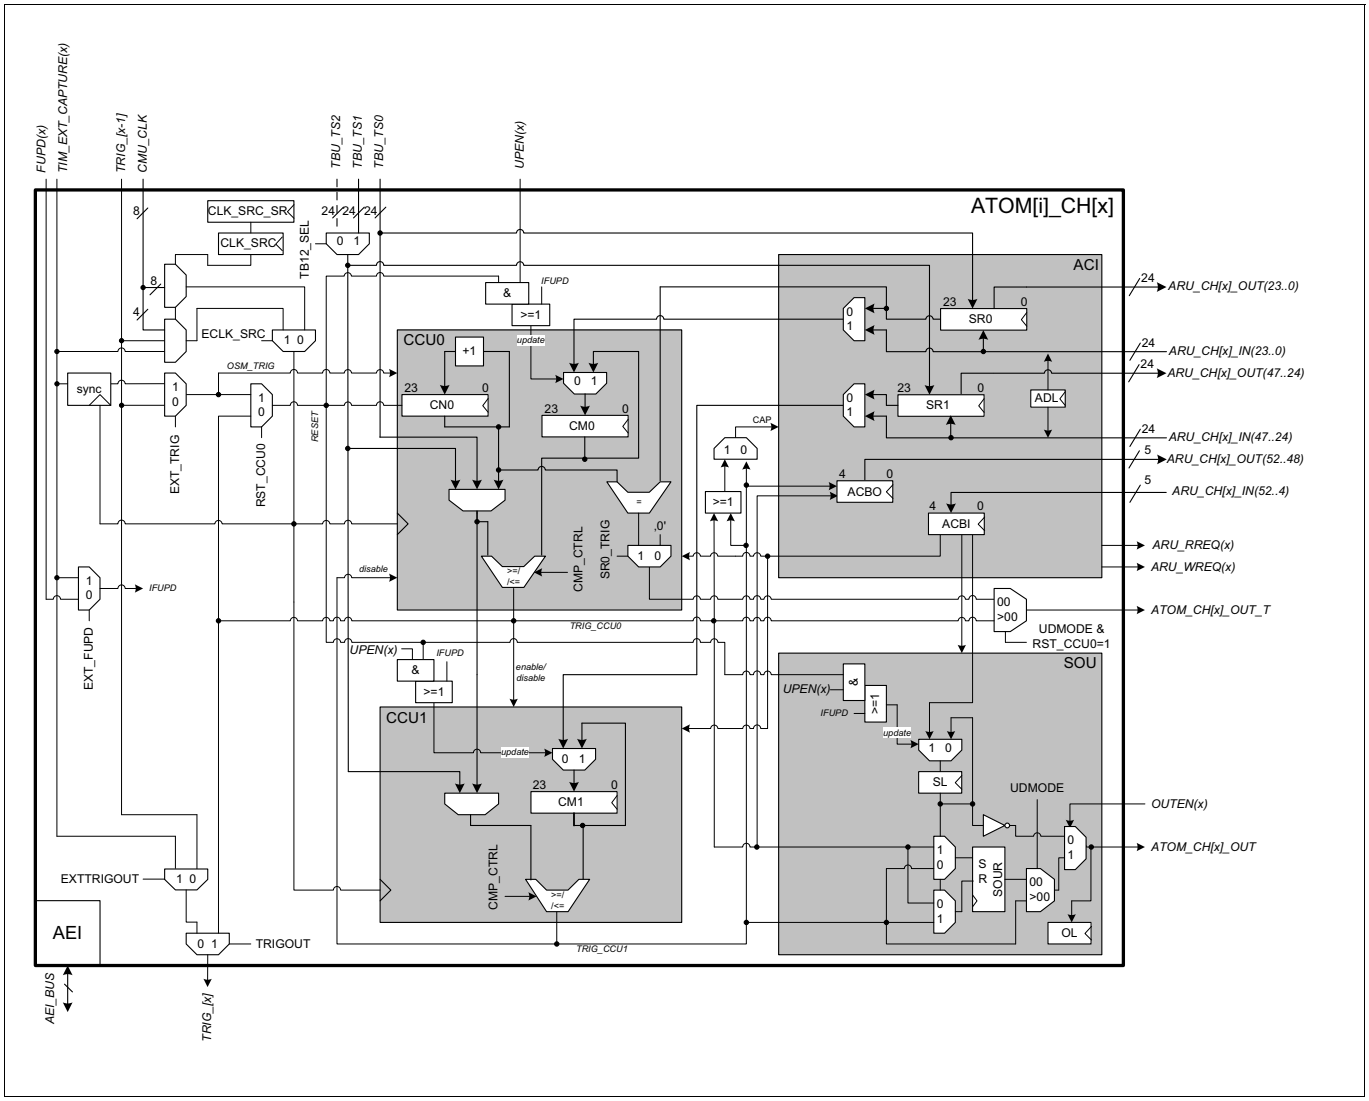

Figure 64 ATOM channel architecture

In all ATOM channels the operation registers **CN0**, **CM0** and **CM1** and the shadow registers **SR0** and **SR1** are the 24 bit width. The comparators inside CCU0 and CCU1 provide a selectable signed greater-equal or less-equal comparison to compare against the GTM time bases *TBU_TS0*, *TBU_TS1* and, if available, *TBU_TS2*. Please refer to TBU (chapter: “Time Base Unit”) for further details. The CCU0 and CCU1 units have different tasks for the different ATOM channel modes.

The cyclic event compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first overflow and then reach the compare value. Please note, that for a correct behavior of this cyclic event compare, the new compare value must not be specified larger/smaller than half of the range of the total time base value (0x7FFFFF).

In SOMC/SOMB mode, the two compare units CCUx can be used in combination to each other. When used in combination, the trigger lines *TRIG_CCU0* and *TRIG_CCU1* can be used to enable/disable the other compare unit on a match event. Please refer to **Section 28.15.3.2** and **Section 28.15.3.5** for further details.

The Signal Output Unit (SOU) generates the output signal for each ATOM channel. This output signal level depends on the ATOM channel mode and on the **SL** bit of the **ATOM[i]_CH[x]_CTRL** register in combination with the two control bits. These two control bits **ACB(1)** and **ACB(0)** can either be received via CPU in the ACB register field of the **ATOM[i]_CH[x]_CTRL** register or via ARU in the ACBI bit field of the **ATOM[i]_CH[x]_STAT** register.

The **SL** bit in the **ATOM[i]_CH[x]_CTRL** register defines in all modes the operational behavior of the ATOM channel.

When the channel and its output are disabled, the output signal level of the channel is the inverse of the **SL** bit.

In SOMI, SOMC and SOMB mode the output signal level depends on the **SL**, **ACB0** and **ACB1** bits. In SOMP mode the output signal level depends on the two trigger signals *TRIG_CCU0* and *TRIG_CCU1* since theses two triggers define the PWM timing characteristics and the **SL** bit defines the level of the duty cycle. In SOMS mode the output signal level is defined by the bit pattern that has to be shifted out by the ATOM channel. The bit pattern is located inside the **CM1** register.

The ARU Communication Interface (ACI) sub-unit is responsible for requesting data routed through ARU to the ATOM channel in SOMI, SOMP, SOMB and SOMS modes, and additionally for providing data to the ARU in SOMC mode.

In SOMC mode the ACI shadow registers have a different behavior and are used as output buffer registers for data send to ARU.

28.15.2.1 ARU Communication Interface

The ATOM channels have an ARU Communication Interface (ACI) sub-unit. This sub-unit is responsible for data exchange from and to the ARU. This is done with the two implemented registers **SR0**, **SR1**, and the **ACBI** and **ACBO** bit fields that are part of the **ATOM[i]_CH[x]_STAT** register. The ACI architecture is shown in **Figure 65**.

If the **ARU_EN** bit is set inside the **ATOM[i]_CH[x]_CTRL** register, the ATOM channel is enabled by setting the enable bits inside the **ATOM[i]_AGC_ENDIS_STAT** register and the CPU hasn't written data not equal to zero into the **CM0**, **CM1, SR0, SR1** register, the ATOM channel will first request data from the ARU before the signal generation starts in SOMP, SOMS, SOMC and SOMB mode.

Note: if in SOMP mode there is data inside the **CM0** or **SR0** register not equal to 0 the channel counter **CN0** will start counting immediately, regardless whether the channel has received ARU data yet.

Note: if in SOMS mode there is data inside the **CM0** or **SR0** register not equal to 0 the channel will start shifting immediately, regardless whether the channel has received ARU data yet.

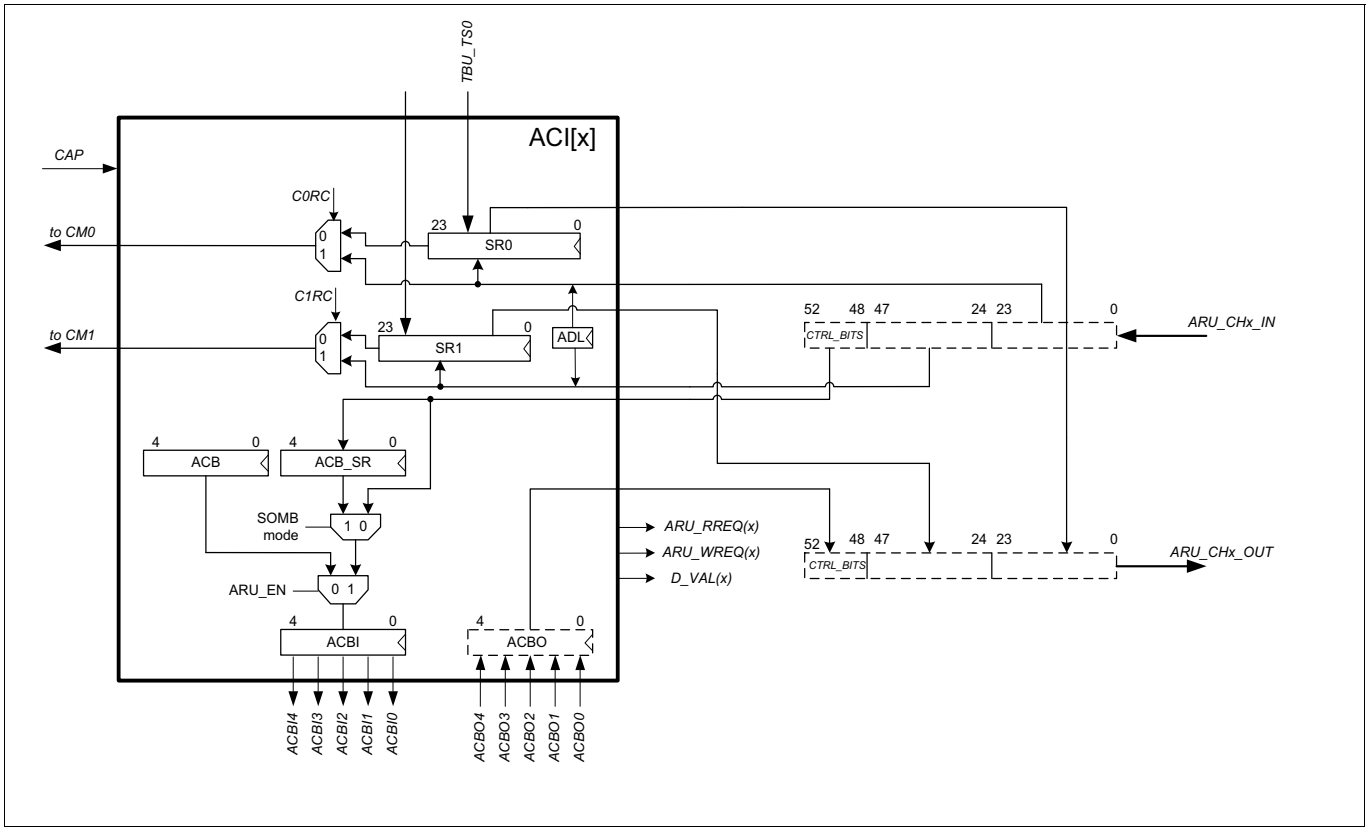

Figure 65 ACI architecture overview

Incoming ARU data (53 bit width signal *ARU_CHx_IN*) is split into three parts by the ACI and communicated to the ATOM channel registers. In SOMI, SOMP, SOMS and SOMB modes incoming ARU data *ARU_CHx_IN* is split in a way that the lower 24 bits of the ARU data (23 downto 0) are stored in the **SR0** register, the upper bits (47 downto 24) are stored in the **SR1** register. The bits 52 downto 48 (*CTRL_BITS*) are stored in SOMI, SOMP and SOMS mode in the **ACBI** bit field of the register **ATOM[i]_CH[x]_STAT**, in SOMB mode in the internal ACB_SR register.

The ATOM channel has to ensure, that in a case when the channel operation registers **CM0** and **CM1** are updated with the **SR0** and **SR1** register content and an ARU transfer to these shadow registers happens in parallel that either the old data in both shadow registers is transferred into the operation registers or both new values from the ARU are transferred.

In SOMC mode incoming ARU data *ARU_CHx_IN* is written directly to the ATOM channel operation register in the way that the lower 24 bits (23 down to 0) are written to **CM0**, and the bits 47 down to 24 are written to register **CM1**. The bits 52 down to 48 are stored in the **ACBI** bit field of the **ATOM[i]_CH[x]_STAT** register and control the behavior of the compare units and the output signal of the ATOM channel.

In SOMC mode the **SR0** and **SR1** registers serve as capture registers for the time stamps coming from TBU whenever a compare match event is signaled by the CCU0 and/or CCU1 sub-units via the *CAP* signal line. These two time stamps are then provided together with actual ATOM channel status information located in the **ACBO** bit field to the ARU at the dedicated ARU write address of the ATOM channel when the ARU is enabled.

The encoding of the ARU control bits in the different ATOM operation modes is described in more detail in the following chapters.

28.15.3 ATOM Channel Modes

As described above, each ATOM channel can operate independently from each other in one of five dedicated output modes:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)
- ATOM Signal Output Mode Buffered Compare (SOMB)

The Signal Output Mode PWM (SOMP) is principally the same like the output mode for the TOM sub-module. In addition, it is possible to reload the shadow registers via the ARU without the need of a CPU interaction. The other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

Note that in any output mode, if a channel is enabled, one-shot mode is disabled (**OSM**=0; only used in modes SOMP and SOMS) and CM0 >= CN0, the counter CN0 is incrementing until it reaches CM0.To avoid unintended counting of **CN0** after enabling a channel, it is recommended to reset a channel (or at least CN0 and CM0) before any change on the mode bits **MODE**, **ARU_EN** and **OSM**.

28.15.3.1 ATOM Signal Output Mode Immediate (SOMI)

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channel generates output signals on the *ATOM[i]_CH[x]_OUT* output port immediate after update of the bit **ACBI(0)** of register **ATOM[i]_CH[x]_STAT** or **ACB(0)** bit of register **ATOM[i]_CH[x]_CTRL**.

If ARU access is enabled by setting bit ARU_EN in register **ATOM[i]_CH[x]_CTRL**, the update of the output *ATOM[i]_CH[x]_OUT* depends on the bit ACBI(0) of register **ATOM[i]_CH[x]_STAT** received at the ACI sub-unit and the bit **SL** bit of register **ATOM[i]_CH[x]_CTRL**. The remaining 48 ARU bits (47 downto 0) have no meaning in this mode.

If ARU access is disabled, the update of the output *ATOM[i]_CH[x]_OUT* depends on the bit **ACB(0)** and the bit **SL** of register **ATOM[i]_CH[x]_CTRL**.

The initial ATOM channel port pin *ATOM[i]_CH[x]_OUT* signal level has to be specified by the **SL** bit field of the **ATOM[i]_CH[x]_CTRL** register when **OUTEN_CTRL** register bit field **OUTEN_CTRLx** is disabled (see **Section 28.15.6.5**) for details.

In SOMI mode the output behavior depends on the **SL** bit of register **ATOM[i]_CH[x]_CTRL** and the bit **ACBI(0)** of the **ATOM[i]_CH[x]_STAT** register or the bit **ACB0** of register **ATOM[i]_CH[x]_CTRL**:

Table 50 Output behavior in SOMI mode

SL	ACBI(0)/ ACB(0)	Output behavior
0	0	Set output to inverse of SL (1)
0	1	Set output to SL (0)
1	0	Set output to inverse of SL (0)
1	1	Set output to SL (1)

The signal level bit **ACBI(0)** is transferred to the SOU sub-unit of the ATOM and made visible at the output port according to the table above immediately after the data was received by the ACI. This can introduce a jitter on the output signal since the ARU channels are served in a time multiplexed fashion.

28.15.3.1.1 Register ATOM[i]_CH[x]_CTRL in SOMI mode

Register ATOM[i]_CH[x]_CTRL in SOMI mode

28.15.3.2 ATOM Signal Output Mode Compare (SOMC)

28.15.3.2.1 Overview

In ATOM Signal Output Mode Compare (SOMC) the output action is performed in dependence of the comparison between input values located in **CM0** and/or **CM1** registers and the two (three) time base values *TBU_TS0* or *TBU_TS1* (or *TBU_TS2*) provided by the TBU. For a description of the time base generation please refer to the TBU specification in chapter “Time Base Unit”. It is configurable, which of the two (three) time bases is to be compared with one or both values in **CM0** and **CM1**.

The behavior of the two compare units CCU0 and CCU1 is controlled either with the bits 4 downto 2 of **ACB** bit field inside the **ATOM[i]_CH[x]_CTRL** register, when the ARU connection is disabled or with the ACBI bit field of the **ATOM[i]_CH[x]_STAT** register, when the ARU is enabled. In that case the **ACB** bit field is updated via the ARU control bits 52 downto 48.

The CCUx trigger signals *TRIG_CCU0* and *TRIG_CCU1* always create edges, dependent on the predefined signal level in **SL** bit in combination with two control bits that can be specified by either ARU or CPU within the aforementioned **ATOM[i]_CH[x]_CTRL** or **ATOM[i]_CH[x]_STAT** registers.

In SOMC mode the channel is always disabled after the specified compare match event occurred. The shadow registers are used to store two time stamp values at the match time. The channel compare can be re-enabled by first reading the shadow registers, either by CPU or ARU and by providing new data for CMx registers through CPU or ARU. For a detailed description please refer to the **Section 28.15.3.2.2** and **Section 28.15.3.2.3**.

If three time bases exist for the GTM there must be a preselection between *TBU_TS1* and *TBU_TS2* for the ATOM channel. This can be done with **TB12_SEL** bit in the **ATOM[i]_CH[x]_CTRL** register.

The comparison in CCU0/1 with time base TBU_TS1 or TBU_TS2 can be done on a greater-equal or less-equal compare according to the **CMP_CTRL** bit. This control bit has no effect to a compare unit CCU0 or CCU1 that compares against TBU_TS0. In this case always a greater-equal compare is done. The bit **CMP_CTRL** is part of the **ATOM[i]_CH[x]_CTRL** register.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the ATOM channel is determined by the **SL** bit in the **ATOM[i]_CH[x]_CTRL** register. If the output is disabled, the signal level is set to the inverse level of the **SL** bit.

If the channel is disabled, the register SOUR is set to the **SL** bit in the **ATOM[i]_CH[x]_CTRL** register.

On a compare match event the shadow register **SR0** and **SR1** are used to capture the TBU time stamp values. **SR0** always holds *TBU_TS0* and **SR1** either holds *TBU_TS1* or *TBU_TS2* dependent on the **TB12_SEL** bit in the **ATOM[i]_CH[x]_CTRL** register.

Please note, that when the channel is disabled and the compare registers are written, the compare registers CMx are loaded with the written value and the channel starts with the comparison on behalf of this values, when the channel is enabled.

28.15.3.2.2 SOMC Mode under CPU control

As already mentioned above the ATOM channel can be controlled either by CPU or by ARU. When the channel should be controlled by CPU, the **ARU_EN** bit inside the **ATOM[i]_CH[x]_CTRL** register has to be reset.

The output of the ATOM channel is set on a compare match event depending on the **ACB10** bit field in combination with the **SL** bit both located in the **ATOM[i]_CH[x]_CTRL** register. The output behavior according to the **ACB10** bit field in the control register is shown in the following table:

Table 51 Output behavior according to the ACB10 bit field in the control register

SL	ACB10(5)	ACB10(4)	Output behavior
0	0	0	No signal level change at output (exception in table **Figure 67** mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in table {REF:ATOM_1809} mode ACB42=001)
1	0	0	No signal level change at output (exception in table {REF:ATOM_1809} mode ACB42=001)

Table 51 Output behavior according to the ACB10 bit field in the control register (cont'd)

SL	ACB10(5)	ACB10(4)	Output behavior
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in table **Figure 67** mode ACB42=001)

The capture/compare strategy of the two CCUx units can be controlled with the **ACB42** bit field inside the **ATOM[i]_CH[x]_CTRL** register. The meaning of these bits is shown in the following table:

Table 52 Capture/compare strategy of the two CCUx units controlled by ACB42 bit field

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see table**Section 67**
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Section 67**
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACB10(5) and ACB10(4).
1	1	1	Cancels pending comparison independent on ARU_EN

The behavior of the **ACBI**/**ACB42** bit combinations 0b000 and 0b001 is described in more detail in the tables of **Figure 66** and **Figure 67**.

Figure 67 ATOM CCUx Serve first definition ACB42 = 0b001

If the ATOM channel is enabled, the **CM0** and/or **CM1** registers and the **ACB42** bit field of the **ATOM[i]_CH[x]_CTRL** register can be updated by the CPU as long as the first match event occurs in case of a ‘serve last’ compare strategy or as long as the overall match event in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers **SR0**/**SR1** and before reading the **SR0** and/or **SR1** register via ARU, the update of the registers **CM0** and/or **CM1** is possible but has no effect.

To set up a new compare action, first the **SR0** and/or **SR1** register containing captured values have to be read and then new compare values have to be written into the register **CM0** and/or **CM1**.

Which **CMx** register has to be updated depends on the compare strategy defined in the **ACB42** bit field of the channel control register. Since the channel immediately starts with the comparison after the **CMx** register was/were written, the compare strategy has to be updated before the **CMx** registers are written.

For the ‘serve last’ compare strategies, if the register **CM0** and **CM1** are updated, it can happen that one or both compare values are already located in the past. In any way the ATOM channel will first wait until both compare values are written before it starts the time base comparisons to avoid a deadlock.

The CPU can check at any time if at least one of the ATOM channels' capture compare register contains valid data and waits for a compare event to happen. This is signaled by the **DV** bit inside the **ATOM[i]_CH[x]_STAT** register. Note, for ‘serve last’ compare strategies, if **DV** bit is currently not set, writing to **CM0** or **CM1** sets immediately the **DV** bit although the compare is only started if both values are written.

An exception for update of register **CM0**/**CM1** exists in SOMC mode and CCUx control mode 'serve last'. If in this mode the CCU0 compare match event occurred, the update of register **CM0**/**CM1** via CPU is blocked until the CCU1 compare match event.

In the ‘serve last’ mode (ACB42= 0b100 or ACB42=0b101) it is possible to generate very small spikes on the output pin by loading **CM0** and **CM1** with two time stamp values for *TBU_TS0*, *TBU_TS1* or *TBU_TS2* close together. The output pin will then be set or reset dependent on the **SL** bit and the specified **ACB10(5)** and **ACB10(4)** bits in the **ACB10** bit field of the **ATOM[i]_CH[x]_CTRL** register on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the **CM1** register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater-equal or less-equal comparison of the CCUx units.

In addition to storing the captured time stamps in the shadow registers, the ATOM channel provides the result of the compare match event in the **ACBO(4)** and **ACBO(3)** bits of the **ATOM[i]_CH[x]_STAT** register. The meaning of the bits is shown in the following table:

Table 53 Compare match event ACBO(4) and ACBO(3) bits of ATOM[i]_CH[x]_STAT

ACBO(4)	ACBO(3)	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the bit **SLA** in the **ATOM[i]_CH[x]_CTRL** register is not set, the **ACBO(4)** bit is always set and the **ACBO(3)** bit is always reset after the compare match event occurred.

The **ACBO** bit field is reset, when the **DV** bit is set.

Depending on the capture compare unit where the time base matched the interrupt *CCU0TCx_IRQ* or *CCU1TCx_IRQ* is raised. Note that in case of 'serve first' compare strategy, if both events CCU0 and CCU1 occur at the same point in time, both interrupts will be raised.

The behavior of an ATOM channel in SOMC mode under CPU control is depicted in **Figure 68**.

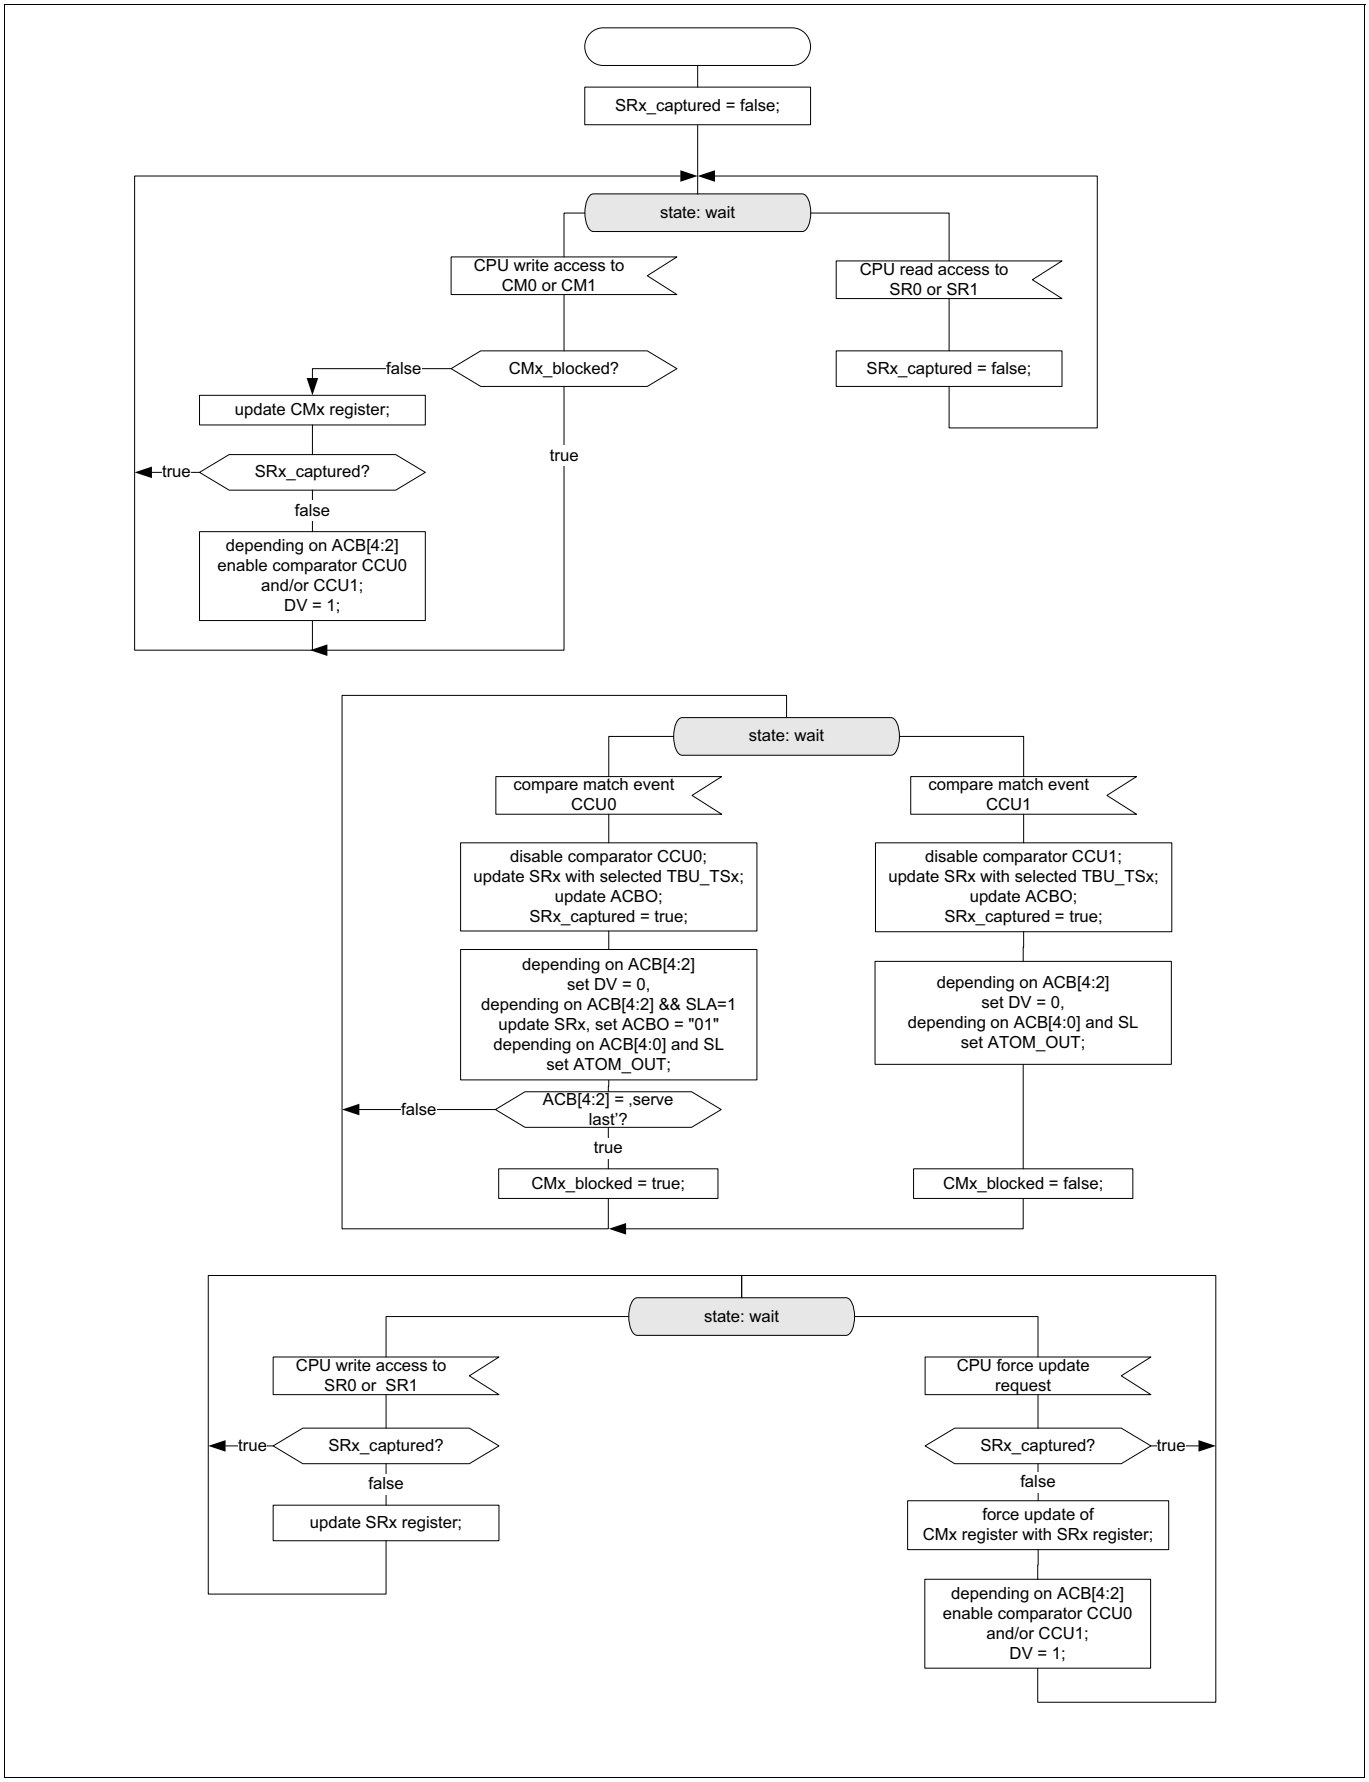

Figure 68 SOMC state diagram for channel under CPU control

28.15.3.2.3 SOMC Mode under ARU control

When the channel should be controlled by ARU, the **ARU_EN** bit inside the **ATOM[i]_CH[x]_CTRL** register has to be set.

In case, the ATOM channel is under ARU control the content for the compare registers **CM0** and **CM1** as well as the update of the compare strategy can be loaded via the 53 bit ARU word.

The ARU word 23 to 0 is loaded into the **CM0** register while the ARU word 47 to 24 is loaded into the **CM1** register. The five ARU control bits 52 to 48 are loaded into the **ACBI** bit field of the **ATOM[i]_CH[x]_STAT** register and control the channel compare strategy as well as the output behavior in case of compare match events.

For the five ARU control bits 52 to 48 the bits 49 and 48 are loaded into the **ACBI** bits 1 and 0. The output behavior also depends on the setting of the **SL** bit inside of the **ATOM[i]_CH[x]_CTRL** register and is shown in the following table:

Table 54 Output behavior depends on SL bit inside of the ATOM[i]_CH[x]_CTRL and ACBI bits 1 and 0

SL	ACBI(1)	ACBI(0)	Output behavior
0	0	0	No signal level change at output (exception in **Figure 66** and **Figure 67** mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Figure 66** and **Figure 67** mode ACB42=001)
1	0	0	No signal level change at output (exception in **Figure 66** and **Figure 67** mode ACB42=001)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Figure 66** and **Figure 67** mode ACB42=001)

For the five ARU control bits 52 to 48 the bits 52 to 50 are loaded into the **ACBI** bits 4 to 2. With these three bits the capture/compare units CCUx can be controlled as shown in the following table:

Table 55 Capture/compare units CCUx controlled by ACBI bits 4 to 2

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Figure 67**
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Figure 66**
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.

Table 55 Capture/compare units CCUx controlled by ACBI bits 4 to 2 (cont'd)

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI(1) and ACBI(0).
1	1	1	Change ARU read address to ATOM_RDADDR1 DV flag is not set. Neither ACBI(1) nor ACBI(0) is evaluated.

It is important to note that the bit combination 0b111 for the **ACBI(4)**, **ACBI(3)** and **ACBI(2)** bits forces the channel to request new compare values from another destination read address defined in the **ATOM_RDADDR1** bit field of the **ATOM[i]_CH[x]_RDADDR** register. After data was successfully received and the compare event occurred the ATOM channel switches back to **ATOM_RDADDR0** to receive the next data from there.

After the specified compare match event, the captured time stamps are stored in **SR0** and **SR1** and the compare result is stored in the **ACBO** bit field of the **ATOM[i]_CH[x]_STAT** register. The meaning of the **ACBO(4)** and **ACBO(3)** bits of the **ATOM[i]_CH[x]_STAT** is shown in the following table:

Table 56 Compare match event ACBO(4) and ACBO(3) bits of ATOM[i]_CH[x]_STAT

ACBO(4)	ACBO(3)	Return value to ARU
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the bit **SLA** in the **ATOM[i]_CH[x]_CTRL** register is not set, the **ACBO(4)** bit is always set and the **ACBO(3)** bit is always reset after the compare match event occurred.

The **ACBO** bit field is reset, when the **DV** bit is set.

Depending on the capture compare unit where the time base matched the interrupt *CCU0TCx_IRQ* or *CCU1TCx_IRQ* is raised.

When CCU0 and CCU1 is used for comparison it is possible to generate very small spikes on the output pin by loading **CM0** and **CM1** with two time stamp values for *TBU_TS0*, *TBU_TS1* or *TBU_TS2* close together. The output pin will then be set or reset dependent on the **SL** bit and the specified **ACBI(0)** and **ACBI(1)** bits in the **ACBI** bit field of the **ATOM[i]_CH[x]_STAT** register on the first match event and the output will toggle on the second match event.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the **CM1** register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater-equal or less-equal comparison of the CCUx units.

For compare strategy 'serve last' the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register **CM0** and **CM1** as well as to **WR_REQ** bit is different.

For the case of bit **ABM**=0 and EUPM=0 (register **ATOM[i]_CH[x]_CTRL**) these access rights by CPU to register **CM0** and **CM1** and the **WR_REQ** are depicted in the following figure.

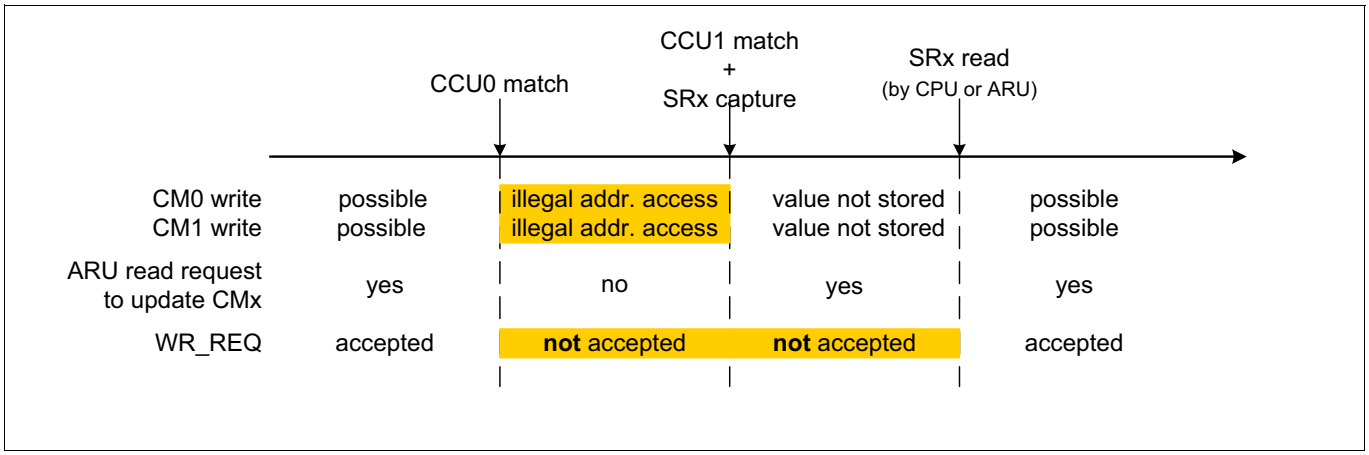

Figure 69 CPU access rights in case of compare strategy 'serve last', ABM=0 and EUPM=0

For the case of bit **ABM**=1 and **EUPM**=0 (register **ATOM[i]_CH[x]_CTRL**) these access rights by CPU to register **CM0** and **CM1** and the **WR_REQ** are depicted in the following figure.

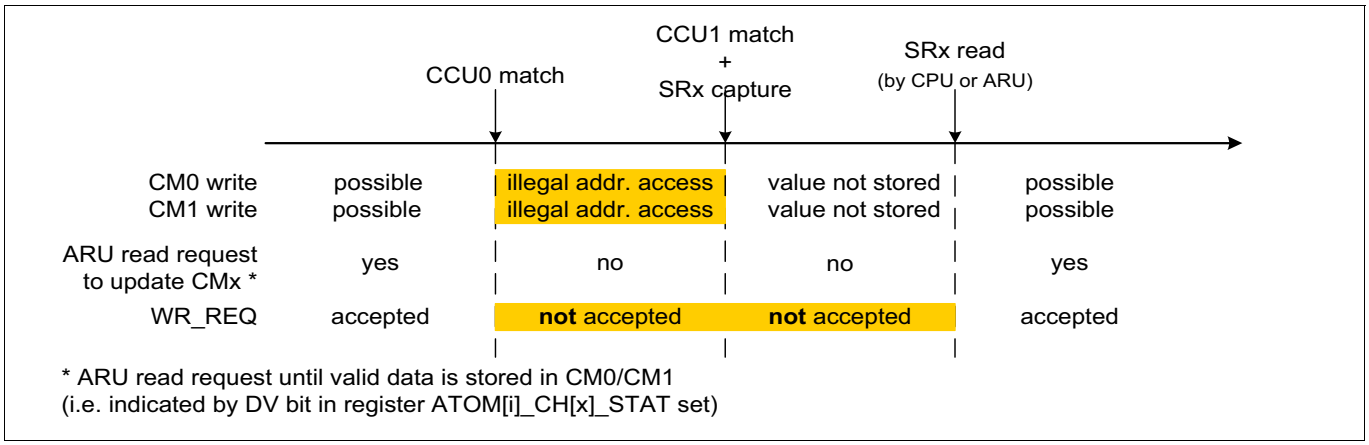

Figure 70 CPU access rights in case of compare strategy 'serve last', ABM=1 and EUPM=0

For the case of bit **EUPM**=1 (register **ATOM[i]_CH[x]_CTRL**), after CCU0 compare match (and before CCU1 compare match) an update of **CM1** as well as a late update via **WR_REQ** is possible. The value is used for compare. After CCU0 compare match an update of **CM0** is not possible, means the value is not stored. The ARU read request is not paused between the compare matches. This behavior is depicted in the following figures.

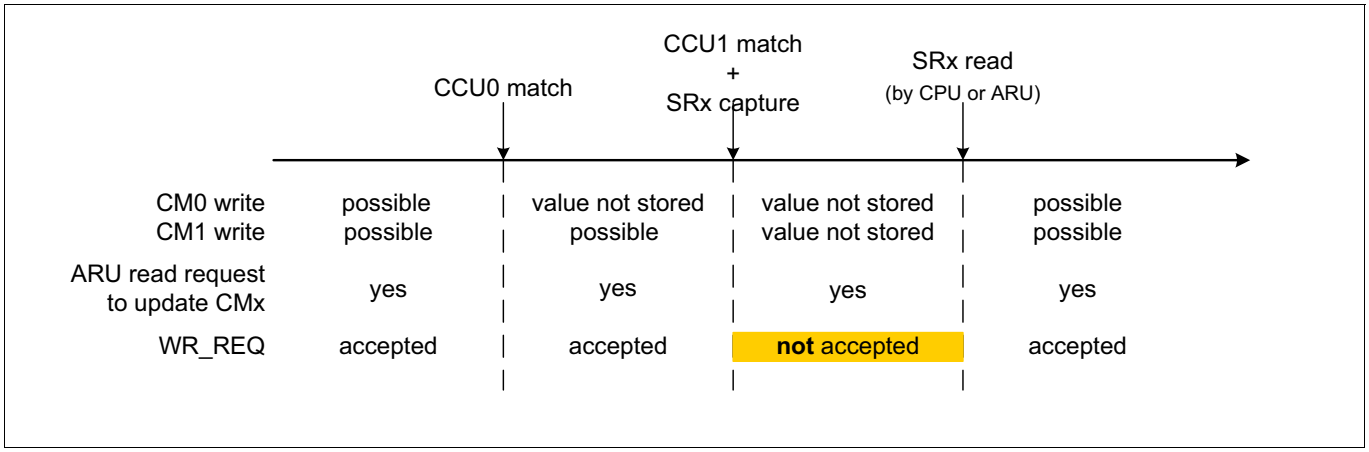

Figure 71 CPU access rights in case of compare strategy 'serve last' ,ABM=0 and EUPM=1

The behavior in case of EUPM=1 and ABM=1 is depicted in the following figure:

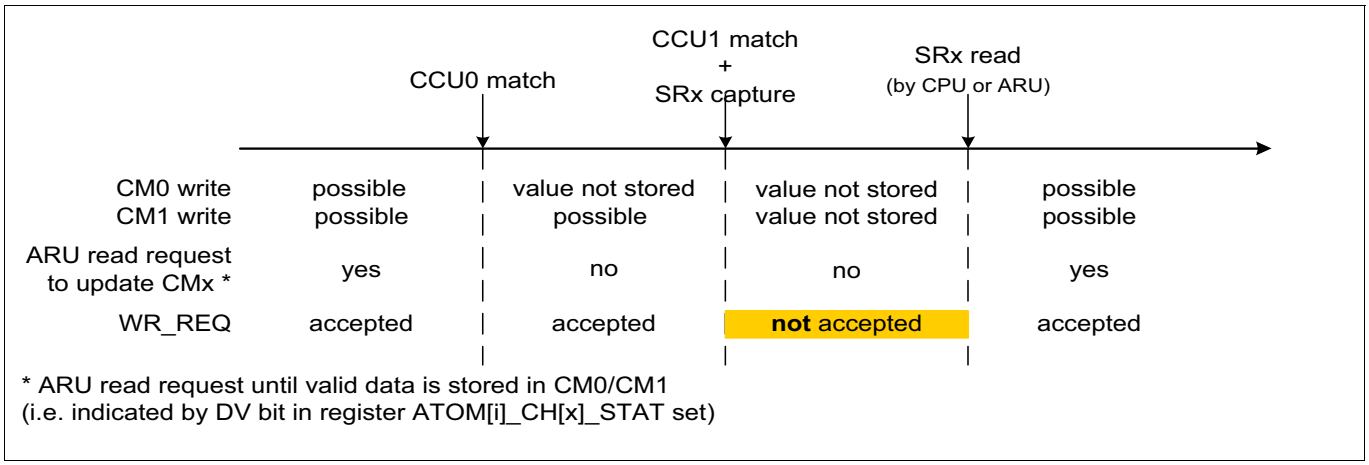

Figure 72 CPU access rights in case of compare strategy 'serve last' ,ABM=1 and EUPM=1

In case of EUPM=1 a write access to CM0 or CM1 never causes an AEI write status 0b10.

ARU Non-Blocking mode

When the compare registers are updated via ARU the update behavior of the channel is configurable with the ABM bit inside the **ATOM[i]_CH[x]_CTRL** register. When the **ABM** bit is reset, the ATOM channel is in ARU non-blocking mode.

In the ARU non-blocking mode, data received via ARU is continuously transferred to the registers **CM0** and **CM1** and the bit field **ACBI** of register **ATOM[i]_CH[x]_STAT** as long as no specified compare match event occurs.

After a compare match event that causes an update of the shadow register **SR0**/**SR1** and before reading the **SR0**/**SR1** register via CPU or ARU, the update of the registers **CM0**/ **CM1** via CPU or ARU is possible but the data is not accepted to be valid (no DV bit set in register ATOM[i]_CH[x]_CTRL).

To set up a new compare action, first the **SR0**/**SR1** register containing captured values have to be read and then new compare values have to be written into the register **CM0**/**CM1**. This can be done either by ARU or by CPU.

When the CPU does the register accesses, only one of the shadow registers has to be read. Dependent on the compare strategy, the CPU has to write one or both of the compare registers.

An exception for update of register **CM0**/**CM1** exists in SOMC mode and CCUx control mode 'serve last' if EUPM=0. If in this mode the CCU0 compare match event occurred, the update of register **CM0**/**CM1** via CPU is not possible until the CCU1 compare match event occurs.

Note that a write access to either CM0 or CM1 in this case leads to a write status 0b10.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signaled by the **DV** bit inside the **ATOM[i]_CH[x]_STAT** register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is disabled is shown in **Figure 73**.

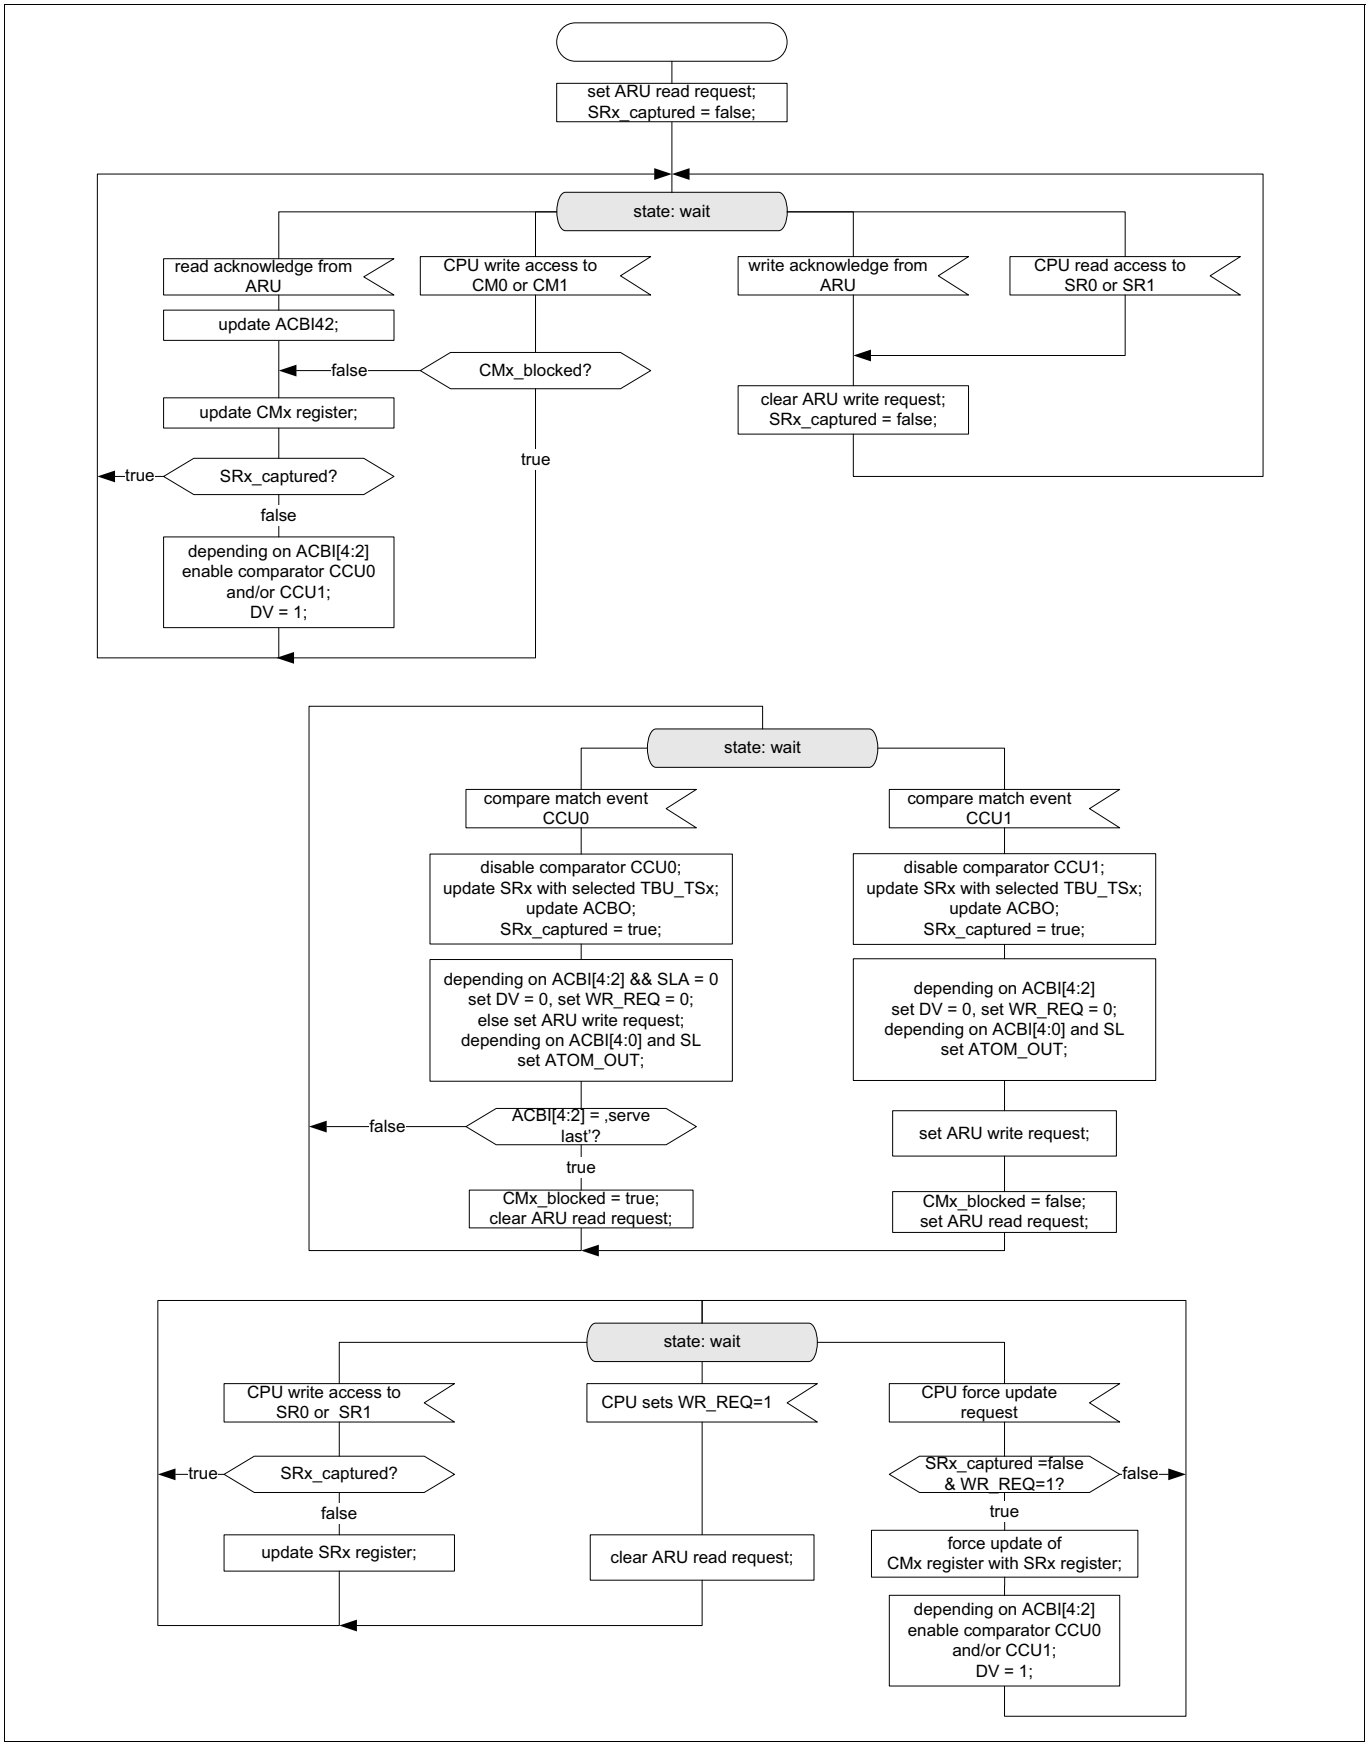

Figure 73 SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

ARU Blocking mode

When the compare registers are updated by ARU, the ATOM channel can be configured to receive ARU data in a blocking manner. This can be configured by setting the **ABM** bit in the **ATOM[i]_CH[x]_CTRL** register.

If the **ABM** and **ARU_EN** bits are set, depending on compare strategy,**CM0** and/or **CM1** can be updated via ARU with new compare values. If the compare registers **CM0** and/or **CM1** are accepting these new data to be valid (indicated by bit DV in register ATOM[i]_CH[x]_STAT), the ATOM channel stops requesting new data via ARU and waits for the compare match event to happen.

When the specified compare match event happens, the shadow registers **SR0** and **SR1** are updated together with the **ACBO** bits in the **ATOM[i]_CH[x]_STAT** register. The data in the shadow registers is marked as valid for the ARU and the **DV** bit or register **ATOM[i]_CH[x]_CTRL** is reset.

If the register **SR0** and **SR1** holding the captured TBU time stamp values are read by either the ARU or the CPU, the next write access to or update of the register **CM0** or **CM1** via ARU or the CPU enables the new compare match check again.

At least one of the registers **SR0** or **SR1** has to be read either via ARU or by CPU, before new data is requested via ARU.

Note that in case of ABM=1 the application has to handle the situation that the ATOM does not request update of new data for CM0/CM1 until the captured values are read. E.g. if an MCS task starts to write via ARU new data (with AWR(I) command) after capture the data in SR0/SR1, the task sticks in the command until captured data is read by another task via ARU or via the CPU interface.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signaled by a set **DV** bit inside the **ATOM[i]_CH[x]_STAT** register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is enabled is shown in **Figure 74**.

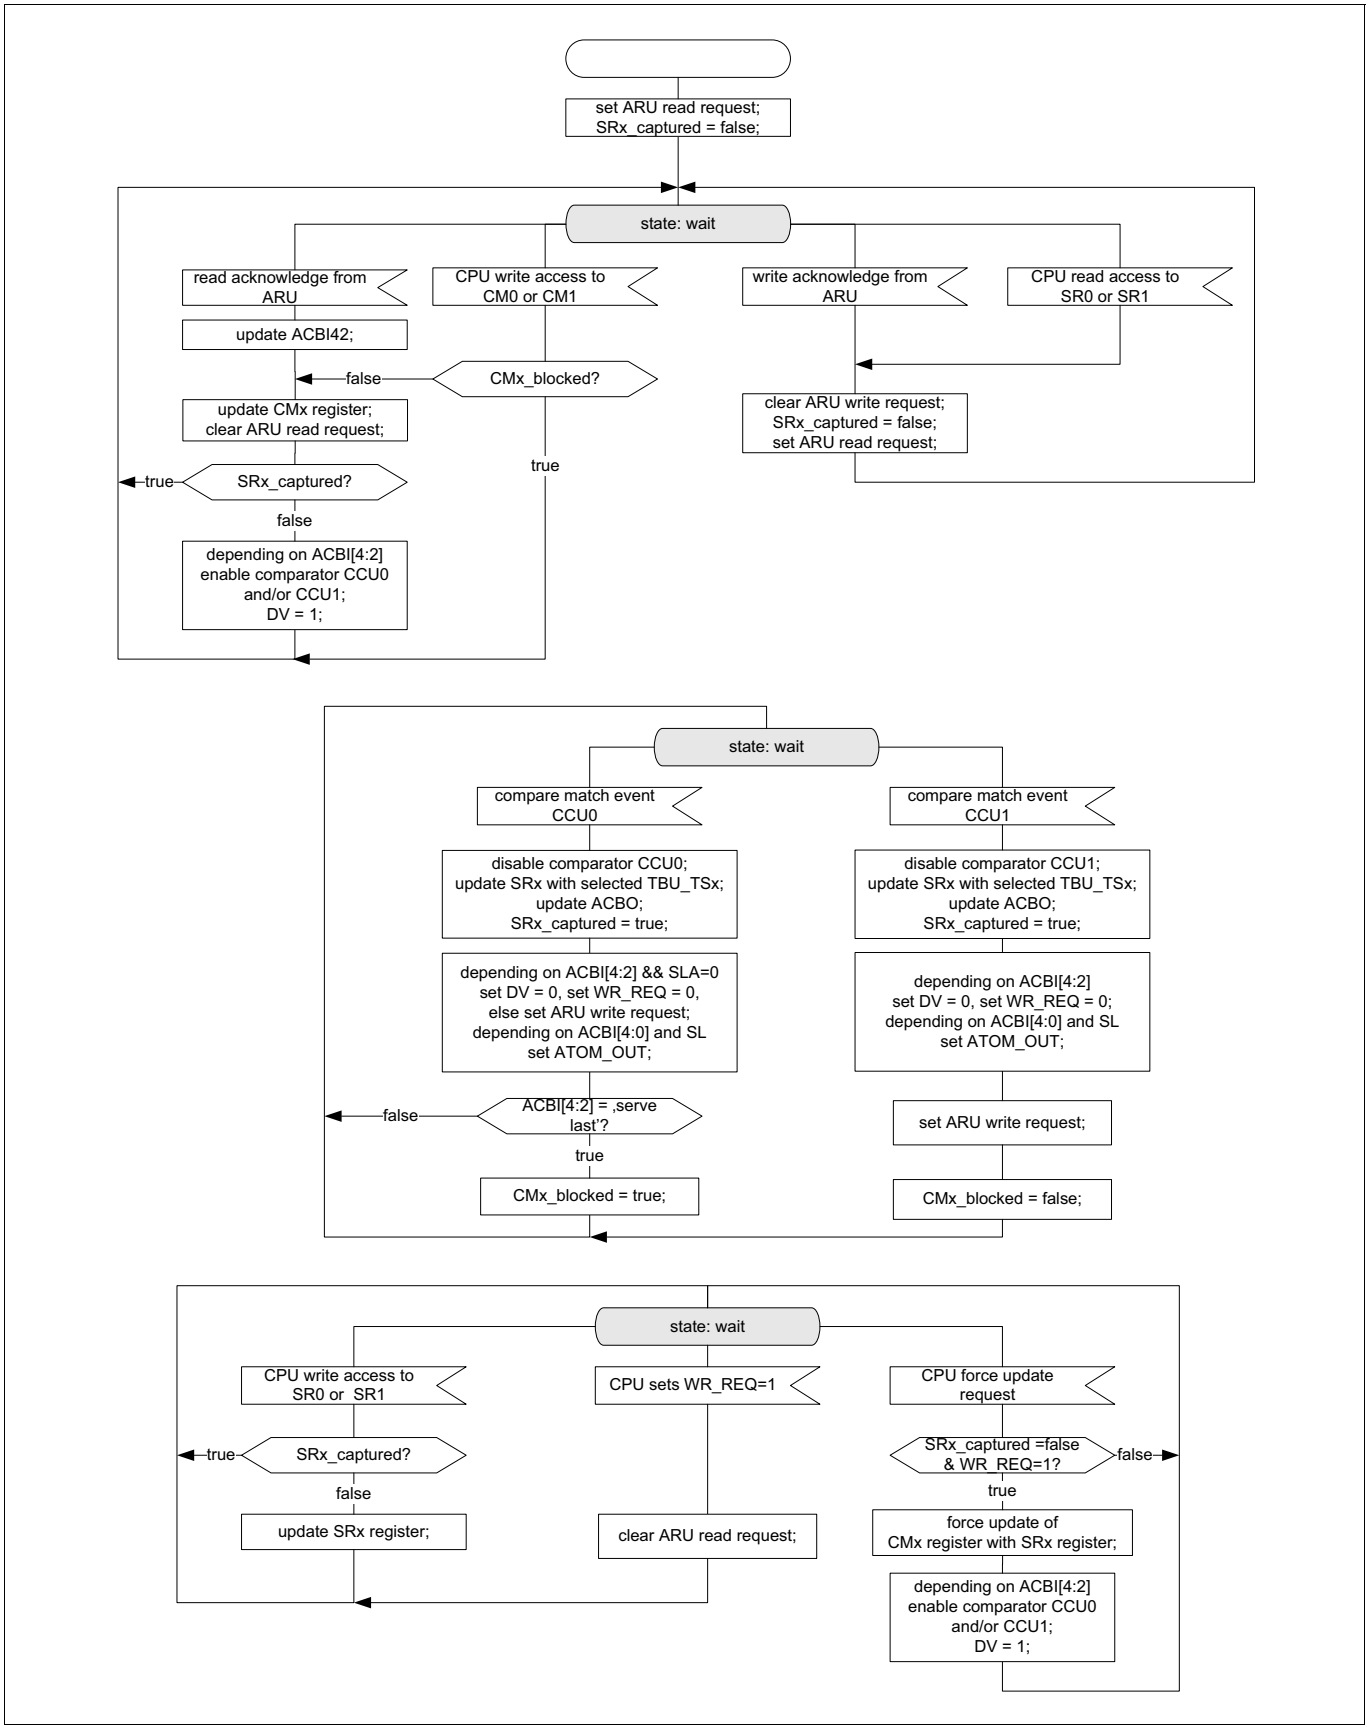

Figure 74 SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

ATOM SOMC Late update mechanism

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the **WR_REQ** bit inside the **ATOM[i]_CH[x]_CTRL** register. By doing this, the ATOM will request no further data from ARU (if ARU access was enabled). The channel will in any case continue to compare against the values stored inside the compare registers (if bit **DV** was set). The CPU can now update the new compare values until the compare event happens by writing to the shadow registers, and force the ATOM channel to update the compare registers by writing to the force update register bits in the **AGC** register.

If the **WR_REQ** bit is set and a compare match event happens, any further access to the shadow registers **SR0**, **SR1** is blocked and the force update of this channel is blocked. In addition, the **WRF** bit is set in the **ATOM[i]_CH[x]_STAT** register. Thus, the CPU can determine that the late update failed by reading the **WRF** bit.

In case of bit **EUPM**=0 (register **ATOM[i]_CH[x]_CTRL**) the following statements are true:

If a compare match event already happened, the **WR_REQ** bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the **WRF** bit is set if the CPU tries to write the **WR_REQ** bit in that case.

In case of bit **EUPM**=1 (register **ATOM[i]_CH[x]_CTRL**) the following statements are true:

If in case of serve last strategy a CCU1 or in any other compare strategy a CCU0 or CCU1 compare match event already happened, the **WR_REQ** bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the **WRF** bit is set if the CPU tries to write the **WR_REQ** bit in that case.

In general, for a late update the following has to be taken into account:

If between a correct **WR_REQ** bit set, a correct shadow register write, and before the force update is requested by the AGC a match event occurs on the old compare values, the **WRF** bit will be set. The force update will be blocked.

The **WRF** bit will be set in any case if the CPU tries to write to a blocked shadow register.

The **WR_REQ** bit and the **DV** bit will be reset on a compare match event.

After a capture event for register **SR0** and/or **SR1** the force update mechanism will be blocked until a read access to the register **SR0** or **SR1** by either the ARU or the CPU happens.Writing to **SR0** or **SR1** after compare match causes an AEI write status 0b10.

The ATOM SOMC late update mechanism from CPU is shown in **Figure 75**.

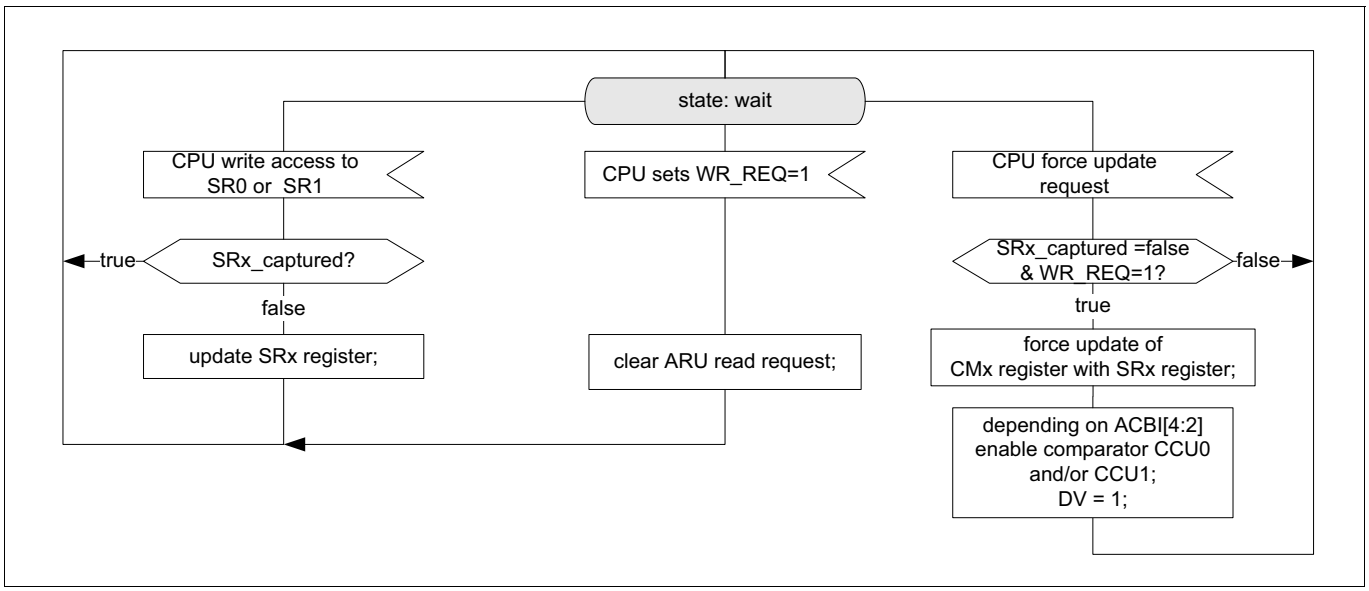

Figure 75 SOMC State diagram for late update requests by CPU

28.15.3.2.4 Register ATOM[i]_CH[x]_CTRL in SOMC mode

Register ATOM[i]_CH[x]_CTRL in SOMC mode

GTM_ATOMi_CHx_SOMC (i=0-11; x=0-7)

Field	Bits	Type	Description
SLA	25	rw	**'Serve last' ARU communication strategy** 0_B Capture SRx time stamps after CCU0 match event not provided to ARU 1_B Capture SRx time stamps after CCU0 match event provided to ARU Note: Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy ("100", "101", or "110"). Note: When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return "10" in that case. Note: By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to "01" in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to "10". When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
Not_used	26	rw	**Not used** Note: Not used in this mode.
ABM	27	rw	**ARU blocking mode** 0_B ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 and ACB bits independent of pending compare match event. 1_B ARU blocking mode enabled: after update of CM0, CM1 and ACB bit via ARU, no new data is read via ARU until compare match event occurred and SR0 and/or SR1 are read.
Reserved	28	r	**Reserved** Read as zero, should be written as zero.
Not_used	29	rw	**Not used** Note: Not used in this mode.
Not_used	30	rw	**Not used** Note: Not used in this mode.
FREEZE	31	rw	**FREEZE** 0_B a channel disable/enable may change internal register and output register 1_B a channel enable/disable does not change an internal or output register but stops counter CN0 (in SOMP mode), comparison (in SOMC/SOMB mode) and shifting (in SOMS mode)

28.15.3.3 ATOM Signal Output Mode PWM (SOMP)

In ATOM Signal Output Mode PWM (SOMP) the ATOM sub-module channel is able to generate complex PWM signals with different duty cycles and periods. Duty cycles and periods can be changed synchronously and asynchronously. Synchronous change of the duty cycle and/or period means that the duty cycle or period

duration changes after the end of the preceding period. An asynchronous change of period and/or duty cycle means that the duration changes during the actual running PWM period.

The signal level of the pulse generated inside the period can be configured inside the channel control register (**SL** bit of **ATOM[i]_CH[x]_CTRL** register). The initial signal output level for the channel is the inverse pulse level defined by the **SL** bit. **Figure 76** depicts this behavior.

The counter **CN0** of each channel can run in two different modes depending on configuration of **UDMODE** in register **ATOM[i]_CH[x]_CTRL.**By default the counter counts only up until it reaches **CM0** and is then reset to 0.In the up down counter mode **CN0** switches between counting up and counting down.

28.15.3.3.1 Continuous Counting Up Mode

In SOMP mode with **UDMODE**=0b00 (i.e. **CN0** counts only up), depending on configuration bits RST_CCU0 of register **ATOM[i]_CH[x]_CTRL** the counter register **CN0** can be reset either when the counter value is equal to the compare value **CM0** (i.e. CN0 counts only from 0 to CM0-1 and is then reset to 0) or when signaled by the ATOM[i] trigger signal *TRIG_[x-1]* of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal *TIM_EXT_CAPTURE*(x) of the assigned TIM channel [x].

In this case, if **UPEN_CTRL[x]**=1, also the working register **CM0,CM1** and **CLK_SRC** are updated.

Note: As an exception, the input TRIG_[0] of instance ATOM0 is triggered by its own last channel cCATO via signal TRIG_[cCATO].

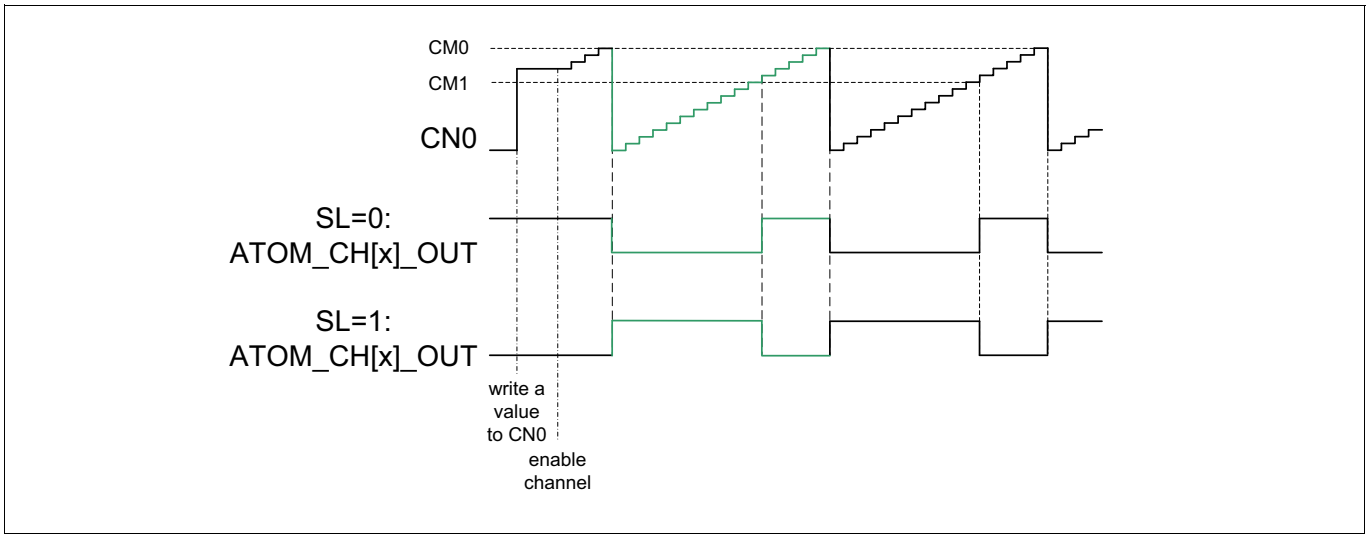

Figure 76 PWM Output behavior with respect to the SL bit in the ATOM[i]_CH[x]_CTRL register if UDMODE = 0b00

On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers. The behavior of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in **Figure 77**.

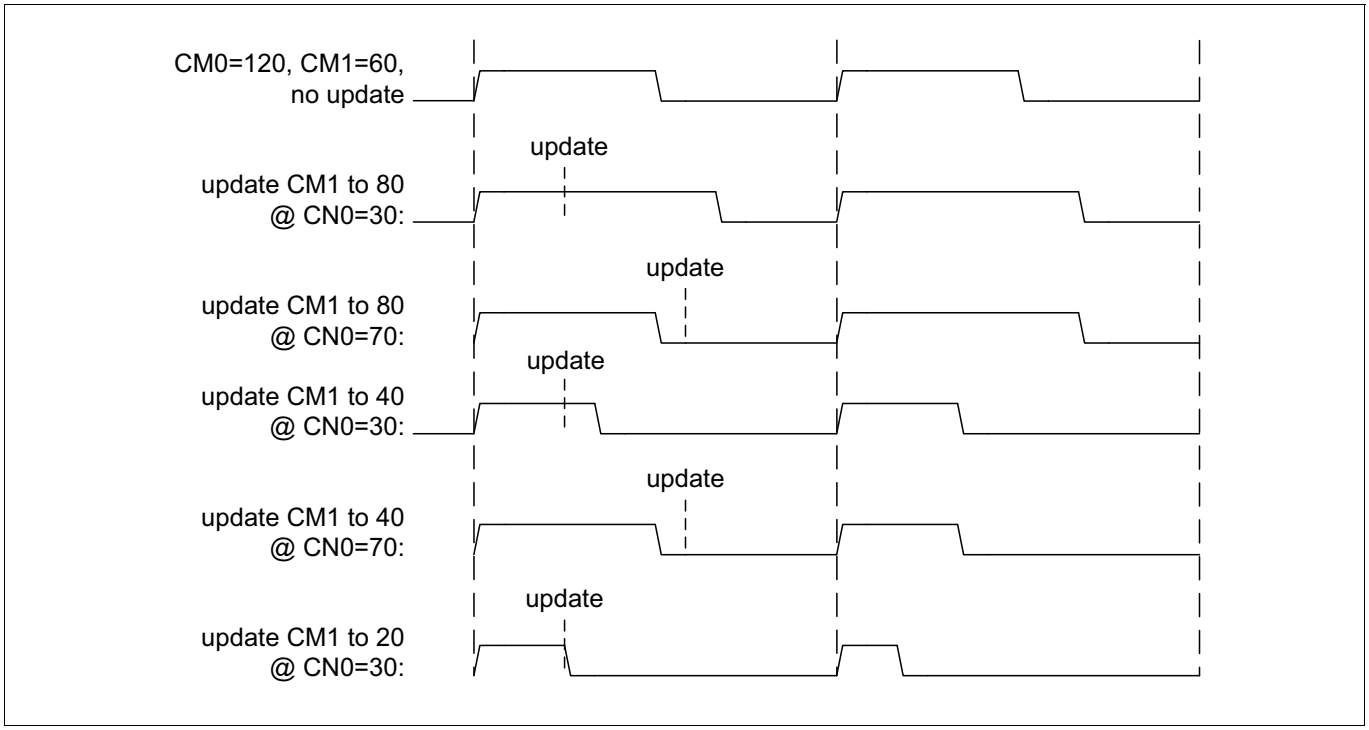

Figure 77 PWM Output behavior in case of an asynchronous update of the duty cycle

The duration of the pulse high or low time and period is measured with the counter in sub-unit CCU0. The trigger of the counter is one of the eight CMU clock signals configurable in the channel control register **ATOM[i]_CH[x]_CTRL**. The register **CM0** holds the duration of the period and the register **CM1** holds the duration of the duty cycle in clock ticks of the selected CMU clock.

If counter register **CN0** of channel x is reset by its own CCU0 unit (i.e. the compare match of **CN0** >=**CM0-1** configured by **RST_CCU0**=0), following statements are valid:

- **CN0** counts from 0 to **CM0**-1 and is then reset to 0
- When CN0 is reset from CM0 to 0, an edge to SL is generated.
- When CN0 is incrementing and reaches CN0 > CM1, an edge to !SL is generated.
- if **CM0**=0 or **CM0**=1, the counter **CN0** is constant 0.
- if **CM1**=0, the output is !SL = 0% duty cycle
- if **CM1** >= **CM0** and **CM0**>1, the output is **SL** = 100% duty cycle

If the counter register **CN0** of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by **RST_CCU0**=1), following statements are valid:

- **CN0** counts from 0 to MAX-1 and is then reset to 0 by trigger signal
- **CM0** defines the edge to **SL** value, **CM1** defines the edge to !**SL** value.
- if **CM0**=**CM1**, the output switches to **SL** if **CN0**=**CM0**=**CM1** (**CM0** has higher priority)
- if **CM0**=0 and **CM1**=MAX, the output is **SL** = 100% duty cycle
- if **CM0** > MAX, the output is !**SL** = 0% duty cycle, independent of **CM1**.

In case the counter value **CN0** reaches the compare value in register **CM0** (in fact CM0-1) or the channel receives an external update trigger via the *FUPD(x)* signal, a synchronous update is performed. A synchronous update means that the registers **CM0** and **CM1** are updated with the content of the shadow registers **SR0** and **SR1** and the **CLK_SRC** register is updated with the value of the **CLK_SRC_SR** register.

The clock source for the counter can be changed synchronously at the end of a period. If ARU access is disabled, this is done by using the bit field **CLK_SRC_SR** of register **ATOM[i]_CH[x]_CTRL** as shadow registers for the next CMU clock source.

28.15.3.3.2 Continuous Counting Up-Down Mode

In SOMP mode, if **CN0** counts up and down (**UDMODE** != 0b00), depending on configuration bit **RST_CCU0** of register **ATOM[i]_CH[x]_CTRL** the counter register **CN0** changes the direction either when the counter value is equal to the compare value **CM0** (in fact CM0-1), has counted down to 0 or when triggered by the ATOM[i] trigger signal *TRIG_[x-1]* of the preceding channel [x-1] (which can also be the last channel of preceding instance ATOM[i-1]) or the trigger signal *TIM_EXT_CAPTURE(x)* of the assigned TIM channel [x].

In this case, if **UPEN_CTRL[x]**=1, also the working register **CM0**, **CM1** and **CLK_SRC** are updated depending on **UDMODE**.

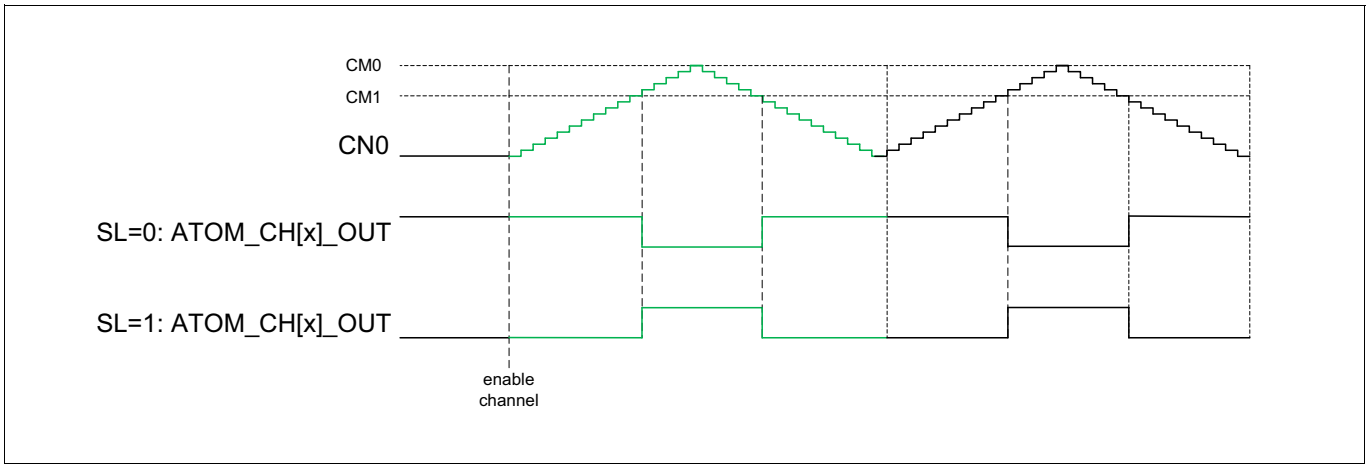

Figure 78 PWM Output behavior with respect to the SL bit in the ATOM[i]_CH[x]_CTRL register if UDMODE != 0b00

The clock of the counter register **CN0** can be one of the CMU clocks CMU_CLKx. If **ARU_EN**=0, the clock for **CN0** is defined by **CLK_SRC_SR** value in register **ATOM[i]_CH[x]_CTRL**.

If **ARU_EN**=1, the clock for **CN0** is defined by **CLK_SRC** value received via ARU.The duration of a period in multiples of selected **CN0** counter clock ticks is defined by the **CM0** configuration value (i.e. **CM0** defines half of period in up-down mode).

CM1 defines the duty cycle value in clock ticks of selected **CN0** counter clock (i.e. **CM0** defines half of duty cycle in up-down mode).

If counter register **CN0** of channel x is reset by its own CCU0 unit (i.e. the compare match of **CN0**>=**CM0-1** configured by **RST_CCU0**=0), following statements are valid:

- **CN0** counts continuously first up from 0 to **CM0**-1 and then down to 0
- if **CN0** >= **CM1**, the output is set to **SL**
- if **CM1**=0, the output is **SL** (i.e. 100% duty cycle)
- if **CM1** >= **CM0**, the output is !**SL** (i.e. 0% duty cycle)
- On output *ATOM[i]_CHx]_OUT* a PWM signal is generated. The period is defined by **CM0**, the duty cycle is defined by **CM1**.

This behavior is depicted in **Figure 78**.

If the counter register **CN0** of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by **RST_CCU0**=1), following statements are valid:

- **CN0** counts continuously first up. On a trigger signal the counter switches to count down mode. If **CN0** has reached 0, it counts up again.
- if **CN0** >= **CM1**, the output is set to **SL**
- if **CM1**=0, the output is **SL** (i.e. 100% duty cycle)
- if **CM1** >= **CM0**, the output is !**SL** (i.e. 0% duty cycle)
- On output *ATOM[i]_CHx]_OUT* a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by **CM1**.
- On output *ATOM[i]_CHx]_OUT_T* a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by **CM0**.

This behavior is depicted in **Figure 79**.

Note that in case of up-down counter mode and RST_CCU0=1 it is recommended that:

- The triggering channel and the triggered channel are both running in up-down mode.
- The time between two triggers signals is equal to the time needed for CN0 of triggered channel to count back to 0 and again up to the same upper value.

The second recommendation can be reached by synchronizing the start of triggering channel and of the triggered channel, i.e. let both channel start with a CN0 value 0.

Note that if there is a synchronization register in the trigger chain (indicated by value ATOM_TRIG_CHAIN in register CCM[i]_HW_CONF), the additional delay of the trigger by one clock period has to be taken into account by starting at triggering channel with a CN0 value 1 (+1 compared to CN0 of triggered channel).

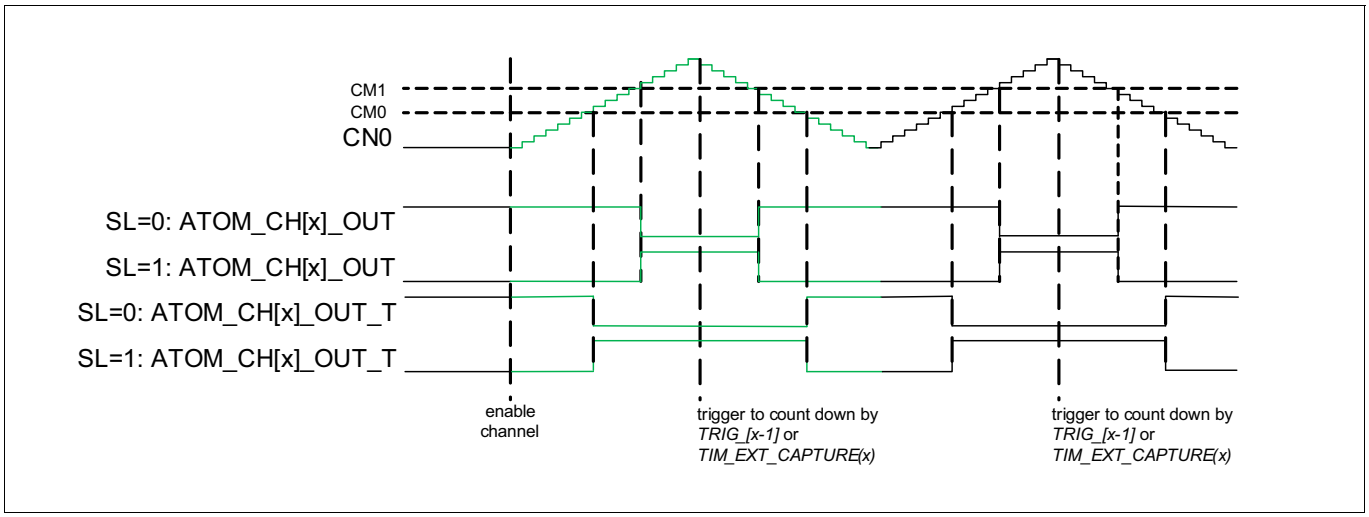

Figure 79 PWM Output behavior in case of RST_CCU0=1

28.15.3.3.3 ARU controlled update

If ARU access is enabled, the bits **ACBI(4)**, **ACBI(3)** and **ACBI(2)** received via ARU and stored in register **ATOM_[i]_CH[x]_STAT** are used as shadow register for the update of the CMU clock source register **CLK_SRC**.

For the synchronous update mechanism the generation of a complex PWM output waveform is possible without CPU interaction by reloading the shadow registers **SR0**, **SR1** and the **ACBI** bit field over the ACI sub-unit from the ARU, while the ATOM channel operates on the **CM0** and **CM1** registers.

This internal update mechanism is established, when the old PWM period ends. The shadow registers are loaded into the operation registers, the counter register is reset, the new clock source according to the **CLK_SRC_SR** and **ACBI(4)**, **ACBI(3)** and **ACBI(2)** bits is selected and the new PWM generation starts.

In parallel, the ATOM channel issues a read request to the ARU to reload the shadow registers with new values while the ATOM channel operates on the operation registers. To guarantee the reloading, the PWM period must not be smaller than the worst case ARU round trip time and source for the PWM characteristic must provide the new data within this time. Otherwise, the old PWM values are used from the shadow registers.

When updated over the ARU the user has to ensure that the new period duration is located in the lower (bits 23 to 0) and the duty cycle duration is located in the upper (bits 47 to 24) ARU data word and the new clock source is specified in the ARU control bits 52 to 50.

This pipelined data stream character is shown in **Figure 80**.

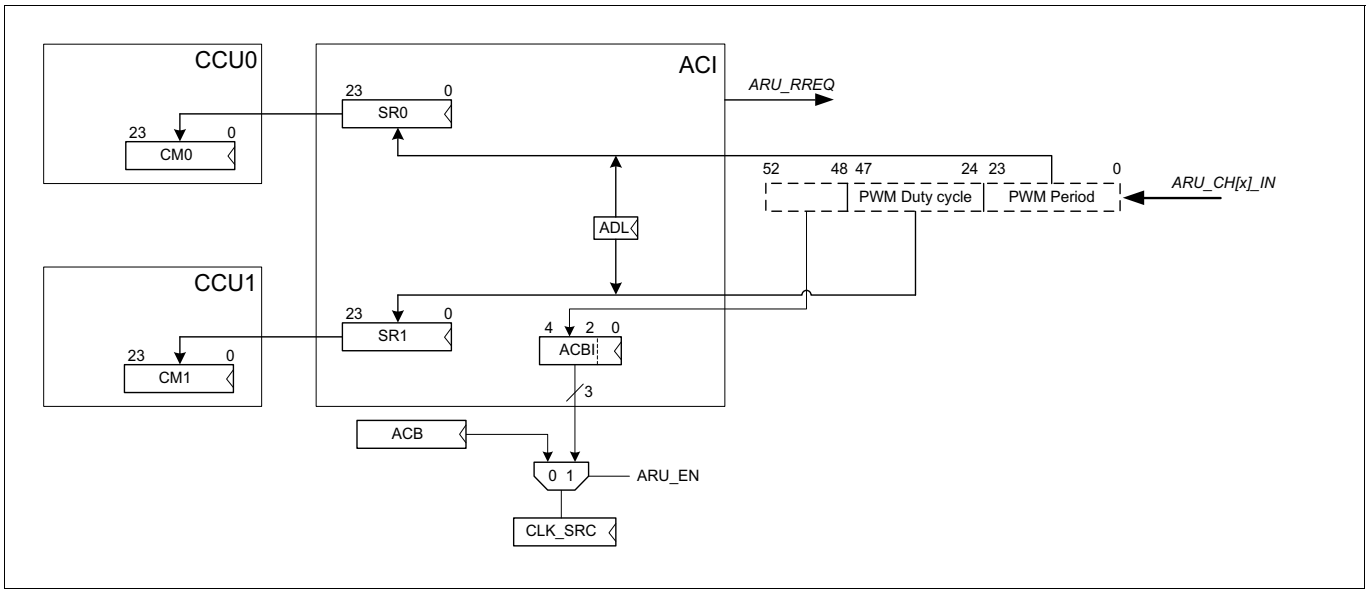

Figure 80 ARU Data input stream pipeline structure for SOMP mode

When an ARU transfer is in progress which means the *ARU_RREQ* is served by the ARU, the ACI locks the update mechanism of **CM0**, **CM1** and **CLK_SRC** until the read request has finished. The CCU0 and CCU1 operate on the old values when the update mechanism is locked.

28.15.3.3.4 CPU controlled update

The shadow registers **SR0** and **SR1** can also be updated over the AEI bus interface. In this case, **ARU_EN** hat to be set to 0.

When updated via the AEI bus the **CM0** and **CM1** update mechanism has to be locked via the **AGC_GLB_CTRL** register with the *UPENx* signal in the AGC sub-unit. To select the new clock source in this case, the CPU has to write to the CLK_SRC_SR bit field of the **ATOM[i]_CH[x]_CTRL** register.

For an asynchronous update of the duty cycle and/or period the new values must be written directly into the compare registers **CM0** and/or **CM1** while the counter **CN0** continues counting. This update can be done only via the AEI bus interface immediately by the CPU or by the *FUPD(x)* trigger signal triggered from the AGC global trigger logic. Values received through the ARU interface are never loaded asynchronously into the operation registers **CM0** and **CM1**. Therefore, the ATOM channel can generate a PWM signal on the output port pin *ATOM[i]_CH[x]_OUT* on behalf of the content of the **CM0** and **CM1** registers, while it receives new PWM values via the ARU interface ACI in its shadow registers.

On a compare match of **CN0** and **CM0** or **CM1** the output signal level of *ATOM[i]_CH[x]_OUT* is toggled according to the signal level output bit **SL** in the **ATOM[i]_CH[x]_CTRL** register.

Thus, the duty cycle output level can be changed during runtime by writing the new duty cycle level into the **SL** bit of the channel configuration register. The new signal level becomes active for the next trigger *CCU_TRIGx* (since bit **SL** is written).

Since the *ATOM[i]_CH[x]_OUT* signal level is defined as the reverse duty cycle output level when the ATOM channel is enabled, a PWM period can be shifted earlier by writing an initial offset value to **CN0** register. By doing this, the ATOM channel first counts until **CN0** reaches **CM0** and then it toggles the output signal at *ATOM[i]_CH[x]_OUT*.

28.15.3.3.5 One-shot Counting Up Mode

The ATOM channel can operate in One-shot mode when the **OSM** bit is set in the channel control register. One-shot mode means that a single pulse with the pulse level defined in bit **SL** is generated on the output line.

First the channel has to be enabled by setting the corresponding **ENDIS_STAT** value.

In one-shot mode the counter **CN0** will not be incremented once the channel is enabled.

A write access to the register **CN0** triggers the start of pulse generation (i.e. the increment of the counter register **CN0**).

If the counter **CN0** is reset from **CM0-1** back to zero, the first edge at *ATOM[i]_CH[x]_OUT* is generated.

To avoid an update of **CMx** register with content of **SRx** register at this point in time, the automatic update should be disabled by setting **UPEN_CTRL[x]** = 0b00 (in register **ATOM[i]_CH[x]_CTRL**)

The second edge is generated if **CN0** is greater or equal than **CM1** (i.e. **CN0** was incremented until it has reached **CM1** or **CN0** is greater than **CM1** after an update of **CM1**).

If the counter **CN0** has reached the value of **CM0-1** a second time, the counter stops.

The new value of **CN0** determines the start delay of the first edge. The delay time of the first edge is given by (**CM0-CN0**) multiplied with period defined by current value of **CLK_SRC**.

Figure 81 depicts the pulse generation in SOMP one-shot mode.

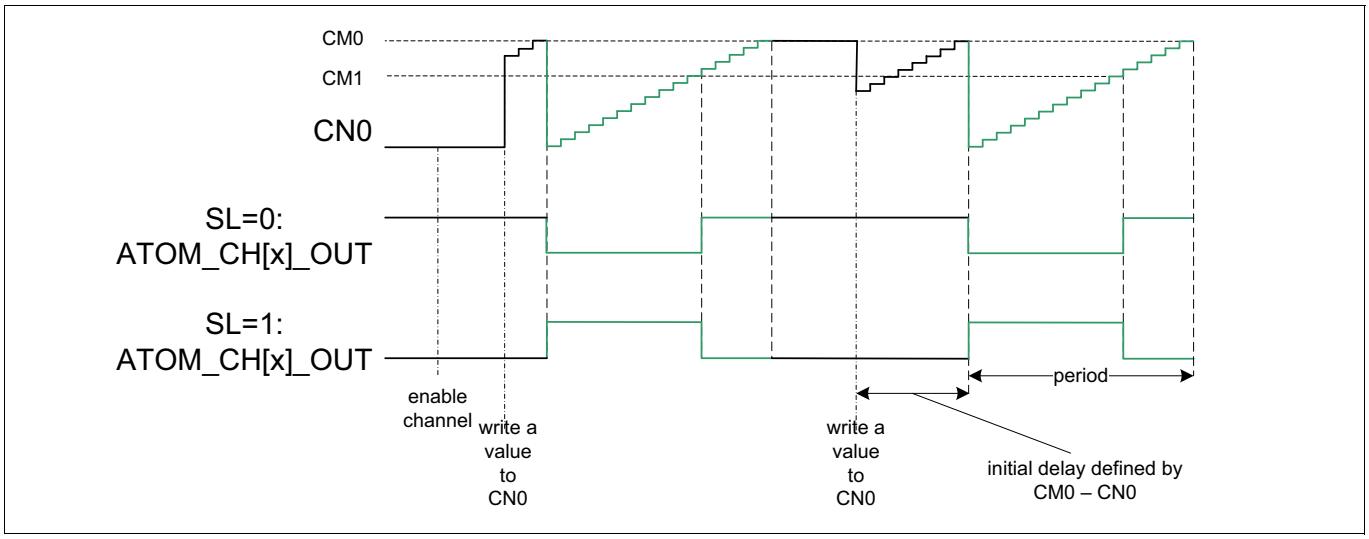

Figure 81 PWM Output with respect to configuration bit SL in One-shot counting up mode: trigger by writing to CN0

Further output of single pulses can be started by a write access to register **CN0**.

If **CN0** is already incrementing (i.e. started by writing to **CN0** a value CN0start < **CM0**), the effect of a second write access to **CN0** depends on the phase of **CN0**:

- phase 1: update of **CN0** before **CN0** reaches first time **CM0** (in fact CM0-1)
- phase 2: update of **CN0** after **CN0** has reached first time **CM0** but is less than **CM1**

- phase 3: update of **CN0** after **CN0** has reached first time **CM0** (in fact CM0-1) and **CN0** is greater than or equal **CM1**

In phase 1: writing to counter **CN0** a value CN0new < **CM0** leads to a shift of first edge (generated if **CN0** is reset first time from **CM0-1 back to 0**) by the time **CM0**-CN0new.

In phase 2: writing to incrementing counter **CN0** a value CN0new < **CM1** while CN0old is below **CM1** leads to a lengthening of the pulse. The counter **CN0** stops if it reaches **CM0**.

In phase 3: Writing to incrementing counter **CN0** a value CN0new while CN0old is already greater than or equal **CM1** leads to an immediate restart of a single pulse generation inclusive the initial delay defined by **CM0** - CN0new.

If a channel is configured to one-shot mode and configuration bit **OSM_TRIG** is set to 1, the trigger signal *OSM_TRIG* (i.e. *TRIG_[x-1]* or *TIM_EXT_CAPTURE(x)*) triggers start of one pulse generation.

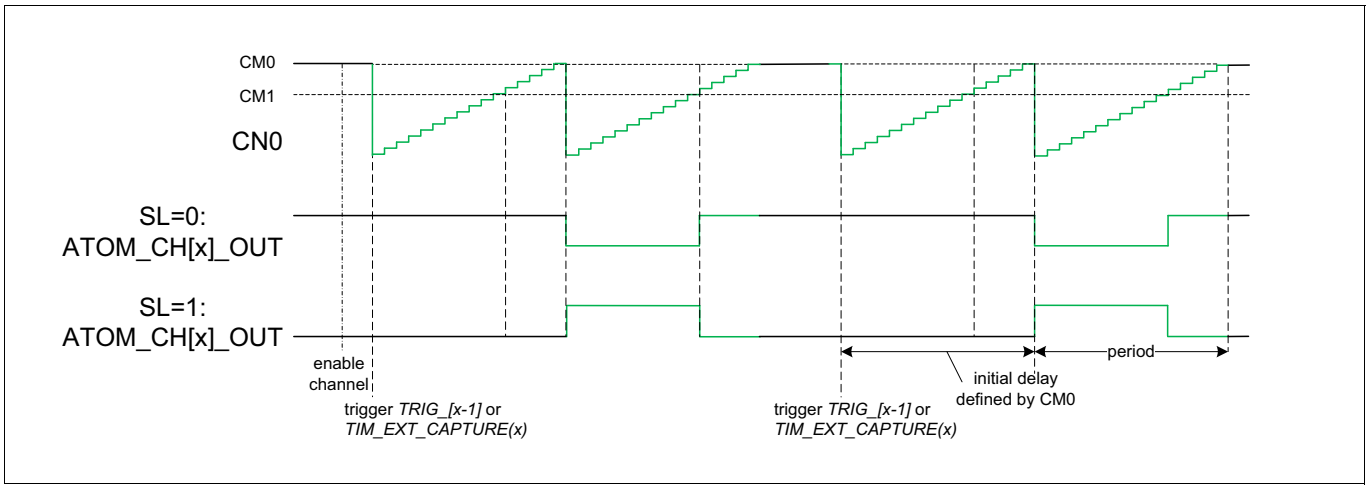

Figure 82 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIG_[x-1] or TIM_EXT_CAPTURE(x)

28.15.3.3.6 One-shot Counting Up-Down Mode

The ATOM channel can operate in one-shot counting up-down mode when the bit **OSM** = 1 and the **UDMODE** != 0b00. One-shot mode means that a single pulse with the pulse level defined in bit **SL** is generated on the output line.

First the channel has to be enabled by setting the corresponding **ENDIS_STAT** value.

In one-shot mode the counter **CN0** will not be incremented once the channel is enabled.

A write access to the register **CN0** triggers the start of pulse generation (i.e. the increment of the counter register **CN0**).

To avoid an update of **CMx** register with content of **SRx** register at this point in time, the automatic update should be disabled by writing **UPEN_CTRL[x]** = 0b01 (see register **ATOM[i]_AGC_GLB_CTRL**)

If the counter **CN0** is greater or equal than **CM1**, the output *ATOM[i]_CH[x]_OUT* is set to **SL** value.

If the counter **CN0** is less than **CM1**, the output *ATOM[i]_CH[x]_OUT* is set to !**SL** value.

If the counter **CN0** has reached the value 0 (by counting down), it stops.

The new value of **CN0** determines the start delay of the first edge. The delay time of the first edge is given by (**CM1-CN0**) multiplied with period defined by current value of **CLK_SRC**.

Figure 83 depicts the pulse generation in SOMP one-shot mode.

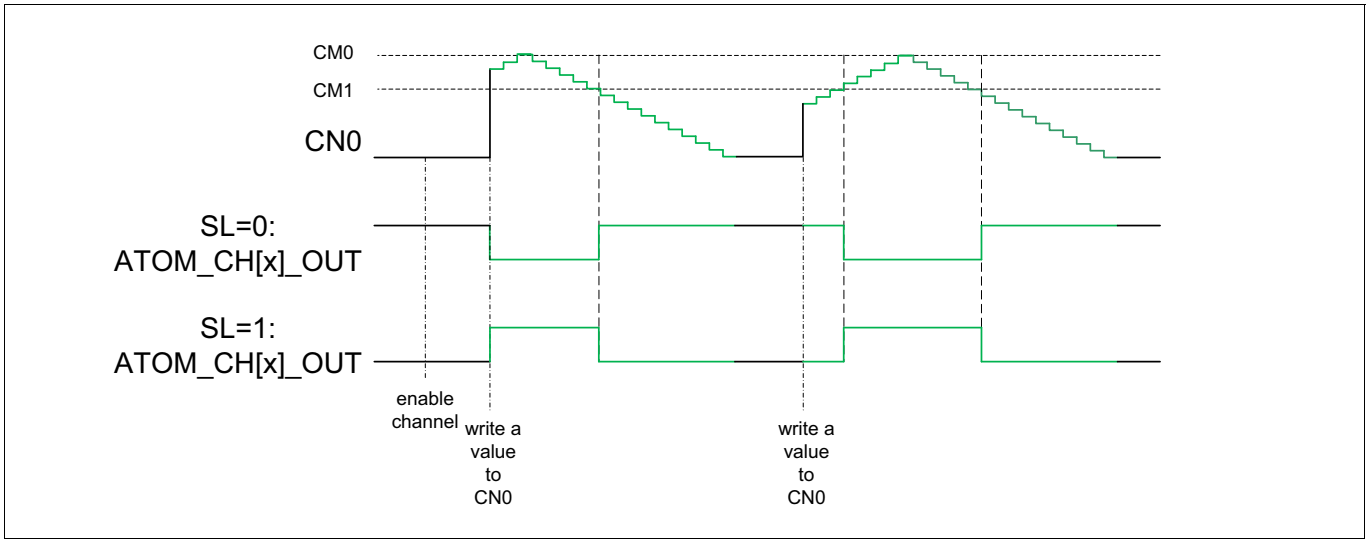

Figure 83 PWM Output with respect to configuration bit SL in one-shot counting up-down mode: trigger by writing to CN0

Further output of single pulses can be started by writing to register **CN0**.

If a channel is configured to one-shot counting up-down mode and configuration bit **OSM_TRIG** is set to 1, the trigger signal *OSM_TRIG* (i.e. *TRIG_[x-1]* or *TIM_EXT_CAPTURE(x)*) triggers start of one pulse generation.

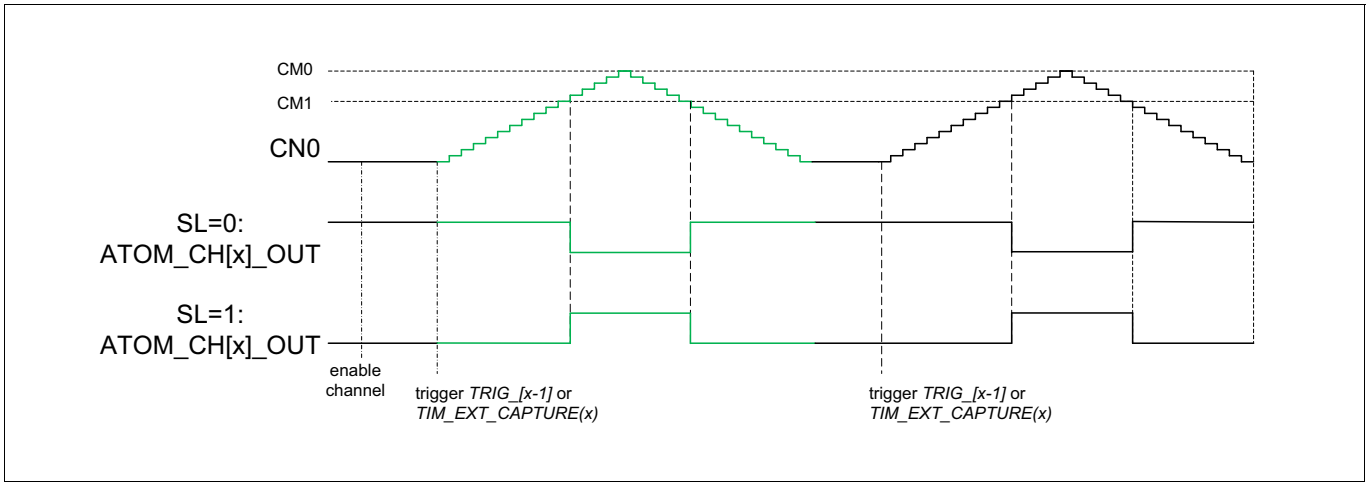

Figure 84 PWM Output with respect to configuration bit SL in one-shot counting up-down mode: trigger by TRIG_[x-1] or TIM_EXT_CAPTURE(x)

28.15.3.3.7 Pulse Count Modulation Mode

At the output *ATOM[i]_CH[x]_OUT* a pulse count modulated signal can be generated instead of the simple PWM output signal in SOMP mode.

The PCM mode is enabled by setting bit **BITREV** to 1 (bit 6 in **ATOM[i]_CH[x]_CTRL** register).Please note that it is device specific, in which channel the PCM mode is available. Please refer to device specific device specific appendix for this information.

With the configuration bit **BITREV**=1 a bit-reversing of the counter output **CN0** is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the **CN0** register value is shown in the following **Figure 85**.

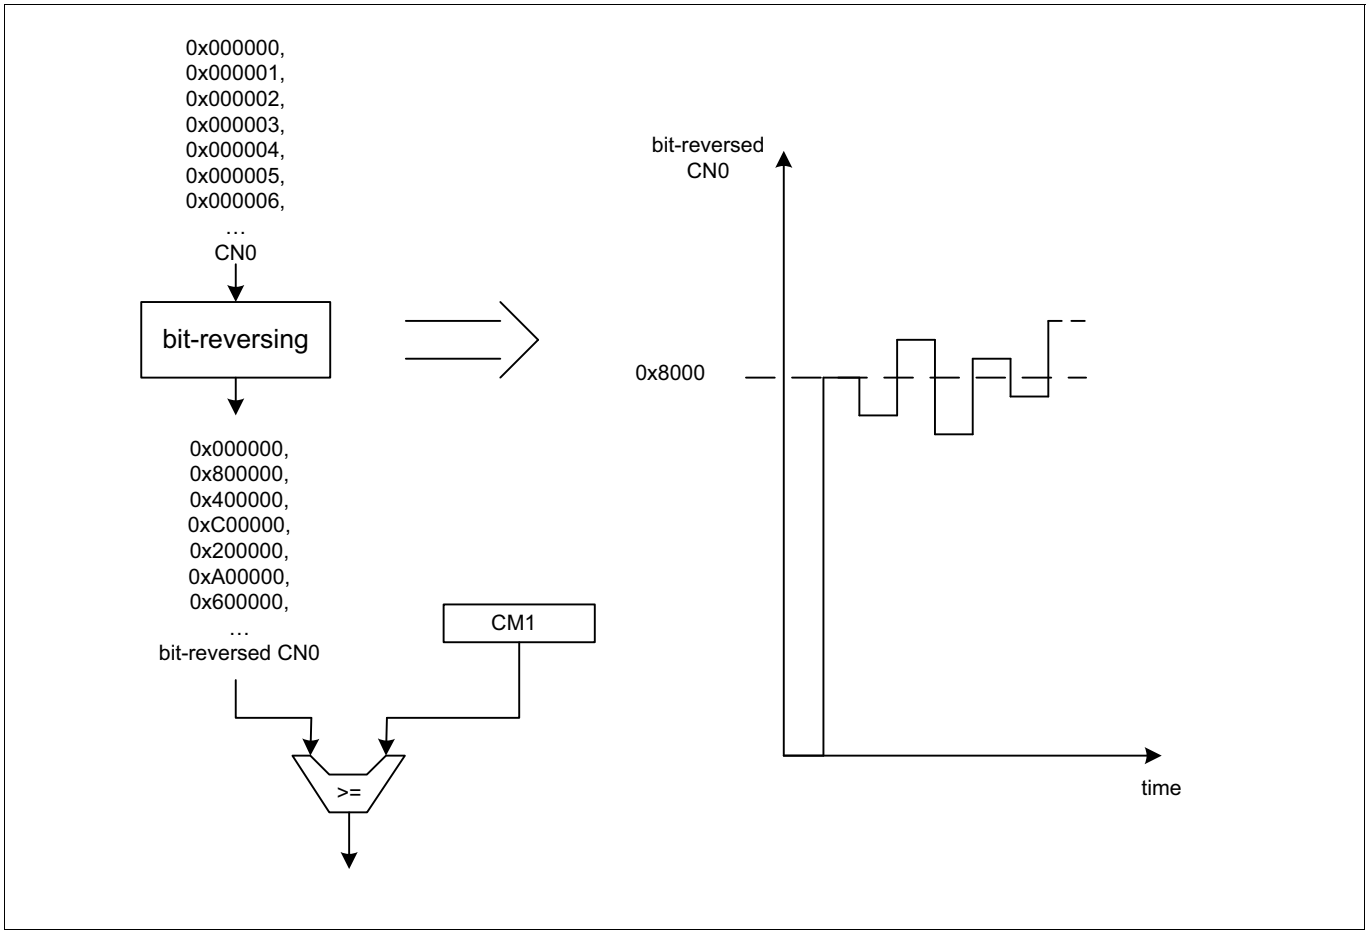

Figure 85 Bit reversing of counter CN0 output

In the PCM mode the counter register **CN0** is incremented by every clock tick depending on configured CMU clock (*CMU_CLK*).

The output of counter register **CN0** is first bit-reversed and then compared with the configured register value **CM1**.

If the bit-reversed value of register **CN0** is greater or equal than **CM1**, the SR-FlipFlop of sub-module SOU is set (i.e. set to inverse value of **SL**) otherwise the SR-FlipFlop is reset (i.e. to the value of **SL**). This generates at the output *ATOM[i]_CH[x]_OUT* a pulse count modulated signal.

In PCM mode the **CM0** register - in which the period is defined - normally has to be set to its maximum value 0xFFFFFF.

To reduce time period of updating duty cycle value in **CM1** register, it is additionally possible to setup period value in **CM0** register to smaller values than maximum value as described before.

Possible values for **CM0** register are each even numbered values to the power of 2 e.g. 0x800000, 0x400000, 0x200000….

In this case the duty cycle has to be configured in the following manner.

Depending on how much the period in **CM0** register is decreased - means shifted right starting from 0x1000000 - the duty cycle in **CM1** register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g.:

period **CM0** = 0x001000 -> shifted 8 bits right from 0x1000000

--> so duty cycle has to be shifted left 8 bit:

e.g. 50% duty cycle = 0x0008000 -> shift 8 bits left -> **CM1** = 0x800000

More examples:

period CM0	-->	duty cycle	-->	no shift	-->	CM1
0xFFFFFF	-->	0x800000	-->	no shift	-->	0x800000
0x800000	-->	0x400000	-->	shift 1 bit left	-->	0x800000
0x400000	-->	0x100000	-->	shift 2 bits left	-->	0x400000
0x200000	-->	0x0FFFFF	-->	shift 3 bits left	-->	0x7FFFF8
0x100000	-->	0x033333	-->	shift 4 bits left	-->	0x333330
0x080000	-->	0x005555	-->	shift 5 bits left	-->	0x0AAAA0
…						
0x000020	-->	0x000008	-->	shift 19 bits left	-->	0x400000
0x000010	-->	0x000005	-->	shift 20 bits left	-->	0x500000
…						

In this mode the interrupt CCU1TC (see register **ATOM[i]_CH[x]_IRQ_NOTIFY**) is set every time if bit reverse value of **CN0** is greater or equal than **CM1** which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

28.15.3.3.8 Trigger generation

For applications with constant PWM period defined by **CM0**, it is not necessary to update regularly the **CM0** register with **SR0** register. For these applications the **SR0** register can be used to define an additional output signal and interrupt trigger.

If bit **SR0_TRIG** in register **ATOM[i]_CH[x]_CTRL** is set, the register **SR0** is no longer used as a shadow register for register **CM0**. Instead, **SR0** is compared against **CN0** and if both are equal, a pulse of signal level 1 is generated at the output *ATOM[i]_CH[x]_OUT_T*.

The bit **SR0_TRIG** should only be set if bit RST_CCU0 of this channel is 0.

Note: If **ARU_EN**=1 and both **SR0** and **SR1** are updated via ARU, the new **SR0** value is used immediately after update. Update of **SR0** via ARU can be suppressed by ADL configuration in register **ATOM[i]_CH[x]_CTRL**.

If bit **SR0_TRIG** is set the interrupt notify flag **CCU1TC** is no longer set on a compare match of **CM1** and **CN0**. Instead, the **CCU1TC** interrupt notify flag is set in case of a compare equal match of **SR0** and **CN0**.

With configuration bit **TRIG_PULSE** one can select if the output *ATOM[i]_CH[x]_OUT_T* is high as long as **CN0**=**SR0** (**TRIG_PULSE**=0) or if there will be only one pulse of length one *SYS_CLK* period when **CN0** becomes **SR0** (**TRIG_PULSE**=1).

The ATOM output signal routing to DTM or GTM top level is described in subchapter “DTM connections on GTM-IP top level“.

FREEZE	31	rw	**FREEZE** 0_B a channel disable/enable may change internal register and output register 1_B a channel enable/disable does not change an internal or output register but stops counter CN0 (in SOMP mode), comparison (in SOMC/SOMB mode) and shifting (in SOMS mode) *Note: If channel is disabled and output is enabled, in SOMP mode with UDMODE!=0b00 the output is depending directly on SL bit, independent on FREEZE mode.*

28.15.3.4 ATOM Signal Output Mode Serial (SOMS)

In ATOM Signal Output Mode Serial (SOMS) the ATOM channel acts as a serial output shift register where the content of the **CM1** register in the CCU1 unit is shifted out whenever the unit is triggered by the selected *CMU_CLK* input clock signal. The shift direction is configurable with the **ACB(0)** bit inside the **ATOM[i]_CH[x]_CTRL** register when ARU is disabled and the **ACBI(0)** bit inside the **ATOM[i]_CH[x]_STAT** register when ARU is enabled.

The data inside the **CM1** register has to be aligned according to the selected shift direction in the **ACB(0)**/**ACBI(0)** bit. This means that when a right shift is selected, that the data word has to be aligned to bit 0 of the **CM1** register and when a left shift is selected, that the data has to be aligned to bit 23 of the **CM1** register.

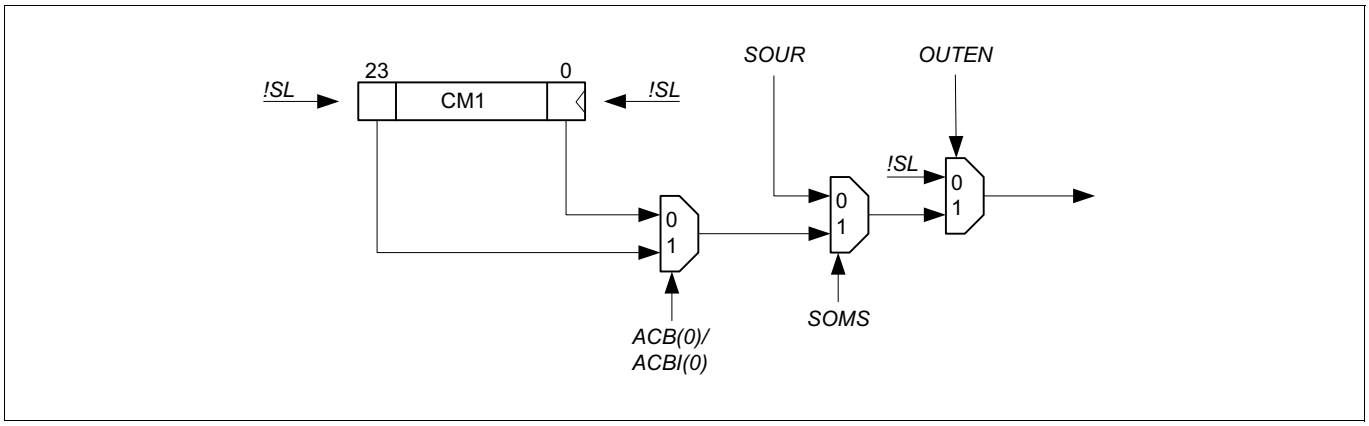

Figure 86 SOMS Mode output generation

Figure 86 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as **CM0**. The total number of bits that are visible at *ATOM_OUT* is **CM0**+1.

When the output is disabled the *ATOM_OUT* is set to the inverse **SL** bit definition.

When the content of the **CM1** register is shifted out, the inverse signal level is shifted into the **CM1** register.

When the output is enabled while **UPEN_CTRL[x]** is disabled, the ATOM_OUT signal level is defined by **CM1** bit 0 or 23, dependent on the shift direction defined by **ACB(0)** or **ACBI(0)** register setting. **Figure 87** should clarify the ATOM channel startup behavior in this case for right shift. For left shift the **CM1** bit 0 in **Figure 87** has to be replaced by **CM1** bit 23.

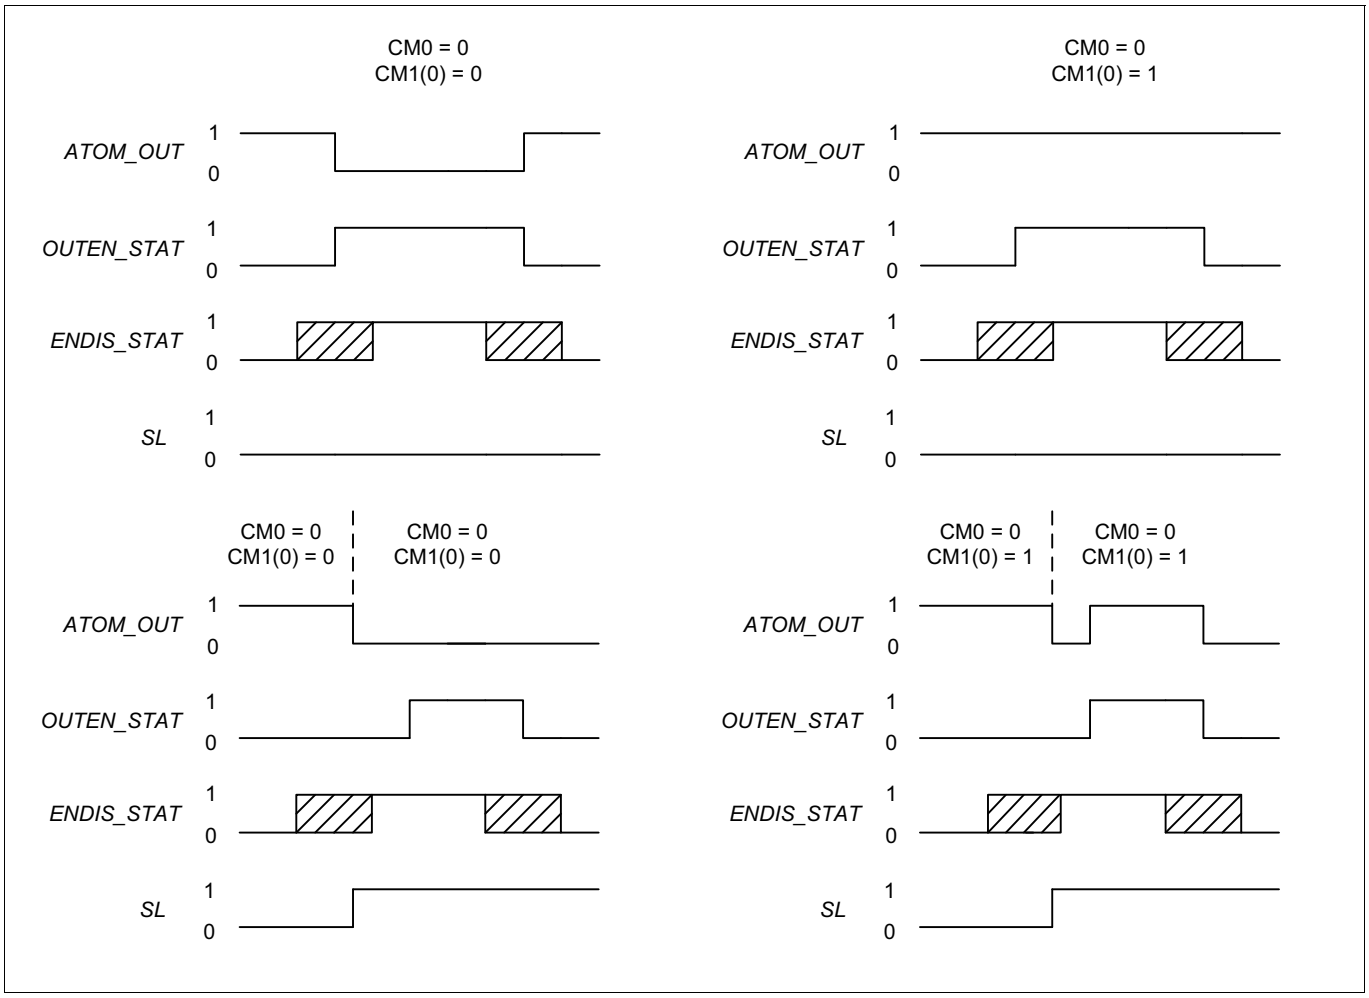

Figure 87 SOMS Output signal level at startup, UPEN_CTRL[x] disabled

If **UPEN_CTRL[x]** is set and the channel is enabled, the output level is defined by bit 0 or 23 of **CM1** register dependent on the shift direction. **Figure 88** shows the output behavior in that case.

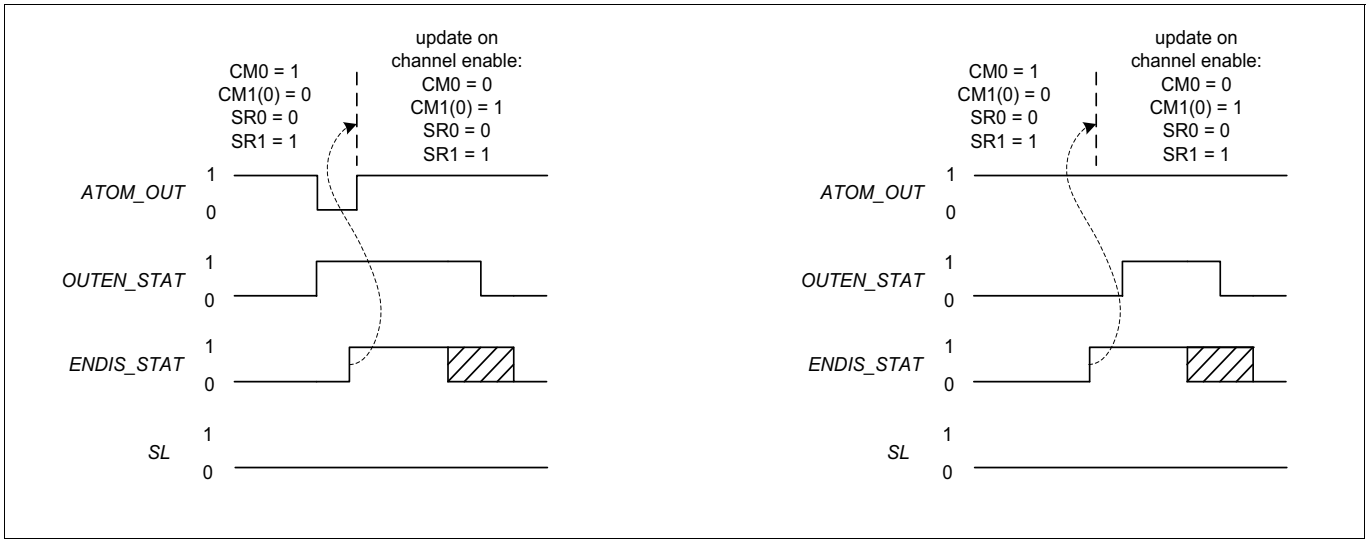

Figure 88 SOMS Output signal level at startup, UPEN_CTRL[x] enabled

When the serial data to be shifted is provided via ARU the number of bits that should be shifted has to be defined in the lower 24 bits of the ARU word (23 to 0) and the data that is to be shifted has to be defined in the ARU bits 47 to 24 aligned according to the shift direction. This shift direction has to be defined in the ARU word bit 48 (**ACB0** bit).

If bit **UPEN_CTRL[x]** of a channel x is set, after update of **CM0**/**CM1** register with the content of the **SR0**/**SR1** register, a new ARU read request is set up.

If bit **UPEN_CTRL[x]** of a channel x is not set, no (further) ARU read request is set up (because the **SR0**/**SR1** register are never used for update) and the ATOM may stop shifting after **CN0** has reached **CM0**. Note, that in this case also no automatic restart of shifting is possible.

If a channel is enabled with the settings SOMS mode and **ARU_EN** = 1, the first received values from ARU are stored in register **SR0** and **SR1**. If **CN0** and **CM0** are 0 (i.e. **CN0** is not counting) and the update of channel x is enabled (**UPEN_CTRL[x]**=1), an immediate update of the register **CM0** and **CM1** is also done. This update of **CM0** and **CM1** triggers the start of shifting.

It is recommended to configure the ATOM channel in One-shot mode when the **ARU_EN** bit is not set, since the ATOM channel would reload new values from the shadow registers when **CN0** reaches **CM0**.

28.15.3.4.1 SOMS mode with ARU_EN = 1 and OSM = 0, UPEN_CTRL[x] = 1

In case of bit **ARU_EN** is set and bit **OSM** is not set, the channel is running in the SOMS continuous mode. Then, if the content of the **CM0** register equals the counter **CN0**, the **CM0** and **CM1** registers are reloaded with the **SR0** and **SR1** content and new values are requested from the ARU. If the update of the shadow registers does not happen before **CN0** reaches **CM0** the old values of **SR0** and **SR1** are used to reload the operation registers.

In contrast to controlling the channel via AEI, the shift direction defined by ARU word bit 48 has only effect after the update of **CMx** operation registers from the **SRx** registers.

28.15.3.4.2 SOMS mode with ARU_EN = 1 and OSM = 1, UPEN_CTRL[x] = 1

In case of bit **ARU_EN** is set and bit **OSM** is set, the channel is running in the SOMS one-shot mode. Then, if the content of the **CM0** register equals the counter **CN0** and if new values are available in **SR0** and **SR1** (bit DV set), the **CM0** and **CM1** registers are reloaded with the **SR0** and **SR1** content and new values are requested from the ARU. If no new values are available in **SR0** and **SR1**, the register **CM0** and **CM1** will not be updated, the counter

CN0 stops and the ATOM channel continues to request new data from ARU. A later reception of new ARU data in **SR0** and **SR1** will immediately force the update of the register **CM0** and **CM1** and restart the counter **CN0**.

28.15.3.4.3 SOMS mode with ARU_EN = 0 and OSM = 0, UPEN_CTRL[x] = 1

In case of bit **ARU_EN** is not set and bit **OSM** is not set, the ATOM channel updates its CM0/CM1 register with the content of the SR0/SR1 register and restarts shifting immediately. The first bit of new CM1 register value will be applied at the output without any gap to the last bit of the previous CM1 register value.

28.15.3.4.4 SOMS mode with ARU_EN = 0 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit **ARU_EN** is not set and bit **OSM** is set, the ATOM channel stops shifting when **CN0** reaches **CM0** and no update of **CM0** and **CM1** is performed.

Then, the shifting of the channel can be restarted again by writing a zero to the **CN0** register again. Please note, that the **CN0** register should be written with a zero since the **CN0** register counts the number of bits shifted out by the ATOM channel.The writing of a zero to **CN0** causes also an immediate update of **CM0**/**CM1** register with the content of **SR0**/**SR1** register.

28.15.3.4.5 SOMS mode with double output

If in SOMS mode additionally the mode bit DSO is set (in register **ATOM[i]_CH[x]_CTRL**) two 12 bit data streams can be shifted out on the outputs *ATOM_OUT* and *ATOM_OUT_T* in parallel.This is reached by splitting the register **CM1** into two parts. The lower 12 bits are used as a shift register of output *ATOM_OUT* (i.e. bit 0 is assigned to output *ATOM_OUT*), the upper 12 bits are used as a shift register of output *ATOM_OUT_T* (i.e. bit 12 is assigned to output *ATOM_OUT_T*).On bit 23 and 11 of register **CM1** the value !**SL** is shifted in. Note: In this mode only shift right is possible. Bit **ACB0** is ignored.This behavior is depicted in the following figure:

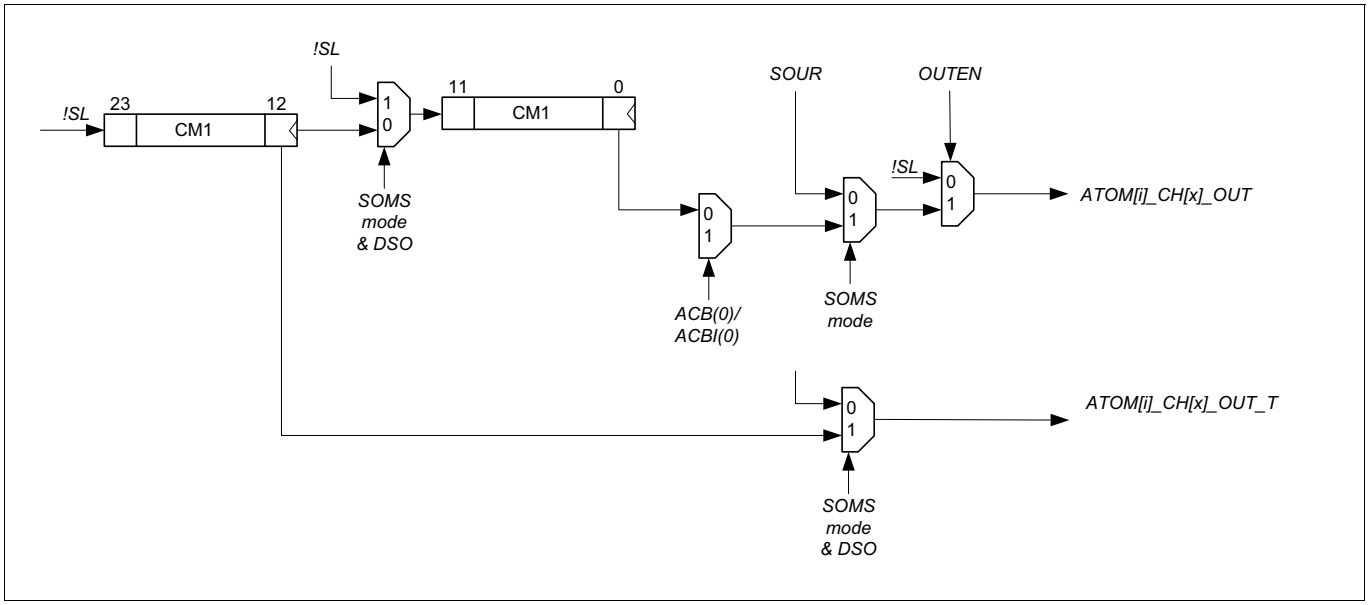

Figure 89 Double Output Shift Mode

28.15.3.4.6 Interrupts in SOMS mode

In ATOM Signal Output Mode Serial only the interrupt CCU0TC (**ATOM[i]_CH[x]_IRQ_NOTIFY**) in case of **CN0** >= **CM0** is generated. The interrupt **CCU1TC** has no meaning and is not generated.

28.15.3.4.7 Register ATOM[i]_CH[x]_CTRL in SOMS mode

28.15.3.5 ATOM Signal Output Mode Buffered Compare (SOMB)

28.15.3.5.1 Overview

In ATOM Signal Output Mode buffered Compare (SOMB) the output action is performed according to the comparison result of the input values located in **CM0** and/or **CM1** registers and the two (three) time base values *TBU_TS0* or *TBU_TS1* (or *TBU_TS2*) provided by the TBU. For a description of the time base generation please refer to the TBU specification in the chapter “Time Base Unite (TBU)”. It is configurable, which of the two (three) time bases is to be compared with one or both values in **CM0** and **CM1**.

The compare strategy of the two compare units CCU0 and CCU1 is controlled by the value of bit field ACBI of register **ATOM[i]_CH[x]_STAT**. This bit field is only readable by CPU. If ARU is disabled, the bit field ACBI can only be updated with the value of bit field **ACB** of register **ATOM[i]_CH[x]_CTRL**. If ARU is enabled, the **ACBI** bit field can be updated with the value of shadow register **ACB_SR** which contains a value received via ARU or the value of bit field **ACB** of register **ATOM[i]_CH[x]_CTRL**.

The table below lists all valid control configurations for bit field **ACBI** of register **ATOM[i]_CH[x]_STAT**.

Table 57 ATOM SOMB compare strategies

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Reserved. Has no effect.
0	0	1	Reserved. Has no effect.
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10/ACBI(1…0) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI[1:0] bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0]. On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0]. On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI[1:0]
1	1	1	Cancels pending comparison independent on ARU_EN

The CCUx trigger signals *TRIG_CCU0* and *TRIG_CCU1* creates edges depending on the combination of the predefined signal level in **SL** bit and the two control bits **ACBI[1:0]**.

In SOMB mode, if ARU access is enabled, the new compare values received via ARU are always stored in the shadow register **SR0** and **SR1** and the **ACB** bits are stores in an internal register **ACB_SR**.

If the scheduled compare matches in CCU0 and/or CCU1 are occurred and the **SRx** register contain new valid values, the register **CM0** and **CM1** are updated automatically with the content of the corresponding **SRx** register, the **ACBI** bit field is updated with the content of internal **ACB_SR** register and the DV bit of register **ATOM[i]_CH[x]_STAT** is set. If the **SRx** register and the **CMx** register contain no valid value, the compare units are waiting in an idle state.

On a compare match of one of the compare units CCUx units the output ATOM_OUT is set according to combination of **ACBI** bit 1 down to 0 (in register **ATOM[i]_CH[x]_STAT**) and the **SL** bit of register **ATOM[i]_CH[x]_CTRL**.

Table 58 ATOM SOMB output control by ACBI[1:0] and SL

SL	ACBI(1)	ACBI(0)	Output Behavior
0	0	0	No signal level change at output.
0	0	1	Set output signal level to 1.
0	1	0	Set output signal level to 0.
0	1	1	Toggle output signal level.
1	0	0	No signal level change at output.
1	0	1	Set output signal level to 0.
1	1	0	Set output signal level to 1.
1	1	1	Toggle output signal level.

In opposite to SOMC mode no time stamp value of TBU is captured in **SRx** register.

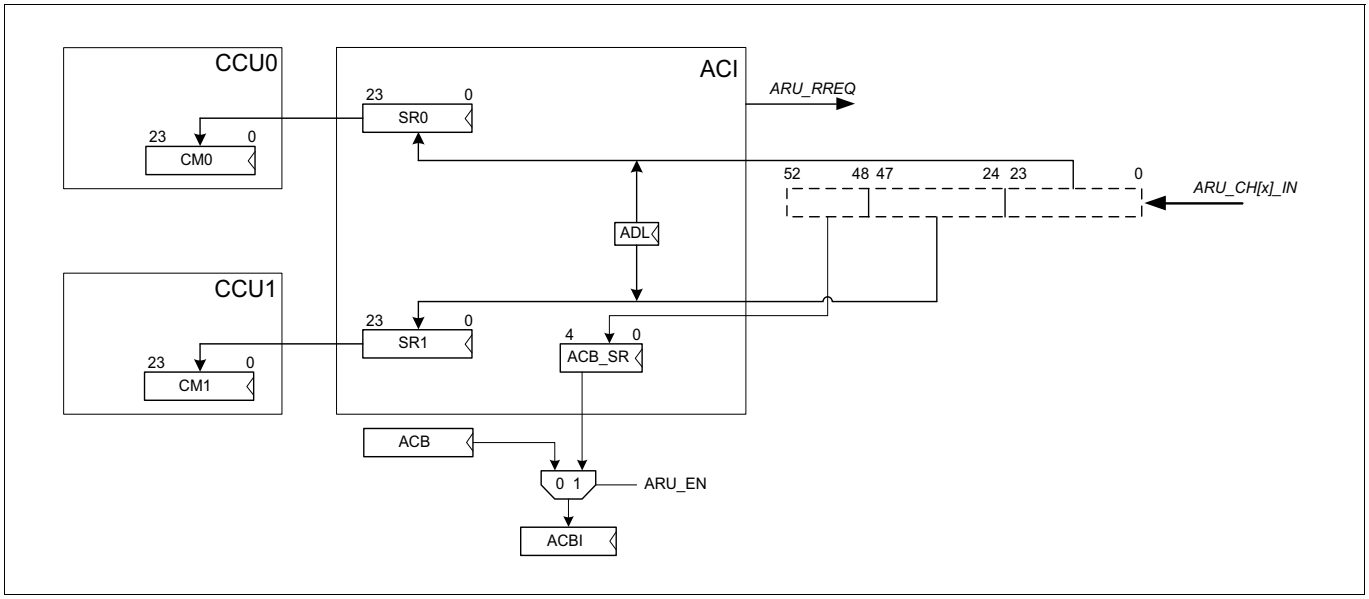

Figure 90 ARU interface behavior in SOMB mode

The flag **DV** of register **ATOM[i]_CH[x]_STAT** indicates that at least one of the **CMx** register contains valid data and a compare event may be pending (if channel is enabled).

The **DV** flag is reset if none of the **CMx** register contains valid data.

28.15.3.5.2 SOMB under CPU control

If bit **ARU_EN** of register **ATOM[i]_CH[x]_CTRL** is not set, the ATOM channel can only be controlled via CPU.

Writing to one of the **CMx** register sets automatically the **DV** bit to validate the new compare value. A comparison depending on value **ACBI** of register **ATOM[i]_CH[x]_STAT** is started immediately.Because only the **ACB** bit of register **ATOM[i]_CH[x]_CTRL** can be written and this bit field serves as a shadow register for the work register **ACBI** (bit field of register **ATOM[i]_CH[x]_STAT)**, it is recommended to first update the **ACB** bit field before updating **CMx**/**SRx** register.

The compare strategy is controlled by the value stored in bit field **ACBI** of register **ATOM[i]_CH[x]_STAT**. If ARU is disabled, this bit field can only be updated with the value of bit field **ACB** of register **ATOM[i]_CH[x]_CTRL**.

The update of bit field **ACBI** can be triggered by a forced update or the normal update mechanism controlled by bit **UPEN_CTRL[x]** in register **ATOM[i]_AGC_GLB_CTRL**.

Writing to one of the **SRx** register and triggering a forced update, updates the **CMx** register with the value of **SRx** register and the **ACBI** bit field with the content of **ACB** bit field of register **ATOM[i]_CH[x]_CTRL**. A new comparison is started.

Writing to one of the **SRx** register while update of **CMx** register is disabled (**UPEN_CTRL[x]** = 0 in **ATOM[i]_AGC_GLB_CTRL**) and enabling update afterwards, triggers the update of **CMx** register and the **ACBI** bit field and starts comparison if previous comparison is finished (**DV** bit was reset).

If ARU access is disabled (**ARU_EN**=0), a force update updates the **CMx** register with the content of **SRx** register and the **ACBI** bit field with the content of **ACB** bit field of register **ATOM[i]_CH[x]_CTRL**.

28.15.3.5.3 SOMB under ARU control

If both compare units CCU0/CCU1 are finished with previous job (depending on compare strategy) and the **SRx** register contain no new value, they are waiting until new data was received via ARU and stored in **SRx** register. Then, an immediately update takes place.

If both compare units are finished with previous job (depending on compare strategy) and there are new data available in **SRx** register, the update the **CMx** register with the value of the **SRx** register and the **ACBI** bit field with the value of internal **ACB_SR** register takes place and a new compare job is started immediately.

After an update of the **CMx** register, a new ARU read request is set.

New compare values received via the ARU are stored in shadow register **SRx**. The **ACB** bits received via ARU are stored in the internal register **ACB_SR**.

If ARU access is enabled (**ARU_EN**=1), a force update updates the **CMx** register with the content of **SRx** register and the **ACBI** bit field with the content of internal **ACB_SR** register.

For compare strategy 'serve last' the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register **CM0** and **CM1** as well as to **WR_REQ** bit is different. These access rights by CPU to register **CM0** and **CM1** and the **WR_REQ** are depicted in the following figure for the case of **EUPM**=0 (register **ATOM[i]_CH[x]_CTRL**)

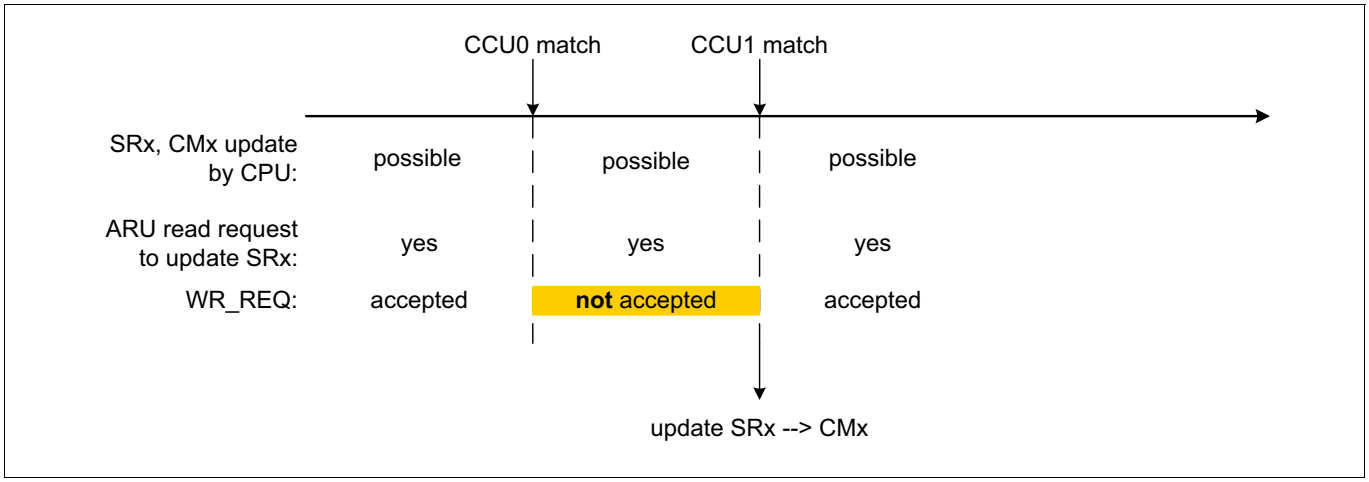

Figure 91 CPU access rights in case of compare strategy 'serve last' and EUPM=0

The access rights by CPU to register **CM0** and **CM1** and the WR_REQ are depicted in the following figure for the case of EUPM=1 (register **ATOM[i]_CH[x]_CTRL**)

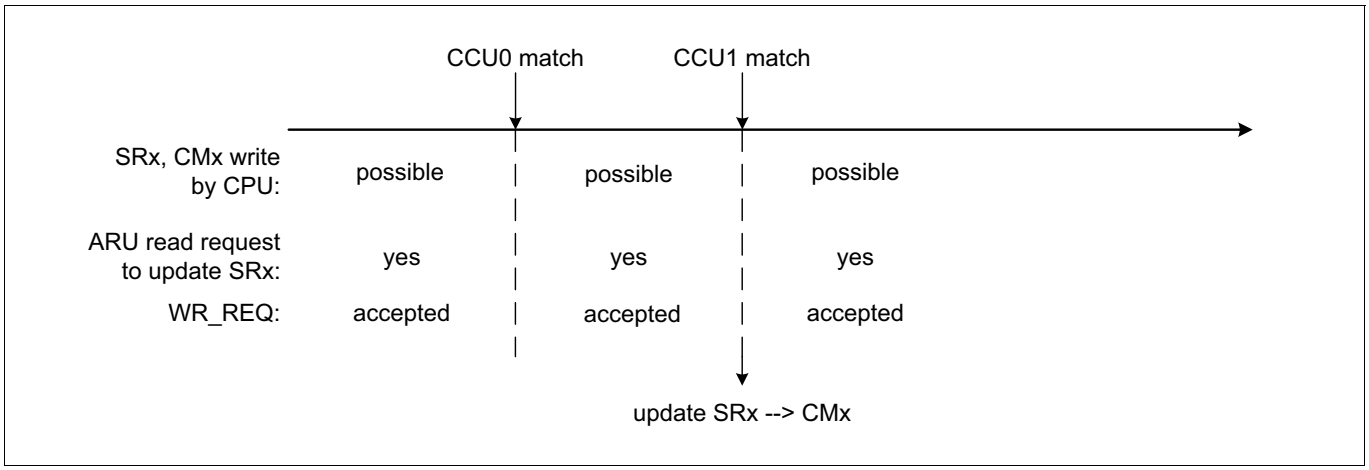

Figure 92 CPU access rights in case of compare strategy 'serve last' in case of EUPM=1

ARU Non-blocking mode

If bit **ABM** in register **ATOM[i]_CH[x]_CTRL** is not set, the ARU blocking mode is disabled. In this case the ATOM channel is continuously reading via ARU and storing new values in the **SRx** register and the ACB shadow register **ACB_SR**.

If **ARU_EN** is not set, the bit **ABM** has no meaning.

ARU Blocking mode

If bit **ABM** in register **ATOM[i]_CH[x]_CTRL** is set, the ARU blocking mode is enabled. In this case the ATOM channel stops requesting new **SRx** values via ARU after reception of a new **SRx** value and restarts requesting a new value via ARU after compare match on both compare units (depending on compare strategy) followed by the immediate update of the **CMx** register with content of **SRx** register and an update of **ACBI** with the content of **ACB_SR**.

If **ARU_EN** is not set, the bit **ABM** has no meaning.

Late Update by CPU

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the **WR_REQ** bit inside the **ATOM[i]_CH[x]_CTRL** register.

If none of the two compare match event happened, the ATOM channel accepts the setting of **WR_REQ** bit. In this case, the ATOM will request no further data from ARU (if ARU access was enabled) and will disable the update of **CMx** register with the content of **SRx** register on a compare match event.

If at least one of the requested compare match events happened (depending on strategy) the **WR_REQ** bit is not set and the **WRF** flag in register **ATOM[i]_CH[x]_STAT** is set to indicate that the late update was not successful.

The channel will in any case continue to compare against the values stored inside the compare registers (if bit **DV** was set). The CPU can now update the compare values by writing to the shadow registers and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

With a force update the **WR_REQ** bit is reset automatically and the ARU read request is set up again (if ARU access was enabled).

Not_used	Not_used			SL	EUPM	CMP_CTRL	ACB[4:2]			ACB[1:0]		ARU_EN	TB12_SEL	MODE	
rw	rw			rw	rw	rw	rw			rw		rw	rw	rw	

Field	Bits	Type	Description
MODE	1:0	rw	**ATOM channel mode select** Not used in ATOM SOMB mode.
TB12_SEL	2	rw	**Select time base value TBU_TS1 or TBU_TS2** 0_B *TBU_TS1* selected for comparison 1_B *TBU_TS2* selected for comparison Note: This bit is only applicable if three time bases are present in the GTM. Otherwise, this bit is reserved.
ARU_EN	3	rw	**ARU Input stream enable** 0_B ARU Input stream disabled 1_B ARU Input stream enabled
ACB[1:0]	5:4	rw	**Signal level control bits** 00_B No signal level change at output. 01_B Set output signal level to 1 when SL bit = 0 else output signal level to 0. 10_B Set output signal level to 0 when SL bit = 0 else output signal level to 1. 11_B Toggle output signal level. Note: These bits are only applicable if ARU_EN = 0.
ACB[4:2]	8:6	rw	**ATOM SOMB compare strategy** 000_B Reserved. Has no effect. 001_B Reserved. Has no effect. 010_B Compare in CCU0 only against *TBU_TS0*. 011_B Compare in CCU1 only against *TBU_TS1* or *TBU_TS2*. 100_B Compare first in CCU0 and then in CCU1. Use *TBU_TS0*. 101_B Compare first in CCU0 and then in CCU1. Use *TBU_TS1* or *TBU_TS2*. 110_B Compare first in CCU0 and then in CCU1. Use *TBU_TS0* in CCU0 and *TBU_TS1* or *TBU_TS2* in CCU1. 111_B Cancel pending comparisons independent on ARU_EN. Note: These bits are only applicable if ARU_EN = 0.

Field	Bits	Type	Description
CMP_CTRL	9	rw	**CCUx compare strategy select** 0_B Greater-equal compare against TBU time base values (TBU_TS1/2 >= CM0/1) 1_B Less-equal compare against TBU time base values (TBU_TS1/2 <= CM0/1) Note: The compare unit CCU0 or CCU1 that compares against TBU_TS0 (depending on CCUx control mode defined by ACB_CM(4:2)) always performs a greater-equal comparison, independent on CMP_CTRL bit.
EUPM	10	rw	**Extended update mode** 0_B No extended update of CM0 and CM1 via CPU or ARU 1_B Extended update mode in case of compare strategy 'serve last': update of CM1 after CCU0 compare match possible via ARU or CPU. Note: If EUPM=1 write access to CM0 or CM1 never causes an AEI write status 0b10. Note: This bit is only applicable in SOMC and SOMB mode.
SL	11	rw	**Initial signal level after channel enable** 0_B Low signal level 1_B High signal level Note: Reset value depends on the hardware configuration chosen by silicon vendor. Note: If the output is disabled, the output ATOM_OUT[x] is set to inverse value of SL. If FREEZE=0, the following notes is valid: If the channel is disabled, the output register of SOU unit is set to value of SL. If FREEZE=1, the following note is valid: If the channel is disabled, the output register of SOU unit is not changed and output ATOM_OUT[x] is not changed.
Not_used	14:12	rw	**Not used** Note: Not used in this mode.
Not_used	15	rw	**Not used** Note: Not used in this mode.
WR_REQ	16	rw	**CPU Write request bit for late compare register update** 0_B No late update requested by CPU 1_B Late update requested by CPU Note: The CPU can disable subsequent ARU read requests by the channel and can update the shadow registers with new compare values, while the compare units operate on old compare values received by former ARU accesses, if occurred. Note: On a compare match event, the WR_REQ bit will be reset by hardware. Note: At the point of the force update only the shadow registers SR0 and SR1 are transferred into the CM0, CM1 registers. The output action is still defined by the ACBI bit field described by the ARU together with the old compare values for CM0/CM1.
Not_used	17	rw	**Not used** Note: Not used in this mode.

Field	Bits	Type	Description
Not_used	19:18	rw	**Not used** Note: Not used in this mode.
Not_used	20	rw	**Not used** Note: Not used in this mode.
Not_used	22:21	r	**Not used** Note: Not used in this mode.
EXTTRIGOUT	23	rw	**TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x]** 0_B signal *TRIG_[x-1]* is selected as output on *TRIG_[x]* (if TRIGOUT=0) 1_B signal *TIM_EXT_CAPTURE(x)* is selected as output on *TRIG_[x]* (if TRIGOUT=0)
TRIGOUT	24	rw	**Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx** 0_B *TRIG_[x]* is *TRIG_[x-1]* or TIM_*EXT_CAPTURE(x)*. 1_B *TRIG_[x]* is *TRIG_CCU0*
Not_used	25	rw	**Not used** Note: Not used in this mode.
Not_used	26	rw	**Not used** Note: Not used in this mode.
ABM	27	rw	**ARU blocking mode** 0_B ARU blocking mode disabled: ATOM reads continuously from ARU and updates SR0, SR1 and ACB bits independent of pending compare match event 1_B ARU blocking mode enabled: after updating SR0,SR1 and ACB bits via ARU, no new data is read via ARU until compare match event occurred.
Reserved	28	r	**Reserved** Read as zero, should be written as zero.
Not_used	29	rw	**Not used** Note: Not used in this mode.
SOMB	30	rw	**SOMB: SOMB mode** 0_B ATOM channel mode defined by bit filed MODE 1_B ATOM SOMB mode enabled
FREEZE	31	rw	**FREEZE** 0_B a channel disable/enable may change internal register and output register 1_B a channel enable/disable does not change an internal or output register but stops counter CN0 (in SOMP mode), comparison (in SOMC/SOMB mode) and shifting (in SOMS mode)

28.15.4 ATOM Interrupt Signals

Table 59 ATOM Interrupt Signals

Signal	Description
CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

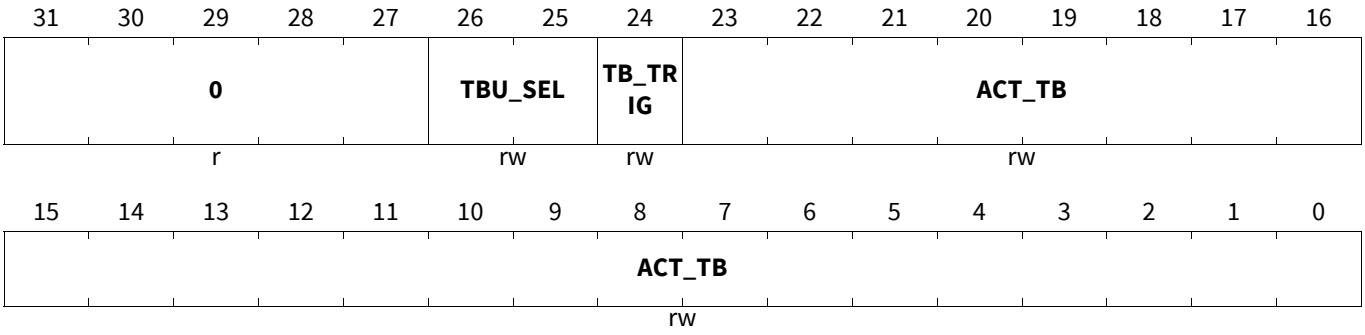
ENDIS_STATx (x=0-7)	2*x+1:2*x	rw	**ATOM channel x enable/disable** If FREEZE=0 and an ATOM channel is disabled, the counter CN0 is stopped and the output register of SOU unit is set to the inverse value of control bit SL. On an enable event, the counter CN0 starts counting from its current value. If FREEZE=1 and an ATOM channel is disabled, the counter CN0 is stopped (SOMP, SOMS mode) and each comparison is stopped (SOMC, SOMB mode). On an enable event, the counter CN0 starts counting from its current value or a comparison is restarted. 00_B Write: Don't care bits, will not be changed; Read: Output disabled. 01_B Write: Disable channel on an update trigger; Read: Unused 10_B Write: Enable channel on an update trigger; Read: Unused 11_B Write: Don’t change bits 1:0 of this register; Read: Output enabled.
0	31:16	r	**Reserved** Read as zero, shall be written as zero.

28.15.6.4 Register ATOM[i]_AGC_ACT_TB

ATOMi AGC Action Time Base Register

ATOMi_AGC_ACT_TB (i=0-11)

ATOMi AGC Action Time Base Register **($0E804C_H$+i*800_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ACT_TB	23:0	rw	**Time base value** Specifies the signed compare value with selected signal TBU_TS[x], x=0..2. If selected TBU_TS[x] value is in the interval [ACT_TB-007FFFFFh,ACT_TB], the event is in the past, and the trigger is generated immediately. Otherwise, the event is in the future, and the trigger is generated if selected TBU_TS[x] is equal to ACT_TB.
TB_TRIG	24	rw	**Set trigger request** Note: This flag is reset automatically if the selected time base unit (*TBU_TS0*or *TBU_TS1*or *TBU_TS2,*if present) has reached the value **ACT_TB**, and the update of the register was triggered. 0_B No trigger request 1_B Set trigger request
TBU_SEL	26:25	rw	**Selection of time base used for comparison** *Note: The bit combination 0b10 is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Please refer to GTM Architecture block diagram on page 3 to determine the number of channels for TBU of this device.* 00_B TBU_TS0 selected 01_B TBU_TS1 selected 10_B TBU_TS2 selected 11_B Same as 0b00
0	31:27	r	**Reserved** Read as zero, shall be written as zero.

28.15.6.5 Register ATOM[i]_AGC_OUTEN_CTRL

ATOMi AGC Output Enable Control Register

ATOMi_AGC_OUTEN_CTRL (i=0-11)

ATOMi AGC Output Enable Control Register($0E8050_H$+i*800_H) **Application Reset Value: 0000 0000_H**

rw	rw			rw	rw	rw	rw					rw	rw	rw	

Field	Bits	Type	Description
MODE	1:0	rw	**ATOM channel mode select** 00_B ATOM Signal Output Mode Immediate (SOMI) 01_B ATOM Signal Output Mode Compare (SOMC) 10_B ATOM Signal Output Mode PWM (SOMP) 11_B ATOM Signal Output Mode Serial (SOMS)
TB12_SEL	2	rw	**Select time base value TBU_TS1 or TBU_TS2** *Note: This bit is only applicable in SOMC mode.* 0_B TBU_TS1 selected for comparison 1_B TBU_TS2 selected for comparison
ARU_EN	3	rw	**ARU input stream enable** 0_B ARU Input stream disabled 1_B ARU Input stream enabled
ACB	8:4	rw	**ATOM Mode control bits** These bits have different meaning in the different ATOM channel modes. Please refer to the mode description sections. SOMI : **Section 28.15.3.1** and **Register ATOM[i]_CH[x]_CTRL in SOMI mode** for register description. SOMC : **Section 28.15.3.2** and **Register ATOM[i]_CH[x]_CTRL in SOMC mode** for register description. SOMP : **Section 28.15.3.3** and **Register ATOM[i]_CH[x]_CTRL in SOMP mode** for register description. SOMS : **Section 28.15.3.4** and **Register ATOM[i]_CH[x]_CTRL in SOMS mode** for register description. SOMB : **Section 28.15.3.5** and **Register ATOM[i]_CH[x]_CTRL in SOMB mode** for register description.

Field	Bits	Type	Description
CMP_CTRL	9	rw	**CCUx compare strategy select** *Note: This bit is only applicable in SOMC mode.* 0_B Greater-equal compare against TBU time base values (TBU_TSx greater than or equal to CMx) 1_B Less-equal compare against TBU time base values (TBU_TSx less than or equal to CMx)
EUPM	10	rw	**Extended update mode** *Note: If EUPM=1, a write access to CM0 or CM1 never causes an AEI write status 10_B.* *Note: This bit is only applicable in SOMC and SOMB mode.* 0_B No extended update of CM0 and CM1 via CPU or ARU 1_B Extended update mode in case of compare strategy 'serve last': update of CM1 after CCU0 compare match possible via ARU or CPU.
SL	11	rw	**Initial signal level** *Note: Reset value depends on the hardware configuration chosen by silicon vendor.* *Note: If the output is disabled, the output ATOM_OUT[x] is set to inverse SL, independent of the ATOM channel mode.* If FREEZE=0, following notes are valid: In SOMP, SOMI, SOMS mode, if the channel is disabled, the internal register SOUR inside ATOM sub-unit SOU is set to inverse value of SL. By enabling the channel, the register SOUR is not changed. Thus, if the output is enabled afterwards, the output ATOM_OUT[x] is the inverse value of SL. In SOMC mode, if the channel is disabled, the internal register SOUR inside ATOM sub-unit SOU is set to value of SL. By enabling the channel, the register SOUR is not changed. Thus, if the output is enabled and the channel is disabled, the output ATOM_OUT[x] is the value of SL. If FREEZE=1, the following notes are valid: If the channel is disabled, the output register of SOU unit is not changed, and output ATOM_OUT[x] is not changed. 0_B Low signal level 1_B High signal level

Field	Bits	Type	Description
CLK_SRC_SR	14:12	rw	**Actual CMU clock source (SOMS)/ shadow register for CMU clock source (SOMP)** If ECLK_SRC=0 / ECLK_SRC=1: *Note: This register is a shadow register for the register CLK_SRC. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done, either by an end of a period or a forced update.* *Note: After (channel) reset, the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use in SOMP mode one of the CMU_CLKx, it is recommended to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel.* *Note: In case of ECLK_SRC=1 and CLK_SRC_SR = 011_B/100_B/101_B/110_B, a force update leads to an immediate update of CM0, CM1 and CLK_SRC.* 000_B CMU_CLK0 selected / CMU_CLK0 selected 001_B CMU_CLK1 selected / CMU_CLK1 selected 010_B CMU_CLK2 selected / CMU_CLK2 selected 011_B CMU_CLK3 selected / reserved 100_B CMU_CLK4 selected / clock stopped 101_B CMU_CLK5 selected / TRIG[x-1] selected 110_B CMU_CLK6 selected / TIM_EXT_CAPTURE[x] selected 111_B CMU_CLK7 selected / CMU_CLK7 selected
ECLK_SRC	15	rw	**Extend CLK_SRC** *Note: This bit is only applicable in SOMP and SOMS mode.* See bit CLK_SRC_SR description for details. 0_B CLK_SRC_SR set 1 selected 1_B CLK_SRC_SR set 2 selected
WR_REQ	16	rw	**CPU Write request bit for late compare register update** *Note: The CPU can disable subsequent ARU read requests by the channel and can update the shadow registers with new compare values, while the compare units operate on old compare values received by former ARU accesses, if occurred.* *Note: On a compare match event, the WR_REQ bit will be reset by hardware.* *Note: At the point of the force update, only the shadow registers SR0 and SR1 are transferred into the CM0, CM1 registers. The output action is still defined by the ACBI bit field described by the ARU together with the old compare values for CM0/CM1.* *Note: This bit is only applicable in SOMC and SOMB mode.* 0_B No late update requested by CPU 1_B Late update requested by CPU

Field	Bits	Type	Description
TRIG_PULSE	17	rw	**Trigger output pulse length of one SYS_CLK period** 0_B Output on TOM[i]_OUT[x]_T is '1' as long as CN0=SR0 (if SR=_TRIG=1) 1_B Output on TOM[i]_OUT[x]_T is '1' for only one SYS_CLK period if CN0=SR0 (if SR=_TRIG=1)
UDMODE	19:18	rw	**Up/down counter mode** *Note: This mode is only applicable in SOMP mode.* 00_B Up/down counter mode disabled: CN0 counts always up 01_B Up/down counter mode enabled: CN0 counts up and down, CM0,CM1 are updated if CN0 reaches 0 (i.e. changes from down to up) 10_B Up/down counter mode enabled: CN0 counts up and down, CM0,CM1 are updated if CN0 reaches CM0 (i.e. changes from up to down) 11_B Up/down counter mode enabled: CN0 counts up and down, CM0,CM1 are updated if CN0 reaches 0 or CM0 (i.e. changes direction)
RST_CCU0	20	rw	**Reset source of CCU0** *Note: If RST_CCU0=1 and UPEN_CTRLx=1 are set, TRIG_[x-1] or TIM_EXT_CAPTURE(x) triggers also the update of work register (CM0, CM1 and CLK_SRC).* *Note: This bit is only applicable in SOMP mode.* *Note: This bit should only be set if bit OSM=0 (i.e. in continuous mode).* 0_B Reset counter register CN0 to 0 on matching comparison with CM0 1_B Reset counter register CN0 to 0 on trigger TRIG_[x-1] or TIM_EXT_CAPTURE(x)
OSM_TRIG	21	rw	**Enable trigger of one-shot pulse by trigger signal OSM_TRIG** *Note: This bit should only be set if bit OSM=1 and bit RST_CCU0=0.* 0_B Signal OSM_TRIG cannot trigger start of single pulse generation 1_B Signal OSM_TRIG can trigger start of single pulse generation (only if bit OSM = 1)
EXT_TRIG	22	rw	**Select TIM_EXT_CAPTURE(x) as trigger signal** 0_B Signal TRIG_[x-1] is selected as trigger to reset CN0 or to start single pulse generation 1_B Signal TIM_EXT_CAPTURE(x) is selected
EXTTRIGOUT	23	rw	**Select TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x]** 0_B Signal TRIG_[x-1] is selected as output on TRIG_[x] (if TRIGOUT=0) 1_B Signal TIM_EXT_CAPTURE(x) is selected as output on TRIG_[x] (if TRIGOUT=0)

Field	Bits	Type	Description
TRIGOUT	24	rw	**Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx** 0_B TRIG_[x] is TRIG_[x-1] or TIM _EXT_CAPTURE(x) 1_B TRIG_[x] is TRIG_CCU0
SLA	25	rw	**Serve last ARU communication strategy** *Note: This bit is only applicable in SOMC mode.* *Note: Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy (100_B, 101_B, or 110_B).* *Note: When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return 10_B in that case.* *Note: By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to 01_B in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to 10_B. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.* 0_B Capture SRx time stamps after CCU0 match event not provided to ARU 1_B Capture SRx time stamps after CCU0 match event provided to ARU
OSM	26	rw	**One-shot mode** *Note: This bit is only applicable in SOMP and SOMS modes.* 0_B Continuous PWM generation after channel enable 1_B A single pulse is generated
ABM	27	rw	**ARU blocking mode** *Note: This bit is only applicable in SOMC and SOMB mode.* 0_B ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 and ACB bits in case of SOMC mode, or SR0, SR1 and ACB bits in case of SOMB mode, independent of pending compare match event 1_B ARU blocking mode enabled: After update of CM0, CM1 and ACB bit in case of SOMC mode, or SR0, SR1 and ACB bits in case of SOMB mode via ARU, no new data is read via ARU until compare match event occurred, and in case of SOMC mode, SR0 and/or SR1 are read

Field	Bits	Type	Description
EXT_FUPD	29	rw	**External forced update** *Note: This bit is only applicable in SOMP and SOMS mode.* 0_B Use FUPD(x) signal from AGC to force update 1_B Use TIM_EXT_CAPTURE signal to force update
SOMB	30	rw	**SOMB mode** 0_B ATOM channel mode defined by bit field MODE 1_B ATOM SOMB mode enabled
FREEZE	31	rw	**FREEZE** *Note: if channel is disabled and ouptut is enabled, in SOMP mode with UDMODE!=0b00 the output is dependng directly on SL bit, independent on FREEZE mode.* 0_B A channel disable/enable may change internal register and output register 1_B A channel enable/disable does not change an internal or output register but stops counter CN0 (in SOMP mode), comparison (in SOMC/SOMB mode) and shifting (in SOMS mode)

28.16 Dead Time Module (DTM)

28.16.1 Overview

Figure 93 gives an overview of the structure of the Dead Time Module (DTM).

Note: In this paragraph, the following is used. Variable n is used for CDTMs, x for channels and i is used for DTMs. (An exception for TIM names.)

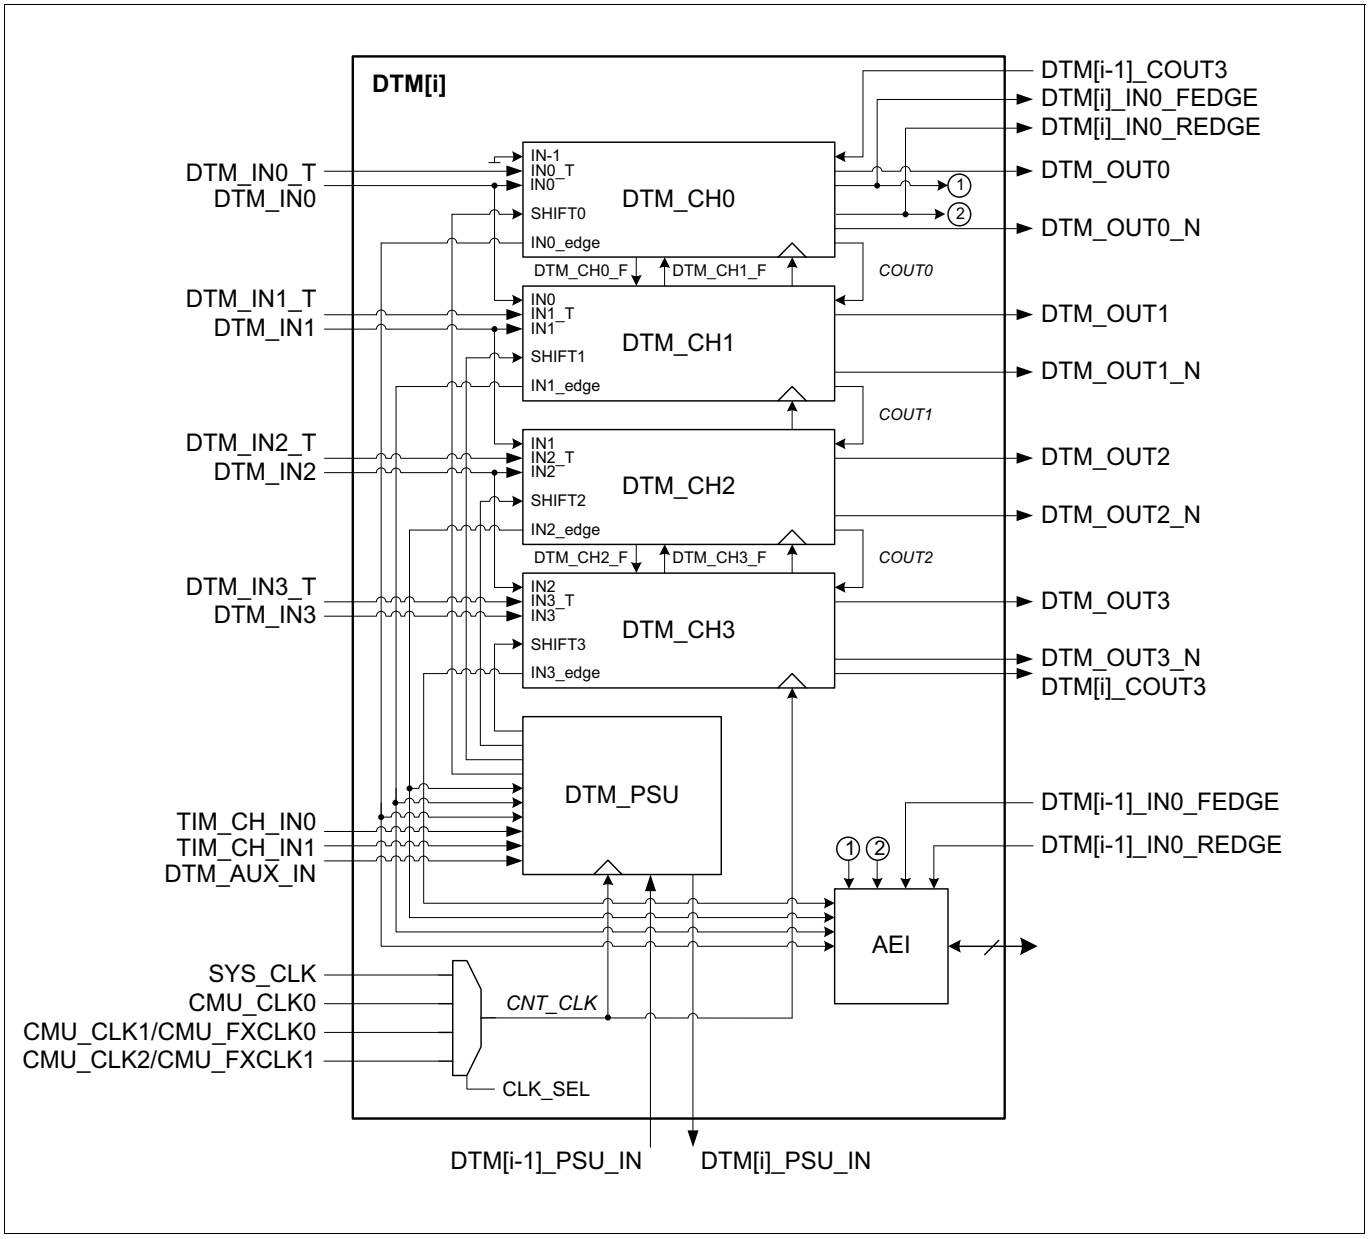

Figure 93 DTM overview

The main function of the DTM is to derive for each input *DTM_IN0* to *DTM_IN3* the individual inverse signal (*DTM[i]_OUT[x]_N*) and to apply an edge specific delay between the edge of the original signal and the edge of the derived inverted signal (i.e., the dead time). This function is mainly used for controlling of half bridges.

A second function provided by DTM is to set the outputs of one channel to the value of the preceding channel if requested by a trigger on input *TIM_CH_IN*0, *TIM_CH_IN1* or *DTM_AUX_IN*. This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

The third function provided by DTM is to (N)AND/(N)OR/X(N)OR combine the input *DTM_IN[x]* signal of one DTM channel with the signal on input *TIM_CH_IN0, TIM_CH_IN1* or *DTM_AUX_IN* (selected inside DTM_PSU and assigned to one of the signals *SHIFT[x]*) or with the combinational output (signal *COUT[x]*) of preceding channel.As a result *COUT2* may be the combined signal of *DTM_IN0* and *TIM_CH_IN0, TIM_CH_IN1* or *DTM_AUX_IN* and the signal *DTM_IN1*. For *COUT3* this chain can be combined again with signal *DTM_IN3*.

The outputs of each channel may be swapped individually to provide the function of combining signals on each output of a channel.

In general, the DTM instances are placed behind the TOM and the ATOM instances, i.e., the outputs *TOM_OUT[x] and TOM_OUT[x]_T* or *ATOM_OUT[x] and ATOM_OUT[x]_T* are each routed to the DTM instance inputs *DTM_IN[y]* and *DTM_IN[y]_T*.Four DTM instances behind a TOM instance i and two DTM instances behind an ATOM instance i are grouped together in a Cluster DTM hierarchy called CDTM[i]. The connections between DTM and the modules TOM and ATOM are depicted in **Figure 94**.

Note, depending on device configuration, not every DTM instance is available. E.g. a device may only have one DTM connected to the first four channels of ATOM. In this case, the other four channels (4 to 7) are connected directly to GTM outputs.For detailed information, which DTM instance is available, refer to corresponding device specific device specific appendix of this specification.

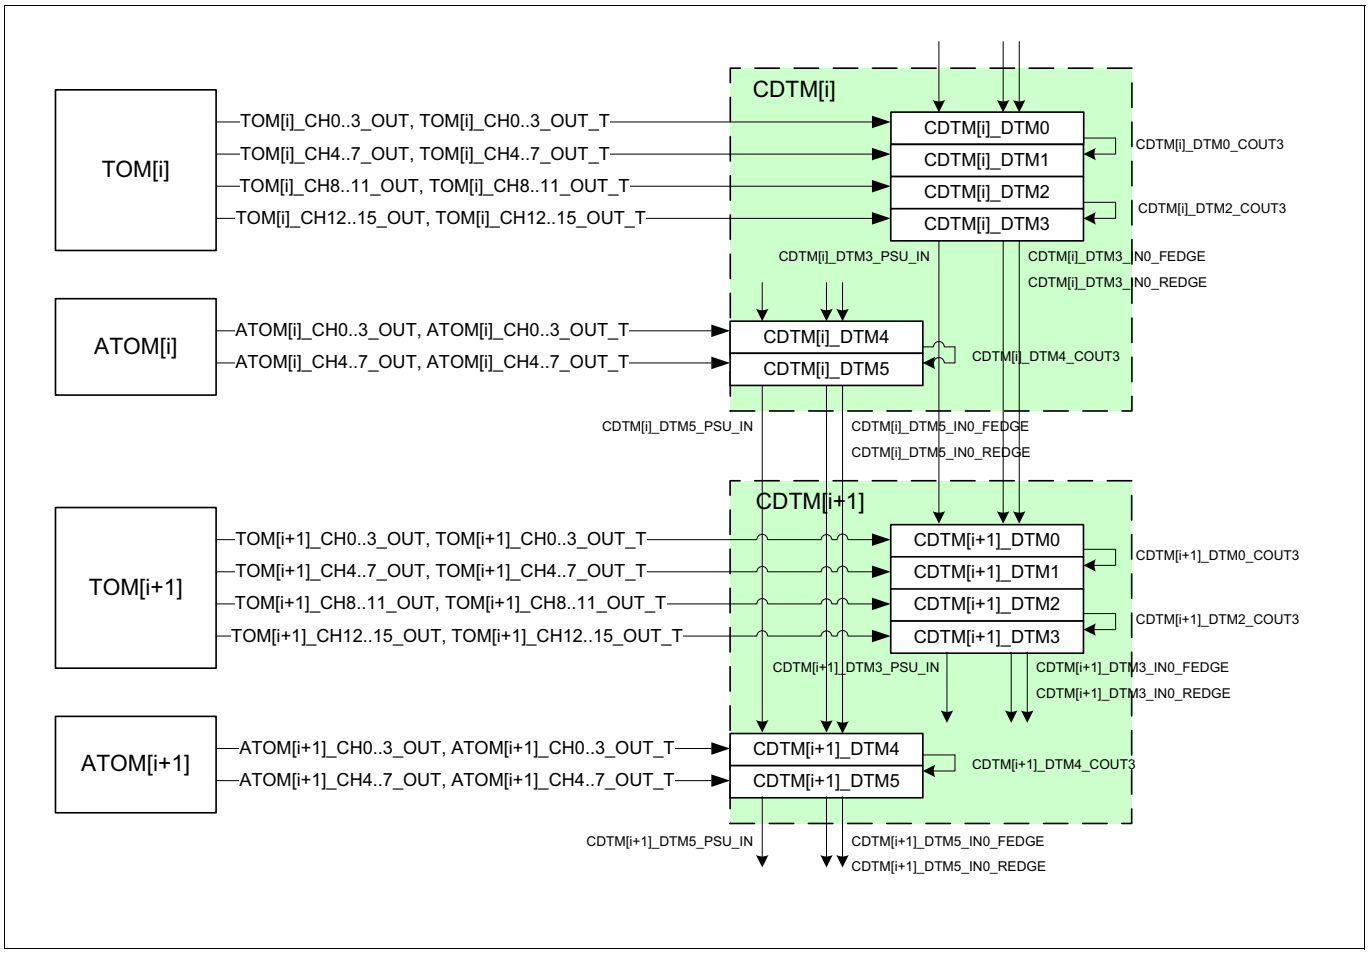

Figure 94 Connections of TOM and ATOM to DTM inputs DTM_IN[y]/DTM_IN[y]_T

Additionally, the DTM instances have inputs *TIM_CH_IN0*/*TIM_CH_IN1* which are driven by TIM output signals *TIM[i]_CH[x]_F_OUT*.

There are two configurations of TIM to DTM connections possible depending on the DTM channel specific configuration bit TIM_SEL.

In case of TIM_SEL=0 the connected TIM input may not be of the same cluster as the DTM.

In case of TIM_SEL=1 the TIM input is of the same cluster as the DTM.

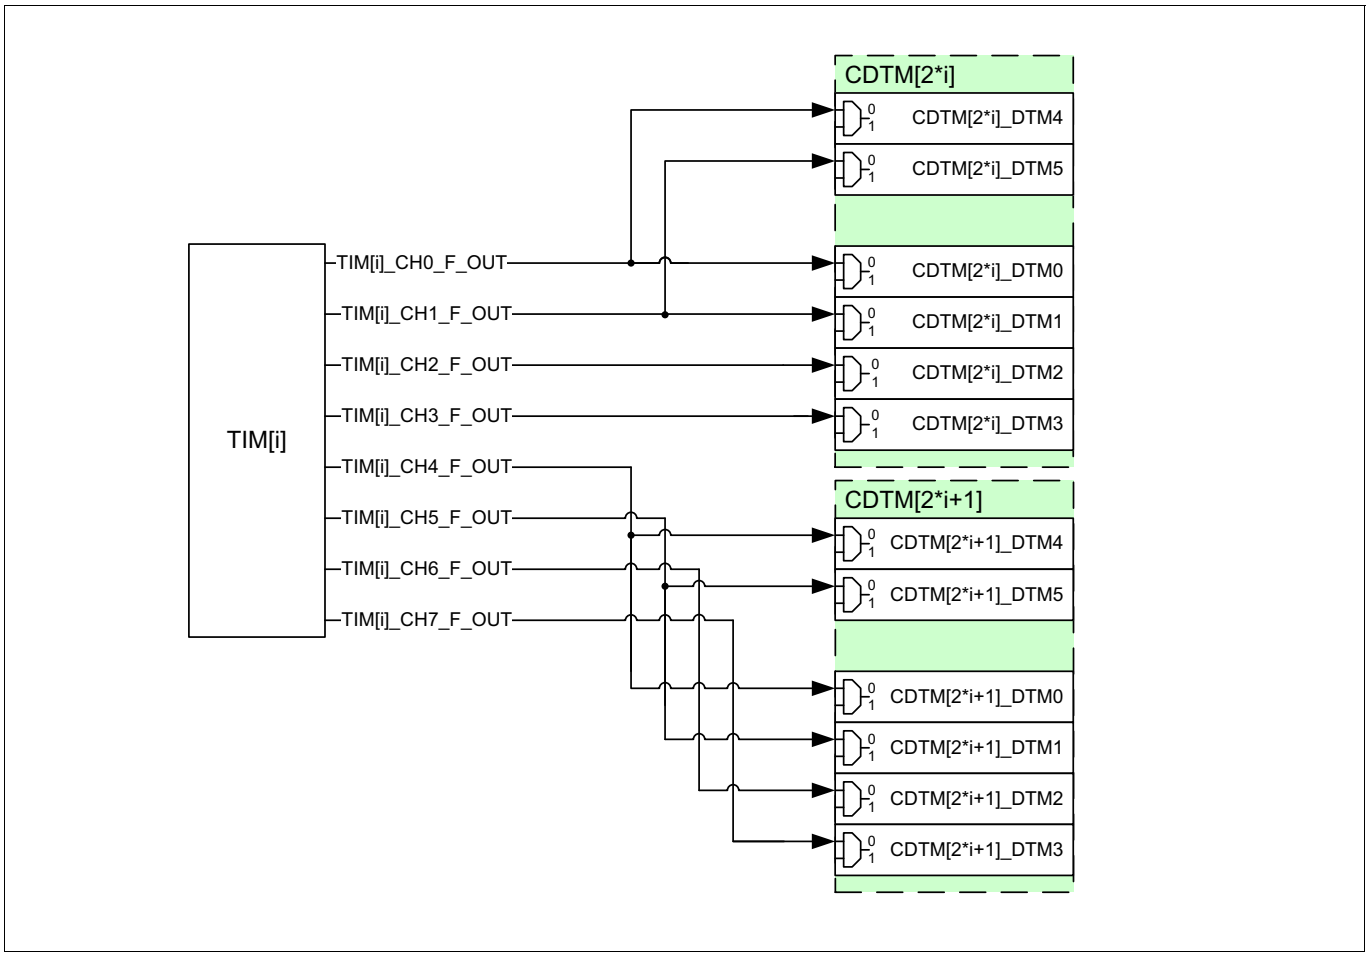

Figure 95 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for TIM_SEL=0

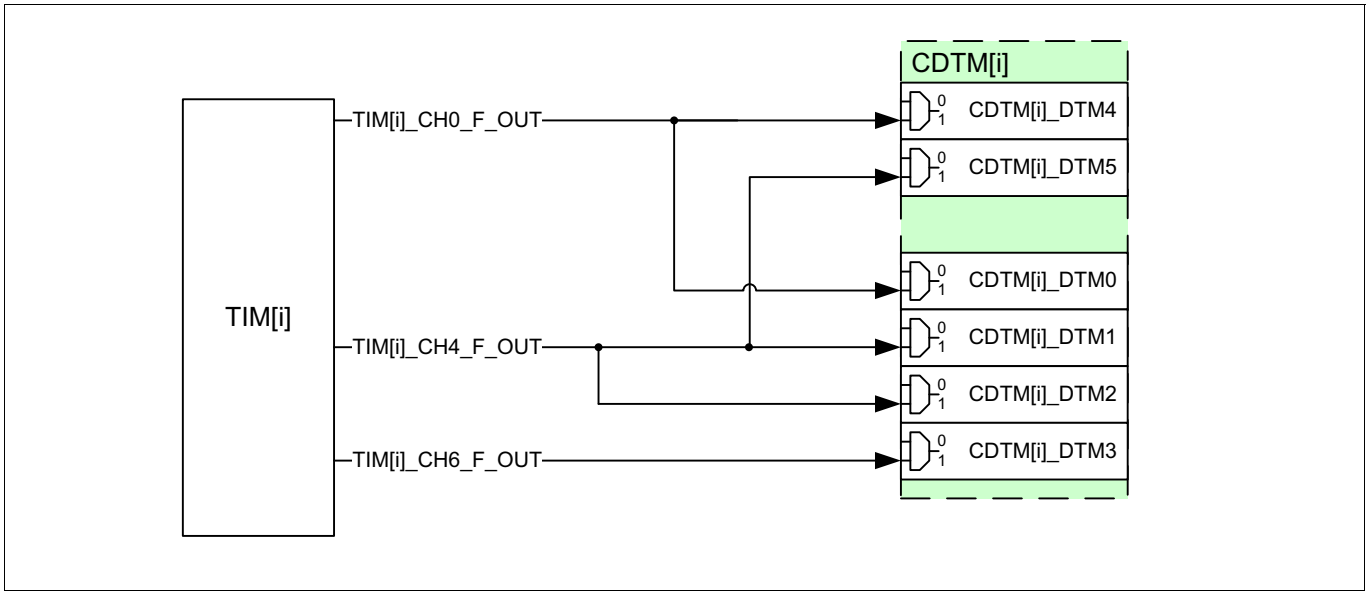

Figure 96 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for TIM_SEL=1

There are also connections between DTM instances of same CDTM instance.For each pair of DTM instance 2i and 2i+1 the combinatorial output *COUT(3)* of DTM[2i] channel 3 is connected to DTM[2i+1] channel 0 *COUT(0-1)*.

With this a combinatorial chain over two neighbored DTM instances can be configured.

If one of the two neighbored DTM instances is not available (i.e. it is an empty instance) the inputs used for connections between two neighbored DTM instances are left open.

Note: For channel x=0 of DTM instance 2i input signals COUT[x-1] is unused and I1SEL[x] is defined as 0.

An additional link between DTM instances behind an ATOM is a forwarding of *DTM[i]_PSU_IN* signal to next available instance of DTM behind an ATOM (e.g. *DTM[i+1]_PSU_IN*).

The same link is available between all available DTM behind a TOM.

Note, for unavailable DTM[i] instances (i.e. the instance DTM[i] is called empty) the signal *DTM[i-1]_PSU_IN* is passed through empty instance DTM[i] to *DTM[i+1]_PSU_IN*, *DTM[i-1]_IN0_FEDGE* and *DTM[i-1]_IN0_REDGE* are passed through DTM[i] to *DTM[i+1]_IN0_FEDGE* and *DTM[i+1]_IN0_REDGE*.

Further connections between neighbored DTM instances are depicted in **Figure 97**:

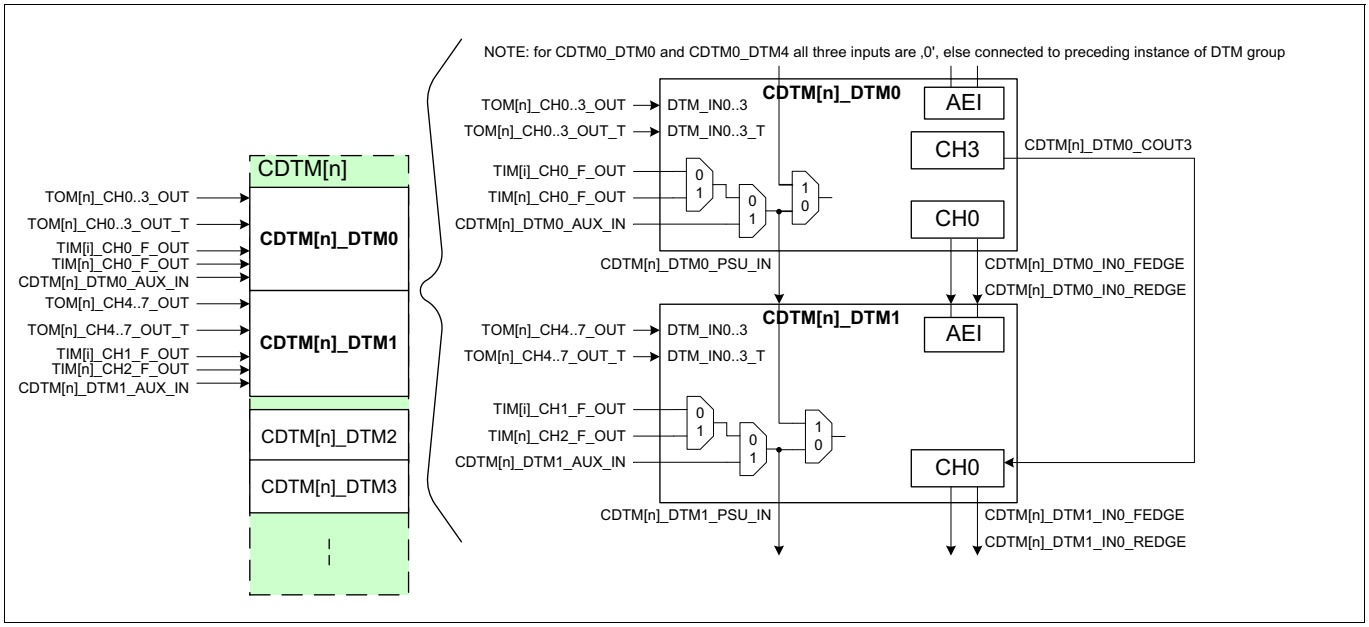

Figure 97 Connections between DTM instances

28.16.2 DTM Channel

Figure 98 depicts the functions of a DTM channel.

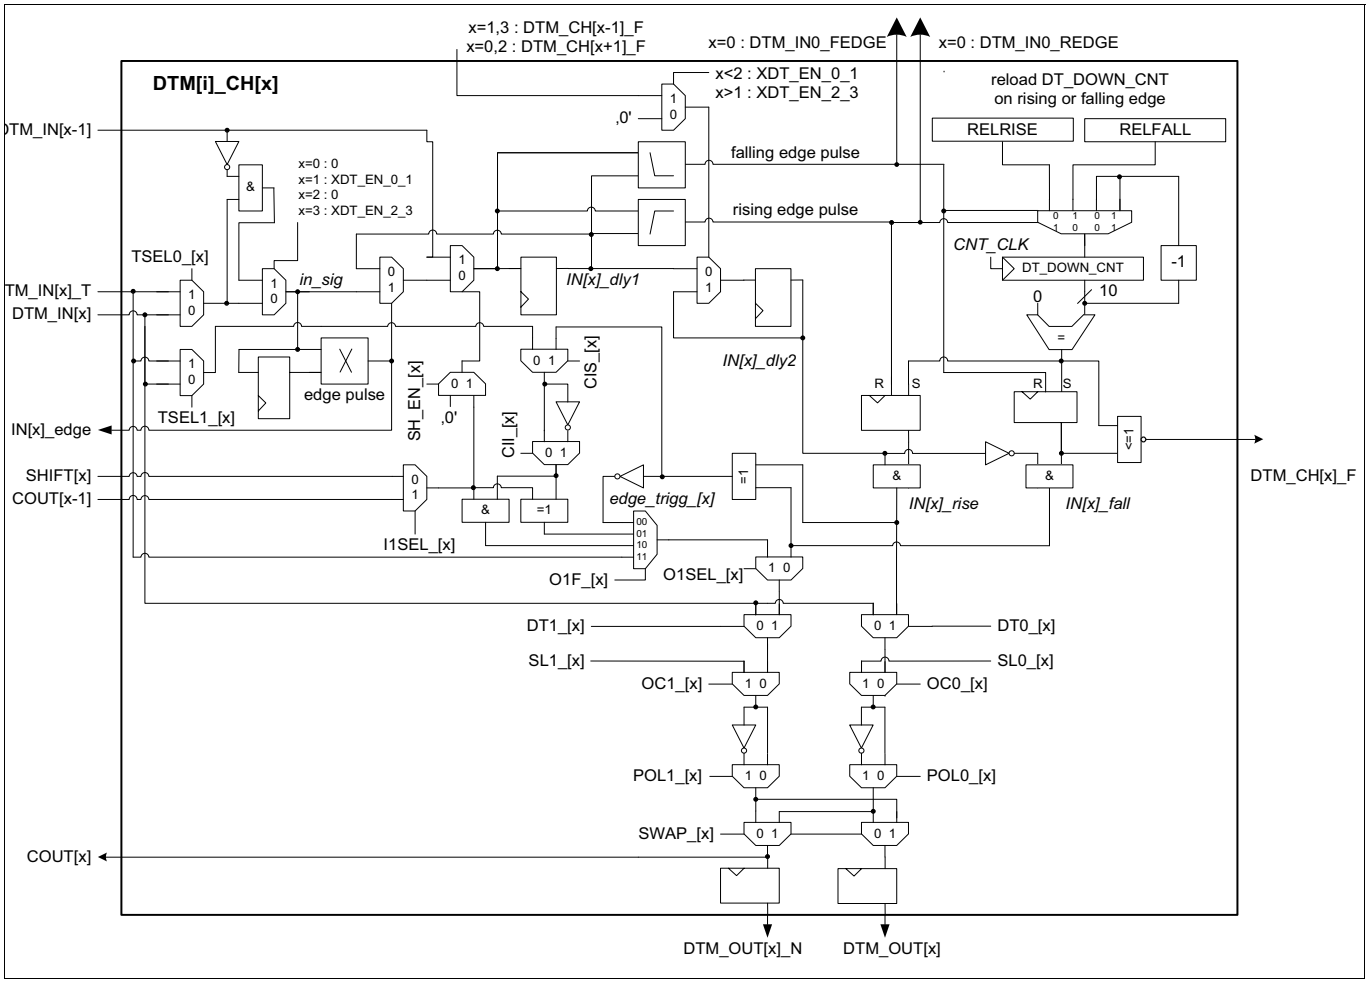

Figure 98 DTM channel overview

The main feature of each channel is to derive the inverse signal out of the input signal *DTM_IN[x]*, apply an edge dependent delay on the two resulting signal paths and provide these signals at the outputs *DTM[i]_OUT[x]* and *DTM[i]_OUT[x]_N*.

There are two possibilities to apply dead time on GTM output signals.One is to use one DTM channel per TOM/ATOM channel and generate inside the DTM the second inverse signal. This is called the standard dead time generation.The second way is to generate two signals out of two TOM/ATOM channel and to apply inside the DTM only the dead time by using two cross linked DTM channel. This is called the cross dead time generation.

28.16.2.1 Standard dead time generation

The dead time can be configured for each edge individually. The bit field **RELRISE** in register **DTM[i]_CH[x]_DTV** contains the reload value for the counter and defines the delay for rising edges in multiples of selected clock ticks.The bit field **RELFALL** in register **DTM[i]_CH[x]_DTV** contains the reload value for the counter and defines the delay for falling edges in multiples of selected clock ticks.

The counter is reloaded with the value of **RELRISE** on a rising edge and reloaded with the value of **RELFALL** on a falling edge on input *DTM_IN[x]* (or *DTM_IN[x-1]* in case of shift enable **SH_EN_[x]**).

On a reload of the counter the flip-flop following the counter output comparator is reset and stays reset until the counter has reached 0.After reload, the counter **DT_DOWN_CNT** counts down until it reaches 0 and stops at 0.

The signal flow for function of standard dead time signal generation is depicted in **Figure 99**.

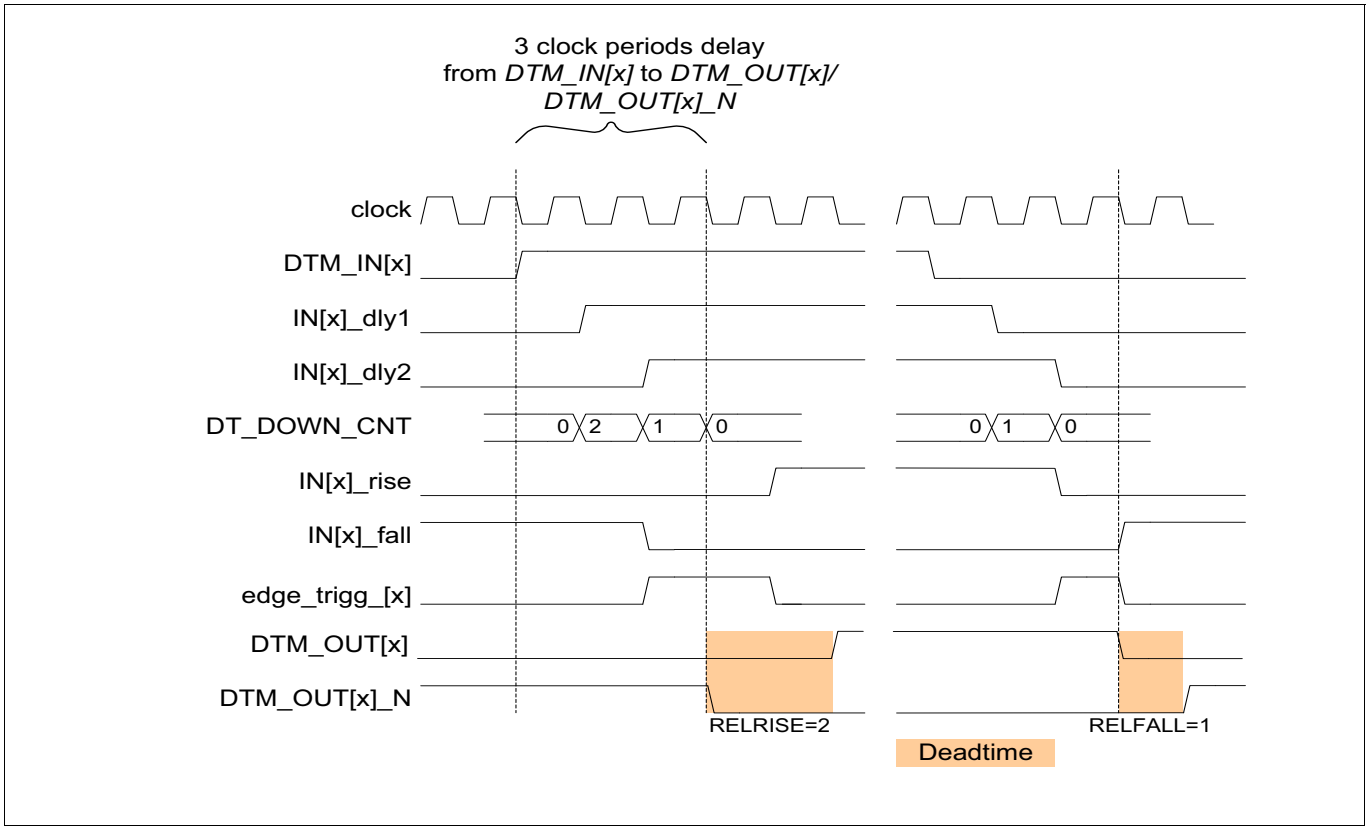

Figure 99 Wave signals for function of dead time generation

*Note: The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is three system clock periods by disabled feed through (see **DT0/1_[x]** in **DTM[i]_CH_CTRL2**).*

*Note: The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is one system clock periods by enabled feed through (see **DT0/1_[x]** in **DTM[i]_CH_CTRL2**).*

*Note: The delay from the input signal DTM_IN[x]_T to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is three system clock periods in case of disabled feed through (see **O1F_[x]** and **O1SEL_[x]** in **DTM[i]_CH_CTRL2**).*

*Note: The delay from the input signal DTM_IN[x]_T to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is one system clock periods in case of enabled feed through (see **O1F_[x]** and **O1SEL_[x]** in **DTM[i]_CH_CTRL2**).*

Note: The reset level of the output signals DTM[i]_OUT[x] connected from ATOM module depends on the hardware configuration value atom_out_reset_level_c chosen by silicon vendor.

Note: The reset level of the output signals DTM[i]_OUT[x]_N connected from ATOM module is defined by the inverse hardware configuration value atom_out_reset_level_c chosen by silicon vendor.

Note: The reset level of the output signals DTM[i]_OUT[x] connected from TOM module is defined by the hardware configuration value tom_out_reset_level_c chosen by silicon vendor.

Note: The reset level of the output signals DTM[i]_OUT[x]_N connected from TOM module is defined by the inverse hardware configuration value tom_out_reset_level_c chosen by silicon vendor.

28.16.2.2 Cross channel dead time

A second way to apply a dead time value on two output signals is the cross channel dead time.

In opposite to the dead time described in **Section 28.16.2.1** the cross channel dead time mode does not generate out of one signal the corresponding inverse signal but tries to apply the dead time on the input signals of two neighbored DTM channel.

To do this, two neighbored DTM input signals (on DTM channel (2k) and (2k+1) for k=0,1) are cross linked together in the way that a falling edge on one channel leads to a hold phase of current signal value on the cross linked channel.

This behavior is reached by the following:

A falling edge on e.g. channel (2k) reloads the **DT_DOWN_CNT** with the value of **RELFALL**. While this counter is counting down, the output signal of the cross linked channel (2k+1) keeps its value. If the counter **DT_DOWN_CNT** has reached 0 again, the channel (2k+1) output is released and can follow the value on its input.The timing of the cross channel dead time is depicted in the following figure:

Figure 100 shows the behavior in case of input edges at *DTM_IN[2k]* and *DTM_IN[2k+1]* occur at the same point in time.Then the falling edge is forwarded immediately (with only two clock cycles delay) and the rising edge is delayed additionally by the number of clock ticks specified by the **RELFALL** parameter of the cross linked channel.

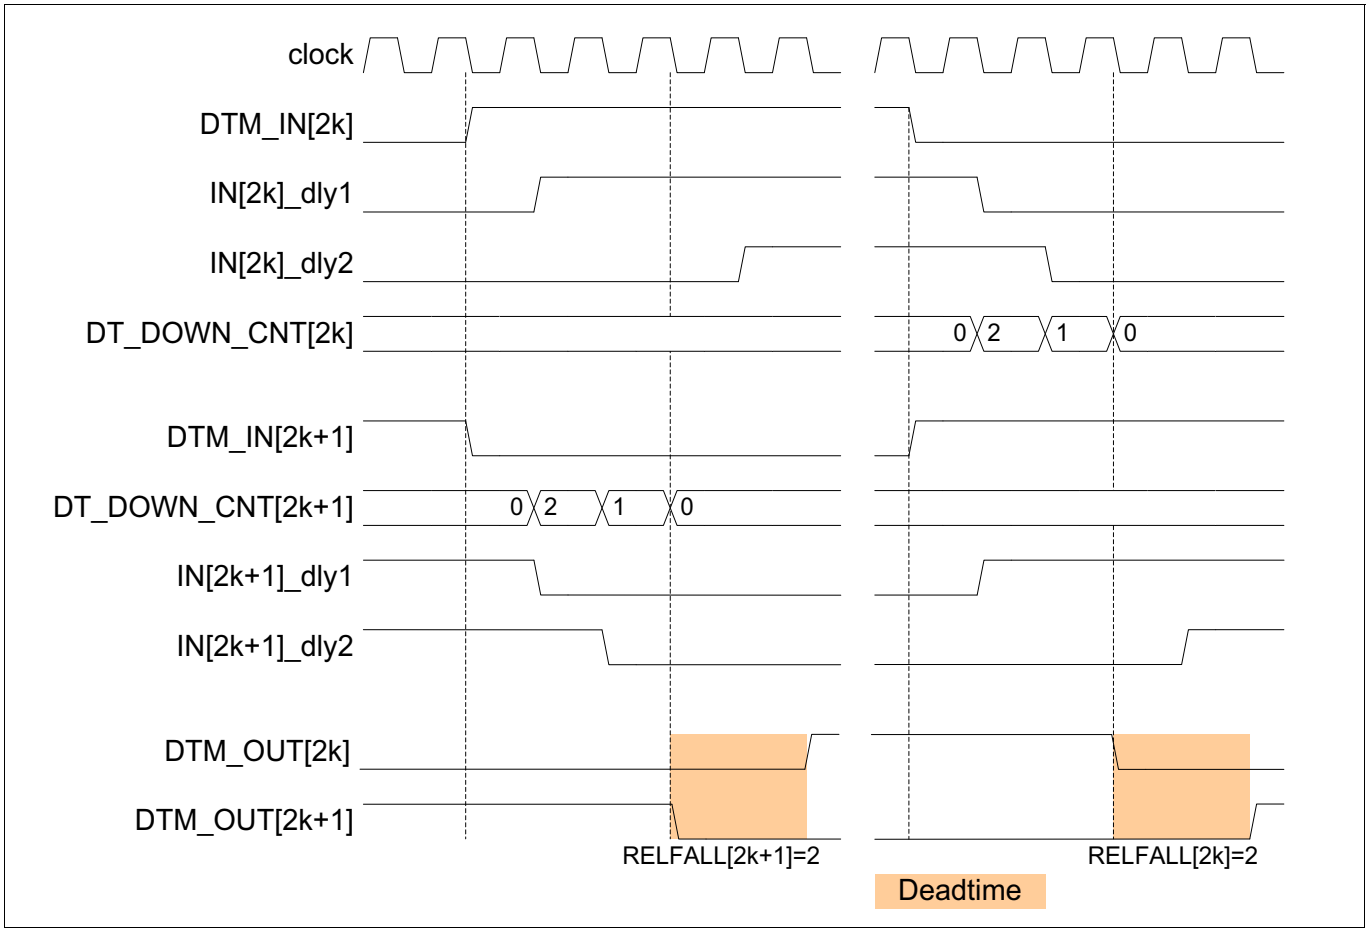

Figure 100 Cross channel dead time timing diagram

In case of high level (i.e. 1) at the DTM inputs *DTM_IN[2k]* and *DTM_IN[2k+1]* at the same point in time, the channel of (2k) has higher priority than the corresponding channel (2k+1). This means that in this case the input *DTM_IN[2k+1]* if forced immediately at channel input to low level (i.e. 0).

As a result the DTM output of channel *DTM_OUT[2k+1]* can never be high if the cross linked channel *DTM_OUT[2k]* is high.

28.16.3 Phase Shift Control Unit

The phase shift unit (DTM_PSU) is depicted in the following figure. It supports the second major function of the DTM module to allow phase shifting of PWM signal on one of the channels.

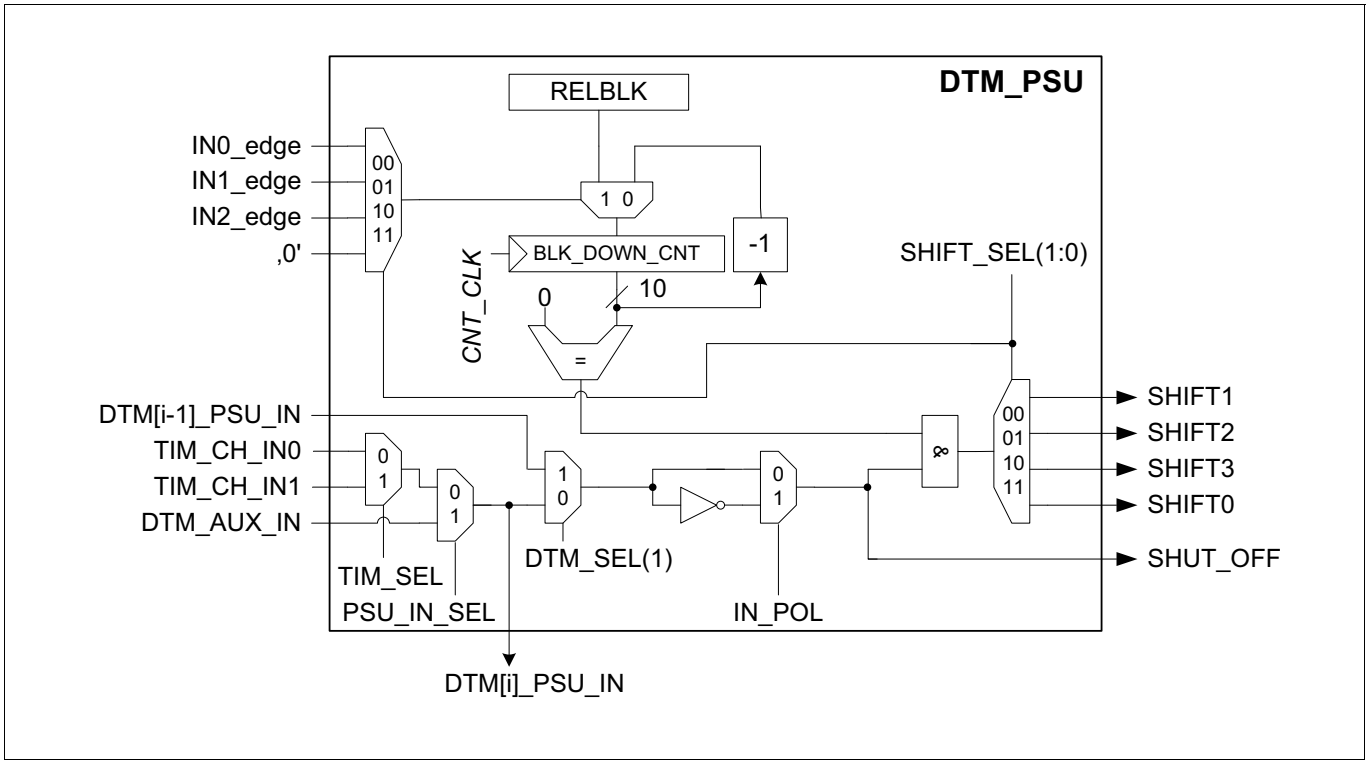

Figure 101 Phase Shift Unit overview

This sub-module provides an additional counter **BLK_DOWN_CNT** and reload register **RELBLK** (bit field of register **DTM[i]_PS_CTRL**). The counter is reloaded on an edge detected on one of the selected signals *IN0_edge* to *IN2_edge* (selected by bit field **SHIFT_SEL** in register **DTM[i]_PS_CTRL**). Then, the counter counts down until it reaches 0. While the counter is counting down, it blocks the trigger (i.e. the selected one of the signals *SHIFT[x]*) of one of the channels by one of the input signals *TIM_CH_IN0, TIM_CH_IN1* or *DTM_AUX_IN*.

If the counter **BLK_DOWN_CNT** is not counting, a pulse on the input *TIM_CH_IN*0, *TIM_CH_IN*1 or *DTM_AUX_IN* is forwarded to one of the selected DTM_PSU outputs *SHIFT[x]*. This signal triggers in the selected channel (if **SH_EN_x**=1) the update of the first flip-flop on channel x (i.e. representing *IN[x]_DLY*) to the input value *DTM_IN[x-1]* of the preceding channel. If this update leads to an edge, the succeeding part of DTM channel derives the inverse signal and applies the corresponding dead time (i.e. the edge delay) to the output signals of the channel.

*Note: For channel x=0 input signals DTM_IN[x-1] is unused and **SH_EN_[x]** is defined as 0.*

Figure 102 shows an example of phase shifting on channel 1.

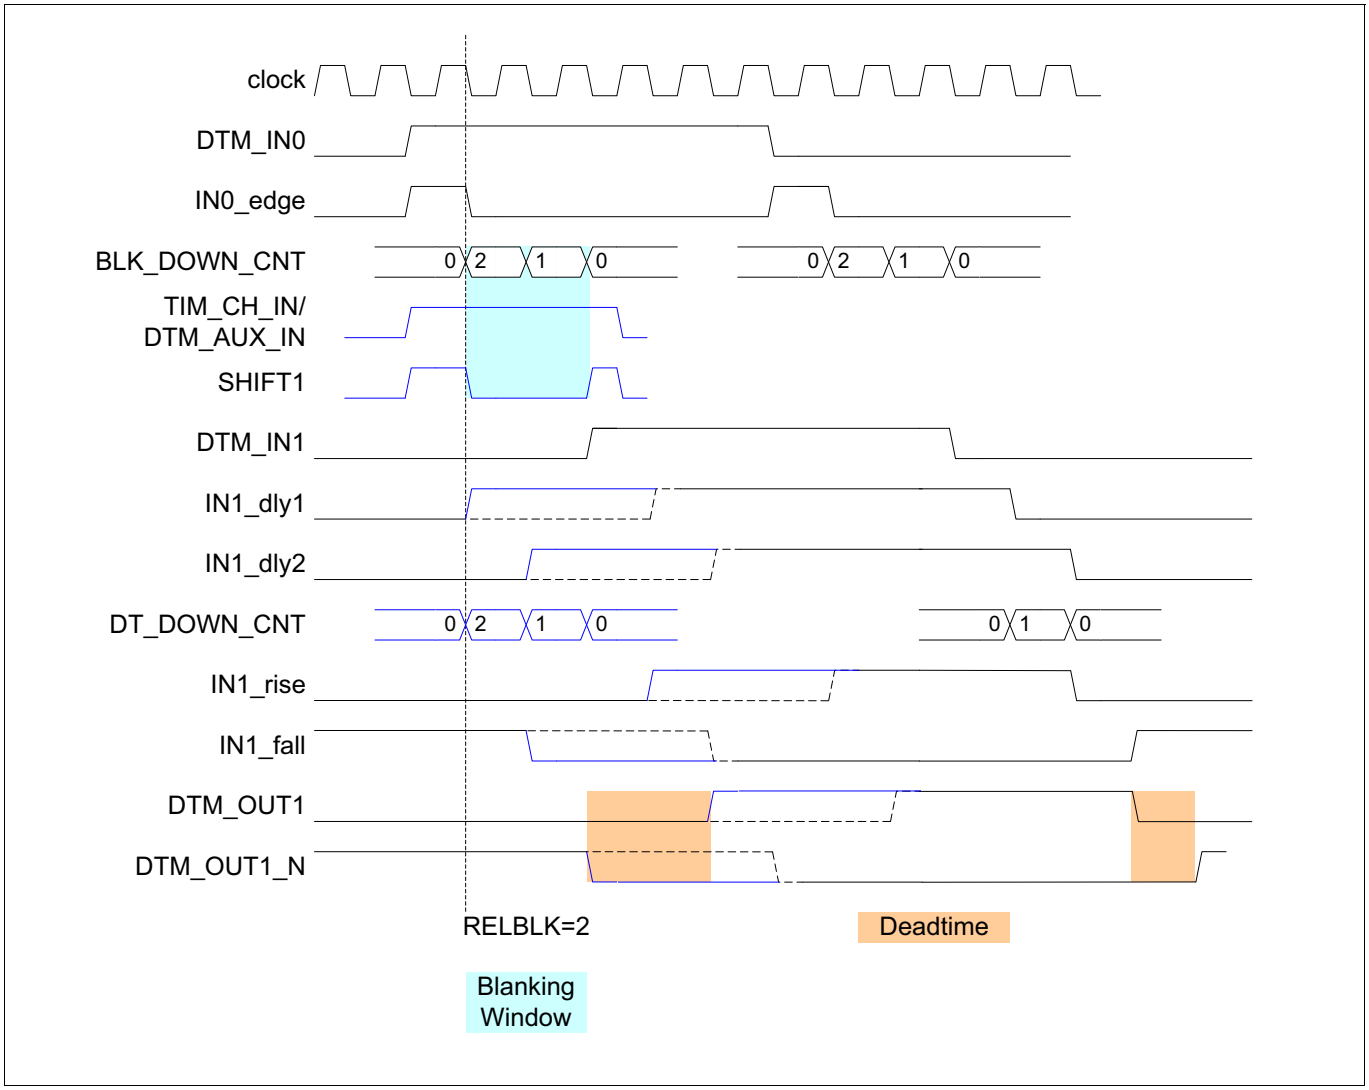

Figure 102 Example wave of phase shift on channel 1

28.16.4 Multiple output signal combination

Each channel provides additionally the possibility to combine the channel inputs *DTM_IN[x]* and *SHIFT[x]* or *COUT[x-1]* (selected by **I1SEL_[x]**) by an AND or an XOR gate (selected by **O1F_[x]**).

It is recommended to use the combination of signals only if bit field **RELBLK** of register **DTM[i]_PS_CTRL** is 0. Otherwise, the signal *TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN* may be disturbed by the blanking window counter.

Together with the inverter inside sub-module DTM_PSU (selected by **IN_POL**), the inverter on each output of a channel (selected by **POL0_[x]**/**POL1_[x]**) and the possibility to change polarity of *DTM_IN[x]* inside connected TOM/ATOM channel, a (N)AND, (N)OR or X(N)OR combination of the signals is possible.

28.16.4.1 Combination of input signal TIM_CH_IN/AUX_IN with TOM/ATOM signal

If the input selection **I1SEL_[x]** of a channel x is set to 0, the output selection **O1SEL_[x]** is set to 1 and **SWAP_[x]** is set to 0, depending on **PSU_IN_SEL** either *TIM_CH_IN0, TIM_CH_IN1* or *DTM_AUX_IN* can be combined with signal *DTM_IN[x]*.

The function of combination on DTM output *DTM[i]_OUT[x]_N* (and also *COUT[x]*) is defined by **O1F_[x]** in the following way:

Table 61 Function of combination on DTM channel x=0 output DTM[i]_OUT[x]_N (and also COUT[x])

	O1F_x	POL1_x	IN_POL	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

*Note: The inversion of the (A)TOM output can be reached by switching the **SL** bit (for TOM and ATOM SOMP/SOMC mode).*

28.16.4.2 Combination of multiple TOM/ATOM output signals

If the input selection **I1SEL_[x]** of a channel x (with x=1…3) is set to 1, the output selection **O1SEL_[x]** is set to 1 and **SWAP_[x]** is set to 0, the output of the preceding DTM channel *COUT[x-1]* can be combined with signal *DTM_IN[x]*.

The function of combination on DTM output *DTM[i]_OUT[x]_N* (and also *COUT[x]*) is defined by **O1F_[x]** in the following way:

Table 62 Function of combination on DTM on channel x=1…3 output DTM[i]_OUT[x]_N (and also COUT[x])

	O1F_x	POL1_x	POL1_x-1	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

By setting **I1SEL_[x]** to 1 on all four channel, a combination of all four signals *DTM_IN0* to *DTM_IN3* can be achieved (combinatorial chain).

To allow also combination of signals generated for output *DTM[i]_OUT[x]*, the outputs 0 and 1 can be swapped by setting bit **SWAP_ [x]** for channel x.

28.16.4.3 Pulse generation on edge

Another feature of the DTM is to generate on the second output *DTM[i]_OUT[x]_N* a pulse on every edge of corresponding input signal *DTM[i]_IN[x]*.

This can be reached by configuring **O1SEL_[x]** to 1, i.e. selecting signal *edge_trigg_[x]* as the output signal (**O1F_[x]** has to be 0b00). The signal *edge_trigg_[x]* is depicted in **Figure 99**.

The pulse length can be adjusted individually for each edge type by the configuration value **REL_RISE** and **REL_FALL** of register **DTM[i]_CH[x]_DV**.

The parameter **REL_RISE** defines the pulse length in case of a rising edge on input *DTM[i]_IN[x]*, the parameter **REL_FALL** define the pulse length in case of a falling edge on input *DTM[i]_IN[x]*.

The generated edge signal *edge_trigg_[x]* can be combined with the output signal of the preceding DTM channel x-1 at channel input *COUT[x-1]* (see **Figure 98**).

With the configuration of **CIS[x]**=1 and **I1SEL_[x]**=1, **CII[x]**=0 and **POL1_[x]**=1, the signal *edge_trigg_[x]* of channel x is ORed with the inverse signal at channel input *COUT[x-1]*. The signal at **COUT[x-1]** can be inverted by changing **POL1_[x-1]** of channel x-1.

As a result of this configuration one can generate at each edge on DTM input *DTM_IN[x]* a pulse signal and OR-combine these generated pulse signals with the generated signal of preceding DTM channel. If the combinatorial chain is configured over all four DTM channel the final signal is available at last DTM output *DTM_OUT3_N*.

28.16.5 Synchronous update of channel control register 2

It is possible to use the shadow register **DTM[i]_CH_CTRL2_SR** and a selected edge of one of the channel 0 to 3 to update the work register **DTM[i]_CH_CTRL2**.

The update mechanism and its configuration are depicted in **Figure 103**.

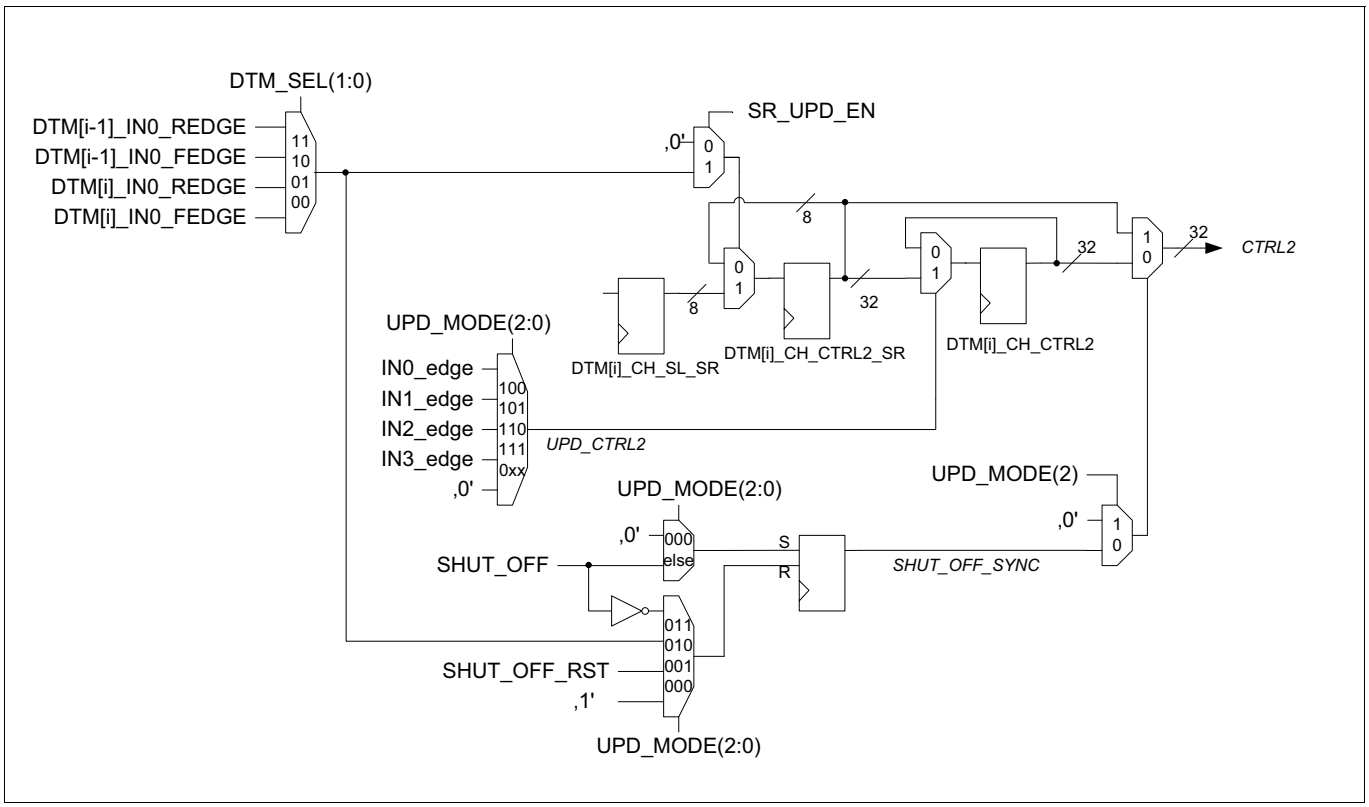

Figure 103 Synchronous update mechanism of register DTM[i]_CH_CTRL2

If enabled by the bit field **UPD_MODE** of register **DTM[i]_CTRL** (i.e. **UPD_MODE**=1xx), the register **DTM[i]_CH_CTRL2_SR** serves as a shadow register of register **DTM[i]_CH_CTRL2**. The update is then triggered by an edge on one of the selected inputs *DTM_IN0* to *DTM_IN3*.

The synchronous update allows the user to change output polarity, the selection of constant signal level, the constant signal level itself and the switch to/from feed through path on all four channels in parallel synchronized to one of the input edges on *DTM_IN0* to *DTM_IN3*.

28.16.6 DTM output shut off

A fast shut off for the eight outputs of DTM instance i can be triggered by one of the two assigned inputs TIM[n]_CH_IN or DTM[i]_AUX_IN or the two inputs TIM[m]_CH_IN or DTM[i-1]_AUX_IN of the previous DTM instance i-1. The selection of the trigger signal source is done by the bits **PSU_IN_SEL** and **DTM_SEL(1)** (see **Figure 101**). The selected trigger signal is named *SHUT_OFF*.

Enabling of the shut off feature is done by setting **UPD_MODE(2:0)** to one of the values 0b001, 0b010 or 0b011.

The shut off behavior of the DTM outputs is defined by the value of register **DTM[i]_CH_CTRL2_SR**.

If the shut off feature is enabled by **UPD_MODE**, as long as the signal *SHUT_OFF_SYNC* is 0, the register **DTM[i]_CH_CTRL2** defines the output signal behavior.

If the signal *SHUT_OFF_SYNC* is 1, the register **DTM[i]_CH_CTRL2_SR** defines the output signal behavior.

The signal *SHUT_OFF_SYNC* is set to 1 if signal *SHUT_OFF* switches to 1.The reset depends on value of **UPD_MODE(2:0)**.

There are three different ways to reset the signal *SHUT_OFF_SYNC* to 0:

- the CPU writes a 1 to bit **SHUT_OFF_RST** of register **DTM_CH_CTRL1**
- synchronous to an edge on DTM channel 0 input of this DTM instance i or on an edge on DTM channel 0 input of preceding DTM instance i-1.
- asynchronous if signal *SHUT_OFF* switches back to 0

Additionally, setting UPD_MODE(2:0) to value 0b000 or 0b1xx resets also the signal SHUT_OFF_SYNC.

Figure 103 depicts the shut off feature and the different shut off release possibilities.

Note: The reset of SHUT_OFF_SYNC has lower priority than the set of this signal.

A second shadow register **DTM[i]_CH_SR** exist for the eight **SL** bits (SLx_y_SR) of the shadow register **DTM[i]_CH_CTRL2_SR**.

If enabled by configuration bit **SR_UPD_EN** of register **DTM[i]_CTRL**, the update of **SL** bits of register **DTM[i]_CH_CTRL2_SR** can be triggered by one of the signals selected by bit field **DTM_SEL** of register **DTM[i]_CTRL**. This trigger signal is either the rising or the falling edge detected on *DTM[i]_IN0* of instance i or the rising or the falling edge on *DTM[i-1]_IN0* of preceding instance i-1.

As depicted in **Figure 95** the DTM input signal *TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN* can be forwarded to the succeeding instance. Thus, it can be used to trigger shut off in two consecutive DTM instances.

28.16.7 DTM connections on GTM top level

The DTM, if present, is placed behind the outputs of a TOM or ATOM. The outputs of the DTM are routed directly to the top level ports of GTM.If there is a DTM placed behind a TOM or ATOM depends on the GTM device configuration.

In case of a DTM behind a TOM or ATOM, the outputs (A)TOM_OUT and (A)TOM_OUT_T are connected to DTM inputs DTM_IN and DTM_IN_T. The outputs of the DTM are routed directly to the top level of GTM.The behavior of DTM after reset is shown in **Figure 104**.

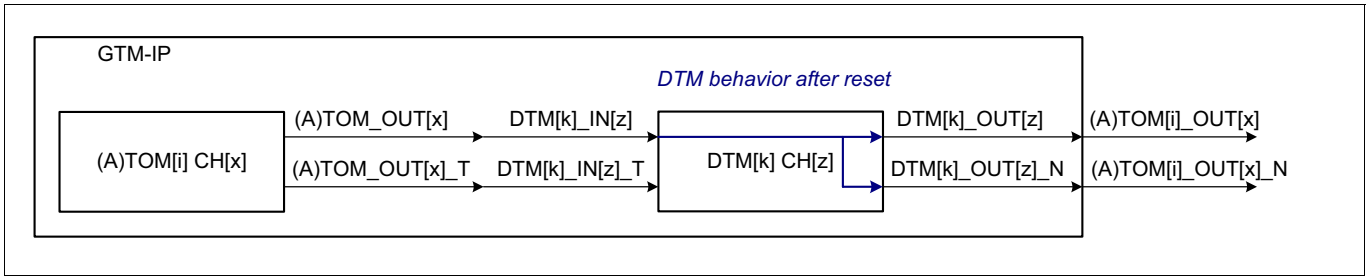

Figure 104 DTM behavior after reset

To route the signal *DTM[k]_IN[z]_T* to the DTM output DTM_[k]_OUT[z]_N, the following DTM channel configuration has to be chosen:

O1F_[x] = 11, **O1SEL_[x]**=1 and **DT1_[x]**=1.

The signals names and the signal routing in the case of no DTM instance is placed behind a TOM or ATOM is shown in **Figure 105**.

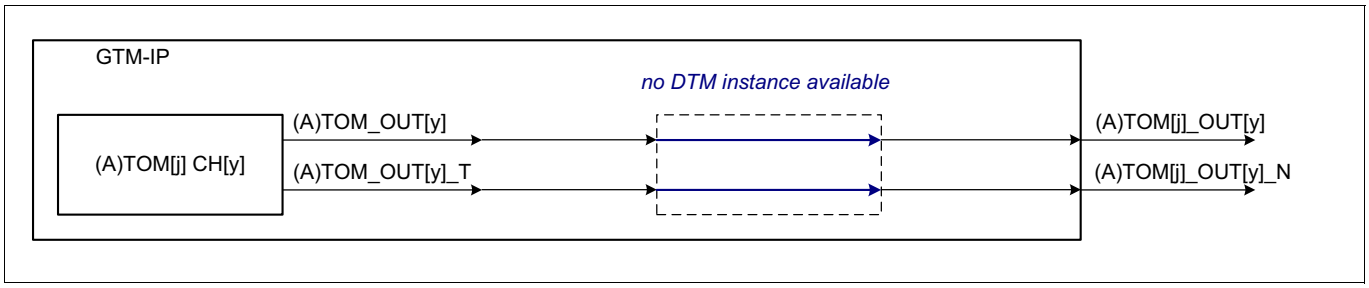

Figure 105 (A)TOM output signal routing in case of no DTM instance available

28.17 Multi Channel Sequencer (MCS)

28.17.1 Overview

The Multi Channel Sequencer (MCS) sub module is a generic data processing module that is connected to the ARU. One of its major applications is to calculate complex output sequences that may depend on the time base values of the TBU and are processed in combination with the ATOM sub module. Other applications can use the MCS sub module to perform extended data processing of input data resulting from the TIM sub module. Moreover, some applications may process data provided by the CPU within the MCS sub module, and the calculated results are sent to the outputs using the ATOM sub modules.

*** 'Generic Design Parameters' on page 348 *** summarizes all available generic design parameters of the MCS hardware structure.

Table 64 Generic Design Parameters

Design Parameter	Description
W	Word width of the data path
T	Number of available MCS channels
RDW	RAM data width of connected RAM
RAW	RAM address width used by the MCS for addressing memory
USR	Use second RAM port (0 - one RAM port available, 1 - two RAM ports available)
BAW	Bus Master Address Width
BDW	Bus Master Data Width
URIP	Use RAM input pipeline registers (0 - no register, 1 - use register)
UROP	Use RAM output pipeline registers (0 - no register, 1 - use register)
UDP	Use Decoder Pipeline register (0 - no register, 1 - use register)
UAP	Use ALU Pipeline register (0 - no register, 1 - use register)
NPS	Total number of pipeline stages (with NPS = 3 + URIP + UROP + UDP + UAP)

All MCS instances in the GTM use the values T=8, W=24, RDW=32, RAW=12, USR=1, BAW = 14, BDW = 32, URIP = 1, UROP = 1, UDP = 1, UAP = 1, and NPS = 7.

28.17.2 Architecture

Figure 106 gives an overview of the MCS architecture assuming that all pipeline registers are implemented.

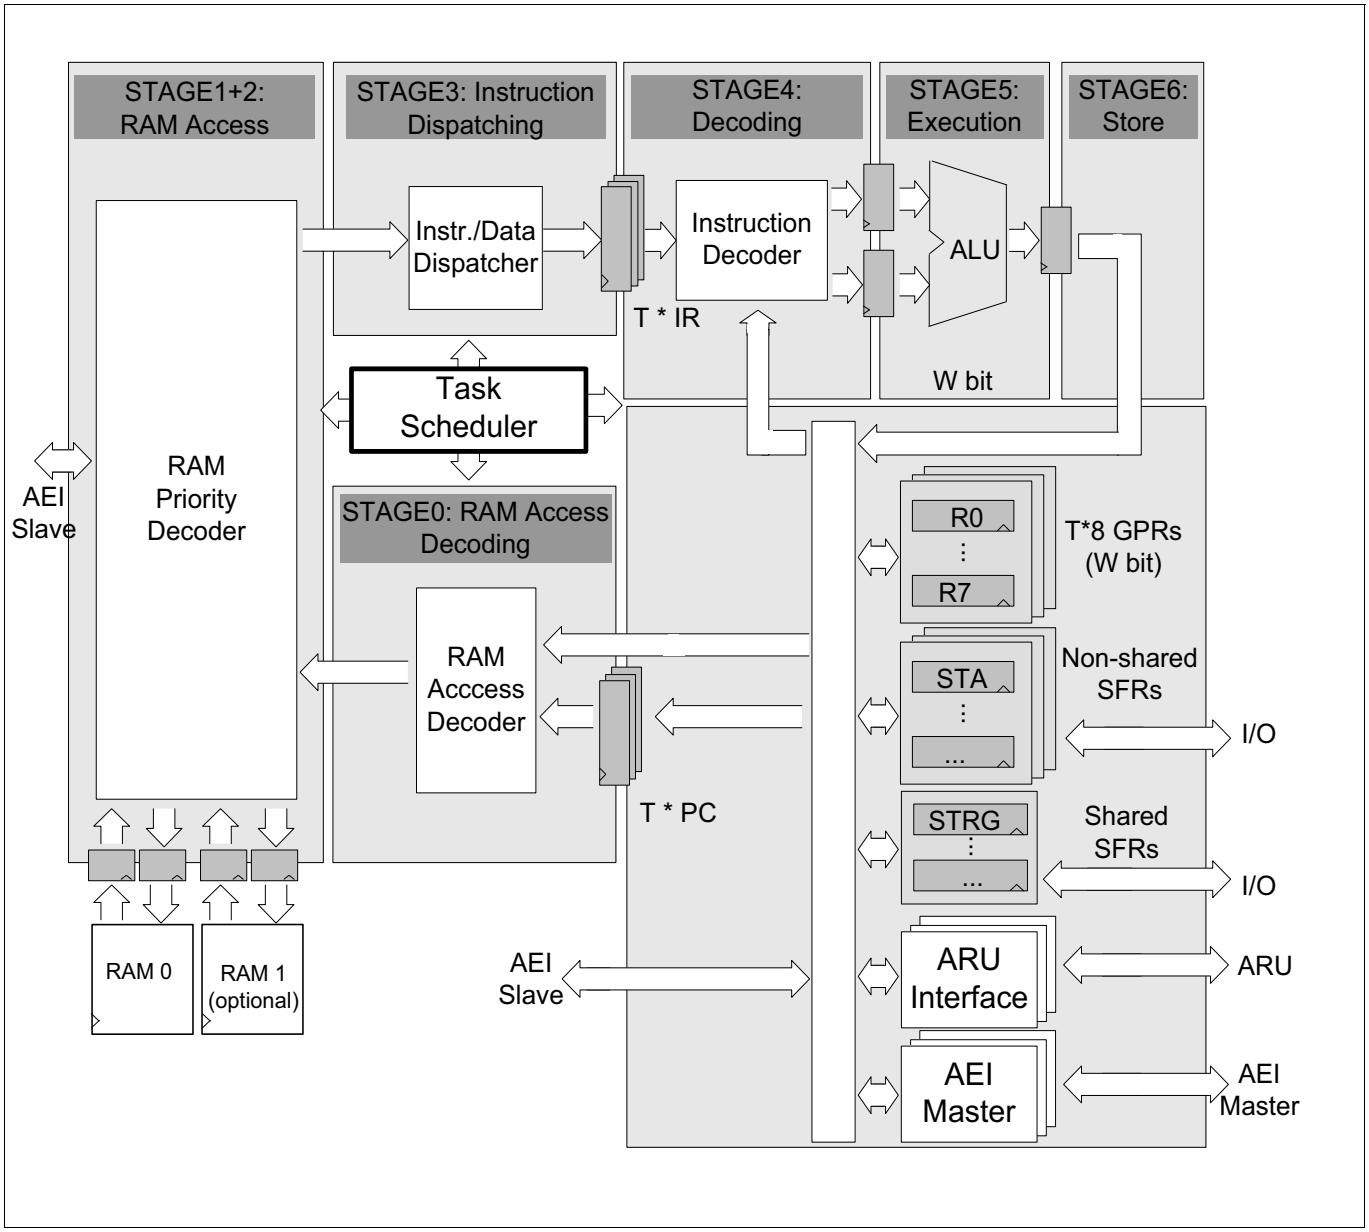

Figure 106 MCS Overview

The data path of the MCS is shared by T so called MCS channels, whereas each MCS channel executes a dedicated micro-program that is stored inside the RAM connected to the MCS module.

The connected RAM may contain arbitrary sized code and data sections that are accessible by all MCS channels and an externally connected master (e.g. a CPU) via AEI Slave interface. More details about the RAM can be found in **Section 28.17.4**

An MCS channel can also be considered as an individual task of a processor that is scheduled to the commonly used data path at a specific point in time. The execution of the different MCS channels on the different pipeline stages is controlled by a central hardware related task scheduler, which enables immediate task switches in parallel to the program execution. Details about the task scheduler and the available scheduling algorithms can be found in **Section 28.17.3**.

Typically, if data has to be exchanged between different MCS channels and/or the CPU, the connected RAM, which is accessible by all MCS channels and the CPU, can be used.

Besides the commonly used data path, each MCS channel has:

- a set of eight General Purpose Registers (GPRs), each W bit wide,
- a set of non-shared Special Function Registers (SFRs) that are only accessible within a dedicated MCS channels.
- a set shared SFRs that are accessible by all MCS channels,
- a channel specific instruction register (IR),
- a channel specific program counter register (PC),
- a dedicated ARU interface for communication with other ARU connected modules,
- and an AEI Bus Master Interface for controlling and configuration of other GTM sub modules.

Generally, the GPRs of an MCS channel x are only accessible by its corresponding MCS channel x. However, the MCS provides a configuration that allows an MCS channel x to access the GPRs of its successor MCS channel x+1. This feature can be used to enlarge the number of registers for a specific MCS channel x and/or to exchange data between neighboring channels.

For safety reasons, the register **MCS[i]_REG_PROT** can be used to define write protections for the neighboring registers of the individual MCS channels.

In order to enable synchronization between different MCS channels and/or the CPU, the MCS provides a common 24 bit wide trigger register that can be accessed as a shared SFR by all MCS channels located in the same module. Writing to **STRG** sets bits and writing to **CTRG** clears bits in the common trigger register. To enable triggering of MCS channels by CPU, the CPU can set bits in the common trigger register by writing to **MCS[i]_STRG** and clear bits by writing to **MCS[i]_CTRG**.

Considering the architecture in the figure above and assuming that all available pipeline stages are implemented (the generic parameters URIP, UROP, UDP, and UAP are set to 1), the main actions of the different pipeline stages are as follows:

- Pipeline stage 0 performs a setup of address, input data, and control signals for the next RAM access of a specific MCS channel.
- The actual RAM access of a specific MCS channel is executed in pipeline stage 1 and 2, assuming an external connection of a synchronous RAM with a latency of one clock cycle.
- Pipeline stage 3 performs pre-decoding and dispatching of instructions and data resulting from the RAM.
- In pipeline stage 4 the instructions are decoded and data from the registers are loaded.
- After that, in pipeline stage 5 the instruction is executed meaning that arithmetic operations are applied.
- Finally, in pipeline stage 6 the calculated results are stored in the registers.

If any of the pipeline registers is not implemented, the adjacent pipeline stages are merged and thus processed within the same clock cycle.

The RAM priority decoder arbitrates RAM accesses that are requested by the CPU via AEI and by the active MCS channel. If both, CPU and an MCS channel request a memory access to the same memory module the MCS channel is prioritized.

Since the internal registers of the MCS can be updated by different sources (MCS write access by various instructions, CPU write access via AEI slave, MCS write access by neighboring channel) a write conflict occurs if more than one source wants to write to the same register. In this case the result of the register is unpredictable. However, the software should setup its application in a way that such conflicts do not occur.

One exception is the common trigger register, which may be written by multiple sources (different MCS channels and CPU) in order to enable triggering of different MCS channels. Typically, the software should setup its application in a manner that different sources should not write the same bits in the trigger register.

28.17.3 Scheduling

The MCS provides a hardware related task scheduler, which globally controls the execution of the tasks in the different pipeline stages. The task scheduler implements four different scheduling modes, that can be selected by the **SCD_MODE** bit field in the **MCS[i]_CTRL_STAT** register. Depending on the selected scheduling mode, the task scheduler is selecting a dedicated MCS channel that will be executed in pipeline stage 0 in the next clock cycle. Additionally, MCS channels that are already present in the pipeline are shifted to its successor pipeline stage, with each clock cycle. This means, that the execution time of an MCS channel in a specific pipeline stage is always one clock cycle.

The MCS task scheduler may also schedule an empty cycle to pipeline stage 0, in order to grant a time slice to the CPU for accessing the connected RAM.

It should be noted, if the task scheduler assigns an MCS channel to pipeline stage 0, but this channel does not access the RAM, the CPU can access the corresponding RAM, even if the scheduler did not reserve an empty clock cycle.

In the following, the available scheduling modes are described.

28.17.3.1 Round Robin Scheduling

The Round Robin Scheduling Mode implements the simplest scheduling algorithm. This algorithm schedules a predefined set of MCS channels in the range [0; **SCD_CH**] in ascending order. After the last channel **SCD_CH** has been assigned to the pipeline, an empty cycle is scheduled in order to enable RAM access for the CPU. The parameter **SCD_CH** can be controlled by the register **MCS[i]_CTRL_STAT**. If the value of **SCD_CH** is greater than T-1, the scheduler assumes a value of T-1 for bit field **SCD_CH**.

Figure 107 shows a timing example of the Round Robin Scheduling with T=8 MCS channels (marked as C_0 to C_7) that are scheduled together with a CPU access to a pipeline with and NPS=7 stages. It is assumed that bit field **SCD_CH** is set to 7.

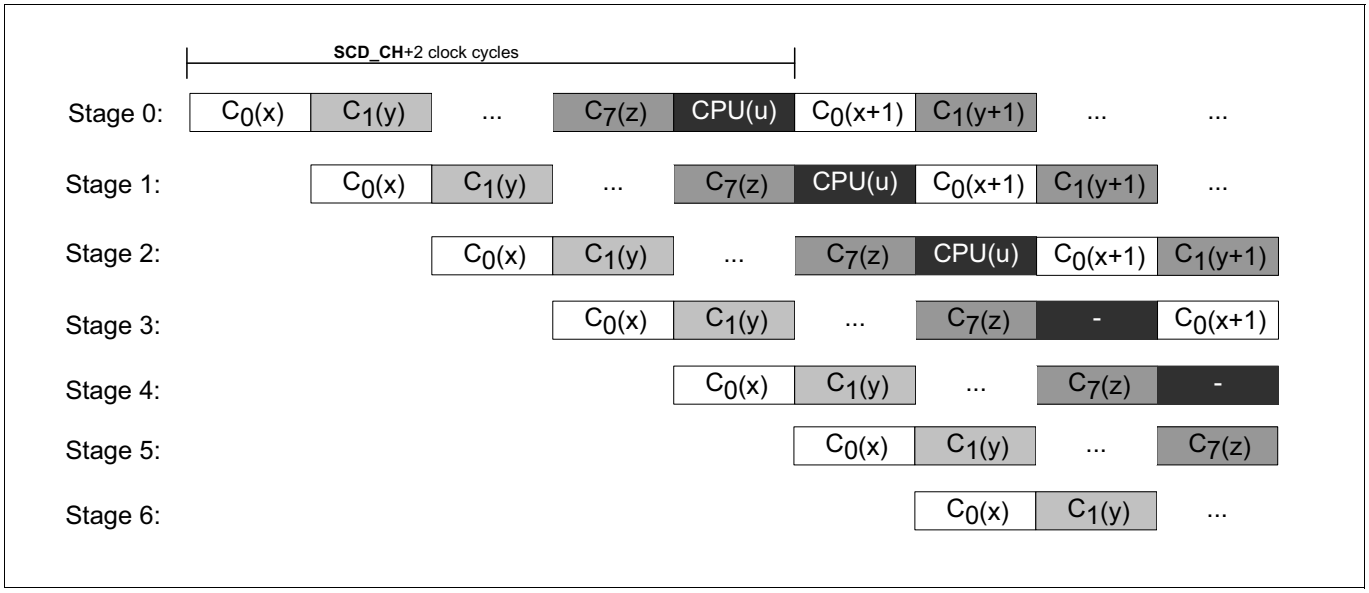

Figure 107 Timing of Round Robin Scheduling

The identifier $C_i(x)$ denotes that MCS channel i is currently executing the instruction or data located in the memory at position x in the corresponding pipeline stage. The figure shows, which MCS channel is activated in specific pipeline stage at a specific point in time.

Moreover, the figure shows that the Round Robin scheduling is always repeated after **SCD_CH**+2 clock cycles, which means that the time duration of an instruction cycle is **SCD_CH**+2 clock cycles. However, if the value

SCD_CH + 2 is less than NPS, the duration of an instruction cycle is limited by the depth of the pipeline to NPS clock cycles. Thus the effective execution time of a single cycle instruction is always MIN(**SCD_CH**+2, NPS) clock cycles, ignoring the latency of the pipeline.

If NPS is greater than T+1, NPS-T-1 additional empty cycles are inserted at the end of a round trip cycle. In this case the round trip time for the scheduler is determined by NPS, and thus the time duration for an instruction cycle is always NPS clock cycles.

The Round Robin scheduling algorithm has the characteristic that it fairly distributes all time slices to all MCS channels and the CPU. This means, that the program execution time of a specific task is independent from the activity of any neighboring task or the CPU RAM access, and thus a correct estimation of the actual program execution time is very easy. However, the round-robin scheduling may waste clock cycles by scheduling MCS channels that are not ready to execute an instruction (e.g. MCS channel is disabled by CPU). The following scheduling modes overcome this issue.

28.17.3.2 Accelerated Scheduling

In order to improve the computational performance, the accelerated scheduling mode provides two key features. Firstly, the scheduler only selects MCS channels that are not suspended and thus can actually execute an instruction. Secondly, the scheduler applies instruction prefetching to minimize empty cycles in the pipeline. An MCS channel is entering suspended state due to one of the reasons:

- An MCS channel is executing a read or write request to an ARU connected sub module (instruction ARD, AWR, ARDI, AWRI, NARD, NARDI).
- An MCS channel is executing a read or write request at its bus master interface (instruction BRD, BWR, BRDI, BWRI).
- An MCS channel waits on a register match event (e.g. instruction WURM), in order to wait on a desired register value (e.g. trigger event from another MCS channel).
- An MCS channel is disabled.

In the case of instruction prefetching, the scheduler will assign an MCS channel C_p to pipeline stage 0, which is already present in another pipeline stage. This means, that the execution of the last instruction of C_p located in the memory MEM(PC/4) is not yet finished completely, whereas PC is the current value of the program counter of MCS channel C_p. Thus, the newly scheduled MCS channel C_p will prefetch a successor instruction MEM(PC/4+PFO) under the assumption that there will be no branch and no memory access in the program between the instructions MEM(PC/4) and MEM(PC/4+PFO). The prefetch offset value PFO is determined by counting the number of already scheduled MCS channels Cp in the pipeline. However, if the assumption fails, the pipeline will be flushed by replacing all MCS channel C_p of the pipeline with an empty cycle, as soon as the instruction decoder detects a branch or a memory access. All other MCS channels unequal to MCS channel C_p within are not affected by the flushing action. The flushing action is always synchronized to the last pipeline stage NPS-1.

Besides the flushing conditions mentioned above, there exist also other conditions that cause a flush of the pipeline for a specific MCS channel. In the following all possible flushing events are summarized:

- An MCS channel is enabled.
- An MCS channel is entering a suspended state.
- An MCS channel is taking a conditional or unconditional branch (instruction JMP, JBS, JBC, CALL, RET, JMPI, JBSI, JBCI, CALLI).
- An MCS channel accessing memory for data transfer (instruction MRD, MWR, MRDI, MWRI, MRDIO, MWRIO, MWRL, MWRIL, PUSH, POP).
- An MCS channel is executing a read or write request at its bus master interface (instruction BRD, BWR, BRDI, BWRI).

- An MCS channel is modifying the trigger register (write access to **CTRG** or **STRG**) and the same channel is reading back this register (read access to **CTRG** or **STRG**) while the delay between both accesses is less than UAP+UDP+1 clock cycles.

In general, each MCS channel can accept instruction prefetching. However, there are some cases in which an upcoming flushing of the pipeline can be easily detected by the MCS hardware due to evaluation of internal states. Therefore, it is defined that an MCS channel accepts instruction prefetching only under the following conditions:

- An MCS channel is currently not in the second cycle of a two-cycle control flow instruction (instruction CALL, RET).
- An MCS channel is currently not in the second cycle of a three-cycle memory access instruction (instruction MWRL, MWRIL).

The accelerated scheduling mode guarantees, that the time duration of an instruction cycle varies between 1 and T+1 cycles. Hence, a single cycle instructions has an effective execution time between 1 to T+1 clock cycles, depending on the number of suspended MCS channels and the actual instruction sequence. The worst case execution time occurs if all channels are active and the CPU also accesses the RAM. The best case occurs e.g. if only one MCS channel is enabled and the executed program sequence has only linear code without branches and memory access.

The algorithm of the accelerated scheduling mode first, evaluates the state of all available MCS channels as well as a CPU request to the RAMs and then it decides if a specific MCS channel or an empty cycle is assigned to pipeline stage 0 in the next clock cycle. It should be noted that the accelerated scheduling mode treats RAM access requests from the CPU in a similar manner as MCS channels, which means that empty cycles for RAM requests are only inserted into the pipeline if there is an active RAM request from the CPU or no other task can be scheduled.

In order to fairly trade all available MCS channels as well as CPU RAM requests and to guarantee a worst case execution time of T+1 clock cycles, an additional task prioritization scheme is applied used that dynamically prioritizes all MCS channels and a CPU memory access depending on the history of the scheduler's decisions. The algorithm of the accelerated scheduler mode is executed every clock cycle and it works in the following manner:

1. Try to find an MCS channel C_r with highest priority that is not suspended and not already scheduled to the pipeline stages 0 to NPS-2. If C_r is found assign C_r to pipeline stage 0 and finish scheduling for current clock cycle.
2. Otherwise, try to find an MCS channel C_p with highest priority that is not suspended and accepts instruction prefetching. If C_p is found assign C_p to pipeline stage 0 and finish scheduling for current clock cycle.
3. Otherwise, try to find an MCS channel C_s with highest priority that is suspended and accepts instruction prefetching. If C_s is found assign C_s to pipeline stage 0 and finish scheduling for current clock cycle.
4. Otherwise, assign an empty cycle to pipeline stage 0 and finish scheduling for current clock cycle.

The underlying task prioritization scheme tracks the history of the scheduled MCS channels in a list consisting of T+1 items. The list is initialized with all MCS channels followed by a reserved time slot for the CPU RAM access. The position of an MCS channel within this list implicitly defines the priority, while the back of this list holds the MCS channel with highest priority. Whenever the scheduling algorithm described above has found an MCS channel C_r or C_p to be scheduled in the next clock cycle, it removes this item from the list and put it to the front of the list. In order to fairly prioritize all MCS channels, the algorithm also removes the item at the back of the list to the second position in the list, after the inserted scheduled front item. Since the list always contains all possible MCS channels and with each clock cycles each nonscheduled item is moved at least one position towards the end of list, it is obvious that each MCS channel will have the highest priority not later than T+1 clock cycles.

Figure 108 shows a timing example of the accelerated scheduling with NPS=7 pipeline stages.

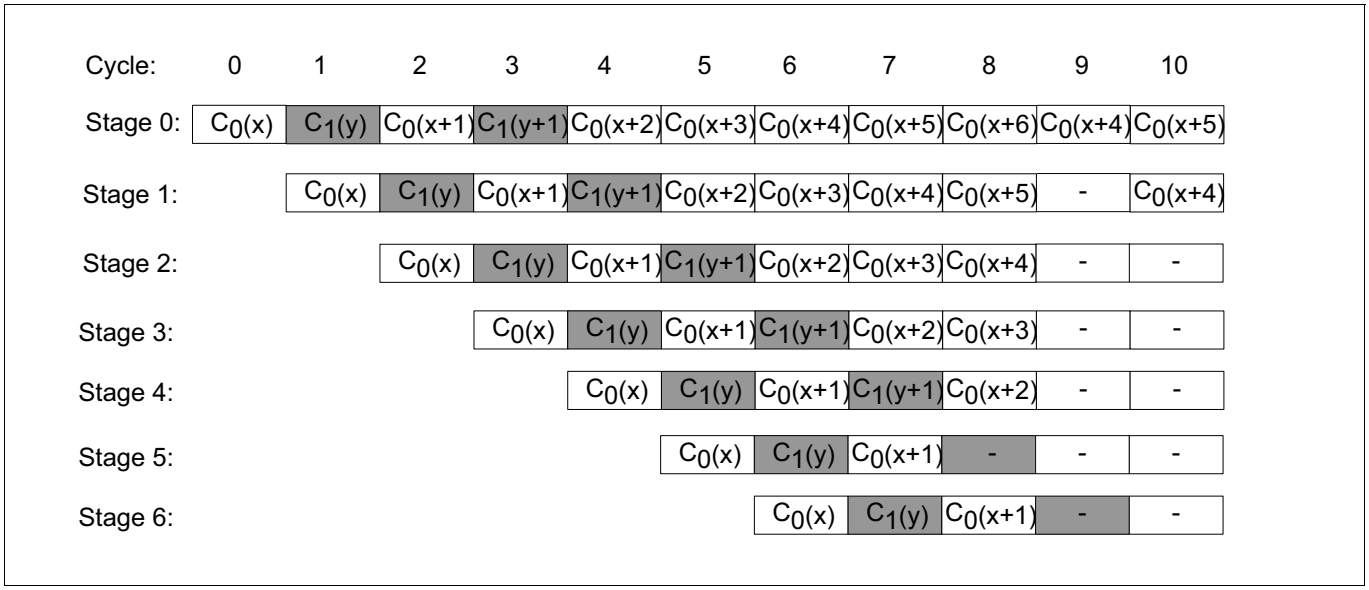

Figure 108 Timing of Accelerated Scheduling

The example assumes that initially MCS channels 0 and 1 are enabled and the program for each MCS channel is located in the RAM as shown in *** 'MCS Code example for Accelerated Scheduling' on page 354 ***.

MCS-Channel 0

Memory Location	Instruction
x+0	ADDL R0, 7
x+1	JBC STA, Z, 4*(x+4)
x+2	MOVL R2, 5

MCS-Channel 1

Memory Location	Instruction
y+0	WURM STRG, R1, 0
y+1	ADDL R2, 5
y+2	ADD R3, R2

Figure 109 MCS Code example for Accelerated Scheduling

Since both channels are ready to run, the scheduler fairly selects the channels in an alternating order, as it can be obtained in stage 0 at the clock cycles before cycle 5. Since MCS channel 1 is entering suspended state (to wait on a trigger bit) at cycle 7 in stage 6 with the instruction of memory location y, the scheduler will only select MCS channel 0 in the following by applying instruction prefetching. Moreover, entering the suspended state in channel 1 also flushes the remaining channels 1 out of the pipeline. But it should be noted, the scheduler applies instruction prefetching during the whole sequence, due to the fact that the number of enabled channels is always less than the available number of pipeline stages NPS.

The actual state of pipeline in cycle 9 and 10 depends on conditional branch instruction of memory location x + 3 (cycle 8 stage 6). If the branch is not taken, the linear code execution of MCS channel 0 is continued. However, if the branch to memory location x+4 is taken, as shown in the Figure, the scheduler will fetch the instruction C0(x+4) in cycle 9 at stage 0 and flush the stages 1 to NPS-1. Note, the flushing of the pipeline only concerns the prefetched instructions of the MCS channel that is currently executed in the last stage. If pipeline stage 1 of cycle 9 would belong to another channel than 0, only the stages greater than 2 would have been flushed.

28.17.3.3 Single Prioritization Scheduling

The Single Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization of a single MCS channel. In this mode, the bit field **SCD_CH** of register **MCS[i]_CTRL_STAT** is used to identify a dedicated MCS channel that is always preferred during scheduling. This

means, that the scheduler will assign preferred MCS channel **SCD_CH** to pipeline stage 0, as long as this channel is not suspended. If the preferred MCS channel is entering its suspended state, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 28.17.3.2**. Whenever the MCS channel **SCD_CH** is resuming from its suspended state, the scheduler switches back and assign the channel **SCD_CH** to pipeline stage 0 until the next suspension event occurs. If the bit field **SCD_CH** contains the value T or higher, the task scheduler will always prioritize CPU access to the RAM. This means, whenever the task scheduler detects that the CPU wants to access an MCS-RAM, the scheduler will assign an empty cycle into pipeline stage 0. If the CPU does not access the RAM any more, it switches back to the accelerated mode, as described previously in **Section 28.17.3.2**.

In consequence, the Single Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS channels, since it strongly depends on the activity of the prioritized MCS channel **SCD_CH**. However, the Single Prioritization Scheduling mode provides the fastest possible execution for MCS channel **SCD_CH**. Moreover, during the time spawn, in which the prioritized MCS channel **SCD_CH** is suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

28.17.3.4 Multiple Prioritization Scheduling

The Multiple Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization for multiple MCS channels. In this mode, the bit field **SCD_CH** of register **MCS[i]_CTRL_STAT** is used to identify a set of dedicated MCS channels, which are always preferred during scheduling. The identifiers of the prioritized MCS channels are in the range [0; **SCD_CH**] and the non-prioritized channels are in the range [**SCD_CH**+1; T-1]. The individual priority for the set of prioritized MCS channels is applied in descending order, which means that MCS channel 0 has the highest priority, followed MCS channel 1, which has the second highest priority, and so on. The non-prioritized MCS channels do not have any priority. A value of T-1 or higher for the bit field **SCD_CH** means that all T MCS channels are prioritized MCS channels.

With each clock cycle, the Multiple Prioritization Scheduling mode will assign the non-suspended MCS channel with the highest priority from the set of prioritized MCS channels to pipeline stage 0, as long as there are non-suspended prioritized MCS channels available. If all prioritized MCS channels are suspended, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 28.17.3.2** and it schedules the non-prioritized channels. Whenever a prioritized MCS channel is resuming from its suspended state, the scheduler switches back and applies the described prioritization scheme until the next suspension event of occurs.

In consequence, the Multiple Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS channels, since it strongly depends on the activity of the prioritized MCS channels. However, the Multiple Prioritization Scheduling mode provides the fastest possible execution for prioritized MCS channels. Moreover, during the time spawn, in which all prioritized MCS channels are suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

28.17.4 Memory Organization

The MCS module supports a memory layout of up to $2^{RAW+USR}$ memory locations each RDW bit wide leading to a maximum byte wise address range from 0 to $2^{RAW+USR+2}$-1.

If two RAM ports are used (USR = 1) the entire address space of the MCS is divided into two seamless memory pages. Further, if the GTM provides a memory configuration sub module (MCFG), memory page 0 begins from (byte wise) address 0 and ranges to address MP0-4 and memory page 1 ranges from MP0 to MP1-4, while MP0 and MP1 are configuration parameters provided by MCFG.

The RAM priority decoder of the MCS will always handle a RAM access from an MCS channel with a higher priority compared to a RAM access from AEI.

However, if a set of active MCS channels are only accessing one common RAM port, the MCS will grant any AEI accesses to the other RAM port in parallel to the related RAM accesses of the running MCS channels, which means that AEI may get the full bandwidth to a dedicated RAM.

Basically, the actual access time to the RAMs via AEI depends on the actual scheduling mode and the activity of tasks. In the modes Round Robin Scheduling and Accelerated Scheduling the scheduler guarantees a maximum write access time of T + 4 clock cycles and a maximum read access time of T + 6 clock cycles. In the scheduling modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, the scheduler cannot guarantee a maximum access time for AEI RAM access.

Depending on the silicon vendor configuration, the connected RAM pages are initialized with zeros in the case of an MCS module reset.

If an ECC Error occurs while an MCS channel reads data from a memory module, the corresponding MCS channel is disabled and the ERR bit in register STA is raised.

If the GTM sub module CCM provides several so called address range protectors (ARPs), some code and data sections of the MCS RAM can be write protected. If an MCS channels x writes to such a protected memory region, the MCS channel x is halted, the **ERR** bit in register **STA** is set and the bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT** is updated.

28.17.5 AEI Bus Master Interface

The MCS module provides an AEI bus master interface, which enables to communicate with externally connected modules. The data width of this interface is BDW bit and the address width is BAW bit leading to a maximum byte wise address ranging from 0 to 2^{BAW+2}-1. The bus master interface is shared among all available MCS channels meaning that each MCS channel may initiate a read or write access on the bus but only one channel can be served at a specific point in time.

However, the AEI bus master interface guarantees, that a bus access is always completed within two instruction cycles and bus access of different MCS channels do not modify the latency of each other. The only exceptions are bus accesses to RAM modules (e.g. accessing memory location in a DPLL RAM or FIFO RAM). AEI bus master accesses to RAM modules cannot be completed within a single clock cycle and thus additional wait cycles have to be inserted into the bus protocol leading to the fact that the MCS channel that is accessing the RAM is entering a suspended state. Moreover, if an MCS channel is accessing a RAM module, the latency of a bus access in another MCS channel can also be modified even if the neighboring channel is accessing only a configuration register.

The AEI bus master interface of an MCS module is connected to AEI slave interface GTM-IP in order to control the sub modules of the GTM within MCS. However, it is not possible to access the entire GTM by a single MCS module. The n-th MCS instance can only access the GTM sub modules that are located within the n-th cluster of the GTM. Details about the available clusters of the GTM can be found inside the “GTM Architecture” Overview chapter.

Additionally, the address map for accessing GTM with the AEI bus master interface of an MCS differs from the address map for an externally connected CPU that is using the GTM's AEI slave interface. The address map for accessing GTM with the AEI bus master interface of an MCS can be found in device specific appendix.

Since the sub modules of the GTM can be accessed by the CPU and the AEI bus master of an MCS, the GTM-IP provides an additional arbitration scheme to manage parallel accesses from both master interfaces. If CPU and an MCS want to access a GTM sub module of the same cluster, the arbiter will grant the access to the MCS. However, if the CPU and all the MCS instances want to access GTM sub modules of different clusters, the accesses can be executed in parallel.

The AEI bus master interface can be controlled by the MCS instructions BRD, BRDI, BWR, and BWRI. These instructions are described in **Section 28.17.7**.

28.17.6 ADC Interface

The clusters of the GTM can optionally provide a dedicated interface for the connection of up to 32 external Analog-Digital-Converter (ADC) channels, which can be mapped arbitrarily to physical instances of single- or multi-channel ADCs.

An ADC Interface is directly mapped into the address map of the AEI bus master interface of the current cluster's MCS meaning that the available AEI bus master instructions (BRD and BRDI as described in **Section 28.17.7**) are used to control the connected ADCs.

Since the control of the connected ADCs is silicon vendor specific, the GTM specification does not provide a complete specification for controlling connected ADCs. However, to ensure software compatibility at least for the basic features of an ADC, the functionality described in the following are common to all silicon vendors.

28.17.6.1 Basic ADC Functions

The address map of the AEI bus master interface reserves two unique address items for each ADC channel. The address items can be referred by the labels **ADC_CH[y]_DATA** and **ADC_CH[y]_STA** for the channel y in the range from 0 to 31. The actual address can be found in the appendix.

The MCS can read from address **ADC_CH[y]_DATA** in order to get the conversion result of the ADC that is connected to ADC channel y. The conversion result is represented as a signed 24 bit value and it is stored in the register A (A $\in$ GREG) as referred by the corresponding MCS instruction BRD or BRDI. Additionally, each read access to **ADC_CH[y]_DATA** triggers the ADC that is connected to channel y. Any read access to **ADC_CH[y]_DATA** also provides 8 status bits that are stored in register **MHB**. The bit **MHB**[7] has always the mnemonic **ADC_ACK** and the bit **MHB**[6] has always the mnemonic **ADC_DATA_DATA**. If bit **ADC_ACK** is set the result of the data conversion (register A) and the corresponding status bits (bits **MHB**[6:0]) are validated. If **ADC_NEW_DATA** is set the current conversion result is new and has never been read by a previous bus read access. The meaning of the bits **MHB**[5:0] are vendor specific. Otherwise, if **ADC_ACK** is cleared the read data is invalid and the **MHB**[4:0] indicate the channel identifier (with **MHB**[4:0] <> y) that is currently processed by the ADC. A write access to **ADC_CH[y]_DATA** has no functionality and is always ignored.

The MCS can read from address **ADC_CH[y]_STA** to get additional 31-bit wide vendor specific status information of ADC channel y. The lower 24 bits of the status information is stored in register A (A $\in$ GREG) as referred by the corresponding MCS instruction BRD or BRDI. The upper 7 bit of the status information is stored in register **MHB**[6:0]. The bit **MHB**[7] has always the mnemonic **ADC_ACK**. If bit **ADC_ACK** is set the result of status information in register A and bits **MHB**[6:0] are validated. Otherwise, if **ADC_ACK** is cleared the status information is invalidated. A write access to **ADC_CH[y]_STA** has no functionality and is always ignored.

Any read or write access to a register **ADC_CH[y]_STA** or ADC_CH[y]_DATA updates the AEI status signal that is evaluated in the sub module CCM. The following status information is defined for the AEI status values:

- 00_B: no error occurred
- 01_B: optional information register not implemented (only register **ADC_CH[y]_STA**)
- 10_B: illegal ADC access (e.g. ADC not enabled)
- 11_B: unsupported address (ADC channel y not available)

Note: *Note: If the received status AEI is unequal to "00" ADC_NEW_DATA is always set and ADC_ACK is always cleared.*

28.17.7 Instruction Set

This section describes the entire instruction set of the MCS sub module. First, a brief overview over all available instructions is given and a detailed description of each instruction can be found in **Section 28.17.7.1** and the following sections.

In general, each instruction is RDW bit wide but the duration of each instruction varies between several instruction cycles. As already described in **Section 28.17.3**, the number of required clock cycles for an instruction cycle can be fixed or variable, depending on the selected scheduling mode. In the case of the Round Robin Scheduling, the duration is fixed with T+1 clock cycles, in the case of the Accelerated Scheduling the duration is variable in the range between 1 and T+1 clock cycles, and in all other Scheduling modes the duration is also variable and may even be more than T+1 clock cycles, depending on the application.

Before the available instructions are described, some commonly used terms, abbreviations and expressions are introduced:

OREG: The operation register set OREG = {R0, R1…R7} || {STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, MHB} include all MCS accessible internal channel specific GPRs {R0, R1…R7} and the sub set {STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TDU_TS2, MHB} of SFRs.

XOREG: The extended operation register set XOREG = OREG || {RS0, RS1…RS7} || {GMI0, GMI1, DSTA, DSTAX} extends the operation registers set OREG by the GPRs of the succeeding MCS channel {RS0, RS1… RS7} and the SFRs {GMI0, GMI1, DSTA, DSTAX}.

WXREG: The extended wait instruction operation register set WXREG = OREG || {GMI0, GMI1, DSTA, DSTAX} extends the operation registers set OREG by the SFRs {GMI0, GMI1, DSTA, DSTAX}.

AREG: The ARU register set AREG = {R0, R1, R2…R7, ZERO} includes the all registers that can be written by incoming ARU transfers (ARD, ARDI, NARD, and NARDI instructions). These registers include all eight general purpose registers. The dummy register ZERO may be used to discard an incoming 24 bit ARU word.

GREG: The general purpose register set GREG = {R0, R1, R2…R7} includes the all channel specific GPRs without GPRs of neighboring channels.

BAREG: The base address register set BAREG = OREG || {RS0, RS1…RS7} extends the register set OREG by the GPRs of neighboring channels.

Note: If the extended operation register set XOREG is disabled (bit **EN_XOREG** of register **MCS[i]_CTRL_STAT** is cleared) the sets **XOREG**, **WXREG**, and **BAREG** only contains the operation register set OREG.

Note: In the following, the register sets **OREG**, **XOREG**, **GREG, WXREG**, **BAREG** and **AREG** are referred by the instructions. Typically, an operation announces W data bits. Whenever, a register of a register set implements less than W bits, it is assumed that these register bits only define the LSBs of an operation. The missing MSBs are always read and written as zeros.

WLIT: The set WLIT = {0,1…2^{W}-1} is a W bit wide literal value used for encoding immediate operands.

ALIT: The set ALIT = {0,1…$2^{RAW+USR}$-1} is a RAW + USR bit wide literal value used for encoding memory addresses.

AOLIT: The set AOLIT = {-$2^{RAW+USR-1}$…-1,0,1…$2^{RAW+USR-1}$-1} is a RAW + USR bit wide literal value used for encoding relative memory address offsets.

ARDLIT: The set ARDLIT = {0,1…2^{9}-1} is a 9 bit literal used for ARU read addresses.

AWRLIT: The set AWRLIT = {0,1…23} is used as ARU write indexes, selecting one of the 24 ARU write address.

BALIT: The set BALIT = {0,1…2^{BAW}-1} is a BAW bit wide literal used for encoding bus master addresses.

SFTLIT: The set SFTLIT = {0,1…W} is used as literal value for shift instructions.

BWSLIT: The set BWSLIT = {1…W} is used as literal value for multiplication instructions.

BITLIT: The set BITLIT = {0,1…15} is a 4 bit literal used for bit indexing.

XBITLIT: The set XBITLIT = {0,1…W-1} is a literal used for bit indexing of register bits.

MSKLIT: The set MSKLIT = {0,1…2^{15}-1} is a 16 bit literal used for bit-masking.

BIT SELECTION: The expression VAR[i] represents the i-th bit of a variable VAR.

BIT RANGE SELECTION: The expression VAR[m:n] represents the bit slice of variable VAR that is ranging from bit n to bit m.

MEMORY ADDRESSING: The expression MEM(X) represents the RDW bit wide value at location x (x ∈ ALIT) of the memory. The expression MEM(x)[m:n] represents the bit slice ranging from bit n to m of the RDW bit wide word at memory location x.

ARU ADDRESSING: In the case of ARU reading, the expression ARU(x) represents the 2*W+5 bit wide ARU word of ARU channel at read address x (x ∈ ARDLIT). In the case of ARU writing, the expression ARU(x) represents a 2*W+5 bit wide ARU word that is written to an ARU channel indexed by the index x (x ∈ AWRLIT). The index x selects a single ARU write channel from the pool of the MCS sub module's allocated ARU write channels. An MCS sub module has 24 dedicated ARU write channels, indexed by values 0 to 23. The expression ARU(x)[m:n] represents the bit slice ranging from bit n to m of the 2*W+5 bit wide ARU word.

BUS MASTER ADDRESSING: In the case of reading/writing from the bus master interface, the expression BUS(x) represents the BDW bit wide data word that is read/written at address x (x ∈ BALIT). The expression BUS(x)[m:n] represents the bit slice ranging from bit n to m of the BDW bit wide data word at the bus.

Figure 110 ff. summarize the entire instruction set of the MCS and **Table 113** ff. shows the encoding of the individual instructions.

	NOP		1	No Operation

Footnotes:

1) Not faster than 1+NPS clock cycles due to pipeline flushing.
2) Not faster than 1+2*NPS clock cycles due to pipeline flushing.
3) Not faster than NPS clock cycles due to pipeline flushing.
4) If the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.
5) Not faster than 2*NPS clock cycles due to pipeline flushing.
6) If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles.
7) Always faster than one ARU round trip cycle.
8) Suspends current MCS-channel if addressed slave inserts at least one wait cycle otherwise 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.
9) Not faster than C+NPS-1 clock cycles due to pipeline flushing.
10) Not faster than C+3+NPS clock cycles due to pipeline flushing.

Figure 114 Instruction Codes (part 2)

The individual instructions are decoded by evaluating the bits '0' and '1' at its expected positions, as mentioned in the table above. If the instruction decoder detects an invalid combination of these bits, the corresponding MCS channel is disabled and the ERR bit in the register STA is set. Bit positions marked as '-' are not relevant for the instruction. The bit position 'a', 'b', and 'c' are reserved for binary encoding of the instruction arguments A, B, and C.

Moreover, each instruction can set the **ERR** bit of register **STA** and stop the program execution, if a register write protection of an associated MCS channel is activated by the register **MCS[i]_REG_PROT**. This behavior is not explicitly mentioned in the instruction descriptions below. If an error occurs due to a write access to a protected register, it is ensured that the protected register is not overwritten. However, it is not ensured that other operations (e.g. PC updates) of the bad instruction are executed.

28.17.7.1 MOVL Instruction

Syntax	Operation	Status	Duration
MOVL A, C	A ← C	Z	1 instruction cycle

Transfer literal value C (C ∈ WLIT) to register A (A ∈ OREG).

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.2 MOV Instruction

Syntax	Operation	Status	Duration
MOV A, B	A ← B	Z	1 instruction cycle

Transfer register B (B ∈ XOREG) to register A (A ∈ XOREG).

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.3 MRD Instruction

Syntax	Operation	Status	Duration
MRD A, C	A ← MEM(C)[W-1:0]; MHB ← MEM(C)[RDW-1:W]	Z	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer the lower W bits of memory content at location C (C ∈ ALIT) to register A (A ∈ OREG).

The upper RDW-W bits of the memory content at location C are transferred to the MHB register.

The zero bit Z of status register STA is set, if the lower W bits of the transferred value are zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW-W-1 of the referred memory location are transferred to MHB.

The program counter PC is incremented by the value 4.

28.17.7.4 MWR Instruction

Syntax	Operation	Status	Duration
MWR A, C	MEM(C)[W-1:0] ← A; MEM(C)[RDW-1:W] ← MHB	-	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer W bit value of register A (A ∈ OREG) together with the MHB register to the memory at location C (C ∈ ALIT).

The W bit value of register A is stored in the LSBs (bit 0 to W-1) of the memory location.

The MHB register is stored in bits W to RDW-W-1 of the referred memory location.

The program counter PC is incremented by the value 4.

28.17.7.5 MWRL Instruction

Syntax	Operation	Status	Duration
MWRL A, C	MEM(C)[W-1:0] ← A	-	3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Transfer W bit value of register A (A ∈ OREG) to memory at location C (C ∈ ALIT).

The W bit value of register A is stored in the LSBs (bit 0 to W-1) of the memory location and the bits W to RDW-W are left unchanged.

The program counter PC is incremented by the value 4.

It should be noted that this operation is not an atomic instruction.

28.17.7.6 MRDI Instruction

Syntax	Operation	Status	Duration
MRDI A, B [, C]	A ← MEM(B[RAW+USR+1:2] + C)[W-1:0] MHB ← MEM(B[RAW+USR+1:2] + C)[RDW-1:W]	Z	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer the bits 0 to W-1 of a memory location to register A (A ∈ OREG) using indirect addressing.

The upper RDW-W bits of this memory location are transferred to MHB register.

The memory location where to read from depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as B[RAW+USR+1:2] + C.

If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C.

The zero bit Z of status register STA is set, if the transferred bits 0 to W-1 are zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW-W-1 of the referred memory location are transferred to MHB.

The program counter PC is incremented by the value 4.

28.17.7.7 MRDIO Instruction

Syntax	Operation	Status	Duration
MRDIO A, B	A ← MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[W-1:0] MHB ← MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[RDW-1:W]	Z	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer the bits 0 to W-1 of a memory location to register A (A ∈ XOREG) using indirect addressing with offset calculation.

The upper RDW-W bits of this memory location are transferred to MHB register.

The memory location where to read from depends on register B (B ∈ BAREG) and register R5 and it is defined as B[RAW+USR+1:2] + R5[RAW+USR+1:2].

The zero bit Z of status register STA is set, if the transferred bits 0 to W-1 are zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A, the bits 0 to RDW-W-1 of the referred memory location are transferred to MHB.

The program counter PC is incremented by the value 4.

28.17.7.8 MWRI Instruction

Syntax	Operation	Status	Duration
MWRI A, B [, C]	MEM(B[RAW+USR+1:2] + C)[W-1:0] ← A; MEM(B[RAW+USR+1:2] + C)[RDW-1:W] ← MHB	-	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer value of register A (A ∈ OREG) to the LSBs 0 to W-1 of a memory location using indirect addressing.

The MHB register is moved to the bits W to RDW-1 at the same memory location.

If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C.

The memory location where to write to depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as B[RAW+USR+1:2] + C.

The program counter PC is incremented by the value 4.

28.17.7.9 MWRIO Instruction

Syntax	Operation	Status	Duration
MWRIO A, B	MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[W-1:0] ← A; MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[RDW-1:W] ← MHB	-	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer value of register A (A ∈ XOREG) to the LSBs 0 to W-1 of a memory location using indirect addressing with offset calculation.

The MHB register is moved to the bits W to RDW-1 at the same memory location.

The memory location where to write to depends on register B (B ∈ BAREG) and register R5 and it is defined as B[RAW+USR+1:2] + R5[RAW+USR+1:2].

The program counter PC is incremented by the value 4.

28.17.7.10MWRIL Instruction

Syntax	Operation	Status	Duration
MWRIL A, B	MEM(B[RAW+USR+1:0])[W-1:0] ← A;	-	3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Transfer W bit value of A (A ∈ OREG) to memory using indirect addressing.

The memory location where to write to is defined by the bits 2 to RAW+1 of register B (B$\in$ OREG).

The W bit value is stored in the LSBs (bit 0 to W-1) of the memory location and the bits W to RDW-1 are left unchanged.

The program counter PC is incremented by the value 4.

It should be noted that this operation is not an atomic instruction.

28.17.7.11 POP Instruction

Syntax	Operation	Status	Duration
POP A	A ← MEM(R7[RAW+USR+1:2])[W-1:0]; MHB ← MEM(R7[RAW+USR+1:2])[RDW-1:W]; R7 ← R7 - 4; SP_CNT ← SP_CNT - 1	Z, EN	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Transfer the LSBs (bit 0 to W-1) from the top of stack to register A (A$\in$ OREG), followed by decrementing the stack pointer register R7 with the value 4.

The upper bits W to RDW-1 from the top of the stack are transferred to register MHB.

If the MHB register is selected as destination register A (A$\in$ OREG), the bits 0 to RDW-W-1 from the top of the stack are transferred to MHB.

The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register R7.

The zero bit Z of status register STA is set, if the lower W bit of the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

The **SP_CNT** bit field inside the **MCS[i]_CH[x]_CTRL** register is decremented.

If an underflow on the **SP_CNT** bit field occurs, the STK_ERR[i]_IRQ is raised.

If an underflow on the **SP_CNT** bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL** is set, the current MCS channel is disabled by clearing the **EN** bit of **STA**.

28.17.7.12 PUSH Instruction

Syntax	Operation	Status	Duration
PUSH A	R7 ← R7 + 4; MEM(R7[RAW+USR+1:2])[W-1:0] ← A; MEM(R7[RAW+USR+1:2])[RDW-1:W] ← MHB SP_CNT ← SP_CNT + 1;	EN	2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Increment the stack pointer register R7 with the value 4, followed by transferring a W bit value of operand A (A$\in$ OREG) together with a MHB register to the new top of the stack. The W bit value of A is stored in the bits 0 to W-1 of the memory location.

The content of the MHB register is stored in the bit W to RDW-1 of the memory location.

The memory location for the top of the stack is referred by the bits 2 to RAW+1 of the stack pointer register.

The program counter PC is incremented by the value 4.

The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is incremented.

If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the current MCS channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the memory write operation for the A and MHB is discarded.

28.17.7.13ARD Instruction

Syntax	Operation	Status	Duration
ARD A, B, C	A ← ARU(C)[W-1:0]; B ← ARU(C)[2*W-1:W]; ACB ← ARU(C)[4+2*W:2*W]	CAT, SAT	Suspends current MCS channel until ARU transfer finished.

Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A $\in$ AREG, B $\in$ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.

If A and B refer to the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discarded.

If any transferred W bit value from the ARU should not be stored in a register, the dummy register ZERO $\in$ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.

The received ARU control bits are stored in the register ACB.

The literal C (C $\in$ ARDLIT) define the ARU address where to read from.

At the beginning of the instruction execution the CAT bit in register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.

The program counter PC is incremented by the value 4.

28.17.7.14ARDI Instruction

Syntax	Operation	Status	Duration
ARDI A, B	A ← ARU(R6[8:0])[W-1:0]; B ← ARU(R6[8:0])[2*W-1:W]; ACB ← ARU(R6[8:0])[4+2*W:2*W]	CAT, SAT	Suspends current MCS channel until ARU transfer finished.

Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A $\in$ AREG, B $\in$ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.

If A and B refer to the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discarded.

If any transferred W bit value from the ARU should not be stored in a register, the dummy register ZERO $\in$ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.

The received ARU control bits are stored in the register ACB.

The read address is obtained from the bits 0 to 8 of the channels register R6.

At the beginning of the instruction execution the CAT bit in register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.

The program counter PC is incremented by the value 4.

28.17.7.15AWR Instruction

Syntax	Operation	Status	Duration
AWR A, B, C	ARU(C)[W-1:0] ← A; ARU(C)[2*W-1:W] ← B; ARU(C)[4+2*W:2*W] ← ACB;	CAT, SAT	Suspends current MCS channel until ARU transfer finished.

Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A$\in$ OREG, B$\in$ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.

The ARU control bits are taken from the register ACB.

The literal C (C$\in$ AWRLIT) defines an index into the pool of ARU write addresses that are used for writing data. This index is mapped to an ARU write address as shown in column "MCS write index" of table "ARU Write Addresses" in device specific appendix.

Each MCS sub module has a pool of several write addresses that can be shared between all MCS channels arbitrarily.

At the beginning of the instruction execution the CAT bit of the register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.

The program counter PC is incremented by the value 4.

28.17.7.16AWRI Instruction

Syntax	Operation	Status	Duration
AWRI A, B	ARU(R6[4:0])[W-1:0] ← A; ARU(R6[4:0])[2*W-1:W] ← B; ARU(R6[4:0])[4+2*W:2*W] ← ACB;	CAT, SAT	Suspends current MCS channel until ARU transfer finished.

Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A$\in$ OREG, B$\in$ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.

The ARU control bits are taken from the register ACB.

The bits 0 to 4 of the register R6 define an index into the pool of ARU write addresses that are used for writing data. This index is mapped to an ARU write address as shown in column "MCS write index" of table "ARU Write Addresses" in device specific appendix.

Each MCS sub module has a pool of several write addresses that can be shared between all MCS channels arbitrarily.

At the beginning of the instruction execution the CAT bit of the register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.

The program counter PC is incremented by the value 4.

28.17.7.17NARD Instruction

Syntax	Operation	Status	Duration
NARD A, B, C	A ← ARU(C)[W-1:0]; B ← ARU(C)[2*W:W]; ACB ← ARU(C)[4+2*W:2*W]	SAT	Suspends current MCS channel until the ARU is selecting the MCS channel.

Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A$\in$ AREG, B$\in$ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits.

The literal C (C$\in$ ARDLIT) defines the ARU address where to read from.

Non-blocking ARU read means that the instruction is suspending the MCS channel until the ARU scheduler is selecting the requesting MCS channel.

If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at the requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.

If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO$\in$ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.

The program counter PC is incremented by the value 4.

28.17.7.18NARDI Instruction

Syntax	Operation	Status	Duration
NARDI A, B	A ← ARU(R6[8:0])[W-1:0]; B ← ARU(R6[8:0])[2*W-1:W]; ACB ← ARU(R6[8:0])[4+2*W:2*W]	SAT	Suspends current MCS channel until the ARU is selecting the MCS channel.

Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A$\in$ AREG, B$\in$ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits. The read address is obtained from bits 0 to 8 of the channel register R6.

Non-blocking ARU read access means that the instruction suspends the MCS channel until the ARU scheduler selects the requesting MCS channel. If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at the requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper W bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO$\in$ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.

The program counter PC is incremented by the value 4.

28.17.7.19BRD Instruction

Syntax	Operation	Status	Duration
BRD A, C	A ← BUS(C)[W-1:0]; MHB ← BUS(C)[BDW-1:W]	-	Suspends current MCS channel if addressed slave inserts at least one wait cycle (e.g. accessing RAM module) otherwise 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Initiate a read access at the bus master interface using the address C (C $\in$ BALIT) and transfer the lower W bits of the received data to register A (A $\in$ GREG).

The upper BDW-W bits of the received data are transferred to the MHB register.

If the delay between a BRD instruction and its successor instruction is one or two system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is reading data resulting from the BRD instruction, a data hazard in the pipeline occurs resulting in a pipeline flush. this means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like BRD R1,0x288; ADD R3,R1 (9 clock cycles) can be accelerated by reformulating the sequence as BRD R1,0x0288; NOP;NOP;NOP;ADD R3,R1; (4 clock cycles).

Since the MHB register is always transferred via AEI bus master it also figures out another data dependency, which can cause a data hazard resulting in a pipline flush. Therefore a sequence like BRD R1, 0x0288; BWR R3, 0x304 (9 clock cycles) could also be optimized by the sequence BRD R1, 0x0288; NOP; NOP; BWR R3, 0x304(4 clock cycles).

The program counter PC is incremented by the value 4.

28.17.7.20BWR Instruction

Syntax	Operation	Status	Duration
BWR A, C	BUS(C)[W-1:0] ← A; BUS(C)[BDW-1:W] ← MHB	-	Suspends current MCS channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 cycle.

Initiate a write access at the bus master interface using the address C (C $\in$ BALIT) and transfer the content of register A (A $\in$ GREG) to the bits 0 to W-1 of the bus.

The content of the MHB register is transferred to the bits W to BDW-W-1 of the bus.

The program counter PC is incremented by the value 4.

28.17.7.21BRDI Instruction

Syntax	Operation	Status	Duration
BRDI A, B	A ← BUS(B[BAW+1:2])[W-1:0]; MHB ← BUS(B[BAW+1:2])[BDW-1:W]	-	Suspends current MCS channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 clock cycles.

Initiate a read access at the bus master interface using indirect addressing and transfer the lower W bits of the received data to register A (A $\in$ GREG).

The upper BDW-W bits of the received data are transferred to the MHB register.

The address for the transfer is identified by the bits 2 to BAW+1 of register B (B$\in$ GREG).

If the delay between a BRDI instruction and its successor instruction is one or two system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is reading data resulting from the BRDI instruction, a data hazard in the pipeline occurs resulting in a pipeline flush. this means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like BRD I R1,R6; ADD R3, R1 (9 clock cycles) can be accelerated by reformulating the sequence as BRDI R1, R6; NOP; NOP; NOP; ADD R3, R1; (4 clock cycles).

Since the MHB register is always transferred via AEI bus master it also figures out another data dependency, which can cause a data hazard resulting in a pipline flush. Therefore a sequence like BRDI R1, R2; BWRI R3, R4 (9 clock cycles) could also be optimized by the sequence BRDI R1, R2; NOP; NOP; BWRI R3, R4 (4 clock cycles).

The program counter PC is incremented by the value 4.

28.17.7.22BWRI Instruction

Syntax	Operation	Status	Duration
BWRI A, B	BUS(B[BAW+1:2])[W-1:0] ← A; BUS(B[BAW+1:2])[BDW-1:W] ← MHB	-	Suspends current MCS channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 instruction cycle.

Initiate a write access at the bus master interface using the indirect addressing and transfer the content of register A (A$\in$ GREG) to the bits 0 to W-1 of the bus.

The content of the MHB register is transferred to the bits W to BDW-W-1 of the bus.

The address for the transfer is identified by the bits 2 to BAW+1 of register B (B$\in$ GREG).

The program counter PC is incremented by the value 4.

28.17.7.23ADDL Instruction

Syntax	Operation	Status	Duration
ADDL A, C	A ← A + C	Z, CY, N, V	1 instruction cycle

Perform addition operation of a register A (A$\in$ OREG) with a W bit literal value C (C$\in$ WLIT) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow/underflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and C are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and C are signed values within the interval [-2^{W-1}; 2^{W-1}-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.24ADD Instruction

Syntax	Operation	Status	Duration
ADD A, B	A ← A + B	Z, CY, N, V	1 instruction cycle

Perform addition operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG). The result is stored in the register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.25ADDC Instruction

Syntax	Operation	Status	Duration
ADDC A, B	A ← A + B + CY	Z, CY, N, V	1 instruction cycle

Perform addition operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG) and the carry flag CY. The result is stored in the register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [$-2^{W.1}$; 2^{W-1}-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.26SUBL Instruction

Syntax	Operation	Status	Duration
SUBL A, C	A ← A - C	Z, CY, N, V	1 instruction cycle

Perform subtraction operation of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT). The result is stored in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and C are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and C are signed values within the interval [-2^{W-1}; 2^{W-1}-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.27SUB Instruction

Syntax	Operation	Status	Duration
SUB A, B	A ← A - B	Z, CY, N, V	1 instruction cycle

Perform subtraction operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG). The result is stored in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^W-1; 2^W-1-1], assuming that both operands A and B are signed values within the interval [-2^W-1; 2^W-1-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.28SUBC Instruction

Syntax	Operation	Status	Duration
SUBC A, B	A ← A - B - CY	Z, CY, N, V	1 instruction cycle

Perform subtraction operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG) and the carry flag CY. The result is stored in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2W-1], assuming that both operands A and B are unsigned values within the interval [0; 2W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.29NEG Instruction

Syntax	Operation	Status	Duration
NEG A, B	A ← - B	Z, N, V	1 instruction cycle

Perform negation operation (2's Complement) with an operand B (B $\in$ XOREG) and store the result in a register A (A $\in$ XOREG).

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval $[-2^{W-1}; 2^{W-1}-1]$, assuming that both operands A and B are signed values within the interval $[-2^{W-1}; 2^{W-1}-1]$.

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

28.17.7.30ANDL Instruction

Syntax	Operation	Status	Duration
ANDL A, C	A ← A AND C	Z	1 instruction cycle

Perform bitwise AND conjunction of a register A (A $\in$ OREG) with a W bit literal value C (C $\in$ WLIT) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.31AND Instruction

Syntax	Operation	Status	Duration
AND A, B	A ← A AND B	Z	1 instruction cycle

Perform bitwise AND conjunction of a register A (A $\in$ XOREG) with an operand B (B $\in$ XOREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.32ORL Instruction

Syntax	Operation	Status	Duration
ORL A, C	A ← A OR C	Z	1 instruction cycle

Perform bitwise OR conjunction of a register A (A$\in$ OREG) with a W bit literal value C (C$\in$ WLIT) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.33OR Instruction

Syntax	Operation	Status	Duration
OR A, B	A ← A OR B	Z	1 instruction cycle

Perform bitwise OR conjunction of a register A (A$\in$ XOREG) with an operand B (B$\in$ XOREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.34XORL Instruction

Syntax	Operation	Status	Duration
XORL A, C	A ← A XOR C	Z	1 instruction cycle

Perform bitwise XOR conjunction of a register A (A$\in$ OREG) with a W bit literal value C (C$\in$ WLIT) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.35XOR Instruction

Syntax	Operation	Status	Duration
XOR A, B	A ← A XOR B	Z	1 instruction cycle

Perform bitwise XOR conjunction of a register A (A$\in$ XOREG) with an operand B (B$\in$ XOREG) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.36SHR Instruction

Syntax	Operation	Status	Duration
SHR A, C	A ← A >> C	Z, CY	1 instruction cycle

Perform right shift operation C (C$\in$ SFTLIT) times of register A (A$\in$ XOREG). The MSBs that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the last LSB that is shifted out of the register. If the shift value C is 0 the carry bit CY is cleared.

The program counter PC is incremented by the value 4.

28.17.7.37SHL Instruction

Syntax	Operation	Status	Duration
SHL A, C	A ← A << C	Z, CY	1 instruction cycle

Perform left shift operation C ($C_{\in}$ SFTLIT) times of register A ($A_{\in}$ XOREG). The LSBs that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the previous MSB that is shifted out of the register. If the register A contains less than W bits or if C is 0, the carry bit CY is always cleared.

The program counter PC is incremented by the value 4.

28.17.7.38ASRU Instruction

Syntax	Operation	Status	Duration
ASRU A, B	A ← A >> B	Z	1 instruction cycle

Perform arithmetic unsigned right shift operation, which means that the unsigned operand of register A ($A_{\in}$ XOREG) is right shifted B times ($B_{\in}$ XOREG). Operand B is also an unsigned type. The MSBs that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.39 ASRS Instruction

Syntax	Operation	Status	Duration
ASRS A, B	A ← A >> B	Z	1 instruction cycle

Perform arithmetic signed right shift operation, which means that the signed operand of register A ($A_{\in}$ XOREG) is right shifted B times ($B_{\in}$ XOREG). Operand B is an unsigned type. The operation also performs a sign extension, which means that value of the MSBs that are shifted into A are determined by the MSB of the original operand A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.40 ASL Instruction

Syntax	Operation	Status	Duration
ASL A, B	A ← A << B	Z, CY, V	1 instruction cycle

Perform arithmetic left shift operation for signed and unsigned numbers, which means that the operand of register A ($A_{\in}$ XOREG) is left shifted B times ($B_{\in}$ XOREG). Operand B is always an unsigned type.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during shifting, otherwise the bit is cleared. An unsigned overflow has occurred if the calculated result A*2B cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during shifting, otherwise the bit is cleared. A signed overflow/underflow has occurred when the calculated result A*2B cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that signed operand A is within the interval [-2^{W-1}; 2^{W-1}-1] and the unsigned operand B is within the interval [0; 2^{W-1}-1].

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.41 MULU Instruction

Syntax	Operation	Status	Duration
MULU A, B[, C]	[[R4,] A] ← A[(C-1):0] * B[(C-1):0]	Z	1 instruction cycle

Perform an unsigned multiplication operation of an operand A (A$_\in$ XOREG) with an operand B (B$_\in$ XOREG). The multiplication is only performed with the bits 0 to C-1 (C$_\in$ BWSLIT) of both operands A and B and the bits C to W-1 are ignored.

If C is less than or equal to W/2, the product of the multiplication is stored in register A and register R4 is left unchanged.

If C is greater than W/2, the bits 0 to W-1 are stored in A and the bits W to 2*C-1 are stored in R4. The results stored in the registers are always zero extended to W bits.

If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C.

The zero bit Z of status register STA is set, if the calculated product is zero, otherwise the zero bit is cleared.

If the delay between a MULU instruction and its successor instruction is one clock cycle (e.g. in accelerated scheduling mode) and the successor instruction is either a WURM, WURMX, WURCX, WUCE, BRDI, BWR or BWRI instruction that is accessing the multiplication result as argument, a data hazard in the pipeline occurs resulting in a pipeline flush.

This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like MULU R1, R2; BWRI R1, R3 (9 clock cycles) can be accelerated by reformulating the sequence as MULU R1, R2; NOP; BWRI R1, R3; (3 clock cycles).

The program counter PC is incremented by the value 4.

28.17.7.42 MULS Instruction

Syntax	Operation	Status	Duration
MULS A, B[, C]	[[R4,] A] ← A[(C-1):0] * B[(C-1):0]	Z, N	1 instruction cycle

Perform a signed multiplication operation of an operand A (A$_\in$ XOREG) with an operand B (B$_\in$ XOREG). The multiplication is only performed with the bits 0 to C-1 (C$_\in$ BWSLIT) of both operands A and B, in which bit C-1 is used as sign bit (-2^(C-1)) and the bits C to W-1 are ignored. If C is less than or equal to W/2, the product of the multiplication is stored in register A and register R4 is left unchanged. If C is greater than W/2, the bits 0 to W-1 are stored in A and the bits W to 2*C-1 are stored in R4. The results stored in the registers are always sign extended to W bits.

If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C.

The zero bit Z of status register STA is set, if the calculated product is zero, otherwise the zero bit is cleared.

The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0).

If the delay between a MULS instruction and its successor instruction is one clock cycle (e.g. in accelerated scheduling mode) and the successor instruction is either a WURM,WURMX,WURCX,WUCE,BRDI,BWR or BWRI instruction that is accessing the multiplication result as argument, a data hazard in the pipeline occurs resulting in a pipeline flush.

This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like MULS R1, R2; BWRI R1, R3 (9 clock cycles) can be accelerated by reformulating the sequence as MULS R1, R2; NOP; BWRI R1,R 3; (3 clock cycles).

The program counter PC is incremented by the value 4.

28.17.7.43 DIVU Instruction

Syntax	Operation	Status	Duration
DIVU A, B[, C]	R4 ← A[(C-1):0] - B[(C-1):0] * | A[(C-1):0] / B[(C-1):0] |; A ← | A[(C-1):0] / B[(C-1):0] |	CY, Z, ERR	C instruction cycles but not faster than C+NPS-1 clock cycles due to pipeline flushing.

Perform an unsigned division operation of operand A (A $\in$ XOREG \\ {R4, B}) divided by operand B (B $\in$ XOREG \\ {R4, A}). The division is only performed with the bits 0 to C-1 (C $\in$ BWSLIT) of the operands and the remaining bits C to W-1 are ignored. This means that the dynamic range of A and B is defined in the interval [0; 2C-1]. The integral part of the quotient is stored in the register A and the remainder of the division is stored in register R4. The resulting quotient A and remainder R4 are always zero extended to W bits.

If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C.

If the bits 0 to C-1 of operand B are zero, the MCS channel is disabled and the ERR bit in the status register STA is set.

The zero bit Z of status register STA is set, if the calculated quotient in A is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if the calculated remainder in R4 is not zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.44 DIVS Instruction

Syntax	Operation	Status	Duration
DIVS A, B[, C]	R4 ← A[(C-1):0] - B[(C-1):0] * | A[(C-1):0] / B[(C-1):0] |; A ← | A[(C-1):0] / B[(C-1):0] |	CY, Z, N, V, ERR	C + 4 instruction cycles but not faster than C+3+NPS clock cycles due to pipeline flushing.

Perform a signed division operation of operand A (A $\in$ XOREG \\ {R4, B}) divided by operand B (B $\in$ XOREG \\ {R4, A}). The division is only performed with the bits 0 to C-1 (C $\in$ BWSLIT) of both operands, in which bit C-1 is used as sign bit (-2^{C-1}) and the bits C to W-1 are ignored. This means that the dynamic range of A[(C-1):0] and B[(C-1):0] is defined in the interval [-2^{C-1}; $2^{C-1}-1$]. The integral part of the quotient is stored in the register A and the remainder

of the division is stored in register R4. The resulting quotient A and remainder R4 are always sign extended to W bits. The integral part of the quotient is always truncated towards 0. The sign of the remainder is always the same sign as the dividend A[(C-1):0]. The absolute value of the remained is always less than the divisor B[(C-1):0].

If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C.

If the bits 0 to C-1 of operand B are zero, the MCS channel is disabled and the ERR bit in the status register STA is set.

The zero bit Z of status register STA is set, if the calculated quotient in A is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if the calculated remainder in R4 is not zero, otherwise the zero bit is cleared.

The overflow bit V of status register STA is set, if the calculated quotient in A cannot be represented in the interval $[-2^{W}-1; 2^{W-1}-1]$, otherwise the overflow bit is cleared.

The negative bit N of status register STA equals the MSB of the quotient, in order to determine if a calculated signed result is negative (N=1) or positive (N=0).

The program counter PC is incremented by the value 4.

28.17.7.45 MINU Instruction

Syntax	Operation	Status	Duration
MINU A, B	A ← MIN(A, B)	Z	1 instruction cycle

Determine the minimum of an unsigned operand A (A $\in$ XOREG) and an unsigned operand B (B $\in$ XOREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.

The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

28.17.7.46 MINS Instruction

Syntax	Operation	Status	Duration
MINS A, B	A ← MIN(A, B)	Z	1 instruction cycle

Determine the minimum of a signed operand A (A $\in$ XOREG) and a signed operand B (B $\in$ XOREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.

The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

28.17.7.47 MAXU Instruction

Syntax	Operation	Status	Duration
MAXU A, B	A ← MAX(A, B)	Z	1 instruction cycle

Determine the maximum of an unsigned operand A (A $\in$ XOREG) and an unsigned operand B (B $\in$ XOREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.

The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

28.17.7.48 MAXS Instruction

Syntax	Operation	Status	Duration
MAXS A, B	A ← MAX(A, B)	Z	1 instruction cycle

Determine the maximum of a signed operand A (A ∈ XOREG) and a signed operand B (B ∈ XOREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.

The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

28.17.7.49ATUL Instruction

Syntax	Operation	Status	Duration
ATUL A, C	A - C	Z, CY	1 instruction cycle

Arithmetic test with an unsigned operand A (A ∈ OREG) and an unsigned W bit literal value C (C ∈ WLIT).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned literal C.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is incremented by the value 4.

28.17.7.50ATU Instruction

Syntax	Operation	Status	Duration
ATU A, B	A - B	Z, CY	1 instruction cycle

Arithmetic Test with an unsigned operand A (A ∈ XOREG) and an unsigned operand B (B ∈ XOREG).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned operand B.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is incremented by the value 4.

28.17.7.51ATSL Instruction

Syntax	Operation	Status	Duration
ATSL A, C	A - C	Z, CY	1 instruction cycle

Arithmetic Test with a signed operand A (A ∈ OREG) and a signed W bit literal value C (C ∈ WLIT).

The carry bit CY of status register STA is set if signed operand A is less than signed literal C.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is incremented by the value 4.

28.17.7.52ATS Instruction

Arithmetic Test with a signed operand A (A$\in$ XOREG) and a signed operand B (B$\in$ XOREG).

Syntax	Operation	Status	Duration
ATS A, B	A - B	Z, CY	1 instruction cycle

The carry bit CY of status register STA is set if unsigned operand A is less than signed operand B.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is incremented by the value 4.

28.17.7.53BTL Instruction

Syntax	Operation	Status	Duration
BTL A, C	A AND C	Z	1 instruction cycle

Bit test of an operand A (A$\in$ OREG) with a W bit literal bit mask C (C$\in$ WLIT).

The bit test is performed by applying a bitwise logical AND operation with operand A and the bit mask C without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.54BT Instruction

Syntax	Operation	Status	Duration
BT A, B	A AND B	Z	1 instruction cycle

Bit test of an operand A (A$\in$ XOREG) with an operand B (B$\in$ XOREG), whereas usually one of the operands is a register holding a bit mask.

The bit test is performed by applying a bitwise logical AND operation with register A and register B without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.55SETB Instruction

Syntax	Operation	Status	Duration
SETB A, B	A[B[4:0]] ←1	Z	1 instruction cycle

Set the B[4:0]-th bit (B ∈ XOREG) of an operand A (A ∈ XOREG) to true. Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of SETB does not modify operand A but the status flag Z is updated.

The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the bit Z is cleared. The Z bit is set e.g. if the B[4:0]-th bit of A is not writable, its value is zero and all other bits of A are cleared.

The program counter PC is incremented by the value 4.

28.17.7.56CLRB Instruction

Syntax	Operation	Status	Duration
CLRB A, B	A[B[4:0]] ← 0	Z	1 instruction cycle

Clear the B[4:0]-th bit (B ∈ XOREG) of an operand A (A ∈ XOREG). Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of CLRB does not modify operand A but the status flag Z is updated.

The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.57XCHB Instruction

Syntax	Operation	Status	Duration
XCHB A, B	A[B[4:0]] ← CY	Z, CY	1 instruction cycle

Exchange the B[4:0]-th bit (B ∈ XOREG) of an operand A (A ∈ XOREG) with the CY bit in the status register. Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of XCHB does not modify operand A but the status flag Z is updated and the bit CY is cleared.

The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

28.17.7.58JMP Instruction

Syntax	Operation	Status	Duration
JMP C	PC ← C << 2	-	1 instruction cycle but not faster than NPS clock cycles due to pipeline flushing.

Execute unconditional jump to the memory location C (C ∈ ALIT).

The program counter PC is loaded with literal C.

28.17.7.59JBS Instruction

Syntax	Operation	Status	Duration
JBS A, B, C	PC ← C << 2 if A[B] is set PC ← PC + 4 if A[B] is clear	-	1 instruction cycle but if the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.

Execute conditional jump to the memory location C (C $\in$ ALIT).

The program counter PC is loaded with literal C if the bit at position B (B $\in$ BITLIT) of operand A (A $\in$ OREG) is set.

Otherwise, if the bit is cleared the program counter PC is incremented by the value 4.

28.17.7.60JBC Instruction

Syntax	Operation	Status	Duration
JBC A, B, C	PC ← C << 2 if A[B] is clear PC ← PC + 4 if A[B] is set	-	1 instruction cycle but if the jump is executed it is not faster than NPS clock cycles due to pipeline flushing.

Execute conditional jump to the memory location C (C $\in$ ALIT).

The program counter PC is loaded with literal C if the bit at position B (B $\in$ BITLIT) of operand A (A $\in$ OREG) is cleared.

Otherwise, if the bit is set the program counter PC is incremented by the value 4.

28.17.7.61CALL Instruction

Syntax	Operation	Status	Duration
CALL C	R7 ← R7 + 4; MEM(R7[RAW+USR+1:2])[RAW+USR+1:0] ← PC + 4; PC ← C << 2; SP_CNT ← SP_CNT + 1	EN	2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Call subprogram at memory location C (C $\in$ ALIT).

The stack pointer register R7 is incremented by the value 4.

The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.

After the stack pointer is incremented, the incremented value of the PC is transferred to the top of the stack.

The program counter PC is loaded with literal C.

The **SP_CNT** bit field inside the **MCS[i]_CH[x]_CTRL** register is incremented.

If an overflow on the **SP_CNT** bit field occurs, the *STK_ERR[i]_IRQ* is raised.

If an overflow on the **SP_CNT** bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL_STAT** is set, the channel current MCS channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL_STAT** is set, the memory write operation of the incremented PC is discarding.

28.17.7.62RET Instruction

Syntax	Operation	Status	Duration
RET	PC ← MEM(R7[RAW+USR+1:2])[RAW+USR+1:2] << 2; R7 ← R7 - 4; SP_CNT ← SP_CNT - 1	EN	2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Return from subprogram.

The program counter PC is loaded with current value on the top of the stack.

Finally, the stack pointer register R7 is decremented by the value 4.

The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.

The SP_CNT bit field inside the **MCS[i]_CH[x]_CTRL** register is decremented.

If an underflow on the SP_CNT bit field occurs, the *STK_ERR[i]_IRQ* is raised.

If an underflow on the SP_CNT bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL** is set, the channel current MCS channel is disabled by clearing the **EN** bit of **STA**.

28.17.7.63JMPI Instruction

Syntax	Operation	Status	Duration
JMPI	PC ← R6[RAW+USR+1:2] << 2	-	1 instruction cycle but not faster than NPS clock cycles due to pipeline flushing.

Execute indirect unconditional jump to the memory location provided in register R6. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.

The program counter PC is loaded with (R6[RAW+USR+1:2] << 2).

28.17.7.64JBSI Instruction

Syntax	Operation	Status	Duration
JBSI A, B	PC ← R6[RAW+USR+1:2] << 2 if A[B] is set PC ← PC + 4 if A[B] is clear	-	1 instruction cycle but if the jump is executed it is not faster than NPS clock cycles due to pipeline flushing.

Execute indirect conditional jump to the memory location provided in register R6. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.

The program counter PC is loaded with (R6[RAW+USR+1:2] << 2) only if the bit at position B ($B_{\in}$ XBITLIT) of operand A ($A_{\in}$ XOREG) is set.

Otherwise, if the bit is cleared the program counter PC is incremented by the value 4.

28.17.7.65JBCI Instruction

Syntax	Operation	Status	Duration
JBCI A, B	PC ← R6[RAW+USR+1:2] << 2 if A[B] is set PC ← PC + 4 if A[B] is clear	-	1 instruction cycle but if the jump is executed it is not faster than NPS clock cycles due to pipeline flushing.

Execute indirect conditional jump to the memory location provided in register R6. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.

The program counter PC is loaded with (R6[RAW+USR+1:2] << 2) only if the bit at position B (B$\in$ XBITLIT) of operand A (A$\in$ XOREG) is cleared.

Otherwise, if the bit is set the program counter PC is incremented by the value 4.

28.17.7.66CALLI Instruction

Syntax	Operation	Status	Duration
CALLI	R7 ← R7 + 4; MEM(R7[RAW+USR+1:2])[RAW+USR+1:0] ← PC + 4; PC ← R6[RAW+USR+1:2] << 2; SP_CNT ← SP_CNT + 1	EN	2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Call subprogram indirectly, where the register R6 is identifying the target memory location. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.

The stack pointer register R7 is incremented by the value 4.

The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.

After the stack pointer is incremented, the incremented value of the PC is transferred to the top of the stack.

The program counter PC is loaded with (R6[RAW+USR+1:2] << 2),

The **SP_CNT** bit field inside the **MCS[i]_CH[x]_CTRL** register is incremented.

If an overflow on the **SP_CNT** bit field occurs, the *STK_ERR[i]_IRQ* is raised.

If an overflow on the **SP_CNT** bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL_STAT** is set, the channel current MCS channel is disabled by clearing the **EN** bit of **STA**.

If an overflow on the **SP_CNT** bit field occurs and the bit **HLT_SP_OFL** of register **MCS[i]_CTRL_STAT** is set, the memory write operation of the incremented PC is discarding.

28.17.7.67WURM Instruction

Syntax	Operation	Status	Duration
WURM A, B, C	Wait until register match.	CWT	Suspends current MCS channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURM instruction and the beginning of the following MCS instruction.

Suspend current MCS channel until the following register match condition occurs:

A = (B AND MASK),

whereas A ∈ OREG, B ∈ OREG, AND is a bitwise AND operation with bitmask MASK.

The bits 16 to 23 of MASK are set to true and the bits 0 to 15 are copied from the instructions literal C ∈ MSKLIT. If the match condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

This instruction can be used to wait for one or more trigger events generated by other MCS channels or the CPU. In this case register B is the trigger register **STRG**, A is a general purpose register holding the bits with the trigger condition to wait for and C is the bitmask that enables trigger bits of interest. The trigger bits can be set by other MCS channels with a write access (e.g. using a MOVL instruction) to the **STRG** register or the CPU with a write access to the **MCS[i]_STRG** register. The trigger bits are not cleared automatically by hardware after resuming an MCS channel, but they have to be cleared explicitly with a write access to the register **CTRG** by the MCS channel or with a write access to the register **MCS[i]_CTRG** by the CPU. Please note that more than one channel can wait for the same trigger bit to continue.

The instruction can also be used to wait on a specific time/angle event provided by the TBU. In this case register B is the interesting TBU register TBU_TS0 or TBU_TS1, register A is a general purpose register holding the value to wait for and bitmask C should be set to 0xFFFF.

28.17.7.68WURMX Instruction

Syntax	Operation	Status	Duration
WURMX A, B	Wait until extended register match.	CWT	Suspends current MCS channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURMX instruction and the beginning of the following MCS instruction.

Suspend current MCS channel until the following register match condition occurs:

A = B AND R6,

whereas A ∈ OREG, B ∈ WXREG, and AND is a bitwise AND operation.

If the match condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

28.17.7.69WURCX Instruction

Syntax	Operation	Status	Duration
WURCX A, B	Wait until extended register change.	CWT	Suspends current MCS channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURCX instruction and the beginning of the following MCS instruction.

Suspend current MCS channel until the following register change condition occurs:

$A \neq B$ AND R6,

whereas $A \in$ OREG, $B \in$ WXREG, and AND is a bitwise AND operation.

If the change condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the change condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

The WURCX instruction can be used for observation of volatile registers (e.g. register DSTAX) in order to react on status signal changes.

28.17.7.70WUCE Instruction

Syntax	Operation	Status	Duration
WUCE A, B	Wait until cyclic event.	CWT	Suspends current MCS channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURE instruction and the beginning of the following MCS instruction.

Suspend current MCS channel until a cyclic event compare matches.

The meaning of a cyclic event is described in section ‘Cyclic Event Compare’. The WUCE instruction can be used to synchronize an MCS program to a cyclic event generated by a TBU channel. If the event is in the future, the MCS channel suspends until the event occurs. If the event is in the past, the WUCE instruction is finished immediately.

The cyclic event compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first overflow and then reach the compare value. Please note, that for a correct behavior of this cyclic event compare, the compare value must not be specified larger/smaller than half of the range of the total time base value (0x7FFFFF).

The actual implementation of the WUCE implementation simply performs the subtraction B - A with each clock cycle and it suspends the MCS channel as long as bit W-1 of the subtraction result is set. If the subtration result is cleared the MCS channel is resumed immediatly.

In order to setup a WUCE instruction correctly, the counting direction of the TBU channel has to be considered. If the TBU channel is counting forward (incrementing), the operand A (A$_{\in}$ OREG) must refer the compare value and operand B (B$_{\in}$ OREG) must refer the desired TBU counter register (e.g. TBU_TS0). On the other hand, if the TBU channel is counting backward (decrementing), the operand A refers the desired TBU counter register and operand B refers the compare value.

If the comparison condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

28.17.7.71NOP Instruction

Syntax	Operation	Status	Duration
NOP	-	-	1 instruction cycle

No operation is performed.

The program counter PC is incremented by the value 4.

28.17.8 MCS Internal Register Description

This section describes the MCS internal registers that can be directly addressed with the MCS instruction set. Many of the registers can also be addressed by the CPU but with another Register Label (for details see section 15.11). Some of the internal registers are also shared between neighboring MCS channels.

28.17.8.1 MCS Internal Register Overview

Table 65 MCS Internal Register Overview

Register Name	Description	see Page
R[y] (y: 0…7)	General Purpose Register y	391
RS[y] (y: 0…7)	Mirror of succeeding channels register R[y]	391
STA	Status Register	392
ACB	ARU Control Bit Register	395
CTRG	Clear Trigger Bits Register	396
STRG	Set Trigger Bits Register	400
TBU_TS0	TBU Timestamp TS0 Register	400
TBU_TS1	TBU Timestamp TS1 Register	401
TBU_TS2	TBU Timestamp TS2 Register	401
MHB	Memory High Byte Register	401
GMI0	GTM Module Interrupt 0 Register	402

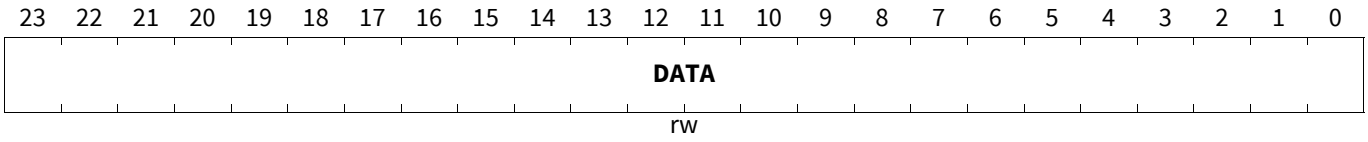
Table 65 MCS Internal Register Overview (cont'd)

Register Name	Description	see Page
GMI1	GTM Module Interrupt 1 Register	403
DSTA	DPLL Status Register	405
DSTAX	DPLL Extended Status Register	406

28.17.9 MCS Internal Register Description

28.17.9.1 Register R[y]

Ry (index)
General Purpose Register y **(0_H+y)** **Reset Value: 000000_H**



Field	Bits	Type	Description
DATA	23:0	rw	**Data field of general purpose register**

*Note: Register **R4** is also used as destination register of upper multiplication result from instructions MULU and MULS.*

*Note: Register **R5** is also used as offset register for the instructions MRDIO and MWRIO.*

*Note: Register **R6** is also used as a mask register for the instruction WURMX and WURCX.*

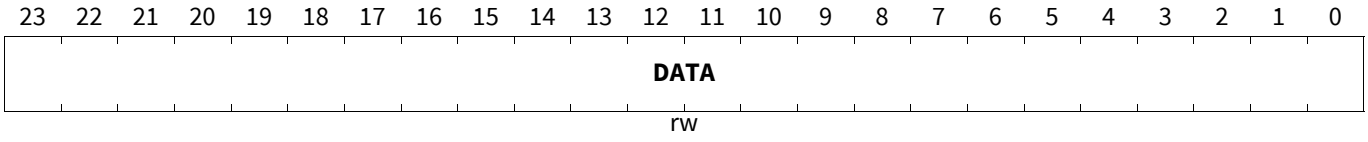
*Note: Register **R6** is also used as address destination register for the instructions JMPI, JBSI, JBCI, and CALLI.*

*Note: Register **R6** used also as index/address register for indirect ARU addressing instructions.*

*Note: Register **R7** is also used as stack pointer register, if stack operations are used in the MCS micro program.*

28.17.9.2 Register RS[y]

RSy (index)
Mirror of succeeding channels register R[y] **(10_H+y)** **Reset Value: 000000_H**



Field	Bits	Type	Description
DATA	23:0	rw	**Data field of general purpose register**

*Note: The register **RS[y]** (with y = 0…7) mirrors the internal general purpose register **R[y]** of the succeeding MCS channel. The successor of MCS channel T-1 is MCS channel 0.*

*Note: The registers **RS[y]** can only be accessed if bit **EN_XOREG** of register **MCS[i]_CTRL_STAT** is set.*

28.17.9.3 Register STA

STA
Status Register **(08_H)** **Reset Value: 000000_H**

23	22	21	20	19	18	17	16
Reserved					SP_CNT		
		r				r	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					SAT	CWT	CAT	N	V	Z	CY	MCA	ERR	IRQ	EN
r					r	r	r	r	r	r	r	rw	rw	rw	rw

Field	Bits	Type	Description
EN	0	rw	**Enable current MCS channel** 0_B Disable current MCS channel. 1_B Enable current MCS channel.
IRQ	1	rw	**Trigger IRQ** 0_B No triggered IRQ signal. 1_B Trigger IRQ signal. Note: An MCS channel triggers an IRQ by writing value 1 to bit IRQ. Writing a value 0 to this bit does not cancel the IRQ, and thus has no effect. Note: This bit mirrors bit 0 of the register **MCS[i]_CH[x]_IRQ_NOTIFY**. Note: The IRQ bit can only be cleared by CPU, by writing a 1 to the corresponding **MCS[i]_CH[x]_IRQ_NOTIFY** register (see **Register MCS[i]_CH[x]_IRQ_NOTIFY**). Note: An MCS channel can read the IRQ bit in order to determine the current state of the IRQ handling. The MCS channel reads a value 1 if an IRQ was released but not cleared by CPU. If an MCS channel reads a value 0 no IRQ was released or it has been cleared by CPU. Note: If NPS > 5 and an MCS program triggers the IRQ (e.g. by MOVL STA, 0x2) the actual interrupt event is delayed by NPS-5 clock cycles, which means that an immediate read of the interrupt notify flag (e.g. by MOV R2, STA) may signalize the state of the IRQ bit before the trigger.

Field	Bits	Type	Description
ERR	2	rw	**Set Error Signal** 0_B No Error occurred. 1_B Error occurred. Note: The **ERR** bit of an MCS channel reflects an Error status that may be caused by one of the following conditions: • MCS channel sets the ERR bit by software (e.g. with instruction ORL STA, 0x4) • ECC RAM Error occurred while accessing the connected RAM (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) • Decoding an instruction with an invalid opcode (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) • A memory address range overflow occurred (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) • Division by zero resulting from a **DIVU**, **DIVS** or **MODU** instruction (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**). • MCS channel wants to write to a GPR that is write protected by register **MCS[i]_REG_PROT** (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) • MCS channel wants to write to a protected memory range defined by an address range protector (ARP) of the sub module CCM (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) • MCS channel performs an invalid AEI bus master access while the bit field **HLT_AEIM_ERR** of register **MCS[i]_CTRL_STAT** is set (also disables the MCS channel by clearing bit **EN** and the first error occurred updates bit field **ERR_SRC_ID** of register **MCS[i]_CTRL_STAT**) Note: If the ERR bit is set due to a memory address range overflow any read or write access to the RAM is blocked. Note: If the GTM includes a MON sub module, the ERR signal is always captured by this module. Note: An MCS channel can set the error bit by writing value 1 to bit ERR. Writing a value 0 to this bit does not cancel the error signal, and thus has no effect. In Addition, writing a value 1 to ERR always triggers the ERR interrupt, independently from the current state of the error signal. Note: The ERR bit can only be cleared by CPU, by writing a 1 to the **MCS[i]_ERR** register (see **Register MCS[i]_ERR**). Note: An MCS channel can read the ERR bit in order to determine the current state of the error signal. The MCS channel reads a value 1 if an ERR occurred previously, but not cleared by CPU. If an MCS channel reads a value 0 no error was set or it has been cleared by CPU.

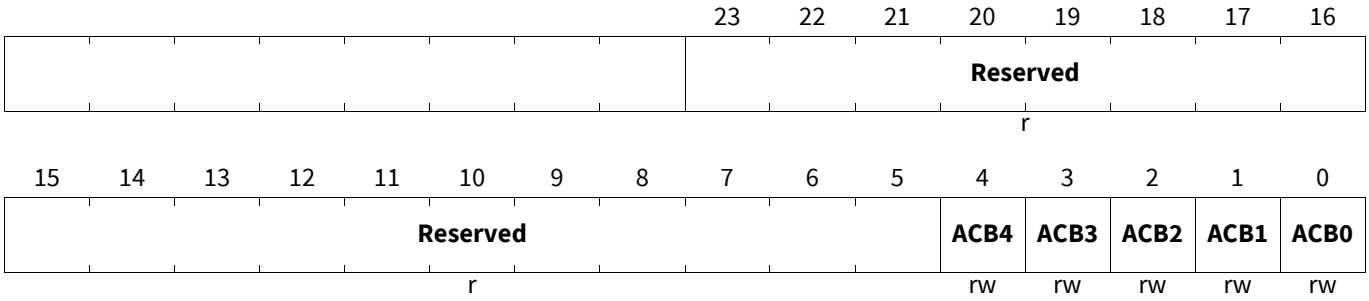
Field	Bits	Type	Description
MCA	3	rw	**MON Activity signaling for MCS channel** 0_B No activity signaled to sub module MON. 1_B Activity singled to sub module MON. *Note: When this bit is set the corresponding channel in the MON sub module register* **MON_ACTIVITY** *is set (see register MON_ACTIVITY_0. This bit is automatically cleared after writing it by the MCS channel program.*
CY	4	r	**Carry bit** The carry bit is updated by several arithmetic and logic instructions. In arithmetic operations, the carry bit indicates an unsigned under/overflow.
Z	5	r	**Zero bit** The zero bit is updated by several arithmetic, logic and data transfer instructions to indicate a result of zero.
V	6	r	**Overflow bit** The overflow bit is updated by arithmetic instructions in order to indicate a signed under/overflow.
N	7	r	**Negative bit** The negative bit is updated by arithmetic instructions in order to indicate a negative result.
CAT	8	r	**Cancel ARU transfer bit** 0_B No cancellation request for ARU transfer. 1_B CPU requests cancellation for ARU transfer. Note: This bit is always cleared at the beginning of the execution of a blocking ARU instruction.
CWT	9	r	**Cancel WURM instruction bit** 0_B Last WURM instruction was not canceled 1_B CPU canceled last WURM instruction of channel. Note: This bit is updated after each WURM instruction and it should be evaluated immediately after the WURM instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.
SAT	10	r	**Successful ARU transfer bit** 0_B ARU data transfer failed. 1_B ARU data transfer finished successfully. Note: This bit is always updated after the execution of ARU instructions in order to show if the ARU data transfer was successful or not. In the case of non-blocking ARU instructions (NARD, NARDI) a cleared SAT flag signalizes that the data source has no data available and in the case of blocking ARU instructions (ARD, ARDI, AWR, AWRI) a cleared SAT flag signalizes that the data transfer was canceled by the CPU.
Reserved	15:11	r	**Reserved** Read as zero, shall be written as zero.
SP_CNT	18:16	r	**Stack pointer counter value** Note: Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.

Field	Bits	Type	Description
Reserved	23:19	r	**Reserved** Read as zero, shall be written as zero.

Note: Writing to bits of the register STA with instructions that do implicitly a read-modify-write operation (e.g. "ANDL STA 0xFFFFFE" or "OR STA R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of the register STA is to use instructions that do not read the content of STA (e.g. "MOVL STA 0x0, MOV STA R1, CLRB STA R0, or SETB STA R1").

28.17.9.4 Register ACB

ACB
ARU Control Bit Register **(09_H)** **Reset Value: 000000_H**



Field	Bits	Type	Description
ACB0	0	rw	**ARU Control bit 0.** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 48 of the ARU word.
ACB1	1	rw	**ARU Control bit 1.** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 49 of the ARU word.
ACB2	2	rw	**ARU Control bit 2.** Note: This bit is updated by each ARUread access and its value is sent to ARU by each ARU write access on bit 50 of the ARU word.
ACB3	3	rw	**ARU Control bit 3.** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 51 of the ARU word.
ACB4	4	rw	**ARU Control bit 4.** Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 52 of the ARU word.
Reserved	23:5	r	**Read as zero, shall be written as zero.**

28.17.10 MCS Configuration Register Overview

The MCS Configuration registers of the MCS module are accessible by the AEI bus interface. Some of these registers simply mirror MCS Internal registers to the AEI. Details can be found in the table below and in the individual register descriptions.

Table 66 MCS Configuration Register Overview$_B$

Register Name	Description	see Page
MCS[i]_CH[x]_CTRL	MCSi channel x control register	409
MCS[i]_CH[x]_ACB	MCSi channel x ARU control Bit register	411
MCS[i]_CH[x]_MHB	MCSi channel x memory high byte register	412
MCS[i]_CH[x]_PC	MCSi channel x program counter register	410
MCS[i]_CH[x]_R[y] (y=0..7)	MCSi channel x general purpose register y (y=0..7)	411
MCS[i]_CH[x]_IRQ_NOTIFY	MCSi channel x interrupt notification register	413
MCS[i]_CH[x]_IRQ_EN	MCSi channel x interrupt enable register	414
MCS[i]_CH[x]_IRQ_FORCINT	MCSi channel x force interrupt register	414
MCS[i]_CH[x]_IRQ_MODE	MCSi channel x IRQ mode configuration register	415
MCS[i]_CH[x]_EIRQ_EN	MCSi channel x error interrupt enable register	416
MCS[i]_CTRL_STAT	MCSi control and status register	417
MCS[i]_REG_PROT	MCSi write protection register	419
MCS[i]_CTRG	MCSi clear trigger control register	420
MCS[i]_STRG	MCSi set trigger control register	421
MCS[i]_RESET	MCSi reset register	422
MCS[i]_ERR	MCSi error register	425
MCS[i]_CAT	MCSi cancel ARU transfer instruction	423
MCS[i]_CWT	MCSi cancel WURM instruction	424

28.17.11 MCS Configuration Register Description

28.17.11.1Register MCS[i]_CH[x]_CTRL

MCSi Channel x Control Register

MCSi_CHx_CTRL (i=0-9;x=0-7)
MCSi Channel x Control Register **($0F0020_H$+i*1000_H+x*80_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													SP_CNT		
r													rh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					SAT	CWT	CAT	N	V	Z	CY	0	ERR	IRQ	EN
r					rh	rh	rh	rh	rh	rh	rh	r	rh	rh	rwh

Field	Bits	Type	Description
EN	0	rwh	**Enable MCS-channel** *Note: Enabling or disabling of an MCS-channel is synchronized to the ending of an instruction, and thus it may take several clock cycles, e.g. active memory transfers or pending WURM transfers have to be finished before disabling the MCS-channel. The internal state of a channel can be obtained by reading bit EN.* *Note: To disable an MCS channel reliably, the EN bit should be cleared, followed by setting the CAT and CWT bits in order to cancel any pending WURM or ARU instructions.* *Note: The EN bit is write protected during RAM reset phase.* 0_B Disable current MCS-channel 1_B Enable current MCS-channel
IRQ	1	rh	**Interrupt state** This bit is read only, and it mirrors the internal IRQ state. 0_B No interrupt pending in MCS-channel x 1_B Interrupt is pending in MCS-channel x
ERR	2	rh	**Error state** This bit is read only, and it mirrors the internal error state. 0_B No error signal pending in MCS-channel x 1_B Error signal is pending in MCS-channel x
CY	4	rh	**Carry bit state** This bit is read only and it mirrors the internal carry flag CY.
Z	5	rh	**Zero bit state** This bit is read only and it mirrors the internal zero flag Z.
V	6	rh	**Overflow bit state** This bit is read only and it mirrors the internal carry flag V.
N	7	rh	**Negative bit state** This bit is read only and it mirrors the internal zero flag N.

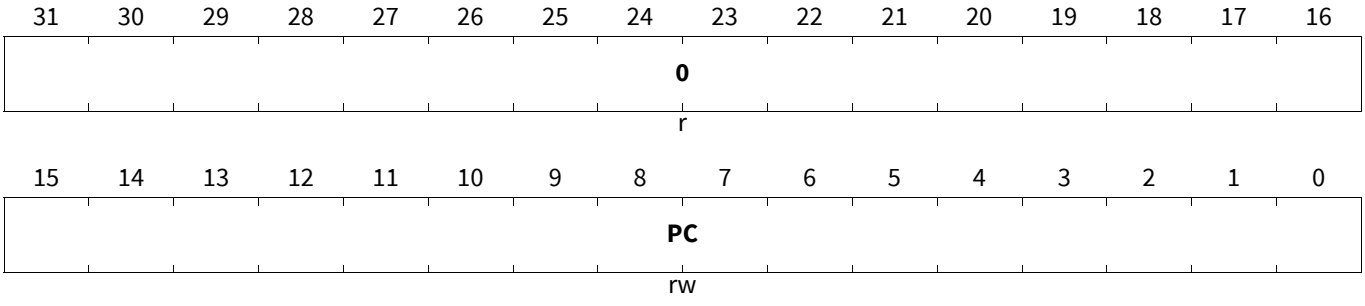
Field	Bits	Type	Description
CAT	8	rh	**Cancel ARU transfer state** This bit is read only and it mirrors the internal cancel ARU transfer status flag CAT.
CWT	9	rh	**Cancel WURM instruction state** This bit is read only and it mirrors the internal cancel WURM instruction status flag CWT.
SAT	10	rh	**Successful ARU transfer bit** This bit is read only, and it mirrors the internal state of the ARU transfer status flag SAT. 0_B ARU data transfer failed 1_B ARU data transfer finished successfully
SP_CNT	18:16	rh	**Stack pointer counter value** Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
0	3, 15:11, 31:19	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.2Register MCS[i]_CH[x]_PC

MCSi Channel x Program Counter Register

MCSi_CHx_PC (i=0-9;x=0-7)

MCSi Channel x Program Counter Register($0F0040_H$+i*1000_H+x*80_H) **Reset Value: Table 67**



Field	Bits	Type	Description
PC	15:0	rw	**Current Program Counter** *Note: The program counter is only writable if the corresponding MCS-channel is disabled. The bits 0 and 1 are always written as zeros.* *Note: The actual width of the program counter depends on the MCS configuration. The actual width is RAW+USR+2 bits meaning that only the bits 0 to RAW+USR+1 are available and the other bits (RAW+USR+2 to 31) are reserved.*
0	31:16	r	**Reserved** Read as zero, shall be written as zero.

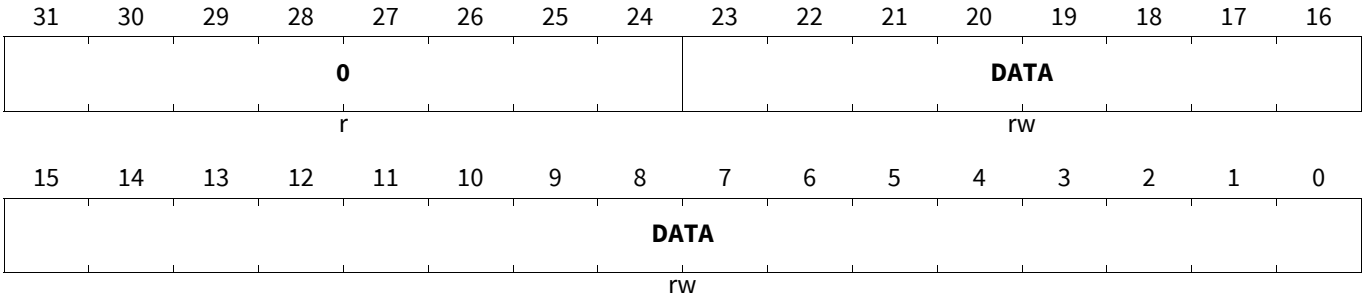
Table 67 Reset Values of MCSi_CHx_PC (i=0-9;x=0-7)

Reset Type	Reset Value	Note
Application Reset	4 * x	

28.17.11.3Register MCS[i]_CH[x]_R[y]

MCSi Channel x General Purpose Register y

MCSi_CHx_Ry (i=0-9;x=0-7;y=0-7)
MCSi Channel x General Purpose Register y($0F0000_H$+i*1000_H+x*80_H+y*4) Application Reset Value: $0000\ 0000_H$

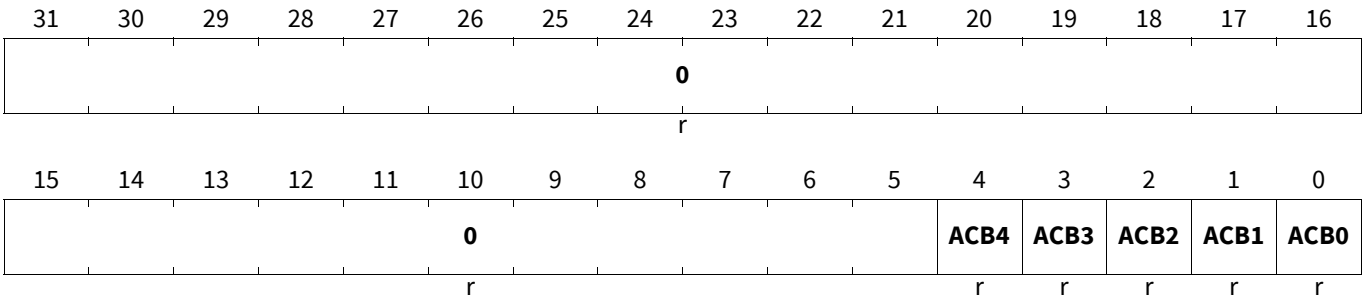


Field	Bits	Type	Description
DATA	23:0	rw	**Data of general purpose register R[y]** *Note: This register is the same as described in internal register section.* *Note: For the register MCS[i]_CH[x]_R6 (see internal register section) an additional write protection during an active ARDI or NARDI instruction is applied*
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.4Register MCS[i]_CH[x]_ACB

MCSi Channel x ARU Control Bit Register

MCSi_CHx_ACB (i=0-9;x=0-7)
MCSi Channel x ARU Control Bit Register($0F0024_H$+i*1000_H+x*80_H) Application Reset Value: $0000\ 0000_H$



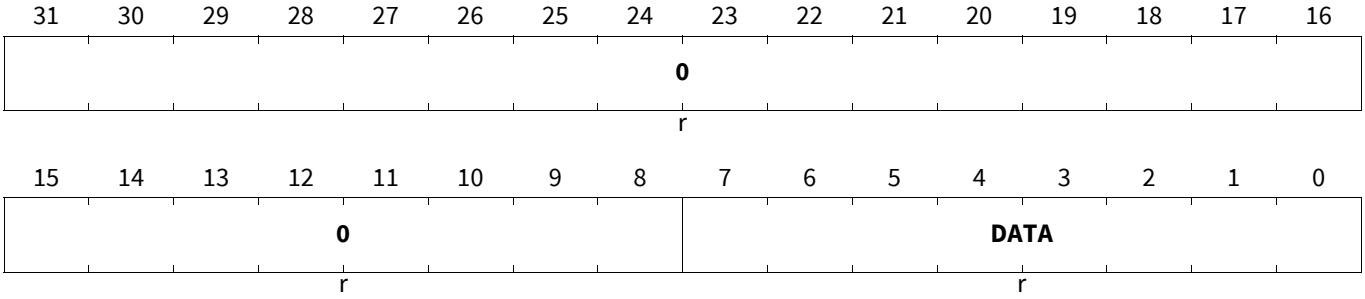
Field	Bits	Type	Description
ACB0	0	r	**ARU Control bit 0** This bit is read only, and it mirrors the internal state.
ACB1	1	r	**ARU Control bit 1** This bit is read only, and it mirrors the internal state.
ACB2	2	r	**ARU Control bit 2** This bit is read only, and it mirrors the internal state.
ACB3	3	r	**ARU Control bit 3** This bit is read only, and it mirrors the internal state.
ACB4	4	r	**ARU Control bit 4** This bit is read only, and it mirrors the internal state.
0	31:5	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.5Register MCS[i]_CH[x]_MHB

MCSi Channel x Memory High Byte Register

MCSi_CHx_MHB (i=0-9;x=0-7)

MCSi Channel x Memory High Byte Register($0F003C_H$+i*1000_H+x*80_H) Application Reset Value: 0000 0000_H

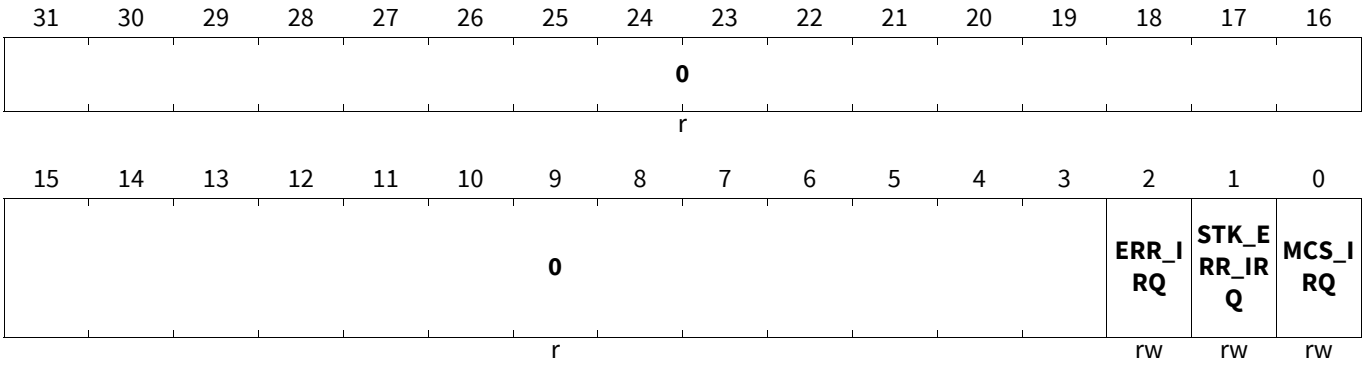


Field	Bits	Type	Description
DATA	7:0	r	**Data of memory high bit register MHB**
0	31:8	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.6Register MCS[i]_CH[x]_IRQ_NOTIFY

MCSi Channel x Interrupt Notification Register

MCSi_CHx_IRQ_NOTIFY (i=0-9;x=0-7)
MCSi Channel x Interrupt Notification Register($0F0044_H$+i*1000_H+x*80_H) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
MCS_IRQ	0	rw	**Interrupt request by MCS-channel x** *Note: This bit will be cleared on a CPU write access with a value of '1'. A read access leaves the bit unchanged.* *Note: By writing a '1' to this register, the IRQ flag in the MCS channel status register STA is cleared.* 0_B No IRQ released 1_B IRQ released by MCS-channel
STK_ERR_IRQ	1	rw	**Stack counter overflow/underflow of channel x** *Note: This bit will be cleared on a CPU write access with a value of '1'. A read access leaves the bit unchanged.* 0_B No IRQ released 1_B A stack counter overflow or underflow occurred
ERR_IRQ	2	rw	**MCS channel x ERR interrupt** *Note: If the ERR bit of register STA is triggered, the ERR_IRQ will also be set.* *Note: This bit will be cleared on a CPU write access with a value of '1'. A read access leaves the bit unchanged.* 0_B No IRQ released 1_B MCS-channel ERR IRQ released
0	31:3	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.7Register MCS[i]_CH[x]_IRQ_EN

MCSi Channel x Interrupt Enable Register

MCSi_CHx_IRQ_EN (i=0-9;x=0-7)

MCSi Channel x Interrupt Enable Register($0F0048_H$+i*1000_H+x*80_H) **Application Reset Value: $0000\ 0000_H$**

0					HLT_AEIM_ERR	EN_XOREG	EN_TIM_FOUT	0	ERR_SRC_ID			0		HLT_SP_OFL	RAM_RST
r					rw	rw	rw	r	r			r		rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				SCD_CH				0						SCD_MODE	
r				rw				r						rw	

Field	Bits	Type	Description
SCD_MODE	1:0	rw	**Select MCS scheduling mode** 00_B Accelerated Scheduling 01_B Round Robin Scheduling 10_B Single Priority Scheduling 11_B Multiple Priority Scheduling
SCD_CH	11:8	rw	**Channel selection for scheduling algorithm** MCS-channel identifier used by several scheduling modes. *Note: The actual width of the bit field SCD_CH is calculated as ceiling[log_2(T+1)].* Unused MSBs are reserved and read as zero.
RAM_RST	16	rw	**RAM reset bit** *Note: The RAM reset initializes the memory content with zeros. RAM access and enabling of MCS channels is disabled during active RAM reset.* *Note: This bit is only writable if the bit RF_PROT in register GTM_CTRL is cleared, and all MCS-channels are disabled.* *Note: The actual reset value of this bit depends on the silicon vendor configuration. The reset value is 1, if the RAM reset is performed together with the sub-module reset, otherwise, the reset value is 0. If the reset value is 1, the reset value is changed to 0 by hardware when the RAM reset has finished.* 0_B READ: no RAM reset is active / WRITE: do nothing 1_B READ: MCS currently resets RAM content / WRITE: trigger RAM reset

Field	Bits	Type	Description
HLT_SP_OFL	17	rw	**Halt on stack pointer overflow** 0_B No halt on MCS-channel stack pointer counter over/underflow 1_B MCS-channel is disabled if a stack pointer counter over/underflow occurs
ERR_SRC_ID	22:20	r	**Error source identifier** *Note: This register is updated once, if an error was detected by the MCS. The register is set to its initial value 000_B after each write access to an existing ERR bit in register MCS[i]_ERR. If multiple errors occur, ERR_SRC_ID is holding the first type of error which has occurred.* 000_B No HW generated Error occurred 001_B Detected ECC error 010_B Detected memory overflow 011_B Detected invalid opcode 100_B Divide by zero 101_B Invalid register write access to GPR from write protected channel 110_B Invalid memory write access to protected memory region 111_B Invalid AEI bus master access
EN_TIM_FOUT	24	rw	**Enable routing of TIM[i]_CH[x]_F_OUT signal** 0_B Read access to register CTRG/MCS[i]_CTRG provides state of the internal trigger registers 1_B Read access to register CTRG/MCS[i]_CTRG provides state of the external signal TIM[i]_CH[x]_F_OUT
EN_XOREG	25	rw	**Enable extended register set** *Note: If the extended operation register sets are disabled, the MCS instructions can only use the subset OREG of the register set as arguments in the instructions. In this case, the upper address bits in the instructions are always read as zeros, which leads to unexpected results of the MCS program if arguments A or B refer to a register that is not part of OREG.* 0_B Extended operation register sets XOREG, BAREG, and WXREG are disabled 1_B Extended operation register sets XOREG, BAREG, and WXREG are enabled

Field	Bits	Type	Description
HLT_AEIM_ERR	26	rw	**Halt on AEI bus master error** *Note: If the register HLT_AEIM_ERR is set, and an MCS channel x is executing an invalid bus master access, the MCS channel x is halted, the ERR bit of its register STA is set, and the bit field ERR_SRC_ID of this register is updated.* *Note: If the bus master is accessing a slave that does not insert wait cycles (e.g. register access), it takes two additional clock cycles until the MCS channel is halted. Within that time span, the MCS channel can continue with its program execution, depending on the selected scheduling mode.* *Note: The registers AEIM_XPT_STA and AEIM_XPT_ADDR of the GTM sub-module CCM are always updated on the first invalid AEI bus master access, independently of the state of HLT_AEIM_ERR* 0_B Ignore invalid AEI bus master access 1_B Halt MCS-channel on invalid AEI bus master access
0	7:2, 15:12, 19:18, 23, 31:27	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.12Register MCS[i]_REG_PROT

MCSi Write Protection Register

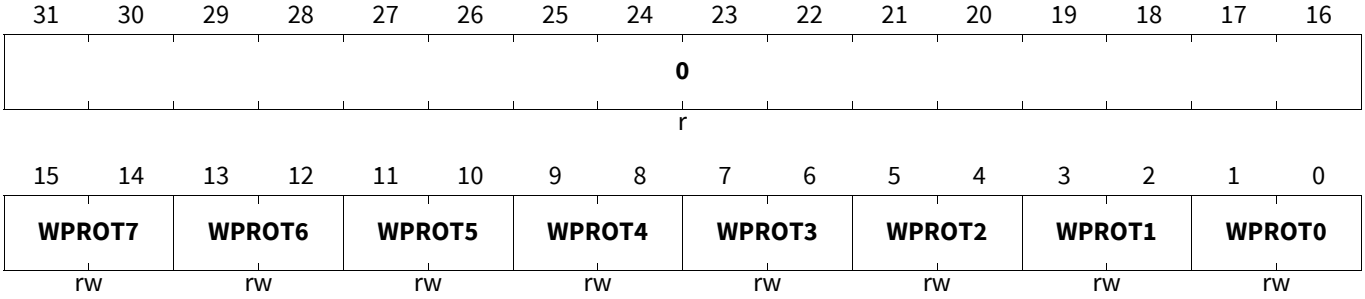
*Note: Only the first T bit fields of this register (bit 0 to 2*T-1) are functionally implemented. The other bits (bit 2*T to 31) are reserved bit fields.*

Note: The predecessor channel of MCS channel 0 is MCS channel T-1.

Note: If an MCS channel x is writing to a general purpose register that is write protected by register MCS[i]_REG_PROT the ERR bit of the register STA is set, the MCS channel x is halted and the ERR_SRC_ID bit field of register MCS[i]_CTRL_STAT is updated.

Note: This register is only writable if the bit RF_PROT in register GTM_CTRL is cleared

MCSi_REG_PROT (i=0-9)
MCSi Write Protection Register **($0F0060_H$+i*1000_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
WPROTx (x=0-7)	2*x+1:2*x	rw	**Register Write Protection of MCS-channel x** 00_B No register write protection activated 01_B Predecessor MCS channel cannot write to its RS[y] registers 10_B Current MCS channel cannot write to its R[y] registers 11_B Reserved
0	31:16	r	**Reserved** Read as zero, shall be written as zero.

28.17.11.13Register MCS[i]_CTRG

MCSi Clear Trigger Control Register

Note: The trigger bits TRGx are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCS[i]_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCS[i]_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.

Note: Besides setting the trigger bits with register STRG/MCS[i]_STRG, the k-th trigger bit TRGx (with k < 16) can also be set by the external capture event that is enabled by the k-th bit of register GTM_EXT_CAP_EN_[i]. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.

Note: In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to MCS[i]_CTRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to MCS[i]_CTRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to MCS[i]_CTRG.

Note: Note: The result of a read access to this register differs in dependency of the bit field EN_TIM_FOUT of register MCS[i]_CTRL_STAT.

MCSi_CTRG (i=0-9;x=0-7)

28.17.11.14Register MCS[i]_STRG

MCSi Set Trigger Control Register

Note: The trigger bits TRGx are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCS[i]_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS channel or the MCS[i]_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.

Note: Besides setting the trigger bits with register STRG/MCS[i]_STRG, the k-th trigger bit TRGk (with k < 16) can also be set by the external capture event that is enabled by the k-th bit of register CCM[I]_EXT_CAP_EN. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.

Note: In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to MCS[i]_STRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to MCS[i]_STRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to MCS[i]_STRG.

r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ERRx (x=0-7)	x	rw	**Error State of MCS-channel x** *Note: The CPU can read the ERRx (x = 0..T-1) bits in order to determine the current error state of the corresponding MCS-channel x.* *Note: The error state is also evaluated by the sub-module MON, if this module is available.* *Note: Writing the value 1 to this bit resets the corresponding error state, and resets the channel internal ERR bit in the STA and channel CTRL registers. Moreover, each write access to this bit also sets the ERR_SRC_ID bit field of register MCS[i]_CTRL_STAT to its reset value.* 0_B No error signal 1_B Error signal is pending
0	31:8	r	**Reserved** Read as zero, shall be written as zero.

28.18 Memory Configuration (MCFG)

28.18.1 Overview

The Memory Configuration submodule (MCFG) is an infrastructure module that organizes physical memory blocks and maps them to the RAM ports 0 and 1 of available Multi Channel Sequencer (MCS) modules.

The following parameters are design variables for the MCFG hardware structure that can vary in its range for different devices:

Constant	Description	Value
MAW	Memory address width of a large physical memory block.	11
ERM	Enable RAM1 MSB (0 - RAM1 MSB disabled, 1 - RAM1 MSB enabled,)	0

It should be noted that the actual value of the parameter ERM can be obtained by the bit **ERM** of the register **CCM[i]_HW_CONF**.

Depending on the value of parameter ERM, the MCFG module assumes externally connected physical RAM modules with different sizes. If ERM = 0, MCFG assumes that each MCS instance provides a large physical memory block with 2^{MAW} memory locations each 32 bit wide which leads to a RAM module with 2^{MAW+2} (byte wise) memory addresses. Further each MCS instance provides a small physical memory block with 2^{MAW-1} memory locations each 32 bit wide leading to a RAM module with 2^{MAW+1} (byte wise) memory addresses. If ERM = 1, MCFG assumes that each MCS instance provides two large physical memory block each with 2^{MAW} memory locations each 32-bit leading to a RAM module with 2^{MAW+2} (byte wise) memory addresses.

In order to support different memory sizes for different MCS instances, the MCFG module provides three layout configurations for reorganization of memory pages mapped to the RAM ports of neighboring MCS modules. Figure **Figure 115** shows all layout configurations for the case that ERM = 0 and **Figure 117** shows the layout configurations for the case that ERM = 1. Each box in these pictures represents a physical memory block.

The layout configuration DEFAULT is always assigning a memory block of size 2^{MAW}x32 bits to MCS RAM port 0. Depending on ERM, RAM port 1 of each MCS is assigned to a memory block of size 2^{MAW-1}x32 bits (ERM = 0) or a memory block of size 2^{MAW}x32 bits (ERM = 1).

The layout configuration SWAP is swapping the memory block assigned to RAM port 1 of the current MCS instance with the memory block assigned to RAM port 0 of the successive MCS instance. If ERM = 0, this means that the memory of the current MCS instance is increased by 2^{MAW-1}x32 bits but the memory of the successor is decreased by 2^{MAW-1}x32 bits compared to the DEFAULT configuration. If ERM = 1, the SWAP configuration has no effect on the memory sizes of the individual MCS instances.

The layout configuration BORROW is borrowing the memory block assigned to RAM port 0 of the successive MCS instance for the current instance. This means, the memory of the current MCS module is increased by 2^{MAW}x32 bits but the memory of the successor is decreased by 2^{MAW}x32 bits compared to the DEFAULT configuration.

Considering the order the mentioned MCS modules, it should be noted that the successor of the last MCS instance is the first MCS instance MCS0.

The actual sizes of the memory pages mapped to the MCS RAM ports 0 and 1 depends on the layout configuration for of current instance MCS[i] and the layout configuration of the preceding memory instance MCS[i-1]. The sizes of these memory pages can be obtained by the layout parameters MP0 and MP1, as described in the specification of the MCS.

Figure 116 and **Figure 118** summarize the layout parameters MP0 and MP1 of MCS instance MCS[i] for the case that ERM = 0 and ERM = 1. Note that the predecessor of instance MCS0 is last available MCS instance.

The addressing of memory port 0 ranges from 0 to MP0-4 and the addressing of memory page 1 ranges from MP0 to MP1-4.

This document assumes that the GTM implementation embeds 8 MCS instances. However, the actual number of implemented MCS instances is specified in device specific appendix.

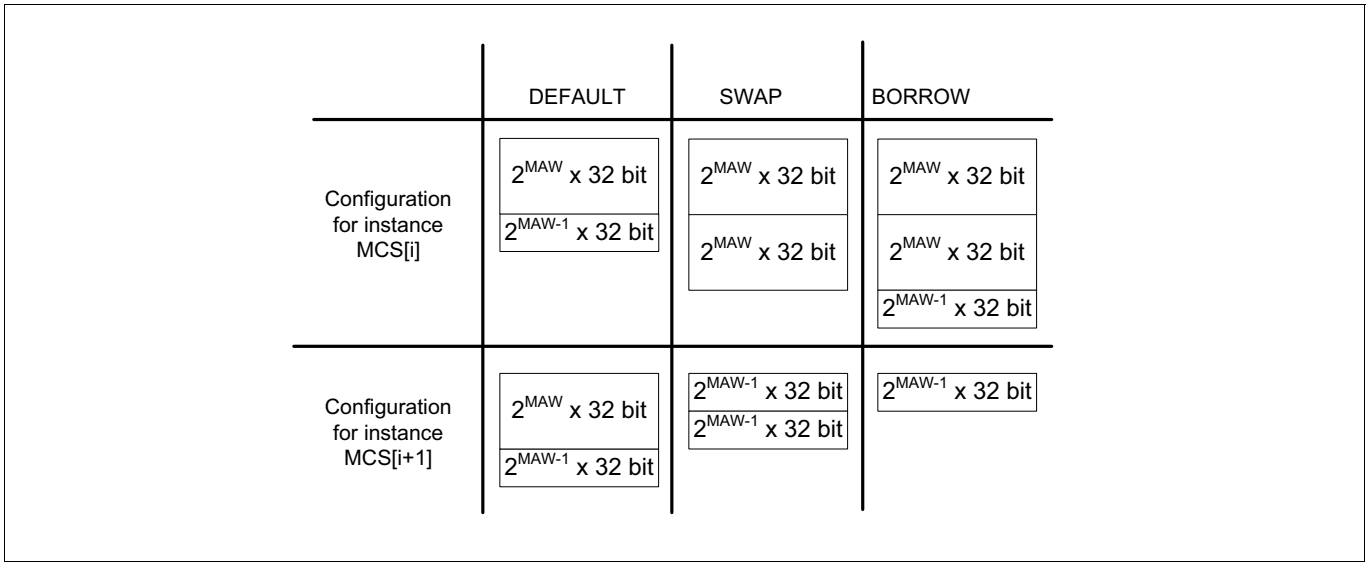

Figure 115 Memory Layout Configurations (ERM = 0)

28.18.3 MCFG Register Description

28.18.3.1 Register MCFG_CTRL

MCFG Memory Layout Configuration Register

It should be noted that the actual GTM implementation may embed less MCS instances than mentioned in this register (see product specific appendix). In this case this register only implements the register bits for available MCS instances.

This register is only writable if the bit **RF_PROT** in register **GTM_CTRL** is cleared.

28.19 TIM0 Input Mapping Module (MAP)

28.19.1 Overview

The MAP submodule generates the two input signals *TRIGGER* and *STATE* for the submodule DPLL by evaluating the output signals of the channel 0 up to channel 5 of submodule TIM0. By using the TIM as input submodule, the filtering of the input signals can be done inside the TIM channels themselves. The MAP submodule architecture is depicted in **Figure 119**.

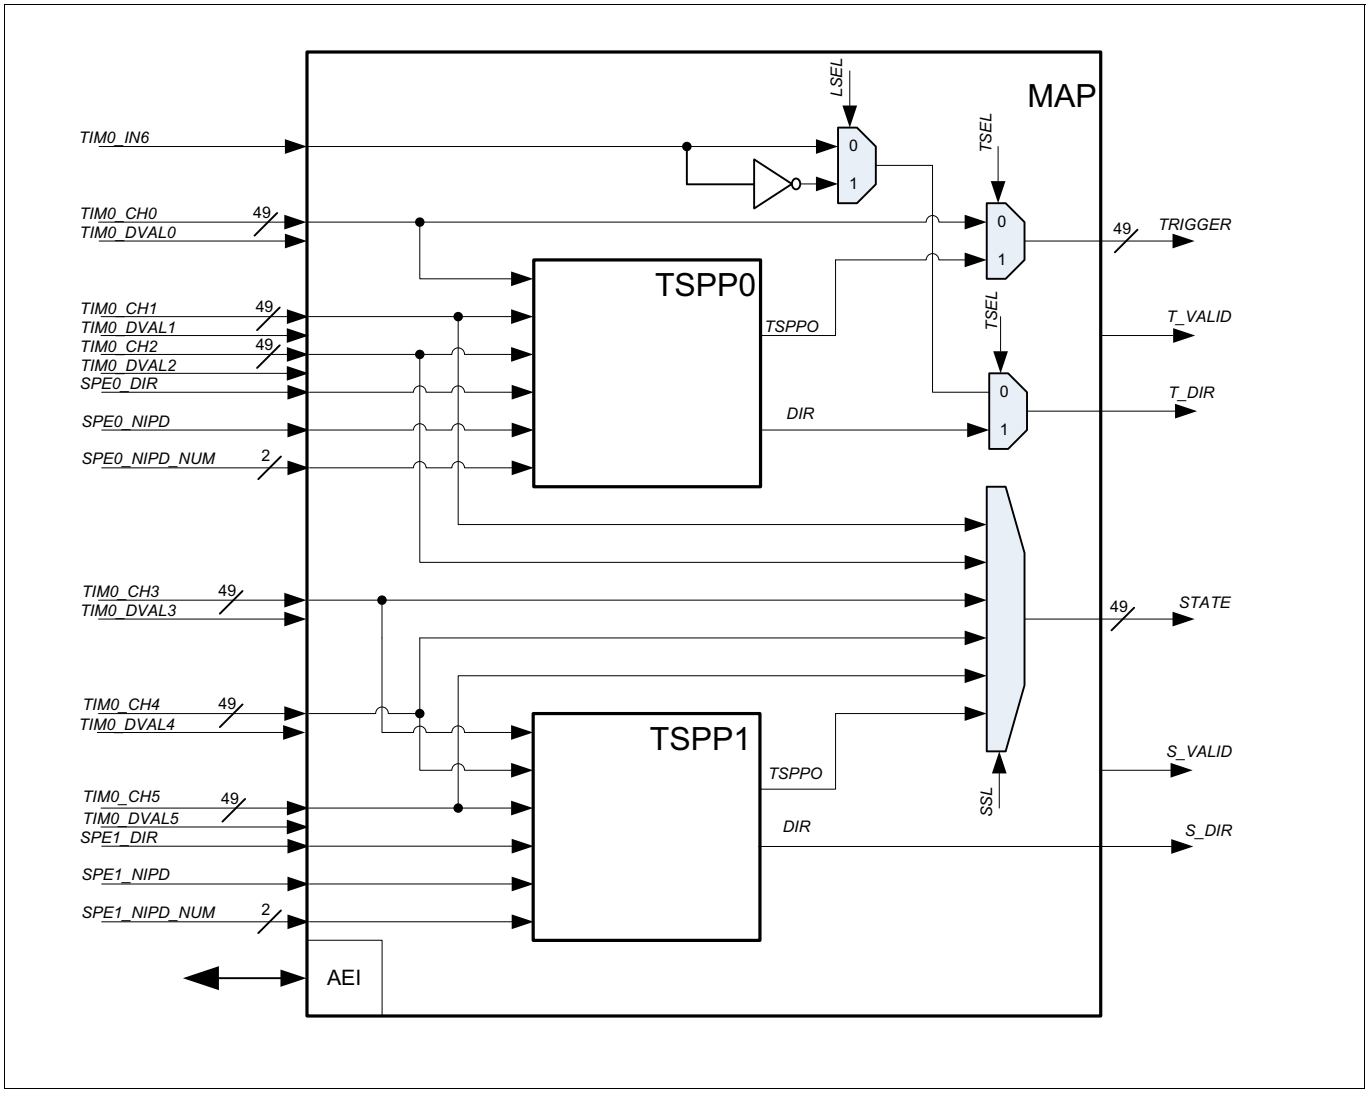

Figure 119 MAP Submodule architecture

Generally, the MAP submodule can route the channel signals coming from TIM0 in three ways. First, it is possible to route the whole 49 bits of data coming from channel 0 of module TIM0 (TIM0_CH0) to the *TRIGGER* signal which is then provided to the DPLL together with the *T_VALID* signal.

Second, the MAP module can route one of the five signals coming from the module TIM0 (i.e. the signals coming from channel 1 up to channel 5) to the output signal *STATE* which is then provided to the module DPLL together with the *S_VALID* signal.

Third, the *TRIGGER*, *T_VALID*, *STATE* and *S_VALID* signals can be generated out of the TIM Signal Preprocessing (TSPP) subunits. This is done in combination with the Sensor Pattern Evaluation (SPE) submodule described in chapter “Sensor Pattern Evaluation “.

There, the signal *TRIGGER* is generated in subunit TSPP0 out of the TIM0 signals coming from channel 0 up to 2.

The signal *STATE* is generated in subunit TSPP1 out of the TIM signals coming from channel 3 up to channel 5.

This is only be done, when the TSSPx subunits are enabled and when the *SPEx_NIPD* signal is raised by the SPE submodule. The *SPEx_NIPD_NUM* signal encodes, which of the 3 *TIMx_CHy* input signals has been changed. The *SPEx_DIR* signal is routed through the TSPPx subunit and implements the *T_DIR* or *S_DIR* signal.

A third method to provide a direction signal to DPLL is to use TIM0 channel 6 input (*TIM0_IN6*) and to route it instead of the *DIR* signal coming from TSSOP0 to the MAP output *T_DIR* (set TSEL=0)

28.19.2 TIM Signal Preprocessing (TSPP)

The TSPP combines the three 49 bit input streams coming from the TIM0 submodule and generates one combined 49 bit output stream *TSPPO*. The input stream combination is done in the unit Bit Stream Combination (BSC). The architecture of the TSPP is shown in **Figure 120**.

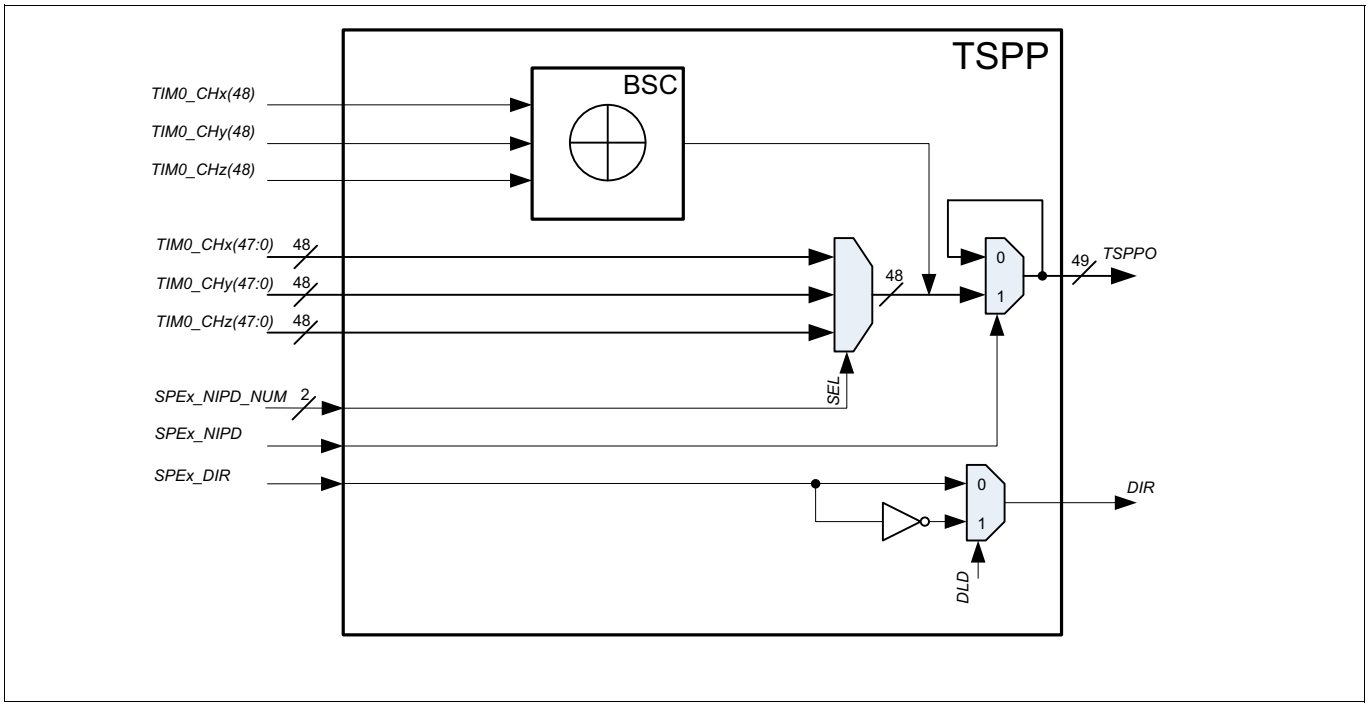

Figure 120 TIM Signal Preprocessing (TSPP) subunit architecture

28.19.2.1 Bit Stream Combination

The BSC subunit is used to XOR-combine the three most significant bits *TIM0_CHx(48)*, *TIM0_CHy(48)* and *TIM0_CHz(48)* of the TIM0 inputs. The XOR-combined signal is merged with the remaining 48 bits of one of the three input signals *TIM0_CHx(47…0)*, *TIM0_CHy(47…0)* or *TIM0_CHz(47…0)* the *TSPPO* signal. The selection is done with the *SPEx_NIPD_NUM* input signal coming from the SPE submodule. The action, when the 49 bits are transferred to the TSPPO and the T_VALID or S_VALID signal is raised is determined by the SPEx_NIPD signal coming from the SPE submodule. The *TSPPO* output signal generation is shown in the example in **Figure 121**.

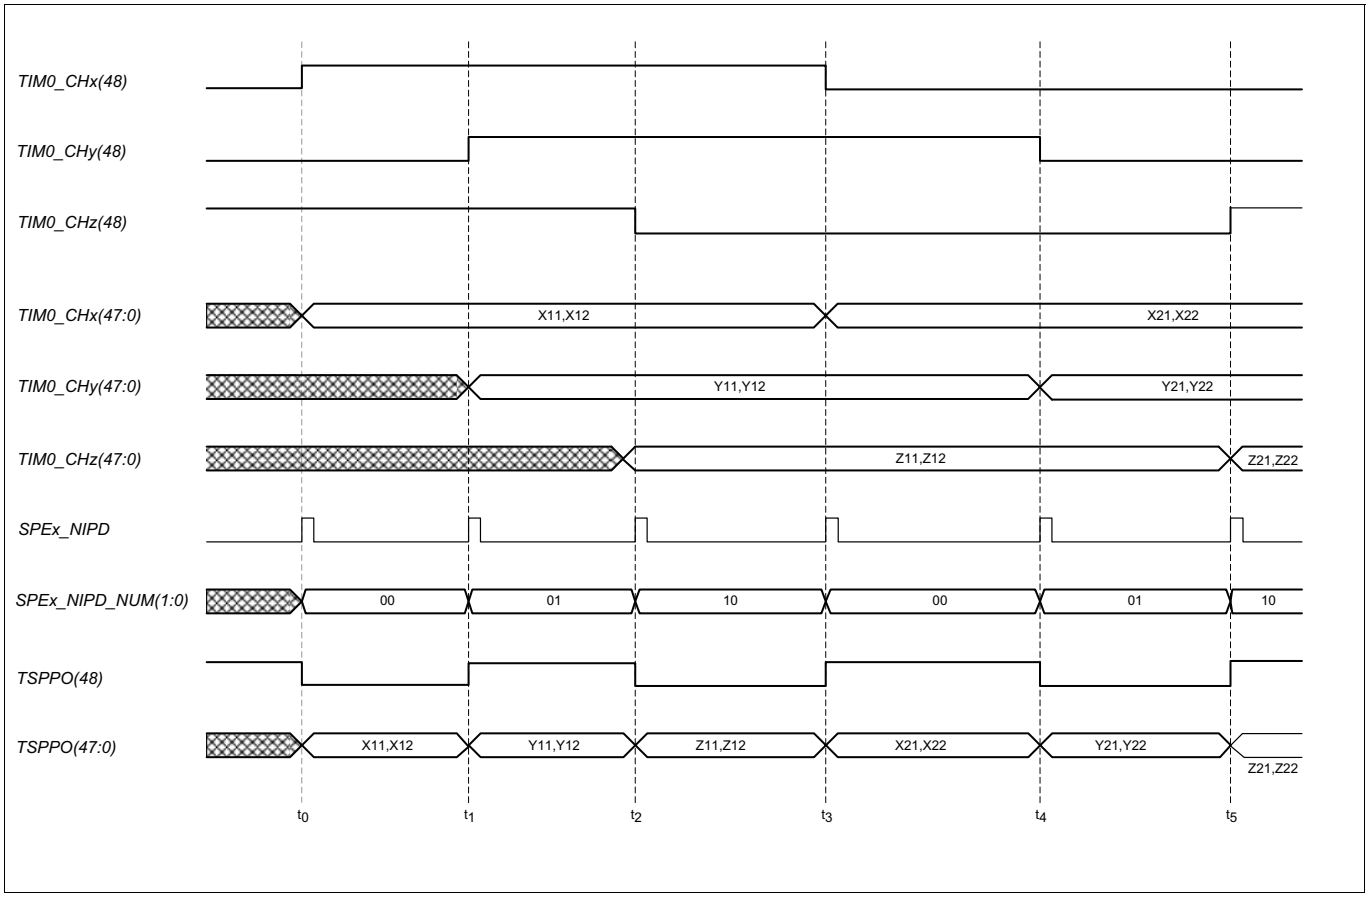

Figure 121 TSPP Signal generation for signal TSPPO

The *SPEx_NIPD_NUM* input signal determines, which data is routed to the *TSPPO* signal. At the first edge of *TIM0_CHx(48)* the new data X11 and X12 are routed to *TSPPO(47:0)*. The values X11 and X12 are the two 24 bit values coming from the TIM input channel TIM0_CHx. The next edge is at time t_1 on signal *TIM0_CHy(48)*. Therefore, at time t_1 the *TSPPO(48)* signal level changes and the *TSPPO(47:0)* is set to Y11 and Y12 and so forth.

28.20 Digital PLL Module (DPLL)

28.20.1 Overview

The digital PLL (DPLL) sub-module is used for frequency multiplication. The purpose of this module is to get a higher precision of position or value information also in the case of applications with rapidly changed input frequencies. There are two input signals *TRIGGER* and *STATE* for which periodic events are processed. The time period between two active events is called an increment. Each increment is divided into a given number of sub increments by pulses called SUB_INC. The resolution of the generated pulses is restricted by the period of the CMU_CLK0 clock or the TS_CLK respectively (see description of the modules TBU, CMU). The input signals *TRIGGER* and *STATE* can have the meaning of position information of linear or angle motions, mass flow values, temperature, pressure or level of liquids.By means of the DPLL the load of the CPU can be reduced essentially by relieving it from repeated or periodic standard tasks.

The DPLL has to perform the following tasks:

- prediction of the duration of the current increment in **Section 28.20.6**
- generation of SUB_INC1,2 pulses for up to 2 position counters in normal or emergency mode (see **Section 28.20.8.3**)
- synchronization of the actual position (under CPU control, see **Section 28.20.8.6.1**)
- possibility of seamless switch to emergency mode and back under CPU control, see configuration register DPLL_CTRL_0 at **Section 28.20.12**
- prediction of position and time related events in **Section 28.20.7**

28.20.2 Requirements and demarcation

The two input signals *TRIGGER* and *STATE* can be sensor signals from the same device or from two independent devices. When they come from the same device the *TRIGGER* input is typically a more frequent signal and *STATE* is a less frequent signal. In such a case the *STATE* signal can support an emergency mode, when no *TRIGGER* signal is available. There are also applications supported when *STATE* and *TRIGGER* are independent signals from different devices. Both input signals are combined with a validation signal *T_VALID* or *S_VALID* respectively, which shows the appearance of new data and must result in a data fetch and a start of the correspondent state machine to perform the calculations (see explanation below).

When *STATE* is a redundant signal of the same device only the *TRIGGER* input is used to generate the SUB_INC1 pulses in normal mode. There is a configuration possible, called emergency mode, for which the SUB_INC1 pulses are generated using the *STATE* input signal.

The decision to switch in the emergency mode and back is made outside the DPLL. The CPU must switch the configuration bit RMO (reference mode) in the DPLL_CTRL_0 register (see **Section 28.20.12**). Because a switch in emergency mode can appear suddenly, the information of the last increment duration of the *STATE* input up to FULL_SCALE should be stored always as a precaution.

The filtering as well as the combination or choice of the input signals is made in the TIM sub-module (see chapter “Timer Input Module (TIM)”) by use of a configurable filter algorithm for each slope and signal as well as in the MAP module (see chapter “TIM0 Input Mapping Module (MAP)”) the right *TRIGGER* or *STATE* signal is selected by a multiplexer or in the SPE module (see chapter “Sensor Pattern Evaluation (SPE)”) different signals are combined to a *TRIGGER* or *STATE* signal by using an antivalence operation.

The filter delay value of the signal is transmitted from the TIM module in the *FT* part of the corresponding signal, because the delay conditions of the signals can change during application.

The filter delays depend also on the filter algorithms used. Only the effective filter delay can be considered in the DPLL.

In order to provide the timing conditions to the DPLL the input trigger signals should have a time stamp (and optional in addition a filter value and a signal level value, as stated above) with an appropriate resolution. The resolution of the time stamps can be either the same resolution as the input time base TBU_TS0 (see **Figure 123**) or 8 times higher, selected by configuration bits in the DPLL_CTRL_1 register (see **Register DPLL_CTRL_1**). The time base TBU_TS0 is used to predict events in the future, called actions.

At the SUB_INCx outputs a predefined number of pulses between each active slope of the *TRIGGER/STATE* signal is generated, when the correspondent pulse generator is enabled by the enable bits SGEx=1 in the DPLL_CTRL_1 register (see **Register DPLL_CTRL_1**).

Dependent on configuration different strategies can be used to correct a wrong pulse number.

The FULL_SCALE range is divided into a fix number of nominal increments. Nominal increments do have the same size. The number of nominal increments in HALF_SCALE is specified in the DPLL_CTRL_0 register (see **Register DPLL_CTRL_0**).For synchronization purposes some *TRIGGER/STATE* input signals can be suppressed in dependency on the current position. Therefore an increment as duration between two active input events can be either a nominal increment or it can consist of more than one nominal increment. While a true nominal increment starts with an active event a virtual increment (of always nominal size) is an increment which starts with a missing event. Each increment which represents a gap (e.g. for synchronization purposes) consists of exactly one true nominal increment and at least one virtual increment, each of them having the same nominal duration (see figure below).

28.20.3 Input signal courses

Typical input signal courses are shown in the figure below.

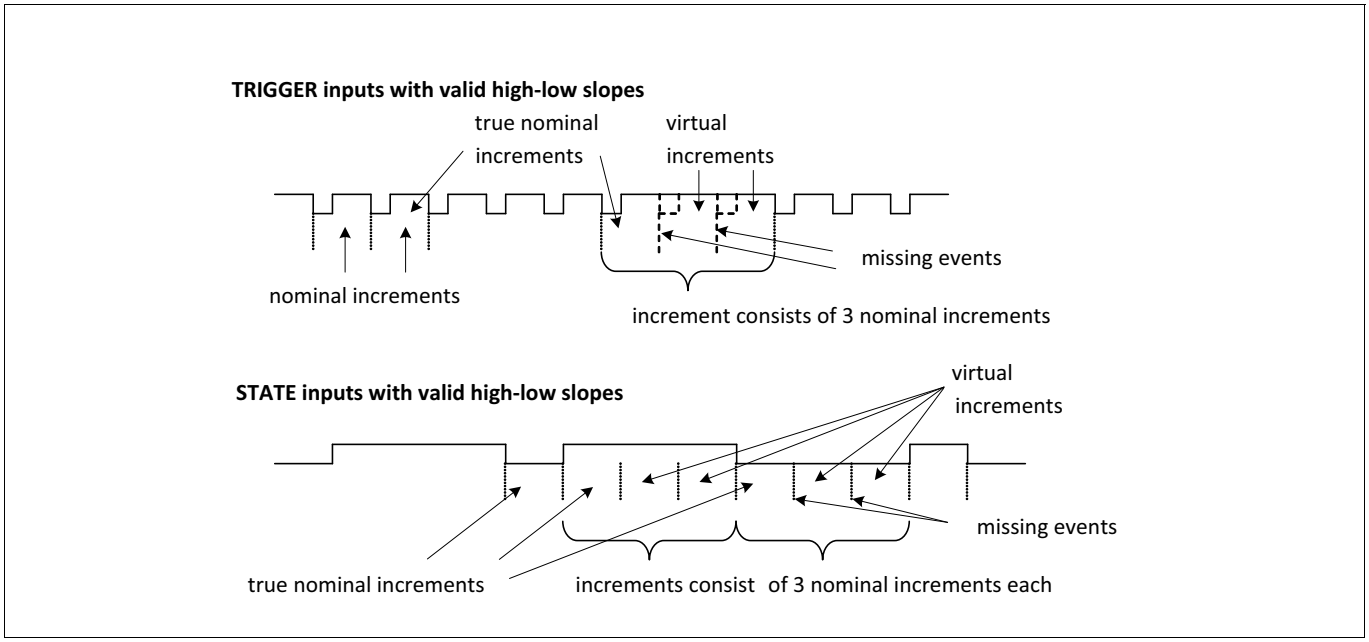

Figure 122 Trigger and State Input Signal

28.20.4 Block and interface description

The block description of the DPLL is shown in the following figure.

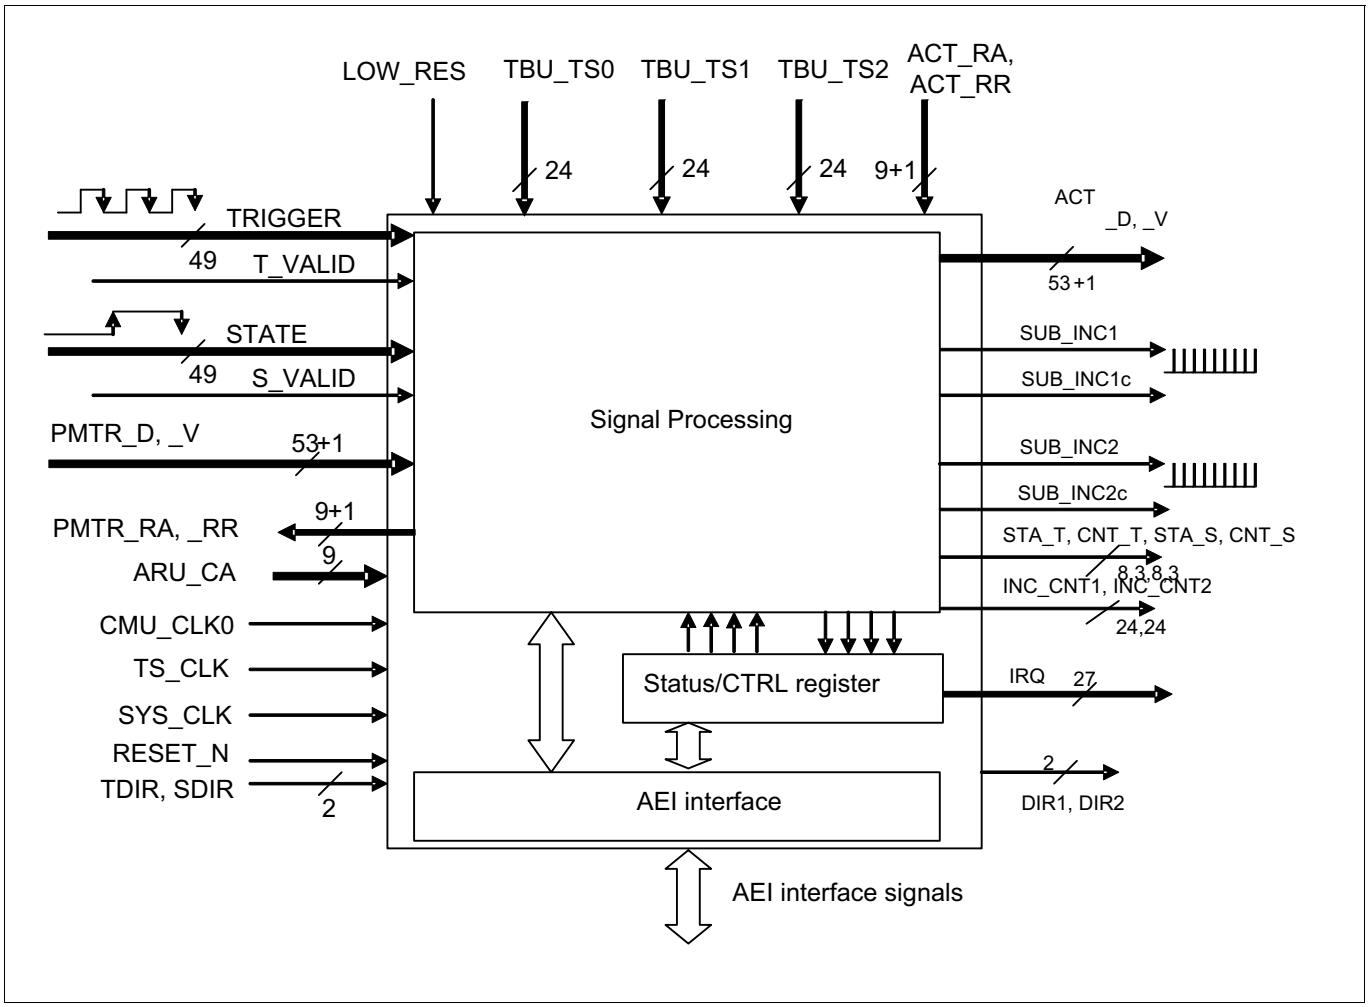

Figure 123 DPLL Block Diagram

Section 28.20.4.1 summarizes the interface signals of the DPLL shown by the block diagram above.

28.20.4.1 Interface description of DPLL

Table 70 Interface description of DPLL

Name	Width	I/O	Description	Comment
TRIGGER	49	I	Normal Signal for triggering DPLL by positions/values Bit(48)= TRIGGER_S Bits(47:24)= TRIGGER_FT Bits(23:0)= TRIGGER_TS	One bit signal value (SV), 24 bits filter delay value info and 24 bits time stamp, filtered in different modes.
STATE	49	I	Assistance signal for synchronization STATE(48)= STATE_S STATE(47:24)= STATE_FT STATE(23:0)= STATE_TS	Replacement of signal *TRIGGER* for emergency situations, or signal from an independent device; bits like above, corresponding
T_VALID	1	I	The values of *TRIGGER* are valid	Announces the arrival of a new *TRIGGER* value
S_VALID	1	I	The values of STATE are valid	Announces the arrival of a new STATE value
PMTR_D	53	I	Position minus time request data, delivered by ARU on request for up to 24 requests PMTR_RR; SV_i=PMTR_D(52:48): ACB bits, directly written to the correspondent DPLL_ACB_j registers PSA[i]=PMTR_D(47:24): position value for action DLA[i]=PMTR_D(23:0) time delay value for action	Data values for calculation of actual Actions; the values are requested by AENi=1[1)] and CAIP=0[2)]; a served request is shown by PMTR_V which signals that valid PMTR data arrived and they are written immediately after that to the corresponding RAM regions and registers; The DLA[i] values must have the same resolution as the TBU_TS0 input.
PMTR_V	1	I	signals a valid PMTR_D value, that means data is delivered on request	when valid: PMTR_D overwrites data in the PSA[i] and DLA[i] registers, also when the corresponding ACT_N[i][3)] bit =1;
ARU_CA	9	I	Channel address; for valid PMTR addresses: demand data by setting PMTR_RR=1 when enabled by AENi=1[1)] and CAIP=0[2)];	counter value of ARU selects PMTR_RA and PMTR_RR when a valid address
PMTR_RA	9	O	read address of PMTR access	reflects ID_PMTR_i according to the selected channel address
PMTR_RR	1	O	read request of PMTR access; suppressed for CAIPi=1 (see DPLL_STATUS register)	reflects the value of the corresponding AENi[1)] bit while the correspondent bit CAIPi=0[2)]

Table 70 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
ACT_D	53	O	Output of a time stamp, a position and a control signal for a calculated action; SV_i=ACT_D(52:48): ACB bits, directly written from the correspondent PMTR_D signals; ACT_D(47:24) is the calculated position value PSAC[i] for the action in relation to TBU_TS1 or 2[4] and ACT_D(23:0) is the time stamp value TSAC[i] for the action in relation to TBU_TS0 [4]	Future time stamp with the resolution as TBU_TS0 input, additional position information and additional control bits;
ACT_V	1	O	ACT_D value is available and valid; blocking read access	for a valid action address: ACT_V reflects the shadow value of ACT_N[i][3] (ACT_N[i] is 1 when new PMTR values are available and the shadow register is updated, when a calculation of the actual PMTR values was done); reset after reading of the ACT_D values
ACT_RA	9	I	ACTION read address;	address bits for selection of all 24 action channels
ACT_RR	1	I	read request of selected action	the action data is demanded from another module
IRQ	27	O	Interrupt request output	Interrupts of DPLL;
SUB_INC1	1	O	Pulse output for *TRIGGER* input filter	sub-position increment provided continuously
SUB_INC2	1	O	Pulse output for *STATE* input filter (when *TRIGGER* and *STATE* are used for 2 independent devices)	sub-position increment provided continuously
SUB_INC1c	1	O	Pulse output for time base unit 1 in compensation mode (can stop in automatic end mode)	sub-position increment related to *TRIGGER* input
SUB_INC2c	1	O	Pulse output for time base unit 2 in compensation mode (can stop in automatic end mode)	sub-position increment related to *STATE* input (when *TRIGGER* and *STATE* are used for 2 independent devices)
TS_CLK	1	I	Time stamp clock	used for generation of the time stamps; this clock is used to generate the SUB_INC1,2 pulses
CMU_CLK0	1	I	CMU clock 0	used for rapid pulse correction of SUB_INC1,2
SYS_CLK	1	I	System clock	High frequency clock

Table 70 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
RESET_N	1	I	Asynchronous reset signal	Low active; After Reset he DPLL is available only after performing the RAM reset procedures by the DPLL hardware.
LOW_RES	1	I	low resolution of TBU_TS0 selected; shows which of the 27 bits of TBU_TS0 are connected to the DPLL	LOW_RES=0: T BU_TS0(DPLL)= lower 24 Bits of TBU_TS0(TBU); LOW_RES=1: TBU_TS0(DPLL)= higher 24 Bits of TBU_TS0(TBU); In the case LOW_RES=1 the TS0_HRT and/or TS0_HRS bits can be set [5]
TBU_TS0	24	I	Actual time stamp from TBU; is needed to decide, if a calculated action is already in the past	24 bit time input, with a resolution of the time stamp clock
TBU_TS1	24	I	Actual position/value stamp 1; for calculation of position stamps (*TRIGGER*/*STATE*)	24 bit pos./val. input, with a resolution of the SUB_INC1 pulses
TBU_TS2	24	I	Actual position/value stamp 2; to be implemented for an additional independent position	ditto for SUB_INC2 for calculation of position stamps (*STATE*) for SMC[6]=RMO[5]=1
TDIR	1	I	Direction of *TRIGGER* input values (TDIR=0 does mean a forward direction and TDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[6]=1 or IDDS=1
SDIR	1	I	Direction of *STATE* input values (SDIR=0 does mean a forward direction and SDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[6]=1
DIR1	1	O	Direction information of SUB_INC1 (count forwards for DIR1=0 and backwards for DIR1=1)	count direction of TBU_CH1_BASE; DIR1 changes always after the evaluation of the corresponding valid *TRIGGER* slope and after incrementing/decrementing of the address pointer
DIR2	1	O	Direction information of SUB_INC2 (count forwards for DIR2=0 and backwards for DIR2=1)	count direction of TBU_CH2_BASE; DIR2 changes always after the evaluation of the corresponding valid *STATE* slope and after incrementing/decrementing of the address pointer
STA_T	8	O	Status of TRIGGER state machine	Output to MCS0. Signals accessible via µC interface as well (DPLL_STA)

Table 70 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
CNT_T	3	O	Count TRIGGER	Output to MCS0.This reflects the count of active *TRIGGER* slopes (mod8).Signals accessible via µC interface as well (DPLL_STA)
STA_S	8	O	Status of STATE state machine	Output to MCS0.Signals accessible via µC interface as well (DPLL_STA)
CNT_S	3	O	Count STATE	Output to MCS0.This reflects the count of active *STATE* slopes (mod8).Signals accessible via µC interface as well (DPLL_STA)
INC_CNT1	24	O	Increment counter of pulse generator 1 (automatic end mode)	Output to MCS0.Signals accessible via µC interface as well (DPLL_INC_CNT1)
INC_CNT2	24	O	Increment counter of pulse generator 2 (automatic end mode)	Output to MCS0.Signals accessible via µC interface as well (DPLL_INC_CNT2)

28.20.5 DPLL Architecture

28.20.5.1 Purpose of the module

The DPLL generates a predefined number of incremental signal pulses within the period between two events of an input *TRIGGER* or *STATE* signal, when the corresponding pulse generator is enabled. The resolution of the pulses is restricted by the frequency of the time stamp clock (TS_CLK). Changes in the period length of the predicted time period of the current increment will result in a change of the pulse frequency in order to get the same number of pulses. This adoption can be performed by DPLL hardware, software or with support of DPLL hardware in different modes.

The basic part of a DPLL is to make a prediction of the current period between two *TRIGGER* and/or *STATE* signal edges. Disturbances and systematic failures must be considered as well as changes of increment duration caused by acceleration and deceleration of the supervised process. Therefore, a good estimation is to be done using some measuring values from the past. When the process to be predicted takes a steady and differentiable course not only the current increment but also some more increments for the future can be predicted. In utilization of such calculations actions for the future can be predicted.

28.20.5.2 Explanation of the prediction methodology

As already shown in **Section 28.20.1** the DPLL has to perform different tasks. The basic function for all these tasks is the prediction of the current increment which is based on a relation between increments in the past. Because the relation between two succeeding intervals at a fixed position remains also valid in the case of acceleration or deceleration the prediction of the duration of the current time interval is done by a similarity transformation. Having a good estimation of the current time interval, all the other tasks can be done easily by calculations explained in **Section 28.20.6**.

28.20.5.3 Clock topology

All registers are read using the system clock *SYS_CLK*. The SUB_INC1,2 pulses generated have in the normal case the highest frequency not higher then *CMU_CLK0* or the half of *TS_CLK* respectively. For individual pulses the frequency can be doubled. All operations can be performed using the system clock.

28.20.5.4 Clock generation

The clock is generated outside the DPLL.

28.20.5.5 Typical frequencies

For the system clock a reasonable clock frequency should be applied to give the DPLL module sufficient computational power to calculate all needed values (prediction of next increment, actions) in time. The typical system clock frequency is in the range from 40 MHz up to 150 MHz.

28.20.5.6 Time stamps and systematic corrections

The time stamps for the input signals *TRIGGER* and *STATE* have 24 bits each. These bits represent the value of the 24 bit free running counter running with a clock frequency selected by the configuration of the TBU. Using a typical frequency of 20 MHz the time stamp represents a relative value of time with a resolution of 50 ns.

The input signals have to be filtered. The filter is not part of the DPLL. The time stamps can have a delay caused by the filter algorithm used. There are delayed and undelayed filter algorithms available and the delay value can depend on a time or a position value.

Systematic deviations of *TRIGGER* inputs can be corrected by a profile, which also considers systematic missing *TRIGGER*s. The increments containing missing *TRIGGER*S are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increments duration.

For each increment this number of enclosed nominal increments is stored in a profile as NT value for *TRIGGER*. When the increment is a nominal increment the NT value is 1.

For the *TRIGGER* input the value NT is stored in the ADT_T field in RAM region 2c.

In the case of **AMT**[4] = 1 the **ADT_T[i]** values in the RAM region 2c must also contain the adapting information for the *TRIGGER* signal, which considers for each increment a systematic physical deviation **PD** from the perfect increment value with a resolution according to the chosen value of MLT+1, which describes the number of SUB_INC1 pulses for a nominal increment.

The value **PD** for the *TRIGGER* describes the amount of missing or surplus pulses with a sint13 value, to be added to MLT+1 directly. The correction value is in this way also applicable in the case of missing *TRIGGER* inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment (MLT+1) is multiplied (MLT+1) + PD is multiplied by NT.

The NT value of the current increment is stored in the variable SYN_T (see **NUTC** register in **Section 28.20.12.14**).

In the case of **RMO**[4]= 1 for **SMC**[5]=0 (emergency mode) the time stamp of *STATE* is used to generate the output signal SUB_INC1.

More inaccuracy should be accepted in emergency mode because usually there are only fewer events available for FULL_SCALE according to the value SNU[5].

For the *STATE* signal the systematic deviations of the increments can be corrected in the same way as for *TRIGGER* by profile and adaptation information as described below.

Systematic deviations of *STATE* inputs can be corrected by a profile, which also considers systematic missing *STATE* events. The increments containing missing *STATEs* are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increments duration.

For each increment this number of enclosed nominal increments is stored in a profile as NS value for *STATE*. When the increment is a nominal increment the NS value is 1.

For the *STATE* input the value NS is stored in the ADT_S field in RAM region 1c3.

In the case of **AMS**[4] = 1 the **ADT_S[i]** values in the RAM region 1c3 must contain the adapting information for the STATE signal, which considers for each increment a systematic physical deviation **PD_S** from the perfect increment value with a resolution according to the chosen value of MLS1, which describes the number of SUB_INC1 pulses for a nominal increment (see below).

The number of pulses SUB_INC1 for a nominal *STATE* increment in emergency mode (for SMC=0) is given by the value of MLS1= (MLT + 1)* (TNU + 1) /(SNU + 1) in order to get the same number of pulses in FULL_SCALE for normal and emergency mode. This value has to be configured by the CPU.

The value **PD_S** for the *STATE* describes the amount of missing or surplus pulses with a sint16 value, to be added to MLS1 directly. The correction value is in this way also applicable in the case of missing *STATE* inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment MLS1 is multiplied by NS first before the PD_S value is added.

The current NS value is stored in the variable SYN_S (see **NUSC** register in **Section 28.20.12.15**).

28.20.5.7 DPLL Architecture overview

As shown in **Figure 123** the DPLL can process different input signals. The signal *TRIGGER* is the normal input signal which gives the detailed information of the supervised process. It can be for instance the information of water or other liquid level representing the volume of the liquid, where each millimeter increasing results in a *TRIGGER* signal generation. In order to get a predefined filling level, without overflow also the inertia of the system must be taken into account. Hence, some delay for closing the inlet valve and also the remaining water amount in the pipe must be considered in order to start the closing action earlier as the filling level will be reached.

A second input signal *STATE* sends an additional (redundant) information for instance at some centimeters and because of intervals with different distances it gives also information about the system state with the direction of the water flow (in or out), while the *TRIGGER* signal must not contain information concerning the flow direction. In some applications the inactive slope of *TRIGGER* can be utilized to transmit a direction information. In the case of faults in the *TRIGGER* signal the *STATE* signal is to be processed in order to reach the desired value nevertheless, maybe with some loss of accuracy.

The measuring scale can have some systematic failures, because not all millimeter or centimeter distances measured mean the same value. This could be due to changes in the thickness of the measuring cylinder or the inaccurate position of the marks. These systematic failures are well known by the system and for improvement of the prediction the signals *ADT_T* and *ADT_S* for the correction of the systematic failures of *TRIGGER* and *STATE* respectively are stored in the internal RAM.

The input signals *TRIGGER* and *STATE* are represented as a time stamp signal each, which is stored in the 24 bit TS-part of the corresponding signal.

Information concerning the delay of this signal by filtering of disturbances is stored in the 24 bit FT-part of the signal.

In order to establish the relation of time stamps to the actual time the TBU_TS0[6] value is also provided showing the actual time value used for prediction of actions in the future.

After reaching the desired water level the water is filled in a bottle by draining. After that the water filling is repeated. The water level at draining is observed by the same sensor signals (the same number of *TRIGGER* pulses), but the duration of the draining could be different from the filling time. Both times together form the FULL_SCALE region, while one of them is a HALF_SCALE region, which can differ in time but not in the number of pulses, especially for *TRIGGER*.

For synchronization purposes some *TRIGGER* marks can be omitted in order to set the system to a proper synchronization value (maybe before the upper filling value is reached).

In emergency situations, when the *TRIGGER* signals are missed the *STATE* signal is used instead of.

The PMTR_i [4] signals announce the request for a position minus time calculation for up to 24 events.

All 24 events can be activated using the 24 AENi[1] (action enable) bits. Each of these enable bits are asked by the routing engine for a read access. The corresponding read request is generated by the AENi bit while CAIPx is zero. CAIP1 and CAIP2 are two bits of the DPLL_STATUS register for 12 actions each with the meaning “calculation of actions in progress”, controlled by the state machine (see **Section 28.20.2**) for scheduling the operations.

When such a request is serviced by the ARU (in the case CAIPx=0) the values for position and time are written in the corresponding RAM 1a region (0x0200… 0x025C for the position value and 0x0260… 0x02BC for the delay value), the control bits for the corresponding action are set accordingly. When a new PMTR value arrives, an old value is overwritten without notice and the shadow bit of ACT_N[i] is cleared while the ACT_N[i] (new action) bit in the DPLL_ACT_STA register is set. The ACT_N[i] is cleared, when the currently calculated action value is in the past. Overwriting of old information is possible without data inconsistency because the read request to ARU is suppressed during action calculations by the CAIP1,2 bits. In this way always the last possible PMTR value is used consistently.

28.20.5.8 DPLL Architecture description

The DPLL block diagram of **Figure 123** will now be explained in detail in combination with some example configurations of the control registers. There are different configuration bits available which can adopt the DPLL to the use case (see **Section 28.20.12**).

Let for example in HALF_SCALE the *TRIGGER* number TNU[4] be 0x3B (which is for TNU+1 = 60 decimal that does mean 120 events in FULL_SCALE) and the number of SUB_INC1 pulses between two *TRIGGER*s MLT[4] be 0x257 (this means 600 pulses per *TRIGGER* event). Than the FULL_SCALE region can be divided into 72000 parts each of them associated with its own SUB_INC1 pulse. For a run through FULL_SCALE all 72000 pulses should appear but maybe with a different pulse frequency between two *TRIGGER* events. For this example after each 600 pulses at the *SUB_INC1* output the next *TRIGGER* event is to be expected with the corresponding new time stamp.

Missing SUB_INC1 pulses due to acceleration have to be taken into account within the next increment. Not one pulse has to be missed or added because of calculation inaccuracy in average for a sufficient number of FULL_SCALE periods. This means that not one pulse is sent in addition and all missing pulses are to be caught up on afterwards.

For the systematic arrangement of *TRIGGER* inputs **the profile** (as already mentioned in **Section 28.20.5.6** is stored in the RAM region 2c (see **Section 28.20.14.3**). In this field the relative position of gaps can be stored in the NT value and also physical deviations in the PD value.

For the consideration of systematic missing *TRIGGER*s the actual NT value of the profile is stored in the SYN_T bits of the NUTC register (see **Section 28.20.12.14**).

In normal mode the physical deviation values PD in the ADT_T field could be used to balance the local systematic inaccuracy of the *TRIGGER* signal. The value of PD (see **Section 28.20.14.3**) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD is a signed integer value using 13 bits: up to +/-4096 pulses can be added for each increment.

The NT value of the profile ADT_T has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NT value is stored in SYN_T of the NUTC register.

Using the *STATE* input there are similar configuration bits available (see **Section 28.20.12**).

Let for example in HALF_SCALE the *STATE* number SNU[5] be 0xB (which is for SNU+1 =12 decimal and while SYSF[5] = 0 that does mean 24 events in FULL_SCALE). In order to get the same number of SUB_INC1 pulses for FULL_SCALE as above for *TRIGGER*s the value (MLT+1)=600 is divided by 2*(SNU+1)=24 and multiplied with 2*(TNU+1)=120. The result 3000 must be stored in MLS1 by the CPU (see **Section 28.20.12.75**).

For the systematic arrangement of *STATE* inputs **the profile** (as already mentioned in **Section 28.20.5.6** is stored in the RAM region 1c3 (see **Section 28.20.12.90**). In this field the relative position of gaps can be stored in the NS value and also physical deviations in the PD_S value.

For the consideration of systematic missing *TRIGGER*s the actual NS value of the profile is stored in the SYN_S bits of the NUSC register (see **Register DPLL_NUSC**).

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the *STATE* signal. The value of PD_S (see **Section 28.20.12.90**) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses per increment. PD_S is a signed integer value using 16 bits: up to +/-32768 pulses can be added for each increment.

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the STATE signal. The value of PD_S (see **Section 28.20.12.90**) is the pulse difference in the corresponding nominal increment and does mean the number of sub pulses to be added to the nominal number of pulses. . PD_S is a signed integer value using 16 bits: up to +/-32768 pulses can be added for each increment.

The NS value of the profile ADT_S has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NS value is stored in SYN_S of the NUSC register.

28.20.5.9 Block diagrams of time stamp processing.

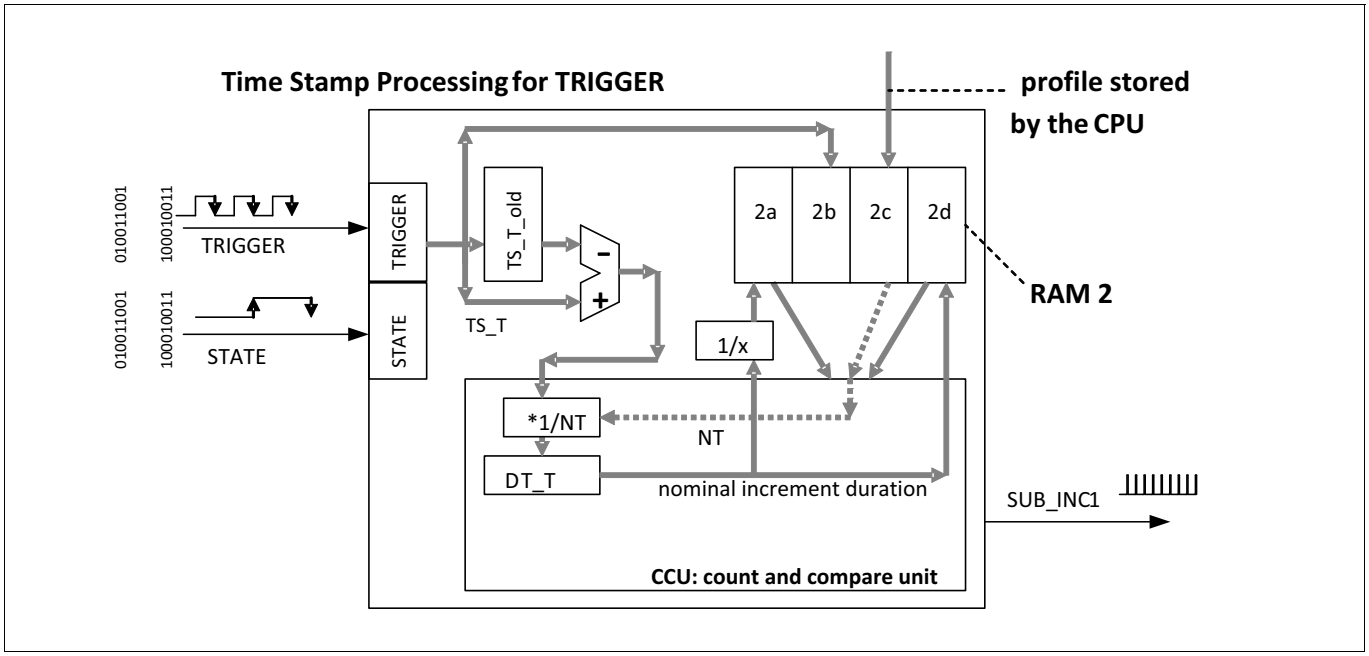

Figure 124 Time Stamp Processing Trigger

As shown in the block diagram above the time stamp difference of two succeeding input events is calculated. For the prediction of the current increment duration such values from the past are used. For this purpose the measured and calculated values of the last FULL_SCALE period are stored in the RAM. For the *TRIGGER* input there are 4 different RAM parts in the RAM region 2:

- 2a stores the reciprocals of each nominal increment duration RDT_T
- 2b stores the time stamps of each valid input event TSF_T
- 2c is used for the profile ADT_T and
- 2d for the nominal increment durations DT_T.

Because the prediction is based on the relations of increments in the past this relation can be calculated easily by the multiplication of increment duration values with the reciprocal value of another increment. In order not to be forced to distinguish between gaps and "normal" increments duration also for gaps only the nominal duration and the correspondent reciprocal values are stored in the RAM field. This is possible by consideration of the NT value in the profile: the measured increment duration is divided by NT.

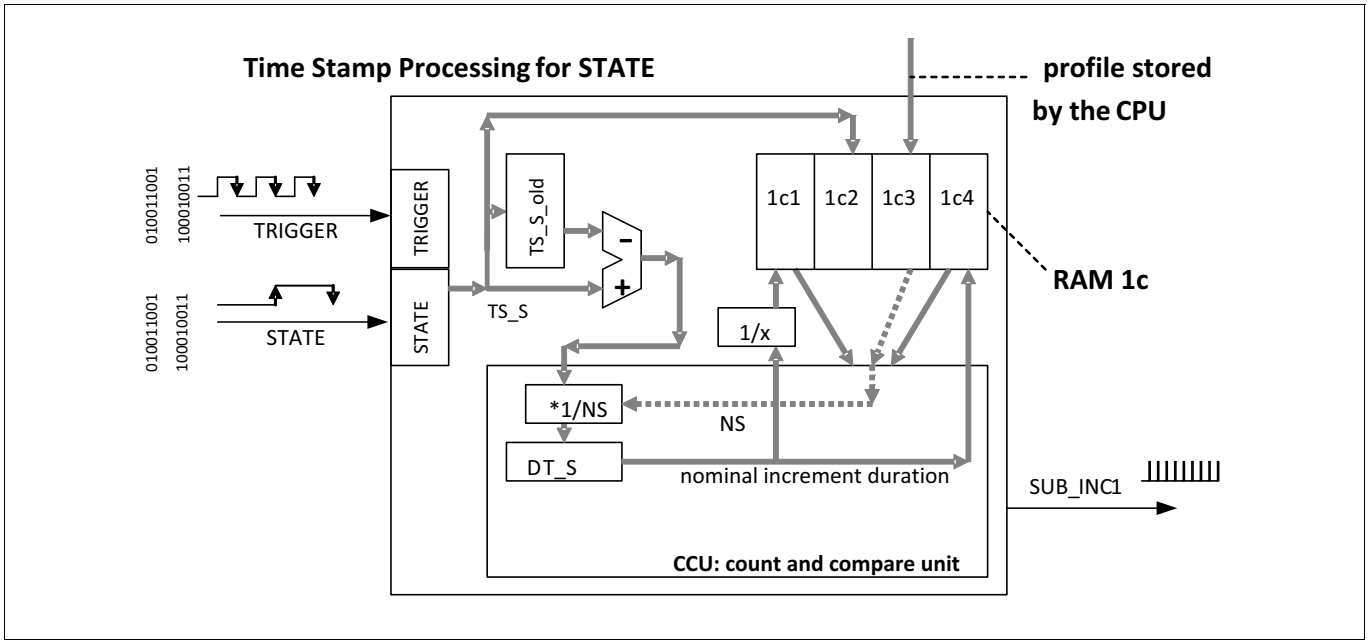

Figure 125 Time Stamp Processing State

For the *STATE* input there are also 4 different RAM parts in the RAM region 1c:

1c1 stores the reciprocals of each nominal increment duration RDT_S

1c2 stores the time stamps of each valid input event TSF_S

1c3 is used for the profile ADT_S and

1c4 for the nominal increment durations DT_S.

The calculations are performed similar as for the *TRIGGER* input. The NS value in the profile shows the appearance of a gap.

28.20.5.10Register and RAM address overview

The address map of the DPLL is divided into register and memory regions as defined in **Table 71**. The addresses from 0x0000 to 0x00FC are reserved for registers, from 0x0100 to 0x01FC is reserved for action registers to serve the ARU at immediately read request.

The RAM is divided into 3 independent accessible parts 1a, 1b+c and 2.

The part 1a from 0x0200 to 0x037C is used for PMTR values got from ARU and intermediate calculation values; there is no write access from the CPU possible, while the DPLL is enabled.

The RAM 1b part from 0x0400 to 0x05FC is reserved for RAM variables and the RAM part 1c from 0x0600 to 0x09FC is used for the *STATE* signal values.

The RAM region 2 from 0x4000 to 0x7FFC is reserved for the *TRIGGER* signal values. RAM region 1a has a size of 288 bytes, Ram 1b+c uses 1,125 Kbytes while RAM region 2 is configurable from 1,5 to 12 Kbytes, depending on the number of *TRIGGER* events in FULL_SCALE. The AOSV_2 register is used to determine the beginning of each part.

Table 71 gives the DPLL Address map overview.

Registers are used to control the DPLL and to show its status. Also parameters are stored in registers when useful. The table below shows the addresses for status and control registers as well as values stored in additional registers. The register meaning explained in the register overview (**Section 28.20.11**) while the bit positions of the status and control registers are described in detail in **Section 28.20.12**.

Time stamps for TRIGGER and *STATE* can have either the same resolution as the TBU_TS0 input or 8 times higher. This is configured in the DPLL_CTRL_1 register (see **Register DPLL_CTRL_1**). While the TBU_TS0 is used for

action predictions the higher resolution of *TRIGGER* and *STATE* inputs can be used for a more accurate pulse generation.

The time stamp fields of *TRIGGER* and *STATE* are stored in the corresponding RAM regions in such a way, that for a gap also entries for the virtual increments are provided. This is due to the necessity to calculate time differences between a given number of (real and virtual) input events independent of a gap. Therefore the gap is extended in the RAM fields 2b and 1c2.For all other RAM regions in RAM 2 and RAM 1c the gap is considered as one increment.

For the access to the RAM fields there must be address pointers. When the device starts all address pointers have a zero value and the first measured and calculated values are stored in the beginning of the corresponding RAM field.Because the position of the device is usually unknown at the beginning no profile information can be used. The profile regions must have their own address pointers each which are set by the CPU as soon as the position is known. By setting the appropriate value to the address pointer APT_2C of the *TRIGGER* profile or APS_1C3 of the *STATE* profile respectively the synchronization bits in the DPLL_STATUS register SYT or SYS are set respectively. In the following the gap information can be used.

Because the time stamp fields are extended at the gaps there must be additional address pointers for these regions: APT_2B for *TRIGGER* time stamps and APS_1C2 for *STATE* time stamps. These address pointers must be incremented by NT or NS respectively when a gap appears.

Table 71 Register and RAM address map

Addr. rangeStart	Addr. rangeEnd	Value number	Byte #	Content	Indication	Region	RAM size
0x0000	0x0FC	64	256	Register	used/reserved	0	no RAM
0x100	0x1FC	64	192	ACTION registers	direct read from ARU	0	no RAM
0x0200	0x03FC	128	384	PMTR values RAM 1a	CPU R/Pw access, when DPLL disabled; ARU has highest priority	1a with own ports	RAM part 1a:384 bytes
0x0400	0x05FC	128	384	Variables RAM 1b	R and monitored W access by the CPU	1b	RAM part 1b+c:1,125 Kbytes
0x0600	0x09FC	256	768	*STATE* data	R and monitored W access by the CPU	**1c**	
0x0600	0x06FC	64	192	RDT_S[i]	*STATE* reciprocal values	1c1	
0x0700	0x07FC	64	192	TSF_S[i]	*STATE* TS values	1c2	
0x0800	0x08FC	64	192	ADT_S[i]	adapted values of *STATE*	1c3	

Table 71 Register and RAM address map (cont'd)

Addr. rangeStart	Addr. rangeEnd	Value number	Byte #	Content	Indication	Region	RAM size
0x0900	0x09FC	64	192	DT_S[i]	nom. STATE inc.	1c4

28.20.5.10.1 RAM Region 1

RAM region 1 has a size of 1,5 Kbytes and is used to store variables and parameters as well as the measured and calculated values for increments of *STATE*. The RAM 1 region is divided into two independent accessible RAM parts (a and b+c) with own ports. The address information is shown in the table above and the detailed description is performed in the following chapters. The RAM 1a is used to store the PMTR values got from ARU and in addition some intermediate calculation results of actions. RAM region 1b is used for variables needed for the prediction of increments, while RAM 1c is used to store time stamps, profile and duration of all the *STATE* inputs of the last FULL_SCALE region. All variables and values of RAM 1b+c part use a data width of up to 24 bits.

The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. This is performed when setting The Init_RAM bit in the DPLL_RAM_INI register. The DPLL is only available after finishing this procedure. The initialization progress is shown in the status bits of the same register.

- **RAM Region 1a**: used for storage of PMTR values got from ARU; read and write access by the CPU is only possible, when the DPLL is disabled.
  The CPU Address range: 0x0200 – 0x03FC
- **RAM Region 1b**: usable for intermediate calculations and auxiliary values, data width of 3 bytes used for 24 bit values; A write access to this region results in an interrupt to the CPU, when enabled.
  Address range: 0x0400 – 0x05FC
- **RAM Region 1c**: Values of all STATE increments in FULL_SCALE, data width of 3 bytes used for 24 bit values; A write access to this region results in an interrupt to the CPU, when enabled.
  Address range: 0x0600 – 0x09FC

In RAM region 1c there is a difference in the amount of data. While for the RAM regions 1c1, 1c3 and 1c4 there are **2*(SNU+1-SYN_NS)** entries for SYSF=0 or **2*(SNU+1) -SYN_NS** entries for SYSF=1, for the RAM region 1c2 there are **2*(SNU+1)** entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without

a gap. For that reason the CPU must extend the stored TSF_S[i] values in the RAM region 1c2 before the APS_1C3 is written. The write access to APS_1C3 sets the SYS bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYS bit is set the PMTR values can consider more than the last increment duration for the action prediction by setting NUSE to a corresponding value.

Note: RAM regions 1b and 1c have a common port.

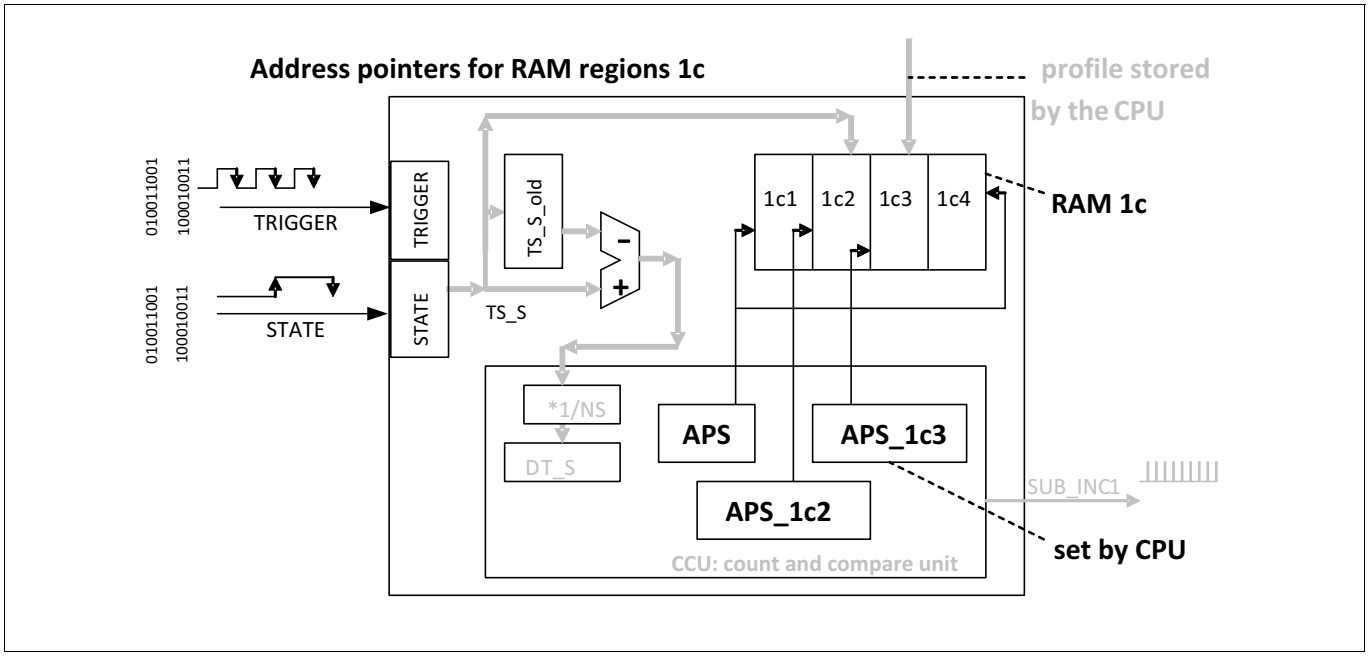

Figure 126 Address Pointer for RAM 1c

The address pointers for RAM region 1c are shown in the diagram above. While the address pointer APS points to the RAM regions 1c1 and 1c4, the address pointer APS_1C2 points to the time stamp field in the region 1c2. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Section 28.20.8.6.1**).The address pointer APS_1C3 is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register (see **Register DPLL_STATUS**) by the SYS bit.

28.20.5.10.2 RAM Region 2

The RAM region 2 has a configurable size of 1,5 to 12 Kilobytes and is used to store measured and calculated values for increments of *TRIGGER*. The address information is explained in **Section 28.20.11** while the meaning is explained in this chapter.

Because of up to 512 *TRIGGER* events in HALF_SCALE the fields 2a, b c and d must have up to 1024 storage places each. For 3 Bytes word size this does mean up to 12 k Byte of RAM region 2.

In order to save RAM size for configurations with less *TRIGGER* events the RAM is configurable by the offset switch Register OSW (0x001C) and the address offset value register of RAM region 2 AOSV_2 (0x0020). The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. The DPLL is only available after finishing this procedure.

In RAM region 2 there is a difference in the amount of data. While for the RAM regions 2a, 2c and 2d there are **2*(TNU+1-SYN_NT)** entries, for the RAM region 2b there are **2*(TNU+1)** entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant

parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_T[i] values in the RAM region 2b before the APT_2C is written.

The write access to APT_2C sets the SYT bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYT bit is set the PMTR values can consider more than the last increment duration for the action prediction by setting NUTE to a value greater than one.

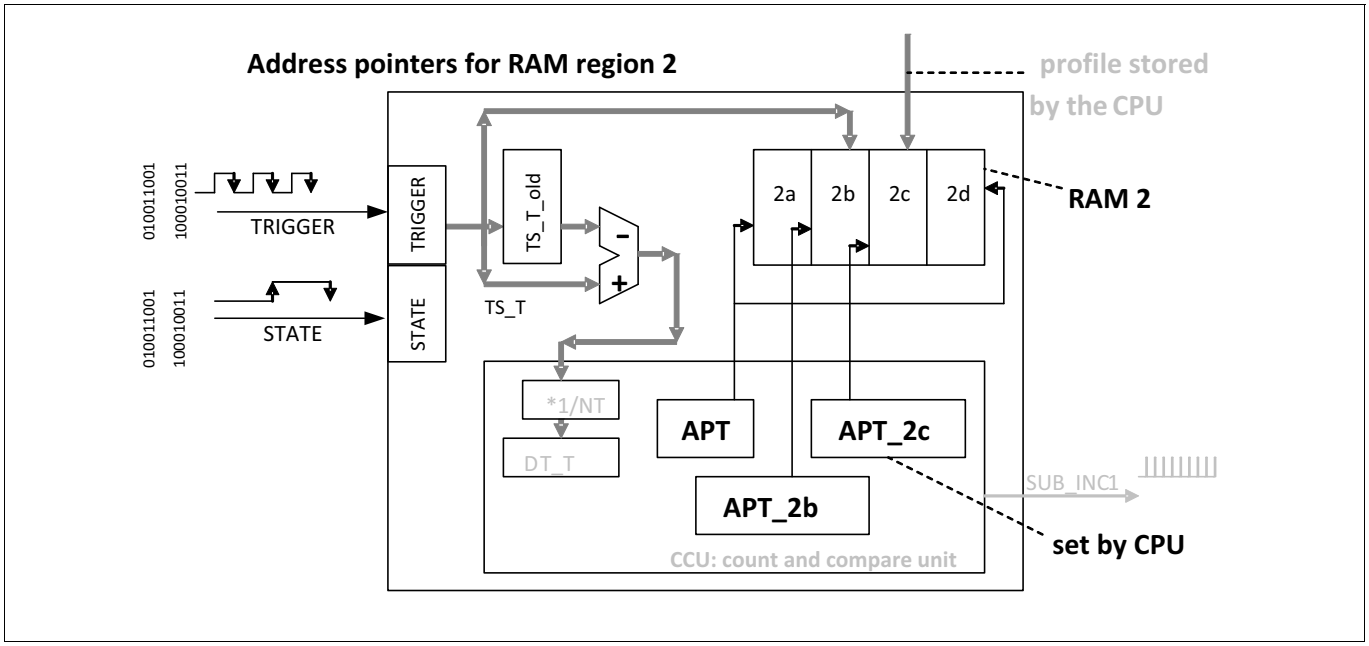

Figure 127 Address Pointer for RAM 2

The address pointers for RAM region 2 are shown in the diagram above. While the address pointer APT points to the RAM regions 2a and 2d, the address pointer APT_2B points to the time stamp field in the region 2b. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Section 28.20.8.6.1**).

The address pointer APT_2C is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register (see **Register DPLL_STATUS**) by the SYT bit.

28.20.5.11Software reset and DPLL deactivation

The DPLL module allows different options of deactivation and/or reset.To stop the operation of the DPLL module it is possible to deactivate the DPLL by setting of DPLL_CTRL_1.DEN = 0. This stops the calculations for the generation of the sub increments and the actions. Some control register areas are only configurable in this mode, some but not all register signals are set into an initial state. The RAM memory is not affected by DPLL deactivation at all. The behavior of the DPLL output signals and registers when deactivated is described in this document.

The deeper option to reconfigure the DPLL is the use of the software reset. When the DPLL module is deactivated setting DPLL_CTRL_1.SWR = 1 performs a reset of all DPLL registers and state controllers. The RAM memory is not affected by the software reset at all. After the software reset the DPLL module remains in deactivated state and the control registers must be configured again before operation (activation by DEN = 1) can start again.

The RAM modules can be reset (written to all zero) by activation of the memory init control bit (INIT_RAM) of the register DPLL_RAM_INI.If the RAM initialization is automatically done after power on reset or not depends on the GTM implementation.

A special case is the configuration of the control bit DPLL_CTRL_11.STATE_EXT. If this bit shall be modified during operation a software reset of the DPLL module is strongly recommended. A RAM initialisation should also be considered depending on the given application case.

28.20.6 Prediction of the current increment duration

28.20.6.1 The use of increments in the past

Past values to be considered for the prediction of TRIGGER

In order to take into account values of increments for *TRIGGER*s in the past, the NUTE value is configured to determine the number of past values. In addition the VTN has a value according to the number of virtual increments in the NUTE region. Because gaps come in to the NUTE region or leave it the VTN value must be updated by the CPU until NUTE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 2a and 2d the value NUTE-VTN is to be considered while for the RAM region 2b only the NUTE value is to be considered. This is due to the fact that the time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

Past values to be considered for the prediction of STATE

In order to take into account values of increments for *STATE* in the past, the NUSE value is configured to determine the number of past values. In addition the VSN has a value according to the number of virtual increments in the NUSE region. Because gaps come in to the NUSE region or leave it the VSN value must be updated by the CPU until NUSE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 1c1 and 1c4 in the past the value NUSE-VSN is to be considered while for the RAM region 1c2 only the NUSE value is to be considered. This is due to the fact that time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

28.20.6.2 Increment prediction in Normal Mode and for first PMSM forwards

For the prediction of increments and actions in normal mode the values are calculated as described in the following equations.

Please note, that the ascending order of calculation must be hold in order not to lose results still needed. It is important for *TRIGGER* values to calculate and store in the RAM region 2 all values according to equations up to DPLL-14 before DPLL-1a4…7, DPLL-1b1 and DPLL-1c1, while the last one overwrites DT_T[i] when NUTE (see **Register DPLL_NUTC**) is set to the FULL_SCALE range. Because the old value of DT_T[i] is also needed for equation DPLL-10 and DPLL-11 this value is stored temporarily at DT_T_ACT as shown by equation DPLL-1a or DPLL-1b respectively until all prediction calculations are done and after that equation DPLL-1a4…7, DPLL-1b1 and DPLL-1b1 updates DT_T[i]: update DT_T[i] after calculations of equation DPLL-14. For p=APT calculates in normal mode.

When using filter information of TRIGGER_FT, selected by IDT=1, it must be distinguished by IFP, if this filter information is time or position related.

In order to make possible to perform the automatic resolution corrections of equations DPLL-1a1a the filter unit in TIM module must operate using the time stamp clock.

28.20.6.2.1 Equations DPLL-1a to calculate TRIGGER time stamps

For calculation of time stamps use the filter delay information and an additional TRIGGER input delay value stored in register TIDEL (initial zero)

- TS_T_1=TRIGGER_TS - TIDEL **(DPLL-1a0)**
- TS_T=TS_T_1- FTV_Tx (for IDT=1 and IFP=0) **(DPLL-1a1)**

with

- FTV_Tx = FTV_T/8 (for LOW_RES = 1 and TS0_HRT = 0) **(DPLL-1a1a)**
- FTV_Tx = FTV_T (for LOW_RES = 0 or TS0_HRT = 1) **(DPLL-1a1b)**

and

- TS_T= TS_T_1- FTV_T *(CDT_TX/NMB_T)_old[1)] for (IDT=1 and IFP=1) **(DPLL-1a2)**

this can be also calculated using the value of ADD_IN_CALN:

- TS_T=TS_T_1 - FTV_T *(1/ADD_IN_CALN_old[1)]) for (IDT=1 and IFP=1) **(DPLL-1a3)**

1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two TRIGGER events. The reciprocal value is stored using a 32-bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL_0 register. The value of 1/ADD_IN_CALN_old or (CDT_TX/NMB_T)_old is set to 0xFFFFFF in the case of an overflow.

Note: CDT_TX is the predicted duration of the last TRIGGER increment and NMB_T the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-5 and DPLL-21 for the current increment after that. Therefore in equation DPLL-1a3 the value ADD_IN of the last increment is used (see equation DPLL-25). SYN_T_OLD is the number of TRIGGER events including missing TRIGGERs as specified in the NUTC register for the last increment, with the initial value of 1.

For storage of time stamps in the RAM see also equations DPLL-1a4 ff. after calculation of actions, **Section 28.20.7.5.1**.

28.20.6.2.2 Equation DPLL-1b to calculate DT_T_ACT (nominal value)

- DT_T_ACT= (TS_T - TS_T_OLD)/SYN_T_OLD **(DPLL-1b)**

For the case SYT=0 (still no synchronization to the profile) the values SYN_T and SYN_T_OLD are still assumed as having the value 1.

Correct the current increment duration value got by equation DPLL-1b in the case of physical deviations (ADT=1) by

- DT_T_ACT = DT_T_ACT * (1 - PDC_T+PDC_T^2+PDC_T^3) **(DPLL-1b1)**

with the relative correction value for the last increment (for SMC=0)

- PDC_T = PD_OLD/(MLT+1) **(DPLL-1b2)**

for SMC=1 use

- PDC_T = PD_OLD/(MLS1) (DPLL-1b3)

Note: The term (1 - PDC_T+PDC_T^2+PDC_T^3) is representing the third order Taylor series of the term 1/(1+PCT_T), which is chosen to reduce the additional time delay due to the more complex computation.

28.20.6.2.3 Equation DPLL-1c to calculate RDT_T_ACT (nominal value)

- RDT_T_ACT= 1/ DT_T_ACT **(DPLL-1C)**

28.20.6.2.4 Equation DPLL-2a1 to calculate QDT_T_ACT

Relation of the recent last two increment values for APT=p in forward direction (DIR1=0)

- QDT_T_ACT = DT_T_ACT * RDT_T[p-1] **(DPLL-2a1)**

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

Note: QDT_T_ACT uses a 6 bit integer part and an 18 bit fractional part.

28.20.6.2.5 Equation DPLL-3 to calculate the error of last prediction

When q = NUTE-VTN considers for the error calculation only the last valid prediction values for DIR1=0:
Calculate the error of the last prediction when using only RDT_T_FS1, DT_T[p-q], DT_T[p-q-1] and DT_T[p-1] for the prediction of DT_T[p]:

- EDT_T=DT_T_ACT-(DT_T[p-1]*QDT_T[p-q]) **(DPLL-3)**

with

- QDT_T[p-q] = DT_T[p-q] * RDT_T[p-q-1] for FST=0 **(DPLL-2b1)**
- QDT_T[p-q] = DT_T[p-q] * RDT_T_FS1 for FST=1 **(DPLL-2b2)**

and FST has the meaning: NUTE=FULL_SCALE (see NUTC register)
while
QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_T[p-q] uses a 6 bit integer part and a 18-bit fractional part.

28.20.6.2.6 Equation DPLL-4 to calculate the weighted average error

for SYT=1 calculate:

- MEDT_T := (EDT_T + MEDT_T)/2 **(DPLL-4)**

28.20.6.2.7 Equations DPLL-5 to calculate the current increment value

nominal increment value (for ADT=0):

- CDT_TX _nom = (DT_T_ACT + MEDT_T)* QDT_T[p-q+1] **(DPLL-5a1)**

nominal increment value (for ADT=1):

- CDT_TX _nom_corr = CDT_TX _nom*(1 + CDC_T) **(DPLL-5a2)**

with for SMC=0

- CDC_T = PD/ (MLT+1) **(DPLL-5a3)**

or for SMC=1 use

- CDC_T = PD/ (MLS1) **(DPLL-5a4)**

and with (for q>1):

- QDT_T[p-q+1] = DT_T[p-q+1] * RDT_T[p-q] **(DPLL-2c)**

and for q=1 use equation DPLL-2a1.

while
QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

The CDT_TX_nom value is limited by the relation

- CTN_MIN < CDT_TX_nom < CTN_MAX. **(DPLL-5c)**

When the calculated value exceeds one of the limit, it is replaced by the corresponding limit value.

The expected duration to the next TRIGGER event is (for ADT=0)

- CDT_TX = CDT_TX _nom * SYN_T **(DPLL-5b)**

The expected duration to the next TRIGGER event is (for ADT=1)

- CDT_TX = CDT_TX _nom_corr * SYN_T **(DPLL-5b)**

Note: QDT_T[p-q+1] uses a 6-bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-5a or b set the value to 0xFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX to 0x0 without any effect to the CTO bit.

28.20.6.3 Increment prediction in Emergency Mode and for second PMSM forwards

Please note, that the ascending order of calculations for *STATE* and storage of the values in the RAM region 1c must be hold in order not to lose results still needed. The same considerations as done for DT_T_ACT are valid for DT_S_ACT (equation DPLL-6a4…7, DPLL-6b1 and DPLL-6b1): update TD_S[i] only after calculations of equation DPLL-14.

When using filter information of STATE_FT, selected by IDS=1, it must be distinguished by IFP, if this filter information is time or position related.

In order to make possible to perform the automatic resolution corrections of equations DPLL-6a1a the filter unit in TIM must operate using the time stamp clock.

28.20.6.3.1 Equations DPLL-6a to calculate STATE time stamps

For calculation of time stamps use the filter delay information, the additional STATE input delay value stored in the register SIDEL (initial zero) and use p=APS while DIR2=0:

- TS_S_1=STATE_TS - SIDEL **(DPLL-6a0)**
- TS_S=TS_S_1 - FTV_Sx (for IDS=1 and IFP=0) **(DPLL-6a1)**

with

- FTV_Sx = FTV_S/8 (for LOW_RES = 1 and TS0_HRS = 0) **(DPLL-6a1a)**
- FTV_Sx = FTV_S (for LOW_RES = 0 or TS0_HRS = 1) **(DPLL-6a1b)**

and

- TS_S=TS_S_1 - FTV_S *(CDT_SX/NMB_S)_old[1] (for IDS=1 and IFP=1) **(DPLL-6a2)**

this can be also calculated using the value of ADD_IN_CALE:

- TS_S=TS_S_1 - FTV_S *(1/ADD_IN_CALE)_old[1] (for IDS=1 and IFP=1) **(DPLL-6a3)**

with

see also equations DPLL-6a4 ff. at **Section 28.20.6.2** for TRIGGER.

1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two STATE events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL_0 register. The value of 1/ADD_IN_CALE_old or (CDT_SX/NMB_S)_old is set to 0xFFFFFF in the case of an overflow.

Note: CDT_SX is the predicted duration of the last STATE increment and NMB_S the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-10 and DPLL-22 respectively for the current increment after that. Therefore in equation DPLL-6a3 the value ADD_IN of the last increment is used (see equation DPLL-26). SYN_S_OLD is the number of increments including missing STATEs as specified in the NUSC register for the last increment with the initial value of 1. The update to the RAM region 1c4 is done after all related calculations (see equation DPLL-6b1 for this reason).

28.20.6.3.2 Equation DPLL-6b to calculate DT_S_ACT (nominal value)

- DT_S_ACT= (TS_S - TS_S_OLD)/SYN_S_OLD **(DPLL-6b)**

For the case SYS=0 (still no synchronization to the profile) the values SYN_S and SYN_S_OLD are still assumed as having the value 1.

Correct the current increment duration value got by equation DPLL-6b in the case of physical deviations (ADS=1) by

- DT_S_ACT = DT_S_ACT * (1 - PDC_S+PDC_S2+PDC_S3) **(DPLL-6b1)**

with the relative correction value for the last increment (for SMC=0)

- PDC_S = PD_S_OLD/(MLS1) **(DPLL-6b2)**

for SMC=1 use

- PDC_S = PD_S_OLD/(MLS2) **(DPLL-6b3)**

Note: The term (1 - PDC_S+PDC_S2+PDC_S3) is representing the third order Taylor series of the term 1/(1+PDC_S), which is chosen to reduce the additional time delay due to the more complex computation.

28.20.6.3.3 Equation DPLL-6c to calculate RDT_S_ACT (nominal value)

- RDT_S_ACT = 1/ DT_S_ACT **(DPLL-6c)**

28.20.6.3.4 Equation DPLL-7a1 to calculate QDT_S_ACT

for APS=p in forward direction (DIR2=0)

- QDT_S_ACT = DT_S_ACT * RDT_S[p-1] **(DPLL-7a1)**

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

Note: QDT_S_ACT uses a 6 bit integer part and a 18 bit fractional part.

28.20.6.3.5 Equation DPLL-8 to calculate the error of last prediction

with q= NUSE-VSN when using QDT_S[p-q] and DT_S[p-1] for the prediction of DT_S[p]

- EDT_S = DT_S_ACT - (DT_S[p-1] * QDT_S[p-q]) **(DPLL-8)**

and with

- QDT_S[p-q] = DT_S[p-q] * RDT_S[p-q-1] for FSS=0 **(DPLL-7b1)**
- QDT_S[p-q] = DT_S[p-q] * RDT_S_FS1 for FSS=1 **(DPLL-7b2)**

and FSS has the meaning: NUSE=FULL_SCALE (see NUSC register)

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_S[p-q] uses a 6 bit integer part and a 18 bit fractional part.

28.20.6.3.6 Equation DPLL-9 to calculate the weighted average error

for SYS=1 calculate:

- MEDT_S := (EDT_S + MEDT_S)/2 **(DPLL-9)**

28.20.6.3.7 Equations DPLL-10 to calculate the current increment (nominal value)

nominal increment value (for ADS=0):

- CDT_SX _nom= (DT_S_ACT + MEDT_S)* QDT_S[p-q+1] **(DPLL-10a1)**

or nominal increment value (for ADS=1):

- CDT_SX _nom_corr= CDT_SX _nom*(1+CDC_S) **(DPLL-10a2)**

with for SMC=0

- CDC_S = PD / (MLS1) **(DPLL-10a3)**

for SMC=1 use

- CDC_S = PD / (MLS2) **(DPLL-10a4)**

and with

- QDT_S[p-q+1] = DT_S[p-q+1] * RDT_S[p-q] (for q>1) **(DPLL-7c)**
  see equation DPLL-7a1 for q=1

while

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

The CDT_SX_nom value is limited by the relation

- CSN_MIN < CDT_SX_nom < CSN_MAX **(DPLL-10c)**

When the calculated value exceeds one of the limit, it is replaced by the corresponding limit value.

The expected duration to the next *STATE* event is (for ADT=0)

- CDT_SX = CDT_SX _nom * SYN_T **(DPLL-10b)**

The expected duration to the next *STATE* event is (for ADT=1)

- CDT_SX = CDT_SX _nom_corr * SYN_S **(DPLL-10b)**

Note: QDT_S[p-q+1] uses a 6 bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-10a or b set the value to 0xFFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX to 0x0 without any effect to the CSO bit. All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

28.20.6.4 Increment prediction in Normal Mode and for first PMSM backwards

28.20.6.4.1 Equations DPLL-2a2 to calculate QDT_T_ACT backwards

- QDT_T_ACT = DT_T_ACT * RDT_T[p+1] **(DPLL-2a2)**

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

28.20.6.4.2 Equation DPLL-3a to calculate of the error of last prediction

When q = NUTE-VTN and DIR1=1 using only QT_T[p+q] and DT_T[p+1] for the prediction of DT_T[p]

- EDT_T=DT_T_ACT-(DT_T[p+1]*QDT_T[p+q] **(DPLL-3a)**

with

- QDT_T[p+q] = DT_T[p+q] * RDT_T[p+q+1] for FST=0 **(DPLL-2b3)**
- QDT_T[p+q] = DT_T[p+q] * RDT_T_FS1 for FST=1 **(DPLL-2b4)**

and FST has the meaning: NUTE=FULL_SCALE (see NUTC register)

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

28.20.6.4.3 Equation DPLL-4 to calculate the weighted average error

For SYT=1 calculate: MEDT_T := (EDT_T + MEDT_T) / 2 (DPLL-4)

28.20.6.4.4 Equation DPLL-5 to calculate the current increment value

nominal increment value (for ADT=0):

- CDT_TX _nom = (DT_T_ACT + MEDT_T)* QDT_T[p+q-1] **(DPLL-5a5)**

nominal increment value (for ADT=1):

- CDT_TX _nom_corr = CDT_TX _nom * (1 + CDC_T) **(DPLL-5a6)**

with for SMC=0

- CDC_T = PD / (MLT + 1) **(DPLL-5a3)**

for SMC=1 use

- CDC_T = PD / (MLS1) **(DPLL-5a3)**

and with

- QDT_T[p+q-1] = DT_T[p+q-1] * RDT_T[p+q] (for q>1) **(DPLL-2c1**

for q=1 use equation DPLL-2a1.

while

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

The CDT_TX_nom value is limited by the relation

- CTN_MIN < CDT_TX_nom < CTN_MAX. **(DPLL-5c)**

When the calculated value exceeds one of the limit, it is replaced by the corresponding limit value.
and the expected duration to the next TRIGGER event (for ADT=0)

- CDT_TX = CDT_TX _nom * SYN_T **(DPLL-5b)**

the expected duration to the next TRIGGER event (for ADT=1)

- CDT_TX = CDT_TX _nom_corr * SYN_T **(DPLL-5b)**

Note: In the case of an overflow in equations DPLL-5a1 or b set the value to 0xFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX(_nom) to 0x0.

28.20.6.5 Increment prediction in Emergency Mode and for second PMSM backwards

28.20.6.5.1 Equation DPLL-7a2 to calculate QDT_S_ACT backwards

- QDT_S_ACT = DT_S_ACT * RDT_S[p+1] **(DPLL-7a2)**

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

28.20.6.5.2 Equation DPLL-8a to calculate the error of the last prediction

While q= NUSE-VSN, use only QDT_S[p+q] and DT_S[p+1] for the prediction of DT_S[p]

- EDT_S = DT_S_ACT - (DT_S[p+1] * QDT_S[p+q]) **(DPLL-8a)**

with

- QDT_S[p-q] = DT_S[p+q] * RDT_S[p+q+1] for FSS=0 **(DPLL-7b3)**
- QDT_S[p-q] = DT_T[p+q] * RDT_S_FS1 for FSS=1 **(DPLL-7b4)**

and FSS has the meaning: NUSE=FULL_SCALE (see NUSC register)

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

28.20.6.5.3 Equation DPLL-9 to calculate the weighted average error

For SYS=1 calculate:

- MEDT_S := (EDT_S + MEDT_S)/2 **(DPLL-9)**

28.20.6.5.4 Equations DPLL-10 to calculate the current increment value

nominal increment value (for ADS=0):

- CDT_SX _nom= (DT_S_ACT + MEDT_S)* QDT_S[p+q-1] **(DPLL-10a5)**

or nominal increment value (for ADS=1):

- CDT_SX _nom_corr= CDT_SX _nom*(1+CDC_S) **(DPLL-10a6)**

with for SMC=0

- CDC_S = PD / (MLS1) **(DPLL-10a3)**

for SMC=1 use

- CDC_S = PD / (MLS2) **(DPLL-10a4)**

and with

- QDT_S[p+q-1] = DT_S[p+q-1] * RDT_S[p+q] (for q>1) **(DPLL-7c1)**

  for q=1 use equation DPLL-7a.

while

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

The CDT_SX_nom value is limited by the relation

- CSN_MIN < CDT_SX_nom < CSN_MAX. **(DPLL-10c)**

When the calculated value exceeds one of the limit, it is replaced by the corresponding limit value.

and calculate the expected duration to the next *STATE* event (for ADT=0)

- CDT_SX = CDT_SX _nom * SYN_T **(DPLL-10b)**

and calculate the expected duration to the next *STATE* event (for ADT=1)

- CDT_SX = CDT_SX _nom_corr * SYN_S **(DPLL-10b)**

Note: In the case of an overflow in equations DPLL-10a1 or b set the value to 0xFFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX(_nom) to 0x0.
All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

28.20.7 Calculations for actions

As already shown for the calculation of the current interval by equations DPLL-1 to DPLL-10 for the prediction of actions a similar calculation is to be done, as shown by the equations DPLL-11. to DPLL-14. The calculation of actions is also needed when the DPLL is used for synchronous motor control applications (SMC=1, see DPLL_CTRL_1 register). For action prediction purposes the measured time periods of the past (one FULL_SCALE back, when the corresponding NUTE or NUSE values are set properly by the CPU) are used. The calculation can be explained by the following assumptions, which are considerably simple:

Take the corresponding increments for prediction in the past and put the sum of it in relation to the increment (DT_T[k], DT_S[k], with k >= 0, which is represented by the time stamp difference) which is exactly one FULL_SCALE period in the past (DPLL-11 or DPLL-13 respectively). Make a prediction for the coming sum of increments using the current measured increment (DT_T_ACT or DT_S_ACT respectively, that means DPLL-1 or DPLL-6 respectively) and add a weighted average error (DPLL-3 and DPLL-4 or DPLL-8 and DPLL-9 respectively, calculated for one increment prediction) before multiplication with the relation of equation DPLL-11 or DPLL-13 respectively in order to get the result as described by equations DPLL-12 or DPLL-14 respectively.

In order to avoid division operations instead of the increment (DT_T[k], DT_S[k], with k > 0) in the past its reciprocal value (RDT_T[k], RDT_S[k], with k > 0) is used, which is stored also in RAM. For the calculation of actions perform always a new refined calculation as long as the resulting time stamp is not in the past. In the other case the TSAC/PSAC values (time/position stamp of action calculated) is set to the time/position stamp of the last input event (TRIGGER/STATE), the ACT_N[i] bit in the DPLL_ACT_STA register is reset, while the corresponding

ACT_N[i] bit in the DPLL_ACT_STA_shadow register is set. Each new PMTR_i value will set this ACT_N[i] bit again and reset the correspondent shadow bit until a new calculation is performed.

Please make sure that the prediction parameters are chosen such that under all conditions (acceleration/deceleration) the values of PDT_T, PDT_S and DTA respectively do not exceed the value 0xFFFFFF. This requirement can limit the predicted position range in the case of very low speed.

Action updates at highest speed

Up to 32 action values can be calculated. For the shortest increment duration (23,4 µs) not all of them can be updated with each active input event. Please notice the following conditions and parameters for an estimation of possible results.

All time estimation values are given for a system clock frequency of 100 MHz and the assumption, that the calculation of the DPLL is not impeded by a remote read or write access to the DPLL RAMs. Each RAM access is to be considered by an additional delay of about 40 ns ($t_{remote\_RAM\_acces}$, to be precised later). When using a different system clock frequency the calculation duration is extended accordingly.

1. Typical time needed for basic operations (RAM update, pointer calculation and SUB_INC generation for normal, emergency mode or one PMSM: t_{basic_0} = 9,9 µs.
2. Typical time needed basic operations (RAM update, pointer calculation and SUB_INC generation for two PMSMs): t_{basic_1} = 11,0 µs.
3. Typical time needed to calculate one action: t_{action_i} = 3,7 µs.

Please notice that the above mentioned values are observed worst case values, when the two state machines of TRIGGER and STATE are both in operation.

These values allow the calculation of at least 3 action values for each input event for all specified increments duration. The complete time needed for the basic operation, n action calculations and k remote RAM access operations can be calculated as follows:

$t_{complete} = t_{basic\_0/1} + n * t_{action\_}i + k * t_{remote\_RAM\_access}$.

Typical applications

Normal and emergency mode

For a typical application with the shortest increment duration of 100 µs in normal or emergency mode the calculation of up to 24 action values can be performed for each active input event.

One PMSM

For one PMSM and a typical shortest increment time of 39 µs there is the calculation of up to 7 action values possible for each input event.

Two PMSMs with restricted action calculations

When only one PMSM uses the action calculation service an the shortest increment duration is 39 µs, there can up to 7 actions served for each valid input event.

Two PMSMs with unrestricted action calculations

When 2 PMSMs are used and both use the action calculation service at a minimal increment duration of 39 µs there are up to 7 action calculations possible for each of the two engines - that means up to 14 action calculations per increment in average.

28.20.7.1 Action calculations for TRIGGER forwards

valid for RMO=0 or for SMC=1 with

p=APT_2B, t=APT, m=NA[i] (part w), mb=NA[i](part b)/1024, NUTE-VTN=q, NUTE=n

28.20.7.1.1 Equation DPLL-11a1 to calculate the time prediction for an action

For DIR1=0 and q>m calculate:

- PDT_T[i] = (TSF_T[p+m-n] - TSF_T[p-n] + mb* DT_Tx[t-q+1]) * RDT_T[t-q] **(DPLL-11a1)**

with

- DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

- DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-11b3)**

and while the multiplication with mb does mean the fractional part of NA[i].

For SMC=0 and RMO=0 calculate for DIR1=0 all 32 actions in forward direction, if requested; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the *TRIGGER* input.

28.20.7.1.2 Equation DPLL-11a2 to calculate the time prediction for an action

For SYT=1, NUTE= 2*(TNU+1), q>m and DIR1=0 equation DPLL-11a2 is equal to

- PDT_T[i] = (TSF_T[p+m] - TSF_T[p]+ mb* DT_Tx[t-q+1]) * RDT_T[t] **(DPLL-11a2)**

with

- DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

- DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-11b3)**

28.20.7.1.3 Equation DPLL-11b to calculate the time prediction for an action

for DIR1=0, NUTE-VTN=q, q (< or =) m, n>1 and t=APT:

- PDT_T[i] = (m+mb)*DT_Tx[t-q+1] * RDT_T[t-q] **(DPLL-11b)**

with

- DT_Tx[t-q+1] = DT_T[t-q+1] for TS0_HRT=0 **(DPLL-11b2)**

or

- DT_Tx[t-q+1] = DT_T[t-q+1]/8 for TS0_HRT=1 **(DPLL-11b3)**

Note: Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

28.20.7.1.4 Equation DPLL-11c to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

- PDT_T[i] = (m+mb)* DT_T_ax* RDT_T[t-1] **(DPLL-11c)**

with

- DT_T_ax = DT_T_ACT for TS0_HRT=0 **(DPLL-1a4a)**

or

- DT_T_ax = DT_T_ACT/8 for TS0_HRT=1 **(DPLL-1a4b)**

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

28.20.7.1.5 Equation DPLL-12 to calculate the duration value until action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] **(DPLL-12)**

Note: All 5 steps in equations DPLL-11 to DPLL-12 are only calculated in normal mode.

28.20.7.2 Action calculations for TRIGGER backwards

valid for RMO=0 or for SMC=1 with

p=APT_2B, t=APT, m=NA[i] (part w), mb=NA[i](part b)/1024, q= NUTE-VTN and n=NUTE

For SMC=0 and RMO=0 calculate for DIR1=1 all 32 actions in backward direction for special purposes; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the *TRIGGER* input.

28.20.7.2.1 Equation DPLL-11a3 to calculate the time prediction for an action

For DIR1=1 and q>m calculate:

- PDT_T[i] = (TSF_T[p-m+n] - TSF_T[p+n] + mb* DT_Tx[t+q-1]) * RDT_T[t+q] **(DPLL-11a3)**

with

- DT_Tx[t+q-1] = DT_T[t+q-1] for TS0_HRT=0 **(DPLL-11b4)**

or

- DT_Tx[t+q-1] = DT_T[t+q-1]/8 for TS0_HRT=1 **(DPLL-11b5)**

28.20.7.2.2 Equation DPLL-11a4 to calculate the time prediction for an action

For SYT=1 and NUTE = 2*(TNU+1), q>m, VTN=2*SYN_NT and hence **NUTE-VTN = 2*(TNU+1-SYN_NT)** for DIR1=1 this is equal to

- PDT_T[i] = (TSF_T[p-m] - TSF_T[p]+ mb* DT_Tx[t+q-1]) * RDT_T[t] **(DPLL-11a4)**

with

- DT_Tx[t+q-1] = DT_T[t+q-1] for TS0_HRT=0 **(DPLL-11b4)**

or

- DT_Tx[t+q-1] = DT_T[t+q-1]/8 for TS0_HRT=1 **(DPLL-11b5)**

Note: Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

28.20.7.2.3 Equation DPLL-11b1 to calculate the time prediction for an action

For NUTE-VTN =q, q (< or =) m the following equation is valid for n>1 and t=APT:

- PDT_T[i] = (m+mb)*DT_Tx[t+q-1] * RDT_T[t+q] **(DPLL-11b1)**

with

- DT_Tx[t+q-1] = DT_T[t+q-1] for TS0_HRT=0 **(DPLL-11b4)**

or

- DT_Tx[t+q-1] = DT_T[t+q-1]/8 for TS0_HRT=1 **(DPLL-11b5)**

28.20.7.2.4 Equation DPLL-11c1 to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

- PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t+1] **(DPLL-11c1)**

with

- DT_T_ax = DT_T_ACT for TS0_HRT=0 **(DPLL-1a4a)**

or

- DT_T_ax = DT_T_ACT/8 for TS0_HRT=1 **(DPLL-1a4b)**

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

28.20.7.2.5 Equation DPLL-12 to calculate the duration value for an action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] **(DPLL-12)**

Use the results of equations DPLL-1a, b, DPLL-3 and DPLL-4 for the above calculation

28.20.7.3 Action calculations for STATE forwards

valid for RMO=1 with

p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i](part b)/1024, NUSE-VSN = q and NUSE=n>m

For SMC=0 and RMO=1 calculate for DIR2=0 all 32 actions in forward direction, if requested; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the *STATE* input.

Note: All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

28.20.7.3.1 Equation DPLL-13a1 to calculate the time prediction for an action

For DIR2=0 and q>m calculate:

PDT_S[i] = (TSF_S[p+m-n] - TSF_S[p-n] + mb* DT_Sx[t-q+1] * RDT_S[t-q] **(DPLL-13a1)**

with

- DT_Sx[t-q+1]= DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

- DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

28.20.7.3.2 Equation DPLL-13a2 to calculate the time prediction for an action

For **SYS=1 and NUSE=2*(SNU+1)**, q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE-VSN = 2*(SNU+1-SYN_NS) equation DPLL-13a1 is equal to

- PDT_S[i] = (TSF_S[p+m] - TSF_S[p]+ mb*DT_Sx[t-q+1]) * RDT_S[t] **(DPLL-13a2)**

with

- DT_Sx[t-q+1] = DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

- DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

28.20.7.3.3 Equation DPLL-13b to calculate the time prediction for an action

For NUSE -VTN=q, q (< or =) m and n>1:

- PDT_S[i] = (m+mb)*DT_Sx[t-q+1] * RDT_S[t-q] **(DPLL-13b)**

with

- DT_Sx[t-q+1] = DT_S[t-q+1] for TS0_HRS=0 **(DPLL-13b2)**

or

- DT_Sx[t-q+1] = DT_S[t-q+1]/8 for TS0_HRS=1 **(DPLL-13b3)**

28.20.7.3.4 Equation DPLL-13c to calculate the time prediction for an action

for n=1

- PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t-1] **(DPLL-13c)**

with

- DT_S_ax = DT_S_ACT for TS0_HRS=0 **(DPLL-6a4a)**

or

- DT_S_ax = DT_S_ACT/8 for TS0_HRS=1 **(DPLL-6a4b)**

28.20.7.3.5 Equation DPLL-14 to calculate the duration value for an action

- DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] **(DPLL-14)**

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

28.20.7.4 Action calculations for STATE backwards

valid for RMO=1 with

p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i](part b)/1024, NUSE-VSN = q and NUSE=n

For SMC=0 and RMO=1 calculate for DIR1=1 all 32 actions in backwards mode for special purposes; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the *STATE* input.

28.20.7.4.1 Equation DPLL-13a3 to calculate the time prediction for an action

For (DIR2= 1 (SMC=1) or DIR1=1 (SMC=0)) and q>m calculate

- PDT_S[i] = (TSF_S[p-m+n] - TSF_S[p+n] + mb* DT_Sx[t+q-1]) * RDT_S[t+q] **(DPLL-13a3)**

with

- DT_Sx[t+q-1]= DT_S[t+q-1] for TS0_HRS=0 **(DPLL-13b4)**

or

- DT_Sx[t+q-1] = DT_S[t+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

28.20.7.4.2 Equation DPLL-13a4 to calculate the time prediction for an action

For SYS=1, **NUSE=2*(SNU+1)**, q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE-VSN = 2*(SNU+1-SYN_NS) equation DPLL-13a3 is equal to

- PDT_S[i] = (TSF_S[p-m] - TSF_S[p]+ mb* DT_Sx[t+q-1]) * RDT_S[t] **(DPLL-13a4)**

with

- DT_Sx[t+q-1]= DT_S[t+q-1] for TS0_HRS=0 **(DPLL-13b4)**

or

- DT_Sx[t+q-1] = DT_S[t+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

28.20.7.4.3 Equation DPLL-13b1 to calculate the time prediction for an action

For NUSE-VSN =q, q (< or =) m, NUSE=n and n>1:

- PDT_S[i] = m*DT_Sx[t+q-1] * RDT_S[t+q] **(DPLL-13b1)**

with

- DT_Sx[t+q-1] = DT_S[t+q-1] for TS0_HRS=0 **(DPLL-13b4)**

or

- DT_Sx[t+q-1] = DT_S[t+q-1]/8 for TS0_HRS=1 **(DPLL-13b5)**

28.20.7.4.4 Equation DPLL-13c1 to calculate the time prediction for an action

for n=1

- PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t+1] **(DPLL-13c1)**

with

- DT_S_ax = DT_S_ACT for TS0_HRS=0 **(DPLL-6a4a)**

or

- DT_S_ax = DT_S_ACT/8 for TS0_HRS=1 **(DPLL-6a4b)**

28.20.7.4.5 Equation DPLL-14 to calculate the duration value until action

DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] (DPLL-14)

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

28.20.7.5 Update of RAM in Normal and Emergency Mode

After considering the calculations for up to all 24 actions according to equations (DPLL-11, DPLL-12), only when going back to state 1 or 21 (because of a new TRIGGER or STATE event, that means when no further PMTR values are to be considered) set time stamp values and duration of increments in the RAM.

28.20.7.5.1 Equation DPLL-1a4 to update the time stamp values for TRIGGER

- TSF_T[s]=TS_Tx **(DPLL-1a4)**

using the following equations for the determination of TS_Tx
For TS0_HRT=0:

- TS_Tx=TS_T **(DPLL-1a4w)**
- DT_T_ax = DT_T_ACT **(DPLL-1a4a)**

For TS0_HRT=1:

- TS_Tx(20:0)=TS_T/8 **(DPLL-1a4x)**
- TS_Tx(23:21)=TBU_TS0_T(23:21) **(DPLL-1a4y)**
  for TBU_TS0_T(20:0) > or = TS_Tx(20:0)
- TS_Tx(23:21)=TBU_TS0_T(23:21) -1 **(DPLL-1a4z)**
  for TBU_TS0_T(20:0) < TS_Tx(20:0)
- DT_T_ax = DT_T_ACT/8 **(DPLL-1a4b)**

Note: the combination of values LOW_RES=0 and TS0_HRT=1 is not possible.

Store the time stamp values in the time stamp field according to the address pointer APT_2B=s, but make this update only after the calculations of actions (**Section 28.20.7**) because the old TSF_T[i] values are still needed for these calculations. Please note that the address pointer after a gap is still incremented by SYN_T_OLD in that case (see state machine step 1 in **Section 28.20.8.6**).

28.20.7.5.2 Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=0

- TSF_T[s-1] = TSF_T[s] -DT_T_ax **(DPLL-1a5)**
- TSF_T[s-2] = TSF_T[s-1] -DT_T_ax **(DPLL-1a6)**

until

- TSF_T[s- r+1] = TSF_T[s- r+2] -DT_T_ax **(DPLL-1a7)**

after the incrementation of the pointer APT_2B by SYN_T_OLD

28.20.7.5.3 Equations DPLL-1a5-7 for backward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=0

- TSF_T[s+1] = TSF_T[s] -DT_T_ax **(DPLL-1a5)**
- TSF_T[s+2] = TSF_T[s+1] -DT_T_ax **(DPLL-1a6)**

until

- TSF_T[s- r+1] = TSF_T[s- r+2] -DT_T_ax **(DPLL-1a7)**

after the incrementation of the pointer APT_2B by SYN_T_OLD

28.20.7.5.4 Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation

- DT_T[p] = DT_T_ACT **(DPLL-1b1)**

save old reciprocal value from RAM before overwriting:

- RDT_T_FS1= RDT_T[p] **(DPLL-1c1)**

after that store new value in RAM

- RDT_T[p]= RDT_T_ACT **(DPLL-1c2)**

Store increment duration and reciprocal value in RAM region 2 in normal mode after calculation of actions only when a new valid TRIGGER slope is detected and in emergency mode directly after calculation of DT_T_ACT or RDT_T_ACT respectively.

28.20.7.5.5 Equation DPLL-6a4 to update the time stamp values for STATE

- TSF_S[s]=TS_Sx **(DPLL-6a4)**

using the following equations for the determination of TS_Sx

For TS0_HRS=0:

- TS_Sx=TS_S **(DPLL-6a4)**
- DT_S_ax = DT_S_ACT **(DPLL-6a4a)**

For TS0_HRS=1:

- TS_Sx(20:0)=TS_S/8 **(DPLL-6a4x)**
- TS_Sx(23:21)=TBU_TS0_S(23:21) for TBU_TS0_S(20:0) > or = TS_Sx(20:0) **(DPLL-6a4y)**
- TS_Sx(23:21)=TBU_TS0_S(23:21) -1 for TBU_TS0_S(20:0) < TS_Sx(20:0) **(DPLL-6a4z)**
- DT_S_ax = DT_S_ACT/8 **(DPLL-6a4b)**

Note: the combination of values LOW_RES=0 and TS0_HRS=1 is not possible.

Store the time stamp value in the time stamp field according to the address pointer APS_1C2=s, but make this update only after the calculation of actions (equations DPLL-13a2, **Section 28.20.7.3.2** or DPLL-13a4 **Section 28.20.7.4.2**, if applicable) because the old TSF_S[i] values are still needed for these calculations. Please note, that the address pointer after a gap is still incremented by SYN_S_OLD in that case (see state machine step 21 in **Section 28.20.8.6**).

28.20.7.5.6 Equations DPLL-6a5-7 to extend the time stamp values for STATE

When SYS=1 and SYN_S_OLD=r>1 and DIR2=0 or DIR1=0 respectively calculate

- TSF_S[s-1] = TSF_S[s] - DT_S_ax **(DPLL-6a5)**
- TSF_S[s-2] = TSF_S[s-1] - DT_S_ax **(DPLL-6a6)**

until

- TSF_S[s- r+1] = TSF_S[s- r+2] - DT_S_ax **(DPLL-6a7)**

after incrementation of the pointer APS_2b by SYN_S_OLD

28.20.7.5.7 Equations DPLL-6a5-7 for backward direction

When SYS=1 and SYN_S_OLD=r>1 and DIR2=1 or DIR1=1 respectively calculate

- TSF_S[s+1] = TSF_S[s] - DT_S_ax **(DPLL-6a5)**
- TSF_S[s+2] = TSF_S[s+1] - DT_S_ax **(DPLL-6a6)**

until

- TSF_S[s+r-1] = TSF_S[s+r-2] - DT_S_ax **(DPLL-6a7)**

after the incrementation of the pointer APS_1C2 by SYN_S_OLD

28.20.7.5.8 Equations DPLL-6b1 and DPLL-6c2 to update the RAM after calculation

- DT_S[p] = DT_S_ACT **(DPLL-6b1)**

save old reciprocal value from RAM before overwriting:

- RDT_S_FS1= RDT_S[p] **(DPLL-6c1)**

after that store new value in RAM

- RDT_S[p] = RDT_S_ACT **(DPLL-6c2)**

when a new active STATE slope is detected in emergency mode or in normal mode (SMC=RMO=0) directly after calculation of the values above.

Store increment duration and reciprocal value in RAM region 1c in emergency mode after calculation of actions only when a new active STATE slope is detected and in normal mode directly after calculation of DT_S_ACT or RDT_S_ACT respectively.

28.20.7.6 Time and position stamps for actions in Normal Mode

28.20.7.6.1 Equation DPLL-15 to calculate the action time stamp

- TSAC[i]= DTA[i] - DLA[i] + TS_Tx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] < 0x800000) **(DPLL-15a)**
- TSAC[i]= TS_Tx (for DTA[i] < DLA[i]) **(DPLL-15b)**
- TSAC[i]= 0x7FFFFF + TS_Tx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] > 0x7FFFFF) **(DPLL-15c)**

*Note: For TS_Tx see equations (DPLL-1a4 and following and following), **Section 28.20.7.5.1***

The calculation is done after the calculation of the current expected duration value according to equation DPLL-12 at **Section 28.20.7.2.5**. The time stamp of the action can be calculated as shown above in equation DPLL-15 using the delay value of the action and the current time stamp

28.20.7.6.2 Equations DPLL-17 to calculate the position stamp forwards

for **DIR1**=0 and TS0_HRT=0:

- PSAC[i] = PSA[i] - (DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17)**

with

- RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T **(DPLL-17a)**

and

- RCDT_TX= 1/CDT_TX **(DPLL-17b)**

for **DIR1**=0 and TS0_HRT=1:

- PSAC[i] = PSA[i] - (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17d)**

with

- RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T **(DPLL-17a)**

and

- RCDT_TX= 1/CDT_TX **(DPLL-17b)**

replace (MLT+1) in equations (DPLL-17) and (DPLL-17d) by MLS1 for SMC=1
use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i

The action is to be updated for each new *TRIGGER* event until the calculated time stamp is in the past.
In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
When DPLL_CTRL_11.ACBU = '1':
- for ACB[z][1]='1':
is used as input signal to control if "action in the past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value.
- for ACB[z][1]='0':
In this case the PSAC[i] is used as calculated by the DPLL.
- for ACB[z][0]='1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value.
- for ACB[z][0]='0':
In this case the TSAC[i] is used as calculated by the DPLL.

Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

28.20.7.6.3 Equations DPLL-17 to calculate the position stamp backwards

For **DIR1**=1 and TS0_HRT=0:

- PSAC[i] = PSA[i] + (DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17c)**

with

- RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T **(DPLL-17a)**

and

- RCDT_TX= 1/CDT_TX **(DPLL-17b)**

For **DIR1**=1 and TS0_HRT=1:

- PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) **(DPLL-17e)**

with

- RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T **(DPLL-17a)**

and

- RCDT_TX= 1/CDT_TX **(DPLL-17b)**

replace (MLT+1) in equations (DPLL-17c) and (DPLL-17e) by MLS1 for SMC=1
use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i

The action is to be updated for each new *TRIGGER* event until the calculated time stamp is in the past.
Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.
In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
When DPLL_CTRL_11.ACBU = '1':
- for ACB[z][1]='1':
is used as input signal to control if "action in the past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value.
- for ACB[z][1]='0':
In this case the PSAC[i] is used as calculated by the DPLL.
- for ACB[z][0]='1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value.
- for ACB[z][0]='0':
In this case the TSAC[i] is used as calculated by the DPLL.

Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

28.20.7.7 The use of the RAM

The RAM is used to store the data of the last FULL_SCALE period. The use of single port RAMs is recommended. The data width of the RAM is usual 3 bytes, but could be extended to 4 bytes in future applications. There are 3 different RAMs, each with separate access ports. The RAM 1a is used to store the position minus time requests, got from the ARU. No CPU access is possible to this RAM during operation (when the DPLL is enabled).

Ram 1b is used for configuration parameters and variables needed for calculations. Within RAM 1c the values of the *STATE* events are stored. RAM 1b and RAM 1c do have a common access port and are also marked as RAM 1bc in order to clarify this fact.

RAM 2 is used for values of the *TRIGGER* events.

Because of the access of the DPLL internal state machine at the one side and the CPU at the other side the access priority has to be controlled for both RAMs 1bc and 2. The access priority is defined as stated below. The CPU access procedure via AE-interface goes in a wait state (waiting for data valid) while it needs a colliding RAM access during serving a corresponding state machine RAM access. In order not to provoke unexpected behavior of the algorithms the writing of the CPU to the RAM regions 1b, 1c or 2 will be monitored and results in interrupt requests when enabled.

CPU access is specified at follows:

1. CPU has highest priority for a single read/write access. The DPLL algorithm is stalled during external bus RAM accesses.
2. After serving the CPU access to the RAM the DPLL gets the highest RAM access priority for 8 clock cycles. Afterwards continue with 1.

The RAM address space has to be implemented in the address space of the CPU.

28.20.7.8 Time and position stamps for actions in Emergency Mode

28.20.7.8.1 Equation DPLL-18 to calculate the action time stamp

- TSAC[i]= DTA[i] - DLA[i] + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] < 0x800000) **(DPLL-18a)**
- TSAC[i]= TS_Sx (for DTA[i] < DLA[i]) **(DPLL-18b)**
- TSAC[i]= 0x7FFFFF + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] > 0x7FFFFF) **(DPLL-18c)**

Note: For TS_Sx see equations (DPLL-6a4 and following), ***Section 28.20.7.5.5***

The calculation is done after the calculation of the current expected duration value according to equation DPLL-14 at **Section 28.20.7.3.5**. The time stamp of the action can be calculated as shown in equation DPLL-18 using the delay value of the action and the current time stamp.

28.20.7.8.2 Equations DPLL-20 to calculate the position stamp forwards

for **DIR2**=0 or DIR1=0 respectively and TS0_HRS=0:

- PSAC[i] = PSA[i] - (DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20)**

with

- RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S **(DPLL-20a)**

and

- RCDT_SX= 1/CDT_SX **(DPLL-20b)**

for **DIR2**=0 or DIR1=0 respectively and TS0_HRS=1:

- PSAC[i] = PSA[i] - (8*DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20d)**

with

- RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S **(DPLL-20a)**

and

- RCDT_SX= 1/CDT_SX **(DPLL-20b)**

replace MLS1 in equations (DPLL-20) and (DPLL-20d) by MLS2 for (SMC=1 and RMO=1)
use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_Di.

The action is to be updated for each new *STATE* event until the calculated time stamp is in the past.
In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal.

When DPLL_CTRL_11.ACBU = ‘0’: Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
When DPLL_CTRL_11.ACBU = ‘1’:
- for ACB[z][1]=’1’:
is used as input signal to control if “action in the past” shall be checked based on position information. If the position has reached “past” use the calculated position stamp of the actual increment as target position value.
- for ACB[z][1]=’0’:
In this case the PSAC[i] is used as calculated by the DPLL.
- for ACB[z][0]=’1’: is used as input signal to control if “action in past” shall be checked based on time information. If the time has reached “past” use the time stamp of the last input event instead of the calculated TSAC[i] value.
- for ACB[z][0]=’0’:
In this case the TSAC[i] is used as calculated by the DPLL.
the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

se the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i.

The action is to be updated for each new *STATE* event until the calculated time stamp is in the past.
In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal.

When DPLL_CTRL_11.ACBU = ‘0’: Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
When DPLL_CTRL_11.ACBU = ‘1’:
- for ACB[z][1]=’1’:
is used as input signal to control if “action in the past” shall be checked based on position information. If the position has reached “past” use the calculated position stamp of the actual increment as target position value.
- for ACB[z][1]=’0’:
In this case the PSAC[i] is used as calculated by the DPLL.
- for ACB[z][0]=’1’: is used as input signal to control if “action in past” shall be checked based on time information. If the time has reached “past” use the time stamp of the last input event instead of the calculated TSAC[i] value.
- for ACB[z][0]=’0’:
In this case the TSAC[i] is used as calculated by the DPLL.
the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value.
Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

28.20.7.8.3 Equations DPLL-20 to calculate the position stamp backwards

For **DIR2**=1 or DIR1=1 respectively and TS0_HRS=0:

- PSAC[i] = PSA[i] + (DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20c)**

with

- RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S **(DPLL-20a)**

and

- RCDT_SX= 1/CDT_SX **(DPLL-20b)**

For **DIR2**=1 or DIR1=1 respectively and TS0_HRS=1:

- PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20e)**

with

- RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S **(DPLL-20a)**

and

- RCDT_SX= 1/CDT_SX **(DPLL-20b)**

replace MLS1 in equations (DPLL-20c) and (DPLL-20e) by MLS2 for (SMC=1 and RMO=1)
use the calculated value of (DPLL-20b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D.

The action is to be updated for each new *STATE* event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

28.20.8 Signal processing

28.20.8.1 Time stamp processing

Signal processing does mean the computation of the time stamps in order to calculate at which time the outputs have to appear. For such purposes the time stamp values have to be stored in the RAM and by calculating the difference between old and new values the duration of the last time interval is determined simply. This difference should be also stored in the RAM in order to see the changes between the intervals by changing the conditions and the speed of the observed process.

28.20.8.2 Count and compare unit

The count and compare unit processes all input signals taking into account the configuration values. It uses a state machine and provides the output signals as described above.

28.20.8.3 Sub pulse generation for SMC=0

28.20.8.3.1 Adder for generation of SUB_INCx by the carry c_{out}

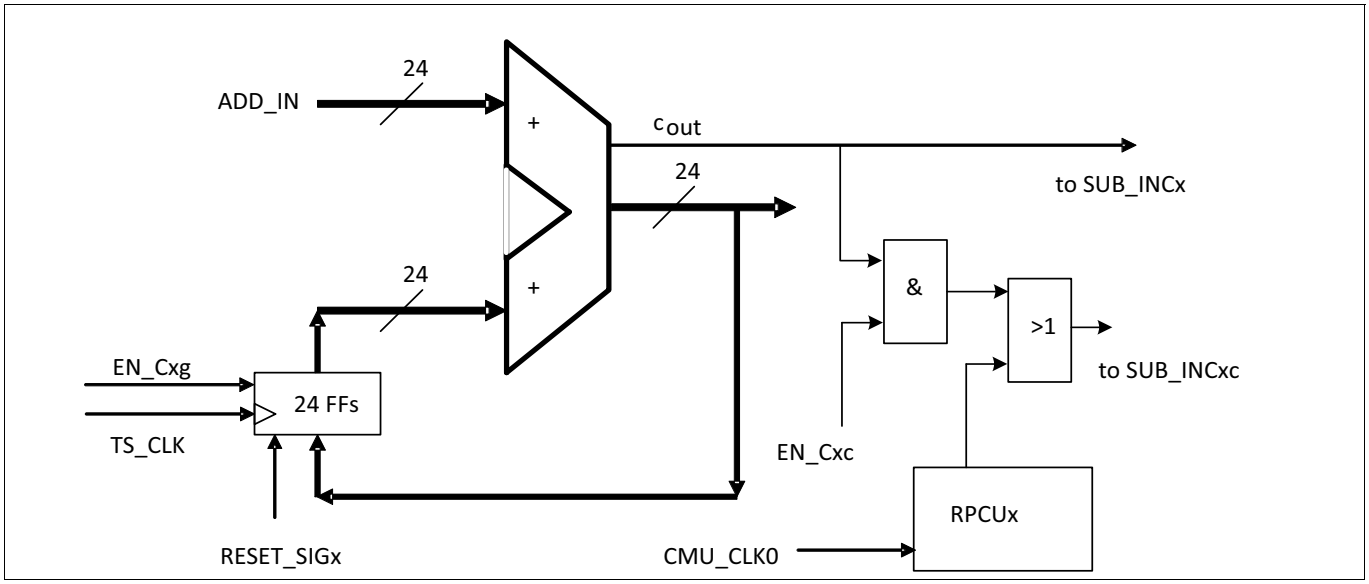

Figure 128 Adder for generation of SUB_INCx by the carry cout

Note: The SUB_INC generation by the circuit above has the advantage, that the resolution for higher speed values is better as for a simple down counter.

After RESET and after EN_Cxg=0 the flip-flops (FF s) should have a zero value. EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. This is controlled by the configuration bits SGE1,2 in the DPLL_CONTROL_1 register. The calculated values for the increment prediction using equations DPLL-2c **Chapter 28.20.6.2.7**, DPLL-2c1 **Chapter 28.20.6.4.4**, DPLL-7c **Chapter 28.20.6.3.7** or DPLL-7c1 **Chapter 28.20.6.4.4** respectively are valid only when at least NUTE>1 TRIGGER values or at least NUSE>1 STATE values are available. For NUTE =1 or NUSE=1 respectively the equations DPLL-25 **Chapter 28.20.8.3.4** and DPLL-26 **Chapter 28.20.8.3.6** use the actual increment value subtracted by the weighted average error.

The generation of SUB_INC1 pulses depends on the configuration of the DPLL. In automatic end mode the counter INC_CNT1 resets the enable signal EN_C1 when the number of pulses desired is reached. In this case only the uncompensated output SUB_INC1 remains active in order to provide pulses for the input filter unit. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event in normal/emergency mode easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. During this time period the EN_Cxg remains cleared. After calculation or providing of a new ADD_IN value the FFs are enabled by EN_Cxg. In this way no pulse is lost. The new pulses are sent out afterwards, when INC_CNT1 is set to the desired value, maybe by adding MLT+1 or MLS1 respectively for the new TRIGGER/STATE event.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation at SUB_INC1 will stop in automatic end mode when the INC_CNT1 register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the loss of pulses can be avoided. When a new TRIGGER/STATE appears the value of SYN_T*(MLT+1) or SYN_S*MLS1 respectively is added to INC_CNT1, when SGE1=1. Therefore for FULL_SCALE 2*(TNU+1)*(MLT+1) pulses SUB_INC1 generated, when INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible. The calculations for the ADD_IN value must be done first. Therefore all values needed for calculation are to be fetched in a forecast.

28.20.8.3.2 Equation DPLL-21 to calculate the number of pulses to be sent in normal mode using the automatic end mode condition

For RMO=0, SMC=0 and DMO=0

- NMB_T = (MLT+1)*SYN_T + MP + PD_store + MPVAL1 **(DPLL-21)**

with

PD_store = ADT_T[12:0], prefetched during last increment
SYN_T = ADT_T[18:16], prefetched during last increment
MPVAL1 = pulse correction value for PCM1_SHADOW_TRIGGER=1

while the value for PD_store is zero for AMT=0
and
the value of MP is zero for COA=0

In order to get a higher resolution for higher speed a generator for the sub-pulses is chosen using an adder. All missing pulses MP are considered using equation DPLL-21 and are determined by counting the number of pulses of the last increment. The value SYN_T is stored from the last increment using NT of the ADT_T[i] value at RAM region 2c.

28.20.8.3.3 Equations DPLL-22-24 to calculate the number of pulses to be sent in emergency mode using the automatic end mode condition for SMC=0

For RMO=1, SMC=0 and DMO=0; the value for PD_S_store is zero for AMS=0

- NMB_S = (MLS1 + PD_S_store) *SYN_S+ MP **(DPLL-22)**

with

- MLS1= (MLT+1) * (TNU+1) / (SNU+1) **(DPLL-23)**

PD_S_store = ADT_S[15:0], prefetched during last increment
SYN_S = ADT_S[21:16], prefetched during last increment
MPVAL1 = pulse correction value for PCM1_SHADOW_STATE=1

while the value for PD_S_store is zero for AMS=0
and
the value of MP is zero for COA=0

Please note, that these calculations above in equations DPLL-21 and DPLL-22 are only valid for an automatic end mode (DMO = 0).
For calculation of the number of generated pulses a value of 0.5 is added as shown in equations DPLL-25 or DPLL-26 respectively in order to compensate rounding down errors at the succeeding arithmetic operations. Because in automatic end mode the number of pulses is limited by **INC_CNT1** it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are caught up for the next increment.

28.20.8.3.4 Equation DPLL-25 to calculate ADD_IN in normal mode for SMC=0

In normal mode (for RMO=0) calculate in the case LOW_RES=TS0_HRT

- ADD_IN_CALN= (NMB_T+0.5) *RCDT_TX **(DPLL-25)**

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b, see **Section 28.20.7.6.3**

In normal mode (for RMO=0) calculate in the case LOW_RES=1 and TS0_HRT=0

- ADD_IN_CALN= (NMB_T+0.5) *(RCDT_TX /8) **(DPLL-25a)**

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b, see **Section 28.20.7.6.3**

For RMO=0 and SMC=0:

- ADD_IN_CAL1 = ADD_IN_CALN **(DPLL-25b)**

LOW_RES=0 and TS0_HRT=1 is not possible. For such a configuration the RCT bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO=0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Figure 128**, to be caught up on with CMU_CLK0 (for COA=0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of TS_CLK. In addition the ADD_IN value should never exceed the value 0x800000. This limitation is only necessary for DMO=0 and COA=0 (see DPLL_CTRL_1 register).

For the normal mode replace ADD_IN of the ADDER (see **Figure 128**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{out} and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

28.20.8.3.5 Enabling of the compensated output for pulses

The c_{out} of the adder influences directly the *SUB_INC1* output of the DPLL (see **Figure 128**). The compensated output SUB_INCxc is in automatic end mode only enabled by EN_Cxc when **INC_CNTx** >0.

28.20.8.3.6 Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC=0

In emergency mode (RMO=1) calculate in the case LOW_RES=TS0_HRS

- ADD_IN_CALE= (NMB_S+0.5)* RCDT_SX **(DPLL-26)**

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b, see **Section 28.20.7.8.2**

In emergency mode (RMO=1) calculate in the case LOW_RES=1 and TS0_HRS=0

- ADD_IN_CALE= (NMB_S+0.5)* RCDT_SX /8 **(DPLL-26a)**

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b, see **Section 28.20.7.8.2**

For RMO=1 and SMC=0:

- ADD_IN_CAL1 = ADD_IN_CALE **(DPLL-26b)**

LOW_RES=0 and TS0_HRS=1 is not possible. For such a configuration the RCS bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO=0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Figure 128**, to be caught up on with CMU_CLK0 (for COA=0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of the system clock. In addition the ADD_IN value should never exceed the value 0x800000 when the TS_CLK frequency exceeds half the frequency of the system clock. This limitation is only necessary for DMO=0 and COA=0 (see DPLL_CTRL_1 register).

For the emergency mode replace ADD_IN of the ADDER (see **Figure 128**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{out} and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

28.20.8.4 Sub pulse generation for SMC=1

28.20.8.4.1 Necessity of two pulse generators

The Adder of picture **Figure 128** must be implemented twice in the case of SMC=1: one for SUB_INC1 controlled by the *TRIGGER* input and (while RMO=1) one for SUB_INC2, controlled by the *STATE* input. In the case described in the chapter above for SMC=0 only one Adder is used to generate SUB_INC1 controlled by the *TRIGGER* in normal mode or by *STATE* in emergency mode.

28.20.8.4.2 Equation DPLL-27 to calculate the number of pulses to be sent for the first device using the automatic end mode condition

For SMC=1 and DMO=0

- NMB_T = (MLS1 + PD_store) *SYN_T + MP + MPVAL1 **(DPLL-27)**

with
PD_store = ADT_T[12:0], prefetched during last increment
SYN_T = ADT_T[18:16], prefetched during last increment
MPVAL1 = pulse correction value for PCM1_SHADOW_TRIGGER=1

while the value for PD_store is zero for AMT=0
and
for COA=0 use zero instead of the value of MP

28.20.8.4.3 Equation DPLL-28 to calculate the number of pulses to be sent for the second device using the automatic end mode condition

for RMO=1, SMC=1 and DMO=0

- NMB_S = MLS2 *SYN_S+ MP + PD_S_store + MPVAL2 **(DPLL-28)**

with
PD_S_store = ADT_S[15:0], prefetched during last increment
SYN_S = ADT_S[21:16], prefetched during last increment
MPVAL2 = pulse correction value for PCM2_SHADOW_STATE=1

while the value for PD_S_store is zero for AMS=0
and
for COA=0 use zero instead of the value of MP

Please note, that these calculations above in equations DPLL-27 and DPLL-28 are only valid for an automatic end mode (DMO = 0). In addition the number of generated pulses is added by 0.5 as shown in equations DPLL-30 or DPLL-31 respectively in order to compensate rounding down errors at the succeeding division operation. Because in automatic end mode the number of pulses is limited by **INC_CNTx** it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are made up for the next increment.

28.20.8.4.4 Equation DPLL-30 to calculate ADD_IN for the first device for SMC=1

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{out} and the following inputs:

- ADD_IN
- the second input is the (delayed) output of the adder, stored with each time stamp clock.

Replace ADD_IN by ADD_IN_CAL1 (when calculated, DLM1=0) or ADD_IN_LD1 (when provided by the CPU, DLM1=1) respectively while:

For SMC=1 and LOW_RES=TS0_HRT

- ADD_IN_CAL1= (NMB_T+0.5) * RCDT_TX **(DPLL-30)**

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b, see **Section 28.20.7.6.3**

For SMC=1,LOW_RES= 1 and TS0_HRT=0

- ADD_IN_CAL1= (NMB_T+0.5) * (RCDT_TX /8) **(DPLL-30a)**

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b, see **Section 28.20.7.6.3**

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

ADD_IN_CAL1 is a 24 bit integer value. The CDT_TX is the expected duration of current *TRIGGER* increment.

The c_{out} of the adder influences directly the *SUB_INC1* output of the DPLL (see **Figure 128**). The SUB_INC1 output is in automatic end mode only enabled by EN_C1 when **INC_CNT1** >0.

28.20.8.4.5 Equation DPLL-31 to calculate ADD_IN for the second device for SMC=1

Replace ADD_IN by ADD_IN_CAL2 (when calculated, DLM2=0) or ADD_IN_LD2 (when provided by the CPU, DLM2=1) respectively while:

for SMC=1, RMO=1 and LOW_RES=TS0_HRS:

- ADD_IN_CAL2= (NMB_S+0.5)* RCDT_SX **(DPLL-31)**

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b, see **Section 28.20.7.8.2**

for SMC=1, RMO=1, LOW_RES=1 and TS0_HRS=0:

- ADD_IN_CAL2= (NMB_S+0.5)* (RCDT_SX /8) **(DPLL-31a)**

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b, see **Section 28.20.7.8.2**

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

The c_{out} of the adder2 influences directly the *SUB_INC2* output of the DPLL (see **Figure 128**).

The SUB_INC2 output is in automatic end mode only enabled by EN_C2 when **INC_CNT2** >0.

Note: Please note, that after RESET and after EN_Cxc=0 (after stopping in automatic end mode) the flip-flops (FFs) have a zero value and also EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. The calculated values for the increment prediction using equations DPLL-2c **Section 28.20.6.2.7**, DPLL-2c1 **Section 28.20.6.4.4**, DPLL-7c **Section 28.20.6.3.7** or DPLL-7c1

Section 28.20.6.4.4 respectively are valid only when NUTE>1 or NUSE>1 respectively. For NUTE=1 or NUSE=1 respectively the equations DPLL-30 (see **Section 28.20.8.4.4**) and DPLL-31 (see **Section 28.20.8.4.5**) use the actual increment value subtracted by the weighted average error.

The generation of *SUB_INCx* pulses depends on the configuration of the DPLL.In automatic end mode the counter **INC_CNTx** resets the enable signal EN_Cxcu when the number of pulses desired is reached. In this case only the uncompensated outputs SUB_INCx remain active in order to provide pulses for the input filter units. A new *TRIGGER* or *STATE* input respectively can reset the FFs and also ADD_IN, especially when EN_Cxc was zero before. In the case of acceleration missing pulses can be determined at the next *TRIGGER/STATE* event easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. After that the pulse counter **INC_CNTx** should be always zero and the new pulses are sent out afterwards, when **INC_CNTx** is set to the desired value by adding MLS1 or MLS2 for the new *TRIGGER* or *STATE* event respectively.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation will stop when the **INC_CNTx** register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the loss of pulses can be avoided.

When a new *TRIGGER* appears the value of SYN_T*MLS1 is added to **INC_CNT1**. Therefore for FULL_SCALE 2*(TNU+1)*MLS1 pulses *SUB_INC1* generated, when **INC_CNT1** reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible.

When a new *STATE* appears the value of SYN_S*MLS2 is added to **INC_CNT2**. Therefore for FULL_SCALE 2*(SNU+1)*MLS2 pulses *SUB_INC2* generated, when **INC_CNT2** reaches the zero value. The generation of SUB_INC2 pulses has to be done as fast as possible.

28.20.8.5 Calculation of the Accurate Position Values

All appearing *TRIGGER* and *STATE* signals do have a time stamp and a position stamp assigned after the input filter procedure. For the calculation of the exact time stamp the filter values are considered in the calculations of equations DPLL-1a **Section 28.20.6.2.1** or DPLL-6a **Section 28.20.6.3.1** respectively. A corresponding calculation is to be performed for the calculation of position values. The PSTC and PSSC values can be corrected by the CPU, when needed.

The PSTC and PSSC values can be corrected by the CPU, when needed.
After reset, while FTD=0 and no active TRIGGER slope is detected:

- PSTC = 0 **(DPLL-32a)**

Calculate the new Position value for each valid TRIGGER event:

- PSTC= PSTC_old + NMB_T_TAR_OLD **(DPLL-32b)**

when FTD=1 and SGE1=1
with
PSTC_old is the last PSTC value and
NMB_T_old is the number of pulses which are calculated
and provided for sending out in the last increment.

After reset, while FSD=0 and no active STATE slope is detected:

- PSSC= 0 **(DPLL-33a)**

Calculate the new Position value for each STATE event:

- PSSC= PSSC_old + NMB_S_TAR_OLD **(DPLL-33b)**

when FSD=1 and SGE1=1 (SMC=0) or SGE2=1 (SMC=1 respectively with
PSSC_old is the last PSSC value and
NMB_S_old is the number of pulses which are calculated and provided for sending out in the last increment.

28.20.8.6 Scheduling of the Calculation

After enabling the DPLL with each active *TRIGGER* or *STATE* event respectively a cycle of operations is performed to calculate all the results shown in detail in the table below **Section 28.20.2**. A state machine controls this procedure and consists of two parts, the first is triggered by an active slope of the signal *TRIGGER*, begins at step 1 and ends at step 20 (in normal mode and for SMC=1). The second state machine is controlled by an active slope of the signal *STATE*, begins at step 21 and ends at step 40 (in emergency mode and also for SMC=RMO=1). Depending on the mode used all 20 steps are executed or already after 2 steps the jump into the initial state is performed, as shown in the state machine descriptions below. For each new extended cycle (without this jump) all prediction values for actions in the case SMC=0 are calculated once more (with maybe improved accuracy because of better parameters) and all pending decisions are made using these new values when transmitted to the decision device.

In **Section 28.20.8.6.6** the steps of the state machine are described. Please note, that the elaboration of the steps depends on the configuration bits described in the comments. The steps 4 to 17 are only calculated in normal mode (in the state machine explanation below marked yellow in **Section 28.20.2**), but steps 24 to 37 are only calculated in emergency mode (in the state machine explanation below marked cyan in **Section 28.20.2**) when SMC=0.

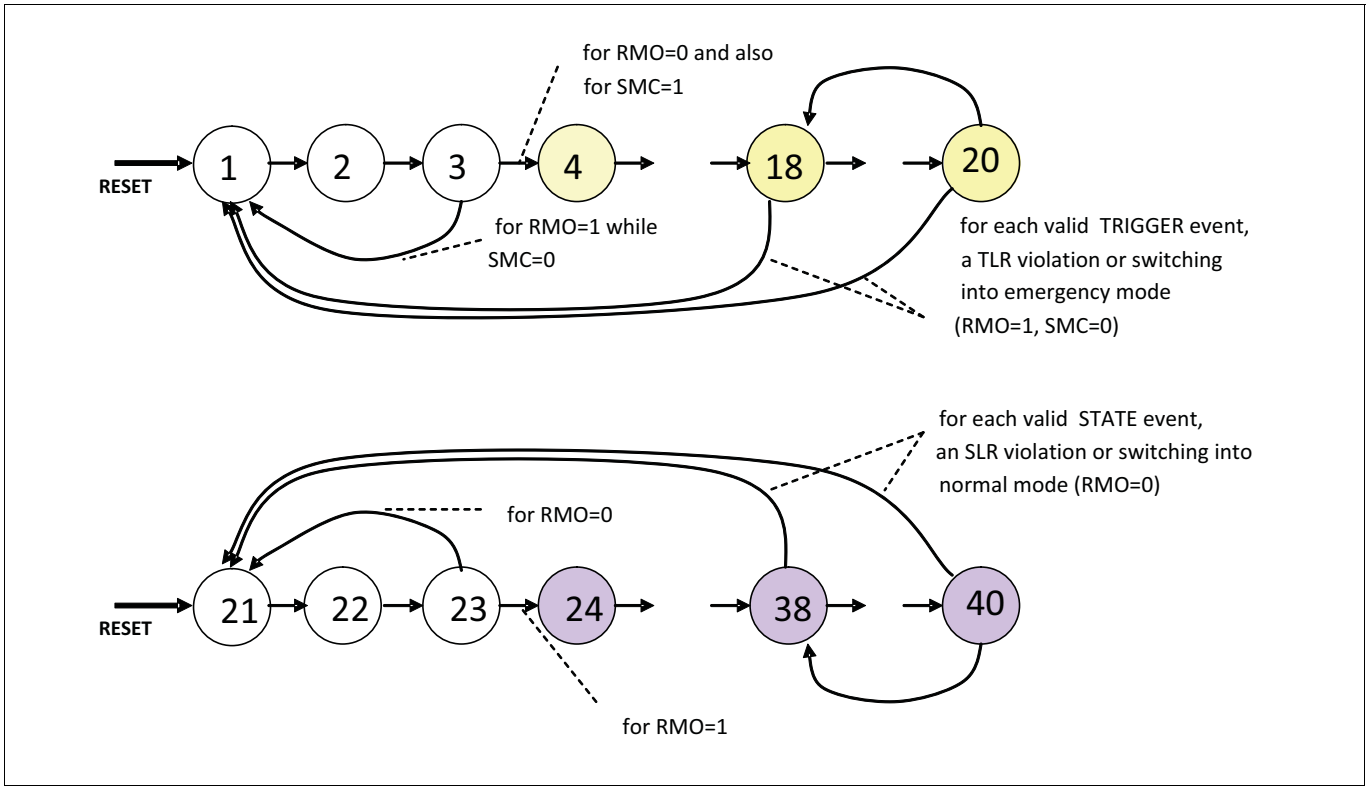

Figure 129 State machine partitioning for normal and emergency mode.

28.20.8.6.1 Synchronization description

TRIGGER

The APT (address pointer for duration and reciprocal duration values of *TRIGGER* increments) is initially set to zero and incremented with each active *TRIGGER* event. Therefore data are stored in the RAM beginning from the first available value. The actual duration of the last increment is stored at DT_T_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUTE is one.

A missing *TRIGGER* is assumed, when at least after TOV* DT_T_ACT no active *TRIGGER* event appears.

The data of equations DPLL-1b1 and DPLL-1c2 **Section 28.20.7.5.4** are written in the corresponding RAM regions and APT is incremented accordingly up to 2*TNU-2*SYN_NT+1.

The APT_2B (address pointer for the time stamp field of *TRIGGER*) is initially set to zero and incremented with each active *TRIGGER* event. When no gap is detected because of the incomplete synchronization process at the beginning, for all *TRIGGER* events the time stamp values are written in the RAM up to 2*(TNU+1) entries, although only 2*(TNU+1-SYN_NT) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Before the CPU sets the APT_2C address pointer in order to synchronize to the profile, it writes the corresponding increment value for the necessary extension of the RAM region 2b value APT_2B_EXT into the register APT_2B_sync and sets the status bit APT_2C_status. This value can be e.g. 2*SYN_NT, when all gaps in FULL_SCALE already passed the input data stream of *TRIGGER*, or less then this value, when up to now e.g. only a single gap is to be considered in the data stream stored already in the RAM region 2b. The number of virtual increments to be considered depends on the number of inputs already got. After writing APT_2C by the CPU, with the next *TRIGGER* event the APT_2B address pointer is incremented (as usual) and then the additional offset value APT_2B_EXT is added to it once (while APT_2B_STATUS=1 and for forward direction). For that reason the APT_2B_STATUS bit is reset after it. The old APT_2B value before adding the offset is stored in the APT_2B_OLD register as information for the CPU where to start the extension procedure. In the following the CPU fills in the time stamp field around the APT_2B_OLD position taking into account the corresponding number of virtual entries stored in the APT_2B_EXT value and the corresponding NT values in the profile. The extension procedure ends when all gaps considered in the APT_2B_EXT value are treated once. In the consequence all storage locations of RAM region 2b up to now do have the corresponding entries. Future gaps are treated by the DPLL. For a backward direction the APT_2C_ext value is subtracted accordingly.

When the CPU writes the APT_2C address pointer the SYT bit is set simultaneously. For SYT=1 in normal mode (SMC=0) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing *TRIGGER* or an additional *TRIGGER* between two synchronization gaps does reset the LOCK1 bit in normal mode. In that case the CPU must correct the SUB_INC pulse number and maybe correct the APT_2C pointer. For this purpose the LL1I interrupt can be used.

When SYT is set the calculations of equations DPLL-1 to DPLL-5 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-1a5 to 7 forwards **Section 28.20.7.5.2** or backwards **Section 28.20.7.5.3**. The APT_2B pointer is for that reason incremented or decremented before this operation considering the virtual increments in addition.

Please note, that for the APT and APT_2C pointers the gap is considered as a single increment.

STATE:

The APS (address pointer for duration and reciprocal duration values of *STATE*) is initially set to zero and incremented with each active *STATE* event. Therefore data are stored in the RAM field beginning at the first

location. The actual duration of the last increment is stored at DT_S_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUSE is one.

A missing *STATE* is assumed, when at least after SOV* DT_S_ACT no active *STATE* event appears.

The data of equations DPLL-6b1 and DPLL-6c2 **Section 28.20.7.5.8** is written in the corresponding RAM regions and APS is incremented accordingly up to 2*SNU-2*SYN_NS+1 (for SYSF=0).

The APS_1C2 (address pointer for the time stamp field of *STATE*) is initially set to zero and incremented with each active *STATE* event. When no gap is detected because of the incomplete synchronization process at the beginning, for all *STATE* events the time stamp values are written in the RAM up to 2*(SNU+1) entries, although (e.g. for SYSF=0) only 2*(SNU+1-SYN_NS) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Before the CPU sets the APS_1C3 address pointer in order to synchronize to the profile, it writes the corresponding increment value APS_1C2_EXT for the necessary extension of the RAM region 1c2 into the register DPLL_APS_SYNC and sets the APS_1C2_STATUS bit there. This value can be e.g. 2*SYN_NS (for SYSF=0) or SYN_NS (for SYSF=1), when all gaps in FULL_SCALE already passed the input data stream of *STATE*. Also less then this value can be considered, when up to now only a single gap is to be considered in the data stream stored already in the RAM region 1c2. The number of increments to be considered depends on the number of inputs already got. After writing APS_1C3 by the CPU, with the next active *STATE* slope the APS_1C2 address pointer is incremented (as usual) and then the additional offset value APS_1C2_EXT is added to it once (while APS_1C2_STATUS=1 and forward direction). For that reason the APS_1C2_STATUS bit is reset after it. The old APS_1C2 value is stored in the APS_1C2_OLD register as information for the CPU where to start the extension procedure. In the following the CPU extends the time stamp field beginning from the APS_1C2_OLD position taking into account the corresponding number of virtual entries according to the APS_1C2_EXT value and also the correspondent NS values in the profile. The extension procedure ends when all gaps considered in the APS_1C2_EXT value are treated once. In the consequence all storage locations of RAM region 1c2 up to now do have the corresponding entries. Future gaps are treated by the DPLL.

For a backward direction the APS_1C2_EXT value is subtracted accordingly.

When the CPU writes the APS_1C3 address pointer the SYS bit is set simultaneously. For SYS=1 in emergency mode (SMC=0 and DMO=1) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing *STATE* or an additional *STATE* between two synchronization gaps does reset the LOCK1 bit in emergency mode. In that case the CPU must correct the SUB_INC1 pulse number and maybe correct the APS_1C3 pointer. For this purpose the LL1I interrupt can be used.

When SYS is set the calculations of equations DPLL-5 to DPLL-10 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-6a5 to 7 forwards **Section 28.20.7.5.6** or backwards **Section 28.20.7.5.7**. The APS_1C2 pointer is for that reason incremented or decremented before this operation considering the virtual increments in addition.Please note, that for the APS and APS_2c pointers the gap is considered as a single increment.

SMC=1:

For SMC=1 it is assumed, that the starting position is known by measuring the characteristic of the device. In this way the APT and APT_2C as well the APS and APS_1C3 values are set properly, maybe with an unknown repetition rate. When no gap is to be considered for *TRIGGER* or *STATE* signals the APT_2B and APS_1C2 address pointers are set equal to APT or APS respectively. It is assumed, that all missing *TRIGGER*s and missing *STATE*s can be also considered from the beginning, when a valid profile with the corresponding adapted values is written in the RAM regions 1c3 and 2c respectively. In that case the TSF_T[i] and TSF_S[i] must be extended by the DPLL according to the profile. Thus the SYT and SYS bits could be set from the beginning and the LOCK1 and LOCK2 bits are set after recognition of the corresponding gaps accordingly. When no gap exists (SYN_NT=0 or SYN_NS=0), the LOCK

bits are set immediately. The CPU can correct the APT_2C and APS_1C3 pointer according to the recognized repetition rate later once more without the loss of Lock1,2.

28.20.8.6.2 Operation for direction change in normal and emergency mode (SMC=0)

When for SMC=0 in normal mode a backwards condition is detected for the TRIGGER input signal (e.g. when THMI is not violated), the LOCK1 bit in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1 (the same for NUSE in NUSC). The address pointers APT_2C as described below (and after that decremented for each following active slope of *TRIGGER* as long as the DIR1 bit shows the backward direction).

Please notice, that in the case of the change of the direction the ITN and ISN bit in the DPLL_STATUS register are reset.

For this transition to the backward direction no change of address pointer APT and APT_2B is necessary.

profile update for TRIGGER when changing direction

The profile address pointer APT_2C is changed step by step in order to update the profile information in SYN_T, SYN_T old and PD_store:

- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, **make calculations**, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new *TRIGGER* event

Note: The update of SYN_T_OLD and the loading of PD_store can be performed in all steps above. The value of APT_2B needs not to be corrected. For a direction change from backwards to forwards make the same corrections by incrementing APT_2C.

Make calculations does mean: the operation of the state machine starts with the calculations of NMB_T and INC_CNT1 using the actual APT_2C address pointer value, see **Section 28.20.2**.

The TBU_TB1 value is to be corrected by the number of pulses sent out in the wrong direction mode during the last and current increment. This correction is done by sending out SUB_INC1 pulses for decrementing TBU_TB1 (while DIR1=1).

Save inc_cnt1 value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.
2. Set inc_cnt1 to the target value of the last increment
   nmb_t_tar_old
3. Add the target number of trigger which were calculated for the current increment when this value was already added to inc_cnt1 before the direction change is detected
   + nmb_t_tar
4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)
   - inc_cnt1_save
5. Calculate the new target pulses to be sent considering the new values of SYN_T and PD_store and add them:
   + nmb_t_tar_new

This does mean the following equation:

inc_cnt1 = nmb_t_tar_old + nmb_t_tar
- inc_cnt1_save + nmb_t_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

When PSTC was incremented/decremented at the active slope and after that the direction change was detected at the same input event, correct **PSTC** once by

- nmb_t_tar_old when changed to backwards

+ nmb_t_tar_old when changed to forwards

in order to compensate the former operation. When the direction information is known before an intended change of PSTC, do not change them.

Store the new calculated value **nmb_t_tar_new** at **nmb_t_tar** for the correct calculation of PSTC at the next input event.

Consequences for STATE

With the next active *STATE* event the direction information is already given. The profile pointer APS_1C3 is to be corrected by a two times decrement in order to point to the profile of the next following increment. In the following it is decremented with each *STATE* event while DIR1=1. The SYN_S and PD_S_store values must be updated accordingly, including SYN_S_OLD and PD_S_store_old.

Because the right direction is already known when an input event appears, make the following corrections:

- decrement APS_1C3, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old
- decrement APS_1C3, **make calculations**, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new *STATE* event.

The update of SYN_S_OLD and the loading of PD_S_store can be performed in all steps above. The value of APS_1C2 needs not to be corrected.

When a new *STATE* event occurs, all address pointers are decremented accordingly as long as DIR1=1.

In **emergency mode** the pulses are corrected as follows:

Save inc_cnt1 value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.
2. Set inc_cnt1 to the target value of the current increment **nmb_s_tar**
   Please notice, that in difference to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because direction information in emergency mode is only given from the TRIGGER input and occurs of a STATE event independently. That means: The calculations at the last STATE event were done for the correct former direction. In addition still no pulse calculations are performed for the current increment, because the direction change is known at the moment of the recent STATE event.
   Later direction changes are considered at the next STATE event:
3. Do not add the calculated number of state pulses because no new STATE event occurred.
4. Subtract the value of still not sent target pulses (remaining value at inc_cnt1_save)
   - inc_cnt1_save
5. Add the new calculated target pulses for the current increment
   + nmb_s_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt1 = nmb_s_tar_old - inc_cnt1_save + nmb_s_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Do not change PSSC and suppress incrementing/decrementing of PSSC at the event directly following to the direction change information.

Store the new calculated value **nmb_s_tar_new** at **nmb_s_tar** for the correct calculation of PSTC at the next input event.

Repeated change to forward direction for TRIGGER

The DIR1 bit remains set as long as the THMI value remains none violated for the following *TRIGGER* events and is reset when for an inactive TRIGGER slope the THMI is violated.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1, ITN, ISN) the opposite correction of the profile address pointer considered.

This does mean two increment operations of the address pointer APS_1C3 including the update of SYN_S and PD_S_store with the automatic update of SYN_S_OLD and PD_S_store_old for STATE and four increment operations of the address pointer APT_2C including the update of SYN_T and PD_store with the automatic update of SYN_T_OLD and PD_store_old for TRIGGER.

The correction of TBU_CH1 is done by sending out the correction pulses with the highest possible frequency at SUB_INC1 while DIR1=0. The number of pulses is calculated as shown above.

Consequences for STATE

see corrections above. After that the address pointers are incremented again with each following active *STATE* event as long as DIR1=0.

28.20.8.6.3 Operation for direction change for TRIGGER (SMC=1)

When for SMC=1 a backwards condition is detected for the *TRIGGER* input signal (TDIR=1, resulting in DIR1=1), the LOCK1 bit in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1. The address pointers APT and APT_2C as well as APT_2B are decremented for each active slope of *TRIGGER* as long as the DIR1 bit shows the backward direction.

Please notice, that in the case of the change of the direction the ITN bit in the DPLL_STATUS register is reset.

Profile update for TRIGGER

Make the same update steps for the profile address pointer as shown in **Section 28.20.8.6.2**: Decrement APT_2C for 2 times with the update of the SYN_T and PD_store values at each step with an automatic update of SYN_T_OLD and PD_store_old:

- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, **make calculations**, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new *TRIGGER* event.

In the normal case no correction of wrong pulses sent is necessary, because the direction change is detected by the pattern immediately.

Nevertheless a correction is necessary as shown below. In the other case: see treatment of pulses TBU_CH1_BASE in normal mode at **Section 28.20.8.6.2**.

Save inc_cntx value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Clear inc_cnt1.
2. Set inc_cnt1 to the target value of the last increment
   nmb_t_tar
   Please notice, that in difference to the normal mode, nmb_t_tar is to be used instead of nmb_t_tar_old, because the direction information is known before the calculation takes place.
3. Do not add the calculated number of trigger pulses because it is not calculated yet before the direction change information is known.

4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)
   - inc_cnt1_save
5. Add the new calculated target pulses for the current increment
   + nmb_t_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt1 = nmb_t_tar_old - inc_cnt1_save + nmb_t_tar_new

All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Suppress changing of PSTC for the TRIGGER event when a direction change is detected.

Store the new calculated value **nmb_t_tar_new** at **nmb_t_tar** for the correct calculation of PSTC at the next input event.

Repeated change to forward direction for TRIGGER

The DIR1 bit remains set as long as the TDIR bit is set for the following *TRIGGER* events and is reset when for an active *TRIGGER* slope the TDIR is zero.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1 and ITN) the opposite correction of the address pointer use.

This does mean two increment operations of the address pointer including the update of SYN_T and PD_store.

A complex correction of TBU_CH1_BASE and INC_CNT1 is in the normal case not necessary, when all increments are equal (SYN_NT=0) and no adapt information is used. In this case only the MLS1 value is added to INC_CNT1 in order to back count the value for the last increment. In the other case: see treatment of pulses TBU_CH1_BASE and ICN_CNT1 in normal mode at **Section 28.20.8.6.2**.

28.20.8.6.4 Operation for direction change for STATE (SMC=1)

When for SMC=1 a backwards condition is detected for the *STATE* input signal (SDIR=1, resulting in DIR2=1), the LOCK2 bit in the DPLL_STATUS register is reset, the NUSE value in NUSC register is set to 1 and the address pointers APS and APS_1C3_f and APS_1C2 are decremented for each active slope of *STATE* as long as the DIR2 bit shows the backward direction.

Please notice, that in the case of the change of the direction the ISN bit in the DPLL_STATUS register is reset.

For this transition to the backward direction no change of address pointer APS and APS_1C2 is necessary.

Profile update for STATE

Make the same update steps for the profile address pointer as shown in **Section 28.20.8.6.2**: Decrement APS_1C3 for 2 times with the update of the SYN_S, SYN_S_OLD, PD_S_store and PD_S_store_old values at each step:

- decrement APT_1c3, load SYN_S, PD_S_store, update SYN_S_OLD
- decrement APT_1c3, **make calculations**, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new *STATE* event.

A complex correction of TBU_CH2_BASE and INC_CNT2 is in the normal case not necessary, when all increments are equal (SYN_NS=0) and no adapt information is used. In this case only the MLS2 value is added to INC_CNT2 in order to back count the value for the last increment. In the other case: see treatment of pulses TBU_CH1_BASE and ICN_CNT1 in normal mode at **Section 28.20.8.6.2**.

For the second PMSM the pulses are corrected as follows:

Save inc_cnt2 value at direction change to inc_cnt2_save.

Calculate the new inc_cnt2 value as follows:

1. Clear inc_cnt2.
2. Set inc_cnt2 to the target value of the last increment
   nmb_s_tar
   Please notice, that in difference to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because no new calculation is performed so far.
3. Do not add the calculated number of state pulses because it is not calculated yet before the direction change information is known.
4. Subtract the value of still not sent pulses (remaining value at inc_cnt2_save)
   - inc_cnt2_save
5. Add the new calculated target pulses for the current increment
   + nmb_s_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

inc_cnt2 = nmb_s_tar_old - inc_cnt2_save + nmb_s_tar_new

All pulses summarized at inc_cnt2 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM2 of DPLL_CTRL1 is possible during direction change.

Do not change PSSC for a STATE event when a direction change is detected.

Store the new calculated value **nmb_s_tar_new** at **nmb_s_tar** for the correct calculation of PSTC at the next input event.

Repeated change to forward direction for STATE

The DIR2 bit remains set as long as the SDIR bit is set for the following *STATE* events and is reset when for an active *STATE* slope SDIR is zero.

Resetting the DIR2 to 0 results (after repeated reset of LOCK2 and FSD) in the opposite correction of the address pointer use.

After a last decrementing of all address pointers the APS_1C3 is incremented 2 times with a repeated update of SYN_S, SYN_S_OLD and PD_S_store after each increment.

28.20.8.6.5 DPLL reaction in the case of non plausible input signals

When the DPLL is synchronized concerning the *TRIGGER* signal by setting the FTD, SYT and LOCK1 bits in the DPLL_STATUS register, the number of active *TRIGGER* events between the gaps is to be checked continuously.

When additional events appear while a gap is expected, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set.

When an unexpected gap appears (missing *TRIGGER*S), the NUTE value in the NUTC register is set to 1, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set. The address pointers are incremented with the next active *TRIGGER* slope accordingly.

The TOR Bit in the DPLL_STATUS register is set, when the time to the next active *TRIGGER* slope exceeds the value of the last nominal *TRIGGER* duration multiplied with the value of the TLR register (see chapter **Section 28.20.12.72**). In this case also the TORI interrupt is generated, when enabled.

When in the following the direction DIR1 changes as described in the chapters above the ITN bit in the DPLL_STATUS register is reset, the use of the address pointers APT_2C is switched and the pulse correction takes place as described above.

In all other cases the CPU can interact to leave the instable state. This can be done by setting the APT_2C address pointer which results in a reset of the ITN bit. In the following NUTE can also be set to higher values.

When the DPLL is synchronized concerning the *STATE* signal by setting the FSD, SYS and LOCK1 (for SMC=0) or LOCK2 (for SMC=1) bits in the DPLL_STATUS register, the number of active *STATE* events between the gaps is to be checked continuously.

When additional events appear while a gap is expected or while an unexpected missing *STATE* event appears, the LOCK1,2 bit is reset and the ISN bit in the DPLL_STATUS register is set.

When an unexpected gap appears for RMO=SMC=1 (missing *STATE*s for synchronous motor control), the NUSE value in the NUSC register is set to 1, the LOCK2 bit is reset and the ISN bit in the DPLL_STATUS register is set. The address pointers are incremented with the next active *STATE* slope accordingly.

When the *STATE* locking range SLR is violated[7)], the state machine 2 will remain in state 21 and the address pointer APS, APS_1C2 and APS_1C3 will remain unchanged until the CPU sets the APS_1C3 accordingly. In this case also the NUSE value in the NUSC register is set to 1. The DPLL stops the generation of the SUB_INC1,2 pulses respectively and will perform no other actions - remaining in step21 of the second state machine (see **Section 28.20.2**).

[7)] The SOR Bit in the DPLL_STATUS register is set, when the time to the next active *STATE* slope exceeds the value of the last nominal *STATE* duration multiplied with the value of the SLR register (see **Section 28.20.12.73**).In this case also the SORI interrupt is generated, when enabled.

When in the following the direction DIR2 changes as described in the chapters above the ISN bit in the DPLL_STATUS register is reset, the use of the address pointers APS_1C3 is switched and the pulse correction takes place as described above. In all other cases the CPU must interact to leave the instable state. This can be done by setting the APS_1C3 address pointers which results in a reset of the ISN bit. In the following NUSE can also be set to higher values.

28.20.8.6.6 State description of the State Machine

Table 72 State description of the State Machine.

Step	Description	Comments

always for DEN=1	**for each inactive TRIGGER slope with TEN=1:**
	check, if the last active TRIGGER slope was passing the PVT check; only in this case perform the following tasks:
	calculate the time stamp difference ΔT to the last active event, store this value at THVAL;
	when THMI >0 is violated (ΔT < THMI):
	generate TINI interrupt,
	set DIR1=0 (forwards)
	set BWD1=0
	(see DPLL_STATUS register)
	else (only for THMI >0):
	set DIR1= 1 (backwards);
	set BWD1=1 (see DPLL_STATUS register)
	after changing the direction correct the pulses WP sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency: WP=NMB_T-DPLL_INC_CNT1;
	correct INC_CNT1 by addition of 2*WP before sending the correction pulses;
	generate the TISI Interrupt.
	check THMA, when THMA is violated, generate the TAXI interrupt; go to step 1
	for each inactive STATE slope with SEN=1:
	set DIR2=DIR1
		for SMC=0;
		set DIR1 always after inc./ decr. the address pointers APT, APT_x;
		go to step 1;
		stop output of SUB_INC1 and correct pulses after changing DIR1 after incr./ decr. of APS_x set DIR2 always after incr./decr. the address pointers APS, APS_x;
		go to step 1

always for DEN=1 and (TEN=1 or SEN=1, respectively)	set DIR1=BWD1=TDIR, set DIR2=BWD2=SDIR; for each change of TDIR go to step 1 after performing the following calculations: correct INC_CNT1 correct the pulses (WP, see above) sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency. For each change of SDIR go to step 21 after performing the following calculations: update of SYN_S, PD_S_store according to **Section 28.20.8.6.2** correct INC_CNT1,2 correct the pulses sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency.	**for SMC=1**; set the direction bits always after incr./decr. the corresponding address pointers;

Table 72 State description of the State Machine. (cont'd)

Step	Description	Comments
1	When DEN = 0 or TEN=0: stay in step 1 until DEN=1, TEN=1 and at least one active *TRIGGER* has been detected (FTD=1); the following steps are performed always (not necessarily in step 1, but also in steps 18 to 20 (when waiting for new PMTR values to be calculated): compare TRIGGER_S with TSL (active slope); **When no active TRIGGER slope appears** and when TS_T_CHECK time is reached: • send missing *TRIGGER* INT, also when a gap is expected according to the profile; set MT=1 (missing *TRIGGER* bit) in the DPLL_STATUS register; do not leave the active step, until a valid active *TRIGGER* appears. **When an active TRIGGER slope appears check PVT** **- when the PVT value is violated:** generate the PWI interrupt, ignore the *TRIGGER* input and wait for the next active TRIGGER slope (ignore each inactive slope); do not store any value **- When the PVT value is fulfilled:** store the actual position stamp at PSTM (value at the TRIGGER event); update the RAM region 2 by equation DPLL-1a-c (see **Section 28.20.7.5**) **store the actual INC_CNT1 value at MP1 as missing pulses***(instead of calculation in step 5)*: store all relevant configuration bits **X** of the DPLL_CTRL(0,1) Registers in **shadow** registers and consider them for all corresponding calculations of steps 2 to 20 accordingly; the relevant bits are explained in the registers itself generate the TASI interrupt; for FTD=0: • set PSTC=PSTM • set FTD (first *TRIGGER* detected) • do not change PSTC,APT, APT_2B • for (RMO=0 or SMC=1) **and SGE1=1**: increment INC_CNT1 by (MLT+1)*) +MPVAL1***) • send SUB_INC1 pulses with highest possible frequency **when SGE1=1** and DPLL_CTRL11_SIP1=0, for SYT=0 and FTD =1: • **dir_crement** APT and APT_2B by one; • **dir_crement** for **SGE1_delay******)=1: PSTC by NMB_T_TAR**) • for (RMO=0 or SMC=1) **and SGE1=1**: increment INC_CNT1 by (MLT+1)*) +MPVAL1***)	Depending on TSL, TEN, DEN step one is leaving with the next *TRIGGER* input; **Note:** Step 1 is also left in emergency mode when an active *TRIGGER* event appears in order to make a switch back to normal mode possible; _old - values are values valid at the last but one active *TRIGGER* event; for the whole table: use always MLS1 instead of (MLT+1) for the case SMC=1; **dir_crement** does mean: increment for DIR1=0 decrement for DIR1=1 *)replace (MLT+1) by MLS1 for SMC=1 **) NMB_T_TAR is the target value of NMB_T of the last increment (see step 5 ff.) ***) add MPVAL1 once to INC_CNT1, that means only when PCM1=1 ****) **SGE1_delay** is the value of SGE1 delayed by one active TRIGGER event *****) PD_store = 0 for AMT=0 (see DPLL_CTRL_0 register)

Table 72 State description of the State Machine. (cont'd)

Step	Description	Comments
1 (cont'd)	for SYT=1 and TOR=0: • **dir_crement** APT, APT_2C, **dir_crement** APT_2B by SYN_T_OLD • **dir_crement** for SGE1_delay[****)]<b>=1 PSTC by NMB_T_TAR[**)] • for (RMO=0 or SMC=1) **and SGE1=1**: increment INC_CNT1 by SYN_T*((MLT+1)[*)]+ PD_store[*****)] + MPVAL1[***)] PD_store is 0 for AMT=0 within the DPLL_STATUS register: • set LOCK1 bit accordingly;	
2	calculate TS_T according to equations DPLL-1a; calculate DT_T_ACT = TS_T - TS_T_OLD calculate RDT_T_ACT calculate QDT_TX according to equation DPLL-2	
3	send CDTI interrupt when NTI_CNT is zero or decrement NTI_CNT when not zero; calculate EDT_T and MEDT_T according to equations DPLL-3 and DPLL-4 for (RMO=1 and SMC=0): update SYN_T, PD_store and go back to step 1	Note: There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_T and PD_store are not updated until a new active TRIGGER slope occurs.
4	calculate CDT_TX according to equation DPLL-5a and b;	for RMO=0 or SMC=1;

5	calculate missing pulses:
	MP1 = INC_CNT1(at the moment of an active TRIGGER slope)
	
	calculate target pulses:
	NMB_T_TAR = (MLT+1)[*)]*SYN_T + PD_store + MPVAL1
	(instead of PD_store use zero in the case AMT=0)

22	calculate TS_S according to equations DPLL-6a; calculate DT_S_ACT = TS_S - TS_S_OLD calculate RDT_S_ACT calculate QDT_SX	
23	send CDSI interrupt; calculate EDT_S and MEDT_S according to equations DPLL-8 and DPLL-9 for RMO=0: go back to step 21 for RMO=0 and update SYN_S and PD_S_store using the current ADT_S[i] values in that case;	Note: There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_S and PD_S_store are not updated until a new active STATE slope occurs.
24	calculate CDT_SX according to equation DPLL-10a and b;	only for RMO=1
25	calculate missing pulses - for TBU_CH1: MP1 = INC_CNT1(active STATE slope) - for TBU_CH2: MP2 = INC_CNT2(active STATE slope) calculate target number of pulses: NMB_S_TAR = (MLS1 + PD_S_store)*SYN_S + PD_S_store+MPVAL1 (for SMC=0) NMB_S_TAR = MLS2*(SYN_S + PD_S_store) + MPVAL2 (for SMC=1) (instead of PD_S_store use zero in the case AMS=0)	only for RMO=1 for SMC=0 instead of MPVAL1 use zero for PCM1=0f or SMC=1 instead of MPVAL2 use zero for PCM2=0; add MPVAL1/2 once to INC_CNT1/2 and reset PCM1/2 after that

Table 72 State description of the State Machine. (cont'd)

Step	Description	Comments
26	sent MPx with highest possible frequency and set NMB_S = NMB_S_TAR	only for RMO=1, DMO=0 and COA=0
27	calculate number of pulses to be sent according to DPLL-22 or NMB_S = NMB_S_TAR + MPx	only for RMO=1, DMO=0 and COA=1
28	NMB_S = SYN_S*CNT_NUM_1 (SMC=0) NMB_S = SYN_S*CNT_NUM_2 (SMC=1)	only for RMO=1, DMO=1
29	update SYN_S and PD_S_store;	Note: There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_S and PD_S_store are not updated until a new active STATE slope occurs.
30	calculate ADD_IN_CAL2 according to equation DPLL-26 and DPLL-26b or DPLL-31 respectively and store this value in RAM use ADD_IN_CAL2 as ADD_IN value for the case DLM=0 use ADD_IN_LD2 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 30); for RMO=1, DMO=DLM=0 and EN_C1u=0 (EN_C1u=0): reset the flip-flops in the SUB_INC1 or SUB_INC2 generator respectively; start sending SUB_INC1 / SUB_INC2;	only for RMO=1 for DLM=0 for DLM=1
31	calculate TS_S_CHECK = TS_S + DT_S _ACT * (SOV);	only for RMO=1;
32	automatic setting of actions masking bits in the DPLL_STATUS register: CAIP1 and CAIP2 for SMC=0 only CAIP2 for SMC=1	for RMO=1
33	for all actions with ACT_N[i]=0 calculate: NA[i] = (PSA[i] - PSSC)/MLS1 for forward direction with w = integer part and b = remainder of the division (fractional part) for backward direction use NA[i] = (PSSC - PSA[i])/(MLS1) and consider in both cases the time base overflow in order to get a positive difference use MLS2 as divider in the case of SMC=1	for SMC=0: 24 actions, for SMC=1: 12 actions; depending on ACT_N[i] in **DPLL_ACT_STA** register
34	calculate PDT_S[i] and DTA[i] for up to 24 action values according to equations DPLL-13 and DPLL-14;	only for RMO=1; for SMC=0 actions 0…23 for SMC=1 actions 12…23
35	calculate TSAC[i] according to equation DPLL-18 and PSAC[i] according to equation DPLL-20	for the relevant actions (see above) and RMO=1

Table 72 State description of the State Machine. (cont'd)

Step	Description	Comments
36	automatic reset of the actions masking bit CAIP in the DPLL_STATUS register: CAIP1=CAIP2=0 for SMC=0 and only CAIP2=0 for SMC=1 set the corresponding ACT_N[i] bits in the DPLL_ACT_STA register	for the relevant actions (see above) and RMO=1 Set ACT_N[i] and reset ACT_WRi for all enabled actions
37	check the duration of the last increment to its predecessor according to the profile and taking into account SOV: set the ISN status bit and reset the corresponding LOCK bit, when not plausible; go to step 38, when no active *STATE* appears **for all following steps 38 to 40:** **go immediately back to step 21, when an active STATE event occurs, interrupt all calculations there and reset all CAIPx in that case;** **when going back to step 21:** store TS_S in RAM 1c2 according to APS_1C2; update RAM 1c1 and RAM 1c4	for all conditions
38	wait for a new PMTR value; set the corresponding CAIPx values and go to step 39 in that case	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs
39	make the requested action calculation according to new PMTR values	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs
40	reset CAIP and go back to step 38	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs

28.20.9 DPLL Interrupt signals

The DPLL provides 27 interrupt lines. These interrupts are shown below.

Table 73 DPLL Interrupt signals

Signal	Description
DPLL_DCGI_IRQ	Direction change
DPLL_SORI_IRQ	STATE is out of range
DPLL_TORI_IRQ	TRIGGER is out of range
DPLL_CDSI_IRQ	STATE duration calculated for last increment
DPLL_CDTI_IRQ	TRIGGER duration calculated for last increment
DPLL_TE4_IRQ	TRIGGER event interrupt 4 request3)
DPLL_TE3_IRQ	TRIGGER event interrupt 3 request3)

Table 73 DPLL Interrupt signals (cont'd)

Signal	Description
DPLL_TE2_IRQ	TRIGGER event interrupt 2 request3)
DPLL_TE1_IRQ	TRIGGER event interrupt 1 request3)
DPLL_TE0_IRQ	TRIGGER event interrupt 0 request3)
DPLL_LL2_IRQ	Loss of lock interrupt for SUB_INC2 request
DPLL_GL2_IRQ	Get of lock interrupt for SUB_INC2 request
DPLL_E_IRQ	Error interrupt request
DPLL_LL1_IRQ	Loss of lock interrupt for SUB_INC1 request
DPLL_GL1_IRQ	Get of lock interrupt for SUB_INC1 request
DPLL_W1_IRQ	Write access to RAM region 1b or 1c interrupt request
DPLL_W2_IRQ	Write access to RAM region 2 interrupt request
DPLL_PW_IRQ	Plausibility window violation interrupt of TRIGGER request
DPLL_TAS_IRQ	TRIGGER active slope while NTI_CNT is zero interrupt request
DPLL_SAS_IRQ	STATE active slope interrupt request
DPLL_MT_IRQ	Missing TRIGGER interrupt request
DPLL_MS_IRQ	Missing STATE interrupt request
DPLL_TIS_IRQ	TRIGGER inactive slope interrupt request
DPLL_SIS_IRQ	STATE inactive slope interrupt request
DPLL_TAX_IRQ	TRIGGER maximum hold time violation interrupt request
DPLL_TIN_IRQ	TRIGGER minimum hold time violation interrupt request
DPLL_PE_IRQ	DPLL enable interrupt request
DPLL_PD_IRQ	DPLL disable interrupt request

Note: TEi_IRQ depends on the TINT value in ADT_T[i]1) and is only active when SYT2) =1.

1) see RAM region 2 explanations; see **Section 28.20.14**

2) see DPLL STATUS register; see **Register DPLL_STATUS**

3) see TINT value in the corresponding ADT_T[i] section of RAM region 2; see **Section 28.20.14.3**

28.20.10 MCS to DPLL interface

A reduced AEI interface is implemented in the DPLL, which can only be accessed by the MCS Bus Master interface in the same cluster. The purpose of this interface is to enable a faster interchange of data between the MCS and the DPLL, while enabling a certain control over the DPLL internal state machine.

28.20.10.1Architecture and organization

The implemented interface has an address width of 4 bits, while the size of the data interface is 24 bits.

The following table shows the implemented AEI addresses from the MCS side. Label RD refers to the label used for the address when reading from the MCS or writing from the DPLL, whereas Label WR refers to the label used for the address when writing from the MCS or reading from the DPLL.

28.20.10.2General functionality

In order to have a better understanding of the implications when this interface is used, the following working concepts are informally defined here. They refer to the STATE engine operation when DPLL_CTRL_11.STATE_EXT is set.

Update of ram:

Operation which stores TSF_S, DT_S_ACTUAL and RDT_S_ACTUAL back to the RAM and reads the profile.

Calculation of sub-increments:

Calculation of DT_S_ACTUAL, RDT_S_ACTUAL, NMB_S and ADD_IN.

Change of direction:

Update of profile and its increment or decrement (only in the STATE processor).

Calculation of actions (PMT):

Where the calculation of PSAC and TSAC is performed (only in state processor).

If **DPLL_CTRL_11.STATE_EXT is not set**, the DPLL will ignore the data written to this interface from the MCS. The DPLL will not update the interface either and a read done to this interface from the MCS can obtain out-of-date information.

If **DPLL_CTRL_11.STATE_EXT is set**, some modifications are done to the way that the DPLL module works when using the STATE engine.

Up to 128 STATE events can be handled.

RAM1c is not used anymore. Instead, the data needed to perform each of the already described operations is fetched from registers in this interface. The data that would have to be written back to RAM1c is also written to this interface.

In each of the procedures described above, the DPLL will enter in one or more stalled states, in which it will wait for one or more words to be written to MCS2DPLL_DEB15 (STATUS_INFO)

Table 74 Correspondence between STA_S values and their unlocking keywords

Operation	STA_S value	First Keyword	Second Keyword
Update of ram	0b00001_001	0xE	0x1
Calculation of sub-increments	0b00010_000	0xD	0x2
Calculation of actions	0b01110_000	0xC	0x3
Change of direction	0b00000_100	0xB	0x4
Change of direction	0b00000_110	0xB	0x4

The stalled STATE in the DPLL is freed by writing the upper keywords to MCS2DPLL_DEB15. Please note the requirements on DPLL level (described in **Section 28.20.15**) regarding the data on the interface that has to be written by the MCS program. If this data is incorrectly delivered or the STATE state machine is unlocked before delivery, the proper signal processing of the DPLL cannot be assured.

For the particular case of an update of ram after a virtual increment, the data field TSF_S is not calculated completely by the DPLL STATE processing unit. Instead, the values needed in order to fill this data field are provided (**Section 28.20.7.5.6** and **Section 28.20.7.5.7**)

28.20.10.3MCS to DPLL Register overview

The following registers of the MCS2DPLL interface are exclusively accessible by the MCS instance of cluster 0 and cannot be accessed directly via CPU.

Table 75 MCS to DPLL Register overview

Address offset	Common Label	Label RD	Label WR	see Page
0x0	MCS2DPLL_DEB0	DT_S_P	DT_S_P1	650
0x4	MCS2DPLL_DEB1	not used	RDT_S_P1	650
0x8	MCS2DPLL_DEB2	TS_SX	RDT_S_PQ1	651
0xC	MCS2DPLL_DEB3	DT_SX	DT_S_PQ	652
0x10	MCS2DPLL_DEB4	SYN_S_OLD	RDT_S_PQ	652
0x14	MCS2DPLL_DEB5	M_DW	DT_S_PQ1	653
0x18	MCS2DPLL_DEB6	not used	ADT_S_P	654
0x1C	MCS2DPLL_DEB7	RDT_S_P_RD	S_P_RD	655
0x20	MCS2DPLL_DEB8	not used	TSF_S_P	655
0x24	MCS2DPLL_DEB9	not used	TSF_S_P_MQ	656
0x28	MCS2DPLL_DEB10	not used	TSF_S_P_PM_MQ	657
0x2C	MCS2DPLL_DEB11	not used	TSF_S_P_PM	657
0x30	MCS2DPLL_DEB12	not used	ADT_S_P1	658
0x34	MCS2DPLL_DEB13	not used	not used	658
0x38	MCS2DPLL_DEB14	not used	not used	659
0x3C	MCS2DPLL_DEB15	not used	STATUS_INFO	659

28.20.11 DPLL Register Memory overview

The available registers and the size of the RAM area 2 depends on the chosen device.

Please refer to device specific appendix.

28.20.11.1Available DPLL register overview

Table 76 Available DPLL register overview

Register name	Description	see Page
DPLL_CTRL_0	DPLL Control Register 0	511
DPLL_CTRL_1	DPLL Control Register 1	514
DPLL_CTRL_2	DPLL Control Register 2 (actions 0-7 enable)	520
DPLL_CTRL_3	DPLL Control Register 3 (actions 8-15 enable)	521
DPLL_CTRL_4	DPLL Control Register 4 (actions 16-23 enable)	522
DPLL_CTRL_5[1)]	DPLL Control Register 5 (actions 24-31 enable)	523
DPLL_ACT_STA	DPLL ACTION Status Register with connected shadow register	524
DPLL_OSW	DPLL Offset and switch old/new address register	525
DPLL_AOSV_2	DPLL Address offset register for APT in RAM region 2	527

Table 76 Available DPLL register overview (cont'd)

Register name	Description	see Page
DPLL_APT	DPLL Actual RAM pointer to RAM regions 2a, b and d	528
DPLL_APS	DPLL Actual RAM pointer to regions 1c1, 1c2 and 1c4	530
DPLL_APT_2C	DPLL Actual RAM pointer to RAM region 2c	531
DPLL_APS_1C3	DPLL Actual RAM pointer to RAM region 1c3	532
DPLL_NUTC	DPLL Number of recent TRIGGER events used for calculations (mod 2*(TNU +1-SYN_NT))	533
DPLL_NUSC	DPLL Number of recent STATE events used for calculations (e.g. mod 2*(SNU +1-SYN_NS) for SYSF=0)	535
DPLL_NTI_CNT	DPLL Number of active TRIGGER events to interrupt	537
DPLL_IRQ_NOTIFY	DPLL Interrupt notification register	538
DPLL_IRQ_EN	DPLL Interrupt enable register	541
DPLL_IRQ_FORCINT	DPLL Interrupt force register	544
DPLL_IRQ_MODE	DPLL Interrupt mode register	546
DPLL_EIRQ_EN	DPLL Error interrupt enable register	546
DPLL_INC_CNT1	DPLL Counter for pulses for TBU_CH1_BASE to be sent in automatic end mode	549
DPLL_INC_CNT2	DPLL Counter for pulses for TBU_CH2_BASE to be sent in automatic end mode when SMC=RMO=1	549
DPLL_APT_SYNC	DPLL old RAM pointer and offset value for TRIGGER	550
DPLL_APS_SYNC	DPLL old RAM pointer and offset value for STATE	551
DPLL_TBU_TS0_T	DPLL TBU_CH0_BASE value at last TRIGGER event	553
DPLL_TBU_TS0_S	DPLL TBU_CH0_BASE value at last STATE event	553
DPLL_ADD_IN_LD1	DPLL direct load input value for SUB_INC1	554
DPLL_ADD_IN_LD2	DPLL direct load input value for SUB_INC2	555
DPLL_STATUS	DPLL Status Register	556
DPLL_ID_PMTR_[z] (z:0…31)[2]	DPLL 9 bit ID information for input signals PMT z 3)	562
DPLL_CTRL_0_SHADOW_TRIGGER	DPLL shadow register of DPLL_CTRL_0	562
DPLL_CTRL_0_SHADOW_STATE	DPLL shadow register of DPLL_CTRL_0	563
DPLL_CTRL_1_SHADOW_TRIGGER	DPLL shadow register of DPLL_CTRL_1	564
DPLL_CTRL_1_SHADOW_STATE	DPLL shadow register of DPLL_CTRL_1	565
DPLL_RAM_INI	DPLL initialization control and status for RAMs	566

1) This register is only available for device 4.

2) The registers DPLL_ID_PMTR 24-31 are not available for all devices.

28.20.11.2RAM Region 1a map description

Table 77 RAM Region 1a map description

Memory name	Description	Details on Page
PSA[i] (i:0…NOAC-1)	Position/Value request for action i	643
DLA[i] (i:0…NOAC-1)	Time to react before PSAi	643
NA[i] (i:0…NOAC-1)	Number of TRIGGER/STATE increments to ACTION i	644
DTA[i] (i:0…NOAC-1)	Calculated relative time to ACTION i	645

[1)] The values PSA24-31, DLA24-31, NA24-31 and DTA24-31 in RAM 1a are not available for all devices. Please refer to device specific appendix.

28.20.11.3RAM Region 1b map description

Table 78 RAM Region 1b map description

Memory name	Description	see Page
TS_T	Actual signal TRIGGER time stamp register TRIGGER_TS	567
TS_T_OLD	Previous signal TRIGGER time stamp register TRIGGER_TS_OLD	567
FTV_T	Actual signal TRIGGER filter value	568
TS_S	Actual signal STATE time stamp register STATE_TS	569
TS_S_OLD	Previous signal STATE time stamp register STATE_TS_OLD	569
FTV_S	Actual signal STATE filter value	570
THMI	TRIGGER hold time min. value	571
THMA	TRIGGER hold time max. value	572
THVAL	measured last pulse time from active to inactive TRIGGER slope	572
TOV	Time out value of TRIGGER, according to the last nominal increment for a missing TRIGGER	573
TOV_S	Time out value of STATE, according to the last nominal increment for a missing STATE	574
ADD_IN_CAL1	calculated ADD_IN value for SUB_INC1 generation	575
ADD_IN_CAL2	calculated ADD_IN value for SUB_INC2 generation	576
MPVAL1	missing pulses to be added/subtracted directly to SUB_INC1 and INC_CNT1 once	577
MPVAL2	missing pulses to be added/subtracted directly to SUB_INC2 and INC_CNT2 once	578
NMB_T_TAR	target number of TRIGGER pulses	579
NMB_T_TAR_OLD	target number of TRIGGER pulses	580
NMB_S_TAR	target number of STATE pulses	581
NMB_S_TAR_OLD	target number of STATE pulses	582
RCDT_TX	reciprocal value of expected increment duration (T)	583

Table 78 RAM Region 1b map description (cont'd)

Memory name	Description	see Page
RCDT_SX	reciprocal value of expected increment duration (S)	583
RCDT_TX_NOM	reciprocal value of the expected nominal increment duration (T)	584
RCDT_SX_NOM	reciprocal value of the expected nominal increment duration (S)	585
RDT_T_ACT	actual reciprocal value of TRIGGER	586
RDT_S_ACT	actual reciprocal value of STATE	586
DT_T_ACT	Duration of last TRIGGER increment	587
DT_S_ACT	Duration of last STATE increment	588
EDT_T	Absolute error of prediction for last TRIGGER increment	589
MEDT_T	Average absolute error of prediction up to the last TRIGGER increment	589
EDT_S	absolute error of prediction for last STATE increment	590
MEDT_S	Average absolute error of prediction up to the last STATE increment	591
CDT_TX	Expected duration of current TRIGGER increment	592
CDT_SX	Expected duration of current STATE increment	592
CDT_TX_NOM	Expected nominal duration of current TRIGGER increment (without consideration of missing events)	593
CDT_SX_NOM	Expected nominal duration of current STATE increment (without consideration of missing events)	594
TLR	TRIGGER locking range value; the TOR bit in the DPLL_STATUS register is set when violated	594
SLR	STATE locking range value; the SOR bit is set when violated	595
PDT_[i] (i:0…NOAC-1)[1)]	predicted time to ACTION i	596
MLS1	Calculated number of sub-pulses between two STATE events (to be set by CPU)	597
MLS2	Calculated number of sub-pulses between two STATE events (to be set by CPU) for the use when SMC=RMO=1	598
CNT_NUM_1	number of sub-pulses of SUB_INC1 in continuous mode, updated by the host only	598
CNT_NUM_2	number of sub-pulses of SUB_INC2 in continuous mode, updated by the host only	599
PVT	Plausibility value of next active TRIGGER slope	600
PSTC	Accurate calculated position stamp of last TRIGGER input;	601
PSSC	Accurate calculated position stamp of last STATE input;	602
PSTM	Measured position stamp at last active TRIGGER input	602
PSTM_OLD	Measured position stamp at last but one active TRIGGER input	602
PSSM	Measured position stamp at last active STATE input	604
PSSM_OLD	Measured position stamp at last but one active STATE input	604
NMB_T	Number of pulses of current increment in normal mode for SUB_INC1 (see equation DPLL-21 or for SMC=1 equation DPLL-27 respectively)	606
NMB_S	Number of pulses of current increment in emergency mod for SUB_INC1 (see equation DPLL-22) or in the case SMC=1 for SUB_INC2 (see equation DPLL-28)	606

1) The values PDT_24 to PDT_31 in RAM1b are not available for all devices.

28.20.11.4RAM Region 1c map description

Table 79 RAM Region 1c map description

Memory name	Description	see Page
RDT_S[i] (i:0…63)	Part of RAM1c1. Reciprocal value of the corresponding successive increment i, for each true nominal increment.	607
TSF_S[i] (i:0…63)	Part of RAM1c2. Time stamp field for state events, for each true nominal increment plus each virtual increment.	608
ADT_S[i] (i:0…63)	Part of RAM1c3. Adapt values for the current STATE increment, for each true nominal increment.	609
DT_S[i] (i:0…63)	Part of RAM1c4. Uncorrected last increment value of STATE for full scale, for each true nominal increment.	610

28.20.11.5Register Region EXT description

Table 80 Register Region EXT description

Register name	Description	see Page
DPLL_TSAC[z] (z:0…NOAC-1)	DPLL calculated action time stamps for action z	611
DPLL_PSAC[z] (z:0…NOAC-1)	DPLL calculated action position stamps for action z	611
DPLL_ACB_[z] (z:0…(NOAC/4)-1)	DPLL control bits for actions ((4*z)…(4*z)+3)	612
DPLL_CTRL_11	DPLL control register	614
DPLL_THVAL2	DPLL immediate THVAL value	622
DPLL_TIDEL	DPLL additional TRIGGER input delay	623
DPLL_SIDEL	DPLL additional STATE input delay	623
DPLL_CTN_MIN	CDT_T_NOM minimum value	624
DPLL_CTN_MAX	CDT_T_NOM maximum value	624
DPLL_CSN_MIN	CDT_S_NOM minimum value	625
DPLL_CSN_MAX	CDT_S_NOM maximum value	625
DPLL_STA	DPLL state machine status information	626
DPLL_INCF1_OFFSET	DPLL ADD_IN_ADDER1 offset for fast pulse generation	630
DPLL_INCF2_OFFSET	DPLL ADD_IN_ADDER2 offset for fast pulse generation	630
DPLL_DT_T_START	DPLL first value of DPLL_DT_T_ACT for the first increment after setting SIP1 from 0 to 1.	631
DPLL_DT_S_START	DPLL first value of DPLL_DT_S_ACT for the first increment after setting SIP2 from 0 to 1.	632
DPLL_STA_MASK	DPLL trigger masks for signals DPLL_STA_T and DPLL_STA_S	632
DPLL_STA_FLAG	DPLL STA_T/S and INC_CNT1/2 flags	633
DPLL_INC_CNT1_MASK	DPLL INC_CNT1 trigger mask	634

Table 80 Register Region EXT description (cont'd)

Register name	Description	see Page
DPLL_INC_CNT2_MASK	DPLL INC_CNT2 trigger mask	635
DPLL_NUSC_EXT1	Extension register number 1 for DPLL_NUSC[1)]	635
DPLL_NUSC_EXT2	Extension register number 2 for DPLL_NUSC[1)]	636
DPLL_APS_EXT	Extension register for DPLL_APS[1)]	637
DPLL_APS_1C3_EXT	Extension register for DPLL_APS_1C3[1)]	639
DPLL_APS_SYNC_EXT	Extension register for DPLL_APS_SYNC[1)]	640
DPLL_CTRL_EXT	Extension register for DPLL_CTRL[1)]	641

1) These registers will return AEI_STATUS = b#10 if DPLL_CTRL_11.STATE_EXT is not set.

28.20.11.6RAM Region 2 map description

Table 81 RAM Region 2 map description

Memory name	Description	see Page
RDT_T[i] (i:0…AOSV_2B/4-1)	Region 2a. Reciprocal value of the corresponding successive increment i, for each true nominal increment.	646
TSF_T[i] (i:0…AOSV_2B/4-1)	Region 2b. Time Stamp Field for TRIGGER event i, for each true nominal increment plus each virtual increment.	647
ADT_T[i] (i:0…AOSV_2B/4-1)	Region 2c. Adapt values for the current TRIGGER increment i, for each true nominal increment.	647
DT_T[i] (i:0…AOSV_2B/4-1)	Region 2d. Uncorrected last increment value of TRIGGER i, for each true nominal increment.	649

Note: For each of the regions, the maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

The description of registers is beginning at the register DPLL_CTRL_0.

The description of RAM regions is beginning at RAM 1a (see below): Bits 31 down to 24 in each RAM region are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Reserved address regions are not protected against writing.

The description of the memory region RAM 1a begins with memory element PSA[i]: The RAM region 1a is writable only for DEN=0 (see DPLL_CTRL_1 register).

The description of memory region RAM1b begins with memory element TS_T.

The description of memory region RAM1c begins with memory element RDT_S.

The description of register region EXT begins with the register DPLL_TSAC[z]: This is an extension of the normal register region above in order to allow up to 32 action calculations and later specification modifications.

The description of the memory region RAM 2 begins with memory element RDT_T.

28.20.12 DPLL Register and Memory description

28.20.12.1Register DPLL_CTRL_0

DPLL Control Register 0

DPLL_CTRL_0
DPLL Control Register 0 **(028000$_H$)** **Application Reset Value: 003B BA57$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RMO	TEN	SEN	IDT	IDS	AMT	AMS	TNU								
rw	rw	rw	rw	rw	rw	rw					rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SNU					IFP	MLT									
		rw			rw						rw				

Field	Bits	Type	Description
MLT	9:0	rw	**Multiplier for TRIGGER** 1) MLT+1 is number of *SUB_INC1* pulses between two *TRIGGER* events in normal mode (1...1024); *Note: For emergency mode the number of SUB_INC1 pulses between two STATE events is calculated by the CPU using the formula MLS1=(MLT+1)* (TNU+1) / (SNU+1) in order to get the same number of SUB_INC1 pulses for FULL_SCALE. This value is stored in RAM at 0x05C0. Change of MLT by the CPU must result in the corresponding change of MLS1 by the CPU for SMC=0.* *Note: The number of MLT events is the binary value plus 1. The value MLT+1 is replaced by MLS1 in the case of SMC=1 (see DPLL_CTRL_1 register) for all relevant calculations.*
IFP	10	rw	**Input filter position** 1) 2) 3) Value contains position or time related information. 0_B TRIGGER_FT and STATE_FT mean time related values, that means the number of time stamp clocks 1_B TRIGGER_FT and STATE_FT mean position related values, that means the number of SUB_INC1 (or SUB_INC2 in the case SMC=1) pulses, respectively

Field	Bits	Type	Description
SNU	15:11	rw	**STATE number** 4) SNU+1 is number of nominal STATE events in HALF_SCALE (1...32). *Note: The number of nominal STATE events is the decimal value plus 1. This value can only be written when (RMO=0 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change, RMO=0 means that the status of RMO=0 must be given before and during writing to the register. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0.* *Note: This register can only be written when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set, the signal cannot be written, the read value is zero.*
TNU	24:16	rw	**TRIGGER number** 4) TNU+1 is number of nominal *TRIGGER* events in HALF_SCALE (1...512). *Note: The number of nominal TRIGGER events is the decimal value plus 1.This value can only be written when (RMO=1 and SMC=0) or DEN=0.* To make sure that this signal is not changed during a mode change RMO=0 means that the status of RMO=0 must be given before and during writing to the register. Set TSL=00 before changing this value and set RMO=0 only after FULL_SCALE with TSL>0.
AMS	25	rw	**Adapt mode STATE** 2) Use of adaptation information of STATE. 0_B No adaptation information is used for STATE 1_B Immediate adapting mode; the values for physical deviation PD_S of ADT_S[i] are considered to calculate SUB_INC1 pulses in emergency mode (SMC=0), or SUB_INC2 pulses for SMC=1
AMT	26	rw	**Adapt mode TRIGGER** 1) Use of adaptation information of TRIGGER. 0_B No adaptation information for TRIGGER is used 1_B Immediate adapting mode; the values for physical deviation PD of ADT_T[i] are considered to calculate the SUB_INC1 pulses in normal mode and for SMC=1
IDS	27	rw	**Input delay STATE** 2) Use of input delay information transmitted in FT part of the STATE signal. 0_B Delay information is not used 1_B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge

Field	Bits	Type	Description
IDT	28	rw	**Input delay TRIGGER** 1) Use of input delay information transmitted in FT part of the TRIGGER signal. 0_B Delay information is not used 1_B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
SEN	29	rw	**STATE enable** 0_B STATE signal is not enabled (no signal considered) 1_B STATE signal is enabled
TEN	30	rw	**TRIGGER enable** 0_B TRIGGER signal is not enabled (no signal considered) 1_B TRIGGER signal is enabled
RMO	31	rw	**Reference mode** 1)2) Selection of the relevant input signal for generation of SUB_INC1. Double synchronous mode for SMC=1: Signal *TRIGGER*is used to generate the *SUB_INC1* signals, and *STATE* is used to generate the *SUB_INC2* signals. *Note: For SMC=0: TRIGGER and STATE are prepared to calculate SUB_INC1. The RMO bit gives a decision only, which of them is used. For changing from normal mode to emergency mode at the following TRIGGER slope (according to the RMO value in the shadow register)[1], the PSSC value is calculated by PSSC = PSSM + correction value (forward direction) or PSSC = PSSM - correction value (backward direction) with the correction value = inc_cnt1 - nmb_t. For changing from emergency mode to normal mode at the following STATE slope (according to the RMO value in the shadow register)[2], the PSTC value is calculated by PSTC = PSTM + correction value (forward direction) or PSTC = PSTM - correction value (backward direction) with the correction value = inc_cnt1 - nmb_s. In case no further TRIGGER or STATE events the CPU has to perform the above corrections.* 0_B Normal mode; the signal TRIGGER is used to generate the SUB_INC1 signals 1_B Emergency mode for SMC=0; signal STATE is used to generate the SUB_INC1 signals

1) stored in an independent shadow register for an active TRIGGER event and for DEN = 1.
2) stored in an independent shadow register for an active STATE event and for DEN = 1. T
3) he time between two active STATE or TRIGGER events must be always greater then 23.4 µs; in addition, the TS_CLK and the resolution must be chosen such that for each nominal increment, the time stamps at the beginning and the end of the increment differ at least in the value of 257.
4) For IFP=1, the time between two active TRIGGER or STATE events must be always greater then 2.34 ms, and the value x of MLT, MLS1 or MLS2 must be chosen such that the number of time stamp pulses between two SUB_INC events must be less than 65536. This is fulfilled when x is greater than 256.

28.20.12.2Register DPLL_CTRL_1

DPLL Control Register 1

DPLL_CTRL_1
DPLL Control Register 1 **(028004$_H$)** **Application Reset Value: B000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSL		SSL		SMC	TS0_HRT	TS0_HRS	SYSF	SWR	LCD	SYN_NT					
rw		rw		rw	rw	rw	rw	rw	rw	rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYN_NS					PCM2	DLM2	SGE2	PCM1	DLM1	SGE1	PIT	COA	IDDS	DEN	DMO
rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
DMO	0	rw	**DPLL mode select** 1) 2) 0_B Automatic end mode; if the number of pulses for an increment is reached, no further pulse is generated until the next active TRIGGER/STATE is received; in the case of getting a new active TRIGGER/STATE before the defined number of pulses is reached, the pulse frequency is changed according to the conditions described below (COA) 1_B Continuous mode; in this mode, a difference between the predefined number of pulses and the actual number of generated pulses can influence the pulse frequency by writing a corresponding pulse number into CNT_NUM_1 or CNT_NUM_2, respectively, in RAM region 1b
DEN	1	rw	**DPLL enable** *Note: The bits 31 down to 0 of the DPLL_STATUS register are cleared, when the DPLL is disabled. Some bits of the control registers can be set only when DEN=0. The protected bits in the DPLL_CTRL_1 register cannot be written when simultaneously DEN is set to 1.* 0_B The DPLL is not enabled; disabling the DPLL will result in a reset state of the DPLL_STATUS register, which remains in this state until DEN=1. No DPLL related interrupt will be generated in that case. 1_B The DPLL is enabled

Field	Bits	Type	Description
IDDS	2	rw	**Input direction detection strategy in the case of SMC=0** *Note: This bit can only be written when the DPLL is disabled and fixed to zero, when not needed for an implementation. Independent of the value of IDDS is the direction information for TRIGGER in the case SMC=0 always considered at the moment when the inactive slope appears.* 0_B The input direction is detected comparing the THMI value with the duration between active and inactive slope of TRIGGER 1_B The input direction is detected using TDIR input signal also in the case SMC=0
COA	3	rw	**Correction strategy in automatic end mode (DMO=0)** 1) 2) For SMC=RMO=1: **COA** is used for SUB_INC1 **and** SUB_INC2. 0_B The pulse frequency of the CMU_CLK0 will be used to make up for missing pulses from last increment; the output of the calculated new pulses will start after resetting the FFs in the pulse generation unit. The frequency of CMU_CLK0 should not exceed half the frequency of the system clock (see Adder for generation SUB_INCx by the carry cout with SMC=0). (see also figure Adder for generation of SUB_INCx by the carry cout, **Figure 128**). 1_B Missing pulses of the last increment are distributed evenly to the next increment, calculations are done when the next active input event appears. The number of missing sub-pulses will be determined by the pulse counter difference between the last two active TRIGGER/STATE events, respectively; the FFs in the pulse generation unit are not reset before sending new pulses.
PIT	4	rw	**Plausibility value PVT to next active TRIGGER is time related** 1) 0_B The plausibility value is position related (PVT contains the number of SUB_INC1 pulses) 1_B The plausibility value is time related (the PVT value is to be multiplied with the duration of the last increment DT_T_ACT and divided by 1024)
SGE1	5	rw	**SUB_INC1 generator enable** 1) 2) 0_B The SUB_INC1 generator is not enabled 1_B The SUB_INC1 generator is enabled

Field	Bits	Type	Description
DLM1	6	rw	**Direct Load Mode for SUB_INC1 generation** 1) 2) 0_B The DPLL uses the calculated ADD_IN_CAL value for the SUB_INC1 generation 1_B The ADD_IN_LD value is used for the SUB_INC1 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
PCM1	7	rw	**Pulse Correction Mode for SUB_INC1 generation** 1) 2) 3) 0_B The DPLL does not use the correction value stored in MPVAL1 1_B The DPLL uses the correction value stored in MPVAL1 in normal and emergency mode
SGE2	8	rw	**SUB_INC2 generator enable** 2) 0_B The SUB_INC2 generator is not enabled 1_B The SUB_INC2 generator is enabled
DLM2	9	rw	**Direct Load Mode for SUB_INC2 generation** 2) 0_B The DPLL uses the calculated ADD_IN_CAL value for the SUB_INC2 generation 1_B The ADD_IN_LD value is used for the SUB_INC2 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
PCM2	10	rw	**Pulse Correction Mode for SUB_INC2 generation** 2) 3) 0_B The DPLL does not use the correction value stored in MPVAL2 1_B The DPLL uses the correction value stored in MPVAL2

Field	Bits	Type	Description
SYN_NS	15:11	rw	**Synchronization number of STATE** Summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing *STATE* events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1) ; the SYN_NS missing *STATES* can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1c3 as value NS in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(SNU+1-SYN_NS) for SYSF=0 or 2*(SNU+1)-SYN_NS for SYSF=1 . This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU. This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0. To make shure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register. This register can only be written when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set, the signal cannot be written, the read value is zero.
SYN_NT	21:16	rw	**Synchronization numberof TRIGGER** Summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing *TRIGGER* events in HALF_SCALE; the SYN_NT missing *TRIGGER* can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 2c as value NT in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(TNU-SYN_NT). This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APT_2C in an appropriate relation to the RAM pointer APT of the actual increment by the CPU. This value can only be written when (RMO=1 and SMC=0) or DEN=0. Set TSL=00 before changing this value and set RMO=0 only after FULL_SCALE with TSL>0. To make shure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register.
LCD	22	rw	**Locking condition definition** This bit can only be written when the DPLL is disabled and fixed to zero, when not needed for an implementation. 0_B Locking condition definition is one times missing TRIGGERs, as expected by the profile in HALF_SCALE (one gap) 1_B Locking condition definition is n-1 times missing TRIGGERs, as expected by the profile in HALF_SCALE (one additional tooth)

Field	Bits	Type	Description
SWR	23	rw	**Software reset** Resets all register and internal states of the DPLL. Setting the SWR bit results only in a software reset when the DPLL is not enabled (DEN=0). 0_B No software reset enabled 1_B Software reset enabled
SYSF	24	rw	**SYN_NS for FULL_SCALE** The value SYN_NS does mean the sum of all systematic missing *STATE* events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1). This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value, and set RMO=1 only after FULL_SCALE with SSL>0. To make sure that this signal is not changed during a mode change, SMC=0 means that the status of SMC=0 must be given before and during writing to the register. 0_B The SYN_NS value is valid for HALF_SCALE 1_B The SYN_NS value is valid for FULL_SCALE
TS0_HRS	25	rw	**Time stamp high resolution STATE** This bit can only be written when the DPLL is disabled. 0_B The resolution of the used DPLL input TBU_TS0 bits is equal to the STATE input time stamp resolution 1_B The STATE input time stamps have an 8 times higher resolution than the TBU_TS0 DPLL input
TS0_HRT	26	rw	**Time stamp high resolution TRIGGER** This bit can only be written when the DPLL is disabled. 0_B The resolution of the used DPLL input TBU_TS0 bits is equal to the TRIGGER input time stamp resolution 1_B The TRIGGER input time stamps have an 8 times higher resolution than the TBU_TS0 input
SMC	27	rw	**Synchronous Motor Control** This bit can only be written when the DPLL is disabled. 0_B TRIGGER and STATE inputs are used for a control different to SMC 1_B The TRIGGER input reflects a combined sensor signal for SMC, and in the case of RMO=1, also STATE reflects a different combined sensor signal

Field	Bits	Type	Description
SSL	29:28	rw	**STATE slope select** Definition of active slope for signal STATE; each active slope is an event defined by SNU. Set by DEN=0 only. If DPLL_STATUS.FSD = '1': Slope sensitive after detection of first STATE input signal. If DPLL_STATUS.FSD = '0': Level sensitive for first STATE input signal edge. *Note: This value can only be written when (RMO=0 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change, SMC=0 means that the status of SMC=0 must be given before and during writing to the register.* 00_B FSD=1: No slope of STATE will be used (this value makes only sense in normal mode); FSD=0: No input signal of STATE will be used (this value makes only sense in normal mode). 01_B FSD=1: Low-to-high slope will be used as active slope, only inputs with a signal value of '1' will be considered; FSD=0: "High" input signal level will be used as active slope, only inputs with a signal value of '1' will be considered. 10_B FSD=1: High-to-low slope will be used as active slope, only inputs with a signal value of '0' will be considered; FSD=0: "Low" input signal level will be used as active slope, only inputs with a signal value of '0' will be considered. 11_B FSD=1: Both slopes will be used as active slopes; FSD=0: Both input signal levels will be used as active slopes.

Field	Bits	Type	Description
TSL	31:30	rw	**TRIGGER slope select** Definition of active slope for signal TRIGGER each active slope is an event defined by TNU. Set by DEN=0 only. If DPLL_STATUS.FTD = '1' "slope sensitive after detection of first TRIGGER input signal" If DPLL_STATUS.FTD = '0' "level sensitive for first TRIGGER input signal edge" *Note: This value can only be written when (RMO=1 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change, SMC=0 means that the status of SMC=0 must be given before and during writing to the register.* 00_B FTD=1: No slope of TRIGGER will be used; this value makes only sense in emergency mode; FTD=0: No input signal of TRIGGER will be used; this value makes only sense in normal mode 01_B FTD=1: Low high slope will be used as active slope, only inputs with a signal value of "1" will be considered; FTD=0: "high" input signal level will be used as active slope, only inputs with a signal value of "1" will be considered 10_B FTD=1: High low slope will be used as active slope, only inputs with a signal value of "0" will be considered; FTD=0: "low" input signal level will be used as active slope, only inputs with a signal value of "0" will be considered 11_B FTD=1: Both slopes will be used as active slopes; FTD=0: Both input signal levels will be used as active slopes

1) Stored in an independent shadow register for a valid TRIGGER event and for DEN = 1.
2) Stored in an independent shadow register for a valid STATE event and for DEN = 1.
3) Bit is cleared, when transmitted to shadow register.

ACT_N															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACT_N															
rw															

Field	Bits	Type	Description
ACT_N	31:0	rw	**New output data values concerning to action i provided** ACT_N[i] is: • Set (for AENi=1 and a new valid PMTR), that means when new action data are to be calculated for the correspondent action. After each calculation of the new actions values, the ACT_N[i] bit updates the corresponding bit in the connected shadow register. The status of the ACT_N[i] bits in the shadow register is reflected by the corresponding DPLL output signal ACT_V (valid bit). • Reset together with the corresponding shadow register bit for AENi=0. • Reset without the corresponding shadow register bit when the calculated event is in the past (the shadow register bit is set, when it was not set before in that case). • The corresponding shadow register bit is reset, when new PMTR data are written or when the provided action data are read (blocking read). • Writeable for debugging purposes together with the corresponding shadow register when DEN=0. *Note: These bits can only be written for test purposes when the DPLL is disabled.* 00000000_H No new output data available after a recent PMT request or actual event value is in the past or invalid 00000001_H New PMTR data received or calculation is to be precised by taking into account new TRIGGER or STATE values

28.20.12.8 Register DPLL_OSW

DPLL Offset and Switch Old/New Address Register

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_OSW

DPLL Offset and Switch Old/New Address Register($02801C_H$) **Application Reset Value: $0000\ 0200_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						OSS		0						SWON_T	SWON_S
r						rw		r						r	r

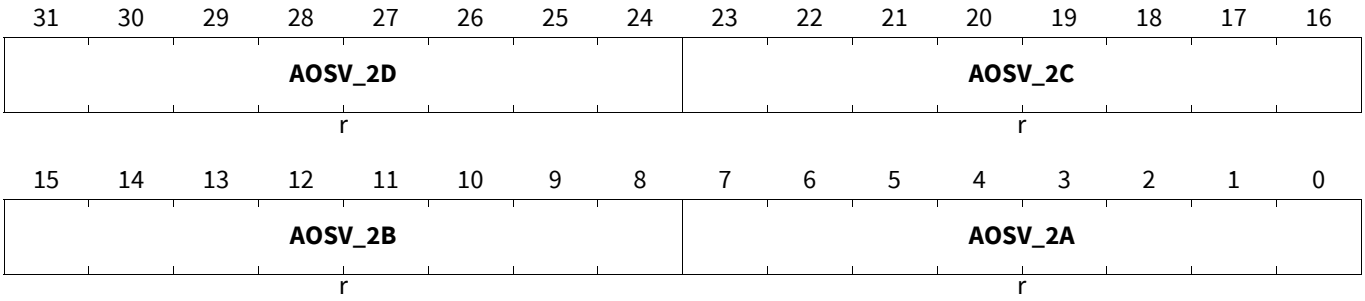
Field	Bits	Type	Description
SWON_S	0	r	**Switch of new STATE** Switch bit for LSB address of STATE. This bit is changed for each write access to TS_S/TS_S_OLD. Using this unchanged address bit SWON_S for any access to TS_S results always in an access to TS_S_OLD. For writing to this address the former old (TS_S_OLD_old) value is overwritten by the new one while the SWON_S bit changes. Thus the former new one is now the old one and the next access is after changing SWON_S directed to this place. Therefore write to TS_S first and after that immediately to FTV_S and PSSM, always before a new TS_S value is to be written. After writing TS_S, FTV_S and PSSM in this order the address pointer AP with LSB(AP)=SWON_S shows for the corresponding address to TS_S_OLD, FTV_S and PSSM while LSB(AP)=/SWON_S results in an access to TS_S, FTV_S_old and PSSM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN=0).
SWON_T	1	r	**Switch of new TRIGGER** Switch bit for LSB address of TRIGGER. This bit is changed for each write access to TS_T/TS_T_OLD. Using this unchanged address bit SWON_T for any access to TS_T results always in an access to TS_T_OLD. For writing to this address the former old (TS_T_OLD_old) value is overwritten by the new one while the SWON_T bit changes. Thus the former new one is now the old one and the next access is after changing SWON_T directed to this place. Therefore write to TS_T first and after that immediately to FTV_T and PSTM, always before a new TS_T value is to be written. After writing TS_T, FTV_T and PSTM in this order the address pointer AP with LSB(AP)=SWON_T shows for the corresponding address to TS_T_OLD, FTV_T and PSTM while LSB(AP)=/SWON_T results in an access to TS_T, FTV_T_old and PSTM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN=0).
OSS	9:8	rw	**Offset size of RAM region 2** At least 128 and at most 1024 values can be stored in each of the RAM 2 regions a to d accordingly. The value can be set only for DEN=0. The change of the OSS value results in an automatic change of the offset values in the DPLL_AOSV_2 register. This value can only be written when the DPLL is disabled. 00_B Offset size 128 of RAM region 2 01_B Offset size 256 of RAM region 2 10_B Offset size 512 of RAM region 2 11_B Offset size 1024 of RAM region 2
0	7:2, 31:10	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.9Register DPLL_AOSV_2

DPLL Address Offset Register of RAM 2 Regions

DPLL_AOSV_2

DPLL Address Offset Register of RAM 2 Regions(028020_H) **Application Reset Value: $1810\ 0800_H$**



Field	Bits	Type	Description
AOSV_2A	7:0	r	**Address offset value of the RAM 2A region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2a. When the APT value is added to this start address, the current RAM cell RDT_Tx is addressed. Value is set automatically when OSS in the PPLL_OSW register is set: OSS=0x0: AOSV_2A= 0x00 OSS=0x1: AOSV_2A= 0x00 OSS=0x2: AOSV_2A= 0x00 OSS=0x3: AOSV_2A= 0x00
AOSV_2B	15:8	r	**Address offset value of the RAM 2B region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2b. When the APT value is added to this start address, the current RAM cell TSF_Tx is addressed. Value is set automatically when OSS in the PPLL_OSW register is set: OSS=0x0: AOSV_2B= 0x02 OSS=0x1: AOSV_2B= 0x04 OSS=0x2: AOSV_2B= 0x08 OSS=0x3: AOSV_2B= 0x10
AOSV_2C	23:16	r	**Address offset value of the RAM 2C region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2c. When the APT value is added to this start address, the current RAM cell ADT_Tx is addressed. Value is set automatically when OSS in the PPLL_OSW register is set: OSS=0x0: AOSV_2C= 0x04 OSS=0x1: AOSV_2C= 0x08 OSS=0x2: AOSV_2C= 0x10 OSS=0x3: AOSV_2C= 0x20

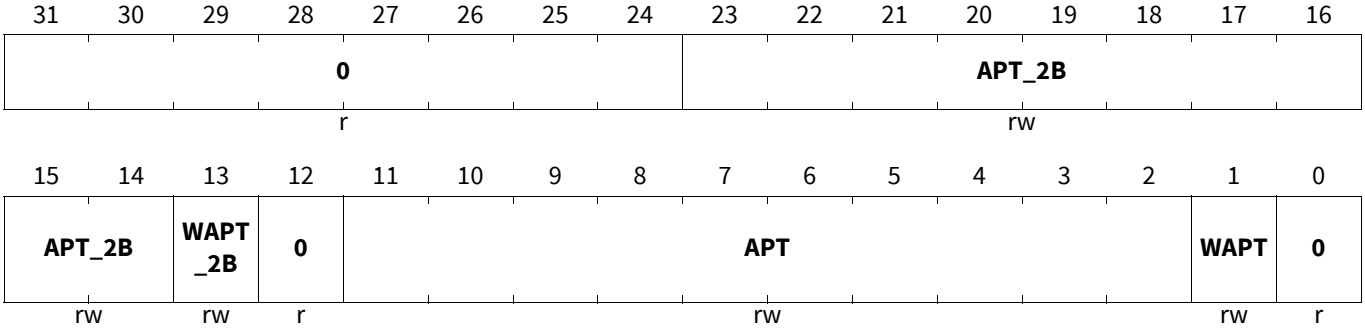
Field	Bits	Type	Description
AOSV_2D	31:24	r	**Address offset value of the RAM 2D region** The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2d. When the APT value is added to this start address, the current RAM cell DT_Tx is addressed. Value is set automatically when OSS in the PPLL_OSW register is set: OSS=0x0: AOSV_2D= 0x06 OSS=0x1: AOSV_2D= 0x0C OSS=0x2: AOSV_2D= 0x18 OSS=0x3: AOSV_2D= 0x30 The offset values are needed to support a scalable RAM size of region 2 from 1,5 Kbytes to 12 Kbytes. The values above must be in correlation with the offset size defined in the OSW register. All offset values are set automatically in accordance to the OSS value in the DPLL_OSW register. This value can be set only for DEN=0.

28.20.12.10Register DPLL_APT

DPLL Actual RAM Pointer Address for TRIGGER

DPLL_APT

DPLL Actual RAM Pointer Address for TRIGGER (028024_H) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
WAPT	1	rw	**Write bit for address pointer APT** Read as zero. 0_B The APT is not writeable 1_B The APT is writeable

Field	Bits	Type	Description
APT	11:2	rw	**Address pointer TRIGGER** Actual RAM pointer address value offset for DT_T[i] and RDT_T[i] in FULL_SCALE for 2*(TNU+1-SYN_NT) TRIGGER events. This pointer is used for the RAM region 2 subsections 2a and 2d. The pointer APT is incremented for each active *TRIGGER* event (simultaneously with APT_2B, APT_2C) for DIR1=0. For DIR1=1 the APT is decremented. The APT offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region The APT pointer value is directed to the RAM position, in which the data values are to be written, which corresponds to the last increment. The APT value is not to be changed, when the direction (shown by DIR1) changes, because it points always to a storage place after the considered increment. Changing of DIR1 takes place always after an active *TRIGGER* event and the resulting increment/decrement. This value can only be written when the WAPT bit is set.
WAPT_2B	13	rw	**Write bit for address pointer APT_2B** Read as zero. 0_B The APT_2B is not writeable 1_B The APT_2B is writeable
APT_2B	23:14	rw	**Address pointer TRIGGER for RAM region 2b** Actual RAM pointer address value for TSF_T[i] Actual RAM pointer address of *TRIGGER* events in FULL_SCALE for 2*(TNU+1) *TRIGGER* periods; this pointer is used for the RAM region 2b. The RAM pointer is initially set to zero. For SYT=1: The pointer APT_2B is incremented by SYN_T_OLD for each active *TRIGGER* event (simultaneously with APT and APT_2C) for DIR1=0 when an active *TRIGGER* input appears. For DIR1=1 (backwards) the APT is decremented by SYN_T_OLD. For SYT=0: APT_2B is incremented or decremented by 1. In addition when the APT_2C value is written by the CPU - in order to synchronize the DPLL- with the next active *TRIGGER* event the APT_2B_EXT value is added/subtracted (while APT_2B_STATUS is one; see DPLL_APT_SYNC register at **Section 28.20.12.24**). This value can only be written when the WAPT_2B bit is set.
0	0, 12, 31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.11Register DPLL_APS

DPLL Actual RAM Pointer Address for STATE

DPLL_APS

DPLL Actual RAM Pointer Address for STATE (028028$_H$) Application Reset Value: 0000 0000$_H$

APS_1C2		WAPS_1C2	0					APS						WAPS	0
rw		rw	r					rw						rw	r

Field	Bits	Type	Description
WAPS	1	rw	**Write bit for address pointer APS** Read as zero 0_B The APS is not writeable 1_B The APS is writeable
APS	7:2	rw	**Address pointer STATE** Actual RAM pointer address value for DT_S[i] and RDT_S[i] Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 64 *STATE* events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c1 and 1c4. APS is incremented (decremented) by one for each active *STATE* event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after an active *STATE* event and the resulting increment/decrement. This value can only be written when the WAPS bit is set.
WAPS_1C2	13	rw	**Write bit for address pointer APS_1C2** Read as zero 0_B The APS_1C2 is not writeable 1_B The APS_1C2 is writeable

Field	Bits	Type	Description
APS_1C2	19:14	rw	**Address pointer STATE for RAM region 1c2** Actual RAM pointer address value for TSF_S[i]. Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 64 *STATE* events but limited to 2*(SNU+1) in normal and emergency mode; this pointer is used for the RAM region 1c2. For SYS=1: APS_1C2 is incremented (decremented) by SYN_S_OLD for each active *STATE* event and DIR2=0 (DIR2=1). For SYS=0: APT_1c2 is incremented or decremented by 1 respectively. The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. In addition when the APS_1C3 value is written by the CPU - in order to synchronize the DPLL- with the next active *STATE* event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at **Section 28.20.12.25**). This value can only be written when the WAPS_1C2 bit is set
0	0, 12:8, 31:20	r	**Reserved** Read as zero, shall be written as zero.

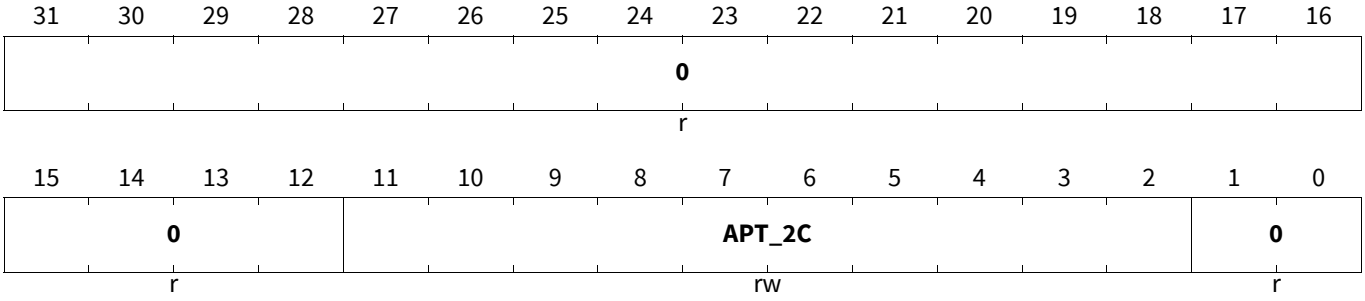
28.20.12.12Register DPLL_APT_2C

DPLL Actual RAM Pointer for Region 2C

Note: The APT_2C pointer values are directed to the RAM position of the profile element in RAM region 2c, which correspond to the current increment. For DIR1=0 (DIR1=1) the pointers APT_2C_x are incremented (decremented) by one simultaneously with APT. For SMC=0 the change of DIR1 takes place always after an active TRIGGER event (by evaluation of the inactive slope) and the resulting increment/decrement. In the case SMC=1 the direction change is known before the input event is processed. The correction of the APT_2C pointer differs: for SMC=0 correct 4 times and for SMC=1 correct only 2 times. The APT_2C_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

DPLL_APT_2C

DPLL Actual RAM Pointer for Region 2C (02802C$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
APT_2C	11:2	rw	**Address pointer TRIGGER for RAM region 2c and Actual RAM pointer address value for ADT_T[i]** Actual RAM pointer address value of TRIGGER adapt events in FULL_SCALE for 2*(TNU+1-SYN_NT) TRIGGER periods depending on the size of the used RAM 2; this pointer is used for the RAM region 2 for the subsection 2c only. The RAM pointer is initially set to zero. The APT_2C value is set by the CPU when the synchronization condition was detected. Within the RAM region 2c initially the conditions for synchronization gaps and adapted values are stored by the CPU.
0	1:0, 31:12	r	**Reserved** Read as zero, shall be written as zero.

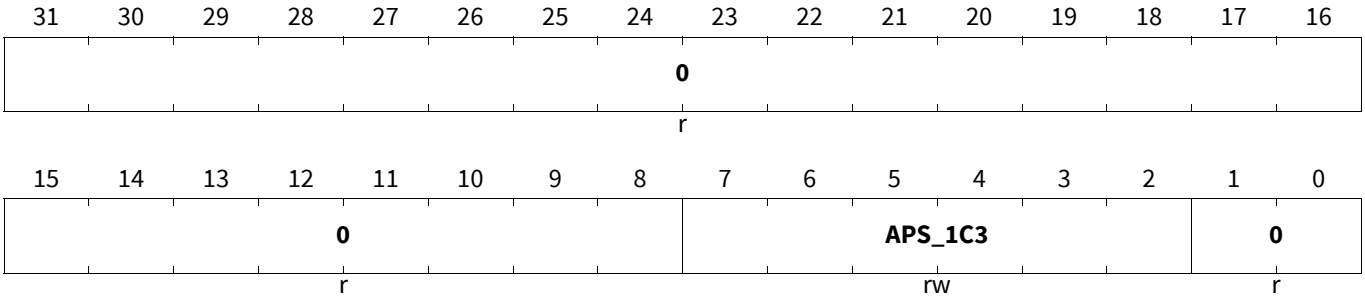
28.20.12.13Register DPLL_APS_1C3

DPLL Actual RAM Pointer for RAM Region 1C3

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 0b10.

Note: The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1c2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before an active STATE event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction.
The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

DPLL_APS_1C3
DPLL Actual RAM Pointer for RAM Region 1C3 (028030_H) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
APS_1C3	7:2	rw	**Address pointer STATE for RAM region 1c3** Actual RAM pointer address value for ADT_S[i]. Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 64 *STATE* events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c3. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected.
0	1:0, 31:8	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.14Register DPLL_NUTC

DPLL Number of Recent TRIGGER Events Used for Calculations

Note: DPLL Number of recent TRIGGER events used for calculations (mod 2(TNU +1-SYN_NT))*.

DPLL_NUTC

DPLL Number of Recent TRIGGER Events Used for Calculations(028034_H) **Application Reset Value: $0001\ 2001_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYN_T			**0**		**FST**	**NUTE**									
rw			r		rw	rw									

Field	Bits	Type	Description
NUTE	9:0	rw	**Number of recent TRIGGER events used for SUB_INC1 and action calculations modulo 2*(TNUmax+1)** Number of recent TRIGGER events used for SUB_INC1 and action calculations modulo 2*(TNUmax+1). NUTE: number of last nominal increments to be considered for the calculations. No gap is considered in that case for this value, but in the VTN value (see below): This value is set by the CPU, but reset automatically to '1' by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. For FULL_SCALE set NUTE= 2*(TNU +1) and for HALF_SCALE NUTE= TNU +1. The relation values QDT_Tx are calculated using NUTE values in the past with its maximum value of 2*(TNU +1). The value zero (in combination with the value FST=1) does mean 2^{11} values in the past. *Note: To prevent that inconsistencies between internal pointer in which NUTE is used and the case decision of different prediction method's for prediction of the next event and PMT(position minus time) occur, the NUTE value is stored internally at that point of time when the internal pointers are calculated for the next event cycle.* *Note: This value can only be written when the WNUT bit is set.* 000_H The NUTE value is less then FULL_SCALE 001_H The NUTE value is equal to FULL_SCALE *This value is set by the CPU, but reset automatically to "0" by a change of direction orloss of LOCK.*
FST	10	rw	**FULL_SCALE of TRIGGER** This value is to be set, when NUTE is set to FULL_SCALE. This value can only be written when the WNUT bit is set.
SYN_T	15:13	rw	**Number of real and virtual events to be considered for the current increment** This value reflects the NT value of the last valid increment, stored in ADT_T[i]; to be updated after all calculations in step 17 of **Table 28.20.8.6.6**. This value can only be written when the WSYN bit in this register is set.
SYN_T_OLD	18:16	rw	**Number of real and virtual events to be considered for the last increment** This value reflects the NT value of the last but one valid increment, stored in ADT_T[i]; is updated automatically when writing SYN_T. This value is updated by the SYN_T value when the WSYN bit in this register is set.

Field	Bits	Type	Description
VTN	24:19	rw	**Virtual TRIGGER number** Number of virtual increments in the current NUTE region This value reflects the number of virtual increments in the current NUTE region; for NUTE=1 this value is zero, when the CPU sets NUTE to a value > 1 , it must also set VTN to the correspondent value; for NUTE is set to FULL_SCALE including NUTE=zero (2^{11} modulo 2^{11}) the VTN is to be set to 2* SYN_NT. The VTN value is subtracted from the NUTE value in order to get the corresponding APT value for the past; the VTN value is not used for the APT_2B pointer. VTN is to be updated by the CPU when a new gap is to be considered for NUTE or a gap is leaving the NUTE region; for this purpose the TINT values in the profile can be used to generate an interrupt for the CPU at the corresponding positions; no further update of VTN is necessary when NUTE is set to FULL_SCALE This value can only be written when the WVTN bit is set.
WNUT	29	rw	**Write control bit for NUTE and FST** Read as zero 0_B The NUTE value is not writeable 1_B The NUTE value is writeable
WSYN	30	rw	**Write control bit for SYN_T and SYN_T_OLD** Read as zero 0_B The SYN_T value is not writeable 1_B The SYN_T value is writeable
WVTN	31	rw	**Write control bit for VTN** Read as zero 0_B The VTN value is not writeable 1_B The VTN value is writeable
0	12:11, 28:25	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.15Register DPLL_NUSC

DPLL Number of Recent STATE Events Used for Calculations

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_NUSC

DPLL Number of Recent STATE Events Used for Calculations(028038_H) Application Reset Value: 0000 2081_H

SYN_S_OLD			SYN_S						FSS	NUSE					
rw			rw						rw	rw					

Field	Bits	Type	Description
NUSE	5:0	rw	**Number of recent STATE events used for SUB_INCx calculations modulo 2*(SNUmax+1)** No gap is considered in that case for this value, but in the VSN value (see below): This register is set by the CPU but reset automatically to “1” by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. The relation values QDT_Sx are calculated using NUSE values in the past with its maximum value of 2*SNU+1. This value can only be written when the WNUS bit is set. *Note: To prevent that inconsistencies between internal pointer in which NUSE is used and the case decision of different prediction method's for prediction of the next event and PMT(position minus time) occur, the NUSE value is stored internally at that point of time when the internal pointers are calculated for the next event cycle.*
FSS	6	rw	**FULL_SCALE of STATE** This value is to be set, when NUSE is set to FULL_SCALE. This value is set by the CPU, but reset automatically to '0' by a change of direction or loss of LOCK. *Note: This value can only be written when the WNUS bit is set.* 0_B The NUSE value is less then FULL_SCALE 1_B The NUSE value is equal to FULL_SCALE
SYN_S	12:7	rw	**Number of real and virtual events to be considered for the current increment** This value reflects the NS value of the last valid increment, stored in ADT_S[i]; to be updated after all calculations in step 37 of **Table 28.20.8.6.6**. This value can only be written when the WSYN bit in this register is set.
SYN_S_OLD	18:13	rw	**Number of real and virtual events to be considered for the last increment** This value reflects the NS value of the last but one valid increment, stored in ADT_S[i]; is updated automatically when writing SYN_S. This value is updated by the SYN_S value when the WSYN bit in this register is set.

Field	Bits	Type	Description
VSN	24:19	rw	**Virtual STATE number** Number of virtual state increments in the current NUSE region. This value reflects the number of virtual increments in the current NUSE region; for NUSE=1 this value is zero, when the CPU sets NUSE to a value > 1 or zero(2^7 modulo 2^7) , it must also set VSN to the correspondent value; the VSN value is subtracted from the NUSE value in order to get the corresponding APS value for the past; the VSN value is not used for the APS_1C2 pointer. VSN is to be updated by the CPU when a new gap is to be considered for NUSE or a gap is leaving the NUSE region; for this purpose the SASI interrupt can be used; no further update of VSN is necessary when NUSE is set to FULL_SCALE This value can only be written when the WVSN bit is set.
WNUS	29	rw	**Write control bit for NUSE** Read as zero. 0= the NUSE value is not writeable 1= the NUSE value is writeable
WSYN	30	rw	**Write control bit for SYN_S and SYN_S_OLD** Read as zero 0= the SYN_S value is not writeable 1= the SYN_S value is writeable
WVSN	31	rw	**Write control bit for VS** Read as zero 0_B The VSN value is not writeable 1_B The VSN value is writeable
0	28:25	r	**Reserved** Read as zero, shall be written as zero.

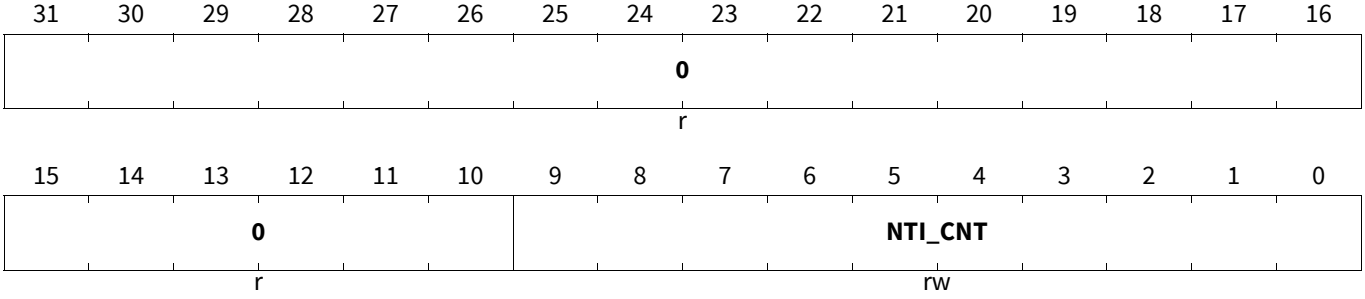
DPLL Number of Active TRIGGER Events to Interrupt

DPLL_NTI_CNT

DPLL Number of Active TRIGGER Events to Interrupt(02803C$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
NTI_CNT	9:0	rw	**Number of TRIGGERs to interrupt** Number of active TRIGGER events to the next DPLL_CDTI interrupt. This value shows the remaining *TRIGGER* events until an active TRIGGER slope results in a DPLL_CDTI interrupt; the value is to be count down for each active *TRIGGER* event.
0	31:10	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.17Register DPLL_IRQ_NOTIFY

DPLL Interrupt Notification Register

Note: All bits in the DPLL_IRQ_NOTIFY register are set permanently until writing a one bit value is performed to the corresponding bit.

DPLL_IRQ_NOTIFY
DPLL Interrupt Notification Register (028040$_H$) Application Reset Value: 0000 0000$_H$

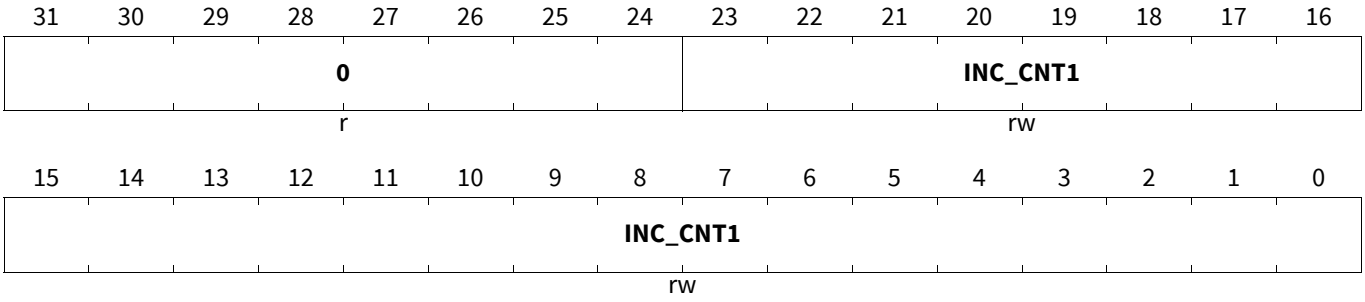
28.20.12.22Register DPLL_INC_CNT1

DPLL Counter for Pulses for TBU_CH1_BASE to be Sent in Automatic End Mode

Counter Value of Sent SUB_INC1 Pulses

DPLL_INC_CNT1
DPLL Counter for Pulses for TBU_CH1_BASE to be Sent in Automatic End Mode(0280B0$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
INC_CNT1	23:0	rw	**Actual number of pulses to be still sent out at the current increment until the next active input signal in automatic end mode** Automatic addition of the number of demanded pulses MLT/MLS1 when getting an active *TRIGGER*/*STATE* input in normal or emergency mode respectively **when SGE1=1**;writeable only for test purposes when DEN=0. In the case of a change of the direction the wrong number of pulses are corrected twice: Add the difference between NMB_T and INC_CNT1 twice to INC_CNT1 before sending out the correction pulses. This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

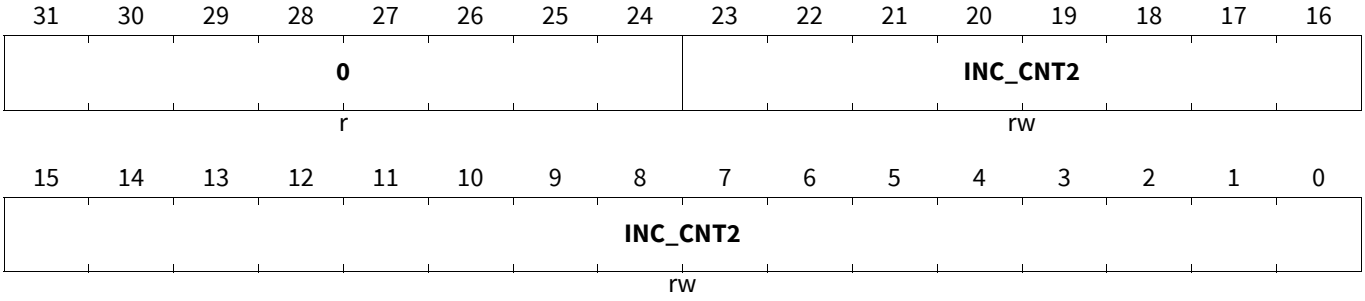
28.20.12.23Register DPLL_INC_CNT2

DPLL Counter for Pulses for TBU_TS2 to be Sent in Automatic End Mode

Counter Value of sent SUB_INC2 values (for SMC=1 and RMO=1)

DPLL_INC_CNT2

DPLL Counter for Pulses for TBU_TS2 to be Sent in Automatic End Mode(0280B4$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
INC_CNT2	23:0	rw	**Actual number of pulses to be still sent out at the current increment until the next active input signal in automatic end mode** Automatic addition of the number of demanded pulses MLS2 when getting an active *TRIGGER*/*STATE* input in normal or emergency mode respectively **when SGE2=1**; writeable only for test purposes when DEN=0; In the case of a change of the direction the wrong number of pulses are corrected twice: Add the difference between NMB_S and INC_CNT2 twice to INC_CNT2 before sending out the correction pulses. This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

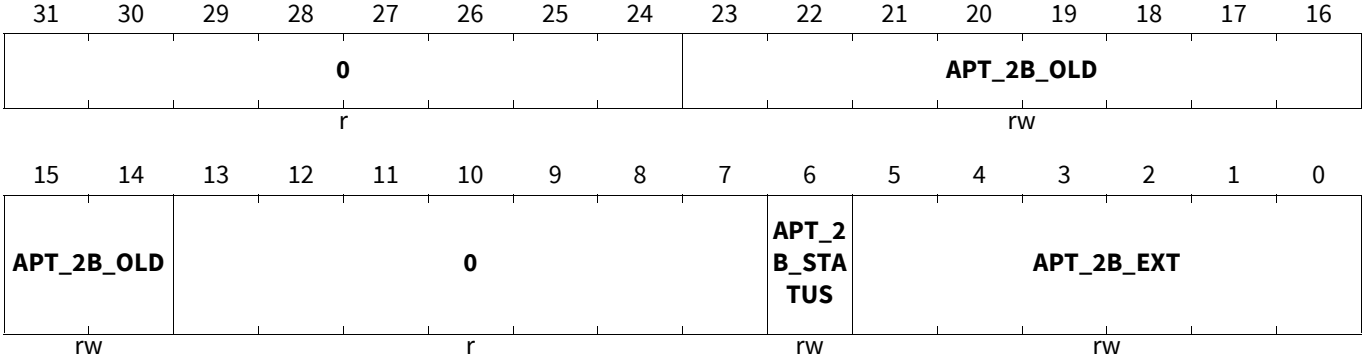
28.20.12.24Register DPLL_APT_SYNC

DPLL Old RAM Pointer and Offset Value for TRIGGER

TRIGGER Time Stamp Field Offset at Synchronization Time

DPLL_APT_SYNC

DPLL Old RAM Pointer and Offset Value for TRIGGER(0280B8$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
APT_2B_EXT	5:0	rw	**Address pointer 2b extension** This offset value determines, by which value the APT_2B is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUTE value to be set and including the next future increment (when SYN_T_OLD is still 1). When the synchronization takes place, this value is to be added to the APT_2B address pointer (for forward direction, DIR1=0) and the APT_2B_STATUS bit is cleared after it. For backward direction subtract APT_2B_EXT accordingly. This correction is done after updating the RAM TSF with the last TS_T value. When the synchronization is intended and the NUTE value is to be set to FULL_SCALE after it, the APT_2B_EXT value must be set to 2*SYN_NT in order to be able to fill all gaps in the extended TSF_T with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APT_2B_EXT value considers only a share according to the corresponding NUTE value to be set after the synchronization.
APT_2B_STATUS	6	rw	**Address pointer 2b status** Set by CPU before the synchronization is performed. The value is cleared when the APT_2B_OLD value is written. 0_B APT_2B_EXT is not to be considered 1_B APT_2B_EXT has to be considered for time stamp field extension
APT_2B_OLD	23:14	rw	**Address pointer TRIGGER for RAM region 2b at synchronization time** This value is set by the current APT_2B value when the synchronization takes place for the first active TRIGGER event after writing APT_2C but before adding the offset value APT_2B_EXT (that means: when APT_2B_STATUS=1). Address pointer APT_2B value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap.
0	13:7, 31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.25Register DPLL_APS_SYNC

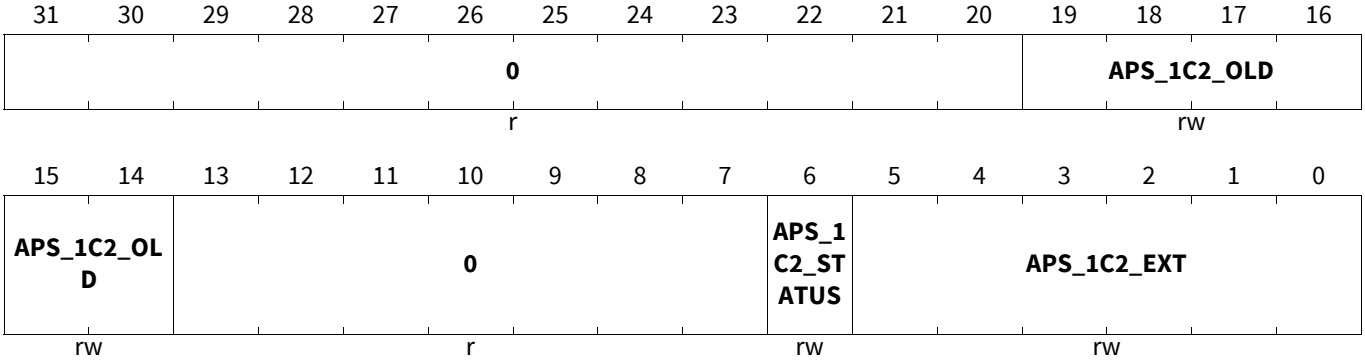
DPLL Old RAM Pointer and Offset Value for STATE

Note: STATE Time Stamp Field Offset at Synchronization Time

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_APS_SYNC

DPLL Old RAM Pointer and Offset Value for STATE(0280BC$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
APS_1C2_EXT	5:0	rw	**Address pointer 1c2 extension** This offset value determines, by which value the APS_1C2 is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and including the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1c2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.
APS_1C2_STATUS	6	rw	**Address pointer 1c2 status** Set by CPU before the synchronization is performed. The value is cleared automatically when the APS_1C2_OLD value is written. 0_B APS_1C2_EXT is not to be considered 1_B APS_1C2_EXT has to be considered for time stamp field extension
APS_1C2_OLD	19:14	rw	**Address pointer STATE for RAM region 1c2 at synchronization time** This value is set by the current APS_1C2 value when the synchronization takes place for the first active STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means: when APS_1C2_STATUS=1). Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap.

Field	Bits	Type	Description
0	13:7, 31:20	r	**Reserved** Read as zero, shall be written as zero.

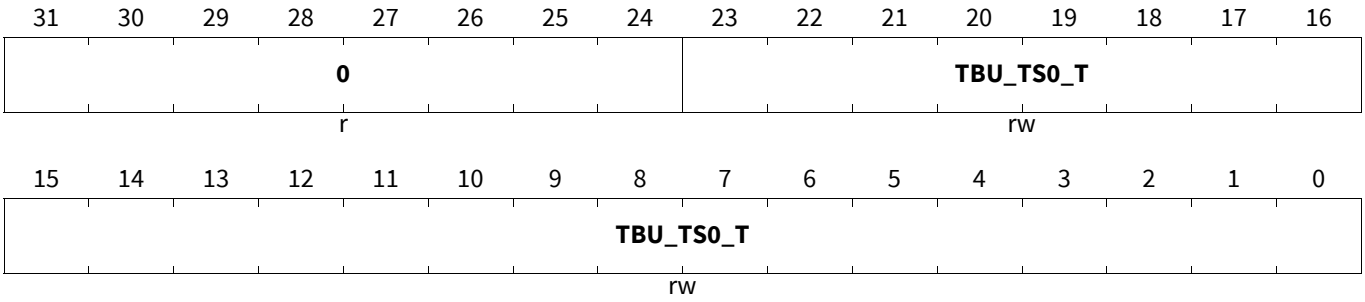
28.20.12.26Register DPLL_TBU_TS0_T

DPLL TBU_TS0 Value at Last TRIGGER Event

Time Stamp Value for the last active TRIGGER

DPLL_TBU_TS0_T

DPLL TBU_TS0 Value at Last TRIGGER Event (0280C0$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TBU_TS0_T	23:0	rw	**Value of TBU_TS0 at the last TRIGGER event** For each T_valid the value of TBU_TS0 is stored in this register; the register is writeable only for test purposes when DEN=0. This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

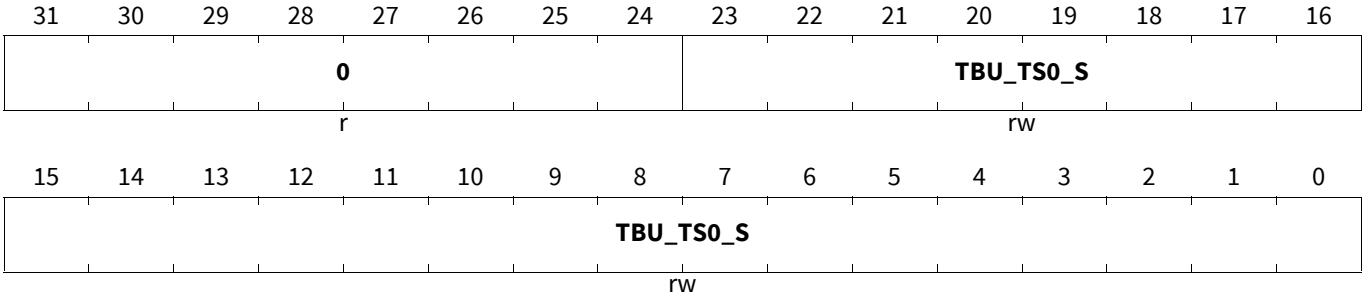
28.20.12.27Register DPLL_TBU_TS0_S

DPLL TBU_TS0 Value at Last STATE Event

Time Stamp Value for the last active STATE

DPLL_TBU_TS0_S

DPLL TBU_TS0 Value at Last STATE Event (0280C4$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TBU_TS0_S	23:0	rw	**Value of TBU_TS0 at the last STATE event** For each S_VALID the value of TBU_TS0 is stored in this register;the register is writeable only for test purposes when DEN=0. This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.28Register DPLL_ADD_IN_LD1

DPLL Direct Load Input Value for SUB_INC1

ADD_IN Value in Direct Load Mode for TRIGGER

DPLL_ADD_IN_LD1

DPLL Direct Load Input Value for SUB_INC1 ($0280C8_H$) **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								**ADD_IN_LD1**							
r								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADD_IN_LD1															
rw															

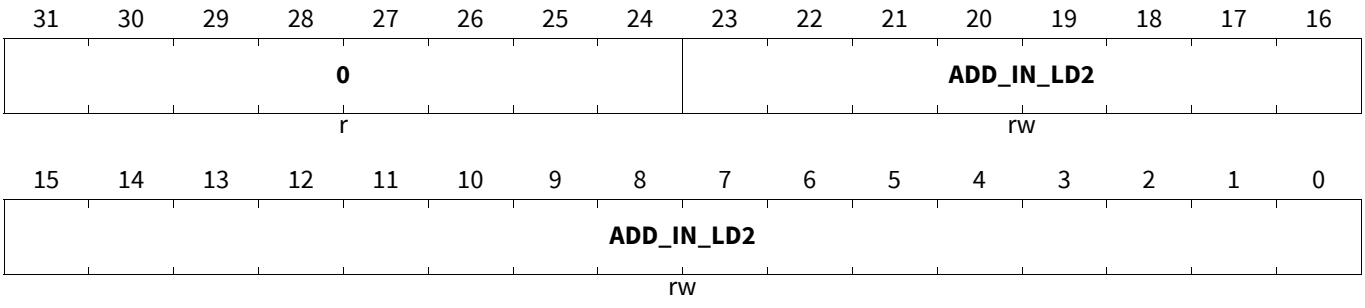
Field	Bits	Type	Description
ADD_IN_LD1	23:0	rw	**Input value for SUB_INC1 generation** Given by CPU. This value can be used in normal und emergency mode (SMC=0) as well as for SMC=1. **For DLM1 = 1:** The value is loaded by the CPU but used by the DPLL only for DLM1=1 (see DPLL_CTRL_1 register). When switching DLM1 to 1, the value in the register is used for the SUB_INC1 generation beginning from the next active *TRIGGER* or *STATE* event respectively independently if new values are written by the CPU or not. When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 10 in the state machine for ADD_IN calculations. If the ADD_IN_LD1 value is zero all pulses are sent with the highest possible frequency. **For DLM1 = 0:** The value loaded by the CPU is stored directly in the internal add_in register which is used to control the sub increment pulse generator directly (see DPLL_CTRL_1 register, DLM1 = 0). When a new ADD_IN_LD1 value is written the output frequency is immediately changed from the moment of writing. The ADD_IN values calculated internally of the DPLL are written to the internal ADD_IN register as well. In the moment when the internal calculation of the ADD_IN values is writing the results into the internal ADD_IN register of the pulse generator the internally calculated ADD_IN values does always have higher priority compared to the values written via the ADD_IN_LD1 register. If the ADD_IN_LD1 value is zero all pulses are sent with the highest possible frequency.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.29Register DPLL_ADD_IN_LD2

DPLL Direct Load Input Value for SUB_INC2

DPLL_ADD_IN_LD2

DPLL Direct Load Input Value for SUB_INC2 (0280CC$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
ADD_IN_LD2	23:0	rw	**Input value for SUB_INC2 generation** Given by CPU. This value can be used for SMC=1 while RMO=1. **For DLM2 = 1:** The value is loaded by the CPU but used by the DPLL only for DLM2=1 (see DPLL_CTRL_1 register). When switching DLM2 to 1, the value in the register is used for the SUB_INC2 generation beginning from the next *STATE* event respectively independently if new values are written by the CPU or not. When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 30 in the state machine for ADD_IN calculations. If the ADD_IN_LD2 value is zero all pulses are sent with the highest possible frequency. **For DLM2 = 0:** The value loaded by the CPU is stored directly in the internal add_in register which is used to control the sub increment pulse generator directly (see DPLL_CTRL_1 register, DLM2 = 0). When a new ADD_IN_LD2 value is written the output frequency is immediately changed from the moment of writing. The ADD_IN values calculated internally of the DPLL are written to the internal ADD_IN register as well. In the moment when the internal calculation of the ADD_IN values is writing the results into the internal ADD_IN register of the pulse generator the internally calculated ADD_IN values does always have higher priority compared to the values written via the ADD_IN_LD2 register. If the ADD_IN_LD2 value is zero all pulses are sent with the highest possible frequency.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.30Register DPLL_STATUS

DPLL Status Register

Note: The DPLL_STATUS register is reset, when the DPLL is disabled (switching DEN from 1 to 0).

DPLL_STATUS
DPLL Status Register **(0280FC$_H$)** **Application Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
FPCE	0	rw	**Fast pulse correction error** 0_B No error at fast pulse correction detected 1_B Negative value of MPVAL1/2 used for fast pulse correction mode
CSO	1	rw	**Calculated STATE duration overflow** Bit is set when equations DPLL-10a or DPLL-10b lead to an overflow. 0_B No overflow at equation DPLL-10a or b 1_B Overflow at equation DPLL-10a or b
CTO	3	rw	**Calculated TRIGGER duration overflow** Bit is set when equations DPLL-5a or DPLL-5b lead to an overflow. When one of the above bits is set the corresponding register contains the maximum value 0xFFFFFF. 0_B No overflow at equation DPLL-5a or b 1_B Overflow at equation DPLL-5a or b
CRO	4	rw	**Calculated Reciprocal value overflow** Bit is set when the calculation of RDT_T_ACT or RDT_S_ACT leads to an overflow. An overflow in calculation of reciprocal values can occur, when the condition of Note [3)] to the DPLL_CTRL_0 register is violated (see **Section 28.20.12.1**). Such an overflow can occur according to the calculations in equations (DPLL-1c) or (DPLL-6c). The overflow is detected when after the calculation and shifting left 32 bits at least one of the bits 31 to 24 is not zero. In that case the corresponding register is set to 0xFFFFFF. 0_B No overflow at any reciprocal calculation 1_B Overflow for at least one reciprocal calculation
RCS	5	r	**Resolution conflict STATE** 0_B No resolution conflict detected 1_B The TS0_HRS value is set to 1 while LOW_RES=0
RCT	6	r	**Resolution conflict TRIGGER** 0_B No resolution conflict detected 1_B The TS0_HRT value is set to 1 while LOW_RES=0
PSE	7	r	**Prediction space configuration error** 0_B No prediction space error detected 1_B Configured offset value of RAM2 is too small in order to store all TNU+1 values twice in FULL_SCALE

Field	Bits	Type	Description
SOR	8	rw	**STATE out of range** The SOR bit is set, when the time to the next active *STATE* slope exceeds the value of the last nominal *STATE* duration multiplied with the value of the SLR register (see **Section 28.20.12.73**) and is reset, when at the current or last active input event a direction change was detected. The SYS bit is not influenced by setting the SOR bit. 0_B All STATE signal events appear within SLR interval or a direction change was detected 1_B At least one STATE signal event is out of SLR; address pointers APS, APS_1C2 and APS_1C3 are frozen, and the generation of pulses SUB_INC1, 2, respectively, is stopped
MS	9	rw	**Missing STATE detected according to SOV** 0_B No missing STATE detected or a new valid STATE slope occurred 1_B At least one missing STATE detected after the last valid slope
TOR	10	rw	**TRIGGER out of range** The TOR bit is set, when the time to the next active *TRIGGER* slope exceeds the value of the last nominal *TRIGGER* duration multiplied with the value of the TLR register (see **Section 28.20.12.72**) and is reset, when at the current or last active input event a direction change was detected. The SYT bit is not influenced by setting the TOR bit. 0_B All TRIGGER signal events appear within TLR interval or a direction change was detected 1_B At least one TRIGGER signal event is out of TLR; address pointers APT, APT_2B and APT_2C are frozen, and the generation of pulses SUB_INC1 is stopped
MT	11	rw	**Missing TRIGGER detected according to TOV** 0_B No missing TRIGGER detected or a new valid TRIGGER slope occurred 1_B At least one missing TRIGGER detected after the last valid slope
RAM2_ERR	12	rw	**DPLL internal access to not configured RAM2 memory space** 0_B No access to not configured RAM2 memory space 1_B Access to not configured RAM2 memory space
LOW_RES	15	r	**Low resolution of TBU_TS0 is used for DPLL input** This value reflects the input signal LOW_RES. 0_B The lower 24 bits of TBU_TS0 are used as input for the DPLL 1_B The higher 24 bits of TBU_TS0 are used as input for the DPLL
CSVS	16	r	**Current signal value STATE** 0_B The last STATE_S value was 0 1_B The last STATE_S value was 1
CSVT	17	r	**Current signal value TRIGGER** 0_B The last TRIGGER_S value was 0 1_B The last TRIGGER_S value was 1
CAIP2	18	r	**Calculation of upper half actions in progress** 0_B Currently no action calculation, new data requests possible 1_B Action calculation in progress, no new data requests possible

Field	Bits	Type	Description
CAIP1	19	r	**Calculation of lower half actionsin progress** 0_B Currently no action calculation, new data requests possible 1_B Action calculation in progress, no new data requests possible
ISN	20	r	**Increment number of STATE is not plausible** 0_B The number of STATE events between synchronization gaps is plausible, a direction change is detected, or the APS_1C3 pointer is written 1_B After setting LOCK1 in emergency mode (SMC=0 and RMO=1) or LOCK2 for SMC=RMO=1, missing or additional STATE signals detected; bit is cleared when a direction change is detected or the APS_1C3 is written
ITN	21	r	**Increment number of TRIGGER is not plausible** Bit is set when the number of TRIGGERS is different to profile. 0_B The number of TRIGGER events between synchronization gaps is plausible, a direction change is detected, or the address pointer APT_2C is written 1_B After setting LOCK1 in normal mode (for SMC=0 or SMC=1) or in emergency mode (only for SMC=0), missing or additional TRIGGER signals detected; bit is cleared when a direction change is detected or the APT_2C is written
BWD2	22	r	**Backwards drive of SUB_INC2** 0_B Forward direction 1_B Backward direction
BWD1	23	r	**Backwards drive of SUB_INC1** 0_B Forward direction 1_B Backward direction
LOCK2	25	r	**DPLL Lock status concerning SUB_INC2** Locking of SUB_INC2 appears **for RMO=SMC=1:** Bit is set, when SYS is set and the number of events between two missing *STATE*s is as expected by the SYN_S values. LOCK2 is set for SMC=RMO=1: for an active STATE event when SYS is set and SYN_NS=0or when SYS is set and the profile stored in the ADT_Si field matches once between two gaps. LOCK2 is reset: for SMC=RMO=1 when a missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. when the corresponding input signal STATE is out of locking range SLR 0_B The DPLL is not locked concerning STATE for SMC=1 1_B The DPLL is locked concerning STATE for SMC=1
SYS	26	r	**Synchronization condition of STATE fixed** This bit is set when the CPU writes to the APS_1C3 address pointer.
SYT	27	r	**Synchronization condition of TRIGGER fixed** This bit is set when the CPU writes to the APT_2C address pointer.

Field	Bits	Type	Description
FSD	28	r	**First STATE detected** No change of FSD for switching from normal to emergency mode or vice versa. 0_B Still no active STATE event was detected after enabling DPLL 1_B At least one active STATE event was detected after enabling DPLL
FTD	29	r	**First TRIGGER detected** No change of FTD for switching from normal to emergency mode or vice versa. 0_B No active TRIGGER event was detected after enabling DPLL 1_B At least one active TRIGGER event was detected after enabling DPLL

Field	Bits	Type	Description
LOCK1	30	r	**DPLL Lock status concerning SUB_INC1** LOCK1 is set: • in normal mode (for RMO=SMC=0, LCD=0): Bit is set for an active TRIGGER event when SYT is set and the number of events between two gaps is as expected by the profile (NT values in the ADT_T[i] field) or when SYN_NT=0 and SYT=1. • in normal mode (for RMO=SMC=0, LCD=1): Bit is set for an active TRIGGER event when SYT is set and the number of events between two increments without missing TRIGGER (no gap) is as expected by the profile (NT values in the ADT_T[i] field) • in emergency mode (for RMO=1 and SMC=0): Bit is set for an active STATE event, when SYS is set and the received events are in correspondence to the profile (NS values in the ADT_S[i] field) for at least two (four in case of direction change) expected missing STATE events or when SYN_NS=0. • for SMC=1: Bit is set for an active TRIGGER even when SYT is set and SYN_NT=0 or when SYT is set and the profile stored in the ADT_T[i] field matches once between two gaps. LOCK1 is reset for RMO=SMC=0: • when a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. • when the corresponding input signal TRIGGER is out of locking range TLR, • when a corresponding direction change is detected: for RMO=1 and SMC=0: • when a corresponding missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. • when the corresponding input signal STATE is out of locking range TLR for SMC=1: • when a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. • when the corresponding input signal TRIGGER is out of locking range TLR, • when a corresponding direction change is detected 0_B The DPLL is not locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1) 1_B The DPLL is locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1)
ERR	31	r	**Error during configuration or operation resulting in unexpected values** 0_B When all bits in position 8 to 0 and 10 and 12 are zero 1_B When at least one bit in position 8 to 0 or 10 or 12 is one

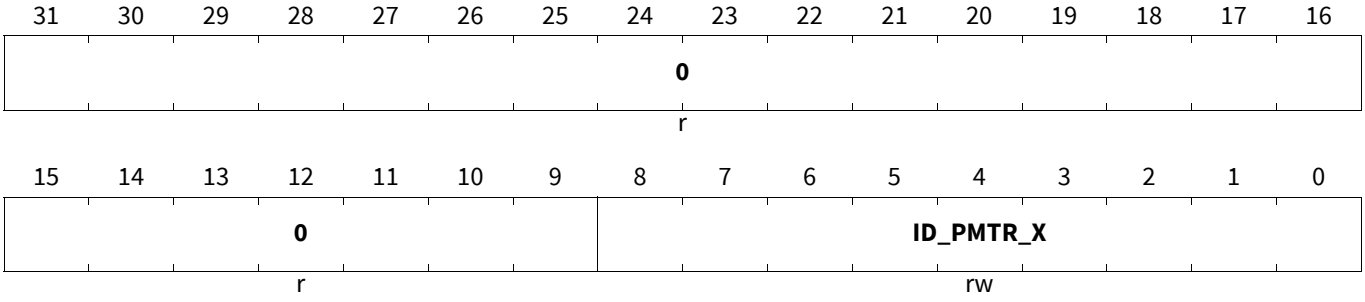
Field	Bits	Type	Description
0	2, 14:13, 24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.31Register DPLL_ID_PMTR_[z]

DPLL ID Information for Input Signal PMT z Register

DPLL_ID_PMTR_z (z=0-31)

DPLL ID Information for Input Signal PMT z Register(028100_H+z*4) **Application Reset Value: 0000 $01FE_H$**



Field	Bits	Type	Description
ID_PMTR_X	8:0	rw	**ID information to the input signal PMTR[z] from the ARU** This value can only be written when the action [z] is disabled by the correspondent bit AENz=0 of the registers DPLL_CTRL_2, ...5, respectively, or when the DPLL is disabled (DEN=0).
0	31:9	r	**Reserved** Read as zero, shall be written as zero.

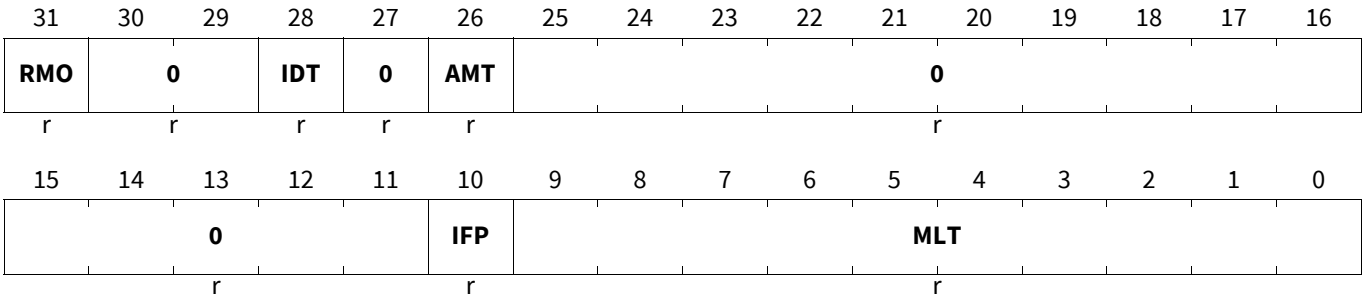
28.20.12.32Register DPLL_CTRL_0_SHADOW_TRIGGER

DPLL Control 0 Shadow Trigger Register

Shadow Register of DPLL_CTRL_0 controlled by an active TRIGGER Slope

DPLL_CTRL_0_SHADOW_TRIGGER

DPLL Control 0 Shadow Trigger Register **($0281E0_H$)** **Application Reset Value: 0000 0257_H**



Field	Bits	Type	Description
MLT	9:0	r	**Multiplier for TRIGGER** 1) MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (1…1024).
IFP	10	r	**Input filter position** 1) Value contains position or time related information.
AMT	26	r	**Adapt mode TRIGGER** 1) Use of adaptation information of TRIGGER.
IDT	28	r	**Input delay TRIGGER** 1) Use of input delay information transmitted in FT part of the TRIGGER signal.
RMO	31	r	**Reference mode** 1) Selection of the relevant the input signal for generation of SUB_INC1.
0	25:11, 27, 30:29	r	**Reserved** Read as zero, shall be written as zero.

1) Only the values characterized by 1) are stored for an active TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

28.20.12.33Register DPLL_CTRL_0_SHADOW_STATE

DPLL Control 0 Shadow STATE Register

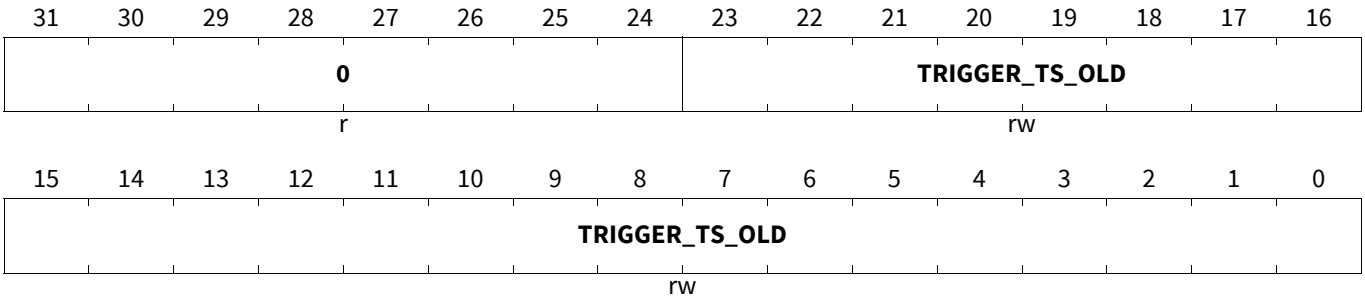
DPLL_TS_T_OLD
DPLL Previous TRIGGER Time Stamp Value **(028404_H)** **Reset Value: Table 83**



Field	Bits	Type	Description
TRIGGER_TS_OLD	23:0	rw	**Time stamp value of the last but one active TRIGGER input** Previous measured TRIGGER time stamp. The LSB address is determined using the SWON_T value in the OSW register (see **Section 28.20.12.8**).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 83 Reset Values of DPLL_TS_T_OLD

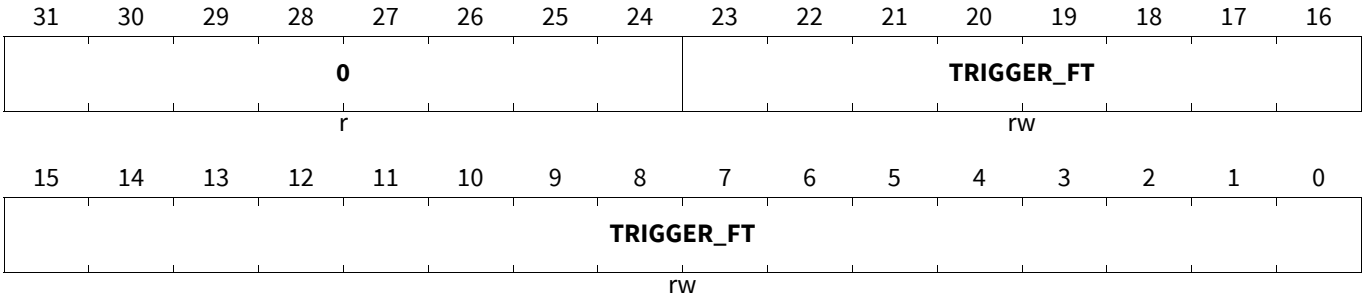
28.20.12.39Memory DPLL_FTV_T

DPLL Actual TRIGGER Filter Value

DPLL_FTV_T
DPLL Actual TRIGGER Filter Value (028408$_H$) Reset Value: Table 84



Field	Bits	Type	Description
TRIGGER_FT	23:0	rw	**Filter value of the last active TRIGGER input** Transmitted filter value. The LSB address is determined using the SWON_T value in the OSW register (see **Section 28.20.12.8**).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

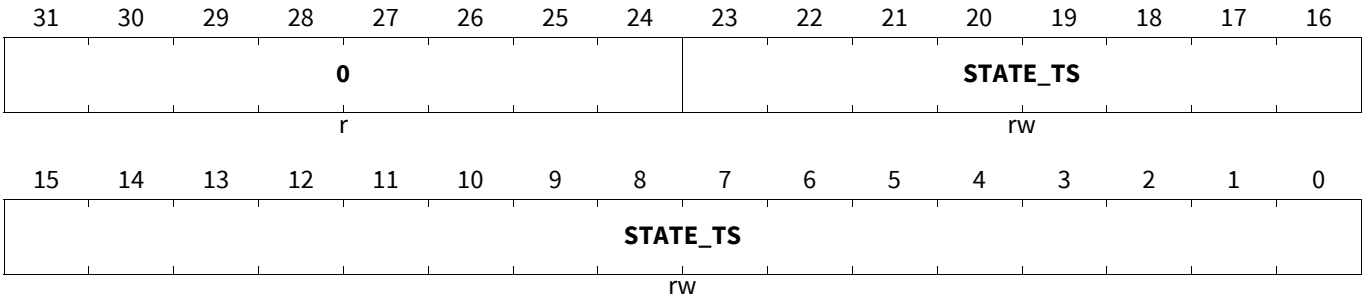
28.20.12.40Memory DPLL_TS_S

DPLL Actual STATE Time Stamp

DPLL_TS_S
DPLL Actual STATE Time Stamp **(028410_H)** **Reset Value: Table 85**



Field	Bits	Type	Description
STATE_TS	23:0	rw	**Time stamp value of the last active STATE input** The LSB address is determined using the SWON_S value in the OSW register (see **Section 28.20.12.8**).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 85 Reset Values of DPLL_TS_S

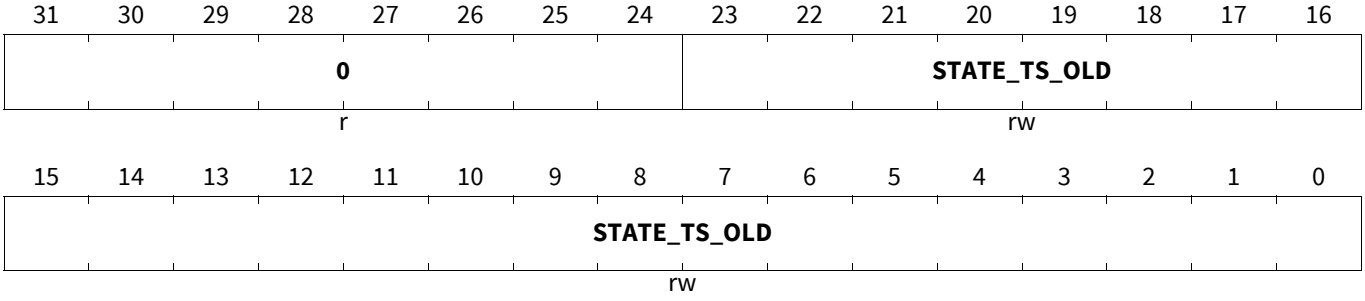
28.20.12.41Memory DPLL_TS_S_OLD

DPLL Previous STATE Time Stamp

DPLL_TS_S_OLD
DPLL Previous STATE Time Stamp **(028414_H)** **Reset Value: Table 86**



Field	Bits	Type	Description
STATE_TS_OLD	23:0	rw	**Time stamp value of the last active STATE input** The LSB address is determined using the SWON_S value in the OSW register (see **Section 28.20.12.8**).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 86 Reset Values of DPLL_TS_S_OLD

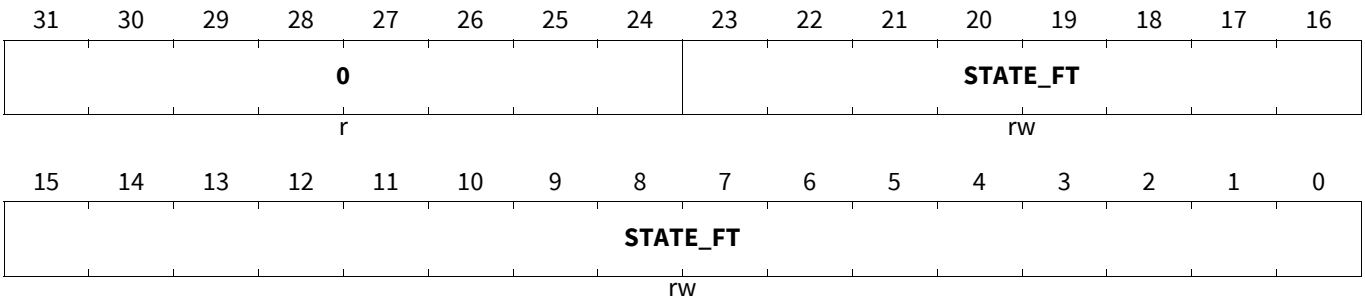
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.42Memory DPLL_FTV_S

DPLL Actual STATE Filter Value

DPLL_FTV_S
DPLL Actual STATE Filter Value (028418$_H$) Reset Value: Table 87



Field	Bits	Type	Description
STATE_FT	23:0	rw	**Filter value of the last active STATE input** transmitted filter value The LSB address is determined using the SWON_S value in the OSW register (see **Section 28.20.12.8**).
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 87 Reset Values of DPLL_FTV_S

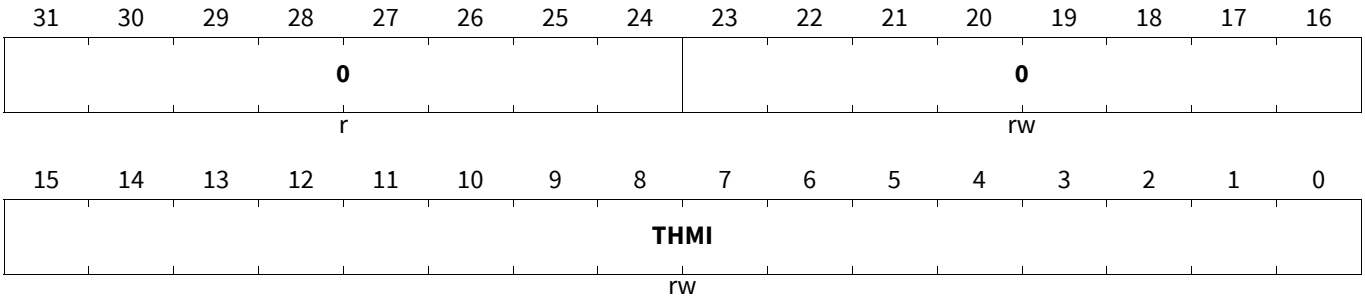
Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.43Memory DPLL_THMI

DPLL TRIGGER Hold Time Minimum Value

DPLL_THMI

DPLL TRIGGER Hold Time Minimum Value **(028420$_H$)** **Reset Value: Table 88**



Field	Bits	Type	Description
THMI	15:0	rw	**Minimal time between active and inactive TRIGGER slope (uint16)** The time value corresponds to the time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (see TBU_CH0_CTRL register) set min. value; generate the TINI interrupt in the case of a violation for THMI>0. Typical retention time values after an active slope can be e.g. between 45 µs (forwards) and 90 µs (backwards). When THMI is zero, consider always a THMI violation (forwards).
0	23:16	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 88 Reset Values of DPLL_THMI

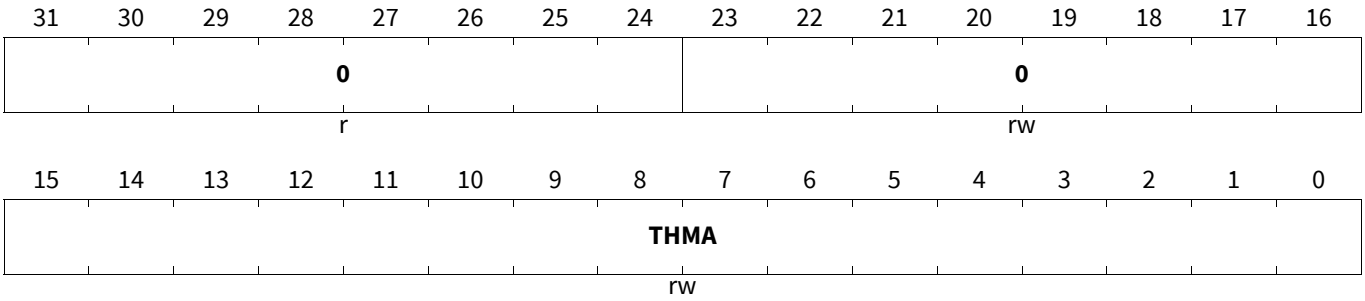
Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.44Memory DPLL_THMA

DPLL TRIGGER Hold Time Maximum Value

DPLL_THMA

DPLL TRIGGER Hold Time Maximum Value (028424$_H$) **Reset Value: Table 89**



Field	Bits	Type	Description
THMA	15:0	rw	**Maximal time between active and inactive TRIGGER slope (uint16)** The time value corresponds to the time stamp clock counts: This does mean the clock selected for the TBU_CH0_BASE (see TBU_CH0_CTRL register) Max. value to be set; generate the TAX interrupt in the case of a violation for THMA>0.
0	23:16	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 89 Reset Values of DPLL_THMA

Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	–-00 0000$_H$	Cleared by state machine

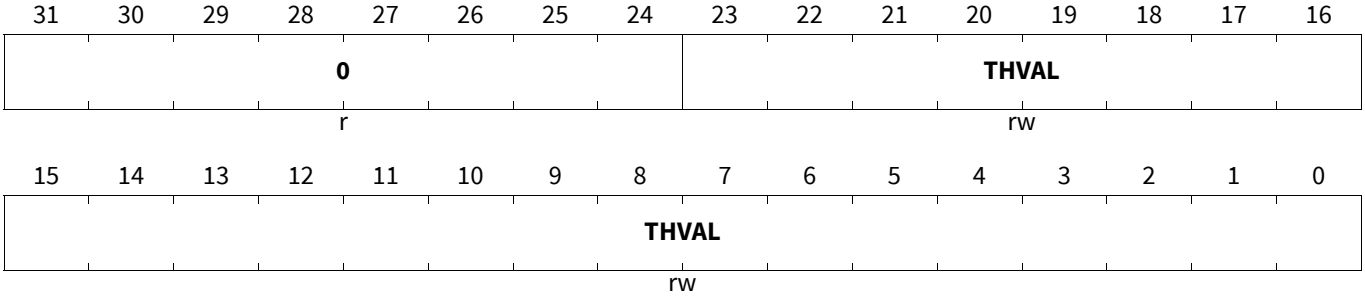
28.20.12.45Memory DPLL_THVAL

DPLL Measured TRIGGER Hold Time Value

Note: In the case of LOW_RES=1 and TBU_HRT=0 the difference between the time stamps of active and inactive slope is multiplied by 8. The register contains this value.

DPLL_THVAL

DPLL Measured TRIGGER Hold Time Value (028428$_H$) **Reset Value: Table 90**



Field	Bits	Type	Description
THVAL	23:0	rw	**Measured time from the last active slope to the next inactive TRIGGER slope in time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (uint16)** The measured value considers all input slope filter delays. From the received input the corresponding filter delays are subtracted before the time stamp difference of active and inactive slope is calculated.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 90 Reset Values of DPLL_THVAL

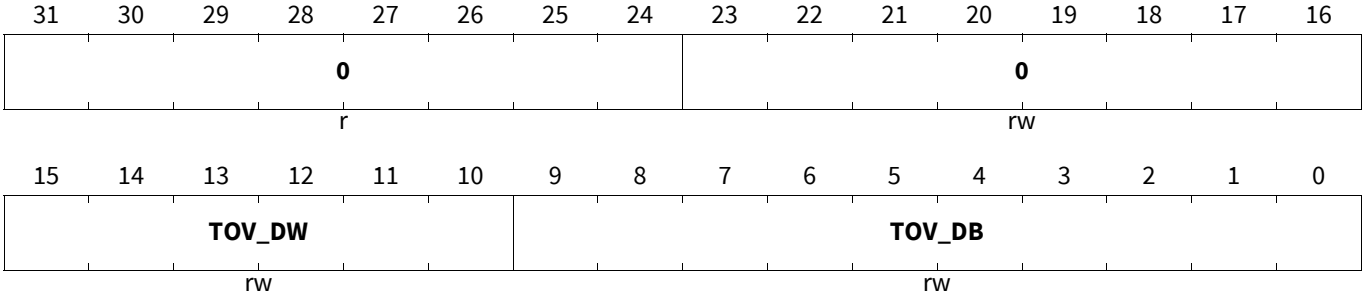
Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.46Memory DPLL_TOV

DPLL Time Out Value of Active TRIGGER Slope

DPLL_TOV

DPLL Time Out Value of Active TRIGGER Slope (028430$_H$) **Reset Value: Table 91**



Field	Bits	Type	Description
TOV_DB	9:0	rw	**Decision value (fractional part) for missing TRIGGER interrupt**

Field	Bits	Type	Description
TOV_DW	15:10	rw	**Decision value (integer part) for missing TRIGGER interrupt** TOV(15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the time-out time value for a missing TRIGGER event. For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_t_ACT and TOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRT=0: use TBU_TS0 and the estimated time point value unchanged.
0	23:16	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 91 Reset Values of DPLL_TOV

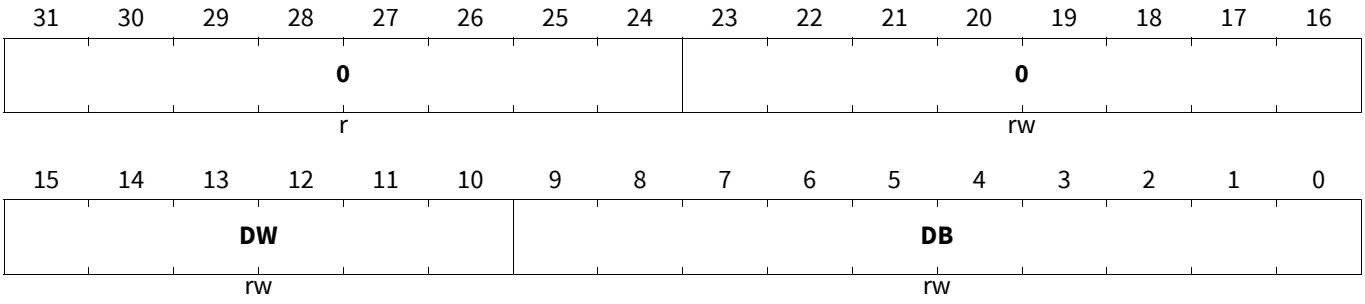
Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	–-00 0000$_H$	Cleared by state machine

28.20.12.47Memory DPLL_TOV_S

DPLL Time Out Value of Active STATE Slope

DPLL_TOV_S

DPLL Time Out Value of Active STATE Slope (028434$_H$) **Reset Value: Table 92**



Field	Bits	Type	Description
DB	9:0	rw	**Decision value (fractional part) for missing STATE interrupt**

Field	Bits	Type	Description
DW	15:10	rw	**Decision value (integer part) for missing STATE interrupt** TOV_S (15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the time-out time value for a missing STATE event. For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_s_ACT and SOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRS=0: use TBU_TS0 and the estimated time point value unchanged.
0	23:16	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

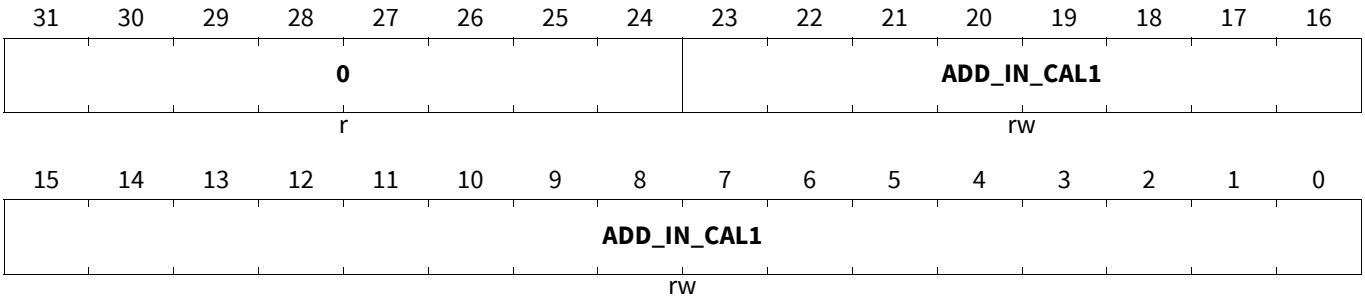
28.20.12.48Memory DPLL_ADD_IN_CAL1

DPLL Calculated ADD_IN Value for SUB_INC1 Generation

DPLL_ADD_IN_CAL1

DPLL Calculated ADD_IN Value for SUB_INC1 Generation(028438$_H$) **Reset Value: Table 93**



Field	Bits	Type	Description
ADD_IN_CAL1	23:0	rw	**Calculated input value for SUB_INC1 generation, calculated by the DPLL** Calculated value. The update of the ADD_IN value by the new calculated value ADD_IN_CAL1 is suppressed for one increment when an unexpected missing TRIGGER (SMC=1 or RMO=0) or an unexpected STATE (RMO=1 and SMC=0) is detected.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

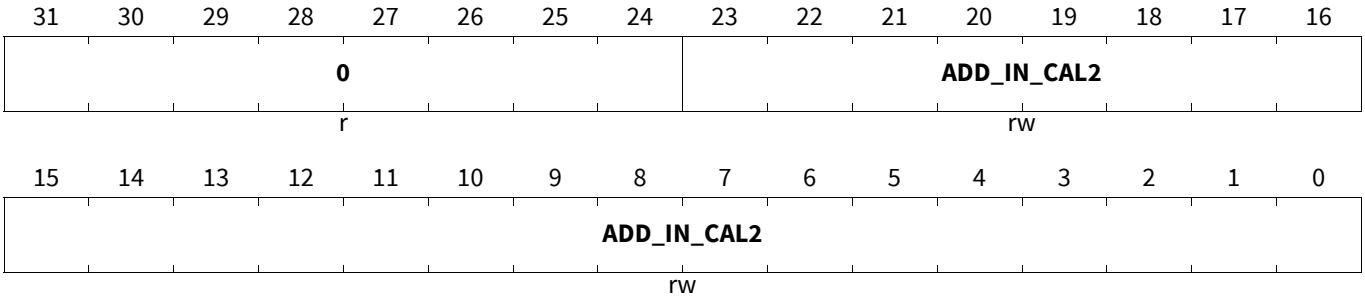
Table 93 Reset Values of DPLL_ADD_IN_CAL1

Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.49Memory DPLL_ADD_IN_CAL2

DPLL Calculated ADD_IN Value for SUB_INC2 Generation

DPLL_ADD_IN_CAL2
DPLL Calculated ADD_IN Value for SUB_INC2 Generation(02843C$_H$) **Reset Value: Table 94**



Field	Bits	Type	Description
ADD_IN_CAL2	23:0	rw	**Input value for SUB_INC2 generation, calculated by the DPLL for SMC=RMO=1** Calculated value. The update of the ADD_IN value by the calculated value ADD_IN_CAL2 is suppressed for one increment when an unexpected missing STATE (RMO=SMC=1) is detected.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 94 Reset Values of DPLL_ADD_IN_CAL2

Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

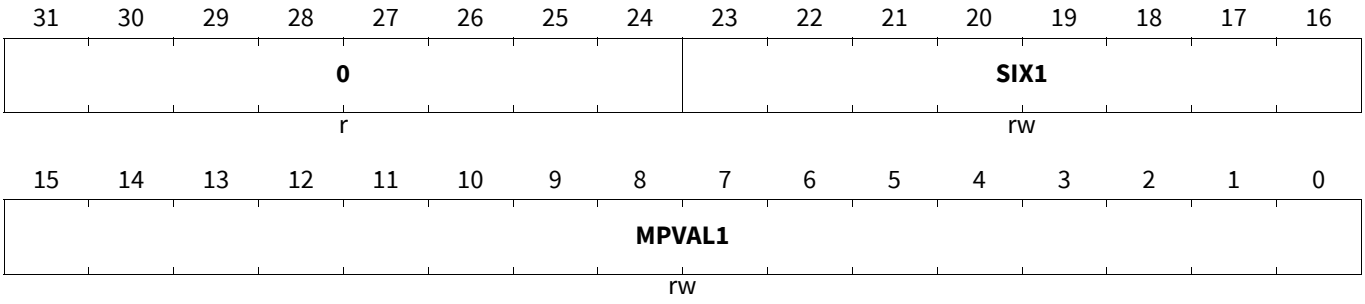
28.20.12.50Memory DPLL_MPVAL1

DPLL Missing Pulses to be Added or Subtracted Directly 1

Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both (MPVAL1 + NT*PD) should not exceed the amount of NT*(MLT+1) or MLS1 respectively.

DPLL_MPVAL1

DPLL Missing Pulses to be Added or Subtracted Directly 1(028440$_H$) **Reset Value: Table 95**



Field	Bits	Type	Description
MPVAL1	15:0	rw	**Missing pulses for direct correction of SUB_INC1 pulses by the CPU (sint16)** Used only for RMO=0 or SMC=1 for the case PCM1=1. Add MPVAL1 once to INC_CNT1 and reset PCM1 after applying once.
SIX1	23:16	rw	**Sign extension for MPVAL1** All bits must be written to either all zeros or all ones. 00_H MPVAL is a positive number 00_H MPVAL1 is a negative number
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 95 Reset Values of DPLL_MPVAL1

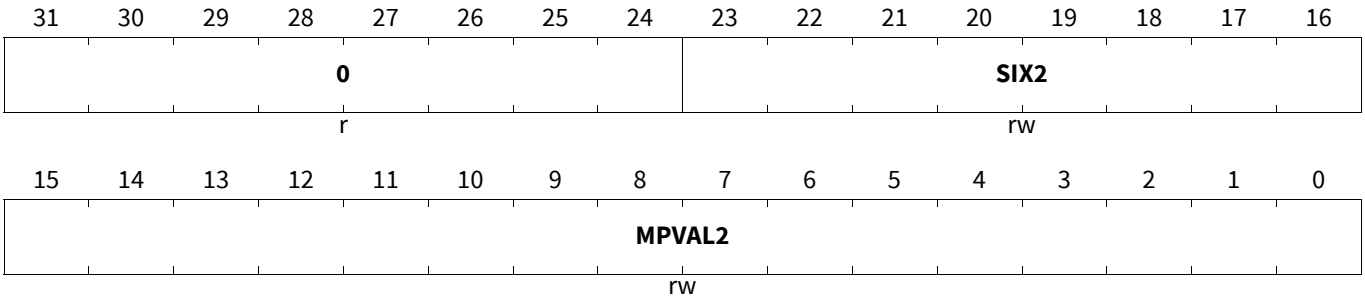
28.20.12.51Memory DPLL_MPVAL2

DPLL Missing Pulses to be Added or Subtracted Directly 2

DPLL_MPVAL2

DPLL Missing Pulses to be Added or Subtracted Directly 2(028444_H) **Reset Value: Table 96**



Field	Bits	Type	Description
MPVAL2	15:0	rw	**Missing pulses for direct correction of SUB_INC2 pulses by the CPU (sint16)** Used only for SMC=RMO=1 for the case PCM2=1. Add MPVAL2 once to INC_CNT2, and reset PCM2 after applying once. Do not provide negative values which exceed the amount of MLS2; when considered negative PD_S values, the sum of both should not exceed the amount of MLS2.
SIX2	23:16	rw	**Sign extension for MPVAL2** All bits must be written to either all zeros or all ones. 00_H MPVAL2 is a positive number FF_H MPVAL2 is a negative number
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

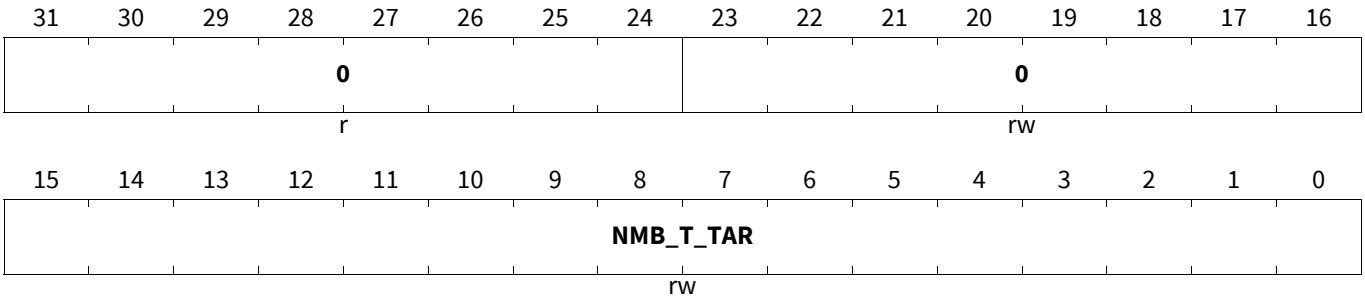
28.20.12.52Memory DPLL_NMB_T_TAR

DPLL Target Number of Pulses to be Sent in Normal Mode

DPLL_NMB_T_TAR

DPLL Target Number of Pulses to be Sent in Normal Mode(028448$_H$) **Reset Value: Table 97**



Field	Bits	Type	Description
NMB_T_TAR	15:0	rw	**Target Number of pulses for TRIGGER** Calculated number of pulses in normal mode for the current *TRIGGER* increment without missing pulses. Calculated target pulse number. The LSB address is determined using the SWON_T value in the OSW register (see **Section 28.20.12.8**).
0	23:16	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

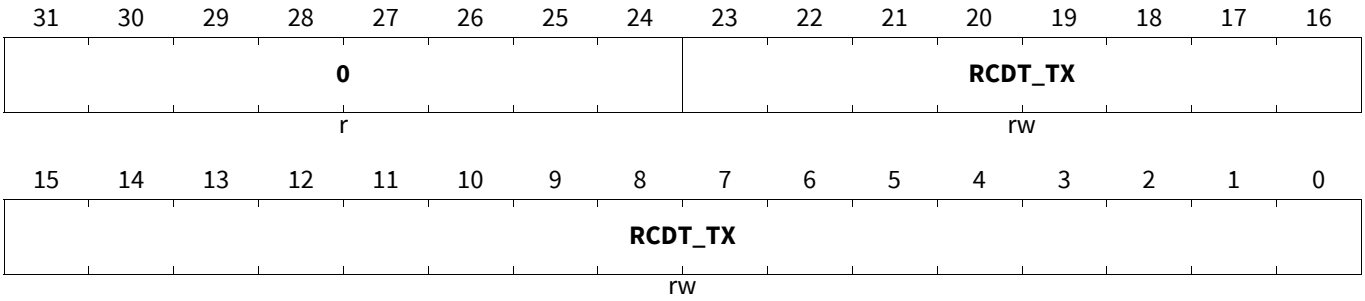
28.20.12.56Memory DPLL_RCDT_TX

DPLL Reciprocal Value of the Expected Increment Duration of TRIGGER

DPLL_RCDT_TX

DPLL Reciprocal Value of the Expected Increment Duration of TRIGGER(028460_H) Reset Value: Table 101



Field	Bits	Type	Description
RCDT_TX	23:0	rw	**Reciprocal value of expected increment duration *2^32 while only the lower 24 bits are used** Calculated value; when an overflow occurs in the calculation, the value is set to 0xFFFFFF.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 101 Reset Values of DPLL_RCDT_TX

Reset Type	Reset Value	Note

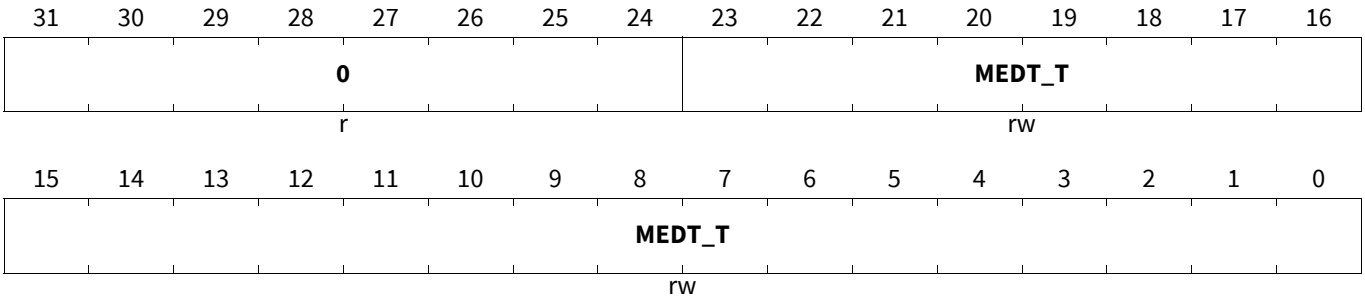
28.20.12.65Memory DPLL_MEDT_T

DPLL Weighted Difference of Prediction Errors of TRIGGER

DPLL_MEDT_T

DPLL Weighted Difference of Prediction Errors of TRIGGER(028484_H) **Reset Value: Table 110**



Field	Bits	Type	Description
MEDT_T	23:0	rw	**Signed middle weighted difference between actual value and prediction of the last TRIGGER increments: sint24** Only calculated for SYT=1. Calculated medium error value, see **Section 28.20.6.2.6**. The value is calculated only after synchronization (SYT=1), and the update is suppressed for one increment when an unexpected missing TRIGGER is detected.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 110 Reset Values of DPLL_MEDT_T

Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On

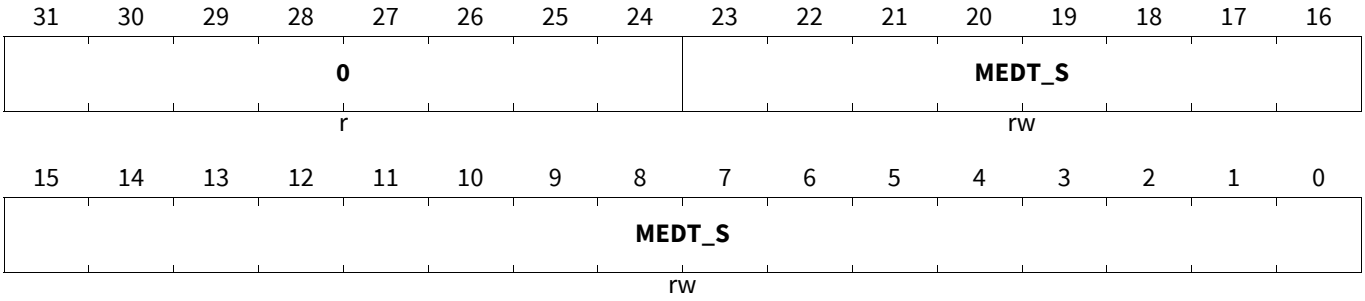
28.20.12.67Memory DPLL_MEDT_S

DPLL Weighted Difference of Prediction Errors of STATE

DPLL_MEDT_S

DPLL Weighted Difference of Prediction Errors of STATE(02848C$_H$) **Reset Value: Table 112**



Field	Bits	Type	Description
MEDT_S	23:0	rw	**Signed middle weighted difference between actual value and prediction of the last STATE increments: sint24; only calculated for SYS=1** Calculated medium error value, see **Section 28.20.6.3.6**. The value is calculated only after synchronization (SYS=1), and the update is suppressed for one increment when an unexpected missing STATE is detected.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

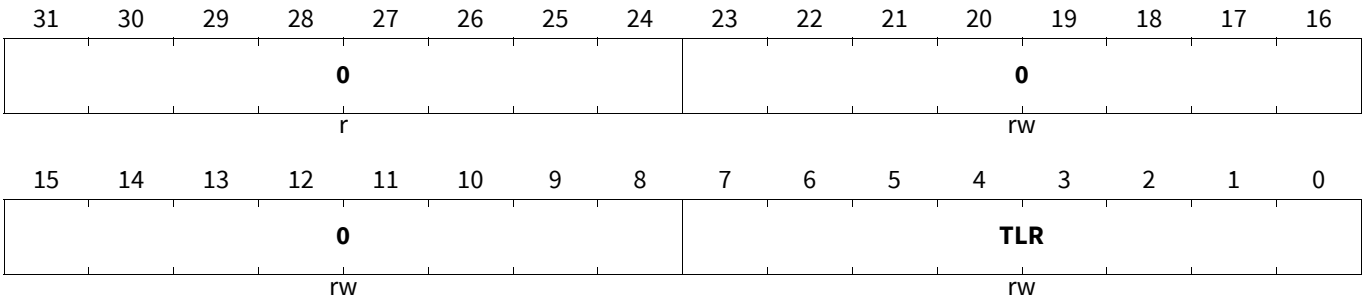
28.20.12.72Memory DPLL_TLR

DPLL TRIGGER Locking Range

DPLL_TLR

DPLL TRIGGER Locking Range (0284A0$_H$) **Reset Value: Table 117**



Field	Bits	Type	Description
TLR	7:0	rw	**Value is to be multiplied with the last nominal TRIGGER duration in order to get the range for the next TRIGGER event without setting TOR in the DPLL_STATUS register** Multiply value with the last nominal increment duration and check violation; when TLR=0 don't perform the check.
0	23:8	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 117 Reset Values of DPLL_TLR

Reset Type	Reset Value	Note

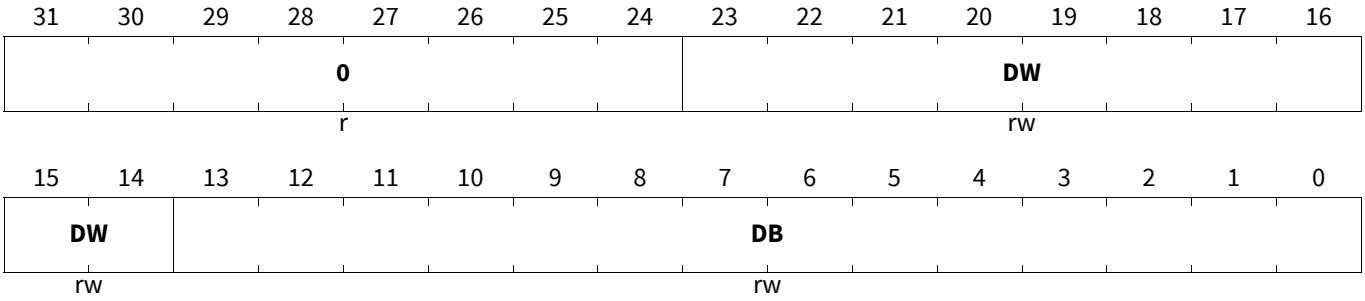
28.20.12.74Memory DPLL_PDT_[z]

DPLL Projected Increment Sum Relations for Action z

DPLL_PDT_z (z=0-31)
DPLL Projected Increment Sum Relations for Action z(028500$_H$+z*4) **Reset Value: Table 119**



Field	Bits	Type	Description
DB	13:0	rw	**Fractional part of relation between TRIGGER or STATE increments**
DW	23:14	rw	**Integer part of relation between TRIGGER or STATE increments** Definition of relation values between *TRIGGER* or *STATE* increments PDT[i] according to Equations DPLL-11 or DPLL-13 (i = 0-31).[1)] The PDT[i] values for actions i=24...31 are only available for device 4 or 5.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

1) The PDT[z] values for actions i=24...31 are not available for all devices.

Table 119 Reset Values of DPLL_PDT_z (z=0-31)

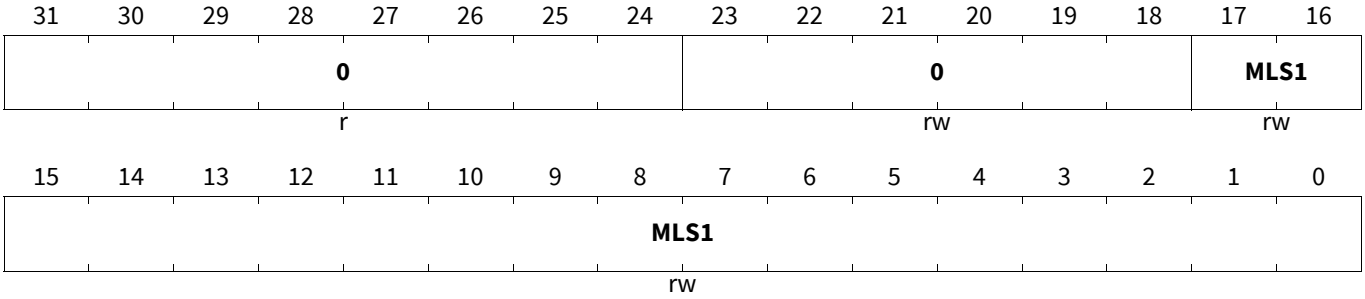
28.20.12.75Memory DPLL_MLS1

DPLL Calculated Number of Sub-Pulses between two Nominal STATE Events for SMC = 0

DPLL_MLS1
DPLL Calculated Number of Sub-Pulses between two Nominal STATE Events for SMC = 0(0285C0$_H$) Reset Value: Table 120



Field	Bits	Type	Description
MLS1	17:0	rw	**Number of pulses between two STATE events** For SMC=0 the value of MLS1 is calculated once by the CPU for fixed values in the DPLL_CTRL_0 register by the formula MLS1 = ((MLT+1)*(TNU+1)/(SNU+1)) and set accordingly. For SMC=1 the value of MLS1 represents the number of pulses between two nominal *TRIGGER* events (to be set and updated by the CPU).
0	23:18	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 120 Reset Values of DPLL_MLS1

Reset Type	Reset Value	Note

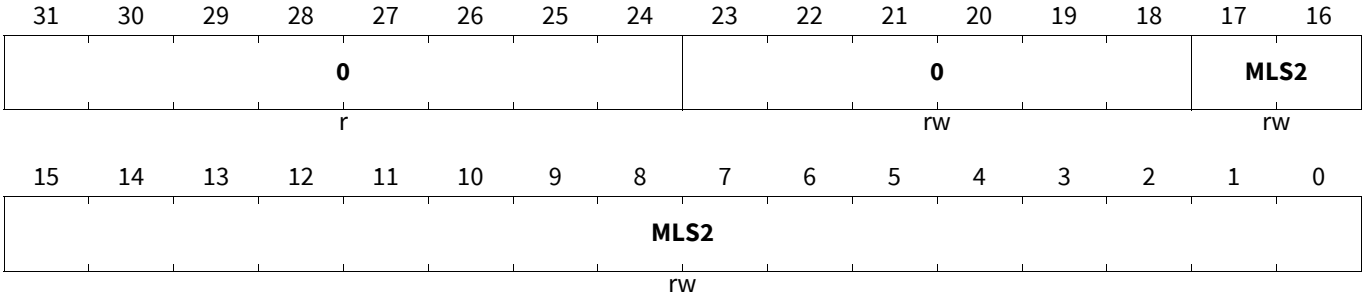
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.76Memory DPLL_MLS2

DPLL Calculated Number of Sub-Pulses between two Nominal STATE Events for SMC = 1 and RMO = 1

DPLL_MLS2
DPLL Calculated Number of Sub-Pulses between two Nominal STATE Events for SMC = 1 and RMO = 1 ($0285C4_H$) **Reset Value: Table 121**



Field	Bits	Type	Description
MLS2	17:0	rw	**Number of pulses between two STATE events (to be set and updated by the CPU)** Using adapt information and the missing *STATE* event information SYN_S, this value can be corrected for each increment automatically.
0	23:18	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 121 Reset Values of DPLL_MLS2

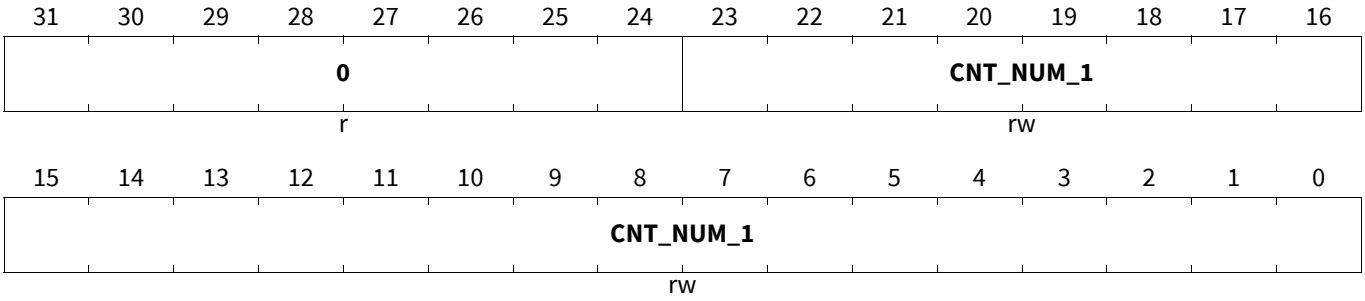
28.20.12.77Memory DPLL_CNT_NUM_1

DPLL Number of Sub-Pulses of SUB_INC1 in Continuous Mode

DPLL_CNT_NUM_1
DPLL Number of Sub-Pulses of SUB_INC1 in Continuous Mode($0285C8_H$) **Reset Value: Table 122**



Field	Bits	Type	Description
CNT_NUM_1	23:0	rw	**Counter for number of SUB_INC1 pulses** Number of pulses in continuous mode for a nominal increment in normal and emergency mode for SUB_INC1, given and updated by CPU only. Count value for continuous mode.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 122 Reset Values of DPLL_CNT_NUM_1

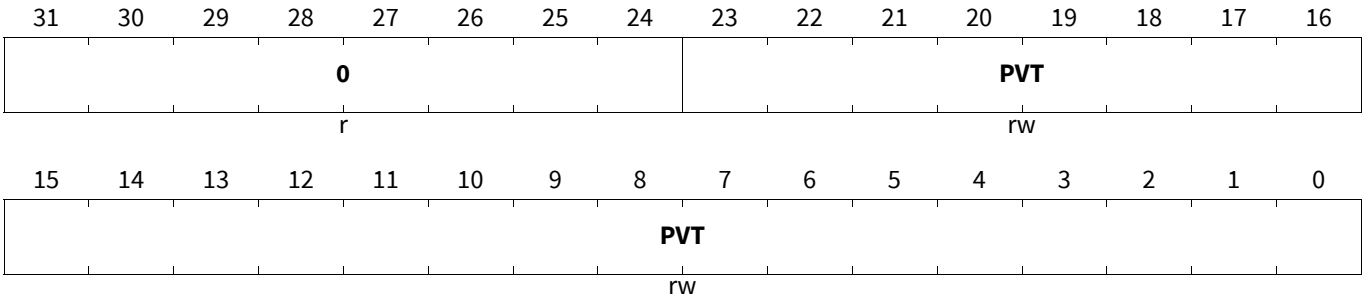
28.20.12.79Memory DPLL_PVT

DPLL Plausibility Value of Next TRIGGER Slope

DPLL_PVT

DPLL Plausibility Value of Next TRIGGER Slope (0285D0$_H$) **Reset Value: Table 124**



Field	Bits	Type	Description
PVT	23:0	rw	**Plausibility value of next active TRIGGER slope** The meaning of the value depends on the value of the PIT value in the DPLL_CTRL_1 register. For PIT=0: the number of SUB_INC1 pulses to be waited for until a next active *TRIGGER* event is accepted. For PIT=1: PVT is to be multiplied with the **last nominal increment time DT_T_ACT** and divided by 1024 and reduced to a 24 bit value in order to get the time to be waited for until the next active *TRIGGER* event is accepted. The wait time must be exceeded for an active slope. *Note: When an active TRIGGER slope is detected while the wait condition is not fulfilled the interrupt PWI is generated. Please note, that the SGE1 must be set, when PIT=0 in order to provide the necessary SUB_INC1 pulses for checking. After an unexpected missing TRIGGER the plausibility check is suppressed for the following increment. In case of direction change the PVT value is automatically set to zero in order to deactivate the check.*
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 124 Reset Values of DPLL_PVT

Reset Type	Reset Value	Note

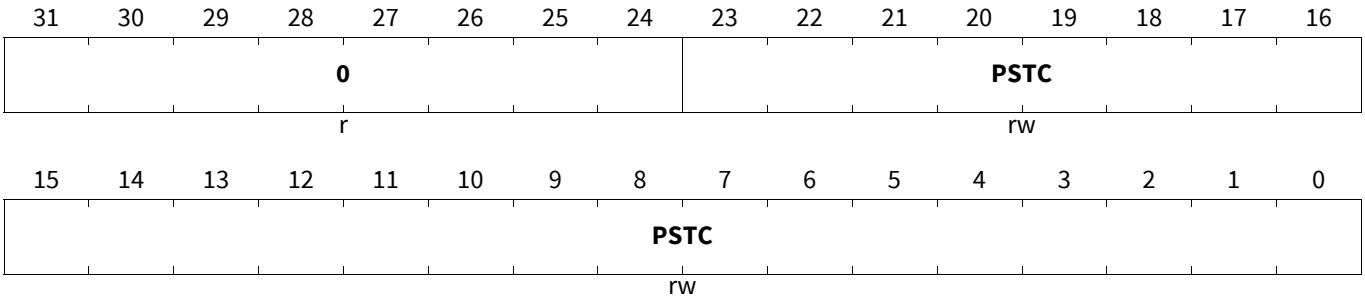
28.20.12.80Memory DPLL_PSTC

DPLL Actual Calculated Position Stamp of TRIGGER

DPLL_PSTC

DPLL Actual Calculated Position Stamp of TRIGGER(0285E0$_H$) **Reset Value: Table 125**



Field	Bits	Type	Description
PSTC	23:0	rw	**Calculated position stamp of last TRIGGER input** Value is set by the DPLL and can be updated by the CPU when filter values are to be considered for the exact position (see **DPLL_STATUS** and **DPLL_CTRL** registers for explanation of the status and control bits used). For each active slope of *TRIGGER* in normal mode. When FTD=0: PSTC is set from actual position value, for the first active *TRIGGER* event (no filter delay considered) the CPU must update the value once, taking into account the filter value. When FTD=1: PSTC is incremented at each *TRIGGER* event by SMC=0: (MLT+1)*(SYN_T) +PD; while PD=0 for AMT=0 SMC=1: (MLS1)*(SYN_T) +PD; while PD=0 for AMT=0
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

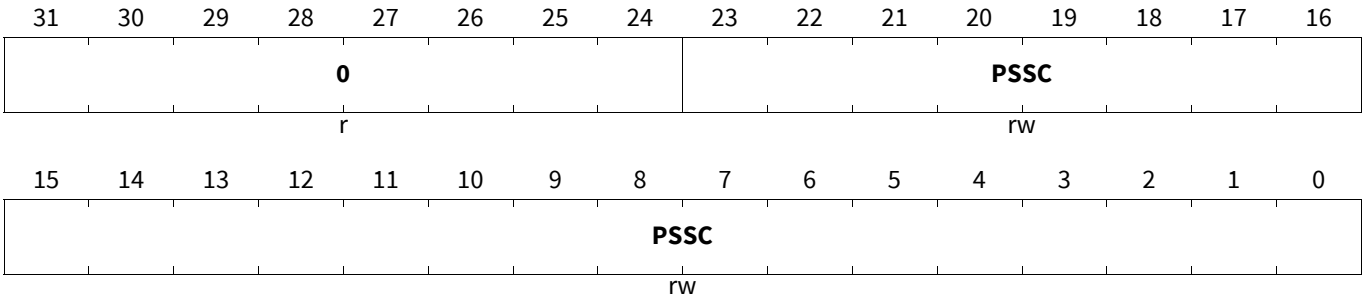
28.20.12.81Memory DPLL_PSSC

DPLL Actual Calculated Position Stamp of STATE

DPLL_PSSC
DPLL Actual Calculated Position Stamp of STATE(0285E4$_H$) **Reset Value: Table 126**



Field	Bits	Type	Description
PSSC	23:0	rw	**Calculated position stamp for the last STATE input** First value is set by the DPLL and can be updated by the CPU when the filter delay is to be considered. For each active slope of *STATE* in emergency mode. When FSD=0: PSSC is set from actual position value(no filter delay considered), the CPU must update the value once, taking into account the filter value When FSD=1: at each active slope of *STATE* (PD_S_store=0 for AMS=0): SMC=0: add MLS1*(SYN_S) + PD_S_store; SMC=1: add MLS2*(SYN_S) + PD_S_store;
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

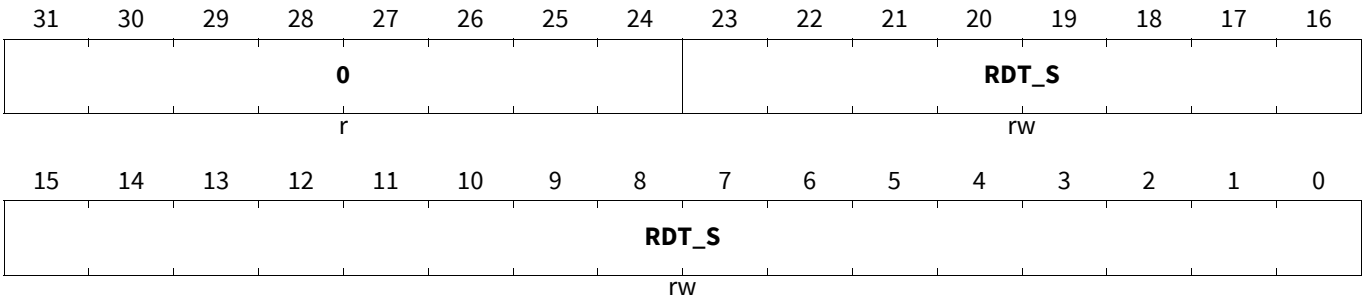
28.20.12.88Memory DPLL_RDT_S[i]

DPLL Reciprocal Values of the Nominal STATE i Increment Duration in FULL_SCALE

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 18.15 and will expect data to be correctly stored there. This means in fact, that the handling of the RDT_S values has to be done outside, in the MCS integrated in the same cluster.

DPLL_RDT_Si (i=0-63)
DPLL Reciprocal Values of the Nominal STATE i Increment Duration in FULL_SCALE(028600$_H$+i*4) Reset Value: Table 133



Field	Bits	Type	Description
RDT_S	23:0	rw	**Reciprocal difference time of STATE** Nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment *2^{32} while only the lower 24 bits are used; no gap considered. The LSB is rounded up when the next truncated bit is 1. There are 2*(SNU+1-SYN_NS) entries for SYSF=0 or 2*(SNU+1)-SYN_NS entries for SYSF=1 respectively.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

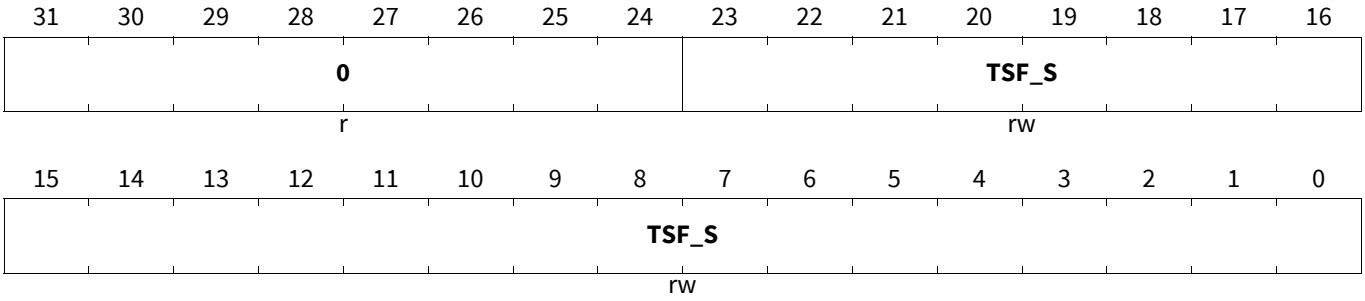
DPLL_RAM_INI.INIT_1BC	--00 0000$_H$	Cleared by state machine

28.20.12.89Memory DPLL_TSF_S[i]

DPLL Time Stamp Values of the Nominal STATE i Events in FULL_SCALE

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 18.15 and will expect data to be correctly stored there. This means in fact, that the handling of the TSF_S values has to be done outside, in the MCS integrated in the same cluster.

DPLL_TSF_Si (i=0-63)
DPLL Time Stamp Values of the Nominal STATE i Events in FULL_SCALE(028700$_H$+i*4) Reset Value: Table 134



Field	Bits	Type	Description
TSF_S	23:0	rw	**Time stamp field of STATE** Time stamp value of each active STATE event. There are 2* (SNU+1) entries.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 134 Reset Values of DPLL_TSF_Si (i=0-63)

Reset Type	Reset Value	Note
PowerOn Reset	XXXX XXXX$_H$	Undefined after Power On

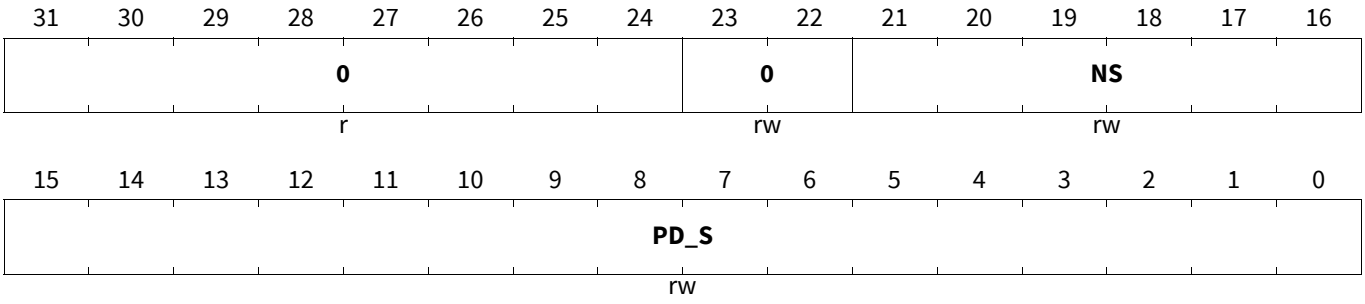
28.20.12.90Memory DPLL_ADT_S[i]

DPLL Adapt and Profile Values of the STATE i Increments in FULL_SCALE

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 18.15 and will expect data to be correctly stored there. This means in fact, that the handling of the ADT_S values has to be done outside, in the MCS integrated in the same cluster.

DPLL_ADT_Si (i=0-63)
DPLL Adapt and Profile Values of the STATE i Increments in FULL_SCALE(028800$_H$+i*4) Reset Value: Table 135



Field	Bits	Type	Description
PD_S	15:0	rw	**Physical deviation of STATE** Adapt values for each *STATE* increment in FULL_SCALE (sint16); This value represents the number of pulses to be added to the correspondent nominal increment. The absolute value of a negative PD_S must not exceed MLS1 or MLS2 respectively. The PD value does mean the number of SUB_INC1 pulses per nominal tooth to be added to NS*((MLS1/2+1) + PD_S);
NS	21:16	rw	**Number of STATEs** Number of nominal STATE parts in the corresponding increment. There are 2*(SNU+1-SYN_NS) entries for SYSF=0 or 2*(SNU+1)-SYN_NS entries for SYSF=1 respectively.
0	23:22	rw	**Not used** Must be written to zero.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

Table 135 Reset Values of DPLL_ADT_Si (i=0-63)

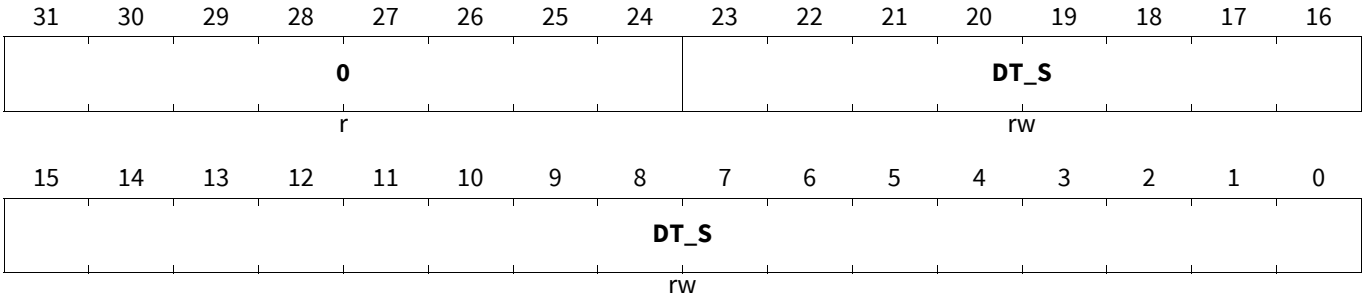
28.20.12.91Memory DPLL_DT_S[i]

DPLL Nominal STATE i Increment Duration in FULL_SCALE

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface chapter "MCS to DPLL Register description" and will expect data to be correctly stored there. This means in fact, that the handling of the DT_S values has to be done outside, in the MCS integrated in the same cluster.

DPLL_DT_Si (i=0-63)
DPLL Nominal STATE i Increment Duration in FULL_SCALE(028900$_H$+i*4) **Reset Value: Table 136**



Field	Bits	Type	Description
DT_S	23:0	rw	**Difference time of STATE** Nominal increment duration values for each *STATE* increment in FULL_SCALE (considering no gap). There are 2*(SNU+1-SYN_NS) entries for SYSF=0 or 2*(SNU+1)-SYN_NS entries for SYSF=1 respectively.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

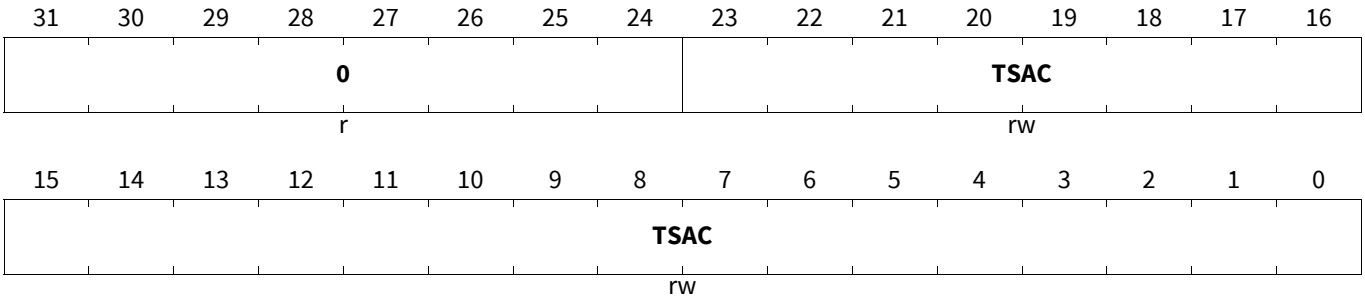
28.20.12.92Register DPLL_TSAC[z]

DPLL Calculated Time Value to start Action z Register

DPLL_TSACz (z=0-31)

DPLL Calculated Time Value to start Action z Register(028E00$_H$+z*4) Application Reset Value: 007F FFFF$_H$



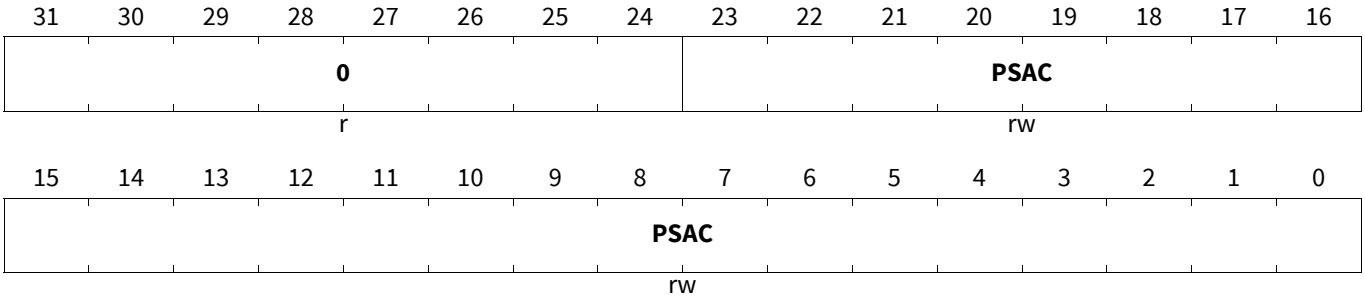
Field	Bits	Type	Description
TSAC	23:0	rw	**Calculated time stamp for ACTION_z** This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.93Register DPLL_PSAC[z]

DPLL ACTION Position/Value Action z Request Register

DPLL_PSACz (z=0-31)

DPLL ACTION Position/Value Action z Request Register(028E80$_H$+z*4) Application Reset Value: 007F FFFF$_H$



Field	Bits	Type	Description
PSAC	23:0	rw	**Calculated position value for the start of ACTION_z in normal or emergency mode according to equations DPLL-17 or DPLL-20, respectively** This value can only be written when the DPLL is disabled.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.94Register DPLL_ACB_[z]

DPLL Control Bits Register z for up to 32 Actions

DPLL_ACB_z (z=0-7)

DPLL Control Bits Register z for up to 32 Actions(028F00$_H$+z*4) **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r			rw					r			rw				

Field	Bits	Type	Description
ACB_0	4:0	rw	**Action Control Bits of ACTION_z** Reflects ACT_D[i](52:48), i=4*z. When DPLL_CTRL_11.ACBU = '0': ACB_0[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_0[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_0[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_0[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_0[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_0[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. This value can only be written via AEI-interface when the DPLL is disabled.

Field	Bits	Type	Description
ACB_1	12:8	rw	**Action Control Bits of ACTION_(i + 1)** Reflects ACT_D[i+1](52:48), i=4*z. When DPLL_CTRL_11.ACBU = '0': ACB_1[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_1[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation.ACB_1[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_1[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far.ACB_1[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_1[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far.This value can only be written via AEI-interface when the DPLL is disabled.
ACB_2	20:16	rw	**Action Control Bits of ACTION_(i + 2)** Reflects ACT_D[i+2](52:48), i=4*z. When DPLL_CTRL_11.ACBU = '0': ACB_2[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_2[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_2[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_2[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_2[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_2[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. This value can only be written via AEI-interface when the DPLL is disabled.

Field	Bits	Type	Description
ACB_3	28:24	rw	**Action Control Bits of ACTION_(i + 3)** Reflects ACT_D[i+3](52:48), i=4*z. When DPLL_CTRL_11.ACBU = '0': ACB_3[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_3[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_3[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_3[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_3[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_3[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. This value can only be written via AEI-interface when the DPLL is disabled.
0	7:5, 15:13, 23:21, 31:29	r	**Reserved** Read as zero, shall be written as zero.

Field	Bits	Type	Description
SIP1	0	rw	**Simplified increment prediction in normal mode and for the first engine in the case SMC=1** For the first increment after setting SIP1 from 0 to 1, the value of DT_T_ACT is replaced by the value of the DT_T_START register. This results in a CDT_TX value which is equal to DT_T_START. Please notice that this DT_T_Start value must be always > 256. *Note: The value of SIP1 influences only the increment prediction CDT_TX and when NUTE-VTN=1. The calculation of QDT_T itself is not influenced by the SIP1 bit. The value of SIP1 can be only be written when WSIP1=1.* *Note: When SIP1=1 is set, the first pulses of the subincrement generator are not generated with highest frequency for the first increment (DPLL_STATUS.FTD = 0, DPLL_CTRL_1.SGE1=1).* 0_B Increment prediction calculation; the current increment duration is calculated using the relation between increment durations in the past, like explained by the corresponding equations 1_B Increment prediction continuation; in this mode, for the increment prediction value calculation of CDT_TX the value of QDT_T is replaced by 1 for all calculations when NUTE-VTN=1; in the other case, the value of SIP1 is ignored, and the calculation is performed like for SIP1=0
ERZ1	1	rw	**Error is assumed as zero in normal mode and for the first engine for SMC=1** The calculation of EDT_T and MEDT_T is performed independently from the ERZ1 value in all modes without any influence to the MEDT_T value itself. The ERZ1 value influences the use of MEDT_T in normal mode and for SMC=1. The value of ERZ1 can be only written when WERZ1=1. 0_B The MEDT_T and MEDT_S values are considered as provided in the corresponding equations 1_B Instead of using MEDT_T, the value '0' is used in the corresponding equations

Field	Bits	Type	Description
PCMF1	2	rw	**Pulse correction mode fast for INC_CNT1** The fast pulse generation is performed immediately within the current increment. MPVAL1 must be positive integers for the fast pulse correction mode - in the case of negative values, the correction is suppressed, and the FPCE (fast pulse correction error) bit in the DPLL_STATUS register is set, causing the EI (error interrupt) when enabled. The setting of PCMF1 prevents the transfer of control bits PCM1 to the corresponding shadow registers with an active input event, and prevents therefore the distribution of the MPVAL1 values over the current or next increment. The MPVAL1 pulses are sent with the fast clock CMU_CLK0 by the rapid pulse generator RPCUx (see chapter 18.8.3.6 of specification v3.0) triggered in the state 6/26 or 18/38 of the state machines (see **Section 28.20.8.6.1**), respectively. The INC_CNT1 is incremented by MPVAL1, respectively. When taken the MPVAL1 value to RPCUx and INC_CNT1, the PCM1 bit is reset immediately, and after that, also the PCMF1 bit. The value of PCMF1 can be only written when WPCMF1=1. Be careful when using the fast pulse correction during a direction change. Because of sending the correction pulses before, during or after the direction change recognition, the result is typically unpredictable. No automatic correction of the fast correction pulses is provided. The necessary corrections must be performed on responsibility of the user. 0_B No fast update of pulses, provided by MPVAL1 1_B When PCM1 is set while PCMF1=1, the pulses provided by MPVAL1 are sent using the rapid pulse generator RPCUx, without waiting for a new input event
FSYL1	3	rw	**Force Synchronization Loss of LOCK1** The synchronization loss resets SYT/SYS and prevents the use of profiles, respectively. The above described effect for FSYL1=1 is only active when WFSYL1=1 simultaneously. 0_B No force of synchronization loss 1_B Reset LOCK1 and reset SYT in normal mode, and for SMC=1, reset SYS in emergency mode

Field	Bits	Type	Description
INCF1	4	rw	**INC_CNT1 fast correction** The calculation of ADD_IN for the SUB_INC generation is performed without adding the 0.5 value to NMB_T/S in equations DPLL_25 ff. The signal RESET_SIGx of the pulse generator is activated for each new active input slope, in order to reset the register values. *Note: The INCF1 value can be only written when WINCF1=1.* *Note: The INCF1 bit should only be written when DPLL_CTRL_1.DEN = '0' (DPLL disabled) to prevent generation of wrong number of sub increments.* 0_B The calculation of a new INC_CNT1 is performed after an active slope was detected and the plausibility check was performed 1_B The calculation of a new INC_CNT1 is prepared before an active slope is detected; the plausibility check is supported by an additional HW checker in order to get the decision earlier, and after this decision, the pulse generator for SUB_INC1 starts immediately sending out pulses
PCMF1_INCCNT_B	5	rw	**No increment of INC_CNT1 when PCMF1 active (automatic end mode)** The PCMF1_INCCNT_B value can be only written when WPCMF1_INCCNT_B =1. 0_B When fast pulse correction is done by PCM1, PCMF1, the MPVAL1 value is as well added to the INC_CNT1 1_B Do not add MPVAL1 value to the INC_CNT1 register when fast pulse correction is done by PCM1 or PCMF1. This means that just fast pulses are done by decrementing current content of INC_CNT1 register as long as INC_CNT1 is not zero (automatic end mode). The number of pulses (MPVAL1) shall be sufficiently smaller than INC_CNT1 when MPVAL1 is written.
ADT	6	r	**Correction of DT_T_ACTUAL,CDT_TX_nom_corr by PD_T** 0_B No correction of DT_T_ACTUAL, CDT_TX_nom_corr by physical deviation (PD_T) defined in profile of TRIGGER processing unit 1_B Correction of DT_T_ACTUAL, CDT_TX_nom_corr by physical deviation (PD_T) defined in profile of TRIGGER processing unit
ADS	7	r	**Correction of DT_S_ACTUAL, CDT_SX_nom_corr by PD_S** 0_B No correction of DT_S_ACTUAL, CDT_SX_nom_corr by physical deviation (PD_S) defined in profile of STATE processing unit 1_B Correction of DT_S_ACTUAL, CDT_SX_nom_corr by physical deviation (PD_S) defined in profile of STATE processing unit

Field	Bits	Type	Description
SIP2	8	rw	**Simplified increment prediction in emergency mode and for the second engine in the case RMO=1** For the first increment after setting SIP2 from 0 to 1, the value of DT_S_ACT is replaced by the value of the DT_S_START register. This results in a CDT_SX value which is equal to DT_S_START. Please notice that this DT_S_START value must be always > 256. The value of SIP2 influences only the increment prediction and error accumulation when NUSE-VSN=1. The calculation of QDT_S itself is not influenced by the SIP2 bit. The value of SIP2 can be only written when WSIP2=1. 0_B Increment prediction calculation; the current increment duration CDT_SX is calculated using the relation between increments duration in the past, like explained by the corresponding equations 1_B Increment prediction value calculation CDT_SX; the value of QDT_S is replaced by 1 for all calculations when NUSE-VSN=1; in the other case, the value of SIP2 is ignored, and the calculation is performed like for SIP2=0
ERZ2	9	rw	**Error is assumed as zero in emergency mode and for the second engine for SMC=1** The calculation of EDT_S and MEDT_S is performed independently from the ERZ2 value in all modes, without any influence to the MEDT_S value itself. The ERZ2 value influences the use of MEDT_S in emergency mode and for SMC=1 with RMO=1. The value of ERZ2 can be only written when WERZ2=1. 0_B The MEDT_S value is considered as provided in the corresponding equations 1_B Instead of using MEDT_S, the value '0' is used in the corresponding equations

Field	Bits	Type	Description
PCMF2	10	rw	**Pulse correction mode fast for INC_CNT2** The fast pulse generation is performed immediately within the current increment. MPVAL2 must be positive integers for the fast pulse correction mode - in the case of negative values, the correction is suppressed, and the FPCE (fast pulse correction error) bit in the DPLL_STATUS register is set, causing the EI (error interrupt) when enabled. The setting of PCMF2 prevents the transfer of control bits PCM2 to the corresponding shadow registers with an active input event, and therefore prevents the distribution of the MPVAL1 values over the current or next increment. The MPVAL2 pulses are sent with the fast clock CMU_CLK0 by the rapid pulse generator RPCUx (of specification v3.0) triggered in the state 6/26 or 18/38 of the state machines. The INC_CNT2 is incremented by MPVAL2, respectively. When taken the MPVAL2 value to RPCUx and INC_CNT2, the PCM2 bit is reset immediately, and after that also the PCMF2 bit. The value of PCMF2 can be only written when WPCMF2=1. Be careful when using the fast pulse correction during a direction change. Because of sending the correction pulses before, during or after the direction change recognition, the result is typically unpredictable. No automatic correction of the fast correction pulses is provided. The necessary corrections must be performed on responsibility of the user. 0_B No fast update of pulses provided by MPVAL2 1_B When PCM2 is set while PCMF2=1, the pulses provided by MPVAL2 are sent using the rapid pulse generator RPCUx, without waiting for a new input event
FSYL2	11	rw	**Force Synchronization Loss of LOCK2** The synchronization loss resets SYS and prevents the use of profiles respectively. The above described effect for FSYL2=1 is only active when WFSYL2=1 simultaneously. 0_B No force of synchronization loss 1_B Reset LOCK2 and reset SYS in emergency mode and for SMC=1
INCF2	12	rw	**INC_CNT2 fast** The INCF2 value can be only written when WINCF2=1. 0_B The calculation of a new INC_CNT2 is performed after an active slope was detected and the plausibility check was performed 1_B The calculation of a new INC_CNT2 is prepared before an active slope is detected; the plausibility check is supported by an additional HW checker in order to get the decision earlier, and after this decision, the pulse generator for SUB_INC2 starts immediately sending out pulses. The calculation of ADD_IN for the SUB_INC generation is performed without adding the 0.5 value to NMB_S in equations DPLL_25 ff. The signal RESET_SIGx of the pulse generator is activated for each new active input slope in order to reset the register values.

Field	Bits	Type	Description
PCMF2_INCCNT_B	13	rw	**No increment of INC_CNT2 when PCMF2 active (automatic end mode)** The PCMF2_INCCNT_B value can be only written when WPCMF2_INCCNT_B=1. 0_B Add MPVAL2 value is as well added to the INC_CNT2 when fast pulse correction is done by PCM2 or PCMF2 1_B Do not add MPVAL2 value to the INC_CNT2 register when fast pulse correction is done by PCM2 or PCMF2. This means, that just fast pulses are done by decrementing current content of INC_CNT2 register as long as INC_CNT2 is not zero (automatic end mode). The number of pulses (MPVAL2) shall be sufficiently smaller than INC_CNT2 when MPVAL2 is written.
STATE_EXT	14	rw	**Use of STATE engine extension** The STATE_EXT value can be only written when WSTATE_EXT=1 and the DPLL is disabled. See 18.10 for a further explanation. If this bit shall be modified during operation, a software reset of the DPLL module is strongly recommended. A RAM initialisation should also be considered depending on the given application case. 0_B STATE extension is not considered 1_B STATE extension is enabled for up to 128 STATE events
ACBU	15	rw	**ACB use; the ACB values of PMTR are used to decide if an action is in the past** Return ACB values together with actions as zero, when the actions are in the future; Set ACB[1]=1, when calculated position value is in the past and the ACB[1] of PMTR was 1. Set ACB[0]=1, when calculated time value is in the past and the ACB[0] of PMTR was 1. The value of ACBU can be only written when WACBU=1. 0_B ACB values of PMTR are not considered in DPLL; the decision, whether an action is in the past, is made considering the calculated time value 1_B ACB values of PMTR are considered in DPLL as follows: If ACB[1] = 1, consider whether the calculated position value of the corresponding action is in the past if ACB[0] = 1; consider whether the calculated time value of the corresponding action is in the past; ACB[1] and ACB[0] can be set also simultaneously to 1
WSIP1	16	rw	**Write enable for simplified increment prediction 1** Enable writing. 0_B Writing to SIP1 is not enabled 1_B Writing to SIP1 is enabled
WERZ1	17	rw	**Write enable for error zero 1** Enable writing. 0_B Writing to ERZ1 is not enabled 1_B Writing to ERZ1 is enabled

Field	Bits	Type	Description

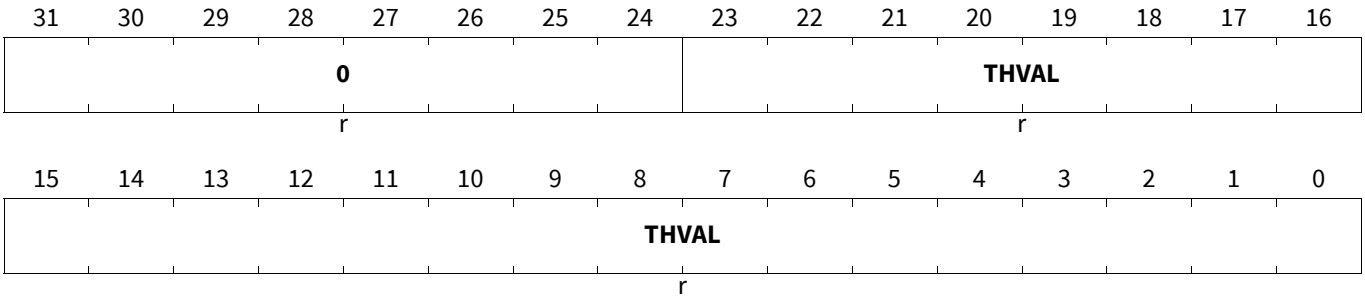
WACBU	31	rw	**Write enable for ACB use** The ACB values of PMTR are used to decide whether an action is in the past. Enable writing. 0_B Writing to ACBU is not enabled 1_B Writing to ACBU is enabled

28.20.12.96Register DPLL_THVAL2

DPLL Immediate THVAL Value Register

DPLL_THVAL2
DPLL Immediate THVAL Value Register (028F24$_H$) Application Reset Value: 0000 0000$_H$



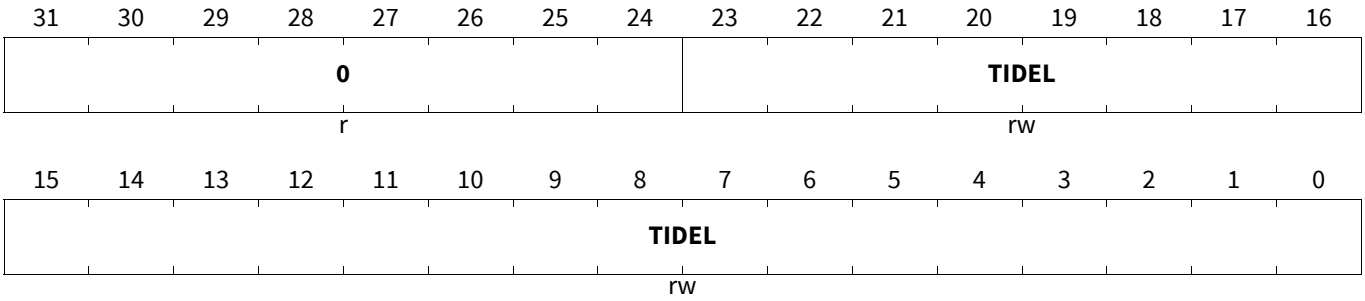
Field	Bits	Type	Description
THVAL	23:0	r	**Measured last pulse time from active to inactive slope of TRIGGER after correction of input slope filter delays** This value is available immediately after the inactive slope of TRIGGER. The measured value considers all input slope filter delays. From the received input the corresponding filter delays are subtracted before the time stamp difference of active and inactive slope is calculated.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.97Register DPLL_TIDEL

DPLL Additional TRIGGER Input Delay Register

DPLL_TIDEL

DPLL Additional TRIGGER Input Delay Register (028F28$_H$) **Application Reset Value: 0000 0000$_H$**



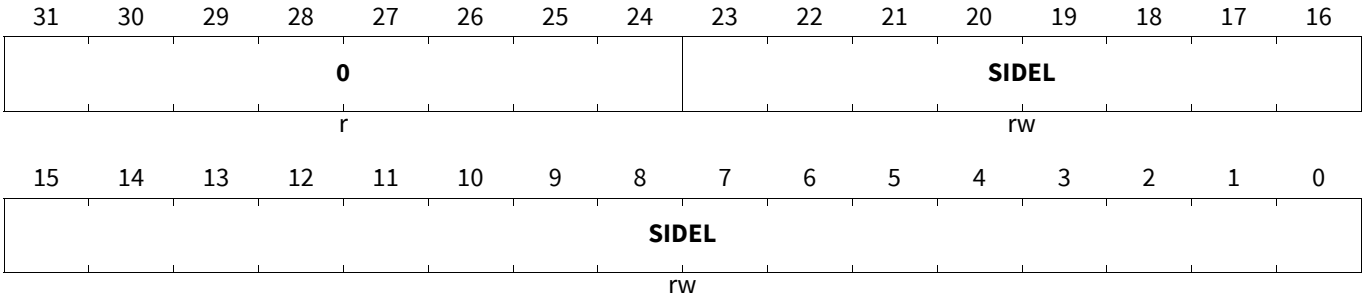
Field	Bits	Type	Description
TIDEL	23:0	rw	**TRIGGER input delay** Transmit this value with each active TRIGGER slope into a shadow register. Subtract this shadow register value from each TRIGGER time stamp (active and inactive slope). This feature is always active and cannot be disabled by a control bit.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.98Register DPLL_SIDEL

DPLL Additional STATE Input Delay Register

DPLL_SIDEL

DPLL Additional STATE Input Delay Register (028F2C$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
SIDEL	23:0	rw	**STATE input delay** Transmit this value with each active STATE slope into a shadow register. Subtract this shadow register value from each STATE time stamp (active and inactive slope). This feature is always active and cannot be disabled by a control bit.

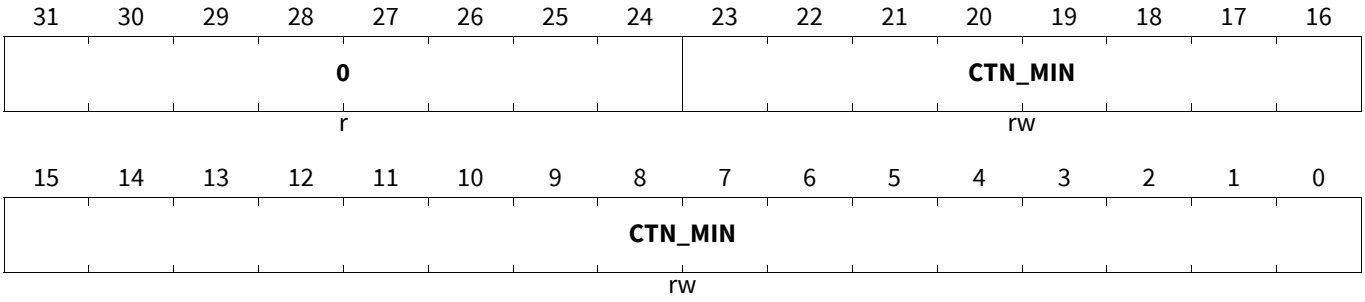
Field	Bits	Type	Description
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.99Register DPLL_CTN_MIN

DPLL Minimum CDT_T Nominal Value Register

DPLL_CTN_MIN

DPLL Minimum CDT_T Nominal Value Register (028F6C$_H$) **Application Reset Value: 0000 0000$_H$**



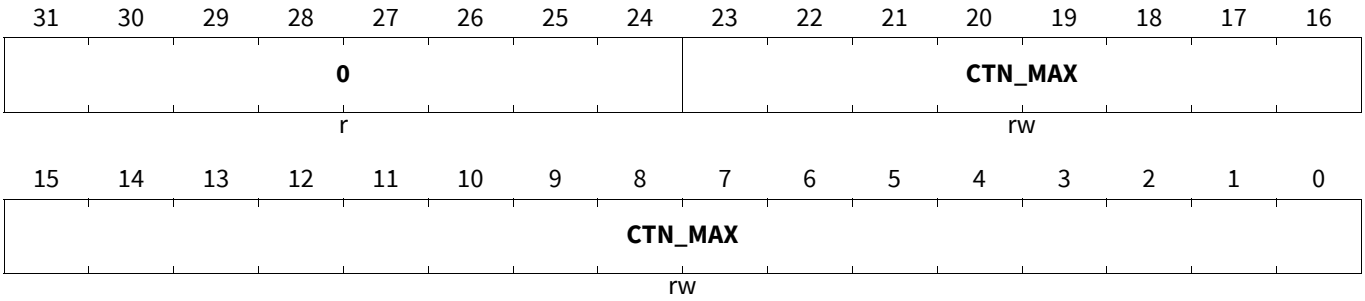
Field	Bits	Type	Description
CTN_MIN	23:0	rw	**CDT_T_NOM min value** Use this register value as CDT_T_NOM value when the calculated value for the nominal increment prediction of TRIGGER is less than the register value.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.100Register DPLL_CTN_MAX

DPLL Maximum CDT_T Nominal Value Register

DPLL_CTN_MAX

DPLL Maximum CDT_T Nominal Value Register (028F70$_H$) **Application Reset Value: 00FF FFFF$_H$**



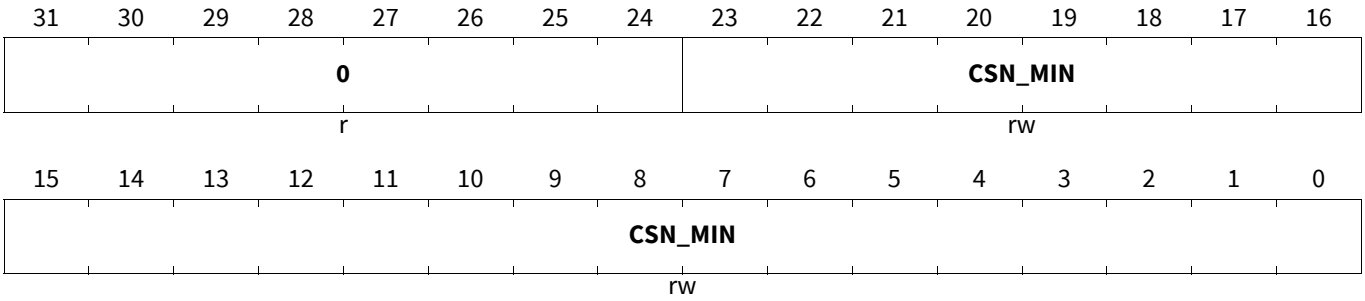
Field	Bits	Type	Description
CTN_MAX	23:0	rw	**CDT_T_NOM max value** Use this register value as CDT_T_NOM value when the calculated value for the nominal increment prediction of TRIGGER is greater than the register value.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.101Register DPLL_CSN_MIN

DPLL Minimum CDT_S Nominal Value Register

DPLL_CSN_MIN

DPLL Minimum CDT_S Nominal Value Register (028F74$_H$) **Application Reset Value: 0000 0000$_H$**



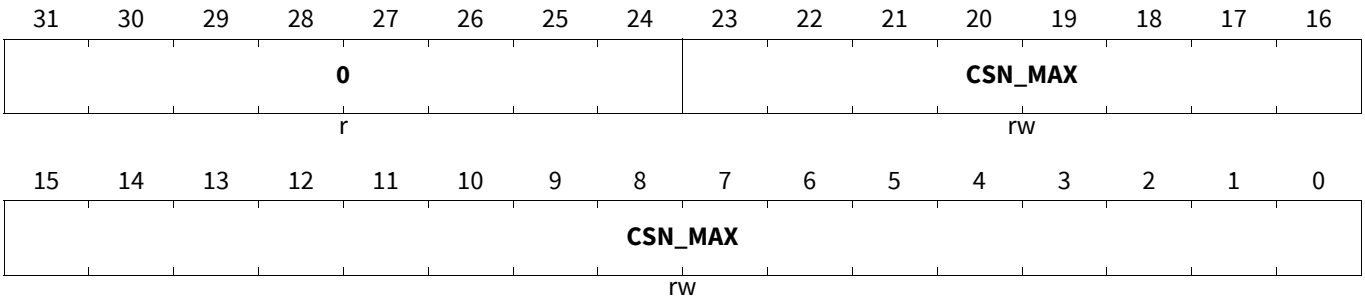
Field	Bits	Type	Description
CSN_MIN	23:0	rw	**CDT_SX_NOM min value** Use this register value as CDT_SX_NOM value when the calculated value for the nominal increment prediction of STATE is less than the register value.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.102Register DPLL_CSN_MAX

DPLL Maximum CDT_S Nominal Value Register

DPLL_CSN_MAX

DPLL Maximum CDT_S Nominal Value Register (028F78$_H$) **Application Reset Value: 00FF FFFF$_H$**



Field	Bits	Type	Description
CSN_MAX	23:0	rw	**CDT_SX_NOM max value** Use this register value as CDT_SX_NOM value when the calculated value for the nominal increment prediction of STATE is greater than the register value.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.103Register DPLL_STA

DPLL Status of the State Machine States Register

DPLL_STA

DPLL Status of the State Machine States Register(028F40$_H$) **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								CNT_S			0	STA_S			
r								r			r	r

STA_S				CNT_T			0	STA_T							
r				r			r	r							

Field	Bits	Type	Description
STA_T	7:0	r	**Status of TRIGGER state machine; state binary coded** This bit field reflects the status of the TRIGGER state machine. The decimal step number 1 to 20 of the state machine is binary coded from 0x01 to 0x14 respectively using the upper 5 bits (8:4). The lower 4 bits (3:0) show substates of the corresponding state machine. When the DPLL is disabled, this field is 0x000. Table STA_T
CNT_T	11:9	r	**Count TRIGGER** This reflects the count of active TRIGGER slopes (mod8). This value shows the number of active TRIGGER slopes (mod8). This value allows distinguishing if the above state machine status is consistent to other status values read before or after it.

Field	Bits	Type	Description
STA_S	19:12	r	**Status of STATE state machine** State binary coded. This bit field reflects the status of the STATE state machine. The decimal step number 21 to 40 of the state machine is binary coded from 0x01 to 0x14 respectively using the upper 5 bits (20:16) after subtraction of 20 to the decimal value. The lower 4 bits (15:12) show substates of the corresponding state machine. When the DPLL is disabled, this field is 0x000. Table_STA_S
CNT_S	23:21	r	**Count STATE** This reflects the count of active STATE slopes (mod8). This value shows the number of active STATE slopes (mod8). This value allows distinguishing if the above state machine status is consistent to other status values read before or after it.
0	8, 20, 31:24	r	**Reserved** Read as zero, shall be written as zero.

Bit description of DPLL_STA

0	1	Wait, DEN=0
0	2	Calculation of 1/mlt+1, mls1, mls2.
0	3	Calculation of direction change issues (pointers and profile update)
0	4	--
0	5	--
0	6	APS_1c3 was incremented
0	7	APS_1c3 was incremented. Update of pointers is finished, perform change of direction operations
1	0	pvt-check
1	1	update of RAM: write RDT_S; DT_S; TSF_S
1	2	loading of profile (syn_s, update syn_s_old) from ADT_S
1	3	SASI-irq, store FTV into RAM1b
1	4	Write PSSC; modify aps, aps_1c2; aps_1c3 (if synchronized); Start fast pulse updates if necessary; Update inc_cnt1/2;

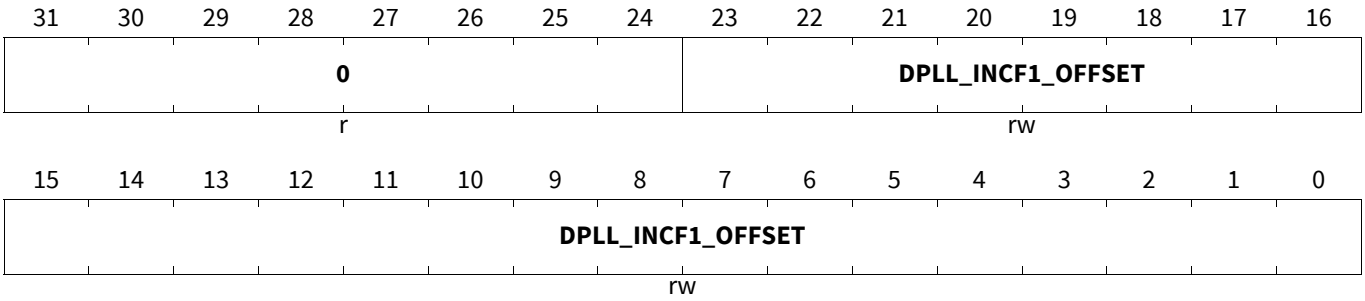
28.20.12.104Register DPLL_INCF1_OFFSET

DPLL Start Value of the ADD_IN_ADDER1 Register

DPLL_INCF1_OFFSET

DPLL Start Value of the ADD_IN_ADDER1 Register(028F44$_H$) **Application Reset Value: 0000 0000$_H$**



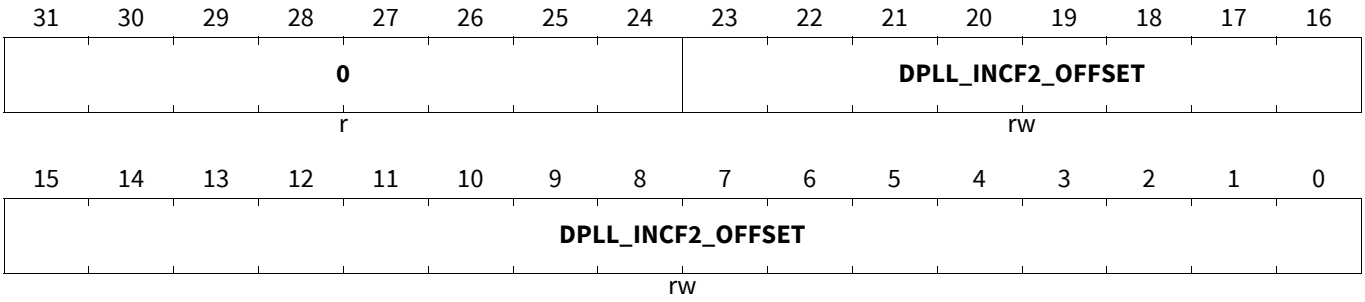
Field	Bits	Type	Description
DPLL_INCF1_OFFSET	23:0	rw	**Start value of the ADD_IN_ADDER1** In the case of set DPLL_CTRL_11-INCF1 the ADD_IN_ADDER1 starts always after an active new input event (TRIGGER in normal mode or STATE in emergency mode respectively) with this offset value. In the case of choosing DPLL_INCF1_OFFSET= 0xFFFFFF the generation of the first SUB_INC1 pulse is performed with the next TS_CLK. In the case of DPLL_INCF1_OFFSET= 0x000000 the first pulse is delayed by a full SUB_INC1 period and in the case of DPLL_INCF1_OFFSET= 0x7FFFFF the first pulse is delayed by a half SUB_INC1 period. Any other value is possible.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.105Register DPLL_INCF2_OFFSET

DPLL Start Value of the ADD_IN_ADDER2 Register

DPLL_INCF2_OFFSET

DPLL Start Value of the ADD_IN_ADDER2 Register(028F48$_H$) **Application Reset Value: 0000 0000$_H$**

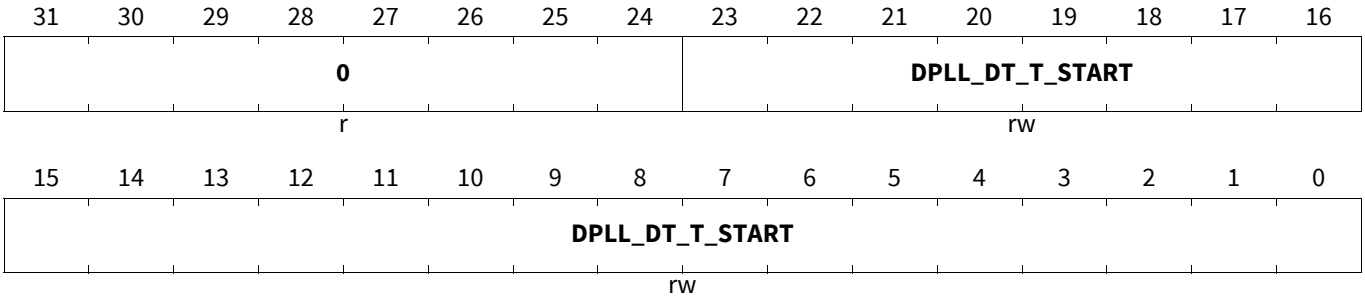


Field	Bits	Type	Description
DPLL_INCF2_OFFSET	23:0	rw	**Start value of the ADD_IN_ADDER2** In the case of set DPLL_CTRL_11-INCF2 the ADD_IN_ADDER2 starts always after an active new input event (STATE) with this offset value. In the case of choosing DPLL_INCF2_OFFSET= 0xFFFFFF the generation of the first SUB_INC2 pulse is performed with the next TS_CLK. In the case of DPLL_INCF2_OFFSET= 0x000000 the first pulse is delayed by a full SUB_INC2 period and in the case of DPLL_INCF2_OFFSET= 0x7FFFFF the first pulse is delayed by a half SUB_INC2 period. Any other value is possible.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.106Register DPLL_DT_T_START

DPLL Start Value of DPLL_DT_T_ACT for the First Increment after SIP1 is Set to 1

DPLL_DT_T_START
DPLL Start Value of DPLL_DT_T_ACT for the First Increment after SIP1 is Set to 1(028F4C$_H$) **Application**
Reset Value: 0000 0101$_H$

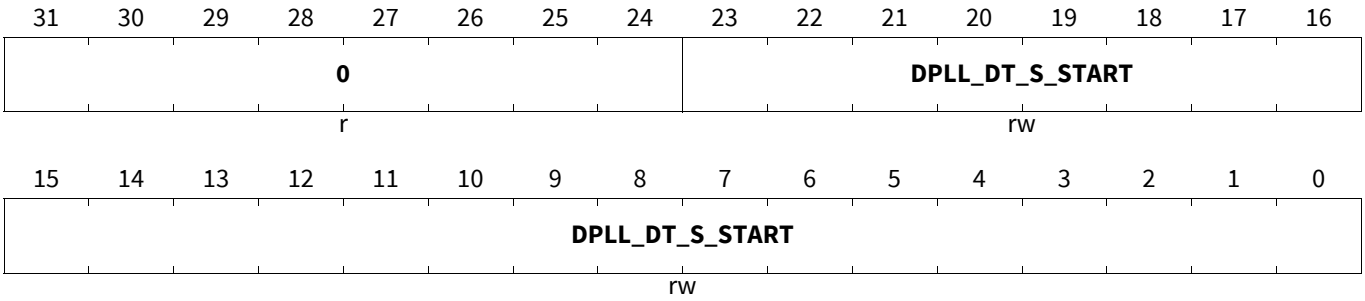


Field	Bits	Type	Description
DPLL_DT_T_START	23:0	rw	**Start value of DPLL_DT_T_ACT for the first increment after SIP1 is set to 1** For the first increment after setting SIP1 from 0 to 1, the value of DPLL_DT_T_START is taken instead of the calculated DPLL_DT_T_ACT for the current increment duration. This value should be always > 256 in order to avoid an overflow during the calculation of DPLL_RDT_T_ACT.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.107Register DPLL_DT_S_START

DPLL Start Value of DPLL_DT_S_ACT for the First Increment after SIP2 is Set to 1

DPLL_DT_S_START
DPLL Start Value of DPLL_DT_S_ACT for the First Increment after SIP2 is Set to 1(028F50$_H$) Application Reset Value: 0000 0101$_H$

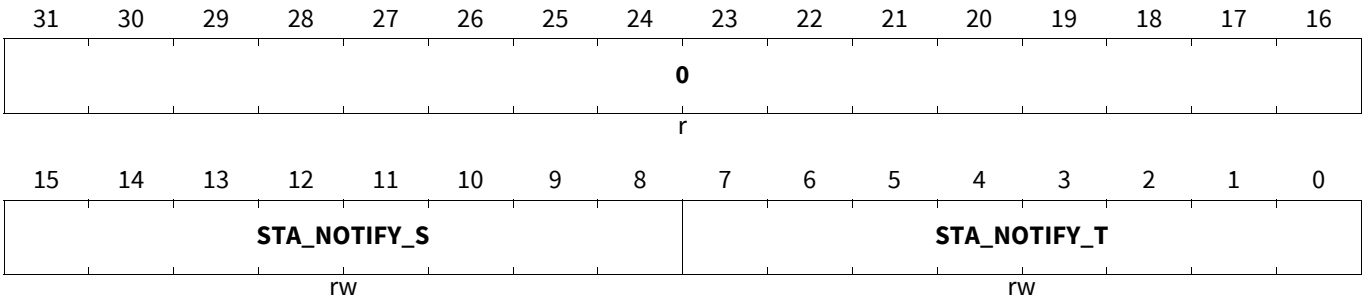


Field	Bits	Type	Description
DPLL_DT_S_START	23:0	rw	**Start value of DPLL_DT_S_ACT for the first increment after SIP2 is set to 1** For the first increment after setting SIP2 from 0 to 1, the value of DPLL_DT_S_START is taken instead of the calculated DPLL_DT_S_ACT for the current increment duration. This value should be always > 256 in order to avoid an overflow during the calculation of DPLL_RDT_S_ACT.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.108Register DPLL_STA_MASK

DPLL Trigger Masks for Signals DPLL_STA_T and DPLL_STA_S

DPLL_STA_MASK
DPLL Trigger Masks for Signals DPLL_STA_T and DPLL_STA_S(028F54$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
STA_NOTIFY_T	7:0	rw	**Notify value for STA_T of register DPLL_STA** The STA_NOTIFY_T is representing a trigger mask of DPLL_STA.STA_T. When DPLL_STA.STA_T reaches the value of STA_NOTIFY_T the flag DPLL_STA_FLAG.STA_FLAG_T is set to '1' when DPLL_STA.STA_T is leaving the state STA_NOTIFY_T.The signal is visible to MCS0 sub module as part of the special function register.
STA_NOTIFY_S	15:8	rw	**Notify value for STA_S of register DPLL_STA** The STA_NOTIFY_S is representing a trigger mask of DPLL_STA.STA_S. When DPLL_STA.STA_S reaches the value of STA_NOTIFY_S the flag DPLL_STA_FLAG.STA_FLAG_S is set to '1' when DPLL_STA.STA_S is leaving the state STA_NOTIFY_S.
0	31:16	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.109Register DPLL_STA_FLAG

DPLL STA Flag Register

DPLL_STA_FLAG
DPLL STA Flag Register **($028F58_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0					INC_CNT2_FLAG	INC_CNT1_FLAG	STA_FLAG_S	0							STA_FLAG_T
r					rw	rw	rw	r							rw

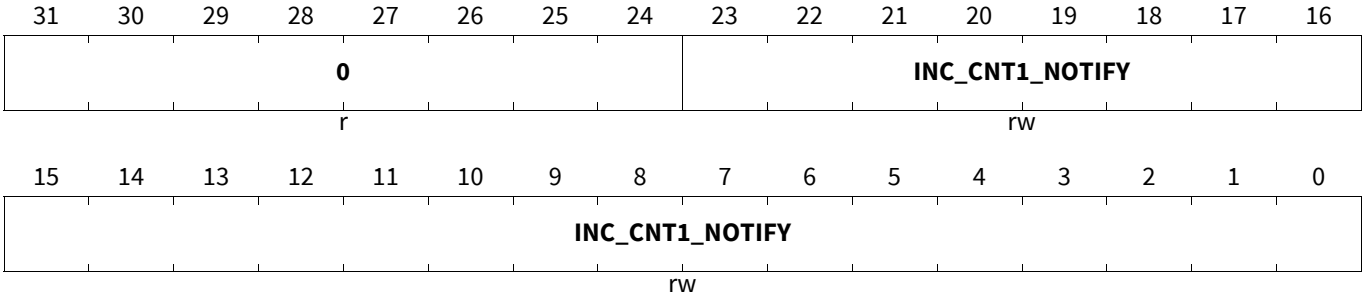
Field	Bits	Type	Description
STA_FLAG_T	0	rw	**Flag according to DPLL_MASK.STA_NOTIFY_T** The STA_FLAG_T is set to '1' indicating that the signal DPLL_STA.STA_T has left the state defined by the trigger mask of DPLL_STA_MASK.STA_NOTIFY_T. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.

Field	Bits	Type	Description
STA_FLAG_S	8	rw	**Flag according to DPLL_STA_MASK.STA_NOTIFY_S** The STA_FLAG_S is set to '1' indicating that the signal DPLL_STA.STA_S has left the state defined by the trigger mask of DPLL_STA_MASK.STA_NOTIFY_S. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
INC_CNT1_FLAG	9	rw	**Flag according to DPLL_INC_CNT1_MASK.INC_CNT1_NOTIFY** The INC_CNT1_FLAG is set to '1' indicating that the signal DPLL_INC:CNT1.INC_CNT1 has left the state defined by the trigger mask of DPLL_INC_CNT1_MASK.INC_CNT1_NOTIFY. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
INC_CNT2_FLAG	10	rw	**Flag according to DPLL_INC_CNT2_MASK.INC_CNT2_NOTIFY** The INC_CNT2_FLAG is set to '1' indicating that the signal DPLL_INC_CNT2.INC_CNT2 has left the state defined by the trigger mask of DPLL_INC_CNT2_MASK.INC_CNT2_NOTIFY. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
0	7:1, 31:11	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.110Register DPLL_INC_CNT1_MASK

DPLL INC_CNT1 Trigger Mask

DPLL_INC_CNT1_MASK
DPLL INC_CNT1 Trigger Mask **($028F5C_H$)** **Application Reset Value: $0000\ 0000_H$**



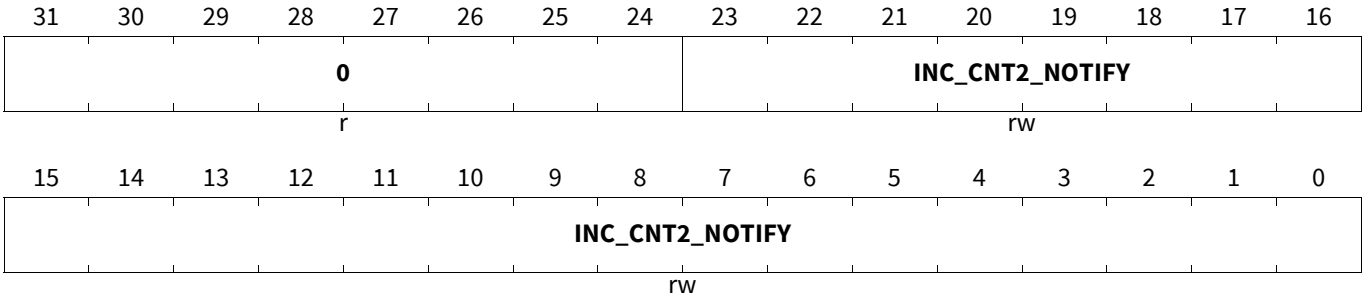
Field	Bits	Type	Description
INC_CNT1_NOTIFY	23:0	rw	**Notify value for INC_CNT1 of register DPLL_INC_CNT1** The INC_CNT1_NOTIFY is representing a trigger mask of DPLL_INC_CNT1.INC_CNT1. When DPLL_INC_CNT1.INC_CNT1 reaches the value of INC_CNT1_NOTIFY the flag DPLL_STA_FLAG.INC_CNT1_FLAG is set to '1' when DPLL_INC_CNT1.INC_CNT1 is leaving the state INC_CNT1_NOTIFY.

Field	Bits	Type	Description
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.111Register DPLL_INC_CNT2_MASK

DPLL INC_CNT2 Trigger Mask

DPLL_INC_CNT2_MASK
DPLL INC_CNT2 Trigger Mask **(028F60$_H$)** **Application Reset Value: 0000 0000$_H$**

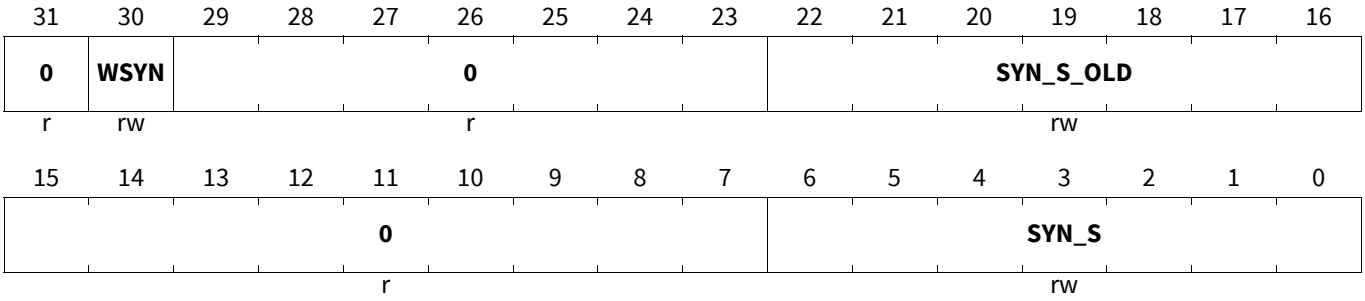


Field	Bits	Type	Description
INC_CNT2_NOTIFY	23:0	rw	**Notify value for INC_CNT2 of register DPLL_INC_CNT2** The INC_CNT2_NOTIFY is representing a trigger mask of DPLL_INC_CNT2.INC_CNT2. When DPLL_INC_CNT2.INC_CNT2 reaches the value of INC_CNT2_NOTIFY the flag DPLL_STA_FLAG.INC_CNT2_FLAG is set to '1' when DPLL_INC_CNT2.INC_CNT2 is leaving the state INC_CNT2_NOTIFY.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.112Register DPLL_NUSC_EXT1

DPLL Extension Register Number 1 for DPLL_NUSC 4

DPLL_NUSC_EXT1
DPLL Extension Register Number 1 for DPLL_NUSC 4(028F64$_H$) **Application Reset Value: 0001 0001$_H$**



Field	Bits	Type	Description
SYN_S	6:0	rw	**Number of real and virtual events to be considered for the current increment** This value reflects the NS value of the last valid increment, stored in ADT_S[i]; to be updated after all calculations in step 37 of Table **Section 28.20.8.6.6**. This value can only be written when the WSYN bit in this register is set.
SYN_S_OLD	22:16	rw	**Number of real and virtual events to be considered for the last increment** This value reflects the NS value of the last but one valid increment, stored in ADT_S[i]; is updated automatically when writing SYN_S. This value is updated by the SYN_S value when the WSYN bit in this register is set.
WSYN	30	rw	**Write control bit for SYN_S and SYN_S_OLD** Read as zero. 0_B The SYN_S value is not writeable 1_B The SYN_S value is writeable
0	15:7, 29:23, 31	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.113Register DPLL_NUSC_EXT2

DPLL Extension Register Number 2 for DPLL_NUSC 4

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set, any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_NUSC_EXT2

DPLL Extension Register Number 2 for DPLL_NUSC 4($028F68_H$) **Application Reset Value: $0000\ 0001_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WVSN	**0**	**WNUS**	**0**						**VSN**						
rw	r	rw	r						rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FSS	**0**								**NUSE**						
rw	r								rw						

Field	Bits	Type	Description
NUSE	6:0	rw	**Number of recent STATE events used for SUB_INCx calculations modulo 2*(SNUmax+1)** No gap is considered in that case for this value, but in the VSN value (see below): This register is set by the CPU but reset automatically to “1” by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. The relation values QDT_Sx are calculated using NUSE values in the past with its maximum value of 2*SNU+1. This value can only be written when the WNUS bit is set.
FSS	15	rw	**This value is to be set, when NUSE is set to FULL_SCALE** This value is set by the CPU, but reset automatically to '0' by a change of direction or loss of LOCK. This value can only be written when the WNUS bit is set. 0_B The NUSE value is less then FULL_SCALE 1_B The NUSE value is equal to FULL_SCALE
VSN	22:16	rw	**Number of virtual state increments in the current NUSE region** This value reflects the number of virtual increments in the current NUSE region; for NUSE=1 this value is zero, when the CPU sets NUSE to a value > 1 or zero(2^7 modulo 2^7) , it must also set VSN to the correspondent value;the VSN value is subtracted from the NUSE value in order to get the corresponding APS value for the past; the VSN value is not used for the APS_1C2 pointer. VSN is to be updated by the CPU when a new gap is to be considered for NUSE or a gap is leaving the NUSE region; for this purpose the SASI interrupt can be used; no further update of VSN is necessary when NUSE is set to FULL_SCALE. This value can only be written when the WVSN bit is set.
WNUS	29	rw	**Write control bit for NUSE** Read as zero. 0_B The NUSE value is not writeable 1_B The NUSE value is writeable
WVSN	31	rw	**Write control bit for VSN** Read as zero. 0_B The VSN value is not writeable 1_B The VSN value is writeable
0	14:7, 28:23, 30	r	**Reserved** Read as zero, shall be written as zero.

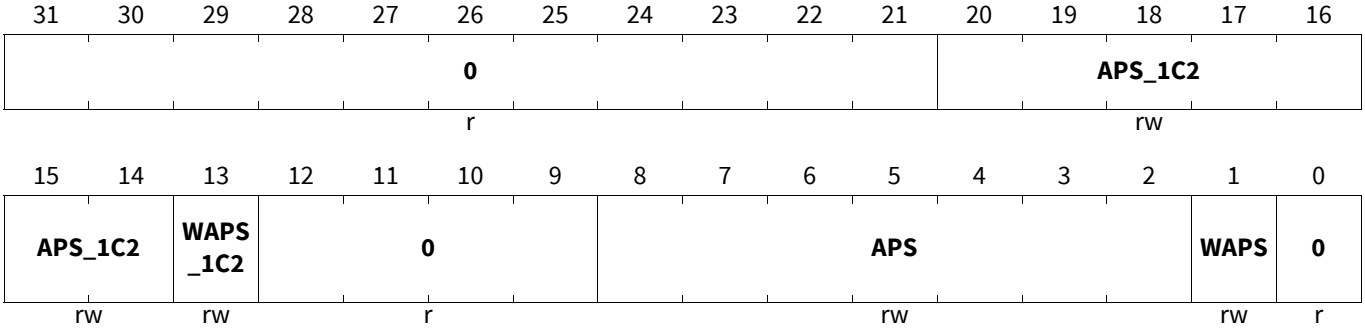
28.20.12.114Register DPLL_APS_EXT

DPLL Extension Register for DPLL_APS

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set, any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_APS_EXT

DPLL Extension Register for DPLL_APS (028F38$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
WAPS	1	rw	**Write bit for address pointer APS** Read as zero. 0_B The APS is not writeable 1_B The APS is writeable
APS	8:2	rw	**Actual RAM pointer address value for DT_S[i] and RDT_S[i]** Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 128 *STATE* events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; See **Section 28.20.10**. APS is incremented (decremented) by one for each active *STATE* event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after an active *STATE* event and the resulting increment/decrement. This value can only be written when the WAPS bit is set.
WAPS_1C2	13	rw	**Write bit for address pointer APS_1C2** Read as zero. 0_B The APS_1C2 is not writeable 1_B The APS_1C2 is writeable

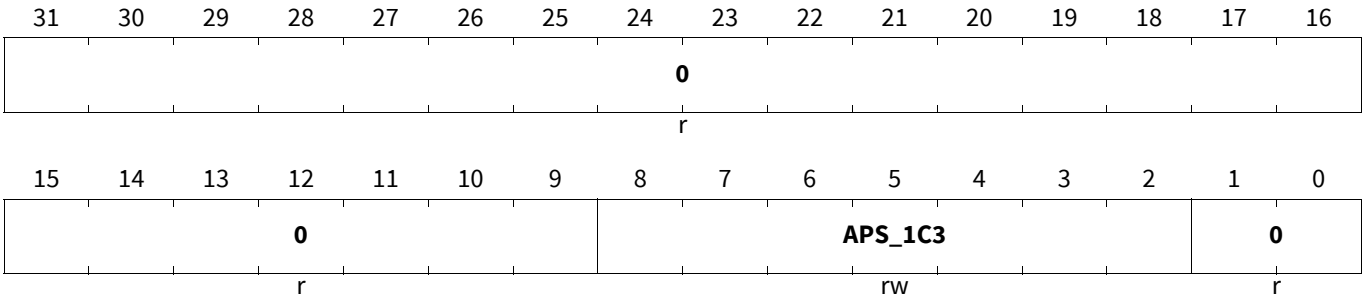
Field	Bits	Type	Description
APS_1C2	20:14	rw	**Actual RAM pointer address value for TSF_S[i]** Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 64 *STATE* events but limited to 2*(SNU+1) in normal and emergency mode; this pointer is used for the RAM region 1c2. For SYS=1: APS_1C2 is incremented (decremented) by SYN_S_OLD for each active *STATE* event and DIR2=0 (DIR2=1). For SYS=0: APT_1c2 is incremented or decremented by 1 respectively. The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. In addition when the APS_1C3 value is written by the CPU - in order to synchronize the DPLL- with the next active *STATE* event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at **Section 28.20.12.25**). This value can only be written when the WAPS_1C2 bit is set
0	0, 12:9, 31:21	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.115Register DPLL_APS_1C3_EXT

DPLL Extension Register for DPLL_APS_1C3

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set, any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_APS_1C3_EXT
DPLL Extension Register for DPLL_APS_1C3 (028F3C$_H$) Application Reset Value: 0000 0000$_H$



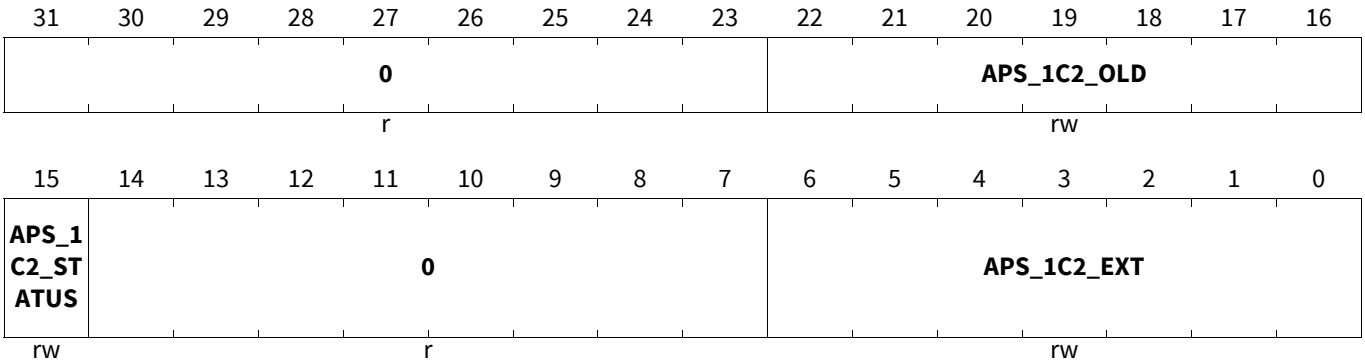
Field	Bits	Type	Description
APS_1C3	8:2	rw	**Actual RAM pointer address value for ADT_S[i]** Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of *STATE* events in FULL_SCALE for up to 128 *STATE* events but limited to 2*(SNU+1-SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c3. See **Section 28.20.10**. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected. The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1c2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before an active *STATE* event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction. The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.
0	1:0, 31:9	r	**Reserved** Read as zero, shall be written as zero.

28.20.12.116Register DPLL_APS_SYNC_EXT

DPLL Extension Register for DPLL_APS_SYNC

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set, any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_APS_SYNC_EXT
DPLL Extension Register for DPLL_APS_SYNC (028F30$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
APS_1C2_EXT	6:0	rw	**Address pointer 1c2 extension** This offset value determines, by which value the APS_1C2 is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and including the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1c2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.
APS_1C2_STATUS	15	rw	**Address pointer 1c2 status** Set by CPU before the synchronization is performed. The value is cleared automatically when the APS_1C2_OLD value is written. 0_B APS_1C2_EXT is not to be considered 1_B APS_1C2_EXT has to be considered for time stamp field extension
APS_1C2_OLD	22:16	rw	**Address pointer STATE for RAM region 1c2 at synchronization time** This value is set by the current APS_1C2 value when the synchronization takes place for the first active STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means: when APS_1C2_STATUS=1). Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap.
0	14:7, 31:23	r	**Reserved** Read as zero, shall be written as zero.

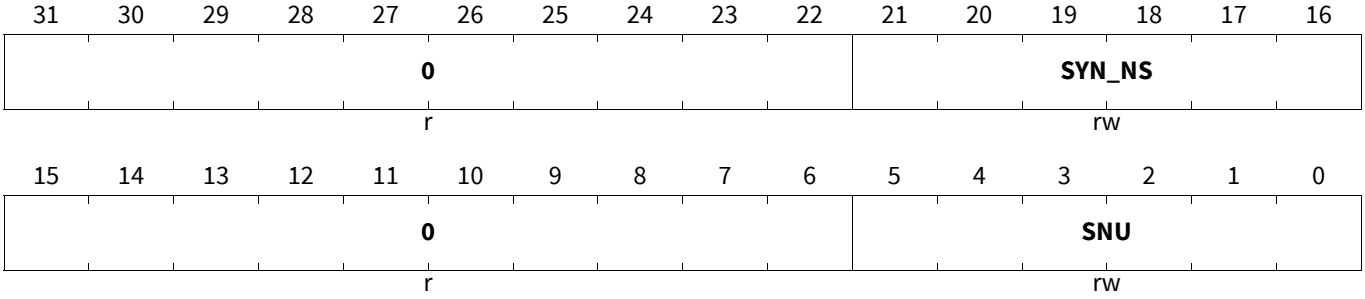
28.20.12.117Register DPLL_CTRL_EXT

DPLL Extension Register for DPLL_CTRL

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set, any read/write access to this register will return AEI_STATUS = 0b10.

DPLL_CTRL_EXT

DPLL Extension Register for DPLL_CTRL (028F34$_H$) Application Reset Value: 0000 0017$_H$



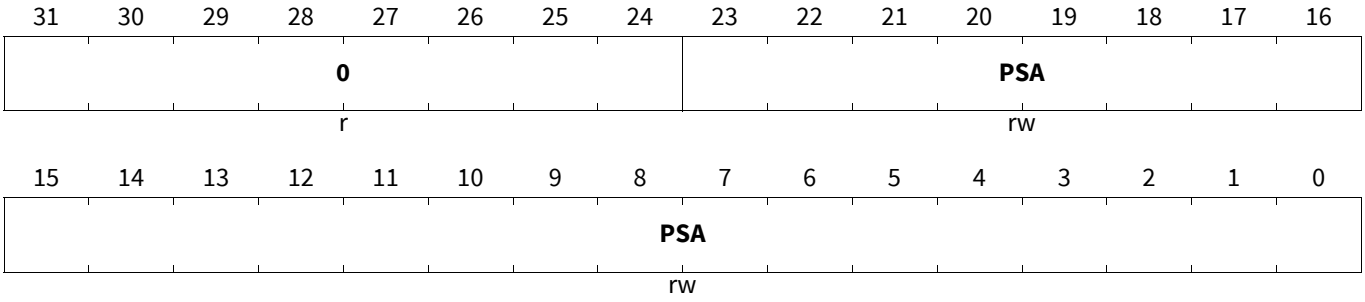
Field	Bits	Type	Description
SNU	5:0	rw	**STATE number** This bit can only be written when the DPLL is disabled. The number of nominal *STATE* events is the decimal value plus 1. This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0.
SYN_NS	21:16	rw	**Synchronization number of STATE** Summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing *STATE* events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1) ; the SYN_NS missing *STATES* can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1c3 as value NS in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(SNU+1-SYN_NS) for SYSF=0 or 2*(SNU+1)-SYN_NS for SYSF=1 . This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU. This value can only be written when the DPLL is disabled. This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0.
0	15:6, 31:22	r	**Reserved** Read as zero, shall be written as zero.

28.20.13 DPLL RAM Region 1a value description

28.20.13.1Memory DPLL_PSA[i]

DPLL ACTION_i Position/Value Request

DPLL_PSAi (i=0-31)
DPLL ACTION_i Position/Value Request **(028200_H+i*4)** **Reset Value: Table 137**



Field	Bits	Type	Description
PSA	23:0	rw	**Position information of a desired action i** This value can only be written when the DPLL is disabled. The PSA values for actions 24...31 are not available for all devices but depends on specific product configuration.
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.21 Sensor Pattern Evaluation (SPE)

28.21.1 Overview

The Sensor Pattern Evaluation (SPE) submodule can be used to evaluate three hall sensor inputs and together with the TOM module to support the drive of BLDC engines. Thus, the input signals are filtered already in the connected TIM channels. In addition, the SPE submodule can be used as an input stage to the MAP submodule if the DPLL should be used to calculate the rotation speed of one or two electric engine(s). The integration of the SPE submodule into the overall GTM architecture concept is shown in **Figure 132**.

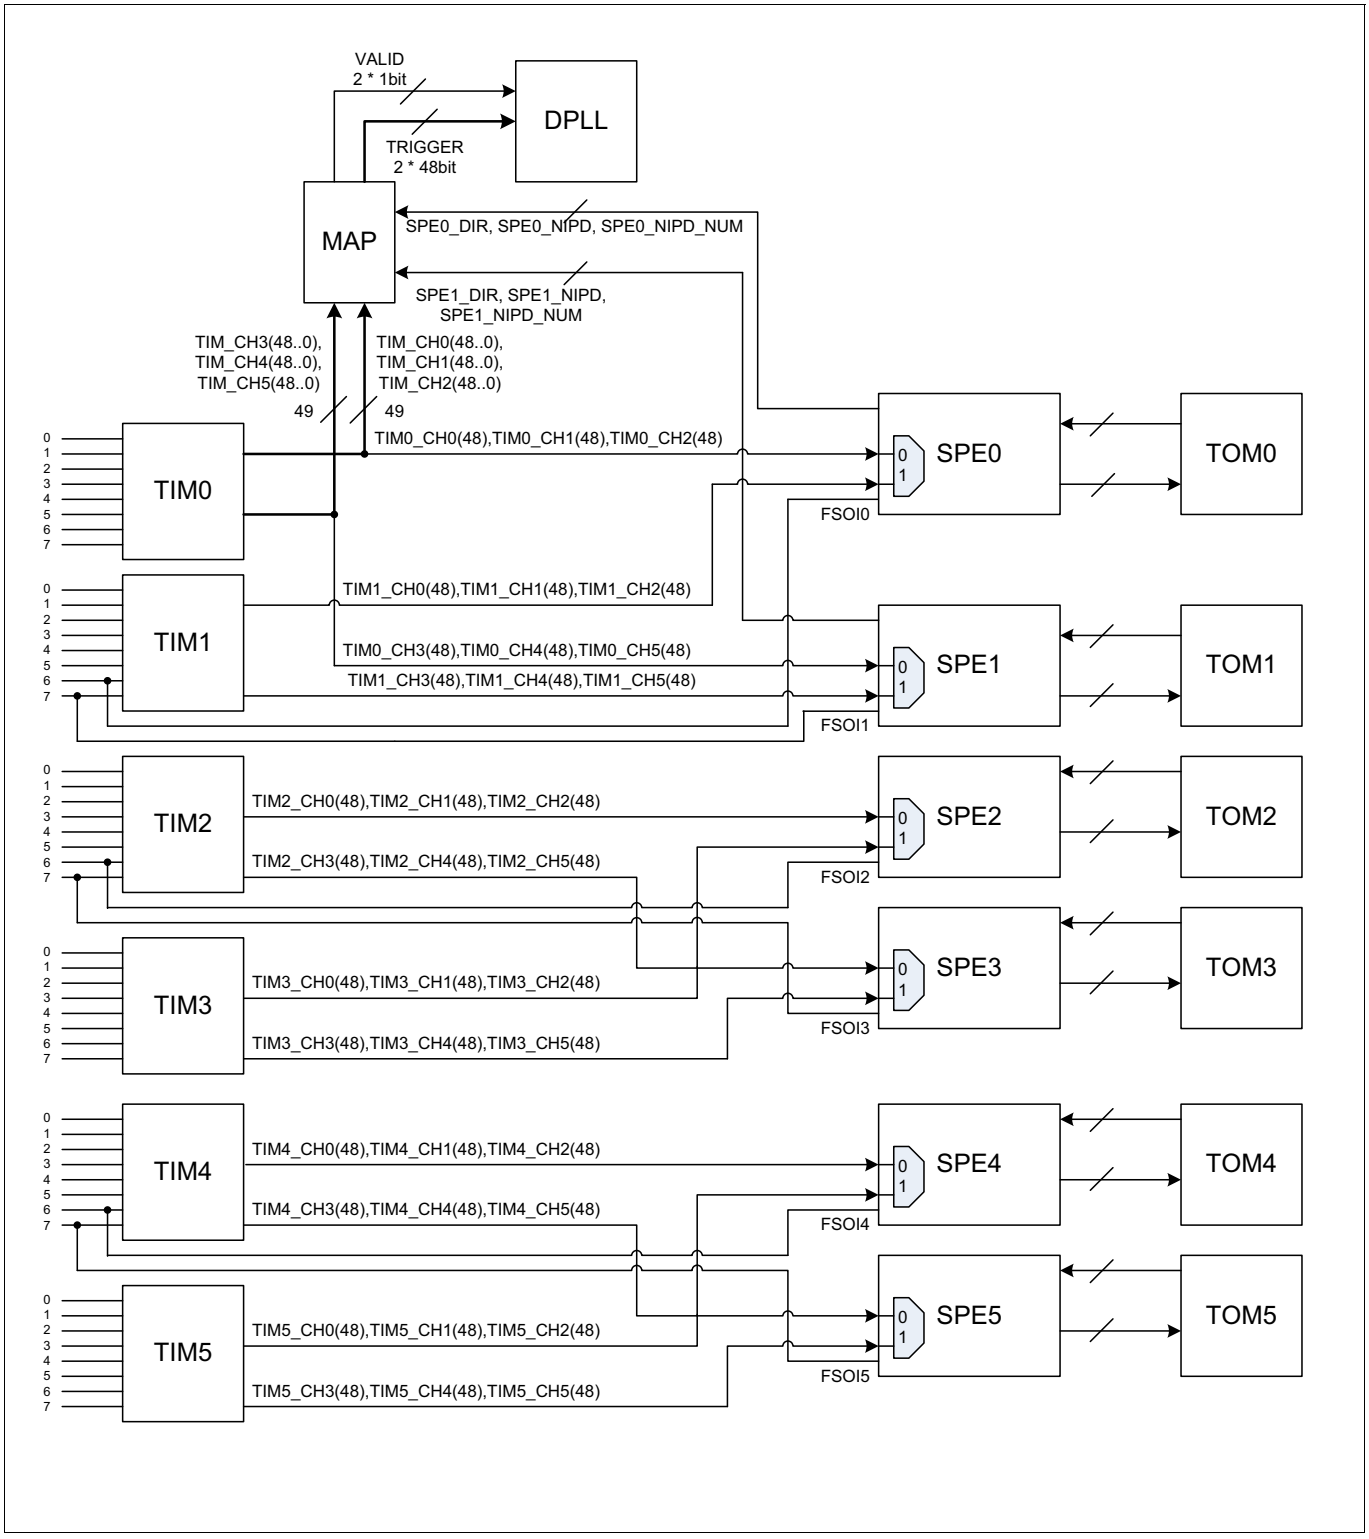

Figure 132 SPE Submodule integration concept into GTM

The SPE submodule can determine a rotation direction out of the combined *TIM[i]_CHx(48)*, *TIM[i]_CHy(48)* and *TIM[i]_CHz(48)* signals. On this input signals a pattern match algorithm is applied to generate the *SPEx_DIR* signal on behalf of the temporal relation between these input patterns. A possible sample pattern of the three input signals is shown in **Figure 133**. In general, the input pattern is programmable within the SPE submodule.

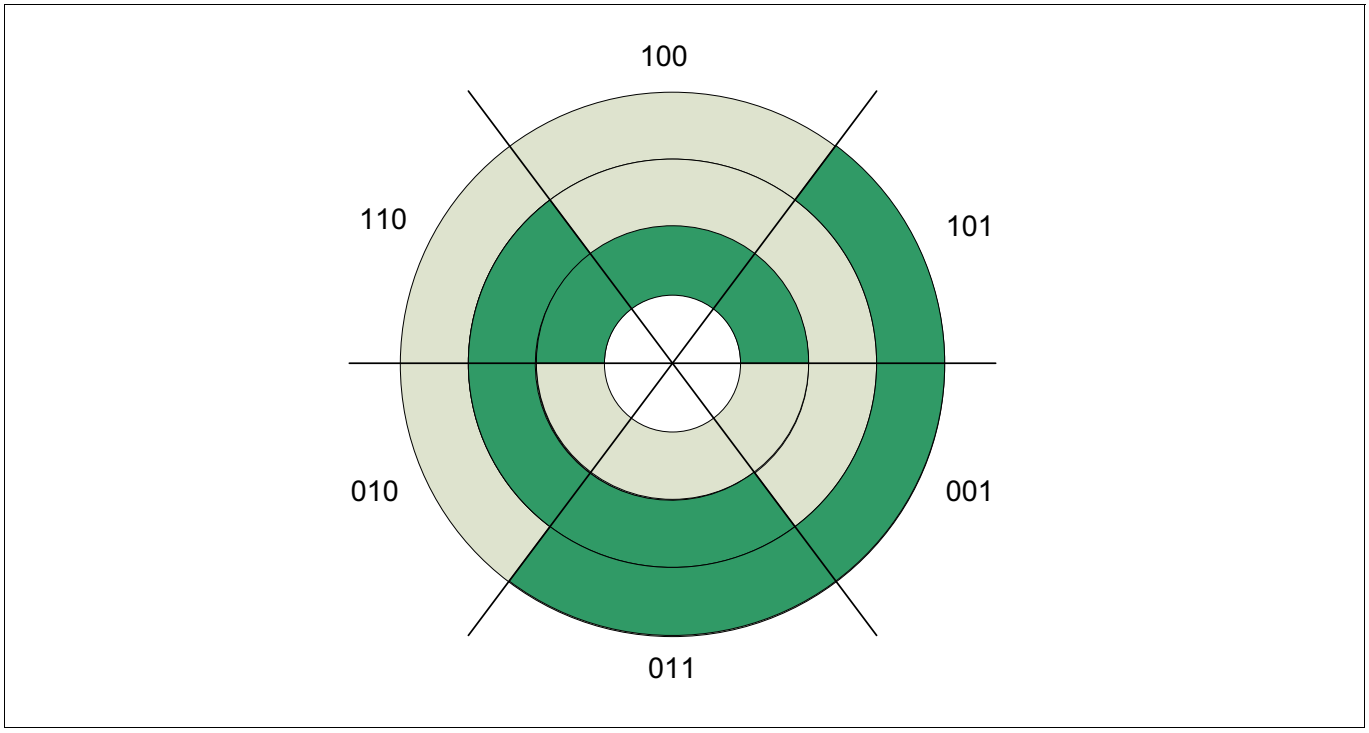

Figure 133 SPE Sample input pattern for TIM[i]_CH[x,y,z](48)

In **Figure 133** the input signals define the pattern from the input sensors which have a 50% high and 50% low phase. The pattern according to **Figure 133** is as follows:

100 – 110 – 010 – 011 – 001 – 101 – 100

where the first bit (smallest circle) represents *TIM[i]_CH[x](48)*, the second bit represents *TIM[i]_CH[y](48)*, and the third bit (greatest circle) represents *TIM[i]_CH[z](48)*.

Note that the SPE module expects that with every new pattern only one of the three input signals changes its value.

28.21.2 SPE Submodule description

The SPE submodule can handle sensor pattern inputs. Every time if one of the input signals *TIM[i]_CH[x](48)*,*TIM[i]_CH[y](48) or TIM[i]_CH[z](48)* changes its value, a sample of all three input signals is made. Derived from the sample of the three inputs the encoded rotation direction and the validity of the input pattern sequence is determined and signaled. When a valid input pattern is detected, the SPE submodule can control the outputs of a dedicated connected TOM submodule. This connection is shown in **Figure 134**.

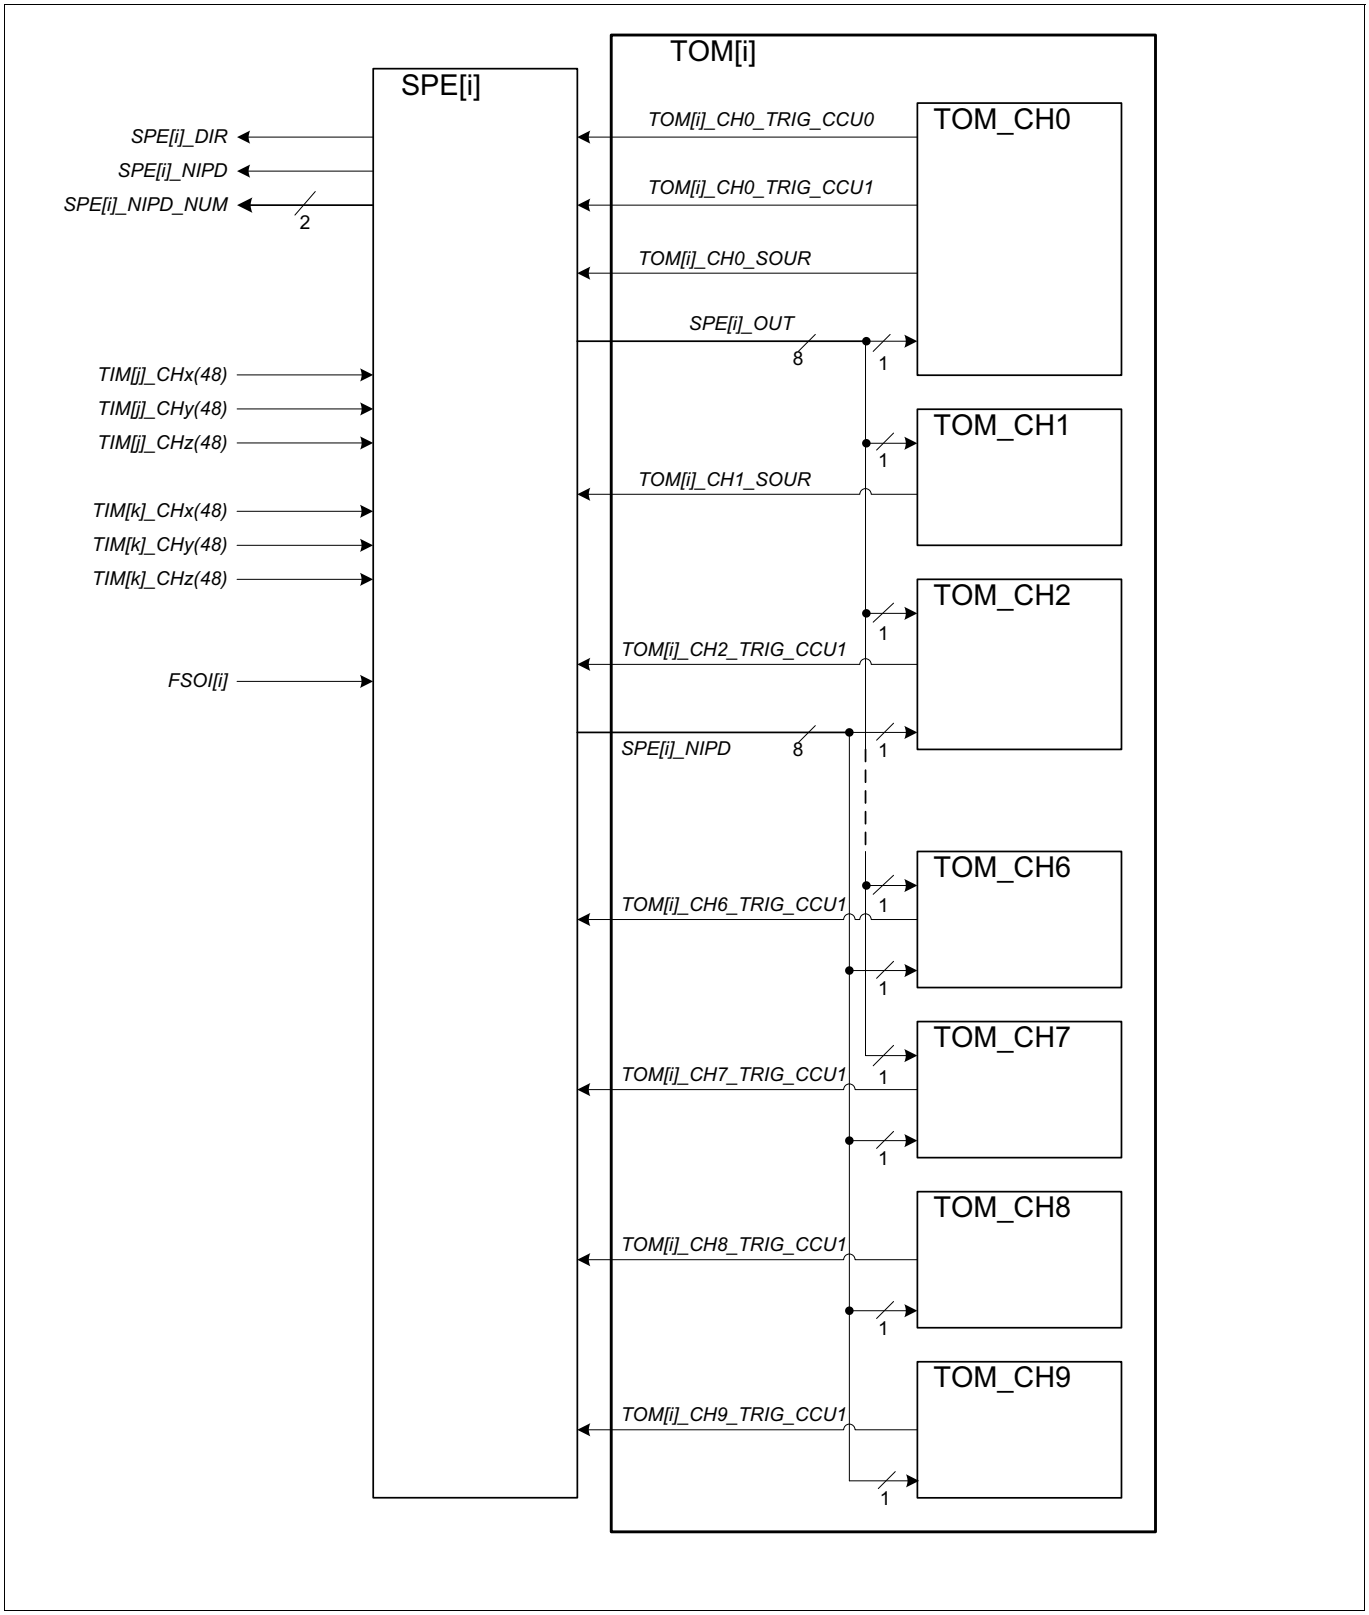

Figure 134 SPE to TOM Connections

The *TOM[i]_CH0_TRIG_CCU[x]* and *TOM[i]_CH[x]_SOUR* signal lines are used to evaluate the current state of the TOM outputs, whereas the *SPE[i]_OUT* output vector is used to control the TOM output depending on the new input pattern. The *SPE[i]_OUT* output vector is defined inside the SPE submodule in a pattern definition table **SPE[i]_OUT_PAT[x]**. The internal SPE submodule architecture is shown in **Figure 135**.

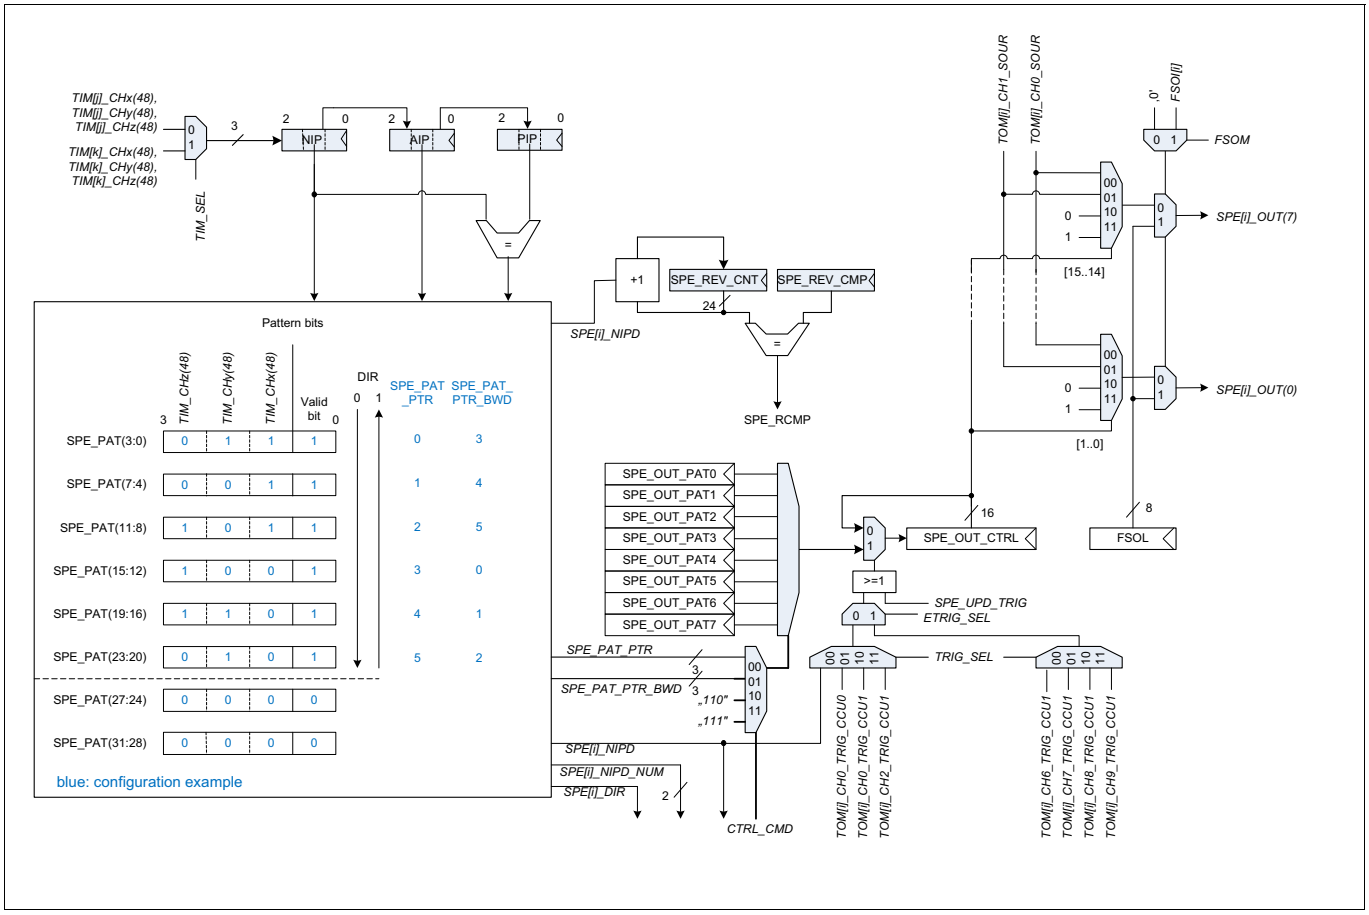

Figure 135 SPE Submodule architecture

The **SPE[i]_PAT** register holds the valid input pattern for the three input patterns *TIM[i]_CH[x](48)*, *TIM[i]_CH[y](48)* and *TIM[i]_CH[z](48)*. The input pattern is programmable. The valid bit shows if the programmed pattern is a valid one. **Figure 135** shows the programming of the **SPE[i]_PAT** register for the input pattern defined in **Figure 133**.

The rotation direction is determined by the order of the valid input pattern. This rotation direction defines if the *SPE_PAT_PTR* is incremented (DIR = 0) or decremented (DIR = 1). Whenever a valid input pattern is detected, the *NIPD* signal is raised, the *SPE_PAT_PTR* is incremented/decremented and a new output control signal *SPE[i]_OUT(x)* is send to the corresponding TOM submodule.

To command directly the forward or backward rotation the SPE provides with **SPE[i]_APT_PTR** and **SPE[i]_PAT_PTR_BWD** two pointers to array **SPE[i]_OUT_PAT[z].** Both can point to different values of **SPE[i]_OUT_PAT[z]** at the same point in time. **SPE[i]_APT_PTR** is intended to point to the pattern for forward commanding and **SPE[i]_PAT_PTR_BWD** is intended to point to the pattern for backward commanding.On startup both pointers have to be configured to an initial value that corresponds to different direction depending start pattern of **SPE[i]_OUT_PAT[z]**.With each valid new input pattern indicated by *SPE_NIPD* both pointers will be incremented or decremented according to the detected direction. Switching from command forward to command backward can then be done by changing the selected pointer to **SPE[i]_OUT_PAT[z]** array, i.e. changing **SPE_CTRL_CMD** in register **SPE[i]_CMD** from selecting **SPE[i]_PAT_PTR** to selecting **SPE[i]_PAT_PTR_BWD** or vice versa. The intended behavior is depicted in the following figure.

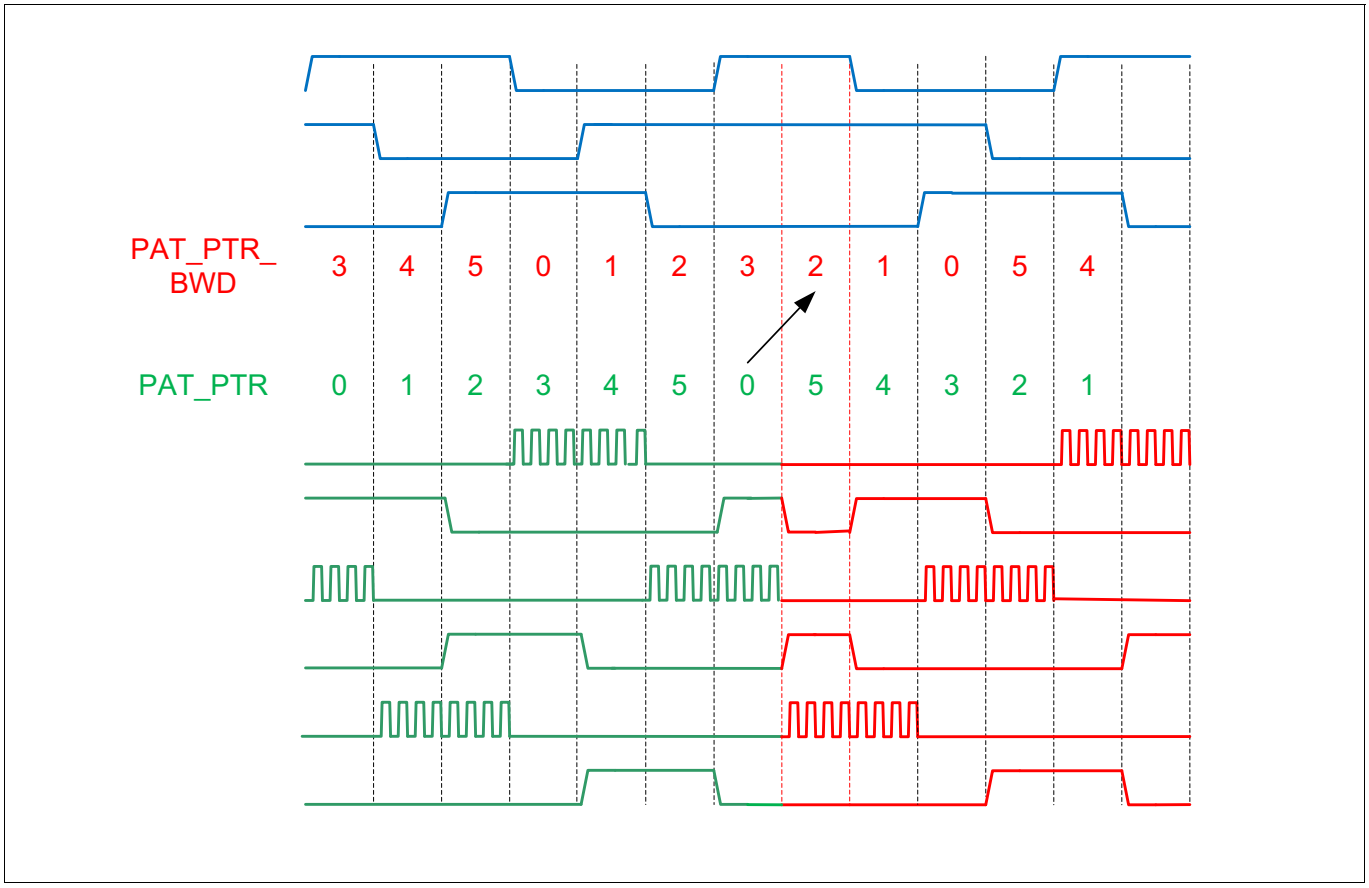

Figure 136 SPE forward - backward commanding

With command **SPE_CTRL_CMD** = 0b10 or 0b11 a dedicated configurable output pattern configured to the pattern **SPE_OUT_PAT6** or **SPE_OUT_PAT7** can be commanded to the outputs.

An example is the introduction of a SW dead time if switching from pointer **SPE[i]_PAT_PTR** to **SPE[i]_PAT_PTR_BWD** or vice versa. E.g. if in **SPE[i]_OUT_PAT6** the value 0b10 for each output (i.e. set *SPE_OUT(n)* to 0) is programmed, this can be used as an intermediate step to introduce this 'all off' when switching between **SPE[i]_PAT_PTR** to **SPE[i]_PAT_PTR_BWD** or vice versa.

Selectable by **TRIG_SEL** and **ETRIG_SEL** the CCU1 trigger of either the TOM channel 2,6,7,8 and 9 can be used together with the SPE module to trigger a delayed update of the **SPE_OUT_CTRL** register after new input pattern detected by SPE (signaled by *SPE[i]_NIPD*).

To do this, the TOM channel z=2,6,7,8 or 9 has to be configured to work in one-shot mode (set bit **OSM** in register **TOM[i]_CH[z]_CTRL**). The SPE trigger of this channel has to be enabled, too (set description of bit **SPEM** and bit **SPE_TRIG** in register **TOM[i]_CH[z]_CTRL**). The SPE module has to be configured to update **SPE_OUT_CTRL** on *TOM[i]_CH[z]_TRIG_CCU1* (set in **SPE[i]_CTRL_STAT** bits **TRIG_SEL** to 0b11). Then, on new input detected by SPE, the signal *SPE[i]_NIPD* triggers the start of the TOM channel z to generates one PWM period by resetting **CN0** to 0. On second PWM edge triggered by CCU1 of TOM channel z, the signal *TOM[i]_CH[z]_TRIG_CCU1* triggers the update of **SPE_OUT_CTRL**.

The update of **SPE[i]_OUT_CTRL** with the content of one of the **SPE_OUT_PAT[z]** register can be triggered at any time by writing a 1 to bit **SPE_UPD_TRIG** in register **SPE[i]_CMD**.

The regular trigger for update of **SPE[i]_OUT_CTRL** (commutation trigger) is selected by **TRIG_SEL** and **ETRIG_SEL**.

According to **Figure 135**, the two input patterns 0b000 and 0b111 are not allowed combinations and will end in a *SPE[i]_PERR* interrupt. These two patterns can be used to determine a sensor input error. A *SPE[i]_PERR*

interrupt will also be raised, if the input patterns occur in a wrong order, e.g. if the pattern 0b010 does not follow the pattern 0b110 or 0b011.

The register **SPE[i]_IN_PAT** bit field inside the **SPE[i]_CTRL_STAT** register is implemented, where the input pattern history is stored by the SPE submodule. The CPU can determine a broken sensor when the SPE[i]_PERR interrupt occurs by analyzing the bit pattern readable via bit field **NIP** inside the **SPE[i]_CTRL_STAT** register. The input pattern in the **SPE[i]_CTRL_STAT** register is updated whenever a valid edge is detected on one of the input lines *TIM[i]_CH[x](48)*, *TIM[i]_CH[y](48)* or *TIM[i]_CH[z](48)*. The pattern bit fields are then shifted. The input pattern history generation inside the **SPE[i]_CTRL_STAT** register is shown in **Figure 137**.

Additionally to the sensor pattern evaluation the SPE module also provides the feature of fast shutoff for all TOM channels controlled by the SPE module. The feature is enabled by setting bit **FSOM** in register **SPE[i]_CTRL_STAT**. The fast shutoff level itself is defined in the bit field **FSOL** of register **SPE[i]_CTRL_STAT**. The TIM input used to trigger the fast shutoff is either TIM channel 6 or TIM channel 7 depending on the TIM instance connected to the SPE module. For details of connections please refer to **Figure 132**.

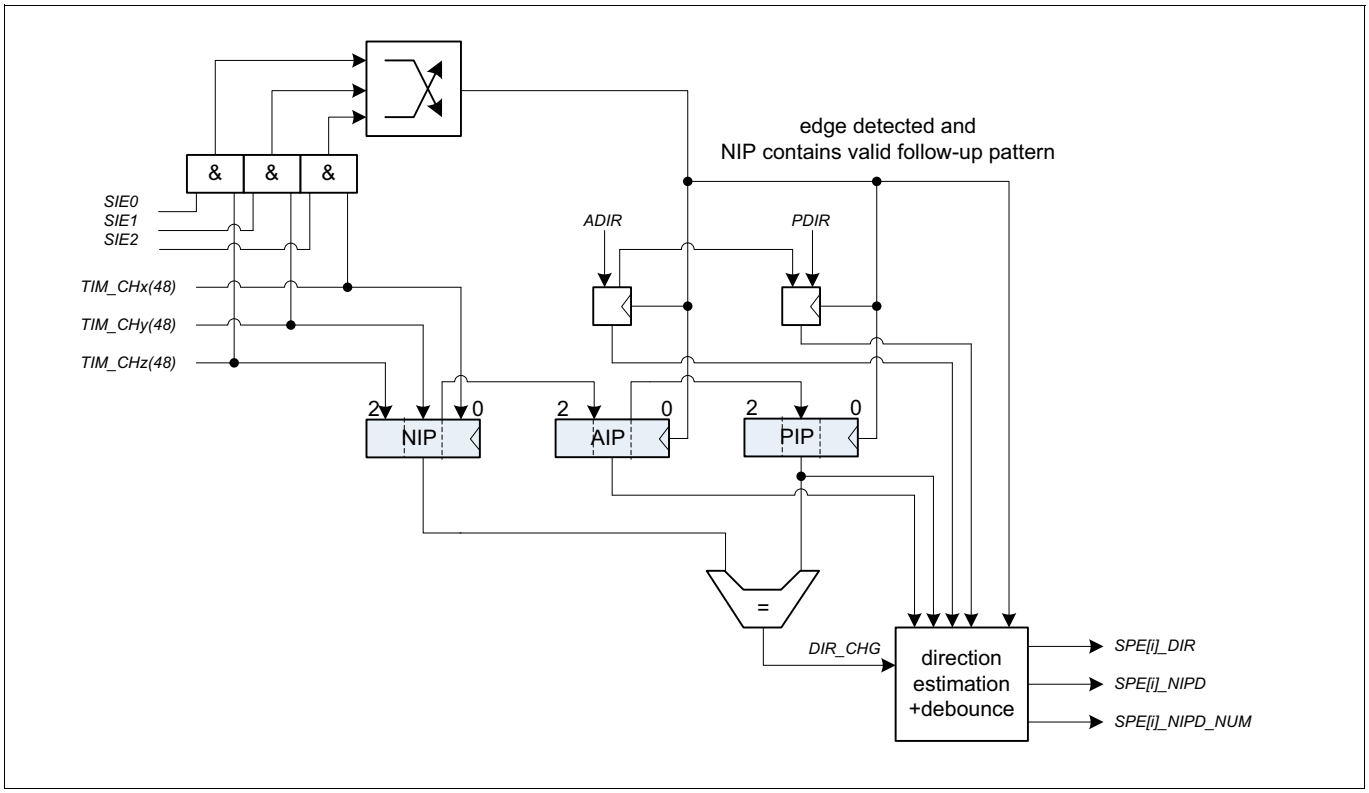

Figure 137 SPE[i]_IN_PAT register representation

The CPU can disable one of the three input signals, e.g. when a broken input sensor was detected, by disabling the input with the three input enable bits **SIE** inside the **SPE[i]_CTRL_STAT** register.

Whenever at least one of the input signal *TIM[i]_CH[x](48)*, *TIM[i]_CH[y](48)* or *TIM[i]_CH[z](48)* changes the SPE submodule stores the new bit pattern in an internal register NIP (New Input Pattern). If the current input pattern in **NIP** is the same as in the Previous Input Pattern (**PIP**) the direction of the engine changed, the *SPE[i]_DCHG* interrupt is raised, the direction change is stored internally and the pattern in the **PIP** bit field is filled with the **AIP** bit field and the **AIP** bit field is filled with the **NIP** bit field. The **SPE[i]_ADIR** bit inside the **SPE[i]_CTRL_STAT** register is toggled and the *SPE[i]_DIR* signal is changed.

If the SPE encounters that with the next input pattern detected new input pattern **NIP** the direction change again, the input signal is categorized as bouncing and the bouncing input signal interrupt *SPE[i]_BIS* is raised.

Immediately after update of register **NIP**, when the new detected input pattern doesn't match the **PIP** pattern (i.e. no direction change was detected), the SPE shifts the value of register **AIP** to register **PIP** and the value of register **NIP** to register **AIP**. The *SPE[i]_NIPD* interrupt is raised.

The number of the channel that has been changed and thus leads to the new input pattern is encoded in the signal *SPE[i]_NIPD_NUM*.

If a sensor error was detected, the CPU has to define upon the pattern in the **SPE[i]_CTRL_STAT** register, which input line comes from the broken sensor. The faulty signal line has to be masked by the CPU and the SPE submodule determines the rotation direction on behalf of the two remaining *TIM[i]_CH[x]* input lines.

The pattern history can be determined by the CPU by reading the two bit fields AIP and PIP of the **SPE[i]_CTRL_STAT** register. The **AIP** register field holds the actual detected input pattern at *TIM[i]_CH[x](48)*, *TIM[i]_CH[y](48)* and *TIM[i]_CH[z](48)* and the PIP holds the previous detected pattern.

After reset the register **NIP**, **AIP** and **PIP** as well as the register **SPE[i]_PAT_PTR** and **SPE[i]_OUT_CTRL** will not contain valid startup values which would allow correct behavior after enabling SPE and detecting the first input patterns.Thus, it is necessary to initialize these register to correct values.To do this, before enabling the SPE, the bit field **NIP** of register **SPE[i]_CTRL_STAT** can be read and depending on this value the initialization values for the register **AIP**, **PIP**, **SPT_PAT_PTR** and **SPE[i]_OUT_CTRL** can be determined.

28.21.2.1 SPE Revolution detection

The SPE submodule is able to detect and count the number of valid input patterns detected at the specified input ports. This is done with a 24 bit revolution counter **SPE_REV_CNT**. The counter is incremented by a value of one (1) when a new valid input pattern indicating forward direction is detected. The counter is decremented by a value of one (1) when a new valid input pattern indicating backward direction is detected.

In addition there exists a 24 bit **SPE_REV_CMP** register. The user can initialize this register with a compare value, where an interrupt *SPE[i]_RCMP* is raised, when the revolution counter equals the compare value either in forward or backward direction.

Both register may be written by software at any time.

28.21.3 SPE Interrupt signals

Table 145 SPE Interrupt signals

Signal	Description
SPE[i]_NIPD	SPE New valid input pattern detected.
SPE[i]_DCHG	SPE Rotation direction change detected on behalf of input pattern.
SPE[i]_PERR	SPE Invalid input pattern detected.
SPE[i]_BIS	SPE Bouncing input signal detected at input.
SPE[i]_RCMP	SPE Revolution counter compare value reached.

28.21.4 SPE Register overview

Table 146 SPE Register overview

Register name	Description	see Page
SPE[i]_CTRL_STAT	SPEi Control status register	670
SPE[i]_PAT	SPEi Input pattern definition register.	671
SPE[i]_OUT_PAT[z]	SPEi Output definition register.	672
SPE[i]_OUT_CTRL	SPEi output control register	673
SPE[i]_REV_CNT	SPEi input revolution counter	674
SPE[i]_REV_CMP	SPEi Revolution counter compare value	674
SPE[i]_IRQ_NOTIFY	SPEi Interrupt notification register.	675
SPE[i]_IRQ_EN	SPEi Interrupt enable register.	676
SPE[i]_EIRQ_EN	SPEi Error interrupt enable register.	678
SPE[i]_IRQ_FORCINT	SPEi Interrupt generation by software.	677
SPE[i]_IRQ_MODE	SPEi Interrupt mode configuration register	678
SPE[i]_CTRL_STAT2	SPEi Control status register 2	679
SPE[i]_CMD	SPEi Command register	680

28.21.5 SPE Register description

Field	Bits	Type	Description
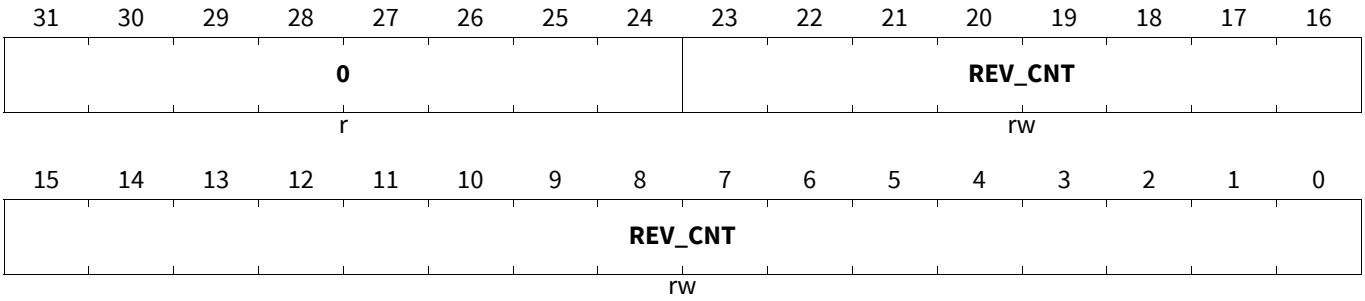
SPE_OUT_CTRL	15:0	rw	**SPE output control value for TOM_CH0 to TOM_CH7** SPE_OUT_CTRL[n+1:n] defines output select signal of TOM_CHn. Current output control selection for SPE[i]_OUT(0..7). 0000_HSet SPE_OUT(n) to TOM_CH0_SOUR 0001_HSet SPE_OUT(n) to TOM_CH1_SOUR 0002_HSet SPE_OUT(n) to 0 0003_HSet SPE_OUT(n) to 1 with n: 0..7
0	31:16	r	**Reserved** Read as zero, shall be written as zero.

28.21.5.5 Register SPE[i]_REV_CNT

SPEi Input Revolution Counter

SPEi_REV_CNT (i=0-5)
SPEi Input Revolution Counter **(000840_H+i*80_H)** **Application Reset Value: 0000 0000_H**

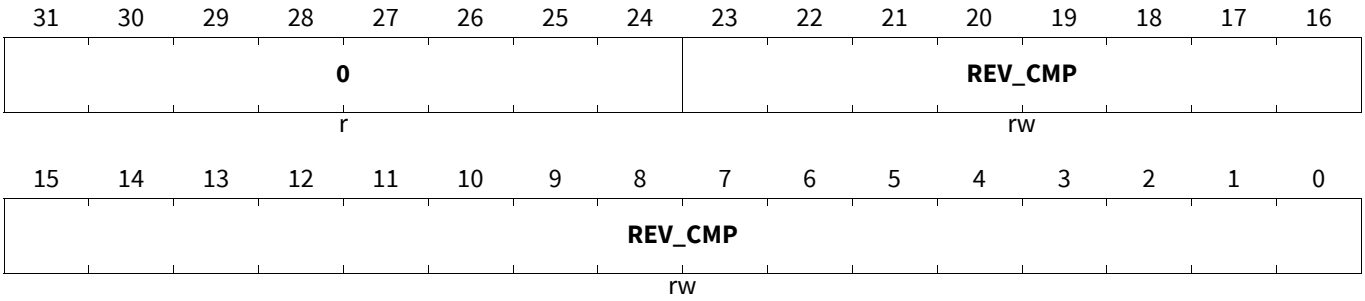


Field	Bits	Type	Description
REV_CNT	23:0	rw	**Input signal revolution counter** The counter is running if SPE module is enabled (bit SPE_EN). REV_CNT is incrementing if SPE_PAT_PTR is incrementing. REV_CNT is decrementing if SPE_PAT_PTR is decrementing-
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.21.5.6 Register SPE[i]_REV_CMP

SPEi Revolution Counter Compare Value

SPEi_REV_CMP (i=0-5)
SPEi Revolution Counter Compare Value **(000844_H+i*80_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
REV_CMP	23:0	rw	**Input signal revolution counter compare value** The interrupt *SPE[i]_RCMP* is raised when the SPE[i]_REV_CNT value equals the SPE[i]_REV_CMP register. It should be noted that *SPE[i]_RCMP* is only raised if an incrementation or decrementation of SPE[i]_REV_CNT is applied, due to an input signal change. Any update of SPE[i]_REV_CNT or SPE[i]_REV_CMP via AEI does not raise a *SPE[i]_RCMP* interrupt.

Field	Bits	Type	Description
0	31:24	r	**Reserved** Read as zero, shall be written as zero.

28.21.5.7 Register SPE[i]_IRQ_NOTIFY

SPEi Interrupt Notification Register

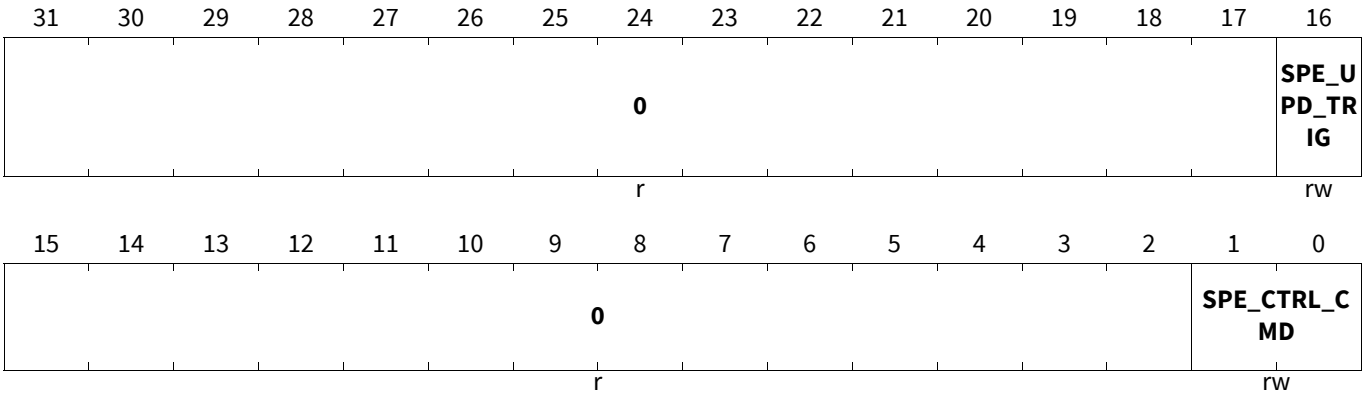
0					SPE_PAT_PTR_BWD			0							
r					rw			r							

Field	Bits	Type	Description
SPE_PAT_PTR_BWD	10:8	rw	**Pattern selector for TOM output signals in case of SPE_CTRL_CMD = 0b01 (e.g. backward direction)** Index into the SPE[i]_OUT_PAT[z] register table in case of SPE_CTRL_CMD = 0b01 which may be used for backward direction. Each register SPE[i]_OUT_PAT[x] is fixed assigned to one bit field IPx_PAT of register SPE[i]_PAT. Thus, the pointer SPE[i]_PAT_PTR_BWD represents an index to the selected SPE[i]_OUT_PAT[x] register as well as the actual detected input pattern IPx_PAT. The index pointer SPE_PAT_PTR_BWD is used if SPE_CTRL_CMD = 0b01. The index pointer SPE_PAT_PTR is used if SPE_CTRL_CMD = 0b00 (by default).
0	7:0, 31:11	r	**Reserved** Read as zero, shall be written as zero.

28.21.5.13Register SPE[i]_CMD

SPEi Command register

SPEi_CMD (i=0-5)
SPEi Command register **($00084C_H$+i*80_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
SPE_CTRL_CMD	1:0	rw	**SPE control command** 00_B Use SPE_PAT_PTR as an index pointer to select SPE[i]_OUT_PAT[z] 01_B Use SPE_PAT_PTR_BWD as an index pointer to select SPE[i]_OUT_PAT[z] 10_B Select SPE[i]_OUT_PAT6 11_B Select SPE[i]_OUT_PAT7
SPE_UPD_TRIG	16	rw	**SPE updater trigger** 1 = trigger update of SPE_OUT_CTRL with register selected by CTR_CMD multiplexer. This bit is automatically reset to 0.
0	15:2, 31:17	r	**Reserved** Read as zero, shall be written as zero.

28.22 Interrupt Concentrator Module (ICM)

28.22.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM interrupt lines of the individual sub-modules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM.

The individual interrupts of the GTM sub-modules and channels have to be enabled or disabled inside the sub-modules and channels.

The feed through architecture of bundled interrupt lines is used for the sub-modules AEI, ARU, BRC, CMP, SPE, PSM, TIM, DPLL, TOM, ATOM and MCS.

To determine the detailed interrupt source the microcontroller has to read the sub-module/channel interrupt notification register **NOTIFY** and serve the channel individual interrupt.

Please note, that the interrupts are only visible inside the ICM and in consequence outside of the GTM, when the interrupt is enabled inside the sub-modules themselves.

28.22.2 Bundling

The GTM sub-module individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signaled to the outside world or bundled a second time into groups and are then signaled to the outside world.The ICM interrupt bundling is described in the following sections.

28.22.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI, ARU, BRC, PSM, SPE and CMP sub-modules. In this interrupt group each individual channel of the sub-modules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM sub-module channel that raised the interrupt. The interrupts are also represented in the **ICM_IRQG_0** register. This register is typically not read by the CPU, but it is readable.

In addition the interrupt line status for 8 channels of each FIFO are shown in the **ICM_IRQG_PSM_0_CI** register. Typically, the interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_PSM_0_CI** register are typically not read out by the CPU, but they are readable.

In addition the interrupt line status for each SPE are shown in the **ICM_IRQG_SPE_CI** register. Typically, the interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_SPE_CI** register are typically not read out by the CPU, but they are readable.

28.22.2.2 DPLL Interrupt Bundling

The DPLL Interrupt group handles the interrupts coming from the DPLL sub-module of the GTM. Each of the individual DPLL interrupt lines has its own dedicated interrupt line to the outside world. The interrupts are additionally identified in the **ICM_IRQG_1** interrupt group register. This register is typically not read out by the CPU, but it is readable.

28.22.2.3 TIM Interrupt Bundling

Inside this group sub-modules which handle GTM input signals are treated. This is the case for the TIM[i] sub-modules. Each TIM sub-module channel is able to generate six (6) individual interrupts if enabled inside the TIM channel. This six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM 32 interrupt lines *TIM[i]_IRQ*[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the **ICM_IRQG_2** and **ICM_IRQG_3** registers are mirrors for the TIM sub-module channel interrupts and typically not read out by the CPU, but it is readable.

Note: The above text is identical to the Bosch text published inside the GTM IP 3.1.5.1 specification. According to the migration guide provided by Bosch AE, the interrupt system scales in the amount with the number TIM modules. Each TIM provides 8 interrupt outputs according to the IRQG_2 and _3 registers. Therefore for adevice with 8 TIM modules 64 interrupts are provided to the outside of the GTM IP module. If Bosch AE publishes a new text this text will be provided by Infineon.

28.22.2.4 MCS Interrupt Bundling

For complex signal output generation, the MCS sub-modules are used inside the GTM. Each of these MCS sub-modules could have 8 channels with one interrupt line. This interrupt line is connected to the ICM sub-module and is feed through directly to the outside world.

In addition the interrupt line status for the first 8 channels of each MCS is shown in the **ICM_IRQG_4** and **ICM_IRQG_5** register. The interrupt line status for all used channels of each MCS are shown in the **ICM_IRQG_MCS[i]_CI** register. Typically, the interrupt source is determined by the corresponding interrupt line and the **ICM_IRQ4(/_5)** and **ICM_IRQG_MCS[i]_CI** register are typically not read out by the CPU, but they are readable.

28.22.2.5 TOM and ATOM Interrupt Bundling

For the TOM and ATOM sub-modules, the interrupts are bundled within the ICM sub-module a second time to reduce external interrupt lines. The interrupts are ORed in a manner that one GTM external interrupt line represents two adjacent TOM or ATOM channel interrupts. For TOM[i] and ATOM[i] the bundling is shown in **Figure 138**.

TOM[i]-input IRQs [i]=0..number of TOM's-1	TOM-output IRQs (OR-ed)		ATOM[i]-input IRQs [i]=0..number of ATOM's-1	ATOM-output IRQs (OR-ed)
TOM[i]_CH0_IRQ	GTM_TOM[i]_IRQ[0]		ATOM[i]_CH0_IRQ	GTM_ATOM[i]_IRQ[0]
TOM[i]_CH1_IRQ			ATOM[i]_CH1_IRQ	
TOM[i]_CH2_IRQ	GTM_TOM[i]_IRQ[1]		ATOM[i]_CH2_IRQ	GTM_ATOM[i]_IRQ[1]
TOM[i]_CH3_IRQ			ATOM[i]_CH3_IRQ	
TOM[i]_CH4_IRQ	GTM_TOM[i]_IRQ[2]		ATOM[i]_CH4_IRQ	GTM_ATOM[i]_IRQ[2]
TOM[i]_CH5_IRQ			ATOM[i]_CH5_IRQ	
TOM[i]_CH6_IRQ	GTM_TOM[i]_IRQ[3]		ATOM[i]_CH6_IRQ	GTM_ATOM[i]_IRQ[3]
TOM[i]_CH7_IRQ			ATOM[i]_CH7_IRQ	
TOM[i]_CH8_IRQ	GTM_TOM[i]_IRQ[4]			
TOM[i]_CH9_IRQ				
TOM[i]_CH10_IRQ	GTM_TOM[i]_IRQ[5]			
TOM[i]_CH11_IRQ				
TOM[i]_CH12_IRQ	GTM_TOM[i]_IRQ[6]			
TOM[i]_CH13_IRQ				
TOM[i]_CH14_IRQ	GTM_TOM[i]_IRQ[7]			
TOM[i]_CH15_IRQ				

Figure 138 TOM and ATOM interrupt bundling within ICM

The interrupts coming from the TOM[i] sub-modules are registered in the **ICM_IRQG_6 / ICM_IRQG_7 / ICM_IRQG_8** register. Always two TOM's are bundled in one ICM register, TOM0 and TOM1 are bundled in **ICM_IRQG_6**. To identify the TOM sub-module channel where the interrupt occurred, the CPU has to read out the **ICM_IRQG_6(/_7/_8)** register first before it goes to the TOM sub-module channel itself.

The **ICM_IRQG_6(/_7/_8)** register bits are cleared automatically, when their corresponding interrupt in the sub-module channels is cleared.

The interrupts coming from the ATOM[i] sub-modules are registered in the **ICM_IRQG_9** / **ICM_IRQG_10 /ICM_IRQG_11** register. Always four ATOM's are bundled in one ICM register. ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in **ICM_IRQG_9.** To identify the ATOM sub-module channel where the interrupt occurred, the CPU has to read out the **ICM_IRQG_9(/_10/_11)** register first before it goes to the ATOM sub-module channel itself.

The **ICM_IRQG_9(/_10/_11)** register bits are cleared automatically, when their corresponding interrupt in the sub-module channels is cleared.

In addition the interrupt line status of two 16 channels TOM are shown in each **ICM_IRQG_TOM_[k]_CI (k:0...2)** register, TOM0 and TOM1 are bundled in **ICM_IRQG_TOM_0_CI**. Typically, the interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_TOM_[k]_CI** register are typically not read out by the CPU, but they are readable.

In addition the interrupt line status of four 8 channels ATOM are shown in each **ICM_IRQG_ATOM_[k]_CI (k:0...2)** register, ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in **ICM_IRQG_ATOM_0_CI**. Typically, the interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_ATOM_[k]_CI** register are typically not read out by the CPU, but they are readable.

28.22.2.6 Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the BRC, FIFO, TIM, MCS, SPE, CMP, DPLL sub-module of the GTM. The Module Error interrupts are additionally identified in the **ICM_IRQG_MEI** error interrupt group register. This register is typically not read out by the CPU, but it is readable.

In addition the error interrupt line status for each SPE are shown in the **ICM_IRQG_SPE_CEI** register. Typically, the error interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_SPE_CEI** register are typically not read out by the CPU, but they are readable.

28.22.2.7 FIFO Channel Error Interrupt Bundling

The FIFO Channel Error Interrupt group handles the error interrupts coming from the FIFO channel of the GTM. The FIFO Channel Error interrupts are additionally identified in the **ICM_IRQG_CEI0** error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The **ICM_IRQG_CEI0** register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

In addition the error interrupt line status for 8 channels of each FIFO are shown in the **ICM_IRQG_PSM_0_CEI** register. Typically, the error interrupt source is determined by the corresponding interrupt line and the **ICM_IRQG_PSM_0_CEI** register are typically not read out by the CPU, but they are readable.

28.22.2.8 TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM. The TIM Channel Error interrupts are additionally identified for the sub-modules TIM0, TIM1, TIM2 and TIM3 in the **ICM_IRQG_CEI1** error interrupt group register and for the sub-modules TIM4, TIM5 and TIM6 in the **ICM_IRQG_CEI2** error interrupt group register. These register are typically not read out by the CPU, but they are readable.

The **ICM_IRQG_CEI1** and **ICM_IRQG_CEI2** register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

28.22.2.9 MCS Channel Error Interrupt Bundling

The MCS Channel Error Interrupt group handles the error interrupts coming from the MCS channel of the GTM. All used 8 MCS Channel Error interrupts are additionally identified for each sub-modules MCS[i] in the **ICM_IRQG_MCS[i]_CEI** error interrupt group register. The first 8 MCS Channel Error interrupts are additionally identified for the sub-modules MCS0, MCS1, MCS2 and MCS3 in the **ICM_IRQG_CEI3** error interrupt group register and for the sub-modules MCS4, MCS5, MCS6 and MCS7 in the **ICM_IRQG_CEI4** error interrupt group register. These register are typically not read out by the CPU, but they are readable.

The **ICM_IRQG_MCS[i]_CEI**, **ICM_IRQG_CEI3** and **ICM_IRQG_CEI4** register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

28.22.2.10 Error Interrupt Cluster Bundling

The Error Interrupt lines of up to 4 clusters are bundled in each **ICM_IRQG_CLS_[i]_MEI**.Actually each cluster collects one EIRQ of one TIM, MCS, SPE and FIFO.These register are typically not read out by the CPU, but they are readable.

28.22.3 ICM Interrupt Signals

Table 147 ICM Interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_ARU_IRQ[2:0]	[0]: ARU_NEW_DATA0 Interrupt [1]: ARU_NEW_DATA1 Interrupt [2]: ARU_ACC_ACK Interrupt
GTM_BRC_IRQ	BRC Shared interrupt
GTM_CMP_IRQ	CMP Shared interrupt
GTM_SPE[i]_IRQ	SPE Shared interrupt (i: 0…number of SPE's-1)
GTM_PSM[i]_IRQ[x]	PSM Shared interrupts (x: 0…7) (i: 0…number of PSM's-1)
GTM_DPLL_IRQ[0]	DPLL_DCGI: DPLL direction change interrupt
GTM_DPLL_IRQ[1]	DPLL_EDI; DPLL enable or disable interrupt
GTM_DPLL_IRQ[2]	DPLL_TINI: DPLL TRIG. min. hold time (THMI) viol. detected
GTM_DPLL_IRQ[3]	DPLL_TAXI: DPLL TRIG. max. hold time (THMA) viol. detected
GTM_DPLL_IRQ[4]	DPLL_SISI: DPLL STATE inactive slope detected
GTM_DPLL_IRQ[5]	DPLL_TISI: DPLL TRIGGER inactive slope detected
GTM_DPLL_IRQ[6]	DPLL_MSI: DPLL Missing STATE interrupt
GTM_DPLL_IRQ[7]	DPLL_MTI: DPLL Missing TRIGGER interrupt
GTM_DPLL_IRQ[8]	DPLL_SASI: DPLL STATE active slope detected
GTM_DPLL_IRQ[9]	DPLL_TASI: DPLL TRIG. active slope det. while NTI_CNT is 0
GTM_DPLL_IRQ[10]	DPLL_PWI: DPLL Plausibility window (PVT) viol. int. of TRIG.
GTM_DPLL_IRQ[11]	DPLL_W2I: DPLL Write access to RAM region 2 interrupt
GTM_DPLL_IRQ[12]	DPLL_W1I: DPLL Write access to RAM region 1b or 1c int.
GTM_DPLL_IRQ[13]	DPLL_GL1I: DPLL Get of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[14]	DPLL_LL1I: DPLL Lost of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[15]	DPLL_EI: DPLL Error interrupt
GTM_DPLL_IRQ[16]	DPLL_GL2I: DPLL Get of lock interrupt for SUB_INC2
GTM_DPLL_IRQ[17]	DPLL_LL2I: DPLL Lost of lock interrupt for SUB_INC2
GTM_DPLL_IRQ[18]	DPLL_TE0I: DPLL TRIGGER event interrupt 0
GTM_DPLL_IRQ[19]	DPLL_TE1I: DPLL TRIGGER event interrupt 1
GTM_DPLL_IRQ[20]	DPLL_TE2I: DPLL TRIGGER event interrupt 2
GTM_DPLL_IRQ[21]	DPLL_TE3I: DPLL TRIGGER event interrupt 3
GTM_DPLL_IRQ[22]	DPLL_TE4I; DPLL TRIGGER event interrupt 4
GTM_DPLL_IRQ[23]	DPLL_CDTI; DPLL calculated duration interrupt for TRIGGER
GTM_DPLL_IRQ[24]	DPLL_CDSI; DPLL calculated duration interrupt for STATE
GTM_DPLL_IRQ[25]	DPLL_TORI; TRIGGER out of range interrupt
GTM_DPLL_IRQ[26]	DPLL_SORI; STATE out of range interrupt
GTM_TIM[i]_IRQ[x]	TIM Shared interrupts (i: 0…number of TIM's-1) (x: 0…7)
GTM_MCS[i]_IRQ[x]	MCS Interrupt for channel x (x: 0…8) (i: 0…number of MCS's-1)
GTM_TOM[i]_IRQ[x]	TOM Shared interrupts for x:0…7 = {ch0||ch1…ch14||ch15} (i: 0…number of TOM's-1)

Table 147 ICM Interrupt Signals (cont'd)

Signal	Description
GTM_ATOM[i]_IRQ[x]	ATOM Shared interrupts for x:0…3 = {ch0||ch1…ch6||ch7} (i: 0…number of ATOM's-1)
GTM_ERR_IRQ	GTM Error Interrupt

Above table shows the GTM interrupt lines that are visible at the outside of the IP.

28.22.4 ICM Configuration Register Overview

Table 148 ICM Configuration Register Overview

Register Name	Description	see Page
ICM_IRQG_0	ICM Interrupt group register covering infrastructure and safety components (ARU, BRC, AEI, PSM0, PSM1, MAP, CMP,SPE)	689
ICM_IRQG_1	ICM Interrupt group register covering DPLL	690
ICM_IRQG_2	ICM Interrupt group register covering TIM0, TIM1, TIM2, TIM3	692
ICM_IRQG_3	ICM Interrupt group register covering TIM4, TIM5, TIM6, TIM7	694
ICM_IRQG_4	ICM Interrupt group register covering MCS0 to MCS3 sub-modules	695
ICM_IRQG_5	ICM Interrupt group register covering MCS4 to MCS6 sub-modules	696
ICM_IRQG_6	ICM Interrupt group register covering GTM output sub-modules TOM0 to TOM1	697
ICM_IRQG_7	ICM Interrupt group register covering GTM output sub-modules TOM2 to TOM3	698
ICM_IRQG_8	ICM Interrupt group register covering GTM output sub-modules TOM4 to TOM5	699
ICM_IRQG_9	ICM Interrupt group register covering GTM output sub-modules ATOM0, ATOM1, ATOM2 and ATOM3	700
ICM_IRQG_10	ICM Interrupt group register covering GTM output sub-modules ATOM4 to ATOM7	701
ICM_IRQG_11	ICM Interrupt group register covering GTM output sub-modules ATOM8 to ATOM11	702
ICM_IRQG_MEI	ICM Interrupt group register for module error interrupt information	703
ICM_IRQG_CEI0	ICM Interrupt group register 0 for channel error interrupt information	705
ICM_IRQG_CEI1	ICM Interrupt group register 1 for channel error interrupt information	706
ICM_IRQG_CEI2	ICM Interrupt group register 2 for channel error interrupt information	707
ICM_IRQG_CEI3	ICM Interrupt group register 3 for channel error interrupt information	708
ICM_IRQG_CEI4	ICM Interrupt group register 4 for channel error interrupt information	709
ICM_IRQG_MCS[i]_CI	ICM Interrupt group MCS i for Channel Interrupt information	710
ICM_IRQG_MCS[i]_CEI	ICM Interrupt group MCS i for Channel Error Interrupt information	710
ICM_IRQG_SPE_CI	ICM Interrupt group SPE for module Interrupt information	711
ICM_IRQG_SPE_CEI	ICM Interrupt group SPE for module Error Interrupt information	712
ICM_IRQG_PSM_0_CI	ICM Interrupt group PSM 0 for Channel Interrupt information of FIFO0, FIFO1, FIFO2	712
ICM_IRQG_PSM_0_CEI	ICM Interrupt group PSM 0 for Channel Error Interrupt information of FIFO0, FIFO1, FIFO2	713
ICM_IRQG_TOM_[k]_CI	ICM Interrupt group TOM k for Channel Interrupt information of TOMm	714

Table 148 ICM Configuration Register Overview (cont'd)

Register Name	Description	see Page
ICM_IRQG_ATOM_[k]_CI	ICM Interrupt group ATOM k for Channel Interrupt information of ATOMm	715
ICM_IRQG_CLS_[k]_MEI	ICM Interrupt group for module Error Interrupt information for each TIMm, MCSm, SPEm, FIFOm	716

28.22.5 ICM Configuration Register Description

28.22.5.1 Register ICM_IRQG_0

ICM Interrupt Group Register Covering Infrastructural and Safety Components ARU, BRC, AEI, PSM0, PSM1, MAP, CMP, SPE

ICM_IRQG_0
ICM Interrupt Group Register Covering Infrastructural and Safety Components ARU, BRC, AEI, PSM0, PSM1, MAP, CMP, SPE **(000600_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				SPE5_IRQ	SPE4_IRQ	SPE3_IRQ	SPE2_IRQ	SPE1_IRQ	SPE0_IRQ	CMP_IRQ	AEI_IRQ	BRC_IRQ	ARU_ACC_ACK_IRQ	ARU_NEW_DATA1_IRQ	ARU_NEW_DATA0_IRQ
r				r	r	r	r	r	r	r	r	r	r	r	r

Field	Bits	Type	Description
ARU_NEW_DATA0_IRQ	0	r	**ARU_NEW_DATA0 interrupt** This bit is only set when the interrupt is enabled in the interrupt enable register of the corresponding sub-module. 0_B No interrupt occurred 1_B Interrupt was raised by the corresponding sub-module
ARU_NEW_DATA1_IRQ	1	r	**ARU_NEW_DATA1 interrupt** Bit coding see bit 0.
ARU_ACC_ACK_IRQ	2	r	**ARU_ACC_ACK interrupt** Bit coding see bit 0.
BRC_IRQ	3	r	**BRC shared sub-module interrupt** Bit coding see bit 0.
AEI_IRQ	4	r	**AEI_IRQ interrupt** Bit coding see bit 0. Set this bit represents an OR function of the seven interrupt sources *AEI_TO_XPT*, *AEI_USP_ADDR*, *AEI_IM_ADDR*, *AEI_USP_BE*, *AEIM_USP_ADDR*, *AEIM_IM_ADDR* or *AEIM_USP_BE*.
CMP_IRQ	5	r	**CMP shared sub-module interrupt** Bit coding see bit 0.
SPE0_IRQ	6	r	**SPE0 shared sub-module interrupt** Bit coding see bit 0. Set this bit represents an OR function of the five interrupt sources *SPE_NIPD*, *SPE_DCHG*, *SPE_PERR*, *SPE_BIS* or *SPE_RCMP* of SPE instance 0.

Field	Bits	Type	Description
SPE1_IRQ	7	r	**SPE1 shared sub-module interrupt** See bit 0 and bit 6.
SPE2_IRQ	8	r	**SPE2 shared sub-module interrupt** See bit 0 and bit 6.
SPE3_IRQ	9	r	**SPE3 shared sub-module interrupt** See bit 0 and bit 6.
SPE4_IRQ	10	r	**SPE4 shared sub-module interrupt** See bit 0 and bit 6.
SPE5_IRQ	11	r	**SPE5 shared sub-module interrupt** See bit 0 and bit 6.
PSM0_CHx_IRQ (x=0-7)	x+16	r	**PSM0 shared sub-module channel x interrupt** See bit 0 and bit 6. Set this bit represents an OR function of the four interrupt sources *FIFO_EMPTY*, *FIFO_FULL*, *FIFO_LOWER_WM* or *FIFO_UPPER_WM* of FIFO instance 0 channel x.
PSM1_CHx_IRQ (x=0-7)	x+24	r	**PSM1 shared sub-module channel x interrupt** See bit 0 and bit 6. Set this bit represents an OR function of the four interrupt sources *FIFO_EMPTY*, *FIFO_FULL*, *FIFO_LOWER_WM* or *FIFO_UPPER_WM* of FIFO instance 1 channel x.
0	15:12	r	**Reserved** Read as zero, shall be written as zero.

28.22.5.2 Register ICM_IRQG_1

ICM Interrupt Group Register Covering DPLL

ICM_IRQG_1

ICM Interrupt Group Register Covering DPLL (000604$_H$) **Application Reset Value: 0000 0000$_H$**

28.23 Output Compare Unit (CMP)

28.23.1 Overview

The Output Compare Unit (CMP) is designed for the use in safety relevant applications (This module is not part of the Infineon safety manual). The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used it is necessary to ensure the total cycle accurate output behavior of the output modules to be compared. This is given when two neighbored DTM channel (CDTM[n]_DTM[2*i] and CDTM[n]_DTM[2*i+1]) generate identical signals with phase shift zero at their outputs. This can be reached if they start their output generation at the same time. This start of synchronization is possible by means of the trigger mechanisms *TRIG_x* provided by the TOM or ATOM as shown in the TOM (chapter “Timer Output Module”) or ATOM (chapter “ARU-connected Timer Output Module”). It is not necessary to compare each output channel with each other.

The CMP enables the comparison of 2x24 channels of the CDTM0, CDTM1 and CDTM2 and is restricted to neighbored channels. The first 24 CMP channels are the first 24 DTM channels placed behind TOM0 and TOM1 and the second 24 CMP channels are the first 24 DTM channels placed behind the ATOM0, ATOM1 and ATOM2.

Note: When the channels were generated with a higher frequency than the frequency of cluster 1 it is not certain to catch the interrupt in the notify register. Avoid a comparison if freqency is unequal cluster 1 AND (cluster 0 OR cluster 2)

TBWC11	CDTM1_DTM1_CH2_OUT	CDTM1_DTM1_CH3_OUT

28.23.3 Configuration of the Compare Unit

Because of the restrictions described in the section above the Compare Unit consists of 24 antivalence (EXOR) elements, a select register **CMP_EN** which selects the corresponding comparisons and a status register **CMP_IRQ_NOTIFY** which shows and stores each mismatching result, when selected.

For each with **CMP_IRQ_EN** enabled mismatching error an interrupt signal on *CMP_IRQ* is generated.

For each with **CMP_EIRQ_EN** enabled mismatching error an interrupt signal on *CMP_EIRQ* is generated.

28.23.4 Error Generator

The error generator generates an error signal to be transmitted directly to the MON unit and independently from the *CMP_IRQ* and *CMP_EIRQ*. The error is set when in the **CMP_IRQ_NOTIFY** register at least one bit is set. The CMP_IRQ_NOTIFY bits are not mask able for this purpose.

Additionally *CMP_ERR* is a primary output port for interrupt actions by CPU itself.

28.23.5 CMP Interrupt Signal

Table 151 CMP Interrupt Signal

Signal	Description
CMP_EIRQ	Mismatching interrupt of outputs to be compared, when enabled
CMP_IRQ	Mismatching interrupt of outputs to be compared, when enabled

The CMP sub-module has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupt can be determined by reading the **CMP_IRQ_NOTIFY** register under consideration of **CMP_IRQ_EN** register and **CMP_EIRQ_EN** register. Each source can be forced separately for debug purposes using the interrupt force **CMP_IRQ_FORCINT** register. **CMP_IRQ_MODE** configures interrupt output characteristic. All interrupt modes are described in detail in the subparagraph “GTM-IP Interrupt Concept”

28.23.6 CMP Configuration Register Overview

28.24 Monitor Unit (MON)

28.24.1 Overview

The Monitor Unit (MON) is designed for the use in safety relevant applications (The MON module is not part of the Infineon Safety Manual). The main idea is to have a possibility to supervise common used circuitry and resources. In this way the activity of the clocks is supervised. In addition the characteristics of output signals can be checked in a MCS channel by a re-read-in via TIM and routing to the MCS. When the comparison fails an error signal is generated in MCS and sent to the monitor unit. One error signal per MCS summarizes the errors of all channels. By generating of an activity signal per channel for each such performed comparison, the activity of TIM, ARU and the used clocks is checked implicitly. In addition the ARU cycle time could be also compared in a MCS channel to given values.

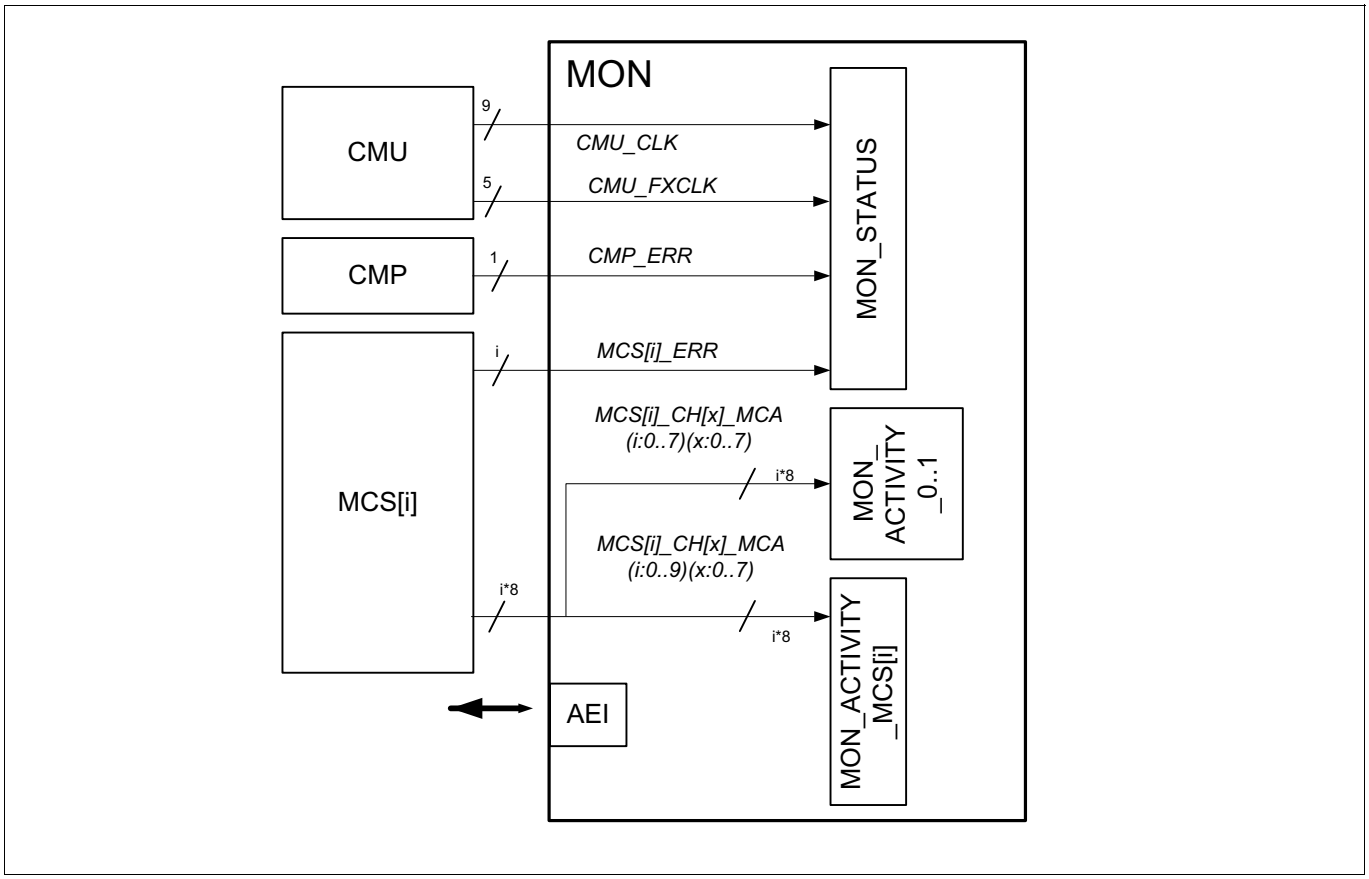

Figure 140 MON Block Diagram

28.24.1.1 Realization without Activity Checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore the clock enables are to be checked to have a high value.

28.24.2 Clock Monitoring

The monitor unit has a connection to each of the 9 clocks *CMU_CLK[x]* (x=0…8), provided by the CMU. Some of these clocks can be used for special tasks (see chapter “Clock Management Unit (CMU)”.

In addition the 5 clock inputs of the TOMs *CMU_FXCLK[y]* (y=0…4) are also connected to the MON unit.

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register **MON_STATUS** is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the CMU.

28.24.3 CMP error Monitoring

The signal CMP_ERR is to be received directly from module CMP and is set if an error occurred.

28.24.4 Checking the Characteristics of Signals by MCS

By use of the MCS some given properties of signals can be checked. Such signals can be generated output signals of TOM or ATOM channels including DTM function, which are reread in into a TIM and the time stamp information is routed via ARU to the MCS module.

The corresponding MCS signal performs the check according to given properties. In this way signal high or low time as well as signal periods can be checked, also taking into account tolerances. When the check fails a MCS internal error signal is generated and ORed with the error signals of the other channels of the MCS module to a summarized error signal *MCS[i]_ERR*.

For each MCS a summarized error signal is transmitted to MON and monitored in the MON_STATUS register.

In order to check the execution of the comparison for each MCS channel an activity signal is generated. In the MCS[i]_CH[x]_MCA (i=0…9) (x=0…7) vector 8 bits for each MCS[i](i=0…9) instance are combined. The activity signals are stored in the **MON_ACTIVITY_MCS[i]** register. In addition the first 8 bits of MCS0…3 are stored in **MON_ACTIVITY_0** and the first 8 bits of MCS4…7 are stored in **MON_ACTIVITY_1**. The bits are set by a one signal and reset by writing a one to it (preferably after polling the status of the register).

Because the activity signal shows the execution of a comparison, the involved units for providing the signals and execution of comparison (like TIM, ARU and MCS itself) are checked implicitly to work accordingly. Also the involved clocks and time bases are checked in this way.

28.24.5 Checking ARU Cycle Time

The cycle time of the ARU can be checked, when this is essential for safety purposes. This check can be performed by an MCS channel. It should be noted that the MCS program for measuring the ARU round trip time must add a tolerance value.

The resulting error is reported to the MON unit using the summarized error signal *MCS[i]_ERR* for each MCS module in addition to an interrupt, generated in MCS. The same signals and status bits are used as in the case of checking the signal characteristics.

The corresponding MCS is programmed to get a fixed data value at address 0x1FF. The data value is always zero and is not blocked. When getting the access the time stamp value TBU_TS0 is stored in a register. The next time getting the access the new TBU_TS0 value is stored and the difference between both values is compared with a given value. When the comparison fails, an error flag is set in the MCS internal status register, an interrupt is generated and the error signal *MCS[i]_ERR* is provided.

When the check is performed, an activity signal MCS[i]_CH[x]_MCA (i=0…9)(x=0…7) is provided for each channel x for each MCS[i](i=0…9) instance together with a summarized interrupt MCS[i]_ERR for each MCS.

The activity signal sets a bit in the MON_ACTIVITY register.
The bits in the MON_ACTIVITY registers are reset by writing a one.
When the check fails, an interrupt is generated and the error signal MCS[i]_ERR is provided for the MON unit.
Figure 140 shows the block diagram of the Monitor Unit.

28.24.6 MON Interrupt Signals

The MON submodule has no interrupt signals.

28.24.7 MON Register Overview

Table 153 MON Register Overview

Register Name	Description	see Page
MON_STATUS	Monitor status register	728
MON_ACTIVITY_0	Monitor activity register 0	729
MON_ACTIVITY_1	Monitor activity register 1	729
MON_ACTIVITY_MCS[z]	Monitor activity register for MCS z	730

28.24.8 MON Configuration Register Description

28.24.8.1 Register MON_STATUS

Monitor Status Register

The MCS can be programmed to generate an error, when the comparison of signal values (duty time, cycle time) fails or also when the cycle time of the ARU (checking of the TBU_TS0 between two periodic accesses) is out of the expected range.

MON_STATUS
Monitor Status Register **(000180$_H$)** **Application Reset Value: 0000 4000$_H$**

28.25.3 GTM Interrupts

In order to trigger an interrupt towards the Interrupt Router, the GTM has to generate a trigger signal with a minimum high length of one SPB clock cycle.

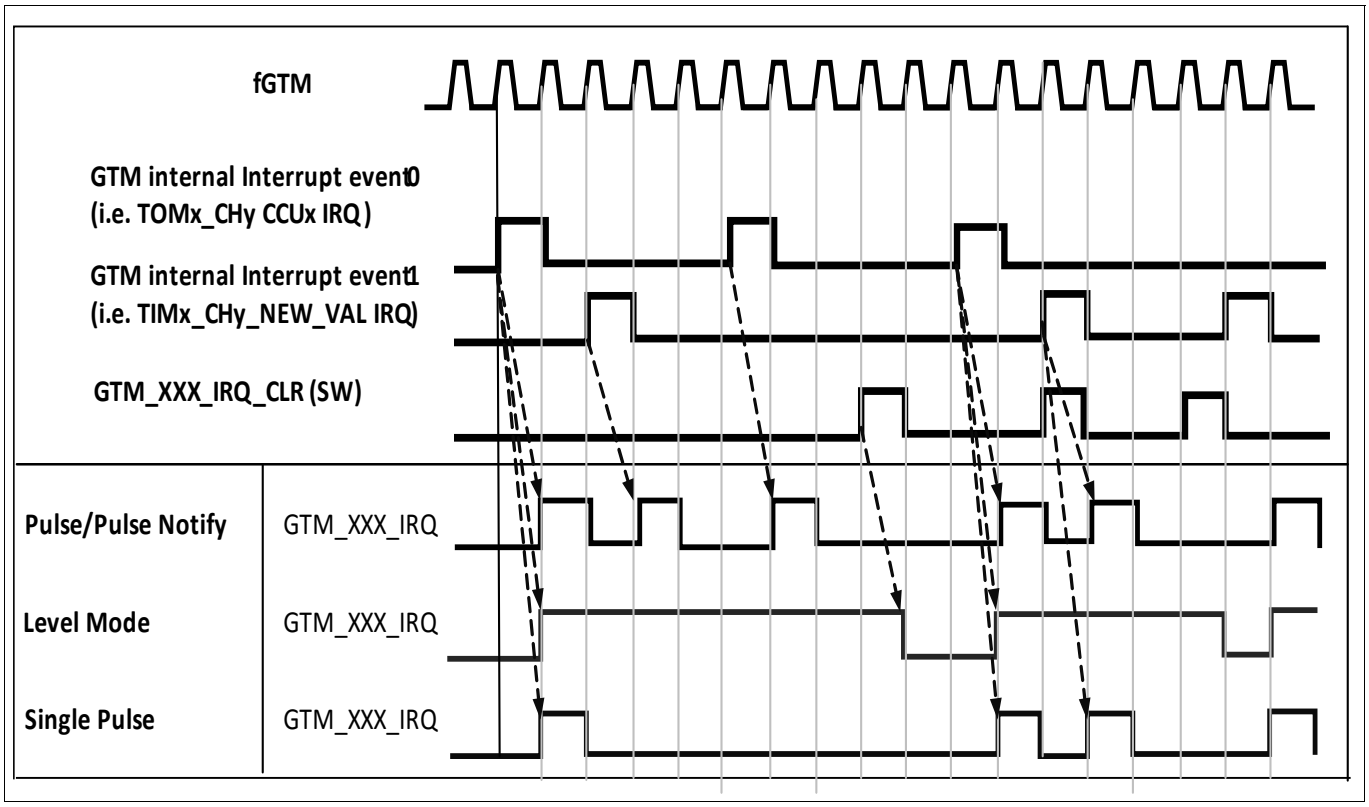

Figure 141 GTM Interrupt generation

After the interrupt ACK has been generated, the SRNs are cleared automatically on the Interrupt Router side, but this signal is not propagated to GTM, therefore to clear an interrupt on the GTM side, a SW approach is needed.

The GTM interrupts can be configured to work in four different modes: Level, Pulse,Pulse-Notify,Single-Pulse.

These modes change the way the GTM triggers are generated toward the Interrupt Router (IR).

Depending on the applications, one mode or the other could be used.

The **Figure 142** shows how the interrupt signal (GTM_IRQ_XXX) triggers an interrupt towards the IR, depending on IRQ_MODE.

From the **Figure 142** it is possible to understand that, using the Level Mode (Infineon default), in case that more internal “interrupt” events are generated (i.e. two TOM channels generating a CCU0 interrupt), just one interrupt signal is sent to the Interrupt Router, and no more interrupts are triggered until the SW clears all the “collected” interrupts.

In case that the Pulse-Notify mode is selected, every internal trigger, will be forwarded to the Interrupt Router.

For more details about the GTM interrupt modes, please refer to the GTM Interrupt concept chapter.

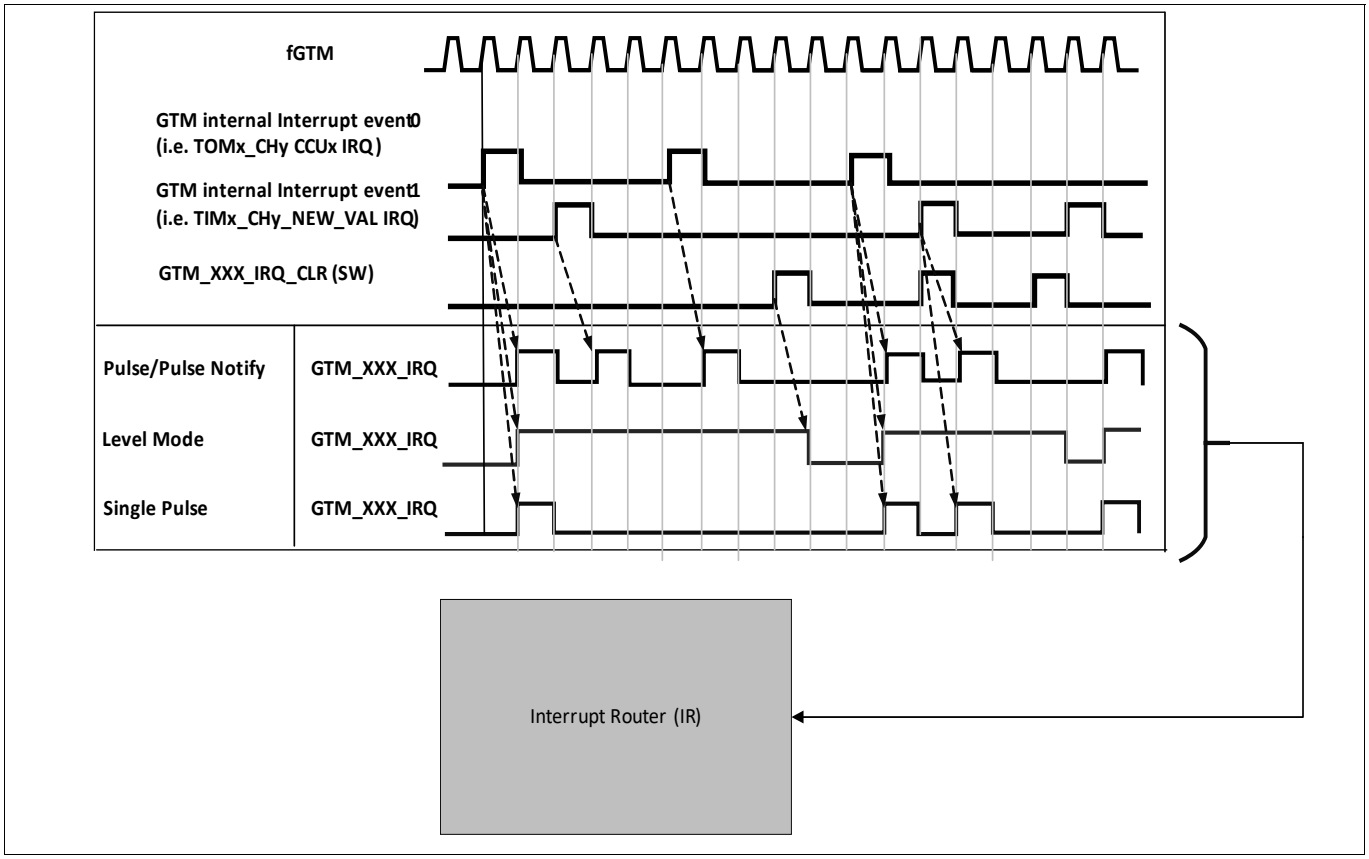

Figure 142 GTM Interrupts Modes

28.25.4 GTM Bridge

Within the infineon specific GTM wrapper, an interface (bridge) has been introduced to convert between the SPB bus protocol and the AEI protocol of the GTM IP in both directions. This introduces an additional delay of one SPB clock cycle per direction. In addition to that, additional pipeline registers have been implemented in the GTM IP to reach the required speed of the logic (200 MHz). Both contribute to an additional latency for read and write accesses towards the GTM IP registers and memories.

28.25.5 GTM Control Registers

This section lists all the Infineon specific registers implemented in the AURIX TC3x.

Table 159 Register Overview - IFX (sorted by Name)

Short Name	Long Name	Offset Address	Page Number

Clock Control Register

The clock control register is used to switch the GTM on or off, and to control its input clock rate. The GTM can be disabled by setting bit DISR to 1.

CLC
Clock Control Register **($09FD00_H$)** **Application Reset Value: $0000\ 0003_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	r	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the GTM module. 0_B No disable requested 1_B Disable requested
DISS	1	r	**Module Disable Status Bit** This bit indicates the current status of the GTM module. 0_B GTM module is enabled 1_B GTM module is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used for module's sleep mode control. 0_B Enabled 1_B Disabled
0	2, 31:4	r	**Reserved** Read as 0, shall be written with 0.

OCDS Control and Status

Note: OCS.SUSSTA is set to 1 (module is suspended) up to 2 gtm_clk cycles earlier before GTM changes into soft suspend mode.

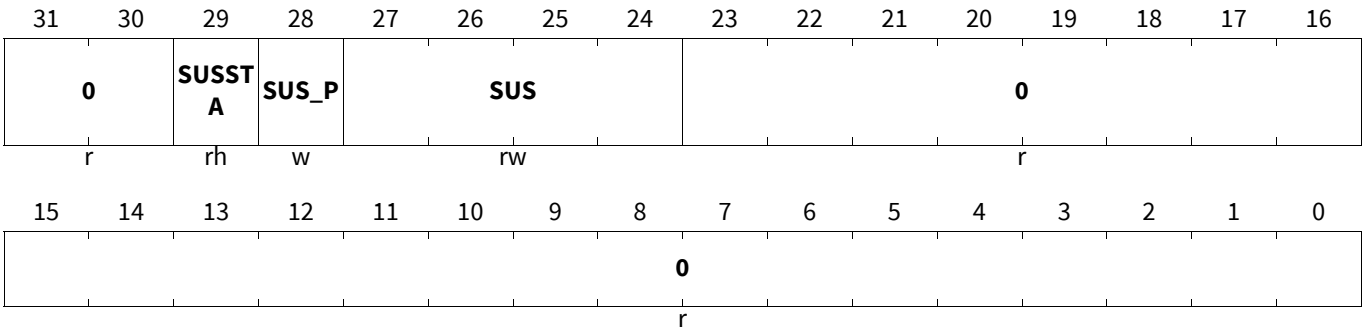
The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging). The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable ='1'). While OCDS is not enabled, OCS reset values/modes are effective.

OCS

OCDS Control and Status (09FD38$_H$) Debug Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. In hard suspend mode, no registers could be read or written. The GTM control registers are not affected, except all the debug registers apart from OCS register, and the TRIGOUT* and INTOUT* registers, which cannot be written as well. 2_H Soft suspend (GTM Halt Mode). In soft suspend mode, registers could be read or written. **others**, Reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise it remains unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0, shall be written with 0.

Table 160 Access Mode Restrictions of OCS sorted by descending priority

Mode Name	Access Mode		Description
write 1 to **SUS_P**	w	SUS	set SUS_P during write access
(default)	rX	SUS	read only

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,,EN31 -> TAG ID 011111B.

All registers and memories of the GTM are protected, except for the following registers:

ACCEN0 and ACCEN1.

ACCEN0

Access Enable Register 0 **($09FD10_H$)** **Application Reset Value: $FFFF\ FFFF_H$**

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B , EN31 -> TAG ID 111111B.

All registers and memories of the GTM are protected, except for the following registers:

ACCEN0 and ACCEN1.

ACCEN1

Access Enable Register 1 **($09FD14_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0, shall be written with 0.

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel, it is necessary to set the RST bits by writing a ´1´ in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order to support modules with two kernels, the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set (cleared) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing to it with ´1´.

Note: This reset function has the effect as bit RST.RST.

RESET1

Kernel Reset Register 0 (09FD08$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0														RSTSTAT	RST
r														rh	rwh

Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related RESET_CLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0, shall be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the GTM kernel. GTM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the GTM kernel, it is necessary to set the RST bits by writing a ´1´ in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

RESET2
Kernel Reset Register 1 **(09FD0C$_H$)** **Application Reset Value: 0000 0000$_H$**

28.25.6 Port Connections

This sections summarizes the port connections which define the boundary of the GTM for the TC3x.

Table 161 GTM Boundary Connections Overview

Description	Table
GTM to GPIO Connections	see Appendix
GPIO to GTM Connections	**Table 28.25.6.2**
DTM_AUX Input connections	See Appendix
GTM EXT CLOCK to GPIO Connections	**Table 162**
GPIO Availability by Package	See Data Sheet

28.25.6.1 GTM Outputs to Port Connections

All pinning information has been moved to the appendix of the corresponding device.

The GTM outputs cmu_eclk[2:0] are connected directly to dedicated ports

Table 162 GTM External Clock to Port Mapping

GTM External Clock	Output to PIN
cmu_eclk0	P23.1
cmu_eclk1	P32.4
cmu_eclk2	P11.12

28.25.6.1.1 GTM Outputs to Port Control Registers (TOUTSEL)

The outputs of the GTM TOM, ATOM and DTM modules are not connected directly to the port output path. Each TOM, ATOM and DTM is connectable to several port alternate inputs via an output multiplexer.

The output signals to the MUX are called *gtm_tout_x*, where x is the running number.

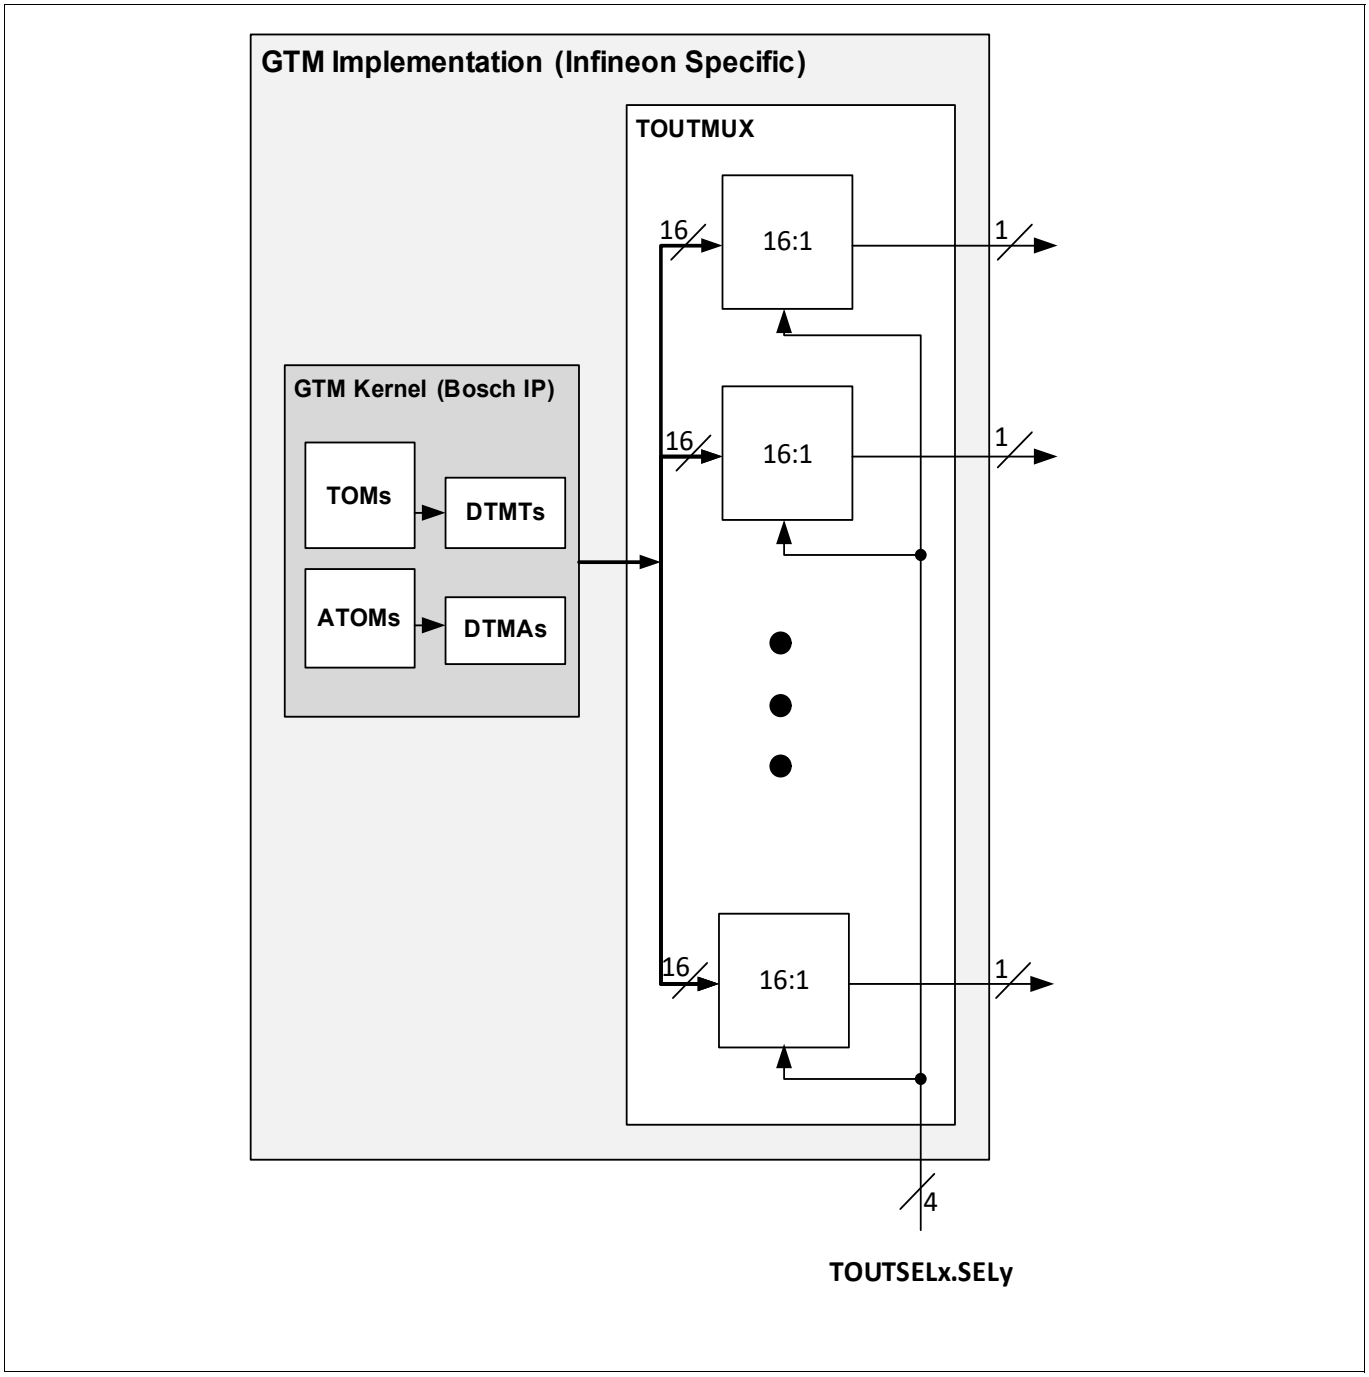

Figure 143 GTM Outputs to Port block diagram

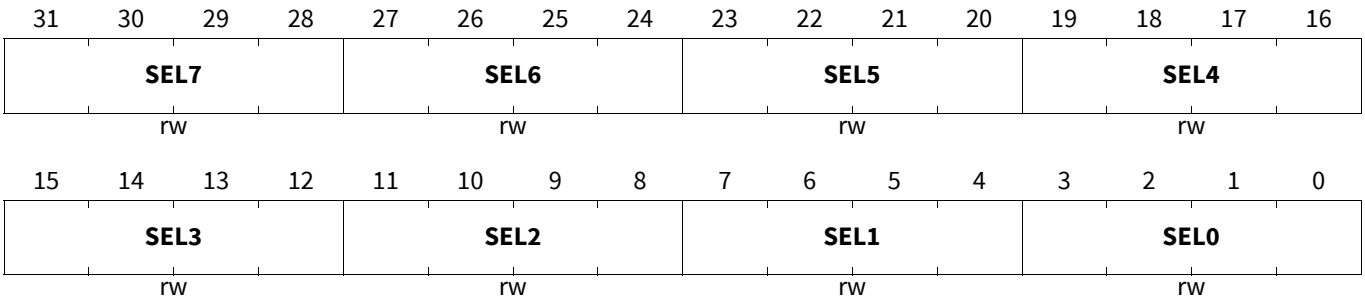
Timer Output Select Register

TOUTSELn (n=0-33)
Timer Output Select Register **($09FD60_H$+n*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SELx (x=0-7)	4*x+3:4*x	rw	**TOUT(n*8 + x) Output Selection** This bit field defines which timer output is connected as TOUT(n*8+x). The mapping is defined in the specific appendix. *Note: If TOUT(n*8+x) is not defined in the specific appendix, this bit field has to be treated as reserved ('0', TOUT not routed to any ports).* *Note: SELx values not explicitly defined here are equivalent to the last defined SELx setting.*

28.25.6.2 GPIO to GTM Connections

The table below shows, for each available port, the GTM Input connections. The GTM Input modules (TIM) can be configured by setting the register.

All pinning information has been moved to the Appendix of the corresponding device.

28.25.6.2.1 Port to GTM Connections (TIMnINSEL)

The inputs to the GTM TIM modules (*gtm_timx_in[7:0]*) are not connected directly to the port input path. Each timed GPIO is connectable to two or more TIMs via an input multiplexer. In addition, the inputs from the on-chip peripherals are connected here, too.

TIMn Input Select Register

28.25.8 EDSADC Connections

28.25.8.1 EDSADC to GTM Connections

These registers define the EDSADC to GTM connections of TC3x.
The 16-to-1 multiplexer is implemented once per TIM0/1/2/3/4/5 module/channel. The input signal from the EDSADC is called *dsadcx_trig_in_y, where* x = number of EDSADC channel, y = SRM / SAUL / SBLL. The output of the multiplexer is called *timy_muxout_x*, (y = 0,1)(x = 0…7).

28.25.8.2 GTM to EDSADC Connections

Registers DSADCOUTSELxy define the GTM to EDSADC connections of TC3x.

The EDSADC trigger inputs (one per EDSADC) 16-to-1 multiplexer is implemented four times per EDSADC module/channel. The output signal to the EDSADC are called *dsadcx_trig0,dsadcx_trig1*, *dsadcx_trig2, and dsadcx_trig3*. The inputs of the multiplexer are called *dsadc_x_muxin[7:0]*, x = number of EDSADC channel.

Which of the possible trigger inputs is used by the EDSADC can be selected in the EDSADC related chapter.

28.25.9 EVADC Connections

These registers define the GTM to EVADC connections of TC3x.
The ADC trigger inputs 16-to-1 multiplexer is implemented four times per ADC module / channel. The output signals to the ADC are called *adcx_trig0, adcx_trig1, adcx_trig2, adcx_trig3,* and *adcx_trig4*.

The inputs of the multiplexer are called *adc_x_muxin[7:0]*, x = number of ADCs.

0	31:16	r	**Reserved** Read as 0, shall be written with 0.

28.25.10 GTM ADC Interface

The GTM ADC Interface connects the MCSi (i=0..4) to all the available EVADC/EDSADC modules.

Each MCSi module (i=0..4) is able to read, in a flexible manner, the GxRES15 result of any EVADC channel, plus the result of any EDSADC channel.

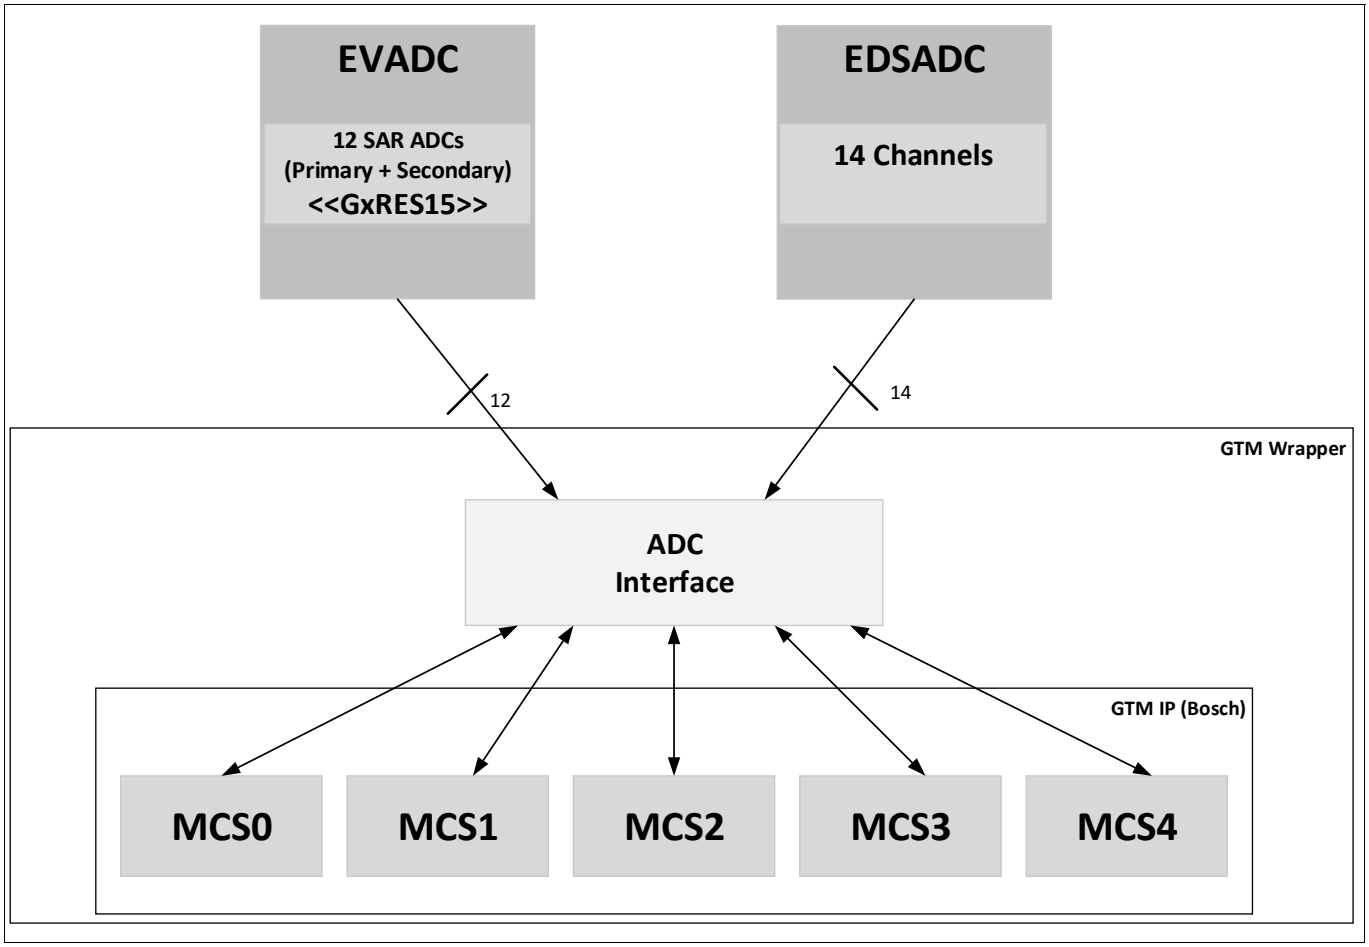

Figure 148 GTM ADC Interface

In order to address the desired EVADC/EDSADC channel, each MCS task should use the BRD (Bus Read) instructions defined in the MCS Chapter.

Inside the GTM Wrapper, the ADC interface is implemented in a way that each EVADC/EDSADC result can be provided to each MCSi (i=0..4) module, without any arbitration.

The ADC interface takes care locally of the valid bit handling.

Valid bit handling

As soon as a new ADC result is available, a local valid bit is set within the ADC interface logic. This information is provided towards the MCS via the ‚valid' signal, which is available along with the upper part of the actual data within the MHB registers (MHB = ack & valid & data[29:24]).

Each MCS read access, to an ADC result, resets the valid bit (i.e. BRD Rx, <ADC_ID>), No data (before the first ADC data becomes available) will be flagged by a „10" ‚req_status' and no ‚ack' pulse (causing an internal MCS error). In this way, the MCS can distinguish between non-available data and invalid data (data provided by the ADC but already read by another MCS or MCS channel).

MCS read access to a not supported address will cause an internal MCS error flagged by ‘req_status = 11’ and no “ack” pulse.

It is possible that two different MCS modules read the same ADC result at the same time, or within two consecutive clock cycles. In this corner case, for both MCS the valid bit will be set. At application level, countermeasures need to be taken in order to avoid such a behavior.

Table 163 ADC Interface Return Codes

CH_INFO	REQ	ACK	VALID	REQ_STATUS
0|1	1	0	1	11: unsupported address, <ADCi_CH=n> not available
0|1	1	1	1	00: new data available in <ADCi_DATA[23:0]> register. (Signed format for EDSADC)
0|1	1	1	0	00: no new data available
0|1	1	0	0	00: conversion in progress or ADC not enabled; No data available yet

MCS Master Interface offsets vs. EVADC/EDSADC

Inside the GTM IP, the connection between the ADI and the MCS is implemented with the MCS master interface (see MCS master interface address map in the product specific appendix), and the MCS should access the wanted ADC by using the defined ADC_CHx_DATA and/or ADC_CHx_STA (x=0..63) offsets.

Note: Currently only x=0..31 is available. The other addresses x=32..63 are reserved for future extensions of the GTM3.x IP. In GTM4 the address map has changed completely, therefore the addresses stay reserved.

Table 164 MCS Master Interface Offsets vs. EVADC/EDSADC

MCS Master Interface offset	EVADC, EDSADC Module
ADC_CH0_DATA	ADC channel 0
ADC_CH0_STA	ADC channel 0

Table 164 MCS Master Interface Offsets vs. EVADC/EDSADC (cont'd)

MCS Master Interface offset	EVADC, EDSADC Module
ADC_CH25_STA	EDSADC channel 9
ADC_CH26_DATA	EDSADC channel 10
ADC_CH26_STA	EDSADC channel 10
ADC_CH27_DATA	EDSADC channel 11
ADC_CH27_STA	EDSADC channel 11
ADC_CH28_DATA	EDSADC channel 12
ADC_CH28_STA	EDSADC channel 12
ADC_CH29_DATA	EDSADC channel 13
ADC_CH29_STA	EDSADC channel 13

MCS Interface Usage

Each MCSi (i=0..4) task can read from an EVADC or EDSADC using the MCS bus read command BRD or BRDI:

Example:

- BRD Rx ADC_CHy_DATA or BRD Rx ADC_CHy_STA[1)]

At the end of the read command, the content of the registers will be the following:

- MHB = ack & valid & MHB[5:0]
- Rx[15:0] = ADC_CHy Result

Reading from EVADC

- MHB[5:0] = MHB[5:4]= 00_B, MHB[3:0]= EVADC channel number
- Rx[23:16] = 0x00000000

Reading from EDSADC

- MHB[5:0] = MHB[5:2]= 0000_B, MHB[1:0]= EDSADC input multiplexer
- Rx[23:16] = each bit is equal to EDSADC[15] (the sign is extended to all leading bits)

28.25.11 SENT Connections

This register defines the GTM to SENT connections of TC3x.
The trigger generation 16-to-1 multiplexer is implemented four times per EVADC module / channel. The output signal to the EVADC is called *adcx_trig0, adcx_trig1,* adcx_trig2, and adcx_trig3.

As the SENT channels overlay and replace ADC channels, the ADC triggers will be also reused for the SENT channels. Therefore, no additional outputs for separate operation are defined here. The *adcx_trig0[x=0-11] are* connected to sent_trig_i [i=0-11].

In addition, also the dsadc_x_trig0 [x=0…3] are connected to the sent_trig_i [i=12-15]

1) ADC_CHx_DATA and ADC_CHx_STA are equivalent, will return the same data

28.25.12 CAN / TTCAN Connection

CAN0/CAN1 Output Select Register

This register holds the selection for the trigger outputs to the CAN0/CAN1 modules. Bit fields SEL0..3 define the selection for triggers 0..3 for CAN0, while bit fields SEL4..7 define the selection for triggers 0..3 for CAN1.

CANOUTSEL0

TOM0_9	T13HRD

28.25.15 PSI5 Connections

This register defines the GTM to PSI5 connections of TC3x.

The PSI5 trigger inputs are generated by 16-to-1 multiplexer that are implemented twice per PSI5 module / channel plus 3 combined for all PSI5 channels together. The output signal to the PSI5 is called *psi5x_trig0*. The inputs of the multiplexer are called *psi5_x_muxin[7:0]*, x = number of PSI5 triggers, TC3x has 6 triggers.

28.25.16 GTM Data Exchange Registers

The registers define additional data exchange and control options for GTM towards the on-chip system of TC3x.

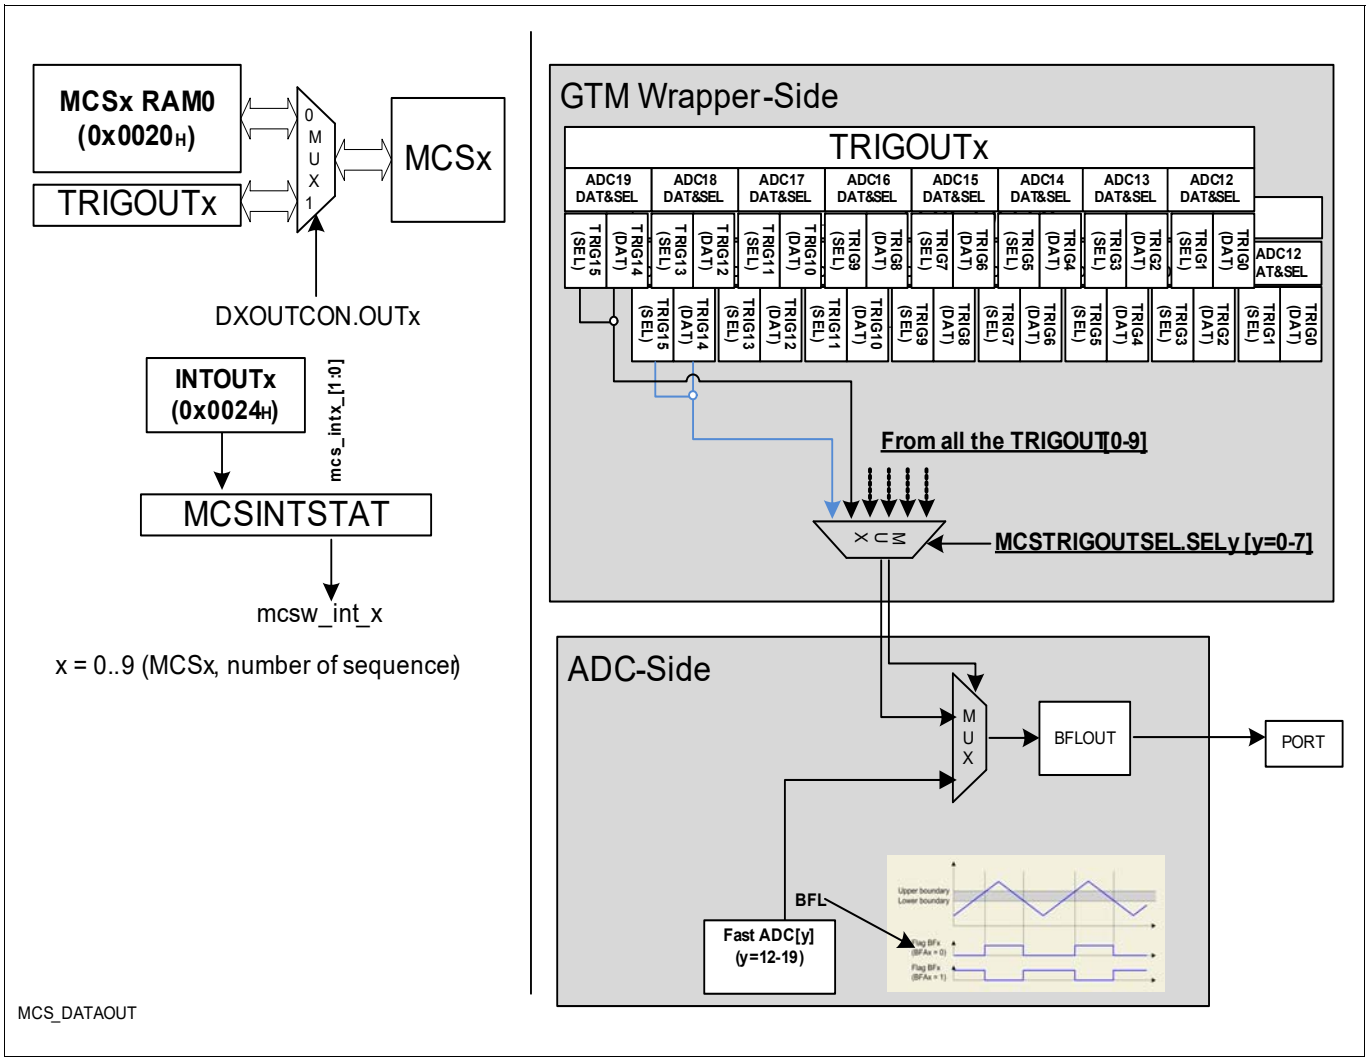

Figure 152 MCS Trigger Output Path to BFLOUT

The TRIGOUTx and INTOUTn registers enable the GTM multichannel sequencers to generate dedicated triggers and interrupts by writing specific values to those registers. The TRIGOUT registers are mirrored to address 0x0020 of the sequencer RAM0 and the INTOUTx to the address 0x0024.

If a write for address $0x0020_H$/$0x0024_H$ updates the RAM or the TRIGOUT/INTOUT registers, is controlled by the bus accessible register DXOUTCON.

This need to be configured only once when setting up the GTM with the reminder of the system.

Register MCSINTSTAT contains interrupt status flags and register MCSINTCLR provides the option to clear these status flags from the system bus. Both registers are optional register.

The data exchange register are also accessible during suspend mode.

Data Exchange Output Control Register

DXOUTCON

0	31:10	r	**Reserved** Read as 0, shall be written with 0.

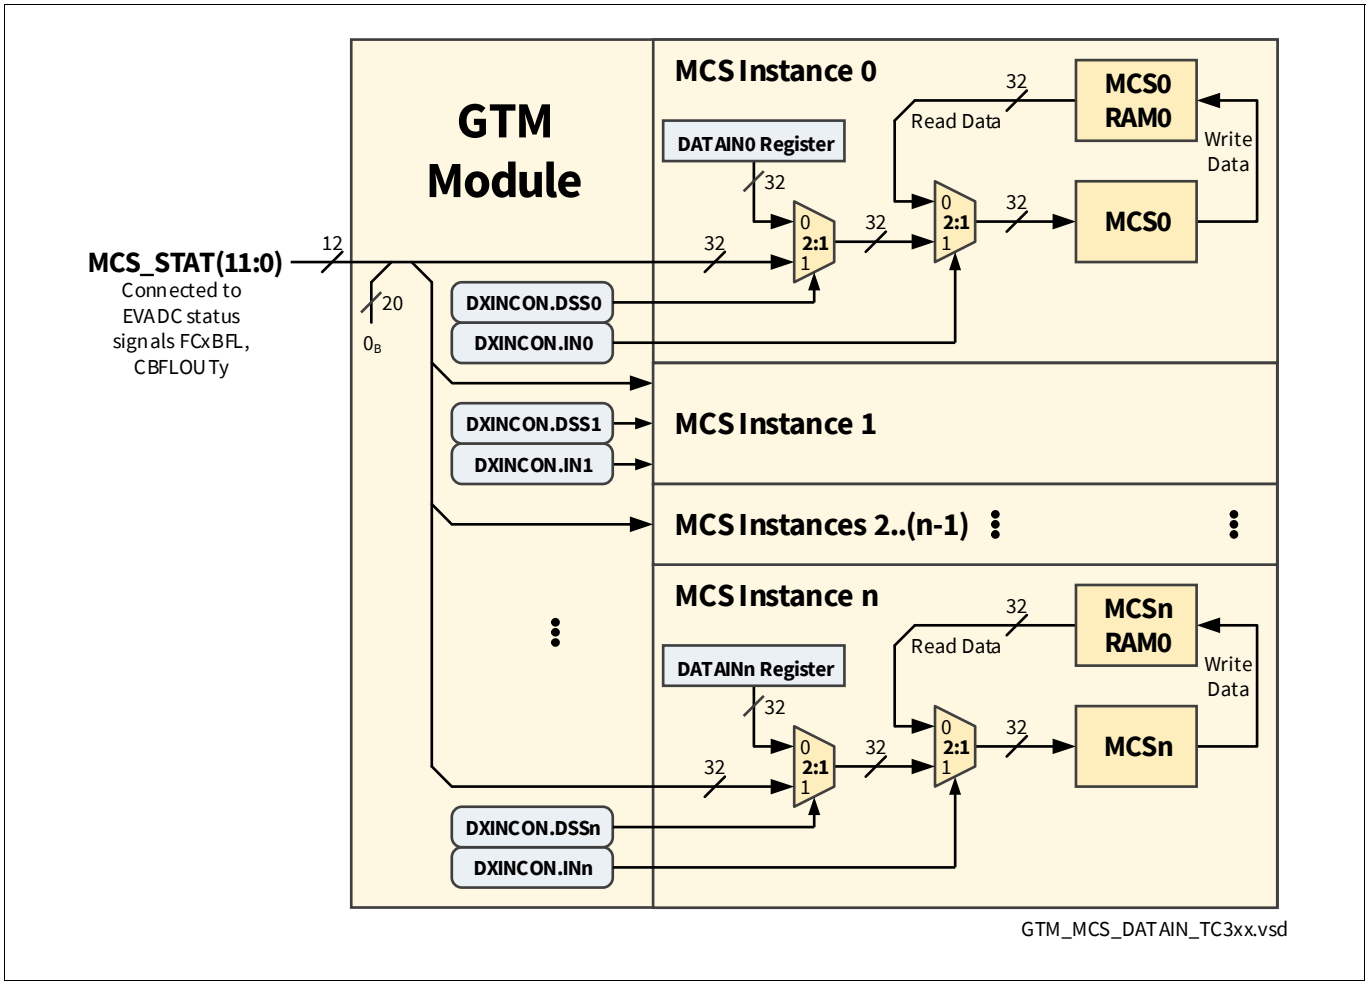

Figure 153 MCS Data Input Path

The DATAIN registers enable the GTM internal sequencers to access data provided by other masters in the system directly in the sequencer data flow without ARU interaction. In addition, the status of dedicated system triggers can also be observed here. The DATAIN registers are mirrored to address 0028_H for sequencer RAM0. Whether a read of address 0028_H fetches data from the RAM or the DATAIN register, is controlled by the bus-accessible register DXINCON in central for all sequencers and there RAMs. In addition, register DATAIN contains the control whether the 12 LSBs of the DATAIN register contain data or the status of the EVADC module (see **Table 169**). This need to be configured only once when setting up the GTM with the remainder of the system.

Table 169 MCS Data Input Signal Connections (cont'd)

MCS Status Input	Input
MCS_STAT9	CBFLOUT1
MCS_STAT10	CBFLOUT2
MCS_STAT11	CBFLOUT3
all other	Reserved

Note: The number of FCxBFL and CBFLOUTx is product specific. Please refer to the specific device appendix, section "EVADC to GTM Connections", for information on which MCS_STATx inputs are connected to FCxBFL/CBFLOUTy signals.

Note: The correct working behavior is guaranteed only if the GTMDIV is set to 0001_B (default value).

28.25.17 SCU Connections

This section summarizes the connections to the SCU (System Control Unit). The TOM3 connection does not exist on the TC37x device and below.

Table 170 GTM to SCU Connections

GTM Output	SCU Input
TOM0_12	Input41 (ERS4.REQ4B)
TOM1_12	Input51 (ERS5.REQ5B)
TOM2_12	Input65 (ERS6.REQ6F)
TOM3_12	Input75 (ERS7.REQ7F)

28.25.18 HSM Connections

This section summarizes the connections to the HSM.

Table 171 GTM to HSM Connections

GTM Output	HSM Input
GTM_TIM0_IRQ4 (TIM0_CH4)	EXT_INT0
GTM_TIM0_IRQ5 (TIM0_CH5)	EXT_INT1
GTM_TIM0_IRQ6 (TIM0_CH6)	EXT_INT2
GTM_TIM0_IRQ7 (TIM0_CH7)	EXT_INT3
GTM_ATOM0_IRQ2 (ATOM0_CH4, ATOM0_CH5)	EXT_INT4
GTM_ATOM0_IRQ3 (ATOM0_CH6, ATOM0_CH7)	EXT_INT5
GTM_MCS0_IRQ0 (MCS0_CH0)	EXT_INT6
GTM_MCS0_IRQ1 (MCS0_CH1)	EXT_INT7

Note: In case of 2 interrupt pulses with less than 3 SPB clock cycles in between, the second one will not be routed to the HSM

28.25.19 GTM Debug Interface

28.25.19.1GTM OCDS Interface

GTM supports software development and debugging with the following features:

- Read/write access to all GTM registers and memories while running or suspended
- Tool read access via DAP/Cerberus are per default non-destructive (controlled via ODA register)
- Selected GTM signals can be routed to device pins
- GTM can be suspended by OCDS (controlled via OCS register)
- Single stepping of MCS channels by using suspend and OTGS
- MCDS trace support for IO signals, MCS, ARU, DPLL and TBU

28.25.19.1.1 GTM Suspend and Single Stepping

When GTM is suspended, all the activities are stopped, but read accesses are possible for evaluating the internal state, whereas write accesses will have no effect on registers. Suspend is globally controlled in OTGS and GTM locally with the OCS register.

For specific and limited MCS software development cases, the suspend functionality can be used by a debugger for single stepping of MCS channels in the following way:

- GTM is suspended
- MCS clock frequency is configured to be the same as SPB clock frequency
- The OTGS TL timer is used by the debugger to generate clock pulses
- The tool checks after each clock pulse whether the next instruction has been reached already

This sequence can be executed by the tool transparent to the user. This single-stepping approach has limitations for specific instructions and ARU accesses, and it is not a replacement for trace based debugging methods.

28.25.19.1.2 OCDS Trigger Bus (OTGB) Interface

Figure 154 shows a block diagram of the GTM with the trigger and trace connections to pins and MCDS. The OTGB0/1 trigger busses are connected via the regular OTGB infrastructure to device pins and MCDS. The GTM specific OTGBM0/1 busses directly to MCDS. OTGB0/1 are 16-bit trigger busses, OTGBM0/1 are 32-bit wide. Further information about OTGB0/1 is available in the OTGM (OCDS Trigger MUX) section of the OCDS chapter.

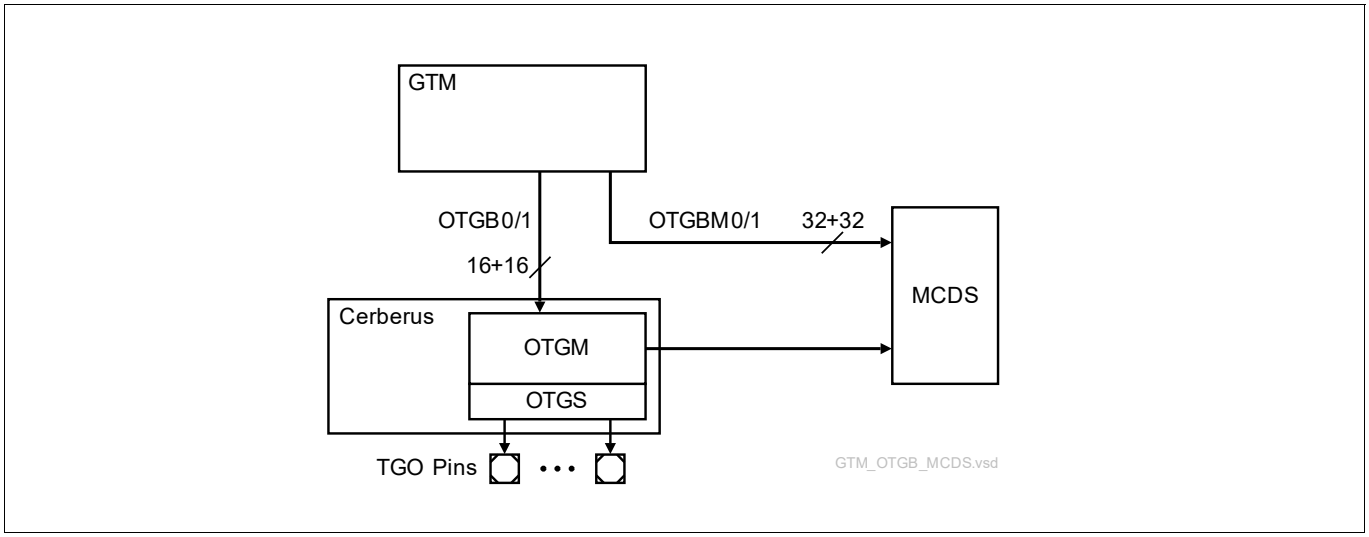

Figure 154 GTM Trigger and Trace Connections

GTM Trigger and Trace Features

- IO signals
  - TIM input signals (after filter)
  - TOM output signals
  - ATOM output signals
  - SPE NIPD and DIR signals
  - Groups of 8 signals (e.g. all inputs of a specific TIM, etc.)
  - Two or four arbitrary groups using OTGB0/1
  - Signals can be used as triggers or processed with OTGS
  - Signals can be routed to TGO device pins via OTGS
- MCS
  - Channel number, PC, and data access type (read or write)[1)]
  - Optional data value on OTGBM1
  - In parallel to IO signal tracing
- ARU
  - ARU_DBG_DATA0/1_H/L (time multiplexed)
  - In parallel to IO signal tracing
  - In parallel to MCS channel number, PC, and data access type tracing
- DPLL
  - TASI and SASI signals as IO signals
  - Accesses to RAM1A/1BC/2 (only one at a time) in parallel to IO signal tracing
- TBU
  - Triggers for individual TBU comparators as IO signals
  - Trace one selected TBU in parallel to IO signal tracing

1) The data captured by EMEM is word aligned (0,1,2..), while MCS PC increments are incremented by 4 (0,4,8,0xC...)

The GTM module has one 16-bit and twelve 32-bit Trigger Sets (**Table 172**), which are selected with the OTSS register.

Table 172 GTM Trigger Sets

Trigger Set	Details
TS16_IOS Trigger Set IO and Other Signals	**Table 174**
TS32_MCA MCS Channel, Address and PC	**Table 175**
TS32_MCD MCS Data	**Table 176**
TS32_ARU Trigger Set ARU	**Table 177**
TS32_DRA1A/1BC/2 DPLLRAM Access Address (3 Sets)	**Table 178**
TS32_DRD1A/1BC/2 DPLLRAM Access Data (3 Sets)	**Table 179**
TS32_TTB0/1/2/3 TBU Time Stamps (3 Sets)	**Table 180**

Table 173 shows all Trigger Set mapping options. OTGB0/1 can be set independently of OTGBM0/1.

Table 173 Trigger Set Mapping Options

OTGB0	OTGB1	OTGBM0	OTGBM1
TS16_IOS	TS16_IOS	TS32_MCA	TS32_MCD
		TS32_DRA1A/1BC/2	TS32_DRD1A/1BC/2
		TS32_ARU	TS32_ARU
		TS32_TTB0/1/2/3	

The OTGB0/1 signals relate to the GTM internal clock, which can be slower or equal to the OTGB clock.

Note: The above trigger sets only exist, if the corresponding resources are existing on the device.

Note: In case of GTM kernel reset (GTM module reset via BPI), the output signals towards the Cerberus (OTBG0/1) and towards the MCDS (OTGBM0/1) will be '1' for 3 SPB clock cycles due to the reset isolation functionality (usually, outputs are driven to '0' during this period). This will assure that a GTM kernel reset can be determined at the debug system.

IO and Other Signals Trigger Sets

The IO Trigger Sets consist of the most important TIM, TOM and ATOM signals in groups of 8. In addition, there are two groups of SPE signals and one group for miscellaneous signals. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16-bit Trigger Set. In addition, it is possible to use one or two 16-bit Trigger Sets with this flexibility. All this is controlled with OTSC0 register.

Please note that the TS16_IOS signals are sampled with the OTGB clock, which can be slower than the GTM clock. For normal clock configurations, this difference will not be more than a factor of two, which means a max. delay of one GTM clock.

Table 174 TS16_IOS Trigger Set IO and Other Signals

Bits	Name	Description	
[7:0]	SG0	A group of 8 signals from a selected TIM, TOM, ATOM or SPE	
		TIM	All 8 input signals after filter F_OUT
		TOML	Lower 8 output signals TOM_OUT
		TOMH	Higher 8 output signals TOM_OUT
		ATOM	All 8 output signals ATOM_CHx_OUT
		SPE	For OTSC0.BxxMI Module Instance 0: Bits 0,1: SPE0_NIPD, SPE_DIR0 Bits 2,3: SPE1_NIPD, SPE_DIR1 Bits 4,5: SPE2_NIPD, SPE_DIR2 (00_B if GTM has no SPE2) Bits 6,7: SPE3_NIPD, SPE_DIR3 (00_B if GTM has no SPE3) For OTSC0.BxxMI Module Instance 1: Bits 0,1: SPE4_NIPD, SPE_DIR4 (00_B if GTM has no SPE4) Bits 2,3: SPE5_NIPD, SPE_DIR5 (00_B if GTM has no SPE5) **others**, reserved (value is 0)
		MISC	Bit 0: DPLL TASI (if DPLL exists) Bit 1: DPLL SASI (if DPLL exists) Bit 4: TBU0 trigger (OTBU0T) Bit 5: TBU1 trigger (OTBU1T) Bit 6: TBU2 trigger (OTBU2T) Bit 7: TBU3 trigger (OTBU3T) (if TBU channel 3 exists) **others**, reserved
[15:8]	SG1	Independent selection with same options as for bits [7:0]	

MCS Trigger Sets

There are two MCS Trigger Sets: TS32_MCA (**Table 175**) and TS32_MCD (**Table 176**). TS32_MCA allows to observe the PC of all or a selected MCS channel(s). If only one channel is selected, the TS32_MCA value will stay stable until the MCS executes this channel again. In case of data access by CPU or by a channel, it represents the data address. With TS32_MCD, the associated data value and even the fetched instruction opcode can be traced. Usually, the latter is avoided to reduce the trace bandwidth. All this is controlled with OTSC1.

Table 175 TS32_MCA MCS Channel, Address and PC

Bits	Name	Description
[13:0]	ADDR	PC of MCS channel or address of data access (32-bit word address)
[15:14]	AQ	ADDR Qualifier 0_H PC of MCS channel 1_H Address of data read 2_H Address of data write 3_H Reserved
[19:16]	CH	MCS channel number
[31:20]		Reserved

Table 176 TS32_MCD MCS Data

Bits	Description
[31:0]	Read or written data value of current channel instruction

ARU Trigger Sets

There are four 29-bit ARU data words with debug information (ARU_DBG_DATA0_L/H and ARU_DBG_DATA1_L/H). These words may get valid in the same GTM kernel clock cycle, but they will never change in consecutive cycles. This property is used to transmit them with time multiplexing over the OTGBM bus.

Table 177 TS32_ARU Trigger Set ARU

Bits	Name	Description
[28:0]	DATA	ARU_DBG_DATA
29		Reserved
[31:30]	DQ	DATA Qualifier 0_H Is ARU_DBG_DATA0_L 1_H Is ARU_DBG_DATA0_H 2_H Is ARU_DBG_DATA1_L 3_H Is ARU_DBG_DATA1_H

DPLL Trigger Sets

The TASI and SASI signals are part of the MISC signal group of TS16_IOS (**Table 174**).

The following tables **Table 178** and **Table 179** define six additional DPLL Trigger Sets for observing the DPLL RAM accesses. Only one of the three DPLL (1A, 1B+C, 2) RAMs can be observed at a time. The Trigger Set selection is done with OTSS.

Table 178 TS32_DRA1A/1BC/2 DPLLRAM Access Address

Bits	Name	Description
[13:0]	ADDR	Address of data access. Range starts with address 0 for the selected RAM (1A, 1B+C or 2). Effective width depends on selected RAM
[15:14]	AQ	ADDR Qualifier 0_H DPLL data read access 1_H DPLL data write access 2_H CPU read access 3_H CPU write access
[31:16]		Reserved

Table 179 TS32_DRD1A/1BC/2 DPLLRAM Access Data

Bits	Name	Description
[23:0]	DATA	Read or written data
[31:24]		Reserved

TBU Trigger Sets

Table 180 defines the Trigger Sets for the observation of the different time bases. The Trigger Set selection (one at a time) is done with OTSS.

Table 180 TS32_TTB0/1/2/3 TBU Time Stamps

Bits	Name	Description
[26:0]	TS	Current TBU_TS0/1/2/3 time stamp. Effective width depends on selected time base.
[31:27]		Reserved

28.25.19.1.3 GTM Debug Registers

All debug control registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not changed by System Reset when OCDS is enabled.

OCDS Trigger Bus (OTGB)

Accesses are only supported for byte, half word and word data, and require Supervisor Mode.

OCDS Trigger Set Select Register

Note: OCS.SUSSTA is set to 1 (module is suspended) up to 2 gtm_clk cycles earlier before GTM changes into soft suspend mode.

Field	Bits	Type	Description
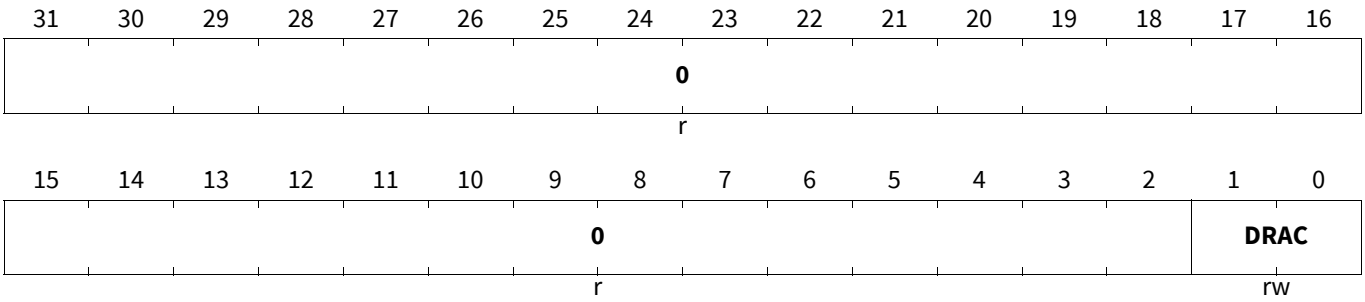
MCS	3:0	rw	**MCS Channel Selection** Required by TS32_MCA and TS32_MCD. 0_H MCS Channel 0 1_H MCS Channel 1 2_H MCS Channel 2 3_H MCS Channel 3 4_H MCS Channel 4 5_H MCS Channel 5 6_H MCS Channel 6 7_H MCS Channel 7 F_H All MCS Channels **others**, Reserved
MI	7:4	rw	**MCS Instance** Required by TS32_MCA and TS32_MCD. Index of the MCS instance. Index starts with 0, the max. value depends on the GTM configuration.
MOE	9	rw	**MCS Opcode Trace Enable** Required by TS32_MCD. 0_B Trigger Set TS32_MCD excludes opcode fetches 1_B Trigger Set TS32_MCD includes opcode fetches
0	8, 31:10	r	**Reserved** Read as 0, shall be written with 0.

OCDS Debug Access Register

Note: OCS.SUSSTA is set to 1 (module is suspended) up to 2 gtm_clk cycles earlier before GTM changes into soft suspend mode.

ODA

OCDS Debug Access Register **($09FD34_H$)** **Debug Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DRAC	1:0	rw	**Debug Read Access Control** Controls Debug Read Access (DRA) of registers with DRA behavior. 00_B Normal read access for all bus masters, but debug read access for Cerberus 01_B Normal read access for all bus masters 10_B Debug read access for all bus masters 11_B Debug read access for all bus masters
0	31:2	r	**Reserved** Read as 0, shall be written with 0.

Note: When the debug read access is enabled, the registers listed below will behave as follows:

3. *AFD[i]_CH[x]_BUF_ACC: Reading these registers will read only the first data available in the fifo. The fifo pointers and the flags (watermark, fifo empty) will not be changed. On multiple reads every time the first data in the fifo will be read.*
4. *TIM[i]_CH[x]_ECNT: Reading these registers will not reset the register (auto clear) when a debug access is active.*
5. *ATOM[i]_CH[x]_SR[0,1]: Reading these registers in ATOM SOMC mode when captured data are available is possible. While debug read access is enabled, read accesses will not enable the setup of a new compare action compared to the behavior of regular read accesses.*
6. *TIM[i]_CH[x]_GPR0/1: Reading these register will reset the ECNT counter.*

OCDS TBU0 Trigger Register

Note: OCS.SUSSTA is set to 1 (module is suspended) up to 2 gtm_clk cycles earlier before GTM changes into soft suspend mode.

OTBU0T
OCDS TBU0 Trigger Register **($09FD18_H$)** **Debug Reset Value: $0000\ 0000_H$**

EN	28	rw	**Enable** 0_B Disabled 1_B Enabled
0	27:24, 31:29	r	**Reserved** Read as 0, shall be written with 0.

28.25.20 GTM Application constraints and limitations

Depending on the specific application, the GTM constraints and limitations listed below need to be taken into account.

Table 181 GTM IP Application Constraints

#	Modules	Description	Required Value	Effect when not considered
1	DPLL	Increment duration (time between two valid inputs of the DPLL: TRIGGER/STATE)	> 23.4 ms	The calculation of at least 3 actions per increment in addition to a proper micro-tick generation (Sub_inc) could not be ensured for a system clock frequency of 100 MHz
2	DPLL	TBU_BASE_CH0 difference for two successive valid input events of the DPLL	256 (for the chosen input resolution)	Overflow in the calculation of the reciprocal values; the increment prediction and all other computations of the DPLL would become wrong
3	DPLL	CMU_CLK0 frequency	less or equal to half the frequency of system clock	The fast pulse correction in automatic end mode could be wrong
4	MCS	Worst Case Execution Time of an N-cycle instruction	less or equal to 9*N system clock periods	MCS program execution may be too long for the application's requirements
5	MCS	If MCS scheduling is configured in round robin mode, the MCS features deterministic program execution (the program of MCS channel x does not modify execution time of MCS channel y). This determinism no longer exists, if an MCS channel of MCS instance 0 is accessing the DPLL RAM with its bus master interface.		No channel independent execution time
6	TOM/ ATOM	If channel is triggered by preceding channel via TRIG_[x-1] signal, the selected FX_CLK/CMU_CLK of both channels has to be the same	Identical FX_CLK/CMU_CLK	The trigger of preceding channel may be lost

Table 181 GTM IP Application Constraints (cont'd)

#	Modules	Description	Required Value	Effect when not considered
7	TIM	If a TIM channel x uses ARU transfer with enabled TDU, the minimal time TIN between two subsequent measurement cycles has to be greater than the maximum time TSAMPLE between two subsequent ARU read request events on TIM channel x	TIN > TSAMPLE (FIFO: TSAMPLE = worst case ARU round trip time, MCS: TSAMPLE = max. time between two (N)ARD(I) instructions for TIM channel x)	The ARU destination of TIM channel x cannot distinguish between a measurement cycle overflow and a time-out with subsequent valid measurement cycle
8	ARU	The ARU round trip time in pure round robin mode is device specific	(ARU_CADDR_END +1) times slow clusters clock period with ARU_CADDR_END = 125 (default value)	If dynamic mode is activated with CLK_WAIT>0, the ARU round trip time becomes longer, and the value is undefined

Table 182 GTM Wrapper Constraints

#	Modules	Description	Required Value	Effect when not considered
1	GTM Wrapper	To switch off (and on again) safely the module, the check of the CLC.DISS (i.e while (CLC.DISS==1) is not enough to guarantee that the module has been effectively switched off..	>= 2 x slow GTM clusters clock period.	Watchdog error

GTM Legacy Addresses

In previous GTM specification, a smaller number of instances of the modules ATOM and MCS were included in the address list. The old address areas of these modules are marked with LEG_ (legacy). These LEG_ areas are mapped to the normal areas.

Accesses to these addresses will not result in a bus error.

The following lists all sub-modules of the which have additional legacy base addresses defined by older GTM Generations. The table is for TC39x, devices with a smaller number on the 4th position only include a subset of the listed features.

ARU_EMPTY_ADDR	0x1FE
ARU_FULL_ADDR	0x1FF

28.25.22 ARU Port Partitioning

All GTM sub-modules which are reading from ARU can be connected to one of two ARU read ports. Therefore, it can be read from two different ARU addresses in parallel.

Table 186 GTM ARU Partitioning

Modules	ARU-0 port	ARU-1 port
ATOM0	X	
ATOM1		X
ATOM2	X	
ATOM3		X
ATOM4	X	
ATOM5		X
ATOM6	X	
ATOM7		X
ATOM8	X	
ATOM9	X	
ATOM10	X	
ATOM11	X	
MCS0	X	
MCS1		X
MCS2	X	
MCS3		X
MCS4	X	
MCS5		X
MCS6	X	
MCS7		X
MCS8	X	
MCS9		X
DPLL		X
BRC		X
PSM0	X	
PSM1		X
PSM2	X	

28.25.23 ARU Read ID

Each ARU connected data destination is defined by a combination of ARU port (ARU0 or ARU1) and an ARU read ID. The two ARU counter are addressing two ARU read IDs in parallel. Depending on the ARU mode, both counter may have different values at different point in time (i.e. in dynamic routing mode). The maximum ARU round-trip time is determined by the value of the last ARU read ID. The following table describes the detailed addressing of GTM sub-modules by ARU read IDs.

The following table shows the ARU read IDs for the superset. It is identical to the table shown in the appendix for the TC39x silicon. The unused IDs are marked with “-”.

Table 187 GTM Read IDs

ARU read ID (dec)	ARU0	ARU1		GTM read ID (dec)	ARU0	ARU1
0	reserved	reserved		64	ATOM4 channel 3	DPLL action 31
1	**ARU0**	**ARU1**		65	MCS4 channel 7	MCS3 channel 7
2	**BRC** channel 0	**DPLL** action0		66	ATOM4 channel 4	**ATOM3** channel 0

28.25.24 MCS Master Interface Address Map

Inside a specific GTM cluster, the MCS can access all the other GTM module registers. The address map for all the GTM registers is the same for each cluster. If a module is not implemented in a cluster, these addresses are reserved.

28.25.25 General remarks

The GTM kernel is a pure 32bit module. Therefore accessing the GTM, shall be not bytewise or half word. This shall not be done and might have strange effects on the module like overwriting registers with scrapped information. For TriCore architecture conform accesses, no error will be shown to the outside.

28.26 Revision History

Table 189 Revision History

Reference	Change to Previous Version	Comment
v2.2.9		
	The GTM family specification has been part of a continuous improvement process. Due to the fact, that there have several changes, this chapter can be regarded as completely new. reworked	
v2.2.10		
	Cleanup of document: Inserted missing links to chapters; correction of typos; added missing frames for figures; format cleanup for notes in register and bit descriptions	
see next column for search text	Wrong name FXCMU_CLK replaced by CMU_FXCLK (see end of section “TGC Sub-unit”, and third paragraph in section “Continuous Counting Up-Down Mode” in chapter “Timer Output Module (TOM)”	
	Further description added to bitfields CCUxTC in registers TOM[i]_CH[x]_IRQ_NOTIFY and ATOM[i]_CH[x]_IRQ_NOTIFY	
	Extended GTM Legacy Address table (see “GTM Legacy Address table” in chapter “GTM Application constraints and limitations”)	
	Updated Table 186, GTM ARU Read IDs (see table “GTM Read IDs” in chapter “ARU Read ID”)	
	Corrected table on GTM Configuration (see table “GTM Configuration by AURIX TC3xx Product” in chapter “GTM Implementation”)	
	Corrected description for MCS Data Input Path; updated figure (see figure “MCS Data Input Path” and paragraph after this figure in chapter “GTM Data Exchange Registers”)	
v2.2.11		
	Cleaning up the document: In case of missinglinks, replaced by full text to be able to search for.	
Blockdiagram page 1	Removed QSPI, as not existing in any silicon.	
ARU Routing Concept 3 paragraphs below figure	Maximum Throuput Mode (MTM), before wrongly named.	
BRC_SRC_z_DEST	Bitfield EN_DEST runvariable changed	
BRC_IRQ_NOTIF	Data inconsistency occurred (new!) for channel x (new end)in MTM mode	

Table 189 Revision History (cont'd)

Reference	Change to Previous Version	Comment
BRC_IRQ_EN	DID_IRQ_ENx (x=0-11) new description	
CMU_CLK_EN	DID_IRQ_ENx (x=0-11) new Enable clock source 0x - now with x insteadof 0.	
CCMi_HW_CONF	Precise reset value	
TOM[i]_TGC[y]_FUPD_CTRL	RSTCN0_CHx (x=0-7) now with x instead of 0	
MCS2DPLL_DEBn	corrected addresses	
ICM_IRQG_ATOM_[k]_CI	now for all ATOMs	
ICM_IRQG_CLS_[k]_MEI	corrected index	
CMP_IRQ_FORCINT	corrected index in bitfield TRG_TBWCx	
RESET1	corrected spelling	
Port Connections	exchanged to see appendix, as port information has been moved	
GTM Outputs to Port Connections	chapter removed as not valid for low end devices.	
table MCSx (x=0..9) Trigger Assignments	MCSTRIG replaced by MCS_TRIG	
OTSC1	corrected spelling	
MCS Master Interface Address Map	corrected addresses and naming	
v2.2.11		
	no relevant changes for family specification	
v2.2.12		
	no relevant changes for family specification	

Table 189 Revision History (cont'd)

Reference	Change to Previous Version	Comment
v2.2.13		
	Changed overview table as TC33x will have fast clusters only.	
v2.2.14		
	Remarks inside the OCDS Registers, concerning status, if TBU channel 3, DPLL or MCS do not exist on a device.	
	CCMi_HW_CONF gets proper bit descriptions, as constants have been all 0x0.	
v2.2.15		
	No changes in this part of the specification	
v2.2.16		
	EXT_TRIG bitfield description changed in Register: TOM[i]_CH[x]_CTRL, ATOM[i]_CH[x]_CTRL in SOMP mode and ATOM[i]_CH[x]_CTRL. TIM_[x-1] exchanged by TRIG_[x-1]	
v2.2.17		
	Removed unmotivated questionmarks and replaced ist by is.	
v2.2.18		
	Corrected Spelling bugs	
	IRQ_Notify providing hint, that this bit is rw and has to be written.	
v2.2.19		
	SPE bit ADIR also now in description as previously described as DIR (identical with signal name)	
	EDIS description including details	
	GTM_CCMi_TIM_AUX_IN_SRC including details	
	CCMi_CFG now included for all clusters	
	CDTM[i]_DTM[j]_CH_CTRL1.I1SEL_n registers corrected to proper bitfield meaning.	
	Minor changes, without any impact on functionality	
v2.2.20		
	Corrected description for ATOM[i]_AGC_ENDIS_CTRL.	
v2.2.21		
	CCMi_TIM_AUX_IN_SRC now the setting for 0x1 is properly setup	
	ADC interface remark, as only 32addresses exist, but 64 are specified. This is due to address reservation for future extensions.	
	MCSINTSTAT? due to very fuzzy description, some clarification and corrections were necessary. Now all signals mentioned can be found.	
v2.2.22		
	Correcting interrupt table, to proper naming	
v2.2.23		
	TC3xx GTM TIM Interrupt Bundling: Note added that according to MIG it is 8 interrupts per TIM module.	

Table 189 Revision History (cont'd)

Reference	Change to Previous Version	Comment
v2.2.24		
	(A)TOMi_CHx_CTRL.EXTTRIGOUT TRIGOUT corrected to TRIGOUT=0	
	ENDIS_CTRL/STAT text improved	
	MCSi_CHx_CTRL access rights corrected	
	DPLL_CTRL1.TSL bits do run from 0 to 3	

29 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application-specific modes, mainly for AC drive control. Special operating modes support the control of Brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported. It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 kernels. The CCU6 module consists of two identical kernels CCU60 and CCU61.

29.1 Feature List

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Supports generation of three-phase PWM (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Many interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

29.2 Overview

The CCU6 is made up of a Timer T12 Block with three capture/compare channels and a Timer T13 Block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive AC-motors or inverters.

This chapter is structured as follows:

29.2.1 Functional Overview

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

The Timer T12 can operate in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel operates in compare mode, whereas another channel operates in capture mode). The Timer T13 can operate in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

Note: The capture/compare module itself is named CCU6 (capture/compare unit 6).
The first instance of a CCU6 module, including kernels CCU60 and CCU61, is named CCU6061.
A capture/compare channel inside this module is named CC6x.
For easier readability, the term “CCU6” is used to refer to a CCU6 module as well as to a CCU6 kernel, unless a distinct differentiation is required.

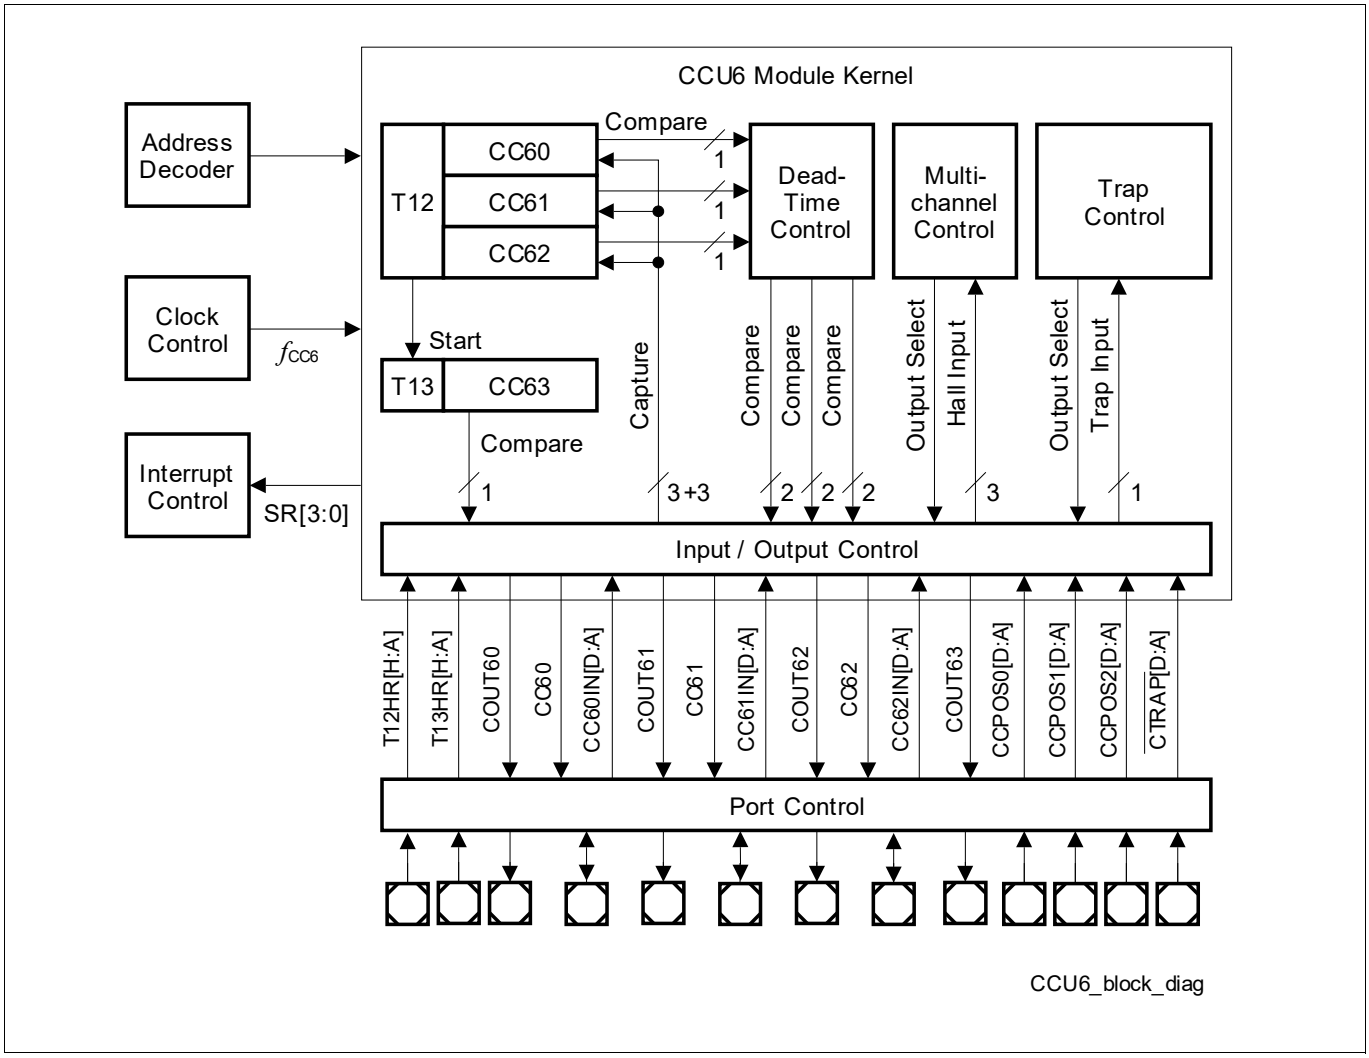

Figure 155 CCU6 Block Diagram

29.2.2 CCU6 Register Overview

Figure 156 shows the kernel registers of a CCU6 . BPI registers are described separately in **Section 29.11.6**, the Module Output Select register MOSEL is described in **Section 29.11.5**.

CCU6 Kernel Register Overview

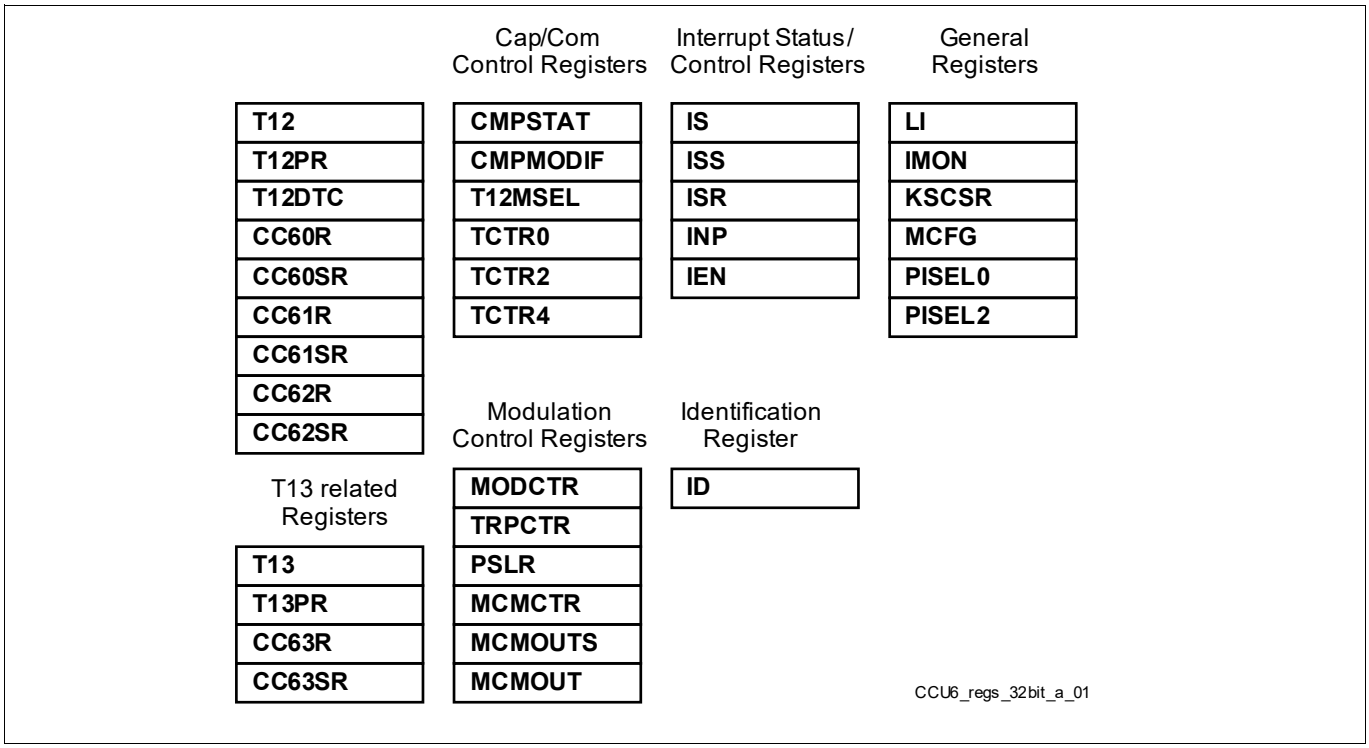

Figure 156 CCU6 Registers

Table 190 summarizes all registers required for programming of a CCU6 . It includes the CCU6 kernel registers, BPI and Module Output Select register, and defines their offset addresses and reset.

For the specific register table, the prefix “CCU6x_” has to be added to the register names in this table to identify the registers of different CCU6 kernels that are implemented. In this naming convention, x indicates the kernel number.

The CCU6 module has no destructive register read mechanisms.

In the case of a write access to addresses inside the address range (that is covered by the same chip select signal), but that are not the addresses explicitly mentioned for the module, the write access is not taken into account for the module. The same principle is valid for read accesses. In case of a read access to another address, the module does not react.

*Note: The exact register address is given by the relative address of the register (given in **Table 190**) plus the kernel base address (given in the appendix).*

Note: The Module Output Select Register MOSEL controls the trigger signals from both CCU6 kernels (CCU60 and CCU61) and is only available in the address space of kernel CCU60.

29.3 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs.
Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see **Section 29.3.1**)
- Counting scheme (see **Section 29.3.2**)
- Compare modes (see **Section 29.3.3**)
- Compare mode output path (see **Section 29.3.4**)
- Capture modes (see **Section 29.3.5**)
- Shadow transfer (see **Section 29.3.6**)
- T12 operating mode selection (see **Section 29.3.7**)
- T12 register description (see **Section 29.3.8**)

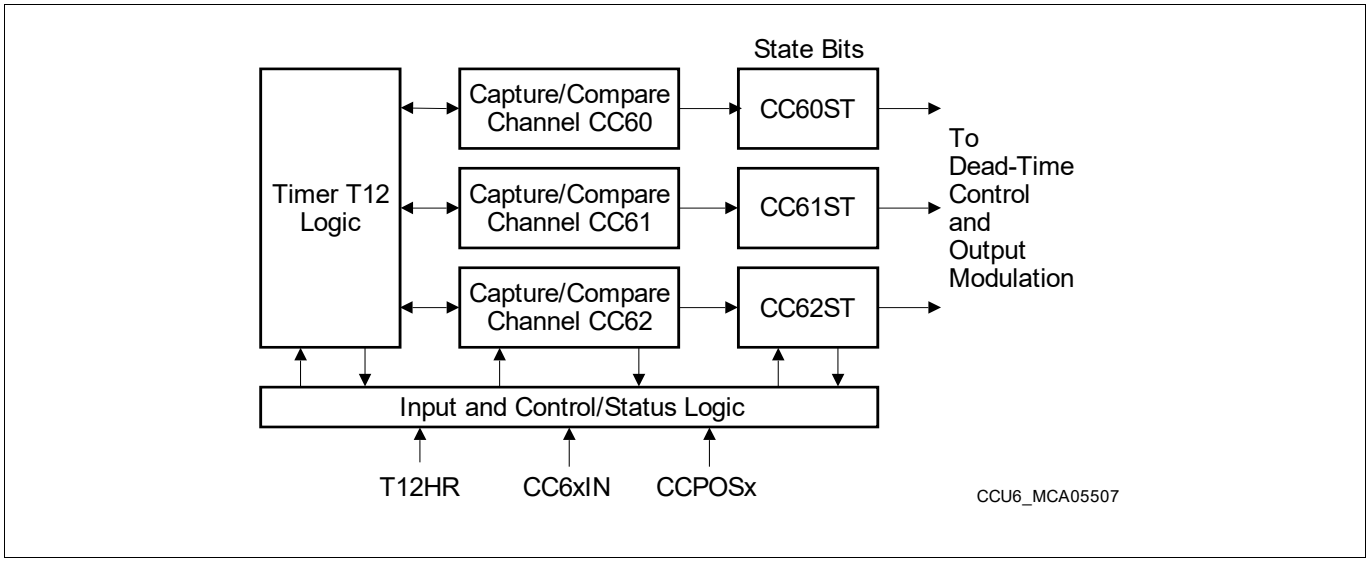

Figure 157 Overview Diagram of the Timer T12 Block

29.3.1 T12 Overview

Figure 158 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL0**.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see **Table 191**). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

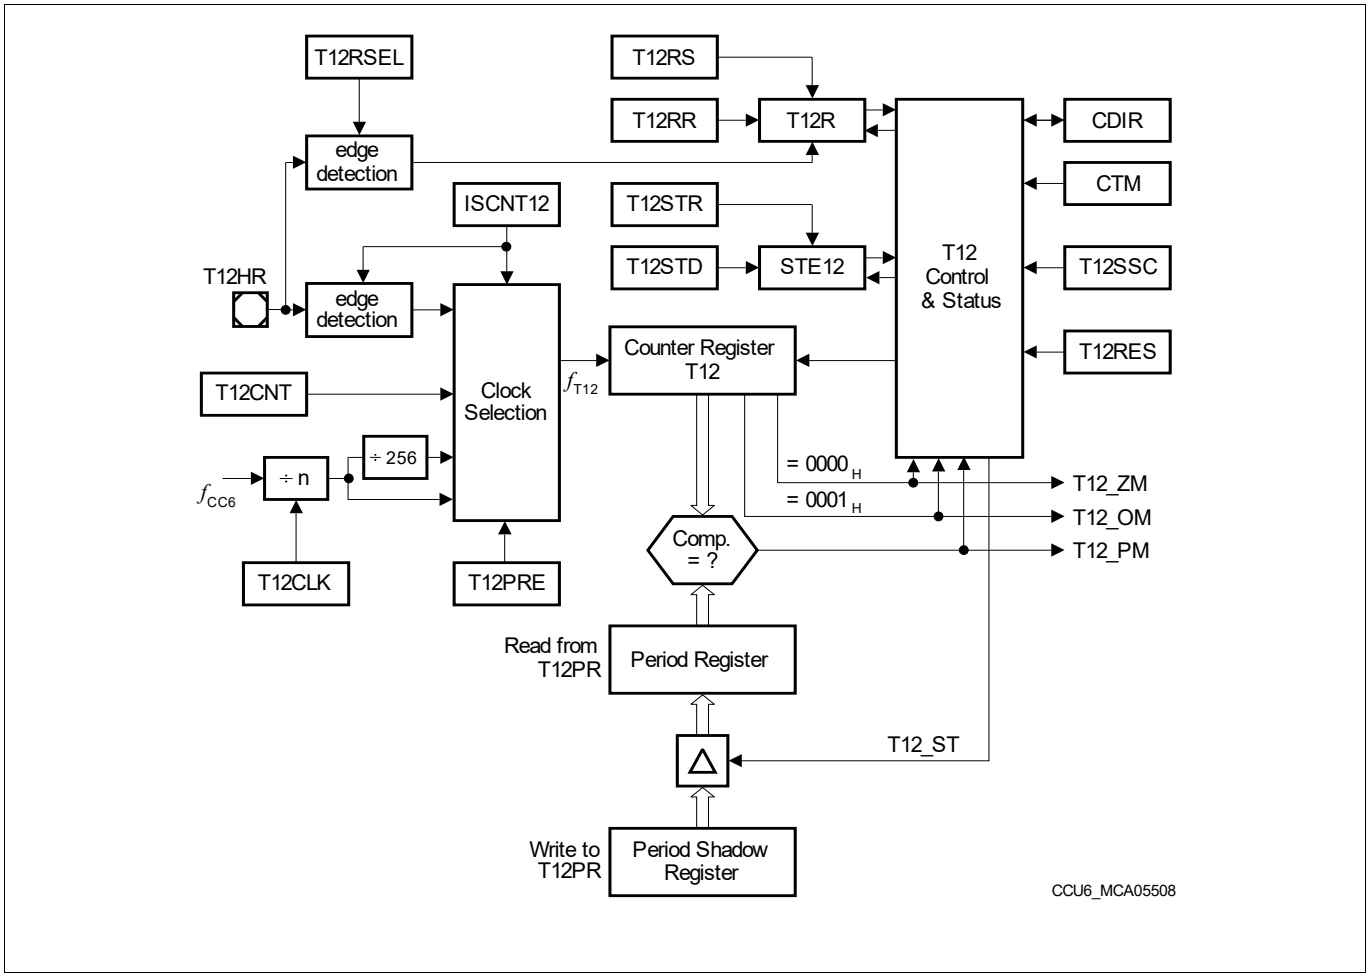

Figure 158 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register **T12** is connected to a Period Register **T12PR**. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from ‘up’ to ‘down’ after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.

A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see **Section 29.3.6**) is controlled via the ‘T12 Shadow Transfer’ control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.

Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode (**Figure 159**) or Center-Aligned mode (**Figure 160**), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 161** and **Figure 162**).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register **TCTR4**. The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR (**TCTR2**.T12RSEL), or it is cleared by hardware according to preselected conditions.
The timer T12 run bit T12R must not be set while the applied T12 period value is zero.
Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.
While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

29.3.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

29.3.2.1 Clock Selection

In **Timer Mode** (**PISEL2**.ISCNT12 = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 191**. The prescaler of T12 is cleared while T12 is not running (**TCTR0**.T12R = 0) to ensure reproducible timings and delays.

Table 191 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock *f*T12 Prescaler Off (T12PRE = 0)	Resulting Input Clock *f*T12 Prescaler On (T12PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to **TCTR4**.T12CNT and **PISEL2**.ISCNT12 = 01_B
- If a rising edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 10_B
- If a falling edge of input signal T12HR is detected and **PISEL2**.ISCNT12 = 11_B

29.3.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

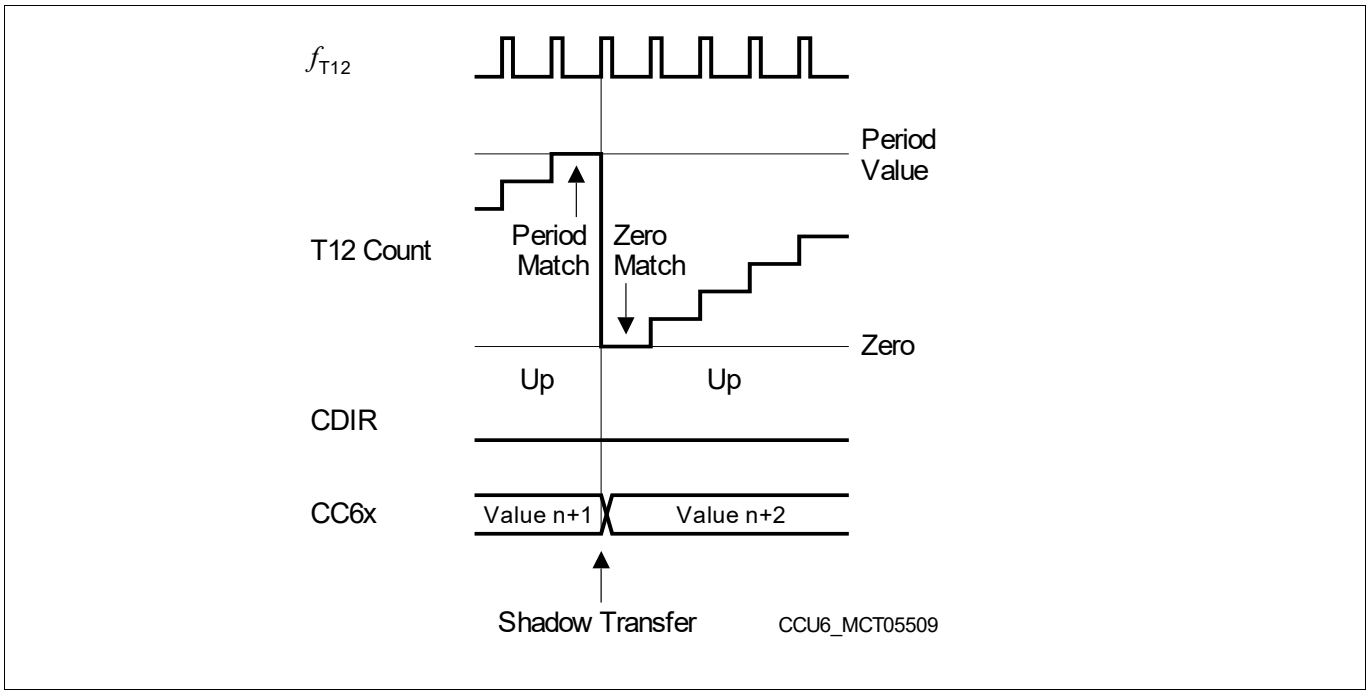

Figure 159 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$T12_{PER}$ = <Period-Value> + 1; in T12 clocks (f_{T12}) (29.1)

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.
When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center.Aligned mode, the timer period is given by:

$T12_{PER}$ = (<Period-Value> + 1) x 2; in T12 clocks (f_{T12}) (29.2)

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

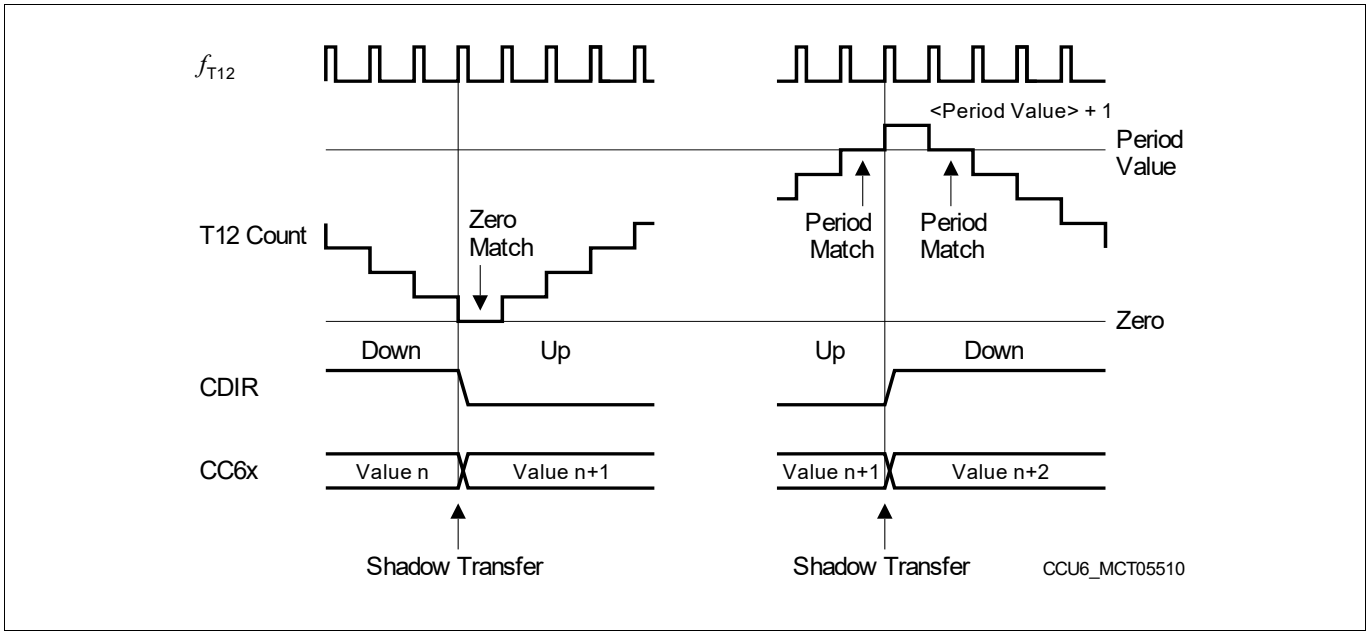

Figure 160 T12 Operation in Center-Aligned Mode

*Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see **Figure 160**).*

29.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see **Figure 161**).

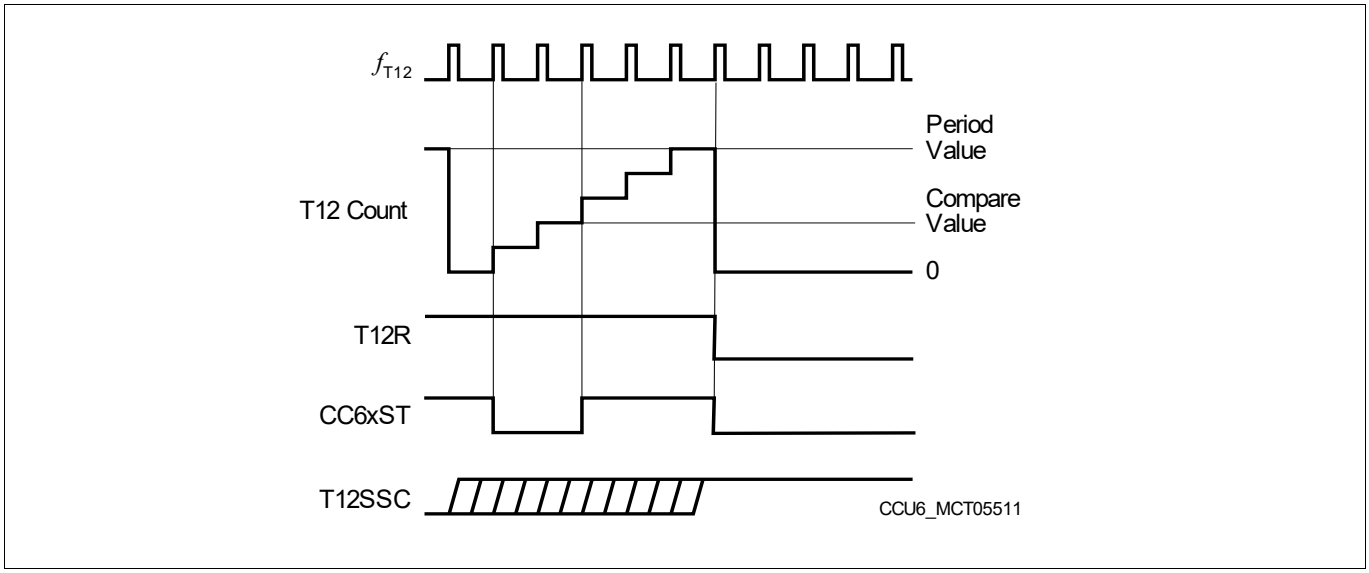

Figure 161 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see **Figure 162**).

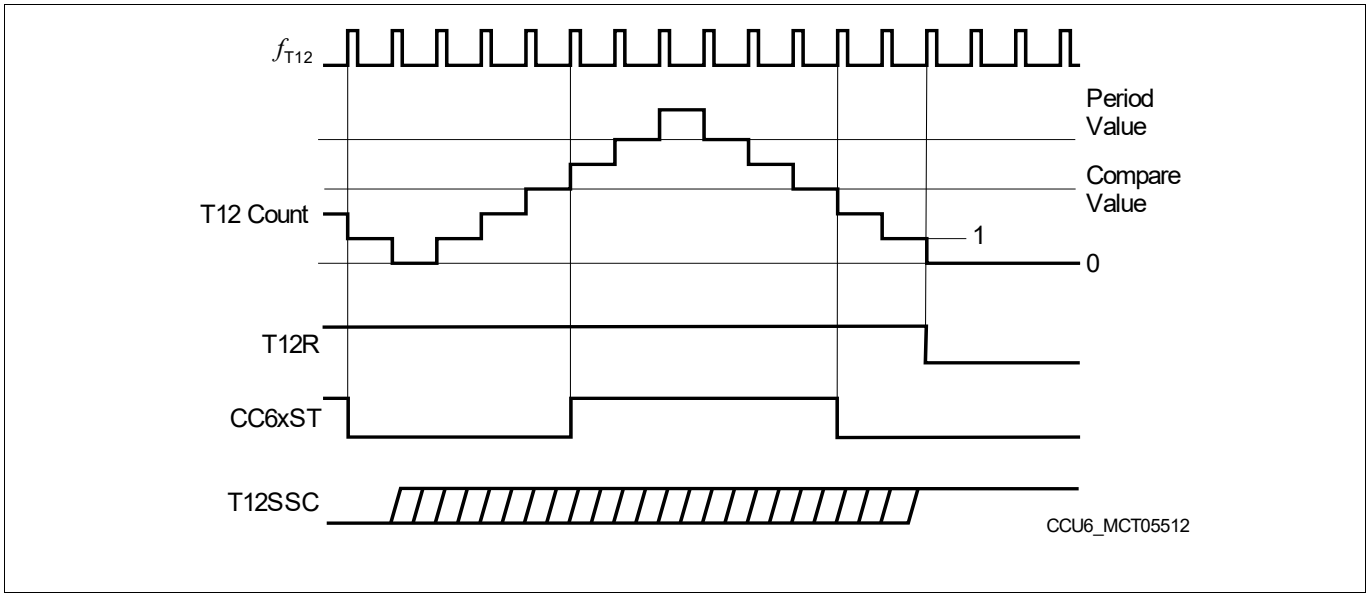

Figure 162 Single-Shot Operation in Center-Aligned Mode

29.3.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in **Section 29.3.5**.

29.3.3.1 Compare Channels

In Compare Mode (see **Figure 163**), the three individual compare channels CC60 CC61, and CC62 can generate a three-phase PWM pattern.

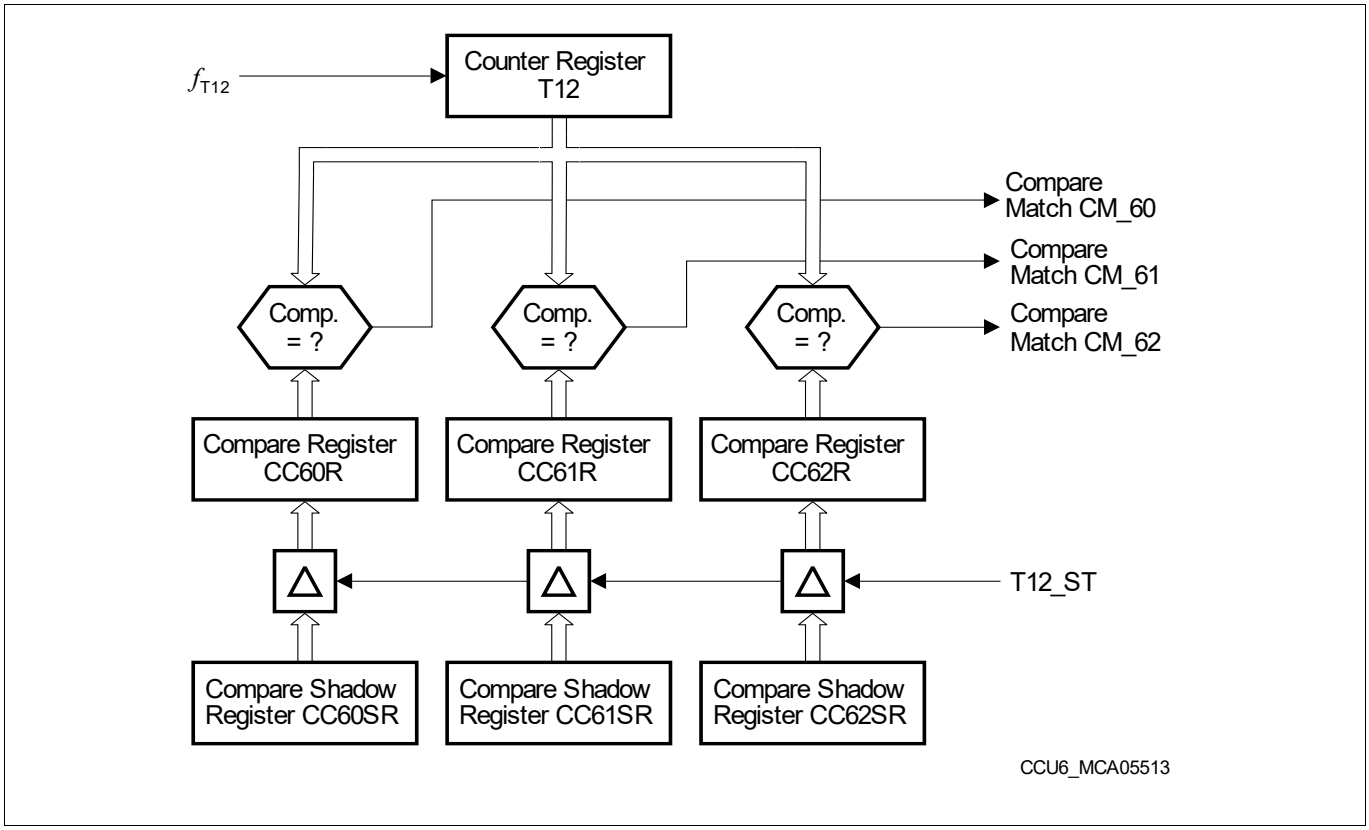

Figure 163 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

29.3.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, **CMPSTAT**.CC6xST, holding the status of the compare (or capture) operation (see **Figure 164**). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

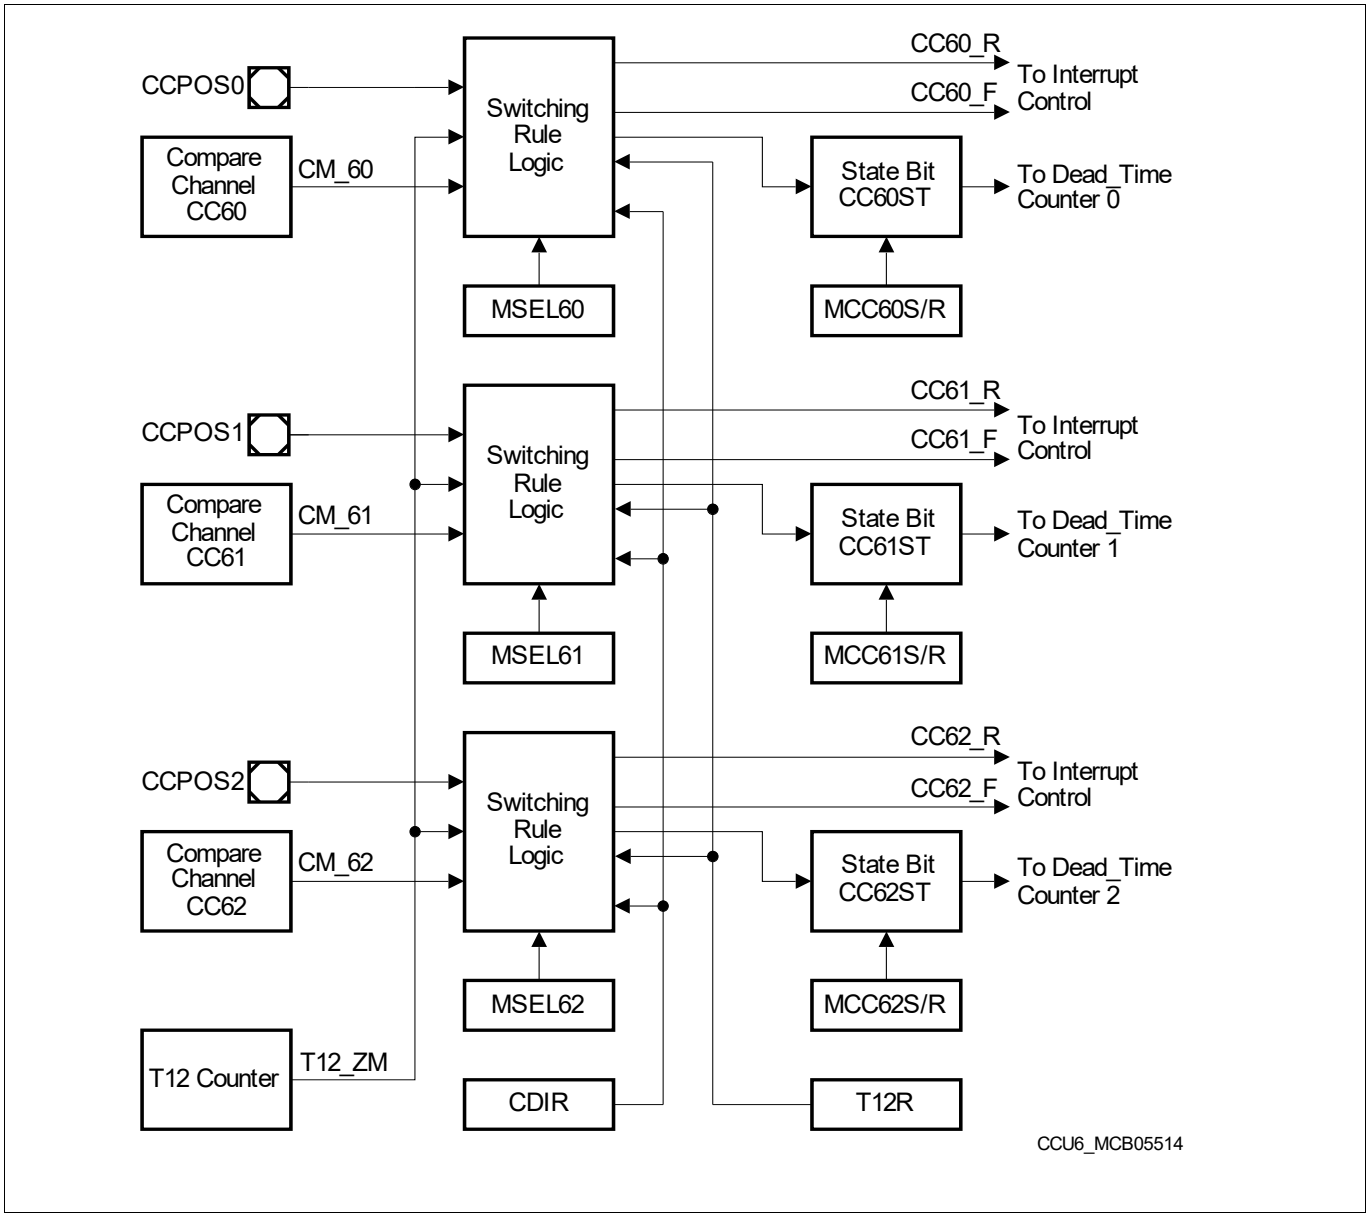

Figure 164 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, **T12MSEL**.MSEL6x.
In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register **CMPMODIF**, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in **Figure 165** and **Figure 166**):

A State Bit **CC6xST is set** to 1:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST is cleared** to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

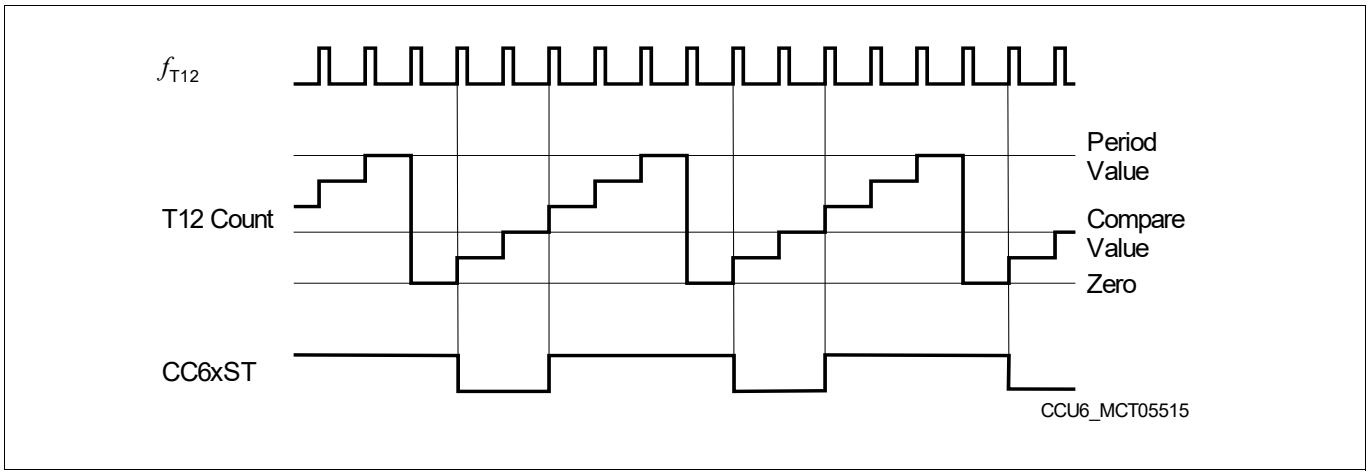

Figure 165 Compare Operation, Edge-Aligned Mode

Figure 167 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

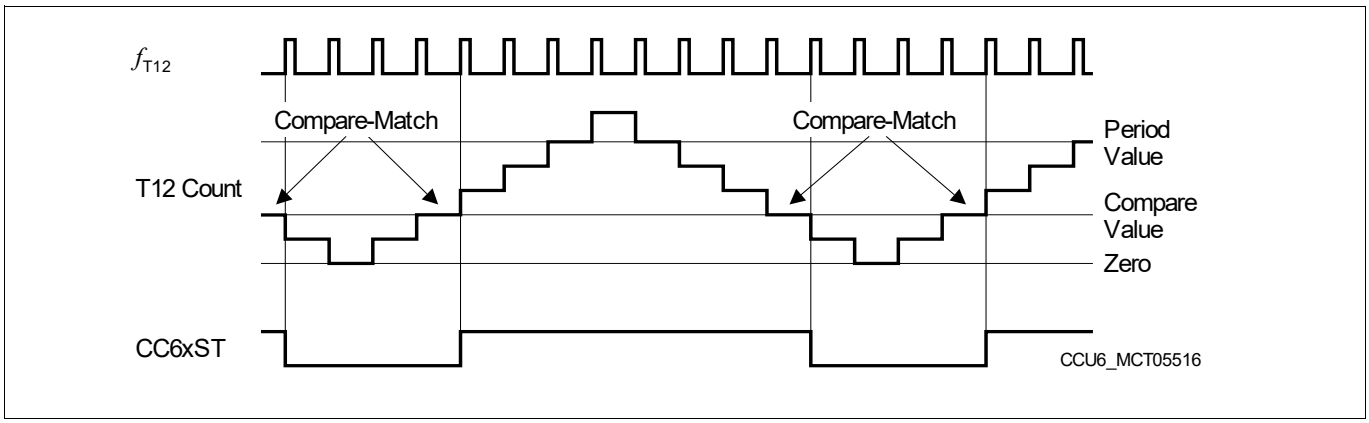

Figure 166 Compare Operation, Center-Aligned Mode

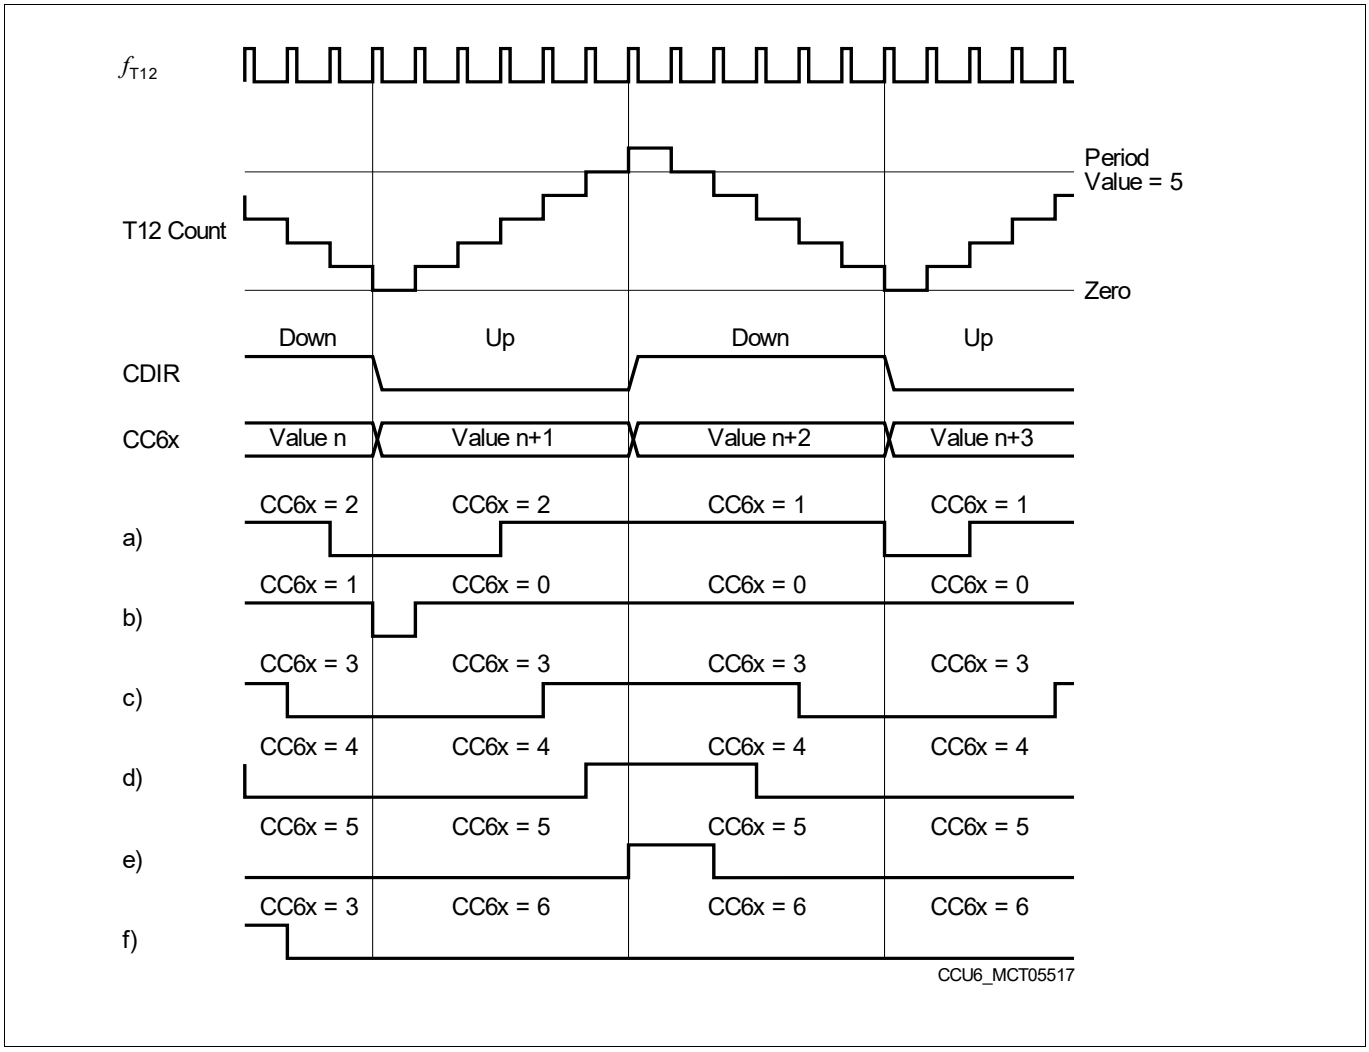

Figure 167 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H. Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H. In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule ‘zero-match AND compare-match’ is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to <Period-Value> + 1, and the State Bit CC6ST remains cleared.

Figure 168 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

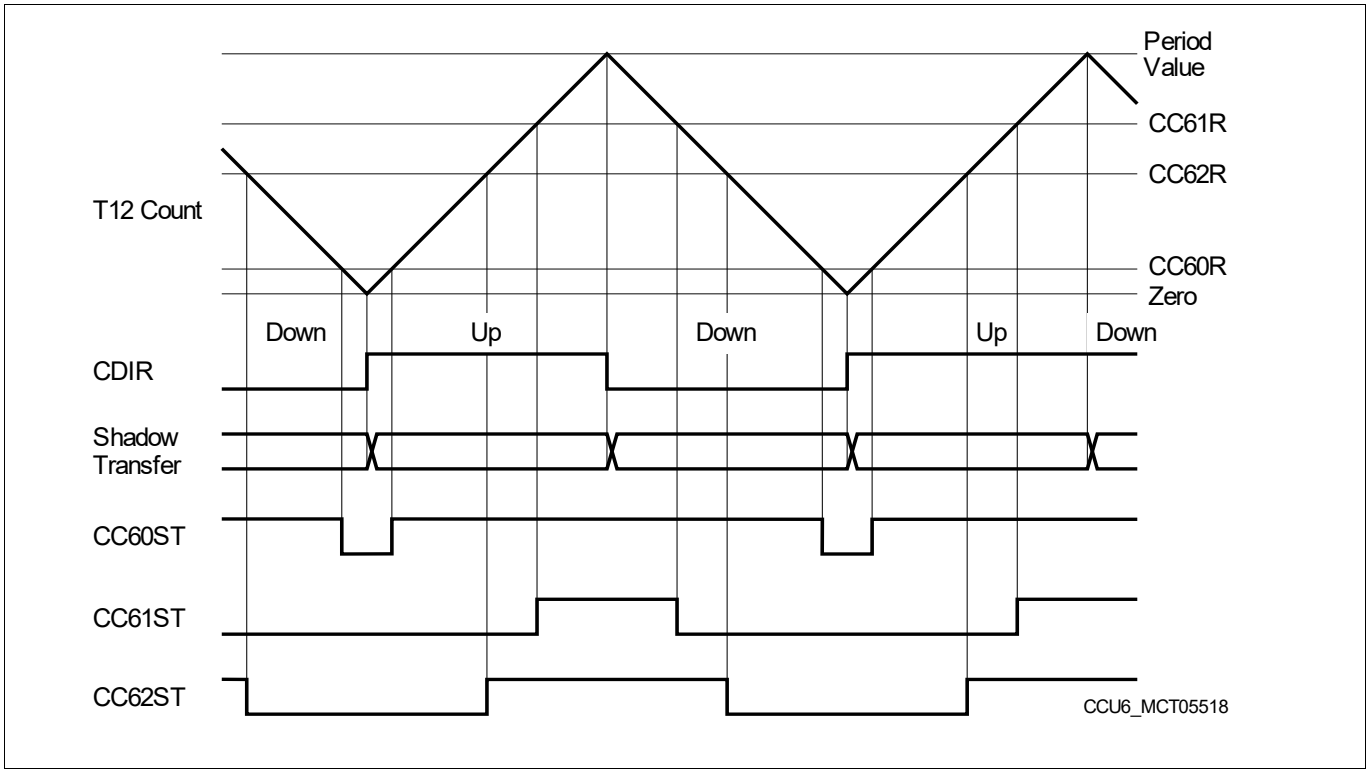

Figure 168 Three-Channel Compare Waveforms

29.3.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode (**T12MSEL**.MSEL6x = 1001_B) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.

As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see **Figure 164** for the state bit logic and **Figure 169** for the output paths).

The CCPOSx inputs are evaluated with f_{CC6}.

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

29.3.4 Compare Mode Output Path

Figure 169 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to **Section 29.3.4.3** for details on the output modulation.

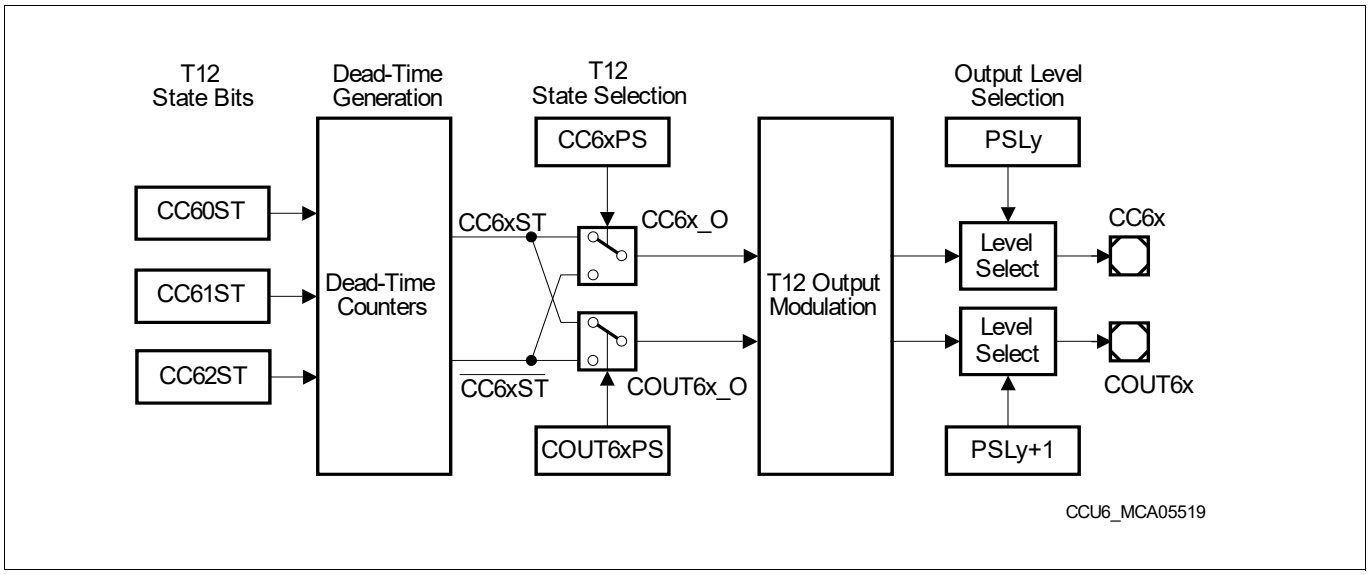

Figure 169 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

29.3.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).
In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in **Figure 170**, is built in a similar way for all three channels of T12. It is controlled by bits in register **T12DTC**. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing **TCTR4**.DTRES = 1 sets all dead-times to passive.

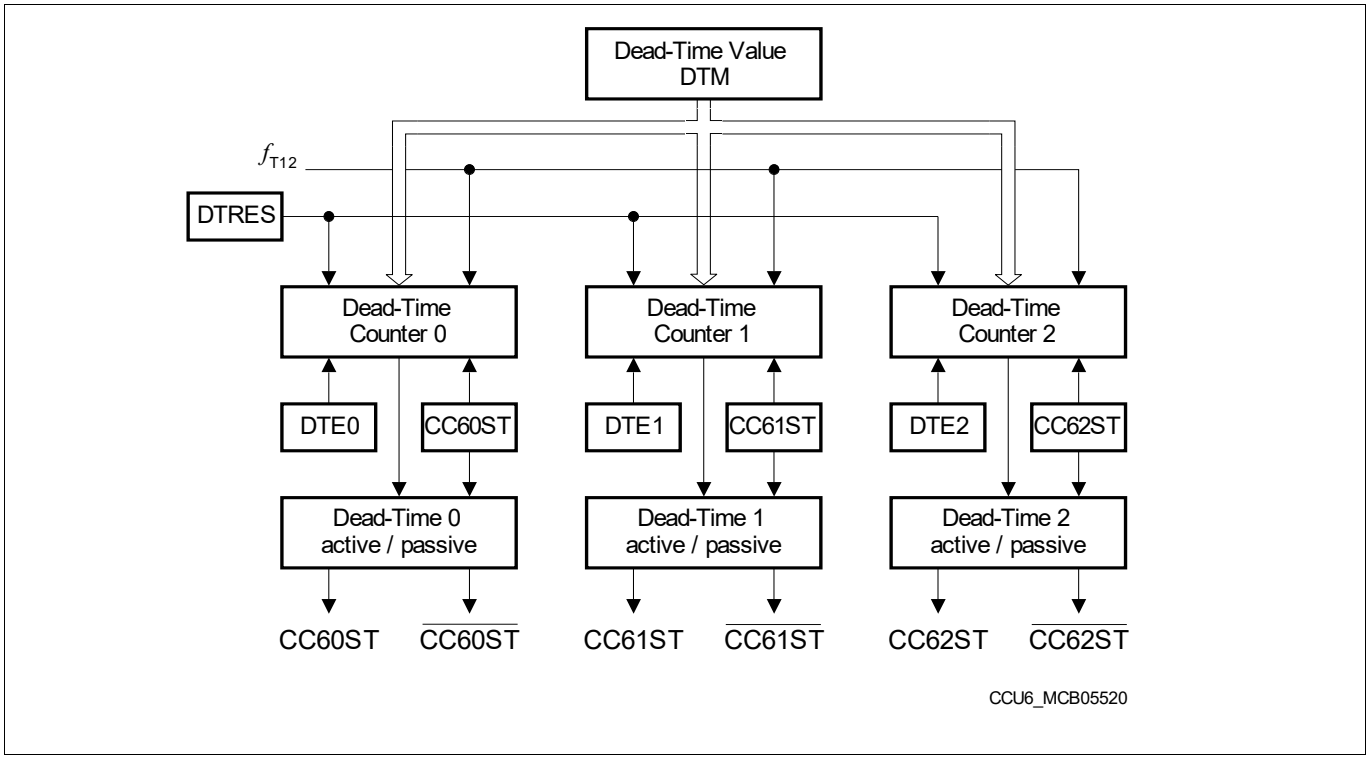

Figure 170 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTEx. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6xST changes too early.
A disabled dead-time counter is always considered as passive and does not delay any edge of CC6xST.
Based on the State Bits CC6xST, the Dead-Time Generation Block outputs a direct signal CC6xST and an inverted signal $\overline{CC6xST}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in **Figure 171**).

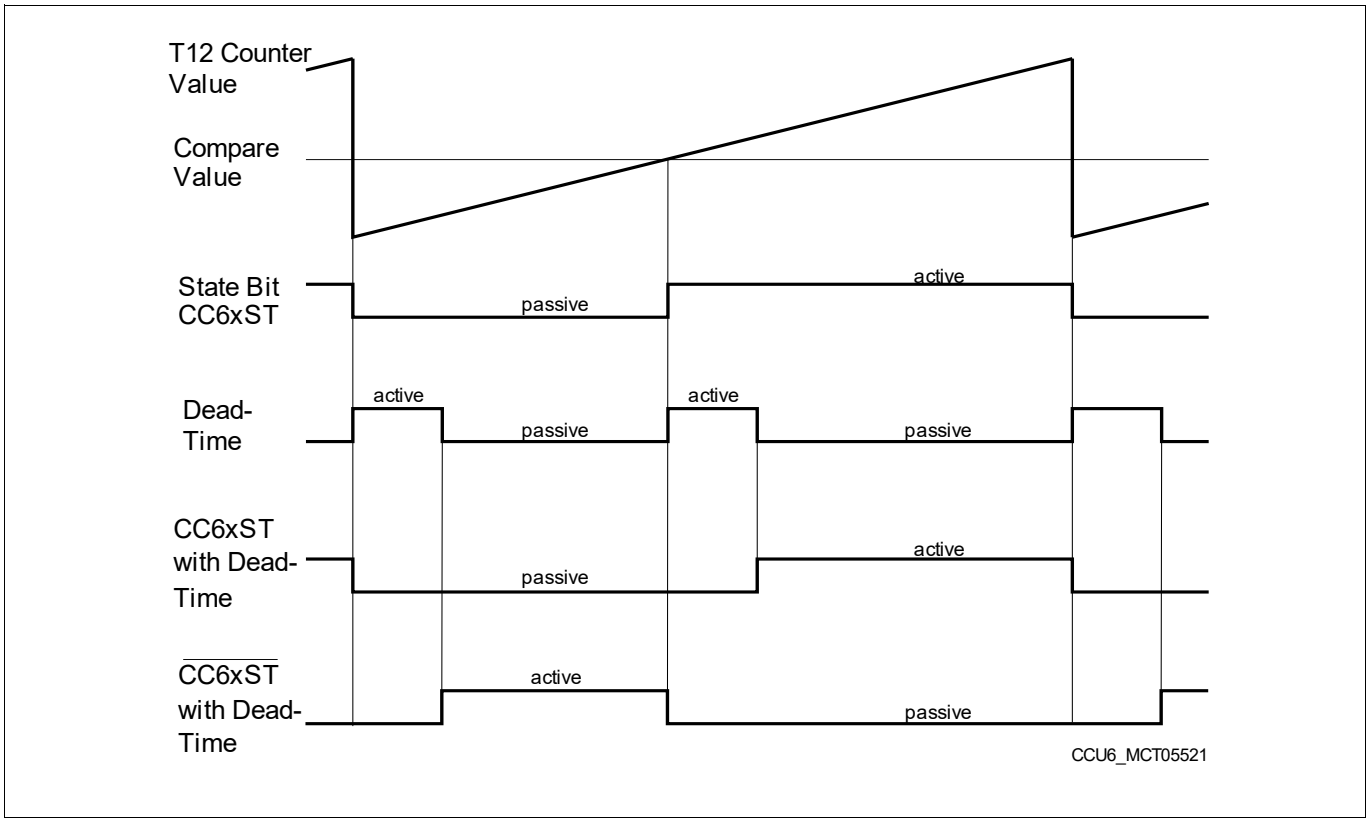

Figure 171 Dead-Time Generation Waveforms

29.3.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals. The state selection is based on the signals CC6xST and $\overline{\text{CC6xST}}$ delivered by the dead-time generator (see **Figure 169**). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit CC6xST.
The user can select independently for each output signal CC6xO and COUT6xO if it should be active before or after the compare value has been reached (see register **CMPSTAT**). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal CC6xO can be active before, whereas COUT6xO can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

29.3.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register **MODCTR**). The following signal sources can be combined here **for each T12 output signal** (see **Figure 172** for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register **PSLR**. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Figure 172 shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

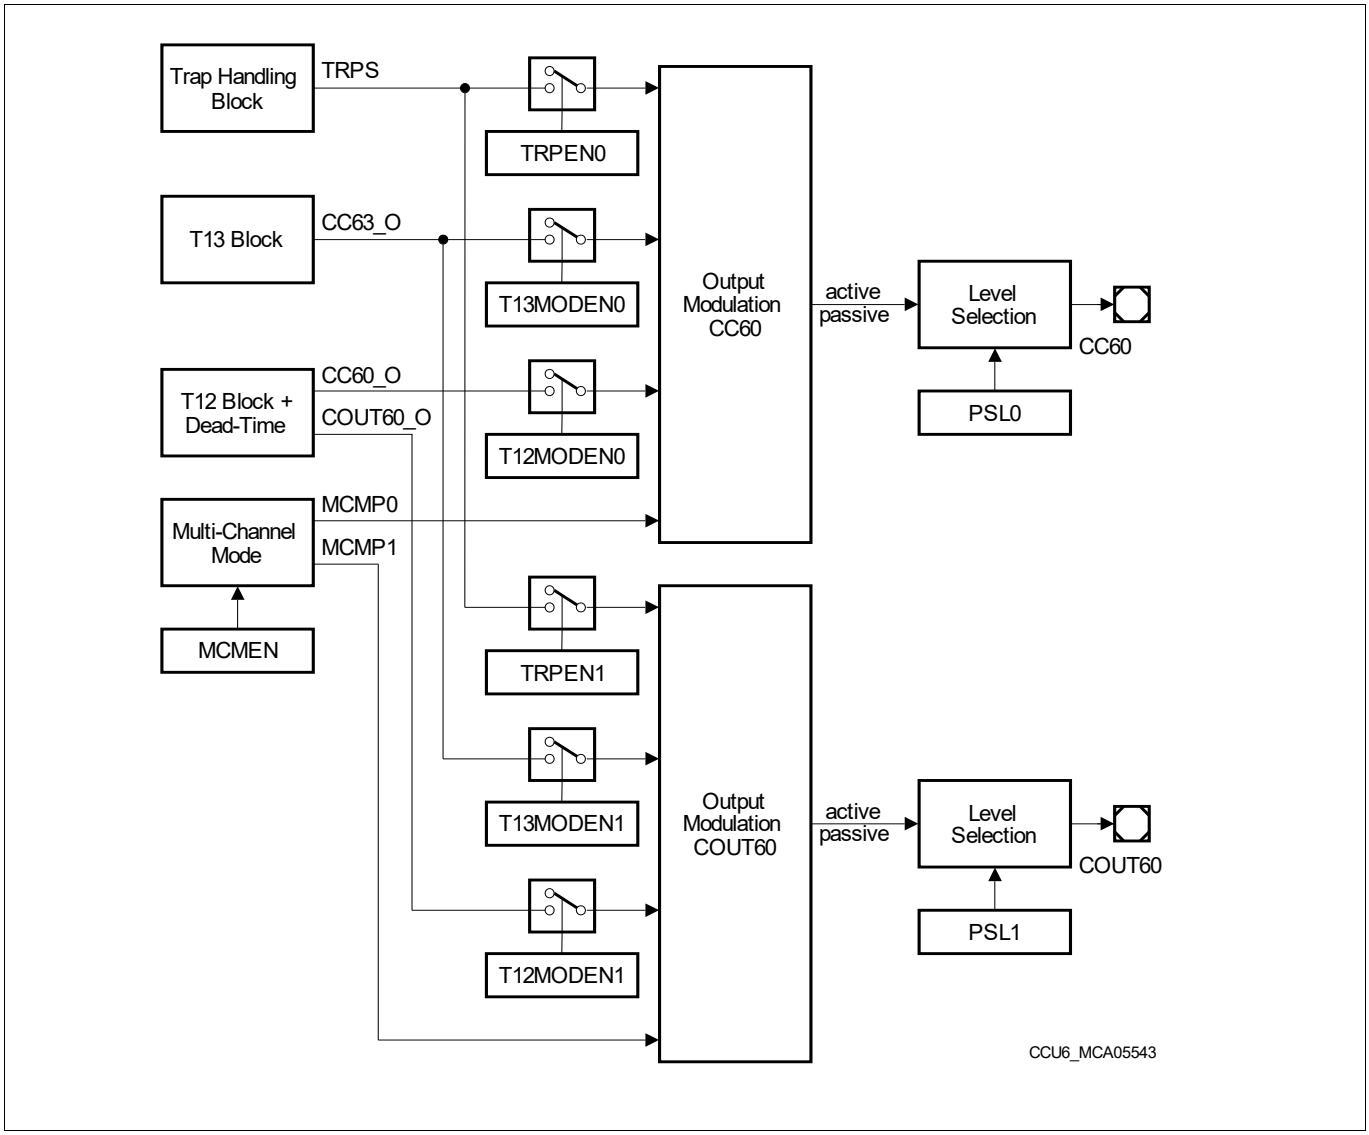

Figure 172 Output Modulation for Compare Channel CC60

29.3.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.
In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the **T12MSEL**.MSEL6x bit fields and can be selected individually for each of the channels.

Table 192 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6xSR Stored in	T12 Stored in
0100_B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101_B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110_B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111_B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 173 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

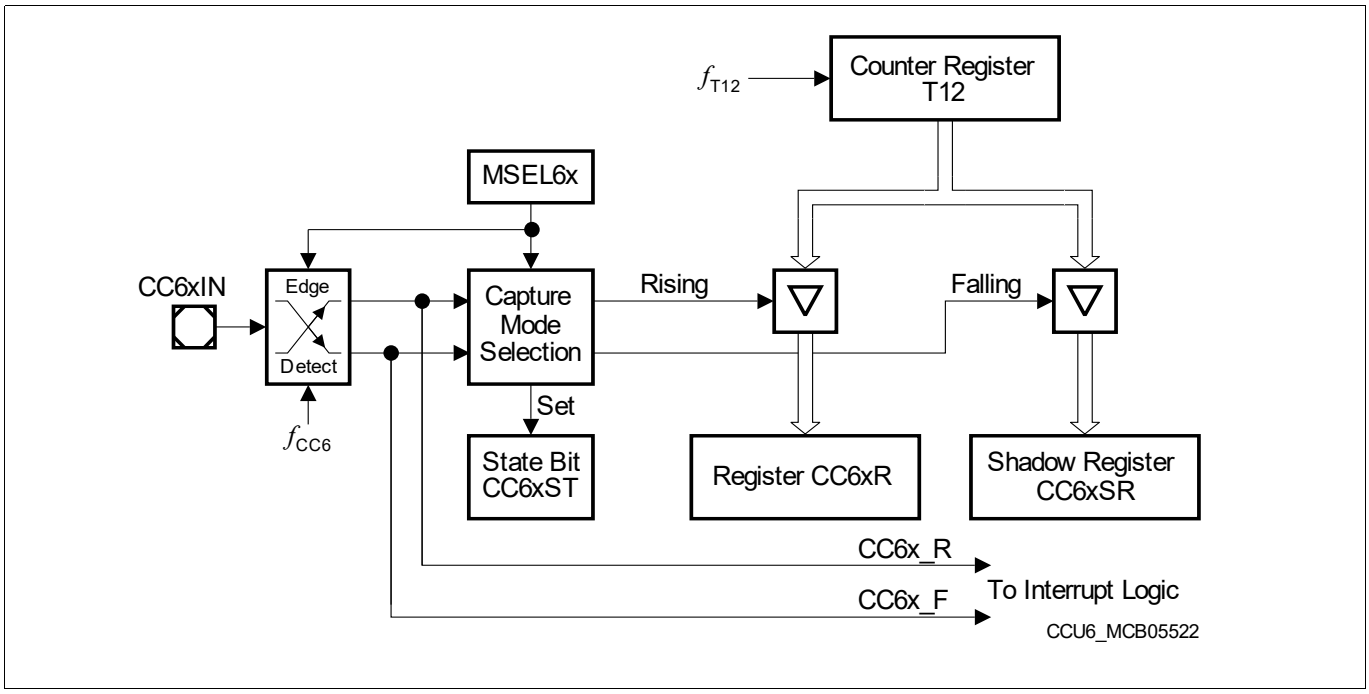

Figure 173 Capture Mode 1 Block Diagram

Capture Modes 2, 3 and 4 are shown in **Figure 174**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 192**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

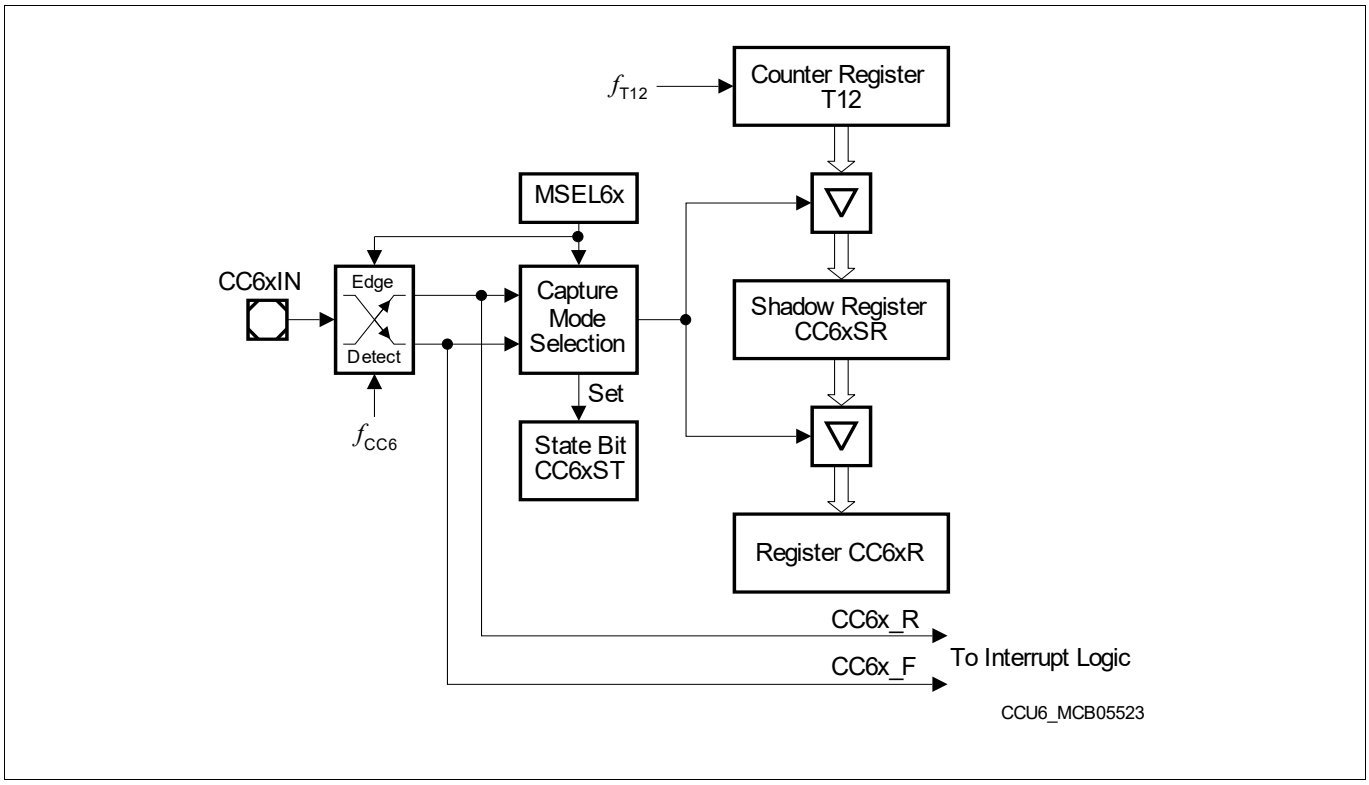

Figure 174 Capture Modes 2, 3 and 4 Block Diagram

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

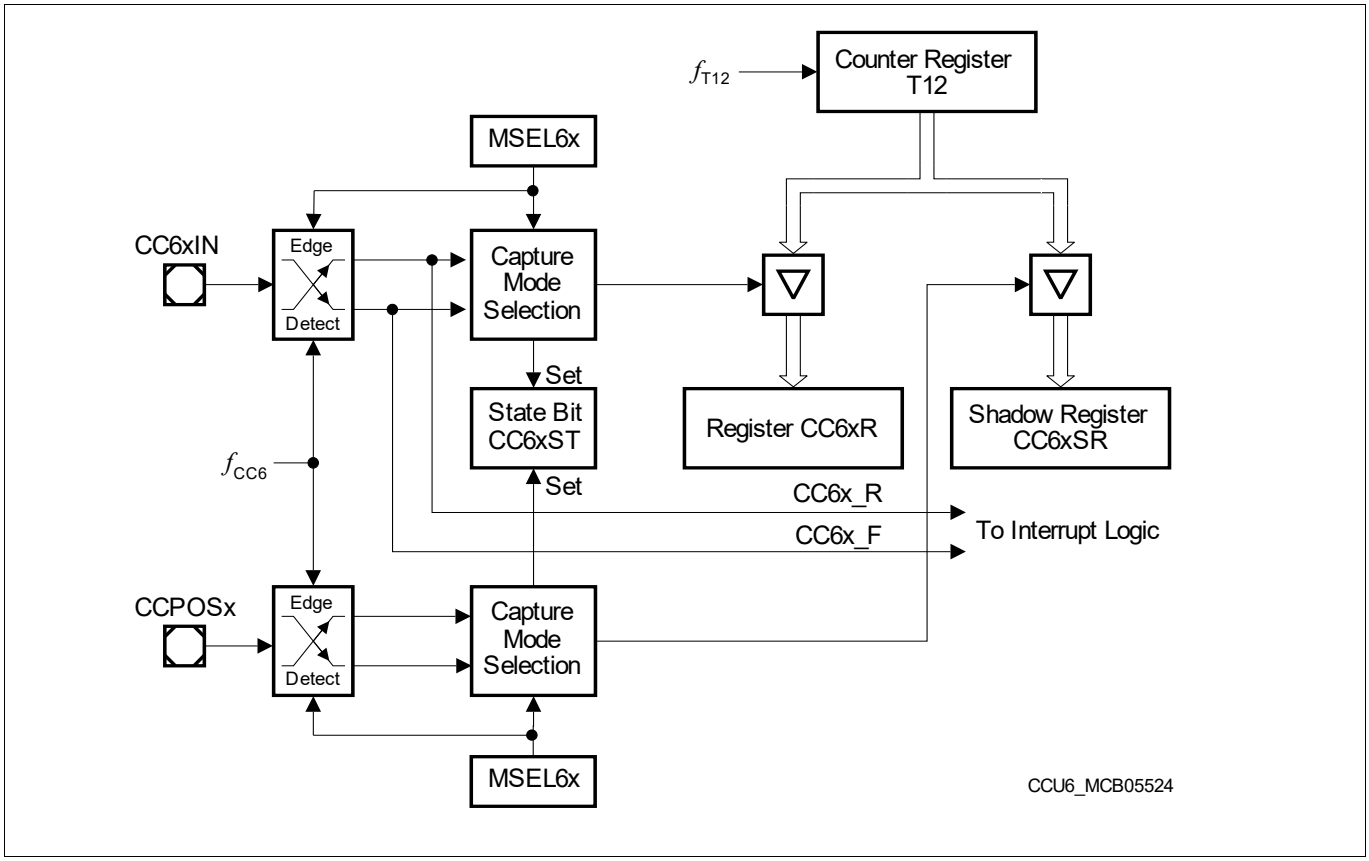

Figure 175 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in **Table 193**.

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also **Section 29.10**).

Table 193 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010_B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011_B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100_B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR

Table 193 Multi-Input Capture Modes Overview (cont'd)

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1101_B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110_B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111_B	–	Reserved (no capture or compare action)		

29.3.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE12 (set by writing 1 to the write-only bit **TCTR4**.T12STR, cleared by writing 1 to the write-only bit **TCTR4**.T12STD).

Figure 176 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

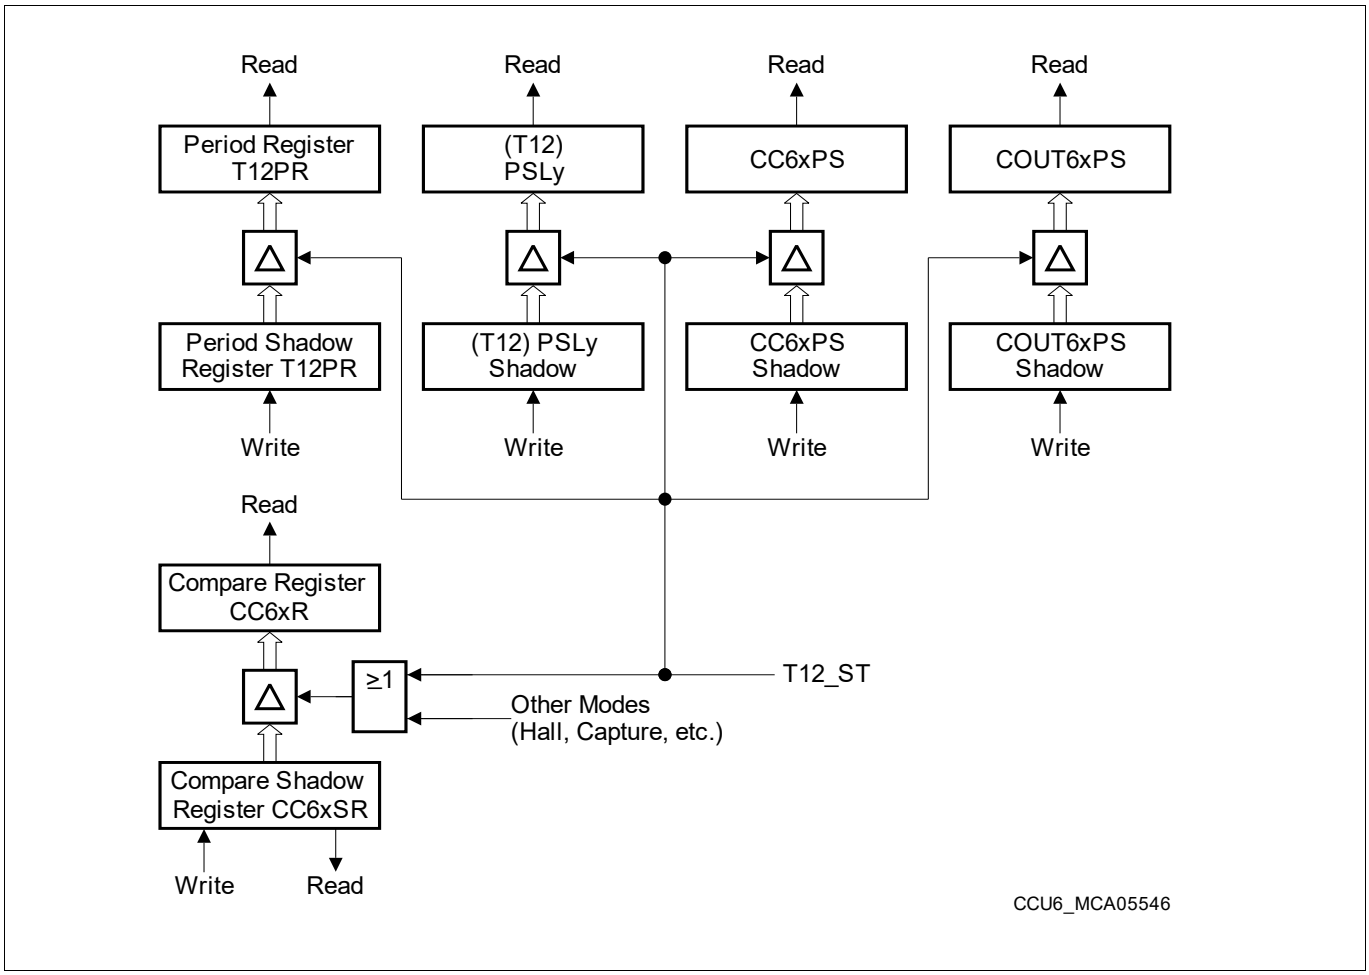

Figure 176 T12 Shadow Register Overview

A T12 shadow register transfer takes place (T12_ST active):

- While timer T12 is not running (T12R = 0), or
- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

29.3.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields **T12MSEL**.MSEL6x.

Table 194 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000_B, 1111_B	Capture/Compare modes switched off
0001_B, 0010_B, 0011_B	Compare mode, see **Section 29.3.3** same behavior for all three codings
$01XX_B$	Double-Register Capture modes, see **Section 29.3.5**
1000_B	Hall Sensor Mode, see **Section 29.8** In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001_B	Hysteresis-like compare mode, see **Section 29.3.3.3**
1010_B 1011_B, 1100_B, 1101_B 1110_B	Multi-Input Capture modes, see **Section 29.3.5**

The clocking and counting scheme of the timers are controlled by the timer control registers **TCTR0** and **TCTR2**. Specific actions are triggered by write operations to register **TCTR4**.

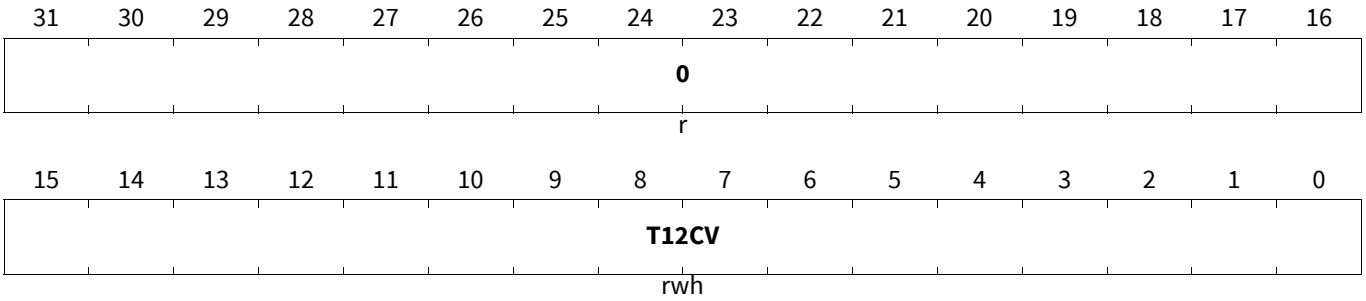
29.3.8 T12 related Registers

Timer T12 Counter Register

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW. In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

T12
Timer T12 Counter Register **(0020_H)** **Application Reset Value: $0000\ 0000_H$**

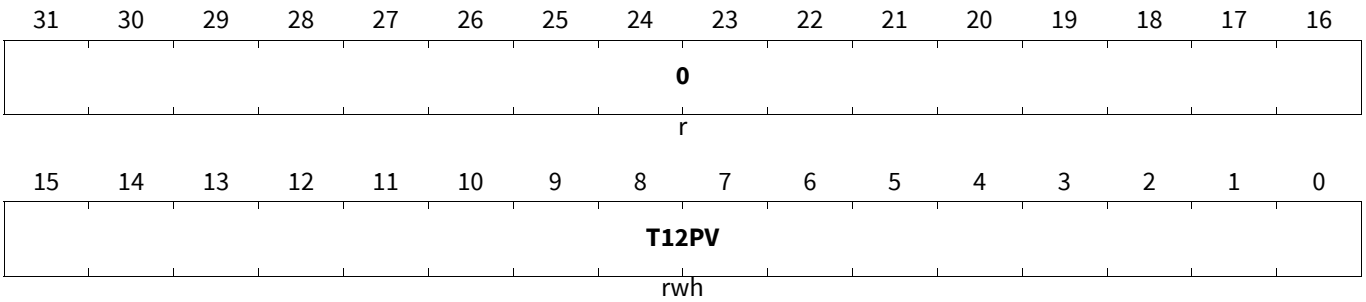


Field	Bits	Type	Description
T12CV	15:0	rwh	**Timer 12 Counter Value** This register represents the 16-bit counter value of Timer12.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Timer 12 Period Register

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value that is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

T12PR
Timer 12 Period Register **(0024_H)** **Application Reset Value: $0000\ 0000_H$**



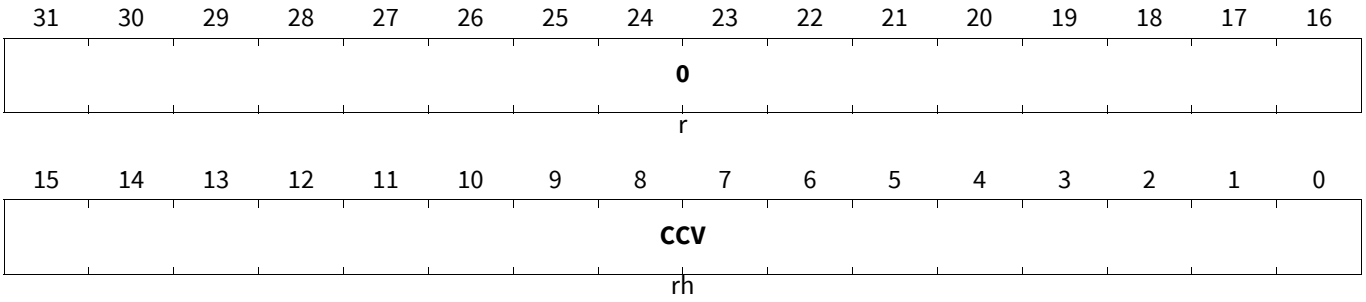
Field	Bits	Type	Description
T12PV	15:0	rwh	**T12 Period Value** The value T12PV defines the counter value for T12 leading to a period-match. When reaching this value, the timer T12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Capture/Compare Register for Channel CC6x

In compare mode, the registers CC6xR (x = 0 - 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

CC6xR (x=0-2)

Capture/Compare Register for Channel CC6x (0030$_H$+x*4) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CCV	15:0	rh	**Capture/Compare Value** In compare mode, the bit fields CCV contain the values, that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

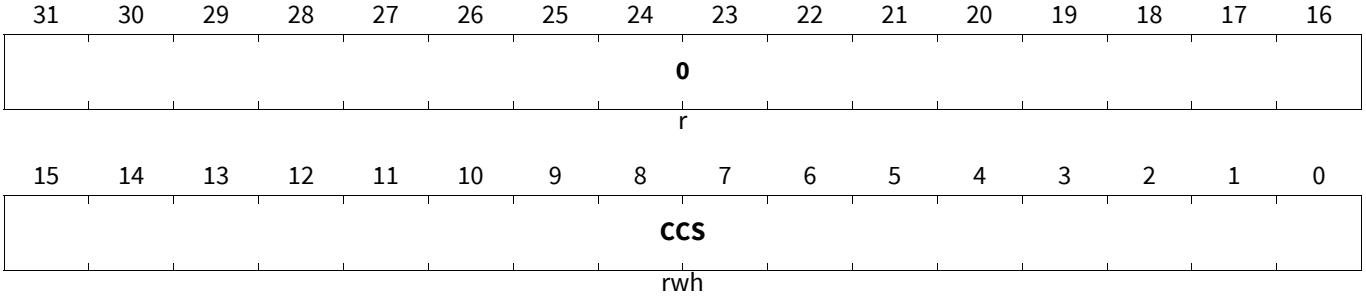
Capture/Compare Shadow Reg. for Channel CC6x

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected capture mode).

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

CC6xSR (x=0-2)

Capture/Compare Shadow Reg. for Channel CC6x(0040_H+x*4) **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CCS	15:0	rwh	**Shadow Register for Channel x Capture/Compare Value** In compare mode, the bit fields contents of CCS are transferred to the bit fields CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

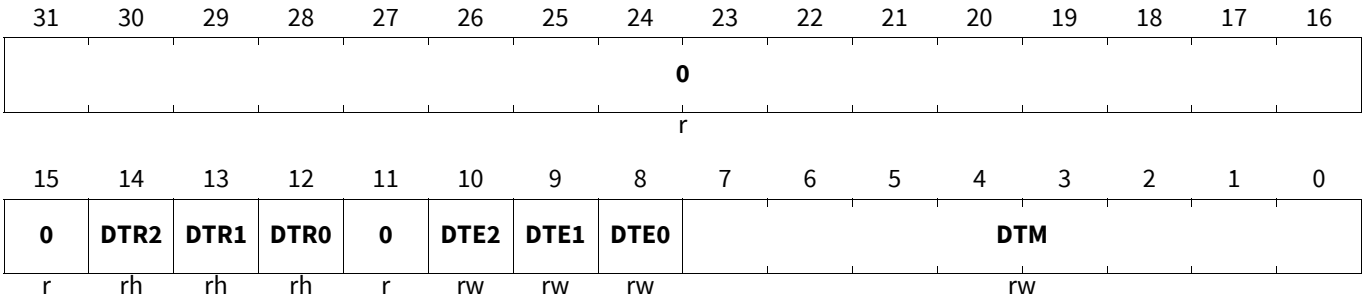
Dead-Time Control Register for Timer12

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM. The dead time counters are clocked with the same frequency as T12. This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead time.

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC

Dead-Time Control Register for Timer12 (0028_H) **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
DTM	7:0	rw	**Dead-Time** Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.

Field	Bits	Type	Description
DTEx (x=0-2)	x+8	rw	**Dead Time Enable Bits DTEx (x=0,1,2)** Bits DTE0…DTE2 enable and disable the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1_B Dead-Time Counter x is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTRx (x=0-2)	x+12	rh	**Dead Time Run Indication Bits DTRx (x=1,2,3)** Bits DTR0…DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is currently in the passive state. 1_B Dead-Time Counter x is currently in the active state.
0	11, 31:15	r	**Reserved;** Returns 0 if read; should be written with 0.

29.3.9 Capture/Compare Control Registers

Compare State Register

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state and control bits defining the active/passive state of the compare channels.

Note: Bits CC6xPS, COUT6xPS (x = 0-2) and COUT63PS have shadow bits and are updated in parallel to the capture/compare registers of T12, T13 respectively. A read action targets the actually used values, whereas a write action targets the shadow bits.

Note: Bit T13IM has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit.

CMPSTAT
Compare State Register **(0060_H)** **Application Reset Value: $0000\ 0000_H$**

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	r	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
CC6xST (x=0-2)	x	rh	**Capture/Compare State Bits for CC6x (x = 0, 1, 2)** Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST (x = 0, 1, 2) are related to T12 and are set and cleared according to the T12 switching rules. 0_B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been cleared by SW the last time. 1_B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.
CCPOS6x (x=0-2)	x+3	rh	**Sampled Hall Pattern Bits** Bits CCPOS6x (x = 0, 1, 2) are indicating the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event HCRDY (Hall Compare Ready) occurs. 0_B The input CCPOSx has been sampled as 0. 1_B The input CCPOSx has been sampled as 1.

Field	Bits	Type	Description
CC63ST	6	rh	**Capture/Compare State Bit for CC63** Bit CC63ST monitors the state of the compare channel. Bit CC63ST is related to T13 and is set and cleared according to the T13 switching rules. 0_B In compare mode, the timer count is less than the compare value. 1_B In compare mode, the counter value is greater than or equal to the compare value.
CC6xPS (x=0-2)	2*x+8	rwh	**Passive State Select for Compare Outputs CC6x (x = 0, 1, 2)** Bits CC6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS (x = 0, 1, 2) are related to T12. In capture mode, these bits are not used. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1.
COUT6xPS (x=0-2)	2*x+9	rwh	**Passive State Select for Compare Outputs COUT6x (x = 0, 1, 2)** Bits COUT6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits COUT6xPS (x = 0, 1, 2) are related to T12. In capture mode, these bits are not used. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1.
COUT63PS	14	rwh	**Passive State Select for Compare Output COUT63** Bit COUT63PS selects the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bit COUT63PS is related to T13. 0_B The corresponding compare signal is in passive state while CC63ST is 0. 1_B The corresponding compare signal is in passive state while CC63ST is 1.
T13IM	15	rwh	**T13 Inverted Modulation** Bit T13IM inverts the T13 signal for the modulation of the CC6x and COUT6x (x = 0, 1, 2) signals. 0_B T13 output CC63_O is equal to CC63ST. 1_B T13 output CC63_O is equal to $\overline{\text{CC63ST}}$.
0	7, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Compare State Modification Register

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped, by a single data

write action. The functionality of a write access to bits concerning the same capture/compare state bit is shown in the following **Table 195**.

Table 195 Write Access to Bit Pair MCC6xR, MCC6xS in Register CMPMODIF

[MCC6xR, MCC6xS]	Function
00_B	Bit CC6xST is not changed
01_B	Bit CC6xST is set
10_B	Bit CC6xST is cleared
11_B	Reserved

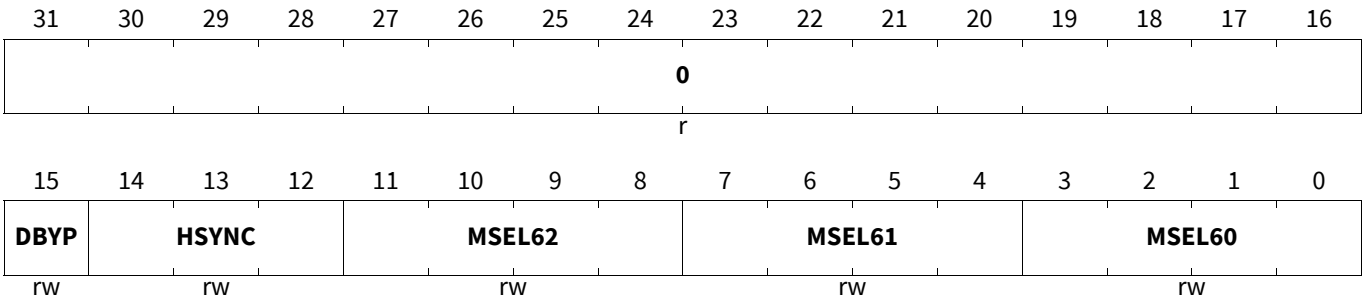
T12 Mode Select Register

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of Timer T12.

T12MSEL

T12 Mode Select Register (0068$_H$) Application Reset Value: 0000 0000$_H$



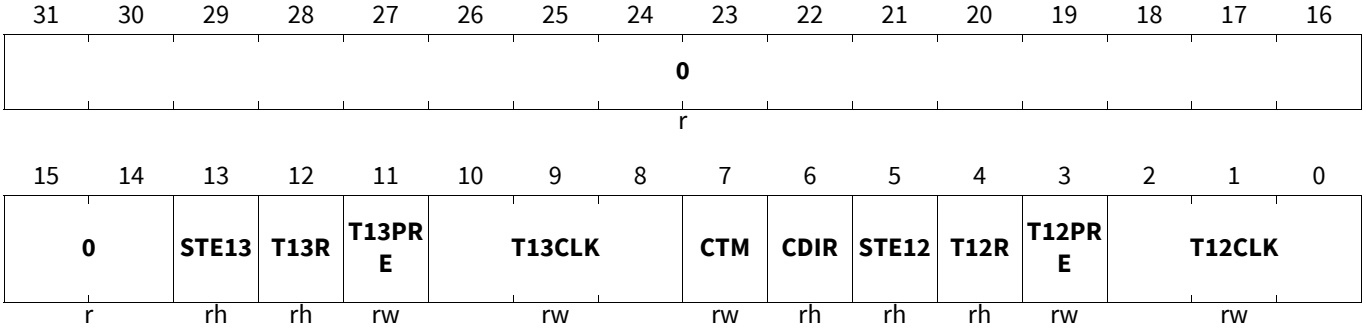
Field	Bits	Type	Description
MSEL6x (x=0-2)	4*x+3:4*x	rw	**Capture/Compare Mode Selection MSEL6x (x=0,1,2)** These bit fields select the operating mode of the three T12 capture/compare channels. Each channel (x = 0, 1, 2) can be programmed individually for one of these modes (except for Hall Sensor Mode). Coding see **Table 194**.
HSYNC	14:12	rw	**Hall Synchronization** Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. Coding see **Table 201**.
DBYP	15	rw	**Delay Bypass** DBYP controls whether the source signal for the sampling of the Hall input pattern (selected by HSYNC) is delayed by the Dead-Time Counter 0. 0_B The bypass is not active. Dead-Time Counter 0 is generating a delay after the source signal becomes active. 1_B The bypass is active. Dead-Time Counter 0 is not used for a delay.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Timer Control Register 0

Register TCTR0 controls the basic functionality of both timers, T12 and T13.

Note: A write action to the bit fields T12CLK or T12PRE is only taken into account while the timer T12 is not running (T12R=0). A write action to the bit fields T13CLK or T13PRE is only taken into account while the timer T13 is not running (T13R=0).

TCTR0
Timer Control Register 0 **(0070_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T12CLK	2:0	rw	**Timer T12 Input Clock Select** Selects the input clock for timer T12 that is derived from the peripheral clock according to the equation $f_{T12} = f_{CC6} / 2^{<T12CLK>}$. 000_B $f_{T12} = f_{CC6}$ 001_B $f_{T12} = f_{CC6} / 2$ 010_B $f_{T12} = f_{CC6} / 4$ 011_B $f_{T12} = f_{CC6} / 8$ 100_B $f_{T12} = f_{CC6} / 16$ 101_B $f_{T12} = f_{CC6} / 32$ 110_B $f_{T12} = f_{CC6} / 64$ 111_B $f_{T12} = f_{CC6} / 128$
T12PRE	3	rw	**Timer T12 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T12. 0_B The additional prescaler for T12 is disabled. 1_B The additional prescaler for T12 is enabled.
T12R	4	rh	**Timer T12 Run Bit** T12R starts and stops timer T12. It is set/cleared by SW by setting bits T12RR or T12RS or it is cleared by HW according to the function defined by bit field T12SSC. 0_B Timer T12 is stopped. 1_B Timer T12 is running.
STE12	5	rh	**Timer T12 Shadow Transfer Enable** Bit STE12 enables or disables the shadow transfer of the T12 period value, the compare values and passive state select bits and levels from their shadow registers to the actual registers if a T12 shadow transfer event is detected. Bit STE12 is cleared by hardware after the shadow transfer. A T12 shadow transfer event is a period-match while counting up or a one-match while counting down. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.

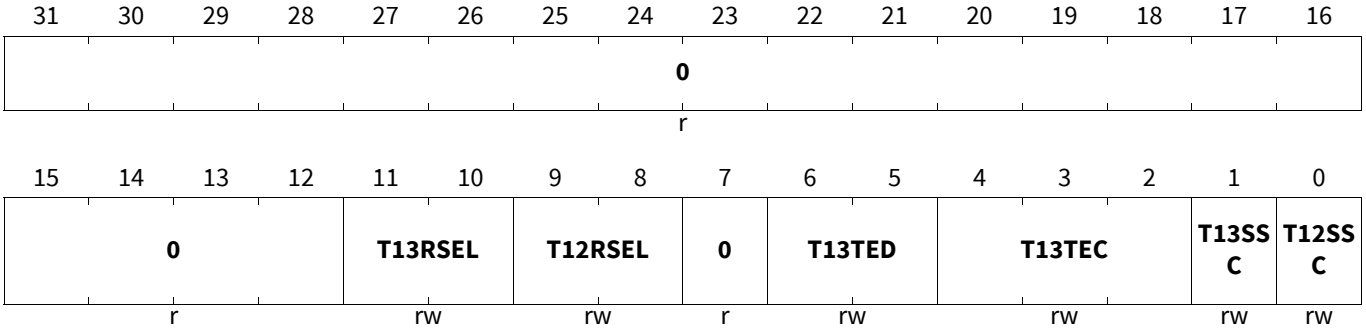
Field	Bits	Type	Description
CDIR	6	rh	**Count Direction of Timer T12** This bit is set/cleared according to the counting rules of T12. 0_B T12 counts up. 1_B T12 counts down.
CTM	7	rw	**T12 Operating Mode** 0_B Edge-aligned Mode: T12 always counts up and continues counting from zero after reaching the period value. 1_B Center-aligned Mode: T12 counts down after detecting a period-match and counts up after detecting a one-match.
T13CLK	10:8	rw	**Timer T13 Input Clock Select** Selects the input clock for timer T13 that is derived from the peripheral clock according to the equation $f_{T13} = f_{CC6} / 2^{<T13CLK>}$. 000_B $f_{T13} = f_{CC6}$ 001_B $f_{T13} = f_{CC6} / 2$ 010_B $f_{T13} = f_{CC6} / 4$ 011_B $f_{T13} = f_{CC6} / 8$ 100_B $f_{T13} = f_{CC6} / 16$ 101_B $f_{T13} = f_{CC6} / 32$ 110_B $f_{T13} = f_{CC6} / 64$ 111_B $f_{T13} = f_{CC6} / 128$
T13PRE	11	rw	**Timer T13 Prescaler Bit** In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T13. 0_B The additional prescaler for T13 is disabled. 1_B The additional prescaler for T13 is enabled.
T13R	12	rh	**Timer T13 Run Bit** T13R starts and stops timer T13. It is set/cleared by SW by setting bits T13RR orT13RS or it is set/cleared by HW according to the function defined by bit fields T13SSC, T13TEC and T13TED. 0_B Timer T13 is stopped. 1_B Timer T13 is running.
STE13	13	rh	**Timer T13 Shadow Transfer Enable** Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0_B The shadow register transfer is disabled. 1_B The shadow register transfer is enabled.
0	31:14	r	**Reserved;** Returns 0 if read; should be written with 0.

Timer Control Register 2

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one

counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12.

TCTR2
Timer Control Register 2 **(0074_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T12SSC	0	rw	**Timer T12 Single Shot Control** This bit controls the single shot-mode of T12. 0_B The single-shot mode is disabled, no HW action on T12R. 1_B The single shot mode is enabled, the bit T12R is cleared by HW if - T12 reaches its period value in edge-aligned mode - T12 reaches the value 1 while down counting in center-aligned mode. In parallel to the clear action of bit T12R, the bits CC6xST (x=0, 1, 2) are cleared.
T13SSC	1	rw	**Timer T13 Single Shot Control** This bit controls the single shot-mode of T13. 0_B No HW action on T13R 1_B The single-shot mode is enabled, the bit T13R is cleared by HW if T13 reaches its period value. In parallel to the clear action of bit T13R, the bit CC63ST is cleared.
T13TEC	4:2	rw	**T13 Trigger Event Control** Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000_B No action 001_B Set T13R on a T12 compare event on channel 0 010_B Set T13R on a T12 compare event on channel 1 011_B Set T13R on a T12 compare event on channel 2 100_B Set T13R on any T12 compare event (ch. 0, 1, 2) 101_B Set T13R upon a period-match of T12 110_B Set T13R upon a zero-match of T12 (while counting up) 111_B Set T13R on any edge of inputs CCPOSx

Field	Bits	Type	Description
T13TED	6:5	rw	**Timer T13 Trigger Event Direction** Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00_B Reserved, no action 01_B While T12 is counting up 10_B While T12 is counting down 11_B Independent on the count direction of T12
T12RSEL	9:8	rw	**Timer T12 External Run Selection** Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by HW. 00_B The external setting of T12R is disabled. 01_B Bit T12R is set if a rising edge of signal T12HR is detected. 10_B Bit T12R is set if a falling edge of signal T12HR is detected. 11_B Bit T12R is set if an edge of signal T12HR is detected.
T13RSEL	11:10	rw	**Timer T13 External Run Selection** Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by HW. 00_B The external setting of T13R is disabled. 01_B Bit T13R is set if a rising edge of signal T13HR is detected. 10_B Bit T13R is set if a falling edge of signal T13HR is detected. 11_B Bit T13R is set if an edge of signal T13HR is detected.
0	7, 31:12	r	**Reserved;** Returns 0 if read; should be written with 0;

Timer Control Register 4

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

Note: A simultaneous write of a 1 to bits that set and clear the same bit will trigger no action. The corresponding bit will remain unchanged.

TCTR4
Timer Control Register 4 **(0078_H)** **Application Reset Value: $0000\ 0000_H$**

0	4, 12:11, 31:16	r	**reserved;** returns 0 if read; should be written with 0;

29.4 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see **Section 29.4.1**)
- Counting scheme (see **Section 29.4.2**)
- Compare mode (see **Section 29.4.3**)
- Compare output path (see **Section 29.4.4**)
- Shadow register transfer (see **Section 29.4.5**)
- T13 counter register description (see **Section 29.4.6**)

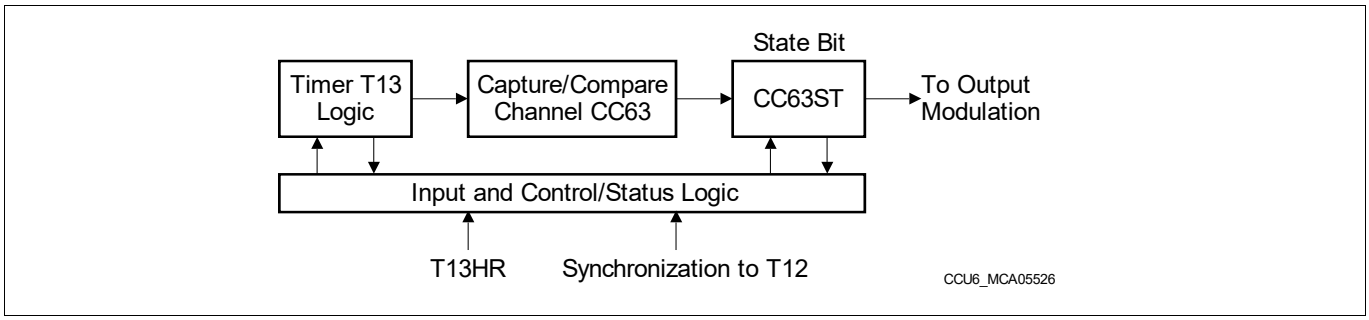

Figure 177 Overview Diagram of the Timer T13 Block

29.4.1 T13 Overview

Figure 178 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL2**.

Timer T13 receives its input clock, f_{T13}, from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T12).

Via a comparator, the timer T13 Counter Register **T13** is connected to the Period Register **T13PR**. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to **Table 29.4.5**).

Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM).

A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see **Figure 180**).

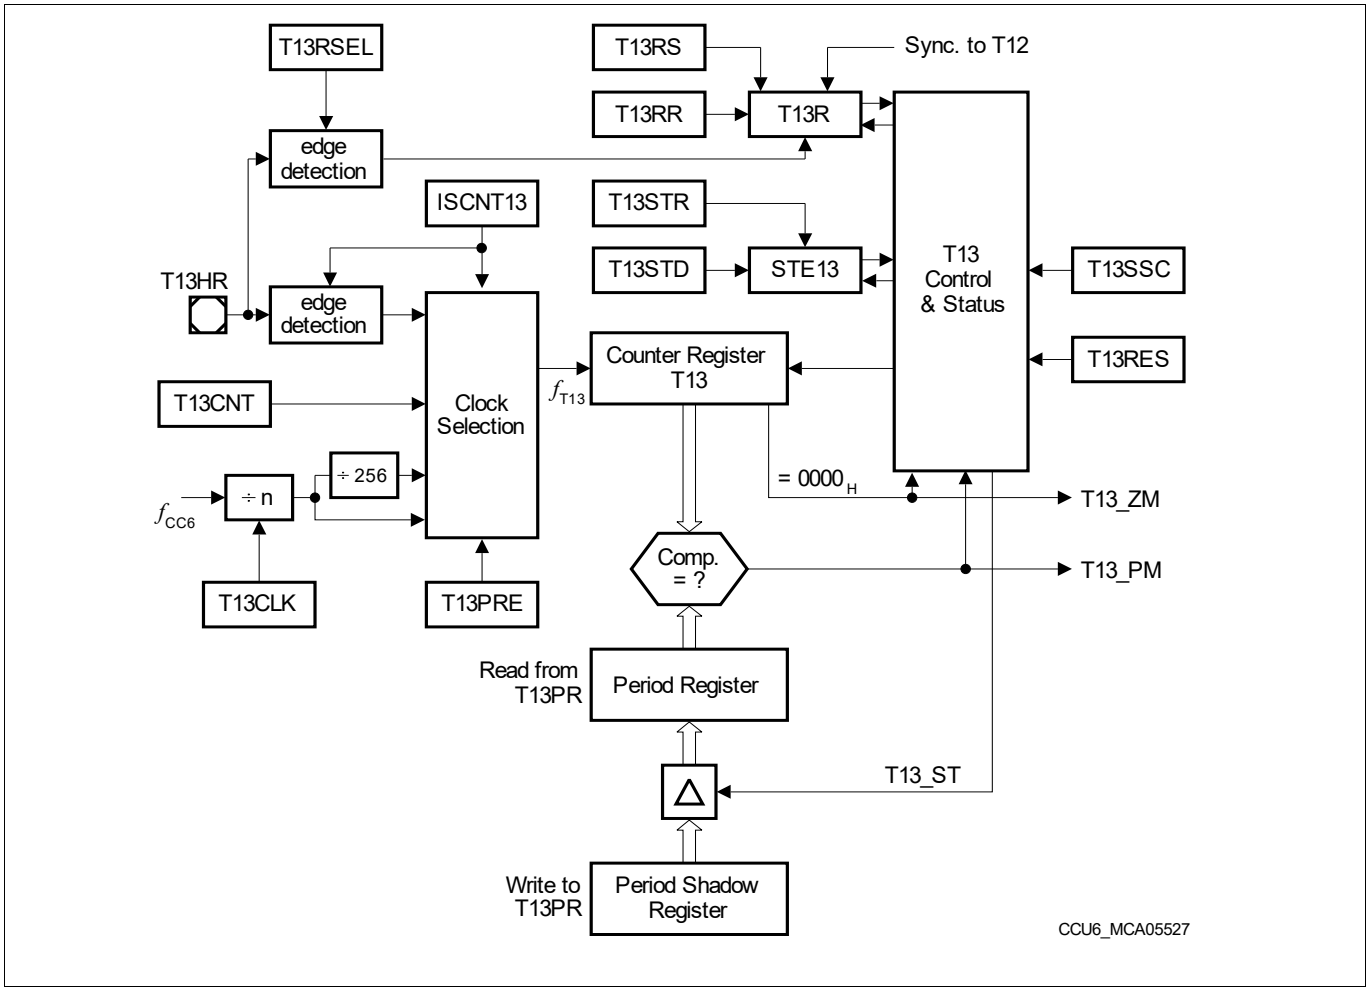

Figure 178 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register **TCTR4**, or it is cleared by hardware according to preselected conditions (single-shot mode).
The timer T13 run bit T13R must not be set while the applied T13 period value is zero.
Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC conversions).
Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.
While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

29.4.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

29.4.2.1 Clock Selection

In **Timer Mode** (**PISEL2**. ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 196**. The prescaler of T13 is cleared while T13 is not running (**TCTR0**.T13R = 0) to ensure reproducible timings and delays.

Table 196 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock *f*T13 Prescaler Off (T13PRE = 0)	Resulting Input Clock *f*T13 Prescaler On (T13PRE = 1)
000_B	f_{CC6}	f_{CC6} / 256
001_B	f_{CC6} / 2	f_{CC6} / 512
010_B	f_{CC6} / 4	f_{CC6} / 1024
011_B	f_{CC6} / 8	f_{CC6} / 2048
100_B	f_{CC6} / 16	f_{CC6} / 4096
101_B	f_{CC6} / 32	f_{CC6} / 8192
110_B	f_{CC6} / 64	f_{CC6} / 16384
111_B	f_{CC6} / 128	f_{CC6} / 32768

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to **TCTR4**.T13CNT and **PISEL2**.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 11_B

29.4.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$T13_{PER}$ = <Period-Value> + 1; in T13 clocks (f_{T13}) (29.3)

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple 'counting rule' for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in **Figure 179**.

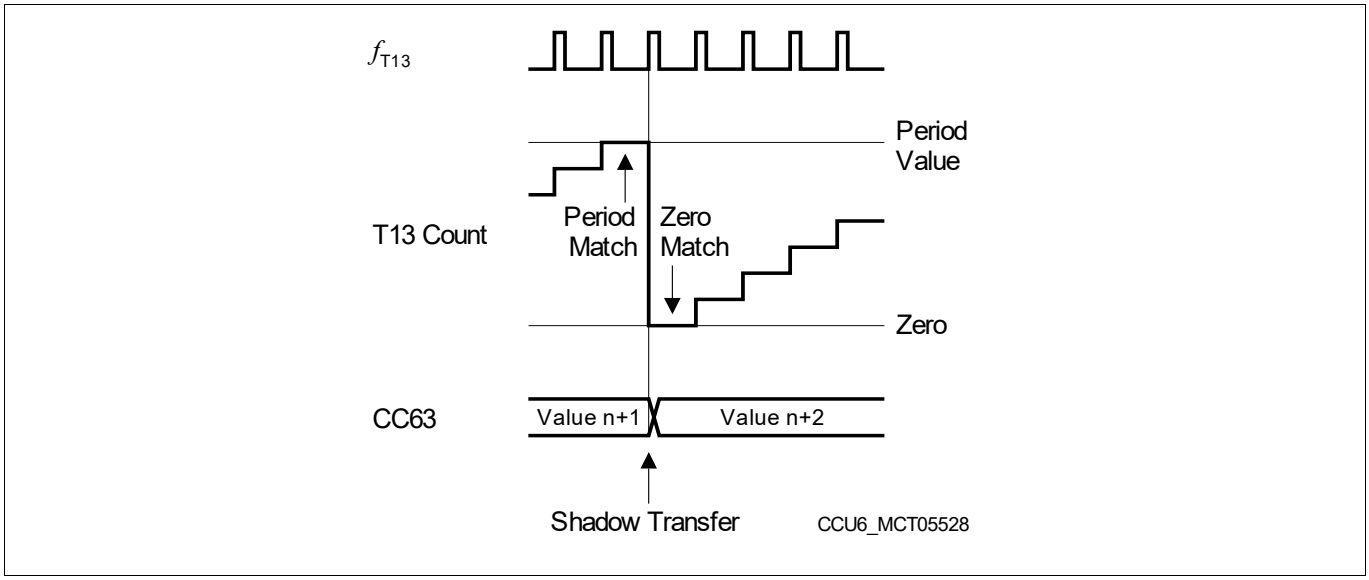

Figure 179 T13 Counting Sequence

29.4.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

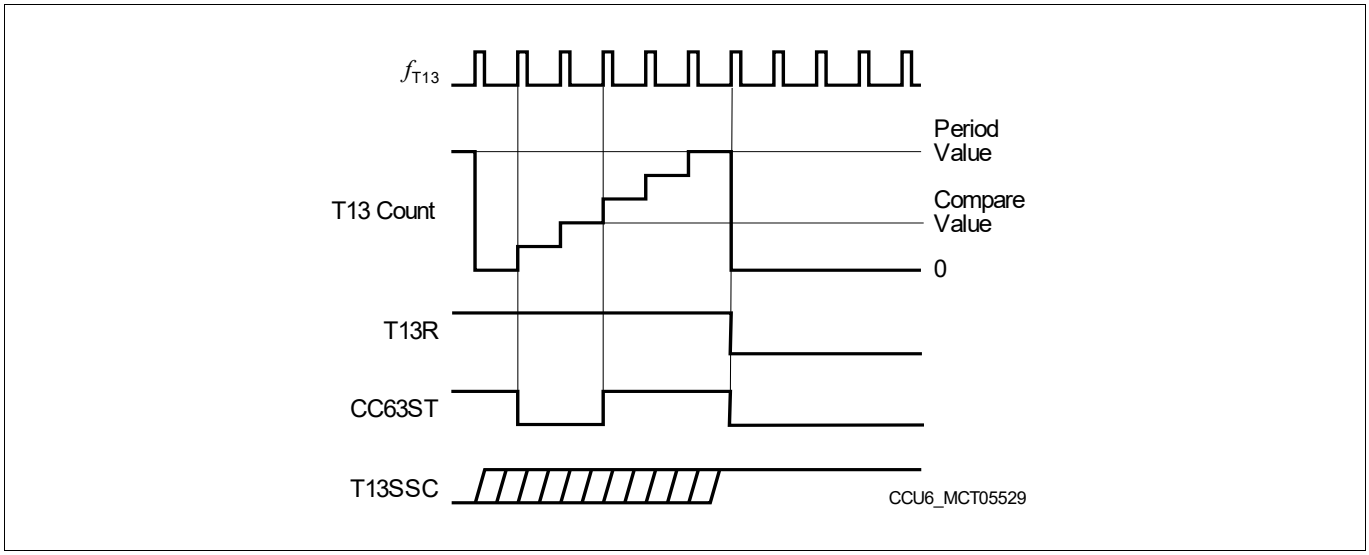

Figure 180 Single-Shot Operation of Timer T13

29.4.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 181 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

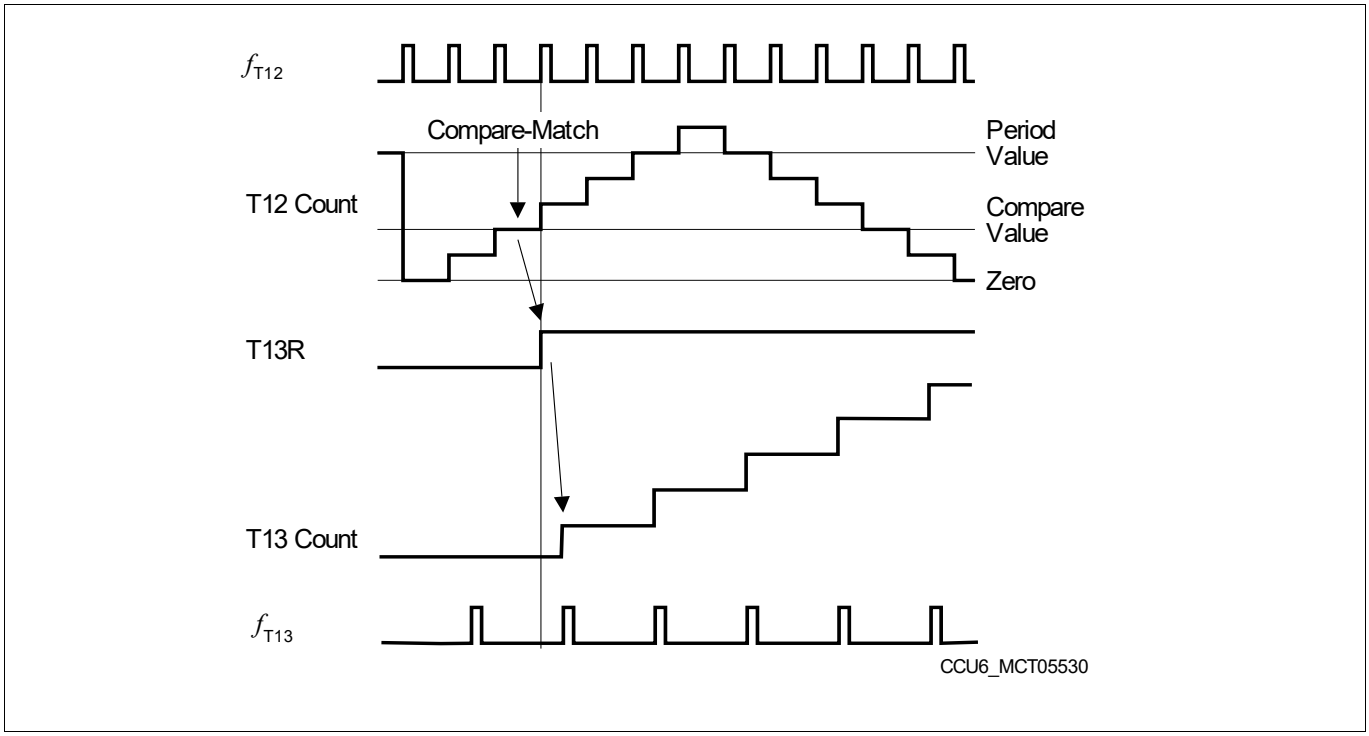

Figure 181 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in **Table 197**. Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see **Table 198**).

Table 197 T12 Trigger Event Selection

T13TEC	Selected Event
000_B	None
001_B	T12 Compare Event on Channel 0 (CM_CC60)
010_B	T12 Compare Event on Channel 1 (CM_CC61)
011_B	T12 Compare Event on Channel 2 (CM_CC62)
100_B	T12 Compare Event on any Channel (0, 1, 2)
101_B	T12 Period-Match (T12_PM)
110_B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111_B	Any Hall State Change

Table 198 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00_B	Reserved, no action
01_B	Selected event is active while T12 is counting up (CDIR = 0)
10_B	Selected event is active while T12 is counting down (CDIR = 1)
11_B	Selected event is active independently of the count direction of T12

29.4.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 177 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, **CC63R**, feeding the comparator, and an associated shadow register, **CC63SR**, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, **CMPSTAT**.CC63ST, holding the status of the compare operation. **Figure 182** gives an overview on the logic for the State Bit.

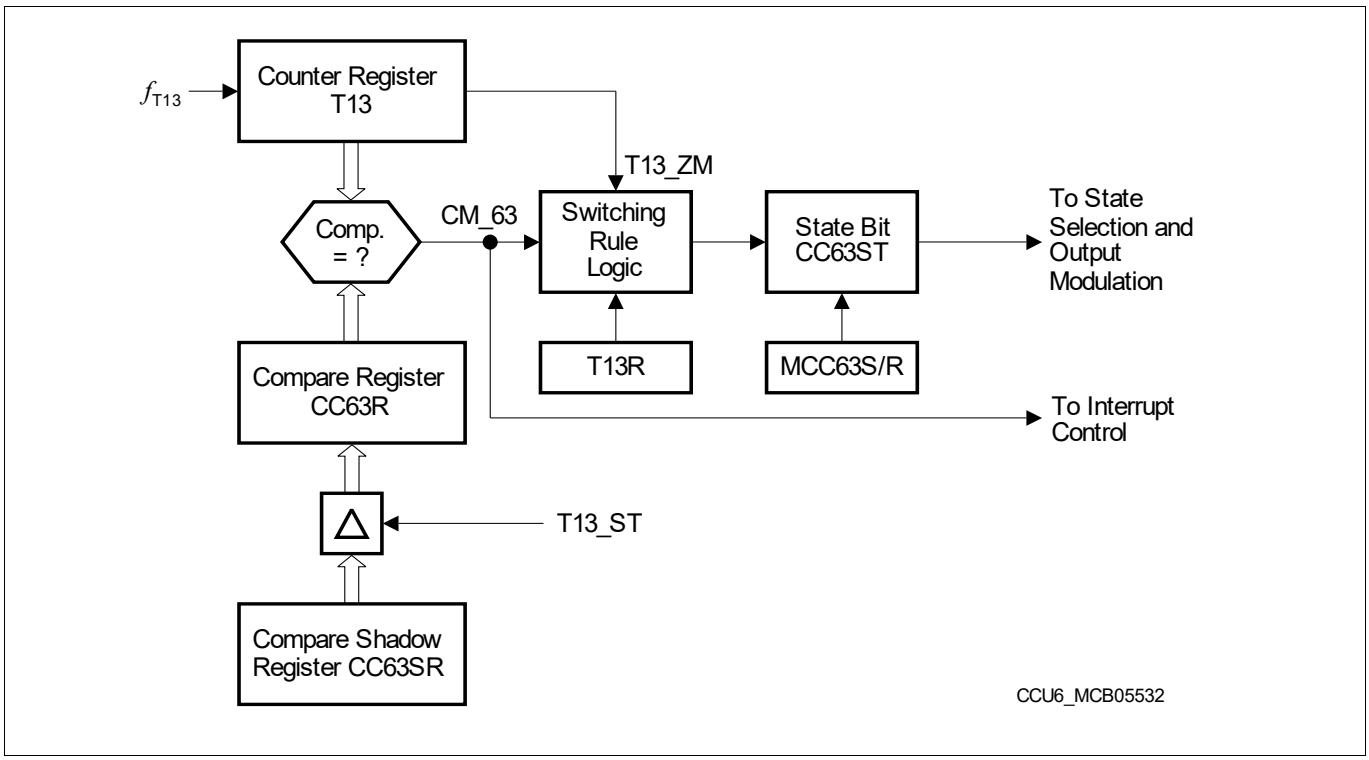

Figure 182 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and MCC63R in register **CMPMODIF**.
A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running (T13R = 1). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit **CC63ST is set** to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit **CC63ST is cleared** to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

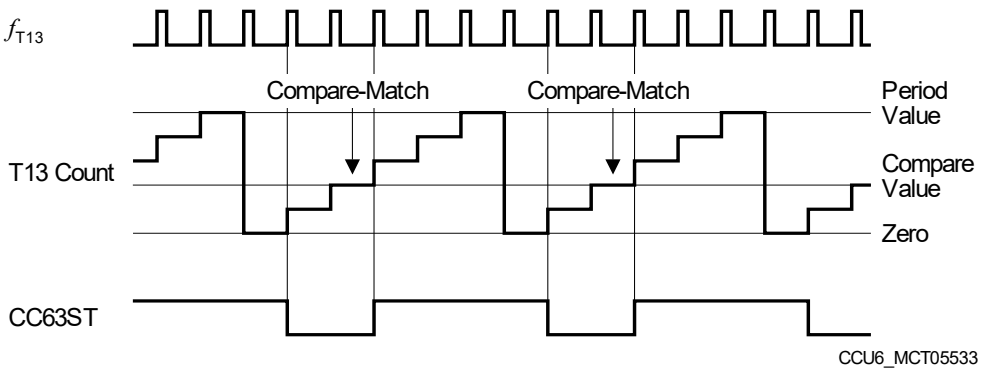

Figure 183 T13 Compare Operation

29.4.4 Compare Mode Output Path

Figure 184 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to **Section 29.3.4.3** for detailed information on the output modulation for T12 signals.

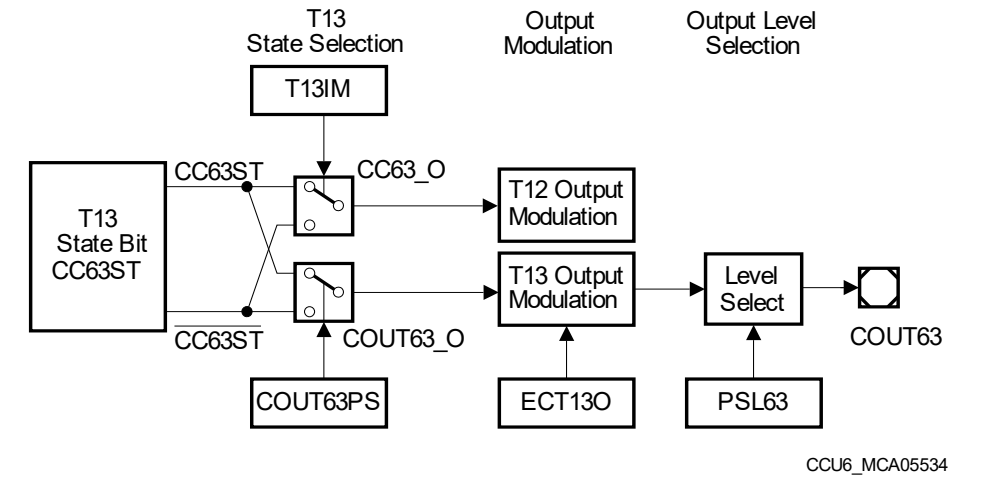

Figure 184 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see **Figure 185**):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit **MODCTR**.ECT13O
- The **trap state** TRPS with an individual enable bit **TRPCTR**.TRPEN13

If the modulation input signal COUT63_O is enabled (ECT13O = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.
If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit **PSLR**.PSL63. If the modulated output signal is in the passive state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

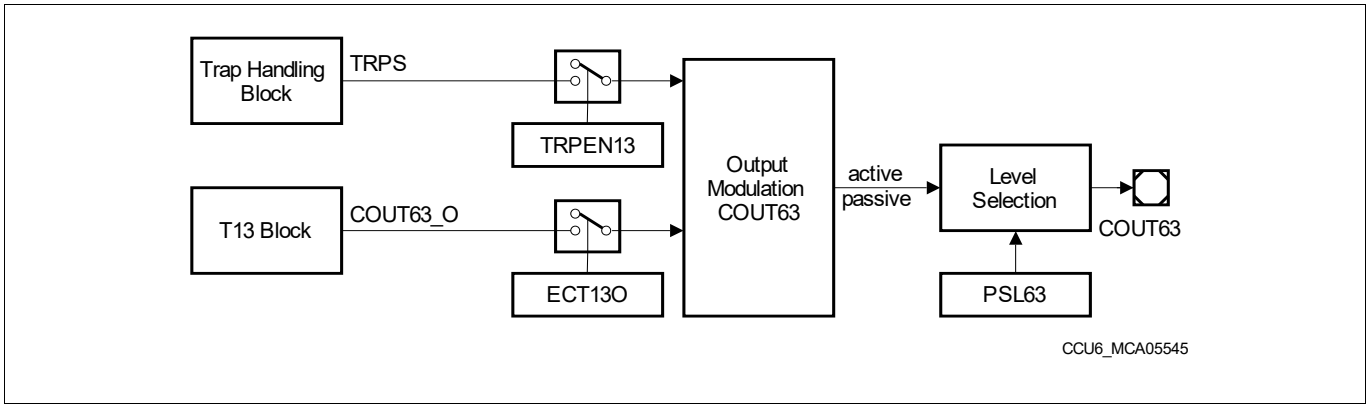

Figure 185 T13 Output Modulation

29.4.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0**.STE13 (set by writing 1 to the write-only bit **TCTR4**.T13STR, cleared by writing 1 to the write-only bit **TCTR4**.T13STD).
When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer.
A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

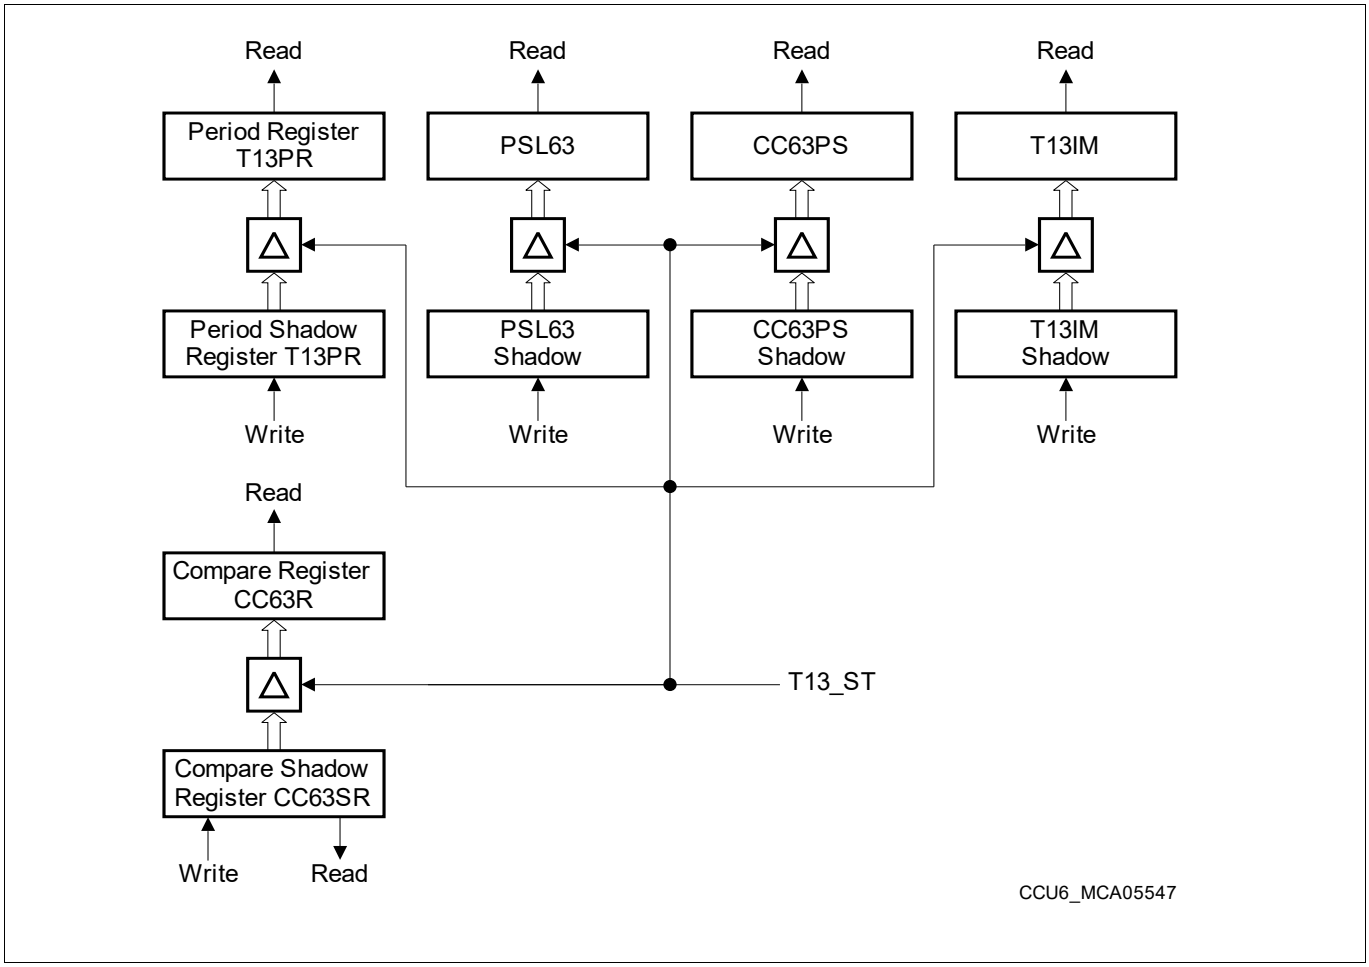

Figure 186 T13 Shadow Register Overview

29.4.6 T13 related Registers

Timer T13 Counter Register

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events. Timer T13 only supports compare mode on its compare channel CC63. Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by SW. Timer T13 only supports edge-aligned mode (counting up).

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

T13
Timer T13 Counter Register **(0050_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

T13CV															
rwh															

Field	Bits	Type	Description
T13CV	15:0	rwh	**Timer 13 Counter Value** This register represents the 16-bit counter value of Timer13.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Timer 13 Period Register

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by SW delivers the value currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

T13PR
Timer 13 Period Register **(0054_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T13PV															
rwh															

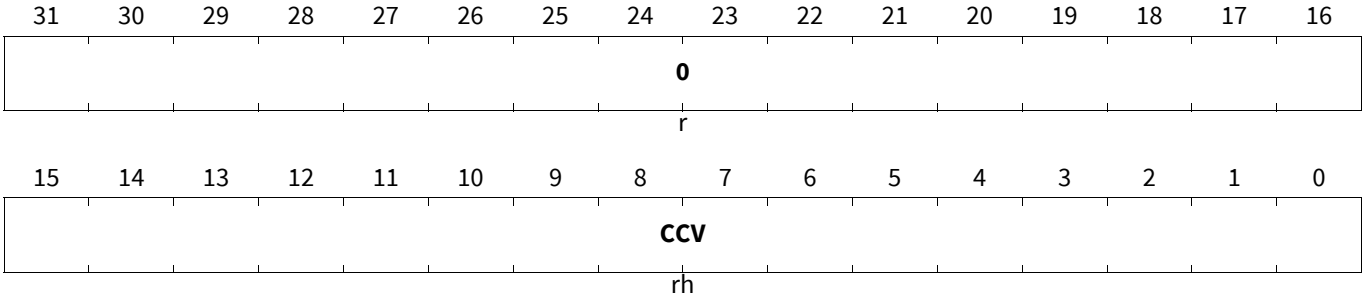
Field	Bits	Type	Description
T13PV	15:0	rwh	**T13 Period Value** The value T13PV defines the counter value for T13 leading to a period-match. When reaching this value, the timer T13 is set to zero.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Compare Register for T13

Registers CC63R is the actual compare register for T13. The values stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register **CMPSTAT**.

CC63R

Compare Register for T13 **(0058_H)** **Application Reset Value: 0000 0000$_H$**



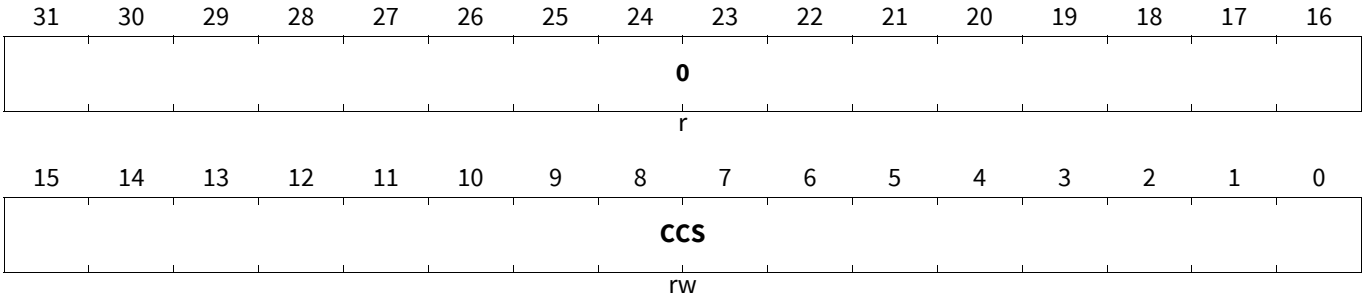
Field	Bits	Type	Description
CCV	15:0	rh	**Channel CC63 Compare Value** The bit field CCV contains the value, that is compared to the T13 counter value.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Compare Shadow Register for T13

The register CC63R can only be read by SW, the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by SW.

CC63SR

Compare Shadow Register for T13 **($005C_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CCS	15:0	rw	**Shadow Register for Channel CC63 Compare Value** The bit field contents of CCS is transferred to the bit field CCV during a shadow transfer.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

29.5 Synchronous Start Feature

Synchronous start of the capture/compare timers is supported by control bit SYSCON.CCTRIG0 in the SCU module. Bit SYSCON.CCTRIG0 is connected to the T12HR and T13HR inputs of the CCU60 and CCU61 kernels, so all timers T12 and T13 can be started synchronously.

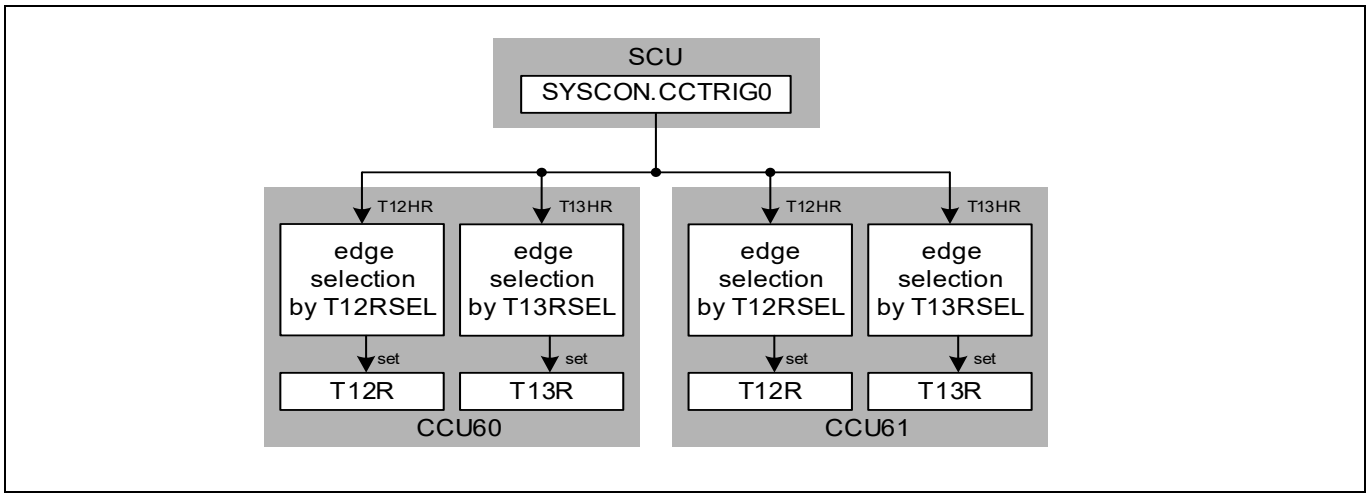


Figure 187 Synchronization Concept

29.6 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal $\overline{\text{CTRAP}}$. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register **TRPCTR**. The trap flags TRPF and TRPS are located in register **IS** and can be set/cleared by SW by writing to registers **ISS** and **ISR**.
Figure 188 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.
When a trap condition is detected ($\overline{\text{CTRAP}}$ = 0) and the input is enabled (TRPPEN = 1), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active).
The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

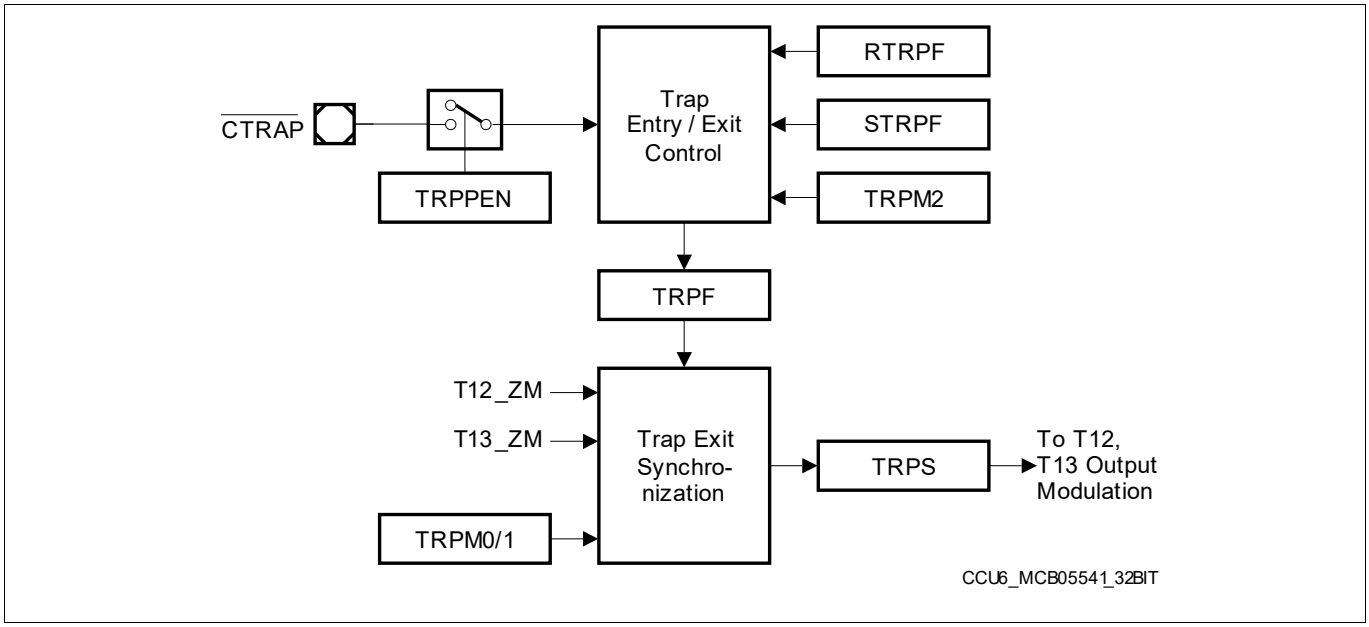

Figure 188 Trap Logic Block Diagram

Clearing of TRPF is controlled by the mode control bit TRPM2. If TRPM2 = 0, TRPF is automatically cleared by HW when $\overline{\text{CTRAP}}$ returns to the inactive level ($\overline{\text{CTRAP}}$ = 1) or if the trap input is disabled (TRPPEN = 0). When TRPM2 = 1, TRPF must be reset by SW after $\overline{\text{CTRAP}}$ has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. **Figure 189** gives an overview on the associated operation.

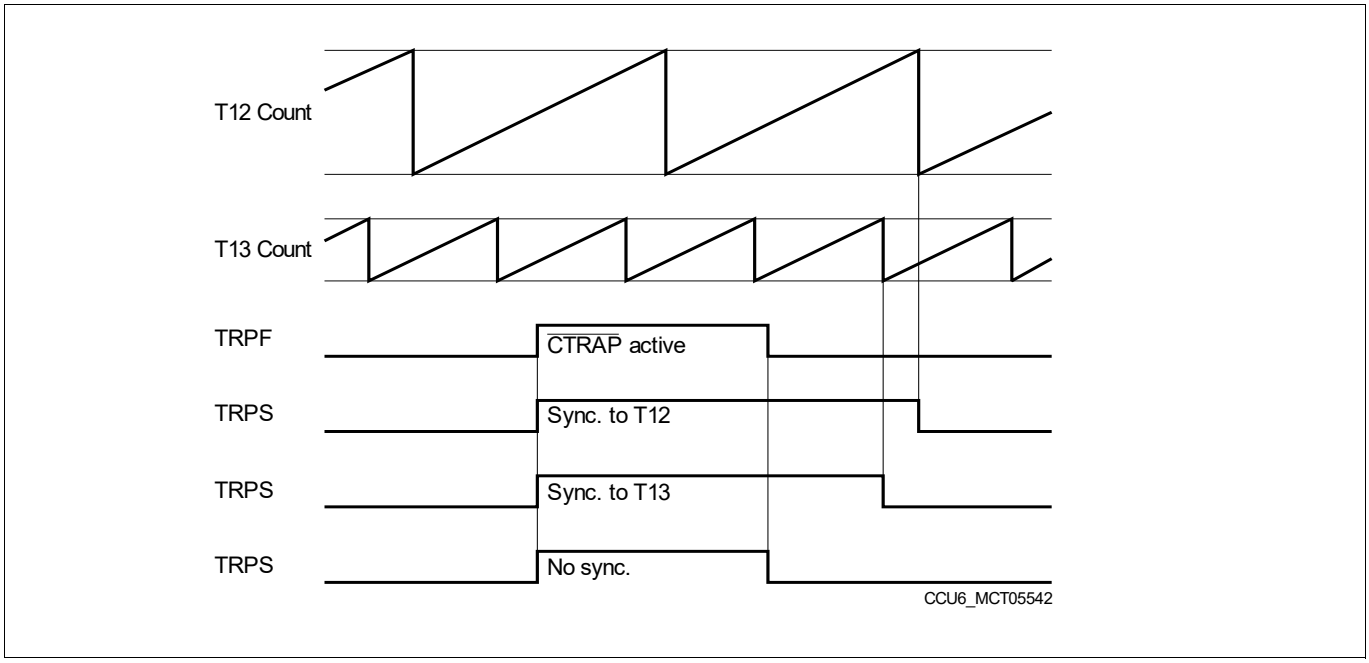

Figure 189 Trap State Synchronization (with TRPM2 = 0)

29.7 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field **MCMOUT**.MCMP are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit **MODCTR**.MCMEN = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field MCMP.
This bit field has its own shadow bit field **MCMOUTS**.MCMPS, that can be written by software. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

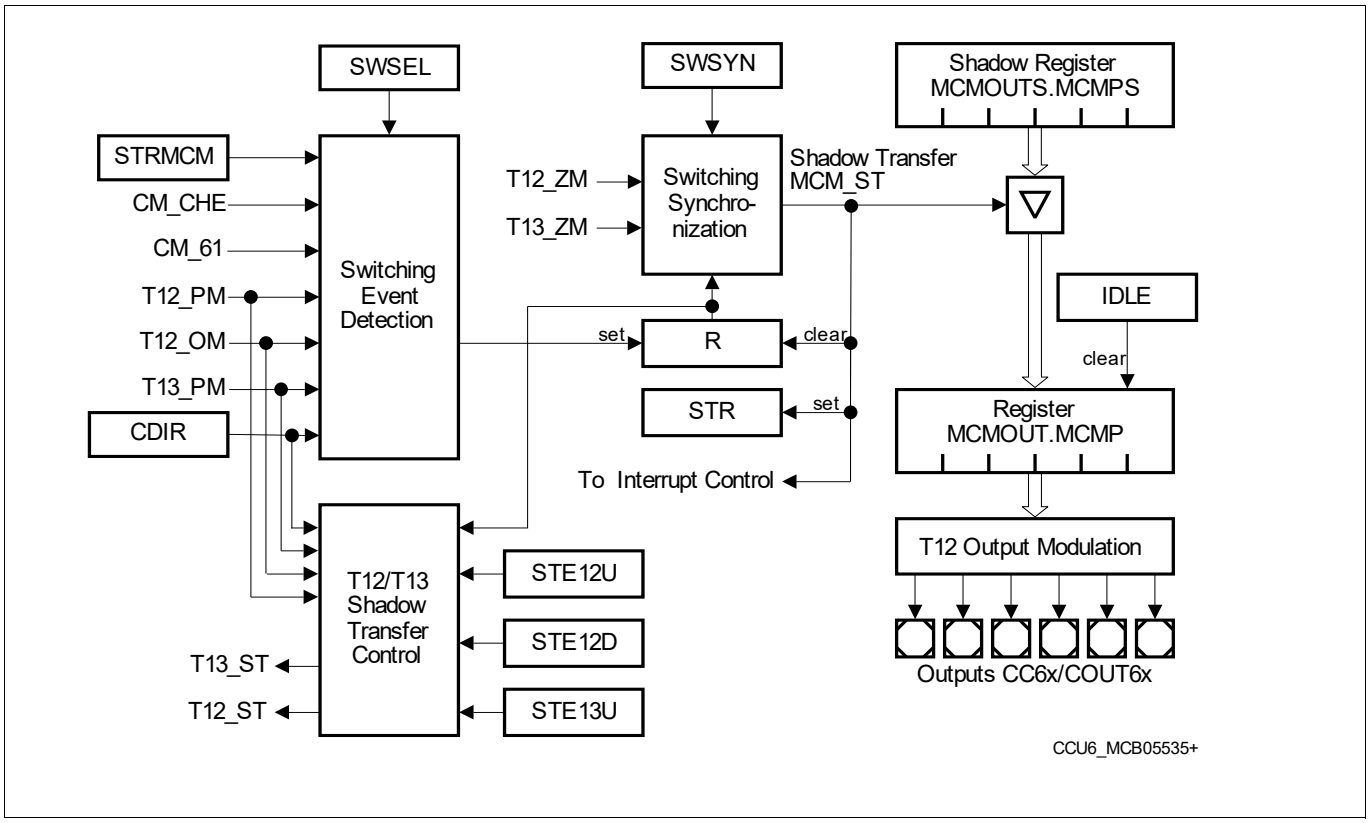

Figure 190 Multi-Channel Mode Block Diagram

Figure 190 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register **MCMCTR**. The event that triggers the update of bit field MCMP is chosen by SWSEL. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event leading to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period. A reminder flag R is set when the selected switching event occurs (the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit **IS**.STR becomes set and an interrupt can be generated.
In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field MCMPS with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for

all settings of SWSEL.
By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 199 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000_B	No automatic event detection
001_B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010_B	T13 Period-Match (T13_PM)
011_B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100_B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101_B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110_B, 111_B	Reserved, no action

Table 200 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00_B	Direct Mode: the trigger event directly causes the shadow transfer
01_B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10_B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11_B	Reserved, no action

29.8 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU load for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register **MCMOUT** holds the actually used values, its shadow register **MCMOUTS** can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.
A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:
CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)
CCPOS1 corresponds to CURH.1 and EXPH.1
CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

29.8.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:
  For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated. Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:
  The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

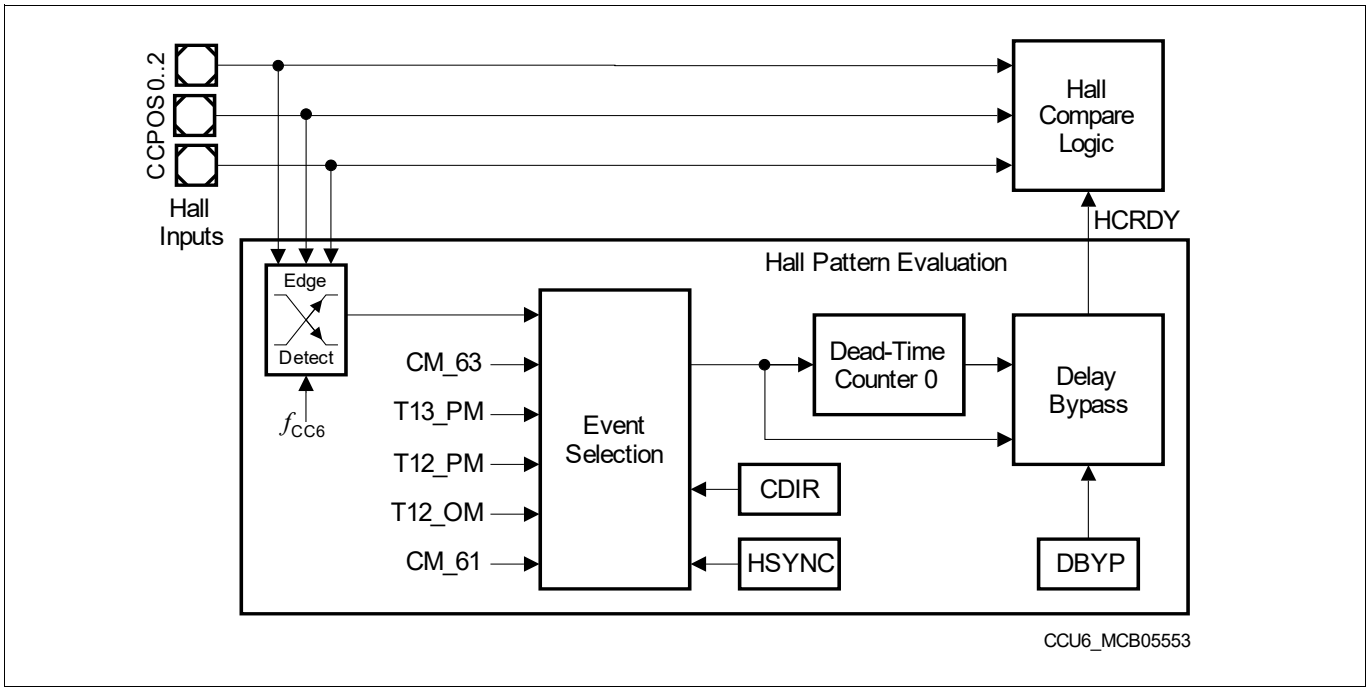

Figure 191 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see **Figure 192**) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

Figure 191 illustrates the events for Hall pattern evaluation and the noise filter logic, **Table 201** summarizes the selectable trigger input signals.

Table 201 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000_B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001_B	A T13 Compare-Match (CM_63).
010_B	A T13 Period-Match (T13_PM).
011_B	Hall sampling triggered by HW sources is switched off.
100_B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101_B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110_B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111_B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

29.8.2 Hall Pattern Compare Logic

Figure 192 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMP is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register **CMPSTAT**). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

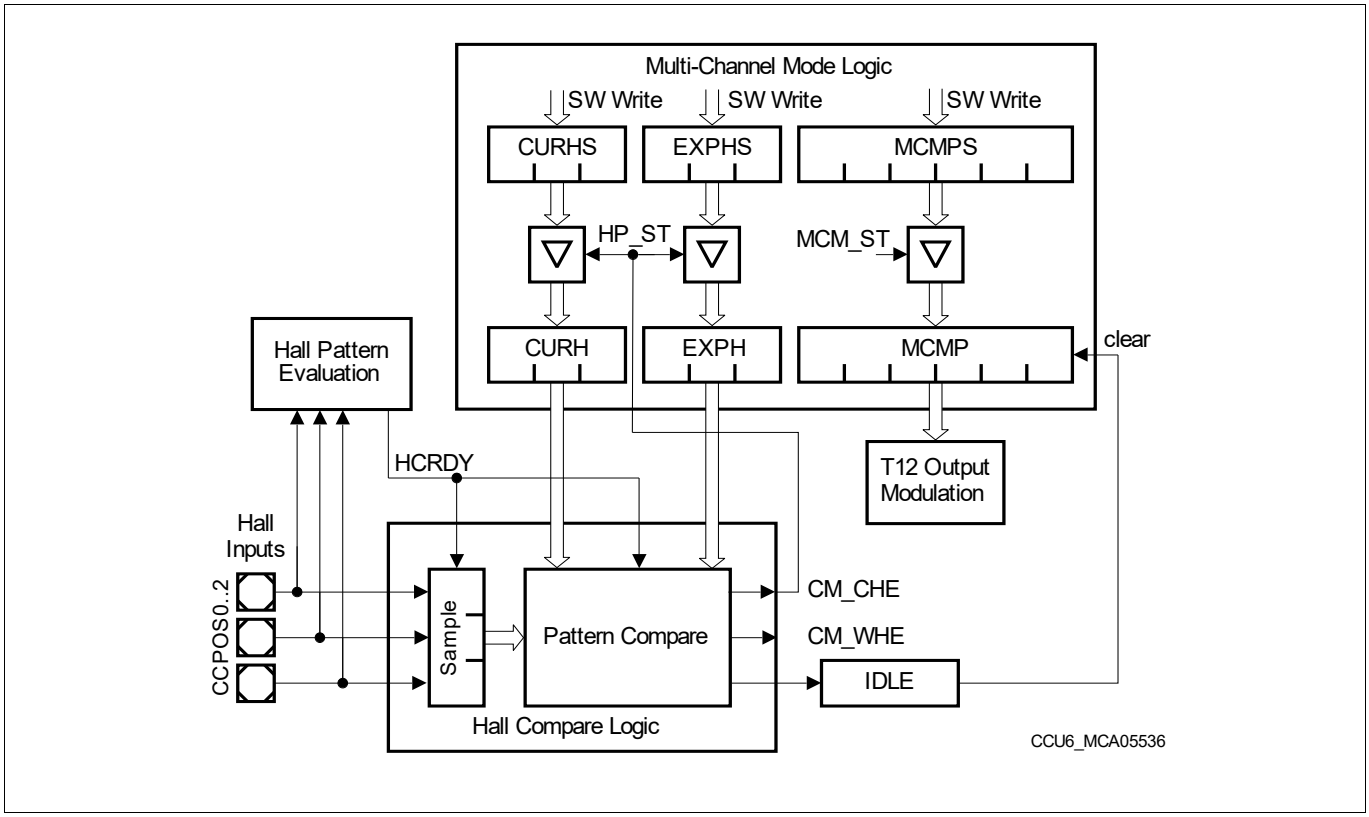

Figure 192 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMP value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.
Loading this register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCMP = 1 (for MCMP).

Note: If in a corner case a hardware event occurs simultaneously with a software write where MCMOUTS.STRHP = 1 or MCMOUTS.STRMCMP = 1, the current contents of MCMOUTS is copied to the corresponding bit fields of MCMOUT. The new value written to MCMOUTS will be loaded upon the next event.

29.8.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag **IS**.CHE (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit **ISS**.SCHE = 1. If enabled by bit **IEN**.ENCHE = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field **INP**.INPCHE defines which service

request output becomes activated in case of an interrupt request.To clear flag CHE, SW needs to write **ISR**.RCHE = 1.
Flag IS.WHE indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.
The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also **Figure 190**).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCMP is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

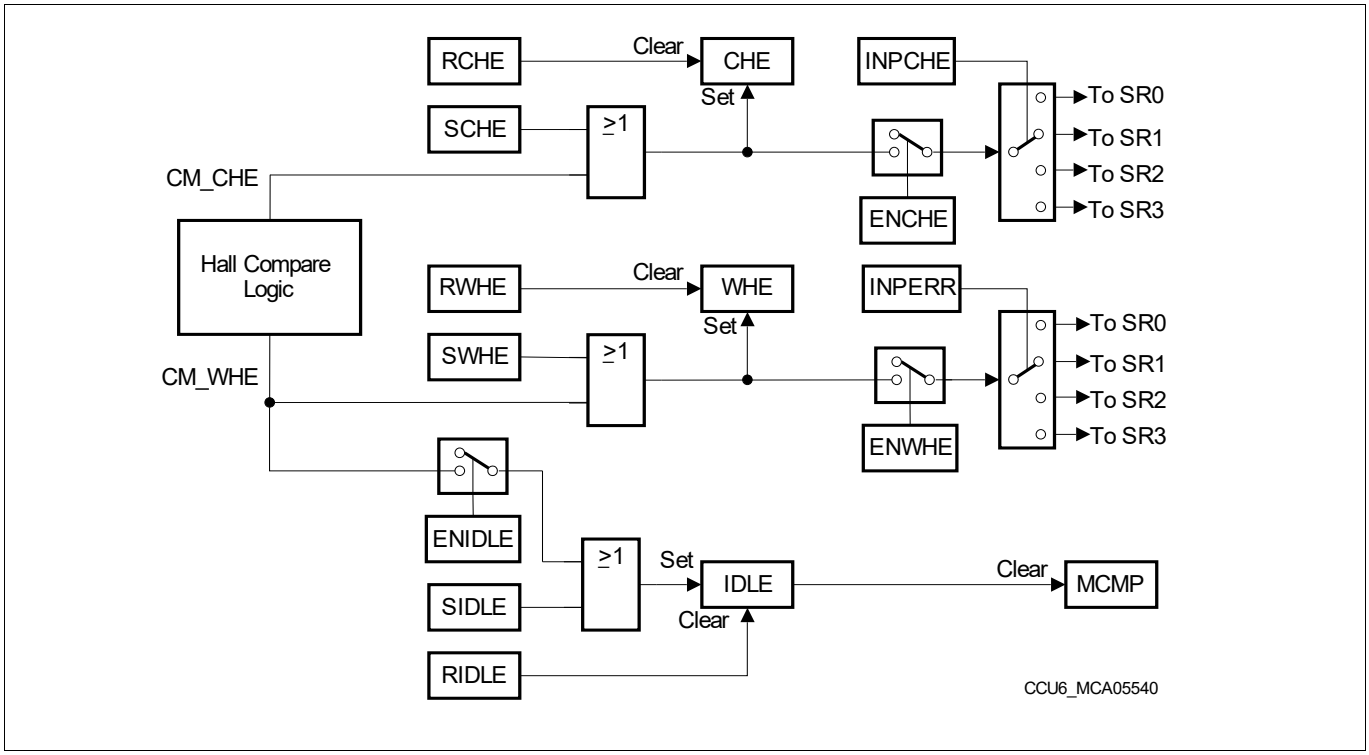

Figure 193 Hall Mode Flags

29.8.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all **T12MSEL**.MSEL6x bit fields of the three T12 Channels to 1000_B.
In this mode, illustrated in **Figure 194**, channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

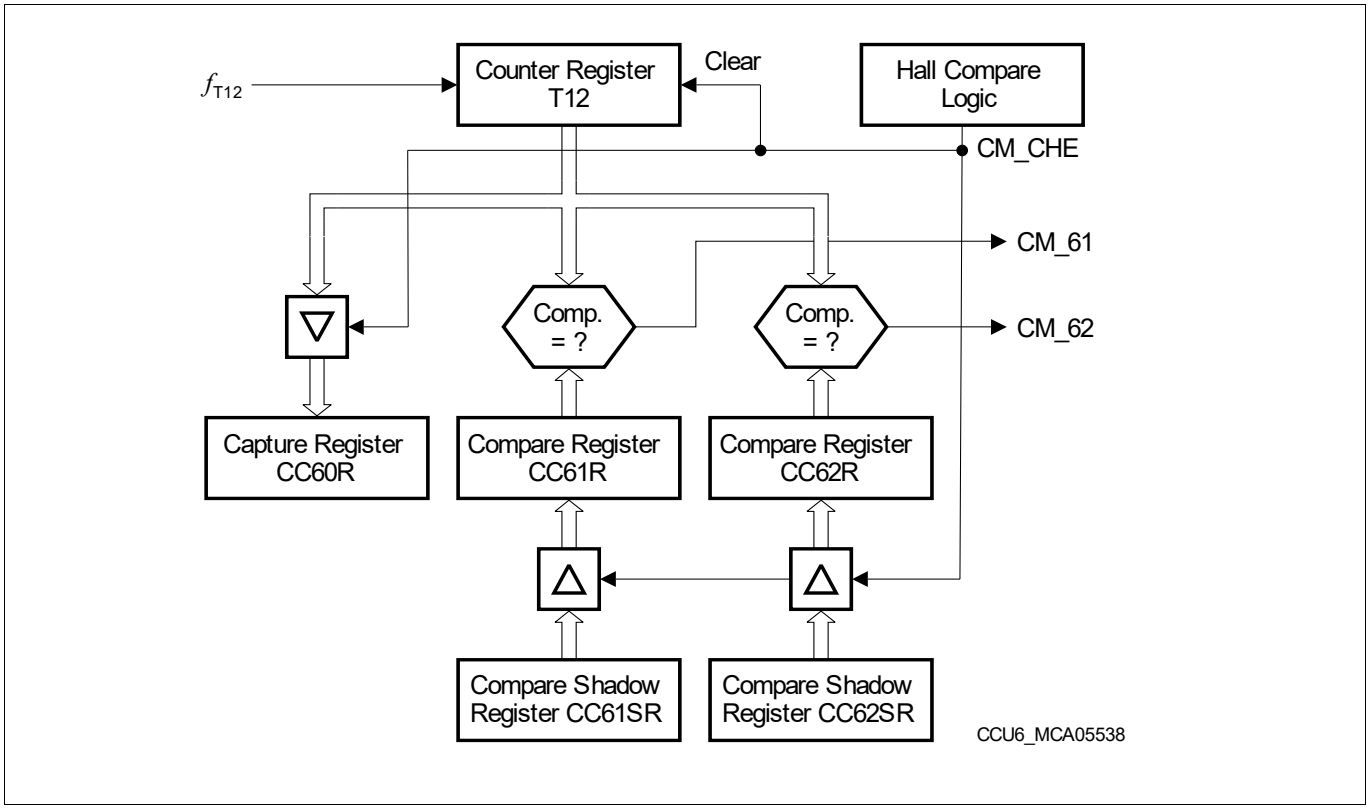

Figure 194 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

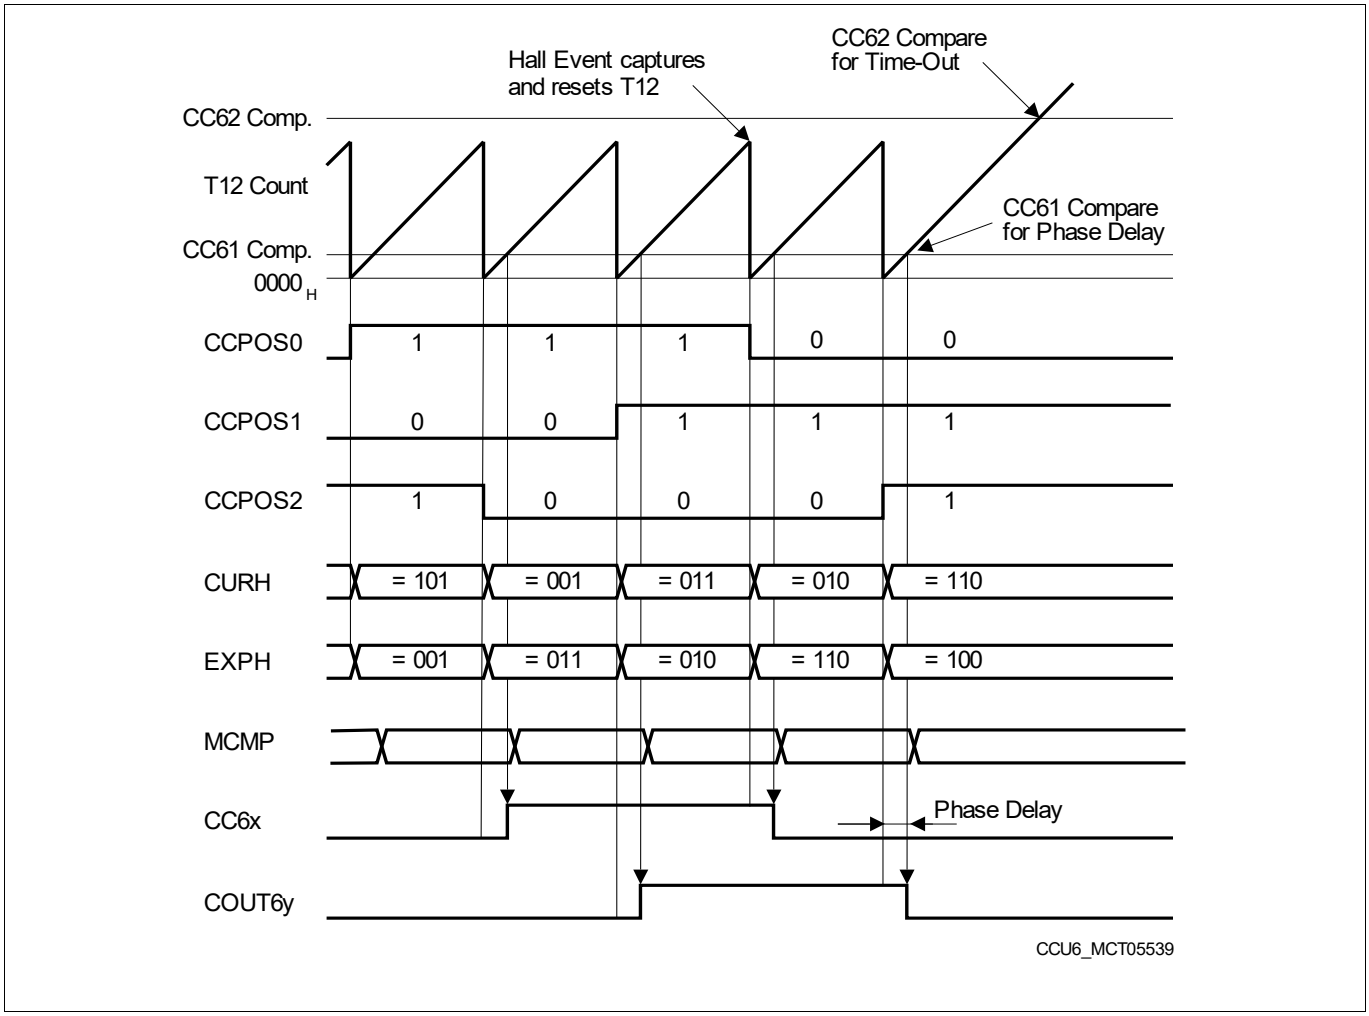

Figure 195 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

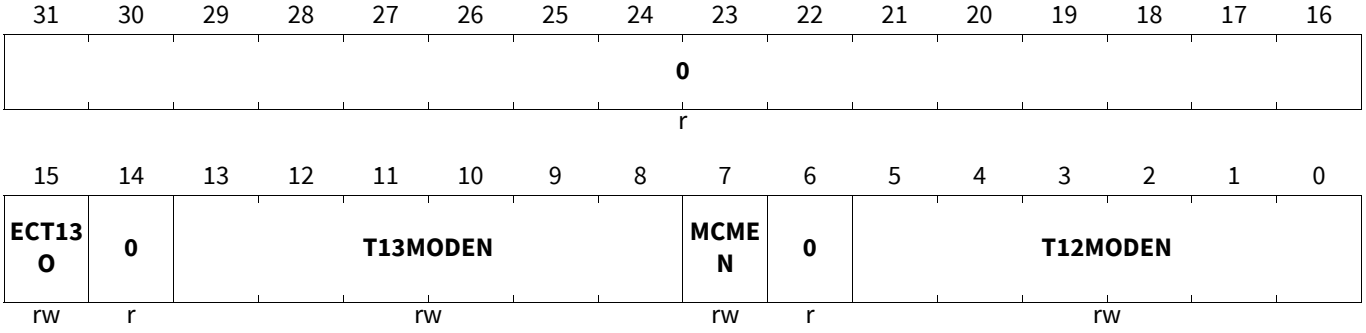
After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field **SWEN**). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see **Section 29.7**). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

29.9 Modulation Control Registers

Modulation Control Register

This register contains bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

MODCTR
Modulation Control Register **(0080_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T12MODEN	5:0	rw	**T12 Modulation Enable** These bits enable the modulation of the corresponding output signal by a PWM pattern generated by timer T12. T12MODEN0 = MODCTR.0 for output CC60 T12MODEN1 = MODCTR.1 for output COUT60 T12MODEN2 = MODCTR.2 for output CC61 T12MODEN3 = MODCTR.3 for output COUT61 T12MODEN4 = MODCTR.4 for output CC62 T12MODEN5 = MODCTR.5 for output COUT62 00_H The modulation of the corresponding output signal by a T12 PWM pattern is disabled. 01_H The modulation of the corresponding output signal by a T12 PWM pattern is enabled.
MCMEN	7	rw	**Multi-Channel Mode Enable** 0_B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is disabled. 1_B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is enabled.

Field	Bits	Type	Description
T13MODEN	13:8	rw	**T13 Modulation Enable** These bits enable the modulation of the corresponding output signal by the PWM pattern CC63_O generated by timer T13. T13MODEN0 = MODCTR.8 for output CC60 T13MODEN1 = MODCTR.9 for output COUT60 T13MODEN2 = MODCTR.10 for output CC61 T13MODEN3 = MODCTR.11 for output COUT61 T13MODEN4 = MODCTR.12 for output CC62 T13MODEN5 = MODCTR.13 for output COUT62 00_H The modulation of the corresponding output signal by a T13 PWM pattern is disabled. 01_H The modulation of the corresponding output signal by a T13 PWM pattern is enabled.
ECT13O	15	rw	**Enable Compare Timer T13 Output** 0_B The output COUT63 is in the passive state. 1_B The output COUT63 is enabled for the PWM signal generated by T13.
0	6, 14, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Trap Control Register

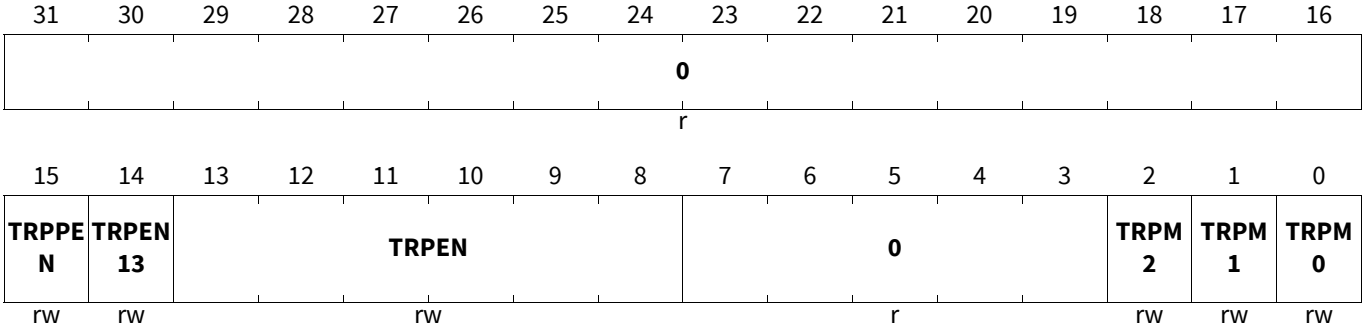
The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the $\overline{\text{CTRAP}}$ input pin, that is monitored (inverted level) by bit IS.TRPF. While TRPF=1 (trap input active), the trap state bit IS.TRPS is set to 1.

The behavior resulting from the combination [TRPM1, TRPM0] of the Trap Mode Control bits TRPM1, TRPM0 is described in **Table 202**.

Table 202 Leaving the Trap State

[TRPM1, TRPM0]	Function
00_B	The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T12 (while counting up) is detected (synchronization to T12).
01_B	The trap state is left (return to normal operation) after TRPF has become 0 again when a zero-match of T13 is detected (synchronization to T13).
10_B	Reserved
11_B	The trap state is left (return to normal operation) immediately after TRPF has become 0 again without any synchronization to T12 or T13.

TRPCTR
Trap Control Register **(0084_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TRPM0	0	rw	**Trap Mode Control Bit 0** Together with bit TRPM1, these two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern avoids unintended pulses when leaving the trap state. The behavior resulting from the combination [TRPM1, TRPM0] is described in **Table 202**.
TRPM1	1	rw	**Trap Mode Control Bit 1** Together with bit TRPM0, these two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern avoids unintended pulses when leaving the trap state. The behavior resulting from the combination [TRPM1, TRPM0] is described in **Table 202**.
TRPM2	2	rw	**Trap Mode Control Bit 2** This bit defines how the trap flag TRPF can be cleared after the trap input condition ($\overline{CTRAP}$ = 0 and TRPPEN = 1) is no longer valid (either by $\overline{CTRAP}$ = 1 or by TRPPEN = 0). 0_B Automatic Mode: Bit TRPF is cleared by HW if the trap input condition is no longer valid. 1_B Manual Mode: Bit TRPF stays 1 after the trap input condition is no longer valid. It has to be cleared by SW by writing ISR.RTRPF = 1.

Field	Bits	Type	Description
TRPEN	13:8	rw	**Trap Enable Control** Setting a bit enables the trap functionality for the following corresponding output signals: TRPEN0 = TRPCTR.8 for output CC60 TRPEN1 = TRPCTR.9 for output COUT60 TRPEN2 = TRPCTR.10 for output CC61 TRPEN3 = TRPCTR.11 for output COUT61 TRPEN4 = TRPCTR.12 for output CC62 TRPEN5 = TRPCTR.13 for output COUT62 00_H The trap functionality of the corresponding output signal is disabled. The output state is independent from bit IS.TRPS. 01_H The trap functionality of the corresponding output signal is enabled. The output state is set to the passive while IS.TRPS=1.
TRPEN13	14	rw	**Trap Enable Control for Timer T13** 0_B The trap functionality for output COUT63 is disabled. The output state is independent from bit IS.TRPS. 1_B The trap functionality for output COUT63 is enabled. The output state is set to the passive while IS.TRPS=1.
TRPPEN	15	rw	**Trap Pin Enable** This bit enables the input (pin) function for the trap generation. An interrupt can only be generated if a falling edge is detected at pin CTRAP while TRPPEN = 1. 0_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is disabled. A CCU6 trap can only be generated by SW by setting bit TRPF. 1_B The CCU6 trap functionality based on the input $\overline{\text{CTRAP}}$ is enabled. A CCU6 trap can be generated by SW by setting bit TRPF or by $\overline{\text{CTRAP}}$=0.
0	7:3, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Passive State Level Register

Register PSLR defines the passive state level of the PWM outputs of the module. The passive state level is the value that is driven during the passive state of the output. During the active state, the corresponding output pin drives the active state level, that is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute “rh”), whereas the shadow bits can only be written (attribute “w”).

PSLR

Passive State Level Register **(0088$_H$)** **Application Reset Value: 0000 0000$_H$**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
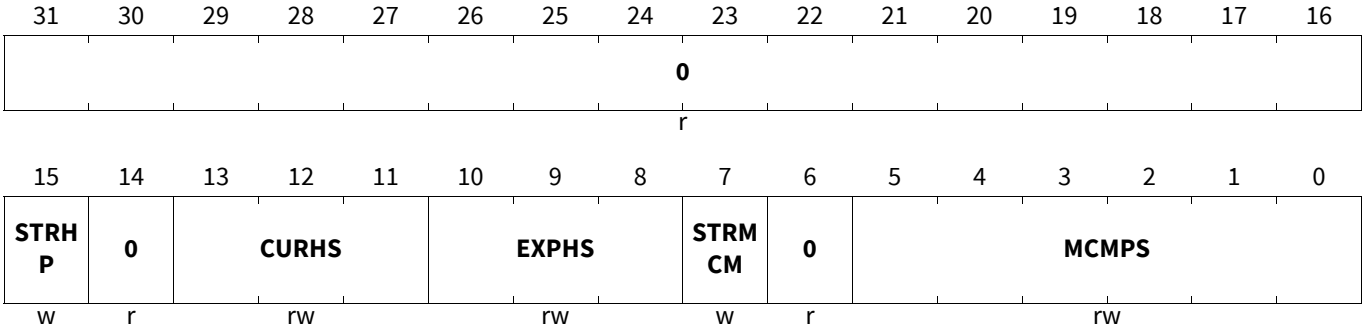
0					STE13U	STE12D	STE12U	0		SWSYN		0	SWSEL		
r					rw	rw	rw	r		rw		r	rw		

Field	Bits	Type	Description
SWSEL	2:0	rw	**Switching Selection** Bit field SWSEL selects one of the following trigger request sources (next multi-channel event) for the shadow transfer MCM_ST from MCMPS to MCMP. The trigger request is stored in the reminder flag R until the shadow transfer is done and flag R is cleared automatically with the shadow transfer. The shadow transfer takes place synchronously with an event selected in bit field SWSYN. 000_B No trigger request will be generated 001_B Correct Hall pattern detected (CM_CHE) 010_B T13 period-match detected (while counting up) 011_B T12 one-match (while counting down) 100_B T12 channel 1 compare-match detected (phase delay function) 101_B T12 period match detected (while counting up) 110_B reserved, no trigger request will be generated 111_B reserved, no trigger request will be generated
SWSYN	5:4	rw	**Switching Synchronization** Bit field SWSYN defines the synchronization mechanism of the shadow transfer event MCM_ST if it has been requested before (flag R set by an event selected by SWSEL) and if MCMEN = 1. This feature permits the synchronization of the outputs to the PWM source, that is used for modulation (T12 or T13). 00_B Direct; the trigger event immediately leads to the shadow transfer 01_B A T13 zero-match triggers the shadow transfer 10_B A T12 zero-match (while counting up) triggers the shadow transfer 11_B reserved; no action
STE12U	8	rw	**Shadow Transfer Enable for T12 Upcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 period match is detected while counting up. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE12D	9	rw	**Shadow Transfer Enable for T12 Downcounting** This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 one match is detected while counting down. 0_B No action 1_B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE13U	10	rw	**Shadow Transfer Enable for T13 Upcounting** This bit enables the shadow transfer T13_ST if flag MCMOUT.R is set or becomes set while a T13 period match is detected. 0_B No action 1_B The T13_ST shadow transfer mechanism is enabled if MCMEN = 1.
0	3, 7:6, 31:11	r	**Reserved;** Returns 0 if read; should be written with 0.

Multi-Channel Mode Output Shadow Register

Register MCMOUTS contains bits used as pattern input for the multi-channel mode and the Hall mode. This register is a shadow register (that can be read and written) for register MCMOUT, indicating the currently active signals.

MCMOUTS
Multi-Channel Mode Output Shadow Register (008C$_H$) **Application Reset Value: 0000 0000$_H$**

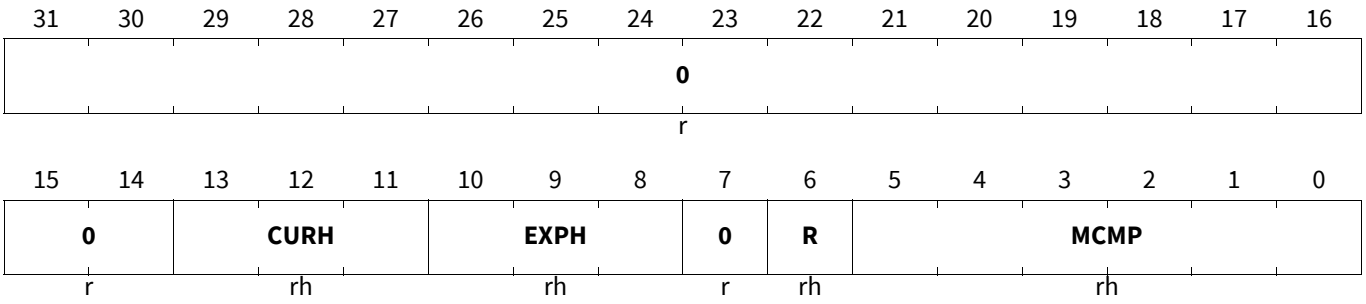


Field	Bits	Type	Description
MCMPS	5:0	rw	**Multi-Channel PWM Pattern Shadow** Bit field MCMPS is the shadow bit field for bit field MCMP. The multi-channel shadow transfer is triggered by MCM_ST according to the transfer conditions defined by register MCMCTR.
STRMCM	7	w	**Shadow Transfer Request for MCMPS** Writing STRMCM = 1 leads to an immediate activation of MCM_ST to update bit field MCMP by the value of MCMPS. When read, this bit always delivers 0. 0_B No action. 1_B Bit field MCMP is updated.
EXPHS	10:8	rw	**Expected Hall Pattern Shadow** Bit field EXPHS is the shadow bit field for bit field EXPH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).
CURHS	13:11	rw	**Current Hall Pattern Shadow** Bit field CURHS is the shadow bit field for bit field CURH. The shadow transfer takes place when a correct Hall event is detected (CM_CHE).
STRHP	15	w	**Shadow Transfer Request for the Hall Pattern** Writing STRHP = 1 leads to an immediate activation of HP_ST to update bit fields EXPH and CURH by EXPHS and CURHS. When read, this bit always delivers 0. 0_B No action. 1_B Bit fields EXPH and CURH are updated.
0	6, 14, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Multi-Channel Mode Output Register

MCMOUT

Multi-Channel Mode Output Register (0090$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
MCMP	5:0	rh	**Multi-Channel PWM Pattern** Bit field MCMP defines the output pattern for the multi-channel mode. If this mode is enabled by MODCTR.MCMEN = 1, the output state of all T12 related PWM outputs can be modified. This bit field is 0 while IS.IDLE = 1. MCMP0 = MCMOUT.0 for output CC60 MCMP1 = MCMOUT.1 for output COUT60 MCMP2 = MCMOUT.2 for output CC61 MCMP3 = MCMOUT.3 for output COUT61 MCMP4 = MCMOUT.4 for output CC62 MCMP5 = MCMOUT.5 for output COUT62 00_H The output is set to the passive state. A PWM generated by T12 or T13 are not taken into account. 01_H The output can be in the active state, depending on the enabled PWM modulation signals generated by T12, T13 and the trap state.
R	6	rh	**Reminder Flag** This flag indicates that the shadow transfer from MCMPS to MCMP has been requested by the selected trigger source. It is cleared when the shadow transfer takes place or while MCMEN=0. 0_B A shadow transfer MCM_ST is not requested. 1_B A shadow transfer MCM_ST is requested, but has not yet been executed, because the selected synchronization condition has not yet occurred.
EXPH	10:8	rh	**Expected Hall Pattern** Bit field EXPH is updated by a shadow transfer HP_ST from bit field EXPHS. If HCRDY = 1, EXPH is compared to the sampled CCPOSx inputs in order to detect the occurrence of the next desired (=expected) hall pattern or a wrong pattern. If the sampled hall pattern at the hall input pins is equal to bit field EXPH, a correct Hall event has been detected (CM_CHE).

Field	Bits	Type	Description
CURH	13:11	rh	**Current Hall Pattern** Bit field CURH is updated by a shadow transfer HP_ST from bit field CURHS. If HCRDY = 1, CURH is compared to the sampled CCPOSx inputs in order to detect a spike. If the sampled Hall pattern at the Hall input pins is equal to bit field CURH, no Hall event has been detected. If the sampled Hall input pattern is neither equal to CURH nor equal to EXPH, the Hall event was not the desired one and may be due to a fatal error (e.g. blocked rotor, etc.). In this case, a wrong Hall event has been detected (CM_WHE).
0	7, 31:14	r	**Reserved;** Returns 0 if read; should be written with 0.

29.10 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

29.10.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see **Figure 196**).

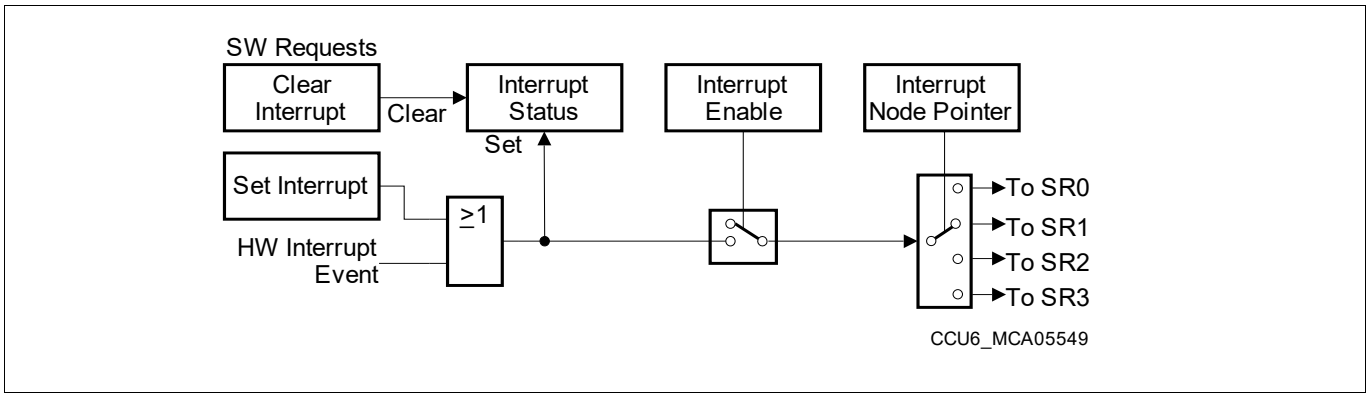


Figure 196 General Interrupt Structure

The available interrupt events in the CCU6 are shown in **Figure 197**.

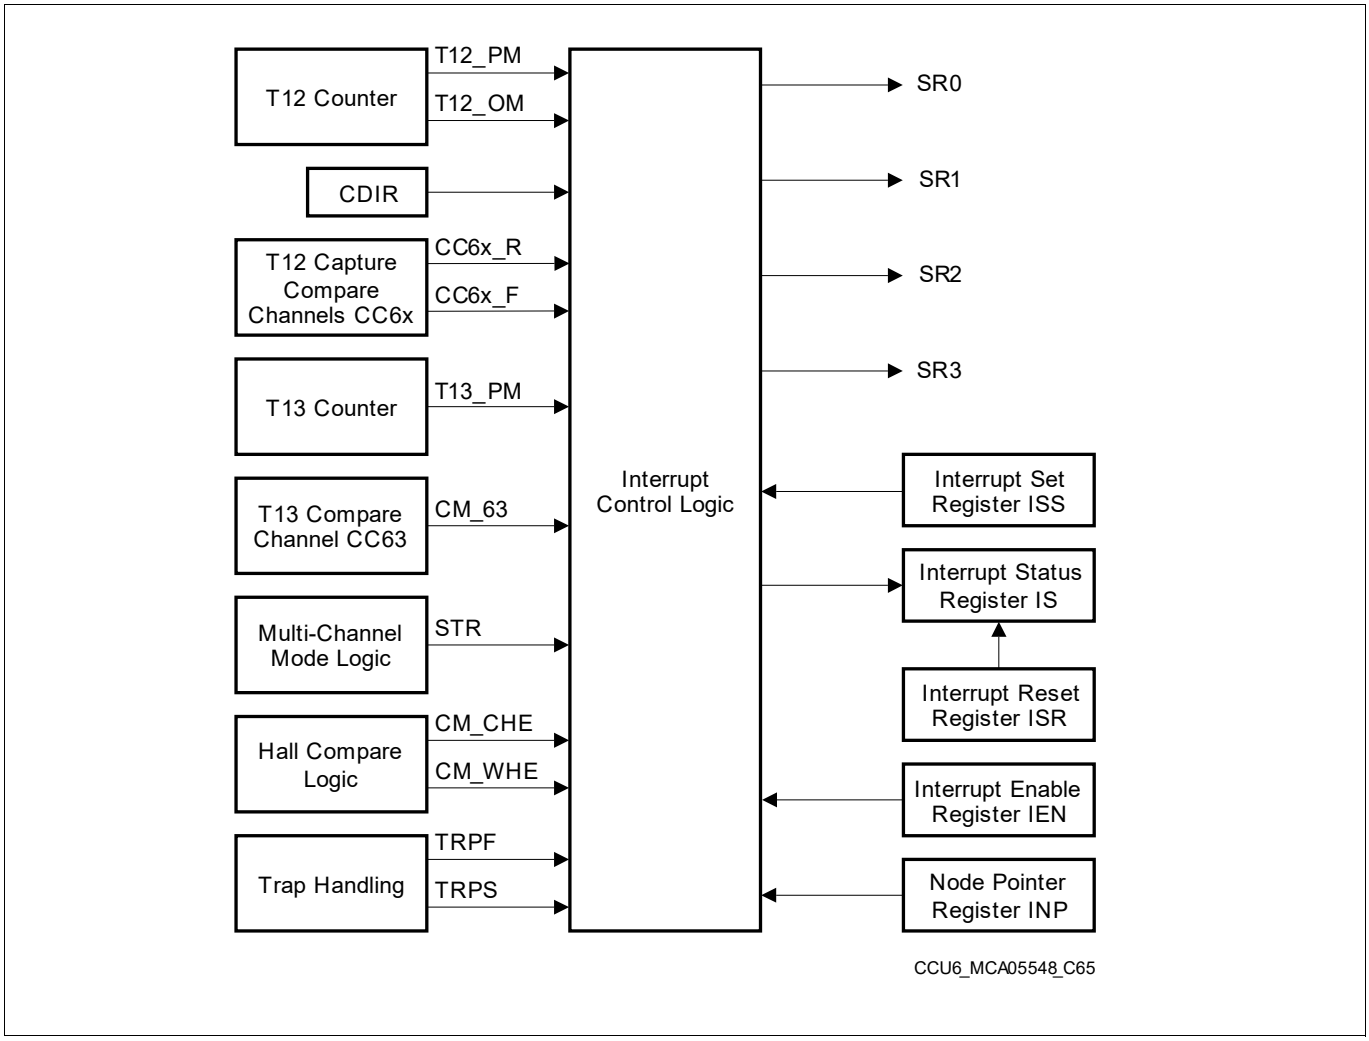

Figure 197 Interrupt Sources and Events

29.10.2 Interrupt Registers

Interrupt Status Register

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or clear the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to clear the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (T1xR=1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS

Interrupt Status Register **(00A0$_H$)** **Application Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
ICC6xR (x=0-2)	2*x	rh	**Capture, Compare-Match Rising Edge Flag ICC6xR (x=0,1,2)** This bit indicates that event CC6x_R has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting up (CM_6x and CDIR = 0) and in capture mode when a rising edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.
ICC6xF (x=0-2)	2*x+1	rh	**Capture, Compare-Match Falling Edge Flag ICC6xF (x=0,1,2)** This bit indicates that event CC6x_F has been detected. This event occurs in compare mode when a compare-match is detected while T12 is counting down (CM_6x and CDIR = 1) and in capture mode when a falling edge is detected at the related input CC6xIN. 0_B The event has not yet been detected. 1_B The event has been detected.

Field	Bits	Type	Description
T12OM	6	rh	**Timer T12 One-Match Flag** This bit indicates that a timer T12 one-match while counting down (T12_OM and CDIR = 1) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T12PM	7	rh	**Timer T12 Period-Match Flag** This bit indicates that a timer T12 period-match while counting up (T12_PM and CDIR = 0) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13CM	8	rh	**Timer T13 Compare-Match Flag** This bit indicates that a timer T13 compare-match (CM_63) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
T13PM	9	rh	**Timer T13 Period-Match Flag** This bit indicates that a timer T13 period-match (T13_PM) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
TRPF	10	rh	**Trap Flag** This bit indicates if a trap condition (input $\overline{\text{CTRAP}}$ = 0 or by SW) is / has been detected. If TRPM2= 0, it becomes cleared automatically if $\overline{\text{CTRAP}}$ = 1 or TRPPEN = 0, whereas if TRPM2 = 1, it has to be cleared by writing RTRPF = 1. 0_B The trap condition has not been detected. 1_B The trap condition is / has been detected.
TRPS	11	rh	**Trap State** This bit indicates the actual trap state. It is set if TRPF = 1 and becomes cleared according to the mode selected in register TRPCTR. 0_B The trap state is not active. 1_B The trap state is active.
CHE	12	rh	**Correct Hall Event** This bit indicates that a correct Hall event (CM_CHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
WHE	13	rh	**Wrong Hall Event** This bit indicates that a wrong Hall event (CM_WHE) has been detected. 0_B The event has not yet been detected. 1_B The event has been detected.
IDLE	14	rh	**IDLE State** If enabled by ENIDLE = 1, this bit is set together with bit WHE and it has to be cleared by SW. 0_B No action. 1_B Bit field MCMP is cleared, the selected outputs are set to passive state.

Field	Bits	Type	Description
STR	15	rh	**Multi-Channel Mode Shadow Transfer Request** This bit indicates that a shadow transfer from MCMPS to MCMP (MCM_ST) has taken place. 0_B The event has not yet been detected. 1_B The event has been detected.
0	31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Interrupt Status Set Register

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled). All bit positions read as 0.

The service request output that will be activated is selected by bit field INPT13.

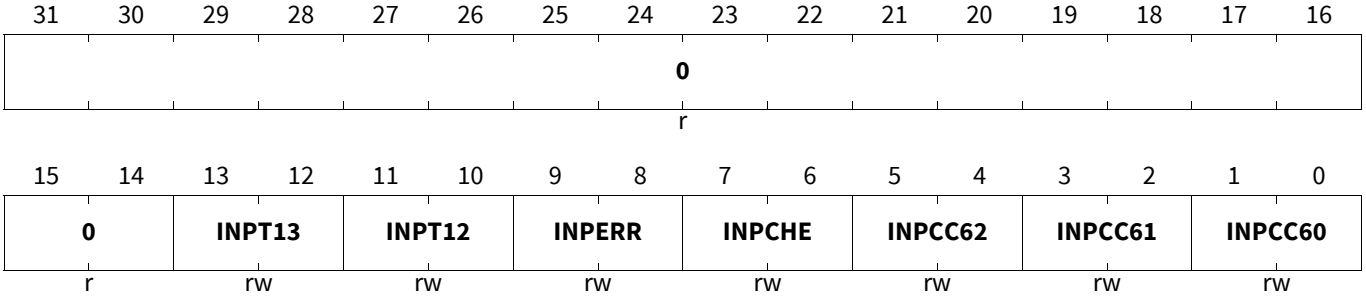
Field	Bits	Type	Description
ENT13PM	9	rw	**Enable Interrupt for T13 Period-Match** 0_B No interrupt will be generated if the set condition for bit T13PM in register IS occurs. 1_B An interrupt will be generated if the set condition for bit T13PM in register IS occurs. The service request output that will be activated is selected by bit field INPT13.
ENTRPF	10	rw	**Enable Interrupt for Trap Flag** 0_B No interrupt will be generated if the set condition for bit TRPF in register IS occurs. 1_B An interrupt will be generated if the set condition for bit TRPF in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENCHE	12	rw	**Enable Interrupt for Correct Hall Event** 0_B No interrupt will be generated if the set condition for bit CHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CHE in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
ENWHE	13	rw	**Enable Interrupt for Wrong Hall Event** 0_B No interrupt will be generated if the set condition for bit WHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit WHE in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENIDLE	14	rw	**Enable Idle** This bit enables the automatic entering of the idle state (bit IDLE will be set) after a wrong hall event has been detected (bit WHE is set). During the idle state, the bit field MCMP is automatically cleared. 0_B The bit IDLE is not automatically set when a wrong hall event is detected. 1_B The bit IDLE is automatically set when a wrong hall event is detected.
ENSTR	15	rw	**Enable Multi-Channel Mode Shadow Transfer Interrupt** 0_B No interrupt will be generated if the set condition for bit STR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit STR in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
0	11, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Interrupt Node Pointer Register

Register INP contains the interrupt node pointers allowing a flexible interrupt handling. These bit fields define which service request output will be activated if the corresponding interrupt event occurs and the interrupt generation for this event is enabled.

INP

Interrupt Node Pointer Register **($00AC_H$)** **Application Reset Value: $0000\ 3940_H$**



Field	Bits	Type	Description
INPCC6x (x=0-2)	2*x+1:2*x	rw	**Interrupt Node Pointer for Channel CC6x Interrupts INPCC6x (x=0,1,2)** This bit field defines the service request output activated due to a set condition for bit CC6xR (if enabled by bit ENCC6xR) or for bit CC6xF (if enabled by bit ENCC6xF). 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
INPCHE	7:6	rw	**Interrupt Node Pointer for the CHE Interrupt** This bit field defines the service request output activated due to a set condition for bit CHE (if enabled by bit ENCHE) of for bit STR (if enabled by bit ENSTR). Coding see INPCC6x.
INPERR	9:8	rw	**Interrupt Node Pointer for Error Interrupts** This bit field defines the service request output activated due to a set condition for bit TRPF (if enabled by bit ENTRPF) or for bit WHE (if enabled by bit ENWHE). Coding see INPCC6x.
INPT12	11:10	rw	**Interrupt Node Pointer for Timer12 Interrupts** This bit field defines the service request output activated due to a set condition for bit T12OM (if enabled by bit ENT12OM) or for bit T12PM (if enabled by bit ENT12PM). Coding see INPCC6x.
INPT13	13:12	rw	**Interrupt Node Pointer for Timer13 Interrupt** This bit field defines the service request output activated due to a set condition for bit T13CM (if enabled by bit ENT13CM) or for bit T13PM (if enabled by bit ENT13PM). Coding see INPCC6x.
0	31:14	r	**Reserved;** Returns 0 if read; should be written with 0.

29.11 General Module Operation

This section provides information about the:

- Input Selection (see **Section 29.11.1**)
- Input Monitoring (see **Section 29.11.2**)
- OCDS Suspend Functionality (see **Section 29.11.3**)
- OCDS Trigger Bus (OTGB) Interface (see **Section 29.11.4**)
- General Register Description (see **Section 29.11.5**)
- BPI Register Description (see **Section 29.11.6**)

29.11.1 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers **PISEL0** and **PISEL2**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention:
The input vector CC60IN[D:A] for input signal CC60IN is composed of the signals CC60INA to CC60IND.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

29.11.2 Input Monitoring

A selected event which occurs at each CCU6 input signal can be monitored through **IMON**.x. Every input signal can be included for the detection of a lost bit event (**IMON**.LBE) if enabled through its individual lost indicator enable bits (**LI**.yEN). The lost bit event occurs if a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled for at least one of the monitored input signals. The lost bit event can be enabled (**LI**.LBEEN) for an interrupt to be generated at one of the SRx line, selected through **LI**.INPLBE. The LBE output signal of the kernel can be connected to a capture input to indicate when the lost bit event happens.

The lost bit event can be used as a kind of interrupt or event watchdog to monitor if an action related to an event has been processed before a second event of the same type occurs. Like this, if a certain event is treated by an interrupt that should be monitored, the related indication flag has to be cleared by SW. If the SW has not yet cleared the flag and the event occurs again, the event is considered as being lost and another interrupt can be generated to inform the system about the loss. This can be also used to indicate that input events occur too often and the main task has not enough time to treat them.

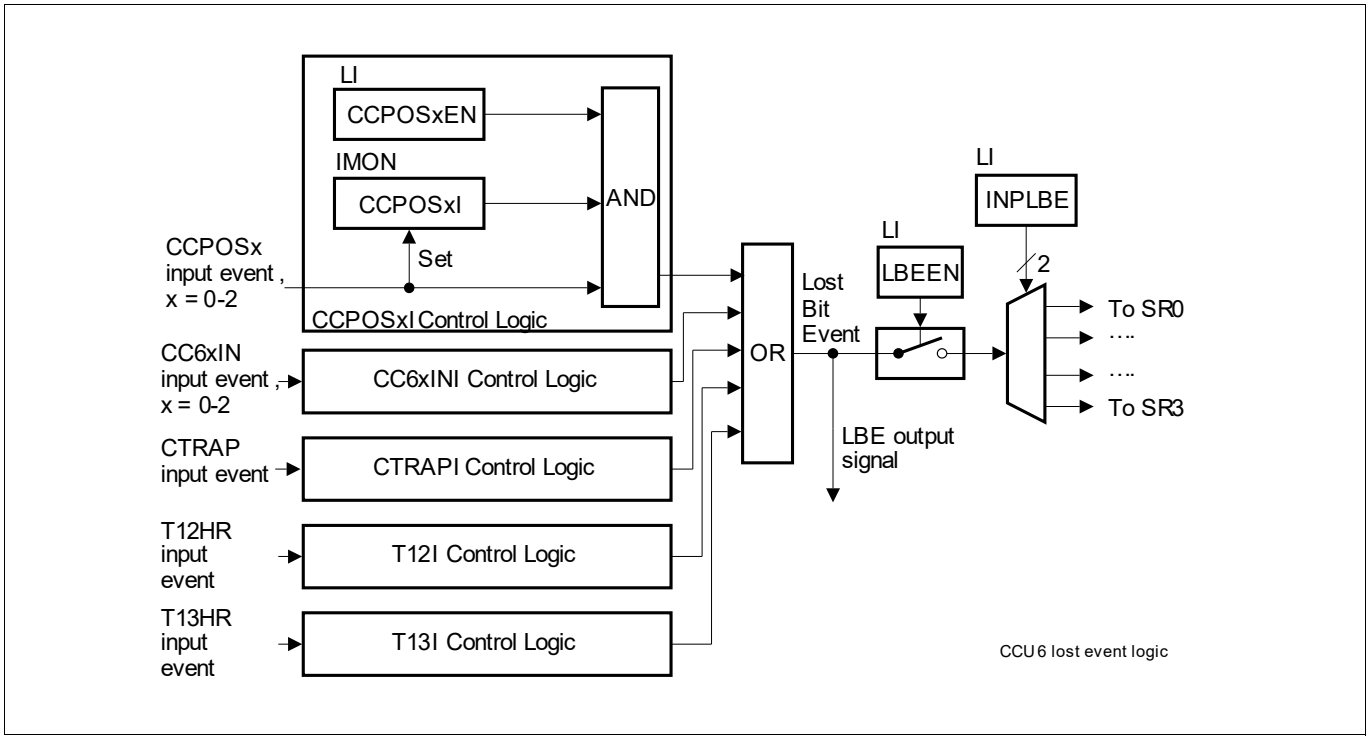


Figure 198 Lost Event Logic

29.11.3 OCDS Suspend

The behavior of CCU6 upon an OCDS suspend request is controlled by the **OCS** register. CCU6 supports both Hard Suspend Mode and Soft Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the CCU6 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a CCU6 kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode

In Soft Suspend Mode CCU6 may finalize specific actions before it enters the suspended state with **OCS**.SUSSTA set. This can be advantageous for applications (e.g. motor control) where critical system states could occur if the kernel clock would be switched off immediately upon an OCDS suspend request.

Soft Suspend mode does not influence the kernel clock. Reading and writing of registers is possible without the side effects that may occur when reading/writing registers in Hard Suspend Mode.

For CCU6 , two basic soft suspend options (**Stop Mode 0**, **Stop Mode 1**) are available, selected via bit field **OCS**.SUS.

In addition, the internal functional blocks (T12, T13, Hall logic, Trap logic) may individually be programmed via their Sensitivity Bits in register **KSCSR** to accept or ignore a suspend request. If the request sensitivity is disabled, the block continues normal operation. If the request sensitivity is enabled, the block operates as specified for the selected stop mode. The mapping of the CCU6 functional blocks to their Sensitivity Bits is shown in **Table 203**.

Stop Mode 0

In Stop Mode 0, if selected to be stopped, the Hall and Trap logic stops immediately, while Timer T12 and/or T13 continues normal operation (if running) until it reaches the end of the PWM period; then it stops (same stop condition as in single shot mode). When Timer T12 stops, the capture inputs CC6xIN are frozen.

Stop Mode 1

In Stop Mode 1, if selected to be stopped, the internal functional blocks (T12, T13, Hall logic, Trap logic) will stop immediately upon a suspend request.

If the sensitivity bits for Timer T12 or T13 are set, the corresponding output lines enabled for the trap condition are set to their passive values (similar to a trap condition).

Table 203 summarizes the reaction of the CCU6 functional blocks to OCDS suspend requests.

Table 203 CCU6 Functional Blocks

Block	Reaction to OCDS Suspend Request	Sensitivity Bit
0	**Timer T12:** if bit SB0 = 1_B, - in **Stop Mode 0** Timer T12 continues (if running) until the end of the PWM period. Then it stops and the CCxIN input stages are frozen. - in **Stop Mode 1** Timer T12 stops immediately and the CC6xIN input stages are frozen. Output lines CC6x, COUT6x with enabled trap functionality are set to their passive states.	KSCSR.SB0
1	**Timer T13:** if bit SB1 = 1_B, - in **Stop Mode 0** Timer T13 continues (if running) until the end of the PWM period. Then it stops. - in **Stop Mode 1** Timer T13 stops immediately. If trap functionality for COUT63 is enabled, it is set to the passive state.	KSCSR.SB1
2	**Hall Logic:** if bit SB2 = 1_B, the hall logic is stopped immediately and the CCPOSx input stages are frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB2
3	**Trap Logic:** if bit SB3 = 1_B, the trap logic is stopped immediately and the CTRAP input stage is frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB3

29.11.4 OCDS Trigger Bus (OTGB) Interface

The CCU6 kernel provides a set of 16 internal status signals that are combined to a Trigger Set. The CCU6 Trigger Set is shown in **Table 204**. It is output on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 204 TS16_CCU6 Trigger Set CCU6

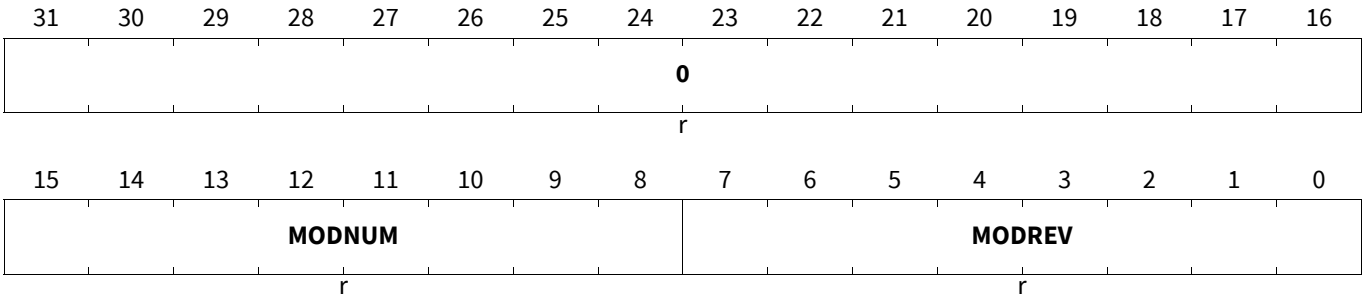
Bits	Name	Description
0	T12pre	T12 prescaler output
1	T13pre	T13 prescaler output
2	T12_cm0	T12 compare match channel 0
3	T12_cm1	T12 compare match channel 1
4	T12_cm2	T12 compare match channel 2
5	T12_pm	T12 period match
6	T12_om	T12 one match
7	T12_cdir	T12 count direction
8	T12_zm	T12 zero match
9	T13_cm	T13 compare match
10	T13_pm	T13 period match
11	T13_zm	T13 zero match
12	mcm_st	MCM shadow transfer
13	che	Correct Hall event
14	whe	Wrong Hall event
15	trpf	Trap flag

29.11.5 General Registers

Module Identification Register

The CCU6 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID
Module Identification Register **(0008_H)** **Reset Value: Table 205**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision), 02_H, 03_H,...up to FF_H.
MODNUM	15:8	r	**Module Number Value** This bit field defines the module identification number for the CCU6: 54_H
0	31:16	r	**Reserved** Read as 0.

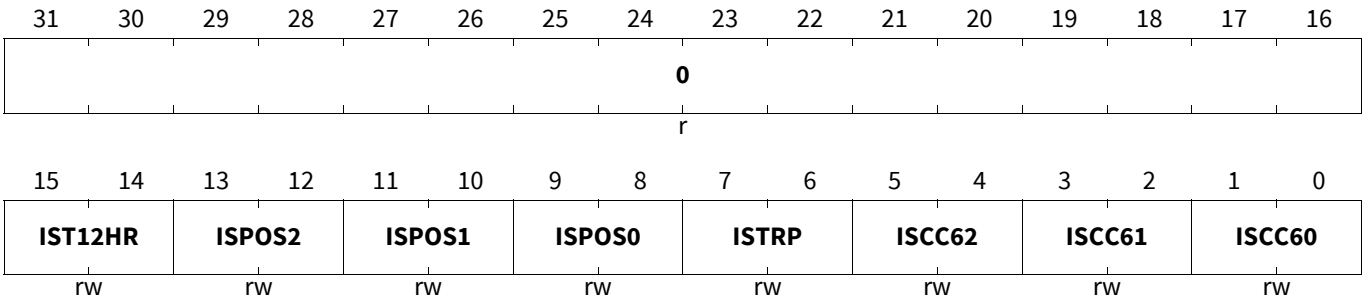
Table 205 Reset Values of ID

Reset Type	Reset Value	Note
Application Reset	0000 $54XX_H$	

Port Input Select Register 0

Registers PISEL0 and PISEL2 contain bit fields selecting the actual input signal for the module inputs.

PISEL0
Port Input Select Register 0 **(0010_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
ISCC6x (x=0-2)	2*x+1:2*x	rw	**Input Select for CC60 ISCC6x (x=0,1,2)** This bit field defines the input signal used as CC6x capture input. 00_B The signal CC6xINA is selected. 01_B The signal CC6xINB is selected. 10_B The signal CC6xINC is selected. 11_B The signal CC6xIND is selected.
ISTRP	7:6	rw	**Input Select for CTRAP** This bit field defines the input signal used as CTRAP input. 00_B The signal CTRAPA is selected. 01_B The signal CTRAPB is selected. 10_B The signal CTRAPC is selected. 11_B The signal CTRAPD is selected.
ISPOSx (x=0-2)	2*x+9:2*x+8	rw	**Input Select for CCPOS0 ISPOSx (x=0,1,2)** This bit field defines the input signal used as CCPOSx input. 00_B The signal CCPOSxA is selected. 01_B The signal CCPOSxB is selected. 10_B The signal CCPOSxC is selected. 11_B The signal CCPOSxD is selected.
IST12HR	15:14	rw	**Input Select for T12HR** This bit field defines the input signal used as T12HR input. 00_B Either signal T12HRA (if T12EXT = 0) or T12HRE (if T12EXT = 1) is selected. 01_B Either signal T12HRB (if T12EXT = 0) or T12HRF (if T12EXT = 1) is selected. 10_B Either signal T12HRC (if T12EXT = 0) or T12HRG (if T12EXT = 1) is selected. 11_B Either signal T12HRD (if T12EXT = 0) or T12HRH (if T12EXT = 1) is selected.
0	31:16	r	**Reserved** Returns 0 if read, should be written with 0.

Port Input Select Register 2

PISEL2

Port Input Select Register 2 **(0014_H)** **Application Reset Value: $0000\ 0000_H$**

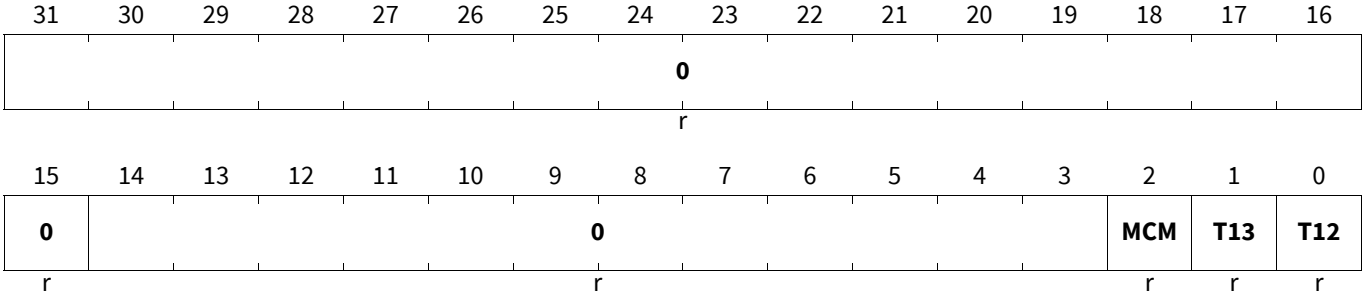
Field	Bits	Type	Description
IST13HR	1:0	rw	**Input Select for T13HR** This bit field defines the input signal used as T13HR input. 00_B Either signal T13HRA (if T13EXT = 0) or T13HRE (if T13EXT = 1) is selected. 01_B Either signal T13HRB (if T13EXT = 0) or T13HRF (if T13EXT = 1) is selected. 10_B Either signal T13HRC (if T13EXT = 0) or T13HRG (if T13EXT = 1) is selected. 11_B Either signal T13HRD (if T13EXT = 0) or T13HRH (if T13EXT = 1) is selected.
ISCNT12	3:2	rw	**Input Select for T12 Counting Input** This bit field defines the input event leading to a counting action of T12. 00_B The T12 prescaler generates the counting events. Bit TCTR4.T12CNT is not taken into account. 01_B Bit TCTR4.T12CNT written with 1 is a counting event. The T12 prescaler is not taken into account. 10_B The timer T12 is counting each rising edge detected in the selected T12HR signal. 11_B The timer T12 is counting each falling edge detected in the selected T12HR signal.
ISCNT13	5:4	rw	**Input Select for T13 Counting Input** This bit field defines the input event leading to a counting action of T13. 00_B The T13 prescaler generates the counting events. Bit TCTR4.T13CNT is not taken into account. 01_B Bit TCTR4.T13CNT written with 1 is a counting event. The T13 prescaler is not taken into account. 10_B The timer T13 is counting each rising edge detected in the selected T13HR signal. 11_B The timer T13 is counting each falling edge detected in the selected T13HR signal.
T12EXT	6	rw	**Extension for T12HR Inputs** This bit extends the 2-bit field IST12HR. 0_B One of the signals T12HR[D:A] is selected. 1_B One of the signals T12HR[H:E] is selected.
T13EXT	7	rw	**Extension for T13HR Inputs** This bit extends the 2-bit field IST13HR. 0_B One of the signals T13HR[D:A] is selected. 1_B One of the signals T13HR[H:E] is selected.
0	31:8	r	**Reserved;** Returns 0 if read; should be written with 0.

Module Configuration Register

The module configuration register contains bits describing the functionality that is available in the CCU6 module.

MCFG
Module Configuration Register **(0004_H)** **Reset Value: Table 206**



Field	Bits	Type	Description
T12	0	r	**T12 Available** This bit indicates if the T12 block is available. 0_B The T12 block is not available. A write access to T12PR is ignored. 1_B The T12 block is available. A write access to T12PR is executed.
T13	1	r	**T13 Available** This bit indicates if the T13 block is available. 0_B The T13 block is not available. A write access to T13PR is ignored. 1_B The T13 block is available. A write access to T13PR is executed.
MCM	2	r	**Multi-Channel Mode Available** This bit indicates if the multi-channel mode functionality is available. 0_B The multi-channel mode functionality is not available. A write access to MCMOUTS is ignored. 1_B The multi-channel mode functionality is available. A write access to MCMOUTS is executed.
0	14:3, 15, 31:16	r	**Reserved;** read as 0; should be written with 0.

Table 206 Reset Values of MCFG

Reset Type	Reset Value	Note
Application Reset	$0000\ 0007_H$	

The input monitoring register monitors the occurrence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

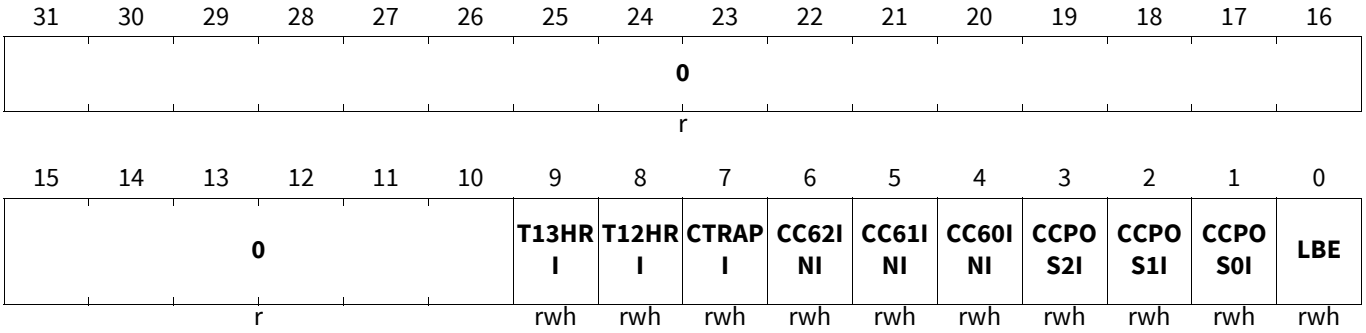
Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

Input Monitoring Register

The input monitoring register monitors the occurrence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

IMON
Input Monitoring Register **(0098_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LBE	0	rwh	**Lost Bit Event** This bit determines if a lost bit event has occurred. A lost bit event occurs when a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled, for at least one of the monitored input signals. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B The lost bit event has not occurred. 1_B The lost bit event has occurred.
CCPOSxI (x=0-2)	x+1	rwh	**Event indication for input signal CCPOSx** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. *Note: The dedicated edge is indicated for a selected event if Hysteretic-like Control or Capture modes are initialized in T12MSEL.MSEL6x. If these modes are not selected, then all edges will be indicated as an event for the inputs.* 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.
CC6xINI (x=0-2)	x+4	rwh	**Event indication for input signal CC6xIN** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.
CTRAPI	7	rwh	**Event indication for input signal CTRAP** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.

Field	Bits	Type	Description
T12HRI	8	rwh	**Event indication for input signal T12HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
T13HRI	9	rwh	**Event indication for input signal T13HR** The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.
0	31:10	r	**Reserved;** Returns 0 if read; should be written with 0.

Register Access Notes

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions.

This affects the bits in register IMON which are cleared by writing 1s.

No problem exists when using direct write instructions (e.g. ST.W).

Lost Indicator Register

The lost indicator register has the lost indicator enable bits for its detected event at the input signals. The lost bit event can then be enabled as an output signal through one of the service request lines.

CCPOSxEN (x=0-2)	x+1	rw	**Lost Indicator Enable for input signal CCPOSx** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.

Field	Bits	Type	Description
CC6xINEN (x=0-2)	x+4	rw	**Lost Indicator Enable for input signal CC6xIN** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
CTRAPEN	7	rw	**Lost Indicator Enable for input signal CTRAP** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T12HREN	8	rw	**Lost Indicator Enable for input signal T12HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
T13HREN	9	rw	**Lost Indicator Enable for input signal T13HR** This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0_B Input signal is disabled for a lost bit event detection. 1_B Input signal is enabled for a lost bit event detection.
LBEEN	13	rw	**Interrupt Enable for Lost Bit Event** This bit determines if a SRx line is activated if lost bit event is detected. 0_B Lost bit event is disabled for the activation of a SRx line. 1_B Lost bit event is enabled for the activation of a SRx line.
INPLBE	15:14	rw	**Interrupt Node Pointer for lost bit event** This bit field defines which service request output line is selected to output an lost event alert for an enabled lost bit event. 00_B Service request output SR0 is selected. 01_B Service request output SR1 is selected. 10_B Service request output SR2 is selected. 11_B Service request output SR3 is selected.
0	0, 12:10, 31:16	r	**Reserved;** Returns 0 if read; should be written with 0.

Kernel State Control Sensitivity Register

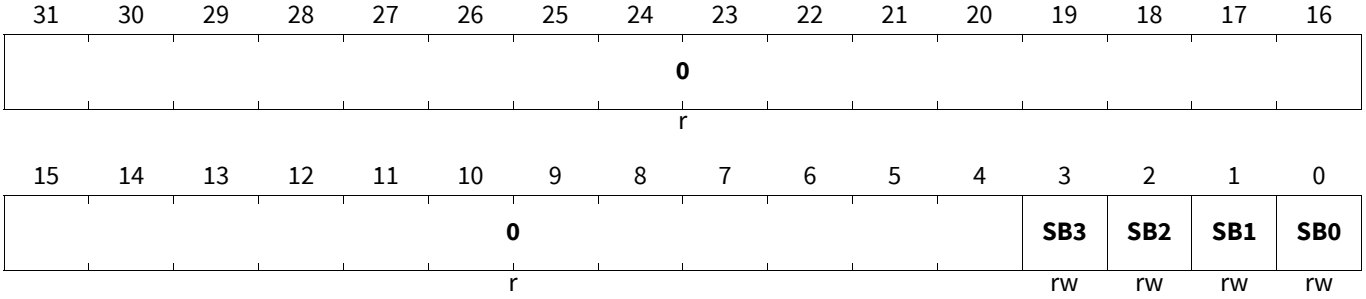
The kernel state control sensitivity register bits define which internal block is affected by Stop Modes 0 and 1, as described in section **Soft Suspend Mode**.

The Kernel State Control Sensitivity Register (KSCSR) is cleared by Debug Reset.

The register can only be written while the OCDS is enabled (OCDS enable = ´1´).

KSCSR

Kernel State Control Sensitivity Register (001C$_H$) Reset Value: Table 207



Field	Bits	Type	Description
SBx (x=0-3)	x	rw	**Sensitivity Block x SBx (x=0,1,2,3)** This bit defines if block x of the CCU6 kernel is sensitive to Stop Mode 0 or Stop Mode 1. The functional definition of the blocks is given in Table 203. 0_B Block x is not sensitive to Stop Mode 0 or Stop Mode 1. It continues normal operation without respecting the defined stop condition. 1_B Block x is sensitive to Stop Mode 0 or Stop Mode 1. It is respecting the defined stop condition.
0	31:4	r	**Reserved;** Returns 0 if read; should be written with 0.

Table 207 Reset Values of KSCSR

Reset Type	Reset Value	Note
Debug Reset	0000 0000$_H$	

Module Output Trigger Selection

Module CCU6 outputs 3 trigger signals (TRIG0, TRIG1, TRIG2) which can be controlled by output signals of the CCU60 and CCU61 kernels. Register **MOSEL** selects the sources of these trigger signals.

Note: To avoid unintended trigger events in the EVADC when modifying bitfields TRIGiSEL, make sure that the respective trigger target is enabled only after selecting the trigger source via register MOSEL.

These trigger signals are connected to the EVADC module.

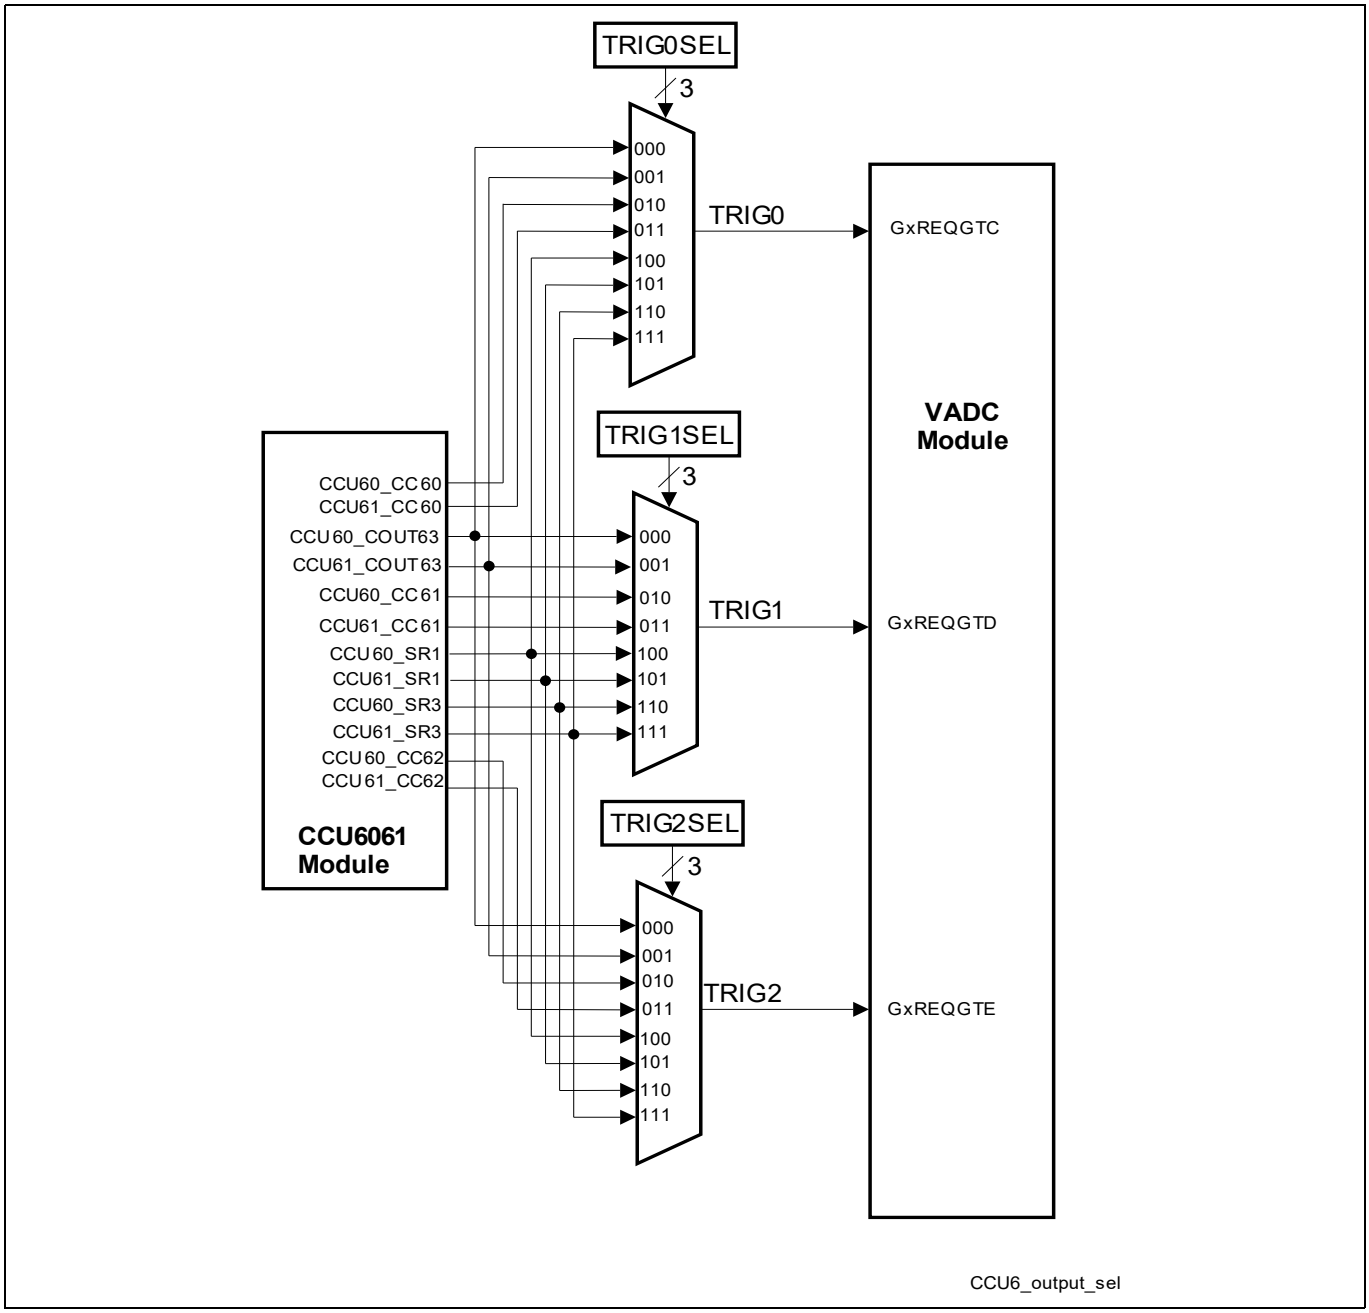


Figure 199 Output Selection for Trigger Signals

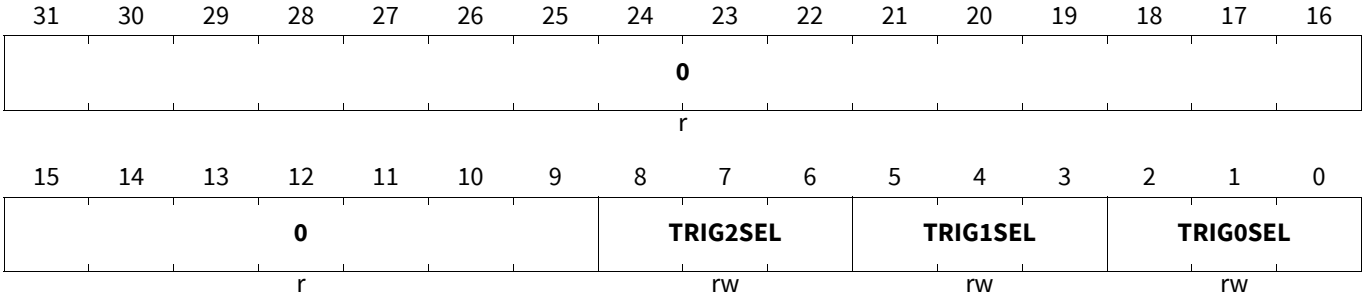
CCU60 Module Output Select Register

MOSEL contains bit fields to select the output signal from module CCU6061 for the trigger signals to the A/D converters in the EVADC module.

*Note: CCU60_MOSEL is located in the address space of kernel CCU60. Therefore, when a reset of kernel CCU60 is triggered via registers CCU60_**KRST0** and CCU60_**KRST1**, register CCU60_MOSEL is also reset. CCU60_MOSEL is **not** reset when a reset of kernel CCU61 is triggered via registers CCU61_KRST0 and CCU61_KRST1. Because CCU60_MOSEL controls both signals from kernel CCU60 and CCU61, the output signals TRIG0 2 will be set to their inactive levels during **any** kernel reset of CCU60 as well as of CCU61 (see also **Figure 199**). Depending on the application, it may make sense to always reset both kernels in this case.*

MOSEL

CCU60 Module Output Select Register (000C$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TRIGxSEL (x=0-2)	3*x+2:3*x	rw	**Output Trigger Select for CCU6061 TRIGx** This bit field defines the output signal from the CCU6061 module used as the trigger signal to the EVADC inputs. 000_B The signal CCU60_COUT63 is selected. 001_B The signal CCU61_COUT63 is selected. 010_B The signal CCU60_CC6x is selected. 011_B The signal CCU61_CC6x is selected. 100_B The signal CCU60_SR1 is selected. 101_B The signal CCU61_SR1 is selected. 110_B The signal CCU60_SR3 is selected. 111_B The signal CCU61_SR3 is selected.
0	31:9	r	**Reserved** Returns 0 if read, should be written with 0.

29.11.6 System Registers

This section describes the registers of the BPI (Bus Peripheral Interface).

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register CLC controls the module clock signal and the reactivity to the sleep signal.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the CCU6 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the CCU6 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

CLC
Clock Control Register **(0000_H)** **Application Reset Value: $0000\ 0003_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.
0	2, 15:4, 31:16	r	**Reserved** Read as 0; should be written with 0.

It is recommended not to write to or read from module registers (except CLC) while the module is disabled. Write operations and read operations from registers that require a clock will generate a bus error.

OCDS Control and Status Register

The OCDS Control and Status register OCS controls the module's behavior in suspend mode (used for debugging). The OCS register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. When OCDS is disabled the OCS suspend control is ineffective.

The default state of the OTGB bus outputs of a peripheral is disabled (all bits are 0). This allows to have an ORed combination of all peripheral OTGBs within the OTGM instead of a multiplexer.

OCS

Note: For additional hints, refer to ***"OCDS Suspend" on Page 84****.*

Access Enable Register 0

The Access Enable Register 0 controls write access[1] for transactions with the on chip bus master TAG ID $00\ 0000_B$ to $01\ 1111_B$ (see On Chip Bus chapter for the mapping of products TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENy: EN0 -> TAG ID $00\ 0000_B$, EN1 -> TAG ID $00\ 0001_B$, … , EN31 -> TAG ID $01\ 1111_B$ (TAG IDs $1X\ XXXX_B$, are not used.

ACCEN0

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. Kernel Reset Registers 0 and 1 each include bit RST. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

A module kernel reset has the following effects:

Table 210 Effects of a Module Kernel Reset

Register	Executed Action
CLC, OCS, ACCEN0	No influence
ID	No influence
KRST0	Bit RST is cleared automatically after reset execution, RSTSTAT indicates a module kernel reset, cleared via KRSTCLR
KRST1	Bit RST is cleared automatically after reset execution
KRSTCLR	No influence
Other registers	Reset to their defined reset values

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.
*A kernel reset, initiated via registers KRST0/KRST1, does not affect the port logic. Because register **PSLR** is set to its default value, the passive level 0 is selected for the outputs CC60…CC62 and COUT60…COUT63 upon a kernel reset. Therefore, software must ensure appropriate levels for the external system at the port pins in case they are different from the default values selected via PSLR.*

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the CLR bit in the related KRSTCLR register.

Notes

1. *During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge*
2. *A kernel reset, initiated via registers KRST0/KRST1, does not affect the port logic. Because register **PSLR** is set to its default value, the passive level 0 is selected for the outputs CC60…CC62 and COUT60…COUT63 upon a kernel reset. Therefore, software must ensure appropriate levels for the external system at the port pins in case they are different from the default values selected via PSLR.*

The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset. The RST bit will be re-set (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

30 General Purpose Timer Unit (GPT12)

The General Purpose Timer Unit blocks GPT1 and GPT2 have very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes.

They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated Timer or Counter Mode, or may be concatenated with another timer of the same block.

Each block has alternate input/output functions and specific interrupts (service requests) associated with it. Input signals can be selected from several sources by register PISEL.

The GPT12 module is clocked with clock f_{GPT}.

30.1 Feature List

Timer Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{GPT}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in **Section 30.2.6**.

The following list summarizes the supported features:

- $f_{GPT}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
  - Incremental Interface Mode
- Reload and Capture functionality
- Separate interrupts

Timer Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{GPT}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in **Section 30.3.7**.

The following list summarizes the supported features:

- $f_{GPT}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
  - Timer Mode
  - Gated Timer Mode
  - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Separate interrupts

You will find the following major sections within this chapter:

“GPT12 Kernel Register Overview” on Page 53, **“General Module Operation” on Page 55**

“Implementation of the GPT12 Module” on Page 63, **“Revision History” on Page 65**.

30.2 Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4. When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT1 are signalled on service request lines SR0, SR1, and SR2.

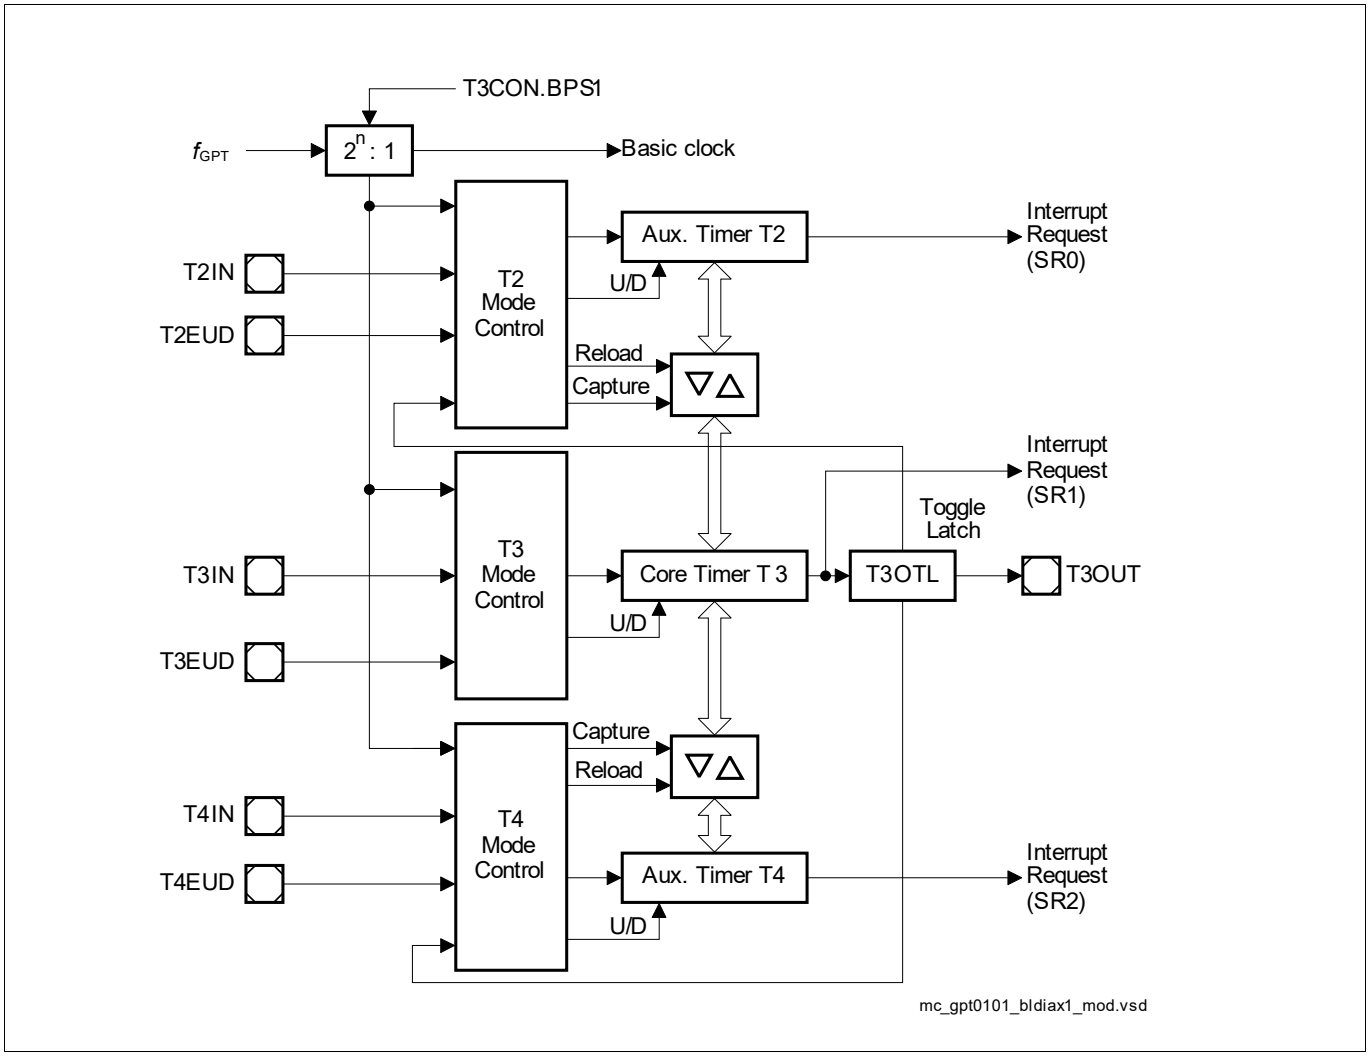

Figure 200 GPT1 Block Diagram

The input and output lines of GPT1 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 30.2.5**, **Section 30.6** summarizes the module interface signals, including pins and interrupt request signals.*

30.2.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T3 is configured and controlled via its control register T3CON.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 217**. The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timer T3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 201** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL’s output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 201**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

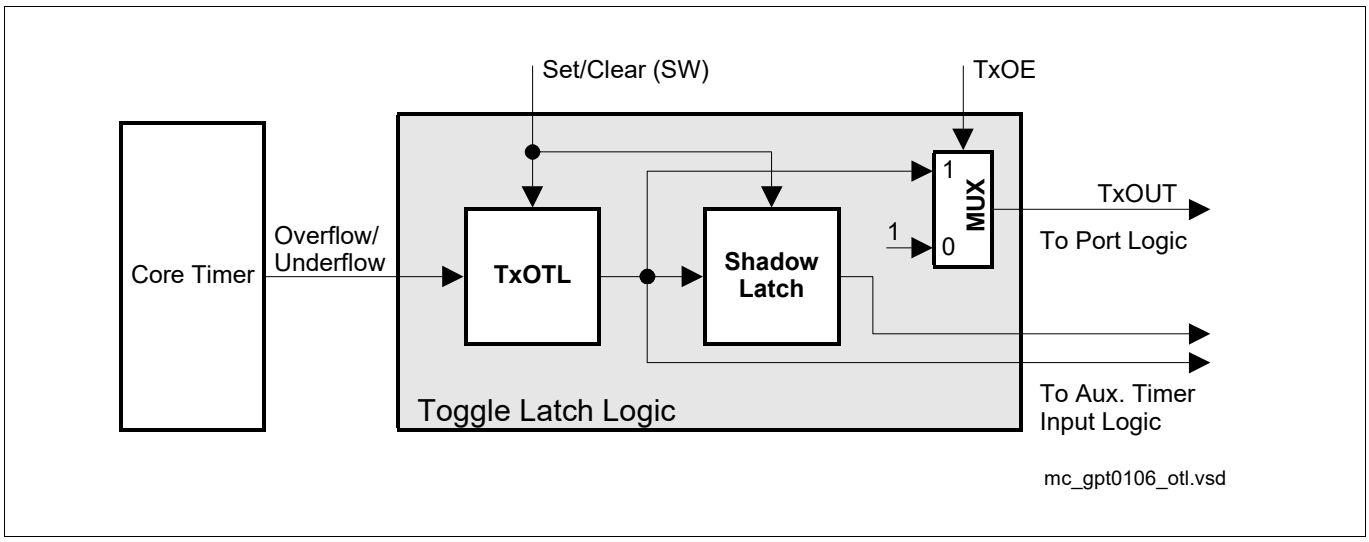

Figure 201 Block Diagram of the Toggle Latch Logic of Core Timer T3 (x = 3)

30.2.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer T3 in Timer Mode

Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see **Section 30.2.5** for details on the input clock options.

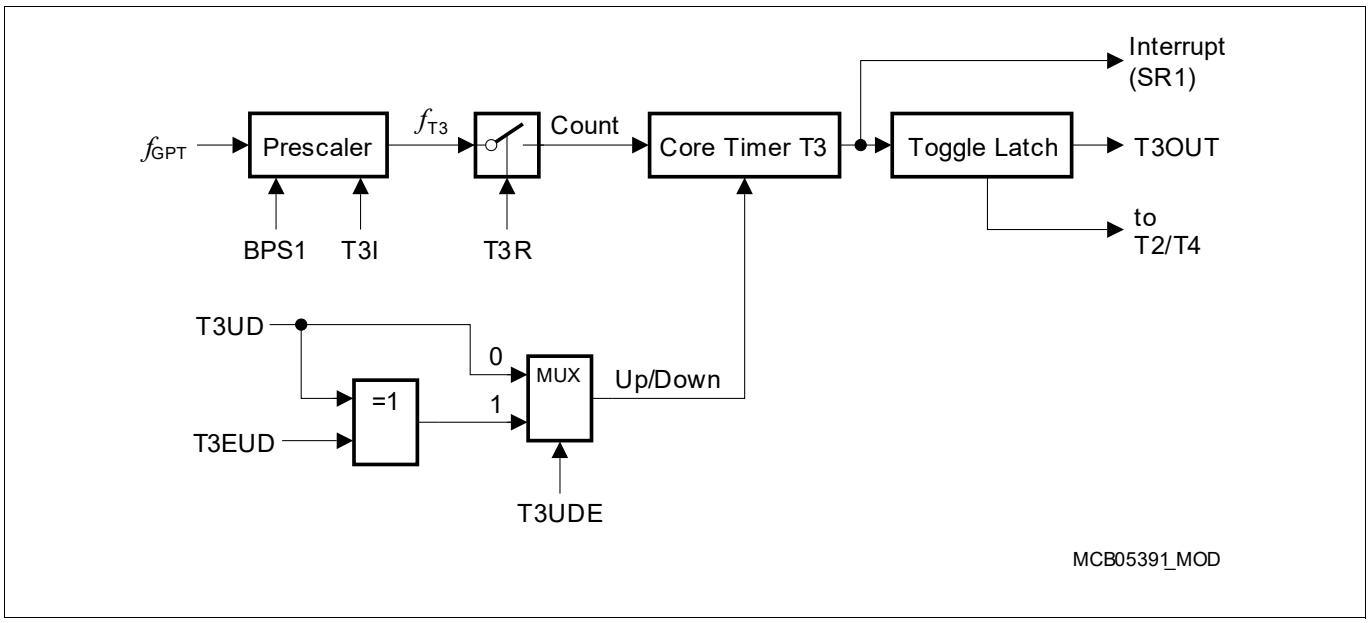

Figure 202 Block Diagram of Core Timer T3 in Timer Mode

Timer T3 in Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 30.2.5**). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).

To enable this operation, the associated pin T3IN must be configured as input.

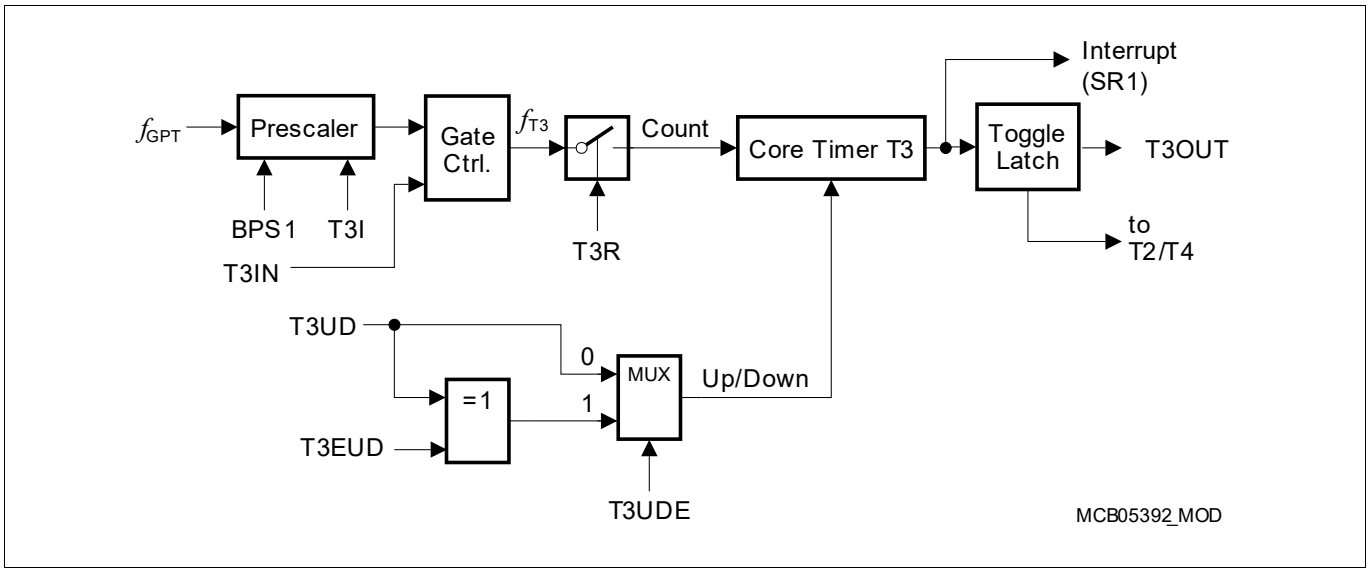

Figure 203 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause a service request via SR1.

Timer T3 in Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see **Table 219**).

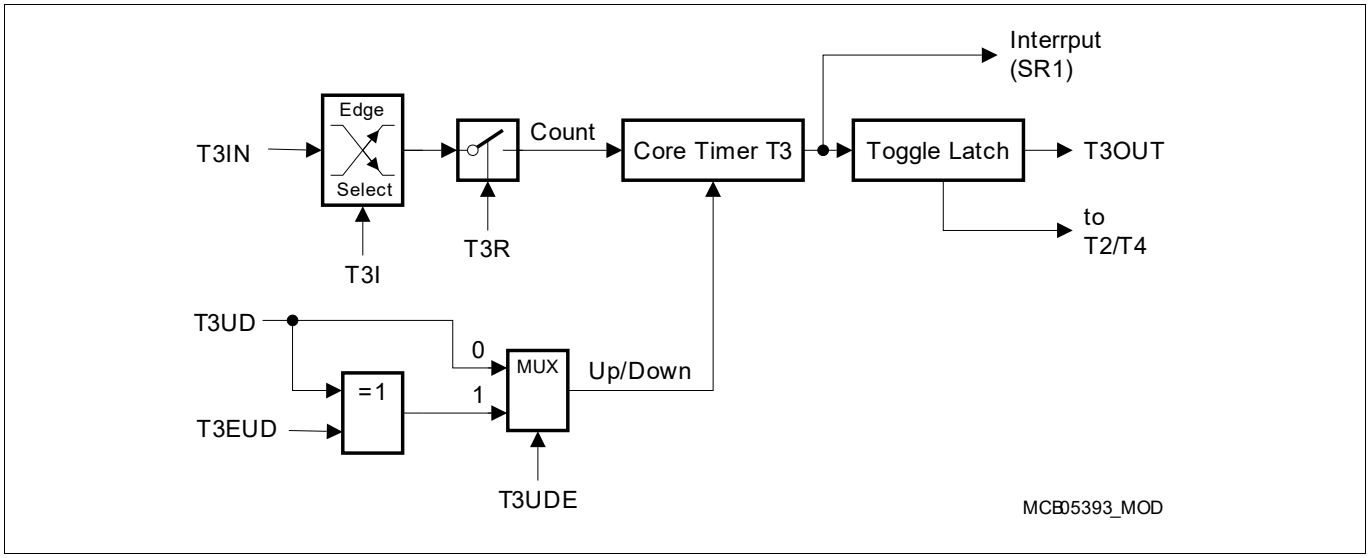

Figure 204 Block Diagram of Core Timer T3 in Counter Mode

For Counter Mode operation, pin T3IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.2.5**.

Timer T3 in Incremental Interface Mode

Incremental Interface Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

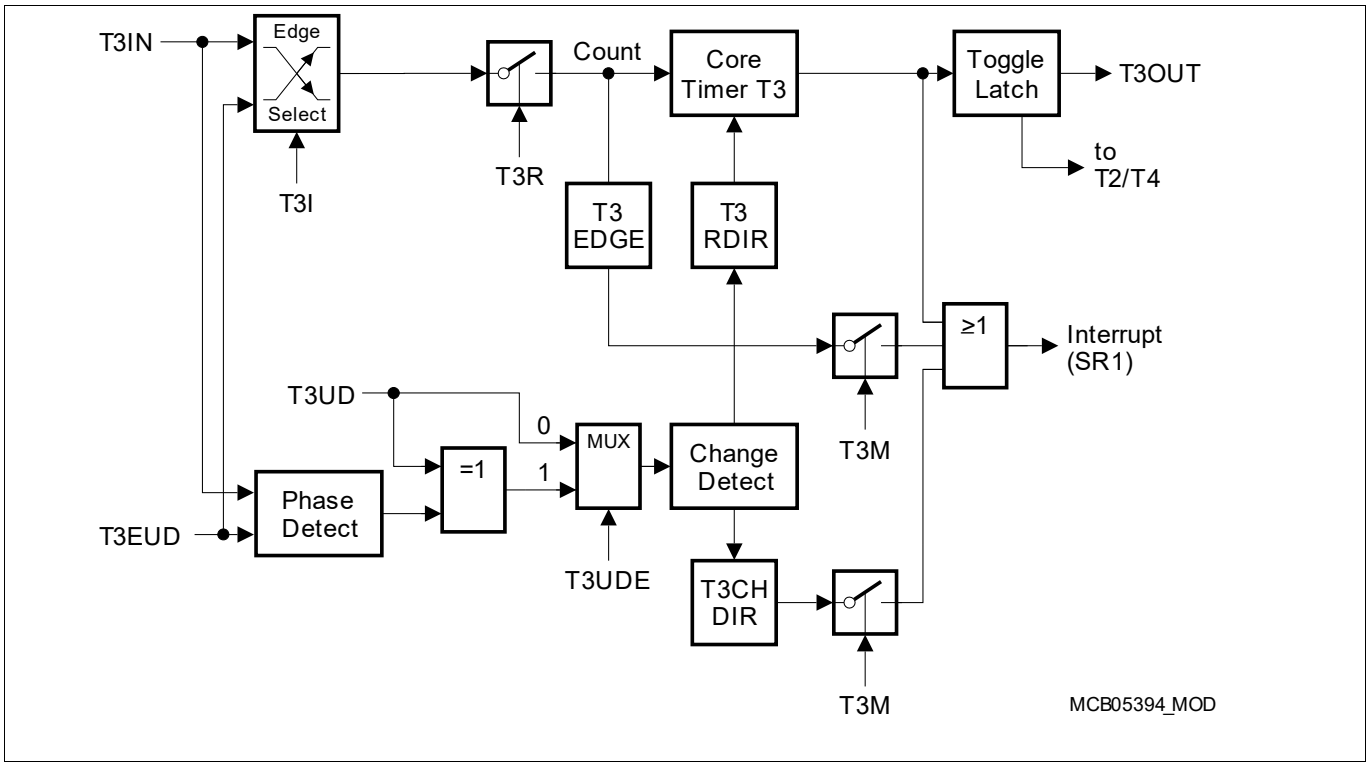

Figure 205 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see **Table 221**). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The service request generation can be selected: In Rotation Detection Mode (T3M = 110_B), a service request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), a service request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

The incremental encoder can be connected directly to the without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, $\overline{A}$) to digital signals (such as A). This greatly increases noise immunity.

Note: The third encoder output T0, that indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3.
*If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt (see bit CLRT3EN in register **T4CON**).*

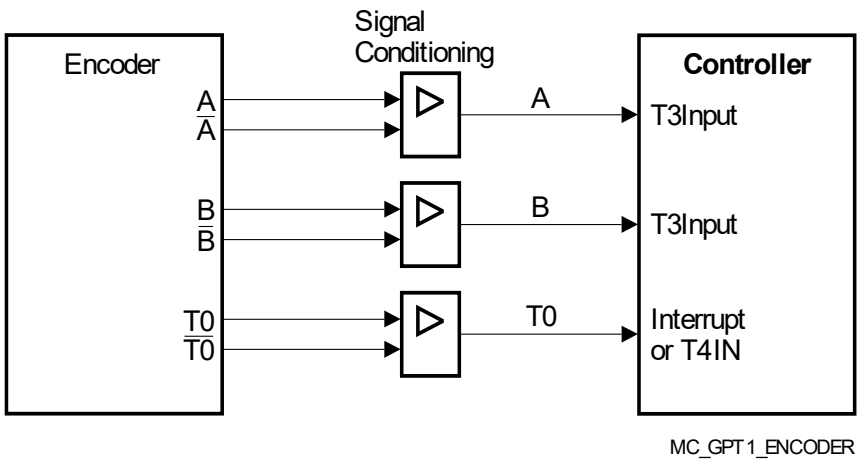

Figure 206 Connection of the Encoder to the AURIX™ TC3xx Platform

For Incremental Interface Mode operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B.
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.2.5**.

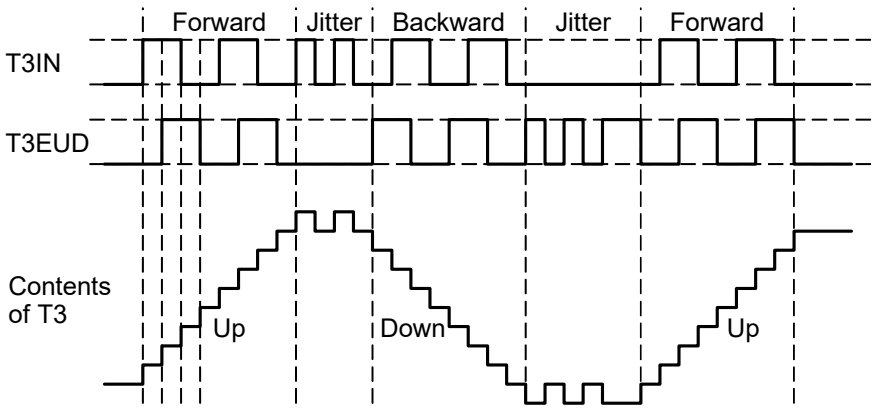
As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. **Table 212** summarizes the possible combinations.

Table 212 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising ↑	Falling ↓	Rising ↑	Falling ↓
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

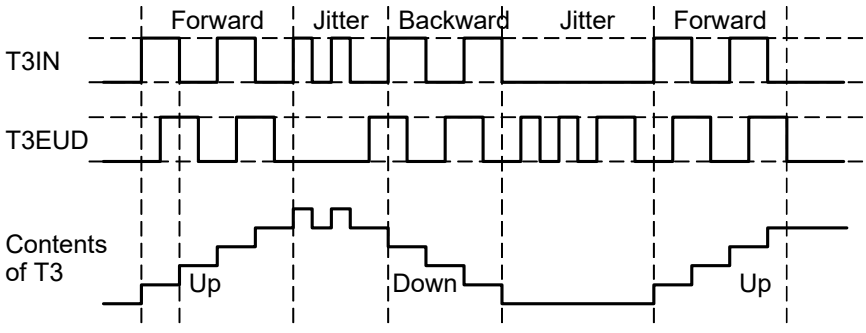
Figure 207 and **Figure 208** give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on any input (T3IN and T3EUD), i.e. T3I = 011_B.

MCT04373

Figure 207 Evaluation of Incremental Encoder Signals, 2 Count Inputs



Note: This example shows the timer behaviour assuming that T3 counts upon any transition on input T3IN, i.e. T3I = 001_B.

MCT04374

Figure 208 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed, acceleration, deceleration) may be obtained by measuring the incoming signal periods (see ***"Combined Capture Modes" on Page 43****).*

30.2.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, that are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in **Table 217**.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

30.2.4 GPT1 Auxiliary Timers T2/T4 Operating Modes

The operation of the auxiliary timers in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timers T2 and T4 in Timer Mode

Timer Mode for an auxiliary timer Tx is selected by setting its bitfield TxM in register TxCON to 000_B.

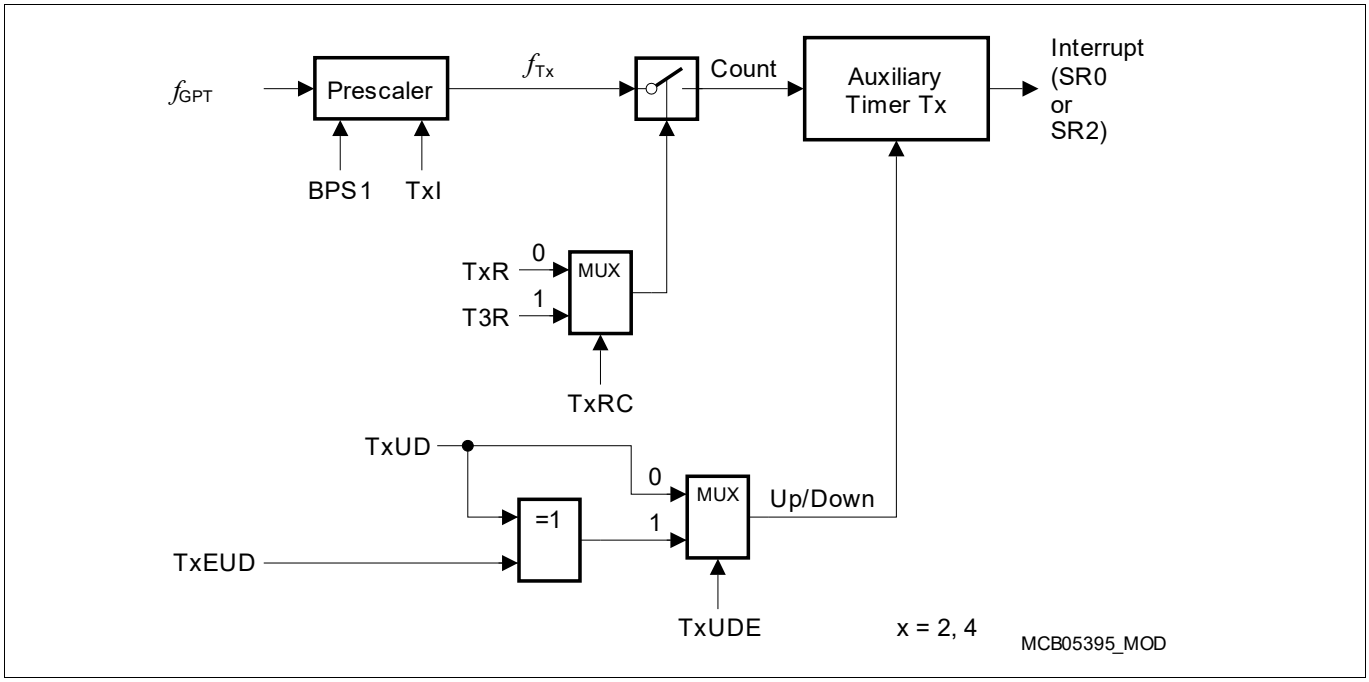


Figure 209 Block Diagram of an Auxiliary Timer in Timer Mode

Timers T2 and T4 in Gated Timer Mode

Gated Timer Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 010_B or 011_B. Bit TxM.0 (TxCON.3) selects the active level of the gate input.

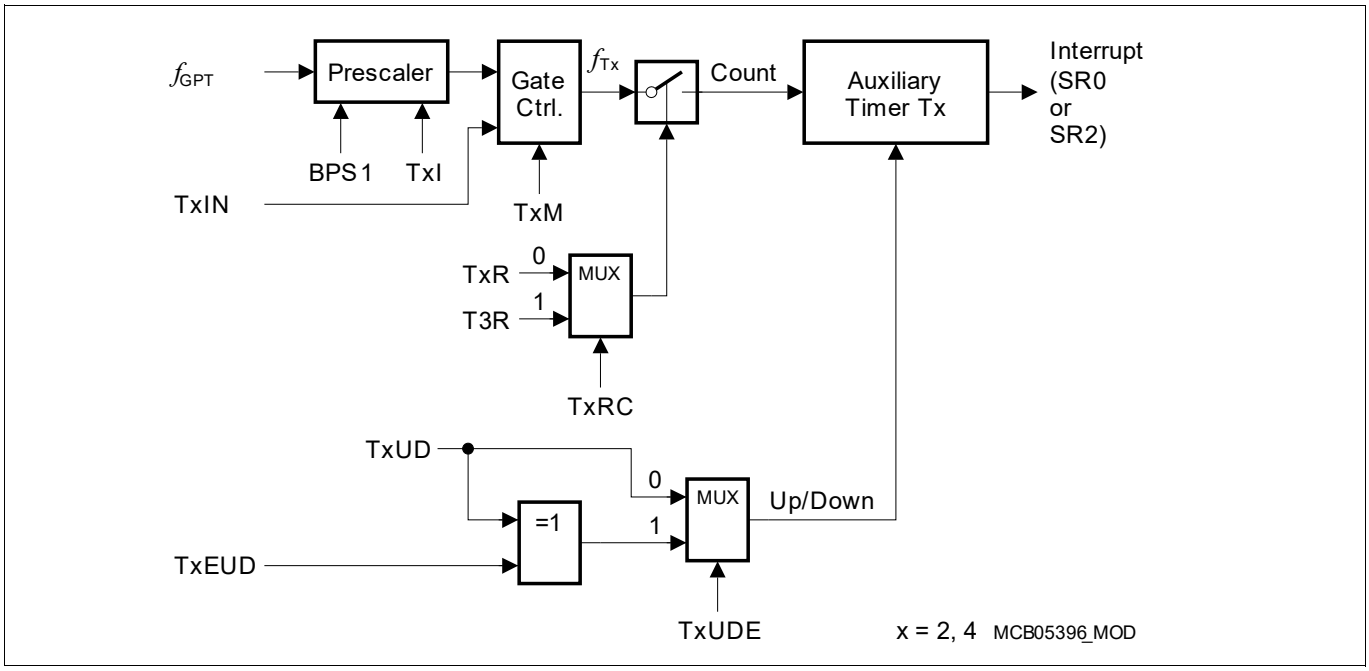

Figure 210 Block Diagram of an Auxiliary Timer in Gated Timer Mode

Note: A transition of the gate signal at TxIN does not cause a service request. Service requests of timer T2 are handled via SR0, and service requests of timer T4 are handled via SR2.
There is no output toggle latch for T2 and T4.
Start/stop of an auxiliary timer can be controlled locally or remotely.

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see **Table 220**).

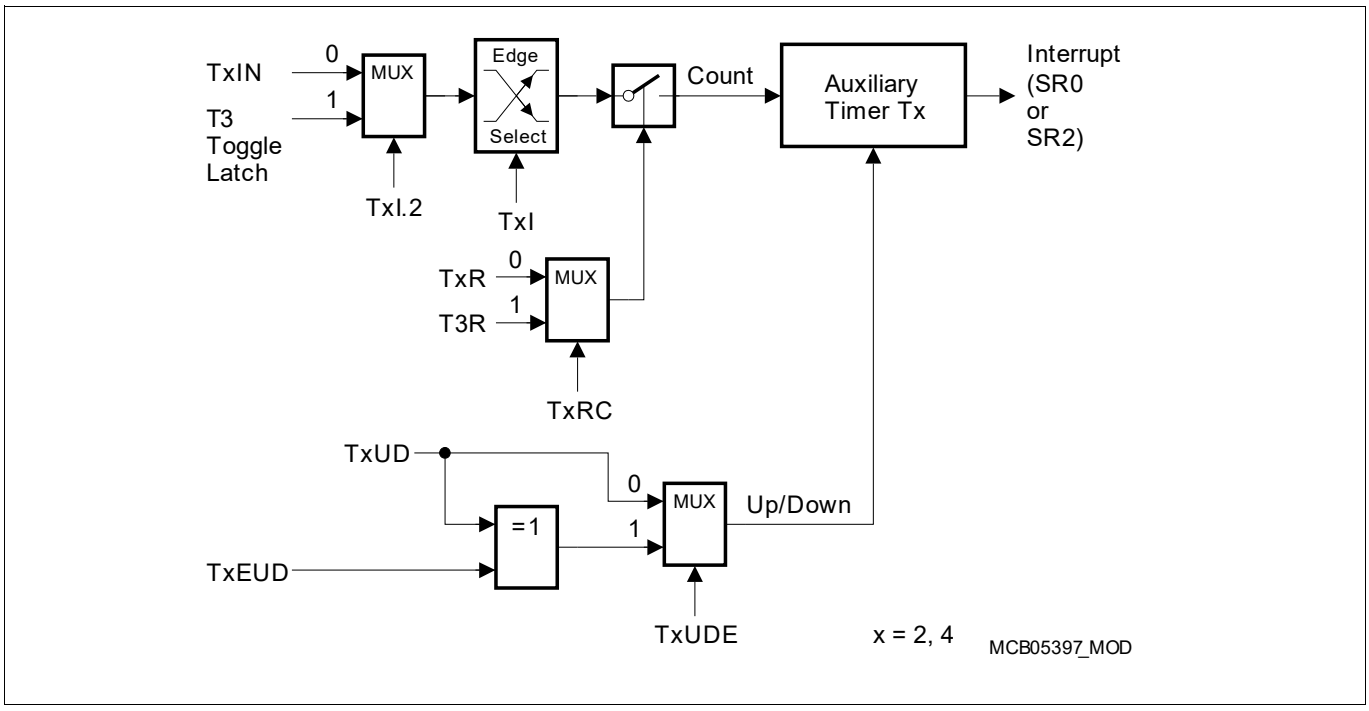

Figure 211 Block Diagram of an Auxiliary Timer in Counter Mode

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.2.5**.

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).
  As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

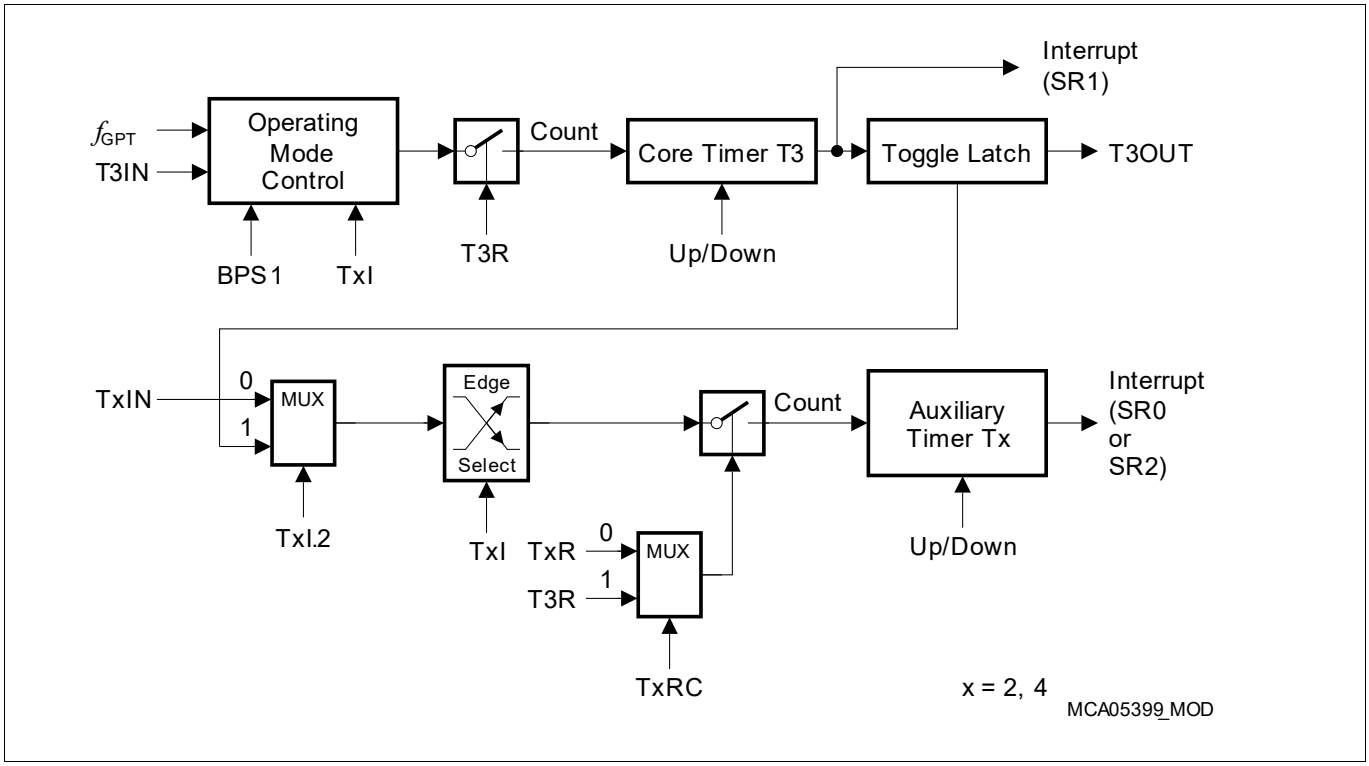

Figure 212 Concatenation of Core Timer T3 and an Auxiliary Timer

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T2) and TIMER_LOW (for core timer T3). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T2
- TIMER_LOW = T3
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 213**
- TIMER_HIGH = T2
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T3

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 213**.

Table 213 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles$_B$

Block Prescaler	BPS1 = 01_B	BPS1 = 00_B	BPS1 = 11_B	BPS1 = 10_B
Number of Module clocks	8	16	32	64

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS1 and the Individual Prescalers TxI (see **Table 218**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time.

Timers T2 and T4 in Incremental Interface Mode

Incremental Interface Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see ***"Combined Capture Modes" on Page 43****).*

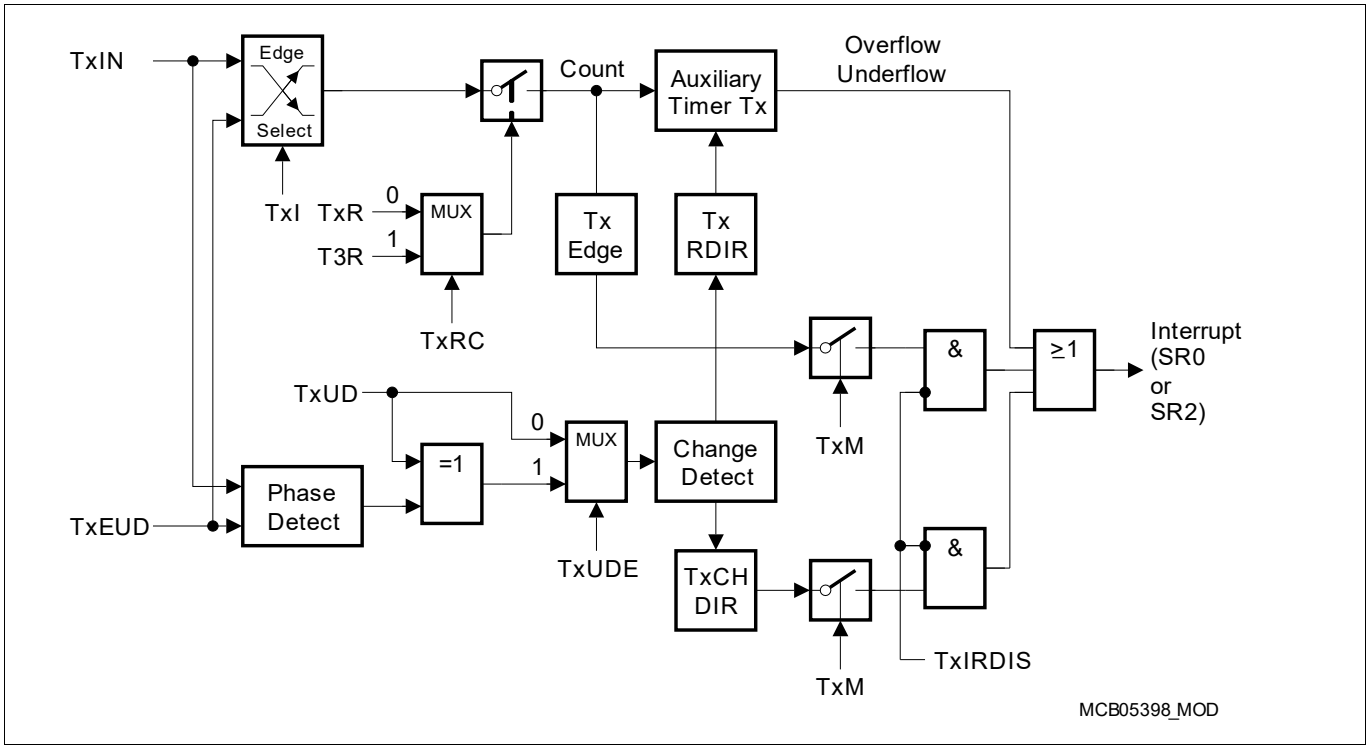

Figure 213 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

Timers T2 and T4 in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In Reload Mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see **Table 220**), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for Reload Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.
The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

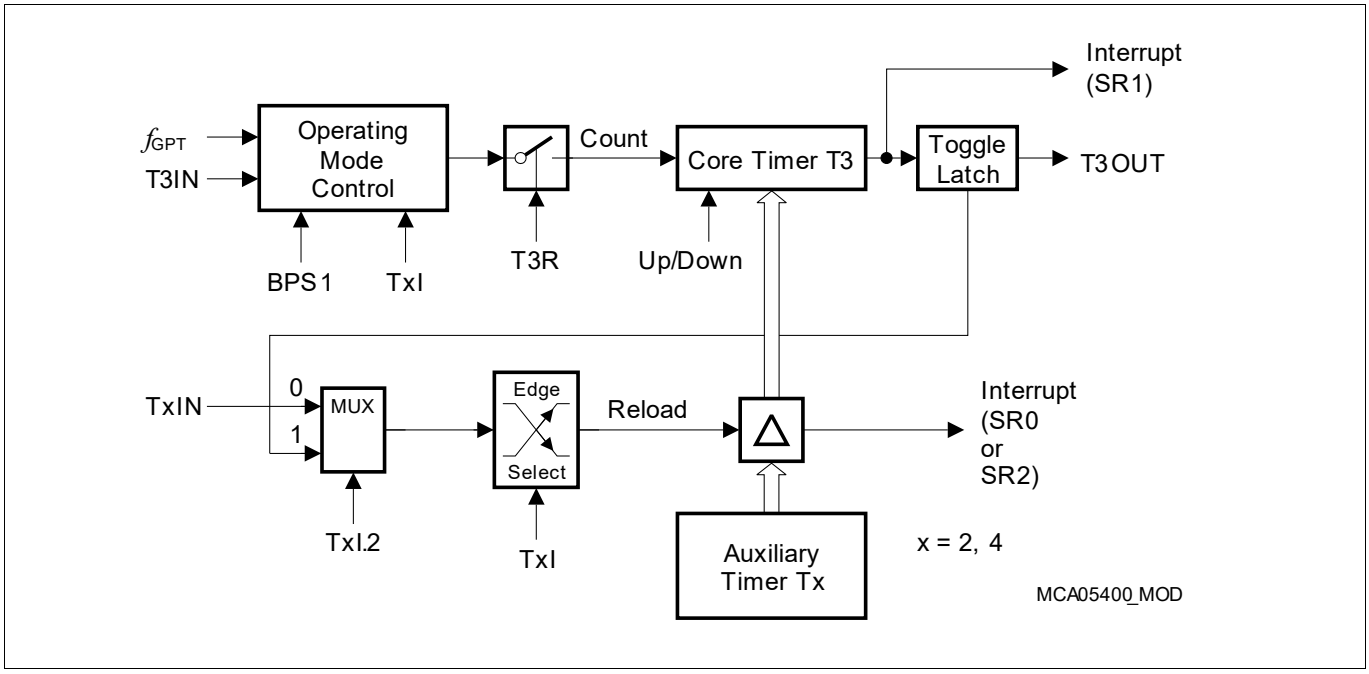

Figure 214 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective service request SR0 or SR2 is activated.

Note: When a T3OTL transition is selected for the trigger signal, service request SR1 will also become active, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.2.5**.

The Reload Mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard Reload Mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this "single-transition" mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition

of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

Figure 215 shows an example for the generation of a PWM signal using the “single-transition” reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

Note: The output toggle latch T3OTL is accessible via software and may be changed, if required, to modify the PWM signal.
However, this will NOT trigger the reloading of T3.

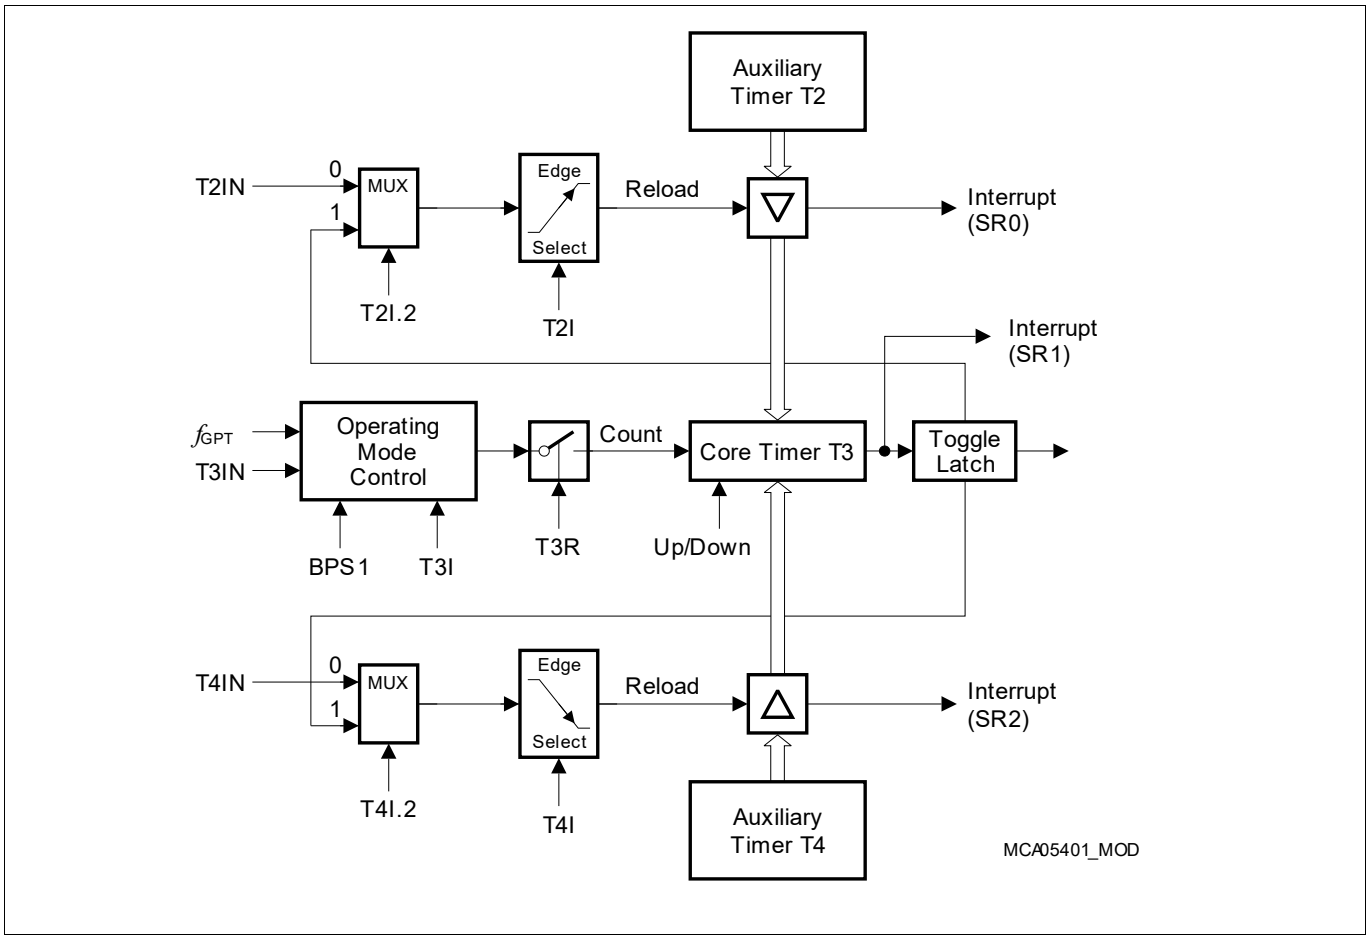

Figure 215 GPT1 Timer Reload Configuration for PWM Generation

Note: Although possible, selecting the same reload trigger event for both auxiliary timers should be avoided. In such a case, both reload registers would try to load the core timer at the same time. If this combination is selected, T2 is disregarded and the contents of T4 is reloaded.

The implementation of the GPT1 finite state machine may require special consideration in following cases.

In Case 1, when T2 or T4 are used to reload T3 on overflow/underflow, and T3 is read by software on the fly, the following unexpected values may be read from T3:

- When T3 is counting up, 0000_H or 0001_H may be read from T3 directly after an overflow, although the reload value in T2/T4 is higher (0001_H may be read in particular if BPS1 = 01_B and T3I = 000_B).
- When T3 is counting down, $FFFF_H$ or $FFFE_H$ may be read from T3 directly after an underflow, although the reload value in T2/T4 is lower ($FFFE_H$ may be read in particular if BPS1 = 01_B and T3I = 000_B).

Note: All timings derived from T3 in this configuration (e.g. distance between service requests, PWM waveform on T3OUT, etc.) are accurate except for the specific case described below.

Recommendation:

- When T3 counts up, and T3_value < reload value is read from T3, T3_value should be replaced with the reload value for further calculations.
- When T3 counts down, and T3_value > reload value is read from T3, T3_value should be replaced with the reload value for further calculations.

Alternatively, if the intention is to identify the overflow/underflow of T3, the T3 service request (SR1) may be used.

In Case 2, when T2 is used to reload T3 in the configuration with BPS1 = 01_B and T3I = 000_B (i.e. fastest configuration/highest resolution of T3), the reload of T3 is performed with a delay of one basic clock cycle.

Recommendation:

To compensate the delay and achieve correct timing,

- Increment the reload value in T2 by 1 when T3 is configured to count up,
- Decrement the reload value in T2 by 1 when T3 is configured to count down.

Alternatively, use T4 instead of T2 as reload register for T3. In this configuration the reload of T3 is not delayed, i.e. the effect described above does not occur with T4.

Timers T2 and T4 in Capture Mode

Capture Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In Capture Mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see **Table 220**). Bit 2 of TxI is irrelevant for Capture Mode and must be cleared (TxI.2 = 0).

Note: When programmed for Capture Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

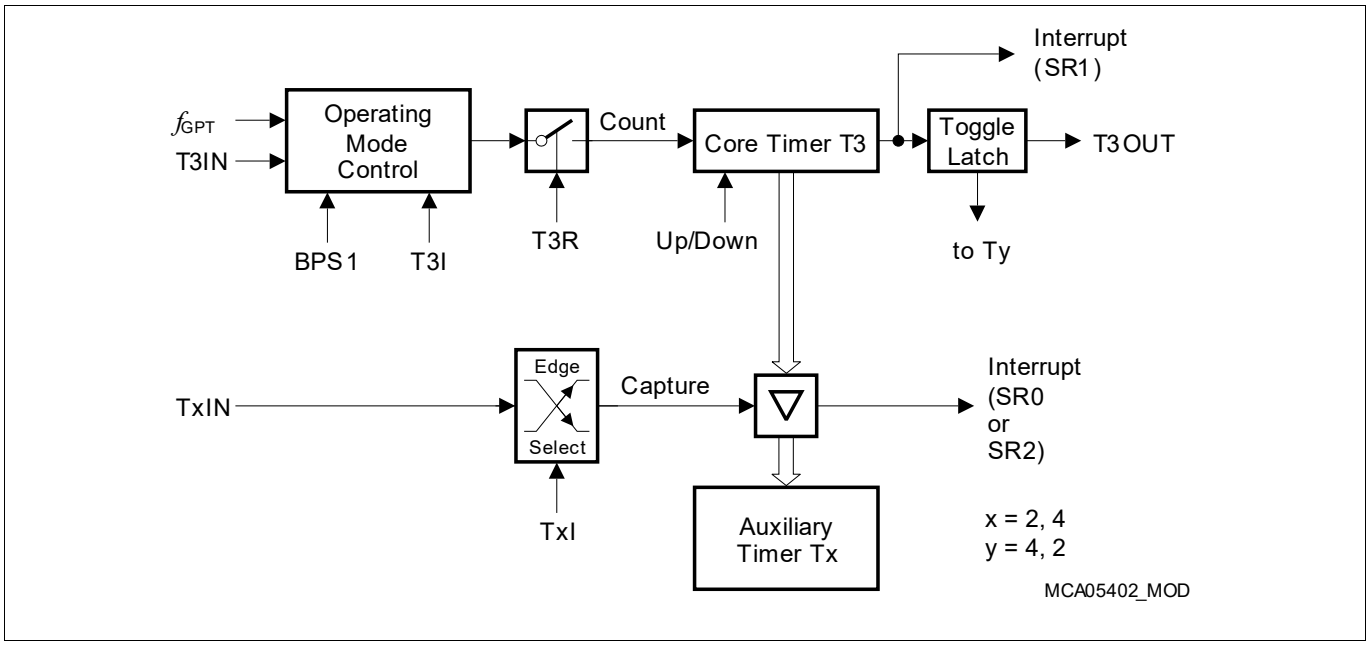

Figure 216 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer T3 are loaded into the auxiliary timer register Tx and the associated service request (SR0 or SR2) will be activated.

For Capture Mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.2.5**.

30.2.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see **Figure 200**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode or Incremental Interface Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 214 Basic Clock Selection for Block GPT1

Block Prescaler[1]	BPS1 = 01_B	BPS1 = 00_B[2]	BPS1 = 11_B	BPS1 = 10_B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$	$f_{GPT}/64$
Input Signal Stable Time	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}	32 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS1.
2) Default after reset.

Notes

1. *The GPT1 block uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T2, T3, T4), these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT1 state machine has 8 states (4 states when BPS1 = 01_B) and processes the timers in the order T3 - T2 (all actions except capture) - T4 - T2 (capture).*
2. *When initializing the GPT1 block after reset, and the block prescaler BPS1 in register T3CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, incremental interface, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.*
   In this case, or when changing BPS1 during operation of the GPT1 block, disable related interrupts before modification of BPS1, and afterwards clear the corresponding service request flags and re-initialize those registers (T2, T3, T4) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS1) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS1) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{30.1}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 218** summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

Table 215 lists GPT1 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor F(BPS1) x $2^{<TxI>}$ and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 215 GPT1 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock f_{GPT} = 100 MHz			Example 2: Module Clock f_{GPT} = 66.5 MHz		
	Frequency	Resolution	Period	Frequency	Resolution	Period
4	25 MHz	40 ns	2.621 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.243 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 µs	83.89 ms	519.53 kHz	1.924 µs	126.14 ms
256	390.6 kHz	2.56 µs	167.8 ms	259.77 kHz	3.850 µs	252.29 ms
512	195.3 kHz	5.12 µs	335.5 ms	129.88 kHz	7.699 µs	504.58 ms
1024	97.7 kHz	10.24 µs	671.1 ms	64.94 kHz	15.398 µs	1.009 s
2048	48.8 kHz	20.48 µs	1.342 s	32.47 kHz	30.797 µs	2.018 s
4096	24.4 kHz	40.96 µs	2.684 s	16.24 kHz	61.594 µs	4.037 s

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see **Figure 200**). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods is required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 216 summarizes the resulting requirements for external GPT1 input signals.

Table 216 GPT1 External Input Signal Limits

GPT1 Divider BPS1	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock f_{GPT} = 100 MHz		Example 2: Module Clock f_{GPT} = 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01_B	$f_{GPT}/8$	4 x t_{GPT}	12.5 MHz	40 ns	8.313 MHz	60.2 ns
00_B	$f_{GPT}/16$	8 x t_{GPT}	6.25 MHz	80 ns	4.156 MHz	120.3 ns
11_B	$f_{GPT}/32$	16 x t_{GPT}	3.125 MHz	160 ns	2.078 MHz	240.6 ns
10_B	$f_{GPT}/64$	32 x t_{GPT}	1.563 MHz	320 ns	1.039 MHz	481.2 ns

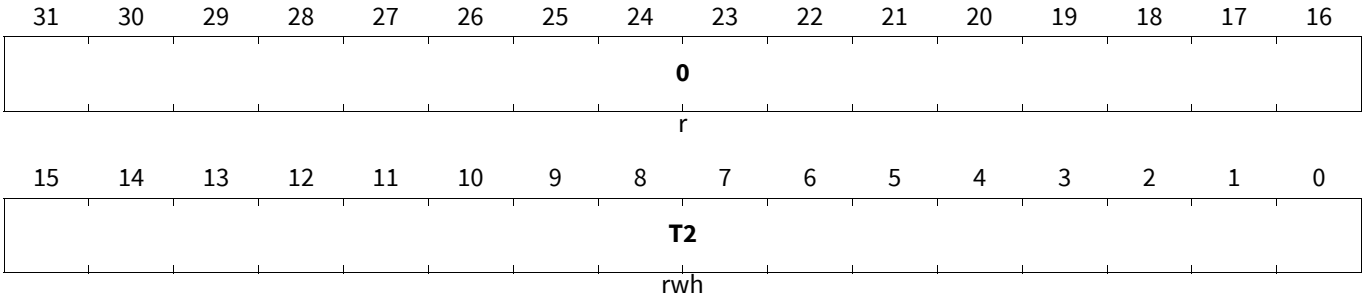
These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

30.2.6 GPT1 Registers

Block GPT1 includes timer registers T2, T3, T4, and control registers T2CON, T3CON, T4CON.

Timer T2 Register

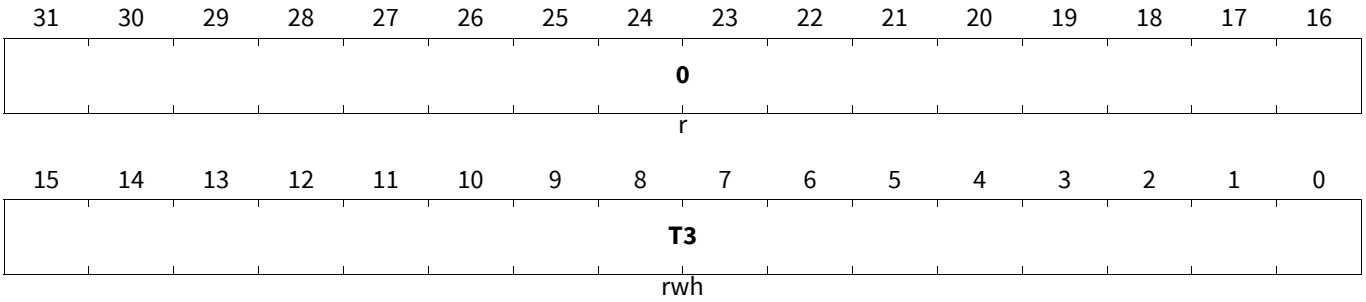
T2
Timer T2 Register **(0034_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T2	15:0	rwh	**Timer T2** Contains the current value of Timer T2.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T3 Register

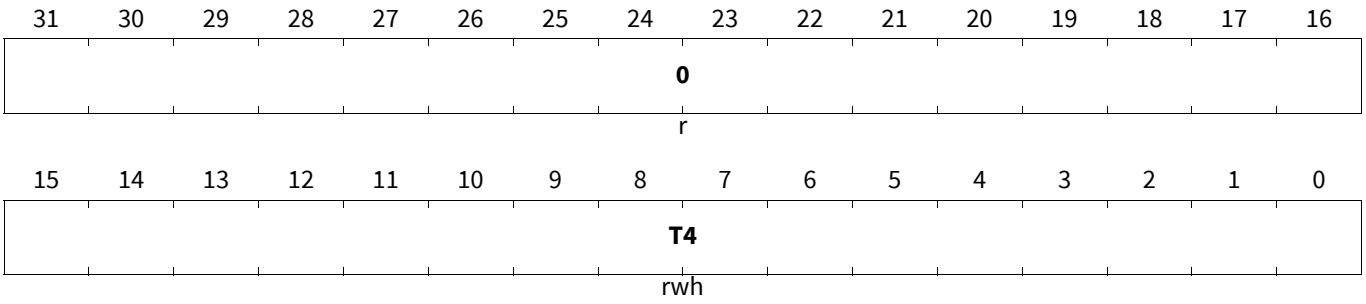
T3
Timer T3 Register **(0038_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T3	15:0	rwh	**Timer T3** Contains the current value of Timer T3.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T4 Register

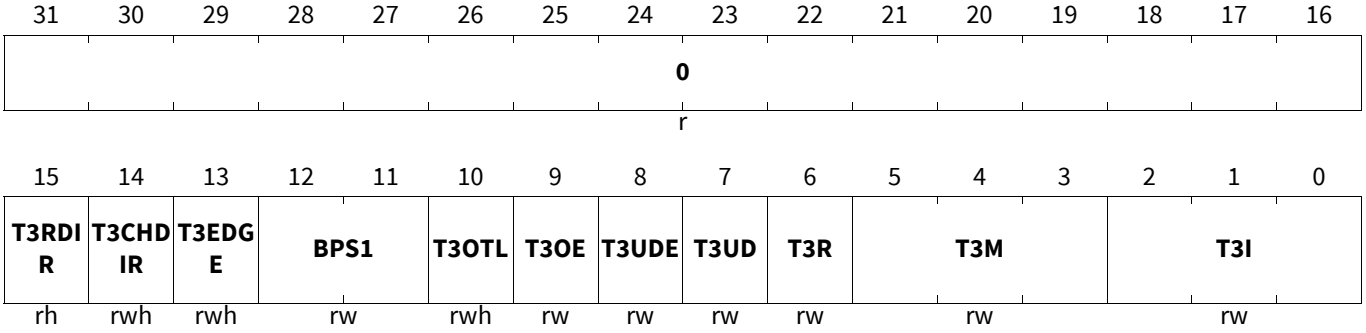
T4
Timer T4 Register **($003C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T4	15:0	rwh	**Timer T4** Contains the current value of Timer T4.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T3 Control Register

T3CON
Timer T3 Control Register **(0014_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T3I	2:0	rw	**Timer T3 Input Parameter Selection** Depends on the operating mode, see respective sections for encoding: **Table 218** for Timer Mode and Gated Timer Mode **Table 219** for Counter Mode **Table 221** for Incremental Interface Mode

Field	Bits	Type	Description
T3M	5:3	rw	**Timer T3 Mode Control** 000_B Timer Mode 001_B Counter Mode 010_B Gated Timer Mode with gate active low 011_B Gated Timer Mode with gate active high 100_B Reserved. Do not use this combination 101_B Reserved. Do not use this combination 110_B Incremental Interface Mode (Rotation Detection Mode) 111_B Incremental Interface Mode (Edge Detection Mode)
T3R	6	rw	**Timer T3 Run Bit** 0_B Timer T3 stops 1_B Timer T3 runs
T3UD	7	rw	**Timer T3 Up/Down Control** *Note: This bit only directly controls count direction of T3 if bit T3UDE = 0.* 0_B Timer T3 counts up 1_B Timer T3 counts down
T3UDE	8	rw	**Timer T3 External Up/Down Enable** 0_B Count direction is controlled by bit T3UD; input T3EUD is disconnected 1_B Count direction is controlled by input T3EUD (see also **Table 217**)
T3OE	9	rw	**Overflow/Underflow Output Enable** 0_B Alternate Output Function Disabled 1_B State of T3 toggle latch is output on pin T3OUT
T3OTL	10	rwh	**Timer T3 Overflow Toggle Latch** Toggles on each overflow/underflow of T3. Can be set or cleared by software (see separate description)
BPS1	12:11	rw	**GPT1 Block Prescaler Control** Selects the basic clock for block GPT1 (see also **Section 30.2.5**) 00_B $f_{GPT}/8$ 01_B $f_{GPT}/4$ 10_B $f_{GPT}/32$ 11_B $f_{GPT}/16$
T3EDGE	13	rwh	**Timer T3 Edge Detection Flag** The bit is set each time a count edge is detected. T3EDGE must be cleared by software. 0_B No count edge was detected 1_B A count edge was detected
T3CHDIR	14	rwh	**Timer T3 Count Direction Change Flag** This bit is set each time the count direction of timer T3 changes. T3CHDIR must be cleared by software. 0_B No change of count direction was detected 1_B A change of count direction was detected

Field	Bits	Type	Description
T3RDIR	15	rh	**Timer T3 Rotation Direction Flag** 0_B Timer T3 counts up 1_B Timer T3 counts down
0	31:16	r	**Reserved** Read as 0; should be written with 0.

$1XX_B$	Reserved. Do not use this combination.

30.3 Timer Block GPT2

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6.

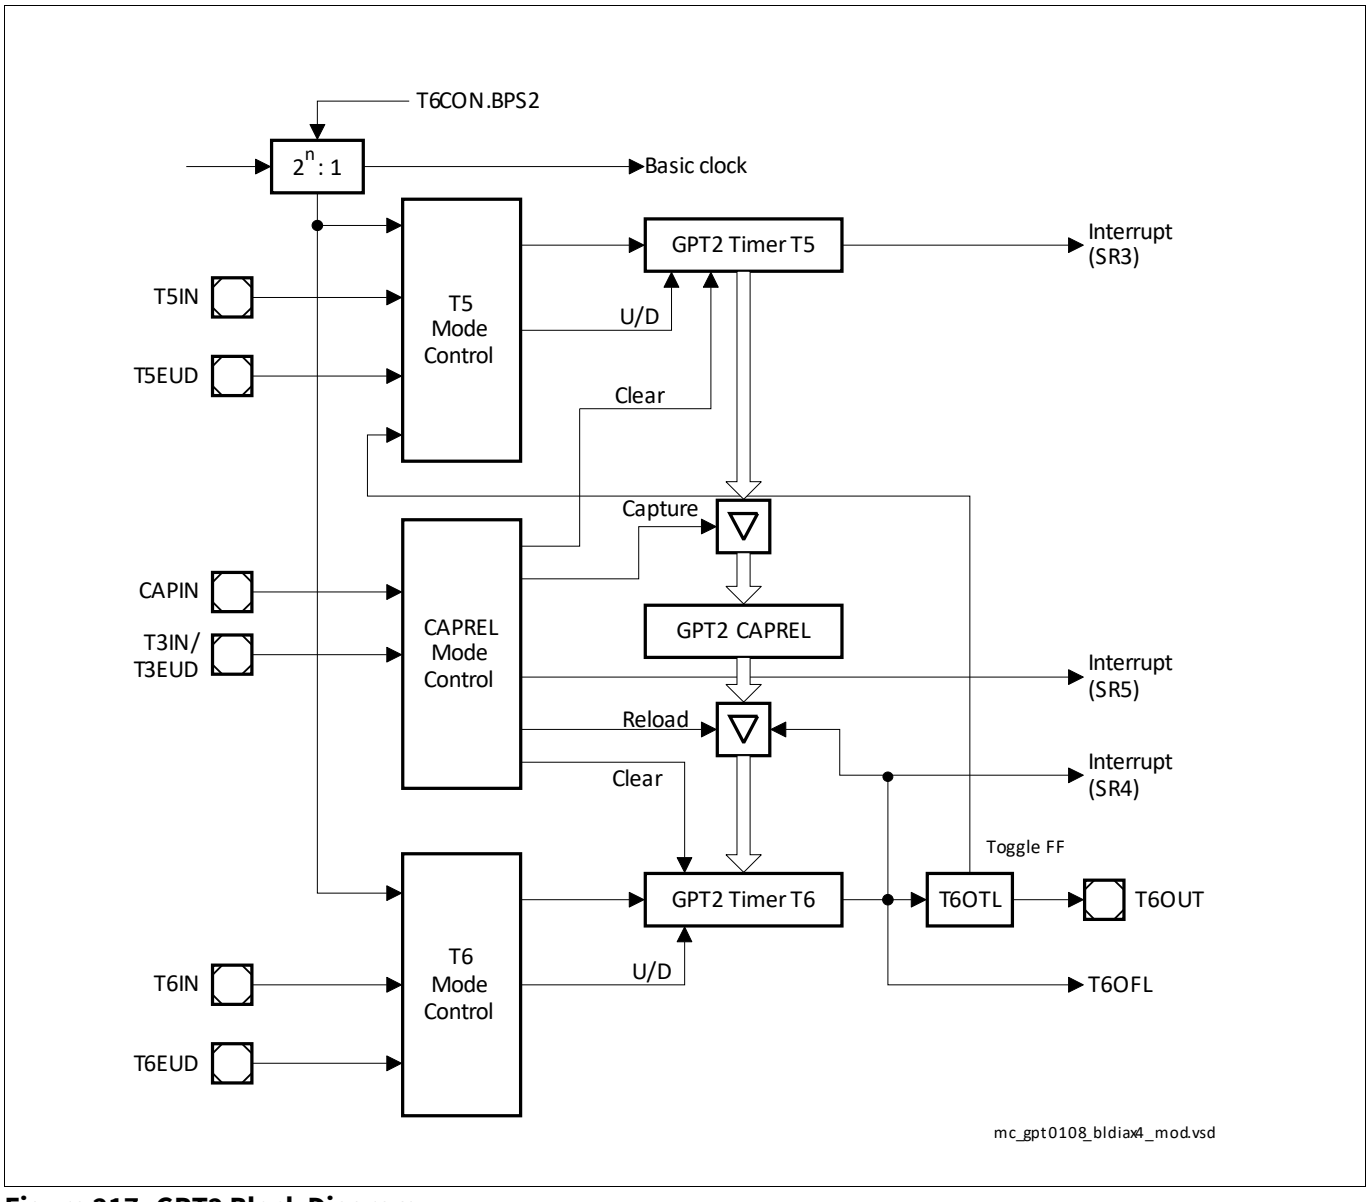

Figure 217 GPT2 Block Diagram

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6. When any of the timer registers is written by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT2 are signalled on service request lines SR3, SR4, and SR5.

The input and output lines of GPT2 are connected to pins. The control registers for the port functions are located in the respective port modules.

*Note: The timing requirements for external input signals can be found in **Section 30.3.6**, **Section 30.6** summarizes the module interface signals, including pins and interrupt request signals.*

30.3.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in **Table 226**. The count direction can be changed regardless of whether or not the timer is running.

Timer T6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 218** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL’s output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timer carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 218**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

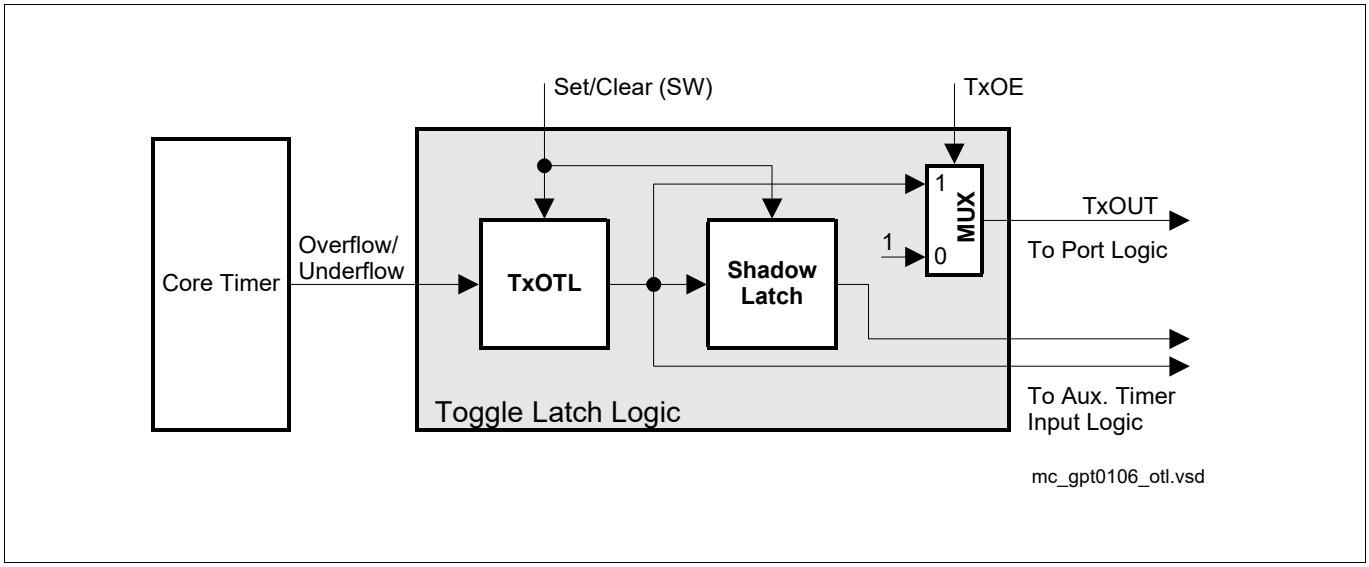

Figure 218 Block Diagram of the Toggle Latch Logic of Core Timer T6 (x = 6)

30.3.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer T6 in Timer Mode

Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see **Section 30.3.6** for details on the input clock options.

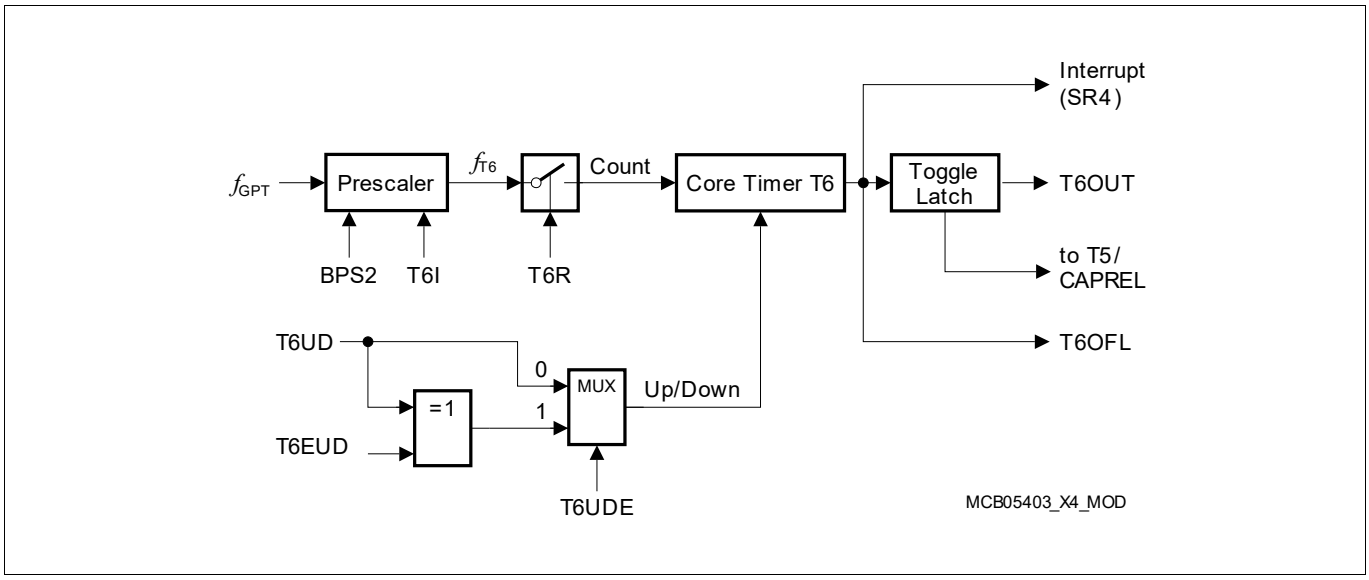

Figure 219 Block Diagram of Core Timer T6 in Timer Mode

Timer 6 in Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see **Section 30.3.6**). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).
To enable this operation, the associated pin T6IN must be configured as input.

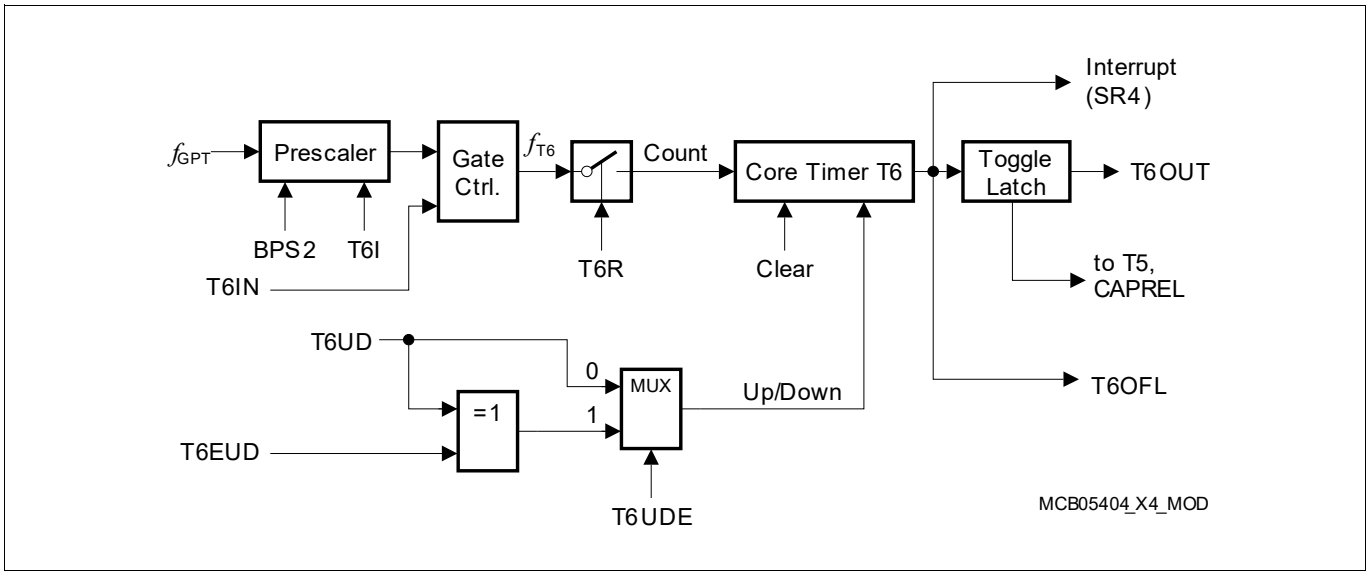

Figure 220 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause a service request.

Timer 6 in Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see **Table 228**).

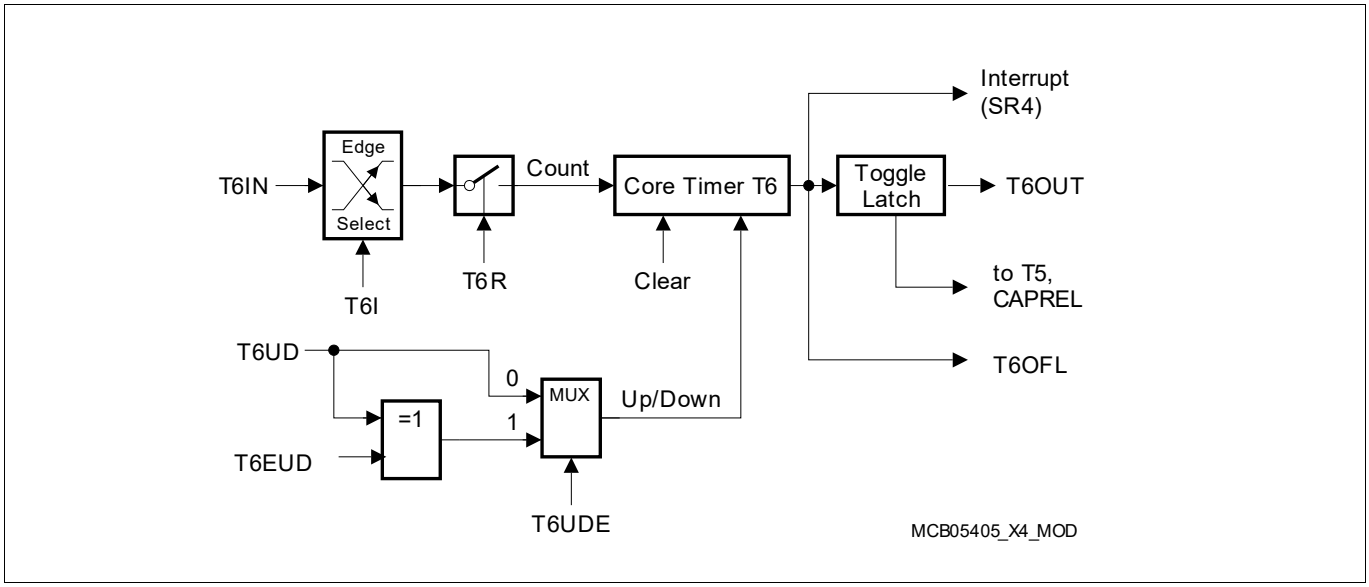

Figure 221 Block Diagram of Core Timer T6 in Counter Mode

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.3.6**.

30.3.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timer can be remotely controlled by the T6 run control bit. Both timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

30.3.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B.

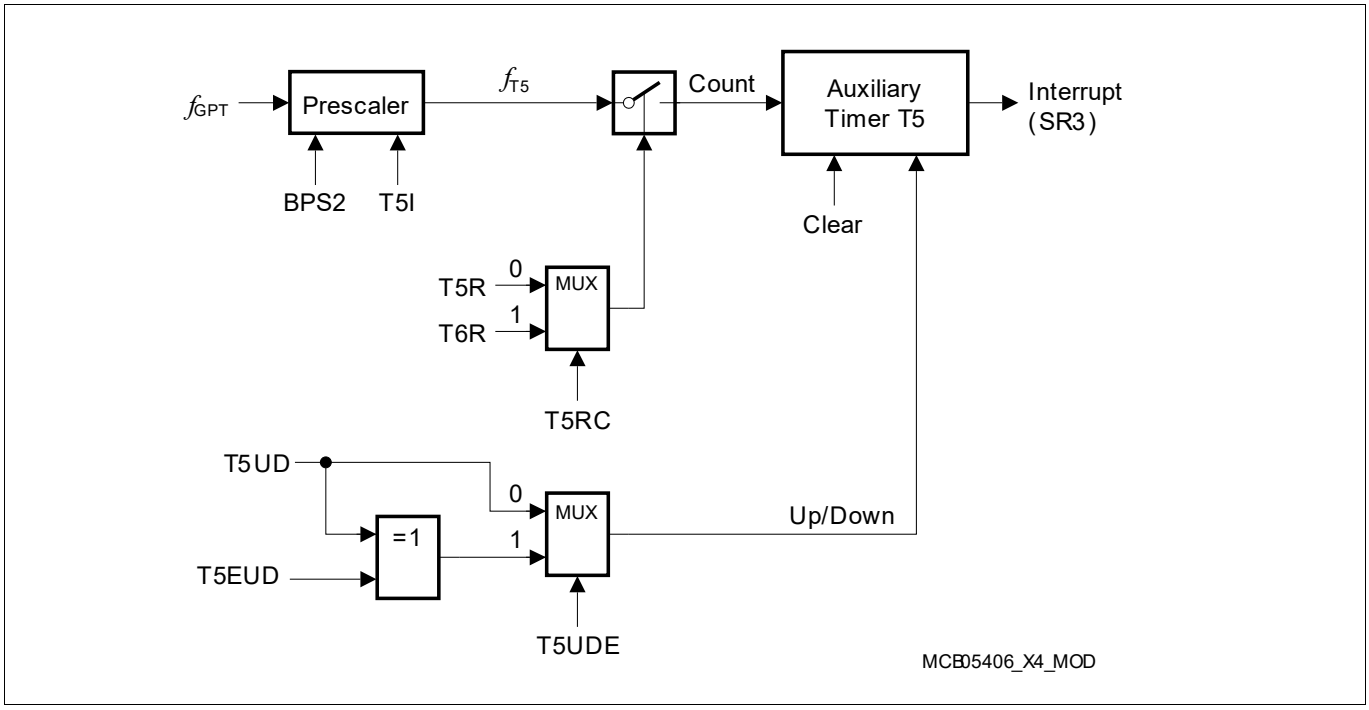

Figure 222 Block Diagram of Auxiliary Timer T5 in Timer Mode

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

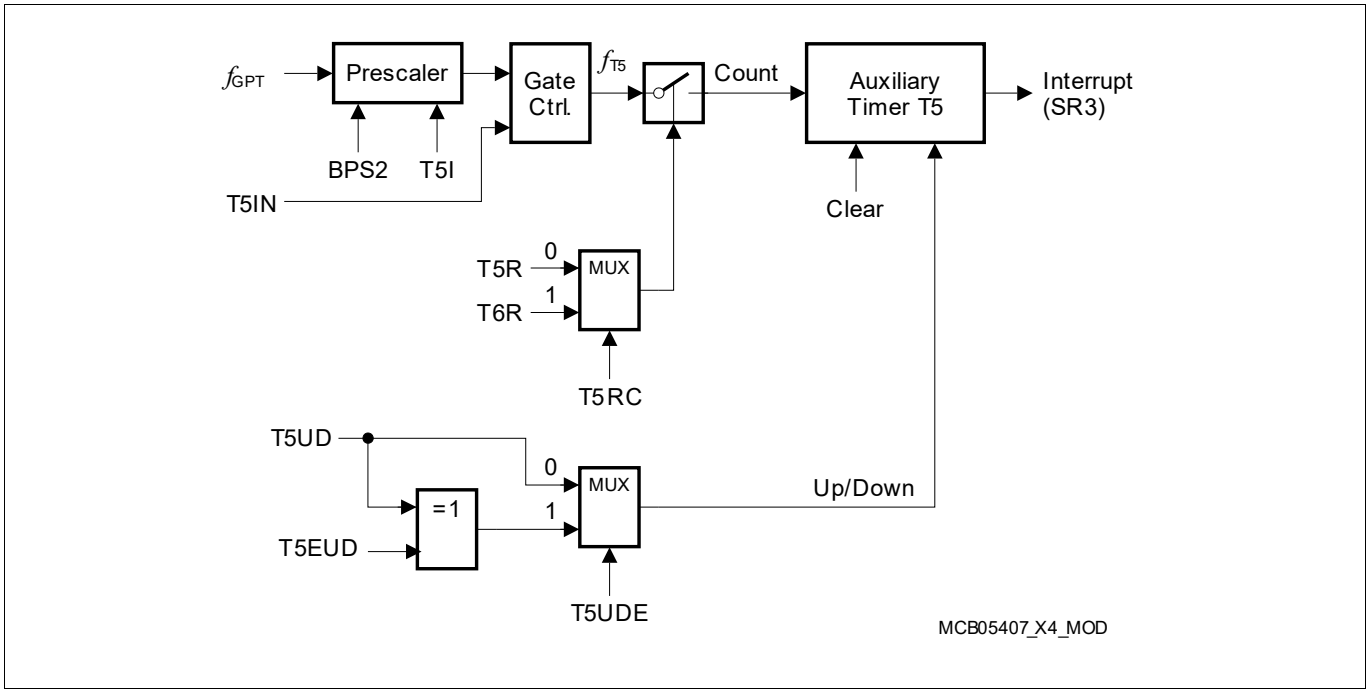

Figure 223 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: A transition of the gate signal at line T5IN does not cause a service request.
There is no output toggle latch for T5.
Start/stop of the auxiliary timer can be controlled locally or remotely.

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see **Table 229**).

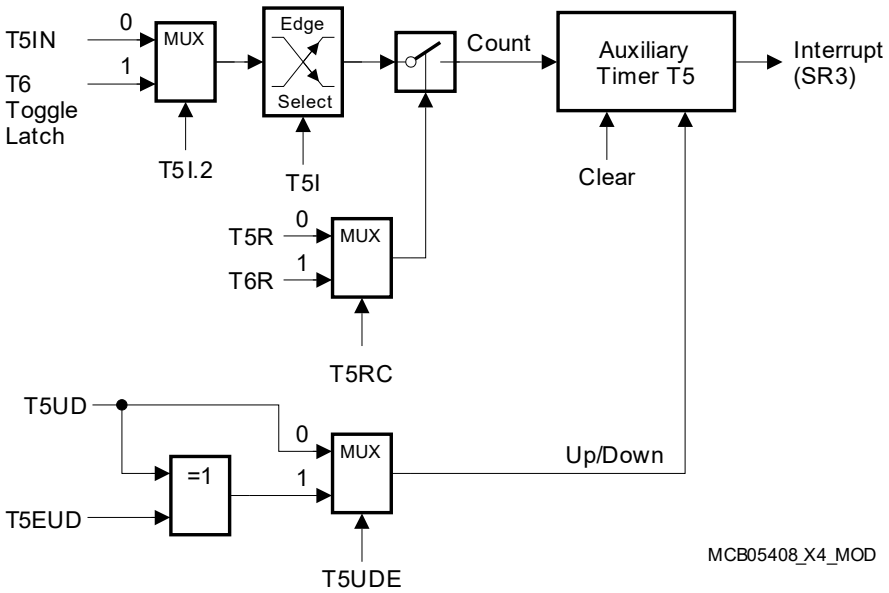

Figure 224 Block Diagram of Auxiliary Timer T5 in Counter Mode

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in **Section 30.3.6**.

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).
  As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

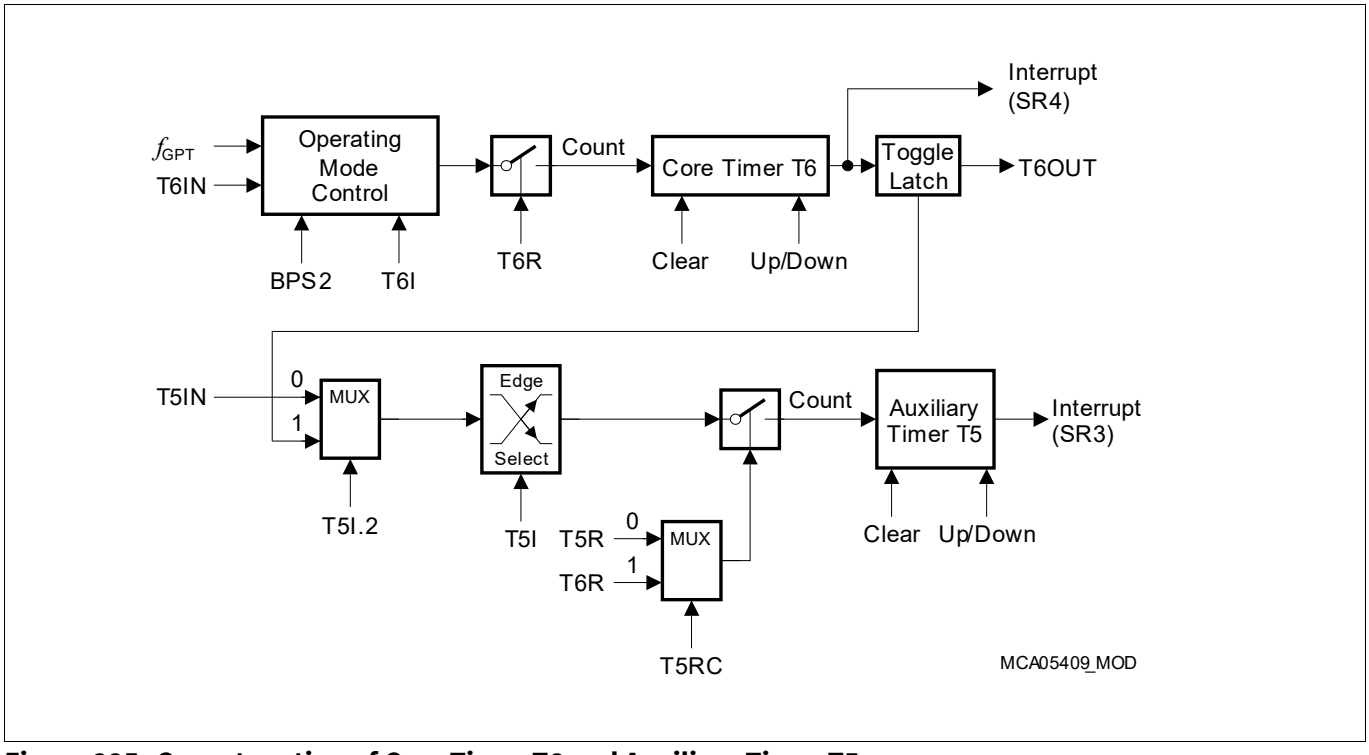

Figure 225 Concatenation of Core Timer T6 and Auxiliary Timer T5

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT2 timers, represented by TIMER_HIGH (for auxiliary timer T5) and TIMER_LOW (for core timer T6). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T5
- TIMER_LOW = T6
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see **Table 222**
- TIMER_HIGH = T5
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T6

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in **Table 222**.

Table 222 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS2 = 01_B	BPS2 = 00_B	BPS2 = 11_B	BPS2 = 10_B
Number of module clocks	4	8	16	32

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS2 and the Individual Prescalers TxI (see **Table 227**), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time. E.g. in order to run T6 at $f_{SYS}/512$, select BPS2 = 00_B, T6I = 111_B, and insert 8 NOPs (or other instructions) to ensure the required waiting time before reading TIMER_HIGH the second time.

30.3.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, by GPT1 timer's T3 input lines T3IN and T3EUD, or by read accesses to GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

The capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

Capture/Reload Register CAPREL in Capture Mode

Capture Mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In Capture Mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. **Table 230** summarizes these options.

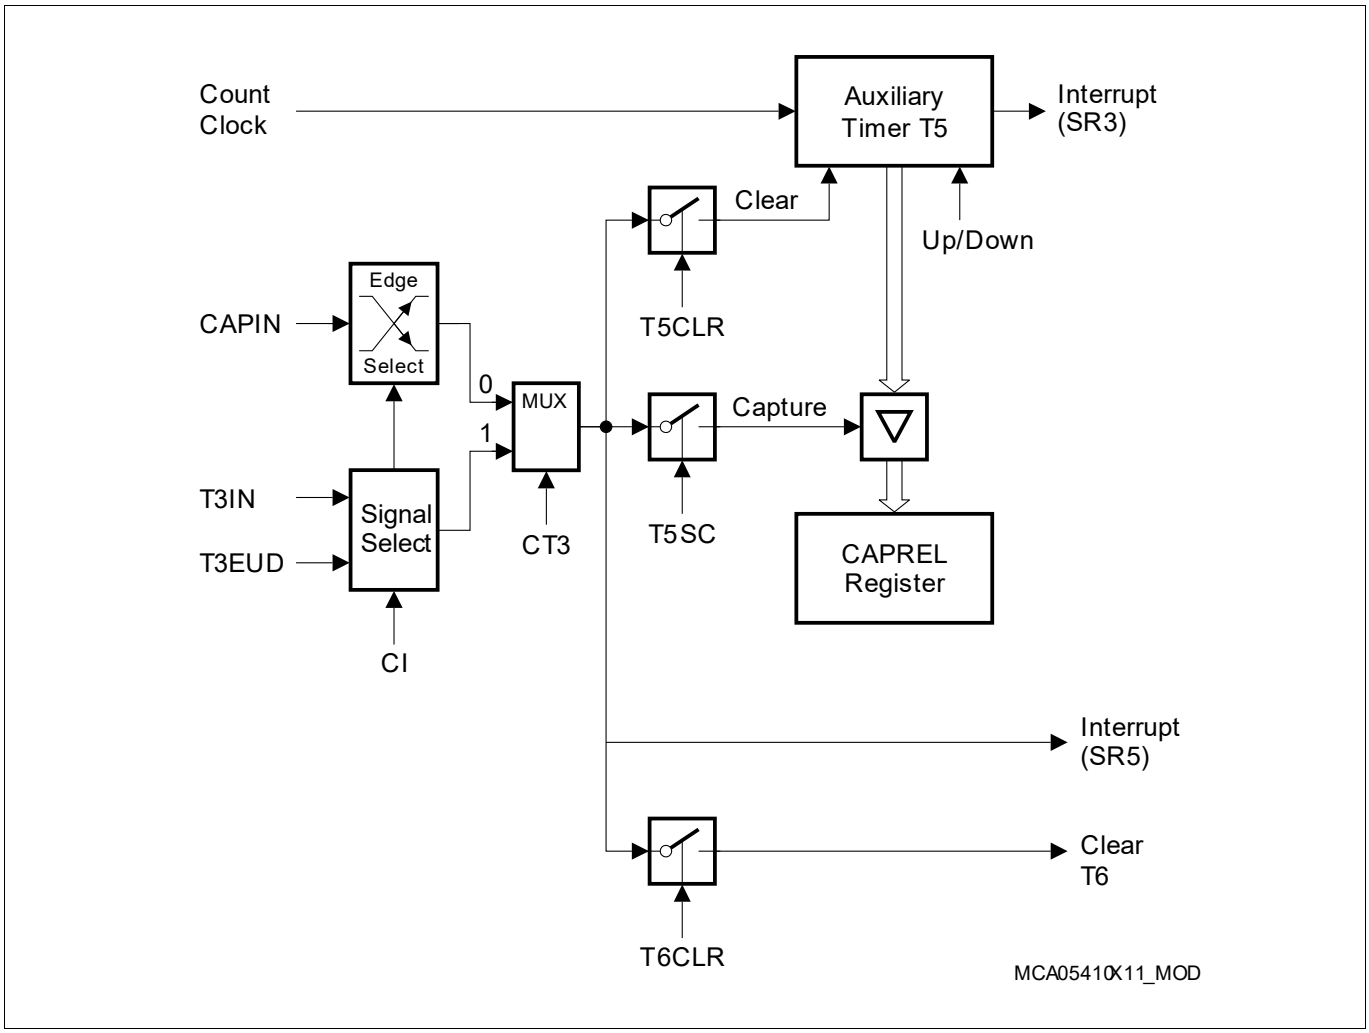

Figure 226 Capture/Reload Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the service request is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is signalled by the CAPREL interrupt request SR5.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For Capture Mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in **Section 30.3.6**.

Capture/Reload Register CAPREL in Reload Mode

Reload Mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In Reload Mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the service request SR5 associated with the CAPREL register. However, service request SR4 will be activated, indicating the overflow/underflow of T6.

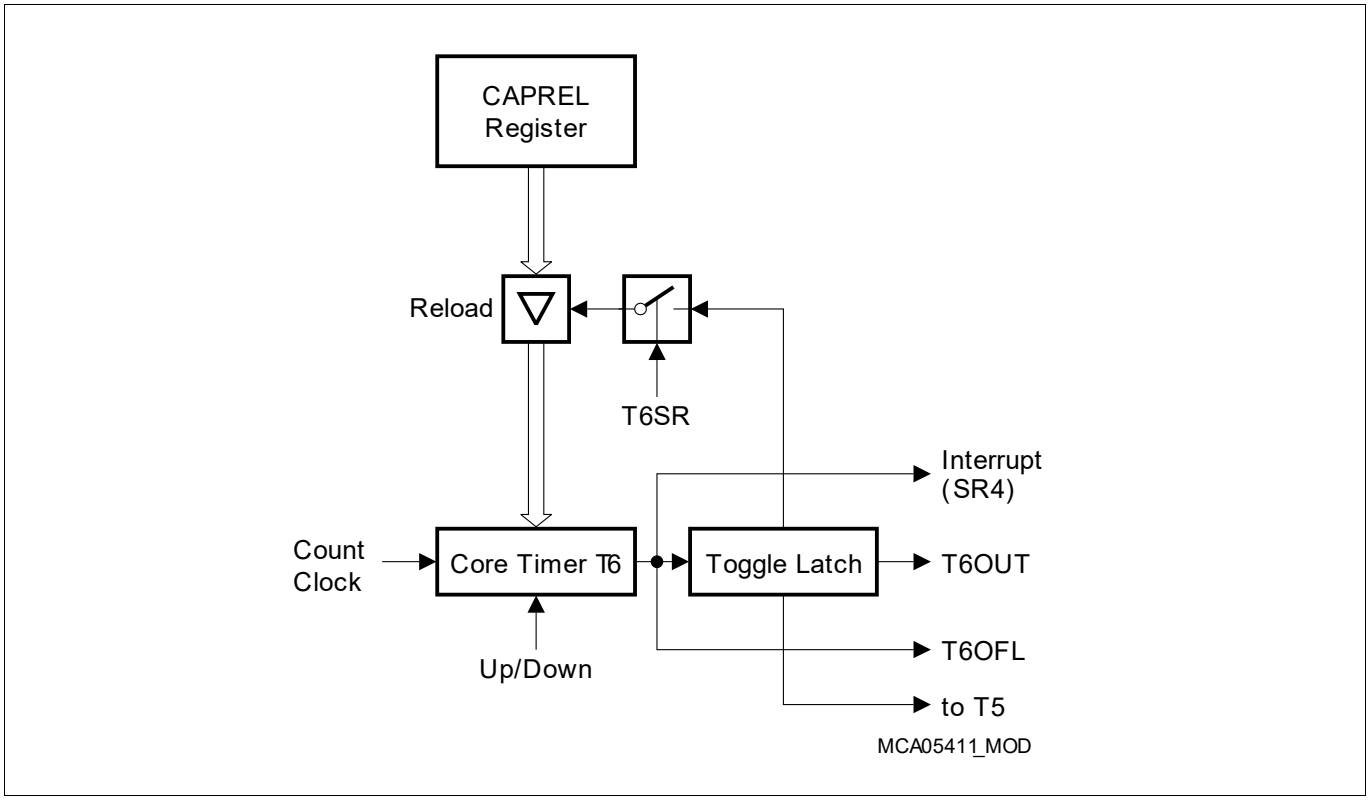

Figure 227 Capture/Reload Register CAPREL in Reload Mode

Capture/Reload Register CAPREL in Capture-And-Reload Mode

Since the reload function and the capture function of register CAPREL can be enabled individually by bits T5SC and T6SR, the two functions can be enabled simultaneously by setting both bits. This feature can be used to generate an output frequency that is a multiple of the input frequency.

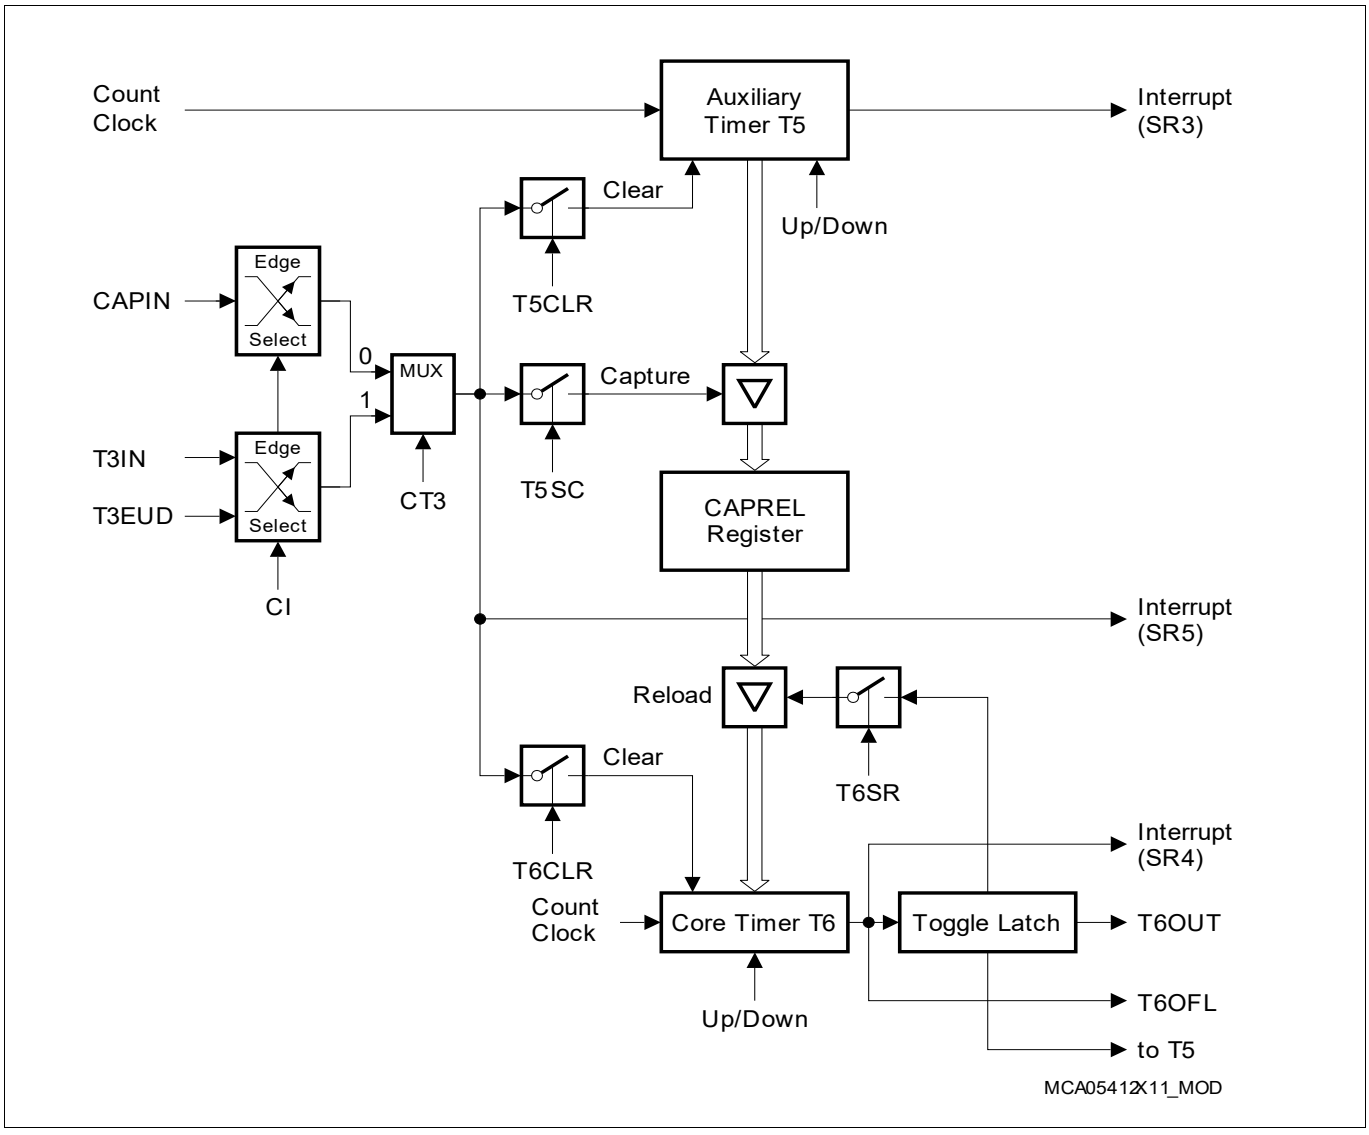

Figure 228 Capture/Reload Register CAPREL in Capture-And-Reload Mode

This combined mode can be used to detect consecutive external events which may occur aperiodically, but where a finer resolution, that means, more ‘ticks’ within the time between two external events is required.

For this purpose, the time between the external events is measured using timer T5 and the CAPREL register. Timer T5 runs in Timer Mode counting up with a frequency of e.g. $f_{GPT}/32$. The external events are applied e.g. to pin CAPIN (or other pins supporting capture mode, see **Table 230**). When an external event occurs, the contents of timer T5 are latched into register CAPREL and timer T5 is cleared (T5CLR = 1). Thus, register CAPREL always contains the correct time between two events, measured in timer T5 increments. Timer T6, which runs in Timer Mode counting down with a frequency of e.g. $f_{GPT}/4$, uses the value in register CAPREL to perform a reload on underflow. This means, the value in register CAPREL represents the time between two underflows of timer T6, now measured in timer T6 increments. Since (in this example) timer T6 runs 8 times faster than timer T5, it will underflow 8 times within the time between two external events. Thus, the underflow signal of timer T6 generates 8 ‘ticks’. Upon each underflow, the interrupt request SR4 will be activated and bit T6OTL will be toggled. The state

of T6OTL may be output on pin T6OUT. This signal on T6OUT has 8 times more transitions than the signal which is applied to the selected input (CAPIN in this example).

*Note: The underflow signal of Timer T6 can furthermore be used to clock functional units in other modules, e.g. one or more of the timers of the capture/compare units CCU6 (connections see **Section 30.6**). This gives the user the possibility to set compare events based on a finer resolution than that of the external events. This connection is accomplished via signal T6OFL.*

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H, so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

This deviation can be compensated for by using T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition at the selected input pin(s), e.g. on CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H. In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied e.g. at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H. So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two external events, but rather its 2's complement. Software will have to convert this value, if it is required for the operation.

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

In general, GPT12 has no destructive read mechanisms, except for this special operation mode ‘capture on position read operations’, where register CAPREL is intentionally updated after a read of T3 or T2/T4 (and T5 or T6 are optionally cleared). In this case, also the associated service request flag in register SRC_GPT120CIRQ is set.

Note: If mode ‘capturing on position read operations’ is selected, and the corresponding timer (T3, or any of T2, T3, T4) is read by a debugger, a capture event may be triggered (T5 is captured into CAPREL, and T5 or T6 may optionally be cleared (if T5CLR = 1 or T6CLR = 1)).

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

30.3.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see **Figure 217**). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 223 Basic Clock Selection for Block GPT2

Block Prescaler[1)]	BPS2 = 01_B	BPS2 = 00_B[2)]	BPS2 = 11_B	BPS2 = 10_B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{GPT}/4$	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$
Input Signal Stable Time	2 x t_{GPT}	4 x t_{GPT}	8 x t_{GPT}	16 x t_{GPT}

1) Please note the non-linear encoding of bitfield BPS2.
2) Default after reset.

Notes

1. *The GPT2 module uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T5, T6) and register CAPREL, these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT2 state machine has 4 states (2 states when BPS2 = 01_B) and processes T6 before T5.*
2. *When initializing the GPT2 block after reset, and the block prescaler BPS2 in register T6CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.*
   In this case, or when changing BPS2 during operation of the GPT2 block, disable related interrupts before modification of BPS2, and afterwards clear the corresponding service request flags and re-initialize those registers (T5, T6, CAPREL) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS2) \times 2^{<TxI>}} \qquad r_{Tx}[\mu s] = \frac{F(BPS2) \times 2^{<TxI>}}{f_{GPT}[MHz]} \tag{30.2}$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 227** summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

Table 224 lists GPT2 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor (F(BPS2) x $2^{<Txl>}$) and the module clock f_{GPT}. Note that some numbers may be rounded.

Table 224 GPT2 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock f_{GPT} = 100 MHz			Example 2: Module Clock f_{GPT} = 66.5 MHz		
	Frequency	Resolution	Period	Frequency	Resolution	Period
2	50 MHz	20 ns	1.311 ms	33.25 MHz	30.1 ns	1.97 ms
4	25 MHz	40 ns	2.621 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.243 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 µs	83.89 ms	519.53 kHz	1.924 µs	126.14 ms
256	390.6 kHz	2.56 µs	167.8 ms	259.77 kHz	3.850 µs	252.29 ms
512	195.3 kHz	5.12 µs	335.5 ms	129.88 kHz	7.699 µs	504.58 ms
1024	97.7 kHz	10.24 µs	671.1 ms	64.94 kHz	15.398 µs	1.009 s
2048	48.8 kHz	20.48 µs	1.342 s	32.47 kHz	30.797 µs	2.018 s

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see **Figure 217**). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 225 summarizes the resulting requirements for external GPT2 input signals.

Table 225 GPT2 External Input Signal Limits

GPT2 Divider BPS2	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock f_{GPT} = 100 MHz		Example 2: Module Clock f_{GPT} = 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01_B	$f_{GPT}/4$	2 x t_{GPT}	25 MHz	20 ns	16.625 MHz	30.1 ns
00_B	$f_{GPT}/8$	4 x t_{GPT}	12.5 MHz	40 ns	8.313 MHz	60.2 ns
11_B	$f_{GPT}/16$	8 x t_{GPT}	6.25 MHz	80 ns	4.156 MHz	120.3 ns
10_B	$f_{GPT}/32$	16 x t_{GPT}	3.125 MHz	160 ns	2.078 MHz	240.6 ns

These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode as well as the capture/reload signals on input CAPREL.

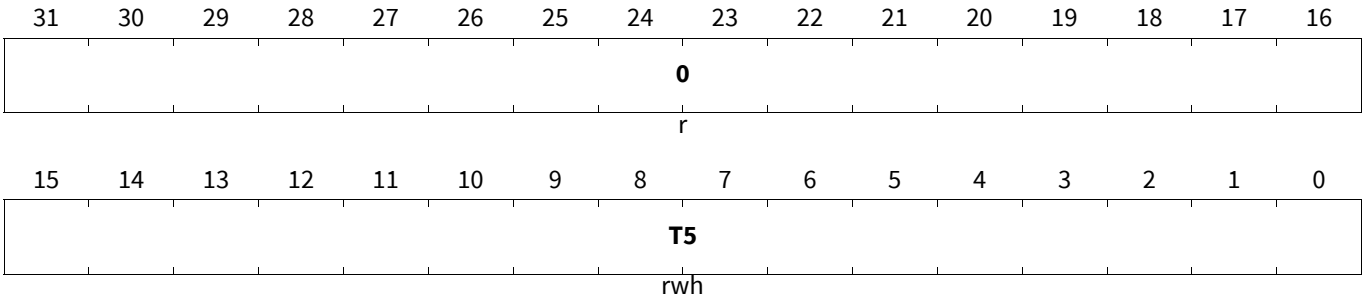
30.3.7 GPT2 Registers

Block GPT2 includes timer registers T5, T6, the capture/reload register CAPREL, and control registers T5CON and T6CON.

Timer T5 Register

T5

Timer T5 Register **(0040_H)** **Application Reset Value: $0000\ 0000_H$**

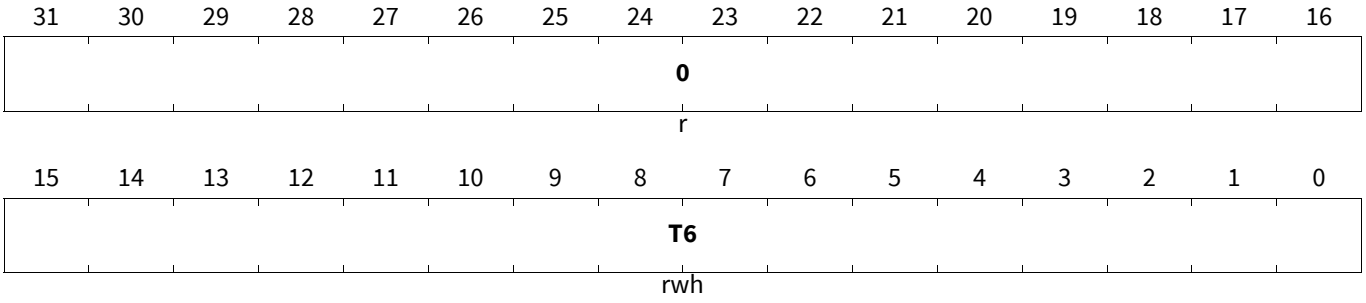


Field	Bits	Type	Description
T5	15:0	rwh	**Timer T5** Contains the current value of Timer T5.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T6 Register

T6

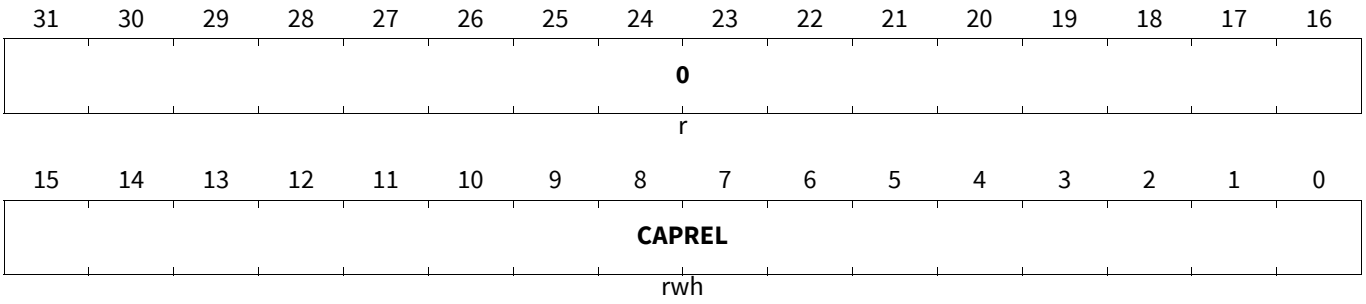
Timer T6 Register **(0044_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T6	15:0	rwh	**Timer T6** Contains the current value of Timer T6.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Capture and Reload Register

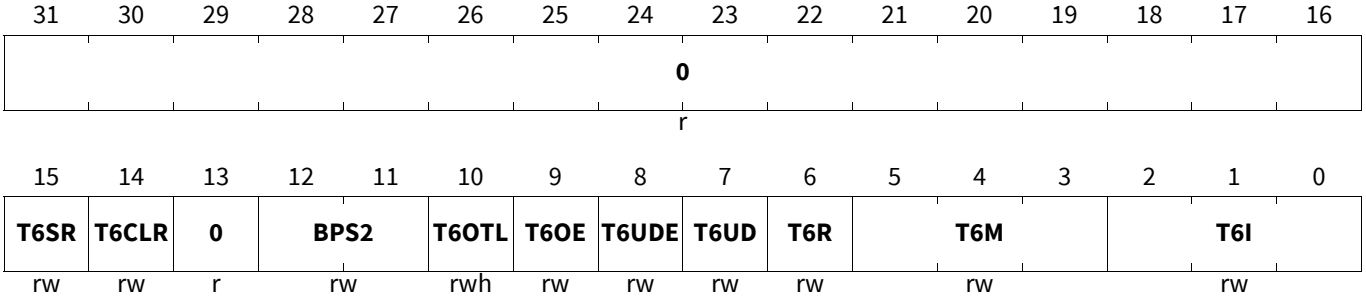
CAPREL
Capture and Reload Register **(0030_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CAPREL	15:0	rwh	**Current reload value or Captured value**
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T6 Control Register

T6CON
Timer T6 Control Register **(0020_H)** **Application Reset Value: $0000\ 0000_H$**

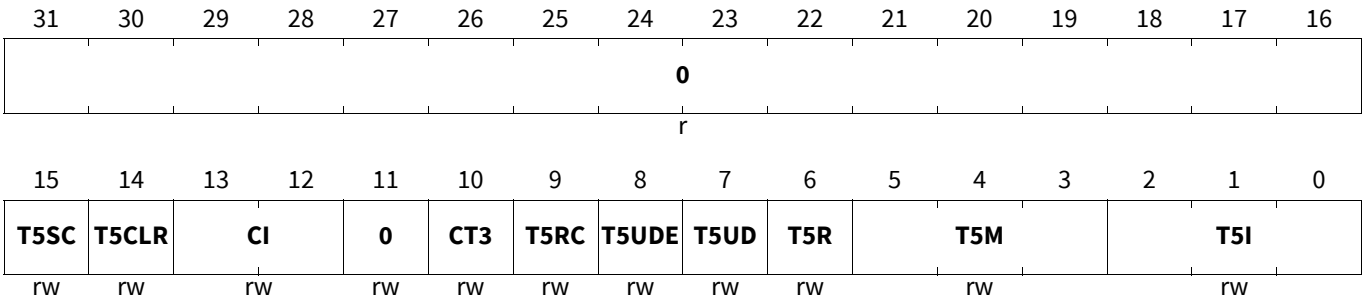


Field	Bits	Type	Description
T6I	2:0	rw	**Timer T6 Input Parameter Selection** Depends on the operating mode, see respective sections for encoding: **Table 227** for Timer Mode and Gated Timer Mode **Table 228** for Counter Mode
T6M	5:3	rw	**Timer T6 Mode Control (Basic Operating Mode)** 000_B Timer Mode 001_B Counter Mode 010_B Gated Timer Mode with gate active low 011_B Gated Timer Mode with gate active high 100_B Reserved. Do not use this combination. … 111_B Reserved. Do not use this combination.

Field	Bits	Type	Description
T6R	6	rw	**Timer T6 Run Bit** 0_B Timer T6 stops 1_B Timer T6 runs
T6UD	7	rw	**Timer T6 Up/Down Control** *Note: This bit only directly controls count direction of T6 if bit T6UDE = 0.* 0_B Timer T6 counts up 1_B Timer T6 counts down
T6UDE	8	rw	**Timer T6 External Up/Down Enable** 0_B Count direction is controlled by bit T6UD; input T6EUD is disconnected 1_B Count direction is controlled by input T6EUD (see also **Table 226**)
T6OE	9	rw	**Overflow/Underflow Output Enable** 0_B Alternate Output Function Disabled 1_B State of timer T6 toggle latch is output on pin T6OUT
T6OTL	10	rwh	**Timer T6 Overflow Toggle Latch** Toggles on each overflow/underflow of timer T6. Can be set or cleared by software (see separate description)
BPS2	12:11	rw	**GPT2 Block Prescaler Control** Selects the basic clock for block GPT2 (see also **Section 30.3.6**) 00_B $f_{GPT}/4$ 01_B $f_{GPT}/2$ 10_B $f_{GPT}/16$ 11_B $f_{GPT}/8$
T6CLR	14	rw	**Timer T6 Clear Enable Bit** 0_B Timer T6 is not cleared on a capture event 1_B Timer T6 is cleared on a capture event
T6SR	15	rw	**Timer T6 Reload Mode Enable** 0_B Reload from register CAPREL Disabled 1_B Reload from register CAPREL Enabled
0	13, 31:16	r	**Reserved** Read as 0; should be written with 0.

Timer T5 Control Register

T5CON
Timer T5 Control Register **($001C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T5I	2:0	rw	**Timer T5 Input Parameter Selection** Depends on the operating mode, see respective sections for encoding: **Table 227** for Timer Mode and Gated Timer Mode **Table 229** for Counter Mode
T5M	5:3	rw	**Timer T5 Mode Control (Basic Operating Mode)** 000_B Timer Mode 001_B Counter Mode 010_B Gated Timer Mode with gate active low 011_B Gated Timer Mode with gate active high 100_B Reserved. Do not use this combination … 111_B Reserved. Do not use this combination
T5R	6	rw	**Timer T5 Run Bit** *Note: This bit only controls timer T5 if bit T5RC = 0.* 0_B Timer T5 stops 1_B Timer T5 runs
T5UD	7	rw	**Timer T5 Up/Down Control** *Note: This bit only directly controls count direction of T5 if bit T5UDE = 0.* 0_B Timer T5 counts up 1_B Timer T5 counts down
T5UDE	8	rw	**Timer T5 External Up/Down Enable** 0_B Count direction is controlled by bit T5UD; input T5EUD is disconnected 1_B Count direction is controlled by input T5EUD (see also **Table 226**)
T5RC	9	rw	**Timer T5 Remote Control** 0_B Timer T5 is controlled by its own run bit T5R 1_B Timer T5 is controlled by the run bit T6R of core timer T6, not by bit T5R

Field	Bits	Type	Description
CT3	10	rw	**Timer T3 Capture Trigger Enable** 0_B Capture trigger from input line CAPIN 1_B Capture trigger from T3 input lines T3IN and/or T3EUD
CI	13:12	rw	**Register CAPREL Capture Trigger Selection** 00_B Capture disabled 01_B Positive transition (rising edge) on CAPIN[1] or any transition on T3IN 10_B Negative transition (falling edge) on CAPIN or any transition on T3EUD 11_B Any transition (rising or falling edge) on CAPIN or any transition on T3IN or T3EUD
T5CLR	14	rw	**Timer T5 Clear Enable Bit** *Note:* 0_B Timer T5 is not cleared on a capture event 1_B Timer T5 is cleared on a capture event
T5SC	15	rw	**Timer T5 Capture Mode Enable** 0_B Capture into register CAPREL disabled 1_B Capture into register CAPREL enabled
0	11	rw	**Reserved** Has to be written with 0.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

1) Rising edge must be selected for triggering the capture/clear operation by the internal GPT1 read signals (see bit field ISCAPIN in register **PISEL** and description in section **“Combined Capture Modes” on Page 43**).

30.3.8 Encoding of Specific Bitfields of GPT2 Registers

Table 226 GPT2 Timer Count Direction Control

Pin TxEUD	Bit TxUDE	Bit TxUD	Count Direction
X	0	0	Count Up
X	0	1	Count Down
0	1	0	Count Up
1	1	0	Count Down
0	1	1	Count Down
1	1	1	Count Up

Table 227 GPT2 Overall Prescaler Factors for Internal Count Clock (Timer Mode and Gated Timer Mode)

Individual Prescaler for Tx	Common Prescaler for Module Clock[1)]			
	BPS2 = 01_B	**BPS2 = 00_B**	**BPS2 = 11_B**	**BPS2 = 10_B**
TxI = 000_B	2	4	8	16
TxI = 001_B	4	8	16	32
TxI = 010_B	8	16	32	64
TxI = 011_B	16	32	64	128
TxI = 100_B	32	64	128	256
TxI = 101_B	64	128	256	512
TxI = 110_B	128	256	512	1024
TxI = 111_B	256	512	1024	2048

1) Please note the non-linear encoding of bitfield BPS2.

Table 228 GPT2 Core Timer T6 (Counter Mode) Input Edge Selection

T6I	Triggering Edge for Counter Increment/Decrement
000_B	None. Counter T6 is disabled
001_B	Positive transition (rising edge) on T6IN
010_B	Negative transition (falling edge) on T6IN
011_B	Any transition (rising or falling edge) on T6IN
$1XX_B$	Reserved. Do not use this combination

Table 229 GPT2 Auxiliary Timer T5 (Counter Mode) Input Edge Selection

T5I	Triggering Edge for Counter Increment/Decrement
$X00_B$	None. Counter T5 is disabled
001_B	Positive transition (rising edge) on T5IN
010_B	Negative transition (falling edge) on T5IN
011_B	Any transition (rising or falling edge) on T5IN
101_B	Positive transition (rising edge) of T6 toggle latch T6OTL

Table 229 GPT2 Auxiliary Timer T5 (Counter Mode) Input Edge Selection (cont'd)

T5I	Triggering Edge for Counter Increment/Decrement
110_B	Negative transition (falling edge) of T6 toggle latch T6OTL
111_B	Any transition (rising or falling edge) of T6 toggle latch T6OTL

Encoding of GPT2 Input Selection for Capture and Timer Clear Function

Table 230 CAPREL Register Input Edge Selection

CT3	CI	Triggering Signal/Edge for Capture Mode and/or T5/T6 Clear
X	00_B	None. Capture Mode is disabled.
0	01_B	Positive transition (rising edge) on CAPIN, or read operation on selected GPT1 timers[1)].
0	10_B	Negative transition (falling edge) on CAPIN.
0	11_B	Any transition (rising or falling edge) on CAPIN.
1	01_B	Any transition (rising or falling edge) on T3IN.
1	10_B	Any transition (rising or falling edge) on T3EUD.
1	11_B	Any transition (rising or falling edge) on T3IN or T3EUD.

1) Rising edge must be selected for triggering the capture/clear operation by the internal GPT1 read signals (see bit field ISCAPIN in register **PISEL** and description in section **"Combined Capture Modes" on Page 43**).

30.4 GPT12 Kernel Register Overview

Table 231 summarizes the GPT12 kernel registers, module external registers and BPI registers, and defines their addresses and reset.

Table 231 Register Overview - GPT12 (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control Register	0000_H	U,SV	SV,E,P	Application Reset	58
PISEL	Port Input Select Register	0004_H	U,SV	U,SV,P	Application Reset	55
ID	Identification Register	0008_H	U,SV	BE	See page 57	57
T2CON	Timer T2 Control Register	0010_H	U,SV	U,SV,P	Application Reset	24

OCS	OCDS Control and Status Register	$00E8_H$	U,SV	SV,P,OEN	See page 59	59
KRSTCLR	Kernel Reset Status Clear Register	$00EC_H$	U,SV	SV,E,P	Application Reset	62
KRST1	Kernel Reset Register 1	$00F0_H$	U,SV	SV,E,P	Application Reset	62
KRST0	Kernel Reset Register 0	$00F4_H$	U,SV	SV,E,P	Application Reset	61
ACCEN0	Access Enable Register 0	$00FC_H$	U,SV	SV,SE	Application Reset	60

30.5 General Module Operation

This section provides information about:

30.5.1 Input Selection

Each GPT12 input signal can be selected from a vector of two or four possible inputs by programming the port input select register **PISEL**. This permits to adapt the pin functionality of the device to the application requirements.
The output pins for the module output signals are chosen in the ports.

Naming convention (example):
The input vector T3IN[D:A] for input signal T3IN is composed of the signals T3INA to T3IND.

*Note: All functional inputs of the GPT12 module are synchronized to the internal basic clock of the GPT1 and GPT2 block, respectively. An edge of an input signal can only be correctly recognized if the high phase and the low phase are longer than one basic clock period. See **Table 216** for GPT1 external input signal limits, and **Table 225** for GPT2 external input signal limits.*

30.5.2 OCDS Suspend

The behavior of GPT12 upon an OCDS suspend request is controlled by the **OCS** register. GPT12 supports only Hard Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the GPT12 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a GPT12 kernel reset might not be sufficient to bring the system into a defined state.

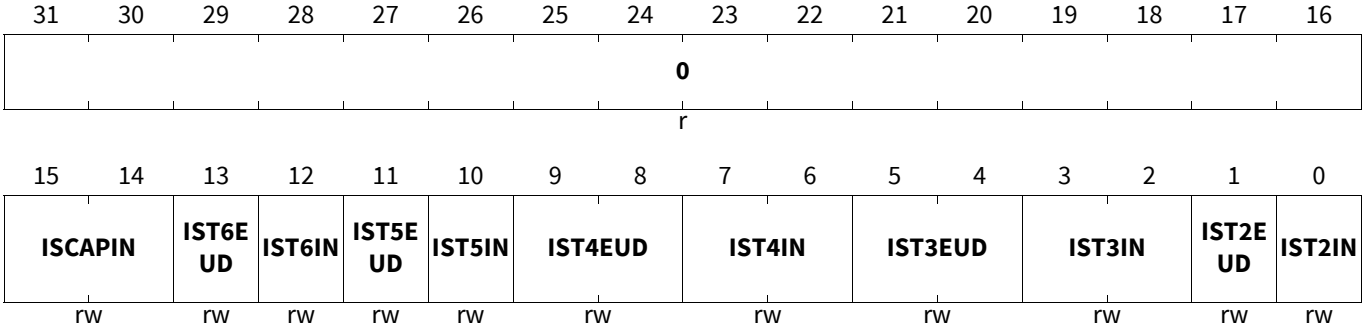
30.5.3 Miscellaneous GPT12 Registers

Port Input Select Register

Register PISEL contains bitfields selecting the actual input signal for the module inputs.

PISEL

Port Input Select Register **(0004_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
IST2IN	0	rw	**Input Select for T2IN** 0_B Signal T2INA is selected 1_B Signal T2INB is selected
IST2EUD	1	rw	**Input Select for T2EUD** 0_B Signal T2EUDA is selected 1_B Signal T2EUDB is selected
IST3IN	3:2	rw	**Input Select for T3IN** 00_B Signal T3INA is selected 01_B Signal T3INB is selected 10_B Signal T3INC is selected 11_B Signal T3IND is selected
IST3EUD	5:4	rw	**Input Select for T3EUD** 00_B Signal T3EUDA is selected 01_B Signal T3EUDB is selected 10_B Signal T3EUDC is selected 11_B Signal T3EUDD is selected
IST4IN	7:6	rw	**Input Select for T4IN** 00_B Signal T4INA is selected 01_B Signal T4INB is selected 10_B Signal T4INC is selected 11_B Signal T4IND is selected
IST4EUD	9:8	rw	**Input Select for T4EUD** 00_B Signal T4EUDA is selected 01_B Signal T4EUDB is selected 10_B Signal T4EUDC is selected 11_B Signal T4EUDD is selected
IST5IN	10	rw	**Input Select for T5IN** 0_B Signal T5INA is selected 1_B Signal T5INB is selected
IST5EUD	11	rw	**Input Select for T5EUD** 0_B Signal T5EUDA is selected 1_B Signal T5EUDB is selected

Field	Bits	Type	Description
IST6IN	12	rw	**Input Select for T6IN** 0_B Signal T6INA is selected 1_B Signal T6INB is selected
IST6EUD	13	rw	**Input Select for T6EUD** 0_B Signal T6EUDA is selected 1_B Signal T6EUDB is selected
ISCAPIN	15:14	rw	**Input Select for CAPIN** 00_B Signal CAPINA is selected 01_B Signal CAPINB is selected 10_B Signal CAPINC (Read trigger from T3) is selected 11_B Signal CAPIND (Read trigger from T2 or T3 or T4) is selected
0	31:16	r	**Reserved** Read as 0; should be written with 0.

Identification Register

ID
Identification Register **(0008_H)** **Reset Value: Table 232**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODNUMBER															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODTYPE								MODREV							
r								r							

Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field indicates the revision number of the module (01_H = first revision).
MODTYPE	15:8	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module
MODNUMBER	31:16	r	**Module Number** This bit field defines the module identification number. For the GPT12 module the module identification number is 68_H.

Table 232 Reset Values of ID

Reset Type	Reset Value	Note
Application Reset	$0068\ C0XX_H$	

30.5.4 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface).

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the GPT12 module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{GPT} module clock signal and Sleep Mode for the module.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the GPT12 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the GPT12 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

CLC

Clock Control Register (0000_H) Application Reset Value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable is not requested. 1_B Module disable is requested.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module is enabled. 1_B Module is disabled.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode. 0_B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1_B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.
0	2, 15:4, 31:16	r	**Reserved** Read as 0; should be written with 0.

It is recommended not to write to or read from module registers (except CLC) while the module is disabled. Write operations and read operations from registers that require a clock will generate a bus error.

OCDS Control and Status Register

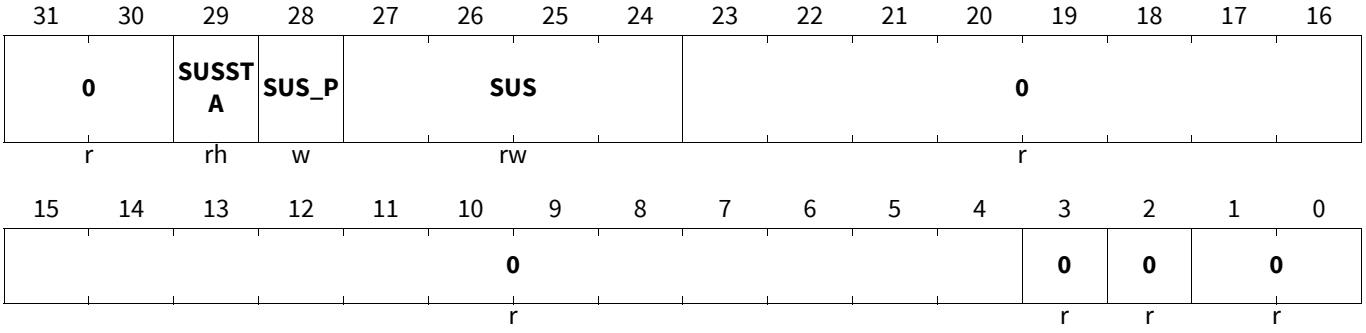
The OCDS Control and Status register OCS controls the module's behavior in suspend mode (used for debugging). The OCS register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. When OCDS is disabled the OCS suspend control is ineffective.

Currently, no trigger set is defined for GPT12. Therefore control bits for the OCDS Trigger Bus (OTGB) in OCS.[3:0] are described as reserved.

OCS

OCDS Control and Status Register **($00E8_H$)** **Reset Value: Table 234**



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. **others**, reserved (will not suspend).
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	3:0, 23:4, 31:30	r	**Reserved** Read as 0; must be written with 0.

Table 233 Access Mode Restrictions of OCS sorted by descending priority

Mode Name	Access Mode		Description

ENy (y=0-31)	y	rw	**Access Enable for Master TAG ID y** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID y 0_B No write access Write access will not be executed 1_B Write access will be executed

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. Kernel Reset Registers 0 and 1 each include bit RST. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

A module kernel reset has the following effects:

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

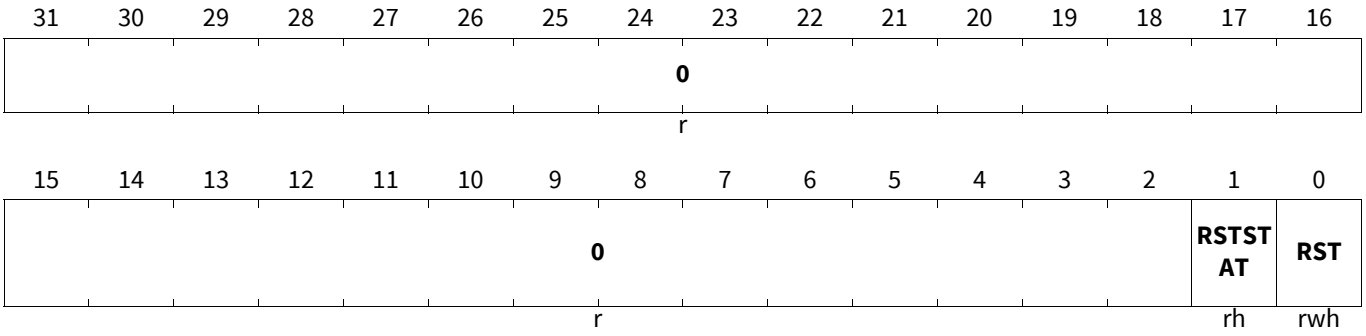
Table 235 Effects of a Module Kernel Reset

Register	Executed Action
CLC, OCS, ACCEN0	No influence
ID	No influence
KRST0	Bit RST is cleared automatically after reset execution, RSTSTAT indicates a module kernel reset, cleared via KRSTCLR
KRST1	Bit RST is cleared automatically after reset execution
KRSTCLR	No influence
Other registers	Reset to their defined reset values

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Kernel Reset Register 0

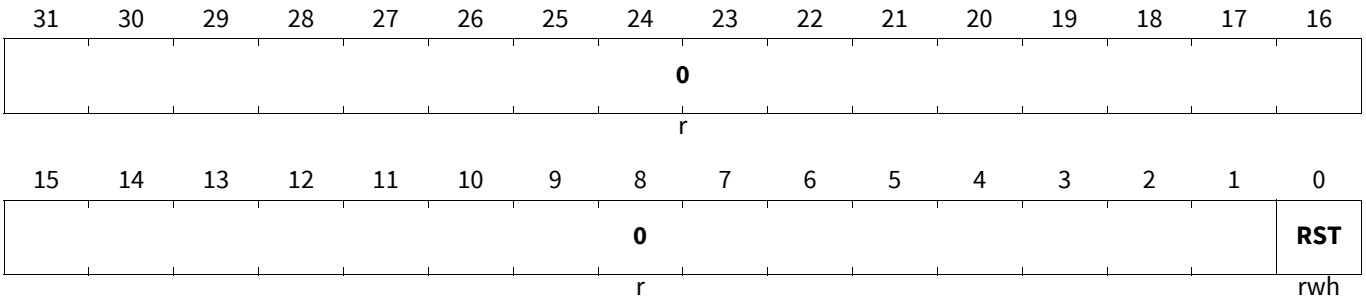
KRST0
Kernel Reset Register 0 (00F4$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

KRST1
Kernel Reset Register 1 **($00F0_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register **($00EC_H$)** **Application Reset Value: $0000\ 0000_H$**

31 Converter Control Block (CONVCTRL)

The converter control block summarizes control functions which are common for all converters implemented in the product. The following functions are provided:

- **Phase Synchronizer (PhSync)**
  provides a clock enable signal to synchronize the clock signals of all analog blocks

The converter control block contains the registers which are required to configure the associated functions.

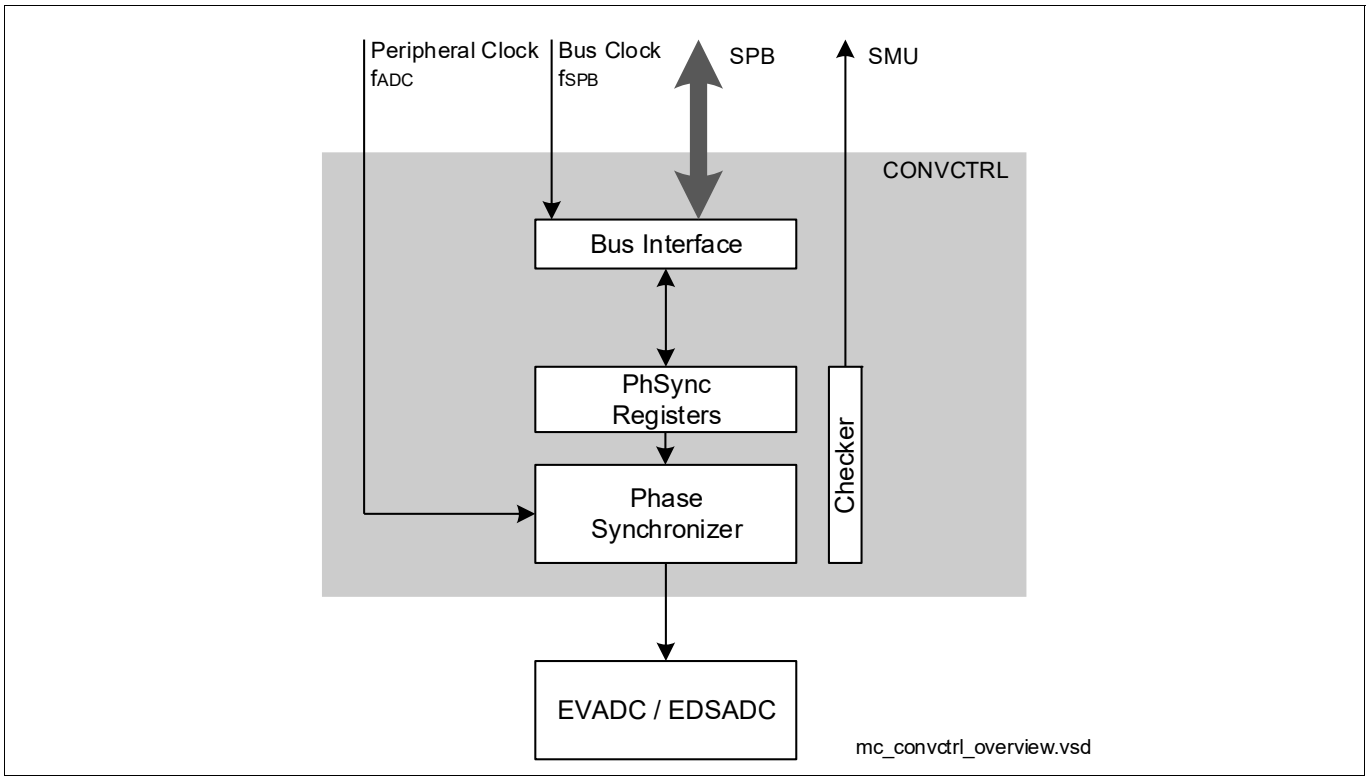

Figure 229 CONVCTRL Module Overview

In addition, the following sections can be found:

- **“Application Considerations” on Page 17**
- **“Summary of Registers and Locations” on Page 20**

Attention: ***This chapter describes the CONVCTRL of the TC3xx family, encompassing the features and functions of all family members.***
The specific characteristics of a product are described in the product-specific appendix.
This product-specific appendix specifies deviations (e.g. downgrades, etc.) from this family documentation.

31.1 Configuration of the CONVCTRL

The configuration of the functional units is done via dedicated registers which are defined in the corresponding functional section. General registers which are common for all blocks are defined here.

Module Identification Register

ID
Module Identification Register **(008_H)** **PowerOn Reset Value: 00FF C001$_H$**

MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUMBER	31:16	r	**Module Number** Indicates the module identification number ($00FF_H$ = CONVCTRL)

Clock Control Register

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. It controls the module clock signal and the reactivity to the sleep signal.

CLC
Clock Control Register **(000_H)** **Application Reset Value: 0000 0003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved, write 0, read as 0**

It is recommended not to write to or read from module registers (except CLC) while the module is disabled. Write operations will generate a bus error.

When the module is disabled (DISR = 1_B) while in suspend state, the corresponding status bit (DISS = 1_B) will only be set after several clock cycles. To generate them, writes to CLC need to be repeated. See OCS note on **Page 4**.

OCDS Control and Status Register

The OCDS Control and Status register OCS controls the module's behavior in suspend mode (used for debugging).

Register OCS is cleared by Debug Reset. It can only be written when OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS

OCDS Control and Status Register **(028_H)** **Reset Value: Table 239**

Table 239 Reset Values of OCS

Reset Type	Reset Value	Note
PowerOn Reset	$0000\ 0000_H$	
Debug Clear	$0000\ 0000_H$	

*Note: During write access in suspend state the clocks are activated for a few cycles to accomplish the access. To prevent state machines from advancing due to this, it is recommended to stop the phase synchronizer by clearing bitfield PHSDIV = 0000_B in register **PHSCFG**.*

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on-chip bus master TAG IDs $00\ 0000_B$ to $01\ 1111_B$ (see On-Chip Bus chapter for the mapping of product TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding. Register ACCEN0 itself is protected by the Safety Endinit feature.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID $00\ 0000_B$, EN1 -> TAG ID $00\ 0001_B$, … , EN31 -> TAG ID $01\ 1111_B$ (TAG IDs $1X\ XXXX_B$ are not used).

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. Kernel Reset Registers 0 and 1 each include bit RST. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

A module kernel reset has the following effects:

Table 240 Effects of a Module Kernel Reset

Register	Executed Action
CLC, OCS, ACCEN0	No influence
ID	No influence
KRST0	Bit RST is cleared automatically after reset execution, RSTSTAT indicates a module kernel reset, cleared via KRSTCLR
KRST1	Bit RST is cleared automatically after reset execution
KRSTCLR	No influence
Other registers	Reset to their defined reset values

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

31.2 Phase Synchronizer (PhSync)

The phase synchronizer provides a specific clock enable signal to synchronize the operation of all analog blocks within modules EVADC and EDSADC.

These analog blocks use the voltage references (V_{AREF} and V_{AGND}) and synchronizing their clock edges avoids performance losses caused by mutual cross-coupling via the reference lines.

The CONVCTRL ensures that all switching activities within the connected analog blocks occur at the same clock edge of f_{PER} so the ringing that occurs on the reference lines does not disturb the operation of another analog block.

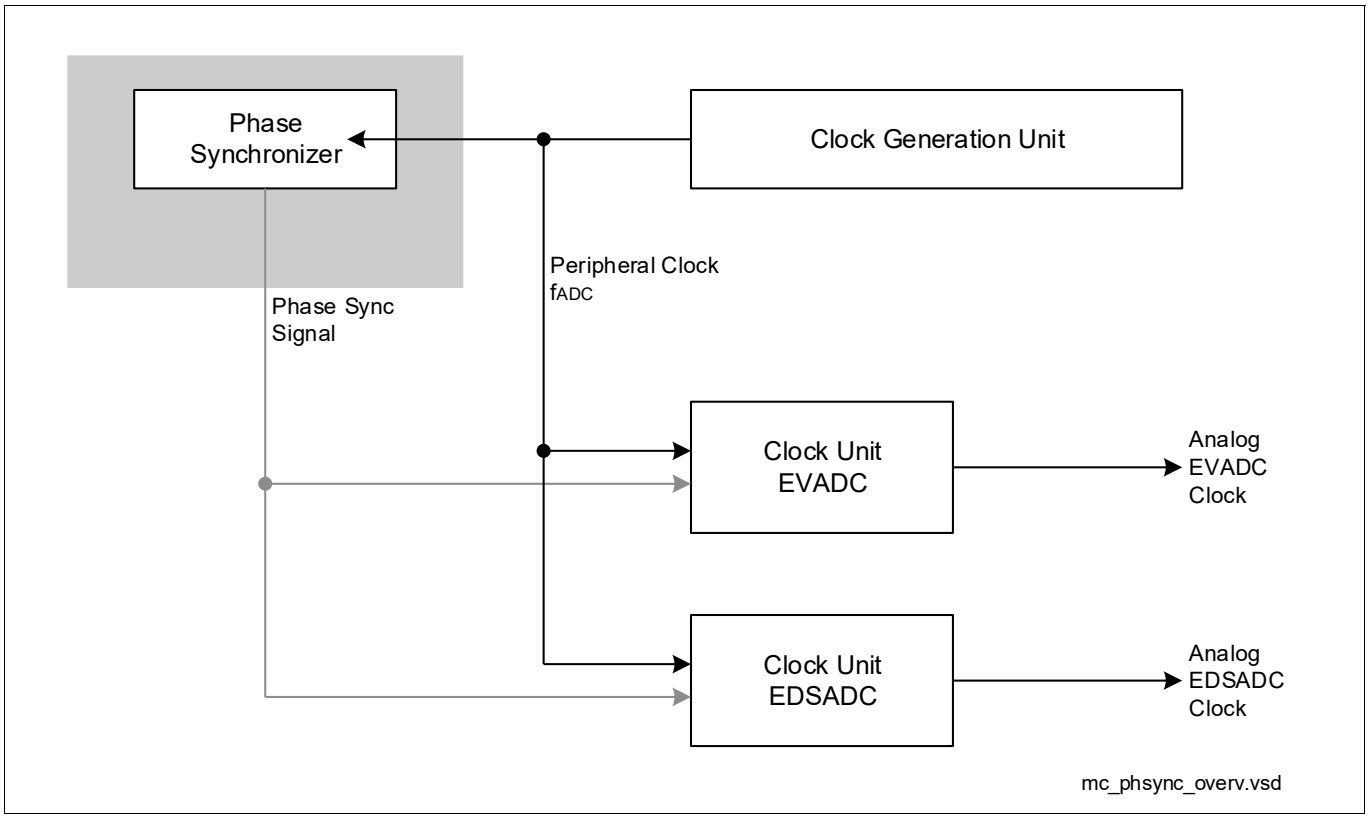

Figure 230 CONVCTRL Module Overview

Features

The following features describe the functionality of the PhSync:

- Synchronization of all analog blocks
  - Centrally generated clock enable signal
  - Local synchronization stages within each module
- Target frequency selectable to adapt to system requirements
- Based on the peripheral clock signal f_{PER} (160 MHz)

You will find the following major sections within this chapter:

- **“Introduction and Basic Structure” on Page 10**
- **“Operation of the PhSync” on Page 11**
- **“Generation of the Analog Clock Signal” on Page 12**
- **“Safety Measures” on Page 13**
- **“Configuration of the PhSync” on Page 16**

31.2.1 Introduction and Basic Structure

The Phase Synchronizer module (PhSync) provides a centralized clock enable signal for all analog blocks (EVADC, EDSADC). This synchronization ensures that the analog blocks do not disturb each other by drawing current peaks from the reference voltage lines at adjacent edges of the basic peripheral clock f_{PER}.

The frequency of the resulting analog clock enable signal is configurable within a certain range.

The PhSync broadcasts its clock enable signal, while each connected module locally generates its own analog clock signal based on the PhSync signal. With this approach no additional clock balancing is required.

The basic module clock is the peripheral clock signal f_{PER}.

The figures below show the analog clock generation mechanisms used in the connected modules.

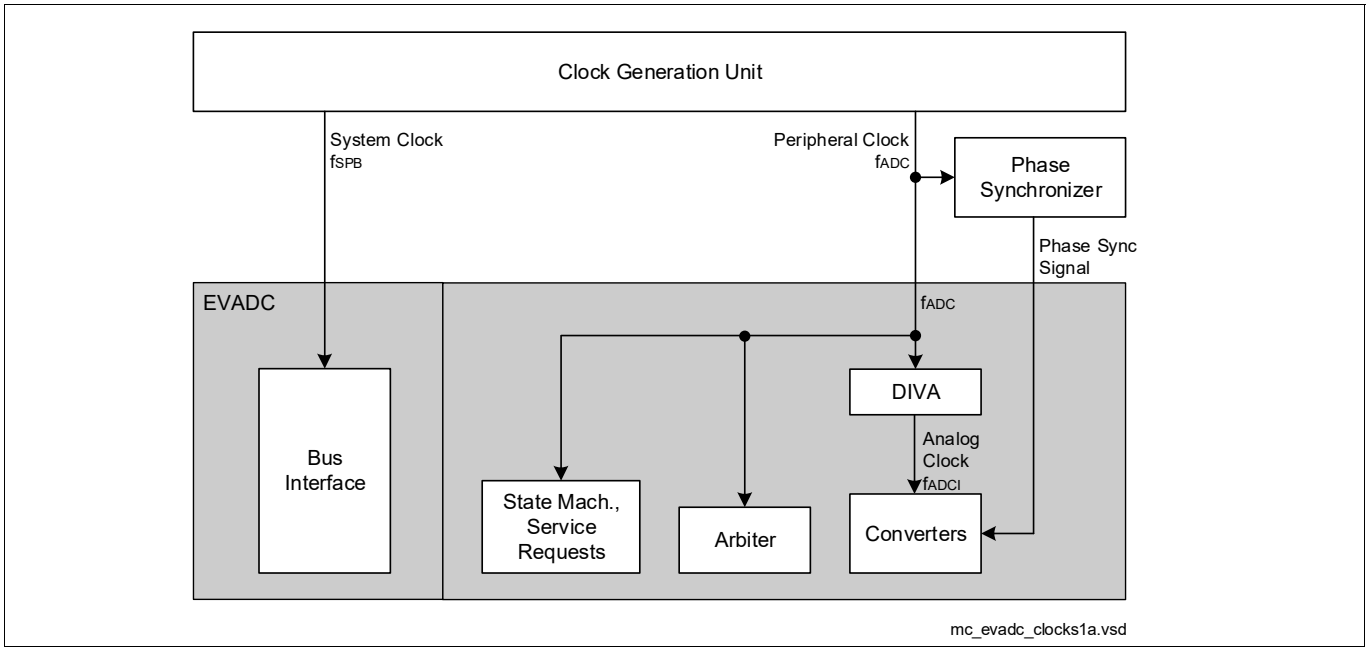

Figure 231 Analog Clock Generation in the EVADC

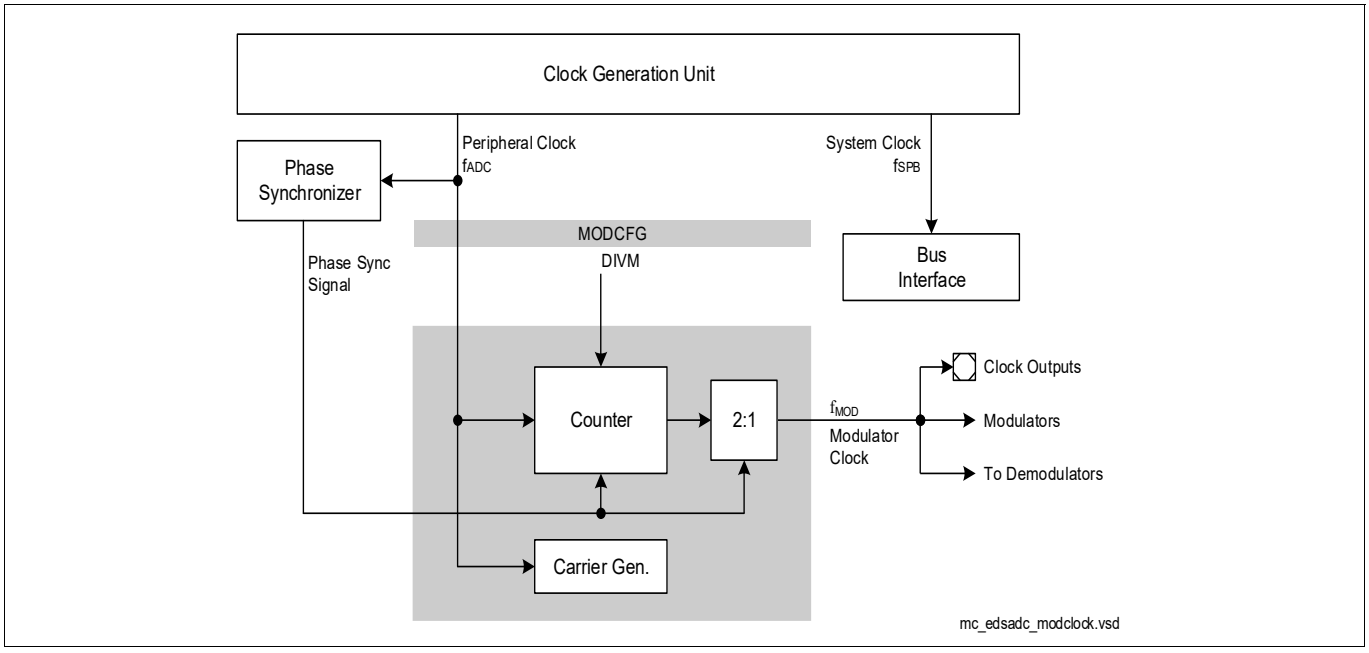

Figure 232 Analog Clock Generation in the EDSADC

31.2.2 Operation of the PhSync

The Phase Synchronizer counts peripheral clock (f_{PER}) cycles and generates a clock enable signal after a configurable number of clock cycles. The prescaling factor can be selected from 2 to 16, which equals an analog clock frequency of 80 MHz to 10 MHz (assuming f_{PER} = 160 MHz).

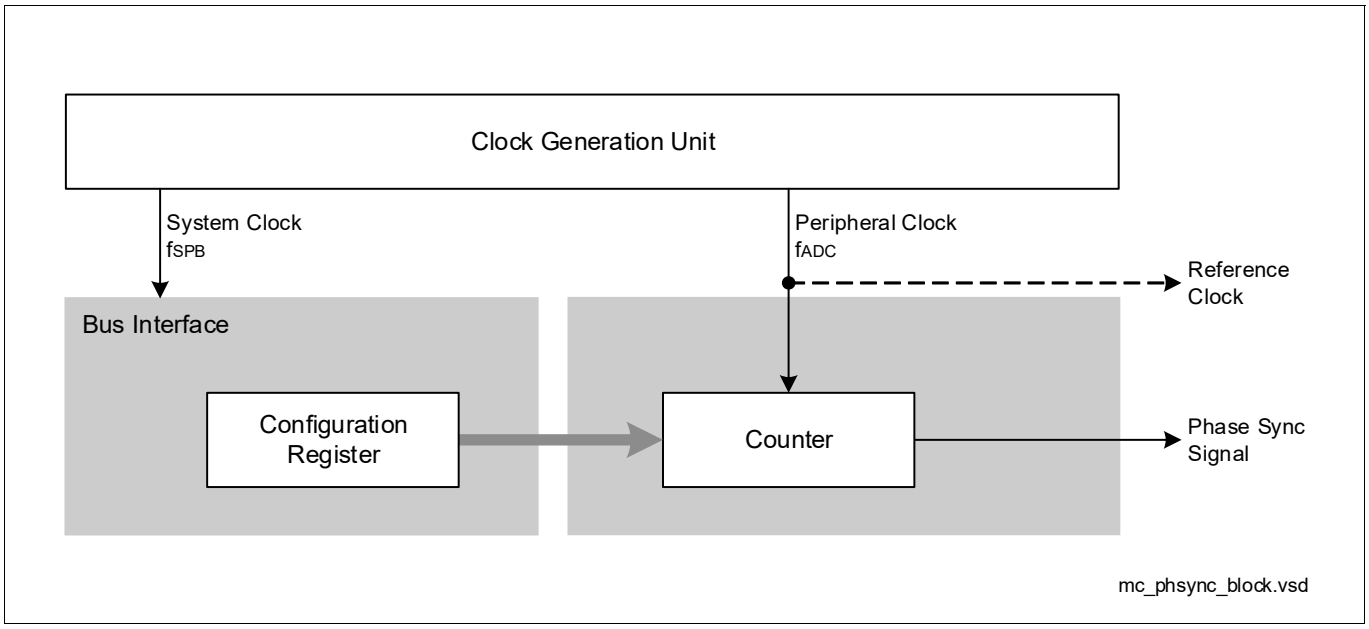

Figure 233 Basic PhSync Block Diagram

The phase synchronization signal triggers all local clock generation blocks to generate a clock edge with a subsequent[1)] rising edge of the common peripheral clock. The figure below shows the resulting timing for prescaler factors of 2 and 8.

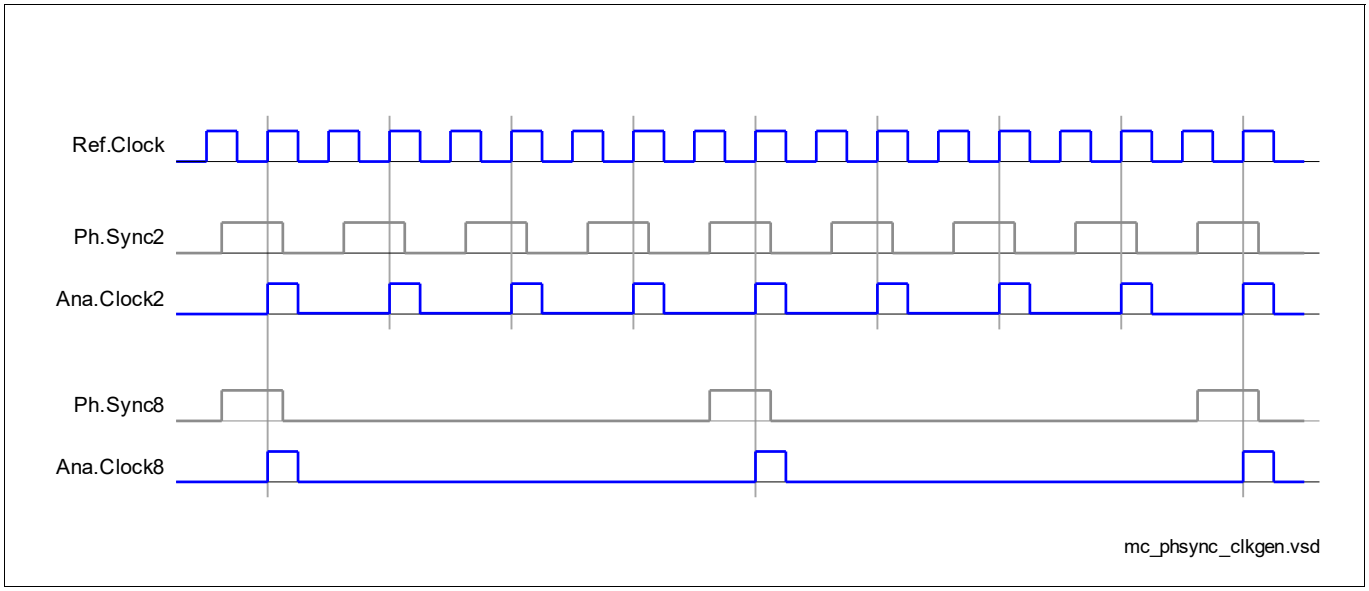

Figure 234 Clock Generation with the Phase Synchronization Signal (Pulse Swallowing)

Note: The PhSync signal is generated centrally by the phase synchronizer, while the analog clock signals (e.g. Ana.Clock2 or Ana.Clock8) are generated locally within the respective module.

1) See "**Generation of the Analog Clock Signal**" for more details.

31.2.3 Generation of the Analog Clock Signal

The local clock generation units generate the respective analog clock signal triggered by the phase synchronization signal. The corresponding analog clock edge or trigger signal is generated upon a subsequent rising edge of the reference clock f_{PER}.

Note: The EVADC evaluates the level of the phase synchronizer signal to start a conversion.
The EDSADC evaluates the rising edge of the phase synchronizer signal to generate clock pulses.
For proper operation, only change the configuration of the phase synchronizer while the converters are idle.

Each unit can configure a certain phase shift for the synchronized analog clock or trigger. This way, all analog modules can switch on exactly the same clock edge, or they can switch in a certain sequence that can be configured by the user.

The figure below shows the effect of the phase shift.

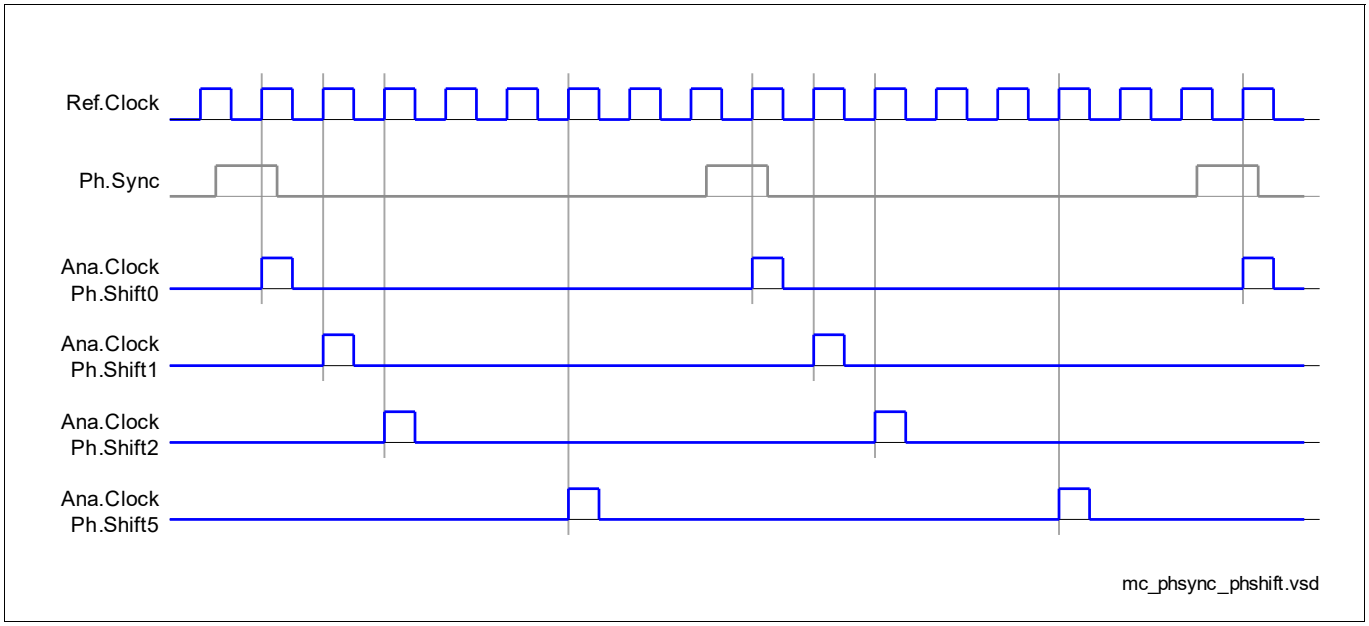

Figure 235 Analog Clock Phase Shift

If pulse swallowing is not feasible, the analog clock can also be generated with defined duty cycles. Still, the rising clock edges are triggered by the phase synchronizer signal.

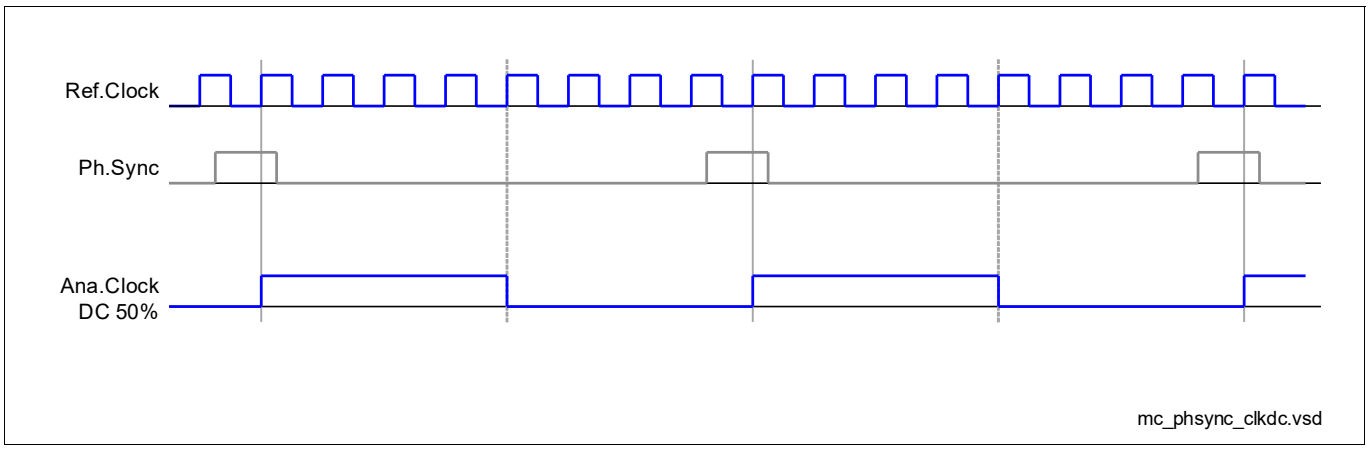

Figure 236 Analog Clock Generation without Pulse Swallowing

31.2.4 Safety Measures

Since the Phase Synchronizer influences all analog-digital-converters, safety measures are implemented to supervise its operation and, as a consequence, the operability of the converters.

Parity-Protection of the Prescaler Value

The additional parity bit helps to detect a corrupted prescaler value, which would result in the wrong synchronization frequency for the converters. The parity bit is generated automatically when writing to bitfield PHSDIV. Parity is then checked constantly.

A parity error caused by the corruption of a prescaler value bit triggers an alarm event.

Run-Time Supervision of the Counter

Two counters are counting in parallel. Their states are constantly compared and a difference triggers an alarm event.

Alarm-Event Signaling

If an alarm event is triggered it sets the sticky alarm flag and activates the alarm output signal.

The output signal is connected to the SMU.

The alarm flag can be cleared by writing a 1 to bit ALFCLR. This also deactivates the alarm output signal.

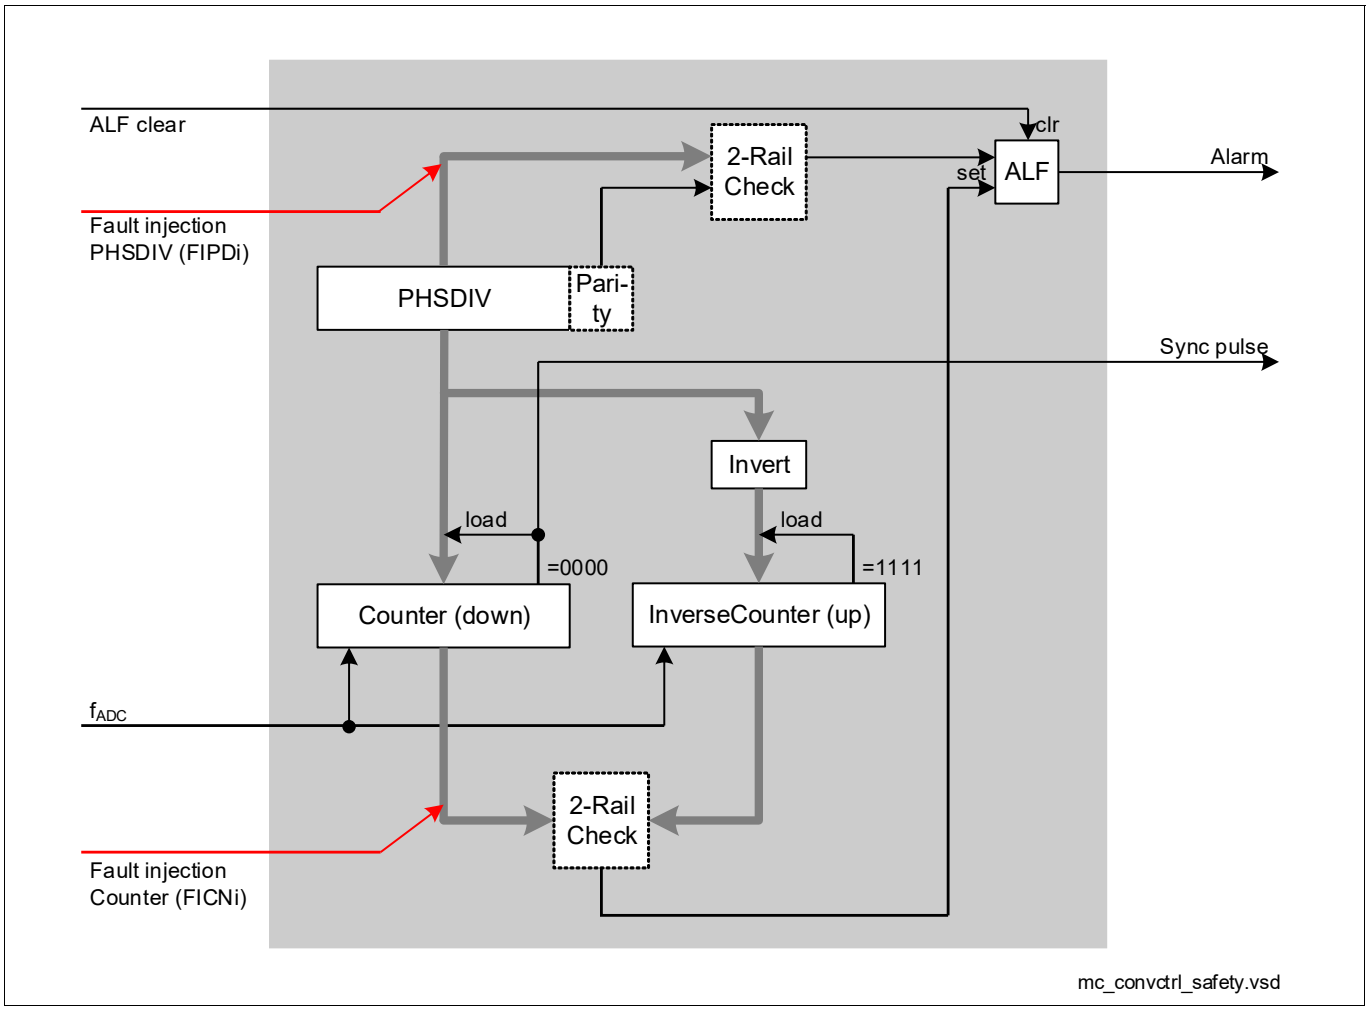

Figure 237 Phase Synchronizer Safety Features

Fault Injection

To test the supervision mechanism, the application software can deliberately inject a fault condition into both mechanisms. This is accomplished by writing a 0 to bit FIPD0/FICN0 and writing a 1 to bit FIPD1/FICN1 at the same time. Bits FIPDi trigger a fault condition in the supervision logic of bitfield PHSDIV, bits FICNi trigger a fault condition in the supervision logic of the phase sync counter.

The alarm flag can be cleared by writing a 1 to bit ALFCLR. This also deactivates the alarm output signal.

Mode Name	Access Mode		Description
write 1 to **PDWC**	rwh	PHSDIV	Set PDWC during write access
(default)	rh	PHSDIV	

Note: Writing to bitfield PHSDIV automatically generates the corresponding parity bit (indicated by rw"h").

31.3 Application Considerations

The operation of the CONVCTRL and, hence, its behavior is programmable. This makes it suitable for different applications while requiring a minimum of handling.

31.3.1 Clock Synchronization

To eliminate the interference of concurrently operating ADC channels, the converters can operate in a synchronized way so each of them can reach its optimum performance. The Phase Synchronizer distributes a clock control signal which is used by the converters to generate a local clock signal.

After reset, the clock synchronization is active within the converters. The Phase Synchronizer, therefore, must be configured to generate the clock synchronization signal. This synchronization signal is used within the EDSADC and the EVADC. The following conditions must be fulfilled for proper operation of the converters:

- **EDSADC**:
  The EDSADC uses the synchronization signal directly to generate its modulator clock. Therefore, the phase synchronizer must be programmed according to the required EDSADC modulator frequency,
  i.e. $f_{PHSYNC} = f_{MOD}$.
  The modulator frequency must be configured accordingly within the EDSADC (DIVM).
- **EVADC**:
  The EVADC uses the synchronization signal to start a conversion. Therefore, the analog clock of the EDVADC f_{ADCI} must be selected as an integer multiple of the phase synchronizer frequency,
  i.e. $f_{ADCI} = f_{PHSYNC}$ or $f_{ADCI} = f_{PHSYNC} \times 2$.
  The analog clock frequency must be configured accordingly within the EVADC (DIVA).

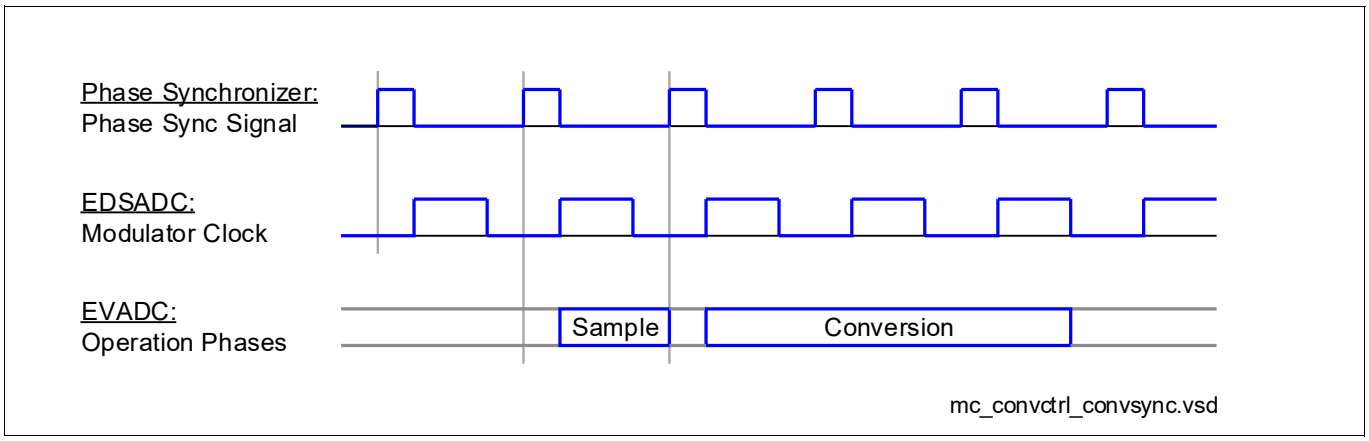

Figure 238 Inter-Module Synchronization

31.3.2 Example Settings for Operation

According to the rules given above the following settings can be derived:

Table 242 Synchronized Converter Clock Scenarios

Phase Synchronizer		EDSADC		EVADC	
Synchronization Frequency f_{PHSYNC}	**PHSDIV**	**Modulator Frequency f_{MOD}**	**DIVM**	**Analog Clock Frequency f_{ADCI}**	**DIVA**
16 MHz	1001_B	16 MHz	011_B	16 MHz	01001_B
				32 MHz	00100_B
20 MHz	0111_B	20 MHz	010_B	20 MHz	00111_B
				40 MHz	00011_B
26.67 MHz	0101_B	26.67 MHz	001_B	26.7 MHz	00101_B
				53.3 MHz	00010_B
40 MHz	0011_B	40 MHz	000_B	40 MHz	00011_B

31.3.3 Basic Initialization Sequence

After reset, the CONVCTRL is disabled to minimize the initial power consumption. By executing the following steps the CONVCTRL can be prepared for operation and be started:

```
CONVCTRL_CLC          = 0x00000000 ;Enable module CONVCTRL
CONVCTRL_CCCTRL       = 0xB0000000 ;Unlock converter control registers
CONVCTRL_PHSCFG       = 0x00008007 ;Synchronizer frequency = 160 MHz / 8 = 20 MHz
CONVCTRL_CCCTRL       = 0x00000000 ;Lock converter control registers
```

*Note: The synchronizer frequency is determined by the overall system setup (see **Table 242**).*

31.3.4 Module Handling in Sleep Mode

The CONVCTRL does not change its operating mode in sleep mode. While sleep mode is evaluated (CLC.EDIS = 0, default after reset), the module clocks are stopped upon a sleep mode request. To achieve the power reduction that is usually intended during sleep mode, the phase synchronizer is off during sleep mode, i.e. the phase synchronization signal is constantly active.

Note: If any activity of connected modules is intended during sleep mode make sure that sleep mode requests are disregarded (CLC.EDIS = 1).
If the CONVCTRL shall enter sleep mode, make sure also the connected modules EVADC and EDSADC are prepared for sleep mode.

31.4 Summary of Registers and Locations

The CONVCTRL is a very small module which is controlled by very few registers.

Registers with write access mode "...,M" are additionally protected from unintended write access by bitfield **CCCTRL**.TC. Set bitfield TC to $1011_B/B_H$ to enable write access to the module registers.

Table 243 Register Overview - CONVERTER (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number

32 Enhanced Versatile Analog-to-Digital Converter (EVADC)

The EVADC provides a series of analog input channels connected to several clusters of Analog/Digital Converters using the Successive Approximation Register (SAR) principle to convert analog input values (voltages) to discrete digital values.

The EVADC is based on SAR converters, each comprising a sample&hold unit and a converter block. An analog multiplexer selects one of several input channels and a dedicated control logic with several request sources defines the sequence of consecutive conversions. This altogether builds a conversion group.
The number of analog input channels and conversion groups depends on the chosen product type. This is described in the product-specific appendix.

Each converter of the ADC clusters can operate independent of the others. The results of each channel can be stored in dedicated channel-specific result registers or in a group-specific result register.

Three clusters with different functionality are available: (section summary on **Page 3**)

- **Primary converter cluster**: Equipped with 8:1 multiplexers and 8-stage queues, conversion time down to below 0.5 µs.[1)]
- **Secondary converter cluster**: Equipped with 16:1 multiplexers and 16-stage queues, conversion time down to below 1 µs.[1)]
- **Fast compare cluster**: Single channels, update rate down to below 0.2 µs.[1)]

In addition to the EVADC clusters also the EDSADC performs analog-digital conversions.

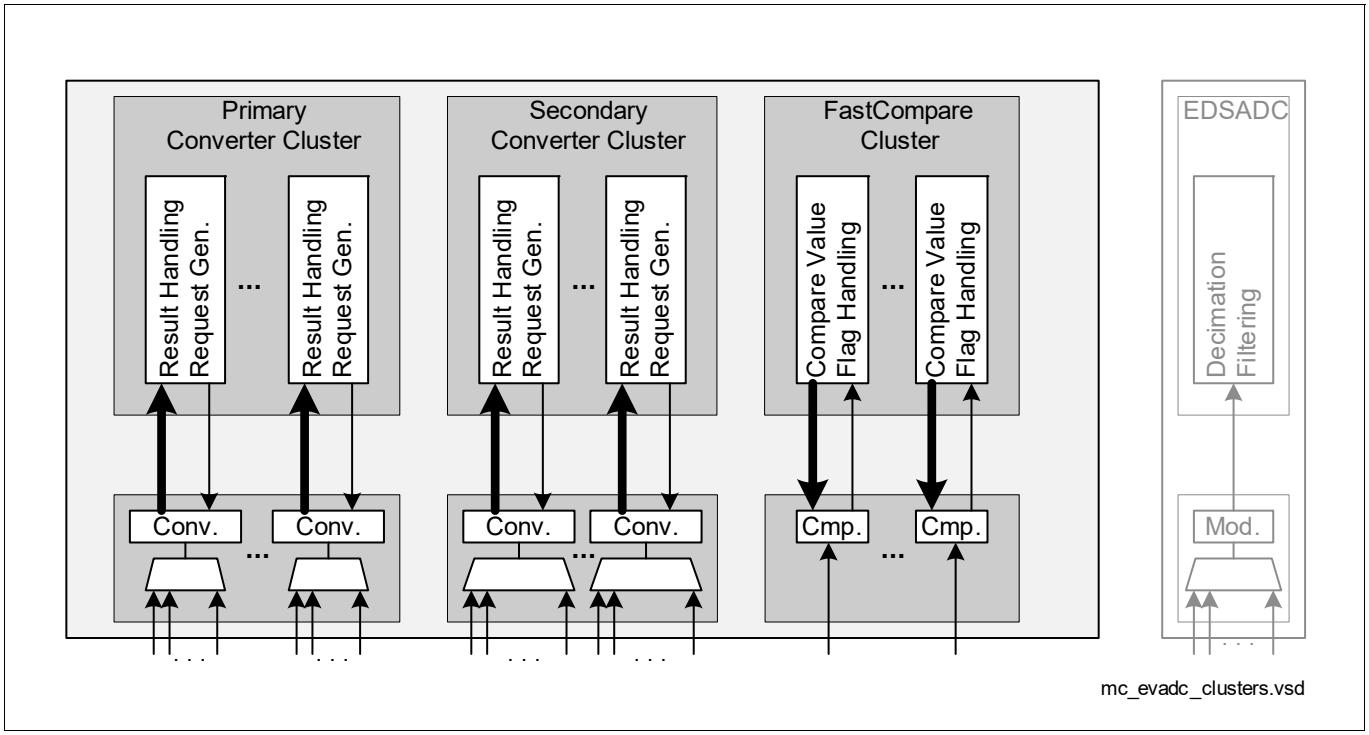

Figure 239 Summary of Clusters

1) Refer to **"Conversion Timing" on Page 86**.

32.1 Feature List

The following features describe the functionality of the ADC clusters:

- Nominal analog supply voltage 5.0 V or 3.3 V
- Input voltage range from 0 V up to analog supply voltage
- Standard (V_{AREF}) and alternate (CH0) reference voltage source selectable for each channel to support ratiometric measurements and different signal scales
- Several independent converters with up to 8/16 analog input channels each
- External analog multiplexer control, including adjusted sample time and scan support
- Conversion speed and sample time adjustable to adapt to sensors and reference
- Conversion time below 0.5 µs for primary channels (depending on sample time, refer to **Section 32.9**)
- Flexible source selection and arbitration
  - Programmable arbitrary conversion sequence (single or repeated)
  - Request source chaining to generate extended conversion sequences
  - Conversions triggered by software, timer events, or external events
  - Cancel-inject-restart mode for reduced conversion delay on priority channels
- Powerful result handling
  - Independent result registers
  - Configurable limit checking against programmable border values
  - Storage of maximum/minimum value
  - Data rate reduction through adding a selectable number of conversion results
  - FIR/IIR filter with selectable coefficients
- Fast Compare Channels with above 5 Msamples/s (refer to **Section 32.9**)
  - Automatic handling of flags and output signals
  - Compare value adjustable via software, via conversion channel or via ramp
- Flexible service request generation based on selectable events
- Built-in safety features
  - Configurable register access protection supports safety applications
  - Broken wire detection
  - Multiplexer test mode to verify signal path integrity
  - Automatic execution of test sequences
- Support of suspend and power saving modes

32.2 Overview

The Enhanced Versatile Analog to Digital Converter module (EVADC) comprises a set of converter blocks that can be operated either independent from each other, sequentially chained for longer conversion sequences, or synchronized for parallel conversion of up to 4 channels.

You will find the following major sections within this chapter:

Attention: This chapter describes the EVADC of the TC3XX family, encompassing the features and functions of all family members.
The specific characteristics of a product are described in the product-specific appendix, which specifies deviations (e.g. downgrades, etc.) from this family documentation.

Table 245 Abbreviations used in EVADC

Abbreviation	Meaning
ADC	Analog to Digital Converter
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
EDSADC	Enhanced Delta-Sigma (conversion principle) Analog to Digital Converter
HDI	Hardware Data Interface
INL	Integral Non-Linearity (error)
LSB_n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)
SCU	System Control Unit of the device
TUE	Total Unadjusted Error

The EVADC is connected to other on-chip modules to support functions on system level (see **Figure 242**).

Each converter block is equipped with a dedicated input multiplexer and dedicated request sources (except for fast compare channels), which together build separate groups, each assigned to a kernel (see **Figure 239**).

Primary groupsprovide 8:1 input multiplexers and deliver the minimum conversion time of approx. 0.5 µs (refer to **Section 32.9**)

Secondary groupsprovide 16:1 input multiplexers and require a higher sample time leading to an increased conversion time.

Fast compare channelsprovide one dedicated input channel each and deliver a compare time of approx. 200 ns.

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

A set of functional units (described further down in this section) can be configured according to the requirements of a given application. These units build a path from the input signals to the digital results.

Each kernel provides a dedicated Sample&Hold unit connected to the input multiplexer and to the converter itself.

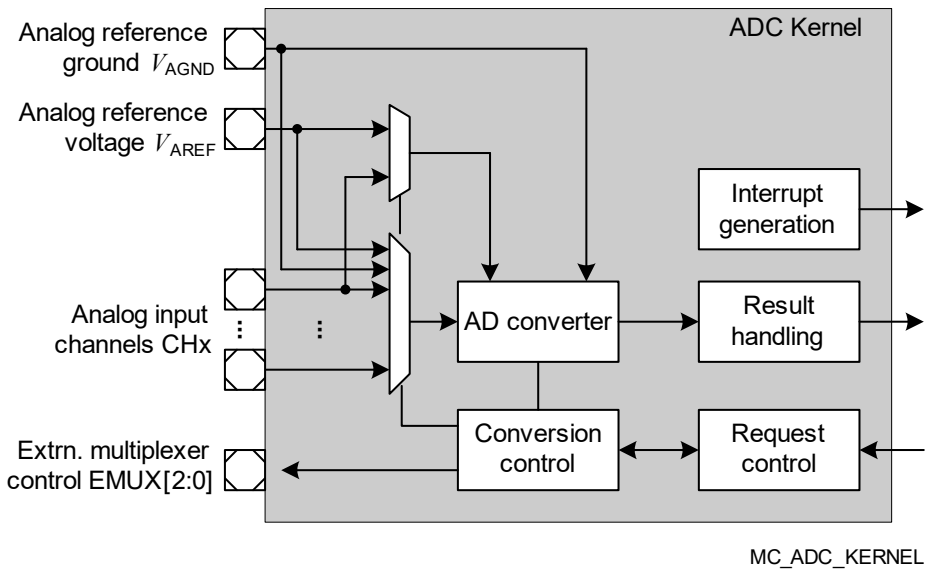

Figure 240 ADC Kernel Block Diagram

The basic module clock f_{ADC} is connected to the peripheral clock signal (see also **"General Clocking Scheme and Control" on Page 18**).

Conversion Modes and Request Sources

Analog/Digital conversions can be requested by three request sources and can be executed in several conversion modes. The request sources can be enabled concurrently with configurable priorities.

- **Fixed Channel Conversion (single or continuous)**A request source requests conversions of one selectable channel (once or repeatedly)
- **Channel Sequence Conversion (single or continuous)**A request source requests a sequence of conversions of up to 8/16 (primary/secondary groups) arbitrarily selectable channels (once or repeatedly)

Note: Extended sequences (more than 8/16 conversions) can be executed by linking several request sources together.

The conversion modes can be used concurrently by the available request sources, i.e. conversions in different modes can be enabled at the same time. Each source can be enabled separately and can be triggered by external events, such as edges of PWM or timer signals, or pin transitions.

Request Source Control

Because all request sources can be enabled at the same time, an arbiter resolves concurrent conversion requests from different sources. Each source can be triggered by external signals, by on-chip signals, or by software. The internal request source timer can request the individual conversions of a configured sequence with a programmable delay.

Requests with higher priority can either cancel a running lower-priority conversion (cancel-inject-repeat mode) or be converted immediately after the currently running conversion (wait-for-start mode). If the target result register has not been read, a conversion can be deferred (wait-for-read mode).

Certain channels can also be synchronized with other ADC kernels, so several signals can be converted in parallel.

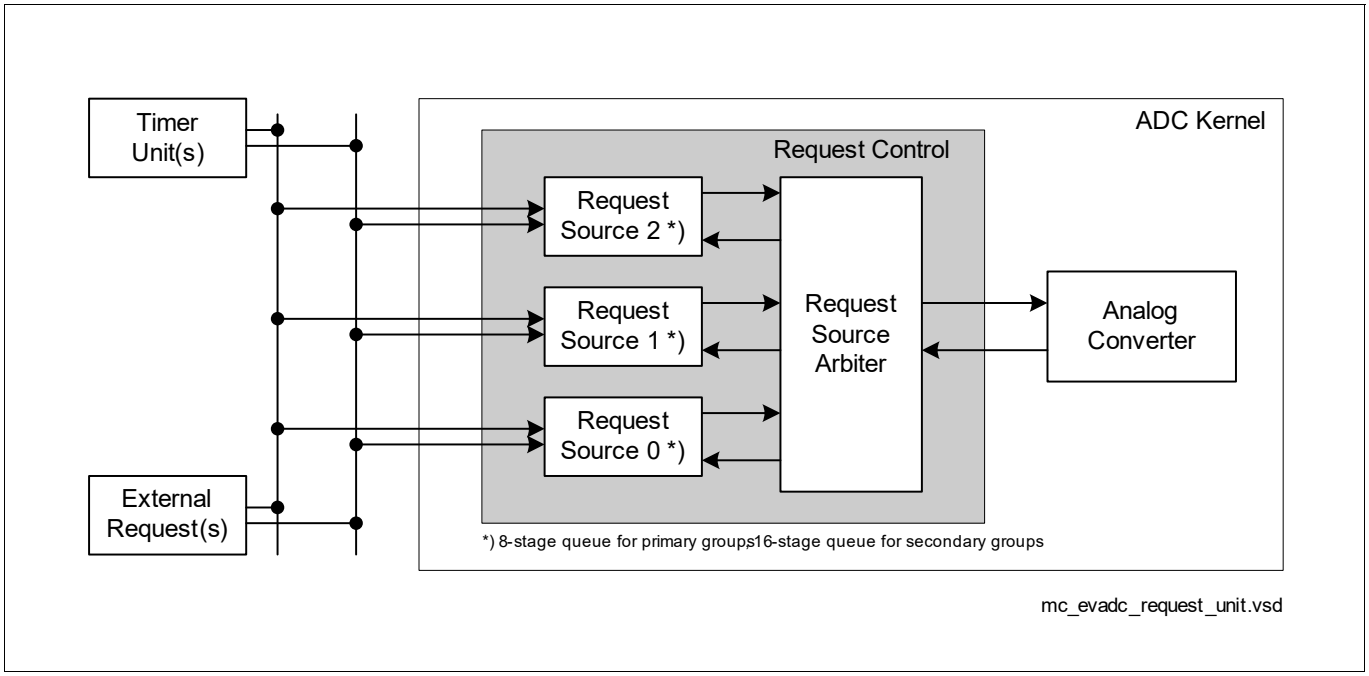

Figure 241 Conversion Request Unit

Input Channel Selection

The analog input multiplexer selects one of the available analog inputs (CH0 - CHx[1)]) to be converted. Three sources can select a linear sequence, an arbitrary sequence, or a specific channel. The priorities of these sources can be configured.

Additional external analog multiplexers can be controlled automatically, if more separate input channels are required than are built in (see **Section 32.13**).

Note: Not all analog input channels are necessarily available in all packages, due to pin limitations. Refer to the implementation description in the product-specific appendix.

Conversion Control

Conversion parameters, such as sample phase duration or conversion mode (noise reduction) can be configured for 4 input classes (2 group-specific classes, 2 global classes). Each channel can be individually assigned to one of these input classes.

Each channel can select either the standard reference voltage or the alternate reference voltage (restrictions see product-specific appendix).

The input channels can, thus, be adjusted to the type of sensor (or other analog sources) connected to the ADC.

This unit also controls the built-in multiplexer and external analog multiplexers, if selected.

Analog/Digital Converter

The selected input channel is converted to a digital value by first sampling the voltage on the selected input and then generating the result bits.

The sample&hold unit of a group is connected to an SAR converter. This converter generates the digital result values for the sampled signal.

Safety features (see **Section 32.12**) help to ensure the plausibility and correctness of the generated result values.

Result Handling

The conversion results of each analog input channel can be directed to one of 16 group-specific result registers and one global result register to be stored there. A result register can be used by a group of channels or by a single channel.

The wait-for-read mode avoids data loss due to result overwrite by blocking a conversion until the previous result has been read.

Data reduction (e.g. for digital anti-aliasing filtering) can automatically add up to 16 conversion results before issuing a service request.

Alternatively, an FIR or IIR filter can be enabled that preprocesses the conversion results before sending them to the result register (available for 2 registers).

Also, result registers can be concatenated to build FIFO structures that store a number of conversion results without overwriting previous data. This increases the allowed CPU latency for retrieving conversion data from the ADC.

The minimum value or maximum value of a sequence of conversions can be determined and stored automatically while the results are being generated.

1) The availablity of input channels depends on the package of the used product type. A summary can be found in the product-specific appendix.

Service Request Generation

Several ADC events can issue service requests to CPU or DMA:

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Channel events** indicate the completion of a conversion for a certain channel. This can be combined with limit checking, so interrupts are generated only if the result is within a defined range of values.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of eight service request nodes. This allows grouping the requests according to the requirements of the application.

Safety Features

Safety-aware applications are supported with mechanisms that help to ensure the integrity of a signal path.

Broken-wire-detection (BWD) discharges the converter network before sampling the input channel. The result will then reflect a reduced value if the input signal is no more connected. If buffer capacitors are used, a certain number of conversions may be required to reach the failure indication level.

Pull Down Diagnostics (PDD) connects an additional strong pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper connection of a signal source (sensor) to the multiplexer.

Multiplexer Diagnostics (MD) connects a weak pull-up or pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper operation of the multiplexer.

Converter Diagnostics (CD) connects an alternate signal to the converter. A subsequent conversion can then confirm the proper operation of the converter.

Fast Compare Channels

Applications that do not require the exact conversion result but just an indication if the input signal is above/below a given threshold (e.g. peak-and-hold operation) are supported by dedicated fast compare channels. A comparison takes approx. 200 ns. The results can control output signal via boundary flags.

The compare reference value can be written by software, can be generated by a ramp generator, or can be provided by another analog input channel.

System Integration and Communication

Besides the connection to the peripheral bus, the EVADC is directly connected to other hardware modules of the AURIX™ TC3xx Platform. **Figure 242** shows an overview of these interconnections. More detailed information can be found within the family documentation of the EVADC as well as of the connected modules.

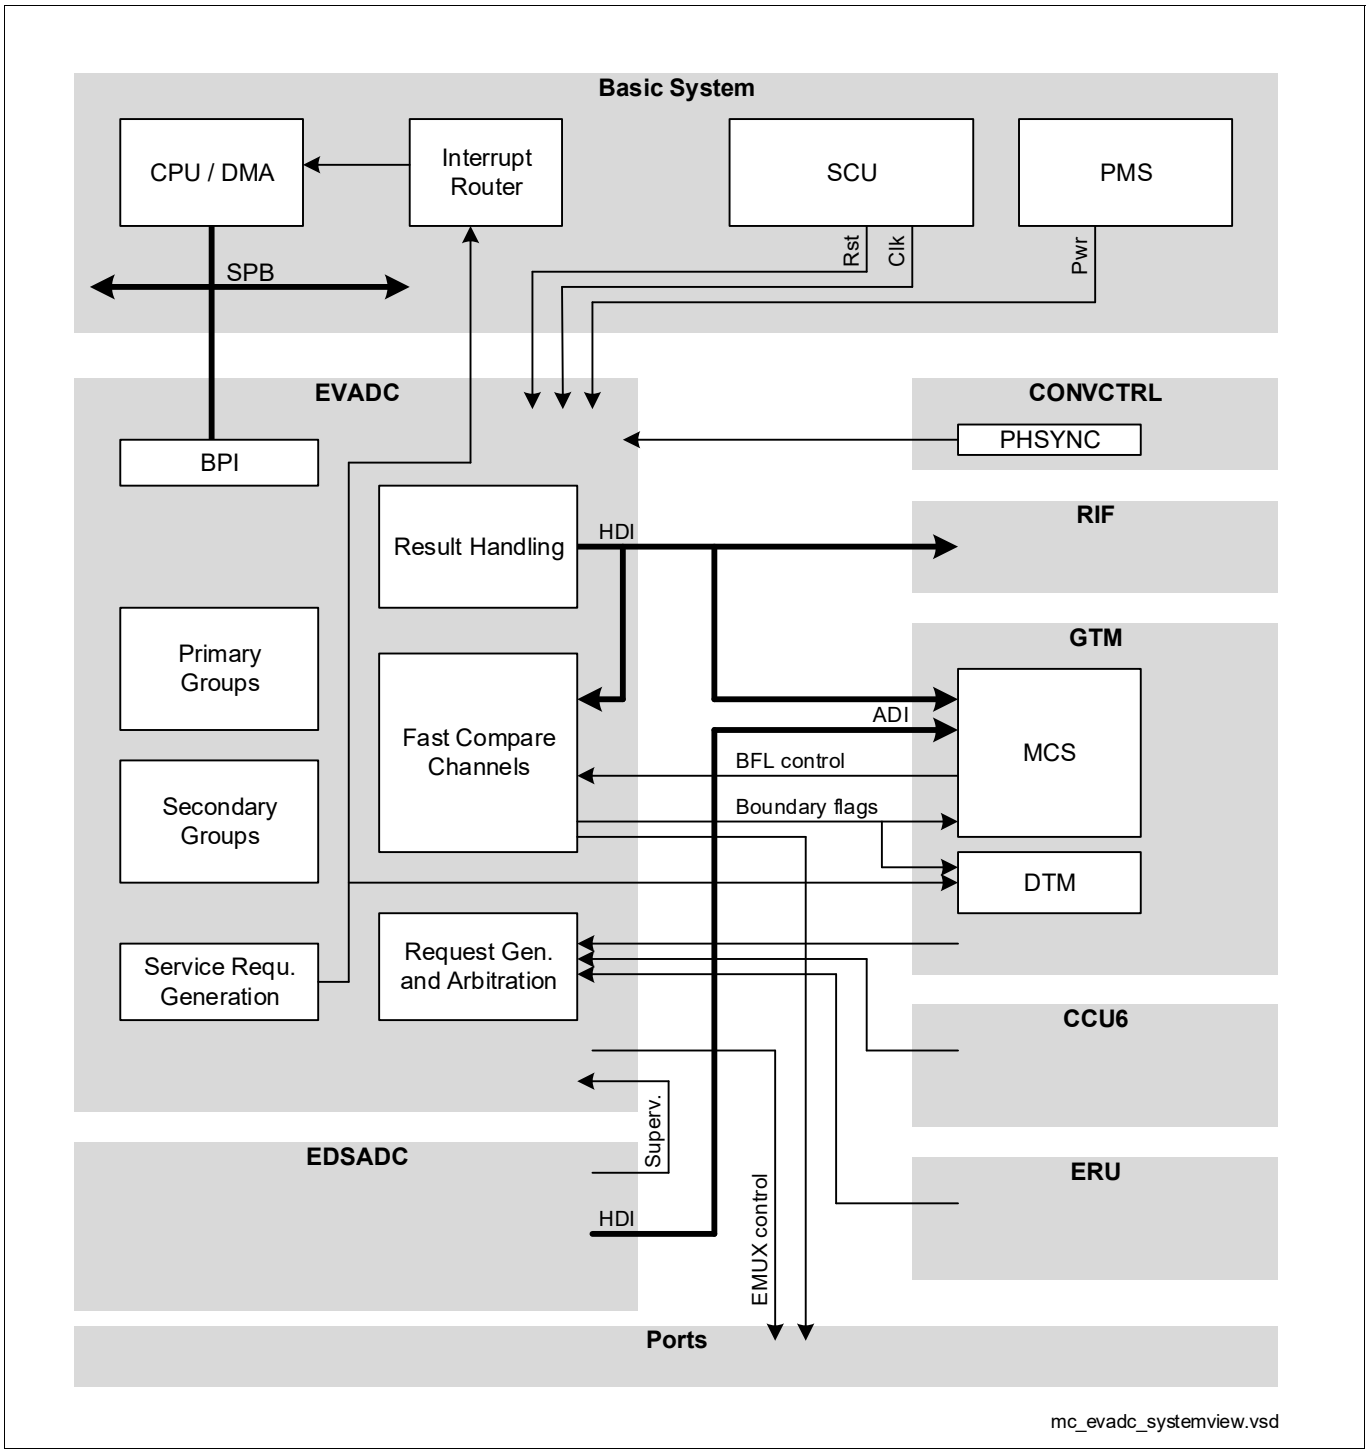

Figure 242 Direct System Interconnections

32.3 Configuration of General Functions

Several parameters can be configured individually for each channel, source, or group, or are valid for all ADC clusters. These parameters adapt the functionality of the EVADC to the requirements of the actual application (see **Section 32.3.5**).

32.3.1 Changing the Configuration

The configuration bitfields control the operation of the functional blocks of the EVADC. To ensure proper operation and interaction of these functional blocks, it is recommended to change the configuration parameters of a converter group only while this group's converter is inactive.
This means: ANONS = 00_B for primary/secondary groups, ANON = 0_B for fast compare channels.

After reset, this is the default state. When changing the configuration during run-time, be aware of the respective implications listed in the table below.

Table 246 Implications When Changing the Configuration

Configuration	Implication
Channel properties (GxCHCTRy, GxICLASSi, GLOBICLASSi, GxALIAS)	These properties are used for the next conversion to be started, so the setup may be inconsistent. Only change the configuration when no conversions for the respective channel are scheduled.
Service request node pointers (GxSEVNP, GxCEVNPi, GxREVNPi, GLOBEVNP)	The association of an event to a service request output may be unclear. Make sure no events are generated while switching pointers.
Boundary values (GxBOUND, GLOBBOUND)	The association of a limit band to a conversion result may be unclear. Only change limits while the corresponding result is not being generated.
Fast compare channels (FCzFCM, FCzFCHYST, FCzFCCTRL, FCzFCBFL except for BFS)	Since compare operations in most cases are triggered constantly, changing the configuration on the fly may lead to unintended intermediate states, e.g. wrong compare levels or missed output signals. It is recommended to stop the channel during reconfiguration.
Analog control (GxANCFG)	May corrupt the current conversion leading to wrong results. Only change while no conversions are running.
Basic configuration (GLOBCFG)	Changing basic configuration parameters during operation may lead to malfunctions or deadlocks. Only change the configuration while all groups are switched off.
Arbiter configuration (GxARBPR)	Changing priorities etc. during operation may lead to unintended conversion sequences. Only change the configuration of inactive request queues.
Request source control (GxQCTRLi, GxQMRi, GxREQTMi GxTRCTR except for COV)	Modifying source and mode of trigger signals may generate unintended trigger events. Only change the configuration while the request queue is inactive.
Result generation (GxRCRy, GLOBRCR)	The result generation properties control how new results are evaluated. A changed configuration may need some time to become effective. Only change the configuration of registers that are currently not targeted by the application.

Table 246 Implications When Changing the Configuration (cont'd)

Configuration	Implication
External multiplexer control (GxEMUXCTR, GxEMUXCS, EMUXSEL)	Modifications during operation may lead to inconsistent conversion sequences or intermediate transitions in the control of external multiplexers. Only change while the respective group is inactive. Exception: subchannel update in steady mode. Only change EMUXSEL while all groups are inactive.
Synchronous conversions GxSYNCTR	Changing the configuration of a synchronization group may lead to inconsistent settings within such a group. Only change the setup of a synchronization group while all involved converter groups are inactive.

32.3.2 Register Access Notes

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions.

No problem exists when using direct write instructions (e.g. ST.W).

This affects the bits in register GxVFR which are cleared by writing 1s.

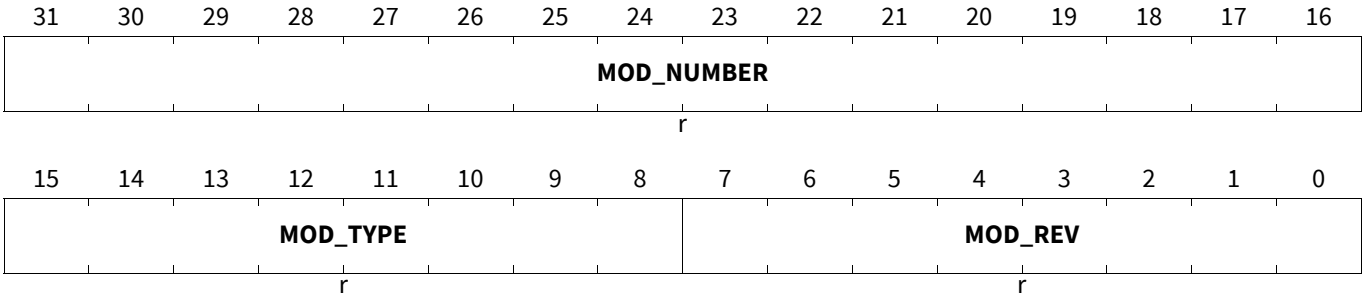
Also the events flags are affected (registers GxSEFLAG, GxCEFLAG, GxREFLAG, GLOBEFLAG) when trying to trigger an event via software while the corresponding bit is set.

32.3.3 Module Identification

The module identification register indicates the version of the EVADC module that is used in this product.

Module Identification Register

ID
Module Identification Register (0008$_H$) PowerOn Reset Value: 00C5 C013$_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to C0$_H$.
MOD_NUMBER	31:16	r	**Module Number** Indicates the module identification number (00C5$_H$ = SARADC).

32.3.4 System Registers

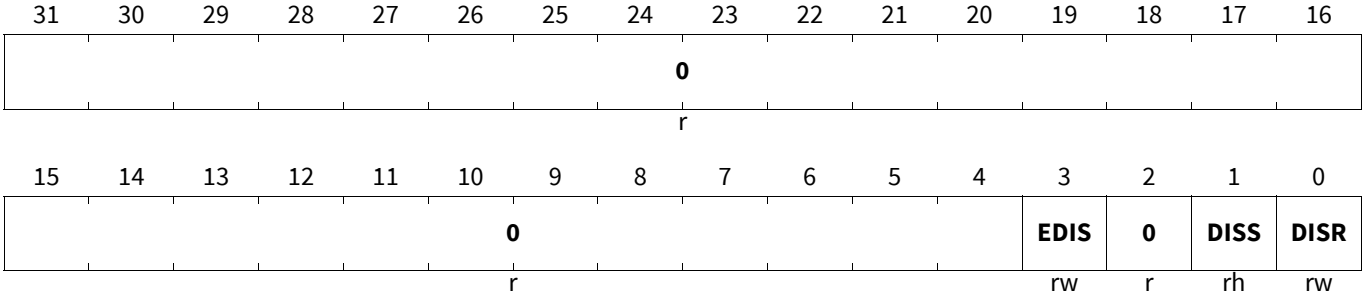
A set of standardized registers provides general access to the module and controls basic system functions.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC
Clock Control Register **(0000_H)** **Application Reset Value: 0000 0003_H**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Also the analog section is disabled by clearing ANONS. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked f_{SPB} and f_{ADC} are disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved, write 0**

It is recommended not to write to or read from module registers (except CLC) while the module is disabled. Write operations will generate a bus error.

When the module is disabled (DISR = 1_B) while in suspend state, the corresponding status bit (DISS = 1_B) will only be set after several clock cycles. To generate them, writes to CLC need to be repeated. See OCS note on **Page 14**.

To avoid unnecessary current consumption, it is recommended to disable the analog parts before disabling the module (GxARBCFG.ANONC = 00_B, GxANCFG.BE = 0_B or FCyFCM.ANON = 0_B).

OCDS Control and Status Register

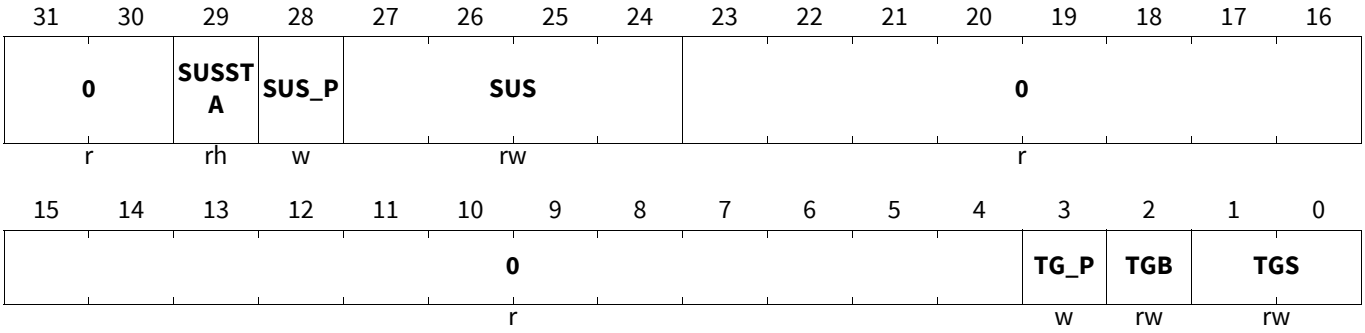
The OCDS Control and Status register OCS controls the module's behavior in suspend mode (used for debugging).

Register OCS is cleared by Debug Reset. It can only be written when OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS

OCDS Control and Status Register **(0028_H)** **Reset Value: Table 248**



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B Trigger Set 1 TS16_SSIGC, input sample signals of primary/secondary groups 10_B Trigger Set 2 TS16_SSIGF, input sample signals of fast compare channels 11_B Reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend: Clocks f_{SPB} and f_{ADC} are switched off immediately. 2_H Soft suspend mode Stop conversions after the currently running one is completed and its result has been stored. The arbiter does not request a subsequent conversion.
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved, write 0, read as 0**

Table 247 Access Mode Restrictions of OCS sorted by descending priority

Mode Name	Access Mode		Description
write 1 to **TG_P**	rw	TGB, TGS	Set TG_P during write access
write 1 to **SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS, TGB, TGS

Reset Type	Reset Value	Note
PowerOn Reset	0000 0000_H	
Debug Reset	0000 0000_H	

Table 249 TS16_SSIGC Trigger Set EVADC

Bits	Name	Description
[11:0]	GxSAMPLE	Input signal sample phase of converter group x (x = 11-0)
[15:12]	0	Reserved

Table 250 TS16_SSIGF Trigger Set EVADC

Bits	Name	Description
[7:0]	FCxSAMPLE	Input signal sample phase of fast compare channel x (x = 7-0)
[15:8]	0	Reserved

*Note: During write access in hard suspend state the clocks are activated for a few cycles to accomplish the access. To prevent state machines from advancing due to this, it is recommended to stop the respective converter by clearing bitfield ANONC = 00_B in register **GxARBCFG (x=0-11)**.*

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on-chip bus master TAG IDs 00 0000_B to 01 1111_B (see On-Chip Bus chapter for the mapping of product TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding. Register ACCEN0 itself is protected by the Safety Endinit feature.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00 0000_B, EN1 -> TAG ID 00 0001_B , ... , EN31 -> TAG ID 01 1111_B (TAG IDs 1X $XXXX_B$ are not used).

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. Kernel Reset Registers 0 and 1 each include bit RST. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

A module kernel reset has the following effects:

Table 251 Effects of a Module Kernel Reset

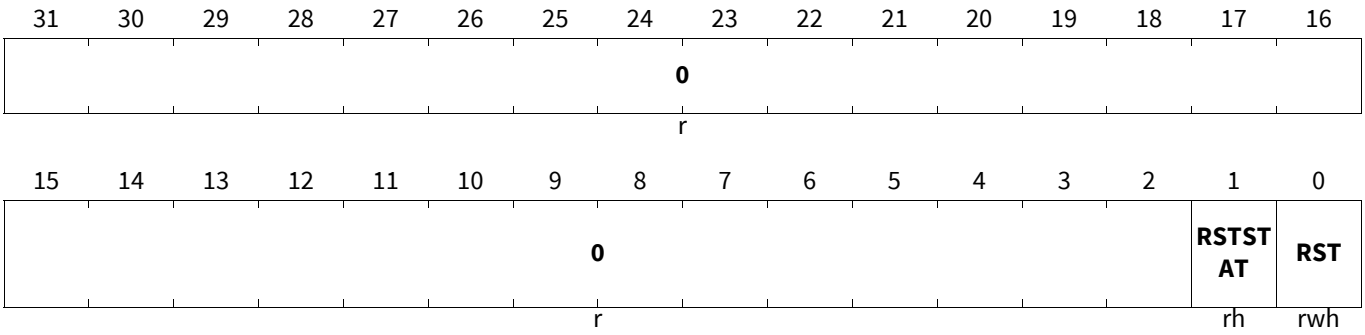
Register	Executed Action
CLC, OCS, ACCEN0	No influence
ID	No influence
KRST0	Bit RST is cleared automatically after reset execution, RSTSTAT indicates a module kernel reset, cleared via KRSTCLR
KRST1	Bit RST is cleared automatically after reset execution
KRSTCLR	No influence
Other registers	Reset to their defined reset values

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Kernel Reset Register 0

KRST0

Kernel Reset Register 0 (0034_H) Application Reset Value: $0000\ 0000_H$

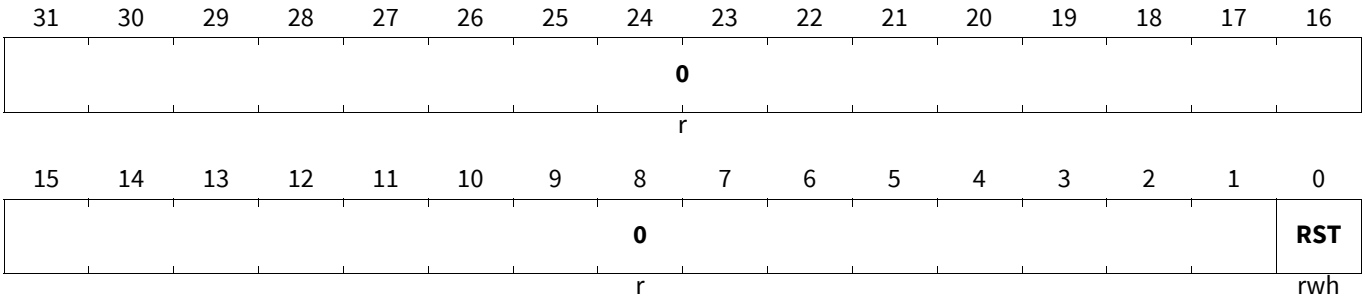


Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. RST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** Indicates an executed kernel reset. RSTSTAT is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear RSTSTAT by setting bit CLR in register KRSTCLR. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved, write 0, read as 0**

Kernel Reset Register 1

KRST1

Kernel Reset Register 1 (0030_H) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. RST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
0	31:1	r	**Reserved, write 0, read as 0**

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (RSTSTAT).

32.3.5 General Clocking Scheme and Control

The EVADC is operated with the peripheral clock signal (f_{ADC}). This clock signal controls all functions of all logic blocks and determines the overall timing. The converters are operated with the analog clock f_{ADCI} (see figure below). The analog clock is based on the analog phase synchronizer. The phase synchronizer defines the initial clock pulse for a conversion. This minimizes disturbances in the analog system. The started conversion is then executed without referring to the phase synchronizer. This ensures deterministic behavior of converters that shall operate in parallel.

*Note: The EVADC evaluates the level of the phase synchronizer signal. In synchronized mode, it will operate while the phase synchronizer signal is high. In unsynchronized mode (**GLOBCFG**.USC = 1), conversions are started independent of the phase synchronizer signal.*
For proper operation, only change the configuration of the phase synchronizer while the converters are idle.

The bus interface is clocked with the system clock f_{SPB}.

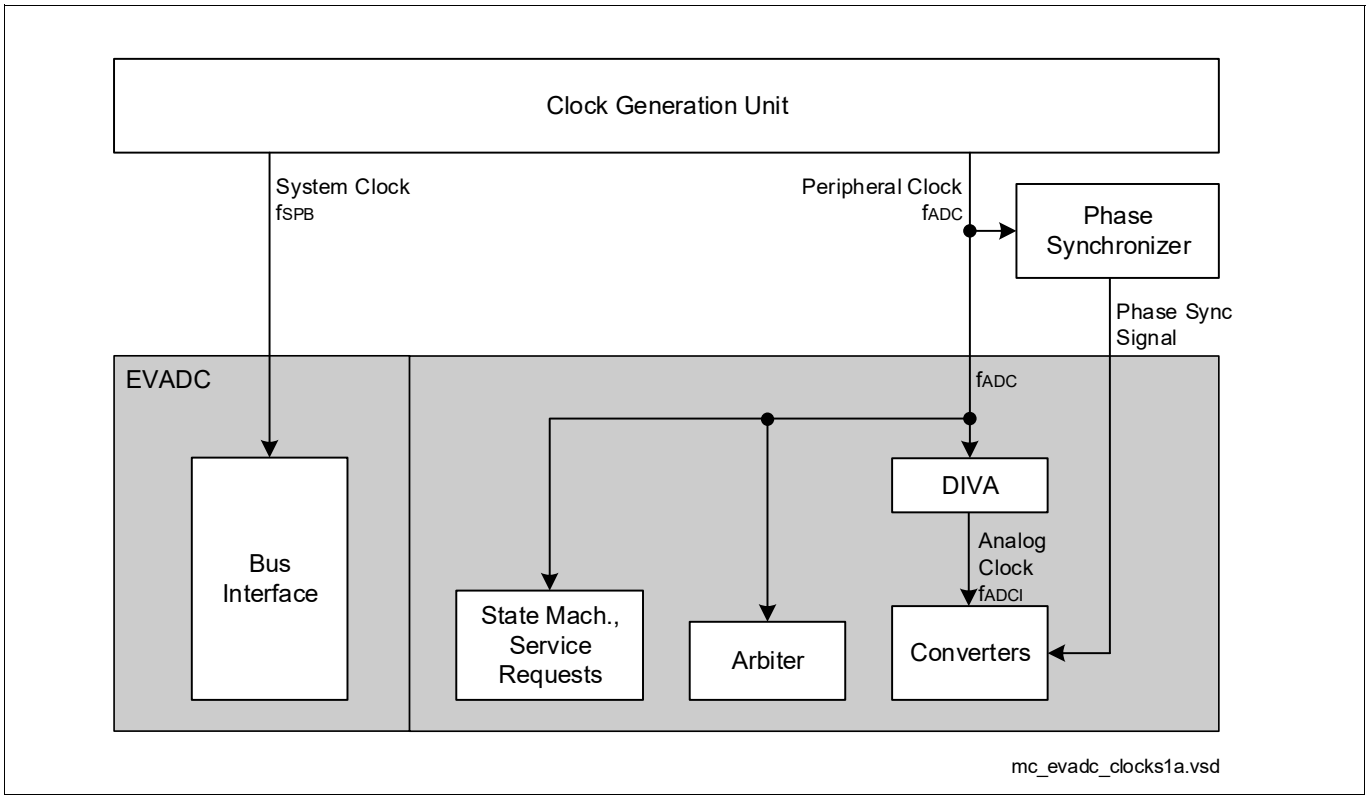

Figure 243 Clock Signal Summary

Attention: To ensure proper synchronization between the clock domains of the EVADC, the peripheral clock must never be slower than the bus clock, i.e. $f_{ADC} >= f_{SPB}$.

Global Configuration

The global configuration register GLOBCFG provides global control and configuration options that are valid for all converters.

Global Configuration Register

GLOBCFG
Global Configuration Register **(0080_H)** **Application Reset Value: $0000\ 0000_H$**

Mode Name	Access Mode		Description
write 1 to **CPWC**	rw	SUPLEV, USC	Set CPWC during write access
(default)	r	SUPLEV, USC	

32.3.6 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the EVADC.

- The registers of the EVADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Registers ACCPROT0/1/2 allow the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. **Table 253** lists the registers that belong to each register group.
  Registers ACCPROT0/1/2 themselves are protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

Access Protection Register 0

Controls write access to initialization registers and channel control registers.

The register below shows the maximum configuration. Other products of the family may have less groups and, consequently, less valid APxx control bits.

ACCPROT0
Access Protection Register 0 **(0088_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

APTF	GLOBTF, GLOBTE	Test functions

32.4 Analog Module Activation and Control

The analog converter of the EVADC is the functional block that generates the digital result values from the selected input voltage. It draws a permanent current during its operation and can be deactivated between conversions to reduce the consumed overall energy.

Note: After reset the analog converters are off. They must be enabled before triggering any action involving a converter.

The accuracy of the conversions is established by executing the start-up calibration (**"Calibration" on Page 25**).

32.4.1 Analog Converter Control

If an application does not require permanent activity of a converter, it can disable this converter intermittently to save energy. This can be done under software control or automatically.

The operating mode is determined by bitfield **GxARBCFG (x=0-11)**.ANONS:

- ANONS = 11_B: **Normal Operation**The converter is active, conversions are started immediately.
  Requires no wakeup time after initial settling (see note below).
- ANONS = 10_B: **Fast Standby mode**The converter enters a power reduction mode while no activity is required. It automatically returns to operation mode while conversions are requested. Fast standby mode reduces the overall power consumption for the ADC supply.
  Requires the standard wakeup time (see below).
- ANONS = 01_B: **Slow Standby mode**The converter enters a power save mode while no activity is required. It automatically returns to operation mode while conversions are requested. Slow standby mode enables the lowest overall power consumption for the ADC supply.
  Requires the extended wakeup time (see below).
- ANONS = 00_B: **Converter switched Off** (default after reset)
  The converter itself is switched off. Furthermore, digital logic blocks are set to their initial state.
  Before starting a conversion, select the active mode for ANONS.
  Requires the extended wakeup time (see below).

Wakeup Time from Analog Powerdown

When the converter is activated, it needs a certain wakeup time (depending on the operating mode) to settle before a conversion can be properly executed. This wakeup time can be established by adding it to the intended sample time.

The standard wakeup time is approximately 1 µs,
the extended wakeup time is approximately 5 µs.
Exact numbers can be found in the respective Data Sheets.

Note: The extended wakeup time is also required after initially enabling the converter.

32.4.2 Analog Signal Buffering

During operation, the converter capacitance must be charged and discharged several times. During the sampling phase it is charged from the selected signal input, during the conversion phase it is charged from the selected reference.

Both phases are supported by unloading the respective analog input by drawing a part of the required charge from the supply voltage.

Buffer for the Analog Input

The analog input buffer boosts the selected analog input signal for a certain time, when enabled. The time during which the input buffer is active can be adapted to the configured sample time by bitfields AIPS/AIPE in register **GxICLASSi (i=0-1;x=0-11)** / **GLOBICLASSi (i=0-1)**, or by bitfield AIPF in register **FCxFCCTRL (x=0-7)**. The input precharge time can be configured to 8, 16, or 32 clocks of f_{ADC}.

After the programmed buffer time the sampling is continued directly from the selected input. The remaining direct sampling time must cover the specified minimum sample time (Data Sheet), i.e. the programmed sample time must cover both phases, buffered sampling and direct sampling. Sample times specified in the data sheet consider a buffered sample time of 200 ns that means the input precharge time has to be configured to 32 clocks of f_{ADC}. For input precharge times lower than 200 ns, the charge consumption from the analog input is increased accordingly.

When the analog input buffer is activated (BE = 1 in register **GxANCFG (x=0-11)**), it needs a certain setup time to settle before a conversion can be properly executed.

The input buffer setup time is approximately 1 µs.
Exact numbers can be found in the respective Data Sheets.

Precharge for the Reference Input

The precharge feature charges the capacitor during conversion for a certain time, when enabled. After that, the capacitor is connected to the selected reference voltage to achieve maximum precision. This reduces the charge that is drawn from the reference (values see Data Sheet).

Reference precharging is controlled by bit RPE = 1 in register **GxANCFG (x=0-11)** or **FCxFCCTRL (x=0-7)**. Clearing bit RPE disables reference precharging. After reset, precharging is enabled.

32.4.3 Alternate Reference Selection

The EVADC control features allow selecting an alternate reference for each channel. This reference signal is taken from channel 0 of a group. The reference source is selected by bit REFSEL in the channel control registers and, therefore, can be configured for each input separately.

32.4.4 Calibration

Calibration automatically compensates deviations caused by process variation and aging. This ensures precise results throughout the operation time.

An initial start-up calibration is required once after a reset for all enabled converters (except for fast compare channels). All converters must be enabled (ANONS = 11_B). The start-up calibration is initiated globally by writing 1 to bit SUCAL in register GLOBCFG.

The duration of the start-up calibration phase depends on the programming, refer to **“Conversion Timing” on Page 86**.

Attention: During the start-up calibration, all converters must be inactive. After reset this is the case anyway. Only start conversions after the calibration has completed (indicated by bit CAL = 0).

After that, calibration cycles can compensate the effects of drifting external parameters, if not disabled. The converter itself requires no further calibration.

Postcalibration steps can be appended to each conversion. Since variation caused by aging is very slow and postcalibration leaves the capacitor discharged, for the current version of the converter postcalibration shall be disabled (most applications are restarted periodically and, therefore, also repeat the start-up calibration).

This also provides the highest conversion rate (refer to **Table 259 “Conversion Timing Overview” on Page 88**).

32.4.5 Noise Reduction Methods

Analog input signals almost always contain a certain amount of noise. This may be generated within the sensor itself or may be added along the signal path to the converter input.

Because the analog-digital converters are integrated into a microcontroller, also some noise generated by the digital blocks of the microcontroller may influence the operation of the converters.

The EVADC provides several means to attenuate the noise components that influence its operation and performance.

Noise-Reduction Conversions

Conversions can be extended by a selectable number of additional steps (1, 3, 7) to refine the generated result value. The noise reduction level is configured by bitfields CMS/CME in register **GxICLASSi (i=0-1;x=0-11)** etc. The influence on the conversion timing is described in **“Standard Converter Channels Timing” on Page 87**.

Spread Early Sample Point

Other than statistical noise, synchronous noise cannot be eliminated by oversampling. The spread early sample point feature attenuates synchronous noise by moving the end of the sample phase in pseudo random steps. The spread early sample point feature is enabled by bits SESPS/SESPE in register **GxICLASSi (i=0-1;x=0-11)** etc. When this feature is enabled, the sample phase is randomly shortened by up to 100 ns. This must be respected when configuring the duration of the sample time.

Accumulated Conversions

Accumulation adds 2 … 16 conversion results to support the calculation of average values. The predefined number of values is automatically accumulated and service requests are generated only after a completed accumulation.

More details are described in **“Data Modification” on Page 101**.

Mutual Interference of Converters

Since all converters use the common reference voltage V_{AREF} (except for the alternate reference), the converters can disturb each other. This can be avoided by synchronizing their operation. The phase synchronizer does this while bit USC = 0 in register **GLOBCFG** (default after reset). In special cases a dedicated phase shift can be selected via bitfield ACSD in register **GxANCFG (x=0-11)**.

Refer also to **“Synchronous Sampling” on Page 113**.

32.4.6 Analog Module Functions

Certain operating modes that control the analog behavior are configurable for each converter separately.

Analog Fct. Config. Register, Group x

DCMSB	25	rw	**Double Clock for the MSB Conversion** Selects an additional clock cycle for the conversion step of the MSB. 0_B 1 clock cycle for the MSB (standard) 1_B 2 clock cycles for the MSB (test only)[1)]
0	15:7, 31:26	r	**Reserved, write 0, read as 0**

1) Not used for standard applications. Keep DCMSB = 0.

32.5 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests. Three request sources can generate requests for the conversion of an analog channel. The arbiter resolves concurrent requests and selects the channel to be converted next.

Upon a trigger event, the request source requests the conversion of a certain analog input channel or a sequence of channels.

- **Software triggers**directly activate the respective request source.
- **Self-timed triggers**are generated by the request timer of the respective source.
- **External triggers**synchronize the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal or from a port pin.

Application software selects the trigger type and source, the channel(s) to be converted, and the request source priority. A request source can also be activated directly by software without requiring an external trigger.

The arbiter regularly scans the request sources for pending conversion requests and selects the conversion request with the highest priority. This conversion request is then forwarded to the converter to start the sampling and conversion of the requested channel.

Each request source can operate in single-shot or in continuous mode:

- **In single-shot mode**,
  the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode**,
  the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

For each request source of a group, external triggers are generated from one of 15 selectable trigger inputs (REQTRx[O:A]) and from one of 16 selectable gating inputs (REQGTx[P:A])[1]. The available trigger signals are listed in the product-specific appendix.

Note: ***Figure 241 "Conversion Request Unit" on Page 5*** *summarizes the request sources.*

Properties of the Queued Request Source

A queued request source provides several buffer stages building a queue and can handle application-specific arbitrary conversion sequences up to the queue size.

Primary groups are equipped with 8-stage queues, secondary channels are equipped with 16-stage queues. Each queue can, therefore, handle all channels associated with the corresponding group.

The channel numbers for this sequence can be freely programmed[2]. Also, multiple conversions of the same channel within a sequence are supported. The programmed sequence is stored in a queue buffer (based on a FIFO mechanism). The requested channel numbers are entered via the queue input, while queue stage 0 defines the channel to be converted next. Each entry can be executed once or can be automatically reloaded to form continuously repeated sequences.

A conversion request is only issued to the request source arbiter if a valid entry is stored in queue stage 0.

If the arbiter aborts a conversion triggered by a queued request source due to higher priority requests, the corresponding conversion parameters are automatically saved in the backup stage. This ensures that an aborted conversion is not lost but takes part in the next arbitration step (before stage 0).

1) The selected gating input can be used as a trigger signal (REQTRxP).

2) The availablity of input channels depends on the package of the used product type. A summary can be found in the product-specific appendix.

Note: Conversion requests that are saved in the backup stage are executed as soon as their priority allows, even if the original conversion request was waiting for a trigger event.

The trigger and gating unit generates trigger events from the selected internal or external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Trigger events start a queued sequence and can be generated either via software or via the selected hardware triggers. The occurrence of a trigger event is indicated by bit QSRx.EV. This flag is cleared when the corresponding conversion is started or by writing to bit QMRx.CEV.

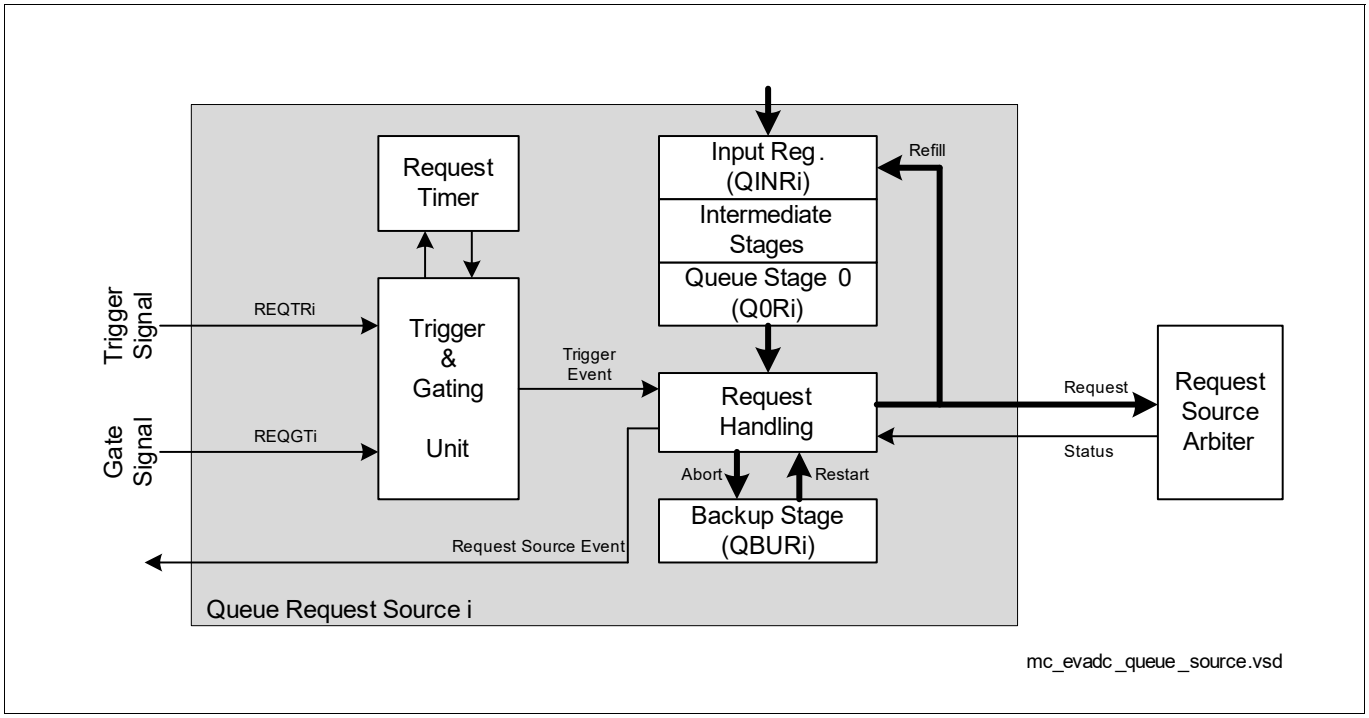

Figure 244 Queued Request Source

A sequence is defined by entering conversion requests into the queue input register (**GxQINRi (i=0-2;x=0-11)**). Each entry selects the channel to be converted and can enable an external trigger, generation of an interrupt, and an automatic refill (i.e. copy this entry to the top of the queue after conversion). The entries are stored in the queue buffer stages.

The content of stage 0 (**GxQ0Ri (i=0-2;x=0-11)**) selects the channel to be converted next. When the requested conversion is started, the contents of this queue stage is invalidated and copied to the backup stage. Then the next queue entry can be handled (if available).

Note: The contents of the queue stages cannot be modified directly, but only by writing to the queue input or by flushing the queue.
*The current status of the queue is shown in register **GxQSRi (i=0-2;x=0-11)**.*
If all queue entries have automatic refill selected, the defined conversion sequence can be repeated without re-programming.

32.5.1 Queued Source Operation

Configure the queued request source by executing the following actions:

- Define the sequence by writing the entries to the queue input **GxQINRi (i=0-2;x=0-11)**. Initialize the complete sequence before enabling the request source, because with enabled refill feature, software writes to QINRx are not allowed.
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper transitions by programming **GxQCTRLi (i=0-2;x=0-11)**.
  Enable the trigger and select the gating mode by programming bitfield ENGT in register **GxQMRi (i=0-2;x=0-11)**.[1)]
- Enable the corresponding arbiter input to accept conversion requests from the queued source (see register **GxARBPR (x=0-11)**).

Start a queued sequence by generating a trigger event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software trigger event by setting GxQMRi.TREV = 1.
- Write a new entry to the queue input of an empty queue. This leads to a (new) valid queue entry that is forwarded to queue stage 0 and starts a conversion request (if enabled by GxQMRi.ENGT and without waiting for an external trigger).

Note: If the refill mechanism is activated, a processed entry is automatically reloaded into the queue. This permanently repeats the respective sequence (autoscan).
In this case, do not write to the queue input while the queued source is running.
Write operations to a completely filled queue are ignored.

Stop or abort an ongoing queued sequence by executing one of the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the queue entries, but only prevents issuing conversion requests to the arbiter.
- Disable the corresponding arbiter input in the arbiter. This does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the queued source:
  - Prevent conversion requests to the arbiter by clearing bitfield ENGT = 00_B.
  - Invalidate the next pending queue entry by setting bit GxQMRi.CLRV = 1.
    If the backup stage contains a valid entry, this one is invalidated, otherwise stage 0 is invalidated.
  - Remove all entries from the queue by setting bit GxQMRi.FLUSH = 1.

Queue Request Source Events and Service Requests

A request source event of a queued source occurs when a conversion is finished and the request timer has expired. A source event service request can be generated based on a request source event according to the structure shown in **Figure 245**. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x=0-11)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x=0-11)**.
The interrupt enable bit is taken from stage 0 for a normal sequential conversion, or from the backup stage for a repeated conversion after an abort.

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid unexpected signal transitions.

The service request output line SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x=0-11)** becomes activated each time the related request source event is detected (and enabled by GxQ0R0.ENSI, or GxQBUR0.ENSI respectively) or the related bit position in register **GxSEFLAG (x=0-11)** is written with a 1 (this write action simulates a request source event).

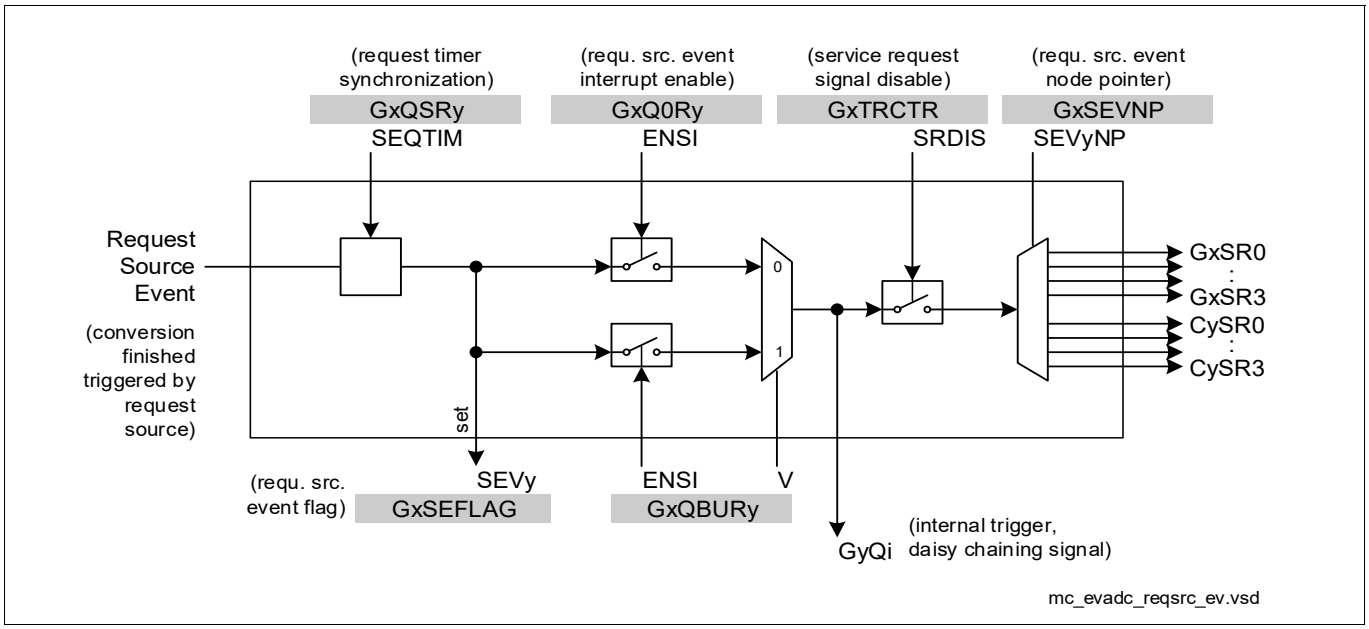

Figure 245 Interrupt Generation of a Queued Request Source

32.5.2 Triggers and Gate Signals

Each source can be started by selectable triggers and/or its operation can be externally controlled by gate signals. These trigger/gate signals can be individually selected from a set of inputs.

The actual signal sources are described in the product-specific appendix.

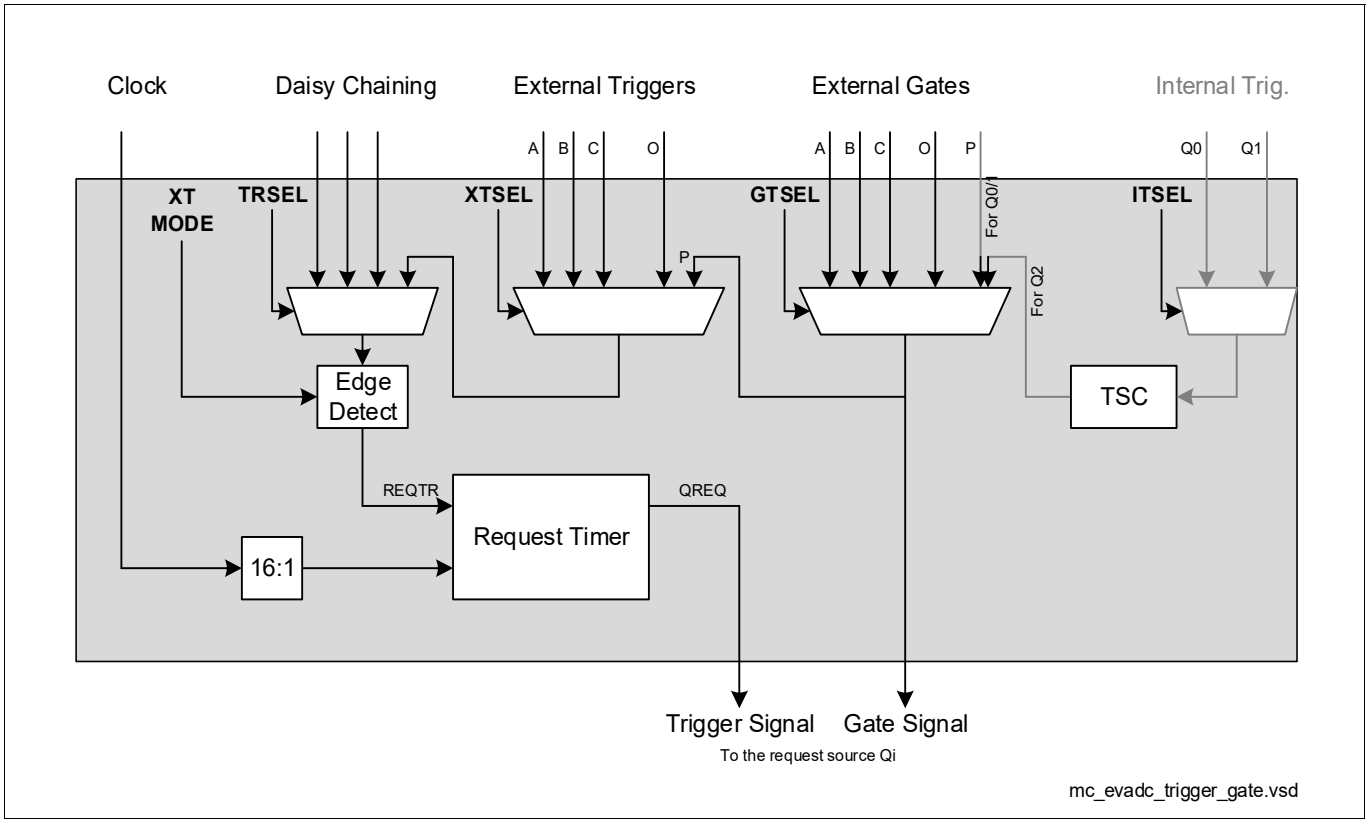

Figure 246 Trigger and Gate Inputs

Enhanced flexibility is provided by using also external gate inputs for the generation of trigger signals. An internal connection of the selected gate input to the uppermost trigger input (GxREQTRyP, XTSEL = 1111_B) provides access to the external gate inputs.

In addition, queue source Q2 can also be triggered by the other request sources of the same group. The selected internal trigger signal is internally connected to the uppermost of the Q2 external gate inputs (GxREQGT2P, GTSEL = 1111_B).

Daisy chaining connects adjacent groups for sequences comprising more than one multiplexer.
This way, extended sequences can be triggered by a single external trigger event.
See also **“Extended Conversion Sequences through Concatenation” on Page 36**.

Self-Timed Execution of Conversion Sequences

The built-in request timer can request conversions of a programmed sequence in configurable intervals. The 16:1 prescaler generates a timebase of 0.1 µs (for f_{ADC} = 160 MHz). The 10-bit timer creates intervals up to 102.4 µs.

The timer is started by a trigger event (generated by hardware or by software), it is not restarted when the queue has run empty. While the request timer is running, additional trigger inputs are ignored.

Several operating modes can be selected:

- **Pause after each conversion**After a trigger event the first conversion is immediately requested. Each subsequent conversion is requested after the request timer has counted the configured number of clock cycles.
- **Wait before first conversion**After a trigger event the request timer is started. The conversion sequence is requested after the request timer has counted the configured number of clock cycles. No further delays are generated then by the timer.
- **Wait before each conversion**After a trigger event the request timer is started. Each conversion of the sequence is requested after the request timer has counted the configured number of clock cycles.

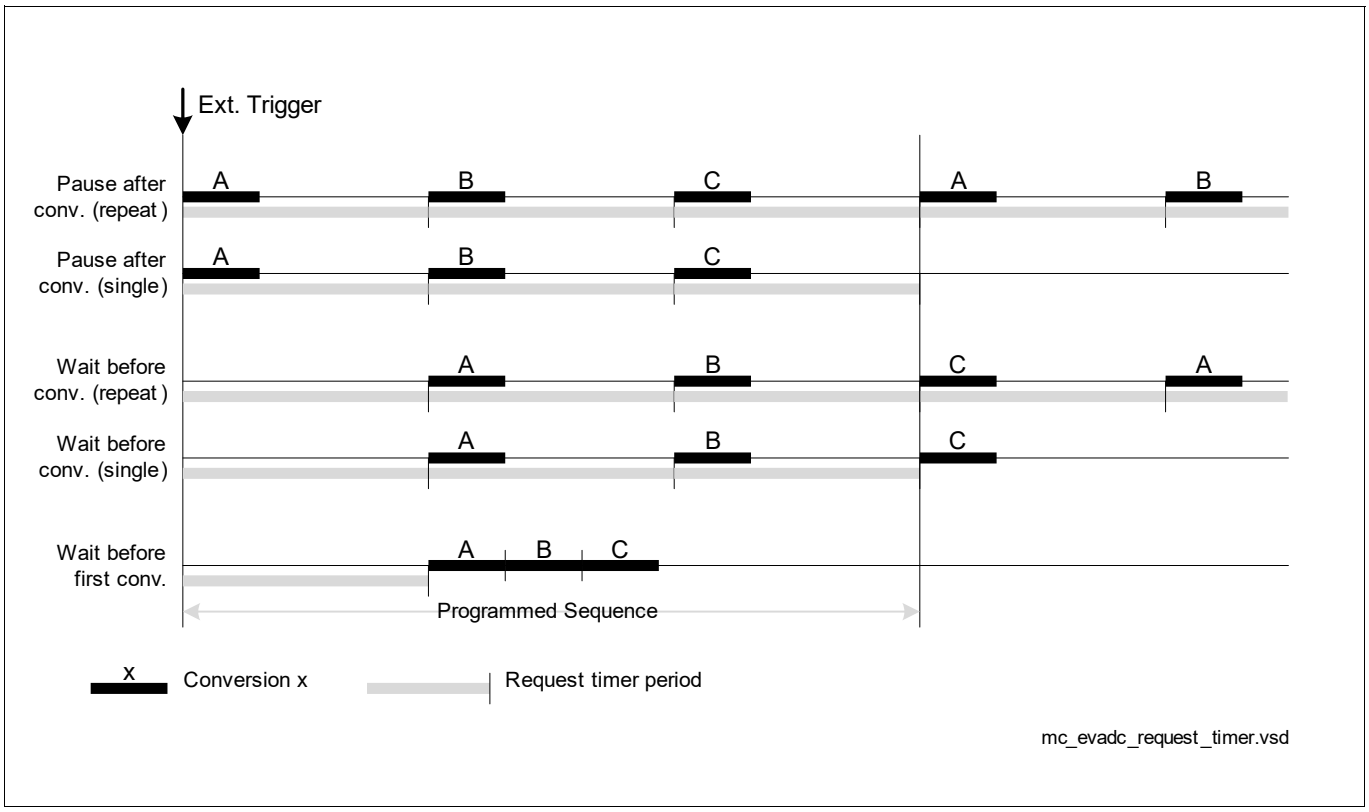

Figure 247 Request Timer Functions

Note: The request timer generates trigger signals for the request source. The conversion commands in the request source determine whether or not a conversion waits for this trigger.
*The first examples in **Figure 247** assume all commands (A, B, C) waiting for a trigger, the last example assumes waiting for a trigger for the first command (A) only.*

When the request timer is active (i.e. GxREQTMi.SEQMOD ≠ 00_B), service request signals are synchronized to the timer. A source event is only signalled at the end of the configured timer period. This ensures equal conversion steps in case of concatenation of sequences using multiple groups. For this functionality the timer must be enabled and the configured period must be long enough to end after the respective conversion.

Controlling Internal and External Triggers

Trigger events can be generated by a transition on the selected hardware trigger signal or by software. In the latter case the external trigger can be excluded from generating trigger events.

When the request timer is enabled, the selected external trigger signal controls the timer itself, while the trigger signal for the corresponding request queue is generated locally by the request timer.

The figure below summarizes the control paths of the engaged blocks.

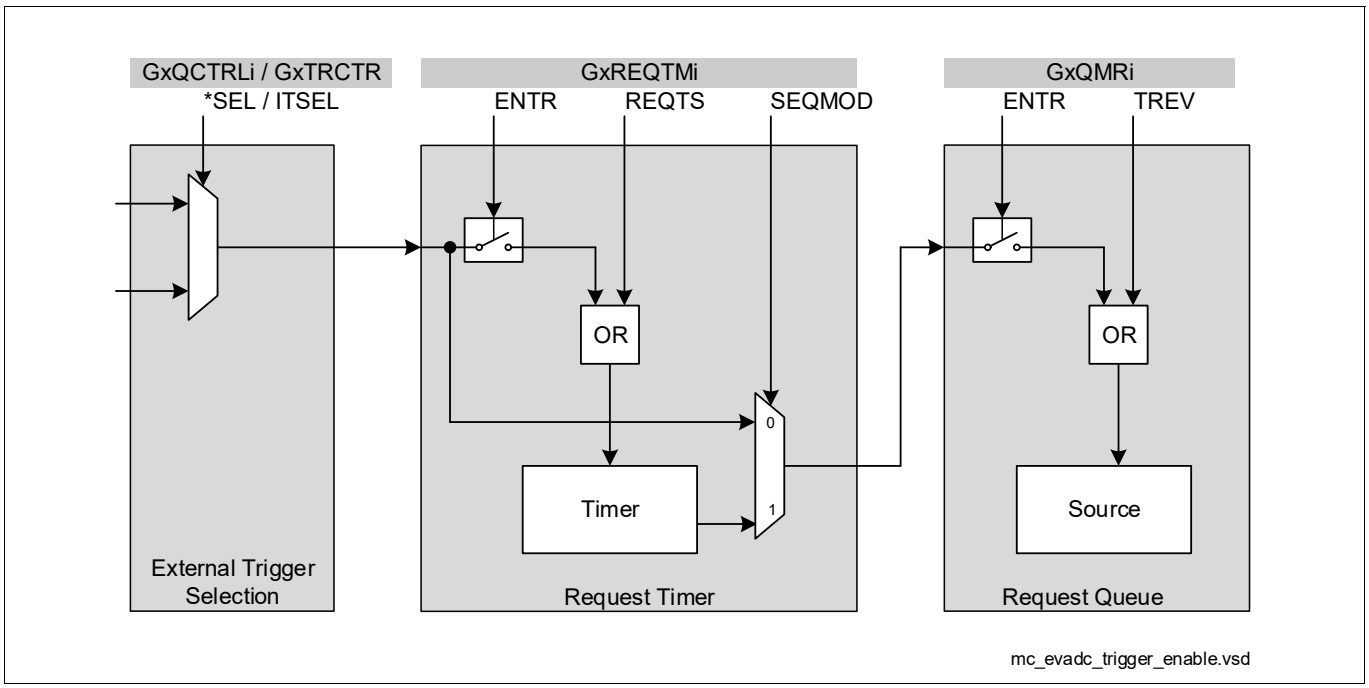

Figure 248 Enabling and Generating Triggers

Controlling the Trigger Output Signal

While a trigger signal usually is a single pulse, its shape can be controlled by writing an appropriate value to bitfield SEQTIMOFF. This is useful to generate the preface time for timer mode, see **“Equidistant Sampling” on Page 112**.

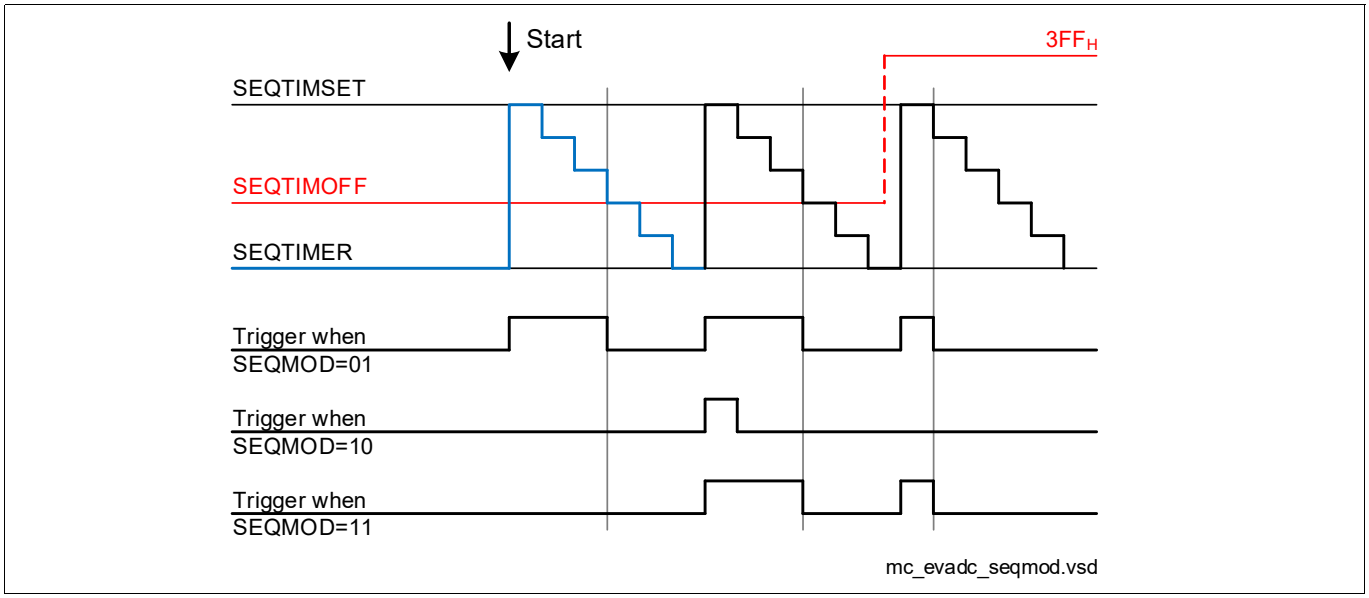

Figure 249 Trigger Output Configuration

32.5.3 Extended Conversion Sequences through Concatenation

A request source can automatically handle sequences of up to 8 or 16 conversions. If longer sequences shall be started with a single trigger event, several request sources can be concatenated, so one source triggers the other.

Three modes of concatenation are possible:

- **Within a group**Request source 2 (Q2) can be internally triggered by another request source of the same group. After the configured sequence has been converted by Q0 or Q1, Q2 is triggered directly (see “Internal Trigger” in **Figure 246**).
  This is useful either to extend the sequence a single queue can handle or to execute test conversions (see additional features of Q2) automatically after a sequence of application conversions.
- **Daisy chaining**If the extended sequence shall cover more channels than available from the respective multiplexer of a given group, a request source can also be triggered by source events of an adjacent group. Daisy chains can be established within a cluster or spanning all groups, sequencing can be done in both directions, wrap-around is possible. These connections are within the module and do not impose any synchronization delays.
  This is useful to configure extended sequences with many channels.
- **Multiple groups**Triggers between groups can also be established by using the service request signal of another group.
  This is useful to configure arbitrary sequences with channels from different groups.

Establishing Daisy-Chain Concatenation

Groups can be concatenated in a configurable daisy-chain. Each group selects a source event of its predecessor group as trigger input.

Example: Concatenation of secondary groups 9-10-11-8:

- Trigger input (rising edge) G10 from G9:
  G10QCTRLi.TRSEL = 01_B, G10QCTRLi.XTMODE = 10_B, G10QMRi.ENTR = 1, G10QINRi.EXTR = 1
- Trigger input (rising edge) G11 from G10:
  G11QCTRLi.TRSEL = 01_B, G11QCTRLi.XTMODE = 10_B, G11QMRi.ENTR = 1, G11QINRi.EXTR = 1
- Trigger input (rising edge) G8 from G11:
  G8QCTRLi.TRSEL = 10_B, G8QCTRLi.XTMODE = 10_B, G8QMRi.ENTR = 1, G8QINRi.EXTR = 1
- Trigger output G9 (no service request):
  G9QINRi.ENSI = 1, G9SEVNP.SEViNP = 1111_B
- Trigger output G10 (no service request):
  G10QINRi.ENSI = 1, G10SEVNP.SEViNP = 1111_B
- Trigger output G11 (no service request):
  G11QINRi.ENSI = 1, G11SEVNP.SEViNP = 1111_B

Establishing Multi-Group Concatenation

Groups can be concatenated via the sevice request lines (see product-specific appendix). The predecessor group routes a source event to a specific service request line, the successor group selects this service request line as trigger input.

Example: Concatenation of queue 0 of group 1 to queue 0 of group 3:

- Generate source event: G1QINR0.ENSI = 1
- Route source event to service request output: G1SEVNP.SEV0NP = 0101_B (common service request C1SR1)
- Select service request as trigger input: G3QCTRL0.XTSEL = 1110_B, G3QCTRL0.XTMODE = 10_B
- Activate trigger for successor group: G3QMR0.ENTR = 1, G3QINR0.EXTR = 1

Note: Do not route other events to the selected service request line.

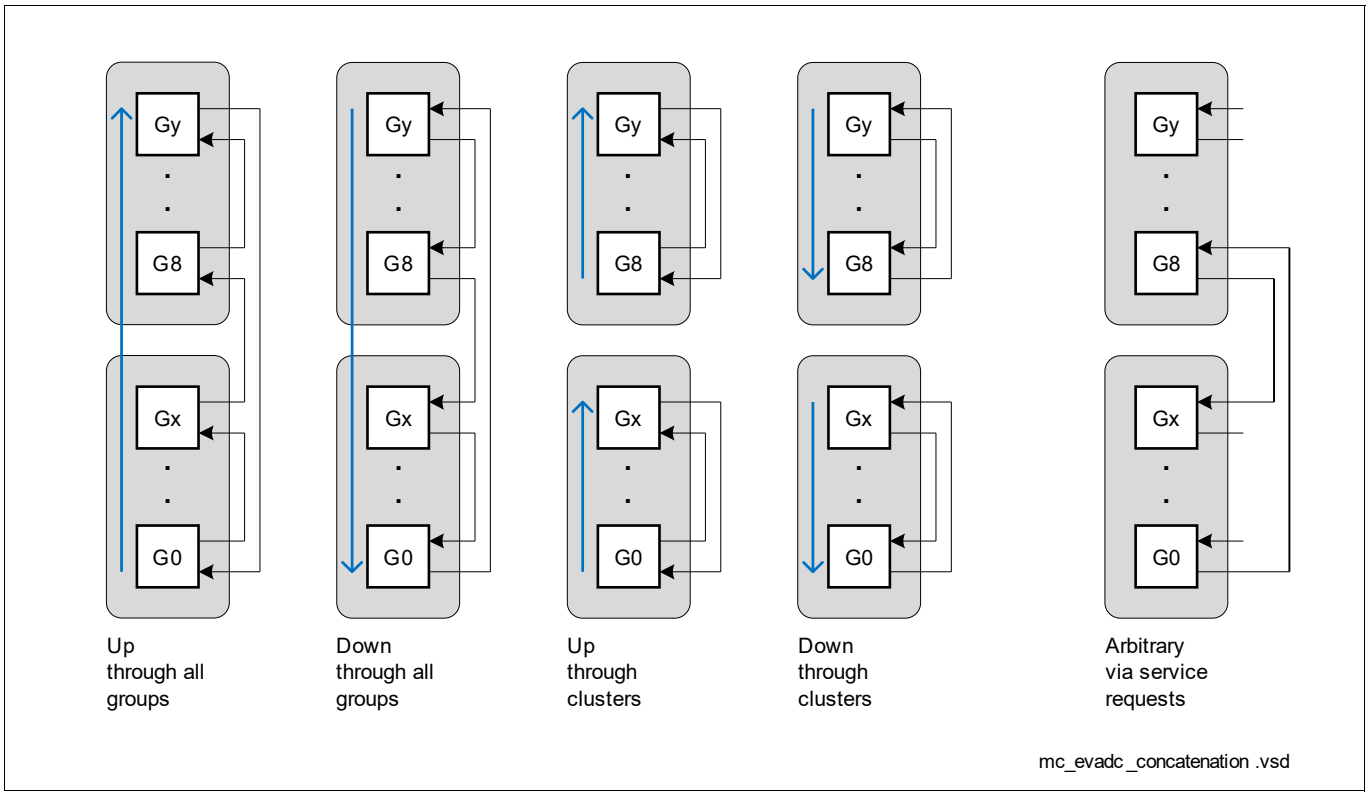

Figure 250 Possibilities for Concatenation

32.5.4 Queue Request Source Control Registers

The following set of registers provides initialization and control of the operation of the queue request sources.

*Note: Requests for channel numbers above the maximum available channel of a group are treated like requests for channel 0. Use the ALIAS feature for higher channel numbers (see **Section 32.7.2**).*

Queue request source Q2 provides two enhancements compared to the other sources Q0 and Q1:

- **Internal Triggers**Q2 can also be internally triggered by request sources Q0/Q1 of the same group (see **GxTRCTR (x=0-11)**).
- **Testfunctions**Q2 can be used to automatically control safety-oriented test conversion sequences. It, therefore, provides the additional control bitfields CDSEL, CDEN, MDPU, MDPD, PDD, which are not available in Q0/Q1.

Queue i Source Contr. Register, Group x

The control register of the queue source selects the external gate and/or trigger signals. Also triggers from other groups can be selected to allow the concatenation of groups to execute extended conversion sequences. Write control bits allow separate control of each function with a simple write access.

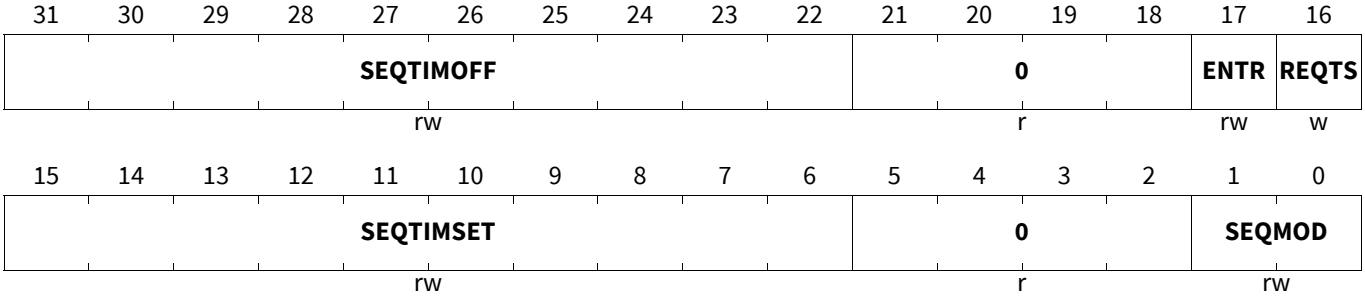
Queue i Requ. Timer Mode Reg., Group x

The Request Timer Mode Register configures the operating mode of a source-specific request timer.

GxREQTMi (i=0-2;x=0-11)

Queue i Requ. Timer Mode Reg., Group x (0518_H+x*400_H+i*20_H) **Application Reset Value: FFC0 0000_H**



Field	Bits	Type	Description
SEQMOD	1:0	rw	**Sequence Mode** Selects how the request timer controls the conversion sequence. Before changing the operating mode, stop the sequence timer, i.e. SEQMOD = 00_B. 00_B Request timer off Trigger events become effective immediately. 01_B Pause after conversion Conversions are requested after a trigger event and each time the request timer has expired. 10_B Wait before first conversion After a trigger event the request timer is started. The conversion sequence is executed after the request timer has expired. 11_B Wait before each conversion After a trigger event the request timer is started. Conversions are requested each time the request timer has expired.
SEQTIMSET	15:6	rw	**Sequence Timer, Set Value** Initial value for the sequence timer in steps of 16 × t_{PER}. This value is loaded into SEQTIMER when a new request timer period is started.
REQTS	16	w	**Request Timer Start Trigger** 0_B No action 1_B Start the request timer immediately via software[1)]
ENTR	17	rw	**Enable External Trigger** 0_B External trigger disabled 1_B The selected edge at the selected trigger input signal starts the request timer
SEQTIMOFF	31:22	rw	**Sequence Timer, Switch Off Value** The generated trigger signal is disabled when the timer value is equal to or below this threshold.
0	5:2, 21:18	r	**Reserved, write 0, read as 0**

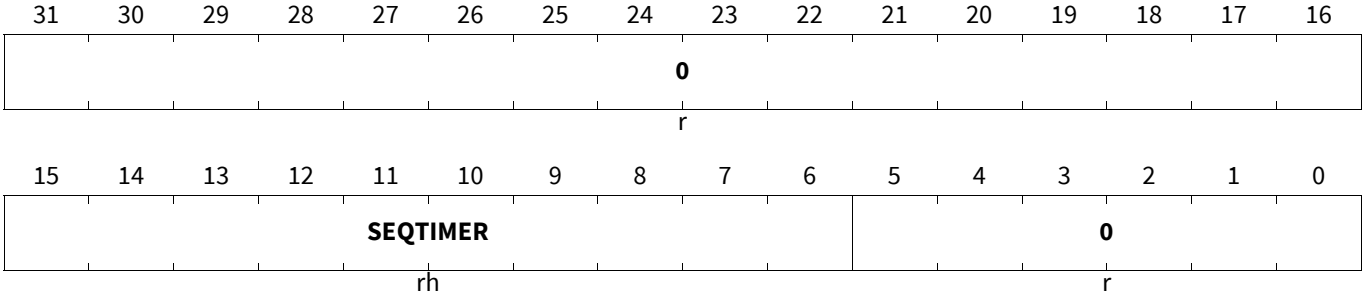
1) Mode and start/stop values must be configured before setting the trigger bit REQTS.

Queue i Requ. Timer Status Reg., Group x

The Request Timer Status Register returns the current value of source-specific request timer.

GxREQTSi (i=0-2;x=0-11)

Queue i Requ. Timer Status Reg., Group x($051C_H$+x*400_H+i*20_H) **Application Reset Value: 0000 0000_H**



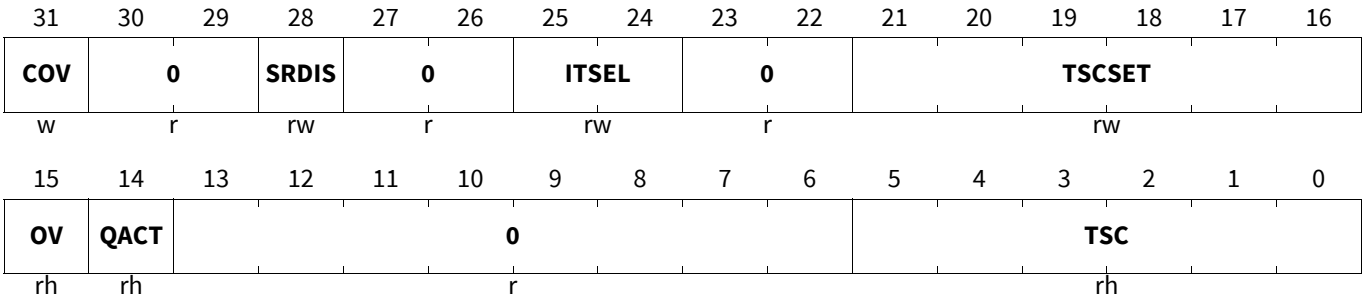
Field	Bits	Type	Description
SEQTIMER	15:6	rh	**Sequence Timer** Counts the request timer periods in steps of 16 × t_{ADC}. This timer is loaded from bitfield SEQTIMSET at the beginning of a period.
0	5:0, 31:16	r	**Reserved, write 0, read as 0**

Trigger Control Register, Group x

For queued request source Q2, the Trigger Control Register configures the trigger sequence counter and the internal trigger sources.

GxTRCTR (x=0-11)

Trigger Control Register, Group x **(0410_H+x*400_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TSC	5:0	rh	**Trigger Sequence Counter** Controls the effect of an incoming internal trigger: If TSC > 00_H: decrement TSC by one. 00_H Issue conversion requests immediately[1)]
QACT	14	rh	**Queue Active** Indicates that request source Q2 is currently executing a sequence. Cleared by writing 1 to bit COV. 0_B No activity 1_B Queue currently active

Field	Bits	Type	Description
OV	15	rh	**Overflow Detected** Indicates that a trigger has been activated while the queue was still active (QACT = 1). Cleared by writing 1 to bit COV. 0_B No trigger event 1_B An irregular trigger event has been detected
TSCSET	21:16	rw	**Trigger Sequence Counter Start Value** Defines the initial value of the trigger sequence counter TSC. TSC is reloaded with the value in TSCSET, when a trigger occurs while TSC = 00_H. TSCSET is automatically copied to TSC when being written.[1)]
ITSEL	25:24	rw	**Internal Trigger Input Selection** Internal triggers are generated by the respective source events. Enable a source event in the selected request source to generate an internal trigger signal. *Note: The selected trigger signal is internally connected to gate input GxREQGTP of this request source. It is selected when XTSEL = GTSEL = 1111_B.* 00_B Select queued request source Q0 01_B Select queued request source Q1 10_B Reserved 11_B Reserved
SRDIS	28	rw	**Service Request Disable** Controls if the source event of the selected trigger source also activates a service request. 0_B Source event generates service request 1_B No service request, only internal trigger generated
COV	31	w	**Clear Overflow Flag** 0_B No action 1_B Clear bits OV and QACT
0	13:6, 23:22, 27:26, 30:29	r	**Reserved, write 0, read as 0**

1) Write zero to bitfield TSCSET, to disable the trigger sequence counter and start the sequence with each incoming trigger.

32.6 Request Source Arbitration

The request source arbiter scans the request sources for pending conversion requests. Each request source is connected to a certain input of the arbiter.

The priority of each request source is user-configurable via register **GxARBPR (x=0-11)**, so the arbiter can select the next channel to be converted, in the case of concurrent requests from multiple sources, according to the application requirements. The synchronization source has always higher priority than all other sources.

After reset, all inputs are disabled and must be enabled (register **GxARBPR (x=0-11)**) to take part in the arbitration process.

The arbiter determines the highest priority conversion request. If this request has sufficient priority the corresponding conversion is started.

The following request sources are available:

- Input 0: **Queued request source Q0**, 8/16-stage sequences in arbitrary order
- Input 1: **Queued request source Q1**, 8/16-stage sequences in arbitrary order
- Input 2: **Queued request source Q2**, 8/16-stage sequences in arbitrary order, intra-group concatenation, test
- Input 3: **Synchronization source**, synchronized conversion requests from another ADC master kernel (always handled with the highest priority in a synchronization slave kernel).

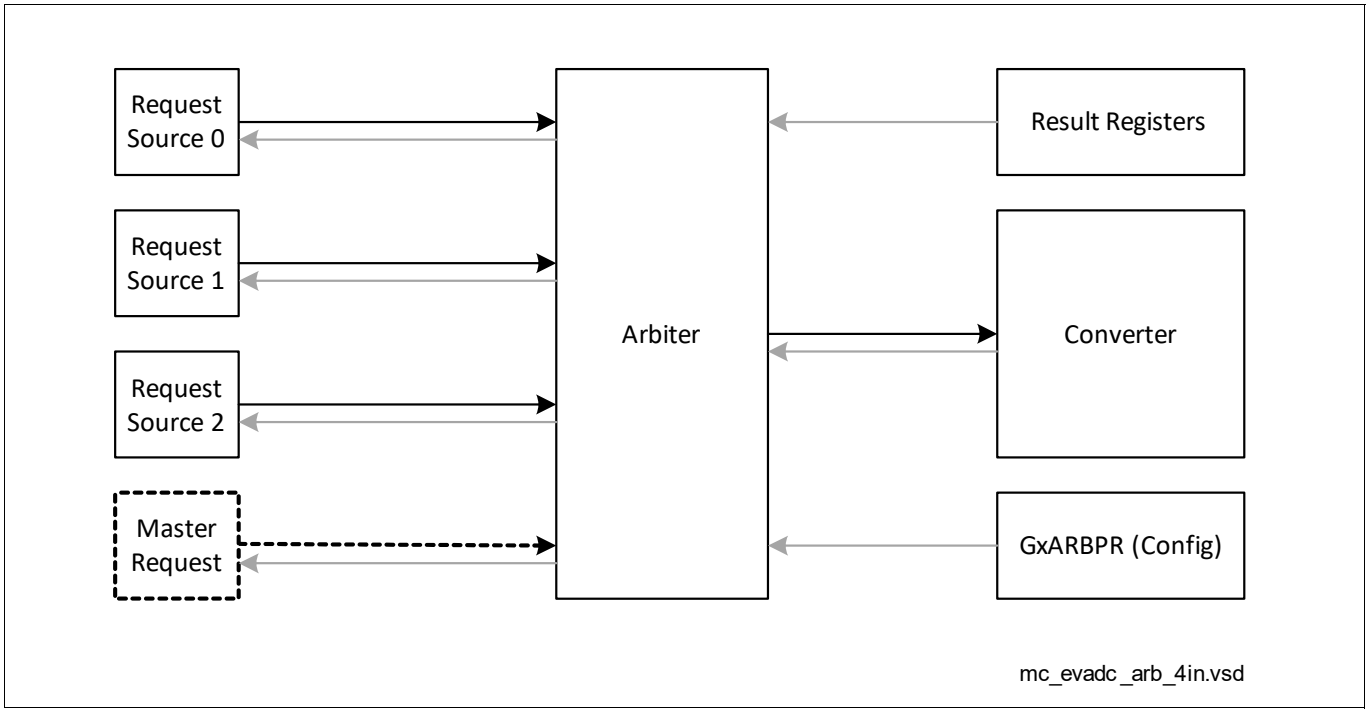


Figure 251 Arbiter with 4 Arbitration Inputs

32.6.1 Arbiter Operation and Configuration

Each request source has a configurable priority (0 = lowest, 3 = highest), so the arbiter can resolve concurrent conversion requests from different sources. The request with the highest priority is selected for conversion. These priorities can be adapted to the requirements of a given application (see register **GxARBPR (x=0-11)**).

The arbiter is controlled by bits in registers GxARBCFG and GxARBPR. A decision is made within one clock cycle, if any conversion request is active. While no conversion request is active, the arbiter remains idle.

The **Conversion Start Mode** determines the handling of the conversion request that has won the arbitration.

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, the converter has to be idle. This is supported in particular by the timer mode (see **“Equidistant Sampling” on Page 112**).

Arbitration Config. Register, Group x

The Arbitration Configuration Register selects the timing and the behavior of the arbiter. Also some group-specific configurations can be selected here.

GxARBCFG (x=0-11)

Arbitration Config. Register, Group x **(0480_H+x*400_H)** **Application Reset Value: 0000 0000_H**

0														ANONC	
r														rw	

Field	Bits	Type	Description
ANONC	1:0	rw	**Analog Converter Control** Defines the value of bitfield ANONS in a stand-alone converter or a converter in master mode. Coding see ANONS or **Section 32.4**.
ANONS	17:16	rh	**Analog Converter Control Status** Defined by bitfield ANONC in a stand-alone kernel or a kernel in master mode. In slave mode, this bitfield is defined by bitfield ANONC of the respective master kernel. See also **Section 32.4**. 00_B Analog converter off 01_B Slow standby mode 10_B Fast standby mode 11_B Normal operation (permanently on)

Field	Bits	Type	Description
CSRC	19:18	rh	**Currently Converted Request Source** Indicates the arbitration slot number of the current (BUSY = 1) or of the last (BUSY = 0) conversion. This bitfield is updated when a conversion is started. 00_B Current/last conversion for request source 0 01_B Current/last conversion for request source 1 10_B Current/last conversion for request source 2 11_B Current/last conversion for synchronization request (slave converter)
CHNR	24:20	rh	**Channel Number** Indicates the current or last converted analog input channel. This bitfield is updated when a conversion is started.
SYNRUN	25	rh	**Synchronous Conversion Running** Indicates that a synchronized (= parallel) conversion is currently running. 0_B Normal conversion or no conversion running 1_B A synchronized conversion is running (cannot be cancelled by higher priority requests!)
CAL	28	rh	**Start-Up Calibration Active Indication** Indicates the start-up calibration phase of the corresponding analog converter. *Note: Start conversions only after the start-up calibration phase is complete, because a start-up calibration will abort a running conversion.* 0_B Completed or not yet started 1_B Start-up calibration phase is active (set one clock cycle after setting bit SUCAL)
BUSY	30	rh	**Converter Busy Flag** 0_B Not busy 1_B Converter is busy with a conversion (set one clock cycle after conversion start)
SAMPLE	31	rh	**Sample Phase Flag** 0_B Converting or idle 1_B Input signal is currently sampled
0	15:2, 27:26, 29	r	**Reserved, write 0, read as 0**

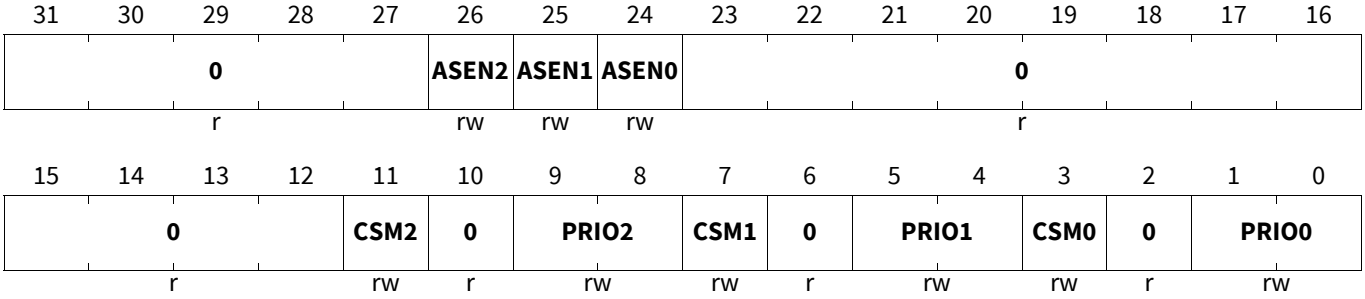
Arbitration Priority Register, Group x

The Arbitration Priority Register defines the request source priority and the conversion start mode for each request source.

Note: Only change priority and conversion start mode settings of a request source while this request source is disabled, and a currently running conversion requested by this source is finished.

GxARBPR (x=0-11)

Arbitration Priority Register, Group x **(0484_H+x*400_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
PRIOi (i=0-2)	4*i+1:4*i	rw	**Priority of Request Source i** Arbitration priority of request source i (at input i) 00_B Select priority level 0 … 11_B Select priority level 3
CSMi (i=0-2)	4*i+3	rw	**Conversion Start Mode of Request Source i** 0_B Wait-for-start mode 1_B Cancel-inject-repeat mode i.e. this source can cancel conversions of other sources.
ASENi (i=0-2)	i+24	rw	**Arbitration Source Input i Enable** Enables the associated arbitration source input of the arbiter. The request source bits are not modified by write actions to ASENi. 0_B The arbitration source input is disabled. Pending conversion requests from the associated request source are disregarded. 1_B The arbitration source input is enabled. Pending conversion requests from the associated request source are arbitrated.
0	10, 6, 2, 23:12, 31:27	r	**Reserved, write 0, read as 0**

32.6.2 Conversion Start Mode

When the arbiter has selected the request to be converted next, the handling of this channel depends on the current activity of the converter:

- Converter is currently idle:
  the conversion of the arbitration winner is started immediately.
- Current conversion has same or higher priority:
  the current conversion is completed, the conversion of the arbitration winner is started after that.
- Current conversion has lower priority:
  the action is user-configurable:
  - **Wait-for-start mode**: the current conversion is completed, the conversion of the arbitration winner is started after that. This mode provides maximum throughput, but can produce a jitter for the higher priority conversion.
    Example in **Figure 252**:
    Conversion A is requested (t1) and started (t2). Conversion B is then requested (t3), but started only after completion of conversion A (t4).
  - **Cancel-inject-repeat mode**: the current conversion is aborted, the conversion of the arbitration winner is started after the abortion (3 f_{ADC} cycles).
    The aborted conversion request is restored in the corresponding request source and takes part again in the next arbitration step. This mode provides minimum jitter for the higher priority conversions, but reduces the overall throughput.
    Example in **Figure 252**:
    Conversion A is requested (t6) and started (t7). Conversion B is then requested (t8) and started (t9), while conversion A is aborted but requested again. When conversion B is complete (t10), conversion A is restarted.
    Exception: If both requests target the same result register with wait-for-read mode active (see **Section 32.10.3**), the current conversion cannot be aborted.

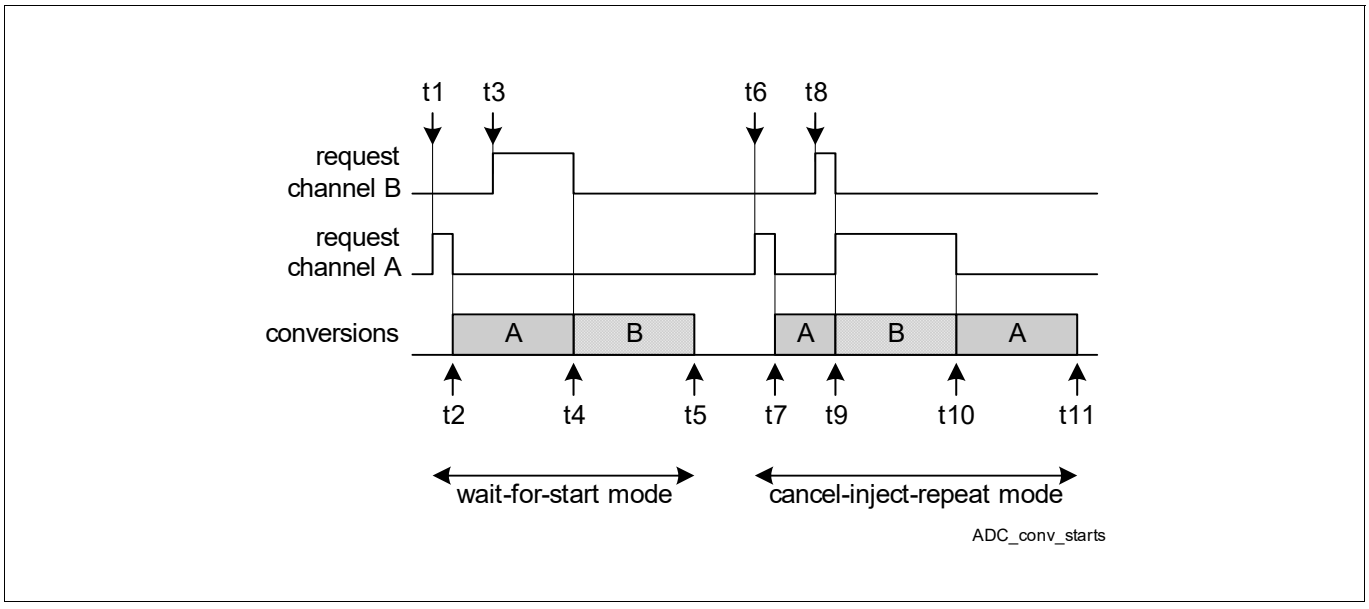


Figure 252 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in register **GxARBPR (x=0-11)** and is applied to all channels requested by the source. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

A cancelled conversion can be repeated automatically in each case, or it can be discarded if it was cancelled. This is selected for each source by bit RPTDIS in the corresponding source's mode register.

Note: Discarding a cancelled conversion is not possible when an external multiplexer is operated in sequence mode. Bit RPTDIS must be 0 in this case.

32.7 Analog Input Channel Configuration

For each analog input channel a number of parameters can be configured that control the conversion of this channel. The channel control registers define the following parameters:

- **Channel Parameters**: The sample time for this channel and analog input precharge option are defined via input classes. Each channel can select one of two classes of its own group or one of two global classes.
- **Reference selection**: an alternate reference voltage can be selected for most channels (exceptions are marked in the product-specific appendix)
- **Result target**: The conversion result values are stored either in a group-specific result register or in the global result register[1]. The group-specific result registers are selected in several ways:
  - channel-specific, selected by bitfield RESREG in register **GxCHCTRy (x=0-7;y=0-7)** etc., with bitfield SRCRESREG = 0000_B
  - source-specific, selected by bitfield SRCRESREG in register **GxQCTRLi (i=0-2;x=0-11)** etc. with bitfield SRCRESREG ≠ 0000_B
  - The global result register is selected when SRCRESREG = 0000_B and RESTGT = 1.
- **Result position**: The result values of standard conversions can be stored left-aligned or right-aligned, other results are stored right-aligned. The global result register GLOBRES always stores results right-aligned. See also **Figure 263 “Result Storage Options” on Page 98**.
- **Compare with Standard Conversions (Limit Checking)**: Channel events can be generated whenever a new result value becomes available. Channel event generation can be restricted to values that lie inside or outside a user-configurable band.
- **Broken Wire Detection**: This safety feature can detect a missing connection to an analog signal source (sensor).
- **Synchronization of Conversions**: Synchronized conversions are executed at the same time on several converters.

The **Alias Feature** redirects conversion requests for channels CH0 and/or CH1 to other channels.

1) Conversion slaves cannot store results to the global result register.
Slaves must use local result registers in this case (GxCHCTRy.RESTGT = 0).

32.7.1 Channel Parameters

Each analog input channel is configured by its associated channel control register.

*Note: For the safety feature "Broken Wire Detection", refer to **Section 32.12.4**.*

Group 0, Channel 0 Control Register

The following features can be defined for each channel:

- The conversion class defines the conversion mode (noise reduction) and the sample time
- Generation of channel events and the result value band, if used
- Target of the result defining the target register and the position within the register

GxCHCTRy (x=0-7;y=0-7)
Group x, Channel y Control Register (0600_H+x*400_H+y*4) Application Reset Value: 0000 0000_H
GxCHCTRy (x=8-11;y=0-15)
Group x, Channel y Control Register (0600_H+x*400_H+y*4) Application Reset Value: 0000 0000_H

Sample Time Control

The sample time is defined by a configurable number of sample clock cycles. The sample clock is the analog clock f_{ADCI}. The sample time can, therefore, be configured in steps of t_{ADCI} = 50/37.5/25 ns (for f_{ADCI} = 20/26.7/40 MHz). The table below lists the possible settings.

Table 255 Sample Time Coding

STCS / STCE / STCF	Additional Clock Cycles	Resulting Sample Time	Time for f_{ADCI} = 20 MHz	Time for f_{ADCI} = 53.3 MHz	Clock Cycle Formula
$0\ 0000_B$	0	2 / f_{ADCI}	100 ns	37.5 ns	2 + STCi
$0\ 0001_B$	1	3 / f_{ADCI}	150 ns	56.25 ns	
…	…	…	…	…	
$0\ 0100_B$	4	6 / f_{ADCI}	300 ns	112.5 ns	
…	…	…	…	…	
$0\ 1111_B$	15	17 / f_{ADCI}	850 ns	318.75 ns	
$1\ 0000_B$	16	18 / f_{ADCI}	900 ns	337.5 ns	2 + (STCi - 15) × 16
$1\ 0001_B$	32	34 / f_{ADCI}	1.7 µs	637.5 ns	
…	…	…	…	…	
$1\ 1110_B$	240	242 / f_{ADCI}	12.1 µs	4.5 µs	
$1\ 1111_B$	256	258 / f_{ADCI}	12.9 µs	4.8 µs	

The configured sample time must include the input buffering time (if selected by bitfields AIPi) and the timespan subtracted by sample point spreading (if selected by bitfields SESPi).

Note: Find more information in section ***"Conversion Timing" on Page 86***.

32.7.2 Alias Feature

The Alias Feature redirects conversion requests for channels CH0 and/or CH1 to other channel numbers. This feature can be used to trigger conversions of the same input channel by independent events and to store the conversion results in different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU/DMA service request latency.
- The sensor signal is connected to only one analog input (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see **Figure 253**), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, service requests, etc.).

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. **Figure 253** shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion results can be stored and read out from the result registers RESx (conversion triggered for CHx) and RESy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

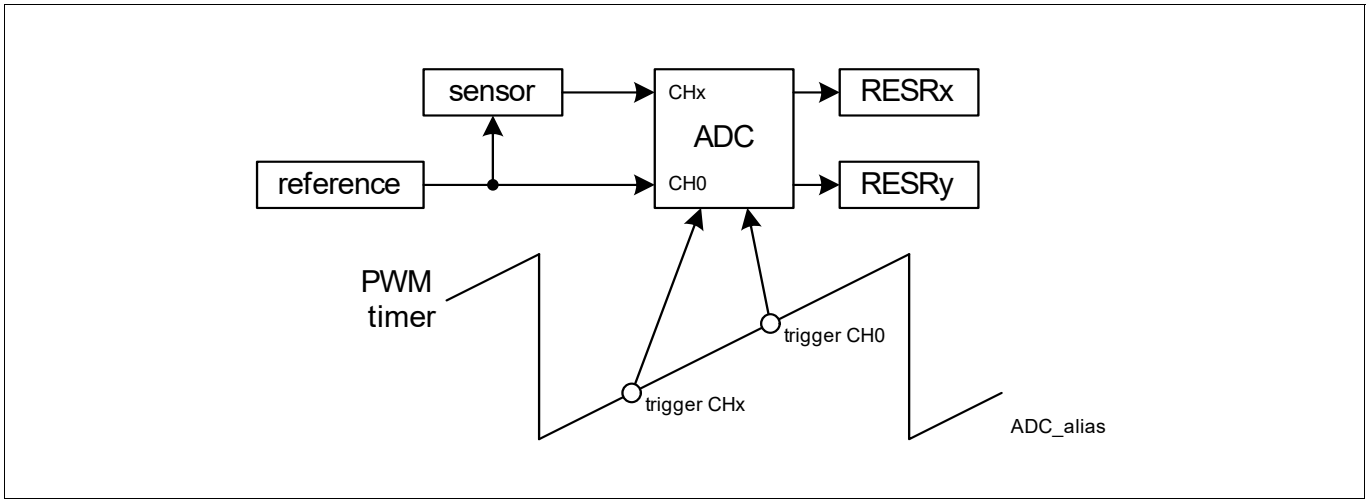

Figure 253 Alias Feature

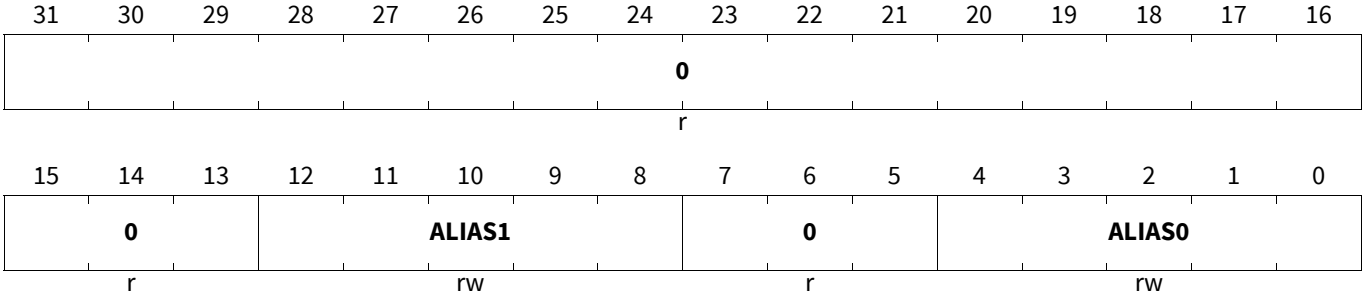
*Note: The redirection via ALIASi remains active until register **GxALIAS (x=0-11)** is reprogrammed.*

Alias Register, Group x

The alias register can replace the channel numbers of channels CH0 and CH1 with another channel number. The reset value disables this redirection.

GxALIAS (x=0-11)

Alias Register, Group x **($04B0_H$+x*400_H)** **Application Reset Value: 0000 0100_H**



Field	Bits	Type	Description
ALIAS0	4:0	rw	**Alias Value for CH0 Conversion Requests** Indicates the channel that is converted instead of channel CH0. The conversion is done with the settings defined for channel CH0.
ALIAS1	12:8	rw	**Alias Value for CH1 Conversion Requests** Indicates the channel that is converted instead of channel CH1. The conversion is done with the settings defined for channel CH1.
0	7:5, 31:13	r	**Reserved, write 0, read as 0**

32.7.3 Compare with Standard Conversions (Limit Checking)

The limit checking mechanism can automatically compare each digital conversion result to an upper and a lower boundary value. A channel event can then be generated when the result of a conversion[1)]/comparison is inside or outside a user-defined band (see bitfield CHEVMODE and **Figure 254**).

This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain predefined conditions.

Note: Channel events can also be generated for each result value (ignoring the band) or they can be suppressed completely.

The boundary values to which results are compared can be selected from several sources (see register GxCHCTRy).

While bitfield BNDSELX = 0000_B, bitfields BNDSELU and BNDSELL select the valid upper/lower boundary value either from the group-specific boundary register **GxBOUND (x=0-11)** or from the global boundary register **GLOBBOUND**. The group boundary register can be selected for each channel of the respective group, the global boundary register can be selected by each available channel.

Otherwise, the compare values are taken from the lower 12 bits of result registers, where bitfield BNDSELX selects the upper boundary value (GxRES1 … GxRES15), the concatenated bitfields BNDSELU||BNDSELL select the lower boundary value (GxRES0 … GxRES15).

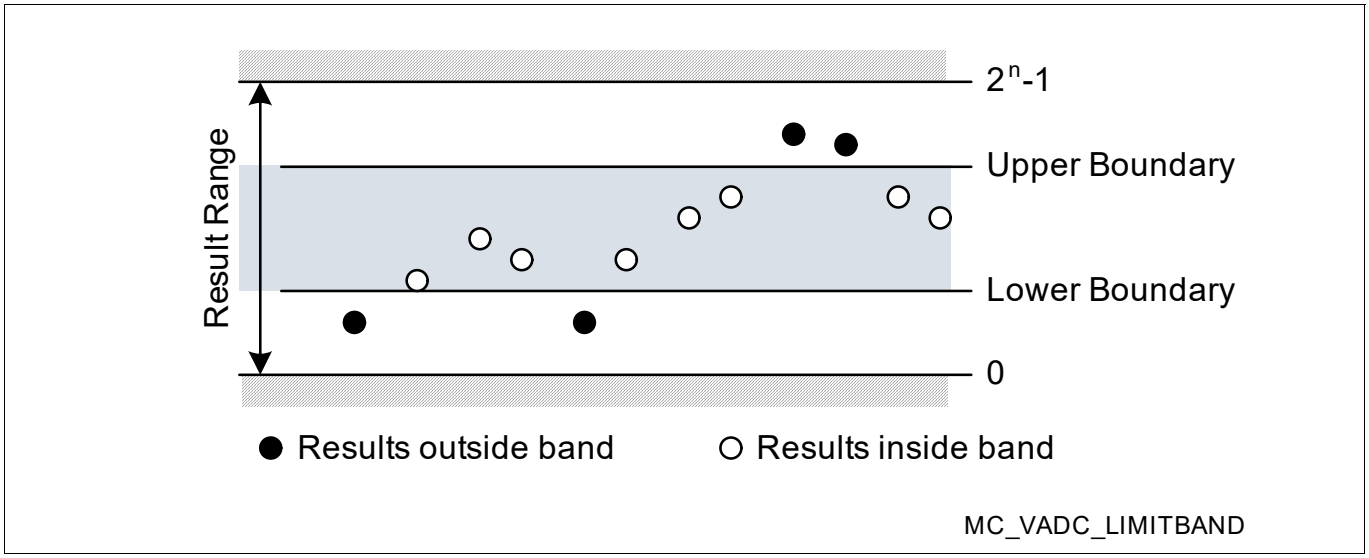


Figure 254 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:
To select the lower part as valid band, set the lower boundary to the minimum value (000_H) and set the upper boundary to the highest intended value.
To select the upper part as valid band, set the upper boundary to the maximum value (FFF_H) and set the lower boundary to the lowest intended value.

1) Limit checking uses the direct conversion result, even if FIR/IIR filters are activated.

Finding Extrema (Peak Detection)

The limit checking mechanism uses standard conversions and, therefore, always can provide the actual conversion result that was used for comparison. Combining this with a special FIFO mode (see also **"Result FIFO Buffer" on Page 99**), that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, provides the usual conversion results and at the same time stores the highest (or lowest) result of a conversion sequence. For this operation the FIFO stage below the standard result must be selected as the compare value. Mode selection is done via bitfield FEN in register GxRCRy.

Before starting a peak detection sequence, write a reasonable start value to the result bitfield in the peak result register (e.g. 0000_H to find the maximum and $0FFF_H$ to find the minimum).

Note: Only the lower 12 bits are compared!
It is, therefore, recommended to use only standard right-aligned conversions.

Selecting Compare Values

Values for digital compare operations can be selected from several sources. The separate GxBOUND registers or the common GLOBBOUND register provide software-defined compare values. Compare values can also be taken from a result register where it can be provided by another channel building a reference.

The compare values are selected via bitfields BNDSELL/BNDSELU and BNDSELX in register GxCHCTR.

Boundary Select Register, Group x

The local boundary register GxBOUND defines group-specific boundary values.

GxBOUND (x=0-11)

32.8 Fast Compare Channel Operation

A Fast Compare channel compares the input signal directly to a reference value[1] stored in bitfield FCREF in register **FCxFCM (x=0-7)**. Delta values define a hysteresis. This comparison returns a binary result (available in bit FCR) which indicates if the compared input voltage is above or below the given reference value. This comparison only requires a few clock cycles and, thus, allows a high sampling rate.

The request timer generates the internal compare triggers for each compare operation. The trigger interval defines the compare rate in the range of 16 … 4 096 clocks (0.1 … 25.6 µs for f_{ADC} = 160 MHz).

*Note: Select the trigger interval according to the configured compare timing (interval > compare time, i.e. $t_{FCTRIV} > t_{FC}$ + 1 CLK, see also **"Fast Compare Channels Timing" on Page 87**).*

The selected external trigger controls the ramp generation or selects the reference value in alternate value mode. In lock BFL mode, it controls the output of the boundary flag. See **Figure 256** and **Section 32.8.1**.

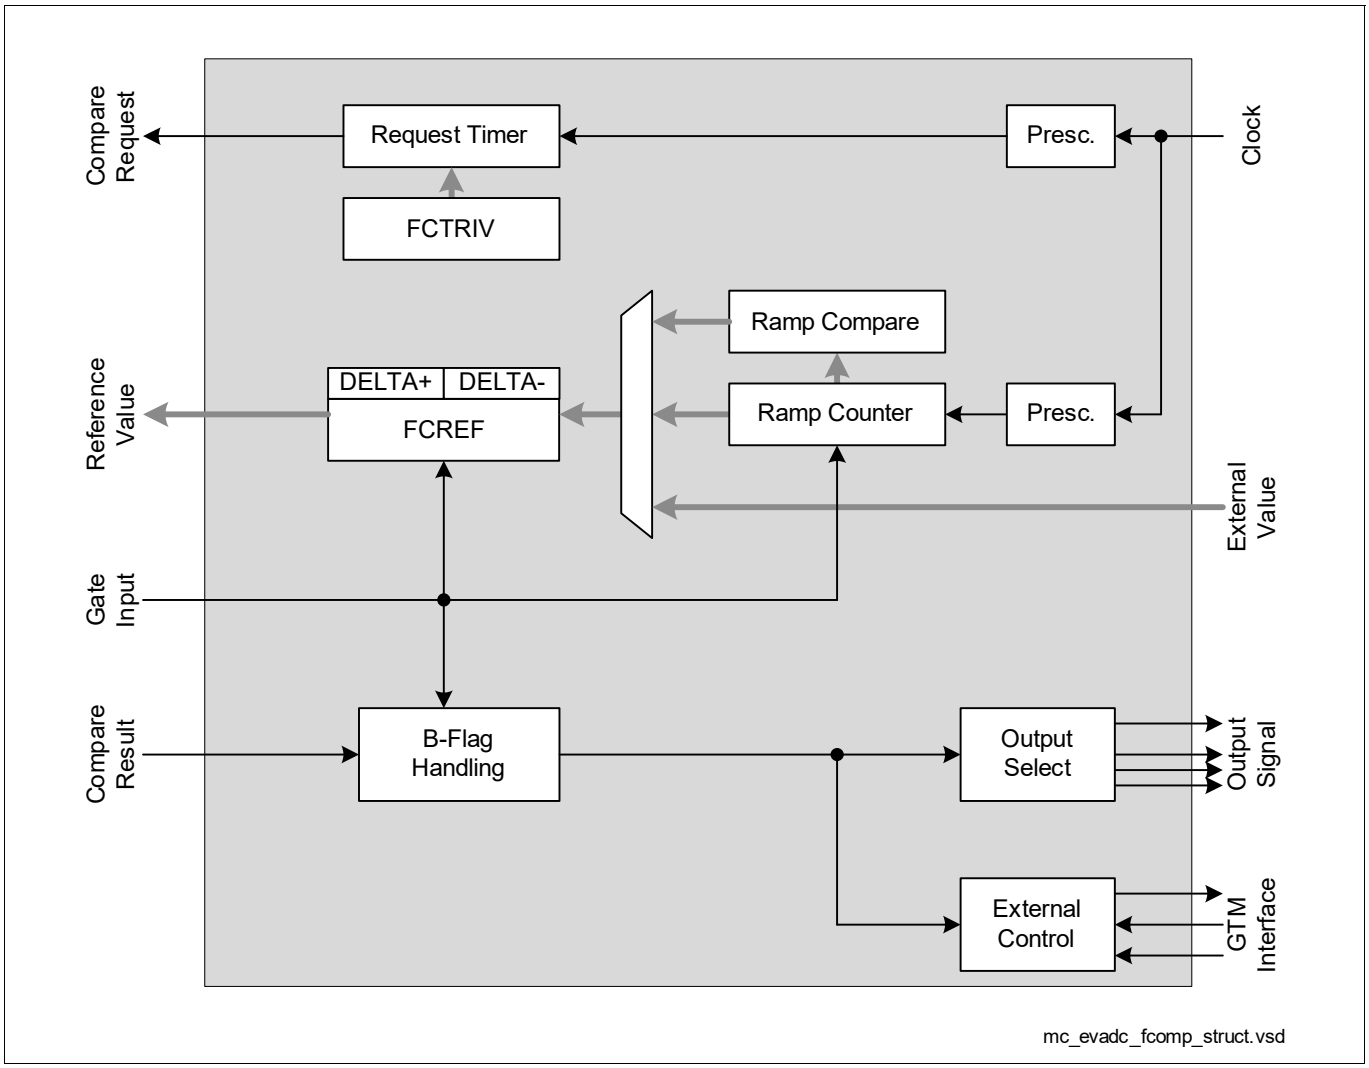

Figure 255 Fast Compare Channel Structure

*Note: See also **Figure 260 "Boundary Flag Control" on Page 83**.*

1) Fast compare channels use 10-bit values and reference to V_{AREF}. The idle precharge function is not supported.

A channel event can be generated when the input signal becomes higher (or lower) than the reference value including a hysteresis that can be defined asymmetrically (see **Figure 258**).

The control interface of a fast compare channel is optimized for its specific functionality. The figure below summarizes the available control functions.

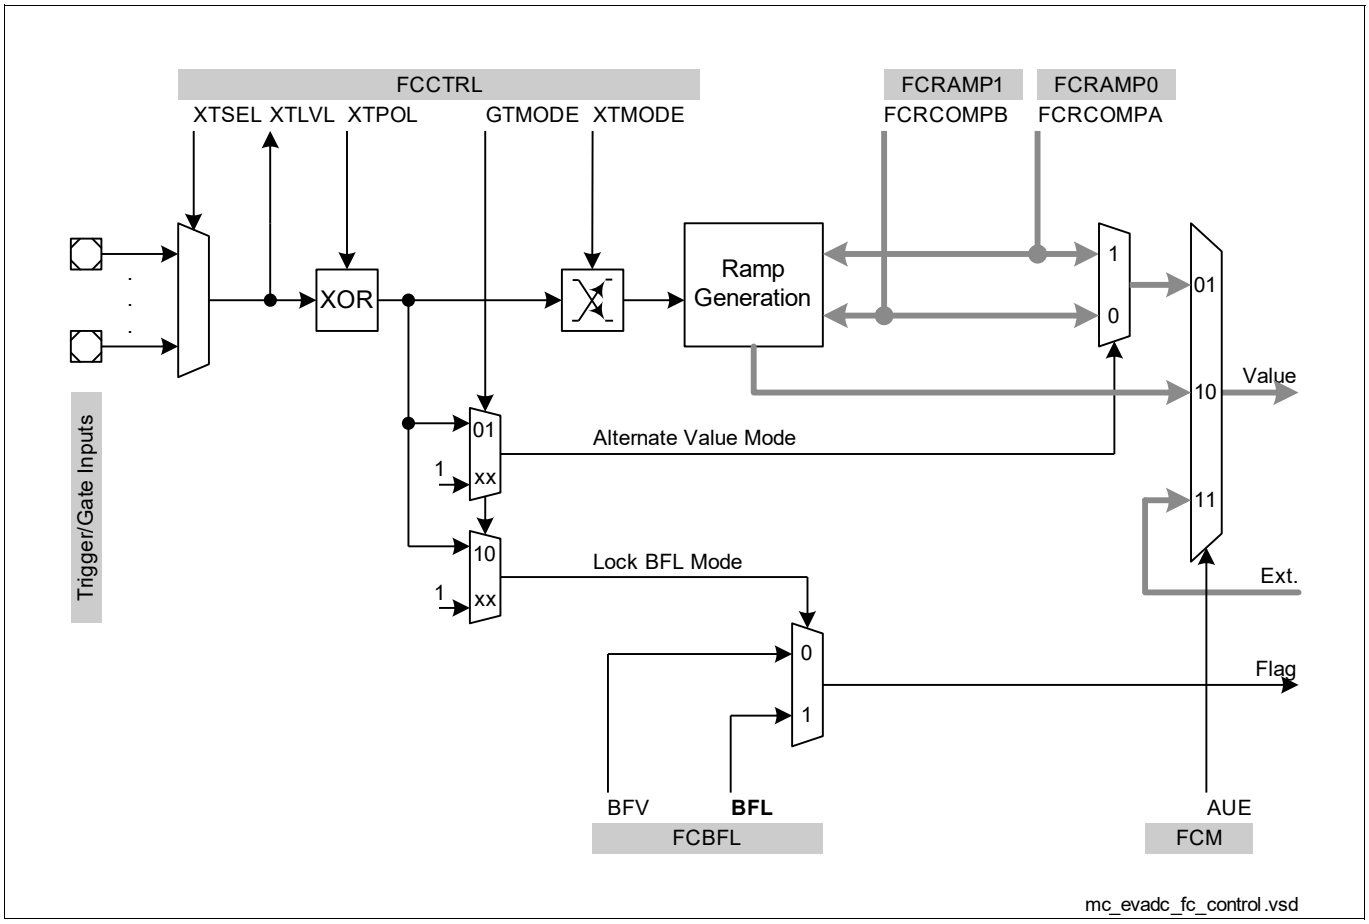

Figure 256 Fast Compare Channel Control Signals

32.8.1 Peak-and-Hold Operation

The Fast Compare channels can implemented hardware-controlled peak-and-hold control loops that operate without software support. The value to be controlled (e.g. current) is observed via the analog input, the target value is given by the reference value, the boundary flag output controls the external circuitry (e.g. power switch).

The reference value can be generated from several sources. Four operating modes are available:

- **Software Mode**
- **Alternate Value Mode**
- **Ramp Mode**
- **External Mode**

The intended operating mode is selected via bitfield AUE in register **FCxFCM (x=0-7)**.

Software Mode

This mode uses a static reference value which is written to bitfield FCREF in register **FCxFCM (x=0-7)**. Software can change this reference value to generate a certain waveform of the controlled signal (see “Update” in **Figure 257**).

Alternate Value Mode

In this mode, one of two predefined reference values is selected by an external gate signal. The reference values are defined by bitfield FCRCOMPA and bitfield FCRCOMPB, depending on the level of the selected hardware gate signal.

- While the gate signal is active (high),
  the reference value in FCRCOMPA (**FCxFCRAMP0 (x=0-7)**) is applied.
- While the gate signal is inactive (low),
  the reference value in FCRCOMPB (**FCxFCRAMP1 (x=0-7)**) is applied.

Ramp Mode

The Fast Compare channel can automatically generate a ramp waveform of the controlled signal. Start and end values for the reference are defined in bitfields FCRCOMPA in register **FCxFCRAMP0 (x=0-7)** and FCRCOMPB in register **FCxFCRAMP1 (x=0-7)**. Bitfield FCRSTEP defines the speed of the generated ramp.

The stepwidth is defined as (FCRSTEP+1) × 8 / f_{ADC}, i.e. 50 ns to 12.8 µs (f_{ADC} = 160 MHz).

This feature can implement e.g. soft start without software support (see “Ramp Up/Down” in **Figure 257**).

The defined slope can also represent an adaptive threshold within one period of the control loop. This is supported by starting the ramp counter upon the leading edge of the gate signal (gate becomes active).

The ramp can also be started automatically by writing a start value to register FCxFCRAMP0.

The ramp stops when the counter reaches FCRCOMPB or, optionally, triggered by an external signal.

See register **FCxFCM (x=0-7)**.

External Mode

The reference value for the Fast Compare channel can be derived from the associated converter group. The result of an analog input of this group can be automatically copied to bitfield FCREF in register **FCxFCM (x=0-7)**. In this mode, the controlled signal will follow the selected input channel of the associated converter group (see “Update” in **Figure 257**).

The reference converter group uses the **“Hardware Data Interface” on Page 107** to copy its result values.

The association of groups and fast compare channels is described in the product-specific appendix.

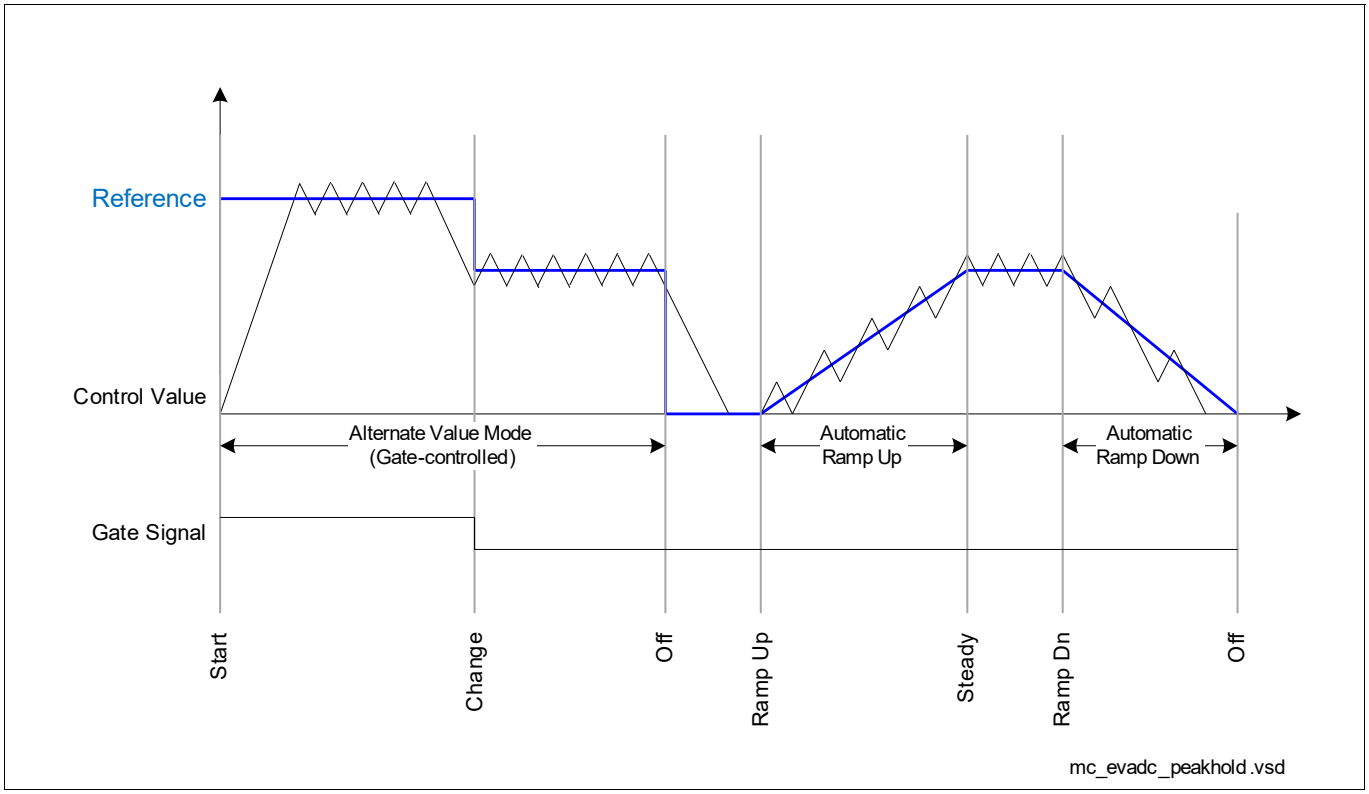

Figure 257 Peak-and-Hold Modes

32.8.2 Fast Compare Channel Control Registers

The following set of registers provides initialization and control of the operation of the fast compare channels.

Note: Only change the configuration while the respective channel is stopped.

Fast Compare Control Register, FC Channel x

The control register of the fast compare channel selects the external gate and/or trigger signals. Write control bits allow separate control of each function with a simple write access.

FCxFCCTRL (x=0-7)

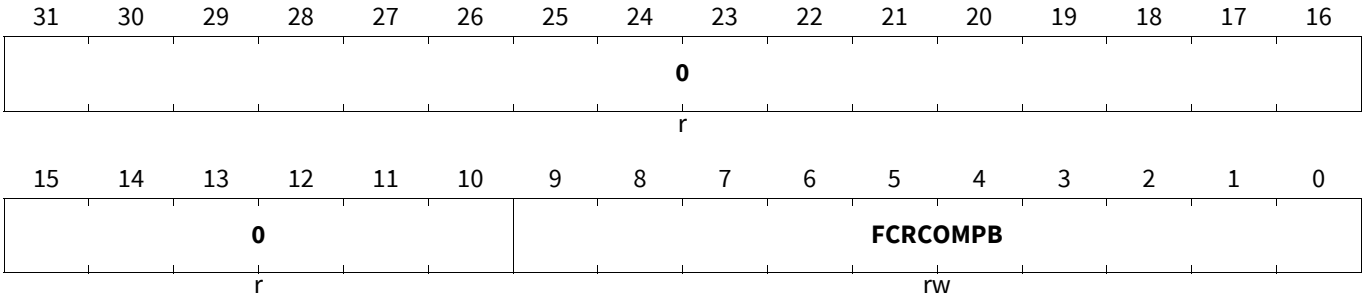
Fast Compare Ramp Register 1, FC Channel x

FCxFCRAMP1 (x=0-7)

Fast Compare Ramp Register 1, FC Channel x($340C_H$+x*100_H) **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
FCRCOMPB	9:0	rw	**Fast Compare Ramp Compare Value B** Defines the stop level of the generated ramp. FCRCOMPB is also used in alternate value mode while the gate is inactive (low).
0	31:10	r	**Reserved, write 0, read as 0**

32.8.3 Boundary Definition

The actual boundaries are defined by the reference value **FCxFCM (x=0-7)**.FCREF and the positive and negative delta values defining the hysteresis band.

Bitfields DELTAMINUS and DELTAPLUS in register **FCxFCHYST (x=0-7)** store the delta values.

The actual used compare value depends on the current result value FCR (see **FCxFCBFL (x=0-7)**):

- FCR = 0: Reference value + upper delta (FCREF + DELTAPLUS)
- FCR = 1: Reference value - lower delta (FCREF - DELTAMINUS)

Note: The resulting compare values are saturated to fit into the fixed result range (000_H … $3FF_H$).

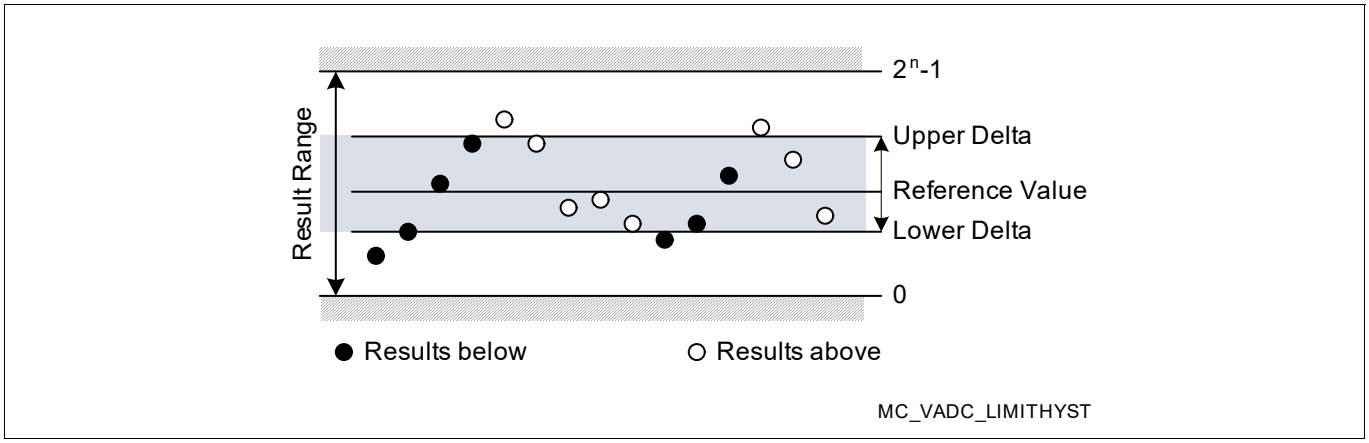


Figure 258 Result Monitoring through Compare with Hysteresis

Fast Comp. Hysteresis Register, FC Channel x

The upper and lower delta limits for Fast Compare operation are defined in the fast compare hysteresis register.

FCxFCHYST (x=0-7)

Fast Comp. Hysteresis Register, FC Channel x(3424_H+x*100_H) **Application Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DELTAMINUS	11:2	rw	**Lower Delta Value** This value is subtracted from the reference value while the last result is 1
DELTAPLUS	27:18	rw	**Upper Delta Value** This value is added to the reference value while the last result is 0
0	1:0, 17:12, 31:28	r	**Reserved, write 0, read as 0**

32.8.4 Boundary Flag Control

The limit checking mechanism can be configured to automatically control the boundary flags. These boundary flags are also available as control signals for other modules. The flags can be set or cleared when the defined level is exceeded and the polarity of the output signal can be selected. A gate signal can be selected to enable the boundary flag operation while the gate is active.

A boundary flag reflects the result of the comparisons with an upper or lower boundary. The basic compare value is provided in bitfield FCxFCM.FCREF, the delta values in register FCxFCHYST define a hysteresis band around the compare value.

A boundary flag is modified by several events:

- when a compare result is generated, the boundary flag is cleared or set as configured by bit FCxFCBFL.BFA, if FCxFCBFL.BFM = 1
- when software writes to bitfield FCxFCBFL.BFS, the boundary flag is cleared, set or toggled
- when the channel is disabled (ANON = 0), the result flag FCR is cleared, the boundary flag is cleared or set as configured by bit FCxFCBFL.BFA, if FCxFCBFL.BFM = 1

Each boundary flag is available at group-specific output lines. Node pointers additionally route them to one of four common boundary signals or one of the associated common service request lines, see bitfield BFLNP.

Note: Clear register GxFCHYST (i.e. the deltas) if a hysteresis is not wanted.

Boundary flags can reflect the result of compare operations, or can be forced to a configurable level (bit BFV) while the corresponding request source gate signal is inactive (low). See bitfield GTMODE in register **FCxFCCTRL (x=0-7)**.

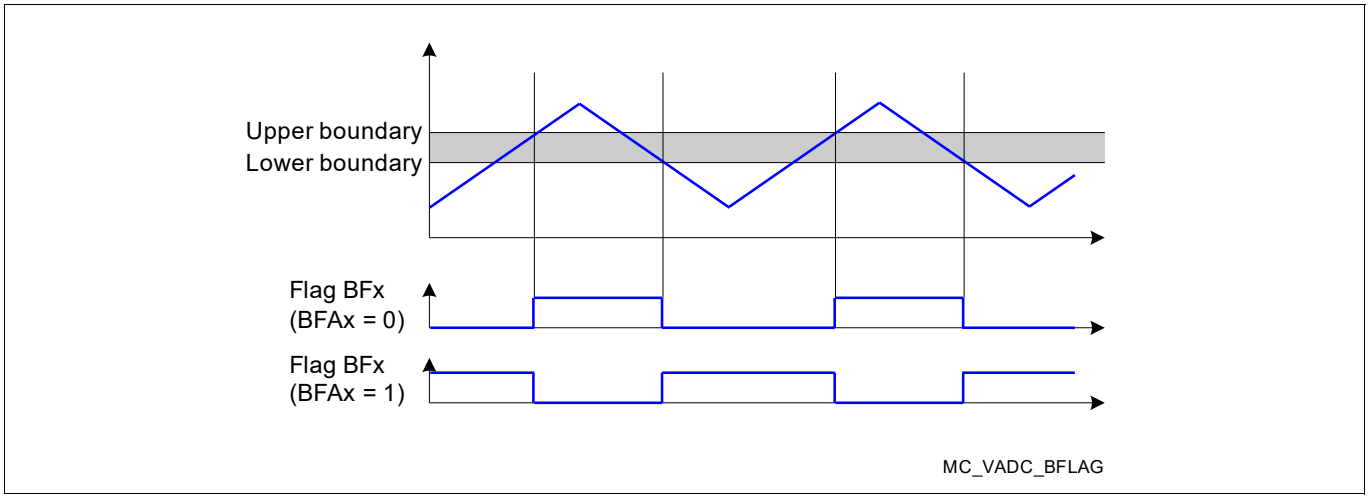

Figure 259 Boundary Flag Switching

The output signal derived from a boundary flag can be controlled by the GTM. A select input and a data input are available to temporarily replace the boundary flag signal before sending it to the output pin (see **Figure 260**).

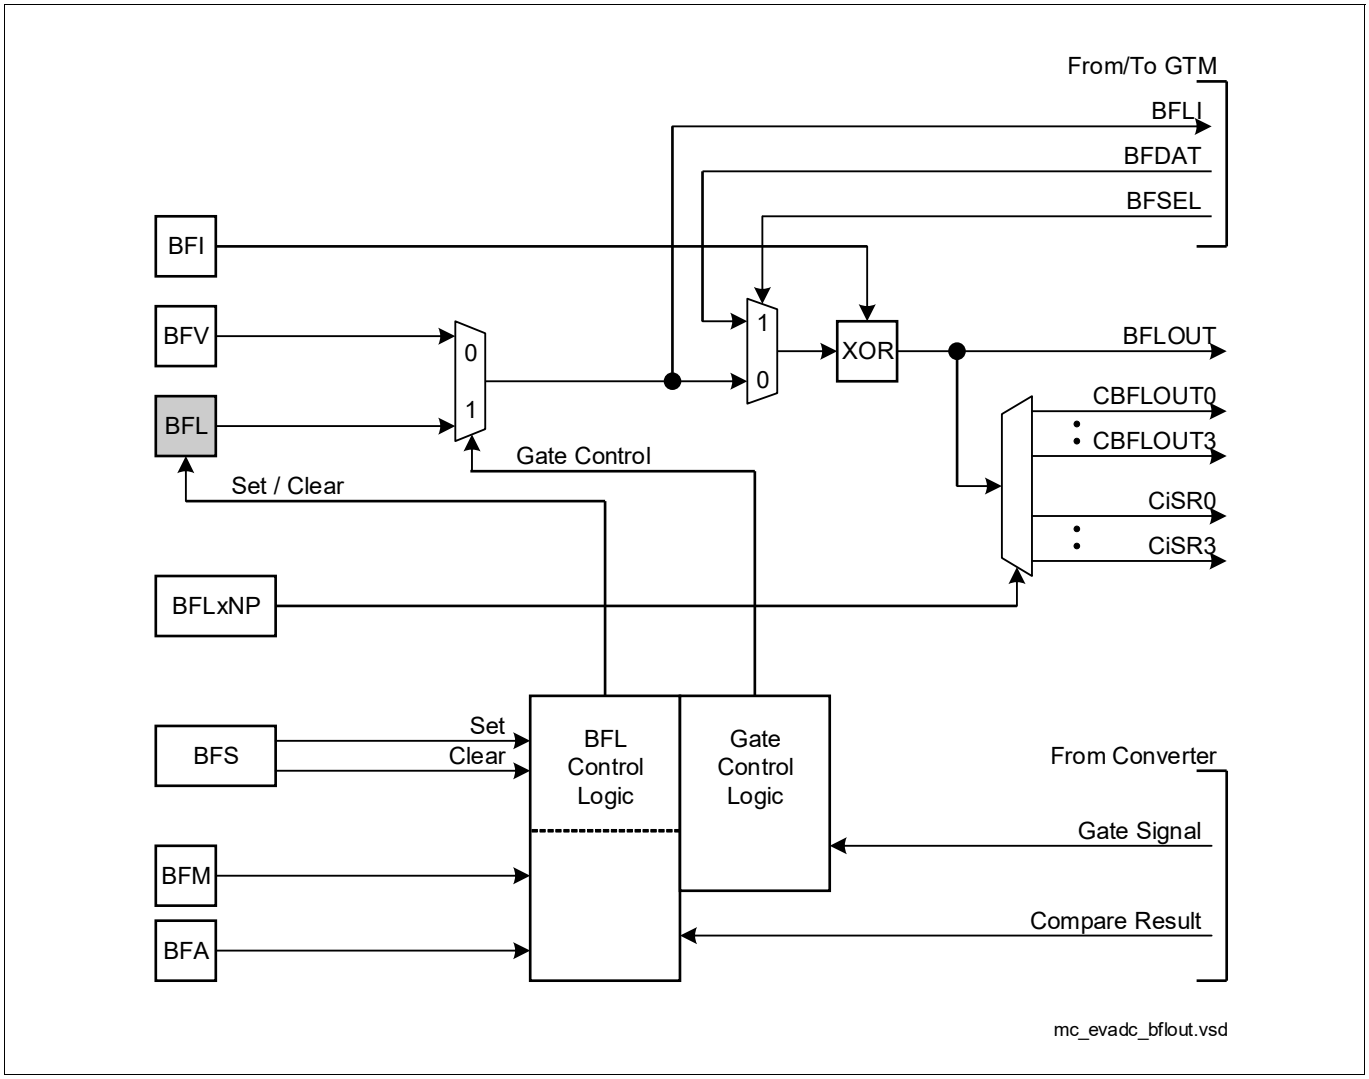

Figure 260 Boundary Flag Control

Software Interaction

Although in an application a fast compare channel will most probably control external hardware directly via the boundary flag outputs, also software interaction is possible, for example for debugging purposes at low speed.

The availability of a new compare result in bit FCxFCBFL.FCR is indicated by setting the valid flag FCxFCBFL.VF. Reading register FCxFCBFL automatically clears the valid flag. Due to internal synchronization this takes several clock cycles.

Polling the valid flag is only recommended for low speed operation, because

- due to the delayed clearing of bit VF a set valid flag may be read several times
- compare operations at a high rate may set a cleared valid flag before software can detect VF = 0

The availability of a new compare result in bit FCxFCBFL.FCR can also be indicated by generating a service request. Select FCxFCM.SRG = 11_B and FCxFCCTRL.CHEVMODE ≠ 00 (depending on the intended operation) to enable the service request path. This can be useful for low speed operation because short trigger intervals generate a high service request rate for the system.

Boundary Flag Register, FC Channel x

The Boundary Flag Register holds the boundary flag itself together with bits to select activation condition, output signal polarity, and basic operating mode.

The node pointer directs signal FCxBFLOUT to alternate on-chip connections with other modules (in addition to the group-specific output). Possible targets are the corresponding common service request lines or the common boundary flag outputs (CBFLOUT0 … CBFLOUT3).

Also software can set or clear the boundary flag.
