32.9 Conversion Timing

The term “conversion timing” not only covers the time required for the conversion to a digital result itself, but also the time required for sampling the respective input signal, the time required for calibration, and additional internal steps.

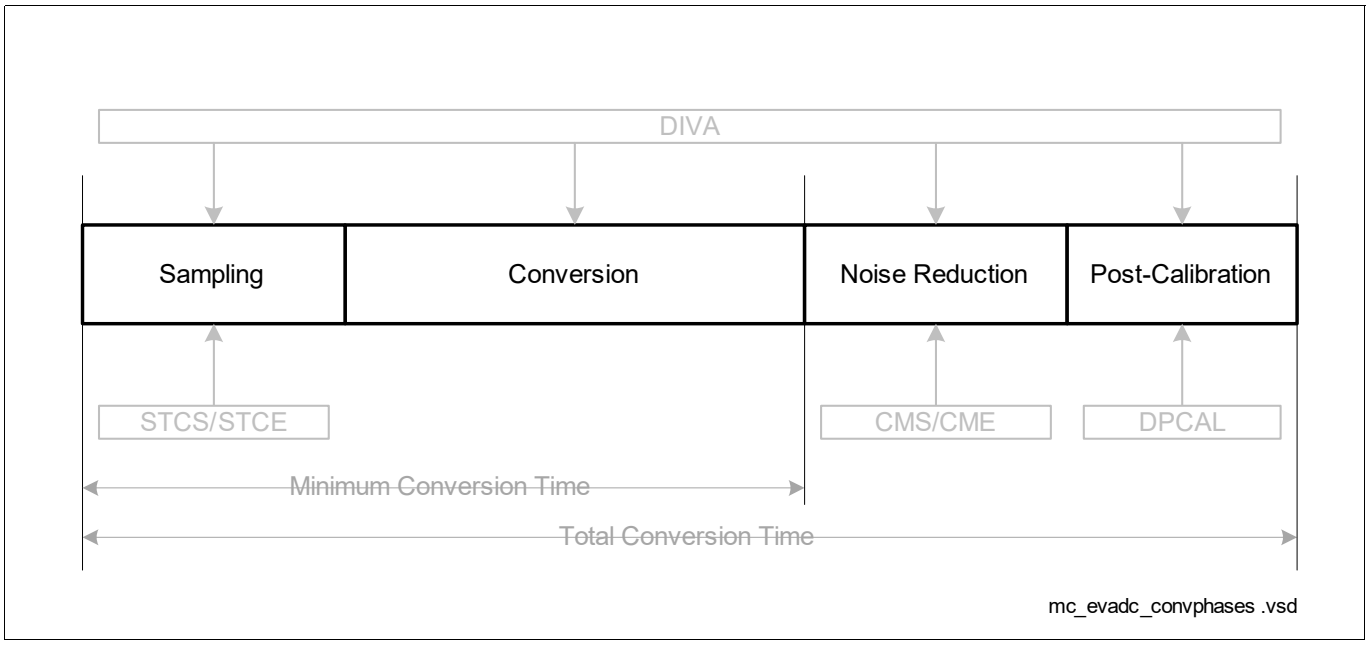

Figure 261 Conversion Phases

All phases of a conversion are configurable by the application. Consequently, the conversion time also depends on the respective configuration. The sections below list the configurable factors and also give some examples for the resulting conversion times.

Note: The time from the trigger event that requests the corresponding conversion until the start of the sample phase depends on the arbitration and can, therefore, only be determined with a known system setup.

32.9.1 Start-Up CalibrationTiming

Start-up calibration is required before operating the EVADC channels. The calibration time can be computed with the following formula:

$t_{SUCAL} = 256 \times ((4 + 2{\times}CALSTC) \times t_{ADCI} + 5 \times t_{ADC})$ [1)]

Timing Examples Start-Up Calibration

System assumptions:f_{ADC} = 160 MHz i.e. t_{ADC} = 6.25 ns, DIVA = 5, f_{ADCI} = 26.67 MHz i.e. t_{ADCI} = 37.5 ns, CALSTC = 00_B.

According to the given formula the following calibration time is required:

$t_{SUCAL} = 256 \times (4 \times t_{ADCI} + 5 \times t_{ADC}) = 256 \times (4 \times 37.5\ ns + 5 \times 6.25\ ns) = 46.4\ \mu s$

Note: The start-up calibration is not part of the actual conversions. Also, the corresponding calibration time does not contribute to the conversion timing.
It is, however, a prerequisite for accurate conversion results.

1) For f_{ADCI} > 40 MHz CALSTC must be 01_B.

32.9.2 Standard Converter Channels Timing

The total conversion time comprises the time from the start of the sample phase until the availability of the result.

The frequency at which conversions can be triggered also depends on several configurable factors:

- The selected sample time, according to the input class definitions. For conversions using an external multiplexer, also the extended sample times count.
- Delays induced by cancelled conversions that must be repeated.
- Delays due to equidistant sampling of other channels.
- The frequency of external trigger signals, if enabled.
- The period of the request timer, if enabled,

The conversion timing depends on the following user-definable factors:

- The ADC conversion clock frequency, where $f_{ADCI} = f_{ADC} / (DIVA+1)$
- The selected sample time, where $t_S = (2 + STC) \times t_{ADCI}$ (STC = additional sample time, see also **Table 255**)[1)]
- The actual result generation (12 bits)
- The duration of the selected noise reduction conversion steps NRS × t_{NR}, where NRS can be 0, 1, 3, 7
- The post-calibration time t_{PC}, if enabled
- Internal steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and internal steps. It can be computed with the following formula:

$t_{C12} = [(2 + STC) \times t_{ADCI}] + [13 \times t_{ADCI}] + [NRS \times t_{NR}] + [t_{PC}] + [3 \times t_{ADC}]$

with:

$t_{NR} = 4 \times t_{ADCI} + 3 \times t_{ADC}$ per conversion step

$t_{PC} = (4 + 2\times CALSTC) \times t_{ADCI} + 5 \times t_{ADC}$ if enabled, otherwise 0

Timing examples in **Table 259**.

32.9.3 Fast Compare Channels Timing

Fast Compare channels execute single compare operations instead of the complete SAR algorithm. The sample time is required in all cases.

The conversion timing depends on the following user-definable factors:

- The ADC conversion clock frequency, where $f_{ADCI} = f_{ADC} / (DIVA+1)$
- The selected sample time, where $t_S = (2 + STCF) \times t_{ADCI}$ (STCF = additional sample time, see also **Table 255**)
- The actual compare operation (1 bit)
- Internal steps done at module clock speed

The comparison time is the sum of sample time, compare step, and internal steps. It can be computed with the following formula:

$t_{FC} = [(2 + STCF) \times t_{ADCI}] + [2 \times t_{ADCI}] + [3 \times t_{ADC}]$

Timing examples in **Table 259**.

Note: To ensure equidistant results, make sure the programmed request period is longer than the maximum compare time.

1) $t_S = (2 + (STC-15)\times16)) \times t_{ADCI}$ for STC > $0F_H$.

32.9.4 Conversion Timing Configurations

The examples in the table below assume a minimum sample time of 100 ns as required for the primary groups. Longer sample times, required by secondary groups or by the properties of the external signal source, lead to increased total conversion times.

The maximum conversion rate can be achieved with postcalibration disabled. This can be done either temporarily or permanently, depending on the requirements of the application.

System assumptions:f_{ADC} = 160 MHz i.e. t_{ADC} = 6.25 ns, single MSB, CALSTC = 0 for $f_{ADCI} \leq$ 40 MHz, CALSTC = 1 for f_{ADCI} = 53.3 MHz

Table 259 Conversion Timing Overview

Element	20.0 MHz (DIVA = 7)	26.7 MHz (DIVA = 5)	40.0 MHz (DIVA = 3)	53.3 MHz (DIVA = 2)
Sample time = 100 ns	2 × 50 ns = 100 ns	3 × 37.5 ns = 112.5 ns	4 × 25 ns = 100 ns	6 × 18.75 ns = 112.5 ns
Sample time = 500 ns	10 × 50 ns = 500 ns	14 × 37.5 ns = 525 ns	34 × 25 ns = 850 ns	34 × 18.75 ns = 637.5 ns
Result generation	13 × 50 ns = 650 ns	13 × 37.5 ns = 487.5 ns	13 × 25 ns = 325 ns	13 × 18.75 ns = 243.75 ns
Postcalibration	4 × 50 ns = 200 ns	4 × 37.5 ns = 150 ns	4 × 25 ns = 100 ns	6 × 18.75 ns = 112.5 ns
Sync postcalibration	5 × 6.25 ns = 31.25 ns	5 × 6.25 ns = 31.25 ns	5 × 6.25 ns = 31.25 ns	5 × 6.25 ns = 31.25 ns
Sync statemachine	3 × 6.25 ns = 18.75 ns	3 × 6.25 ns = 18.75 ns	3 × 6.25 ns = 18.75 ns	3 × 6.25 ns = 18.75 ns
Noise reduction step (0, 1, 3, 7)	218.75 ns	168.75 ns	118.75 ns	93.75 ns
Conversion with postcalibration	1000 ns	800 ns	575 ns	518.75 ns
Conversion with 3 noise red. steps (CMS = 10_B) and postcalibration	1656.25 ns	1306.25 ns	931.25 ns	800 ns
Conversion without postcalibration, primary groups	768.75 ns	618.75 ns	443.75 ns	375 ns
Conversion without postcalibration, secondary groups	1168.75 ns	1031.25 ns	1193.75 ns	900 ns
Maximum conversion rate	1.3 MS/s	1.6 MS/s	2.2 MS/s	2.6 MS/s
Compare steps	2 × 50 ns = 100 ns	2 × 37.5 ns = 75 ns	2 × 25 ns = 50 ns	2 × 18.75 ns = 37.5 ns
Fast compare operation	218.75 ns	206.25 ns	168.75 ns	168.75 ns
Maximum fast compare rate	4.5 MS/s	4.8 MS/s	5.9 MS/s	5.9 MS/s

32.10 Conversion Result Handling

The A/D converters can preprocess the conversions result data to a certain extent before storing them for retrieval by the CPU or a DMA channel. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** to user-configurable registers
- **Data Alignment** according to endianess
- **Wait-for-Read Mode** to avoid loss of data
- **Result FIFO Buffer** to store subsequent result values
- **Result Event Generation**
- **Data Modification** supports data reduction or anti-aliasing filtering
- **Hardware Data Interface** provides result values to other modules

32.10.1 Storage of Conversion Results

The conversion result values of a certain group can be stored in one of the 16 associated group result registers or in the common global result register (see **Selecting a Result Register**).

This structure provides different locations for the conversion results of different sets of channels. Depending on the application needs (data reduction, auto-scan, alias feature, etc.), the user can distribute the conversion results to minimize CPU load and/or optimize the performance of DMA transfers.

The compare result values of the fast compare channels is stored in bit FCR of register **FCxFCBFL (x=0-7)**.

Each result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the corresponding result register or bit and can be read out.

Note: The valid flag indicates results generated by the converter. The standard result registers can also be written by software. In this case, after writing to a result register the valid flag is undefined.

For standard conversions, result values are available in bitfield RESULT.

Result registers can be read via two different views. These views use different addresses but access the same register data:

- When a result register is read via the **application view**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When a result register is read via the **debug view**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

The application can retrieve conversion results through several result registers:

- Group result register:
  Returns the result value and the channel number
- Global result register:
  Returns the result value and the channel number and the group number

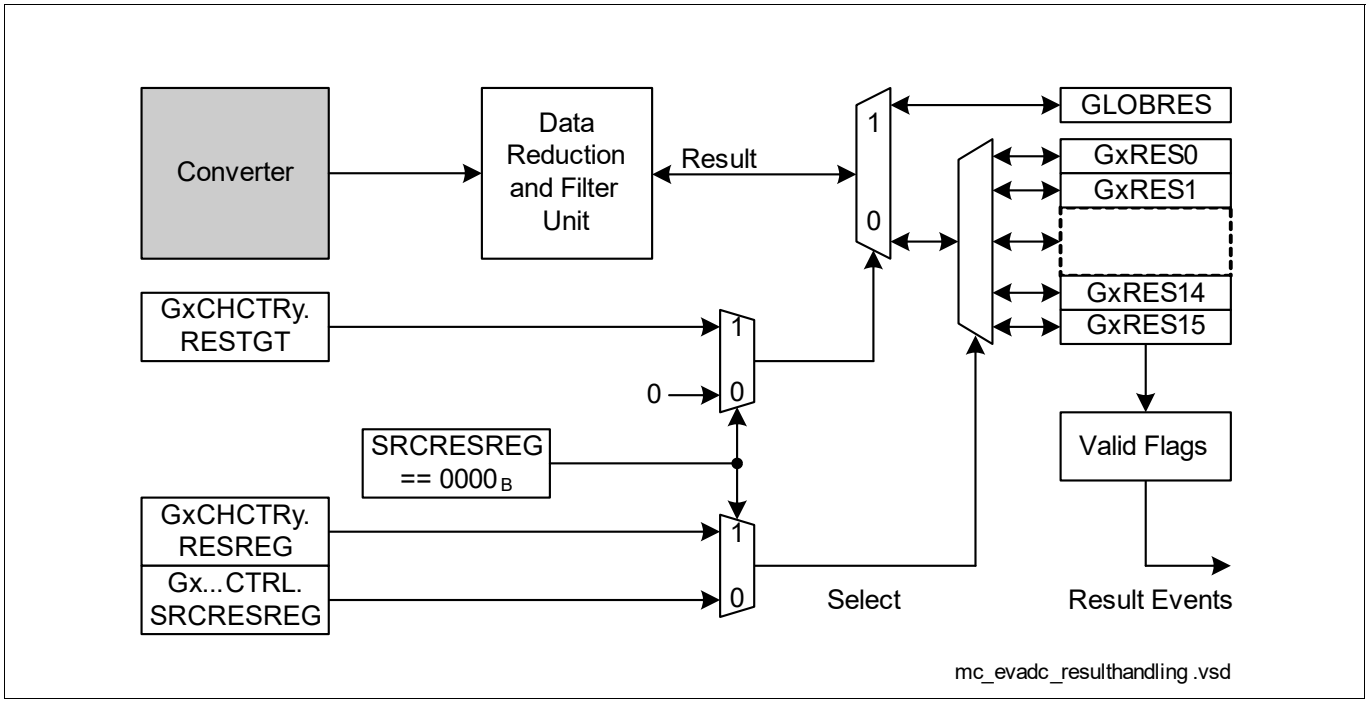

Figure 262 Conversion Result Storage

Selecting a Result Register

Conversion results are stored in result registers that can be assigned by the user according to the requirements of the application. The following bitfields direct the results to a register:

- SRCRESREG in register **GxQCTRLi (i=0-2;x=0-11)** etc.
  Selects the group-specific result register GxRES1 … GxRES15
  when source-specific result registers are used
- RESTGT in register GxCHCTRy
  Selects the global result register instead of the group-specific result registers
- RESREG in register GxCHCTRy
  Selects the group-specific result register GxRES0 … GxRES15
  when channel-specific result registers are used (see below).

Using source-specific result registers allows separating results from the same channel that are requested by different request sources. Usually these request sources are used by different tasks and are triggered at different times.

Using the global result register allows convenient handling of results from different groups, e.g. in the case of daisy chaining. This way, a single DMA channel can unload all results.
When using GLOBRES as the target, make sure only one result at a time is written to it, so no result values get lost.

Note: Bitfield SRCRESREG is disregarded for synchronized conversions triggered by another master. In this case no request source is involved and the selection is taken from the channel control register.

Group x Result Control Register y

The group result control registers select the behavior of the result registers of a given group.

GxRCRy (x=0-11;y=0-15)

0	31:16	r	**Reserved, write 0, read as 0**

32.10.2 Data Alignment

The number of valid bits of a conversion result value within the selected result register depends on the configuration (see **Figure 263**):

- The selected result position (Left/Right-aligned[1)], for standard conversion results)
- The selected data modification mode (accumulation, difference, filter: always right-aligned, RESPOS = 0!)

These options provide the conversion results in a way that minimizes data handling for the application software.

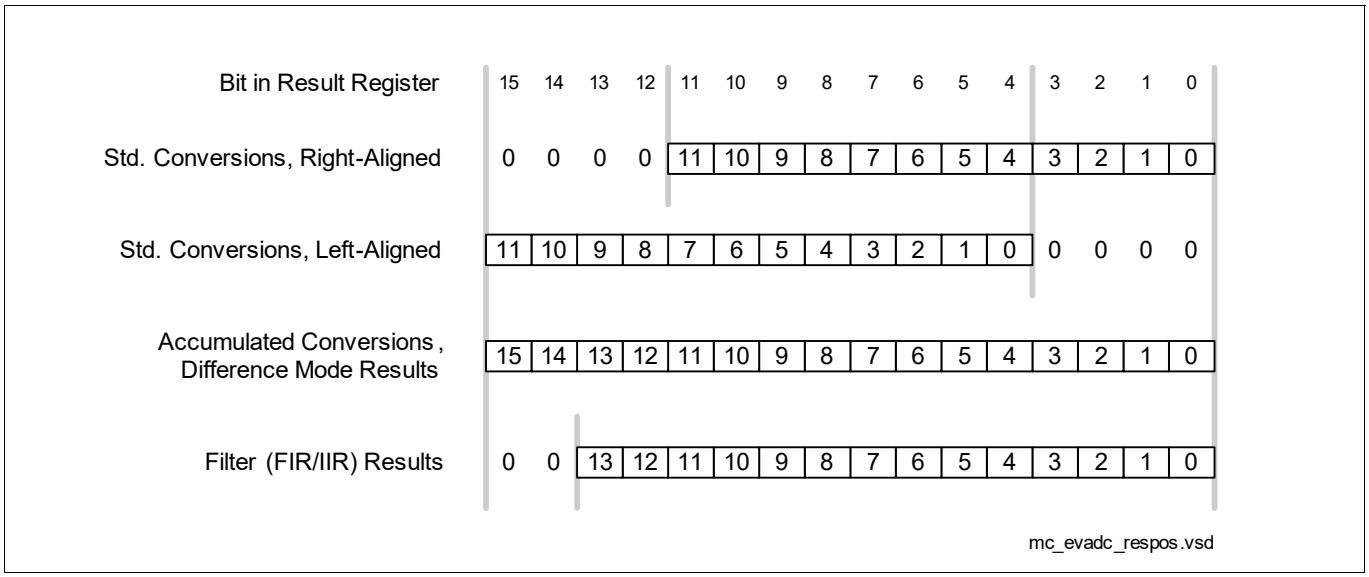

Figure 263 Result Storage Options

32.10.3 Wait-for-Read Mode

The wait-for-read mode prevents data loss due to overwriting a result register with a new conversion result before the CPU (or DMA) has read the previous data. For example, auto-scan conversion sequences or other sequences with “relaxed” timing requirements may use a common result register. However, the results come from different input channels, so an overwrite would destroy the result from the previous conversion[2)].

Wait-for-read mode automatically suspends the start of a conversion for this channel from this source until the current result has been read. So a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU/DMA capability to read the formerly converted result (latency).

If wait-for-read mode is enabled for a result register (bit GxRCRy.WFR = 1), a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VF = 1) or if a currently running conversion targets the same result register.

If two request sources target the same result register with wait-for-read mode selected, a higher priority source cannot interrupt a lower priority conversion request started before the higher priority source has requested its conversion. Cancel-inject-repeat mode does not work in this case. If the higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

1) RESPOS = 1 left-shifts the read result value by four bits. This, therefore, only makes sense for standard 12-bit conversion results. The global result register GLOBRES always stores results right-aligned.

2) Repeated conversions of a single channel that use a separate result register will not destroy other results, but rather update their own previous result value. This way, always the actual signal data is available in the result register.

If request sources from different groups target the global result register with wait-for-read mode selected (bit GLOBRCR.WFR = 1), a conversion request can only be suppressed when GLOBRES.VF is already set. Concurrent requests may lead to conflicts, because several request sources may see the global valid flag cleared during the begin of the sequence.

To avoid this, ensure that these conversions are only requested sequentially, as it is the case for daisy chaining.

*Note: Wait-for-read mode is ignored for synchronized conversions of synchronization slaves (see **Section 32.11**).*

32.10.4 Result FIFO Buffer

Result registers can either be used as direct target for conversion results or they can be concatenated with their upper neighbor result register of the same ADC group to form a result FIFO buffer (first-in-first-out buffer mechanism). A result FIFO stores several measurement results that can be read out later with a “relaxed” CPU response timing. It is possible to set up more than one FIFO buffer structure with the available result registers.

Result FIFO structures of two or more registers are built by concatenating result registers to their upper neighbor result register (with next higher index, see **Figure 264**). This is enabled by setting bitfield GxRCRy.FEN = 01_B. Conversion results are stored to the register with the highest index of a FIFO structure (GxRCRy.FEN = 00_B). Software reads the values from the FIFO register with the lowest index.

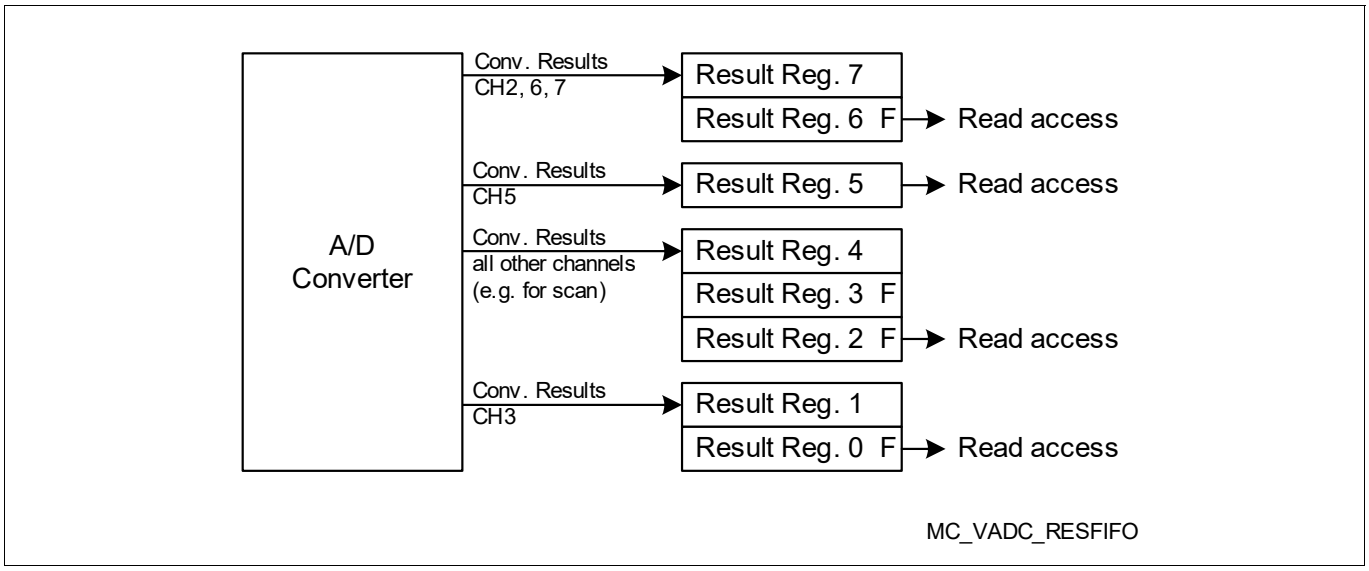

Figure 264 Result FIFO Buffers

In the example shown the result registers have been configured in the following way:

- 2-stage buffer consisting of result registers 7-6
- dedicated result register 5
- 3-stage buffer consisting of result registers 4-3-2
- 2-stage buffer consisting of result registers 1-0

Note: If GxRES15 is the input stage of a FIFO buffer, result values written to it are only reflected on the HDI if this value fills the FIFO completely. Intermediate results are not written to the HDI. If the HDI shall be used, select a lower result register as the input stage.

Table 260 summarizes the required configuration of result registers if they are combined to build result FIFO buffers.

Table 260 Properties of Result FIFO Registers

Function	Input Stage	Intermed. Stage	Output Stage
Result target[1)]	YES	no	no
Application read	no	no	YES
Data reduction mode	YES	no	no
Wait-for-read mode	YES	no	no
Result event interrupt	no	no	YES
Valid read data	no	no	YES
FIFO enable (FEN)	00_B	01_B	01_B
Registers in example	7, 4, 1	3	6, 2, 0

1) To enable proper functionality of a FIFO, direct results only to the input stage of a FIFO structure.

Note: If enabled, a result interrupt is generated for each data word in the FIFO.

Minimum/Maximum Detection

A special FIFO mode, that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, stores the highest (or lowest) result of a conversion sequence. This is enabled by setting bitfield GxRCRy.FEN = 10_B (maximum) or GxRCRy.FEN = 11_B (minimum).

Note: Write a reasonable start value to the result bitfield in the peak result register before the conversion sequence to be monitored begins.
Use 0000_H to find the maximum and $0FFF_H$ to find the minimum (only the lower 12 bits are compared!).
The actual result value is available from the result register targetted by the respective channel.

Result FIFO buffer timing

To update the output of the result FIFO buffer, there is a latency of 6 system peripheral bus cycles (f_{SPB}) and 6 ADC clock cycles (f_{ADC}). This latency has to consider for the read-out by CPU or DMA:

- The data transfer from result FIFO buffer to the CPU is usually done with a consecutive procedure of single read commands. The architectural defined access time from CPU to system peripheral bus is given by 5 system peripheral bus cycles (f_{SPB}). Therefore, a waiting time between the consecutive reads of 1 f_{SPB} cycle and 6 f_{ADC} cycles has to consider.
- To ensure data integrity, it is mandatory to use a DMA configuration that considers the described FIFO timing. From DMA perspective, the configuration based on a single transfer and multiple data moves would be the preferred choice. However, this configuration does not fulfill the FIFO timing. For the initial data move, the execution time is defined by 6 system peripheral bus clock cycles (f_{SPB}) and 13 system resource interface clock cycles (f_{SRI}). All subsequent data moves require 3 f_{SPB} clock cycles and 11 (f_{SRI}) clock cycles. To use the result FIFO buffer together with the DMA, a Linked List DMA configuration could be used. Using this kind of configuration, it is ensured that the DMA latency ($6\times f_{SPB} + 13\times f_{SRI}$) is longer than the update of the result FIFO buffer needs ($6\times f_{SPB} + 6\times f_{ADC}$).

32.10.5 Data Modification

The data resulting from conversions can be automatically modified before being used by an application. Several options can be selected (bitfield DMM in register **GxRCRy (x=0-11;y=0-15)** etc.) which reduce the CPU/DMA load required to unload and/or process the conversion data.

- **Standard Data Reduction Mode (for GxRES0 ... GxRES15):**Accumulates 2 up to 16 result values within each result register before generating a result interrupt. This can remove noise from the input signal or preprocess the result data for the application.
- **Result Filtering Mode (FIR, for GxRES7, GxRES15):**Applies a 3rd order Finite Impulse Response Filter (FIR) with selectable coefficients to the conversion results for the selected result register.
- **Result Filtering Mode (IIR, for GxRES7, GxRES15):**Applies a 1st order Infinite Impulse Response Filter (IIR) with selectable coefficients to the conversion results for the selected result register.
- **Difference Mode (for GxRES1 ... GxRES15):**Subtracts the contents of result register GxRES0 from the conversion results for the selected result register. Bitfield DRCTR is not used in this mode.

Table 261 Function of Bitfield DRCTR

DRCTR	Standard Data Reduction Mode (DMM = 00_B)	DRCTR	Result Filtering Mode (DMM = 01_B)[1)]
0000_B	Data Reduction disabled	0000_B	FIR filter: a=2, b=1, c=0
0001_B	Accumulate 2 result values	0001_B	FIR filter: a=1, b=2, c=0
0010_B	Accumulate 3 result values	0010_B	FIR filter: a=2, b=0, c=1
0011_B	Accumulate 4 result values	0011_B	FIR filter: a=1, b=1, c=1
0100_B	Accumulate 5 result values	0100_B	FIR filter: a=1, b=0, c=2
0101_B	Accumulate 6 result values	0101_B	FIR filter: a=3, b=1, c=0
0110_B	Accumulate 7 result values	0110_B	FIR filter: a=2, b=2, c=0
0111_B	Accumulate 8 result values	0111_B	FIR filter: a=1, b=3, c=0
1000_B	Accumulate 9 result values	1000_B	FIR filter: a=3, b=0, c=1
1001_B	Accumulate 10 result values	1001_B	FIR filter: a=2, b=1, c=1
1010_B	Accumulate 11 result values	1010_B	FIR filter: a=1, b=2, c=1
1011_B	Accumulate 12 result values	1011_B	FIR filter: a=2, b=0, c=2
1100_B	Accumulate 13 result values	1100_B	FIR filter: a=1, b=1, c=2
1101_B	Accumulate 14 result values	1101_B	FIR filter: a=1, b=0, c=3
1110_B	Accumulate 15 result values	1110_B	IIR filter: a=2, b=2
1111_B	Accumulate 16 result values	1111_B	IIR filter: a=3, b=4

1) The filter registers are cleared while bitfield DMM ≠ 01_B.

Standard Data Reduction Mode

The data reduction mode can be used as digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 16 conversion values to generate a final result.

Each result register can be individually enabled for data reduction, controlled by bitfield DRCTR in registers GxRCRy and GLOBRCR. The data reduction counter DRC indicates the actual status of the accumulation.

Note: Conversions for other result registers can be inserted between conversions to be accumulated.

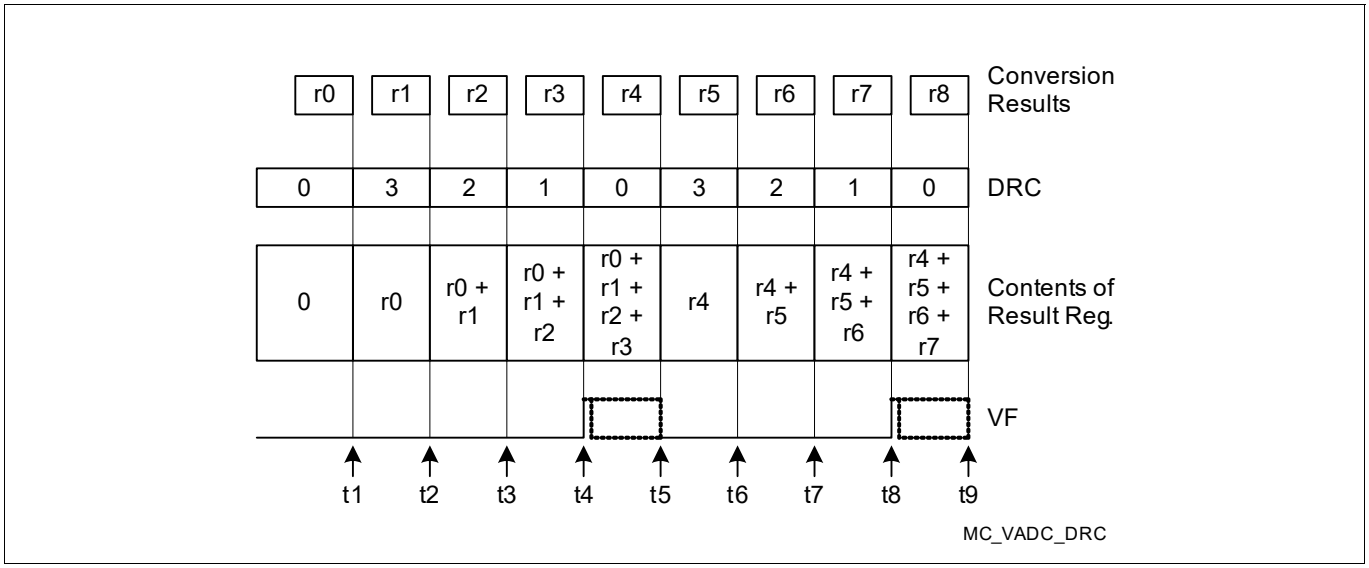

Figure 265 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 … r7) are accumulated and produce 2 final results.

When a conversion is complete and stores data to a result register that has data reduction mode enabled, the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).
- If DRC > 0 (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register.
  DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.
  The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

*Note: Software can clear the data reduction counter DRC by clearing the corresponding valid Flag (via **GxVFR (x=0-11)**).*

The response time to read the final data reduction results can be increased by associating the adjacent result register to build a result FIFO (see **Figure 266**). In this case, the final result of a data reduction sequence is loaded to the adjacent register. The value can be read from this register until the next data reduction sequence is finished (t8 in the 2nd example).

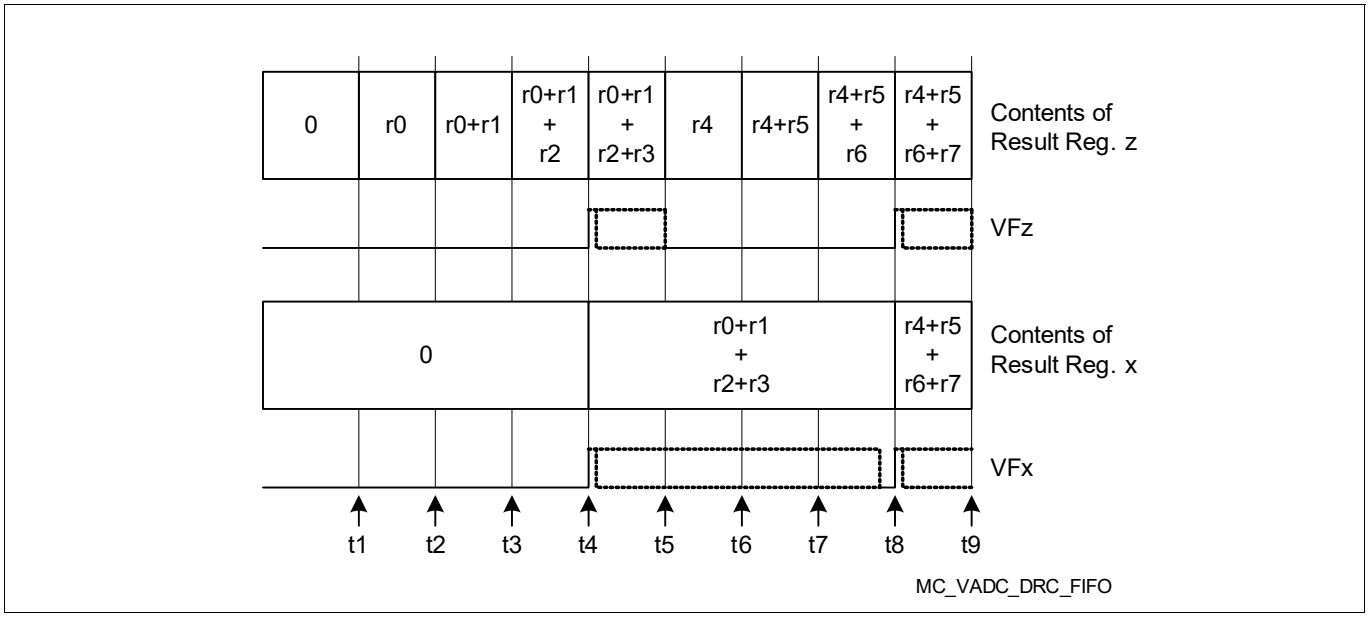

Figure 266 Standard Data Reduction Filter with FIFO Enabled

Finite Impulse Response Filter Mode (FIR)

The FIR filter (see **Figure 267**) provides 2 result buffers for intermediate results (RB1, RB2) and 3 configurable tap coefficients (a, b, c).

The conversion result and the intermediate result buffer values are added weighted with their respective coefficients to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 261**) in registers GxRCR7 and GxRCR15. These coefficients lead to a gain of 3 or 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

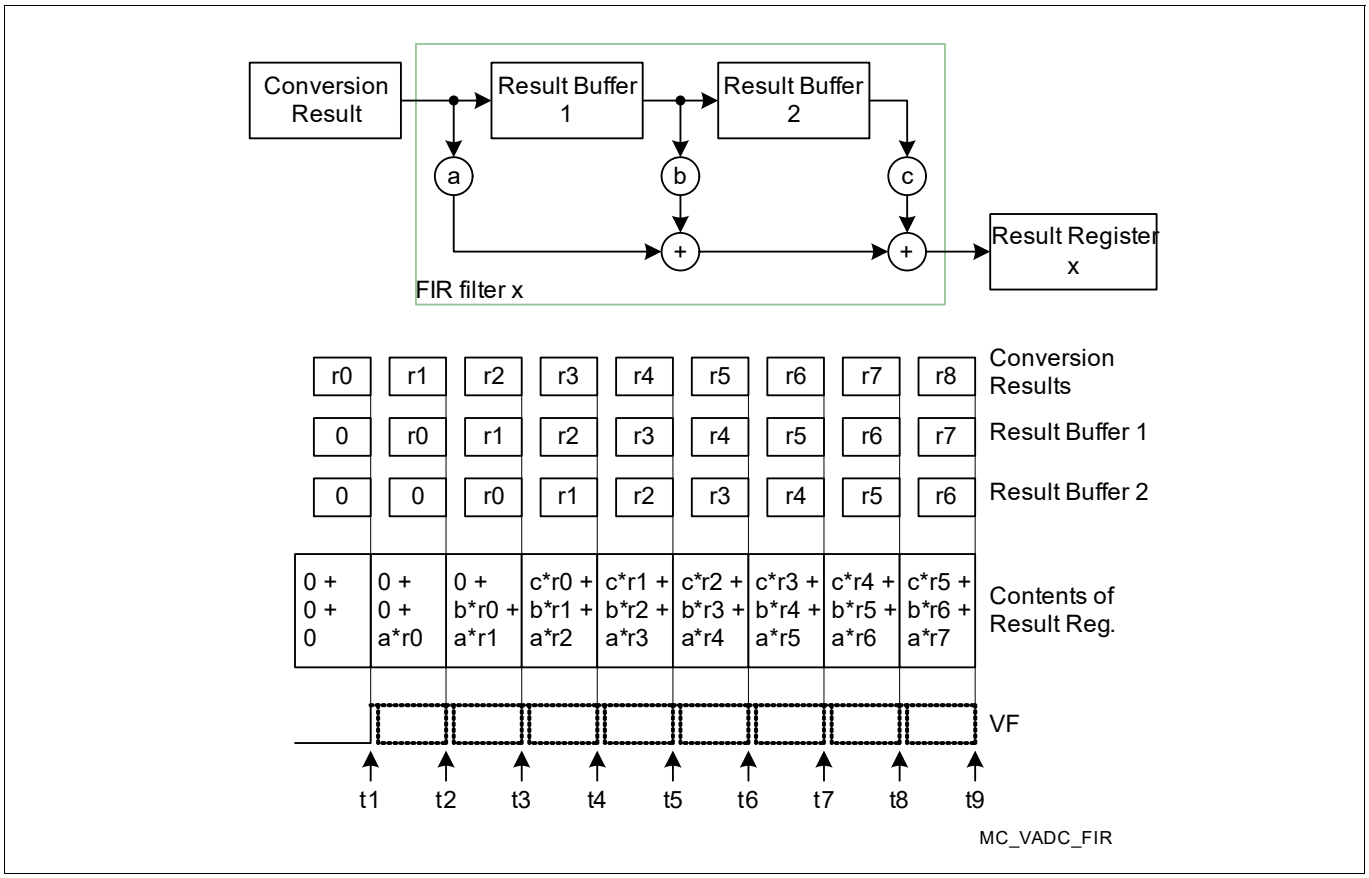

Figure 267 FIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Infinite Impulse Response Filter Mode (IIR)

The IIR filter (see **Figure 268**) provides a result buffer (RB) and 2 configurable coefficients (a, b). It represents a first order low-pass filter.

The conversion result, weighted with the respective coefficient, and a fraction of the previous result are added to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in **Table 261**) in registers GxRCR7 and GxRCR15. These coefficients lead to a gain of 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

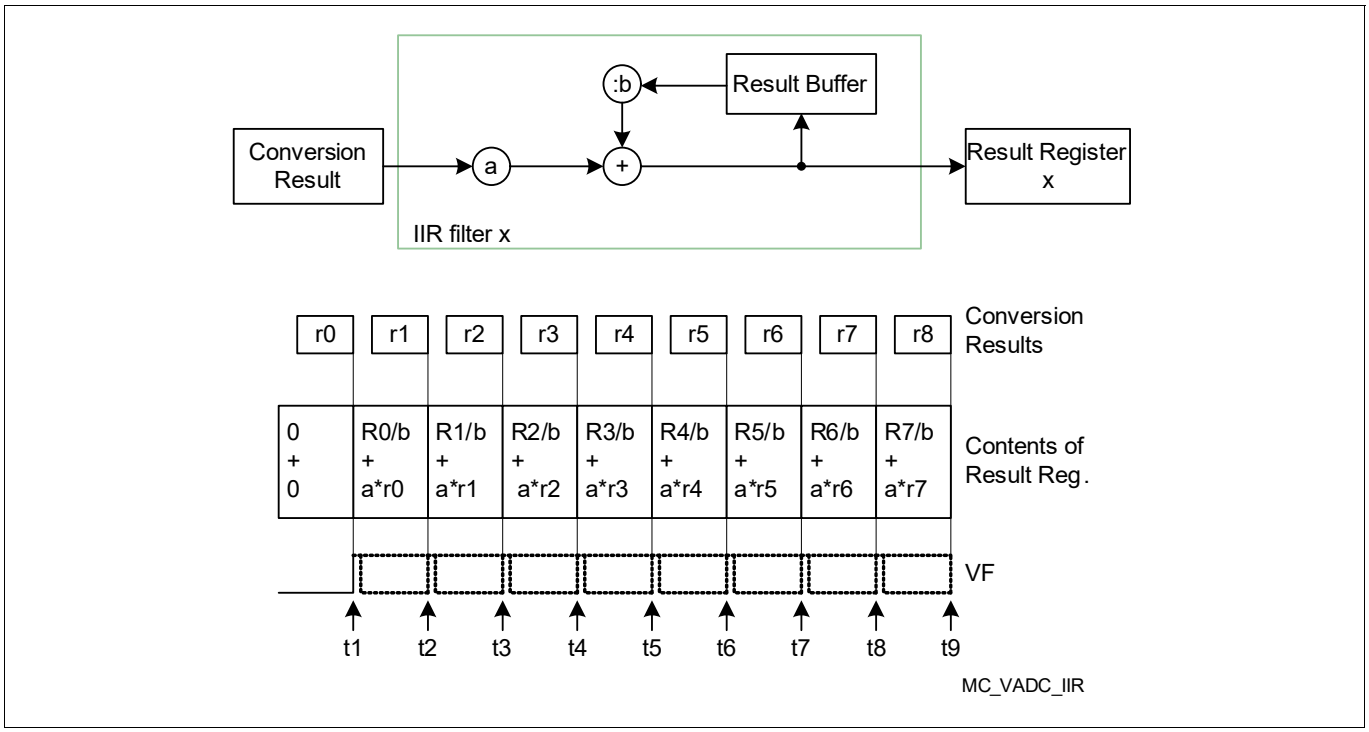

Figure 268 IIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Difference Mode

Subtracting the contents of result register 0 from the actual result puts the results of the respective channel in relation to another signal. No software action is required.

The reference channel must store its result(s) into result register 0. The reference value can be determined once and then be used for a series of conversions, or it can be converted before each related conversion.

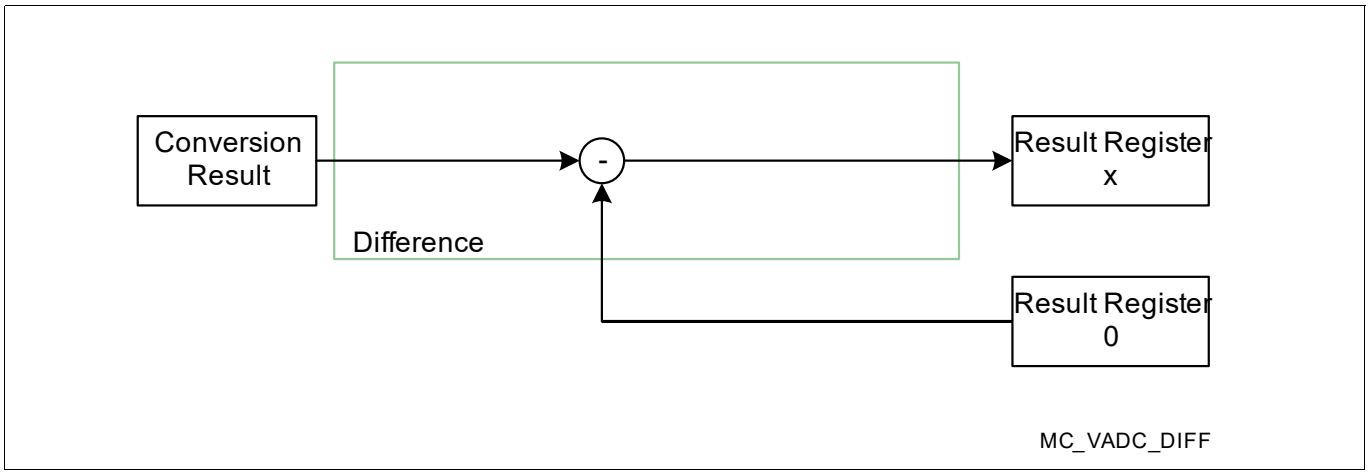

Figure 269 Result Difference

32.10.6 Result Event Generation

A result event can be generated when a new value is stored to a result register. Result events can be restricted due to data accumulation and be generated only if the accumulation is complete.

Result events can also be suppressed completely.

32.10.7 Hardware Data Interface

The digital conversion results are directly available to other modules via the hardware data interface (HDI). Result register GxRES15 outputs its content to this interface. Each time GxRES15 is updated, the HDI updates the data vector and generates a write strobe indicating the availability of a new result value.

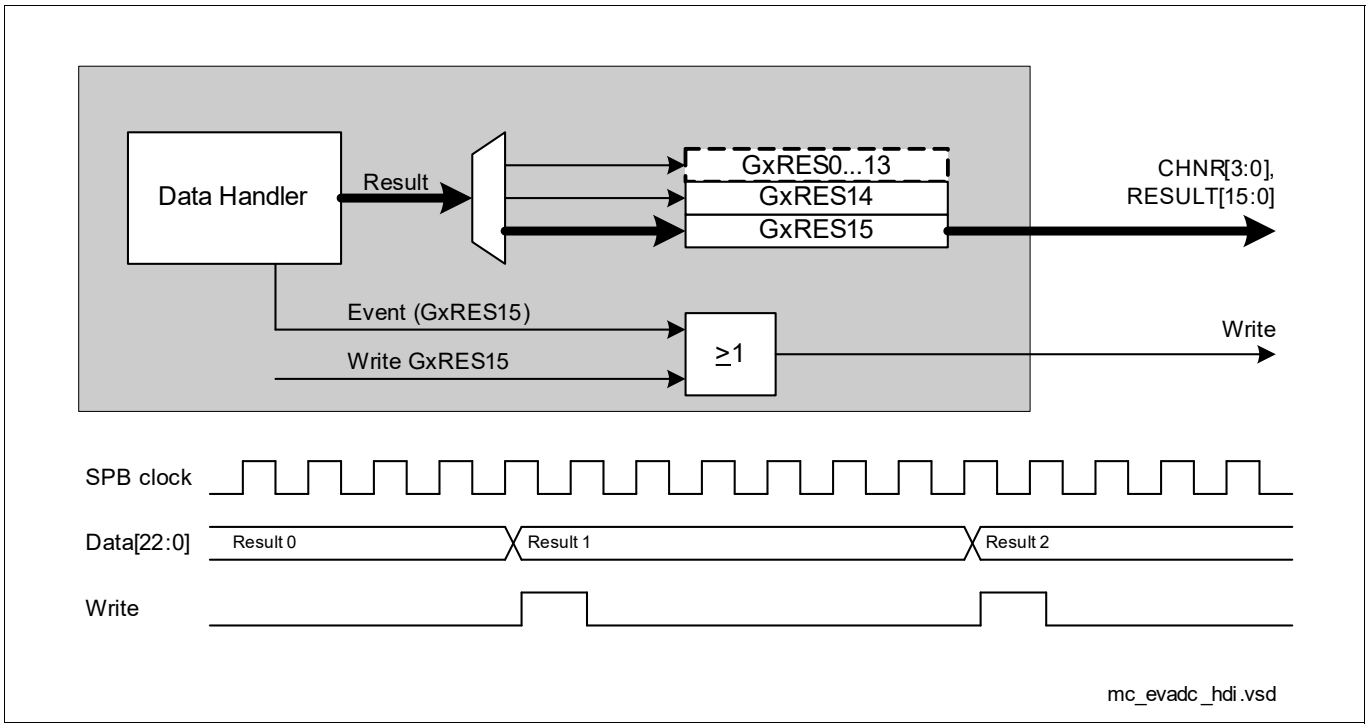

Figure 270 Hardware Data Interface

The data from this interface can be used for several purposes:

- Update the reference value of the associated Fast Compare Channel (see appendix)
- Write results to the SPU (signal processing unit) via the RIF (radar interface)
- Write results to the GTM to make them available for the MCSs equipped with an analog data interface (ADI)

Note: If GxRES15 is the input stage of a FIFO buffer, result values written to it are only reflected on the HDI if this value fills the FIFO completely. Intermediate results are not written to the HDI. If the HDI shall be used, select a lower result register as the input stage.

The hardware interface provides access to the result data of result register 15 of each group. The following data elements are available through the HDI:

Table 262 HDI Data Assignment

Bit Position	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data Content				CHNR					Conversion Result (GxRES15.RESULT)															

Note: The number of valid CHNR bits depends on the respective multiplexer. Unused bits are 0.
When GxRES15 is updated via software, bits 20:16 of the HDI reflect the last value stored in bitfield GxRES15.CHNR, because bitfield GxRES15.CHNR is not writeable.

32.11 Synchronization of Conversions

The conversions of an ADC kernel can be scheduled either self-timed according to the kernel's configuration or triggered by external (outside the ADC) signals:

Synchronized conversions support parallel conversion of channels within a synchronization group[1]. This optimizes e.g. the control of electrical drives.

Equidistant sampling supports conversions in a fixed raster with minimum jitter. This optimizes e.g. filter algorithms or audio applications.

32.11.1 Synchronized Conversions for Parallel Sampling

Several independent ADC kernels[1] can be synchronized for simultaneous measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.

The synchronization mechanism for parallel conversions ensures that the sample phases of the related channels start simultaneously. Synchronized kernels convert the same channel that is requested by the master. Different values for the sample phase length of each kernel for a parallel conversion are supported.

A parallel conversion can be requested individually for each input channel (one or more). In the example shown in **Figure 271**, input channels CH3 of the ADC kernels 0, 1, 2 are converted synchronously, whereas other input channels do not lead to parallel conversions.

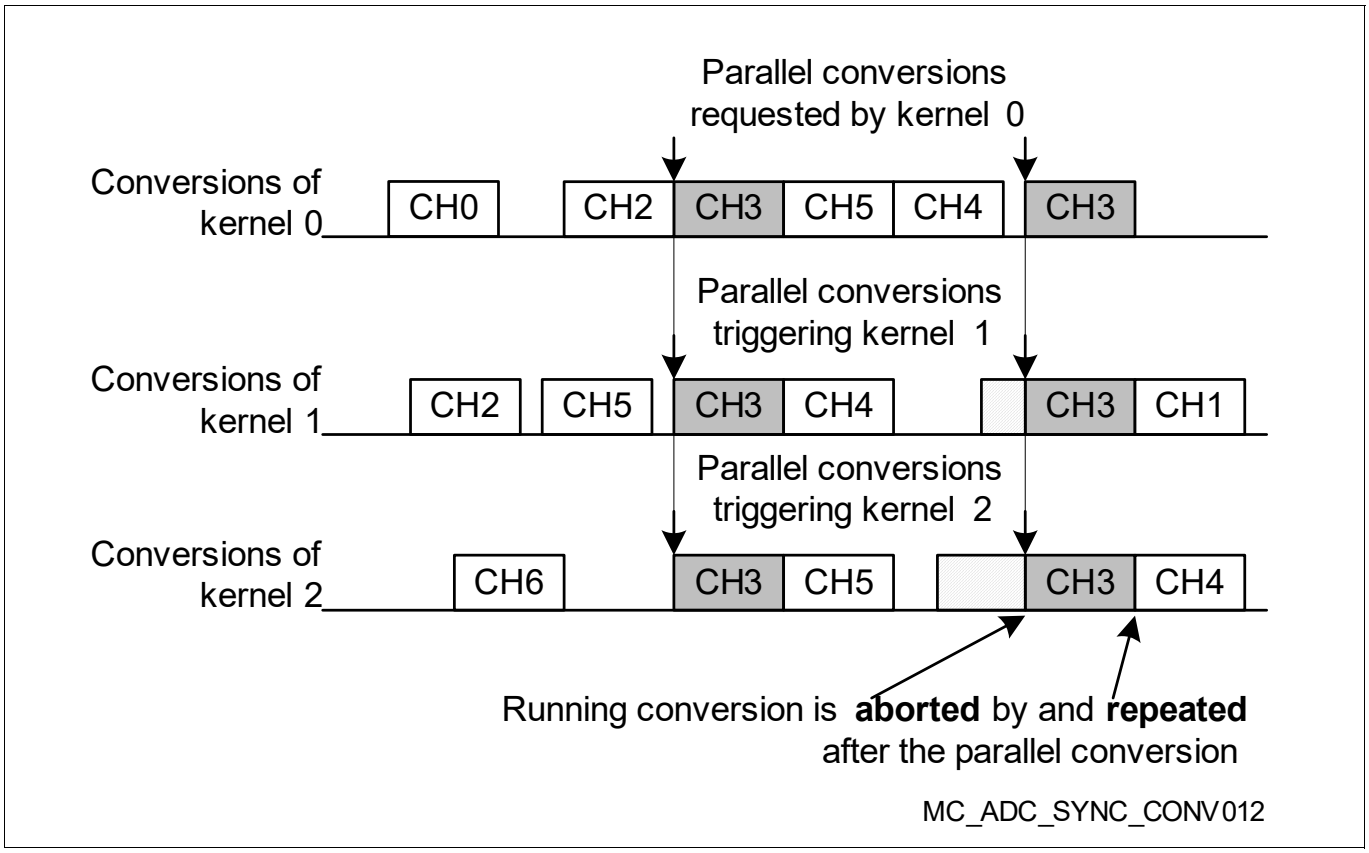

Figure 271 Parallel Conversions

One kernel operates as synchronization master, the other kernel(s) operate(s) as synchronization slave. Each kernel can play either role.

Master and slave kernels form a "synchronization group" to control parallel sampling:

1) For a summary, refer to "Synchronization Groups" in the product-specific appendix.

- **The synchronization master** controls the slave(s) by providing the control information **GxARBCFG (x=0-11)**.ANONS (see **Figure 272**) and the requested channel number.
  - Bitfield **GxSYNCTR (x=0-11)**.STSEL = 00_B selects the master's ANON information as the source of the ANON information for all kernels of the synchronization group.[1)]
  - The ready signals indicate when a slave kernel is ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x=0-11)**.EVALRy = 1 enables the control by the ready signal (in the example, kernels 1 and 2 are slaves, so EVALR1 = EVALR2 = 1).
  - The master requests a synchronized conversion of a certain channel (SYNC = 1 in the corresponding channel control register GxCHCTRy), which is also requested in the connected slave ADC kernel(s).
  - Wait-for-read mode is supported for the master.
- **The synchronization slave** reacts to incoming synchronized conversion requests from the master. While no synchronized conversions are requested, the slave kernel can execute "local" conversions.
  - Bitfield **GxSYNCTR (x=0-11)**.STSEL = $01_B/10_B/11_B$ selects the master's ANON information as the source of the ANON information for all kernels of the synchronization group[1)] (in the example kernel 0 is the master, so STSEL = 01_B).
  - The ready signals indicate when the master kernel and the other slave kernels are ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x=0-11)**.EVALRy = 1 enables the control by the ready signal (in the example kernel 0 is the master, so EVALR1 = 1, kernel 1 and 2 are slaves, so EVALR2 = 1).
  - A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode.
  - Wait-for-read mode is ignored in the slave. Previous results may be overwritten, in particular, if the same result register is used by other conversions.
- Once started, a parallel conversion cannot be aborted.
  This ensures consistent results for the respective synchronization group.
  To achieve a deterministic behaviour in an application, make sure the master receives highest priority for synchronized conversions, so that it is not interrupted. This way, synchronous and standard conversions are arbitrated in the same way.

*Note: Synchronized conversions request the same channel number, defined by the master. Using the alias feature (see **Section 32.7.2**), analog signals from different input channels can be converted. This is advantageous if e.g. CH0 is used as alternate reference.*

1) STSEL = 00_B selects the own ANON information. The other control inputs (STSEL = $01_B/10_B/11_B$) are connected to the other kernels of a synchronization group in ascending order (see also "Synchronization Groups" in the product-specific appendix).

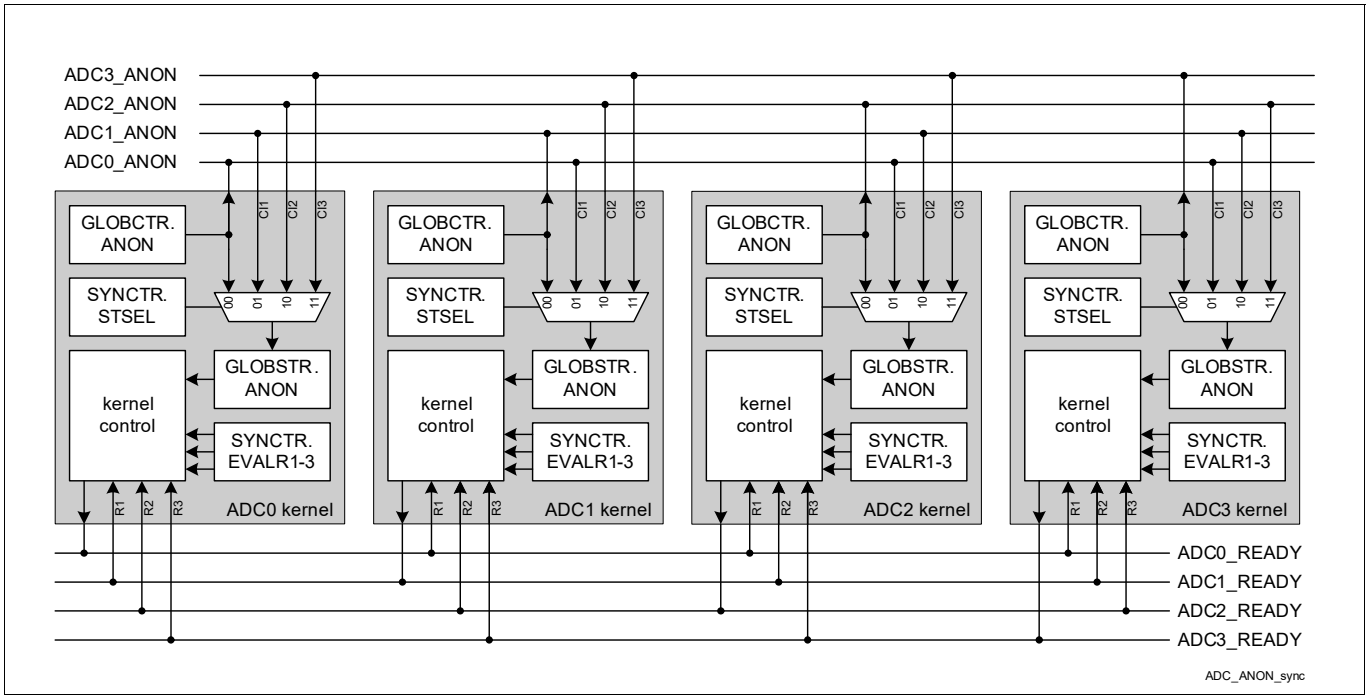

Figure 272 Synchronization via ANON and Ready Signals

Synchronization Control Register, Group x

The Synchronization Control Register controls the synchronization of kernels for parallel conversions.

Note: Program register GxSYNCTR only while bitfield GxARBCFG.ANONS = 00_B in all ADC kernels of the synchronization group. Set the master's bitfield ANONC to 11_B afterwards.

32.11.2 Equidistant Sampling

To optimize the input data e.g. for filter applications, conversions can be executed in a fixed timing raster. Conversions for equidistant sampling are triggered by a timer signal.

Select timer mode (TMEN = 1 in register **GxQCTRLi (i=0-2;x=0-11)** etc.) for the intended source of equidistant conversions. In timer mode, a request of this source is triggered (by the rising trigger signal edge) and arbitrated, but only started when the trigger signal is removed (see **Figure 273**) and the converter is idle.

The frequency of the trigger signal REQTRx defines the sampling rate. Its high time defines the preface time interval where the corresponding request source takes part in the arbitration, while no other conversions are started.

The preface time (see **Figure 273**) must be longer than two clock cycles plus the highest possible conversion time.

The period of the trigger signal must be long enough to let the equidistant conversion and optional lower priority conversions complete before the next rising trigger edge.

The trigger signal for timer mode can be generated locally by the source request timer, which runs on the module clock. It generates periods up to ~100 µs. The preface time can be selected via bitfield SEQTIMOFF.

The trigger signal for timer mode can also be generated by an external timer. This allows a wider range of periods on the expense of the synchronization jitter, because the timer has an independent time base.

To ensure that the converter is idle and the start of conversion can be controlled by the trigger signal, the equidistant conversion requests must receive highest priority. The preface time between request trigger and conversion start must be long enough for a currently active conversion to finish.

Equidistant sampling is also supported for a sequence of channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

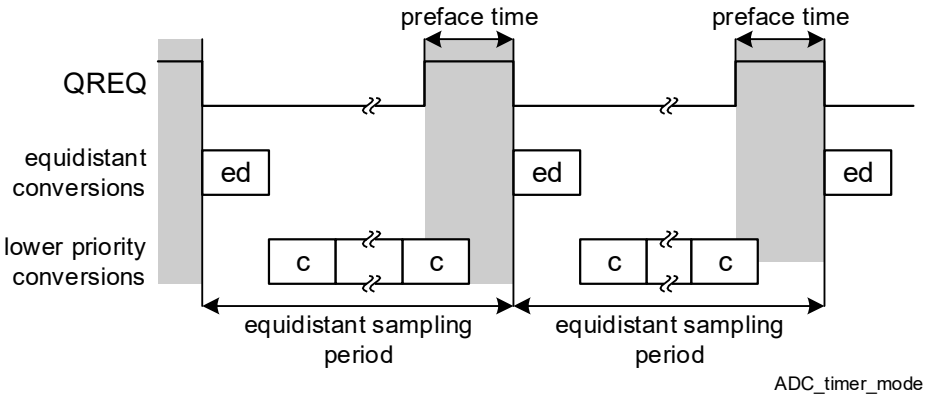

Figure 273 Timer Mode for Equidistant Sampling

Note: In timer mode, the trigger edge detector reacts on each rising edge. To achieve a deterministic behaviour (i.e. only one trigger), only use XTMODE = 10_B (i.e. rising edge) while timer mode is active.

32.11.3 Synchronous Sampling

Also the sampling phase can be aligned with the phase synchronizer. In this case (enabled by setting bit SSE in register **GxANCFG (x=0-11)**) a sampling phase is only started upon a trigger signal from the phase synchronizer.

The figure below summarizes the effects of sampling phase synchronization in combination with conversion synchronization.

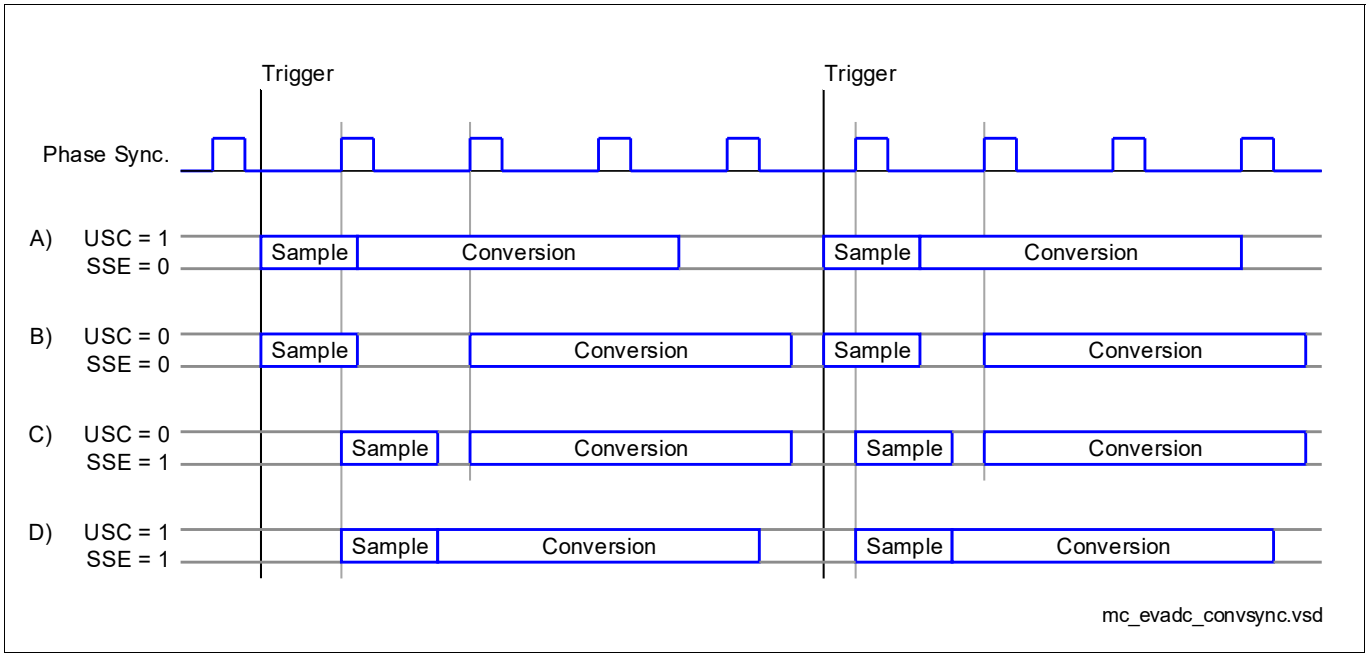

Figure 274 Synchronization of Sampling Phase

Table 263 Effects of Synchronization of Sampling and Conversion

Example in Figure	Sampling Synchronization	Conversion Synchronization	Description	Note
A	SSE = 0, unsynchronized	USC = 1, unsynchronized	Sampling starts immed. after the trigger, conversion starts immed. after sampling	As in previous products
B [1)]	SSE = 0, unsynchronized	USC = 0, synchronized	Sampling starts immed. after the trigger, conversion starts upon next PHSYNC pulse	Default after Reset
C [2)]	SSE = 1, synchronized	USC = 0, synchronized	Sampling starts upon next PHSYNC pulse, conversion starts upon next PHSYNC pulse	Optimized synchronization
D	SSE = 1, synchronized	USC = 1, unsynchronized	Sampling starts upon next PHSYNC pulse, conversion starts immed. after sampling	Not recommended

1) Provides minimum sample jitter with respect to the trigger signal.

2) Further reduces coupling effects when EDSADC channels are active.

*Note: Bit SSE controls the sampling of analog inputs. If the analog reference voltages are sampled (directly via CH30, CH31, or implicitly during the presample phase when broken wire detection is enabled) the sampling is controlled by bit USC in register **GLOBCFG**.*

32.12 Safety Features

Most analog inputs are connected to both EVADC and EDSADC channels, thus providing a basic redundancy.

Several additional test structures can be activated to test the signal path from the sensor to the input pin and the internal signal path from the input pin through the multiplexer to the converter. These test structures apply additional loads to the signal path (see summary in **Figure 275**) and aim at different sections of the signal flow. They can be controlled directly by software or can be configured for automatic execution.

- **Pull-Down Diagnostics** validates the connection of the external sensor
- **Multiplexer Diagnostics** validates the operation of the internal analog input multiplexer
- **Converter Diagnostics** validates the operation of the Analog/Digital converter itself
- **Broken Wire Detection** validates the connection from the sensor to the input pin
- **On-Chip Supervision Signals** enable additional monitoring

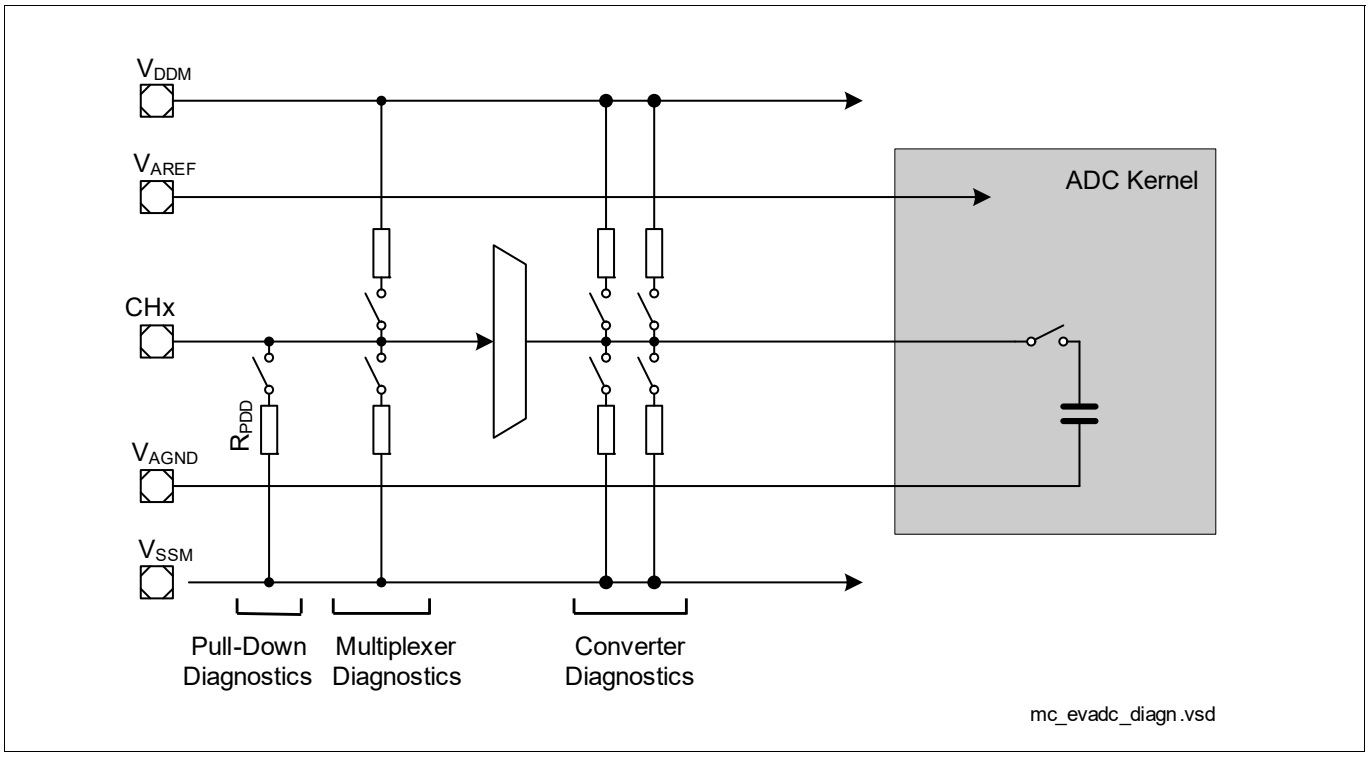

Figure 275 Signal Path Test

32.12.1 Pull-Down Diagnostics

One single input channel provides a further strong pull-down (R_{PDD}) that can be activated to verify the external connection to a sensor. The strong pull-down can be used to discharge an external buffer capacitor, which allows to generate diagnostic results quickly.

Pads belonging to IO ports need to be configured in the following way:

- Pn_PDISC.PDISi = 0, to enable the pull device, for normal operation disable the digital pad circuitry.
- Pn_PCSR.SELi = 1, to enable the test function.

32.12.2 Multiplexer Diagnostics

To test the proper operation of the internal analog input multiplexer, additional pull-up and/or pull-down devices can be connected to channels CH1 and CH2. In combination with a known external input signal this test function shows if the multiplexer connects any pin to the converter input and if this is the correct pin.

Multiplexer diagnostics uses the pull devices built into the pads. The strength of the pull devices depends on the respective pad properties. The Datasheet defines values for automotive level and TTL level.

Note: Class D pads (see pin description in Datasheet) are not configurable and use automotive level values.

Pads belonging to IO ports need to be configured in the following way:

- Pn_PDISC.PDISi = 0, to enable the pull devices.
- Pn_PCSR.SELi = 1, to enable the test function.
- Pn_PDRi.PLx selects the input level of the pad (if possible) and along with this the value of the pull devices.

Note: For normal operation (without multiplexer diagnostics) it is recommended to disable the digital pad circuitry (Pn_PDISC.PDISi = 1) to minimize noise.

32.12.3 Converter Diagnostics

To test the proper operation of the converter itself, several signals can be connected to the converter input. The test signals can be connected to the converter input either instead of the standard input signal or in parallel to the standard input signal.

To use the converter diagnostics without a connected input, select a non-existent channel number via the alias feature (**Section 32.7.2**). Redirect channel 0 or 1 to channel 24 (not connected), the conversion result can then be read from the selected result register for channel 0 or 1. This operating mode is recommended, as the test signals are not influenced by external circuitry in this case.

Bitfield CDSEL in register **GLOBTF** or **GxQINRi (i=0-2;x=0-11)** selects four different test signals (see **Figure 275**): V_{DDM}, V_{SSM}, $1/2 \times V_{DDM}$, $2/3 \times V_{DDM}$.

Note: The maximum result value (when using V_{DDM}) the converter can generate is 4 095 (FFF_H), the minimum result value (when using V_{SSM}) is 0 (000_H). Results are generated according to V_{AREF}.

32.12.4 Broken Wire Detection

To test the proper connection of an external analog sensor to its input pin, the converter's capacitor can be discharged before the regular sample phase. If the connection to the sensor is interrupted the subsequent conversion value will rather represent a reduced value than the expected sensor result. Because the precharge voltage is outside the expected result range (broken wire detection uses V_{AGND}) a valid measurement (sensor connected) can be distinguished from a failure (sensor detached).

While broken wire detection is disabled, the converter's capacitor is precharged to $V_{AREF}/2$, if idle precharge is enabled.

Note: The duration of the complete conversion is increased by the preparation phase (same as the sample phase) if the broken wire detection is enabled. This influences the timing of conversion sequences.

Broken wire detection can be enabled for each channel separately by bitfield BWDEN in the corresponding channel control register (GxCHCTRy).

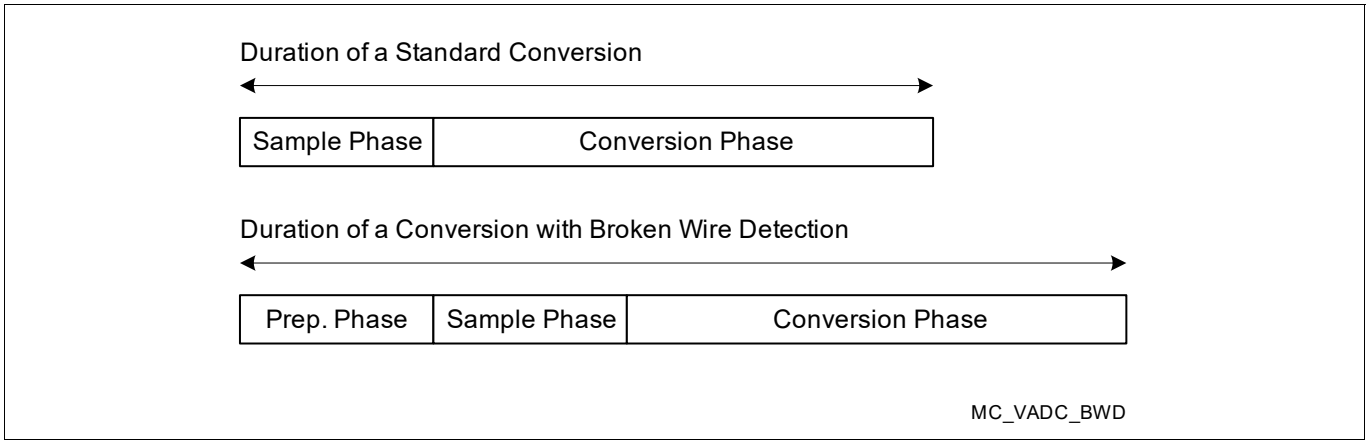

Figure 276 Broken Wire Detection

32.12.5 On-Chip Supervision Signals

Information about the basic functionality of the EVADC can be obtained via special on-chip signals, which supports common cause diagnosis. Every group can measure (primary/secondary) or compare (fast compare) a replica of a reference voltage generated by a bandgap inside the power management system (PMS). The expected results are related to the external reference voltage V_{AREF}.

Table 264 Supervision Signals

Channel	Signal	Description
GxCH28[1)]	$V_{ANACOMM}$	Common reference signal, available to all converters. Can be fed to the converters through analog input pin AN11.
GxCH29[1)]	V_{MTS}	Module test signal, provides the comparator supply voltage V_{DDK}, which is controlled by the bandgap in the power subsystem. See figure below.
GxCH30[1)]	V_{AGND}	External reference ground.
GxCH31[1)]	V_{AREF}	External reference voltage.
G10CH15	V_{EDSADC}	Supervision signal from module EDSADC. This supervision signal is enabled and selected within the EDSADC.[2)]

1) Use the alias feature to select these channels.

2) This signal requires an increased sample time of at least 1 µs.

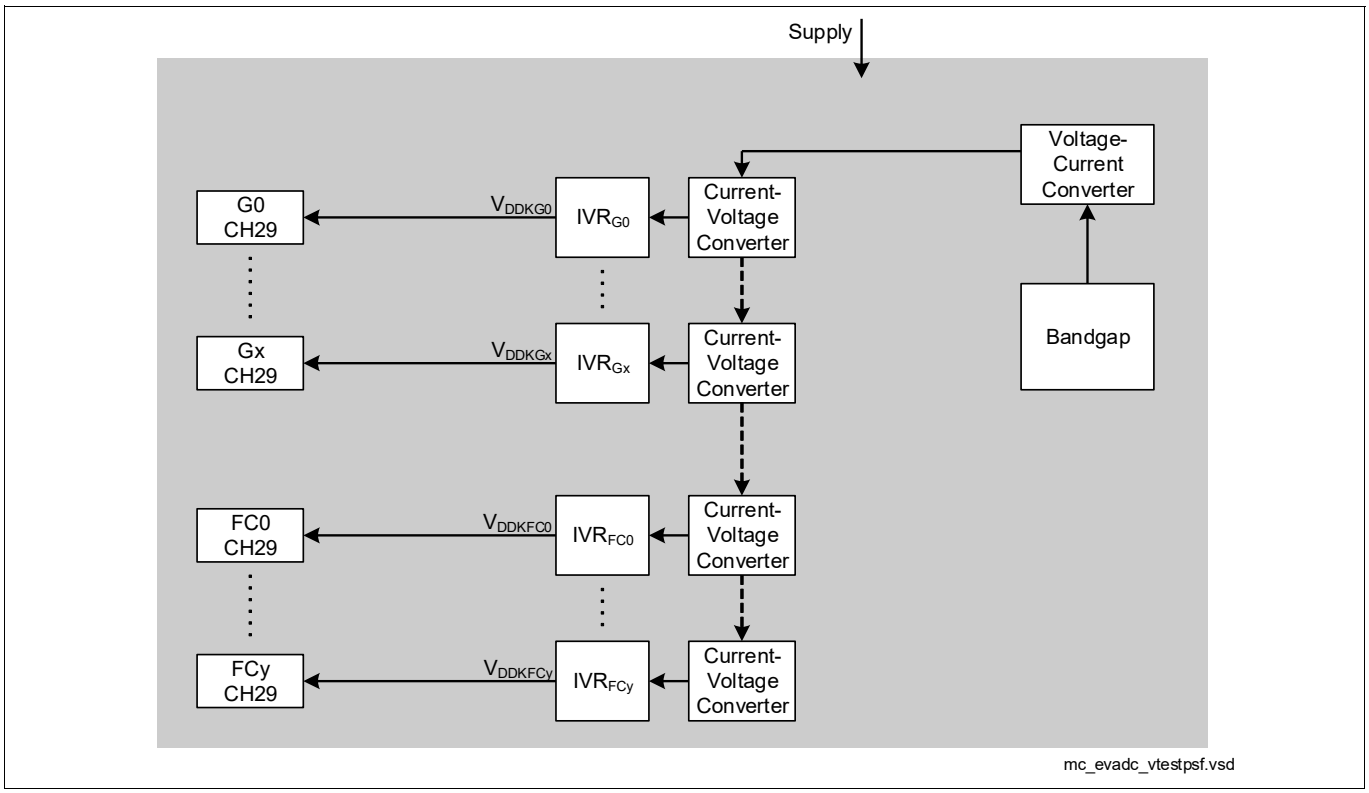

Figure 277 Test Voltages for Supervision

Measuring V_{DDK} enables two test features:

- Compare the result with the expected value (RESULT = V_{DDK} / V_{AREF} × 2^{12}).
- Compare the individual results of all converters to find deviations.

The variation of the values for V_{DDK} depends on manufacturing variation, on the supply voltage V_{DDM}, and on the die temperature. To compensate this variation, device-specific base values are measured during production and are stored in the on-chip Flash. The lower halfword of a record (see **Table 265**) stores the voltage at -40°C (VDDKC in [mV]), the next halfword stores the temperature deviation (DVDDK in [µV/K]).

The following formula uses the current die temperature (T_J in [°C]):

V_{DDK} = VDDKC + (DVDDK × (T_J + 40) / 1 000) mV

This provides a device-specific base value for V_{DDK} at the current temperature.

Example:

For T_J = 125°C, VDDKC = $04D9_H$ (1 241 mV), DVDDK = $005A_H$ (90 µV/K):

V_{DDK} = $04D9_H$ + (($5A_H$ × (125 + 40) / 1 000) mV = 1 241 + (90 × 165 / 1 000) mV =
= 1 241 + 15 mV = 1.256 V

Applying a deviation of +/-2% results in a range (for V_{AREF} = 5.0 V) of

1.231 V ... 1.281 V --> 1 008 ... 1 049 = $03F0_H$ ... 0419_H.

Stored Calibration Values

The device-specific calibration values are stored in the User Configuration Block (UCB_USER) within the on-chip Flash memory. The area assigned to the EVADC begins at offset 0020_H and provides records of two 32-bit words per group. The channel-specific records, therefore, can be read from offset [0020_H + 8×GroupNr.] within block UCB_USER. The table below shows the structure of a record.

Table 265 Structure of EVADC Calibration Records

	Halfword 3	Halfword 2	Halfword 1	Halfword 0
Location G0	0026_H	0024_H	0022_H	0020_H
Location G1	$002E_H$	$002C_H$	$002A_H$	0028_H
:	:	:	:	:
Stored value	Reserved	Reserved	DVDDK	VDDKC

The parameters are stored in the following format as 16-bit 2's complement numbers:

The low-temperature voltage VDDKC is stored in [mV], ranging from 1.15 V … 1.35 V ($047E_H$ … 0546_H).

The temperature deviation DVDDK is stored in [µV/K], ranging from -500 µV/K … 500 µV/K ($FE0C_H$ … $01F4_H$).

32.12.6 Configuration of Test Functions

Test functions allow software control of pull-up and pull-down devices and internal reference channels. Various test levels can be applied controlling the devices in an adequate way. Because these test functions interfere with the normal operation of the A/D Converters, they are controlled by a separate register set.

Not all test options are available for each channel. Selecting an unavailable function has no effect.

Test conversion sequences (i.e. conversions with activated test functions) can automatically be executed via request source Q2.

Global Test Functions Register

Note: All diagnostic functions are activated for the selected group (CDGR). Converter diagnostics (CDEN, CDSEL) and pull-down diagnostics (PDD) are activated directly by setting the associated bits, multiplexer diagnostics (MDPD, MDPU) are activated for the selected channel (CDCH).

CDGR	7:4	rw	**Conversion Diagnostics Group** Defines the group number to be used for diagnostic conversions. Applies to all test functions of primary and secondary groups.
CDEN	8	rw	**Converter Diagnostics Enable** 0_B All diagnostic pull devices are disconnected 1_B Diagnostic pull devices connected as selected by bitfield CDSEL
CDSEL	10:9	rw	**Converter Diagnostics Pull-Devices Select** 00_B Connected to VDDM 01_B Connected to VSSM 10_B Connected to 1/2 VDDM 11_B Connected to 2/3rd VDDM
CDWC	15	w	**Write Control for Conversion Diagnostics** 0_B No write access to parameters 1_B Bitfields CDSEL, CDEN, CDGR, CDCH can be written

Field	Bits	Type	Description
PDD	16	rw	**Pull-Down Diagnostics Enable** *Note: Channels with pull-down diagnostics device are marked in the product-specific appendix.* 0_B Disconnected 1_B The pull-down diagnostics device is active
MDPD	17	rw	**Multiplexer Diagnostics Pull-Down-Devices Enable** Connecting combinations of pull-up and/or pull-down devices generate various loads for testing. *Note: Channels with pull-down diagnostics device are marked in the product-specific appendix.* 0_B Disconnected 1_B The respective pull-down device is active
MDPU	18	rw	**Multiplexer Diagnostics Pull-Up-Devices Enable** Connecting combinations of pull-up and/or pull-down devices generate various loads for testing. *Note: Channels with pull-up diagnostics device are marked in the product-specific appendix.* 0_B Disconnected 1_B The respective pull-up device is active
MDWC	23	w	**Write Control for Multiplexer Diagnostics** 0_B No write access to parameters 1_B Bitfields MDPD, MDPU, PDD can be written
0	14:11, 22:19, 31:24	r	**Reserved, write 0, read as 0**

Table 266 Access Mode Restrictions of GLOBTF sorted by descending priority

Mode Name	Access Mode		Description
write 1 to **CDWC**	rw	CDCH, CDEN, CDGR, CDSEL	Set CDWC during write access
write 1 to **MDWC**	rw	MDPD, MDPU, PDD	Set MDWC during write access
(default)	r	CDCH, CDEN, CDGR, CDSEL, MDPD, MDPU, PDD	

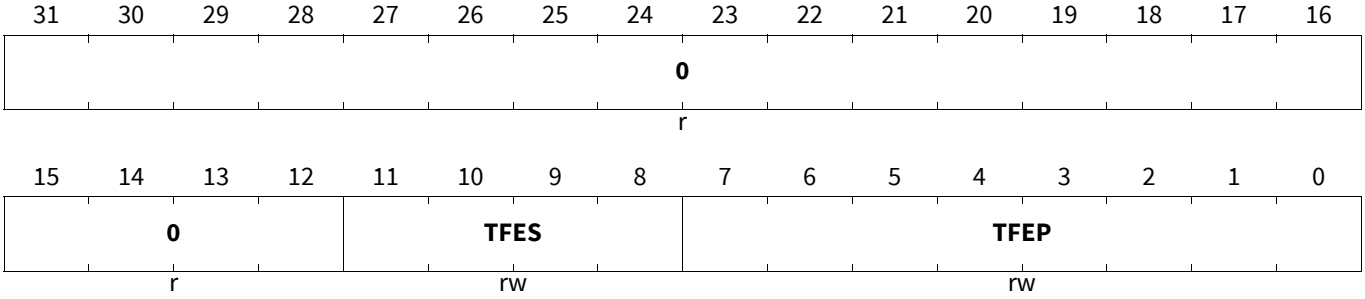
When automatic test sequences (see **Section 32.12.7**) are enabled, the scheduled conversions will activate the configured test devices. To make sure that this does not happen inadvertently, the activation of the test functions must be particularly enabled.

The release is done by setting the corresponding bit in the Global Test Enable register (GLOBTE). This prevents spurious control signals from spoiling a configured test sequence. GLOBTE can be write-protected via bit APTF in register ACCPROT2 (ACCPROT2 itself is safe-endinit protected).

*Note: The pull device control bits in register **GLOBTF** can only activate the test pull devices of a group, when the corresponding control bit in register **GLOBTE** is zero.*

Global Test Enable Register

GLOBTE
Global Test Enable Register (0164$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TFEP	7:0	rw	**Test Function Enable, Primary Groups** Each bit of this bitfield is associated with the corresponding group. 0: No test functions for group x sequences 1: Test functions can be activated by group x sequences
TFES	11:8	rw	**Test Function Enable, Secondary Groups** Each bit of this bitfield is associated with the corresponding group. 0: No test functions for group x sequences 1: Test functions can be activated by group x sequences
0	31:12	r	**Reserved, write 0, read as 0**

32.12.7 Automatic Execution of Test Sequences

Validating the correct connection of an input signal (sensor) to the converter in a system requires some action, depending on the properties of the signal to be converted. For example, sensors with a limited signal range can be validated by checking the conversion result for values outside of the defined signal range.

In other cases pull devices (up / down) can be connected to the signal input, which alter the signal level and, as a consequence, the conversion result in a known way. The alteration can be anticipated when the signal source impedance is known.

Timing Considerations

Test sequences that are executed during the initialization of a system usually are not time-critical. They increase the start-up time but otherwise have no impact on the application. Safety-critical systems, however, monitor the operability of the system during the operation time. In this case, the test sequences must be interleaved with the normal application sequences. A test sequence shall be executed immediately after an application sequence, so the relaxation time until the next application sequence becomes maximal.

Test sequences can be triggered by each available request source.

In either case the overall timing must be selected so overlaps are avoided.

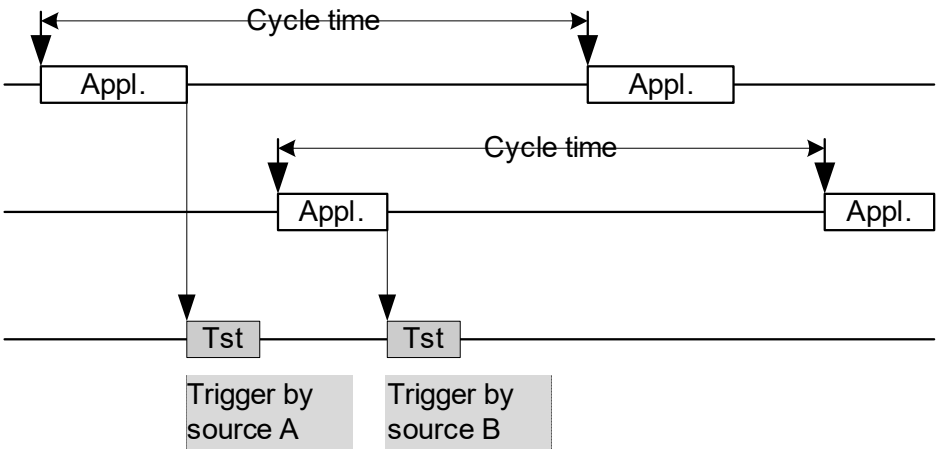


Figure 278 Positions of Test Sequences

Note that the test conversions can target arbitrary channels.

Using the Test Queue

The test queue request source (queue 2) is similar to the standard queued request sources with some additional control bits to select test functions of the pins.

Leaving these control bits as zero allows using queue 2 as an additional request source for the application.

Queue 2 can be activated by external triggers (same as other sources) or by internal triggers from the other group request sources. These additional internal trigger signals are selected by an additional multiplexer whose output is connected to the uppermost input of the gate multiplexer. To use the internal triggers, select the uppermost trigger input (XTSEL = 1111_B) and the uppermost gate input (GTSEL = 1111_B).

A trigger counter activates queue 2 after a defined number of triggers. Test sequences can, therefore, be inserted into the application-specific conversion sequences at a certain rate without additional software intervention.

Control the internal triggers and the trigger counter via register **GxTRCTR (x=0-11)**.

Queue 2 contains entries building a sequence of test conversions which enable arbitrary diagnostic functions. A trigger for a test sequence is generated automatically when the sequence of a standard request source is completed.

The trigger sequence counter starts a (test) sequence after a programmable number of triggers. The (test) sequence is started if the trigger sequence counter equals 0 when the trigger occurs. For other values of the trigger sequence counter, each trigger decrements the counter. No software intervention is required to interleave test sequences into the normal operation.

Activation/Deactivation of Pull-Devices

When specific test functions are enabled for an entry in queue 2, the corresponding enabled pull-devices are controlled automatically:

They are activated when the sample phase for this conversion begins.
They are deactivated automatically after the sample phase is completed.[1)]

Depending on the properties of the connected sensor, a test sequence may require an additional settling time. This can be covered by selecting an increased sample time for these test conversions.

Detecting Irregular Test Sequences

An overflow bit (OV) is set when an internal trigger for queue 2 occurs while the queue is active (ind. by bit QACT). This indicates that a (test) sequence has been triggered when it cannot be executed as expected.

Queue 2 is assumed to be active (QACT = 1) between the occurrence of an internal trigger (set QACT) and the generation of a source event of queue 2 (clear QACT). This phase is indicated by bit QACT = 1.

Software can clear bits OV and QACT by writing 1 to bit COV (see register **GxTRCTR (x=0-11)**).

Securing the Test Functions

When test sequences are enabled, the scheduled conversions will activate the configured test pull devices. To make sure that this does not happen inadvertently, the activation of the test functions must be explicitly enabled.

The release is done by setting the corresponding bit in the Global Test Enable register (**GLOBTE**). This prevents spurious control signals from spoiling a configured test sequence. GLOBTE can be write-protected via bit APTF in register ACCPROT2 (ACCPROT2 itself is safe-endinit protected).

*Note: The pull device control bits in register **GLOBTF** can only activate the test pull devices of a group, when the corresponding control bit in register **GLOBTE** is zero.*

Evaluation of Test Results

The effect of the selected test pull devices depends on the properties of the connected signal source. These properties are system-specific and are not known to the controller. Therefore, the system software must evaluate the test results by comparing them to the expected results. This is influenced by several parameters:

- Selected pull device
- Properties of signal source, e.g. impedance
- Properties of input signal (e.g. current level of dynamic signals)
- Acceptable failure detection time

These aspects must be evaluated to assess the validity of the input signal on the channel being checked.

1) Do not deactivate the converter inbetween, to avoid the pull devices remaining active.

32.13 External Multiplexer Control

The number of analog input channels can be increased by connecting external analog multiplexers to an input channel. The EVADC can be configured to control these external multiplexers automatically.

Each available EMUX control interface can be controlled by an arbitrary group (see register **EMUXSEL**). One channel or a set of channels from that group can be selected for this operating mode (see register **GxEMUXCS (x=0-11)**). The EVADC supports 1-out-of-8 multiplexers with several control options:

- **Steady mode** converts the configured external channel
  when the selected channel is encountered. Conversion sequences:
  --4-32-2-1-0- -4-32-2-1-0- -4-32-2-1-0- -… (for configuration as shown in **Figure 279**)
  --4-32-2-12-0- -4-32-2-12-0- -4-32-2-12-0- -… (for configuration with EMUX channels 1 and 3)
- **Single-step mode** converts one external channel of the configured sequence
  when the selected channel is encountered. Conversion sequences:
  --4-32-2-1-0- -4-31-2-1-0- -4-30-2-1-0- -4-32-… (for configuration as shown in **Figure 279**)
  --4-32-2-11-0- -4-30-2-12-0- -4-31-2-10-0- -4-32-… (for configuration with EMUX channels 1 and 3)
  (Single-step mode works best with one channel)
- **Sequence mode** automatically converts all configured external channels[1)]when the selected channel is encountered. Conversion sequences:
  --4-32-31-30-2-1-0- -4-32-31-30-2-1-0- -… (for configuration as shown in **Figure 279**)
  --4-32-31-30-2-12-11-10-0- -4-32-31-30-2-… (for configuration with EMUX channels 1 and 3)
- **Block mode** converts the same external channel of the configured sequence for all EMUX channels[2)]when a selected channel is encountered. Conversion sequences:
  --4-32-2-12-0- -4-31-2-11-0- -4-30-2-10-0- -4-32-… (for cfg. with EMUX channels 1 and 3, EMUXCCB = 01_H)

*Note: The example in **Figure 279** has an external multiplexer connected to channel CH3. The start selection value EMUXSET is assumed as 2. The conversion sequence is assumed as 4-3-2-1-0.*
The alternate sequences described in the list above assume a similar EMUX circuitry on channel CH1.

Bitfield EMUXACT determines the control information sent to the external multiplexer.
In single-step mode, EMUXACT is updated after each conversion of an enabled channel. If EMUXACT = 000_B it is reloaded from bitfield EMUXSET, otherwise it is decremented by 1.

Additional external channels may have different properties due to the modified signal path. Local filters may be used at the additional inputs (R_{EXT2}-C_{EXT2} on CH3x in **Figure 279**). For applications where the external multiplexer is located far from the ADC analog input, it is recommended to add an RC filter directly at the analog input of the ADC (R_{EXT1}-C_{EXT1} on CH3 in **Figure 279**). Each RC filter limits the bandwidth of the analog input signal.C_{EXT1} must be charged from the respective C_{EXT2} circuit after switching the external multiplexer.

Conversions for external channels, therefore, use the alternate settings (AIPE, CME, SESPE) defined in the ICLASS registers. This automatically selects a different conversion mode if required.

Switching the external multiplexer usually requires an additional settling time for the input signal. Therefore, the alternate sample time setting STCE is applied each time the external channel is changed. This automatically fulfills the different sampling time requirements in this case. If enabled by bit EMXST STCE can also be applied for each conversion for external channels.

1) In sequence mode, the main channel number is preserved in register GxQBURi (see **Section 32.5**).
Invalidating GxQBURi aborts the current EMUX sequence and must be avoided. Please note following restrictions:
- Discarding a cancelled conversion is not possible when an external multiplexer is operated in sequence mode. Bit RPTDIS must be 0 in this case. See also **Section 32.6.2**.
- Do not clear valid flags via software (GxQMR.CLRV).

2) The external channel number is switched when the channel defined in bitfield EMUXCCB is converted.
EMUXCCB should, therefore, contain the channel that is converted last within a sequence.

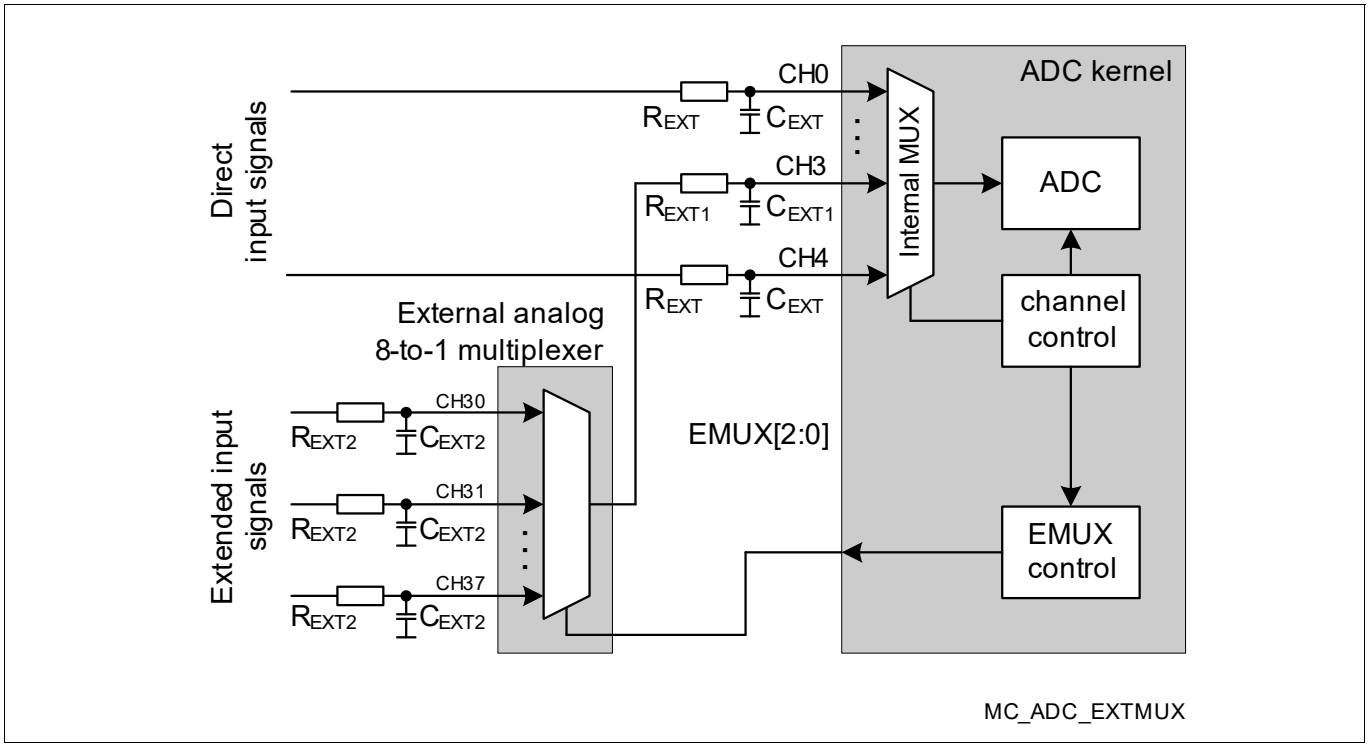

Figure 279 External Analog Multiplexer Example

Control Signals

The external channel number that controls the external multiplexer can be output in standard binary format or Gray-coded. Gray code avoids intermediate multiplexer switching when selecting a sequence of channels, because only one bit changes at a time. **Table 267** indicates the resulting codes.

Table 267 EMUX Control Signal Coding

Channel	0	1	2	3	4	5	6	7
Binary	000_B	001_B	010_B	011_B	100_B	101_B	110_B	111_B
Gray	000	001	011	010	110	111	101	100

Operation Without External Multiplexer

If no external multiplexers are used in an application, the reset values of the control registers provide the appropriate setup.

EMUXMODE = 00_B disables the automatic EMUX control.

Since the control output signals are alternate port output signals, they are only visible at the respective pins if explicitly selected.

In each group an arbitrary channel (EMXCCS = 0) or set of channels (EMXCCS = 1) can be assigned to external multiplexer control via register **GxEMUXCS (x=0-11)**.

Each available port interface selects the group whose control lines are output (register **EMUXSEL**).

Field	Bits	Type	Description
EMUXGRP0	3:0	rw	**External Multiplexer Group for Interface 0** Defines the group whose external multiplexer control signals are routed to EMUX interface 0 (pins EMUX0x).
EMUXGRP1	7:4	rw	**External Multiplexer Group for Interface 1** Defines the group whose external multiplexer control signals are routed to EMUX interface 1 (pins EMUX1x).
0	31:8	r	**Reserved, write 0, read as 0**

1) The pins that are associated with each EMUX interface are listed in the product-specific appendix.

32.14 Service Request Generation

Each A/D Converter can activate up to 4 group-specific service request output signals and up to 4 shared service request output signals to issue an interrupt or to trigger a DMA channel. Two common service request groups are available, see product-specific appendix.

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events:** indicate that a request source completed the requested conversion sequence and the application software can initiate further actions.
  For a group queue source, the event is generated according to the programming, i.e. when a channel with enabled source interrupt has been converted or when an invalid entry is encountered.
- **Channel events:** indicate that a conversion is finished. Optionally, channel events can be restricted to result values within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Optionally, result events can be generated only at a reduced rate if data reduction is active.
  For example, a single DMA channel can read the results for a complete auto-scan sequence, if all channels of the sequence target the same result register and the transfers are triggered by result events.

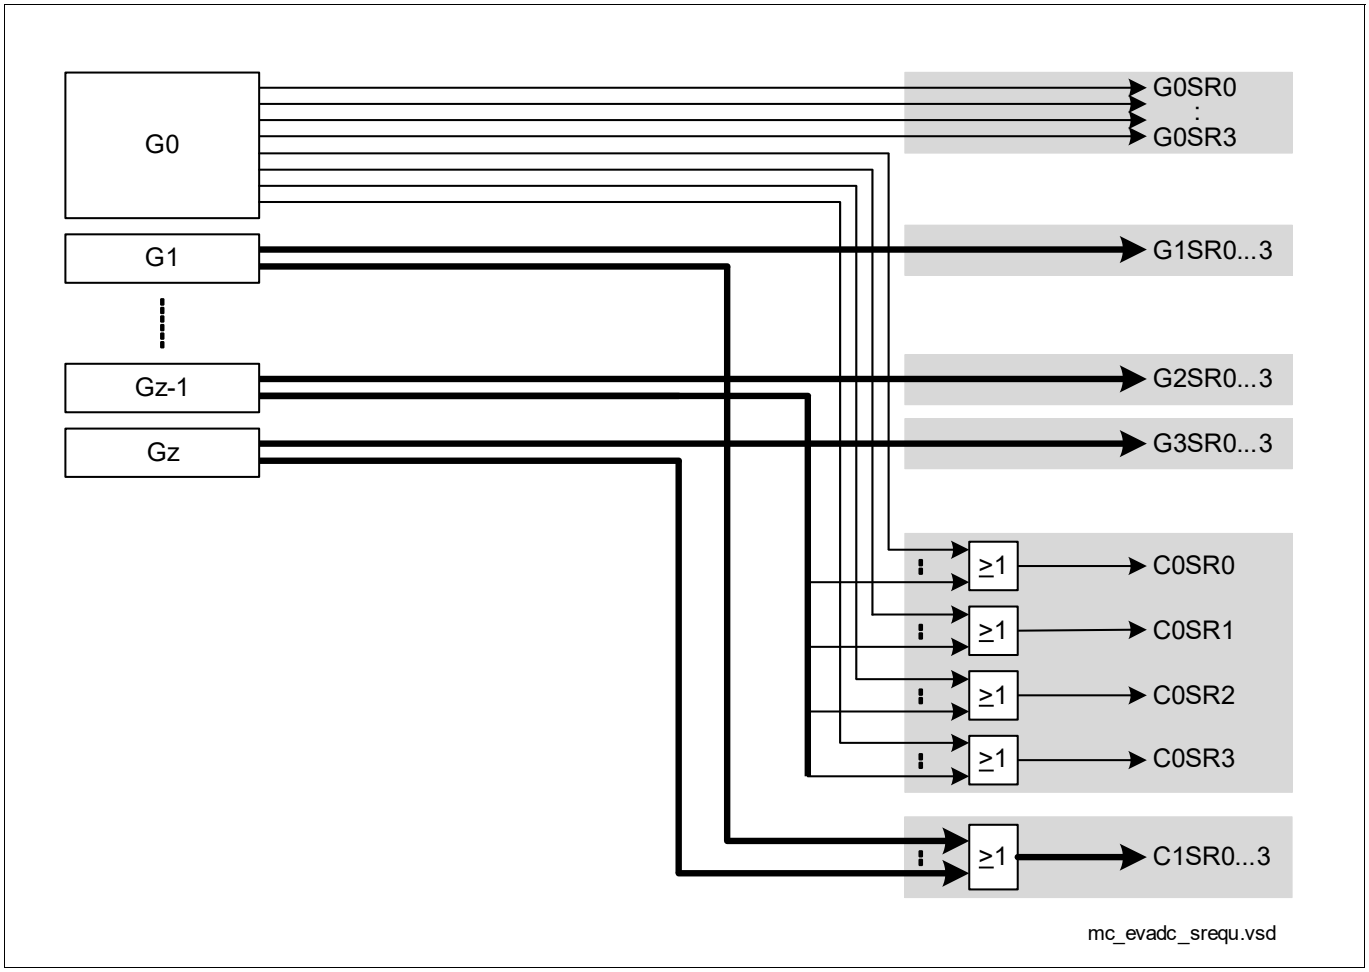

Figure 280 Service Request Overview

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding

event indication flag. This ensures efficient DMA handling of ADC events (the ADC event can generate a service request without the need to clear the indication flag).

Event flag registers indicate all types of events that occur during the ADC's operation. Software can set each flag by writing a 1 to the respective position in register GxCEFLAG/GxREFLAG to trigger an event. Software can clear each flag by writing a 1 to the respective position in register GxCEFCLR/GxREFCLR. If enabled, service requests are generated for each occurrance of an event, even if the associated flag remains set.

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

32.14.1 Source Event Flag Registers, Group x

These registers handle the events generated by the conversion request sources (Q0, Q1, Q2).

Note: Software can set all flags in register GxSEFLAG and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear all flags in register GxSEFLAG by writing 1 to the respective bit in register GxSEFCLR.

32.14.2 Channel Event Flag Registers, Group x

These registers handle the events generated by conversions, in particular during limit checking.

Note: Software can set all flags in register GxCEFLAG and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear all flags in register GxCEFLAG by writing 1 to the respective bit in register GxCEFCLR.

Channel Event Flag Register, Group x

The layout of this register depends on the multiplexer configuration.

Primary groups have 8 channels and, consequently, 8 channel event flags (CEV7 ... CEV0).

Secondary groups have 16 channels / channel event flags (CEV15 ... CEV0).

32.14.6 Service Requests for Fast Compare Channels

Each Fast Compare Channel can issue service requests via a dedicated service request line. Each service request can be activated by several configurable events.

The active event is selected by bitfields SRG in register **FCxFCM (x=0-7)** and CHEVMODE in register **FCxFCCTRL (x=0-7)**.

The figure below summarizes the configuration of Fast Compare Channel events to trigger a service request.

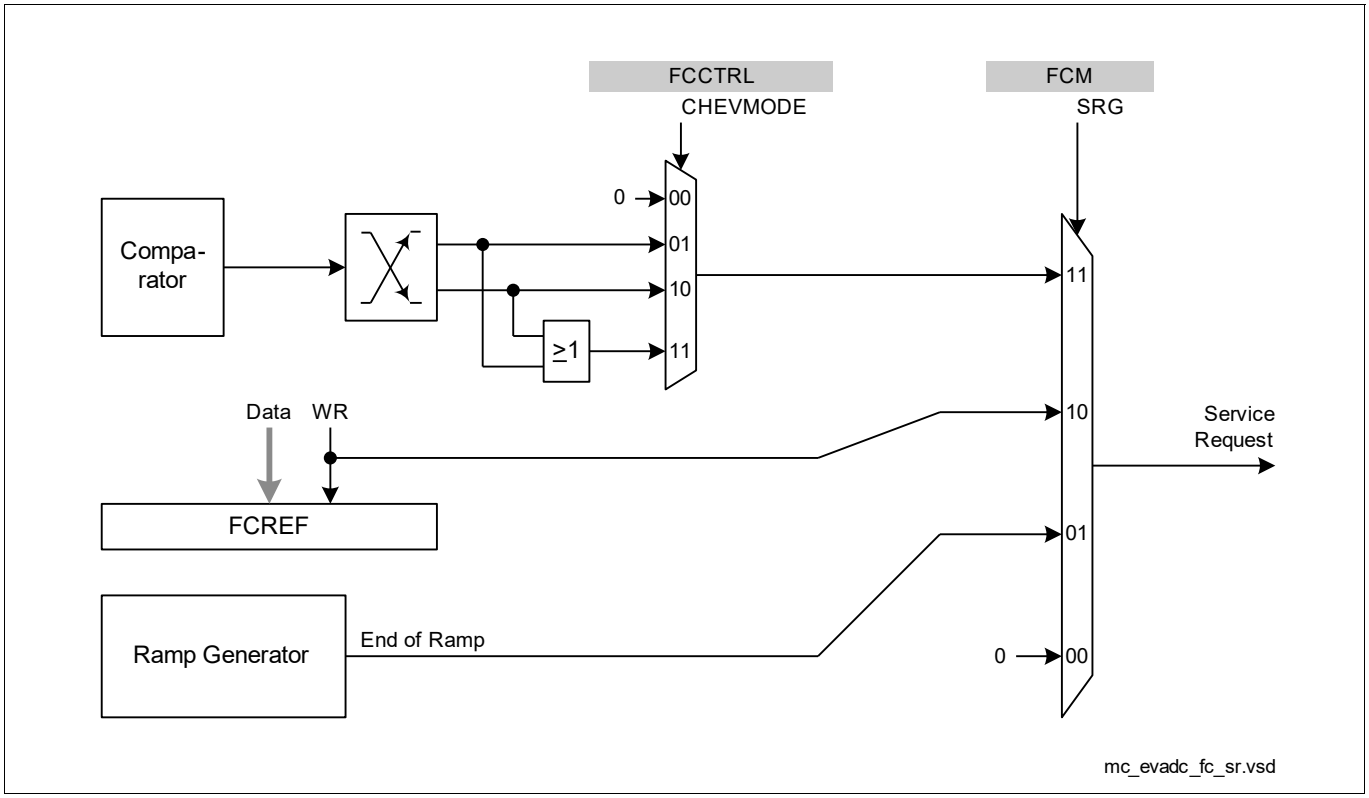

Figure 281 Fast Compare Channel Service Requests

32.15 Application Considerations

The operation of the EVADC and, hence, its behavior is programmable in a wide range. This makes it suitable for different applications while requiring a certain amount of initialization and/or handling during operation.

As far as possible the configuration options can be handled by initialization. Several functions, for example power control or calibration, have been automated so they require an absolute minimum of handling during operation.

Additional hints in section **"Changing the Configuration" on Page 9**.

32.15.1 Clock Synchronization

To eliminate the interference of concurrently operating ADC channels, the converters can operate in a synchronized way so each of them can reach its optimum performance. The phase synchronizer distributes a clock control signal which is used by the converters to start their operation. See **Section 32.3.5**.

After reset, the clock synchronization is active. Setting the phase synchronizer is mandatory for the EVADC to deliver its documented performance.

32.15.2 Calibration Recommendation

The actual calibration algorithm is executed automatically by hardware, so only a few configurations need to be selected before starting the algorithm.

Note: The calibration algorithm compensates manufacturing tolerances. It is, therefore, recommended to execute the start-up calibration once after a reset.

Before triggering the start-up calibration, enable the analog blocks and select the corresponding calibration sample time (CALSTC).

Attention: During the start-up calibration, all converters must be inactive. After reset this is the case anyway. Only start conversions after the calibration has completed (indicated by bit CAL = 0).

Trigger the start-up calibration by writing 1 to bit SUCAL in register **GLOBCFG**. The completion of the start-up calibration is indicated by bit CAL in register **GxARBCFG (x=0-11)**.

Calibration is done in steps smaller than LSB_{12}. Repeated calibration steps, therefore, may lead to reduced resolution due to the internally applied rounding.

In systems with a stable reference voltage, it is recommended to disable postcalibration permanently to avoid these effects by setting bit DPCAL in register **GxANCFG (x=0-11)**.

In systems where the reference voltage is influenced by temperature, postcalibration can be enabled temporarily during certain operation phases to compensate these effects.

32.15.3 Examples for Operation

The final configuration of the EVADC very much depends on the targeted application case. The following examples list some considerations to achieve stable operating modes.

- **Clocks**:
  In most cases the highest possible clock frequency shall be selected. The maximum analog clock frequency (DIVA) maximizes the performance and provides higher off-times to save energy when using the standby modes.
- **Sample time**:
  The minimum time required for sampling within the different clusters is specified in the corresponding Data Sheet.

If analog input precharge is used (AIPi $\neq 00_B$) the selected precharge time must be added to the minimum sample time. If the spread sample point feature is used (SESPi = 1) the maximum cut-off time must be added to the minimum sample time.

- **Noise handling**:
  Several features are provided to reduce the impact of noise (external or internal).
  The features are based on additional conversion steps or multiple conversions of the input signal. Computing averages from multiple conversion result, however, also requires increased overall conversion times.
  Therefore, the degree of usage depends on the properties of the input signal, i.e. its dynamic behavior.

32.15.4 Basic Initialization Sequence

After reset, the EVADC is disabled to minimize the initial power consumption. By executing the following steps the EVADC can be prepared for operation and be started:

Enable and configure the phase synchronizer according to the overall system requirements.

This is described in section “Application Considerations” in chapter CONVCTRL.

Enable the EVADC module and prepare it for operation

```
EVADC_CLC      = 0x00000000   ;Enable module EVADC
```

Enable a primary/secondary group and prepare it for operation

```
EVADC_GxANCFG  = 0x00300000   ;Analog clock frequency is 160 MHz / 4 = 40 MHz (example)
                              ;CALSTC = 00
EVADC_GxARBCFG= 0x00000003    ;Enable analog block
WAIT                          ;Pause for extended wakeup time (≥ 5 µs)
EVADC_GLOBCFG  = 0x80000000   ;Begin start-up calibration
                              ;(other operations can be executed in the meantime)
EVADC_GxARBPR  = 0x01000000   ;Enable arbitration slot 0
EVADC_GxQMR0   = 0x00000001   ;Enable request source 0
EVADC_GxICLASS0=0x00000002    ;Select 4 clocks for sampletime 4 / 40 MHz = 100 ns
                              ;The default setting stores results in GxRES0,
                              ;service requests are issued on GxSR0
EVADC_GxRCR0   = 0x80000000   ;Enable result service requests, if required
EVADC_GxQINR0  = 0x00000020   ;Request channel 0 in auto-repeat mode
WAIT                          ;Wait for start-up calibration to complete
                              ;(other operations can be executed in the meantime)
                              ;---> This starts continuous conversion of the channel
```

Note: Calibration start-up time tSUCAL or flag GxARBCFG.CAL=0

Enable fast compare channel and prepare it for operation

```
EVADC_FCxFCCTRL= 0x00000C00   ;Use default: Analog clock is 160 MHz / 4 = 40 MHz (ex.)
                              ;No trigger/gate, no service request, connect to input
EVADC_FCxFCBFL= 0x03010000    ;Output boundary flag directly on CBFLOUT3
EVADC_FCxFCHYST= 0x00A40050   ;Define hysteresis as +0.2 V / -0.1 V
EVADC_FCxFCM   = 0xA8E00421   ;Set reference to 3.3 V, no auto update, no service requ.,
                              ;trigger period 0.5 µs, enable analog block, start ch.
                              ;---> This starts continuous comparisons at the sel. rate
```

Retrieve Conversion Results

The selected channels will be converted/compared continuously now.

Conversions results of primary/secondary groups are indicated by service requests and can be read from GxRES0, compare results of fast compare channels are signaled on the boundary flags.

32.15.5 Module Handling in Sleep Mode

The EVADC does not change its operating mode in sleep mode. While sleep mode is evaluated (**CLC**.EDIS = 0, default after reset), the module clocks are stopped upon a sleep mode request. To achieve the power reduction that is usually intended during sleep mode, the application needs to disable the EVADC, or parts of it as required, before entering sleep mode.

*Note: If any activity is intended during sleep mode make sure that sleep mode requests are disregarded (**CLC**.EDIS = 1) and make sure the phase synchronizer is not disabled in this case.*

32.16 Electrical Models

Each conversion of an analog input voltage to a digital value consists of two consecutive phases:

- During the sample phase, the input voltage is sampled and stored.
  The **Input Signal Path** is a simplified model for this.
- During the conversion phase the stored voltage is converted to a digital result.
  The **Reference Voltage Path** is a simplified model for this.

Input Signal Path

The ADC uses a switched capacitor field represented by C_{AINS} (small parasitic capacitances are present at each input pin). During the sample phase, the capacitor field C_{AINS} is connected to the selected analog input CHx via the input multiplexer (modeled by ideal switches and series resistors R_{AIN}).

When precharge sampling is enabled (path (P)), the input charge consumption is defined by $Q_{AINS} = C_{SWT} \times V_{AINmax}$.

The switch to CHx is closed during the sample phase and connects the capacitor field to the input voltage V_{AINx}.

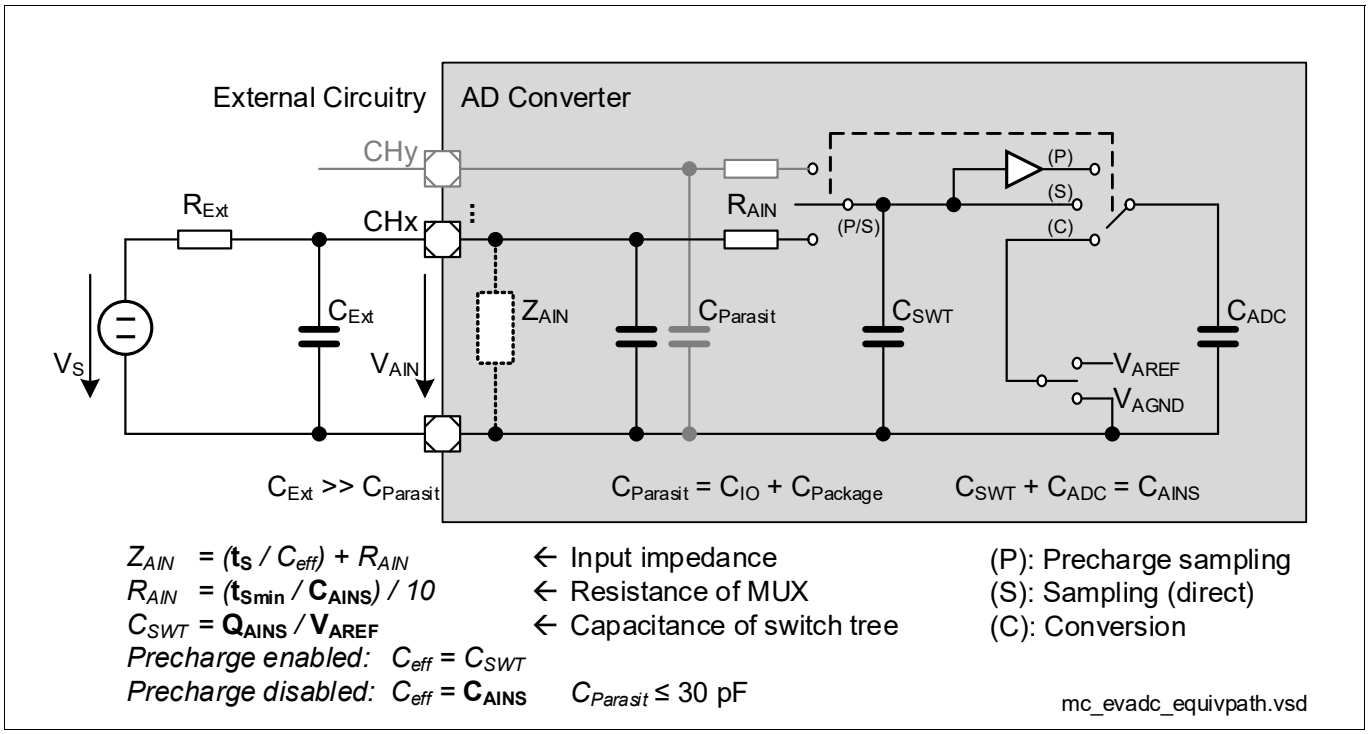

Figure 282 Signal Path Model

A simplified model for the analog input signal path is given in **Figure 282**. An analog voltage source (value V_S) with an internal impedance of R_{Ext} delivers the analog input that should be converted.

During the sample phase the corresponding switch is closed and the capacitor field C_{AINS} is charged. Due to the low-pass behavior of the resulting RC combination, the voltage at C_{ADC} to be actually converted does not immediately follow V_S. The value R_{Ext} of the analog voltage source and the desired precision of the conversion strongly define the required length of the sample phase.

To reduce the influence of R_{Ext} and to filter input noise, it is recommended to introduce a fast external blocking capacitor C_{Ext} at the analog input pin of the ADC. Like this, mainly C_{Ext} delivers the charge during the sample phase. This structure allows a significantly shorter sample phase than without a blocking capacitor, because the low-pass time constant defining the sample time is mainly given by the values of R_{AIN} and C_{AINS}.

The resulting low-pass filter of R_{EXT} (usually a parameter of the signal source) and C_{EXT} should be dimensioned according to the application's requirements:

- For quickly changing dynamic signals, a smaller capacitor allows V_{AINx} to follow V_S between two sample phases of the same analog input channel.
- For high-precision conversions, an external blocking capacitor C_{Ext} in the range of at least $2^n \times C_{AINS}$ keeps the voltage change of V_{AINx} during the sample phase below 1 LSB_n. This voltage change is due to the charge redistribution between C_{Ext} and C_{AINS}.

Leakage current through the analog input structure of the ADC can generate a voltage drop over R_{Ext}, introducing an error. The ADC input leakage current increases at high temperature and if the input voltage level is close to the analog supply ground V_{SSM} or to the analog power supply V_{DDM}. The input leakage current of an ADC channel can be reduced by avoiding input voltages close to the supplies.
An overload condition (input voltage exceeds the supply range) at adjacent analog inputs injects an additional leakage current (defined by a coupling factor) .

The capacitor C_{AINS} is automatically precharged to a voltage of approximately half the standard reference voltage V_{AREF} while the converter is idle and while idle precharge is enabled[1]. Due to varying parameters and parasitic effects, the precharge voltage of C_{AINS} is typically smaller than V_{AREF} / 2.

Note: When conversions are executed in a sequence, or when a conversion cancels a running conversion, the sample phase starts immediately.
The converter does not become idle in this case and C_{AINS} is not precharged!

Calculation Example

The following parameters are assumed as given from the Datasheet:

C_{AINS} = 3.4 pF (max. value), Q_{AINS} = 3.5 pC (primary group, max. value), V_{AREF} = 5.0 V, t_{Smin} = 100 ns (primary group).

The following parameters can be calculated, as indicated in **Figure 282**.

$R_{AIN} = t_{Smin} / C_{AINS}$ = 100 ns / 3.4 pF / 10 = 2.94 kOhm

$C_{SWT} = Q_{AINS} / V_{AREF}$ = 3.5 pC / 5.0 V = 0.7 pF

The input impedance, therefore, can be calculated as:

Z_{AIN} = 100 ns / 0.7 pF + 2.94 kOhm = 145.8 kOhm (with sample precharge enabled)

Z_{AIN} = 100 ns / 3.4 pF + 2.94 kOhm = 32.4 kOhm (without sample precharge, min. sample time)

Z_{AIN} = 200 ns / 3.4 pF + 2.94 kOhm = 61.8 kOhm (without sample precharge, increased sample time)

If no external blocking capacitor C_{Ext} is used, the input channel sees the series resistance ($R_{Ext} + Z_{AIN}$) during the sample time. The analog input voltage, therefore, will be $V_{AIN} = V_S \times Z_{AIN} / (R_{Ext} + Z_{AIN})$.

The first example above then leads to $V_{AIN} = V_S \times 0.936$ (assuming R_{Ext} = 10 kOhm).

An average current that is drawn from the signal source when the corresponding input is converted repeatedly.

This current depends on the configured sampling mode (buffer on/off) and on the actual conversion rate i.e. the conversion cycle time t_{CT}. A conversion cycle time of t_{CT} = 10 µs leads to the following currents:

When sample precharging is disabled, the average current can be calculated as
$I_{avg} = (V_{AIN} / Z_{AIN}) \times (t_S / t_{CT})$ = (5.0 V / 32.4 kOhm) × (100 ns / 10 µs) = 154.3 µA × 0.01 = 1.54 µA (max. input voltage).
When sample precharging is enabled, the average current can be calculated as
$I_{avg} = (V_{AIN} / Z_{AIN}) \times (t_S / t_{CT})$ = (5.0 V / 145.8 kOhm) × (100 ns / 10 µs) = 0.35 µA,
or the average current can simply be calculated as
$I_{avg} = Q_{AINS} / t_{CT}$ = 3.5 pC / 10 µs = 0.35 µA.

1) Fast compare channels do not provide the idle precharge function.

Reference Voltage Path

During the conversion phase, parts of the capacitor field (represented by C_{AREFSW}) are switched to a reference input (V_{AREF} or CH0) or to V_{AGND}. Using CH0 as alternate reference source allows conversions of 5.0 V and 3.3 V based analog input signals with the same ADC kernel.

Stable and noise-free reference and analog supply voltages support accurate conversion results. Because noise can also be introduced from other modules (e.g. switching pins), it is strongly recommended to carefully decouple analog from digital signal domains.

The switching of parts of C_{AREFS} requires a dynamic current at the selected reference input. The impedance R_{RefExt} of the reference voltage source V_R has to be low enough to supply the reference current during the conversion phase. An external blocking capacitor C_{RefExt} can supply the peak currents and minimize the current to be delivered by the reference source.

The reference current I_{AREF} introduces a voltage drop at R_{RefExt} that should not be neglected for the calculation of the overall accuracy. The average reference current during a conversion depends on the reference voltage level and the time t_{CONV} between two conversion starts: $I_{AREF} = C_{AREFS} \times V_{AREF} / t_{CONV}$.

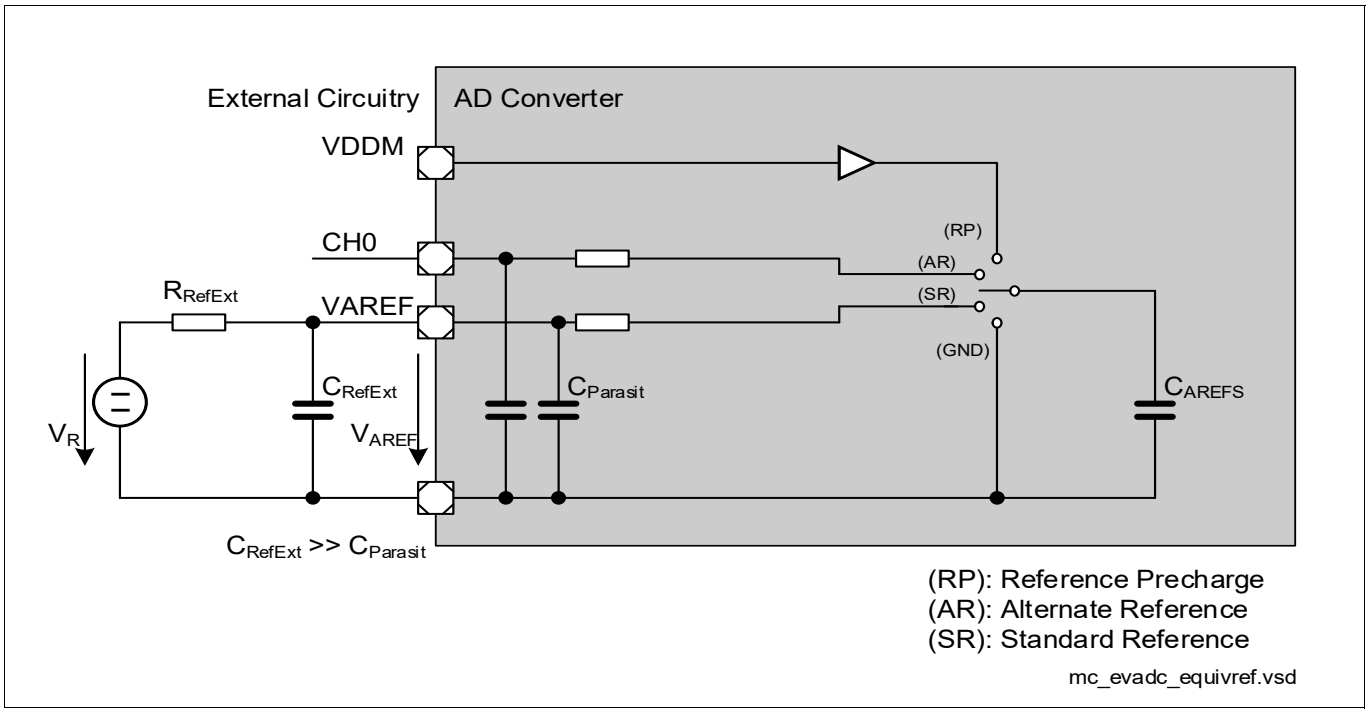

Figure 283 Reference Path Model

Reference Signal Connection

The reference voltages (V_{AREF}, V_{AGND}) have a strong influence on the digital result of a conversion. It is, therefore, recommended to carefully avoid noise on these inputs. Filter structures help to cancel high-frequency noise.

- Capacitors between corresponding reference pins (V_{AREF}, V_{AGND}) provide peak currents for the conversion steps
- Use low-ESR capacitors connected closely to the pins
- Connect reference pins via separate lines to star points close to the sensor supply
- Additional resistors in the reference lines (R_F) must be able to carry the average reference current, to avoid inaccuracy due to voltage drop
- The reference ground lines shall be connected to the common ground plane

Due to the charge redistribution between C_{REFEXT} and C_{AREFSW}, the voltage V_{AREF} decreases during the conversion phase. The error introduced by this effect is limited by the external blocking capacitor.
A blocking capacitor of $C \geq 2^n \times C_{AREFSW}$ limits this error to 1 LSB_n.

Assuming 12-bit conversions and C_{AREFSW} = 6 pF leads to: $C_{REFEXT} > 2^{12} \times 6$ pF = 24.6 nF per active converter.
The total required capacitor value depends on the number of simultaneously active converters:
Assuming 13 converters being active at the same time leads to: 24.6 nF × 13 = 320 nF.

Analog ground (V_{SSA}) and digital ground (V_{SSD}) are internally connected to an on-chip star point. These pins shall, therefore, be connected to a single common ground plane.

Note: A specific application note is available offering hints for the calculation of filter structures for the analog reference and the analog inputs. This application note also provides guidelines for PCB design.

Transfer Characteristics and Error Definitions

The transfer characteristic of the ADC describes the association of analog input voltages to the 2^n discrete digital result values (n bits resolution). Each digital result value (in the range of 0 to 2^n-1) represents an input voltage range defined by the reference voltage range divided by 2^n. This range (called quantization step or code width) represents the granularity (called LSB_n) of the ADC. The discrete character of the digital result generates a system-inherent quantization uncertainty of ±0.5 LSB_n for each conversion result.
The ideal transfer curve has the first digital transition (between 0 and 1) when the analog input reaches 0.5 LSB_n. The quantization steps are equally distributed over the input voltage range. Analog input voltages below or above the reference voltage limits lead to a saturation of the digital result at 0 or 2^n-1.

The real transfer curve can exhibit certain deviations from the ideal transfer curve:

- The **offset error** is the deviation of the real transfer line from the ideal transfer line at the lowest code. This refers to best-fit lines through all possible codes, for both cases.
- The **gain error** is the deviation of the slope of the real transfer line from the slope of the ideal transfer line. This refers to best-fit lines through all possible codes, for both cases.
- The **differential non-linearity error** (DNL) is the deviation of the real code width (variation of the analog input voltage between two adjacent digital conversion results) from the ideal code width.
- The **integral non-linearity error** (INL) is the deviation of the real transfer curve from an adjusted ideal transfer curve (same offset and gain error as the real curve, but equal code widths).
- The **total unadjusted error** (TUE) describes the maximum deviation between a real conversion result and the ideal transfer characteristics over a given measurement range. Since some of these errors noted above can compensate each other, the TUE value generally is much less than the sum of the individual errors.
  The TUE also covers production process variations.
- The **noise-induced error** (RMS) describes internal noise effects that need to be added to the TUE.
  External switching noise generated by the system may add an additional error.

32.17 Summary of Registers and Locations

The EVADC is built from a series of converter blocks that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see table below). The exact register location is obtained by adding the respective register offset to the base address (see product-specific appendix) of the corresponding group.

Due to the regular group structure, several registers appear within each group. Other registers are provided for each channel. This is indicated in the register overview table by formulas.

Registers with write access mode "...,M" can additionally be protected from unintended write access by setting the corresponding protection bit in register ACCPROTn. Refer to **"Register Access Control" on Page 21** for more details and an association table.

Table 269 Register Overview - EVADC (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write

33 Enhanced Delta-Sigma Analog-to-Digital Converter (EDSADC)

The Enhanced Delta-Sigma Analog-to-Digital Converter module (EDSADC) provides a series of analog input channels connected to on-chip modulators using the Delta/Sigma (DS) conversion principle. Digital input channels accept data streams from external modulators (section summary on **Page 3**).

The on-chip demodulator channels convert these inputs to discrete digital values.

The number of inputs and EDSADC channels depends on the chosen product type. This is described in the product-specific appendix.

Each converter channel can operate independent of the others, controlled by a dedicated set of registers. The results of each channel can be stored in a dedicated channel-specific result register.

The on-chip filter stages generate digital results from the selected modulator signal.

The EDSADC accepts data from different types of external modulators. Their data streams can be fed through selectable input pins.

Also, on-chip modulators are available that accept differential or single-ended input signals.

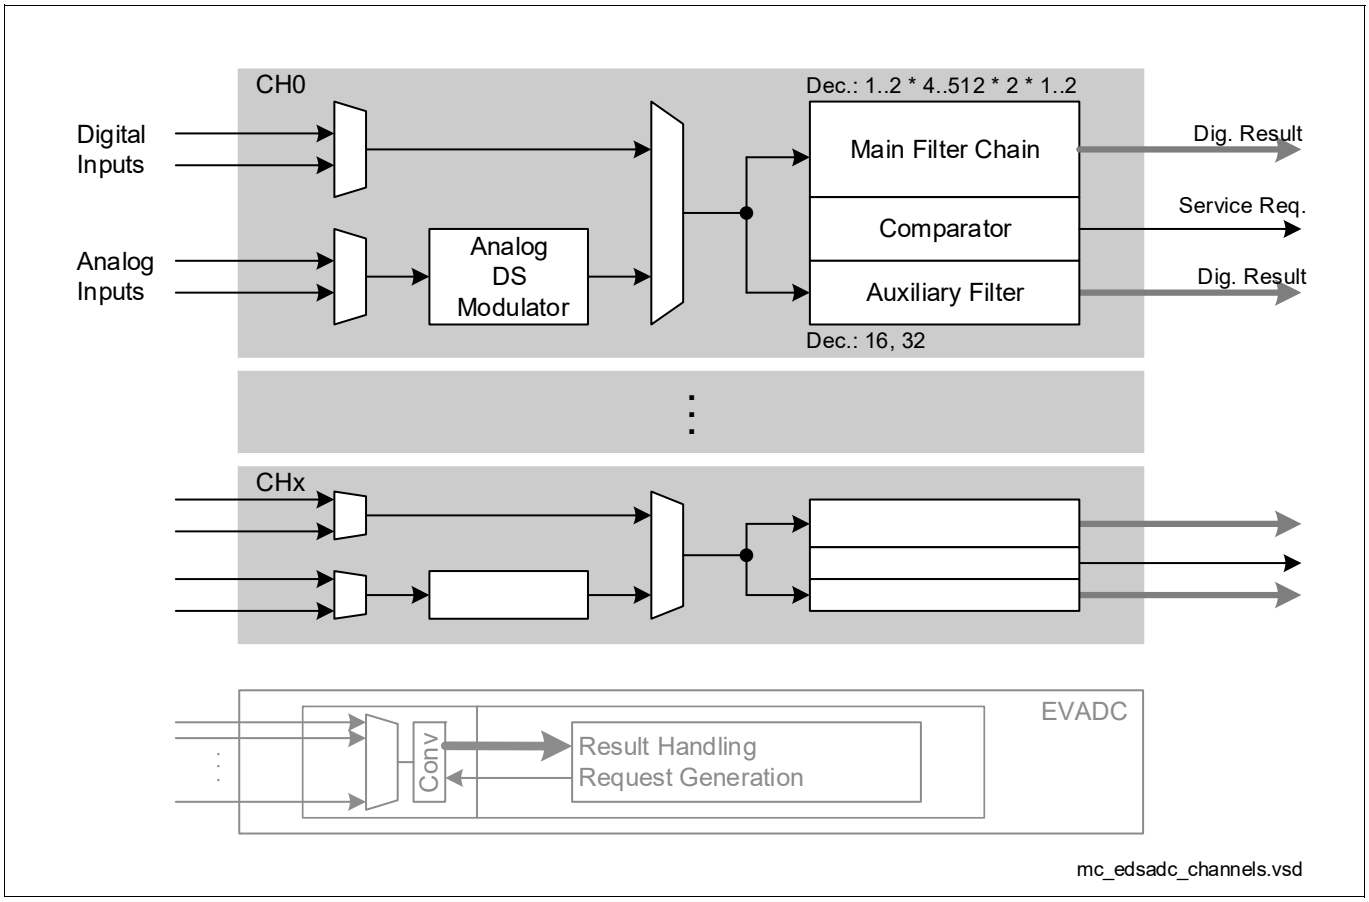

Figure 284 EDSADC Module Overview

33.1 Feature List

The following features describe the functionality of a DS Converter:

- Switched-capacitance input structure
  - Input voltage range 0…5 V
  - Common mode voltage: V_{AREF} / x (x = 2, 4, 8), connection selectable for each pin
  - Programmable gain (1:1 / 1:2 / 1:4)
  - DC Offset <5 mVDC, gain error < ±0.2% (calibrated, on product level)
  - Equivalent input impedance 500 kΩ typ. (for gain = 1, f_{MOD} = 26.67 MHz)
- On-chip modulator, single-bit second-order feed-forward modulator, sample frequency 16 … 40 MHz
- Options to connect external standard DS modulators
  - Selectable data stream inputs
  - Selectable DS clock input or output
- Demodulator (concatenated hardware filter stages)
  - Configurable CIC filter with decimation rates of 4…512
  - Overshoot compensation filter, optional
  - FIR filter with 8 coefficients (10-bit) with decimation rate 2 (FIR0)
  - FIR filter with 28 coefficients (10-bit) with decimation rate 1 or 2 (FIR1)
  - Pass Band 0.723 … 100 kHz, output sampling rate f_d = 2.17 … 300 kHz (decim. rate FIR1 = 2:1),
    Pass Band 0.723 … 10 kHz, output sampling rate f_d = 4.34 … 60 kHz (decim. rate FIR1 = 1:1),
    Pass band ripple: df_d < ±1%
  - Stop band attenuation: 0.5…1 × f_d: >40 dB / 1…1.5 × f_d: >45 dB /
    1.5…2 × f_d: > 50 dB / 2…2.5 × f_d: >55 dB / 2.5…OSR/2 × f_d: > 60 dB
  - Limit checking support
- Optional high-pass filter for DC compensation ($f_{-3dB} = 10^{-5} \times f_d$), configurable
- Hardware offset/gain calibration and compensation
- Parallel auxiliary CIC filter with limit checking for alarm generation
- Support for resolver applications
  - Carrier signal generator (differential sine output)
  - Signal evaluation including rectification, delay compensation and carrier elimination
- Automatic limit checking
  - Two-level boundary comparator
  - Separate indication signals

33.2 Overview

The Delta-Sigma Analog to Digital Converter module provides several channels providing an on-chip modulator with an associated demodulator including a configurable filter chain for demodulation, decimation, and filtering (see **Figure 285**).

You will find the following major sections within this chapter:

Attention: ***This chapter describes the EDSADC of the TC3XX family, encompassing the features and functions of all family members.***
The specific characteristics of a product are described in the product-specific appendix.
This product-specific appendix specifies deviations (e.g. downgrades, etc.) from this family documentation.

Table 271 Abbreviations used in EDSADC

Abbreviation	Meaning
ADC	Analog to Digital Converter
CIC	Cascaded Integrator Comb (filter)
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
DS	Delta-Sigma (conversion principle)
EVADC	Enhanced Versatile Analog-Digital Converter
FIR	Finite Impulse Response (filter)
HDI	Hardware Data Interface
INL	Integral Non-Linearity (error)
LSB_n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2^n equally distributed steps)

Table 271 Abbreviations used in EDSADC (cont'd)

Abbreviation	Meaning
OSR	Oversampling Ratio
PWM	Pulse Width Modulation

The EDSADC is connected to other on-chip modules to support functions on system level (see **Figure 286**).

The on-chip Single-Bit Second-Order Feed-Forward modulator converts an analog input signal to a datastream.

Several types of external modulators can be connected to the input path. The modulator clock signal can be generated internally or can be fed from an external clock source.

The digital filter chain (see **Figure 285**) builds the demodulator which produces result values at a configurable output rate. The elements of the filter chain can be activated according to the requirements of the application. The filter chain configuration determines the attenuation and delay properties of the filter. The decimation at a configurable rate reduces the modulator's input sampling rate to a lower result data rate that is suitable for the application.

The CIC filter provides the basic filtering and decimation with a selectable decimation rate.

Two FIR filters, each with a decimation rate of 2 (also 1 for FIR1), allow effective signal shaping by attenuating the upper frequencies of the signal spectrum.

The high-pass filter provides offset compensation by removing the DC component of the input signal.

The integrator accumulates a configurable amount of result values. The number of samples is programmable by software or can be controlled by a hardware signal.

Functionality of the integrator:

- further reduction of the data output rate for the application
- calculation of average values with selectable start point e.g. for shunt current measurement applications
- support for resolver applications to get the baseband signal for the motor position calculation

Each channel can generate service requests to trigger DMA transfers or to request CPU service.

Offset calibration and gain calibration are done in hardware. The calibration values are determined automatically by a hardware algorithm. This can be triggered initially after a reset or repeatedly during operation.

The on-chip carrier signal generator produces a selectable output signal (sine, triangle, rectangle) which can be used to drive a resolver. Synchronization of each input signal to the carrier signal ensures correct integration of the resolver input signals.

The basic module clock is the peripheral clock signal f_{ADC}.

A comparator supports limit checking, e.g. for overcurrent detection. Two limit values can be defined to restrict the generation of service requests to result values within a configurable area. This saves CPU performance and/or DMA bandwidth while continuously monitoring the input signal.

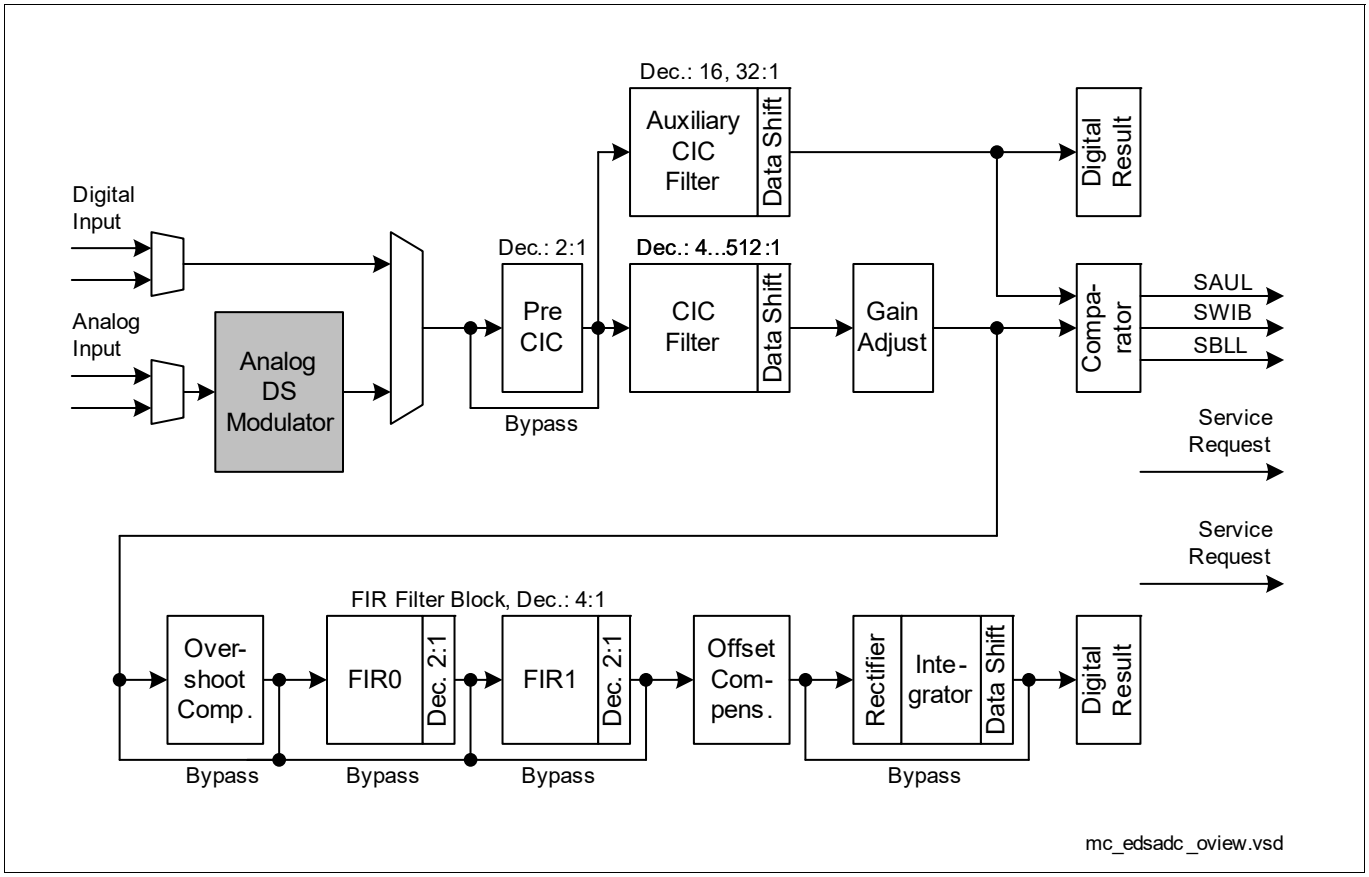

Figure 285 EDSADC Structure Overview

System Integration and Communication

Besides the connection to the peripheral bus, the EDSADC is directly connected to other hardware modules of the AURIX™ TC3xx Platform. **Figure 286** shows an overview of these interconnections. More detailed information can be found within the family documentation of the EDSADC as well as of the connected modules.

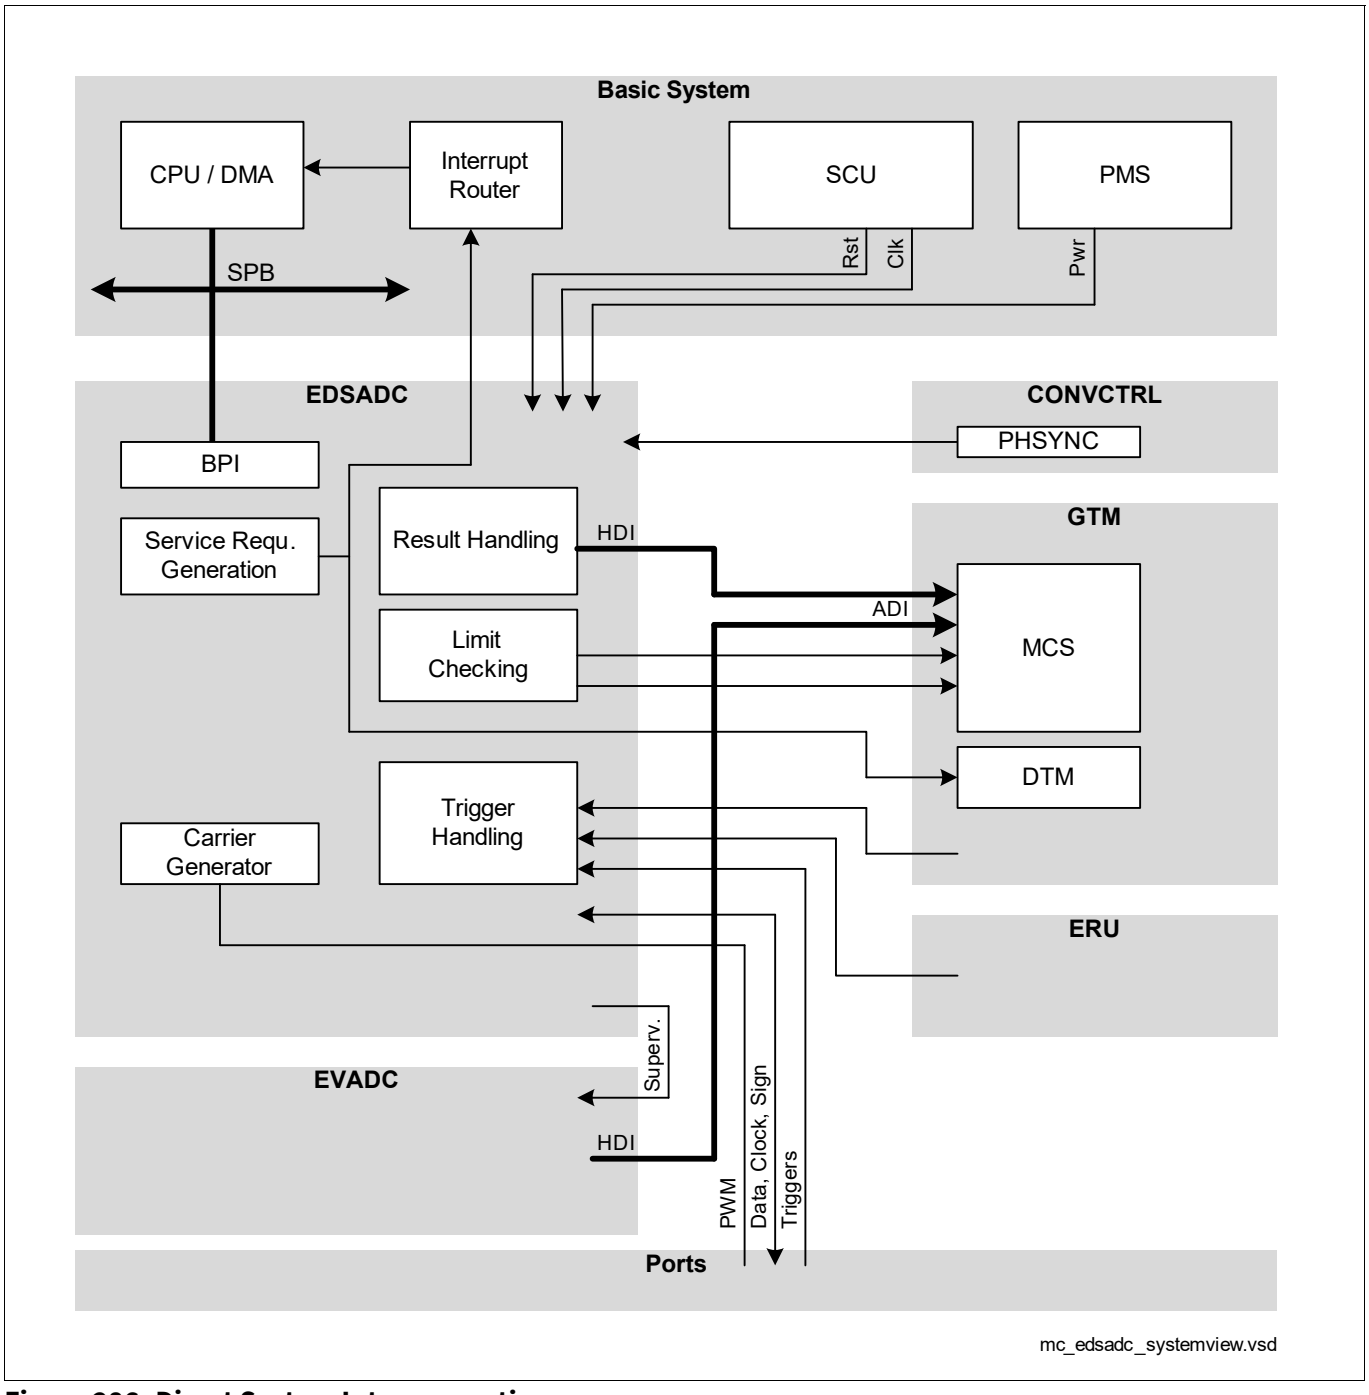

Figure 286 Direct System Interconnections

33.3 Configuration of General Functions

Several parameters can be configured to adapt the functionality of the EDSADC to the requirements of the actual application (see **Section 33.3.5**).

All configurations become effective when the corresponding channel is started, i.e. MxRUN becomes 1 for modulator-specific settings, CHxRUN becomes 1 for demodulator-specific settings.

33.3.1 Changing the Configuration

The configuration bitfields control the operation of the functional blocks of the EDSADC. To ensure proper operation and interaction of these functional blocks, it is recommended to change the configuration parameters of a channel only while this channel is inactive.
This means: MxRUN = CHxRUN = 0_B for channel x.

After reset, this is the default state. When changing the configuration during run-time, be aware of the respective implications listed in the table below.

Table 272 Implications When Changing the Configuration

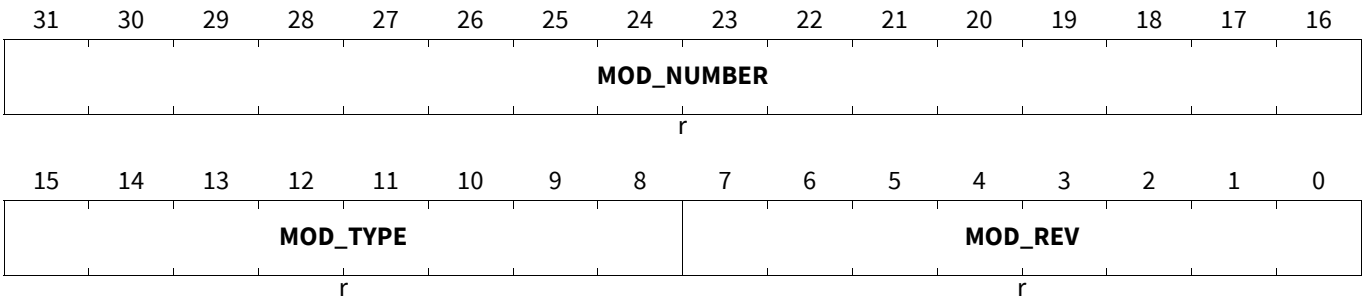
Configuration	Implication
Change during calibration	Wrong calibration or calibration error (to be avoided)
Modulator properties (INCFGP, INCFGN, GAINSEL)	Changes only become active after switching the analog multiplexer setting (if available) or after restarting the modulator (MxRUN = 1). Other modifications become effective immediately.
Change during operation	A change can cause resettling of modulator or filter chain, leading to delayed effect on the result values.

33.3.2 Module Identification

The module identification register indicates the version of the EDSADC module that is used in this product.

Module Identification Register

ID
Module Identification Register **(0008_H)** **PowerOn Reset Value: $00C6\ C007_H$**



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.

Field	Bits	Type	Description
MOD_NUMBER	31:16	r	**Module Number** Indicates the module identification number ($00C6_H$ = EDSADC)

33.3.3 System Registers

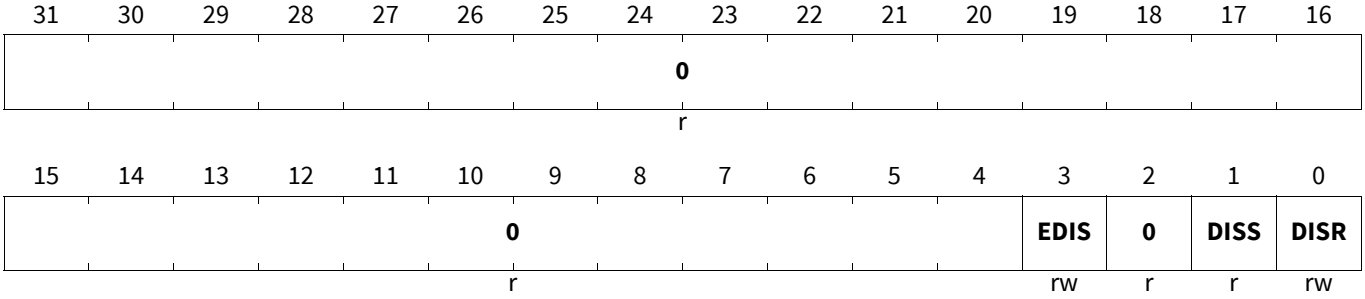
A set of standardized registers provides general access to the module and controls basic system functions.

Clock Control Register

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register **CLC** controls the module clock signal and the reactivity to the sleep signal.

CLC
Clock Control Register **(0000_H)** **Application Reset Value: $0000\ 0003_H$**



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	r	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked f_{SPB} and f_{ADC} are disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved, write 0**

It is recommended not to write to or read from module registers (except CLC) while the module is disabled. Write operations and read operations from registers that require a clock will generate a bus error.

OCDS Control and Status Register

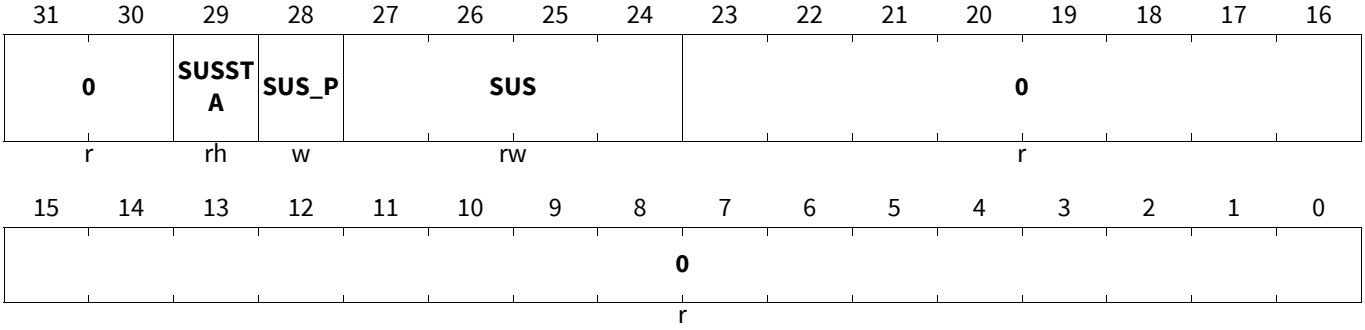
The OCDS Control and Status register OCS controls the module's behavior in suspend mode (used for debugging).

Register OCS is cleared by Debug Reset. It can only be written when OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS

OCDS Control and Status Register **(0028_H)** **Reset Value: Table 274**



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS). In soft suspend mode, the respective channel is stopped after the next result has been stored. For products with less channels the upper codes are reserved. 0_H Will not suspend 1_H Hard suspend: Clock is switched off immediately. 2_H Soft suspend channel 0 … F_H Soft suspend channel 13
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved, write 0, read as 0**

Table 273 Access Mode Restrictions of OCS sorted by descending priority

Mode Name	Access Mode		Description
write 1 to **SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

Table 274 Reset Values of OCS

Reset Type	Reset Value	Note
PowerOn Reset	$0000\ 0000_H$	
Debug Reset	$0000\ 0000_H$	

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on-chip bus master TAG IDs 00 0000_B to 01 1111_B (see On-Chip Bus chapter for the mapping of product TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding. Register ACCEN0 itself is protected by the Safety Endinit feature.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00 0000_B, EN1 -> TAG ID 00 0001_B , ... , EN31 -> TAG ID 01 1111_B (TAG IDs 1X $XXXX_B$ are not used).

ACCEN0

Access Enable Register 0 **($003C_H$)** **Application Reset Value: FFFF $FFFF_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B No write access 1_B Write access will be executed

Individual Module Reset

The Kernel Reset Registers **KRST0**/**KRST1** are used to reset the related module kernel. Kernel Reset Registers 0 and 1 each include bit RST. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

A module kernel reset has the following effects:

Table 275 Effects of a Module Kernel Reset

Register	Executed Action
CLC, OCS, ACCEN0	No influence
ID	No influence
KRST0	Bit RST is cleared automatically after reset execution, RSTSTAT indicates a module kernel reset, cleared via KRSTCLR
KRST1	Bit RST is cleared automatically after reset execution

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

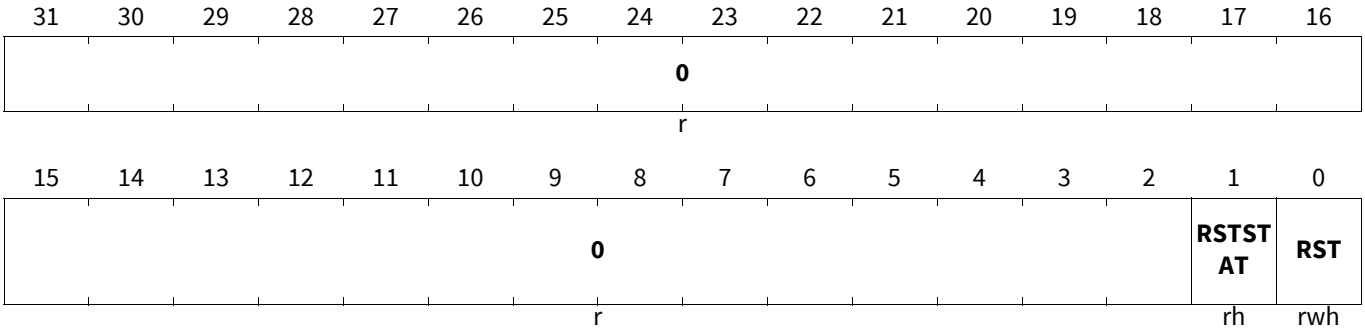
Table 275 Effects of a Module Kernel Reset (cont'd)

Register	Executed Action
KRSTCLR	No influence
Other registers	Reset to their defined reset values

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Kernel Reset Register 0

KRST0
Kernel Reset Register 0 (0034_H) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. RST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** Indicates an executed kernel reset. RSTSTAT is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear RSTSTAT by setting bit CLR in register KRSTCLR. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved, write 0, read as 0**

Kernel Reset Register 1

33.3.4 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the EDSADC.

- The registers of the EDSADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Register ACCPROT allows the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. **Table 276** lists the registers that belong to each register group.
  Register ACCPROT itself is protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

33.3.5 Global Configuration Registers

The EDSADC can operate in several configurations:

- Using the on-chip modulator, running from the internal clock
- Using an external modulator, running on a clock generated on-chip
- Using an external modulator, running on its own clock

The global configuration register GLOBCFG selects several operational or trimming values.

The global run control register GLOBRC controls the general operation of the available channels. For every EDSADC channel, register GLOBRC supports an individual bit for the related modulator (GLOBRC.MxRUN) and the related digital filter chain (GLOBRC.CHxRUN), where x depends on the number of implemented channels in the respective TC3x device. For applications where two or more EDSADC channels have to provide synchronous results, all related channels should be enabled synchronously using a single write access to register GLOBRC. This approach guarantees synchronization between EDSADC channels under all loading conditions of the system peripheral bus (SPB).

Global Configuration Register

1) Additional run control via the selected gate signal is possible by the automatic power control feature (bitfield APC in register MODCFG).

33.4 Input Channel Configuration

The input data for a channel can be obtained from different sources:

- **On-Chip Modulator**: The on-chip modulator can directly convert a differential or single-ended analog input signal to an input data stream. The on-chip modulator runs on the internal clock.
  The figure below summarizes the data path through the on-chip modulator.
- **External Modulator Without Clock Source**: This type of modulator requires a modulator clock signal. This clock signal is provided by the EDSADC, the data stream produced by the modulator is input as a digital signal.
- **External Modulator With Clock Source**: This type of modulator generates the modulator clock signal along with the data stream. In this case, both the modulator clock and the data stream produced by the modulator are input as digital signals.

Note: An external modulator can be used, in particular, in systems where high voltages are to be sampled. This allows for galvanic decoupling.
Several input pins can be selected.

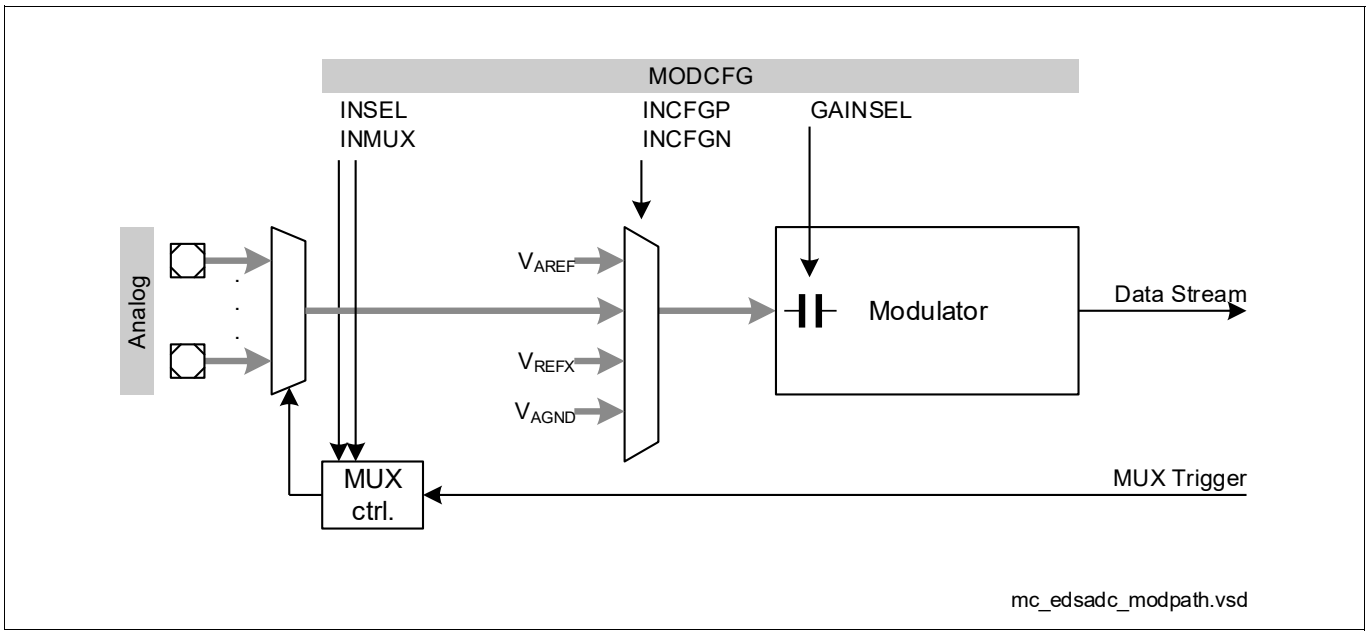

Figure 287 Analog Input Path

Note: To avoid clipping due to overdrive (the data stream contains all 1s) the on-chip modulator is built with an intrinsic gain factor of FM = 0.6945. This allows to handle a certain level of overshoots without entering overdrive.
The behavior of external modulators is described in the respective specification.

The modulator clock can be generated in different ways:

- The modulator clock is derived on-chip from the peripheral clock f_{ADC}. It is used for the on-chip modulators and can be output via a selectable modulator clock pin to be used by an external modulator. It also is the time basis for the timestamp counter.
- The external modulator can generate the clock signal which is then input via one of the modulator clock pins.

A trigger signal can be selected from different inputs. These inputs are connected to on-chip peripherals or to pins. The digital connection table in the product-specific appendix describes the available connections.

This trigger signal can be used for different purposes:

- Integration trigger:
  The external signal defines the integration window, i.e. the timespan during which result values are integrated.
- Timestamp trigger:
  The external signal requests the actualization of the timestamp register.
- Input multiplexer trigger:
  The external signal requests the switching of the analog input multiplexer to the next lower input or to the defined start value, respectively.
- Modulator run gate:
  The on-chip modulator can be controlled by an external gate signal while it is enabled. In this case it can be disabled temporarily to save power.
- Service request gate:
  Service requests for the filter chain can be restricted to the high or low times of the selected trigger signal.

Note: Trigger signals shall be active for at least 1 period of f_{ADC} to properly trigger an action.

The figure below summarizes these three signal paths and indicates the source of the corresponding control information.

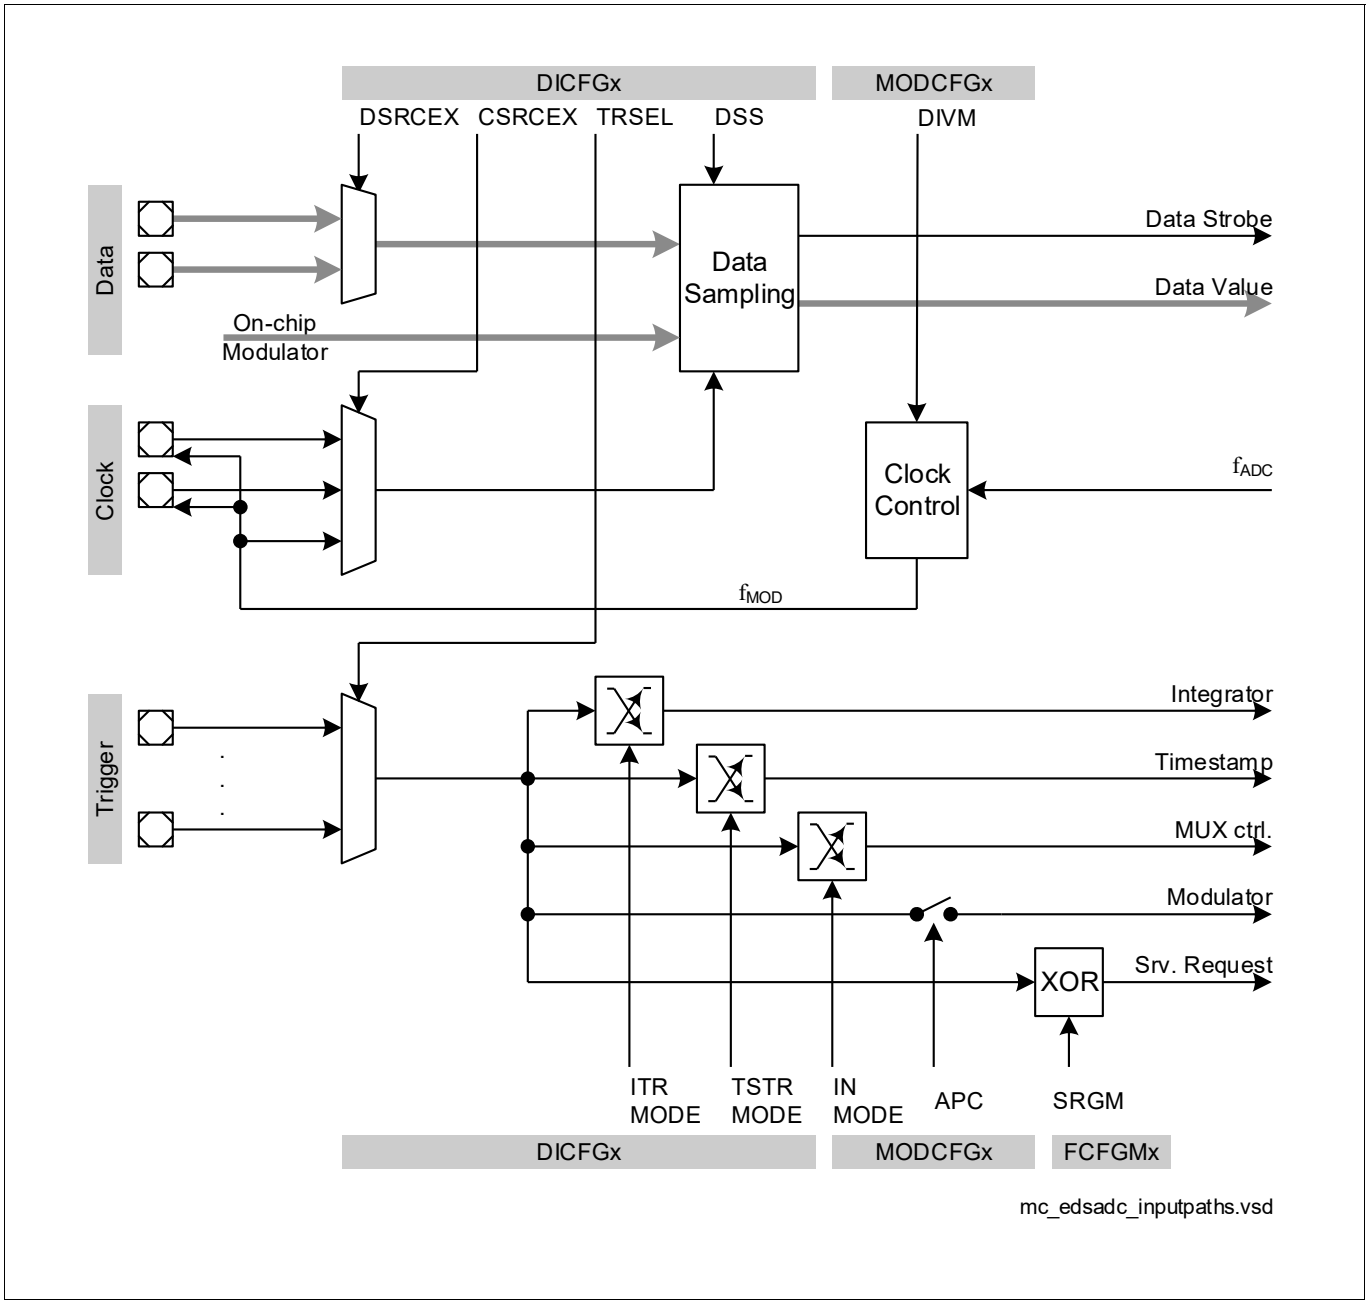

Figure 288 Input Path Summary

33.4.1 Modulator Clock Generation

The modulator clock signal can be generated on-chip or can be generated by an external modulator and be input through a pin (clock input).

The on-chip clock signal is used for the on-chip modulator or can be used for an external modulator through a selectable clock output pin. The on-chip modulator clock is based on the analog phase synchronizer. The phase synchronizer defines the rising edges of the modulator clock, the period is defined by bitfield DIVM (modulator clock period).

For proper operation the duty cycle of the on-chip modulator clock must be 50%. A separate 2:1 prescaler flipflop ensures this while the modulator clock is generated on-chip.

*Note: The EDSADC evaluates the rising edge of the phase synchronizer signal. In synchronized mode, it will operate while the phase synchronizer signal is toggling. In unsynchronized mode (**GLOBCFG**.USC = 1), the modulator clock is generated independent of the phase synchronizer signal.*
For proper operation, only change the configuration of the phase synchronizer while the converters are idle.

The bus interface is clocked with the system clock f_{SPB}.

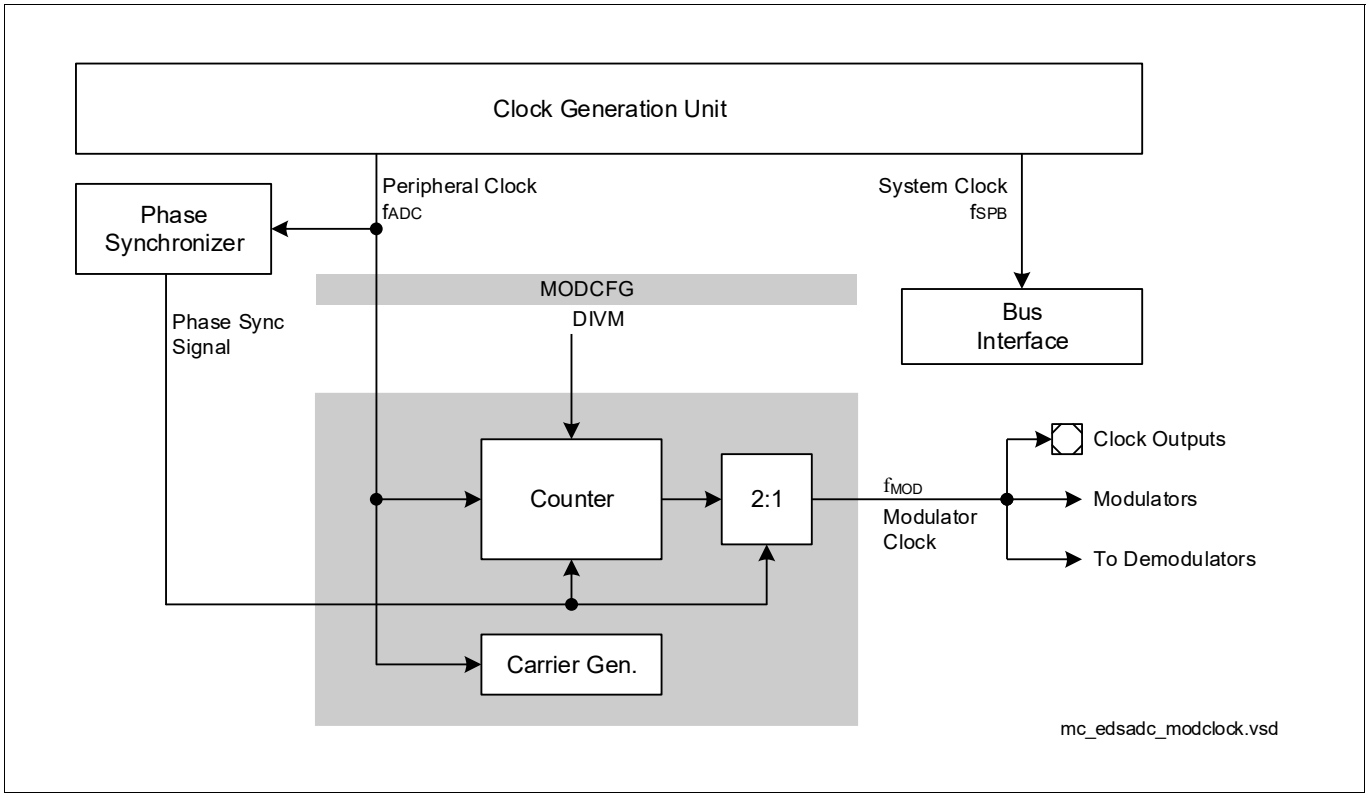

Figure 289 Modulator Clock Configuration

An external clock signal is synchronized to the module clock. A configurable edge detector selects the clock signal edges that generate the data strobes which read the next input data and trigger the demodulator (see **Figure 290**).

Note: To ensure proper synchronization, an external clock signal must have high/low phases of at least two periods of f_{ADC} to be safely synchronized (f_{IN} <= f_{ADC}/4).

When the clock signal is generated on-chip (see **Figure 289**) and is selected as an output signal at a connected pin, this clock signal can drive an external modulator.

Bitfield DSS in register **DICFGx (x=0-13)** selects the data source for each channel. For external modulators it also selects the clocking mode, i.e. the clock edges that put a new input data sample into the filter chain. In this case also the clock source can be selected.

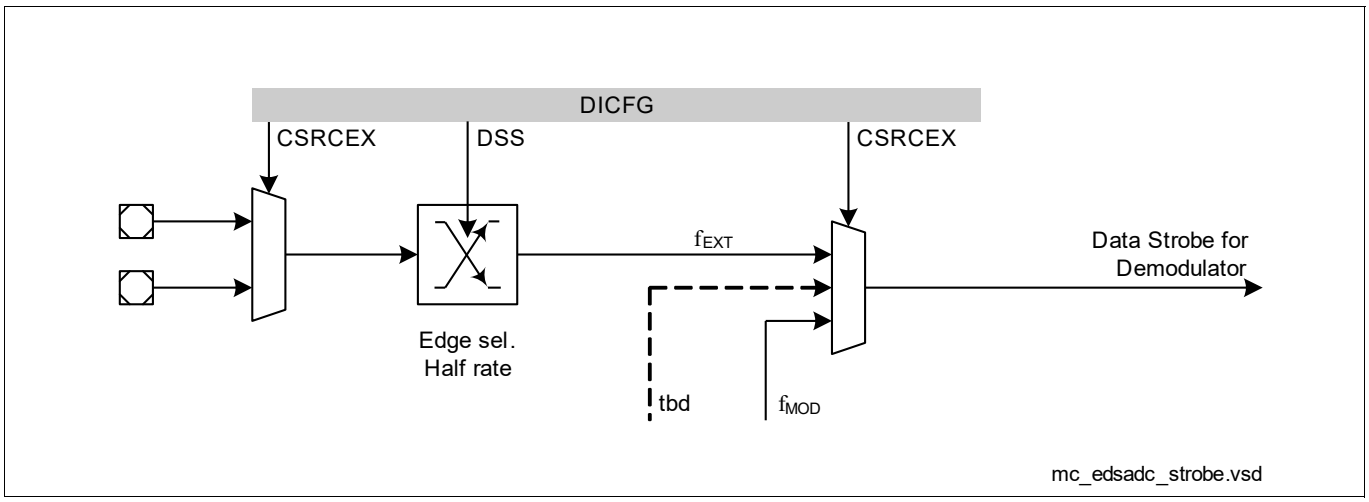

Figure 290 Demodulator Data Strobe Selection

33.4.2 Input Data Selection

The data stream of an external modulator can be input from a selectable pin. This signal can optionally be inverted.

The data stream can also be generated by the on-chip modulator. The selected input datastream is converted to the CIC filter's input format.

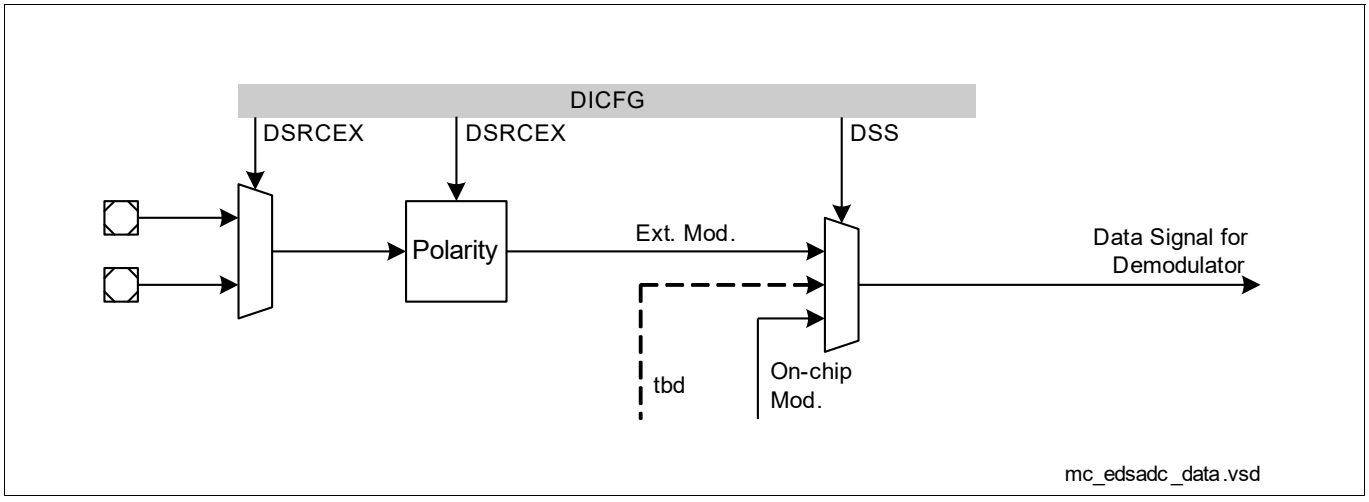

Figure 291 Demodulator Data Signal Selection

All options are configured by the demodulator input configuration register **DICFGx (x=0-13)**.

33.4.3 External Modulator

The input data stream can be obtained from an external modulator via a selectable pin. This modulator may, for example, be connected to a high driving voltage and be galvanically decoupled.

In this case, the modulator's data output is connected to the selected pin and is fed to the filter chain. The data input signal can optionally be inverted.

The sample clock signal can be generated on-chip or can be input from the external modulator. The data strobe that enters a new value into the filter chain can be generated upon configurable clock edges of the modulator clock to support different types of modulators.

33.4.4 On-Chip Modulator

The on-chip modulator is a 2nd order feed-forward modulator. It operates at a sample frequency of 40 MHz, 26.67 MHz, 20 MHz or 16 MHz. This sample frequency is derived from the actual module frequency (see **“Modulator Clock Generation” on Page 22**).

The analog input signal is fed to the sample stage via two input lines (differential input) or via one input line with the other input internally grounded (single-ended input).

Analog input multiplexers connect the input lines to different pins. The product-specific appendix details the available channels and their inputs. The input multiplexers are controlled by register **MODCFGx (x=0-13)**.

The gain factor of the input stage can be programmed to 1, 2, 4. The common mode voltage can be enabled or disabled.

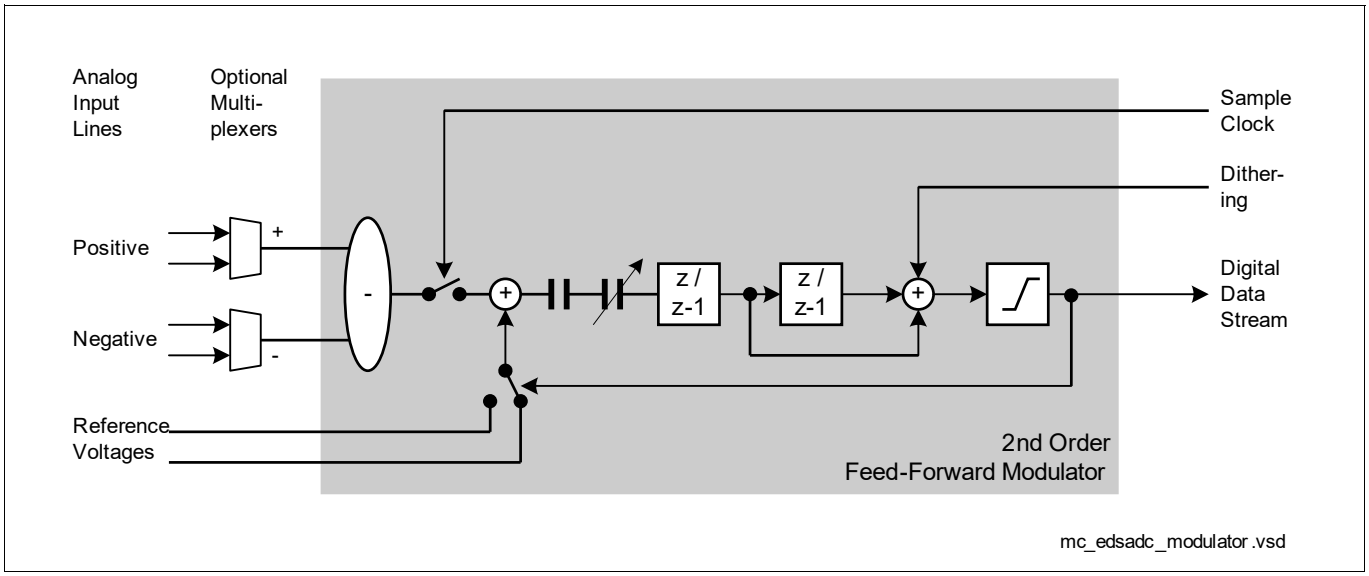

Figure 292 Structure of the On-Chip Modulator

Offset compensation and gain compensation improve the performance of the modulator. The calibration algorithm can be enabled during the initialization phase and also during operation, e.g. to compensate temperature drift.

Power Reduction via External Run Control

If an application does not require permanent activity of a channel, it can disable its modulator intermittently to save energy. This can be done under software control or automatically.

The operating mode is determined by bitfield **MODCFGx (x=0-13)**.APC:

- APC = 00_B: **Normal Operation**: The modulator is controlled by software.
- APC = 01_B: **Slow Standby mode**: Voltage regulator and on-chip modulator are switched off while the gate signal is inactive. They automatically return to normal operation when the gate signal becomes active. Requires the standard wakeup time (see below).
- APC = 10_B: **Fast Standby mode**: The on-chip modulator is switched off while the gate signal is inactive. It automatically returns to normal operation when the gate signal becomes active. Requires the standard wakeup time (see below).

Note: The standard wakeup time is also required after initially enabling the converter. If an external modulator is used, no wakeup time has to be considered. Slow Standby mode and Fast Standby mode are identical.

Wakeup Time from Analog Powerdown

When the modulator is activated, it needs a certain wakeup time (depending on the operating mode) to settle before proper data can be delivered. Make sure to include this settling time in the on-off cycles of the gate signal.

The standard wakeup time is maximum 20 µs.

Internal Dithering

Static or low-frequency input signals can generate so-called idle tones which could degrade the SNR. The internal dithering avoids this phenomenon.

The internal dithering can also reduce the so-called dead-zone.

Internal dithering is disabled by default, see bit DITHEN in register **MODCFGx (x=0-13)**.

Handling of Overload, Overdrive and Overflow Conditions

Operating an EDSADC channel outside its specified operating range requires additional careful handling and precautions. This ensures the generation of useful result values and prevents damaging the device.

An overload condition occurs if the input voltage on the respective pin exceeds the supply voltage. In this case the protection diodes try to limit the input voltage by becoming conducting. The resulting current must be limited to prevent damage to the protection structures. This is specified in the Datasheet.

An overdrive condition occurs if the resulting input voltage to the on-chip modulator becomes too high so the modulator can only generate a bitstream of all 1s. This may happen when an analog gain factor of 2 or 4 is selected. The susceptibility to an increased input voltage (e.g. overshoots) is reduced by the modulator's intrinsic gain factor of FM = 0.6945 (see also section **"CIC Filter" on Page 44**). The overdrive condition is determined by the input voltage, the analog gain factor selected by bitfield MODCFGx.GAINSEL and the reference voltage.

An overdrive condition, therefore, exists if ($V_{AIN} \times 2^{GAINSEL} \times 0.6945$) > V_{AREF}. In this case, the result value is <CALTARGET> × 1/0.6945.

The recovery from an overdrive condition would cause a non-constant group delay for the subsequent filter chain. This can be avoided by clearing the analog integrator stages of the modulator. Integrator clearing is done automatically if enabled by setting bit MODCFGx.IREN = 1[1)].

An overflow condition can, in turn, be generated by an overdrive condition. This can result in an overflow of the digital result that is obtained from the filter chain's output. To avoid this, the calibration target value must be selected below $2^{15} \times 0.6945$ = 22 757 and the data shifter after the CIC filter and the corresponding correction factor be set accordingly (see formula for CICSHIFT in section **"CIC Filter" on Page 44**).

Calibration targets above 22 757 do not cause overdrive if the input voltage V_{AIN} is limited by the system and does not exceed (2^{15} / <CALTARGET>) * (V_{AREF} / $2^{GAINSEL}$). The default value (after reset) of 25 000, for example, provides result values with a resolution of 0.2 mV/LSB.

The subsequent filter chain provides a normalized gain of 1.

Attention: ***Overload conditions while a gain factor of 4:1 is selected lead to an internal stress condition which can reduce the product's life time if the overall duration of this condition exceeds a total of 10 s. Make sure the application software recognizes this stress condition (easiest way is to detect the overdrive condition) and disables the respective modulator or reduces the gain factor within 10 ms. Limit checking can help to detect this situation automatically. This supervision allows to tolerate approx. 1000 occurrences of the internal stress condition over life time.***

1) It is recommended to enable integrator reset as a standard means to deal with on-chip modulator overdrive for applications where overdrive conditions can occur.

33.4.5 Input Path Control

The input for the EDSADC is fed through several stages before being evaluated and filtered. Registers MODCFGx and DICFGx select the available options for these signal stages.

The following features can be configured:

- Signal input pin selection
- Configuration of input stage and on-chip modulator
- Generation method of input data
- Modulator clock source and/or frequency
- Trigger input pin selection

Signal Input Pin Selection

Some modulator inputs provide analog input multiplexers which connect them to several input pins. These input multiplexers can be controlled directly by software or can be switched triggered by an external control signal. Software selects the desired position via bitfield INSEL, bitfield INMUX indicates the actual setting of the input multiplexer. Bitfield INMODE defines the condition for a trigger event, bitfield INMAC selects the way in which the multiplexer is controlled:

- Software control:
  Control bitfield INMUX follows bitfield INSEL, software directly selects the intended input pins.
- Preset mode:
  The (software-written) value in bitfield INSEL is copied to bitfield INMUX upon a trigger event. Software can preselect the next intended multiplexer setting which then becomes active when the next trigger event occurs.
- Single-step mode:
  Bitfield INMUX is decremented upon each trigger event. If INMUX = 00_B when the trigger occurs, it is loaded from bitfield INSEL instead. In this mode, a predefined sequence of input pins can be scanned automatically.

The trigger signal itself is selected by bitfield TRSEL in register **DICFGx (x=0-13)**.

Note: Not all channels provide input multiplexers. Also, the width of the input multiplexers may differ from channel to channel. The product-specific appendix details the available channels and their inputs inputs.

Modulator Configuration Register x

The modulator configuration register selects the operation mode of the on-chip modulator:

- Input line clamping
- Gain factor of input signal path
- Modulator operating mode
- Divider factor for modulator clock

Note: Changes to bitfields INCFGP, INCFGN, GAINSEL only become active after switching the analog multiplexer setting (if available) or after restarting the channel (MxRUN = 1).

33.4.6 Common Mode Voltage

Some applications require the assertion of a common mode voltage e.g. to support passive differential sensors. The common mode voltage V_{CM} is derived from the analog reference voltage V_{AREF}: $V_{CM} = V_{AREF} / X$ and is enabled via bit VXON and configured via bitfield VREFXSEL in register **VCMx (x=0-13)**.

Bits INyVCz in register **VCMx (x=0-13)** select the connection to V_{CM} for each of the possible input pins. Two nibbles are assigned to each channel (positive and negative inputs) and contain the control bits for each possible input of the respective channel.

While the input pins are not connected to the input lines of the channel (e.g. while the analog input multiplexer selects different pins or while the modulator is off), each individual analog input pin that is intended to be used for the EDSADC can remain connected to the common mode voltage V_{CM}. This ensures that the sensor input is biased and does not float away while the respective input line is disconnected or the modulator is disabled.

Note: The available channels provide different numbers of input pins. The product-specific appendix details the available channels and their inputs inputs. Only those INyVCz bits in VCMx are valid that correspond to an existing input pin.

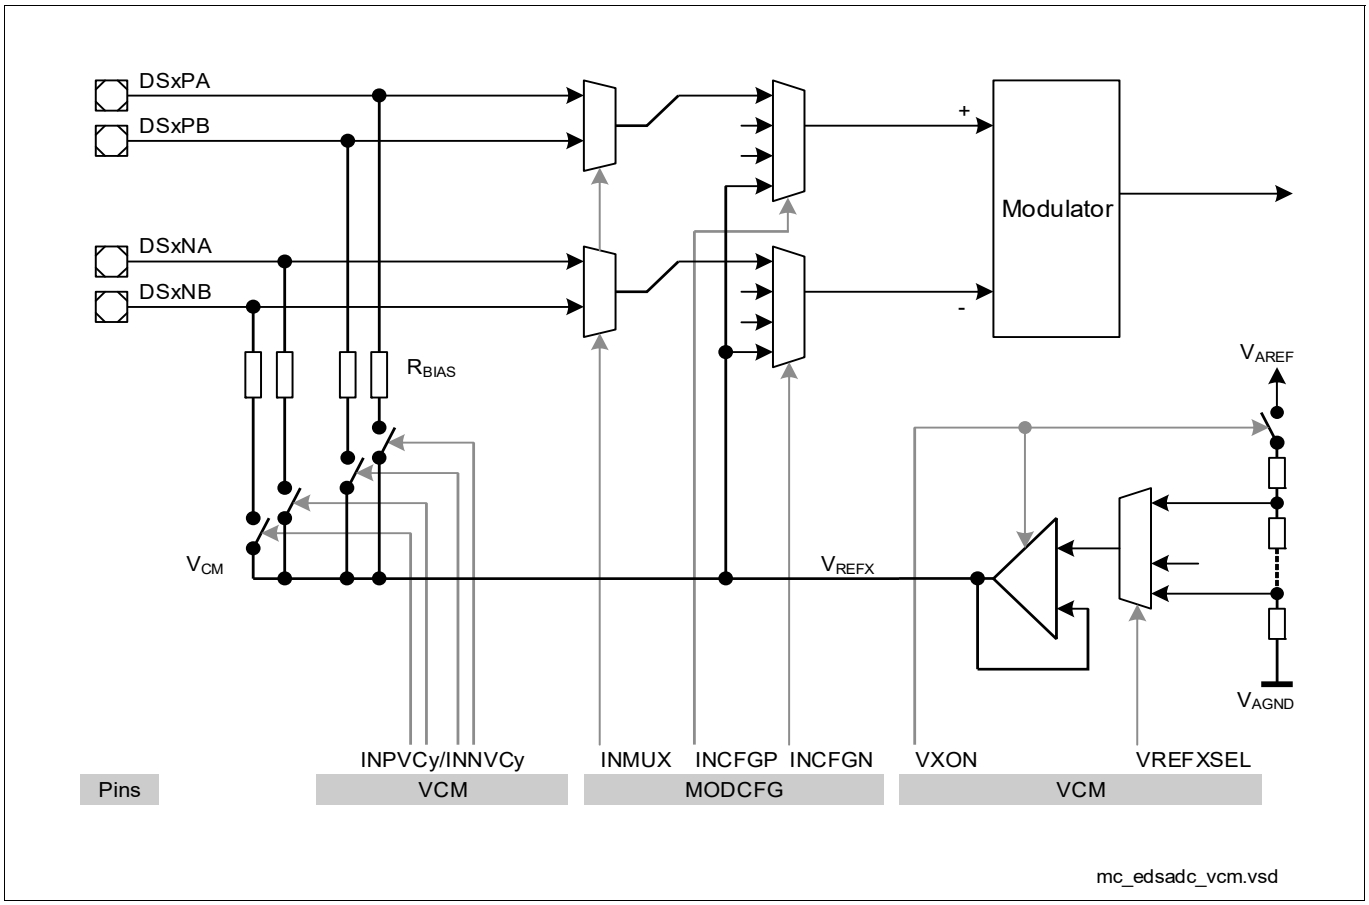

Figure 293 Control of VCM Switches

Common Mode Voltage Register x

The common mode voltage registers enable the voltage generators and select which input pins are connected to the common mode hold voltage.

Only those bits are valid that correspond to an existing input pin (see product-specific appendix).

33.4.7 Calibration Support

The performance of the EDSADC can be improved by applying some calibration techniques.

The calibration algorithm for gain and offset is executed automatically. Since it takes a certain time during which no conversions can be executed, two modes can be used:

- Software can determine when the algorithm is executed by setting bit CALIB in register **FCFGMx (x=0-13)**.
- In the case of gated operation the calibration algorithm can also be started automatically when the gate closes (set bit AUTOCAL in register **FCFGMx (x=0-13)**).

The calibration algorithm supports differential and single-ended mode with gain settings of 1 and 2. The respective calibration mode is derived from registers **MODCFGx (x=0-13)** and **VCMx (x=0-13)** as shown in the table below:

Table 280 Supported Calibration Modes

Selected Mode	Corresponding Bitfields in MODCFG
Differential, gain 1 / gain 2	INCFGP = INCFGN = 00_B, GAINSEL = 0000_B or 0001_B
Single-ended, gain 1	INCFGx = 00_B, INCFGy = 11_B, GAINSEL = 0000_B
Single-ended, gain 2	INCFGx = 00_B, INCFGy = 10_B, GAINSEL = 0001_B, VCMx.VREFXSEL = 00_B

Note: An initial calibration must be triggered once after a reset.
Calibration for a gain factor of 4 is executed with gain setting 2.

Repeated Calibration During Operation

To compensate temperature effects it is recommended to repeat the calibration sequence when the device temperature has changed by approximately 20°C. This can be done by simply setting bit CALIB in register **FCFGMx (x=0-13)** or by enabling automatic calibration (AUTOCAL = 1). After calibration, the channel will resume its normal operation.

Calibration Timing

The calibration uses a sequential search algorithm to determine the correct calibration factor. The duration of the calibration algorithm, therefore, depends on the deviation to be calibrated (algorithm), and also on the configuration of the module, i.e. on the modulator frequency ($f_{MOD} = f_{ADC} / (4 + 2\times DIVM)$) and on the decimation rate used for calibration ($DC = 8 \times 2^{CICDEC}$).

The calibration time, therefore, is determined by $t_{ADC} = 1 / f_{ADC}$ and $t_{MOD} = 1 / f_{MOD}$.

The following formula describes the required maximum calibration time: $t_{CAL} = 16 \times DC \times t_{MOD} + 4\,200 \times t_{ADC}$.
If gain factor 2 is selected the calibration algorithm is extended by: $t_{2nd} = 12 \times DC \times t_{MOD} + 8\,300 \times t_{ADC}$,
so the total maximum calibration time will be: $t_{CAL2} = 28 \times DC \times t_{MOD} + 12\,500 \times t_{ADC}$.

Table 281 Calibration Times [µs] for f_{ADC} = 160 MHz, Gain1 (Gain2)

DIVM [f_{MOD}] --->	0 [40]	1 [26.7]	2 [20]	3 [16]
CICDEC = 4, DC = 128	78 (168)	104 (213)	129 (258)	155 (303)
CICDEC = 5, DC = 256	129 (258)	180 (347)	232 (437)	283 (527)
CICDEC = 6, DC = 512	232 (437)	334 (616)	436 (795)	539 (975)

Note: Higher decimation rates require more calibration time but offer a higher calibration precision.
*The end of calibration is indicated in bitfield CAL in register **FCNTCx (x=0-13)**.*

Range Adaptation

The application can select the digital full-scale result value that corresponds to an input of $V_{AIN} = V_{AREF}$.

The intended full-scale value (CALTARGET) is reached by configuring the decimation rate of the CIC filters, selecting the corresponding position of the data shifter and configuring the resulting multiplication factor for the gain adjust unit, written to register **GAINCORRx (x=0-13)** (see links below).

The signal to noise ratio defines the effective number of result bits: ENOB = (SNR - 1.76) / 6.02.

Since (80 dB - 1.76) / 6.02 = 13 bit, selecting a minimum 14-bit target value is recommended.

When choosing the full-scale value, note, however, that using the full 15-bit range may lead to overflows in case of overshoots. See **"Handling of Overload, Overdrive and Overflow Conditions" on Page 26**.

Summary of Calibration Parameters

During calibration the settings of CIC filter and gain correction are replaced by specific values which are valid for the calibration algorithm. The application needs to compute and configure these values in addition to the values used during operation.

The calibration algorithm will trim the channel according to the configured calibration target value (CALTARGET).

Note: The formula to determine the GAINFACTOR is given in section ***"Data Shifter and Decimation Factor" on Page 45***.

33.4.8 Correction for External Circuitry

The built-in calibration support is optimized for low-impedance inputs. Operation using higher impedances (>100 Ohm) incurs gain errors due to the external circuitry (series resistance and buffer capacitor.

- Single-ended operation (see **Figure 295**):
  One input line usually internally connected to ground.
  An additional compensation factor can be calculated to compensate the error caused by the average input current I_{RMS} flowing through the resistance of the external path R_{EXT}:
  $F_{GR} = 1 + (I_{RMS} \times R_{EXT}) / 5\ V$
- Differential operation (see **Figure 296**):
  Both input lines connected to signal source.
  An additional compensation factor can be calculated to compensate the error caused by the average input current I_{RMS} flowing through the resistances of the external path R_{EXTP} and R_{EXTN}:
  $F_{GR} = 1 + (I_{RMS} \times (R_{EXTP} + R_{EXTN})) / 5\ V$

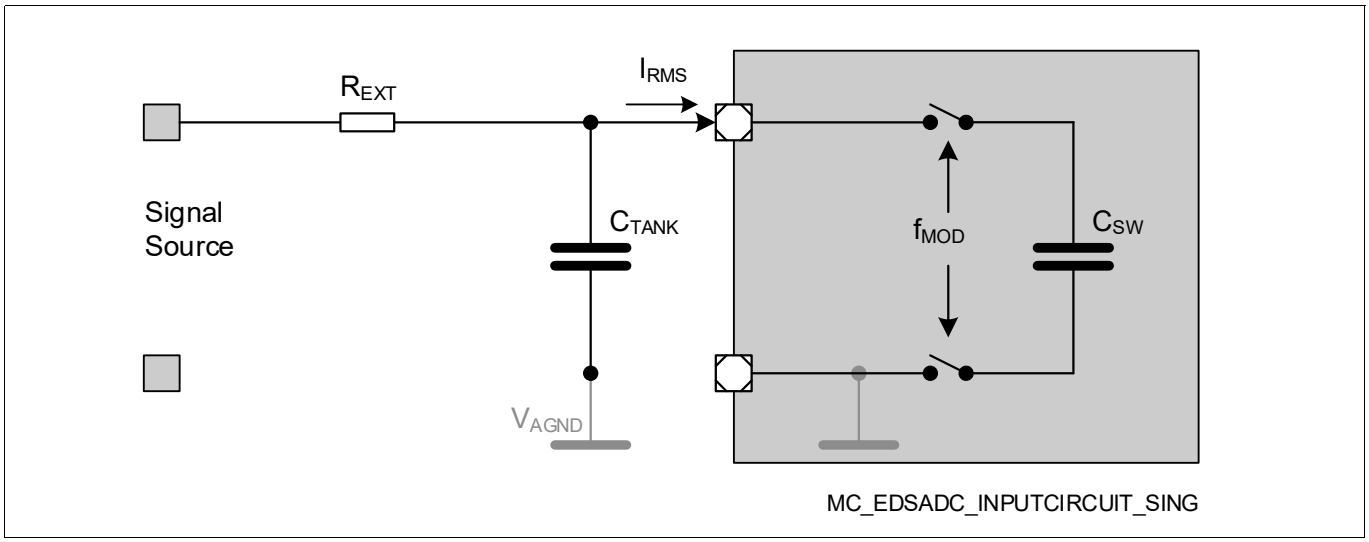

Figure 295 Single-Ended Input Circuitry of a Channel

*Note: This description example assumes the single-ended sensor signal to be connected to the positive input and the negative input to be grounded internally (indicated in grey in **Figure 295**).*

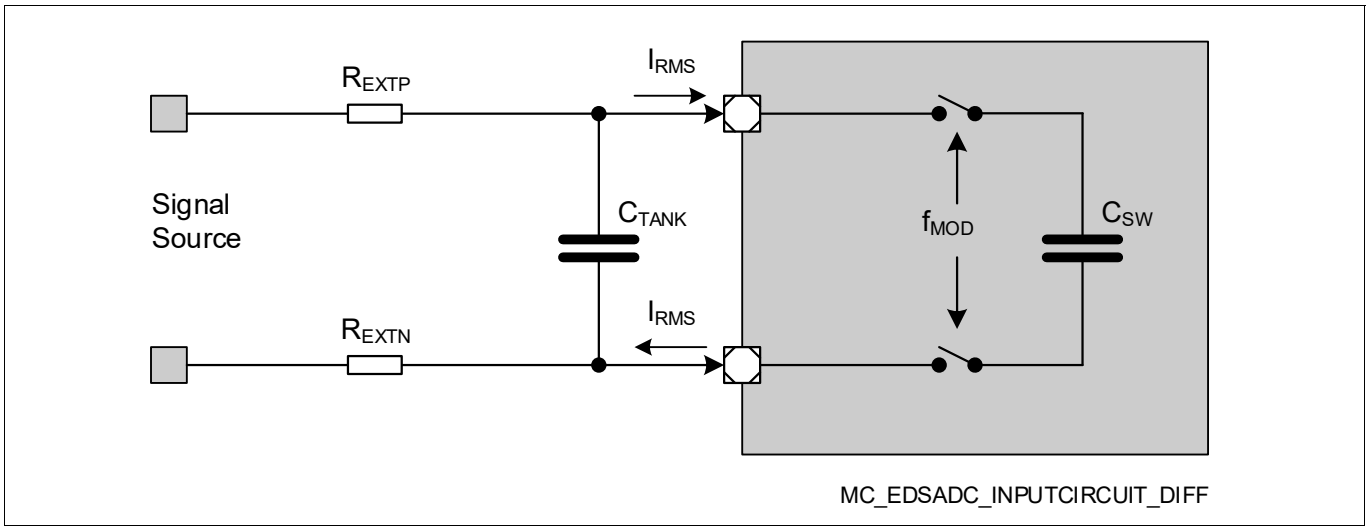

Figure 296 Differential Input Circuitry of a Channel

The buffer capacitor C_{TANK} not only is a part of the anti-alias filter but also minimizes the gain error of the complete input path. The maximum value for C_{TANK} is determined by the maximum signal frequency that shall be converted by the respective channel.

Also the buffer capacitor itself causes a small additional gain error. This can be compensated with the following formula:

$F_{GC} = 1 + I_{RMS} / (f_{MOD} \times C_{TANK} \times 5\ V)$

These factors can be combined with the range adaptation factor and CIC correction factor and be written into register **GAINCORRx (x=0-13)**.

Stored Calibration Values

The average input current is measured during production and the value is stored in the on-chip Flash (value IRMS, see below). The application can, therefore, calculate a device-specific correction factor.

The stored measurement value is referenced to a voltage of 5.0 V, a modulator frequency of 26.67 MHz and a gain factor of 1:1. So the actual input current is $I_{RMS} = (IRMSx / 100) \times (f_{MOD} / 26.67) \times 2^{GAINSEL}$.

The device-specific calibration values are stored in the User Configuration Block (UCB_USER) within the on-chip Flash memory. The area assigned to the EDSADC begins at offset 0080_H and provides records of two 32-bit words per channel. The channel-specific records, therefore, can be read from offset [0080_H + 8×CHNr.] within block UCB_USER. The table below shows the structure of a record.

Table 282 Structure of EDSADC Calibration Records (Generated at f_{MOD} = 26.67 MHz)

	Halfword 3	Halfword 2	Halfword 1	Halfword 0
Location CH0	0086_H	0084_H	0082_H	0080_H
Location CH1	$008E_H$	$008C_H$	$008A_H$	0088_H
:	:	:	:	:
Stored value	IRMS	Reserved	Reserved	Reserved

The parameters are stored in the following format:

Current = IRMSx × 0.01 µA, i.e. $03E8_H$ = 10 µA.

Example:

For R_{EXT} = 10 kOhm, IRMS = $042E_H$ (10.7 µA), C_{TANK} = 330 pF, f_{MOD} = 40 MHz, GAINSEL = 0:

The real current at 40 MHz, therefore, is I_{RMS} = 10.7 µA × 40 / 26.67 × 2^0 = 16.05 µA:

F_{GR} = 1 + (16.05 µA × 10 kOhm) / 5 V = 1.0321

F_{GC} = 1 + 16.05 µA / (40 MHz × 330 pF × 5 V) = 1.00024

The total factor will be $F_G = F_{GR} \times F_{GC}$ = 1.0321 × 1.00024 = 1.03235

Assuming a range adaptation factor of 1.2 (25 000 to 30 000), the overall factor would be 1.2 × 1.03235 = 1.2388, so the value for bitfield GAINFACTOR is 5 074 = $13D2_H$.

33.5 Filter Chain

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio.

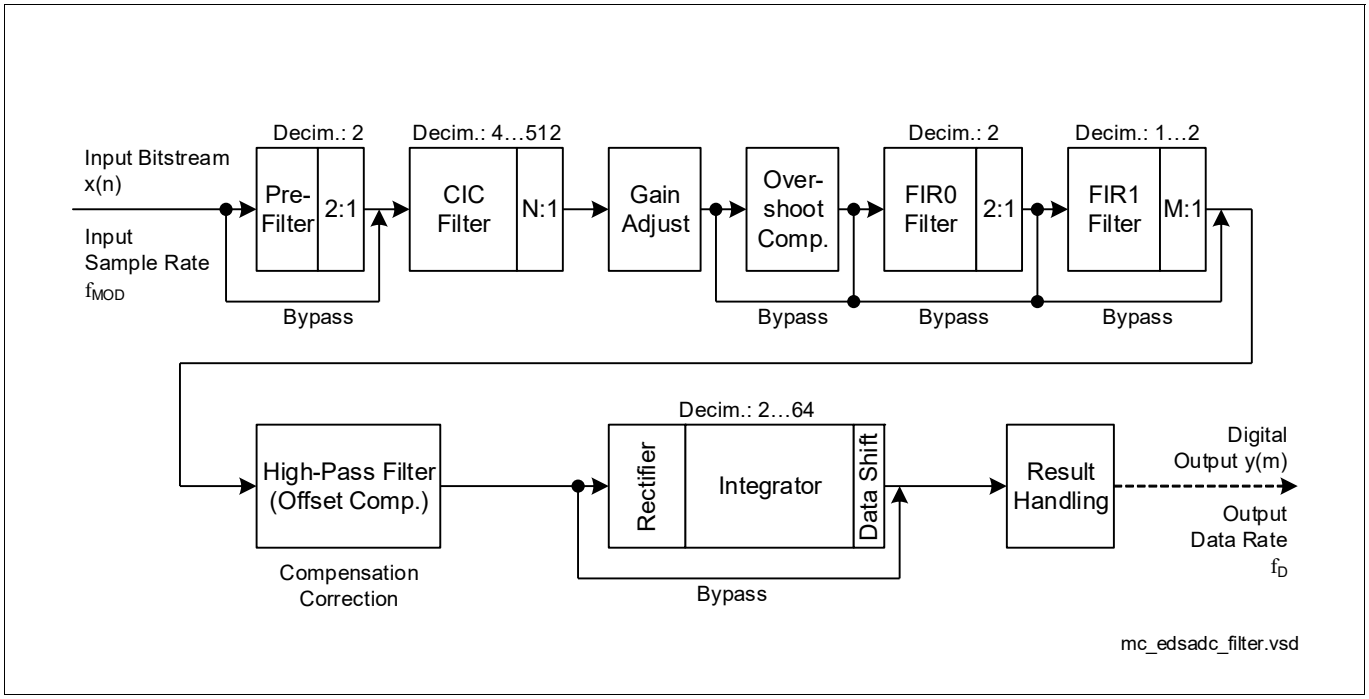

Figure 297 Structure of the Filter Chain

Most elements of the filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application. This comprises the frequency attenuation as well as the total decimation rate.

The filter chain consists of the following elements:

- **CIC Filter**
- **Gain Correction**
- **Overshoot Compensation**
- **FIR Filters**
- **Offset Compensation**
- **Integrator Stage**

*Note: Reconfiguring filter parameters while the channel is active incurs some implications. Refer to **Section 33.3.1**.*

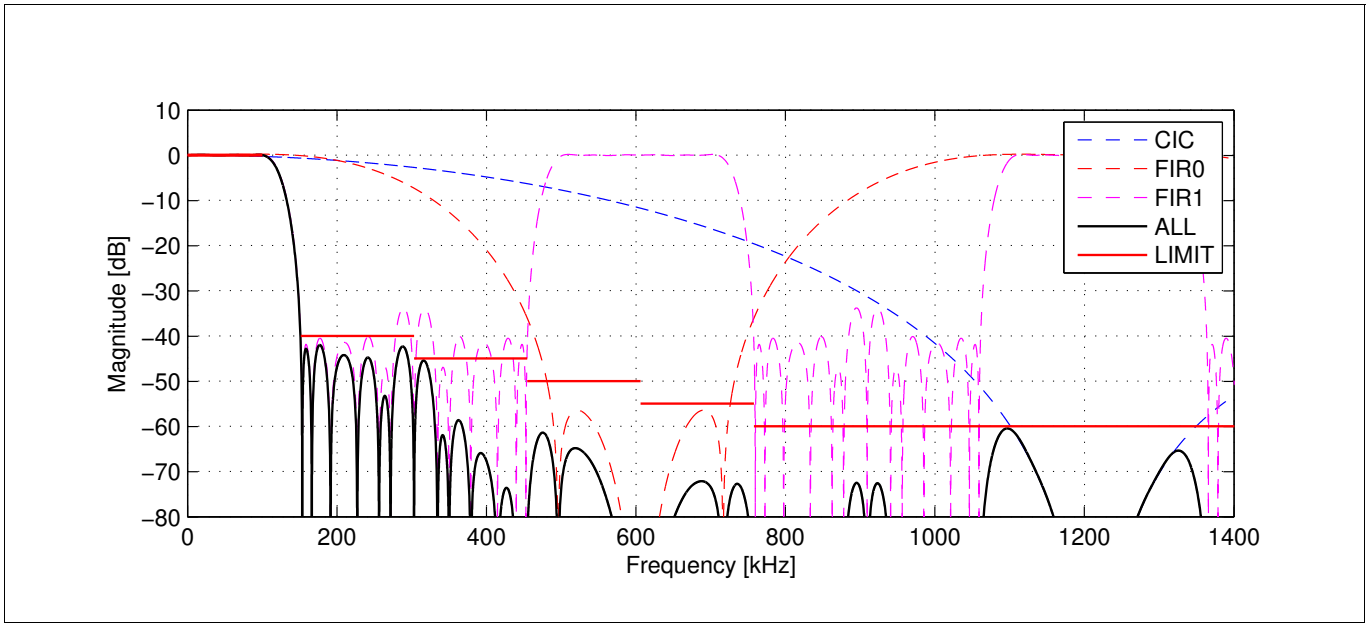

Figure 298 Frequency Response of the Complete Filter Chain (Example for 100 kHz Passband Setup)

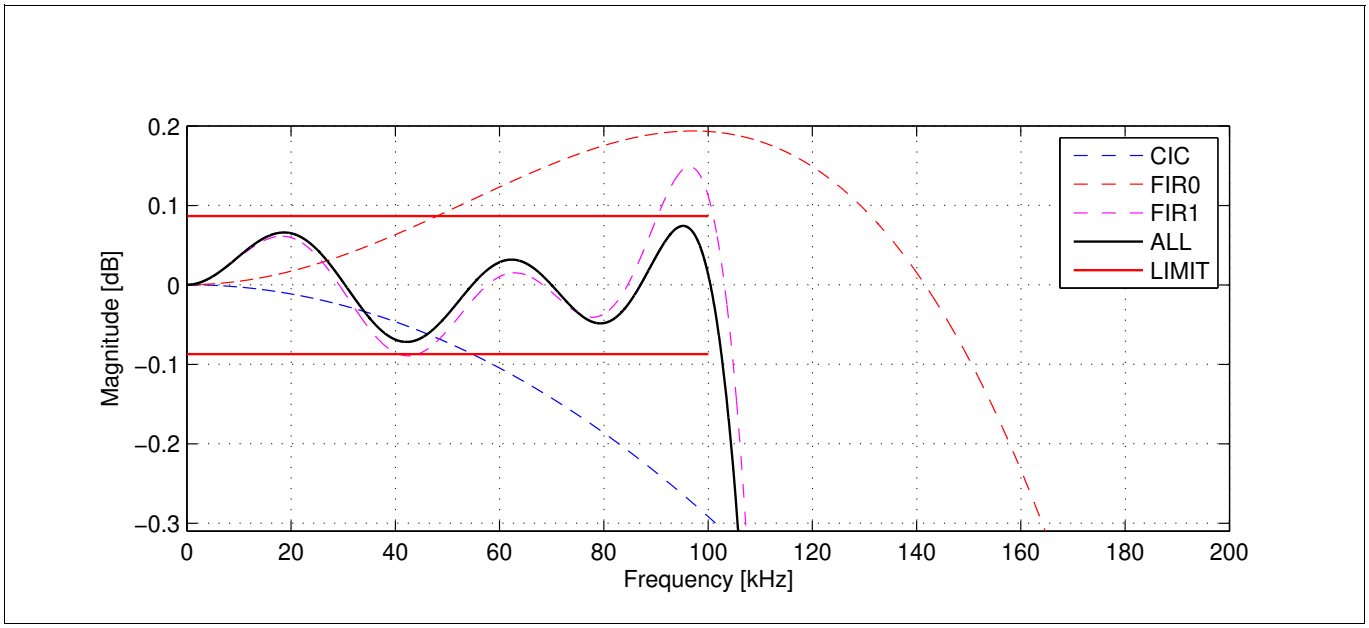

Figure 299 Passband Ripple (Example for 100 kHz Passband Setup)

33.5.1 CIC Filter

The Cascaded Integrator Comb filter (CIC filter, a.k.a. SINC filter) is a simple but very efficient low-pass filter. Three comb filter stages are cascaded to improve the frequency characteristics (CIC3). The decimation rate is programmable within a wide range from 4 to 512.

A prefilter reduces the data rate for modulator frequencies above 20 MHz. The prefilter is a CIC3 filter with a fixed decimation rate of 2.

To synchronize filters of different channels with fine granularity, the decimation counter starts from an arbitrary start value. This start value can be different from the decimation factor and is loaded only once when the counter is started.

The decimation counter is also restarted (i.e. loaded with the start value) when the selected integration trigger event occurs (see **Section 33.5.6**).

Table 283 CIC Filter Properties (N = Decimation Rate)

Stages	Data Width	Maximum Delay	Peak Output Value
CIC3	25 bits signed	3N	[-N^3, +N^3]

The CIC3 filter consists of 3 cascaded CIC filter stages.

Frequency domain, frequency response function:

$$H(z) = \left(\frac{1 - z^{-N}}{1 - z^{-1}} \right)^{k}$$

$$\left| H(j\omega) \right| = \left(\frac{\sin(\omega N / 2)}{\sin(\omega / 2)} \right)^{3}$$

Time domain:

The figure below illustrates the response of the CIC3 filter:

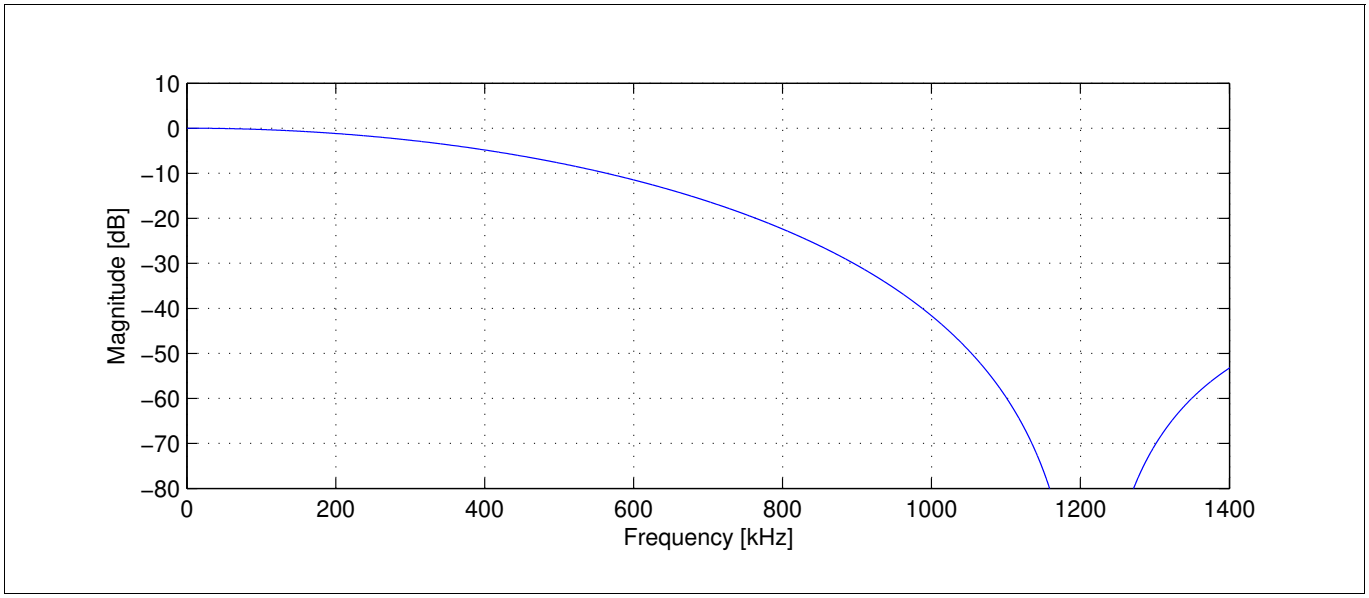

Figure 300 CIC3 Filter Frequency Response (Example for 1.212 MHz Output Data Rate)

Data Shifter and Decimation Factor

At the CIC filter output the valid data bits are selected for the subsequent blocks. The selected portion of the filter output is determined by the selected decimation factor and the employed modulator. These parameters define the maximum possible data value and, hence, the proper position for the extracted output value. During operation, the data shifter is controlled by bitfield GAINCORRx.CICSHIFT, during calibration by bitfield GAINCTRx.CICSHIFT.

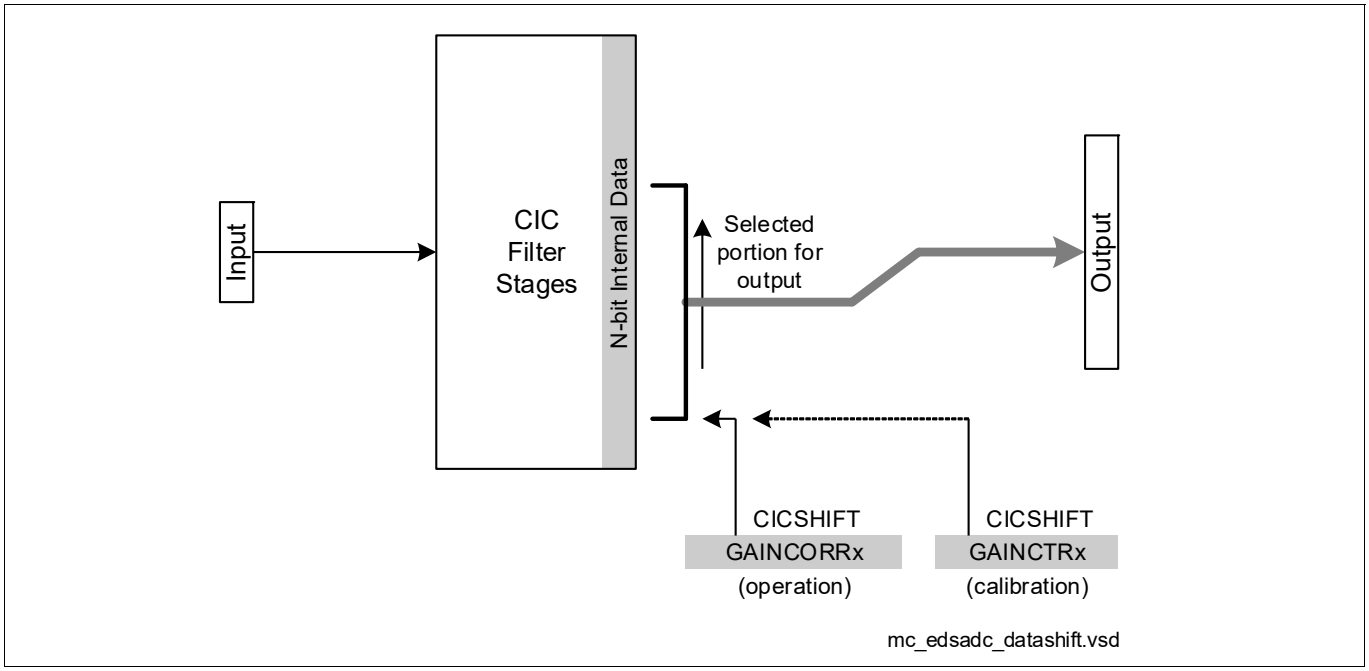

Figure 301 Data Shift Unit

The value for bitfield CICSHIFT is determined with this formula:

<CICSHIFT> = roundup(14 - ld(2 × AFS / (N^3 × 4 × FM)))

The following parameters are used:

- N = selected decimation factor
- AFS = calibrated full-scale value (25 000 after reset), refers to the analog full-scale ($V_{IN} = V_{AREF}$)
- FM = modulator gain factor
  - on-chip modulator: FM = 0.6945
  - external modulator: FM depends on used type

The gap that comes from the rounding in above formula can be closed by computing a corresponding gain correction factor:

<GAINFACTOR> = truncate(((2 × AFS / (N^3 × 4 × FM)) × 2^(<CICSHIFT>-14)) × 4096)

Example:

For N = 50, on-chip modulator:

N^3 × 4 × 0.6945 = 347 250

<CICSHIFT> = roundup(14 - ld(2 × 25 000 / 347 250)) = roundup(14 - (-2.796)) = 17 (11_H)

The correction factor will be:

<GAINFACTOR> = (2 × 25 000 / 347 250) × 2^3 = 1.1519

The bitfield value will then be truncate(1.1519 × 4 096) = truncate(4 718.1824) = 4 718 = $126E_H$.

33.5.2 Gain Correction

Gain calibration is done by multiplying the raw results with a correction value and a calibration value.

The application correction value is determined by the application based on the selected decimation factor etc., and is used to compensate the reduced digital gain that results from decimation factors in the CIC filter that are not 2^N (see **"Data Shifter and Decimation Factor" on Page 45**).

The calibration value is determined during the calibration sequence by the calibration algorithm. The automatic calibration algorithm normalizes the overall gain factor of the filter chain to 1.000, independent of their configuration. The full-scale value of the result is adapted to <CALTARGET> (25 000 after reset), representing the reference voltage.

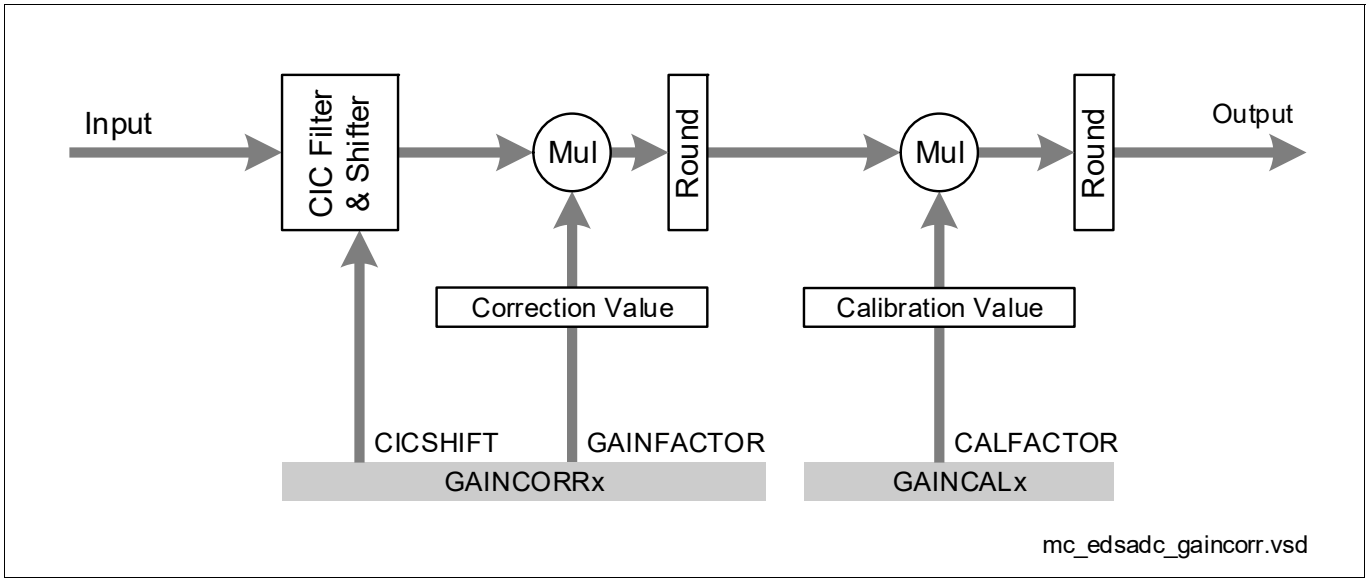

Figure 302 Gain Correction

Note: The calibration algorithm ensures that the configured target value (CALTARGET) is reached at the output of the gain correction unit within the specified precision when $V_{IN} = V_{AREF}$.

The correction value in register GAINCORR is calculated from application parameters either during compile time for static configurations, or during run time for dynamic configurations.

The calibration value in register GAINCAL is generated automatically by the calibration algorithm. This value is generated during the initial startup calibration and is adapted by subsequent calibration cycles that are triggered either by software or automatically.

Both factors can be in the range of 0.000 to 1.999, with an initial value of 1.000.

While the calibration sequence is executing, the configuration selected for operation is replaced with the configuration selected for calibration (in register **GAINCTRx (x=0-13)**). Configure both settings before starting a channel.

*Note: An overview of the calibration mechanism is given in **"Calibration Support" on Page 36**. The formula to determine the GAINFACTOR is given in section **"Data Shifter and Decimation Factor" on Page 45**.*

33.5.3 Overshoot Compensation

Due to their properties, the FIR filters tend to produce overshoots when the input signal changes rapidly. The overshoot compensation block monitors the data flow, detects a step in the input signal (rapid change), and recontours the signal so the FIR filters do not produce the unwanted overshoot.

Several aspects of the overshoot compensation are configurable via register **OVSCFGx (x=0-13)**:

- **Step Detection Threshold**
  Defines the numeric difference between samples that activates the overshoot compensation (SDTH). The threshold is compared to the magnitude of the difference, i.e. it is valid for both directions signal change.
- **Step Detection Mode**
  Defines if the current sample is compared to the last sample or to the second-last sample (SDM).
- **Slew Rate Filter Run Time**
  Defines the duration of the overshoot compensation (SRFRT).
- **Slew Rate Filter Strength**
  Defines the signal recontouring effect (SRFS).

The figure below shows how overshoot compensation modifies the output signal generated by the FIR filters.

33.5.4 FIR Filters

The FIR filter further attenuates the higher frequency bands that pass the CIC filter. This improves the overall frequency response of the filter chain.

The FIR filter is realized as two subsequent FIR blocks. FIR0 adds a decimation factor of 2, FIR1 adds a decimation factor of 1 or 2, so the total decimation factor (i.e. the oversampling rate, including the CIC filter) is 2×N or 4×N.

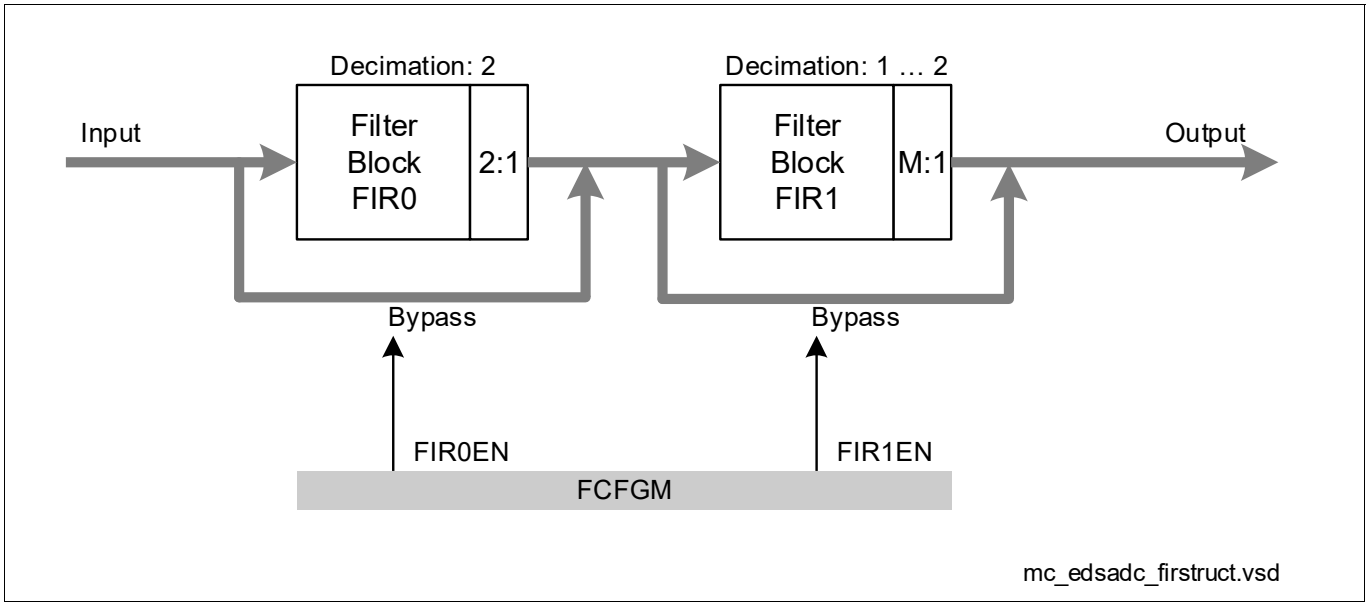

Figure 304 FIR Filter Blocks

The FIR filters can be described as:

$$y_1(m_1) = \sum_{i=0}^{N_1-1} a_1(i)\,x(2m_1 - i)$$

$$y(m) = \sum_{i=0}^{N_2-1} a_2(i)\,y_1(2m - i)$$

The coefficients of both FIR filters are fixed (see **Table 284** and **Table 285**). The filters are symmetric and have linear phase.

FIR0 has N1 = 8 coefficients, and generates the following response:

Table 284 Coefficients of FIR0

a0	a1	a2	a3	a4	a5	a6	a7
-29	-43	143	441	441	143	-43	-29

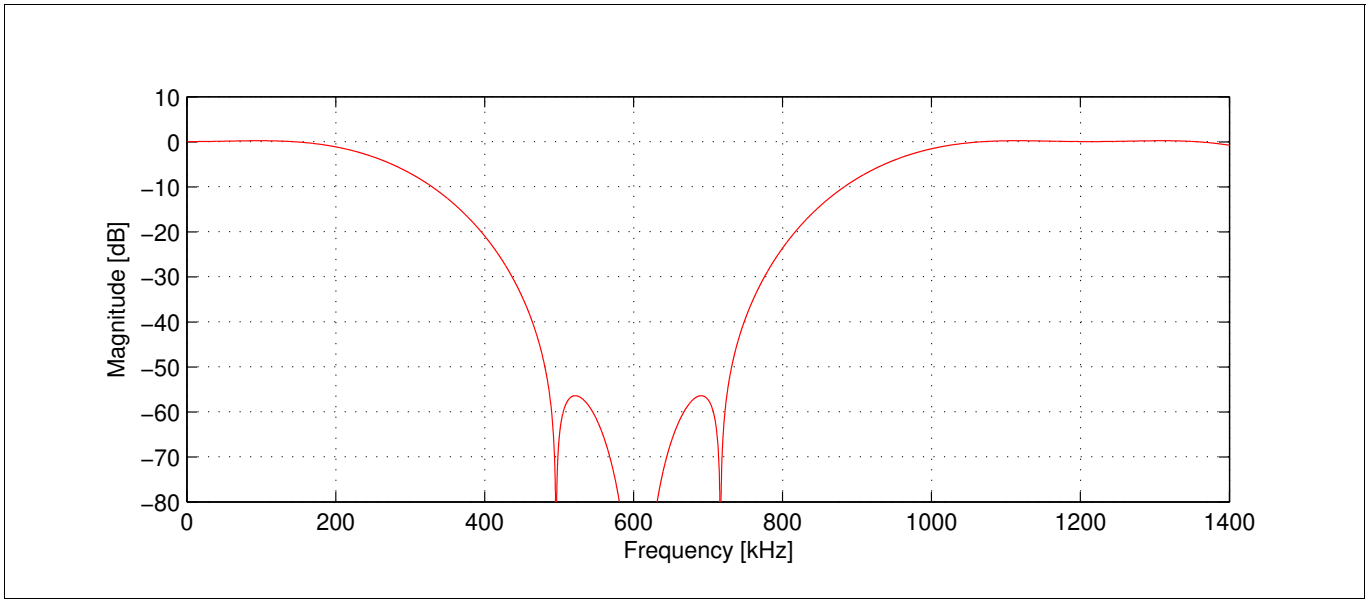

Figure 305 FIR0 Filter Frequency Response (Example for 606.06 kHz Output Data Rate)

FIR1 N2 = 28 coefficients and provides the following response:

Table 285 Coefficients of FIR1

33.5.5 Offset Compensation

The offset component that is present in most input signals can be removed automatically in order to receive the original sensor signal. The offset compensation stage can operate in two basic modes:

- **Highpass Filter**
  in this mode, the offset compensation can automatically remove the static component of a cyclic differential signal. This is achieved by the implemented IIR filter.
- **Offset Correction**
  in this mode, the offset compensation can remove the offset component of a static signal by subtracting a predefined value from the raw results. The IIR filter is disabled in this mode.

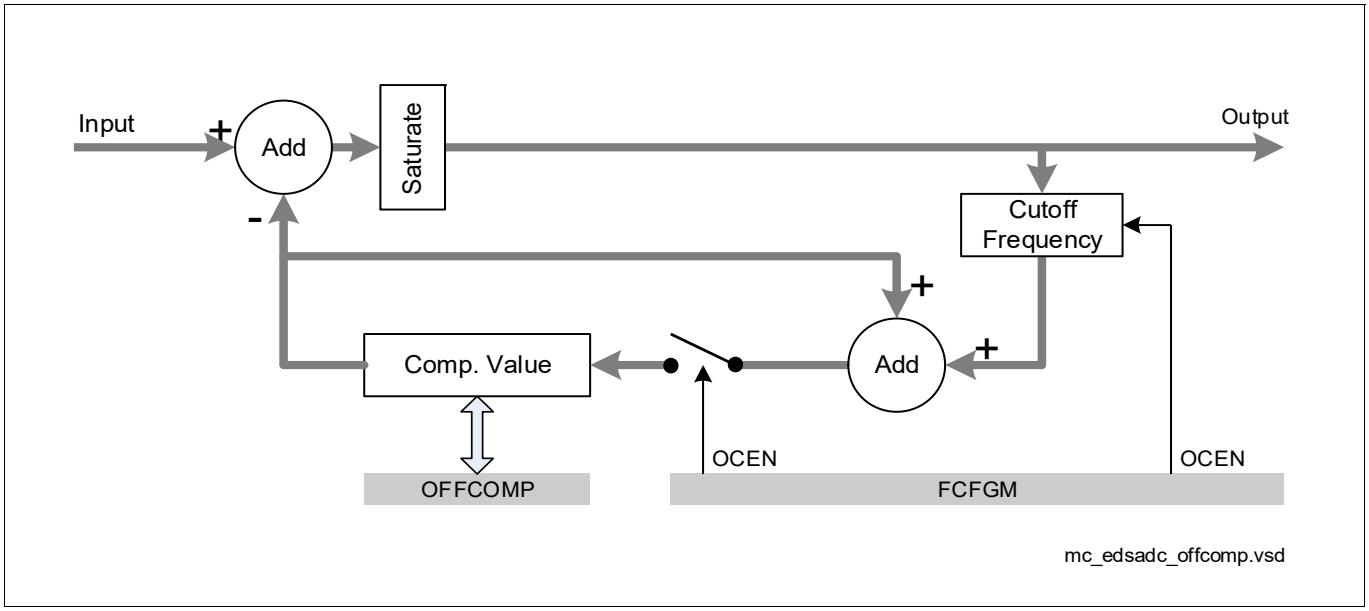

Figure 307 Offset Compensation

- **When the highpass filter is active**, the compensation value in register **OFFCOMPx (x=0-13)** is automatically updated by the filter. This attenuates the signal by a factor of at least DCF = -3 dB for frequencies below the selected cutoff frequency ($\geq 10^{-5} \times f_d$).
  The settling time of the highpass filter can be reduced by writing an initial compensation value instead of using the default value of zero. The general settling time is also adjustable by changing the filter properties, see bitfield **FCFGMx (x=0-13)**.OCEN and **Figure 308**.
- **When the highpass filter is off**, half of the current value in register **OFFCOMPx (x=0-13)** is subtracted from each raw value. The correction value can be determined and updated by the calibration sequence. Alternatively, it can be defined by the application or the calibrated value can be adjusted.
  Updating the offset value by the calibration sequence can be prohibited by setting bit OFFPROT in register **FCFGMx (x=0-13)**. This preserves the value written by the user.

*Note: An overview of the calibration mechanism is given in **"Calibration Support" on Page 36**.*

Since the filter chain internally uses more than 16 bits, the value in bitfield OFFSET is used shifted by one. This adds an additional bit to the LSB, which reduces the quantization error when several result values are accumulated. This, for example, is done when using the integrator.

A correction value of 233, therefore, is stored as $01D2_H$, $01D3_H$ would equal 233.5.

The high-pass filter can be described as (α = OCEN for OCEN > 000_B):

$$H(z) = \frac{1 - z^{-1}}{1 + (2^{2\alpha-16} - 1)z^{-1}}$$

The high-pass filter provides the following frequency responses:

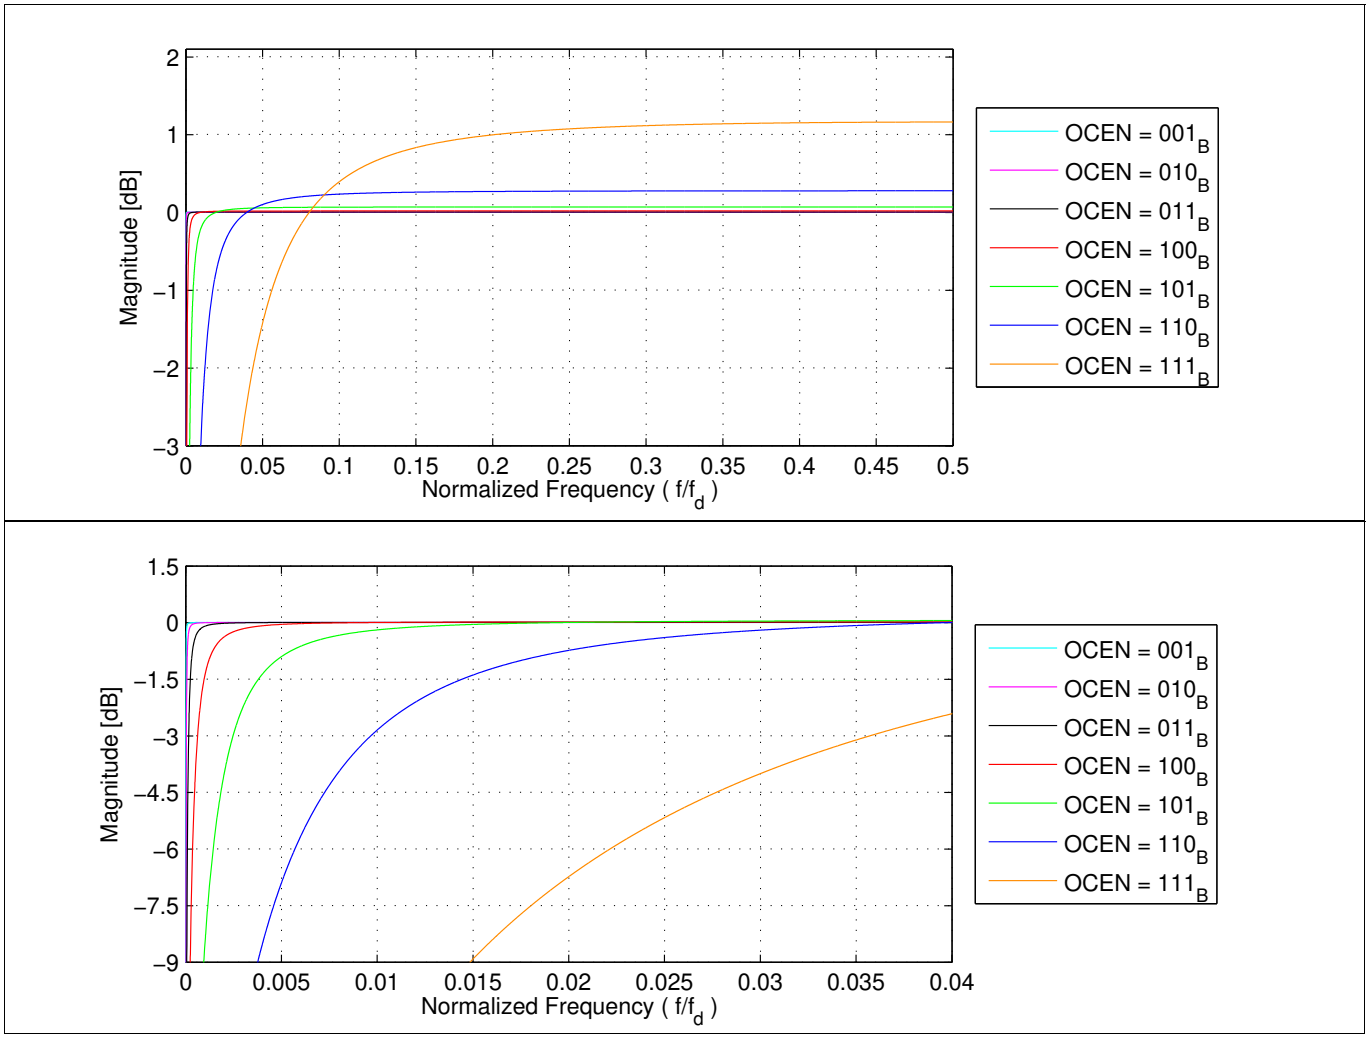

Figure 308 High-Pass Filter Frequency Responses

As shown in the figure above, bitfield **FCFGMx (x=0-13)**.OCEN selects different filter parameters:

Table 286 Offset Compensation Filter Parameters

OCEN	Cutoff Frequency (-3 dB)	Note
000_B	---	Offset compensation filter off
001_B	$1 \times 10^{-5} \times f_d$	Lowest cutoff frequency
010_B	$4 \times 10^{-5} \times f_d$	
011_B	$16 \times 10^{-5} \times f_d$	
100_B	$62 \times 10^{-5} \times f_d$	
101_B	$25 \times 10^{-4} \times f_d$	
110_B	$1 \times 10^{-2} \times f_d$	
111_B	$4 \times 10^{-2} \times f_d$	Highest cutoff frequency

33.5.6 Integrator Stage

The integrator integrates the result values generated during the defined integration window by adding a configurable number of values to build the final result value. The integration window can be started triggered by an internal or external signal.

A configurable number of values can automatically be discarded after the trigger before the integration window is started. This positions the integration window exactly into a timeframe where the filter is stable or where the signal to be measured is free of system-generated noise.

Integration can be used to measure currents through shunt resistors at defined positions in the signal waveform. It also can remove the carrier signal component in resolver applications. In this case, the values to be integrated can be rectified to yield the maximum amplitude of the receiver signal. The delay between the carrier signal (generated by the on-chip carrier generator) and the received position signals can be compensated automatically. also refer to **Section 33.12**.

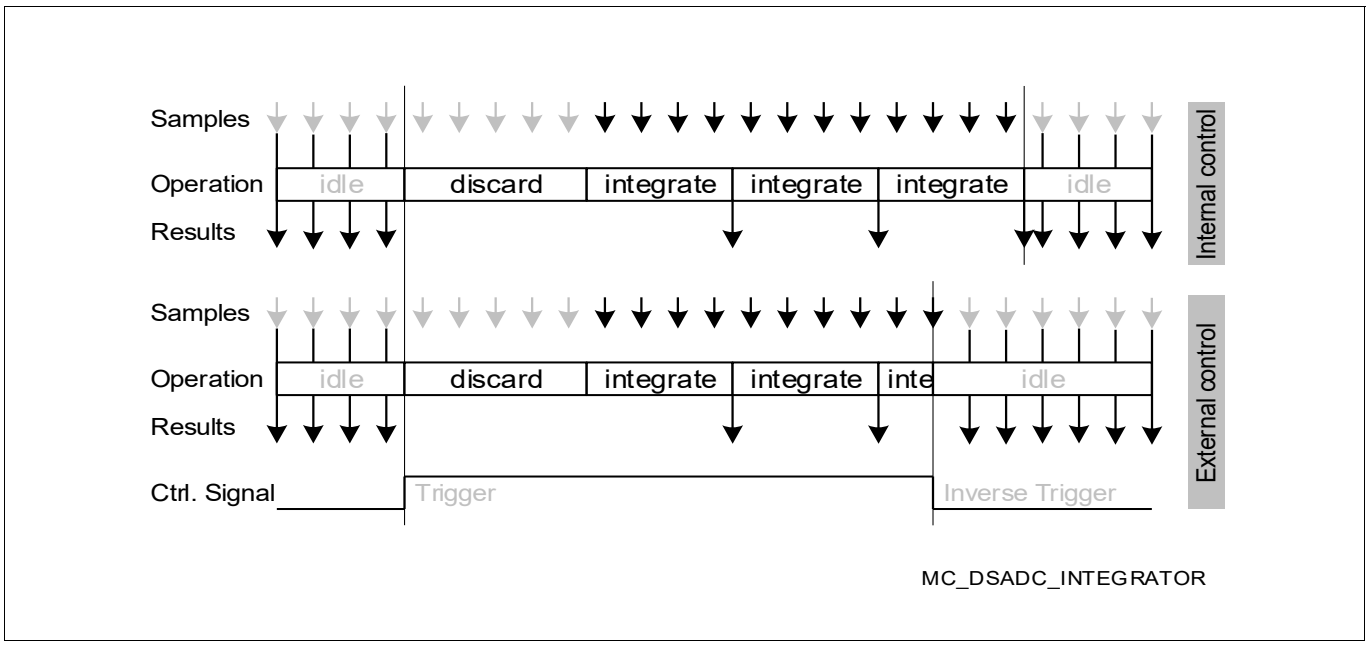

Figure 309 Integrator Operation

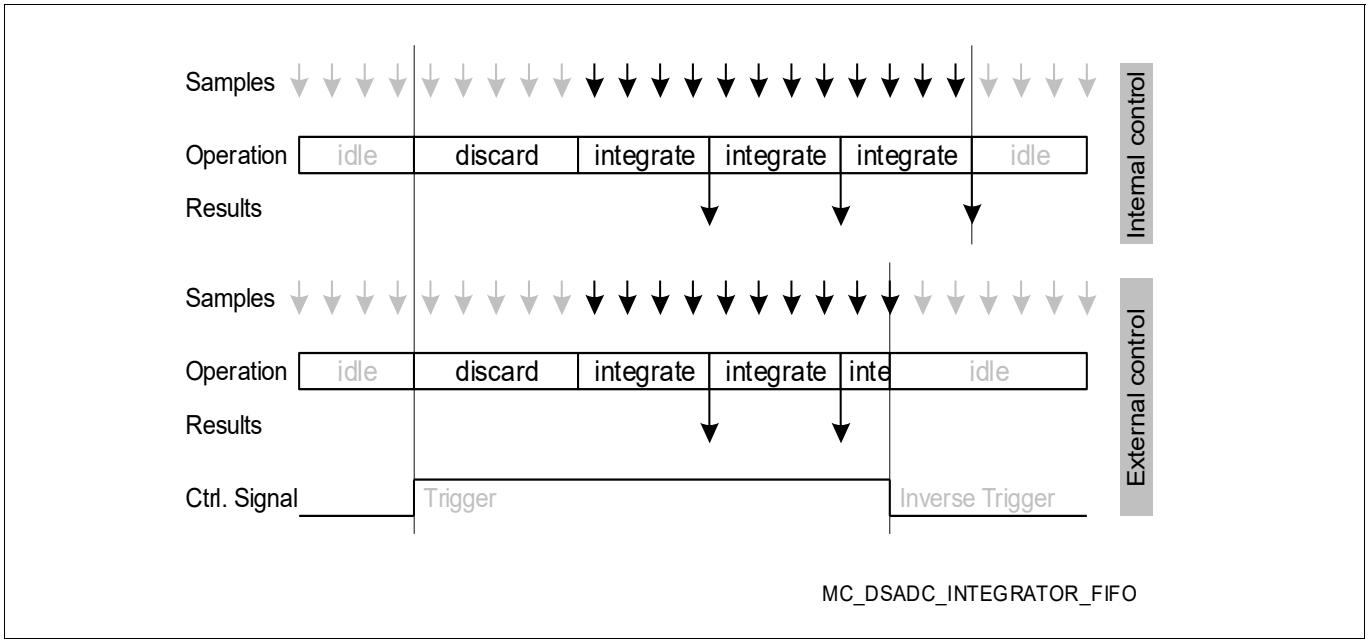

Figure 310 Integrator Operation with FIFO

Starting the Integration Window

The integration window starts when bit INTEN becomes 1:

- Software-Controlled Mode:
  Select software-controlled integration mode by setting bitfield ITRMODE = 11_B
- Trigger-Controlled Mode:
  Select trigger-controlled integration mode (ITRMODE = 01_B or 10_B)
  and generate the selected trigger edge at the configured trigger input

The external integration trigger signal is selected by bitfield TRSEL in register **DICFGx (x=0-13)**. Bitfield ITRMODE selects the transition of the selected signal to generate the trigger event. Select the trigger source first before enabling it.

When the integration window is started (INTEN becomes 1) the filter chain can be restarted (FRC = 0). This means, every non recursive filter element of the Filter Chain (CIC3, FIR0, FIR1, Integrator Stage) is cleared to zero and the related decimation counters are loaded with their start value (see **Section 33.5.1**). This ensures a deterministic start of an integration sequence. Simultaneously, the CIC filter of the Auxiliary Filter is cleared to zero and the related decimation counter is set to its initial value (see **Section 33.6**). This allows a synchronous operation of Filter Chain and Auxiliary Filter.
Keeping the filter chain running (FRC = 1) avoids the group delay until the first valid result values. In this case, the delay between start of integration window and the first result value depends on the current status of the filter chain.

After this the integration counter starts counting. After <NVALDIS> values the counter is reset and the integrator is started (if NVALDIS is zero the integration starts immediately).

Executing Integration Cycles

During an integration cycle <NVALINT+1> input values are integrated. After that, the integration result is stored in the result register and the integrator and the counter are cleared. If bit INTEN = 1 the next integration cycle is started.

Stopping the Integration Window

The integration window stops when bit INTEN becomes 0:

- Software-Controlled Mode:
  Disable software-controlled integration mode by setting bitfield ITRMODE = 00_B
- Trigger-Controlled Mode:
  - Internally controlled end of integration (IWS = 0, see upper part of **Figure 309**):
    After <REPVAL+1> integration cycles INTEN is cleared and the integration window closes after (<NVALINT+1> × <REPVAL+1>) input values
  - Externally controlled end of integration (IWS = 1, see lower part of **Figure 309**):
    Generate the selected inverse trigger edge at the configured trigger input (ITRMODE = 01_B or 10_B)
  - Integration may also be stopped by software by setting bitfield ITRMODE = 00_B
  - The source for the result register (RESMx) changes from the integrator output to the upstreamed filter chain. This means, the last result of the trigger-controlled integration is available in the result register (RESMx) only for the timeframe that is defined by the data rate period of the upstreamed filter chain. Using the result FIFO (DICFGx.DSM=0B and DICFGx.TSM=0_B), the integration result is kept in the result register up to the time where another trigger-controlled integration is initiated. For this purpose, the result FIFO has to use one of the following configuration:
    DICFGx.ITRMODE=10_B, FCFGMx.SRGM=10_B, RFCx.SRLVL=00_B
    DICFGx.ITRMODE=01_B, FCFGMx.SRGM=10_B, RFCx.SRLVL=00_B
    These configurations have the effect that service requests are only generated during integration window. In case of disabled integrator stage (ISTATx.INTEN=0_B), results generated by the upstreamed filter chain will not trigger service requests. However, results from the upstreamed filter chain will be stored in higher stages of the result FIFO. When the FIFO stages are fully loaded, all other results from the upstreamed filter chain are discarded.

After the integration has stopped, the current integration value can be read from register **IIVALx (x=0-13)**.

Integrator Data Output Format

Since the integrator accumulates a series of result values, the magnitude of its output increases depending on the size of the selected integration interval. A data shifter (controlled by bitfield ISC) compensates this for intervals of 2^N. If intervals other than 2^N are selected, the magnitude of the result value will be decreased accordingly.

Integration Window Control Register x

33.5.7 Group Delay and Settling Time

Data that enter a digital filter need a certain number of filter clocks before they appear at the filter's output and can be used by the system. When the digital filter chain is in steady state, the corresponding delay is defined by the group delay. The effective group delay depends on the configuration of the filter chain. **Table 287** summarizes the delays incurred by the elements of the filter chain. "N" indicates the selected oversampling rate (decimation factor) of the CIC filter. Delays are listed in modulator clock cycles.

Steady state condition is reached as soon the digital filter chain is settled. The effective settling time depends on the configuration of the filter chain. Due to the cascaded topology of the filter chain, the configuration specific settling time is defined by the step response of the terminating filter chain element. Generally, the filter chain characteristics like passband frequency (f_{PB}) and settling time are normalized to the data output rate (f_D). The data output rate (f_D) depends on the selected oversampling rate of the CIC filter and the enabled filter chain elements. **Table 288** summarizes the settling time for the different filter chain elements.

Table 287 Group Delay Summary

Filter Chain Element	Delay [t_{MOD}]	Notes
On-chip modulator	1	Delay of analog frontend
Input select/adjust unit	0.5	Synchronization of input signal
CIC3	$3 \times (2^{PRE} \times N - 1) / 2$	PRE = 0 or 1 if the prefilter is off (0) or on (1)
FIR0	$3.5 \times 2^{PRE} \times N$	To be added to CIC delay
FIR1	$13.5 \times 2^{PRE} \times N \times 2^{F0}$	F0 = 0 or 1 if FIR0 decimation is off (0) or on (1)
Offset correction/compensation	0	
Integrator	IWCTRx.NVALINT × $2^{PRE} \times N \times 2^{F0} \times 2^{F1} / 2$	Depends on the number of integrated values. F1 = 0 or 1 depending if FIR1 decimates (1) i.e. FIR1DEC = 0 or not (0) i.e. FIR1DEC = 1

Table 288 Settling Time Summary

Filter Chain Element	Settling Time [t_D]	Notes
CIC3	3 + 1	Settling time is defined by 3rd order of the CIC filter
FIR0	8 / 2 + 1	Settling time is defined by the 8 taps of FIR0 and the decimation of 2
FIR1	$28 / 2^{1\text{-FCFGMx.FIR1DEC}} + 1$	Settling time is defined by the 28 taps of FIR1 and the configurable decimation (FCFGMx.FIR1DEC)
Offset correction/compensation	$1 / (5 \times f_{-3dB})$	Cutoff frequency (f_{-3dB}) can be configured by bit-field FCFGMx.OCEN
Integrator	1 + 2	Mathematically, the integrator behave like a 1st order CIC filter

Example

f_{MOD} = 40 MHz, t_{MOD} = 25 ns,

prefilter active, OSR(CIC3) = 32, FIR0 active, FIR1 active and decimating, OC off, integration of 10 values.

$f_D = f_{MOD} / (2 \times 32 \times 2 \times 2 \times 10) = 15.625$ kHz

$t_D = 1 / f_D$

Group delay:
$[1 + 0.5 + (3 \times 63 / 2) + (3.5 \times 2 \times 32) + (13.5 \times 2 \times 32 \times 2) + (9 \times 2 \times 32 \times 2 \times 2 / 2)] \times t_{MOD} =$
$(1.5 + 94.5 + 224 + 1\,728 + 1\,152) \times t_{MOD} = 3\,200 \times 25$ ns = 80.0 µs
At the given oversampling rate of 2×32×2×2×10 = 2 560 this equals a delay of $1.25 \times t_D$ (data output rate cycles).
Without integration we get $(1.5 + 94.5 + 224 + 1\,728) \times t_{MOD} / 2{\times}32{\times}2{\times}2 = 2\,048 / 256 = 8 \times t_D$.
Settling time:
$[1 + 2] \times t_D$ = 192 µs
Without integration, data output rate (f_D) is defined by $f_D = f_{MOD} / (2 \times 32 \times 2 \times 2) = 156.25$ kHz, tD = 1/ f_D = 6.4 µs
Corresponding settling time is defined by
[28 / 2 + 1] × 6.4 µs = 96 µs

Note: When changing the input source (e.g. by switching the analog input multiplexer, if available), the second result value will safely belong to the newly selected input. Result values that correspond to the new input level, however, can only be retrieved after the corresponding group delay.

Note: With a configuration for the filter chain where only the CIC3 filter is used and the calibration is triggered (FCFGM.CALIB) immediately after modulator enabling (GLOBRC.MxRUN), the settling time of the filter chain reduces to a single cycle of t_D. The calibration algorithm uses the CIC3 filter and the settling occurs during execution of the calibration algorithm. When calibration is running, the filter chain provides no data.

33.5.8 Filter Configuration Options

The filter chain can be configured according to the requirements of the intended application. The following pages describe the available bitfields in the control registers.

Filter Configuration Register x, Main

FCFGMx (x=0-13)

Field	Bits	Type	Description
CFMDCNT	8:0	rh	**CIC Filter Decimation Counter** The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate. CFMDCNT counts down from the respective start value.
CAL	31:30	rh	**Calibration Status Flag** *Note: Bitfield CAL is set to 01_B in the next clock cycle after setting bit CALIB or after detecting the selected trigger (if auto-calibration is activated).* 00_B Uncalibrated, initial state after reset 01_B The calibration algorithm is currently running 10_B Calibrated, normal operation is possible 11_B Calibration terminated incorrectly
0	29:9	r	**Reserved, write 0, read as 0**

33.6 Auxiliary Filter

The parallel auxiliary filter uses a simple CIC filter for decimation. The decimation rate is restricted to 16 or 32. This reduces the filter delay, so the auxiliary filter can be used to supervise the input signal and detect abnormal input values, such as overcurrent, earlier than the main filter chain.

Note: Limit checking using the parallel auxiliary filter at a low decimation rate produces results with a reduced resolution, but generates an alarm earlier than the threshold values are seen at the output of the regular filter chain.

Depending on the application, alarms can be generated either from the main filter chain or from the auxiliary filter. This is selected via register **FCFGAx (x=0-13)**.
For the functionality of the comparator, refer to **"Limit Checking" on Page 79**.

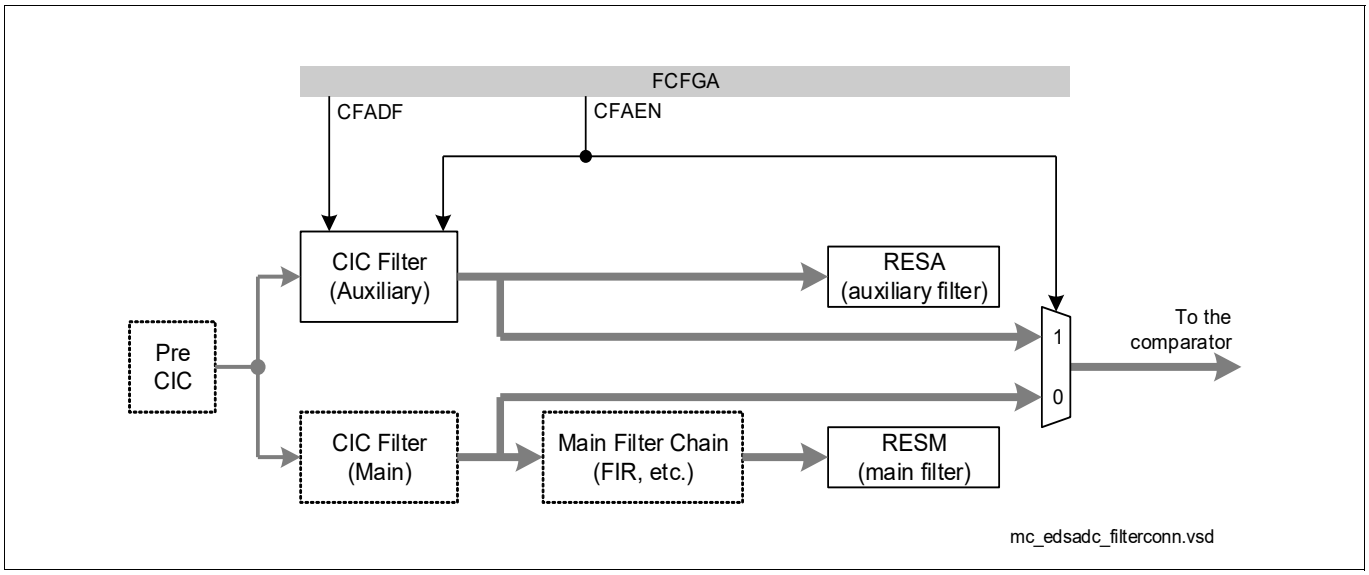

Figure 311 Connection of the Auxiliary Filter

33.7 Time-Stamp Support

Some applications need to determine the result value at certain points of time inbetween two regular output values. The interpolation algorithm needs to determine the position of the required point of time in relation to the regular results.

This interpolation is supported by providing a timestamp that marks the delay since the last regular output value. This timestamp is the number of modulator clock cycles that have passed since the last result value has been generated. Depending on the configured decimation/integration factors this defines the fraction of an output cycle and, therefore, enables the interpolation.

The timestamp information is generated by the timestamp counter. This 16-bit counter is clocked with the optionally prescaled modulator clock (see **TSCNTx (x=0-13)**.TSCLK). It covers the following cycles:

- CIC filter decimation: up to 512
- FIR filter decimation: up to 4
- Integrator decimation: up to 64

The timestamp information is captured into the timestamp register upon a trigger event. For this purpose, the trigger signal is used, which is selected by bitfield TRSEL in register **DICFGx (x=0-13)**. Bitfield TSTRMODE selects the edge(s) that capture(s) timestamp information.

A timestamp trigger can generate a service request if selected by bitfield SRGA in register **FCFGMx (x=0-13)**.

The valid flag TSVAL is set when timestamp information is stored and is cleared when register TSTMP is read. This indicates to the application software if or not a timestamp trigger has occurred before the corresponding result value was generated.

When timestamp information is stored, a service request can optionally be generated. This allows application software to operate on all result data, even if multiple timestamp triggers occur before a regular result service request. The timestamp data is also available via the standard result register (see **Table 290** and **"Result Service Request Generation and Read Sequencing" on Page 76**).

TSCLK	17:16	rw	**Timestamp Counter Clock Selection** 00_B $f_{TSTMP} = f_{MOD}$ 01_B $f_{TSTMP} = f_{MOD} / 2$ 10_B $f_{TSTMP} = f_{MOD} / 4$ 11_B $f_{TSTMP} = f_{MOD} / 8$
TSCRUN	19	rw	**Timestamp Counter Run Control** 0_B Timestamp counter is off 1_B Timestamp counter is counting at the rate selected by bitfield TSCLK
AMXCOPY	20	rw	**Analog MUX Setting Copy Enable** Allows copying of bitfield AMX into bitfield TIMESTAMP (in register **TSTMPx**). 0_B Do not copy, timestamp uses all 16 bits 1_B Copy AMX to bits TIMESTAMP[15:14], timestamp uses lower 14 bits
0	18, 31:21	r	**Reserved, write 0, read as 0**

33.8 Conversion Result Handling

The EDSADC preprocesses the conversions result data before storing them for retrieval by the CPU or a DMA channel.

Conversion result handling comprises the following functions:

- **Filtering and Post-Processing**
- **Storage of Conversion Results** to FIFO and result register
- **Result Service Request Generation and Read Sequencing**
- **Hardware Data Interface** provides result values to other modules

33.8.1 Filtering and Post-Processing

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio. The selectable integrator can further reduce the output data rate while executing accumulation and averaging.

Several elements of the filter chain can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application.

The result values are multiplied by a factor that serves for gain calibration and data format normation. An offset can be subtracted automatically from each result value before being fed to the integrator or being written to the result register.

For differential mode applications, the offset can alternatively be removed automatically by the high-pass filter.

Due to the differential input stage, the results are signed values. Usually, these results are stored in a 16-bit two's-complement format. For the specific quasi-differential operating modes (single-ended input using common mode voltage) the results can be stored as 16-bit unsigned integer values (see **DICFGx (x=0-13)**).

The CIC filter's output value depends on the selected filter parameters and decimation factor. A data shifter extracts the most significant bits from this filter result. A multiplier adjusts the magnitude of the result values to the result range required by the application.

33.8.2 Storage of Conversion Results

The conversion result values are stored in a FIFO-structure which is accessible via the result register RESMx.

This enables the following features:

- Buffering increases the allowable latency for retrieving result values
- Two result values can be retrieved by one single read access
- Two subsequent read accesses enable the efficient transfer of up to 4 result values[1)]
- The previous result value is still available to calculate interpolation values for timestamp operation

Also timestamp information can be accessed through the result register (either directly or via the FIFO). This enables access to all relevant data using a single DMA channel.

To optimize access to result values, the result register can be read in several modes:

Table 290 Result Register Read Modes

Read Mode[1)]	RESMx[31:16] (high)	RESMx[15:0] (low)	Notes
Single-word read mode, sign-extended ($DRM = 00_B$) (SSSS'RRRR)	Extended sign value (only valid for result values)	Next result value (from FIFO stage 1)	TSM = 0, 16-bit read access[2)] ($SRLVL = 00_B, 01_B, 10_B, 11_B$)
		Timestamp[3)], then initial result value, then next result value (from FIFO stage 1)	TSM = 1, gate-controlled timestamp mode, 16-bit read access[2)] ($SRLVL = 10_B, 11_B$)
Single-word read mode ($DRM = 01_B$) (0000'RRRR, TTTT'RRRR)	0000_H	Recent result value (FIFO not used, overwrite RESULTLO)	TSM = 0, 16-bit read access
	Timestamp	Recent result value (FIFO not used, overwrite RESULTLO)	TSM = 1, 32-bit read access
Double-word read mode ($DRM = 10_B$) (NNNN'RRRR)	Subsequent res. value (from FIFO stage 2)	Next result value (from FIFO stage 1)	TSM = 0 32-bit read access[4)], (low bus load) ($SRLVL = 01_B, 11_B$)
	Initial result value, then subsequent value (from FIFO stage 2)	Timestamp[3)], then next result value (from FIFO stage 1)	TSM = 1, gate-controlled timestamp mode, 32-bit read access[4)] ($SRLVL = 11_B$)

1) Selected by bitfields DRM and TSM in register **DICFGx (x=0-13)**.
2) Due to the sign extension, result values can also be read as signed 32-bit values.
3) The timestamp is inserted once when the selected gate opens. The FIFO is flushed when the selected gate closes.
4) In double-word read mode, a service request shall only be generated when the result double buffer holds 2 values.

FIFO Control

Result values are only written to the FIFO ($DRM = X0_B$) while service requests are enabled. This enables the application e.g. to read stored values after the service request gate has closed.The FIFO is flushed when the service request gate opens, so it provides an actual set of result values.

In gate-controlled timestamp mode, the FIFO is flushed when the gate closes, so it can store the current result value in stage 2.

1) Also refer to **"Result Service Request Generation and Read Sequencing" on Page 76**.

Result Handling Without FIFO

In a special single-word read mode (DRM = 01_B) the result values are stored in RESMx directly.

The low word returns the latest result value, the high word either is cleared or returns the current timestamp counter value.

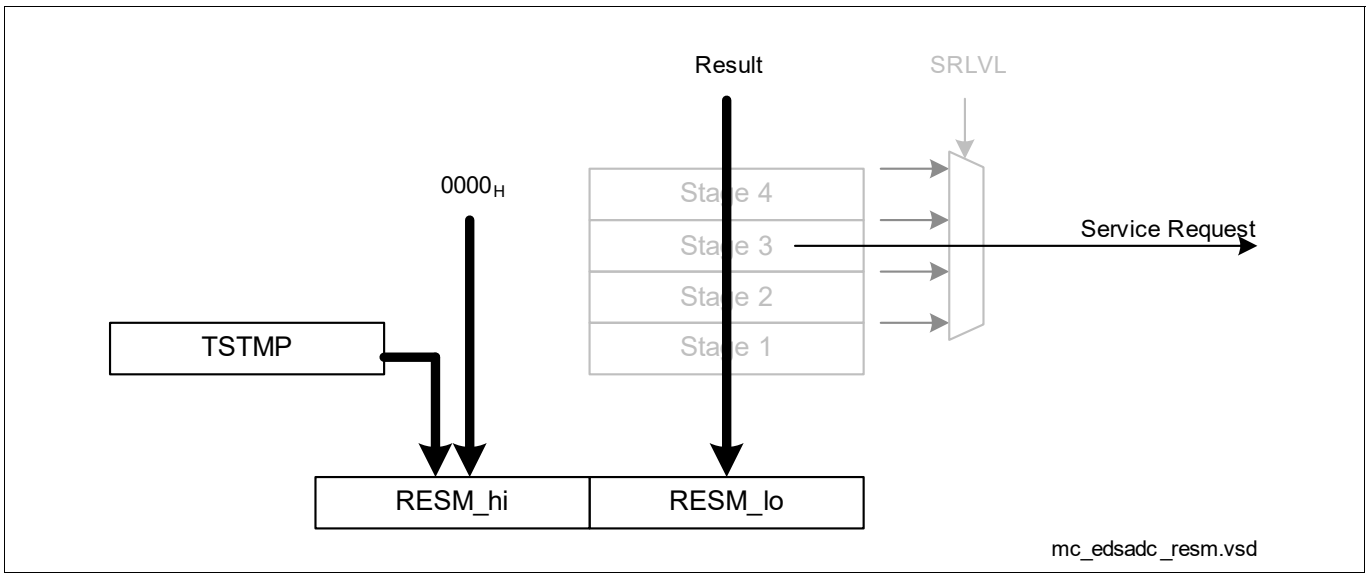

Figure 312 Direct Result Storage

Result Handling Via FIFO

The result values are not directly written to RESMx but are stored in a FIFO structure. From there they are retrieved when RESMx is read. In timestamp mode, the FIFO is transparent while the gate signal is inactive, i.e. all input values are directly forwarded to stage 2 of the FIFO. When the gate opens (this is the trigger event) a timestamp is generated and inserted to stage 1 of the FIFO. Subsequent input values are then piled into the FIFO.

A service request is generated when a certain number of values has been stored in the FIFO. The respective FIFO fill level is selected in bitfield SRLVL.

FIFO control and status bitfields are available in register **RFCx (x=0-13)**.

33.8.3 Result Service Request Generation and Read Sequencing

The generated result values (including timestamp values, if enabled) are retrieved in a defined sequence. This sequence depends on the selected result register read mode, the availability of result/timestamp values, and the system's response to service requests.

Result events are generated for each available result value. Result service requests are generated depending on the configured read mode and the FIFO fill level. Each data transfer (result data values or timestamp information) is initiated by a service request. This service request is issued when a defined number of values becomes available.

Figure 314 shows different situations for standard data transfers:

- Single Read:
  The service request is generated when one result value is available
  and is serviced by 16-bit read access (D0, D1)
- Double Read:
  The service request is generated when two result values are available
  and is serviced by 32-bit read access (D3/D2, D5/D4)
- Single Transfer Mode:
  The service request is answered with a single transfer.
  This transfer either transfers 16 or 32 bits.
- Double Transfer Mode:
  The service request is answered with two subsequent transfers[1].
  These transfers either transfer 16 or 32 bits.

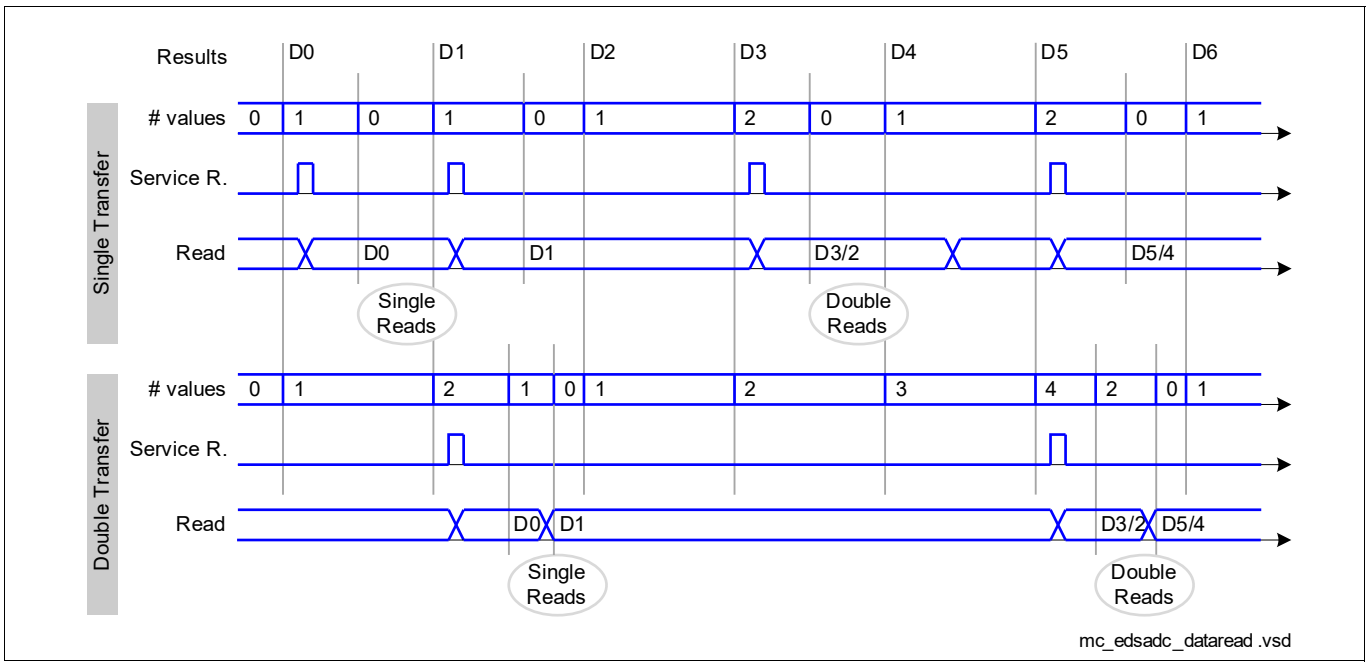

Figure 314 Standard Read Sequences

1) Synchronizing the result values between the two clock domains and controlling the result FIFO takes up to 8 cycles of f_{SPB}. Read accesses, therefore, must have at least 8 cycles of f_{SPB} in between them.

Timestamp mode supports applications using service request gating. A timestamp is generated when the gate opens (defined timestamp trigger). When the configured number of values (including the timestamp) is available, a service request is generated.

Figure 315 shows different situations for timestamp usage:

- Single Read:
  A timestamp trigger is generated when the service request gate opens. Read accesses return the timestamp value, the result before the timestamp (D0), and then subsequent result values. Note that D1 may be generated shortly after the timestamp event.
- Double Read:
  A timestamp trigger is generated when the service request gate opens. Read accesses return the result before the timestamp (D0) and the timestamp value, and then subsequent result value pairs. Accumulating 4 values and transferring them with two subsequent transfers provides the most efficient way to store data.

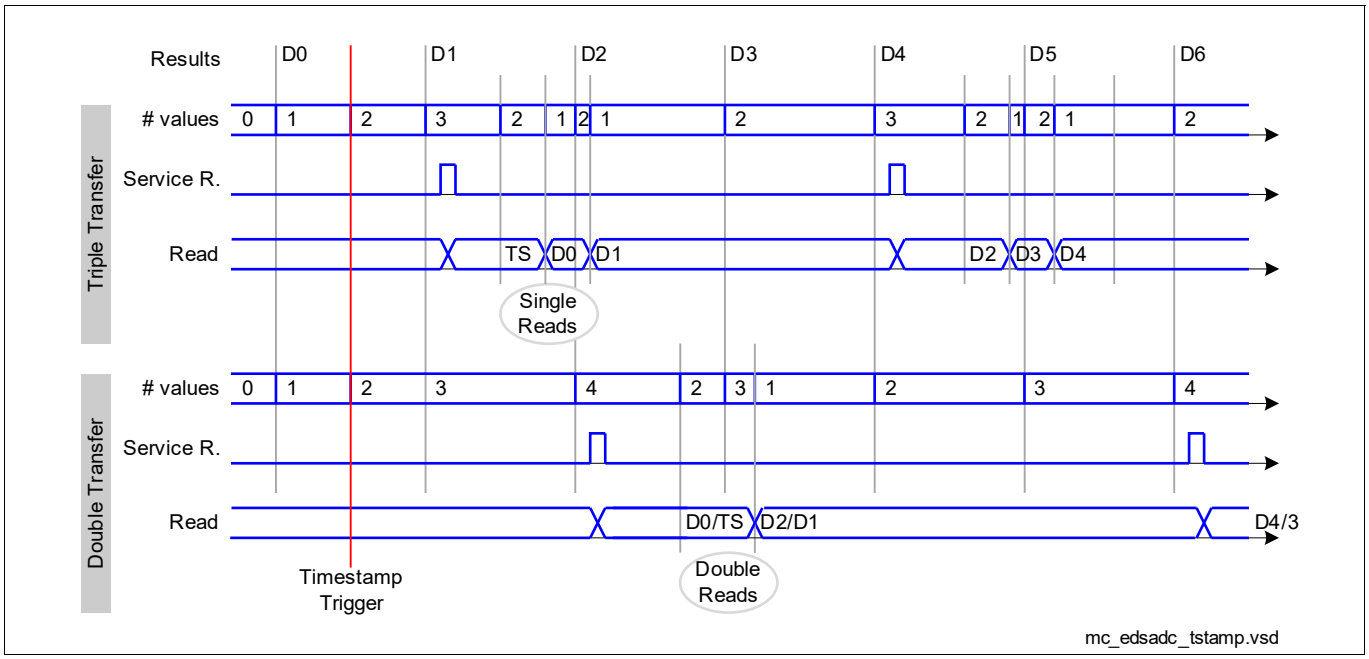

Figure 315 Read Sequences With Timestamp

Note: When setting up the service request level and e.g. DMA functionality, note that timestamp value and subsequent data value (D1) may be generated within a short timeframe, i.e. there are then 3 values in the FIFO.

33.8.4 Hardware Data Interface

The digital conversion results are directly available to other modules via the hardware data interface (HDI). Each value that is written to the result FIFO structure is also output to this interface. Each time a result event is generated, the HDI updates the data vector and generates a write strobe indicating the availability of a new result value.

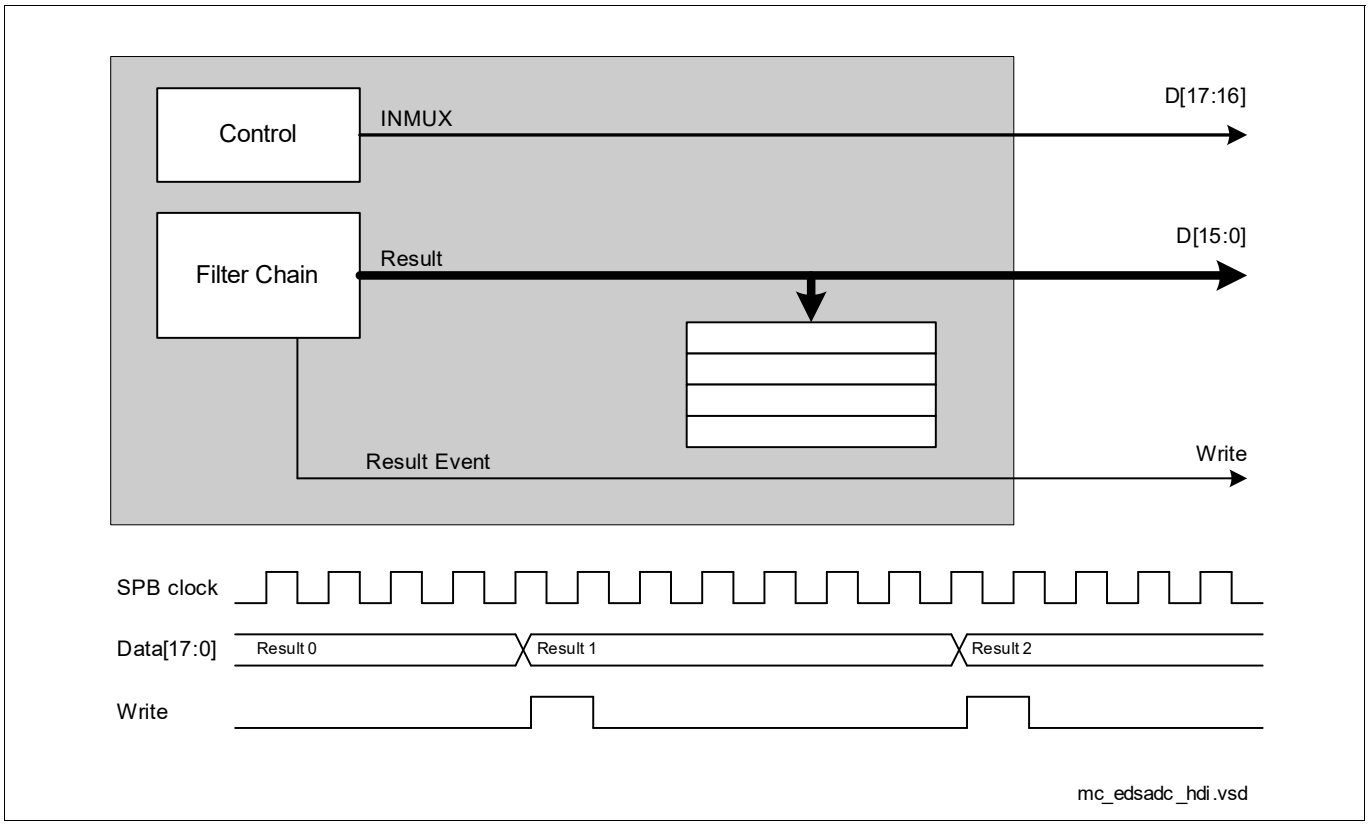

Figure 316 Hardware Data Interface

This interface writes results to the GTM to make them available for the MCSs equipped with an analog data interface (ADI).

The following data elements are available through the HDI:

Table 291 HDI Data Assignment

Bit Position	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data Content							MUX		Conversion Result															

Note: The availability of the MUX indicator bits depends on the respective channel. Unused bits are 0.

33.9 Limit Checking

A comparator provides automatic limit checking by comparing each result to two configurable reference values. This feature can be used to supervise the input signal and detect abnormal input values. The comparator can generate a separate service request.

The two reference values are defined in the select register **BOUNDSELx (x=0-13)** and determine the valid result value band.

The result values can be taken either from the main filter chain or from the auxiliary filter. Please refer to **"Auxiliary Filter" on Page 67**.

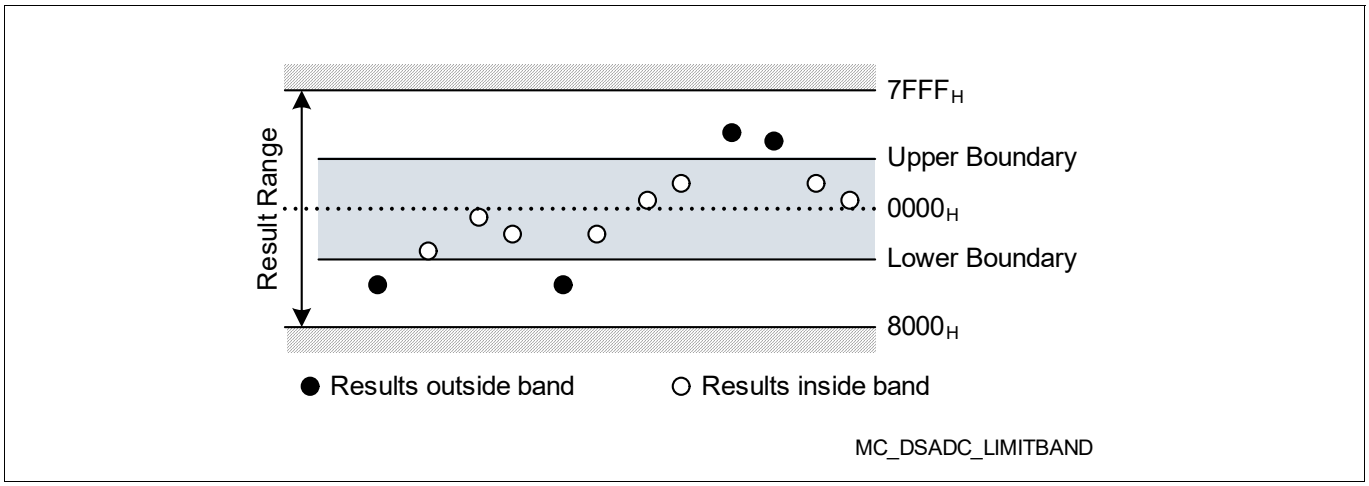

Figure 317 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:
To select the lower part as valid band, set the lower boundary to the minimum value (8000_H) and set the upper boundary to the highest intended value.
To select the upper part as valid band, set the upper boundary to the maximum value ($7FFF_H$) and set the lower boundary to the lowest intended value.

The limit checker can generate two types of output:

- Service requests, optionally restricted by the comparators
- Range signals, indicating the result level with respect to the defined limits:
  - Signal SAULx, indicating when the results are above the upper limit
  - Signal SWIBx, indicating when the results are within the defined band
  - Signal SBLLx, indicating when the results are below the lower limit

An alarm event can be generated when a new conversion result becomes available. Alarm events can be restricted to result values that are inside or outside a user-defined band (see **Figure 317**). This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain conditions. For example, an input value can be monitored and an alarm indicates a certain threshold.

Alarm events can also be suppressed completely. Bitfields SRGA and ESEL in register **FCFGMx (x=0-13)** select the service request generation mode.

The range signals (SAULx, SWIBx, SBLLx) are generated independent of service requests.

Boundary Select Register x

BOUNDSELx (x=0-13)

BOUNDARYU	31:16	rw	**Upper Boundary Value for Limit Checking** This (two's complement) value is compared to the upper bits of the CIC filter results.

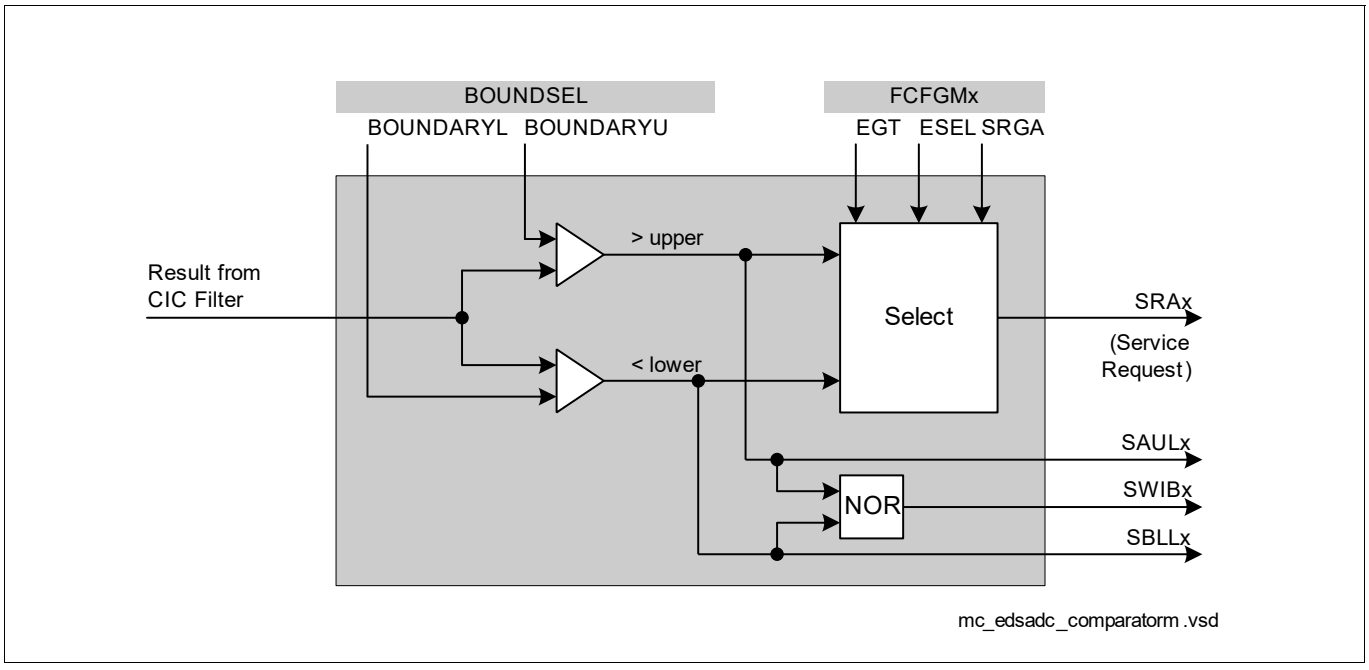

Figure 318 Comparator Structure

Selecting the Boundary Values

The comparator can be fed with result values from either the main CIC filter or from the auxiliary CIC filter. Since these filters generate result values in different formats, also the corresponding boundary values must fit to the selected format.

- The auxiliary CIC filter generates results in a fixed 1Q15 format. Due to the intrinsic gain of the on-chip modulator full-scale ranges from -22 757 to +22 757. When using an external modulator, the full-scale values depend on the gain of the used modulator.
- The main CIC filter generates results in a user-configurable format, where the full-scale value is defined by bitfield GAINCALx.CALTARGET.

For proper operation, the boundary values must relate to the selected filter's data format.

Note: There is no calibration in the auxiliary filter path. Offset and gain error must, therefore, be handled by the application software.
*The respective values can be obtained from registers **GAINCALx (x=0-13)** and **OFFCOMPx (x=0-13)** after calibration.*

33.10 Safety Features

Most analog inputs are connected to both EVADC and EDSADC channels, thus providing a basic redundancy.

On-Chip Supervision Signals

Information about the basic functionality of the EDSADC can be obtained via special on-chip signals, which supports common cause diagnosis. Every channel can output a replica of a reference voltage generated by a bandgap inside the power management system (PMS). The selected output voltage can be measured via a specific channel of the EVADC.

The selection of the supervision signal is controlled centrally via register **GLOBCFG**:

- Bitfield SVSIG enables the supervision function by selecting one of two voltages
- Bitfield SVCH selects the channel for which the supervision signal is connected to the common output.

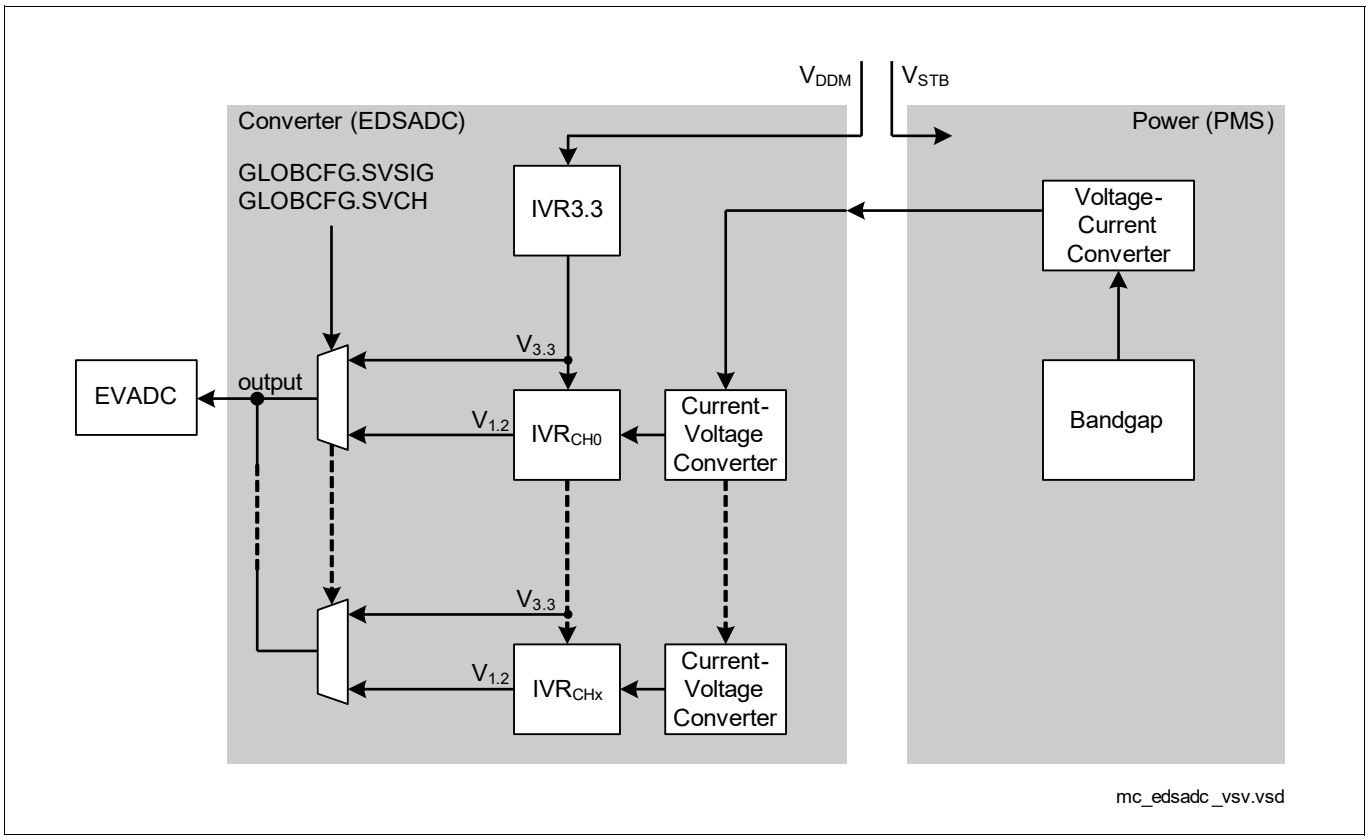

Figure 319 Test Voltages for Supervision

Measuring these voltages enables two test features:

- Compare the result with the expected value (RESULT = V_{Test} / V_{AREF} × 2^{12}).
  With V_{AREF} = 5.0 V and V_{DDK} = 1.2 V, RESULT = $3D7_H$.
- Compare the individual results of all channels to find deviations.

33.11 Service Request Generation

The EDSADC can activate service request output signals to issue an interrupt, to trigger a DMA channel, or to trigger other on-chip modules. Each channel provides 2 service request lines, SRxM and SRxA.

The product-specific appendix details the available service request connections.

Several events can be assigned to each service request output. Service requests can be generated by several types of events:

- **Result events:** indicate the availability of new valid results. Usually, this triggers a read action by CPU or DMA. Result events are generated at the output rate of the configured filter chain (indicated by bits RESEVx in register **EVFLAG**). The output rate of result service requests depends on the selected FIFO fill level (see bitfield SRLVL in register **RFCx (x=0-13)**).
  Can be issued via SRxM.
- **Alarm events:** indicate that a conversion result value is within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
  Can be issued via SRxA.
- **Special events:** indicate specific circumstances of previously configured functions.
  - Timestamp trigger event can generate a service request.
    Can be issued via SRxM (see read sequences) or SRxA (separate).
  - Capture event for sign delay measurement can generate a service request.
    Can be issued via SRxA.

Each event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of EDSADC events (the event can generate a service request without the need to clear the indication flag).

Note: Event flags SDCVAL are cleared when the filter chain is initialized,
i.e. when the channel is started (CHxRUN = 1), when an integration window is started with FCR = 0, or when the calibration algorithm begins or ends.
Event flags ALEVx, TSVAL and RESEVx are cleared when the channel is started (CHxRUN = 1).

Note: The following registers provide a set of bits for each available channel.
The number of available channels depends on the chosen device type.

Event Flag Register

The register below shows the maximum configuration.

Other products of the family may have less channels and, consequently, less valid RESEVx/ALEVx flags.

0	15:14, 31:30	r	**Reserved, write 0, read as 0**

Note: Software can set flags RESEVx and ALEVx and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear these flags by writing 1 to bit RESECx and ALECx, respectively.

33.12 Resolver Support

Resolver applications determine the rotation angle by evaluating the signals from two orthogonally placed coils. These coils are excited by the magnetic field of a third coil.
Several features are available to support these applications by offering the almost complete interface hardware (except for power stages) and by preprocessing the input data (rectification, integration) to optimize evaluation by higher level software algorithms.

33.12.1 Resolver System Overview

The EDSADC can read the two return signals using two input channels and can also generate the excitation sine signal (carrier). It also provides synchronization logic to compensate the delay between the generated carrier signal and the received position signals. The integrator stage converts the carrier-based return signals to position-based values (carrier cancellation).

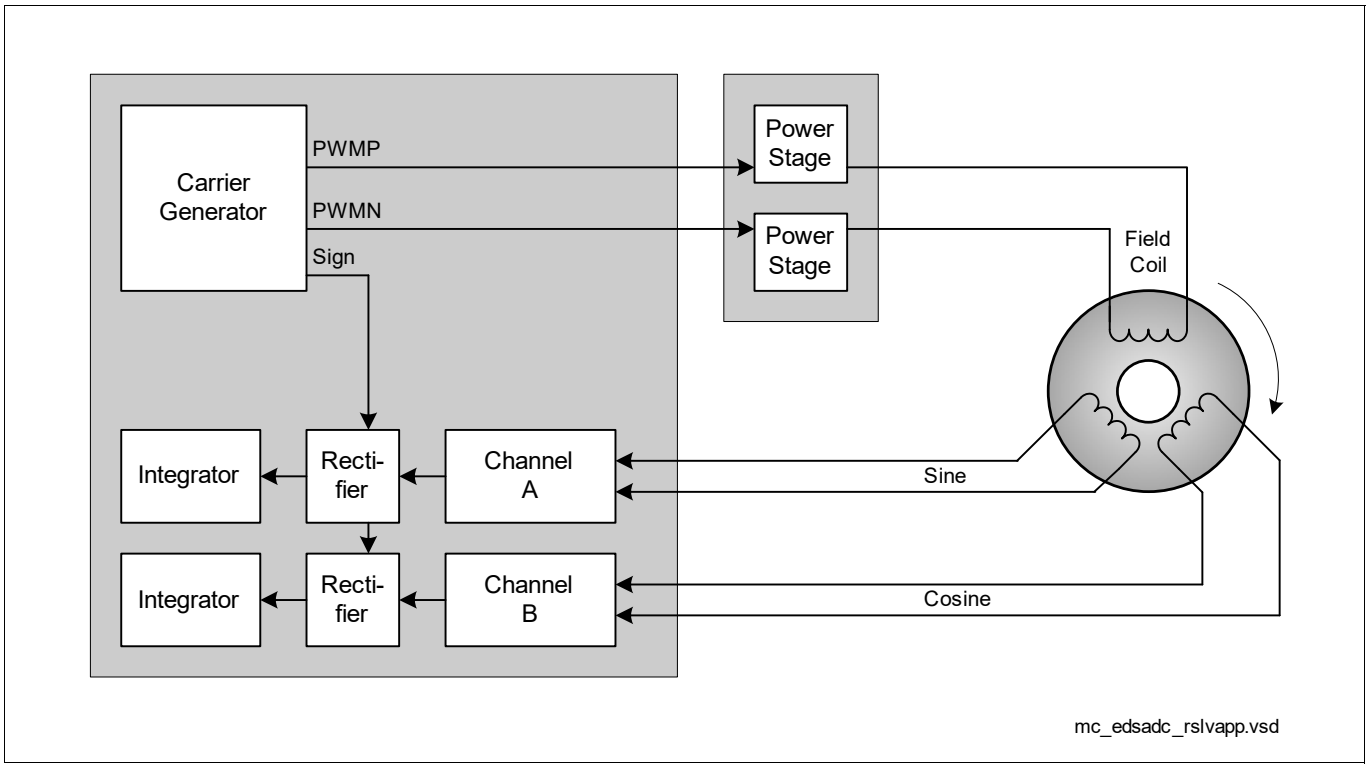

Figure 320 Resolver Application

33.12.2 Carrier Signal Generation

The carrier signal generator (CG) is supplied with the module clock signal and outputs a PWM signal that induces a sine signal in the excitation coil of the resolver. Alternatively, it can generate PWM patterns that resemble triangle or square signals (see **Figure 322**). The polarity of the carrier signal can be selected.

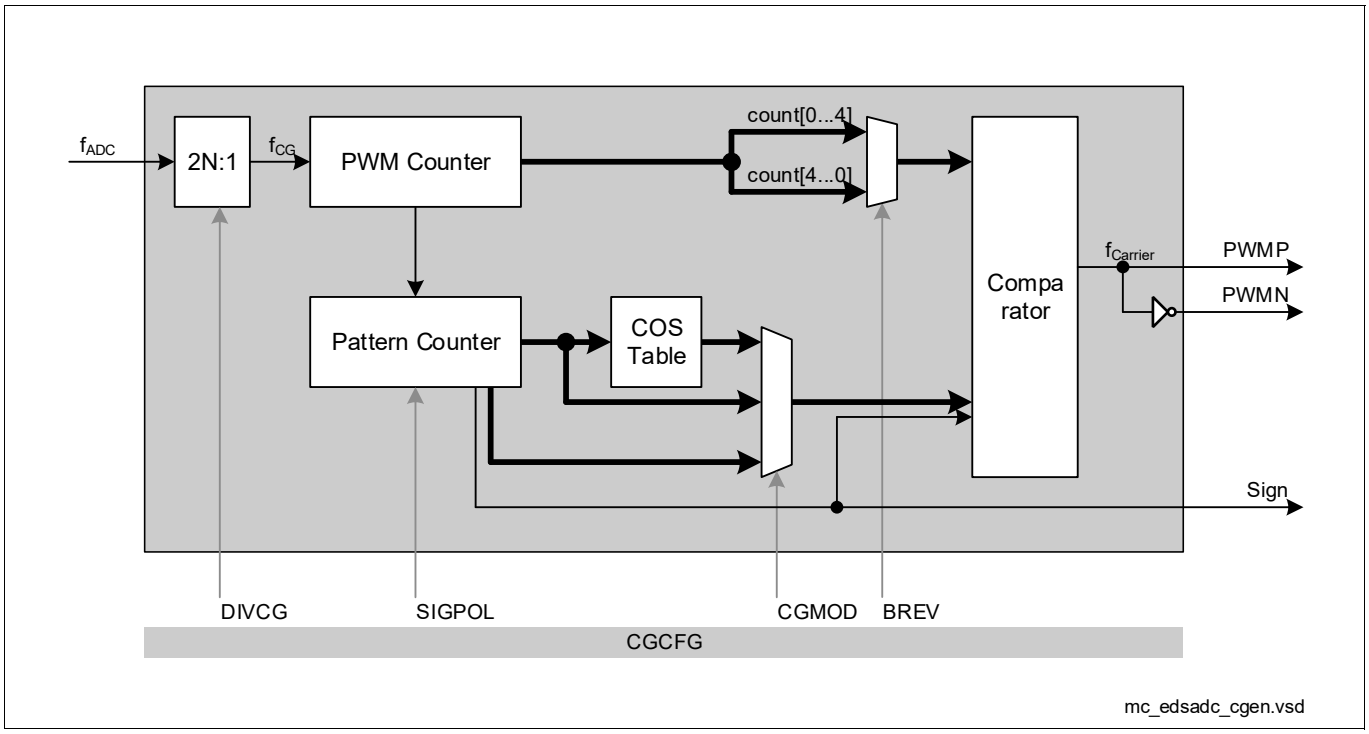

Figure 321 Carrier Generator Block Diagram

A carrier signal period consists of 32 steps. Each step equals a PWM period of 32 cycles.

Bit-reverse generation mode increases the frequency spectrum to yield a smoother induced sine signal. This is done by distributing the 0 and 1 bits over the 32 cycles of a PWM period.

The generated pattern is actually a cosine signal, i.e. it starts at the maximum output value. This is advantageous if the output pin is pulled high before the carrier signal is generated. In case of a pull-down the inverted output signal should be selected.

Note: All configurations become effective, when the carrier generator is started.

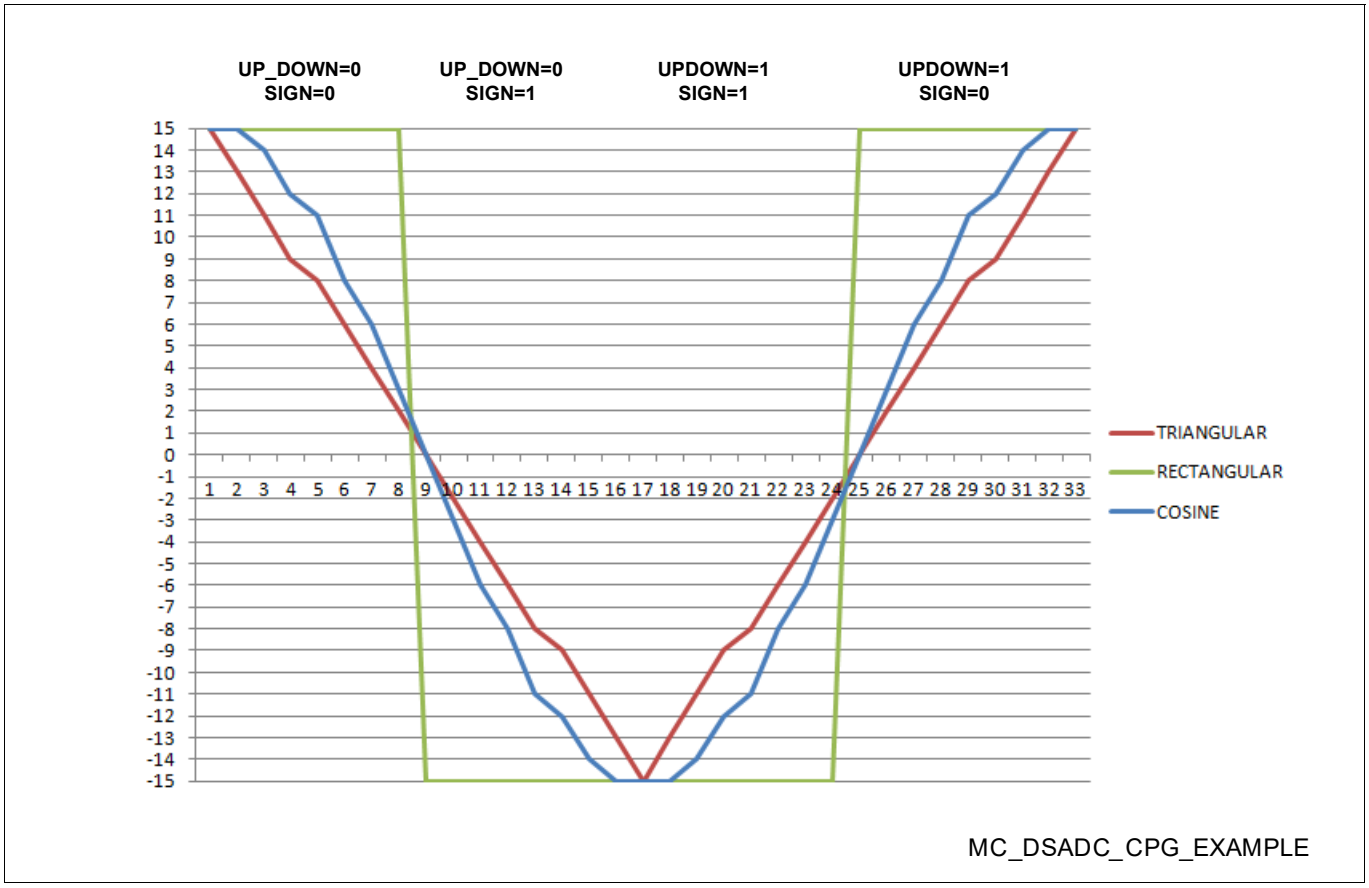

Figure 322 Example Pattern/Waveform Outputs

Carrier Generator Configuration Register

Note: The current position within a carrier signal period is indicated by bitfields STEPD, STEPS and STEPCOUNT.

CGCFG

Carrier Generator Configuration Register (00A0$_H$) Application Reset Value: 0710 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	SGNCG	STEPD	STEPS	0	STEPCOUNT			0			BITCOUNT				
r	rh	rh	rh	r	rh			r			rh

RUN	0							DIVCG				SIGPOL	BREV	CGMOD	
rh	r							rw				rw	rw	rw	

Field	Bits	Type	Description
CGMOD	1:0	rw	**Carrier Generator Operating Mode** Stopping the carrier generator (CGMOD = 00_B) terminates the PWM output after completion of the current period (indicated by bit RUN = 0). 00_B Stopped 01_B Square wave 10_B Triangle 11_B Sine wave
BREV	2	rw	**Bit-Reverse PWM Generation** 0_B Normal mode 1_B Bit-reverse mode
SIGPOL	3	rw	**Signal Polarity** 0_B Normal: carrier signal begins with +1 1_B Inverted: carrier signal begins with -1
DIVCG	7:4	rw	**Divider Factor for the PWM Pattern Signal Generator** Defines the input frequency of the carrier signal generator, derived from the selected internal clock source: $f_{CG} = f_{ADC}$ / CGP. *Note: The frequency of the carrier signal itself is f_{CG} / 1024.* 0_H CGP = 2 … F_H CGP = 32
RUN	15	rh	**Run Indicator** 0_B Stopped (cleared at the end of a period) 1_B Running
BITCOUNT	20:16	rh	**Bit Counter** Counts the 32 cycles generated for each step
STEPCOUNT	26:24	rh	**Step Counter** Counts the 8 steps generated for each quadrant of the carrier signal period
STEPS	28	rh	**Step Counter Sign** Indicates the sign of the step counter value 0_B Step counter value is positive 1_B Step counter value is negative
STEPD	29	rh	**Step Counter Direction** 0_B Step counter is counting down 1_B Step counter is counting up
SGNCG	30	rh	**Sign Signal from Carrier Generator** 0_B Positive values 1_B Negative values
0	14:8, 23:21, 27, 31	r	**Reserved, write 0, read as 0**

33.12.3 Return Signal Synchronization

In a resolver, the received return signals are induced by the carrier signal and their amplitudes are modulated with the sine and cosine magnitudes corresponding to the current resolver position. These amplitudes are determined by integrating the return signals over a carrier signal period.

To properly integrate their magnitude, the return signals must be rectified. For this purpose the carrier generator provides the sign information of the generated carrier signal (SGNCG in register **CGCFG**).

Alternatively, an external carrier signal generator can be used. If this generator delivers a sign signal, this can be input to a pin and is then used as external carrier sign signal. If no sign signal is available, the carrier signal itself can be converted by another input channel (SSCH in register **RECTCFGx (x=0-13)**) and its sign signal is then used as alternate carrier sign signal.

The rectification of the received signals must be delayed to compensate the round trip delay through the system (driver, resolver coils, cables, etc.). For the rectification, the received values are multiplied with the delayed carrier sign signal (SGND in register **RECTCFGx (x=0-13)**). This synchronization is done for each channel separately, to achieve the maximum possible amplitudes for each signal.

Note: The rectification unit is part of the integrator stage. Therefore, it is only active while the integrator is active.

The delay is realized with the sign delay counter SDCOUNT. SDCOUNT is cleared and started upon a falling edge of the carrier's sign signal (SGNCS), i.e. at the begin of the positive halfwave of the carrier signal. After counting SDPOS results from the filter chain, also the rectification signal (SGND) is cleared, indicating positive values from now on. After counting SDNEG values, the rectification signal is set, indicating negative values (see also **Figure 323**).

The compare values SDPOS and SDNEG are stored by the application software. SDPOS is the delay value that accounts for the resolver signal's round trip delay. This delay is constantly measured by capturing the current counter value into bitfield SDCAP when the first positive result (after negative results) is received in the respective channel. Software can read these value and compute a delay value e.g. by averaging a series of measured values to compensate noise. The delay for the negative halfwave (SGND = 0) is determined by adding the duration of a carrier signal halfwave. This value is written to bitfield SDNEG.

A new captured value is indicated by setting the flag SDCVAL. This flag is cleared when reading register CGSYNCx.

Capturing a new value can trigger a service request. The alternate service request line is used for this purpose. This alternate request source is selected by bitfield SRGA in register **FCFGMx (x=0-13)**.

Note: When the filter chain is initialized, bitfields SGND, SDCVAL, SDCAP and SDCOUNT are cleared.

Carrier Generator Synchronization Reg. x

CGSYNCx (x=0-13)

Carrier Generator Synchronization Reg. x (01A0$_H$+x*100$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDCAP								SDCOUNT							
rh								rh							

Field	Bits	Type	Description
SDCOUNT	7:0	rh	**Sign Delay Counter** Counts the result values from the filter chain to delay the carrier sign signal
SDCAP	15:8	rh	**Sign Delay Capture Value** Indicates the result values counted between the begin of the positive halfwave of the carrier signal and the first received positive value.
SDPOS	23:16	rw	**Sign Delay Value for Positive Halfwave** Defines the content of SDCOUNT to generate a negative delayed sign signal (SGND).
SDNEG	31:24	rw	**Sign Delay Value for Negative Halfwave** Defines the content of SDCOUNT to generate a positive delayed sign signal (SGND).

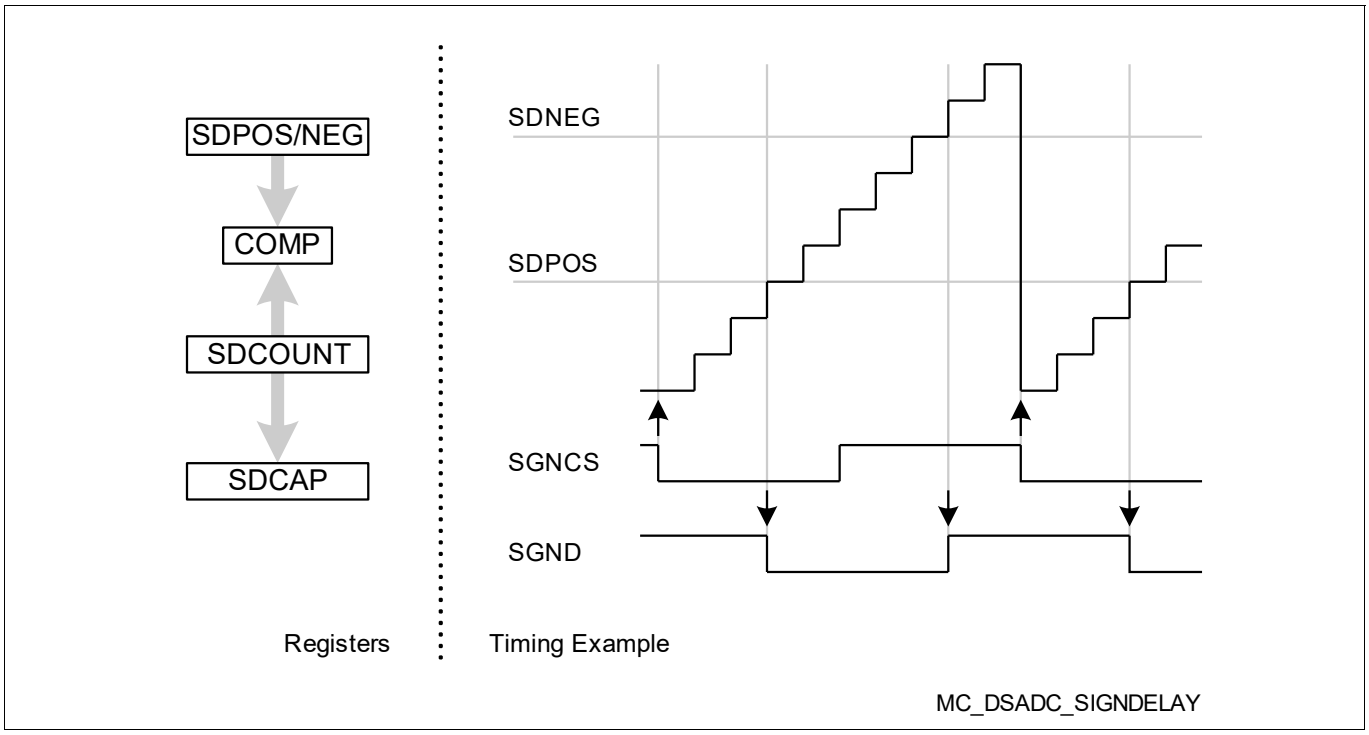

Figure 323 Sign Delay Example

Note: Whenever a new result value becomes available from the filter chain, the rectification counter is updated and the rectified value is forwarded to the integrator.

Rectification Configuration Register x

RECTCFGx (x=0-13)

Rectification Configuration Register x **($01A8_H$+x*100_H)** **Application Reset Value: 8000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SDCVAL	0			SSCH				0		SSRC		0			RFEN
rh	r			rw				r		rw		r			rw

Field	Bits	Type	Description
RFEN	0	rw	**Rectification Enable** General control of the rectifier circuit. *Note: Rectification is only active while the integrator is active.* 0_B No rectification, data not altered 1_B Data are rectified according to SGND
SSRC	5:4	rw	**Sign Source** Selects the sign signal that is to be delayed. 00_B On-chip carrier generator 01_B Sign of result of channel selected by bitfield SSCH 10_B External sign signal A 11_B External sign signal B
SSCH	11:8	rw	**Sign Source Channel** Selects the channel providing the sign signal if SSRC = 01_B. Other products of the family may have less channels and, consequently, less valid SSCH codes. Not listed combinations are reserved. 0_H Sign result from channel 0 … D_H Sign result from channel 13
SDCVAL	15	rh	**Valid Flag** Indicates a new value in bitfield SDCAP. 0_B No new result available 1_B Bitfield SDCAP has been updated with a new captured value and has not yet been read
SGNCS	30	rh	**Selected Carrier Sign Signal** 0_B Positive values 1_B Negative values
SGND	31	rh	**Sign Signal Delayed** 0_B Positive values 1_B Negative values

Field	Bits	Type	Description
0	3:1, 7:6, 14:12, 29:16	r	**Reserved, write 0, read as 0**

33.13 Application Considerations

The operation of the EDSADC and, hence, its behavior is programmable in a wide range. This makes it suitable for different applications while requiring a certain amount of initialization and/or handling during operation.

As far as possible the configuration options can be handled by initialization. Several functions, for example power control or calibration, have been automated so they require an absolute minimum of handling during operation.

Additional hints in section **"Changing the Configuration" on Page 7**.

33.13.1 Clock Synchronization

To eliminate the interference of concurrently operating ADC channels, the converters can operate in a synchronized way so each of them can reach its optimum performance. The Phase Synchronizer distributes a clock control signal which is used by the converters to generate a local clock signal. See **Section 33.4.1**.

After reset, the clock synchronization is active. Setting the Phase Synchronizer is mandatory for the EDSADC to deliver its documented performance.

33.13.2 Calibration Recommendation

The actual calibration algorithm is executed automatically by hardware, so only a few configurations need to be selected before starting the algorithm.

The automatic calibration algorithm is executed for gain factors of 1:1 and 1:2. If a factor of 1:4 is selected calibration is done for factor 1:2.

The optimum mode for offset calibration depends on the properties of the input signal. The high-pass filter can automatically remove the offset level of a differential input signal. For irregular input signals or for single-ended operation the filter must be disabled to receive an undisturbed signal.

Note: The calibration algorithm compensates manufacturing tolerances and adjusts the channel to the selected decimation rate. It is, therefore, recommended to execute the algorithm at least once after a reset.

Define the intended full-scale value for the calibration in bitfield CALTARGET in register **GAINCALx (x=0-13)** (default value 25 000). Trigger the calibration algorithm by setting bit CALIB in register **FCFGMx (x=0-13)**. The completion and status of the calibration algorithm is indicated by bitfield CAL in register **FCNTCx (x=0-13)**.

*Note: Set bit AUTOCAL in register **FCFGMx (x=0-13)** to enable automatically triggered calibration sequences.*

33.13.3 Examples for Operation

The digital filters provide a number of configuration options to control their operation. The automatic calibration algorithm normalizes the overall gain factor of the filter chain to 1.000, independent of their configuration. The full-scale value of the result is adapted to <CALTARGET> (25 000 after reset), representing the reference voltage.

Different full-scale values can be achieved by choosing a different value for CALTARGET (see **"Handling of Overload, Overdrive and Overflow Conditions" on Page 26**).

The usable passband is a fraction of the configured output data rate.
For passbands in the range of 10 … 100 kHz this fraction is 1/3rd,
for passbands in the range of 4 … <10 kHz this fraction is 1/6th.

The output data rate is determined by the modulator frequency divided by the total oversampling rate.

Example:
CIC filter active with oversampling rate of 64, FIR0/FIR1 active (both 2:1), integrator inactive, f_{MOD} = 26.67 MHz:
Total oversampling rate is 64 × 2 × 2 = 256, output data rate is 26.67 MHz/ 256 = 104.2 kHz.

33.13.4 Supported Operating Ranges

The EDSADC can be configured for various operating modes, depending on the application's requirements. The focus can be on the input impedance, on the power consumption, or on the signal-noise-ratio SNR.

The configured oversampling rate (or decimation rate) OSR defines the SNR within a wide range. The reachable SNR is limited by thermal noise within the on-chip modulator. The relation between OSR and SNR is, therefore, no more linear in the upper area.

The table below lists some properties of these operating modes. Shown SNR values are valid for the analog supply voltage range (VDDM) between 4.5 V and 5.5 V. For analog supply voltages higher than 2.97 V and lower than 4.5 V, the SNR values degrades by 6 dB.

Note: To achieve the passbands given in this table, both FIR filters must be enabled.

Table 292 Properties of Operating Ranges

Modulator Frequency f_{MOD}	Input Current I_{RMS} [1]	$f_{PB} \le 10$ kHz [2]		$f_{PB} \le 30$ kHz [3]		$f_{PB} \le 50$ kHz [3]		$f_{PB} \le 100$ kHz [3]	
		SNR [4]	OSR	SNR [4]	OSR	SNR [4]	OSR	SNR [4]	OSR
16 MHz (f_{ADC} / 10)	6 µA	≥78 dB	≥267	≥78 dB	≥178	≥74 dB	≥107	≥65 dB [5]	≥54
20 MHz (f_{ADC} / 8)	7.5 µA	≥80 dB	≥334	≥78 dB	≥223	≥74 dB	≥134	≥68 dB [5]	≥67
26.67 MHz (f_{ADC} / 6) [6]	10 µA	**≥80 dB**	≥445	**≥80 dB**	≥297	**≥78 dB**	≥178	**≥74 dB**	≥89
40 MHz (f_{ADC} / 4)	15 µA	≥80 dB	≥667	≥80 dB	≥445	≥78 dB	≥267	≥74 dB	≥134

1) These typical values refer to an input voltage of 5 V and the typical value of the switched capacitor: $I_{RMS} = 5\,V \times f_{MOD} \times 2 \times C_{SW}$. I_{RMS} defines the equivalent input impedance.
2) Passband = f_d / 6
3) Passband = f_d / 3
4) The reachable signal-noise-ratio is limited by thermal noise within the modulator.
5) With this configuration, the signal-noise-ratio is limited by quantization noise.
6) These OSRs reference the Datasheet values.

Note: Related to hardware characteristic for passband frequency ≤ 10 kHz the FIR1 has to be used with a decimation rate of 1:1.

The equivalent input impedance, which is seen by the external sensor, depends on the input current I_{RMS}. The input current is proportional to the effective switched input capacitance, which itself depends on the selected gain factor.

Table 293 Equivalent Input Impedance

Modulator Frequency	Input Current for Gain 1 / 2 / 4	Impedance for Gain factor = 1	Impedance for Gain factor = 2	Impedance for Gain factor = 4
16 MHz	6 µA / 12 µA / 24 µA	R_{IN} = 833 kΩ	R_{IN} = 416 kΩ	R_{IN} = 208 kΩ
20 MHz	7.5 µA / 15 µA / 30 µA	R_{IN} = 666 kΩ	R_{IN} = 333 kΩ	R_{IN} = 166 kΩ
26.67 MHz	10 µA / 20 µA / 40 µA	R_{IN} = 500 kΩ	R_{IN} = 250 kΩ	R_{IN} = 125 kΩ
40 MHz	15 µA / 30 µA / 60 µA	R_{IN} = 333 kΩ	R_{IN} = 166 kΩ	R_{IN} = 83 kΩ

Quasi-Differential Input Mode

When operating the EDSADC in single-ended mode, the smaller input voltage range reduces the achievable SNR by 6 dB. Quasi-differential input mode is realized by connecting the unused input line to the common mode voltage instead of to reference ground. This centers the result values around zero.

Using gain factor 2 doubles the result value range (-full-scale for input=ground, +full-scale for input=reference). In this case the achievable SNR is reduced by only 3 dB.

33.13.5 Basic Initialization Sequence

After reset, the EDSADC is disabled to minimize the initial power consumption. By executing the following steps the EDSADC can be prepared for operation and be started:

Enable and configure the phase synchronizer according to the overall system requirements.

This is described in section “Application Considerations” in chapter CONVCTRL.

Enable the EDSADC module and prepare it for operation

```
EDSADC_CLC      = 0x00000000 ;Enable module EDSADC
EDSADC_GLOBCFG  = 0x00000000 ;Use default: auto level, sync. operation, min. dithering
EDSADC_MODCFG0  = 0x80028000 ;Mod. frequency = 160 MHz / 8 = 20 MHz,
                             ;enable differential input on channel 0-A (example)
EDSADC_DICFG0   = 0x84000000 ;Single-word read mode, no timestamp, no FIFO
EDSADC_GAINCTR0= 0x061B1193  ;Calibrate with OSR 512, calibration factor 1.0984
EDSADC_GAINCORR0=0x0011126E  ;Set shifter for operation, operation factor 1.1519
EDSADC_FCFGC0   = 0x00310031 ;Select a data rate of 100 kHz (= 20 MHz / 200);200 =
50[CIC] * 4[FIR]
EDSADC_GLOBRC   = 0x00010001 ;Enable modulator and filter chain of channel 0 (example)
WAIT                         ;Pause for wakeup time (approx. 20 µs)
                             ;(other operations can be executed in the meantime)
EDSADC_FCFGM0   = 0x90038003 ;Enable service request and FIR filters,
                             ;start calibration
```

For applications where two or more DSADC channels have to provide synchronous results, all related channels shall be enabled synchronously using a single write access to register GLOBRC. To handle the EDSADC channel specific modulator settling time, the following sequence is proposed:

- Enable all modulators of the application specific synchronization group by a single write access to the corresponding MxRUN bits in the upper half-word of the Global Run Control Register:
  - GLOBRC = XXXX °°°°H, where XXXXH depends on the number of implemented modulators;
- Wait for modulator settling time tMSET (see Data Sheet);
- Enable all modulators and corresponding digital filter chains of the application specific synchronization group by a single write access to the corresponding MxRUN and CHxRUN bits in the Global Run Control Register:
  - GLOBRC = XXXX XXXXH, where XXXXH depends on the number of implemented modulators/demodulator channel

Retrieve Conversion Results

After the calibration has finished, the channel will begin to convert the input signal.Conversions results are indicated by service requests and can be read from RESM0.

33.13.6 Module Handling in Sleep Mode

The EDSADC does not change its operating mode in sleep mode. While sleep mode is evaluated (CLC.EDIS = 0, default after reset), the module clocks are stopped upon a sleep mode request. To achieve the power reduction that is usually intended during sleep mode, the application needs to disable the EDSADC, or parts of it as required, before entering sleep mode.

Note: If any activity is intended during sleep mode make sure that sleep mode requests are disregarded (CLC.EDIS = 1) and make sure the phase synchronizer is not disabled in this case.

33.13.7 Overlap of CH9 and CH12

In some products of the TC3XX family the inputs of channels CH9B and CH12A are connected to the same pair of pins. Both channels can be used to convert input signals from these pins. To avoid coupling effect from one channel to the other, it is recommended to enable only one input path at a given time.

Note: While CH12A is operating, CH9A may operate on another input.

33.14 Summary of Registers and Locations

The EDSADC is built from a series of channels that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see **Table 294**). The exact register location is obtained by adding the respective register offset to the base address (see product-specific appendix) of the corresponding channel.

Due to the regular structure, several registers appear within each channel. This is indicated in the register overview table by formulas.

Registers with write access mode "...,M" can additionally be protected from unintended write access by setting the corresponding protection bit in register ACCPROT. Refer to **"Register Access Control" on Page 14** for more details and an association table.

Table 294 Register Overview - EDSADC (ascending Offset Address)

34 Inter-Integrated Circuit (I2C)

This chapter describes the Inter-Integrated Circuit (short I2C) Module. The I2C module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed. The I2C module contains the following sections:

Note: The I2C module register names described in this chapter are referenced in the User's Manual by the module name prefix "I2Cm_" with m being the number of the module.

34.1 Feature List

- Compatible with I2C-bus specification version 2.1 **[1]**. See module functional restrictions in **Section 34.3.1.3**
- Master mode supported
- Multi-master mode supported (See restriction in **Section 34.3.1.3**)
- Slave mode supported
- Different speed ranges available for data transfer:
  - Standard mode up to 100 kbit/s (20kbit/s - 100kbit/s)
  - Fast mode up to 400 kbit/s (100kbit/s - 400kbit/s)
  - High-speed mode up to 3.4 Mbit/s (500kbit/s - 3.4Mbit/s)
- 7-bit and 10-bit I2C-bus addressing supported
- Automatic execution of low-level tasks like:
  - (De)Serialization of the bus data
  - Generation/detection of start and stop signal
  - Generation/detection of acknowledge signal
  - Bus state detection
  - Bus access arbitration in multi-master mode (See restriction in **Section 34.3.1.3**)
  - Recognition of device address in slave mode
  - Configurable detection of general call address
  - Configurable repeated start in master mode
- Flexible clock and timing control:
  - Prescaler for I2C kernel clock (from 0 to 255)
  - Bit rate generation via fractional divider
  - I2C-bus signal timing adjustment

- FIFO for buffering data from/to CPU with following features:
  - 8 FIFO stages based on 32 bit width
  - Configurable data alignment (byte, half word, word)
  - Configurable sizes for burst, transmit and receive package
  - FIFO usable as flow controller (seamless DMA flow)
- Advanced interrupt handling:
  - 4 data transfer interrupts (burst, last burst, single, last single)
  - Protocol interrupt with 7 sources (address match, general call, master code, arbitration lost, not-acknowledge received, transmission end, receive mode)
  - Error interrupt with 4 sources (FIFO transmit/receive overflow/underflow)
- Pretended Networking:
  - High-speed mode, fast mode and standard mode work with a minimum frequency of 5MHz in spb domain.

34.2 Overview

The I2C module communicates with the external world via a pair of I/O lines. A serial data line (SDA) and a serial clock line (SCL) carry the information between the devices. These lines are connected to a positive supply voltage via pull-up resistors. In quiescent state, when the bus is free, both lines are high. During communication the lines are alternatively pulled to low. The output stages of devices connected to the bus must have an open-drain (CMOS) or open-collector (bipolar) to perform a wired-AND function.

Figure 324 shows a block diagram of the I2C module.

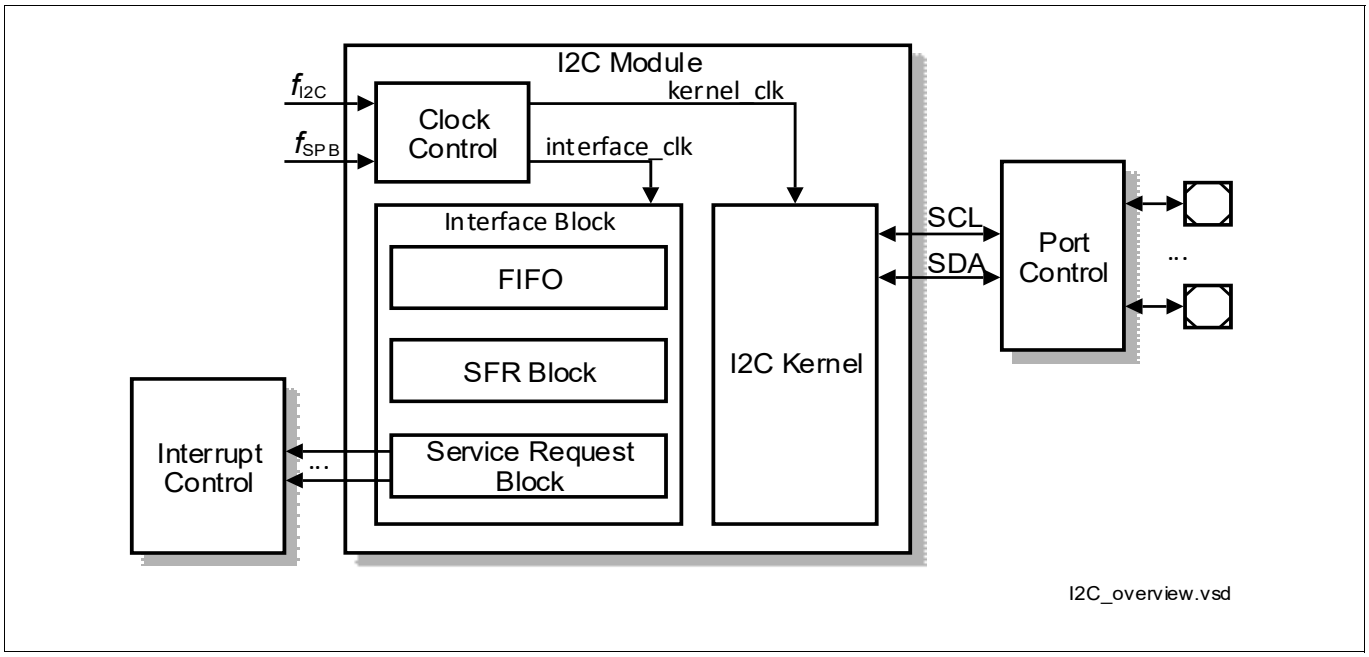

Figure 324 Block Diagram of the I2C Module

The I2C protocol was developed to provide a simple and efficient data transfer between multiple devices over a short distance. It uses a bidirectional serial bus with two wires.

The device can work as master or as slave. The master initiates the transfer, generates the clock pulses and terminates the transfer; it addresses a slave via a 7-bit or 10-bit address. Data can flow in either direction. In many applications there is only one master, typically a single-chip microcontroller, which communicates with several

slaves, e.g. general purpose peripherals or application specific circuits. But also multi-master systems with arbitration and collision detection are possible.

Data on the I2C-bus can be transferred at rates of up to 100 kbit/s in standard mode, up to 400 kbit/s in fast mode and up to 3.4 Mbit/s in high-speed mode. A slow slave may stretch the clock period. The number of devices connected to the same I2C-bus is limited only by a maximum bus capacitance of 400 pF.

The module relieves the CPU from many time-critical tasks.

The clock for the kernel of the I2C module is derived from the system clock via a prescaler. An additional fractional divider generates the desired bit rate. The exact timing of the I2C-bus signals can be adjusted.

A FIFO is used for data transfer between CPU and I2C module during transmission and reception. This allows writing and reading of multiple bytes. Data alignment and data sizes can be configured.

Six separate interrupt requests are available: for filling or emptying the FIFO, for reacting on certain protocol events and for handling of errors.

34.3 Functional Description

Description of the kernel, module implementation and integration.

34.3.1 I2C Kernel Description

Functional description of the I2C kernel.

34.3.1.1 I2C Protocol

Data is transmitted bit-by-bit on line SDA in conjunction with the clock on line SCL. To start communication, a master device generates a so called start condition. Subsequently data transfer starts. Therefore the data on the SDA line must be stable during the high period of the clock and may only change during SCL low phase. After all data have been transferred, the master closes transmission with a stop condition (see **Figure 325**).

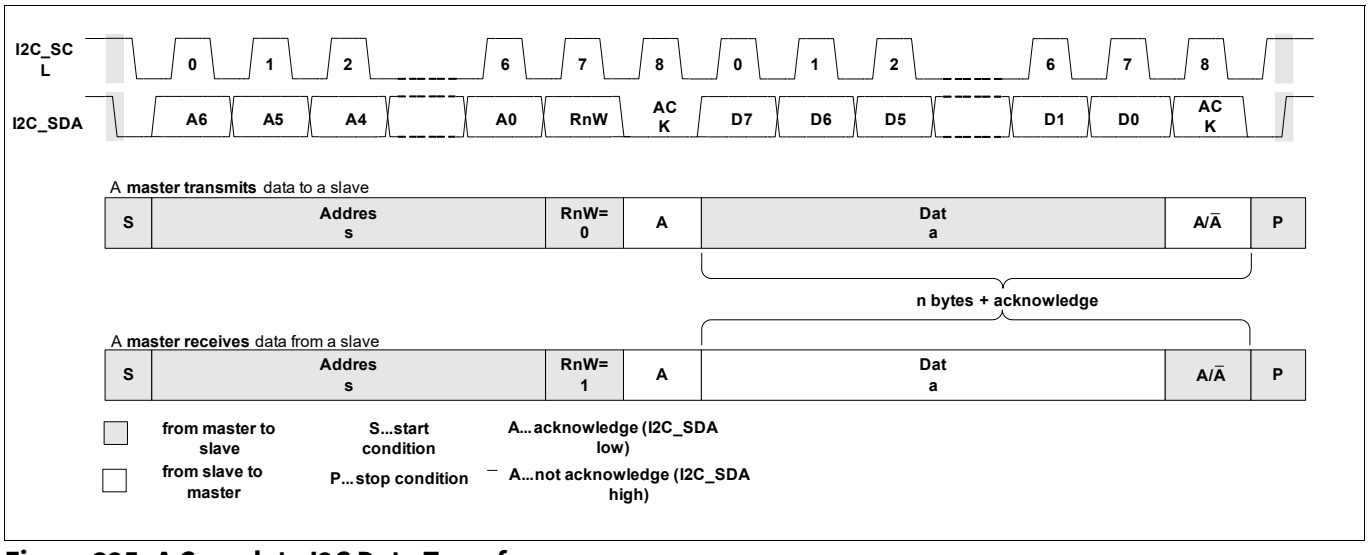

Figure 325 A Complete I2C Data Transfer

Start, Restart and Stop Conditions

A start condition is indicated by a high to low transition on line SDA while SCL remains high, a stop condition is defined by low to high transition under the same condition of high level on line SCL. The bus is considered to be busy after a start condition and to be free again after a stop condition. To allow continuous data transmission or reception without first generating a stop condition, a third condition has been introduced - the restart condition.

The bus stays busy if this condition is generated and the same or another slave can be addressed. Start and restart condition are functionally identical.

Address Transmission

After the start condition a slave address is sent. Normally the address is 7 bits long followed by an 8th bit that is a data direction bit (Read/not Write see **Figure 326**). A zero indicates a transmission (write operation); a one indicates a request to data (read operation). Following the address transmission the addressed device responds with an acknowledge (low on line SDA). If no acknowledge is returned, the master can then generate either a stop condition to abort the transfer or a repeated start condition to start another new transfer.

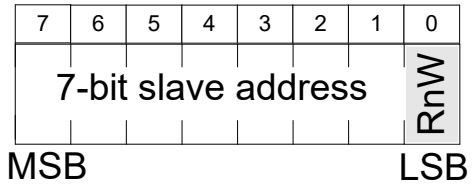

Figure 326 Address Byte Composition

Two groups of eight addresses are reserved for purposes, as shown in **Table 296**. For example the bit combination “11110XX” is reserved for 10-bit addressing mode.

Table 296 Reserved I2C-bus Addresses

Address	RnW	Description
0000000	0	General call address
0000000	1	Start byte - no device is allowed to acknowledge
0000001	x	CBUS address - I2C-bus devices may not respond
0000010	x	Reserved for different bus format
0000011	x	Reserved for future use
00001XX	x	High-speed mode master code
11111XX	x	Reserved for future use
11110XX	x	10-bit slave addressing mode

General Call

A general call is characterized by transmission of address “0000000” and RnW bit = 0. It is used for addressing every device connected to the I2C-bus. However, if a device doesn’t need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgement. Otherwise it acknowledges this general call and the following data bytes (if required) and behaves like a slave-receiver. The received data (e.g. programmable part of slave address, address of I2C-bus master) has to be handled by software. For further information the reader is referred to the I2C-bus specification version 2.1 **[1]**.

Data Transmission

Each byte transferred over the I2C-bus has to be 8 bits long whereby the number of bytes transmitted per transfer is unrestricted. Bytes are transferred MSB (Most Significant Bit) first. If the slave cannot receive or transmit a data byte until it has performed another function, it can hold the clock line SCL low (wired AND connection) to force the master into a wait state. Data transfer continues when the slave releases the clock line.

Acknowledge

Each transferred respectively received byte has to be followed by an acknowledge bit that is set by the recipient (master or slave depending on the transmission direction) onto the data line SDA. The acknowledge-related clock pulse is generated by the master. The device that has to set the acknowledge bit must pull down the SDA line during the acknowledge clock pulse so that it remains stable low during the high period of this clock pulse. Therefore in case of a slave the clock line may be held low until an acknowledge is released.

When the recipient of data doesn't acknowledge the data, for example because it was unable to receive the data or to transmit any data, the data line must be left high. A master-receiver that does not acknowledge the data from a transmitting slave device thereby tells the slave to stop transmission. The master then generates a stop condition to abort transfer or a repeated start condition to continue.

Clock Synchronization

To transfer messages a master generates its own clock on the SCL line. Data is only valid during the high period of the clock. Therefore data on line SDA has to be stable during this period and may only be changed during the low period of clock.

Two special cases must be considered. First, slave devices (or master devices operating as slaves) never generate clocks but are permitted to delay them. According to **Figure 327**, if device 1 as master device for example sets line SCL to low, device 2 as slave device may extend the low phase by setting its SCL output to low. A device such as a microcontroller with limited hardware for the I2C-bus can thereby slow down the bus clock and adapt the master to the internal operating rate of this device.

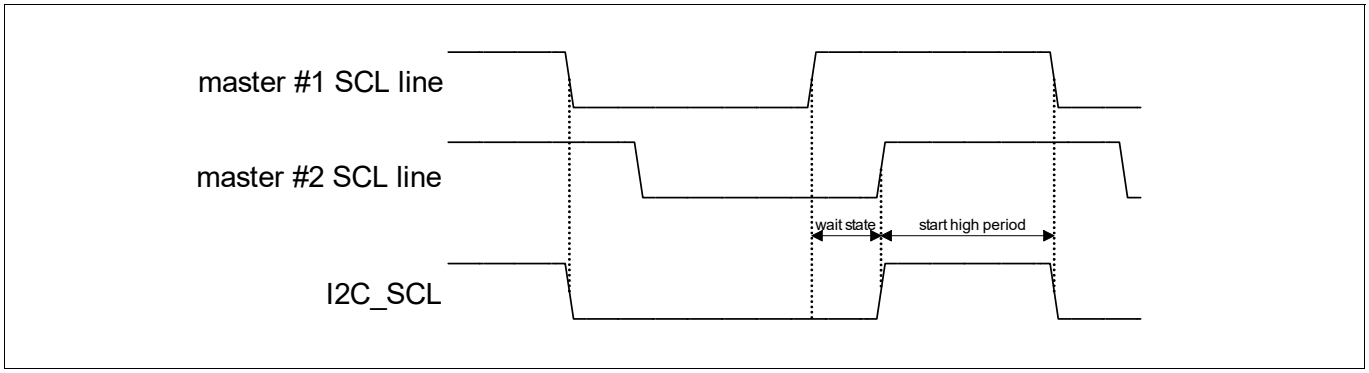

Figure 327 Clock Synchronization

Second, if several master devices access the I2C-bus at the same time, the SCL line is influenced by more than one device. As shown in the previous example, the SCL line will be held low by the device with the longest SCL low period. Devices with shorter periods enter a wait state during this time. In this way a synchronized SCL clock is generated.

Arbitration

To allow multi-master mode operation, bus arbitration is required. A master may start a transfer only if the bus is free. Two or more masters may generate a defined start condition simultaneously within a minimum hold time.

Arbitration takes place on the SDA line while SCL line is high, when one master transmits a high level while another master transmits a low level. Because of the wired AND functionality, the low level dominates the high level. As result the device that was trying to transmit a high level recognizes a different level on the SDA line and switches off its SDA and SCL output (see **Figure 328**).

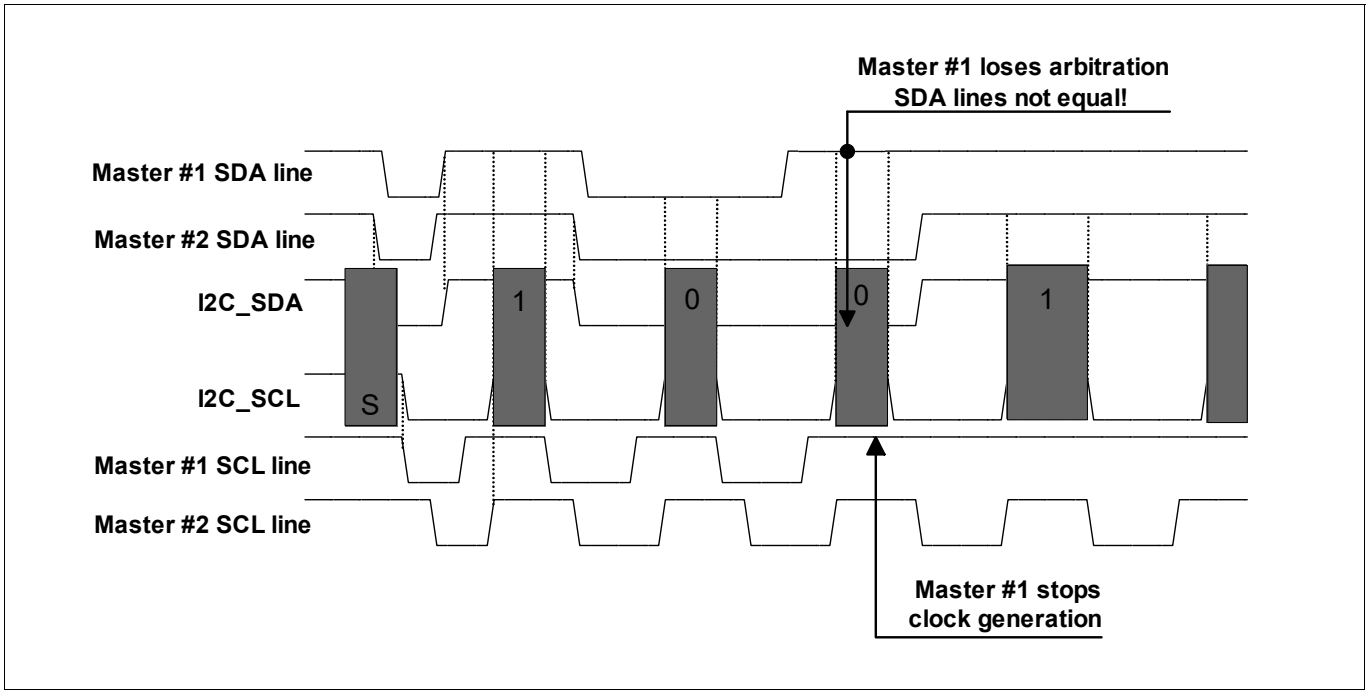

Figure 328 Example of an Arbitration Procedure

Arbitration may occur in different stages of transmission. A different level may potentially first appear during comparison of the address bits. If the masters are each trying to address the same device, arbitration continues with comparison of the RnW bit and subsequent data bits (if the masters are transmitting) or acknowledge bits (if the masters are receiving). Because information on the I2C-bus is determined by the winning master, no information is lost during the arbitration process. Since control of the I2C-bus is decided only by comparison of the data transmission stream over line SDA, there is no central master or any order of priority on the bus.

I2C-bus Formats

With the described rule types the formats shown in **Figure 329** are possible.

- Master-transmitter transmits to slave-receiver and stops after not-acknowledge.
- Master reads slave immediately after transmission of the RnW bit (high level) and the acknowledge from the slave, whereas the master becomes master-receiver and the slave becomes slave-transmitter.
- In combined format the just described regular sequences are handled, except for the repeated start condition instead of the stop condition between two sequences.

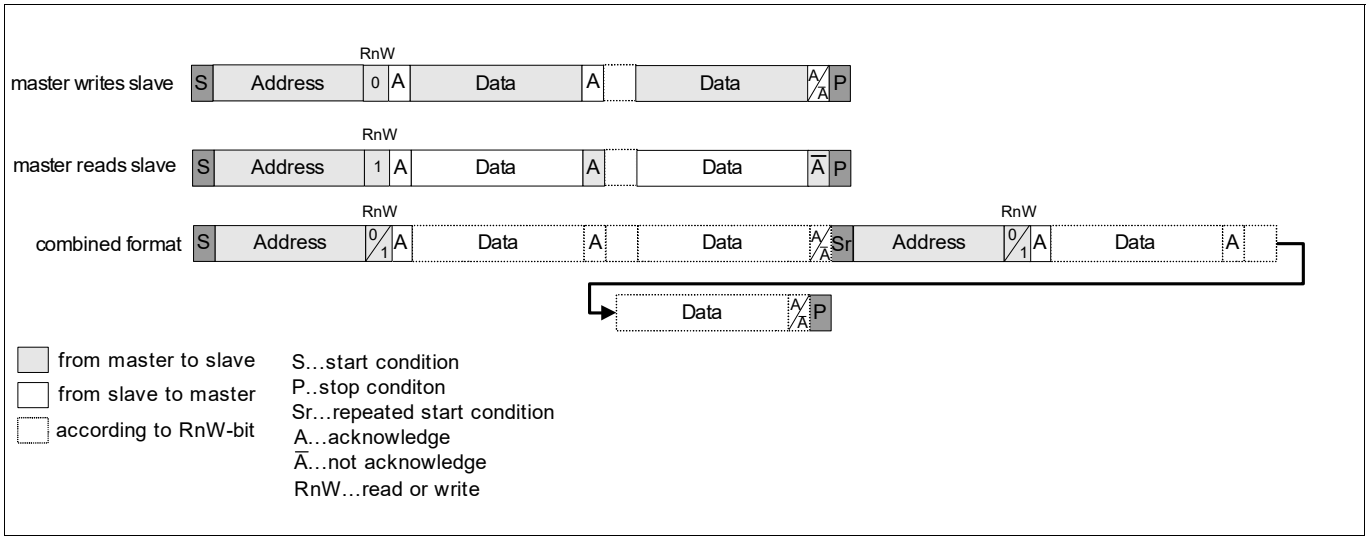

Figure 329 Types of I2C-bus Formats

10-bit Addressing Mode

The I2C address area is restricted to 112 applicable addresses with the 7-bit address mechanism described above. It turned out, that more combinations were required to prevent problems with the allocation of slave addresses for new devices. This problem was resolved with the 10-bit addressing scheme that is compatible with 7-bit addressing. Both modes may be used simultaneously. The following formats are possible:

To use 10 bits for addressing, the preamble address “11110XX” with RnW bit = 0 has to be used, including the two most significant bits “XX” of the 10-bit address, followed by an acknowledge from at least one 10-bit address matching slave and the second address byte containing the eight least significant bits. Only the (combined) 10-bit address matching slave now acknowledges. Data packages may now be transmitted to the addressed slave until stop condition or restart condition. If the master needs to read the slave, a combined format with a restart condition is necessary to

- First transmit the 10-bit address (first data package after preamble address contains 2nd address byte, RnW bit is 0) and (after the restart condition)
- Receive the requested data packages. Note that after the restart condition the preamble address “11110XX” has to be sent one more time, now with RnW bit = 1; the matching slave remembers that it was addressed before (see **Figure 330**). In case of a non matching preamble address, a not-acknowledge is returned.

The slave remains active as slave-transceiver until a stop condition or a restart condition occurs. According to the value of the following RnW bit a new slave may be addressed or the same slave is requested to transmit more data. Additionally the following combined formats (and mixtures of these formats) are allowed (**Figure 330**):

- A master transmits data to a slave and then reads back data from the same slave. The transfer direction is changed after the restart condition.
- A master transmits data to one slave and then transmits data to another slave.
- 10-bit and 7-bit addressing combined in one serial transfer. After restart condition the new addressing mode is selected by the address itself.

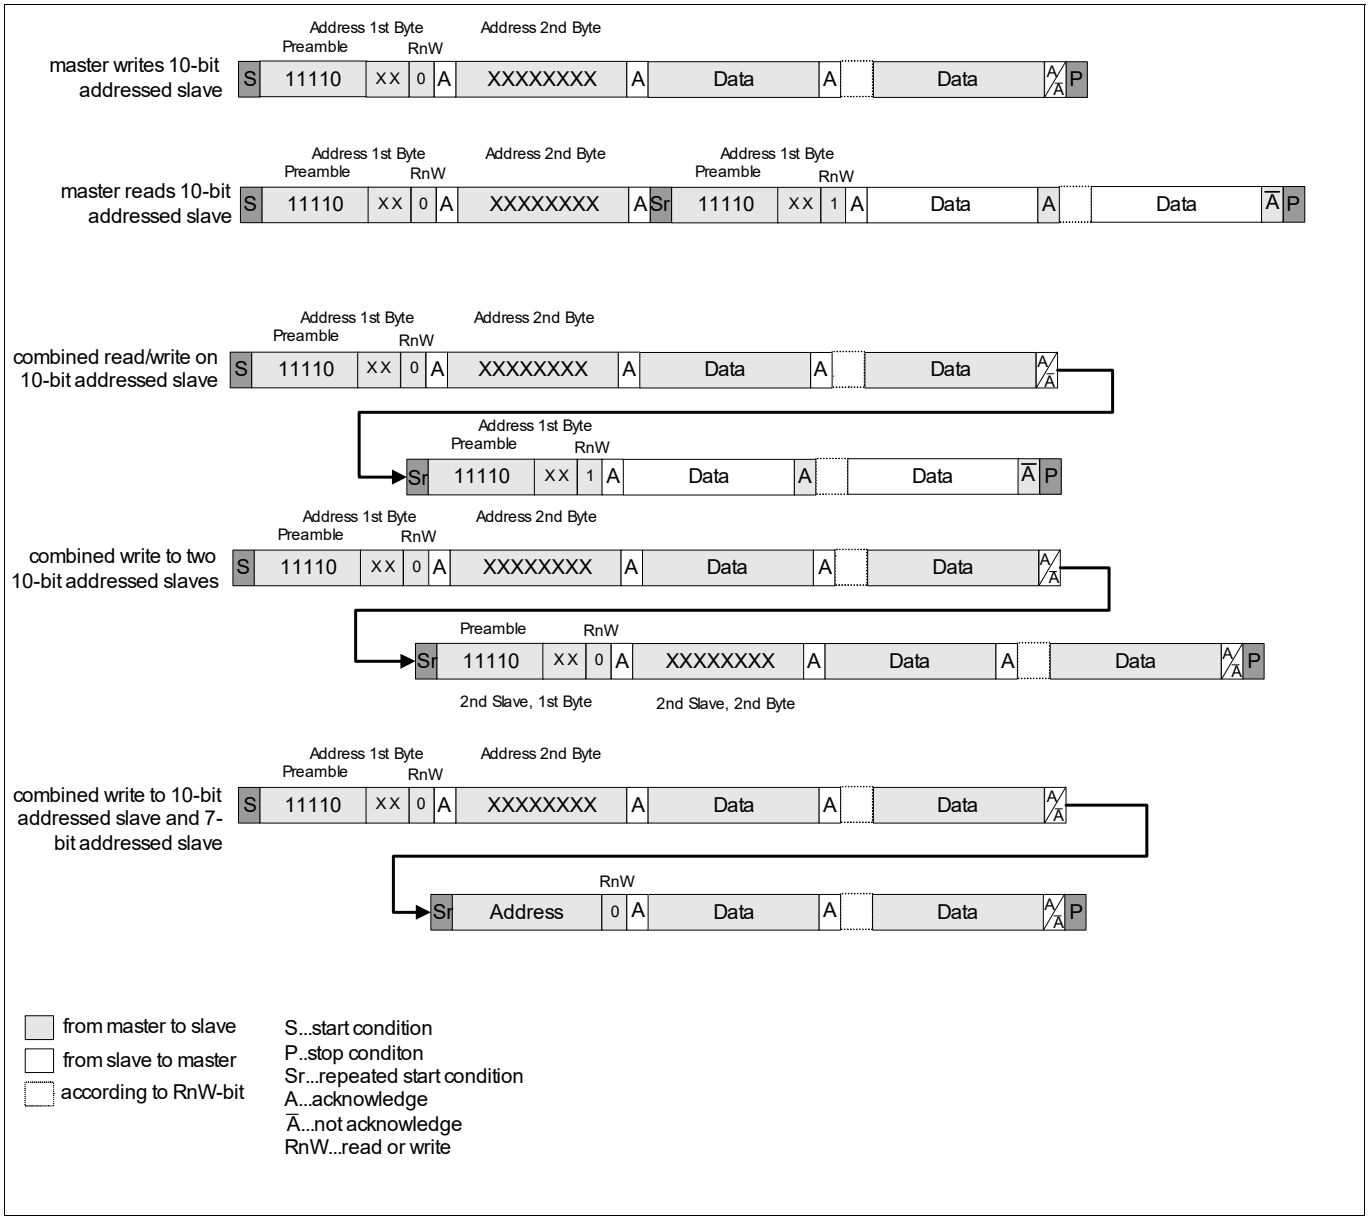

Figure 330 Types of I2C-bus 10-bit Address Formats

High-speed Mode

To support higher baud rates on the I2C-bus (up to 3.4 MBaud) the specification introduces the high-speed mode. To communicate at this higher baud rate the protocol uses a so called master code in place of the address byte to indicate that a master wants to change to the high-speed mode.

Special attention must be paid to meet the requirements of rise and fall times of the signal edges and other timing characteristics when working in high-speed mode. Also it is necessary to disconnect I2C-bus devices which are not able to follow the fast communication.

After the master sends this master code, no device is allowed to acknowledge it. The involved devices change to high-speed mode and the master starts the communication. The high-speed mode transmission behavior is the same as at lower baud rates with the exception that only restart conditions and stop conditions appear (no start condition). Since the master code determines a unique master device to control the bus, the arbitration process is finished after the master code sequence is put on the bus and must not be continued when working at the new communication speed.

Improvements to the regular I2C-bus specification for high-speed mode are given in section 13.1 of the I2C-bus specification version 2.1 **[1]**.

For high-speed mode there exists a separate configuration register **FDIVHIGHCFG** to program the baud rate; see also **Baudrate Generation for Master Mode**.

For more information, see the following documentation:

[1] I2C-bus specification version 2.1 standard (released January-2000)

34.3.1.3 Functional restrictions

There are some functional restrictions in this I2C module.

Multi-master mode - Master collision

The Multi-master mode is supported with a limitation/restriction in the following situation:

- The I2C module operates in master mode

- Another master wants to access/address the I2C module as slave

The resulting "master collision (problem)" cannot be handled correctly because the incoming address sent by the other master cannot be evaluated. So, if collision occurs second master has to restart access and retransmit the data.

Multi-master mode - Hold Time for the (repeated) Start condition

In a special situation this design step of the I2C module violates this timing specification by ~30% for Standard mode and by ~18,6% for Fast mode (min . 2.8 µs instead 4.0 µs for Standard mode and min. 0,488 µs instead 0,6 µs for Fast mode).

This occurs when data is written into TX FIFO, the I2C module is ready to start transmission an another master starts driving its startbit shortly before the I2C module starts driving. In this case the I2C Finite State Machine tries to win arbitration by reloading approximately half period in baudrate generator, so next SCL clock edge of the I2C module comes earlier than defined by t_7.

High-speed mode

The standard for the clock duty cycle ratio of the I2C high speed mode is 1:2. See **Chapter 34.3.1.4** in order to achieve the best duty cycle ratio for high speed mode. Note that not for every f_{I2C} frequencies 0% duty cycle ratio deviation can be achieved

34.3.1.4 Clock and Timing Control

The I2C module offers the following features to control clock and timing:

- Module clock control for integration logic clock and I2C kernel clock (see **Section 34.3.2.2**)
- Baudrate generation
- I2C signal timing adjustment

34.3.1.4.1 Baudrate Generation for Master Mode

A baudrate generation unit in the I2C kernel generates the SCL signal from the kernel_clk, controlled by settings of parameters **INC**, **DEC**, and **FS_SCL_LOW** in registers **FDIVCFG** (normal and fast mode), **FDIVHIGHCFG** (high speed mode), and **TIMCFG**.

The I2C standard has some special requirements for the clock, like

- asymmetric duty cycle
- slave or other masters are allowed to delay the clock by extending the low period. For this reason, a master must check, if any slave holds the clock line low after the master set the clock line to high. This implies that the state machine of a master needs at least 1 internal clock cycle delay between setting the clock to high and reading it back to check if it actually reached high level already. In addition more delay cycles can be introduced by the time constant of the pull up resistor and the line capacity. In any case, this protocol has the consequence that the actual baud rate will always be lower than the nominal baud rate.

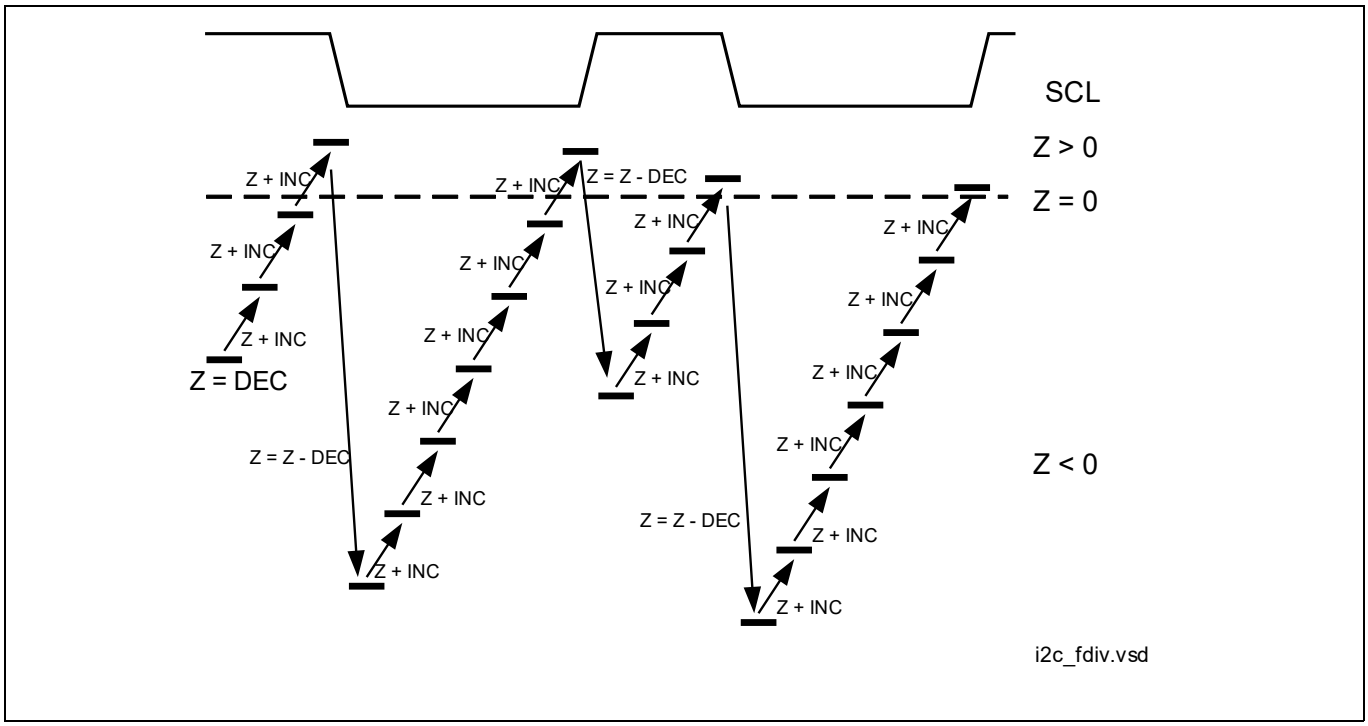

Figure 331 FDIV Principle - example for high speed mode

The operation principle of I2C fractional divider is shown in **Figure 331**. A counter Z is set to value **DEC** and is incremented using value **INC**. When counter reaches Z=0 it will be decremented using value **DEC**. With each decrementing operation SCL is toggled to achieve the required SCL waveform. Correction values are also applied to this mechanism but not shown above.

The formulas in the **Table 297** show how to calculate **DEC** and **INC** for a configured f_{SCL} frequency and a given f_{I2C}.

EN_SCL_LOW_LEN, **FS_SCL_LOW** and **SCL_LOW_LEN** are bit-fields in register **TIMCFG**.

Table 297 I2C Baudrate Generation Configuration for Master Mode

MODE	EN_SCL_LOW_LEN	FS_SCL_LOW	f_{SCL}	Low Time Correction	Duty Cycle
Standard	0	0	$fSCL = \frac{INC}{2DEC + 3INC} \times fI2C$ (34.1)	-	-
Fast	0	1		-	-
	1	X		1) $SCL\_LOW\_LEN = \frac{3INC}{2}$ (34.2)	-
High speed	X	X	$fSCL = \frac{INC}{5DEC + 2INC} \times fI2C$ (34.3)	-	1:2

1) This formula can be use to achieve a 50% duty cycle. **SCL_LOW_LEN** can be program with other values, but not greater than **DEC**.

In **Table 298** some example settings to program **INC**, **DEC** and LTC (bit-field **SCL_LOW_LEN**) are given and information about the duty cycle is shown.

Table 298 I2C INC/DEC Settings for Master Mode

I2C MODE	f_{I2C} [MHz]	INC	DEC	SCL_LOW_LEN	Duty Cycle [%]	f_{SCL} [MHz]
Standard	66.6	1	332	-	56.3	0.099
Fast	66.6	2	170	3	50	0.384
High speed	66.6	46	162	-	30.6	3.399

If a slave device is sensitive for violation of max frequency according I2C standard (eg. 3.4 MHz in High-speed mode) it is recommended to select a target SCL frequency with some margin to this limit.

34.3.1.4.2 Baudrate Generation for Slave Mode

Baudrate generation is mainly used for master mode, but there is one corner case where a support of the baudrate generation is required in slave mode: when I2C is in slave mode with a pending transmit data request and FIFO is currently empty then SCL is kept low until FIFO is filled after some time. Then transmit data is sent out immediately. SCL is kept low for a min. time of t_4.

In order to keep the set-up time,t_4 , according to I2C standard, the baudrate generation is used to guarantee the delay on SCL. The formulas in the 3rd and the 4th column of **Table** show how to configure **DEC** and **INC** for a given f_{I2C} and the intended set-up time. The formulas in column **Resulting t4 [µs]** define the real value of t_4 with the selected **DEC** and **INC** values.

The same value for **DEC** and **INC** as in master mode is not recommended and would lead to additional delay, as requested by the standard, in most cases.

Table 299 I2C Baudrate Generation Configuration for Slave Mode

MODE	min t_4[µs]	DEC / INC	Resulting t_4 [µs] 1)2)
Standard	0.25	$DEC = \frac{8}{9}((fI2C) \times (t_4) \times INC + INC)$ (34.4)	$C = INT\left(\frac{DEC + DEC(div)8}{INC} - 1\right)$ (34.5) $\frac{C}{fI2C} = t_4$ (34.6)
Fast	0.1	$DEC = \frac{4}{5}((fI2C) \times (t_4) \times INC + INC)$ (34.7)	3) $C = INT\left(\frac{DEC + DEC(div)4}{INC} - 1\right)$ (34.8) $\frac{C}{fI2C} = t_4$ (34.9)
High speed	0.01	$DEC = INC + 1$ (34.10)	$C = INT\left(\frac{DEC}{INC} + 1\right)$ (34.11) $\frac{C}{fI2C} = t_4$ (34.12)

1) The used abbreviation INT is the integer function.
2) The operator div denotes the integer division: a div b = greatest integer not greater than a/b.
3) SCL_LOW_LEN can not be greater than DEC.

In the following table some example settings are given to program **INC** / **DEC**.The used abbreviation INT is the integer function.

Table 300 I2C INC/DEC Settings for Slave Mode

I2C MODE	f_{I2C} [MHz]	INC	DEC	t_4 [ns]
Standard	66.6	20	314	250
Fast	66.6	25	160	105.1
High speed	66.6	250	251	30

The minimum kernel frequency is 8MHz for Standard and Fast Mode and 55MHz for High Speed Mode.

34.3.1.4.3 I2C Timing Adjustment

The I2C standard includes a number of requirements for the SCL and the SDA timing. These cannot always be fulfilled by the timing of the pads. Therefore, additional timing adjustment options are provided in the controller logic.

Various timings of signals can be shifted by multiples of kernel_clk cycles, as defined in register **TIMCFG**.

These settings offer a wide range of timing compensation. Not all of the values can be used and will result in a valid I2C timing, even clock or data hang-up is possible. Detailed analyses should be done - eg. during chip evaluation - taking actual kernel_clk and external timing into account.

SDA_DEL_HD_DAT

- Delays SDA output data starting from SCL falling edge for a defined number of kernel_clks.
- Must not exceed SCL low period to keep setup time for collision detection at next SCL rising edge.

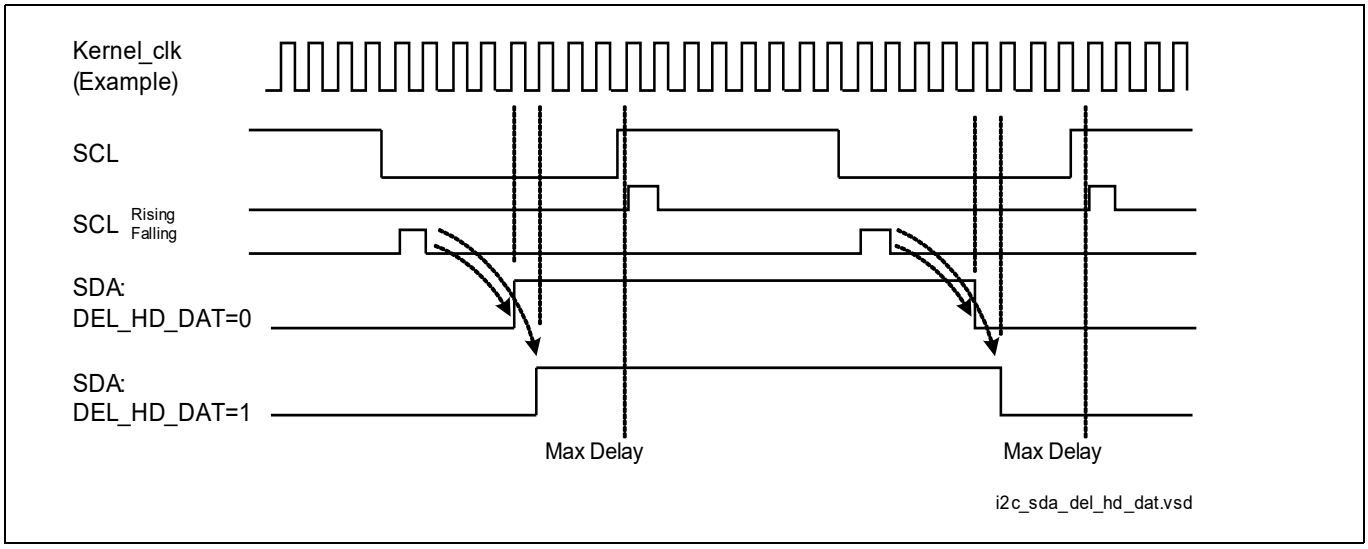

Figure 332 SDA_DEL_HD_DAT

High Speed Mode corrections

In **Figure 333**, the base period and delay corrections are shown for the entering and stop phases of HS mode.

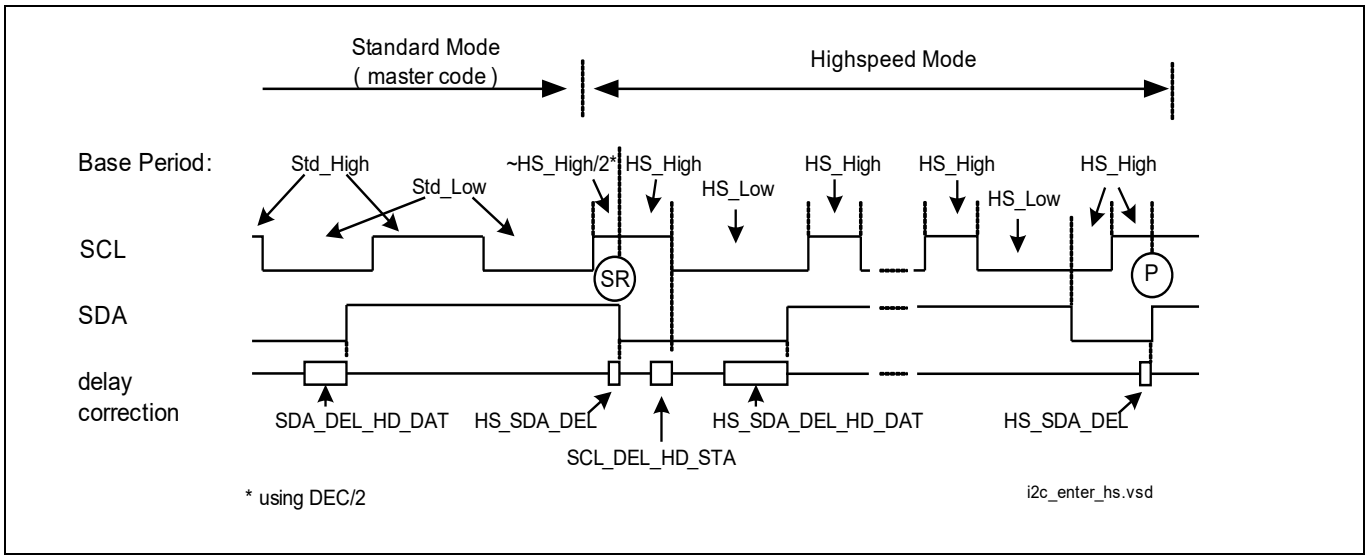

Figure 333 High Speed Mode corrections

34.3.1.5 I2C Kernel Control Logic

The I2C kernel can work in four different modes:

- Master-transmitter
- Master-receiver
- Slave-transmitter
- Slave-receiver

A state machine description can give a good and fast overview of the functionality. Also nearly all possible conditions can be rebuilt by stepping through the state machine and most of the error handling is covered by it. So this method is used to describe the I2C kernel.

Beginning with the top-level state machine, the starting up procedure is covered and together with the slave process and the master process sub-state machines, the active operations are comprehensible. These three state machines and their state transitions are described in the following.

As the I2C-bus working principle is packet orientated, the FIFO is typically configured as flow controller and so it issues the burst- and single-requests. This configuration is established by programming the bits **RXFC** and **TXFC** of the **FIFOCFG** register. Writing to the **TPS** bit-field of the **TPSCTRL** register starts the transfer.

Notes

1. *Peripheral is flow controller. As the I2C working principle is packet oriented, the FIFO is configured as flow controller and with this issues the burst- and single-requests. This configuration is established by programming the bit FC of the FIFOCFG register. Writing to the TPS-bitfield of the TPS_CTRL register starts the transfer.*
2. *Peripheral is not flow controller. In principle it is possible to use the FIFO in non flow controller mode. When the FIFO is not configured to operate as flow controller, the behavior of the FIFO operation has to be considered. The update of the FIFO fill level is only done when a stage is filled completely. In case of a (not protocol compliant) stopped transfer of the transmitter, the device is not able to evaluate the valid bytes since the FIFO issues interrupts/updates fill level only when a stage is filled completely. To prevent this behavior, the FIFO can be, for example, programmed to word alignment, so every received byte issues an interrupt/update. Anyway the software has to take care of such upcoming not protocol compliant data transmission stops, and has to handle this for example by programming an appropriate time-out.*

The Top-level State Machine

Figure 334 shows the top-level state machine. There are four states in the top-level state machine:

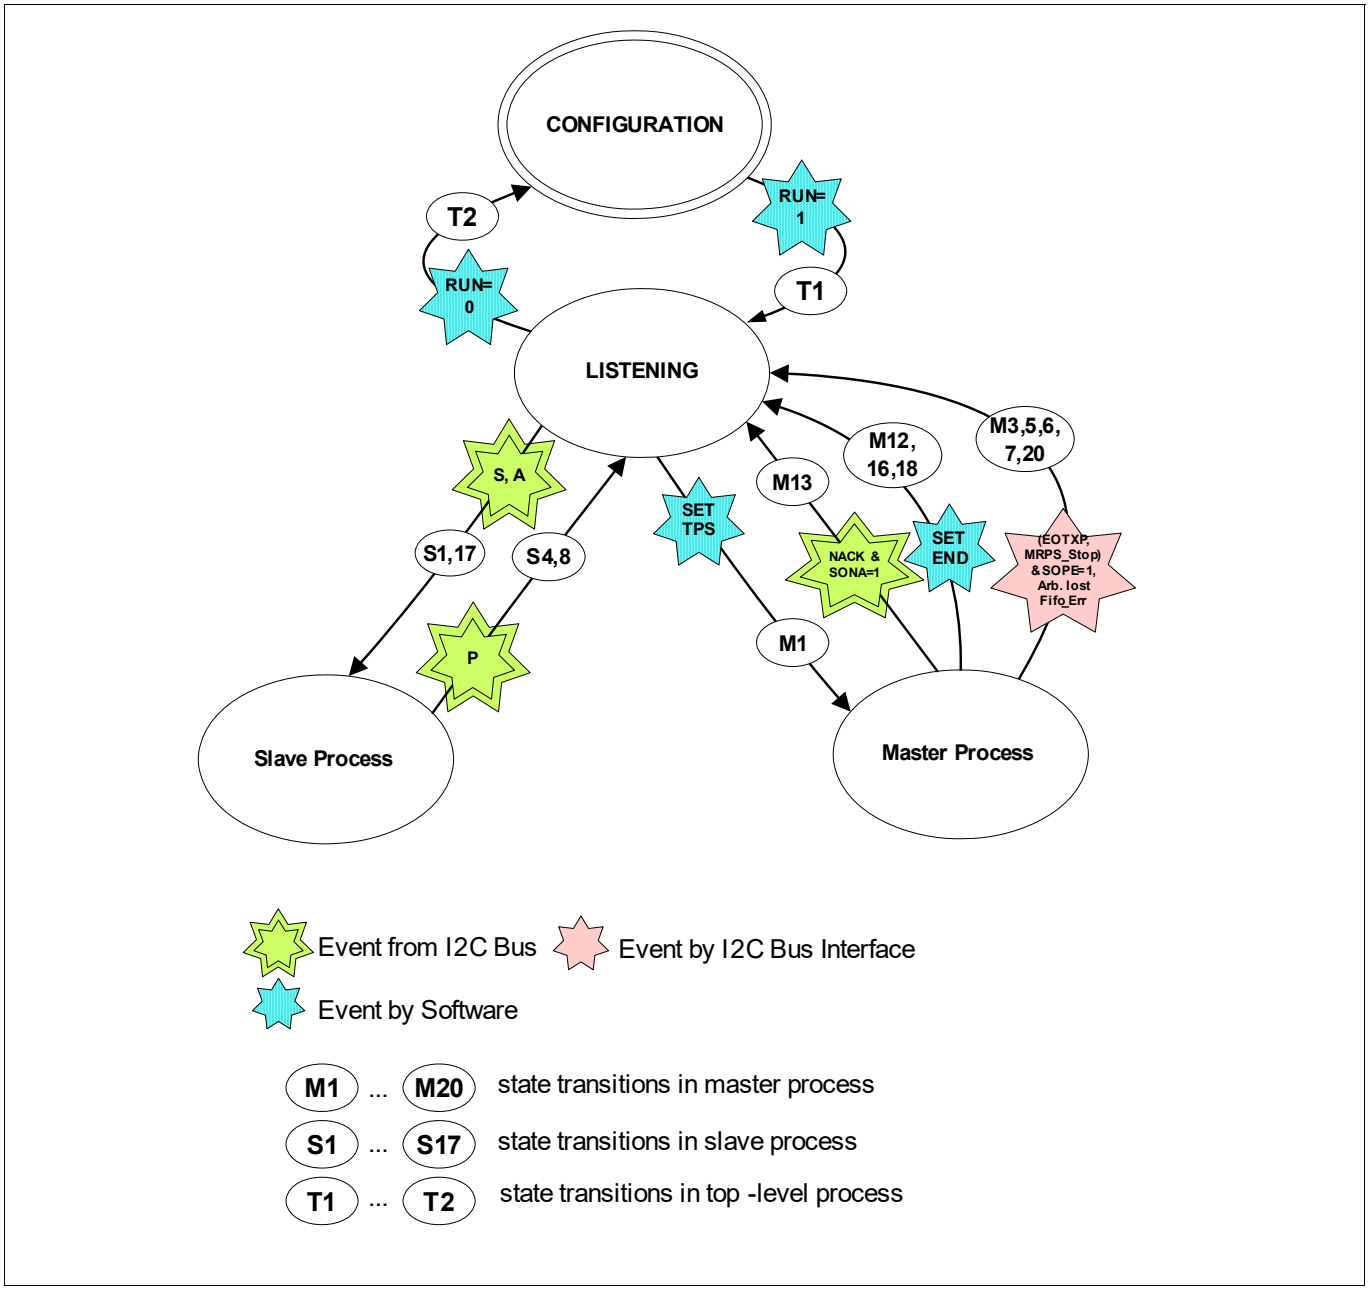

Figure 334 Top-level State Machine

CONFIGURATION: The peripheral is inactive; this is indicated by the **RUN** bit in **RUNCTRL** register, which is set to 0. In this state the peripheral should be configured by software by writing appropriate data words to the **ADDRCFG**, **FDIVCFG**, and **FIFOCFG** registers. This determines the following features:

- Peripheral is master or slave
- Address when accessed by another device
- Answering behavior to master calls and general calls
- Operating speed on the I2C-bus
- FIFO behavior

LISTENING: The peripheral has been activated by software. This state is entered in master and slave mode. The peripheral has to observe the bus for a certain time[1)] to ensure that there is no running transmission on the bus after this state has been entered. If no transitions on the I2C-bus are detected during this time period, the bus is supposed to be free. Otherwise the bit-field **BS** (bus status) in register **BUSSTAT** is set to 01_B (bus busy). Further functionality depends on the configuration: If the peripheral is a slave, only the slave process can be entered. If the device works as master, slave and master processes can be entered.

SLAVE PROCESS: A Start condition has been detected. The device is waiting for commands from the I2C-bus. This state represents the operation when acting as slave-transmitter or slave-receiver and is itemized in an own sub state machine.

MASTER PROCESS: The device is able to control the bus and work either as master-receiver or master-transmitter. Before the master can control the bus it has to set its clock frequency by programming its fractional divider with the appropriate value by writing it to the **FDIVCFG** register (when the I2C-bus is also operating in high-speed mode the appropriate values for INC and DEC have to be written to). The master process state is itemized in an own sub state machine.

The transition between the three states on the top-level are:

T1. The **RUN** bit has been set to 1 by software. The peripheral is activated and ready to observe the I2C-bus or react on transmission start commands.

T2. The **RUN** bit has been set to 0 again. I.e., because of new configuration effort, the peripheral is switched back to CONFIGURATION mode.

IMPORTANT: When “turning off” the peripheral it must be assured that no I2C-bus control responsibility is owned by the interface! Therefore the shut off process has to change the peripheral into a “secure” state and free the I2C-bus if necessary (generate a stop condition if in master mode). There are signals provided by the interface block which can be used to guarantee a secure shut off when turning off the I2C kernel.

1) One period of 1/100 kHz should be sufficient.

Slave Process Sub-state Machine

Figure 335 shows the slave process sub-state machine. There are 5 plus 1 (the listening state belongs to master and slave) different states in this sub-state machine:

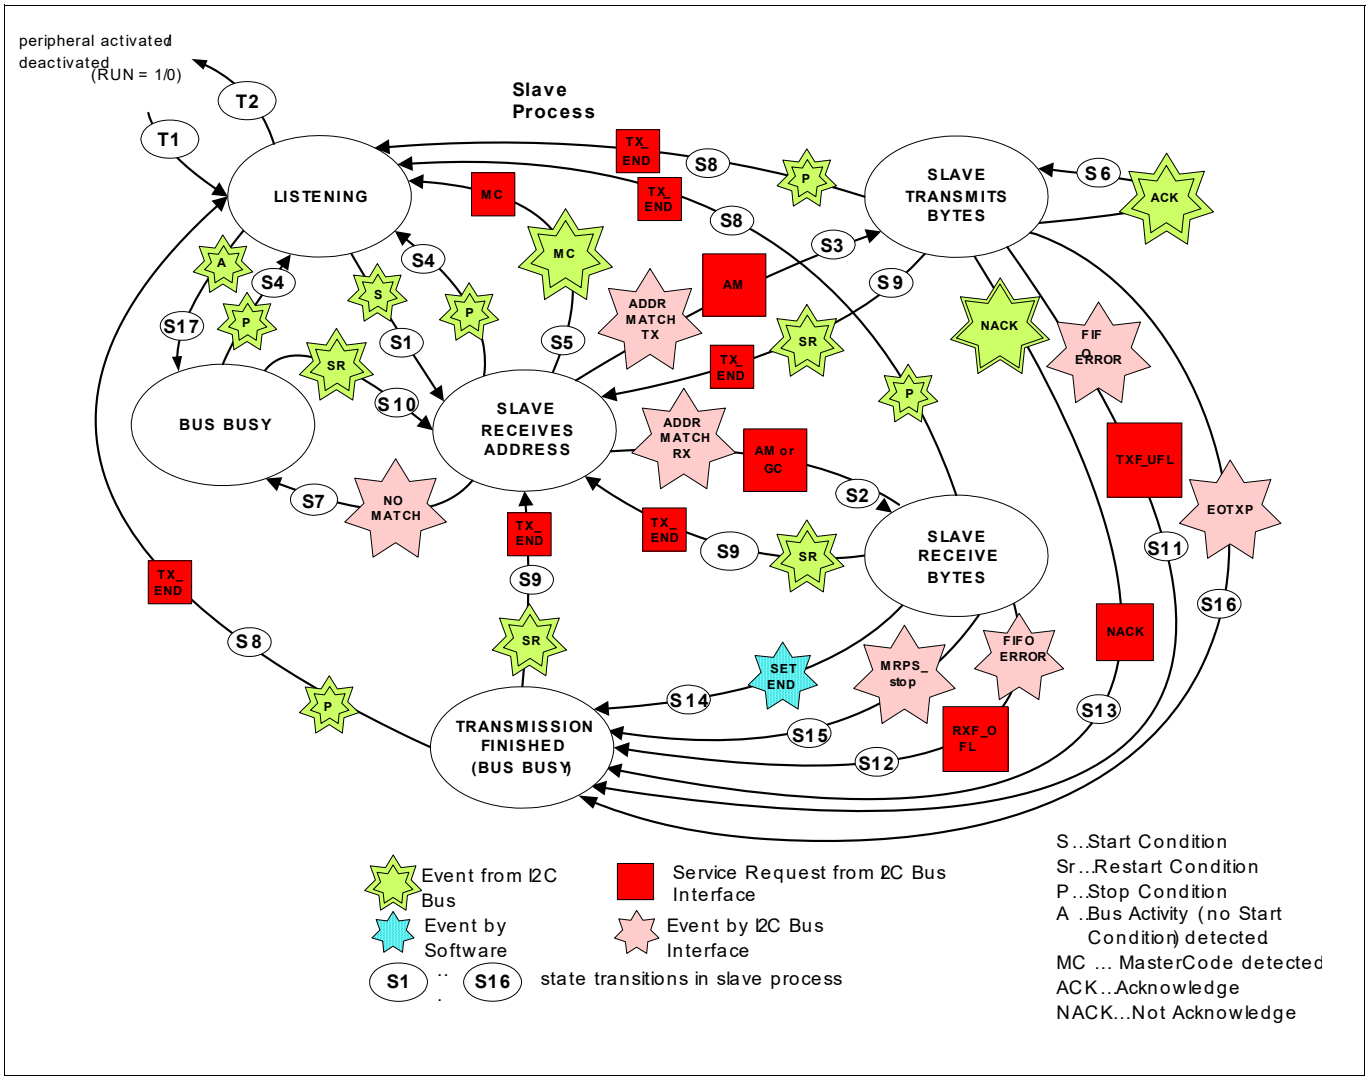

Figure 335 Slave Process Sub-state Machine

LISTENING: This state has been previously described (**Figure 334**). If the device is configured as slave, the module is listening only to the bus activity.

SLAVE RECEIVES ADDRESS: The module is shifting in the serial bits from the I2C-bus and acknowledges if the received byte(s) (first one in 7-bit address mode, first and second one in 10 bit address mode) match the adjusted address. During address matching the slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit, since this can be used as a bit-by-bit handshake procedure.

Note: The address byte(s) is (are) not shifted into the FIFO.

SLAVE RECEIVES BYTES: The module is shifting in the serial bits from the I2C-bus and acknowledges when the whole data byte has been transported to the FIFO. The slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit since this can be used as a bit-by-bit handshake procedure.

SLAVE TRANSMITS BYTES: The slave is allowed to hold down the SCL line when preparing the data for transmission. When valid data is available the slave releases the SCL line and waits for the clock cycles from the

master. The interrupt routine which proceeds when entering this state may write to the **TPSCTRL** register to initiate a transmission. This is only allowed if the bit-field **BS** (bus status) in register **BUSSTAT** in combination with the **RnW** clearly identifies the slave-transmitter mode of the peripheral. Otherwise writing to this register has no effect. First the I2C kernel gets a byte from the FIFO and puts it into a shift register. The module is then putting single data bits onto the I2C-bus and releases the SDA line after the 8th bit is sent.

*Note: Since the data flow control responsibility is task of the master device the slave should not stop transmitting bytes until the master tells it to do so. Therefore the **TPS** value in register **TPSCTRL** should be large enough to not run out of data bytes. In case of running out of data, the TRANSMISSION FINISHED state is reentered. The I2C data line is released to high level. The master continues receiving wrong values (0xFF).*

BUS BUSY: The bus is busy and the module is not involved in any data transfer. This is also the entry state when the bus is not free when starting up procedure is taking place (see state S17).

TRANSMISSION FINISHED (BUS BUSY): The module was involved in any data transfer. In distinction to the BUS BUSY state, the slave is still addressed by a master. Every time this state is left, caused due to a stop/restart condition, a TX_END request is generated as indication that the previous transmission has been closed.

The transitions which are connecting the several states are in detail:

S1: The module is detecting a start condition on the bus. It has to set the bit-field **BS** (bus status) in register **BUSSTAT** to 01_B. When this situation is occurring the I2C kernel is initialized since this indicates a new data transmission.

S2: The address which has been received matches the one stored in the address field in the **ADDRCFG** register. The **RnW** bit (8th bit in the first received byte) was set to 0. This means that the master wants to write to the slave. The corresponding bit **RnW** in register **BUSSTAT** is set to 1, i.e. the device continues working as slave-receiver. Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field **BS** (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request.

If the general call (GC) address matching is enabled by setting bit **GCE** in the **ADDRCFG** register, the device has to react also when it receives a general call (0x00). The GC request is issued and also an acknowledge has to be set on the I2C-bus when the GC is detected.

S3: The address which has been received matches the one stored in the address field in the **ADDRCFG** register and the SDA line was at a high level when the **RnW** bit was sent. This means that the remote master wants to read from the slave. The corresponding bit **RnW** in the **BUSSTAT** register has to be set to 0 (write). Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field **BS** (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request. The device is now working as a slave-transmitter.

S4: The device detects a stop condition on the I2C-bus and switches back to SLAVE LISTENING state. No interrupt is generated after the device was not addressed. The bit-field **BS** (bus status) in register **BUSSTAT** is set to 00_B (bus free).

S5: If the device is configured via bit MCE (master code enable) in the **ADDRCFG** register to react on a master code, the device can change baud rate to high-speed (Hs) mode when a remote master sends a master code. No device is allowed to acknowledge this master call. The interrupt routine which is called (MC request issued), has to handle the clearing of the interrupt bit in register **PIRQSC**. The LISTENING state is reentered. From now on the device works as slave in high-speed mode until a stop condition occurs.

S6: The slave-transmitter has received an acknowledge from the master-receiver and continues transmission.

S7: After the reception of the address bytes has been finished and no address match has taken place, the device changes to BUS BUSY state.

S8: The device has detected a stop condition on the I2C-bus after/while it was addressed. A TX_END (transmission end) request is generated, the bus is free again respectively the bit-field BS (bus status) in register **BUSSTAT** has to be set to 00_B again. The slave is now in LISTENING state.

S9: The slave has received a restart condition (repeated start condition) after/while it was addressed. A TX_END (transmission end) request is generated, the state switches back to SLAVE RECEIVES ADDRESS. The slave is reset again to a new transmission pending state (bit-field BS in register **BUSSTAT** = 01_B.). When the TBAM is activated (configuration register) the slave has to remember that it was addressed before because this event may be followed by a read access of the master to this device. So the address procedure after reset can be shortened and the transition S3 occurs one byte earlier (master sends 10-bit address mode byte with RnW bit = 1 (read)).

S10: A running transmission is ended by a remote master and this device wants to continue without losing control of the I2C-bus. The slave was not in transmission and resets to receive address bytes again since the new data transmission is concerning all connected slaves.

S11: The peripheral has problems to read data bytes from the FIFO (underflow/not ready). This is indicated by generating a TXF_UFL (TX FIFO underflow) request. It also changes to TRANSMISSION FINISHED state.

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B.) until a stop or restart condition occurs.*

S12: The peripheral has problems to write the received byte into the FIFO (overflow/not ready). This is indicated by generating a RXF_OFL (RX FIFO overflow) request. The slave-transmitter puts a not-acknowledge on the I2C-bus to indicate its situation to the controlling master. This byte is not valid and will be discarded.

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B.) until a stop or restart condition occurs.*

S13: The remote master wishes to close the connection to this slave and sets a not-acknowledge on the I2C-bus. The device generates a NACK (not-acknowledge) request and changes to TRANSMISSION FINISHED state (bit-field BS in register **BUSSTAT** = 01_B.). The interrupt routine can clear the appropriate bit via the corresponding bit in the **PIRQSC** register.

S14: The slave wants to stop the transmission and sets the **SETEND** bit in register **ENDDCTRL**. It puts a not-acknowledge on the I2C-bus after the next received byte. With this the slave gets the possibility to cancel the transmission via software intervention.

S15: The value of received bytes is equal to bit-field MRPS (maximum receive packet size) of the FIFO register **MRPSCTRL**. The FIFO part of the interface generates the signal MRPS_stop to the I2C kernel, which indicates the end of the received packet capacity. The slave produces a not-acknowledge to the master and changes to TRANSMISSION FINISHED. For more details on FIFO MRPS operation see **Section 34.3.1.6.5**.

S16: The number of transmitted bytes is equal to the TPS bit-field of the FIFO register **TPSCTRL**. The FIFO controller generates the EOTXP (end of transmit packet) signal to the I2C kernel, which indicates the last byte to transmit. After the last byte the device changes to TRANSMISSION FINISHED. For more details on FIFO EOTXP operation see **Section 34.3.1.6.2**.

Note: The master is not informed about this situation. Since the data flow control responsibility is task of the master device, it may continue receiving wrong values (0xFF).

S17: The module detects bus activity; no start condition has been detected before. A transmission may be currently in progress. The device changes to BUS BUSY state. This transition is performed if a start condition has been missed because the device was not activated (CONFIGURATION state).

Master Process Sub-state Machine

Figure 336 shows the master process sub-state machine. There are four different states in this sub-state machine:

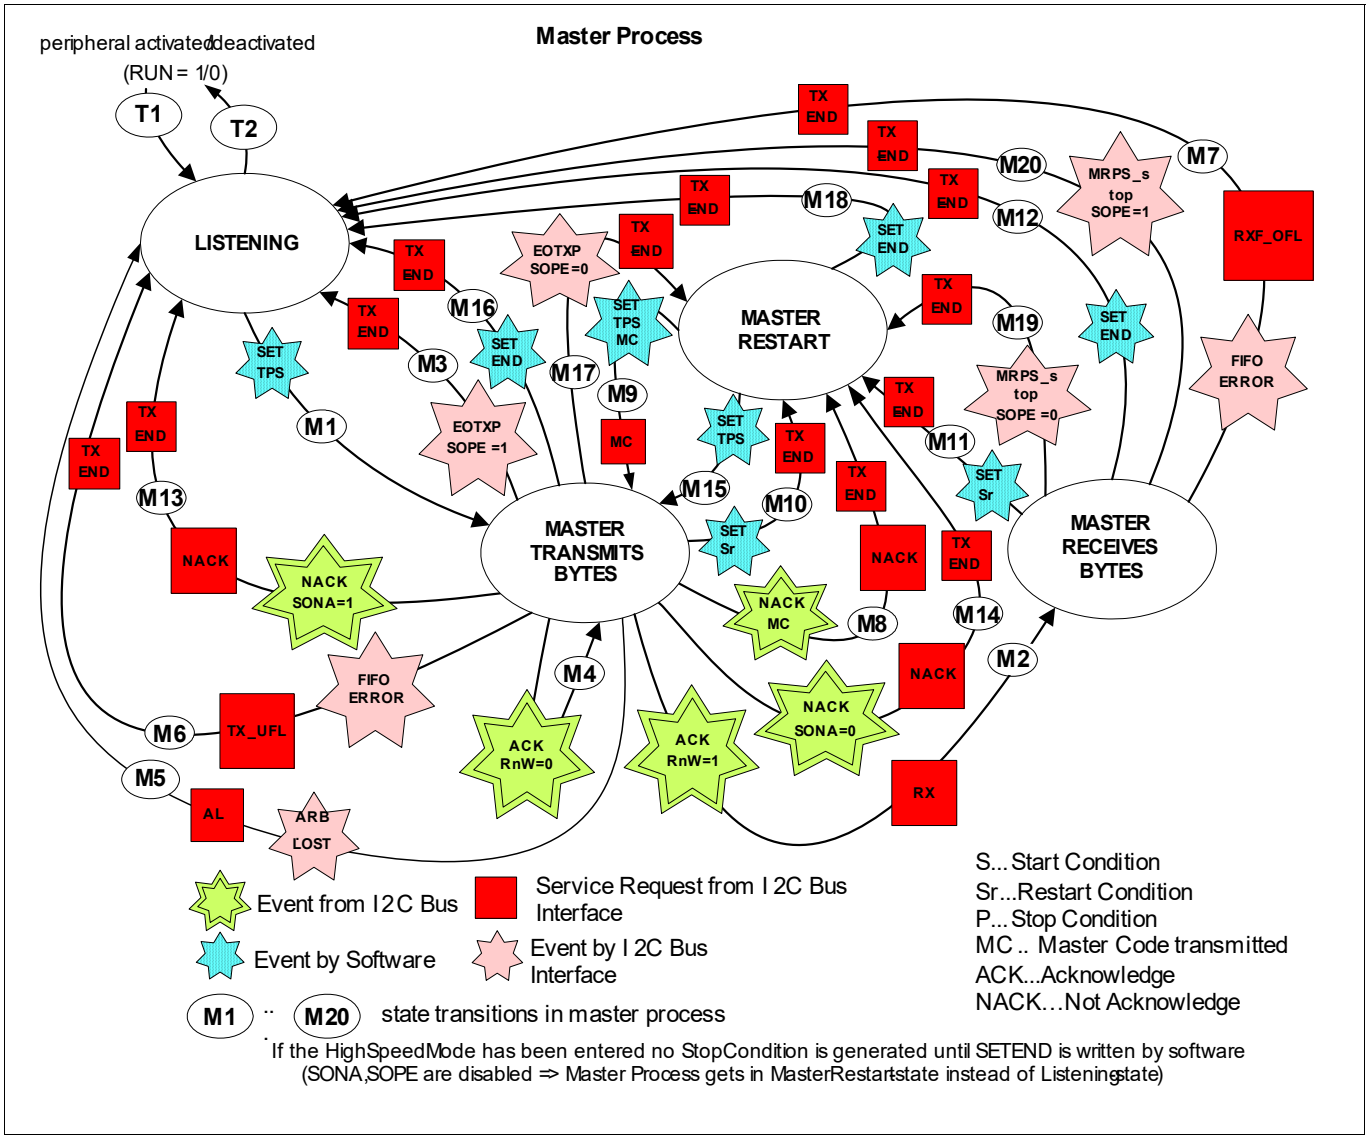

Figure 336 Master Process Sub-state machine

LISTENING: This state has been previously described (**Figure 334**). If the device is configured as master, it is listening to events either from software (writing to **TPSCTRL** register) or from the I2C-bus.

MASTER TRANSMITS BYTES: The device has started a transmission on the I2C-bus by software. The first byte after a start condition contains the address byte including the RnW bit. According to this bit (RnW bit in **BUSSTAT** register is set by hardware) the direction of the following transfer is determined. Bytes are transmitted on the I2C-bus until the FIFO is empty or a stop is initiated by software.

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RESTART: The device wants to restart a transmission without losing the control over the I2C-bus. The clock SCL stays low as long as no further communication is requested. The only event that should occur in this state is writing to the **TPSCTRL** register. Nevertheless the device can give up the I2C-bus control by writing to bit

SETEND in the **ENDDCTRL** register. Of course, when this situation occurs, the peripheral produces a stop condition on the I2C-bus.

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RECEIVES BYTES: The master has ordered bytes from the slave and handles the data transfer from the I2C-bus to the FIFO. This means that the bits are shifted into a buffer register in the I2C kernel and afterwards are passed to the FIFO. Every time a byte was transferred to the FIFO successfully the master-receiver produces an acknowledge in the according position.

The state transitions in the master process are:

M1: The software has written the number of bytes which have to be transmitted over the I2C-bus into the control register **TPSCTRL**. The FIFO generates appropriate data transfer requests which transfers valid data into the FIFO. A start condition is set on the bus and the bit-field BS (bus status) in register **BUSSTAT** is set to 10_B (busy master). The first (the first and the second) byte is (are) the 7-bit (10-bit) address of the slave which shall be accessed.

If the master wishes to initiate a transition to high-speed mode, the transition is only valid in combination with the MCE (master code enable) bit in the **ADDRCFG** register. The software has to write the master code into the FIFO, this means also the value of the **TPSCTRL** is predetermined with 1.

M2: The master receives an acknowledge from slave and the bit RnW in the **BUSSTAT** register was set to 1 during the addressing phase. A slave has been addressed successfully as transmitter, the state moves to MASTER RECEIVES BYTES. An RX (Receive) request is generated to distinguish between transmit- and receive-FIFO requests in non flow controller mode.

M3: The valid data packet from the FIFO was transferred successfully to the I2C-bus and the FIFO indicates this by the EOTXP (end of transmit packet) signal. If the RnW bit was set to 0 (writing to a slave) and bit SOPE (stop on packet end) in register **ADDRCFG** was set to 1, the transfer is closed by putting a stop condition on the bus. After this stop condition has been detected the peripheral indicates this successful transfer to the software via the TX_END (transmission end) request. The bus status bit-field is set to 0x0 (bus free).

M4: After the master transmits a byte it releases the SDA line to allow the addressed slave to pull down the SDA line (acknowledge). If this event occurs (and RnW in register **BUSSTAT** was set to 0), the master can continue to transfer bytes on the I2C-bus.

M5: The SDA line level is not equal to the one that is set by the master. This means that another master also tries to control the I2C-bus. This is indicated by the AL (arbitration lost) request and the device switches to the LISTENING state. The interrupt routine has to clear bit AL in the **PIRQSC** register. The Arbitration lost indication is not executable when the device works in high-speed mode (no arbitration procedure in high-speed mode since there is only one master remaining). The arbitration process must be operating at each bit which is sent by the master! Before interrupting the CPU, the bit-field BS (bus status) in register **BUSSTAT** is set to 01_B.

M6: If the master wants to transmit bytes but the FIFO is empty (underflow), it has to generate a TXF_UFL (TX FIFO underflow) request. The bit-field BS (bus status) in register **BUSSTAT** is reset to 00_B, and a TX_END (transmission end) request is generated after the master has put a stop condition on the bus.

M7: The I2C kernel wants to transfer bytes to the FIFO but without success. Then it has to produce an RXF_OFL (RX FIFO overflow) request. The current byte is not-acknowledged and a stop condition is put on the bus (bit-field BS in register **BUSSTAT** is set to 00_B and a TX_END (transmission end) request is generated). Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO. (

M8: If master code has been transmitted by the device and a NACK (not-acknowledge) has been received, the MASTER RESTART state is entered. The clock SCL stays low as long as no further communication is requested. This is done by writing bit-field TPS in register **TPSCTRL** (see transition M9).

M9: A new communication in high-speed mode is started by writing bit-field TPS in register **TPSCTRL** when a master code has been previously transmitted (M8). The switch into high-speed mode (MC request) is done as soon

as clock and data are released to high (see **Figure 337**). State MASTER TRANSMITS BYTES is entered. During high-speed mode, all fast and standard mode devices must be disconnected from the bus. This can be done in the MC request.

M10: Bit SETRSC has been set during the transmission of the data (the software wants to change direction/slave and therefore writes to the **ENDDCTRL** register). The I2C kernel resets and changes to MASTER RESTART state and a TX_END (transmission end) request is generated. Therefore, the master does not lose the control of the I2C-bus after the transmission has ended. The master stops transmission after the current byte was acknowledged/not acknowledged. Valid data in the FIFO are discarded. In this situation the FIFO is flushed to produce an initial situation.

M11: If the master wants to change direction/slave immediately in this state, it has to write to bit SETRSC in the **ENDDCTRL** register. The master puts a not-acknowledge on the appropriate place during the current transmitted byte. This indicates the slave-transmitter to stop transmission. The master switches to MASTER RESTART state; a TX_END (transmission end) request is generated.

M12: By sending a not-acknowledge on the bus, the master indicates the slave an upcoming stop of the transmission. This is established by writing to bit SETEND in register **ENDDCTRL**. Stop condition and TX_END (transmission end) request are generated. Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO. The LISTENING state is entered; the bit-field BS (bus status) in register **BUSSTAT** is set to 00_B.

M13: If the master is receiving a not-acknowledge and bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 1, it produces a stop condition, resets the bit-field BS (bus status) in register **BUSSTAT** and issues a NACK (not-acknowledge) request and a TX_END (transmission end) request. The FIFO is flushed; remaining data in the FIFO stages are discarded.

M14: If bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 0, the peripheral wants to remain the controlling master of the I2C-bus after receiving a not-acknowledge. The next state is MASTER RESTART. A NACK (not-acknowledge) request and a TX_END (transmission end) request indicate this event to the software. The FIFO transfers the valid data to the memory.

M15: The master decided to transfer data on the bus again and writes to the **TPSCTRL** register. The first byte is interpreted as address byte (the 8th bit indicates RnW). The appropriate data transfer requests are activated by the FIFO controller. After the SCL line is high again (slave can stretch the low period) the master is allowed to put a restart condition onto the bus and is again in the MASTER TRANSMITS BYTES state starting to transmit bytes again.

M16: The software has written the SETEND bit in the **ENDDCTRL** register. The peripheral stops transmission of bytes after the current byte has been written on the bus. The I2C kernel flushes the FIFO since the remaining data in the FIFO is invalid. A TX_END (transmission end) request is generated.

M17: The FIFO indicates the end of the data packet and the peripheral was configured to go into MASTER RESTART state after that event. Since the data transfer has ended as intended a TX_END (transmission end) request is produced.

M18: The master has no data to send anymore but still controls the I2C-bus. Therefore it can use the SETEND bit to give up the I2C-bus control by setting a stop condition. A TX_END (transmission end) request is generated.

M19: A value different to zero is programmed to bit-field MRPS (maximum receive packet size) of the **MRPSCTRL** register. If the number of received bytes is equal to the MRPS bit-field, the FIFO produces the MRPS_stop signal. When bit SOPE (stop on packet end) in the **ADDRCFG** register is set to 0, the master generates a not-acknowledge and changes to MASTER RESTART state, so the master does not lose the control over the I2C-bus. A TX_END (transmission end) request is generated.

M20: (See also M19.) The FIFO produces the MRPS_stop signal which indicates that the desired amount of received data bytes is reached. The peripheral generates a not-acknowledge and changes to LISTENING state because bit SOPE (stop on packet end) in the **ADDRCFG** register is set to 1. Of course, the interface produces a

stop condition; so the I2C-bus is free again (change also the bus status bit-field!). A TX_END (transmission end) request is also generated. Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO. The LBREQ or the LSREQ indicate the completed reception of data. For more details on FIFO MRPS operation see **Section 34.3.1.6.5**.

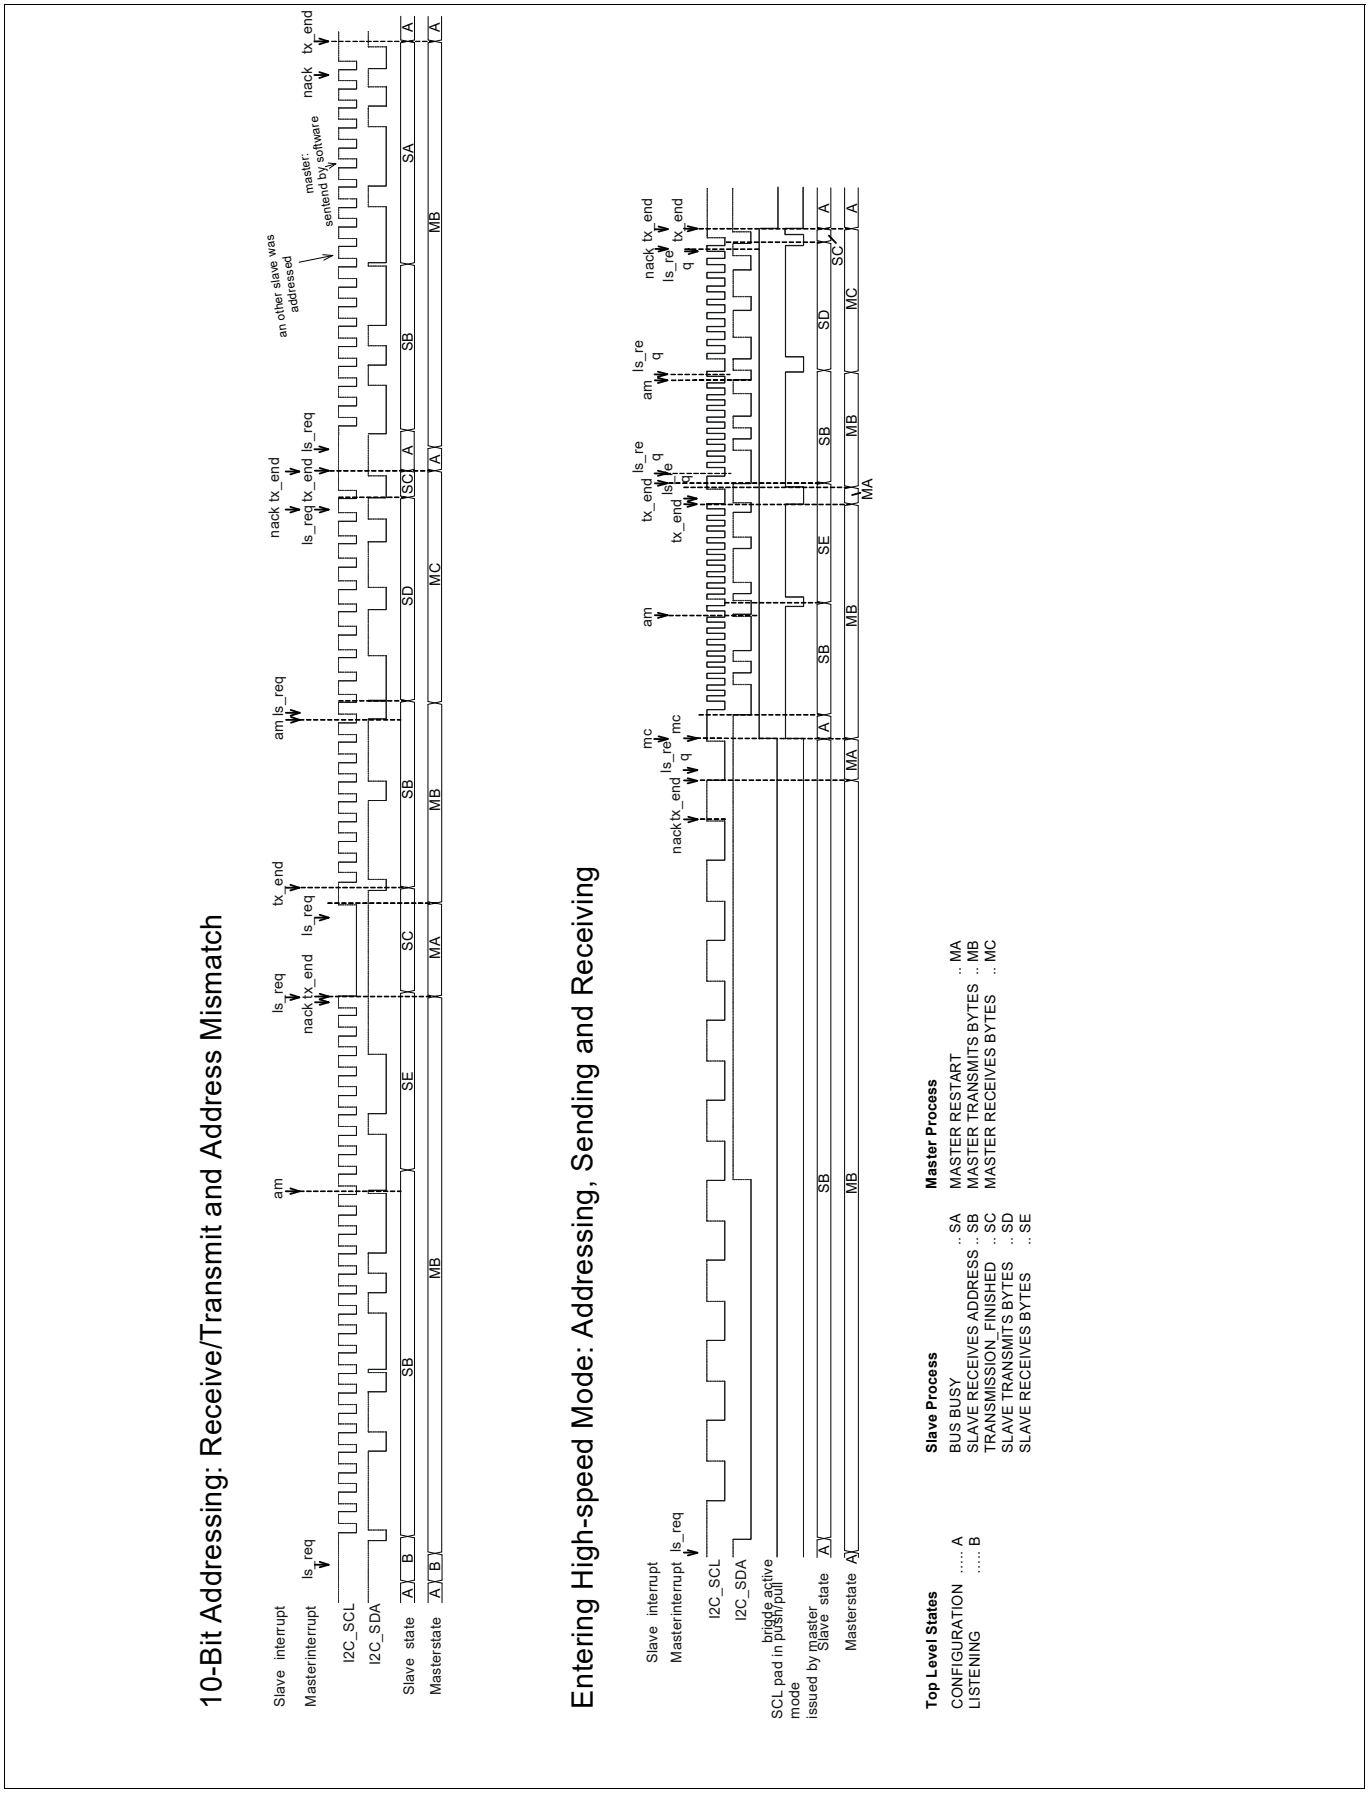

Figure 337 Connection Examples including Requests in Master and Slave Mode

34.3.1.6 FIFO Operation

The I2C module uses a FIFO between its kernel and the bus, in order to adapt the character processing speed of the peripheral to the transfer rate of the bus system. The FIFO has a transmission state and a reception state. **Figure 338** shows the bidirectional half duplex FIFO unit with the input and output lines and with the corresponding FIFO registers.

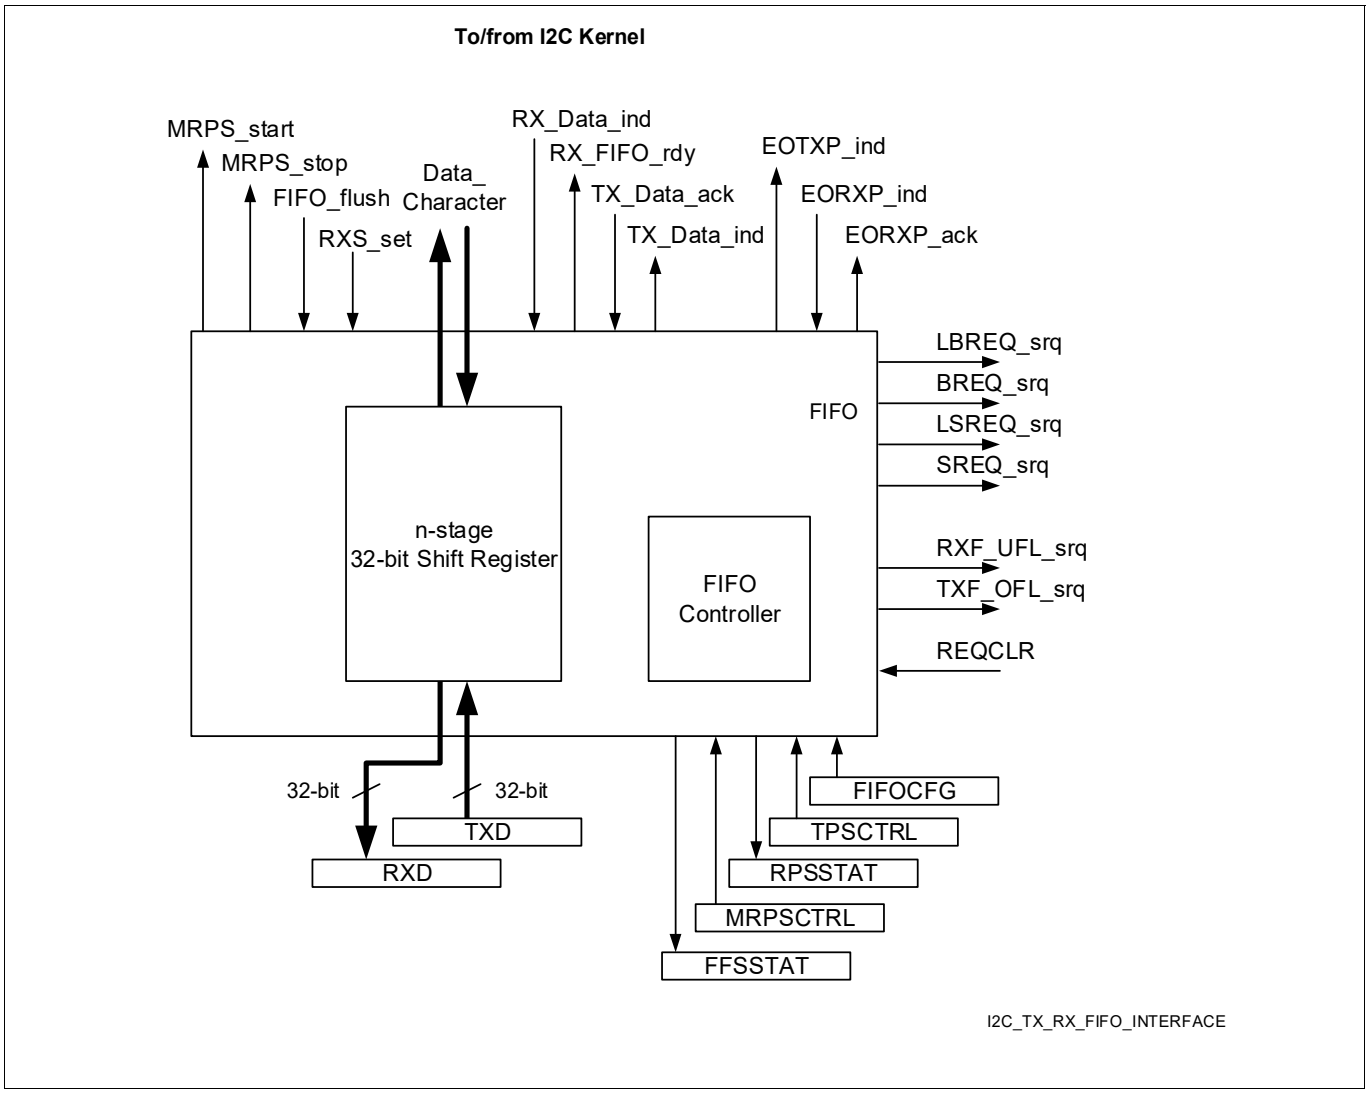

Figure 338 Bidirectional Half Duplex FIFO

Notes

1. *When the FIFO isn't serviced in time (transmission: filled with transmit data, reception: read the received data), an underflow/overflow event will lead to abortion of the transaction.To avoid this behaviour the software shall be configured to transfer a maximum of 32 bytes per transfer. If more than 32 bytes should be transmitted, the transmissions should be divided in maximum 32 data bytes per transfer*
2. *If bit-field **CRBC** in register **FIFOCFG** is disable, a linked list should be used to avoid that the CPU has to get active to clear the request. The DMA channel that serves I2C has to be configured with a linked list that first makes the FIFO-TX/RX transfer and second clears the interrupt by writing 0x0 to register ICR (Interrupt Clear Register) .*

34.3.1.6.1 Data Transmission

The software can move transmit data to the FIFO by writing to the Transmission Data Register **TXD**. Moving data to the FIFO can be done according to the data transfer request signals generated by the FIFO controller as described in **Section 34.3.1.6.2**. But with the register **FFSSTAT**, which indicates the number of full FIFO stages, the data transfer to the FIFO can be handled completely without data transfer requests. The data alignment within the FIFO is described in **Section 34.3.1.6.3**. The FIFO shifts data to the I2C kernel by means of the handshake lines tx_data_ind and tx_data_ack.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (see **Section 34.3.1.6.2**) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

In bit-field **CRBC** in the register **FIFOCFG**can be configured how to clear the FIFO request.

The I2C-bus interface should know when it is receiving the last character of a data packet from the FIFO. Therefore the software should define a transmit packet size in bit-field TPS of register **TPSCTRL** and then the FIFO controller indicates the last character of the packet to the I2C kernel by setting the EOTXP (end of transmit packet) signal.

Since TPS is double buffered the software can write the size of the next packet into **TPS** as soon as the **TPS** value of the current packet has been loaded into the TPS counter, i.e. reading **TPS** returns 0. It loads the new TPS value as soon as ithas room in the FIFO.

Also the characters of the next packet can be moved to the FIFO immediately after the current packet characters as indicated in **Figure 339**. If byte or half word alignment is used as described in **Section 34.3.1.6.3**, then the characters of two different packets must not be aligned in a single stage.

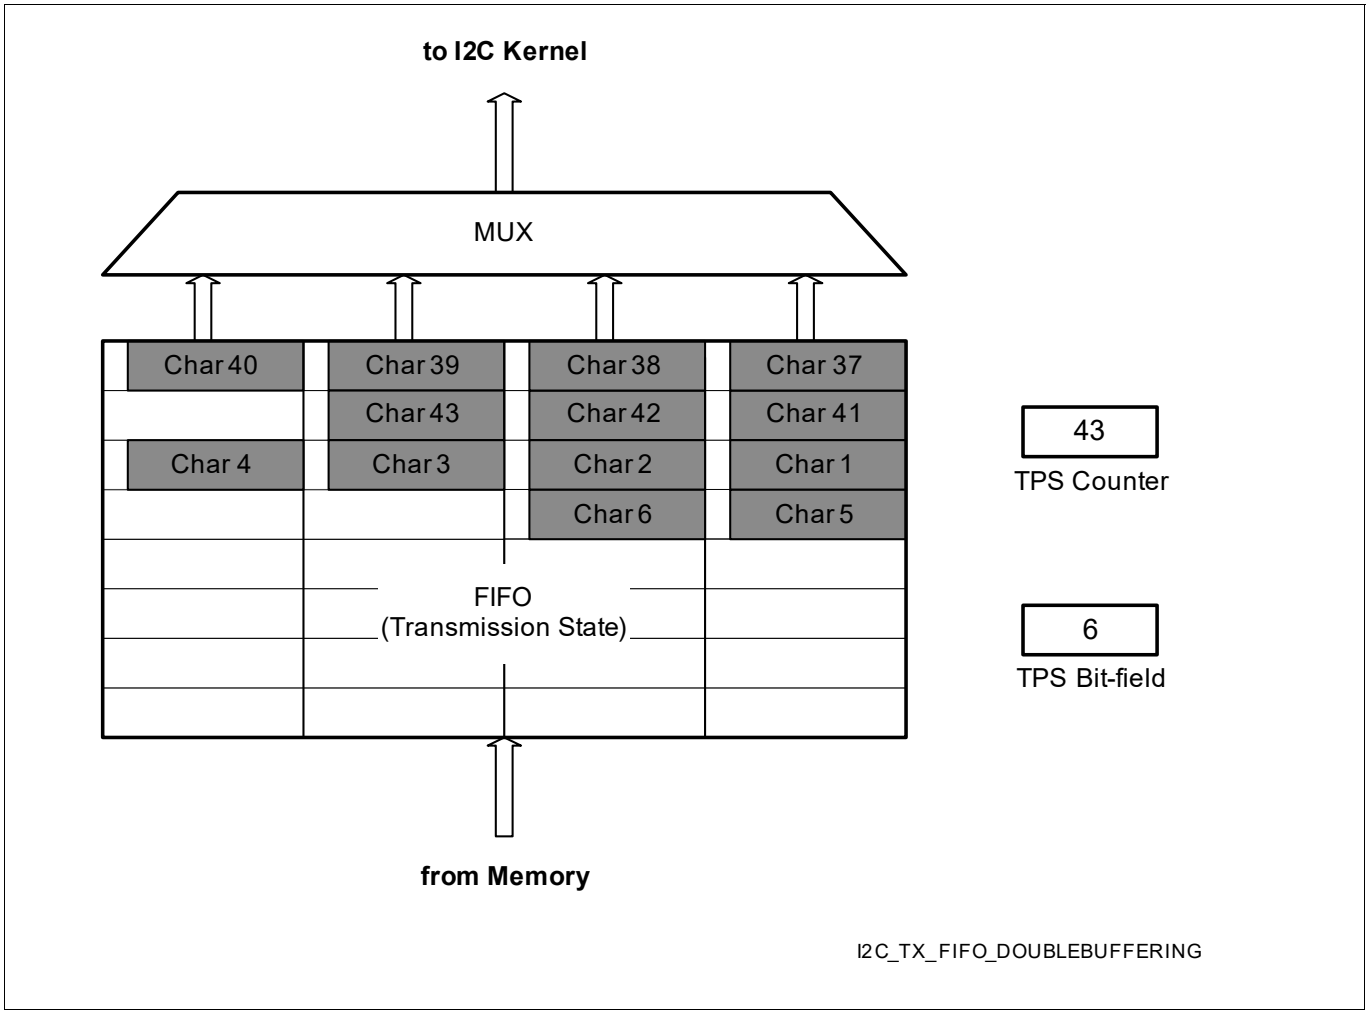

Figure 339 FIFO Containing Data of Two Different Transmit Packets

Error Handling

- If a TX FIFO overflow occurs (i.e. the software writes data too fast to the FIFO), then the new incoming character is discarded and a TX FIFO overflow interrupt request is generated.
- If a TX FIFO underflow occurs (i.e. the I2C kernel tries to read from an empty FIFO), then the I2C kernel generates a TX FIFO underflow interrupt request.

34.3.1.6.2 Transmit Request Generation

For the following it is assumed that the FIFO is used as flow controller, selected via bit **TXFC** of the **FIFOCFG** register.

In this case the bit-field **TPS** of the **TPSCTRL** register is not only used for the generation of the EOTXP (end of transmit packet) signal (see **Section 34.3.1.6.1**), but also to initiate the whole data transfer. I.e. the software indicates that it wants to transmit a data packet by writing the packet size to the bit-field **TPS**. Then the FIFO unit asserts burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size set in bit-field **TXBS** of register **FIFOCFG**. At this point, if the remaining data is equal to the burst size, then a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

If a data transfer (BREQ, LSBREQ, SREQ, LSREQ) request is pending, then no more request/interrupt will be done until the corresponding signal REQCLR has been cleared. The CPU (software) or DMA have to transfer the data to the FIFO and clear the generated interrupt.

Notes

1. *Pre-loading **TPS** with the packet size of the next frame, before the current packet has been transmitted completely, enables a continuous data throughput (e.g. of audio data).*
2. *If the FIFO is not used as flow controller, the I2C-bus interface should use bit-field **TPS** of the **TPSCTRL** register to set the EOTXP signal. A burst request BREQ is generated each time the number of empty FIFO stages is equal or greater than the burst size set in bit-field **TXBS** and the previous request was cleared. No single requests SREQ and LSREQ will be issued.*

34.3.1.6.3 Transmit Data Alignment

Depending on bit-field **TXFA** (TX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Note: Byte alignment is synonymous with character alignment, half word alignment with character alignment of two data characters, and word alignment with character alignment of four characters.

Byte Aligned TX Characters

If the TX characters are byte aligned, then the FIFO extracts the bytes and shifts them to the I2C kernel via a multiplexer as it is shown in **Figure 340**.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 4, the last word must be filled up with dummy bytes if necessary. The FIFO transmits only the valid bytes of the last word depending on the setting of the bit-field **TPS** of the **TPSCTRL** register.

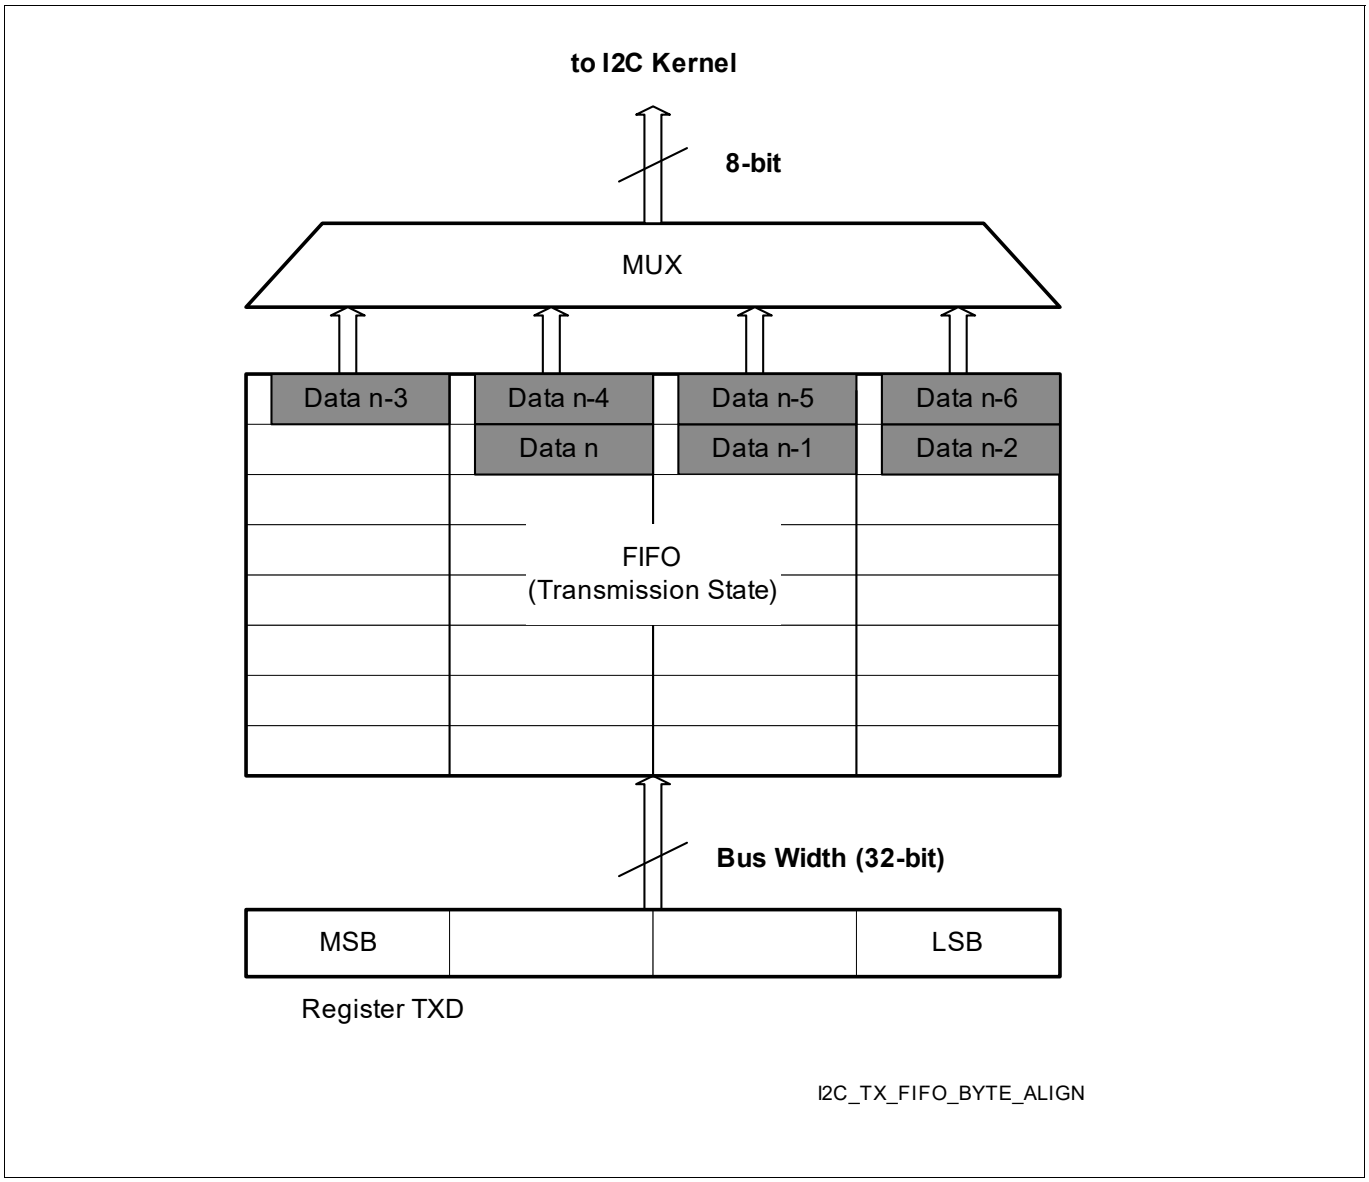

Figure 340 FIFO in Transmission State with Byte Aligned Data

Half Word Aligned

If the TX characters are half word aligned, then the FIFO extracts the half words and shifts them to the I2C kernel via a multiplexer as it is shown in **Figure 341**.

Note: The I2C kernel extracts the right data bits from the half word it receives from the FIFO.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 2, the last word must be filled up with a dummy half word if necessary. The FIFO transmits only the valid half words of the last word depending on the setting of the bit-field **TPS**.

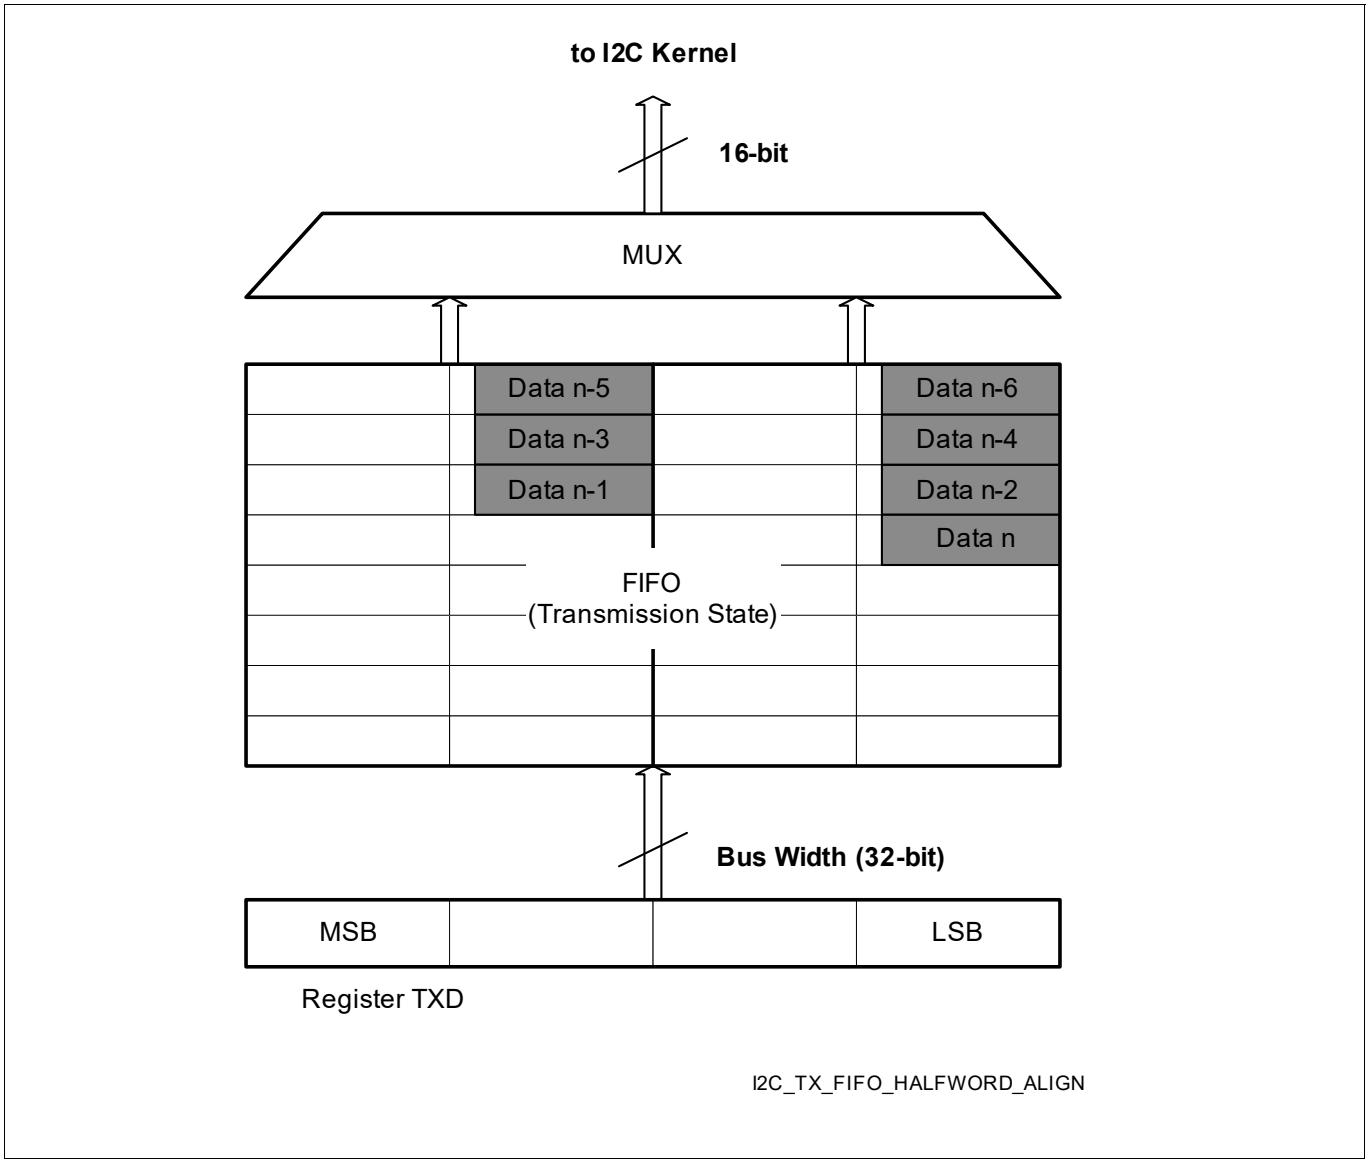

Figure 341 FIFO in Transmission State with Half Word Aligned Data

Word Aligned

If the TX characters are word aligned, then the FIFO shifts them to the I2C kernel as it is shown in **Figure 342**.

Note: The I2C kernel extracts the right data bits from the word it receives from the FIFO.

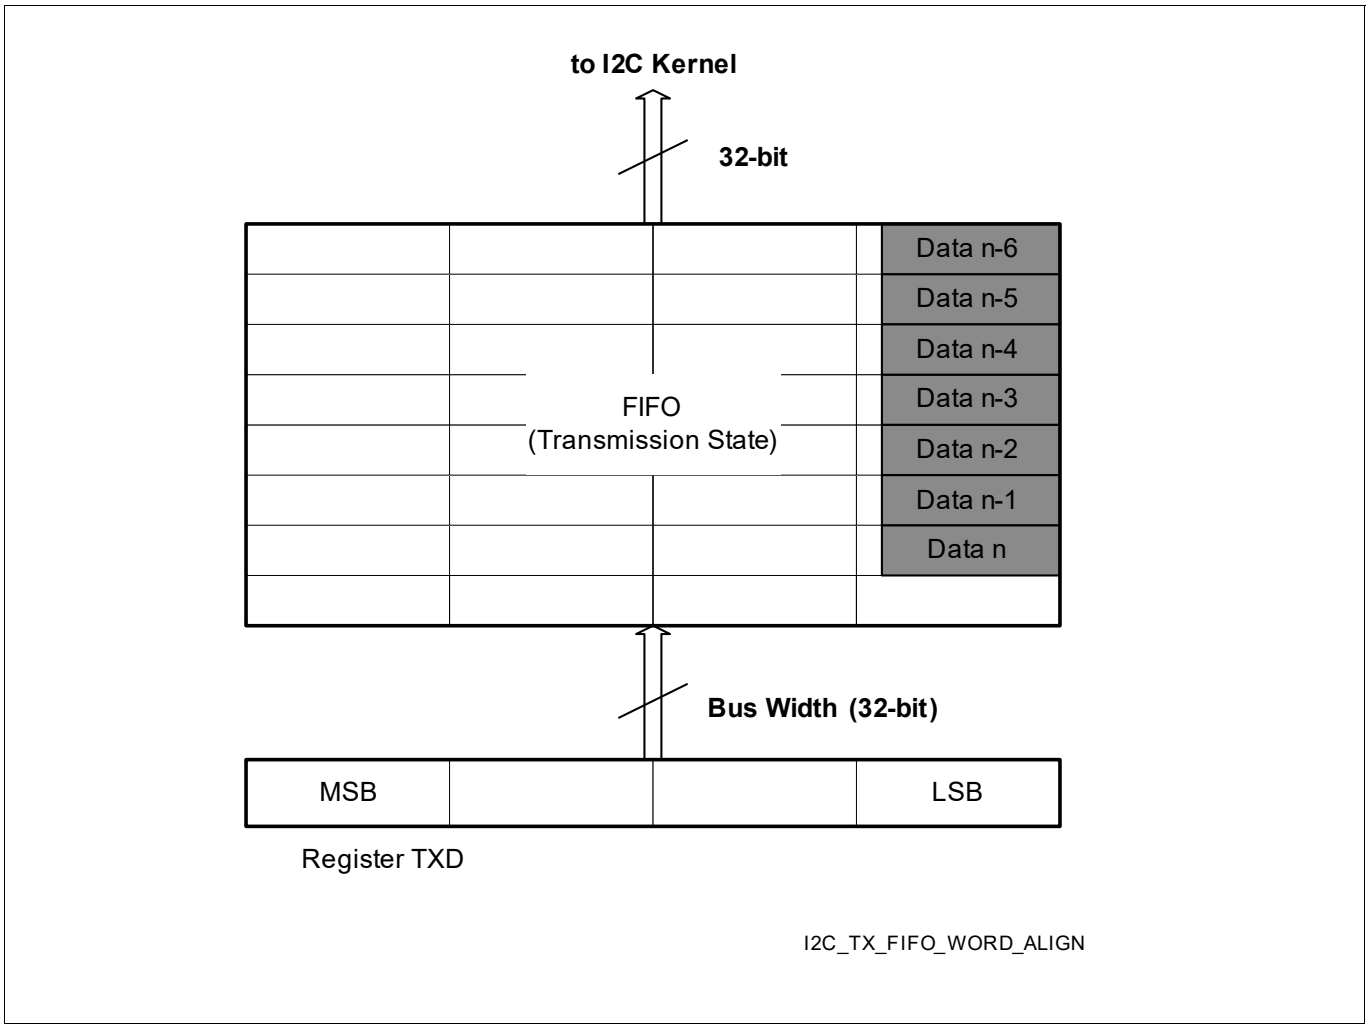

Figure 342 FIFO in Transmission State with Word Aligned Data

34.3.1.6.4 Data Reception

The software can read received data from the FIFO by reading the Reception Data Register **RXD**. Reading data from the FIFO should be done according to the data transfer request signals generated by the FIFO controller. The register **FFSSTAT** indicates the number of filled FIFO stages. The data alignment within the FIFO is described in **Section 34.3.1.6.6**. The I2C kernel shifts data into the FIFO by means of the handshake signals RX_FIFO_rdy and RX_Data_ind.

Before the first reception starts, the I2C kernel has to set the RXS_set line. This causes the assertion of RX_FIFO_rdy to indicate the I2C kernel that one data character can be written into the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request is pending and the FIFO is configured as flow controller, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

In bit-field **CRBC** in the register **FIFOCFG**can be configured how to clear the FIFO request.

Error Handling

- If the RX FIFO is completely full (i.e. the software reads out the data too slow), then the I2C kernel generates an RX FIFO overflow interrupt request.
- If an RX FIFO underflow occurs (i.e. the software reads from empty FIFO), then an RX FIFO underflow interrupt request is generated.
- If an error (including the FIFO overflow condition described above) is detected in the I2C kernel and the current reception is stopped, then it also has to generate an EORXP_ind signal, so that the remaining characters in the FIFO can be moved out by means of data transfer requests.

34.3.1.6.5 Receive Request Generation

If the whole data of the current received packet has been moved into the buffer, then the I2C kernel will set the EORXP_ind (end of receive packet indication) signal. The received characters, which are shifted in the FIFO, are counted by anRPS (received packet size) counter. If an EORXP_ind occurs, then the content of the RPS counter is moved to the register **RPSSTAT** and the counter is reset. If data alignment in the FIFO is used, then the **RPSSTAT** value can be used to check for valid characters in the last read word (see **Section 34.3.1.6.6**).

For the following it is assumed that the FIFO is used as flow controller, selected via bit RXFC of the **FIFOCFG** register.

The FIFO unit asserts burst requests BREQ each time the FIFO filling level is greater than the burst size set in bit-field RXBS of register **FIFOCFG**. An EORXP_ind causes the FIFO unit to assert burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size. At this point, if the remaining data is equal to the burst size, a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

If a data transfer (BREQ, LSBREQ, SREQ, LSREQ) request is pending, then no more request/interrupt will be done until the corresponding signal REQCLR has been cleared. The CPU (software) or DMA have to get the data from the FIFO and clear the generated interrupt.

When the packet has been shifted out of the FIFO by software, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.

The next received packet may be shifted into FIFO immediately after the current packet, so that the FIFO contains data of two different packets. But the EORXP_ind of the next packet must not be asserted before the EORXP_ind of the current packet has been acknowledged. The **RPS** counter is counting the characters of the next packet, while in the register **RPSSTAT** the packet size of the current packet remains readable. The first character of the new packet is always shifted in a new FIFO stage as indicated in **Figure 343**. (The FIFO data alignment is described in **Section 34.3.1.6.6**.)

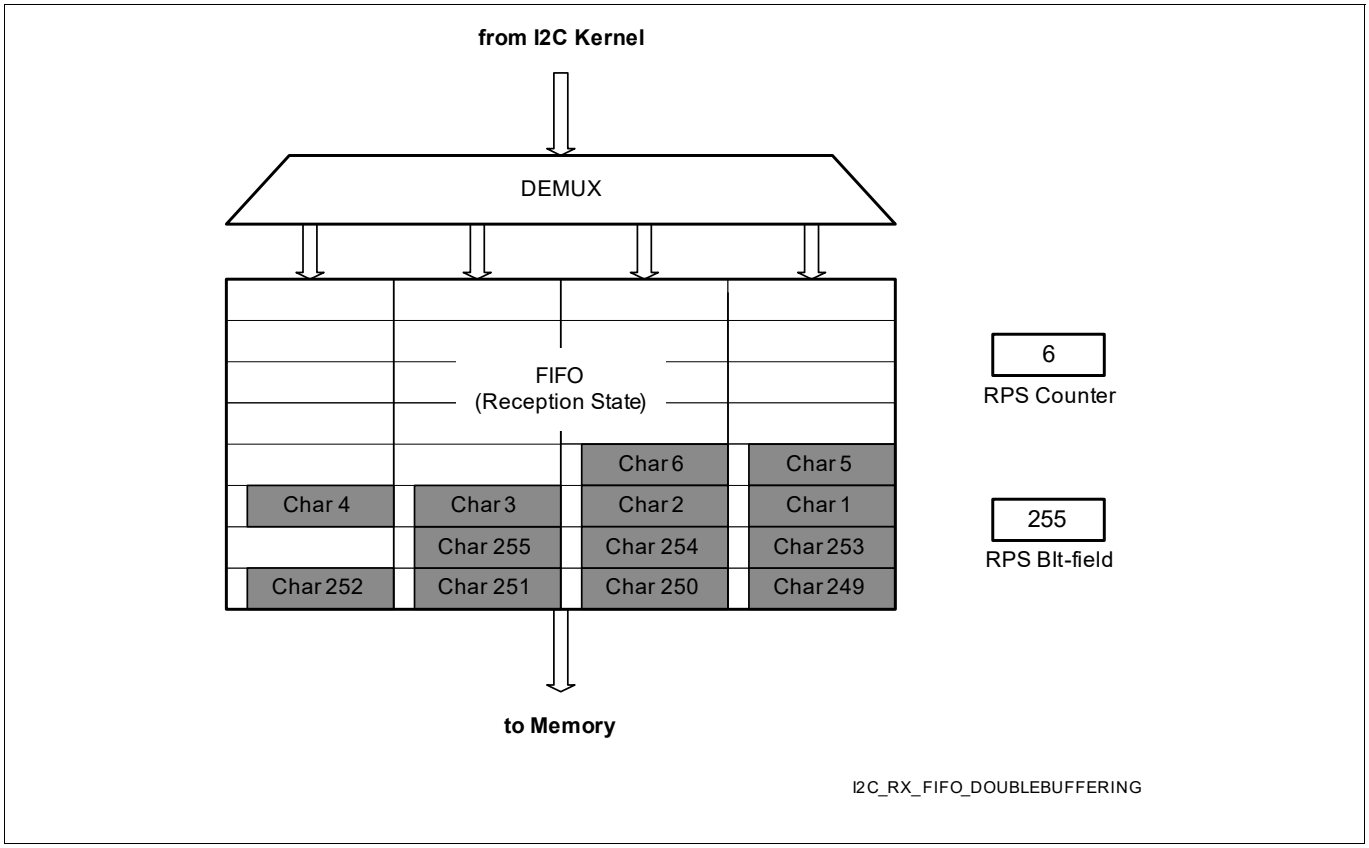

Figure 343 FIFO Containing Data of Two Different Receive Packets

If the number of the received characters of one packet is equal to the maximum received packet size, which is defined by bit-field MRPS in register **MRPSCTRL**, then the FIFO controller gets into the state, where it generates LBREQ or SREQ and LSREQ. If the I2C kernel generates an EORXP_ind in this state, then this indication is valid for the received packet and the FIFO accepts no more characters from the I2C kernel until the current packet has been moved out of the FIFO or the start of a new packet has been detected by asserting RXS_set.

The bit-field **MRPS** is double buffered, i.e. the software can write the **MRPS** value of the next packet as soon as the current **MRPS** value has been loaded, i.e. reading **MRPS** returns 0. It loads the new MRPS value as soon as it has room in the FIFO. If an **MRPS** overflow occurs (one character before the last character is received), then the MRPS_stop trigger to the I2C kernel is generated. But if the next **MRPS** value is written to **MRPS** before the last data character of current frame has been completely received, then no MRPS_stop is generated. The I2C-bus interface will use the MRPS_stop trigger to stop the reception of the corresponding data packet.

But the **MRPS** bit-field can also be used to initiate a reception, when the peripheral is master-receiver. Therefore writing to MRPS generates a trigger MRPS_start to the I2C kernel. The next MRPS value written to **MRPS** generates only an MRPS_start when an MRPS_stop was generated before.

The MRPS features can only be used if the FIFO is the flow controller.

Notes

1. *When the MRPS control feature of the FIFO is used to limit the packet size of a continuous incoming data stream (MRPS is only written once and left unchanged), characters exceeding MRPS are discarded. The FIFO can not handle more than two packets. When the FIFO is filled with data characters of two packets then a further RXS_set will be overseen by the FIFO. Additionally the FIFO does not set the RX_FIFO_rdy.*
2. *If the FIFO is not used as flow controller, a single request SREQ is always generated as soon as the readable FIFO stage is filled up with characters. Additionally, a burst request BREQ is generated as soon as the number of filled FIFO stages is equal to or greater than the burst size set in bit-field RXBS of register FIFOCFG. When the I2C kernel*

sets EORXP_ind, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.

34.3.1.6.6 Receive Data Alignment

Depending on bit-field **RXFA** (RX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Byte Aligned

If the RX data should be byte aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in **Figure 344**.

Since the number of characters of the received packet is not necessarily a multiple of 4, the upper bytes of the last word can be invalid. The software has to check for invalid bytes of the last word by means of the bit-field **RPS** (received packet size) in register **RPSSTAT**.

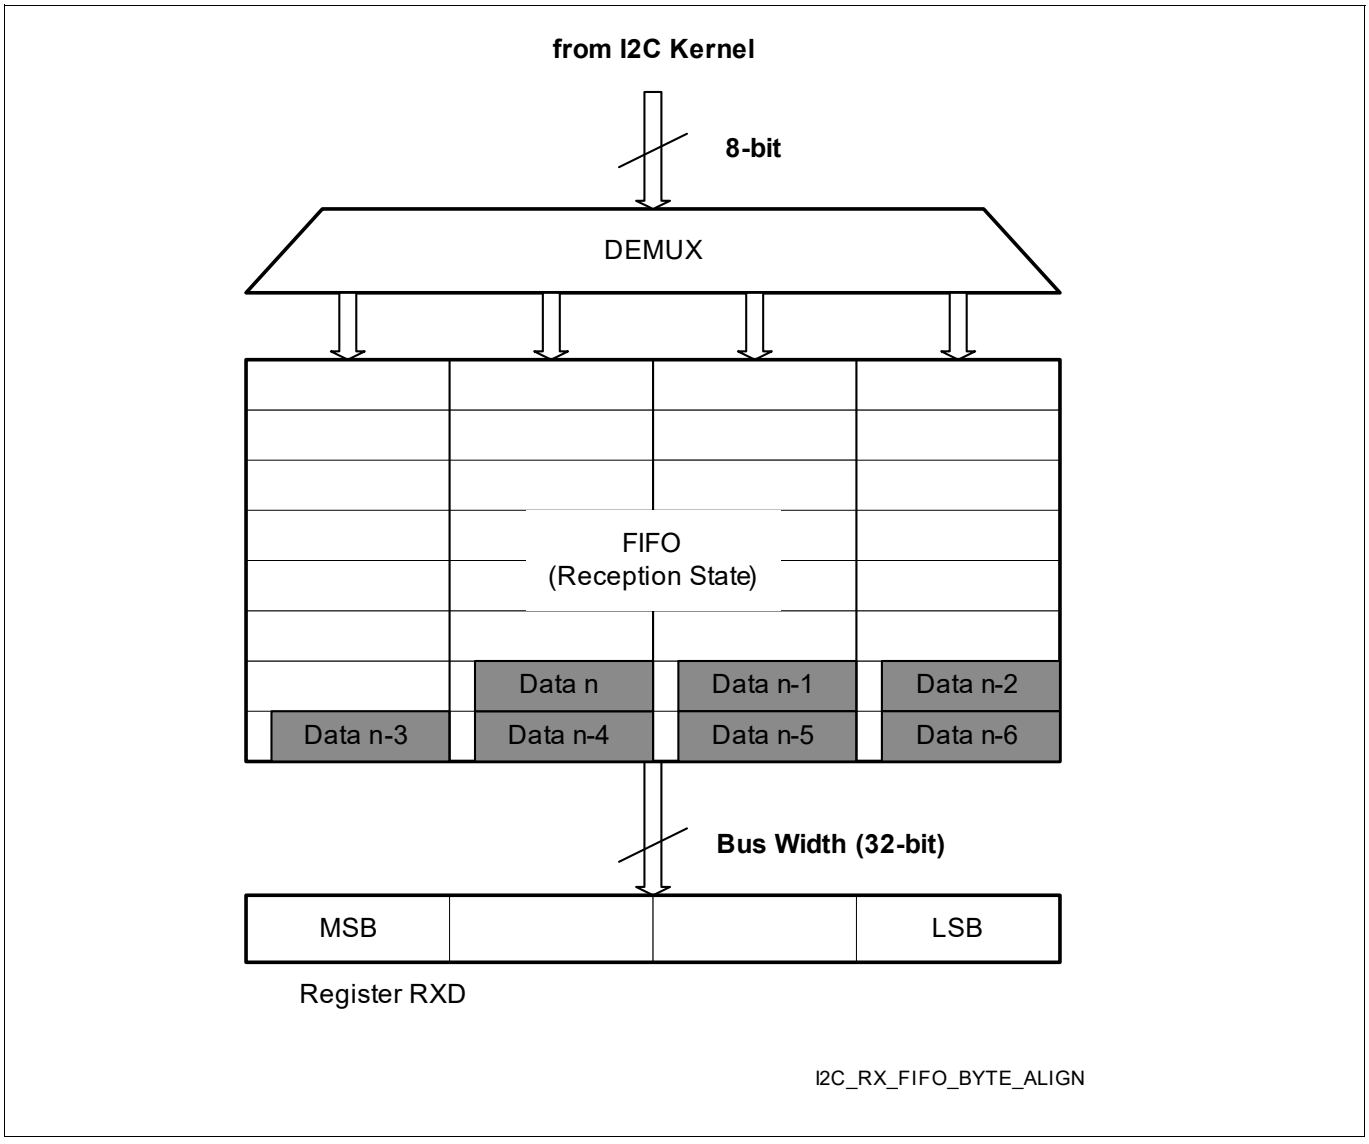

Figure 344 FIFO in Reception State with Byte Aligned Data

Half Word Aligned

If the RX data should be half word aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in **Figure 345**.

Note: The I2C kernel fills up the half words with dummy bits.

Since the number of characters of the received packet is not necessarily a multiple of 2, the upper bytes of the last word can be invalid. The software has to check for invalid half words of the last word by means of the bit-field RPS (received packet size) in register **RPSSTAT**.

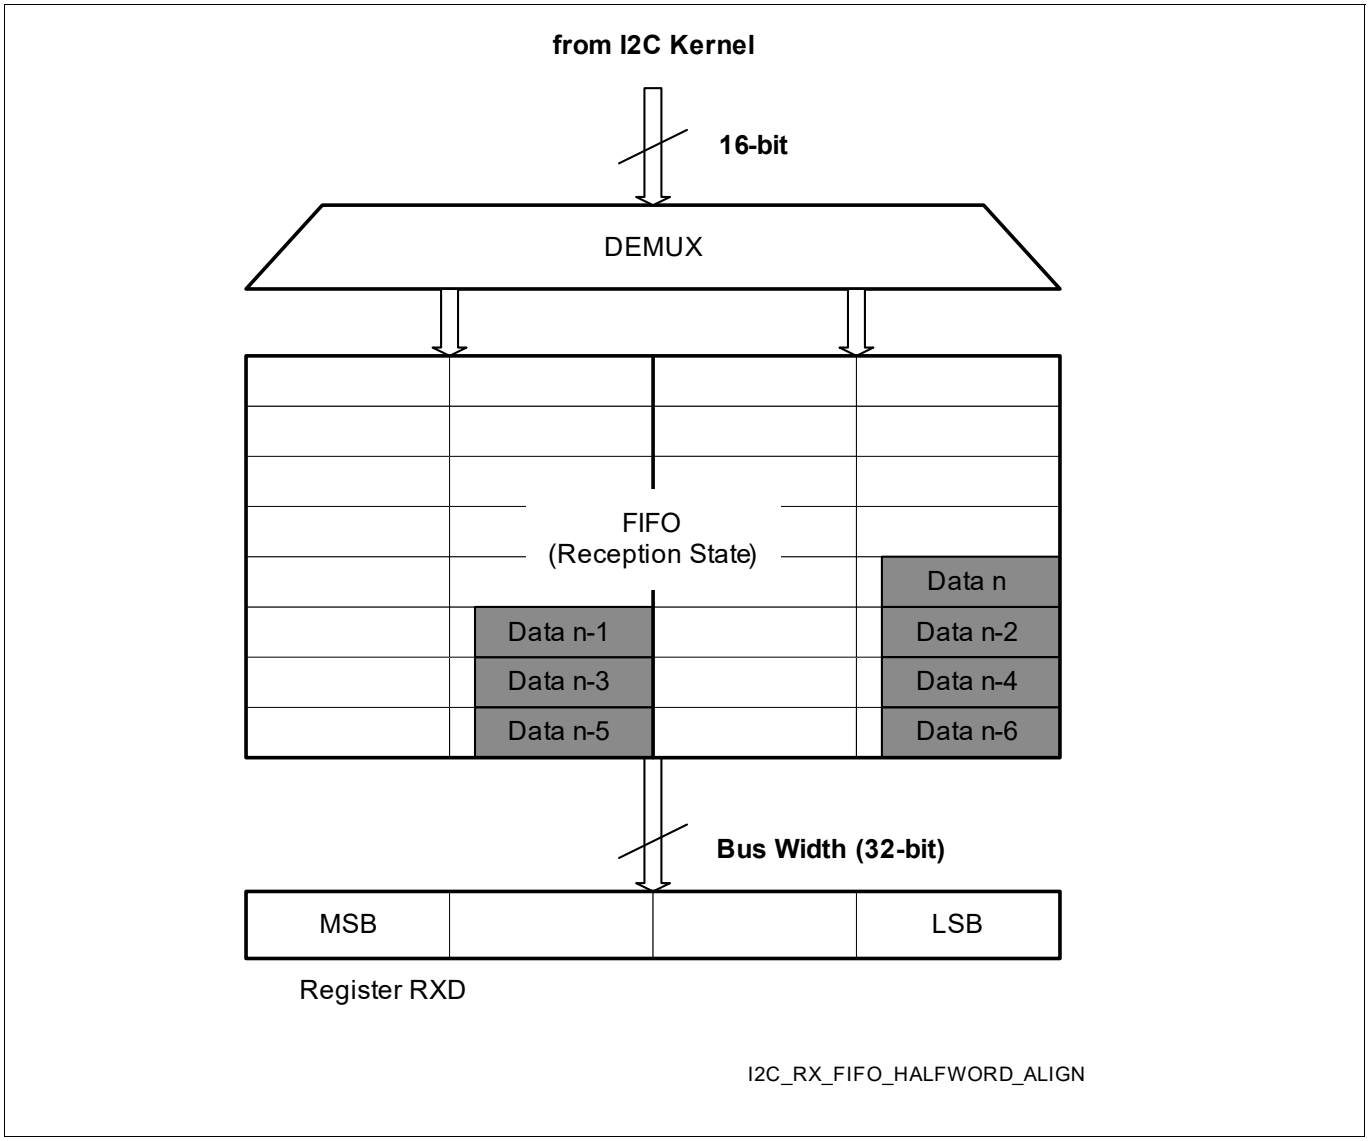

Figure 345 FIFO in Reception State with Half Word Aligned Data

Word Aligned

If the RX data should be word aligned, then the characters from the I2C kernel are shifted to the FIFO as it is shown in **Figure 346**.

Note: The I2C kernel fills up the words with dummy bits.

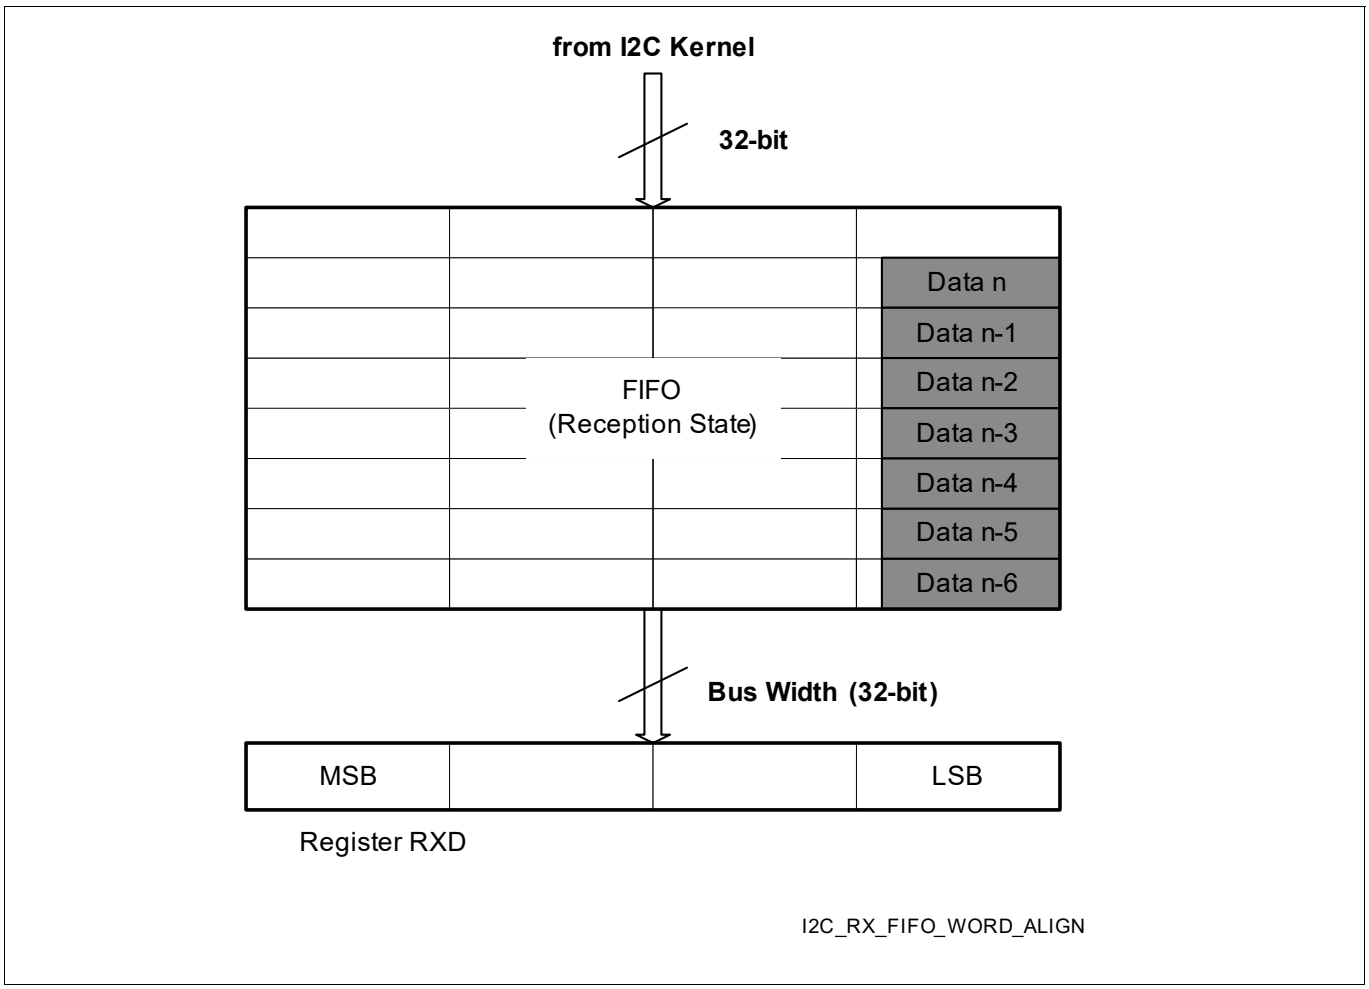

Figure 346 FIFO in Reception State with Word Aligned Receive Data

34.3.1.6.7 Switching between Transmission and Reception

Initially, the FIFO is in the TX state, so that the software can initiate a TX transfer simply by writing data to the bit-field **TXD**. If the I2C kernel wants the FIFO to switch to the RX state in the meantime, then it can set the RXS_set line and even if transmission is ongoing the TX transfer is aborted. This causes the FIFO to flush its content, switch to the RX state and reset the received packet size counter. If the software wants to write to the register **TXD** when the FIFO is in RX state, then this causes a bus error. As soon as the FIFO has received an EORXP_ind signal from the kernel and the software has moved all RX characters out of the FIFO via the register **RXD**, the FIFO automatically switches back into the TX state.

If the software writes to the register **TPSCTRL** when the FIFO is in the RX state, the TPS value is pending until the FIFO returns to the TX state. Then the transmission is initiated, if the FIFO is the flow controller.

If the FIFO is flow controller and the software writes to the register **MRPSCTRL**, then an MRPS_start is generated independent of the state of the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (xREQ) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

If the FIFO has been cleared in the RX state, then it switches back to the TX state afterwards.

34.3.1.6.8 Switching between Reception and Transmision

When the I2C kernel is changing from RX state to TX state the FIFO is flushed. To avoid loosing data when the FIFO is flushed the software should proceed in the right sequence. In a scenario where the device is addressed as slave and is asked to return data, this new data must be entered in the FIFO only after detection of the address and TX_END interrupt requests and then can transfer the data to the FIFO or can trigger the DMA that fills the FIFO for the TX transfer.

34.3.1.7 Service Request Block Operation

The SRB (Service Request Block) of the I2C module is used to prepare the interrupt and data transfer requests for the interrupt controller.

34.3.1.7.1 Overview of Service Requests

The I2C service requests are partially combined in the SRB (see **Section 34.4.4** and **Section 34.4.5**). **Figure 347** shows an overview of the service requests. **Table 301** provides a list of all service requests of the I2C module.

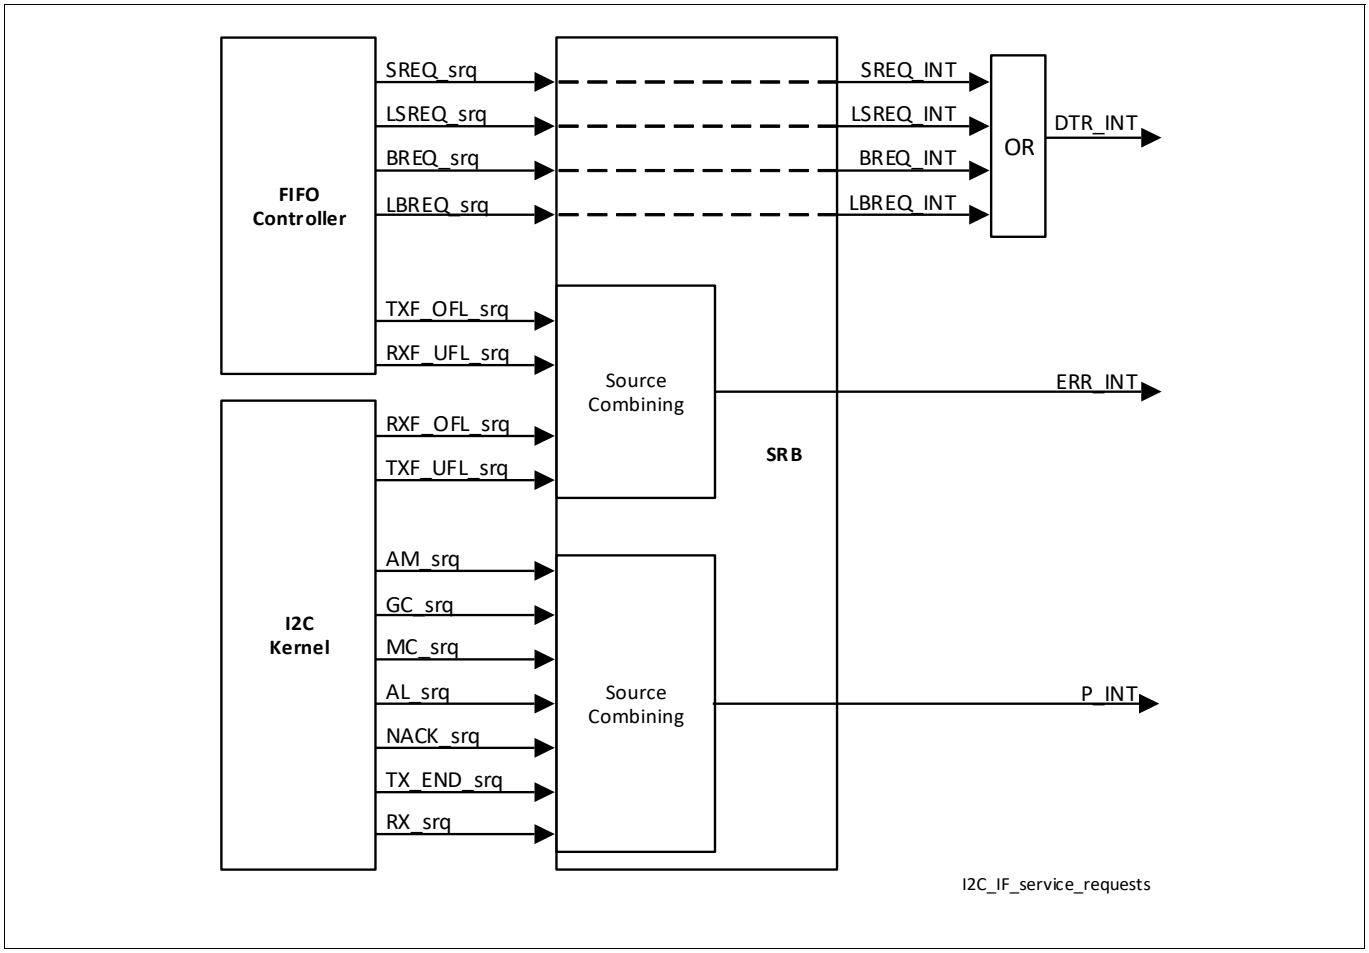

Figure 347 Overview of I2C Module Service Requests

Table 301 I2C Module Service Requests

Service Request	Interrupt Request	Description
BREQ_srq	DTR_INT	**Burst Data Transfer Request** FIFO requests a transfer of a programmed burst number of words from/to the memory.
LBREQ_srq	DTR_INT	**Last Burst Data Transfer Request** FIFO requests a last burst transfer from/to the memory.
SREQ_srq	DTR_INT	**Single Data Transfer Request** FIFO requests a single transfer of a word from/to the memory.
LSREQ_srq	DTR_INT	**Last Single Data Transfer Request** FIFO requests a last single transfer from/to the memory.
TXF_OFL_srq	ERR_INT	**TX FIFO Overflow Request** FIFO has detected a TX FIFO overflow.
TXF_UFL_srq	ERR_INT	**TX FIFO Underflow Request** I2C kernel has detected a TX FIFO underflow. The transmission is finished after the current byte. A stop condition is generated if the kernel works as master. The kernel changes to listening state.
RXF_OFL_srq	ERR_INT	**RX FIFO Overflow Request** I2C kernel has detected an RX FIFO overflow and the incoming character is discarded. The kernel puts a not-acknowledge on the bus and changes to listening state. A stop condition is generated if the kernel works as master.
RXF_UFL_srq	ERR_INT	**RX FIFO Underflow Request** FIFO has detected an RX FIFO underflow.
AM_srq	P_INT	**Address Match Request** Device (master/slave) has been addressed by a remote master (also indicated in bit-field BS in register **BUSSTAT**).
GC_srq	P_INT	**General Call Request** When the general call matching process is activated this interrupt indicates that another master has put a general call on the I2C-bus.
MC_srq	P_INT	**Master Code Request** When the master code matching process is activated this interrupt indicates the appearing of a master code on the I2C-bus issued by a remote master. The request is generated after a not-acknowledge and the clock is released to high again.
AL_srq	P_INT	**Arbitration Lost Request** Arbitration is lost after the device has tried to start a transmission on the I2C_bus.
NACK_srq	P_INT	**Not-acknowledge Received Request** Not-acknowledge received when working as transmitter (i.e. RnW bit is 0).

Table 301 I2C Module Service Requests (cont'd)

Service Request	Interrupt Request	Description
TX_END_srq	P_INT	**Transmission End Request** In master mode this event is produced by the I2C kernel to indicate that the transmission of the current packet has ended properly after the stop condition has been put on the I2C-bus or MASTER RESTART state has been entered. (At this point, a restart condition can be generated or the connection can be finished by generating a stop condition). This request is created in master mode at any stop condition to indicate that the bus is free again and it could be obtained. In slave mode this event is produced by the I2C kernel if it was addressed by a master and the current transmission was terminated by a stop or restart condition.
RX_srq	P_INT	**Receive Mode** Request I2C kernel indicates to the FIFO switching from transmit to receive mode. When FIFO is operating in non flow controller mode, this service request can be used to distinguish between transmit and receive FIFO data requests.

The generation of these events is visualized in the state machine **Figure 334**, **Figure 335** and **Figure 336**. The timing is shown in **Figure 337**.

34.3.1.7.2 Interrupt Service Request Structure

The I2C module provides level based service request lines, which can be processed by an interrupt controller. The service requests must be cleared in the interrupt service routine. For test purposes, all service requests can also be set by SW via a register bit. All service requests can be masked within the peripheral. Furthermore, requests that are not necessarily mutually exclusive are combined in order to reduce the number of request lines.

Flow of Data Transfer Requests

Figure 348 shows the flow of a data transfer request, which comes from the FIFO controller.

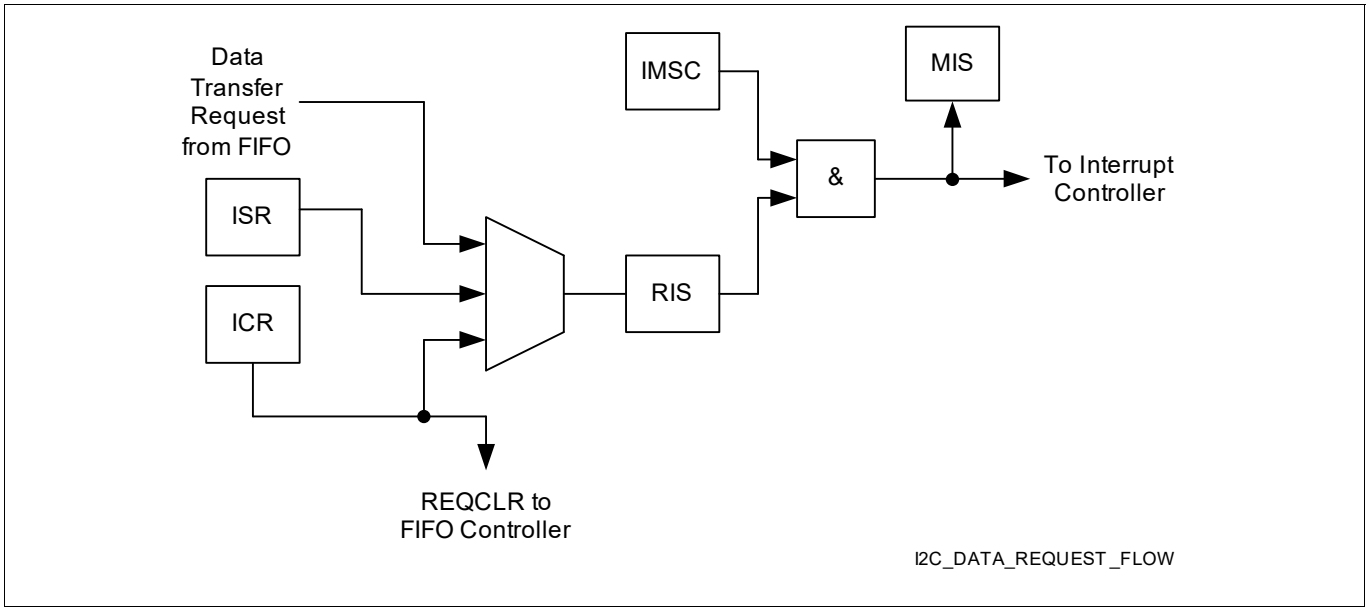

Figure 348 Data Transfer Request Flow

A data transfer request sets the corresponding status bit in the Raw Interrupt Status Register **RIS**. The status bit can also be set by writing 1 to the corresponding bit in the Interrupt Set Register **ISR**. It will be cleared by writing 1 to the corresponding bit in the Interrupt Clear Register **ICR**.

The Interrupt Mask Control Register **IMSC** enables or disables the requests to the interrupt controller. The Masked Interrupt Status Register **MIS** contains the current masked values of the requests.

If a request is disabled via register **IMSC** while the request is active, the request will be removed but only until the **IMSC** bit is set again, unless the request has been cleared in the meantime.

If a request is disabled via register **IMSC** and the source becomes active, then the request bit will only be set in the **RIS** register. If the corresponding **IMSC** bit is later enabled, the request will consequently become active in the **MIS** register.

Before enabling a request, it is good practice to always first clear the corresponding bit in the **RIS** register via **ICR**.

Multiple Source Interrupt Requests

For error and protocol interrupt requests which have multiple sources, the interrupt structure is extended. Additional register sets are implemented within the SRB.

Figure 349 gives an overview of the combining of several request sources to a single request.

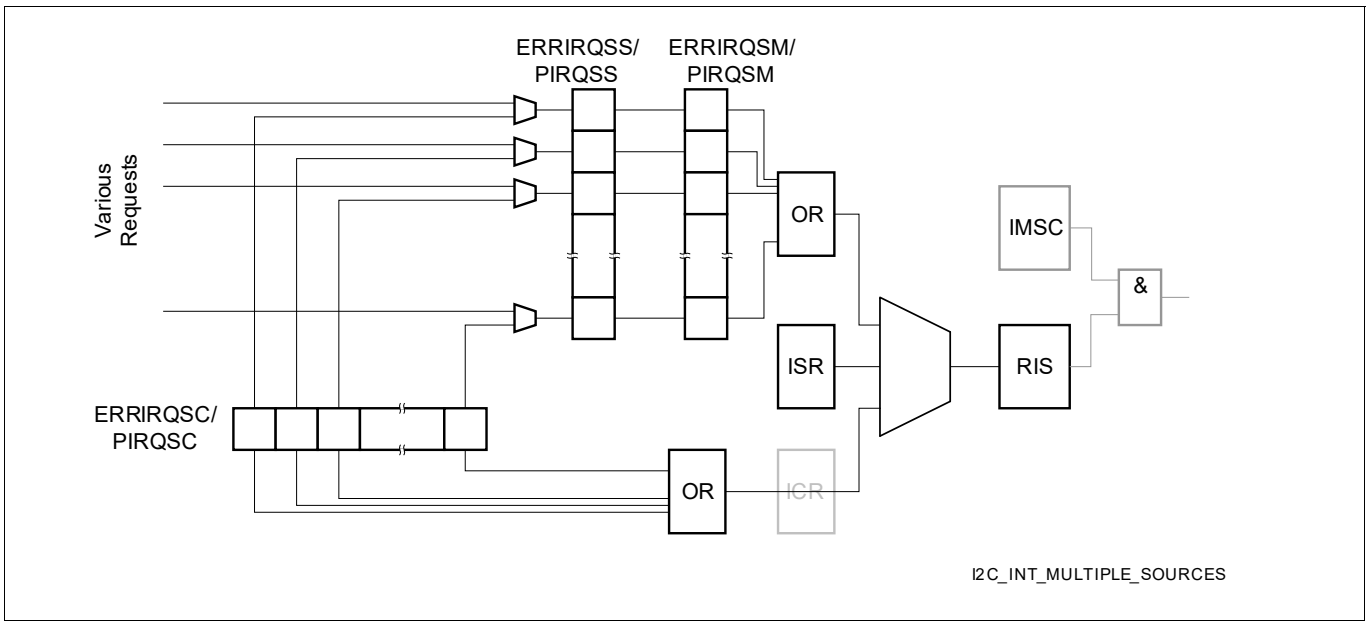

Figure 349 Interrupt Request with Multiple Sources

An interrupt request sets the corresponding raw status bit in the Interrupt Request Source Status Register **ERRIRQSS** (for error) or **PIRQSS** (for protocol).

The status bits can be cleared via the Interrupt Request Source Clear Register **ERRIRQSC** (for error) or **PIRQSC** (for protocol). If no further error/protocol request sources are active, the whole error/protocol interrupt request is cleared. This register replaces the functionality of the bit I2C_ERR_INT (for error) or bit I2C_P_INT (for protocol) in the Interrupt Clear Register **ICR**.

The Interrupt Request Source Mask Register **ERRIRQSM** (for error) or **PIRQSM** (for protocol) enables or disables the interrupt requests. The request lines from the enabled sources are combined (OR) to a single level sensitive request line, which acts as input for the corresponding bit I2C_ERR_INT (for error) or I2Cm_bit I2C_P_INT (for protocol) in the Raw Interrupt Status Register **RIS**.

34.3.2 I2C Module Implementation

This section describes I2C module interfaces with the clock control, port control and interrupt control.

34.3.2.1 Interfaces of the I2C Module(s)

Figure 350 shows the specific implementation details and interconnections of the I2C module(s):

- A clock control block generates the clock signals required for the module.
- For the I2C-bus lines SCL and SDA, different I/O lines can be selected.
- The interrupt outputs of the module are connected to the interrupt control unit.

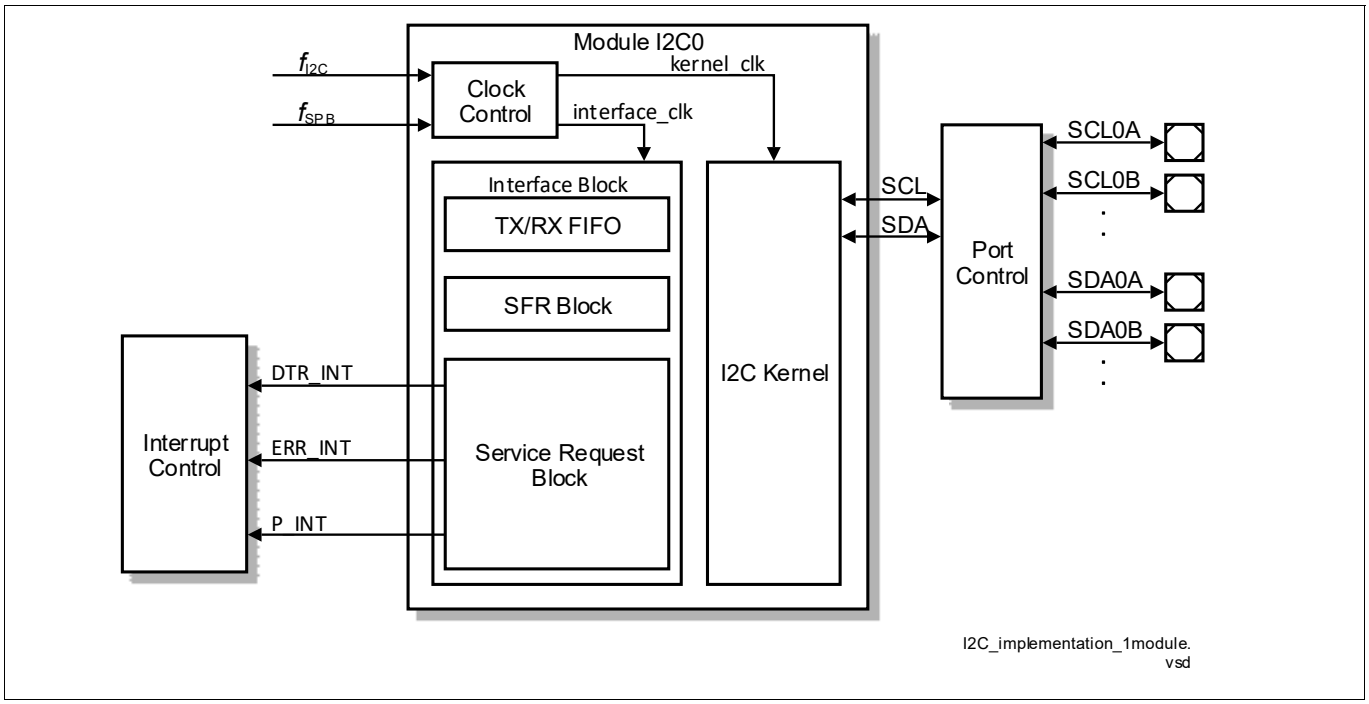

Figure 350 I2C Module Implementation and Interconnections

34.3.2.2 Module Clock Control

The clock control allows the programmer to adapt the peripherals functionality and power consumption to the application's requirement. By programming the kernel's operating frequency, an optimal ratio between power consumption, EMC behavior and functionality can be achieved. Furthermore, for power saving reasons the peripheral can be disabled as a whole by switching off the peripheral's clocks via clock gating cells.

A simplified description of the clock control is shown in **Figure 351**. See register **CLC1** for a description of the clock control parameters.

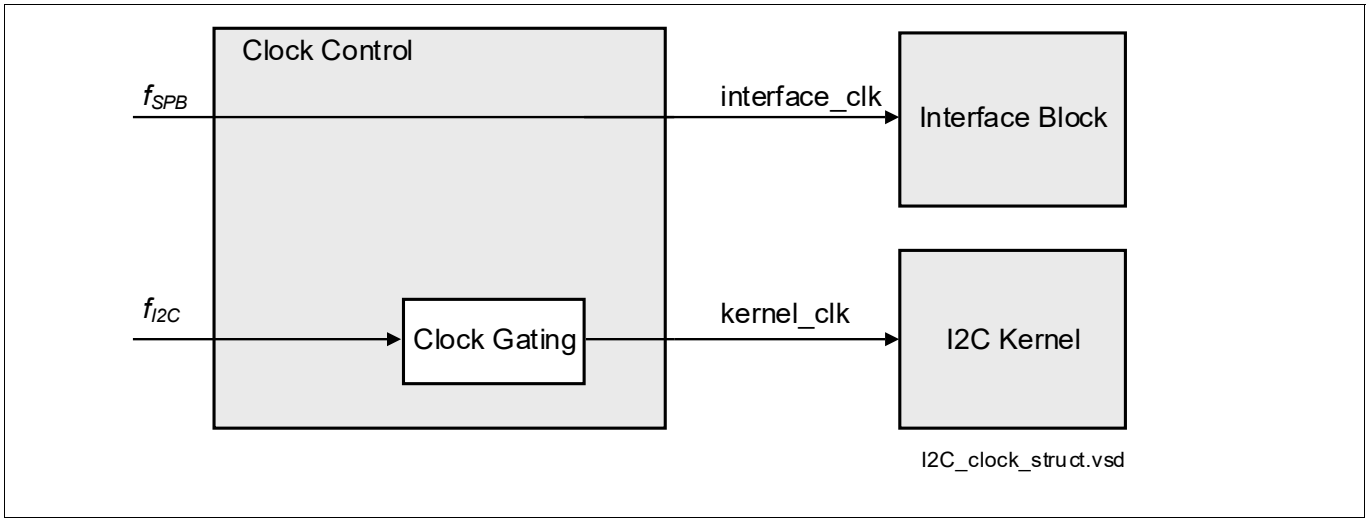

Figure 351 Module Clock Control

The following clocking modes are supported for the peripheral:

- Disabled mode
- OCDS suspend mode

Disabled Mode

In Disabled Mode, the clocks are stopped and register write accesses are not possible (except access to **CLC1** register itself).

There are several ways possible to bring the module into Disabled mode:

- Software disable
  - Set **CLC1**.DISR = 1 (software disable request)
- Hardware disable
  - Must be enabled via **CLC1**.EDIS = 0
  - Drive input signal sleep_n_i = 0(active low: 0= disable; 1= enable)

In all cases, current bus accesses are finished and a kernel handshake is issued to make sure that the state machine is in a safe state (same as **CLC1**.FSOE = 0 in OCDS Suspend Mode; see description below).

Module is in Disabled Mode after reset and must be enabled by setting **CLC1**.DISR = 0 and **CLC1**.RMC > 0-.

OCDS Suspend Mode

In this mode the clocks are disabled. If bit SPEN in register **CLC1** is set, the mode can be entered by activating the input module_ocds.

In OCDS suspend mode all registers of the suspended module can be read. Note that each read during disabled clock can not affect hardware. For example multiple reads to FIFO port registers always return the same value as the FIFO control is not working.

No write access to the registers is supported during suspend mode, except writes to the **CLC1** register. For writing other registers the suspend mode for the module has to be removed first by clearing bit SPEN. After the write access is executed, bit SPEN should be set again.

OCDS suspend mode supports two different disable features, selectable by bit FSOE in register **CLC1**:

*Note: To write to SPEN or FSOE, bit SBWE in register **CLC1** must also be set in the same write access.*

- **Secure Clock Switch Off**

Disabling the clock via secure clock switch off additionally activates the handshake mechanism with the peripheral. The peripheral is switched to a secure state before disabling the clock.

Note: This feature is only available in slave mode. In master mode, there is no difference and I2C will always perform "fast clock switch off".

- **Fast Clock Switch Off**

Selecting the fast clock switch off stops the clock immediately after all pending read and write accesses are finished (including synchronization mechanisms with the I2C kernel).

34.3.2.3 Bus Peripheral Interface Registers

Clock Control 1 Register

This register controls the clock gating and dividing circuitry of the peripheral.

CLC1
Clock Control 1 Register **(00000_H)** **Application Reset Value: $0000\ 0003_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								0

rwh								r		rw	w	rw	rw	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B Module disable not requested 1_B Module disable requested
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module enabled 1_B Module disabled
SPEN	2	rw	**Module Suspend Enable Bit for OCDS** 0_B Module suspend disabled 1_B Module suspend enabled
EDIS	3	rw	**External Request Disable** *Note: This bit is not used in AURIX™ TC3xx Platform and should always be written with 0.* 0_B External clock disable request is enabled 1_B External clock disable request is disabled
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** This bit is always read as 0. 0_B Bits SPEN and FSOE are write protected 1_B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE
FSOE	5	rw	**Fast Switch Off Enable** 0_B FSOE Clock switch off in OCDS suspend mode via Disable Control Feature (Secure Clock Switch Off) 1_B Fast clock switch off in OCDS suspend mode

Field	Bits	Type	Description
RMC	15:8	rwh	**Clock Divider for Standard Run Mode** Max. 8-bit divider value If RMC is set to 0 the module is disabled. *Note: As long as the new divider value RMC is not valid, reading register returns 0000 00XX$_H$*
0	7:6, 23:16, 31:24	r	**Reserved** Read as 0; should be written with 0.

34.3.2.4 Port and I/O Line Control

Not only the interconnections between the I2C module and the port I/O lines have to be configured, but also the function and the characteristics of the port pins. The following control operations must be executed for the used port pins:

- Selection of I2C module via output port multiplexer
- Configuration of output port function with open drain
- Configuration of pad driver characteristics
- Selection of I2C input lines

34.3.2.5 Interrupt Control

The interrupt functionality is described in the chapter for the interrupt router (IR).

The signal names used in the interrupt router description are explained in **Table 302**.

Table 302 Interrupt Router Signal Names for I2Cm Module (m = 0/1)

Signal Name	Name in Module	Explanation
SRC_I2CmDTR	DTR_INT	**Data Transfer**
SRC_I2CmERR	ERR_INT	**Error**
SRC_I2CmP	P_INT	**Protocol**

34.3.3 Module Integration

This section describes the topics regarding the integration of the module on chip.

34.3.3.1 Integration Overview

The I2C module consists of a delivery providing an AHB bus interface integrated into the FPI bus system by using an FPI2AHB adapter.

The adapter contains a slave bus interface providing translation between the FPI and the AHB bus protocols. The module supports additionally the following features:

- power saving (sleep mode)
- debug suspend
- local module reset
- PISEL - port input selection regarding the serial data input

The power saving and debug suspend features are supported by the AHB based I2C module itself, and the local module reset and PISEL features are supported by the FPI2AHB adapter, see **Figure 352**.

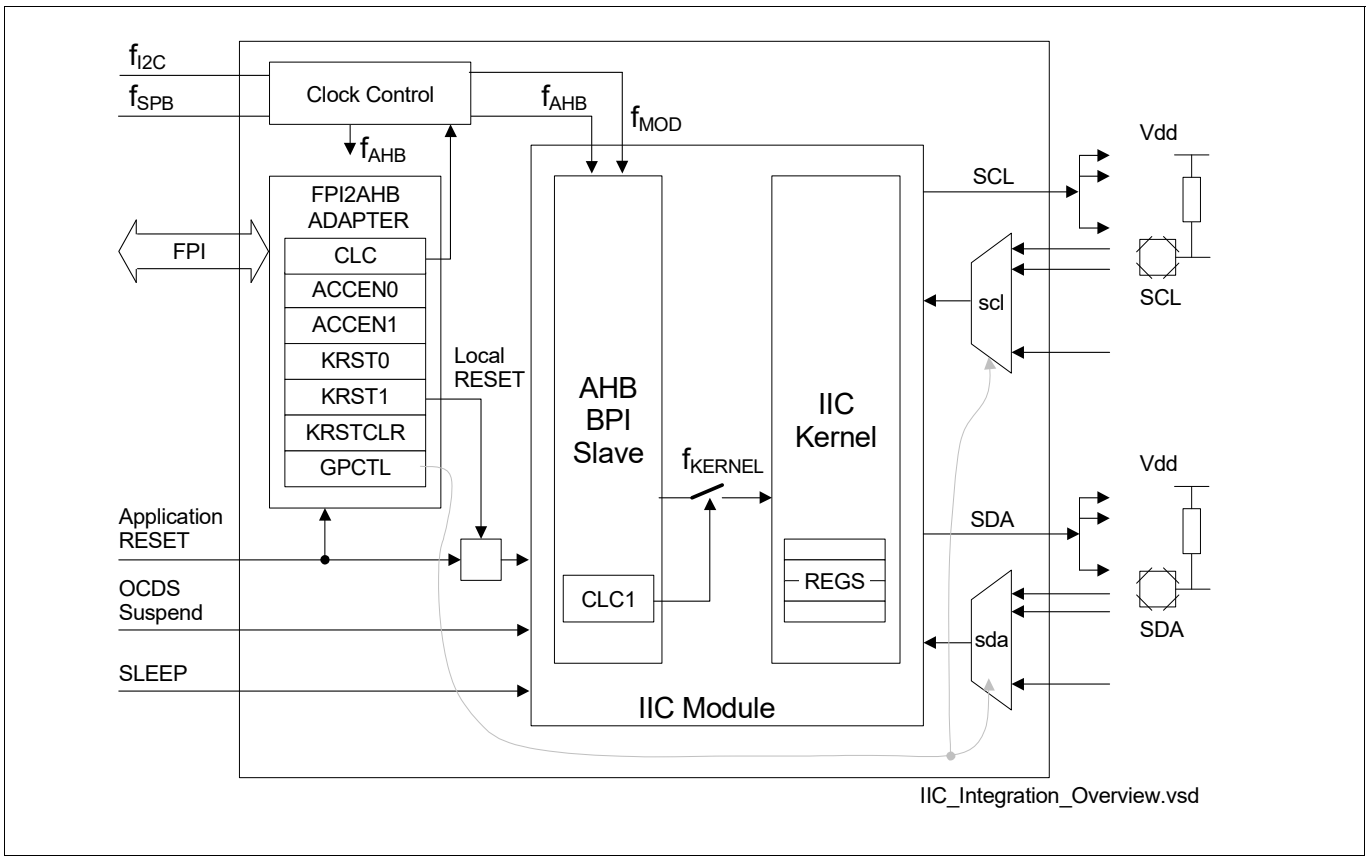

Figure 352 Integration Overview

34.3.3.2 BPI_SPB Module Registers Overview

Figure 353 shows all registers associated with the BPI_FPI module, configured for one kernel. See also **Table 303** for the address mapping.

BPI_FPI Registers Overview

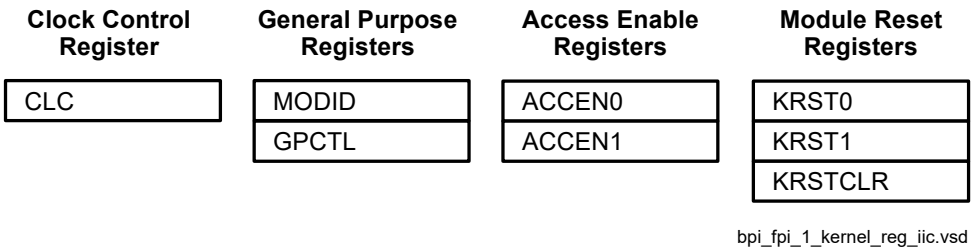

Figure 353 BPI_FPI Registers

This section describes the registers implemented in the slave (FPI2AHB) adapter component.

34.3.3.2.1 BPI_SPB Module Registers

Kernel Reset

If a kernel reset is requested, the adapter will synchronously assert the internal kernel reset output and error any ongoing accesses on the FPI bus not addressed to the adapter's internal SFRs.

The method of using the kernel reset output from the adapter to initialise the associated AHB module is module specific and outside the scope of this specification.

Any AHB accesses in progress will be synchronously terminated.

GPCTL

A single, adapter specific, SFR is implemented in the adaptor.

The SFR contains general purpose read/write control bits without ENDINIT protection. All the bits are connected to output ports on the FPI2AHB entity. The SFR will implement no safety requirements and is not be suitable for controlling hardware related to safety functions. The SFR supports, byte, half word and word transactions only. All other transactions are rejected with an FPI error termination.

Note: In the I2C module, this register implements the PISEL functionality. The SDA and SCL input multiplexors are controlled in parallel with each PISEL setting. Since 3 bits are implemented for PISEL, up to 8 sets of SDA and SCL pins can be defined.

Principle of Operation

When the controlling state machine detects an FPI access, it compares the address to the address of the SFR. In the case that the address matches the SFR address, the normal state machine transitions are interrupted and the access is not passed to the AHB bus.

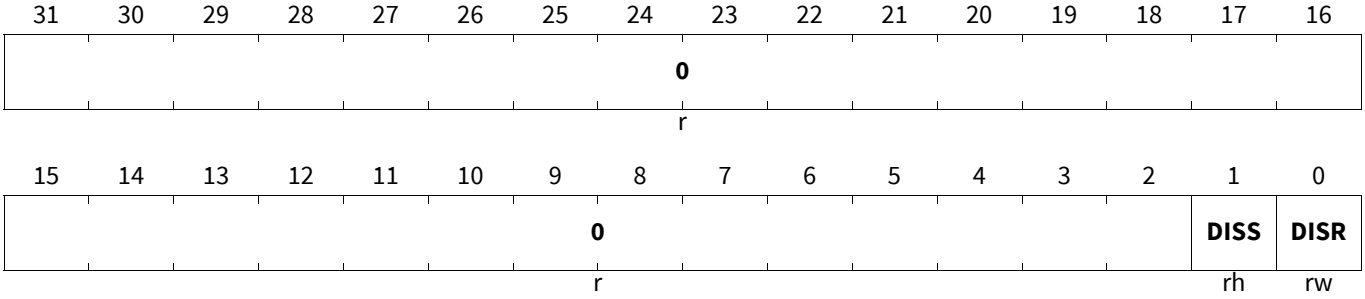
If the access opcode is not SDTB, SDTH or SDTW, then the access is terminated with an FPI error. If the opcode is supported, the SFR data will be returned on the FPI bus if the transaction is a read or the appropriate bits of the register will be updated if the access is a write.

Clock Control Register

The Clock Control Register, CLC, acts globally and allows the complete AHB module to be disabled to reduce power consumption when the module is not required. When the module is disabled (DISS=1_B), only register accesses to the adapter register address space are permitted. All other accesses to the module address space will be errored.

CLC

Clock Control Register **(10000_H)** **Application Reset Value: $0000\ 0003_H$**



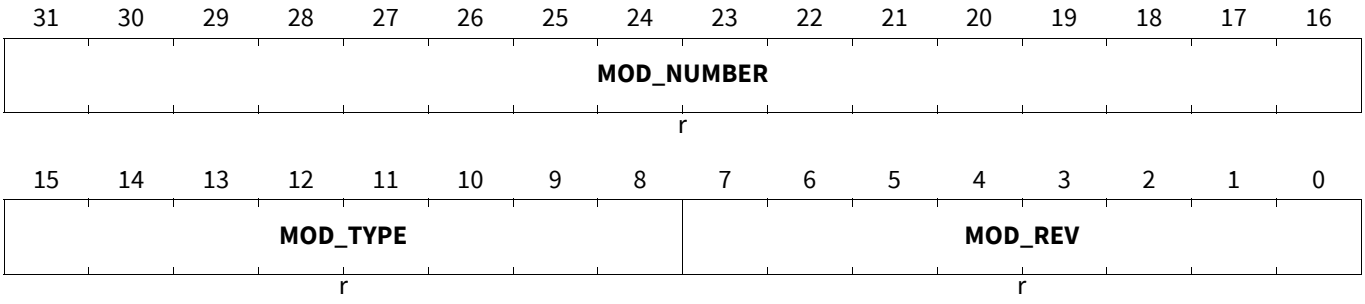
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The identification register allows the programmer version-tracking of the module.

MODID

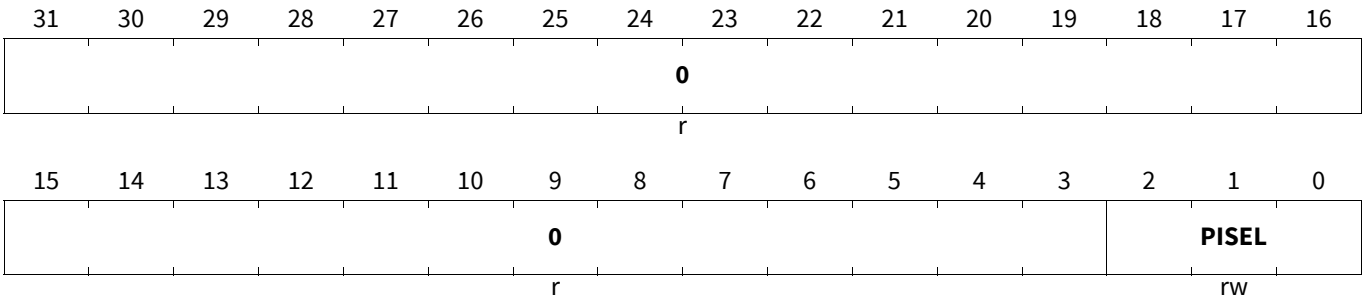
Module Identification Register **(10004_H)** **Application Reset Value: $00C2\ C0XX_H$**



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	15:8	r	**Module Type** The bit field is set to C0H which defines the module as a 32-bit module.
MOD_NUMBER	31:16	r	**Module Number Value** This bit field defines a module identification number.

General Purpose Control Register

GPCTL
General Purpose Control Register (10008$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
PISEL	2:0	rw	**Port Input Select** Used to select the input pins providing the serial data and clock input signals, in the range of 0 to 7. *Note: In AURIX™ TC3xx Platform, not all PISEL options are available. See Data Sheet.* 000_B SDA0A and SCL0A are selected. 001_B SDA0B and SCL0B are selected. 010_B SDA0C and SCL0C are selected. 011_B SDA0D and SCL0D are selected. 100_B SDA0E and SCL0E are selected. 101_B SDA0F and SCL0F are selected. 110_B SDA0G and SCL0G are selected. 111_B SDA0H and SCL0H are selected.
0	31:3	r	**reserved** Reads 0. Should be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions to registers with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The adapter is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,...,EN31 -> TAG ID 011111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN0

Access Enable Register 0 **(1000C$_H$)** **Application Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENj (j=0-31)	j	rw	**Access Enable for Master TAG ID j** This bit enables write access to the module register addresses for transactions with the Master TAG ID j 0_B Write access will not be executed. Read accesses will be executed. 1_B Write and read accesses will be executed

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). These tags are not used in this system and so no programmable bits are provided.

ACCEN1

Access Enable Register 1 **(10010$_H$)** **Application Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
RES	31:0	r	**Reserved** Read as 0; should be written with 0.

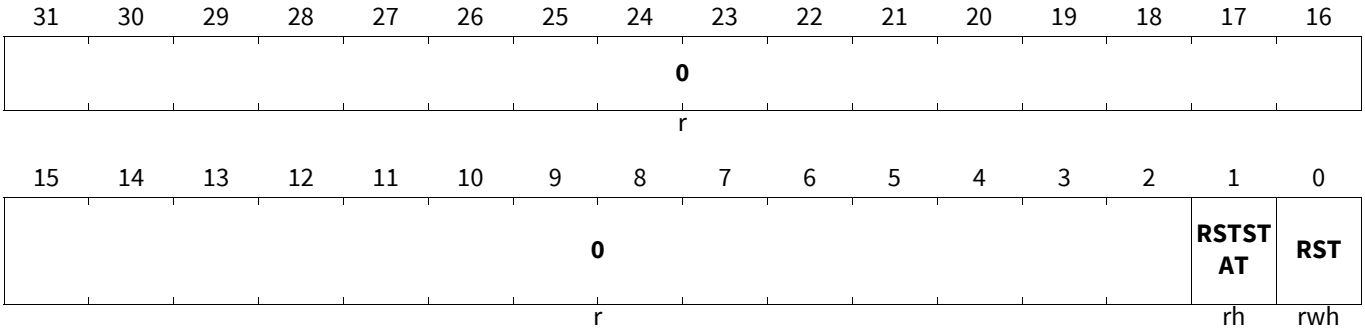
Kernel Reset Register 0

The Kernel Reset function is used to synchronously reset the AHB module. To activate the kernel reset, it is necessary to set the RST bits by writing with 1_B in both Kernel Reset Registers.The RST bit will be re-set by the adapter with the end of the adapter kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, write accesses to the module registers will result in an error acknowledge. Adapter registers can still be accessed.

KRST0
Kernel Reset Register 0 **(10014_H)** **Application Reset Value: $0000\ 0000_H$**



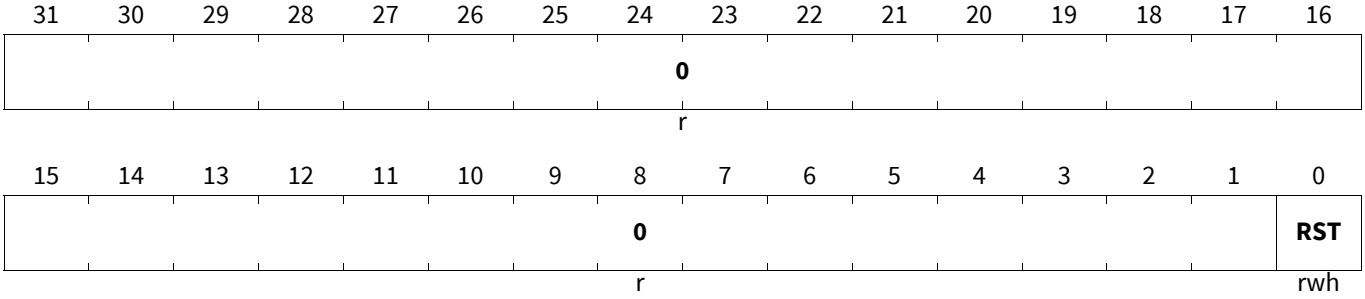
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to 0_B) b after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **(10018_H)** **Application Reset Value: $0000\ 0000_H$**



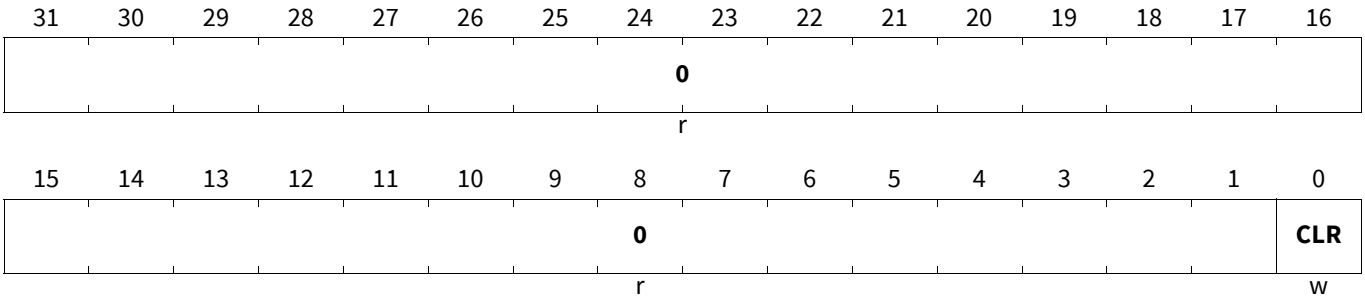
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to 0_B) after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0_B; should be written with 0_B.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **($1001C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0_B. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0_B; should be written with 0_B.

34.4 Registers

This section describes the internal registers of the I2C module. All register names described in this section are also referenced in other parts of the User's Manual by the module name prefix "I2Cm_". For an overview of all internal module registers, see **Section 34.4**.

In the following, the registers of the I2C module are listed. First of all, some explanation on the access conditions is given.

Special I2C Register Access Condition

Besides the general register protection, the I2C module has two main modes that must be considered when programming the peripheral:

- **Configuration Mode:** In this mode the peripheral can be prepared for transmission and reception via the configuration registers, which are only writable in this mode. The peripheral is in the configuration mode when bit RUN is set to 0.
- **Run Mode:** In this mode the peripheral is ready to transmit or receive data. Its configuration registers are locked for write access which will generate a bus error. The peripheral is in the run mode when bit **RUN** is set to 1.

I2C Registers Overview

There are the following blocks of registers (see **Figure 354**):

- Bus Peripheral Interface Registers
- Global Module Control Registers
- FIFO Registers
- Basic Interrupt Registers
- Error Interrupt Source Registers
- Protocol Interrupt Source Registers

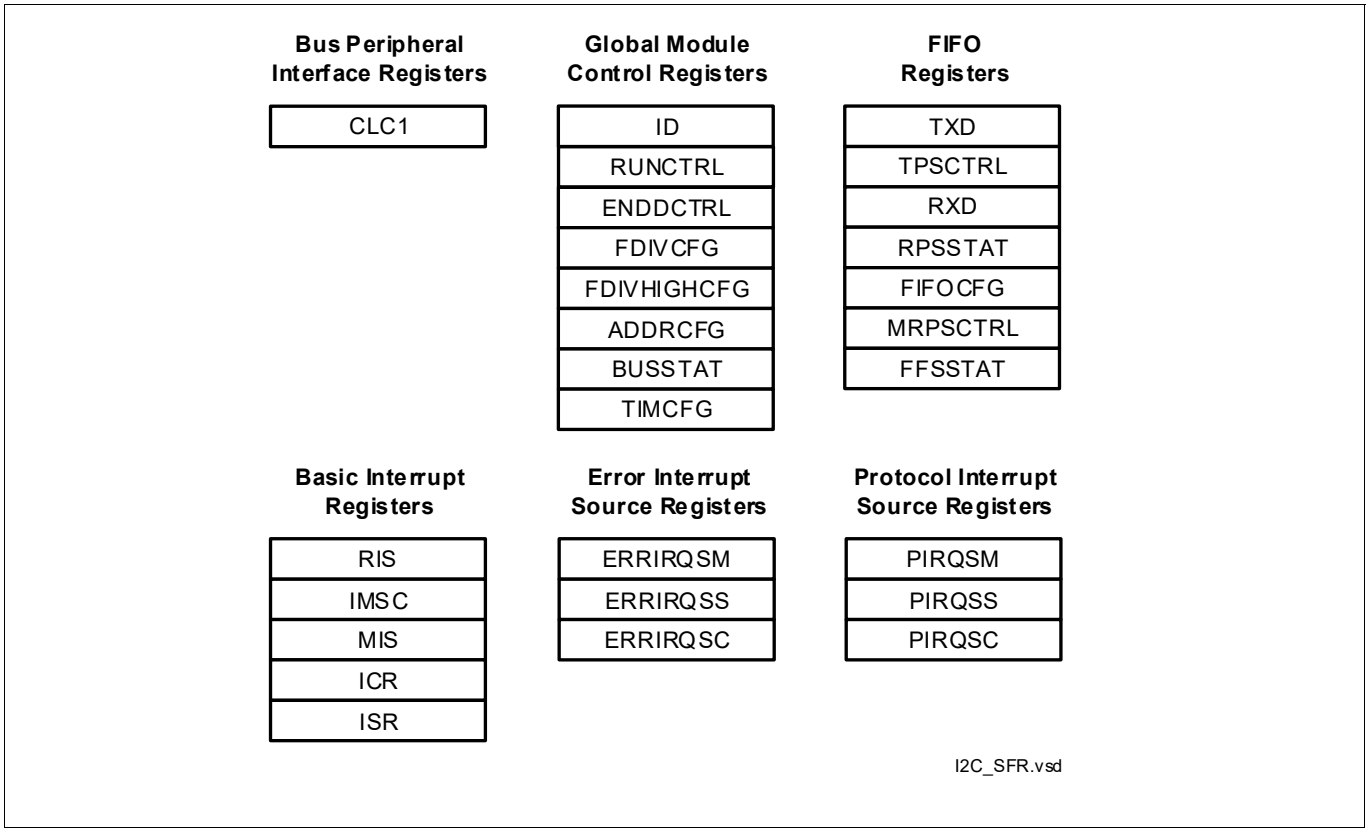


Figure 354 I2C Module Registers

The registers overview in **Table 303** shows the internal register names of the module instances, the offset addresses and the links to the names used in this specification.

Table 303 Register Overview - I2C (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC1	Clock Control 1 Register	00000_H	U,SV	U,SV,P	Application Reset	45

Notes

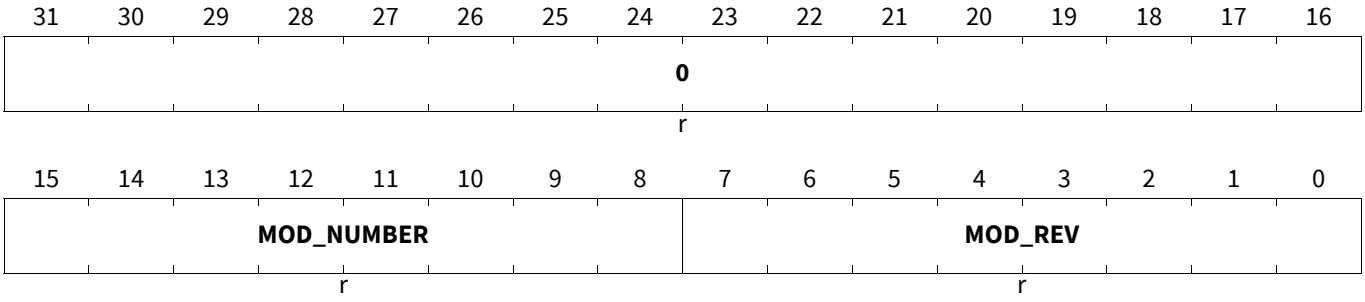
1. *All I2C registers are Application Reset registers.*

34.4.1 Global Module Control Registers

Module Identification Register

This register contains read-only information about the module and its revision.

ID
Module Identification Register **(00008_H)** **Application Reset Value: $0000\ 5705_H$**

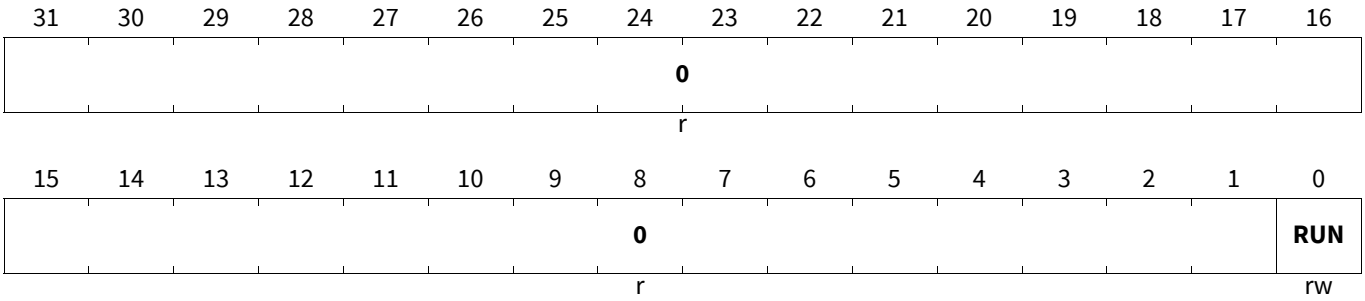


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** This bit-field defines the revision number.
MOD_NUMBER	15:8	r	**Module Number** This bit-field defines the module identification number.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

RUN Control Register

This register selects configuration mode or run mode.

RUNCTRL
RUN Control Register **(00010_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RUN	0	rw	**Enable I2C-bus Interface** 0_B I2C-bus interface disabled; write access to configuration registers enabled 1_B Participation in I2C-bus communication enabled (if properly configured); write access to configuration registers disabled

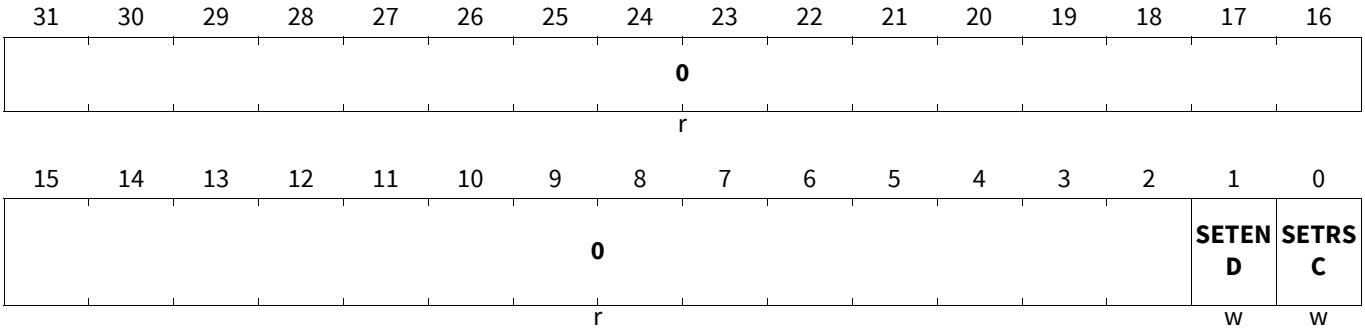
Field	Bits	Type	Description
0	31:1	r	**Reserved** Read as 0; should be written with 0.

End Data Control Register

This register is used to either turn around the data transmission direction or address another slave without sending a stop condition. Also the software can stop the slave-transmitter by sending a not-acknowledge when working as master-receiver or even stop data transmission immediately when operating as master-transmitter. The writing to the bits of this control register is only effective in certain states.

ENDDCTRL

End Data Control Register **(00014_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SETRSC	0	w	**Set Restart Condition** This bit is always read as 0. 0_B Has no effect. 1_B The master wants to restart a data transmission (changing slave/direction). The effect depends on the current state. MASTER RECEIVES BYTES: The master puts a not-acknowledge on the bus and switches to MASTER RESTART state. MASTER TRANSMITS BYTES: After the current byte has been sent, the master switches to MASTER RESTART state.

Field	Bits	Type	Description
SETEND	1	w	**Set End of Transmission** This bit is always read as 0. *Note: Do not write 1 to this bit when bus is free. This will cause an abort after the first byte when a new transfer is started.* 0_B Has no effect. 1_B The effect depends on the current state. MASTER RECEIVES BYTES: After receiving the current byte, the master puts a not-acknowledge on the bus to indicate the transmission end to the slave-transmitter. Next it produces a stop condition on the bus and changes its state to LISTENING. MASTER TRANSMITS BYTES: After sending the current byte and receiving an acknowledge or not-acknowledge from the slave-receiver, the master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. MASTER RESTART: The master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. SLAVE RECEIVES BYTES: The slave-receiver puts a not-acknowledge on the bus after the received byte and changes its state to TRANSMISSION FINISHED.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Address Configuration Register

This configuration register contains the I2C-address (when addressed as a slave) and some bits that control the basic operation of the peripheral.

ADDRCFG
Address Configuration Register **(00020_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0										SOPE	SONA	MnS	MCE	GCE	TBAM
r										rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						ADR									
r						rw									

Field	Bits	Type	Description
ADR	9:0	rw	**I2C-bus Device Address** This bit-field determines the address of the device when addressed as a slave. (Watch out for reserved addresses by referring to I2C-bus spec V2.1.) Depending on setting of TBAM, this is either a 7-bit address (bits [7:1]) or a 10-bit address (bits [9:0]).

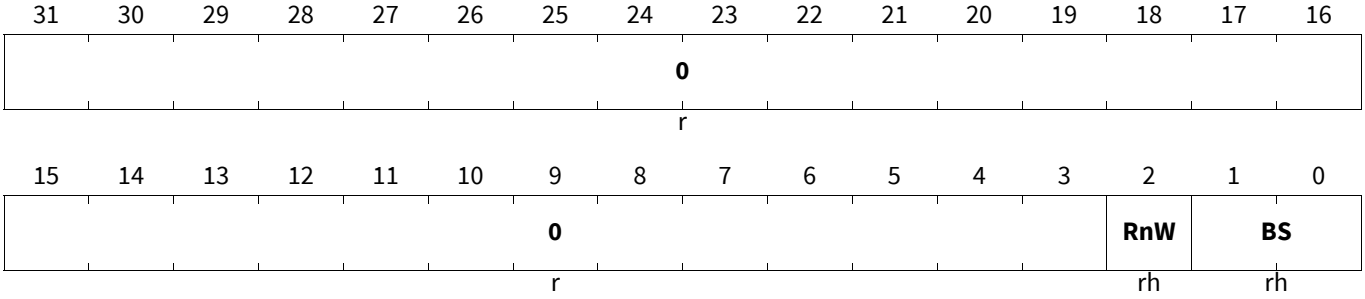
Field	Bits	Type	Description
TBAM	16	rw	**Ten Bit Address Mode** *Note: When this bit is zero, only bits 7 down to 1 of the ADR field are valid.* 0_B 7-bit address mode enabled. 1_B 10-bit address mode enabled.
GCE	17	rw	**General Call Enable** 0_B Ignore general call occurrence. 1_B Enable general call detection; when detected, an acknowledge will be put on the bus
MCE	18	rw	**Master Code Enable** 0_B Device is not able to get along with high-speed mode 1_B Device is able to handle master code
MnS	19	rw	**Master / not Slave** 0_B Peripheral is configured as slave 1_B Peripheral is configured as master
SONA	20	rw	**Stop on Not-acknowledge** *Note: After successful transmission of a master code (during high-speed mode) SONA is not considered till a stop condition is manually generated by SETEND.* 0_B Device changes to MASTER RESTART state. 1_B Device puts a stop condition on the bus and changes to LISTENING state.
SOPE	21	rw	**Stop on Packet End** **Notes** *1. This bit-field should be used only in Master Mode. In slave modeshould always be 0.* *2. If device works as receiver a not-acknowledge is always generatedon package end.* *3. After successful transmission of a master code (during high-speedmode) SOPE is not considered till a stop condition is manually generated by SETEND.* 0_B Device enters MASTER RESTART state when the data packet end is indicated by the FIFO. 1_B Device puts a stop condition on the bus when the data packet end is indicated by the FIFO and changes to MASTER LISTENING state.
0	15:10, 31:22	r	**Reserved** Read as 0; should be written with 0.

Bus Status Register

This register contains status information of the I2C-bus. This additional information can be used by software to start appropriate actions.

BUSSTAT

Bus Status Register **(00024$_H$)** **Application Reset Value: 0000 0000$_H$**



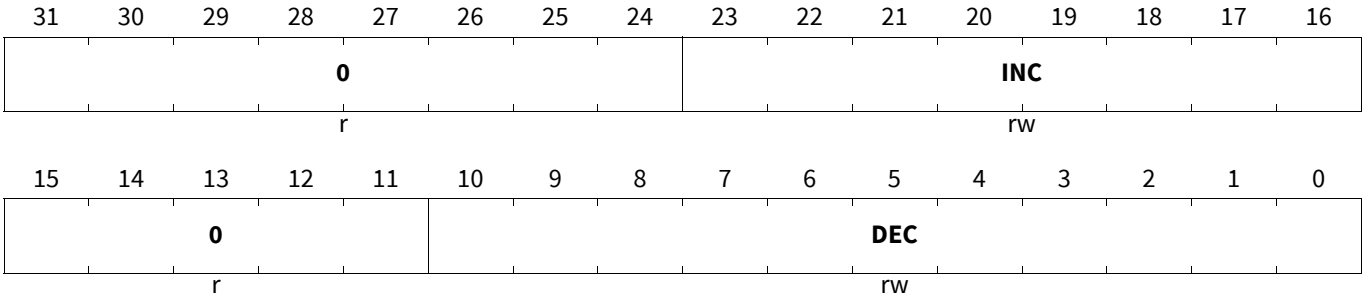
Field	Bits	Type	Description
BS	1:0	rh	**Bus Status** Shows the current status on the I2C-bus. 00_B I2C-bus is free (no start condition detected). 01_B A start condition has been detected on the bus (bus busy). 10_B The device is working as master and has claimed the control on the I2C-bus (busy master). 11_B A remote master has accessed this device as slave.
RnW	2	rh	**Read/not Write** Set by hardware automatically after address byte has been sent/received. 0_B Working as transmitter (Write to I2C-bus). 1_B Working as receiver (Read from I2C-bus).
0	31:3	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for standard and fast mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured.

FDIVCFG

Fractional Divider Configuration Register **(00018$_H$)** **Application Reset Value: 0000 0000$_H$**



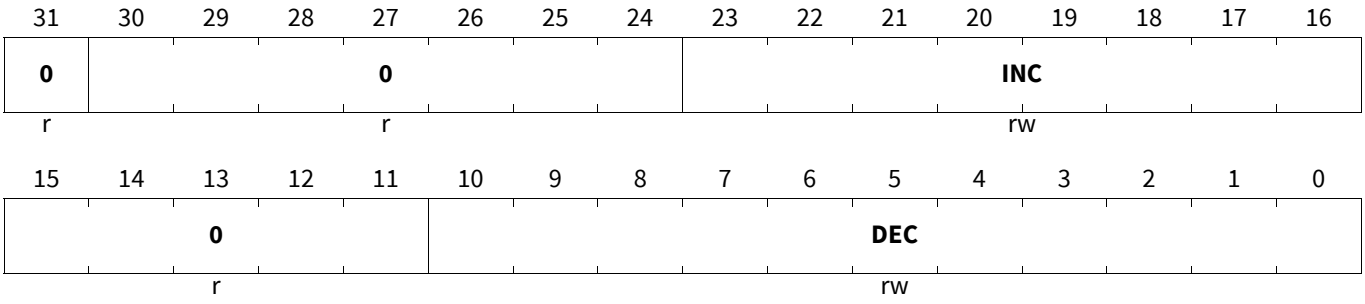
Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For standard/fast mode, see **Clock and Timing Control**.

Field	Bits	Type	Description
INC	23:16	rw	**Increment Value of Fractional Divider** For standard/fast mode, see **Clock and Timing Control**.
0	15:11, 31:24	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider High-speed Mode Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for high-speed mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured if high-speed mode is used.

FDIVHIGHCFG
Fractional Divider High-speed Mode Configuration Register($0001C_H$) Application Reset Value: $0000\ 0000_H$



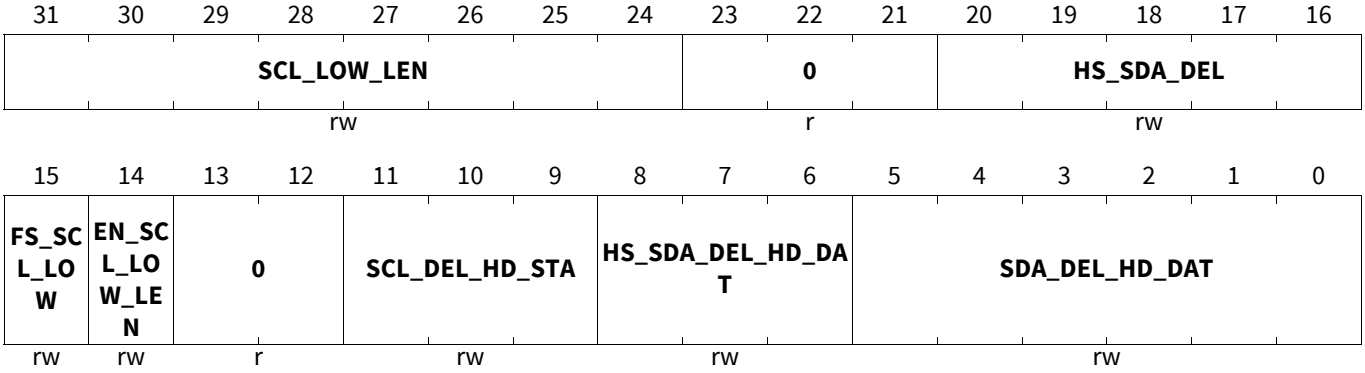
Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For high-speed mode, see **Clock and Timing Control**.
INC	23:16	rw	**Increment Value of Fractional Divider** For high-speed mode, see **Clock and Timing Control**.
0	15:11, 30:24, 31	r	**Reserved** Read as 0; should be written with 0.

Timing Configuration Register

This configuration register adjusts some timings of the I2C-bus signals SCL and SCA. The delays are given in kernel_clk cycles (denoted as stages below).

The delayed stages may have +/- 1 stage deviation.

TIMCFG
Timing Configuration Register **(00040_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SDA_DEL_HD_DAT	5:0	rw	**SDA Delay Stages for Data Hold Time in Standard and Fast modes** SDA delay stages for data hold time in standard and fast modes. *Note: SDA delay from SCL falling edge but will also affect SDA Setup time relative to next SCL rising edge* 00_H 3 stages delay … $3F_H$ 66 stages delay
HS_SDA_DEL_HD_DAT	8:6	rw	**SDA Delay Stages for Data Hold Time in High-speed Mode** SDA delay stages for data hold time in HS mode. *Note: SDA delay from SCL falling edge but will also affect SDA Setup time relative to next SCL rising edge* 000_B 3 stages delay … 111_B 10 stages delay
SCL_DEL_HD_STA	11:9	rw	**SCL Delay Stages for Hold Time Start (Restart) Bit** 000_B 2 stages delay … 111_B 9 stages delay
EN_SCL_LOW_LEN	14	rw	**Enable Direct Configuration of SCL Low Period Length in Fast Mode** 0_B SCL low period is a fixed part of the whole period, as defined by FS_SCL_LOW 1_B SCL low period is determined by the setting of SCL_LOW_LEN

Field	Bits	Type	Description
FS_SCL_LOW	15	rw	**Set Fast Mode SCL Low Period Timing** The internal duration of the SCL low time with respect to the period length as defined by the baudrate setting, can be enlarged for the Fast Speed Mode, in order to meet the asymmetric duty cycle requirements from the standard. The detailed formulas are given in the functional specification. 0_B Standard mode SCL low period timing. For INC = 1 it is 5/8 of period. 1_B Fast mode SCL low period timing. For INC = 1 it is 6/8 of period.
HS_SDA_DEL	20:16	rw	**SDA Delay Stages for Start/Stop bit in High-speed Mode** 00_H 3 stages delay … 07_H 10 stages delay
SCL_LOW_LEN	31:24	rw	**SCL Low Length in Fast Mode** If enabled by EN_SCL_LOW_LEN setting, this field determines the extension of the SCL low time. In case of INC = 1, the low time is extended by the number of kernel_clk cycles. In general, there is a more complex formula, as given in the functional specification. The total period time is not changed, i.e., the SCL high period is reduced accordingly. Setting SCL low time to period length or higher is not supported and would lead to unpredictable results.
0	13:12, 23:21	r	**Reserved** Read as 0; should be written with 0.

34.4.2 FIFO Registers

Transmission Data Register

The software has to write the characters to be transmitted into this register.

A larger address range (8000_H to $BFFC_H$) is reserved for the FIFO. Accessing any address in the defined range has the same effect as accessing the first address.

A read access to TXD register is not possible, it will return 0 in all cases. Reading has no effect on the FIFO

When using byte or half word access from the bus, the TX FIFO pointer will only be increased, if one of the following conditions is fulfilled:

- The most significant byte or half word of the FIFO stage is written
- The packet end is reached

TXD
Transmission Data Register (08000_H) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXD															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TXD															
w															

Field	Bits	Type	Description
TXD	31:0	w	**Transmission Data** Characters to be transmitted

Transmit Packet Size Control Register

This register is used to indicate the peripheral the size of the packet to be transmitted. Writing the packet size to this register if the FIFO controller is configured for flow controller mode initiates the data requests (BREQ, SREQ, ...).Writing to this register in configuration state has no impact.

TPSCTRL
Transmit Packet Size Control Register (00034_H) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		TPS													
r		rwh													

Field	Bits	Type	Description
TPS	13:0	rwh	**Transmit Packet Size** Length in characters of the transmit packet, write value range: 1 to 16383 Reading returns the written value as long as it is not loaded to an internal counter. After that, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

Reception Data Register

The software can read the received characters from this register.

A larger address range ($C000_H$ to $FFFC_H$) is reserved for the FIFO . Reading from any address in the defined range has the same effect as reading from the first address.

RXD

Reception Data Register **($0C000_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		MRPS													
r		rwh													

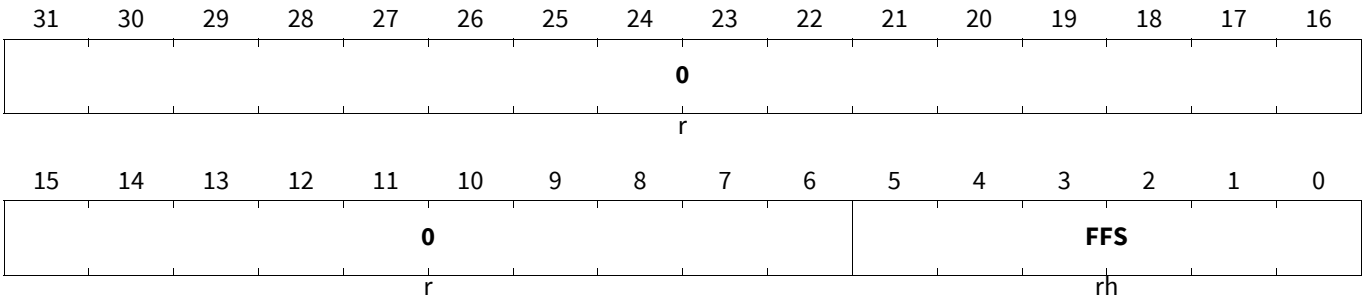
Field	Bits	Type	Description
MRPS	13:0	rwh	**Maximum Received Packet Size** Length in characters of packet to be received; write value range: 0 (unlimited size) to 16383 Reading returns the written value as long as the previous packet has not been read completely from the FIFO. After that, MRPS is loaded to an internal register, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

Filled FIFO Stages Status Register

This register is used to indicate the number of filled FIFO stages.

FFSTAT

Filled FIFO Stages Status Register **(00038_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FFS	5:0	rh	**Filled FIFO Stages** Number of filled FIFO stages (0 to 8)
0	31:6	r	**Reserved** Read as 0; should be written with 0.

34.4.3 Basic Interrupt Registers

For an overview of the Service Request Block (SRB) see **Section 34.3.1.7**.

Raw Interrupt Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the interrupt request sources. One status bit is provided for each request. A write to this register has no effect. The status bits are set by hardware or software (via register **ISR**) and can be cleared by software (via register **ICR**).

RIS

Raw Interrupt Status Register **(00080_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LBREQ_INT	2	rh	**Last Burst Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
BREQ_INT	3	rh	**Burst Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
I2C_ERR_INT	4	rh	**I2C Error Interrupt** This is the combined bit for indication of FIFO errors due to overflow and underflow. 0_B No interrupt request 1_B Interrupt request pending

Field	Bits	Type	Description
I2C_P_INT	5	rh	**I2C Protocol Interrupt** This is the combined bit for indication of a protocol event in the I2C kernel. 0_B No interrupt request 1_B Interrupt request pending
0	31:6	r	**Reserved** Read as 0; should be written with 0.

Interrupt Mask Control Register

A write of 1 to a particular bit of this register enables the corresponding interrupt request; a write of 0 disables it. A read to this register returns the current mask bits. After reset all requests are disabled.

IMSC
Interrupt Mask Control Register **(00084_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
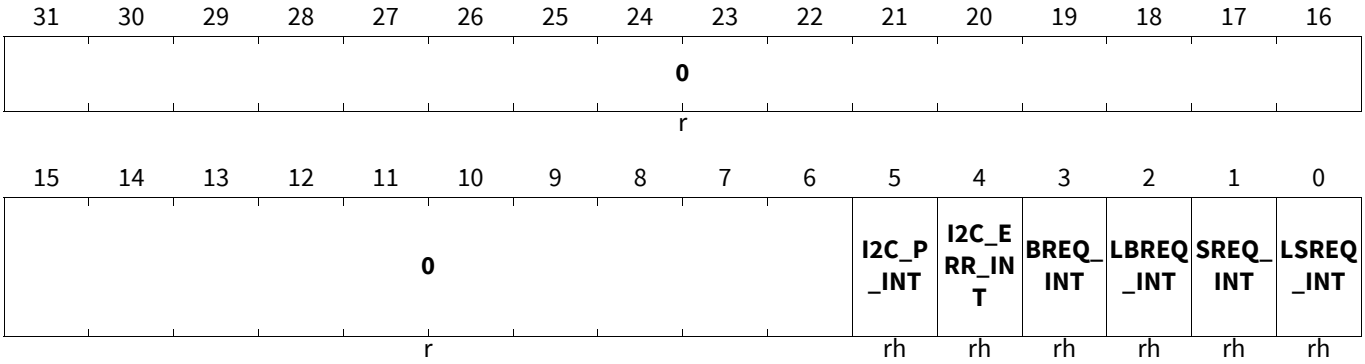
0	31:6	r	**Reserved** Read as 0; should be written with 0.

Masked Interrupt Status Register

This read-only register returns the masked status value (derived from registers **RIS** and **IMSC**) of the corresponding interrupt requests. A write to this register has no effect.

MIS

Masked Interrupt Status Register **(00088_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
LSREQ_INT	0	rh	**Last Single Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
SREQ_INT	1	rh	**Single Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending

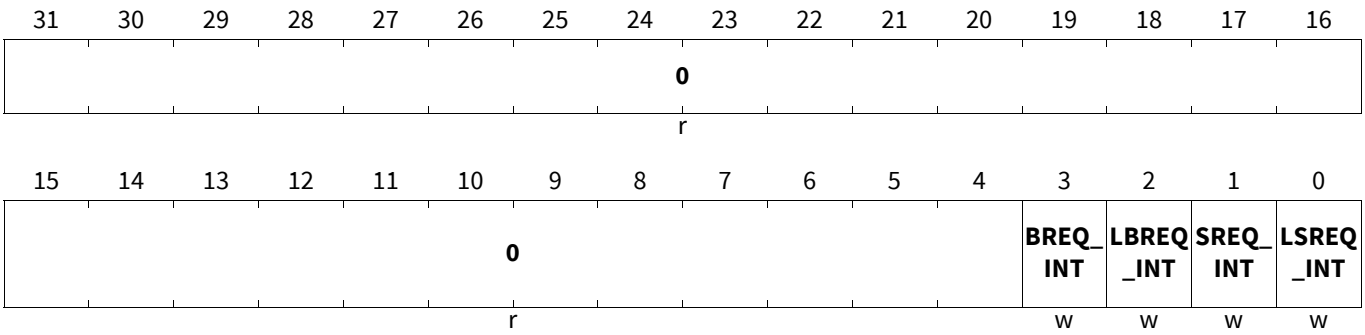
BREQ_INT	3	rh	**Burst Request Interrupt** 0_B No interrupt request 1_B Interrupt request pending
I2C_ERR_INT	4	rh	**I2C Error Interrupt** This is the combined bit for indication of FIFO errors due to overflow and underflow. 0_B No interrupt request 1_B Interrupt request pending
I2C_P_INT	5	rh	**I2C Protocol Interrupt** This is the combined bit for indication of a protocol event in the I2C kernel. 0_B No interrupt request 1_B Interrupt request pending
0	31:6	r	**Reserved** Read as 0; should be written with 0.

Interrupt Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding interrupt request is cleared; a write of 0 has no effect. Reading the register returns 0.

ICR
Interrupt Clear Register **(0008C$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
LSREQ_INT	0	w	**Last Single Request Interrupt** 0_B No change 1_B Clear interrupt request
SREQ_INT	1	w	**Single Request Interrupt** 0_B No change 1_B Clear interrupt request
LBREQ_INT	2	w	**Last Burst Request Interrupt** 0_B No change 1_B Clear interrupt request
BREQ_INT	3	w	**Burst Request Interrupt** 0_B No change 1_B Clear interrupt request
0	31:4	r	**Reserved** Read as 0; should be written with 0.

Interrupt Set Register

On a write of 1 to a particular bit of this write-only register, the corresponding interrupt request is set; a write of 0 has no effect. Reading the register returns 0.

ISR

Interrupt Set Register **(00090$_H$)** **Application Reset Value: 0000 0000$_H$**

0	31:6	r	**Reserved** Read as 0; should be written with 0.

34.4.4 Error Interrupt Source Registers

For an overview of the source register operation see **Section 34.3.1.7.2**.

Error Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding error interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register **ERRIRQSS**.

ERRIRQSM

Error Interrupt Request Source Mask Register (00060$_H$) **Application Reset Value: 0000 000F$_H$**

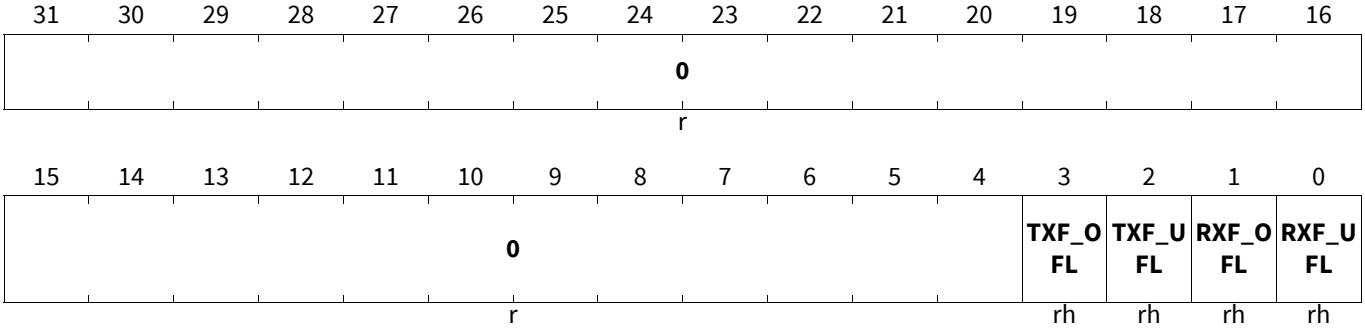
RXF_OFL	1	rw	**RX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TXF_UFL	2	rw	**TX FIFO Underflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TXF_OFL	3	rw	**TX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
0	31:4	r	**Reserved** Read as 0; should be written with 0.

Error Interrupt Request Source Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the error interrupt request sources. A write to this register has no effect. The error status bits are set by hardware and can be cleared by software (via register **ERRIRQSC**).

ERRIRQSS

Error Interrupt Request Source Status Register (00064$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RXF_UFL	0	rh	**RX FIFO Underflow** The FIFO has detected an RX FIFO underflow. 0_B No interrupt request 1_B Interrupt request pending
RXF_OFL	1	rh	**RX FIFO Overflow** The I2C kernel has detected a RX FIFO overflow 0_B No interrupt request 1_B Interrupt request pending
TXF_UFL	2	rh	**TX FIFO Underflow** The I2C kernel has detected a TX FIFO underflow. 0_B No interrupt request 1_B Interrupt request pending
TXF_OFL	3	rh	**TX FIFO Overflow** The FIFO has detected a TX FIFO overflow. 0_B No interrupt request 1_B Interrupt request pending
0	31:4	r	**Reserved** Read as 0; should be written with 0.

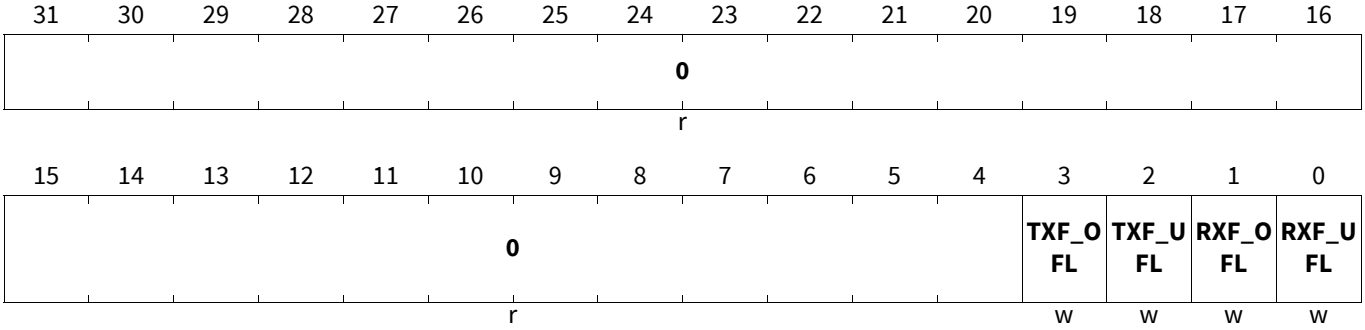
Error Interrupt Request Source Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding error interrupt request source is cleared and if no further error interrupt request sources are active, the whole error interrupt is cleared. If the corresponding bit is set by SW via the **ISR** register, then it can be cleared by setting any non-reserved bit of the interrupt request source clear register**.** A write of 0 has no effect. Reading the register returns 0.

The interrupts are explained in detail in description of register **ERRIRQSS**.

ERRIRQSC

Error Interrupt Request Source Clear Register (00068$_H$) **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RXF_UFL	0	w	**RX FIFO Underflow** 0_B No change 1_B Clear interrupt request source
RXF_OFL	1	w	**RX FIFO Overflow** 0_B No change 1_B Clear interrupt request source
TXF_UFL	2	w	**TX FIFO Underflow** 0_B No change 1_B Clear interrupt request source
TXF_OFL	3	w	**TX FIFO Overflow** 0_B No change 1_B Clear interrupt request source
0	31:4	r	**Reserved** Read as 0; should be written with 0.

34.4.5 Protocol Interrupt Source Registers

For an overview of the source register operation see **Section 34.3.1.7.2**.

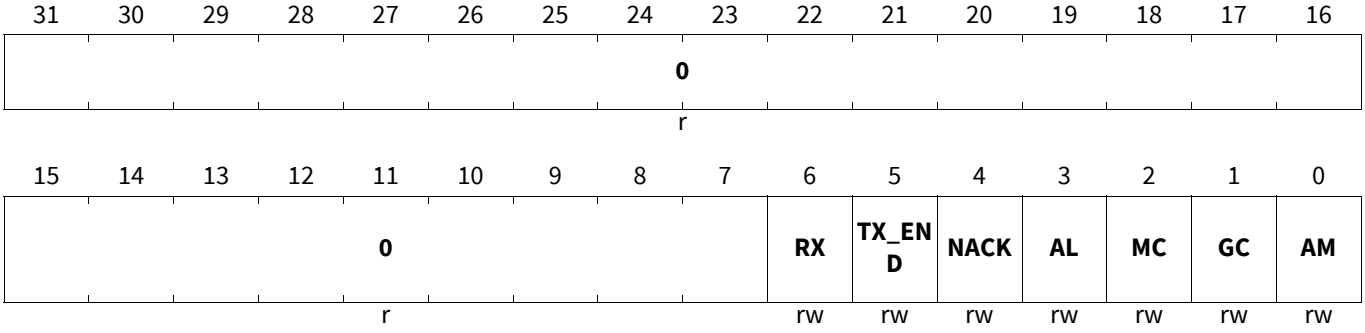
Protocol Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding protocol interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register **PIRQSS**.

PIRQSM

Protocol Interrupt Request Source Mask Register(00070_H) **Application Reset Value: $0000\ 007F_H$**



Field	Bits	Type	Description
AM	0	rw	**Address Match** 0_B Interrupt request source disabled 1_B Interrupt request source enabled

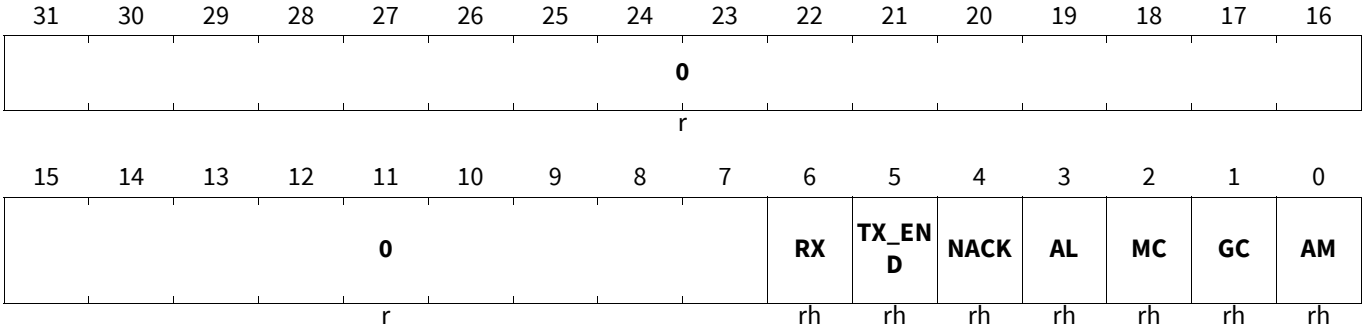
RX	6	rw	**Receive Mode** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
0	31:7	r	**Reserved** Read as 0; should be written with 0.

Protocol Interrupt Request Source Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the protocol interrupt request sources. A write to this register has no effect. The protocol interrupt status bits are set by hardware and can be cleared by software (via register **PIRQSC**).

PIRQSS

Protocol Interrupt Request Source Status Register(00074_H) **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
AM	0	rh	**Address Match** Device (in master or slave mode) is addressed by remote master (matching device address). Accordingly, bit-field BS in register **BUSSTAT** is set to 11_B. 0_B No interrupt request 1_B Interrupt request pending
GC	1	rh	**General Call** Remote master has transmitted a general call. 0_B No interrupt request 1_B Interrupt request pending
MC	2	rh	**Master Code** Remote master has transmitted a master call. 0_B No interrupt request 1_B Interrupt request pending
AL	3	rh	**Arbitration Lost** Device (master mode) lost the control on the I2C-bus due to losing arbitration procedure. Accordingly, bit-field BS in register **BUSSTAT** is set to 01_B. 0_B No interrupt request 1_B Interrupt request pending
NACK	4	rh	**Not-acknowledge Received** When working as transmitter this interrupt indicates a not-acknowledge from the remote receiver. The SW has to decide what further steps have to be taken. 0_B No interrupt request 1_B Interrupt request pending

Field	Bits	Type	Description
TX_END	5	rh	**Transmission End** The device has ended the data transfer properly (after stop condition has been put on the bus or the MASTER RESTART state has been entered.) 0_B No interrupt request 1_B Interrupt request pending
RX	6	rh	**Receive Mode** I2C kernel indicates switching from transmitting data to receiving data. 0_B No interrupt request 1_B Interrupt request pending
0	31:7	r	**Reserved** Read as 0; should be written with 0.

Protocol Interrupt Request Source Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding protocol interrupt request source is cleared and if no further protocol interrupt request sources are active, the whole protocol interrupt is cleared. If the corresponding **RIS** bit is set by SW via the **ISR** register, then it can be cleared by setting any non-reserved bit of the interrupt request source clear register**.** A write of 0 has no effect. Reading the register returns 0.

The interrupts are explained in detail in description of register **PIRQSS**.

35 High Speed Serial Link (HSSL)

The HSSL module provides point-to-point communication of both single data values and of large data blocks, called streams. The communicating devices can be complex microcontrollers, or a microcontroller and a device with only basic execution capabilities. There are four channels to transfer single values to/from target. They support direct writing of 8/16/32 bit data from the initiator into a target's register, as well as reading a value from a target, performed by a modules internal master on the target side. For transferring large data blocks there is a channel containing FIFOs. The HSSL module implements Transport Layer tasks and hands over the data to another module which provides Data Link Layer and Physical Layer services, data serialization and transmission. All transfers are protected by safety features like CRC and timeout.

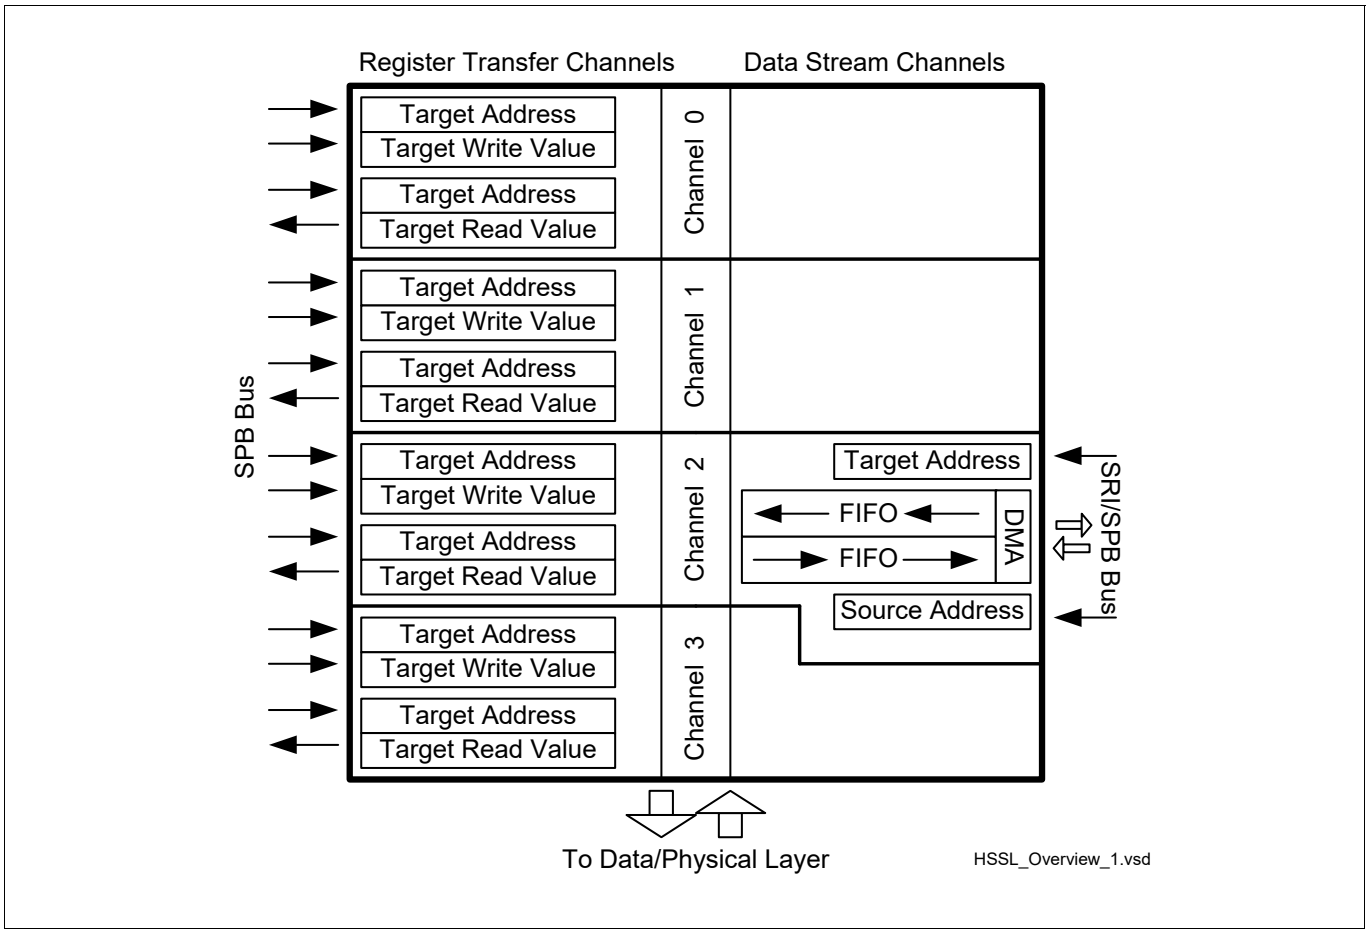

Figure 355 Block Diagram HSSL

35.1 Feature List

- Connects microcontroller to microcontroller or to any digital device
- Writing a single 8 / 16 / 32 bit data value into the register of a target device
- Reading single data from an 8 / 16 / 32 bit register of a target device
- Support of 32-bit address range
- Transfers protected by CRC16
- Programmable time outs for detection of blocked answer transfers
- Automatic frame transfer ID generation for detection of dropped frames
- Support of DMA driven multiple register write / read transfers
- Efficient transmission and reception of large data blocks / streams

- Acknowledge for command and stream frames to reduce latency of error detection
- Two stage FIFOs for transmitting and receiving streaming data
- Automatic FIFO flush when entering the run mode, for error handling
- Write protection by an external Memory Protection Unit MPU
- Remote trigger of event / interrupt in the target device by the initiator
- Identification of the target by the JTAG ID number
- Feature set identification of the HSSL module possible by using the JTAG ID number
- Access protection from an external master

Description

The HSSL module generates all necessary protocol formats in order to enable two devices to communicate to each other. Two basic modes are supported.
In register transfer mode the transmitter (“sending device”) provides an address and a data value by writing them into dedicated registers of the HSSL module. The HSSL module puts it into an envelop (called frame) and forwards it via physical layer to the target device. The target takes the information out of the frame and writes the received data into the address which came in the same frame as the data. If the sender wants to read the content of a register or a memory location, it simply sends only the address. The target device reads the value from the specified location and replies it to the sender by transferring it through an answer frame, which has a format of it’s own.

The transfer of register / memory contents is protected by several security levels. A 16 bit CRC value (called CRC16) is attached to the end of each frame. Each transfer process triggers a watchdog, which makes sure that the communication happens within a deterministic schedule. The target device itself offers the capability to define access windows, which allow reading or writing only from / into certain address ranges.

Each frame must be acknowledged by the target by sending an appropriate response frame. If the response frame does not come inside a predefined time window, the initiator module triggers a timeout interrupt.

In data stream mode data blocks of user defined size can moved from the memory of the sending device into the memory of the target device. A DMA master, which can be configured with any source address and source length, autonomously fetches data, breaks it into smaller blocks of programmable size, and puts it into a FIFO. The lower level companion module of the HSSL module empties the FIFO from the “other side” to the physical lines, which connect two devices. In the target device receives a structure, which is inverse to the sender system, the data blocks, puts them into a FIFO, which is in turn emptied by a DMA master into the target memory.

All streaming data transfers are subject to the protection features which are available for the register transfer mode.

After module reset, most registers are only released for read for remote access. They have to be unlocked by the local SW.

In order to ensure consistent initialization of the communication channel there is a possibility to determine the feature set of the module by using the JTAG ID of the device, which uniquely identifies the available HW options of the module. ASIC versions of the HSSL interface may only employ stripped down instances.

35.2 Overview

The following section gives an overview of the lower communication layers of the HSSL protocol.

35.2.1 Lower Communication Layers (HSCT, PLL, Pads)

The lower layer companion module and logic control the lower communication layers positioned between two devices, the data and the physical layer. They consist of High Speed Communication Tunnel (HSCT) module, a corresponding PLL and pads. For more information on the lower communication layers, see the HSCT chapter.

The chip to chip interface employs a digital interface for inter chip communication between a master IC and a slave IC. The interface is capable of running in a master or in a slave mode. During configuration phase the role of the Interface (master or slave) has to be defined. It is not intended to change the system role during an application.

The interface consists of a full-duplex RX and TX high-speed data interface based on double ended differential signals (in total 4 lines) and a master clock interface (SYS_CLK). The master IC owns the crystal and provides the clock to the slave. The interface reset is derived from the System reset and provided by chip internal reset signaling.

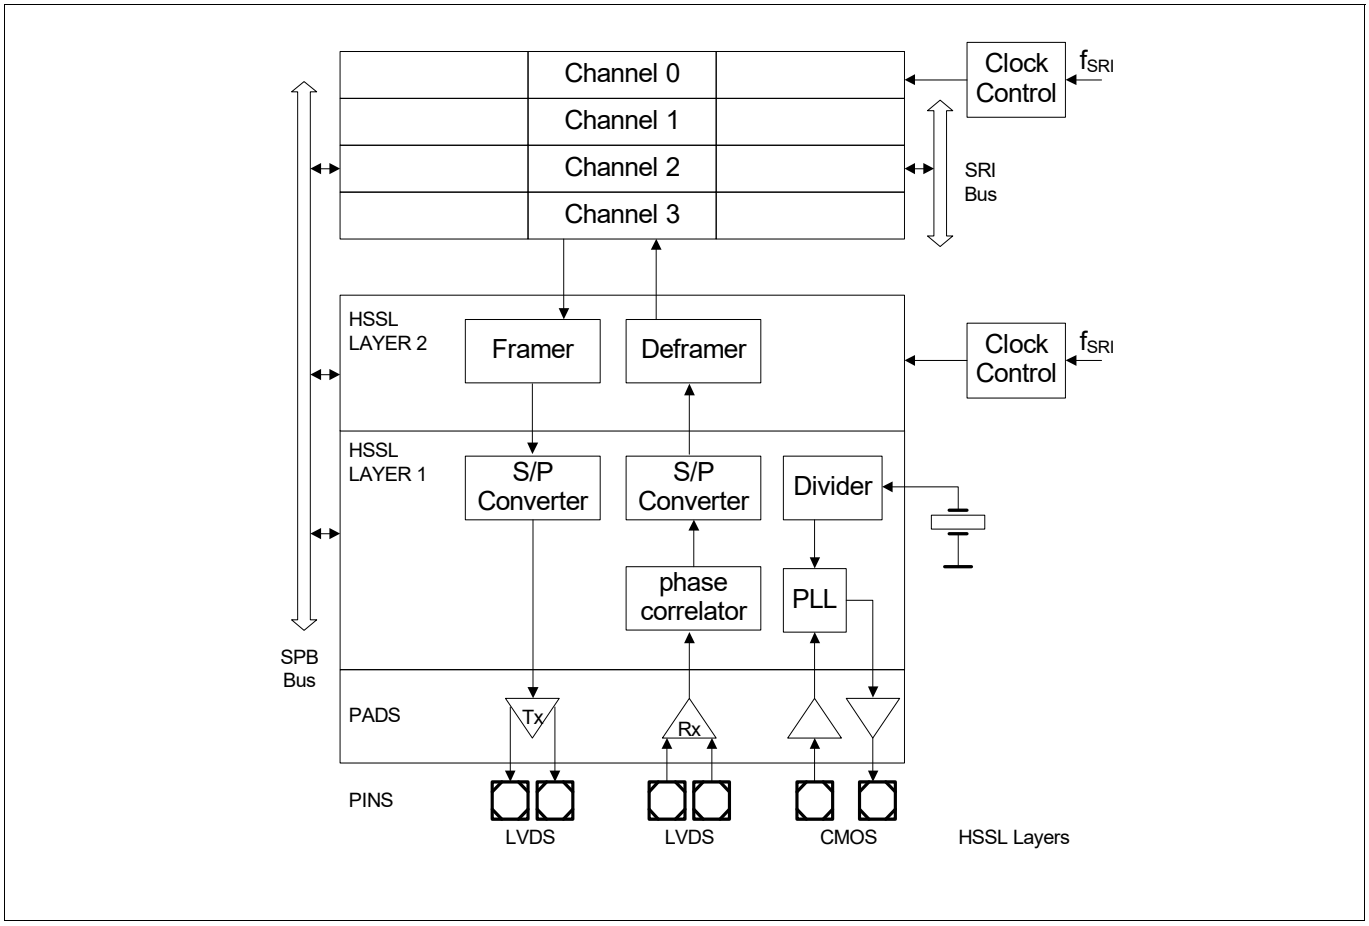

Figure 356 Physical Layer

Features:

- Transmission of symbol information from the master IC to the slave IC
- Receive symbol information sent from the slave IC to the master IC
- System Clock provided by the master IC (crystal owner) to the slave IC
- Exchange of control information in both directions
- Clear To Send indication in both directions
- Unsolicited status in both directions
- Regular data transfer in both directions based on data channels
- Master IC data transfer speed 5 MBaud and 320 MBaud
- Three slave IC data transfer speeds available based on 20 MHz SYS_Clk:
  5 MBaud (low speed)
  20 MBaud (medium speed)
  320 MBaud (high speed)
- Two slave IC data transfer speeds available based on 10 MHz SYS_Clk (lower EMI):
  5 MBaud (low speed)
  320 MBaud (high speed)
- The interface is based on IEEE 1596.3 LVDS input-output pads
- To reduce the voltage swing a configuration option is available

35.3 Functional Description

This section describes the HSSL protocol and it's implementation.

35.3.1 HSSL Protocol Definition

This section describes the high level protocol definition of the HSSL interface.

The HSSL communication normally consists of two stage transactions, sending a command and an receiving a response. It involves two participants:

- an initiator, which starts a transaction by sending a command
- a target, which responds to the command

35.3.1.1 List of Abbreviations, Acronyms, and Term Definitions

ACK - Acknowledge Frame

NACK - Not Acknowledge Frame (Target Error Frame)

CRC - Cyclic Redundancy Check

HSSL - High Speed Serial Link

TO - Time Out

TT - Transaction Tag

TTERR - Transaction Tag Error

SPB - Serial Peripheral Bus

SRI - Shared Resource Interconnection

SoC - System on Chip

Initiator - Device that starts a HSSL transaction by sending a command frame

Target - Device that responds to a command frame sent by an initiator

35.3.1.2 Frame Types

The HSSL module generates a serial frame by:

- taking the payload delivered by a CPU or a DMA
- first wrapping it in a HSSL frame by adding header and CRC fields, and then
- wrapping the HSSL frame in a HSCT frame by adding Sync, Header and End bit fields (see **Figure 357**)

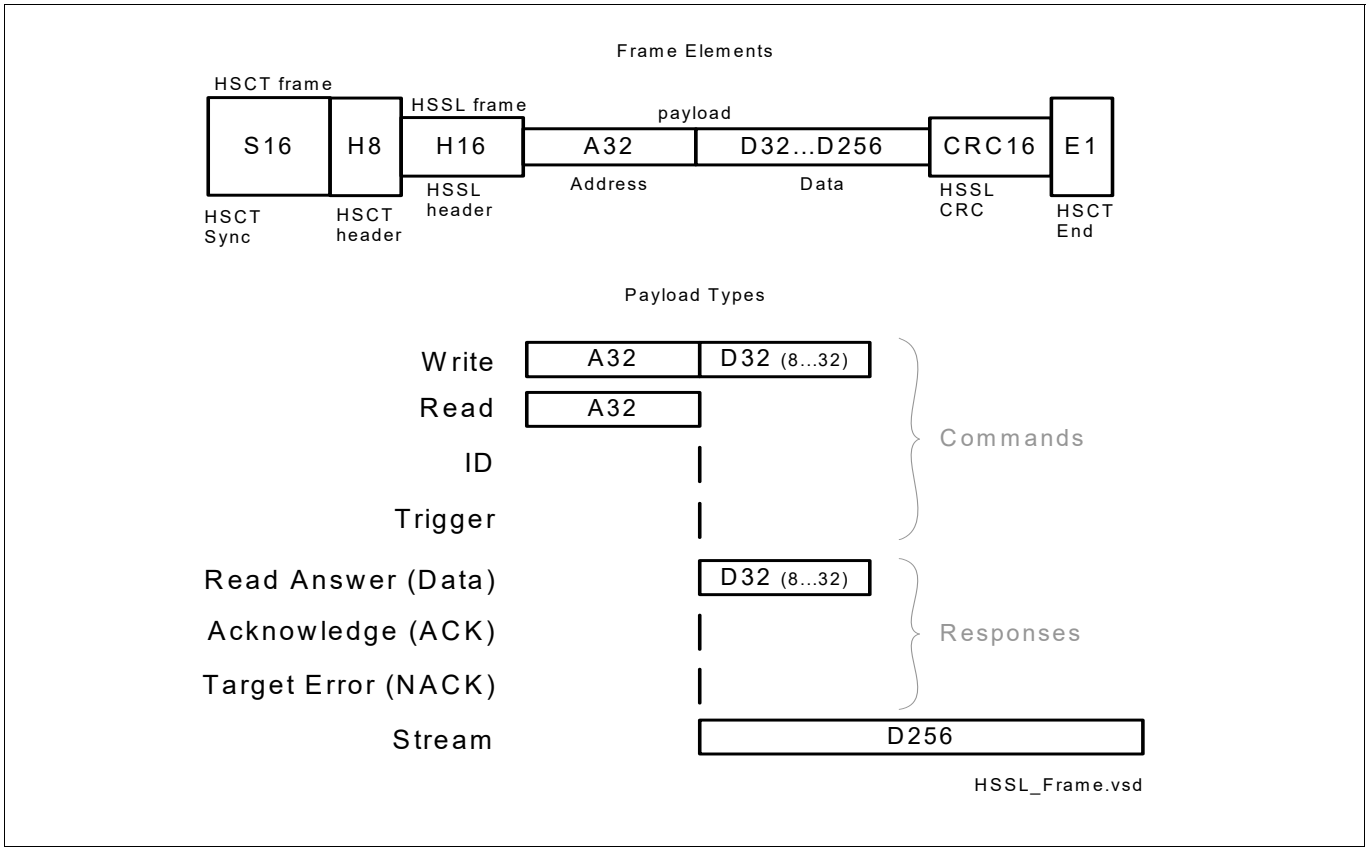

Figure 357 HSSL Frame Types

There are several types of frames:

Command Frames

Command frames are sent by the initiator to request an action by the target. There are four types of command frames:

- **Write Frame**
  - Used by the initiator to request the target controller to write the data to the address, both provided by the initiator.
- **Read Frame**
  - Used by the initiator to request the target controller to read and deliver a content from an address from its address space.
- **Read ID Frame**
  - Used by the initiator to request the target controller to read and deliver a content uniquely defining the target device. The answer is a standard Read Data Answer Frame.
- **Trigger Frame**
  - Used by the initiator to trigger the trigger interrupt in the target module.

In this document, the command frames are sometimes referred to as WRT frames.

Response Frames

Response frames are sent by the target either to deliver the requested data or to report a successful or unsuccessful completion of a request. There are three types of response frames:

- **Read Data Answer Frame**

  - Used by the target to deliver the data, requested by the initiator with a read command frame. It is frequently referred to as a Data frame.
- **Acknowledge Frame**
  - Used by the target to confirm the completion of a write or trigger command. It is frequently referred to as an ACK frame.
- **Target Error Frame**
  - Used by the target to report the unsuccessful attempt to complete a write or read command. It is frequently referred to as a NACK frame.

Stream Frame

Used by the initiator controller for sending data streams. It behaves similar to a write command frame which contains long 256-bit data block, is acknowledged in the same way, but the acknowledge uses sliding window with depth of 2 (instead of 1 as for the simple command frames).

35.3.1.2.1 Frame and Payload Lengths

Each type of frame has a single data length associated with it. The length of the frame depends on the length of the payload. Different frame types have different payload lengths, but the payload length for one type is constant for all variations of the frame type.

For example all data frames have the same length, although they can carry 8, 16 or 32 bit data. This is due to the fact that the data field in the frame is always 32 bit long, and if the data itself is shorter, it is copied several times to fill in the whole field. The same behavior is valid for the read answer frames.

The rest of the frame, consisting of sync and header fields, has always the same length (see **Figure 361**).

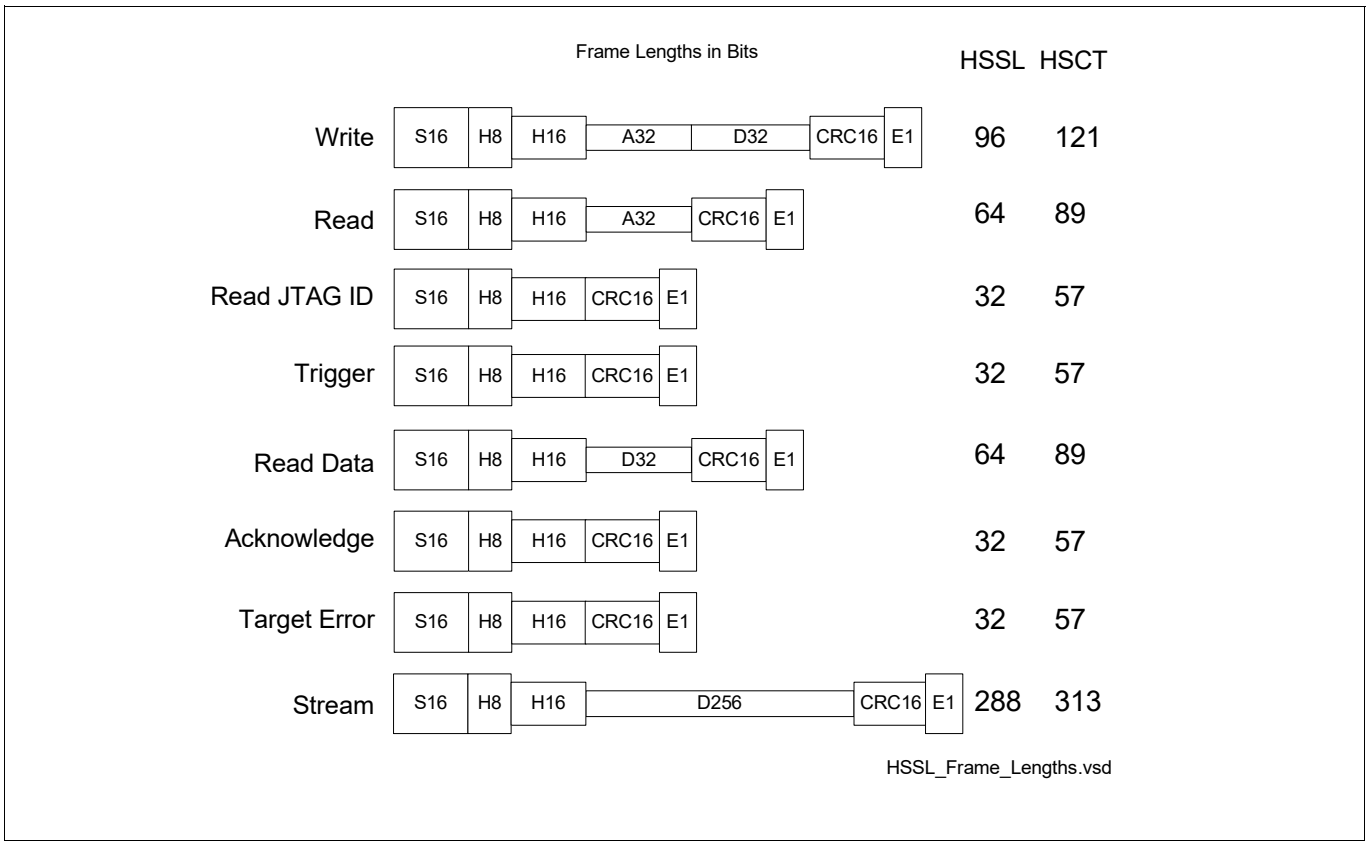

Figure 358 Frame Lengths

35.3.1.2.2 Data Types

There are four types of HSSL data:

- 8-bit
- 16-bit
- 32-bit
- 256-bit stream block

The in case of 8/16/32 bit data types, the transmitted number of bits is always 32, where the shorter data types are copied several times to fill up this length (see **Figure 359**).

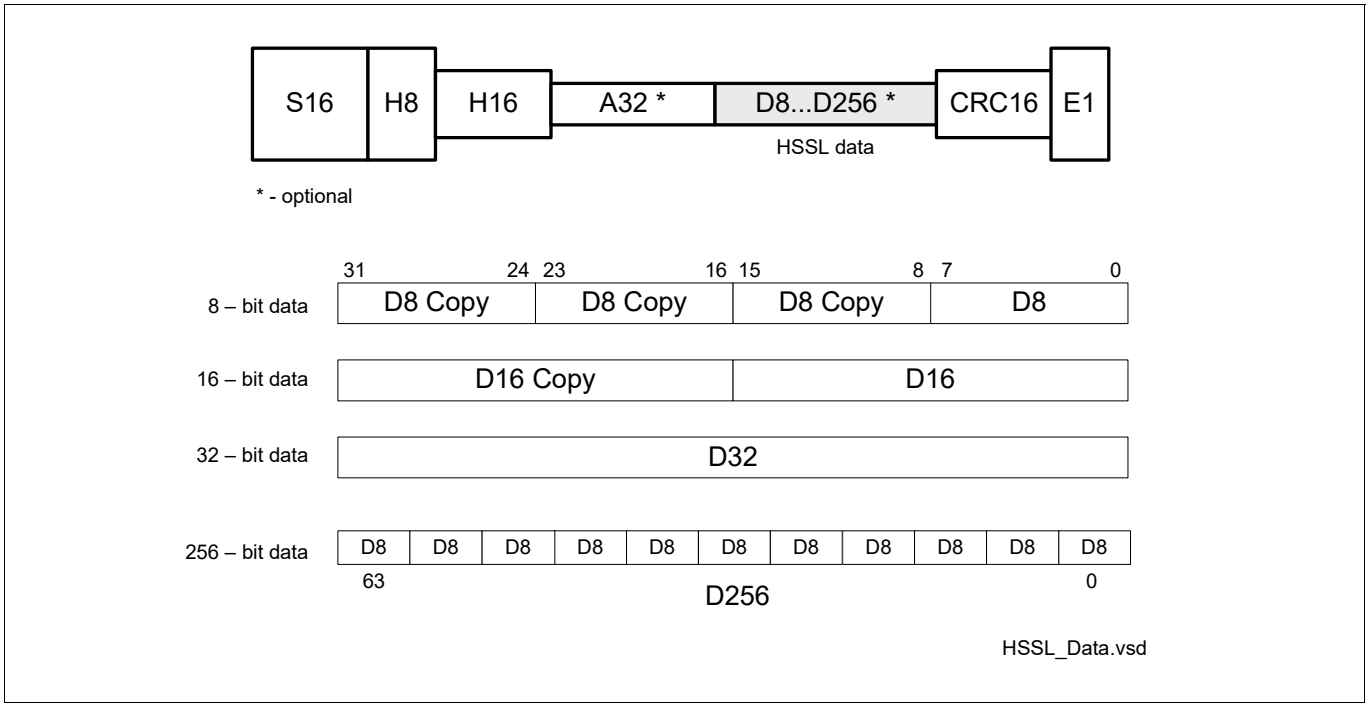

Figure 359 Data Types

35.3.1.2.3 Cyclic Redundancy Check Field - CRC

The HSSL protocol uses the CRC-16-CCITT polynomial: $x^{16} + x^{12} + x^5 + 1$ with the following standard properties:

- seed: 0xFFFF
- calculation direction: MSB first (header msb to lsb, then payload msb to lsb)
- CRC result direction: MSB first

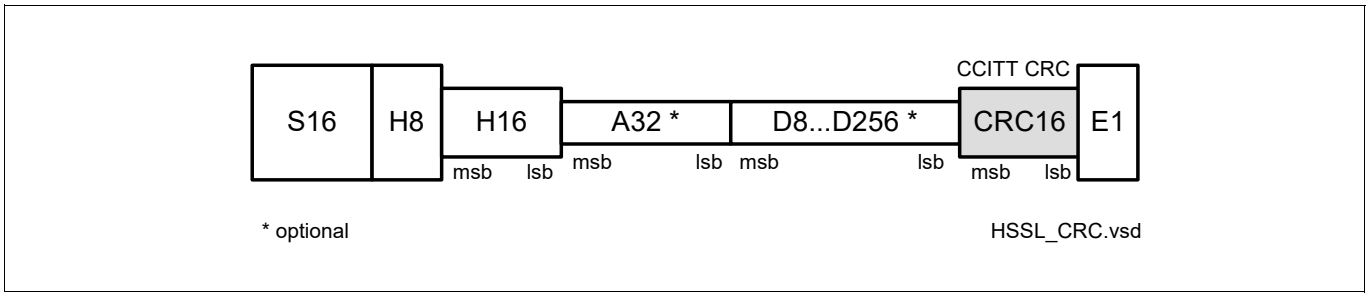

Figure 360 CRC Field

35.3.1.2.4 Header Structure

The HSSL header contains the protocol information that is required additionally to the raw payload data. The HSSL header describes the payload data regarding the length and the type, and carries additional information like channel number code and transaction tag. It also carries stand-alone information in case of frames without payload, like acknowledge and trigger frames.

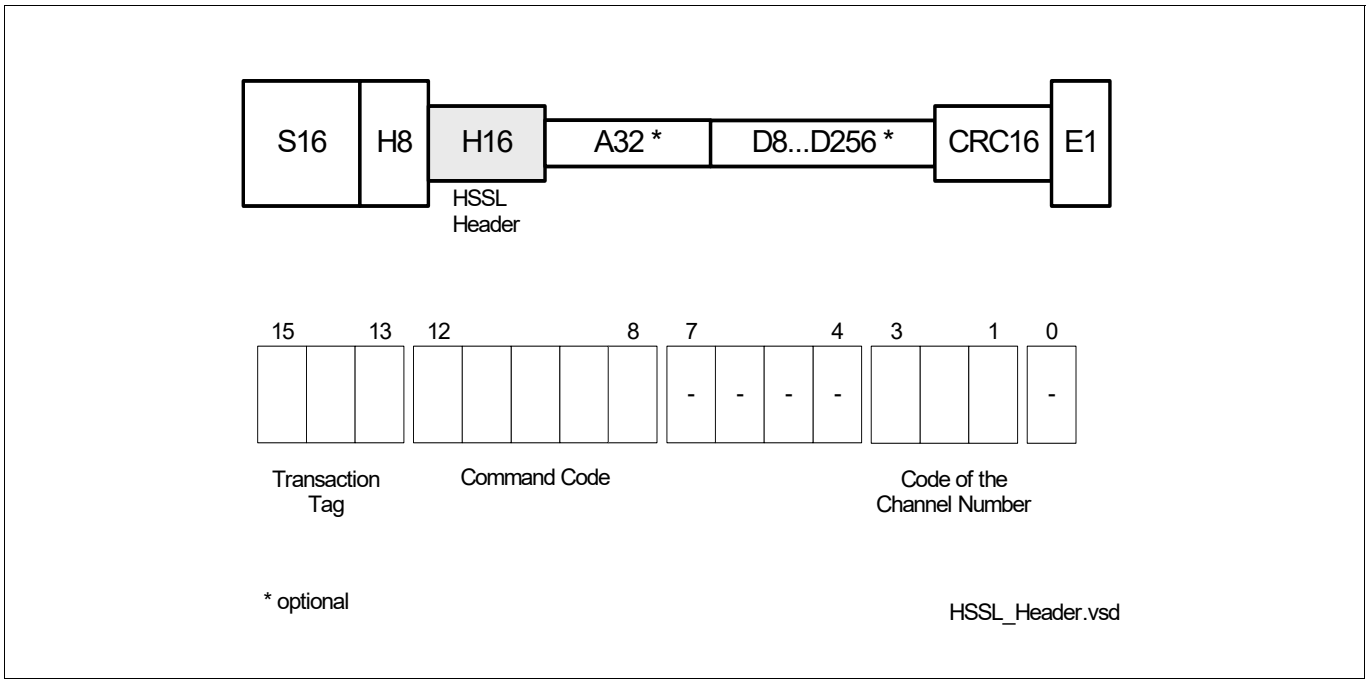

Figure 361 Header Types

Note: The unused bits in the header are padded with 0.

Table 306 Mapping of HSSL to HSCT channel codes

HSSL Channel Number	HSSL Channel Number, Binary Code	HSSL Channel Number, Special Code	HSCT Channel	HSCT Channel Code
0	000	100	A	0100
1	001	101	B	0101
2	010	110	C	0110
3	011	111	D	0111

11110	RFU	-
11111	RFU	-

35.3.1.3 Single and Block Transfers

Single frame transfers are always performed expecting an acknowledge.

35.3.1.4 Streaming Interface

Stream frame transfers are always performed with acknowledge.

There are only write streams possible. Read streams are not possible.

35.3.1.5 Sliding Window Protocol

For flow control the HSSL module implements two variants of the "Sliding Window" protocol regarding the sliding window depth:

- depth of one used for command frames
  - The depth of one means that a single timer tracks the arrival of the corresponding response frame. A new command can be sent only after the response to the previous command has been received, or a timeout occurred
- depth of two used for streaming frames
  - the depth of two means that there are two timers tracking the acknowledge times for the two latest streaming frames. In this case, a second stream frame can be sent although an acknowledge / timeout to the previous stream frame has not been received yet. After the second stream frame, no third stream frame can be sent before the first one has been acknowledged

An example of communication using sliding window with depth of one protocol is shown in **Figure 362**. Here, the initiator sends commands originating from one and the same channel, for example channel 0 (labeled with the capital letter "A"), and the corresponding acknowledge frames from the target are labeled with the small letter "a".

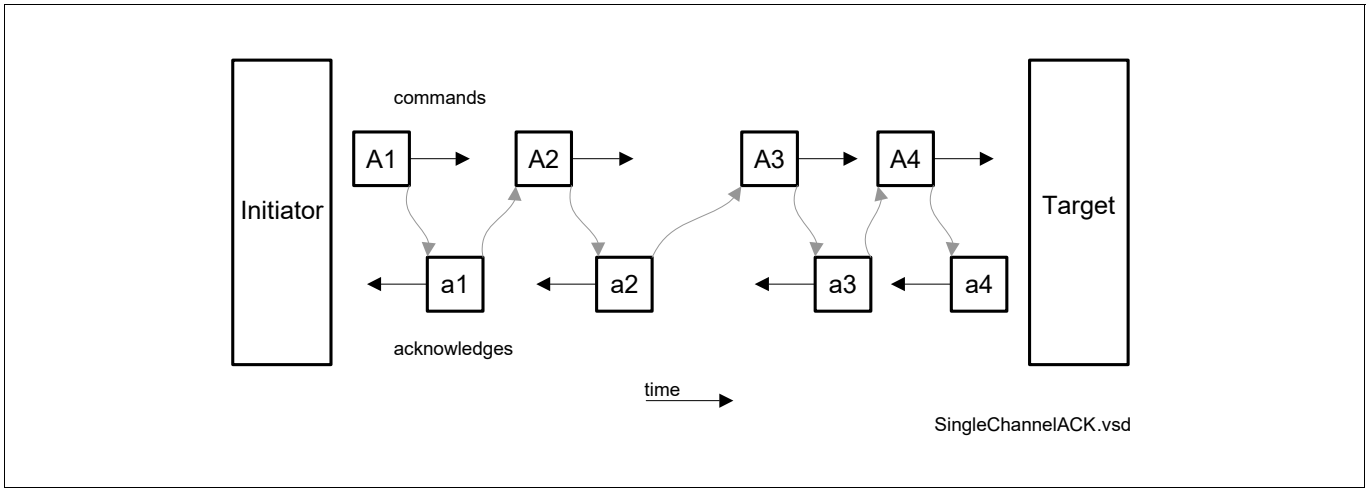

Figure 362 Flow Control, Single Channel, Sliding Window With Depth of One

The sliding window protocol requires capability of sending acknowledge frames in the target and timeout timers in the initiator. Every time the target receives a frame without detecting an error, it sends a response / acknowledge to the initiator. If the target detects a frame with a CRC error, it does not send an acknowledge. The missing acknowledge causes a timeout event in the initiator channel.

If the command frames are longer than the acknowledge frames plus the reaction time, like for example in case of streaming, back to back transfers are easily possible, see **Figure 363**.

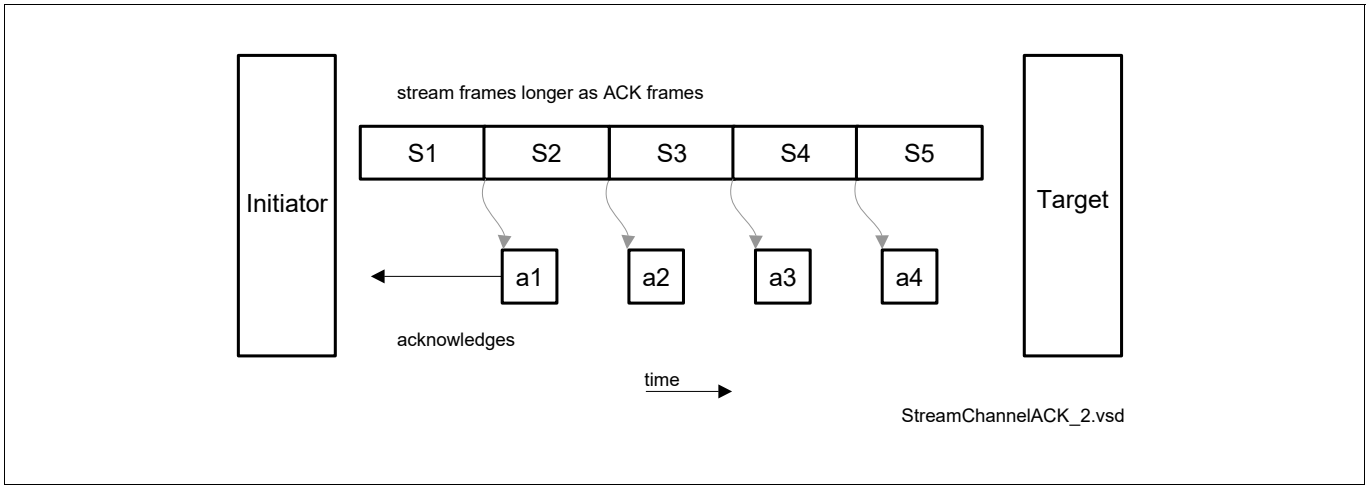

Figure 363 Flow Control, Streaming Frames

35.3.1.6 Error Management

The HSSL protocol defines four types of errors:

- Time Out
- Transaction Tag Error
- CRC Error
- Target Error

Time Out Error

A time out error is detected at the initiator side, if the expected ACK frame was not received within the expected time window. This can occur if a frame had been sent by the initiator, and the target detected an CRC error and

did not answer with an acknowledge, or the connection between the initiator and the target is physically damaged in one or the other direction.

Transaction Tag Error

A transaction tag error occurs at the initiator side, if instead the expected ACK frame with the expected TAG number, an acknowledge with an unexpected transaction tag was received. This would indicate a missing frame or missing acknowledge. Transaction tag error generate frames that pass the CRC checking stage.

CRC Error

A CRC Error can occur:

- at the target side, in which case:
  - the CRC error flag is set
  - the received command frame with a CRC error is discarded
  - no acknowledge frame is sent and
  - a channel unspecific EXI error interrupt is generated, if enabled.
- at the initiator side, in which case:
  - the CRC error flag is set
  - the received response frame with a CRC error is discarded
  - a channel unspecific EXI error interrupt is generated, if enabled

Both scenarios lead to a time out at the initiator side.

In both cases the CRC error flag is set at the side receiving the erroneous frame (either initiator or target) and an interrupt is generated, if enabled.

For the purpose of CRC error injection, a bit field with an XOR mask used for toggling the bits of the calculated CRC is provided, see **CRC**.XORMASK. In order to switch on this feature, the E (Endinit) protected bit must be set by the application software. The error injection only influences the generation of the transmitted CRC.

Target Error

A Target Error can occur at the target side, when accessing the target memory a bus error or memory protection error occurs. In such a case, the target responds with an NACK frame indicating the error.

35.3.1.7 Shift Direction

In general, the HSSL interface makes a copy of a memory location or block from the address space of one microcontroller into the address space of the other microcontroller.

The HSSL module delivers 32-bit parallel data.

The transfer over HSCT serial link is done by using MSB first shifting at 32-bit level.

The overview of the path from the memory to the serial bus is shown in the **Figure 364**.

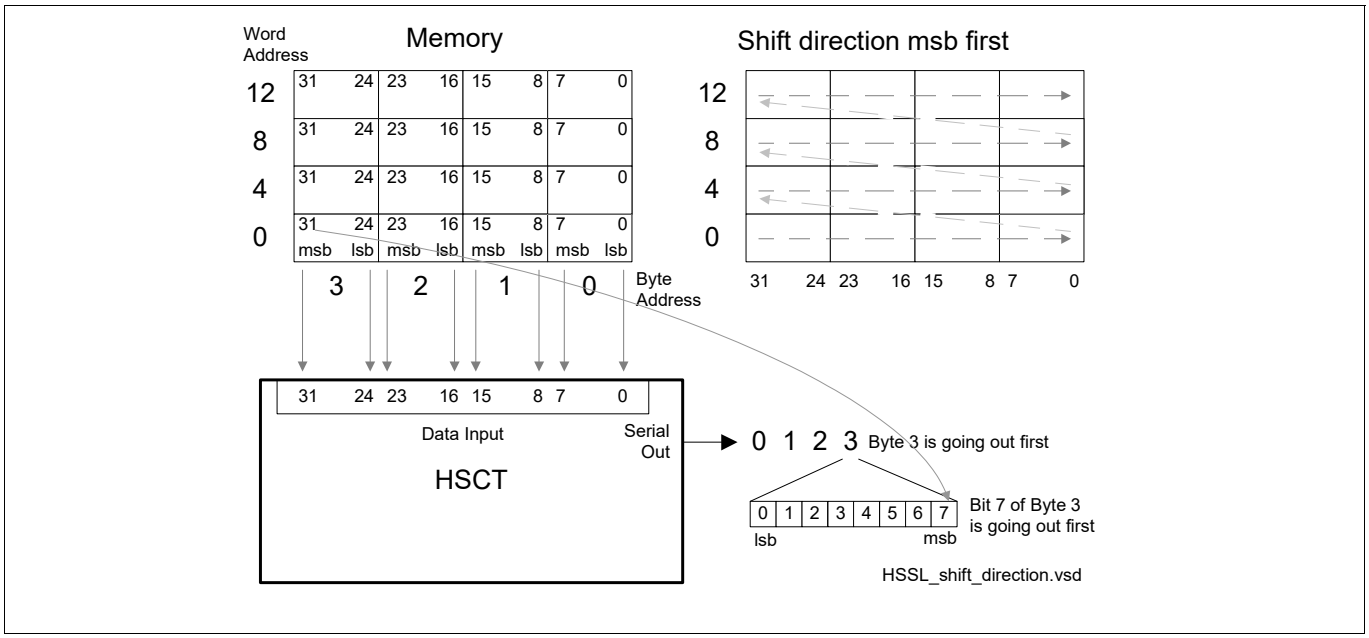

Figure 364 Shift Direction in Case of HSCT Layer

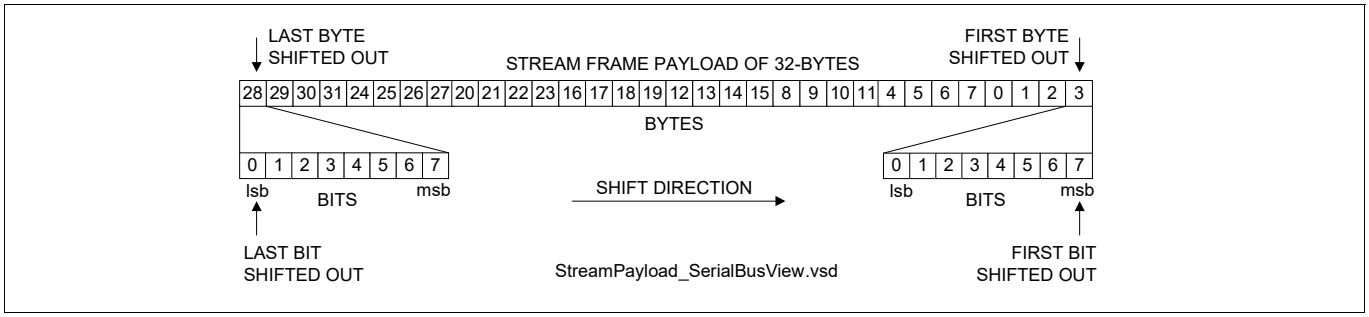

Figure 365 Stream Frame in Case of HSCT Layer

35.3.2 HSSL Implementation

This section describes the implementation of the HSSL protocol.

35.3.3 Overview

The HSSL module is connected to the SRI bus using a master interface and to the SPB bus using a BPI slave interface.

Additionally, it is connected to the SPB bus using a master interface.

The SRI master interface is capable of performing single and burst reads and writes on the SRI bus. Additionally, the HSSL kernel provides logic for performing streaming communication. The write and read accesses are always performed in User Mode.

The SPB BPI slave interface is used by an SPB master (DMA, CPU, HSSL SPB Master) for writing the HSSL registers, thus configuring the module and performing single read and write operations.

The SPB master interface is capable of performing single read operations, write operations, and streaming communication using BTR4 burst accesses on the SPB bus. The SPB master accesses are always performed in User Mode.

The HSSL module to use the SRI or the SPB master depending on the address of the access. Accesses to the SPB address space are automatically routed to the SPB master, accesses to the SRI address space are automatically routed to the SRI master. The address window F000 0000_H - F7FF $FFFF_H$ is used for the SPB bus, otherwise SRI.

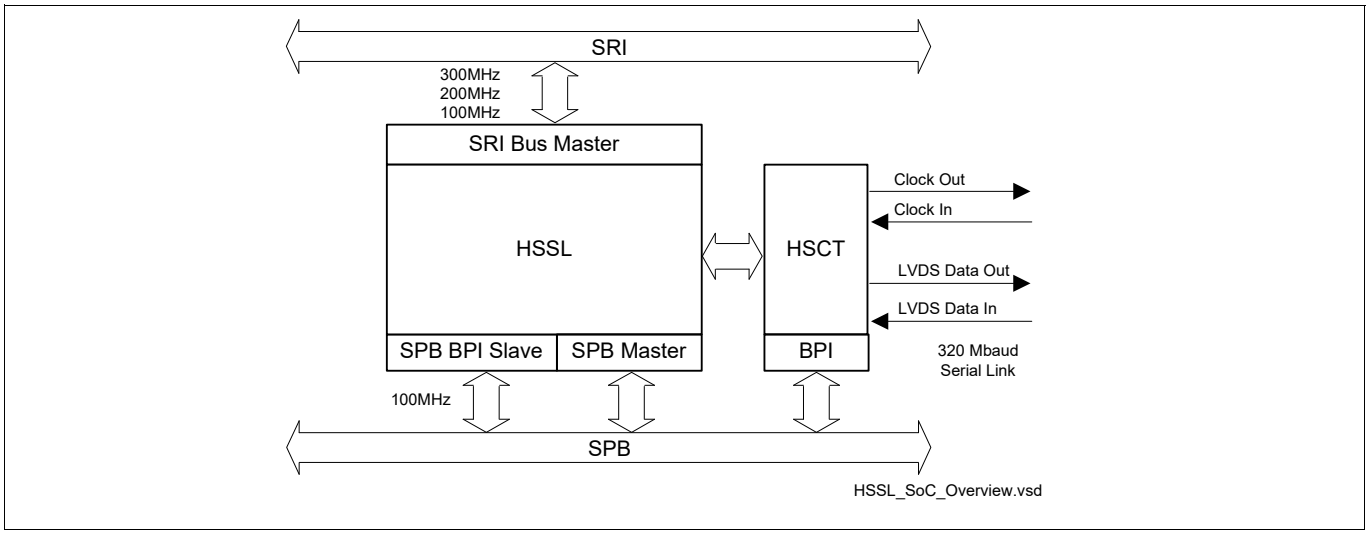

Figure 366 HSSL Subsystem Overview

35.3.3.1 HSSL Module Operation

The HSSL module consists of separate transmitter and receiver, each containing four channels.

The transmitter contains an arbiter block and a wrapper block, which are common for all channels. The arbiter provides fixed arbitration between the channels which are ready to send when the serial link is available, with channel 0 having the highest priority, and the channel 3 having the lowest priority. The wrapper block generates the CRC.

The receiver unwraps the HSSL frame, discards the frames with a CRC error, and distributes the error free commands and acknowledges to the channels.

A common prescaler generates the time basis for all channels, in particular for their timeout timers.

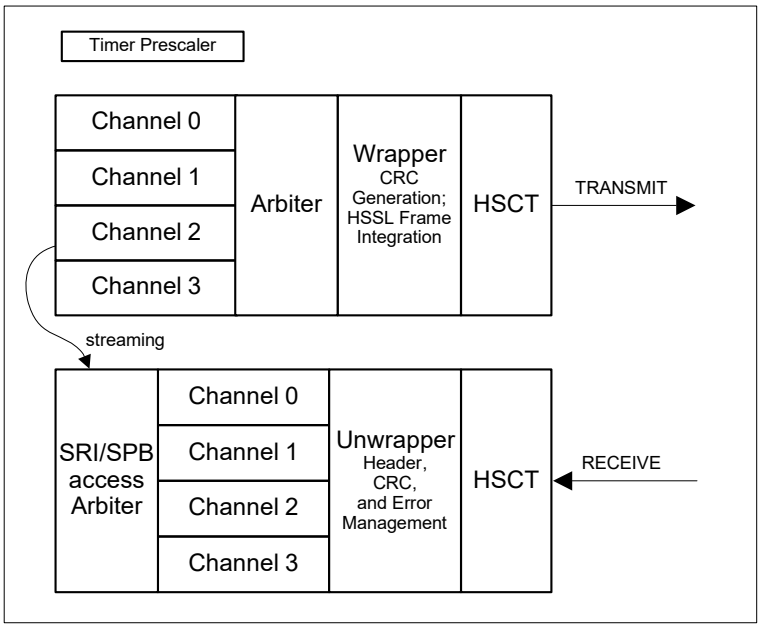

Figure 367 HSSL Layer Architecture

35.3.3.1.1 Frame Transmission Priorisation

When more than one frames are pending, an arbitration is performed between them.

Each channel activates two flags: initiator command flag and response flag: channel 0 I0 and R0, channel 1 I1 and R1, … .

Between the response and command frame request types, the response request type has higher priority. Among the requests of a same type, lower channel number has higher priority, see **Figure 368**. A pending frame is indicated with a corresponding request flag in the register **QFLAGS**.

The SRI/SPB bus master sets the response requests (“R” flags).

The software write accesses via the SPB bus set the initiator requests (“I” flags).

The transmit arbiter clears the “I” and “R” flags of the arbitration winner.

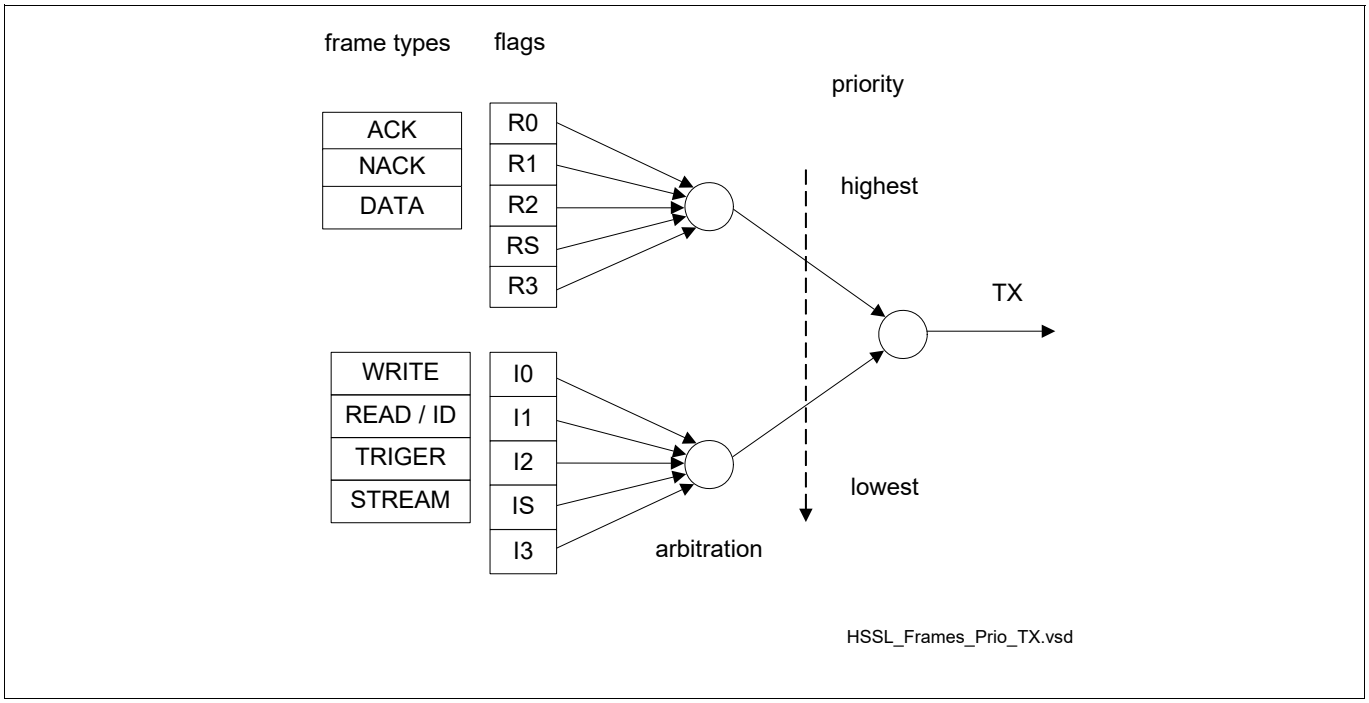

Figure 368 Frame Priorities in the HSSL module

35.3.3.1.2 Received Frame Management and Command Execution

After a frame passes the CRC check, it is checked for its type. A received command frame sets a request flag for the SRI/SPB master, a received response frame resets the expect flag and stops the appropriate channel timeout, see **Figure 369**.

The target flags “T” are set by the frame distributor, and cleared by the arbiter of the SRI/SPB master.

The expect flags “E” are set by the Tx arbiter, and reset by the Rx distributor.

The ISB and ISF flags operate together to control the streaming process. The ISB flag (Initiator Stream Block flag) is set by the software to enable the streaming. The ISF flag (Initiator stream FIFO flag) is set/cleared by the TXFIFO according to its filling level.

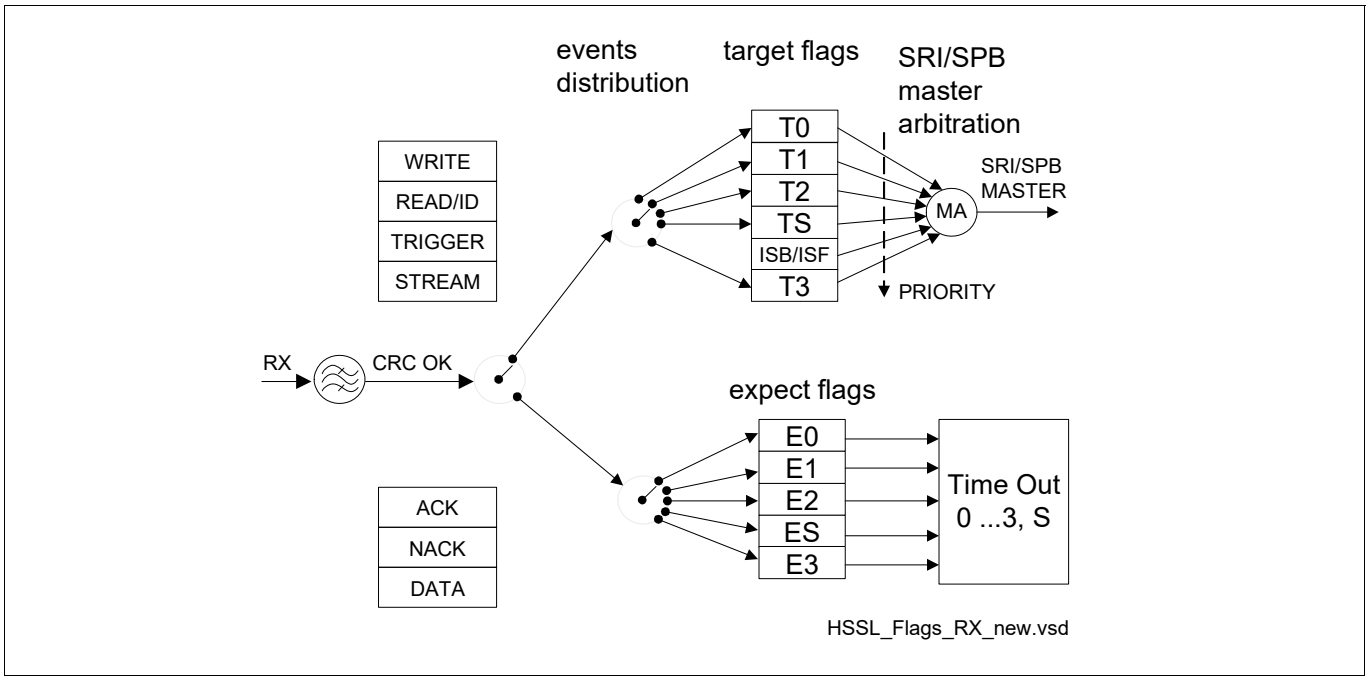

Figure 369 Received Frames Management

The CRC and Transaction Tag error flags are located in the **MFLAGS** register.

An overview of a full communication cycle over all sections of a channel (initiator, target or receive, transmit) is shown in **Figure 370**.

See also the **QFLAGS** register description.

If the channel does not have a command pending and does not expect a response, it is ready.

Note: In case of at trigger command frame, the target command distributor sets the corresponding Rx flag, and not the corresponding Tx flag, due to the fact that the service request is triggered directly, and not by the SRI/SPB master,

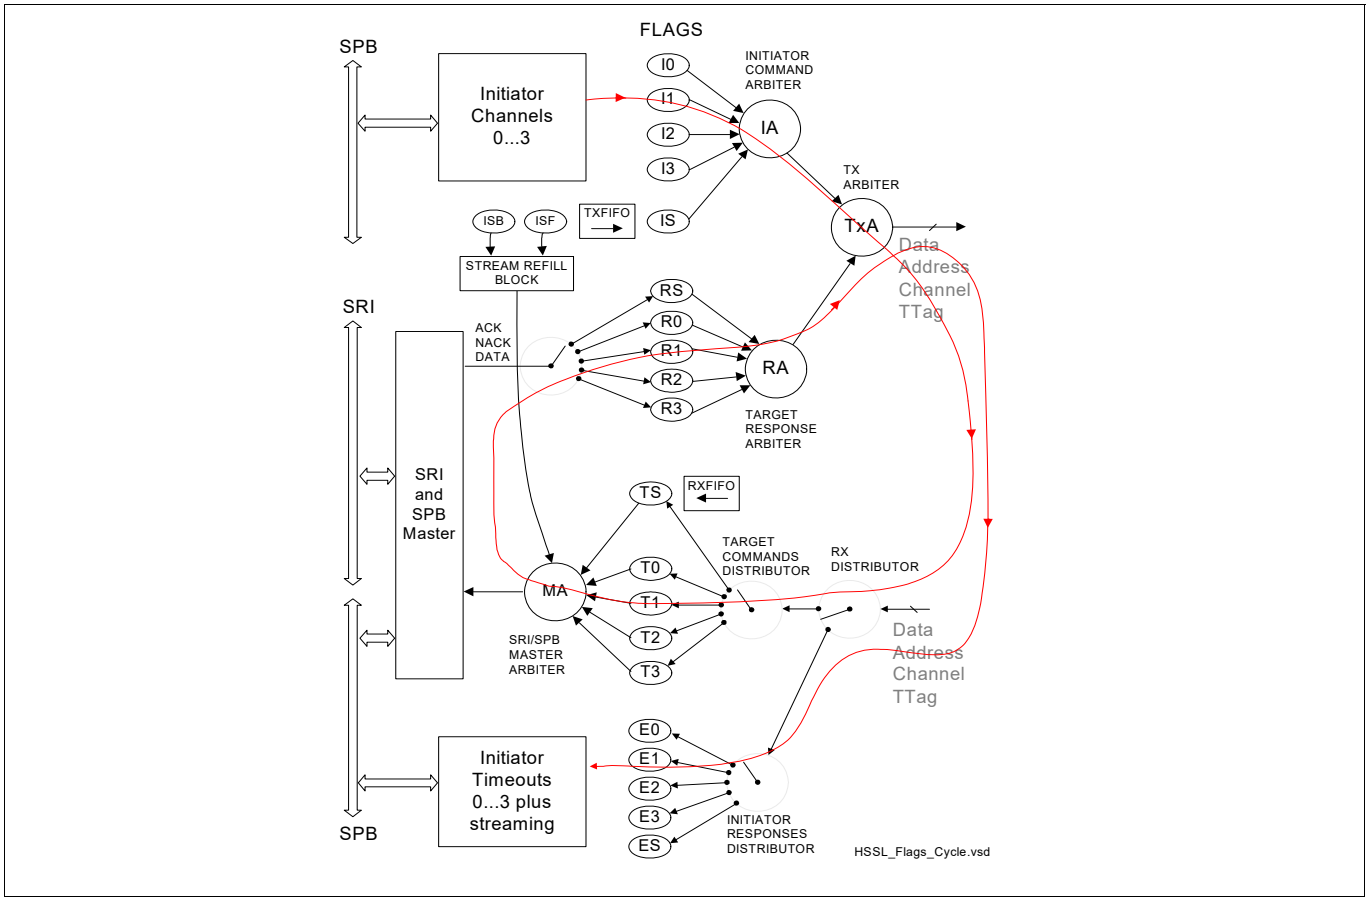

Figure 370 Request Flags Overview and a Communication Cycle Example

Table 308 Set and Clear of Request Flags

	I	R	T	E	ISB	ISF
SPB Software Write	set	-	-	-	set	-
Tx Arbiter	clear	clear	-	set	-	-
Rx Distributor	-	-[1)]	set	clear	-	-
SRI / SPB Master	-	set	clear	-	-	-
Stream Refill Block	-	-	-	-	clear	clear
TXFIFO	-	-	-	-	-	set

1) In case of a trigger command, an R flag is set by the Rx Distributor instead of a T Flag, because a trigger command is not executed by the SRI/SPB master.

35.3.3.2 HSSL Channel Architecture

The HSSL module contains four channels. The functionality of each channel can be subdivided in two ways:

- transmitter and receiver functionality
  - The transmit functionality generates an appropriate header for each frame
  - The receiver generates an appropriate acknowledge header with the tag and channel number code. The read and writes are performed by the SRI/SPB master. Therefore, the module can send back to the transmitter a target error frame if an SRI/SPB bus error occurs and the transfer on the bus can not be executed.
  - The timeout monitoring on one hand and the acknowledge management on the other hand involve both the transmitter and receiver channels
- initiator and target functionality
  - The initiator functionality transmits write, read or trigger command frames in random sequence, after the previous command has been responded to.
  - Generation/comparison of a Transaction Tag per channel is an initiator functionality
  - The timeout management is a pure initiator functionality.
  - The target functionality is to receive commands, executes them, and generates and transmits responses.

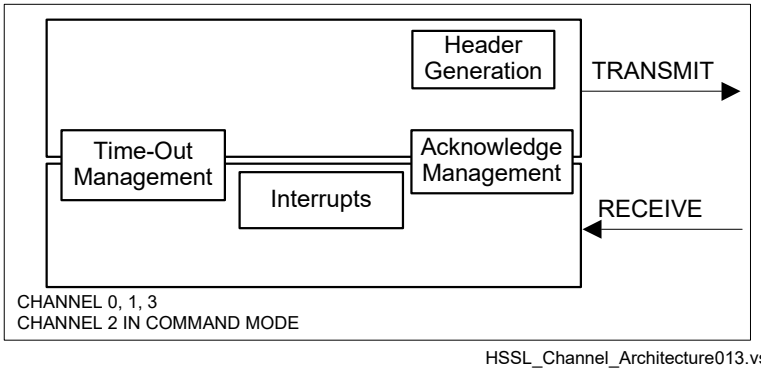

Figure 371 Architecture of Channels 0,1, 3 and Channel 2 in Command Mode

Channel 2 can be switched between command and streaming mode of operation. In single mode a single data register is used and in streaming mode a FIFO is used.

Channel 2 contains one initiator and one target address counter which are used to fill a memory range with data. Each counter contains two start address registers and one stream frame count register.
At reaching the predefined frame count, a wrap around is automatically executed.

The granularity of the start address is 256-bit.

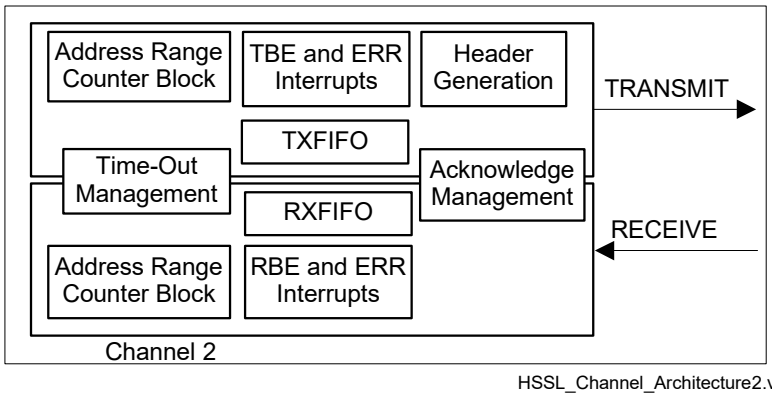

Figure 372 HSSL Architecture of Channel 2

A classification of the various channel functions is shown in **Figure 373**.

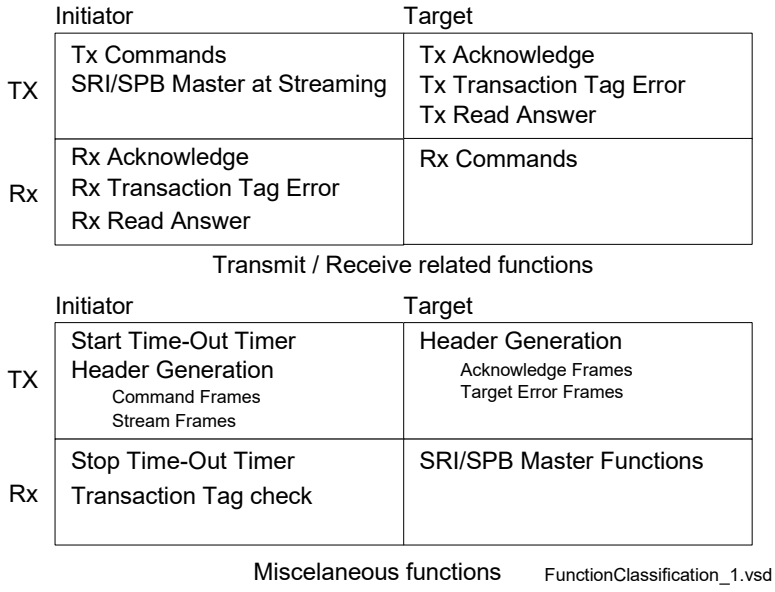

Figure 373 Overview of Channel Functions

35.3.3.3 Acknowledge Responses

A read or write command is executed by the SRI / SPB master. The SRI / SPB master reads or writes to the SRI / SPB bus and signals either a successful transaction or an error. The are the following cases:

- When the SRI master writes or reads an SRI memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.
- When the SPB master writes or reads an SPB module or memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.

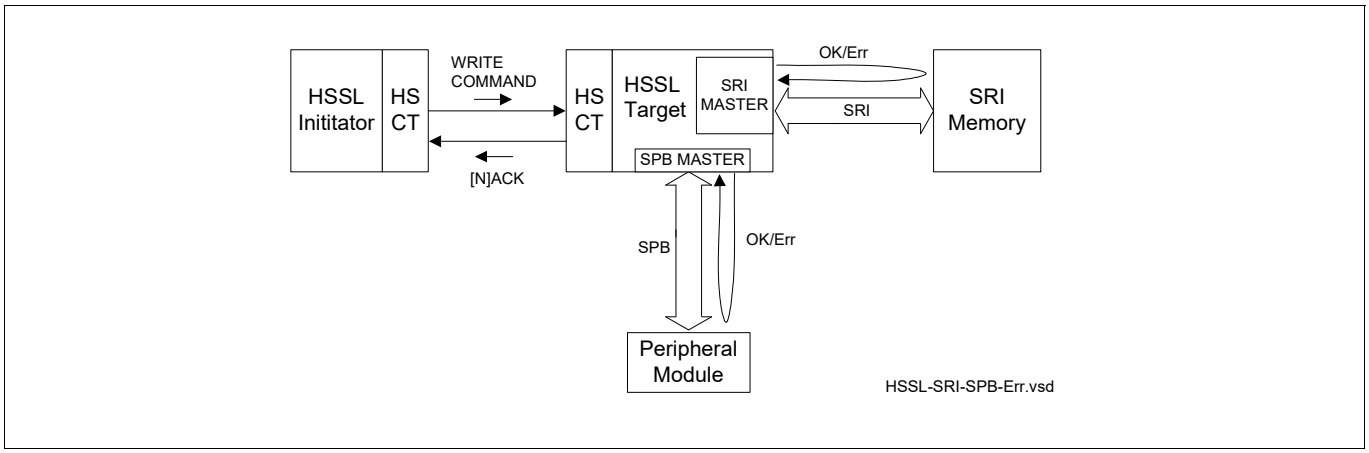

Figure 374 Bus Error Feedback Paths

35.3.3.4 Cross Dependencies Between the Frame Types

For a channel in a target role, there are cross-dependencies between command frame arrival and triggering of an ACK or NACK frame for a channel. Each command frame received with correct CRC of types Write, Stream, or Trigger Frame will result in either ACK or NACK (target error) response frame. Each Read Frame received with correct CRC will result either with Data Frame (Read Response Frame) or with NACK (Target Error Frame), see **Figure 375**.

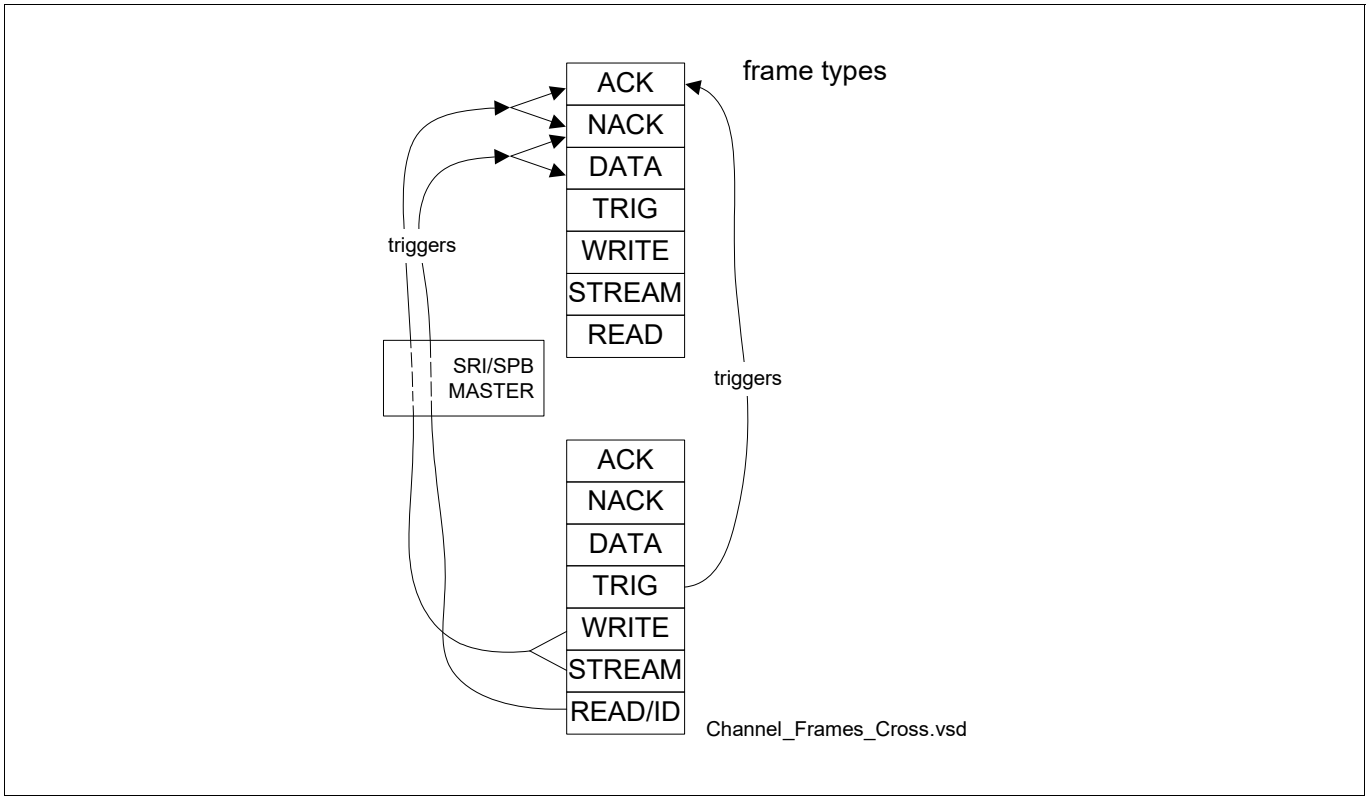

Figure 375 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in a Target Role

Additionally, generating a response frame involves copying of the transaction tag of the command frame into the response frame. The response frame is triggered by an SRI/SPB master signalling either a successful SRI/SPB bus transaction or an SRI/SPB bus error. Only a Trigger Command Frame triggers immediate acknowledge, because it results in an interrupt flag being set, and not in a bus transaction.

On the initiator side, there is a forward looking cross dependency between a command frame and the expected response, see **Figure 376**. Setting a transmission request flag for a certain command is accompanied in parallel with:

- capturing the current transaction tag in the bit field **ICONx (x=0-3)**.CETT.
- generating the next transaction tag by incrementing a three bit counter per channel, the **ICONx (x=0-3)**.ITTAG.
- starting the timeout counter at the moment when the command wins the arbitration
- setting an expect tag indicating that the timeout is running and a response frame is expected. See **MFLAGS**.Ex bit fields.

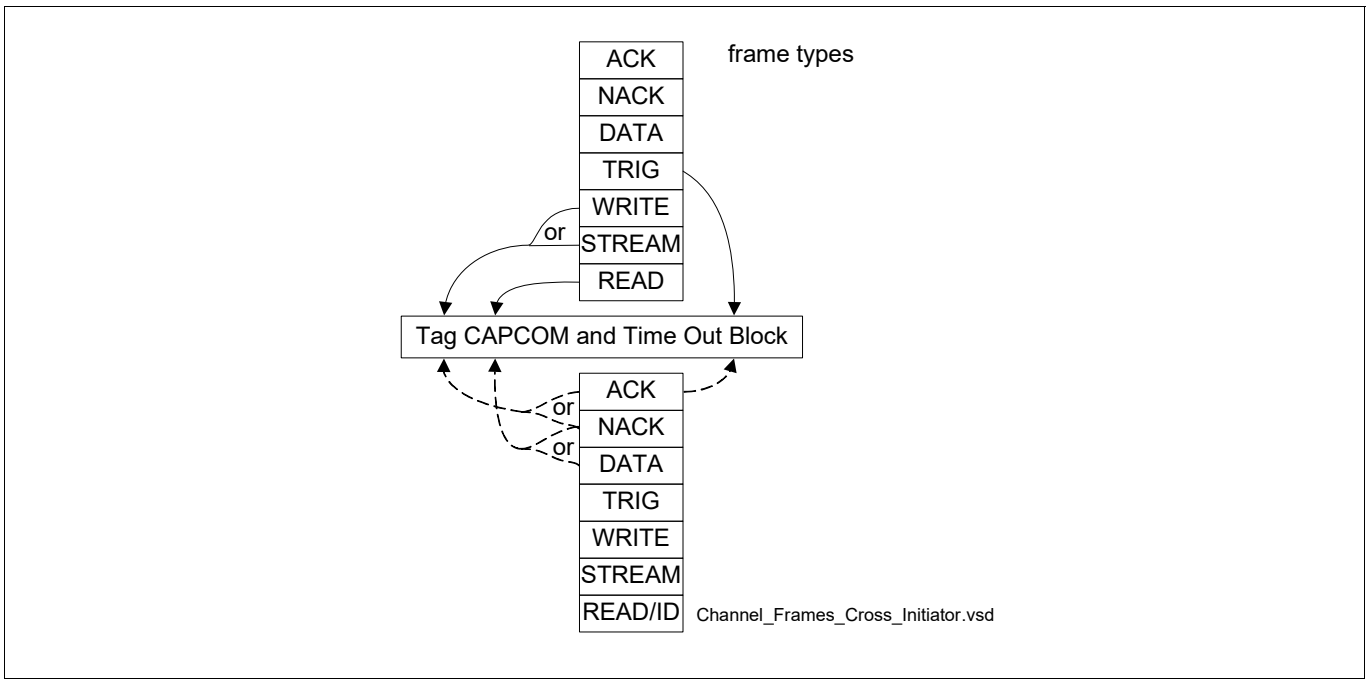

Figure 376 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in an Initiator Role

35.3.3.5 Command Timeout

A timeout timer is started when a frame wins the arbitration and is delivered by the channel for transmission. The timeout timer is stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, and the timeout timer reaches zero, the timer is stopped, a timeout error is triggered and the expect flag is cleared.

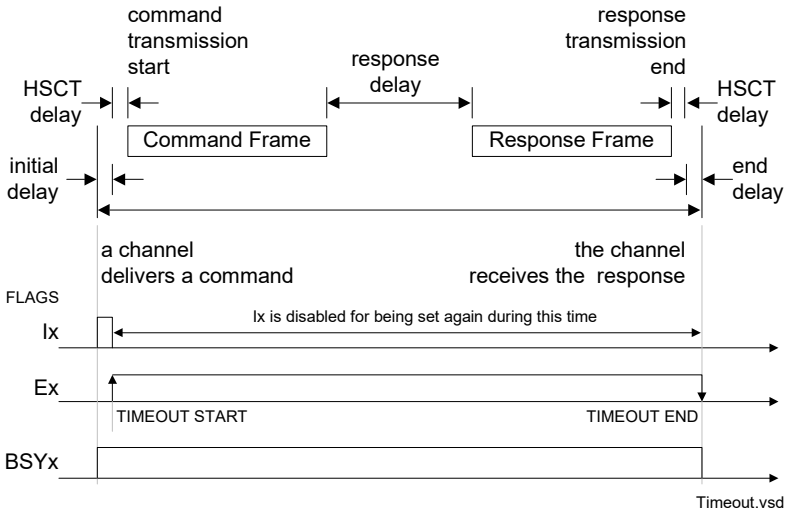

Figure 377 Command Timeout Measurement

35.3.3.5.1 Command Timeout Operation

The HSSL module contains one prescaler common to all channels, and one channel specific timer block per channel. The timer block generates the transaction tag for the channel by incrementing a three bit counter, captures the current transaction tag and compares it with the arrived response. In case of an error sequence CRC and timeout error, the timeout block generates a timeout signal. The timeout timer is reloaded and starts down-counting when the command transmission process starts.

The current timeout timer current value is indicated in the bit field **ICONx (x=0-3)**.TOCV, and the timeout reload value is configured in the bit field **ICONx (x=0-3)**.TOREL.

The currently expected transaction tag is indicated in the bit field **ICONx (x=0-3)**.CETT, the captured value of the latest erroneous transaction tag is indicated in the bit field **ICONx (x=0-3)**.LETT.

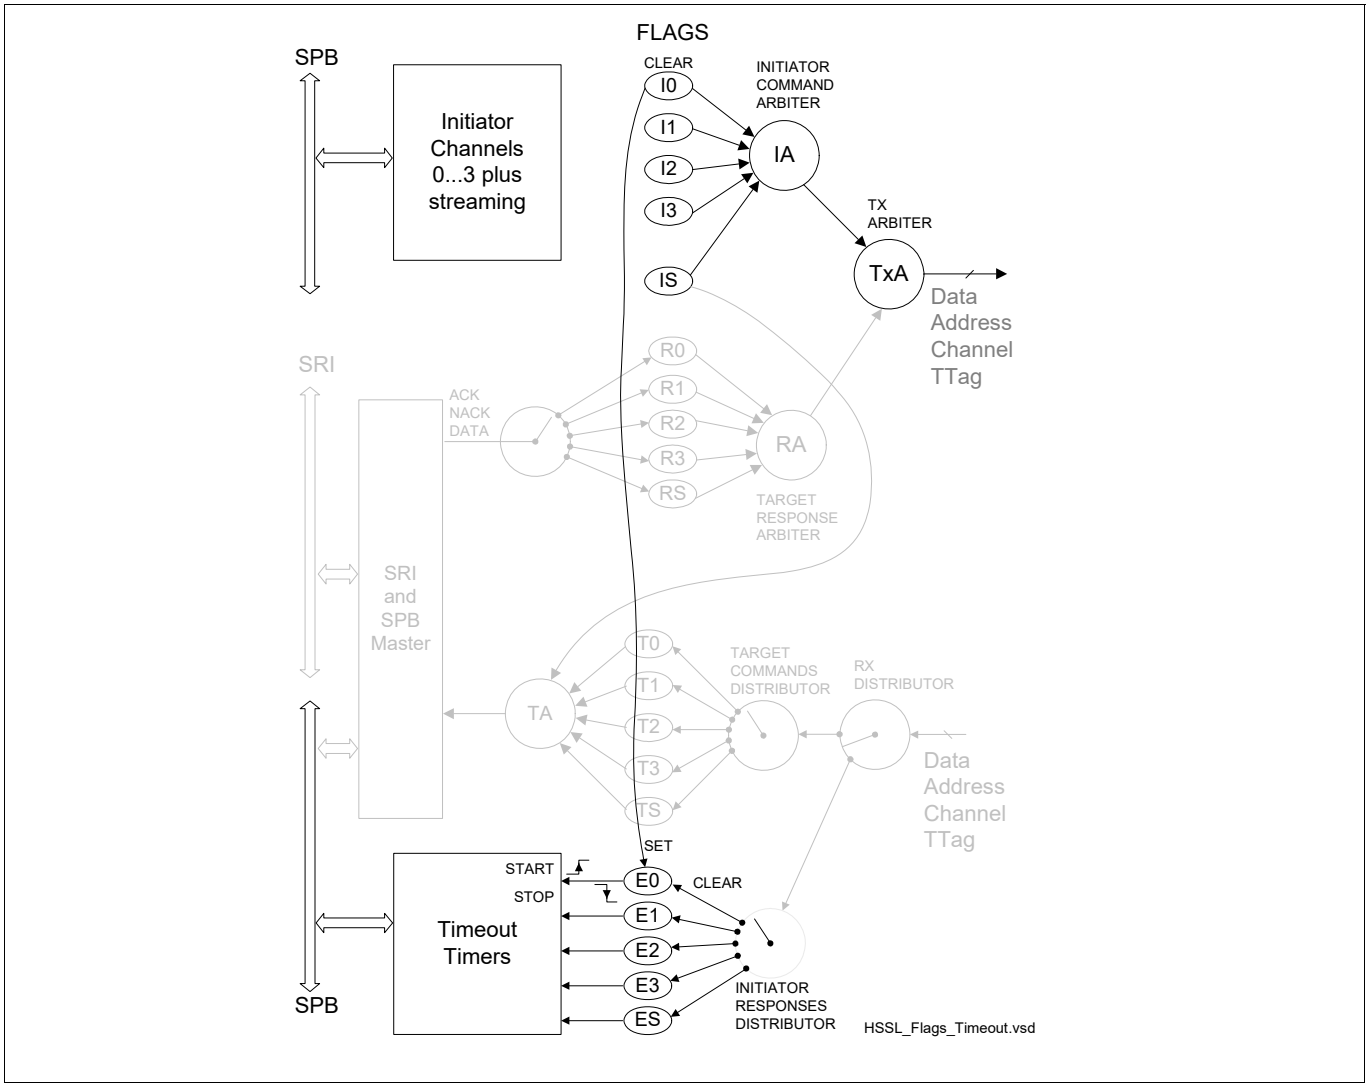

Figure 378 Request Flags Overview and a Communication Cycle Example

From the point of view of the flags, the timeout starts with the rising edge of the **QFLAGS**.Ex flag and ends with its falling edge, see **Figure 376**. The Ex flag is set by the falling edge of the Ix flag, which is reset when its command request wins the transmit arbitration, see **Figure 378**.

35.3.3.6 Stream Timeout

A free timeout timer block is started when a frame wins an arbitration round and is delivered by the channel for transmission. The timeout timer block is reset to zero and stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, a timeout error is triggered and the timeout timer block is reset.

The stream initiator keeps track of the expected acknowledges using a virtual expect fifo having a virtual filling level EXFL. Each new stream frame transmission increment the EXFL, receiving a correct acknowledge decreases the EXFL. As long as the expect fifo is full (filling level 2) no new transmit request can be issued. In order a new stream frame request to be issued, which means the flag IS to be set by the module, three conditions must be met:

- EXFL<2 - the expect level must be below two,
- TXFL>0 - the TXFIFO must be not-empty and
- ISB = 1 - the bit ISB bit must have been set by the software.

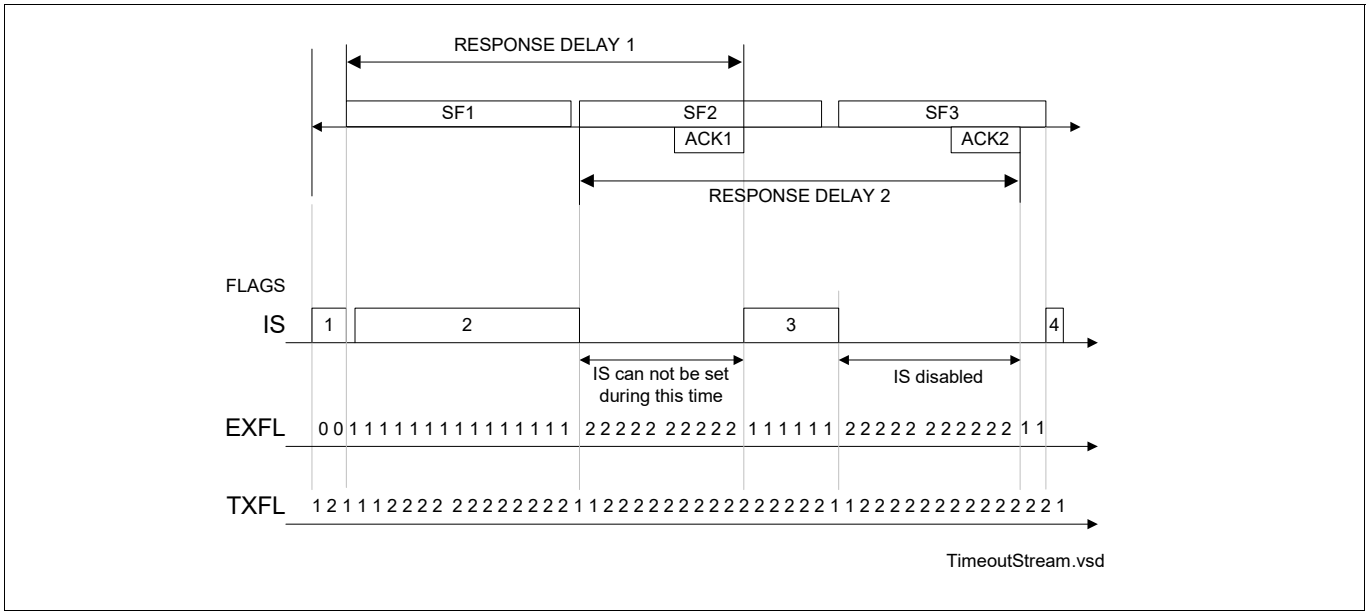

Figure 379 Stream Timeout Measurement

35.3.3.6.1 Stream Timeout Operation

The stream channel monitors the arrivals of the stream frame responses by using two timeout timer blocks. A single timer block is shown in **Figure 380**.

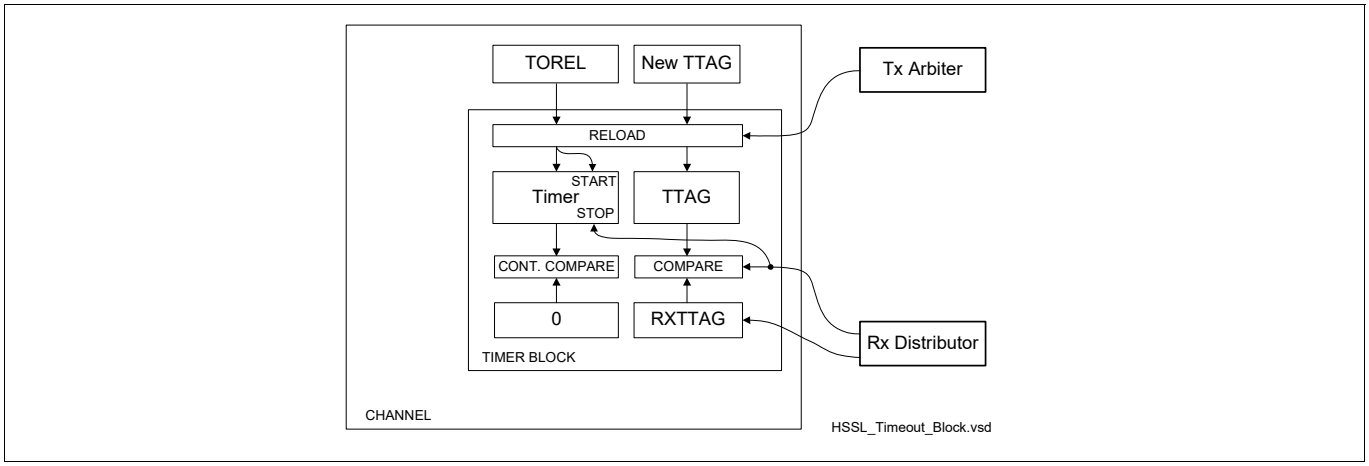

Figure 380 Single Timeout Block

The new initiator TTAG value which will be used for the next frame is visible in the bit field **ICONx (x=0-3)**.ITTAG. The **ICONx (x=0-3)** register also contains the TOREL and the TOCV bit fields.

The streaming functionality uses two timers sharing the same reload value, as defined by the **ICONx (x=0-3)**.TOREL, i=2. The timeout timer blocks simulate the behavior of a FIFO (named Expect FIFO), by having additionally a “write” and “read” pointer:

- the “write” or transmit pointer points to the timer block where the next command frame will trigger the writing of the timer reload value and the transaction tag,
- the “read” or receive pointer points to the block which performs the transaction tag comparison with the currently arrived stream acknowledge TTAG.
- The EXFL or virtual filling level indicating how many timers are active 0, 1 or 2

The EXFL is visible in the register **SFSFLAGS**.

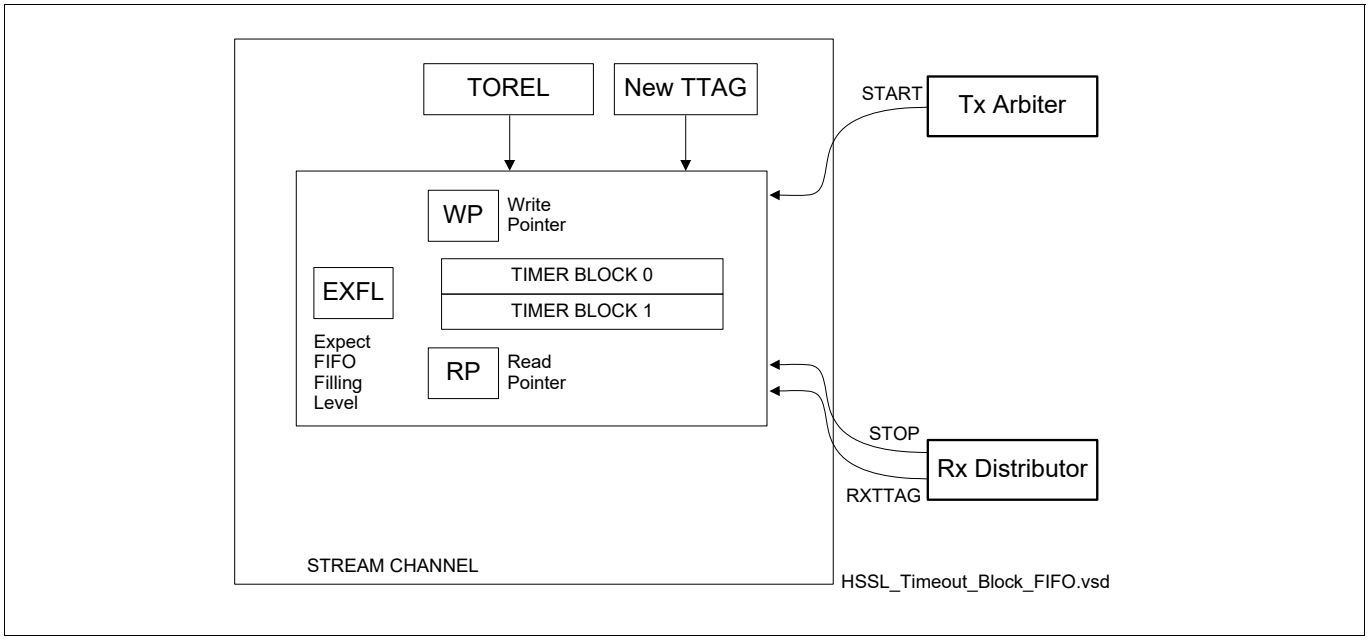

Figure 381 Stream Timeout Block

35.3.3.7 Data FIFOs of the Streaming Channel 2

Each stream frame delivers 256 bit data. This data is transferred by the SRI/SPB bus master in a memory by using BTR4 bursts. The start address and the end address is aligned at 256-bit block border, see **ISSAx (x=0-1)**, **ISFC**, **TSSAx (x=0-1)**, **TSFC**.

The channel expects one full streaming frame of 256 bit to be delivered before triggering either the SRI/SPB master or the HSCT module for fetching the data. The streaming is full duplex capable, which means one FIFO for each direction is available, and also Priorisation for the requests to the SRI/SPB master.

Emptying the RXFIFO has higher priority than filling the TXFIFO.

A service request to the SRI/SPB master is generated when the complete payload of a streaming frame is available in a FIFO.

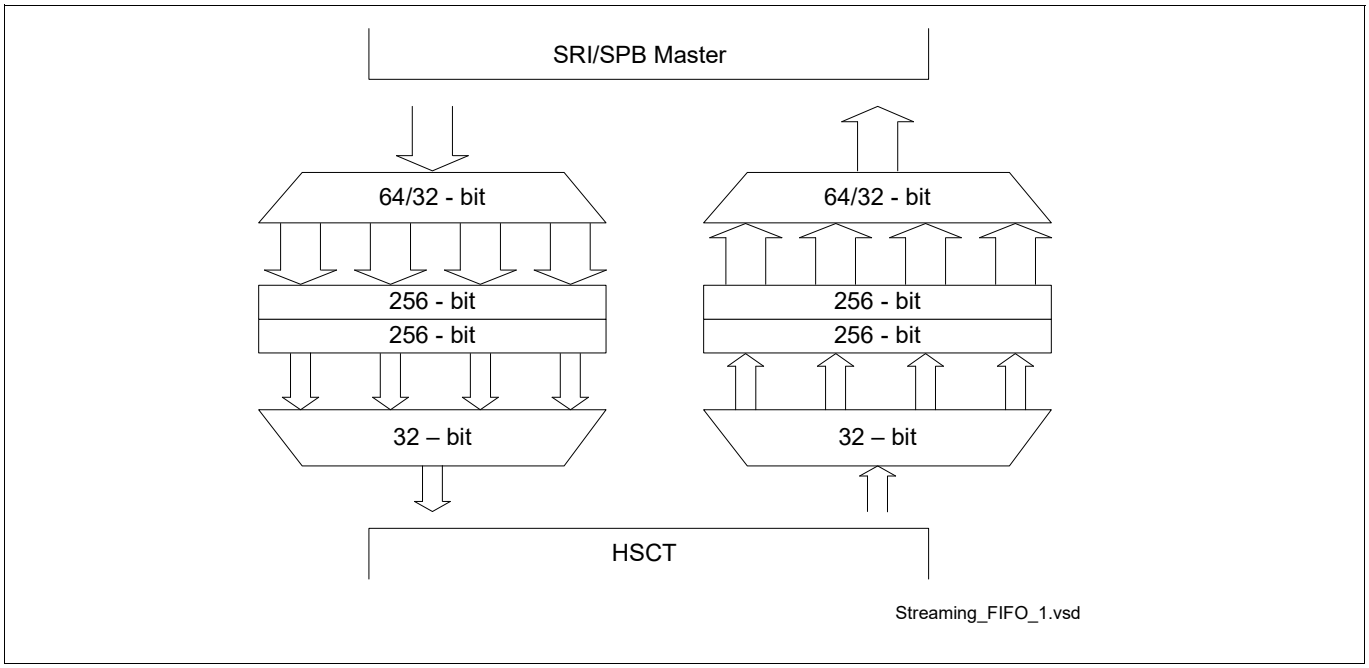

Figure 382 Streaming FIFO

35.3.4 Modes of Operation

The HSSL module has the following modes:

- Disabled mode (software controlled via DISR bit)
- Initialize mode (software via INI bit, sleep & suspend signals)
- Run mode (INI bit, sleep and suspend signals)
- OCDS soft suspend mode (OCDS suspend signal)
- Sleep mode (sleep signal)

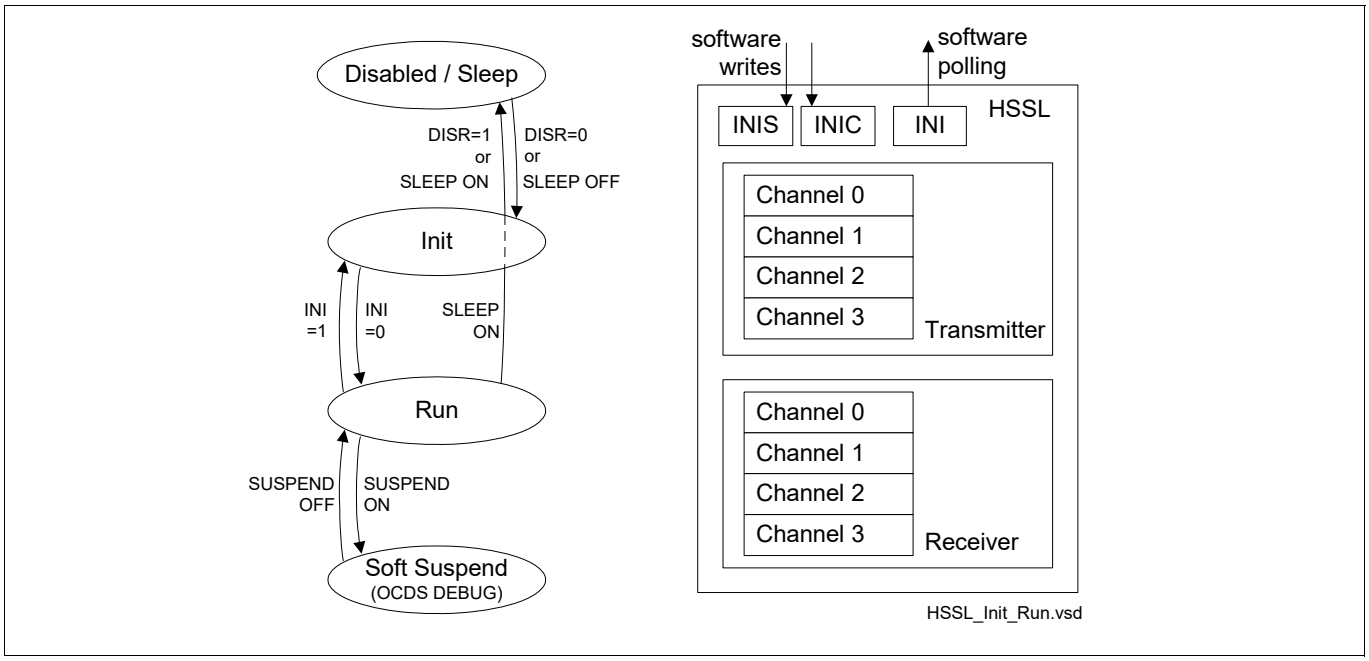

Figure 383 Modes of operation

After INIT state has been requested by using the **MFLAGSSET**.INIS bit, the HSSL module immediately stops starting new SRI/SPB transactions and new command, response and stream frame transmissions by resetting all request bits (I, T and R) in the **QFLAGS** register and disabling these bits for being set again. The already started transactions/transmissions will be finished. Afterwards, it waits for all pending response frames to arrive or the corresponding timeout events to be raised. This condition is achieved when all expect bits in the **QFLAGS** register has been cleared by the hardware, and there are no ongoing transmission and SRI/SPB master activities. Subsequently the module enters the Init state and the **MFLAGS**.INI flag is set. The CTS signal is deactivated in order to inform the peer module about the Init state.

During the transition from run to sleep state, triggered by the sleep signal, the **MFLAGS**.INI bit is automatically set by the hardware (behaves as INI bit was set by software). When the sleep period is over and the sleep signal is deactivated, the module goes into the Init state and must be set to Run state by software, by writing **MFLAGSCL**.INIC=1.

At the state transition of Init -> Run the timeout timers and all the flags are reset. The RUN state starts with all channels inactive.

At the state transition SoftSuspend -> Run the timers are not reset but continue to run and the flags states are preserved, because the module continues operating from the point at which it was suspended.

When leaving the Run state towards Sleep the CTS signal is deactivated and the transmission of the pending commands is stopped.

When a soft suspend is requested, the module stops the transmission of the pending command and stream frames, waits until all expect flags are cleared, then deactivates the CTS signal and at the end acknowledges the

soft suspend request and sets the bit **OCS**.SUSSTA. Incoming target frames are served until the CTS signal stops the other side from sending new command and stream frames.

Hard Suspend request causes immediate switching off of the module clocks. After ending the Hard Suspend state both HSSL and HSCT modules must be reset by the application software and communication restarted from reset state.

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a HSSL kernel reset might not be sufficient to bring the system into a defined state.

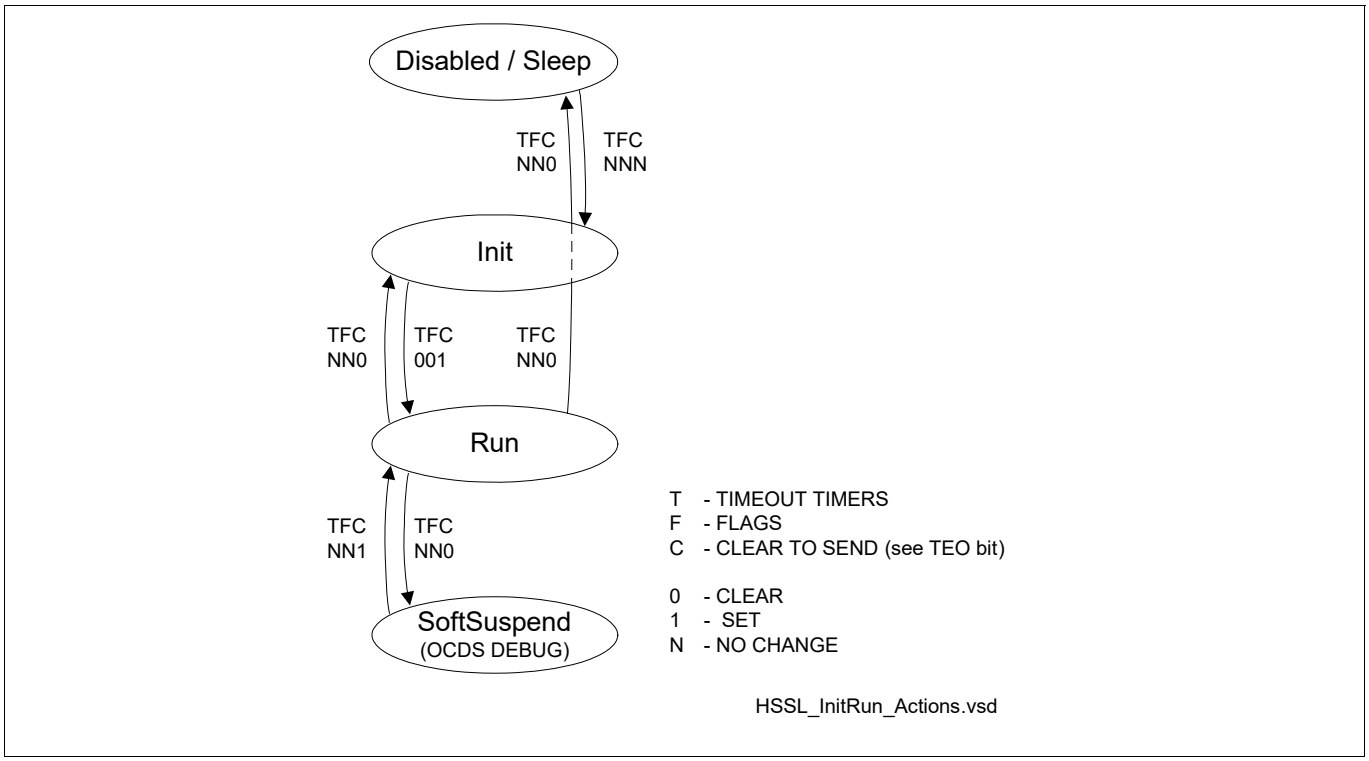

Figure 384 Actions on State Transitions

35.3.5 Interrupts

The HSSL module generates four types of interrupts per channel and one channel unspecific module interrupt.

Command Channel Interrupts

Each HSSL command channel generates four interrupts:

- Command OK interrupt COK
- Read Data interrupt RDI
- Error interrupt ERR
- Trigger interrupt, triggered by a trigger command frame TRG

The names of the interrupt signals are COK_INT, RDI_INT, ERR_INT and TRG_INT correspondingly.

An arrival of an error free frame response (ACK frame) triggers a COK interrupt, otherwise an ERR interrupt is triggered. An arrival of a read response frame triggers at the initiator side, additionally to the COK interrupt, an RDI interrupt.

An arrival of a trigger frame at the target side triggers a TRG interrupt there.

ERR interrupt is disjunct to COK and RDI the , meaning that for one frame, either ERR or COK and optionally RDI can occur. After an ERR interrupt, normal transmission must be resumed by software, because an optional DMA would remain not retriggered and would wait for COK indefinitely.

Stream Channel Interrupts

The HSSL stream transmit sub-channel generates three interrupts:

- TBE - Transmit Block End interrupt, shared with the COK interrupt of the command mode of the channel 2
- error interrupt ERR, shared with the ERR interrupt of the command mode of the channel 2
- RBE - Receive Block End interrupt, shared with the TRG interrupt of the command mode of the channel 2.

Exception Interrupt EXI

If the receive stage of the HSSL module detects a CRC error or any inconsistency in the received data the global EXI Interrupt is activated, which is not channel specific.

Note: The HSCT module uses channels A to D for the HSSL channels 0 to 3. So, HSCT channel 0100_B corresponds to 000_B (binary code) or 100_B (special code) in the HSSL header.

The EXI interrupt is also raised on an edge of the TEI signal (HSCT CTS output).

In total, the HSSL module provides 4*4 + 1 = 17 interrupt lines.

35.3.6 Operating a Command Channel

All HSSL command channel provide identical functionality.

35.3.6.1 Initiating a Single Write Command

In order to initiate a write command, the software must

- configure the data width and the type of the request which will follow (read or write)
- provide the new data (most frequently, but not necessary)
- provide new address

Write to the address register requests the predefined type of the transfer

35.3.6.2 Initiating a Single Read Command

In order to initiate a read command, the software must

- configure the data width and the type of the request which will follow (read or write)
- skip providing of the data step, or provide dummy data
- provide new address

Write to the address register requests the predefined type of the transfer

35.3.6.3 Initiating a Single Trigger Command

In order to initiate a trigger command, the software can either

- request a trigger type of frame and provide dummy data and address
- directly request a trigger frame by writing **ICONx (x=0-3)**.TQ

35.3.6.4 DMA Operated Command Queues

It is possible to use DMA to initiate lists of commands, by moving memory blocks containing the command lists to the HSSL module. In order to support such a way of operation, each channel provides three registers arranged in a particular way: first **IWDx (x=0-3)**, followed by **ICONx (x=0-3)** and **IRWAx (x=0-3)** at the end. For executing a list of write commands all three registers must be written for each command; for executing a list of read commands the first register **IWDx (x=0-3)** is optional (dummy write possible) but the last two **ICONx (x=0-3)** and **IRWAx (x=0-3)** are mandatory; for executing a trigger command only writing **ICONx (x=0-3)**.TQ is mandatory, but optionally even all three registers can be written: dummy write to **IWDx (x=0-3)**, write to **ICONx (x=0-3)**.RWT and write to **IRWAx (x=0-3)** to issue the request.

The answer data to a read command is available in the **IRDx (x=0-3)** register.

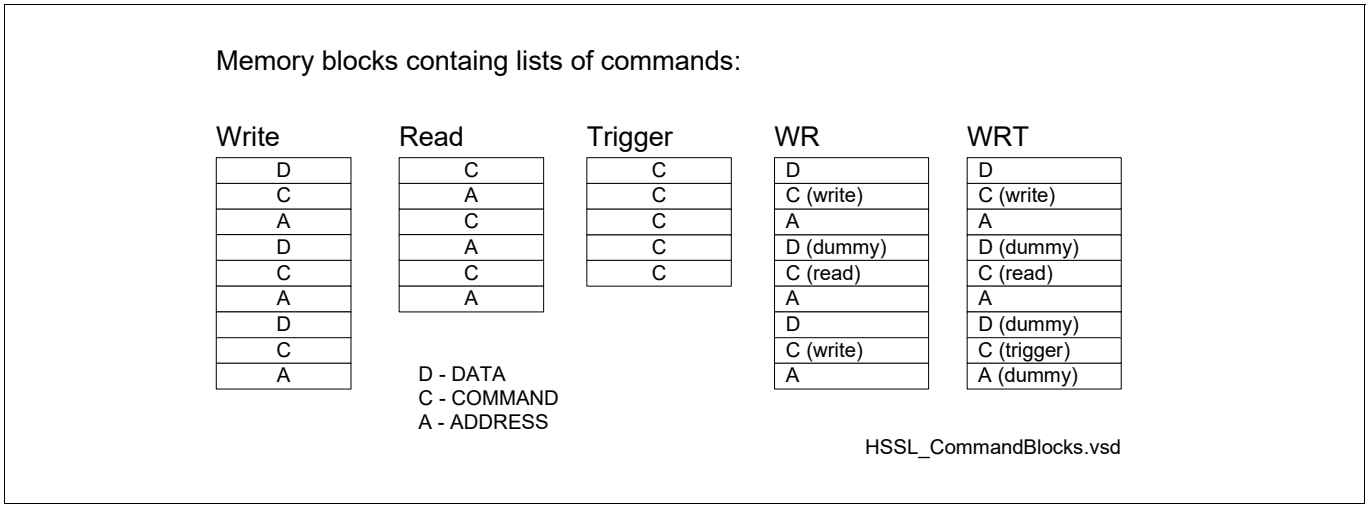

Figure 385 Command Queues

35.3.6.5 Receiver Error Handling

The HSSL receiver generates three error signals, two channel specific and one general:

- channel specific timeout and transaction tag errors and
- channel unspecific CRC error
- command frames, which pass the CRC check, containing an RFU command code are ignored
- Command frames, which pass the CRC check, containing invalid (greater than 3) channel number are ignored.

- If a command frame is received and the acknowledge of the previous command has not been sent yet, the new command frame is discarded.
- If a response frame comes, and the channel does not expect any more a response (the E flag is 0), than an incoming response is discarded without any error interrupts, additional to the timeout interrupt. This scenario can occur if a response is received after a timeout, and before the next command has been sent.
- If a channel in command mode receives a stream frame, the stream frame will be ignored.
- if a channel in streaming mode receives a command frame, the command frame will be ignored.

35.3.6.5.1 Timeout Error

Error triggered by the initiator.

35.3.6.5.2 Transaction Tag Error

Error triggered by the initiator.

35.3.6.6 Global Error

Global, channel not specific error is triggered if a CRC error, inconsistency between the HSCT and HSSL header, and SRI/SPB error occurs.

CRC error is triggered:

- by the target: when erroneous command frames has been received and
- by the initiator for erroneous response frames.

There is a dedicated interrupt named EXI which signals the CRC error. There is no indication if the CRC error was caused by a command or response frame. The CRC error caused by a response frame will be followed by a timeout interrupt. The received data is discarded; it is not available for the software in any register(s).

Additionally, the CRC error interrupt signals an inconsistency between the data length and channel number code delivered by the HSCT module and the information contained in the HSSL header. The differentiation between the two types of error can be done by reading the **MFLAGS**.CRCE, PIE1 and PIE2 flags. All three error types can occur and are detected independently of each other, so that more than one flag can be set at the same time.

An SRI error interrupt (EXI) is triggered if there was a transaction ID error, ECC error or SRI error acknowledge on the SRI bus. The flag **MFLAGS**.SRIE indicates this type of error. In case of an SRI read data ECC error, the READ_PH_ERR_ALARM signal reports this event to the SMU module.

An SPB error also triggers the global error interrupt (EXI) and sets the **MFLAGS**.SRIE flag.

35.3.7 Memory Block Transfer Modes of the Stream Channel

HSSL streaming channel is capable of transmitting one stream and receiving one stream in parallel. Streaming operates either in single block mode or continuous mode.

In single block mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives the preconfigured memory block, generates an interrupt signal and waits for the next trigger.

In continuous mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives two memory blocks of the same size in a round robin fashion indefinitely, or after being stopped by the software.

The streaming mode of the initiator/transmitter is configured by using the **CFG**.SMT bit. The streaming mode of the target/receiver is configured by using the **CFG**.SMR bit.

Triggering/enabling a block or continuous stream is done by using the Stream Block Request bit **MFLAGS**.ISB/TSE bit. In single block mode, the hardware resets this bit after performing a block transfer. In continuous mode, the transfer is ongoing continuously (**MFLAGS**.ISB/TSE remains set) and a stop of the transfer must be requested by writing one to **MFLAGSCL**.ISBC/TSEC bit.

On the initiator side, after completing the transfer of the current memory block that is currently read from the memory, the transmitter will be stopped and the **MFLAGS**.ISB will be cleared.

On the target side, after completing the transfer of the current memory block that is currently written to the memory, the receiver will be stopped and the **MFLAGS**.TSE will be cleared.

SRI/SPB error on the target triggers an error interrupt and the hardware stops. The TSE bit (and the RXFIFO) will be cleared by the hardware and the incoming frames are ignored.

Any error on the initiator side (like SRI/SPB error, target error, timeout, transaction tag error) triggers an error interrupt and the hardware stops streaming. The bit ISB (and the TXFIFO) will be cleared by hardware. All the incoming frames will be ignored, including the acknowledge frames of the previous frames.

Error can also occur at the beginning of a new memory block, while the last frames of the previous memory block are still in the TXFIFO. These frames are also lost, and the previous memory block remains incompletely received.

After an error while streaming in one direction the software must restart the streaming in that direction at both sides. The streaming will restart with a new block.

An error while streaming in most cases leaves the target waiting in the middle of a block. The target receiver can be stopped immediately (and afterwards restarted) by clearing the **MFLAGS**.TSE only when **TSFC**.CURCOUNT equals **TSFC**.RELCOUNT. Normally, CURCOUNT equals RELCOUNT before the start of a transfer of a block or between block transfers. Otherwise, while waiting in the middle of a block transfer, RELCOUNT can be made equal to CURCOUNT by writing the CURCOUNT value to RELCOUNT. This can be done either locally, by the target itself, or remotely, by the initiator using HSSL command frames.

The two initiator start addresses are configured in **ISSAx (x=0-1)**. The single block size is configured in the **ISFC** register. The current address being transferred is indicated in the read only (rh) **ISCA** register. The bit **MFLAGS**.IMB selects the corresponding **ISSAx (x=0-1)** register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **ISSAx (x=0-1)** is copied to the **ISCA** register.

The two target start addresses are configured in **TSSAx (x=0-1)**. The single block size is configured in the **TSFC** register. The current address being transferred is indicated in the read only (rh) **TSCA** register.The bit **MFLAGS**.TMB selects the corresponding **TSSAx (x=0-1)** register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **TSSAx (x=0-1)** is copied to the **TSCA** register.

The HSSL stream transmitter generates one dedicated interrupt and several error events:

- transmit block end interrupt, generated after the acknowledge of the last frame has been received.
- error events that can trigger a channel error interrupt (target, timeout, transaction tag, unexpected error)
- a global SRI/SPB error interrupt (check if the ISB bit is cleared by hardware)

The HSSL stream receiver generates one dedicated interrupt and several error events:

- receive block end interrupt event, generated after the last stream frame in a block has been written to the memory and the SRI/SPB master has received a confirmation (an acknowledge, but not an error).
- error event (target error that triggers an NACK frame)
- a SRI/SPB global error interrupt (check if the TSE bit is cleared by hardware)

As long as the ISB bit is low, the TXFIFO and the expect FIFO are cleared and kept in the empty state.

As long as the TSE bit is low, the RXFIFO is cleared and kept in the empty state.

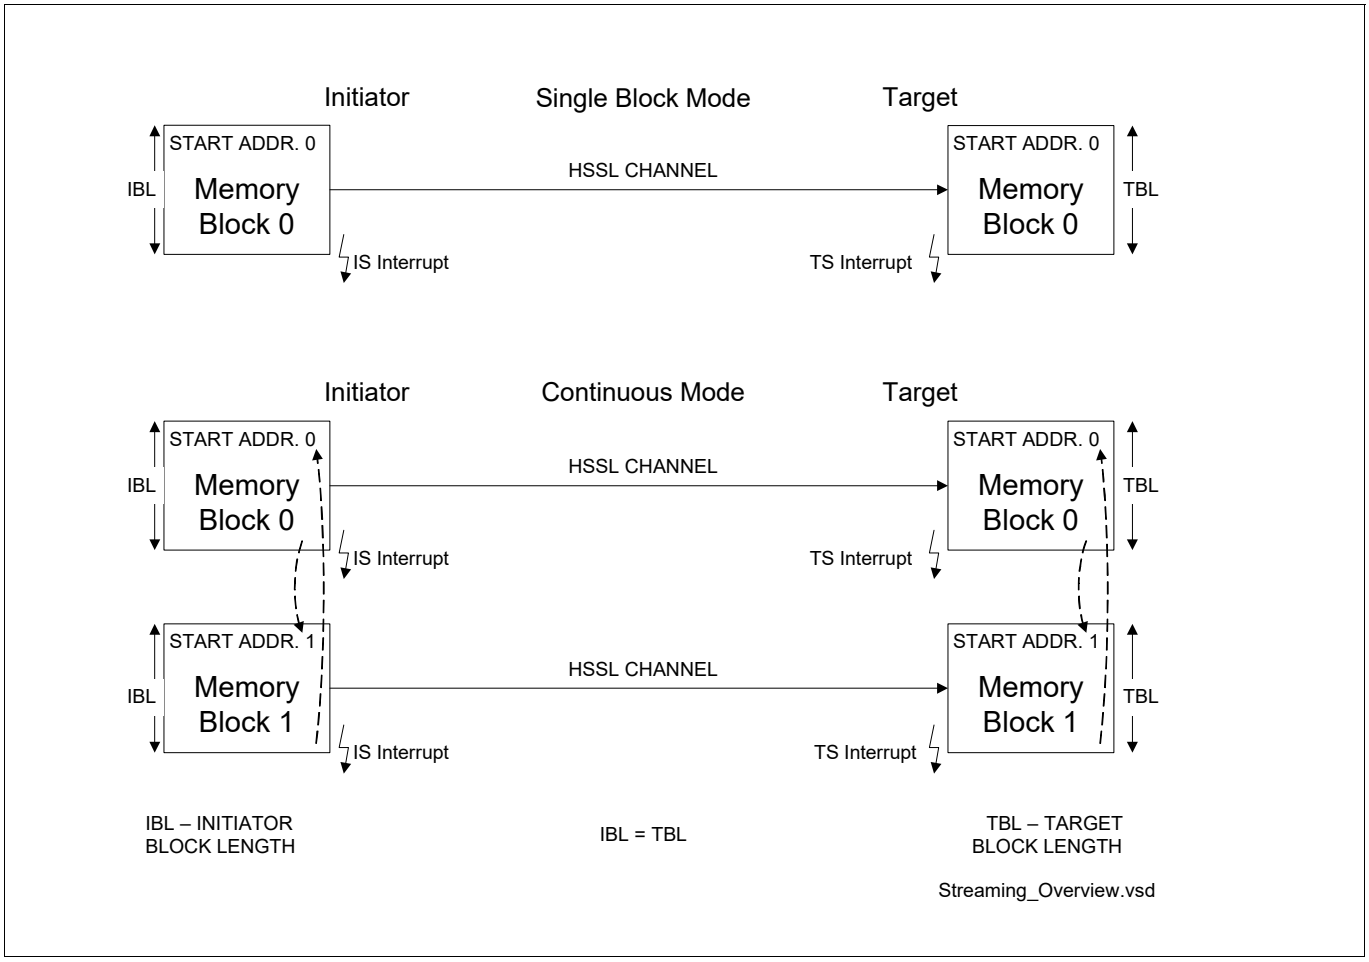

Figure 386 Stream Modes of Operation

35.3.8 HSSL Reset

Both HSCT and the HSSL modules must be reset together.

35.3.9 OCDS SRI / SPB Master Suspend

The SRI /SPB master access on the bus can be suspended by using the OCDS suspend request. When the master reaches idle state the suspend acknowledge signal is activated.

35.3.10 OCDS Trigger Sets

In order to support the debugging activities, the HSSL module provides a set of internal signals to the on-chip debug system OCDS. An overview of this feature is shown in **Figure 387**. Its configuration is done by using the bits **OCS**.TGS and TGB.

An edge on any module internal signal belonging to the selected set going out on one of the two OTGB busses triggers an action of the OCDS system.

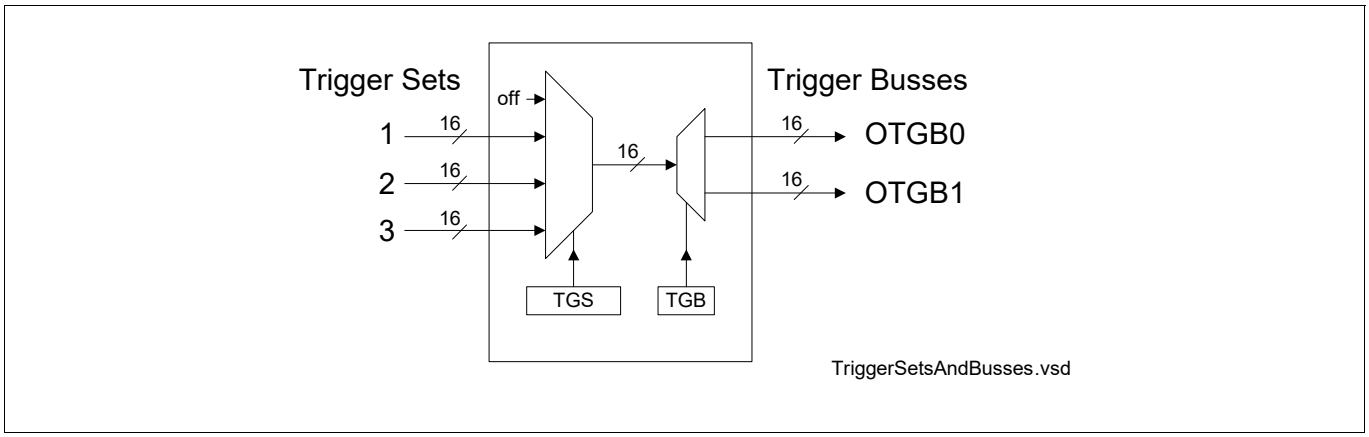

Figure 387 Overview of the Trigger Sets and Busses

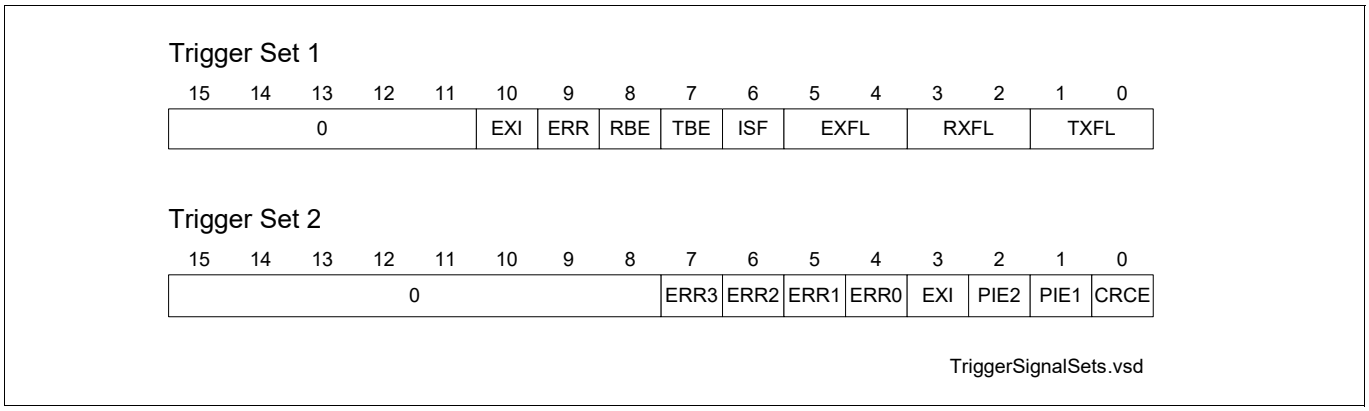

Figure 388 Overview of the Trigger Signal Sets

Table 309 HSSL Trigger Sets

Name	Description
TS16_STR	Streaming Channel Trigger Set (Trigger Set 1)
TS16_ERR	Error Trigger Set (Trigger Set 2)

The trigger sets 1 and 2 are used, the set 3 is not used (padded with 0).

Set 1, streaming channel debugging:

- 2 bits: TXFIFO filling level **SFSFLAGS**.TXFL
- 2 bits: RXFIFO filling level **SFSFLAGS**.RXFL
- 2 bits: Expect FIFO filling level **SFSFLAGS**.EXFL
- 1 bit: Initiator Stream Frame Request **SFSFLAGS**.ISF
- 4 bits: streaming channel interrupt signals TBE, RBE, ERR, EXI, see **Interrupts**.

- others: not used

Set 2, timeout errors caused by unspecific errors debugging:

- 1 bit: CRC error **MFLAGS**.CRCE
- 1 bit: Phy Inconsistency error, inconsistent channel number code, **MFLAGS**.PIE1
- 1 bit: Phy Inconsistency error, inconsistent data length, **MFLAGS**.PIE2
- 5 bits: error interrupt signals 1 x EXI and 4 x ERR, see **Interrupts**.
- others: not used

Note: The signal lists from above are mapped to the trigger sets in the following way: first item from the list to the trigger signal 0,… to 15.

35.3.11 Access Protection

The HSSL module provides memory access protection in form of four memory access windows. Each window can be located anywhere within the address space, having an arbitrary size with the granularity of 256 bytes.

Each window defines a memory range where an access is allowed. All four windows create a sort of an access filter that protects the memory from external writing or reading. A window can be a read only, write only or read and write window.

Each window is defined with:

- window start address, see register **AWSTARTi (i=0-3)**
- window end address, see register **AWENDi (i=0-3)** and
- access rule: read only, write only or read and write, see register **AR**

If two access windows overlap, one read only and one write only, the common address range is read and write accessible. If no access window overlaps with r, w or rw window, the r, w or rw window wins. No access window means window disabled.

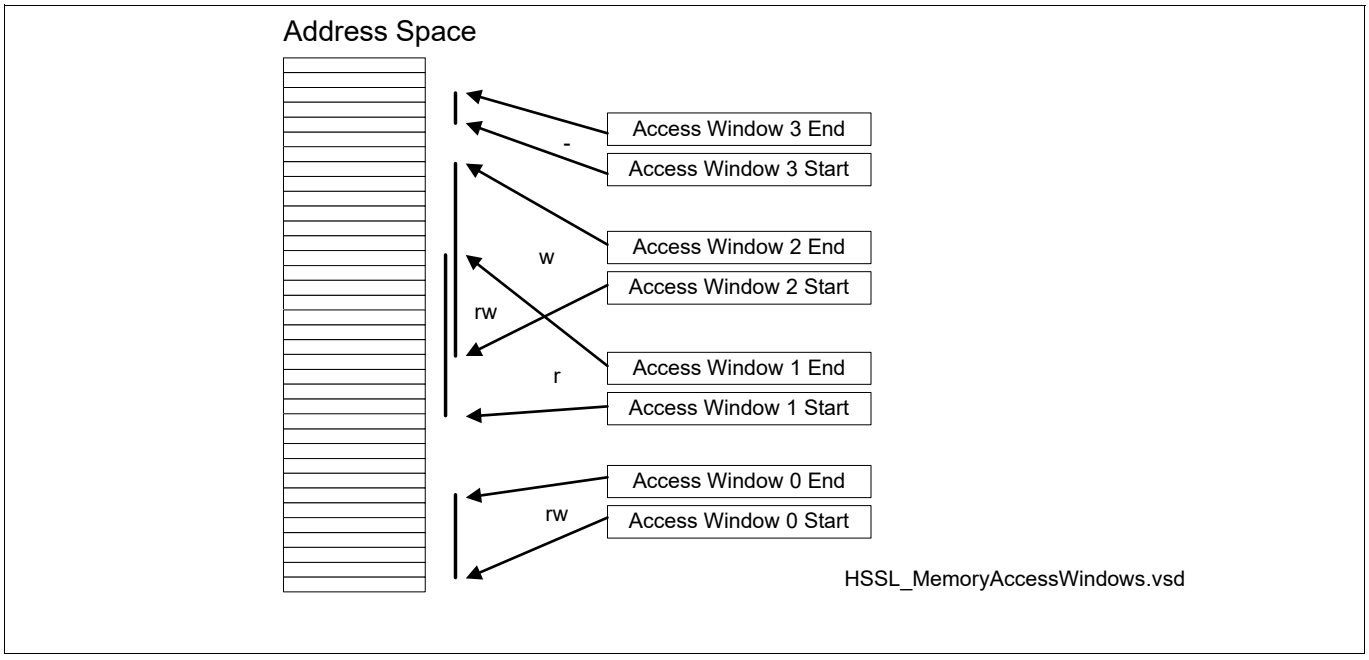

Figure 389 HSSL Access Windows

Normally, it is expected that the End Address is higher then or equal to the Start Address. Otherwise, the window is invalid and no commands can pass through the up-side-down range.

The **AWSTARTi (i=0-3)** registers define the first address of the first 256-byte block of an address window. The **AWENDi (i=0-3)** registers define the first address of the last 256-byte block of an address window. The following diagram shows the details of the address window definition.

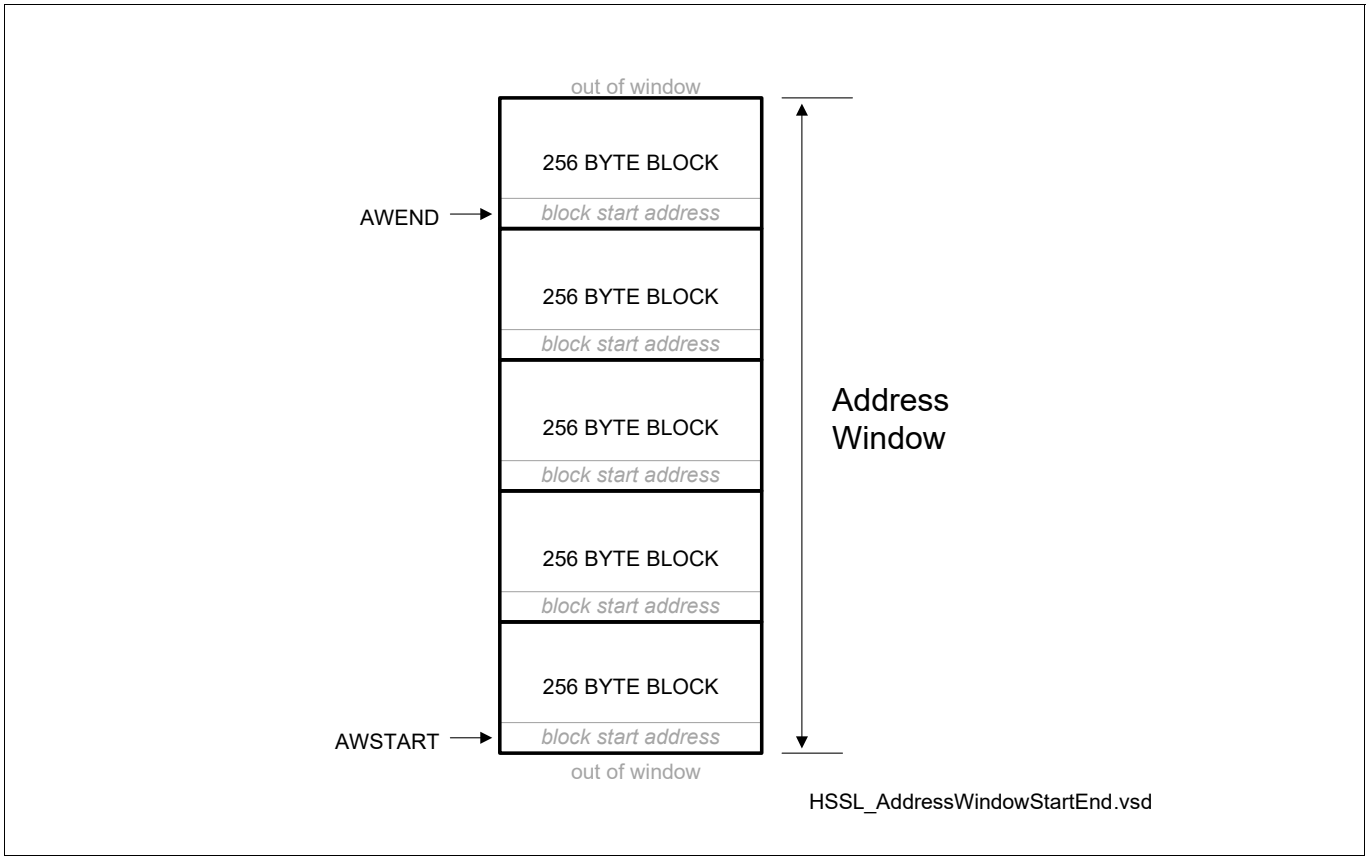

Figure 390 Access Windows Definition

These command frames are subject to filtering:

- Register Read
- Register Write and
- Stream Frame

These command always pass through:

- Read Answer
- ACK
- NACK
- Trigger
- ID Request

Command Frames Access Protection

If a HSSL target receives a read or write command frame with an address which passes through one of the windows, the command is executed and a response frame is sent back.

If a HSSL target receives a command frame with an address which does not pass through any windows, the command is not executed, a NACK response is sent back. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered in the target.

Streaming Access Protection

In contrast to the read and write command frames, the stream frames do not contain an address information. There are two cases to distinguish, target side and initiator side.

At the target side, when the streaming starts, the initiator has already programmed the target addresses in the **TSSAx (x=0-1)** registers by using write frames, which pass through and carry the stream address in their data field. Therefore, the memory filtering uses the current access address, visible in the **TSCA** register, and if the current streaming address passes through the access protection filter, the read or write is executed, else a NACK frame is sent as a response.

If a HSSL target receives a stream frame and the current access address does not pass through any windows, the access is not executed, a NACK response is sent back. The TSE bit will be cleared by hardware and the incoming frames will be ignored. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered in the target.

At the initiator side, the **ISSAx (x=0-1)** registers, which are externally accessible, define the memory range to be transmitted. Therefore, the access filtering at the initiator side covers the streaming read accesses by using the current access address, visible in the **ISCA** register.

At the initiator side, access violation stops the streaming, and the ISB bit is cleared by hardware. The memory access violation flag **MFLAGS**.MAV is set, the access violating channel is captured in the bit field **AR**.MAVCH, and the EXI interrupt is triggered.

Public and Private Registers

The HSSL module contains two types of registers:

- public registers, which can be both read and written by the HSSL module itself
- private registers, which can be only read by the HSSL module itself

This behavior of the HSSL module registers is implemented by using the User Mode (U) and Supervisor Mode (SV) of writing registers. The private registers are writable in SV mode, the public registers are writable in U and SV mode.

The memory access protection registers **AWSTARTi (i=0-3)**, **AWENDi (i=0-3)** and **AR** including the **TIDADD** register are all writable only in Supervisor Mode, and are consequently private. The HSSL itself makes only User Mode accesses, so that it can not write these registers.

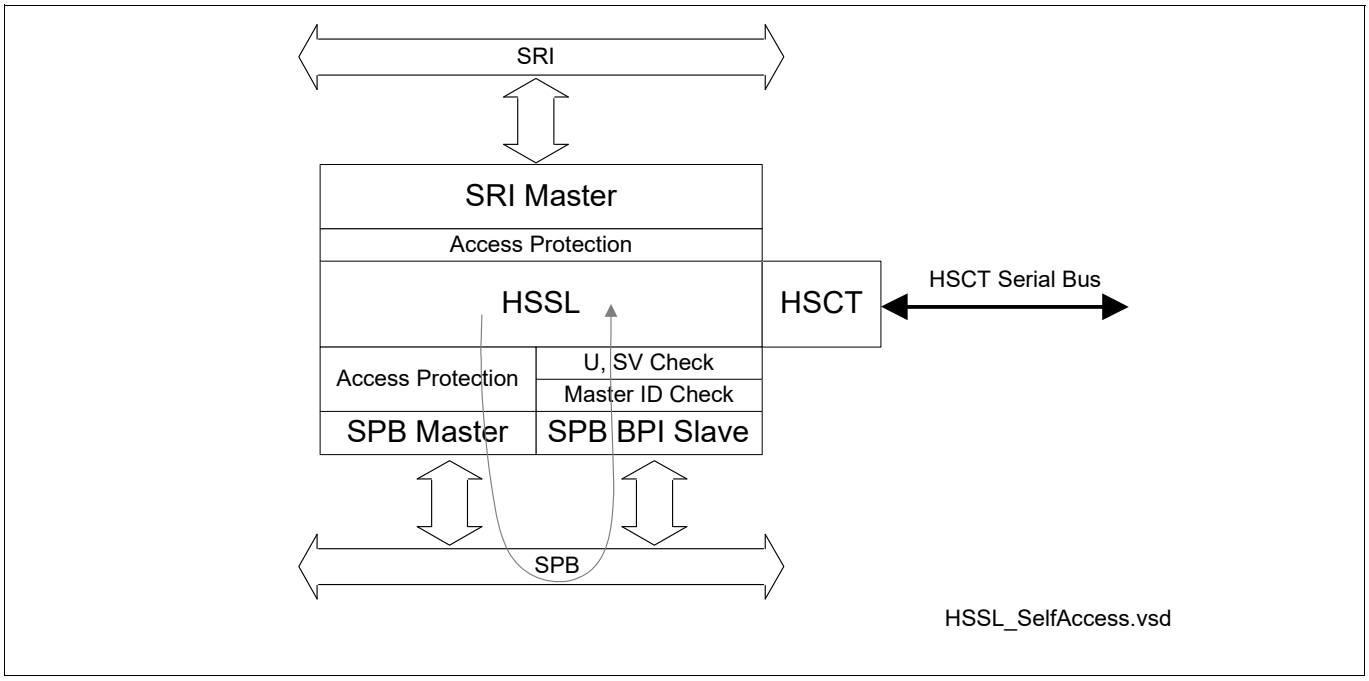

Figure 391 HSSL access to its own registers

35.3.12 Multi-Slave Operation

In multi slave use-cases, one HSSL master can communicate with up to three slaves. The master generates the reference clock from the HSCT module point of view and selects the active counterpart for the connection. The slaves receive the reference clock and are being selected by the master one at a time.

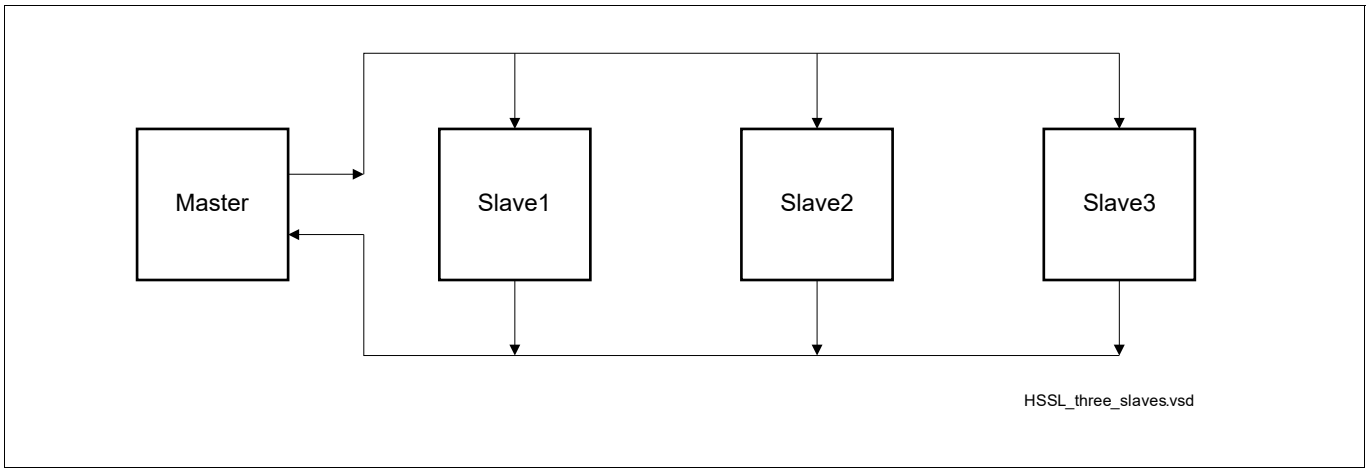

Figure 392 Three Slave HSSL Connection

The communication is connection based - at any point in time there can be only one active connection (or zero) between the master and one slave. There are no broadcast or multicast messages on the HSSL level. There is a defined procedure for terminating a connection with one slave and activating a connection with another slave. During an active connection both master and slave can be initiators and targets.

After power-on reset, the transmit outputs of the slaves and the transmit output of the master are high impedance. Up to three slaves can be enabled for reception by software.

35.3.12.1 Slave Tag and Slave Control

The multi slave operation uses the identical set of command and stream frames as the standard HSSL two-device operation. The slaves are selected with two bits in the HSSL header. These bits are used to filter the frames which are relevant for a slave by comparing them with the slave internal two bit tags, see **MSCR**.SLAVETAG.

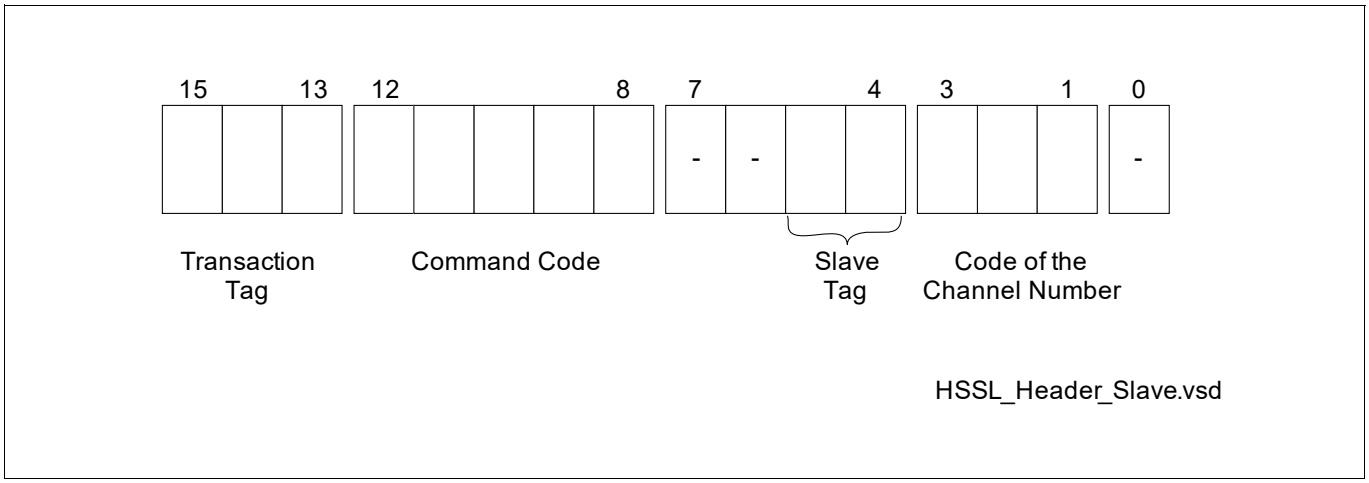

Figure 393 HSSL Header with Slave Tag

35.3.12.2 Slave Tag Frame Filter and Translator

The filter is located after the CRC block. In receive direction, if there is a match, the frame is passed through and handled in a standard HSSL two-device-connection way. If no match, the frames are discarded. In transmit direction, the headers of transmitted frames get the appropriate tag inserted. In case of a CRC error in a frame sent by the master, all slaves may detect the CRC error. The CRC checker discards the frames with CRC error, and even the addressed slave does not get the frame with a CRC error delivered. Frames with PIE1 and PIE2 error are also discarded. The corresponding error interrupts can be triggered if enabled.

The slaves have their tags fixed in the initialization phase and they never change. The software of the master changes its slave tag when establishing connection with different slave. First the HSCT link must be established. The master must have its **MSCR**.SLAVETAG configured before starting with sending HSSL commands or stream frames to the appropriate slave.

The **MSCR**.EN and **MSCR**.SLAVETAG bit fields are propagated to the HSCT module in order to ensure consistent operation of the whole communication channel.

If the multi slave operation is disabled (**MSCR**.EN=0), then both the injection of the slave tag in transmit direction and the filtering of the slave frames in the receive direction are not performed. The header remains unchanged and all the incoming frames pass through.

It is not intended to set the **MSCR**.ITXSTOP bit in the master.

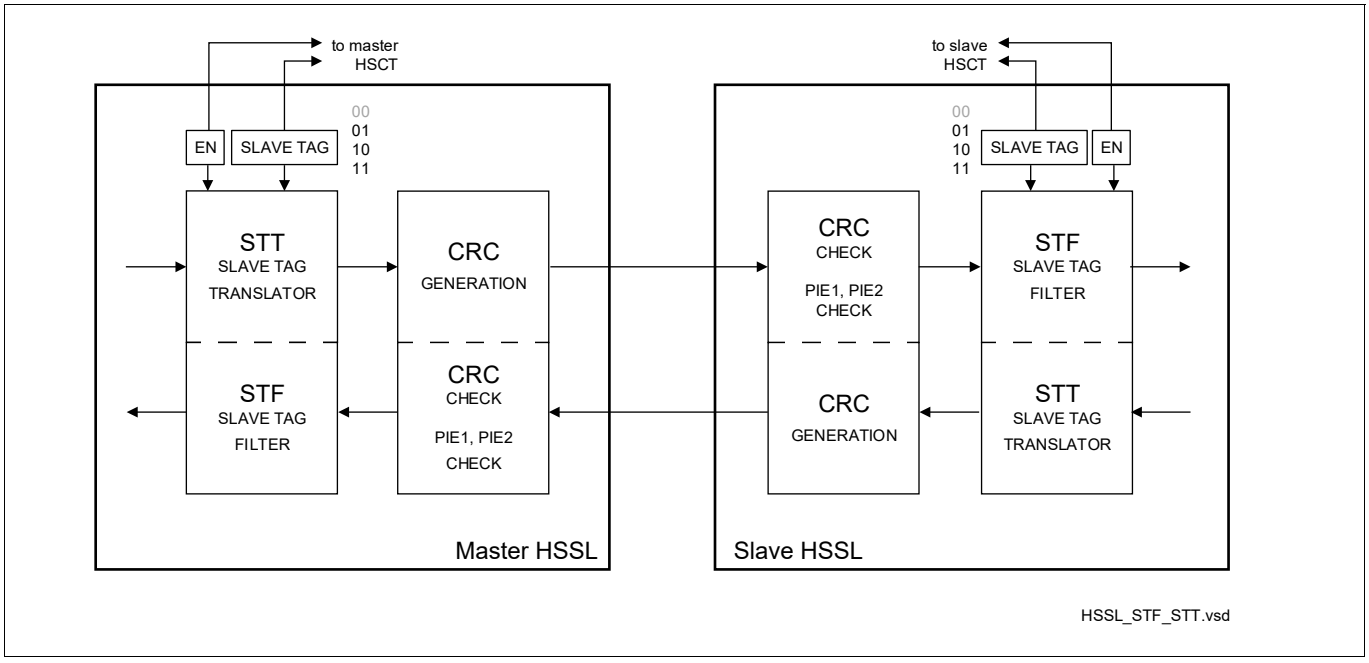

Figure 394 Slave Frame Filter

35.3.12.3 Activating a Slave

Activating a slave is done in two steps:

- The master enables the LVDS transmitter pads of one slave by using slave specific HSCT command. The Tx enable HSCT commands for the slaves 1, 2 and 3 have payloads 51_H, 52_H and 53_H correspondingly.
- The second step is either soft or hard HSSL activation:
  - Soft activation - the master notifies the slave by using standard HSSL commands, according to a pre-defined procedure. For example, master can issue a write command to a certain location, send an interrupt trigger command frame, and a slave having a CPU can start transmitting using the HSSL module.

– Hard activation - the master clears the **MSCR**.ITXSTOP bit by using standard HSSL 16-bit write command frame (an appropriate address window for the HSSL registers must have been already set up). In the next step, the master notifies the slave, for example with a trigger command, or enables the operation of the slave by setting an appropriate bit(s). The slave continues the operation from the point its initiator transmission has been stopped.

35.3.12.4 Deactivating a Slave

Master can deactivate a slave in two ways, soft and hard.

Soft Deactivation

Soft deactivation procedure uses software handshake procedure to bring the slave in a state where all ongoing slave initiator transactions has been completed, including streams, no new slave transactions are initiated and the slave notifies the master that the safe deactivation state has been reached. Subsequently, the master disables the LVDS pad.

The soft deactivation sequence consists of:

- Soft HSSL deactivation - using software handshake with standard HSSL commands, like writing to memory location and triggering interrupts
- Switching off the LVDS Tx pads with slave unspecific (broadcast) HSCT command with payload 32_H

Hard Deactivation

Hard deactivation is intended to provide faster deactivation with bounded reaction time, primarily for slaves without CPU and use-cases without streaming.

The hard deactivation sequence consists of:

- Hard HSSL deactivation
  - the master sets the **MSCR**.ITXSTOP bit by using standard HSSL 16-bit write command frame (an appropriate address window for the HSSL registers must have been already set up)
  - The master must assure that slave initiator commands have been processed by itself and that the acknowledge frames have been sent to the slave. For example, the master polls the slave E (expect) flags by using standard HSSL 16-bit read commands until it reads back 0.
  - Additionally, the master must assure that its command frames have been processed and acknowledged by the slave. For example, the master can poll its own expect flags until it reads 0.
- Switching off the LVDS Tx pads with slave unspecific (broadcast) HSCT command with payload 32_H

The slave HSSL module initiator transmit path remains inactive and later, after being re-activated by the master, continues the operation from the point where it has been stopped. The master is not allowed to send commands to a deactivated slave.

35.3.12.5 MSCR HSSL to HSCT Connections

The HSSL module provides the **MSCR**.EN and **MSCR**.SLAVETAG bit fields at the module border as outputs. These signals are connected to the HSCT module and provide single point of configuring the behavior of both HSSL and HSCT regarding multi slave behavior.

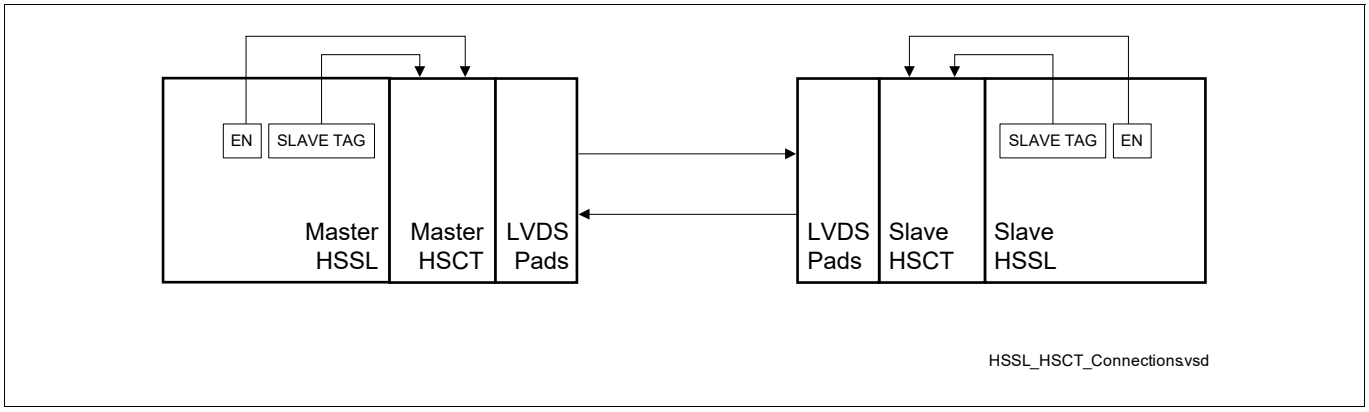

Figure 395 HSSL to HSCT Connections

35.4 Registers

This section describes the registers of the HSSL module.

Note: The HSSL module occupies 1KByte of address space, although only the first 256 bytes are used. Accessing a not used address location generates a bus error.

There are no registers in the HSSL with the destructive read property, where a read access would generate some action in the hardware.

Table 310 Register Overview - HSSL (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control Register	000_H	U,SV	SV,E,P	Application Reset	77

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

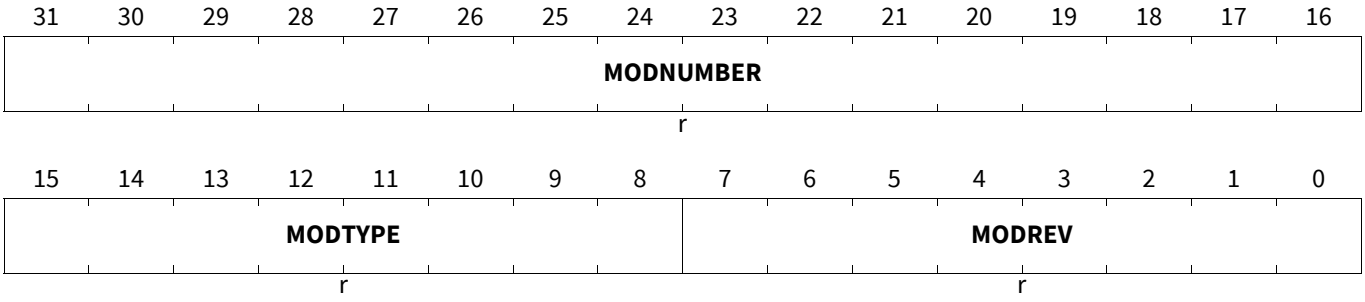
SE - Safety ENDINIT

35.4.1 Global Registers

Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(008_H)** **Application Reset Value: 00CB C0XX$_H$**



Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module.
MODNUMBER	31:16	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

CRC Control Register

This register only influences the generation of the CRC in the transmit direction.

CRC
CRC Control Register **($00C_H$)** **Application Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
XORMASK	15:0	rw	**Value to be XORed with the Calculated CRC** Used for error injection / test purposes.
XEN	16	rw	**Enable the Error Injection via XORMASK** 0_B disabled 1_B enabled

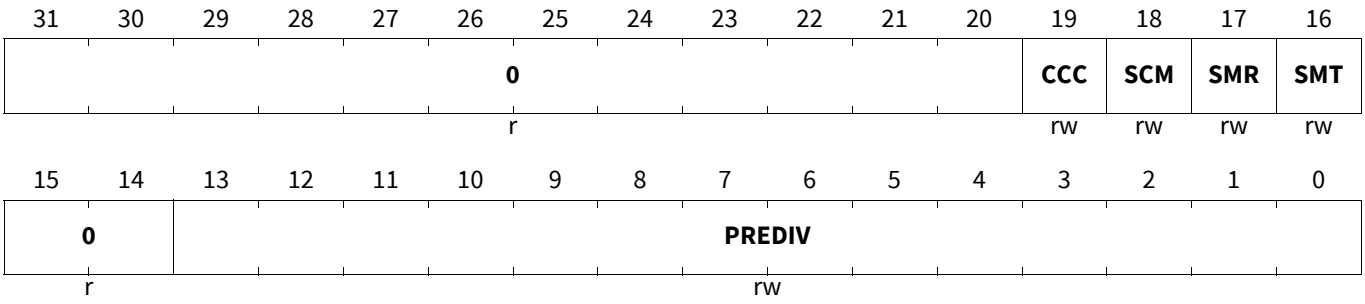
Field	Bits	Type	Description
0	31:17	r	**Reserved**

Configuration Register

The CFG register is used to configure the HSSL module. It shall only be written in the Initialize Mode.

Note: The duration of a timeout interval may vary for an amount of one predivider clock period. Therefore the predivider should be set as low as possible, and the timeout length as many predivider periods as possible.

CFG
Configuration Register **(010_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
PREDIV	13:0	rw	**Global Predivider** Defines the down-scaled module clock to be used by all channel timeout timers. 0000_H1 0001_H2 0002_H3 **others**, corresponding down-scale factor
SMT	16	rw	**Streaming Mode Transmitter** 0_B Continuous 1_B Single
SMR	17	rw	**Streaming Mode Receiver** 0_B Continuous 1_B Single
SCM	18	rw	**Streaming Channel Mode** Defines if the channel 2 is used in a streaming or command mode. 0_B Command 1_B Streaming
CCC	19	rw	**Channel Code Control** Defines the coding of the channel number in the HSSL header. 0_B Binary 1_B Special
0	15:14, 31:20	r	**Reserved**

35.4.2 Channel.Flags Registers

Request Flags Register

This register contains flags indicating if an appropriate action request is pending or not.

QFLAGS

Request Flags Register **(014_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ES	**TS**	**RS**	**IS**	**0**				**E3**		**E2**		**E1**		**E0**	
rh	rh	rh	rh	r				rh		rh		rh		rh	

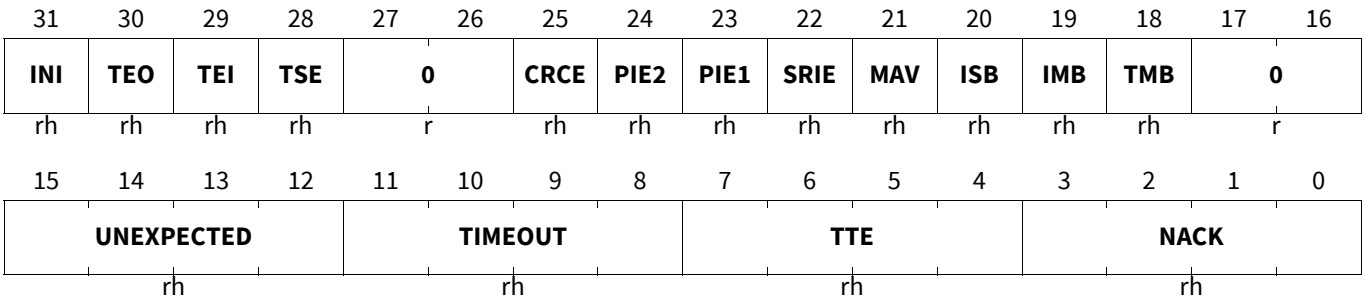
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				**R**				**T**				**I**			
r				rh				rh				rh			

Field	Bits	Type	Description
I	3:0	rh	**Request Flags for Initiated Commands** These flags are set by the corresponding channel when a WRTS command is initiated. The WRT commands are initiated via the SPB bus. The S(tream) commands are initiated by the module internally, by the TXFIFO, except for the first stream frame start, which is done via the SPB bus. See MFLAGS.ISB and ISF flags. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others**, corresponding combination of requests
T	7:4	rh	**Request Flags for Commands Arrived at Target** These flags are set by the hardware according to the header information of a frame arrived at the target without a CRC error. They are used by the arbiter of the SRI/SPB master and cleared when the appropriate command is executed. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others**, corresponding combination of requests

Field	Bits	Type	Description
R	11:8	rh	**Request Flags for Response Frames at the Target** After a command has been executed by the SRI/SPB master, an appropriate flag is being set which indicates that an ACK/NACK/DATA is pending. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others**, corresponding combination of requests
E0	17:16	rh	**Expect Flags for Activated Timeout Timer 0** An appropriate two bit flag is set by the hardware when a timeout timer for a channel is started. The hardware clears the appropriate flag when any response frame arrives at the initiator. In case of an unexpected response the flag UNEXPECTED is additionally set. 00_B No request pending 01_B write request pending 10_B read request pending 11_B trigger request pending
E1	19:18	rh	**Expect Flags for Activated Timeout Timer 1**
E2	21:20	rh	**Expect Flags for Activated Timeout Timer 2**
E3	23:22	rh	**Expect Flags for Activated Timeout Timer 3**
IS	28	rh	**I Flag for Stream Frames** See the “I” flag description above. 0_B No request pending 1_B Request pending
RS	29	rh	**R Flag for Stream Frames** See the “R” flag description above. 0_B No request pending 1_B Request pending
TS	30	rh	**T Flag for Stream Frames** See the “T” flag description above. 0_B No request pending 1_B Request pending
ES	31	rh	**E Flag for Stream Frames** See the “E” flag description above. 0_B No request pending 1_B Request pending
0	15:12, 27:24	r	**Reserved**

Miscellaneous Flags Register

MFLAGS
Miscellaneous Flags Register **(018_H)** **Application Reset Value: $8000\ 0000_H$**



Field	Bits	Type	Description
NACK	3:0	rh	**Not Acknowledge Error - Target Error** Indicates for each channel that a target error frame has been received.
TTE	7:4	rh	**Transaction Tag Error** Indicates for each channel if a CRC correct acknowledge frame with an unexpected transaction tag number has been received.
TIMEOUT	11:8	rh	**Timeout Error** Indicates for each channel if an timeout event has occurred.
UNEXPECTED	15:12	rh	**Unexpected Type of Frame Error** Indicates for each channel if an unexpected or inappropriate response is received. For example a NACK for a Trigger frame or DATA for WRITE frame.
TMB	18	rh	**Target Memory Block** Selects the currently active memory block used by the target as a target for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1
IMB	19	rh	**Initiator Memory Block** Selects the currently active memory block used by the initiator as a source for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1
ISB	20	rh	**Initiator Stream Block Request** Indicates if stream block request is pending. Set by the software to start a stream block transfer by using the MFLAGSSET.ISBS bit; clear by the software possible (if needed) by using the MFLAGSCL.ISBC bit; cleared by hardware at the end of the current block transfer in single mode, but not in continuous mode. 0_B No request or streaming ongoing 1_B Streaming ongoing

Field	Bits	Type	Description
MAV	21	rh	**Memory Access Violation** Indicates a memory access violation. 0_B No violation 1_B Violation
SRIE	22	rh	**SRI/SPB Bus Access Error** Indicates an error on the SRI bus - transaction ID, ECC error or error acknowledge. Indicates an error on the SPB bus, error acknowledge or timeout. 0_B No error 1_B Error
PIE1	23	rh	**PHY Inconsistency Error 1(Channel Number Code Error)** Indicates if HSCT to HSSL channel number code comparator has detected an inconsistency error. 0_B No error 1_B Error
PIE2	24	rh	**PHY Inconsistency Error 2(Data Length Error)** Indicates if HSCT to HSSL data length comparator has detected an inconsistency error. 0_B No error 1_B Error
CRCE	25	rh	**CRC Error** Indicates if CRC checker has detected a CRC error. 0_B No error 1_B Error
TSE	28	rh	**Target Stream Enable** Used by the hardware to handle the single and continuous streaming. In single mode, cleared by hardware after the current block transfer ends. The module ignores afterwards the incoming steam frames. 0_B Disabled 1_B Enabled
TEI	29	rh	**Transmit Enable Input** Indicates the state of the TEI input signal of the HSSL module, which is driven by the CTS output signal of the HSCT module. Any edge on this signal triggers an EXI interrupt. This low level signal stops the transmission of both command and response frames.
TEO	30	rh	**Transmit Enable Output** Indicates the state of the TEO output signal of the HSSL module, which drives thee CTS input signal of the HSCT module. This bit is cleared by hardware at entering the INIT and Soft Suspend state.
INI	31	rh	**Initialize Mode** Indicates if the module is in the Initialize or Run mode. 0_B Run mode 1_B Initialize mode
0	17:16, 27:26	r	**Reserved**

Miscellaneous Flags Set Register

Note: Read access to this register returns all zero.

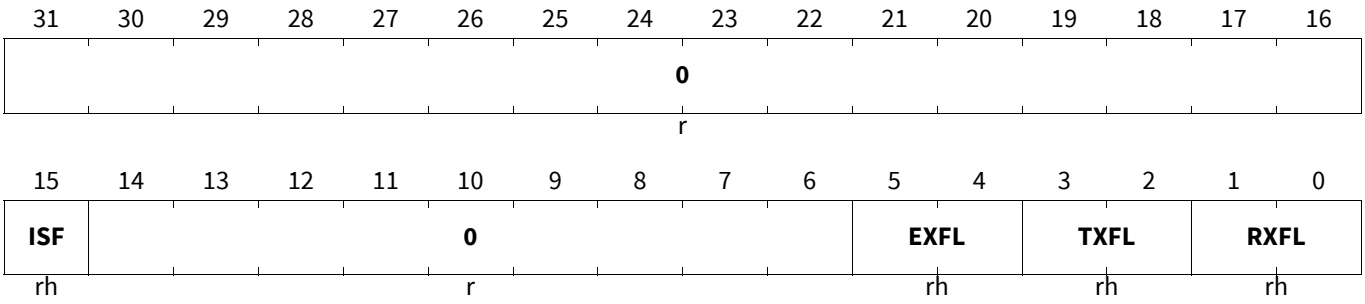
Stream FIFOs Status Flags Register

SFSFLAGS

Stream FIFOs Status Flags Register (028$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RXFL	1:0	rh	**Stream RxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)
TXFL	3:2	rh	**Stream TxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)
EXFL	5:4	rh	**Stream Expect FIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)
ISF	15	rh	**Initiator Stream Frame Request** Indicates if stream TXFIFO request is pending. Set and cleared by the TXFIFO. 0_B TXFIFO fill request not pending 1_B TXFIFO fill request pending
0	14:6, 31:16	r	**Reserved**

35.4.3 Channel.Initiator Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions. In order to support command queues, the addresses of the **IWDx (x=0-3)**, **ICONx (x=0-3)**, **IRWAx (x=0-3)**, and **IRDx (x=0-3)** registers are ordered in a sequence of IWD0, ICON0, IRWA0, IRD0, IWD1, ICON1, IRWA1, IRD1, IWD2, ICON2, IRWA2, IRD2, IWD3, ICON3, IRWA3, IRD3, see **DMA Operated Command Queues**. For the timeout handling description, see **Command Timeout Operation**.

Initiator Write Data Register x

The IWD register contains the data part of a write command.

IWDx (x=0-3)
Initiator Write Data Register x **(030_H+x*10_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA															
rw															

Field	Bits	Type	Description
DATA	31:0	rw	**Data Part of the Payload of a Write Frame** For 8-bit and16-bit write command frames, the whole frame payload width of 32-bit is automatically filled with copies of the lower 8-bits or 16-bits of the register.

Initiator Control Data Register x

The ICON register contains the control and the configuration bits of a channel.

Bitfields TOREL and ITTAG are used for command frames, and also reused for streaming frames in channel 2. All other bit fields are used only for command frames.

ICONx (x=0-3)
Initiator Control Data Register x **(034_H+x*10_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TOREL								ITTAG			BSY	RWT		DATLEN	
rw								rh			rh	rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TOCV								CETT			LETT			TQ	IDQ
rh								rh			rh			w	w

Field	Bits	Type	Description
IDQ	0	w	**Read ID Request** This bit provides the only way to request a read ID frame. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No read ID request 1_B Read ID frame request
TQ	1	w	**Trigger Request** This bit provides an alternative way to request a trigger frame, without having to write to the channel address register. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No trigger request 1_B Trigger frame request
LETT	4:2	rh	**Last Error Transaction Tag**
CETT	7:5	rh	**Currently Expected Transaction Tag**
TOCV	15:8	rh	**Time Out Current Value**
DATLEN	17:16	rw	**Data Length** Defines the length of the data in bits of the write and read command. 00_B 8-bit 01_B 16-bit 10_B 32-bit 11_B Reserved (implemented as 32-bit)
RWT	19:18	rw	**Read Write Trigger Command Type** Defines if the write to the IRWA register will trigger read, write or trigger request. 00_B No action 01_B Read Frame 10_B Write Frame 11_B Trigger Frame
BSY	20	rh	**Channel Busy**
ITTAG	23:21	rh	**Initiator Transaction Tag** This bit displays the current value of the three bit counter generating the new transaction tag value.
TOREL	31:24	rw	**Time Out Reload Value** Defines the duration of the timeout in units of prescaled clock periods. This parameter is valid both in command and stream mode of the channel 2.

Initiator Read Write Address Register x

The IRWA register contains the address part of a write command. Writing the IRWA register triggers a transmit request for the appropriate channel.

IRWAx (x=0-3)

Initiator Read Write Address Register x **(038_H+x*10_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS															
rw															

Field	Bits	Type	Description
ADDRESS	31:0	rw	**Address Part of the Payload of a Write Frame** Writing to this registers triggers transmission of a Write Frame. The address must be aligned according to the data width: byte addresses for 8-bit data, half-word addresses for 16-bit data, word addresses for 32-bit data.

Initiator Read Data Register x

The IRD register contains the data read from the target, which has been fed back as a response to a read command.

IRDx (x=0-3)

Initiator Read Data Register x **($03C_H$+x*10_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DATA	31:0	rh	**Data Delivered by a Read Response Frame**

35.4.4 Channel.Target Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions.

Target Current Data Register i

The TCD register contains the data part of a write command which is currently being processed by the channel on the target side, or the latest data which has been read by the SRI/SPB master in case of a read command.

TCDi (i=0-3)

Target Current Data Register i **(070_H+i*8)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
D															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D															
rh															

Field	Bits	Type	Description
D	31:0	rh	**Data Part of the Payload of a Write Command Frame or Read Data of a Read Command Frame**

Target Current Address Register i

The TCA register contains the address part of a read or write command which is currently being processed by the channel on the target side.

In case of Read ID frame, the address is copied from the register TIDADD.

TCAi (i=0-3)

Target Current Address Register i **(074_H+i*8)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A															
rh															

Field	Bits	Type	Description
A	31:0	rh	**Address Part of the Payload of a Write Command Frame or a Read Command Frame or ID Frame**

Target Status Register

The TSTAT register contains the status bits of the common target functionality.

TSTAT

Target Status Register **(090_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LASTTT3			LASTCC3					LASTTT2			LASTCC2				
rh			rh					rh			rh				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LASTTT1			LASTCC1					LASTTT0			LASTCC0				
rh			rh					rh			rh				

Field	Bits	Type	Description
LASTCCx (x=0-3)	8*x+4:8*x	rh	**Last Command Code** Indicates the latest command code from the header for the corresponding channel.
LASTTTx (x=0-3)	8*x+7:8*x+5	rh	**Last Transaction Tag** Indicates the transaction tag of the latest command or stream frame for the corresponding channel.

Target ID Address Register

The TIDADD register contains the address from which the target ID is fetched. After the Power-On Reset, System Reset, and Application Reset the start-up software writes this register with the address of CBS_JTAGID register. After Kernel Reset, the start-up software is not executed, and the reset value is not changed.

TIDADD

Target ID Address Register **(094_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A															
rw															

Field	Bits	Type	Description
A	31:0	rw	**Address Pointer** Address pointer containing the address of the memory location containing the unique ID data.

35.4.5 Initiator Stream Registers

(>> **Memory Block Transfer Modes of the Stream Channel**)

Initiator Stream Start Address Register

ISSAx (x=0-1)
Initiator Stream Start Address Register **($0A0_H$+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
START															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
START											0				
rw											r				

Field	Bits	Type	Description
START	31:5	rw	**Start Address for the Memory Range** Aligned on 256-bit limit (stream frame payload size).
0	4:0	r	**Reserved**

Initiator Stream Current Address Register

ISCA
Initiator Stream Current Address Register **($0A8_H$)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CURR															
rh															

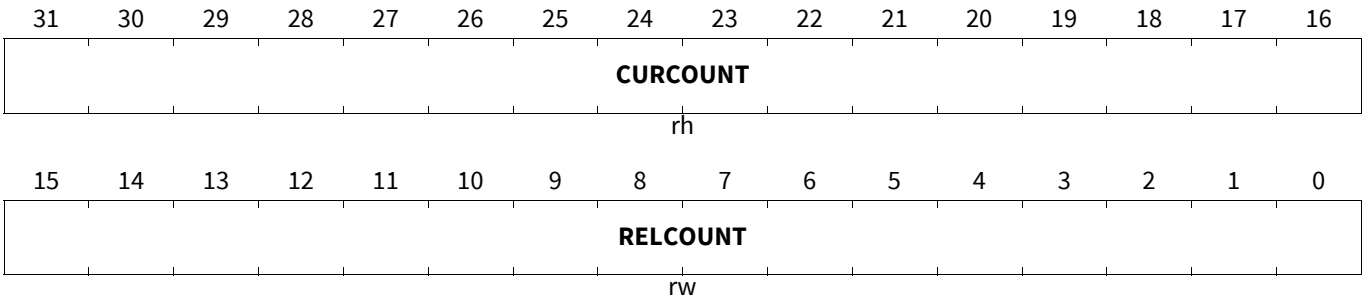
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CURR											0				
rh											r				

Field	Bits	Type	Description
CURR	31:5	rh	**Address of the Memory Location for the Current Transfer** Aligned on 256-bit limit (stream frame payload size).
0	4:0	r	**Reserved**

Initiator Stream Frame Count Register

ISFC

Initiator Stream Frame Count Register (0AC$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RELCOUNT	15:0	rw	**Reload Count Number** Contains the number of frames to transfer per memory block. Bit field length depends on application requirements. 0000$_H$1 0001$_H$1 0002$_H$2 0003$_H$3 **others**, corresponding number of frames
CURCOUNT	31:16	rh	**Current Count Number** Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.

35.4.6 Target Stream Registers

(>> **Memory Block Transfer Modes of the Stream Channel**)

Target Stream Start Address Register x

TSSAx (x=0-1)

Target Stream Start Address Register x **($0B0_H$+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR											0				
rw											r				

Field	Bits	Type	Description
ADDR	31:5	rw	**Start Address for the Memory Range** Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	4:0	r	**Reserved**

Target Stream Current Address Register

TSCA

Target Stream Current Address Register **($0B8_H$)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CURR															
rh															

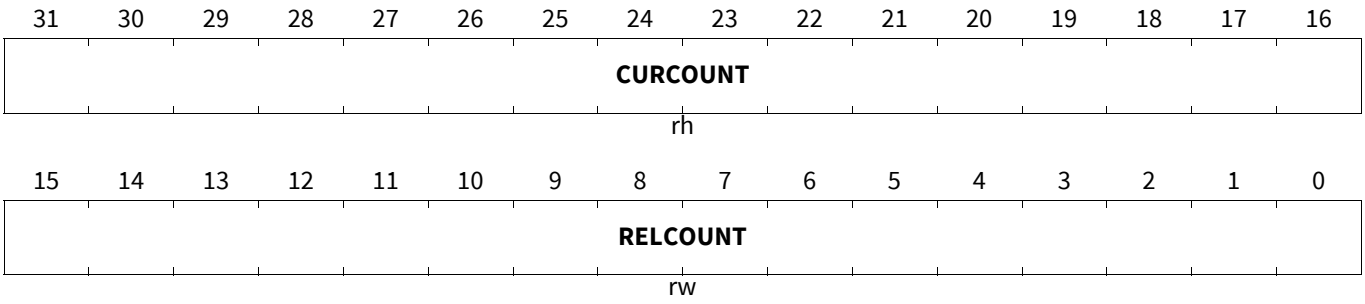
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CURR											0				
rh											r				

Field	Bits	Type	Description
CURR	31:5	rh	**Address of the Memory Location for the Current Transfer** Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	4:0	r	**Reserved**

Target Stream Frame Count Register

TSFC

Target Stream Frame Count Register (0BC$_H$) Application Reset Value: 0000 0000$_H$



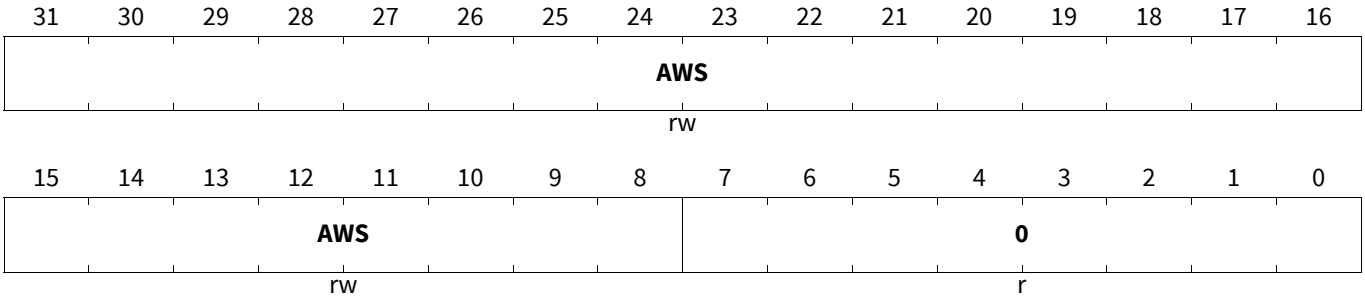
Field	Bits	Type	Description
RELCOUNT	15:0	rw	**Reload Count Number** Contains the number of frames to transfer per memory block. Bit field length depends on application requirements. 0000_H1 0001_H1 0002_H2 0003_H3 **others**, corresponding number of frames
CURCOUNT	31:16	rh	**Current Count Number** Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.

35.4.7 Access Protection Registers

This sub section describes the registers defining the access windows where the HSSL accesses are allowed. These registers are writable only in supervisor mode, which makes them not writable by the HSSL itself.

Access Window Start Register i

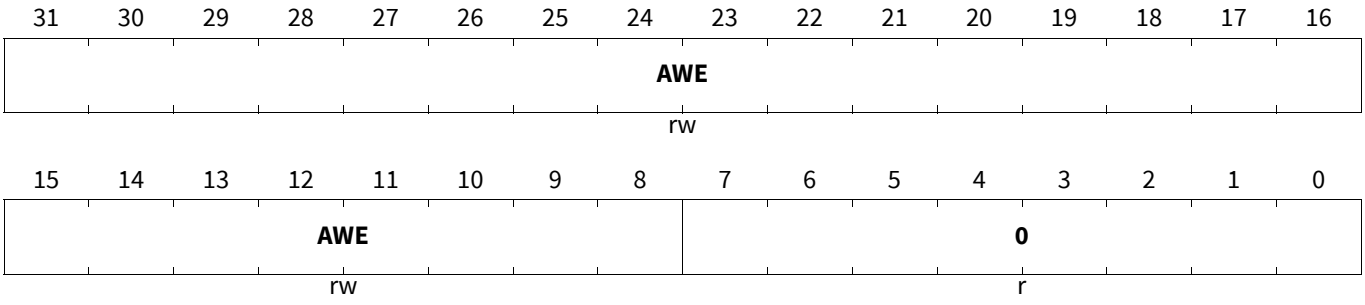
AWSTARTi (i=0-3)
Access Window Start Register i **($0C0_H$+i*8)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
AWS	31:8	rw	**Access Window Start Address** This bit field defines the upper 24 bits of the start address of the corresponding access window. This results in a granularity of 256 bytes for the start address.
0	7:0	r	**Reserved**

Access Window End Register i

AWENDi (i=0-3)
Access Window End Register i **($0C4_H$+i*8)** **Application Reset Value: 0000 0000_H**

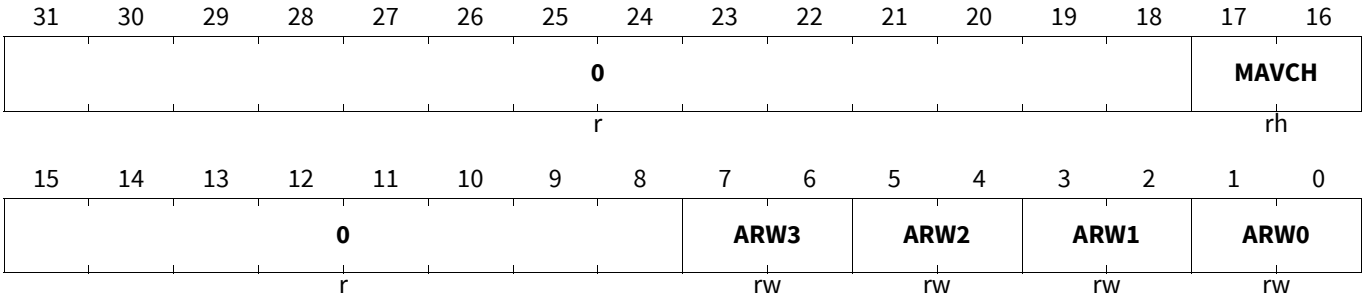


Field	Bits	Type	Description
AWE	31:8	rw	**Access Window End Address** This bit field defines the upper 24 bits of the end address of the corresponding access window. This results in a granularity of 256 bytes for the end address.
0	7:0	r	**Reserved**

Access Rules Register

AR

Access Rules Register **($0E0_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
ARWx (x=0-3)	2*x+1:2*x	rw	**Access Rule for Window x** 00_B No access (window disabled) 01_B Read access allowed 10_B Write access allowed 11_B Read and write access allowed
MAVCH	17:16	rh	**Memory Access Violation Channel** This bit field shows the number of the latest channel that attempted a not allowed access. 00_B Channel 0 01_B Channel 1 10_B Channel 2 11_B Channel 3
0	15:8, 31:18	r	**Reserved**

35.4.8 Security and Multi Slave Registers

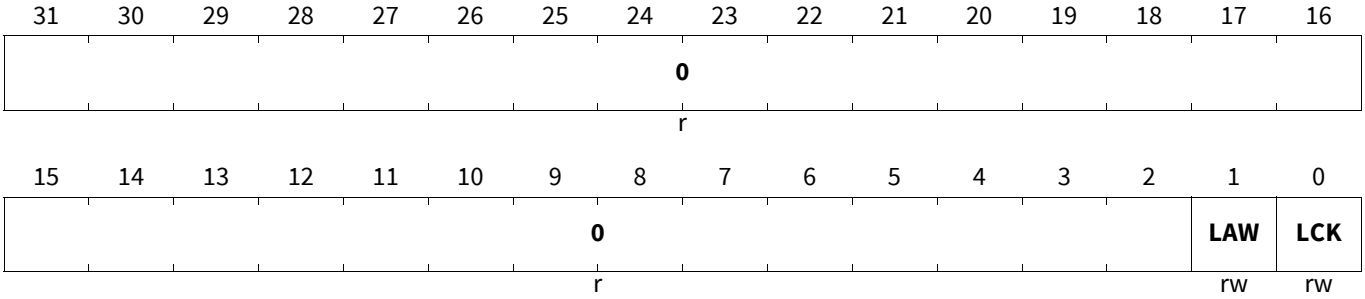
This sub section describes two registers: one handling the security aspects regarding the HSSL module operation and one configuring the multi slave mode of operation.

Security Control Register

This register can only be written by an access from the HSM master (TAG = 000011B). A write operation performed by any other master is ignored and the bit remains unchanged.

SEC

Security Control Register **(098_H)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
LCK	0	rw	**Lock the HSSL Module** Setting this bit field prevents the MFLAGS.INI bit to be cleared, that is prevents to leave the INIT state and go to RUN mode. If INIT bit has already been cleared, it is possible to set it, but not to clear it afterwards. This bit can only be written by an access from the HSM master (TAG = 000011B). A write operation performed by any other master is ignored and the bit remains unchanged. 0_B Unlocked 1_B Locked
LAW	1	rw	**Lock the Address Windows Registers** This bit field shows if the Address Window Registers AWSTARTx, AWENDx, AR and TIDADD are locked or not. If locked, the properties of the address windows cannot be changed any more. This bit can only be written by an access from the HSM master (TAG = 000011B). A write operation performed by any other master is ignored and the bit remains unchanged. 0_B Unlocked 1_B Locked
0	31:2	r	**Reserved**

Multi Slave Control Register

MSCR
Multi Slave Control Register **($09C_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															ITXSTOP
r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													SLAVETAG		EN
r													rw		rw

Field	Bits	Type	Description
EN	0	rw	**Multi Slave Mode Enable** This bit enables the multi slave mode of operation of the HSSL module. 0_B Disabled 1_B Enabled
SLAVETAG	2:1	rw	**Slave Tag** The master uses this bit field to define the current slave it sends to and receives from. The slave uses this bit field to pass through only the relevant incoming frames and to tag its own transmit frames. This tag is injected in the header by the Slave Tag Translator block and used for filtering in Slave Tag Filter Block. 00_B Reserved 01_B Slave 1 10_B Slave 2 11_B Slave 3
ITXSTOP	16	rw	**Initiator Transmission Stop** This bit is intended to be set or cleared by the master in a multi-slave operation by using 16-bit write command frames. MSCR.ITXSTOP functionality can be activated only if MSCR.EN = 1, otherwise it is ignored. Setting this bit stops the arbitration and transmission of new command and stream frames of the initiator but does not stop the ongoing frames. 0_B Initiator transmission active 1_B Initiator transmission stopped
0	15:3, 31:17	r	**Reserved**

35.4.9 BPI_FPI Module Registers

Figure 396 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC is mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_SPB register is to map them to the end address of the peripheral address range together with the peripherals SRNs.

BPI_FPI Registers Overview

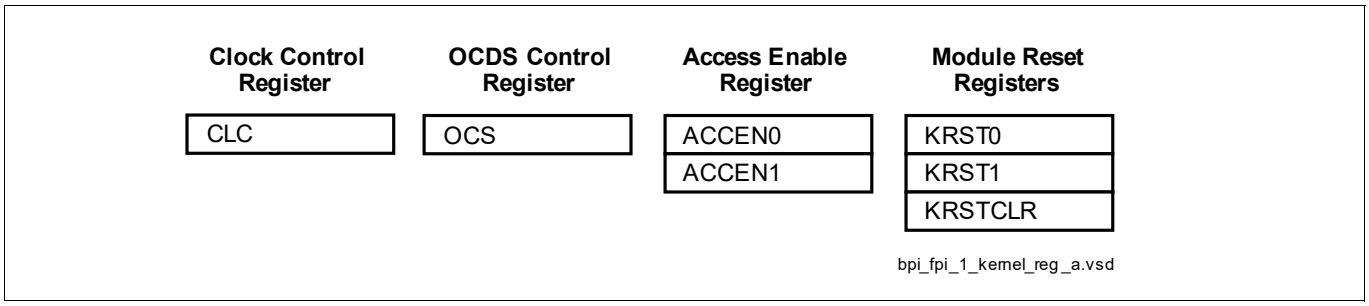


Figure 396 BPI_FPI Registers

The writes of the bus masters to the HSSL module is controlled by Access Protection registers ACCENx.

The HSSL implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC

Clock Control Register **(000_H)** **Application Reset Value: 0000 0003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.

Field	Bits	Type	Description
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

Note: The bit SUSSTA is set only at entering the suspend state from the run state. It will not be set if the soft suspend request comes in any other state than run state, like init or disabled/sleep state.

OCS
OCDS Control and Status **($0E8_H$)** **Debug Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												**TG_P**	**TGB**	**TGS**	
r												w	rw	rw	

Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B TS16_STR, Streaming Channel Trigger Set 10_B TS16_ERR, Errors Trigger Set 11_B Reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved,
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding. The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,…, EN31 -> TAG ID 011111B.

ACCEN0
Access Enable Register 0 **($0FC_H$)** **Application Reset Value: $FFFF\ FFFF_H$**

Access Enable Register 1

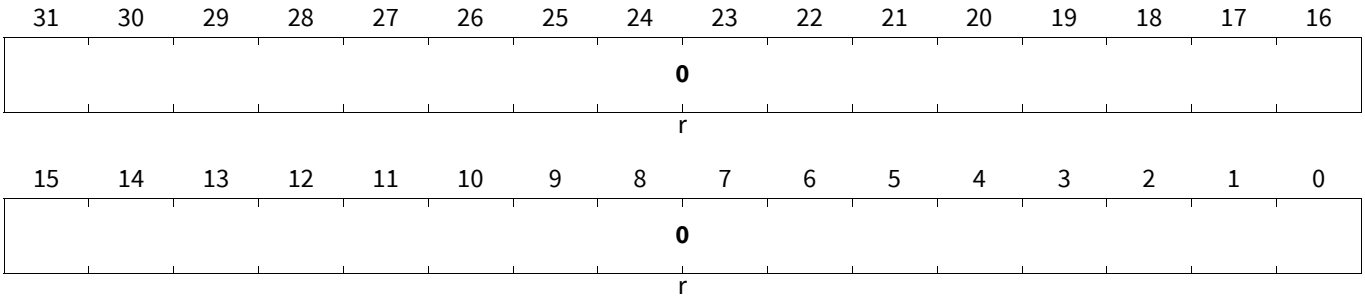
The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B,…, EN31 -> TAG ID 111111B.

1)

ACCEN1

Access Enable Register 1 **(0F8$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0

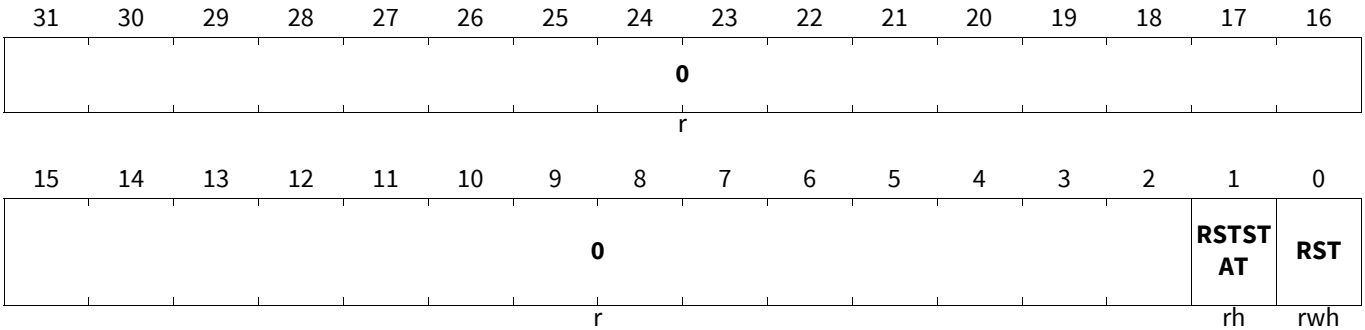
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 **(0F4$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

35.7 High Speed Communication Tunnel (HSCT)

This chapter describes the High Speed Communication Tunnel interface for the Microcontroller high speed data communication including the physical layer and the control (link) layer.

35.7.1 Feature List

The HSCT interface features can be separated in common features, features supported by single Slave connection and features supported by multi-slave (max 3 slaves) connection to the microcontroller. The multi slave connection has restrictions, which are also listed in the multi-slave feature list.

HSCT common interface basic features:

- TX-link: Transmit Symbol information from the Master interface to the Slave interface
- RX-link: Receive Sample information from the Slave interface to the Master interface
- System Clock provided by the Master interface (crystal owner) to the Slave interface
- TX-link data transfer speed 5 MBaud and 320 MBaud.
- RX-link data transfer speed based on f_{SYSCLK} = 20 MHz:
  5 MBaud (low speed)
  20 MBaud (medium speed)
  320 MBaud (high speed)
- RX-link data transfer speed based on 10 MHz SysClk:
  5 MBaud (low speed)
  320 MBaud (high speed)
- High speed data transfer rate can be reduced by implemented dividers (2, 4, 8, 16)
- The interface is based on IEEE 1596.3 LVDS IO's and provides Driver swing amplitude configuration

Single Slave connection features

- Control information on TX link and RX link
- Clear To Send indication in both directions
- Unsolicited Status in both directions
- Regular data transfer in both directions based on data channels
- Sleep Mode

Multi Slave (max 3 Slave) connection features and restrictions:

- Control information on TX link only
- Multi-Drop configuration (Master is addressing all slaves connected to the trace line)
- Clear To Send indication not supported
- Unsolicited Status not supported
- Regular data transfer in both directions based on data channel only (derived by Higher layer protocol)
- Multiple sender active/driving the RX link the same time is prohibited (ensured by system Master SW)
- Slave communication channel to a selected slave by higher layer SW; Only one Slave can be addressed and communication must be finished before the next Slave can be addressed
- Slaves driving the LVDS trace line the simultaneously are prohibited
- Connection of 2 Slaves to the LVDS trace line limits the max Baud rate to 160 MBaud
- Connection of 3 Slaves to the LVDS trace line limits the max Baud rate to 80 MBaud

- Discrete termination resistor for differential receiver trace line impedance matching is required on PCB with 100 Ohm +/-5% (check PCB layout guidelines from IFX); internal resistor is not supported

35.7.2 Overview

The HSCT TC3xx employs an interface for inter chip communication between a Master interface and a Slave interface. The interface is based on LVDS IO technology and developed to function as a Master or a Slave interface. During initialization phase the role of the Interface (Master or Slave) must to be defined. It is not intended to change the system role after initialization phase.

The interface is a full-duplex interface for TX and RX data transfer. The data transfer speed can be configured to function in low or high speed and allows to configure in each transfer direction an independent transfer speed in order to reduce power and EMI, based on transfer speed requirements. A sleep mode for the LVDS IO's is implemented, which reduces power on the IO, if the interface is not in use (Note: only available in single slave mode, not available in multi slave mode).

The Master interface is defined to own the crystal and provides the clock (**HSCT SysClk**) to the Slave interface. The HSCT Master/Slave interface allows from system point of view one crystal only. In this scenario the HSCT SysClk input at Slave Side is used as reference clock for other PLL's like SysPLL. The interface reset is derived from System reset and supports common reset behavior, including module reset. The name of the SysClk signal driven by the Master is SYSCLK_OUT. The name of the SysClk signal received by the Slave is SYSCLK_IN.

In **Figure 397** a system level view of the interface and interface connection is shown.

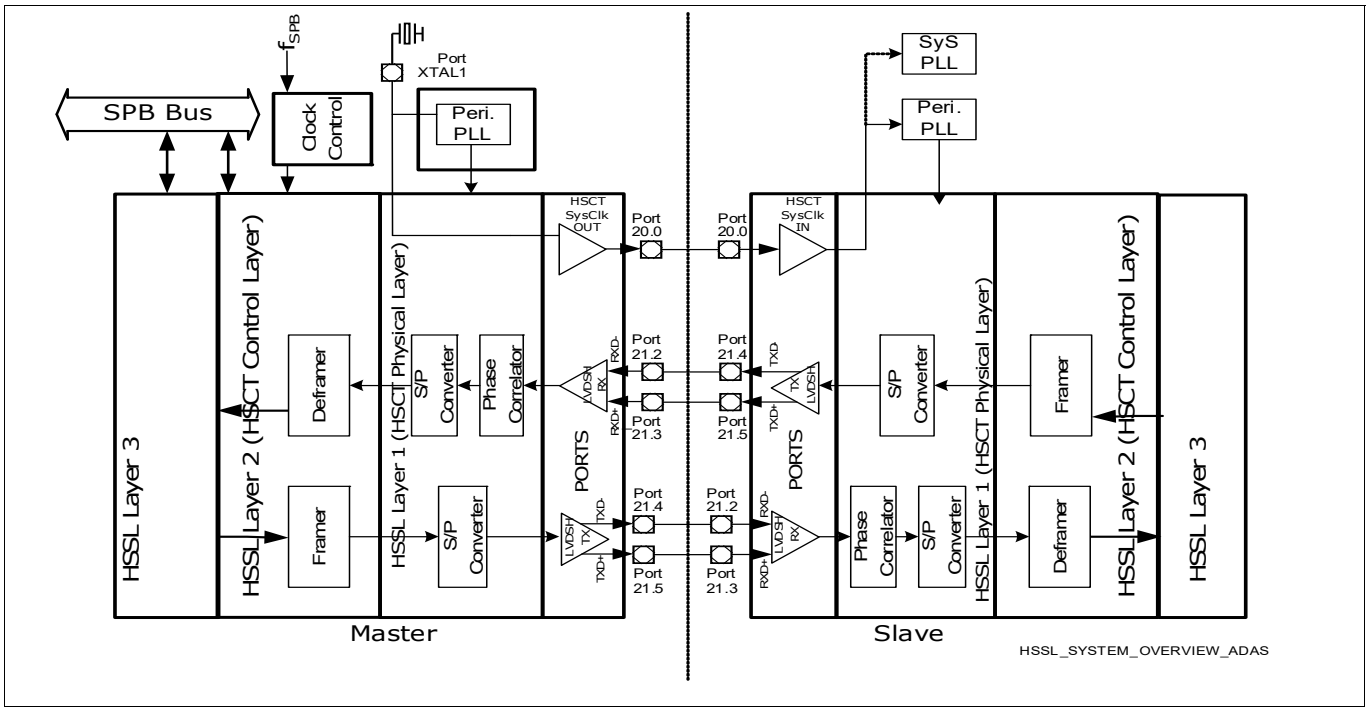

Figure 397 Overview of Interface Signals

35.7.3 Functional Description

35.7.3.1 Introduction

The initial HSCT communication is always established from Master interface. The LVDS IO's are based on standard IO technology following IEEE 1596.3 specification with minor limitations (see Datasheet). The HSCT LVDS IO common voltage is defined to be a 1.2 V. Compared to IEEE 1596.3 the differential voltage level can be reduced via configuration option to reduce EMI.

The intention is to implement the interface either as a Master interface or as a Slave interface. So the interface is able to handle both roles (Master or Slave). The following detailed description describes both roles, which requires the following definitions:

- TX line or TxData link (TX_DAT, TX_DATX) defines the data transfer from the Master interface to the Slave interface.
- RX line or RxData link (RX_DAT, RX_DATX) defines the data transfer from the Slave interface to the Master interface.
- Transmit direction, outbound data (or transmission) describes to send out data independent of the role the interface does have.
- Receive direction, inbound data (or receiving) describes to receive data independent of the role the interface does have.

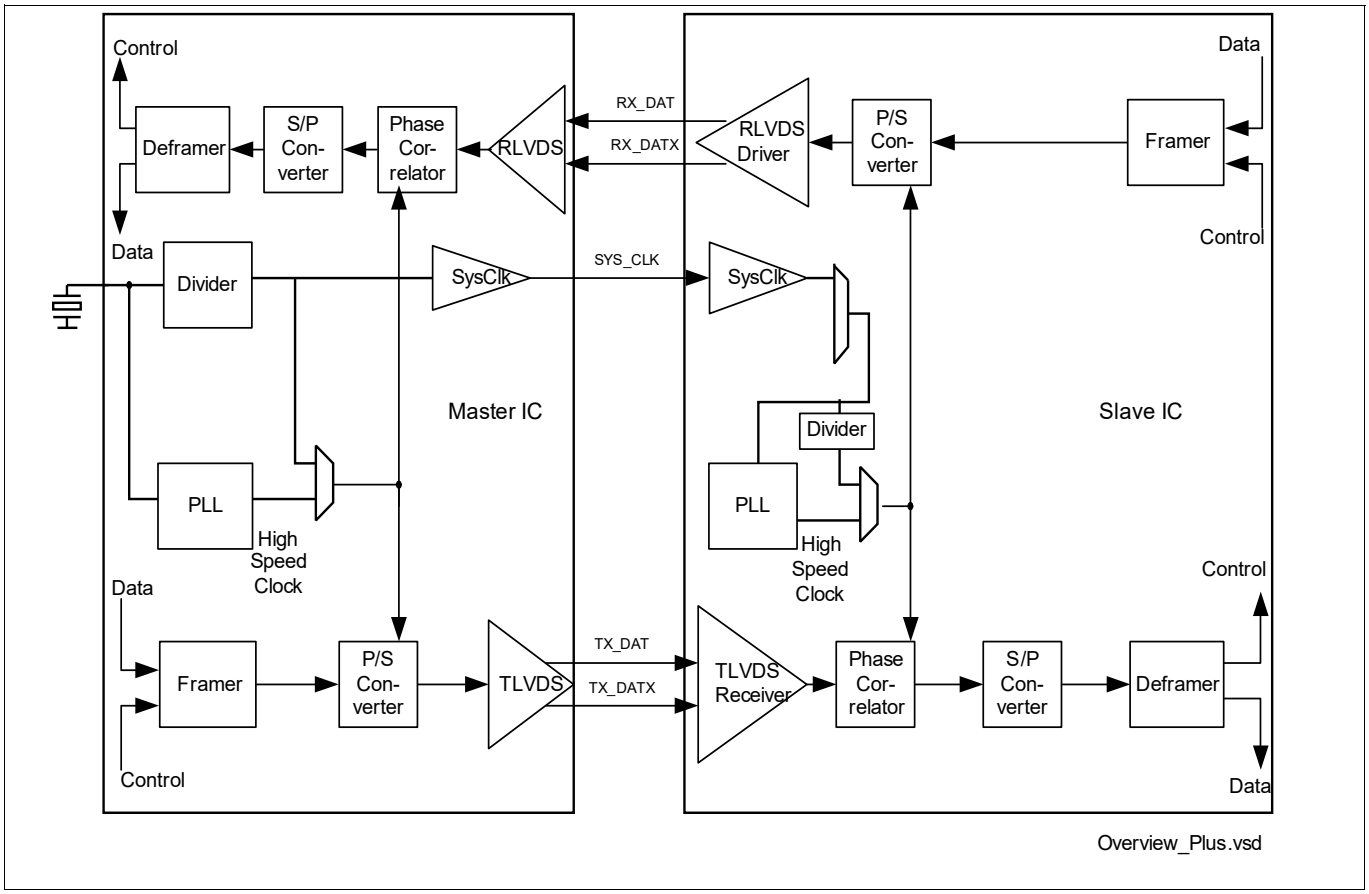

Figure 398 Overview internal block structure

35.7.3.2 Physical Layer

35.7.3.2.1 RX / TX Data communication

During initialization the associated TxData link starts in low-speed mode, with the high-speed clock not enabled or generators turned off and the RxData Link disabled. An interface control sequence, initiated by software, allows to switch the interface in high-speed mode.

The data interface can transmit with a max Baud rate of 320 Mbit/s in the RX and the TX direction (full-duplex). The data is recovered from RX data stream (RX_DAT, RX_DATX) in the Master interface and from TX (TX_DAT,TX_DATX) data stream in the Slave interface. **Table 313** shows the interconnects of the differential data lines for control and data transfer between the Master interface and the Slave interface and shows the limitations for multi Slave connections.

At TX link differential data with the configured baud rate is transmitted from the Master interface to the Slave interface. Proper phase selection is processed at receiver side via five different phases.

At RX link differential data is transferred from the Slave interface to the Master interface. A proper phase selection is processed for data recovery at the Master receiver path via five different phases derived from the clock generator (Peripheral PLL). The Slave interface reference clock must be the HSCTSysClk, driven by the interface Master. The Slave must receive the SysClk from Master interface to be enabled to perform reliable data transfer. A clock at Slave side derived from a crystal will lead to improper data communication, as frequency drift variation is uncontrollable and bigger then deriving it from a single clock source. The Slave interface max frequency (320 MHz data clock) is generated internally from the HSCT SysClk.

The HSCT SysClk at the Slave interface is also the reference clock for other PLLs on the chip.

Note: A local crystal at the Slave interface taken as reference clock for the interface PLL is not allowed as the data recovery based on clock phase shift works on a common reference clock source only!

Table 313 Physical Interconnects

Direction	Name	Description
Transmit (Single Slave)	**TX_DAT**, **TX_DATX**	Channel TX data and control information at a max rate of 320 Mbit/s from the Master interface to the Slave interface
Receive (Single Slave)	**RX_DAT**, **RX_DATX**	Channel RX data and control information at a max rate of 320 Mbit/s from the Slave interface to the Master interface
Transmit (Two Slave)	**TX_DAT**, **TX_DATX**	Channel TX data and control information at a max rate of 160 Mbit/s from the Master interface to the Slave interface
Receive (Two Slave)	**RX_DAT**, **RX_DATX**	Channel RX data and control information at a max rate of 160 Mbit/s from the Slave interface to the Master interface
Transmit (Three Slave)	**TX_DAT**, **TX_DATX**	Channel TX data and control information at a max rate of 80 Mbit/s from the Master interface to the Slave interface
Receive (Three Slave)	**RX_DAT**, **RX_DATX**	Channel RX data and control information at a max rate of 80 Mbit/s from the Slave interface to the Master interface

The RxDAT link (Slave TX) enters shutdown mode by Interface control logical channel command and exit shutdown mode by control command, again. The Slave transmission line is disabled by default and must be enabled by the Master. The Master Interface control commands are used to set the link into operation. TX or RX enable/disable shall not be changed during an active frame transmission or during sleep mode.

Payload content is transferred most significant bit first. For example, if a 32-bit payload contains a message derived from a 32-bit register at TX side, b31 of the register (the MSb) shall be the first bit of payload transmitted and b0 (LSb) shall be the last. Larger payloads should be built up according to the same principle.

35.7.3.2.2 Differential Signaling Principle Based on LVDS

The voltage at the termination resistor of the receiver is either positive or negative, which depends on the direction of the current flowing through it. This is determined by the state of the switches at the transmit stage. The voltage V_{OD} should be evaluated by a comparator with hysteresis.

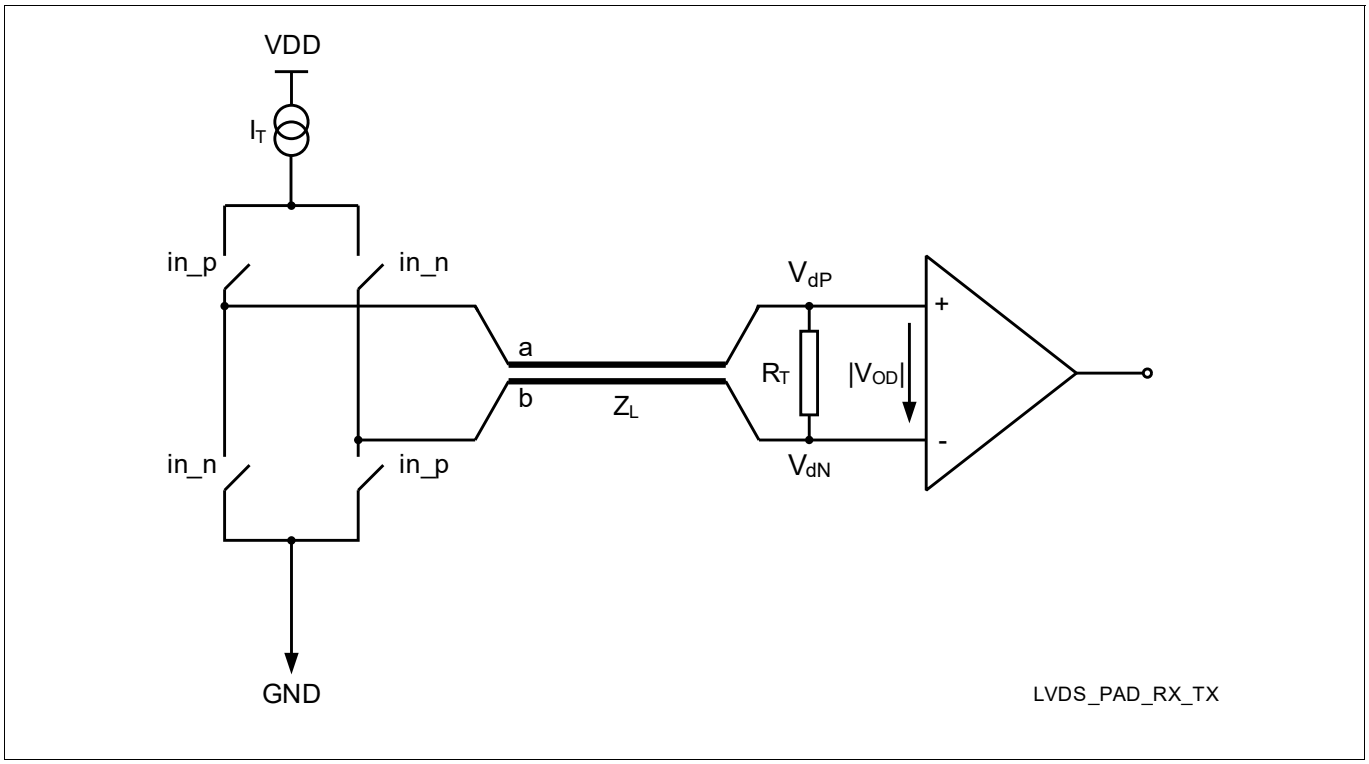

Figure 399 Pad Driver and Pad Receive

The HSCT interface defines no specific test for an error-free transmission, although the signal quality of course suffers from attenuation and noise and in particular it depends on proper wave propagation. Therefore the interconnect lines need to have a characteristic wave impedance Z_L equal to 100 Ω differential, corresponding to the termination resistor R_T at the receiver side.

Note: Due to the nature of wave propagation a termination other than with the characteristic line impedance leads to inevitable signal degradations. Therefore any operation mode other than 100 Ω termination is only supported from a functional point of view (i.e. the corresponding electrical configuration is possible) without any further guarantee of an error-free transmission.

Note: The interface receiver provides an input termination impedance of 100 Ω +/- 20% at the IO. If a more precise termination is required the design offers to disable the internal termination impedance and allow an external termination on the PCB. In multi Slave approach the internal termination impedance must be disabled and a resistor with 100 Ω +/- 5% must be placed on PCB instead (exact placement can be discovered in IFX PCB layout guidelines) as close as possible to the receiver IO.

The differential output voltage V_{OD} is defined as the difference of the voltages V_{dP} and V_{dN} at the receiver input pins.

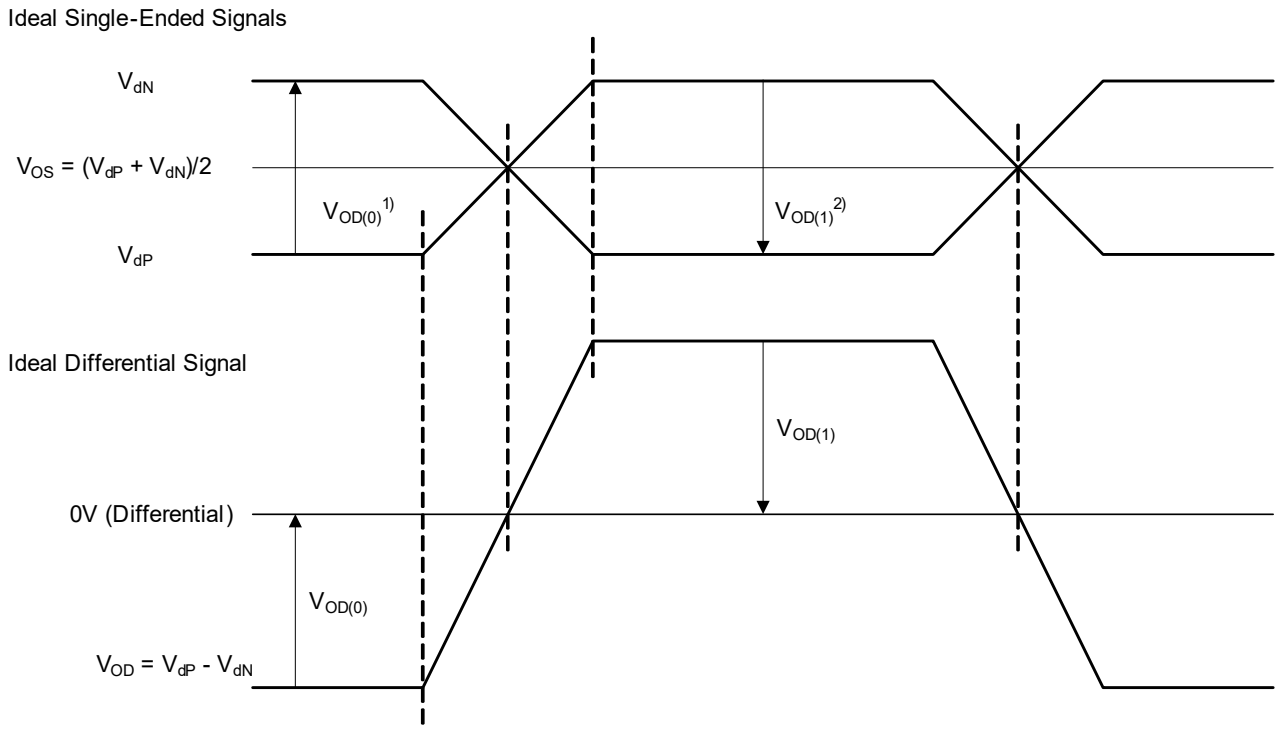
$$V_{OD} = V_{dP} - V_{dN} \quad (35.1)$$

The common-mode voltage V_{OS} is defined as the arithmetic mean value of the voltages at the receiver input pins:

(35.2)

$$V_{OS} = \frac{V_{dP} + V_{dN}}{2}$$

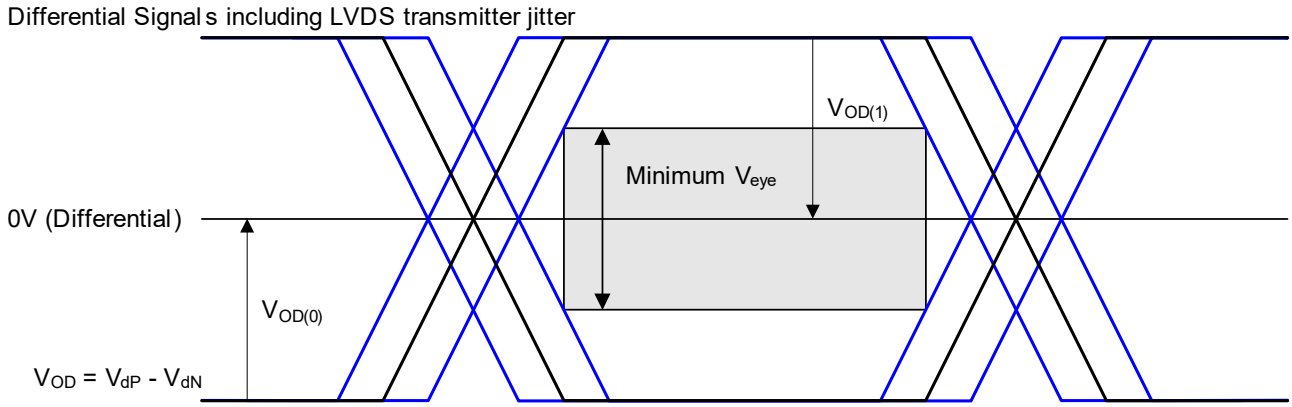
V_{OD}, V_{OS}, and the corresponding minimum differential eye opening V_{eye} considering LVDS transmitter jitter are exemplarily shown in **Figure 400** and **Figure 401** for ideal signals.



1) $V_{OD(0)}$ negative differential voltage representing a logic Zero

2) $V_{OD(1)}$ positive differential voltage representing a logic One

Figure 400 Ideal Single-Ended and Ideal Differential Signals



1) $V_{OD(0)}$ negative differential voltage representing a logic Zero

2) $V_{OD(1)}$ positive differential voltage representing a logic One

Figure 401 Differential Eye Opening

LVDS Pads in Multi Slave Mode

In multi slave mode, the procedure of changing the active slave consists of three steps:

- disabling the currently active slave LVDS transmitter,
- waiting for the LVDS pads to stabilize into Hi-Z state.
- enabling the LVDS transmitter of the next slave,
- waiting for the LVDS bus to stabilize into active state.

Afterwards the first HSSL command can be sent to the newly activated slave.

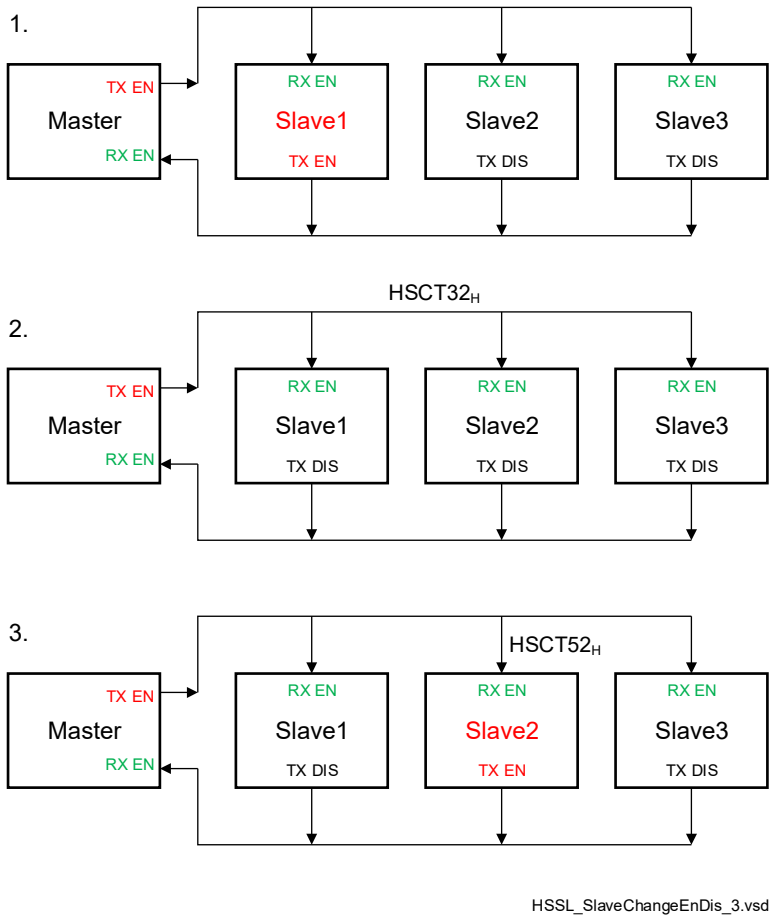


Figure 402 Changing the Active Slave

In the step 2, the output bus of the slaves is not driven by any slave, all LVDS Tx drivers are disabled. The differential voltage is equal to zero, and the offset voltage can take any value between the ground and power supply level.

The enable time and disable time of the LVDS pads shown in **Figure 403** are defined in the data sheet of the corresponding device as parameters t_{LVDSEN} and $t_{LVDSDIS}$.

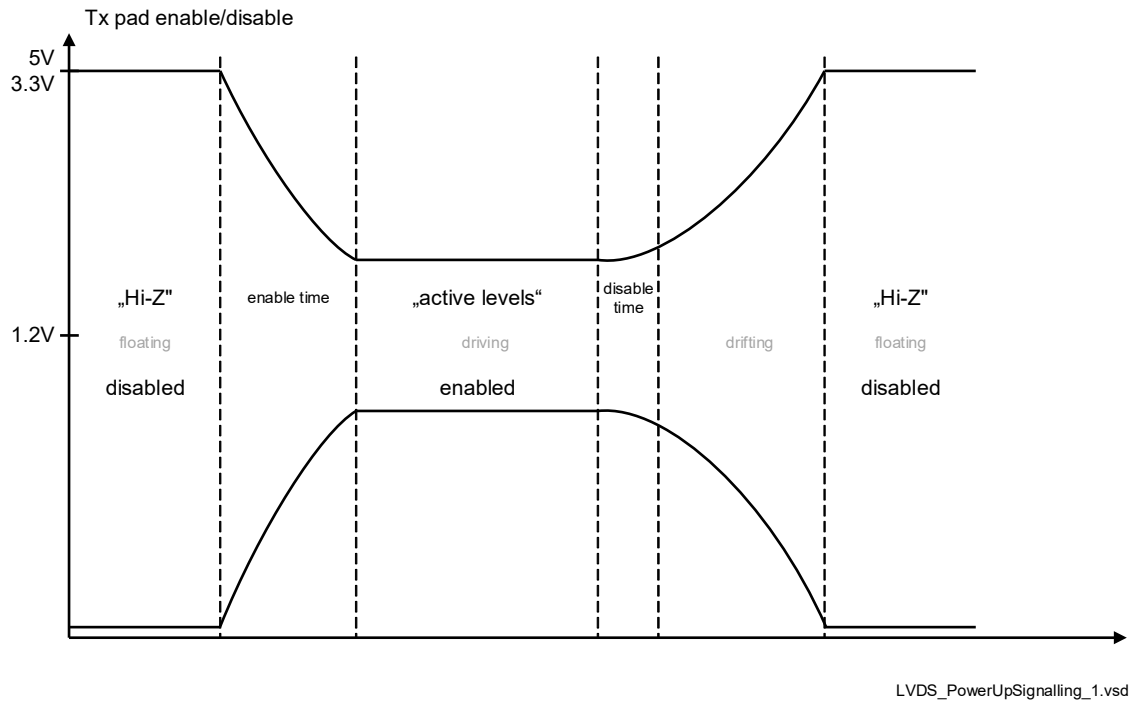

Figure 403 Voltage Levels on the Slave Driven Bus

35.7.3.2.3 Electrical Characteristics Based on LVDS for Reduced Link trace length

The characteristics are based on the LVDS standard IEEE P1596.3-1995 with some limitations, defined in the Datasheet. It is adapted for low power consumption and lower supply voltages for short ranges. It is defined that the interface supply voltages meet the common mode voltage for the differential signaling based on 1.2 V.

Operating Modes

The HSCT interface comprises the following operating modes:

- **Terminated Mode**: The data transmitter requires a 100 Ω external termination between the pins **TX_DAT** and **TX_DATX**. The termination is given by a 100 Ω resistor at the receiver input, of the opposite LVDS device, for matching the differential characteristic impedance of the line with the impedance of the receiver. PCB design has to follow guidelines on differential signal routing. The PCB placed termination resistor can be chosen very precise. Via configuration option an 100 Ω LVDS receiver internal resistor can be enabled with a +/- 20% tolerance and shall not be enabled for a multi Slave scenario (PCB placed and +/- 5% tolerance according to IFX PCB guidelines).
- **Power up**: The line receiver is always be enabled after power up and SysClk is active. The data decoder behind the receiver is not enabled at this point. It is enabled when the first transition on the data lines is detected by the line receiver (8 zero’s at configured Baud rate). The line driver must be enabled on the Master side via SW control. On the Slave side the line driver must be enabled by sending interface message control commands from the Master. After power up the link starts in low speed mode. After line driver enable some time is required to power up the LVDS transmitter line. The data link in RX and TX direction is ready to transmit and receive data after the defined setup time.
- **Sleep mode**: In terminated operation the differential voltage across the resistor will be reduced to nominally zero (-5mV to 20mV at 100 Ω +/- 20%) and hence, the line driver current requirement will reduce to internal bias currents. The common-mode voltage, however, should be maintained. The PLL is not switched off during sleep mode.

- **Power down**: When any interface driver supply voltage is removed, the driver shall provide a weak pull-down to 0 V to ensure that the signals are held in a well-defined state. It is a requirement to be free of cross- and bias current during power down. This can be configured in the LVDS port control.

Note: The line driver in the Master interface shall be turned on before the line driver in the Slave interface is activated, i.e. before sending the transmitter activation command to the Slave interface, in order to avoid receiving undefined data in the Slave interface.

Due to the strong dependency on link length and layout, as well as the susceptibility to noise and interference, it is recommended, to have the termination available on the PCB:

- Receiver internal termination mode not active (PCB termination): can be programmed inside LPCRx.TERM (LVDS Pad Control Register, see Ports chapter). The data transmitter is operated without a termination inside the differential receiver pair.
- Receiver internal termination mode active: allows to have a 100 Ω resistor internally with a +/-20% tolerance (prohibited use in multi Slave scenario).

Sleep Mode

Unless sleep mode is used the interface shall be held in the logic zero state, between frames, for a minimum of one bit period for the actual configured clock rate. This ensures to allow clock phase detection mechanism to initialize. The interface frame gap logic zero remains active until the next frame is send. The sleep mode is initiated by the interface line driver and the line receiver side, which reacts on a sleep request. This means the Master interface TX and the Slave interface TX can send out a sleep request independent of each other. The sleep request is sent out, based on missing data from higher layer TX datapath.

To enter sleep mode, the line driver shall assert a logic one for the bit period immediately following the last bit of the Frame, instead of the usual logic zero. Recognizing the sleep request at the end of the frame, the line driver shall enter a low power state in which the common mode voltage of the interface is maintained, but the differential voltage is reduced to between -5 mV and -20 mV (measured as TX_DAT relative to TX_DATX or RX_DAT relative to RX_DATX). Sleep mode shall be disabled by default (reset) on the line driver. Only after receiving a frame with sleep indication the sleep mode can be activated.

The primary objective in sleep mode is to reduce line driver current in the case where a terminating resistor is in use. By reducing the differential voltage across the resistor to nominally zero the line driver current requirement will reduce to internal bias currents only. The common-mode voltage should be maintained by the line driver, to avoid the risk of transients when full drive is restored.

The line driver and line receiver have implemented sleep mode in order to save power. In low-power state the common mode voltage of the interface is maintained.

The interface receive path may still be active and receive data during the time the transmit path is in sleep mode. During this situation it could reach an internal situation, which not allows to receive further data. With the Clear to send back pressure mechanism activated (Note: Only available in single slave mode) this situation must be reflected by sending out a frame with CTS bit cleared. As the transmitter is currently in sleep mode, it is required to wake up the transmit path, send out a CTS frame and enter sleep mode again. After the higher layer receive datapath can accept new data the HSCT control engine takes this information to send out a frame with CTS active, again. If the transmitter is still in sleep mode and new data can be accepted a wake-up mechanism is triggered and send out a CTS frame, again. After the frame is send out the interface enters sleep mode again, if still not requested to wake-up by higher layer data availability or a new HSCT frame sent.

During sleep mode there can also be the situation of sending a control command, ping answer or unsolicited status message. As this logical data type are initiated via the control interface, also in this situation leads to a wake-up of the interface and transmission of the frame. After the frame is send out the interface enters sleep mode again, if the higher layer HW still not requests to wake-up.

35.7.3.2.4 Data Rates

The Slave interface shall be ready to receive frames whenever the HSCT SysClk is running. The link shall initialize in low-speed mode with the high-speed clock generators turned off or high-speed clock from Peripheral PLL to HSCT disabled and the RxData link disabled. Subsequent speed and mode changes shall be commanded by the Master interface, except sleep mode on the RXData link, which is controlled by the Slave interface. Except when using sleep mode, both links shall default to the logic zero state, while dormant and between frames. This is required, to ensure that data will not be lost during a speed change.

Interface data rate change on both the TxData and the RxData link shall be possible without losing data. It is highly recommended to keep the link quiet during the time the interface transfer speed is changed. Changing transfer data rate on an active link does not guarantee stable data transfer.

The HSCT provides three different data speed modes

- Low speed mode
- Medium speed mode (only available on RX link)
- High speed mode

Additionally the HSCT module provides different data speed modes, derived from the crystal frequency. Taking the Automotive common crystal frequency of 20 MHz the following data rates can be produced based on the available multiplication factors. Future 40 MHz crystals are supported, too with a similar calculation procedure.

SysClk; RefClk = Crystal frequency = 20 MHz

- 5 MHz = Crystal frequency / 4 (Low Speed)
- 20 MHz = Crystal frequency (Medium Speed)
- 320 MHz = Crystal frequency * 16 (High Speed)

Low Speed mode and Medium Speed mode frequencies are generated directly out of the Crystal frequency. High Speed mode frequency requires a PLL, which takes the Crystal clock as reference clock. The following figure shows a Frequency Scheme based on 20 MHz crystal clock / HSCT SysClk as an example.

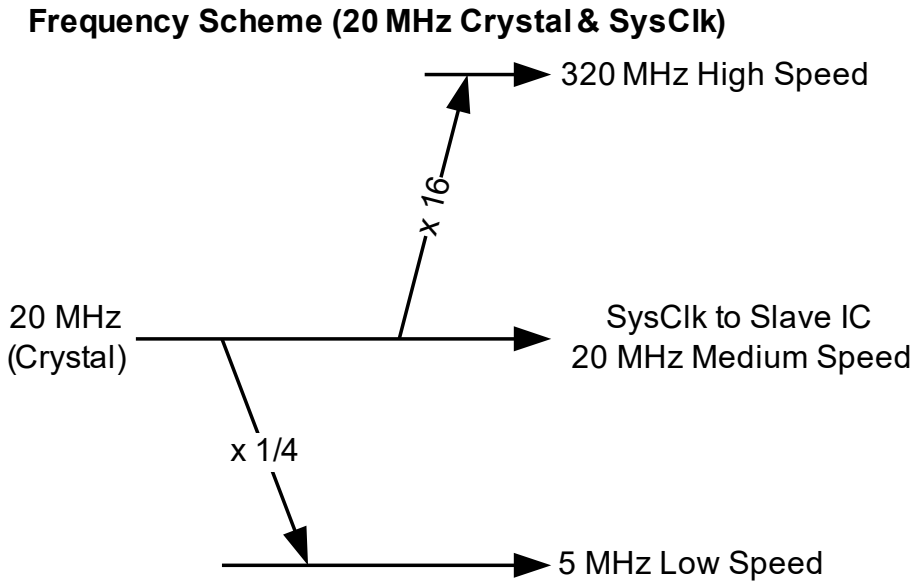

Figure 404 Frequency Scheme

Connecting a 20 MHz or 40 MHz Crystal to the system allows to generate the Automotive frequency scheme.

The following table (**Table 314**) shows the data transfer direction and the available Automotive transfer speed based on Crystal clock frequency.

Table 314 HSCT Data Rates

Direction	Data Rate	Operating Mode
Master interface to Slave interface	5 Mbit/s	“low speed mode” for startup / fallback
Master interface to Slave interface	320 Mbit/s	“high speed mode” (Single Slave only); Multi Slave divide
Slave interface to Master interface	5 Mbit/s	“low speed mode” for startup / fallback
Slave interface to Master interface	20 Mbit/s	“medium speed mode” *Note: only available, if reference clock; SysClk is at 20 MHz (Crystal)*
Slave interface to Master interface	320 Mbit/s	“high speed mode” (Single Slave only); Multi Slave divide

PLL configuration and Baud Rates

The PLL supports different speed modes and frequency modes, which will be described in this section. Each mode and transfer direction can be configured separately.

Starting from a reference clock selection in the CCU it is possible to configure a REFCLK divider (**INIT**.SRCF) for the internal clock switches and correlator circuit as well as configure the SYSCLK divider (**INIT**.SSCF), which generates the SysClk provided by the Master interface. The REFCLK DIV generated PHY_CLK is considered in Low Speed and Medium Speed mode. During configuration of the reference clock path the role of the interface (Master or Slave) needs to be considered.

The HSCT as Master Interface requires to enable the XTAL path. The preferred XTAL frequency for HSCT is 20 MHz. Based on the XTAL frequency a PHY_CLK of 20 MHz shall be configured using the REFCLK DIV. In addition the Master Interface provides the SysClk having f_{SYSCLK}, which is configured using SYSCLK DIV based on the Reference Clock frequency. Recommended SysClk out frequency is 20 MHz

The HSCT as Slave Interface requires to enable the SYSCLK PAD path. The preferred SysCLK frequency for HSCT is 20 MHz. Based on the SysClk frequency the PHY_CLK shall be configured using REFCLK DIV. Also in this case 20 MHz is recommended. A 10 MHz PHY_CLK leads to not availability of medium speed (20 MBaud).

The data path high speed transfer rate (Baud rate) can be configured independent per link direction using the **INIT**.TXHD and **INIT**.RXHD.

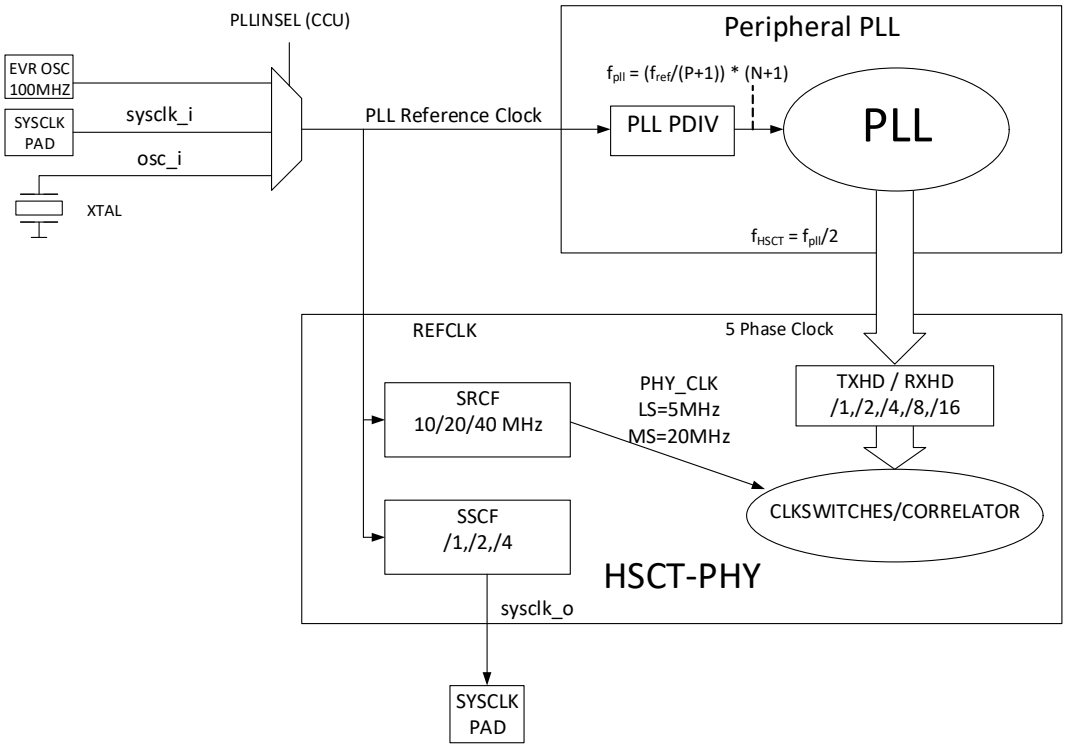

Figure 405 Frequency generation and clock divider

The following table gives more detailed information about the Baud rate configuration and the configuration bit's involved. The peripheral PLL reference frequency and their PLL frequency control word Multiplication factor (Peripheral PLL PDIV and NDIV) defines the PLL speed and are used to configure the output frequency of the PLL. The interface baud rate can be configured separately in TX direction (TXHD) and RX direction (RXHD). The table below (*** 'High Speed Mode selection' on page 96 ***) exemplarily shows the TX direction.

Table 315 High Speed Mode selection

PLL Speed fHSCT [MHz]	**320**	**320**	**320**
PLL reference frequency [MHz]	40	20	10
PLL PDIV (Peripheral PLL) [hex]	0x1	0x0	0x0
PLL NDIV (Peripheral PLL) [hex]	0x1F	0x1F	0x3F
TXHD 1/1 [MBaud] (max Baud single Slave)	320	320	320
TXHD 1/2 [MBaud] (max Baud two Slave)	160	160	160
TXHD 1/4 [MBaud] (max Baud three Slave)	80	80	80
TXHD 1/8 [MBaud]	40	40	40
TXHD 1/16 [MBaud]	20	20	20

35.7.3.2.5 Correlator

Data transfer from the Master interface to the Slave interface can either be in “high speed mode” or “low speed mode” (**for example Crystal**/4 at 20 MHz HSCT SysClk or SysClk/2 at 10 MHz SysClk). A correlator is used to select the optimum sample phase for the frame based data transfer.

Phase Selection

Every frame starts with a 16-bit sync field (see **Figure 406**) containing a synchronization pattern. Note that the sync pattern starts with 1, so a new frame always starts on the rising edge. In between frames, there is always at least one bit 0 in normal mode. By sending 1 immediately after the last bit in a frame, the Master interface controller demands sleep mode as described in Section Sleep Mode. Neither the Master interface nor the Slave interface may assume that the other side will maintain data phasing between frames. The receiving interface shall use the sync pattern to determine the start time of the frame relative to the local clock.

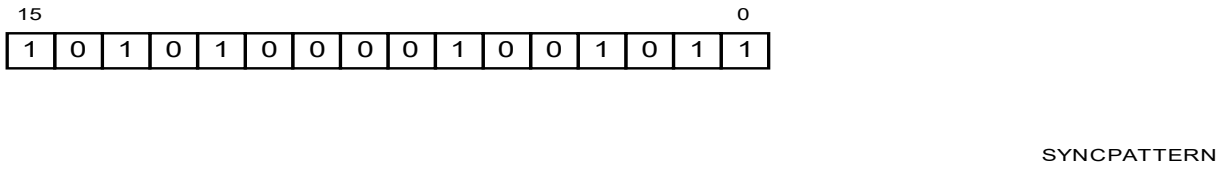

Figure 406 Synchronization Pattern

The synchronization pattern is only needed for selecting the optimum sample phase, so it is not feed through to the output register of the correlator.

Payload Size Decoding

Every frame consists of three parts: a 16-bit synchronization pattern, an 8-bit header and the payload field which can be 8, 32, 64, 96, 128, 256 or 288 bits. The header contains information about payload size and logical channel type. Although decoding the header is task of the deframer, the payload size shall also be evaluated inside the correlator for finding the end of a frame.

The header is sent most significant bit first. The first 3 bits (bit5, bit6 and bit7) contain the payload size of this frame (see **Table 316**).

Table 316 Payload Size Coding

b7:b5	Payload Size (bits)	Total Frame Size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	512	536 (not supported)
111	288	312

Note: In a harsh Automotive environment a payload of 512 bit may cause increased error bit streams, due to the long distance from one synchronization pattern to the next. This is the reason why this data transfer length is not supported.

The correlator shall decode the payload size field and count the number of received bytes. After the last byte in a frame has been fed through to the correlator output register, the tuning of the multiplexer unit becomes invalid. In between frames at least one bit 0 shall be transmitted. The comparison procedure is started again as soon as there is a 1 at the MSB position in the shift registers.

The 8-bit header and the payload are used as input for the deframer block.

Note: The sync pattern and inter-frame bits are not passed to the deframer. An error in the sync pattern generates an error and is detected by the Physical layer.

Transmission initiated Sleep Mode - bringing receiver path into sleep mode

By sending a 1 immediately after the last bit in a frame, the interface indicates that its LVDS line driver is sent to sleep mode, and suggests sleep mode to the receiver LVDS.

To leave sleep mode, the Master interface shall send 8 bits of 0. This is performed in high speed mode and in low speed mode and allows the receiver to wake-up.

35.7.3.2.6 Jitter Budget

The system clock is distributed directly from the Master interface to the Slave interface (see **Figure 407**).

Subsequently, all jitter investigations considered in the following sections are referenced to the system clock f_{SYSCLK}.

Each system clock distribution has an associated filter function that comprehends the worst case combination of PLL bandwidth/peaking and equivalent jitter. The effective jitter seen at the LVDS receivers clock-data recovery inputs is a function of the difference in LVDS receiver and LVDS transmitter PLL bandwidth and peaking convolved with the jitter spectrum of the system clock.

System Clock variations contain jitter over a wide range of frequencies, some of which will be tracked by the LVDS receiver or otherwise removed by the combination of the LVDS transmitter and the LVDS receiver PLLs. Consequently, the nature of the filter functions is in part dependent on the way of how the system clock is distributed. In general, the system clock jitter is filtered by the PLL difference function which comprehends the “mismatch” between LVDS transmitter and LVDS receiver PLL and also accounts for the impact of the transport delay.

Direct System Clock Distribution

This architecture implies direct distribution of the crystal clock as system clock from the Master interface to the Slave interface. Hence, the system clock is directly supplied to both LVDS transmitter PLL and LVDS receiver PLL. Hence, a major part of the clock jitter is sourced equally through LVDS transmitter and LVDS receiver PLLs. **Figure 407** illustrates the direct system clock distribution, depicting noise sources, delay, and PLL transform sources. The amount of jitter appearing at the data recovery block is then defined by the transfer function difference of the LVDS transmitter and LVDS receiver PLLs, and by the sum of the clock jitter of the LVDS transmitter PLL, $X_{clkMaster(s)}$, and the LVDS receiver PLL, $X_{clkSlave(s)}$.

Based on the above clock architecture, a difference function may be defined that describes the “mismatch” between LVDS transmitter and LVDS receiver PLLs. As a first approximation second order transfer functions are assumed.

The jitter of the direct system clock distribution is described by the phase noise power spectral density function as the absolute square of $X_{d(s)}$, as follows.

$$|X_d(s)|^2 = |X(s)|^2|H_1(s)e^{-sT} - H_2(s)|^2 + |X_{clkMaster}(s)|^2 + |X_{clkSlave}(s)|^2 \quad (35.3)$$

where

$$H_1(s) = \frac{2s\ \zeta_1\omega_{n1} + \omega^2_{n1}}{s^2 + 2s\ \zeta_1\ \omega_{n1} + \omega^2_{n1}} \quad (35.4)$$

and

$$H_2(s) = \frac{2s\ \zeta_2\omega_{n2} + \omega^2_{n2}}{s^2 + 2s\ \zeta_2\ \omega_{n2} + \omega^2_{n2}} \quad (35.5)$$

H2

Conversion between the natural PLL frequency ω_n and the -3 dB point is given by the following expression.

$$\omega_{3dB} = \omega_n \sqrt{1 + 2\zeta^2 + \sqrt{(1 + 2\zeta^2)^2 + 1}} \quad (35.6)$$

Under the assumption that crystal clock jitter can be ignored, i.e.,

$$X(s) \approx 0 \quad (35.7)$$

and LVDS transmitter to LVDS receiver transport delay can be neglected, i.e.,

$$e^{-sT} \approx 1 \quad (35.8)$$

the phase noise power spectral density of the direct system clock distribution can be simplified, as follows.

$$|X_d(s)|^2 = |X_{clkMaster}(s)|^2 + |X_{clkSlave}(s)|^2 \quad (35.9)$$

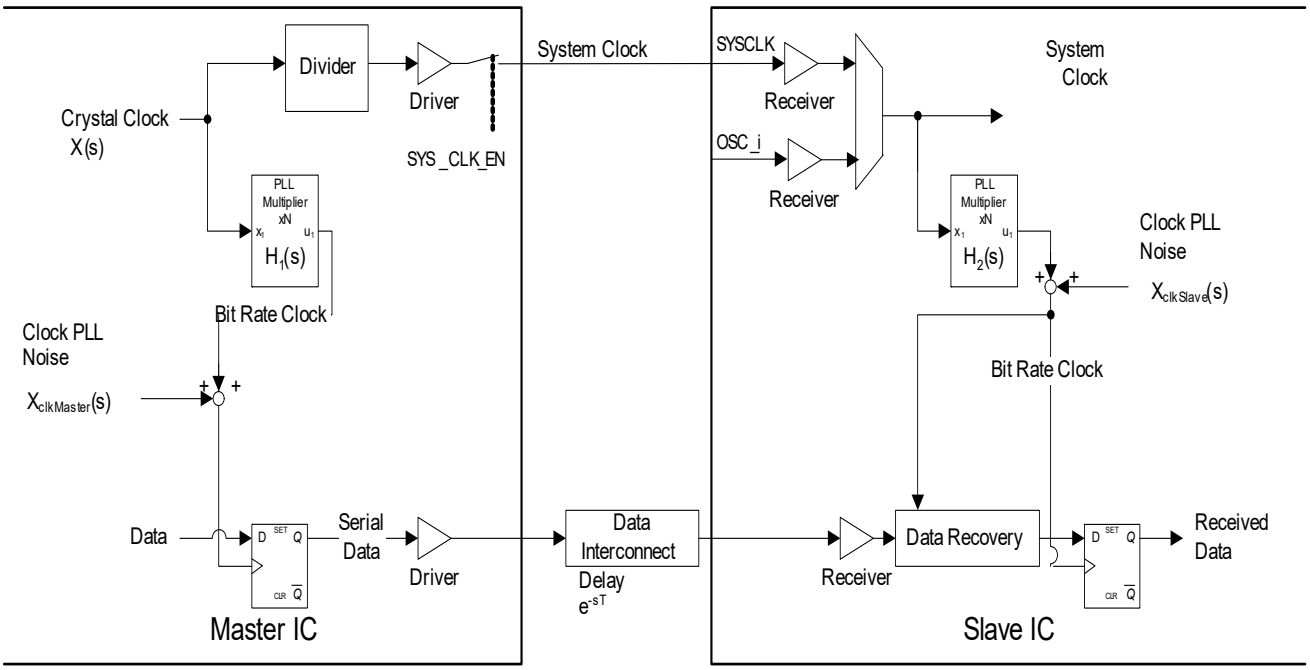

Figure 407 Direct System Clock Distribution

In the direct system clock distribution the overall jitter is given by the sum of both phase noise spectral densities from the LVDS transmitter PLL, $X_{clkMaster(s)}$, and the LVDS receiver PLL, $X_{clkSlave(s)}$.

Note: The Slave interface requires a HSCT SysClk from the Master always as reference clock. It is not supported by the interface to have a separate crystal as reference clock at the Slave interface. The Master interface generated HSCT SysClk needs to be enabled.

Jitter Budgeting - Direct System Clock Distribution

To estimate the total rms jitter of LVDS transmitter PLL and LVDS receiver PLL for data recovery the following procedure has to be followed.

- Piece wise linear integration of the additive SSB (Single Sideband) phase noise for direct clock distribution to obtain the total phase noise power of the LVDS transmitter PLL.
- Calculation of the rms jitter of the LVDS transmitter PLL as shown in **Figure 408**.
- Calculation of the total rms jitter *RJ* as the square root of the sum of the squares of the rms jitter from the LVDS transmitter PLL and the LVDS receiver PLL.
- Calculation of total jitter, i.e., random and deterministic, considering duty-cycle distortion and other effects to guarantee minimum eye opening at the interface.

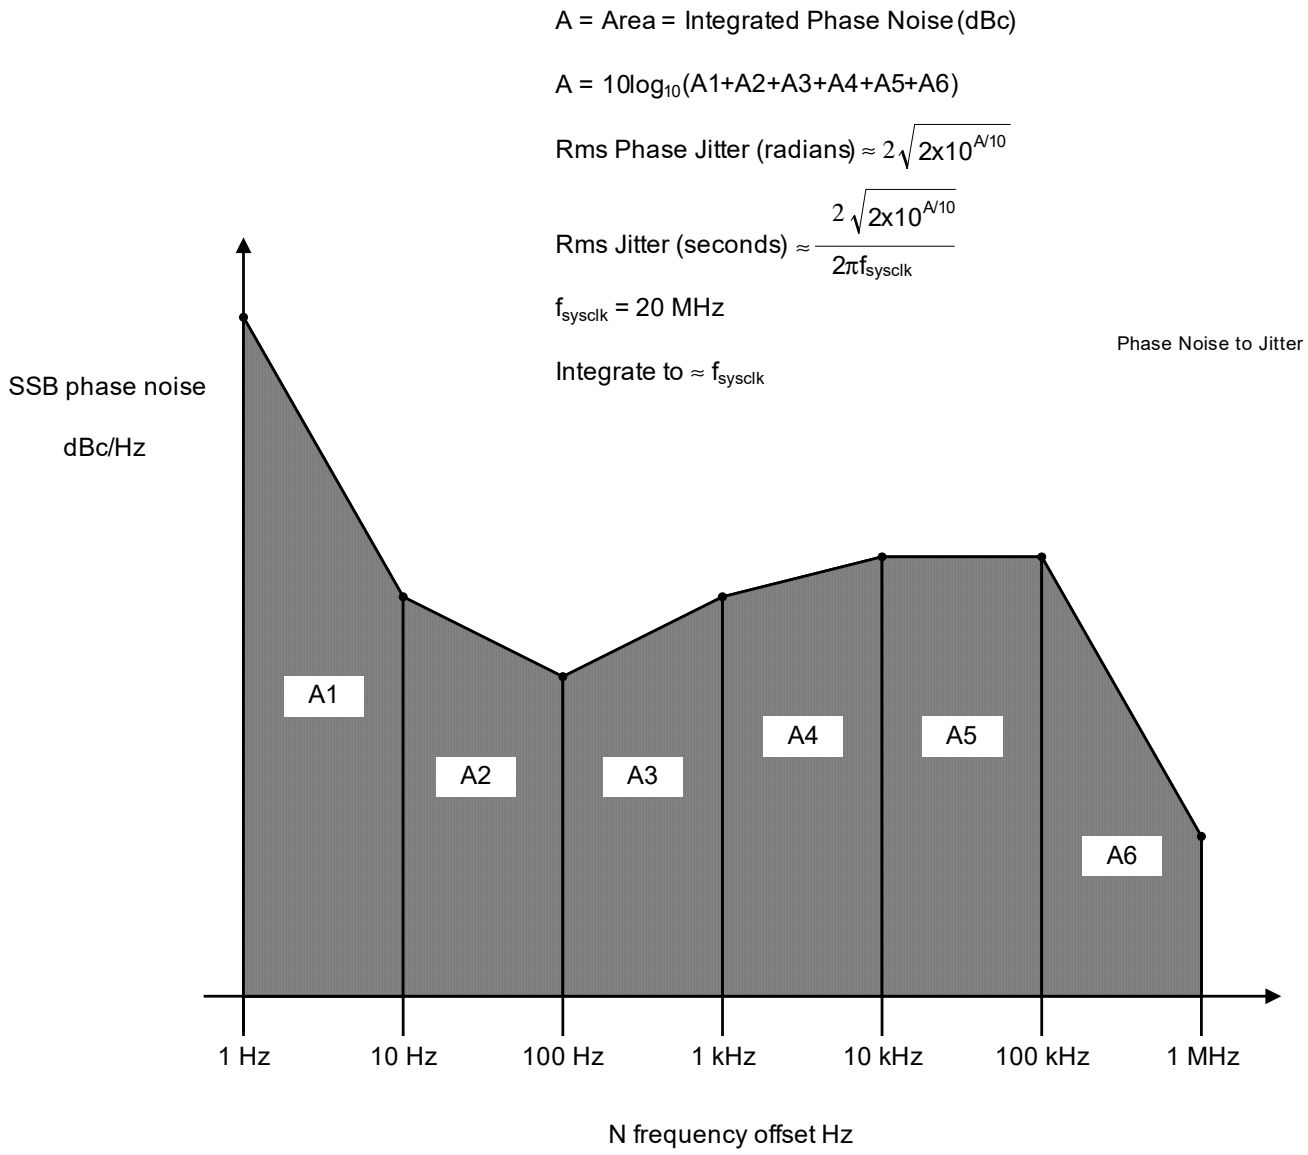

Figure 408 Calculation of Jitter from SSB Phase Noise

Calculation of Total Jitter Budget - Direct System Clock Distribution

To estimate the total jitter budget allowed for the random rms jitter *RJ* as described in the sections before, the following procedure for direct clock distribution has to be followed.

- Calculation of the jitter headroom available for the ideal jitter-free case given by the minimum eye opening, i.e., 55% of a 320 MHz period.
- Calculation of the total jitter headroom required under the assumption that the total long-term jitter *TJ* will not exceed the maximum peak-to-peak jitter specified.
- Subtraction of two phases of the oversampling frequency used for data recovery taking into account the data-recovery uncertainty in multiples of phases of the oversampling frequency. The data-recovery uncertainty is implementation specific and determined by the data-recovery oversampling factor DR_{OS}. **Figure 409** depicts the case where the selected sampling phase of the data recovery is almost one sample phase away from the

ideal sampling point. Thus, the budget left for the peak jitter is reduced by almost one sample phase and hence, the peak-to-peak jitter is reduced by almost two phases.

- The remaining sum represents the jitter budget which is the upper limit for the peak-to-peak jitter calculated from the random rms jitter distribution *RJ* described in the sections before. Given a required bit error rate BER = 10^{-12} for SysClk 20 MHz and BER = 10-9 for SysClk 10 MHz.

The jitter budget is given by the following equation.

$$TJ_{pp} = DJ_{PP} + RJ_{PP} = (DJ_{TX} + DJ_{RX}) + 2 * Q * \sqrt{J_{ABS}^2 + J_{ACC}^2}_{T} \quad (35.10)$$

Sampling Phase Selection

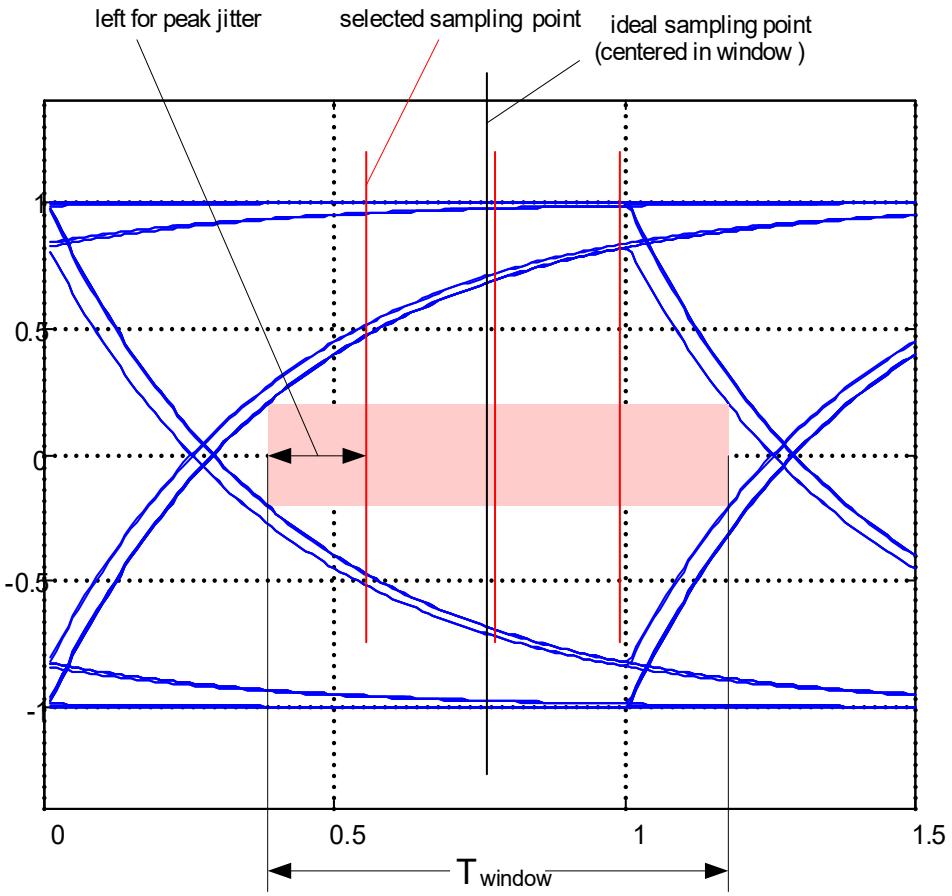

Figure 409 Sampling Point Selection

35.7.3.3 Protocol Layer

The protocol layer is between the higher layer protocol (HSSL) and the physical layer. The protocol Layer is performing the frame generation in transmit direction and extracts the payload out of a frame in receive direction, called deframing.

35.7.3.3.1 Deframer

The deframer's tasks are decoding the 8-bit header and separating the data stream according to the logical channel type.

During Microcontroller reset, the deframer shall ignore all data coming in from the correlator. This is a precaution measure to eliminate possible malfunctions due to floating HSCT lines.

Additionally the deframer checks the header for potential errors, e.g. size is matching received data or size is allowed and received type is allowed. An error in the header discards the received data.

Header Decoding

The first 8-bit in a frame, after the sync pattern has been filtered out by the correlator, is the header or frame type field. It contains information about the payload size and logical channel type coding (see **Figure 317**). Please note again that all transfers are most significant bit first.

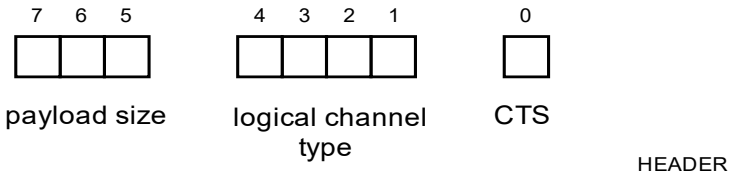

Figure 410 Header (Frame Type Field)

- The payload size coding can be seen in **Table 316** in the previous.
- Bits 1 to 4 define the logical channel type. See **Table 317** for details on the logical channel type coding. Note that some kinds of transfer are exclusively used from the Master interface to the Slave interface or from the Slave interface to the Master interface.
- Bit 0 is used as Clear To Send bit CTS for transfers from the Slave interface to the Master interface (Requires an enable via configuration). For transfers from the Master interface to the Slave interface also the Master interface can send CTS, which must also be enabled via configuration before. Also CTS from Master interface indicates the Master to the Slave, no more data can be accepted. This feature requires for the Master interface as well as for the Slave interface that higher layer indicates in HW early enough that no more data can be accepted with the next frame. This needs to be send out with the frame based CTS signaling. (Consider the transferred payload size for early enough CTS signaling via a frame.)

Table 317 Logical Channel Type Coding

b4:b1	Logical Channel Type Master interface to Slave interface (TX Link)	Logical Channel Type Slave interface to Master interface (RX Link)
0000	Interface Control; restrictions in multi Salve Mode	Interface Control (PING answer, 32-bit value; not supported in multi Slave mode)
0001	Master interface Unsolicited Status (32-bit only; not supported in multi Slave mode)	Slave interface Unsolicited Status (32-bit only; not supported in multi Slave mode)
0010	Reserved - receiver error interrupt	Reserved - receiver error interrupt
0011	CTS Transfers; not supported in multi Slave mode	CTS Transfer; not supported in multi Slave mode
0100	Data Channel A	Data Channel A
0101	Data Channel B	Data Channel B
0110	Data Channel C	Data Channel C

Table 317 Logical Channel Type Coding (cont'd)

b4:b1	Logical Channel Type Master interface to Slave interface (TX Link)	Logical Channel Type Slave interface to Master interface (RX Link)
0111	Data Channel D	Data Channel D
1000	Data Channel E (not supported, receiver generates an error interrupt)	Data Channel E (receiver error interrupt)
1001	Data Channel F (not supported, receiver error interrupt)	Data Channel F (receiver error interrupt)
1010	Data Channel G (not supported, receiver error interrupt)	Data Channel G (receiver error interrupt)
1011	Data Channel H (not supported, receiver generates an error interrupt)	Data Channel H (receiver error interrupt)
1100	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1101	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1110	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1111	Reserved - receiver error interrupt	Reserved - receiver error interrupt

Note: A logical channel type TX transfer request of not supported or reserved types is not stopped or prevented to be send out. Receiver side is expected to react with an error indication.

*Note: The received header information can be checked by SW reading Header status register (**STAT**). An error in the header is a severe error in a running system. Application SW must handle the situation by interface link checks (PING; PING not supported in multi Slave scenario). Additionally it is suggested to restart a running stream, if data loss cannot be tolerated. Received header frames are discarded, the same as the CTS information inside this error frame.*

Payload Size for transmission Data

For a transmission data transfer it is recommended to use max 288-bit payload size. TC3xxHSCTTC3xx

Logical Channel Separation

Reflecting the logical channel type to the higher level interface, the deframer sends the frame payload. The payload, as all other parts in a frame, is sent most significant bit first. The HSCT in the multi Slave scenario is used as a data protocol tunnel engine. Any addressing of the connected Slaves is done at a higher layer in HW.

- All data received on and decoded as channel A to D data are sent via an 32-bit data interface to the higher layer HW level.
- Data TC3xx can be sent using the 32-bit, 64-bit, 96-bit or 288-bit payload size.

Note: Receiving a 8-bit header size on a logical channel results in an header error.

35.7.3.3.2 Framer

The framer combines data and control information from the higher layer protocol to the frame payload. Note that the payload again is sent most significant bit first. The framer codes the logical channel type and the payload size in the header according to the HSCT header format (see **Figure 410**). Then a complete frame consisting of 16-bit synchronization pattern (see **Figure 406**), 8-bit header and payload field is put together.

The following logical channels are used for transmissions between Master interface and Slave interface:

- Data from the transmit Unit: The frame will be sent to the receiving interface side as soon as the higher HW layer transmit path contains enough data for the required payload size. The appropriate values will be signaled with the payload size signal and in the logical channel type field in the header. For data transfer, only

the logical channel types Data Channel A to D are be used! Receiving a header type reflecting the type Data Channel E to H generates an error.

- Unsolicited status information can be send by Master interface and Slave interface based on a 32-bit payload size. An unsolicited status can be used to send an unexpected and urgent message to the other side. Receiving an unsolicited message results in an interrupt at the receiving side. The Unsolicited status information can only be send in single Slave scenario. In multi Slave Scenario this feature is not available.

Note: The Slave interface in single Slave scenario (RX link) can send out a control command (channel type encoding Hex 0), which is the predefined PING answer having a defined 32-bit payload. All other control commands are not available for the RX link to send. Receiving a header types not supported on RX link or TX link generates an error.

The handling of all frame parts is done by the framer. For determining the end of a frame, the framer shall count the number of payload bits sent to the receiver side. In between frames bits 0 shall be transmitted.

Clear to Send (CTS) - only available in single Slave scenario

The HSCT interface is able to use “data pull” in both directions (Master interface to Slave interface and Slave interface to Master interface) to perform flow control on the transmission data path. Therefore the CTS bit in the header is asserted, when the other side is allowed to send more data, and it is negated when the other side should stop transferring data.

A CTS deactivation can be send out in a “normal” transmit frame, indicated by the header bit. The following payload is not discarded at receiving interface side and processed normally. CTS deactivation can be send out in a CTS type transmit frame, if no actual transmit data is available. The clear to send information is indicated by the header CTS bit deactivation. Following payload is discarded at receiving side. A received clear to send deactivation requires to stop the transmission immediately after the actual frame being in transmission or prevent to send a new frame, if currently no transmission is active. Control frames can still be send.

The clear to send is independent of the channel having caused the back pressure. It simply stops the data channel transfer. As soon as the traffic jam is resolved the CTS bit in the next transmitted frame is activated again, or a separate CTS frame is send with the CTS bit activated.

Higher Layer software must analyze which channel caused the traffic jam and can send the information to the other side.

The usage of the CTS signaling is optional. CTS signaling can be disabled by disabling the CTS_FRAME **CTSCTRL**.

Per default the CTS bit in the header is set to 1. When the situation in the receive data path is reached, where no more data can be accepted , the CTS bit shall be reset to 0 in the header of the next frame sent. If there are currently no data in the higher layer module transmission data path to be sent in a new frame, a dedicated CTS transfer according to the logical channel type in **Table 317** is generated. This transfer always uses the 8-bit payload size containing dummy bits. The payload in a CTS transfer will be discarded by the receiving side. Generation of dedicated CTS frames can be disabled by resetting bit CTS_FRAME in register **CTSCTRL** to 0.

The CTS bit is set to 1 again when the receive data path at the higher layer HW protocol allows to accept new data. This is reflected by activating the CTS signal again.

The CTS signals are full duplex signals and are side information in the transferred data frame. The deframer filters the TXCTS information from the received frame header. The TXCTS is presented to the higher layer TX interface frame based. Changes within a frame is not intended. At the higher layer receiver side the higher layer does activate the RXCTS signal, if no more data can be received. The Framer sends the RXCTS information with the header of the next frame.

Sleep Mode for line driver path

TC3xx offers an optional transmission sleep mode in between frames. Whether the transition to the transmission sleep mode can be performed, depends on the actual symbol data rate, as well as the protocol payload size, because it takes the LVDS line driver some time to wake up from sleep mode, as defined in data sheet. In sleep mode, TC3xx suggests sleep mode to the other side by sending an 1 immediately after the last bit in a frame. Setting the SLPEN bit field to 1 enables Transmission sleep mode.

Transmission sleep mode shall be triggered after every frame in case there is no more data to be send from HSCT or higher layer HW. When Transmission sleep mode shall be triggered to the opposite receiving side, the physical layer inserts a 1 after the last bit in a frame, and activates the sleep to the transmission LVDS driver.

The sleep signal is reset as soon as a data frame transmission from higher layer HW requests a wake-up due to availability of data , or when any HSCT frame information shall be sent, . These events trigger the wake-up counter. The LVDS line driver becomes ready for operation within the time as defined in the data sheet. This wake-up time is converted to a counter value, derived from Register SLEEPCTRL.WKUPCNT and clocked by SRI clock frequency. After the wake-up time the physical layer starts sending eight bits 0 for signalling the start of a new frame to the receiving side. Subsequently the framer generates the new frame to be sent to the receiving side.

Note: If the sleep mode is used, the application software has to configure the counter SLEEPCTRL.WKUPCNT to a value corresponding to the LVDS pad wake-up time defined in the data sheet.

35.7.3.3.3 Interface Control

The Master interface is configured via a CPU based configuration. The Slave interface can be configured by sending an interface control command from the Master interface. The interface control command is used to configure the Slave interface into the defined mode. The receiving Slave interface shall take no action, if a reserved payload value is received. Instead it generates an error interrupt. HW reacts on the received control command.

After startup the interface is enabled to work at low speed (based on 20 MHz HSCT SysClk) and the PLL can/might be off (if not used by other peripherals), no matter of the mode it had been before. Therefore shutting down TC3xx causes the interfaceTC3xx to leave loopback-mode, clock test mode and sleep mode, if it was previously in any of these modes, and forces the receiver and transmitter to power down mode.

The interface transmitter path is disabled per default. It shall be enabled by using the appropriate interface control, which is a payload command for the Slave interface and a control via SW for the Master interface.

Note: No data can be transferred to the other side as long as the transmitter is disabled. In this case all data in TX direction are discarded!

The Interface Control Logical Channel transfer command always uses the 8-bit payload size and is send by the Master interface only. Payload is send MSb first. The interface control payload values are shown in **Table 318**. All other payload values are reserved for future use. Whenever a reserved payload value is received it shall be ignored and reported by an error. In addition the table is enhanced with a column describing the availability of the command in multi Slave scenario.

Table 318 Interface Control Payload Values

Value (hex)	Function	Multi Slave availability[1)]
00_H	"ping" (send by Master interface. Slave interface sends back a fixed 32-bit payload result.)	No
01_H	Reserved	No
02_H	Slave interface clock multiplier start (in preparation for high speed mode)[2)]	Yes
04_H	Slave interface clock multiplier stop[3)]	No
08_H	Select low speed mode for transfers from the Master interface to the Slave interface	Yes
10_H	Select high speed mode for transfers from the Master interface to the Slave interface	Yes
20_H	Select low speed mode for transfers from the Slave interface to the Master interface	Yes
40_H	Select medium speed mode for transfers from the Slave interface to the Master interface. *Note: Not allowed, if SysClk = Crystal/2 (10 MHz) at Slave interface.*	Yes
80_H	Select high speed mode for transfers from the Slave interface to the Master interface	Yes
31_H	Enable Slave interface transmitter[4)]	No
32_H	Disable Slave interface LVDS transmitter[4)]	Yes
34_H	Turn on clock test mode (Send 101010… on Rx line continuously using currently configured Rx line rate; cancelled by issuing the "test mode off" command. Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the "test mode off" function, which turns off the clock test mode, and re-initializes for normal operation, retaining whichever interface speed mode is currently configured.	No
38_H	Turn off test mode (cancel clock test mode and payload loopback)	No
51_H	Enable Slave interface LVDS transmitter of Slave 1 (only available in Multi Slave Mode)	Yes
52_H	Enable Slave interface LVDS transmitter of Slave 2 (only available in Multi Slave Mode)	Yes
53_H	Enable Slave interface LVDS transmitter of Slave 3 (only available in Multi Slave Mode)	Yes
FF_H	Turn on payload loopback (incoming frames at Slave interface are looped back until cancelled by a Frame containing "test mode off"). Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the "test mode off" function, which turns off the loop back mode, and re-initializes for normal operation, retaining whichever interface speed mode is currently configured. *Note: Requires same speed configuration for RX- and TX-link.*	No

1) In Multi Slave mode, it is not allowed for the user to use the commands marked as unavailable in Multi Slave mode.
2) The Slave PLL (Peripheral PLL) on a TC3x Product is also clock source for other modules on the SoC can only be switched on from Master side, using Higher layer Protocol commands or with initialization SW running on the Slave side. The command shows no effect on a TC3x product at Slave Interface side. For ASIC's and backward compatibility it is still supported.
3) The Slave PLL (Peripheral PLL) on a TC3x Product is also clock source for other modules on the SoC can only be switched off from Master side, using Higher layer Protocol commands or with initialization SW running on the Slave side. The command shows no effect on a TC3x product at Slave Interface side. For ASIC's and backward compatibility it is still supported.
4) For more details check **Figure** RX link State Machine

Note: Before changing the speed mode SW has to take care that data Transmission on both links is stopped and the interface remains quiet.

As a general principle, after a mode change the Master interface should request a data transfer from the Slave interface to stimulate a frame, which confirms the correct reception and the mode change was successful. The PING function, available in the interface control logical channel in single Slave scenario only shall be used to verify a successful speed change. The Master interface generated PING has to be send in system defined time intervals, to verify the link is still alive. Sending out a ping requires system SW to activate a system timer. Not receiving the PING answer in single Slave scenario within the system defined time, the link cannot be considered as stable and a new initialization is required. The Slave interface sends back in single Slave scenario only a fixed, known response based on a control command, at the currently configured link rate on RxData line.

Data Baud Rate configuration from Slow to Fast:

The slow to fast interface speed change can apply to only one of the interfaces data transfer directions or to both at the same time. At both sides Clock multipliers are needed, when either interface is to run at high speed. If the RXData link is not enabled, but needs to be, the Master interface sends “Enable Slave Interface transmitter”. If the Slave interface clock multiplier is not already running the Master interface sends “Slave interface clock multiplier start” to the Slave interface at low speed (on TC37x products via higher layer protocol commands the Peripheral PLL register needs to be directly configured and activate the PLL). The Master interface enables its own clock multiplier, if it is not already running. After the proper settling time, the Master interface sends “select high speed” to the Slave interface at the currently configured speed for the TXData link. The Slave interface switches the requested interface to high speed. The Master interface switches the requested interface to high speed. The Master interface sends a frame to the Slave interface requiring a response at the currently configured speed for the TxData Link. The Slave interface responds with a frame to confirm the mode change has worked. In order to select high speed for both RXData and TXData links the Master interface sends “select high speed” for the RxData link first and then for the TxData link. As described before it is suggested to send the PING for verifying a successful speed change. The PING command can only be send in single Slave scenario. For multi Slave scenario the validity of the speed transition shall be performed using higher layer protocol.

Fast to Slow:

The fast to slow interface speed change is the converse of the slow-to-fast transition. Both clock multipliers must be running for either interface to operate in high-speed mode.

Before configuring, enabling and entering high speed mode it shall be assured that the high speed clock is available. This can be achieved by reading back Peripheral PLL lock information from PLL status register via higher layer protocol register access mechanism. If a command for entering high speed mode is received and the PLL is not locked, the command is ignored and lost. Interface control command value 0x02 (PLL start) or 0x04 (PLL stop), are not supported by a TC3x products as the high speed reference clock comes from a common PLL also used by many other peripherals. Switching on/off via commands might lead to safety issues. PLL switch on/off must be performed by register configuration via higher layer protocol or via SW routines established in the application SW. Nevertheless the command is produced and send out if required for backward compatibility.

Figure 411 shows the TX transmission state machine, which controls transfers from the Master interface to Slave interfaceTC3xx. The interface control value int_ctrl represents the received interface control payload value according to **Table 318**.

Note: Application Software has to ensure, that no data communication is active on RX-link or TX-link during the time the interface speed is changed. Otherwise a save speed change without data loss can not be guaranteed interface.

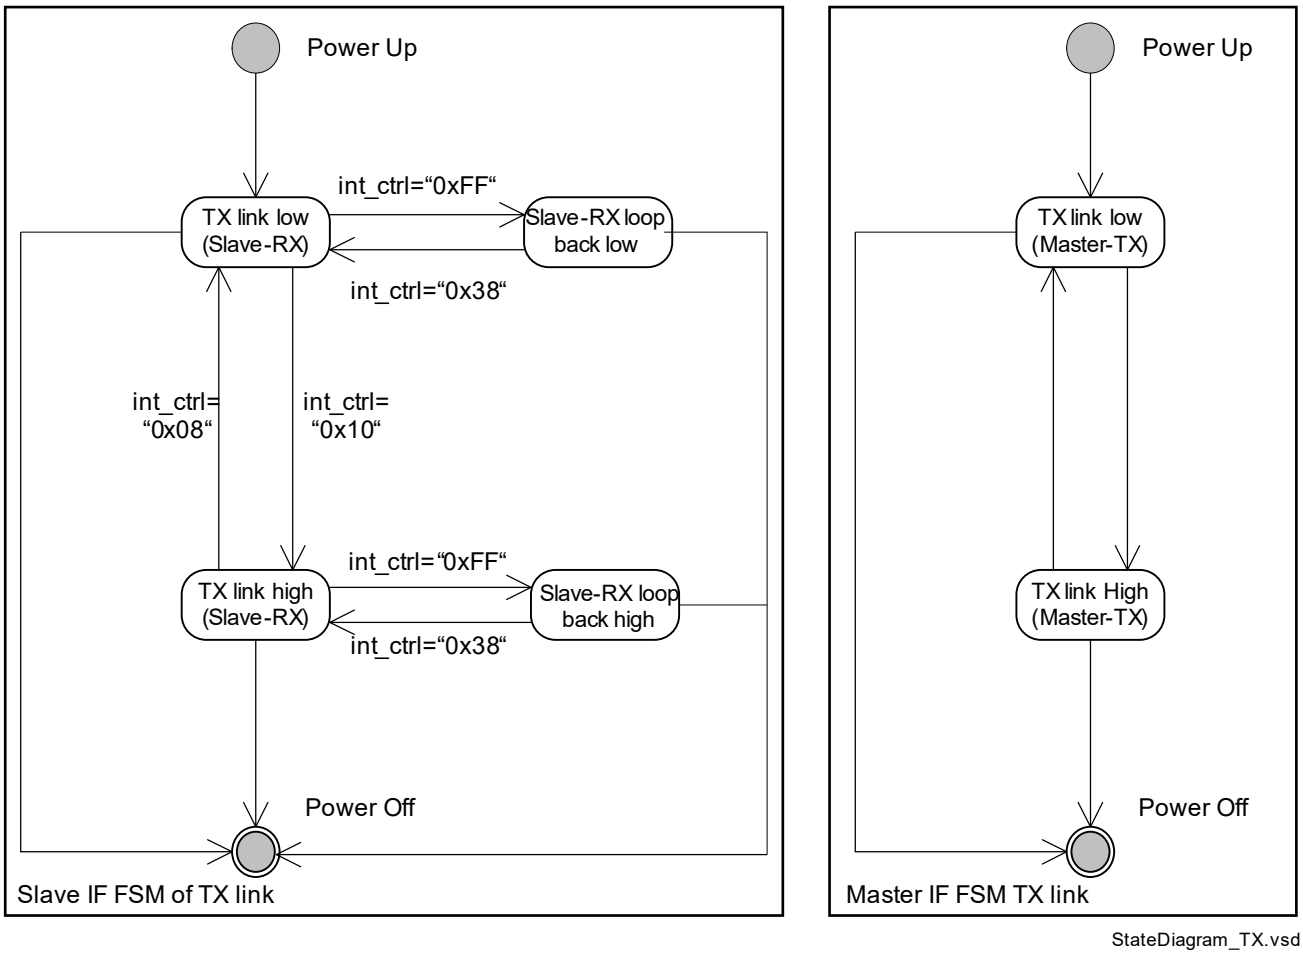

Figure 411 TX link State MachineTC3xx

The loopback mode (only in single Slave scenario) is used for test and verification to identify BER. When the Master interface demands loopback mode, the Slave interface internally loops back all received payload values in the following frames using the currently configured clock speed on the receive data link, without applying further processing internally. (Transmit and receive chains internally shall be disabled.) The header configuration is the same as in the incoming frame and the CTS bit in the header shall be asserted. Payload contents are ignored at Slave interface in loopback mode, except for the "turn off test mode" interface control value, which ends loopback mode. The "turn off test mode" frame shall not be looped back to the Master interface. After leaving loopback mode, the interface is prepared for normal operation at the previously used clock speed.

Note: The "loopback on" function has been intentionally coded at a large Hamming distance from the other codes (minimum of 5, usually 7, thus requiring at least five bit-errors in the Header field for another function to be corrupted into "loopback on".

The RX link state machine, which is responsible for controlling transfers from TC3xx to the Master interface, can be seen in **Figure 412**. The state machine is implemented on Slave interface at transmitting path. The interface control value int_ctrl represents the received interface control payload value according to **Table 318**.

HSCT

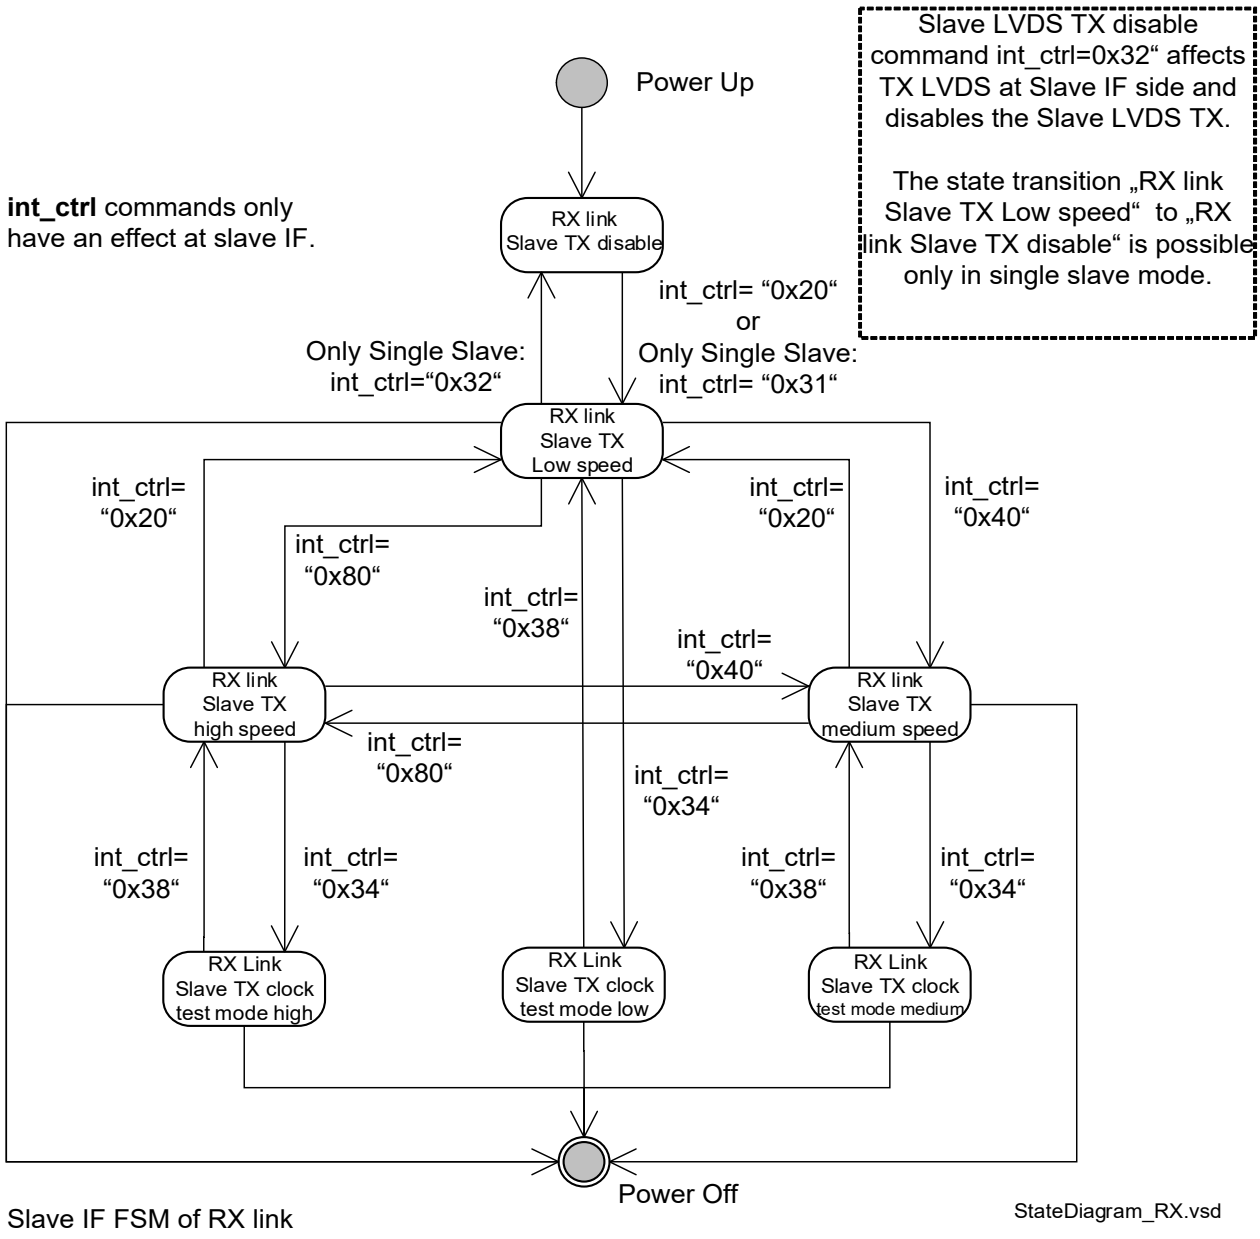

Figure 412 RX link State Machine

The Slave Interface TX, which is the RX link of the HSCT interfacing can be activated from disabled into Low speed mode using command “Select low speed mode for transfers from the Slave interface to the Master interface” (0x20) or in Single Slave mode also the command “Enable Slave interface LVDS transmitter” allows to change into “RX link Slave TX Low speed” mode. Receiving the command “Disable Slave interface LVDS transmitter” in any of the other states a disable of the LVDS TX at slave side is achieved, but no state transition. This means for example being in high speed mode and receiving the “Disable Slave interface LVDS transmitter” command only the TX LVDS is disabled, but the state remains in high speed.

Note: The Medium speed mode is only available, if the reference clock (SysClk) is running at 20 MHz.

In clock test mode (only in single Slave scenario) the transmitter sends ‘101010 …’ continuously using the currently configured clock speed. Clock test mode can be left by sending the interface control value “turn off test mode”.

The ping function in TC3xx always uses the 32-bit payload size sending back the value 0xABCDEF01 (see **Figure 413**) using the logical channel type Hex 0 (PING Status - on RX link).

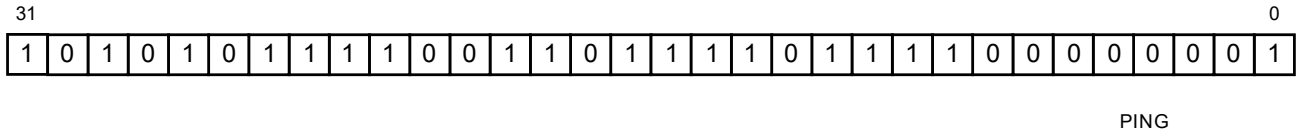

Figure 413 The Slave interface “ping” Response

The Interface control commands to configure the Slave interface have to be written into the Master interface register **IFCTRL**.IFCVS. For sending the control frame a logic 1 needs to be written to the **IFCTRL**.SIFCV register to trigger the frame transfer. The 8 register bits **IFCTRL**.IFCVS represent the same functionality as defined for the interface control payload values. Coding is as shown in **Table 318**. The register field **IFCTRL**.IFCVS shall be written with the appropriate interface control payload value for every state transition shown in **Figure 411** and **Figure 412**. The interface control in the Slave interface can alternatively be performed by programming the **IFCTRL**.IFCVS. This allows controllability of the Slave interface besides the frame based configuration. The Master interface is controlled by register configuration of physical layer only.

In **Table 319** the processing times for the time consuming interface control transitions (defined in **Table 318**) are listed.

Table 319 Processing Times for Interface Control

IFCVS (Hex)	Transition Description	Timing parameter reference (datasheet)
02_H	Slave interface clock multiplier off to Slave interface high speed clock avail.[1)]	n.a.
04_H	Slave interface clock multiplier on to Slave interface clock multiplier off.[2)]	n.a.
08_H	TX high speed mode to TX low speed mode	t_{HSLS}
10_H	TX low speed mode to TX high speed mode	t_{LSHS}
20_H	RX high or medium speed to RX low speed mode	t_{HMSLS}
40_H	RX high or low speed to RX medium speed mode	t_{HLSMS}
80_H	RX low or medium speed to RX high speed mode	t_{MLSHS}
31_H	TX disabled to TX low speed mode	t_{tx}

1) TC3xx Slave IF shows no action, if this command is received. PLL is automatically activated after power on.

2) TC3xx Slave IF shows no action, if this command is received. PLL switch off to be done using higher layer protocol command, if required.

35.7.3.3.4 Power up sequence

The power up sequence of the HSCT Physical Layer and the LVDS IO requires to have the stable bandgap and bias distributor voltages before they can be enabled. Bandgap enabling and bias distributor stabilization is automatically executed by HW after power on reset and takes t_{SET_LVDS} time. For HSCT master, LVDS TX/RX PADS can be enabled in two possible ways depending on the value of bit TEN_CTRL/REN_CTRL set in the LVDS PAD

Control register (LPCR). If TEN_CTRL/REN_CTRL =0 (port controlled condition), the LVDS TX/RX PADS are enabled in PORTS control by enabling the TX_EN/RX_EN bit in the LPCR register. If TEN_CTRL/REN_CTRL =1 (HSCT controlled condition), the LVDS TX/RX PADS are enabled via bit TX_DIS/RX_DIS in transmission disable register (DISABLE). The required time to power up LVDS TX PADS is about t_{tx} and LVDS RX PADS is t_{rxi}. For HSCT Slave interface mode, the slave LVDS TX PADS are enabled/disabled with interface commands from master and LVDS RX PADS should always be enabled. Therefore, TEN_CTRL and REN_CTRL bits in the LVDS PAD Control register needs to be enabled by startup software during initialization process. After the LVDS is ready the physical layer can be powered by enabling **Configuration Physical Layer Register**.PON. On enabling this bit the module is ready to transfer data after t_{PON}time.

Note: For actual values of the parameters please check the HSCT parameters section in the product specific data sheet.

35.7.3.4 Use Cases

The HSCT is as the name says a High Speed Communication Tunnel, which is used after initialization phase as high speed data transfer tunnel by higher layer protocol engines like HSSL. The interface is intended for chip to chip communication. The Micro Controller (MC) is from a system point of view intended to be the Master interface, if it owns the crystal. The connected Slave interface get's the clock (HSCT SysClk) provided by the master and can be operated without an additional reference clock for the internal PLL's. The reference clock at the Slave interface clocking the PLL is used to clock the data recovery path. The interface role definition (Master or Slave) is not allowed to change after the interface initialization phase.

There are two major UseCase scenarios in TC3xx the first one is the LVDS based point to point connection and the second is a point to multi point connection.

In both cases it is highly recommended to follow IFX PCB layout guidelines, which can be take as a reference to design a reliable PCB and meet the defined BER of 10-12.

35.7.3.4.1 HSCT point to point LVDS based communication

The HSCT point to point LVDS based communication is a full-duplex link in TX and RX direction, which allows independent data transfer per link direction. It allows max Baudrate of 320 MBaud with continuos data transfer in both directions. Subsequently some use cases are listed, which are an example of potential system scenarios.

MC to ASIC or FPGA

The MC (Master) is connected to the ASIC (Slave) and allows data streaming in both directions derived from higher layer HW protocol (e.g. HSSL). In addition the HSCT is used by the higher layer HW protocol to access Slave control register (read/write) and have therefore full controllability. This allows the MC to enhance it's system functions with the functions available in the connected ASIC or FPGA.

MC to MC

This use case allows to connect two MC's together, whereas one of them gets, from the Interface point of view, the Master function and the other the Slave function. Potential application would be register control or data streaming via higher layer HW protocol (e.g. HSSL).

35.7.3.4.2 HSCT point to multi point LVDS based communication

The HSCT is enhanced with the capability to have multiple Salves (max 3 Slaves) connected to one Master. Scenarios like MC connected to three ASICs or MC connected to two ASICs and one MC are supported. The initial Master configuration is fix and is not allowed to change during operation.

The connection of two ASIC's (or ASIC and 1 MC) via LVDS allows max Baud rate of 160 MBaud.

The connection of three ASIC's (or 2 ASIC's and 1 MC) via LVDS additional reduces the max Baud rate to 80 MBaud.

The communication with each of the connected Slave devices is time sequential, derived by the MC. Only one Slave can be addressed (selection by Higher layer HW protocol) and communication must be finished before the next Slave can be addressed. Rest of the Slaves stay quiet during the time one slave is addressed (selected). Higher Layer SW running on HSSL ensures this behavior and also addresses the respective slave device. Several transmitter driving the same LVDS link at once is prohibited. Electrical collisions are not allowed.

During Slave configuration phase HSCT commands are used and the Master is addressing all Slaves based on a Multi-Drop communication.

To achieve this scenario's careful high speed PCB design based on MicroStrip trace lines is required with well routed differential trace lines on PCB and good termination at the receiver input. In the multi Slave scenario the termination resistor needs to be a discrete 100 Ohm +/-5% or with less tolerance. An internal LVDS resistor is not supported in multiple Slave scenario. The location of the discrete resistor is suggested to be placed as close as possible to the Slave with a max geometrical distance from master defined (check IFX PCB layout guidelines for more details).

The LVDS IO (based on IEEE1596.3) offers several driver swing configurations, which allow application based adaptation.

35.7.3.5 Suspend, Sleep and Power-Off Behavior

Generally, the HSCT module transmits and receives data and control information via the differential signal interface.

A power down of the module can be done in any situation of the transmission. It is strongly recommended to have the transfers stopped from the higher layer protocol before sending the HSCT layer into power down state. In order to power down the module in a well defined way, the user software must take care that the power down request is issued after finishing the transfers or stop the transfers before. Issuing an power down within a transfer - all data is lost.

35.7.3.5.1 OCDS Suspend

OCDS suspend request, for debugging purposes, simply freezes the HSCT module in the current state. This corresponds to the hard suspend of the whole module, that is both the transmitter and the receiver. After the end of the suspend state, the receive data will be most probably corrupted. Therefore, the whole interface must be reset, re initialized and reactivated.

35.7.3.5.2 HSCT Protocol Sleep Mode

Going into HSCT protocol sleep mode requires that the HSCT module has finished all transfer activities and that the HSSL transmit path or HSCT has no more frames available for sending and the last data of the current frame are send out. The user enables or disables sleep mode (SLEEPCTRL.**SLPEN**) during module initialization phase.

If the sleep mode is used, the application software has to configure the counter SLEEPCTRL.WKUPCNT to a value corresponding to the LVDS pad wake-up time defined in the data sheet.

35.7.3.5.3 Disable Request (Power-Off)

Going into power off requires that the HSCT module has finished all activities, which needs to be ensured by SW before going into power off mode. It is also required that the higher level HSSL protocol has finished the transfers. It is the software responsibility to change to low speed mode and disable the transmitter and the receiver according to the application, by writing the appropriate registers, because the speed mode change and transmitter and receiver disabling do not occur automatically. The HSCT high speed dividers need to be disabled (**INIT**.RXHD = 0 and **INIT**.TXHD = 0), before the physical layer is set to Power-Off mode. Power-Off mode of Physical

Layer can be achieved by disabling the 5 phases provided by Peripheral PLL with **CONFIGPHY**.PON. The clocks of the other parts of the HSCT module can be switched off by the **CLC**.DISR request bit or by the chip system sleep mode control (see **CLC**.EDIS).

35.7.4 Registers

35.7.4.1 Registers Definition

This section describes the kernel registers of the HSCT module and the System related register in single kernel configuration. All HSCT kernel register will be referenced in other parts of the TC3xx User's Manual by the module name prefix "HSCT_".

HSCT Kernel Register Overview

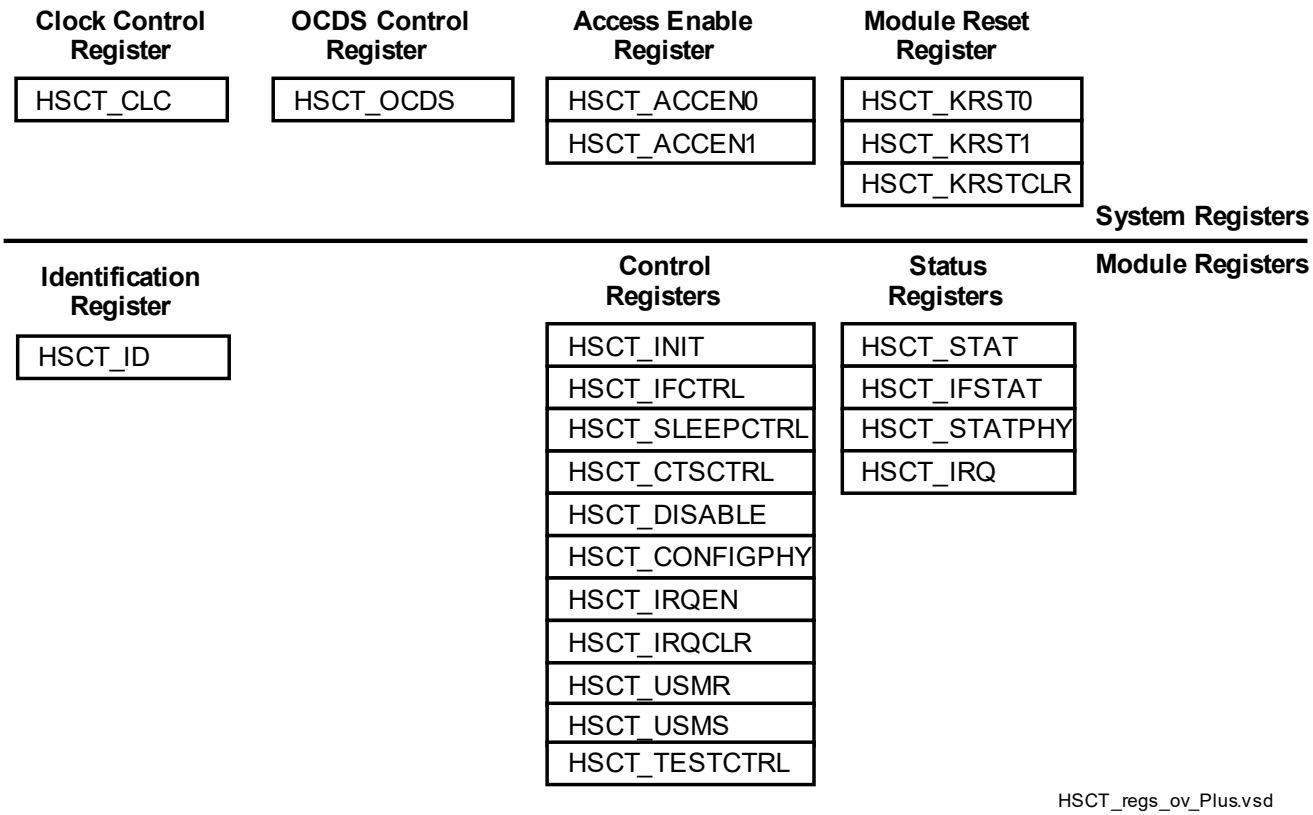

Figure 414 HSCT Register Overview

The complete and detailed address map of the HSCT modules is described in the next chapter.

35.7.4.1.1 HSCT Kernel Register Definitions

Table 320 Register Overview - HSCT (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control Register	00000_H	U,SV	SV,E,P	Application Reset	134

ACCEN0	Access Enable Register 0	$0FFFC_H$	U,SV	SV,SE	Application Reset	136

Note: The absolute register address is calculated as follows: Module Base Address + Offset Address

A register is addressed word wise.

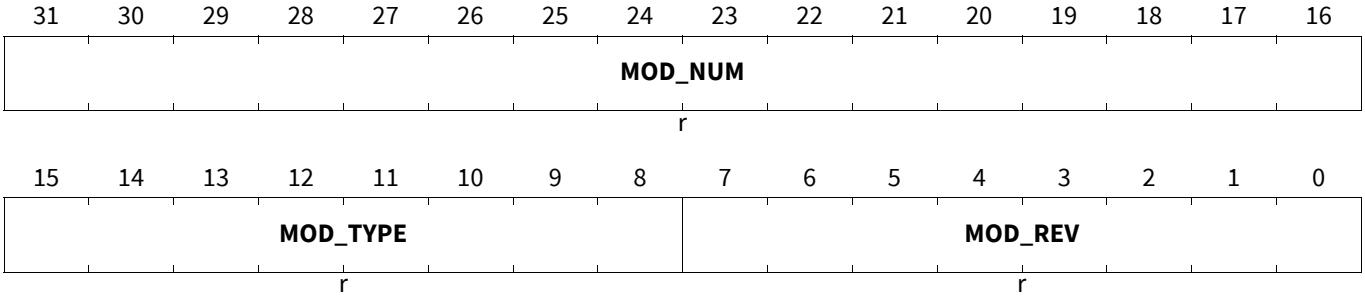
Note: Register bits marked reserved in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID

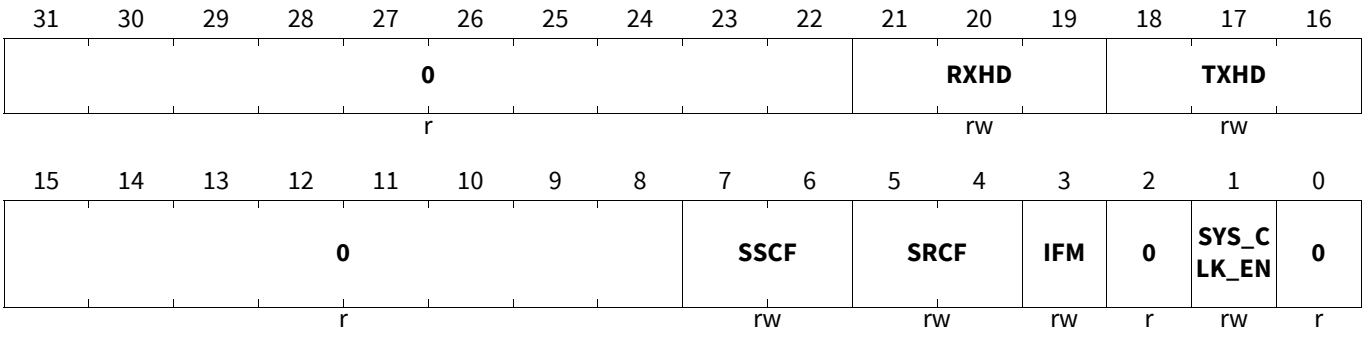
Module Identification Register (00008_H) Application Reset Value: $00B4\ C002_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** 02_H The value of a module revision starts with 02_H (second revision).
MOD_TYPE	15:8	r	**Module Number Type** $C0_H$ 32 bit peripheral
MOD_NUM	31:16	r	**Module Number for module identification** $00B4_H$ Is the module identification number for the HSCT interface.

Initialization Register

INIT
Initialization Register **(00010_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SYS_CLK_EN	1	rw	**Enable HSCT SysClk in Master interface** SysClk enable activates the SysClk. This feature is only available in the Master interface. In Slave interface mode the register setting does not have an effect. 0_B Disable (default) 1_B Enabled
IFM	3	rw	**Select Interface Mode** Select the Interface Mode (Master IF or Slave IF). 0_B Master IF 1_B Slave IF
SRCF	5:4	rw	**Select Reference Clock Frequency Divider** Defines physical layer reference frequency (PHY_CLK) and respective input frequency divider. The configuration is valid for Low speed and Medium Speed mode. 00_B REFCLK 10MHz, LS 5MBaud, MS n.a. 01_B REFCLK 20MHz, LS 5MBaud, MS=20MBaud 10_B REFCLK 40MHz, LS 5MBaud, MS=20MBaud 11_B For future use
SSCF	7:6	rw	**Select SysClk Frequency Divider** For master interface defines SysClk pad output frequency. The allowed SysClk frequency is 10MHz or 20MHz. 00_B SYSCLK DIV 1/1 01_B SYSCLK DIV 1/2 10_B SYSCLK DIV 1/4 11_B For future use

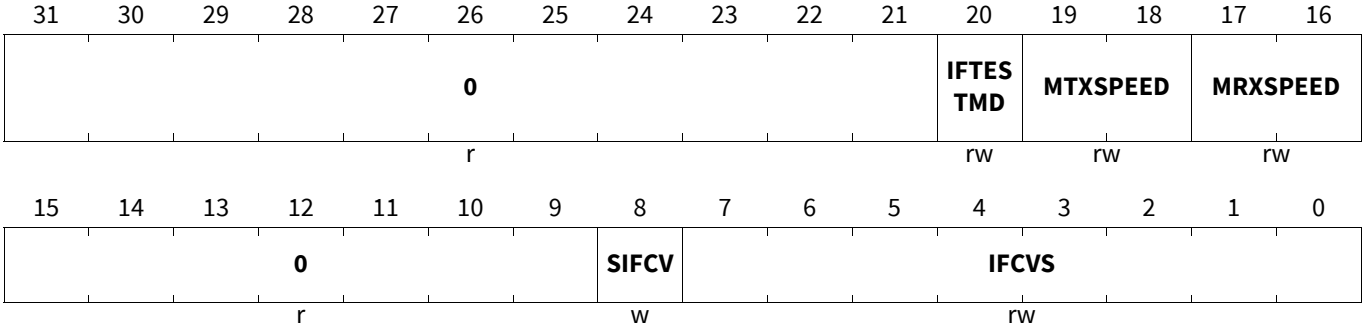
Field	Bits	Type	Description
TXHD	18:16	rw	**Transmit High Speed Divider.** The Transmit High Speed data rate can be reduced by dividing factors. The Transmit High Speed data rate is separated from the Receive High Speed data rate. 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. … 111_B For future use.
RXHD	21:19	rw	**Receive High Speed Divider.** The Receive High Speed data rate can be reduced by dividing factors. The Receive High Speed data rate is separated from the Transmit High Speed data rate. *Note: For future use configuration leads to no output clock delivered to the correlator.* 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. … 111_B For future use.
0	0, 2, 15:8, 31:22	r	**Reserved**

Interface Control Register

This register allows to configure the transfer Speed of the Master Interface and is also used to send the command frame to the Slave.

Note: The Master interface link speed configuration immediately takes place. Therefore the Master interface speed transition must not be changed with a Slave interface command send activity.

IFCTRL
Interface Control Register **(00014$_H$)** **Application Reset Value: 0000 0000$_H$**

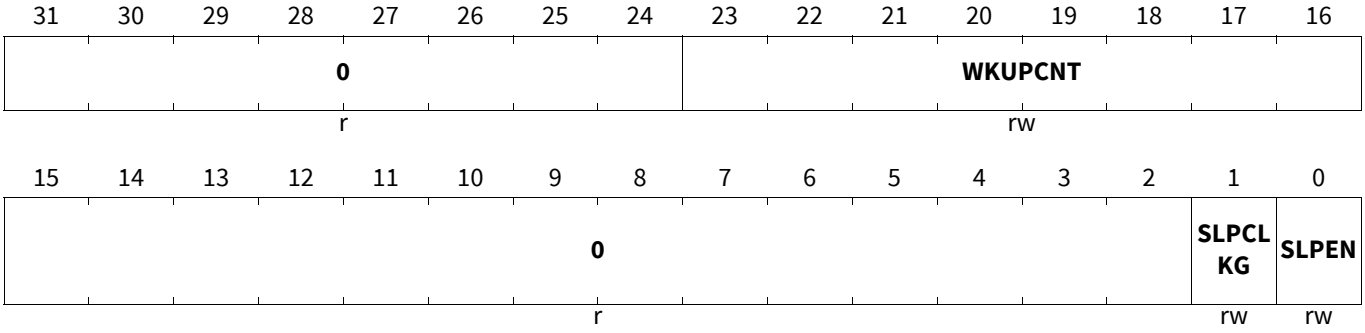


Field	Bits	Type	Description
IFCVS	7:0	rw	**Master Mode - Trigger for Interface Control Value to be send to Slave interface** See the table "Interface Control Payload Values". Master IF Mode: The value is taken as control frame value send as payload to the Slave IF. Slave IF Mode: The value is a new configuration of the Slave IF (not recommended flow!!!).
SIFCV	8	w	**Master Mode - Slave IF control frame trigger** Changing the interface configuration, software must guarantee not having transfers active on the interface. This register bit always reads back zero. 0_B The IFCVS field configured value has no effect (default). 1_B Writing a one to the register bit sends the control frame configured in register field IFCVS, if the interface is configured as Master. In Slave Mode the trigger has an effect and takes the IFCTRL.IFCVS value. In Slave mode this is not the recommended control flow. A frame based configuration shall be used instead. A control frame has higher priority then a register control. At a simultaneous occurrence of both configuration source the register configuration in Slave mode is lost.
MRXSPEED	17:16	rw	**Master Mode RX speed** *Note: Register setting only valid in interface Master mode.* 00_B Low Speed 01_B Medium Speed 10_B High Speed 11_B For future use

Field	Bits	Type	Description
MTXSPEED	19:18	rw	**Master Mode TX speed** *Note: Register setting only valid in interface Master mode.* 00_B Low Speed 01_B for future use 10_B High Speed 11_B For future use
IFTESTMD	20	rw	**Interface TX Test Mode** 0_B Test Mode disabled 1_B Test Mode enabled - send out 101010101… test pattern continuously.
0	15:9, 31:21	r	**Reserved**

Sleep Control Register

SLEEPCTRL
Sleep Control Register **(00018_H)** **Application Reset Value: $0020\ 0000_H$**



Field	Bits	Type	Description
SLPEN	0	rw	**Sleep mode enabled** Sleep mode is enabled and performed after receiving a 1 at the end of a received frame or in transmission direction, if no more data to be send. 0_B Sleep mode disabled. 1_B Sleep mode enabled.
SLPCLKG	1	rw	**Clock Gating in Sleep Mode** In sleep mode the clock for HSCT (framer, deframer) can be gated in order to minimize power consumption. *Note: Clock gating: Receiving path and transmitting path is separated.* 0_B Clock gating in sleep mode disabled. 1_B Clock gating in sleep mode enabled.

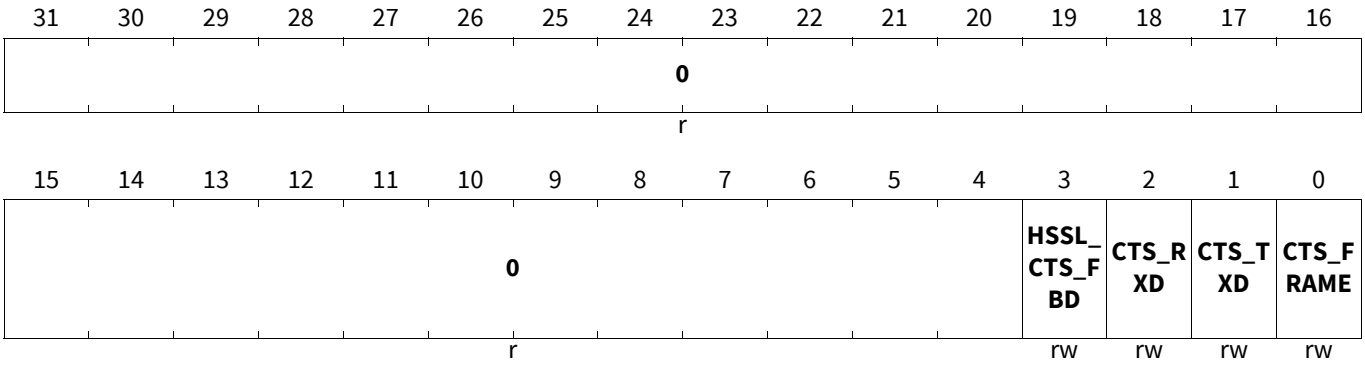
Field	Bits	Type	Description
WKUPCNT	23:16	rw	**Counter Value for Determining the Wake-up Time of the LVDS Line Driver** This counter value corresponds to wake-up time the LVDS requires from sleep to wake-up. Counter is clocked by SRI clock.
0	15:2, 31:24	r	**Reserved**

Clear To Send Control Register

The Clear To Send function is not available in multi Slave scenario. This function is an automatic HW controlled function and in multi Slave mode not easy to control. Therefore it is removed in this mode.

CTSCTRL

Clear To Send Control Register **($0001C_H$)** **Application Reset Value: $0000\ 0001_H$**



Field	Bits	Type	Description
CTS_FRAME	0	rw	**Transmit CTS Frame Generation** Dedicated CTS frames are generated after the receive data path is not able to accept more data. The situation is indicated by the CTS header bit in case there is currently no data to be transferred. 0_B Generation of dedicated CTS frames disabled. 1_B Generation of dedicated CTS frames enabled.
CTS_TXD	1	rw	**Disable TX CTS signaling** If this bit is set to 1, CTS signaling is not performed at the interface and the status remains at the clear to send for every frame send. 0_B Enable CTS signaling (default). 1_B Disable CTS signaling.
CTS_RXD	2	rw	**Disable RX CTS detection** If this bit is set to 1, CTS detection is not performed at the receiver and the status remains internally at clear to send for every frame received. 0_B Enable CTS detection (default). 1_B Disable CTS detection.
HSSL_CTS_FBD	3	rw	**Disable HSSL interface CTS Frame Blocking** If this bit is set to 1, CTS signaling is not performed at the interface and the status remains at the clear to send for every frame send. 0_B Enable CTS frame blocking (default). 1_B Disable CTS frame blocking.

Field	Bits	Type	Description
0	31:4	r	**Reserved**

Transmission Disable Register

DISABLE
Transmission Disable Register (00020$_H$) Application Reset Value: 0000 0003$_H$

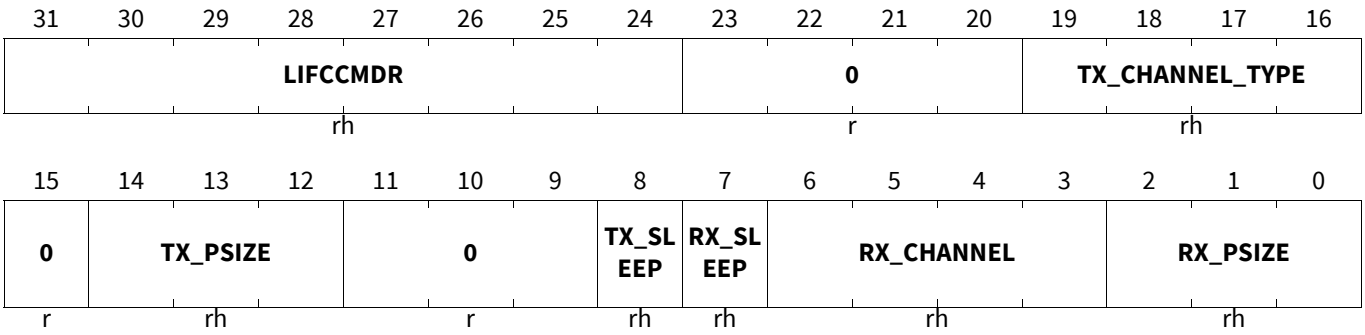
r													rw	rw	rw

Field	Bits	Type	Description
TX_DIS	0	rw	**Disable HSCT Transmit path in Master interface** Disable the transmit path of the HSCT interface. If this bit is set to 1 - no transfer can be initiated and the LVDS driver is disabled. 0_B Enable 1_B Disable
RX_DIS	1	rw	**Disable HSCT Receive path in Master interface** Disable the receive line path of the HSCT interface. If this bit is set to 1 - no transfer from the other side can be received and the Master RX path is in a low power state. This feature is only available in the Master interface. Slave interface RX path can not be disabled and a write to the register has no effect. 0_B Enable 1_B Disable
RX_HEPD	2	rw	**Disable RX Header Error Discard Payload data.** Instead of discarding the Payload data at a header error the payload data is passed to the higher layer (HSSL). Only channel data to HSSL is affected. This function is available in Master and in Slave mode. 0_B Header error received data is discarded 1_B Header error received data is passed to the higher hardware layer.
0	31:3	r	**Reserved**

Status Register

STAT
Status Register **(00024_H)** **Application Reset Value: $0000\ 0000_H$**

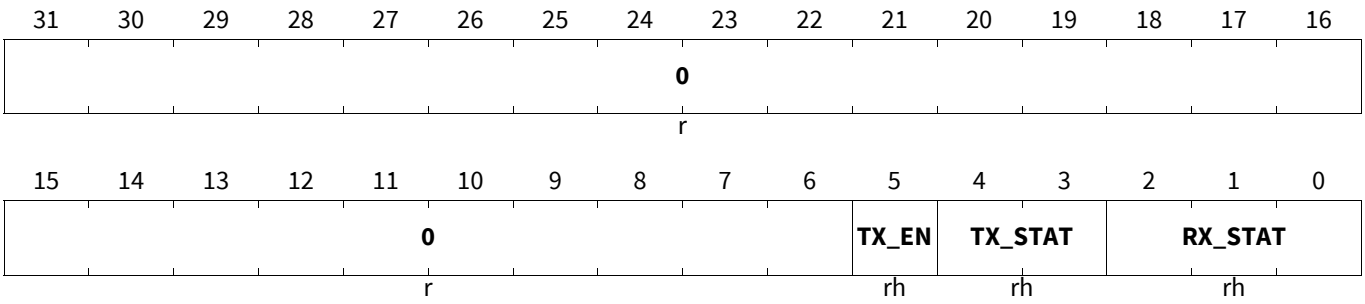


Field	Bits	Type	Description
RX_PSIZE	2:0	rh	**RX (Receiving) Payload Size** Contains the payload size of the last received frame.
RX_CHANNEL	6:3	rh	**RX (Receiving) Logical Channel Type** Contains the logical channel type of the last received frame. See Table "Logical Channel Type Coding".
RX_SLEEP	7	rh	**RX (Receiving) Sleep Mode Status** 0_B HSCT is in receive direction active 1_B HSCT is in receive direction in sleep mode
TX_SLEEP	8	rh	**TX (Transmission) Sleep Mode Status** 0_B HSCT is in transmit direction active 1_B HSCT is in transmit direction in sleep mode
TX_PSIZE	14:12	rh	**Transmission Payload Size** Coding of the logical channel type is according to the Table: Payload Size Coding. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.
TX_CHANNEL_TYPE	19:16	rh	**Transmission Logical Channel Type** Coding of the logical channel type is according to the Table: Logical Channel Type Coding. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.
LIFCCMDR	31:24	rh	**Last Interface Control Command Received** The bit value reflects the last control command received. The bit is active in Slave interface mode only. In Master mode it reflects logic 0 always. (See **Table 318**)
0	11:9, 15, 23:20	r	**Reserved**

Interface Status Register

Clock test mode and Loopback mode are only available in single Slave scenario. In multi Slave scenario are not available.

IFSTAT
Interface Status Register **(00028_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
RX_STAT	2:0	rh	**HSCT Slave interface Status for RX link** *Note: Slave interface transmitter only* 000_B Interface is disabled in RX link direction. 001_B Interface runs at low speed on RX link. 010_B Interface runs at medium speed on RX link. 011_B Interface runs at high speed on RX link direction. 100_B Reserved 101_B Clock test mode and low speed on RX ink 110_B Clock test mode and medium speed on RX link 111_B Clock test mode and high speed on RX link.
TX_STAT	4:3	rh	**HSCT Slave interface Status for TX link** *Note: Slave interface receiver only* 00_B Interface runs at low speed on TX link. 01_B Interface runs at high speed on TX link. 10_B Loopback mode low speed. 11_B Loopback mode high speed.
TX_EN	5	rh	**HSCT LVDS Slave interface TX enable** *Note: Slave interface only* 0_B LVDS TX disabled. 1_B LVDS TX enabled.

Interrupt Clear Register

This register is the Interrupt clear register. By writing a logic 1 to the register the interrupt in the IRQ register is cleared by a clear pulse. This means the interrupt clear methodology is write one to clear. Reading from this register presents the logic value 0 to software.

IRQCLR
Interrupt Clear Register **(00048_H)** **Application Reset Value: $0000\ 0000_H$**

USMR															
rh															

Field	Bits	Type	Description
USMR	31:0	rh	**Unsolicited status message received** The register contains the last received unsolicited status message.

Unsolicited Status Message Send

A write to the register activates the interface to send out an unsolicited status message to the other interface side. The Logical Channel Type reflected in the header is Hex 1 and the Payload is 32-bit always. An unsolicited frame has a higher priority then a Frame based on a data channel. In between frames the USMS gets higher priority then the data transfer requested by the HSSL. This function is not available in multi Slave scenario.

USMS

Unsolicited Status Message Send **(00054$_H$)** **Application Reset Value: 0000 0000$_H$**

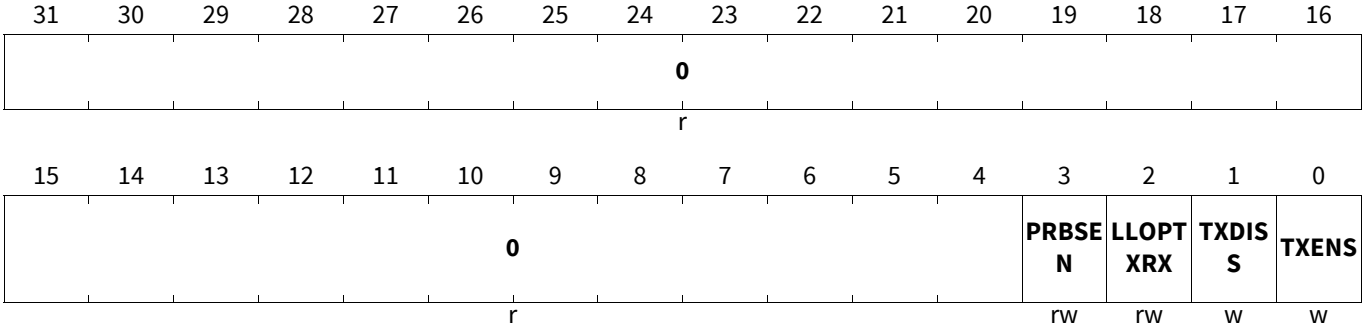
Field	Bits	Type	Description
USMS	31:0	rw	**Unsolicited status message send** Writing to the register triggers an unsolicited status message to be send to the other interface side.

Test Control Register

Note: The TESTCTRL.LLOPTXRX bit is not working with IFCTRL.IFTESTMD. Data is not transported to HSCT controller part (link layer).

TESTCTRL
Test Control Register **(00060$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TXENS	0	w	**Enable Slave TX path (Slave interface mode only)** *Note: This function should be only used during interface testing the mode and SW development. In functional mode the Slave interface should only be controlled via transfer commands received from Master interface. (This trigger register reads back 0 always.) If TXENS and TXDISS are written one, TXDISS has higher priority. The status is visible in IFSTAT.TX_EN.* 0_B Writing logic 0 has no effect 1_B Triggers the Slave interface TX enable.
TXDISS	1	w	**Disable Slave TX path (Slave Interface mode only)** *Note: This function should be only used during interface testing the mode and SW development. In functional mode the Slave interface should only be controlled via transfer commands received from Master interface. (This trigger register reads back 0 always.) If TXENS and TXDISS are written one, TXDISS has higher priority. The status is visible in IFSTAT.TX_EN.* 0_B Writing logic 0 has no effect 1_B Triggers the Slave interface TX disable.
LLOPTXRX	2	rw	**LVDS loop back TX to RX enable** Transmit data at LVDS is directly looped back to the LVDS RX. Data transfer speed is defined by the TX speed configuration. (The data path in the SoC is using the complete Transmit path through all functional layers and is looped back at LVDS from TX to RX. Also at RX data path all SoC data layers are active.) *Note: Requires same speed configuration for RX- and TX-link before enabled.* 0_B Disabled LVDS TX to RX data Loop back test mode 1_B Enabled TX to RX data loop back test mode.

Field	Bits	Type	Description
PRBSEN	3	rw	**PRBS Pattern enable** Enable of the PRBSEN bit allows a continuos PRBS stream with the configured transfer speed Baud rate. This feature is available to measure ISI during the time other SoC functions are running in an applicative mode. This feature is for measurement purpose only. 0_B Disabled PRBS pattern generation on TX 1_B Enabled PRBS pattern generation on TX.
0	31:4	r	**Reserved**

35.7.4.1.2 BPI_FPI Module Registers (Single Kernel Configuration)

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the HSCT module. Where a module kernel is connected to the CLC clock control interface, CLC register controls the module clock, SoC system sleep mode and disable mode for the module.

CLC
Clock Control Register **(00000_H)** **Application Reset Value: $0000\ 0003_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	r	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control (clock and local access) of the module. This bit switches the clock off immediately, therefore the software has to take care that the HSSL and HSCT communication has been terminated properly before setting this bit.
DISS	1	r	**Module Disable Status Bit** Bit indicates the current status of the module and is set after the requested disable is active.
EDIS	3	rw	**Chip System Sleep Mode Control** The EDIS bit in the CLC register controls whether or not a module is stopped during Chip System initiated Sleep Mode. If EDIS is 0, a Sleep Mode request can be recognized by the module and, when received, its clock is immediately shut off. Therefore the software has to take care that the HSSL and HSCT communication has been terminated properly before activating the sleep mode request. If EDIS is set to 1, a Sleep Mode request is disregarded by the module and the module continues its operation. Note: This chip system sleep mode has nothing to do with the HSCT protocol sleep mode.
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

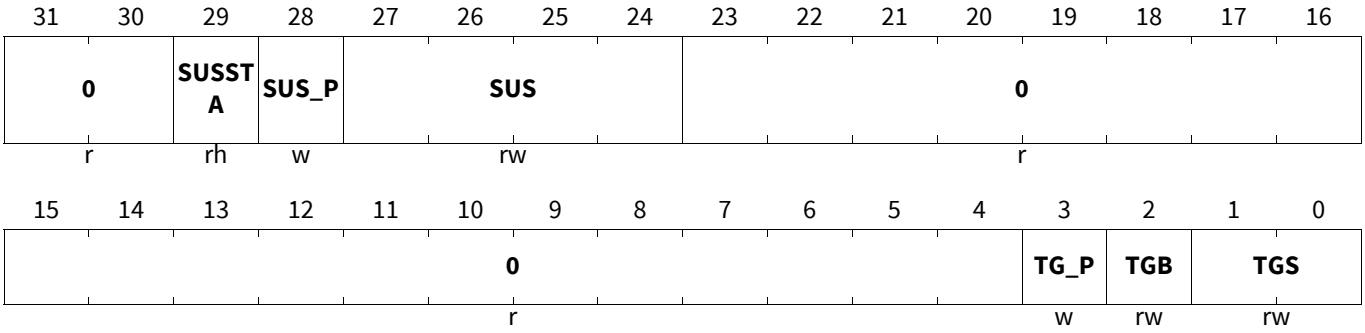
If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32-bit always.

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = ´1´). While OCDS is not enabled, OCS reset values/modes are effective.

OCS

OCDS Control and Status (0FFE8$_H$) Debug Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** Others reserved (no Trigger Set selected) 00_B No Trigger Set output 01_B TS16_HSCT
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Others reserved *Note: After a Hard suspend the HSCT and higher layer protocol module must be reset. A a new initialization sequence is required afterwards* 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately (read from registers still possible).
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved** Read as 0; must be written with 0.

The HSCT has one OCDS Trigger set available which gives a maximum of 16 triggers. The next table describes the available triggers.

Table 321 TS16_HSCT OCDS Trigger Set

Bits	Name	Description
0	HRXRQ	HSSL Interface RX transfer direction request
1	HRXCTS	HSSL Interface RX transfer direction CTS
2	HTXCTS	HSSL Interface TX transfer direction CTS
3	HTXRQ	HSSL Interface TX transfer direction request
4	TXF	First Byte transfer of transfer frame in TX transfer direction at Controller to Physical Layer interface
5	TXL	Last Byte transfer of transfer frame tin TX transfer direction at Controller to Physical Layer interface
6	TXW	Transmit direction wake-up at controller to physical layer interface
7	TXS	Transmit direction sleep indication at controller to physical layer interface
8	RXFS	Receive direction frame start at physical layer to controller interface.
9	DFSMI	Deframer state machine not in idle.
10	IFCT	Slave interface frame command trigger.
[15:11]		Reserved (value is 0)

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions with the on chip bus Master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID Master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,…,EN31 -> TAG ID 011111B.

ACCEN0

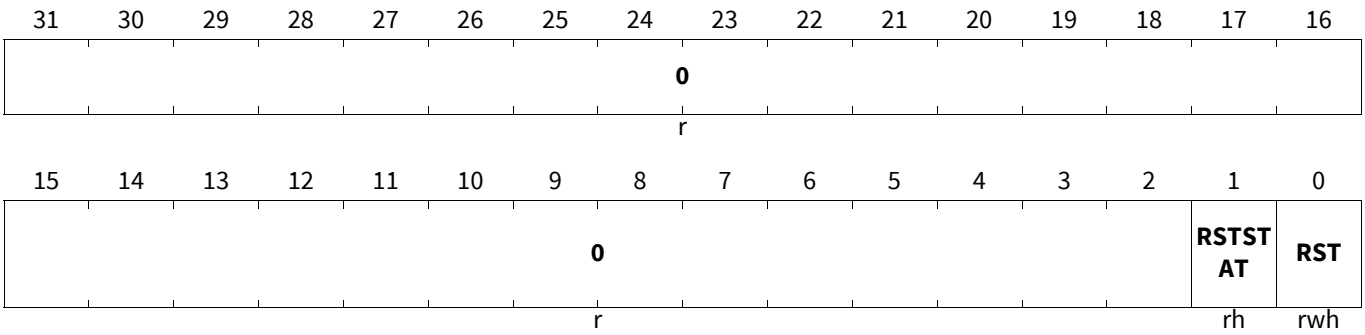
Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel and the HSCT physical layer. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the module kernel and the physical layer it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

KRST0
Reset Register 0 **(0FFF4$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. *Note: It is strongly recommended to reset the HSCT and HSSL in sequence to avoid communication issues.* 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

36 Asynchronous/Synchronous Interface (ASCLIN)

The main purpose of the ASCLIN module is to provide asynchronous serial communication with external devices using only data-in, data-out signals.

The focus of the module is set to fast and flexible communication: either fast point-to-point or master-to-many slaves communication using the LIN protocol.

Additionally, the module supports the synchronous SPI communication.

Figure 415 shows an overview of the ASCLIN module.

Note: The RX, TX, RTS, CTS, SCLKO, SLSO signal names are prefixed with "A" in order to achieve unique names on chip level, distinct from signal names of other communication modules.

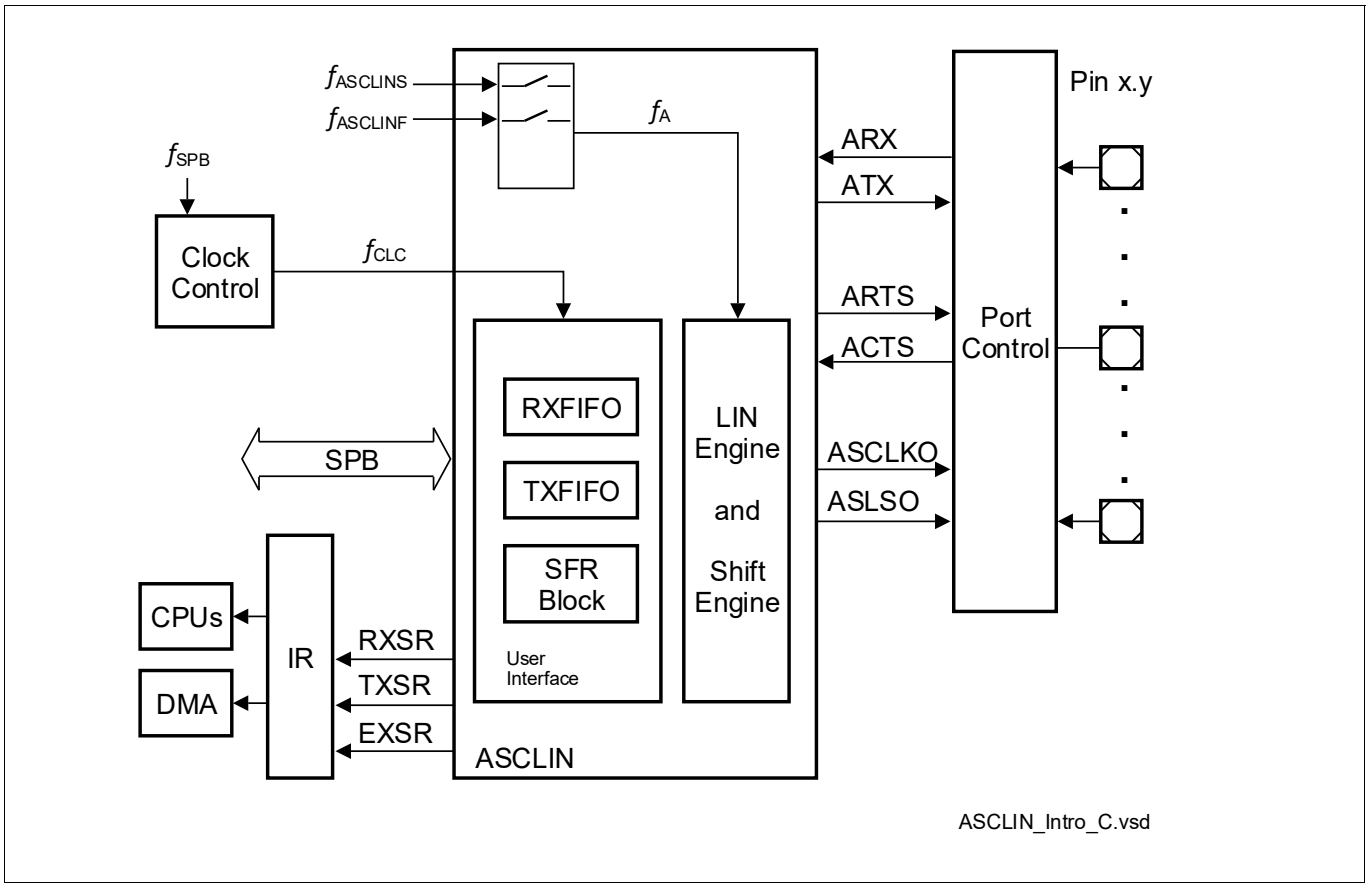

Figure 415 Block Diagram of the ASCLIN module.

36.1 Feature List

This section describes the features of the ASCLIN module.

General Features

- 16 bytes TxFIFO
- 16 bytes RxFIFO
- Pack / unpack capabilities of the Tx and Rx FIFO
- Interrupt generation
  - On a configurable transmit FIFO level
  - On a configurable receive FIFO level
  - On an error condition (frame, parity, overrun error)
  - On various module internal events (end of ASC/SPI frame, LIN events)
- Interrupt signals capable of triggering either a CPU or a DMA
- Programmable oversampling of 4 to 16 times per bit
- Programmable sampling point position
- Programmable digital glitch filter and median filter for incoming bit stream
- Shift direction LSB first for ASC and LIN mode, and programmable LSB/MSB first for SPI mode
- Internal loop-back mode

Standard ASC Features

- Full-duplex asynchronous operating mode
  - 7-bit, 8-bit or 9-bit (or up to 16-bit) data frames, LSB first
  - Parity-bit generation/checking
  - One or two stop bits
  - Max baud rate f_A / 16 (6.25 MBaud @ 100 MHz f_A module clock)
  - Min. baud rate f_A / 268 435 456 (0.37 Baud @ 100 MHz f_A module clock)
- Optional RTS / CTS handshaking

Extended ASC Features

- Programmable oversampling of 4 to 16 times per bit
  - module capability of up to 4 times higher baud rates (f_A / 4) then the standard ASC
  - system considerations like pad type, incoming signal quality and accumulated PLL jitter can lead to constraints regarding the usable oversampling ratios (for example f_A / 8 = 200MHz / 8 = 25 MBaud)
- Programmable sampling point position

LIN Features

- Support of
  - LIN version 1.3
  - LIN version 2.0
  - LIN version 2.1
  - LIN version 2.2 and
  - J2602

- Break detection
- Break injection
- Sync field generation
- Auto baud detection based on Sync Field measurement
- Optional Collision detection, required for LIN version 2.1
- LIN Watchdogs
  - Header time-out
  - Frame or Response time-out
- Stuck at zero/one monitoring
- Bus idle time monitoring
- Wake-Up
- Minimum CPU load in master mode
  - Single interrupt indicating the end of the frame
- Minimum CPU load in slave mode
  - Single interrupt at the end of the header reception
  - Single interrupt at the end of the response or end of frame
- Standard operation with one interrupt per transmitted or received byte supported

SPI Features

- SPI master modes (slave mode not supported):
  - Four-wire or three-wire (with / without slave select output signal)
- Up to 16-bit data width
- Full-duplex and half-duplex
  - Min. baud rate f_A / 268 435 456 MBaud (= 0.37 Baud @ 100 MHz f_A module clock)
  - Max. baud rate f_A / 4 MBaud (= 25 MBaud @ 100 MHz f_A module clock)
- Programmable leading and trailing delays

36.2 Overview

This section shows the essential sub blocks of the module when used as standard ASC, as LIN or as SPI master.

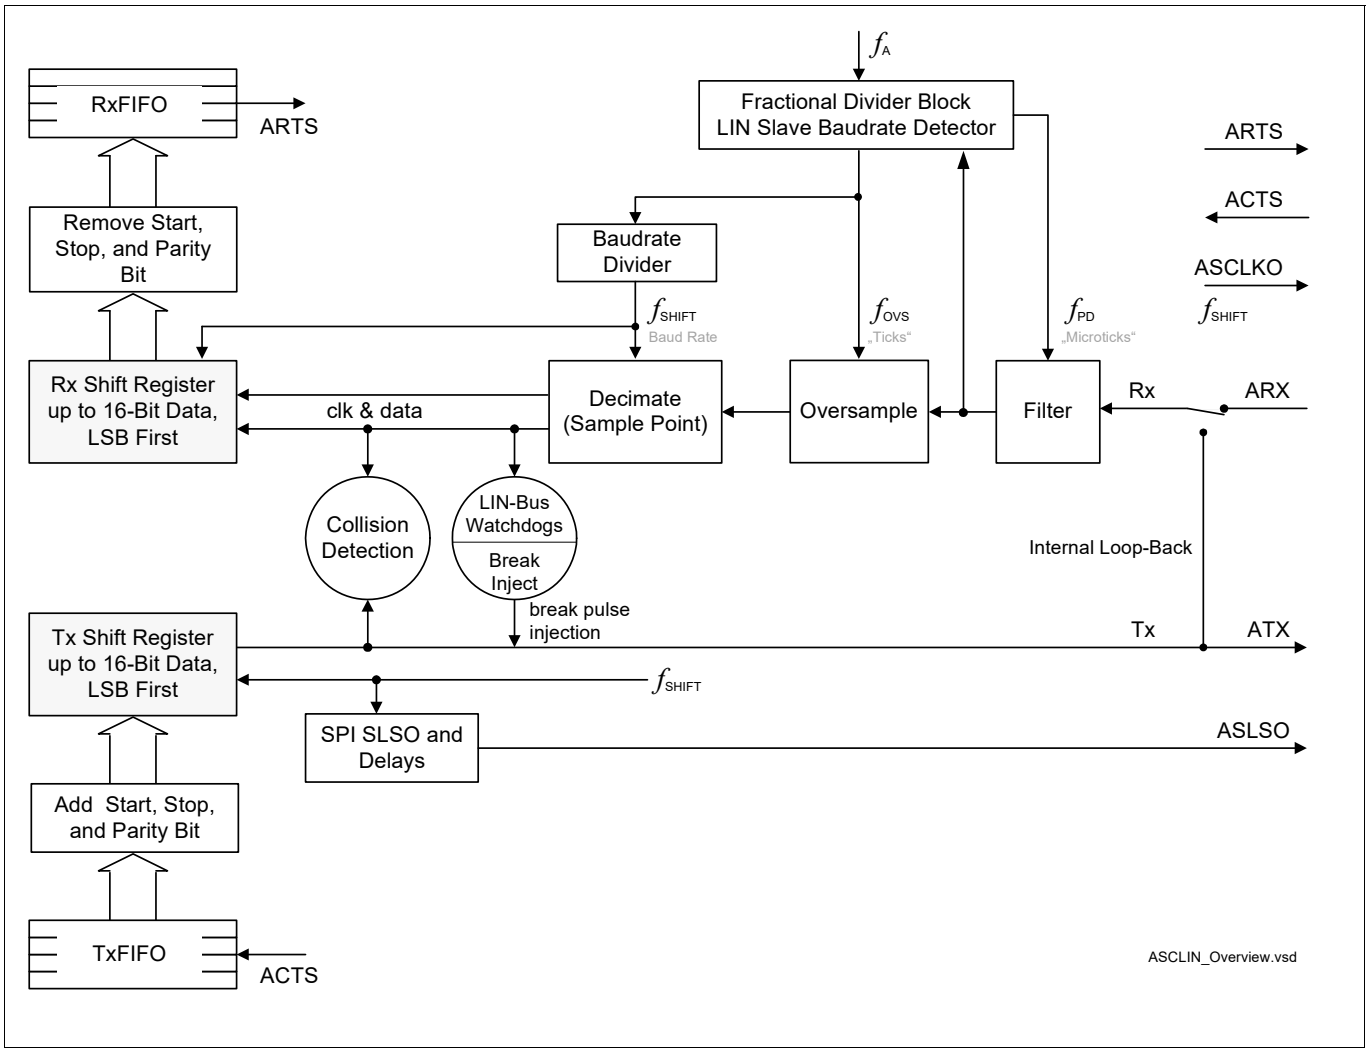

Figure 416 Architecture Overview

Notes

1. *Collision detection is mandatory only in the LIN specification V2.1.*
2. *In LIN mode, both ARX and ATX signal must be connected to the LIN bus in order ASCLIN module to work properly.*

36.3 Functional Description

36.3.1 External Signals

The ASCLIN module provides the following external signals:

- Serial clock output ASCLK
- Receive data input ARX (Master Receive MR input in SPI mode)
- Transmit data output ATX (Master Transmit MT output in SPI mode)
- Slave select signal output ASLSO
- Request to send handshake output ARTS
- Clear to send handshake input ACTS

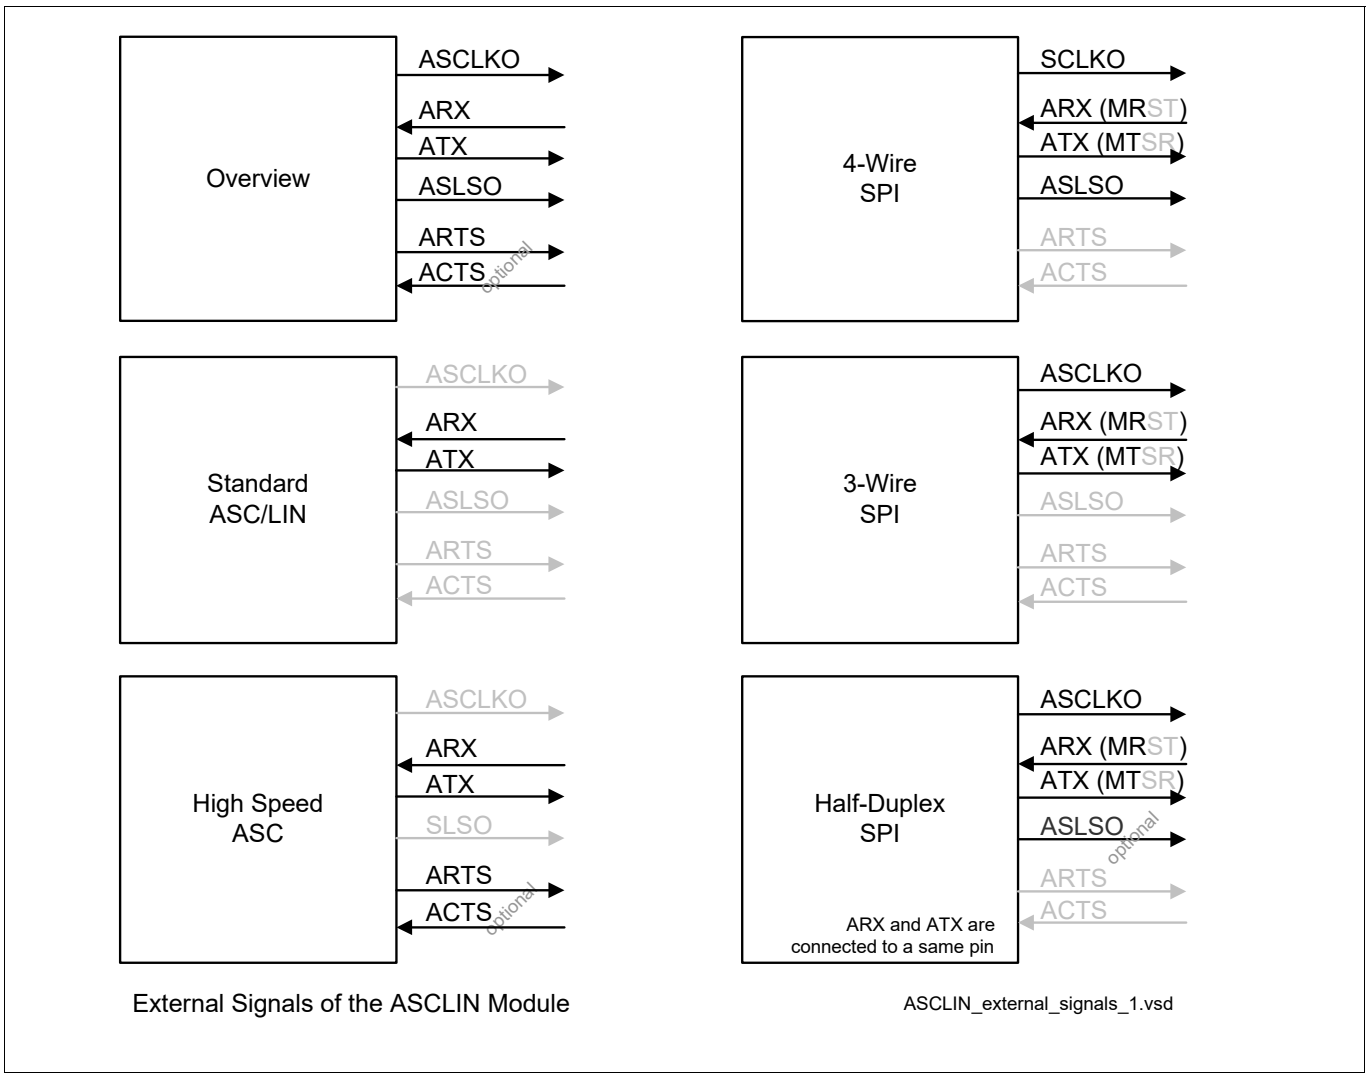

Figure 417 External Signals of the ASCLIN Module in Different Modes

36.3.2 User Interface

The user interface contains a Tx FIFO and a Rx FIFO.

They provide the following services: takes data packets with width optimal for the FPI[1)] bus and packs them to serial frames, buffers the FPI bus data, manages handshaking. These features are designed to optimize the use of the module in LIN, high-speed ASC and SPI mode. They also optimize the use of the module in standard ASC mode.

36.3.2.1 TxFIFO Overview

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame. It also has the ability to pack 32-bit writes from the FPI bus to four up-to-8-bit or two up-to-16-bit frames.

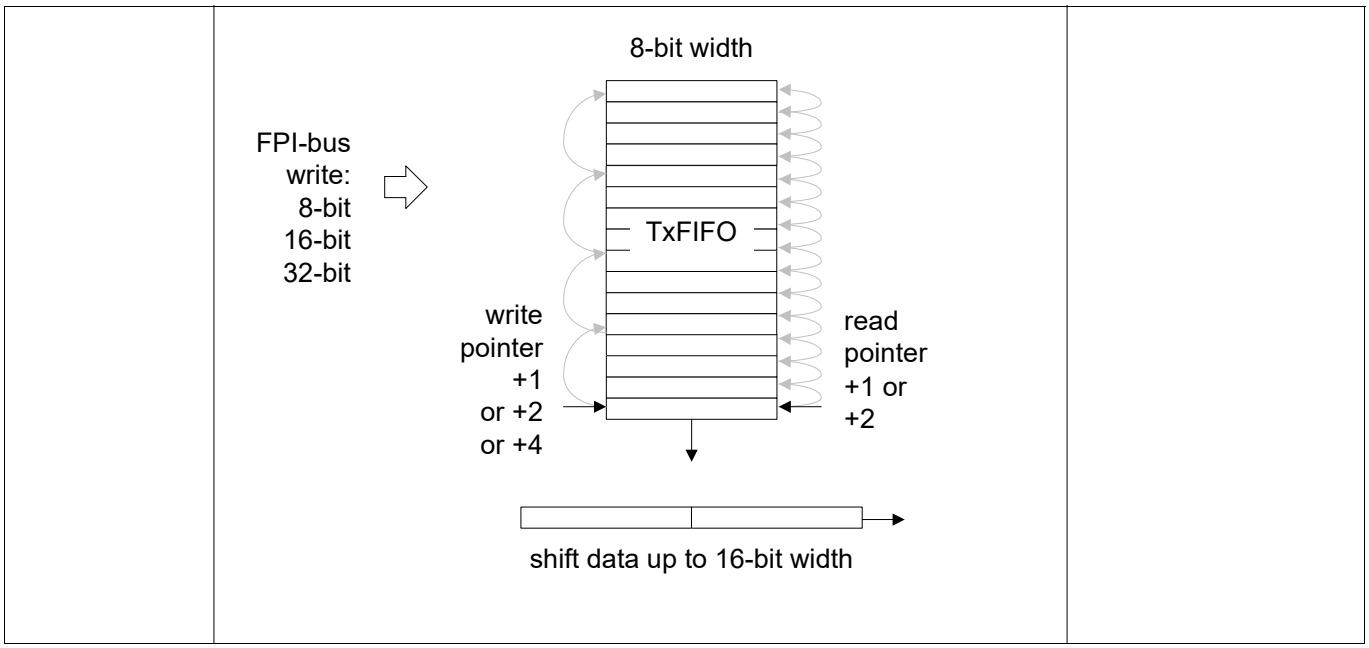

Figure 418 TXFIFO Overview

The number of bytes written to the TxFIFO is always defined with the TXFIFOCON.INW (**TX FIFO Configuration Register**), does not depend on the SPB write width, and should be equal to it.

If the SPB write width is shorter than INW, then the missing part is padded with zeros.

If the SPB write width is longer then INW, then the excessive part is lost.

On the shift register side, the TxFIFO is always emptied by a number of bytes as needed for the data width field DATCON.DATLEN (**Data Configuration Register**).

The table **Inlet Width versus SPB Write Width** describes all the possible write (fill) combinations. The bytes which will be filled into the TXFIFO are labeled as A, B, C, D and 0.

1) FPI is the protocol used on the System Peripheral Bus (SPB).

Table 324 Inlet Width versus SPB Write Width

TxFIFO Contents		SPB Bus Write Width		
		8-Bit A	**16-Bit BA**	**32-Bit DCBA**
Inlet Width INW	**8-Bit**	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

36.3.2.2 Using the TxFIFO

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame.

Note: Some (but not all) use-cases are described in the sections below. The software can always access the TXFIFO 8, 16 or 32 bit wide, according to its requirements.

36.3.2.2.1 Standard ASC Mode

The most standard usage of the ASC module is to transmit 7 or 8-bit values, and to fill the FIFO with 8-bit wide FPI-bus accesses. The FPI bus access is 8-bit wide, and there is only BS0 (Byte Select 0) signal active.

The transmit data is written to the address TXDATA (**Transmit Data Register**). The Tx_Inlet_Width is 8-bit, and the Tx_Outlet_Width is 8-bit.

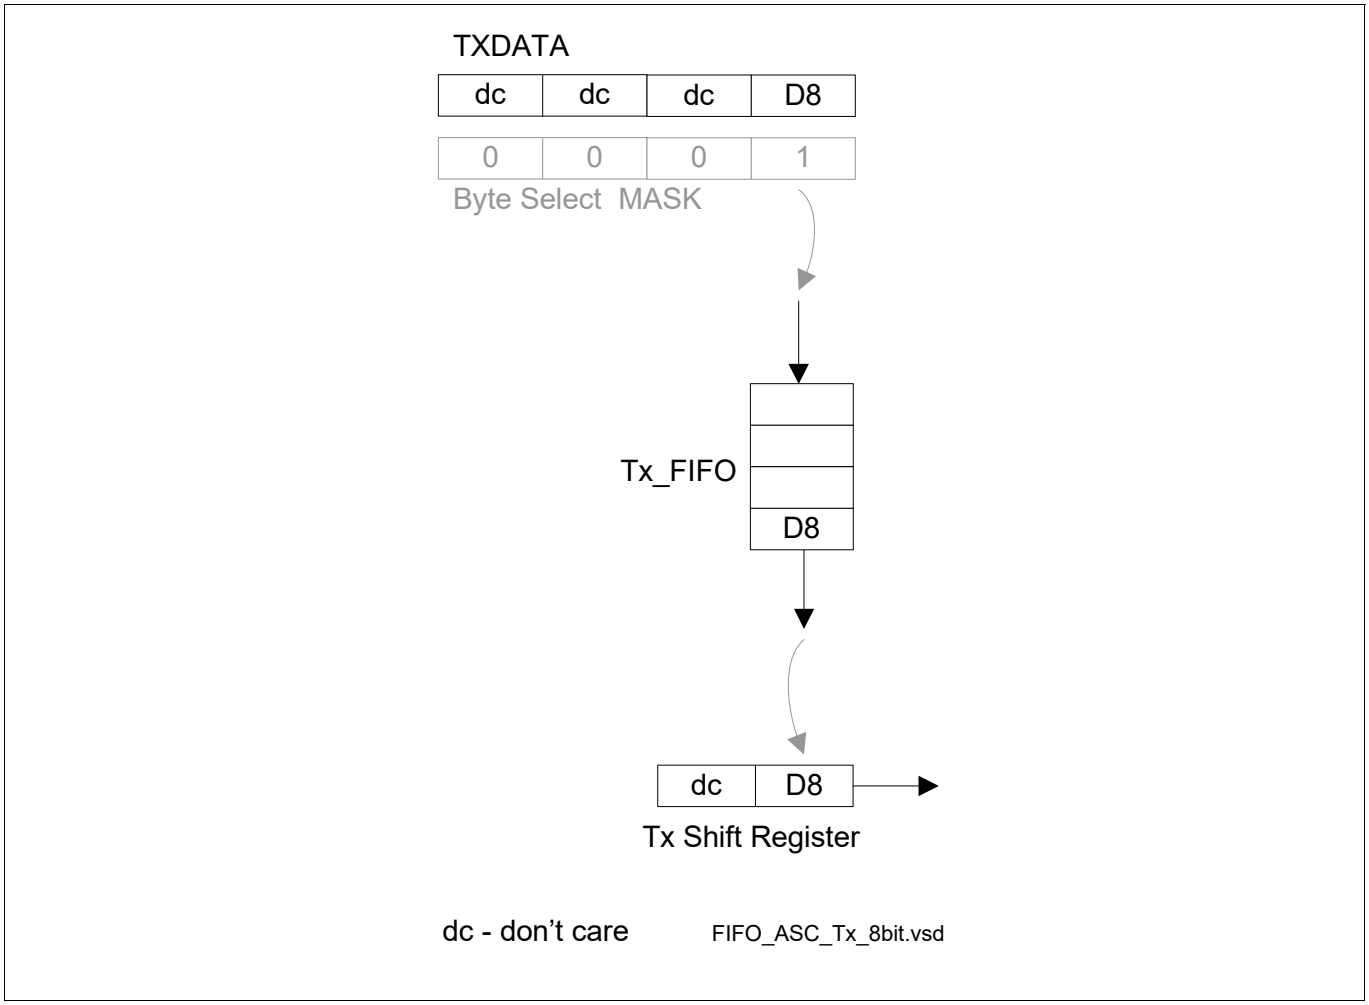

Figure 419 FIFO Operation in 7- or 8-Bit ASC Mode, with or without Parity

A less common mode of operation of the ASC module is to transmit 9-bit values, containing either 9-bit data or 8-bit data. The FPI bus access should be 16-bit wide, and there are BS0 and BS1 (Byte Select 0 and 1) signals active. The shift register is filled with two 8-bit values at the location read pointer and read pointer + 1.

The transmit data is written to the address TXDATA (**Transmit Data Register**).The Tx_Inlet_Width is 16-bit, and the Tx_Outlet_Width is 16-bit.

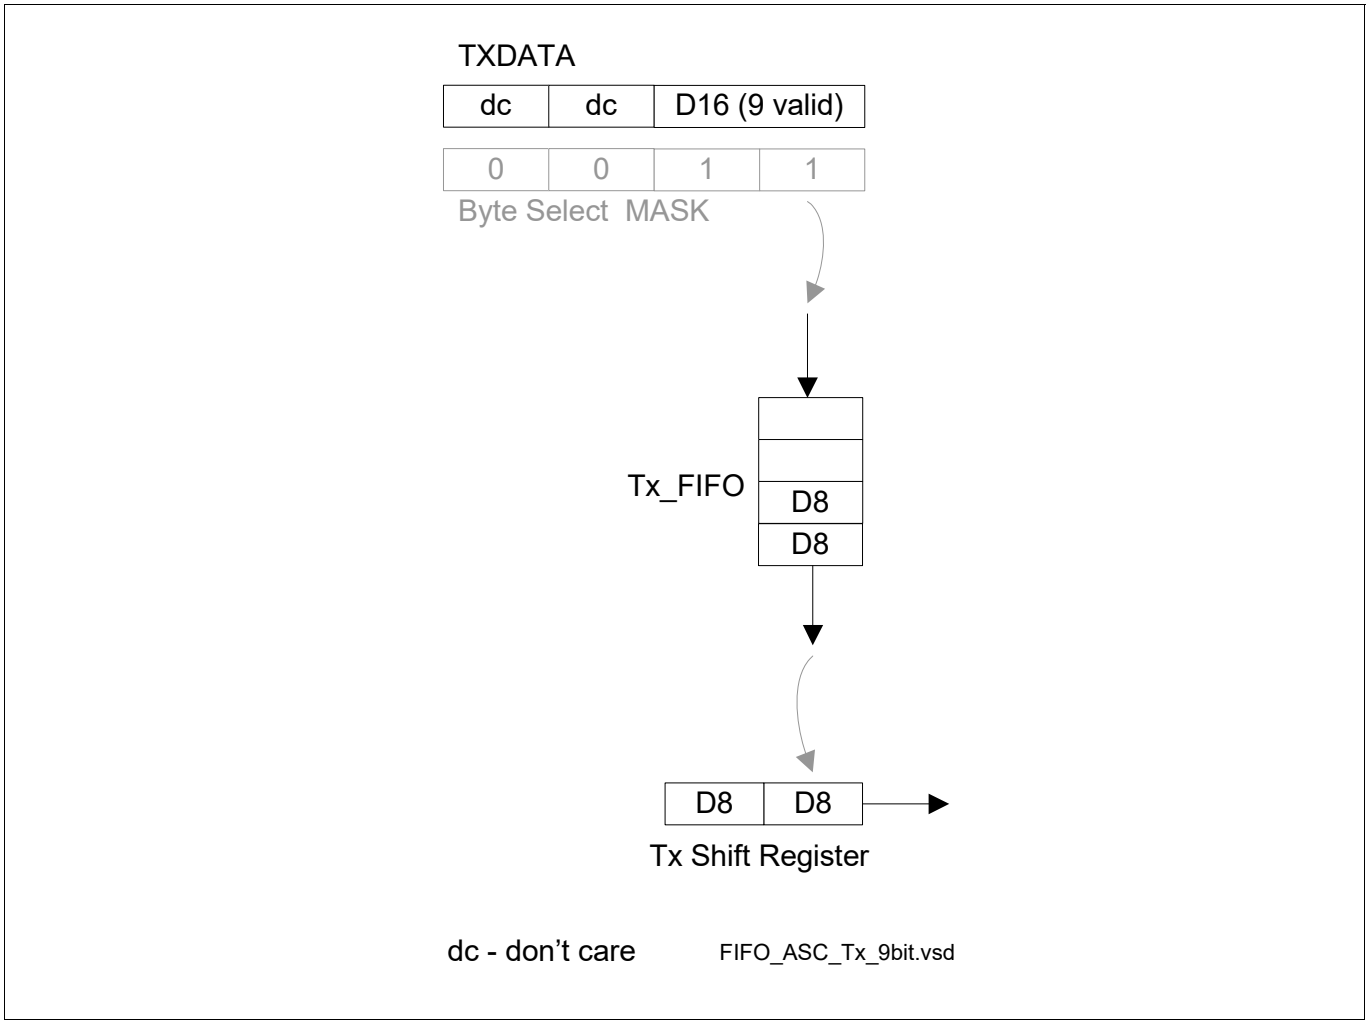

Figure 420 FIFO Operation in 9-Bit ASC Mode

36.3.2.2.2 High Speed ASC Mode

In order to reduce the FPI bus load by not using a 32-bit move for 7 or 8-bit values, one option is to fill the FIFO with 32-bit wide accesses containing four 8-bit wide values. All Byte Select signals BS[3:0] are active, and all four bytes are written in the TX FIFO in one cycle. At the same time, the write pointer of the TXFIFO jumps by the amount of four.

The transmit data is written to the address TXDATA (**Transmit Data Register**). The Tx_Inlet_Width is 32-bit, and the Tx_Outlet_Width is 8-bit.

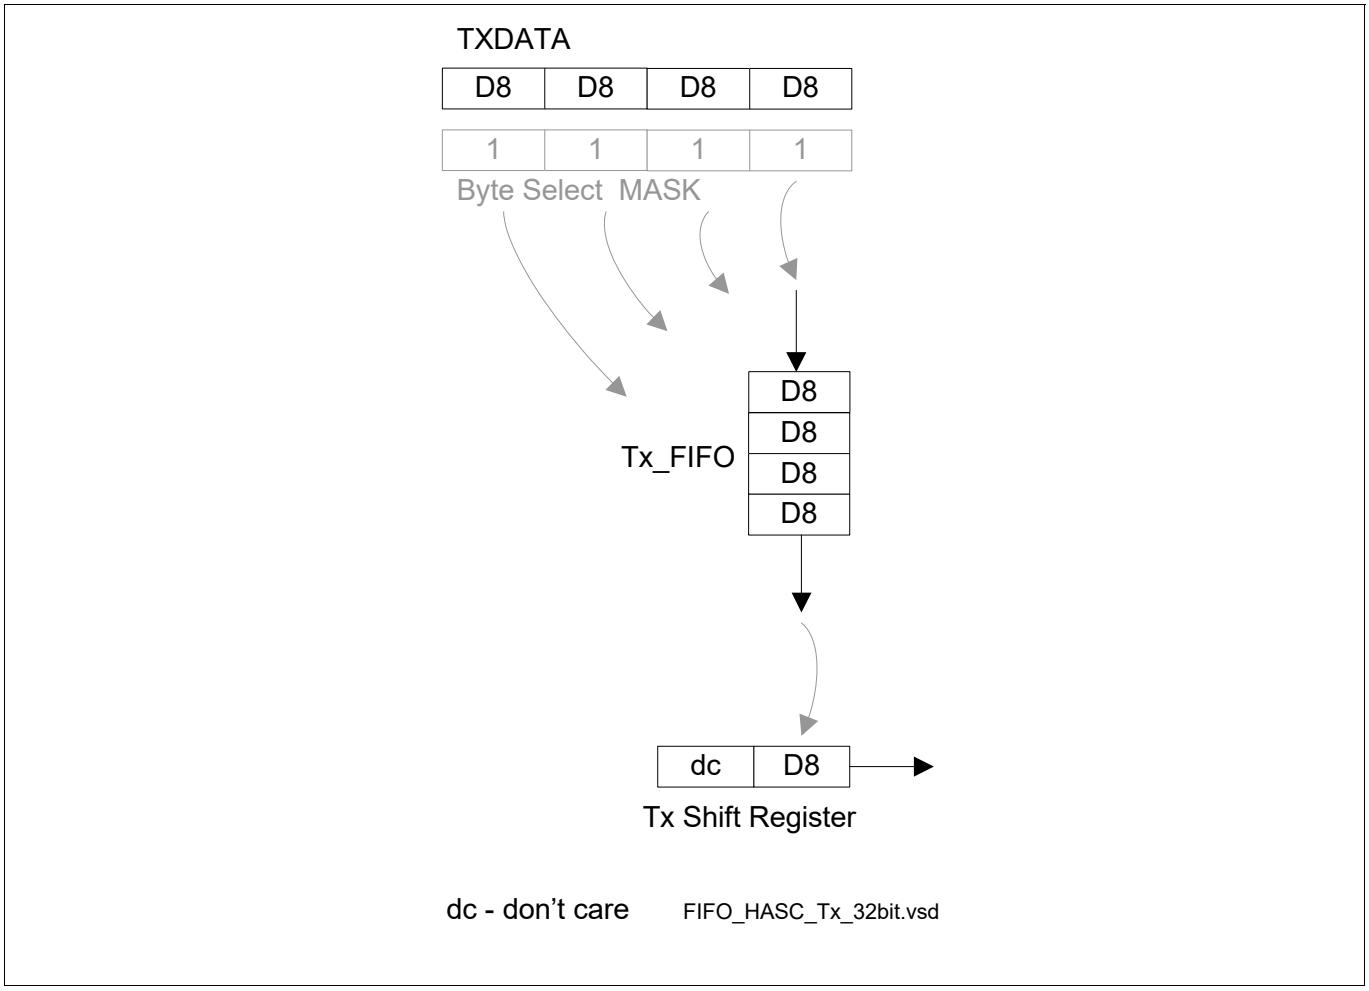

Figure 421 High-Speed Communication Scenario

36.3.2.2.3 LIN Mode

In LIN mode, several 8-bit frames are preceded by a low break pulse.

The generation of the break pulse is programmable with an 6 bit timer in units of bits, where the wide range of break pulses can be generated, for example in a range between 13 and 26 bits and beyond (up to 64 bits, but these lengths would violate the maximum LIN header length). The detection of the break pulse is programmable with an 8 bit timer in units of bits. Among others, the standard thresholds of 10 and 11 bit times can be set.

The pulse is generated by an module internal timer. The transmit sequence consists of filling the stopped TXFIFO (**Transmit Data Register**) with the appropriate bytes, and then starting the break pulse, which activates the TxFIFO.

The transmit data is written to the address TXDATA (**Transmit Data Register**). The Tx_Inlet_Width can be 8-bit (or 16-bit, or 32-bit), and the Tx_Outlet_Width is 8-bit.

36.3.2.2.4 SPI Mode

SPI mode is used most often to send or receive data of 8 or 16-bits length, or some length in between. Therefore the reading out of the Tx FIFO must be 8 or 16-bit wide, and write could be 16-bit wide, or even 32-bit wide if two frames are packed in one FPI bus access.

The transmit data is written to the address TXDATA (**Transmit Data Register**). The Tx_Inlet_Width is up to 32-bit, and the Tx_Outlet_Width is up to 16-bit.

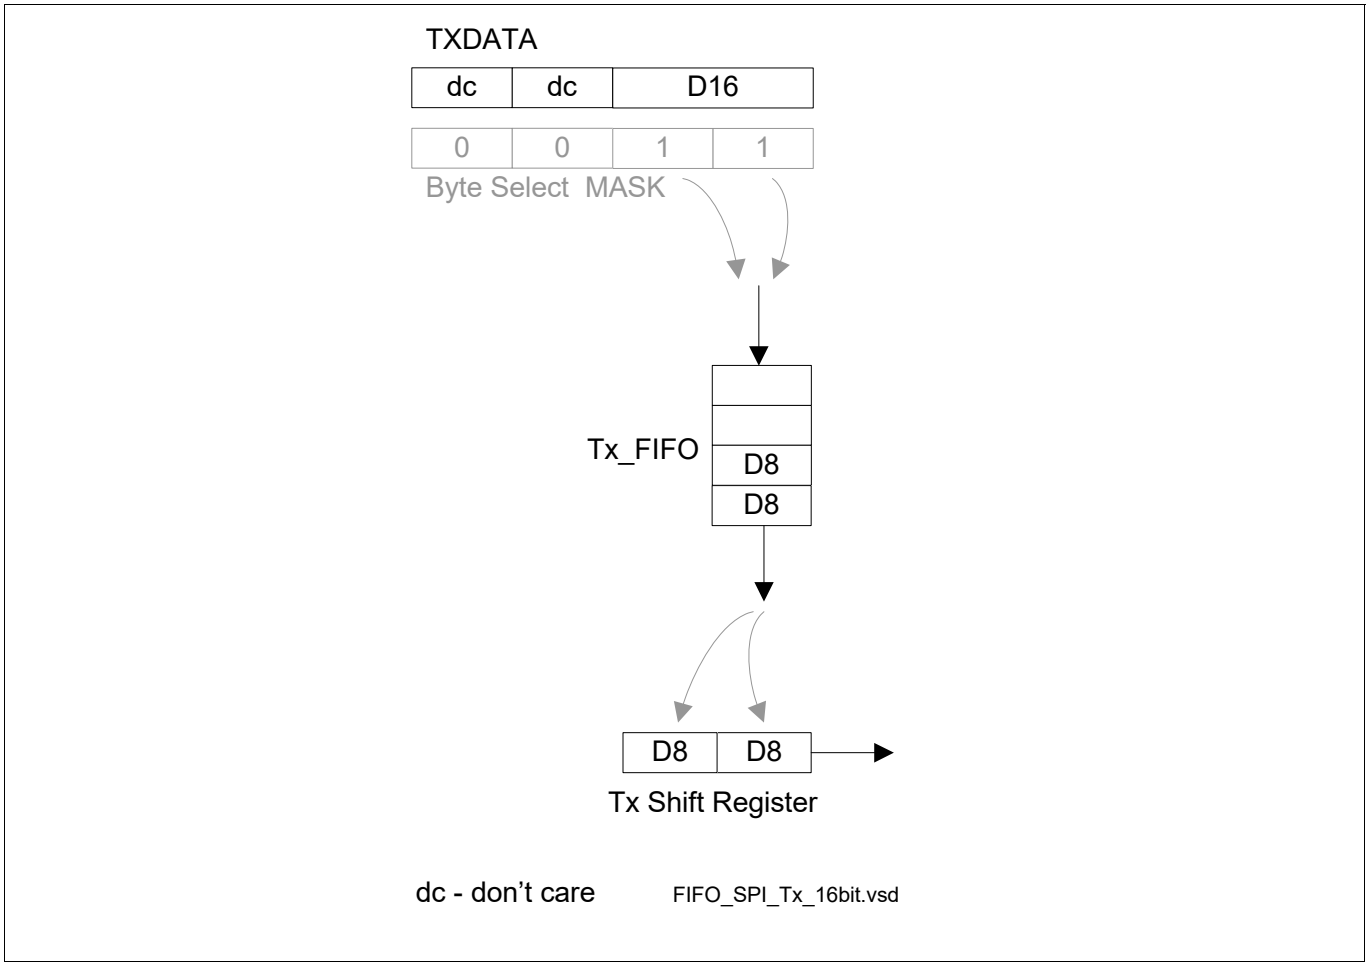

Figure 422 TXFIFO Operation in SPI Mode

36.3.2.3 TXFIFO Interrupt Generation

The TXFIFO provides three interrupt generation modes, selected by the bit-field TXFIFOCON.FM (**TX FIFO Configuration Register**):

- Single Move Mode
- Batch Move Mode
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single Move Mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

The single move mode supports primarily a DMA operation using single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available.

If the write:

- makes the TXFIFO full (no more empty elements), or
- the next write would make the TXFIFO overflow taking TXFIFOCON.INW (**TX FIFO Configuration Register**) into account

an interrupt is not generated in order to prevent overflow. It is generated later when the shift register reads one element from the TXFIFO, making it sufficiently not full to accept one INW wide element.

The **Figure 423**, shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

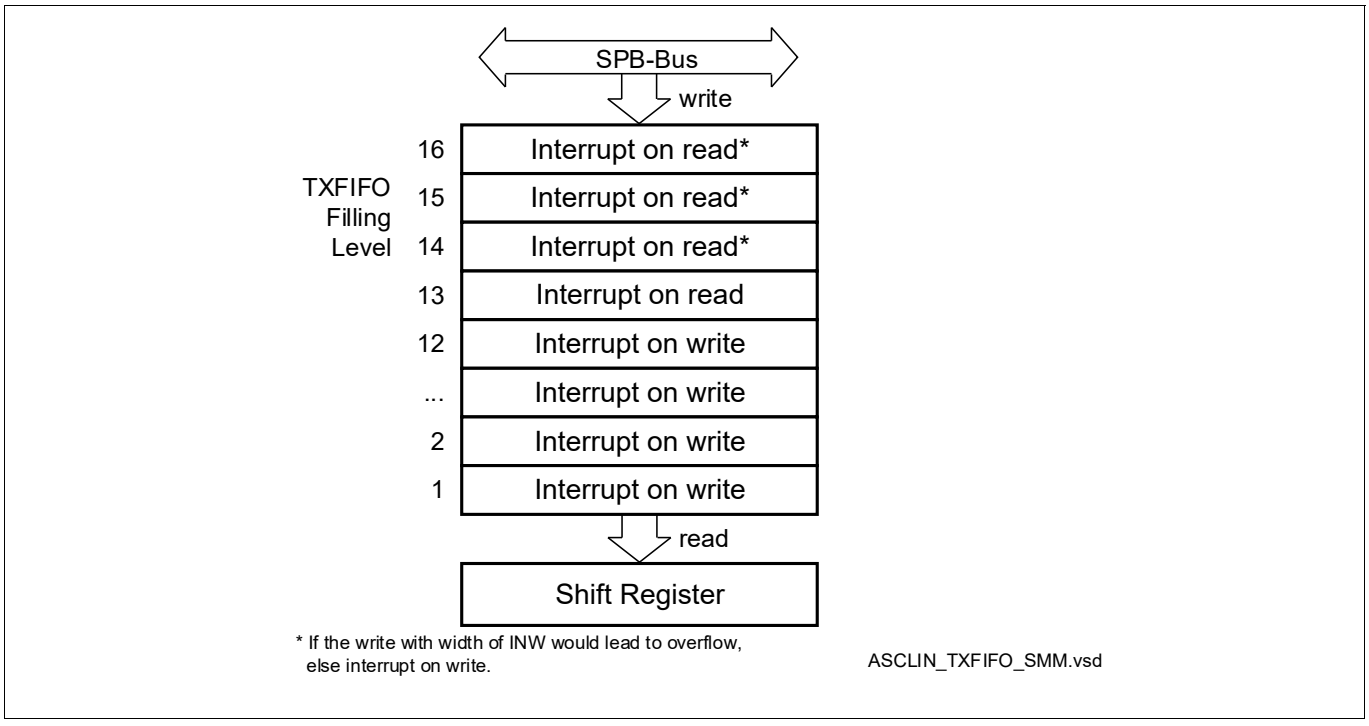

Figure 423 Interrupt Generation in the Single Move Mode

In order to initiate the very first interrupt in the chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TXFIFO or by setting the interrupt flag in the TXFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

Attention: ***In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used. In Single Move Mode, when the TXFIFO is almost full (the next write operation causes the TXFIFO full) or when the TXFIFO is full, a flush on TXFIFO will trigger an interrupt (FLAGS.TFL)***

Batch Move Mode

Batch Move Mode supports the following use case:

- CPU servicing the TXFIFO

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one TXFIFO elements are empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

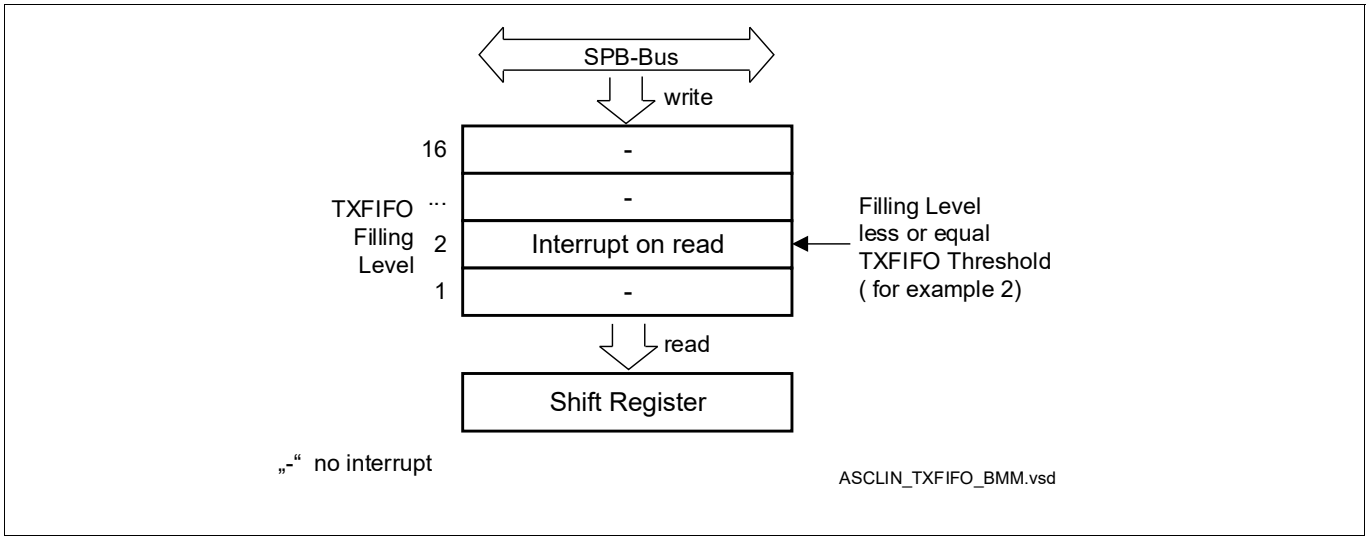

Figure 424 TXFIFO - Interrupt Generation in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls to or below the programmed threshold, as described in TXFIFOCON.INTLEVEL, implying that there are at least the predefined number of empty TXFIFO elements available.

Attention: ***The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.***

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted, the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Combined (Compatibility) Mode

An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO, as defined in the TXFIFOCON.INTLEVEL (**TX FIFO Configuration Register**). This is the mode which is compatible with the previous versions of the ASCLIN module and described in the TXFIFOCON.INTLEVEL bit field.

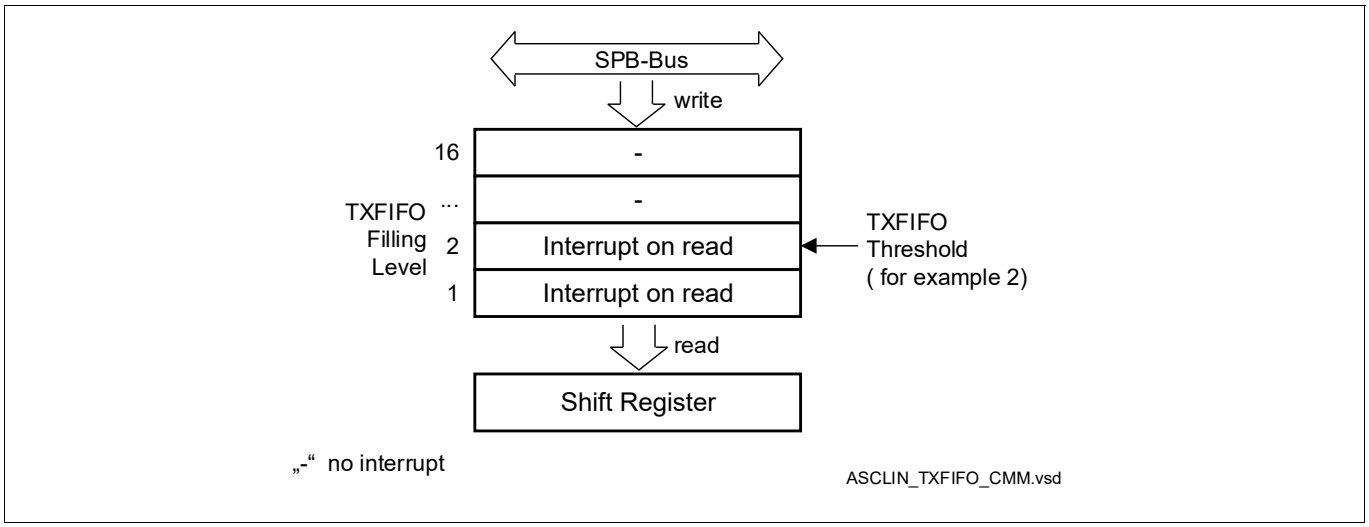

Figure 425 TXFIFO - Interrupt Generation in the Combined Mode

36.3.2.4 RxFIFO Overview

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus. It also has the ability to pack four up-to-8-bit or two up-to-16-bit frames to one 32-bit write to the FPI bus.

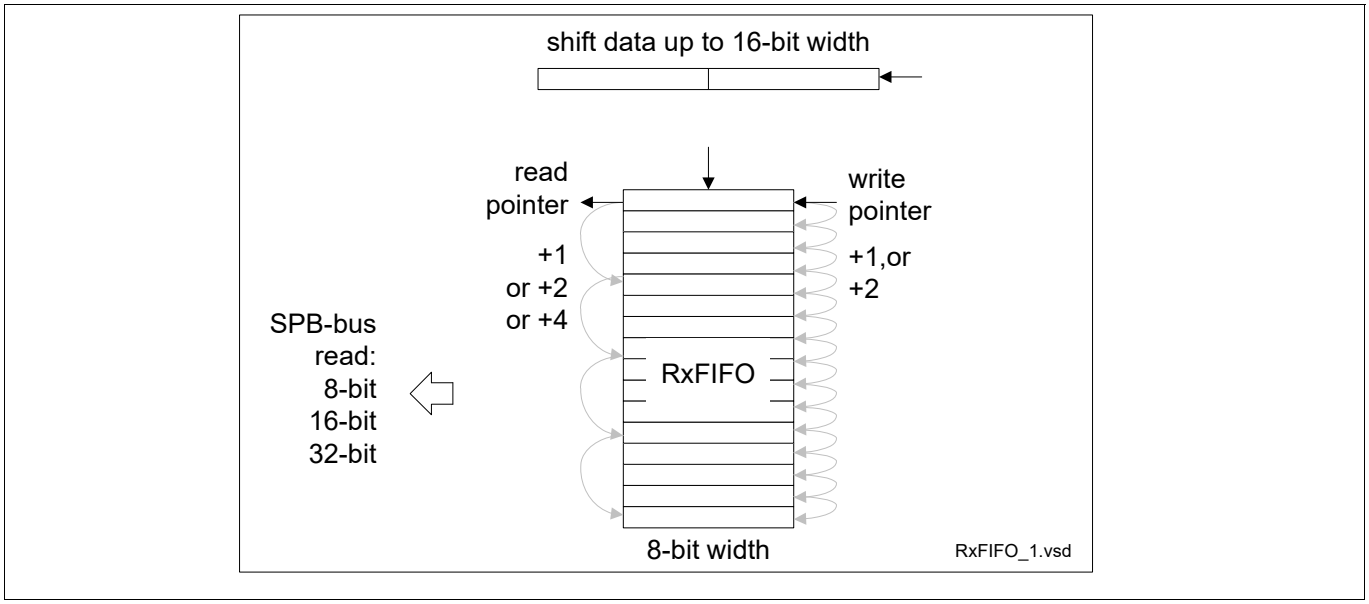

Figure 426 RXFIFO Overview

The number of bytes taken out of the RxFIFO is always RXFIFOCON.OUTW (**RX FIFO Configuration Register**), does not depend on the SPB bus read width, which should be normally equal to OUTW.

If the SPB read width is shorter than the OUTW, then the excessive part is lost.

If the SPB read width is longer than the OUTW, then the missing part is padded with zeros.

On the shift register side, the RxFIFO is always filled with a number of bytes as needed for the data width field DATCON.DATLEN (**Data Configuration Register**).

The table **Outlet Width versus SPB Read Width** describes all the possible combinations. The bytes in the RxFIFO are named A, B, C and D, A being the first one to take out. The padding byte is 0.

*Note: In case of an underflow, i.e. when a read access is performed to RXDATA (**Receive Data Register**) and the number of bytes to be taken out of the FIFO as given by the setting of RXFIFOCON.OUTW (**RX FIFO Configuration Register**) exceeds the number of bytes that are actually stored in the FIFO, as indicated by RXFIFOCON.FILL, then the RXFIFO delivers the available data padded with zeros up to the read access width. However, the data remain in the FIFO and the filling level RXFIFOCON.FILL is not changed. To remove the data, the user software must flush the RXFIFO. The bit FLAGS.RFU (**Flags Register**) is set.*

Table 325 Outlet Width versus SPB Read Width

SPB-Read Data, taken from the RxFIFO		SPB Bus Read Width		
		8-Bit	**16-Bit**	**32-Bit**
Outlet Width OUTW	**8-Bit**	A	0A	000A
	16-Bit	A	BA	00BA
	32-Bit	A	BA	DCBA

36.3.2.5 Using the RxFIFO

36.3.2.5.1 Standard ASC Mode

The received data is read from the address RXDATA (**Receive Data Register**).

In case of data width of 7 or 8 bits, one read on this address delivers one byte and empties the FIFO for one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

In case of data width of 9 bits, one read on this address delivers two byte and empties the FIFO for two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

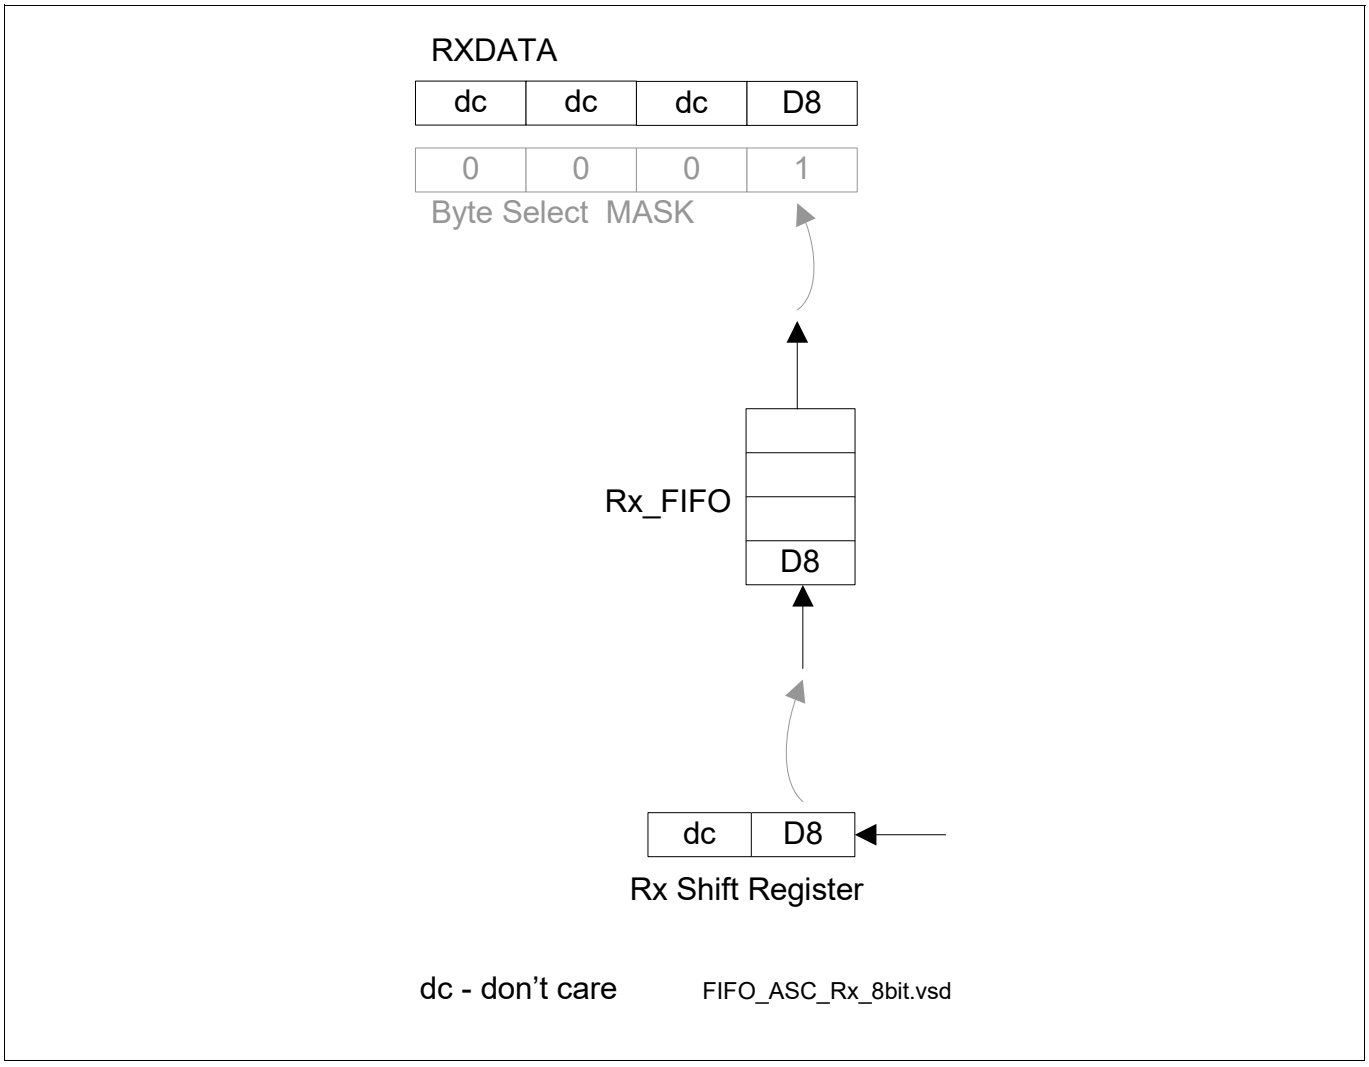

Figure 427 8-Bit ASC Reception

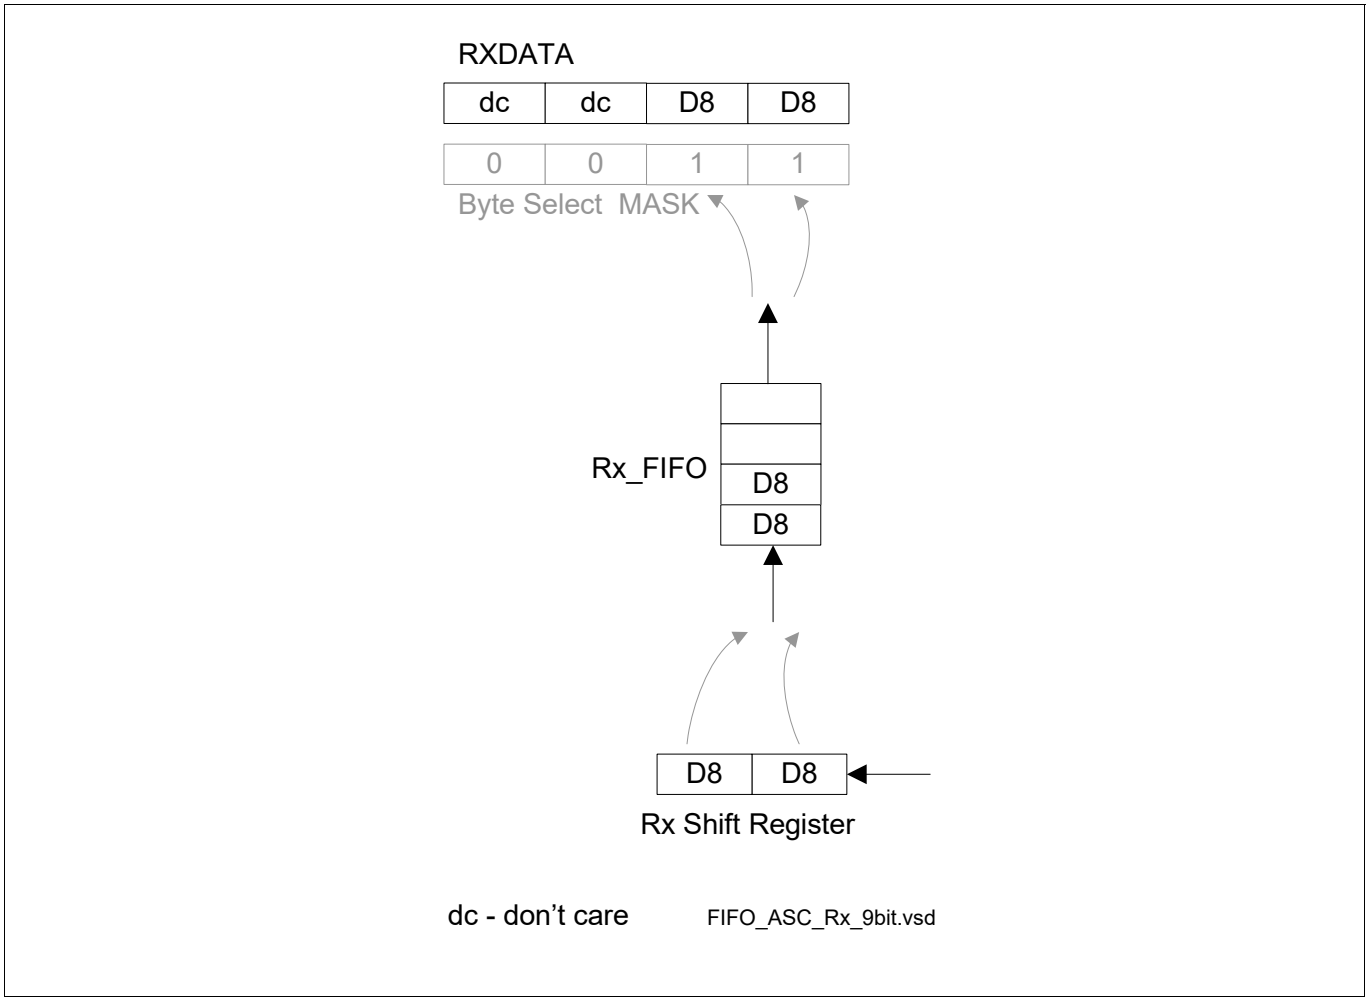

Figure 428 9-Bit ASC Reception

36.3.2.5.2 High Speed ASC Mode

The received data is read from the address RXDATA (**Receive Data Register**).

In case of data width of 7 or 8 bits, one read on this address can deliver (one or two or) four bytes and empties the FIFO by four elements, if the Rx_Outlet_Width is 32-bit. The Rx_Inlet_Width is 8-bit.

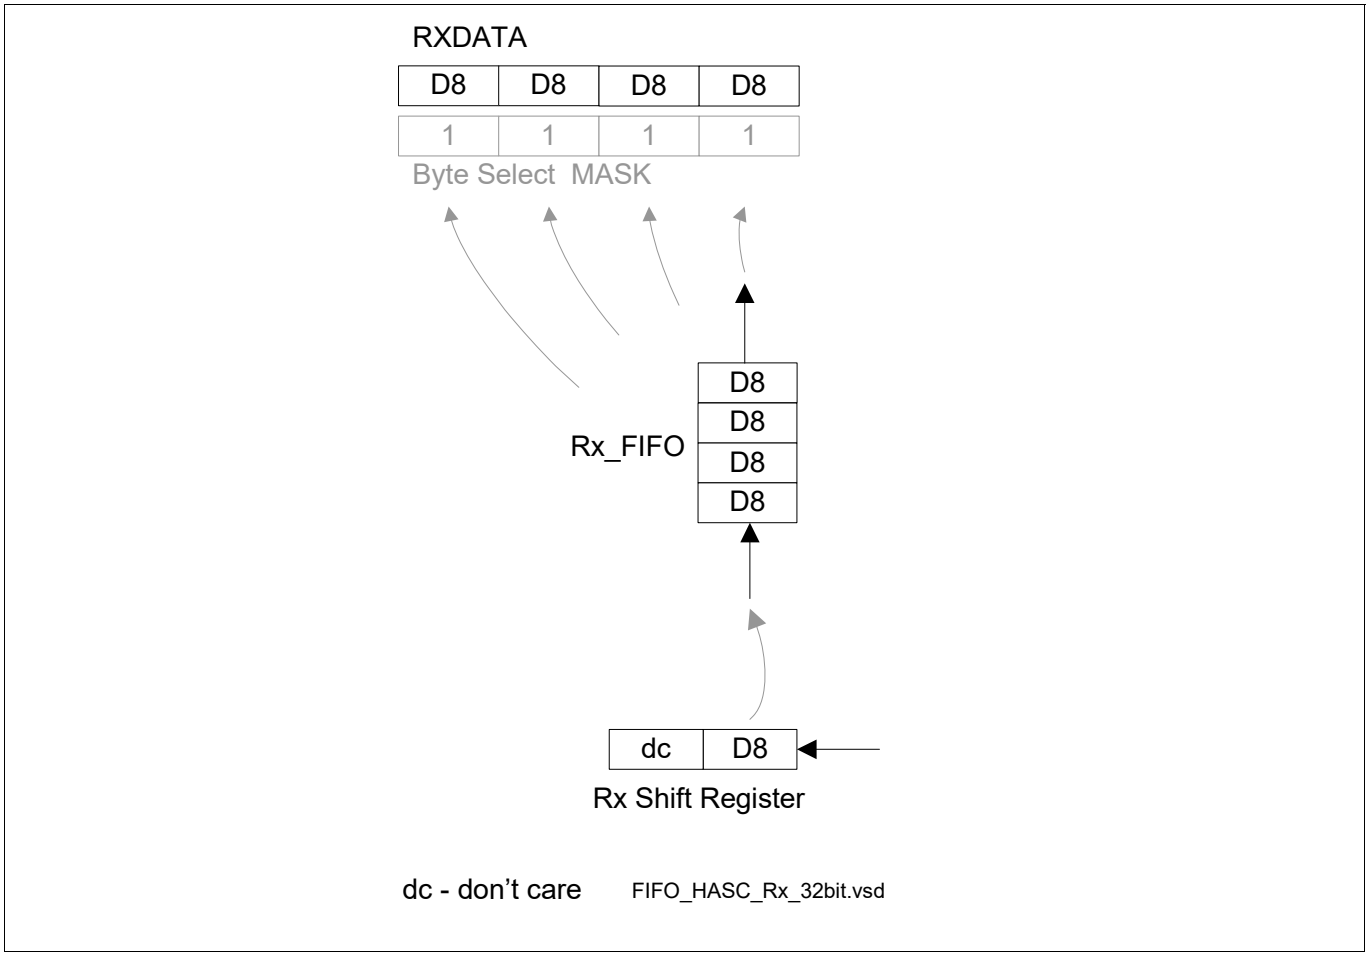

Figure 429 High Speed ASC Communication

36.3.2.5.3 LIN Mode

The received data is read from the address RXDATA (**Receive Data Register**).

The read data width is 8 bits (or 16 bit or 32 bit), one read on this address delivers one byte and empties the FIFO by one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit

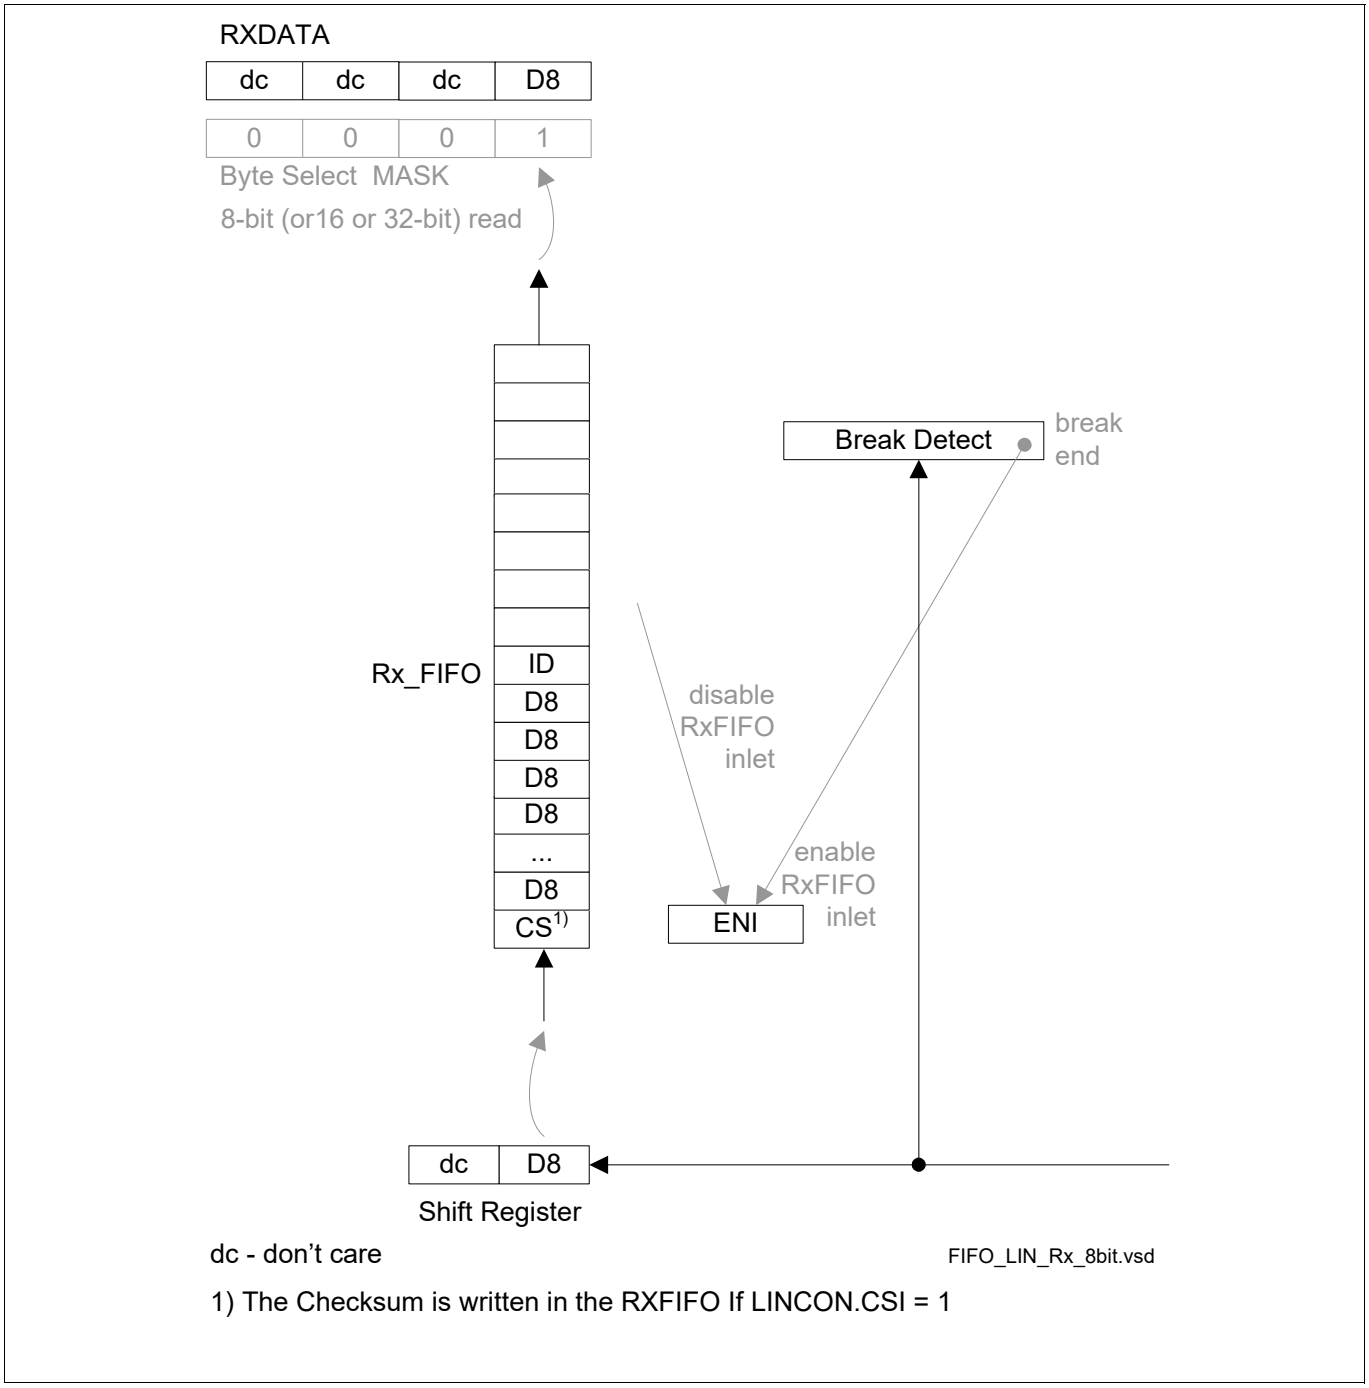

Figure 430 RXFIFO Operation in LIN Mode

36.3.2.5.4 SPI Mode

The received data is read from the address RXDATA (**Receive Data Register**).

In case of data width of 16 bits, one read on this address delivers two bytes and empties the FIFO by two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit

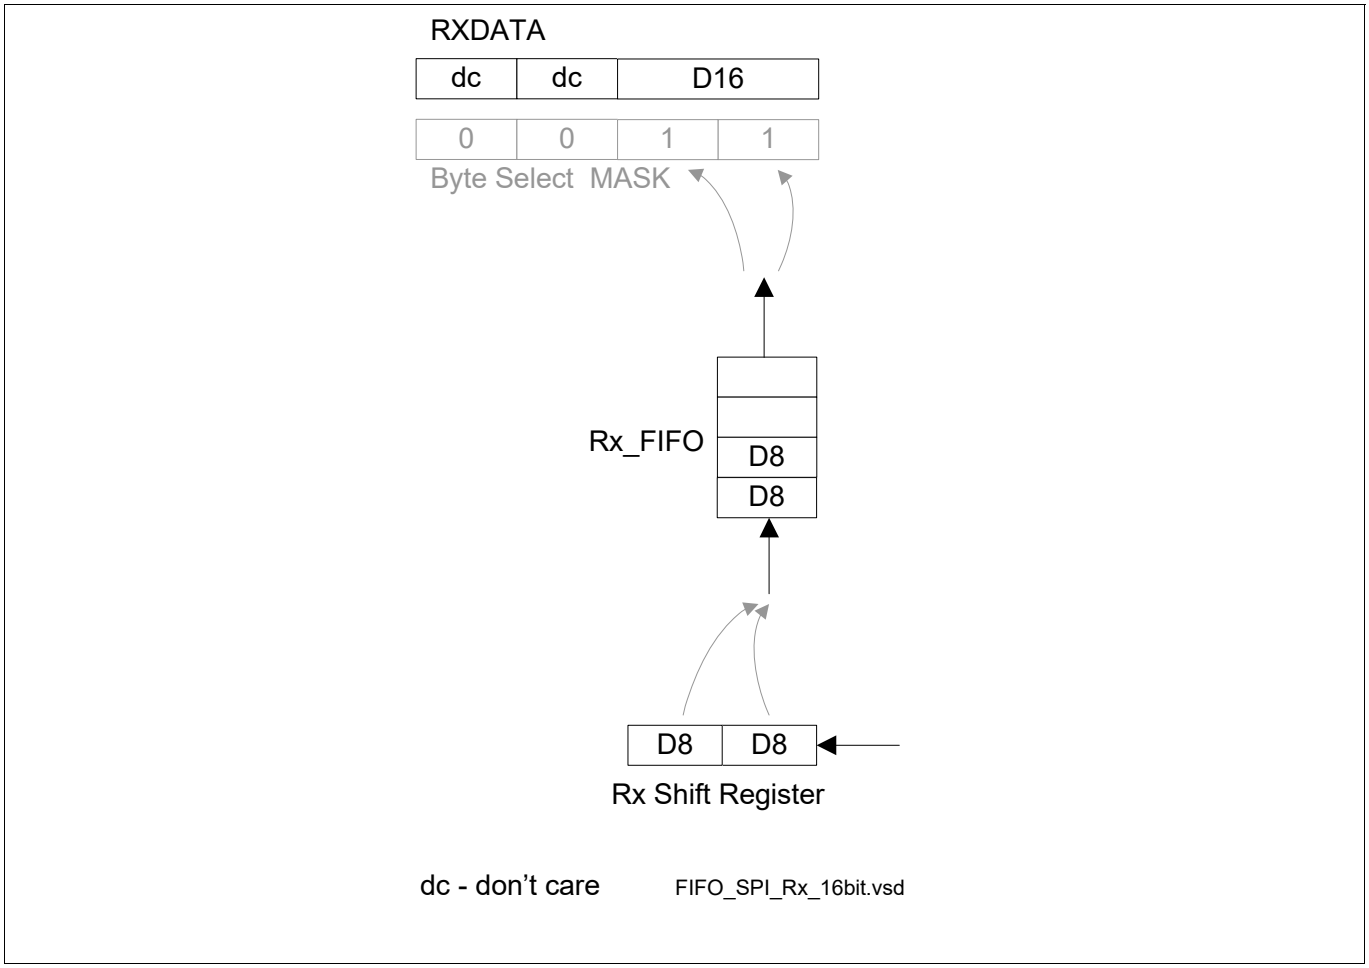

Figure 431 RXFIFO Operation in SPI Mode

36.3.2.6 RTS / CTS Handshaking

A receiver deactivates the RTS (Request to Send) output signal when the RXFIFO is almost full, in order to avoid its overload. When the emptying of the RXFIFO starts, for example by a DMA, and the filling level falls below the threshold level, the RTS output is activated again. The threshold level is fixed to RXFIFO size minus four, in order to support byte, two bytes and four bytes DMA transfers.

The transmitter receives the RTS output of the receiver on its CTS input and accordingly pauses and resumes the transmission.

36.3.2.7 RXFIFO Interrupt Generation

The RXFIFO provides three interrupt generation modes, selected by the bit field RXFIFOCON.FM (**RX FIFO Configuration Register**):

- Single Move Mode
- Batch Move Mode
- Combined (Compatibility) Mode

Single Move Mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

The single move mode supports primarily a DMA operation using single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty.

If the read:

- makes the RXFIFO empty, or
- the next read would make the RXFIFO underflow taking RXFIFOCON.OUTW (**RX FIFO Configuration Register**) into account

an interrupt is not generated in order to prevent underflow. It is generated later when the shift register writes one element to the RXFIFO, making it sufficiently full to provide one OUTW wide element.

The **Figure 432**, shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

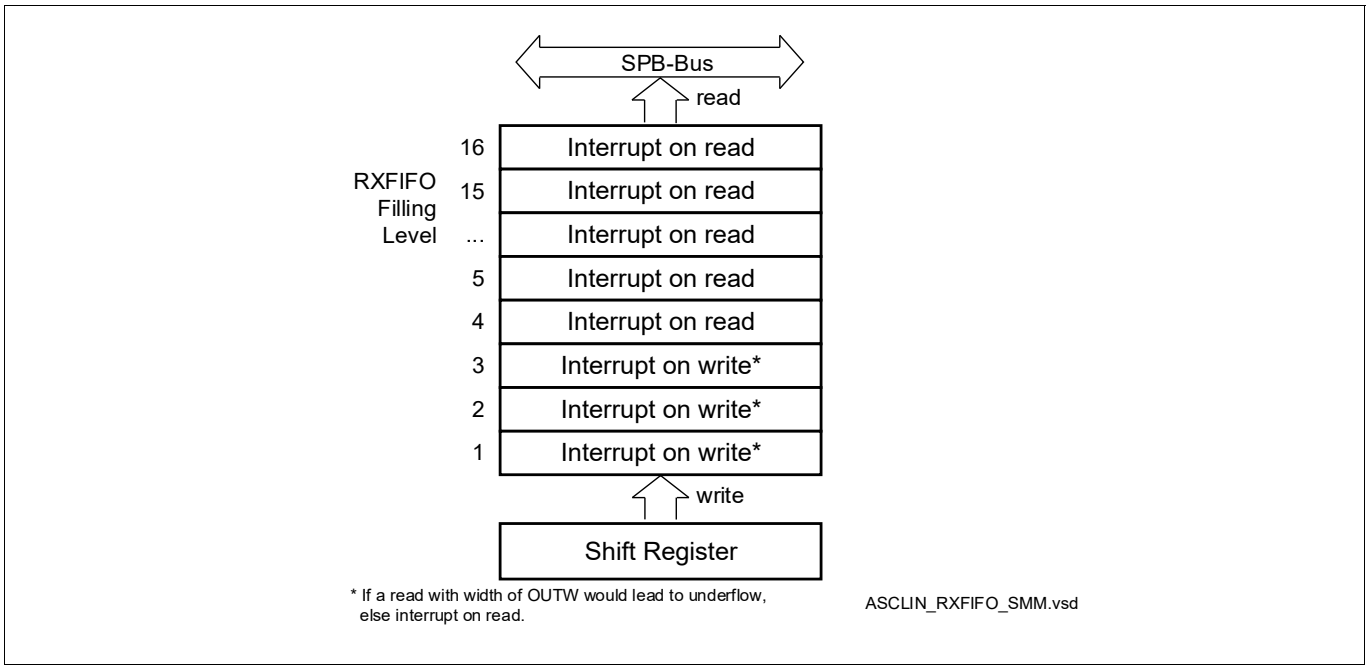

Figure 432 RXFIFO - Interrupt Triggering in the Single Move Mode

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of re-fetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention: ***In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.***

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one RXFIFO elements are full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

Batch Move Mode supports the following use case:

- CPU servicing the RXFIFO

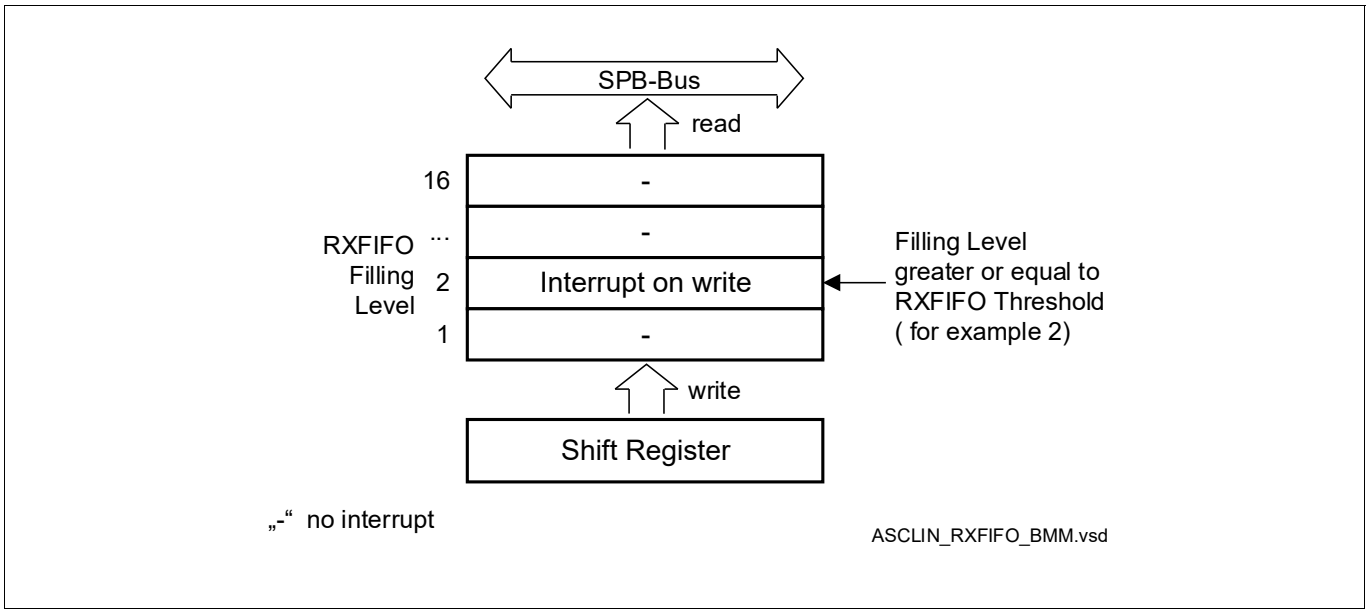

Figure 433 RXFIFO - Interrupt Triggering in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the RXFIFO, when the filling level rises to or above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available. The description refers to the interpreted value of RXFIFOCON.INTLEVEL (register value +1) (**RX FIFO Configuration Register**).

Attention: ***It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.***

At high baud rates and short frames, it could be possible that more than one frames have been received until the moment the RXFIFO is re-emptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames have been received, the RXFIFO will become full, and re-empty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect can not occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Combined (Compatibility) Mode

An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO, as defined in the RXFIFOCON.INTLEVEL (**RX FIFO Configuration Register**). The description refers to the interpreted value of RXFIFOCON.INTLEVEL (register value +1). This is the mode which is compatible with the previous versions of the ASCLIN module and described in the RXFIFOCON.INTLEVEL bit field.

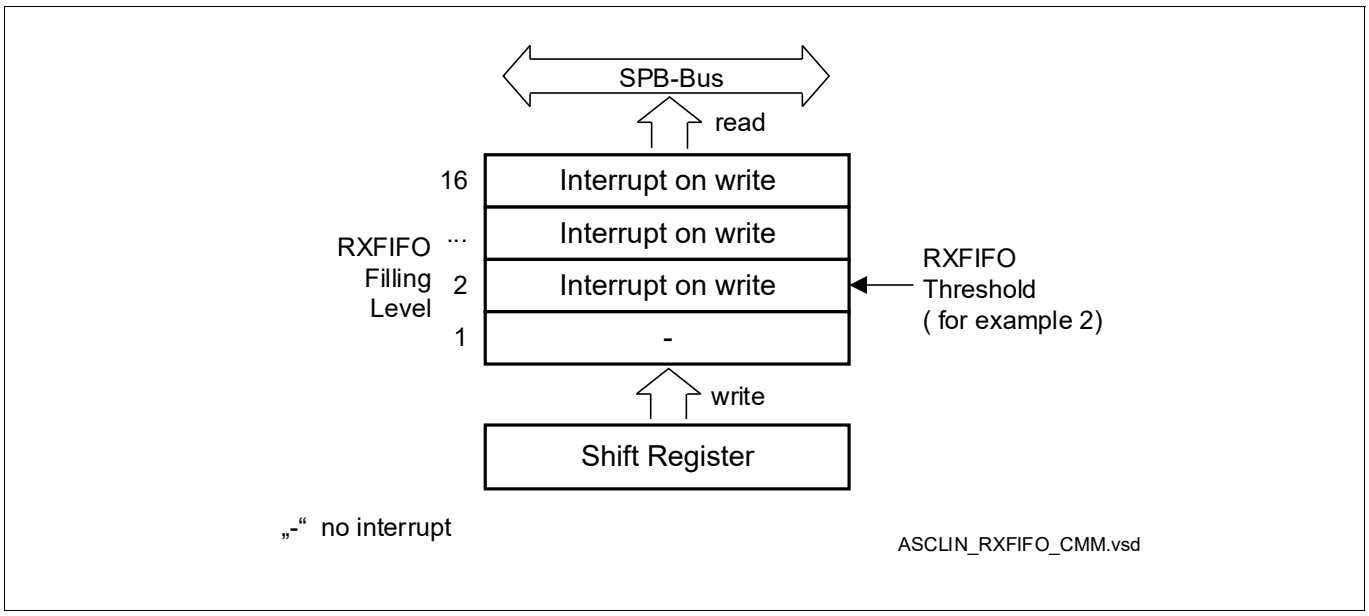

Figure 434 RXFIFO - Interrupt Triggering in the Combined Mode

36.3.3 Clock System

The clock system generates all the clocks needed for the proper operation of the ASCLIN module: digital filter clock, oversampling clock, bit time and serial SPI clock.

The clock used for the clock system f_A is independent from the SPB bus clock and remains constant if the SPB bus clock changes, for example in power saving scenarios. The bit field CSR.CLKSEL (**Clock Selection Register**) selects the clock source for the f_A frequency, which can be synchronous or asynchronous, higher or lower than the SPB bus frequency.

36.3.3.1 Baud Rate Generation

Fractional Divider, n-divider and oversampling divider with configurable sample point.

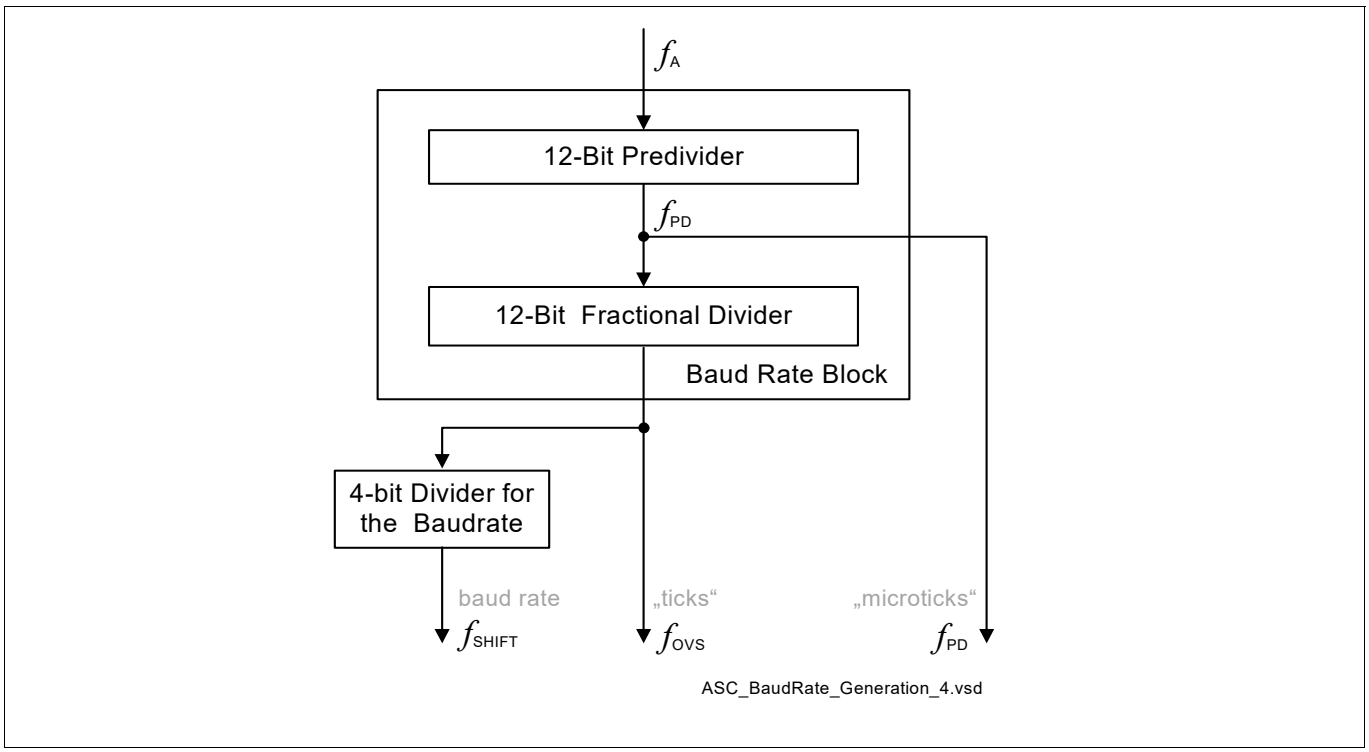

Figure 435 Baud Rate Generation

The following bit fields are available for configuring of the 28-bit baud rate divider chain:

- BITCON.PRESCALER (**Bit Configuration Register**) - the division ratio of the pre-divider
- BRG.NUMERATOR (**Baud Rate Generation Register**) - the numerator of the fractional divider
- BRG.DENOMINATOR (**Baud Rate Generation Register**) - the denominator of the fractional divider
- BITCON.OVERSAMPLING (**Bit Configuration Register**) - the division ratio of the baudrate post divider

The chain of the generated frequencies from f_A down to the f_{SHIFT} (the baudrate) is calculated as follows:

$f_{PD} = f_A$ / (BITCON.PRESCALER + 1)

$f_{OVS} = f_{PD}$ * BRG.NUMERATOR / BRG.DENOMINATOR,

$f_{SHIFT} = f_{OVS}$ / (BITCON.OVERSAMPLING + 1)

*Note: Fractional division requires that BRG.NUMERATOR is less or equal than the BRG.DENOMINATOR. (**Baud Rate Generation Register**)*

The overall formula is given as follows:

$$BAUDRATE = \frac{f_A \times NUMERATOR}{(PRESCALER + 1) \times DENOMINATOR \times (OVERSAMPLING + 1)} \quad (36.1)$$

36.3.3.2 Bit Timing Properties

The ASCLIN module provides flexible programming of the bit oversampling, sampling point and input signal filtering properties.

The oversampling factor for the incoming bit-stream is configurable from 4 to 16 ticks (or time quanta) per bit.

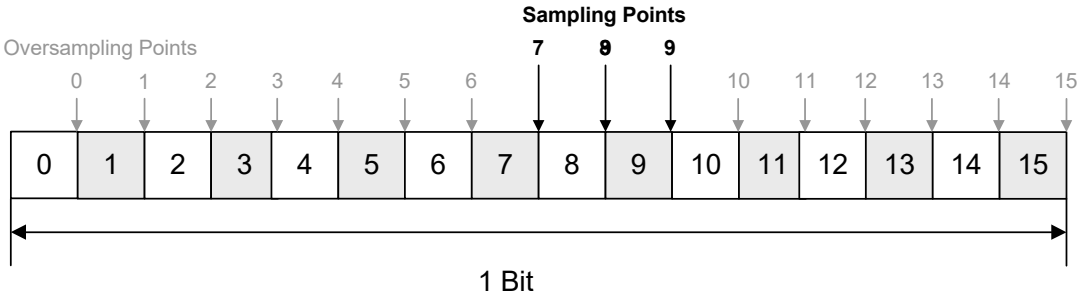
At the same time, using the oversampling frequency, a digital median filter can be enabled to filter the incoming bit stream. The filtering uses the standard majority out of three procedure. If the filter is disabled, then each bit is sampled only once.

The sampling point is also configurable and should be used in conjunction with the oversampling factor. One standard setting is 16x oversampling and using the samples 7, 8 and 9 for the data. Another possible setting could be 8x oversampling and using the samples 3, 4, and 5 for data.

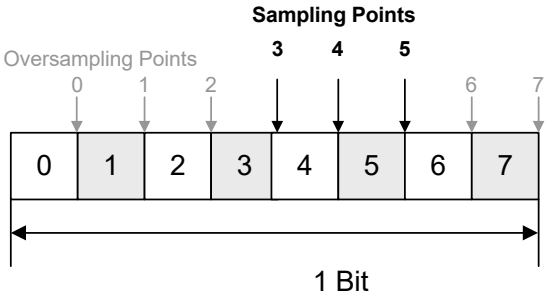
The following bitfields are available for configuring the bit properties:

- BITCON.PRESCALER (**Bit Configuration Register**) - the twelve bit integer divider defining the microtick used by the fractional divider to generate the baud rate, and by the digital filter for the de-glitching of the RX input signal.
- BITCON.SAMPLEPOINT (**Bit Configuration Register**) - the bit field defining the sampling point position, and the duty cycle in the SPI mode.
- BITCON.SM (**Bit Configuration Register**) - the bit enables the digital median filter (majority out of three): 1 or 3 samples per bit.
- IOCR.DEPTH (**Input and Output Control Register**) - the bitfield defining the floating average filter depth: off or 1 to 63 microticks
- BITCON.OVERSAMPLING (**Bit Configuration Register**) - the bitfield defining the number of ticks per bit, in the range of 4 to 16. This is a post-divider located after the fractional divider.

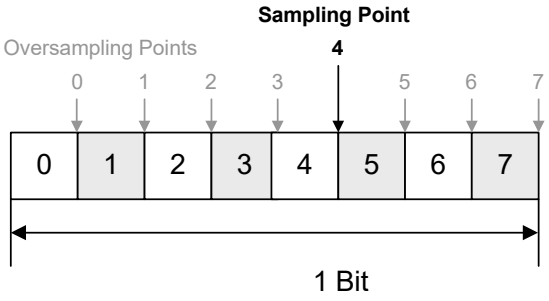
16x Oversampling, 3 sample points, relevant sample position 8



8x Oversampling, 3 sample points, relevant sample position 4



8x Oversampling, 1 sample point, relevant sample position 4



16x Oversampling, 1 sample point, relevant sample position 12

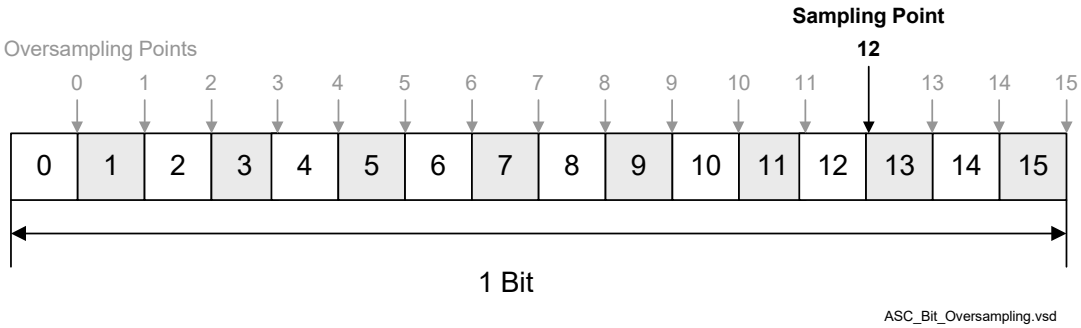


Figure 436 ASCLIN Bit Structure

Generally, the sampling point should be placed in the middle of the bit. This position is optimal in case the baud rate (the oscillator frequency) is not very precise and stable.

If the oscillator precision is very high, which is usually the case when two microcontrollers driven by quartz oscillators communicate, but the signal edges are very unsymmetrical, which is the case if open drain half-duplex connection is used, it can be of advantage to move the sample point somewhere in the second half of the bit. Open drain connection usually causes the “0” bits to be longer than the “1” bits. In such a case, optimizing the sampling point would mean placing it in the middle of the shorter “1” bit.

At the end, different combinations of oscillator precision, asymmetry of the edges, and loop-delays for collision detection result in different optimal positions of the sampling point.

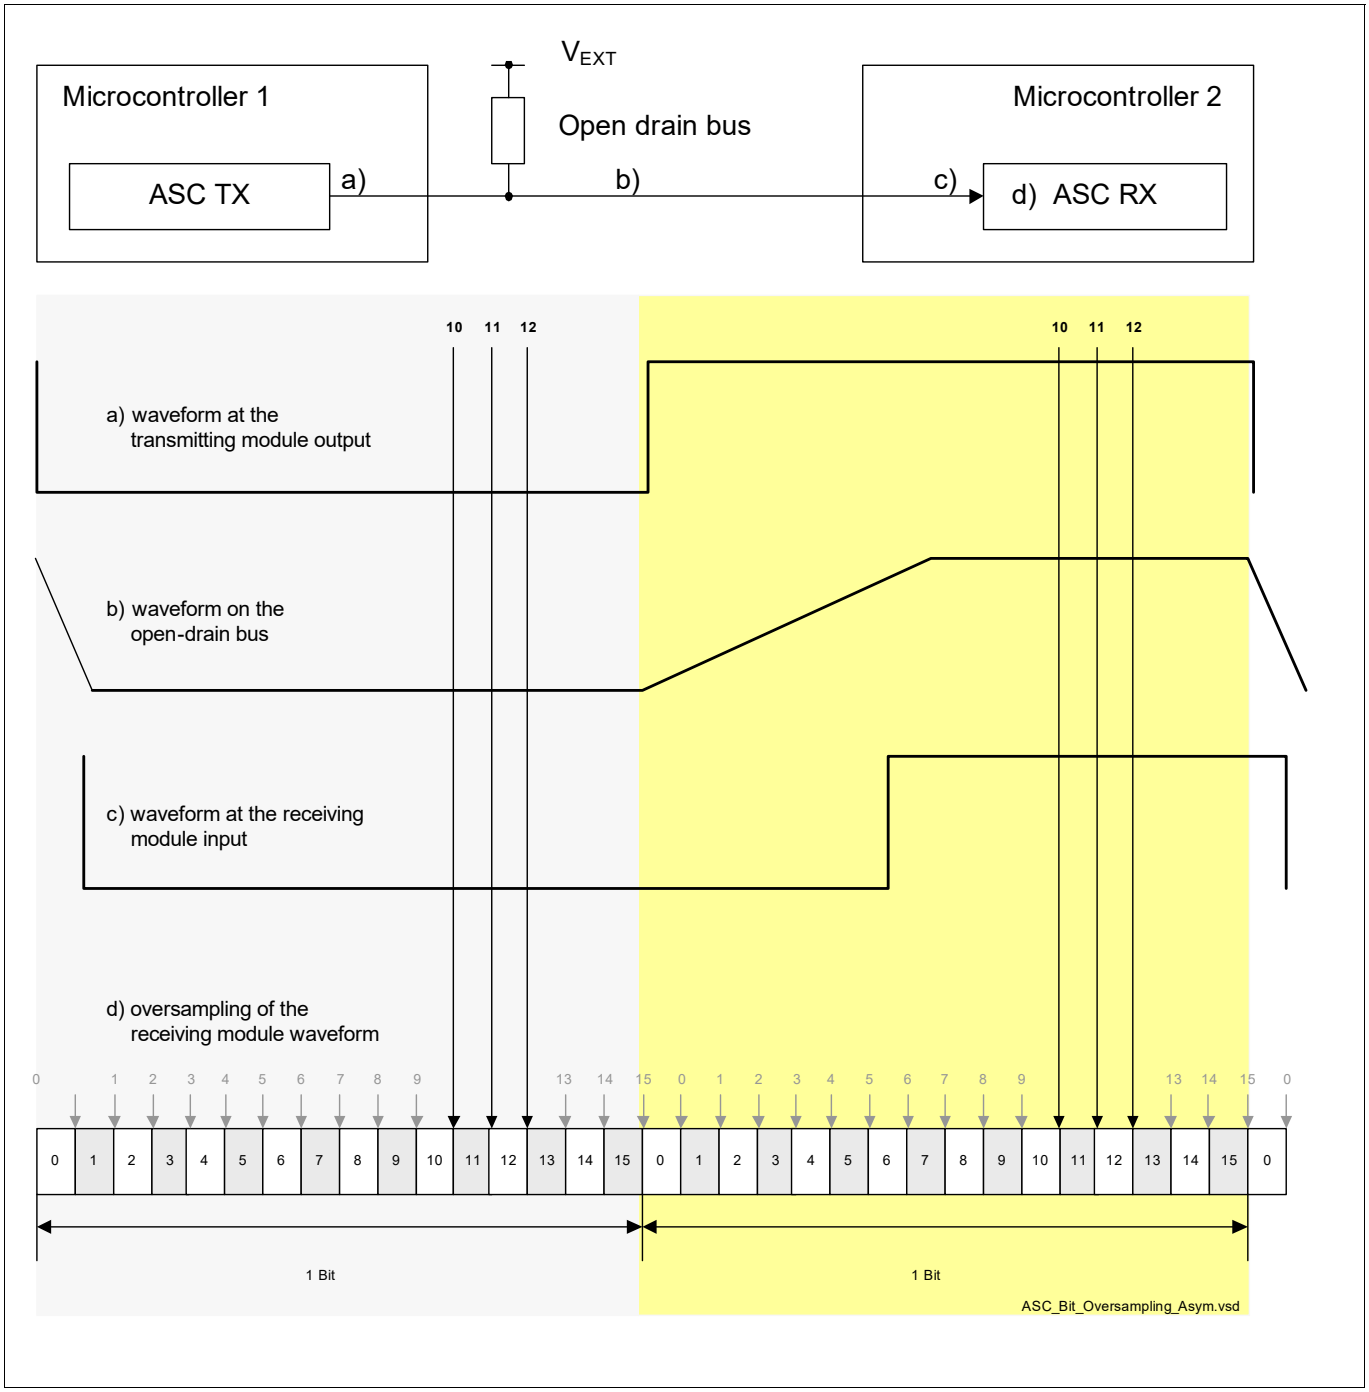

Figure 437 Bit Length Asymmetry and the Sampling Point

36.3.4 Data Frame Configuration

Applicable as transmitter and receiver, the parity scheme is configured in the bit fields FRAMECON.ODD (**Frame Control Register**), the data length in the bit fields DATCON.DATLEN (**Data Configuration Register**) and the stop bits in the bit fields FRAMECON.STOP.

36.3.5 Miscellaneous Configuration

Loop - back

36.3.6 Synchronous Mode

In synchronous mode the module supports the SPI setting of shift edge first, than the latch edge, see **Figure 438**. The module is set in synchronous mode by using the bit field FRAMECON.MODE (**Frame Control Register**).

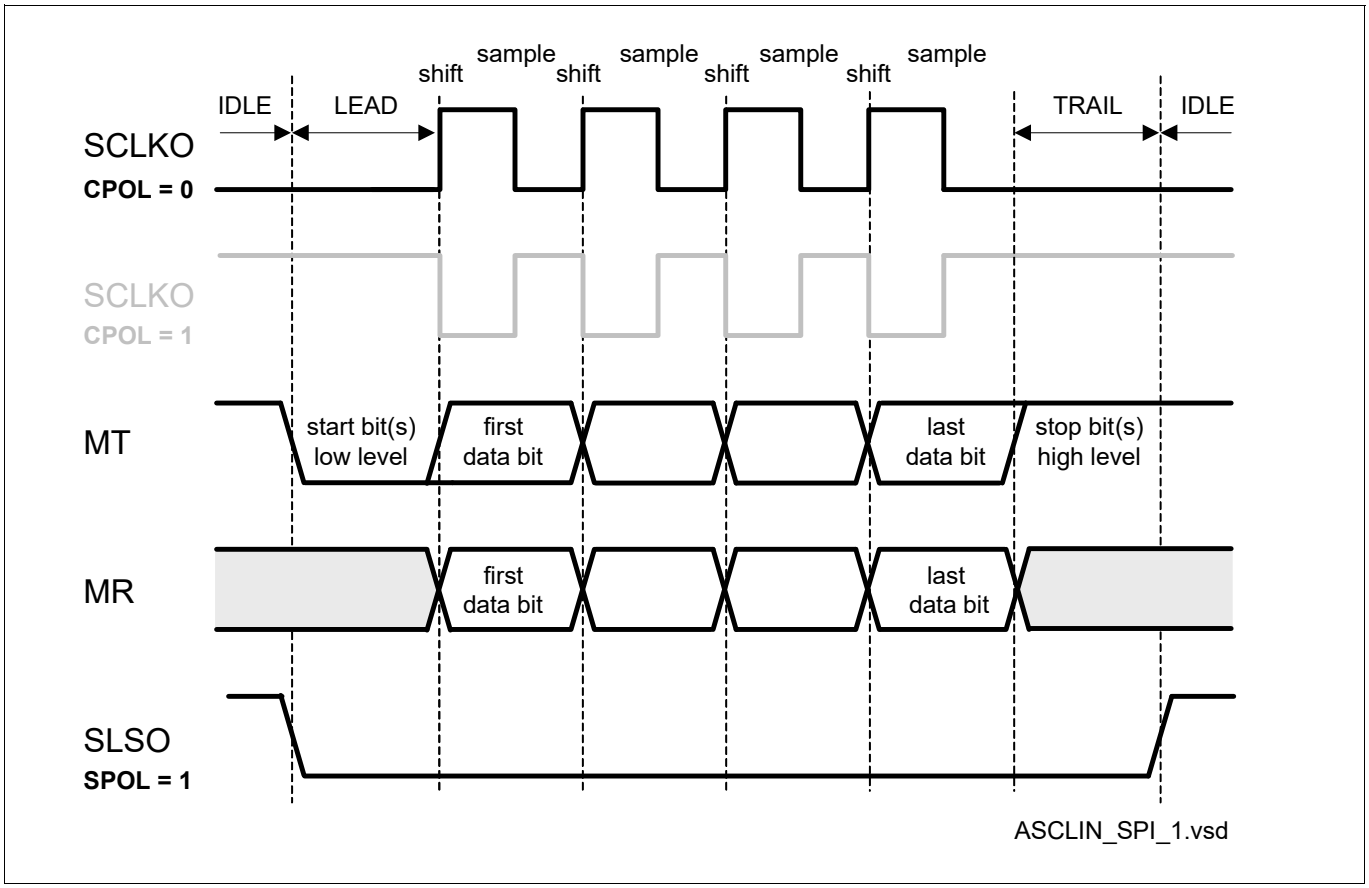

Figure 438 SPI Timing

36.3.6.1 Baud Rate and Clock Generation

The baud rate and clock generation in the synchronous mode uses generally the same counters and principles as in the asynchronous mode. It uses the same prescaler, fractional divider, and oversampling divider with configurable sample point. The only difference is that the shift clock is driven as output signal at the pin SCLKO. If a symmetrical shift clock is required, the oversampling ratio should be an even number, and the sampling point should be set to one half of the oversampling ratio (see the **Bit Configuration Register**).The clock polarity is configured in the bit IOCR.CPOL (**Input and Output Control Register**).

36.3.6.2 Data Frame Configuration

The leading and trailing delays are configured in the bit fields FRAMECON.LEAD (**Frame Control Register**) and FRAMECON.STOP. The IDLE phase duration is configured using the bit field FRAMECON.IDLE. The data length of 2 to 16 bit is defined in the bit field DATCON.DATLEN (**Data Configuration Register**).

36.3.6.3 Slave Selects Configuration

The SPI master activates automatically the slave select output signal for each data word. The polarity of the slave select can be configured by using IOCR.SPOL (**Input and Output Control Register**).

36.3.6.4 Miscellaneous Configuration

Loop - back

36.3.7 LIN Support

The ASCLIN module provides hardware support for the LIN protocol.

It supports all four elementary LIN transactions:

- TxH - Transmission of Header
- TxR - Transmission of Response
- RxH - Reception of Header
- RxR - Reception of Response

By supporting additionally the combinations of these elementary transactions, the module actually supports all LIN use cases: sending and receiving headers and responses as

- LIN master or
- LIN slave

A LIN master is engaged in three elementary transactions: TxH, TxR, RxR. It never engages in RxH, because a master never receives a header, it only transmits a header.

A LIN slave engages also in three elementary transactions: RxH, TxR, RxR. It never engages in TxH, because a slave never transmits a header, it only receives a header.

Each elementary transaction needs some hardware resources in order to be completed with minimum CPU intervention. Here is a list of tasks per transaction, supported by hardware, and the required hardware resources:

- TxH - Transmission of Header - master mode only
  - Break generation: 6-bit bit-field defining the break length in units of bits
  - Sync-field generation: hard coded 55H byte
  - ID transmission with interrupt generation
- TxR - Transmission of Response - master and slave mode
  - Number of bytes parameter: bit-field of length 4
  - Checksum generation: hardware engine, supporting classic and enhanced checksum, which can be enabled or disabled
- RxH - Reception of Header - slave mode only
  - Optional auto-baud detection: fractional divider with programmable nominator and denominator
  - Number of bytes parameter: bit-field of length 4
  - Interrupt at end of header (necessary to set the number of bytes for the RxR phase)
  - Timeout on overflow: 8-bit timer

  - Break detection:8 bit timer with programmable threshold in units of bits
- RxR - Reception of Response - master and slave mode
  - Number of bytes parameter: bit-field of length 4
  - Checksum detection: hardware that supports classic and enhanced checksum, which can be enabled or disabled; a checksum error is flagged, and an error interrupt can be triggered, if enabled
  - Checksum: the received checksum is optionally delivered in the RXFIFO
  - Timeout on overflow: 8-bit timer

The break detection feature is always active.

Wake-up signal generation in both slave and master mode.

For many LIN configuration parameters, the hardware of the ASCLIN module provides wider ranges than the LIN standard parameters. Therefore the application software shall take care that appropriate LIN standard values are used to configure the module. Such configuration parameters are:

- Break length
- Data width
- Break threshold
- Wake-up length
- Header, frame and response timeout
- Idle time

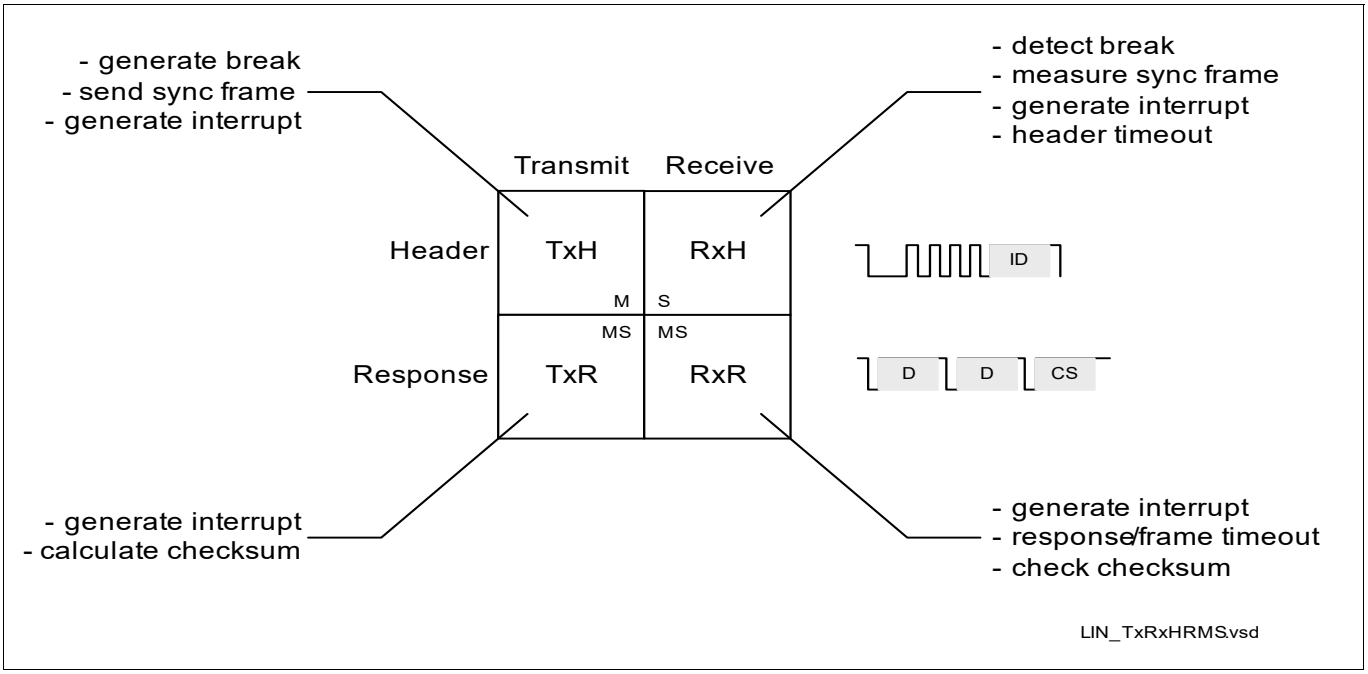

Figure 439 Overview of the elementary LIN transactions

36.3.7.1 LIN Watchdog

The LIN watchdog monitors the duration of the header, the frame or the response, and appearance of break pulses. It checks against the pre-defined time limits.
If the limits are violated, timeout interrupts are generated.

The LIN watchdog is necessary in slave mode.

The wake pulse generation is performed using the shift register and an appropriate data byte containing several consecutive zero bits. The wake pulse detection is done using falling edge detection.

For monitoring the bus for long idle or zero states there are flags for rising and falling edge available. These flags can be polled with some appropriate time raster (in microseconds or milliseconds range).

The header timeout value is known at module initialization time and remains constant for all frames.

The frame or response timeout value depends on the length of the response (1 to 8 bytes) and must be set by software depending on the received ID, after the header has been received. The initial value of this timeout should be set by software to the maximum allowed by the timer, that is 256.

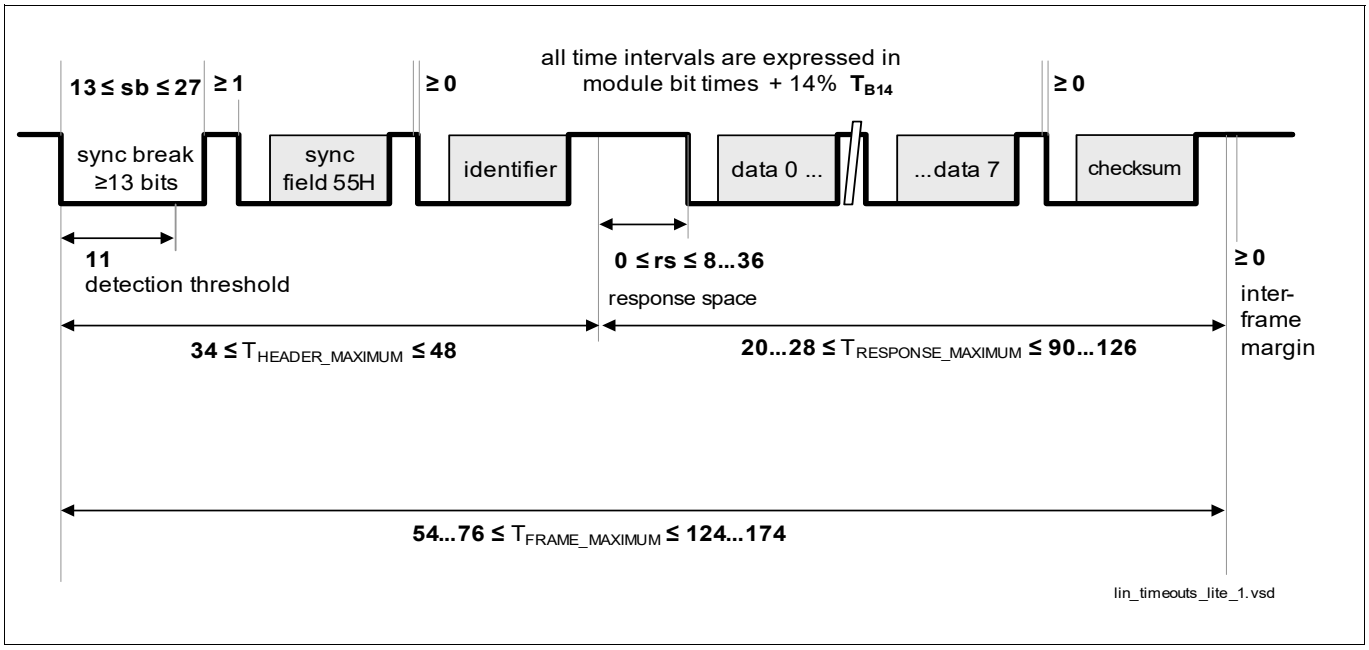

Figure 440 Duration of the Elements of a LIN Frame

The module provides timer blocks running in parallel, performing watchdog functions on specific timing requirements of the LIN protocol.

36.3.7.1.1 LIN Break, Wake, Stuck Handling

This subsection describes:

- the monitoring of the LIN Bus
- Break Pulse detection and generation and
- Wake Pulse detection and generation.

Monitoring the Bus

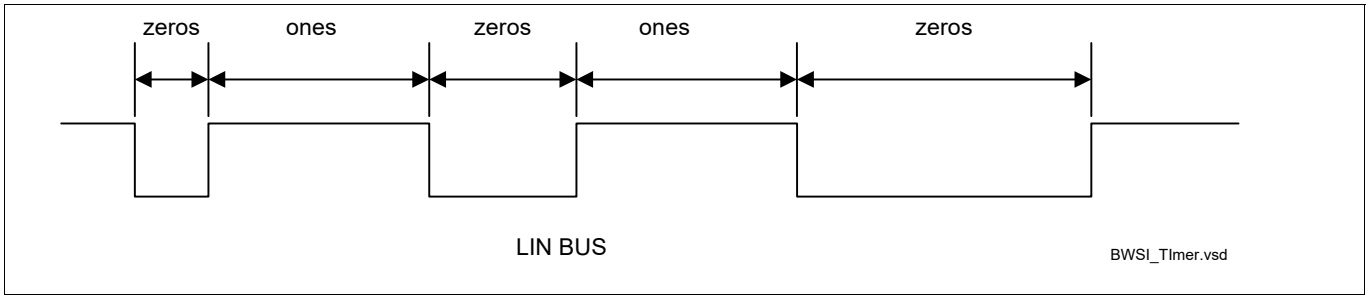

Figure 441 LIN Bus View as Sequence of Sequences of Zeros and Ones

Monitoring the bus for long idle periods (or stuck periods) is supported by providing the bit fields FLAGS.RED (**Flags Register**) and FLAGS.FED. Polling these fields periodically within some time raster defined by the operating system or timer for example each 1 ms or each 10 ms can be used for detecting very long inactive periods in the range, for example, of 150 ms to 10 s. Additionally, an interrupt on edge can be enabled by using the corresponding enable bits in the FLAGSENABLE (**Flags Enable Register**) registers. Setting and clearing the flags can be done by software by using the FLAGSSET (**Flags Set Register**) and FLAGSCLEAR (**Flags Clear Register**) register.

Note: The low break or wake up pulses do not cause a dummy byte to be transferred to the receive FIFO and do not cause a frame violation error interrupt. After the pulse the shift register goes into initial state and waits for the falling edge of the start bit of the next frame.

Break and Wake Pulse Detection

The detection of the break pulse, which is defined as low pulse with a minimum duration of 13 bit times, is performed using a threshold of either 10 or 11 bit times. The break detection threshold is set using the bitfield LINBTIMER.BREAK (**LIN Break Timer Register**).

Detecting a break pulse anywhere in the frame resets the LIN state machine to the “Break Delimiter Detected” state BDD and the whole sequence inclusive the watchdog timeout counting starts from the beginning.

Note: Detecting a break pulse anywhere in the frame could result in setting the Frame Error Flag (FE)

Wake low-pulse detection is done by monitoring the bus for a falling edge in sleep mode. If an early wake-up shall be suppressed, the parameter IOCR.DEPTH (glitch filter) (**Input and Output Control Register**) may be used.

Break and Wake Pulse Generation

The generated break low-pulse duration is defined by the bit field LINBTIMER.BREAK (**LIN Break Timer Register**) in the range of 1 to 64 bits.

Wake low-pulse is nominal 5 bit times long, but can be set to any value between 1 and 9, by writing the appropriate character in the TXFIFO and requesting its transmission as the wake pulse by setting FLAGS.TWRQ (**Flags Register**).

Note: Injecting the low pulse disables the reception with the shift register, so that this low pulse is not detected or treated as a normal ASC frame.

36.3.7.1.2 LIN Header and Response Timers

The LIN header and response times can be monitored separately.

- Header duration measurement
  - In master mode starting point of the time measurement is falling edge of the break pulse.
  - In slave mode starting point of the time measurement is the moment of detecting that there is a break pulse going on, that is the moment of detection of a low pulse longer than either 10 or 11 bit times, as configured in the LINBTIMER (**LIN Break Timer Register**) register.
- Response duration measurement
  - In master and slave mode the response duration measurement starts with the end of the header and ends with the end of the response.

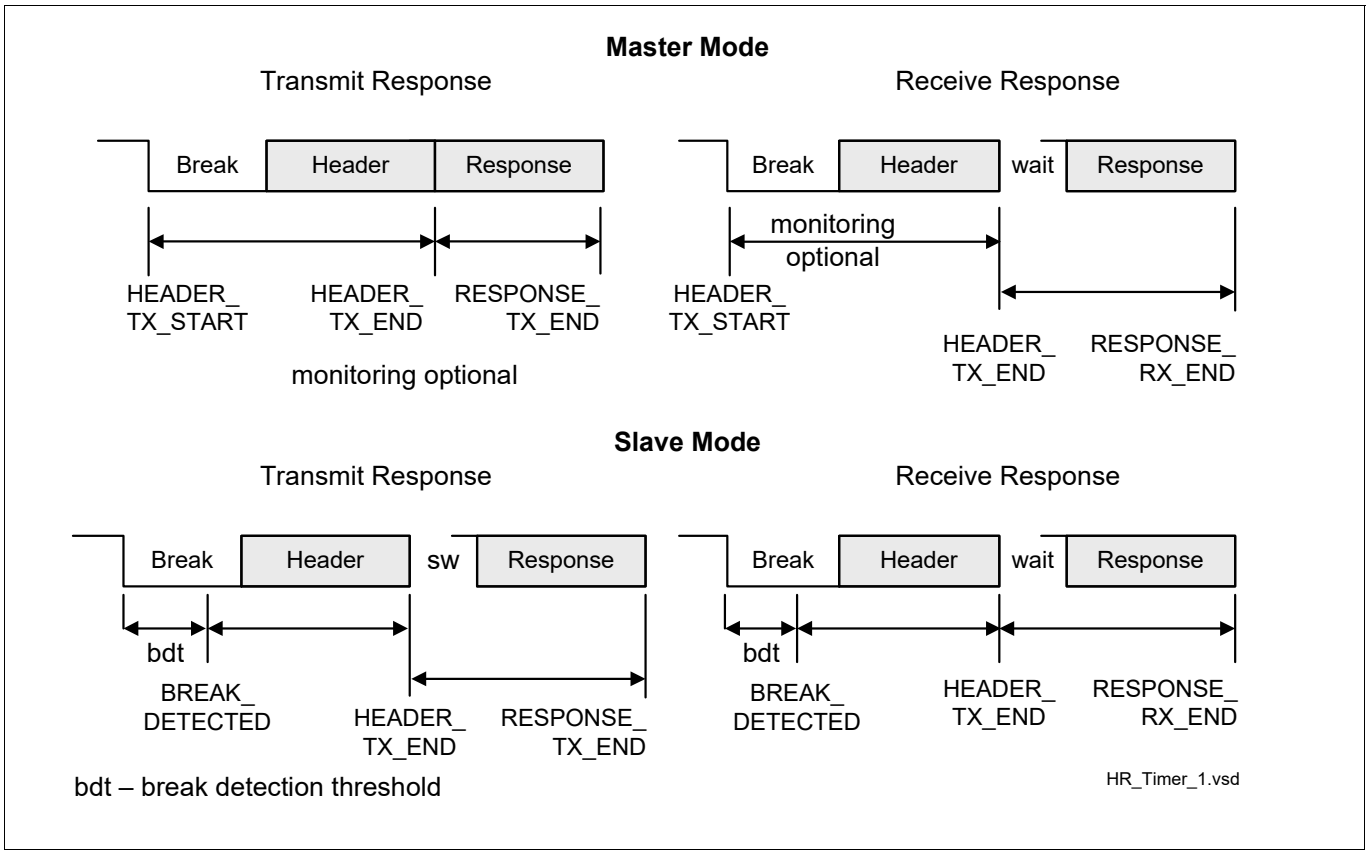

Figure 442 Duration Measurement of the Header and Response

Note: Transmitting master node can optionally monitor its own header or response timeouts, in order to detect some error conditions, like TXFIFO not containing the ID or data to be transmitted. However, these error conditions can be detected also in other ways.

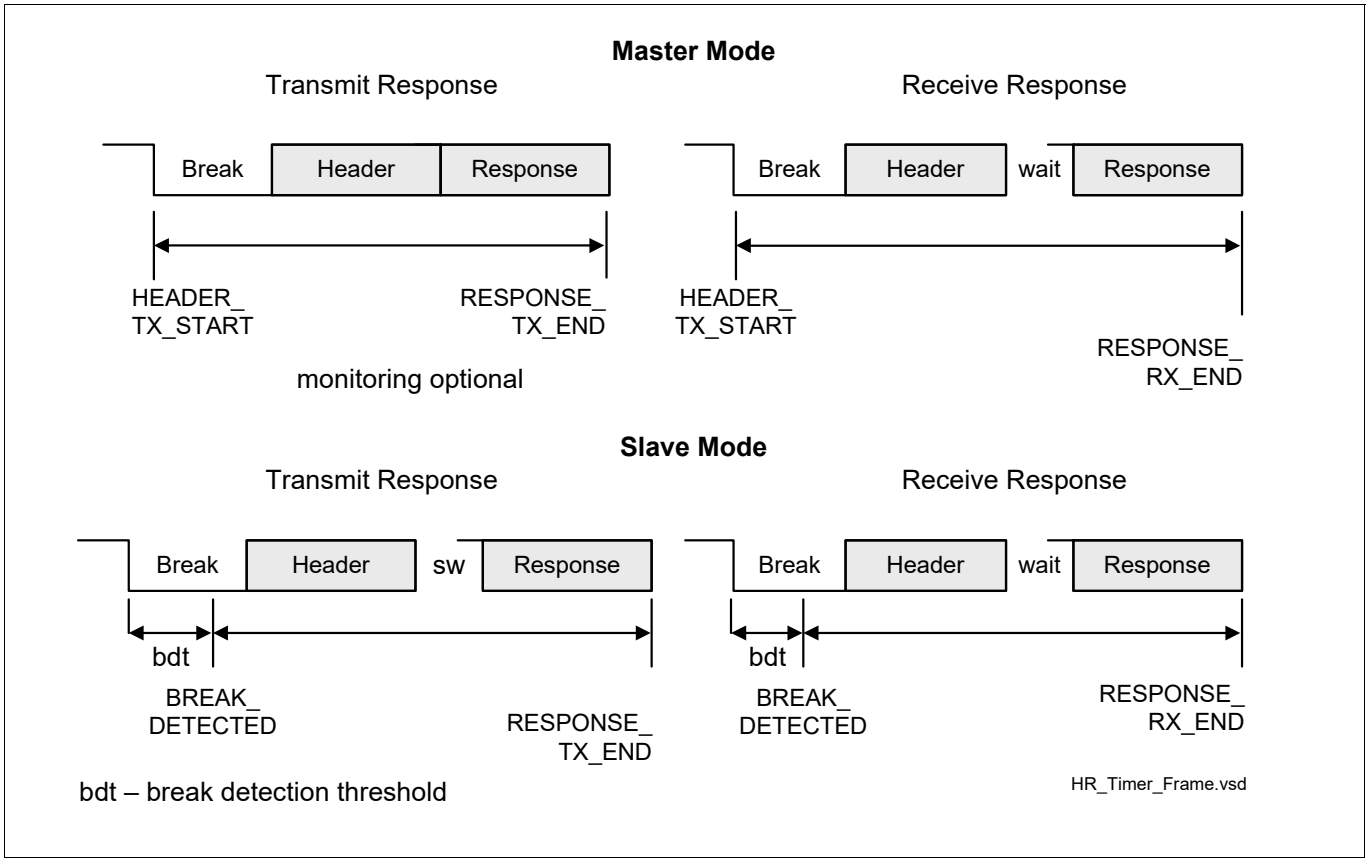

Figure 443 Duration Measurement of the Response or Frame

According to the setting of the bit DATCON.RM (**Data Configuration Register**), the DATCON.RESPONSE bit field defines response or frame duration threshold.

36.3.7.2 LIN Master Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in LIN master mode

- Deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- Wait or poll for **CSR**.CON = 0 (see also Clock Reconfiguration)
- Enter the INIT mode : **FRAMECON**.MODE = INIT
- Activate the clock source : set **CSR**.CLKSEL
- Wait or poll for **CSR**.CON = 1
- Deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- Wait or poll for **CSR**.CON = 0
- Select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- Configure the master mode : **LINCON**.MS = 1
- Configure the baud rate : **BRG**
- Configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- Configure the bit sampling : **IOCR**.DEPTH, **BITCON**.SM, SAMPLEPOINT
- Configure the frame parameter : **FRAMECON**.PEN=0 (no parity), STOP = 1
- Configure the break length : **LINBTIMER**.BREAK = 13 (typ)
- Configure the delay parameter : **FRAMECON**.LEAD, **FRAMECON**.IDLE
- Configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- Activate the clock source : set **CSR**.CLKSEL
- Wait or poll for **CSR**.CON = 1

Send only a header [master task]

- Configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- Configure the RXFIFO : **RXFIFOCON**.ENI = 0 (or 1), OUTW, BUF=0, flush
- Configure the TXFIFO : **TXFIFOCON**.ENO = 0, INW, flush
- Clear the event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LC, TFOC/LC, RFOC/UC/LC
- Enable the TX interrupt event : **FLAGSENABLE**.THE
- Enable the EX interrupt events : **FLAGSENABLE**.HTE, CEE, (FEE, LPE)
- Write into the TXFIFO : **TXDATA** = ID byte
- Start the header transmission : **FLAGSSET**.THRQS = 1
- Configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

React to the interrupt(s) indicating the end of transmission (and reception) of the ID byte:

- Check the error flags : **FLAGS**.HT, CE (FE, LP)

- Read from the RXFIFO : **RXDATA**=received ID, if no error has been detected

Check the transmitted / received ID to determine with which response sequence: transmit, receive or ignore to continue (same procedure as in the slave mode).

Send a response to the latest header [slave task]:

- Configure the response count : **DATCON**.DATLEN
- Configure the watchdog timer : **DATCON**.RESPONSE
- Configure the checksum mode: **DATCON**.CSM
- Configure the RXFIFO : **RXFIFOCON**.ENI =0
- Configure the TXFIFO : **TXFIFOCON**.ENO = 1
- Clear the event flags : **FLAGSCLEAR**.TRC, TFOC/UC, CEC, RTC, BDC
- Enable the TX interrupt event : **FLAGSENABLE**.TRE
- Enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE (RTE), BDE
- Write into the TXFIFO : **TXDATA** = data bytes D0, D1, … (and optionally the checksum byte if the hardware checksum generation is disabled)
- Start response transmission : **FLAGSSET**.TRRQS = 1
- The corresponding interrupts signal an error or the end of the response transmission

Receive a response to the latest header [slave task]

- Configure the response count : **DATCON**.DATLEN
- Configure the watchdog timer : **DATCON**.RESPONSE
- Configure the checksum mode: **DATCON**.CSM
- Configure the RXFIFO : **RXFIFOCON**.ENI = 1
- Clear the event flags : **FLAGSCLEAR**.RRC, RFOC/UC, FEC, LCC, RTC, FEDC, REDC, BDC
- Enable the RX interrupt event : **FLAGSENABLE**.RRE
- Enable the EX interrupt events: **FLAGSENABLE**.RFOE/UE, FEE, (LCE), RTE, BDE
- The corresponding interrupts signal that the whole response has been received (= end of the frame) or an error has occurred.

Note: If checksum injection has been enabled, the received (custom) checksum is also written into the RXFIFO and should be taken into account.

- Fetch from the RXFIFO : **RXDATA** = received data, if no error occurred

*Note: The hardware checksum check can be enabled using the bit **LINCON**.CSEN. The received checksum write to the RXFIFO can be enabled using the **LINCON**.CSI.*

Ignore the latest header [slave task]

- Configure the response timer **DATCON**.RESPONSE=0xFF
- Configure the RXFIFO : **RXFIFOCON**.ENI = 0
- Set the header only mode : **DATCON**.HO = 1
- Clear the event flags : **FLAGSCLEAR**.FEDC, REDC, BDC

The LIN master always knows if the header is followed by a response transmission (by himself) or a response reception (by a slave) or the response transmission is from slave to slave, except in case of a slave that does not respond always, but driven by internal events.

In case of addressing an always responding slave, it is recommended first to configure the header and response (transmission or reception), and afterwards to start the header transmission and optionally, at the same time, the response transmission.

To start a transaction consisting of sending a header and sending or receiving a response, which makes one whole LIN frame [master node]:

- Configure the response count : **DATCON**.DATLEN
- Configure the watchdog timer : **DATCON**.RESPONSE
- Configure the checksum mode : **DATCON**.CSM
- Configure the RXFIFO : **RXFIFOCON**.BUF = 0, flush, ENI = 0
- Configure the TXFIFO : **TXFIFOCON**.flush, ENO = 0
- Clear the interrupt event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LCC, TFOC/UC/LC, RFOC/UC/LC, FEDC, REDC, BDC
- Send case
  - Enable the TX interrupt event : **FLAGSENABLE**.TRE, (THE, HTE)
  - Enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE, (FEE, RTE, LPE, BDE)
- Receive case
  - Enable the RX interrupt event: **FLAGSENABLE**.RRE. (THE, HTE)
  - Enable the EX interrupt events: **FLAGSENABLE**.RFOE/UEE, CEE, FEE, RTE, (LCE, BDE)
- Write into the TXFIFO : **TXDATA** = ID byte
- Send case
  - Write to TXFIFO : **TXDATA** = data bytes (and optionally checksum byte if the hardware checksum is disabled)
- Start the header transmission : **FLAGSSET**.THRQS = 1
- Configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

- Send case
  - Start transmit response : also set **FLAGSSET**.TRRQS = 1
- The corresponding interrupt signals an error or the end of the response transmission
- Read from the RXFIFO : if no error detected, **RXDATA** = received ID
- Receive case
  - Fetch from the RXFIFO : if no error has been detected, **RXDATA** = received data bytes and optionally the checksum byte

36.3.7.3 LIN Slave Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in slave mode

- Deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- Wait or poll for **CSR**.CON = 0 (see also Clock Reconfiguration)
- Enter the INIT mode : **FRAMECON**.MODE = INIT
- Activate the clock source : set **CSR**.CLKSEL
- Wait or poll for **CSR**.CON = 1
- Deactivate the clock source : **CSR**.CLKSEL = 0 (off)
- Wait or poll for **CSR**.CON = 0
- Select the operation mode : **FRAMECON**.MODE = 3 (LIN)
- Configure the slave mode : **LINCON**.MS = 0
- Configure the baud rate : **BRG** , autobaud detection enable, **BRD**.UPPER / LOWERLIMIT
- Configure the bit timing : **BITCON**.PRESCALER and OVERSAMPLING
- Configure the bit sampling : **IOCR**.DEPTH , **BITCON**.SM , SAMPLEPOINT
- Configure the frame parameter : **FRAMECON**.PEN = 0 (no parity), STOP= 1
- Configure the break length : **LINBTIMER**.BREAK = 11 (typ)
- Configure the header timeout : **LINHTIMER**.HEADER
- Configure the delay parameter : **FRAMECON**.IDLE
- Configure the checksum mode : **LINCON**.CSEN, **LINCON**.CSI
- Activate the clock source : set **CSR**.CLKSEL
- Wait or poll for **CSR**.CON = 1

In slave mode, the module waits for a header from the master, that is, it waits for a break pulse followed by the sync byte and the ID.

Configure for header reception [slave task]

- Configure the watchdog timer : **DATCON**.RESPONSE =256 (max)
- Configure the RXFIFO : **RXFIFOCON** bufmode = 0, flush, ENI = 0
- Clear the interrupt flags : **FLAGSCLEAR**.RHC, TRC, RRC, FEC, HTC, RTC, BDC, LPC, LAC, LCC, TFOC/UC/LC, RFOC/UC/LC
- Enable the RX interrupt event : **FLAGSENABLE**.RHE
- Enable the EX interrupt event : **FLAGSENABLE**.HTE, CEE, FEE, LAE, LPE

React to the interrupt(s) generated after receiving the ID byte:

- Check error flags : **FLAGS**.HT, FE, LA, LP
- Read from the RXFIFO : if no error detected, **RXDATA** = received ID

Check the received ID to determine which response sequence (send, receive or ignore header) to use next.

The LIN slave does not know in advance if it will respond to the header with a transmission himself or it will receive a response by another slave. It looks up the received ID and decides if this ID is associated with a transmit or receive response or if it is don't care (it is for some other slave). This look-up and the subsequent configuration of the module must be performed by software within the allowed response time.

Send a response to the latest header [slave task]

(same sequence as in master mode)

Receive a response to the latest header [slave task]

(same sequence as in master mode)

Ignore the latest header (if the received ID contains an error or is not for this slave) [slave task]

(same sequence as in master mode)

36.3.7.4 Using the ENI and HO Bits

Both the ENI (Enable Input) and HO (Header Only) bits affect the reception of the various byte types in the LIN frame.

The HO bit is normally used in cases where the response part of a frame should be ignored; the module waits for the next break signal. The ENI bit can be set by the user software, but is also set by the hardware in slave mode after the sync byte reception, in order to enable the transfer of the ID byte of the header in the RXFIFO.

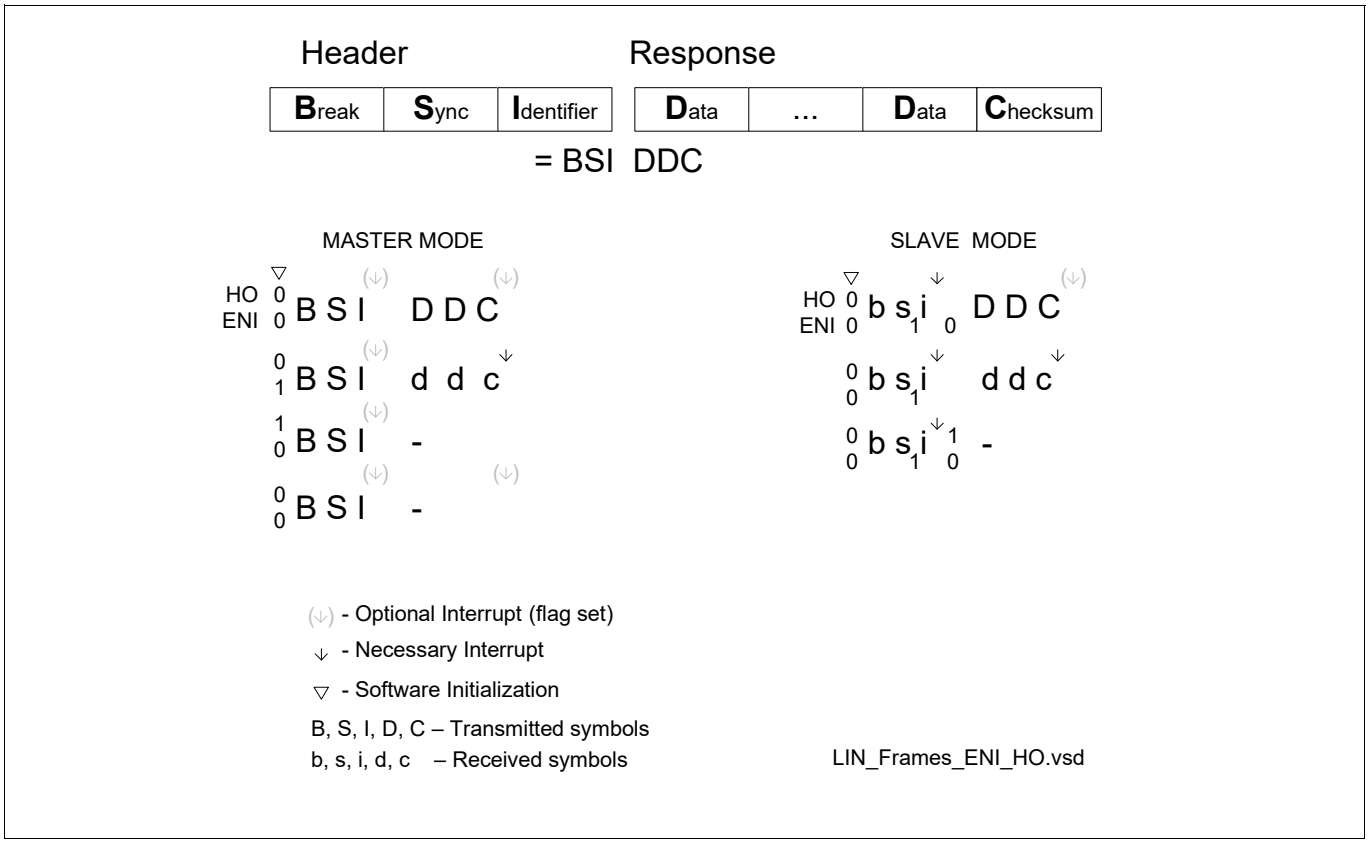

Figure 444 ENI and HO bits

36.3.7.5 LIN Error Recovery

This section describes the behavior of the module in case of errors detected during reception and during transmission of a LIN frame.

Reception Related Errors

In case of a reception error, the receive state machine goes into the state “waiting for break”, and the corresponding interrupt is triggered.

ID Parity error

Checksum error

Timeout error

Framing error

Baud Rate error

Transmission Related Errors

Collision error (LIN2.1 mandatory). If the collision detection mechanism is enabled FRAMECON.CEN (**Frame Control Register**), the frame will be aborted and the transmitter state machine goes to the idle state.

36.3.7.6 LIN Sleep and LIN Wake-Up

Wake up low pulse in duration of 250 µs to 5 ms can be generated by the module.

Wake up low pulse in duration longer than 150 µs wakes up a sleeping module.

A master node which has received a wake up pulse can start polling the slaves, it can start sending break pulses and headers, and send or receive the corresponding responses.

A slave which has been woken up shall be capable of receiving LIN headers after a wake-up time of maximum 100 ms. A slave issuing a wake-up pulse expects to receive a header within 150 ms to 250 ms after the end of the wake-up pulse. If the header does not come, the slave issues a wake up pulse again.

36.3.8 Auto Baud Rate Detection

Auto baud rate detection is active in slave mode during the reception of the sync field in the LIN header. It measures the longest time interval between two falling edges in the 55H sync field. The measured value is loaded in the denominator of the fractional divider and used afterwards for generating the baudrate for the reminder of this frame if the auto baud rate usage is enabled (LINCON.ABD = 1) (**LIN Control Register**).

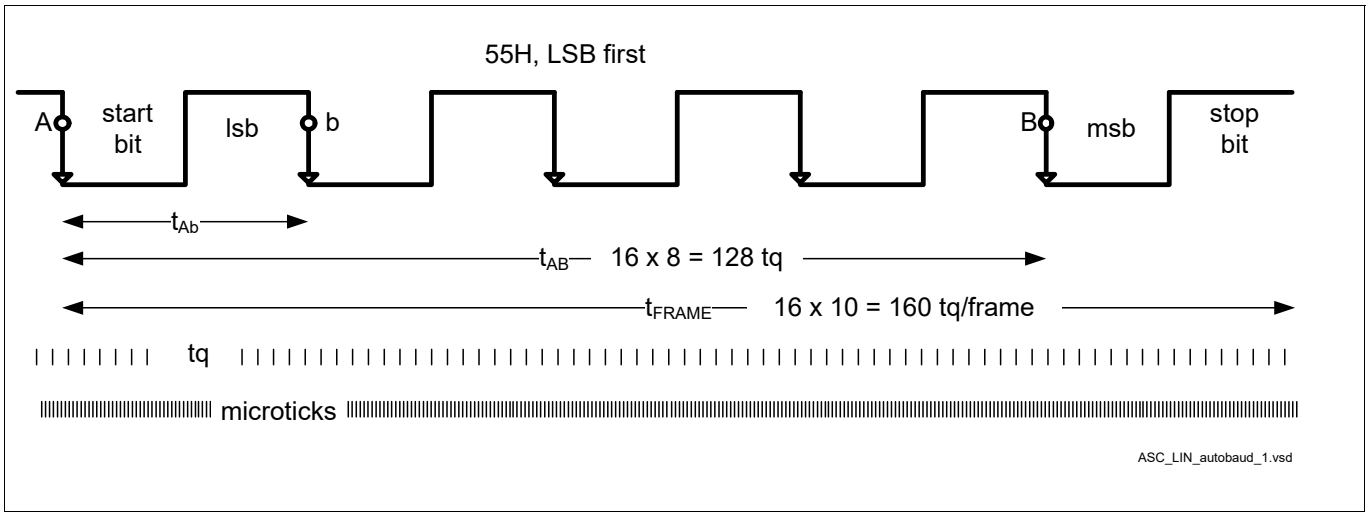

Figure 445 Measurement of the Sync field

The following bitfields are available for monitoring the autobaud detection:

- BRD.MEASURED - the measured time interval between the first and the fifth falling edge of the sync byte
- BRD.UPPERLIMIT - In case the LIN autobaud detection measures a baud rate 14% lower than the nominal one, that is it measures a time interval longer than the UPPERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.
- BRD.LOWERLIMIT - In case the LIN autobaud detection measures a baud rate 14% higher than the nominal one, that is it measures a time interval shorter than the LOWERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.

Auto Baud Rate Operation

The BRD.UPPERLIMIT defines the maximum allowed duration for 8 bits in microticks, and therefore the minimum allowed baud rate. In order to define 14% lower baud rate, 8-bit duration 16% longer than the nominal must be entered in the UPPERLIMIT bit field. This is due to the fact that BaudRate = 1 / BitTime, and UPPERLIMIT defines the time.

The BRD.LOWERLIMIT defines the minimum allowed duration for 8 bits in microticks, and therefore the maximum allowed baud rate. In order to define 14% higher baud rate, 8-bit duration 12% shorter than the nominal must be entered in the LOWERLIMIT bit field. This is due to the fact that BaudRate = 1 / BitTime, and LOWERLIMIT defines the time.

If the autobaud is activated, the fractional divider uses a numerator value of 8 x (BITCON.OVERSAMPLING + 1) (**Bit Configuration Register**) and ignores the bit field BRG.NUMERATOR (**Baud Rate Generation Register**). For the standard LIN protocol oversampling of 16 (BITCON.OVERSAMPLING = 15), the numerator value used internally is 128 and ignores the bit field BRG.NUMERATOR. Nevertheless, programming 128, or 8 x (OVERSAMPLING + 1) in BRG.NUMERATOR may increase the clarity of the software.

Regarding the denominator of the fractional divider, defined in BRG.DENOMINATOR (**Baud Rate Generation Register**), its initial value is the nominal value and is set by the application software. During the operation of the

module, the BRD.MEASURED value is automatically loaded into the denominator of the fractional divider, as long as it is within the limits.

Note: For correct behaviour of the fractional divider, It has to be ensured that the numerator value i.e., 8 X (OVERSAMPLING + 1) is less than or equal to the denominator value (BRD.MEASURED) which is calculated by the Auto Baud Detection mechanism. There is no check implemented by the hardware.

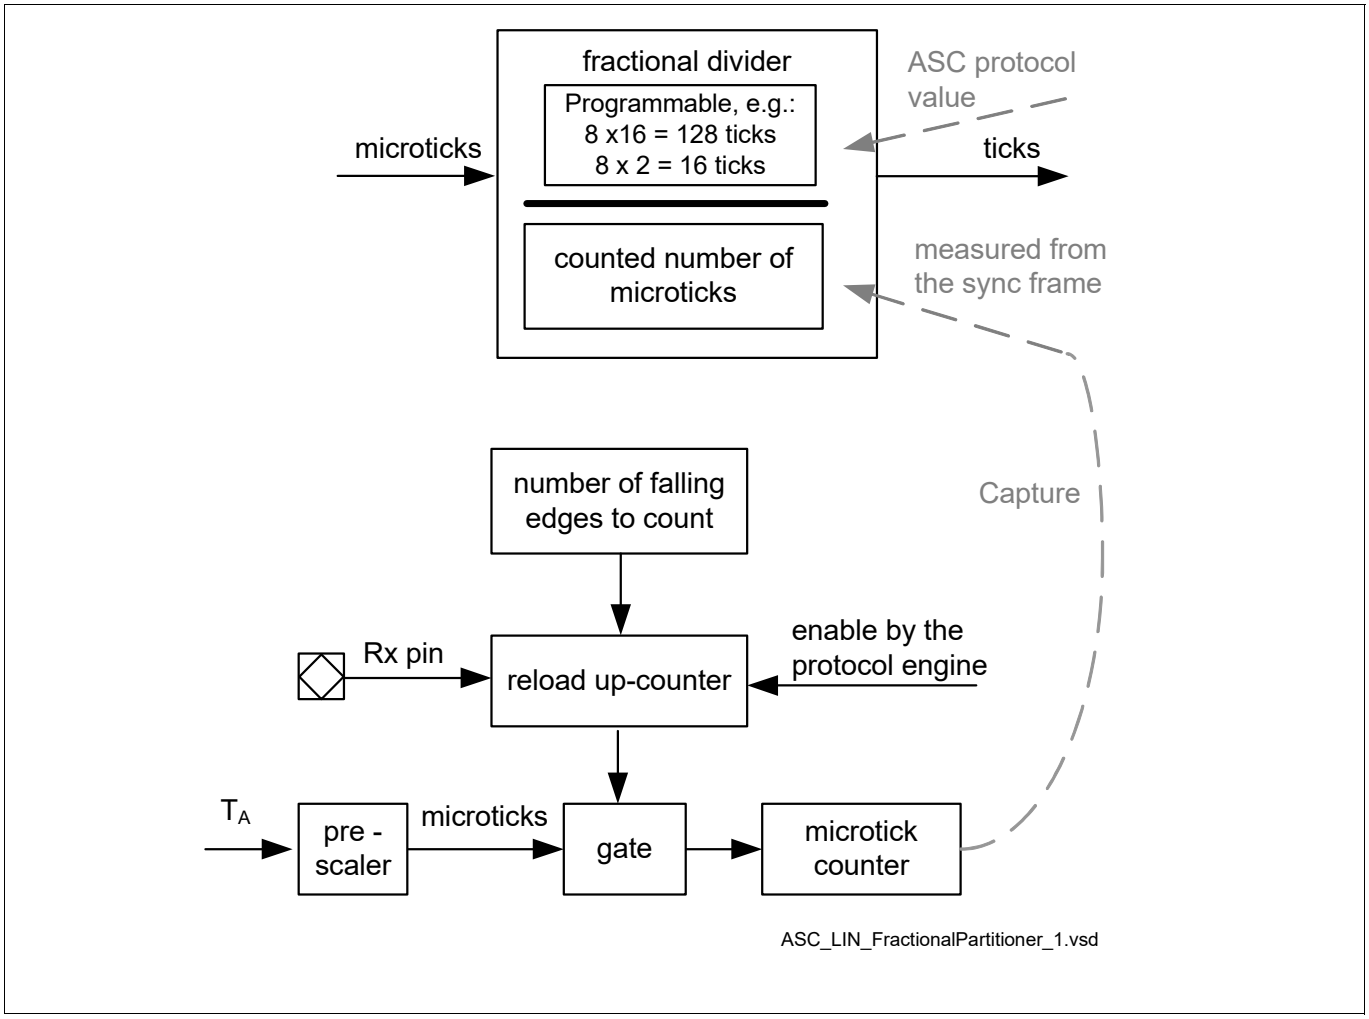

Figure 446 Overview of the LIN Auto Baud Detection Principle

Auto baud rate detection measures the time between the first and the fifth falling edge of the sync field in T_{SYS} units and loads this number in the denominator. The LIN protocol uses baud rates in a range between 2400 Baud to 19200 Baud.The expected time at 19.2 KBaud is 8 * 52.1 us = 416.8 us and the expected denominator value at T_A = 10ns is in the range of 417us / 10ns = 41 700.

The numerator operates internally with the time quanta for 8 bits, 16 times oversampling for LIN protocol: 8*16=128. The bit field BRG.NUMERATOR (**Baud Rate Generation Register**) is ignored.

36.3.9 Collision Detection

Collision detection monitors the consistency of transmitted and the echoed received bytes in LIN mode and half duplex SPI modes.

36.3.10 LIN Protocol Control

There is a central LIN protocol state machine. It is connected to the receiver and the transmitter shift registers, the Tx and Rx FIFOs, the checksum logic and the watchdog timers. The machine takes care of generating the sync byte of 55_H and the automatic handling of the checksum. Both the classic LIN V1.3 and the enhanced LIN V2.0 / V2.1 checksum are supported. The hardware checksum feature is switchable on and off, and the choice between using the classical and the enhanced checksum is done by software with the DATCON.CSM (**Data Configuration Register**) bit on a frame by frame basis. As can be seen in the **Figure 448**, for the LIN version 2.0 and 2.1, the enhanced checksum is calculated for the identifiers 0…59, and the classical checksum for the identifiers 60…63.

Additionally, the parity of the ID field is generated in master mode, and checked in slave mode. In slave mode, in case of a mismatch between the received and the calculated parity, an error interrupt is raised.

In receive case, if LINCON.CSI = 1 (**LIN Control Register**), the received checksum byte is written to the RXFIFO after the last data byte.

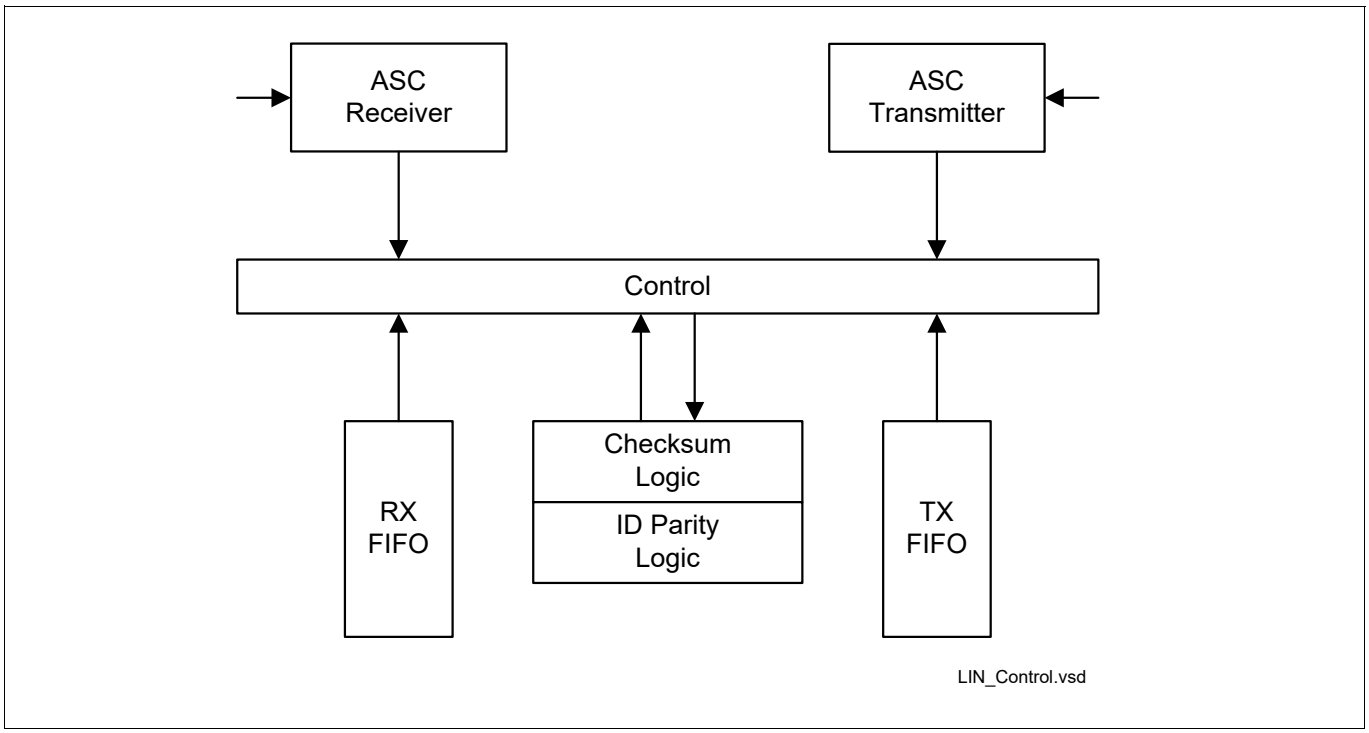

Figure 447 Block Diagram of the LIN Control Subsystem

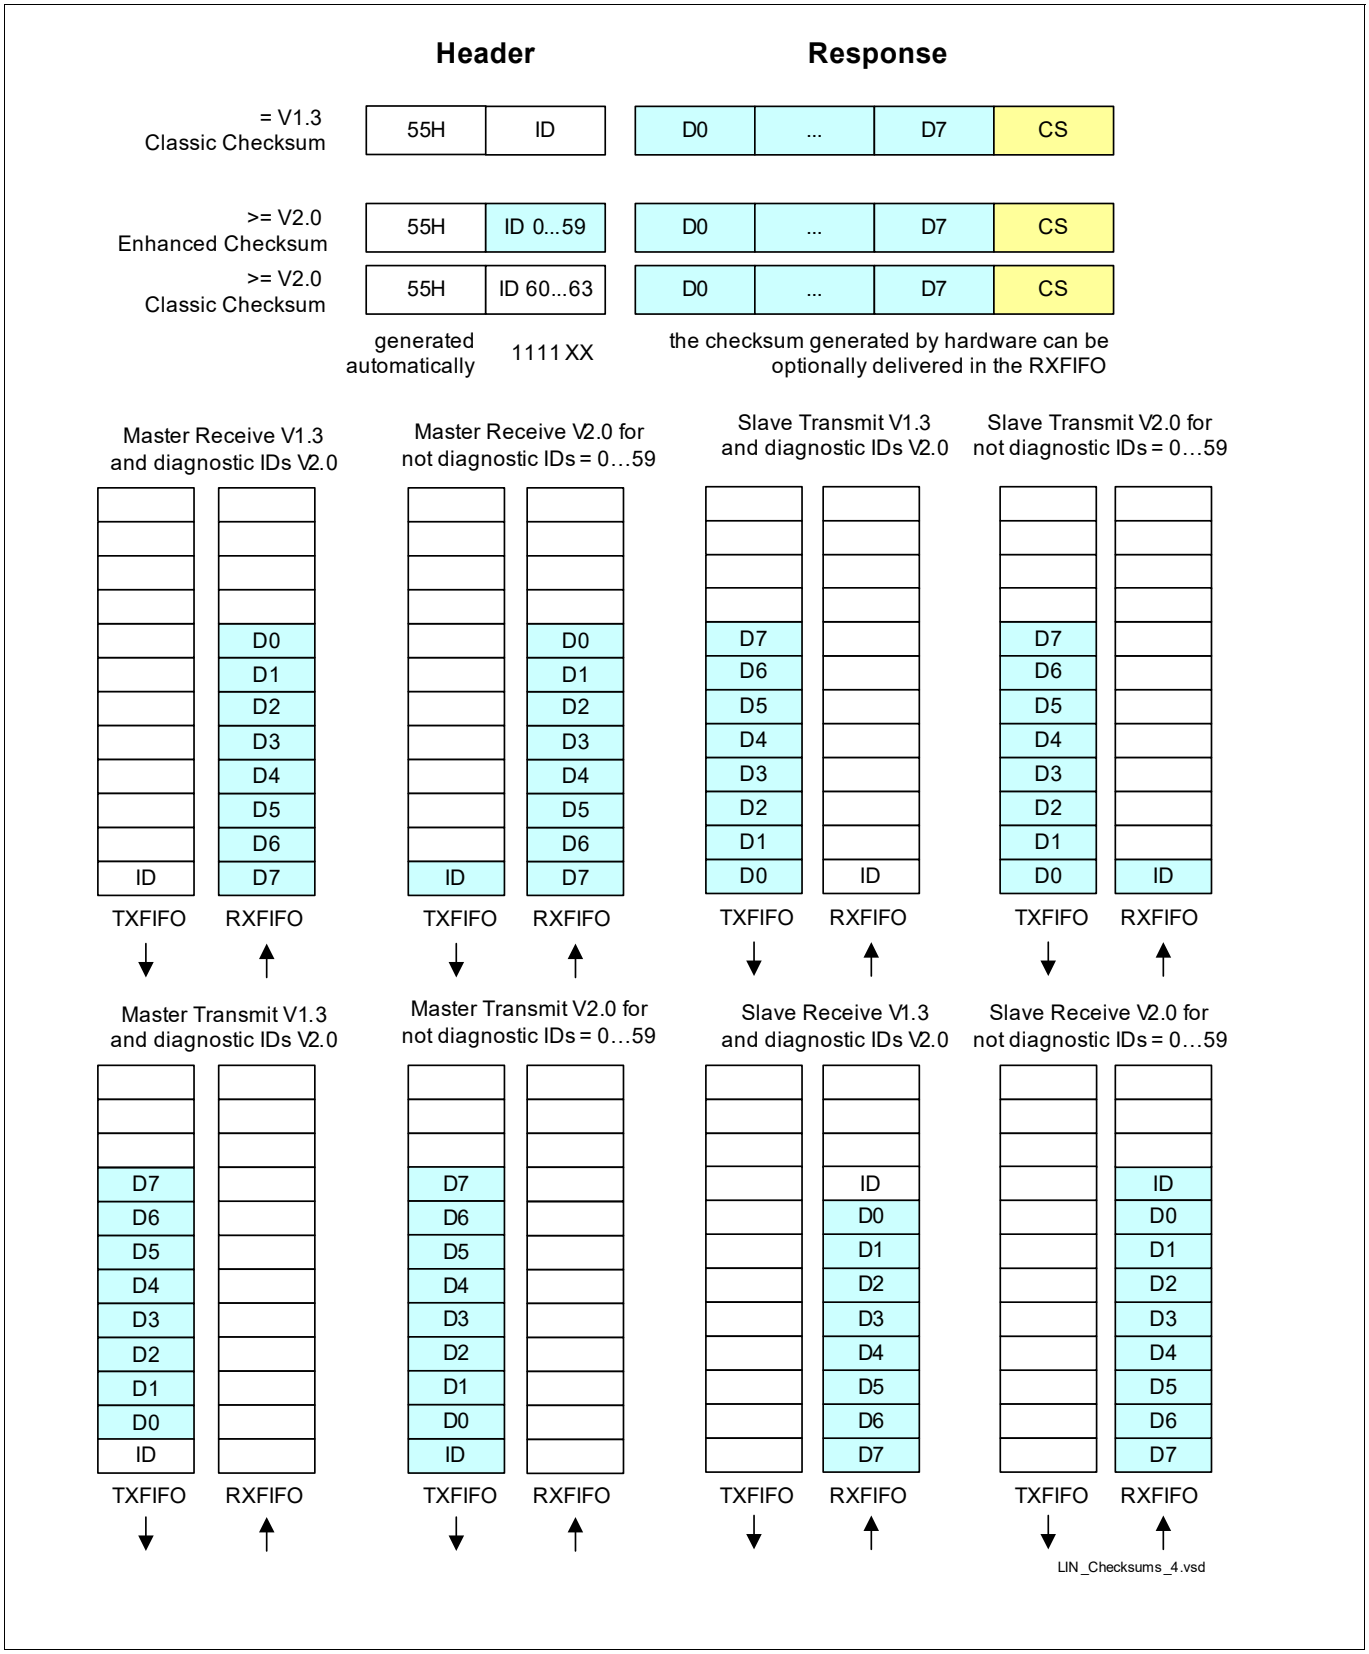

Figure 448 Coverage of the Checksum in Different Use Cases

36.3.11 Interrupts

The ASCLIN module generates three interrupts:

- TX - Transmit Interrupt
  - Signals the TxFIFO level event (FLAGS.TFL) (**Flags Register**)
- RX - Receive Interrupt
  - Signals the RxFIFO level event (FLAGS.RFL) (**Flags Register**)
- EX - Extended Error Interrupt
  - Signals every error (FLAGS.PE, FE, CE, RFO, RFU, TFO) (**Flags Register**) and
  - Some additional events (FLAGS.FED, RED)

The LIN events related to transmission and reception of header and response are mapped to the corresponding transmit, receive and extended error interrupts

- TX:
  - Transmission of the header in master mode completed (FLAGS.TH) (**Flags Register**)
  - Transmission of a response completed (FLAGS.TR)
- RX:
  - Reception of the header in a slave mode completed (FLAGS.RH) (**Flags Register**)
  - Reception of the response completed (FLAGS.RR)
- EX:
  - LIN protocol (FLAGS. BD, TC) (**Flags Register**) and
  - LIN error events (FLAGS.HT, RT, LP, LA, LC)

In order to determine which event is the source of a LIN interrupt, the FLAGS (**Flags Register**) register must be polled.

Triggering a DMA

The interrupt signals are used also as DMA trigger signals. The interrupt signals are connected to the Interrupt Router Module, which routes the interrupts either to a CPU or to a DMA. There are no separate DMA trigger signals.

Relationship between the Service Request Nodes and the Event Nodes

There are several events mapped to each service request node.

Each service request (interrupt) node contains an SRC (Service Request Control) register containing a sticky flag bit and the associated set, clear and enable bits. The SRC registers are located in the IR (Interrupt Router) module.

The service request flags in the SRC registers are set by hardware, and if the enable bit is set, will be cleared by hardware when the interrupt servicing starts.

One interrupt node may be triggered by more than one events. Each event which causes an interrupt also has a sticky flag bit and associated set, clear and enable bits. These bits are distributed in four registers: FLAGS (**Flags Register**), FLAGSSET (**Flags Set Register**), FLAGSCLEAR (**Flags Clear Register**), and FLAGSENABLE (**Flags Enable Register**) located in the ASCLIN module. Each set of four bits associated to one event builds a virtual “event node”, see **Figure 449**.

The event flags are set by hardware and if enabled, trigger an interrupt. They are not cleared by hardware. They are cleared only by software in the corresponding interrupt service routine, which usually polls the flags to find the cause for the interrupts. The event flags can be also set by software for test purposes.

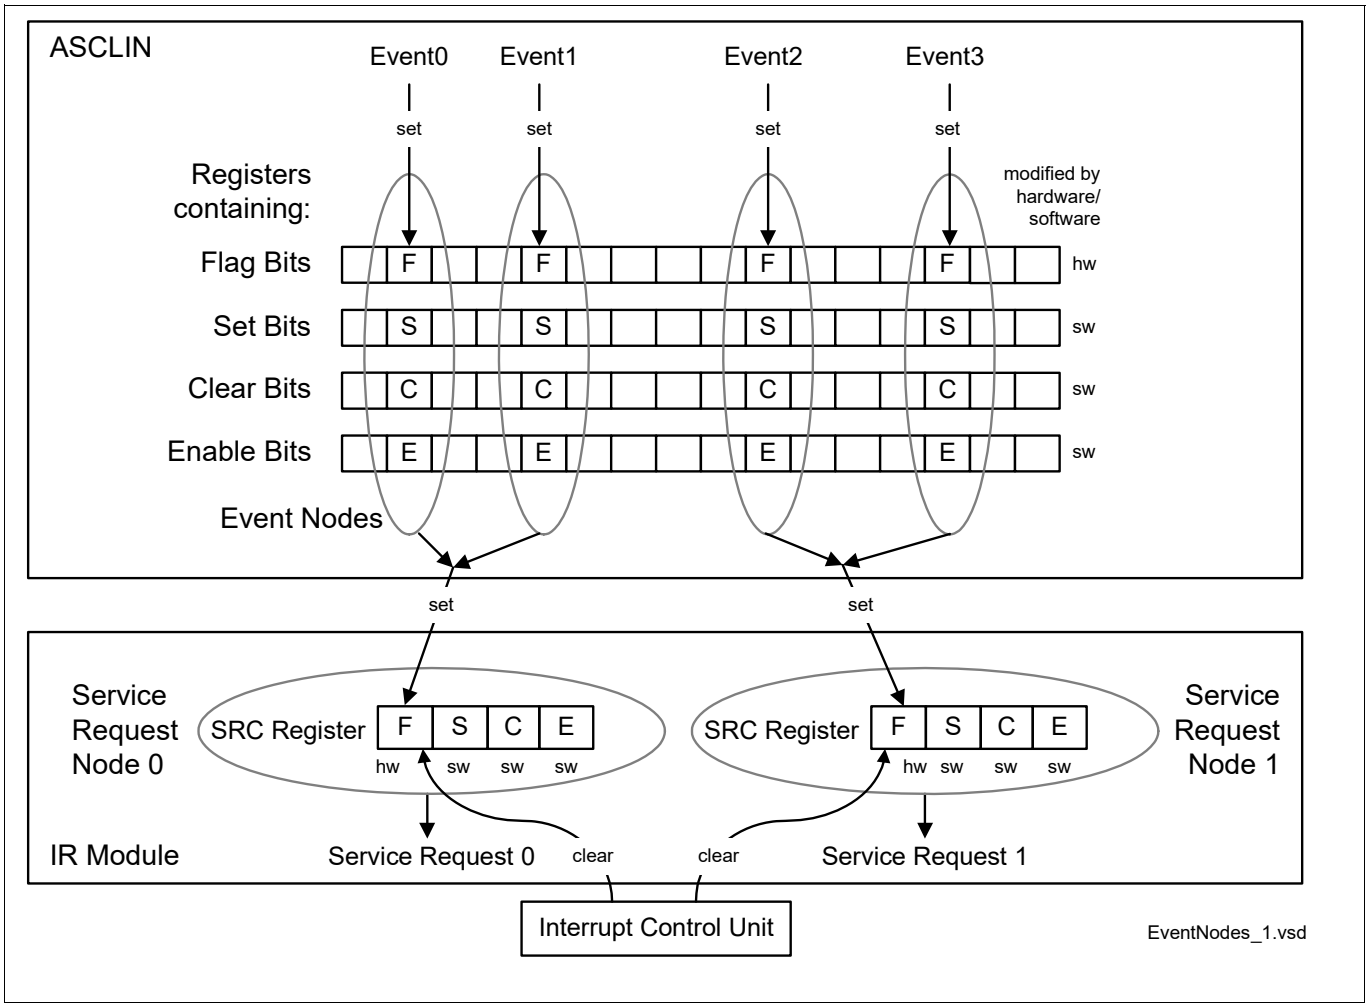

Figure 449 Relationship between Event Nodes and Service Request Nodes

Some flags do not generate interrupts and do not have enable bits. They are used either for issuing requests, which are subsequently acknowledged by hardware, or only for polling by software, see **Figure 450**.

Clearing a request / acknowledge flag by software is ignored (for example FLAGS.TRRQ, THRQ, TWRQ (**Flags Register**)).

There are no pure polled only flags in the ASCLIN module, although by letting the enable bits disabled, all interrupt event flags can be used as polled only (for example idle and stuck monitoring by using FLAGS.FED, RED (**Flags Register**)). Setting such bits per software in such a case is meaningless, except for test purposes.

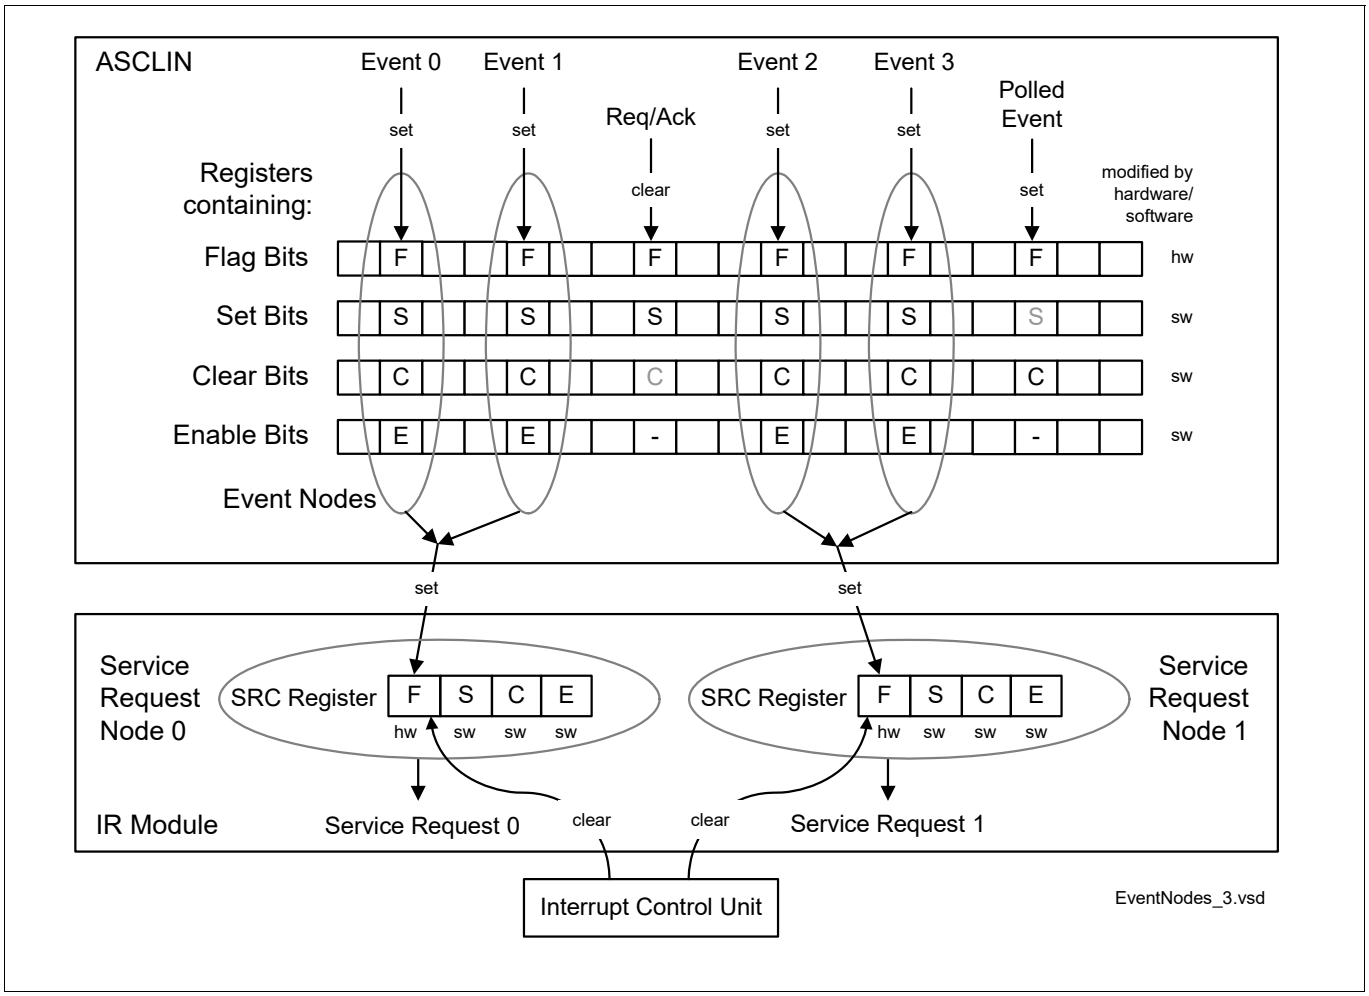

Figure 450 Acknowledge Flags and Polled Flags

36.3.12 Digital Glitch Filter

The digital glitch filter removes short glitches from the input data signal by using an increment / decrement counter with programmable threshold. On the other hand, the filter introduces a delay into the signal path, depending on the digital filter sampling frequency f_{PD} and the threshold programmed in the bit field IOCR.DEPTH (**Input and Output Control Register**). Hence the glitch filter should not be enabled in SPI mode.

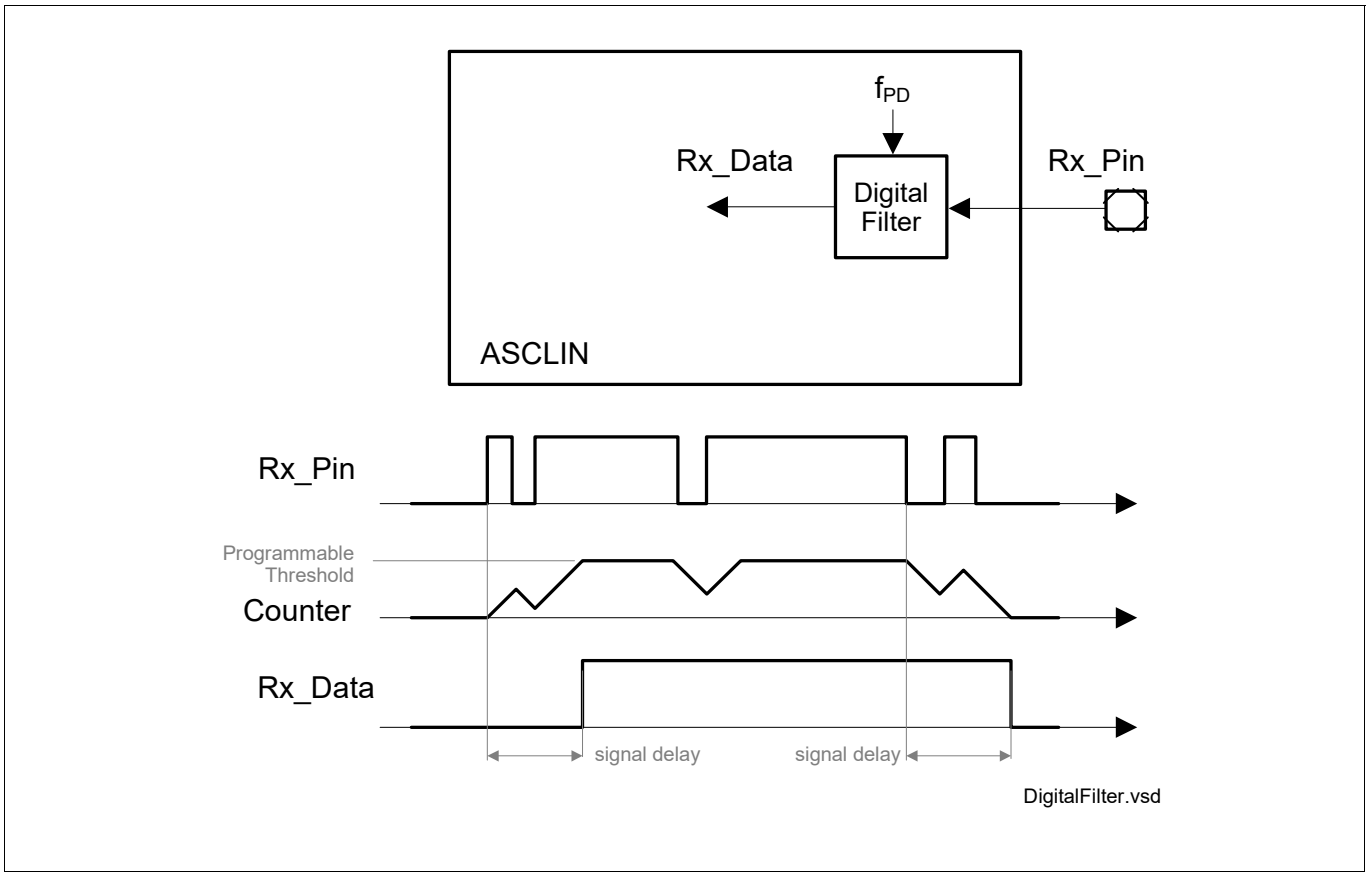

Figure 451 Digital Filter

36.3.13 Suspend, Sleep and Power-Off Behavior

Generally, the ASCLIN module transmits short data frames, not longer than 16 bits, mostly 8 bit long, sometimes with very low baud rates, down to few KBaud. In LIN mode, the data frames build LIN frames.

Simply freezing the module in the middle of an asynchronous ASC frame mostly results in an erroneous data at the receiver side, depending on the data content.

Freezing the module inside the LIN frame transmission, but between the transmission of single bytes results in a timeout error at the receiver side.

If the ASCLIN module gets a request for switching off the clock, it disables immediately all request lines towards the DMA in order to stop further DMA transfers.

In order to power down the module in a well defined way, the user software must take care that the power down request is issued when there is no ongoing single frame or LIN frame transfer and that both FIFOs are empty.

36.3.13.1 OCDS Suspend

OCDS soft suspend request suspends the module activity at the end of the current transaction. In ASC and SPI cases, this is the end of the current frame. In LIN case, this is the end of the current LIN frame (regular end of response, header timeout, or response timeout).

OCDS hard suspend request, for debugging purposes, immediately freezes the ASCLIN module in the current register state. The SPB clock feeding the kernel clock f_{CLC} is immediately switched off and the asynchronous clock f_A remains switched on.

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so an ASCLIN kernel reset might not be sufficient to bring the system into a defined state.

36.3.13.2 Sleep Mode

Going into sleep mode implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a sleep request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur.

The ASCLIN module behaves in the same way as in case of disable request.

36.3.13.3 Disable Request (Power-Off)

Going into power off implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a power-off request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur. This is no issue if the power-off procedure is one-way, that is no continuation of operation without re-initialization of the module is expected.

The ASCLIN module sets immediately all outputs to inactive, stops reacting to inputs, the internal state machines go to initial state, the registers remain unchanged, and then the module acknowledges the request. All clocks to the module are switched off.

36.3.14 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bit in the kernel register KRSTx0.RST and KRSTx1.RST.

KRSTx.RST bit resets the kernel only (not the BPI registers).

BPI reset executes an Application Reset, which resets all the registers except the OCS (**OCDS Control and Status**) register. All output signals get the reset value.

The OCS register (**OCDS Control and Status**) is reset by the Debug Reset.

36.3.15 Implementation

This section describes the product specific configuration of the ASCLIN module and its interconnection with the rest of the system. The exact amount of ASCLIN modules is documented inside the appendix.

36.3.15.1 BPI_FPI Module Registers

36.3.15.1.1 System Registers

Figure 452 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

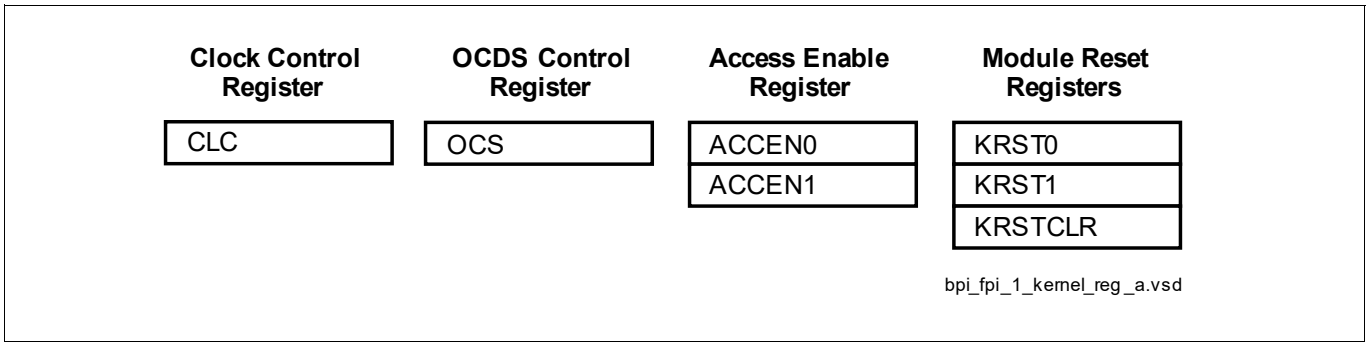

Figure 452 BPI_FPI Registers

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_A module clock signal, sleep mode and disable mode for the module.

CLC

Clock Control Register **(000_H)** **Application Reset Value: $0000\ 0003_H$**

r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode, that is if the sensitivity of the module to the sleep signal is enabled to react to it or disabled to ignore it. 0_B Enabled 1_B Disabled
0	2, 31:4	r	**Reserved** Read as 0; must be written with 0.

OCDS Control and Status

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging). The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS

OCDS Control and Status **($0E8_H$)** **Debug Reset Value: $0000\ 0000_H$**

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The register ACCEN0 provides one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B

ACCEN0

Access Enable Register 0 **(0FC$_H$)** **Application Reset Value: FFFF FFFF$_H$**

ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

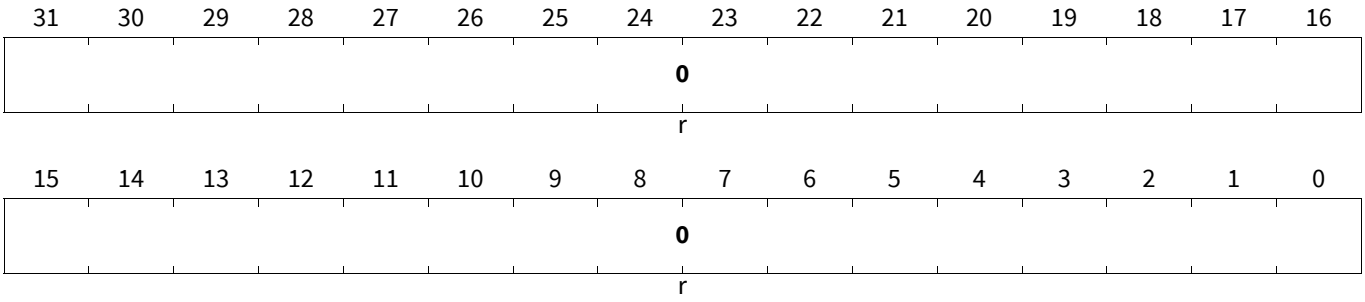
The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, …, EN31 -> TAG ID 111111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ACCEN1

Access Enable Register 1 **(0F8$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0

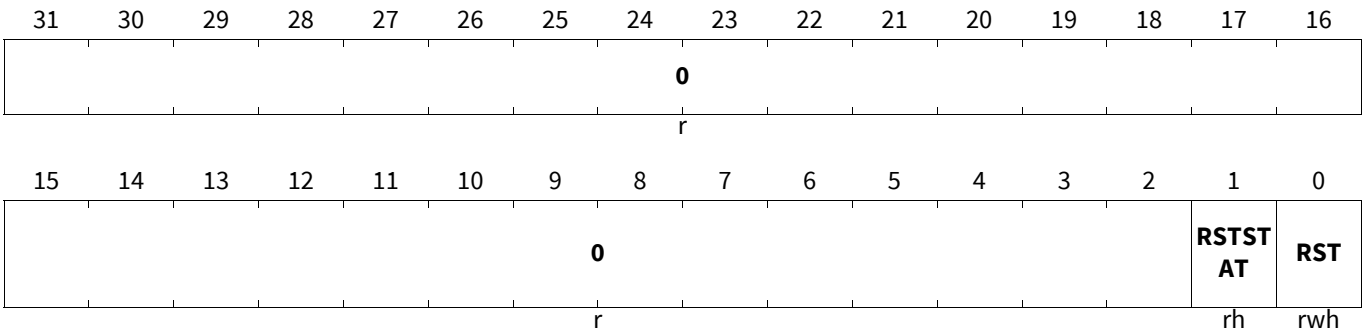
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 **(0F4$_H$)** **Application Reset Value: 0000 0000$_H$**



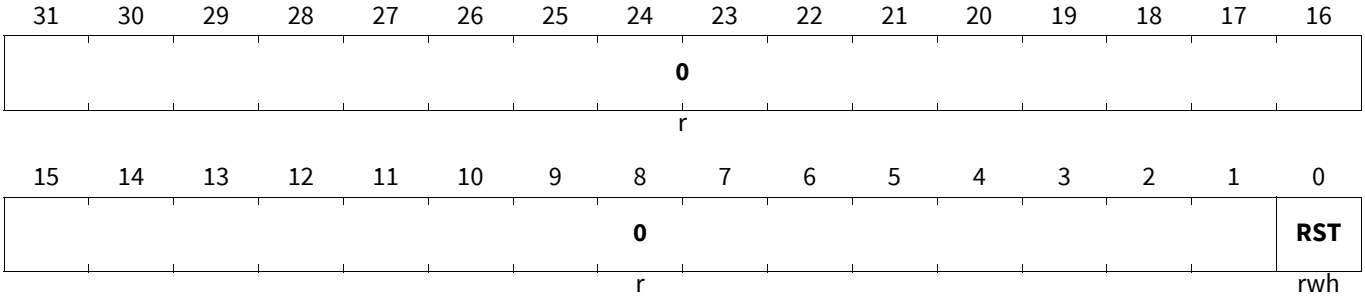
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1 **($0F0_H$)** **Application Reset Value: $0000\ 0000_H$**



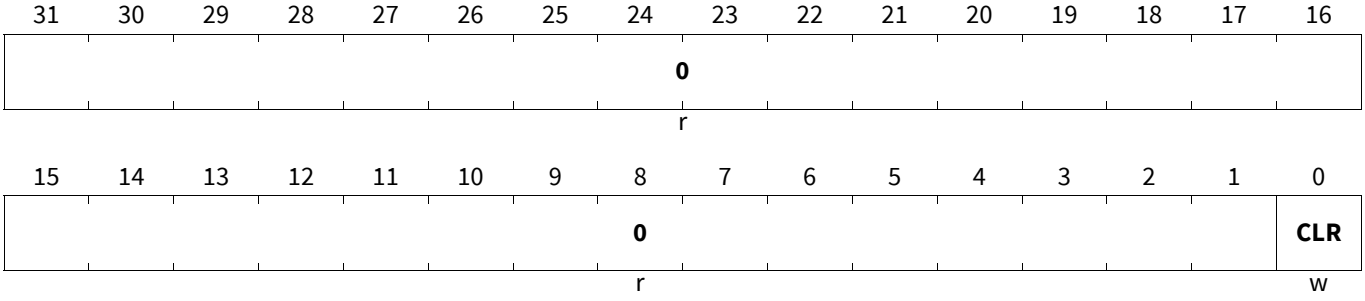
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **($0EC_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

36.3.16 On-Chip Connections

This section describes the on-chip connections of the ASCLINx module instances.

Port/Pin Connections

The connections of the ASCLIN modules to the pins / ports is described in the chapters describing the pinning and the ports.

Input signals not connected to ports/pins are connected as follows:

- The unconnected ARX signals in the lower half range (RXA to RXD) are connected to (active) low level, “0”
- The unconnected ARX signals in the upper half range (RXE to RXH) are connected to (inactive) high level, “1”
- The unconnected ACTS signals are connected to low level “0”, which is after reset the inactive level (but disabled via IOCR.CTSEN (**Input and Output Control Register**) bit field, meaning don’t care)

ASCLIN Connection to Itself

the following connection is defined for each ASCLIN instance:

ARTS -> ACTSD

This connection can be useful in the SPI mode, where frequently the transmission and the reception of data are performed in parallel. If this connection is selected by using IOCR.CTS (**Input and Output Control Register**), the TXFIFO will deliver data for transmission only if there is a free space in the RXFIFO. If not, the TXFIFO will wait for emptying of the RXFIFO by software and then automatically continue the transmission.

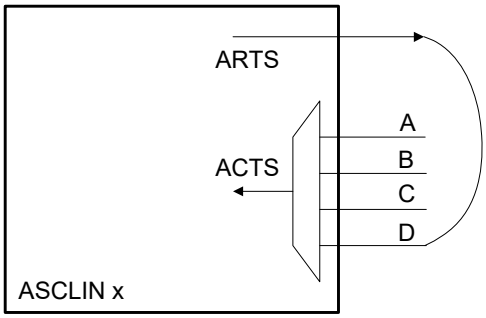


Figure 453 ASCLIN ARTS to ACTS Connection

36.3.17 ASC at CAN Support

The ASC Tx and Rx signals are overlaid with CAN Rx and Tx signal. See the Ports chapter and the Pinning chapter for the particular pin assignments.

A virgin device with a completely erased flash memory can be booted via ASC at CAN pins. See the Boot chapter for details on the implementation.

36.4 Registers

This section describes the kernel registers of the ASCLIN module. All ASCLIN kernel register names described in this section will be referenced in other parts of this device by the module name prefix “ASCLIN0_” for the ASCLIN0 interface and “ASCLIN1_” for the ASCLIN1 interface.

All registers in the ASCLIN address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

36.4.1 Kernel Registers

Input and Output Control Register

The Input and Output Control Register IOCRx determines several properties of the RX and TX signal path:

For the RX signal:

- The alternate input
- The filter depth

For the TX signal:

- The trigger source

Note: IOCR is only writable, if CSR.CLKSEL=0.

IOCR

Input and Output Control Register (004_H) Application Reset Value: $X000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXM	RXM	CTSEN	LB	SPOL	CPOL	RCPOL	0							CTS	
rh	rh	rw	rw	rw	rw	rw	r							rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						DEPTH						0		ALTI	
r						rw						r		rw	

Field	Bits	Type	Description
ALTI	2:0	rw	**Alternate Input Select** Selects the alternate input for the RX signal: 000_B Alternate Input A selected 001_B Alternate Input B selected 010_B Alternate Input C selected 011_B Alternate Input D selected 100_B Alternate Input E selected 101_B Alternate Input F selected 110_B Alternate Input G selected 111_B Alternate Input H selected
DEPTH	9:4	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with microticks that are taken into account for the calculation of the floating average. The higher the DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 00_H off, default 01_H 1 … $3F_H$ 63
CTS	17:16	rw	**CTS Select** Selects the CTS input pin out of maximum four possible. 00_B ACTSA 01_B ACTSB 10_B ACTSC 11_B ACTSD
RCPOL	25	rw	**RTS CTS Polarity** RCPOL defines the active level or the RTS and CTS signals. Active means ready/clear to send. 0_B Active high 1_B Active low
CPOL	26	rw	**Clock Polarity in Synchronous Mode** CPOL defines the idle level of the clock signal if the module is set in the SPI mode. The idle level is the level outside the data transmission time intervals. Default is low level. 0_B Idle low 1_B Idle high
SPOL	27	rw	**Slave Polarity in Synchronous Mode** Defines the idle level of the SLSO signal, which is the level outside the data transmission, leading and trailing time intervals. 0_B Idle low 1_B Idle high

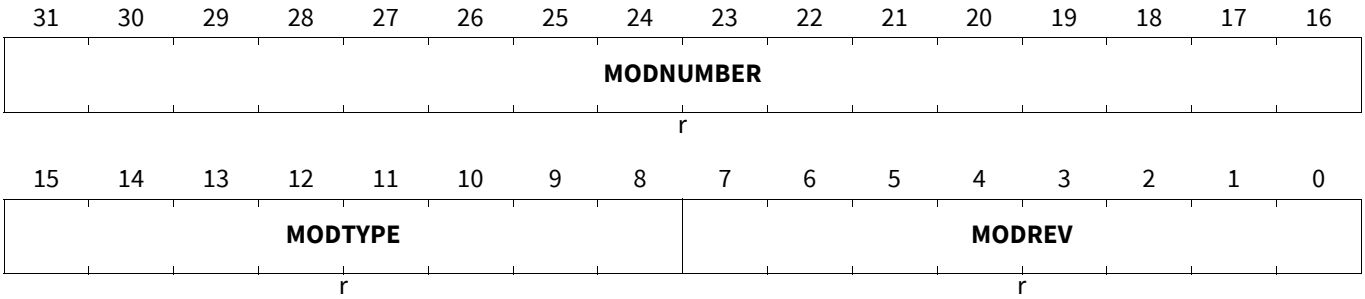
Field	Bits	Type	Description
LB	28	rw	**Loop Back Mode** Enables the in module connection of the transmit signal to receive signal. If Loop-back is enabled, the module can be run and tested without an external connection, in ASC and SPI modes. In LIN mode, loopback should not be used, because the module can be either master or slave. 0_B Disabled 1_B Enabled
CTSEN	29	rw	**Input Signal CTS Enable** Enables the sensitivity of the module to the external CTS signal. If disabled, the CTS signal is considered being permanently active. 0_B Disabled 1_B Enabled
RXM	30	rh	**Receive Monitor** Shows the status of the receive signal. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor** Shows the status of the transmit signal. 0_B Current signal is low. 1_B Current signal is high.
0	3, 15:10, 24:18	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(008_H)** **Application Reset Value: $00C1\ C0XX_H$**



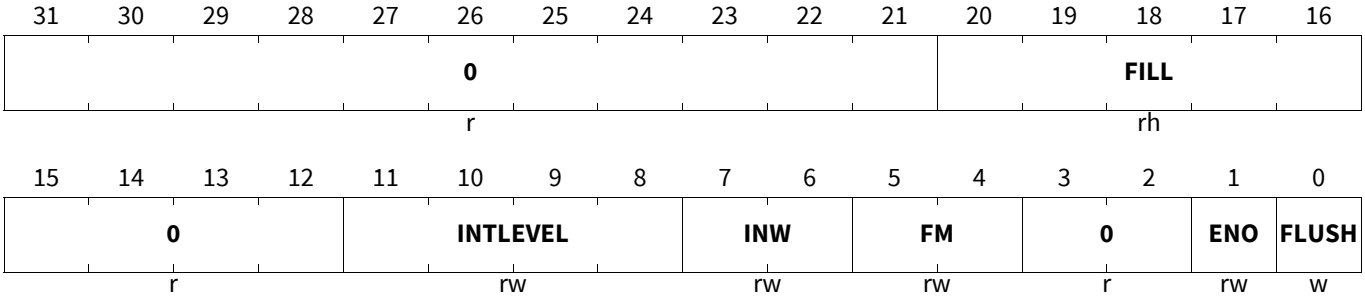
Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field is $C0_H$. It defines a 32-bit module.

Field	Bits	Type	Description
MODNUMBER	31:16	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

TX FIFO Configuration Register

TXFIFOCON

TX FIFO Configuration Register **($00C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
FLUSH	0	w	**Flush the transmit FIFO** Write of 1 brings the Tx FIFO in empty state. Write of 0 has no effect. 0_B No effect / This value will be always read back from the Bit. 1_B Empty the Tx FIFO
ENO	1	rw	**Transmit FIFO Outlet Enable** Enables the TxFIFO outlet. In SPI and ASC modes, data transmission starts immediately when the data is available, whereas in LIN case the transmission start is controlled by the protocol engine. 0_B Disabled. In LIN case, if the protocol engine tries to fetch data. 1_B Enabled. In LIN case, no data is moved to the shift register until it is fetched by the protocol engine.
FM	5:4	rw	**TXFIFO Mode** Selects between the TXFIFO Modes. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved
INW	7:6	rw	**Transmit FIFO Inlet Width** Defines the number of bytes written to the Tx FIFO with one FPI bus write. 00_B 0 01_B 1 10_B 2 11_B 4

Field	Bits	Type	Description
INTLEVEL	11:8	rw	**FIFO Interrupt Level** Defines the filling level that triggers a re-fill interrupt or DMA access. An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO. This behavior corresponds to the Combined/Compatibility Mode of interrupt generation. See also Single Move Mode and Batch Move Mode for two additional modes. 0_H 0 … F_H 15
FILL	20:16	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00_H 0 … 10_H 16 11_H Reserved … $1F_H$ Reserved
0	3:2, 15:12, 31:21	r	**Reserved** Read as 0; should be written with 0.

RX FIFO Configuration Register

RXFIFOCON

RX FIFO Configuration Register **(010_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BUF	**0**										**FILL**				
rw	r										rh				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				**INTLEVEL**				**OUTW**		**FM**		**0**		**ENI**	**FLUSH**
r				rw				rw		rw		r		rwh	w

Field	Bits	Type	Description
FLUSH	0	w	**Flush the receive FIFO** Write of 1 brings the Rx FIFO in empty state. Write of 0 has no effect. 0_B No effect / This value will be always read back from the module. 1_B Empty the Rx FIFO

Field	Bits	Type	Description
ENI	1	rwh	**Receive FIFO Inlet Enable** Enables the receiver and the filling of the Rx FIFO through the shift register. In LIN slave mode, this bit is set by hardware after the correct reception of the sync byte. The software can clear this bit after reception of an foreign ID in order to suppress the reception of the following response. 0_B Disabled 1_B Enabled
FM	5:4	rw	**RXFIFO Mode** Selects between the RXFIFO Modes. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved
OUTW	7:6	rw	**Receive FIFO Outlet Width** Defines the number of bytes read to the Rx FIFO with one FPI bus read. 00_B 0 01_B 1 10_B 2 11_B 4
INTLEVEL	11:8	rw	**FIFO Interrupt Level** Defines the filling level that triggers a drain interrupt or DMA access. An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO. This behavior corresponds to the Combined/Compatibility Mode of interrupt generation. See also Single Move Mode and Batch Move Mode for two additional modes. 0_H 1 … F_H 16
FILL	20:16	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO. 00_H 0 … 10_H 16 11_H Reserved … $1F_H$ Reserved
BUF	31	rw	**Receive Buffer Mode** If this bit is zero, then the RXFIFO behaves normally as described in this document. If this bit is set, the RXFIFO behaves as simple 32-bit one stage RX buffer, which is overwritten with each new received data. The received bits appear in the RXDATA register on the lowest bit locations. The upper locations are padded with zeros. 0_B RXFIFO 1_B Single Stage RX Buffer

Field	Bits	Type	Description
0	3:2, 15:12, 30:21	r	**Reserved** Read as 0; should be written with 0.

Bit Configuration Register

The BITCON Register defines the integer timer parameters in the baud rate generation block.
Note: The register is only writable, if CSR.CLKSEL=0.

BITCON
Bit Configuration Register **(014_H)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SM		**0**		**SAMPLEPOINT**				**0**				**OVERSAMPLING**			
rw		r		rw				r				rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				**PRESCALER**											
r				rw											

Field	Bits	Type	Description
PRESCALER	11:0	rw	**Prescaling of the Fractional Divider** Prescaler bit-field with values in the range of 0 to 4095, defining division ratios from 1 to 4096. Used also as a microtick generator for the input digital filter.
OVERSAMPLING	19:16	rw	**Oversampling Factor** Defines the bit length in ticks in the range of 1 to 16. The lengths of 1 to 3 are not allowed. The position of the sampling points is shown in **Figure 436**. 0_H 1 (not allowed) 1_H 2 (not allowed) 2_H 3 (not allowed) 3_H 4 … F_H 16
SAMPLEPOINT	27:24	rw	**Sample Point Position** Programmable in the range of 0 to 15 according to the **Figure 436**. For example, if three sample points at position 7, 8, 9 are required, this bit field would contain 9. In SPI mode, this bit field + 1 defines the length of the first SCLK half period in ticks. Values equal or higher then the OVERSAMPLING value are forbidden. 0_H 0 (not allowed) 1_H 1 … F_H 15

Field	Bits	Type	Description
SM	31	rw	**Sample Mode** Number of samples per bit. 0_B 1 1_B 3
0	15:12, 23:20, 30:28	r	**Reserved** Read as 0; should be written with 0.

Frame Control Register

The parameters regarding the properties of the message frame of the ASC communication are controlled by the Frame Control Register FRAMECON.
Note: The register is only writable, if CSR.CLKSEL=0.

FRAMECON
Frame Control Register **(018_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ODD	**PEN**	**CEN**	**MSB**	**0**										**MODE**	
rw	rw	rw	rw	r										rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	**LEAD**			**STOP**			**IDLE**			**0**					
r	rw			rw			rw			r					

Field	Bits	Type	Description
IDLE	8:6	rw	**Duration of the IDLE delay** Defines the duration of the IDLE delay in bit times. If more characters are available in the TXFIFO, this is the pause inserted between the characters. In the SPI mode, this is the idle time between the frames. In the ASC and LIN mode, this is the pause inserted between transmission of bytes. Idle also applies to the pause between the header and the response (response space). *Note: The collision detection runs in parallel to the idle delay and in LIN master mode it may extend the time between two bytes for one bit length. This effect may occur if the round trip delay including the digital filter delay is longer than the idle delay. For LIN slave mode use IDLE=0.* 000_B 0 … 111_B 7

Field	Bits	Type	Description
STOP	11:9	rw	**Number of Stop Bits** Defines the number of stop bits in ASC and LIN mode, or the trailing delay in SPI mode. In ASC mode, standard values are 1 and 2. In LIN mode, standard value is 1. In SPI mode there is no standard value. Nevertheless, all settings are possible in all modes. 000_B 0 (not allowed in ASC and LIN modes) 001_B 1 … 111_B 7
LEAD	14:12	rw	**Duration of the Leading Delay** Defines the leading delay in bit times in SPI mode. Has no meaning in the ASC mode. In LIN mode, this is a delay inserted between the end of the break and the start of the sync character. 000_B 0 (not allowed in LIN mode and 4-Wire SPI mode) 001_B 1 … 111_B 7
MODE	17:16	rw	**Mode Selection** This bit field defines the basic operating mode of the module. In INIT mode, all outputs are at inactive level, and the module does not respond to the input signals. Changing the mode of the module must be done by switching first to INIT mode, and then to the other mode. The SCLK signal generated by the module is active only in the SPI mode. The CTS output generated by the module is active only in the ASC mode. 00_B INIT mode 01_B ASC mode 10_B SPI mode 11_B LIN mode
MSB	28	rw	**Shift Direction** Defines the shift direction of the shift register. Relevant for the SPI mode. In ASC and LIN modes, should be set to zero. Parity bit is shifted out last independently of the shift direction. 0_B LSB first 1_B MSB first
CEN	29	rw	**Collision Detection Enable** Enables the collision detection mechanism. 0_B Disabled 1_B Enabled
PEN	30	rw	**Parity Enable** Enables the parity bit attached to the data bits. Parity bit can be used for ASC and SPI protocols. The standard LIN bytes do not use this parity bit. 0_B Disabled 1_B Enabled

Field	Bits	Type	Description
ODD	31	rw	**Parity Type** Defines the type of parity bit attached to the data bits. This setting is valid for all modes of operation (ASC, LIN, SPI). 0_B Even 1_B Odd
0	5:0, 15, 27:18	r	**Reserved** Read as 0; should be written with 0.

Data Configuration Register

DATCON register defines the number of bits in the ASC (affecting the LIN protocol, if used) and SPI frames, data length or the number of data bytes in a LIN response (if any) and the checksum mode. It additionally defines the time window for the LIN response.

In case the whole LIN response does not fit in this time window, an error interrupt is generated. The measurement starts at the end of the last bit of the header, and ends at the end of the last bit of the response.

DATCON
Data Configuration Register **($01C_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								RESPONSE							
r								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSM	RM	HO	0									DATLEN			
rw	rw	rw	r									rw			

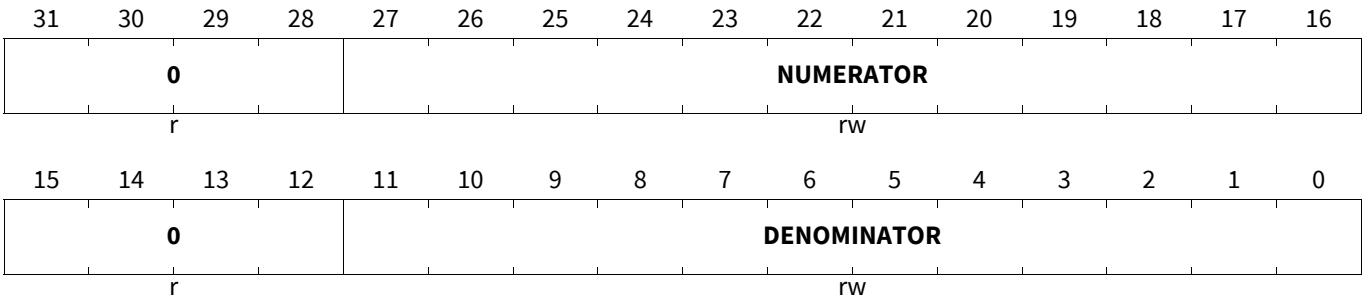
Field	Bits	Type	Description
DATLEN	3:0	rw	**Data Length** Defines the number of bits in a character. In the ASC mode, standard length is 7, 8, or 9 bits. In the SPI mode, there is no standard length. In ASC and SPI modes, any length from 2 to 16 bits is possible, although not standard for some protocols. In LIN mode, standard length is 8 bits per character. Therefore, this field defines the number of data bytes of the response. 0_H 1 … F_H 16
HO	13	rw	**Header Only** Defines if the LIN frame shall consist of a header and response or of a header only. 0_B Header and response expected 1_B Header only expected, response ignored

Field	Bits	Type	Description
RM	14	rw	**Response Mode** Defines if the RESPONSE bit field defines a LIN Response or LIN Frame timeout threshold. See **Figure 443**. 0_B Frame 1_B Response
CSM	15	rw	**Checksum Mode** Defines if the classic or the enhanced checksum will be calculated by the checksum block. 0_B Classic 1_B Enhanced
RESPONSE	23:16	rw	**Response Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times.
0	12:4, 31:24	r	**Reserved** Read as 0; should be written with 0.

Baud Rate Generation Register

Configures the numerator and the denominator of the fractional divider in the baud rate generation block.
Note: The register is only writable, if CSR.CLKSEL=0.

BRG
Baud Rate Generation Register **(020_H)** **Application Reset Value: $0000\ 0000_H$**

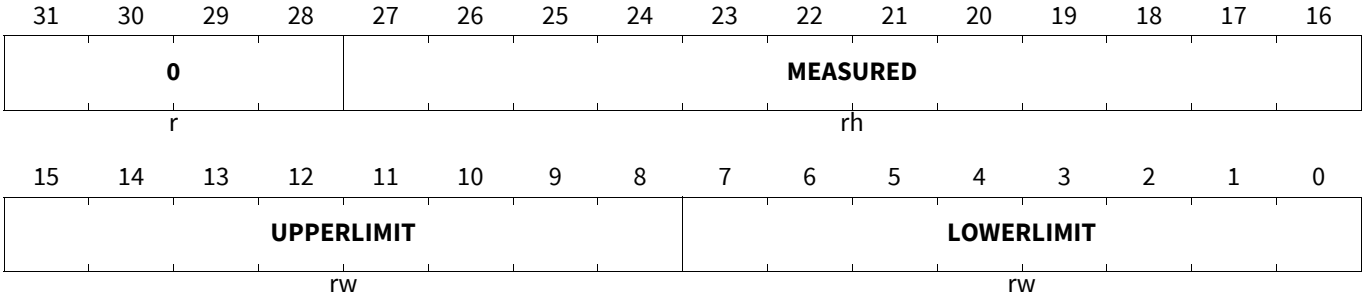


Field	Bits	Type	Description
DENOMINATOR	11:0	rw	**Denominator** Programmed by software, in a range of 0 to 4095. The setting of 0 is not allowed If the module is used as ASC, SPI, LIN master and LIN slave without autobaud detection, this value determines the baud rate. In slave mode with autobaud detection, it contains the nominal value. For the value measured by the autobaud detection hardware, see the **BRD** register.
NUMERATOR	27:16	rw	**Numerator** Defines the numerator of the fractional divider in a range of 0 to 4095. Programmed by software. The setting of 0 is not allowed.
0	15:12, 31:28	r	**Reserved** Read as 0; should be written with 0.

Baud Rate Detection Register

The BRD defines the properties specific for the automatic baud rate detection when the module operates as a LIN slave.
Note: The register is only writable, if CSR.CLKSEL=0.

BRD
Baud Rate Detection Register **(024_H)** **Application Reset Value: 0000 0000$_H$**

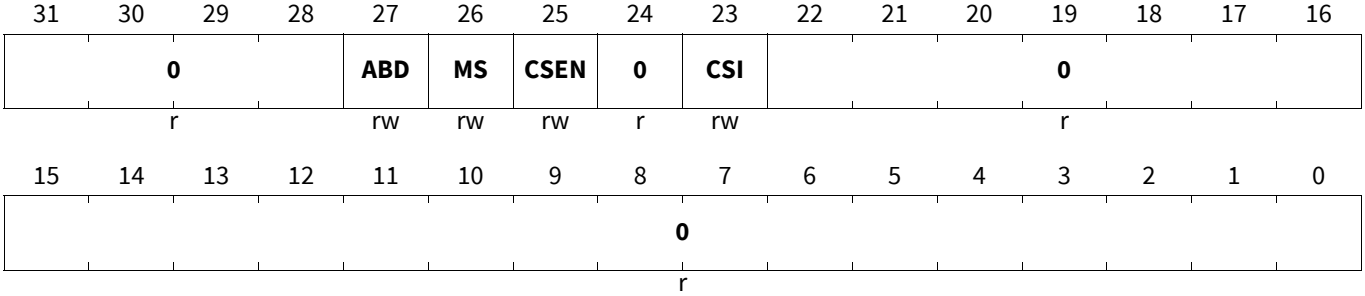


Field	Bits	Type	Description
LOWERLIMIT	7:0	rw	**Lower Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
UPPERLIMIT	15:8	rw	**Upper Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B. See **Auto Baud Rate Detection**.
MEASURED	27:16	rh	**Measured Value of 8-bits from Sync Field** This bit field contains the measured value of the duration of 8-bits form the sync field of the LIN header in microticks. It is automatically loaded in the denominator of the fractional divider, in case of LIN slave operation with autobaud detection.
0	31:28	r	**Reserved** Read as 0; should be written with 0.

LIN Control Register

LINCON contains bits that control LIN specific features of the module.
Note: The register is only writable, if CSR.CLKSEL=0.

LINCON
LIN Control Register **(028_H)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CSI	23	rw	**Checksum Injection** Defines if the received checksum byte is written into the RXFIFO or not. See **LIN Protocol Control**. 0_B Not written 1_B Written
CSEN	25	rw	**Hardware Checksum Enable** Enables the hardware checksum generation and checking. 0_B Disabled 1_B Enabled
MS	26	rw	**Master Slave Mode** Configures if the module in LIN mode operates as master or as slave. 0_B Slave 1_B Master
ABD	27	rw	**Autobaud Detection** Enables the autobaud detection feature in LIN slave mode. In all other operating modes of the module (LIN master, ASC, SPI) not effective. If the autobaud detection is disabled (the oscillator precision of the slave is sufficient), the sync field (byte field and stop bit) is checked if correct. If not correct, a framing error is triggered. 0_B Disabled 1_B Enabled
0	22:0, 24, 31:28	r	**Reserved** Read as 0; should be written with 0.

LIN Break Timer Register

This register defines

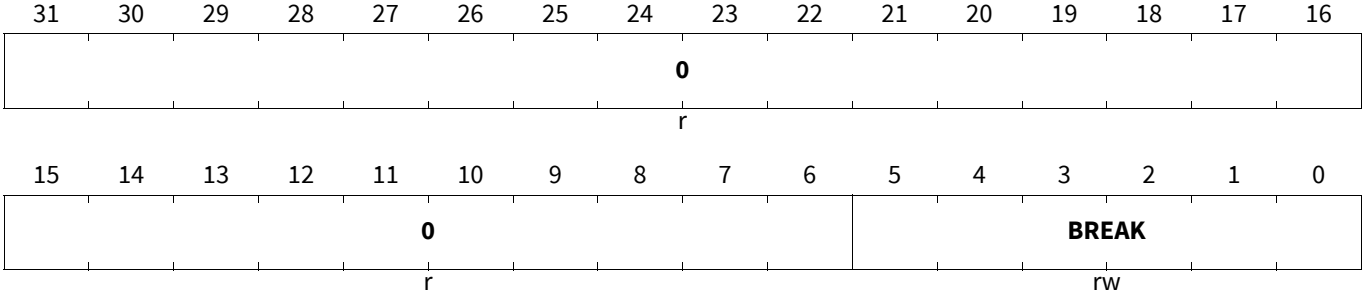
- break detection limit if the module operates as LIN slave or
- length of the generated break pulse if the module operates as LIN master.

The break timer, if enabled, monitors the bus continuously.

Note: The register is only writable, if CSR.CLKSEL=0.

LINBTIMER

LIN Break Timer Register **($02C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
BREAK	5:0	rw	**Break Pulse Generation and Detection** In LIN slave mode, this bit field defines the duration of the detection threshold for the break pulse. In LIN master mode, this bit field defines the duration of the transmitted break pulse. The time unit is bit time.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

LIN Header Timer Register

LINHTIMER register defines the time windows for the header of a LIN frame.

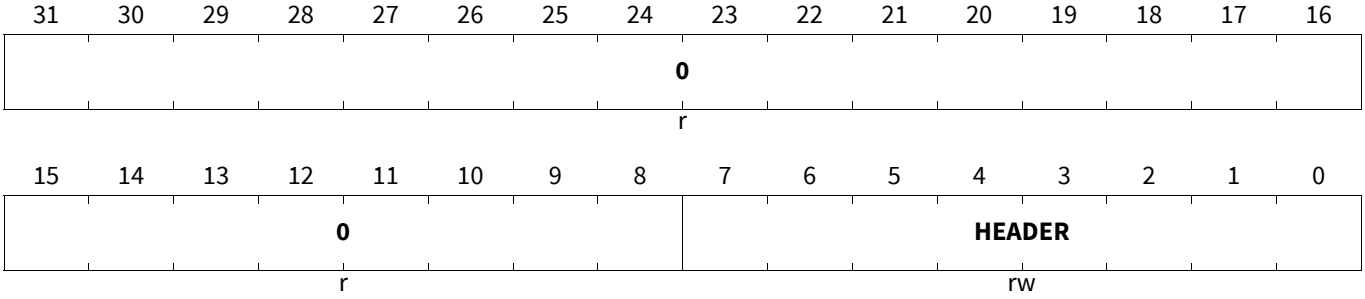
In master mode, the timer starts counting at the falling edge of the break pulse, and stops counting when the last bit of the header (including the stop bits) has been transmitted. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

In slave mode, the timer starts counting when the break pulse has been detected, after a low time of 10 or 11 bit times, and stops counting when the last bit of the header has been received. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

Note: The register is only writable, if CSR.CLKSEL=0.

LINHTIMER

LIN Header Timer Register **(030_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
HEADER	7:0	rw	**Header Timeout Threshold Value** Defines the timer limit in the range of 0 to 255 bit times.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

Flags Register

The FLAGS register contains all the flag bits of the ASCLIN module: the LIN phase flags (header and response transmit and receive), the overflow flags of the LIN timers, and the standard ASC error flags.

A corresponding interrupt triggering can be enabled using the FLAGSENABLE register.

FLAGS

Flags Register **(034$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	r						rh	rh	r	rh	rh	rh	rh

Field	Bits	Type	Description
TH	0	rh	**Transmit Header End Flag** Signals the HEADER_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No HEADER_TX_END event since the last clear by software 1_B New HEADER_TX_END event since the last clear by software
TR	1	rh	**Transmit Response End Flag** Signals that RESPONSE_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No RESPONSE_TX_END event since the last clear by software 1_B New RESPONSE_TX_END event since the last clear by software
RH	2	rh	**Receive Header End Flag** Signals that HEADER_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No HEADER_RX_END event since the last clear by software 1_B New HEADER_RX_END event since the last clear by software
RR	3	rh	**Receive Response End Flag** Signals that RESPONSE_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No RESPONSE_RX_END event since the last clear by software 1_B New RX_RESPONSE_END event since the last clear by software
FED	5	rh	**Falling Edge from Level 1 to Level 0 Detected** This bit is set by hardware when a falling edge is detected on the RX line. 0_B No falling edge detected 1_B Falling edge detected
RED	6	rh	**Rising Edge from Level 0 to Level 1 Detected** This bit is set by hardware when a rising edge is detected on the RX line. 0_B No rising edge detected 1_B Rising edge detected

Field	Bits	Type	Description
TWRQ	13	rh	**Transmit Wake Request Flag** Signals that transmission of wake has been requested. No interrupt triggered. As soon as the wake pulse transmission starts, the bit is cleared by the hardware. 0_B No Transmit Wake Request pending 1_B Transmit Wake Request pending.
THRQ	14	rh	**Transmit Header Request Flag** Signals that transmission of header has been requested. No interrupt triggered. As soon as the header transmission starts, the bit is cleared by the hardware. 0_B No Transmit Header Request pending 1_B Transmit Header Request pending.
TRRQ	15	rh	**Transmit Response Request Flag** Signals that transmission of response has been requested. No interrupt triggered. As soon as the response transmission starts, the bit is cleared by the hardware. 0_B No Transmit Response Request pending 1_B Transmit Response Request pending.
PE	16	rh	**Parity Error Flag** Signals parity error. If enabled, an error interrupt is triggered. Parity error occurs if the internally calculated parity bit is not equal to the received parity bit. 0_B Last message received error free 1_B Last message received with parity error
TC	17	rh	**Transmission Completed Flag** Signals an end of an ASC or SPI frame. This bit is set after the last stop bit transmission in ASC mode, or after the trailing delay in case of SPI mode. In LIN mode, if the node is transmitting a header this flag is set after each transmission break (incl lead) field, Sync field or PID field. If the node is transmitting a response, this flag is set after each byte is transmitted. If enabled, an EX interrupt is triggered. Should be cleared by software. 0_B No end of frame event occurred 1_B End of frame event occurred
FE	18	rh	**Framing Error Flag** Signals framing error. If enabled, an error interrupt is triggered. Framing error occurs if “0” is received at a stop bit position. If autobaud detection is deactivated, then the sync field is checked for framing error. 0_B Last message received error free 1_B Last message received with error
HT	19	rh	**Header Timeout Flag** Signals violation of the header duration limit. If enabled, an error interrupt is triggered. 0_B No HEADER_OVERFLOW event since the last clear by software 1_B New HEADER_OVERFLOW event since the last clear by software

Field	Bits	Type	Description
RT	20	rh	**Response Timeout Flag** Signals violation of the response or frame duration limit as defined in **DATCON**.RM bit. If enabled, an error interrupt is triggered. 0_B No timeout event since the last clear by software 1_B New timeout event since the last clear by software
BD	21	rh	**Break Detected Flag** Signals a detection of a break pulse. If enabled, an error interrupt is triggered. Slave mode only. 0_B No Break/Wake/Stuck event since the last clear by software 1_B New Break/Wake/Stuck event since the last clear by software
LP	22	rh	**LIN Parity Error Flag** Signals parity error in the LIN identifier. If enabled, an error interrupt is triggered. Applies to LIN mode only. LIN parity error occurs if the internally calculated parity bits are not equal to the received parity bits. 0_B Last ID received error free 1_B Last ID received with parity error
LA	23	rh	**LIN Autobaud Detection Error Flag** Signals baudrate outside the range defined by **BRD**.LOWERLIMIT and **BRD**.UPPERLIMIT. 0_B No autobaud detection error 1_B Autobaud detection error
LC	24	rh	**LIN Checksum Error Flag** Signals checksum error when receiving response, if the internally calculated checksum is different than the received checksum. If enabled, an error interrupt is triggered. 0_B Last checksum error free 1_B Last checksum shows an error
CE	25	rh	**Collision Detection Error Flag** When transmitting, signals if the transmitted data differs from the received data. If enabled, an error interrupt is triggered in case of a mismatch. Collision detection is mandatory only when supporting LIN version 2.1. 0_B No mismatch 1_B Mismatch detected
RFO	26	rh	**Receive FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error occurred 1_B Overflow error occurred
RFU	27	rh	**Receive FIFO Underflow Flag** Signals an underflow error. If enabled, an error interrupt is triggered. See also **RxFIFO Overview**. 0_B No underflow error occurred 1_B Underflow error occurred

Field	Bits	Type	Description
RFL	28	rh	**Receive FIFO Level Flag** This flag signals whenever a RXFIFO fill interrupt is generated based on RXFIFOCON.FM mode. 0_B No receive interrupt occurred 1_B Receive interrupt occurred
TFO	30	rh	**Transmit FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error occurred 1_B Overflow error occurred
TFL	31	rh	**Transmit FIFO Level Flag** This flag signals whenever a TXFIFO refill interrupt (if enabled) is generated based on TXFIFOCON.FM mode. 0_B No transmit interrupt occurred 1_B Transmit interrupt occurred
0	4, 12:7, 29	r	**Reserved** Read as 0; should be written with 0.

Flags Set Register

The FLAGSSET register contains the write only bits used to set the corresponding bits in the FLAGS register by software. Setting a flag bit triggers an interrupt, if the corresponding interrupt enable bit is set. A read access to the register always results in 0.

FLAGSSET
Flags Set Register **(038_H)** **Application Reset Value: $0000\ 0000_H$**

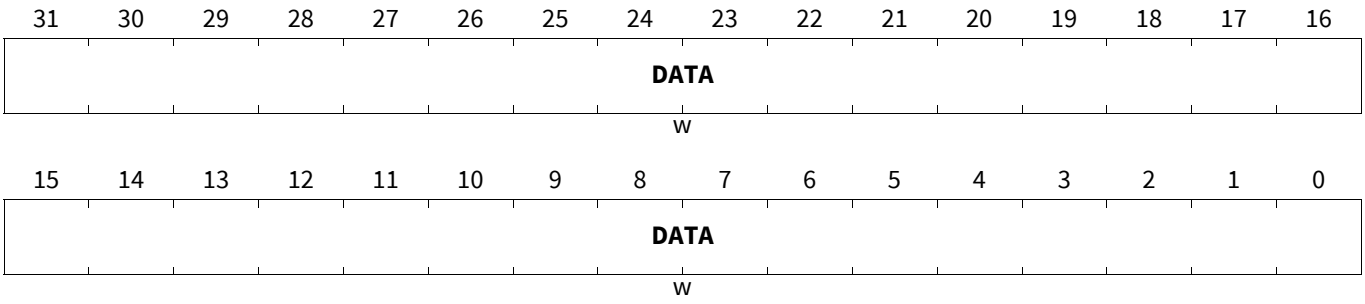
TFLE	31	rw	**Flag Enable Bit** This bit enables the interrupt for the flag at the corresponding position in the FLAGS register. 0_B Disabled 1_B Enabled
0	4, 15:7, 29	r	**Reserved** Read as 0; should be written with 0.

Transmit Data Register

Writing data to this register enters the data to the TXFIFO.

TXDATA
Transmit Data Register (044_H) Application Reset Value: $0000\ 0000_H$

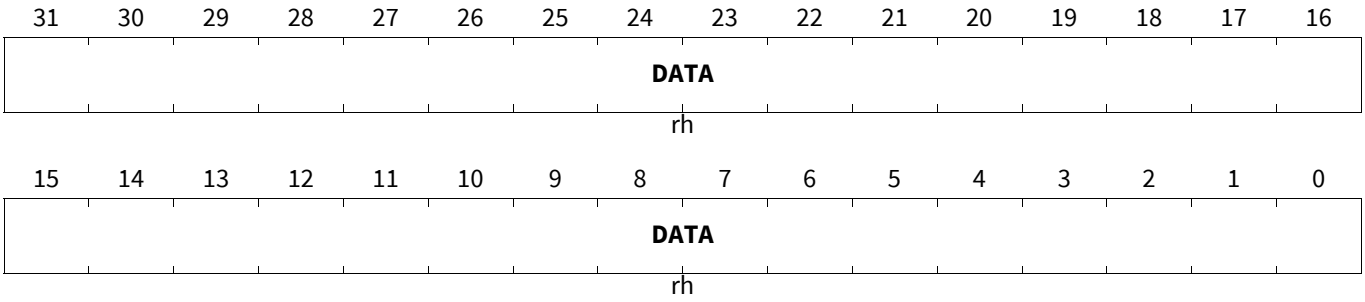


Field	Bits	Type	Description
DATA	31:0	w	**Data** Writing to this bit field writes the content to the TXFIFO, depending on the write width - 8, 16 or 32 bit (configured in TXFIFOCON.INW). A read access to this register returns 0x0.

Receive Data Register

Reading data from this register takes data from the RXFIFO.

RXDATA
Receive Data Register **(048_H)** **Application Reset Value: $0000\ 0000_H$**

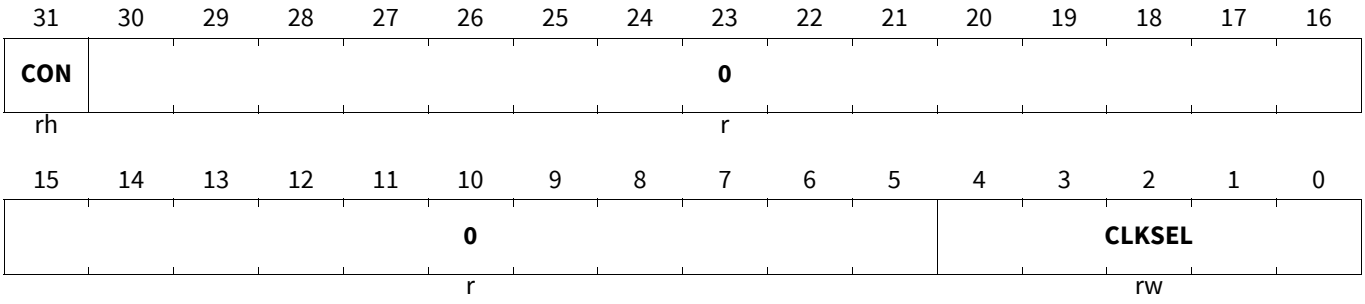


Field	Bits	Type	Description
DATA	31:0	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit (configured in RXFIFOCON.OUTW). A write access to this register has no effect.

Clock Selection Register

This register is used to select the clock source for the baud rate generation, detection, timeouts and the SPI delays.

CSR
Clock Selection Register **($04C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLKSEL	4:0	rw	**Baud Rate Logic Clock Select** 00_H No clock supplied 02_H $f_{ASCLINF}$ 04_H $f_{ASCLINS}$ (and f_{OSC0}, see CCU) **others**, not allowed
CON	31	rh	**Clock On Flag** Shows if the clock in the bit time domain is switched on or off. Many configuration registers can be written only if this bit shows 0 (see header of registers IOCR, BITCON, FRAMECON, BRG, BRD, LINCON, LINBTIMER, LINHTIMER). 0_B Clock is off 1_B Clock is on

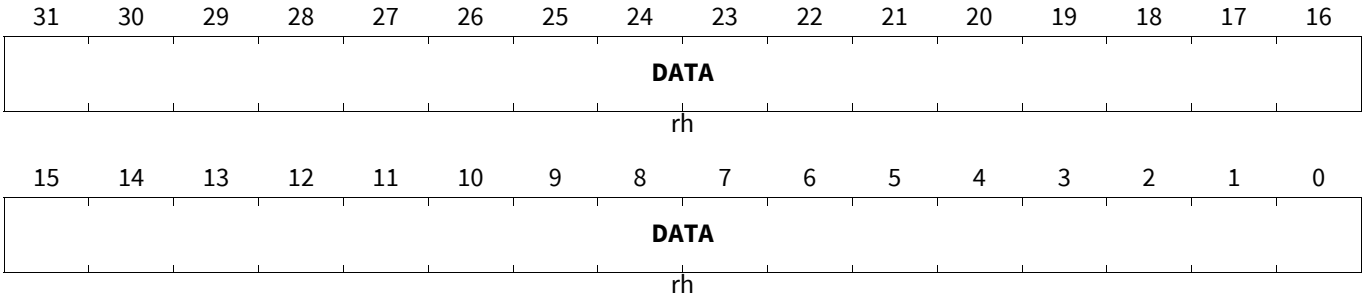
Field	Bits	Type	Description
0	30:5	r	**Reserved** Read as 0; should be written with 0.

Receive Data Debug Register

Reading data from this register takes data from the RXFIFO, but does not influence the read pointer. This virtual register provides non-destructive read to the RXFIFO.

RXDATAD

Receive Data Debug Register **(050_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DATA	31:0	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit (see RXFIFOCON.OUTW), but does not influence the read pointer of the RXFIFO. A write access to this register has no effect.

Clock Reconfiguration

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum T_W ^{3} 4 * $(1/f_A)$ + 2 * $(1/f_{CLC})$ must be inserted by software, where f_A is the frequency being switched off with the first write.

Additionally, always activate the asynchronous clock for at least two f_A cycles:

- after entering the INIT state and
- after device reset

This is an example of a correct sequence:

- CSR.CLKSEL = No_Clock (equals the reset state) (**Clock Selection Register**)
- Wait T_W or poll for CSR.CON = 0 (**Clock Selection Register**)
- FRAMECON.MODE = INIT (**Frame Control Register**)
- CSR.CLKSEL = Clock_On (**Clock Selection Register**)
- Wait T_W or poll for CSR.CON = 1
- CSR.CLKSEL = No_Clock (**Clock Selection Register**)
- Wait T_W or poll for CSR.CON = 0 (**Clock Selection Register**)
- FRAMECON.MODE = ASC (or SPI or LIN) (**Frame Control Register**)
- CSR.CLKSEL = Clock_On (**Clock Selection Register**)

- Wait T_W or poll for CSR.CON = 1 (**Clock Selection Register**)

See also LIN Slave Sequences

Abort Sequence

If a header has been transmitted in ASCLIN master mode, and the corresponding response does not come, the waiting for the response can be aborted by first entering the INIT mode and then entering the LIN mode. The sequence is identical with the example sequence above.

36.5 Use Cases

This section explains the core functionality of the ASCLIN interface with a code example. The example uses the ASC feature of the module to transmit and receive a data set via loop back mode (see also **Architecture Overview**). The following settings are used:

- The module initialized in this example is module 0.
- Data length: 8 bit
- Baud rate: 9600 Bd
- One stop bit, parity bit checking, oversampling factor 16, sampling points 7,8 and 9
- Rx and Tx interrupt

Step description to initialize the ASC module with the settings from above

(Line 1) reset ENDINIT to get access to ENDINIT protected register, here ASCLIN0_CLC (see also ENDINIT protection chapter.

(Line 2) enable the control of the module in the clock control register CLC (**Clock Control Register**)

(Line 3) store CLC (**Clock Control Register**) register in a dummy variable (has to be defined before). Read back to avoid pipeline effects.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) The clk source gets set in the clock selection register CSR (**Clock Selection Register**). Before setting a source, no clk supply (CSR(4:0)=0) must be set. Final clk selection in Line 20.

(Line 6) This line sets the loop back mode in the input and output control register IOCR (**Input and Output Control Register**). (see also **Figure 416**)

(Line 7) This line clears and enables the Tx FIFO and also defines the writing size of 1 byte per clk. The Tx FIFO filling level to trigger an interrupt gets set to 0 ([11:8] =0). The Tx FIFO triggers a Tx interrupt, if the Tx FIFO filling level falls to or below that defined level. The Tx interrupt get enabled in Line 14. (see also section TxFIFO Overview and register TXFIFOCON (**TX FIFO Configuration Register**))

(Line 8) This line installs the Rx FIFO identically like the Tx FIFO from the line above. (see also register RXFIFOCON (**RX FIFO Configuration Register**) and section RxFIFO Overview)

(Line 9) The oversampling factor (here 16), the sample points (here 7,8 and 9) and the prescaler for the baudrate (here 10) gets configured in the bit configuration register BITCON (**Bit Configuration Register**). (see also section Clock System)

(Line 10) One stop bit and initialize mode as basic operation mode (necessary before switching to another mode) are getting configured in the FRAMECON (**Frame Control Register**) register. The parity bit feature with parity type even gets also enabled.

(Line 11) The data length of 8 bits gets set in the DATCON (**Data Configuration Register**) register.

(Line 12) the clk divider for the baud rate gets set to 48/3125 in the baud rate generation register BRG (**Baud Rate Generation Register**) (see also section Clock System)

*Note: Assuming f_A = 100 MHz and (defined in line 8) prescaler = 10, oversampling = 16: fshift = (fclc/prescaler * 48/3125) / oversampling = 9600 Bd*

(Line 13) Clear all interrupt flags in the FLAGSCLEAR (**Flags Clear Register**) register. Before setting the respective interrupt flags in Line 14

(Line 14) enable the Tx and Rx interrupts in the FLAGSENABLE (**Flags Enable Register**) register. The interrupts getting triggered by the FIFO's (see Line 6/7).

(Line 15) This line enables the Tx interrupt in the service request control register SRC_ASCLIN0TX and sets the interrupt priority to ASC0TX_PRIO (1…255).

(Line 16) This line enables the Rx interrupt in the service request control register SRC_ASCLIN0RX and sets the interrupt priority to ASC0RX_PRIO (1…255).

(Line 17 and 18) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority ASC0TX_PRIO respectively ASC0RX_PRIO.

(Line 19) setting operating mode finally to ASC (see also Line 9).

Note: your Tx ISR function prototype would be: void ASC0_TX_ irq (void); here could be your ISR code;

Initialization of the ASC interface

```
(1)    SCU_vResetENDINIT (0);              // enable ENDINIT register(2)ASCLIN0_CLC =
0x000;                                  // disable module control (3)dummy = ASCLIN0_CLC;
//read back(4)SCU_vSetENDINIT (0);        // lock ENDINIT register(5)ASCLIN0_CSR = 0;
// clk source, no clk(6)ASCLIN0_IOCR = 0x10000001;       // Loopback(7)
ASCLIN0_TXFIFOCON = 0x00000043;                  // init TXFIFO(8)ASCLIN0_RXFIFOCON
= 0x00000043;                                    // init RXFIFO(9)ASCLIN0_BITCON =
0x830F0009;                                 // OS 16, SP 7,8,9, PS 10(10)
ASCLIN0_FRAMECON = 0x40000200;                   // 1 Stop, Init Mode, P(11)
ASCLIN0_DATCON = 0x7;               //8 Data Bits(12)ASCLIN0_BRG = 0x00300C35; //
divider for Baudrate (13)ASCLIN0_FLAGSCLEAR = 0xFFFFFFFFF;// Clear all Flags(14)
ASCLIN0_FLAGSENABLE = 0xF0000000;                // Enable TX/RX Int.
(15)   SRC_ASCLIN0TX = (1 << 10) | ASC0TX_PRIO;  (16)SRC_ASCLIN0RX = (1 << 10) |
ASC0RX_PRIO;(17)interruptHandlerInstall (ASC0TX_PRIO, & ASC0_TX_irq);
(18)   interruptHandlerInstall (ASC0RX_PRIO, & ASC0_RX_irq);
(19)   ASCLIN0_FRAMECON |= 0x00010000;// Mode ASC
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):
__enable();
to set this bit. (See also Architecture Manual for more details)

37 Queued Synchronous Peripheral Interface (QSPI)

The main purpose of the QSPI module is to provide synchronous serial communication with external devices using clock, data-in, data-out and slave select signals. The focus of the module is set to fast and flexible communication: either point-to-point or master-to-many slaves communication.

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

>> **BPI_FPI Module Registers**

37.1 Feature List

This section describes the features of the QSPI module.

- Master and Slave Mode operation
  - Full-duplex operation
  - Half-duplex operation
  - Automatic slave select control
  - Four-wire and three-wire type of connection
- Flexible data format
  - Programmable number of data bits: 2 to 32 data bits (plus parity: 3 to 33 bits)
  - Programmable shift direction: LSB or MSB shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock phase: data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Baud rates generated from high precision PLL clock, asynchronous to the system PLL
- Interrupt generation
  - On a transmitter FIFO event
  - On a receiver FIFO event
  - On an error condition (receive, baud rate, transmit error, parity error)
  - On a phase transition (start of frame, end of frame ...)
- QSPI supports control and data handling by the DMA controller
- Flexible QSPI pin configuration
- Hardware supported parity mode
  - Odd / even / no parity
- Seven slave select inputs $\overline{\text{SLSIB...H}}$ in Slave Mode
- Sixteen programmable slave select outputs SLSO[15:0] in Master Mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control
  - External demultiplexing of the slave select outputs support
- Several module reset options
  - State machine reset per software (only the state machine)
  - Module reset per software (both FIFOs, all registers and the state machine)
  - Automatic stop option of the state machine in slave mode after baud rate error
- Loop-Back mode
- Interoperability with SSC and USIC modules of Infineon microcontroller families, and with popular (Q)SPI interfaces of multiple suppliers
- Communication stop on RxFIFO full
  - Shift register full and RxFIFO full can pause the communication
  - Interrupt generation
- High Speed Input Capture (HSIC)
  - Provides input capture functionality for ADAS applications
  - 15-bit counter with resolution of f_{PER}

37.2 Overview

This section gives a top-level overview of the QSPI.

37.2.1 Abstract Overview

An abstract overview of the QSPI module is shown in **Figure 455**. This document describes the QSPI module according to this view: the State Machine with its configuration and status capabilities, the User Interface, and the Interrupts (in this order).

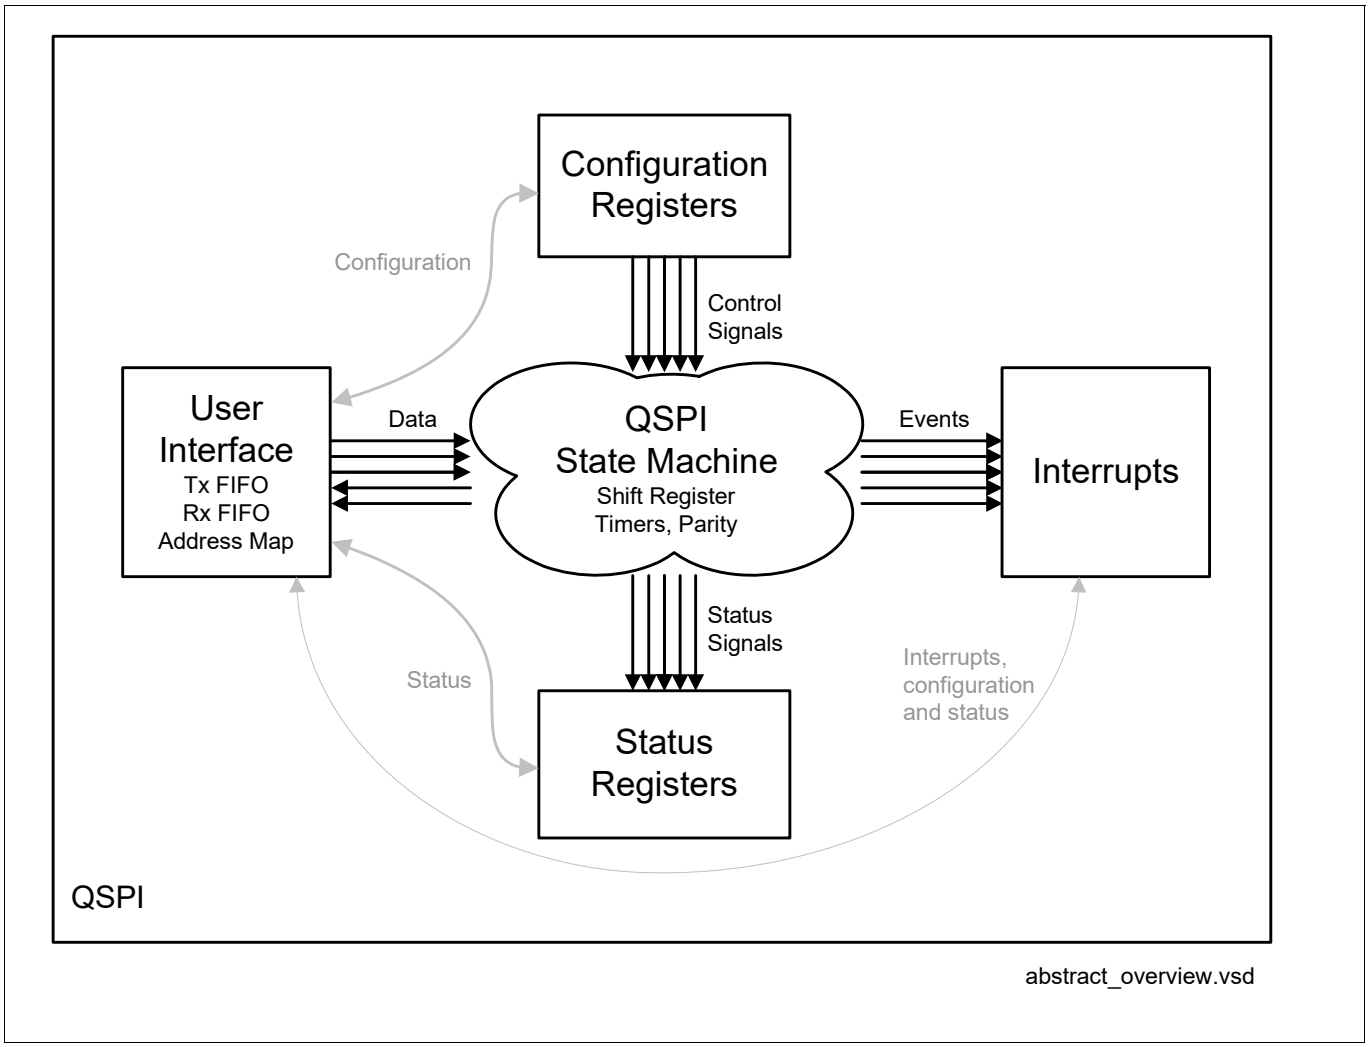

Figure 455 QSPI - Abstract Overview

37.2.2 External Signals

The communication between two devices using QSPI generally uses four signals:

- Serial clock SCLK
- Data in master to slave direction MTSR (Master Transmit Slave Receive)
- Data in slave to master direction MRST (Master Receive Slave Transmit)
- Slave select signal SLS

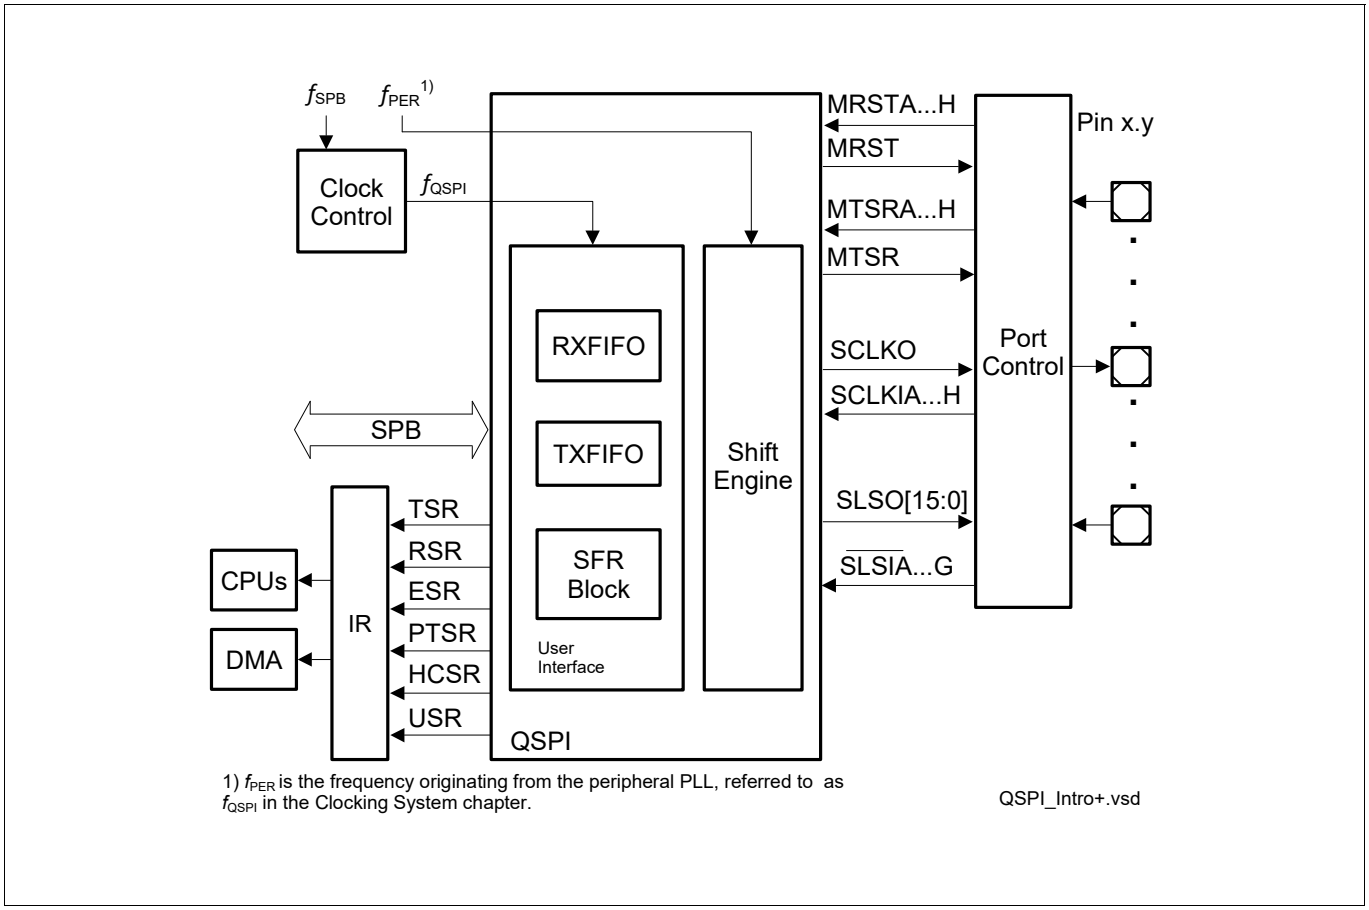

Figure 456 External Signals of the QSPI Module

37.2.3 Operating Modes

The QSPI operates in one of two modes regarding the generation of the serial clock and slave select signals: master or slave mode. The master generates and drives the clock and select signals, the slave receives these signals.

The QSPI operates in one of three modes regarding the direction of the communication and depending whether the transmission and the reception appear simultaneously or not: duplex, half-duplex and simplex mode.

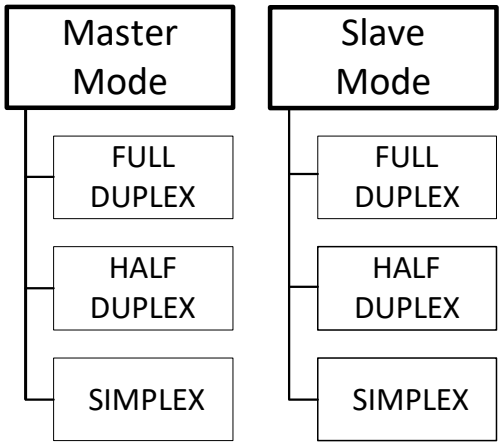

Figure 457 Operating Modes Overview

This gives six possible combinations for the operating mode of the QSPI: master duplex, half-duplex, and simplex; slave duplex, half-duplex, and simplex.

Note: The half-duplex mode can be implemented either by short-cut connection between two different pins on the pcb, one data output and one data input pin, or by using single pins mapped to both data input and data output signals. See the pinning and port chapters for the pinning definition of a particular product. The module itself does not differentiate between the full-duplex, half-duplex or simplex connection.

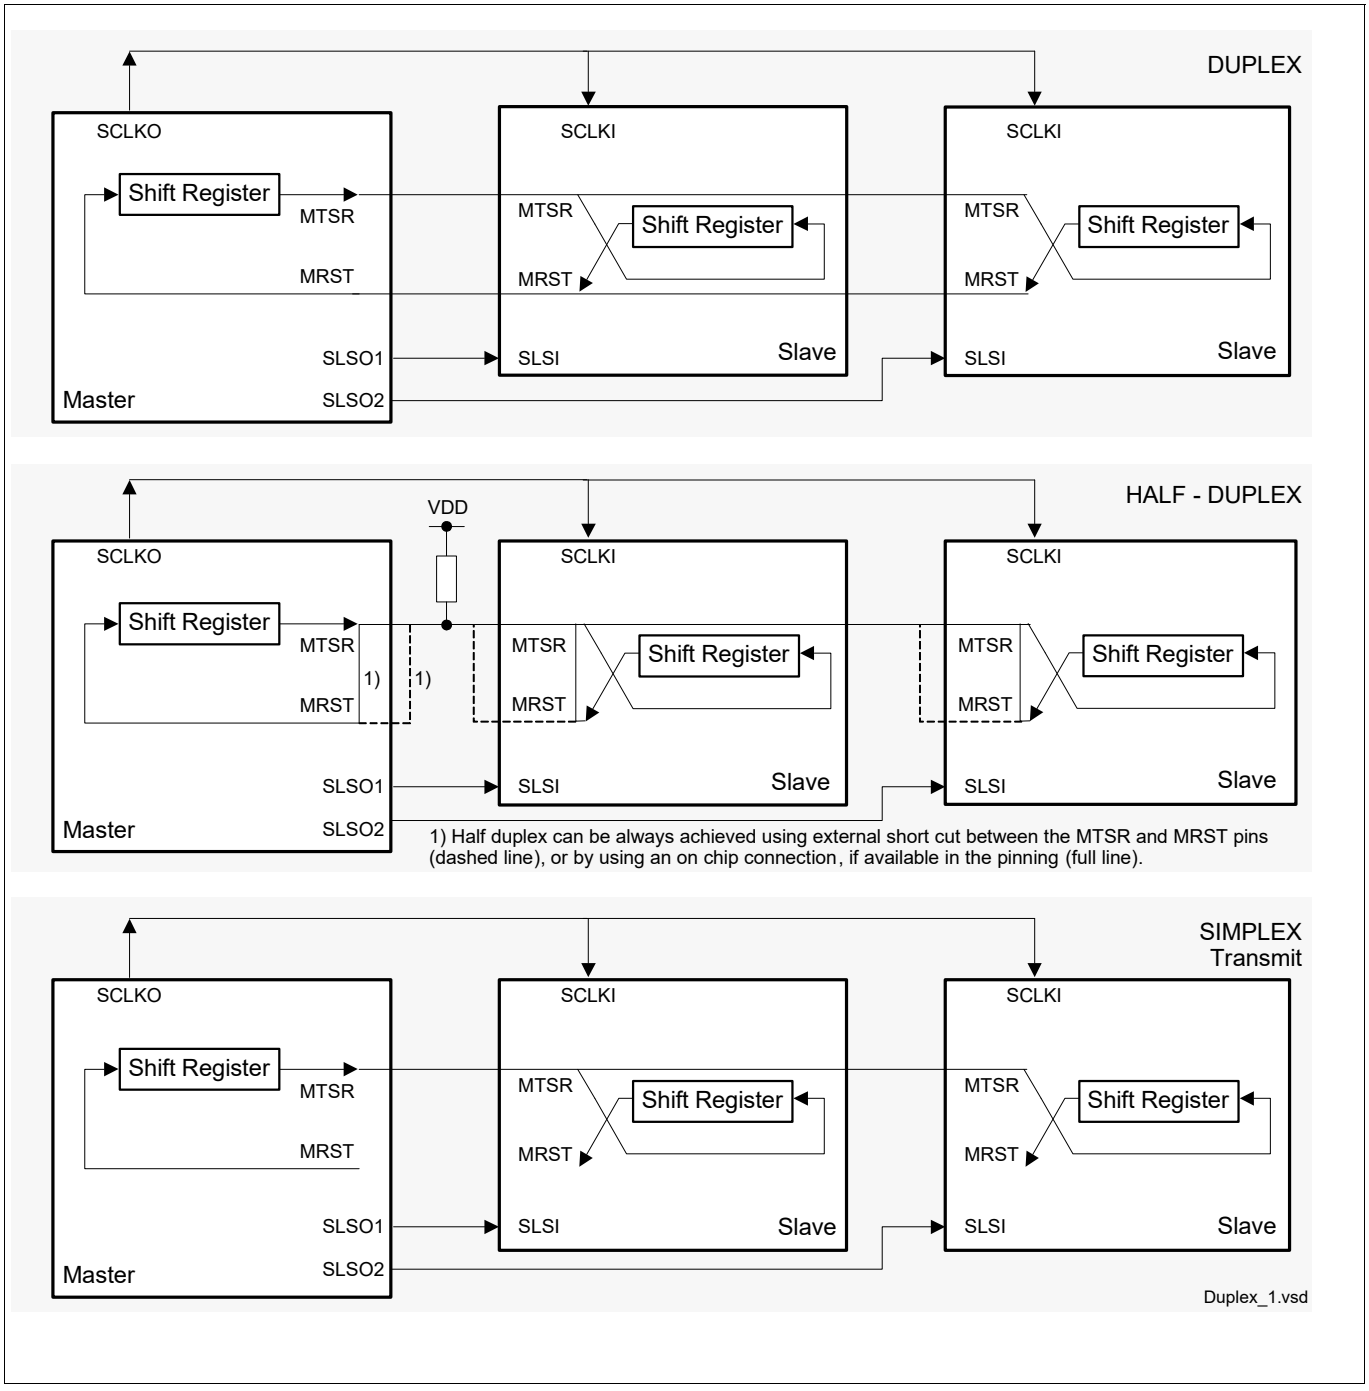

Figure 458 Operating Modes and Types of Connections

37.2.4 Queue Support Overview

The term “Queue Support” is used in this context to describe the functionality implemented for comfortable switching of the timing configuration of the QSPI frames, depending on the slave select signal which is to be activated. The main feature of the module is the possibility to take both the configuration and data to the TXFIFO, and to track down which TXFIFO entry is configuration, and which data. The QSPI module expects 32 basic configuration bits to be moved with one move (for example DMA move) from some on-chip general purpose RAM to the TXFIFO. These 32 configuration bits from the TXFIFO and the configuration bits from the 8 configuration extension registers **ECONz (z=0-7)**z contained in the QSPI module, define together the full configuration of the module (see **Figure 459**). One extension register is used for two slave selects: ECON0 for SLSO0 and SLSO8, ECON1 for SLSO1 and SLSO9...

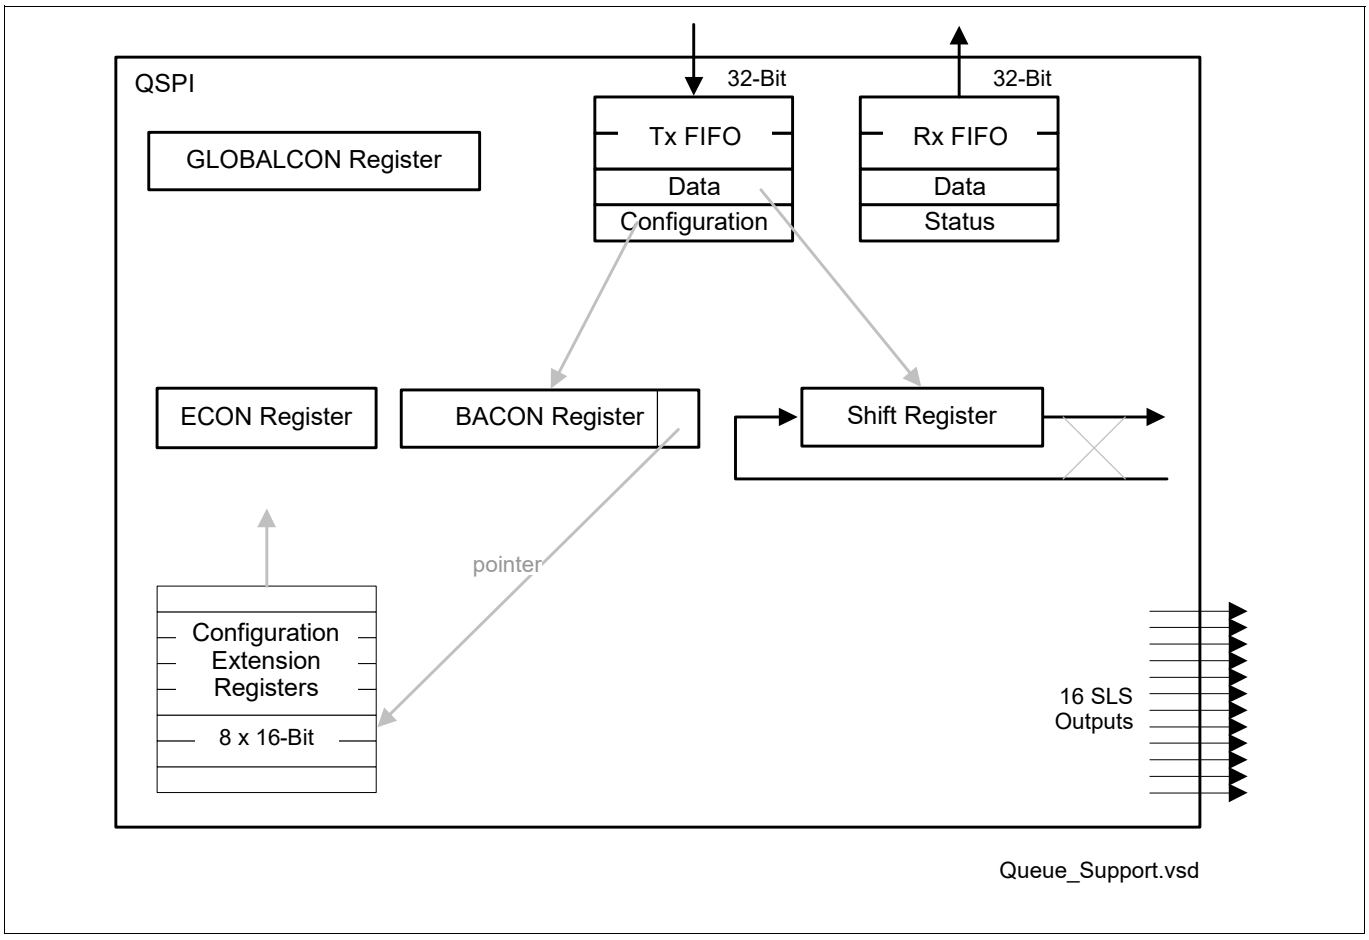

Figure 459 Queue Support Overview

37.2.5 Architecture Overview

The **Figure 460** shows the main blocks of the QSPI module. The TxFIFO and RxFIFO provide the user interface. The Shift Register and the “Miscellaneous Logic” block build the state machine of the module. The “Configuration Extensions” block provides comprehensive capabilities for configuring the QSPI frames.

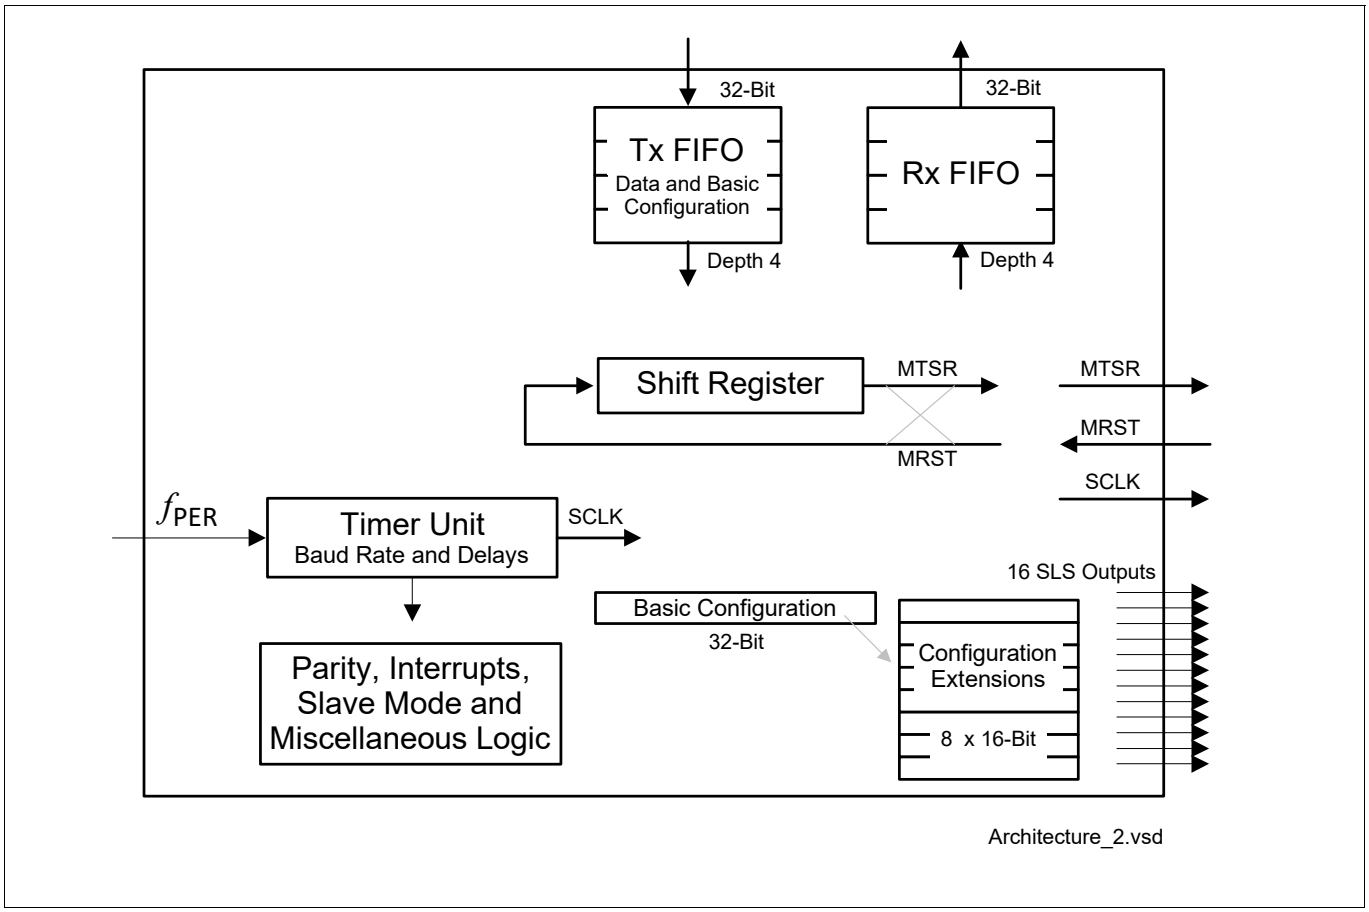

Figure 460 QSPI - Architecture Overview

37.2.6 Three Wire Connection

The term “Three Wire Connection” is used in this context to describe a connection without slave select signal. This connection relies solely on counting bits for determining the end of the current frame and resetting the shift register state machine, instead of using the slave select signal for this purpose. This way of communication is less robust than communication with slave select, but it saves a pin on both master and slave device.

The name “three wire connection” is true only in case of full-duplex connection, where exactly three signals (clock, data-in, data-out) are needed. In case of half-duplex and simplex connections only two signals (clock, data-in/data-out common data line) are necessary.

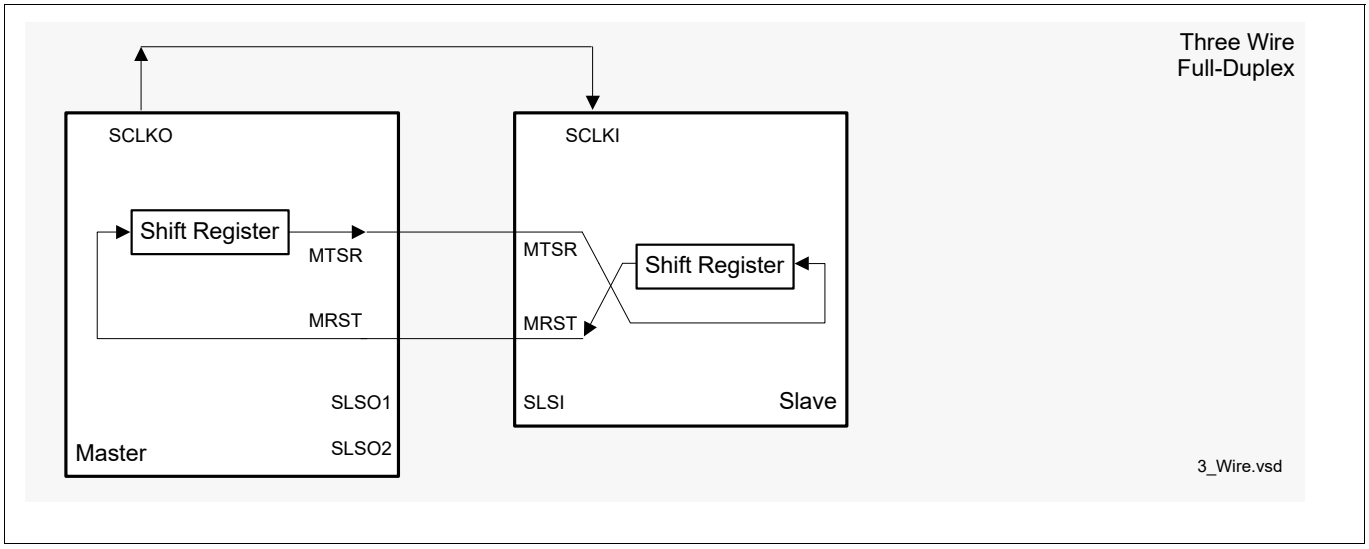

Figure 461 Three Wire Connection

37.3 Functional Description QSPI

37.3.1 Frequency Domains

The state machine of the QSPI is placed in a separate frequency domain operating with a frequency f_{PER} which is generated by the peripheral PLL. This clock is completely asynchronous to f_{SPB}.

In the Chapter Clock System, in the CCU (Clock Control Unit) section, this f_{PER} is referenced to as f_{QSPI} for overview purposes.

The baud rate is determined by the f_{PER} frequency divided by an integer equal or greater than four.

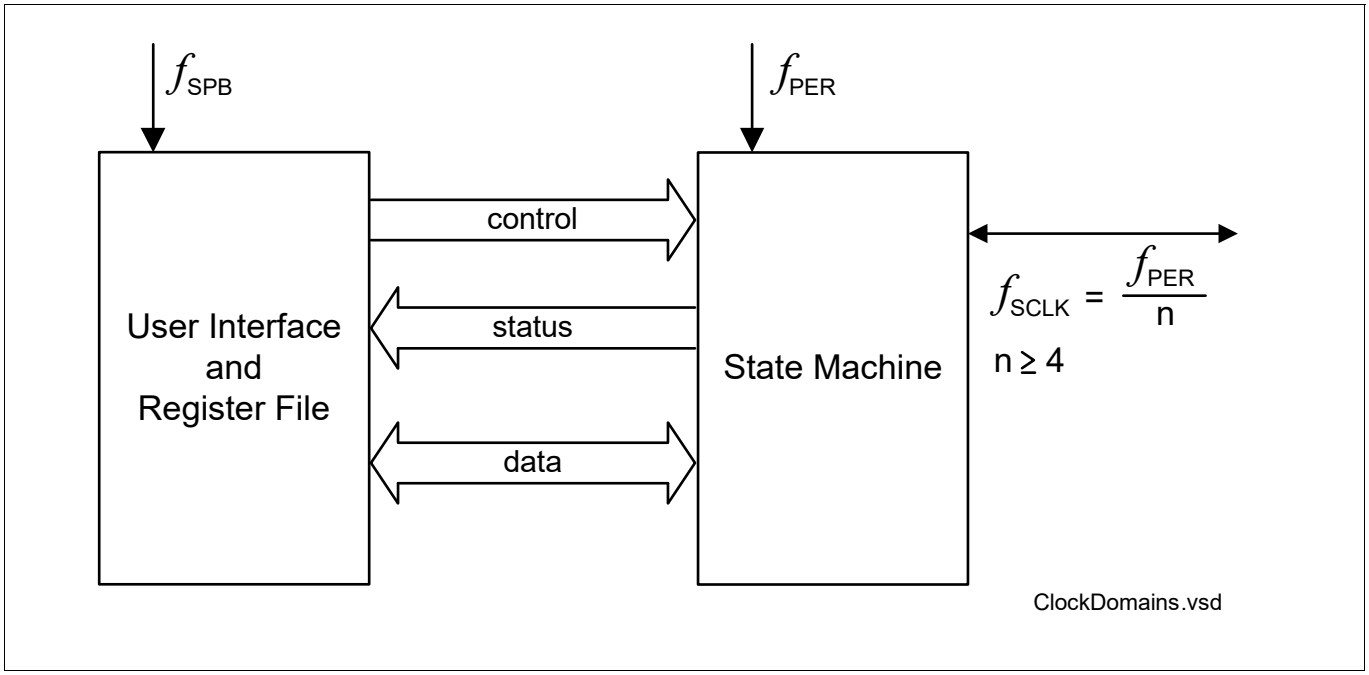

Figure 462 QSPI - Frequency Domains

37.3.2 Master Mode State Machine

In master mode, the QSPI module generates the timings, the serial clock, and the slave select signals.

37.3.2.1 Phases of one Communication Cycle

This section describes the possibilities available for configuring the length of the phases of the QSPI communication: timing delays, data length, duty cycle and data sampling.

A QSPI frame starts with activating a slave select signal SLSO (at transition from idle to leading delay phase), and ends with its deactivation (at transition from trailing delay to wait or idle phase). It is a sequence of five phases: idle delay, leading delay, data phase, trailing delay and an optional wait phase. The idle phase is subdivided in two phases of equal length: idle A and idle B.

Figure 463 shows a full and a compressed view of a QSPI frame and its phases. The full view shows all four signals needed for a QSPI connection. The compressed view represents the phases in a single row, in a way suitable to discuss their properties.

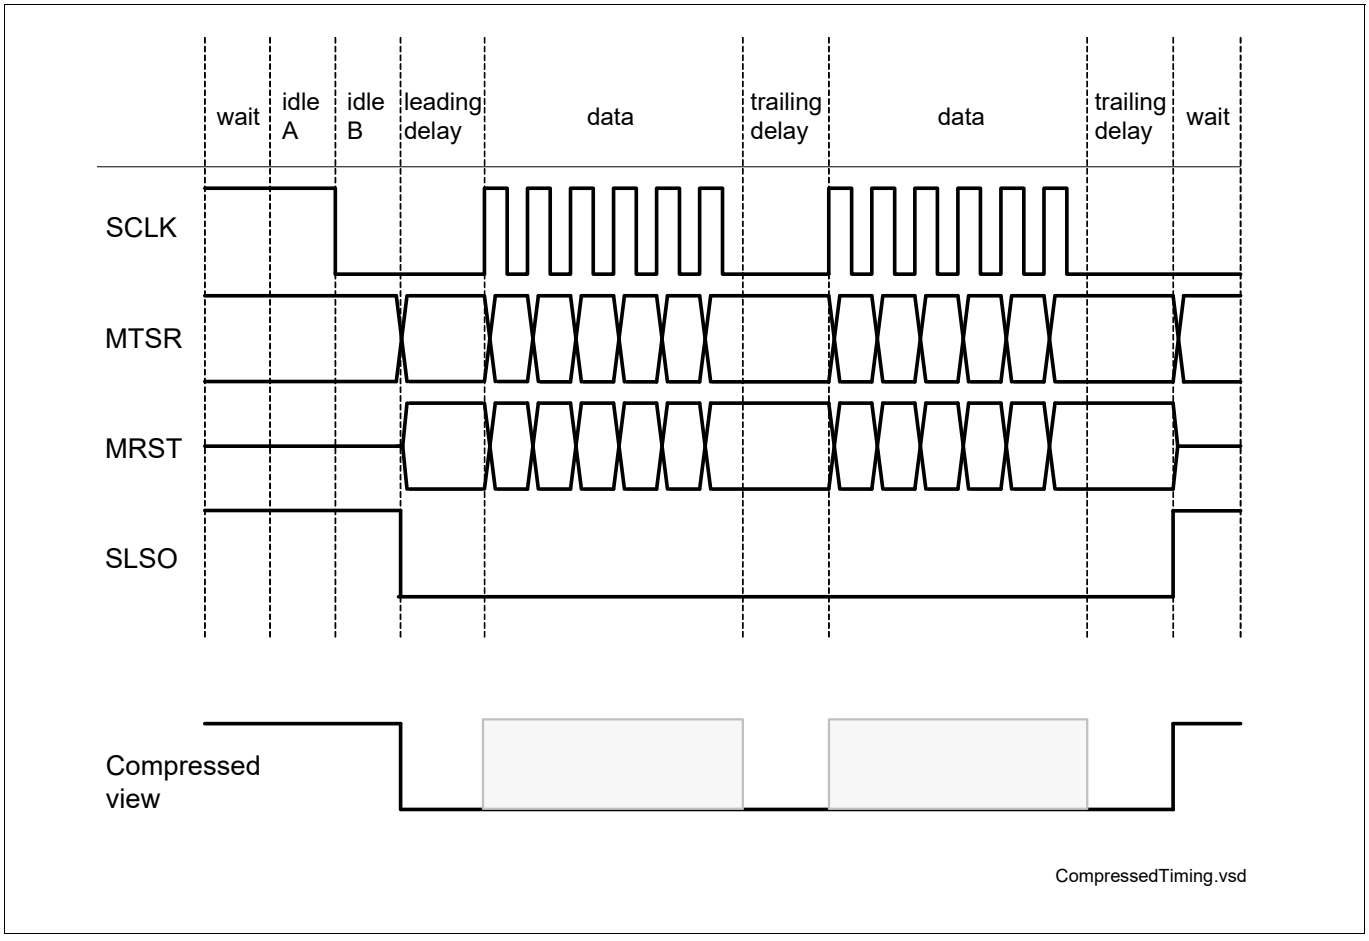

Figure 463 Phases of a QSPI Frame (Example for Data Length of 5 Bits)

The flexible timing control of the QSPI allows to program each phase in a very wide time range, with sufficient precision. Some examples of QSPI frames, in compressed view, with different lengths of the phases, are shown in **Figure 464**.

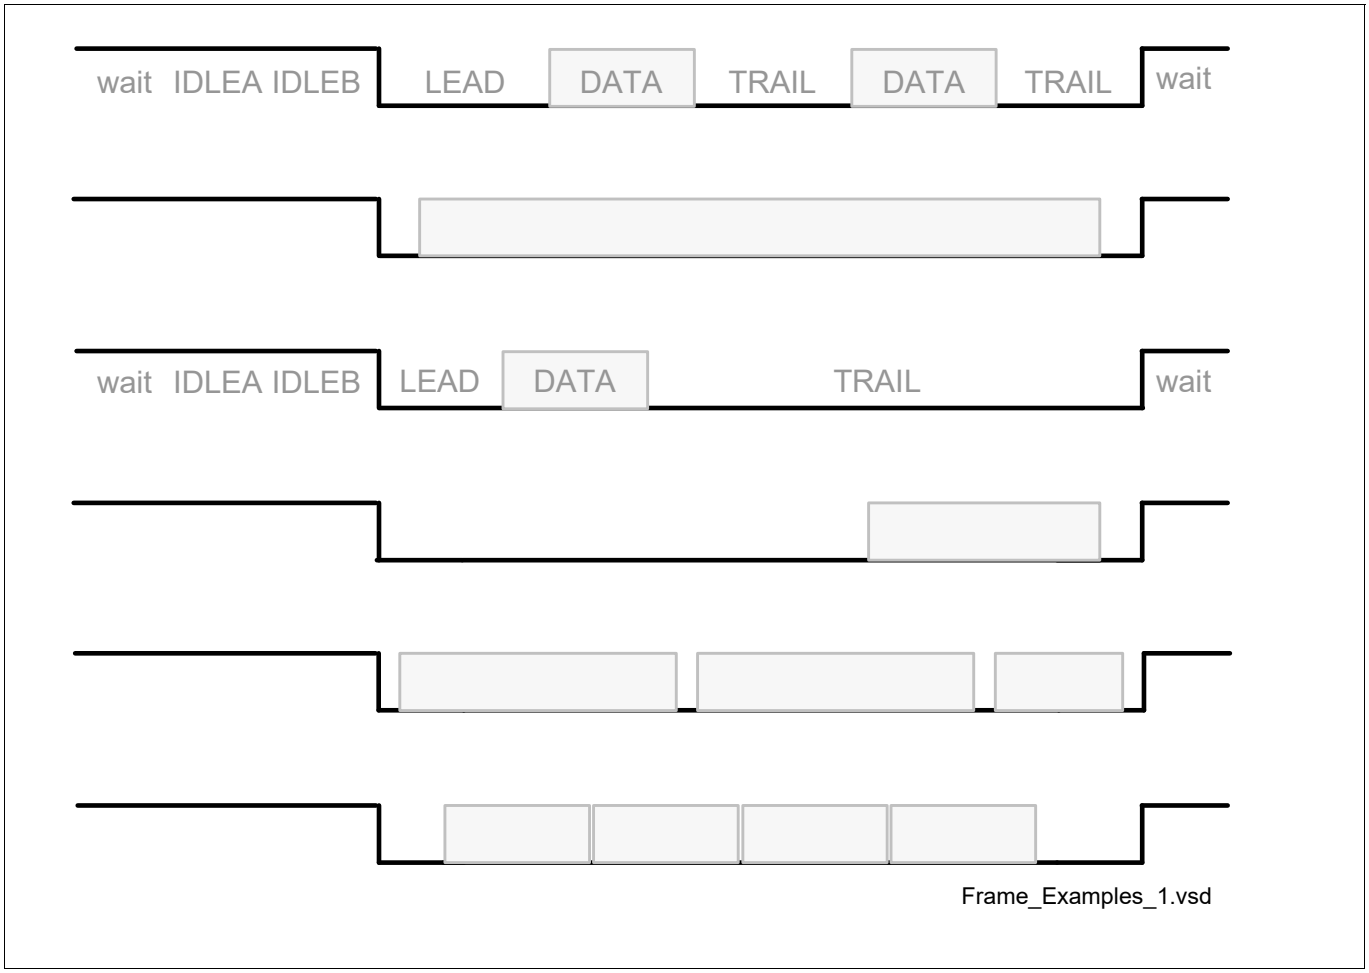

Figure 464 Examples of QSPI Frames in Compressed View

The length of the phases is programmed using the corresponding bit fields in the register **BACON**. There are four main bit fields defining the length of the phases in t_Q units and several modifier bit fields defining their range and granularity:

- IDLE
- LEAD
- DATA
- TRAIL

The WAIT phase is simply a loop waiting for a write to the Tx FIFO, without predefined duration, and consequently without a defining bit field.

The IDLE bit field defines two sub-phases with the same length IDLEA and IDLEB. At the transition between them the polarity of the serial clock signal for the next slave is set / changed.

In addition, the flexible timing control allows to program the duty cycle and the sampling point properties of the serial clock. This allows to improve to a certain extent the achievable baud rate taking into account the clock asymmetries and the loop-delay.

The **ECONz (z=0-7)** bit fields A, B and C define the length of the corresponding bit segments. The sampling point is always at the transition between phases B and C, and the clock duty cycle is defined by the phases A and B+C.

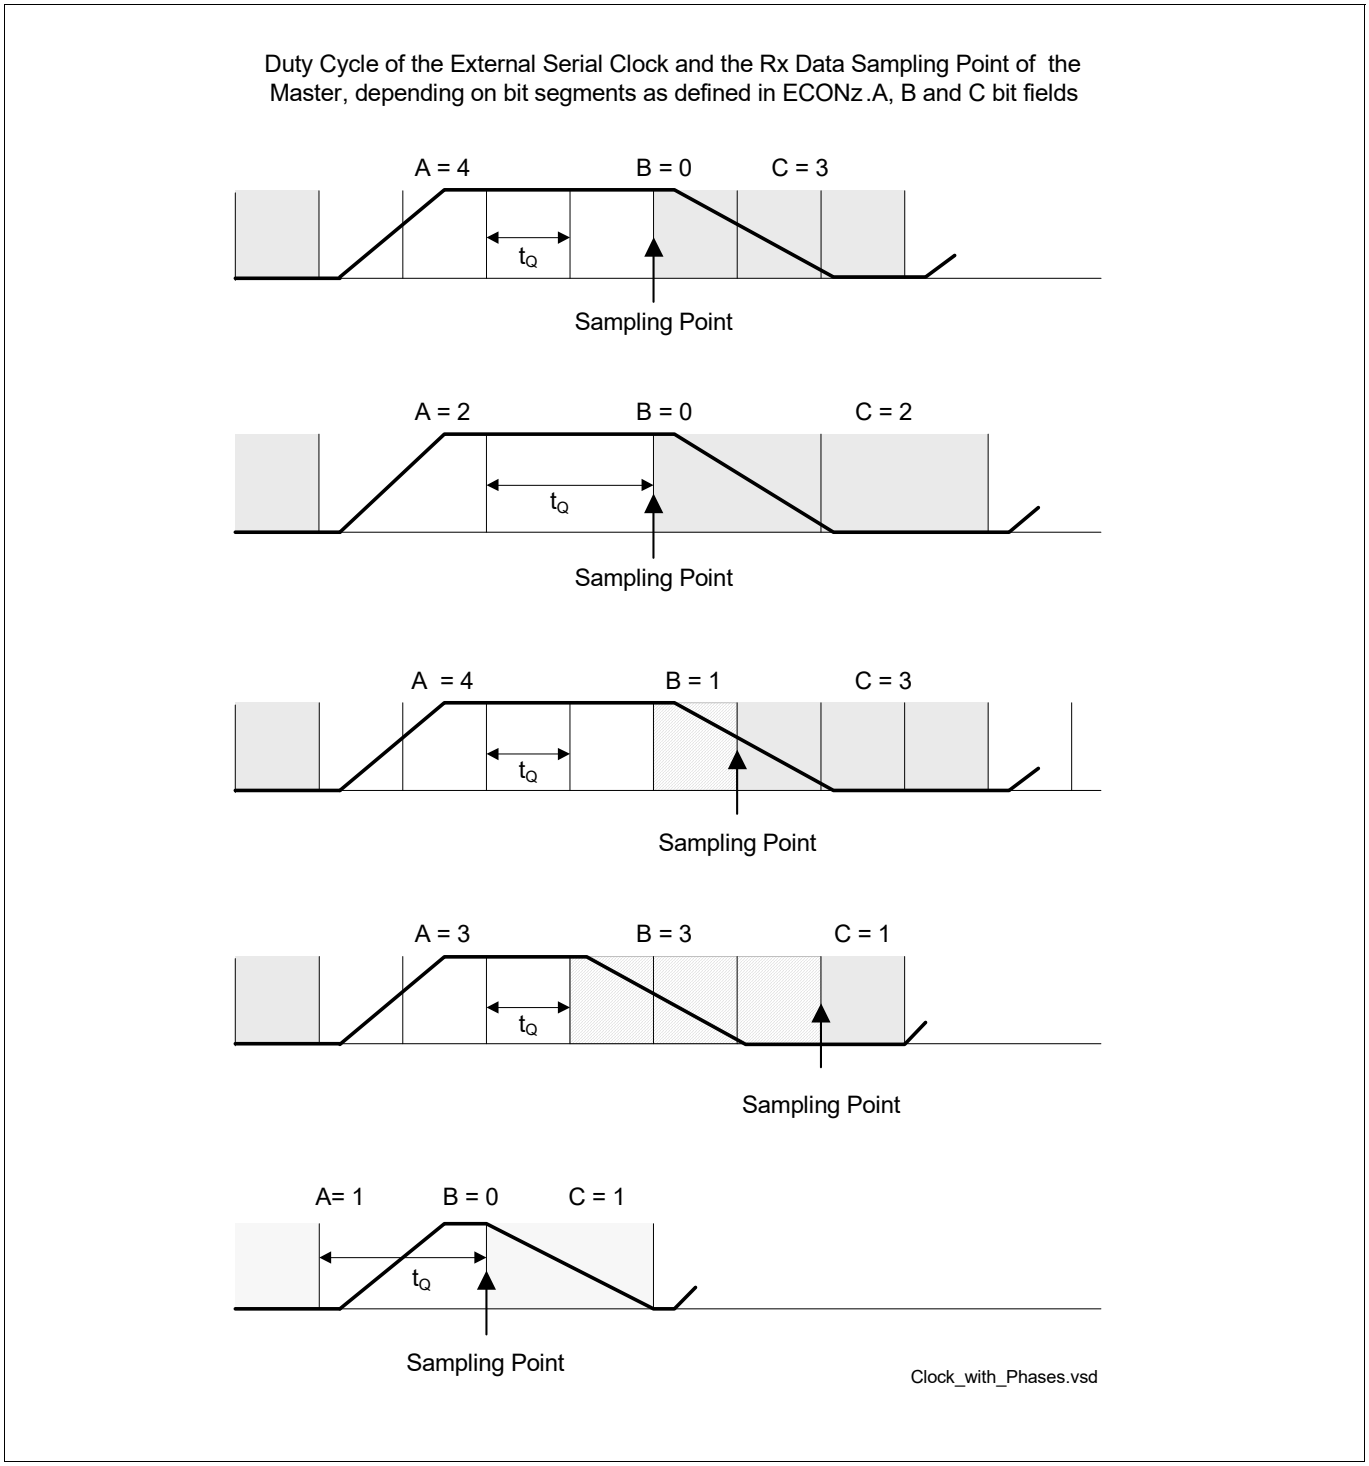

Figure 465 SCLKO Duty Cycle and the Rx Data Sampling Point Relative to SCLKO, in Master Mode

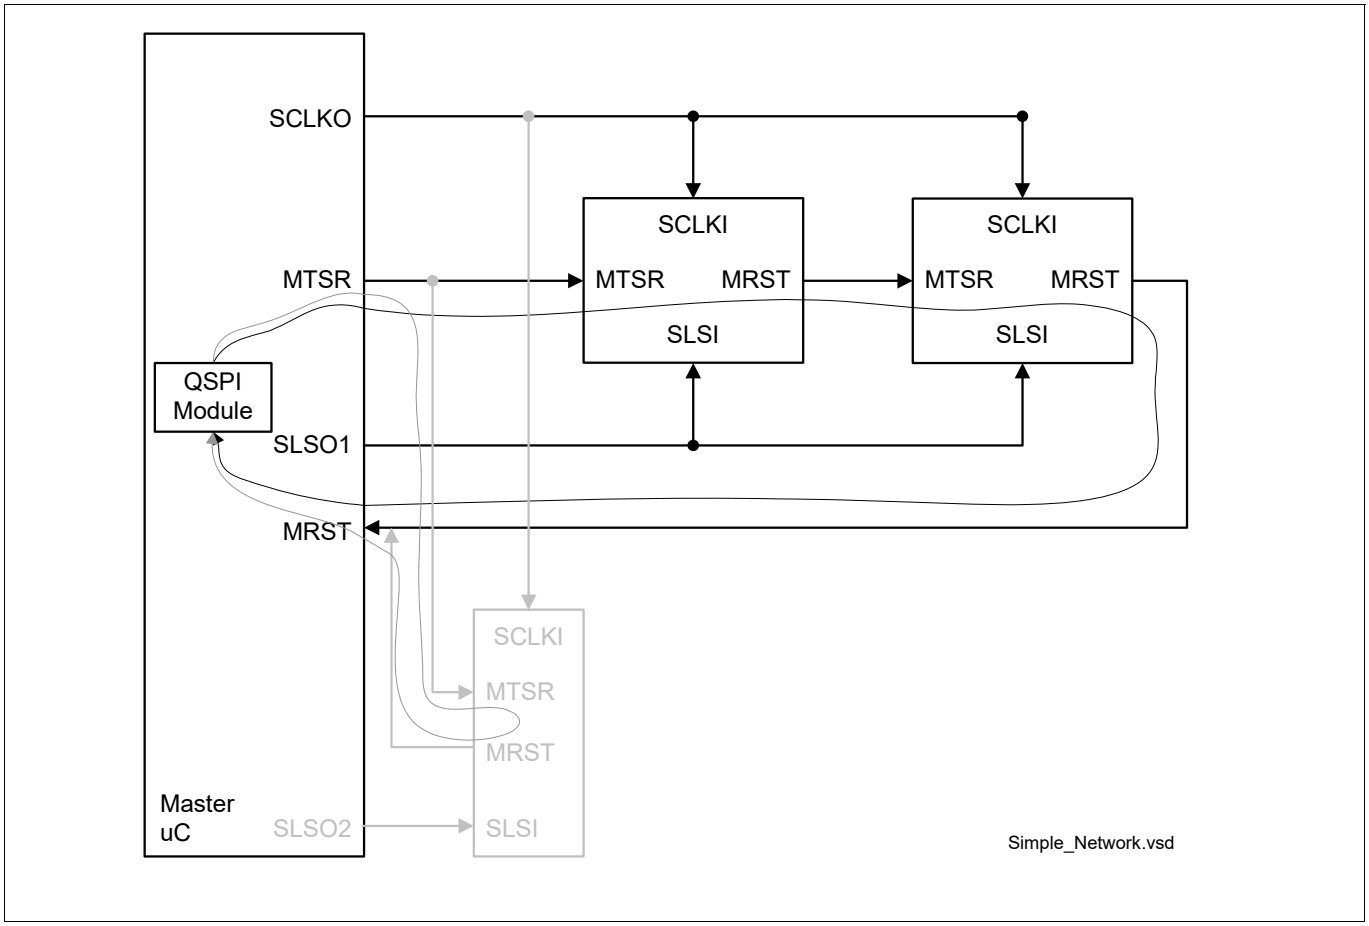

Figure 466 Closed-loop delays in a simple network consisting of one daisy-chain and one point to point connection in parallel

The purpose of the duty cycle control is:

- To compensate the influence of the path and pad asymmetry on the duty cycle
- To compensate the considerable asymmetry of the edges in case of half-duplex connection implemented as open-drain driver with pull-up resistor
- To adjust the duty cycle optimally to the timing properties of the master and slave, and to the properties of the connection (distance and capacitive load)
- To help achieve optimal baud rate, especially at higher baud rates which need an odd division factor (for example 5 = 3 high time + 2 low time or 5 = 2 high time + 3 low time)

The purpose of the sampling point control is to allow reliable reception of the data transmitted by the slave, at as high as possible baud rates.

In master receive direction the slave transmitted data reaches the master considerably late relative to the shift edge of the serial clock. This is caused by the loop delay consisting of:

- The propagation delay of the shift clock edge from the master to the slave
- The response delay of the slave
- The propagation delay of the data from the slave to the master

Last but not least, the flexible timing control allows to configure the phase and the polarity of the shift clock.

The clock polarity is configured by bit field **ECONz (z=0-7)**.CPOL. This bit field sets the clock idle polarity to low or high.

The clock phase is configured by bit field **ECONz (z=0-7)**.CPH. This bit field sets the initial clock delay to 0 or Bit Segment A, as defined by the bit field **ECONz (z=0-7)**.A.

The CPOL and CPH settings control the master mode. The slave mode timing behavior is fixed to CPOL=0 and CPH=1, and these values must be programmed in the **ECONz (z=0-7)** register pointed by **BACON**.CS. The **ECONz (z=0-7)**.A, B and C do not influence the sampling point in the slave mode, the sampling is at the falling edge of the SCLKI.

The **Figure 467** shows the QSPI timings for clock phase CPH = 0.

ECONz (z=0-7).CPH = 0 is used when communicating with a slave that delivers a valid value of the first bit immediately after being selected with an SLS signal. In such a case the first clock edge in a frame is used to latch the first bit. The second edge delivers the second bit value, and so on. The last edge in a frame delivers a bit with don't care value.

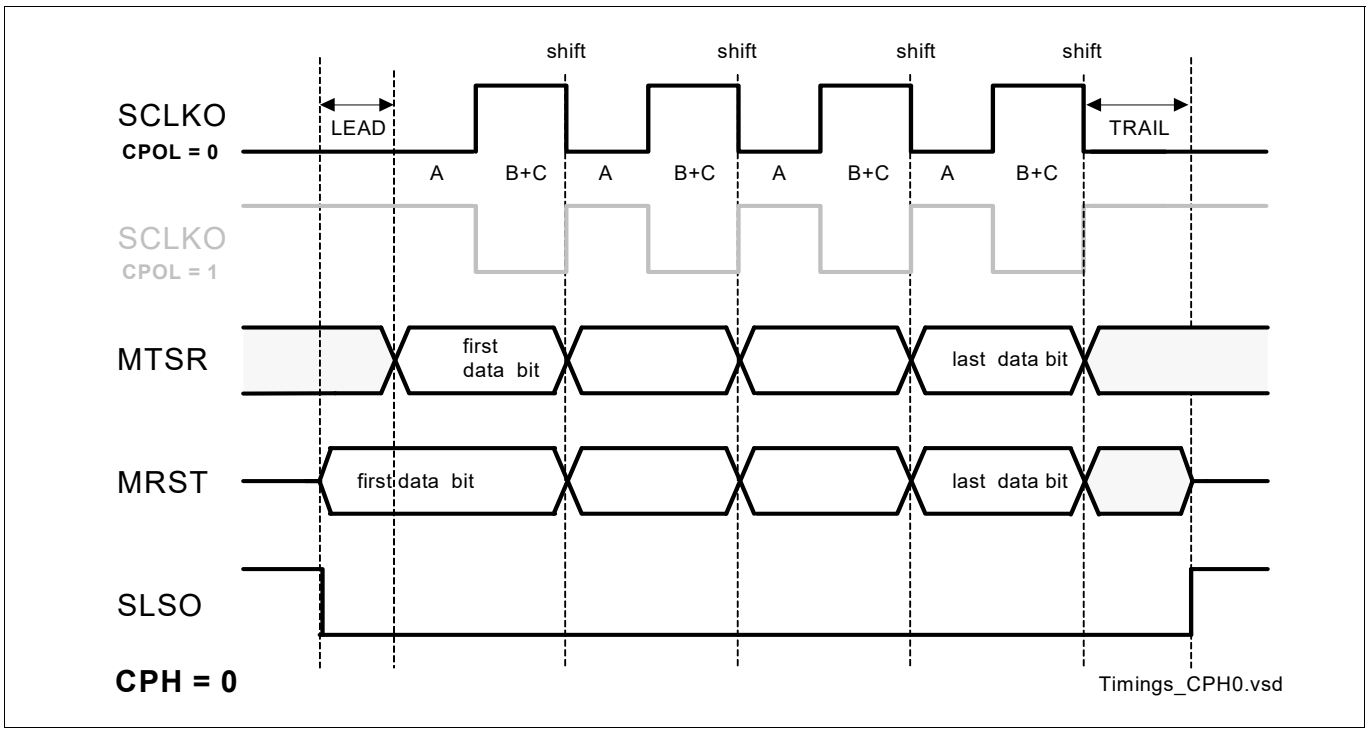

Figure 467 Timing of a transfer with CPH = 0 (Example for Data Length of 4 Bits)

The trailing delay starts after the last shift clock period of a data block and is followed either by the deactivating edge of SLSO, or a new data block in continuous mode.

Attention: ***If CPH = 0, then the total delay between the SLSO activating edge and the first edge of the serial clock SCLKO is LEAD + ECONz (z=0-7).A***

Figure 468 shows the QSPI timings for clock phase CPH = 1.

ECONz (z=0-7).CPH = 1 is used when communicating with a slave that delivers a bit with a random or don't care value immediately after being selected with the SLSO signal. In such a case the first clock edge in a frame is used by the slave to shift out the first valid data bit. The second edge latches this bit value, and so on. The last edge in a frame is used to latch the last valid data bit, which normally remains driven until the end of the frame.

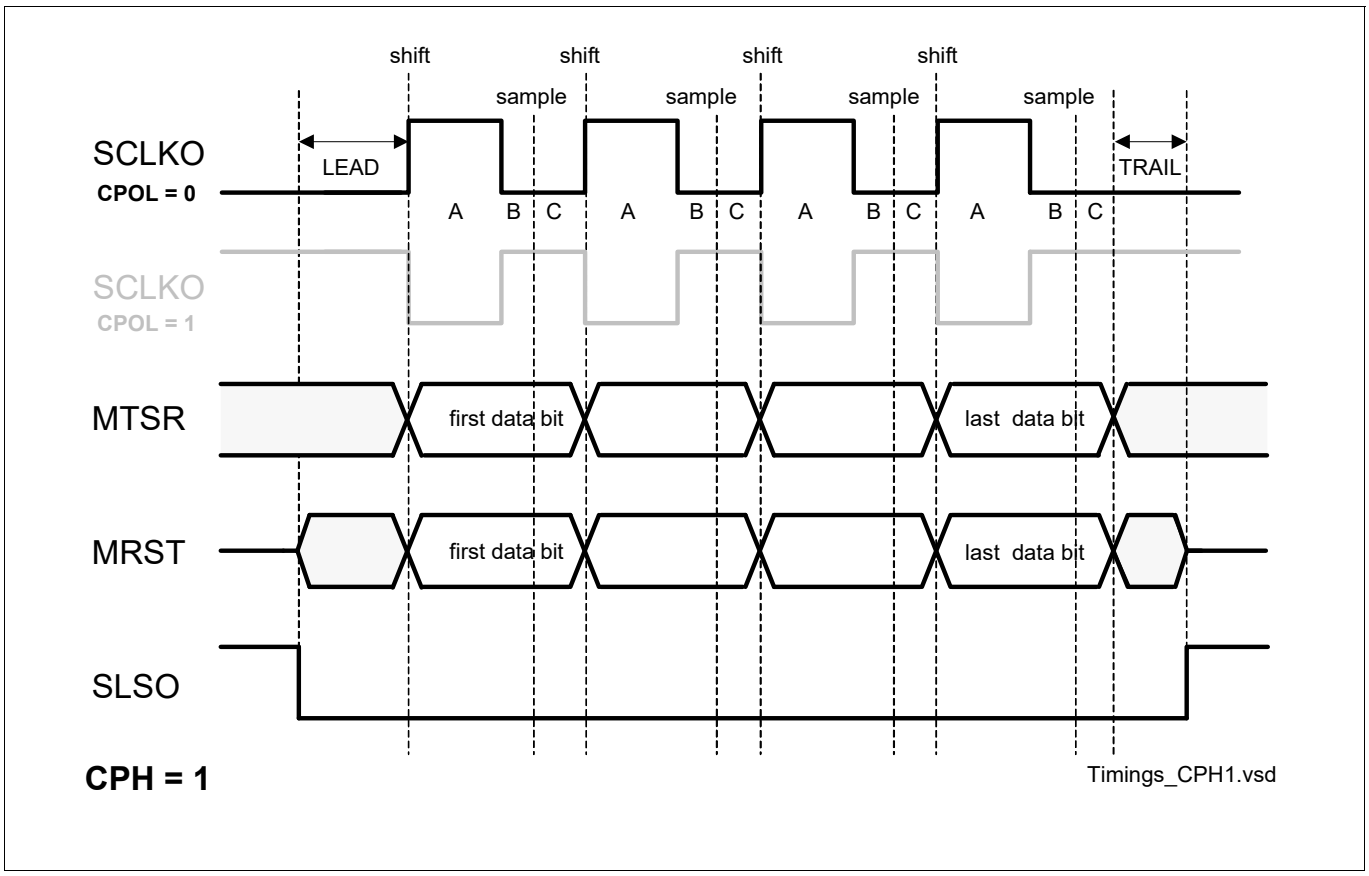

Figure 468 Timing of a transfer with CPH = 1 (Example for Data Length of 4 Bits)

The leading delay lasts between the active edge of the SLSO and the first shift clock edge.

Attention: ***If CPH = 1, then the total delay between the last edge of the SCLKO and the SLSO deactivating edge is TRAIL + ECONz (z=0-7).B + ECONz (z=0-7).C***

Attention: ***When 3 wire mode is used, and the polarity of CPH or CPOL is changing, a dummy frame is required. The pad enable to be after the dummy frame. The values of the clock and data signals are not defined before the first data is transmitted.***

37.3.2.2 Configuration Extensions

This section describes the possibilities available for configuring the phases of the QSPI communication: timing delays, data lengths, their ranges and granularity.

The QSPI module controls 16 communication channels, which are individually programmable. Each channel is associated to one slave select output and to the corresponding timing and other properties (baud rate, delays, data width, parity...).

The 16 slave select channels of the QSPI module are subdivided in two groups of 8 slave select channels:

- Channels 0 to 7
- Channels 8 to 15, channel 8 having the same **ECONz (z=0-7)** settings as channel 0, channel 9 as channel 1, and so on.

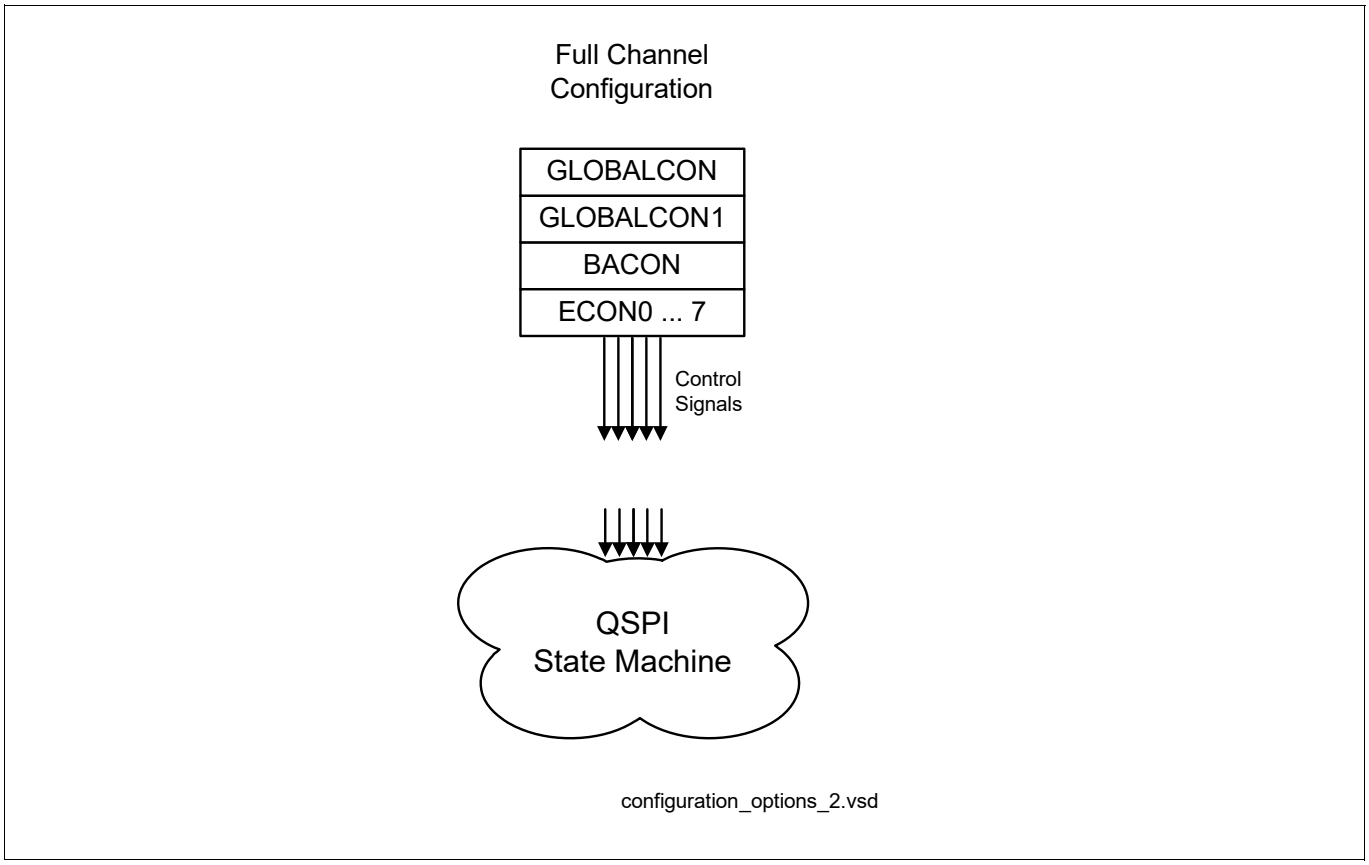

Figure 469 Flexible Configuration Concept

37.3.2.3 Details of the Baud Rate and Phase Duration Control

The QSPI phases correspond to states of a simple state machine defining a sequence of simple states and loops. Due to the strict sequential nature of the communication cycle one timer is enough to define the length of each phase. The length of each phase is defined in time quanta, and the length of a time quantum is defined by a time quantum timer. Each QSPI slave select channel has its own time quantum length, based on the module time quantum length: T_{PER} clock period -> one module time quantum -> one channel time quantum

Each QSPI module generates a module time quantum which is further downscale to a channel quantum. This affects both the delays and the baud rates. The assumption is that the pad strength setting, the capacitive load and the corresponding QSPI network layout properties do not allow extreme differences in the baud rates for the different slaves connected to one module. They all have similar speed range: high speed, or medium speed, or low speed. Mixing very high speed and very low speed slaves does not make much sense. Many slaves produce high accumulated capacitive load on the clock and data outputs, which influences the possible baud rates for all slaves. Variations in the baud rates of the slaves of one module in the range of 6:1 is possible by varying the bit segment phases in each channel. Additional two-bit counter per slave allows for additional scaling of 1, 2, 4, or 8, making a total bit-time variation of 48:1 between the channels in one module possible.

Each QSPI slave select channel has its own set of phase lengths, depending on $T_{PER} = 1 / f_{PER}$

- $T_{SCLKz} = T_{PER}$ * **GLOBALCON**.TQ * **ECONz (z=0-7)**.Q * (A + B + C)
- $T_{LEAD} = T_{PER}$ * **BACON**.LPRE * **BACON**.LEAD
- $T_{TRAIL} = T_{PER}$ * **BACON**.TPRE * **BACON**.TRAIL
- $T_{IDLEA,B} = T_{PER}$ * **BACON**.IPRE * **BACON**.IDLE
- $T_{STROBE} = T_{PER}$ * **GLOBALCON**.TQ * **ECONz (z=0-7)**.Q * **GLOBALCON**.STROBE

*Note: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value. For the formulas using the actual binary values of the bit-fields, see **Figure 471** and **Figure 472**.*

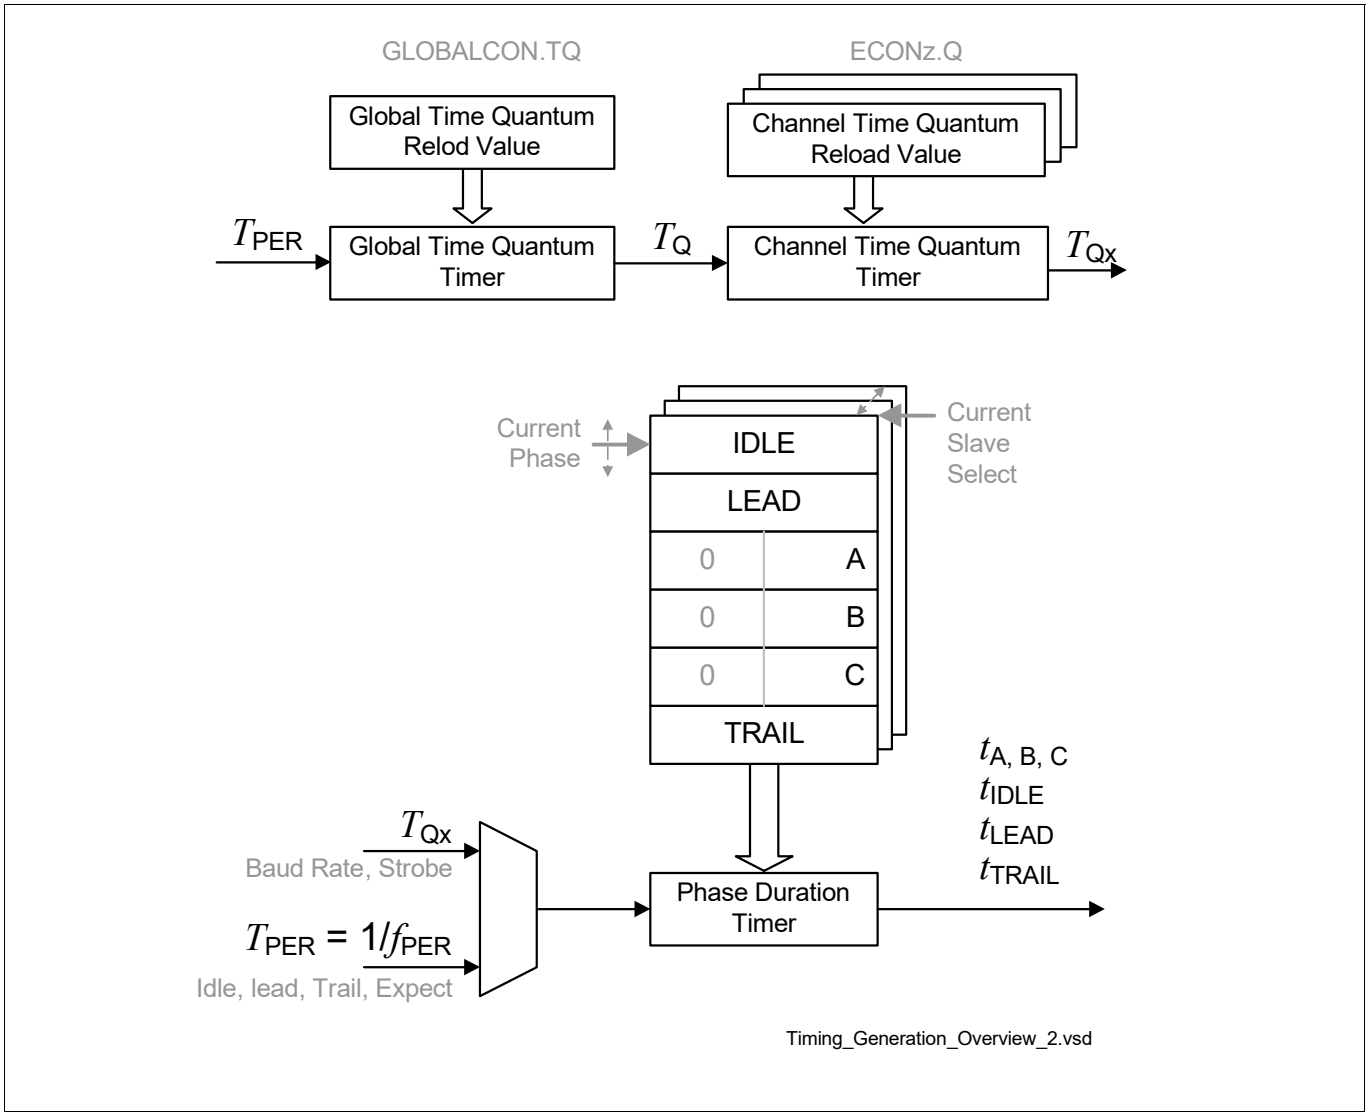

Figure 470 Phase Duration Control, Overview

37.3.2.4 Calculation of the Baud Rates and the Delays

This section gives another alternative view to the calculation of the baud rate and the duration of the delays.

The baud rate generation chain for a channel starts with a common TQ divider. The resulting global time quantum is used by the dedicated Q and A,B,C dividers to generate the baud rates per channel (slave select). See **Figure 471**.

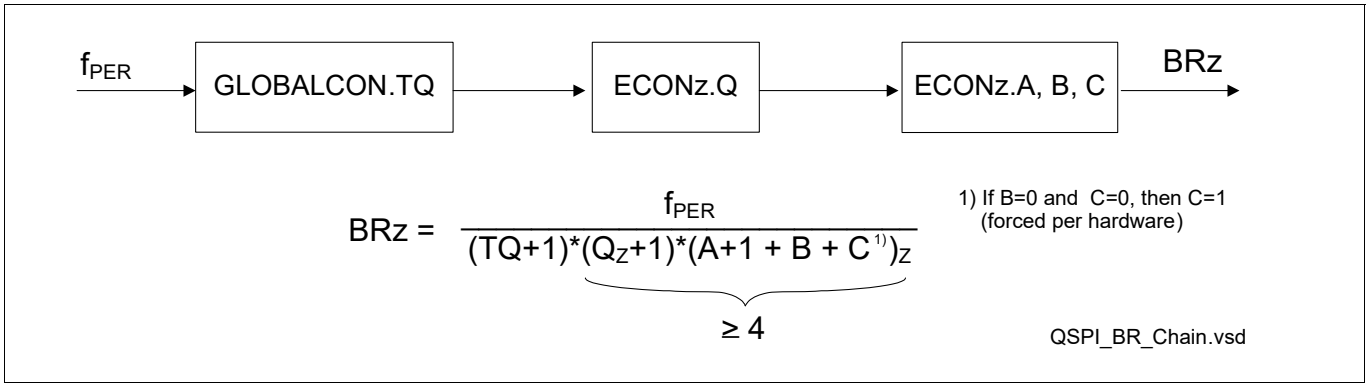

Figure 471 Baud Rate Calculation

Attention: The following condition must be satisfied: (Q+1)*(A+1 +B +C) >= 4. Or alternatively formulated: bit length must be at least 4*T_Q.

Each delay of an active channel (slave select) has a separate and independent divider chain starting with a power-of-four prescaler and an n-divider. See **Figure 472**.

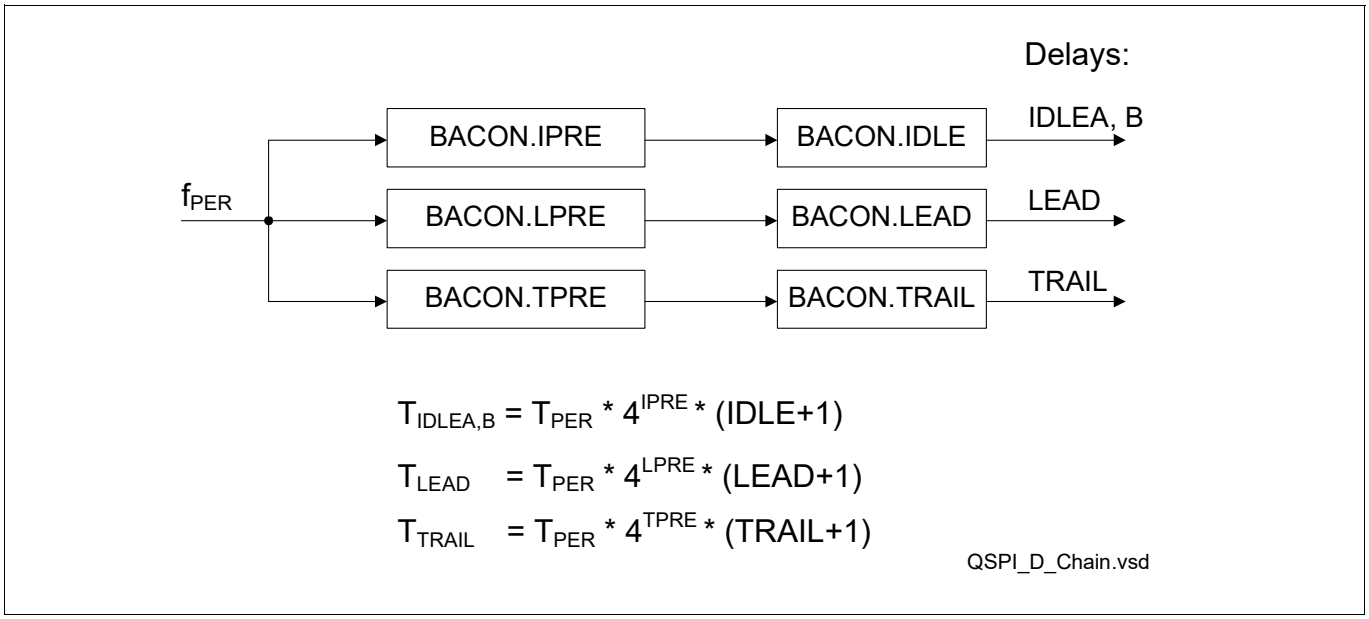

Figure 472 Calculation of the delays

37.3.2.5 State Diagram of Standard Communication Cycle

Figure 473 shows the top view of the standard communication cycle of the QSPI state machine in a hierarchical way. The “Data” state consists of a loop of several “Bit” states, where the number of repetitions is defined with the data width bit field. Each “Bit” state consists of a simple sequence of “A”, “B”, and “C” states.

A complete (or standard) communication cycle containing all phases, starting with activating the slave select and ending with its deactivation, is executed only if the bit **BACON**.LAST = 1. Otherwise, the slave select remains active and the module waits for more FIFO data entries.

In Master Mode, the Phase Transition Interrupt events, PTI1 and PTI2, each signal one of the phase transitions which are shown in **Figure 473** . The events are flagged via **STATUS**.PT1F and **STATUS**.PT2F. The values of **GLOBALCON1**.PT1 and **GLOBALCON1**.PT2 determine which of the transitions cause the events. The events will also cause interrupts if **GLOBALCON1**.PT1EN and **GLOBALCON1**.PT2EN are set to 1. The event flags are cleared via the programming of the **FLAGSCLEAR** register.

For the Move Counter Mode, see **MC**.

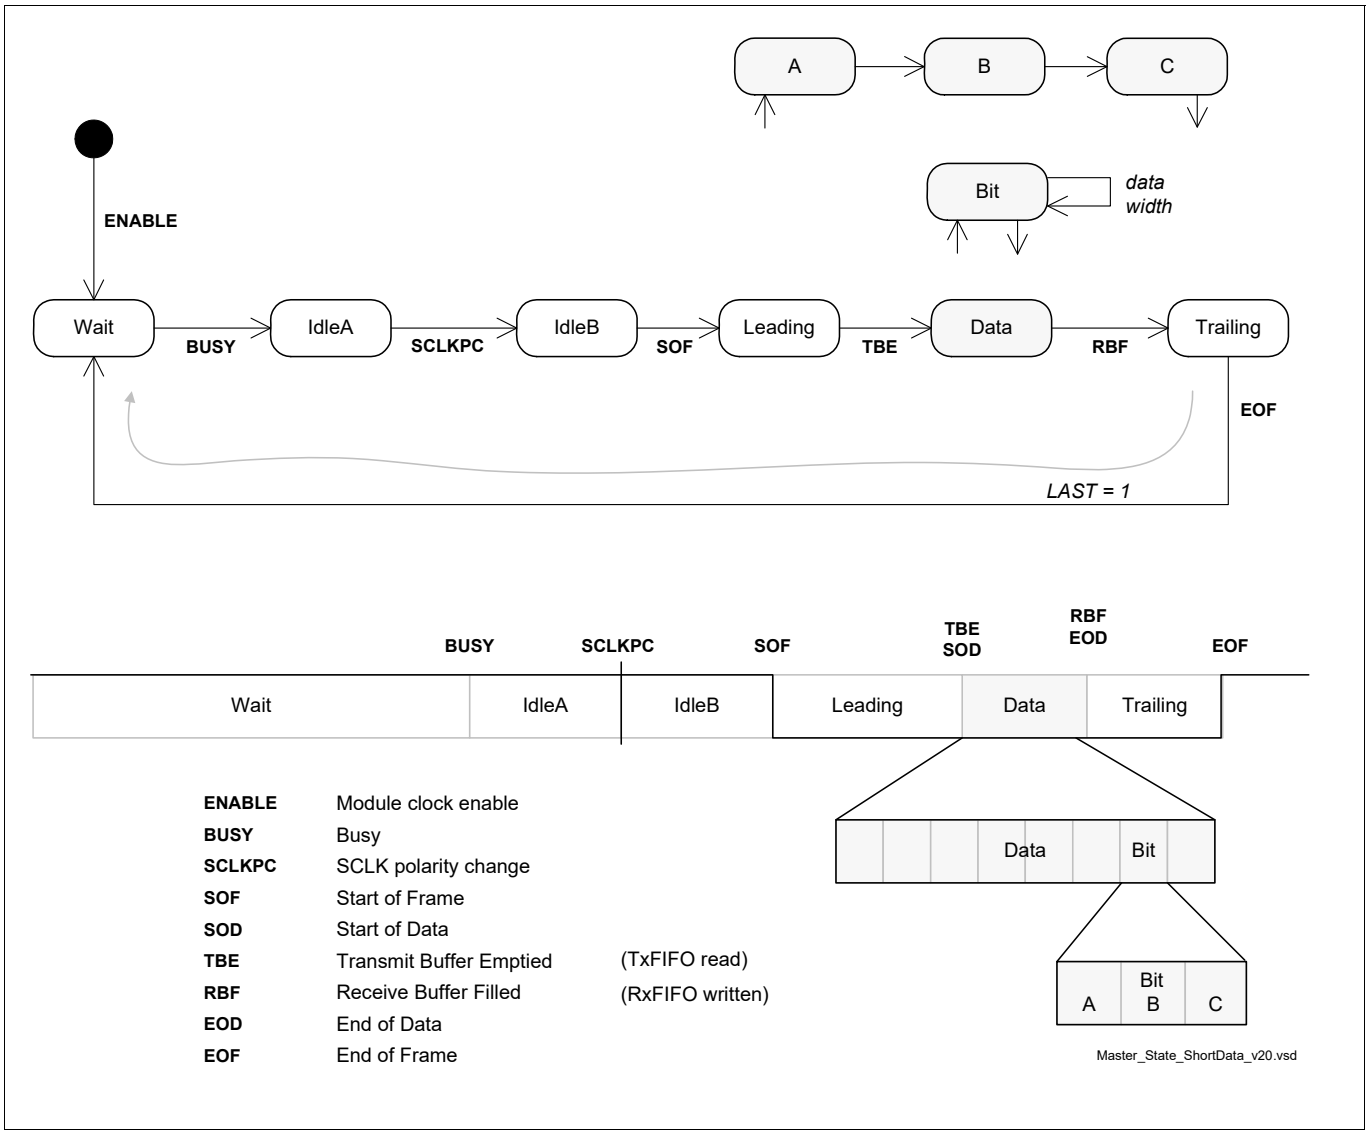

Figure 473 Standard Communication Cycle of the State Machine (Short Data)

(>>**Interrupts**)

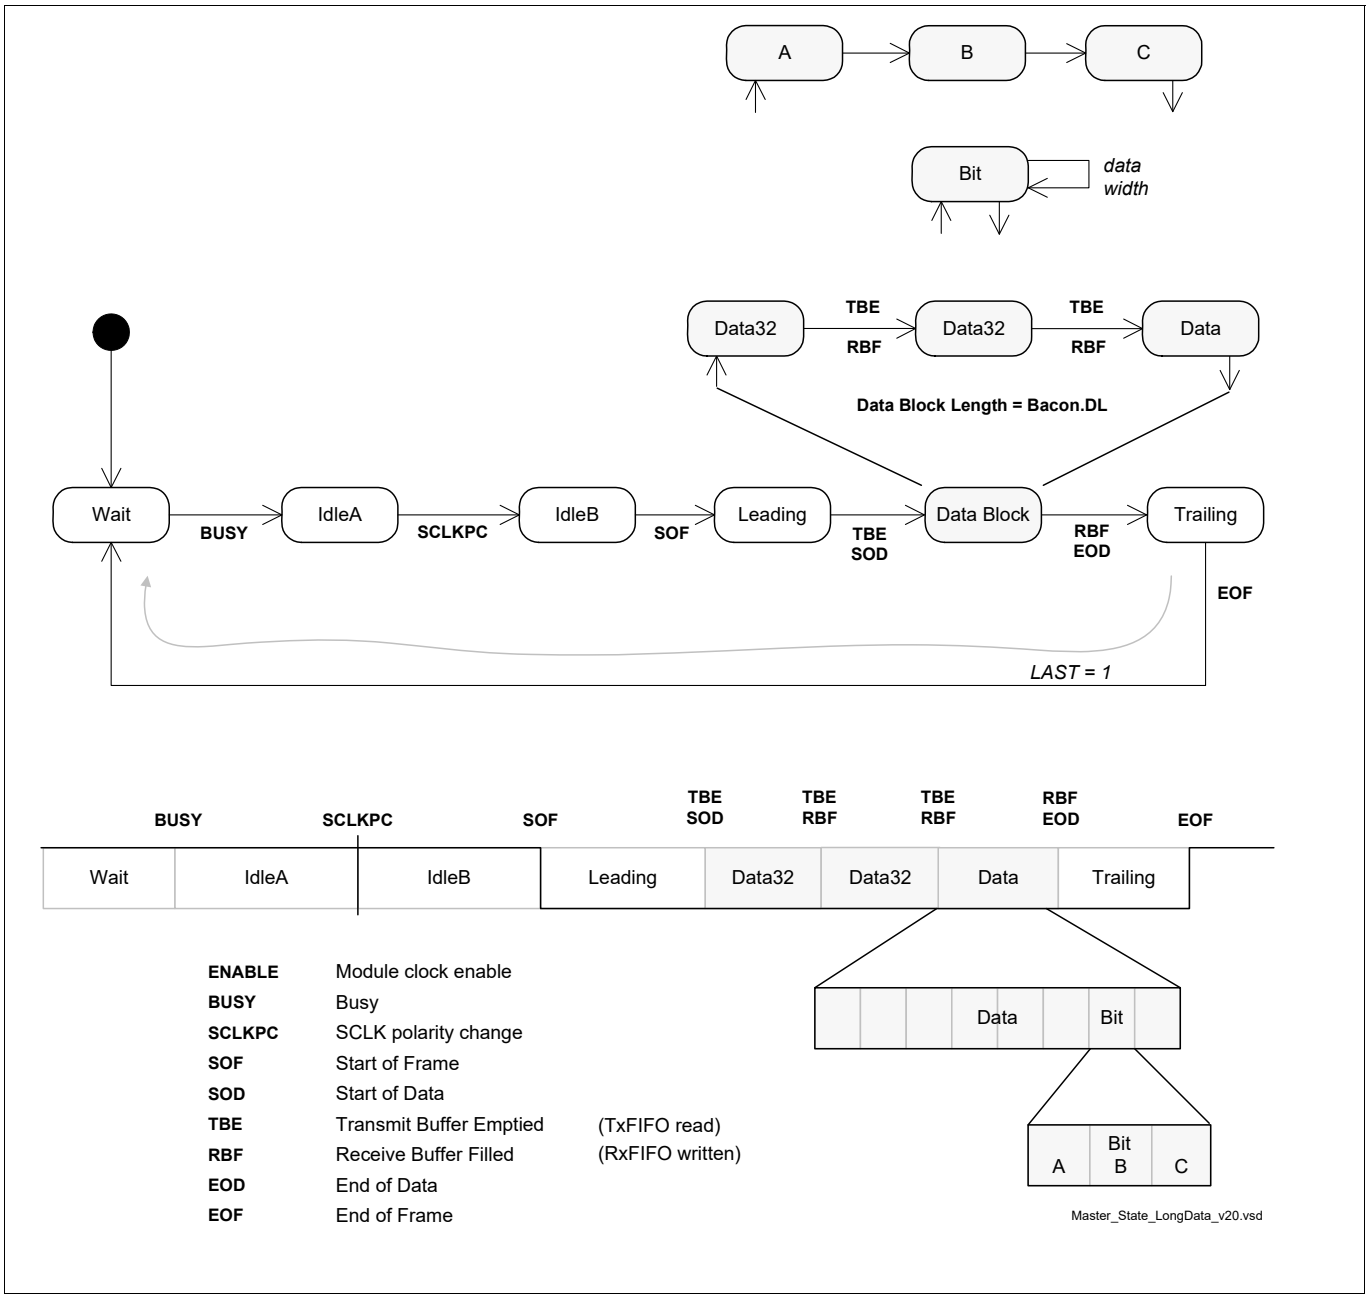

Figure 474 Standard Communication Cycle of the State Machine (Long Data)

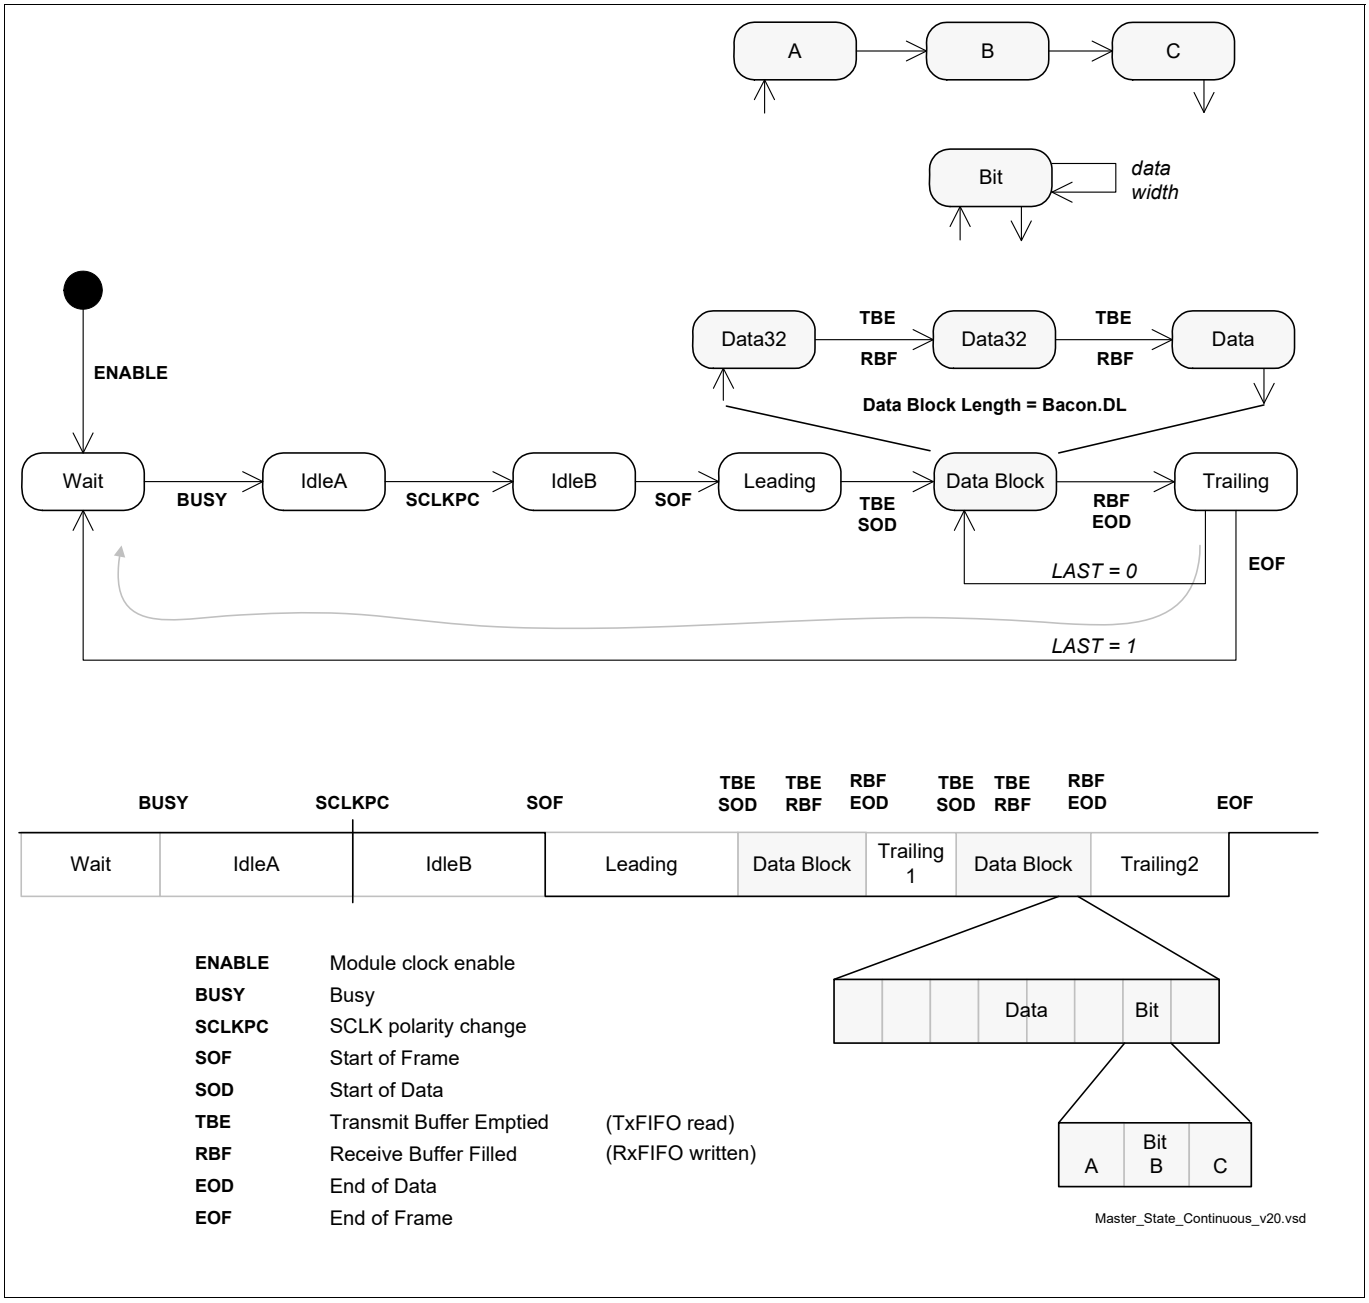

Figure 475 Standard Communication Cycle of the State Machine (Continuous)

"Data Block" in **Figure 475** refers to either short data or long data block. When concatenating data blocks in continuous mode, each block can be configured independently as short or long, according to its **BACON** configuration.

37.3.2.6 Expect Phase

Figure 476 shows the EXPECT state in the QSPI state machine diagram. This state can be entered in the long data mode and in the continuous mode, where one frame consists of more than one TXFIFO entries. Its purpose is to provide monitoring of the latencies on the FPI bus. In this case, after one FIFO entry has been shifted out and the module expects more bits to shift, according to the **BACON**.DL, a time-out counting starts. If the expected FIFO entry does not come in time, a time-out occurs.

The duration of the EXPECT state is zero if at the end of the current DATA state the new data is already available in the FIFO.

The duration of the EXPECT state can be anywhere between zero and the programmed upper limit, if the next data is written into the TXFIFO any time within the allowed time window. In this case the current frame continues with the SLSO signal remaining active.

The duration of the EXPECT state is exactly maximum if the data did not come in time. Then the current frame is stopped, but the SLSO is not deactivated. A TO (Time - Out) interrupt is raised. The state machine continues the EXPECT state in a loop, waiting for the software intervention, generating an interrupt signal after each expect time interval.

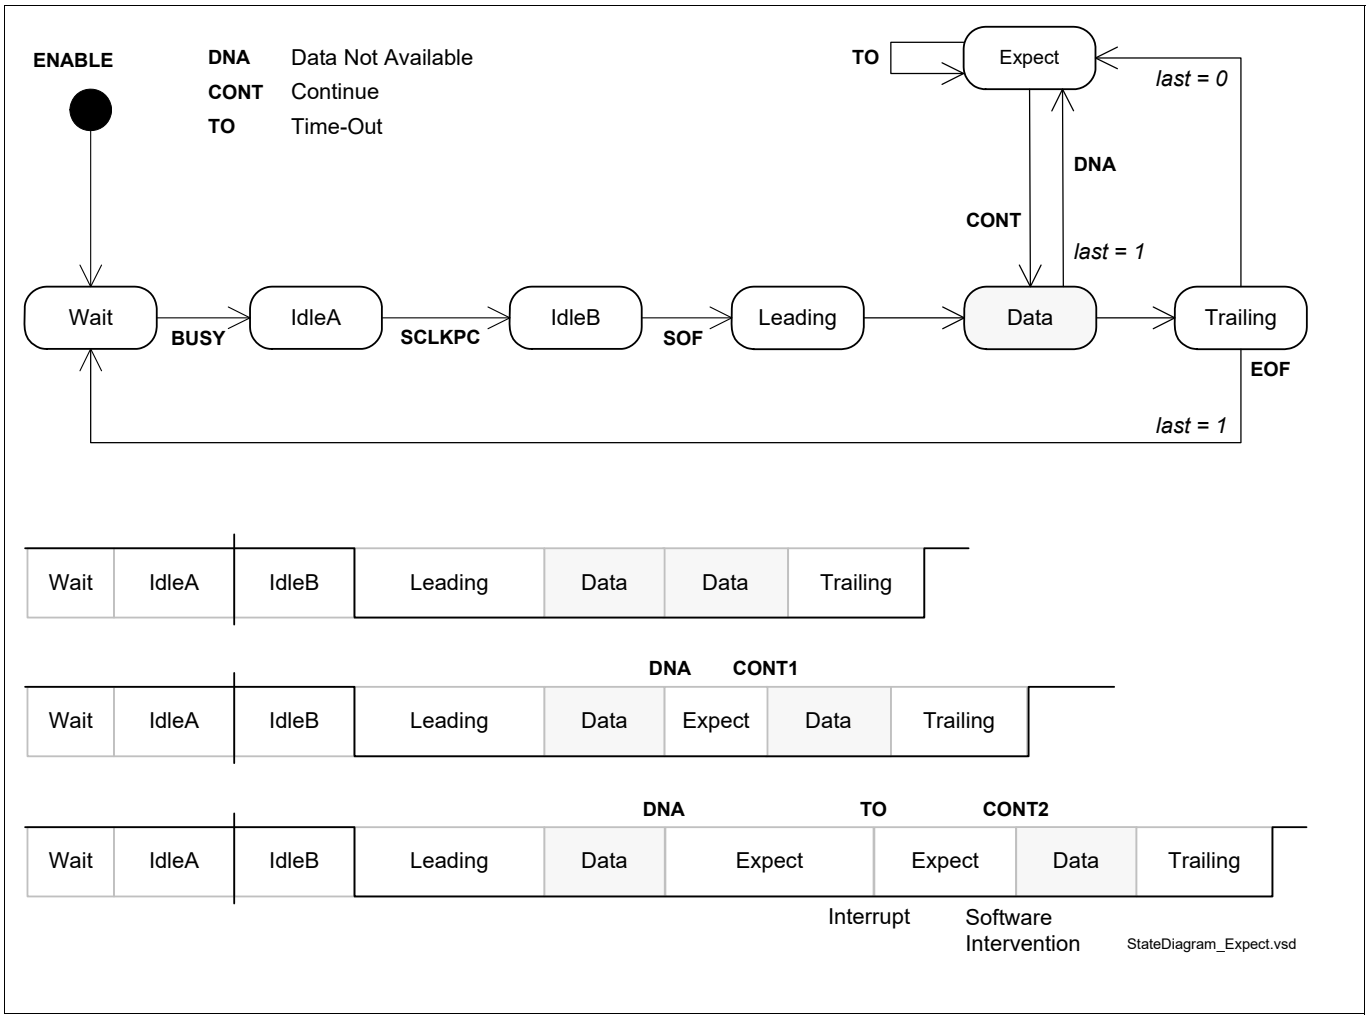

Figure 476 EXPECT Cycles of the QSPI State Machine

37.3.2.7 External Slave Select Expansion

In this mode the bit field **BACON**.CS drives directly the SLSO1 to SLSO4 signals, not demultiplexed by the QSPI, but chip-externally. **SSOC**.AOL bits can invert the SLSO0...4 signal levels individually; **SSOC**.OEN bits enable the signals to the output pins. External Slave Select Expansion Mode (Delayed Mode for SLSO0) is activated with the bit **GLOBALCON**.DEL0.

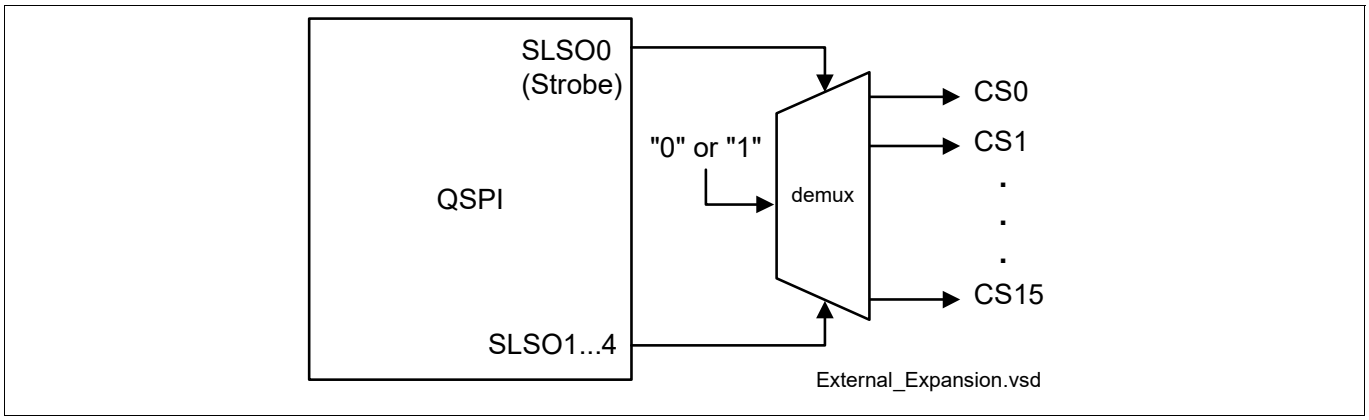

Figure 477 Demultiplexing the Slave Select Signals Externally

In order to ensure glitch free selection, a strobe signal is provided, driven at SLSO0 pin. This signal is delayed relative to the SLSO1...4 signals for LS (Lead_Strobe) and TS (Trail_Strobe) delays, equal in duration and configurable in the range of 1 to 16* f_{PER}. The duration of the LS and TS delays is set in the **GLOBALCON**.STROBE.

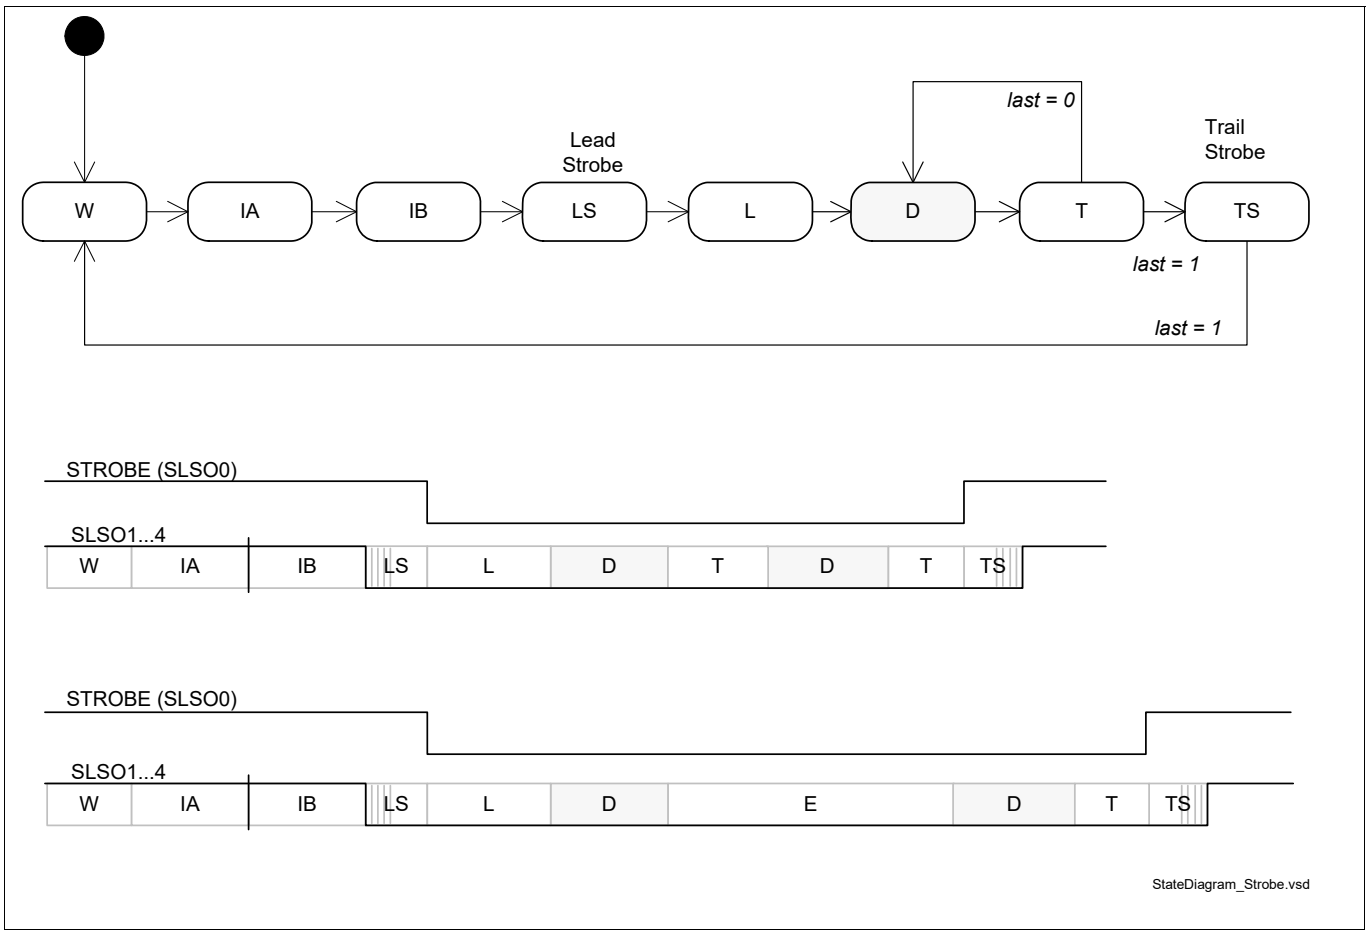

Figure 478 State Machine and SLS Signals in Strobed Mode

37.3.3 Slave Mode

The slave mode is entered by setting the bit field **GLOBALCON**.MS to value 1x. Before entering the slave mode, the related parameters must be configured, including pin selection for SCLKI, SLSI and MTSR, pin input level, and pull-up/pull-down configuration. The configuration should be done before data transmission starts. Reconfiguration is only allowed when the module is in a wait state. Subsequently state machine reset should be performed and afterwards the slave mode should be entered.

In slave mode data is being pushed into or out of the module through the serial pins by an external master. The RXFIFO must be regularly emptied by the system in order to avoid data loss, and the TXFIFO must be regularly fed by the system to avoid delivering all “1” data in case of empty TXFIFO.

If the slave mode relies on a slave select signal to mark the start and, in parallel to the bit counting, the end of a frame, then deactivating the slave signal by the master automatically resets the shift register state machine to wait state.

If the slave mode relies solely on bit counting for determining the frame end, then any SCLKI clock period longer than two bit times is treated as an end of a frame and simultaneously as a baud rate error.

In slave mode, the module simply immediately responds to external clock edges. Therefore, the settings for the leading, trailing, idle delays, and duty cycle and sampling point are irrelevant. From all timing settings, only the data length and the baud rate divider setting are relevant. The baud rate setting is important because of its role of watchdog timer of the incoming serial clock.

Generally, the slave mode supports the same user interface as the master mode. This means the BACON-Data sequences remain the same. The SRF bit is ignored.

Limit the data length setting in the slave mode to the range of 2 to 32 bits. The byte setting **BACON**.BYTE is to be set to zero, that is, it always defines bits.

In case of receive only (simplex receive) the user software must reset the module in order to switch to transmit and receive mode (full duplex). Generally, mode reconfiguration (slave mode to master mode) requires module reset which resets the internal state machines and counters.

In case of slave transmit, the user software must write data to the TXFIFO before the first SCLKI edge of a frame arrives. If the TXFIFO is empty at this point of time, an underflow occurs, all “1” data is delivered, and underflow error interrupt is triggered if enabled. If the TXFIFO is written at the same time when the first SCLKI edge starts the shifting, the underflow occurs, interrupt will be triggered and data from the TXFIFO will be transmitted possibly corrupted - the first bit will be “1”.

In case of TXFIFO / RXFIFO underflow the fifos deliver all “1” data.

In case of TXFIFO / RXFIFO overflow, the last data is lost. In such case data or optionally status in the RXFIFO can be lost.

The bit counting in the slave mode operates according to the following rules:

- The incoming bits (or shift clock shift edges) are counted and when the number defined in the **BACON**.DL is reached, the bits are transferred in the RXFIFO
- If the SLSI input gets deactivated, the internal bit counter is reseted.

In slave mode, sleep requests may be enabled only when there is no pending transmit queue and no pending transmission and the TXFIFO is empty.

Phase Interrupts in the Slave Mode

PT1 interrupt signals the following events:

- BUSY -> option 000 from GLOBALCON1.PT1. Transmit data is present and is waiting for the shift clock.
- SOF -> option 010 from GLOBALCON1.PT1. Transmission of the first data bit started. It is not connected to SLSI active edge, but to first clock pulse received.

- TBE -> option 011 from GLOBALCON1.PT1. Data is taken from the TXFIFO by the QSPI shift engine. It will be transmitted with the first shift clock pulse.
- RBF -> option 100 from GLOBALCON1.PT1. Received data is written to the RXFIFO.
- EOF -> option 101 from GLOBALCON1.PT1. The last data bit has been received.
- DNA -> option 110 from GLOBALCON1.PT1. Transmit data not available at the first shift clock edge reception.

PT2 interrupt signals the following events:

- EOF -> option 101 from GLOBALCON1.PT2. SLSI deactivated (rising edge on the SLSI pin)

37.3.3.1 Shift Clock Phase and Polarity in Slave Mode

In slave mode the shift clock phase and polarity are fixed to CPH=1 and CPOL=0 (have to be programmed accordingly in the **ECONz (z=0-7)** register selected by **BACON**.CS) and slave select polarity is fixed to low active. The baud rate that the slave expects is defined in the **ECONz (z=0-7)** register pointed at by the **BACON**.CS.

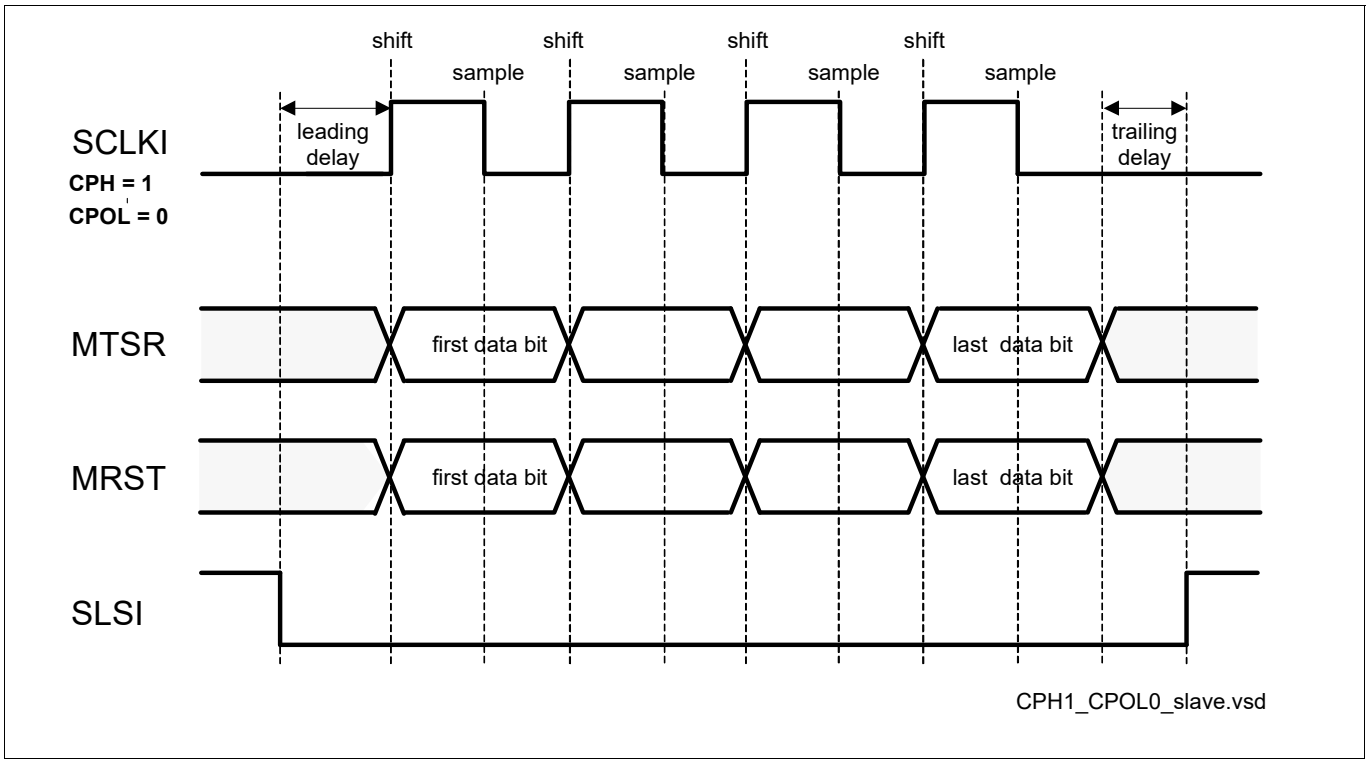

Figure 479 Slave transfer, CPH = 1, CPOL = 0

Attention: Slave re-configuration must only be performed in a gap between the frames. However, as a general recommendation, slave mode configuration should be done once only and before the transition starts.

37.3.3.2 Shift Clock Monitoring

The QSPI module provides two mechanisms for monitoring the shift clock input signal in slave mode. These mechanisms monitor:

- if the receiving shift clock frequency (baud rate) lies within a certain range and
- if there are spikes on the shift clock input.

In case such disturbances are detected, the reaction is always the same:

- the corresponding error flags in **STATUS**.ERRORFLAGS are set, which can be cleared with **FLAGSCLEAR**.ERRORCLEARS
- the common error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS and
- the bit **GLOBALCON**.EN is automatically cleared, if this feature is enabled by the bit **GLOBALCON**.AREN. The user software can activate a reset afterwards

In case of too high baud rate error, baud rate detection and spike detection both react, where spike detection is more effective. Spike detection reacts immediately, baud rate detection requires several bits with higher baud rate. Baud rate detection uses a window two nominal bit times wide and counts the real bit times: double baud rate error requires at least four real shift clock pulses to be detected, triple baud rate error requires six and so on.

Baud rate detection does not react to all spikes smaller than one kernel clock period.In case of too low baud rate, baud rate error detection reacts immediately, spike detection ignores this case.

37.3.3.2.1 Baud Rate Error Detection

If the shift clock has less than half or more than double the expected baud rate, then:

- the corresponding flag is set in **STATUS**.ERRORFLAGS
- error interrupt is raised if enabled in **GLOBALCON1**.ERRORENS
- automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

37.3.3.2.2 Spike Detection

Short spikes on the clock line due to ground bouncing or clock ringing due to over/undershoots would cause one or more extra bits to be written to the front end receive FIFO of the slave. This extra bit, if no measures are taken by the software, would cause all the subsequent received frames to be corrupted (shifted).

The spike detection mechanism operates up to 50 MBaud and checks if a bouncing spike has occurred on the clock line near to the correct receiving clock edges.

If a spike is detected, the software should use **GLOBALCON**.RESET bit field, and should clear the corresponding status flags. Alternatively a complete module reset may be performed via registers **KRST0**/**KRST1**.

The spike detection is based on two mechanisms:

- detection of two close writes to the front end receive FIFO by detecting filling level of two
- using an inverted watchdog set to ca. 75% to 80% SCLKI clock period, which is the optimal range.

The inverted watchdog is a timer which starts to count triggered on the write event to the front-end receive FIFO of the slave. During the time the watchdog counts, no edge is allowed to occur. An edge in the forbidden time raises a spike error event.

If a spike occurs in the last 25% of the SCLKI period, when the watchdog has stopped counting, the watchdog will be triggered to count by the spike. The next regular edge will violate the forbidden time and raise a spike event.

The watchdog counts **ECONz (z=0-7)**.B + **ECONz (z=0-7)**.C time quantas. The following constraint applies: 50% $*T_{SCLKI}$<**ECONz (z=0-7)**.B + **ECONz (z=0-7)**.C <100%$*T_{SCLKI}$.

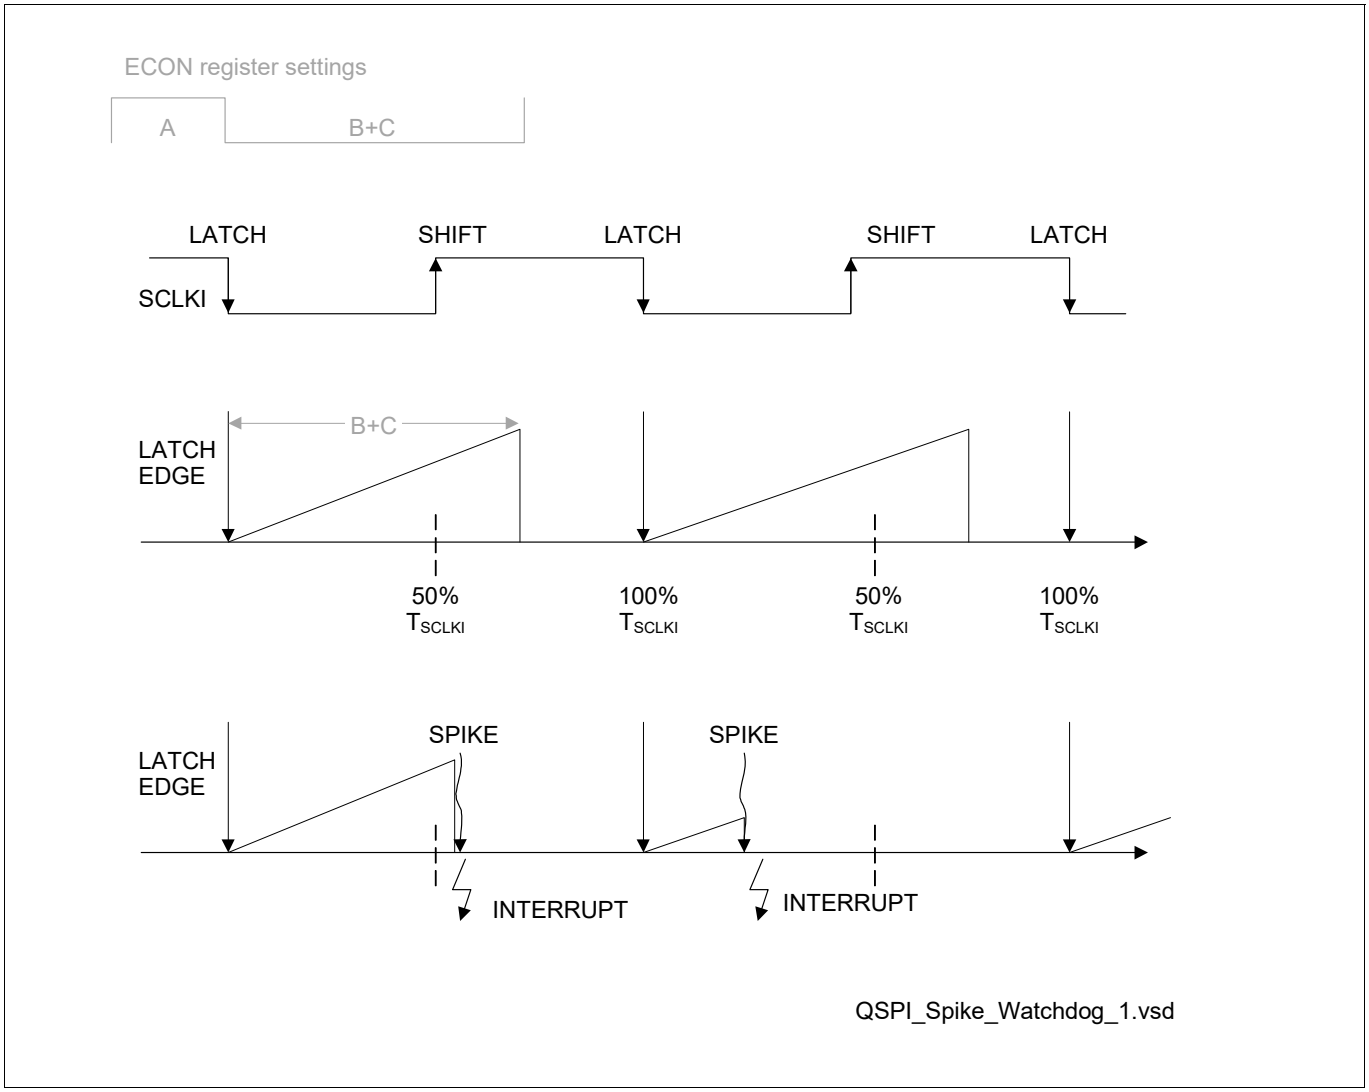

Figure 480 Spike Watchdog

37.3.3.2.3 Shift Clock Monitor Flags

The spike detection mechanism sets the flag **STATUS1**.SPD, if it has detected a spike. The baud rate error detection mechanism sets the flag **STATUS1**.BRD, if it has detected excessive baud rate deviation.

Writing 1 to SPD and BRD sets the bit and causes an interrupt, if enabled. Writing 0 has no effect.

Both signals are ORed. This combined signal is shown in **STATUS**.ERRORFLAGS and raises an interrupt, if enabled in **GLOBALCON1**.ERRORENS. Automatic clear of **GLOBALCON**.EN follows, if enabled by **GLOBALCON**.AREN.

If the **STATUS**.ERRORFLAGS[2] bit is cleared via **FLAGSCLEAR**.ERRORCLEARS[2], both flags SPD and BRD are automatically cleared.

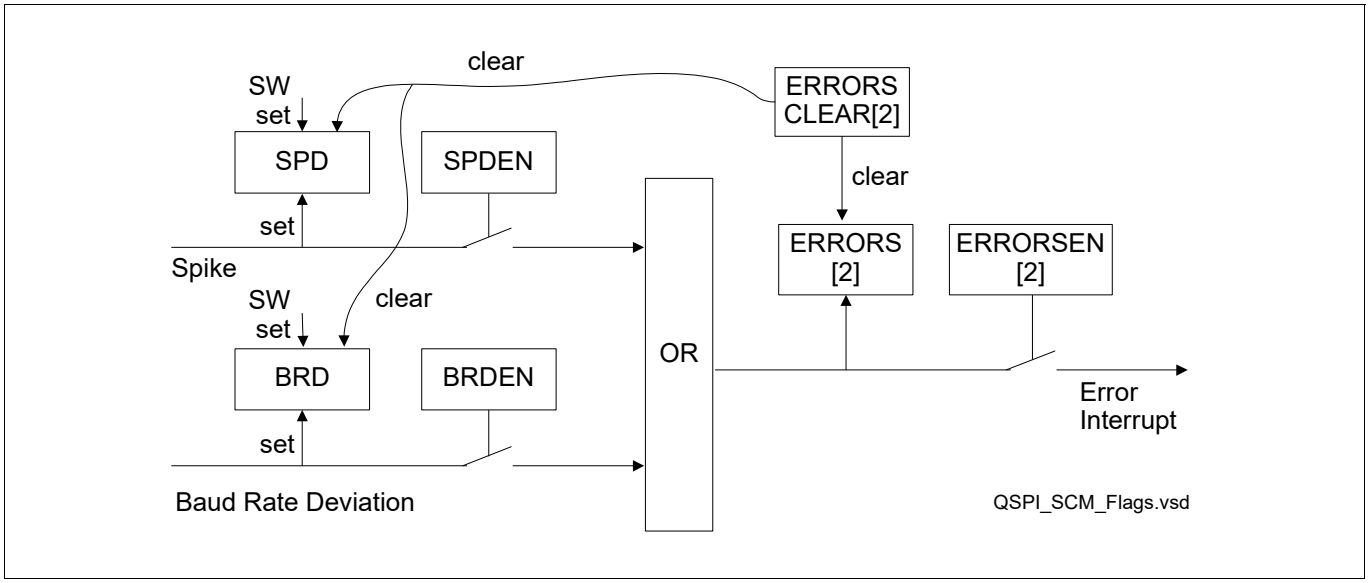

Figure 481 Shift Clock Monitor Flags

37.3.3.3 Parity

Parity settings for transmit and receive are defined by the corresponding bit fields in the **BACON** register.

The parity bit is concatenated to the data bits at transmission time. That means that a frame containing 16 bit data is 17 bits long (data + 1 parity). The transmitted parity bit can be read from the **STATUS**.TPV bit.

The parity bit is removed from the received bits at receive time automatically. The received parity bit can be read from the **STATUS**.RPV bit.

Attention: Parity is available only in short mode, that is, only for data of up to 32 bits length.

Attention: The parity bit is concatenated to the data at the LSB location. If the bit field BACON.MSB = 0 it is shifted out first, else it is shifted out last.

37.3.4 Operation Modes

Generally, the QSPI module transmits a RAM queue of an arbitrary length, fed by a DMA module, and makes pauses between the queues. The QSPI module does not know anything about the queue length or the current position within the queue or the future schedule of the messages that may come.

If the QSPI module gets a request for switching off the clock or pausing the module, it disables all service request lines.

The QSPI module provides two options for switching off the clocks or pausing the module: hard suspend (as soon as possible regarding for example the length of interrupt request pulses), and soft suspend (transition to the PAUSE state after reaching predefined state). The requests can be triggered by hardware signals (disable, suspend, sleep) or by software write to **GLOBALCON**.EN bit.

Disable, Pause and Run

After being enabled by clearing the **CLC**.DISR bit, the QSPI enters the PAUSE state. In this state, the QSPI module can be initialized, the TXFIFO pre-filled, and then, by setting the **GLOBALCON**.EN bit, put into a RUN state.

The software requests PAUSE state of the running module by clearing the **GLOBALCON**.EN bit. The software can detect that the QSPI module has reached the PAUSE state by polling for the **GLOBALCON**.EN=0 and **STATUS**.PHASE=0 (indicating WAIT state, master mode only).

In PAUSE state, the user interface of the module is active. The registers and the FIFOs can be read and written. However, both the receive and transmit state machines are inactive, in master as well as in the slave mode. This allows for reconfiguration of the module without affecting the serial bus.

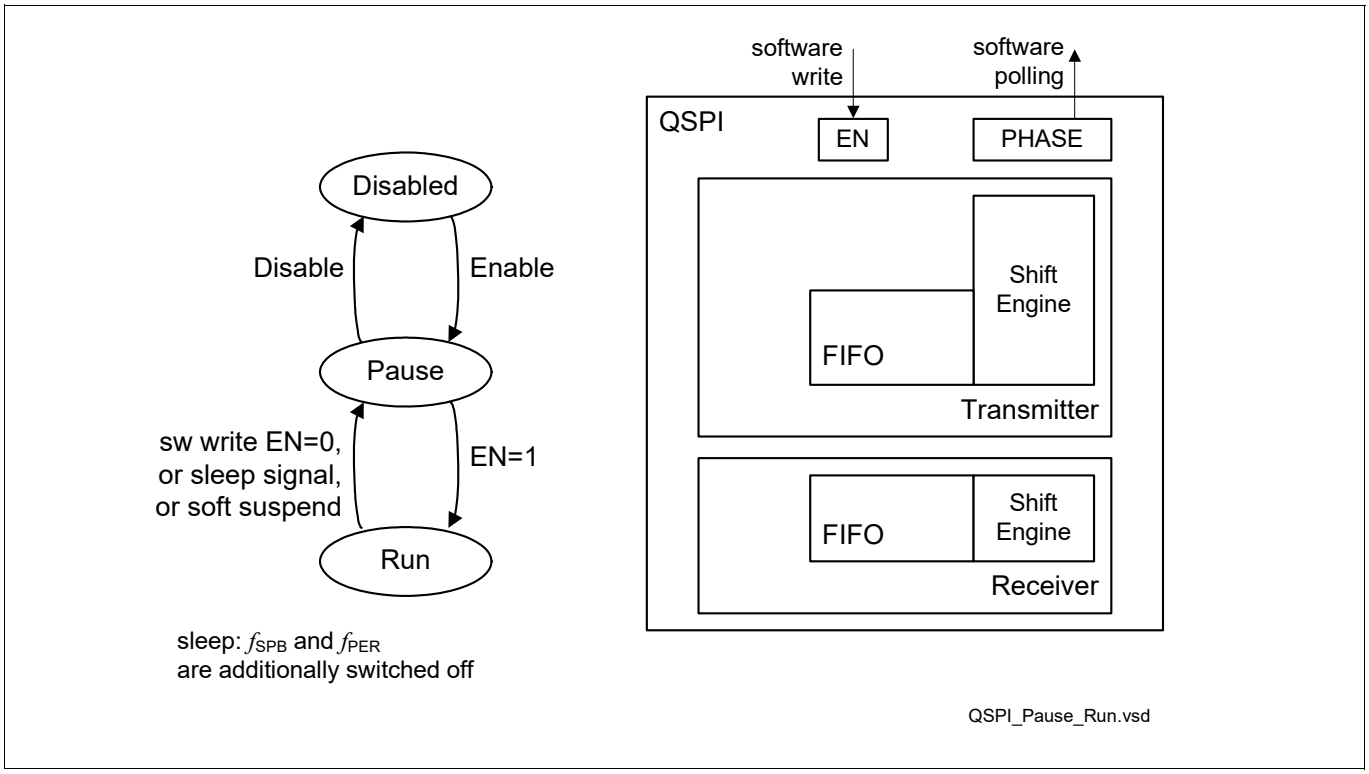

Figure 482 Pause and Run Overview

The concept of the PAUSE state is reused for handling the soft OCDS suspend and Sleep requests. In contrast to active Pause state and OCDS suspend, the sleep state has the special property that (due to the low power requirement) both FPI and QSPI clocks are switched off.

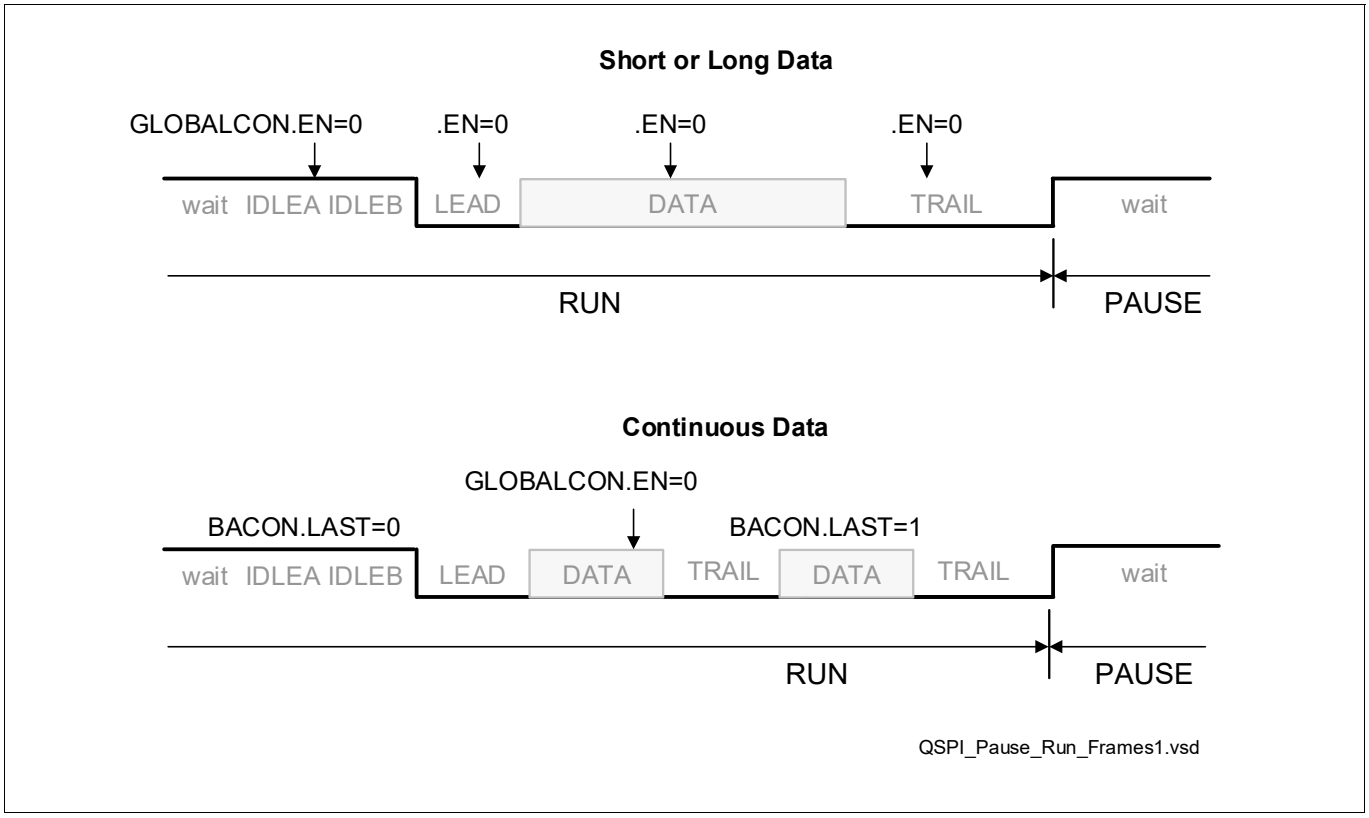

Figure 483 Entering the Pause State With GLOBALCON.EN=0

If a running module receives a request to PAUSE, it waits for the end of the last TRAIL phase of a frame.

For all modes (Short, Long and Continuous), the PAUSE state is indicated by **GLOBALCON**.EN=0 and **STATUS**.PHASE=0, master mode only.

37.3.4.1 OCDS Suspend

The OCDS hard suspend request, for debugging purposes, simply freezes the QSPI module in the current state. No signal is changed including the service request lines, which remain frozen in the current state.

The QSPI responds to an OCDS soft suspend request by entering the PAUSE state immediately after the subsequent end of a trail phase, and then sending acknowledge (see **Figure 484**). The behavior is the same as for entering the **Sleep Mode**.

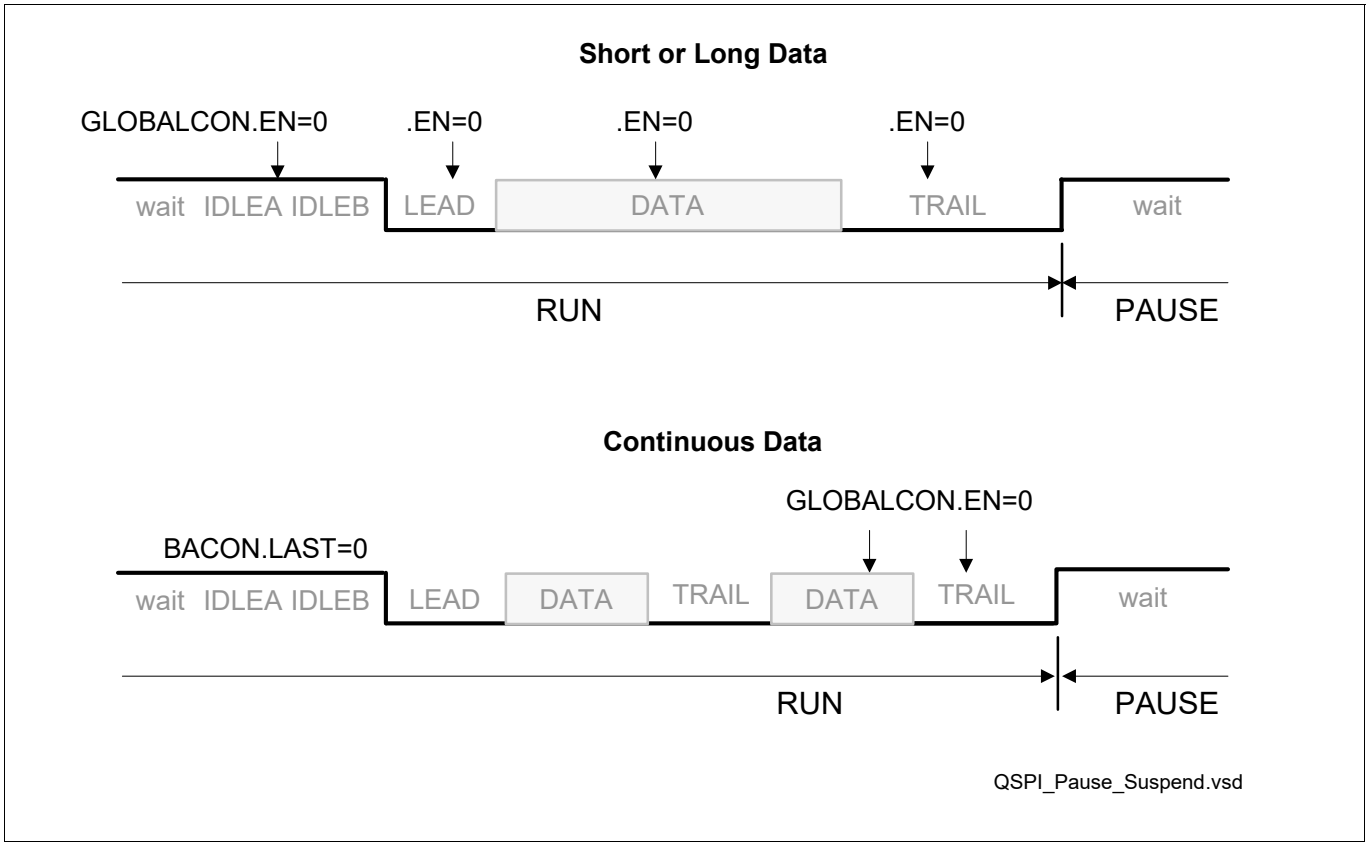

Figure 484 Entering the Sleep, Soft Suspend, and Disable State

Reading the FIFO entries by the Cerberus (detected by the FPI master tag) does not modify the FIFO content nor the read and write pointers.

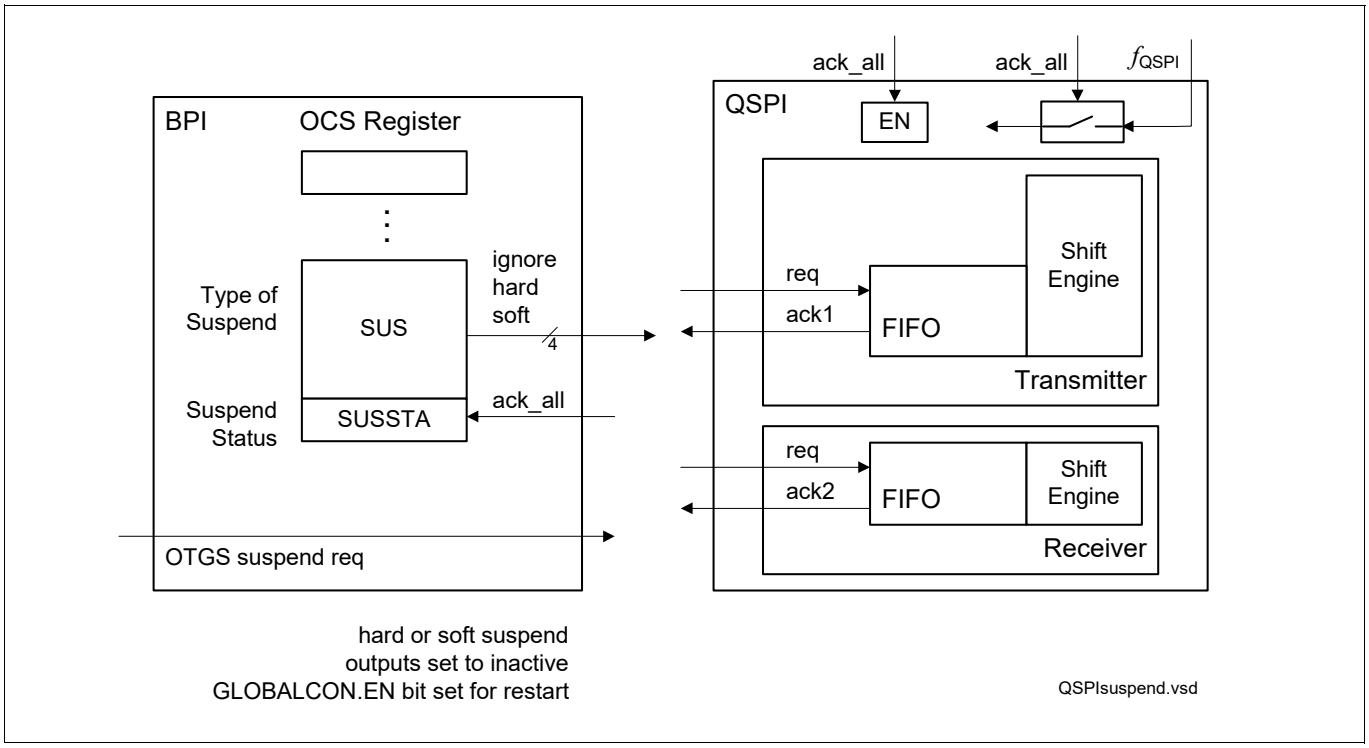

Figure 485 Suspend Overview

Please note the following:

- In Hard Suspend Mode:
  - the QSPI kernel clock is switched off immediately
  - Writing to registers is possible but will enable the kernel clock for a few cycles. Attention: these clock pulses in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a QSPI kernel reset might not be sufficient to bring the system into a defined state
  - Read access to a register does not let through any clock cycles, but is done in combinatorial way. Therefore, RXFIFO pointer does not move
- In Soft Suspend Mode:
  - the QSPI kernel clock is switched on, the module is only paused
  - Each read and write can cause state transition in some state machine in the module. Therefore RXFIFO reacts to the read accesses.

37.3.4.2 Sleep Mode

Sleep signal is a system wide hardware signal requesting from all modules to go to low power saving state as soon as possible. For the QSPI module, going to sleep mode can be disabled or enabled by setting or clearing the **CLC**.EDIS bit. The module enters the sleep as soon as possible and remains in this state as long as the hardware sleep signal is active. Upon deactivation of the sleep signal, the QSPI wakes in PAUSE state (**GLOBALCON**.EN bit is cleared by the QSPI module) and waits for the software to enable the **GLOBALCON**.EN bit.

If **CLC**.EDIS bit is cleared, the sleep mode is enabled and the module enters the sleep state:

in master mode

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL field
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty
- or immediately if the SLSI is inactive (the one selected by PISEL)

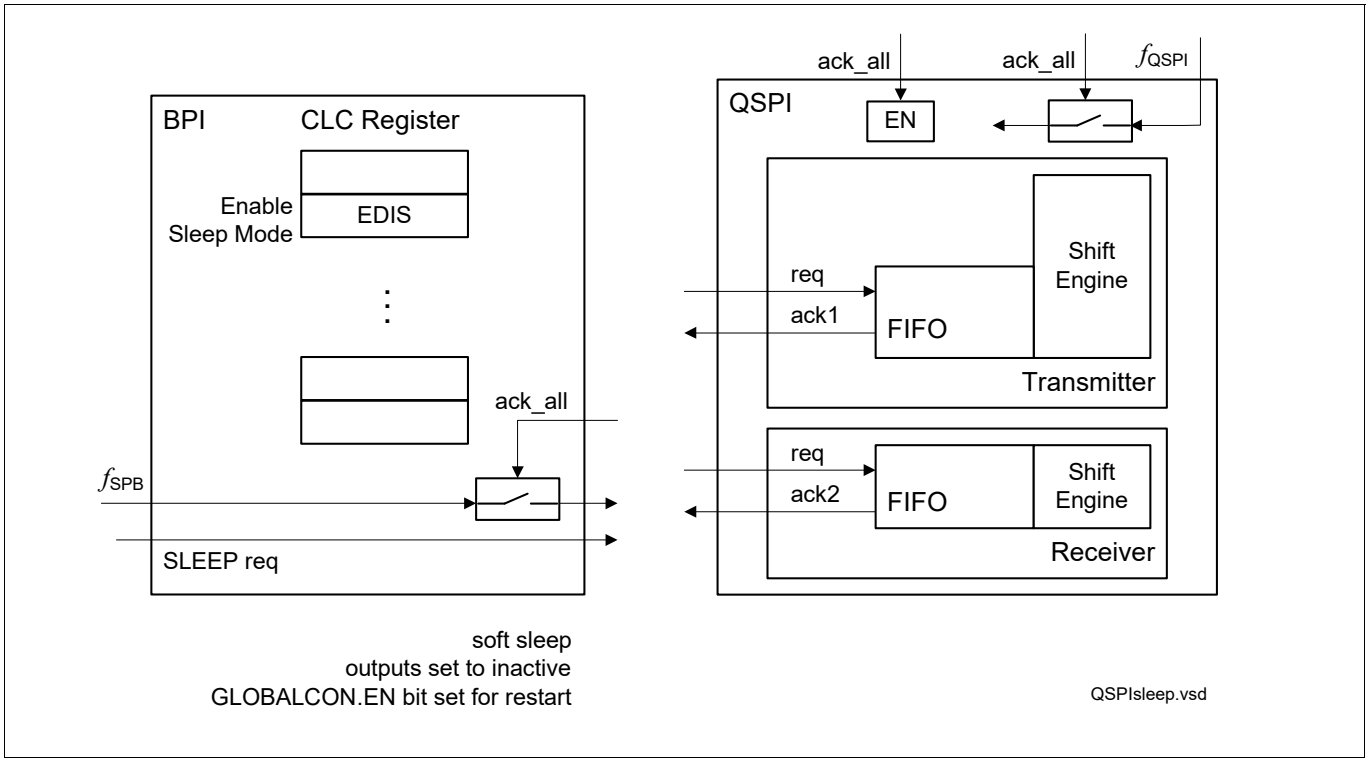

Figure 486 Sleep Overview

It is responsibility of the user software to have the sleep enabled in a safe time intervals, where no race conditions or pipeline effects between the QSPI module and the DMA can occur in case of sleep request.

Note: CLC disable request and sleep request block immediately kernel register write accesses. This includes also the TXFIFO access. Therefore if the module expects more data (like in long or continuous mode), it will enter the expect phase and remain there and never do an acknowledge and enter the required state. Periodic timeout interrupts will be generated. Therefore it is not recommended to request a sleep or disable during an ongoing long or continuous transfer.

37.3.4.3 Disabling the QSPI

The software can switch off the QSPI module by setting the **CLC**.DISR bit. It is responsibility of the user software to issue a disable request in a safe time interval, where no race conditions or pipeline effects between the QSPI module and the DMA can occur. This is no issue if the switch-off procedure is one-way, that is no continuation of operation without reinitialization/reset of the module is expected. **GLOBALCON**.EN bit is cleared.

The QSPI module itself behaves in the following way.

in master mode like entering the sleep mode:

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in **BACON**.DL and BYTE bit fields, if a transmission is ongoing or
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty

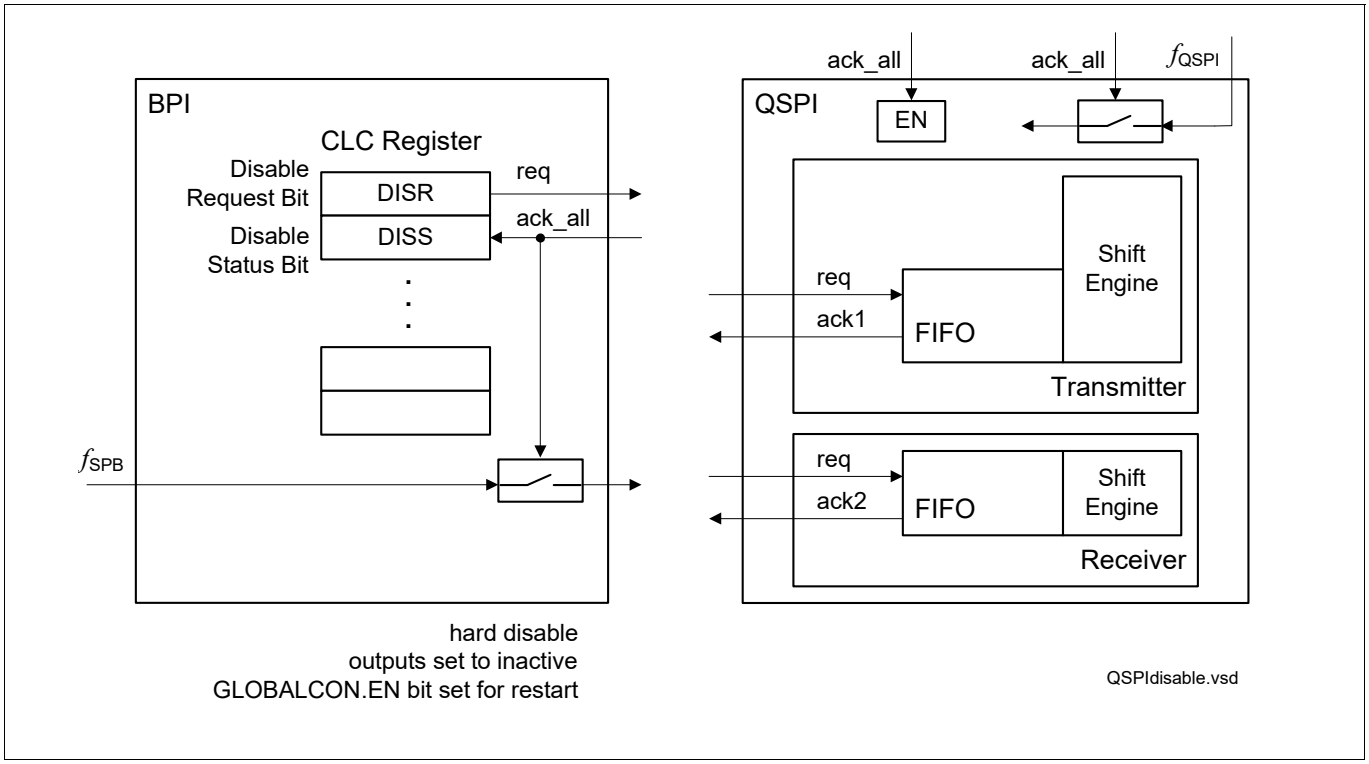

Figure 487 Disable Overview

37.3.5 User Interface

This section describes the possibilities available for transferring data between the on-chip RAM memories and the QSPI module using the transmit and receive FIFOs. The QSPI features one 4 x 32-bit Tx FIFO and one 4 x 32-bit Rx FIFO. The address ranges for writing data and configuration to the Tx FIFO and for reading data and status from the Rx FIFO consist of address locations with special properties:

- Tx FIFO
  - DATA_ENTRY - writes to any of these eight functionally identical locations are always interpreted as data
  - BACON_ENTRY - writes to this location are always interpreted as configuration
  - MIX_ENTRY - writes to this location are interpreted as data or configuration, based on a set of rules
- Rx FIFO
  - RX_EXIT - reads from this location deliver either data and optionally status, based on a set of rules.

Use either MIX_ENTRY or the combination DATA_ENTRY / BACON_ENTRY for sending a frame. Do not combine DATA_ENTRY/BACON_ENTRY and MIX_ENTRY for sending a frame.

The following list gives an overview of the operating modes of QSPI and usage of the TxFIFO entry addresses:

- Short Mode: MIX_ENTRY, DATA_ENTRY / BACON_ENTRY
- Long Mode: MIX_ENTRY, DATA_ENTRY / BACON_ENTRY
- Continuous Mode: MIX_ENTRY, DATA_ENTRY / BACON_ENTRY
- Single Configuration
  Multiple Frames: MIX_ENTRY
- XXL Mode: DATA_ENTRY / BACON_ENTRY
- Move Counter Mode: DATA_ENTRY / BACON_ENTRY

37.3.5.1 Transmit and Receive FIFOs

The Tx_FIFO is filled with both configuration and data entries, which are distributed to the **BACON** and the shift register at the exit of the Tx_FIFO. The TxFIFO keeps track if an entry is configuration or data. The control and the data elements are automatically distributed to the **BACON** and shift register. If no data is available, the new BACON is pending.

If a frame is finished and there is data in the FIFO

- in short mode, a new frame starts automatically with the same configuration as the previous one.
- in long mode, the extra data are ignored.

TXFIFO error conditions:

- FPI bus write to a full TXFIFO generates an overflow interrupt. The write is ignored.
- In case of slave mode, (**GLOBALCON**.MS = 1X), in case of an underflow, only “1” are delivered.

RXFIFO error conditions:

- FPI bus read from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits.
- Hardware attempt to write a full RXFIFO with data or status generates an overflow interrupt. The write attempt is ignored by the RXFIFO.
- If the **GLOBALCON**.SRF bit is set, the communication is stopped in case of full FIFO in master mode. In slave mode, the bit is ignored, no stop can be done.
- If the FPI bus frequency is very slow, and the baud rate very high, it can happen that some data is lost on the way between the shift register and a not full RXFIFO. In such a case, an overflow interrupt is generated, although the RXFIFO is not full.

The Rx_FIFO can be filled with both status and received data entries, depending on **GLOBALCON**.SI.

Note: If a 8-bit or 16-bit write is executed to the TXFIFO entry addresses, the data is mapped 1:1 to its location within the 32-bit wide TXFIFO entry, and the rest is padded with zeros.

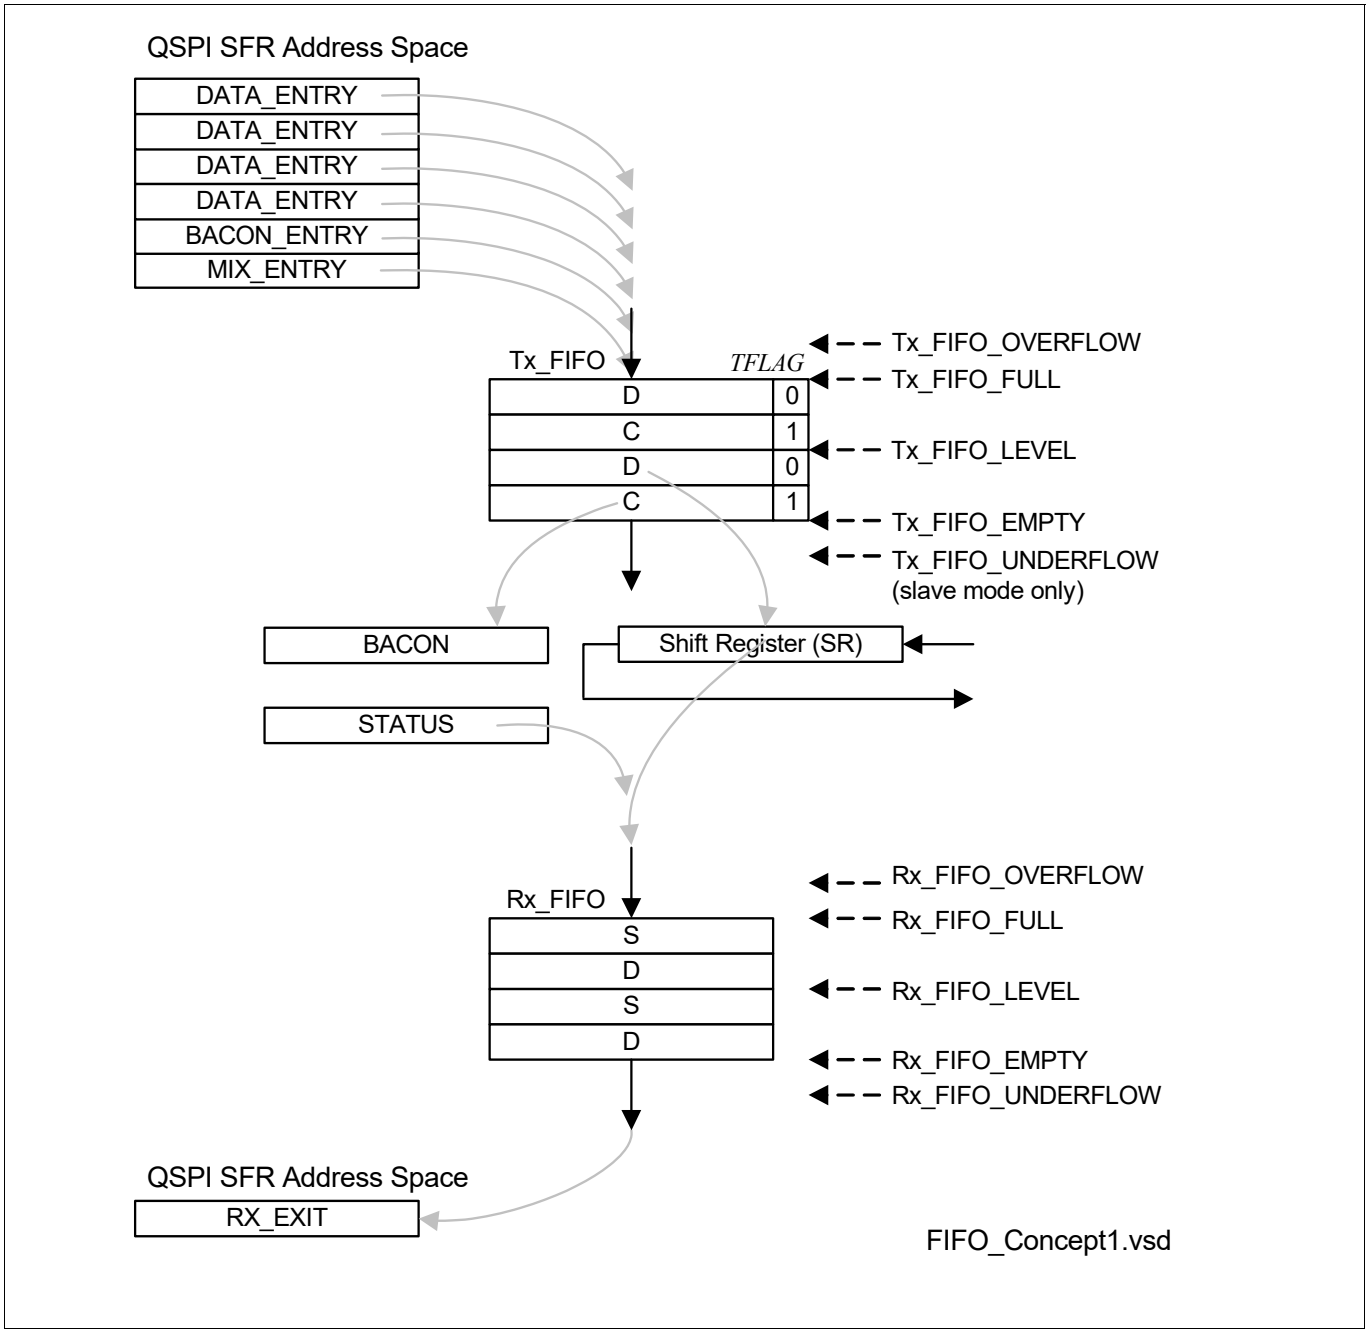

Figure 488 Architecture of the Tx and Rx FIFOs

(>>**Interrupts**)

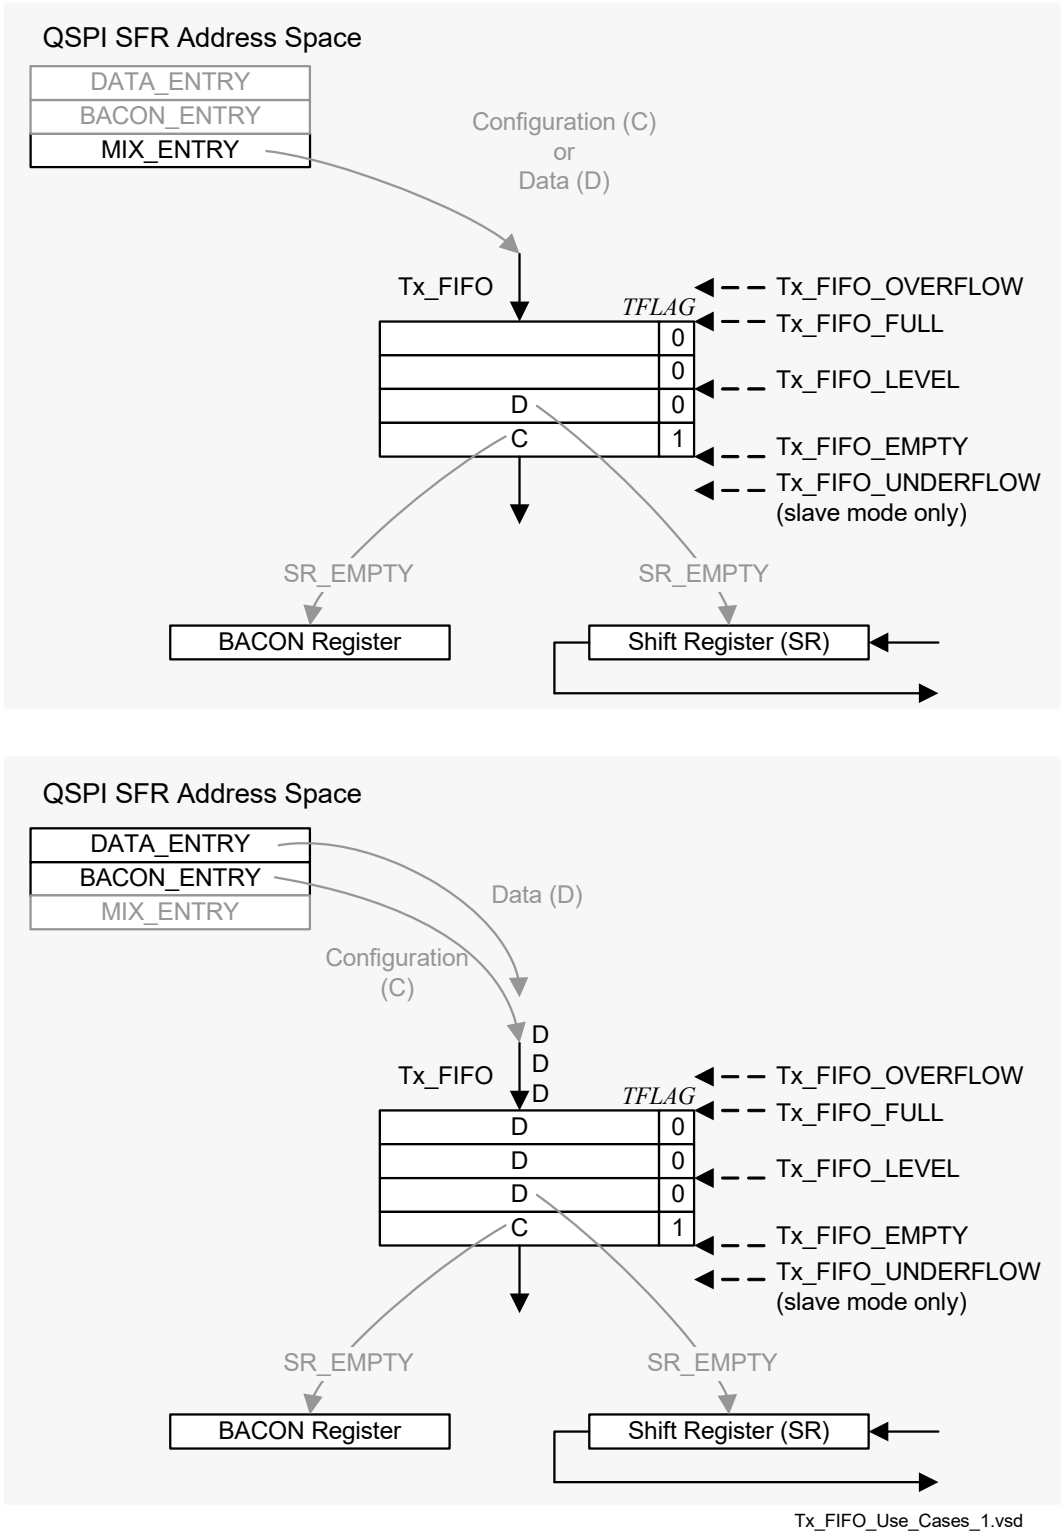

Figure 489 Using Tx FIFO Mix and Bacon / Data Entries

37.3.5.1.1 Short Data Mode

In Short Data Mode, the QSPI module transmits single data with a length of 2 to 32 bits in one frame. This mode is defined by **BACON**.LAST = 1 and **BACON**.BYTE = 0.

The transfer cycle is a sequence of the following phases: W?_I_L_D_T. The symbol “?” means that the phase is optional (duration of 0 allowed).

For example, a Tx_FIFO event can be used to trigger one DMA transfer (consisting of two 32-bit moves) to transfer both the BACON and DATA entries from an on-chip RAM memory to the QSPI module.

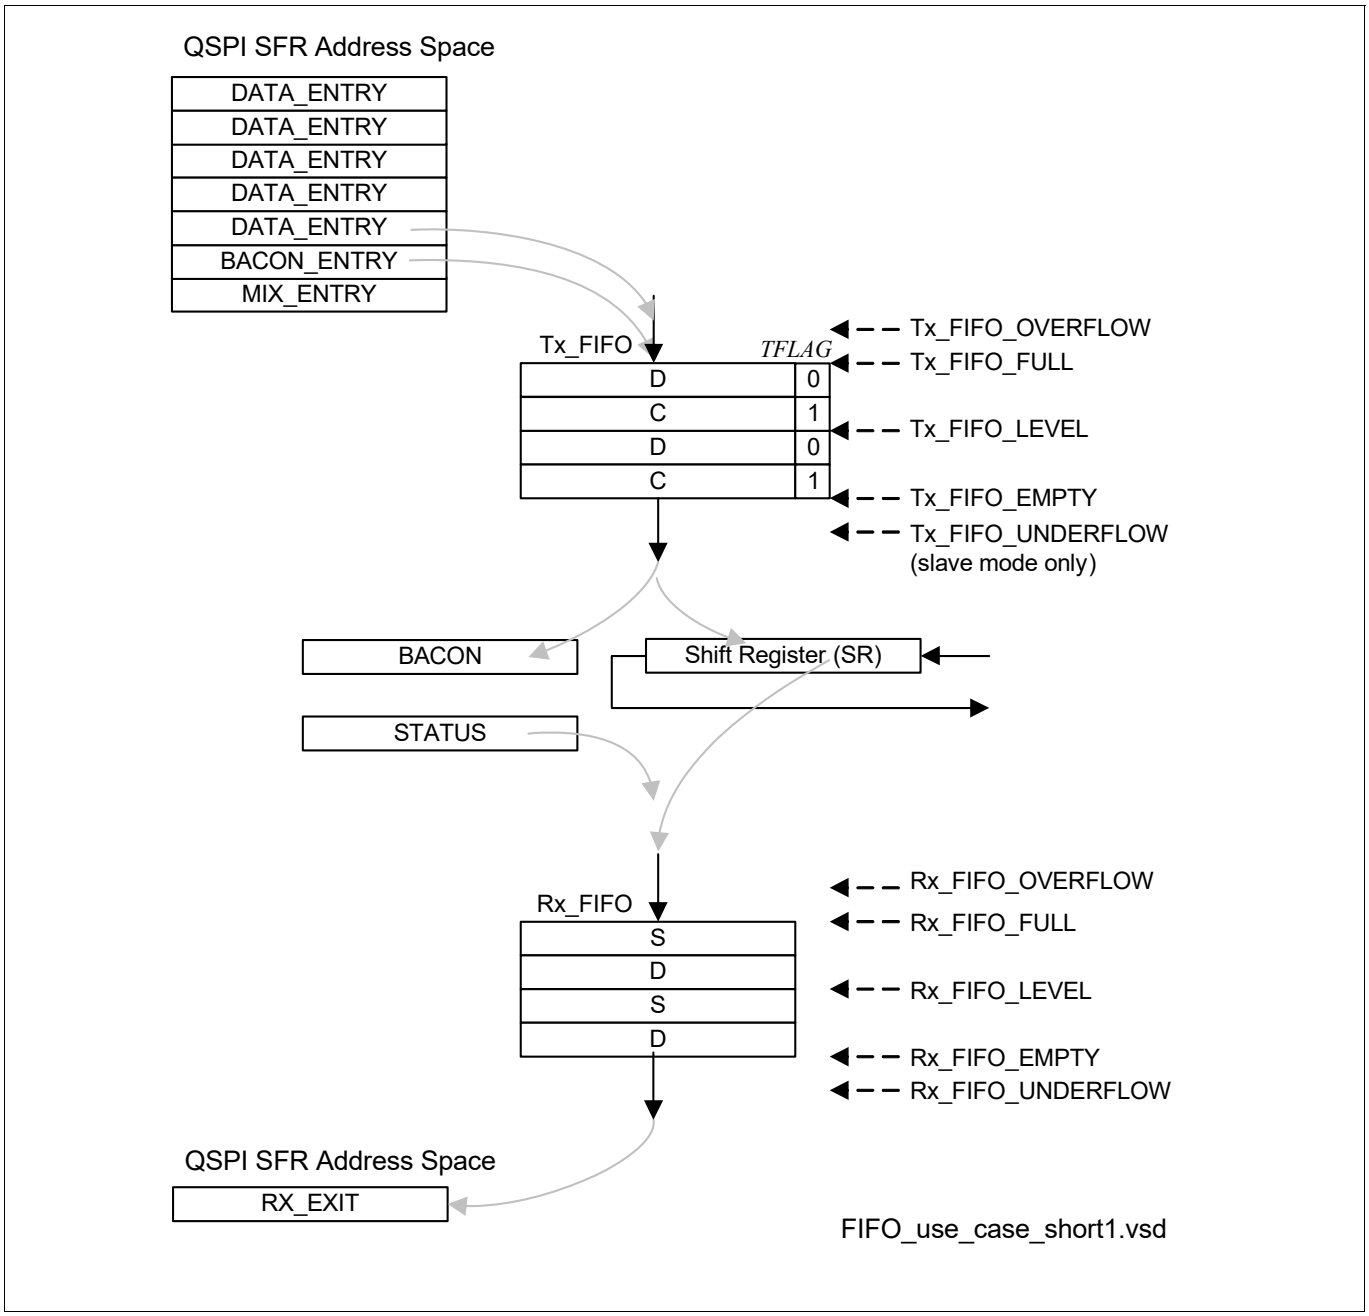

Figure 490 User Interface in Short Data Mode

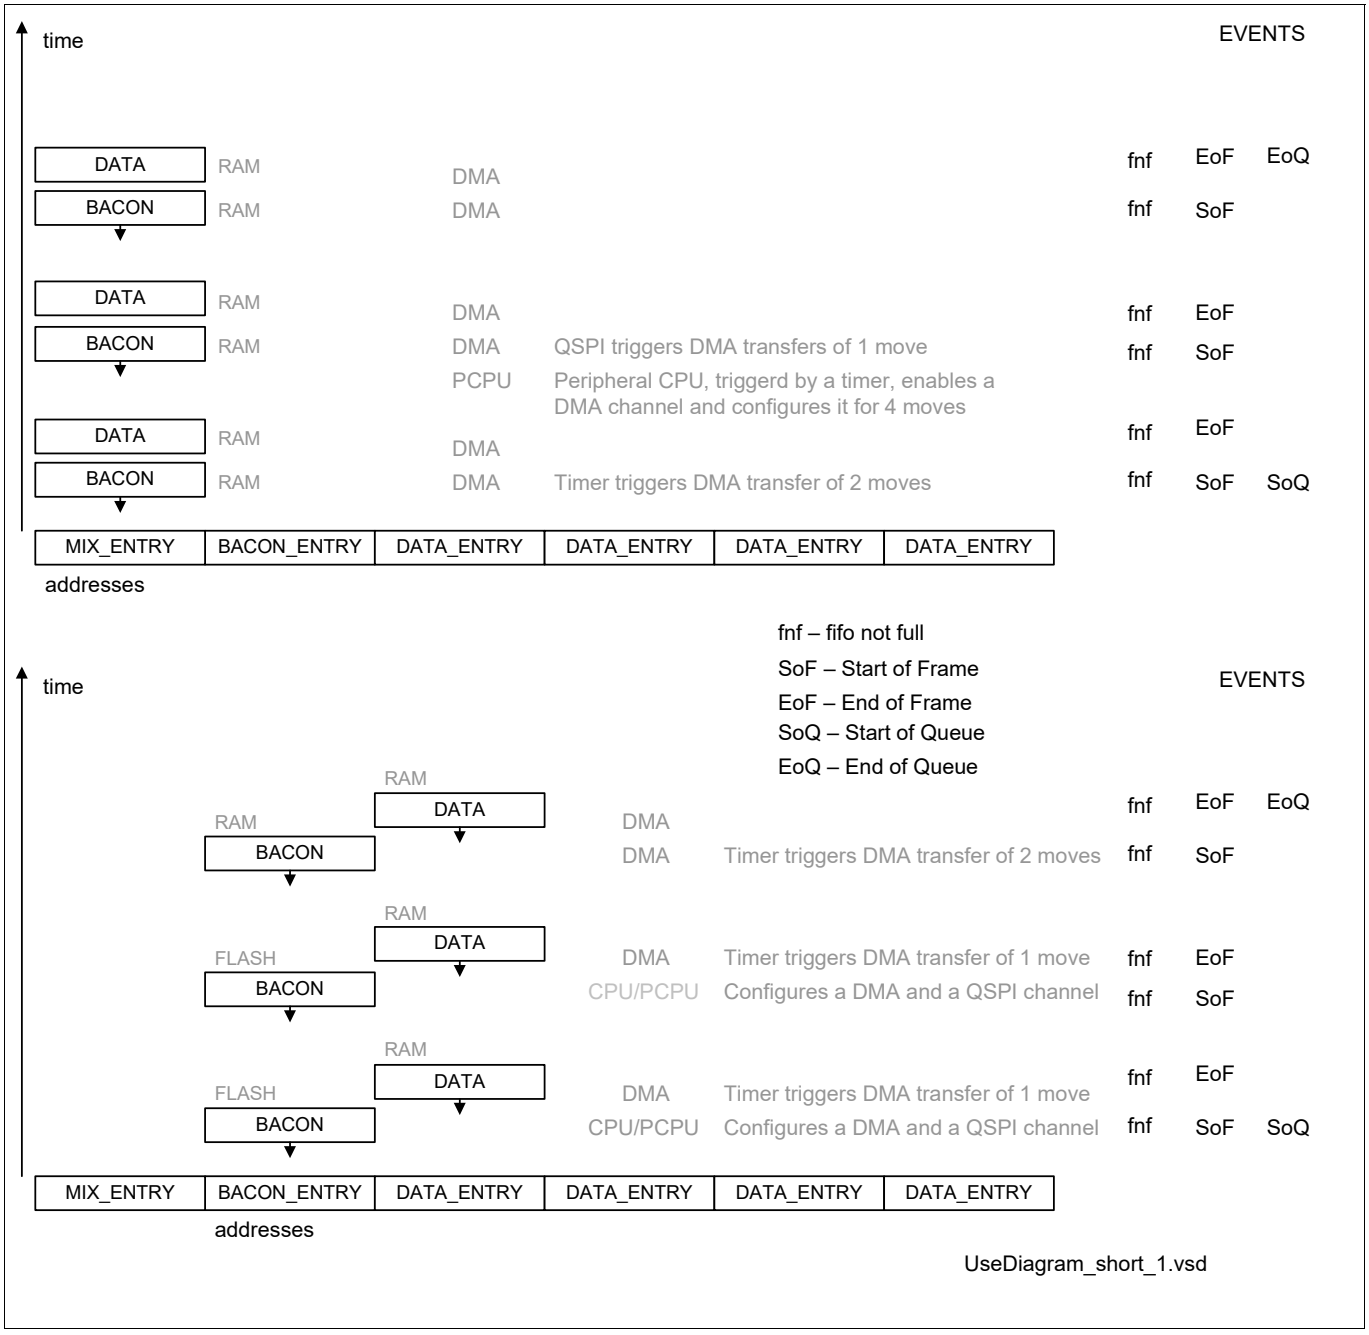

Figure 491 Use Diagram of the User Interface in Short Data Mode

37.3.5.1.2 Long Data Mode

In Long Data Mode, the QSPI module transmits bursts of up to 32 bytes (256 bits) in one frame. This mode is defined by programming **BACON**.LAST = 1 and **BACON**.BYTE = 1.

One transfer cycle in long data mode is a sequence of the following phases: W?_I_L_D_T. The W_I_L_D_T_I_L_D_T sequence is possible. The symbol "?" indicates that the phase is optional (duration of 0 allowed). Each "D" indicates a data length as defined with **BACON**.DL and **BACON**.BYTE, that is, up to 32 bytes. One "D" is made of a number of 32-bit TXFIFO entries "d" and one rest at the end "b", which can be written as D=ddddddb.

The Long Data Mode can be extended by using the **XXLCON** register.

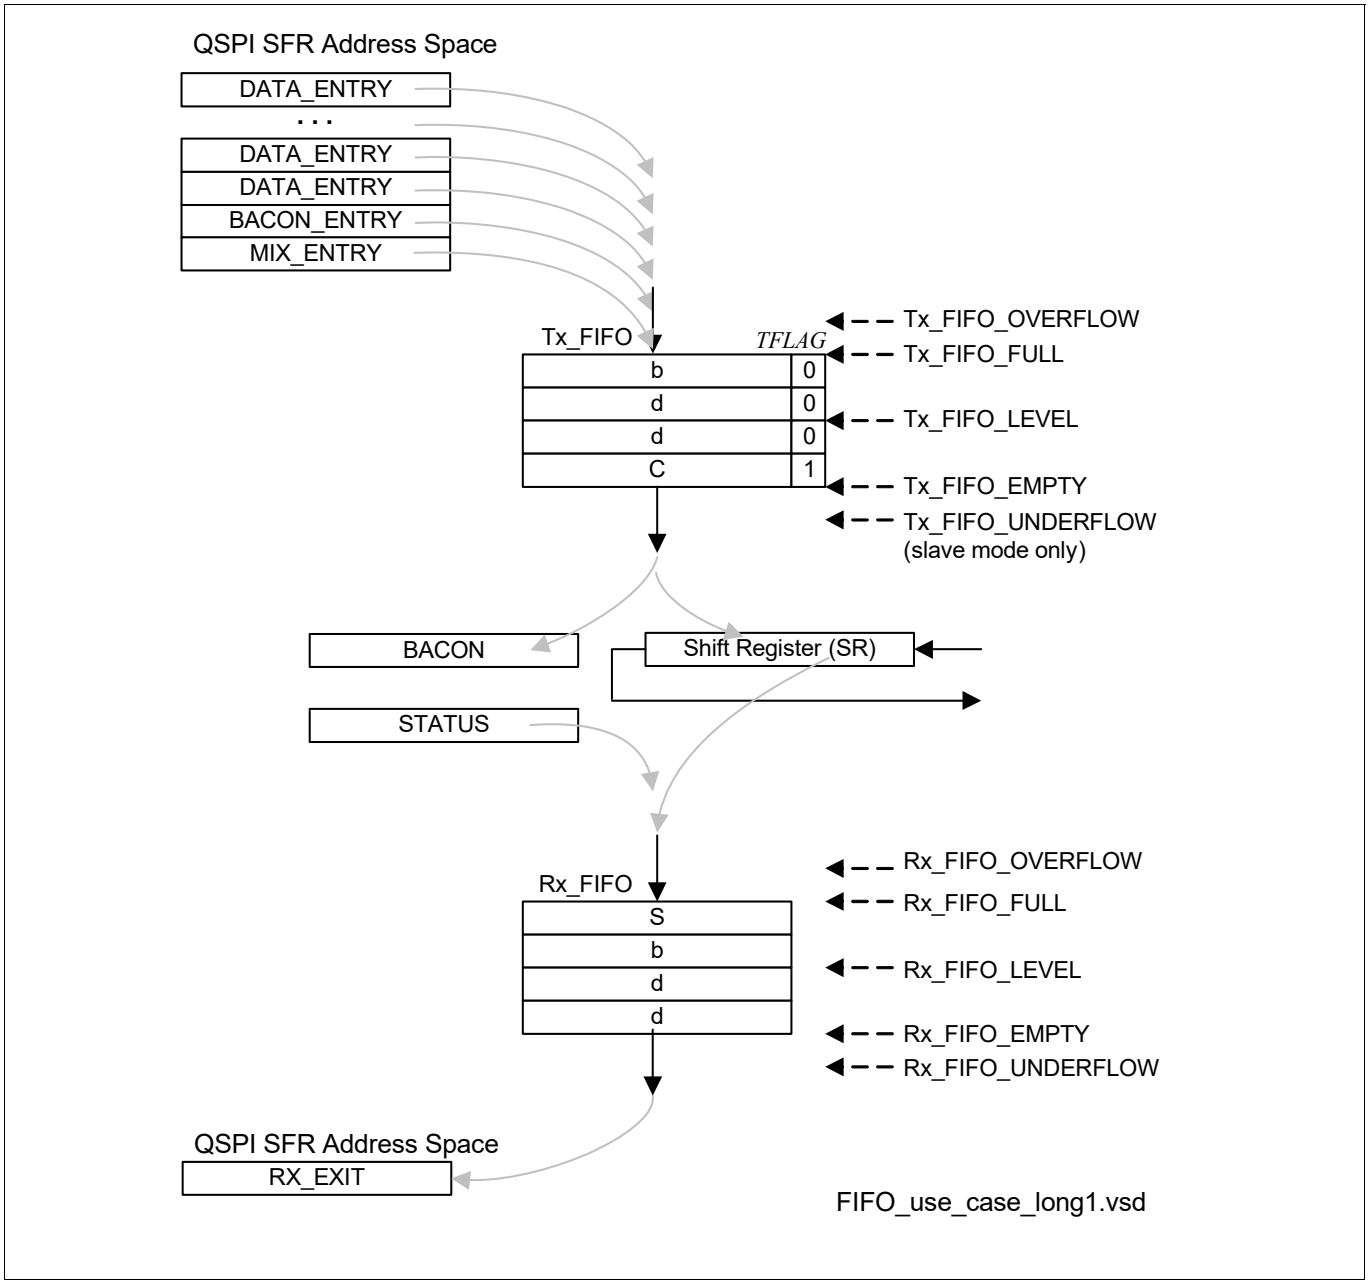

Figure 492 User Interface in Long Data Mode

In a DMA transfer example, a Tx_FIFO_EMPTY event can be used to trigger one DMA transfer (consisting of, for example, four 32-bit moves) to transfer the BACON and three DATA entries from RAM memory to the QSPI module.

The three data words could contain 80 bits (10 bytes) of data. The three data words could also contain 40 bits (5 bytes), 64 bits (8 bytes) plus one dummy word. In this way short bursts of up to 96 bits can be transmitted.

In such 4 words DMA transfer example, the Tx_FIFO event can be used to transfer two 32-bit words per transfer.

If a configuration word is written when a data word is expected, the configuration word is ignored, and an Unexpected Configuration Error is raised.

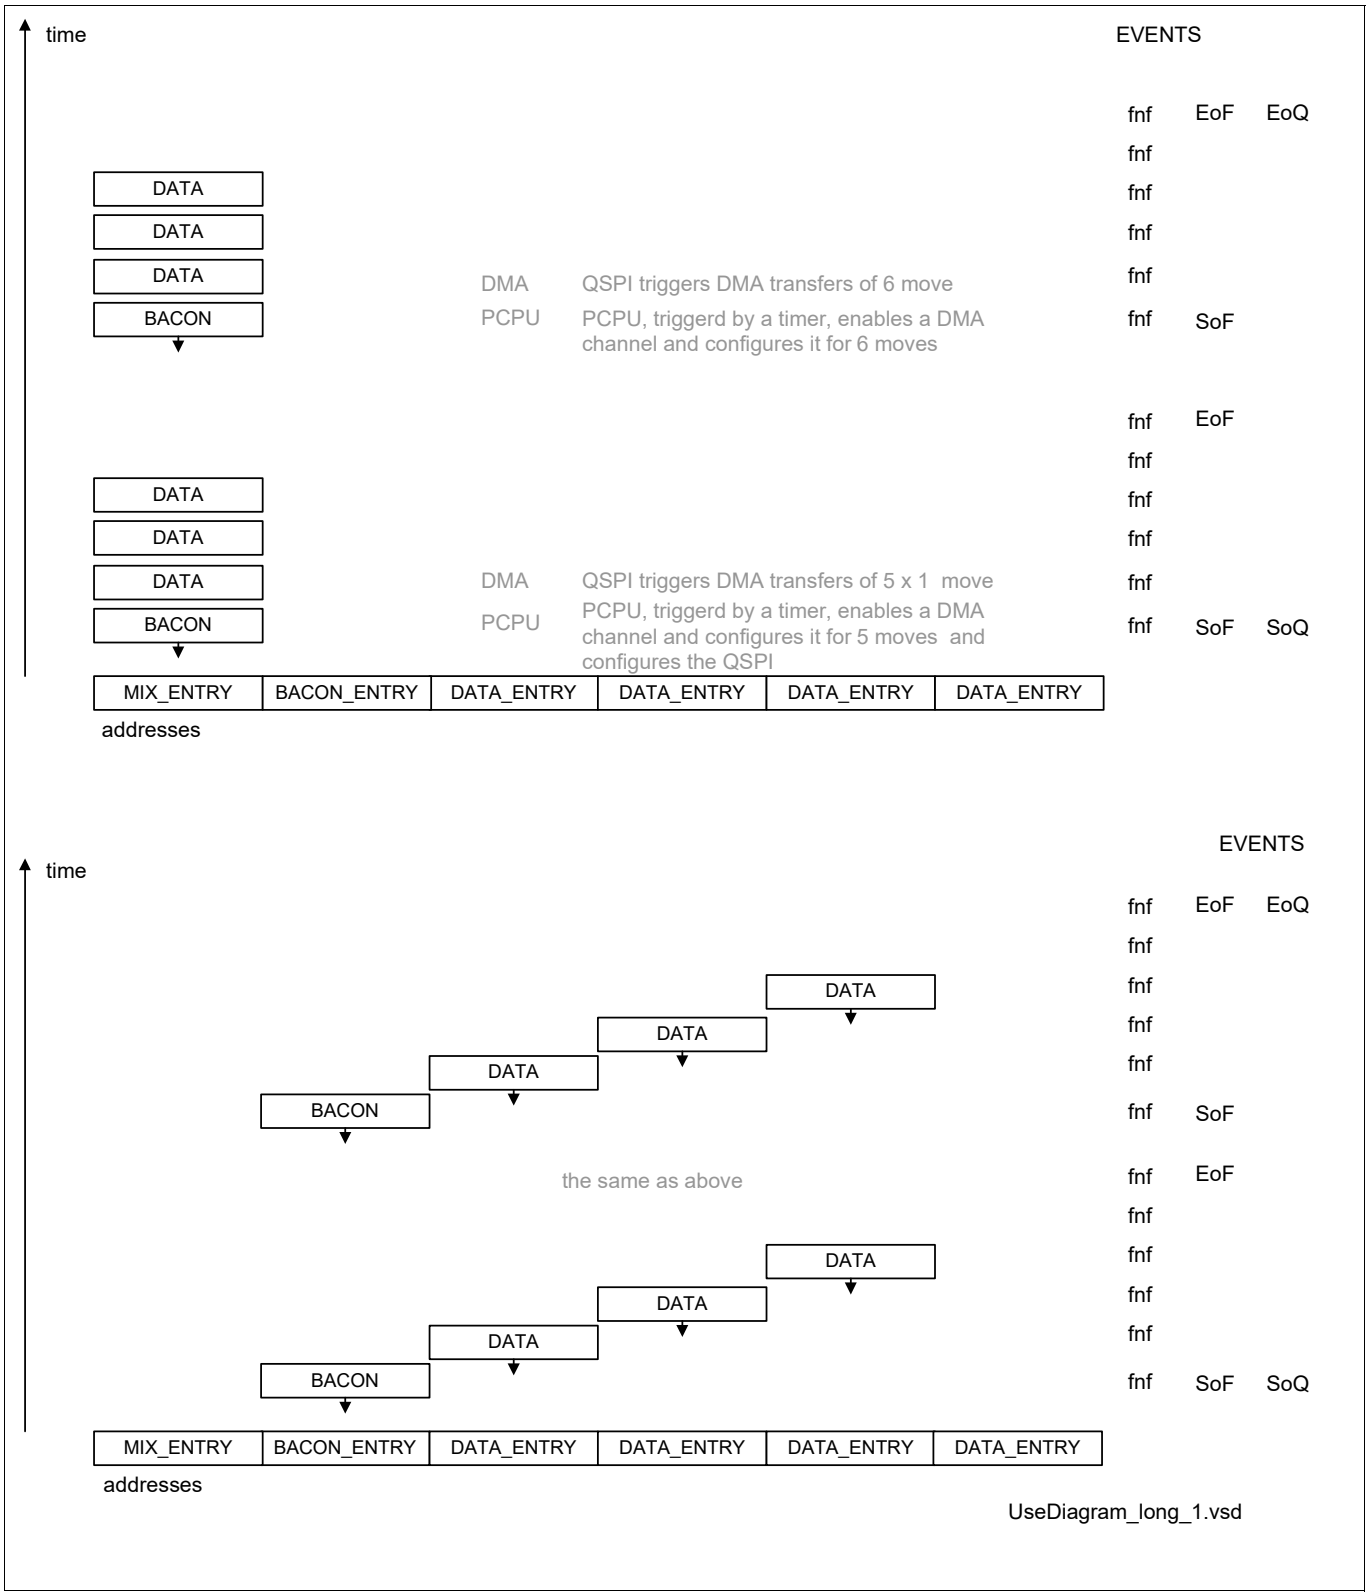

Figure 493 Use Diagram of the User Interface in Long Data Mode

37.3.5.1.3 Continuous Data Mode

In Continuous Data Mode, the QSPI transmits a stream of data with an arbitrary length and an active slave select signal. It can be used with both short and long data.

This mode starts by programming a control word containing **BACON**.LAST = 0 and the first data. The communication continues with the subsequent data entries written. The mode ends with a control word containing **BACON**.LAST = 1 and the last data. If LAST = 0, then TRAIL is a delay between data blocks. The W_I_L_D_T_D_T_D_T sequence appears. Each “D” represents data block as defined with **BACON**.DL and **BACON**.BYTE (up to 256 bits). If LAST = 1 then TRAIL is trailing delay, see **Figure 464**.

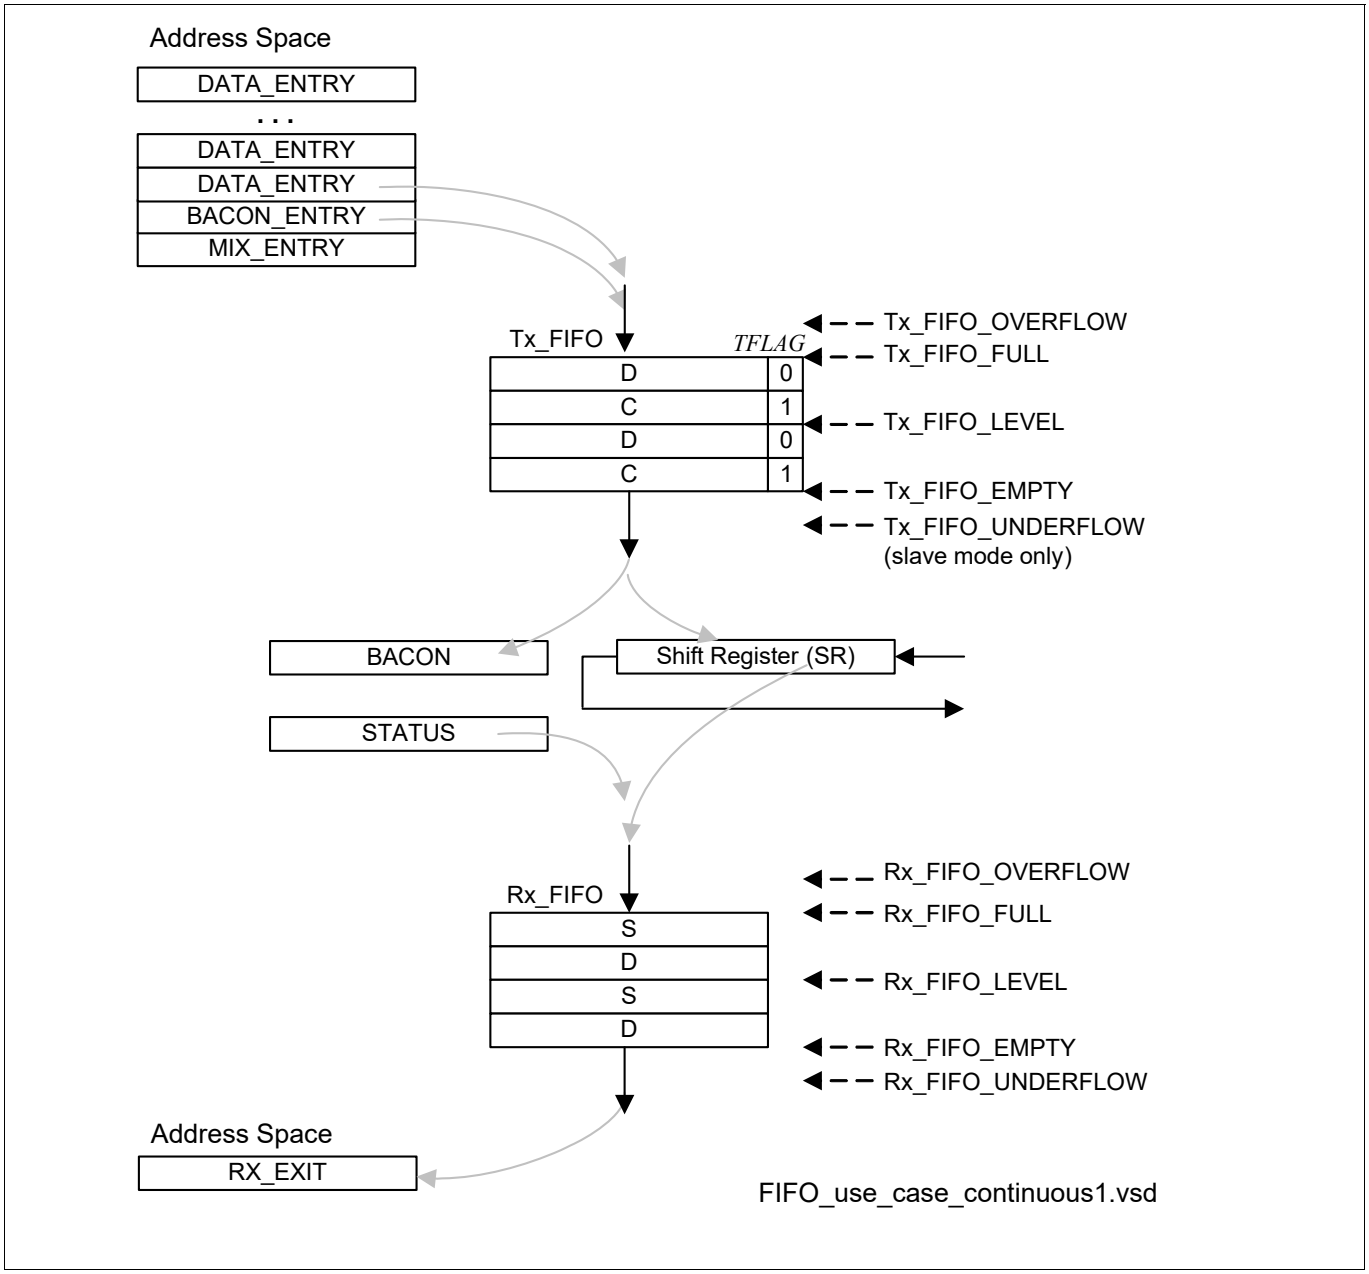

Figure 494 User Interface in Continuous Data Mode

The **Figure 495** shows an example of continuous data mode using short data. Here, the CPU starts the stream by writing BACON to the BACON_ENTRY address, and afterwards a DMA transfers the whole stream except the last BACON and DATA.

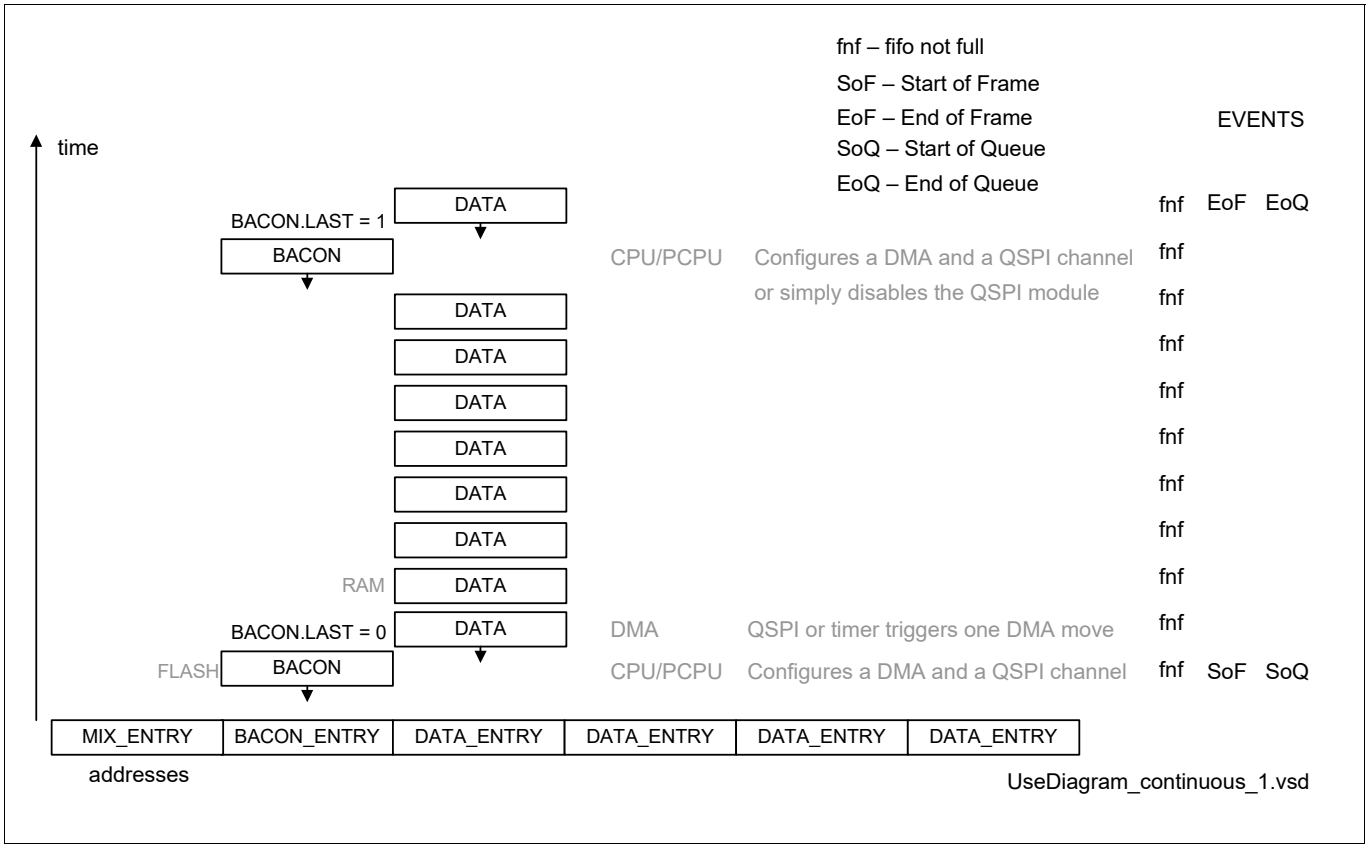

Figure 495 Use Diagram of Continuous Data Mode with Short Data

The **Figure 496** shows an example of continuous data mode using long data. Here, the first BACON must be repeated after each data block, but on the other hand, the whole transfer can be done using only the MIX entry and one single DMA channel, without CPU involvement. The loss of efficiency because of the unnecessary extra BACONs can be minimized by using long data blocks.

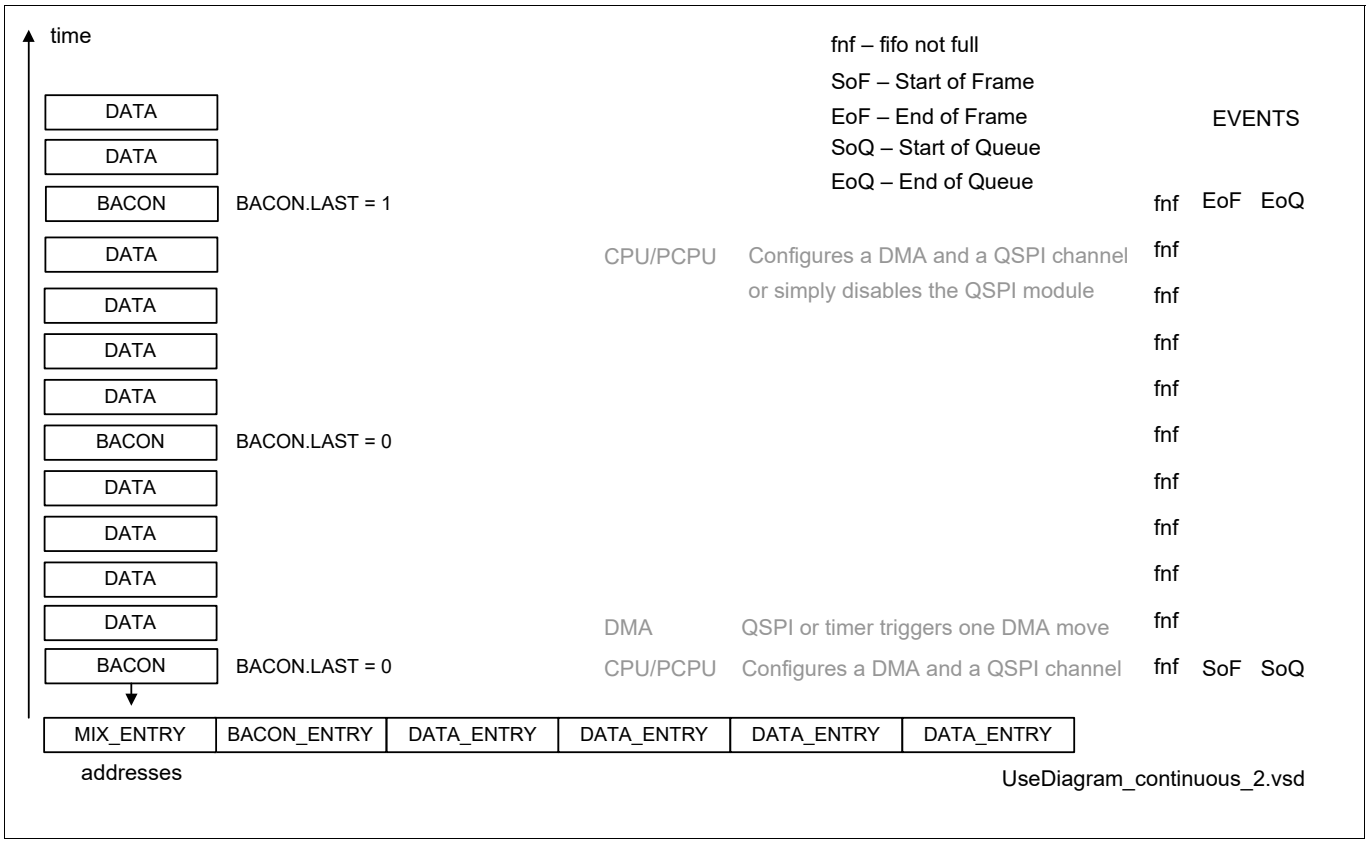

Figure 496 Use Diagram of Continuous Data Mode with Long Data

37.3.5.1.4 Single Configuration - Multiple Frames Behavior

If longer sequences of data with length of up to 16 bit have to be sent to single slave in separate frames, then the DMA move for the repeating configuration word can be saved. An example of a TxFIFO contents and the resulting message sequence is shown in **Figure 497**.

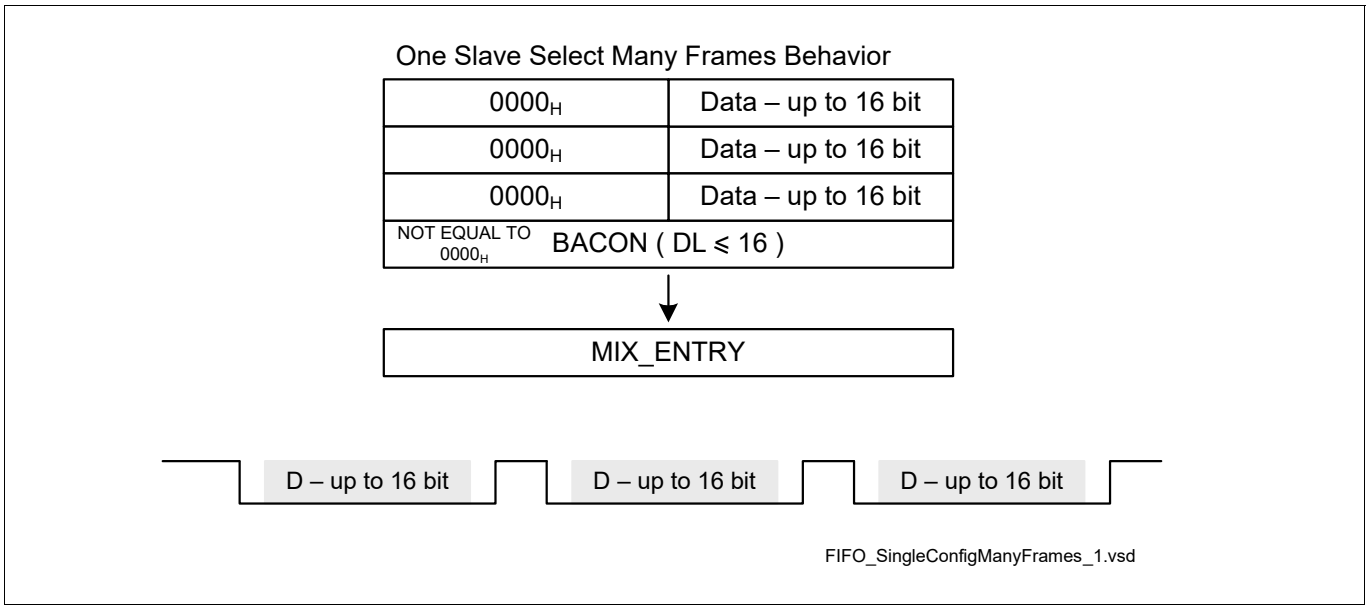

Figure 497 Multiple Frames to One Channel (Example of up to 16 Bit Data)

In order to support sending short multiple frames to single channel without having to send the same configuration each time, the TXFIFO follows this rule:

- If **BACON**.DL less or equal 15 (up to 16 bit data length)
- if MIX_ENTRY address is used
- then if the upper 16 bit of a 32-bit MIX_ENTRY are 0, the entry is considered data, else configuration. Note that there is no valid configuration word with upper 16 bits equal to 0.
- In such a case the TXFIFO marks the entry as data.

*Note: In case the **BACON**.LAST = 0, the slave select remains active between the frames. The behavior is equal to the continuous mode. The disadvantage of this method is that only up to 16 bits data can be transferred with one FPI bus move. The advantage is that continuous mode is possible using the mix entry.*

37.3.5.1.5 Big Endian Data Format

The bit-field **ECONz (z=0-7)**.BE activates the permutation of the data bytes written to the shift register and read from it to the big endian format and back.

ECONz (z=0-7).BE allows for switching between big and little endian per slave (SLSO signal).

See **Figure 498** and **Figure 499**.

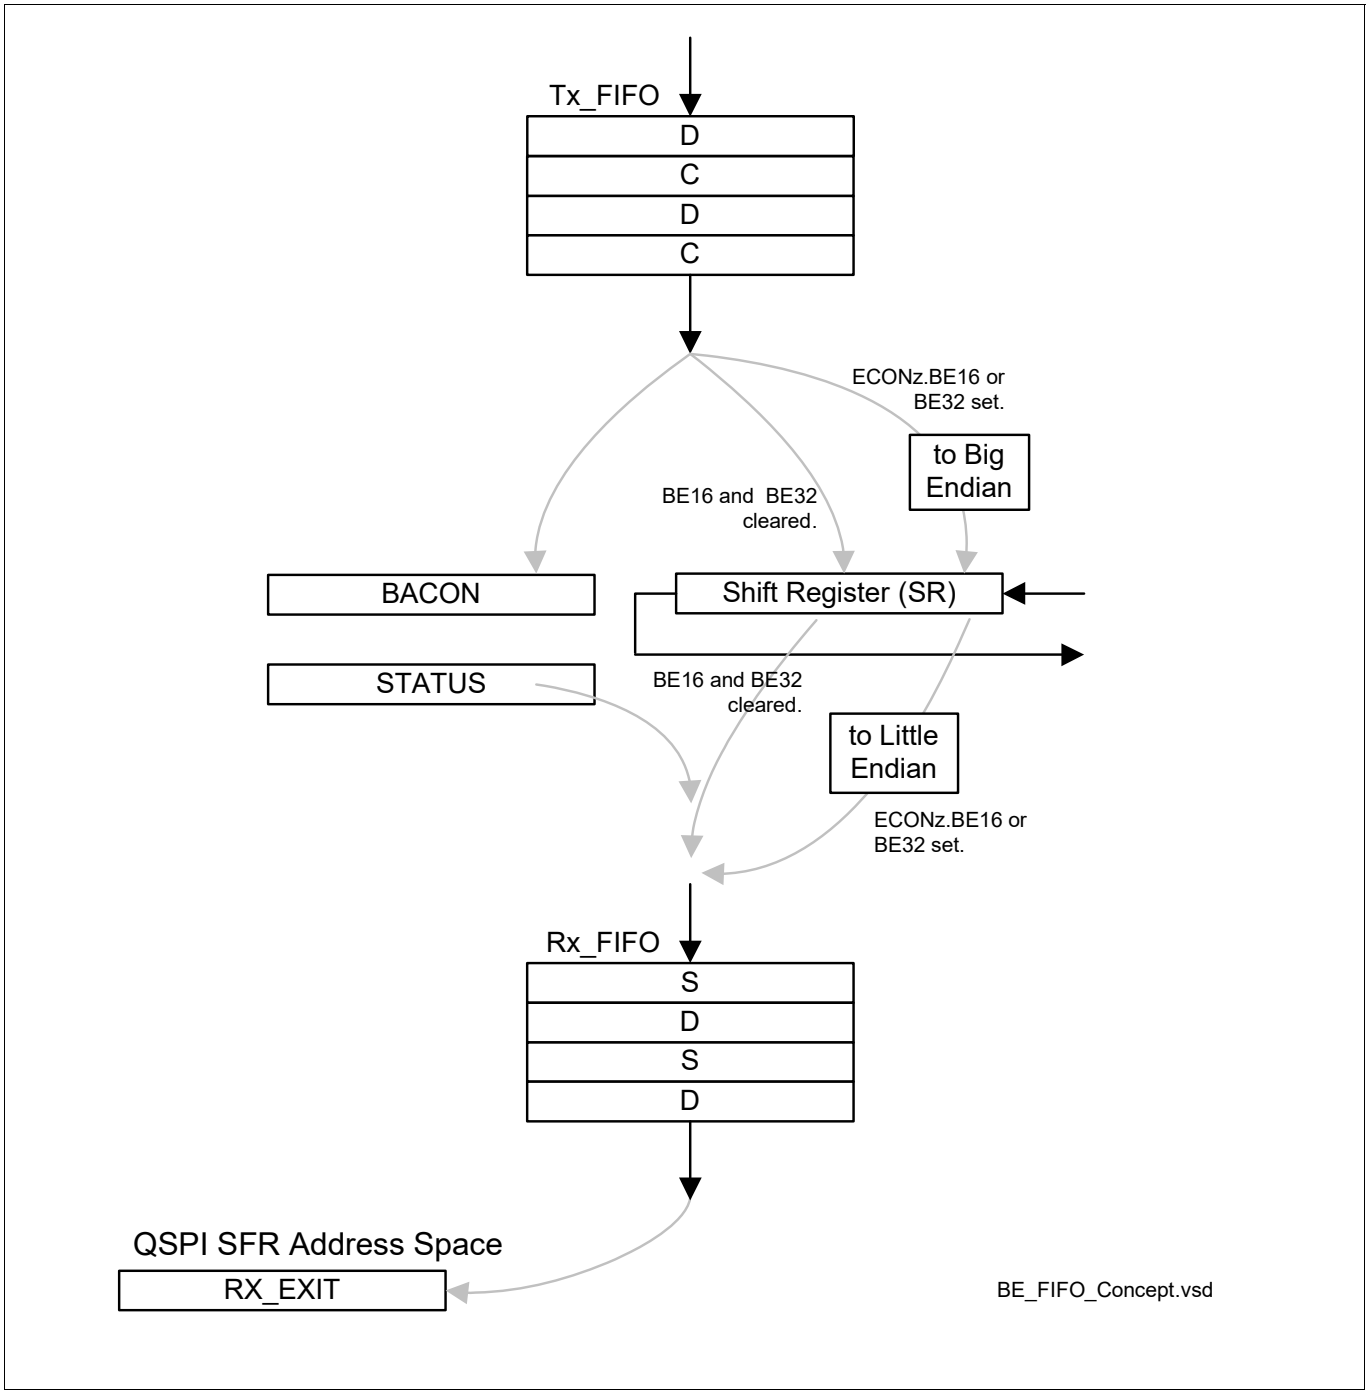

Figure 498 Big Endian Data Path

Converting data from little to big endian and other way around requires one and the same permutation of the data bytes, as shown in **Figure 498**, one permutation block is located before and one after the shift register, so that only data can be permutated, and not **BACON** or **STATUS**.

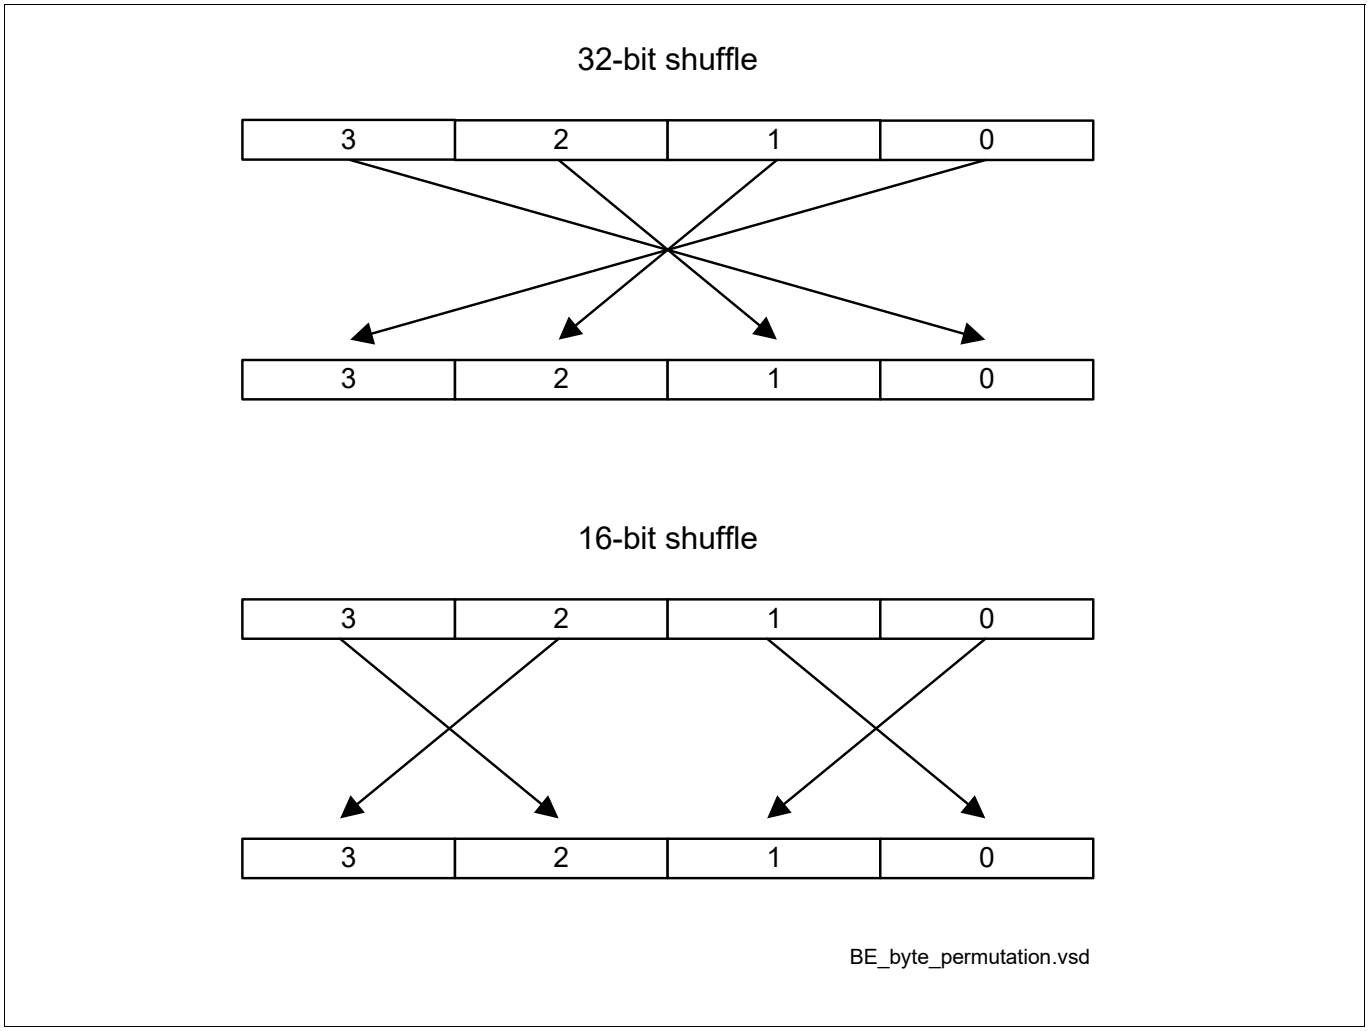

Figure 499 Endianness Byte Permutation

The endianness byte permutation should be used only for 16-bit and 32-bit data (and multiples of it), and not for other data lengths.

37.3.5.2 Loop-Back Mode

Loop-Back mode is a master mode test feature used for establishing a module internal connection between the transmit and the receive signal, the same as if the transmit and receive pins would be short connected. It is activated by setting the **GLOBALCON**.LB bit.

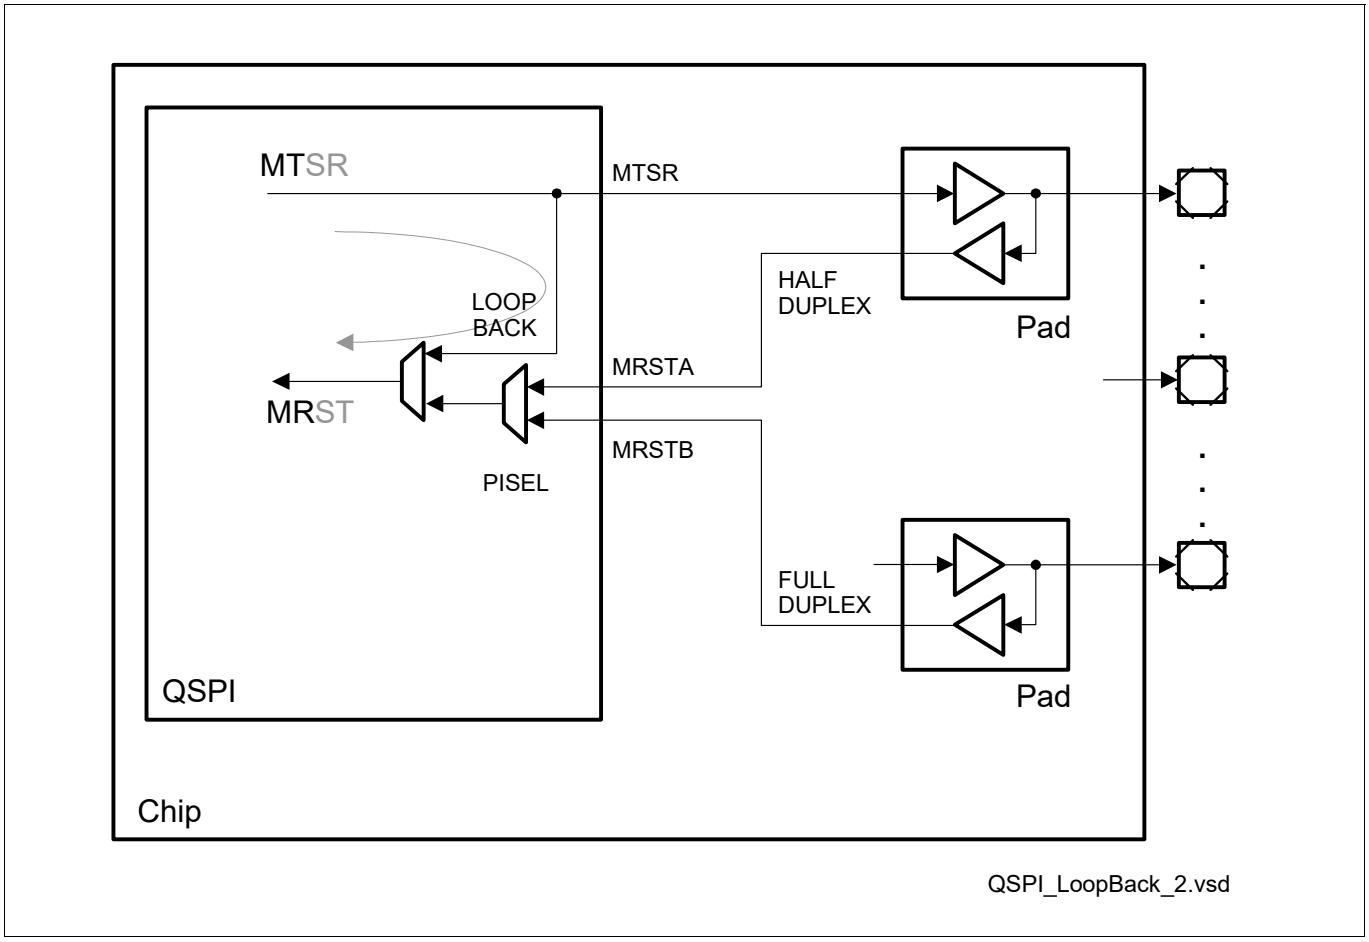

Figure 500 Loop-Back Mode

37.3.6 Interrupts

There are several types of interrupts:

- Interrupts related to the user interface
  - FIFO related interrupts
- Interrupts related to the shift engine (state machine)
  - error interrupts
  - phase transition interrupts

According to this classification, here follows the complete list of all the interrupts:

- FIFO related interrupts
  - TX - Transmit FIFO Interrupt, requests feeding of the TXFIFO, but does not signal the error events of overflow and underflow (see **Figure 488**)
  - RX - Receive FIFO Interrupt, requests emptying of the RxFIFO, but does not signal the error events of overflow and underflow (see **Figure 488**)
- ERR - Error Interrupt
  - signals every error condition
  - signals TX_FIFO_OVERFLOW, TX_FIFO_UNDERFLOW
  - signals RX_FIFO_OVERFLOW, RX_FIFO_UNDERFLOW
- PT - Phase transition interrupt, signalling two out of all phase transitions in the QSPI communication cycle (see **Figure 473** and **Figure 476**)
  - PT1 event
  - PT2 event
- U - User Interrupt
  - triggered by the PT1 event during the time **BACON**.UINT bit keeps this event enabled.
- MC - Move Counter Mode Interrupts
  - Interrupt before last - triggered when move counter was decremented to 1.
  - Interrupt after last - triggered when move counter was decremented to 0.

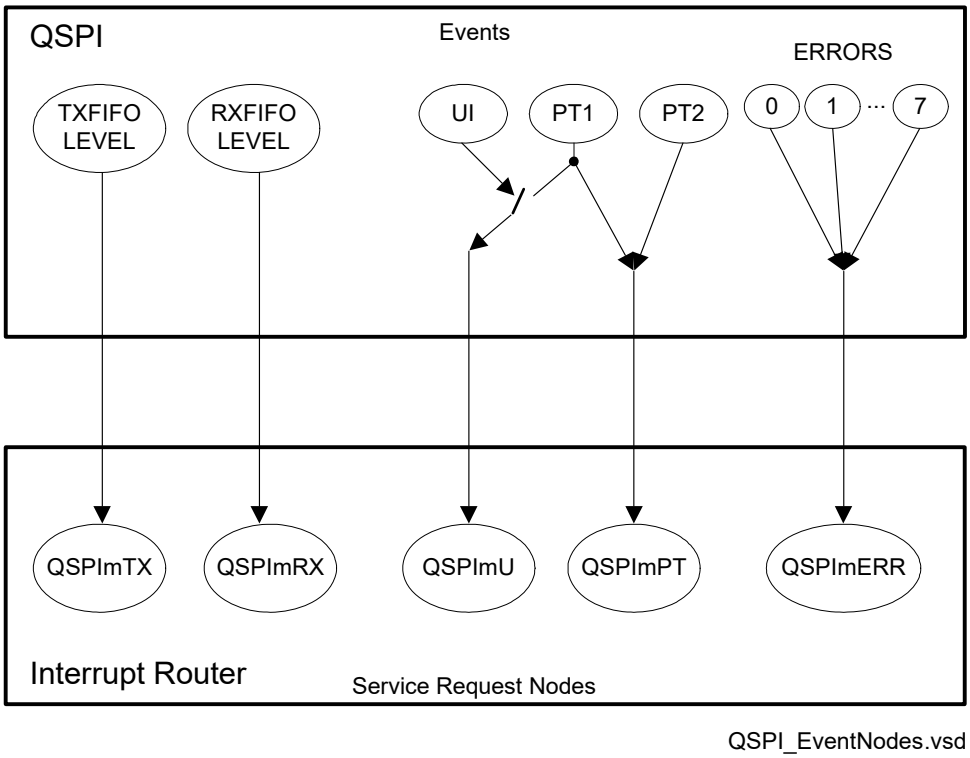

Figure 501 Events and Interrupts Overview

37.3.6.1 Slave Mode SLSI Interrupt

In slave mode, deactivating the SLSI signal (SLSI rising edge) triggers the PT interrupt, if PT2 enabled.

37.3.6.2 Interrupt Flags Behavior

A state of an event flag (low or high) does not influence the flow of its event signal. If an event occurs recurrently, and the event flag remains set (if not cleared by the software interrupt handler), the interrupt flag (which is cleared by hardware, by an ICU, when the interrupt wins an arbitration round) would receive recurrent triggers, and the flag would be constantly set all the time.

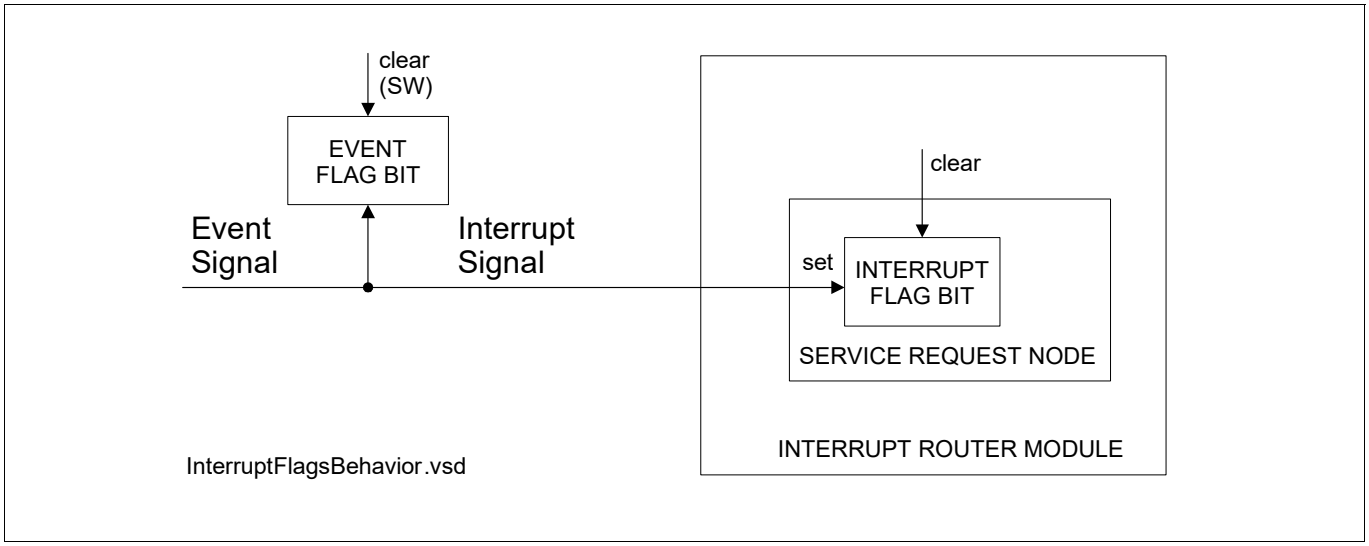

Figure 502 Events and Interrupts Overview

37.3.6.3 TXFIFO Interrupt Generation

The TXFIFO provides two interrupt generation modes, selected by the bit-field **GLOBALCON1**.TXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single Move Mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

An example use case could be using single move mode with a DMA performing single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available. If the write makes the TXFIFO full (no more empty elements), an interrupt is not generated in order to prevent overflow. It is generated later when the shift register (or BACON) reads one element from the TXFIFO, making it not full.

The **Figure 503**, shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

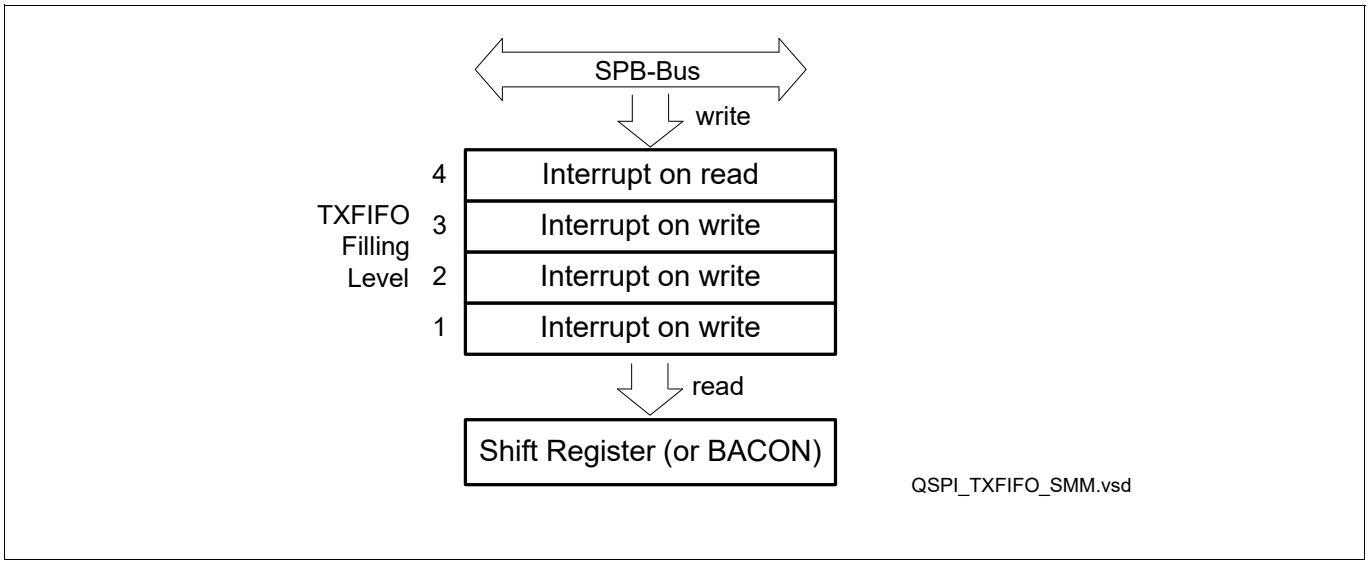

Figure 503 Interrupt Generation in the Single Move Mode

In order to initiate the very first chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TXFIFO, or sets the interrupt flag in the TXFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

Attention: ***In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.***

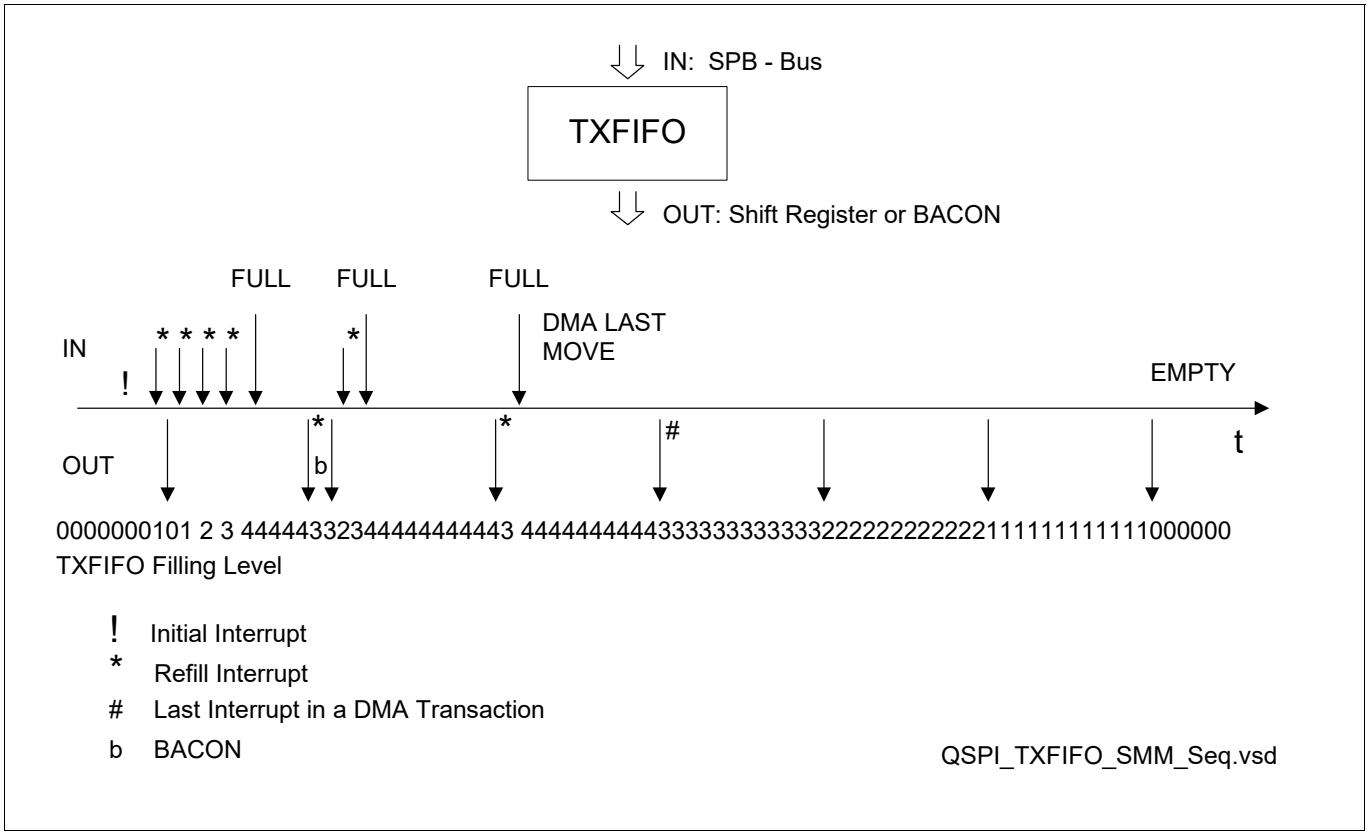

Figure 504 TXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more than one TXFIFO element is empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

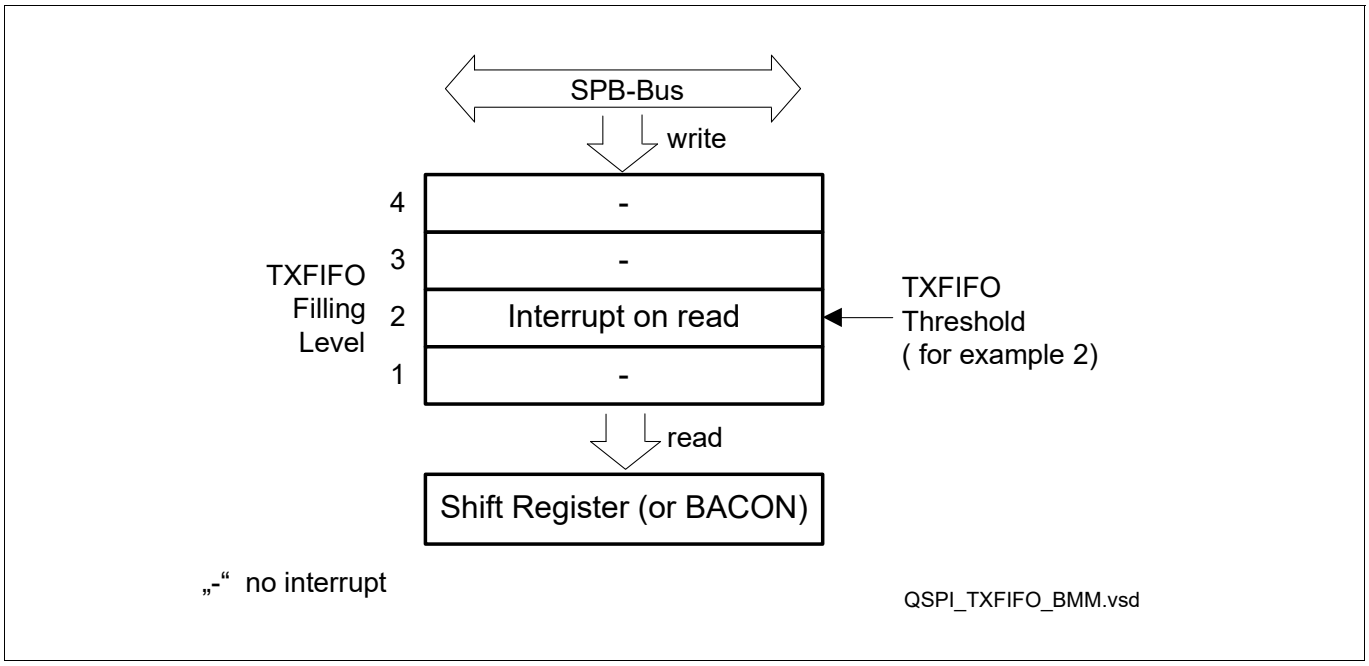

Figure 505 TXFIFO - Interrupt Generation in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls below the programmed threshold, implying that there are at least the predefined number of empty TXFIFO elements available.

Attention: The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted (or frame and BACON), the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Combined Mode

TXFIFO generates interrupt each time a data is fetched from it below the pre-programmed threshold, as defined in the **GLOBALCON1**.TXFIFOINT. Consequently, it generates two close interrupts when delivering BACON and the first following data. If the BACON TX interrupt is not serviced until the DATA1 TX interrupt comes, which will always be the case due to their time proximity, the BACON TX interrupt will be lost. Therefore, it is recommended that a DMA should always perform two moves per interrupt trigger (transfer size of two). Otherwise, the TXFIFO average filling level will go down with the time and at the end remain oscillating between zero and one (except in continuous mode). The DMA transaction loss event that may be raised by the DMA should be ignored.

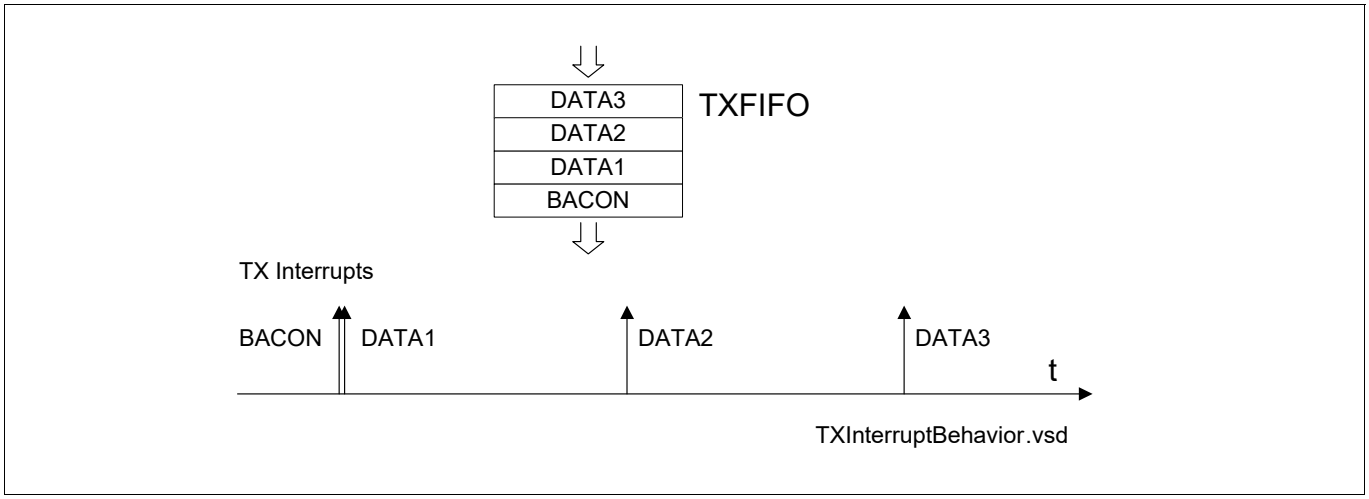

Figure 506 Events and Interrupts Overview

37.3.6.4 RXFIFO Interrupt Generation

The RXFIFO provides two interrupt generation modes, selected by the bit field **GLOBALCON1**.RXFM:

- Single Move Mode
- Batch Move Mode
- Combined Mode

Single Move Mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

An example use case could be using single move mode with a DMA performing single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty. If the read makes the RXFIFO empty, an interrupt is not generated in order to prevent underflow. It is generated later when the shift register (or STATUS) writes new element to the empty RXFIFO.

The **Figure 507**, shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

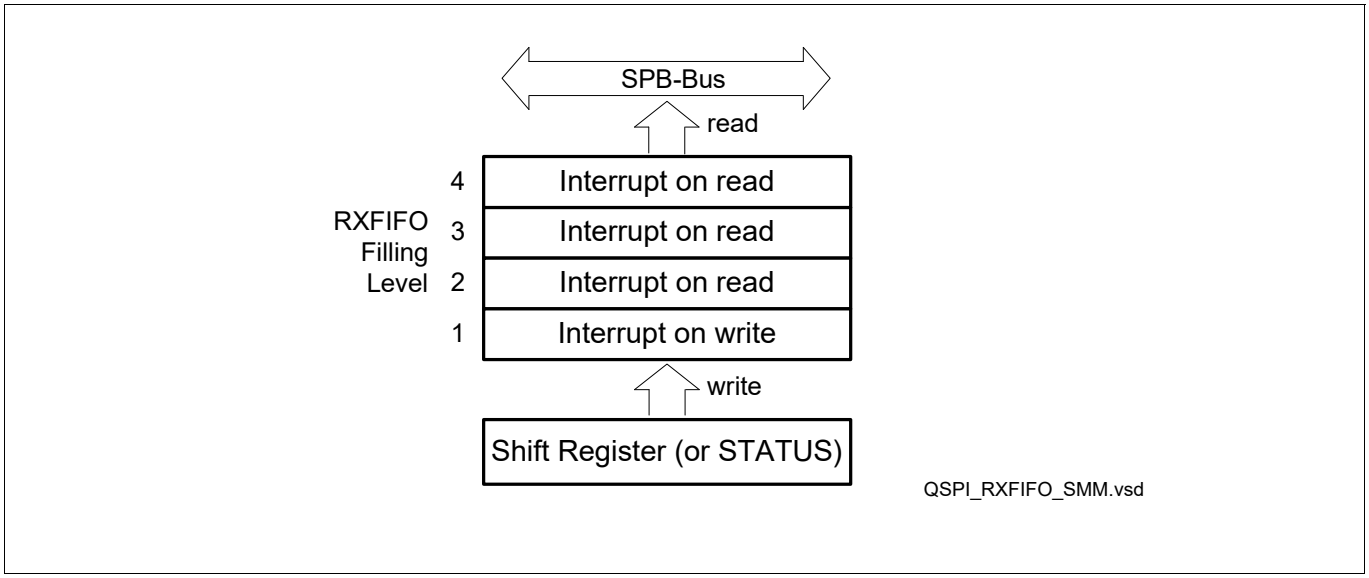

Figure 507 RXFIFO - Interrupt Triggering in the Single Move Mode

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of re-fetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention: ***In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.***

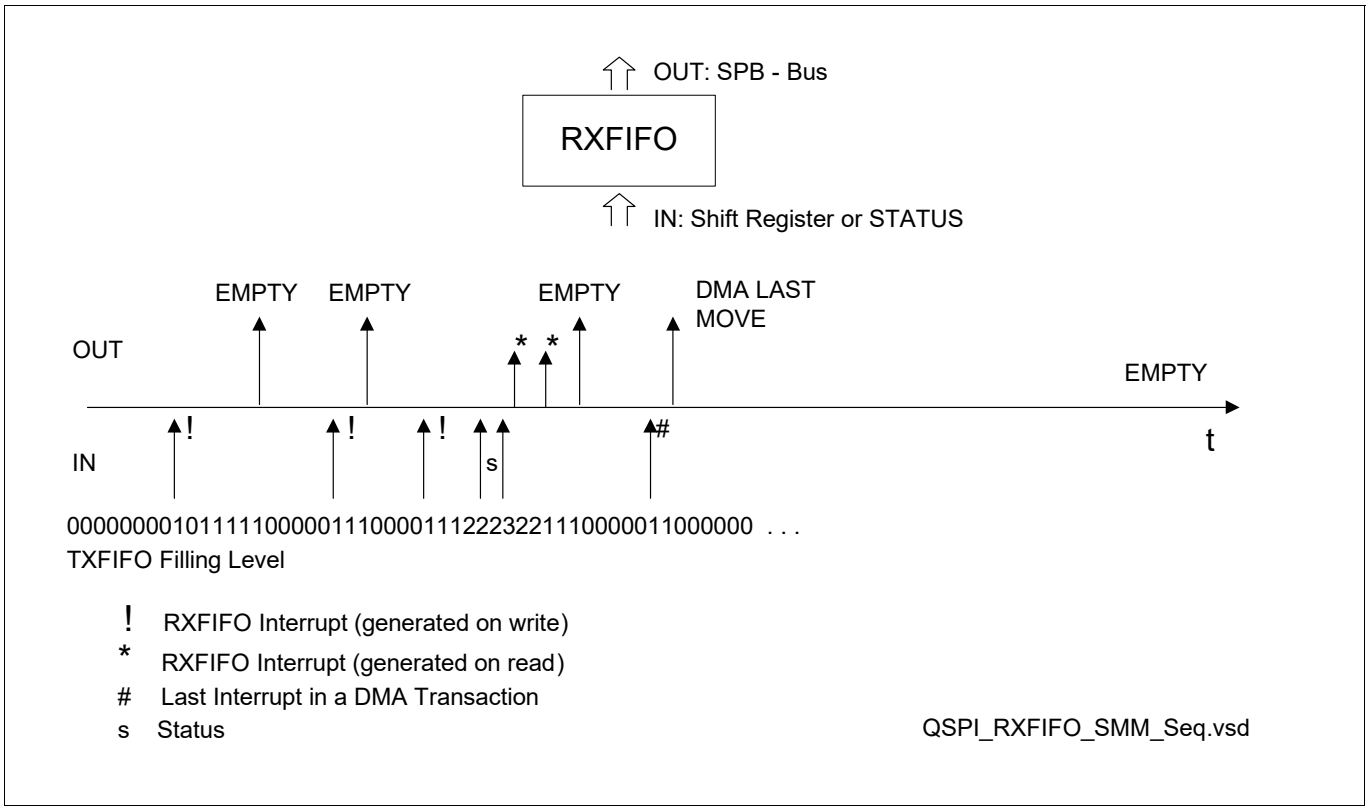

Figure 508 RXFIFO - Interrupt Operation in Single Move Mode

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more than one RXFIFO element is full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

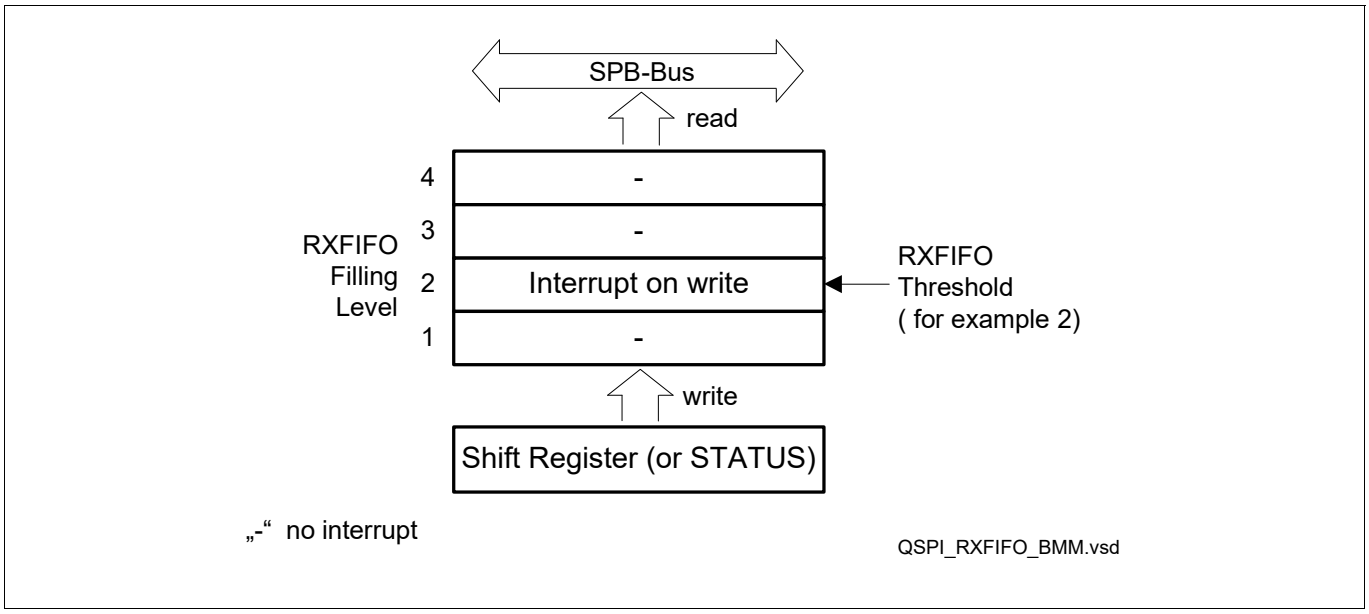

Figure 509 RXFIFO - Interrupt Triggering in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the RXFIFO, when the filling level rises above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available.

Attention: It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frame has been received until the moment the RXFIFO is re-emptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames have been received (or a frame and STATUS), the RXFIFO will become full, and re-empty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect cannot occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Combined Mode

RXFIFO generates interrupt each time a data is written to it above the preprogrammed level, as defined in the **GLOBALCON1**.RXFIFOINT. Consequently, it generates two close interrupts when filled with data and STATUS. If the data RX interrupt is not serviced until the STATUS RX interrupt comes, which will always be the case due to their time proximity, the STATUS RX interrupt will be lost. In such a case, it is recommended that the DMA performs two moves per interrupt trigger (transfer size of two). Otherwise, the RXFIFO average filling level will go up with the time and at the end overflow.

37.3.7 Reset Behavior

There are two sources of reset provided by the module for it's operation:

- BPI (Bus Peripheral Interface) registers **KRST0**/**KRST1**
- Reset bits in the kernel register - **GLOBALCON**.RESETS

BPI reset puts the whole QSPI module in reset state. All outputs get the reset value.

Software writing the **GLOBALCON**.RESETS bit will select what will be Reset (TX_FIFO, RX_FIFO, protocol statemachine, registers)

KRSTx resets the whole Module while **GLOBALCON**.RESETS 11 resets only a subset of all the available registers in the module.

37.3.8 QSPI Module Implementation

This section describes the interfaces of the QSPI module instances with the clock control, port connections, interrupt control, and address decoding.

37.3.8.1 Interfaces of the QSPI Modules

Figure 510 shows the implementation details and interconnections of the QSPI module.

Each of the QSPI modules is supplied with a separate clock control, interrupt control, and address decoding logic. Two interrupt outputs can be used to generate DMA requests. The QSPIx I/O lines are connected to the ports as described in the pinning and ports chapters.

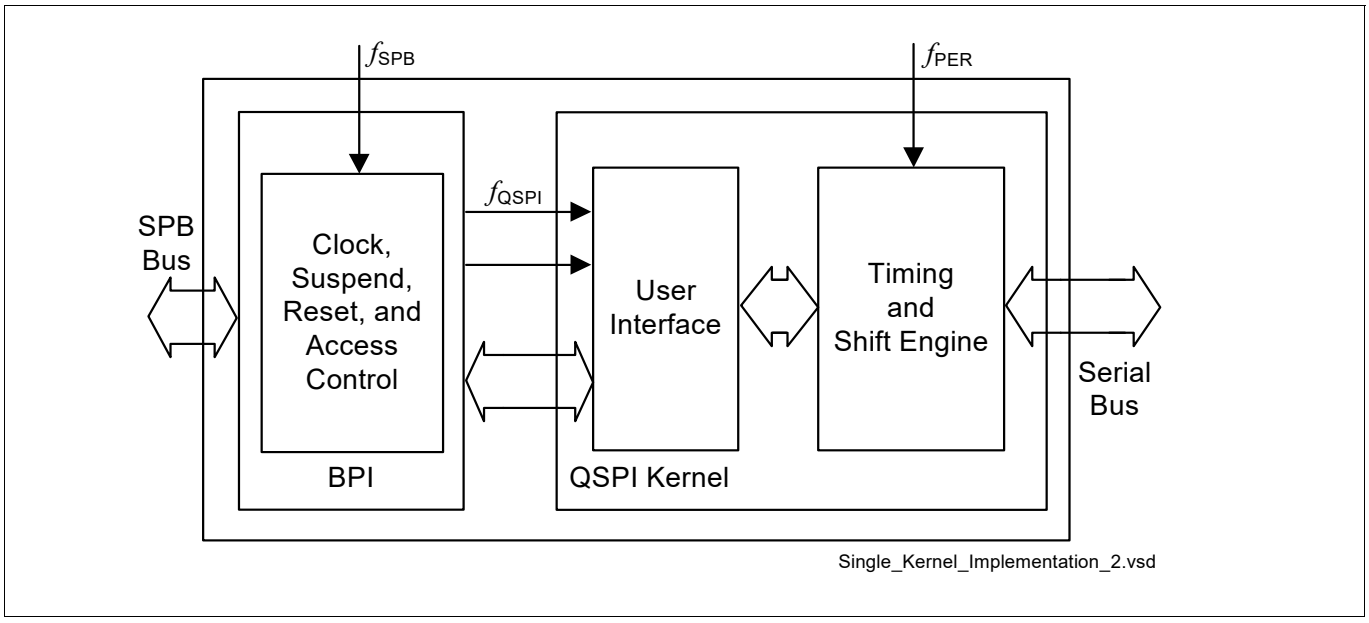

Figure 510 Module Implementation Overview

37.3.8.2 On-Chip Connections

This section describes the on-chip connections of the QSPIx module instances.

SCU Connections

Wake-up from sleep is done by the SCU.ERU triggering a software interrupt on a programmable edge on SLSI pin.

DMA Requests

There are no dedicated DMA request lines. The interrupt or service request signals are general purpose request signals that can be routed to each service provider.

Port/Pin Connections

The connections of the QSPI modules to the pins / ports is described in the chapters regarding the pinning and the ports.

The MTSR and MRST signals are also mapped to LVDS output and input pads. For details see the Ports chapter and the Pinning chapter.

Note: If LVDSH receiver pad is used, the software must take into account the corresponding control and configuration bits, located in the HSCT module and in the corresponding port registers.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected SCLKI signals are connected to low level “0”
- The unconnected SLSI signals are connected to (inactive) high level “1”
- The unconnected MRST input signals are connected to low level “0”.

Interrupt Connections

The interrupts of the QSPI module are controlled by six service request control registers, located in the IR (Interrupt Router) module:

- QSPIxTX Transmit Interrupt
- QSPIxRX Receive Interrupt
- QSPIxERR Error Interrupt
- QSPIxPT Phase Transition Interrupt
- QSPIxHC High Speed Capture Interrupt
- QSPIxU User Interrupt

37.3.8.3 BPI_FPI Module Registers

Figure 511 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

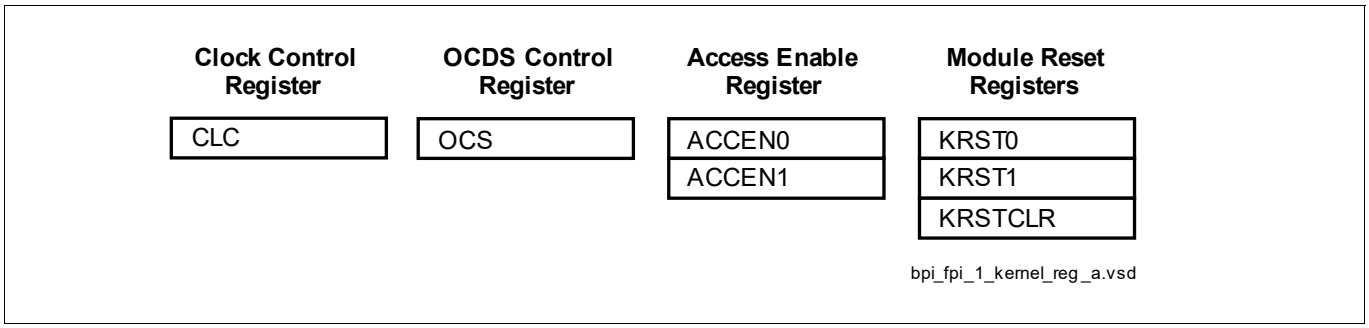

Figure 511 BPI_FPI Registers

The writes of the bus masters to the QSPI module is controlled by Access Protection registers ACCENx.

The QSPI implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC

Clock Control Register **(000_H)** **Application Reset Value: 0000 0003$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to enable the module's sleep mode. 0_B Enabled 1_B Disabled
0	2, 31:4	r	**Reserved** Read as 0; Should be written with 0.

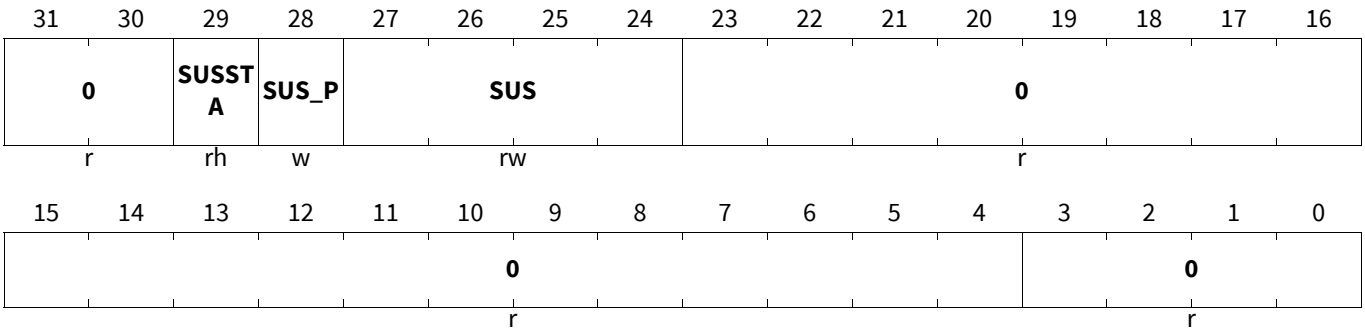
OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

OCS

OCDS Control and Status **($0E8_H$)** **Debug Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. 2_H Soft suspend **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	3:0, 23:4, 31:30	r	**Reserved** Reserved, shall be written with '0' to read '0'.

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B. The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN0

Access Enable Register 0 **(0FC$_H$)** **Application Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B. The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN1

Access Enable Register 1 **(0F8$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r

0															
r															

Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

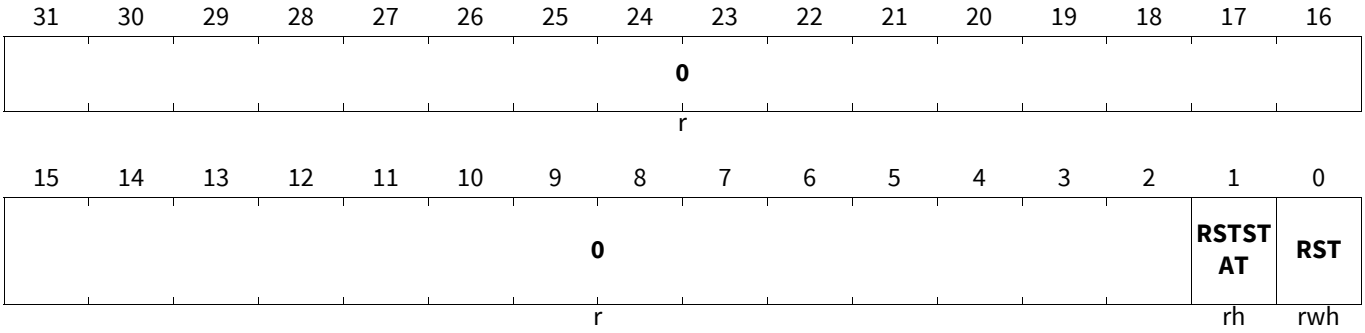
Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($0F4_H$)** **Application Reset Value: $0000\ 0000_H$**



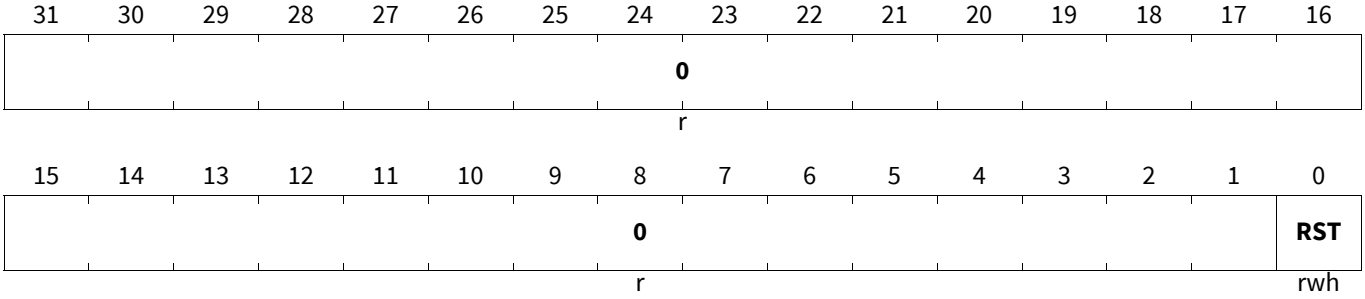
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **(0F0$_H$)** **Application Reset Value: 0000 0000$_H$**



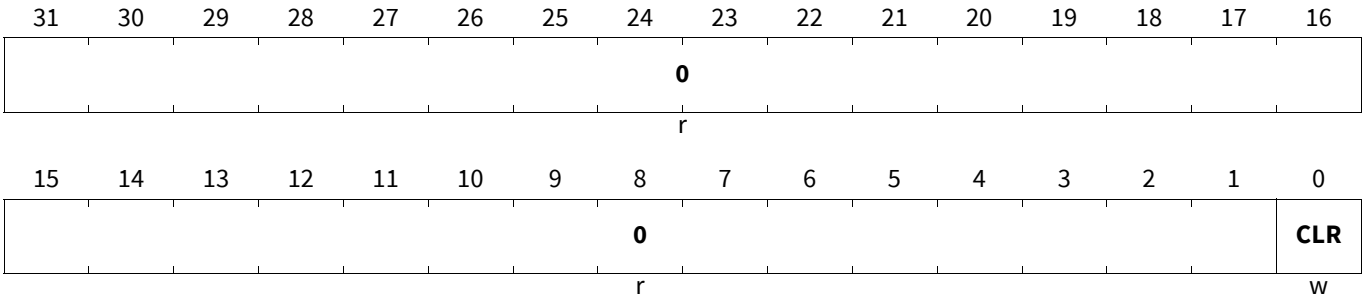
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **(0EC$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

37.3.8.4 Further QSPI Related External Registers

Figure 512 summarizes the module-related external registers which are required for QSPI programming. These are:

- port registers and
- service request node registers,

described in the corresponding chapters.

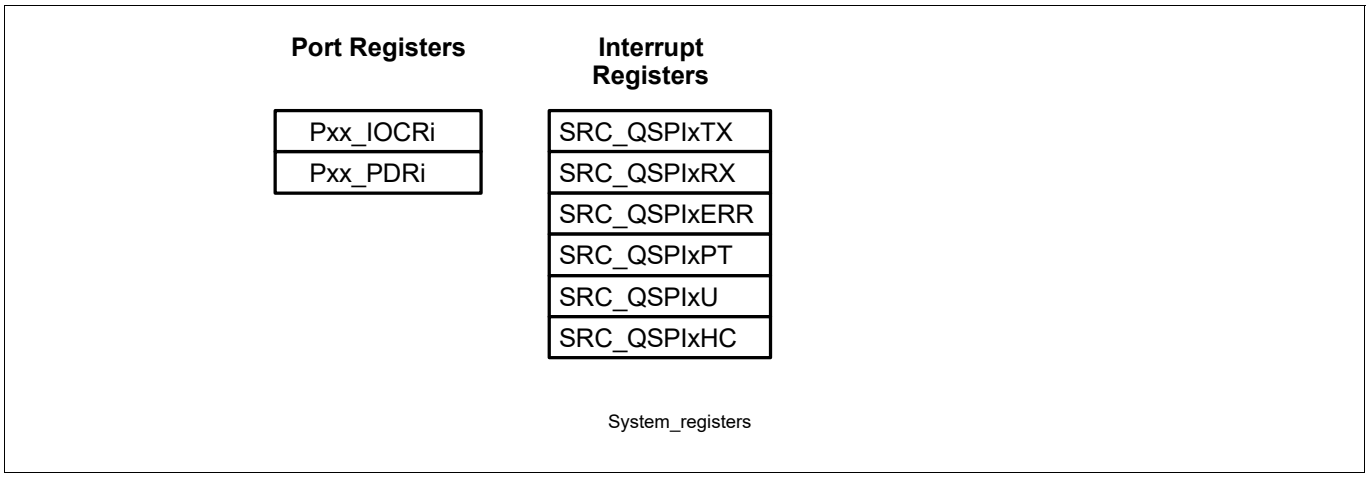


Figure 512 Implementation-specific Special Function Registers

37.4 Functional Description HSIC

The HSIC sub-module provides high precision measurement of relatively low speed input signals. It contains 15-bit timer can be configured to continuously measure:

- whole period (rising edge to rising edge),
- high time (rising edge to falling edge) or
- low time (falling edge to rising edge)
- whole period (falling edge to falling edge)

The resolution of the counter is f_{PER}. The result is provided in a capture register and an interrupt is raised after each capture.

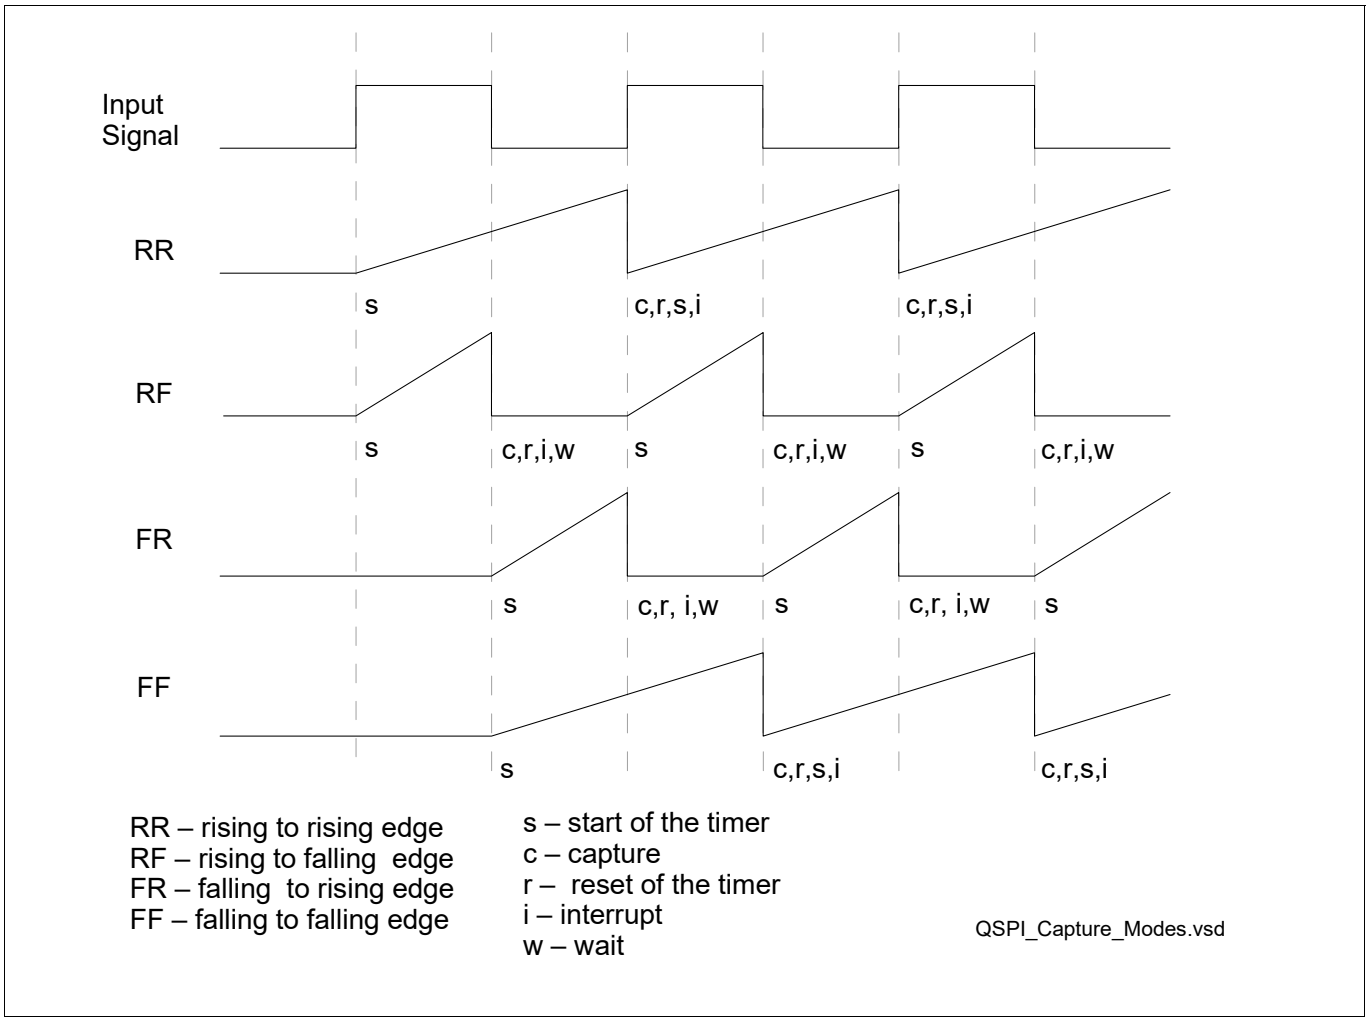

Figure 513 HSIC Modes of Operation

Each capture event causes the content of a 15-bit counter to be captured to the **CAPCON**.CAP bit field, see **Figure 514**.

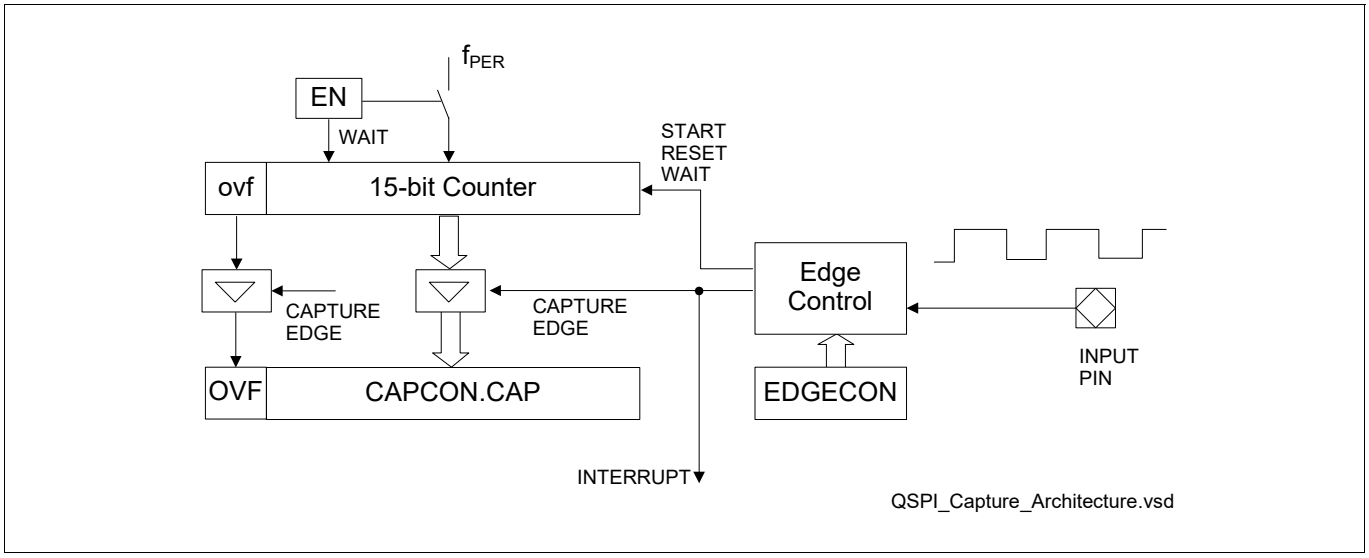

Figure 514 Capture Timer Architecture

The interrupt raised by the capture event is routed to the HC interrupt, see **Figure 515**. The flag bit, set, clear and select bits are located in the **CAPCON** register.

The first interrupt after enabling the HSIC block by setting **CAPCON**.EN may deliver random **CAPCON**.CAP value, depending on the level of the input signal at the moment of enabling. Therefore, the software should discard the first value captured immediately after enabling the HSIC block.

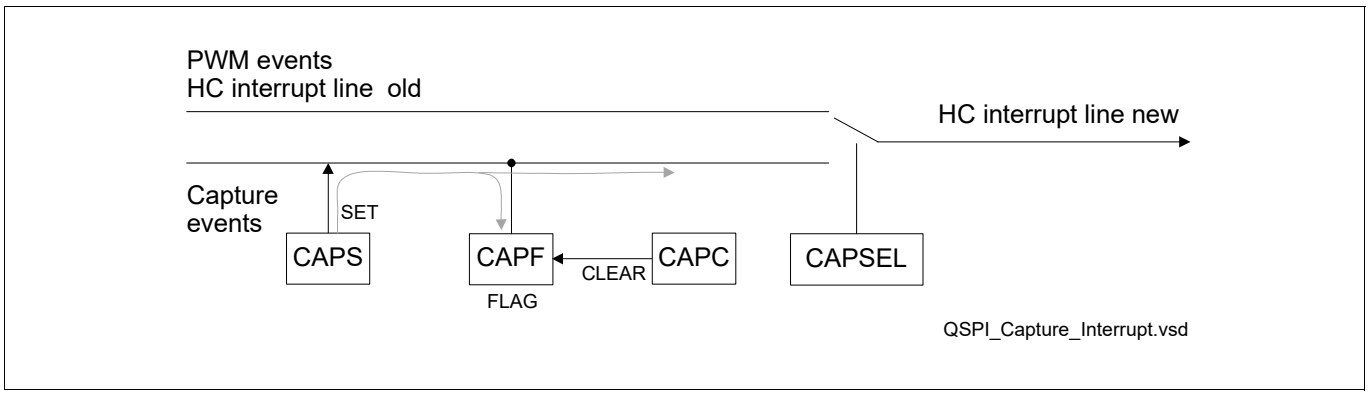

Figure 515 HSIC Interrupt Path

Note: The frequency range of the input signal used for the verification of the HSIC feature should be 3KHz to 30KHz.

Disable Request

Clearing the disable request bit **CLC**.DISR switches the clock of the whole QSPI module including the HSIC block on.

Setting the bit **CAPCON**.EN enables the HSIC sub-module. The counter first enters wait state, waiting for the first start edge as defined in the **CAPCON**.EDGECON. Afterwards, it operates according to the **Figure 513**.

If **CLC**.DISR is cleared when **CAPCON**.EN = 1, the counter is cleared to zero, waits for the next start edge (as defined in **CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 513**.

Debug Suspend

Suspend of the QSPI module causes suspend of the HSIC; separate suspend is not possible. Nevertheless, the targeted use cases are either HSIC timer active, or QSPI communication, but not both.

Active and enabled hard debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter continues counting. Writing to a register in hard suspend state causes the HSIC block to receive a couple of clock cycles, which causes the counter to increase its value.

Active and enabled soft debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 513**.

Sleep Mode

Active and enabled sleep signal stops the HSIC block. After the sleep signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **CAPCON**.EDGECON) to start counting, and continues operating according to the **Figure 513**.

Reset

The **GLOBALCON**.RESETS do not reset the HSIC. Other resets (like Application resets ; **KRST0**/**KRST1**) of the QSPI module causes reset of the HSIC sub-module. A separate reset of the HSIC only is not possible.

37.4.1 HSIC Implementation

This Feature is not in all products present. Please look up in the Appendix at Chapter 1.1 IP Specific Configuration if the is HSIC is implemented. The HSIC block is included in the QSPI2 and QSPI3.

For the connections to the pins, see the pinning chapter.

The unconnected input lines are tied to zero.

37.5 Registers

All Registers of the QSPI kernel and the HSIC Sub-module are described in this chapter. Further Registers required for the System integration of the module are explained in the chapter QSPI Module Implementation.

37.5.1 Kernel Registers

This section describes the kernel registers of the QSPI module. All QSPI kernel register names described in this section will be referenced in other parts of the module name prefix “QSPI0_” for the QSPI0 interface, “QSPI1_” for the QSPI1 interface and so on.

All registers in the QSPI address spaces are reset with the application reset.

QSPI Kernel Register Overview

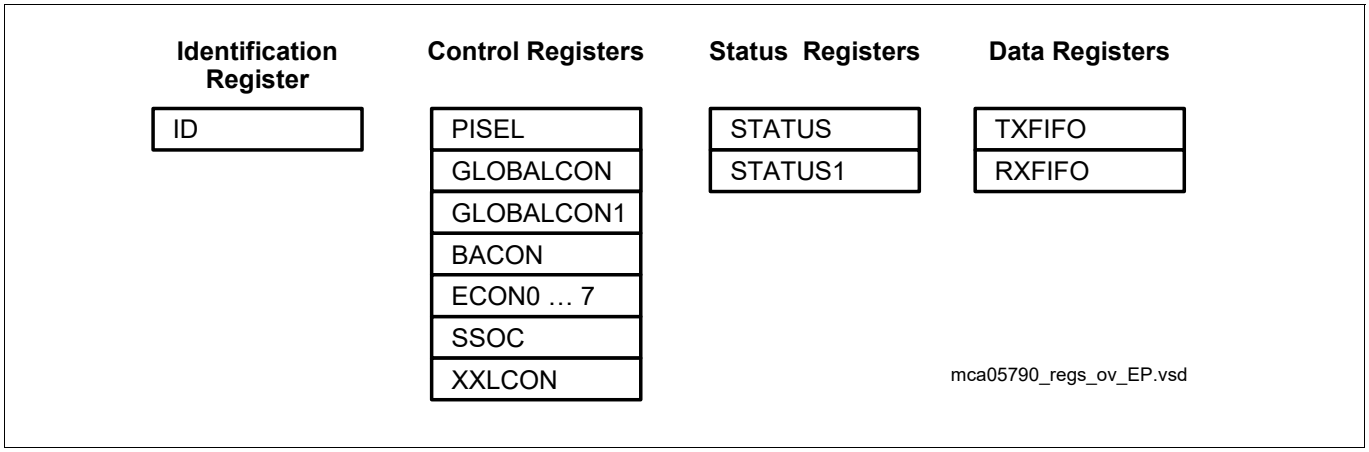

Figure 516 QSPI Kernel Registers

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

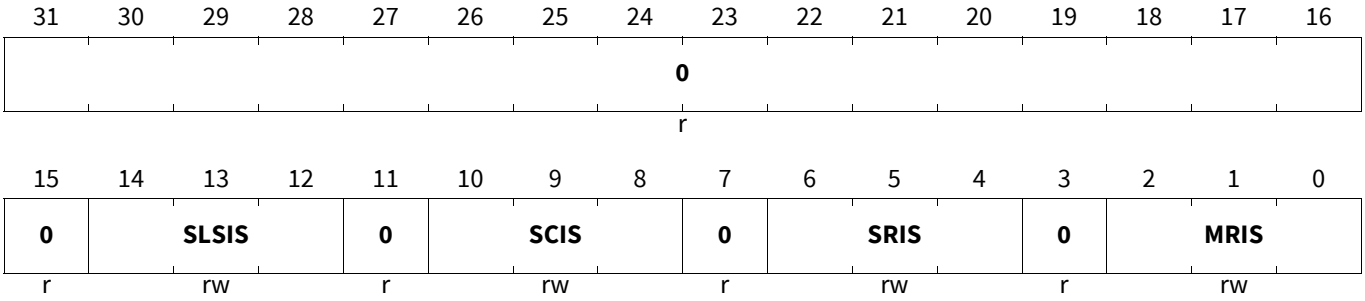
37.5.1.1 Register Description

Port Input Select Register

The PISEL register controls the input signal selection of the SSC module.

PISEL

Port Input Select Register **(004_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
MRIS	2:0	rw	**Master Mode Receive Input Select** MRIS selects one out of eight MRST receive input lines, used in Master Mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. The following signal sources are available in this product (if supported by the package!) 000_B MRST input line A is selected for operation 001_B MRST input line B is selected for operation 010_B MRST input line C is selected for operation 011_B MRST input line D is selected for operation 100_B MRST input line E is selected for operation 101_B MRST input line F is selected for operation 110_B MRST input line G is selected for operation 111_B MRST input line H is selected for operation

Field	Bits	Type	Description
SRIS	6:4	rw	**Slave Mode Receive Input Select** SRIS selects one out of eight MTSR receive input lines, used in Slave Mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. The following signal sources are available in this product (if supported by the package!) 000_B MTSR input line A is selected for operation 001_B MTSR input line B is selected for operation 010_B MTSR input line C is selected for operation 011_B MTSR input line D is selected for operation 100_B MTSR input line E is selected for operation 101_B MTSR input line F is selected for operation 110_B MTSR input line G is selected for operation 111_B MTSR input line H is selected for operation
SCIS	10:8	rw	**Slave Mode Clock Input Select** SCIS selects one out of eight module kernel SCLK input lines that is used as clock input line in slave mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. The following signal sources are available in this product (if supported by the package!) 000_B SCLK input line A is selected for operation 001_B SCLK input line B is selected for operation 010_B SCLK input line C is selected for operation 011_B SCLK input line D is selected for operation 100_B SCLK input line E is selected for operation 101_B SCLK input line F is selected for operation 110_B SCLK input line G is selected for operation 111_B SCLK input line H is selected for operation
SLSIS	14:12	rw	**Slave Mode Slave Select Input Selection** The SLSIS must be programmed properly before the slave mode is set with GLOBALCON.MODE and the module is set to RUN mode. The following signal sources are available in this product (if supported by the package!) 000_B Slave select input lines are deselected QSPI is operating without slave select input functionality. 001_B SLSI input line A is selected for operation 010_B SLSI input line B is selected for operation 011_B SLSI input line C is selected for operation 100_B SLSI input line D is selected for operation 101_B SLSI input line E is selected for operation 110_B SLSI input line F is selected for operation 111_B SLSI input line G is selected for operation
0	3, 7, 11, 31:15	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(008$_H$)** **Application Reset Value: 00C0 C0XX$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODNUMBER															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODTYPE								MODREV							
r								r							

Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** MODREV defines the module revision number. The value of a module revision starts with 01$_H$ (first revision).
MODTYPE	15:8	r	**Module Type** This bit field is C0$_H$. It defines a 32-bit module.
MODNUMBER	31:16	r	**Module Number Value** This bit field together with MODTYPE uniquely identifies a module.

Global Configuration Register

GLOBALCON contains configuration parameters which affect all channels.

Note: If the EN bit is cleared first, and then the partial state machine reset activated, then the state machine goes into PAUSE state.

*Note: Switching the peripheral clock off and on is done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write switching on the clock source. Between the first and the second write a delay of minimum 4 * (1/f_{PER}) + 2 * (1/f_{CLC}) must be inserted by software, where f_{PER} is the frequency being switched off with the first write. This also applies if between the writes the clock frequency is changed in the CCU.*

GLOBALCON
Global Configuration Register **(010$_H$)** **Application Reset Value: 000F 30FF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DEL0	LB	EXPECT				SI	0	TQ							
rw	rw	rw				rw	r	rw							

Field	Bits	Type	Description
TQ	7:0	rw	**Global Time Quantum Length** Common n-divider scaling the baud rates of all channels in direction of higher or lower baud rates. Must not be changed during a running transaction. 00_H division by 1 01_H division by 2 … FF_H division by 256
SI	9	rw	**Status Injection** Selects if the status register content injection into the RxFIFO is enabled or disabled. The status injections, if enabled, is performed after each data block, depending on the **BACON**.DL and BYTE setting. 0_B Disabled 1_B Enabled
EXPECT	13:10	rw	**Time-Out Value for the Expect Phase** expressed in T_{QSPI} units 0_H 64 (2^6) 1_H 128 (2^7) … F_H 2.097152E6 (2^21)
LB	14	rw	**Loop-Back Control** Selects if the transmit output is internally connected to the receive input for test purposes. For detailed description, see the Loop-Back Mode section. 0_B Loop-Back inactive 1_B Loop-Back active
DEL0	15	rw	**Delayed Mode for SLSO0** Switches the delayed mode (external slave select expansion mode) on and off 0_B Delayed mode off 1_B Delayed mode on
STROBE	20:16	rw	**Strobe Delay for SLSO0 in Delayed Mode** Defines the length of the SLSO0 delay in T_Q time units as defined for channel z (T_Q units) selected by the current **BACON**.CS, if **GLOBALCON**.DEL0 = 1. 00_H 1 01_H 2 … $1F_H$ 32

Field	Bits	Type	Description
SRF	21	rw	**Stop on RxFIFO Full** If this bit is set, the data fetching out of the TxFIFO by the shift register stops when the RxFIFO is full, in order to prevent RxFIFO overflow. Master mode only. 0_B Feature disabled 1_B Feature enabled
STIP	22	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the QSPI slave select input signals are inactive (PISEL.SLSIS ¹ 000_B). 0_B MRST = 0 when QSPI is deselected in Slave Mode. 1_B MRST = 1 when QSPI is deselected in Slave Mode
EN	24	rwh	**Enable Bit** Used to request transition between PAUSE and RUN mode per software. Cleared by hardware automatically at leaving the following states: disabled, suspend and sleep. In order to determine if the requested state has actually been reached, the **STATUS**.PHASE bit field should be polled. See also Operation Modes. 0_B PAUSE requested 1_B RUN requested
MS	26:25	rw	**Master Slave Mode** Selects if the module operates in master or slave mode. This bit field must be configured before the first write to the TXFIFO. 00_B Master Transmit and Receive 01_B Reserved 10_B Slave Transmit and Receive 11_B Slave Transmit and Receive
AREN	27	rw	**Automatic Reset Enable** Enables the reset of the **GLOBALCON**.EN on baud rate and spike error in slave mode. 0_B Disabled 1_B Enabled
CLKSEL	29	rw	**Clock Select** Selects the clock source for the asynchronous block. 0_B no clock 1_B f_{PER}

Field	Bits	Type	Description
RESETS	31:30	w	**Bits for resetting sub-modules per software** Write to this bit field triggers a reset operation. The duration of reset operation depends on the used clock setups. It is 10 times of the slowest clock between SPB and Kernel. *Note: CLOCKSEL shall be enabled to use GLOBALCON.RESETS. After the Reset the CLOCKSEL will be also cleared in case of 10 11.* For resetting the whole module kernel, use alternatively the registers **KRST0** / **KRST1** reset mechanism. 00_B No reset triggered 01_B State Machine, TXFIFO and RXFIFO reset, registers not reseted. Only control structures shall be reset. It avoids a re-configuration of the whole IP. After this reset Communication can be restarted. 10_B Registers reset. Clears the configuration of the QSPI registers. New setup have to be programmed. 11_B State Machine, TXFIFO and RXFIFO reset and registers reset
0	8, 23, 28	r	**Reserved** Read as 0; should be written with 0.

Global Configuration Register 1

GLOBALCON1 contains bit fields for control of the extension of the slave select signals by using an external demultiplexer.

GLOBALCON1
Global Configuration Register 1 (014_H) Application Reset Value: $0005\ 0000_H$

0	13, 14, 30, 31	r	**Reserved** Read as 0; should be written with 0.

Basic Configuration Register

Defines the basic configuration parameters for the current slave select. It can be read by software, or written through a write to the TXFIFO.

If an application does not use the SLSO signals of the QSPI module, but uses software channel selection, then the alternate function multiplexer in the ports must be configured so that the signal SLSO is not selected, but the corresponding bit Pn.OUT.

Alternatively, to emulate SLSO functionality, the software can disable (low) all the **SSOC**.OEN bits, and then toggle the **SSOC**.AOL bits.

Status Register

Status register contains bits flagging the current status of the module and its sub-modules.

Note: It is not recommended to set the STATUS register flags per software for purposes other than testing. In such cases, use write instructions only, not read-modify-write instructions or bit instructions which compile to read-modify-write instructions.

3. When using the RXFIFO status injection feature, only bits 22 to 31 reflect the status at the moment of injection, that is for the latest frame. Due to pipeline effects, the other bits contain not-latest information.

Note: Slave TXFIFO underflow error is activated if the transmission has been started by the master at the time when the slave FIFO was empty, or at the same moment updated. In the second case inconsistent data will be transmitted.

4. *Reading the TXFIFO filling level bit field returns a value which can be used to calculate how many writes can be performed by a CPU without causing an overflow (in case no DMA is programmed to access the TXFIFO in parallel). For example, if the TXFIFO level was one, maximum three (TXFIFO depth of four minus one) write accesses are possible. Due to the volatility of the bit field, the filling level can go down in some nanoseconds after the read.*
5. *Reading the RXFIFO filling level bit field returns a value which shows directly how many reads can be performed by a CPU without causing an underflow. Due to the volatility of the bit field, the filling level can go up in some nanoseconds after the read.*
6. *Reading the PHASE bit field shows a previous phase of the frame, and a PT1F and PT2F flags indicate previous phase transitions. If the communication speed is not too high or the phases duration not very short compared to the software latency delays, which would normally be the case, these would be the latest completed phase and the latest phase transitions. Nevertheless, in case of high baud rates, the duration of the phases must be taken into consideration, but only if these bit fields are used in an application, and not only for debugging purposes.*

STATUS

Status Register **(040_H)** **Application Reset Value: $0000\ 0000_H$**

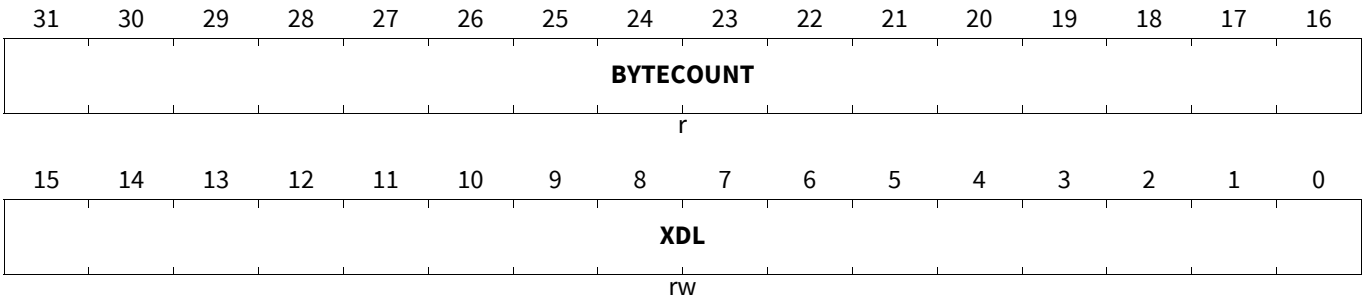
Extra Large Data Configuration Register

The XXLCON register provides counter for sending frames with very long blocks of data by extending the long data mode. It avoids a need for further BACON entries, like those needed in continuous mode.

Data length in this register overrides the **BACON**.DL setting in XXL mode, when **BACON**.BYTE=1 and **BACON**.DL=0. The data is sent to the corresponding slave as defined by **BACON**.CS bit field.

XXLCON

Extra Large Data Configuration Register (058$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
XDL	15:0	rw	**Extended Data Length** Defines the length of the data block in bytes in range of 2 to 65536. Overrides **BACON**.DL when **BACON**.BYTE=1 and **BACON**.DL=0. 0000_H2 bytes 0001_H2 bytes … $FFFF_H$65536 bytes
BYTECOUNT	31:16	r	**Extended Data Length** In the XXL mode, shows the current state of the internal byte down counter (bytes remaining to be sent). In short and long modes, the value of this bit field is don't care. 0000_H0 bytes 0001_H2 bytes … $FFFF_H$65536 bytes

Move Counter Register

In Move Counter Mode, the slave select signal SLSO remains active during the time **MC**.MCOUNT write accesses (for example DMA moves) to the TXFIFO are being shifted out. The **MC** mode is enabled when **MCCON**.MCEN=1

and **BACON**.BYTE = 0 and **BACON**.LAST = 0. After the frame has been completed, SLSO is automatically deactivated. Then, the software should clear the MCEN if the move counter is not needed any more. The move counter is a down-counter that triggers an interrupt (if enabled):

- after the move before last has been shifted out
- after the last move has been shifted out

The range of counting is 8191 to 1. The bit field **MC**.CURRENT shows the currently transmitted frame, the last one being 1. The update of the CURRENT bit field takes place with a couple of cycles delay due to the asynchronous frequency domain of the shift engine. The decrementing is done after shifting the last bit of each data. **MC**.CURRENT= 0 means no data pending, the complete data of the frame has been shifted out.

The enable, flag, set and clear bits for the Interrupt Before Last (IBL) and Interrupt After Last (IAL) are defined in **MCCON** register. The interrupt signals are mapped to the User Interrupt line, but have separate enable bits in the **MCCON** register and do not depend on **BACON**.UINT. Therefore on user interrupt in **MC** mode, the software must also check the **MCCON**.IALF and IBLF flags. All other standard QSPI phase interrupts are triggered as usual. If the data is not fed to the TXFIFO in time, EXPECT phase is activated.

An example sequence of using **MC** mode is: CPU writes the configuration for the frame once at the start in the **BACONENTRY** address, afterwards DMA writes DATA in DATAENTRY. MIXENTRY shall not be used. The TXFIFO interrupts trigger the DMA, which itself counts the moves in parallel to the **MC** register.

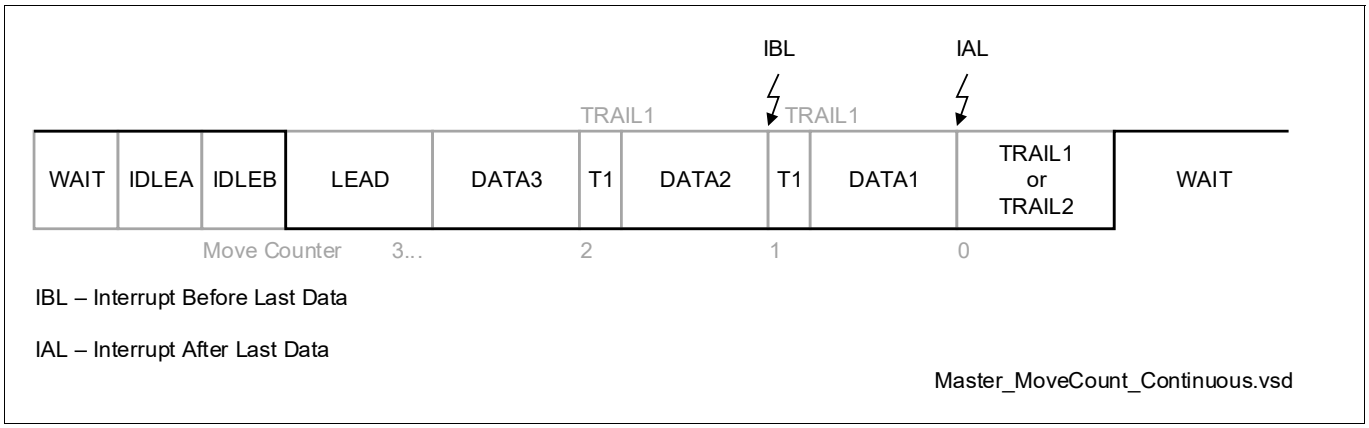


Figure 517 Frame Sequence of Phases in Short Move Counter Continuous Mode

Another usage example of using MC mode is daisy-chaining: Here the CPU writes the number of frames for all slaves to the MC register. Afterwards it writes the configuration for the frame of the fist slave (BACON3 in the figure) in the BACONENTRY address, afterwards DMA writes the for the first slave (DATA3_2 and DATA3_1) in DATAENTRY. MIXENTRY shall not be used. The TXFIFO interrupts trigger the DMA, which until all data for the first slave has been written. Then the configuration of the second slave (BACON2) needs to be written to BACONENTRY, followed by its data (DATA2_3, DATA2_2 and DATA2_1). This process may be repeated until the whole daisy-chain is filled (in the figure this is an additional BACON1 and DATA1_1). The different BACONs may only vary in the BACON.DL and/or BACON.MSB setting.

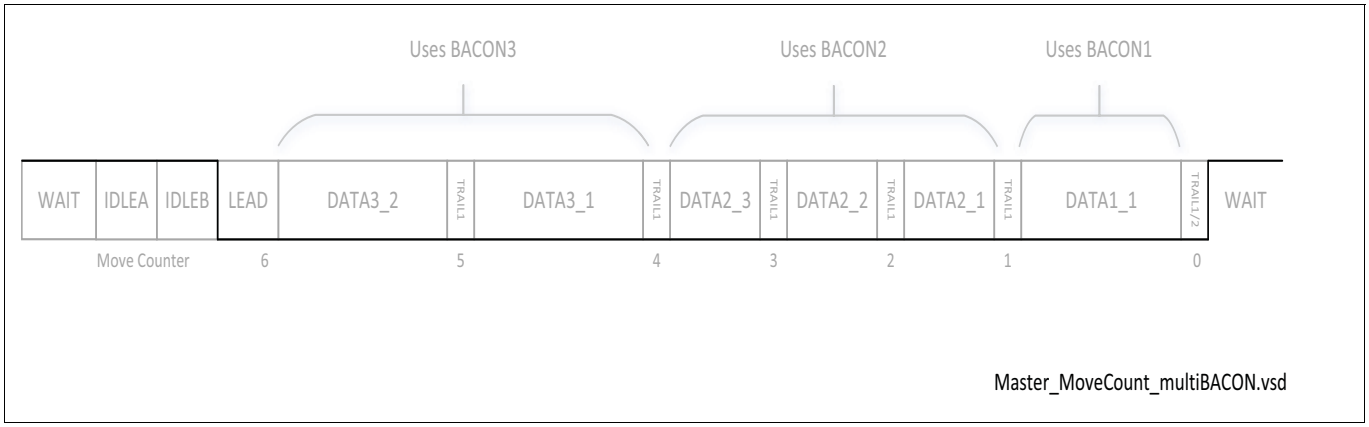

Figure 518 Frame Sequence of Phases in Move Counter implementing daisy-chaining

It is possible to combine Continuous Long Mode with Move Counter Mode so that a frame starts with one or more Continuous Long Mode transmissions and ends with one Move Counter Mode transmission.

MC

Move Counter Register (0A4$_H$) Application Reset Value: 0000 0000$_H$

0										TRAIL2			TPRE2		
r										rw			rw		

Field	Bits	Type	Description
TPRE2	2:0	rw	**Prescaler for the Trailing Delay 2** Trailing delay injected in the configuration register for the last data if T2EN is set. Length in units T_{PER} 000_B 1 001_B 4 010_B 16 … 111_B 16384
TRAIL2	5:3	rw	**Last Trailing Delay** Trailing delay injected in the configuration register for the last data if T2EN is set. Defines the length of the leading delay, in T_{PER} units pre scaled with TPRE 000_B 1 unit 001_B 2 units … 111_B 8 units
IBLEN	16	rw	**Interrupt Before Last Enable** Enable bit for this event. 0_B Disabled 1_B Enable
IBLF	17	rh	**Interrupt Before Last Flag** Flag bit for this event. 0_B No event 1_B Event occurred
IBLC	18	w	**Clear Bit for IBLF** Writing 1 clears the IBLF. Writing 0 has no effect. Returns 0 on read.
IBLS	19	w	**Set Bit for IBLF** Writing 1 sets the IBLF and triggers an interrupt (if enabled). Writing 0 has no effect. Returns 0 on read.
IALEN	20	rw	**Interrupt After Last Enable** Enable bit for this event. 0_B Disabled 1_B Enable

Field	Bits	Type	Description
IALF	21	rh	**Interrupt After Last Flag** Flag bit for this event. 0_B No event 1_B Event occurred
IALC	22	w	**Clear Bit for IALF** Writing 1 clears the IALF. Writing 0 has no effect. Returns 0 on read.
IALS	23	w	**Set Bit for IALF** Writing 1 sets the IALF and triggers an interrupt (if enabled). Writing 0 has no effect. Returns 0 on read.
T2EN	30	rw	**TRAIL 2 Injection Enable** This bit has to be configured before the transmission of the frame starts. If set, a new value for the last trailing delay will be injected for the last data block, as defined with the bit field TRAIL2. If not set, the TRAIL value from the latest **BACON** will be valid also as the last trailing delay.
MCEN	31	rw	**Move Counter Enable** Enables the Move Counter feature. If enabled, the MCOUNT value is taken in consideration, otherwise the standard continuous mode is active.
0	15:6, 29:24	r	**Reserved** Read as 0; should be written with 0.

MIX_ENTRY Register

MIXENTRY
MIX_ENTRY Register **($05C_H$)** **Application Reset Value: $0000\ 0000_H$**

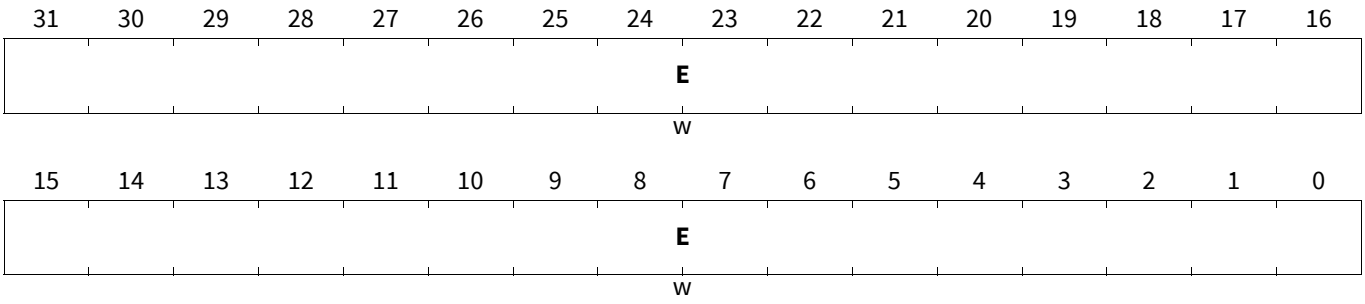
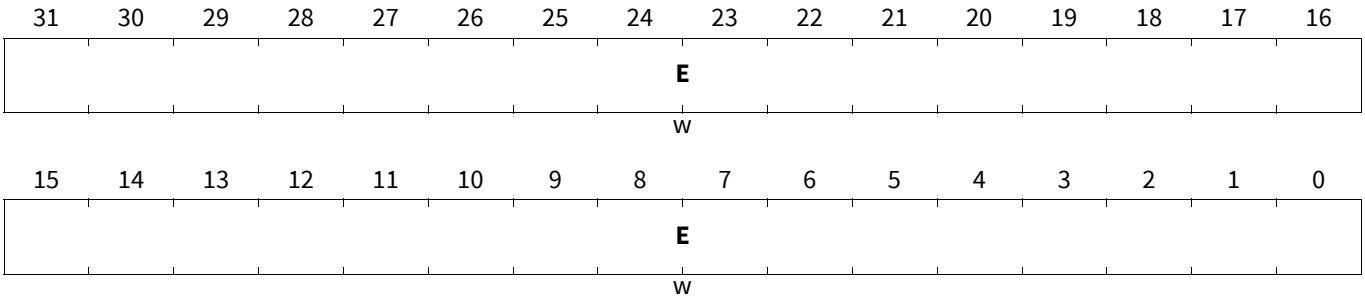
BACONENTRY
BACON_ENTRY Register **(060_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
E	31:0	w	**Entry Point to the TxFIFO**

DATA_ENTRY Register x

DATAENTRYx (x=0-7)
DATA_ENTRY Register x **(064_H+x*4)** **Application Reset Value: 0000 0000_H**



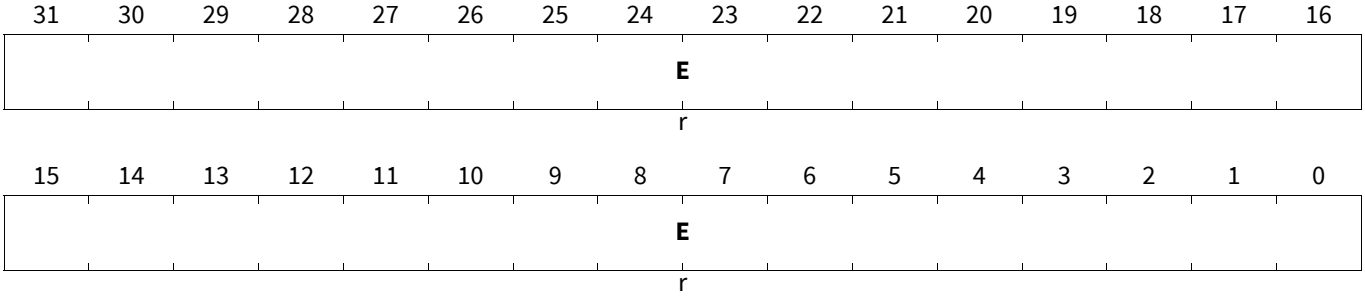
Field	Bits	Type	Description
E	31:0	w	**Entry Point to the TxFIFO**

RX_EXIT Register

The RXFIFO has a property that a read access from an empty RXFIFO generates an underflow interrupt, and delivers only “1” bits, which overrules the reset value. Therefore reading from a non initialized RXFIFO delivers all “1” and not all ”0”.

RXEXIT

RX_EXIT Register **(090$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
E	31:0	r	**Read Point from the RxFIFO**

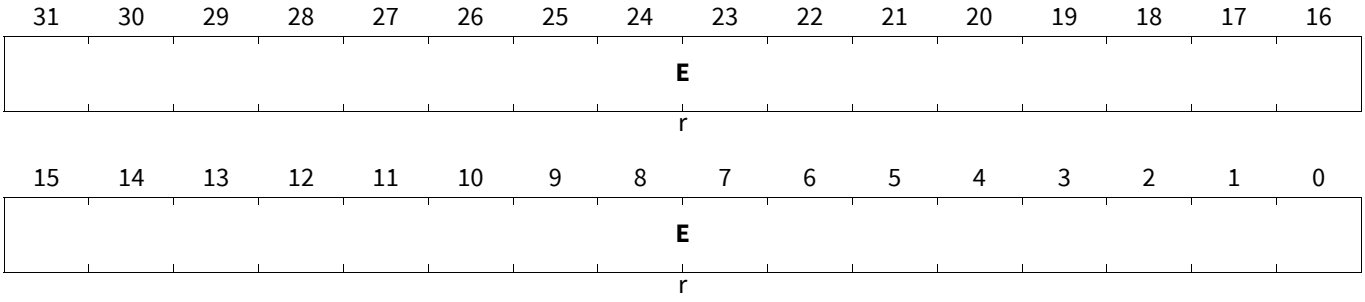
RX_EXIT Debug Register

The register **RXEXITD** provides a non-destructive address, showing the next available value in the RXFIFO.

*Note: This register provides a non-volatile access to the RXFIFO. It delivers the same value as **RXEXIT**, but without affecting read pointer and the filling level of the RXFIFO.*

RXEXITD

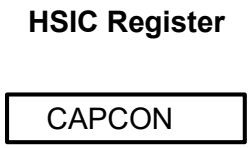
RX_EXIT Debug Register **(094$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
E	31:0	r	**Read Point from the RxFIFO**

37.5.2 HSIC Registers

The HSIC sub-module is optionally added to the QSPI and have one Register.



HSIC-reg

Figure 519 HSIC Registers

Capture Control Register

CAPCON is the only control register for the HSIC sub-module. It contains the configuration, control bits and the captured value of the counter.

CAPCON
Capture Control Register **(0A0$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OVF	**CAP**														
rh	rh														

Field	Bits	Type	Description
CAP	14:0	rh	**Captured Value** Provides the latest capture value from the capture timer.
OVF	15	rh	**Overflow Flag** Signals if an overflow event of the capture timer occurred in the latest measurement. Shows a value of 1 if one or more overflows of the capture timer occurred during the latest measurement. Each capture event refreshes this bit with the new value.
EDGECON	17:16	rw	**Edge Configuration** Configures the capture mode of the counter, defining which edge starts the counting, which edge captures its contents. 00_B RR mode (rising edge to rising edge) 01_B RF mode (rising edge to falling edge) 10_B FR mode (falling edge to rising edge) 11_B FF mode (falling edge to falling edge)

Field	Bits	Type	Description
INS	19:18	rw	**Input Selection** Selects one of four input lines for the capture signal. 00_B INA selected 01_B INB selected 10_B INC selected 11_B IND selected
EN	20	rw	**Enable Bit of the Capture Timer** Enables the capture timer clock. Enabled timer waits for the next start edge as defined in EDGECON, before it starts counting. 0_B Disabled 1_B Enabled
CAPC	28	w	**Capture Flag Clear** Writing 1 to this bit clears the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPS	29	w	**Capture Flag Set** Writing 1 to this bit sets the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPF	30	rh	**Capture Flag** Indicates if a capture event has occurred since the last clear event by the bit CAPC.
CAPSEL	31	rw	**Capture Interrupt Select Bit** Select if the capture events are routed to the HC interrupt line. 0_B Not routed (capture interrupt disabled) 1_B Routed (capture interrupt enabled)
0	27:21	r	**Reserved**

38 Micro Second Channel (MSC)

This chapter describes the Micro Second Channel Interface. It contains the following sections:

- Functional description of the MSC kernel (see **Page 3**)
- MSC kernel register descriptions (see **Page 54**)
- Implementation-specific details and registers of the MSC module (port connections and control, interrupt control, address decoding, and clock control, see **Page 43**)

*Note: The MSC kernel register names described in **Section 38.4** are also referenced in theAURIX™ TC3xx PlatformUser's Manual by the module name prefix "MSCx_".*

MSC Applications

The MSC is a serial interface that is especially designed to connect external power devices. The serial data transmission capability minimizes the number of pins required to connect such external power devices. Parallel data information (coming from the timer units) or command information is sent out to the power device via a high- speed synchronous serial data stream (downstream channel). The MSC receives data and status back from the power device via a low-speed asynchronous serial data stream (upstream channel).

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

Figure 520 shows a typical application in which an MSC interface controls two power devices. Output data is provided by the module.

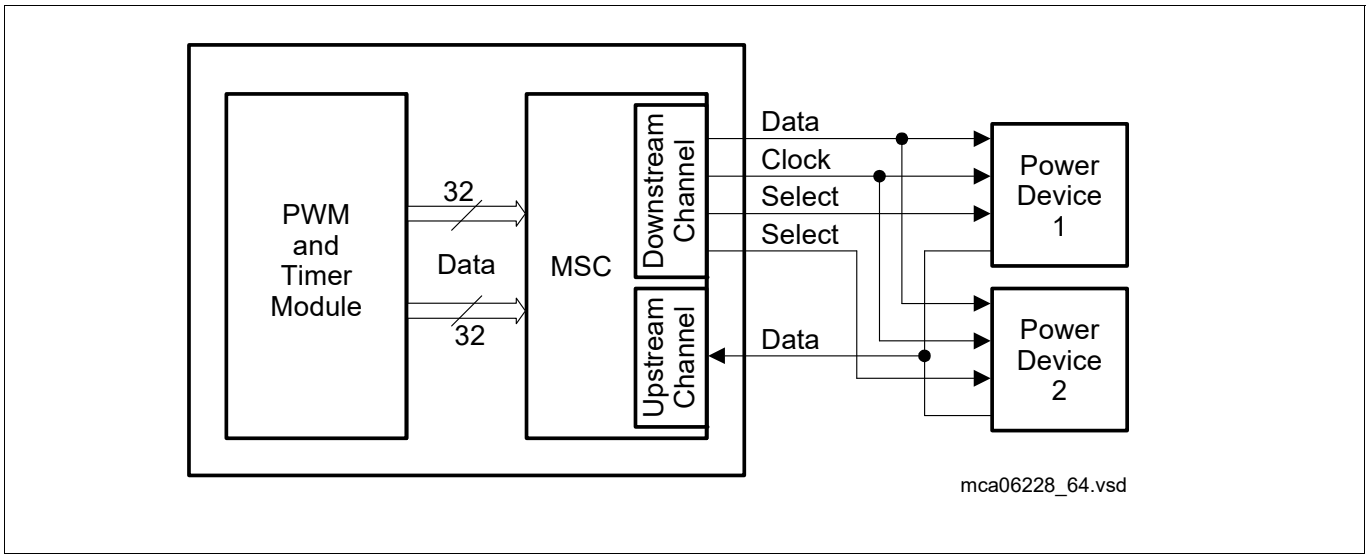

Figure 520 MSC to External Power Device Connection

Some applications are:

- Control of the external power switching unit via the downstream channel
- Receiving information back from power switching unit
- Serial connections to other peripheral devices

38.1 Feature List

- Fast synchronous serial interface to connect power switches in particular, or other peripheral devices via serial buses

- High-speed synchronous serial transmission on downstream channel
  - Serial output clock frequency: $f_{FCL} = f_{MSC}/2$ (f_{MSCmax} = 100 MHz)
  - Fractional clock divider for precise frequency control of serial clock f_{MSC}
  - Command, data, and passive frame types
  - Start of serial frame: Software-controlled, timer-controlled, or free-running
  - Transmission with or without SEL bit
  - Flexible chip select generation indicates status during serial frame transmission
  - Emergency stop without CPU intervention
- Low-speed asynchronous serial reception on upstream channel
  - Baud rate: f_{MSC} divided by 4, 8, 16, 32, 64, 128, or 256 (f_{MSCmax} = 100 MHz)
  - Standard asynchronous serial frames
  - Programmable upstream data frame length (16 or 12 bits)
  - Parity error checker
  - 8-to-1 input multiplexer for SDI lines
  - Built-in spike filter on SDI lines
  - Programmable delay of the receive interrupt after the last stop bit (0 or 1 bit time)
- Selectable pin types of downstream channel interface:
  four LVDS differential output drivers or four digital GPIO pins
- Module reset available
- Advanced features:
  - Asynchronous Baud Rate Adjustment Block
  - one extra interrupt
  - 64-bit data frames extension
  - fully compatible with the 32-bit data frames module version

38.2 Overview

The MSC interface provides a serial communication link typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel. **Figure 521** shows a global view of the MSC interface signals.

The MSC module features functional extensions, but is backward compatible with the previous microcontroller generations.

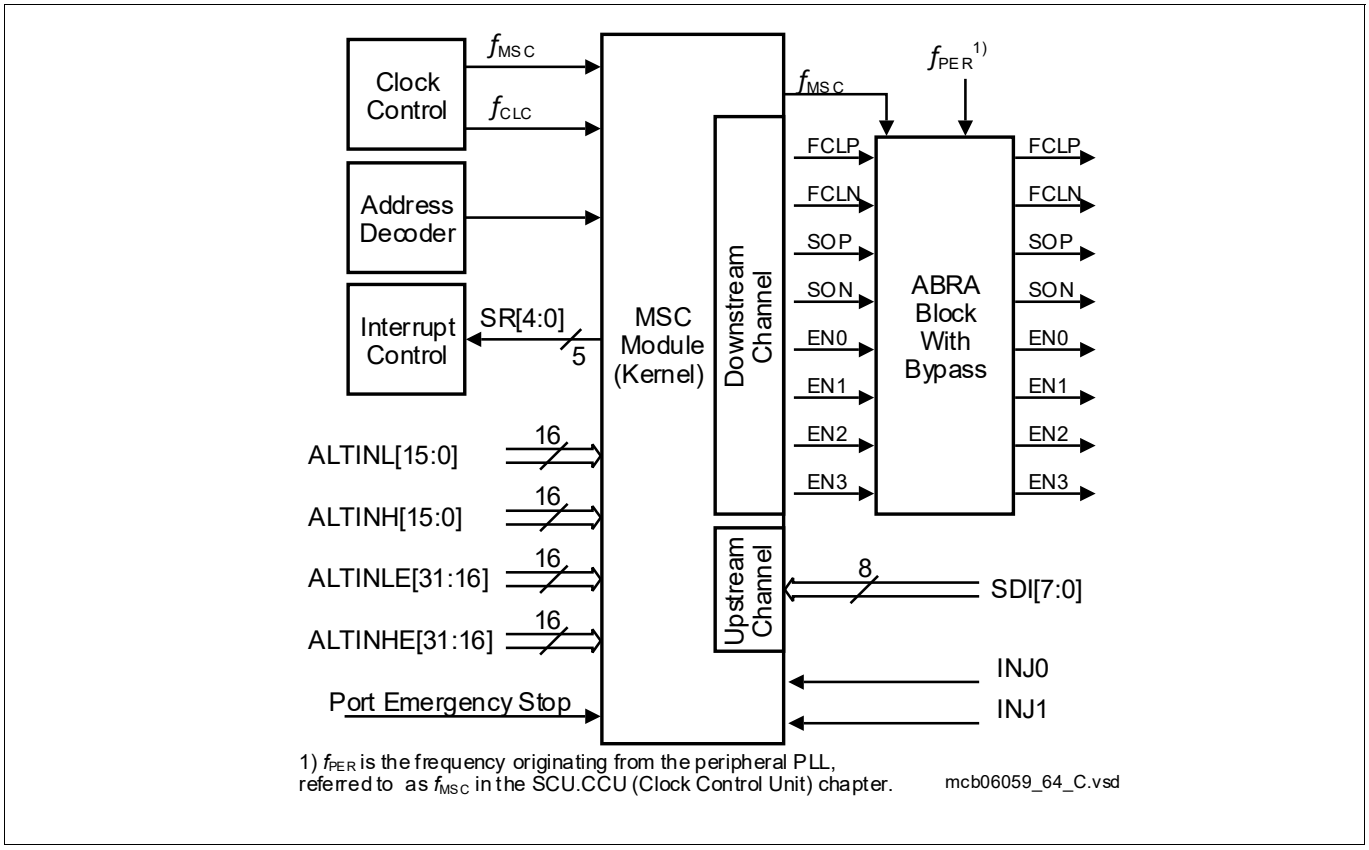

Figure 521 General Block Diagram of the MSC Interface

The downstream and upstream channels of the MSC module communicate with the external world via nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data, and enable signals). One out of eight input lines SDI[7:0] is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC register contents or data that is provided at the ALTINL/ALTINH input lines. These input lines are typically connected to other on-chip peripheral units (for example with a timer unit like the GTM). An Port Emergency Stop input signal makes it possible to set bits of the serial data stream to dedicated values in emergency case.

Clock control, address decoding, and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

38.3 Functional Description

This section describes the MSC kernel, the Command Extension Mode. the Asynchronous Baud Rate Adjustment Block an the module implementation.

38.3.1 MSC Kernel Description

This section describes the functionality of the MSC kernel.

38.3.1.1 Downstream Channel

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 64-bit shift register is divided into two 32-bit parts, SRL and SRH. Each bit of SRL and SRH can be selected to be delivered by the Downstream Data Register DD, by the Downstream Command Register DC, or by two 16-bit wide input signal buses ALTINL and ALTINH. In the 64-bit extended mode, set with the bit **DSCE**.EXEN = 1, the MSC module provides two 16-bit extension buses, ALTINLE and ALTINHE.

Figure 522 is a diagram of the MSC downstream channel.

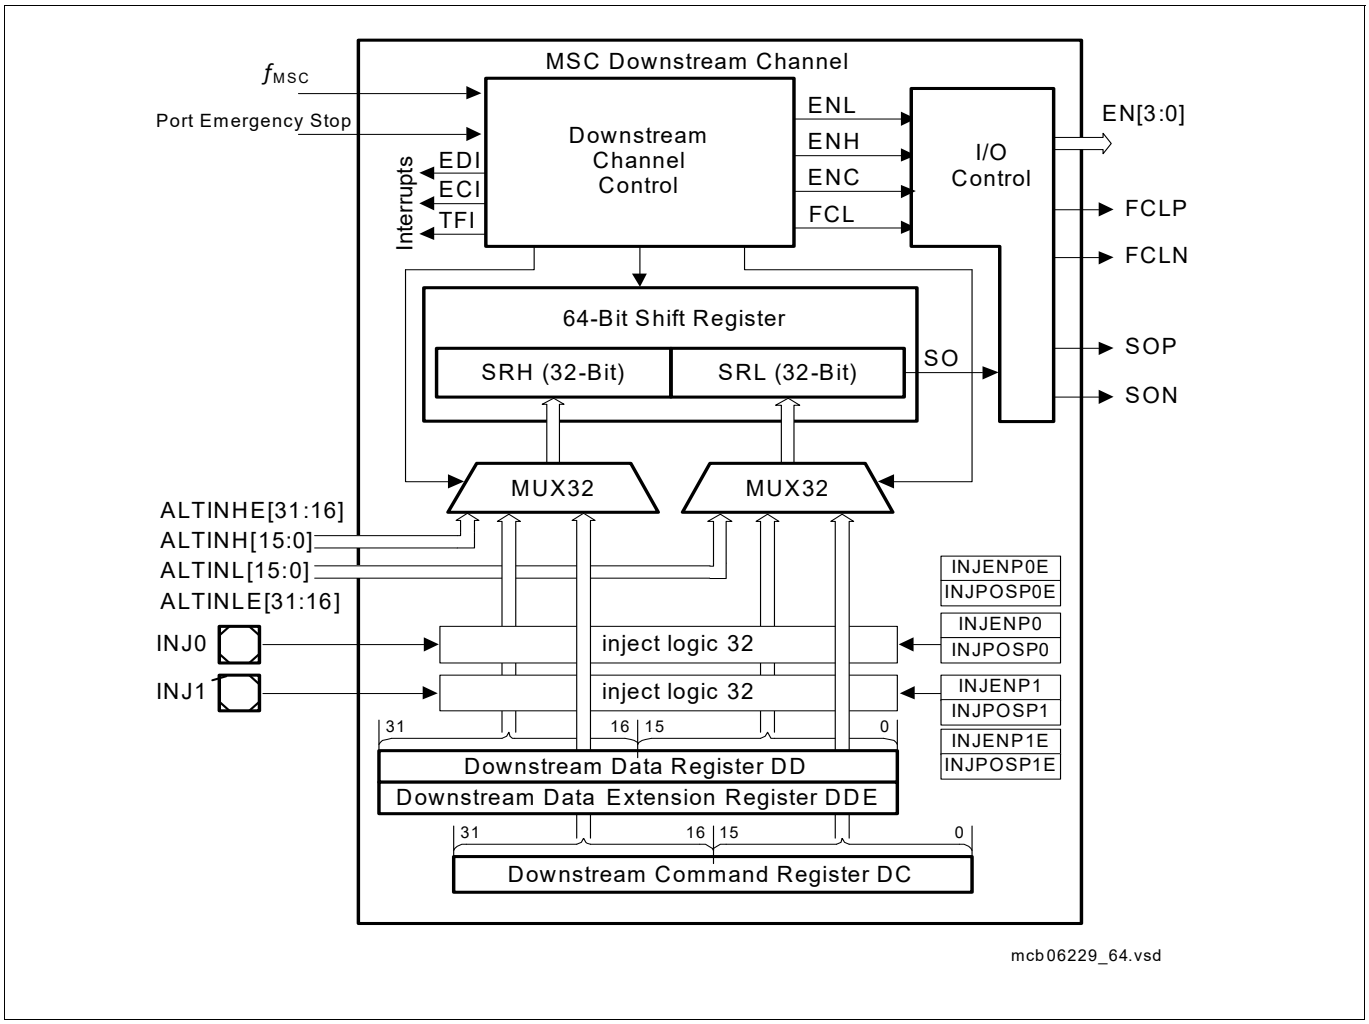

Figure 522 Downstream Channel Block Diagram

The enable signals ENL, ENH, and ENC indicate certain phases of the serial transmission in relation to the serial clock FCL. In the I/O control logic, these signals can be combined to four enable/select outputs EN[3:0]. For supporting differential output drivers, the serial clock output FCL and the serial data output SO are available in both polarities, indicated by the signal name suffix “P” and “N”.

The Port Emergency Stop input is used to indicate an emergency stop condition of a power device. In emergency case, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL, ALTINH, ALTINLE and ALTINHE buses.

38.3.1.1.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the MSC.

Basic Definitions

Figure 523 shows the layout and definitions of a downstream frame. A downstream frame is composed of an active phase and a passive phase. During the active phase, data transmission takes place and during the passive phase no data is transmitted at SO. The active phase is split into two parts: The SRL active phase in which the content of the shift register low part SRL is transmitted, and the SRH active phase in which the content of the shift register high part SRH is transmitted. At the beginning of the SRL and SRH active phase, a selection bit (SELL) can be optionally inserted into the serial data stream. In the frame shown in **Figure 523**, SELL is generated at the beginning of the SRL active phase (not for the SRH active phase). The least significant bits of SRL and SRH are sent out first.

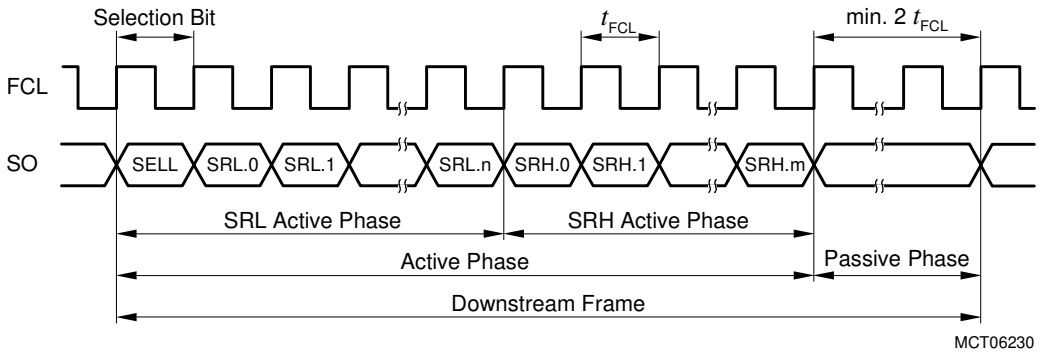

Figure 523 Downstream Channel Frame

The MSC downstream channel uses three types of frame formats for operation:

- Command frames, indicated by SELL = 1
- Data frames, indicated by SELL = 0 or SELL bit insertion disabled
- Passive time frame, indicated by ENL = ENH = 0

Command Frames

A command frame has two active phase parts, SRL active phase and SRH active phase. The command frame always starts with a high-level selection bit, independently whether the selection bit insertion (as defined by bit DSC.ENSELL) is enabled or not. The number of the bits transmitted during SRL and SRH active phases (except the selection bit) is defined by bit field **DSC**.NBC. SRL and SRH are combined to a value up to 32-bit whose length can be selected from 0 up to 32 bits. In other words, whenever bits of SRH are transmitted, they are always preceded by the transmission of the complete SRL content. In the command extension mode, activated with the **DSTE**.CX bit, the commands can be up to 64-bit long (see **CX (Command Extension) Mode**).

During the active phase of a command frame, the enable output signal ENC becomes active. The enable output signals ENL and ENH remain inactive.

The passive phase of a command frame always has a fixed length of 2 x t_{FCL}. The diagram shown in **Figure 524** assumes that the FCL clock is only generated during the active phase of the command frame (OCR.CLKCTRL = 0).

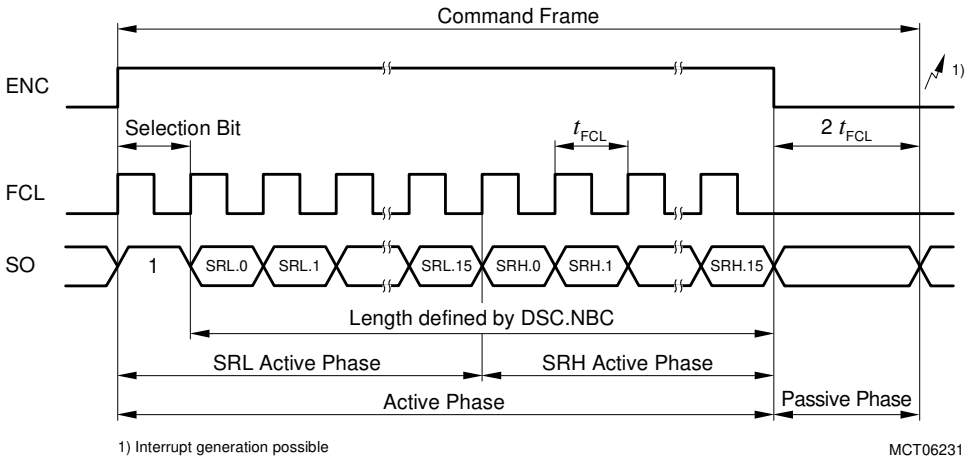

Figure 524 Command Frame Layout

Table 332 shows the programming of the bits to be transmitted and the resulting length of the complete command frame.

Table 332 Command Frame Length

DSC.NBC	SRL/SRH Bits that are Transmitted in Active Phase	Command Frame Length in t_{FCL} Periods
000000_B	No bit shifted out	1 + 0 + 2 = 3
000001_B	SRL[0] shifted out	1 + 1 + 2 = 4
000010_B	SRL[1:0] shifted out	1 + 2 + 2 = 5
000011_B	SRL[2:0] shifted out	1 + 3 + 2 = 6
…	…	…
001111_B	SRL[14:0] shifted out	1 + 15 + 2 = 18
010000_B	SRL[15:0] shifted out	1 + 16 + 2 = 19
010001_B	SRL[15:0] and SRH[0] shifted out	1 + 17 + 2 = 20
010010_B	SRL[15:0] and SRH[1:0] shifted out	1 + 18 + 2 = 21
010011_B	SRL[15:0] and SRH[2:0] shifted out	1 + 19 + 2 = 22
…	…	…
011111_B	SRL[15:0] and SRH[14:0] shifted out	1 + 31 + 2 = 34
100000_B	SRL[15:0] and SRH[15:0] shifted out	1 + 32 + 2 = 35
Other NBC combinations	Reserved; do not use these bit combinations.	

Data Frames

A data frame has two active phase parts, SRL active phase and SRH active phase. The number of bits that are transmitted can be programmed separately for each of these two phases. Bit field DSC.NDBL determines the number of SRL bits that are transmitted during the SRL active phase and DSC.NDBH determines the number of SRH bits that are transmitted during the SRH active phase.

SRL and SRH active phases can start with a low-level selection bit when enabled by bits DSC.ENSELL or DSC.ENSELH.

During the SRL active phase of a data frame, the enable output signal ENL becomes active and during the SRH active phase of a data frame, the enable output signal ENH becomes active. The enable output signal ENC remains inactive.

The length of the data frame's passive phase is variable and is defined by bit field DSC.PPD. It can be within a range of 2 x t_{FCL} up to 31 x t_{FCL}. The diagram shown in **Figure 525** assumes that the FCL clock is only generated during the active phase of the data frame (OCR.CLKCTRL = 0).

Table 333, **Table 334**, and **Table 336** show the definitions of the five data frame parameters that determine the layout of the data frame.

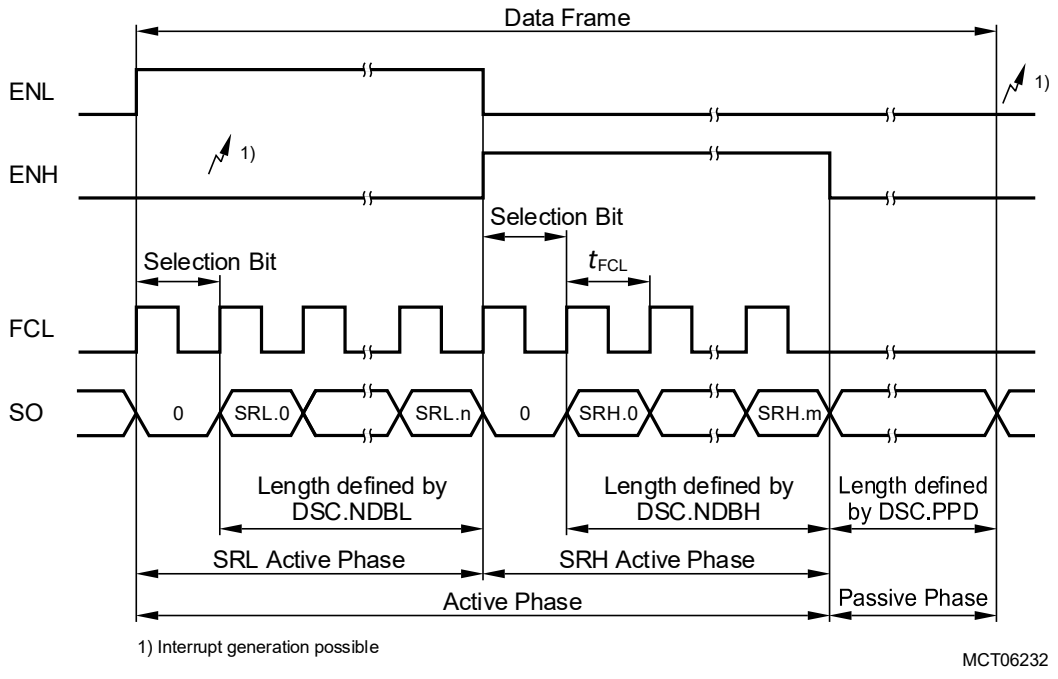

Figure 525 Data Frame Layout

Table 333 Data Frame Selection Bit Parameters

DSC.ENSELL	Selection Bit	DSC.ENSELH	Selection Bit
0	No selection bit inserted at the beginning of the SRL active phase	0	No selection bit inserted at the beginning of the SRH active phase
1	A low level selection bit is inserted at the beginning of the SRL active phase	1	A low level selection bit is inserted at the beginning of the SRH active phase

*Note: The MSC module can operate in two modes: standard (up to 32 data bits) or extended (up to 64 data bits). The mode is selected by using the bit **DSCE**.EXEN.*

Table 334 Data Frame SRL/SRH Length Parameters, Standard Mode

$1\ 10000_B$	SRL[31:0]	$1\ 10000_B$	SRH[31:0]
Other bit combinations	Reserved; do not use these bit combinations.	Other bit combinations	Reserved; do not use these bit combinations.

Table 336 Data Frame Passive Phase Length

DSC.PPD	Passive Phase Length
00000_B	2 x t_{FCL}
00001_B	2 x t_{FCL}

Table 336 Data Frame Passive Phase Length (cont'd)

DSC.PPD	Passive Phase Length
00010_B	2 x t_{FCL}
00011_B	3 x t_{FCL}
…	…
11110_B	30 x t_{FCL}
11111_B	31 x t_{FCL}

The following formula determines the number of t_{FCL} cycles of an up to 32-bit data frame:
All parameters (bits and bit fields) are located in register DSC.

$$Ncycles = ENSELL + NDBL + ENSELH + NDBH + PPD \quad (38.1)$$

Note that in the formula above, PPD must be set to 2 when DSC.PPD ≤ 00010_B.

The following formula determines the number of t_{FCL} cycles of an extended, up to 64-bit data frame, in case DSC.NDBL and DSC.NDBH are not equal to zero:

$$Ncycles = ENSELL + NDBL + NDBLE \cdot EXEN \cdot 16 + ENSELH + NDBH + NDBHE \cdot EXEN \cdot 16 + PPD + PPDE \cdot 32 \quad (38.2)$$

Otherwise, the corresponding factor NDBLE*EXEN*16 or NDBHE*EXEN*16 must be taken as zero (see **Table 335**).

Note that in the formula above, PPD must be set to 2 when DSC.PPD ≤ 00010_B.

The parameters (bits and bit fields) are located in registers DSC and DSCE.

Attention: ***In order to calculate the time between two consecutive TRPs (Time Reference Point), always use ENSELL=1 in the formulas above. ENSELL does not influence the time between two consecutive TRPs, but only the length of a data frame. The difference in the starting point of a frame with ENSELL=0 and 1 is shown in the Figure 531 and Figure 532.***

Passive Time Frames

A passive time frame has the length defined by the five data frame parameters according **Equation (38.1)**. They are generated only in Data Repetition Mode. Under special conditions (command frame insertion), passive time frames can be shortened (see **Figure 529**).

During passive time frames, the data output SO has to be considered as invalid at the receiving device and the clock output FCL may toggle or not (as selected by bit OCR.CLKCTRL). The ENL and ENH enable signals remain at low level during a passive time frame.

38.3.1.1.2 Shift Register Operation

This section describes the SRL and SRH shift register loading.

SRL Shift Register Loading

During the SRL/SRH shift register load operation at the beginning of each downstream frame transmission, several parameters determine which information is loaded into the bits of the shift register. **Figure 526** shows the logic that is implemented for the SRL shift register loading operation. The logic for the SRH shift register loading operation is equivalent to the one for the SRL register. Its differences in data sources and register controls are described later in this section.

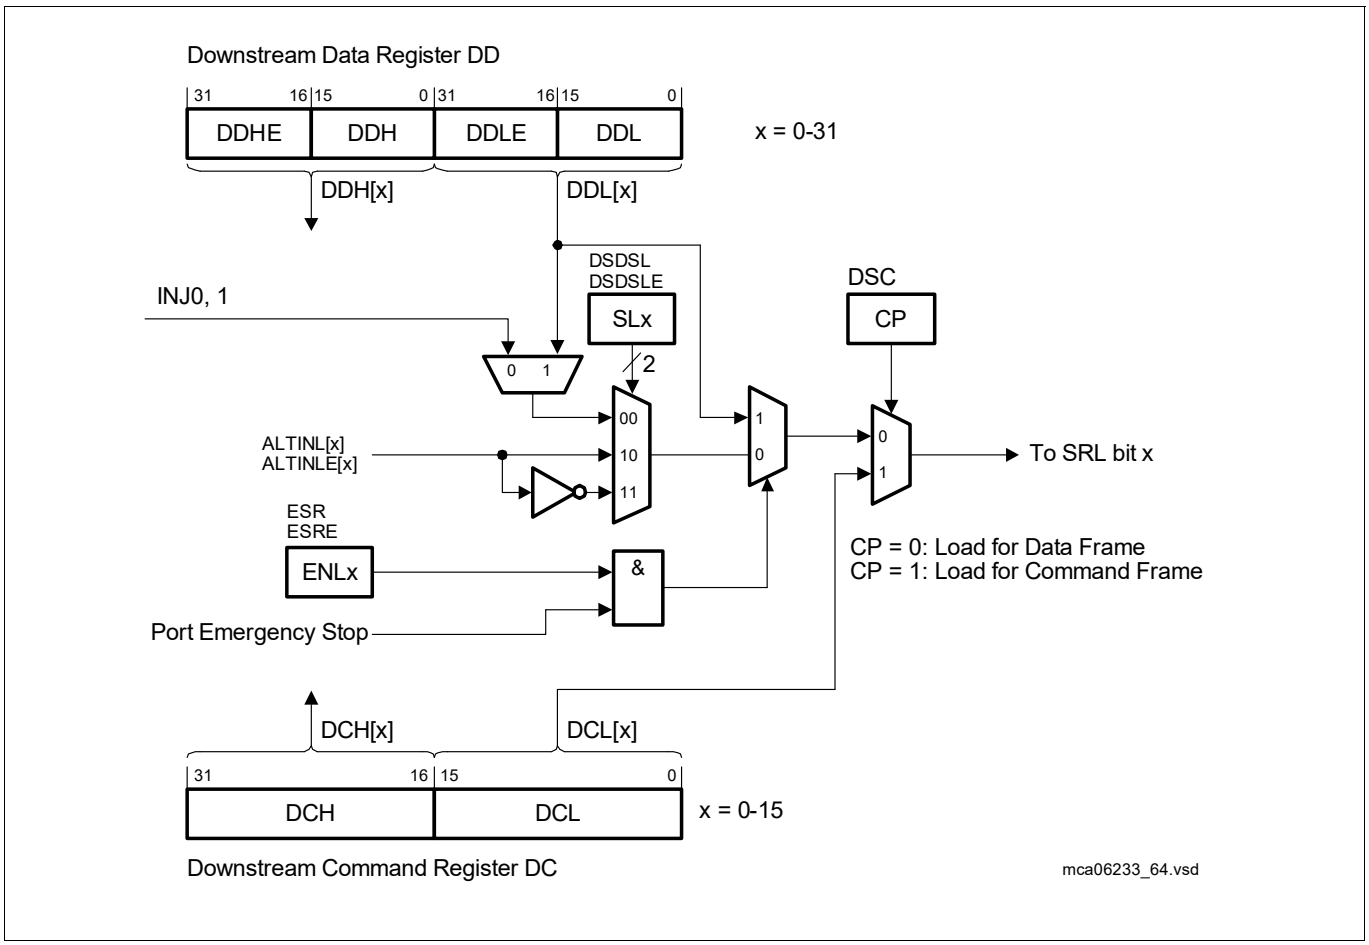

Figure 526 SRL Shift Register Data Loading Control

Four data sources can be selected for each SRL bit by using several control bits and one control signal:

- ALTINL, ALTINLE input line (non-inverted)
- ALTINL, ALTINLE input line (inverted)
- Bit of DD.DDL, DDLE (downstream data register)
- Bit of DC.DCL (downstream control register)

When SRL is loaded for data frame transmission (DSC.CP = 0), bit fields DSDSL.SLx determine bit-wise which data is loaded into SRL bit x. The data source selection as controlled by DSDSL.SLx will only be effective when Port Emergency Stop is inactive (at low level). When Port Emergency Stop = 1 (active) during the load operation, all SRL[x] bits that are enabled for the emergency stop feature (bit ESR.ENLx = 1) are loaded directly with the corresponding bit DDL[x] of the downstream data register DD.

When SRL is loaded for command frame transmission (DSC.CP = 1), always the lower 16-bit part DCL of the downstream control register is loaded completely into SRL.

Table 337 summarizes all SRL data source selection capabilities (x = 0-31):

- in standard mode, **DSCE**.EXEN = 0, the selection configuration of up to 16 bits (x = 0-15) is taken into account
- in extended mode, **DSCE**.EXEN = 1, the selection configuration of up to 32 bits (x = 0-31) is taken into account

Table 337 SRL Data Source Selection Capabilities

DSC. CP	DSDSL.SLx DSDSLE.SLx	ESR. ENLx	Port Emergency Stop	Selection
0	00_B	0	–	Bit DD.DDL[x] is loaded into SRL[x].
	01_B			Reserved.
	10_B			State of ALTINL[x] input is loaded into SRL[x].
	11_B			Inverted state of ALTINL[x] input is loaded into SRL[x].
	XX_B	1	1	Bit DD.DDL[x] is loaded into SRL[x].
1	XX_B	X	X	Bit fields DCL and DCH are completely loaded into SRL and SRH, respectively.

*Note: The data signals can be overruled by injected pin signals INJ0 and INJ1. See **DSCE** register.*

SRH Shift Register Loading

The SRH shift register load operation is equivalent to the SRL shift register load operation. The following differences must be taken into account for SRH shift register loading:

- Input lines ALTINH are connected instead of ALTINL input lines.
- DSDSH register bits control data source selection instead of DSDSL register.
- Emergency stop is enabled by ESR.ENHx bits instead of ESR.ENLx bits.
- Bits of the downstream data register high part DDH are selected instead of DDL.
- Downstream control register high part DCH is selected instead of DCL.

38.3.1.1.3 External Signal Injection

Input signals from two pins can be independently injected at two data bit positions in a data frame. The injection takes place both in normal and in extended mode. The external signals are always injected at the defined position, and if the data frame is shorter than this position, than these signals remain unused. For example, if **DSCE**.INJPOS0 defines injection at the position 14 of the SRL, and the **DSC**.NBDL=12, then all the data bits from position 12 and up remain unused, including the injected signal.

In normal mode the bits are counted from 0 to 31 from LSB to MSB, and in extended mode the bits are counted from 0 to 63 from LSB to MSB, see **Figure 527**. The injection position is always counted as if the frame has the maximal length. In the first step of the preparation for a transmission the injection takes place, and then in the second step, if some fields are configured to be shorter or omitted (for example DDLE or DDH or any other), the unused bits are discarded and only the remaining valid bits are shifted out.

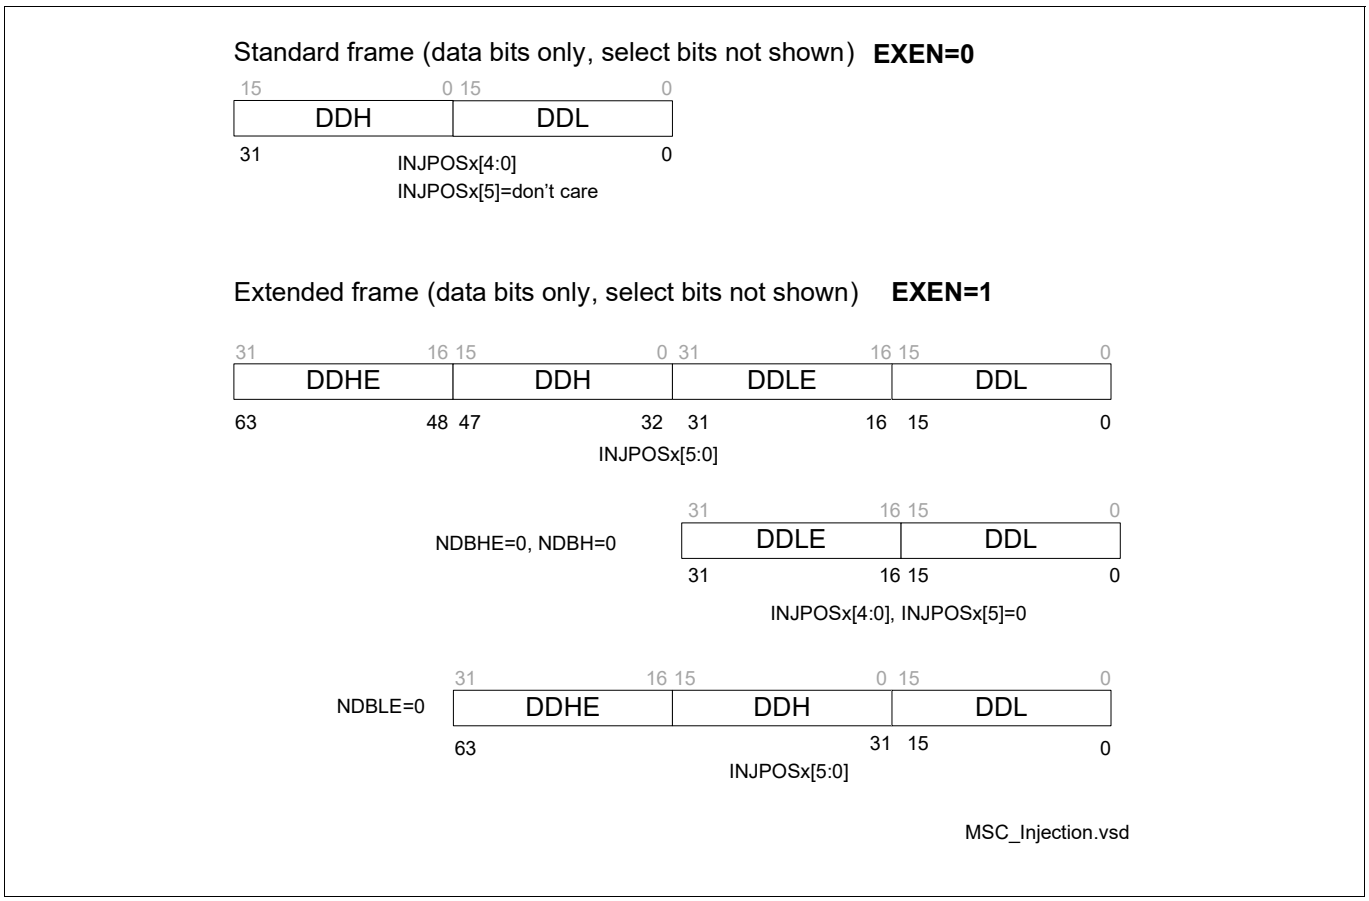

Figure 527 External Signal Injection

38.3.1.1.4 Transmission Modes

The downstream channel of the MSC makes it possible to select between two transmission modes:

- Triggered Mode, selected by DSC.TM = 0, or
- Data Repetition Mode, selected by DSC.TM = 1

Triggered Mode

In Triggered Mode, command frames or data frames are sent out as a result of a software event. When a frame transmission has been finished and no further frame transmission has been requested, the downstream channel returns to idle state and waits for the next frame transmission to be triggered by software.

Setting the DSC.TM bit triggers immediately a frame transmission using the values existing at that moment.

When the Downstream Command Register DC is written, the command pending bit DSC.CP becomes set and a command frame will be immediately started and sent out if the downstream channel is idle. If a data or command frame is currently processed and output, the command frame transmission is delayed, and started when the active downstream frame has been finished. The command pending bit DSC.CP becomes cleared by hardware.

If the downstream channel is idle and the data pending bit DSC.DP is set by writing bit ISC.SDP with 1, a data frame will be immediately started and sent out if the downstream channel is idle. If a data frame or a command frame is currently processed and output, the data frame transmission is delayed and started when the active downstream frame has been finished. The data pending bit DSC.DP becomes cleared by hardware.

A command frame always has priority over the data frame. This means that if both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first. Therefore, a pending data frame transmission will be delayed as long as no further command frame transmission is running or requested.

Figure 528 is a flow diagram of the Triggered Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be sent first, followed by the data frame (assuming no further command frame has been requested).

The type of the active frame that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current frame.

In Triggered Mode, the shift register loading event as described in **Section 38.3.1.1.2** occurs just before a command or data frame transmission is started.

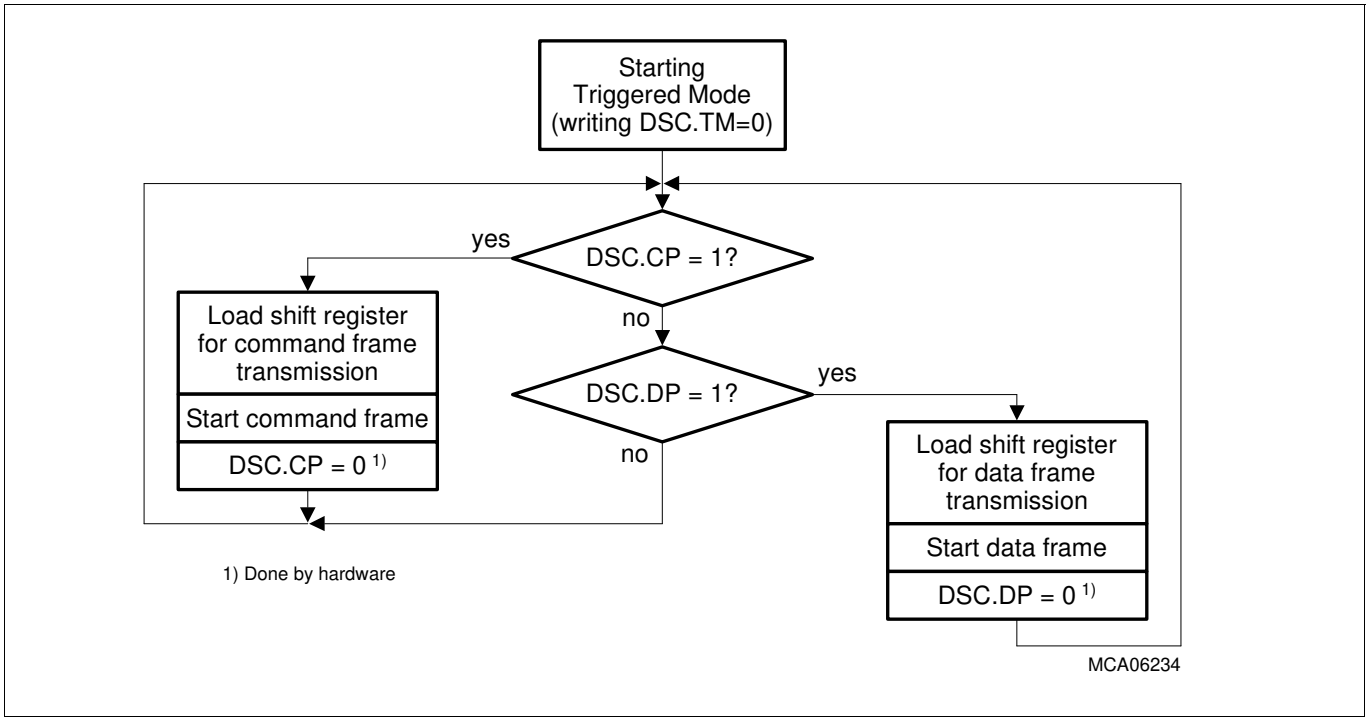

Figure 528 Triggered Mode Flow Diagram

Data Repetition Mode

In Data Repetition Mode, data frames are sent out continuously without any software interaction. In the time gap between two consecutive data frames, passive time frames can be inserted. The number of passive time frames to be inserted (0 to 15) is defined by bit field DSS.NPTF. The duration of data frame (t_{DF}) and passive time frames (t_{PTF}) is determined by the data frame parameters as described in **Equation (38.1)** and **Equation (38.2)**. These parameters determine the time reference points (TRP) at which a data, command or passive time frame is started (see diagram A in **Figure 529** and the **Note on Page 10**).

The automatic data frame generation is controlled by the data pending bit DSC.DP. This bit is set at the end of the last passive time frame if a command frame is running or starts at this TRP, overruling a data frame. DSC.DP is cleared by hardware when the pending data frame starts with transmission at the next TRP. Data Frames are always aligned to time reference points. This means they always start at a TRP. Passive time frames can be shortened. This is especially the case when command frames are inserted.

Continuous data frame transmission can be interrupted by insertion of command frames. Command frames are initiated by software. When the downstream command register DC is written, the command pending bit DSC.CP is set by hardware. CP = 1 indicates that the MSC starts a command frame at the next TRP, independently of whether a data frame (indicated by DSC.DP = 1) or passive time frame should be started with the next TRP. This means also that command frames are always aligned to time reference points.

The bit field **DSCE**.CDCM provides an option for automatic insertion of data frame between two consecutive command frames.

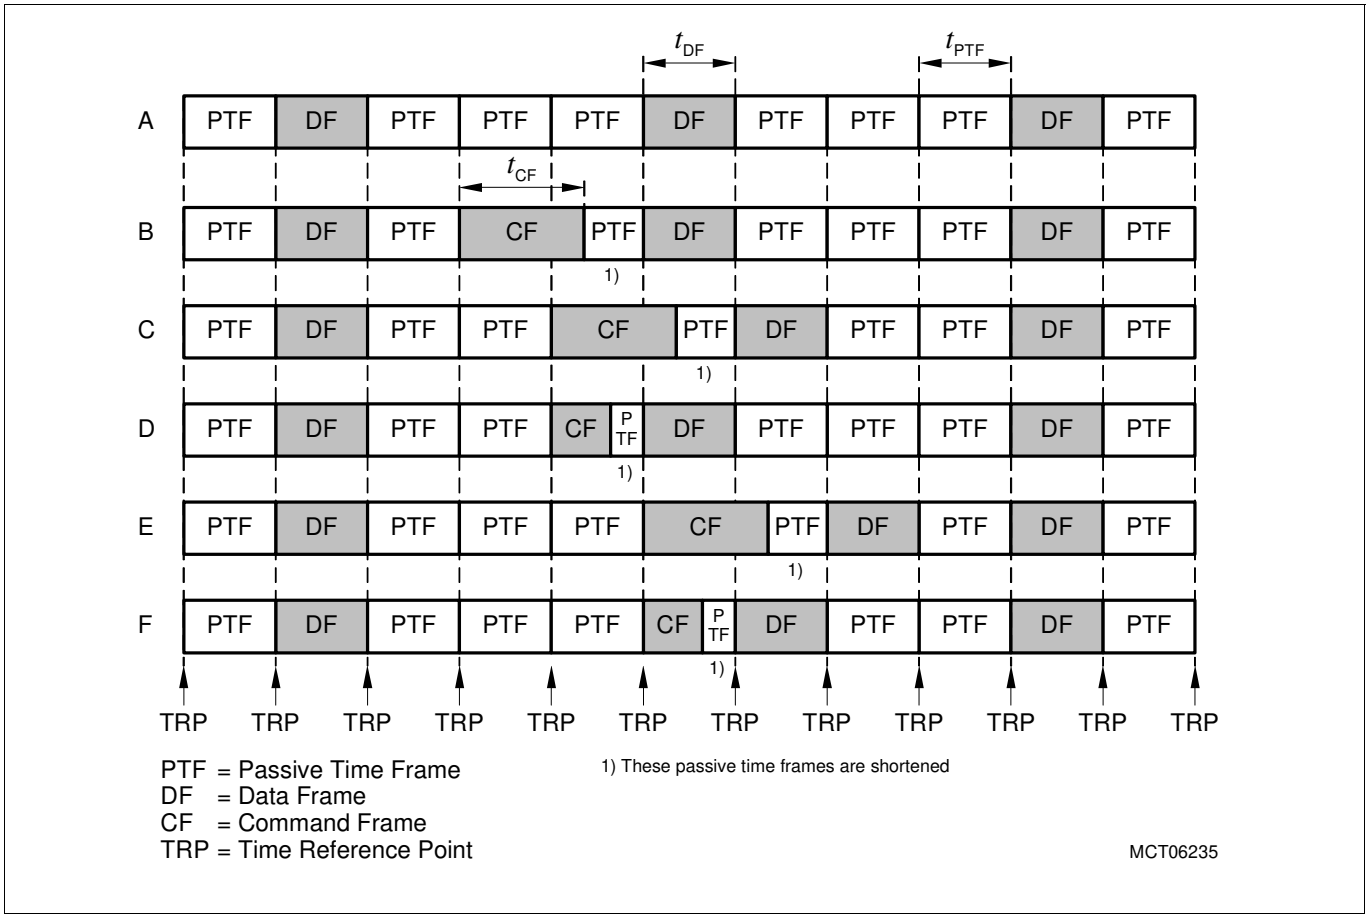

Figure 529 Data Repetition Mode Frame Examples with DSS.NPTF = 0011_B

Diagrams B to F in **Figure 529** show the command frame insertion in Data Repetition Mode.

In diagram B, a command frame has been requested during the first passive time frame after the data frame, and is inserted at the next TRP. In diagrams C and D, a command frame has been requested during the second passive time frame, and is inserted at the time reference point of the last nominal passive time frame.

When the command frame and data frame is not of the same length (this is the case in diagram B to F), a shortened passive time frame is inserted until the next TRP is reached. This ensures that the next data or normal passive time frame is again aligned to a TRP.

When the last passive frame is transmitted and in case of a conflict with command frame, DSC.DP becomes set by hardware. This triggers the start of a data frame when the next TRP is reached.

The type of the active frame (data or command frame) that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current data, command, or passive time frame.

As in Triggered Mode, the shift register loading event as described in **Section 38.3.1.1.2** occurs in Data Repetition Mode just before a TRP, this means shortly before a command or data frame transmission is started.

Passive Frame Counter in Data Repetition Mode

In Data Repetition Mode, a passive time frame counter DSS.PFC indicates how many time frames have been already transmitted after the last regular data frame occurrence. The passive time frame counter counts up from 0000_B to the value which has been written into bit field DSS.NPTF (number of passive time frames). DSS.PFC = 0000_B indicates that a data frame is requested for transmission.

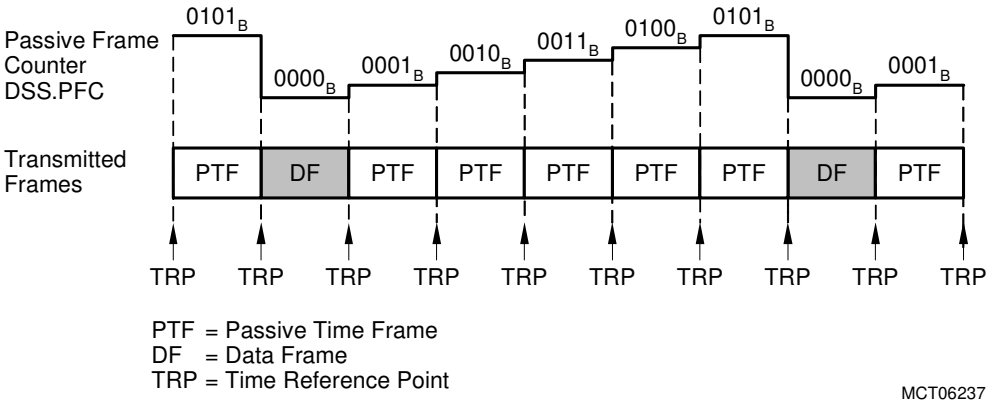

Figure 530 Passive Frame Counter Operation (with DSS.NPTF = 0101_B)

38.3.1.1.5 Downstream Counter and Enable Signals

During downstream channel operation, a 8-bit downstream counter DSS.DC is counting FCL shift clock periods. With the loading of the shift register, the downstream counter is reset to 00_H and started for counting up to the end of the downstream frame (end of passive phase).

In Triggered Mode, the downstream counter stops counting at the end of the passive phase and waits until a new downstream frame is started.

In Repetition Mode, the downstream counter does not stop at the end of the passive phase but is reset and starts counting up again with the next frame, independently whether a data frame, command frame, or passive time frame is started as next frame.

Figure 531 shows an example of downstream channel data frame transmission. In this example, the selection bit for the SRL active frame is enabled (ENSELL = 1), and the selection bit for the SRH active frame is disabled (ENSELH = 0). With loading of the shift register SRL/SRH, the downstream counter is reset and then starts counting up with each FCL clock until the end of the passive phase. ENL is set to high level at the beginning of the SRL active frame selection bit.

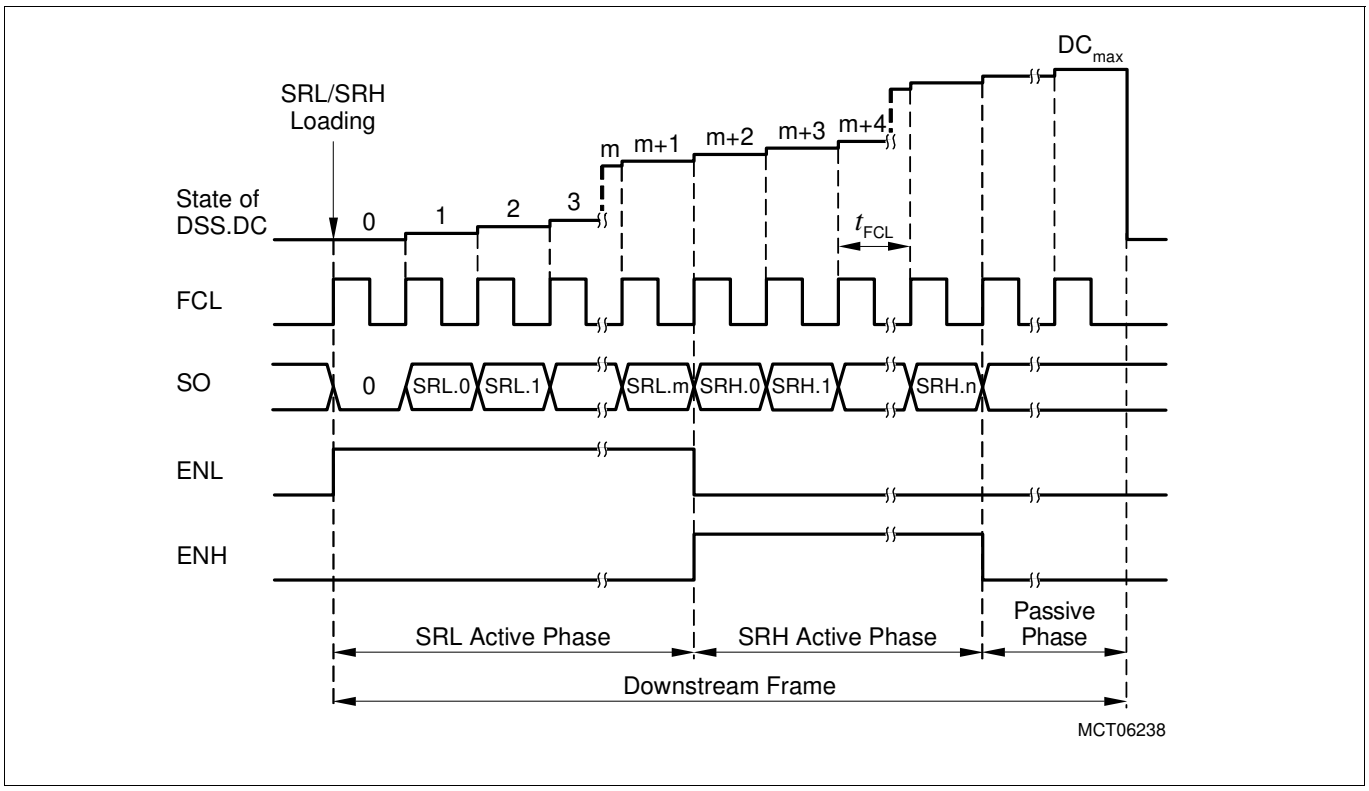

Figure 531 Shift Clock Counting: Data Frame with ENSELL = 1 and ENSELH = 0

When the selection bit for the SRL active frame is disabled (ENSELL = 0, see **Figure 532**), the loading of the shift register SRL/SRH (and reset of the downstream counter) occurs one FCL clock cycle before the first data bit SRL.0 is output. ENL is set to high level with the beginning of the first data bit SRL.0.

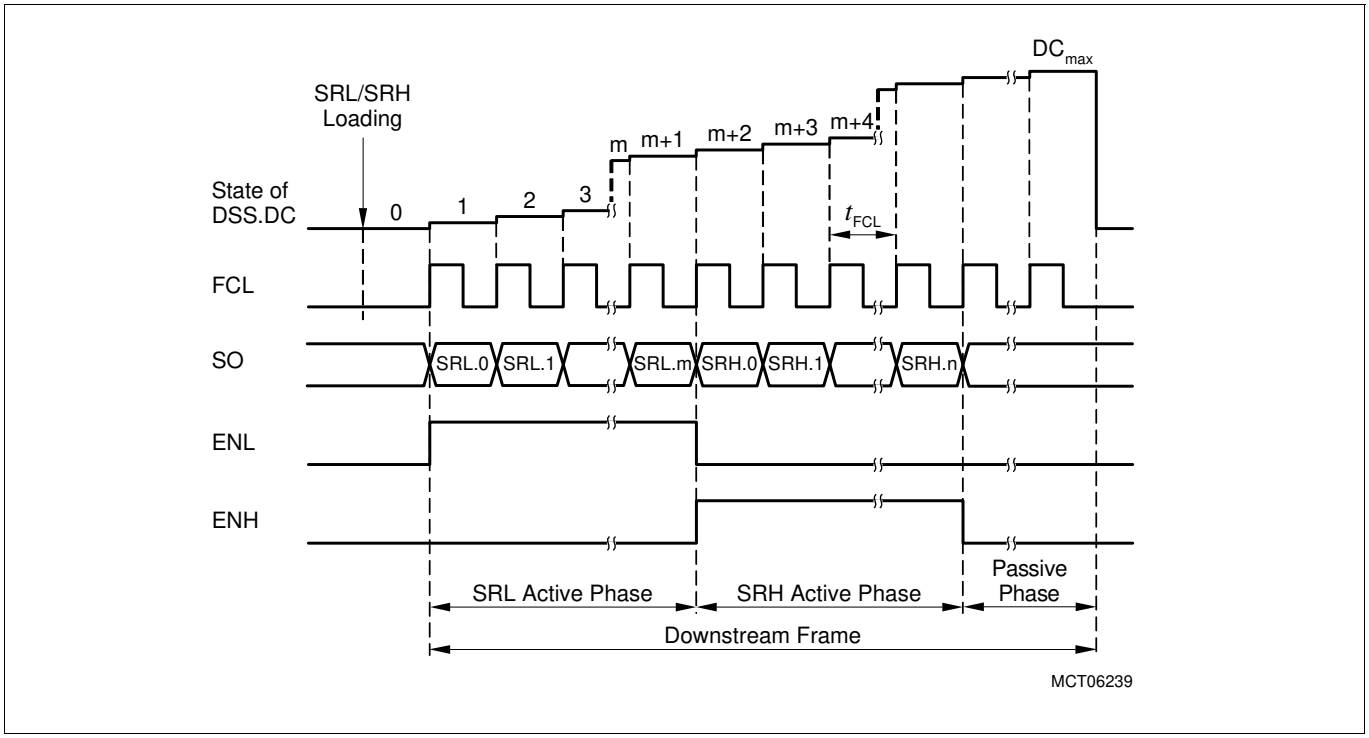

Figure 532 Shift Clock Counting: Data Frame with ENSELL = 0 and ENSELH = 0

38.3.1.1.6 Baud Rate

The baud rate of the downstream channel's serial transmission is defined by the frequency of the serial clock FCL, and is always $f_{MSC}/2$. The f_{MSC} generation is device specific and depends on the implementation of the MSC module. The clock generation is described on **Page 49**.

38.3.1.1.7 Abort of Frames

Only a reset condition of the device can abort a current transmission. The MSC module does not start a new frame transmission when the downstream channel becomes disabled, the suspend mode is requested, or the sleep mode is entered. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no Time Frame Finished Interrupt is generated any more.

38.3.1.2 Upstream Channel

The MSC upstream channel is an asynchronous serial receiver based on the standard asynchronous data transfer protocol. It is dedicated to receive a serial data stream from a peripheral device via its serial data input SDI, using two specific data frame formats.

Figure 533 is a block diagram of the MSC upstream channel.

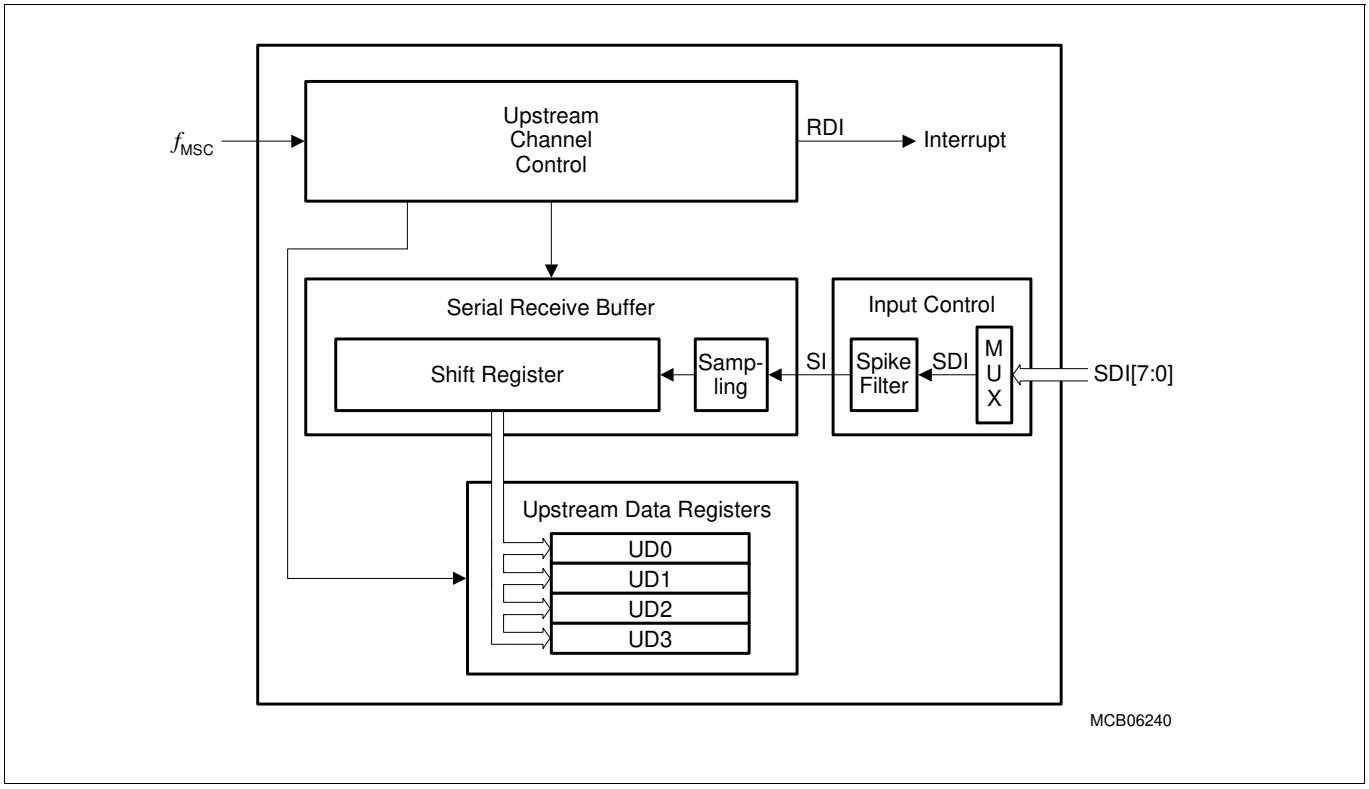

Figure 533 Upstream Channel Block Diagram

The incoming data at SI is sampled after it has been filtered for spikes. The detected logic states of the serial input are clocked into a shift register. After the complete reception of the serial data frame, the content of the shift register is transferred into one of the four data registers, and an interrupt can be generated optionally.

The reception baud rate is directly coupled to the module clock f_{MSC}, and can be within a range of $f_{MSC}/4$ up to $f_{MSC}/256$.

Note: If the ABRA block is used, fractional divider with a fractional ratio generates the upstream sampling rate, and in order to compensate the additional fractional divider jitter, the reception baud rate must be less than $f_{MSC}/10$, or $f_{MSC}/(8 \text{ to} 256)^* n/1024 < f_{MSC}/10$.

38.3.1.2.1 Data Frames

The asynchronous data frames used by the upstream channel include four basic parts:

1. One start bit, always at low level
2. An 8-bit data field D[7:0] with LSB first
3. An optional 4-bit address field A[3:0] with LSB first
4. One parity bit and two stop bits, that are always at high level

The receive interrupt is generated after the second stop bit, but its generation can be delayed by one bit time by setting the bit **USR**.SRDC.

As shown in **Figure 534**, the 16-bit upstream data frame includes an additional 4-bit address field. The upstream frame type is selected by bit USR.UFT.

- USR.UFT = 0: 12-bit upstream data frame selected
- USR.UFT = 1: 16-bit upstream data frame with 4-bit address field selected

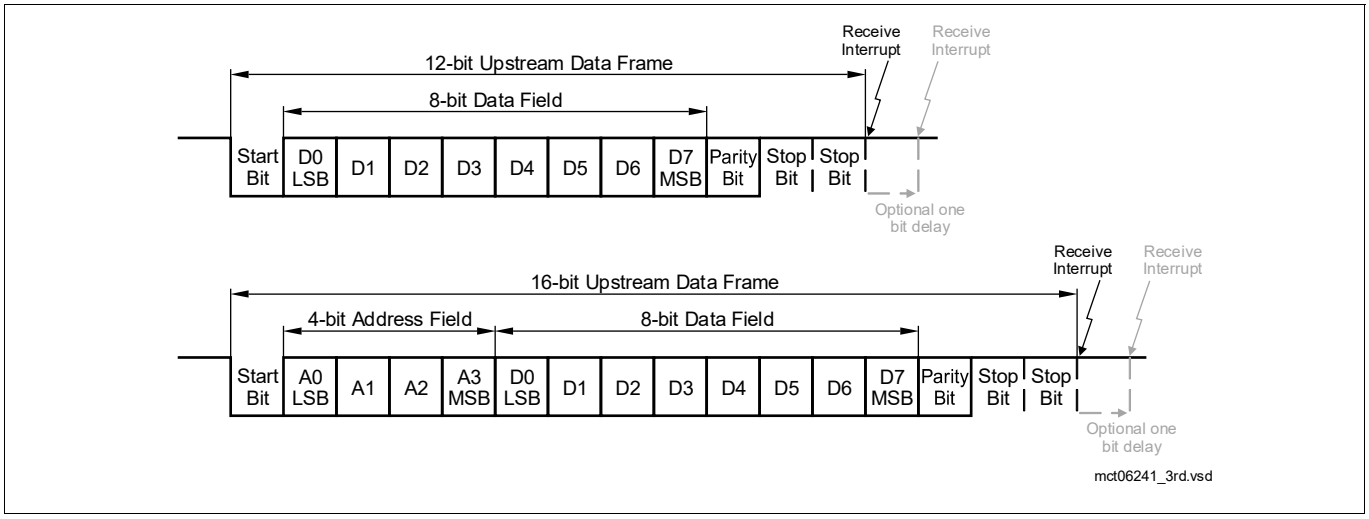

Figure 534 Upstream Channel Frame Types

38.3.1.2.2 Parity Checking

The incoming parity bit of the data frames can be checked by the upstream channel. When a parity error is detected, the parity error flag PERR in the related Upstream Data Register UDx is set. Note that a setting of the parity error flag PERR does not generate an interrupt. The PERR bits must be checked by software. The UDx registers also store the parity bit of the incoming data frame (UDx.P) and the parity bit that is generated internally (UDx.IPF).

Bit USR.PCTR determines the parity mode, even or odd, that is selected for parity checking. With USR.PCTR = 0, even parity mode is selected. Even parity means that the parity bit is set on an odd number of 1s in the data field (12-bit upstream data frame) or in the address plus data field (16-bit upstream data frame). With USR.PCTR = 1, odd parity mode is selected. In odd parity mode, the parity bit is set on an even number of 1s of the related data.

The parity checking logic in the upstream channel also controls whether start bit and the two stop bits of the upstream data frame are at correct logic level. If the start bit is not at low level and the two stop bits are not at high level at the end of the frame reception, the parity error flag UDx.PERR is set, too.

38.3.1.2.3 Data Reception

The reception of the upstream frame is started with a falling edge (1-to-0 transition) on the SI line. When the start bit is detected, serial reception is enabled and the receive circuit begins to sample the incoming serial data and

to buffer it in the receive buffer. After the second stop bit has been detected, the content of the receive buffer is transferred to one of four upstream data registers UDx. The receive circuit then waits for the next start bit (1-to-0 transition) at the SI line. When the content of the receive buffer has been transferred to UDx, the valid bit UDx.V is set by hardware, and a receive interrupt can be generated, independent if PERR occurred or not.

The data reception mechanism does not involve destructive read mechanisms, that is reading the UDx registers does not change any bits automatically.

*Note: The SI input line is the filtered non-inverted (OCR.ILP = 0) or inverted (OCR.ILP = 1) SDI input signal. The SI input signal selection is described on **Page 28**).*

Frame Reception with Address Field

Frame reception for a 16-bit data frame (see **Figure 535**) is selected by USR.UFT = 1. When the content of the receive buffer has been received completely, it is transferred to one of the four UDx registers. The two most significant address bits A[3:2] of the received 4-bit address field select the number x of register UDx in which the received frame content is stored. Register UDx is loaded with the two least significant address bits A0 and A1 (UDx.LABF), the 8-bit data (UDx.DATA), the received parity bit (UDx.P), the calculated parity bit (UDx.IPF), and the parity checking result (UDx.PERR). Finally, the valid bit UDx.V is set to indicate that the UDx register contains valid data.

The current state of the frame reception is indicated by the content of an upstream counter that is readable via bit field USR.UC. The upstream counter is a 5-bit counter that counts the upstream frame bits during reception. As shown in **Figure 535**, the upstream counter is loaded with 10000_B at the detection of a start bit. It counts down and is again at 00000_B when the second stop bit has been detected and the frame reception is finished.

The state of the serial input data line SI is sampled in the middle of a bit cell and shifted into the receive buffer at the end of the bit cell. The frequency of the shift clock f_{BR} depends on the selected baud rate (see **Page 24**).

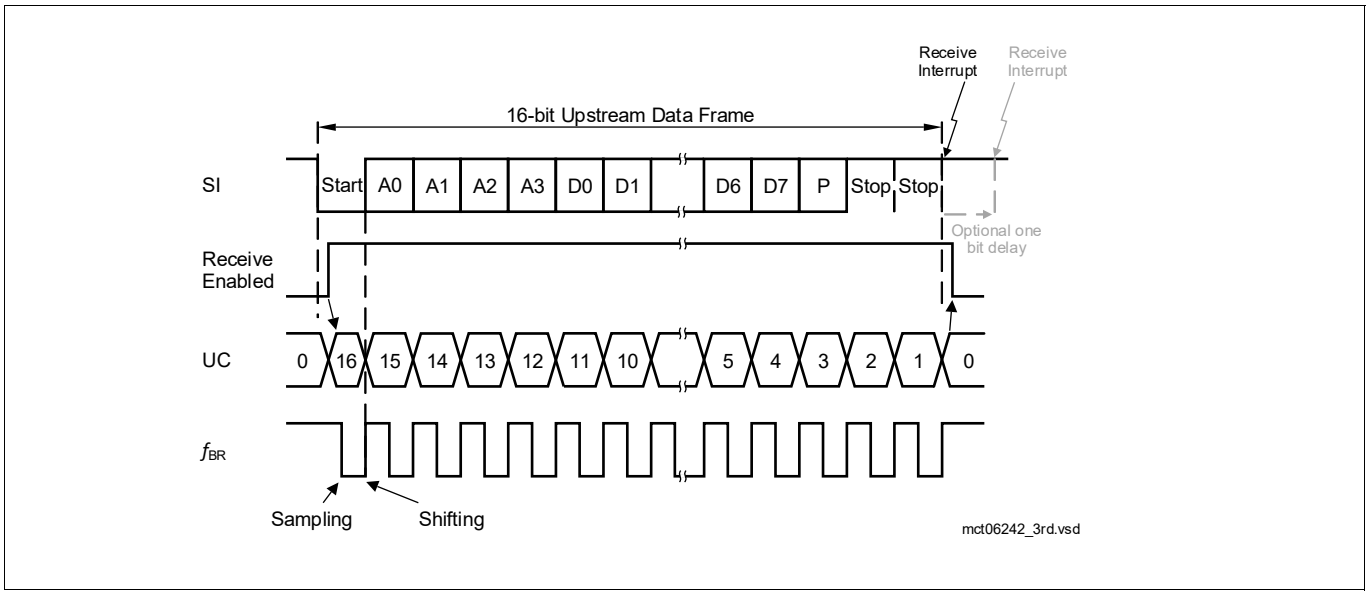

Figure 535 16-bit Upstream Reception

Data Reception without Address Field

Frame reception for a 12-bit data frame is selected by USR.UFT = 0. The reception scheme is comparable with that of the 16-bit data frame reception but there are a few differences:

- The upstream counter is initially loaded with 01100_B.
- The received frame content is always stored in register UD0.

- Bit field UD0.LABF is always loaded with 00_B when the frame is stored.

38.3.1.2.4 Baud Rate

The baud rate of the upstream channel is derived from the MSC module clock f_{MSC}. **Figure 536** shows the configuration of the upstream channel clock circuitry.

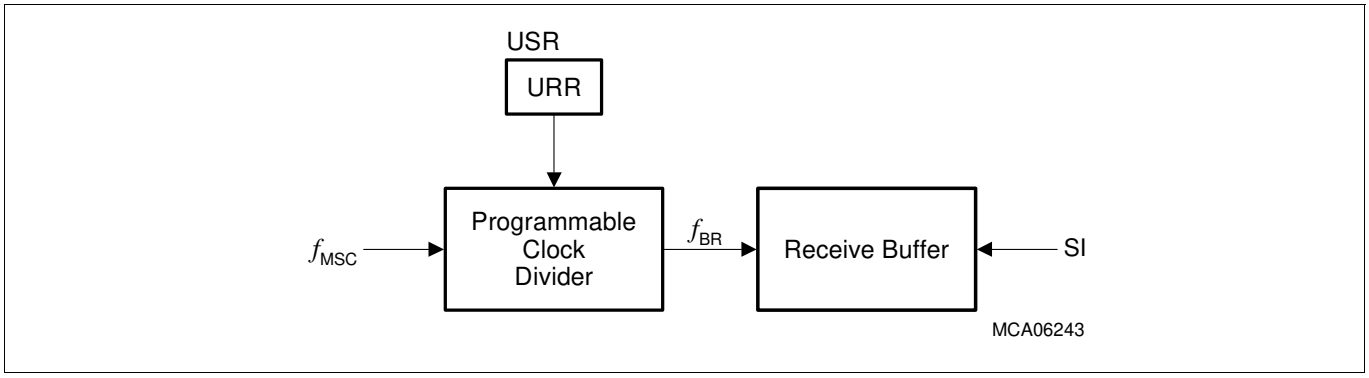

Figure 536 Upstream Channel Clock Circuitry

The serial data input SI is evaluated with the baud rate clock f_{BR} in the middle of each bit cell, and latched in case of a data bit. The baud rate clock f_{BR} is derived from f_{MSC} by a programmable clock divider. The frequency of f_{BR} determines the width of a received bit cell and therefore the baud rate for the received data. The content of bit field USR.URR selects the baud rate according **Table 338**. The resulting baud rate formula is:

$$\text{Baud rate}_{\text{MSC Upstream Channel}} = \frac{f_{MSC}}{DF} \quad (38.3)$$

Table 338 Upstream Channel Divide Factor DF Selection & Baud Rate

USR.URR	Divide Factor DF	Baud Rate
000_B	Reception disabled	–
001_B	4	$f_{MSC}/4$
010_B	8	$f_{MSC}/8$
011_B	16	$f_{MSC}/16$
100_B	32	$f_{MSC}/32$
101_B	64	$f_{MSC}/64$
110_B	128	$f_{MSC}/128$
111_B	256	$f_{MSC}/256$

Note: With the USR.URR = 000_B the upstream channel is disabled and data reception is not possible.

The content of bit field USR.URR determines the operation of an internal sampling reload counter that is clocked with f_{MSC}. **Figure 537** shows the operation of the sampling counter at the beginning of an upstream frame with a divide factor DF of 8 (USR.URR = 010_B is equal to DF = 8) which means eight sampling clocks per each frame bit cell.

When the upstream channel is in idle state, it waits for a falling edge (1-to-0 transition) at SI. Therefore, the sample counter starts counting up and is reset when the selected divide factor DF as shown in **Table 338** is reached. In the middle of the sampling counter's count range, the logic state at SI is evaluated and, in case of a data bit, latched in the receive buffer's shift register. With the reload of the sampling counter, the shift register is shifted by one bit position.

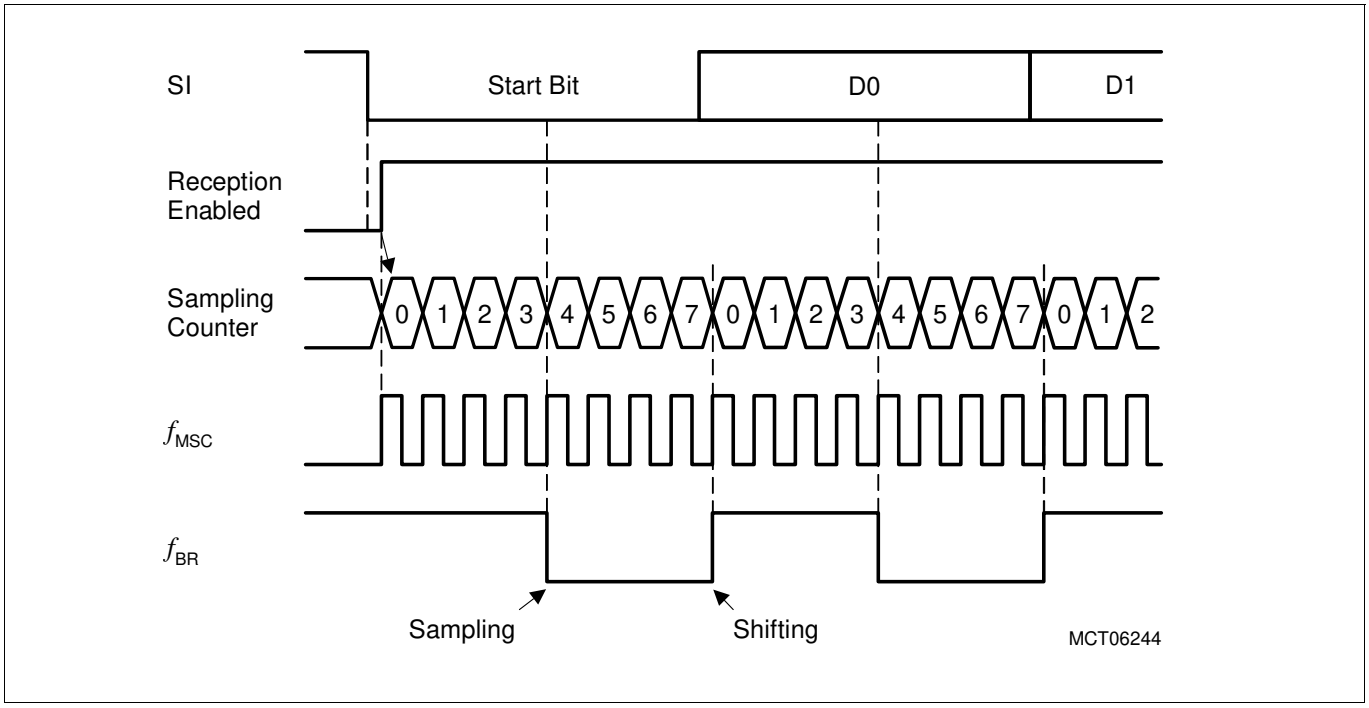

Figure 537 Upstream Channel Sampling with URR = 010_B

38.3.1.2.5 Spike Filter

The upstream channel input line SDI is sampled using a built-in spike filter with synchronization stage, both clocked with f_{MSC}. The spike filter is a chain of flip-flops with a majority decision logic (2 out of 3). A sampled value that is found at least twice in three samples is taken as data input value for SI.

38.3.1.2.6 Upstream Timer

The upstream timer monitors the time interval between two subsequent upstream frames. The timer reloads its starting values from the register **USCE** and starts counting downwards. If the time interval between two frames is longer than allowed, the counter reaches the value of zero, raises an upstream timer interrupt and stops counting. The counter reloads and starts counting on four events:

- Enabling of the MSC module after reset via **CLC**.DISR
- Resetting the module
- Writing the bit fields **USCE**.USTOPRE or **USCE**.USTOVAL per software
- Detecting the falling edge of the start bit of a frame

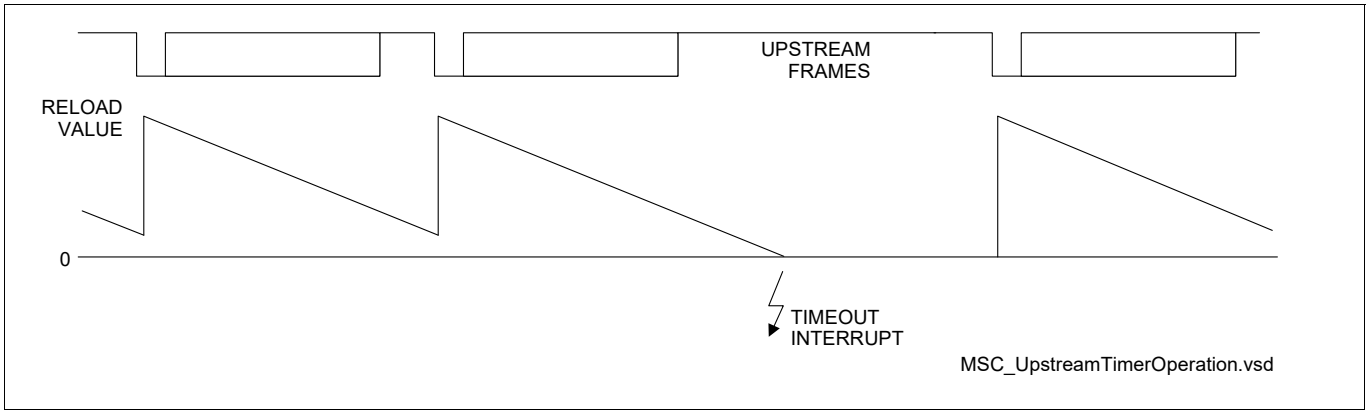

Figure 538 Upstream Timer Operation

The upstream watchdog timer counts bit times. The time window in which the next upstream frame must occur can be calculated according to the formula:

Time-out = BitTime * $2^{(USTOPRE+1)}$ * (USTOVAL+1)

38.3.1.3 I/O Control

The types of I/O control logic for the MSC module I/O lines are shown in **Figure 539**. The downstream channel generates five output signals that control eight MSC module outputs, split into four chip select outputs, two clock outputs, and two serial data outputs. The upstream channel has one input signal.

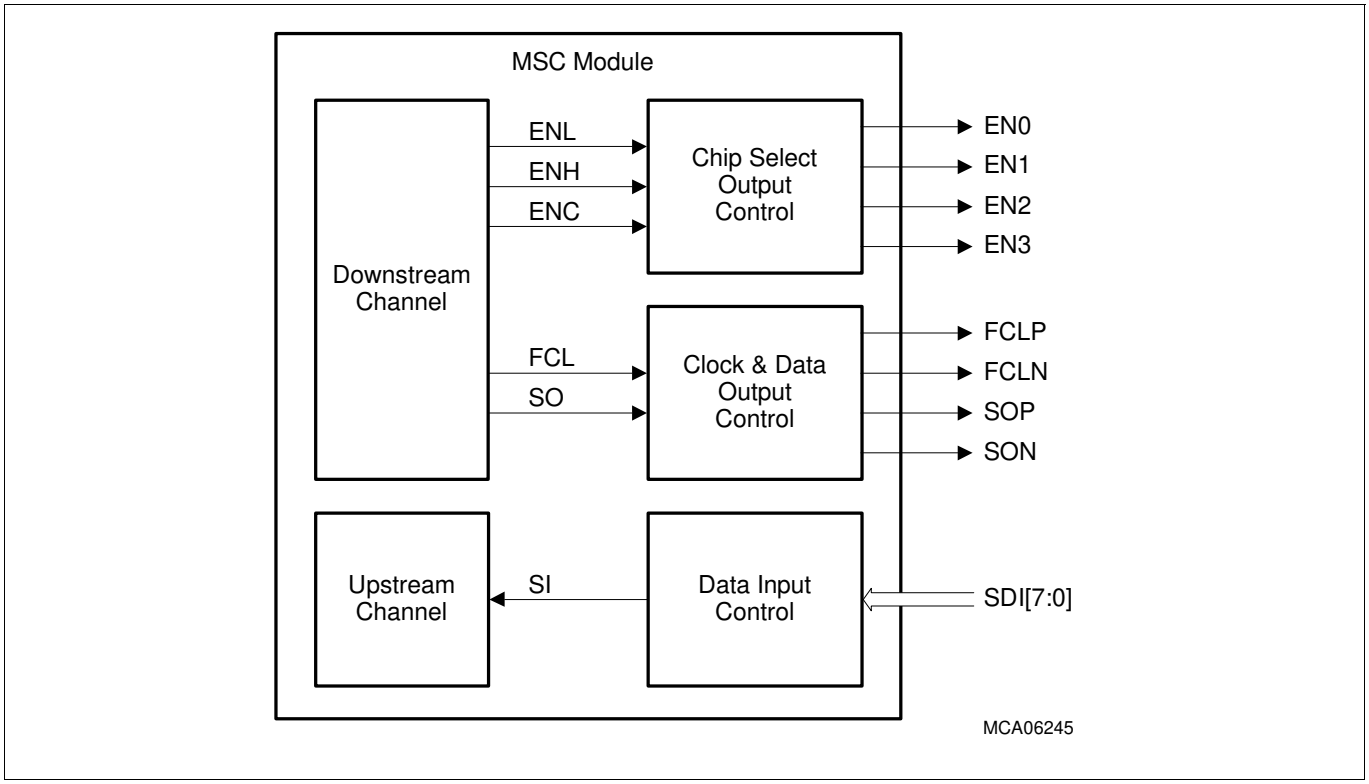

Figure 539 I/O Control

The MSC module I/O signals is controlled by bit fields that are located in the Output Control Register OCR.

38.3.1.3.1 Downstream Channel Output Control

As shown in **Figure 524** and **Figure 525**, the active phases during downstream channel operation are indicated by three enable signals:

- ENL indicates the SRL active phase of a data frame
- ENH indicates the SRH active phase of a data frame
- ENC indicates the active phase of a command frame

The chip select output control logic of the MSC uses a signal compressing scheme (similar to the interrupt request compressing scheme in **Figure 547**) that allows each of the three enable signals to be directed via a 2-bit selector to one of the four chip enable outputs EN[3:0]. This also makes it possible to connect more than one internal enable signal (ENL, ENH, ENC) to one chip enable output ENx. Three bit fields in register OCR (CSL, CSH, and CSC) determine which chip enable output becomes active on a valid internal enable signal.

In the MSC, enable signals are high-level active signals. If required in a specific application, all chip enable outputs ENx can be assigned for low-level active polarity by setting bit OCR.CSLP.

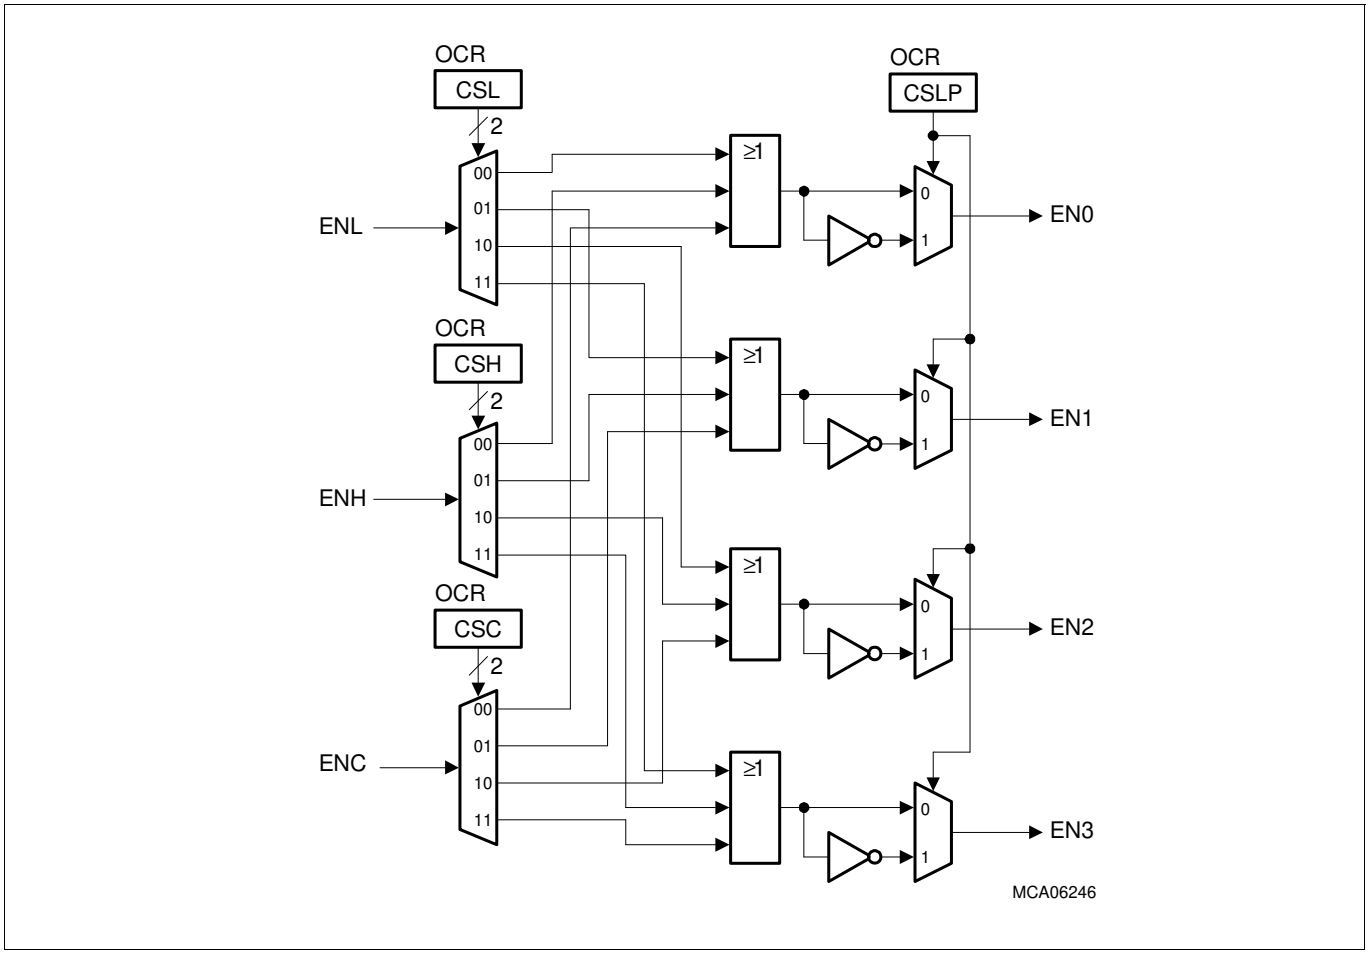

Figure 540 Downstream Channel: Chip Enable Output Control

At the MSC downstream channel, the internal serial clock output FCL and data output line SO are available outside the MSC module as two signal pairs with inverted signal polarity, FCLP/FCLN and SOP/SON. Both, clock and data outputs, are generated from the module internal signals FCL and SO according to **Figure 541**.

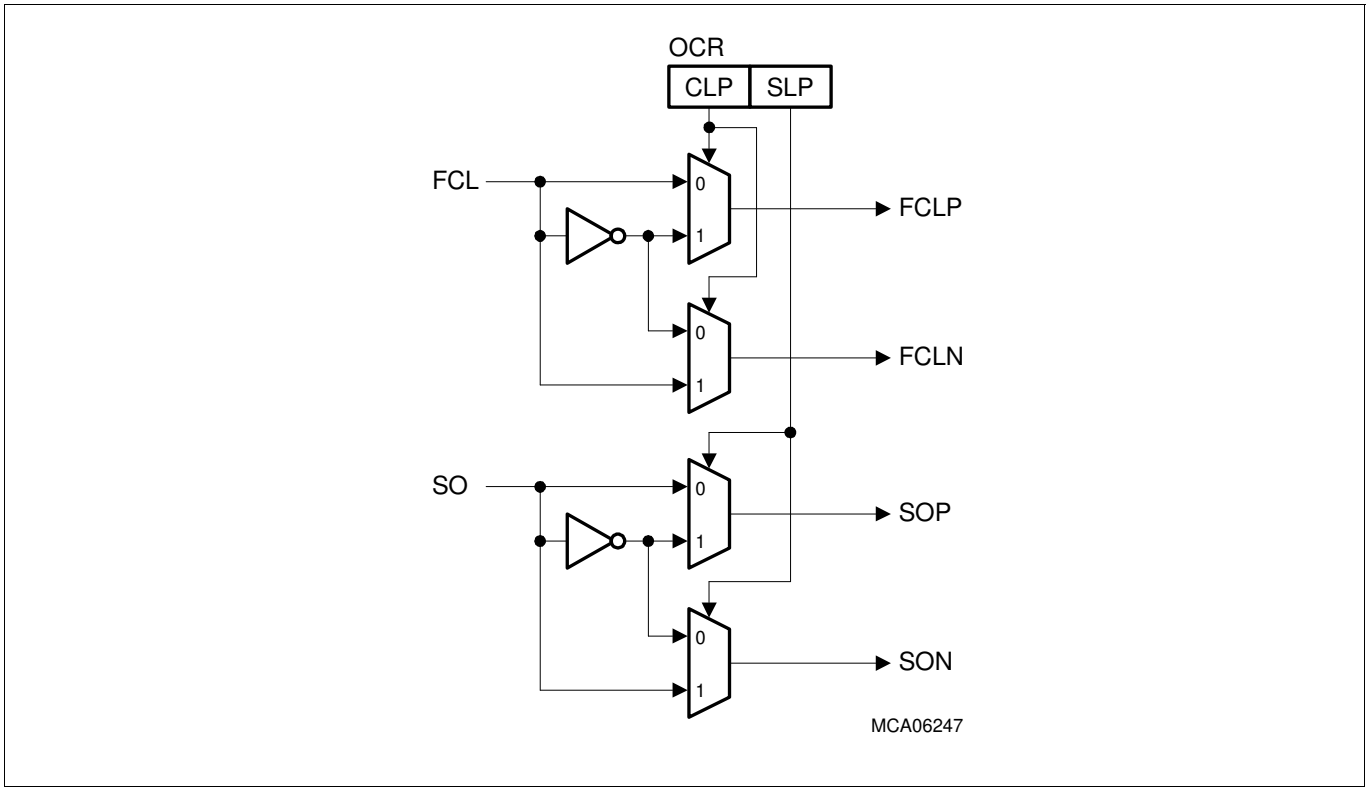

Figure 541 Downstream Channel: Clock and Data Output Control

With OCR.CLP = 0, FCLP has identical and FCLN has inverted polarity compared to FCL. Setting OCR.CLP, exchanges the signal polarities of FCLP and FCLN. An equivalent control capability is available for the SOP and SON data outputs (controlled by OCR.SLP).

One additional control capability not shown in **Figure 541** is available for the FCL signal. With OCR.CLKCTRL = 1, the FCL clock signal will always be generated, independently whether a downstream frame is currently transmitted or not. If OCR.CLKCTRL = 0, FCL becomes only active during the active phases of data or command frames (not during passive time frames).

38.3.1.3.2 Upstream Channel

As shown in **Figure 542**, the MSC upstream channel can be connected to up to eight SDI[7:0] serial inputs. Bit field OCR.SDISEL selects one out of these input lines (input signal SDI). If OCR.ILP = 0, SDI is directly connected to the serial receive buffer input SI. If OCR.ILP = 1, SDI is connected to input SI via an inverter.

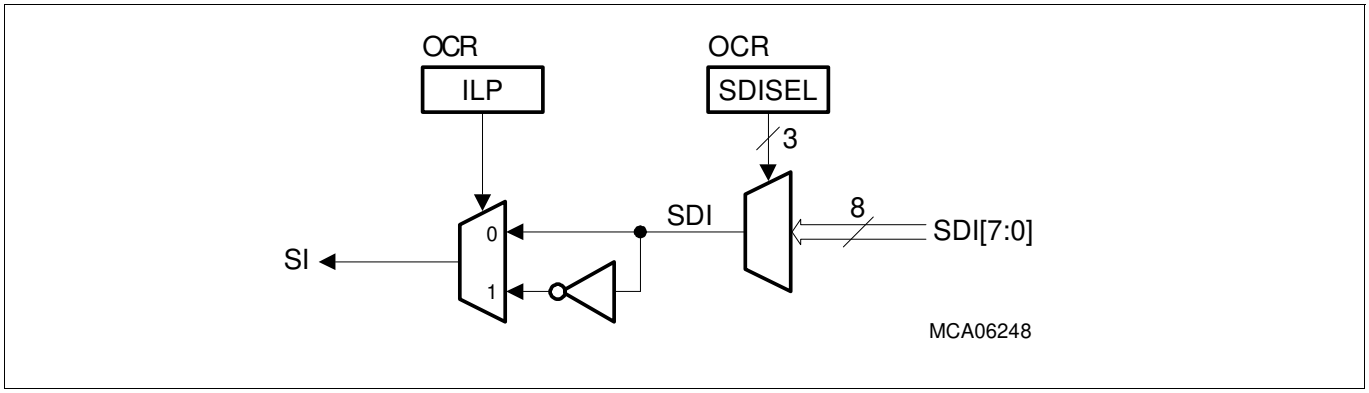

Figure 542 Upstream Channel Serial Data Input Control

38.3.1.4 MSC Interrupts

The MSC module has seven interrupt sources and five service request outputs. A service request output is able to generate interrupts (controlled by a service request control register) or DMA requests. The service request output assignment, interrupt or DMA request, is specific for each microcontroller that is using the MSC. In this section, the term “interrupt request” has the meaning of “service request” that is able to handle interrupt or DMA requests.

Each interrupt source is provided with a status flag, enable bit(s) with software set/clear capability, and an interrupt node pointer. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag that is located in the Interrupt Status Register ISR. All interrupt status flags can be set or cleared individually by software via the interrupt Set Clear Register ISC. Software-controlled interrupt generation can be initiated by setting the interrupt status flag of the corresponding interrupt. Each interrupt source can be enabled or disabled individually. When an interrupt event is enabled, a 2-bit interrupt node pointer determines which of the service request outputs will be activated. See **Figure 547**.

Table 339 shows the seven MSC interrupt sources.

Table 339 MSC Interrupt Sources

Interrupt Type	Generated by
Data frame interrupt	Downstream Channel
Command frame interrupt	
Time frame finished interrupt	
Receive data interrupt	Upstream Channel
Upstream Time-out Interrupt	
Sync FIFO overflow	ABRA Block
Sync FIFO underflow	

38.3.1.4.1 Data Frame Interrupt

A data frame interrupt can be generated when either the first or the last data bit of the downstream channel is shifted out and becomes available at the SO output line (see also **Figure 525**). Bit ICR.EDIE selects which case is selected.

Note: If ICR.EDIE = 10_B, an interrupt at the first data bit is only generated if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active.

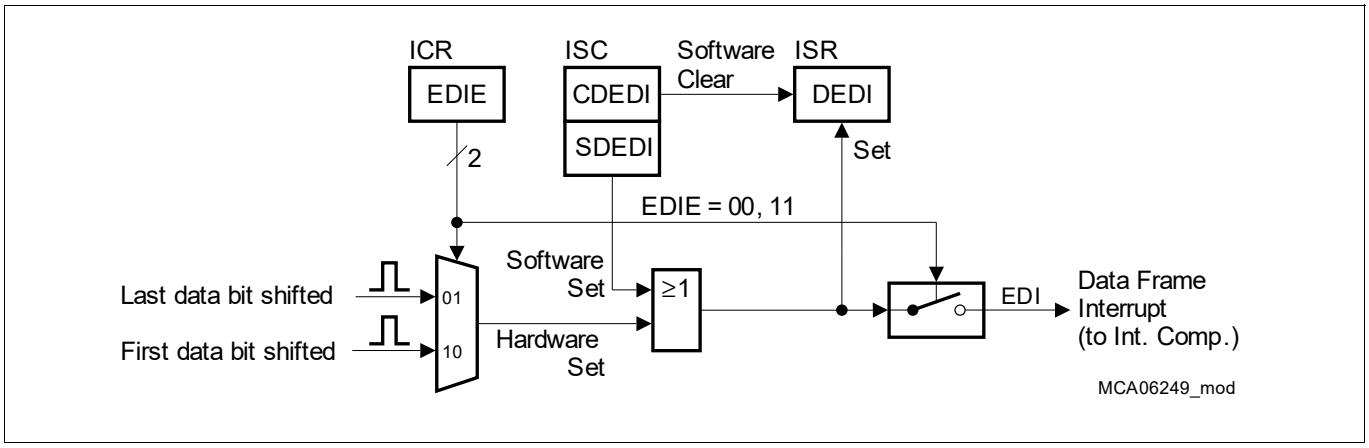

Figure 543 Data Frame Interrupt Control

38.3.1.4.2 Command Frame Interrupt

A command frame interrupt can be generated at the end of a downstream channel command frame, directly after the active phase, see also **Figure 524**.

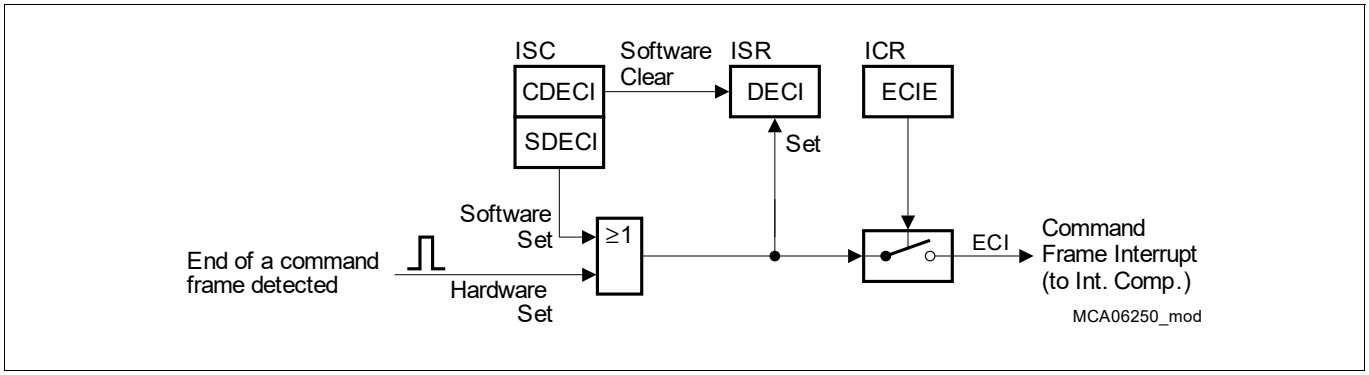

Figure 544 Command Frame Interrupt Control

38.3.1.4.3 Time Frame Finished Interrupt

A time frame finished interrupt can be generated at the end of a downstream channel passive phase.

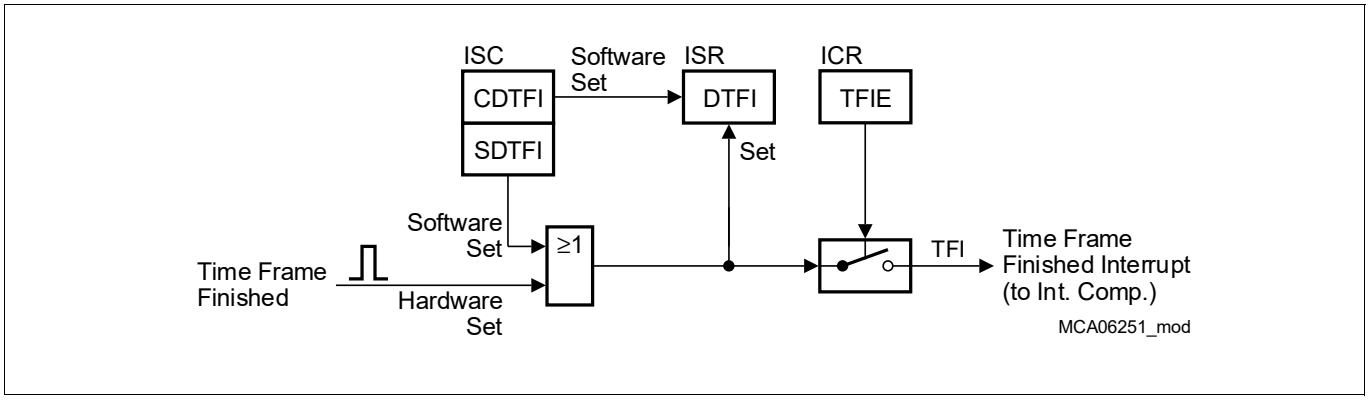

Figure 545 Time Frame Finished Interrupt Control

38.3.1.4.4 Receive Data Interrupt

Whenever the upstream channel receives data in registers UDx (x = 0-3), the MSC is able to generate an interrupt. Three interrupt generation conditions can be selected for the receive data interrupt:

- Each update of UDx (x = 0-3) generates a receive data interrupt.
- Each update of UDx (x = 0-3) generates a receive data interrupt when the updated value is not equal 00_H.
- Only an update of register UD3 generates a receive data interrupt.

The selection of the interrupt generation condition is controlled by bit field ICR.RDIE. Setting ICR.RDIE = 0 disables the receive data interrupt in general. ISR.URDI is the interrupt status flag that can be set or cleared when writing bits ISC.SURDI or ISC.CURDI with a 1. If the fractional divider is used, then the software should clear the URDI flag by using ISC.CURDI with a delay of one bit time after the interrupt signal has been generated. The same applies to clearing the UDx.V flag via UDx.C. Otherwise, due to the latencies introduced by the fractional divider, the clear may fail.

The receive interrupt is generated either after the second stop bit, or delayed for one bit time by setting the **USR**.SRDC, as shown in **Figure 534**.

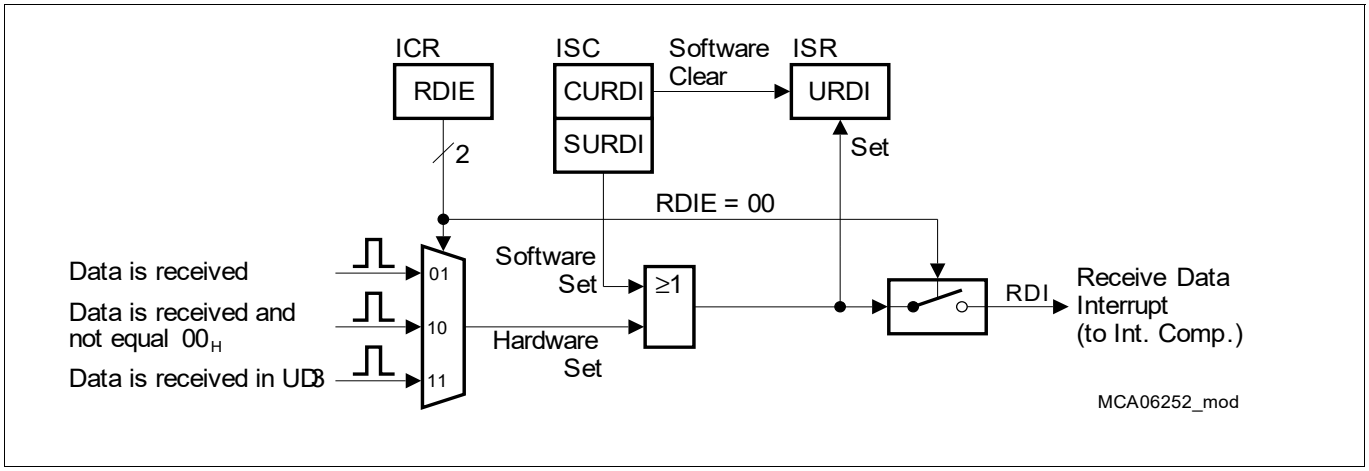

Figure 546 Receive Data Interrupt Control

38.3.1.4.5 Interrupt Request Compressor

The interrupt control logic of the MSC uses an interrupt compressing scheme that allows high flexibility in interrupt processing. The seven interrupt sources can be directed to five service request outputs SR[4:0] as shown in the **Figure 547**. This makes it possible to connect more than one interrupt source to one interrupt output SRx.

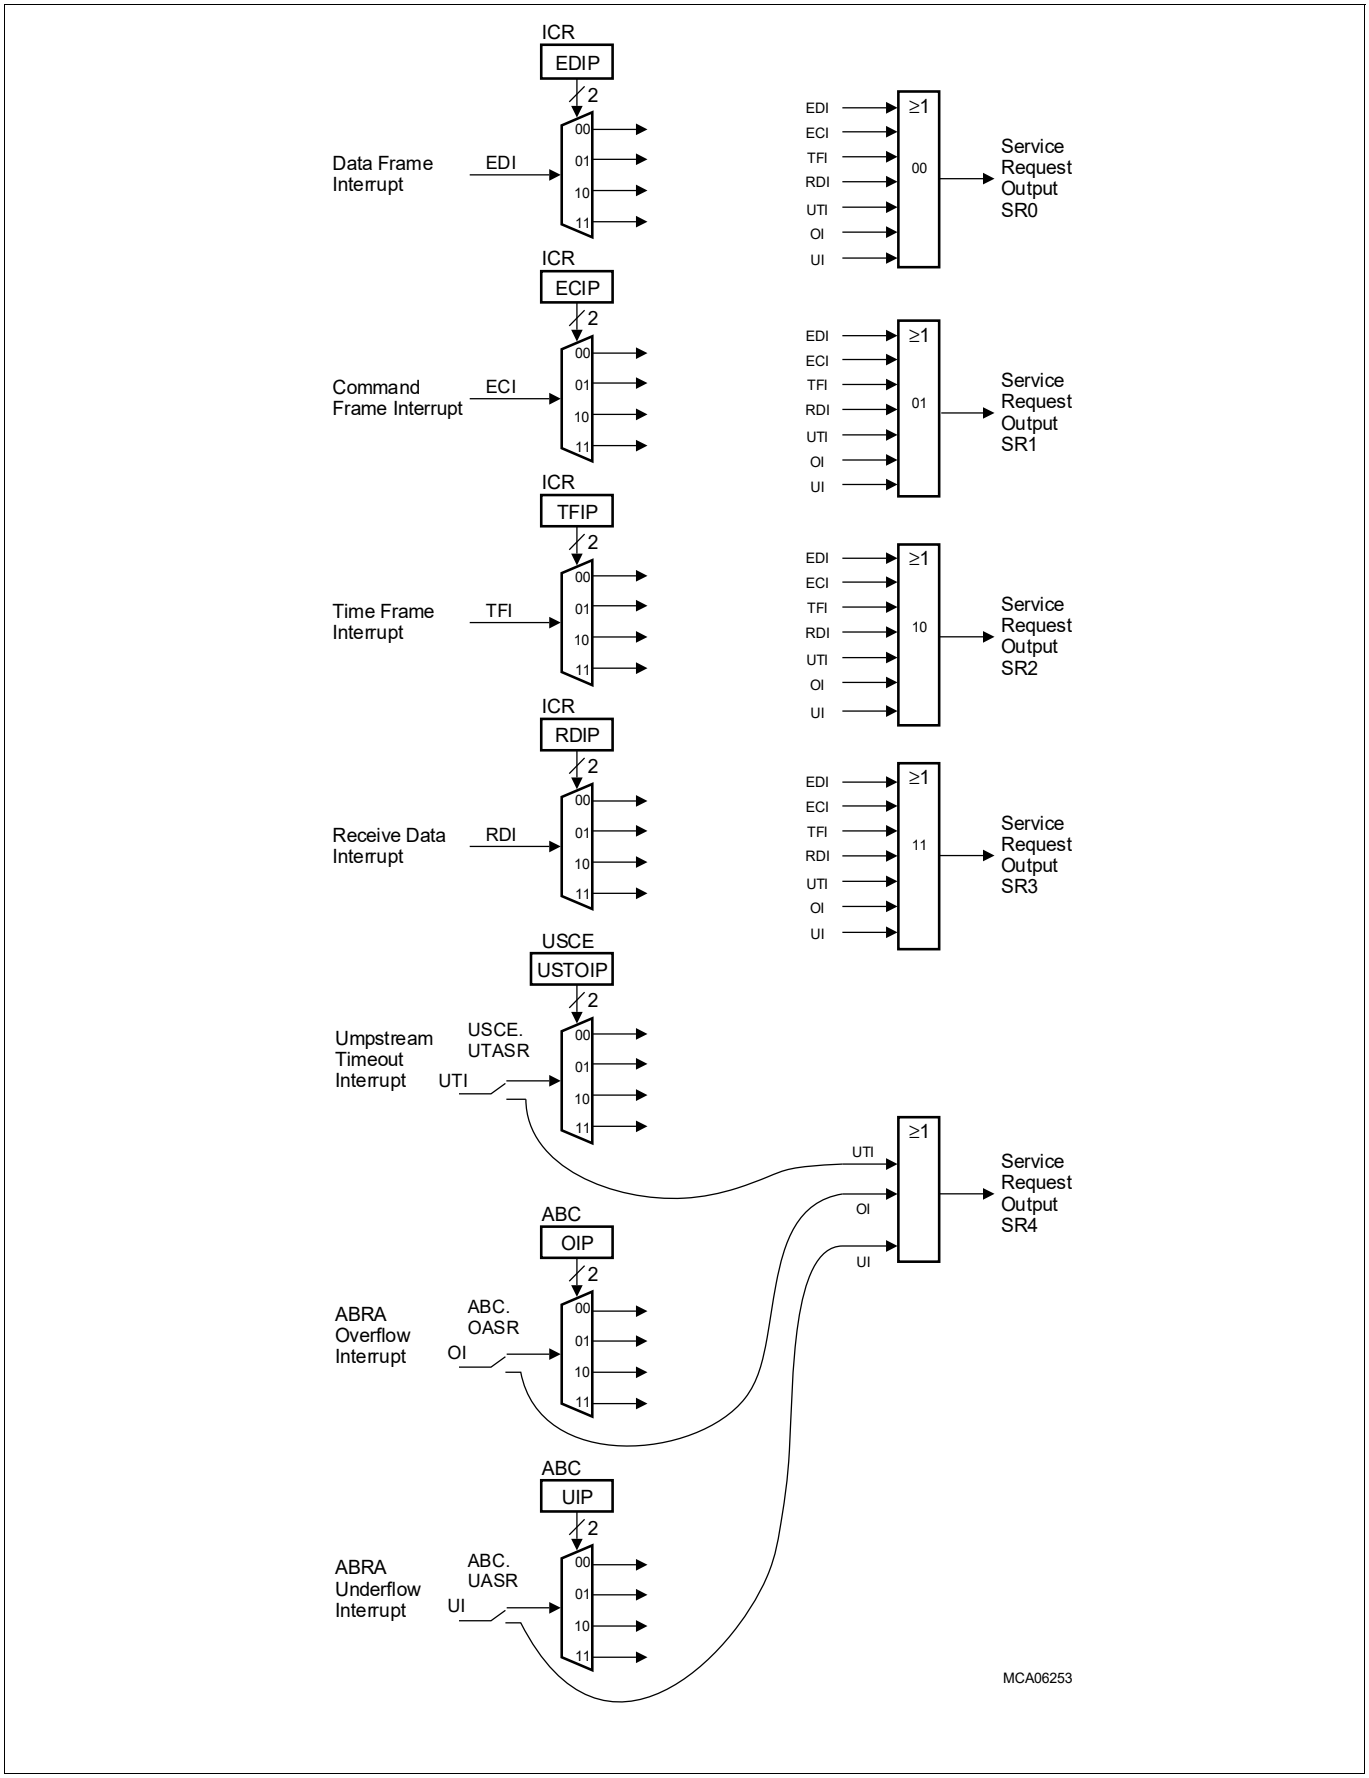

Figure 547 MSC Interrupt Request Compressor

38.3.2 CX (Command Extension) Mode

Command Extension Mode overrides the following standard features of the MSC protocol:

- Command Frames:
  - Instead of 32 bits, Command Frames contain up to 2x32 bits and two select bits set to “1”, one before each 32-bit block. One command Frame now contains two commands, both with same length
  - The bit field **DSC**.NBC is reused as is, and defines the length of both commands
  - The command chip select ENC is active during the whole active phase of the frame
  - The passive phase extension is lenghtened to cover 2 to 127 bit times, see bit field **DSTE**.PPCE and **DSTE**.PPCEM. This is valid only in ABRA active mode. When ABRA bypassed, the command passive phase is constant and fixed to two. The PPCEM bit is needed and extends the command passive phase only in the CX mode (CX=1), where a command can be up to 64 bit long. If CX=0. PPCEM bit is ignored and treated as always 0.
- Data Frames:
  - Instead of activating two enable signals ENL and ENH, Data Frames activate only one Enable Signal, ENL
  - It is responsibility of the user to mandatory activate the select bits in the data frames with **DSC**.ENSELL and ENSELH, in order to ensure the same frame structure of the command and the data frames.
  - the existing data frame length bit fields are reused as they are: **DSC**.NDBL, **DSC**.NDBH, **DSCE**.NDBLE, and **DSCE**.NDBHE. It is the user responsibility to program them symmetrically if required, and program the **DSCE**.EXEN, for example to set the same data frame length as the command frame length, which is the standard use-case.
  - The passive phase of the data frames is reused as is
- Baud Rate: it is possible to configure the MSC module to drive with maximal speed of 80 MBaud. The divider **DSTE**.NDD divides the module kernel frequency. When NDD=0 the module runs with 100MHz, with NDD=2 with 33MHz.

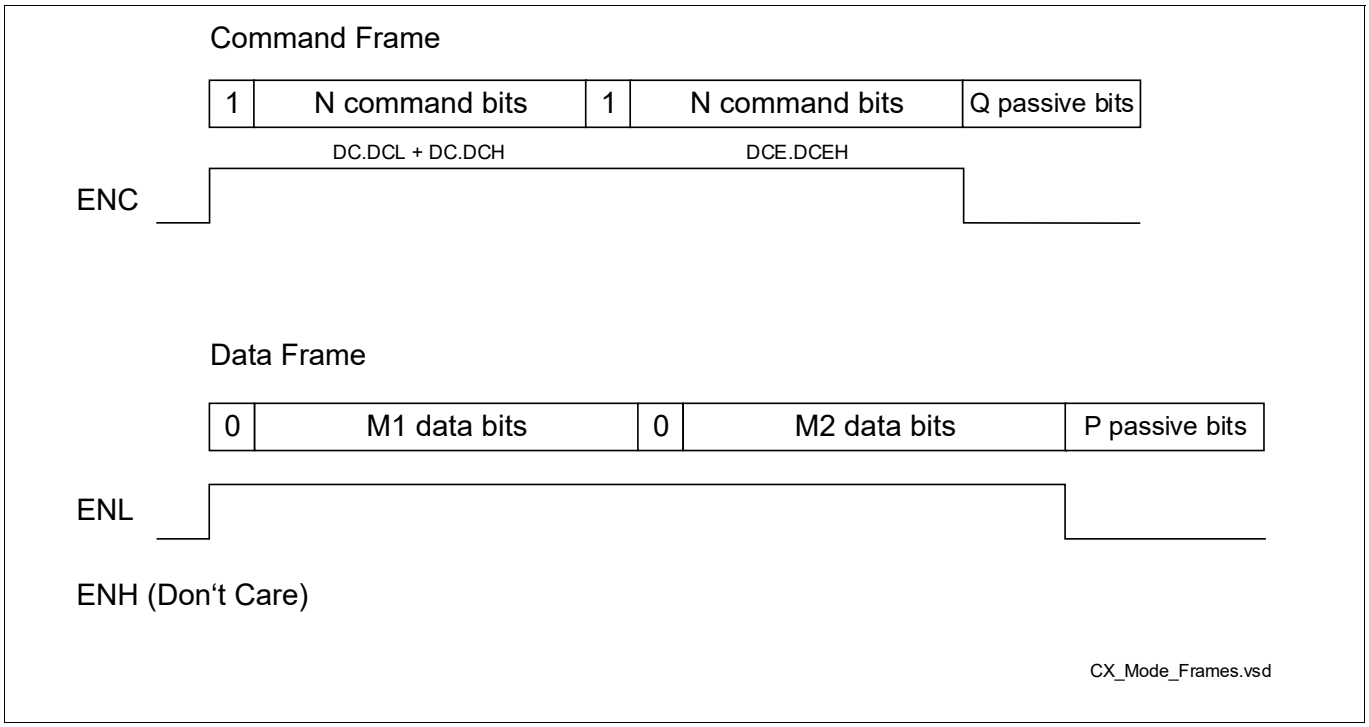

Figure 548 MSC Frames in CX mode

This is the list of the additional bit fields and registers correlated to CX mode.

- **DSTE**.CX bit, activating the CX mode
- **DSTE**.FM bit, activating the fast mode (up to 80MBaud)
- **DSTE**.UL1 protection bit, for unlocking the CX and FM bits for one clock cycle
- **DSTE**.PPCE extended by one bit, in order to lenghten the passive phase of the command frame
- **DCM**, Downstream Command Mirror register, providing convenient way to send more than 32 bit long commands by using DMA with memory address wrap around.
- **DCE**, Downstream Command Extension register, defining the second half of the command frame. In CX mode, always write first the **DCE** register, and then **DC** or **DCM**, because write to the **DC** / **DCM** triggers the command transmission

38.3.3 ABRA (Asynchronous Baud Rate Adjustment Block)

The Asynchronous Baud Rate Adjustment Block (ABRA) takes as an input a serial MSC stream with one baud rate and outputs the same serial stream with another baud rate, asynchronous to the input one. The input signal bundle consists of serial clock, data and select signal, and the output signal bundle consists of the same signals.

Additionally, the output clock of an MSC without ABRA can be only set to 50% duty cycle, while with the ABRA block, other duty cycles are also possible.

38.3.3.1 Overview

The ABRA block is located between the MSC kernel and the output pins.

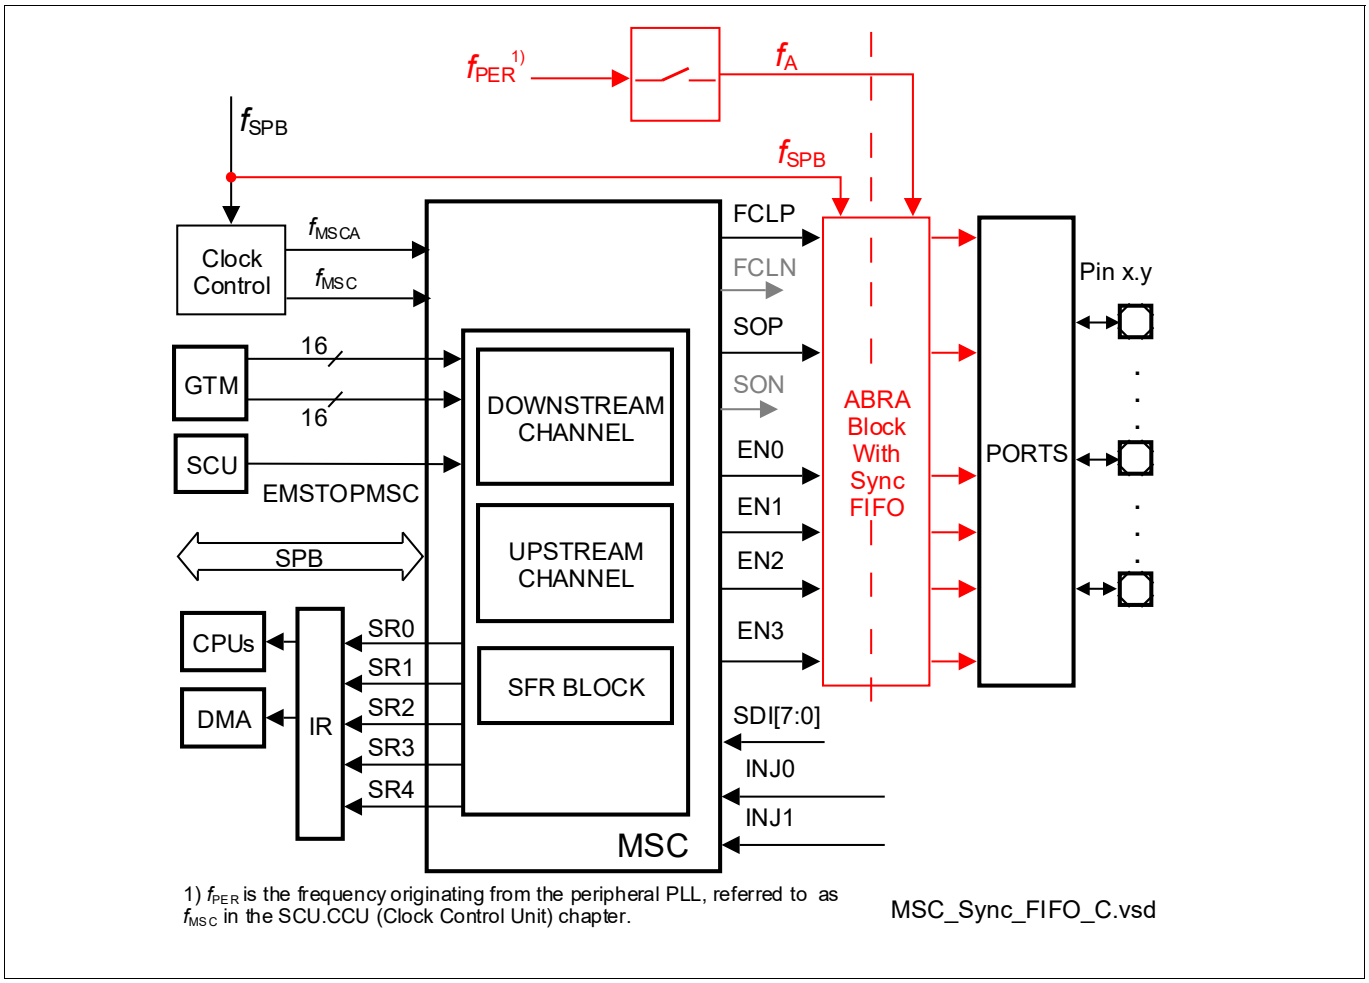

Figure 549 ABRA Overview

The user has two possibilities: either to use the ABRA block, or to bypass it. In case of using ABRA, additional delay in the signal path between the module and the pins of up to three f_A periods is to be taken into account. Additionally, some margin between the input frame length and the output frame length must be guaranteed by the customer, in order to avoid overflow of the ABRA block.

If the ABRA is not used, the behavior of the MSC module is identical with the previous implementations. The user can also choose between using the 64-bit extension or not, which makes 4 combinations in total, as shown in **Figure 550**

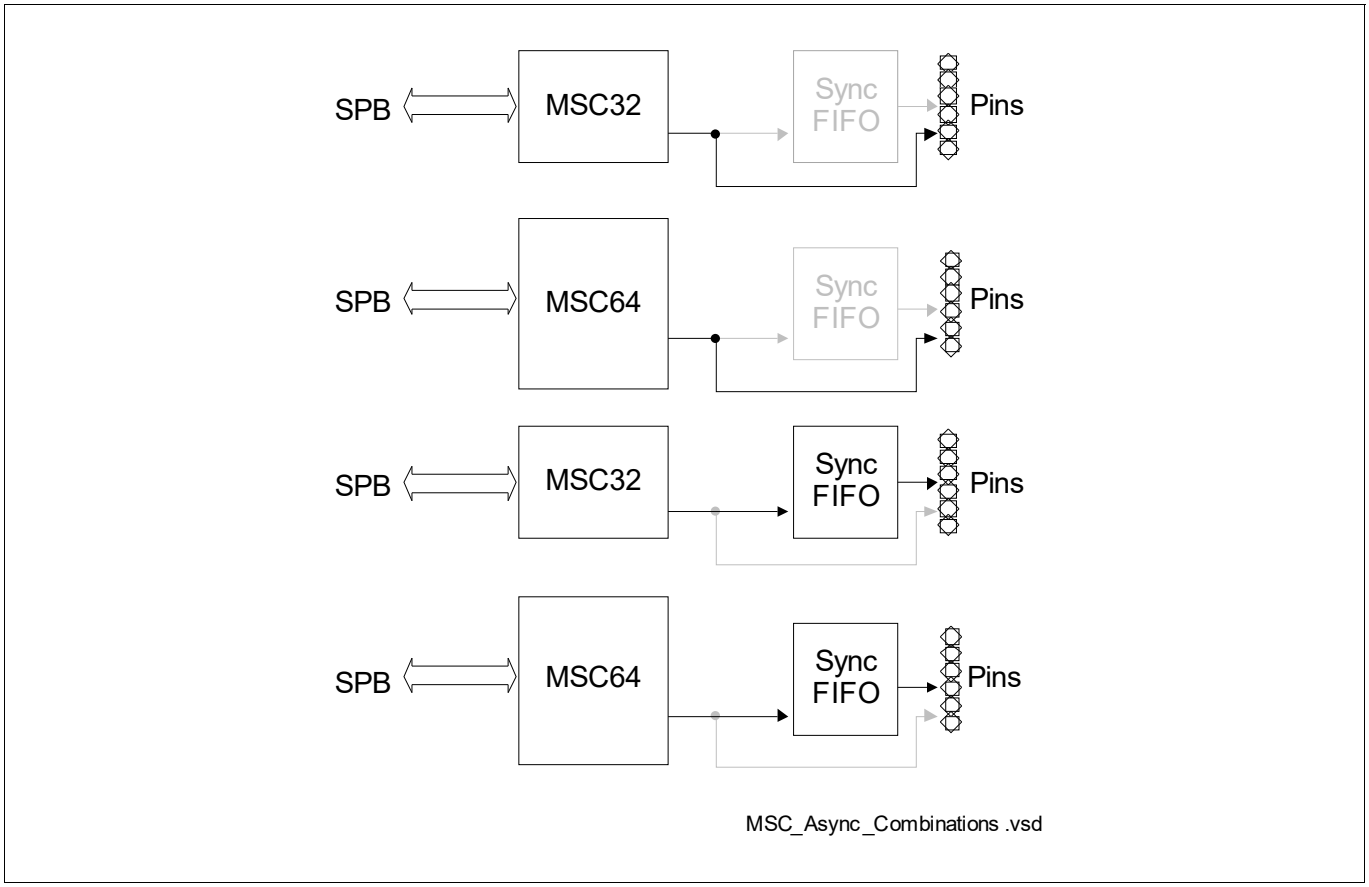

Figure 550 Use-Case Combinations

All configuration parameters related to the ABRA block are located in the ABC (Asynchronous Block Configuration) register.

38.3.3.2 Timing Issues

The ABRA block introduces a delay in the signal path from the MSC module to the pins. However it does not influence significantly the timings between the signals themselves. The output delays between the shift clock, data and enable signals remain approximately the same as if the ABRA block is not used, and are covered in the timings of the MSC module as defined in the data sheet.

38.3.3.3 Adjusting the Passive Phase of a Frame

The main purpose of the Asynchronous Baud Rate Adjustment block is to transform a frame going in with a higher baud rate (for example 50Mbaud), to a frame going out with a lower baud rate (for example 40MBaud). Therefore, the duration of the outgoing frame is longer then the duration of the incoming frame. In order not to overflow the ABRA block with too many incoming frames, there must be a pause between them, which is adjusted by

configuring the passive phase of the frames. This pause plus the incoming frame duration must be longer or equal to the outgoing frame duration plus some margin.

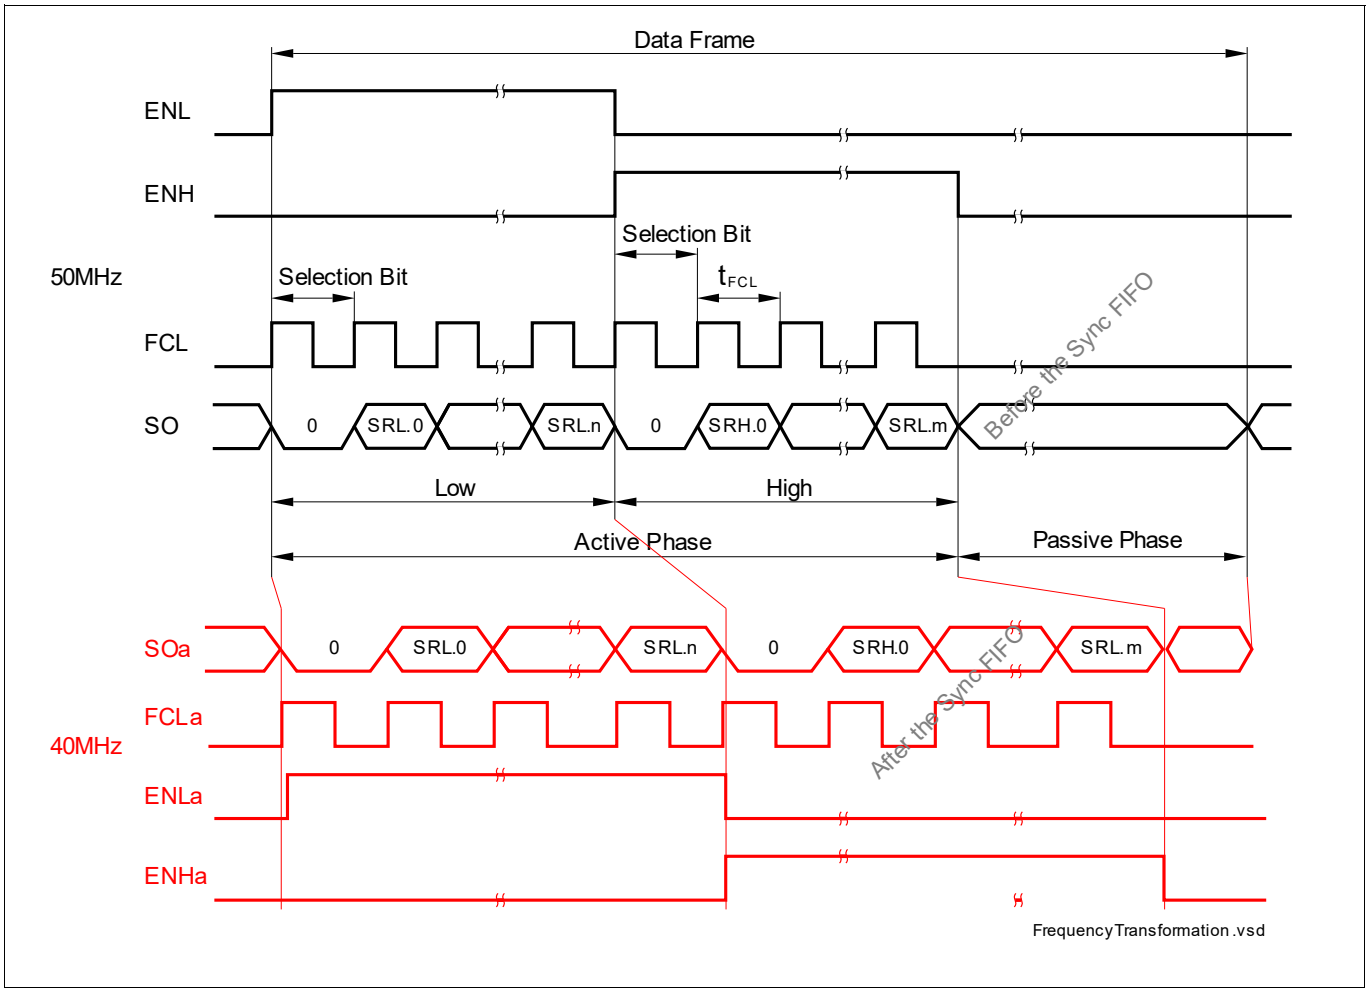

Figure 551 Passive Phase Adjustment

In order to allow for frame length adjustments:

- for command frames, the bit field **DSTE**.PPCE defines a programmable passive phase in a range of 2 to 65 input frequency cycles, and
- for data frames, the bit field **DSTE**.PPDE extends the passive phase from 2 to 31 to 2 to 127 bit times.

The length of the frame in the MSC domain (data and passive bits) must be longer than the length of the frame in the asynchronous domain, in order to prevent overload in case of back to back transmission:

$(N_D + N_P) * T_{FCL} > (N_D + N_{PA}) * T_{FCLA}$

which results to the following inequality for setting the length of the passive phase in the MSC domain:

$N_P > (N_D + N_{PA}) * T_{FCLA} / T_{FCL} - N_D$ or equivalently $N_P > (N_D + N_{PA}) * f_{FCL} / f_{FCLA} - N_D$

for example if f_{FCL} = 50MBaud, f_{FCLA} = 40MBaud, N_D=32 and N_{PA}=3, then $N_P > (32 + 3) * 1.25 - 32$, $N_P > 12$

Where:

T_{FCL}: serial clock period in the MSC domain with activated ABRA: $T_{FCL} = 1 / BaudRate_{MSCA}$,
$BaudRate_{MSCA} = f_{SPB} / (2*m)$, see **Intermediate Downstream Channel Baud Rate** with ABRA block.

T_{FCLA}: serial clock period of the ABRA block $T_{FCLA} = 1 / BaudRate_{ABRA}$,
$BaudRate_{ABRA} = f_A / [($**ABC**. NDA+1) * (**ABC**.LOW+1 + **ABC**.HIGH+1)]

N_P: number of the passive bits in the MSC domain (see **DSTE**.PPDE and **DSC**.PPD)

N_{PA}: number of the targeted passive bits in the asynchronous domain

N_D: number of data bits **DSC**.NDBH+NDBL+SELH+SELL+**DSCE**.NDBLE+NDBHE in both domains.

Note: If the passive phase settings in the MSC module are not correctly configured in such a way that two frames merge, that is, there is no passive phase on the pins at all, an overflow interrupt is triggered. If the passive phase is wrongly shorter, no error signal is generated.

Input/Output Baud Rate Ratio

The ABRA output baud rate going to the pins must be lower than the input baud rate coming from the MSC module and higher than roughly half of the input baud rate (more precisely higher than 57% of the input baud rate in worst-case, due to the fact that in worst-case MSC data frame can contain 64 data bits plus additionally two select bits).

38.3.3.4 Jitter of the Downstream Frames

This section describes the jitter effects affecting the starting point of the downstream frames, depending on the setting of the serial clock - serial clock only during the active phase of a frame, or continuous clock.

38.3.3.4.1 Jitter in Active Phase Clock Mode

The active phase clock mode is set when **OCR**.CLKCTRL = 0. In this mode the serial clock is generated only during the transmission of the data bits. The ABRA outgoing frame passive phase duration jitters for +- one f_A cycle. The example in the **Figure 552** assumes 50MBaud input and 40MBaud output baud rate, f_A = 80MHz, back to back frames.

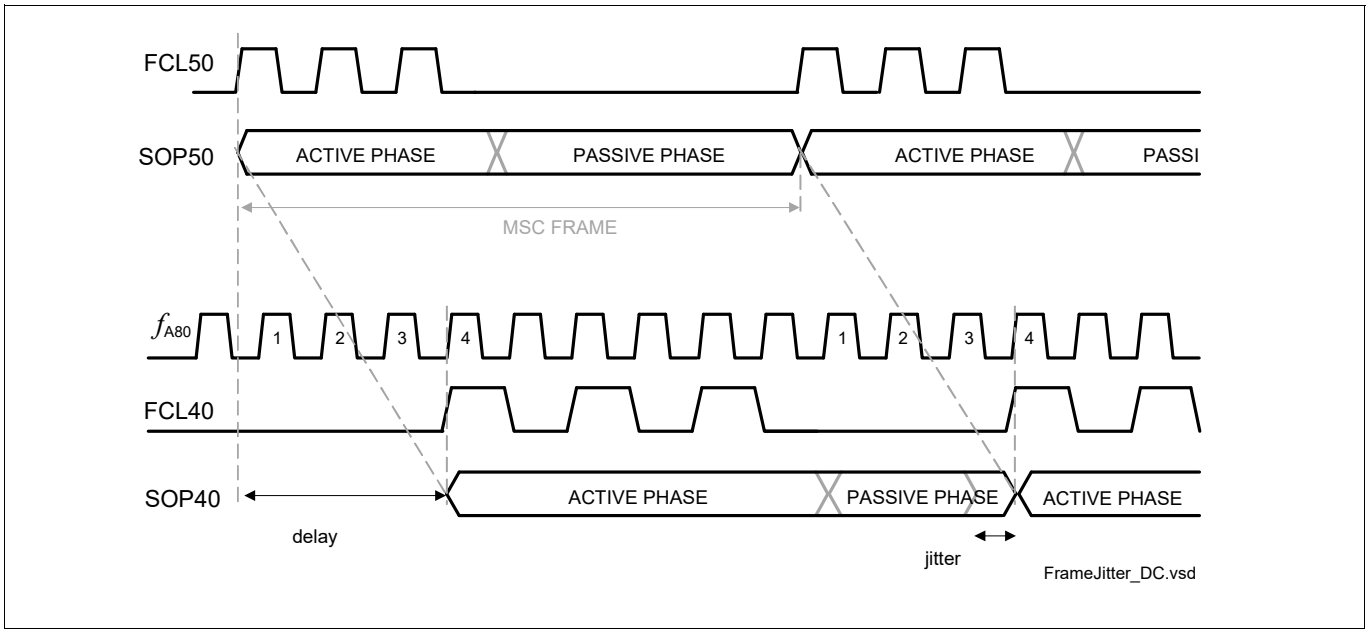

Figure 552 Frame Jitter in Active Phase Clock Mode

38.3.3.4.2 Jitter in Continuous Clock Mode

Continuous clock mode is set when **OCR**.CLKCTRL = 1. In this mode the serial clock is always on. The jitter is one output bit time.

The average length of the output frames is equal to the length of the input frames. The ABRA block generates an averaging effect similar to that of a fractional divider. It introduces occasionally jitter of one bit time in the output frame length, in the passive phase of the frame, in order to adjust the average output time raster to the ideal input time raster. The granularity of the input time raster is one input bit time (for example 20ns at 50MBaud), the granularity of the output time raster is one output bit time (for example 25ns at 40MBaud).

The example in the **Figure 553** assumes 50MBaud input baud rate and 40MBaud output baud rate, f_A = 80MHz, back to back frames.

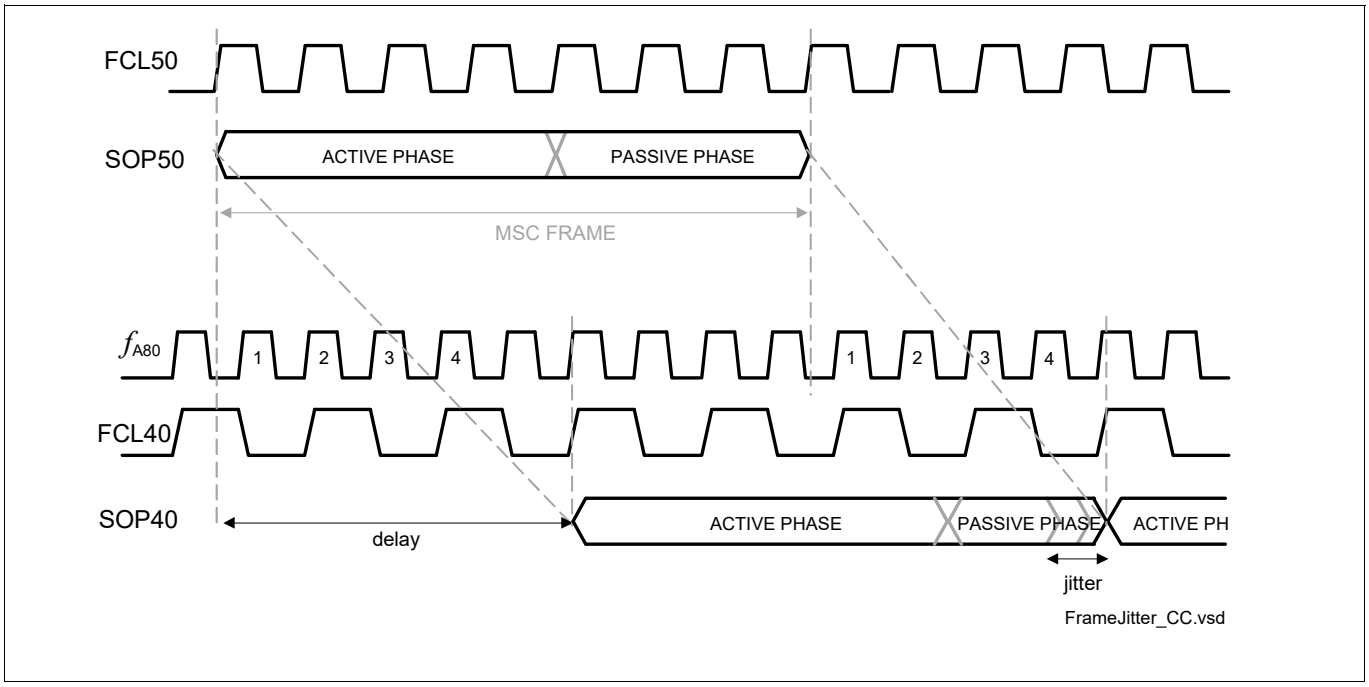

Figure 553 Frame Jitter in Continuous Clock Mode

38.3.3.5 Interrupt Position with the ABRA Block

The position of the MSC interrupts within a frame depends only on the internal time schedule of the MSC module in both use cases with and without ABRA block. Therefore the interrupt position in the internal time raster is constant and is the same as in the previous versions of the MSC module, and does not depend on the asynchronous baud rate which is seen on the pins. This behavior affects only the downstream interrupts, which are:

- Data Frame Interrupt
- Command Frame Interrupt
- Time Frame Finished Interrupt

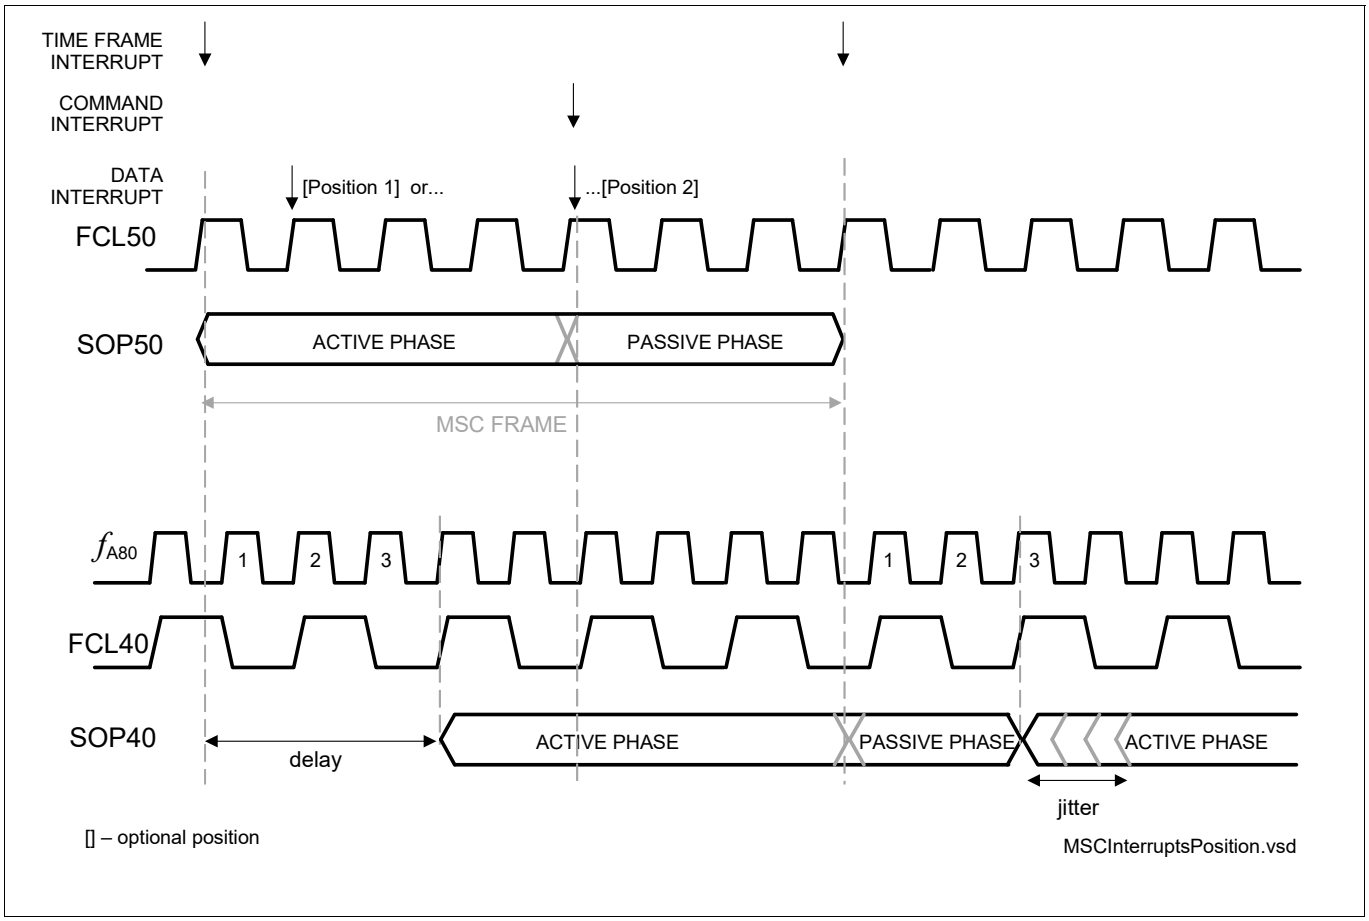

Figure 554 Interrupt Position with the ABRA Block

The downstream interrupts can be used for updates of the shadowed rw bit fields for the next frame transmission. Such bit fields are located in the Data Register **DD**, Command Register **DC**, Data Control **DSC** and Data Status **DSS**. Due to the next-frame-update effect, the small jitter and delay effects of the frames as seen on the pins is not relevant, as well as the position of the interrupt in the asynchronous frame.

38.3.3.6 Configuring the ABRA block

This section describes all the configurable parameters of the ABRA block. They are located in the **ABC** (Asynchronous Block Configuration) register.

Output Baud Rate

The ABRA block shifts out the data with a baud rate generated by dividing the clock f_A by using the bit fields **ABC**.HIGH, **ABC**.LOW and **ABC**.NDA.

The high and the low time of the shift clock are generated by a separate 4-bit n-divider, each operating in the range of 1 to 16. Therefore the duty cycle can be finely configured to be 50% or any other ratio. This may provide some advantages when the communicating devices have asymmetrical timings (output delays or set-up/hold times). See the description of the bit-fields **ABC**.HIGH and **ABC**.LOW.

The output baud rate of the ABRA block is defined with the formula:

Baud Rate = f_A / [(**ABC**. NDA+1) * (**ABC**.LOW+1 + **ABC**.HIGH+1)]

Committed Baud Rates

The following table defines the settings for the baud rates that are mandatory for the ABRA block for various devices. The ABRA **ABC**.LOW and HIGH are equal in the range of 0 to 7, and divide the f_A with 2, 4, 6, 8, 10, 12, 14, 16. The clock pre divider **ABC**.NDA=000_B.

The planned f_A frequencies for the various devices are the following:

- 160 MHz (80 MHz) and 200 MHz without FMPLL, 100 MHz with FMPLL

This results in the following table (* baud rates above 40MBaud are beyond the standard MSC specification):

Table 340 Committed Baud Rates in MBaud

Division ratio	200 MHz	160 MHz	100 MHz	80 MHz
2	-	80,00[1)]	50,00*	40,00
4	50,00*	40,00	25,00[1)]	20,00
6	33,33	26,67[1)]	16,67	13,33
8	25,00[1)]	20,00	12,50	10,00
10	20,00	16,00	10,00	8,00
12	16,67	13,33	8,33	6,67
14	14,29	11,43	7,14	5,71
16	12,50	10,00	6,25	5,00

1) For baud rate of 80 MBaud, FM mode with NDD=0 must be used. For baud rates of 25MBaud and 26,67 MBaud, it is recommended to use FM mode with NDD=2, so that the MSC module fills the ABRA FIFO with baud rate of 33.3 MBaud.

Continuous Shift Clock

As defined in the bit field **OCR**.CLKCTRL, the shift clock signal can be active either:

- only during the data transmission time
- continuously

Overflow and Underflow Interrupts

If the input and the output timings of the ABRA block are not adjusted to each other, an overflow of the ABRA block will occur and an error interrupt will be triggered on line X.

Overflow occurs either if the input data rate is too high or the output data rate is too low.

The corresponding bit fields are **ABC**.OVF, OFM, OIE.

Underflow occurs either if the input data rate is too low or the output data rate is too high.

The corresponding bit fields are **ABC**.UNF, UFM, UIE

See also **Interrupt Request Compressor**.

This feature can not guarantee protection against software errors like reconfigure the baud rates in the middle of a frame.

The configuration of the ABRA block and the MSC kernel is static and the time behavior is deterministic and calculable. Therefore, an overflow/underflow event always signals some configuration error resulting in unadjusted input/output baud rate ratio (see **Input/Output Baud Rate Ratio**). In normal operation and with correctly configured baud rates (clocks and clock dividers) these events do not occur.

In case of underflow/overflow event the output frame will be corrupt. The simplest solution to a sporadic event caused by a transient (noise, alpha particle) is to reset the module, reconfigure and restart the communication.

Bypass Mode

If the ABRA block is not used, it is disabled and bypassed via the bit field **ABC**.ABB.

38.3.3.7 Implementation Issues

The ABRA block operates using synchronization FIFO. The MSC module writes its serial stream to the synchronization FIFO with its serial shift clock, and the same data is read out of the FIFO by using the ABRA serial shift clock, generating out of the f_A.

Three signals are being transformed: the serial shift clock, the serial data stream and the enable (chip select) signals.

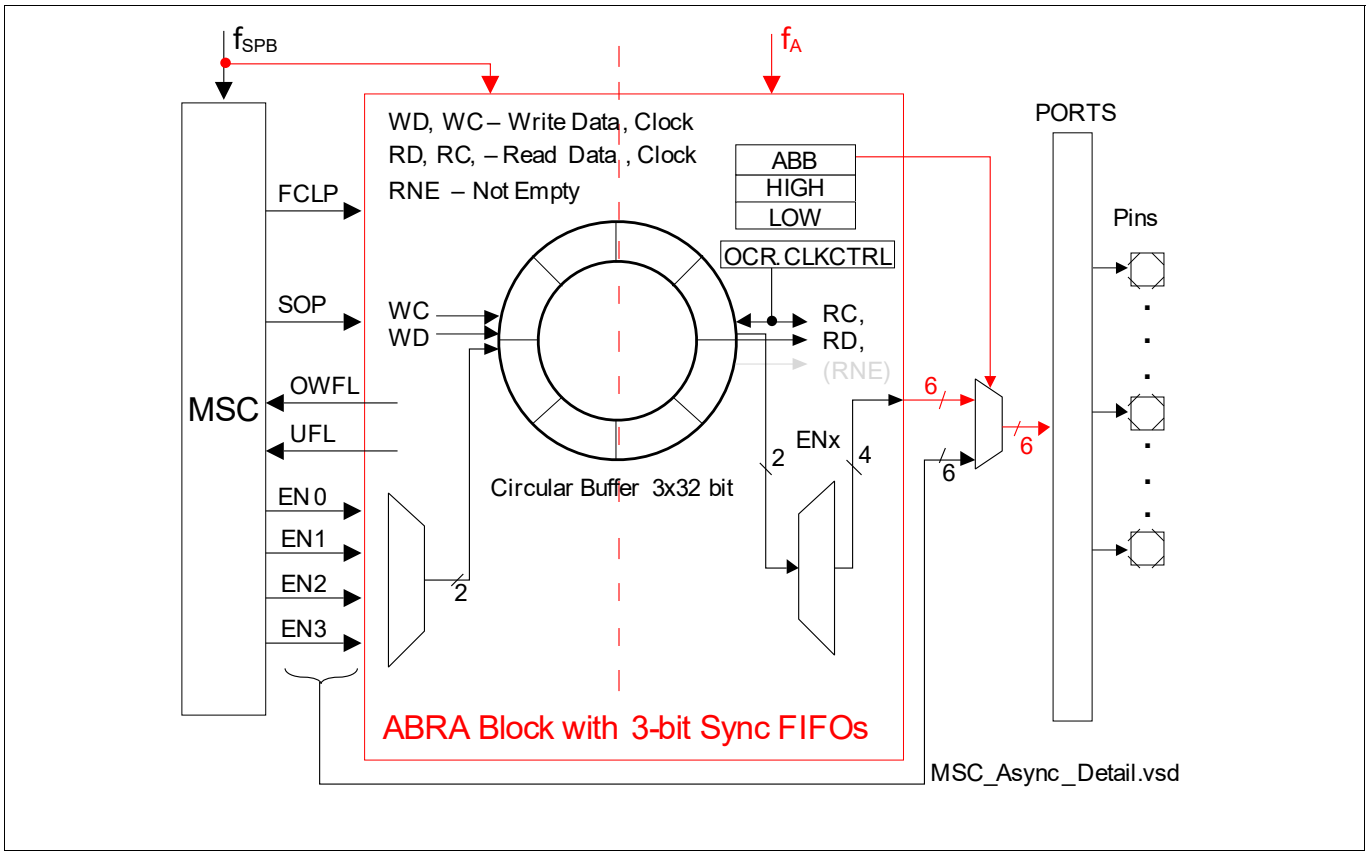

Figure 555 Implementation Details of the ABRA Block

38.3.3.8 ABRA Disable, Sleep and Suspend Behavior

This section describes the behavior of the MSC module in case of:

- switching the module on/off - disable behavior
- power saving - sleep mode
- debugging - OCDS suspend mode

The main concept is to provide behavior as similar as the behavior of the MSC module without the ABRA block, as much as possible.

38.3.3.8.1 Disable and Sleep Behavior

There is no difference in the behavior of the module in case of entering / leaving the disable and sleep state. Disable state is controlled by a bit set / cleared by software, sleep state is controlled by a hardware signal which can be disabled or enabled.

On disable/sleep state request, the module finishes the possibly ongoing frames (downstream or upstream), then acknowledges the request and the module clock is switched off.

On leaving the disable/sleep state, the module continues with the operation at the same point where it entered the corresponding state.

38.3.3.8.2 OCDS Suspend Behavior

In case of Hard Suspend, the clock is switched off immediately. A running frame will not be finished.

In case of Soft Suspend, the state is entered after the following two conditions are met:

- any ongoing upstream reception is completed, and
- any ongoing downstream frame transmission is completed, both from the MSC kernel and the ABRA block side

38.3.4 MSC Module Implementation

This section describes the MSC module interface as implemented in the device. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

38.3.4.1 BPI_FPI Module Registers (Single Kernel Configuration)

38.3.4.1.1 System Registers

Figure 556 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

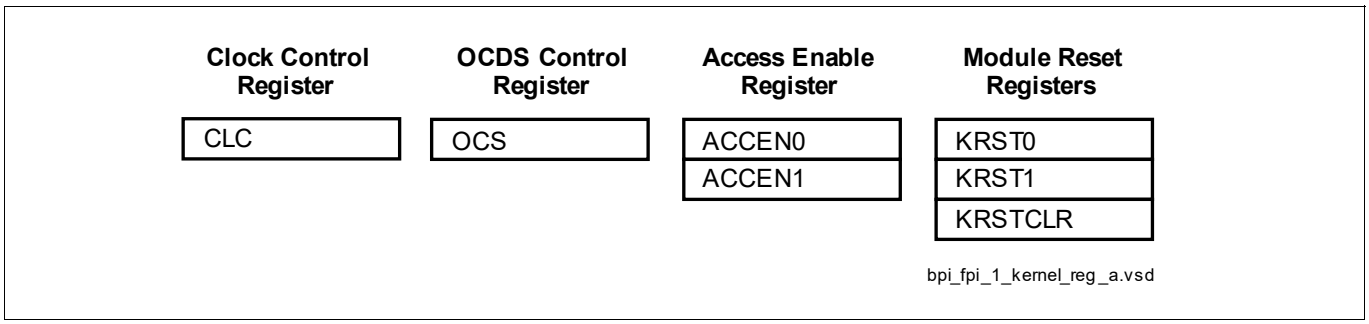

Figure 556 BPI_FPI Registers

The writes of the bus masters to the MSC module is controlled by Access Protection registers ACCENx.

The MSC implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the $f_{<>}$ module clock signal, sleep mode and disable mode for the module.

CLC

Clock Control Register (000_H) Application Reset Value: $0000\ 0003_H$

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.

Field	Bits	Type	Description
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	2, 31:4	r	**Reserved** Read as 0; shall be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

OCS

OCDS Control and Status (0E8$_H$) Debug Reset Value: 0000 0000$_H$

0	23:0, 31:30	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1)] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is

prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, …, EN31 -> TAG ID 011111B.

Access Enable Register 1

The Access Enable Register 1 controls write access[1] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the T3xx devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, …, EN31 -> TAG ID 111111B.

0	31:0	r	**Reserved** Read as 0; shall be written with 0.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be reset by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is reset by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be reset to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

38.3.4.2 Interface Connections of the MSC Module

The MSC module is supplied with a separate clock control, address decoding, and interrupt control logic. The service request outputs are connected with the interrupt nodes in the Interrupt Router module. Outputs of the GTM module are connected to the alternate input buses ALTINL/ALTINH. The Port Emergency Stop output from the SCU controls the corresponding inputs of each MSC module.

The serial data and clock outputs of the downstream channels of the MSC module are connected to combined GPIO/LVDS differential output drivers. Details about these four pins are defined in the ports chapter.

38.3.4.3 MSC Module-Related External Registers

Figure 557 summarizes the module-related external registers which are required for MSC programming (see also **Figure 561** for the module kernel specific registers). Generally, additionally to programming the MSC kernel and BPI registers, the Fractional Divider, the ports registers located in the Ports module and interrupt registers located in the Interrupt Router module.

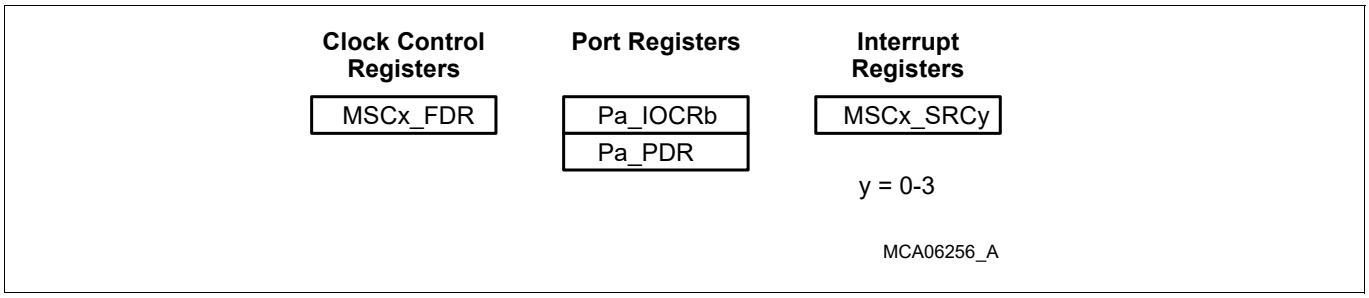

Figure 557 MSC Implementation-specific Special Function Registers

38.3.4.4 Clock Control

The following section describes the clock control and the baud rate generation of the MSC module.

The MSC module is provided with two independent clock signals (**Figure 558**):

- f_{CLC}
  This is the module clock that is used inside the MSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is always identical to the system clock frequency f_{SPB}. The clock control register MSC_CLC makes it possible to enable/disable f_{CLC} under certain conditions.
- f_{MSC}
  This clock is the module clock that is used inside the MSC for baud rate generation of the serial upstream and downstream channel. The fractional divider register MSC_FDR controls the frequency of f_{MSC} and makes it possible to enable/disable it independent of f_{CLC}.
- f_{MSCA}
  This clock is the downstream clock which is used together with the ABRA block. In this case, the upstream baud rate can be fine-tuned with the fractional divider, and the downstream channel frequency is configured with an N-Divider.

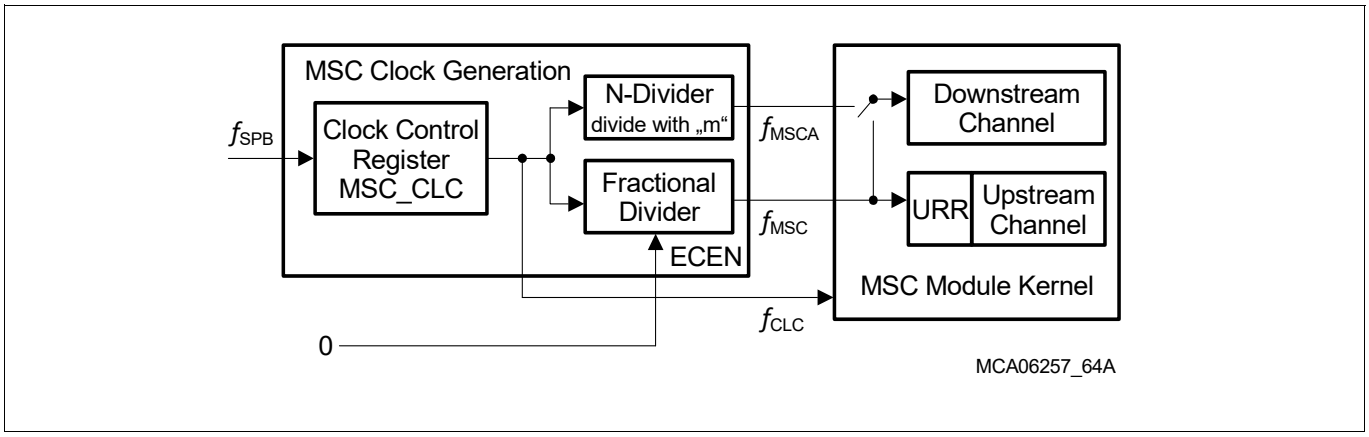

Figure 558 MSC Module Clock Generation

38.3.4.4.1 Clock Control Without the ABRA Block

Not using the ABRA block is the standard, compatibility use-case, which guarantees the full compatibility with the standard MSC module not containing the ABRA block. The clock generation is therefore identical with the standard MSC clock generation. The additional N-Divider (dividing with the division factor named “m”) is not used. Only the fractional divider is used (using the factor named “n” in the formulas below).

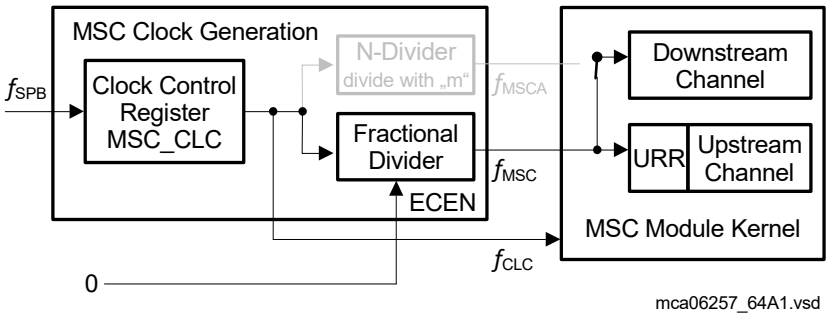

Figure 559 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \quad \text{with n = 1024 - MSC.FDR.STEP} \tag{38.4}$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \quad \text{with n = 0-1023} \tag{38.5}$$

Downstream Channel Baud Rate

As the clock signal FCL of the synchronous downstream channel is always half the frequency of f_{MSC}, the resulting downstream channel baud rate is defined by:

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{2 \times (1024 - \text{MSC.FDR.STEP})} \tag{38.6}$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{2 \times 1024} \tag{38.7}$$

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field USR.URR (see also **Equation (38.3)** on **Page 24**). The divide factor DF can be at minimum 4 and at maximum 256.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - \text{MSC.FDR.STEP})} \tag{38.8}$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{DF \times 1024} \tag{38.9}$$

Equation (38.4), **Equation (38.6)**, and **Equation (38.8)** are valid for normal divider mode (FDR.DM = 01_B). **Equation (38.5)**, **Equation (38.7)**, and **Equation (38.9)** are valid for fractional divider mode (FDR.DM = 10_B).

38.3.4.4.2 Clock Control when using the ABRA Block

Using the ABRA block makes additional considerations regarding the baud-rate adjustments necessary.

An additional N-Divider **DSTE**.NDD is used for configuring the intermediate downstream baud rate the MSC module is using for writing to the ABRA block (dividing the f_{SPB} with the integer division factor named “m” in the formulas below). The final output downstream baud rate is configured in the ABRA block itself. The following restriction applies: the ABRA output downstream baud rate is between half and whole intermediate baud rate.

When ABRA block is active, the fractional divider **FDR**.STEP is used only for adjusting the upstream baud rate (using the factor named “n” in the formulas below).

Attention: ***The following restriction applies: the upstream baud rate must be less than one tenth of the f_{SPB}. See also Upstream Channel.***

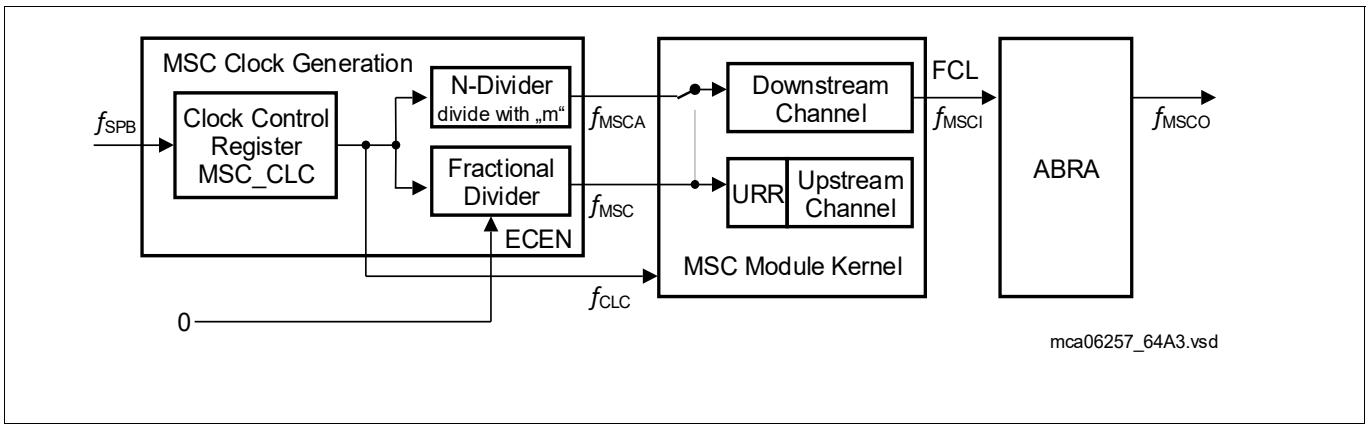

Figure 560 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \text{ with n = 1024 - MSC.FDR.STEP} \quad (38.10)$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \text{ with n = 0-1023} \quad (38.11)$$

The following formula defines the frequency of f_{MSCA}:

$$f_{MSCA} = f_{SPB} \times \frac{1}{m} \text{ with m = 1 - 16} \quad (38.12)$$

Intermediate Downstream Channel Baud Rate

When the ABRA block and the downstream N-divider are enabled with **ABC**.ABB, the intermediate clock signal FCL with frequency f_{MSCI} of the synchronous downstream channel going into the ABRA block is always half the frequency of f_{MSCA}:

$$\text{Baud rate}_{MSCI} = f_{SPB} \times \frac{1}{2 \times m} \quad (38.13)$$

The final output baud rate f_{MSCO} can be calculated as described in **Output Baud Rate**.

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field USR.URR (see also **Equation (38.3)** on **Page 24**). The divide factor DF can be at minimum 4 and at maximum 256. Nevertheless, the minimum DF factor when using ABRA block should be 8. See the note on **Page 20**.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - MSC.FDR.STEP)} \quad (38.14)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{MSC.FDR.STEP}{DF \times 1024} \quad (38.15)$$

Equation (38.10), **Equation (38.11)**, and **Equation (38.14)** are valid for normal divider mode (FDR.DM = 01_B). **Equation (38.11)** and **Equation (38.15)** are valid for fractional divider mode (FDR.DM = 10_B).

Example for Setting the Fractional Divider

This example shows how to receive upstream frames generated from 40MHz downstream clock, when the module baud-rate frequency is 100MHz/2=50MHz. The fractional divider is used to adjust the FCL clock of 50MHz to FCL clock of 40MHz, that is, it multiplies with 4/5. The best approximation of 4/5 with x/1024 is for x=819, giving an error of 0.025%. So in this case, the optimal setting for FDR.STEP is 819. In the next stage of the divider cascade, the DF power-of-two-divider divides the clock further to the final baud rate, matching the baud rate generated by the MSC slave device.

38.3.4.4.3 Fractional Divider Register

Fractional Divider Register

The Fractional Divider Register controls the clock rate of the shift clock f_{MSC}.

FDR
Fractional Divider Register **(00C$_H$)** **Application Reset Value: 0000 0000$_H$**

rw		r		r	r	rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
ENHW	30	rw	**Enable Hardware Clock Control** Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{MSC} signal.
0	10, 11, 13:12, 27:26, 28, 29	r	**Reserved** Read as 0; shall be written with 0.

38.3.4.5 Port Control

Clock and data output lines are connected to dedicated LVDS differential output drivers. Some of the MSC module I/O lines are connected to I/O ports and therefore controlled in the port logic.

The following port control operations selections must be executed for these I/O lines:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

38.4 Registers

This section describes the kernel registers of the MSC module. All MSC kernel register names described in this section will be referenced in other parts of the User's Manual by the module name prefix "MSCx_".

All registers in the MSC address spaces are reset with the application reset (definition see SCU section "Reset Operation").

MSC Kernel Register Overview

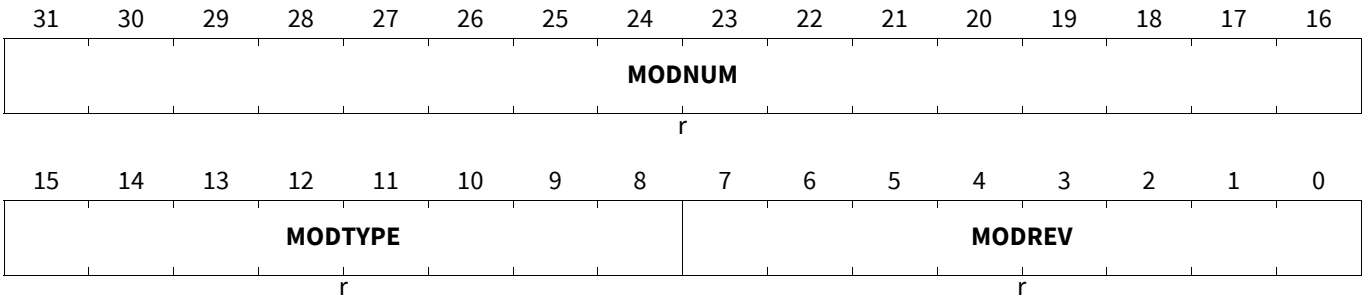
38.4.1 Module Identification Register

Module Identification Register

The MSC Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register (008$_H$) Application Reset Value: 0028 C01X$_H$



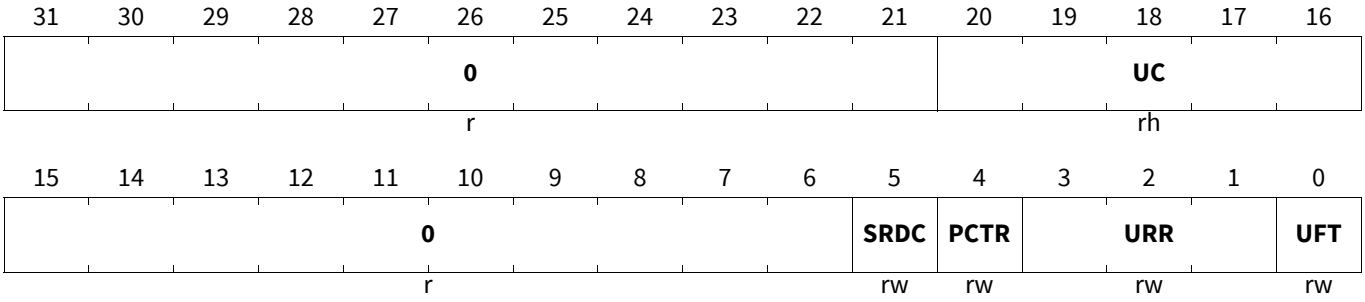
Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the MSC: 0028_H

38.4.2 Status and Control Registers

Upstream Status Register

The Upstream Status Register is used to configure the upstream channel data format, baud rate, and parity type. It also provides the status information of the upstream counter (UC).

USR
Upstream Status Register (010$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
UFT	0	rw	**Upstream Channel Frame Type** This bit determines the frame type used by the upstream channel for data reception. 0_B 12-bit upstream frame selected 1_B 16-bit upstream frame selected (with 4-bit address field)
URR	3:1	rw	**Upstream Channel Receiving Rate** This bit field determines the baud rate for the upstream channel. 000_B Upstream channel disabled; no reception is possible 001_B Baud rate = $f_{MSC}/4$ 010_B Baud rate = $f_{MSC}/8$ 011_B Baud rate = $f_{MSC}/16$ 100_B Baud rate = $f_{MSC}/32$ 101_B Baud rate = $f_{MSC}/64$ 110_B Baud rate = $f_{MSC}/128$ 111_B Baud rate = $f_{MSC}/256$
PCTR	4	rw	**Parity Control** This bit determines the parity mode used by the upstream channel for data reception. 0_B Even parity mode is selected. A parity bit is set on an odd number of 1s in the serial address/data stream. 1_B Odd parity mode is selected. A parity bit is set on an even number of 1s in the serial address/data stream.
SRDC	5	rw	**Service Request Delay Control** This bit determines the additional delay inserted by the upstream channel when triggering the receive interrupt. Only the hardware generated interrupt can be delayed. The software generated interrupt by writing the ISC.SURDI bit is never delayed. 0_B No delay 1_B Delay of 1 bit time

Field	Bits	Type	Description
UC	20:16	rh	**Upstream Counter** This bit field indicates the content of the upstream counter that counts the bits during upstream channel reception.
0	15:6, 31:21	r	**Reserved** Read as 0; shall be written with 0.

Downstream Control Register

The Downstream Control Register is used to control the operation mode and frame layout of the downstream channel transmission. It also contains the two pending status bits.

Note: The "rw" bits in the DSC register are buffered in a shadow buffer at the start of a corresponding frame transmission.

Note: If the asynchronous mode (ABRA=1) is enabled and no data-bit (zero data-bits) in a data frame is configured (DSC.NDBL=DSC.NDBH=00000), then the first select-bit must be set to active (DSC.ENSELL=1).

DSC
Downstream Control Register (014$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DSDIS	**ENSELH**	**ENSELL**	**NDBH**					**NDBL**					**DP**	**CP**	**TM**
rh	rw	rw	rw					rw					rh	rh	rw

Field	Bits	Type	Description
TM	0	rw	**Transmission Mode** This bit selects the transmission mode of the downstream channel. 0_B Triggered Mode selected 1_B Data Repetition Mode selected
CP	1	rh	**Command Pending** This bit is set when the downstream command register DC is written. CP is cleared when the first bit of the related command frame is sent out.
DP	2	rh	**Data Pending** In Triggered Mode, this bit is set when the set data pending bit ISC.SDP is set by software. In Data Repetition Mode, this bit is set by hardware at the last passive time frame. At the start of the data frame, DP is cleared by hardware.

Field	Bits	Type	Description
NDBL	7:3	rw	**Number of SRL Bits Shifted at Data Frames** NDBL determines the number of shift register low part (SRL) bits that are shifted out on SO during a data frame. Other bit combinations are reserved; do not use these bit combinations. 00_H No SRL bit shifted 01_H SRL[0:0] shifted … 10_H SRL[15:0] shifted **others**, reserved
NDBH	12:8	rw	**Number of SRH Bits Shifted at Data Frames** NDBH determines the number of shift register high part (SRH) bits that are shifted out on SO during a data frame. Other bit combinations are reserved; do not use these bit combinations. 00_H No SRH bit shifted; no selection bit is generated, the SRH active phase is completely skipped. 01_H SRH[0:0] shifted … 10_H SRH[15:0] shifted **others**, reserved
ENSELL	13	rw	**Enable SRL Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRL active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.
ENSELH	14	rw	**Enable SRH Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRH active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.
DSDIS	15	rh	**Downstream Disable** This bit indicates the state of the downstream channel operation. 0_B The downstream channel is enabled. A frame transmission can take place (Triggered Mode) or takes place (Data Repetition Mode). 1_B Downstream Counter becomes disabled. No new frame transmission is started. A running frame transmission is always completed.
NBC	21:16	rw	**Number of Bits Shifted at Command Frames** This bit field determines how many bits of the SRL/SRH shift registers are shifted out during transmission of a command frame. 00_H No bit shifted 01_H SRL[0:0] shifted … 10_H SRL[15:0] shifted 11_H SRL[15:0] and SRH[0:0] shifted … 20_H SRL[15:0] and SRH[15:0] shifted **others**, reserved

Field	Bits	Type	Description
PPD	28:24	rw	**Passive Phase Length at Data Frames** This bit field determines the length of the passive phase of a data frame. 00_H Passive phase length is 2 x t_FCL 01_H Passive phase length is 2 x t_FCL 02_H Passive phase length is 2 x t_FCL … $1F_H$ Passive phase length is 31 x t_FCL
0	23:22, 31:29	r	**Reserved** Read as 0; shall be written with 0.

Downstream Control Enhanced Register 1

The Downstream Control Enhanced Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

DSCE

Downstream Control Enhanced Register 1 (058_H) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCF	**EXEN**	**0**												**NDBLE**	**NDBHE**
rh	rw	r												rw	rw

Field	Bits	Type	Description
NDBHE	0	rw	**Number of SRH Bits Shifted at Data Frames Extension** Additional MSB bit extension of the NDBH bit field. Adds 16 to the resulting NDBH value if set.
NDBLE	1	rw	**Number of SRL Bits Shifted at Data Frames Extension** Additional MSB bit extension of the NDBL bit field. Adds 16 to the resulting NDBL value if set.
EXEN	14	rw	**Extension Enable** Enables the extension bit fields. 0_B disabled 1_B enabled
CCF	15	rh	**Command-Command Flag** This bit flags that a second command frame has been written without data frame to be sent in between. It is active only if CDCM=1. Otherwise it is always low. 0_B no second command 1_B second command frame pending

Field	Bits	Type	Description
INJENP0	16	rw	**Injection Enable of the Pin 0 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled
INJPOSP0	22:17	rw	**Injection Position of the Pin 0 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame. If both PIN0POS and PIN1POS point to a same bit, PIN0POS has the higher priority, that is PIN0 level will be visible in the data frame.
INJENP1	24	rw	**Injection Enable of the Pin 1 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled
INJPOSP1	30:25	rw	**Injection Position of the Pin 1 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame.
CDCM	31	rw	**Command-Data-Command in Data Repetition Mode** This bit selects if a data frame is automatically inserted between two consecutive command frame requests. 0_B Automatic data insertion disabled 1_B Automatic data insertion enabled
0	13:2, 23	r	**Reserved** Read as 0; shall be written with 0.

Upstream Control Enhanced Register 1

The Upstream Control Enhanced Register is used to control the upstream channel time-out feature.

USCE

Upstream Control Enhanced Register 1 ($05C_H$) Application Reset Value: 0000 00FF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
USTOIP		UTASR	0	USTS	USTC	USTF	USTO EN	USTOVAL				USTOPRE			
rw		rw	r	w	w	rh	rw	rw				rw			

Field	Bits	Type	Description
USTOPRE	3:0	rw	**Upstream Time-out Prescaler** Prescaler for the upstream time-out limit. Expressed in upstream bit times. 2^n divider in the range of 1 to 16384. Write to this bit field triggers new start of the watchdog timer. 0_H 1 … E_H 16384 F_H reserved
USTOVAL	7:4	rw	**Upstream Time-out Value** Upstream time-out value for the N-divider in the range of 1 to 16, expressed in number of upstream bit time lengths (the upstream bit time is the reciprocal value of the upstream baud rate). Time-out = BitTime * $2^{(USTOPRE+1)}$ * (USTOVAL+1). Write to this bit field triggers new start of the watchdog timer.
USTOEN	8	rw	**Upstream Time-out Interrupt Enable** Enable bit for the upstream time-out interrupt. The Time-out counter runs continuously independently of the USTOEN bit. The USTOEN enables only the interrupt generation. 0_B Disabled 1_B Enabled
USTF	9	rh	**Upstream Time-out Flag** Signals an upstream timer event. If set by software, the interrupt is also triggered, if enabled. The watchdog timer runs continuously and sets the USTF flag at overflow, independently from the enable bit. Therefore this bit must be cleared with the same write access which enables the interrupt. 0_B Disabled 1_B Enabled
USTC	10	w	**Upstream Time-out Clear** Clears the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Clear
USTS	11	w	**Upstream Time-out Set** Sets the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Set
UTASR	13	rw	**Upstream Time-out Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 547**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected

Field	Bits	Type	Description
USTOIP	15:14	rw	**Upstream Time-out Interrupt Node Pointer** USTOIP selects the service request output line SRn (n = 0-3) for the time-out interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
0	12, 31:16	r	**Reserved** Read as 0; shall be written with 0.

Downstream Status Register

The Downstream Status Register DSS contains counter bit fields, status bits, and indicates the number of passive time frames.

DSS

Downstream Status Register (018$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw		rw	r	rw		rw	r	rw		rw		rw	

Field	Bits	Type	Description
EDIP	1:0	rw	**Data Frame Interrupt Node Pointer** EDIP selects the service request output line SRn (n = 0-3) for the data frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
EDIE	3:2	rw	**Data Frame Interrupt Enable** This bit field determines the enable conditions for the data frame interrupt. 00_B Interrupt generation disabled 01_B An interrupt is generated when the last data bit has been shifted out. 10_B An interrupt is generated when the first data bit has been shifted out, but only if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active. 11_B Interrupt generation disabled

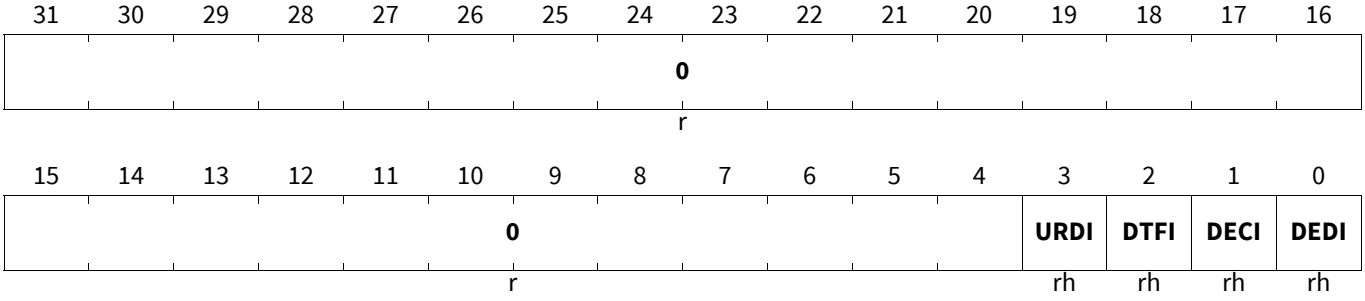
Field	Bits	Type	Description
ECIP	5:4	rw	**Command Frame Interrupt Node Pointer** ECIP selects the service request output line SRn (n = 0-3) for the command frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
ECIE	7	rw	**Command Frame Interrupt Enable** This bit enables the command frame interrupt. 0_B Interrupt generation disabled. 1_B Interrupt generation enabled.
TFIP	9:8	rw	**Time Frame Interrupt Pointer** TFIP selects the service request output line SRn (n = 0-3) for the time frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
TFIE	11	rw	**Time Frame Interrupt Enable** This bit enables the time frame interrupt. 0_B Interrupt generation disabled. 1_B Interrupt generation enabled.
RDIP	13:12	rw	**Receive Data Interrupt Pointer** RDIP selects the service request output line SRn (n = 0-3) for the receive data interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
RDIE	15:14	rw	**Receive Data Interrupt Enable** This bit field determines the enable conditions for the receive data interrupt. 00_B Interrupt generation disabled. 01_B An interrupt is generated when data is received and written into the upstream data registers UDx (x = 0-3). 10_B An interrupt is generated as with RDIE = 01_B but only if the received data is not equal to 00_H. 11_B An interrupt is generated when data is received and written into register UD3.
0	6, 10, 31:16	r	**Reserved** Read as 0; shall be written with 0.

Interrupt Status Register

The Interrupt Status Register ISR holds the interrupt status flags that indicate an interrupt occurrence in downstream and upstream channels.

ISR

Interrupt Status Register **(044_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DEDI	0	rh	**Data Frame Interrupt Flag** This flag is always set by hardware when a downstream channel data frame interrupt is generated. DEDI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SDEDI or ISC.CDEDI set.
DECI	1	rh	**Command Frame Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt is generated, whether or not it is enabled. DECI can be set or cleared by software when writing to register ISC with the appropriate bits SDECI or CDECI set.
DTFI	2	rh	**Time Frame Interrupt Flag** This flag is always set by hardware when a downstream channel time frame interrupt is generated, whether or not it is enabled. DTFI can be set or cleared by software when writing to register ISC with the appropriate bits SDTFI or CDTFI set.
URDI	3	rh	**Receive Data Interrupt Flag** This flag is always set by hardware when an upstream channel receive data interrupt is generated, whether or not it is enabled. URDI can be set or cleared by software when writing to register ISC with the appropriate bits SURDI or CURDI set.
0	31:4	r	**Reserved** Read as 0; shall be written with 0.

Interrupt Set Clear Register

The Interrupt Set Clear Register ISC is used to set or clear the MSC interrupt flags located in the Interrupt Status Register ISR. Reading ISC always returns $0000\ 0000_H$.

Note: When the ISC register is written with both bits (set and clear bit) for a specific interrupt flag, the clear operation takes place and the set operation is ignored.

ISC

Interrupt Set Clear Register **(048_H)** **Application Reset Value: $0000\ 0000_H$**

r	rw		rw		rw		rw	r				rw	rw	rw	rw

Field	Bits	Type	Description
CLP	0	rw	**FCLP Line Polarity** 0_B FCLP and FCL signal polarity is identical. FCLN signal has inverted FCL signal polarity. 1_B FCLP signal has inverted FCL signal polarity. FCLN and FCL signal polarities are identical.
SLP	1	rw	**SOP Line Polarity** 0_B SOP and SO signal polarity is identical. SON signal has inverted SO signal polarity. 1_B SOP signal has inverted SO signal polarity. SON and SO signal polarities are identical.
CSLP	2	rw	**Chip Selection Lines Polarity** Bit CSLP is buffered during a frame transmission. This means that any change of CSLP becomes valid first with the start of the next frame transmission. 0_B EN[3:0] and ENL, ENH, ENC signal polarities are identical (high active). 1_B EN[3:0] signal polarities are inverted (low active) to the ENL, ENH, ENC signal polarities.
ILP	3	rw	**SDI Line Polarity** 0_B SDI and SI signal polarities are identical. 1_B SDI and SI signal polarities are inverted.
CLKCTRL	8	rw	**Clock Control** This bit determines the activation of clock output FCL. 0_B FCL is activated only during the active phases of data or command frames (not during passive time frames). 1_B FCL is always active whether or not a downstream frame is currently transmitted.
CSL	10:9	rw	**Chip Enable Selection for ENL** This bit field selects the chip enable output ENx that becomes active during the SRL active phase (ENL = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENL. 01_B EN1 line is selected for ENL. 10_B EN2 line is selected for ENL. 11_B EN3 line is selected for ENL.

Field	Bits	Type	Description
CSH	12:11	rw	**Chip Enable Selection for ENH** This bit field selects the chip enable output ENx that becomes active during the SRH active phase (ENH = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENH. 01_B EN1 line is selected for ENH. 10_B EN2 line is selected for ENH. 11_B EN3 line is selected for ENH.
CSC	14:13	rw	**Chip Enable Selection for ENC** This bit field selects the chip enable output ENx that becomes active during the active phase (ENC = 1) of a command frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENC. 01_B EN1 line is selected for ENC. 10_B EN2 line is selected for ENC. 11_B EN3 line is selected for ENC.
SDISEL	18:16	rw	**Serial Data Input Selection** This bit field selects the source for the serial data input SDI of the upstream channel. 000_B SDI0 input is selected for SDI. 001_B SDI1 input is selected for SDI. 010_B SDI2 input is selected for SDI. 011_B SDI3 input is selected for SDI. 100_B SDI4 input is selected for SDI. 101_B SDI5 input is selected for SDI. 110_B SDI6 input is selected for SDI. 111_B SDI7 input is selected for SDI.
0	7:4, 15, 31:19	r	**Reserved** Read as 0; shall be written with 0.

Downstream Select Data Source Low Extension Register

The bit fields of the Downstream Select Data Source Low Extension Register DSDSLE determine the data source for the upper 16 bits in the shift register SRL.

DSDSLE

0			PPCEM	NDD				PPCE						PPDE	
r			rw	rw				rw						rw	

Field	Bits	Type	Description
PPDE	1:0	rw	**Passive Phase Length at Data Frames Extension** Additional MSB bits extension of the PPD bit field.
PPCE	7:2	rw	**Passive Phase Length at Control Frames Extension** Additional MSB bits extension of the fixed length of 2 of the command frames passive phase. The final length is 2 + PPCE resulting in a range of 2 to 65. 00_H 2 … $3F_H$ 65
NDD	11:8	rw	**N Divider Downstream** Defines the division ratio in the range of 1 to 16. 0_H 1 … F_H 16
PPCEM	12	rw	**PPCE Extension Bit on the MSB Side** This bit is the MSB extension bit for the PPCE bit field, extending command frame passive phase to the value of 127. The values of 128 and 129 are not allowed. 0_B MSB value of 0 1_B MSB value of 1
FM	16	rw	**Fast Mode** Activates the fast mode and writing to the ABRA FIFO with 100 MBaud input baud rate, in order to provide 80MBaud output baud rate. It is also recommended for baud rate of 26,67 MBaud, as defined in the **Table 340**. FM=0 is the compatibility setting with the previous generations of the MSC. 0_B Fast Mode deactivated 1_B Fast Mode activated
CX	28	rw	**Command Extension Mode** Activates 64 bit command frame feature. 0_B CX mode deactivated 1_B CX mode activated

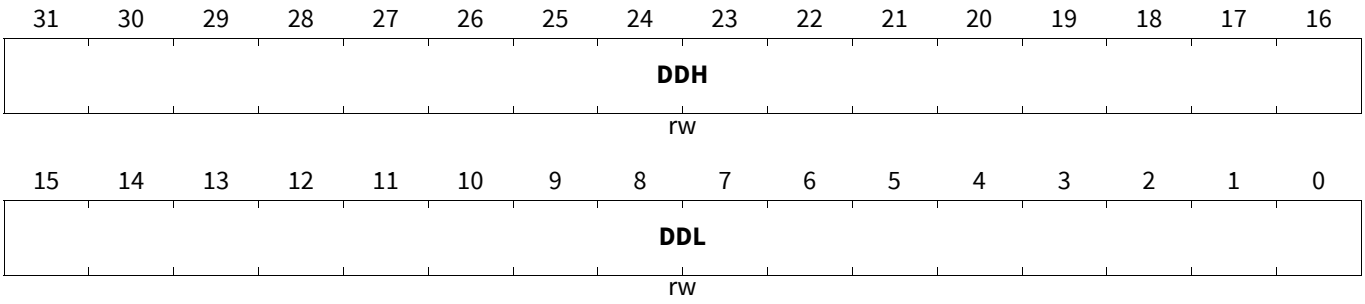
Field	Bits	Type	Description
UL1	31	w	**Unlock CX and FM for one write access** Write access with UL1 = 1 unlocks the CX and FM bit fields for the current write access. Write accesses to these bit fields with UL1 = 0 do not have any effect. Returns zero on read.
0	15:13, 27:17, 30:29	r	**Reserved** Read as 0; shall be written with 0.

38.4.3 Data Registers

Downstream Data Register

The Downstream Data Register DD contains data to be transmitted during data frames.

DD
Downstream Data Register **($01C_H$)** **Application Reset Value: $0000\ 0000_H$**

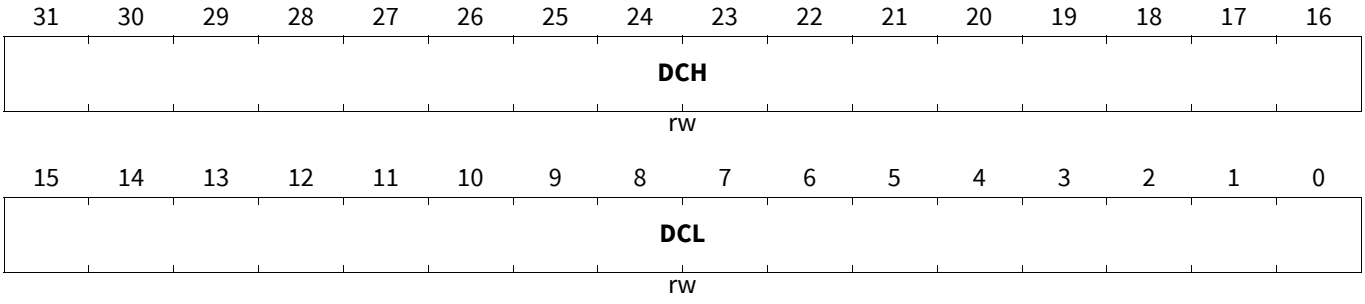


Field	Bits	Type	Description
DDL	15:0	rw	**Downstream Data for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDH	31:16	rw	**Downstream Data for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

Downstream Command Register

The Downstream Command Register DC contains command information to be transmitted during command frames. Every write access to the DC register triggers a transmission of a command frame.

DC
Downstream Command Register **(020_H)** **Application Reset Value: $0000\ 0000_H$**



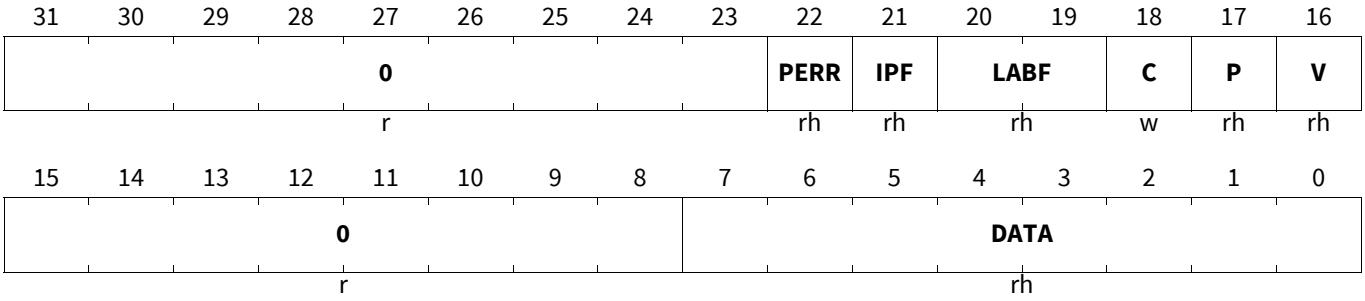
Field	Bits	Type	Description
DCL	15:0	rw	**Downstream Command for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a command frame.
DCH	31:16	rw	**Downstream Command for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a command frame.

Upstream Data Register x

The four Upstream Data Registers UDx store the content (data, addresses, received and calculated parity bit, parity error bit) of a received upstream channel data frame.

UDx (x=0-3)

Upstream Data Register x **(030_H+x*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DATA	7:0	rh	**Received Data** This bit field contains the 8-bit receive data.
V	16	rh	**Valid Bit** This bit is set by hardware when the received data is written to UDx. Writing bit C = 1 clears V. If hardware setting and software clearing of the valid bit occur simultaneously, bit V will be cleared.
P	17	rh	**Parity Bit** This flag contains the parity bit that has been received with the data frame.
C	18	w	**Clear Bit** C is always read as 0. 0_B No operation. 1_B Bit V is cleared.
LABF	20:19	rh	**Lower Address Bit Field** This bit field contains the two address bits A[1:0] of the 4-bit address field (16-bit data frame). If 12-bit data frame is selected, LABF is always set to 00_B.
IPF	21	rh	**Internal Parity Flag** This bit contains the parity bit that has been calculated in the MSC during data frame reception.
PERR	22	rh	**Parity Error** This bit indicates if a start bit error, parity error, or stop bit error occurred during frame reception. 0_B No error detected. 1_B Error detected.
0	15:8, 31:23	r	**Reserved** Read as 0; shall be written with 0.

38.4.4 Extension Registers

This sub-chapter describes the registers related to 64-bit extension of the MSC module.

Emergency Stop Extension Register

The Emergency Stop Extension Register ESRE determines which bits of SRL and SRH are enabled for emergency operation.

ESRE

Emergency Stop Extension Register (068$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENH31	**ENH30**	**ENH29**	**ENH28**	**ENH27**	**ENH26**	**ENH25**	**ENH24**	**ENH23**	**ENH22**	**ENH21**	**ENH20**	**ENH19**	**ENH18**	**ENH17**	**ENH16**

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENLx (x=16-31)	x-16	rw	**Emergency Stop Enable for Bit x in SRL** This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit is of the data register DD.DDL[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRL[x] is disabled. 1_B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x=16-31)	x	rw	**Emergency Stop Enable for Bit x in SRH** This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DD.DDH[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRH[x] is disabled. 1_B The emergency stop feature for bit SRH[x] is enabled.

Downstream Data Extension Register

The Downstream Data Extension Register DDE contains data to be transmitted during data frames.

DDE

Downstream Data Extension Register (074$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DDHE															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DDLE															
rw															

Field	Bits	Type	Description
DDLE	15:0	rw	**Downstream Data Extension for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHE	31:16	rw	**Downstream Data Extension for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

Downstream Data Mirror Register

The Downstream Data Mirror Register DDM provides alternative address for the DD register. The purpose of this alternative address is to provide convenient way to write up to 64 bit data blocks to the MSC module by using DMA with automatic address increment and wrap around. The DMA writes first to the DDE register, and then to the DDM register, which behaves in the same way as a write to the DD register.

DDM
Downstream Data Mirror Register (070$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DDHM															
w

DDLM															
w															

Field	Bits	Type	Description
DDLM	15:0	w	**Downstream Data Mirror for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHM	31:16	w	**Downstream Data Mirror for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

Downstream Command Mirror Register

The Downstream Command Mirror Register DCM provides alternative address for the DC register. This alternative address provides convenient way to write up to 64 bit data blocks to the MSC module by using DMA with automatic address increment and wrap around. The DMA writes first to the DCE register, and then to the DCM register. Every write to DCE triggers a command transmission the same way as a write to the DC register.

DCM

Downstream Command Mirror Register (078$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DCHM															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCLM															
w															

Field	Bits	Type	Description
DCLM	15:0	w	**Downstream Command Mirror of the DC.DCL Bit Field** Contains alternate write location for the command bits to be transmitted during the SRL active phase of a command frame.
DCHM	31:16	w	**Downstream Command Mirror of the DC.DCH Bit Field** Contains the alternate write location for the command bits to be transmitted during the SRH active phase of a command frame.

Downstream Command Extension Register

The Downstream Data Extension Register DDE contains data to be transmitted during data frames, which are concatenated to the standard 32-bit commands, after the second select bit.

DCE

Downstream Command Extension Register (07C$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCEH															
rw															

Field	Bits	Type	Description
DCEH	31:0	rw	**Downstream Command Extension for SRH Shift Register** Contains the data bits to be transmitted during the second half of the command frame in CX mode.

38.4.5 Asynchronous Block Registers

Asynchronous Block Configuration Register

The Asynchronous Block Configuration register ABC contains all the bit fields related to the ABRA block.

>> **Configuring the ABRA block**

*Note: Switching the peripheral clock off and on is done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write switching on the clock source. Between the first and the second write a delay of minimum 4 * (1/f_{PER}) + 2 * (1/f_{CLC}) must be inserted by software, where f_{PER} is the frequency being switched off with the first write. This also applies if in-between the writes the clock frequency is changed in the CCU.*

ABC

Asynchronous Block Configuration Register (080_H) Application Reset Value: $0000\ 0000_H$

HIGH	7:4	rw	**Duration of the High Phase of the Shift Clock** Defines the duration of the high phase of the shift clock in periods of f_A in the range of 1 to 16. 0_H 1 … F_H 16
OIP	9:8	rw	**Overflow Interrupt Node Pointer** OIP selects the service request output line SRn (n = 0-3) for the overflow interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected

Field	Bits	Type	Description
OASR	10	rw	**Overflow Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 547**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
OVF	12	r	**Overflow Flag** Indicates if overflow error has occurred. 0_B No overflow error 1_B Overflow error
OFM	14:13	w	**Overflow Flag Modify** Sets or clears the overflow flag OVF. 00_B No action 01_B Set (and triggers the overflow interrupt if enabled) 10_B Clear (additionally flushes the ABRA FIFO and resets the bit counter) 11_B No action
OIE	15	rw	**Overflow Interrupt Enable** Enables or disables the path of the interrupt signal towards the interrupt node. If enabled, an overflow event triggers an interrupt, and if disabled then not. The OVF flag always indicates the occurrence of an overflow event, independently of OIE. 0_B Overflow interrupt disabled 1_B Overflow interrupt enabled
NDA	18:16	rw	**N Divider ABRA** Defines the division ratio in the range of 1 to 8. 000_B 1 … 111_B 8
UIP	20:19	rw	**Underflow Interrupt Node Pointer** UIP selects the service request output line SRn (n = 0-3) for the underflow interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
UASR	21	rw	**Underflow Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. See **Figure 547**. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
UNF	23	r	**Underflow Flag** Indicates if underflow error has occurred. 0_B No underflow error 1_B Underflow error

Field	Bits	Type	Description
UFM	25:24	w	**Underflow Flag Modify** Sets or clears the underflow flag UNF. 00_B No action 01_B Set (also triggers the underflow interrupt if enabled) 10_B Clear (additionally flushes the ABRA FIFO and resets the bit counter) 11_B No action
UIE	26	rw	**Underflow Interrupt Enable** Enables or disables the path of the interrupt signal towards the interrupt node. If enabled, an underflow event triggers an interrupt, and if disabled then not. The UNF flag always indicates the occurrence of an underflow event, independently of UIE. 0_B Underflow interrupt disabled 1_B Underflow interrupt enabled
CLKSEL	29:27	rw	**Clock Select** Selects the clock source for the ABRA block. 000_B no clock 001_B f_{PER} **others**, reserved (no clock)
ABB	31	rw	**Asynchronous Block Bypass** Defines if the asynchronous block and the n-divider of the MSC downstream path (located parallel to the fractional divider) are used or not. If bypassed, then also disabled. 0_B Bypassed and disabled 1_B Not bypassed and active
0	11, 22, 30	r	**Reserved** Read as 0; shall be written with 0.

38.5 Use Cases

This section provides a code example for the MSC module to give an overview about the core functionality. It describes how to send data frames continuously without any software interaction, called data repetition mode. This examples uses interface MSC 0.

Each interface can send command and data frames (see also **Frame Formats and Definitions**) via downstream channel. Between each data frame one or more passive frames can be inserted (see also **Figure 529**). This example realizes sending out only data frames in repetition mode with one passive frame in between. The module has more features than the example shows. For further details please see user's manual.

The MSC module can also receive frames with the upstream channel. These frames are usually status frames from the external devices. The example keeps the focus on sending out via downstream channel so the upstream channel is not part of this chapter. The initialization process follows the following order:

1. Enable MSC 0
2. Initialize MSC 0 for down streaming
3. Start sending

Step description to initialize the MSC module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter).

(Line 2) enable control of the module, in clock control register **CLC**.

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) This line loads the fractional divider register **FDR**. DM=01 sets the module to normal divider mode while STEP defines the Baudrate.

Note: Assuming fclc=100MHz and STEP=3FE --> Baudrate =25 Mbaud

(Line 5) set ENDINIT to lock the protected register again.

(Line 6) This line loads the downstream control register **DSC**. TM=1 sets the module to data repetition mode, NDBL and NDBH are defining the length of the SRL and SRH active phase, here set to 15 bit (see also **Figure 525**). PPD=2 sets the length of the passive frame to 2 x tFCL and DSDIS=1 disables sending. Sending will be enabled after initialization.

(Line 7) This line set the number of passive time frames in the downstream status register **DSS**. NPTF=1 --> one passive time frame gets inserted.

(Line 8) The data gets loaded in the downstream data register **DD**. The data itself is here just an example.

(Line 9) This line resets DSDIS, so the module starts sending out data and passive time frames.

Initialization of the MSC module:

```
// enable MSC 0
(1)     SCU_vResetENDINIT (0);              // enable ENDINIT reg
(2)     MSC0_CLC.U = 0x000;                 // disable module control
(3)     dummy = MSC0_CLC.U;                 // read to check the made changes
(4)     MSC0_FDR.U = (1 << 14) | 0x3FE;     // DM=01, STEP=3FE
(5)     SCU_vSetENDINIT (0);                // lock ENDINIT reg
// Initialize MSC 0 for down streaming
(6a)    MSC0_DSC.U = 0x02001081;            // PPD=2,NDBH=16,NDBL=16,TM=1
(6b)    MSC0_ISC.U = (0x1 << 22);           // DSDIS=1
(7)     MSC0_DSS.U = (1 << 8);              // NPTF=1
(8)     MSC0_DD.U = 0x5555AAAA;             // downstream data (example)
```

```
// Start sending
(9)     MSC0_ISC.U = (0x1 << 6);            // DSDIS=0
```

38.6 IO Interfaces

This section describes the on-chip connections of the MSCx module.

The table below lists the interfaces of the MSC to other modules in the device.

Table 343 List of MSC64 Interface Signals

Interface Signals	I/O	Description
clocks		**Clock socket**
sx_dft_clocks		**DfT Clock socket**
reset		**Reset socket**
bus_fpi_slave		**FPI slave socket**
protect		**Protection socket**
sx_sff		
debug		**OCDS socket**
standard_spll		**Scan socket**
standard_ppll		**Scan socket**
sx_irq_msc		**Interrupt socket**
sx_gtm2msc		**GTM signal socket**
SR0_INT	out	**MSC Service Request 0**

ALTINH(15:0)	in	**GTM timer output vector - high part**
ALTINHEXT(15:0)	in	**GTM timer output vector - high extension part**
prdcfg	in	**product configuration**
INJ0	in	**Injection signal from port**
INJ1	in	**Injection signal from port**
EN(3:0)	out	**Chip Select**
EMGSTOPMSC	in	**Emergency stop signal from SCU**
FCLN	out	**Shift-clock inverted part of the differential signal**
FCLP	out	**Shift-clock direct part of the differential signal**
SDI(7:0)	in	**Upstream asynchronous input signal**
SON	out	**Data output - inverted part of the differential signal**
SOP	out	**Data output - direct part of the differential signal**

38.6.1 Port Emergency Stop Signal (from SCU)

The emergency stop input signal Port Emergency Stop of the MSCx modules is connected to the output signal of the emergency stop input control logic. This logic is located in the SCU. Its functionality is controlled by the SCU emergency stop register.

Note: If the Port Emergency Stop signal is used by the MSC module, setting the SCU.EMSR.MODE=0 is mandatory. MODE=1 is not allowed to be used with the MSC module.

38.6.2 Interrupt Service Requests

All five service request outputs SR[4:0] are connected to the Interrupt Router Module. There they are routed further to a CPU or a DMA. The MSCx_SRCy registers are also located in the IR (Interrupt Router) Module.

38.6.3 GTM Connections

Each MSC module can be connected to up to 64 TOM or ATOM outputs of the GTM module. For description of the connections between the GTM and MSC modules, see the section “MSC Connections” in the GTM chapter, which contains detailed description of the signals sets and the multiplexing options.

39 Single Edge Nibble Transmission (SENT)

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

Figure 562 shows a global view of the SENT interface.

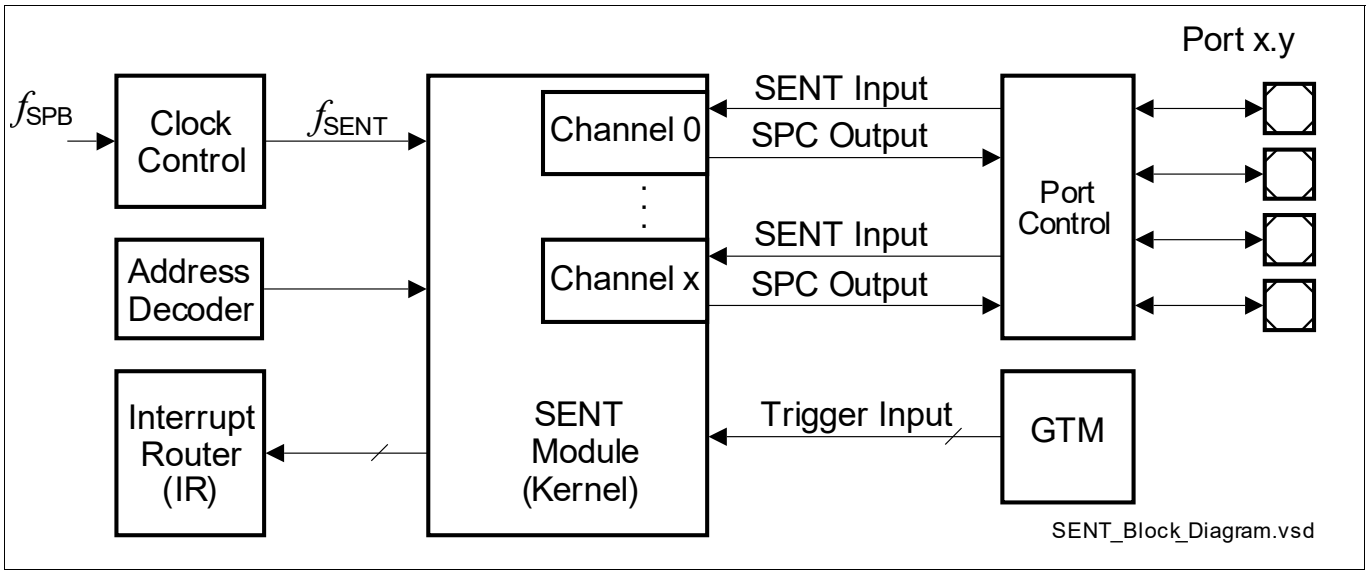

Figure 562 General Block Diagram of the SENT Interface

39.1 Feature List

FEATURE LIST

- Conformance with SENT SAE J2716 042016 (fully backward compatible with SAE J2716 2010 standard specifications)
- Data rates of up to 65,8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
- Support of standard tick times (3 µs through 90 µs)
- 25 SENT channels implemented, all working independently in parallel
- Message tick time programmable between 0.2 µs and 1024 µs, see restrictions in **Chapter 39.3.4.1**
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
- The receiver module will monitor the message for the following error conditions:
- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks

- Too many or too few nibbles between calibration pulses.
- Checksum error.
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to relief CPU
- Time stamp generation
- Watch Dog on incoming frames
- Support frequency drift analysis based on frame length for frames with pause pulse

REFERENCES

This Internal Target Specification is based on: SAE Standard "**SAE J2716 042016**".

39.2 Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification SAE J2716 042016.
While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by SAE J2716 042016. SPC enables the use of enhanced protocol functionality like "synchronous", "range selection" and "ID selection" protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

39.3 Functional Description

39.3.1 General Operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost

alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 563 shows a typical application in which a SENT interface reads a sensor device.

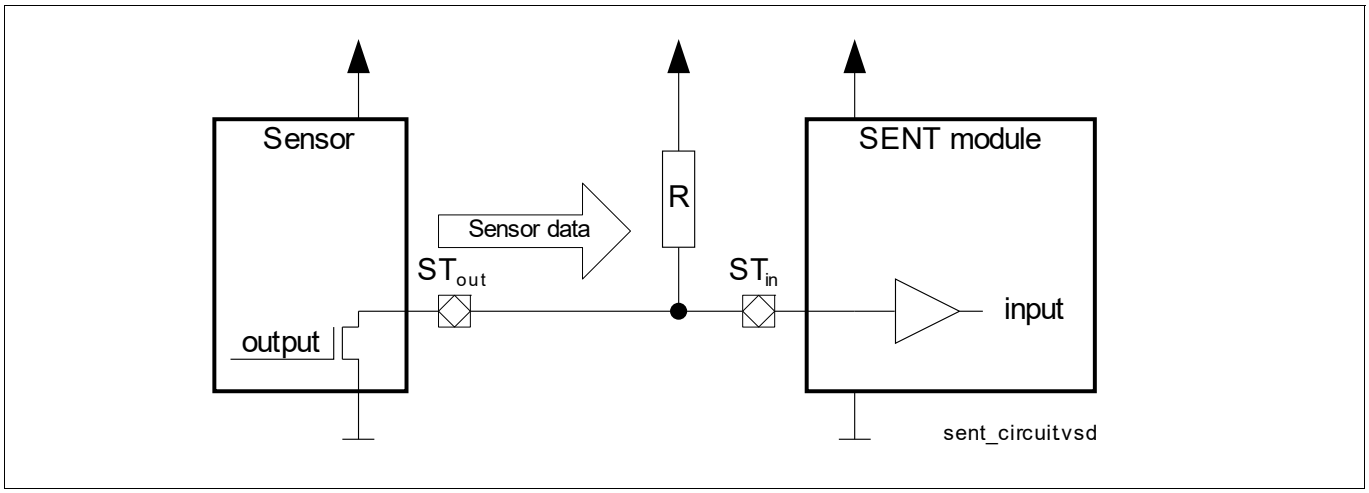

Figure 563 SENT to External Device Connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of unidirectionality as said above while keeping conformance to the standard.

Figure 564 shows a typical application in which an SPC enabled SENT ECU reads an SPC enabled SENT sensor device.

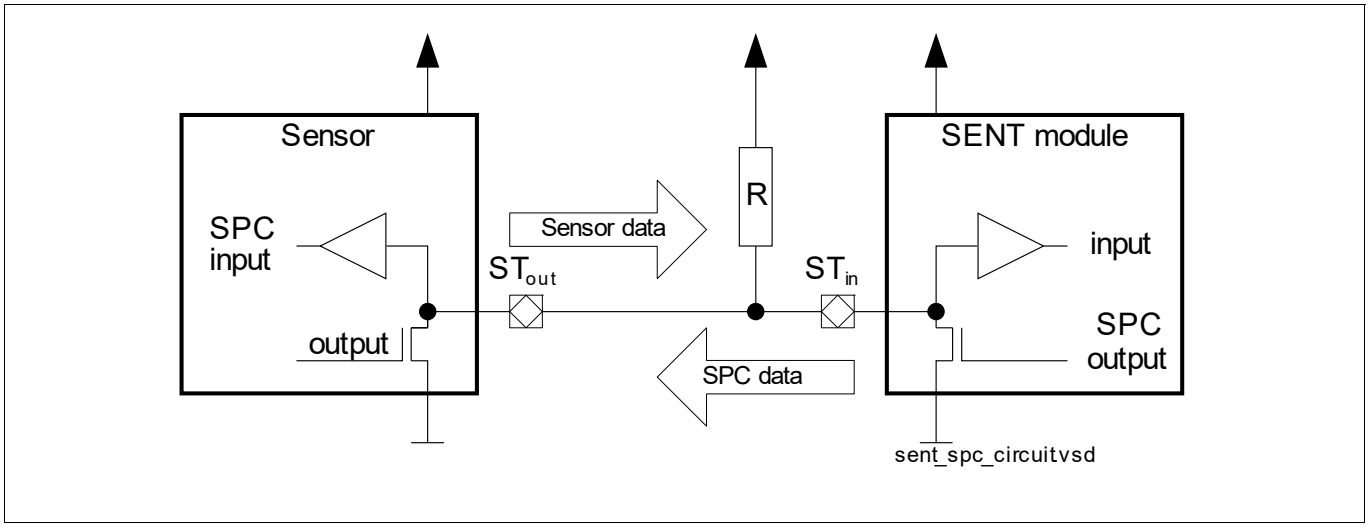

Figure 564 SENT SPC to External Device Connection

Some applications are:

- Read out of the external throttle position sensor (e.g. SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel.
- Serial connections to other peripheral devices

39.3.1.1 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SPC: Short PWM Code

PWM: Pulse Width Modulation

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

39.3.2 Standard SENT Operation

Standard SENT Mode supports communication fully compliant to SAE J2716 042016, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. **Figure 565** shows the block diagram of the SENT Module when operating in Standard SENT Mode.

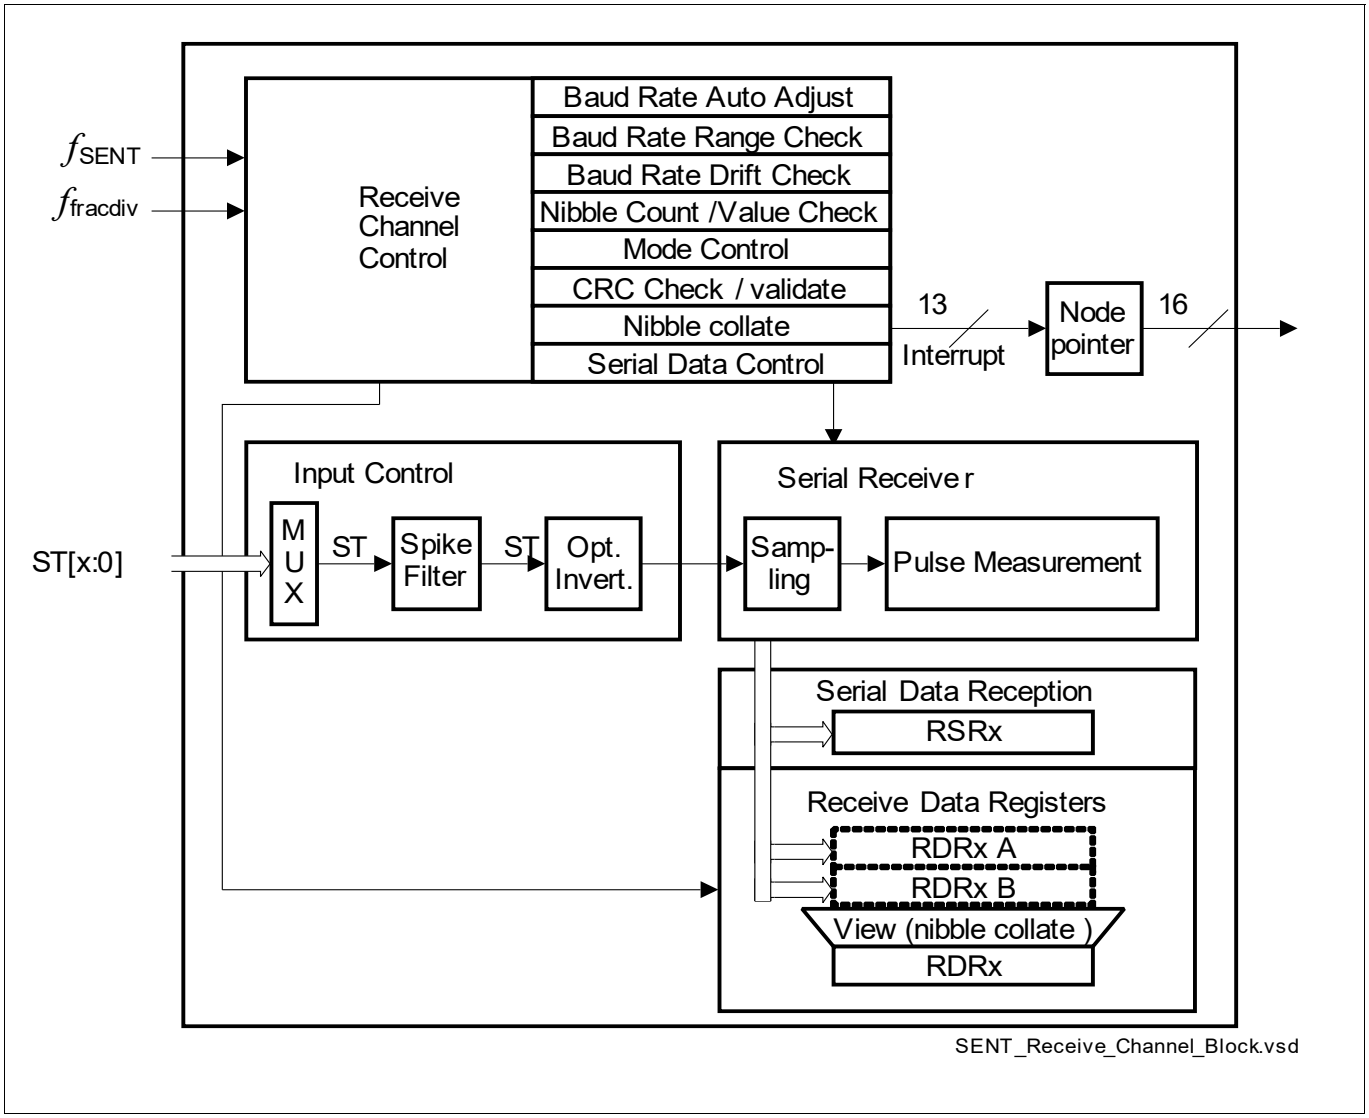

Figure 565 Standard SENT Mode Operation

39.3.2.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic Definitions

Figure 566 shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

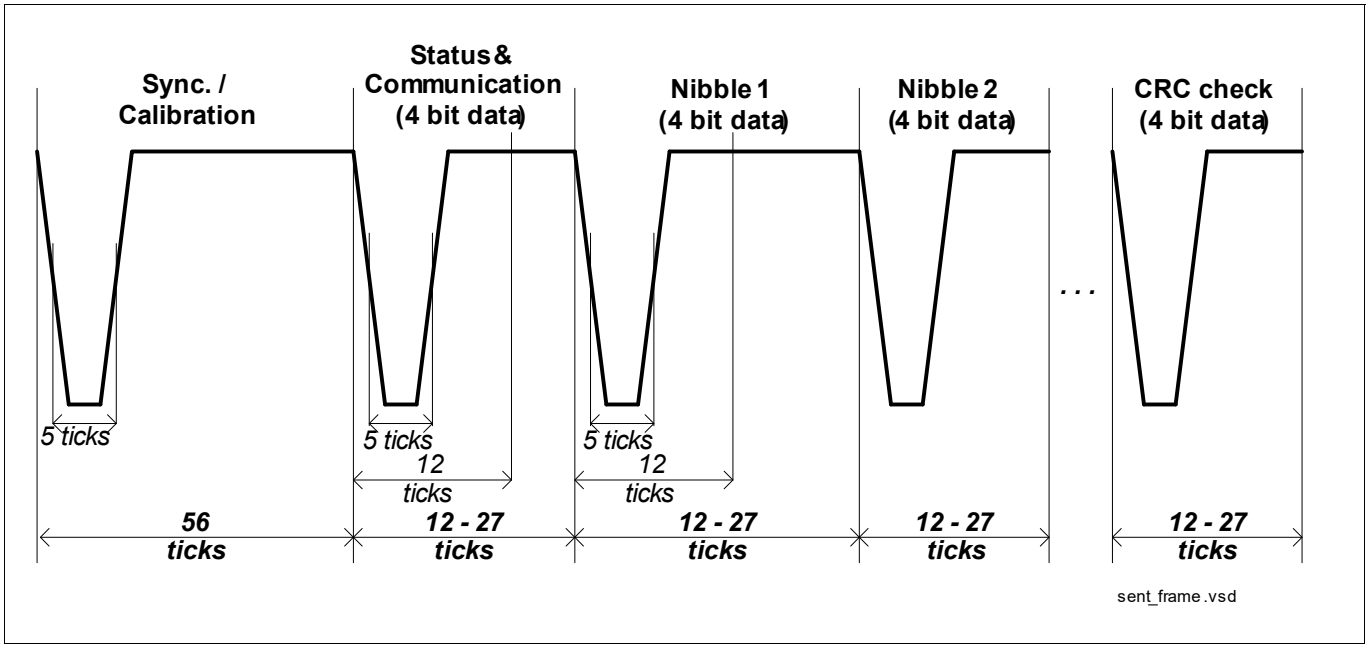

Figure 566 Standard Encoding Frame

Serial Data Encoding in Status and Communication Nibble

The Status and Communication nibble is used by sensors that transmit extra serial data such as part numbers or diagnostic information. Data bits from this nibble are constructed across multiple SENT messages to form a Short Serial Message or an Enhanced Serial Message. These messages are alternately referred to as “Slow Channel” data in the SAE J2716 042016.

Table 345 Short Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

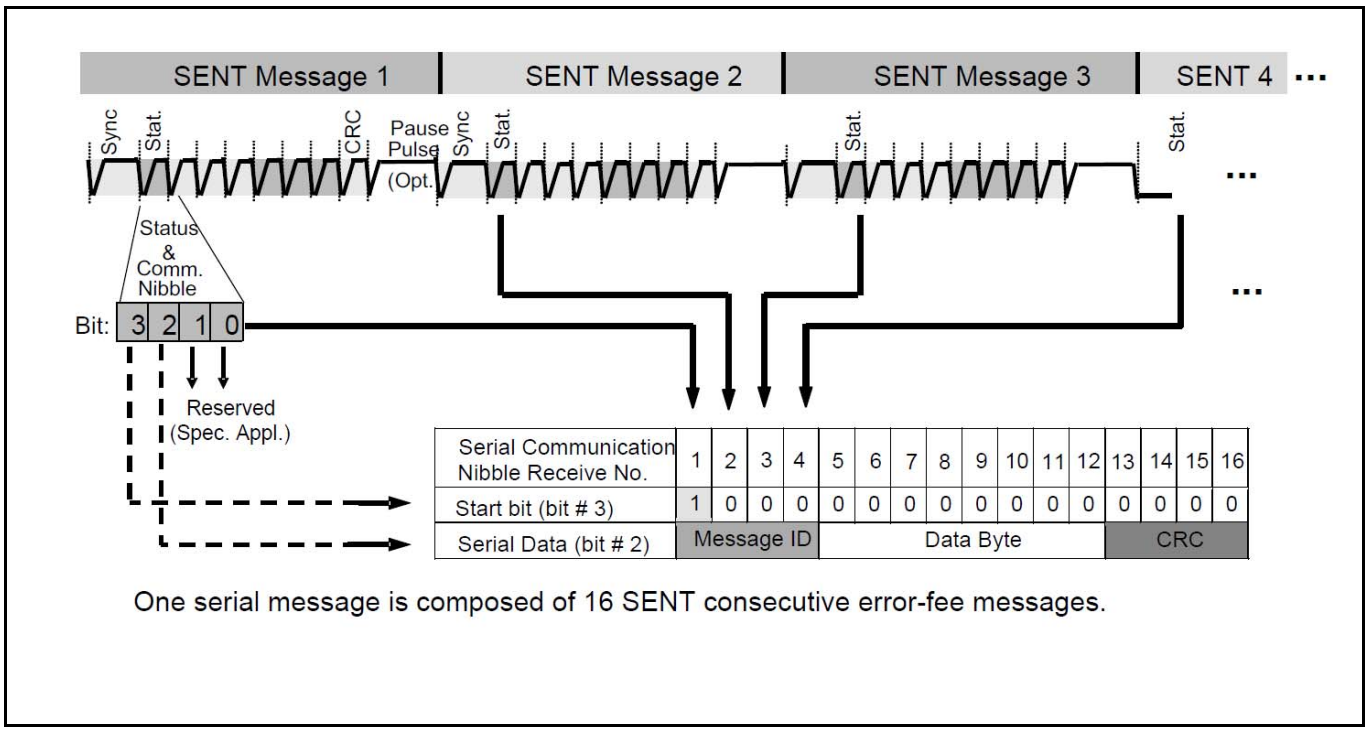

Figure 567 Short Serial Message, Serial Data Encoding over 16 messages

Short Serial Message Format

The SENT kernel supports the Short Serial Message Format defined in the SAE J2716 042016. The Short Serial Message Format provides 16 bits of data, constructed across 16 SENT messages. Each of the 16 messages contains one bit of Short Serial Message data in Status and Communication nibble bit 2.

Serial data is communicated in a 16-bit sequence as shown in **Table 346**. The start of a Short Serial Message is indicated by a 1 in bit 3 of the Status and Communication nibble. That SENT message and the next 15 must be successfully received (no errors) for the Short Serial Message data to be received. The CRC generation is identical to the CRC generation on the data nibbles. Short Serial Message data is provided in the SDSx register.

Table 346 Short Serial Message Format

Serial Communication Nibble Receive No.	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**	**16**
Startbit (bit # 3)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Serial Data (bit # 2)	Message ID				Data Byte								CRC			

CRC Calculation

SENT signal data and Short Serial Message data is secured with a 4 bit CRC. The standard CRC calculation method is defined in the SAE J2716 042016.

RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial x^4 +x^3 + x^2 + 1 with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used e.g. in the sensor TLE4998 for the signal data. See **Figure 568** for details.

// Fast way for any µC with low memory and compute capabilities

```
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {…};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15, 2, 8, 5};
CheckSum= 5; // initialize checksum with seed “0101”
for (i=0; i<7; i++) {
CheckSum = CheckSum ^ Data[i];
CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

For the “Enhanced Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

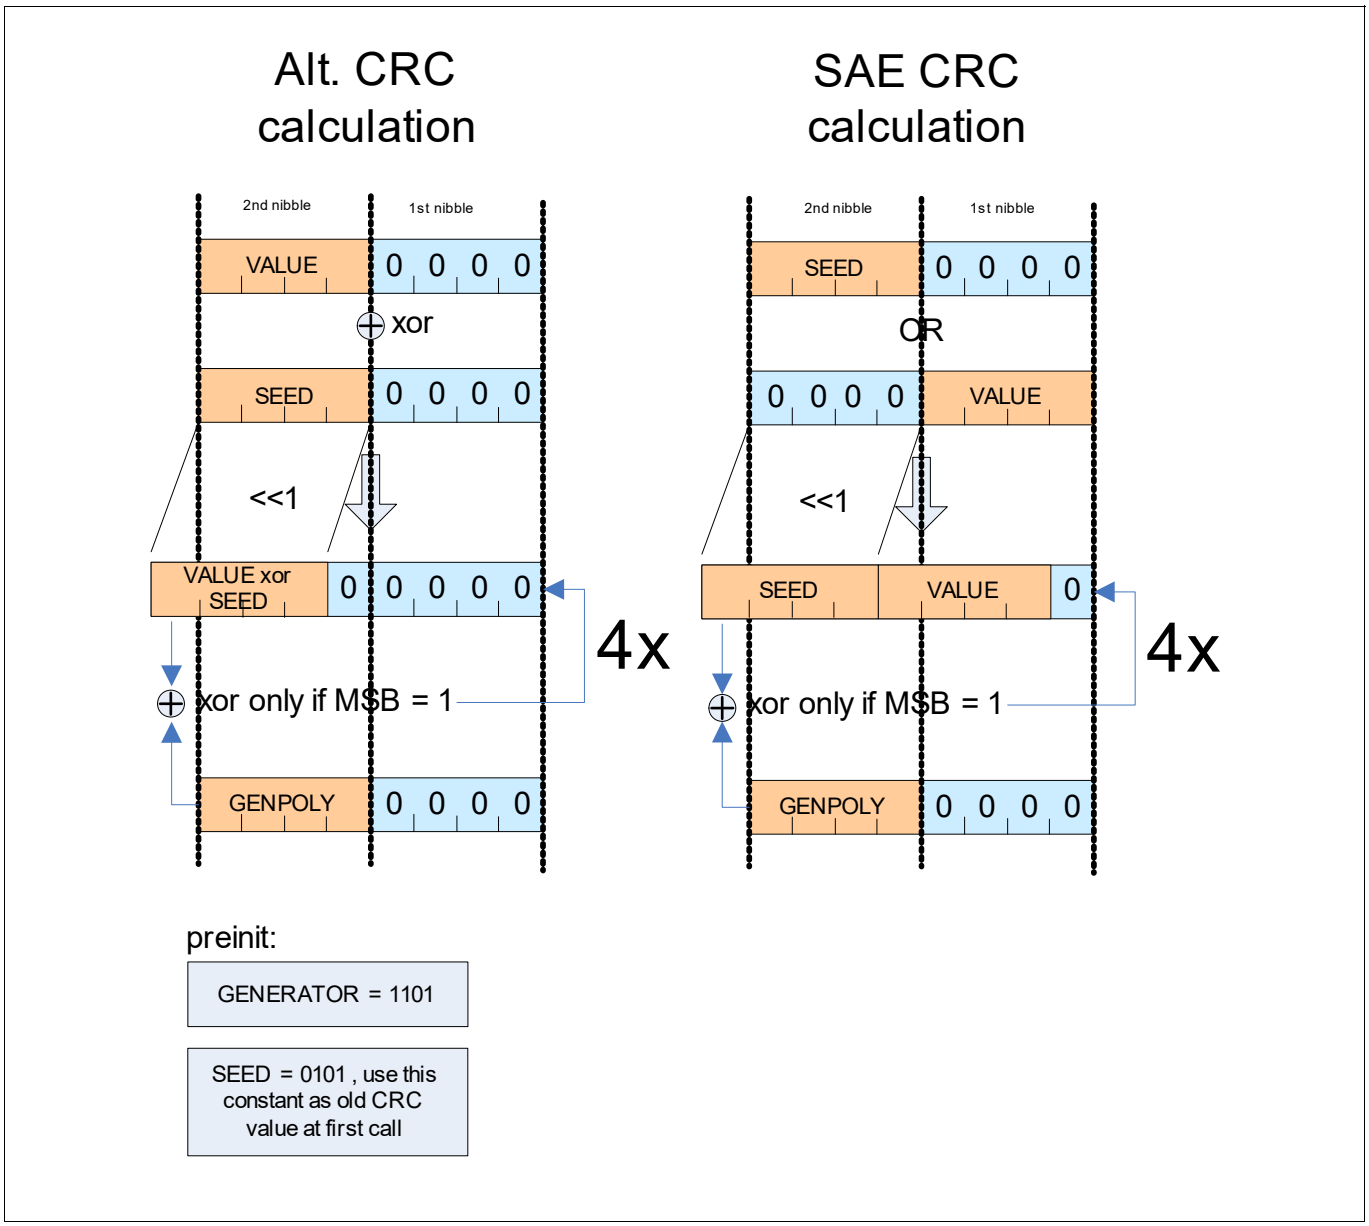

Figure 568 Alternate vs. SAE CRC Calculation

Enhanced Serial Message Format

The SENT kernel supports the Enhanced Serial Message Format defined in the SAE J2716 042016. The Enhanced Serial Message Format provides 21 bits of message data and a 6-bit CRC, constructed across 18 SENT messages. The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

Table 347 Enhanced Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1 1 1 1 1 1 0

Enhanced Serial Message Frame

Serial data is communicated in an 18 frame sequence as shown in **Table 348**. The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit #3 of the status and communication nibble, constructed across 7 SENT messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive SENT messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The 6-bit Enhanced Serial Message CRC is different from the 4-bit CRC on SENT (fast channel) messages. (See SENT Standard)

An Enhanced Serial Message contains 21 bits of message data and a 6-bit frame-check sequence. A configuration bit (serial data bit #3 of the 8th SENT message's Serial Communication Nibble) determines how the SENT module interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID, see **Table 349**
- Configuration bit = 1: 16-bit data and 4-bit message ID, see **Table 350**

Enhanced Serial Message data is provided in the SDSx register.

Table 348 Enhanced Serial Message Frame

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	C	8-bit ID (7-4)				0	8-bit ID (3-0) or 4-bit data				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Note:

10. Message 8 Status Nibble bit # 3 is Configuration Bit C that defines the Enhanced Serial Data format:
*0: 12-bit data, 8-bit ID, see **Table 349***
*1: 16-bit data, 4-bit ID, see **Table 350***
11. Messages 17-14 Status Nibble bit # 3 contain either the lower 4 bits (Bit 3-0) of 8bit ID or 4 additional data bits.

Table 349 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

Table 349 Enhanced Serial Message Configuration - Bit = 0

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	0	8-bit ID (7-4)				0	8-bit ID (3-0)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Table 350 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

Table 350 Enhanced Serial Message Configuration Bit = 1

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	1	4-bit ID (3-0)				0	4-bit data (15-12)				0
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

39.3.3 SPC Operation

The module supports a SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by SAE J2716 042016. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

39.3.3.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin. This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble decoding and indicates that the data line is idle again. The timing diagram in **Figure 569** visualizes a synchronous transmission

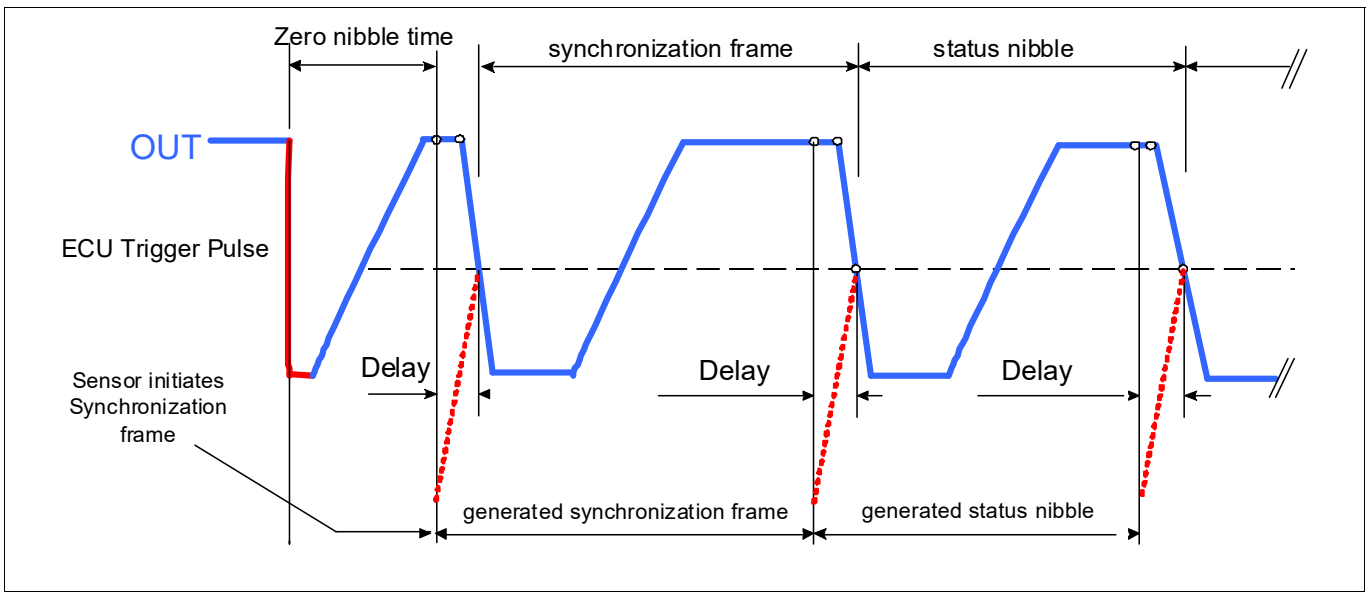

Figure 569 Synchronous Transmission (SPC)

39.3.3.2 Range Selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

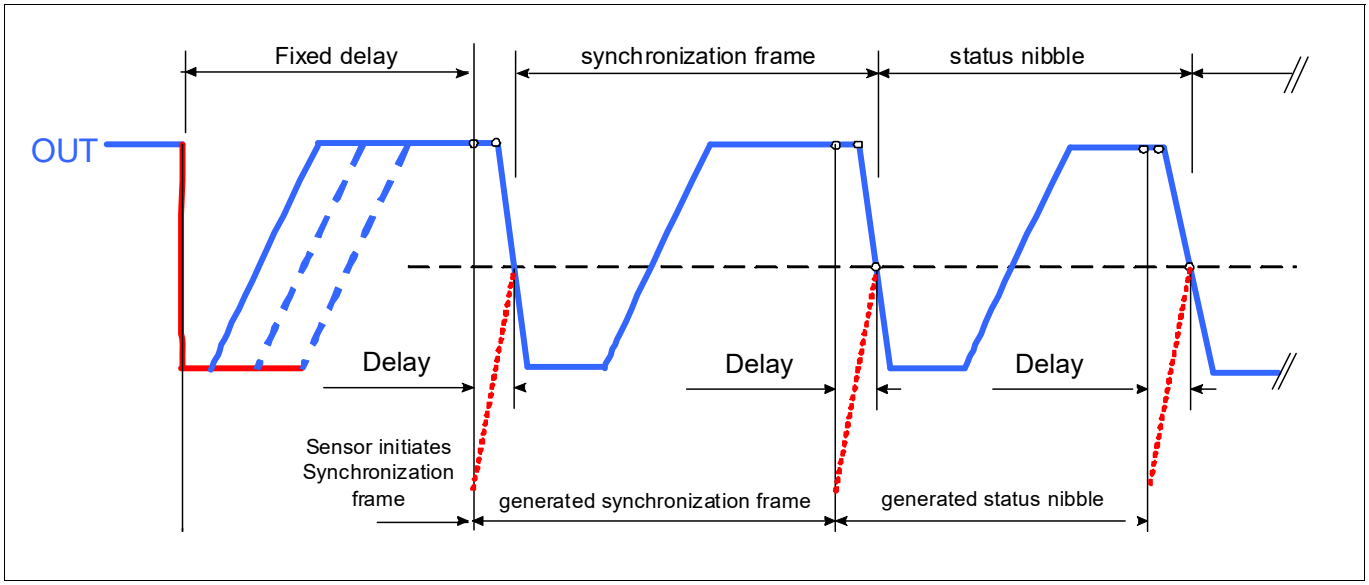

Figure 570 Range (SPC)

39.3.3.3 ID Selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in **Figure 571**.

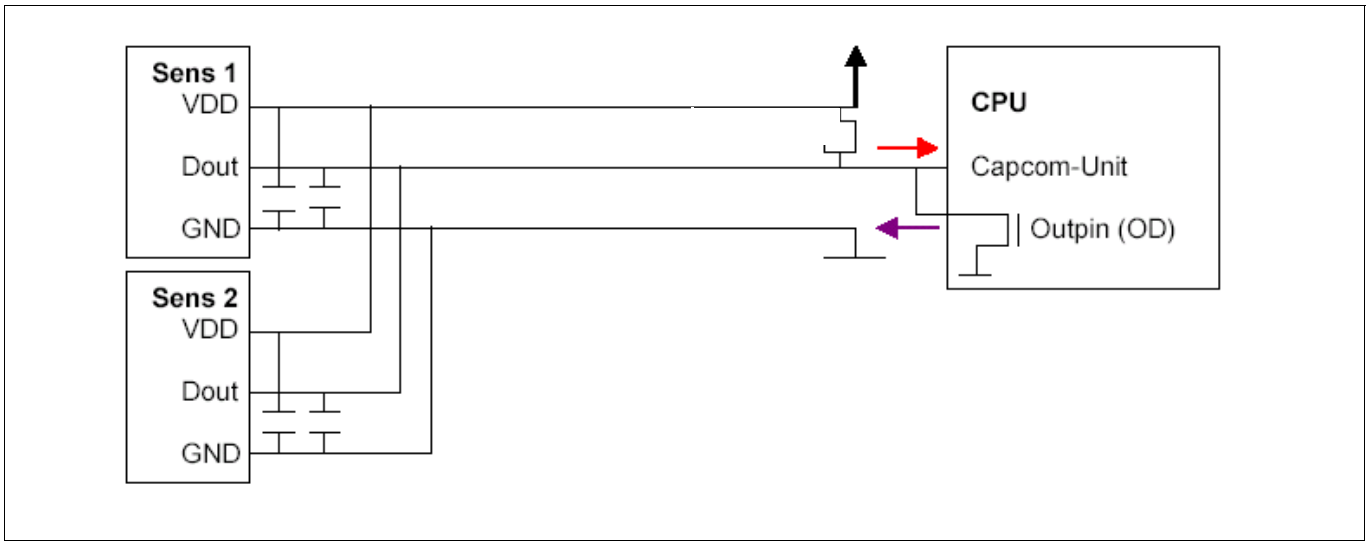

Figure 571 ID Selection (SPC)

39.3.3.4 Bidirectional Transmit Mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in **Figure 572**.

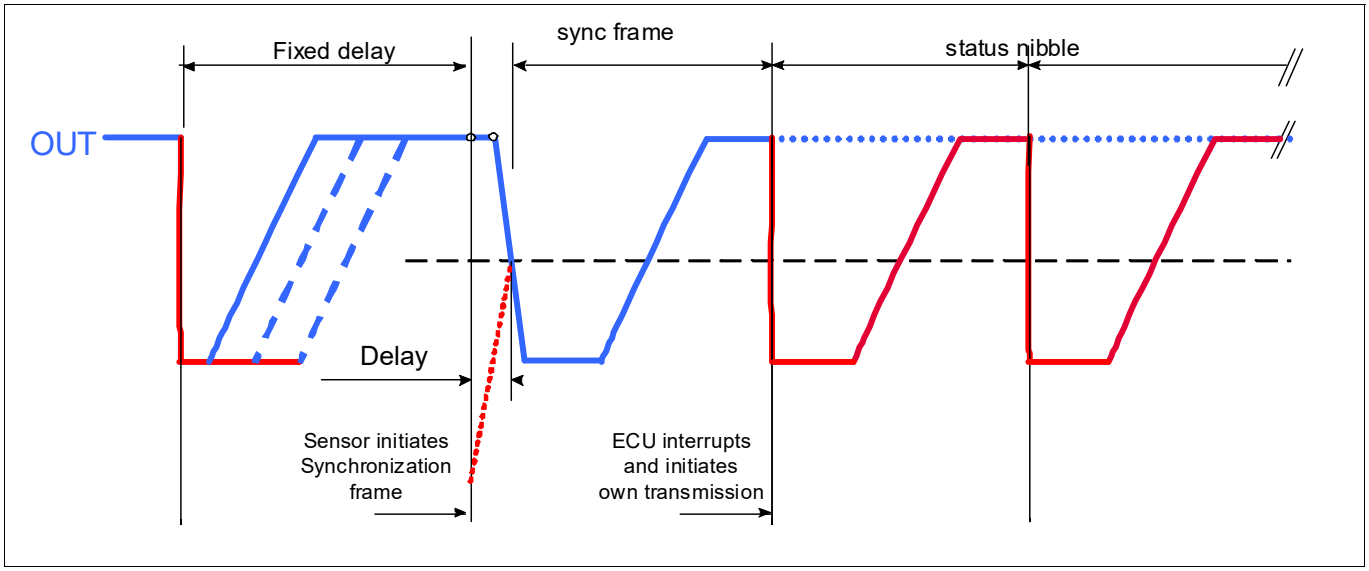

Figure 572 Bidirectional Transmit Mode (SPC)

39.3.3.5 SPC Timing

An SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold Vthf. The sensor detects that the OUT line has been released as soon as Vthr is crossed. **Figure 573** shows the timing definitions for the master pulse. The master low time tmlow as well as the total trigger time tmtr are individual for the different SPC modes and are given in the sensors specifications.It is recommended to chose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: tmlow,typ = (tmlow, min + tmlow, max) / 2.

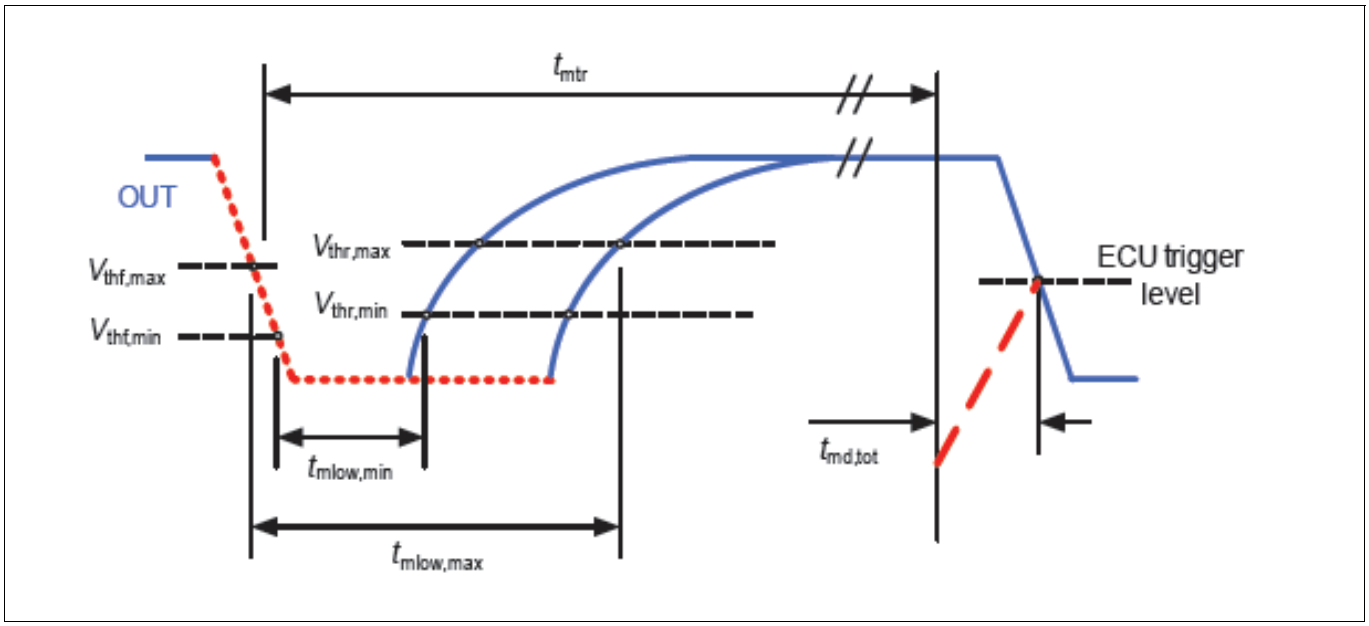

Figure 573 Timing (SPC)

39.3.3.6 Abort of Frames

Only a reset condition of the device, a hard suspend or choosing Mode 0 by clearing bit field SCRx.TRIG can abort a current SPC transmission immediately. During hard suspend, the port output drives its current value until suspend is terminated. If the receive channel becomes disabled, the soft suspend mode is requested, or the sleep mode is entered, the SENT module still does start a new frame transmission. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no frame finished interrupt is generated any more.

Received frames are aborted immediately on a disable, suspend or sleep request.

39.3.4 Baud Rate Generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending from the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +/- 25% as specified in SAE J2716 042016.

Chapter 39.3.4 shows in detail how the baud rate for each channel is adjusted. 1 / f_{tick_x} defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +/-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization / Calibration pulses of 1.5625% (1/64) and adapt the own baud rate.

The tick time is typically 3 µs but can vary by standard and take values up to 90 µs. To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency.

The SENT module provides two clock signals to the channels (**Figure 574**):

- f_{SENT}
  This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{SPB}. The clock control register SENT_CLC makes it possible to enable/disable f_{SENT} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

The channels generate two local clock signals:

- f_{pdiv_x}
  This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx controls the frequency of f_{pdiv_x}.
- f_{tick_x}
  This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx controls the frequency of f_{tick_x}.The higher the value of DIV the higher the precision with which the Synchronization / Calibration pulse and the deviation in the length of 2 consecutive Synchronization / Calibration pulses (drift) can be measured.
  DIV must be set in the range of [2200, 49100].

Each time a Synchronization / Calibration pulse starts DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x}. At the end of the Synchronization / Calibration pulse this value is taken as new divider of the CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with DIVM / 2. This is required to center the data eye and to make the margin symmetrical.

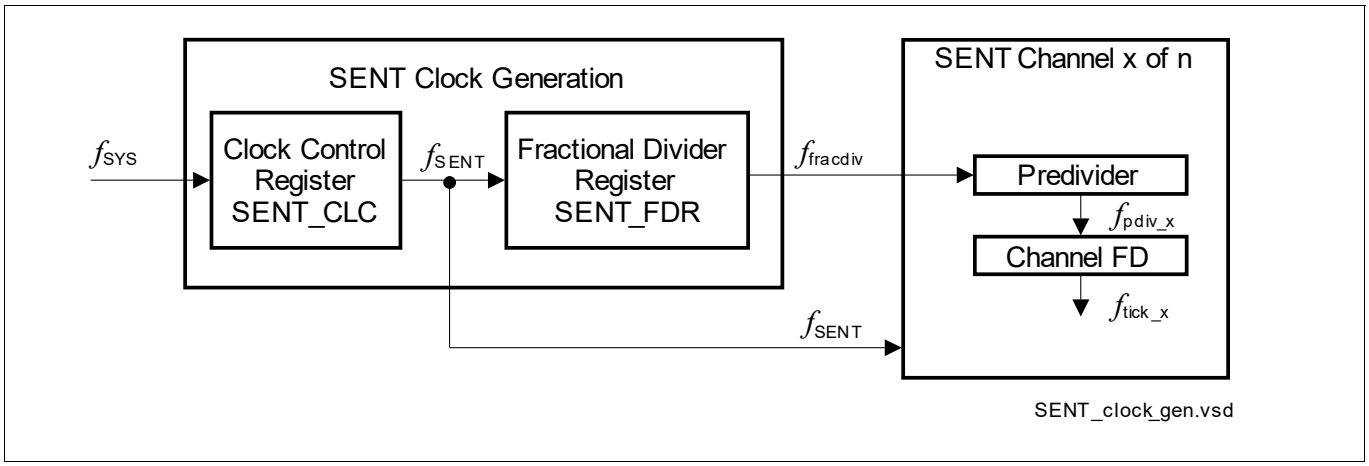

Figure 574 SENT Module Clock Generation

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{SENT}$ / (1024 - SENT_FDR.STEP); FDR.DM = 01_B (39.1)

$f_{fracdiv} = f_{SENT}$ x SENT_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10_B (39.2)

The following formula defines the frequency of f_{pdiv_x}:

$f_{pdiv\_x} = f_{fracdiv}$ / (SENT_CPDRx.PDIV + 1) (39.3)

The following formula defines the nominal frequency of f_{tick_x}. For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$f_{tick\_x} = f_{pdiv\_x}$ x 56 / SENT_CFDRx.DIV with DIV = 2200… 49100 (39.4)

39.3.4.1 Operation outside the granted Standard Limits

The SENT module is granted to comply SAE J2716 042016. The tolerances given in this standard are valid for tick times of 3 ... 90 µs. Nevertheless, the SENT module can operate outside this standard. A minimum tick time of 0.2 µs is programmable. In these use cases outside the standard it is in the responsibility of the system integrator to do proper jitter calculation and system design. Same holds true for tick times of > 90 µs. Note that the low pass filter as given in SAE J2716 042016 needs to be replaced by a circuit fit for the intended use case as well. Such use is not recommended, as a standard is missing for the system.

39.3.5 Error Detection Capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol Level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15
- Wrong Status and Communication nibbles
- Serial Communication CRC error

Transfer Management Level:

- Receive Data Buffer Overrun
- SPC Data Buffer Underrun

39.3.6 Support for Frequency Drift Analysis in Frames with Pause Pulse (FDFL)

Each SENT channel supports FDFL mode, i.e. monitoring the following condition for messages with pause pulse and fixed message length:

Ratio of calibration pulse to message length varies by > 1/64 or < -1/64 from one message to another.

The FDFL mode is entered if RCR.FDFL, RCR.IEP and RCR.IDE are set. RCR.CFC is ignored in this mode.

There is no automatic calculation or check done by HW in this mode nor is FDI issued. Frames that have an invalid frequency drift and would cause an FDI are still accepted and not dropped by HW. (FRI is not affected by this mode. I.e. the HW still checks the sensor frequency range.) The calculation of the ratio and the comparison with

the ratio of the preceding frame needs to be done in SW. The SW needs to decide whether or not to accept the frame based on this calculation.

The value for the calibration pulse length can be read by SW from CFDR.DIVM.

The value for the message length including pause pulse can be read by SW from RSR.FRLEN only if RCR.FDFL, RCR.IEP and RCR.IDE are set.Both values are valid after RSI. RSI indicates the Frame Buffer valid immediately after the Pause Pulse belonging to the current frame is received if no other error occurs.

FRLEN is a 16 bit counter with saturation (stops at 0xFFFF / 65.535) and is driven by f_{pdiv}.These factors limit the maximum supported length of frames including pause pulses. For the typical use case 1 / f_{tick} = 3 µs a good choice for f_{pdiv} is 16.6 MHz (PDIV = 5; f_{SENT} = 100 MHz). Thus, the frame length can be counted up to 3.93 ms.

Note that the nominal frame length must be 20% shorter to allow the system to compensate a 20% frequency drift. This is just an example calculation and not all products may support all frequencies.

Figure 575 shows the two times that are measured and that need to be set in relation to each other:

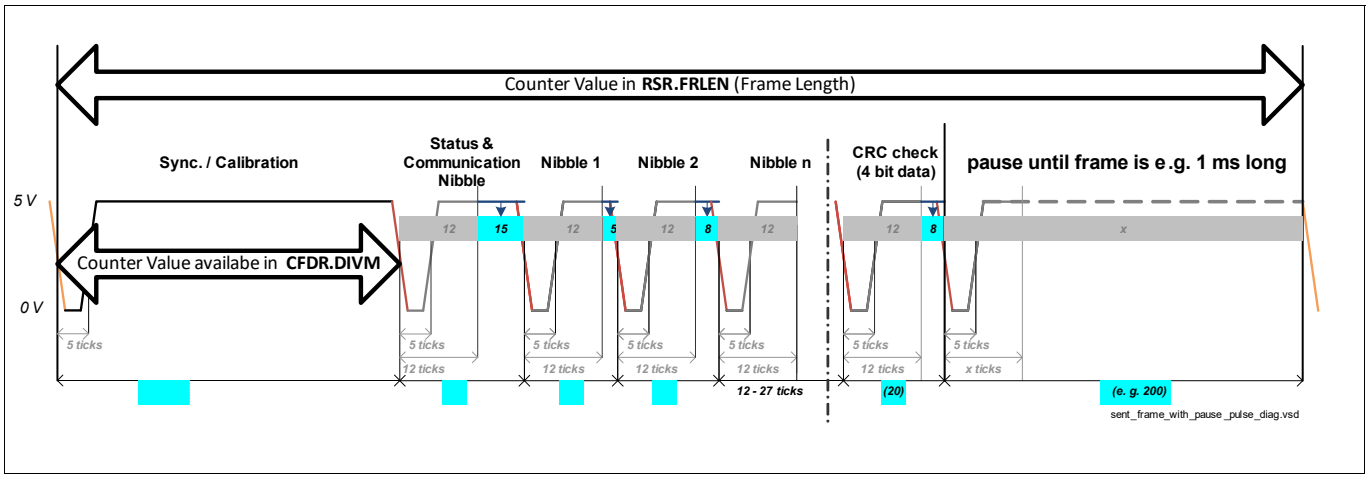

Figure 575 Frequency Drift Analysis in Frames with Pause Pulse

39.3.7 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{pdiv} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{pdiv}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 576 shows the digital glitch filter:

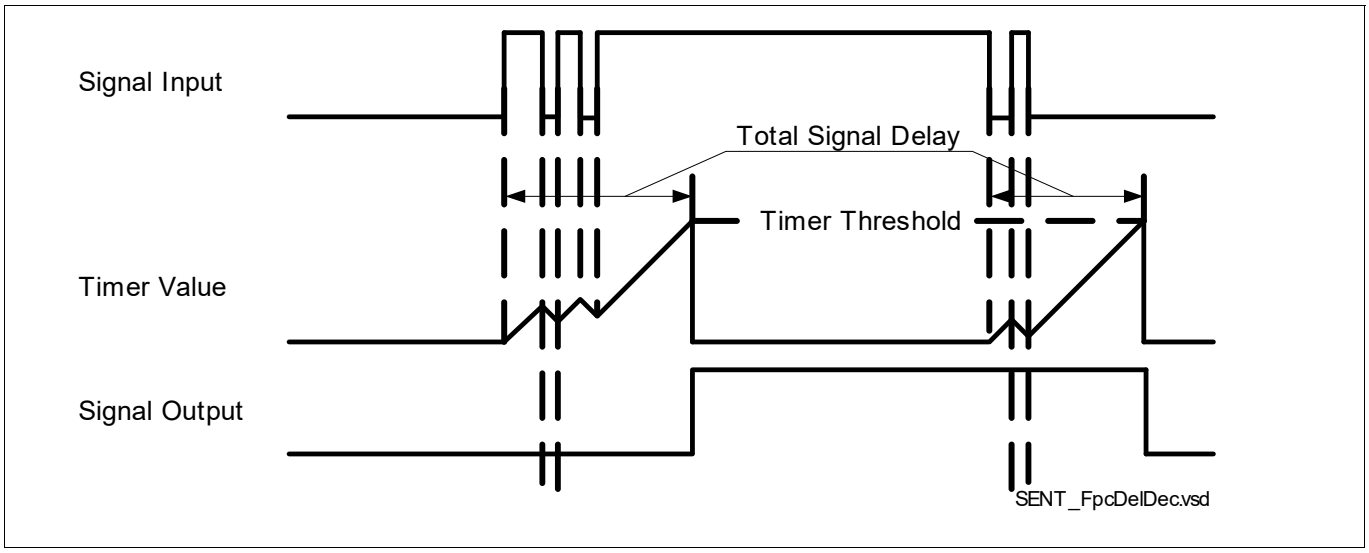

Figure 576 Digital Glitch Filter

39.3.8 Interrupts

10 Interrupt request lines are available for the SENT module.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. RSI indicates a receive frame success interrupt, i.e. the CRC was successful. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. TDI indicates a transmit interrupt. It is activated when data is moved from a SCR to a transmit shift register. TBI indicates a transfer buffer under run interrupt. It is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. In addition the protocol error interrupts are available: FRI, FDI, NNI, NVI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to SAE J2716 042016. WSI, SDI SCRI treat the interrupts referring to the Status and Communication nibble. WDI is the Watch Dog Error Interrupt. It is issued if the time between two frames is too long.

For acceleration of the interrupt service routine, a Register INTOV is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.
If more than one interrupt source is connected to the same interrupt node pointer (in register INPx), the requests are combined to one common line.

39.3.9 Interface Connections of the SENT Module

Figure 577 shows a more specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. Outputs of the GTM module are connected to the timer inputs.

The inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are mapped to the same port pin like the referring SENT data input line on a specific product, they can be used in a quasi bidirectional mode (i.e. open drain out and input on the same pin).

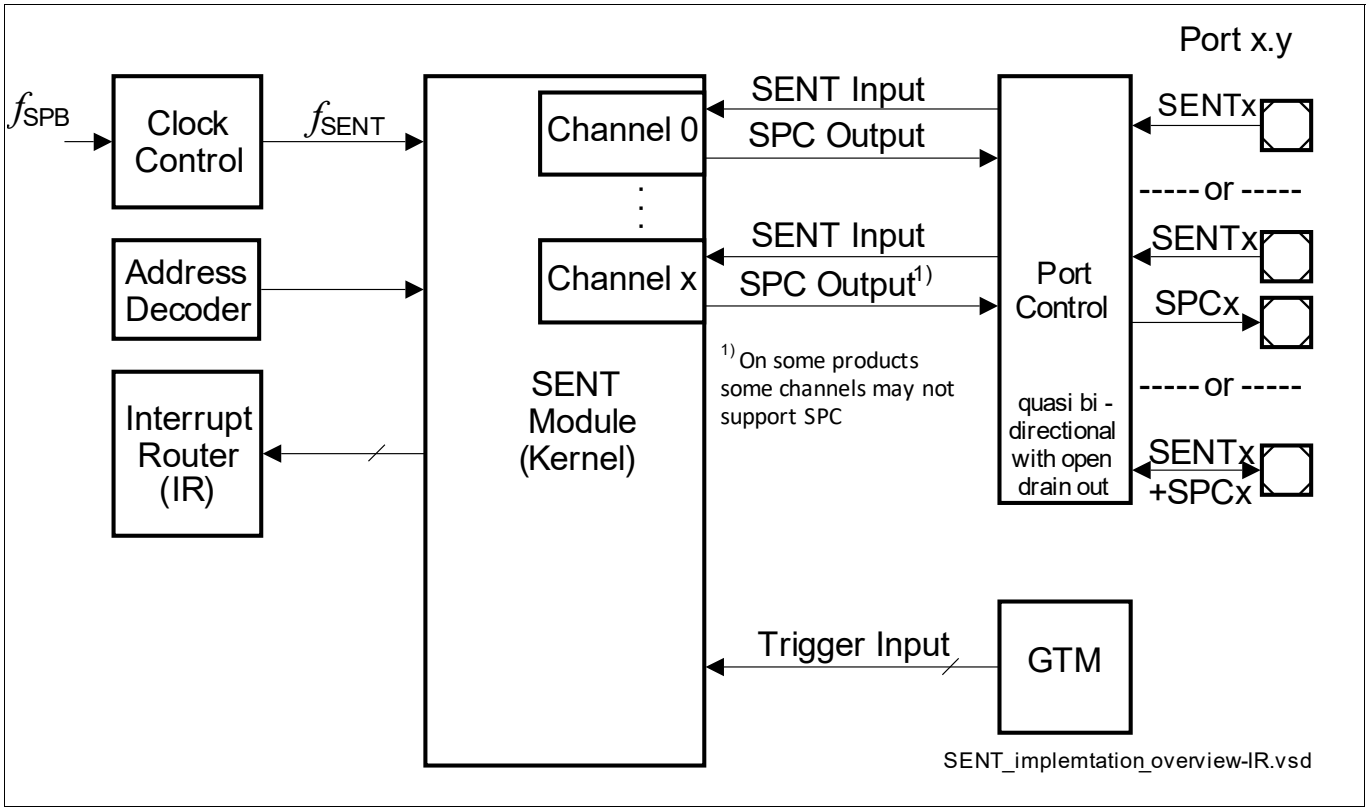

Figure 577 SENT Module Implementation and Interconnections

39.3.9.1 Trigger Inputs

The module has 25 SENT channels and the same number of trigger inputs but not more than n+1 = 16. They can be randomly chosen by programming IOCRx.ETS. The trigger inputs (TRIG[n:0]) of the SENT module are connected to the GTM as shown in Device Specific Appendix.

39.3.10 Port Control

The SENT input channels are overlain with standard ADC channels as they are replacing former analog signals. In addition each channel is connected to general purpose I/O pads as well. The selection from one of up to 4 alternate inputs per channel is done by application SW by programming SENT_IOCRx.ALTI.

Depending on the implementation some products support SPC output as well on some of the channels.

The following port control operations must be executed for the SPC output I/O pads:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

39.3.10.1 Input/Output Function Selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlain with SENT digital input and no output option on this pad.
- Standard general purpose input/output function on two different I/O pads per channel. I.e. input on ADC or on I/O pad while the output is chosen to be on a different I/O pad. This allows the use of external transceivers.
- SPC open drain output on a digital I/O pad and SENT input from same digital I/O pad ("quasi bidirectional SENT/SPC mode")

The SENT module overlays dedicated analog to digital converter (ADC) pads as digital input pad.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5 V compatible ADC pads. Vddm must be supplied with 5V for SENT operation.

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output), alternate output selection, pull-up/down devices (for pure inputs only), and open-drain selections. The I/O pads for the SENT module are controlled by the Port input/output control registers shown below. Please refer to the Port chapter to make conscious decisions here!

Quasi bidirectional settings are possible only, where an SPC output and a SENT input of the same channel are connected to the same pad. This configuration is not available on all SENT inputs pads and varies by product.

For some channels SPC outputs and SENT input are connected to the same I/O pad. This allows for quasi bidirectional operation: I.e. the output is configured as open drain (e.g. P00_IOCR0.PC1 = 11110_B) while the same pad is used as input (e.g. P00_IOCR0.PC1 = $0XXXX_B$). The port in the example may not be present in all products.

Note that in the examples, figures and tables of this chapter, no quasi bidirectional operation is shown. Only pure inputs and pure outputs are shown for the sake of simplicity.

Alternate inputs that are not connected to any pin are connected to GND internally. E.g. the input selected by SENT_IOCRx.ALTI = 0011_B (aka: "input D") is frequently not in use.

39.4 Registers

This section describes the registers of the SENT module. All SENT register names described in this section will be referenced in other parts of the User's Manual by the module name prefix "SENT_" for the SENT interface.

All registers in the SENT address spaces are reset with the application reset with one exception: OCS is reset with debug reset only.

x can take the values 0 … 24

Table 351 Register Overview - SENT (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control Register	000_H	SV,U	SV,E,P	Application Reset	53

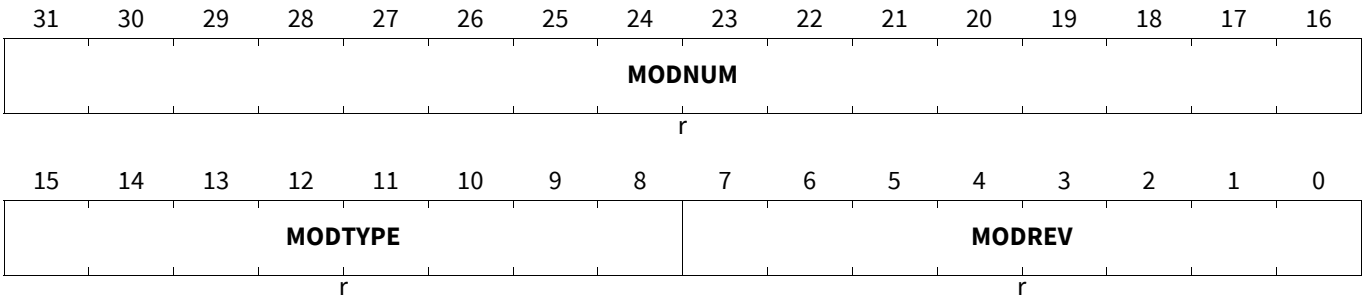
39.4.1 Module Control

Module Identification Register

The SENT Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(008_H)** **Application Reset Value: 0080 C0XX$_H$**

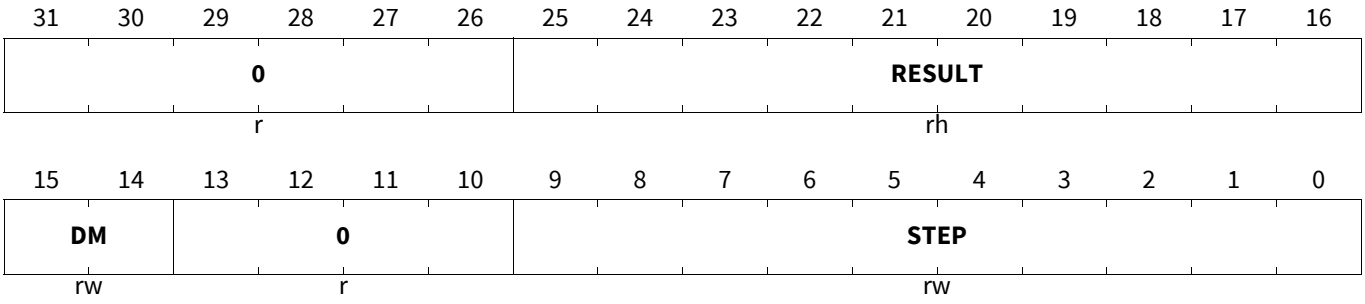


Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the SENT: 0080_H

SENT Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$ of all SENT channels.

FDR
SENT Fractional Divider Register **($00C_H$)** **Application Reset Value: 0000 0000$_H$**



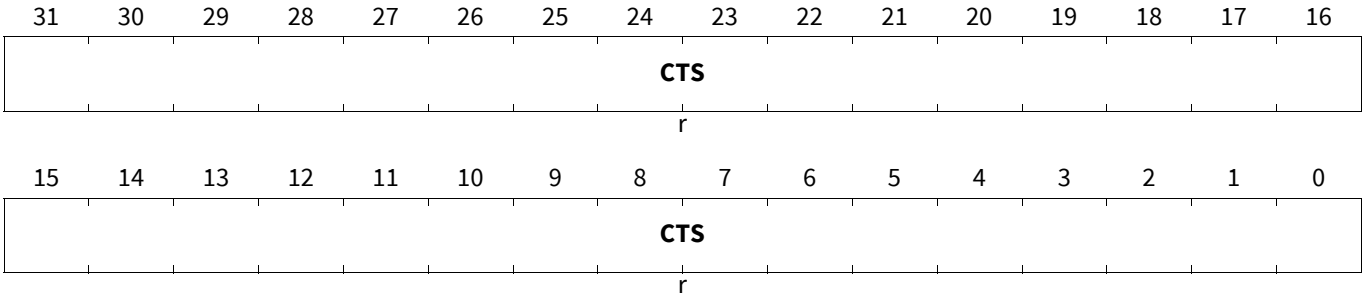
Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.

Field	Bits	Type	Description
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register

The SENT Module Time Stamp Register contains read-only information about the current time given in clock cycles generated from TPD since last reset while module was clocked. Writing to TPD clears this register.

TSR
Module Time Stamp Register (018_H) Application Reset Value: $0000\ 0000_H$



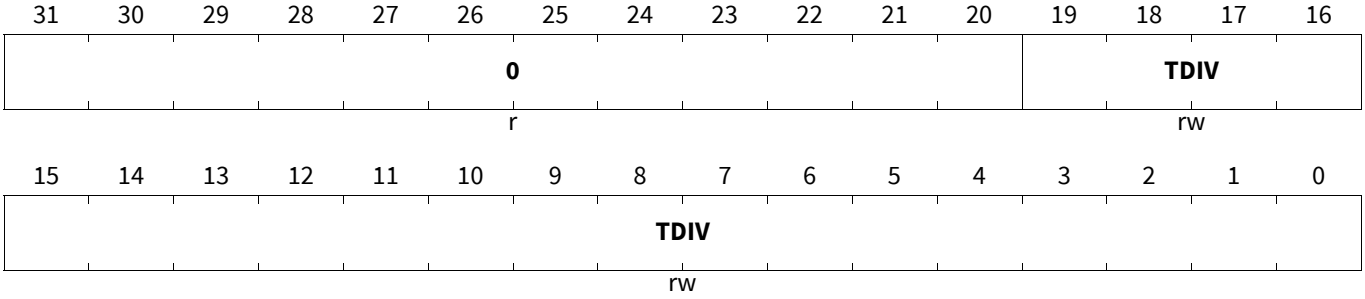
Field	Bits	Type	Description
CTS	31:0	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.

Time Stamp Predivider Register

The SENT Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of TSR. Writing to TPD clears register TSR.

TPD

Time Stamp Predivider Register (01C$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
TDIV	19:0	rw	**Divider Factor of Pre Divider for TSR** Divides $f_{fracdiv}$ by (TDIV + 1) and drives TSR.
0	31:20	r	**Reserved** Read as 0; should be written with 0.

39.4.2 Channel Baud Rate Registers

Channel Pre Divider Register x

The Channel Pre Divider Register CPDRx contains the pre divider that is related to the SENT channel baud rate.

See **Equation (39.3)**

CPDRx (x=0-24)

Channel Pre Divider Register x **(100_H+x*40_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				PDIV											
r				rw											

Field	Bits	Type	Description
PDIV	11:0	rw	**Divider Factor of Pre Divider for Channel x** Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	31:12	r	**Reserved** Read as 0; should be written with 0.

Channel Fractional Divider Register x

The Channel Fractional Divider Register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See **Equation (39.4)** in **Chapter 39.3.4** for a detailed description.

CFDRx (x=0-24)

Channel Fractional Divider Register x **(104_H+x*40_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIVM															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIV															
rw															

Field	Bits	Type	Description
DIV	15:0	rw	**Divider Value** Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value.RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV. DIV must be set in the range of [2200, 49100].
DIVM	31:16	rh	**Measured Divider Value** DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.

39.4.3 Receiver Control and Status Registers

Receiver Control Register x

The Receiver Control Register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x=0-24)

Receiver Control Register x **(108_H+x*40_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											FDFL	SUSEN	IDE	ESF	CRZ
r											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRL								CFC	CDIS	SCDIS	SDP	SNI	ACE	IEP	CEN
rw								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CEN	0	rw	**Channel Enable** When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0_B channel x disabled (default) 1_B channel x enabled
IEP	1	rw	**Ignore End Pulse** When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range. 0_B End Pulse not ignored (default) 1_B End Pulse ignored
ACE	2	rw	**Alternative CRC Mode Enable** When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path. If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored. 0_B Serial CRC calculation as specified in J2716 JAN2010 (default) 1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.
SNI	3	rw	**Status Nibble Included in CRC** When SNI is set, the status Nibble is included in (signal data) CRC. 0_B Status Nibble not included in CRC (default) 1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).

Field	Bits	Type	Description
SDP	4	rw	**Serial Data Processing Mode** This bit switches automatic serial data processing on. 0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default) 1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.
SCDIS	5	rw	**CRC for Serial Data Disabled Mode** This bit selects the CRC disabled mode. 0_B CRC is enabled (default) 1_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.
CDIS	6	rw	**CRC Disabled Mode** This bit selects the CRC disabled mode. 0_B CRC is enabled (default) 1_B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

Field	Bits	Type	Description
CFC	7	rw	**Consecutive Frame Check** This bit determines the way the most recently received frame buffer is indicated as valid. Note: If FDFL is set, CFC is ignored and the checks described here are not executed. 0_B Check against Past Sync Pulse The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid (RSI) immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued. 1_B Check against Future Sync Pulse The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. In case the check passes and no other error occurs the Frame Buffer is indicated valid (RSI) immediately after the Synchronization / Calibration Pulse following the current frame. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.

Field	Bits	Type	Description
FRL	15:8	rw	**Frame Length** FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong. 00_H No data nibble 01_H 1 data nibble 02_H 2 data nibbles 03_H 3 nibbles … 07_H 7 nibbles 08_H 8 nibbles Maximum in normal length mode 09_H 9 nibbles … FF_H 255 nibbles
CRZ	16	rw	**CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles) The enhanced serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard. 0_B Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) (default) 1_B Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames).
ESF	17	rw	**Enhanced Serial Frame Mode** This bit selects the serial frame structure. 0_B short (16 frames, 4 bit ID, 8 bit data, 4 bit CRC) 1_B enhanced (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)
IDE	18	rw	**Ignore Drift Error Mode** This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated. Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful. 0_B Drift Errors enabled (default) 1_B Drift Errors disabled

Field	Bits	Type	Description
SUSEN	19	rw	**Suspend Enable** This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support): Bit SUSEN is reset via OCDS Reset. 0_B An OCDS suspend trigger is ignored by this SENT channel. 1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded.
FDFL	20	rw	**Frequency Drift Check based on Frame Length** This bit is used for frames with pause pulse only. If set the drift error is not checked by HW. Instead, counter values DIVM and FRLEN are provided to the SW for checking the frequency drift. IEP (Pause Pulse expected) and IDE (no HW check of drift error) must always be set (=1) together with FDFL. Note: If FDFL is set, RCR.CFC is ignored and the checks described there are not executed. 0_B FDFL mode deactivated, RCR.CFC is valid (if IDE is cleared). 1_B FDFL mode is activated, IEP and IDE must be set too for proper function! RCR.CFC is ignored. If no other error occurs the Frame Buffer is indicated valid (RSI) immediately after the Pause Pulse belonging to the current frame.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

Watch Dog Timer Register x

The Watch Dog Timer Register WDTx contains the time out value for channel x. The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0. Normally the WDTx.WDL is configured only once at module setup. However, if WDTx.WDL is written again with a value larger than 0 during frame reception, the internal Watch Dog timer is NOT cleared and restarted. Instead, the Watch Dog Timer keeps on counting and comparing to the new value. This is not recommended but offers flexibility in exceptional cases. Still, if WDTx.WDL is written with 0 during frame reception, the internal Watch Dog timer is cleared and stopped.

The value entered here defines the time in multiples of Ttick_x (defined in CFDR) from the last RDI on channel x. The internal Watch Dog Timer is compared to WDLx. A match triggers interrupt WDI and stops the internal Watch Dog Counter x. After such a match, the Watch Dog Timer will be cleared and started automatically with clearing bit WDI (by setting INTCLR.WDI). I.e. the Watch Dog Counter is running only if interrupt flag WDI is cleared. If WDL is cleared, the WDTx is stopped/disabled.

WDTx (x=0-24)

Watch Dog Timer Register x **(134_H+x*40_H)** **Application Reset Value: 0000 0000_H**

0				SCN				0		CST		CRC			
r				r				r		r		r			

Field	Bits	Type	Description
CRC	3:0	r	**CRC** of last frame. CRC0 is on bit position 0.
CST	5:4	r	**Channel Status** CST shows the current status of channel x. 00_B STOP Channel is disabled and can be configured 01_B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10_B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11_B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	11:8	r	**Status and Communication Nibble** of last frame. SCN0 is on bit position 8.

Field	Bits	Type	Description
FRLEN	31:16	r	**Frame Length including Pause Nibble** of last frame. Bit FRLEN0 is on bit position 16. FRLEN is a 16 bit counter with saturation (stops at 0xFFFF / 65.535) and is driven by f_{pdiv}. This counter supports monitoring the following condition for messages with pause pulse and fixed message length: Ratio of calibration pulse to message length varies by > 1/64 or < -1/64 from one message to another. FRLEN is valid after RSI. See chapter “Support for Frequency Drift Analysis in Frames with Pause Pulse”.
0	7:6, 15:12	r	**Reserved** Read as 0; should be written with 0.

Serial Data and Status Register x

The Serial (Receive) Data and Status Register provides the data and status information of channel x.

SDSx (x=0-24)

Serial Data and Status Register x **(110_H+x*40_H)** **Application Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SD	15:0	r	**Serial Data** of last serial data frame. SD0 is on bit position 0. Usually all 16 data bits are used. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.
MID	23:16	r	**Message ID** of last serial data frame. ID0 is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	29:24	r	**SCRC** CRC of last serial data frame. CRC0 is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID
0	30	r	**Reserved** Read as 0; should be written with 0.

39.4.4 Input and Output Control

Input and Output Control Register x

The Input and Output Control Register IOCRx determines for the SENT channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit

- the trigger source
- the output signal polarity

IOCRx (x=0-24)

Input and Output Control Register x **(114_H+x*40_H)** **Application Reset Value: X000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rh	rh	r	w	rw	rw	rw				r		rw	

Field	Bits	Type	Description
ALTI	1:0	rw	**Alternate Input Select** Selects the alternate input for channel y: 00_B Alternate Input 0 selected 01_B Alternate Input 1 selected 10_B Alternate Input 2 selected 11_B Alternate Input 3 selected
DEPTH	7:4	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with f_{pdiv} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0_H off, default 1_H 1 T_{pdiv} 2_H 2 … F_H 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high

Field	Bits	Type	Description
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is active low 1_B Pulse polarity is active high
CEC	10	w	**Clear Edge Counter** If this bit is set, IOCR.EC is cleared. Always reads back as '0'.
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x REG is cleared by setting CREG. 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x FEG is cleared by setting CFEG. 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge
CREG	14	rw	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG CREG always read zero. 0_B REG is not cleared 1_B REG is cleared
CFEG	15	rw	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG CFEG always read zero. 0_B FEG is not cleared 1_B FEG is cleared
ETS	19:16	rw	**External Trigger Select** Selects the external trigger line if SCRx.TRIG is programmed to 11B. In some products, not all inputs are connected. See **Chapter 39.3.9.1**. 0_H TRIG0 … F_H TRIG15
EC	27:20	rh	**Edge Counter** This bit field contains a counter with saturation (stops at 0xFF). It is incremented with any falling edge that appears on the input pin selected by IOCR.ALTI. Note that this holds true in all states (STOP, INITIALIZED, RUNNING, SYNCHRONIZED). It is intended for debugging, in particular to find a bubbling idiot that sends before enabling the module.
CTR	28	rw	**Clear Trigger Monitor Flag for Channel x** Clears the status flag TRM CTR always read zero. Reset value of CTR is 0. 0_B TRM is not cleared 1_B TRM is cleared

Field	Bits	Type	Description
TRM	29	rh	**Trigger Monitor Flag for Channel x** Shows the status of the trigger detection of channel x TRM is cleared by setting CTR. Reset value of TRM is 0. 0_B No Trigger detected 1_B Trigger detected (one or several)
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. Reset value of RXM is X. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. Reset value of TXM is X. 0_B Current signal is low. 1_B Current signal is high.
0	3:2, 11	r	**Reserved** Read as 0; should be written with 0.

39.4.5 Receive Data Registers

Receive Data Register x

The Receive Data Registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

Register VIEW must be set up correctly to see all data nibbles of the frame! By default the application software set VIEW to 7654 3210_H.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

RDRx (x=0-24)

Receive Data Register x **(080_H+x*4)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RD7				RD6				RD5				RD4

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RD3				RD2				RD1				RD0			
rh				rh				rh				rh			

Field	Bits	Type	Description
RDy (y=0-7)	4*y+3:4*y	rh	**Receive Data Nibble y** RDy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000H. I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

Receive Time Stamp Register x

The SENT Channel x Receive Time Stamp Register contains read-only information about the time the last frame for channel x was received. Time is captured with the second falling edge, i.e. at the Status/Communication data pulse.

RTSx (x=0-24)

Receive Time Stamp Register x **($A80_H$+x*4)** **Application Reset Value: 0000 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LTS															
r															

Field	Bits	Type	Description
LTS	31:0	r	**Last Receive Time Stamp for Channel x** This bit field shows the time stamp of the last frame on channel x.

Receive Data View Register x

The Receive Data View Registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles. The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7. If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones. Example: two 12 bit values are transmitted. One with most significant nibble first and one with least significant nibble first. The frame looks like this: 456321_H. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble. The actual signal values are $0x123_H$ and $0x456_H$. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: 73 654 012_H. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: 0x0456 0123_H to the host.

In the example RDR nibbles 3 and 7 contain $0x0000_B$ as the Receive Buffer is always cleared (0x0000 0000_H) before new data is received.

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. 7654 3210_H.

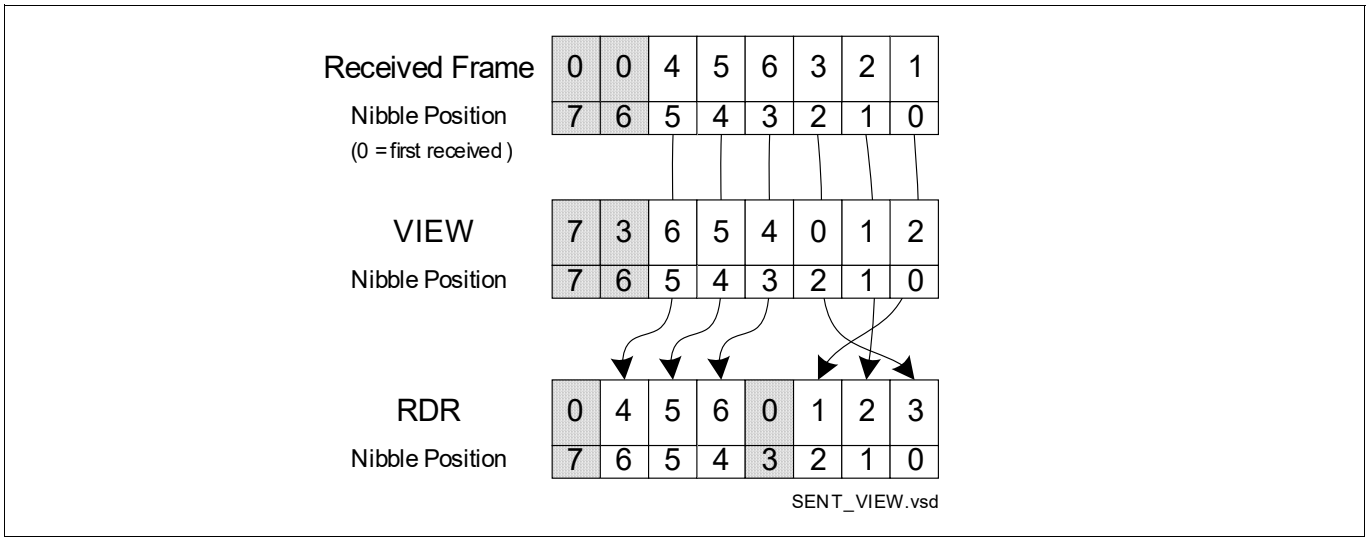

Figure 578 Functionality of VIEW Register

VIEWx (x=0-24)

Receive Data View Register x **($11C_H$+x*40_H)** **Application Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RDNPy (y=0-7)	4*y+2:4*y	rw	**Receive Data Target Nibble Pointer y** RDNPy points to the Nibble in Receive Data Register RDRx where the nibble y from the received frame is sorted to. Nibble 0 is the first data nibble in the frame. It gets moved to the position defined in RDNP0. And on. RDNPy must be written before first frame reception. All RDNPy must have different values. (Higher RDNPy overwrite lower RDNPy.) 000_B Nibble 0 selected … 111_B Nibble 7 selected
0	3, 7, 11, 15, 19, 23, 27, 31	r	**Reserved** Read as 0; should be written with 0.

39.4.6 SPC Control

SPC Control Register x

The SPC Control Register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is used to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode “Bidirectional transmit”. Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal is sufficient and no further SW intervention is required. Here the data can be changed (“ID-Selection” Mode) or simply left constant (“Sync” Mode). Only a HW trigger needs to be set up.

In Mode 0, SPC is deactivated for this channel. A write access to SCRx does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCRx is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TBIx is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. After the data was transferred to the internal transmission register, interrupt TDIx signals that a new value can be written. INTSTATx.TDIx must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse. This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode “Bidirectional Transmit” this mode is useful to synchronize the transmission. TDIx and TBIx work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCRx.ETS). This is most useful in SPC “sync” mode. TDIx and TBIx work as in Mode 1.

SCRx (x=0-24)

SPC Control Register x **(118_H+x*40_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRQ	BASE	DEL						TRIG		PLEN					
r	rw	rw						rw		rw					

Field	Bits	Type	Description
PLEN	5:0	rw	**Pulse Length** Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 00_H Pulse length is 0 ticks … $3F_H$ Pulse length is 63 ticks
TRIG	7:6	rw	**Trigger Source and Mode Selection** Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00_B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01_B Pulse starts immediately (no auto repetition) 10_B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11_B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	13:8	rw	**Delay Length** Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 00_H Pulse is not delayed 01_H Pulse is delayed by 1 tick 02_H Pulse is delayed by 2 ticks … $3F_H$ Pulse is delayed by 63 ticks
BASE	14	rw	**Time Base** Selects the Pulse Time Base 0_B Pulse is based on measured frequency of last Synchronization/Calibration Pulse 1_B Pulse is based on nominal frequency
TRQ	15	r	**Transfer Request in Progress** While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

39.4.7 Interrupt Control Registers

Interrupt Overview Register

INTOV
Interrupt Overview Register (014$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
IPCy (y=0-24)	y	rh	**Interrupt Pending on Channel y** If any interrupt requested flag is set for channel y in register INTSTATy AND the referring interrupt is enabled in INTENx then IPCy is set. It is automatically reset if all flags in INTSTATy are cleared for which the referring interrupt is enabled in INTENx. *Note: Not all IPC0-24 are available on all products, the number of Interrupt Pending on Channel is equivalent to the SENT channels available, e.g 4 SENT channels has 4 Interrupt Pending IPC0-3 and vice versa.*
0	31:25	r	**Reserved** Read as 0.

Interrupt Status Register x

The Interrupt Status Register INTSTATx contains status bits that show the status of any interrupt of SENT channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATx (x=0-24)
Interrupt Status Register x (120$_H$+x*40$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		WDI	SCRI	SDI	WSI	CRCI	NVI	NNI	FDI	FRI	TBI	TDI	RBI	RDI	RSI
r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. Depending on bit RCRx.CDIS this indicates a successful check of the CRC. This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct or not checked (if RCRx.CDIS is cleared). For frames with more than 8 nibbles RDI is issued after 8 nibbles. After the last nibbles of the frame are received, a last RDI and an RSI are issued together. Note that this is true independently from RCR.FDFL. This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.The old data is overwritten by the new data. This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TDI	3	rh	**Transfer Data Interrupt Request Flag** This bit is set after the trigger condition was detected. Data to be transferred has been moved internally. Thus a new value can be written to SCRx. This can be used for back to back transfers. This bit is automatically cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TDI. This bit can be set by bit INTSETx.TDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
TBI	4	rh	**Transmit Buffer Underflow Interrupt Request Flag** This bit is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. This bit is NOT cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TBI. This bit can be set by bit INTSETx.TBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
FRI	5	rh	**Frequency Range Interrupt Request Flag** This bit is set after a Synchronization / Calibration pulse was received that deviates more than +/- 25% from the nominal value. The referring data is ignored. This bit can be cleared by bit INTCLRx.FRI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
FDI	6	rh	**Frequency Drift Interrupt Request Flag** This bit is set after a subsequent Synchronization / Calibration pulse was received that deviates more than 1.5625% (1/64) from its predecessor. (See RCR.CFC) This bit can be cleared by bit INTCLRx.FDI. This bit can be set by bit INTSETx.FDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NNI	7	rh	**Number of Nibbles Wrong Request Flag** This bit is set after more nibbles have been received than expected or a Synchronization / Calibration Pulse is received too early thus too few nibbles have been received. This bit can be cleared by bit INTCLRx.NNI. This bit can be set by bit INTSETx.NNI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NVI	8	rh	**Nibbles Value out of Range Request Flag** This bit is set after a too long or too short nibble pulse has been received. I.e. value < 0 or value > 15. This bit can be cleared by bit INTCLRx.NVI. This bit can be set by bit INTSETx.NVI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

Field	Bits	Type	Description
CRCI	9	rh	**CRC Error Request Flag** This bit is set if the CRC fails. This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
WSI	10	rh	**Wrong Status and Communication Nibble Error Request Flag** In Short Serial Frame Mode (RCR.ESF is cleared), this bit is set if the Status and Communication nibble shows a start bit in a frame other than frame number n x 16. In Enhanced Serial Frame Mode this bit is without function. This bit can be cleared by bit INTCLRx.WSI. This bit can be set by bit INTSETx.WSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
SDI	11	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Status and Communication nibble. Depending on bit RCRx.SCDIS this indicates a successful check of the CRC. This bit can be cleared by bit INTCLRx.SDI. This bit can be set by bit INTSETx.SDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
SCRI	12	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. In Enhanced Serial Message Format, this includes a check of the Serial Communication Nibble for correct 0 values of bit 3 in frames 7, 13 and 18. This bit can be cleared by bit INTCLRx.SCRI. This bit can be set by bit INTSETx.SCRI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
WDI	13	rh	**Watch Dog Error Request Flag** This bit is set if the Watch Dog Timer of the channel x expires. This bit can be cleared by bit INTCLRx.WDI. This bit can be set by bit INTSETx.WDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
0	31:14	r	**Reserved** Read as 0.

Interrupt Set Register x

The Interrupt Set Register INTSETx contains control bits that trigger an interrupt pulse for any interrupt of SENT channel x.

INTSETx (x=0-24)
Interrupt Set Register x **(124_H+x*40_H)** **Application Reset Value: 0000 0000_H**

Interrupt Node Pointer Register x

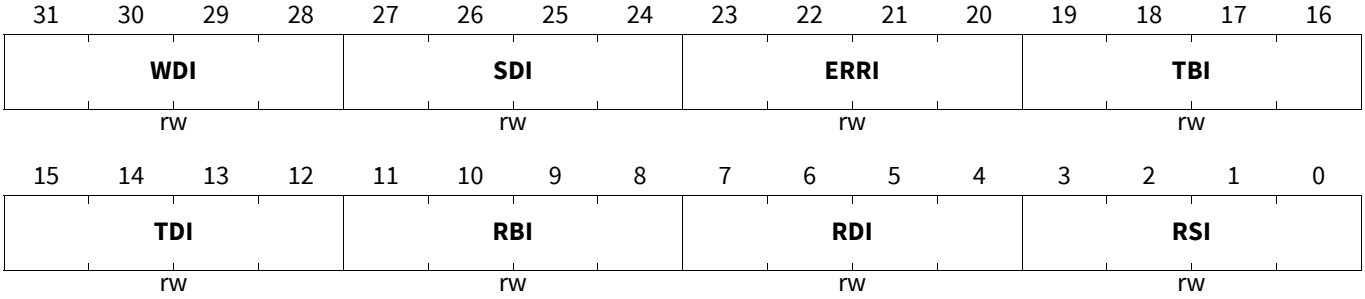
The Interrupt Node Pointer Register INPx contains the node pointers of SENT channel x.

Node Pointer ERRI is one single node pointer for the following error interrupts:

- FRI
- FDI
- NNI
- NVI
- CRCI
- WSI
- SCRI

INPx (x=0-24)

Interrupt Node Pointer Register x **(130_H+x*40_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
RSI	3:0	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RSI (if enabled by bit INTENx.RSI). 0_H Trigger Output TRIGO0 is selected … F_H Trigger Output TRIGO15 is selected
RDI	7:4	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	11:8	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.
TDI	15:12	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TDI (if enabled by bit INTENx.TDI). For bit field definition, see RSI.
TBI	19:16	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TBI (if enabled by bit INTENx.TBI). For bit field definition, see RSI.
ERRI	23:20	rw	**Interrupt Node Pointer for Interrupt FRI, FDI, NNI, NVI, CRCI, WSI, SCRI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FRI (if enabled by bit INTENx.FRI) or INTSTATx.FDI (if enabled by bit INTENx.FDI) or INTSTATx.NNI (if enabled by bit INTENx.NNI) or INTSTATx.NVI (if enabled by bit INTENx.NVI) or INTSTATx.CRCI (if enabled by bit INTENx.CRCI) or INTSTATx.WSI (if enabled by bit INTENx.WSI) or INTSTATx.SCRI (if enabled by bit INTENx.SCRI) For bit field definition, see RSI.

Field	Bits	Type	Description
SDI	27:24	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
WDI	31:28	rw	**Interrupt Node Pointer for Interrupt WDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.WDI (if enabled by bit INTENx.WDI). For bit field definition, see RSI.

39.4.8 Bus Control Interface Registers

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

Notes

1. *After a hardware reset operation, the f_{SENT} and $f_{fracdiv}$ clocks are switched off and the SENT module is disabled (DISS set).*

CLC

Clock Control Register (000_H) Application Reset Value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

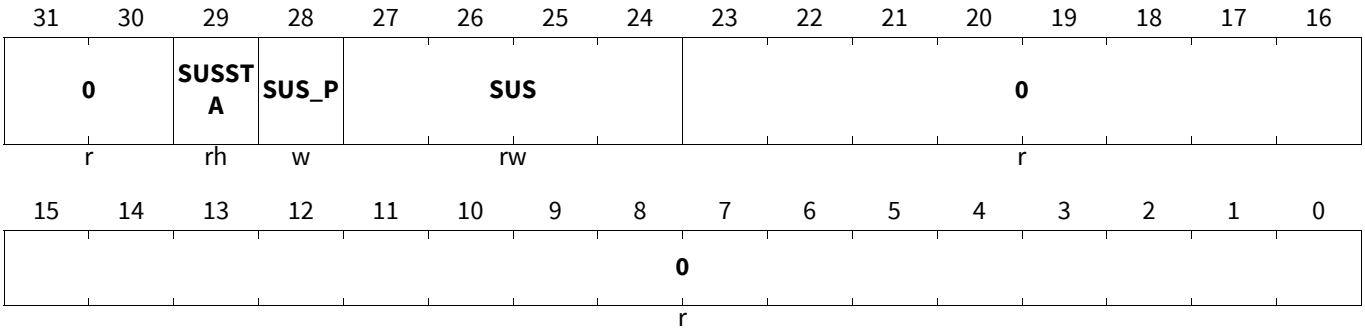
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Enable Control** Used to control module's sleep mode.
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status (0E8$_H$) Debug Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is switched off immediately. (SPC low pulse breaks immediately, Port Pin keeps the last value if suspend state is entered) 2_H Soft suspend (SPC low pulse will be finished before suspend state is entered) **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended (for channels where SUSEN is set)
0	23:0, 31:30	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access[1] for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ACCEN0

Access Enable Register 0 **(0FC$_H$)** **Application Reset Value: FFFF FFFF$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN31	**EN30**	**EN29**	**EN28**	**EN27**	**EN26**	**EN25**	**EN24**	**EN23**	**EN22**	**EN21**	**EN20**	**EN19**	**EN18**	**EN17**	**EN16**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN15	**EN14**	**EN13**	**EN12**	**EN11**	**EN10**	**EN9**	**EN8**	**EN7**	**EN6**	**EN5**	**EN4**	**EN3**	**EN2**	**EN1**	**EN0**
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENn (n=0-31)	n	rw	**Access Enable for Master TAG ID n** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register 1

The Access Enable Register 1 controls write access[1)] for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the TC3xx devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

ACCEN1

Access Enable Register 1 **(0F8$_H$)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 0

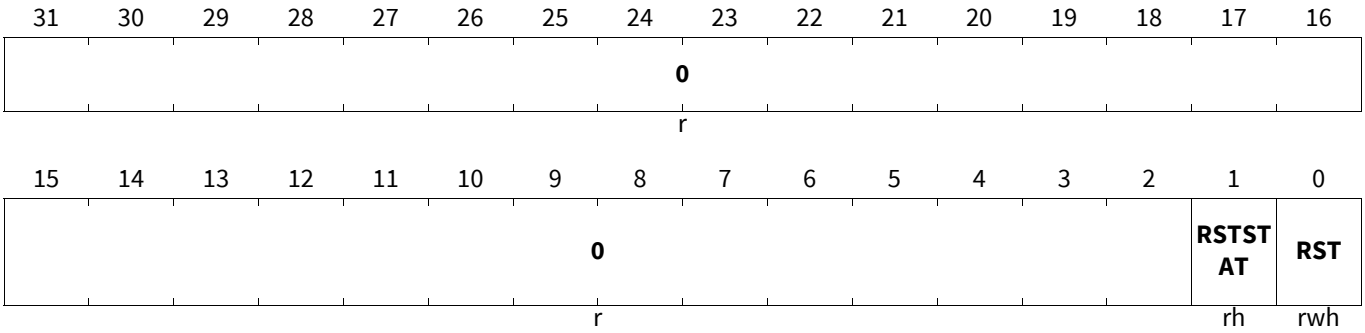
The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 **($0F4_H$)** **Application Reset Value: $0000\ 0000_H$**



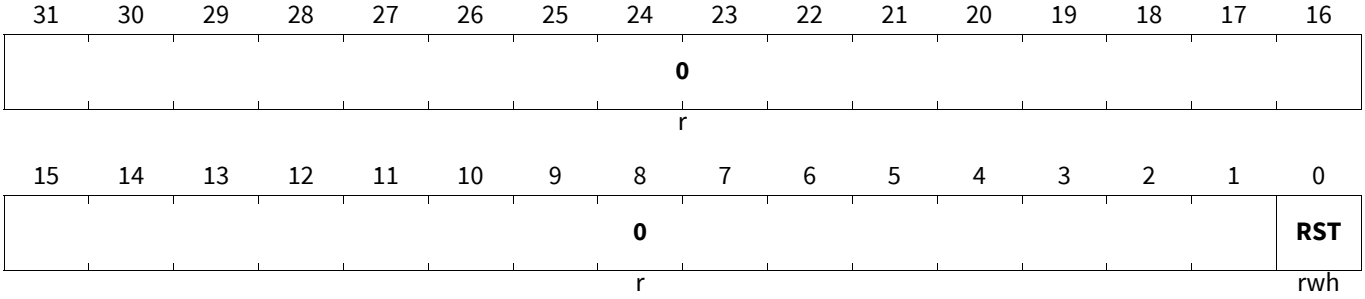
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **($0F0_H$)** **Application Reset Value: $0000\ 0000_H$**



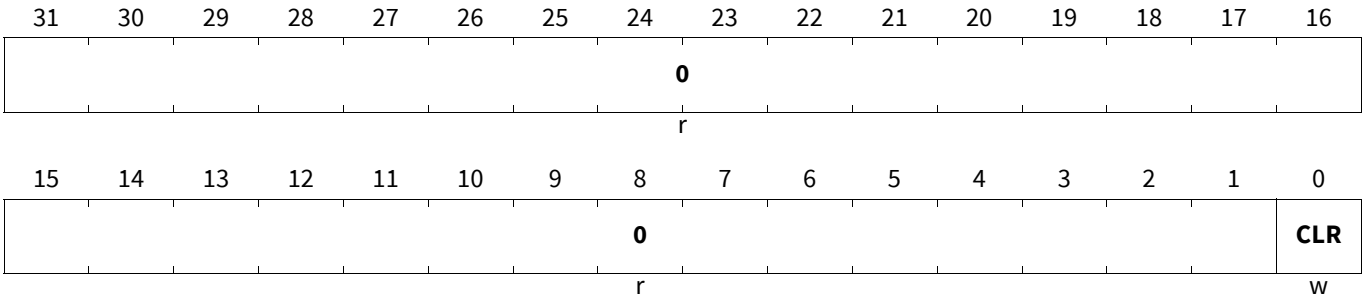
Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Status Clear Register

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register **($0EC_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CLR	0	w	**Kernel Reset Status Clear** Read always as 0. 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	**Reserved** Read as 0; should be written with 0.

39.5 IO Interfaces

40 CAN Interface (MCMCAN)

The MCMCAN implements Bosch M_CAN as CAN nodes. The M_CAN performs communication according to ISO 11898-1 and according to ISO 11898-4 (Time-triggered communication on CAN). The M_CAN provides all features of time-triggered communication specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation.In addition the M_CAN supports classical CAN and CAN FD communication according to ISO 11898-1. The CAN FD option can be used together with event-triggered and time-triggered CAN communication.

Figure 579 shows the AURIX™ TC3xx Platform specific implementation details and interconnections of the MCMCAN module. The I/O lines of the MCMCAN module (two I/O lines of each CAN node) are connected to the Ports listed in **Chapter 40.3.1.3**. The MCMCAN module is also supplied by clock control, interrupt control, and address decoding logic.

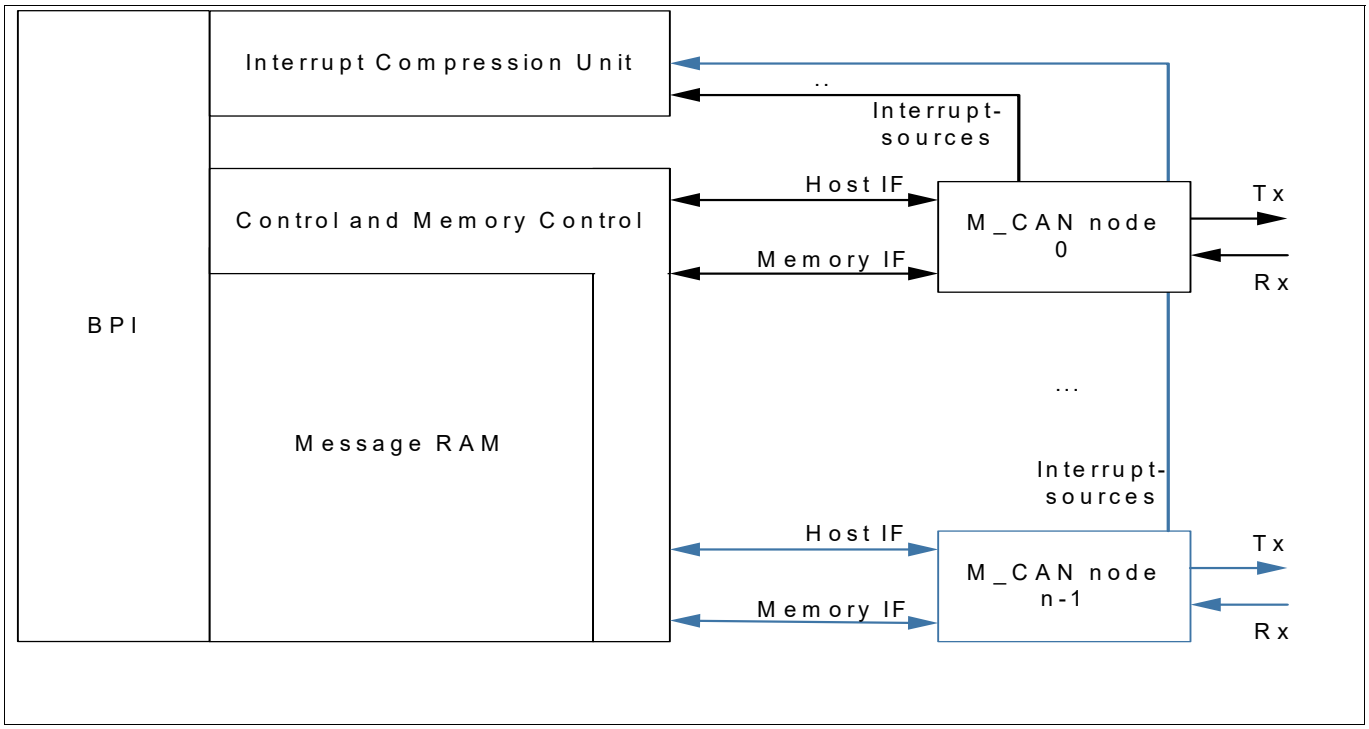

Figure 579 MCMCAN Module

40.1 Feature List

The following are the features of the MCMCAN module

- ISO 11898-1, -4
- CAN FD with up to 64 data bytes supported
- TTCAN protocol level 1 and level 2 completely in hardware
- Event synchronized time-triggered communication supported
- CAN Error Logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 4 CAN nodes
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32-bit Generic Slave Interface for connection customer-specific Host CPUs

Features offered by each M_CAN node:

- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO

40.1.1 Delta to AURIX

MCMCAN is the new CAN interface, in which the user interface to the module is different than the previous MultiCAN+ CAN interface. The following are the notable changes:

- Message Objects are replaced by configurable Message RAM
- Supports Debug on CAN

40.2 Overview

An overview of an MCMCAN module is shown in **Figure 579**. The MCMCAN supports the following variants of CAN communication protocols.

- Classical CAN and CAN FD according to ISO 11898-1
- Time Triggered CAN according to ISO 11898-4

The MCMCAN consists of Bosch M_CAN as CAN nodes and a wrapper around the M_CAN called as the user interface. M_CAN provides the following functionality:

- CAN protocol Contoller
- Receive and transmit time stamp generation

- Transmit Handler
- Receive Handler

The user interface of MCMCAN provides the following functionality:

- A configurable Message RAM to store the message to be transmitted or received. The message RAM is shared by all the CAN nodes within a MCMCAN module
- Grouping and signalling of interrupts through Interrupt Compression Unit
- Clock selection and generation through Clock Control Block
- Access protection through BPI
- Timer based transmission of CAN frame and timeouts for reception of CAN frames.

Note: Refer appendix of a product variant for the number of MCMCAN modules, number of M_CAN nodes within a module and Message RAM allocation for individual nodes.

40.3 Functional Description

This section describes the functionality of MCMCAN. The functionality is described as three different sub-sections:

- User Interface
- M_CAN functionality
- TTCAN operation

40.3.1 MCMCAN User Interface

The MCMCAN User Interface describes about the clock generation, grouping of interrupts, external connections to the module and IO configurations.

40.3.1.1 MCMCAN Clockpaths

A general overview of clocks within the MCMCAN module.

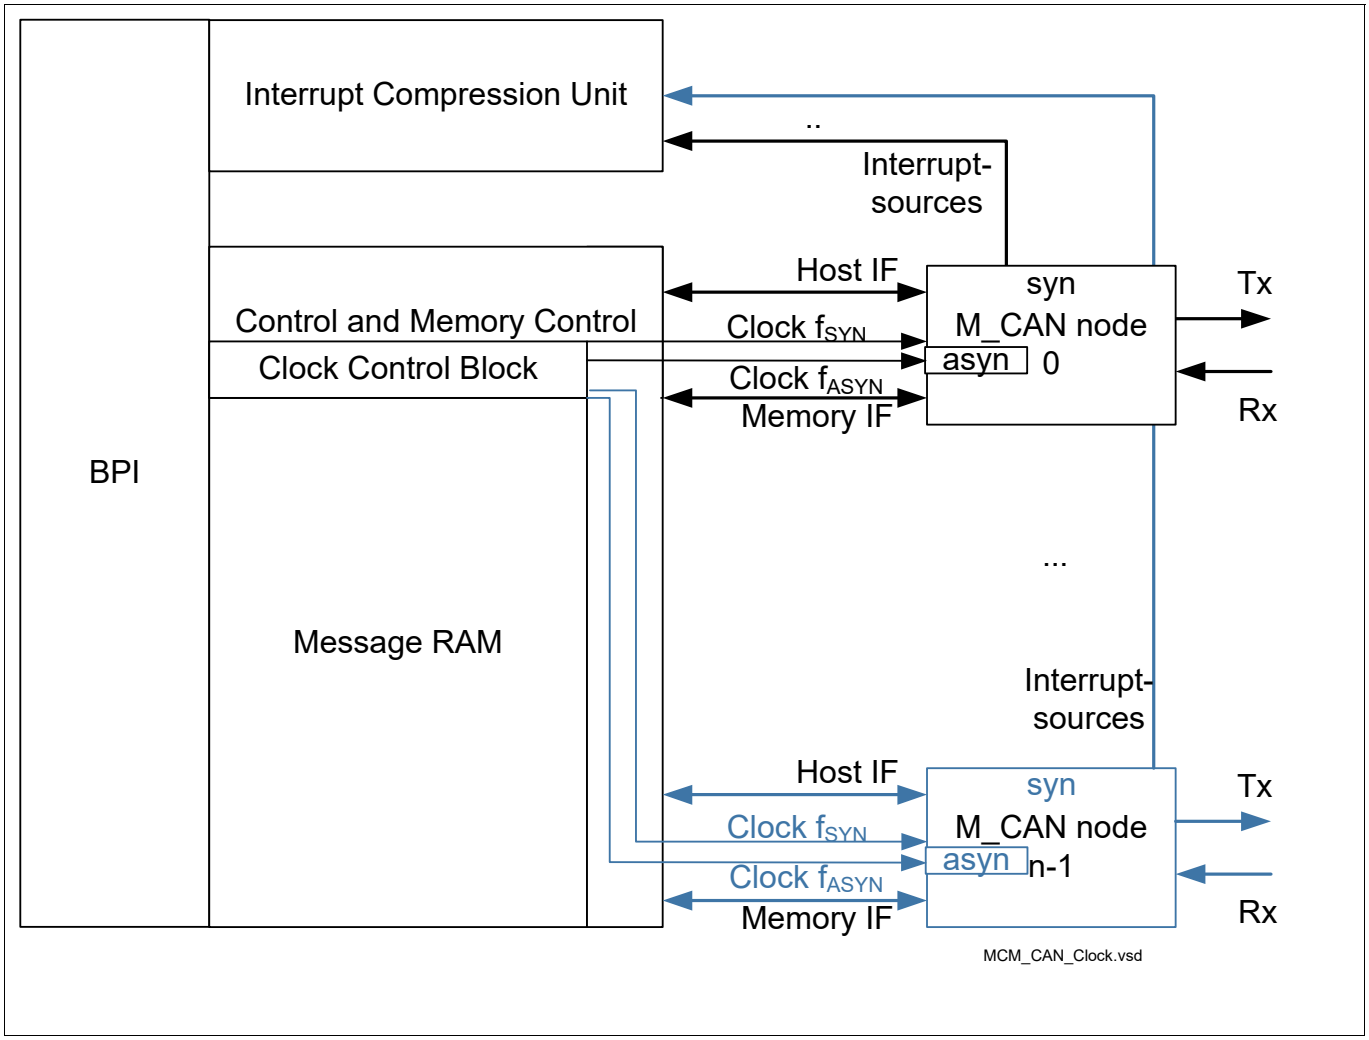

Figure 580 MCMCAN Clock Interconnects with CCU

The MCMCAN module clock inputs are connected to the Clock Control Unit (CCU). The CLC setting supplies the global module registers with its clocks. To supply the M_CAN nodes with the corresponding clocks, the **MCR**.CLKSELi registers have to be set. See **Figure 581** and **Table 354**. The asynchronous clock as well as the synchronous clock of each single M_CAN node can be switched on/off via MCR.CLKSELi register bitfields as shown in **Figure 582** and **Table 354** below.

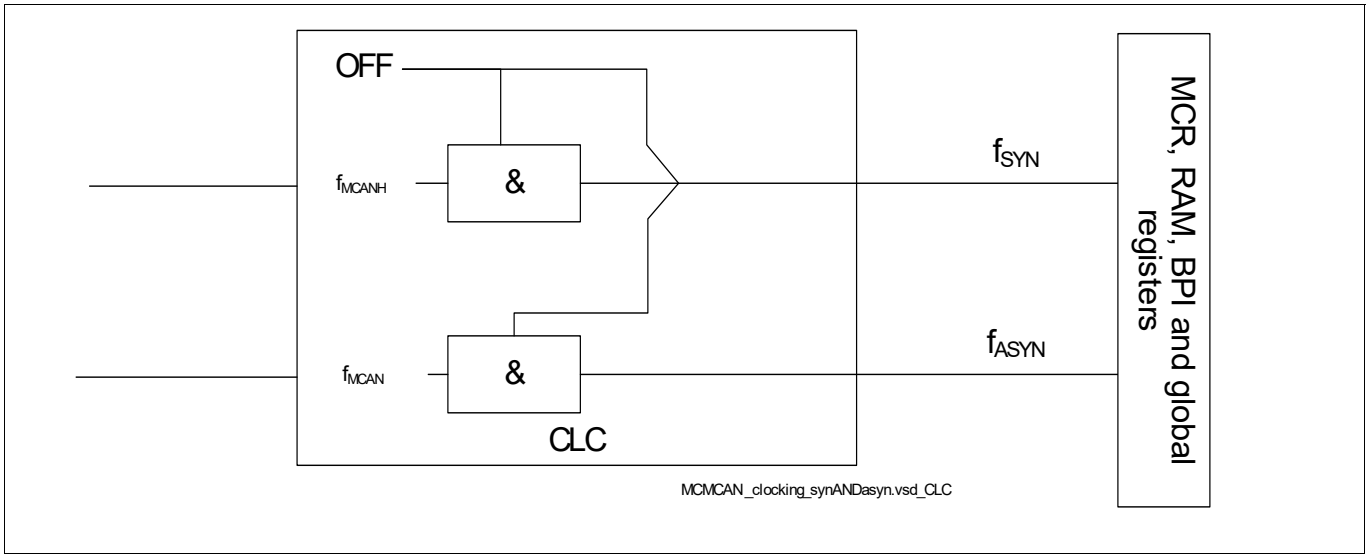

Figure 581 MCMCAN Clock Switch via CLC

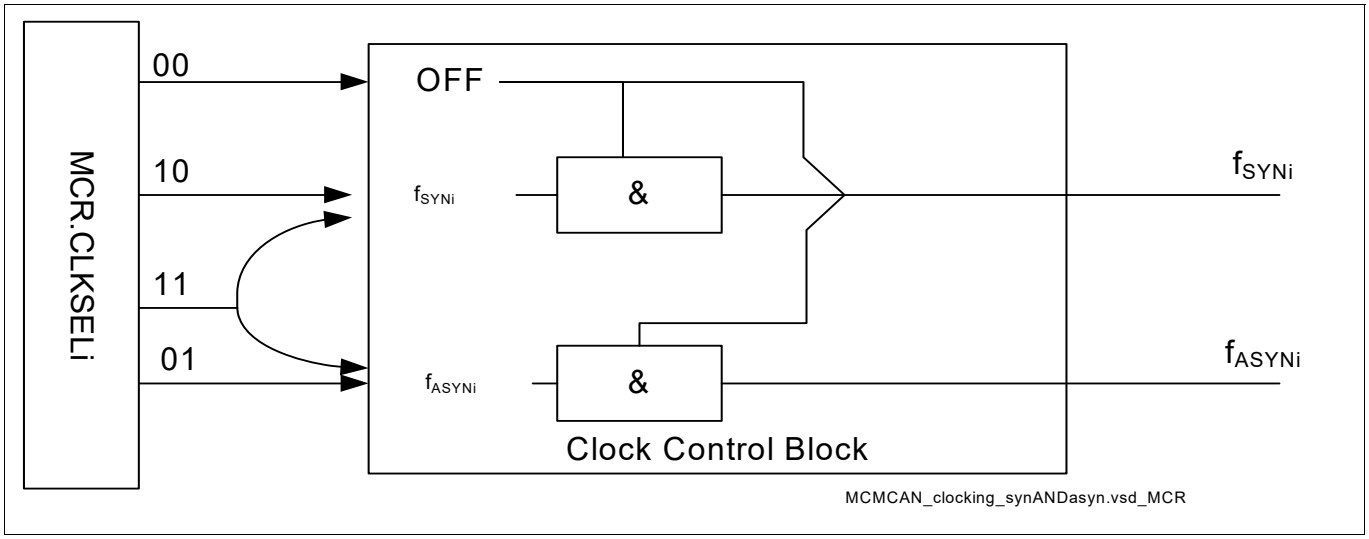

Figure 582 MCMCAN Clock Switch for single nodes

$f_{SYN}$is supplied from f_{MCANH} and f_{ASYN} is supplied from f_{MCAN} from CCU. f_{SYN} is used as the clock source for Register and RAM interface,f_{ASYN} is used to generate the nominal and fast CAN FD baudrates. It is recommended to use f_{ASYN} as 80, 40, 20 MHz from the Peripheral clock or also from f_{OSC}, in order to achieve commonly used nominal and fast CAN FD baudrates. The condition that f_{SYN} >= f_{ASYN} is essential for proper functioning of MCMCAN.

Note: *f_{SPB} is used as the clock source for SSH of MCMCAN RAM . Since a synchronization between f_{SPB} and f_{MCANH} happens within SSH, during normal operation of MCMCAN, f_{SPB} should be configured to frequency equal to f_{MCANH}. During Pretended Networking where f_{SPB} is on reduced frequency than f_{MCANH}, the MCMCAN SSH registers should be accessed only after leaving the Pretended Networking Mode. Refer to MTU chapter for additional details.*

Table 354 MCMCANClock Interconnects

CAN Clock Inputs	Connected to	Description
f_{MCAN}	CCU	f_{MCAN} of the MCMCAN module is one of the clock inputs of the Clock Control Block, providing the MCMCAN with the clock for the asynchronous clock path f_{ASYN}.
f_{MCANH}	CCU	f_{MCANH} of the MCMCAN module is the clock input of the Clock Control Register Block, providing the main kernel clock f_{SYN}.
f_{SYN}	CLC	f_{MCANH} becomes f_{SYN} within the module
f_{ASYN}	CLC	f_{MCAN} becomes f_{ASYN} within the module
f_{SYNi}	MCR.CLKSELi	f_{SYN} becomes f_{SYNi} clocking the synchronous part of M_CAN node i (Nodes can be switched on/off individually)
f_{ASYNi}	MCR.CLKSELi	f_{ASYN} becomes f_{ASYNi} clocking the asynchronous part of M_CAN node i (Nodes can be switched on/off individually)

40.3.1.1.1 Module Clock Generation

This chapter describes the clock generation and clock destinations.

Clock Selection

The asynchronous clock part of the M_CAN and the rest of the MCMCAN module are separate frequency domains and can be driven by separate independent frequencies. The clocks for the module are chosen within the clock control unit. The asynchronous clock can be chosen in the CCU among the Peripheral PLL or with direct drive from the oscillator.

The purpose of supplying the asynchronous clock part with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of by a high precision quartz crystal.

As shown in **Figure 581**, the clock signals for the MCMCAN module are generated and controlled by a clock control unit. This clock control unit is responsible for the enable/disable control, the clock frequency adjustment.

Clock control register

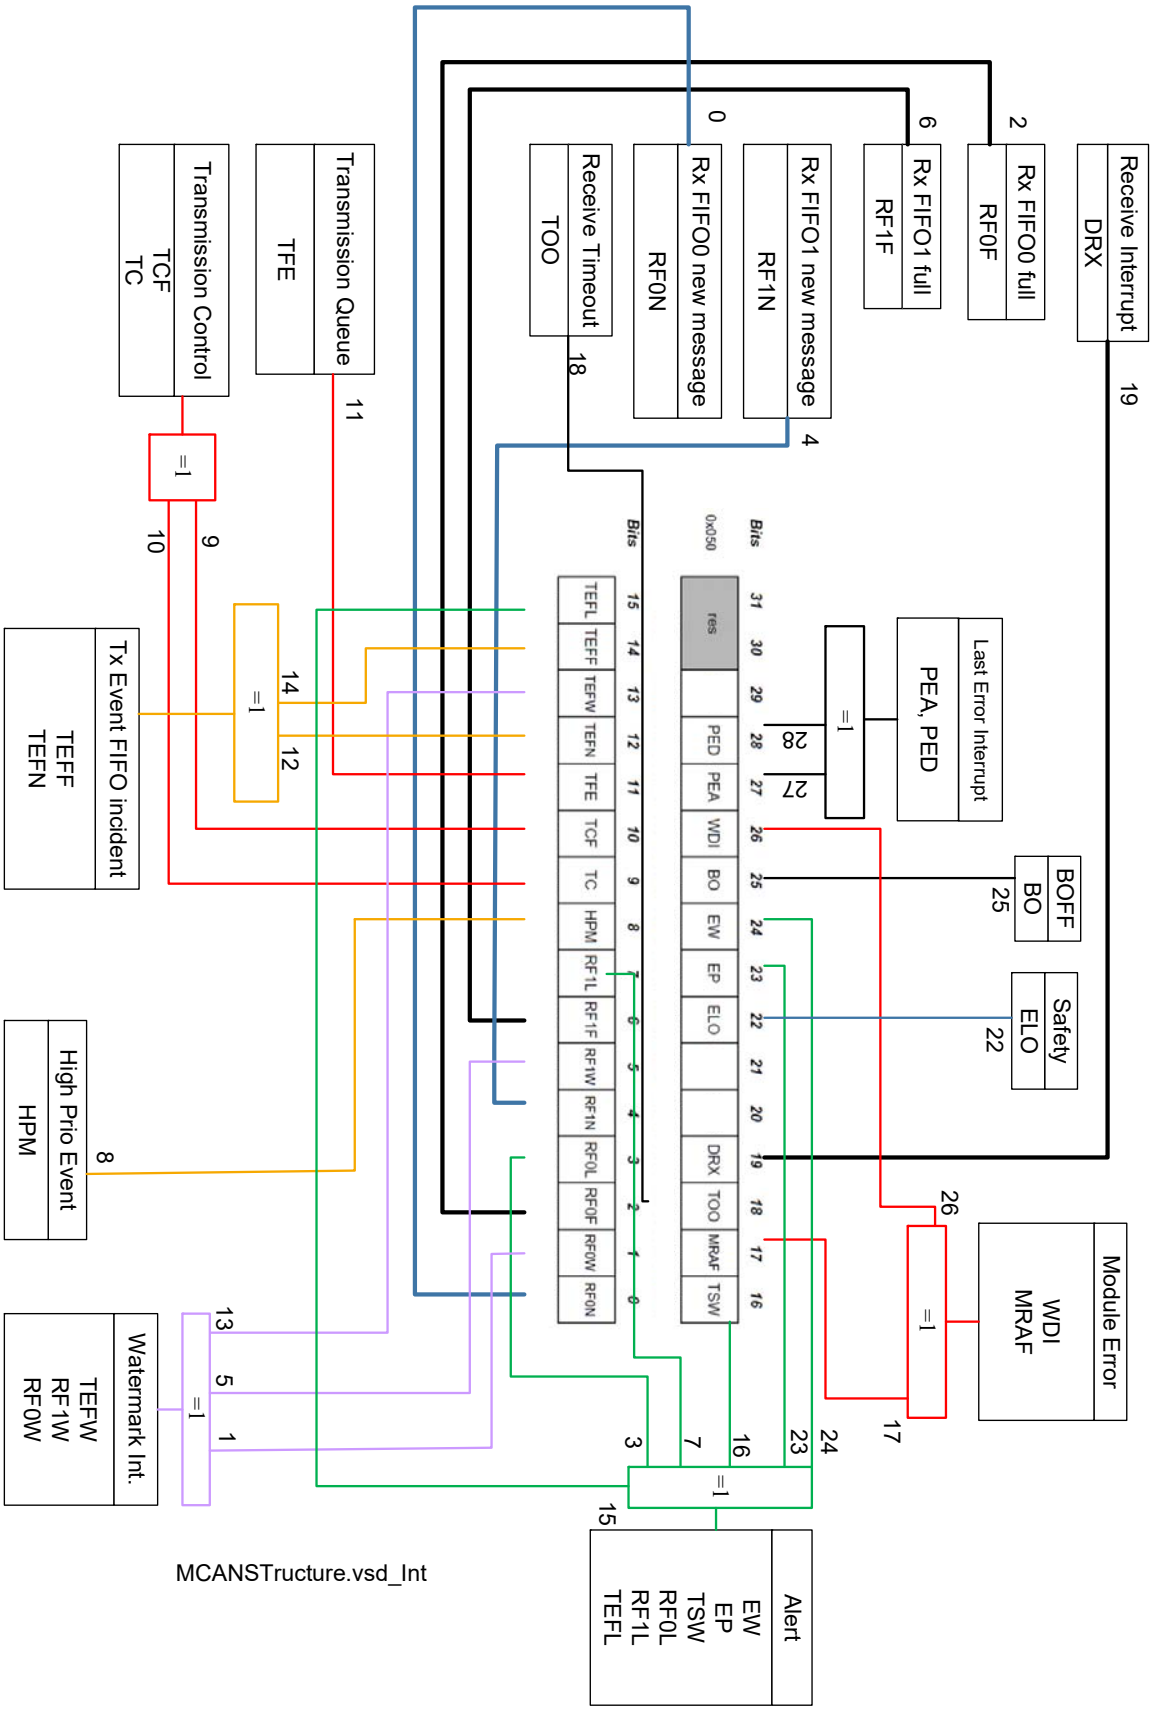
The global registers do include the **CLC** register: Module clock enabled. The module control clock f_{SYN} is used inside the MCMCAN module for control purposes such as clocking of control logic and register operations. The frequency of f_{SYN} is sourced by f_{MCANH} from CCU module. This clock is independent to f_{SPB} and allows M_CAN to continue operation when f_{SPB} is reduced in frequency, thus enabling pretended networking. The clock control register CLC makes it possible to enable/disable f_{SYN} and f_{ASYN} under certain conditions.

40.3.1.2 Interrupt groups

Interrupt grouping is fixed, as shown in figure **Figure 583** and **Figure 584**. For the complete module, 16 interrupt nodes are existing. The interrupt groups can be freely assigned to the nodes by using **GRINT1i (i=0-3)** and **GRINT2i (i=0-3)**.

40.3.1.2.1 Mapping of interrupts

The interrupt assignment from the interrupt register, only forwarding the enabled interrupt sources is as following:



MCANSTructure.vsd_Int

Figure 583 Mapping of interrupts into groups (without TTCAN)

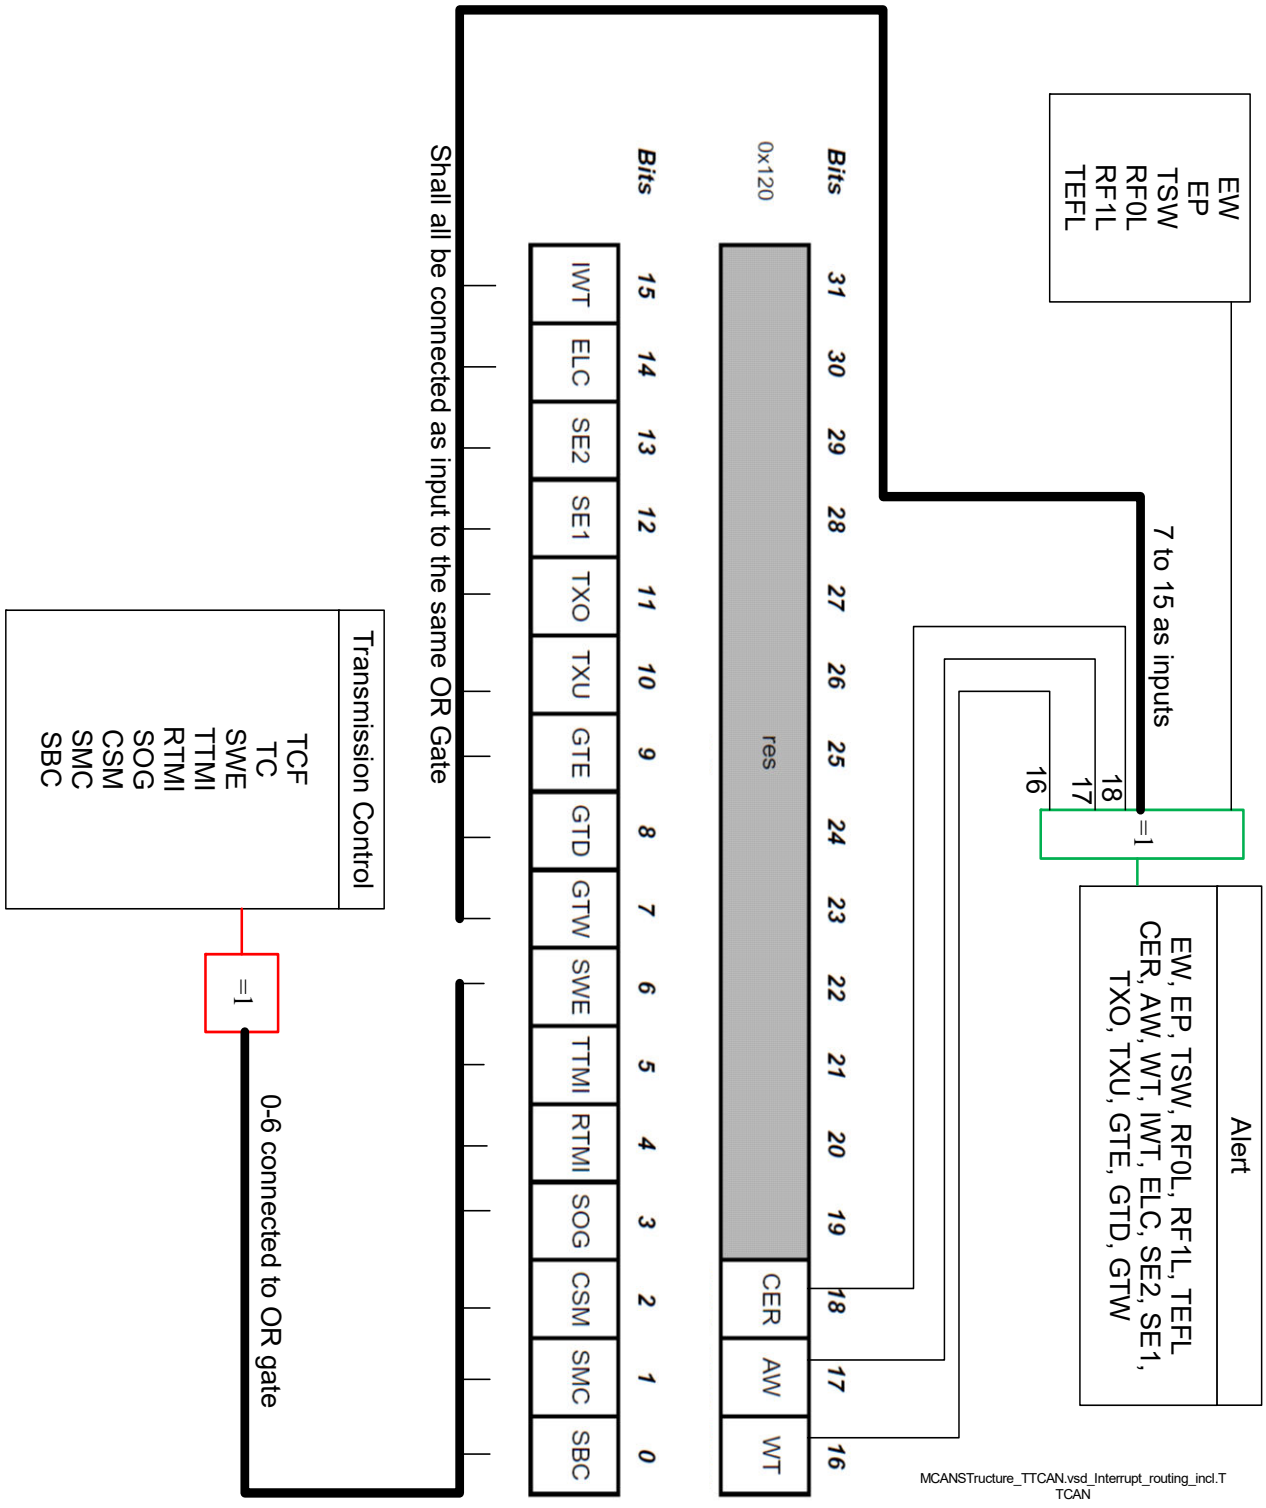


Figure 584 Mapping of TTCAN interrupts into groups

40.3.1.2.2 Signalling interrupts of groups

The groups defined in the previous paragraph are also shown in an **Interrupt Signalling Register i**. 0 means, that no interrupt is pending on the corresponding interrupt, 1 means pending.

40.3.1.2.3 Connections to Interrupt Router Inputs

The interrupt output line INT_O0-15 of MCMCAN is connected to the Interrupt Router module, see **Table 355**.

Table 355 Interrupt Router Inputs

Interrupt Router Input	Connected to CAN Interrupt Output
SRC_CANzINT0	INT_O0 MCMCAN
SRC_CANzINT1	INT_O1 MCMCAN
SRC_CANzINT2	INT_O2 MCMCAN
SRC_CANzINT3	INT_O3 MCMCAN
SRC_CANzINT4	INT_O4 MCMCAN
SRC_CANzINT5	INT_O5 MCMCAN

SRC_CANzINT7	INT_O7 MCMCAN
SRC_CANzINT8	INT_O8 MCMCAN
SRC_CANzINT9	INT_O9 MCMCAN
SRC_CANzINT10	INT_O10 MCMCAN
SRC_CANzINT11	INT_O11 MCMCAN
SRC_CANzINT12	INT_O12 MCMCAN
SRC_CANzINT13	INT_O13 MCMCAN
SRC_CANzINT14	INT_O14 MCMCAN
SRC_CANzINT15	INT_O15 MCMCAN

Interrupt Control

The general interrupt structure is shown in **Figure 585**. The interrupt event can trigger the interrupt generation. The interrupt pulse is generated based on the interrupt flag in the interrupt (status) register (**IRi (i=0-3)** and **TTIR0**) and the interrupt enable bit in Interrupt Enable register (**IEi (i=0-3)**and **TTIE0**). It is purely based on AND logic between the interrupt flags and interrupt enable bit fields. The interrupt flag can be reset by software by writing a '1' to the CANn_IRi bit.

If enabled by the related interrupt enable bit in the corresponding interrupt enable register (**IEi (i=0-3)**, **NTRTRi (i=0-3)**.TEIE and **TTIE0**), an interrupt pulse can be generated at one of the 16 interrupt output lines INT_On of the MCMCAN module using **GRINT1i (i=0-3)** and **GRINT2i (i=0-3)**. If more than one interrupt source is connected to the same interrupt node (in **GRINT1i (i=0-3)** and **GRINT2i (i=0-3)**), the requests are combined to one common line.

The interrupt groups are only ORing the interrupts of the corresponding CAN nodes. The interrupt request has to be reset in the node.

Note: Enabling an interrupt in Interrupt Enable register when the corresponding flag is already set in Interrupt Register will also generate an interrupt pulse. Hence it is recommended to clear the interrupt flags before enabling the corresponding interrupts.

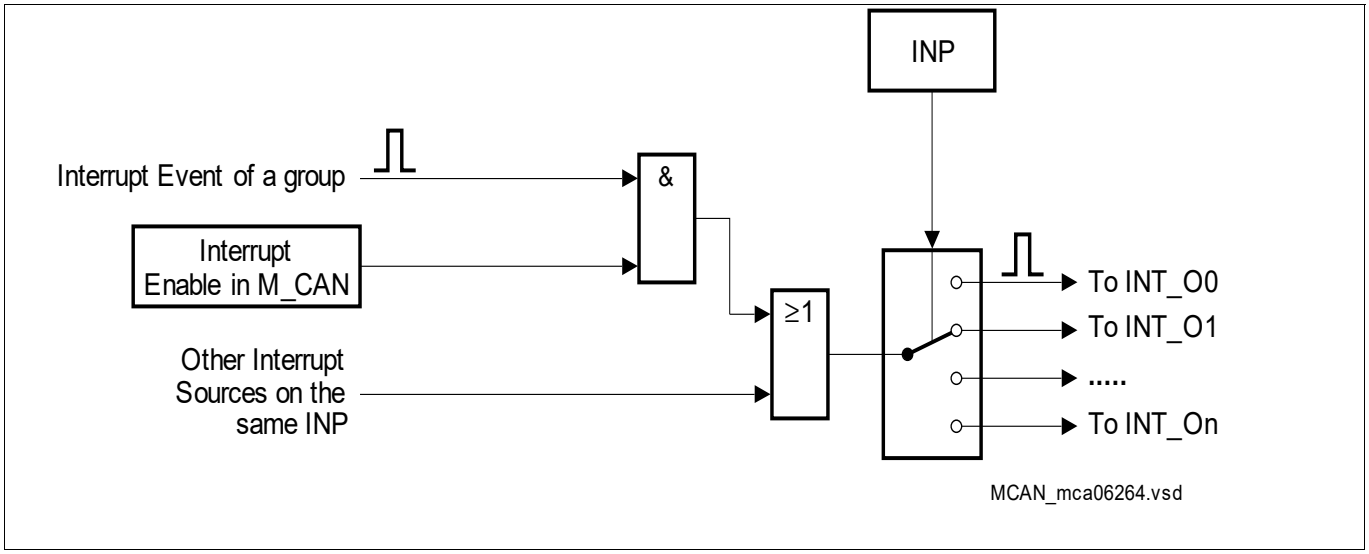

Figure 585 General Interrupt Structure

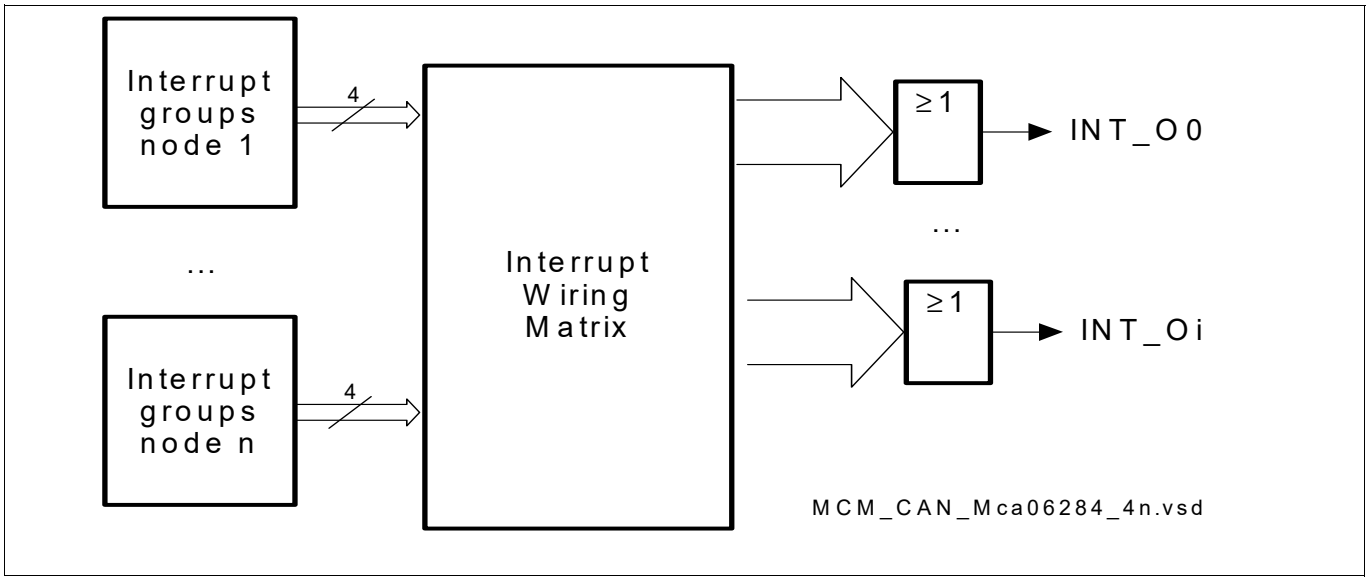

Figure 586 Interrupt compression Unit

40.3.1.3 Port, I/O Line Control and Interconnects

The interconnections between the MCMCAN module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)
- This chapter describes all connections, which are in relation

40.3.1.3.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MCMCAN module are controlled by the port input/output control registers, which are described in the port chapter.

Table 356 shows the corresponding pins, sorted by node. Even though the table is pair wise, it is possible to select a different pairing for RXD and TXD. In addition the RXSEL value to be programmed for the Receive Pins is part of this table. For more information on RXSEL please see **Node Receive Input Selection**.

Note: It is recommended to use "Fast Pads with Strong driver, medium/sharp edge" configuration when CAN-FD is used."

Table 356 MCMCAN I/O Control Selection and Setup

Node Receive Input Selection

Additionally to the I/O control selection, as defined in the port chapter, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register **NPCRi (i=0-3)** must be set according to **Table 356**. Values for **NPCRi (i=0-3)**.RXSEL other than those of the table mentioned above will result in a recessive receive input for node x. As a hint for the RXSEL values, a receive pin ending with A results in 0x0, B in 0x1 until H resulting in the value of 0x7.

40.3.1.3.2 Trigger inputs

The following paragraph describes all interconnections, which are relevant for triggering events.

40.3.1.3.3 External CAN Time Trigger Inputs

The external CAN time trigger inputs ECTT[8:1] of MCMCANcan be used as a transmit trigger for a reference message. In the AURIX™ TC3xx Platform, these input lines are connected as shown in **Table 357**.

Table 357 External CAN Time Trigger Inputs

Multiplexer Input	Connected to	From / to Module
ECTT1	P2.4 / ECTT1	Port 2
ECTT2	P2.5 / ECTT2	Port 2
ECTT3	Output IOUT2	External Request Unit (SCU)
ECTT4	Output IOUT3	External Request Unit (SCU)
ECTT5	eray.eray_tint0_o	Timer Service Request 0 (E-Ray)
ECTT6	eray.eray_tint1_o	Timer Service Request 1 (E-Ray)
ECTT7	gtm_0.sx_gtm2mcan_mcan 0.0	GTM TTCAN Trigger 0
ECTT8	gtm_0.sx_gtm2mcan_mcan 0.1	GTM TTCAN Trigger 1

40.3.1.3.4 CAN Transmit Trigger Inputs

The CAN transmit trigger inputs of MCMCAN are used to trigger for transmission of a message. In the AURIX™ TC3xx Platform, these input lines are connected as shown in **Table 358**. **Table 358** is CAN0 only, for CAN1 and following the mcan0 has to be exchanged to mcan1 and following.

TC39xA only: The cross connections from GTM are identical for CAN1 and CAN2.

Table 358 CAN Transmit Trigger Inputs

Receive Input	Connected to	From / to Module
CAN Node 0

40.3.1.3.5 TT Capture Time Trigger Input

The CAN local time register capture input of MCMCAN is used to trigger the capture of the TT Cycle Time & Count (TTCTC) to the TT Capture Time (TTCPT). In the AURIX™ TC3xx Platform, the input lines are connected as shown in **Table 359** and can be selected using **TTCR0**.TTCTSS.

Table 359 TT Capture Time Register Trigger Input

Receive Input	Connected to	From / to Module
TTCPT_TRIG1	STM0.SR0_INT	System Timer Module (STM)
TTCPT_TRIG2	STM1.SR0_INT	System Timer Module (STM)
TTCPT_TRIG3	STM2.SR0_INT	System Timer Module (STM)
TTCPT_TRIG4	Output IOUT4	External Request Unit (SCU)

Transmit Trigger for a Reference Message

The transmission of a reference message can be triggered by a time mark or by an external event. If it is triggered by a time mark, the "Next is Gap" bit (TTOCN0.NIG for receiving **TTOST0**.WFE) of the previous reference message has been 0. If it is triggered by an external event, the "Next is Gap" bit of the previous reference message has been 1.

The software can set bit **TTOCN0**.NIG in order to initiate the synchronization of a reference message to an event. This event can be an edge at an external input or a software action (write bit **TTOCN0**.FGP = 1, software trigger event).

The transmit trigger generation logic for the reference message is shown in **Figure 587**. The edge detection for ECTTx contains a synchronization stage.

The trigger event can be selected by bit field **TTCR0**.ETESEL (external trigger event selection). Only trigger events are taken into account for the transfer of a reference message that have been detected after the start of the current basic cycle.

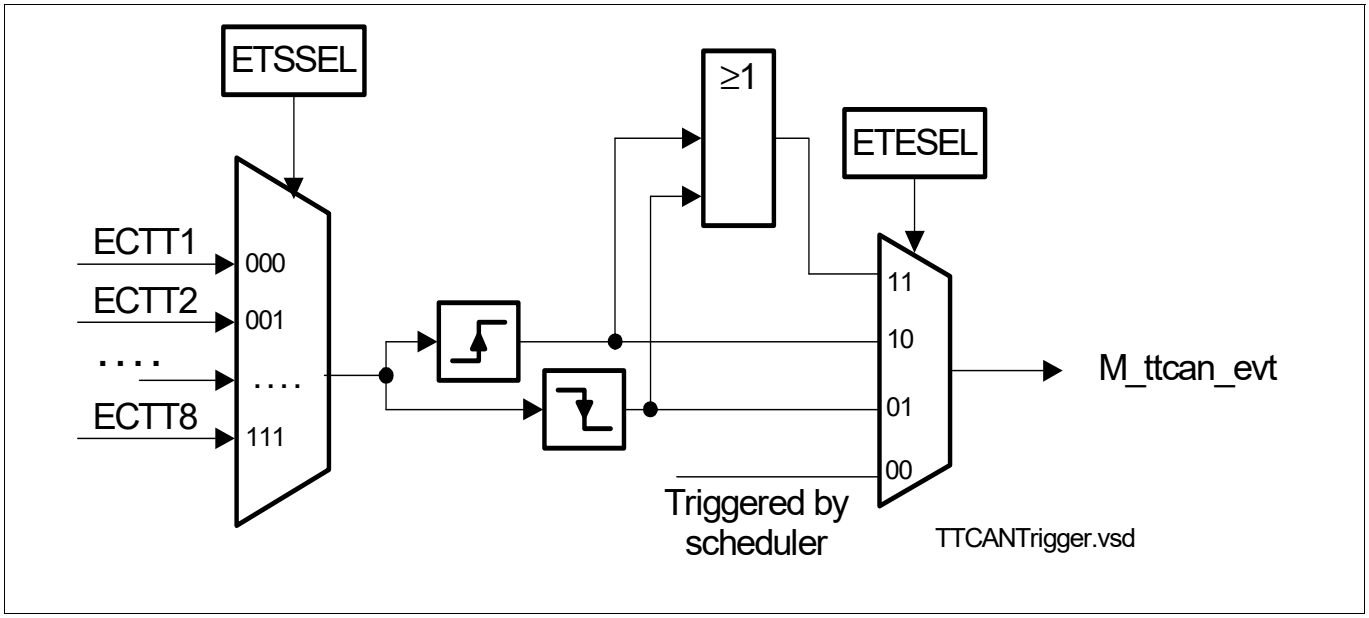

Figure 587 External Trigger Generation and Transmit Trigger for the Reference Message

40.3.1.3.6 Signals to other modules

GTM: Interrupt 12 to 15 are connected to GTM inputs.

Connections to General Timer Module (GTM) Inputs

The interrupt output line INT_O12-15 of MCMCAN is connected to the General Timer Module, see **Table 360**.

Table 360 General Timer Module Inputs

GTM Input	Connected to CAN Interrupt Output

40.3.1.4 Connecting the module to the outside world

The MCMCAN module can be connected per node either to a port configuring the **NPCRi (i=0-3)**.RXSEL for the input, or can be connected to an module internal CAN bus.

40.3.1.4.1 Module internal Loop-Back Mode

The MCMCAN module provides a Module internal Loop-Back Mode to enable an in-system test of the MCMCAN module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MCMCAN module) and a bus select switch for each CAN node. With the switch, each CAN node can be connected either to the internal CAN bus (Internal Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Internal Loop-Back Mode is selected for CAN node x by setting the Node x Port Control Register bit **NPCRi (i=0-3)**.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

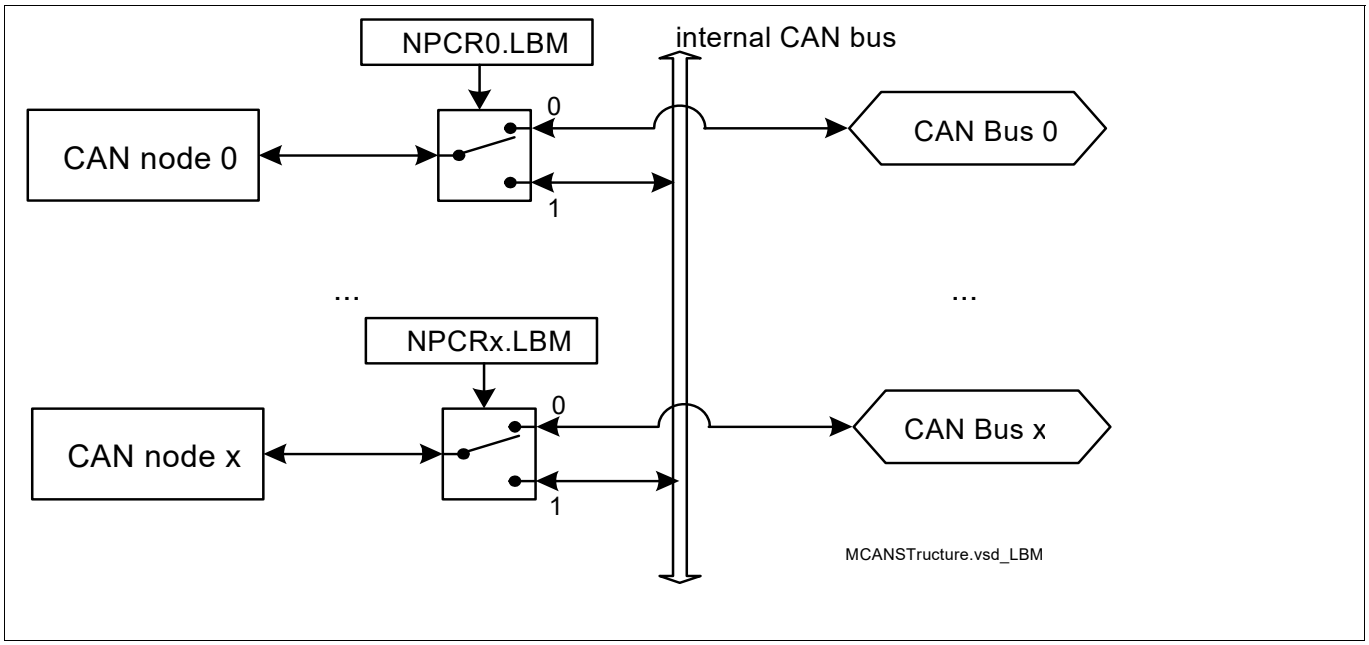

Figure 588 Module Internal Loop-Back Mode

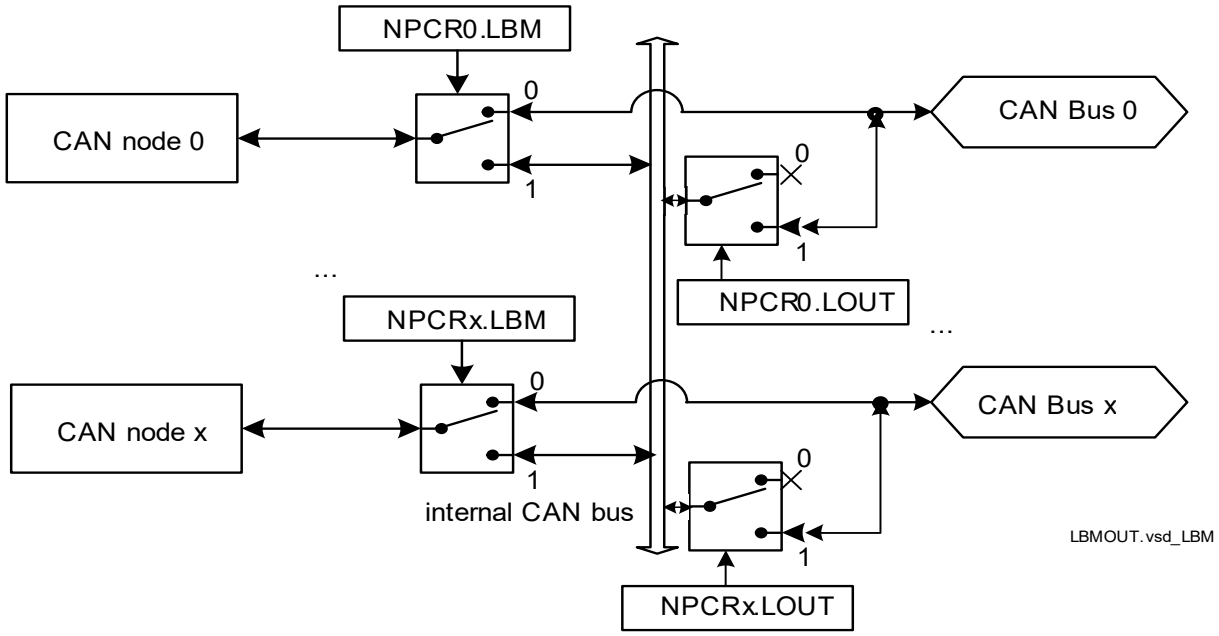

Figure 589 Module Loop-Back Mode Out

40.3.1.4.2 Module Loop Back Mode Out (B-step feature)

Setting **NPCRi (i=0-3)**.LOUT bit will send the signals from the internal loop back bus to the corresponding pins of the CAN node and vice versa. Therefore a receive and transmit between internal loop back bus and a bus system outside is possible. When **NPCRi (i=0-3)**.LOUT is set to one, the internal loop back bus and the external bus will be communicating with each other. The table below explains the behaviour of the CAN module for different combinations **NPCRi (i=0-3)**.LOUT and **NPCRi (i=0-3)**.LBM.

Table 365 Combinations of Internal Loop Back Mode and Loop Back Mode Out

NPCR.LOUT	NPCR.LBM	Description
0	0	Normal CAN operation. Internal and loop back out mode deactivated
0	1	Internal Loop Back mode
1	0	Loop Back Mode Out
1	1	Reserved

40.3.1.5 Fixing the address protection for the CAN nodes

Inside the BPI part, the address protection is defined. Here the nodes become protectable, as well as the control area. With the nodes a certain RAM area is assigned, therefore a start address and an end address per node is necessary. An overlap of the protected areas, is not found by the hardware. **STARTADRi (i=0-3)** and **ENDADRi (i=0-3)** registers, give the possibility to define a range within CAN RAM, belonging to a node, which can only be written by certain masters. The mechanism is identical to ACCEN registers. The RAM will only be write and not read protected.

40.3.1.6 Node Timing Functions

A CAN node offers the following timing functions:

- A receive time-out mode that can detect the reception within message buffers. The timeout expires, when no message has been received.
- Without CPU involvement, a selectable message buffers can be transmitted periodically, triggered by a timer, a System Timer (STM) or General Timer Module (GTM).

The clocking options for the node timer is controlled by Node Timer Clock Control Register, **Node i Timer Clock Control Register**, the node timing functions for Receive Timeout Mode is controlled by Node x Timer Receive Timeout Register, **Node i Timer Receive Timeout Register** and for Transmit Trigger Mode is controlled by Node x Timer A/B/C Transmit Trigger Registers, **Node i Timer A Transmit Trigger Register**, **Node i Timer B Transmit Trigger Register**, **Node i Timer C Transmit Trigger Register**. Links are only for CAN0, but the feature is available for all CAN modules. In general, the timers will not run, without setting the START bit and not without setting the RELOAD value, to a different value than 0. Whatever comes last, will start the timer.

Modes with Timer Usage

A CAN node timer is driven by the synchronous clock or by the corresponding clock sources, divided by a prescaler selected via bit field TPSC in the corresponding timer control register. The timers are enabled by writing to the RELOAD bits in the relevant node timer registers; then it decrements from its initial value. The further behavior depends on the selected timer mode:

- **Receive Timeout Mode:**The receive timeout function is valid for the receive buffers. A receive time-out check is enabled, which may be a received frame or remote data frame. If any of the message buffers receives before the timer is 0, the timer will be reloaded. When the timer reaches 0, it will stop. Bit TE in **NTRTRi (i=0-3)** register will be set. With bit **NTRTRi (i=0-3)**.TEIE = 1, an interrupt will be generated.
- **Transmit Trigger Mode:**When the timer reaches 0, the TXRQ of the corresponding message buffer is selected.

Transmit Trigger by System Timer or General Timer Module

For Node i Timer the trigger for transmission of a message can also be set by a System Timer (STM) trigger event or General Timer Module (GTM) trigger event. See **Figure 590**.
Bit **NTCCRi (i=0-3)**.TRIGSRC in the timer clock control register enables this feature and the timer is started once values are written to the RELOAD bits of the relevant **NTATTRi (i=0-3)**, **NTBTTRi (i=0-3)**, or **NTCTTRi (i=0-3)** registers. In transmit trigger mode, when a trigger event occurs (STM or GTM), the node timer will be decremented per trigger event timing prescaled by (TPSC+1) till it reaches zero where the transmit request is set for the corresponding transmit message buffer.

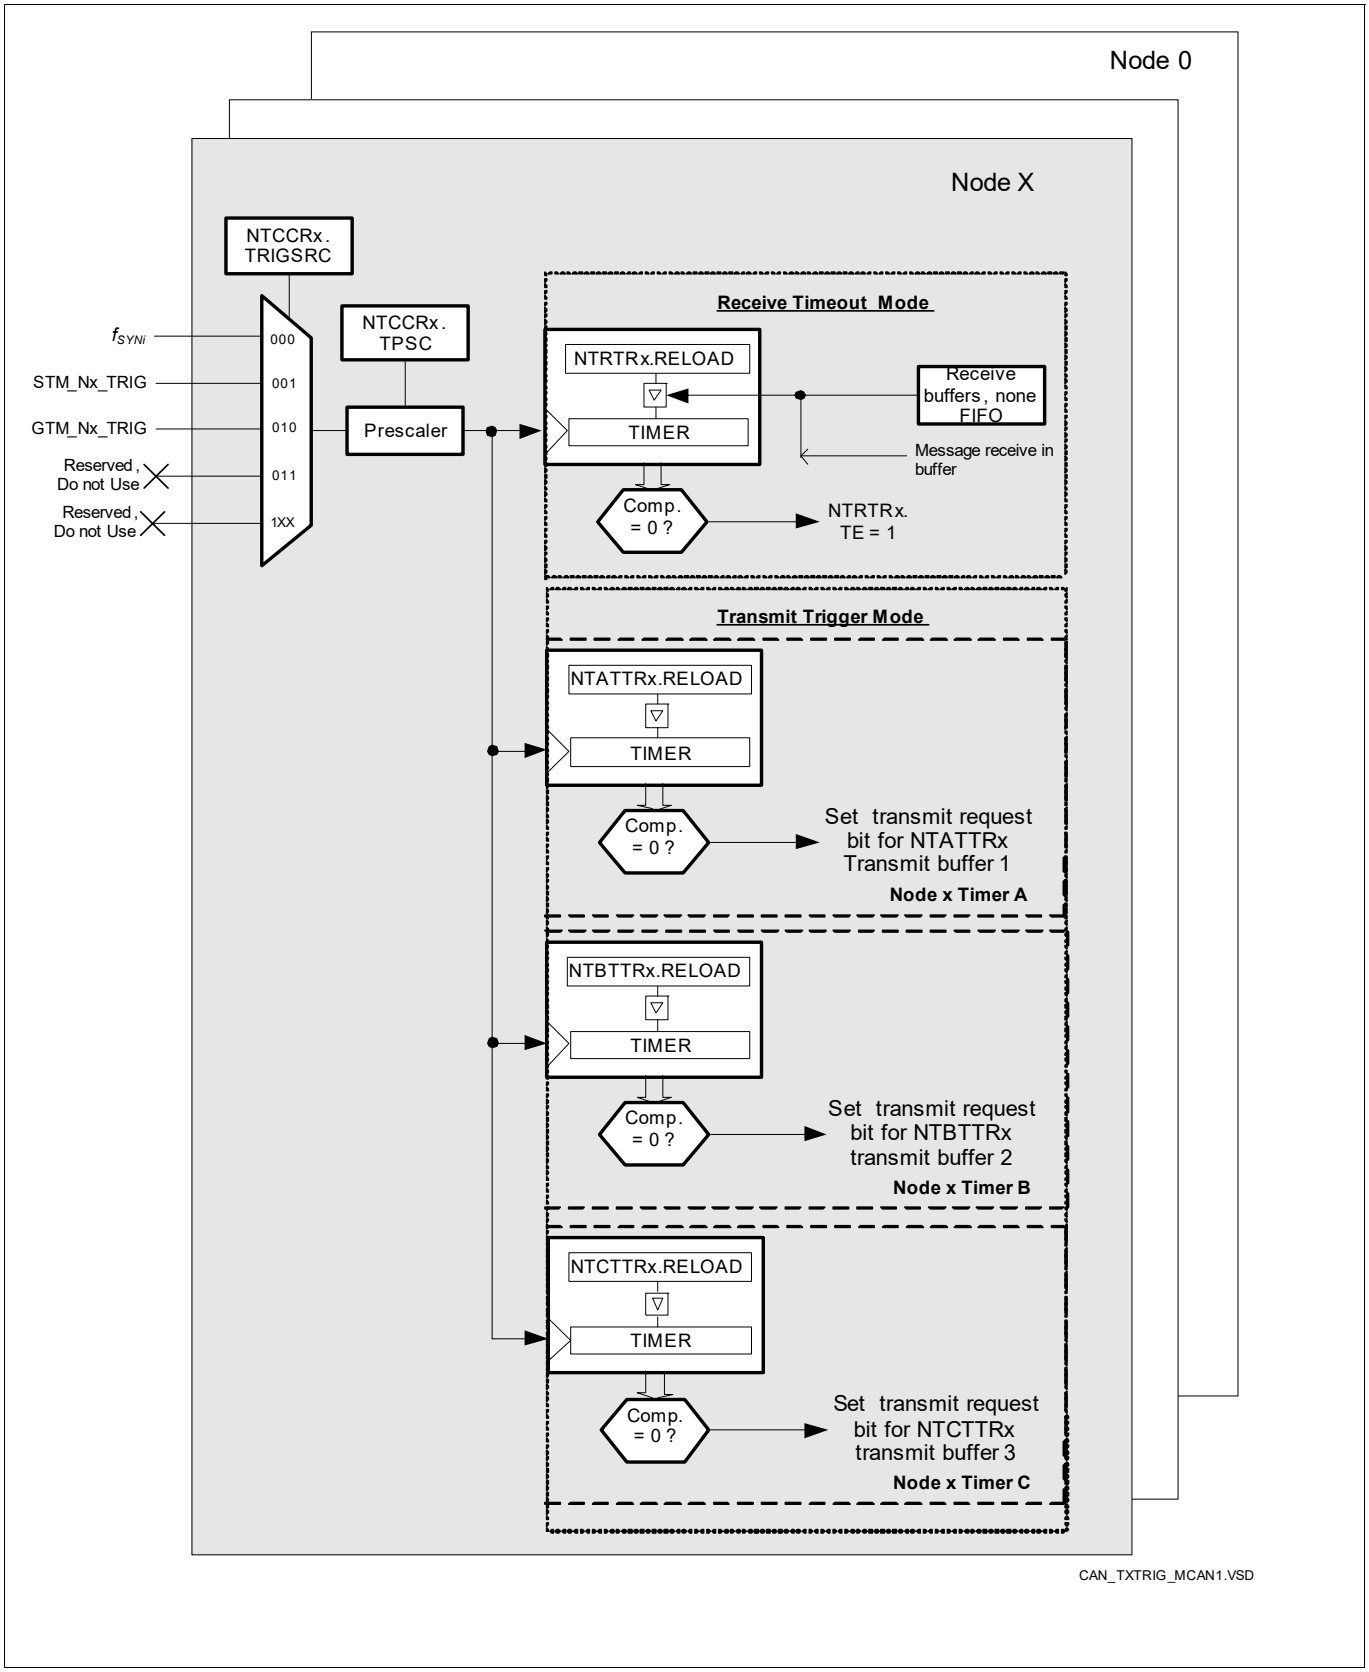

Figure 590 CAN Node Timing Modes

40.3.1.6.1 Automatic transferring of messages

NTATTRi (i=0-3), **NTBTTRi (i=0-3)**, **NTCTTRi (i=0-3)** registers enable the M_CAN IP to trigger messages on timer events. The timer per module have one clock source. The counting events can take place on an STM interrupt, a GTM interrupt or by f_{SYNi}. These timers can be used to enable Pretended Networking, or to have hardware support for a gateway functionality. This functionality needs a receive interrupt or a watermark interrupt within a FIFO, triggering a DMA transfer. The transmit objects will be automatically triggered to transfer the messages below, via timer underflow. As the transmit triggers are fixed to message RAM buffers 1-3, this feature only works if these buffers are available.

40.3.1.7 Destructive Debug Entry

On destructive debug entry ie., when DMU_SP_PROCONHSMCFG.DESTDBG = 11b and DMU_HF_PROCONDBG.EDM = 11b, the CAN transmit data output (TXD) is tied to “Recessive state” (logic ‘1b’). This blocks any further CAN transmission when AURIX™ TC3xx Platform has entered the Destructive Debug state.

40.3.2 M_CAN Functional Description

40.3.2.1 Operating Modes

40.3.2.1.1 Software Initialization

Software initialization is started by setting bit CCCRi.INIT, either by software or by a hardware reset, or by going Bus_Off. While **CCCRi (i=0-3)**.INIT is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output TXD is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting **CCCRi (i=0-3)**.INIT does not change any configuration register. Resetting **CCCRi (i=0-3)**.INIT finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits **CCCRi (i=0-3)**.INIT and **CCCRi (i=0-3)**.CCE are set (protected write).

CCCRi (i=0-3).CCE can only be set/reset while **CCCRi (i=0-3)**.INIT = '1'. **CCCRi (i=0-3)**.CCE is automatically reset, when CCCRi.INIT is cleared.

The following registers are reset when **CCCRi (i=0-3)**.CCE is set

- **HPMSi (i=0-3)** - High Priority Message Status
- **RXF0Si (i=0-3)** - Rx FIFO 0 Status
- **RXF1Si (i=0-3)** - Rx FIFO 1 Status
- **TXFQSi (i=0-3)** - Tx FIFO/Queue Status
- **TXBRPi (i=0-3)** - Tx Buffer Request Pending
- **TXBTOi (i=0-3)** - Tx Buffer Transmission Occurred
- **TXBCFi (i=0-3)** - Tx Buffer Cancellation Finished
- **TXEFSi (i=0-3)** - Tx Event FIFO Status
- **TTOST0** - TT Operation Status
- **TTLGT0** - TT Local & Global Time, only Global Time TTLGT0.GT is reset
- **TTCTC0** - TT Cycle Time & Count
- **TTCSM0** - TT Cycle Sync Mark

The Timeout Counter value **TOCVi (i=0-3)**.TOC is preset to the value configured by **TOCCi (i=0-3)**.TOP when **CCCRi (i=0-3)**.CCE is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while **CCCRi (i=0-3)**.CCE = '1'.

The following registers are only writeable while **CCCRi (i=0-3)**.CCE = '0'

- **TXBARi (i=0-3)** - Tx Buffer Add Request
- **TXBCRi (i=0-3)** - Tx Buffer Cancellation Request

CCCRi (i=0-3).TEST and **CCCRi (i=0-3)**.MON can only be set by the Host while **CCCRi (i=0-3)**.INIT = '1' and **CCCRi (i=0-3)**.CCE = '1'. Both bits may be reset at any time. **CCCRi (i=0-3)**.DAR can only be set/reset while **CCCRi (i=0-3)**.INIT = '1' and **CCCRi (i=0-3)**.CCE = '1'.

40.3.2.1.2 Normal Operation

The M_CAN's default operating mode after hardware reset is event-driven CAN communication without time triggers (TTOCF0.OM = "00"). It is required that both **CCCRi (i=0-3)**.INIT and **CCCRi (i=0-3)**.CCE are set before the TT Operation Mode can be changed.

Once the M_CAN is initialized and **CCCRi (i=0-3)**.INIT is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

40.3.2.1.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame. The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = recessive signifies a CAN FD frame, FDF = dominant signifies a Classical CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. The coding of res = recessive is reserved for future expansion of the protocol. In case the M_CAN receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting bit **PSRi (i=0-3)**.PXE. When Protocol Exception Handling is enabled (**CCCRi (i=0-3)**.PXHD = '0'), this causes the operation state to change from Receiver (**PSRi (i=0-3)**.ACT = "10") to Integrating (**PSRi (i=0-3)**.ACT = "00") at the next sample point. In case Protocol Exception Handling is disabled (**CCCRi (i=0-3)**.PXHD = '1'), the M_CAN will treat a recessive res bit as an form error and will respond with an error frame.CAN FD operation is enabled by programming **CCCRi (i=0-3)**.FDOE. In case **CCCRi (i=0-3)**.FDOE = '1', transmission and reception of CAN FD frames is enabled. Transmission and reception of Classical CAN frames is always possible. Whether a CAN FD frame or a Classical CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With **CCCRi (i=0-3)**.FDOE = '0', received frames are interpreted as Classical CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. CCCRi.FDOE and CCCRi.BRSE can only be changed while CCCRi.INIT and CCCRi.CCE are both set.With CCCRi.FDOE = '0', the setting of bits FDF and BRS is ignored and frames are transmitted in Classical CAN format. With **CCCRi (i=0-3)**.FDOE = '1' and **CCCRi (i=0-3)**.BRSE = '0', only bit FDF of a Tx Buffer element is evaluated. With **CCCRi (i=0-3)**.FDOE = '1' and **CCCRi (i=0-3)**.BRSE = '1', transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classical CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classical CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classical CAN communication.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to **Table 366** below.

Table 366 Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Nominal Bit Timing & Prescaler Register NBTPi. In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing & Prescaler Register **DBTPi (i=0-3)**. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (asynchronous clock). Example: with a CAN clock frequency of 20 MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s. (As 4 tq is quite tight, please check if this works in your environment.)

Note: MCMCAN supports upto 5 Mbit/s considering the physical medium CAN-FD timing requirements from ISO 11898-2:2016. At f_{MCAN} = 80MHz, CAN-FD data phase bit rate can be extended to 8 Mbit/s, while the bit asymmetry effect from CAN-FD transceiver, physical layer network topology etc., has to be considered by the user.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

40.3.2.1.4 Transmitter Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin TXD the protocol controller receives the transmitted data from its local CAN transceiver via pin RXD. The received data is delayed by the CAN transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver and port delay.

For the transmitter delay compensation the following boundary conditions have to be considered:

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit **DBTPi (i=0-3)**.TDC.The received bit is compared against the transmitted bit at the Secondary Sample Point. The Secondary Sample Point position is defined as the sum of the measured delay from the M_CAN's transmit output TX through the transceiver to the receive input RX plus the transmitter delay compensation offset as configured by **TDCRi (i=0-3)**.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.PSRi.TDCV shows the actual transmitter delay compensation value. **PSRi (i=0-3)**.TDCV is cleared when CCCRi.INIT is set and is updated at each transmission of an FD frame while **DBTPi (i=0-3)**.TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from TX to RX and the configured transmitter delay compensation offset **TDCRi (i=0-3)**.TDCO has to be less than 6 bit times in the data phase.The sum of the measured delay from RX to RX and the configured transmitter delay compensation offset TDCRi.TDCO has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the Secondary Sample Points.

Transmitter Delay Compensation Measurement

If transmitter delay compensation is enabled by programming **DBTPi (i=0-3)**.TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input RX of the transmitter. The resolution of this measurement is one mtq.

Figure 591 below describes how the transmitter loop delay is measured.

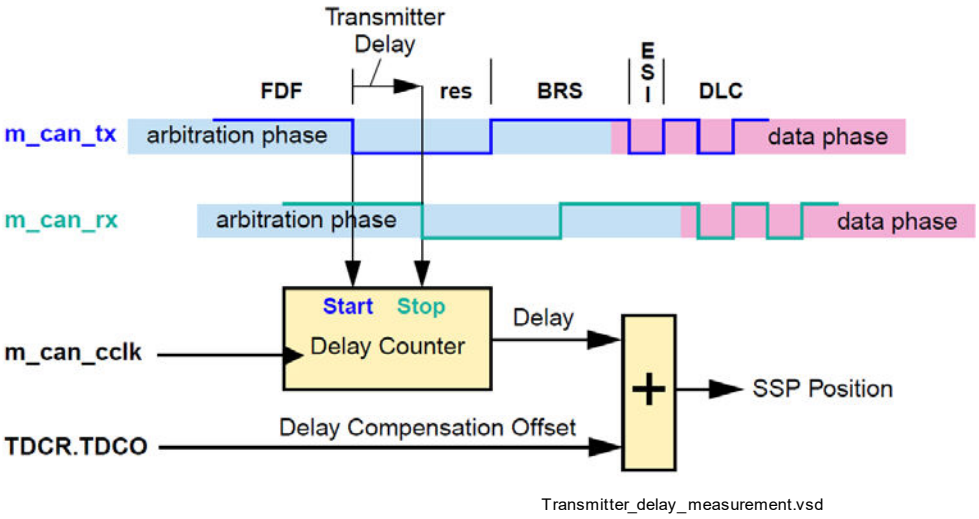

Figure 591 Transmitter delay measurement

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received “res” bit, resulting in a to early Secondary Sample Point position, the use of a transmitter delay compensation filter window can be enabled by programming **TDCRi (i=0-3)**.TDCF.This defines a minimum value for the Secondary Sample Point position. Dominant edges on RX, that would result in an earlier Secondary Sample Point position are ignored for transmitter delay measurement. The measurement is stopped when the Secondary Sample Point position is at least **TDCRi (i=0-3)**.TDCF AND RX is low.

40.3.2.1.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle to resynchronize itself to the CAN communication. The error counters (**ECRi (i=0-3)**.REC and **ECRi (i=0-3)**.TEC) are frozen while Error Logging (**ECRi (i=0-3)**.CEL) is active. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCRi.ASM. The bit can only be set by the Host when both CCCRi.CCE and CCCRi.INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset **CCCRi (i=0-3)**.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

40.3.2.1.6 Bus Monitoring Mode

The M_CAN is set in Bus Monitoring Mode by programming **CCCRi (i=0-3)**.MON to one or when error level S3 (**TTOST0**.EL = “11”) is entered. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode register TXBRP is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. **Figure 592** shows the connection of signals TXD and RXD to the M_CAN in Bus Monitoring Mode.

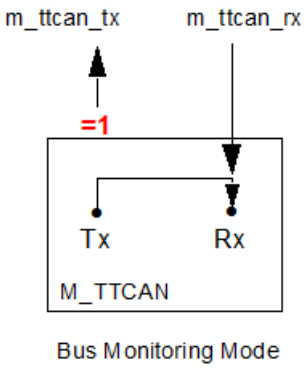

Figure 592 Pin Control in Bus Monitoring Mode

40.3.2.1.7 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via **CCCRi (i=0-3)**.DAR.

Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit **TXBRPi (i=0-3)**.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit **TXBTOi (i=0-3)**.TOx set
  - Corresponding Tx Buffer Cancellation Finished bit **TXBCFi (i=0-3)**.CFx not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit **TXBTOi (i=0-3)**.TOx set
  - Corresponding Tx Buffer Cancellation Finished bit **TXBCFi (i=0-3)**.CFx set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit **TXBTOi (i=0-3)**.TOx not set
  - Corresponding Tx Buffer Cancellation Finished bit **TXBCFi (i=0-3)**.CFx set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = "10" (transmission in spite of cancellation).

40.3.2.1.8 Power Down (Sleep Mode)

The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register **CCCRi (i=0-3)**.CSR. As long as the clock stop request signal is active, bit **CCCRi (i=0-3)**.CSR is read as one.

When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then **CCCRi (i=0-3)**.INIT to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting **CCCRi (i=0-3)**.CSA to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to **CCCRi (i=0-3)**.INIT will have no effect. Now the module clocks may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC Control Register flag **CCCRi (i=0-3)**.CSR. The M_CAN will acknowledge this by resetting **CCCRi (i=0-3)**.CSA. Afterwards, the application can restart CAN communication by resetting bit **CCCRi (i=0-3)**.INIT.

40.3.2.1.9 Test Modes

To enable write access to register TEST (see **Test Register i**), bit **CCCRi (i=0-3)**.TEST has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin TXD by programming **TESTi (i=0-3)**.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at pin RXD can be read from **TESTi (i=0-3)**.RX. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to **TESTi (i=0-3)**.TX until the new configuration is visible at output pin TXD. This applies also when reading input pin RXD via **TESTi (i=0-3)**.RX.

Note: Test modes should be used for production tests or self test only. The software control for pin TXD interferes with all CAN protocol functions. It is not recommended to use test modes for application.

External Loop Back Mode

The M_CAN can be set in External Loop Back Mode by programming **TESTi (i=0-3)**.LBCK to one. In Loop Back Mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO. **Figure 593** shows the connection of TXD and RXD to the M_CAN in External Loop Back Mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back Mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the RXD input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the TXD pin.

Internal Loop Back Mode

Internal Loop Back Mode is entered by programming bits **TESTi (i=0-3)**.LBCK and **CCCRi (i=0-3)**.MON to one. This mode can be used for a "Hot Selftest", meaning the M_CAN can be tested without affecting a running CAN system connected to the pins TXD and RXD. In this mode pin RXD is disconnected from the M_CAN and pin TXD is held recessive. **Figure 593** shows the connection of TXD and RXD to the M_CAN in case of Internal Loop Back Mode.

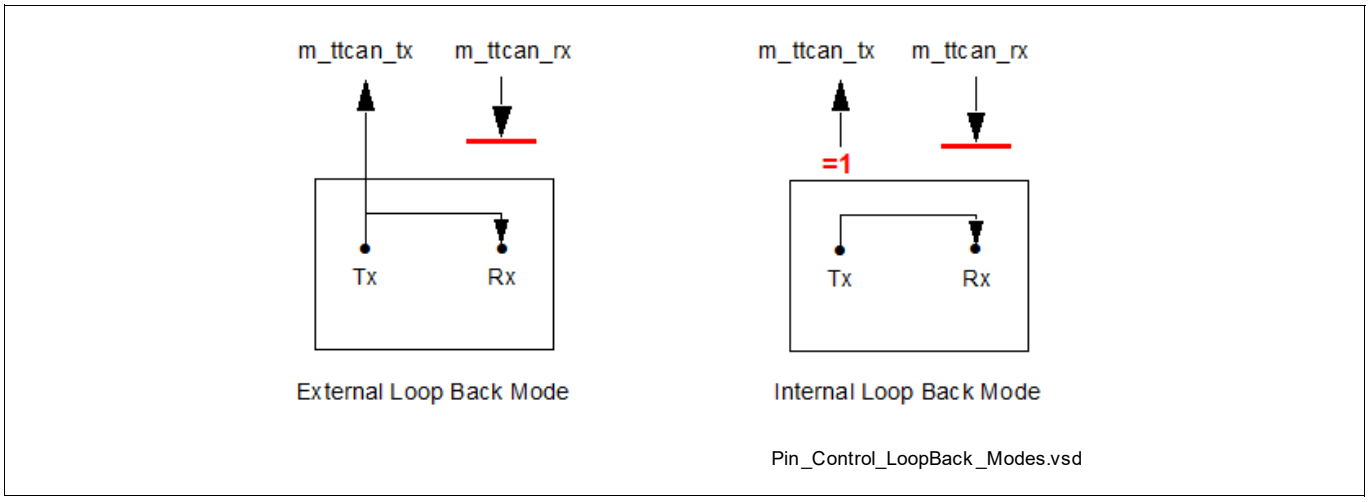

Figure 593 Pin Control in Loop Back Modes

40.3.2.1.10 Application Watchdog

The application watchdog is served by reading register **TTOST0**. When the application watchdog is not served in time, bit **TTOST0**.AWE is set, all TTCAN communication is stopped, and the M_CAN is set into Bus Monitoring Mode.

The TT Application Watchdog can be disabled by programming the Application Watchdog Limit **TTOCF0**.AWL to 0x00. The TT Application Watchdog should not be disabled in a TTCAN application program.

40.3.2.2 Timestamp Generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler **TSCCi (i=0-3)**.TCP can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via **TSCVi (i=0-3)**.TSC. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag **IRi (i=0-3)**.TSW is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit **TSCCi (i=0-3)**.TSS an external 16-bit timestamp can be used. The external timer can be controlled using the **NTCCRi (i=0-3)** register. The external timer can be started by setting **NTCCRi (i=0-3)**.STSTART. It can be reset to zero by setting **NTCCRi (i=0-3)**.STRESET. A write of '1b' to **NTCCRi (i=0-3)**.STSTART is effective only when **NTCCRi (i=0-3)**.STRESET is '0b' ie., the external timer cannot be started when **NTCCRi (i=0-3)**.STRESET is '1b'.

40.3.2.3 Timeout Counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by **TSCCi (i=0-3)**.TCP as the Timestamp Counter. The Timeout Counter is configured via register **TOCCi (i=0-3)**. The actual counter value can be read from **TOCVi (i=0-3)**.TOC.

The Timeout Counter can only be started while **CCCRi (i=0-3)**.INIT = '0'. It is stopped when **CCCRi (i=0-3)**.INIT = '1', e.g. when the M_CAN enters Bus_Off state.

The operation mode is selected by **TOCCi (i=0-3)**.TOS. When operating in Continuous Mode, the counter starts when CCCRi.INIT is reset. A write to **TOCVi (i=0-3)** presets the counter to the value configured by **TOCCi (i=0-3)**.TOP and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by **TOCCi (i=0-3)**.TOP. Down-counting is started when the first FIFO element is stored. Writing to **TOCVi (i=0-3)** has no effect.

When the counter reaches zero, interrupt flag **IRi (i=0-3)**.TOO is set. In Continuous Mode, the counter is immediately restarted at **TOCCi (i=0-3)**.TOP.

Note: The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

40.3.2.4 Rx Handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

40.3.2.4.1 Acceptance Filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration **GFCi (i=0-3)**
- Standard ID Filter Configuration **SIDFCi (i=0-3)**
- Extended ID Filter Configuration **XIDFCi (i=0-3)**
- Extended ID AND Mask **XIDAMi (i=0-3)**

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag **IRi (i=0-3)**.HPM
- Set High Priority Message interrupt flag **IRi (i=0-3)**.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer
New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see **PSRi (i=0-3)**.LEC respectively **PSRi (i=0-3)**.FLEC.

Rx FIFO
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see **PSRi (i=0-3)**.LEC respectively **PSRi (i=0-3)**.FLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in **Rx FIFO Overwrite Mode** have to be considered.

Note: When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

Range Filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

EFT = “00”: The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied

EFT = “11”: The Extended ID AND Mask (XIDAM) is not used for range filtering

Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

Standard Message ID Filtering

Figure 594 below shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in **Section 40.4.6.5**.

Controlled by the Global Filter Configuration **GFCi (i=0-3)** and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

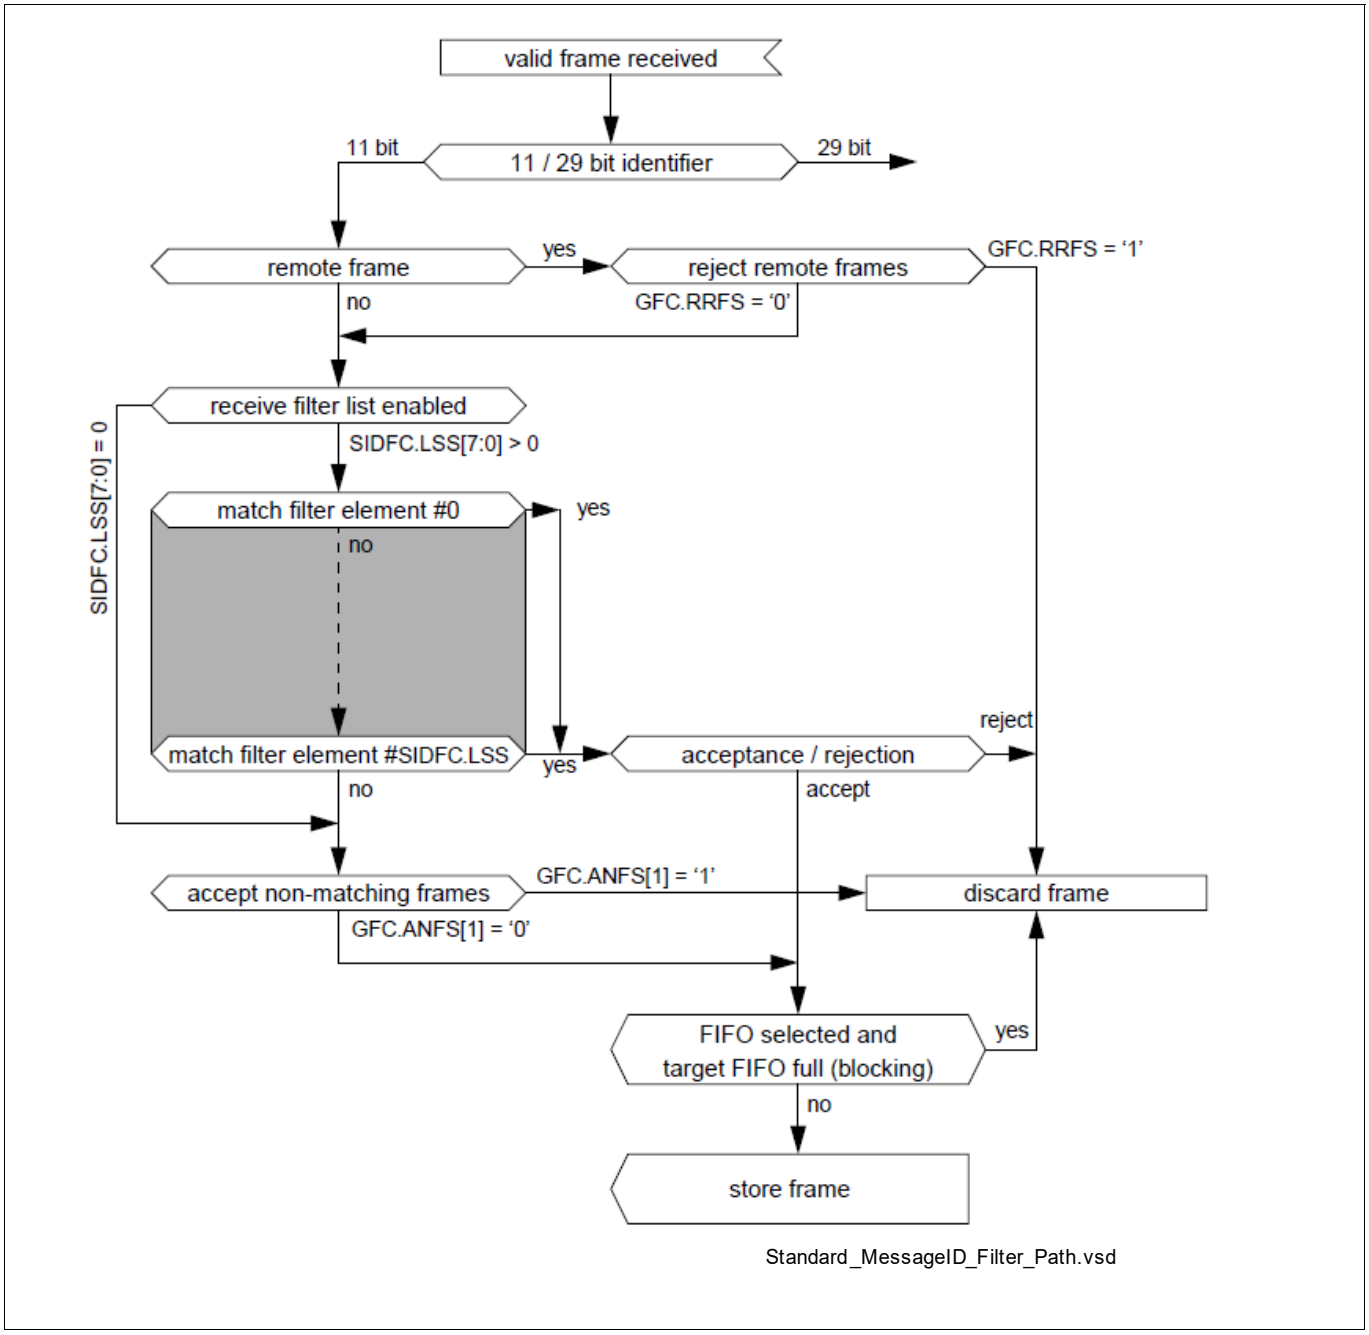

Figure 594 Standard Message ID Filter Path

Extended Message ID Filtering

Figure 595 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in **Section 40.4.6.6**.

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask XIDAM is ANDed with the received identifier before the filter list is executed.

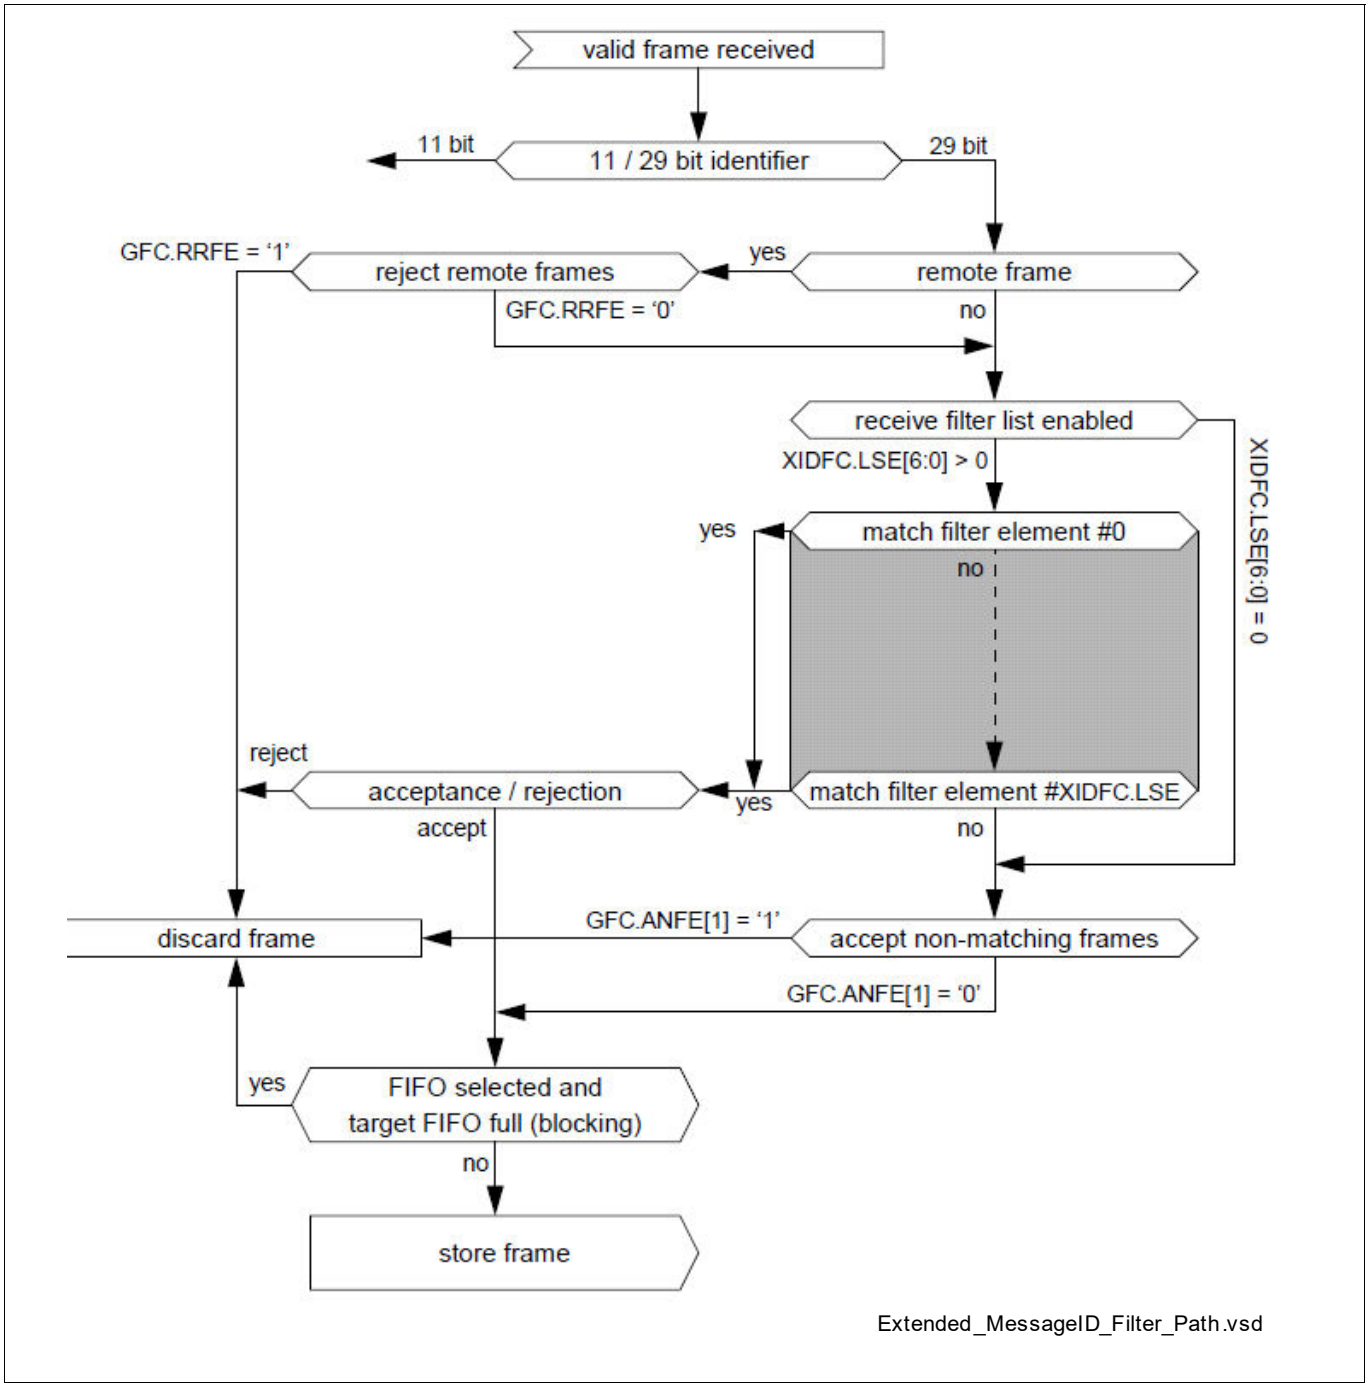

Figure 595 Extended Message ID Filter Path

40.3.2.4.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers **RXF0Ci (i=0-3)** and **RXF1Ci (i=0-3)**.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see **Section 40.3.2.4.1**. The Rx FIFO element is described in **Section 40.4.6.2**.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag IRi.RFnW is set. When the Rx FIFO Put Index reaches the Rx

FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS.FnF. In addition interrupt flag **IRi (i=0-3)**.RFnF is set.

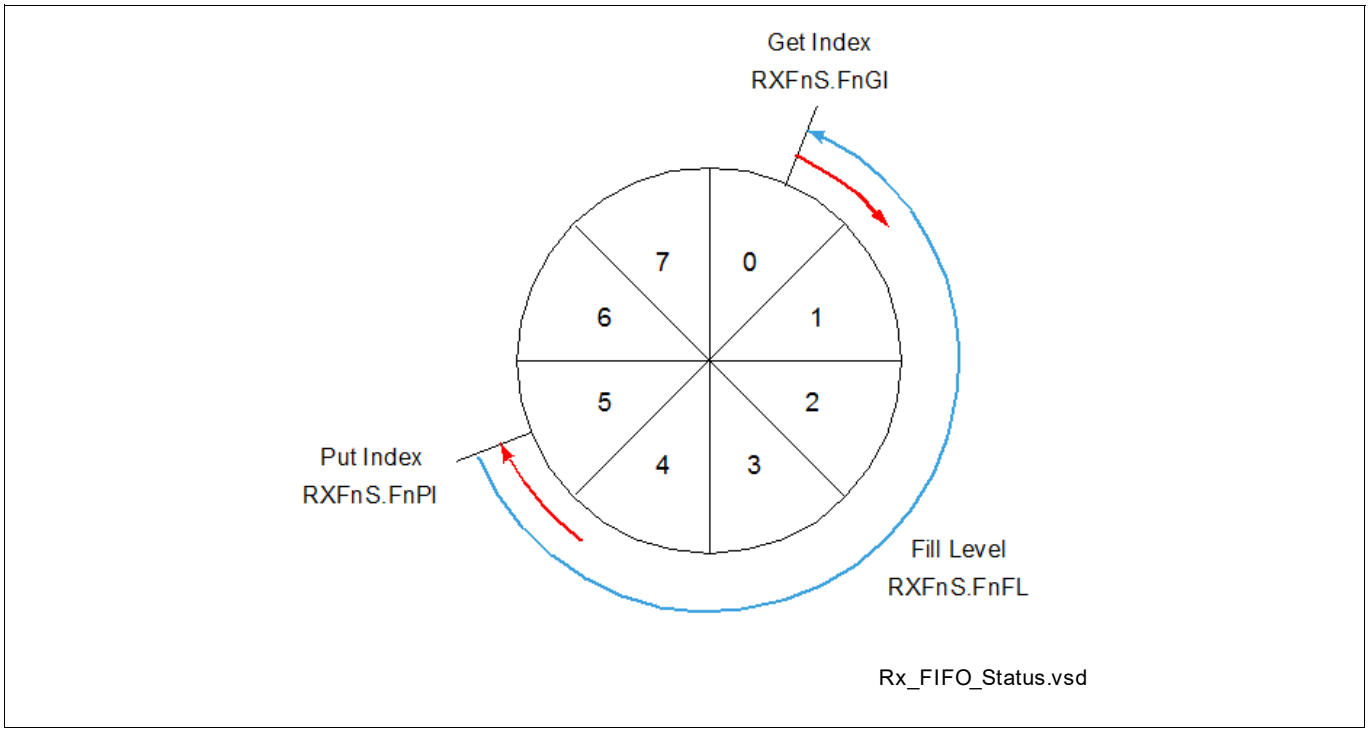

Figure 596 Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS.FnGI • FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC.FnSA.

Table 367 Rx Buffer / FIFO Element Size

RXESCi.RBDS[2:0] RXESCi.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC.FnOM = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS.FnF = ‘1’. In addition interrupt flag IRi.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS.RFnL = ‘1’. In addition interrupt flag IRi.RFnL is set.

Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signalled by RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. **Figure 597** shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

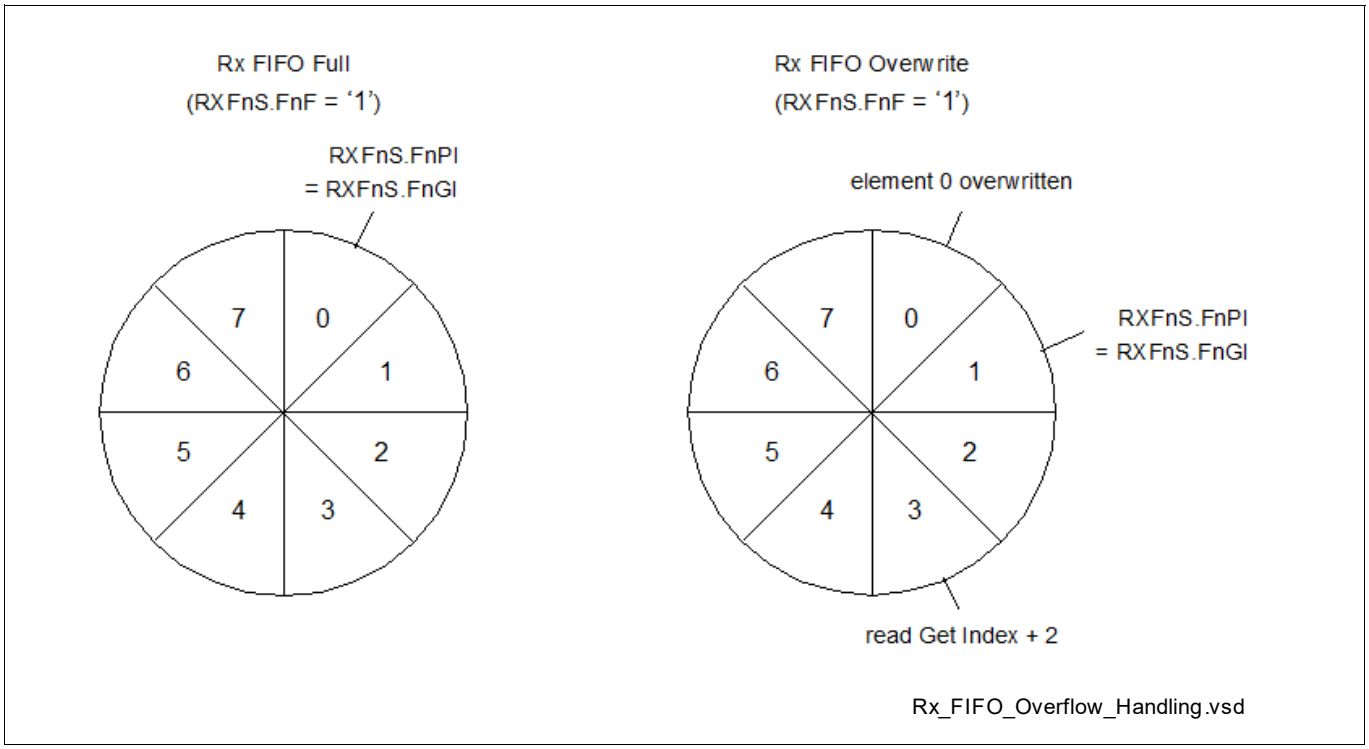

Figure 597 Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = ‘0’).

40.3.2.4.3 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via **RXBCi (i=0-3)**.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = “111” and SFID2 / EFID2[10:9] = “00” has to be configured (see **Section 40.4.6.5** and **Section 40.4.6.6**).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IRi.DRX (Message stored in dedicated Rx Buffer) in the interrupt register is set.

Table 368 Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register **NDAT1i (i=0-3)**,**NDAT2i (i=0-3)** is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

Rx Buffer Handling

- Reset interrupt flag IRi.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

40.3.2.5 Tx Handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in **Section 40.4.6.3**. **Table** below describes the possible configurations for frame transmission.

Table 369 Possible Configuration for Frame Transmission

CCCR		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classical CAN
0	1	0	ignored	Classical CAN
0	1	1	ignored	FD without bit rate switching
1	1	0	ignored	Classical CAN
1	1	1	0	FD without bit rate switching
1	1	1	1	FD with bit rate switching

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register **TXBRPi (i=0-3)** is updated, or when a transmission has been started.

40.3.2.5.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If e.g. CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit **CCCRi (i=0-3)**.TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (**CCCRi (i=0-3)**.TXP = '0').

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

40.3.2.5.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an "Add Request" via **TXBARi (i=0-3)**.ARn. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see **Chapter 40.3.2.5.3**). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) • Element Size to the Tx Buffer Start Address **TXBCi (i=0-3)**.TBSA.

Table 370 Tx Buffer / FIFO / Queue Element Size

TXESCi.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

40.3.2.5.3 Tx FIFO

Tx FIFO operation is configured by programming **TXBCi (i=0-3)**.TFQM to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index **TXFQSi (i=0-3)**.TFGI. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level **TXFQSi (i=0-3)**.TFFL as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index **TXFQSi (i=0-3)**.TFQPI. An "Add Request" increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (**TXFQSi (i=0-3)**.TFQF = '1') is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via **TXBARi (i=0-3)**. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see **Table 370**). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index **TXFQSi (i=0-3)**.TFQPI (0…31) • Element Size to the Tx Buffer Start Address **TXBCi (i=0-3)**.TBSA.

40.3.2.5.4 Tx Queue

Tx Queue operation is configured by programming **TXBCi (i=0-3)**.TFQM to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx Buffer referenced by the Put Index **TXFQSi (i=0-3)**.TFQPI. An "Add Request" cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (**TXFQSi (i=0-3)**.TFQF = "1"), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see **Table 370**). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index **TXFQSi (i=0-3)**.TFQPI (0…31) • Element Size to the Tx Buffer Start Address **TXBCi (i=0-3)**.TBSA.

40.3.2.5.5 Mixed Dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBCi.NDTB. The number of Tx Buffers assigned to the Tx FIFO is configured by **TXBCi (i=0-3)**.TFQSi. In case **TXBCi (i=0-3)**.TFQS is programmed to 0x0, only dedicated Tx Buffers are used.

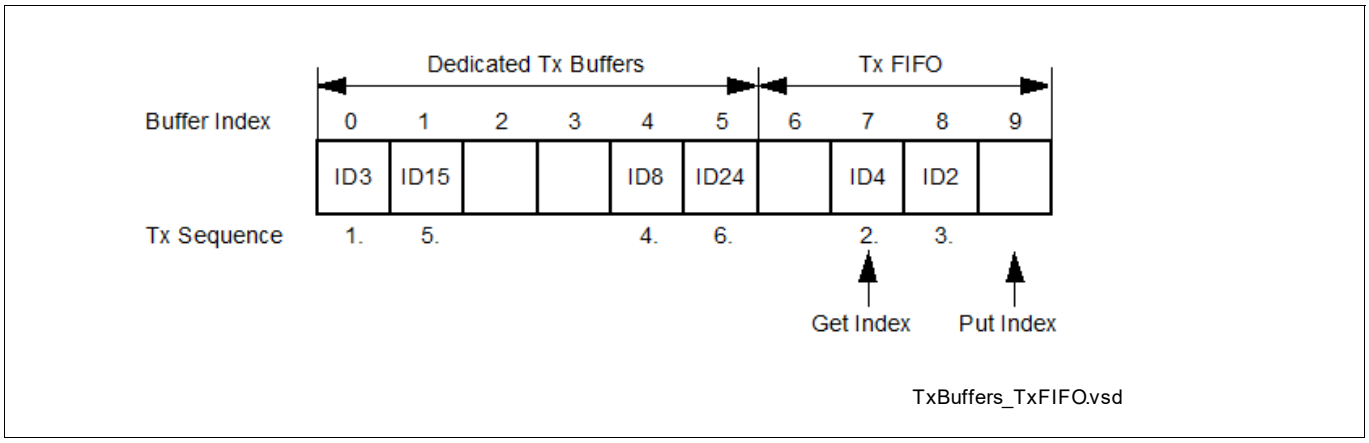

Figure 598 Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by **TXFQSi (i=0-3)**.TFGI)
- Buffer with lowest Message ID gets highest priority and is transmitted next

40.3.2.5.6 Mixed Dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by **TXBCi (i=0-3)**.NDTB. The number of Tx Queue Buffers is configured by **TXBCi (i=0-3)**.TFQSi. In case **TXBCi (i=0-3)**.TFQS is programmed to zero, only Dedicated Tx Buffers are used.

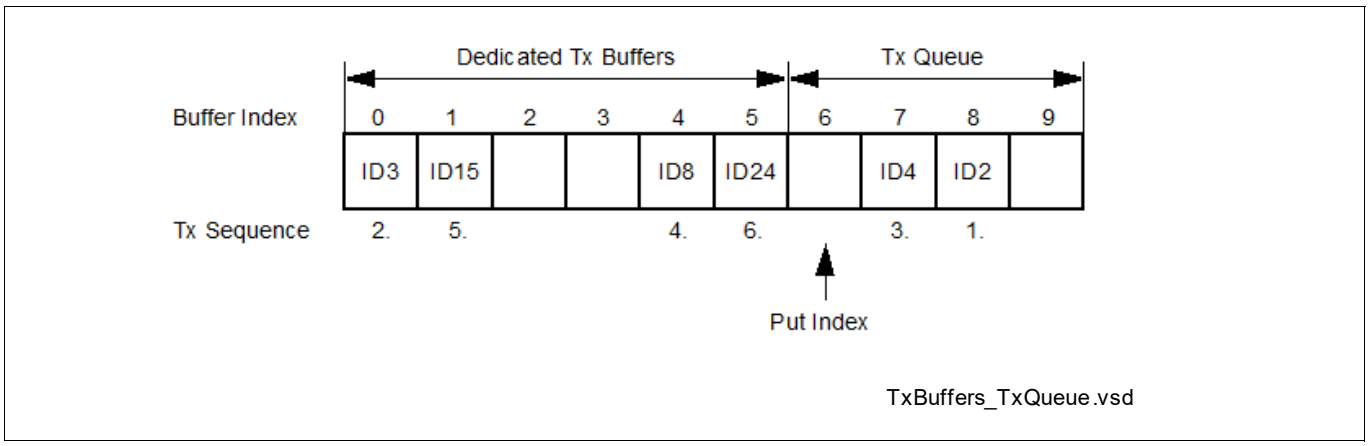

Figure 599 Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

40.3.2.5.7 Transmit Cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a Dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register **TXBCRi (i=0-3)**. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

40.3.2.5.8 Tx Event Handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in **Section 40.4.6.4**.

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by **IRi (i=0-3)**.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag **IRi (i=0-3)**.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by **TXEFCi (i=0-3)**.EFWM, interrupt flag IRi.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index **TXEFSi (i=0-3)**.EFGI has to be added to the Tx Event FIFO start address **TXEFCi (i=0-3)**.EFSA.

40.3.2.6 FIFO Acknowledge Handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see **Rx FIFO 0 Acknowledge i**, **Rx FIFO 1 Acknowledge i**, and **Tx Event FIFO Acknowledge i**). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.

When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

40.3.2.7 OCDS Suspend Behaviour Support

In case of Hard Suspend, the clock is switched off to the MCMCAN module, and any ongoing transmission or reception event will be suspended immediately.

In case of Soft Suspend, the clock is switched off to the MCMCAN module after completion of ongoing transmission and reception events. The CCCR.INIT bit will be set during the Soft Suspend. Hence, when leaving the Soft Suspend, the debugger has to ensure clearing of the CCCR.INIT bit, inorder to continue normal CAN operation.

40.3.3 TTCAN Operation

40.3.3.1 Reference Message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the Time Master (sender of the reference message).

For Level 1 the data length must be at least one; for Level 0,2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to 8 potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference message is configured via register TTRMC.

The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted Master_Ref_Mark is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (Next_is_Gap bit) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters.

The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

40.3.3.1.1 Level 1

Level 1 operation is configured via TTOCF0.OM = “01” and TTOCF0.GEN. External clock synchronization is not available in Level 1.

The information related to the reference message is stored in the first data byte as shown in **Table 371** below. Cycle_Count is optional.

Table 371 First byte of Level 1 reference message

Bits	7	6	5	4	3	2	1	0
First Byte	Next_is_Gap	0	Cycle_Count[5:0]					

40.3.3.1.2 Level 2

Level 2 operation is configured via TTOCF0.OM = “10” and TTOCF0.GEN.

The information related to the reference message is stored in the first four data bytes as shown in **Table 372** below. Cycle_Count and the lower four bits of NTU_Res are optional. The M_CAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Table 372 First four bytes of Level 2 reference message

Bits	7	6	5	4	3	2	1	0
First Byte	Next_is_Gap	0	Cycle_Count[5:0]					
Second Byte	NTU_Res[6:4]			NTU_Res[3:0]				Disc_Bit
Third Byte	Master_Ref_Mark[7:0]							
Fourth Byte	Master_Ref_Mark[15:8]							

40.3.3.1.3 Level 0

Level 0 operation is configured via TTOCF0.OM = “11”. External event-synchronized time-triggered operation is not available in Level 0.

The information related to the reference message is stored in the first four data bytes as shown in **Table 372** below. In Level 0 Next_is_Gap is always zero. Cycle_Count and the lower four bits of NTU_Res are optional. The M_CAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Table 373 First four bytes of Level 0 reference message

Bits	7	6	5	4	3	2	1	0
First Byte	Next_is_Gap	0	Cycle_Count[5:0]					
Second Byte	NTU_Res[6:4]			NTU_Res[3:0]				Disc_Bit
Third Byte	Master_Ref_Mark[7:0]							
Fourth Byte	Master_Ref_Mark[15:8]							

40.3.3.2 TTCAN Configuration

40.3.3.2.1 TTCAN Timing

The Network Time Unit NTU is the unit in which all times are measured. The NTU is a constant of the whole network and is defined a priori by the network system designer. In TTCAN Level 1 the NTU is the nominal CAN bit time. In TTCAN Level 0 and Level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable.

In TTCAN Level 0 and Level 2 the length of the NTU is defined by the Time Unit Ratio TUR. The TUR is in principle a non-integer number and given by the formula TUR = TURNA0.NAV/TURCF0.DC. The length of the NTU is given by the formula NTU = CAN Clock Period • TUR.

The TUR Numerator Configuration NC is an 18-bit number, TURCF0.NCL[15:0] can be programmed in the range 0x0000-0xFFFF. TURCF0.NCH[17:16] is hard wired to 0b01. When the number 0xnnnn is written to TURCF0.NCL[15:0], TURNA0.NAV starts with the value 0x10000 + 0x0nnnn = 0x1nnnn. The TUR Denominator Configuration TURCF0.DC is a 14-bit number. TURCF0.DC may be programmed in the range 0x0001 - 0x3FFF, 0x0000 is an illegal value.

In Level 1, NC must be ≥ 4 • TURCF0. DC. In Level 0,2 NC must be ≥ 8 • TURCF0.DC to allow the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets TURCF0.DC to 0x1000 and TURCF0.NCL to 0x10000, resulting in an NTU consisting of 16 CAN clock periods. Local time and application watchdog are not started before either the CCCRi.INIT is reset, or TURCF0.ELT is set. TURCF0.ELT may not be set before the NTU is configured. Setting TURCF0.ELT to ‘1’ also locks the write access to register TURCF0.

At startup TURNA0.NAV is updated from NC (= TURCF0.NCL + 0x10000) when TURCF0.ELT is set. In TTCAN Level 1 there is no drift compensation. TURNA0.NAV does not change during operation, it always equals NC.

In TTCAN Level 0 and Level 2 there are two possibilities for TURNA0.NAV to change. When operating as time slave or backup time master, and when TTOCF0.ECC is set, TURNA0.NAV is updated automatically to the value calculated from the monitored global time speed, as long as the M_CAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization it returns to NC. When operating as the actual time master, and when TTOCF0.EECS is set, the Host may update TURCF0.NCL. When the Host sets TTOCN0.ECS, TURNA0.NAV will be updated from the new value of NC at the next reference message. The status flag TTOST0.WECS as is set when TTOCN0.ECS is set and is cleared when TURNA0.NAV is updated. TURCF0.NCL is write locked while TTOST0.WECS is set.

In TTCAN Level 0 and Level 2 the clock calibration process adapts TURNA0.NAV in the range of the Synchronization Deviation Limit SDL of NC ± $2^{(TTOCF0.LDSDL+5)}$. TURCF0.NCL should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of TURNA0.NAV.

The synchronization deviation SD is the difference between NC and TURNA0.NAV (SD = |NC - TURNA0.NAV|). It is limited by the Synchronization Deviation Limit SDL, which is configured by its dual logarithm TTOCF0.LDSDL (SDL = $2^{(TTOCF0.LDSDL+5)}$) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new Basic Cycle. When the calculated TURNA0.NAV deviates by more than SDL from NC, or if the Disc_Bit in the reference message is set, the drift compensation is suspended and TTIR0.GTE is set and TTOSC.QCS is reset, or in case of the Disc_Bit = ‘1’, TTIR0.GTD is set.

TUR configuration examples are shown in **Table 374** below.

Table 374 TUR Configuration Examples

TUR	8	10	24	50	510	125000	32.5	100/12	529/17
NC	0x1FFF8	0x1FFFE	0x1FFF8	0x1FFEA	0x1FFFE	0x1E848	0x1FFE0	0x19000	0x10880
TURCF0.DC	0x3FFF	0x3333	0x1555	0x0A3D	0x0101	0x0001	0x0FC0	0x3000	0x0880

TTOCN0.ECS schedules NC for activation by the next reference message. TTOCN0.SGT schedules TTGTP0.TP for activation by the next reference message. Setting of TTOCN0.ECS and TTOCN0.SGT requires TTOCF0.EECS to be set (external clock synchronization enabled) while the M_CAN is actual time master.

The M_CAN module provides an application watchdog to verify the function of the application program. The Host has to serve this watchdog regularly, else all CAN bus activity is stopped. The Application Watchdog Limit TTOCF0.AWL specifies the number of NTUs between two times the watchdog has to be served. The maximum number of NTUs is 256. The Application Watchdog is served by reading register TTOST0. TTOST0.AWE indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag TTIR0.AW is set. For software development, the application watchdog may be disabled by programming TTOCF0.AWL to 0x00 (see also **Chapter 40.3.2.1.10**).

40.3.3.2.2 Message Scheduling

TTOCF0.TM controls whether the M_CAN operates as a potential time master or as a time slave. If it is a potential time master, the three LSBs of the reference message's identifier TTRMC.RID define the master priority, 0 giving the highest and 7 giving the lowest priority. There may not be two nodes in the network using the same master priority. TTRMC.RID is used for recognition of reference messages. TTRMC.RMPS is not relevant for time slaves.

The Initial Reference Trigger Offset TTOCF0.IRTO is a 7-bit-value that defines (in NTUs) how long a backup time master waits before it starts the transmission of a reference message when a reference message is expected but the bus remains idle. The recommended value for TTOCF0.IRTO is the master priority multiplied with a factor depending on the expected clock drift between the potential time masters in the network. The sequential order of the backup time masters, when one of them starts the reference message in case the current time master fails, should correspond to their master priority, even with maximum clock drift.

TTOCF0.OM decides whether the node operates in TTCAN Level 0, Level 1, or Level 2. In one network, all potential time masters have to operate on the same level. Time slaves may operate on Level 1 in a Level 2 network, but not vice versa. The configuration of the TTCAN operation mode via TTOCF0.OM is the last step in the setup. With TTOCF0.OM = "00" (event-driven CAN communication), the M_CAN operates according to ISO 11898-1, without time triggers. With TTOCF0.OM = "01" (Level 1), the M_CAN operates according to ISO 11898-4, but without the possibility to synchronize the basic cycles to external events, the Next_is_Gap bit in the reference message is ignored. With TTOCF0.OM = "10" (Level 2), the M_CAN operates according to ISO 11898-4, including the event-synchronized start of a basic cycle. With TTOCF0.OM = "11" (Level 0), the M_CAN operates as event-driven CAN but maintains a calibrated global time base as in Level 2.

TTOCF0.EECS enables the external clock synchronisation, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in Level 0,2 only) the global clock phase to an external reference.

TTMLM.ENTT in the TT Matrix Limits register specifies the number of expected Tx_Triggers in the system matrix. This is the sum of Tx_Triggers for exclusive, single arbitrating and merged arbitrating windows, excluding the Tx_Ref_Triggers. Note that this is usually not the number of Tx_Trigger memory elements; the number of basic cycles in the system matrix and the trigger's repeat factors have to be taken into account. An inaccurate configuration of TTMLM.ENTT will result in either a Tx Count Underflow (TTIR0.TXU = '1' and TTOST0.EL = "01", severity 1) or in a Tx Count Overflow (TTIR0.TXO = '1' and TTOST0.EL = "10", severity 2).

Note: In case the first reference message seen by a node does not have Cycle_Count zero, this node may finish its first matrix cycle with its Tx count resulting in a Tx Count Underflow condition. As long as a node is in state Synchronizing its Tx_Triggers will not lead to transmissions.

TTMLM.CCM specifies the number of the last basic cycle in the system matrix. The counting of basic cycles starts at 0. In a system matrix consisting of 8 basic cycles TTMLM.CCM would be 7. TTMLM.CCM is ignored by time slaves, a receiver of a reference message considers the received cycle count as the valid cycle count for the actual basic cycle.

TTMLM.TXEW specifies the length of the Tx enable window in NTUs. The Tx enable window is that period of time at the beginning of a time window where a transmission may be started. If the sample point of the first bit of a transmit message is not inside the Tx enable window because of e.g. a slight overlap from the previous time window's message, the transmission cannot be started in that time window at all. TTMLM.TXEW has to be chosen with respect to the network's synchronisation quality and with respect to the relation between the length of the time windows and the length of the messages.

40.3.3.2.3 Trigger Memory

The trigger memory is part of the external Message RAM to which the M_CAN is connected via its Generic Master Interface (see **Figure 605**). It stores up to 64 trigger elements. A trigger memory element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, Filter Type FTYPE, Message Number MNR, Message Status Count MSC, Time Mark Event Internal TMIN andTime Mark Event External TMEX.

The time mark defines at which cycle time a trigger becomes active. The triggers in the trigger memory have to be sorted by their time marks. The trigger element with the lowest time mark is written to the first trigger memory word. Message number and cycle code are ignored for triggers of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, and End_of_List.

When the cycle time reaches the time mark of the actual trigger, the TTCAN node switches to the next trigger and starts to read the following trigger from the trigger memory. In case of a transmit trigger, the Tx Handler starts to read the message from the Message RAM as soon as the TTCAN node switches to its trigger. The RAM access speed defines the minimum time step between a transmit trigger and its preceding trigger, the Tx Handler has to be able to prepare the transmission before the transmit trigger's time mark is reached. The RAM access speed also limits the number of non-matching (with regard to their cycle code) triggers between two matching triggers, the next matching trigger must be read before its time mark is reached. If the reference message is n NTU long, a trigger with a time mark< n will never become active and will be treated as a configuration error.

Starting point of the cycle time is the sample point of the reference message's start of frame bit. The next reference message is requested when cycle time reaches the Tx_Ref_Trigger's time mark. The M_CAN reacts on the transmission request at the next sample point. A new Sync_Mark is captured at the start of frame bit, but the cycle time is incremented until the reference message is successfully transmitted (or received) and the Sync_Mark is taken as the new Ref_Mark. At that point in time, cycle time is restarted. As a consequence, cycle time can never (with the exception of initialisation) be seen at a value< n, with n being the length of the reference message measured in NTU.

Length of a basic cycle: Tx_Ref_Trigger's time mark+1 NTU+1 CAN bit time

The trigger list will be different for all nodes in the TTCAN network. Each node knows only the Tx_Triggers for its own transmit messages, the Rx_Triggers for those receive messages that are processed by this node, and the triggers concerning the reference messages.

Trigger Types

Tx_Ref_Trigger (TYPE = "0000") and Tx_Ref_Trigger_Gap (TYPE = "0001") cause the transmission of a reference message by a time master. A configuration error (TTOST0.EL = "11", severity 3) is detected when a time slave encounters a Tx_Ref_Trigger(_Gap) in its trigger memory. Tx_Ref_Trigger_Gap is only used in external event-synchronised time-triggered operation mode. In that mode, Tx_Ref_Trigger is ignored when the M_CAN synchronisation state is In_Gap (TTOST0.SYS = "10").

Tx_Trigger_Single (TYPE = "0010"), Tx_Trigger_Continous (TYPE = "0011"), Tx_Trigger_Arbitration (TYPE = "0100"), and Tx_Trigger_Merged (TYPE = "0101") cause the start of a transmission. They define the start of a time window.

Tx_Trigger_Single starts a single transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit is reset.

Tx_Trigger_Continous starts a transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit remains set, and the message buffer is transmitted again in the next matching time window.

Tx_Trigger_Arbitration starts an arbitrating time window, Tx_Trigger_Merged a merged arbitrating time window. The last Tx_Trigger of a merged arbitrating time window must be of type Tx_Trigger_Arbitration. A Configuration Error (TTOST0.EL = "11", severity 3) is detected when a trigger of type Tx_Trigger_Merged is followed by any other

Tx_Trigger than one of type Tx_Trigger_Merged or Tx_Trigger_Arbitration. Several Tx_Triggers may be defined for the same Tx message buffer. Depending on their cycle code, they may be ignored in some basic cycles. The cycle code has to be considered when the expected number of Tx_Triggers (TTMLM.ENTT) is calculated.

Watch_Trigger (TYPE = “0110”) and Watch_Trigger_Gap (TYPE = “0111”) check for missing reference messages. They are used by both time masters and time slaves. Watch_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, a Watch_Trigger is ignored when the M_CAN synchronisation state is In_Gap (TTOST0.SYS = “10”).

Rx_Trigger (TYPE = “1000”) is used to check for the reception of periodic messages in exclusive time windows. Rx_Triggers are not active until state In_Schedule or In_Gap is reached. The time mark of an Rx_Trigger shall be placed after the end of that message’s transmission, independent of time window boundaries. Depending on their cycle code, Rx_Triggers may be ignored in some basic cycles. At the time mark of the Rx_Trigger, it is checked whether the last received message before this time mark and after start of cycle or previous Rx_Trigger had matched the acceptance filter element referenced by MNR. Accepted messages are stored in one of the two receive FIFOs, according to the acceptance filtering, independent of the Rx_Trigger. Acceptance filter elements which are referenced by Rx_Triggers should be placed at the beginning of the filter list to ensure that the filtering is finished before the Rx_Trigger’s time mark is reached.

Time_Base_Trigger (TYPE = “1001”) are used to generate internal/external events depending on the configuration of ASC, TMIN, and TMEX.

End_of_List (TYPE = “1010…1111”) is an illegal trigger type, a configuration error (TTOST0.EL = “11”, severity 3) is detected when an End_of_List trigger is encountered in the trigger memory before the Watch_Trigger or Watch_Trigger_Gap.

Restrictions for the Node’s Trigger List

There may not be two triggers that are active at the same cycle time and cycle count, but triggers that are active in different basic cycles (different cycle code) may share the same time mark.

Rx_Triggers and Time_Base_Triggers may not be placed inside the Tx enable windows of Tx_Trigger_Single/Continuous/Arbitration, but they may be placed after Tx_Trigger_Merged.

Triggers that are placed after the Watch_Trigger (or the Watch_Trigger_Gap when TTOST0.SYS = “10”) will never become active. The watch triggers themselves will not become active when the reference messages are transmitted on time.

All unused trigger memory words (after the Watch_Trigger or after the Watch_Trigger_Gap when TTOST0.SYS = “10”) must be set to trigger type End_of_List.

A typical trigger list for a potential time master will begin with a number of Tx_Triggers and Rx_Triggers followed by the Tx_Ref_Trigger and the Watch_Trigger. For networks with external event- synchronized time-triggered communication, this is followed by the Tx_Ref_Trigger_Gap and the Watch_Trigger_Gap. The trigger list for a time slave will be the same but without the Tx_Ref_Trigger and the Tx_Ref_Trigger_Gap.

At the beginning of each basic cycle, that is at each reception or transmission of a reference message, the trigger list is processed starting with the first trigger memory element. The FSE looks for the first trigger with a cycle code that matches the current cycle count. The FSE waits until cycle time reaches the trigger’s time mark and activates the trigger. Afterwards the FSE looks for the next trigger in the list with a cycle code that matches the current cycle count.

Special consideration is needed for the time around Tx_Ref_Trigger and Tx_Ref_Trigger_Gap. In a time master competing for master ship, the effective time mark of a Tx_Ref_Trigger may be decremented in order to be the first node to start a reference message. In backup time masters the effective time mark of a Tx_Ref_Trigger or Tx_Ref_Trigger_Gap is the sum of its configured time mark and the Reference Trigger Offset TTOCF0.IRTO. In case error level 2 is reached (TTOST0.EL = “10”), the effective time mark is the sum of its time mark and 0x127. No other trigger elements should be placed in this range otherwise it may happen, that the time marks appear out of order

and are flagged as a configuration error. Trigger elements which are coming after Tx_Ref_Trigger may never become active as long as the reference messages come in time.

There are interdependencies between the following parameters:

- Host clock frequency
- Speed and waiting time for Trigger RAM accesses
- Length of the acceptance filter list
- Number of trigger elements
- Complexity of cycle code filtering in the trigger elements
- Offset between time marks of the trigger elements

Example for Trigger Handling

The example below shows how the trigger list is derived from a node's system matrix. Assumed node A is first time master and has knowledge of the section of the system matrix shown in **Table 375** below.

Table 375 System Matrix Node A

Cycle Count	Time Mark1	Time Mark2	Time Mark3	Time Mark4	Time Mark5	Time Mark6	Time Mark7
0	Tx7					TxRef	Error
1	Rx3		Tx2, Tx4			TxRef	Error
2						TxRef	Error
3	Tx7		Rx5			TxRef	Error
4	Tx7			Rx6		TxRef	Error

The cycle count starts with 0 and runs until 0, 1, 3, 7, 15, 31, 63 (the number of basic cycles in the system matrix is 1, 2, 4, 8, 16, 32, 64). The maximum cycle count is configured by TTMLM.CCM. The Cycle Code CC is composed of repeat factor (= value of most significant '1') and the number of the first basic cycle in the system matrix (= bit field after most significant '1').

Example:with a cycle code of 0b0010011 (repeat factor: 16, first basic cycle: 3) and a maximum cycle count of TTMLM.CCM = "0x3F"matches occur at cycle counts 3, 19, 35, 51

A trigger element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, and Message Number MNR. For transmission MNR references the Tx Buffer number (0…31). For reception MNR references the number of the filter element (0…127) that matched during acceptance filtering. Depending on the configuration of the Filter Type FTYPE, the 11-bit or 29-bit message ID filter list is referenced.

In addition a trigger element can be configured for Asynchronous Serial Communication ASC, generation of Time Mark Event Internal TMIN, and Time Mark Event External TMEX. The Message Status Count MSC holds the counter value (0…7) for scheduling errors for periodic messages in exclusive time windows at the point in time when the time mark of the trigger element became active.

Table 376 Trigger List Node A

Trigger	Time Mark TM[15:0]	Cycle Code CC[6:0]	Trigger Type TYPE[3:0]	Mess. No. MNR[6:0]
0	Mark1	0b0000100	Tx_Trigger_Single	7
1	Mark1	0b1000000	Rx_Trigger	3
2	Mark1	0b1000011	Tx_Trigger_Single	7
3	Mark3	0b1000001	Tx_Trigger_Merged	2

Table 376 Trigger List Node A (cont'd)

Trigger	Time Mark TM[15:0]	Cycle Code CC[6:0]	Trigger Type TYPE[3:0]	Mess. No. MNR[6:0]
4	Mark3	0b1000011	Rx_Trigger	5
5	Mark4	0b1000001	Tx_Trigger_Arbitration	4
6	Mark4	0b1000100	Rx_Trigger	6
7	Mark6	n.a.	Tx_Ref_Trigger	0 (Ref)
8	Mark7	n.a.	Watch_Trigger	n.a.
9	n.a.	n.a.	End_of_List	n.a.

Tx_Trigger_Single, Tx_Trigger_Continous, Tx_Trigger_Merged, Tx_Trigger_Arbitration, Rx_Trigger, and Time_Base_Trigger are only valid for the specified cycle code. For all other trigger types the cycle code is ignored.

The FSE starts the basic cycle with scanning the trigger list starting from zero until a trigger with time mark > cycle time and with its Cycle Code CC matching the actual cycle count is reached, or a trigger of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, or Watch_Trigger_Gap is encountered.

When the cycle time reached the Time Mark TM, the action defined by Trigger Type TYPE and Message Number MNR is started. There is an error in the configuration when End_of_List is reached.

At Mark6 the reference message (always TxRef) is transmitted. After transmission of the reference message the FSE returns to the beginning of the trigger list. When the Watch Trigger at Mark7 is reached, the node was not able to transmit the reference message; error treatment is started.

Detection of Configuration Errors

A configuration error is signalled via TTOST0.EL = "11" (severity 3) when:

The FSE comes to a trigger in the list with a cycle code that matches the current cycle count but with a time mark that is less than the cycle time.

The previous active trigger was a Tx_Trigger_Merged and the FSE comes to a trigger in the list with a cycle code that matches the current cycle count but that is neither a Tx_Trigger_Merged nor a Tx_Trigger_Arbitration nor a Time_Base_Trigger nor an Rx_Trigger.

The FSE of a node with TTOCF0.TM='0' (time slave) encounters a Tx_Ref_Trigger or a Tx_Ref_Trigger_Gap.

Any time mark placed inside the Tx enable window (defined by TTMLM.TXEW) of a Tx_Trigger with a matching cycle code.

A time mark is placed near the time mark of a Tx_Ref_Trigger and the Reference Trigger Offset TTOST0.RTO causes a reversal of their sequential order measured in cycle time.

40.3.3.2.4 TTCAN Schedule Initialization

The synchronisation to the M_CAN's message schedule starts when CCCRi.INIT is reset. The M_CAN can operate strictly time-triggered (TTOCF0.GEN = '0') or external event-synchronized time-triggered (TTOCF0.GEN = '1'). All nodes start with cycle time zero at the beginning of their trigger list with TTOST0.SYS = "00" (out of synchronisation), no transmission is enabled with the exception of the reference message. Nodes in external event-synchronised time-triggered operation mode will ignore Tx_Ref_Trigger and Watch_Trigger and will use instead Tx_Ref_Trigger_Gap and Watch_Trigger_Gap until the first reference message decides whether a Gap is active.

Time Slaves

After configuration, a time slave will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message before reaching the Watch_Triggers. When it reaches Init_Watch_Trigger, interrupt flag TTIR0.IWT is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). The first received reference message will restart the FSE and the cycle time.

Note: Init_Watch_Trigger is not part of the trigger list. It is implemented as an internal counter which counts up to 0xFFFF = maximum cycle time.

When a time slave has received any message but the reference message before reaching the Watch_Triggers, it will assume a severe error (TTOST0.EL = “11”, severity 3), set interrupt flag TTIR0.WT, switch off its CAN bus output, and enter the bus monitoring mode (CCCRi.MON set to ‘1’). In the bus monitoring mode it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

Note: To leave the severe error state, the Host has to set CCCRi.INIT = ‘1’. After reset of CCCRi.INIT, the node restarts TTCAN communication.

When no error is encountered during synchronisation, the first reference message sets TTOST0.SYS = “01” (Synchronizing), the second sets the TTCAN synchronization state (depending on its Next_is_Gap bit) to TTOST0.SYS = “11” (In_Schedule) or TTOST0.SYS = “10” (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

Potential Time Masters

After configuration, a potential time master will start the transmission of a reference message when it reaches its Tx_Ref_Trigger (or its Tx_Ref_Trigger_Gap when in external event-synchronized time-triggered operation). It will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message or transmit the reference message successfully before reaching the Watch_Triggers (assumed reason: all other nodes still in reset or configuration, giving no acknowledge). When it reaches Init_Watch_Trigger, the attempted transmission is aborted, interrupt flag TTIR0.IWT is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). Resetting TTIR0.IWT will re-enable the transmission of reference messages until next time the Init_Watch_Trigger condition is met, or another CAN message is received. The FSE will be restarted by the reception of a reference message.

When a potential time master reaches the Watch_Triggers after it has received any message but the reference message, it will assume a severe error (TTOST0.EL = “11”, severity 3), set interrupt flag TTIR0.WT, switch off its CAN bus output, and enter the bus monitoring mode (CCCRi.MON set to ‘1’). In bus monitoring mode, it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

When no error is detected during initialization, the first reference message sets TTOST0.SYS = “01” (synchronizing), the second sets the TTCAN synchronization state (depending on its Next_is_Gap bit) to TTOST0.SYS = “11” (In_Schedule) or TTOST0.SYS = “10” (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

A potential time master is current time master (TTOST0.MS = “11”) when it was the transmitter of the last reference message, else it is backup time master (TTOST0.MS = “10”).

When all potential time masters have finished configuration, the node with the highest time master priority in the network will become the current time master.

40.3.3.3 TTCAN Gap Control

All functions related to Gap control apply only when the M_CAN is operated in external event- synchronized time-triggered mode (TTOCF0.GEN = ‘1’). In this operation mode the TTCAN message schedule may be interrupted by inserting Gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a Gap, all transmissions are stopped and the CAN bus remains idle. A Gap is finished when the next reference message starts a new basic cycle. A Gap starts at the end of a basic cycle that itself was started by a reference message with bit Next_is_Gap = ‘1’ e.g. Gaps are initiated by the current time master.

The current time master has two options to initiate a Gap. A Gap can be initiated under software control when the application program writes TTOCN0.NIG = ‘1’. The Next_is_Gap bit will be transmitted as ‘1’ with the next reference message. A Gap can also be initiated under hardware control when the application program enables the event trigger input by writing TTOCN0.GCS = ‘1’. When a reference message is started and TTOCN0.GCS is set, a HIGH level at the event trigger will set Next_is_Gap = ‘1’.

As soon as that reference message is completed, the TTOST0.WFE bit will announce the Gap to the time master as well as to the time slaves. The current basic cycle will continue until its last time window. The time after the last time window is the Gap time.

For the actual time master and the potential time masters, TTOST0.GSI will be set when the last basic cycle has finished and the Gap time starts. In nodes that are time slaves, bit TTOST0.GSI will remain at ‘0’.

When a potential time master is in synchronization state In_Gap (TTOST0.SYS = “10”), it has four options to intentionally finish a Gap:

Under software control by writing TTOCN0.FGP = ‘1’.

Under hardware control (TTOCN0.GCS = ‘1’) an edge from HIGH to LOW at the event-trigger sets TTOCN0.FGP and restarts the schedule.

The third option is a time-triggered restart. When TTOCN0.TMG = ‘1’, the next register time mark interrupt (TTIR0.RTMI = ‘1’) will set TTOCN0.FGP and start the reference message.

Finally any potential time master will finish a Gap when it reaches its Tx_Ref_Trigger_Gap, assuming that the event to synchronize on did not occur in time.

Neither of these options can cause a basic cycle to be interrupted with a reference message.

Setting of TTOCN0.FGP after the Gap time has started will start the transmission of a reference message immediately and will thereby synchronize the message schedule. When TTOCN0.FGP is set before the Gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger – there will be no Gap time in the message schedule.

In strictly time-triggered operation, bit Next_is_Gap = ‘1’ in the reference message will be ignored, as well as the event-trigger and the bits TTOCN0.NIG, TTOCN0.FGP, and TTOCN0.TMG.

40.3.3.4 Stop Watch

The stop watch function enables capturing of M_CAN internal time values (local time, cycle time, or global time) triggered by an external event.

To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via TTOCN0.SWS. When TTOCN0.SWS is ≠ “00” and TT Interrupt Register flag TTIR0.SWE is ‘0’, the actual value of the time selected by TTOCN0.SWS will be copied into TTCPT.SWV on the next rising/falling edge (as configured via TTOCN0.SWP) on stop watch trigger. This will set interrupt flag TTIR0.SWE. After the application program has read TTCPT.SWV, it may enable the next stop watch event by resetting TTIR0.SWE to ‘0’.

40.3.3.5 Local Time, Cycle Time, Global Time, and External Clock Synchronization

There are two possible levels in time-triggered CAN: Level 1 and Level 2. Level 1 only provides time-triggered operation using cycle time. Level 2 additionally provides increased synchronisation quality, global time and external clock synchronisation. In both levels, all timing features are based on a local time base - the local time.

The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented 8 times each NTU. If the length of the NTU is shorter than 8 CAN clock periods (as may be configured in Level 1, or as a result of clock calibration in Level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only 4 times each NTU.

Figure 600 describes the synchronisation of the cycle time and global time, performed in the same manner by all TTCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message's frame synchronisation event. This frame synchronisation event occurs at the sample point of each Start of Frame (SoF) bit and causes the local time to be stored as Sync_Mark. Sync_Marks and Ref_Marks are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the Cycle Sync Mark (Cycle Sync Mark = Sync_Mark - Ref_Mark) stored in register TTCSM. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (Cycle Time = Local Time - Ref_Mark).

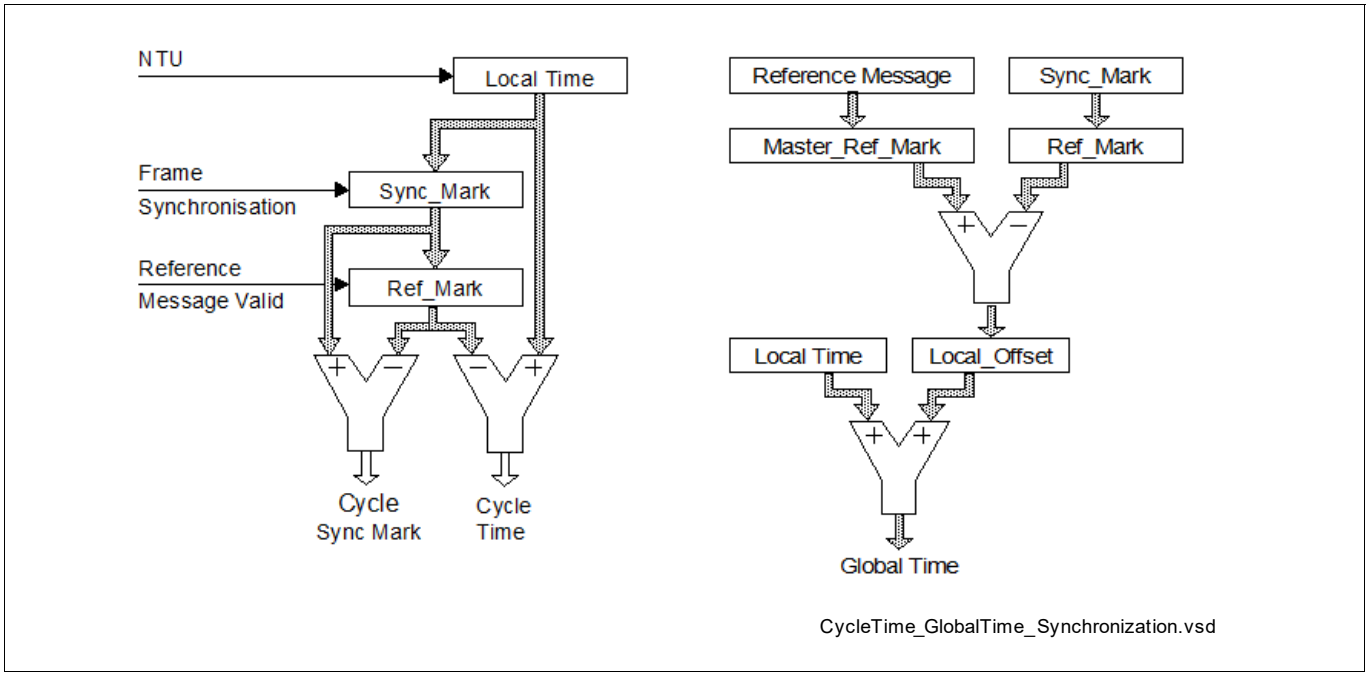

Figure 600 Cycle Time and Global Time Synchronization

The cycle time that can be read from TTCTC0.CT is the difference of the node's local time and Ref_Mark, both synchronized into the Host clock domain and truncated to 16 bits.

The global time exists for TTCAN Level 0 and Level 2 only, in Level 1 it is invalid. The node's view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master will use its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3, 4). The global time that can be read from TTLGT0.GT is the sum of the node's local time and its local offset, both synchronized into the Host clock domain and truncated to 16 bits. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark (see **Figure 600**). The node's view of the global time is local time + local offset. In a potential time master that has never received another time master's reference message, Local_Offset will be zero. When a node becomes the current time master after first having received other reference messages, Local_Offset will be frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signalled by Disc_Bit in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register TTLGT is smoothed by a low-pass filtering to have a continuous monotonic value.

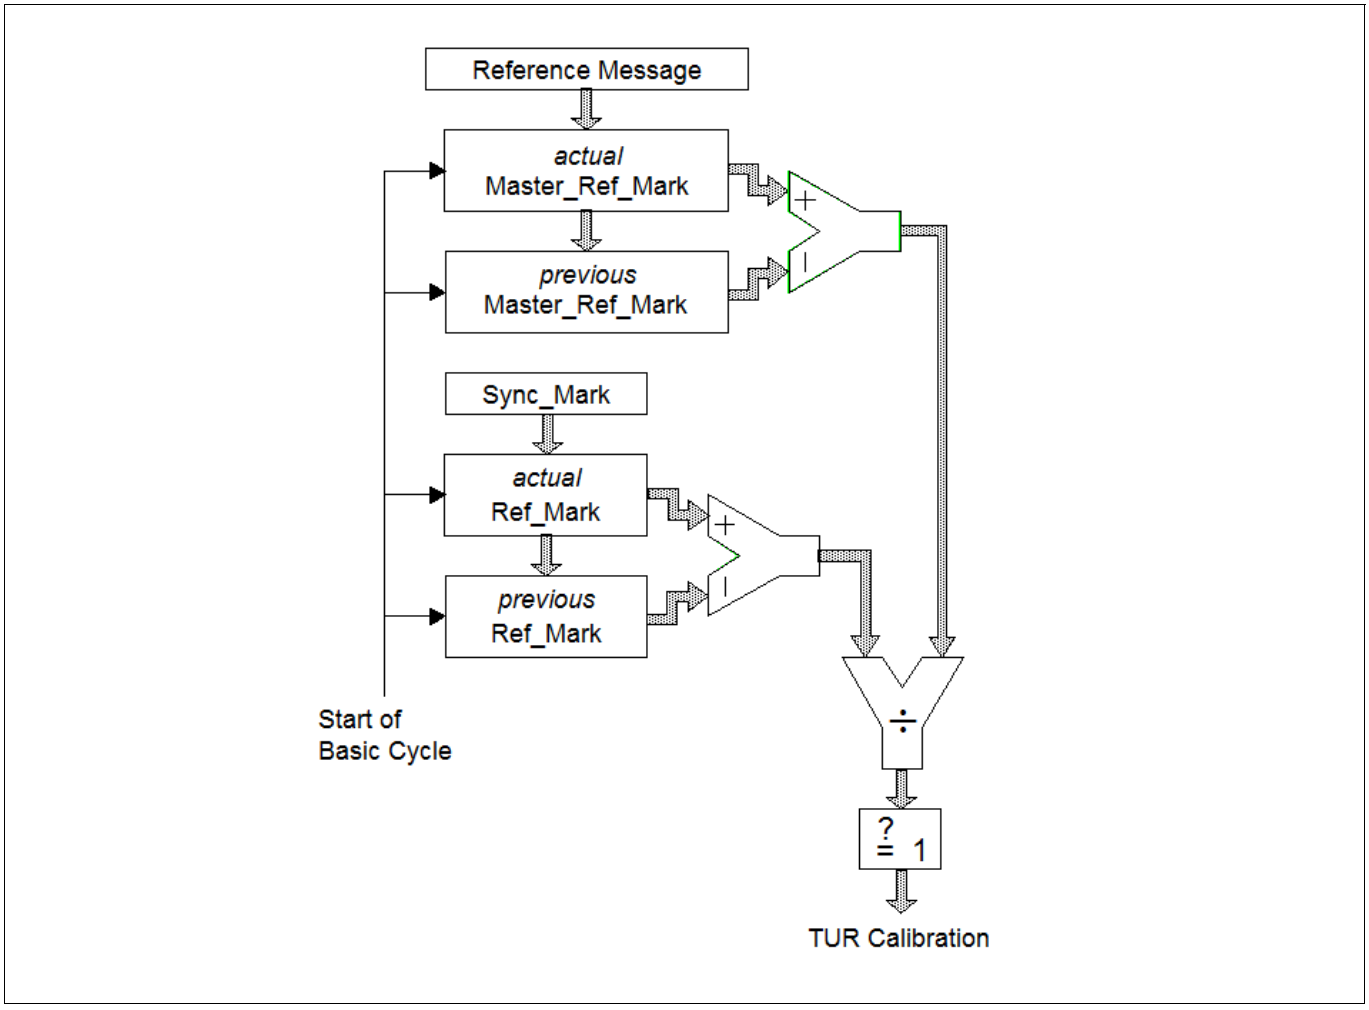

Figure 601 TTCAN Level 0 and Level 2 Drift Compensation

Figure 601 describes how in TTCAN Level 0,2 each time receiving node compensates the drift between its own local clock and the time master's clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the Disc_Bit in the reference message is not set, a new value for TURNA0.NAV is calculated. If the Synchronisation Deviation SD = |NC - TURNA0.NAV| ≤ SDL (Synchronisation Deviation Limit), the new value for TURNA0.NAV takes effect. Else the automatic drift compensation is suspended.

In TTCAN Level 0 and Level 2, TTOST0.QCS indicates whether the automatic drift compensation is active or suspended. In TTCAN Level 1, TTOST0.QCS is always '1'.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit TTOCF0.EECS.

The stop watch function (see **Section 40.3.3.4**) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated Numerator Configuration Low to TURCF0.NCL (TURCF0.DC cannot be updated during operation). The new value takes effect by writing TTOCN0.ECS to '1'.

The global time phase is adjusted by first writing the phase offset into the TT Global Time Preset register TTGTP0. The new value takes effect by writing TTOCN0.SGT to '1'. The first reference message transmitted after the global time phase adjustment will have the Disc_Bit set to '1'.

TTOST0.QGTP shows whether the node's global time is in phase with the time master's global time. TTOST0.QGTP is permanently '0' in TTCAN Level 1 and when the Synchronisation Deviation Limit is exceeded in TTCAN Level 0,2 (TTOST0.QCS = '0'). It is temporarily '0' while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a Disc_Bit = '1' or when TTOST0.QCS='0'.

40.3.3.6 TTCAN Error Level

The ISO 11898-4 specifies four levels of error severity:

S0 - No Error

S1 - Warning
Only notification of application, reaction application-specific.

S2 Error
Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (i.e. no data or remote frames may be started). Potential time masters still transmit reference messages with the Reference Trigger Offset TTOST0.RTO set to the maximum value of 127.

S3 - Severe Error
Notification of application. All CAN bus operations are stopped, i.e. transmission of dominant bits is not allowed, and CCCRi.MON is set. The S3 error condition remains active until the application updates the configuration (set CCCRi.CCE).

If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by TTIR0.ELC. The error level is monitored by TTOST0.EL.

The M_CAN signals the following error conditions as required by ISO 11898-4:

Config_Error (S3)

Sets Error Level TTOST0.EL to "11" when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.

Watch_Trigger_Reached (S3)

Sets Error Level TTOST0.EL to "11" when a watch trigger was reached because the reference message is missing.

Application_Watchdog (S3)

Sets Error Level TTOST0.EL to "11" when the application failed to serve the application watchdog. The application watchdog is configured via TTOCF0.AWL. It is served by reading register TTOST0. When the watchdog is not served in time, bit TTOST0.AWE and interrupt flag TTIR0.AW are set, all TTCAN communication is stopped, and the M_CAN is set into bus monitoring mode (CCCRi.MON set to '1').

CAN_Bus_Off (S3)

Entering CAN_Bus_Off state sets error level TTOST0.EL to "11". CAN_Bus_Off state is signalled by PSRi.BO = '1' and CCCRi.INIT = '1'.

Scheduling_Error_2 (S2)

Sets Error Level TTOST0.EL to “10” if the MSC of one Tx_Trigger has reached 7. In addition interrupt flag TTIR0.SE2 is set. The Error Level TTOST0.EL is reset to “00” at the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.

Tx_Overflow (S2)

Sets Error Level TTOST0.EL to “10” when the Tx count is equal or higher than the expected number of Tx_Triggers TTMLM.ENTT and a Tx_Trigger event occurs. In addition interrupt flag TTIR0.TXO is set. The Error Level TTOST0.EL is reset to “00” when the Tx count is no more than TTMLM.ENTT at the start of a new matrix cycle.

Scheduling_Error_1 (S1)

Sets Error Level TTOST0.EL to “01” if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than 2, or if one of the MSCs of an exclusive Rx_Trigger has reached 7. In addition interrupt flag TTIR0.SE1 is set. If within one matrix cycle none of these conditions is valid, the Error Level TTOST0.EL is reset to “00”.

Tx_Underflow (S1)

Sets Error Level TTOST0.EL to “01” when the Tx count is less than the expected number of Tx_Triggers TTMLM.ENTT at the start of a new matrix cycle. In addition interrupt flag TTIR0.TXU is set. The Error Level TTOST0.EL is reset to “00” when the Tx count is at least TTMLM.ENTT at the start of a new matrix cycle.

40.3.3.7 TTCAN Message Handling

40.3.3.7.1 Reference Message

For potential time masters the identifier of the reference message is configured via TTRMC.RID. No dedicated Tx Buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte (TTCAN Level 1) resp. the first four data bytes (TTCAN Level 0 and Level 2) will be provided by the FSE.

In case the reference message Payload Select TTRMC.RMPS is set, the rest of the reference message’s payload (Level 1: bytes 2-8, Level 0,2: bytes 5-6) is taken from Tx Buffer 0. In this case the data length DLC code from message buffer 0 is used.

Table 377 Number of Data Bytes transmitted with a reference messages

TTRMC.RMPS	TXBRPi.TRP0	Level 0	Level 1	Level 2
0	0	4	1	4
0	1	4	1	4
1	0	4	1	4
1	1	4 + MB0	1 + MB0	4 + MB0

To send additional payload with the reference message in Level 1 a DLC > 1 has to be configured, for Level 0,2 a DLC > 4 is required. In addition the transmission request pending bit TXBRPi.TRP0 of message buffer 0 must be set (see **Table 377**). In case bit TXBRPi.TRP0 is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the Reference Identifier TTRMC.RID is used.

40.3.3.7.2 Message Reception

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (see **Chapter 40.3.2.4**).

The Message Status Count MSC is part of the corresponding trigger memory element and has to be initialized to zero during configuration. It is updated while the M_CAN is in synchronization states In_Gap or In_Schedule. The update happens at the message's Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

40.3.3.7.3 Message Transmission

For time-triggered message transmission the M_CAN supplies 32 dedicated Tx buffers (see **Chapter 40.3.2.5.2**). A Tx FIFO or Tx queue is not available when the M_CAN is configured for time-triggered operation (TTOCF0.OM = “01” or “10”).

Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle.

The application program has to update the data regularly and on time, synchronized to the cycle time. The Host CPU is responsible that no partially updated messages are transmitted. To assure this the Host has to proceed in the following way:

Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration

- Check whether the previous transmission has completed by reading TXBTO
- Update the Tx buffer’s configuration and/or payload
- Issue an "Add Request" to set the Tx Buffer Request Pending bit

Tx_Trigger_Continous

- Issue a Cancellation Request to reset the Tx Buffer Request Pending bit
- Check whether the cancellation has finished by reading TXBCF
- Update Tx buffer’s configuration and/or payload
- Issue an "Add Request" to set the Tx Buffer Request Pending bit

The message’s MSC stored with the corresponding Tx_Trigger provides information on the success of the transmission.

The MSC is incremented by one when the transmission could not be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and could not be completed successfully. The MSC is decremented by one when the message was transmitted successfully or when the message could have been started within its transmit enable window but was not started because transmission was disabled (M_CAN in Error Level S2 or Host has disabled this particular message).

The Tx buffers may be managed dynamically, i.e. several messages with different identifiers may share the same Tx buffer element. In this case the Host has to assure that no transmission request is pending for the Tx buffer element to be reconfigured by checking TXBRPi.

If a Tx buffer with pending transmission request should be updated, the Host first has to issue a cancellation request and check whether the cancellation has completed by reading TXBCF before it starts updating.

The Tx Handler will transfer a message from the Message RAM to its intermediate output buffer at the trigger element which becomes active immediately before the Tx_Trigger element which defines the beginning of the transmit window. During and after the transfer time the transmit message may not be updated and its TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be e.g. a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger has to be large enough to guarantee that the Tx Handler can read four words from the Message RAM even at high RAM access load from other modules.

Transmission in Exclusive Time Windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continous. There is no arbitration on the bus with messages from other nodes. The MSC is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx Buffer Request Pending bit is reset. After successful transmission started by a Tx_Trigger_Continous the respective Tx Buffer Request Pending remains set. When the transmission was not successful due to disturbances, it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

Transmission in Arbitrating Time Windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The MSC is not updated. When the transmission was not successful (lost arbitration or disturbance), it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

Transmission in Merged Arbitrating Time Windows

The purpose of a merged arbitrating time window is to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a single node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission will not be started if the corresponding Transmission Request Pending flag was reset by a successful Tx cancellation.

In single transmit windows, the Tx Handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmissions will be attempted in the sequence defined by the trigger list. If the time mark of a fourth message is read before the first is transmitted (or cancelled by the Host), the fourth request will be ignored.

The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window will be started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if there is competing bus traffic. This has to be considered for the configuration of the trigger list. Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx Buffer needs to be updated.

40.3.3.8 TTCAN Interrupt and Error Handling

The TT Interrupt Register TTIR consists of four segments. Each interrupt can be enabled separately by the corresponding bit in the TT Interrupt Enable register TTIE. The flags remain set until the Host clears them. A flag is cleared by writing a “1” to the corresponding bit position.

The first segment consists of flags CER, AW, WT, and IWT. Each flag indicates a severe error condition where the CAN communication is stopped. With the exception of IWT, these error conditions require a re-configuration of the M_CAN module before the communication can be restarted.

The second segment consists of flags ELC, SE1, SE2, TXO, TXU, and GTE. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, e.g. by disturbances on the CAN bus, they will be handled by the TTCAN protocol’s failure handling and do not require intervention by the application program.

The third segment consists of flags GTD, GTW, SWE, TTMI, and RTMI. The first two flags are controlled by global time events (Level 0,2 only) that require a reaction by the application program. With a Stop Watch Event triggered by a rising/falling edge the internal time values are captured. The Trigger Time Mark Interrupt notifies the application that a specific Time_Base_Trigger is reached. The Register Time Mark Interrupt signals that the time referenced by TTOCN0.TMC (Cycle, Local, or Global) equals time mark TTTMK.TM. It can also be used to finish a Gap.

The fourth segment consists of flags SOG, CSM, SMC, and SBC. These flags provide a means to synchronize the application program to the communication schedule.

40.3.3.9 Level 0

TTCAN Level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in TTCAN Level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1.

Level 0 operation is configured via TTOCF0.OM = “11”. In this mode the M_CAN operates in event-driven CAN communication, there is no fixed schedule, the configuration of TTOCF0.GEN is ignored. External event-synchronized operation is not available in Level 0. A synchronized time base is maintained by transmission of reference messages.

In Level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (TTIR0.TTMI) is set when the cycle time has reached TTOCF0.IRTO * 0x200, it reminds the Host to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (TTIR0.WT) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks.

Register time mark interrupts (TTIR0.RTMI) are also possible.

The reference message is configured as for Level 2 operation. Received reference messages are recognized by the identifier configured in register TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the Host sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:

- TTRMC
- TTOCF except EVTP, AWL, GEN
- TTMLM except ENTT, TXEW
- TURCF

Level 0 operation is controlled via:

- TTOCN except NIG, TMG, FGP, GCS, TTMIE
- TTGTP
- TTTMK
- TTIR excluding bits CER, AW, IWT SE2, SE1, TXO, TXU, SOG (no function)
- TTIR the following bits have changed function
  - TTMI not defined by trigger memory - activated at cycle time TTOCF0.IRTO * 0x200
  - WT not defined by trigger memory - activated at cycle time 0xFF00

Level 0 operation is signalled via:

- TTOST excluding bits AWE, WFE, GSI, GFI, RTO (no function)

40.3.3.9.1 Synchronizing

Figure 602 below describes the states and state transitions in TTCAN Level 0 operation. Level 0 has no In_Gap state.

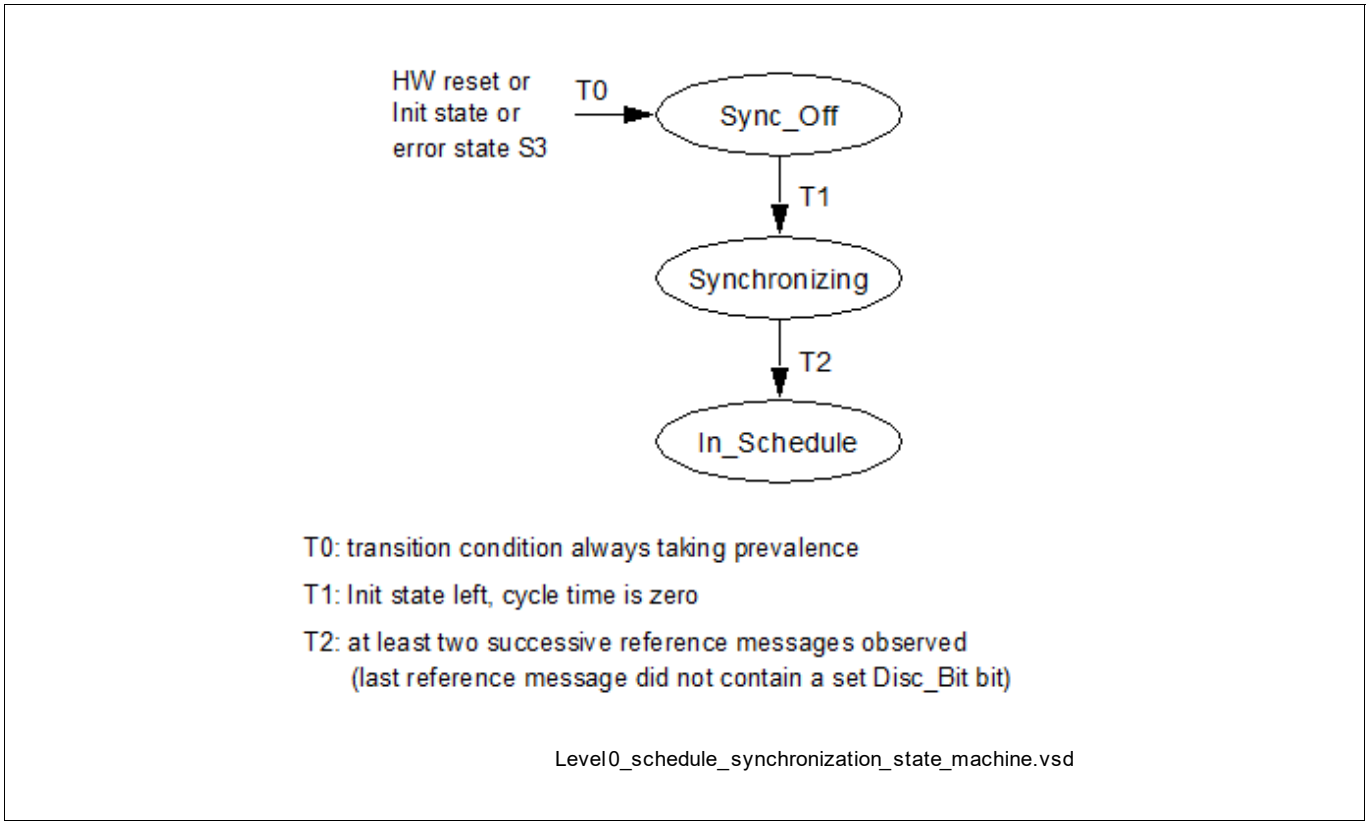

Figure 602 Level 0 schedule synchronization state machine

40.3.3.9.2 Handling of Error Levels

During Level 0 operation only the following error conditions may occur:

- Watch_Trigger_Reached (S3), reached cycle time $FF00_H$
- CAN_Bus_Off (S3)

Since no S1 and S2 error are possible, the error level can only switch between S0 (No Error) and S3 (Severe Error). In TTCAN Level 0 an S3 error is handled differently. When error level S3 is reached, both TTOST0.SYS and TTOST0.MS are reset, and interrupt flags TTIR0.GTE and TTIR0.GTD are set.

When error level S3 (TTOST0.EL = “11”) is entered, bus monitoring mode is, contrary to TTCAN Level 1 and Level 2, not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.

40.3.3.9.3 Master Slave Relation

Figure 603 below describes the master slave relation in TTCAN Level 0. In case of an S3 error the M_CAN returns to state Master_Off.

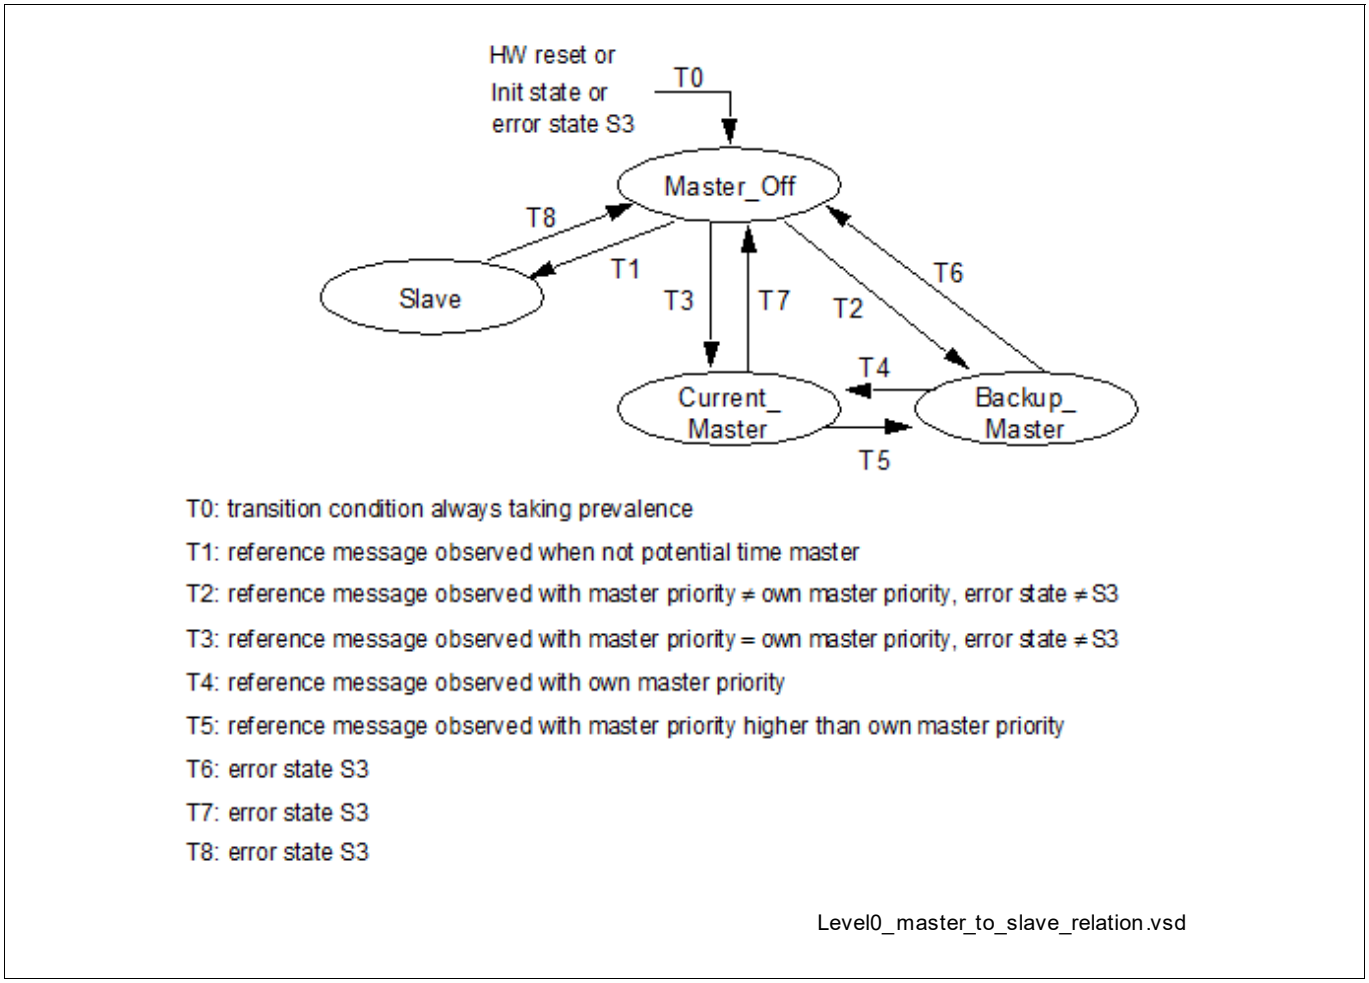

Figure 603 Level 0 master to slave relation

40.3.3.10 Synchronization to external Time Schedule

This feature can be used to synchronize the phase of the M_CAN's schedule to an external schedule (e.g. that of a second TTCAN network or FlexRay network). It is applicable only when the M_CAN is current time master (TTOST0.MS = "11").

External synchronization is controlled by event trigger input. If bit TTOCN0.ESCN is set, a rising edge at the event trigger the M_CAN compares its actual cycle time with the target phase value configured by TTGTP0.CTP.

Before setting TTOCN0.ESCN the Host has to adapt the phases of the two time schedules e.g. by using the TTCAN gap control (see **Section 40.3.3.3**). When the Host sets TTOCN0.ESCN, TTOST0.SPL is set.

If the difference between the cycle time and theTTIR0.target phase value TTGTP0.CTP at the rising edge at the event trigger is greater than 9 NTU, the phase lock bit TTOST0.SPL is reset, and interrupt flag TTIR0.CSM is set. TTOST0.SPL is also reset (and TTIR0.CSM is set), when another node becomes time master.

If both TTOST0.SPL and TTOCN0.ESCN are set, and if the difference between the cycle time and the target phase value TTGTP0.CTP at the rising edge at the event trigger is less or equal 9 NTU, the phase lock bit TTOST0.SPL remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

Note: The rising edge detection at the event trigger is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with TTGTP0.CTP. All further edges until the beginning of the next basic cycle are ignored.

40.4 Registers

This section describes the registers within the MCMCAN module. All the registers are prefixed as CAN0_, CAN1_ or CAN2_ for MCMCAN modules, if the corresponding module exist for a particular product variant (Refer Appendix). The registers are grouped as three different sections:

- General Configuration Registers
- User Interface Registers
- Registers within M_CAN

The registers listed in **Figure 604** are not included in the MCMCAN module kernel (part of general module IP blocks), some registers must be programmed for proper operation of the MCMCAN module.

The additional ACCEN registers, are MCMCAN specific.

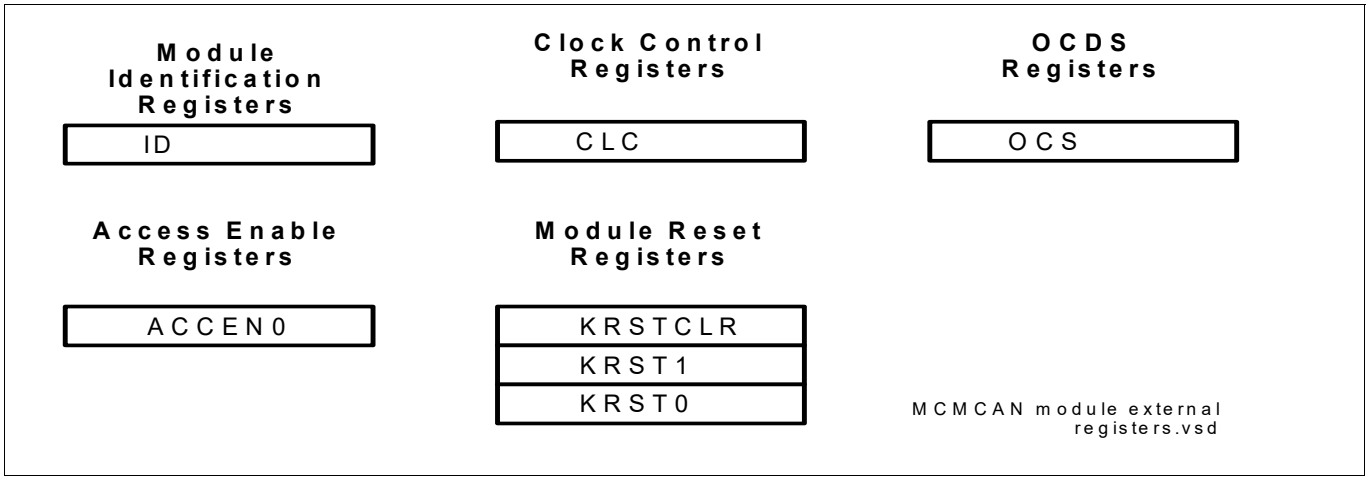

Figure 604 CAN Implementation-specific Special Function Registers

40.4.1 MCMCAN RAM address space

Table 378 Register Address Space - MCMCAN RAM

Module	Base Address	End Address	Note
CANRAM0	F020 0000$_H$	F020 7FFF$_H$	RAM Area CAN0
CANRAM1	F021 0000$_H$	F021 3FFF$_H$	RAM Area CAN1
CANRAM2	F022 0000$_H$	F022 3FFF$_H$	RAM Area CAN2

Note: Refer Appendix of a product variant for the register address space of MCMCAN and available RAM modules.

40.4.2 MCMCAN register overview

Table 379 Register Overview - CAN (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
RAM	Embedded SRAM for messages (008000_H Byte)	000000_H				
CLC	CAN Clock Control Register	008000_H	U,SV	SV,E,P	Application Reset	83
ID	Module Identification Register	008008_H	U,SV	nBE	Application Reset	70

40.4.3 General Configuration Registers

This section describes the global module registers, system registers, access enable registers and kernal reset registers.

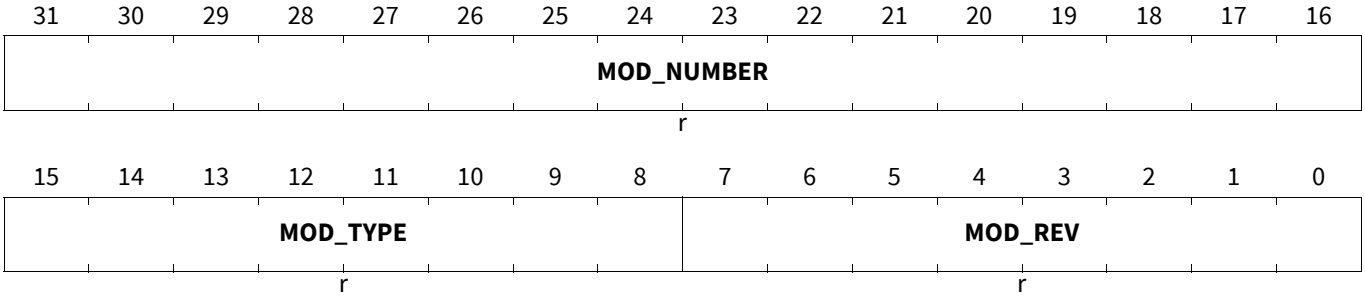
40.4.3.1 Global Module Registers

Global Module Registers, are registers, which are not part of M_CAN nodes.

Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID
Module Identification Register **(008008_H)** **Application Reset Value: $00B8\ C0XX_H$**



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** MOD_REV defines the revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	15:8	r	**Module Type** $C0_H$ Define the module as a 32-bit module.
MOD_NUMBER	31:16	r	**Module Number Value** This bit field defines the MCMCAN module identification number $00B8_H$.

Module Control Register

The Module Control Register MCR contains basic settings that determine the operation of the MCMCAN module.

The write access to the lowest byte of the MCR register becomes only valid, if and only if, MCR.CCCE and MCR.CI are already set during write access. To switch the clocks on or off, the bits of MCR.CCCE and MCR.CI have to be reset afterwards. Before this sequence hasn't taken place, no write access to the corresponding nodes, can be done.

Note: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.

To be able to change the clock settings the following programming sequence needs to be met:

```
uwTemp = CANn_MCR.U;
uwTemp |= (0xC0000000 | CLKSELx);
CANn_MCR.U = uwTemp;
uwTemp &= ~0xC0000000;
```

CANn_MCR.U = uwTemp;
The clock settings for CAN nodes becomes active.
To be able to start the RAM initialization, the following programming sequence need to be met:
CANn_MCR |= 0xC0000000;
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
Set CANn_MCR.RINIT to 1b
Dummy read CANn_MCR
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
CANn_MCR &= ~0xC0000000;
RAM initialization is finished

MCR
Module Control Register **(008030_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCCE	**CI**	**RINIT**	**RBUSY**	**DXCM**	**NODE**			**0**							
rw	rw	rw	rh	rw		rw		r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								**CLKSEL3**		**CLKSEL2**		**CLKSEL1**		**CLKSEL0**	
r								rw		rw		rw		rw	

Field	Bits	Type	Description
CLKSEL0	1:0	rw	**Clock Select 0** This bitfield is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
CLKSEL1	3:2	rw	**Clock Select 1** This bitfield is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
CLKSEL2	5:4	rw	**Clock Select 2** This bitfield is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on

Field	Bits	Type	Description
CLKSEL3	7:6	rw	**Clock Select 3** This bitfield is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
NODE	26:24	rw	**Node** This bit field determines the CAN node i which is used for debug over CAN. This bitfield only exists on CAN0. 000_B Node 0 … 011_B Node 3
DXCM	27	rw	**Debug Over CAN Messages Enable** This bit enables the debug over serial connections between DAP and CAN0 module. If enabled the lowest receive/transmit message buffer is reserved for debugger communication. DXCM is described in detail in the OCDS chapter. This bit only exists on CAN0. 0_B DXCM disabled 1_B DXCM enabled
RBUSY	28	rh	**RAM BUSY** This bit shows that the RAM Initialization is running. This bit is set back to 0b by hardware when the RAM intialization is completed.
RINIT	29	rw	**RAM Init** This bit is MCR.CI and MCR.CCCE protected. This bit starts the initialization of the RAM block to all 0x0. The RAM initialization is started only when this bit is changed from 0b to 1b and also RBUSY is 0b.
CI	30	rw	**Change Init** Needs to be set to enable and disable clocks. 0_B Change Init disabled 1_B Change Init enabled (takes effect with CCCE:=1)
CCCE	31	rw	**Clock and RAM Change Enable** Needs to be set to enable and disable the clocks. 0_B Clock and RAM Change disabled 1_B Clock and RAM Change enabled (takes effect with CI:=1)
0	23:8	r	**Reserved** Shall read 0; shall be written with 0.

Debug over CAN (DXCM feature)

The MCMCAN controller supports debugging using standard CAN tool access in parallel to regular CAN bus traffic. This is achieved by transmitting DAP telegrams and replies as regular CAN messages (DXCM DAP over CAN Messages). DXCM uses the lowest message buffers and it is strongly recommended to use also the same CAN pins as for DXCPL (DAP over CAN Physical Layer). DXCM is enabled with the MCR.DXCM bit. Please refer to the OCDS chapter for more information about DAP, DXCM and DXCPL.

Debug over CAN shall be only available on CAN0. TX Buffer 0 will be the sending transmit object. For receive at least one message buffer has to be configured. Meaning that RX Buffer 0 will be used for receiving DAP telegrams. The starting address of the message buffer and the receiving address of the message buffer have to be configured within BUFADR register.

Assigning the buffer start address

The following register assigns the start address to all features needing the message buffers inside the corresponding M_CAN, which are for receive and transmit.

Buffer receive address and transmit address

BUFADR

Buffer receive address and transmit address (008034$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		RXBUF													
r		rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		TXBUF													
r		rw													

Field	Bits	Type	Description
TXBUF	13:0	rw	**Transmit Buffer start address** This is the start address of the first dedicated transmit buffer.
RXBUF	29:16	rw	**Receive Buffer start address** This is the start address of the first dedicated receive buffer.
0	15:14, 31:30	r	**Reserved** Shall read 0; shall be written with 0.

Pretended Networking

The registers above are intended to support Pretended Networking. As an application example, the SPB bus is clocked at 40MHz. The asynchronous module part is clocked either with 40MHz as well or even more power saving with direct drive from the oscillator. The cores are in idle mode.

Messages can be received and a receive interrupt can be generated. It is possible to trigger messages with or without changing the content by the timers provided. For example the network management message and two related messages can be triggered without any CPU interaction.

As mostly the operating system is still running, messages can be changed without any problem during the time, where the operating system is active.

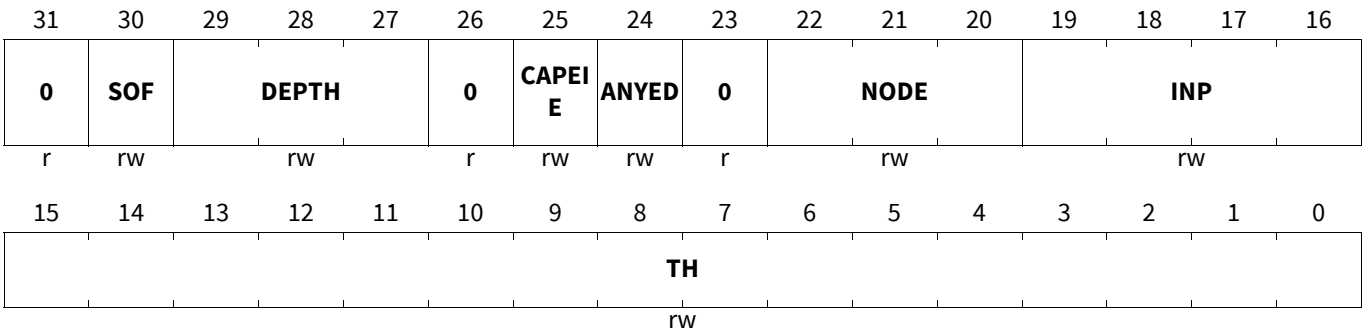
Oscillator calibration

The following registers support the oscillator calibration on which the decision is taken to increase or decrease the frequency. A detailed description will be provided as Application Node.

Measure Control Register

The Measure Control Register MECR controls the CAN edge timing measurement function for calibration purposes. This feature only exists on CAN0.

MECR
Measure Control Register **(008040_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
TH	15:0	rw	**Threshold** This bit field contains the threshold value for the measurement timer. If TH = 0000_H, the timer is stopped and the capture function is disabled.
INP	19:16	rw	**Interrupt Node Pointer** INP selects the interrupt output line INT_Om (m = 0-15) for a capture event interrupt. 0_H Interrupt output line INT_O0 is selected … F_H Interrupt output line INT_O15 is selected
NODE	22:20	rw	**Node** This bit field determines the CAN node i whose input line RXDCANi is used for start and capture of the measurement timer. 000_B Node 0 … 011_B Node 3
ANYED	24	rw	**Any Edge** This bit enables capture on any edge of CAN input line specified by NODE. 0_B Capture on falling (dominant) edge only 1_B Capture on rising (recessive) or falling (dominant) edge
CAPEIE	25	rw	**Capture Event Interrupt Enable** This bit enables the capture event interrupt. Bit field INP selects the interrupt output line which becomes activated at this type of interrupt. 0_B Capture event interrupt is disabled 1_B Capture event interrupt is enabled

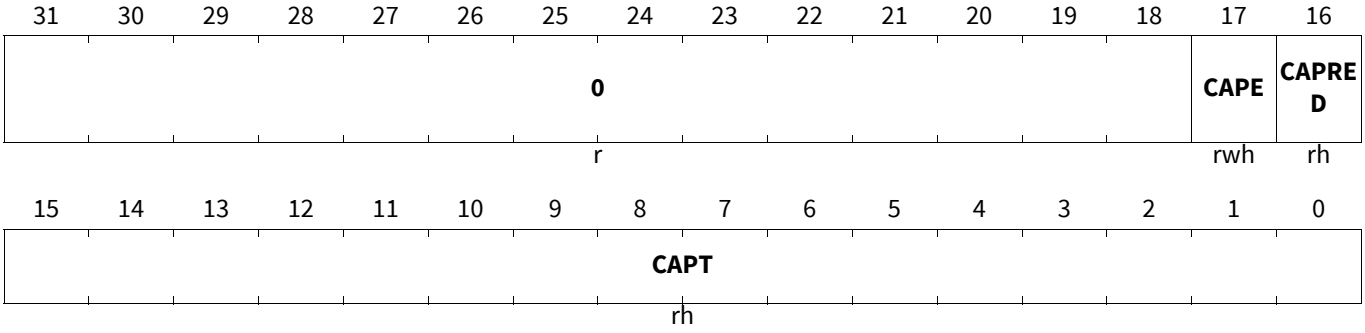
Field	Bits	Type	Description
DEPTH	29:27	rw	**Digital Glitch Filter Depth** DEPTH determines the number of input samples clocked with f_{SYNi} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000_B off, default 001_B Filter depth of 8 cycles 010_B Filter depth of 16 cycles 011_B Filter depth of 32 cycles 100_B Filter depth of 64 cycles 101_B Filter depth of 128 cycles 110_B Filter depth of 255 cycles 111_B not allowed, reserved
SOF	30	rw	**Start Of Frame** This bit selects falling edge or any edge as measurement for start of frame detection. 0_B Measurement starts with any falling edge 1_B Measurement starts with falling Start of Frame edge. i.e any falling edge that occurs while the CAN node is in idle state
0	23, 26, 31	r	**Reserved** Shall read 0; shall be written with 0.

Measure Status Register

The Measure Status Register MESTAT contains the status information of the CAN edge timing measurement. This feature only exists on CAN0.

MESTAT

Measure Status Register **(008044_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CAPT	15:0	rh	**Captured Timer** This bit field contains the captured measurement timer content. The timer itself is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node specified by MECR.NODE. The timer is incremented by the module control clock f_{SYNi} and will be stopped when $FFFF_H$ is reached. If MECR.TH = 0000_H, the timer is always stopped. A capture will take place if all the following conditions are met: 1. MECR.TH > 0000_H 2. Timer is cleared and started by new frame 3. Timer reaches MECR.TH 4. This node is not sending and first edge (as specified by MECR.ANYED) after 3. occurs on input line Capture will be repeated for the following CAN frames until MECR.TH is cleared.
CAPRED	16	rh	**Captured Rising Edge** This bit indicates the type of edge that caused the last capture event. 0_B Capture occurred on falling (dominant) edge 1_B Capture occurred on rising (recessive) edge
CAPE	17	rwh	**Capture Event** This flag is set on a capture event. It must be reset by software. An interrupt request is generated if MECR.CAPEIE = 1. If CAPE=1 then no further measurement results are posted to MESTAT.CAPT and MESTAT.CAPRED. CAPE bit has to be cleared to re-enable update of MESTAT.CAPT and MESTAT.CAPRED. 0_B No capture event has occurred since last flag reset 1_B Capture event has occurred since last flag reset
0	31:18	r	**Reserved** Shall read 0; shall be written with 0.

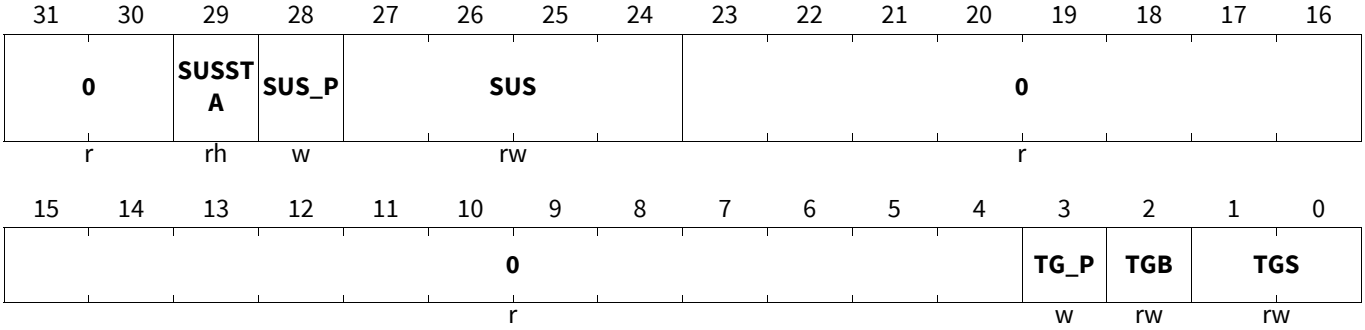
40.4.3.2 System Registers

OCDS Control and Status

OCDS Trigger Bus (OTGB) The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access requires Supervisor Mode.

OCS

OCDS Control and Status **(0080E8$_H$)** **Debug Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B TS16_CAN **others**, reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clock is off immediately. Do not use this mode in normal CAN applications, this mode is meant for debugging the peripheral IP. 2_H Soft suspend of CAN nodes. **others**, reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B CAN nodes are not (yet) suspended 1_B All CAN nodes are suspended
0	23:4, 31:30	r	**Reserved** Shall read 0; shall be written with 0.

OCDS Trigger Bus (OTGB) Interface

The MCMCAN Trigger Set is shown in **Table 380**. Its output is on OTGB0 or OTGB1 controlled by the **OCDS Control and Status** register. Links are only for CAN0, but the feature is available for all CAN modules.

Table 380 TS16_CAN Trigger Set MCMCAN

Values	Name	Description
i	AF	Acceptance filtering done for node i
i + 4	MR	Message successfully received on node i
i + 8	FDR	Fast Data Phase reception on node i
i + 12	FDT	Fast Data Phase transmission on node i.

40.4.3.3 Access Enable Registers ACCEN

The access enable bits control the access on the module itself.

Access Enable Register 0

The Access Enable Register 0 controls write access[1] for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 provides one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENy: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, … ,EN31 -> TAG ID 011111_B.

ACCEN0

Access Enable Register 0 ($0080FC_H$) Application Reset Value: $FFFF\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ENy (y=0-31)	y	rw	**Access Enable for Master TAG ID y** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID y. 0_B Write access will not be executed 1_B Write access will be executed

40.4.3.4 Additional Access Enable Registers ACCENCTR and ACCENNODEi

The access enable bits help the application to control the access rights via bus master TAG ID. Inside the CAN node registers, an additional address range can be defined, called STARTADR and ENDADR.

The ACCENNODEi registers are protecting node i and the memory range defined in the STARTADRi and ENDADRi register. To disable the mechanism the STARTADRi has to be higher than the corresponding ENDADRi of the node.

1) The BPI_FPI Access Enable functionality controls only write transactions. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers-

Access Enable Register Control 0

The Access Enable Register Control 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID ↔ master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCENCTR0 provides one enable bit for each possible 6-bit TAG ID encoding. The control registers (address range 8020_H to $804F_H$) are protected by this register.

Mapping of TAG IDs to ACCENCTR0.ENy: EN0 → TAG ID 000000_B, EN1 → TAG ID 000001_B, … ,EN31 → TAG ID 011111_B.

ACCENCTR0
Access Enable Register Control 0 ($0080DC_H$) Application Reset Value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
ENy (y=0-31)	y	rw	**Access Enable for Master TAG ID y** This bit enables write access to the module kernel addresses for transactions with the Master TAG ID y 0_B Write access will not be executed 1_B Write access will be executed

Access Enable Register CAN Node i 0

The Access Enable Register CAN Node i Control 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID ↔ master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCENNODEi0 provides one enable bit for each possible 6-bit TAG ID encoding. This register controls node y registers, including the STARTADR0 and ENDADR0 register included in the node control area (8100_H+i*0400_H to 8400_H+i*0400_H-1). This means, that this area is including these registers and also the STARTADRi and ENDADRi. If the programming of the CPU leads to the fact, that it is disabling its own access, it will not be able to correct such a setting afterwards.

Mapping of TAG IDs to ACCENNODEi0.ENy: EN0 → TAG ID 000000_B, EN1 → TAG ID 000001_B, … , EN31 → TAG ID 011111_B.

40.4.3.5 Kernel Reset Registers

The Kernel Reset Registers give the user the possibility to reset the module without resetting the device.

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers related to the module kernel reset.The RST bit will be reset by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is reset by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be reset to ´0´ by writing to KRSTCLR.CLR with ´1´.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0 **($0080F4_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0														RSTSTAT	RST
r														rh	rwh

Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested

Field	Bits	Type	Description
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Shall read 0; shall be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRST1.RST and KRST0.RST) related to the module kernel reset. The RST bit will be reset (cleared to ‘0’) by the BPI with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **($0080F0_H$)** **Application Reset Value: $0000\ 0000_H$**

40.4.4 MCMCAN User Interface Registers

This section describes the registers for clock control, port connections, interrupt control, and address decoding.

40.4.4.1 The Clock Control Register

CAN Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the standard interface for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{SYN} and f_{ASYN} module clock signal, sleep mode and fast shut-off mode for the module.

CLC

CAN Clock Control Register **(008000_H)** **Application Reset Value: $0000\ 0003_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The synchronous and asynchronous clock is switched on/off Note that no register access is possible to any register while module is disabled. A disable request is granted, if the M_CAN clock is disabled, or all M_CAN nodes acknowledge the disable request.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**Sleep Mode Disable Control** Used to control module's sleep mode.
0	2, 31:4	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.2 Interrupt Grouping and Signalling Registers

Interrupt routing for Groups 1 i

GRINT1i is the first of two grouping registers. In this register, the interrupt line within the module is fixed. Please be reminded, that the interrupt sources need to be enabled to be mapped. The total module has 16 interrupts and the interrupt node can be chosen within GRINT1i and GRINT2i.

Meaning:

0000_B Interrupt output line INT_O0 is selected.

0001_B Interrupt output line INT_O1 is selected.

$\cdots_B \cdots$

1110_B Interrupt output line INT_O14 is selected.

1111_B Interrupt output line INT_O15 is selected.

GRINT1i (i=0-3)

Interrupt routing for Groups 1 i **(008114_H+i*400_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOI				BOFF				SAFE				MOER			
rw				rw				rw				rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALRT				WATI				HPE				TEFIFO			
rw				rw				rw				rw			

Field	Bits	Type	Description
TEFIFO	3:0	rw	**Transmit Event FIFO Incidents** are mapped here. IR.TEFF (Transmit Event FIFO Full) and IR.TEFN (Transmit Event FIFO New Entry)
HPE	7:4	rw	**High Priority Events** are mapped here, giving IR.HPM an interrupt level
WATI	11:8	rw	**Watermark interrupts** are mapped here: IR.TEFW (Transmit FIFO warning interrupt reached), IR.RF1W (Receive FIFO 1 warning interrupt reached). IR.RF0W (Receive FIFO 0 warning interrupt reached)
ALRT	15:12	rw	**ALERTS** All kind of alerts are mapped here. IR.EW (warning status), IR.EP (error passive), IR.TSW (timestamp wrap around), IR.TEFL (Transmit Event FIFO Element Lost), IR.RF0L (Receive FIFO 0 Message Lost), IR.RF1L (Receive FIFO 1 Message Lost). The following TTCAN error messages and warnings are also shown here: TTIR. CER (Configuration Error), TTIR.AW Application Watchdog, TTIR.WT (Watch Trigger), TTIR.IWT Initialization Watch Trigger, TTIR.ELC (Error Level Changed), TTIR.SE2 (Scheduling Error 2), TTIR.SE1 (Scheduling Error), TTIR.TXO (Tx Count Overflow), TTIR.TXU (TX Count Underflow), TTIR.GTE (Global Time Error), TTIR.GTD (Global Time Discontinuity) and TTIR.GTW (Global Time Wrap)
MOER	19:16	rw	**Module errors** IR.WDI (watchdog interrupt) and IR.MRAF (message RAM access failure) are mapped here.
SAFE	23:20	rw	**Safety counter overflow** The interrupt node for IR.ELO showing a safety counter overflow
BOFF	27:24	rw	**Bus Off has been reached** Mapped to IRi.BO flag indication the change in Bus_Off status. To get out of bus off, the CCCRn.INIT bit has to be reset.

Field	Bits	Type	Description
LOI	31:28	rw	**Last Error Interrupts** The interrupt sources IR.PED (Protocol Error in Data Phase) and IR.PEA (Protocol Error in Arbitration Phase) are signalled here.

Interrupt routing for Groups 2 i

GRINT2i has the same functionality as GRINT1i, but for other interrupt sources. The interrupt sources need to be enabled to be mapped.

GRINT2i (i=0-3)
Interrupt routing for Groups 2 i **(008118_H+i*400_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TRACO				**TRAQ**				**RETI**				**RxF0N**			
rw				rw				rw				rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RxF1N				**RxF0F**				**RxF1F**				**REINT**			
rw				rw				rw				rw			

Field	Bits	Type	Description
REINT	3:0	rw	**Message stored in dedicated receive buffer interrupt (IR.DRX)** is assigned to interrupt node.
RxF1F	7:4	rw	**IR.RF1F** Receive FIFO1 full interrupt assigned to an interrupt node
RxF0F	11:8	rw	**IR.RF0F** Receive FIFO0 full interrupt assigned to an interrupt node
RxF1N	15:12	rw	**IR.RF1N** Receive FIFO1 new message assigned to an interrupt node
RxF0N	19:16	rw	**IR.RF0N** Receive FIFO0 new message assigned to an interrupt node
RETI	23:20	rw	**Receive Timeouts** can be assigned here. IR.TOO (time-out event) and TE (Timer Event)
TRAQ	27:24	rw	**Transmission Queue Events** can be assigned here. IR.TFE Transmission FIFO Empty
TRACO	31:28	rw	**Interrupts of the transmission control** can be assigned here. IR.TCF (Transmission Cancellation Finished) and IR.TF (Transmission Completed). As an additional information the copy of a local time event is shown here with TTIR.SWT (Stop Watch Event). Further on the TTIR.TTMI Trigger Time Event Internal, TTIR.RTMI (Register Time Mark), TTIR.SOG (Start of Gap), TTIR.CSM (Change of Synchronization Mode), TTIR.SMC (Start Matrix Cycle) and TTIR.SBC (Start of Basic Cycle) are shown here.

Interrupt Signalling Register i

The groups by the GRINT registers are also shown inside the ISREG (interrupt signalling register) register. Inside the interrupt signalling register a 1 means, that one of the corresponding bits inside the interrupt (status) register of the corresponding M_CAN node, at least one group member is showing an interrupt. ISREG is purely ORing the interrupt status bits of the group to enable SW to have proper handling of the bits. Writing to ISREGi has no effect.

If ISREGi is written, this shall have no effect on the interrupt status inside the M_CAN nodes. The bits have to be reset inside the corresponding M_CAN nodes, see register CANn_IRi.

ISREGi (i=0-3)

Interrupt Signalling Register i **(008110_H+i*400_H)** **Application Reset Value: $0000\ 0000_H$**

40.4.4.3 Node Port Control Register

Node i Port Control Register

The Node Port Control Register NPCRi configures the CAN bus transmit/receive ports.

NPCRi (i=0-3)

Node i Port Control Register **(008140_H+i*400_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

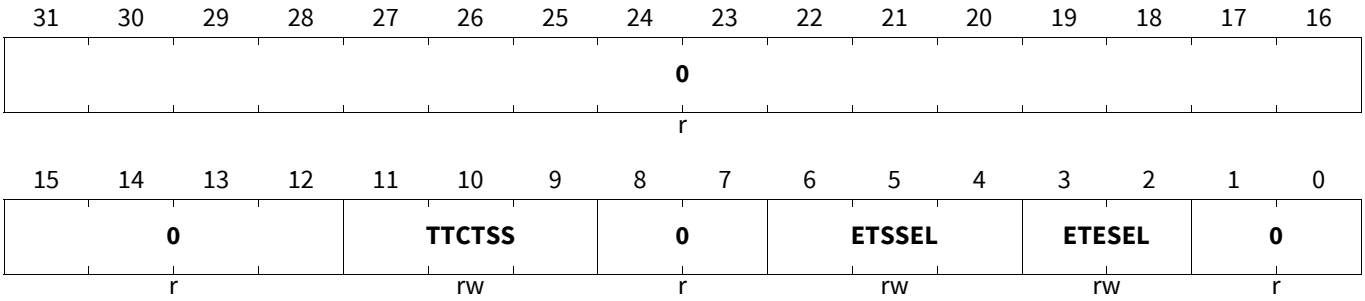
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					DELE	LOUT	LBM	0					RXSEL		
r					rw	rw	rw	r					rw		

Field	Bits	Type	Description
RXSEL	2:0	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed by the selected input. (see the device related chapter for RXSEL)
LBM	8	rw	**Loop-Back Mode** 0_B Loop-Back Mode is disabled. 1_B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
LOUT	9	rw	**Loop Back Mode Out** The loop back bus is switched to the external CAN bus of the node.
DELE	10	rw	**Enable destructive read on ECRi.CEL** If this bit is set, the destructive read on ECRi.CEL and on the PSR register takes place. Meaning, that with read access on ECRi, the CEL is reset. The same is true for the PSR register, for the bits PXE, RFDF, RBRS, RESI, LEC and DLEC. After the destructive read it is advised to reset the bit again.
0	7:3, 31:11	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.4 Time Trigger Control Register

Time Trigger Control Register

TTCR0
Time Trigger Control Register **(0081F0$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
ETESEL	3:2	rw	**External Trigger Event Selection** This bit field defines the external trigger event that can be used to trigger the transmission of the reference message. The event causes the Event Trigger to be triggered. Control settings for this will not be influenced. 00_B The external event ECTTx does not trigger the transmission of the reference message. 01_B The reference message will be transmitted when a negative edge is detected at the selected input line ECTTx. 10_B The reference message will be transmitted when a positive edge is detected at the input line ECTTx. 11_B The reference message will be transmitted when a negative edge or a positive edge is detected at the input line ECTTx.
ETSSEL	6:4	rw	**External Trigger Source Selection** This bit fields selects the input source for the external reference message trigger. 000_B External trigger input line ECTT1 selected 001_B External trigger input line ECTT2 selected 010_B External trigger input line ECTT3 selected 011_B External trigger input line ECTT4 selected 100_B External trigger input line ECTT5 selected 101_B External trigger input line ECTT6 selected 110_B External trigger input line ECTT7 selected 111_B External trigger input line ECTT8 selected
TTCTSS	11:9	rw	**TTCapture Time Trigger Source Select** This bit selects the input source for the TT Capture Time (TTCPT) trigger. This register influences the stop watch event trigger 000_B No TTCPT trigger input allowed 001_B Local time register capture trigger input TTCPT_TRIG1 selected … 100_B Local time register capture trigger input TTCPT_TRIG4 selected **others**, Reserved; do not use this combination

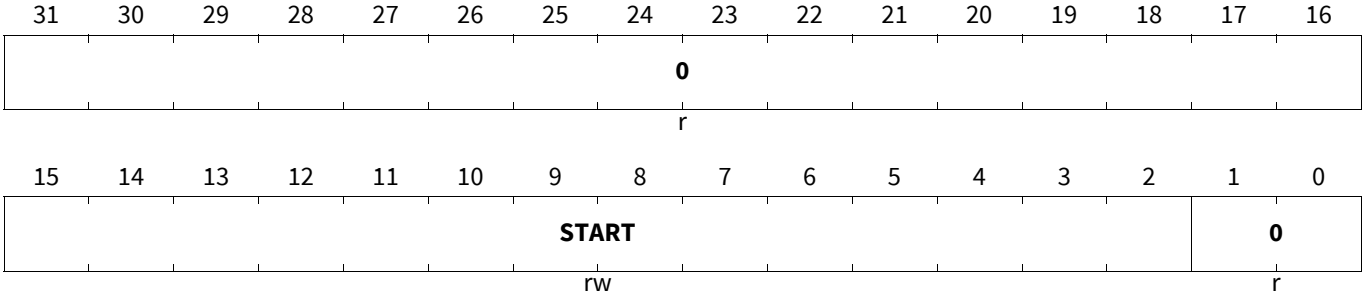
Field	Bits	Type	Description
0	1:0, 8:7, 31:12	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.5 Message RAM start address register

Start Address Node i

In case the RAM shall not be protected, the STARTADR has to be higher than the corresponding ENDADR of the node.

STARTADRi (i=0-3)
Start Address Node i **(008108_H+i*400_H)** **Application Reset Value: 0000 0000_H**

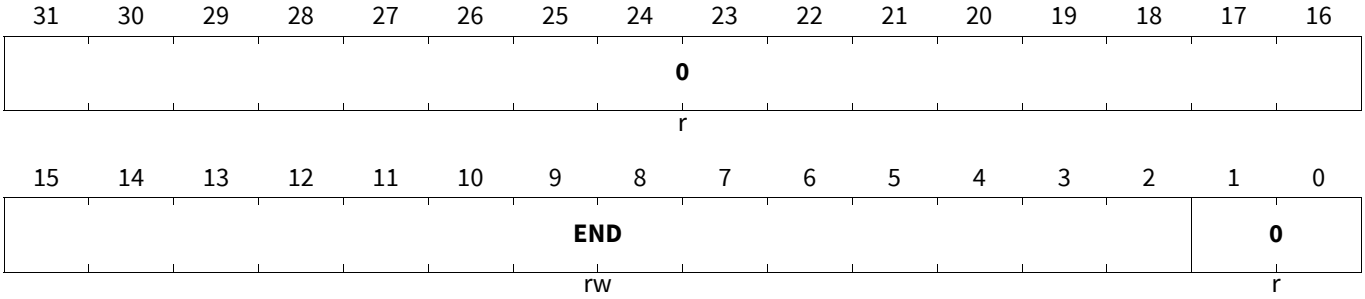


Field	Bits	Type	Description
START	15:2	rw	**Message RAM start** The address within the RAM area of the MCMCAN, of node i, where the message RAM to be protected starts
0	1:0, 31:16	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.6 Message RAM end address register

End Address Node i

ENDADRi (i=0-3)
End Address Node i **($00810C_H$+i*400_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
END	15:2	rw	**Message RAM end** The address within the RAM area of the MCMCAN, of node i, where the message RAM to be protected ends
0	1:0, 31:16	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.7 NTCCR

The Node i Timer Clock Control and Node i Timer A/B/C Transmit Trigger Registers offer additional timing functions for the node.

Node i Timer Clock Control Register

The Node i Timer Clock Control Register NTCCRi controls the functions of the node timer.

NTCCRi (i=0-3)
Node i Timer Clock Control Register **(008120_H+i*400_H)** **Application Reset Value: $0000\ 0000_H$**

STSTART	STRESET	0		TPSC				0							
rw	rw	r		rw				r							

Field	Bits	Type	Description
TPSC	11:8	rw	**Timer Prescaler** The duration of one timer clock is given by (TPSC + 1) CAN bit times for all NTCCRi.TRIGSRC settings.
STRESET	14	rw	**Stamping Reset** This bit gives the possibility to reset the time stamp for CAN FD messages.
STSTART	15	rw	**Stamping Start** This bit starts the external timer used for CAN FD messages. The source and the prescaler are identical to the timers A/B/C.

Field	Bits	Type	Description
TRIGSRC	20:18	rw	**Trigger Source** This bit selects the trigger source for the different modes in the node timer. 000_B Node i Timer is decremented per f_{SYNi} prescaled by (TPSC + 1) timing to 0. 001_B System Timer (STM) trigger event enabled Node i Timer is decremented per STM trigger event prescaled by (TPSC + 1). 010_B General Timer (GTM) trigger event enabled Node i Timer is decremented per GTM trigger event prescaled by (TPSC + 1). **others**, Reserved, do not use
0	7:0, 13:12, 17:16, 31:21	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.8 CAN Node timers for pretended networking

Node i Timer A Transmit Trigger Register

The Node i Timer A Transmit Trigger Register NTATTRi controls the node timing functions for Transmit Trigger Mode.

NTATTRi (i=0-3)
Node i Timer A Transmit Trigger Register (008124_H+i*400_H) **Application Reset Value: 0001 0000_H**

RELOAD															
rw															

Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit trigger is fixed to transmit buffer 1
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.

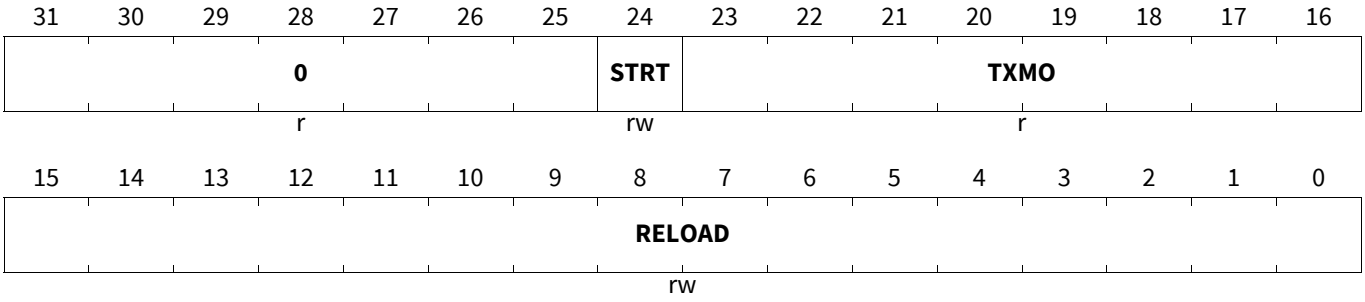
Field	Bits	Type	Description
0	31:25	r	**Reserved** Shall read 0; shall be written with 0.

Node i Timer B Transmit Trigger Register

The Node i Timer B Transmit Trigger Register NTBTTRi controls the node timing functions for Transmit Trigger Mode.

NTBTTRi (i=0-3)

Node i Timer B Transmit Trigger Register (008128$_H$+i*400$_H$) Application Reset Value: 0002 0000$_H$



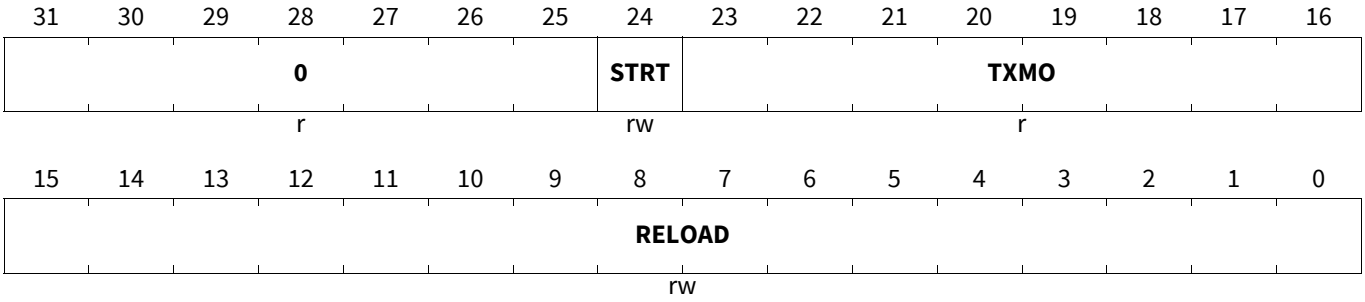
Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit object is fixed to transmit buffer 2
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	31:25	r	**Reserved** Shall read 0; shall be written with 0.

Node i Timer C Transmit Trigger Register

The Node i Timer C Transmit Trigger Register NTCTTRi controls the node timing functions for Transmit Trigger Mode.

NTCTTRi (i=0-3)

Node i Timer C Transmit Trigger Register (00812C$_H$+i*400$_H$) Application Reset Value: 0003 0000$_H$



Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit trigger is fixed to transmit buffer 3
STRT	24	rw	**Timer Start** This bit field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	31:25	r	**Reserved** Shall read 0; shall be written with 0.

40.4.4.9 Node Timer Receive Timerout Register

Node i Timer Receive Timeout Register

The Node i Timer Receive Timeout Register NTRTRi controls the node timing functions for Receive Timeout Mode. This feature is independent of Classical CAN and CAN FD.

This mode exists, to have for example network management supervision.

NTRTRi (i=0-3)
Node i Timer Receive Timeout Register **(008130_H+i*400_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								TE	TEIE	0					
r								rwh	rw	r					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD															
rw															

Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit field contains the reload value for the timer. The timer will start when RELOAD ≠ 0 is written. After half the time of the RELOAD value, the interrupt flags of the receive buffers will be cleared automatically, to ensure, that no message receive will be missed.
TEIE	22	rw	**Timer Event Interrupt Enable** This bit enables the node timer event interrupt of CAN node i. Bit field GRINT2.RETI selects the interrupt output line which becomes activated at this type of interrupt. 0_B Timer event interrupt is disabled 1_B Timer event interrupt is enabled

Field	Bits	Type	Description
TE	23	rwh	**Timer Event** This flag is set on a node timer transition from 1 to 0 in Receive Timeout Mode. This bit must be reset (i.e Write to '0') by software, writing a '1' has no effect. An interrupt request is generated if TEIE = 1. 0_B No timer event has occurred since last flag reset 1_B Timer event has occurred since last flag reset
0	21:16, 31:24	r	**Reserved** Shall read 0; shall be written with 0.

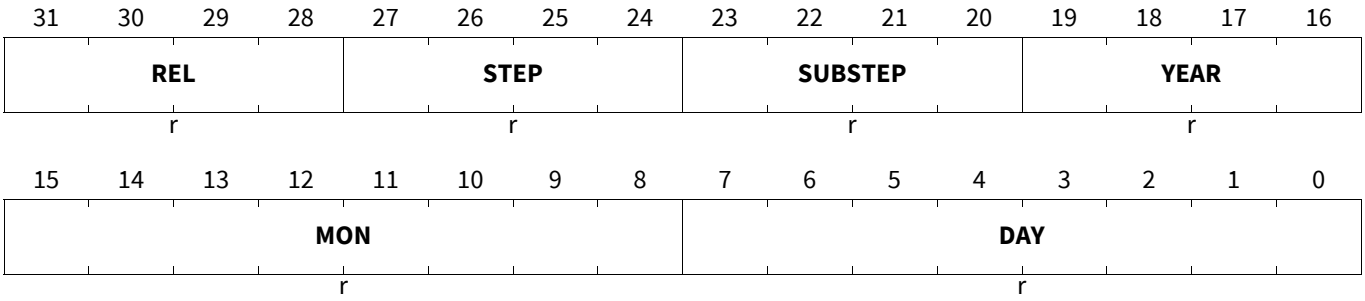
40.4.5 Registers within M_CAN

40.4.5.1 Standard Registers

Core Release Register i

CRELi (i=0-3)

Core Release Register i **(008200_H+i*400_H)** **Reset Value: Table 381**



Field	Bits	Type	Description
DAY	7:0	r	**Time Stamp Day**
MON	15:8	r	**Time Stamp Month**
YEAR	19:16	r	**Time Stamp Year**
SUBSTEP	23:20	r	**Sub-step of Core Release** One digit, BCD-coded.
STEP	27:24	r	**Step of Core Release** One digit, BCD-coded.
REL	31:28	r	**Core Release** One digit, BCD-coded.

Table 381 Reset Values of CRELi (i=0-3)

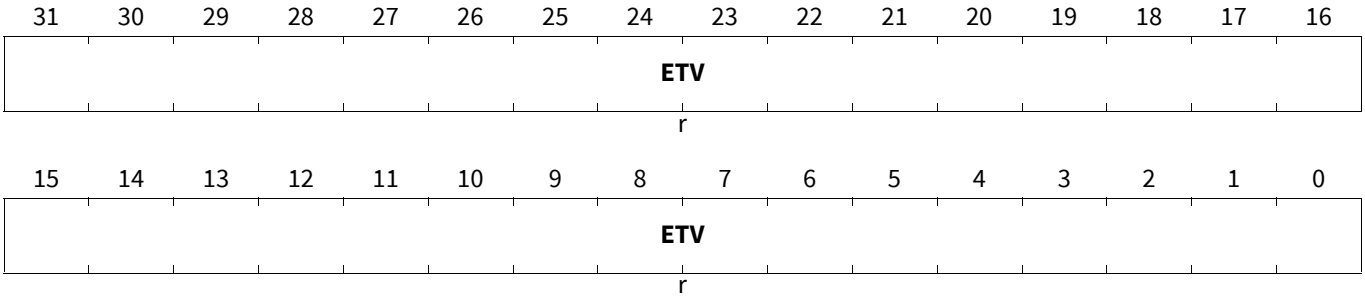
Endian Register i **(008204_H+i*400_H)** **Application Reset Value: $8765\ 4321_H$**



Field	Bits	Type	Description
ETV	31:0	r	**Endianness Test Value** The endianness test value is 0x87654321.

Data Bit Timing & Prescaler Register i

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 clock cycles. t_q = (DBRP + 1) clock cycles.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

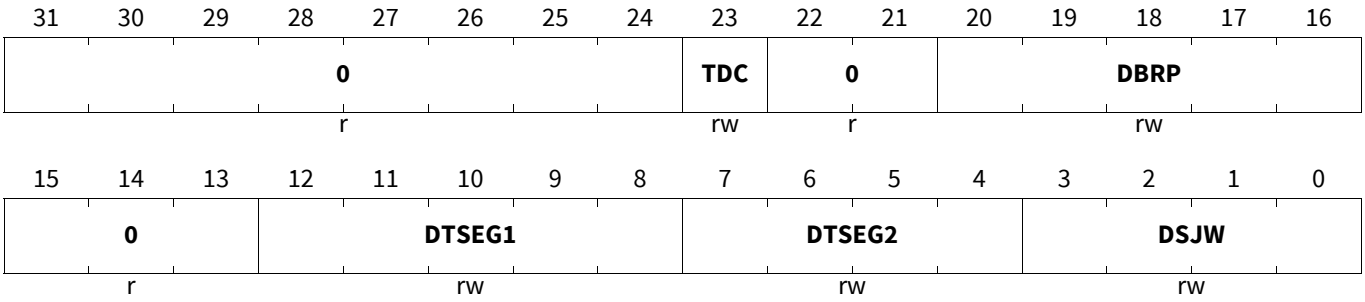
The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Notes

1. *With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.*
2. *The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.*

DBTPi (i=0-3)

Data Bit Timing & Prescaler Register i **($00820C_H$+i*400_H)** **Application Reset Value: 0000 $0A33_H$**



Field	Bits	Type	Description
DSJW	3:0	rw	**Data (Re) Synchronization Jump Width** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
DTSEG2	7:4	rw	**Data time segment after sample point** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

Field	Bits	Type	Description
DTSEG1	12:8	rw	**Data time segment before sample point** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
DBRP	20:16	rw	**Data Baud Rate Prescaler** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
TDC	23	rw	**Transmitter Delay Compensation** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Transmitter Delay Compensation disabled 1_B Transmitter Delay Compensation enabled
0	15:13, 22:21, 31:24	r	**Reserved** Shall read 0, shall be written with 0.

Test Register i

Write access to the Test Register has to be enabled by setting bit CCCR.TEST to ‘1’. All Test Register functions are set to their reset values when bit CCCR.TEST is reset.

Loop Back Mode and software control of transmit pin are hardware test modes. Programming of TEST.TX ≠ “00” may disturb the message transfer on the CAN bus.

TESTi (i=0-3)
Test Register i **(008210_H+i*400_H)** **Application Reset Value: 0000 00X0$_H$**

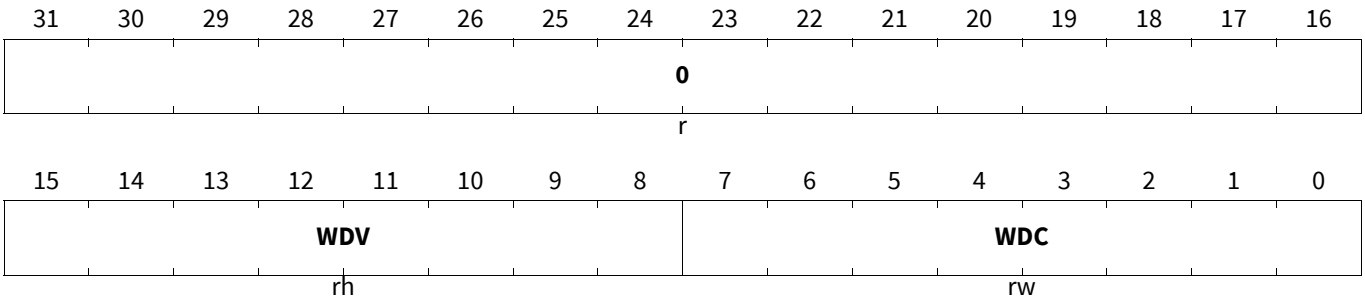
RAM Watchdog i

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by RWD.WDC. The counter is reloaded with RWD.WDC when the Message RAM signals successful completion. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag IR.WDI is set. The RAM Watchdog Counter is clocked by the Host clock.

RWDi (i=0-3)

RAM Watchdog i **(008214_H+i*400_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
WDC	7:0	rw	**Watchdog Configuration** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start value of the Message RAM Watchdog Counter. With the reset value of “00” the counter is disabled. 00_H Watchdog disabled **others**, Start value of the Message RAM Watchdog Counter
WDV	15:8	rh	**Watchdog Value** Actual Message RAM Watchdog Counter Value.
0	31:16	r	**Reserved** Shall read 0, shall be written with 0.

CC Control Register i

The CCCRi register enables and disables CAN bus participation and basic protocol functions. Due to synchronization mechanisms between the clock domains, after a write operation to CCCRi, the register shall be read back, until the set values are written to the register. Please keep in mind, that the register also includes hardware influenced bits.

Note: After enabling the CAN clocks in MCR register, the application software has to wait for 10 hostclock cycles before accessing the kernel registers.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for rwh bits in this register.

CCCRi (i=0-3)
CC Control Register i **(008218_H+i*400_H)** **Application Reset Value: 0000 0001_H**

Field	Bits	Type	Description
INIT	0	rwh	**Initialization** *Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.* 0_B Normal Operation 1_B Initialization is started
CCE	1	rw	**Configuration Change Enable** 0_B The CPU has no write access to the protected configuration registers 1_B The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
ASM	2	rwh	**Restricted Operation Mode** Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. In can also be set by the M_CAN. The bit can be reset by the Host at any time. For a description of the Restricted Operation Mode see paragraph Restricted Operation Mode. 0_B Normal CAN operation 1_B Restricted Operation Mode active
CSA	3	rh	**Clock Stop Acknowledge** 0_B No clock stop acknowledged 1_B M_CAN may be set in power down by stopping the synchronous and the asynchronous clock source
CSR	4	rw	**Clock Stop Request** 0_B No clock stop is requested 1_B Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
MON	5	rwh	**Bus Monitoring Mode** Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. 0_B Bus Monitoring Mode is disabled 1_B Bus Monitoring Mode is enabled
DAR	6	rw	**Disable Automatic Retransmission** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Automatic retransmission of messages not transmitted successfully enabled 1_B Automatic retransmission disabled

Field	Bits	Type	Description
TEST	7	rw	**Test Mode Enable** The TEST register can only be set, if CCE, INIT and TEST are set. Writes to test will only have effect, if all three bits are set. 0_B Normal operation, register TEST holds reset values 1_B Test Mode, write access to register TEST enabled
FDOE	8	rw	**FD Operation Enable** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B CAN FD frame format disabled. 1_B CAN FD frame format enabled.
BRSE	9	rw	**Bit Rate Switch Enable** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Bit rate switching for transmission disabled. 1_B Bit rate switching for transmission enabled.
PXHD	12	rw	**Protocol Exception Handling Disable** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Protocol exception handling enabled. 1_B Protocol exception handling disabled. (When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
EFBI	13	rw	**Edge Filtering during Bus Integration** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Edge filter disabled 1_B Two consecutive dominant tq required to detect an edge for hard synchronization.
TXP	14	rw	**Transmit Pause** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame (see **Tx Handling**). 0_B Transmit pause disabled 1_B Transmit pause enabled
NISO	15	rw	**Non ISO Operation** If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0_B CAN FD frame format according to ISO11898-1 1_B CAN FD frame format according to Bosch CAN FD Specification V1.0
0	11:10, 31:16	r	**Reserved** Shall read 0, shall be written with 0.

Nominal Bit Timing & Prescaler Register i

This register is only writable if bits CCCR.CCE and CCCR.INIT are set.

The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 clock periods. t_q = (NBRP + 1) clock periods.

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With a CAN clock of 8 MHz, the reset value of 0600_H0A03 configures the M_CAN for a bit rate of 500 kbit/s.

NBTPi (i=0-3)

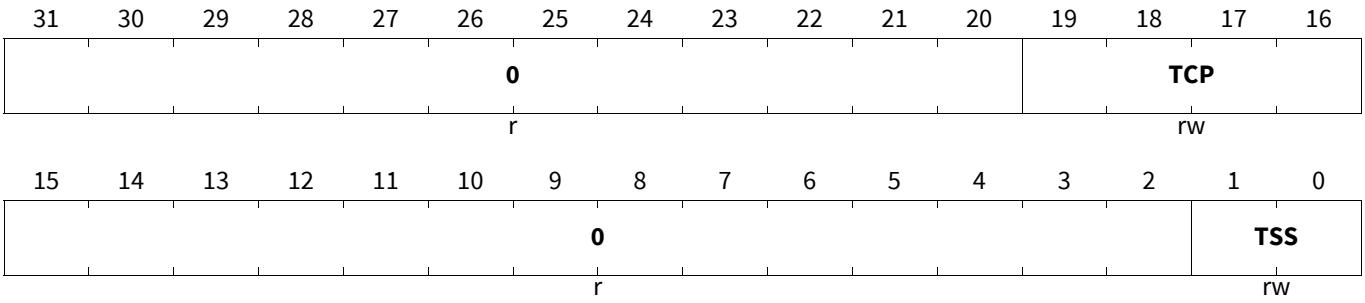
Field	Bits	Type	Description
NTSEG2	6:0	rw	**Nominal Time segment after sample point** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 1 to 127. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
NTSEG1	15:8	rw	**Nominal Time segment before sample point** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 1 to 255. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
NBRP	24:16	rw	**Baud Rate Prescaler** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
NSJW	31:25	rw	**(Re) Synchronization Jump Width** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Field	Bits	Type	Description
0	7	r	**Reserved** Shall read 0, shall be written with 0.

Timestamp Counter Configuration i

For a description of the Timestamp Counter see chapter Timestamp Generation

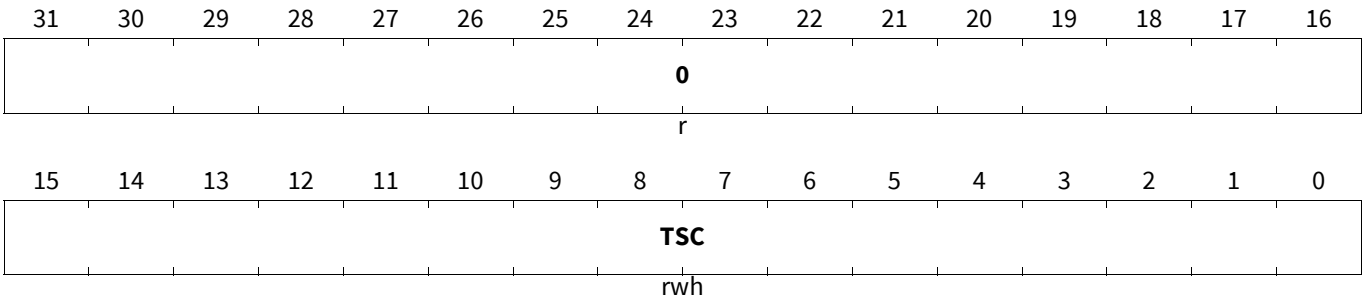
TSCCi (i=0-3)
Timestamp Counter Configuration i **(008220_H+i*400_H)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
TSS	1:0	rw	**Time segment before sample point** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 01_B Timestamp counter value incremented according to TCP 10_B External timestamp counter value used, timer to be started in NTCCRy, the clock source as well as the chosen prescaler has to be configured before using this feature. **others**, Timestamp counter value always 0x0000
TCP	19:16	rw	**Timestamp Counter Prescaler** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1…16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. *Note: With CAN FD an external counter is required for timestamp generation (TSS = "10")*
0	15:2, 31:20	r	**Reserved** Shall read 0, shall be written with 0.

Timestamp Counter Value i

TSCVi (i=0-3)
Timestamp Counter Value i **(008224_H+i*400_H)** **Application Reset Value: 0000 0000_H**

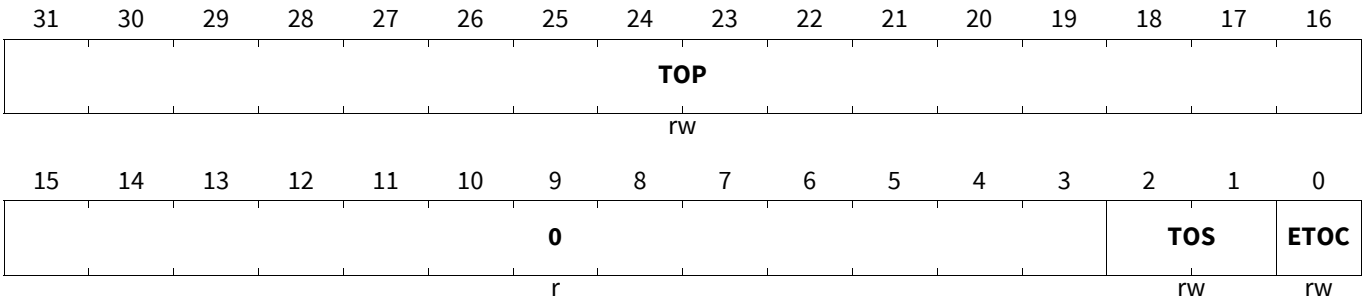


Field	Bits	Type	Description
TSC	15:0	rwh	**Timestamp Counter** The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = “01”, the Timestamp Counter is incremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero. When TSCC.TSS = “10”, TSC reflects the external Timestamp Counter value. A write access has no impact. *Note: A “wrap around” is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.*
0	31:16	r	**Reserved** Shall read 0, shall be written with 0.

Timeout Counter Configuration i

For a description of the Timeout Counter see **Timeout Counter**

TOCCi (i=0-3)
Timeout Counter Configuration i **(008228_H+i*400_H)** **Application Reset Value: FFFF 0000_H**

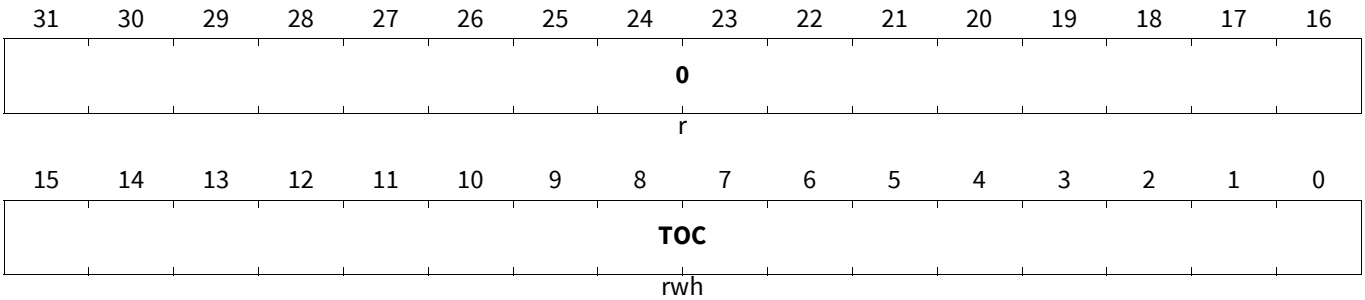


Field	Bits	Type	Description
ETOC	0	rw	**Enable Timeout Counter** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. *Note: For use of timeout function with CAN FD see chapter Timeout Counter.* 0_B Timeout Counter disabled 1_B Timeout Counter enabled
TOS	2:1	rw	**Timeout Select** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC.TOP. Down-counting is started when the first FIFO element is stored. 00_B Continuous operation 01_B Timeout controlled by Tx Event FIFO 10_B Timeout controlled by Rx FIFO 0 11_B Timeout controlled by Rx FIFO 1
TOP	31:16	rw	**Timeout Period** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start value of the Timeout Counter (down-counter). Configures the Timeout Period.
0	15:3	r	**Reserved** Shall read 0, shall be written with 0.

Timeout Counter Value i

TOCVi (i=0-3)

Timeout Counter Value i **($00822C_H$+i*400_H)** **Application Reset Value: 0000 FFFF$_H$**



Field	Bits	Type	Description
TOC	15:0	rwh	**Timeout Counter** The Timeout Counter is decremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC.TCP. When decremented to zero, interrupt flag IR.TOO is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via TOCC.TOS. Any write access will lead to clearing of the counter.
0	31:16	r	**Reserved** Shall read 0, shall be written with 0.

Error Counter Register i

ECRi (i=0-3)
Error Counter Register i **(008240_H+i*400_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RP	REC							TEC							
rh	rh							rh							

Field	Bits	Type	Description
TEC	7:0	rh	**Transmit Error Counter** Actual state of the Transmit Error Counter, values between 0 and 255 *Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.*
REC	14:8	rh	**Receive Error Counter** Actual state of the Receive Error Counter, values between 0 and 127 *Note: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.*
RP	15	rh	**Receive Error Passive** 0_B The Receive Error Counter is below the error passive level of 128 1_B The Receive Error Counter has reached the error passive level of 128

Field	Bits	Type	Description
CEL	23:16	rh	**CAN Error Logging** The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR.ELO. The counter is reset on read, if the bit NPCRi.DELE is set for the node.
0	31:24	r	**Reserved** Shall read 0, shall be written with 0.

Protocol Status Register i

PSRi (i=0-3)

Protocol Status Register i **(008244_H+i*400_H)** **Application Reset Value: 0000 0707_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TDCV						
r									r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	PXE	RFDF	RBRS	RESI	DLEC			BO	EW	EP	ACT		LEC		
r	rh	rh	rh	rh	rh			rh	rh	rh	rh		rh		

Field	Bits	Type	Description
LEC	2:0	rh	**Last Error Code** The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This bit field is set to 0x7 on read, if NPCRi.DELE is set. *Note: The Bus_Off recovery sequence (see ISO11898-1) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.* 000_B No Error: No error occurred since LEC has been reset by successful reception or transmission. 001_B Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010_B Form Error: A fixed format part of a received frame has the wrong format. 011_B Ack Error: The message transmitted by the M_CAN was not acknowledged by another node. 100_B Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101_B Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110_B CRC Error: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111_B No Change: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Field	Bits	Type	Description
ACT	4:3	rh	**Activity** Monitors the module's CAN communication state. *Note: ACT is set to "00" by a Protocol Exception Event.* 00_B Synchronizing - node is synchronizing on CAN communication 01_B Idle - node is neither receiver nor transmitter 10_B Receiver - node is operating as receiver 11_B Transmitter - node is operating as transmitter
EP	5	rh	**Error Passive** 0_B The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1_B The M_CAN is in the Error_Passive state
EW	6	rh	**Warning Status** 0_B Both error counters are below the Error_Warning limit of 96 1_B At least one of error counter has reached the Error_Warning limit of 96
BO	7	rh	**Bus_Off Status** 0_B The M_CAN is not in Bus_Off[1)] 1_B The M_CAN is in Bus_Off state
DLEC	10:8	rh	**Data Phase Last Error Code** Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. This bit field is set to 0x7 on read, if NPCRi.DELE is set. *Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.*
RESI	11	rh	**ESI flag of last received CAN FD Message** This bit is set together with REDF, independent of acceptance filtering. This bit is reset after read access, if NPCRi.DELE is set. 0_B Last received CAN FD message did not have its ESI flag set 1_B Last received CAN FD message had its ESI flag set
RBRS	12	rh	**BRS flag of last received CAN FD Message** This bit is set together with REDF, independent of acceptance filtering. This bit is reset after read access, if NPCRi.DELE is set. 0_B Last received CAN FD message did not have its BRS flag set 1_B Last received CAN FD message had its BRS flag set

Field	Bits	Type	Description
RFDF	13	rh	**Received a CAN FD Message** This bit is set independent of acceptance filtering. This bit is reset after read access, if NPCRi.DELE is set. 0_B Since this bit was reset by the CPU, no CAN FD message has been received 1_B Message in CAN FD format with FDF flag set, has been received
PXE	14	rh	**Protocol Exception Event** This bit is reset after read access, if NPCRi.DELE is set. 0_B No protocol exception event occurred since last read access 1_B Protocol exception event occurred
TDCV	22:16	r	**Transmitter Delay Compensation Value** Position of the secondary sample point, defined by the sum of the measured delay from TX to RX and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
0	15, 31:23	r	**Reserved** Shall read 0, shall be written with 0.

1) The Bus_Off recovery sequence (see ISO11898-1) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.

Transmitter Delay Compensation Register i

TDCRi (i=0-3)

Transmitter Delay Compensation Register i(008248_H+i*400_H) **Application Reset Value: $0000\ 0000_H$**

r	rw							r	rw						

Field	Bits	Type	Description
TDCF	6:0	rw	**Transmitter Delay Compensation Filter Window Length** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Defines the minimum value for the Secondary Sample Point position, dominant edges on RX that would result in an earlier Secondary Sample Point position are ignored for transmitter delay measurement. This feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are from 0 to 127 mtq.

Field	Bits	Type	Description
TDCO	14:8	rw	**Transmitter Delay Compensation Offset** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Offset value defining the distance between the measured delay from TX to RX and the secondary sample point. Valid values are 0 to 127 mtq. The duration of one mtq is equal to the fASYNi clock period.
0	7, 31:15	r	**Reserved** Shall read 0, shall be written with 0.

Interrupt Register i

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a “1” to the corresponding bit position. Writing a “0” has no effect. The configuration of IE controls whether an interrupt is generated.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.

IRi (i=0-3)
Interrupt Register i **(008250_H+i*400_H)** **Application Reset Value: 0000 0000_H**

TEFL	15	rwh	**Tx Event FIFO Element Lost** 0_B No Tx Event FIFO element lost 1_B Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
TSW	16	rwh	**Timestamp Wraparound** 0_B No timestamp counter wrap-around 1_B Timestamp counter wrapped around

Field	Bits	Type	Description
MRAF	17	rwh	**Message RAM Access Failure** The flag is set, when the Rx Handler • has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. • was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the M_CAN is switched into Restricted Operation Mode. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0_B No Message RAM access failure occurred 1_B Message RAM access failure occurred
TOO	18	rwh	**Timeout Occurred** 0_B No timeout 1_B Timeout reached
DRX	19	rwh	**Message stored to Dedicated Rx Buffer** The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0_B No Rx Buffer updated 1_B At least one received message stored into an Rx Buffer
ELO	22	rwh	**Error Logging Overflow** 0_B CAN Error Logging Counter did not overflow 1_B Overflow of CAN Error Logging Counter occurred
EP	23	rwh	**Error Passive** 0_B Error_Passive status unchanged 1_B Error_Passive status changed
EW	24	rwh	**Warning Status** 0_B Error_Warning status unchanged 1_B Error_Warning status changed
BO	25	rwh	**Bus_Off Status** 0_B Bus_Off status unchanged 1_B Bus_Off status changed
WDI	26	rwh	**Watchdog Interrupt** 0_B No Message RAM Watchdog event occurred 1_B Message RAM Watchdog event due to missing READY

Field	Bits	Type	Description
PEA	27	rwh	**Protocol Error in Arbitration Phase** (Nominal Bit Time is used) 0_B No protocol error in arbitration phase 1_B Protocol error in arbitration phase detected (PSR.LEC ≠ 0,7)
PED	28	rwh	**Protocol Error in Data Phase** (Data Bit Time is used) 0_B No protocol error in data phase detected 1_B Protocol error in data phase detected (PSR.DLEC ≠ 0,7)
0	20, 21, 29, 31:30	r	**Reserved** Shall read 0, shall be written with 0.

Interrupt Enable i

The settings in the Interrupt Enable register determine which status changes in the Interrupt Register will be signalled on an interrupt line.

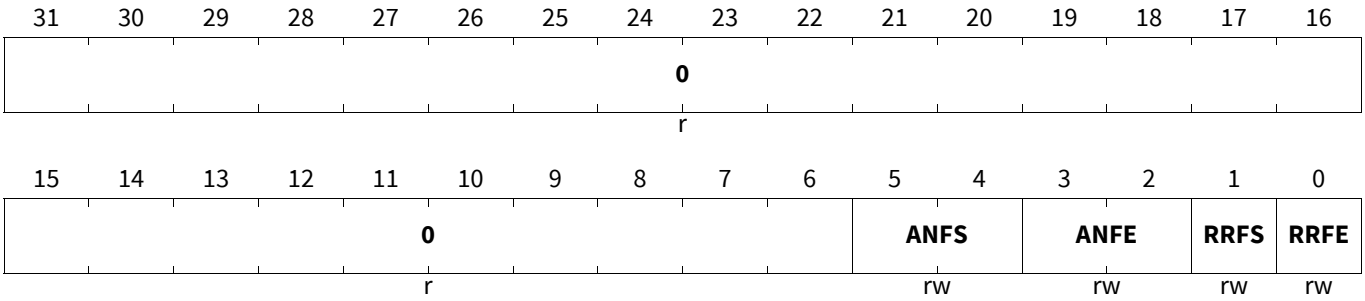
Global Filter Configuration i

Global settings for Message ID filtering. The Global Filter Configuration controls the filter path for standard and extended messages as described in **Figure 594** and **Figure 595**.

GFCi (i=0-3)
Global Filter Configuration i **(008280_H+i*400_H)** **Application Reset Value: 0000 0000_H**



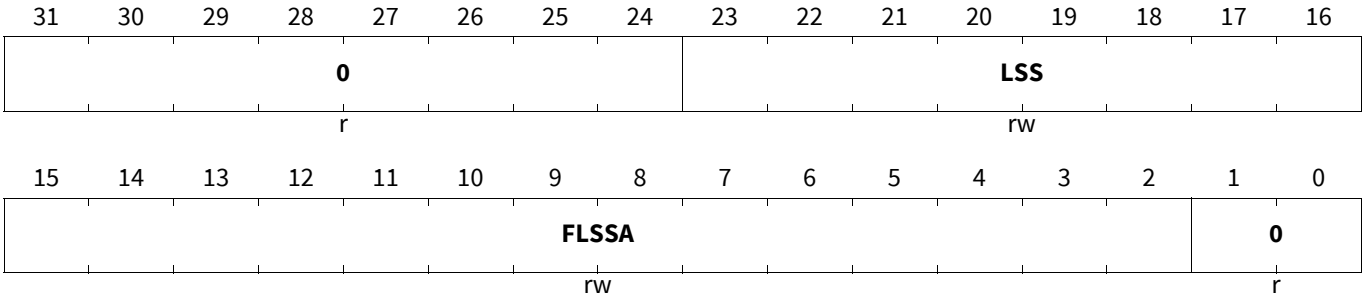
Field	Bits	Type	Description
RRFE	0	rw	**Reject Remote Frames Extended** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Filter remote frames with 29-bit extended IDs 1_B Reject all remote frames with 29-bit extended IDs
RRFS	1	rw	**Reject Remote Frames Standard** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Filter remote frames with 11-bit standard IDs 1_B Reject all remote frames with 11-bit standard IDs
ANFE	3:2	rw	**Accept Non-matching Frames Extended** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated. 00_B Accept in Rx FIFO 0 01_B Accept in Rx FIFO 1 10_B Reject 11_B Reject
ANFS	5:4	rw	**Accept Non-matching Frames Standard** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated. 00_B Accept in Rx FIFO 0 01_B Accept in Rx FIFO 1 10_B Reject 11_B Reject
0	31:6	r	**Reserved** Shall read 0, shall be written with 0.

Standard ID Filter Configuration i

Settings for 11-bit standard Message ID filtering. The Standard ID Filter Configuration controls the filter path for standard messages.

SIDFCi (i=0-3)

Standard ID Filter Configuration i **(008284_H+i*400_H)** **Application Reset Value: 0000 0000_H**

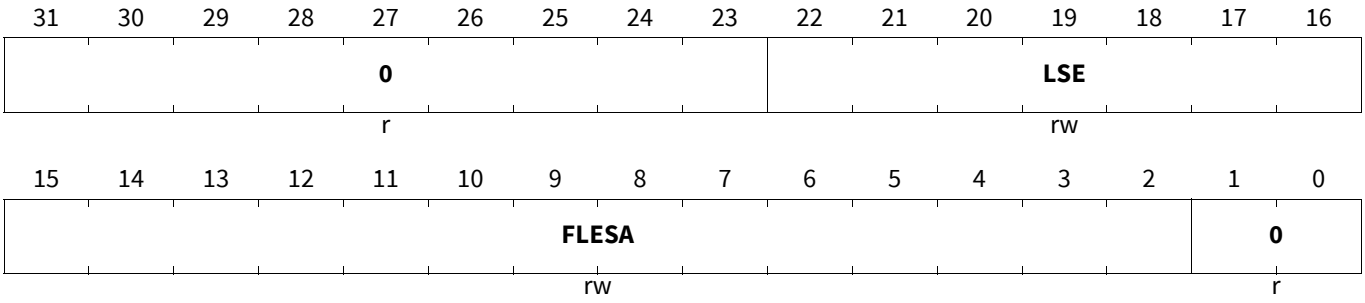


Field	Bits	Type	Description
FLSSA	15:2	rw	**Filter List Standard Start Address** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of standard Message ID filter list (32-bit word address).
LSS	23:16	rw	**List Size Standard** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_H No standard Message ID filter 01_H 1 Message ID filter elements … 80_H 128 Message ID filter elements **others**, 128 Message ID filter elements
0	1:0, 31:24	r	**Reserved** Shall read 0, shall be written with 0.

Extended ID Filter Configuration i

Settings for 29-bit extended Message ID filtering. The Extended ID Filter Configuration controls the filter path for standard messages as described in **Figure 595**.

XIDFCi (i=0-3)
Extended ID Filter Configuration i **(008288_H+i*400_H)** **Application Reset Value: 0000 0000_H**



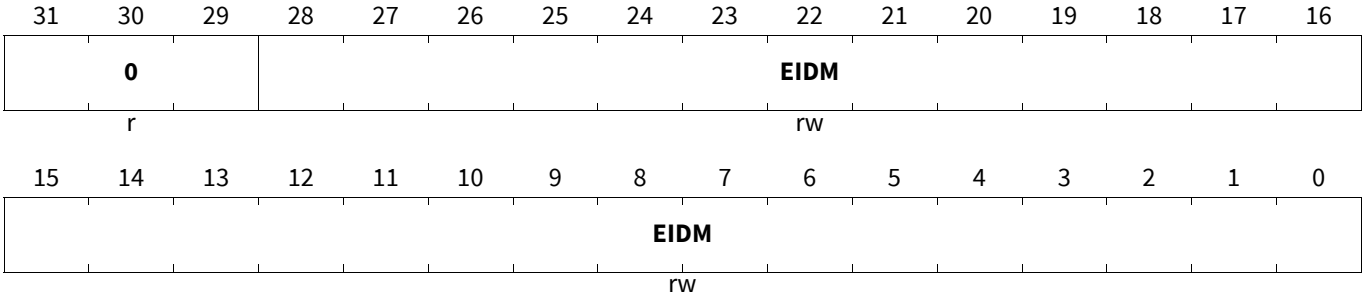
Field	Bits	Type	Description
FLESA	15:2	rw	**Filter List Extended Start Address** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of extended Message ID filter list (32-bit word addess).
LSE	22:16	rw	**List Size Extended** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_H No standard Message ID filter 01_H 1 extended Message ID filter element … 40_H 64 extended Message ID filter element **others**, 64 extended Message ID filter elements

Field	Bits	Type	Description
0	1:0, 31:23	r	**Reserved** Shall read 0, shall be written with 0.

Extended ID AND Mask i

XIDAMi (i=0-3)

Extended ID AND Mask i **(008290_H+i*400_H)** **Application Reset Value: 1FFF FFFF$_H$**



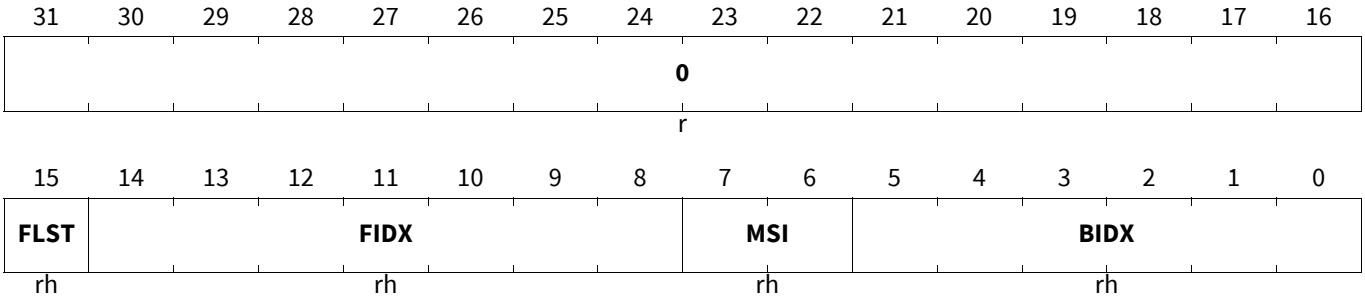
Field	Bits	Type	Description
EIDM	28:0	rw	**Extended ID Mask** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.
0	31:29	r	**Reserved** Shall read 0, shall be written with 0.

High Priority Message Status i

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

HPMSi (i=0-3)

High Priority Message Status i **(008294_H+i*400_H)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
BIDX	5:0	rh	**Buffer Index** Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = '1'.
MSI	7:6	rh	**Message Storage Indicator** 00_B No FIFO selected 01_B FIFO message lost 10_B Message stored in FIFO 0 11_B Message stored in FIFO 1
FIDX	14:8	rh	**Filter Index** Index of matching filter element. Range is 0 to SIDFC.LSS - 1 resp. XIDFC.LSE - 1.
FLST	15	rh	**Filter List** Indicates the filter list of the matching filter element. 0_B Standard Filter List 1_B Extended Filter List
0	31:16	r	**Reserved** Shall read 0, shall be written with 0.

New Data 1 i

The register holds the New Data flags of Rx Buffers 0 to 31.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.

NDAT1i (i=0-3)
New Data 1 i **(008298_H+i*400_H)** **Application Reset Value: 0000 0000_H**

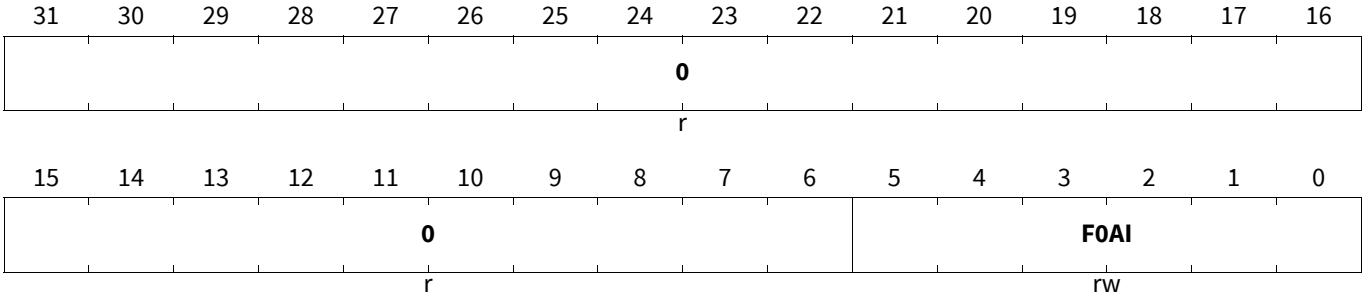
r		rh						r		rh					

Field	Bits	Type	Description
F0FL	6:0	rh	**Rx FIFO 0 Fill Level** Number of elements stored in Rx FIFO 0, range 0 to 64.
F0GI	13:8	rh	**Rx FIFO 0 Get Index** Rx FIFO 0 read index pointer, range 0 to 63.
F0PI	21:16	rh	**Rx FIFO 0 Put Index** Rx FIFO 0 write index pointer, range 0 to 63.

Field	Bits	Type	Description
F0F	24	rh	**Rx FIFO 0 Full** 0_B Rx FIFO 0 not full 1_B Rx FIFO 0 full
RF0L	25	rh	**Rx FIFO 0 Message Lost** This bit is a copy of interrupt flag IR.RF0L. When IR.RF0L is reset, this bit is also reset. *Note: Overwriting the oldest message when RXF0C.F0OM = '1' will not set this flag.* 0_B No Rx FIFO 0 message lost 1_B Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
0	7, 15:14, 23:22, 31:26	r	**Reserved** Shall read 0, shall be written with 0.

Rx FIFO 0 Acknowledge i

RXF0Ai (i=0-3)
Rx FIFO 0 Acknowledge i **($0082A8_H$+i*400_H)** **Application Reset Value: 0000 0000_H**

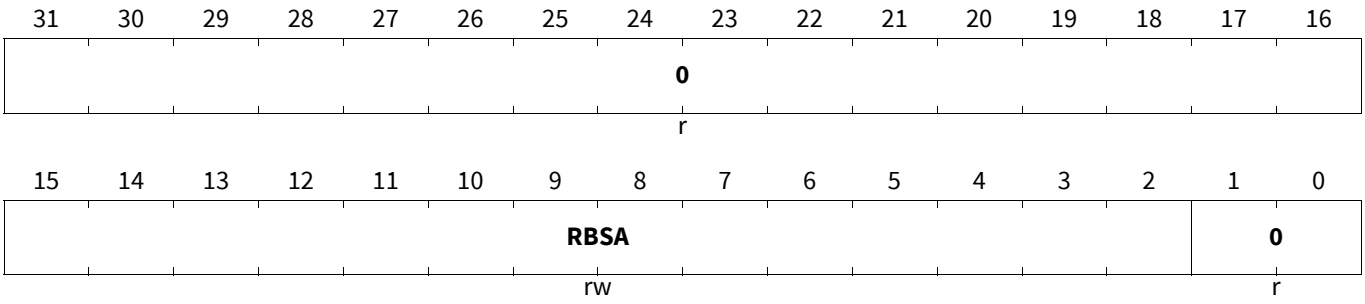


Field	Bits	Type	Description
F0AI	5:0	rw	**Rx FIFO 0 Acknowledge Index** After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This will set the Rx FIFO 0 Get Index RXF0S.F0GI to F0AI + 1 and update the FIFO 0 Fill Level RXF0S.F0FL.
0	31:6	r	**Reserved** Shall read 0, shall be written with 0.

Rx Buffer Configuration i

RXBCi (i=0-3)

Rx Buffer Configuration i **(0082AC$_H$+i*400$_H$)** **Application Reset Value: 0000 0000$_H$**

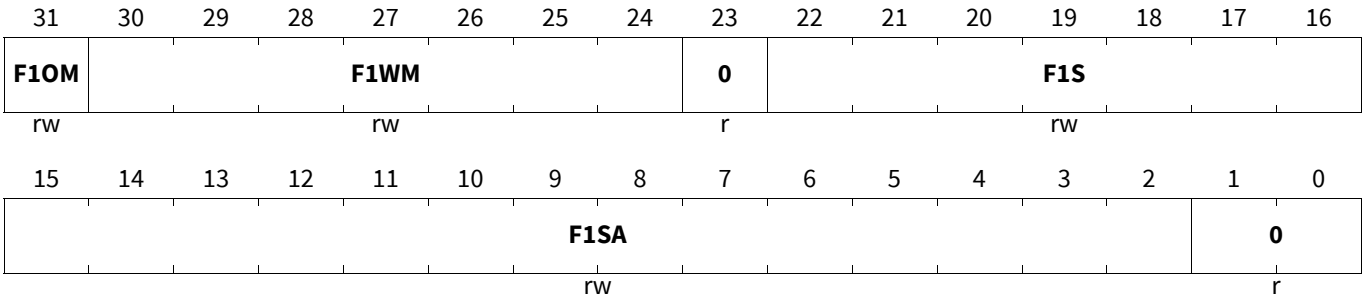


Field	Bits	Type	Description
RBSA	15:2	rw	**Rx Buffer Start Address** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Configures the start address of the Rx Buffers section in the Message RAM (32-bit word address).
0	1:0, 31:16	r	**Reserved** Shall read 0, shall be written with 0.

Rx FIFO 1 Configuration i

RXF1Ci (i=0-3)

Rx FIFO 1 Configuration i **(0082B0$_H$+i*400$_H$)** **Application Reset Value: 0000 0000$_H$**



Field	Bits	Type	Description
F1SA	15:2	rw	**Rx FIFO 1 Start Address** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of Rx FIFO 1 in Message RAM (32-bit word address).

Field	Bits	Type	Description
F1S	22:16	rw	**Rx FIFO 1 Size** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_H No Rx FIFO 1 01_H 1 Rx FIFO 1 elements … 40_H 64 Rx FIFO 1 elements **others**, 64 Rx FIFO 1 elements
F1WM	30:24	rw	**Rx FIFO 1 Watermark** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 01_H Level for Rx FIFO 1 watermark interrupt (IR.RF1W) … 40_H Level for Rx FIFO 1 watermark interrupt (IR.RF1W) **others**, Watermark interrupt disabled
F1OM	31	rw	**FIFO 1 Operation Mode** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. FIFO 1 can be operated in blocking or in overwrite mode. 0_B FIFO 1 blocking mode 1_B FIFO 1 overwrite mode
0	1:0, 23	r	**Reserved** Shall read 0, shall be written with 0.

Tx Buffer Request Pending i

Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR.

TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (Tx Handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).

A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.

After a cancellation has been requested, a finished cancellation is signalled via TXBCF

- after successful transmission together with the corresponding TXBTO bit
- when the transmission has not yet been started at the point of cancellation
- when the transmission has been aborted due to lost arbitration
- when an error occurred during frame transmission

In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.

Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this "Add Request" is cancelled immediately, the corresponding TXBRP bit is reset.

TXBRPi (i=0-3)

Tx Buffer Add Request i

Each Tx Buffer has its own "Add Request" bit. Writing a ‘1’ will set the corresponding "Add Request" bit; writing a ‘0’ has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to

TXBAR. TXBAR bits are set only for those Tx Buffers configured via TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored. LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.

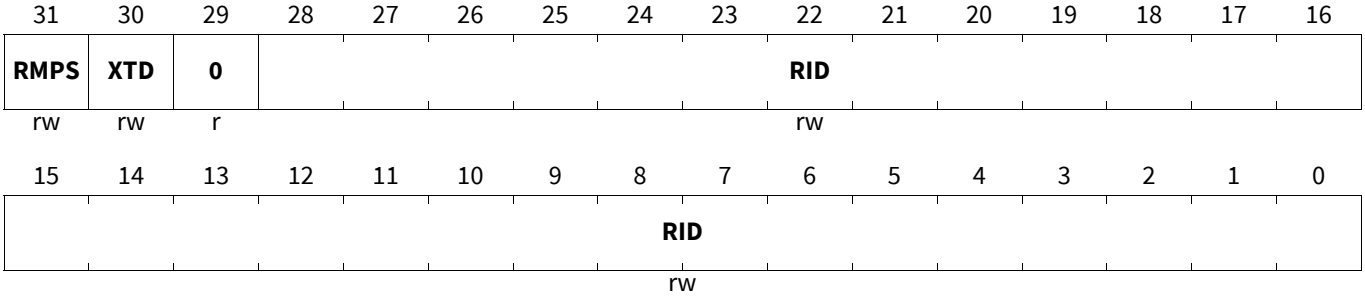
TMSA	15:2	rw	**Trigger Memory Start Address** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of Trigger Memory in Message RAM.
TME	22:16	rw	**Trigger Memory Elements** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_H No Trigger Memory 01_H 1 Trigger Memory element … 40_H 64 Trigger Memory element **others**, 64 Trigger Memory elements
0	1:0, 31:23	r	**Reserved** Shall read 0, shall be written with 0.

TT Reference Message Configuration 0

The TTCAN function exists only on CAN0 node 0. For details about handling of reference messages.

TTRMC0

TT Reference Message Configuration 0 (008304$_H$) Application Reset Value: 0000 0000$_H$



Field	Bits	Type	Description
RID	28:0	rw	**Reference Identifier** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Identifier transmitted with reference message and used for reference message filtering. Standard or extended reference identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
XTD	30	rw	**Extended Identifier** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B 11-bit standard identifier 1_B 29-bit extended identifier
RMPS	31	rw	**Reference Message Payload Select** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Ignored in case of time slaves. 0_B Reference message has no additional payload 1_B The following elements are taken from Tx Buffer 0: Message Marker MM, Event FIFO Control EFC, Data Length Code DLC, Data Bytes DB (Level 1: bytes 2-8, Level 0,2: bytes 5-8)
0	29	r	**Reserved** Shall read 0, shall be written with 0.

TT Operation Configuration 0

The TTCAN function exists only on CAN0 node 0.

TTOCF0

TT Operation Configuration 0 **(008308$_H$)** **Application Reset Value: 0001 0000$_H$**

Field	Bits	Type	Description
OM	1:0	rw	**Operation Mode** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_B Event-driven CAN communication, default 01_B TTCAN level 1 10_B TTCAN level 2 11_B TTCAN level 0
GEN	3	rw	**Gap Enable** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Strictly time-triggered operation 1_B External event-synchronized time-triggered operation
TM	4	rw	**Time Master** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Time Master function disabled 1_B Potential Time Master
LDSDL	7:5	rw	**LD of Synchronization Deviation Limit** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. The Synchronization Deviation Limit SDL is configured by its dual logarithm LDSDL with SDL = $2^{(LDSDL+5)}$. It should not exceed the clock tolerance given by the CAN bit timing configuration. LD of Synchronization Deviation Limit (SDL ≤ 32…4096)
IRTO	14:8	rw	**Initial Reference Trigger Offset** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Positive offset, range from 0 to 127

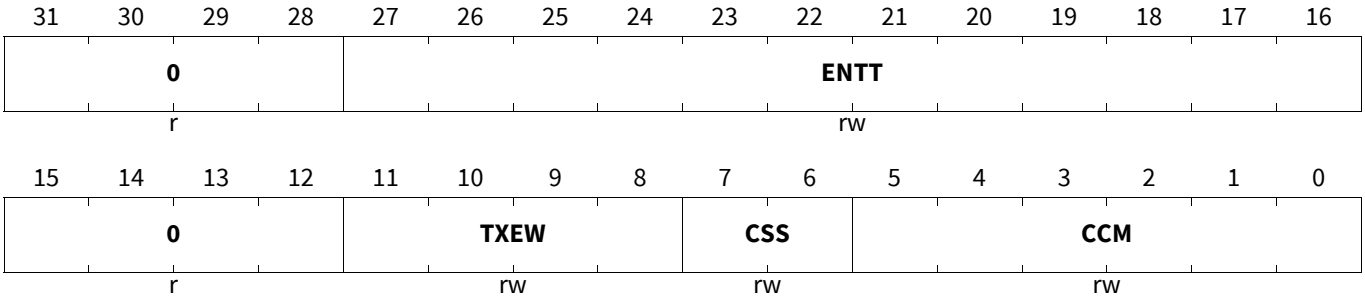
Field	Bits	Type	Description
EECS	15	rw	**Enable External Clock Synchronization** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. If enabled, TUR configuration (TURCF.NCL only) may be updated during TTCAN operation. 0_B External clock synchronization in TTCAN Level 0,2 disabled 1_B External clock synchronization in TTCAN Level 0,2 enabled
AWL	23:16	rw	**Application Watchdog Limit** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. The application watchdog can be disabled by programming AWL to 0x00. Maximum time after which the application has to serve the application watchdog. The application watchdog is incremented once each 256 NTUs.
EGTF	24	rw	**Enable Global Time Filtering** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Global time filtering in TTCAN Level 0,2 is disabled 1_B Global time filtering in TTCAN Level 0,2 is enabled
ECC	25	rw	**Enable Clock Calibration** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Automatic clock calibration in TTCAN Level 0,2 is disabled 1_B Automatic clock calibration in TTCAN Level 0,2 is enabled
EVTP	26	rw	**Event Trigger Polarity** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Rising edge trigger 1_B Falling edge trigger
0	2, 31:27	r	**Reserved** Shall read 0, shall be written with 0.

TT Matrix Limits 0

The TTCAN function exists only on CAN0 node 0.

TTMLM0

TT Matrix Limits 0 **($00830C_H$)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CCM	5:0	rw	**Cycle Count Max** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. *Note: ISO 11898-4, 5.2.1 requires, that only the listed cycle count values are configured. Other values are possible but may lead to inconsistent matrix cycles.* 00_H 1 Basic Cycle per Matrix Cycle 01_H 2 Basic Cycles per Matrix Cycle 03_H 4 Basic Cycles per Matrix Cycle 07_H 8 Basic Cycles per Matrix Cycle $0F_H$ 16 Basic Cycles per Matrix Cycle $1F_H$ 32 Basic Cycles per Matrix Cycle $3F_H$ 64 Basic Cycles per Matrix Cycle **others**, Reserved
CSS	7:6	rw	**Cycle Start Synchronization** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Enables sync pulse output at start of cycle. 00_B No sync pulse 01_B Sync pulse at start of basic cycle 10_B Sync pulse at start of matrix cycle 11_B Reserved
TXEW	11:8	rw	**Tx Enable Window** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Length of Tx enable window, 1-16 NTU cycles
ENTT	27:16	rw	**Expected Number of Tx Triggers** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Expected number of Tx Triggers in one Matrix Cycle
0	15:12, 31:28	r	**Reserved** Shall read 0, shall be written with 0.

TUR Configuration 0

The TTCAN function exists only on CAN0 node 0.

The length of the NTU is given by: NTU = CAN Clock Period x NC / DC

NC is an 18-bit value. Its high part, NCH[17:16] is hard wired to 0b01. Therefore the range of NC is 10000_H…$1FFFF_H$. The value configured by NCL is the initial value for TURNA.NAV[15:0]. DC is set to 1000_H by hardware reset and it may not be written to 0000_H.

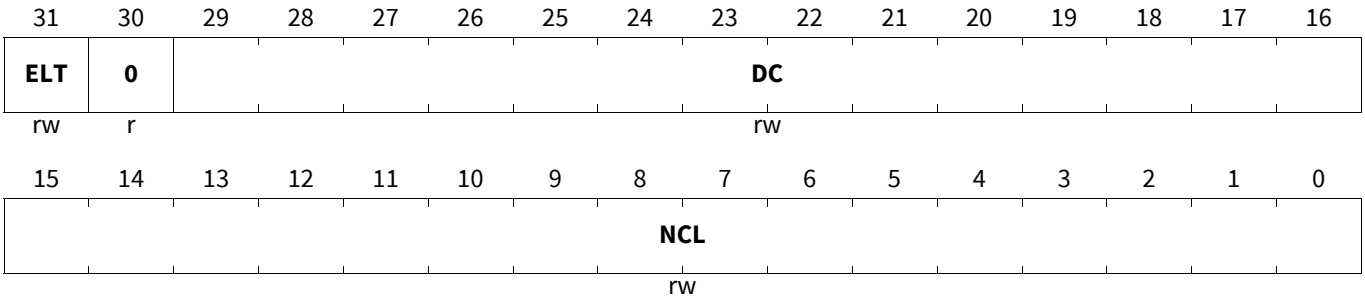
Level 1: NC ≥ 4 x DC and NTU = CAN bit time

Level 0,2: NC ≥ 8 x DC

The actual value of TUR may be changed by the clock drift compensation function of TTCAN Level 0 and Level 2 in order to adjust the node's local view of the NTU to the time master's view of the NTU. DC will not be changed

by the automatic drift compensation, TURNA.NAV may be adjusted around NC in the range of the Synchronisation Deviation Limit given by TTOCF.LDSDL. NC and DC should be programmed to the largest suitable values in order to allow the best computational accuracy for the drift compensation process.

TURCF0
TUR Configuration 0 **(008310_H)** **Application Reset Value: $1000\ 0000_H$**



Field	Bits	Type	Description
NCL	15:0	rw	**Numerator Configuration Low** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. Write access to the TUR Numerator Configuration Low is only possible during configuration with TURCF.ELT = ‘0’ or if TTOCF.EECS (external clock synchronization enabled) is set. When a new value for NCL is written outside TT Configuration Mode, the new value takes effect when TTOST.WECS is cleared to ‘0’. NCL is locked TTOST.WECS is ‘1’. *Note: If NC < 7 x DC in TTCAN Level 1, then it is required that subsequent time marks in the Trigger Memory must differ by at least 2 NTU.* 0000_HNumerator Configuration Low … $FFFF_H$Numerator Configuration Low
DC	29:16	rw	**Denominator Configuration** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. 0000_HIllegal value 0001_HDenominator Configuration … $3FFF_H$Denominator Configuration

Field	Bits	Type	Description
ELT	31	rw	**Enable Local Time** This bitfield is CCE and INIT protected. Writes will only have effect, if both bits are set. *Note: Local time is started by setting ELT. It remains active until ELT is reset or until the next hardware reset. TURCF.DC is locked when TURCF.ELT = '1'. If ELT is written to '0', the readable value will stay at '1' until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register remains locked.* 0_B Local time is stopped, default 1_B Local time is enabled
0	30	r	**Reserved** Shall read 0, shall be written with 0.

TT Operation Control 0

The TTCAN function exists only on CAN0 node 0.

TTOCN0

TT Operation Control 0 **(008314_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	r	rw	rwh	rw	rwh	rw	rw	rw		rw	rw		rw	rwh	rwh

Field	Bits	Type	Description
SGT	0	rwh	**Set Global time** Writing a '1' to SGT sets TTOST.WGDT if the node is the actual Time Master. SGT is reset after one Host clock period. The global time preset takes effect when the node transmits the next reference message with the Master_Ref_Mark modified by the preset value written to TTGTP.
ECS	1	rwh	**External Clock Synchronization** Writing a '1' to ECS sets TTOST.WECS if the node is the actual Time Master. ECS is reset after one Host clock period. The external clock synchronization takes effect at the start of the next basic cycle.
SWP	2	rw	**Stop Watch Polarity** 0_B Rising edge trigger 1_B Falling edge trigger

Field	Bits	Type	Description
SWS	4:3	rw	**Stop Watch Source** 00_B Stop Watch disabled 01_B Actual value of cycle time is copied to TTCPT.SWV 10_B Actual value of local time is copied to TTCPT.SWV 11_B Actual value of global time is copied to TTCPT.SWV
RTIE	5	rw	**Register Time Mark Interrupt Pulse Enable** Register time mark interrupts are configured by register TTTMK. A register time mark interrupt pulse with the length of one TTCAN clock period is generated when the time referenced by TTOCN.TMC (cycle, local, or global) equals TTTMK.TM, independent of the synchronization state. 0_B Register Time Mark Interrupt output disabled 1_B Register Time Mark Interrupt output enabled
TMC	7:6	rw	**Register Time Mark Compare** *Note: When changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = "00", then reconfigure TTTMK, and finally set TMC to the intended time reference.* 00_B No Register Time Mark Interrupt generated 01_B Register Time Mark Interrupt if Time Mark = cycle time 10_B Register Time Mark Interrupt if Time Mark = local time 11_B Register Time Mark Interrupt if Time Mark = global time
TTIE	8	rw	**Trigger Time Mark Interrupt Pulse Enable** External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the M_CAN is in synchronization state In_Schedule or In_Gap. 0_B Trigger Time Mark Interrupt output disabled 1_B Trigger Time Mark Interrupt output enabled
GCS	9	rw	**Gap Control Select** 0_B Gap control independent from event trigger 1_B Gap control by the event trigger
FGP	10	rwh	**Finish Gap** Set by the CPU, reset by each reference message 0_B No reference message requested 1_B Application requested start of reference message
TMG	11	rw	**Time Mark Gap** 0_B Reset by each reference message 1_B Next reference message started when Register Time Mark interrupt TTIR.RTMI is activated

Field	Bits	Type	Description
NIG	12	rwh	**Next is Gap** This bit can only be set when the M_CAN is the actual Time Master and when it is configured for external event-synchronized time-triggered operation (TTOCF.GEN = '1') 0_B No action, reset by reception of any reference message 1_B Transmit next reference message with Next_is_Gap = '1'
ESCN	13	rw	**External Synchronization Control** If enabled the M_CAN synchronizes its cycle time phase to an external event signalled by a rising edge at the event trigger. 0_B External synchronization disabled 1_B External synchronization enabled
LCKC	15	rh	**TT Operation Control Register Locked** Set by a write access to register TTOCN. Reset when the updated configuration has been synchronized into the CAN clock domain. 0_B Write access to TTOCN enabled 1_B Write access to TTOCN locked
0	14, 31:16	r	**Reserved** Shall read 0, shall be written with 0.

TT Global Time Preset 0

If TTOST.WGDT is set, the next reference message will be transmitted with the Master_Ref_Mark modified by the preset value and with Disc_Bit = '1', presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a reference message with Disc_Bit = '1' becomes valid or if the node is not the current Time Master. TP is locked while TTOST.WGTD = '1' after setting TTOCN.SGT until the reference message with Disc_Bit = '1' becomes valid or until the node is no longer the current Time Master.

The TTCAN function exists only on CAN0 node 0.

TTGTP0

TT Global Time Preset 0 **(008318_H)** **Application Reset Value: $0000\ 0000_H$**

QCS	7	rh	**Quality of Clock Speed** Only relevant in TTCAN Level 0 and Level 2, otherwise fixed to '1'. 0_B Local clock speed not synchronized to Time Master clock speed 1_B Synchronization Deviation ≤ SDL
RTO	15:8	rh	**Reference Trigger Offset** The Reference Trigger Offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F). There is no notification when the lower limit of -127 is reached. In case the M_CAN becomes Time Master (MS[1:0] = "11"), the reset of RTO is delayed due to synchronization between Host and CAN clock domain. For time slaves the value configured by TTOCF.IRTO is read. Actual Reference Trigger offset value
WGTD	22	rh	**Wait for Global Time Discontinuity** 0_B No global time preset pending 1_B Node waits for the global time preset to take effect. The bit is reset when the node has transmitted a reference message with Disc_Bit = '1' or after it received a reference message.
GFI	23	rh	**Gap Finished Indicator** Set when the CPU writes TTOCN.FGP, or by a time mark interrupt if TMG = '1', or via event trigger input if TTOCN.GCS = '1'. Not set by Ref_Trigger_Gap or when Gap is finished by another node sending a reference message. 0_B Reset at the end of each reference message 1_B Gap finished by M_CAN
TMP	26:24	rh	**Time Master Priority** 000_B Priority of actual Time Master … 111_B Priority of actual Time Master
GSI	27	rh	**Gap Started Indicator** 0_B No Gap in schedule, reset by each reference message and for all time slaves 1_B Gap time after Basic Cycle has started
WFE	28	rh	**Wait for Event** 0_B No Gap announced, reset by a reference message with Next_is_Gap = '0' 1_B Reference message with Next_is_Gap = '1' received

Field	Bits	Type	Description
AWE	29	rh	**Application Watchdog Event** The application watchdog is served by reading TTOST. When the watchdog is not served in time, bit AWE is set, all TTCAN communication is stopped, and the M_CAN is set into Bus Monitoring Mode. 0_B Application Watchdog served in time 1_B Failed to serve Application Watchdog in time
WECS	30	rh	**Wait for External Clock Synchronization** 0_B No external clock synchronization pending 1_B Node waits for external clock synchronization to take effect. The bit is reset at the start of the next basic cycle.
SPL	31	rh	**Schedule Phase Lock** The bit is valid only when external synchronization is enabled (TTOCN.ESCN = '1'). In this case it signals that the difference between cycle time configured by TTGTP.CTP and the cycle time at the rising edge at the event trigger is less or equal 9 NTU. 0_B Phase outside range 1_B Phase inside range
0	21:16	r	**Reserved** **Shall read 0, shall be written with 0.**

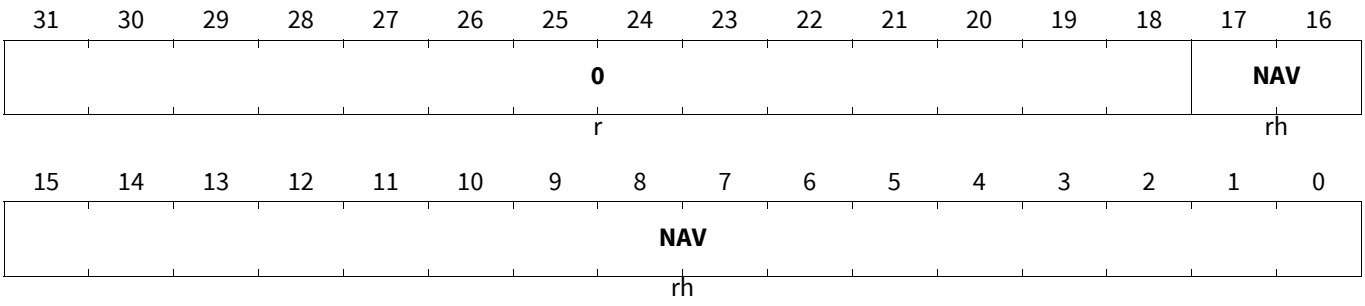
TUR Numerator Actual 0

The TTCAN function exists only on CAN0 node 0.

There is no drift compensation in TTCAN Level 1 (NAV = NC). In TTCAN Level 0 and Level 2, the drift between the node's local clock and the time master's local clock is calculated. The drift is compensated when the Synchronisation Deviation (difference between NC and the calculated NAV) is not more than $2^{(TTOCF.LDSDL + 5)}$. With TTOCF.LDSDL ≤ 7, this results in a maximum range for NAV of (NC - 0x1000) ≤ NAV ≤ (NC + 0x1000).

TURNA0

TUR Numerator Actual 0 **(008330_H)** **Application Reset Value: $0001\ 0000_H$**



Field	Bits	Type	Description
NAV	17:0	rh	**Numerator Actual Value** $0F000_H$ Actual numerator value … $20FFF_H$ Actual numerator value **others**, Illegal value

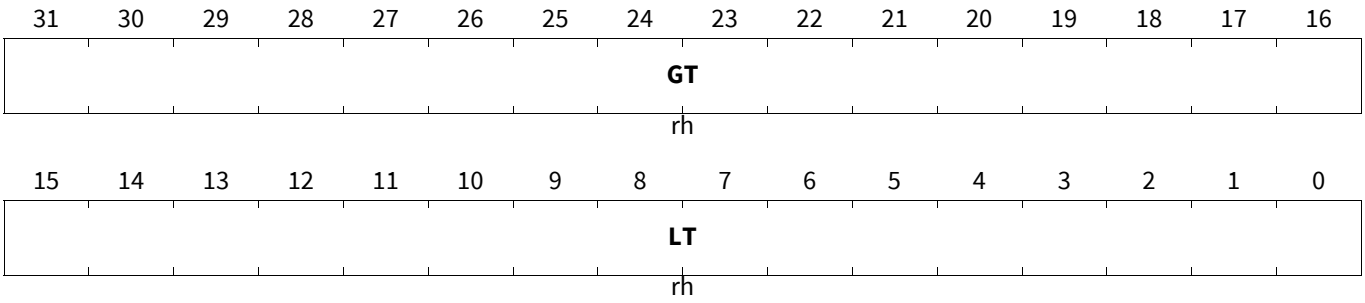
Field	Bits	Type	Description
0	31:18	r	**Reserved** Shall read 0, shall be written with 0.

TT Local & Global Time 0

The TTCAN function exists only on CAN0 node 0.

TTLGT0

TT Local & Global Time 0 **(008334$_H$)** **Application Reset Value: 0000 0000$_H$**



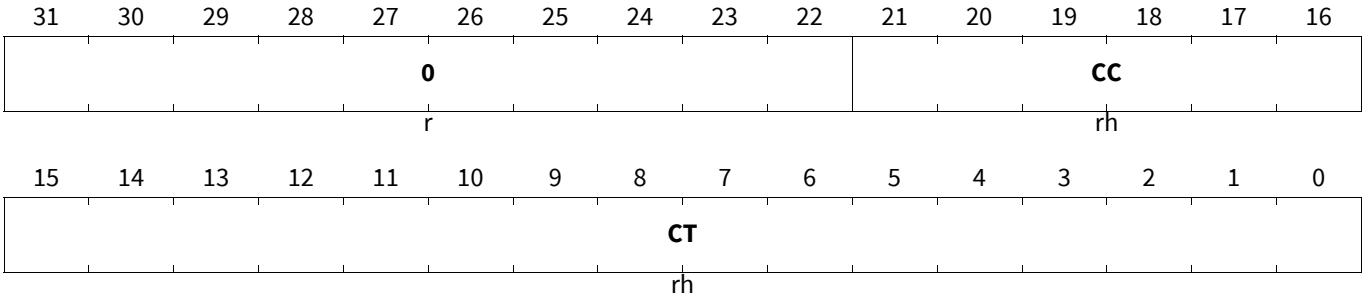
Field	Bits	Type	Description
LT	15:0	rh	**Local Time** Non-fractional part of local time, incremented once each local NTU. Local time value of TTCAN node
GT	31:16	rh	**Global Time** Non-fractional part of the sum of the node's local time and its local offset. Global time value of TTCAN network

TT Cycle Time & Count 0

The TTCAN function exists only on CAN0 node 0.

TTCTC0

TT Cycle Time & Count 0 **(008338$_H$)** **Application Reset Value: 003F 0000$_H$**



Field	Bits	Type	Description
CT	15:0	rh	**Cycle Time** Non-fractional part of the difference of the node's local time and Ref_Mark. Cycle time value of TTCAN Basic Cycle

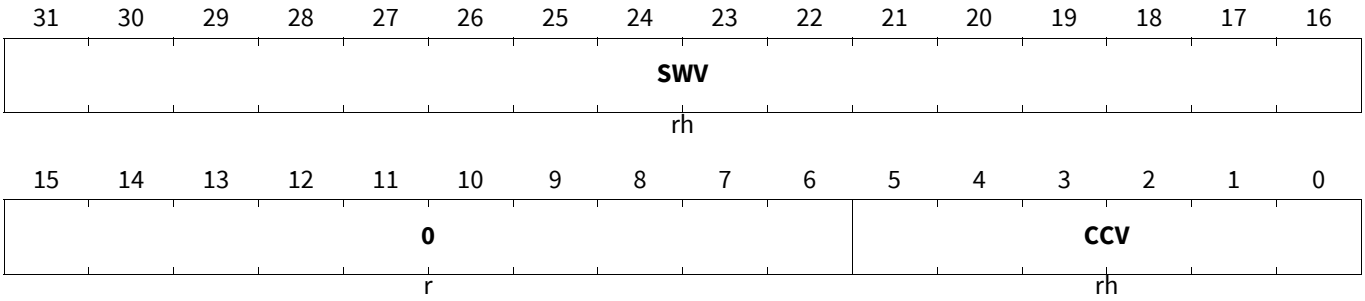
Field	Bits	Type	Description
CC	21:16	rh	**Cycle Count** Number of actual Basic Cycle in the System Matrix
0	31:22	r	**Reserved** Shall read 0, shall be written with 0.

TT Capture Time 0

The TTCAN function exists only on CAN0 node 0.

TTCPT0

TT Capture Time 0 **(00833C$_H$)** **Application Reset Value: 0000 0000$_H$**



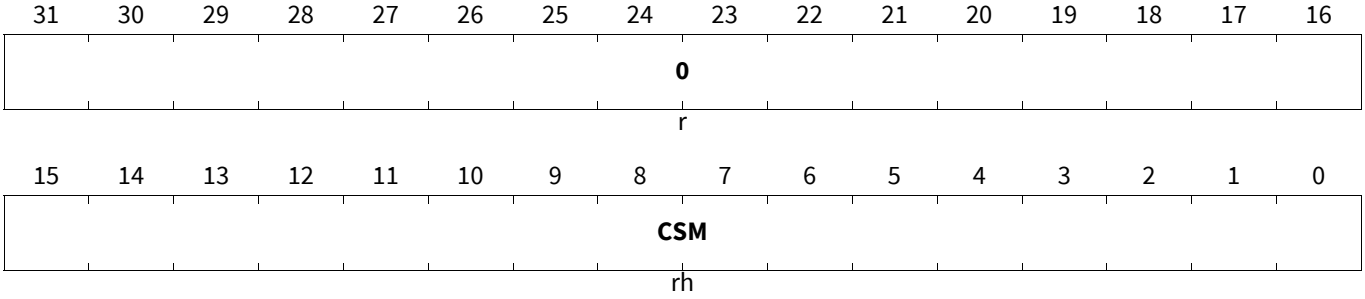
Field	Bits	Type	Description
CCV	5:0	rh	**Cycle Count Value** Cycle count value captured together with SWV. Captured cycle count value
SWV	31:16	rh	**Stop Watch Value** On a rising/falling edge (as configured via TTOCN.SWP) at the Stop Watch Trigger, when TTOCN.SWS is ≠ “00” and TTIR.SWE is ‘0’, the actual time value as selected by TTOCN.SWS (cycle, local, global) is copied to SWV and TTIR.SWE will be set to ‘1’. Capturing of the next stop watch value is enabled by resetting TTIR.SWE. Captured Stop Watch value
0	15:6	r	**Reserved** Shall read 0, shall be written with 0.

TT Cycle Sync Mark 0

The TTCAN function exists only on CAN0 node 0.

TTCSM0

TT Cycle Sync Mark 0 **(008340_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
CSM	15:0	rh	**Cycle Sync Mark** The Cycle Sync Mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid. Captured cycle time
0	31:16	r	**Reserved** Shall read 0, shall be written with 0.

40.4.6 Message RAM

M_CAN

40.4.6.1 Message RAM Configuration

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESCi.F0DS, RXESCi.F1DS, RXESCi.RBDS, and TXESCi.TBDS.

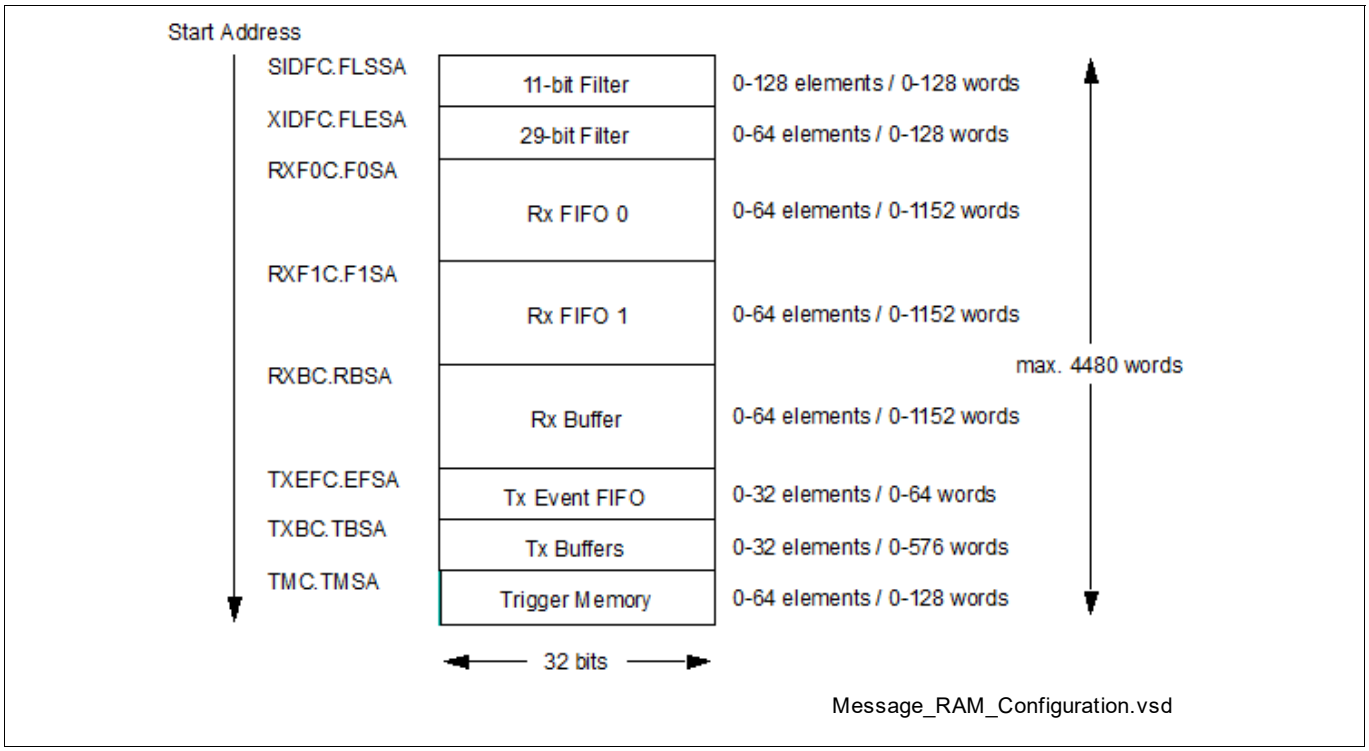


Figure 605 Message RAM Configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

40.4.6.2 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in **Table 382** below. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESCi.

Table 382 Message Layout - Rx Buffer and FIFO Element

Field	Bits	Type	Description
DB	7:0	rwh	**Data Byte m**

Note: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3…17) are used for storage of a CAN message's data field.

40.4.6.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBCi.TFQS and TXBCi.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESCi.

Table 383 Message Layout - Tx Buffer Element

41 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ [1)] protocol specification v2.1, developed for automotive applications. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

41.1 Feature List

The E-Ray IP-module supports the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
  Input Buffer: Holds message to be transferred to the Message RAM
  Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines
- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.
- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

41.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

41.2.1 E-Ray Kernel Description

Figure below shows a global view of the E-Ray interface.

1) Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™ is a trademark of FlexRay Consortium.

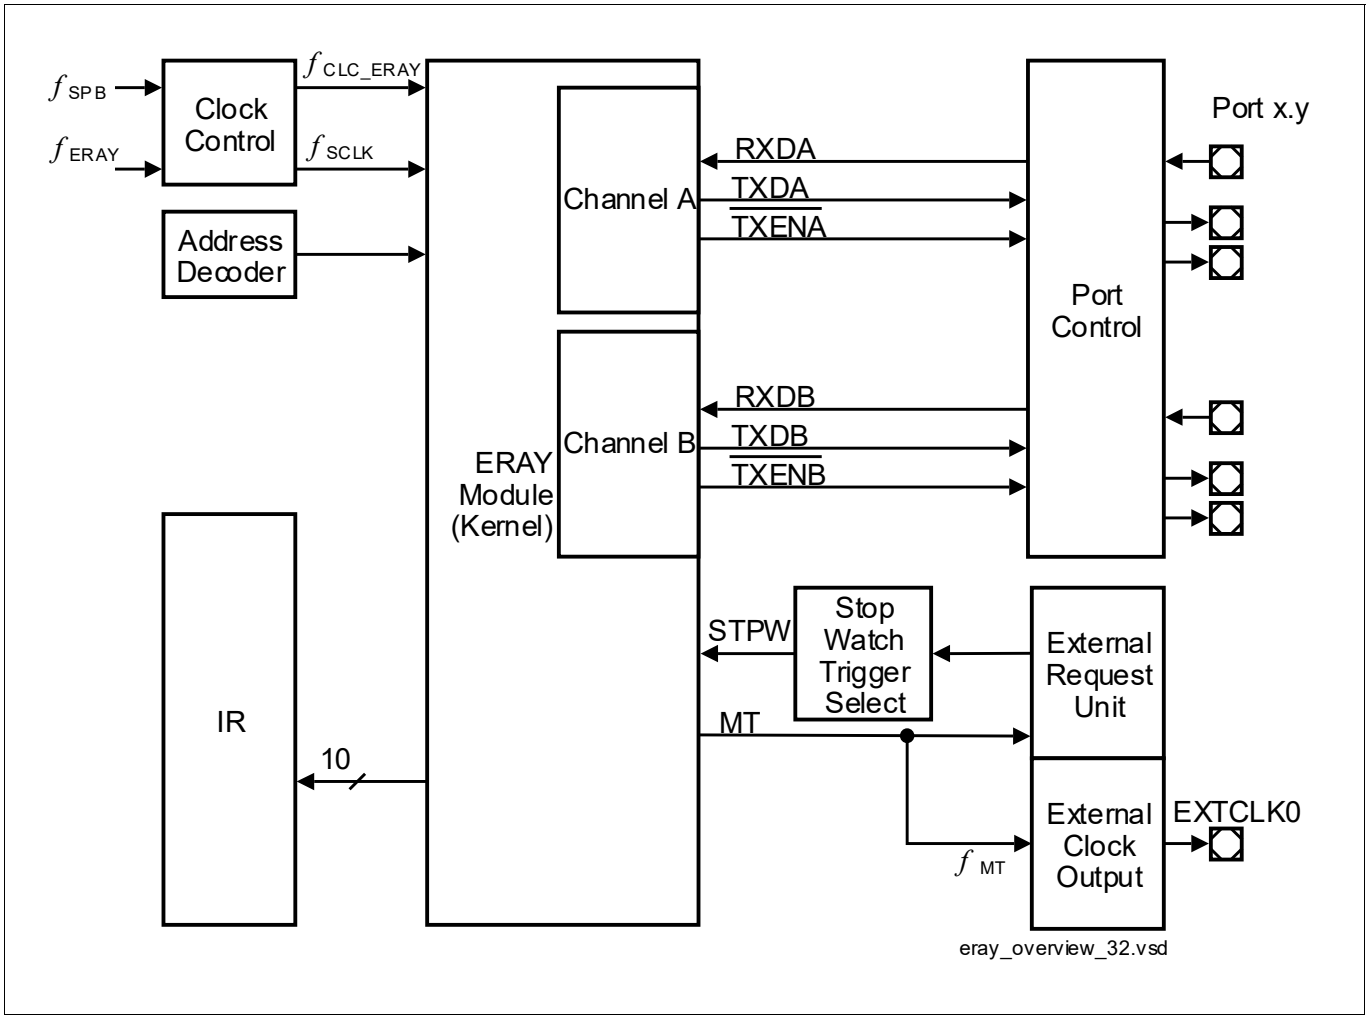

Figure 606 General Block Diagram of the E-Ray Interface

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDAx and RXDBx lines are the receive data input signals, TXDA and TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

41.2.2 Block Diagram

The E-Ray is built up by the following main submodules:

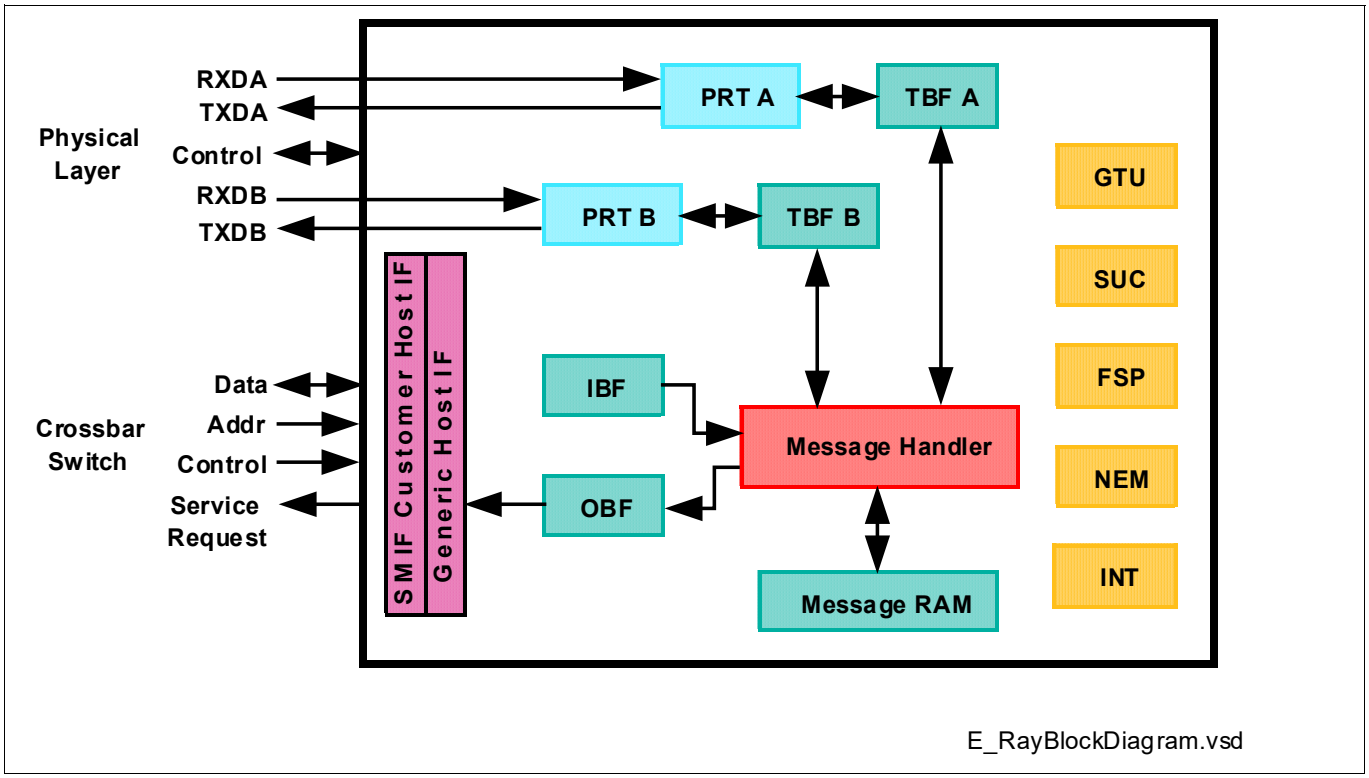

Figure 607 E-Ray Block Diagram

Customer Host Interface (CIF)

Connects the FPI Bus to the E-Ray IP-module via the Generic Host Interface.

Generic Host Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic Host Interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed via the Generic Host Interface.

Input Buffer (IBF)

For write access to the Message Buffers configured in the Message RAM, the Host can write the Header and Data Section for a specific Message Buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected Message Buffer in the Message RAM.

Because the Input Buffer (IBF) Scheme does only allow to write the entire Message Frame, not only parts of it, the number of IBF has been increased from originally 2 to 4. This enables to fill the buffer partly and at the end request transfer into Message RAM. Therefore 2 extra bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for Host writes.

Output Buffer (OBF)

For read access to a Message Buffer configured in the Message RAM the Message Handler transfers the selected Message Buffer to the Output Buffer. After the transfer has completed, the Host can read the Header and Data Section of the transferred Message Buffer from the Output Buffer.

Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay™ Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ Message Buffers together with the related configuration data (Header and Data Partition).

Transient Buffer RAM (TBF 1/2)

Stores the Data Section of two complete messages.

FlexRay™ Channel Protocol Controller (PRT A/B)

The FlexRay™ Channel Protocol Controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ Frames and symbols
- Check of Header CRC
- Generation / check of Frame CRC
- Interfacing to bus driver

The FlexRay™ Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Service Request Control

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of Frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network Management (NEM)

Handles of the Network Management vector

Service Request Control (INT)

The Service Request Controller performs the following functions:

- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

41.3 Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

41.3.1 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

41.3.2 Communication Cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized Macrotick.

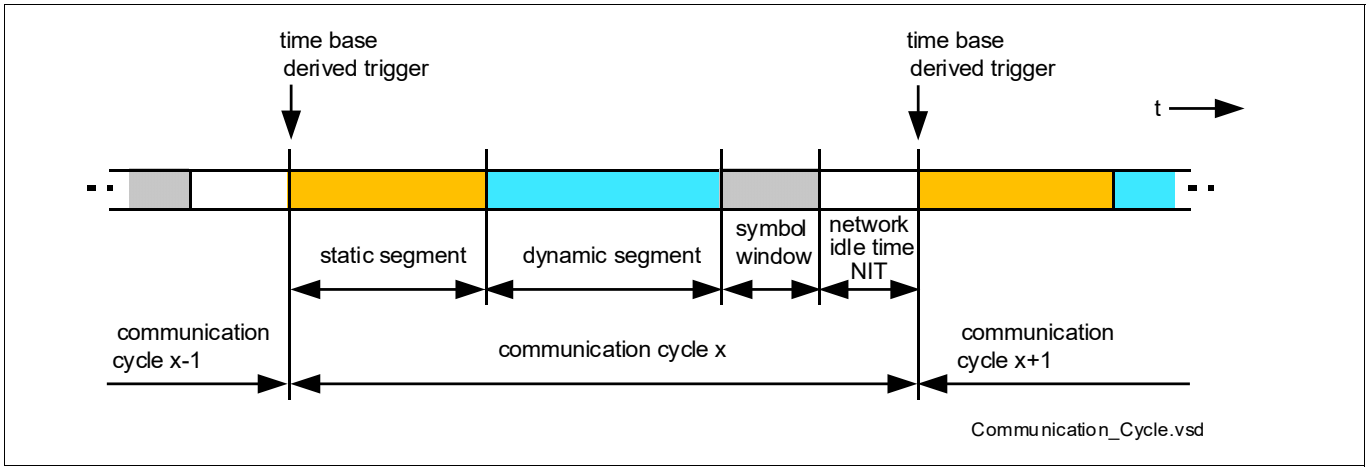

Figure 608 Structure of Communication Cycle

41.3.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all Frames on both channel

Parameters: Number of Static Slots GTUC07.NSS, Static Slot Length GTUC07.SSL, Payload Length Static MHDC.SFDL, Action Point Offset GTUC09.APO.

41.3.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots GTUC08.NMS, Minislot Length GTUC08.MSL Minislot Action Point Offset GTUC09.MAPO, Start of Latest Transmit (last minislot) MHDC.SLT.

41.3.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in “NORMAL_ACTIVE” state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset GTUC09.APO (same as for static slots), Network Idle Time Start GTUC04.NIT.

41.3.2.4 Network Idle Time (NIT)

During network idle time the Communication Controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple Macroticks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start GTUC04.NIT, Offset Correction Start GTUC04.OCS.

41.3.2.5 Configuration of Network Idle Time (NIT) Start and Offset Correction Start

The number of Macroticks per cycle (gMacroPerCycle) is assumed to be m. It is configured by programming GTUC02.MPC = m.

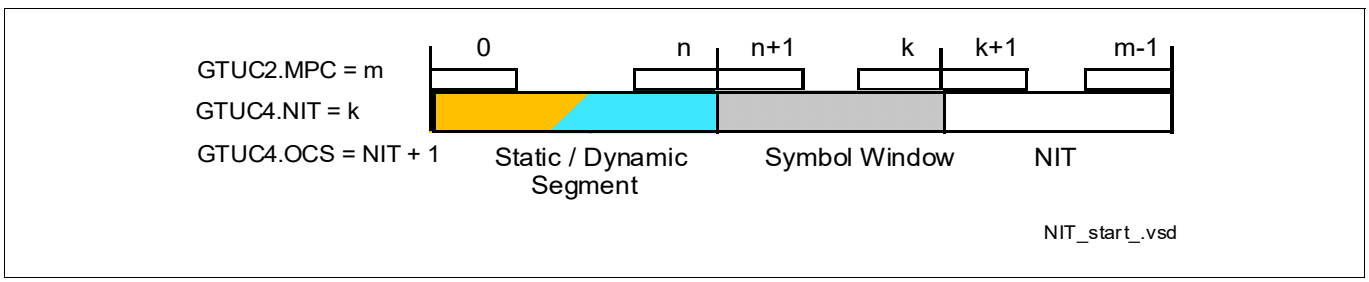

Figure 609 Configuration of network idle time (NIT) start and offset correction start

The static / dynamic segment starts with Macrotick 0 and ends with Macrotick n:

n = static segment length + dynamic segment offset + dynamic segment length - 1 Macrotick

n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset
+ gNumberOfMinislots • gdMinislot - 1 Macroticks

The static segment length is configured by GTUC07.SSL and GTUC07.NSS.
The dynamic segment length is configured by GTUC08.MSL and GTUC08.NMS.

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The network idle time (NIT) starts with Macrotick k+1 and ends with the last Macrotick of cycle m-1. It has to be configured by setting GTUC04.NIT = k.

For the E-Ray the offset correction start is required to be

GTUC04.OCS ≥ GTUC04.NIT + 1 = k+1.

The length of symbol window results from the number of Macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

41.3.3 Communication Modes

The FlexRay™ Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static**: minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic**: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

41.3.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC Frames from other nodes.

41.3.4.1 Global Time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

41.3.4.2 Local Time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

41.3.4.3 Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of **every** communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: “NORMAL_ACTIVE” → “NORMAL_PASSIVE” → “HALT”)
- Correction value is an integer number of Microticks
- Correction done in **odd** numbered cycles, distributed over the Macroticks beginning at offset correction start up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened / shortened)

Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of **odd** numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next **even / odd** cycle pair (Macroticks lengthened / shortened)

Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

SYNC Frame Transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames SUCC1.TXSY must be set to 1.

41.3.4.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

41.3.5 Error Handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit EIR.PEMC in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signalled by CCEV.ERRM in the Communication Controller Error Vector register.

Table 389 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE (green)	**Full operation**, State: “NORMAL_ACTIVE” The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR.
PASSIVE (yellow)	**Reduced operation**, State: “NORMAL_PASSIVE”, Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR.
COMM_HALT (red)	**Operation halted**, State: “HALT”, Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers EIR and SIR. The bus drivers are disabled.

41.3.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the maximum “without clock correction passive” limit defined by SUCC3.WCP, the POC transits from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. When it reaches the “maximum without clock correction fatal” limit defined by SUCC3.WCF, it transits “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to the “HALT” state. Both limits are defined in the SUC Configuration Register 3.

The Clock Correction Failed Counter CCEV.CCFC allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any **odd** numbered communication cycle where either the Missing Offset Correction signal SFS.MOCS nor the Missing Rate Correction signal SFS.MRCS flag is set. The two flags are located in the SYNC Frame Status register, while the Clock Correction Failed Counter is located in the Communication Controller Error Vector register.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the Missing Offset Correction signal SFS.MOCS nor the Missing Rate Correction signal SFS.MRCS flag is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value SUCC3.WCF as defined in the SUC Configuration Register 3 is reached (i.e. incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The Clock Correction Failed Counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

41.3.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. SUCC1.PTA in the SUC Configuration Register 1 defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If SUCC1.PTA is reset to zero the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

41.3.5.3 HALT Command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing SUCC1.CMD = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit EIR.CNA in the Error Service Request Register is set to 1. If enabled an service request to the Host is generated.

41.3.5.4 FREEZE Command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing SUCC1.CMD = 0111_B in the SUC Configuration Register 1. The FREEZE command triggers the entry of the “HALT” state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL.

41.3.6 Communication Controller States

This chapter introduces the states of the Communication Controller.

41.3.6.1 Communication Controller State Diagram

State transitions are controlled by externals the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector SUCC1.CMD located in the SUC Configuration Register 1.

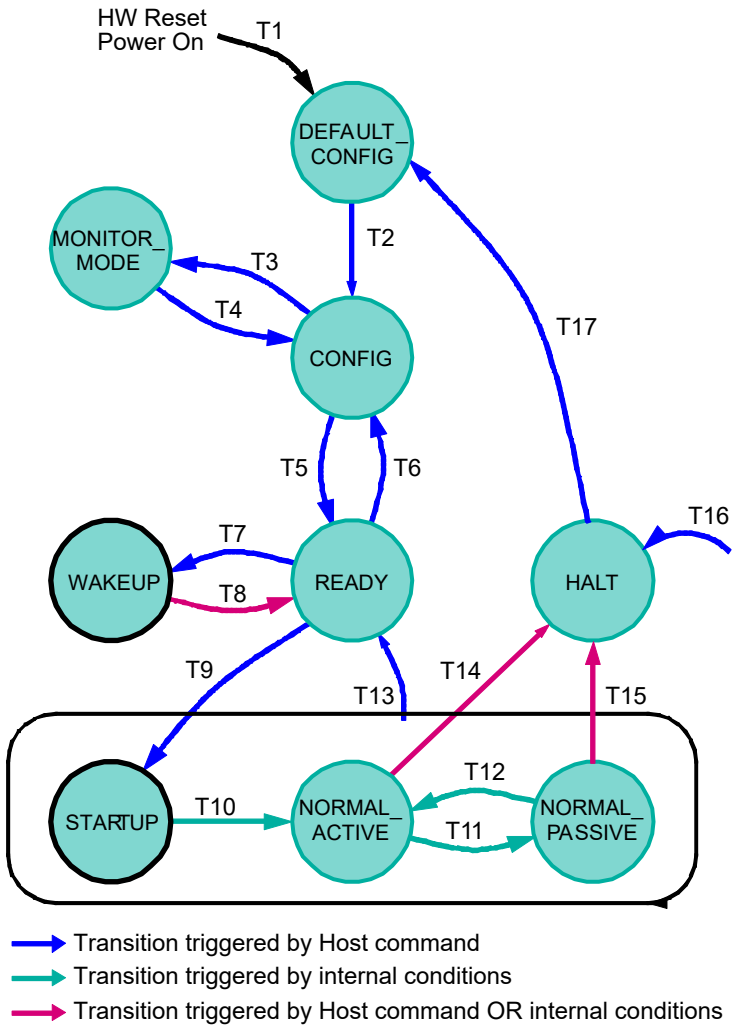

Figure 610 Overall State Diagram of E-Ray Communication Controller

The Communication Controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 390 State Transitions of E-Ray Overall State Machine

T#	Condition	From	To
1	application reset	HW Reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001_B	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011_B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001_B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010_B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001_B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011_B	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010_B	WAKEUP	READY
9	Command RUN SUCC1.CMD = 0100_B	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010_B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_PASSIVE	HALT

Table 390 State Transitions of E-Ray Overall State Machine (cont'd)

T#	Condition	From	To
16	Command FREEZE, SUCC1.CMD = 0111_B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001_B	HALT	DEFAULT_CONFIG

41.3.6.2 DEFAULT_CONFIG State

In "DEFAULT_CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The Communication Controller enters this state

- When leaving application reset
- When exiting from "HALT" state

To leave "DEFAULT_CONFIG" state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to "CONFIG" state.

41.3.6.2.1 CONFIG State

In "CONFIG" state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the Communication Controller configuration.

The Communication Controller enters this state

- When exiting from "DEFAULT_CONFIG" state
- When exiting from "MONITOR_MODE" or "READY" state

When the state has been entered via "HALT" and "DEFAULT_CONFIG" state, the Host can analyze status information and configuration. Before leaving "CONFIG" state the Host has to assure that the configuration is fault-free.

To leave "CONFIG" state, the Host has to perform the unlock sequence as described on "LCK". Directly after unlocking the "CONFIG" state the Host has to write SUCC1.CMD in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves "CONFIG".

Note: The Message Buffer Status Registers (MHDS, TXRQ1 to TXRQ4, NDAT1 to NDAT4, MBSC1 to MBSC4) and status data stored in the Message RAM and are not affected by the transition of the POC from "CONFIG" to "READY" state.

When the Communication Controller is in "CONFIG" state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK}, f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

41.3.6.3 MONITOR_MODE

After unlocking "CONFIG" state and writing SUCC1.CMD = 1011_B the Communication Controller enters "MONITOR_MODE". In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions

in Monitor Mode (FRF.RSS will be ignored, filtering not functional).This mode can be used for debugging purposes in case e.g. that startup of a FlexRay™ network fails. After writing SUCC1.CMD = 0001_B the Communication Controller transits back to “CONFIG” state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits MBS.VFRA, MBS, MBS.MLST, MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA resp. SIR.MTSB are set. SIR.CAS has no function in “MONITOR_MODE”.

41.3.6.4 READY State

After unlocking “CONFIG” state and writing SUCC1.CMD = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to WAKEUP state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state

- When exiting from “CONFIG”, “WAKEUP”, “STARTUP”, “NORMAL_ACTIVE”, or “NORMAL_PASSIVE” state by writing SUCC1.CMD = 0010_B (READY command).

The Communication Controller exits from this state

- To “CONFIG” state by writing SUCC1.CMD = 0001_B (CONFIG command)
- To “WAKEUP” state by writing SUCC1.CMD = 0011_B (WAKEUP command)
- To “STARTUP” state by writing SUCC1.CMD = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

Note: Status bits MHDS, registers TXRQ1 to TXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.

41.3.6.5 WAKEUP State

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.1.

The Communication Controller enters this state

- When exiting from “READY” state by writing SUCC1.CMD = 0011_B (WAKEUP command).

The Communication Controller exits from this state to “READY” state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing SUCC1.CMD = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian (if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit SUCC1.WUCS in the SUC Configuration Register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit SIR.WST in the Status Service Request Register. The wakeup status vector can be read from the Communication Controller Status Vector register CCSV.WSV. If a valid wakeup pattern was received also either flag SIR.WUPA or flag SIR.WUPB in the Status Service Request Register is set.

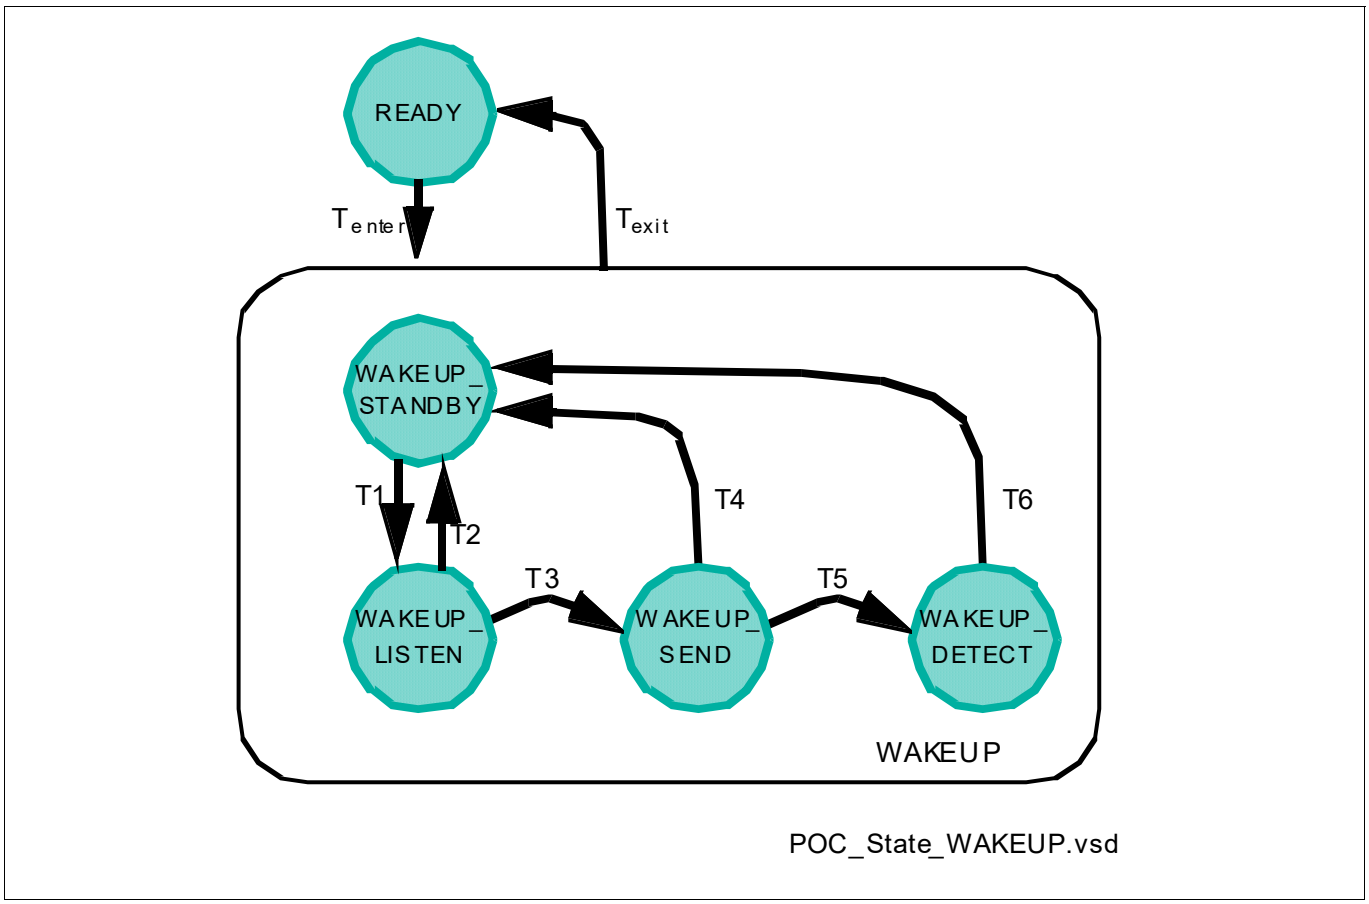

Figure 611 Structure of POC State WAKEUP

Table 391 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to “WAKEUP” state by writing SUCC1.CMD = 0011_B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to “WAKEUP_LISTEN” state	WAKEUP_ STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_ LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_ LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_ SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_ SEND	WAKEUP_DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration Register 1 OR Frame Header received on either available channel	WAKEUP_ DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to “READY” state by writing SUCC1.CMD = 0010_B (READY command). This command also resets the wakeup FSM to “WAKEUP_STANDBY” state	WAKEUP	READY

The “WAKEUP_LISTEN” state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out SUCC2.LT and listen time-out noise SUCC2.LTN. Both values can be configured in the SUC Configuration Register 2. listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In “WAKEUP_SEND” state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into “STARTUP” state by CHI command RUN.

In “WAKEUP_DETECT” state the Communication Controller attempts to identify the reason for the wakeup collision detected in “WAKEUP_SEND” state. The monitoring is bounded by the expiration of listen time-out as configured by SUCC2.LT in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to “READY” state. Otherwise WAKEUP_DETECT is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in “CONFIG” state
  - Select wakeup channel by programming bit SUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command Communication Controller to start wakeup on the configured channel by writing SUCC1.CMD = 0011_B
  - Communication Controller enters “WAKEUP
  - Communication Controller returns to “READY” state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag CCSV.CSI by writing SUCC1.CMD = 1001_B (ALLOW_COLDSTART command))
- Reset Coldstart Inhibit flag CCSV.CSI in the CCSV register by writing SUCC1.CMD = 1001_B (ALLOW_COLDSTART command), coldstart node only
- Command Communication Controller to enter startup by writing SUCC1.CMD = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter “STARTUP” state by writing SUCC1.CMD = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT Configuration Registers PRTC1 and PRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by PRTC2.TXL
- Wakeup symbol idle time used to listen for activity on the bus, configured by PRTC2.TXI
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by PRTC1.RWP (2 to 63 repetitions)
- Wakeup symbol receive window length configured by PRTC1.RXW
- Wakeup symbol receive low time configured by PRTC2.RXL
- Wakeup symbol receive idle time configured by PRTC2.RXI

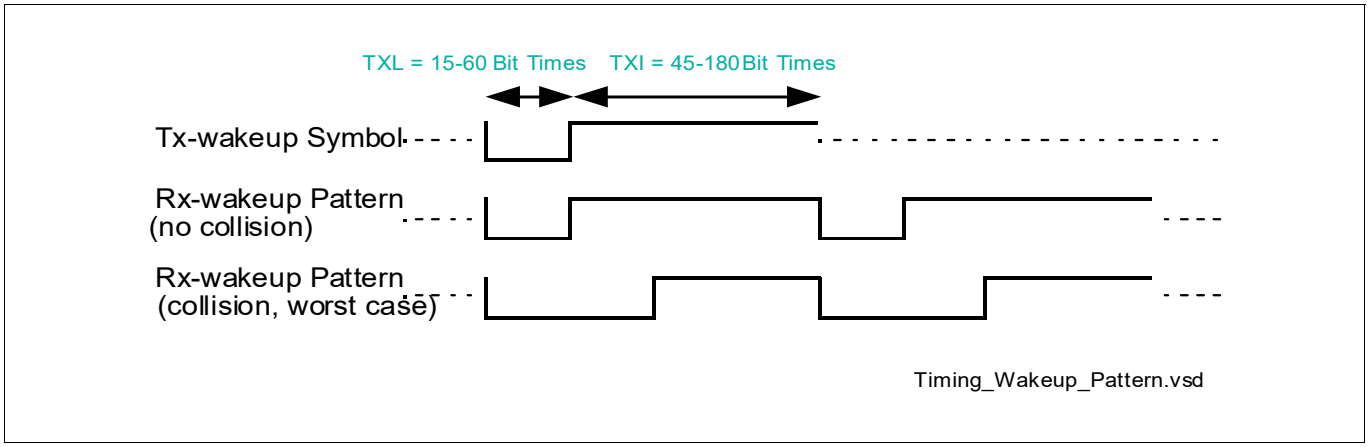

Figure 612 Timing of Wakeup Pattern

41.3.6.6 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state via (see **Figure 613**):

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit Startup Frame in Key Slot bit SUCC1.TXST and Transmit SYNC Frame in Key Slot bit SUCC1.TXSY in the SUC Configuration Register 1 set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by SUCC1.CSA in the SUC Configuration Register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive SYNC Frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

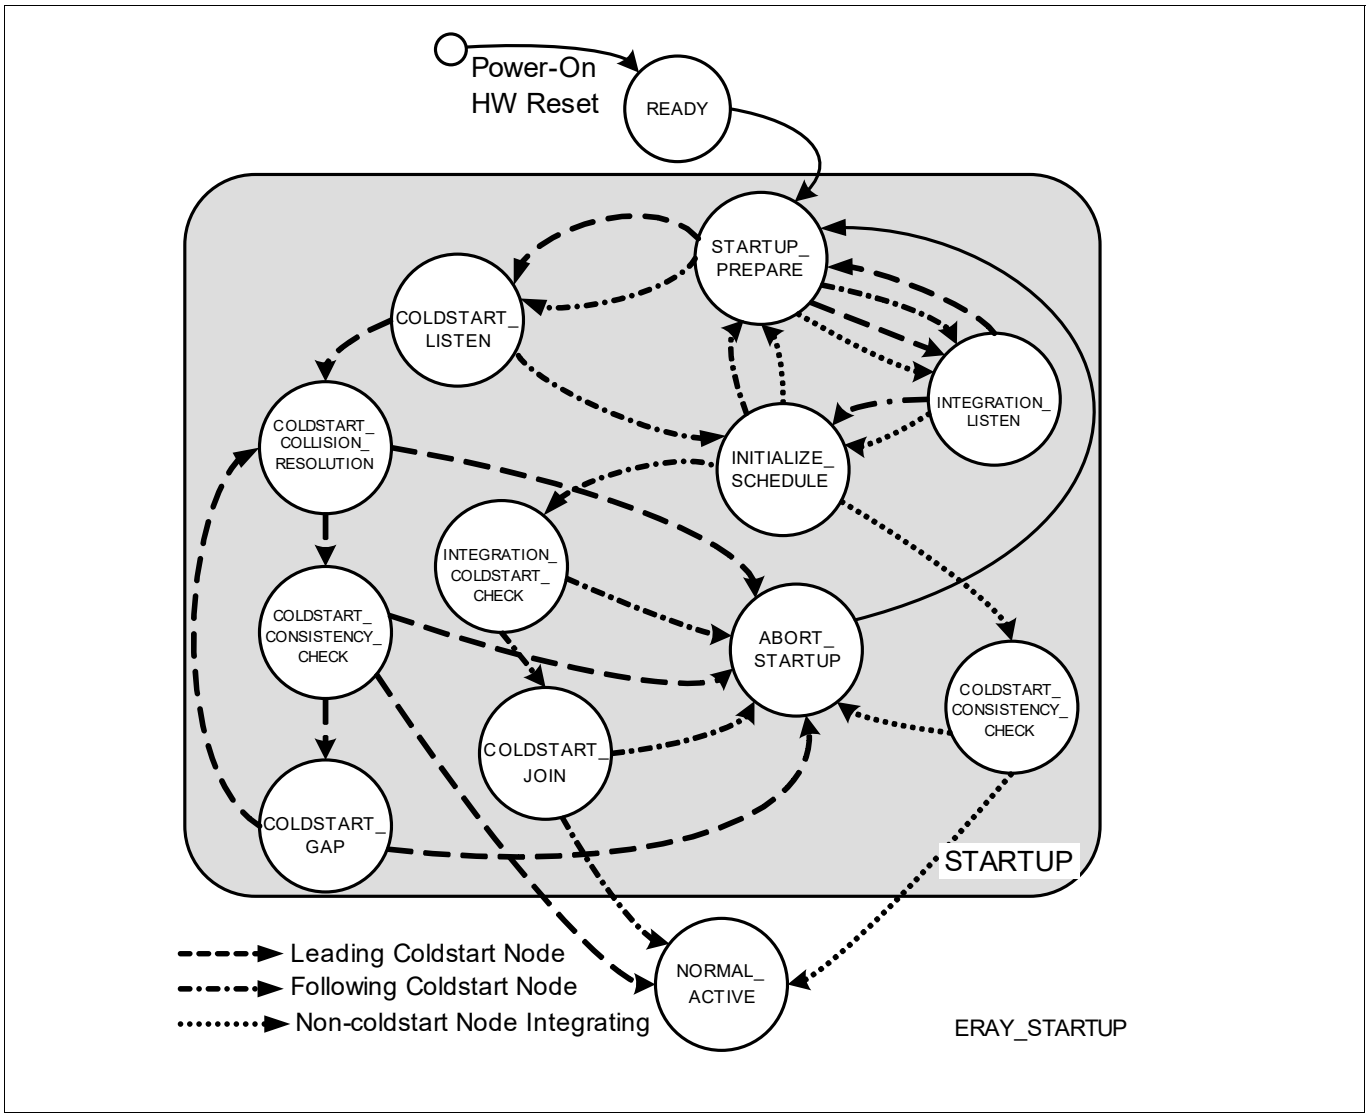

Figure 613 State Diagram Time-Triggered Startup

Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit CCSV.CSI in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit CCSV.CSI is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (SUCC1.CMD = 1001_B)

41.3.6.7 Startup Time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the “COLDSTART_LISTEN” state. The expiration of either of these timers causes the node to leave the initial sensing phase (“COLDSTART_LISTEN” state) with the intention of starting up communication.

Note: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values SUCC2.LT and SUCC2.LTN from the SUC Configuration Register 2.

Startup Time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming SUCC2.LT (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Both channels reaching idle state while in “COLDSTART_LISTEN” state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the “COLDSTART_LISTEN” state
- When the “COLDSTART_LISTEN” state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup Noise Time-out

At the same time the startup timer is started for the first time (transition from “STARTUP_PREPARE” state to “COLDSTART_LISTEN” state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming SUCC2.LTN (gListenNoise - 1) in the SUC Configuration Register 2 (see “**SUCC2**).

The startup noise time-out is:
pdListenTimeout • ´gListenNoise = SUCC2.LT • (SUCC2.LTN + 1)

The startup noise timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Reception of correctly decoded Headers or CAS symbols while the node is in “COLDSTART_LISTEN” state

The startup noise timer is stopped when the “COLDSTART_LISTEN” state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won’t be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

41.3.6.8 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_ RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by SUCC1.CSA in the SUC Configuration Register 1. The number of remaining coldstarts attempts CCSV.RCA can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

Path of following Coldstart Node (responding to leading Coldstart Node)

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_ CHECK state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_ACTIVE. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

41.3.6.9 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering “STARTUP” via coldstart path) and one additional node have entered the “NORMAL_ACTIVE” state, the startup phase for the cluster has finished. In the “NORMAL_ACTIVE” state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- “HALT” state by writing SUCC1.CMD = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing SUCC1.CMD = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “ACTIVE” to “COMM_HALT”
- “NORMAL_PASSIVE” state due to change of the error state from “ACTIVE” to “PASSIVE”
- “READY” state by writing SUCC1.CMD = 0010_B (READY command)

41.3.6.10 NORMAL_PASSIVE State

“NORMAL_PASSIVE” state is entered from “NORMAL_ACTIVE” state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In “NORMAL_PASSIVE” state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the “NORMAL_ACTIVE” state the node does not actively participate in communication, i.e. neither symbols nor Frames are transmitted.

In “NORMAL_PASSIVE” state

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- “HALT” state by writing SUCC1.CMD = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing SUCC1.CMD = 0111_B (FREEZE command, immediately)

- “HALT” state due to change of the error state from “PASSIVE” to “COMM_HALT”
- “NORMAL_ACTIVE” state due to change of the error state from “PASSIVE” to “ACTIVE”. The transition takes place when CCEV.PTAC from the Communication Controller Error Vector register equals SUCC1.PTA - 1.
- “READY” state by writing SUCC1.CMD = 0010_B (READY command)

41.3.6.11 HALT State

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state

- By writing SUCC1.CMD = 0110_B (HALT command) while the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state
- By writing SUCC1.CMD = 0111_B (FREEZE command) from all states
- When exiting from “NORMAL_ACTIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from “NORMAL_PASSIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to “DEFAULT_CONFIG” state

- By writing SUCC1.CMD = 0001_B (CONFIG command)

When the Communication Controller enters “HALT” state, all configuration and status data is maintained for analyzing purposes.

When the Host writes SUCC1.CMD = 0110_B (HALT command), the Communication Controller sets bit CCSV.HRQ in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes SUCC1.CMD = 0111_B (FREEZE command), the Communication Controller enters “HALT” state immediately and sets the CCSV.FSI bit in the Communication Controller Status Vector register.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL.

41.3.7 Network Management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 (NMVx (x = 1-3)). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set via WRHS1.PPIT. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

Note: In case a Message Buffer is configured for transmission / reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by NEMC.NML.
When the Communication Controller transits to “HALT” state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.

41.3.8 Filtering and Masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by

comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance / transmit filtering are allowed:

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

Note: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

41.3.8.1 Frame ID Filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive Buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit Buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

41.3.8.2 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see Table below).

Table 392 Channel Filtering Configuration

CHA	CHB	**Transmit Buffer**transmit Frame	**Receive Buffer**store valid receive Frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Receive Buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective NDn (n = 0-31) to NDn (n = 96-127) flag in the New Data NDAT1 to NDAT4 register is set. In both cases, if bit RDHS1.MBI in the Header Section of the respective Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

Transmit Buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit WRHS1.MBI in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

41.3.8.3 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits TXST, TXSY, and TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

*Note: Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in Table below.

Table 393 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
$000000x_B$	all Cycles		
$000001c_B$	every second Cycle	at (Cycle Count)mod2	= c
$00001cc_B$	every fourth Cycle	at (Cycle Count)mod4	= cc
$0001ccc_B$	every eighth Cycle	at (Cycle Count)mod8	= ccc
$001cccc_B$	every sixteenth Cycle	at (Cycle Count)mod16	= cccc
$01ccccc_B$	every thirty-second Cycle	at (Cycle Count)mod32	= ccccc
$1cccccc_B$	every sixty-fourth Cycle	at (Cycle Count)mod64	= cccccc

Table below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 394 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0000011_B	1-3-5-7- ….-63 ↵
0000100_B	0-4-8-12- ….-60 ↵
0001110_B	6-14-22-30- ….-62 ↵
0011000_B	8-24-40-56 ↵
0100011_B	3-35 ↵
1001001_B	9 ↵

Receive Buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit Buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

41.3.8.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for **Channel** (2 bits), **Frame ID** (11 bits), and **Cycle Code** (7 bits). Rejection filter and rejection filter mask can be configured in "DEFAULT_CONFIG" or "CONFIG" state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

41.3.9 Transmit Process

The transmit process is described in the following sections.

41.3.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

41.3.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID's which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID's on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by SLT in the MHD Configuration Register 1 defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

41.3.9.3 Transmit Buffers

A portion of the E-Ray Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done via the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment: channel A **or** channel B, channel A **and** channel B
- Dynamic segment: channel A **or** channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during runtime. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during runtime it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer.

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit STXRH in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID **and** cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

41.3.9.4 Frame Transmission

To prepare a transmit buffer for transmission the following steps are required:

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer.
- To transfer a transmit message from Input Buffer to the Message RAM proceed as described on “Data Transfer from Input Buffer to Message RAM”.
- If configured in the Input Buffer Command Mask register the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed, and the Message Buffer is ready for transmission.
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1 to 4 registers (single-shot mode only).

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not

transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit WRHS1.MBI in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled an service request is generated.

41.3.9.5 NULL Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID's and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

41.3.10 Receive Process

The receive process is described in the following sections.

41.3.10.1 Frame Reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register.

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1) it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data NDn (n = 0-31) to NDn (n = 96-127) flag in the New Data NDAT1 to NDAT4 registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set. If bit RDHS1.MBI in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled an service request is generated.

To read a receive buffer from the Message RAM via the Output Buffer proceed as described on “Data Transfer from Message RAM to Output Buffer”.

Note: The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

41.3.10.2 NULL Frame reception

The Payload Segment of a received NULL Frame is **not** copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

41.3.11 FIFO Function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by FFB and ending with the Message Buffer referenced by LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

41.3.11.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFCL in the Status Service Request Register is set when the last available Message Buffer belonging to the FIFO is written, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

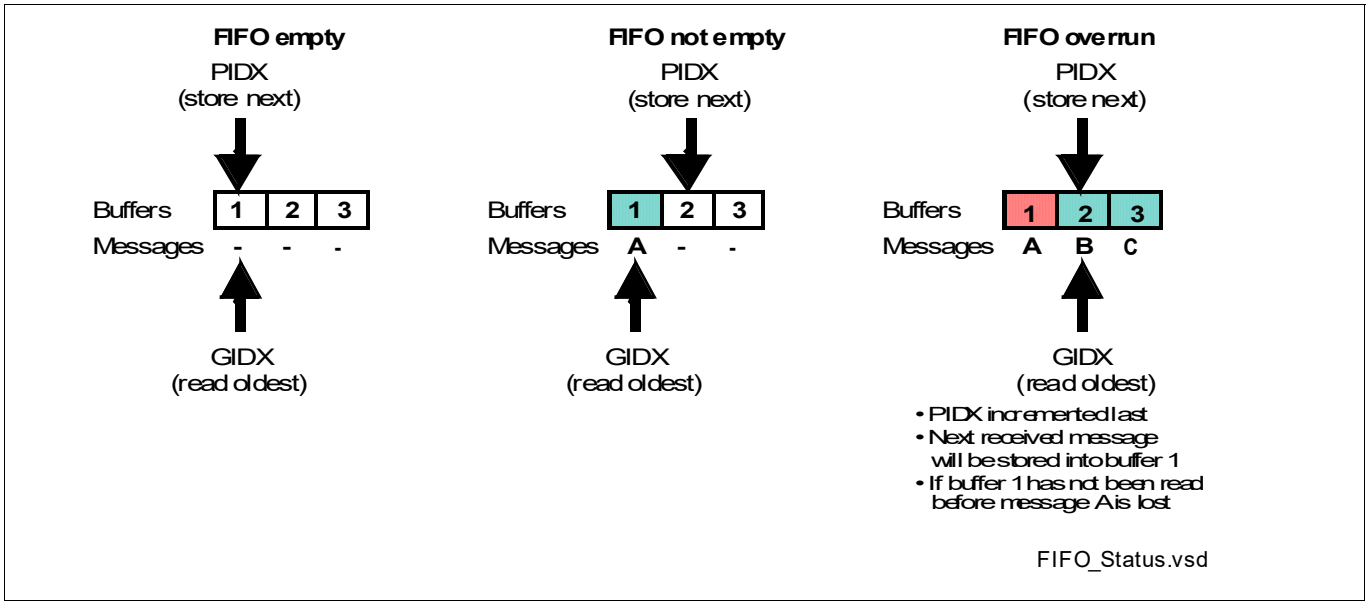

Figure 614 FIFO Status: Empty, Not Empty, Overrun

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 614** for a three Message Buffer FIFO.

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “don’t care” for rejection filtering.

41.3.11.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured via the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via WRHS1.MBI to avoid generation of RX interrupts.
If the payload length of a received Frame is longer than the value programmed by WRHS2.PLC in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.

41.3.11.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

41.3.12 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM's are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

41.3.12.1 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input / Output Buffer Command Mask registers can be used to write / read Header and Data Section of the selected Message Buffer separately. If bit STXRS in the Input Buffer Command Mask register is set (STXRS = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

If bit STXRS in the Input Buffer Command Mask register is reset (STXRS = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

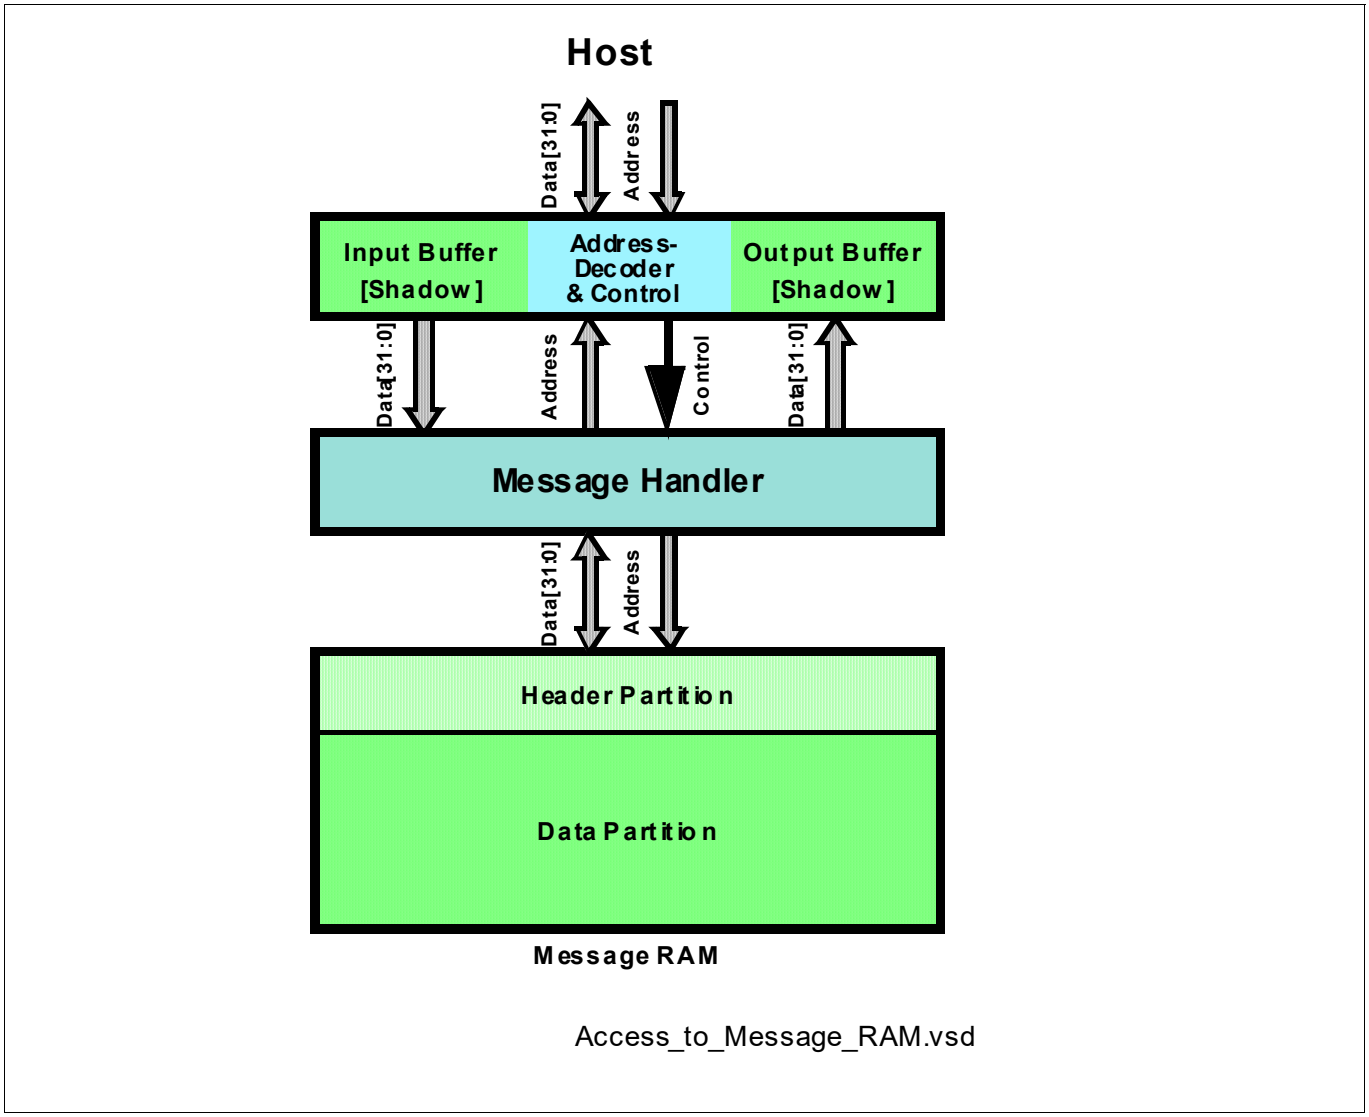

Figure 615 Host Access to Message RAM

Data Transfer from Input Buffer to Message RAM

To configure / update a Message Buffer in the Message RAM, the Host has to write the data to WRDSnn (nn = 01-64) and the Header to WRHS1, WRHS2, WRHS3. Two sets of WRDSnn (nn = 01-64) are available in parallel and selected by CUST1.IBF1PAG and CUST1.IBF2PAG. CUST1.IBFS shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. WRHS1, WRHS2, and WRHS3 does only exist once. The specific action is selected by configuring the Input Buffer Command Mask IBCM.

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register IBCR, IBF Host and IBF Shadow are swapped (see **Figure 615**).

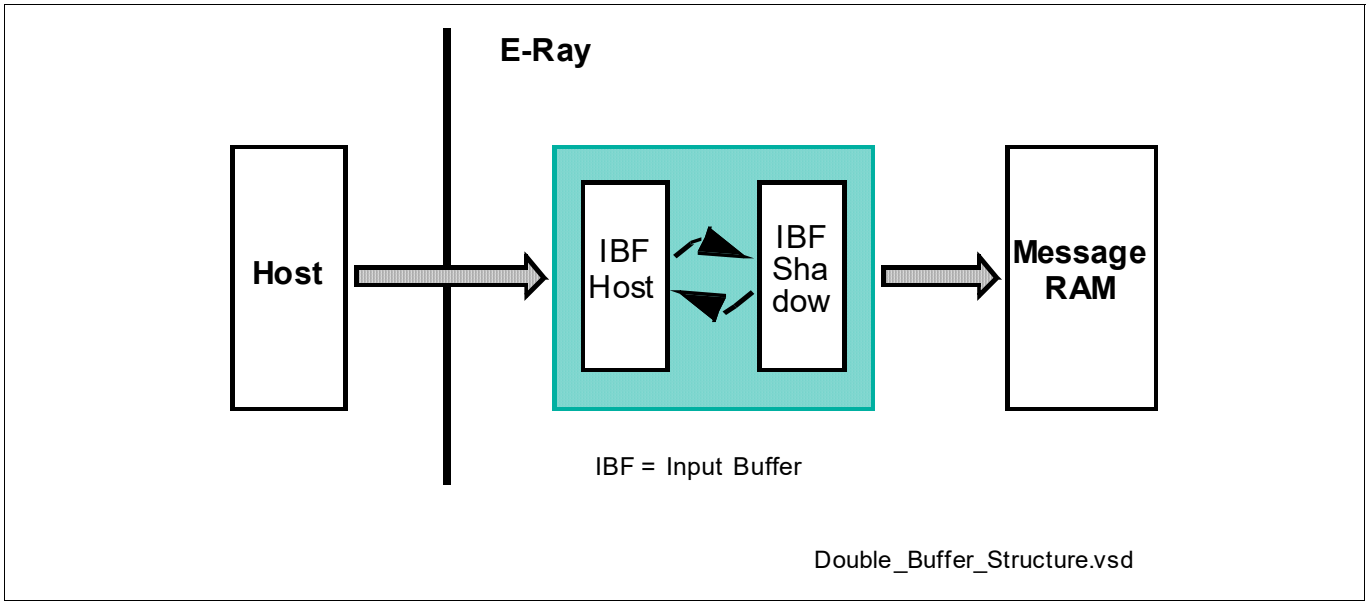

Figure 616 Swapping of IBCM and IBCR Bit

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see Figure below).

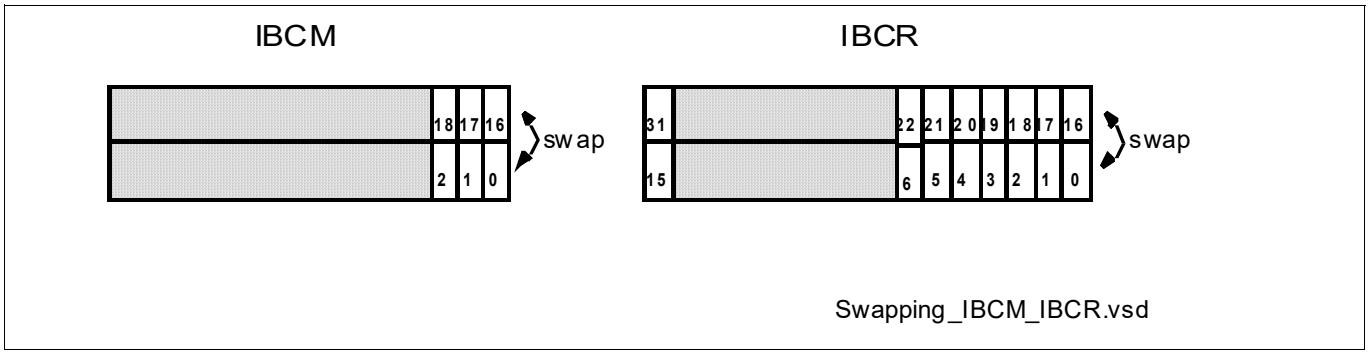

Figure 617 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 395 Assignment of Input Buffer Command Mask Bit

Pos.	Access	Bit	Function
18	rh	STXRS	Set Transmission Request Shadow
17	rh	LDSS	Load Data Section Shadow
16	rh	LHSS	Load Header Section Shadow
2	rwh	STXRH	Set Transmission Request Host
1	rwh	LDSH	Load Data Section Host
0	rwh	LHSH	Load Header Section Host

Table 396 Assignment of Input Buffer Command Request Bit

Pos.	Access	Bit	Function
31	rh	IBSYS	**IBF Busy Shadow,** signals ongoing transfer from IBF Shadow to Message RAM
22…16	rh	IBRS	**IBF Request Shadow,** number of Message Buffer currently / last updated
15	rh	IBSYH	**IBF Busy Host,** transfer request pending for Message Buffer referenced by IBRH
6-0	rwh	IBRH	**IBF Request Host,** number of Message Buffer to be updated next

Data Transfer from Message RAM to Output Buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register OBCR to trigger the data transfer as configured in Output Buffer Command Mask OBCM register. After the transfer has completed, the Host can read the transferred data from RDDSnn (nn = 01-64), RDHS1, RDHS2, RDHS3, and MBS.

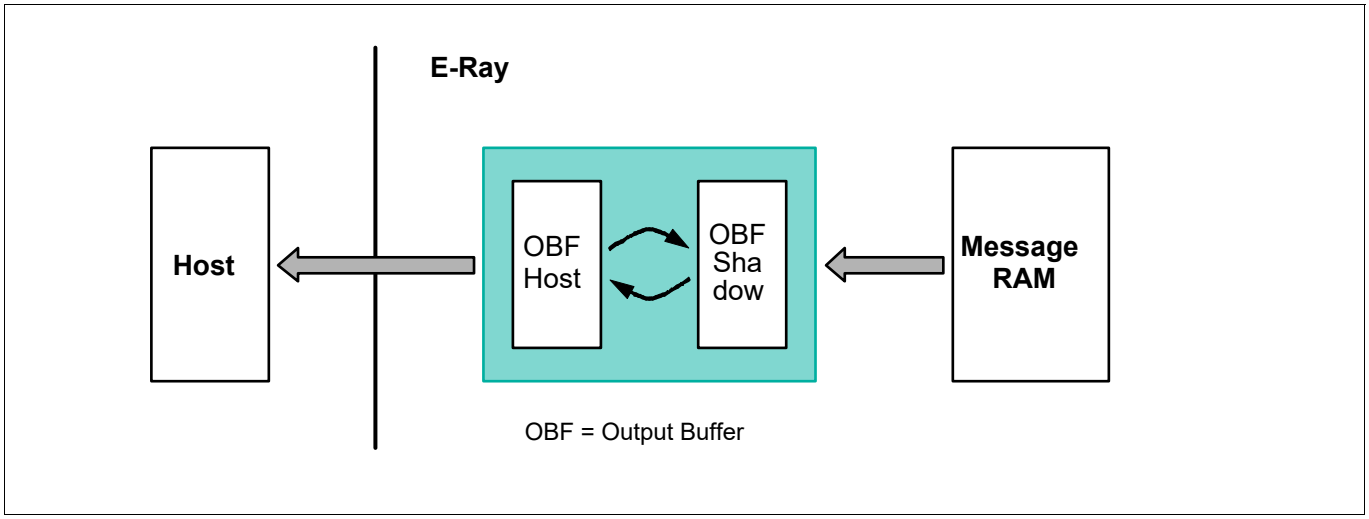

Figure 618 Double Buffer Structure Output Buffer

OBF Host and OBF Shadow as well as bits OBCM.RHSS, OBCM.RDSS, OBCM.RHSH, OBCM.RDSH and bits OBCR.OBRS, OBCR.OBRH are swapped under control of bits OBCR.VIEW and OBCR.REQ.

Writing bit OBCR.REQ to 1 copies bits OBCM.RHSS, OBCM.RDSS and bits OBCR.OBRS to an internal storage (see **Figure 619**).

After setting OBCR.REQ to 1, OBCR.OBSYS is set to 1, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the OBCR.OBSYS bit is set back to 0. Bits OBCR.REQ and OBCR.VIEW can only be set to 1 while OBCR.OBSYS is 0.

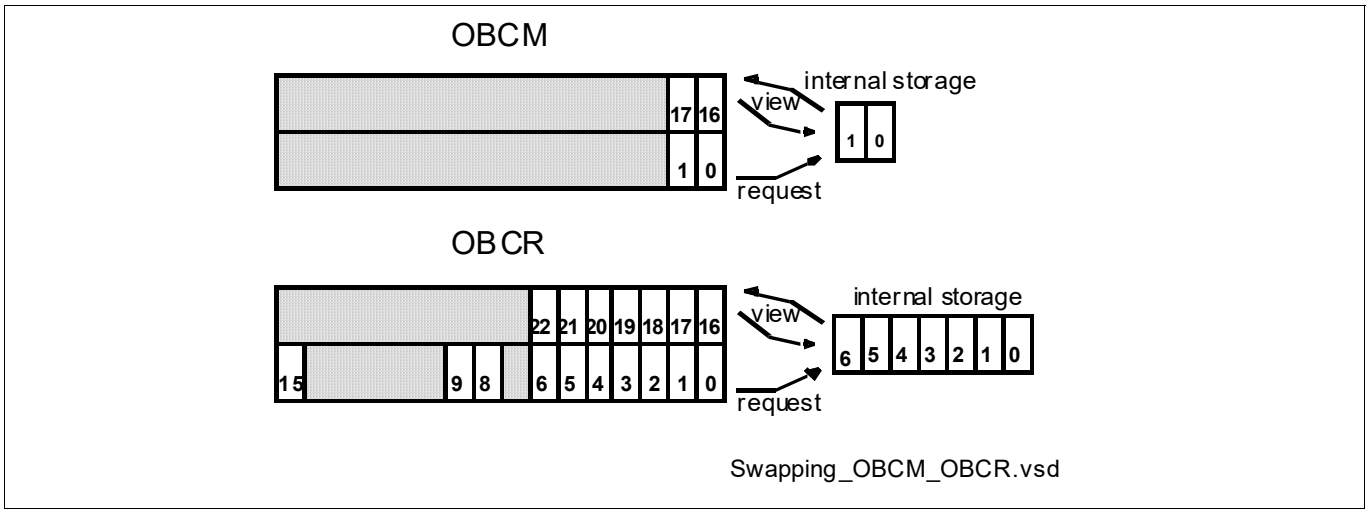

Figure 619 Swapping of OBCM and OBCR Bit

OBF Host and OBF Shadow are swapped by setting bit OBCR.VIEW to 1 while bit OBCR.OBSYS is 0 (see **Figure 619**).

In addition bits OBCR.OBRH and bits OBCM.RHSH, OBCM.RDSH are swapped with the registers internal storage thus assuring that the Message Buffer number stored in OBCR.OBRH and the mask configuration stored in OBCM.RHSH, OBCM.RDSH matches the transferred data stored in OBF Host (see **Figure 619**).

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 397 Assignment of Output Buffer Command Mask Bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data Section available for Host access
16	rh	RHSH	Header Section available for Host access
1	rwh	RDSS	Read Data Section Shadow
0	rwh	RHSS	Read Header Section Shadow

Table 398 Assignment of Output Buffer Command Request Bit

Pos.	Access	Bit	Function
22…16	rh	OBRH	**OBF Request Host** number of Message Buffer available for Host access
15	rh	OBSYS	**OBF Busy Shadow** signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	**Request Transfer from Message RAM to OBF Shadow**
8	rw	VIEW	**View OBF Shadow, swap OBF Shadow, and OBF Host**
6…0	rw	OBRS	**OBF Request Shadow** number of Message Buffer for next request

41.3.12.2 Data Transfers between IBF / OBF and Message RAM

This document uses the following terms and abbreviations:

Table 399 Terms and Abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)
IBF⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF⇒ TBF	Transfer from MBF to TBF
TBF⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure below.

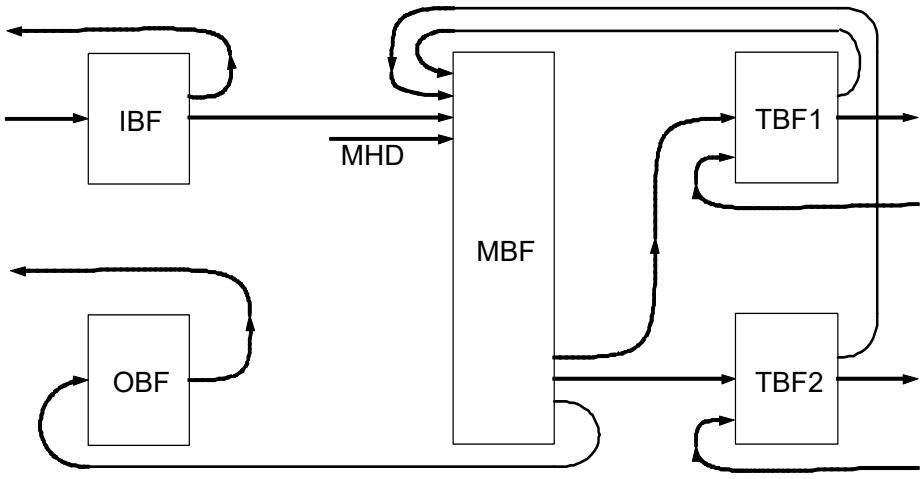

Figure 620 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of

2-byte words the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is e.g. 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

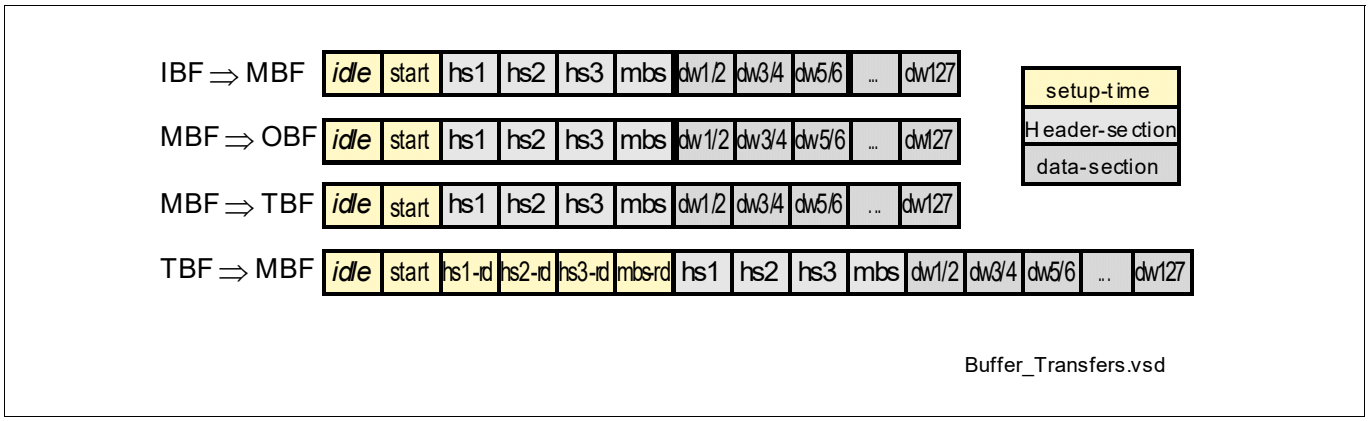

Figure 621 Different Possible Buffer Transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

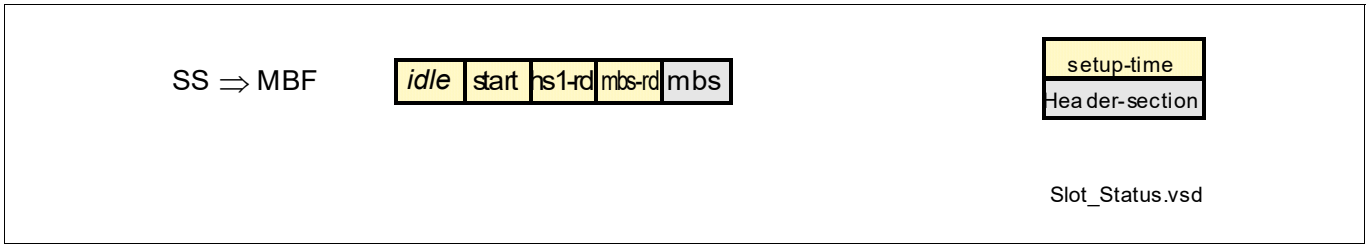

Figure 622 Update of Slot Status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY}periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IB FÞ MBF is started short after a TBF Þ MBF or SS Þ MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure below)

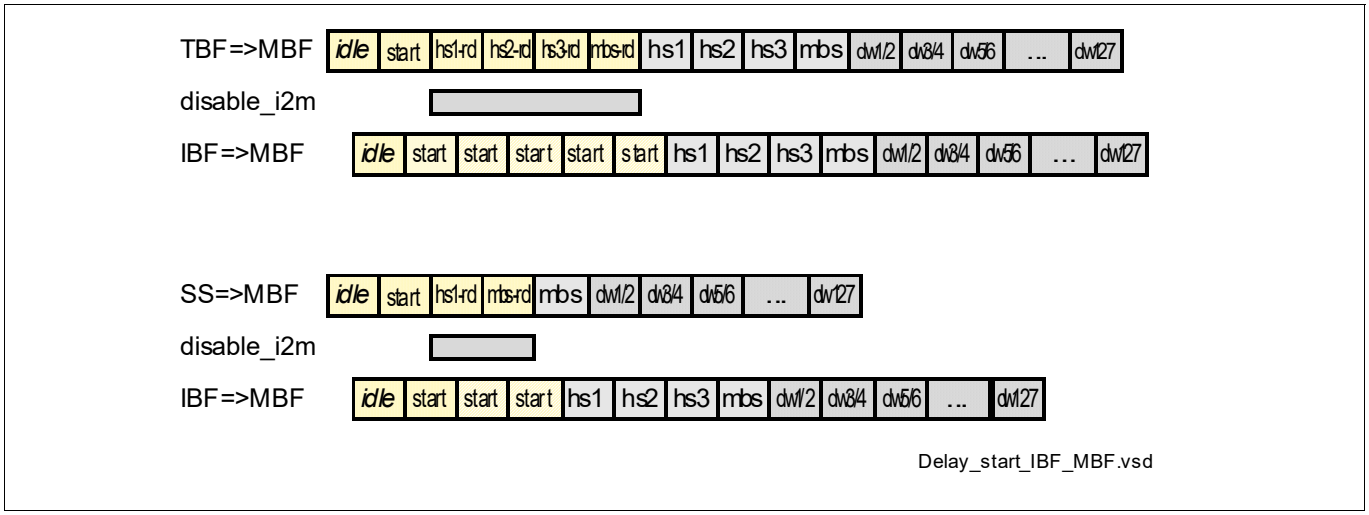

Figure 623 Delay start of IBF => MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that e.g. a IBF⇒ MBF has been started shortly before a MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that e.g. a second IBF⇒ MBF is requested, a MBF⇒ OBF is requested and a IBF⇒ MBF is ongoing, the MBF⇒ OBF has to wait until the first IBF⇒ IBF has completed. The second IBF=MBF has to wait until the MBF⇒ OBF has completed (see figure below) independent whether MBF⇒ OBF or second IBF⇒ MBF is requested first.

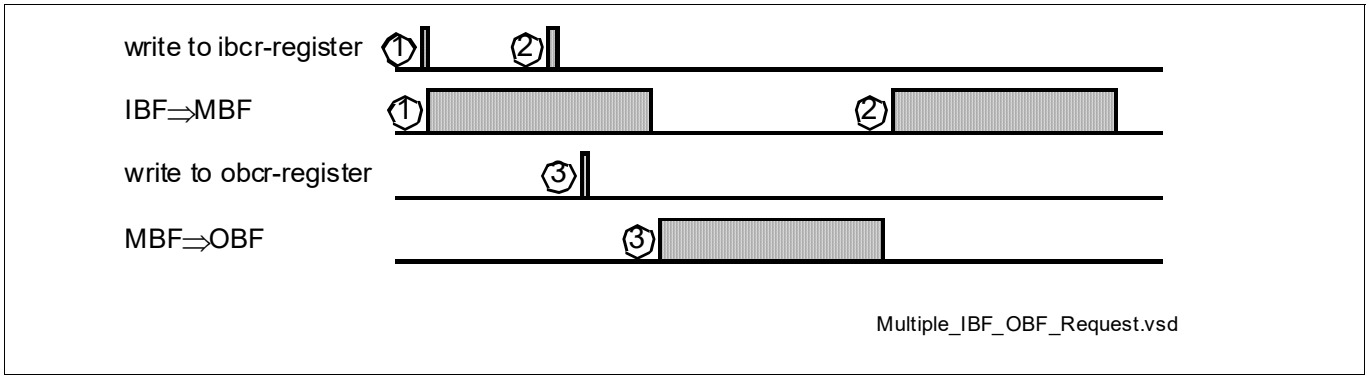

Figure 624 Multiple IBF/OBF Request

Worst case for single request

When a message with a large payload length is received the TBF⇒ MBF is started at the begin of the next slot (n+1). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF⇒ MBF has not finished until begin of the next but one slot (n+2). In this case the TBF⇒ MBF will be service requested (break) to start a transmission in the next but one slot (MBF⇒ TBF) and/or to update the slot status (SS⇒ MBF) for the RX-buffer corresponding with next slot (n+1). After this interruption the TBF⇒ MBF is continued.

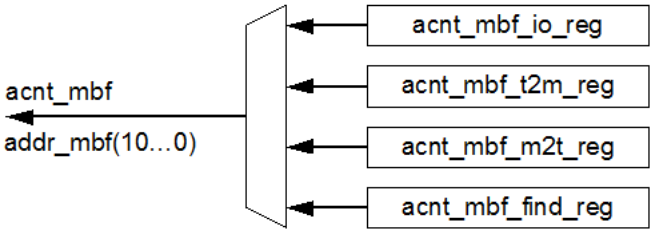

Figure 625 Address Counter Scheme of Message RAM (simplified)

For the transfers IBF⇒ MBF / MBF⇒ OBF, TBF⇒ MBF and MBF⇒ TBF separate address-counter are implemented (see **Figure 625**).

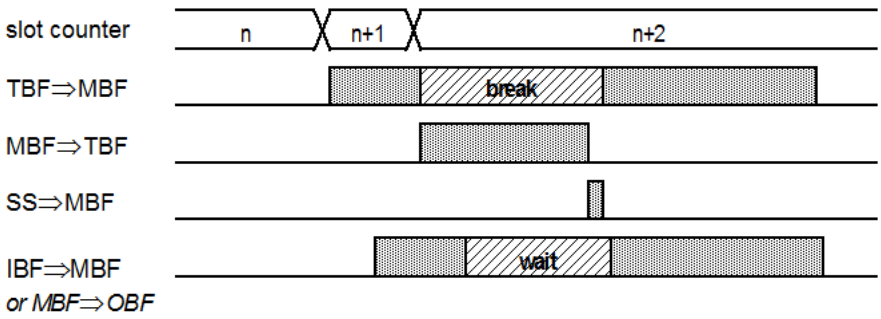

Figure 626 interruption of TBF to MBF

If the address-counter for IBF⇒ MBF / MBF⇒ OBF (acnt_mbf_io_reg) reaches the address of the interrupted TBF=>MBF (acnt_mbf_t2m_reg) the IBF⇒ MBF / MBF⇒ OBF has to wait until the TBF⇒ MBF is continued (see **Figure 626**).

The relative time is measured in f_{CLC_ERAY}cycles. Absolute time depends on the actual f_{CLC_ERAY}cycle period.

tbf_to_mbf_break time$_{max}$ =	(setup time + mbf_to_tbf time$_{max}$) + (setup time + ss_to_mbf)
cycles$_{req}$ =	(number of concurrent tasks) x ((setup time + (number of 4-byte words)$_{req}$) + tbf_to_mbf_break time)
setup time =	2 f_{CLC_ERAY}cycles

Worst case for one IBF⇒ MBF or MBF⇒ OBF:

Max. break time: tbf_to_mbf_break time$_{max}$ =	(2+68) + (4+1) = 75
Max. number of f_{CLC_ERAY}cycles: cycles$_{req}$ =	3 x (6 + 68 + 75) = 435

Worst case for multiple transfers

If a second IBF⇒ MBF and a MBF⇒ OBF (see **Figure 624**) is requested directly after the first IBF⇒ MBF has started following worst case timing could appear:

$cycles_{trans}$ =	(remaining cycles of transfer running) + (cycles of second requested transfer) + (cycles of third requested transfer)
$cycles_{trans}$ =	$cycles_{rem}$ + $cycles_{req\_2}$+ $cycles_{req\_3}$
Max. number of f_{CLC_ERAY}cycles: $cycles_{trans}$ =	447 + 435 + 447 = 1329

41.3.12.3 Minimum f_{CLC_ERAY}

To calculate the minimum $f_{CLC_ERAY}$the worst case scenario has to be considered.

The worst case scenario depends on the following parameters

- maximum payload length
- minimum minislot length
- number of configured Message Buffers (excluding FIFO)
- used channels (single/dual channel)

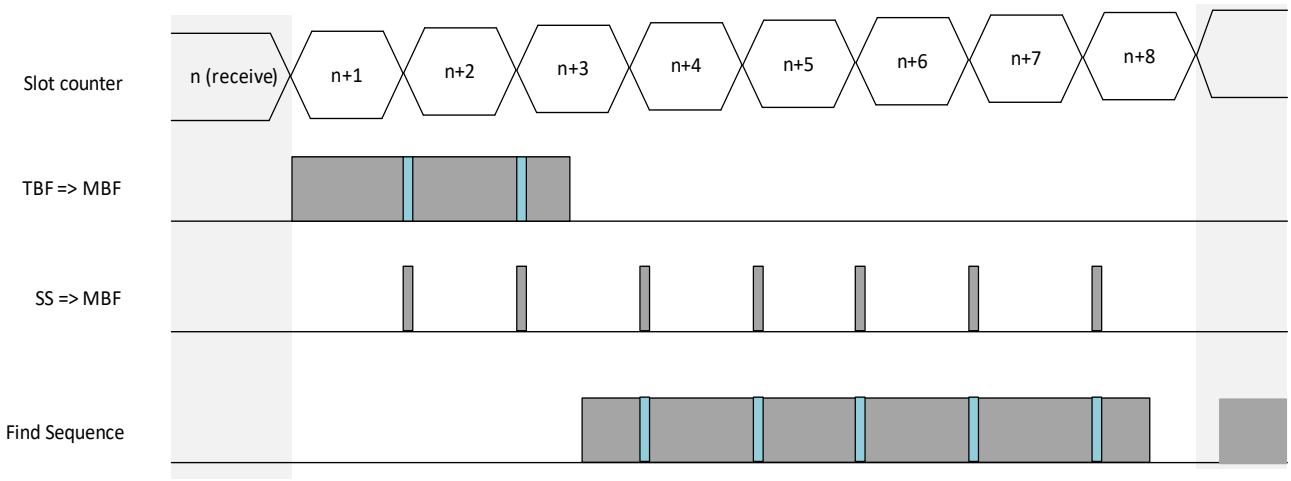

Figure 627 worst case scenario

Worst case scenario:

- reception of message with a maximum payload length in Slot n (n is 7,15,23,31,39,…)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,…) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8,16,24,32,40,…). It has to be finished until the next find-sequence is requested.

The length of a TBF⇒ MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$f_{CLC\_ERAY}cycles_{t2m}$ = number of concurrent tasks) x (setup $time_{t2m}$ + (number of 4-byte words)$_{t2m}$)

A SS⇒ MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

f_{CLC_ERAY} $cycles_{ss2m}$ = (number of concurrent tasks) x 5

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

f_{CLC_ERAY} $cycles_{find}$ = (number of concurrent tasks) x (setup $time_{find}$ + (number of configured buffers))

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 µs. A sequence of 8 minislots has a length of

$time_{8minislots}$ = 8 x gdMinislot x cdMinMTNom

The maximum period $T_{CLC\_ERAY} = 1/f_{CLC\_ERAY}$ can be calculated as followed:

$time_{8minislots} \geq$ (f_{CLC_ERAY} period in µs) x ((f_{CLC_ERAY} $cycles_{t2m}$) + 7 x (f_{CLC_ERAY} $cycles_{ss2m}$) + ($f_{CLC\_ERAY}cycles_{find}$))

f_{CLC_ERAY}period in ms ≤

$$\frac{time_{8minislots}}{(cycles_{t2m}) + 7 \times (cycles_{ss2m}) + (cycles_{find})}$$

minimum $time_{8minislots}$ = 8 x 2 x 1 µs = 16 µs

maximum f_{CLC_ERAY} $cycles_{t2m}$ = 3 x (6 + 68) = 222

maximum f_{CLC_ERAY} $cycles_{ss2m}$ = 3 * 5 = 15

maximum f_{CLC_ERAY} $cycles_{find}$ = 3 * (2 + 128) = 390

f_{CLC_ERAY} period in ms ≤

$$\frac{16\mu s}{222+7\times15+390} \approx 22.315 ns$$

The minimum f_{CLC_ERAY} frequency for this worst case scenario is 44.8125 MHz.

A too low f_{CLC_ERAY} frequency can cause a malfunction of the E-Ray.

The E-Ray can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (MHDF) register.

41.3.12.3.1 Minimum f_{CLC_ERAY} for various maximum payload length

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various maximum payload length assuming:

- a minimum minislot length of 2 µs.
- a maximum of 128 configured Message Buffers.

- dual channels in use.

Table 400 Minimum f_{CLC_ERAY} for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum f_{CLC_ERAY}	32,82 MHz	33,57 MHz	35,07 MHz	38,07 MHz	44,1 MHz

41.3.12.3.2 Minimum f_{CLC_ERAY} for various minimum minislot length

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various minimum minislot length assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a maximum 128 configured Message Buffers.
- dual channels in use.

Table 401 Minimum f_{CLC_ERAY} for different minimum minislot length

gdMinislot at dMinMTNom = 1 µs	2 µs	3 µs	4 µs	7 µs	8 µs
minimum f_{CLC_ERAY}	44,82 MHz	29,88 MHz	22,412 MHz	12,8 MHz	9,96 MHz

41.3.12.3.3 Minimum f_{CLC_ERAY} for various amount of configured Message Buffers

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various amount of configured Message Buffers assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a minimum minislot length of 2 µs.
- dual channels in use.

Table 402 Minimum f_{CLC_ERAY} for different amount of configured Message Buffers

Configured maximum amount of Message Buffers	128	64	32
minimum f_{CLC_ERAY}	44,82 MHz	32,82 MHz	26,82 MHz

41.3.12.3.4 Minimum f_{CLC_ERAY} for a typical configuration

´The minimum required f_{CLC_ERAY} frequency for various assuming the following typical E-Ray configuration:

- a maximum payload length of 32 bytes / 8 four-byte-words.
- a minimum minislot length of 7 µs.
- a maximum 128 configured Message Buffers.
- dual channels in use

The minimum f_{CLC_ERAY} frequency for this typical example would be 10 MHz.

41.3.12.4 FlexRay™ Protocol Controller access to Message RAM

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

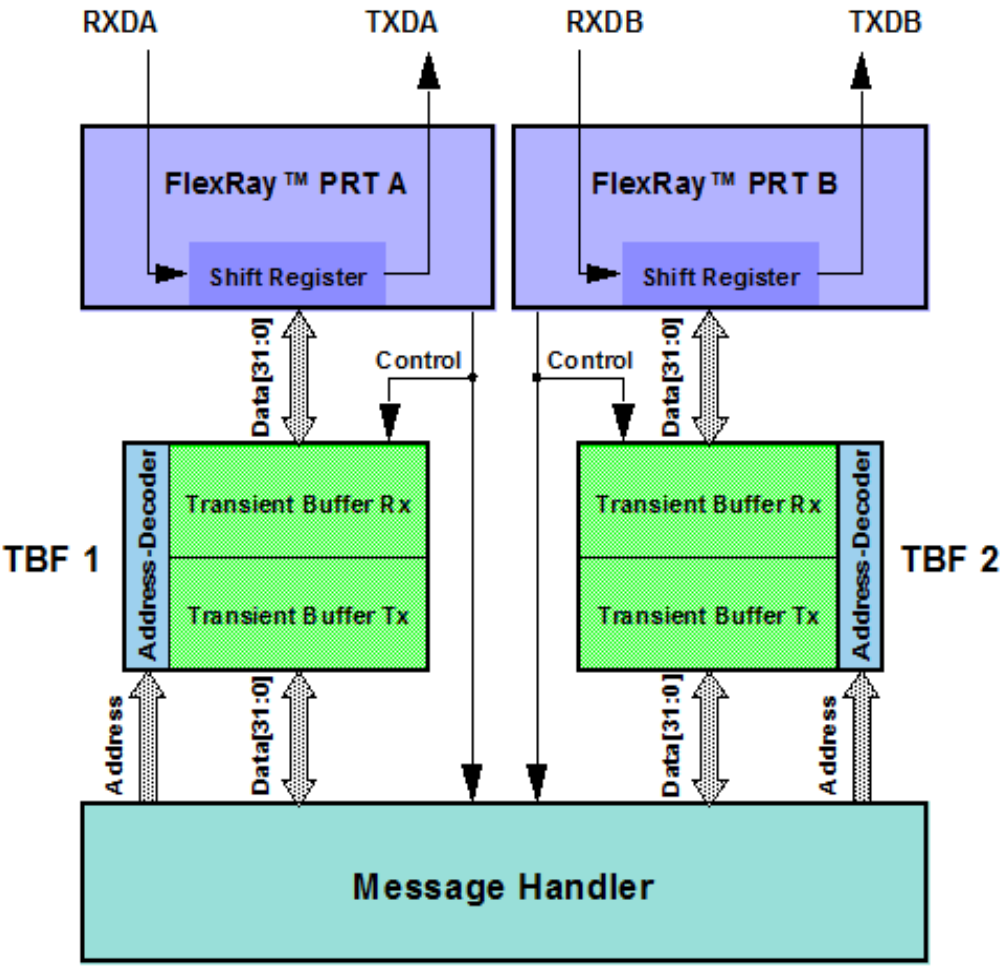

Figure 628 Access to Transient Buffer RAMs

41.3.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception / transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized in 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in **Figure 629**.

The Data Partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

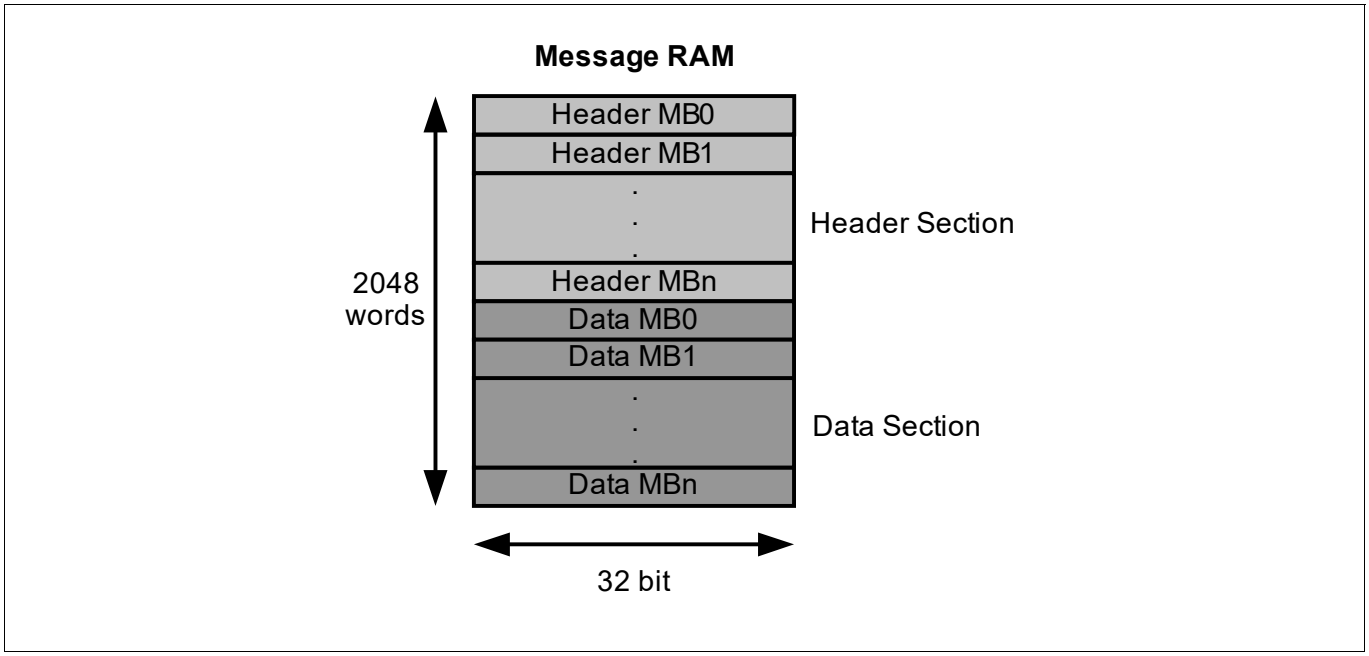

Figure 629 Structure of Message RAM

Header Partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 of each Message Buffer holds the11 bit pointer to the respective Data Section in the Data Partition

Data Partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each
- Or 56 Message Buffers with 128 byte Data Section each
- Or 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

41.3.13.1 Header Partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received PLR, Receive Cycle Count RCC, Received on Channel Indication RCI, Startup Frame Indication bit SFI, Sync bit SYN, NULL Frame Indication bit NFI, Payload Preamble Indication bit PPI, and Reserved bit RES are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status MBS information.

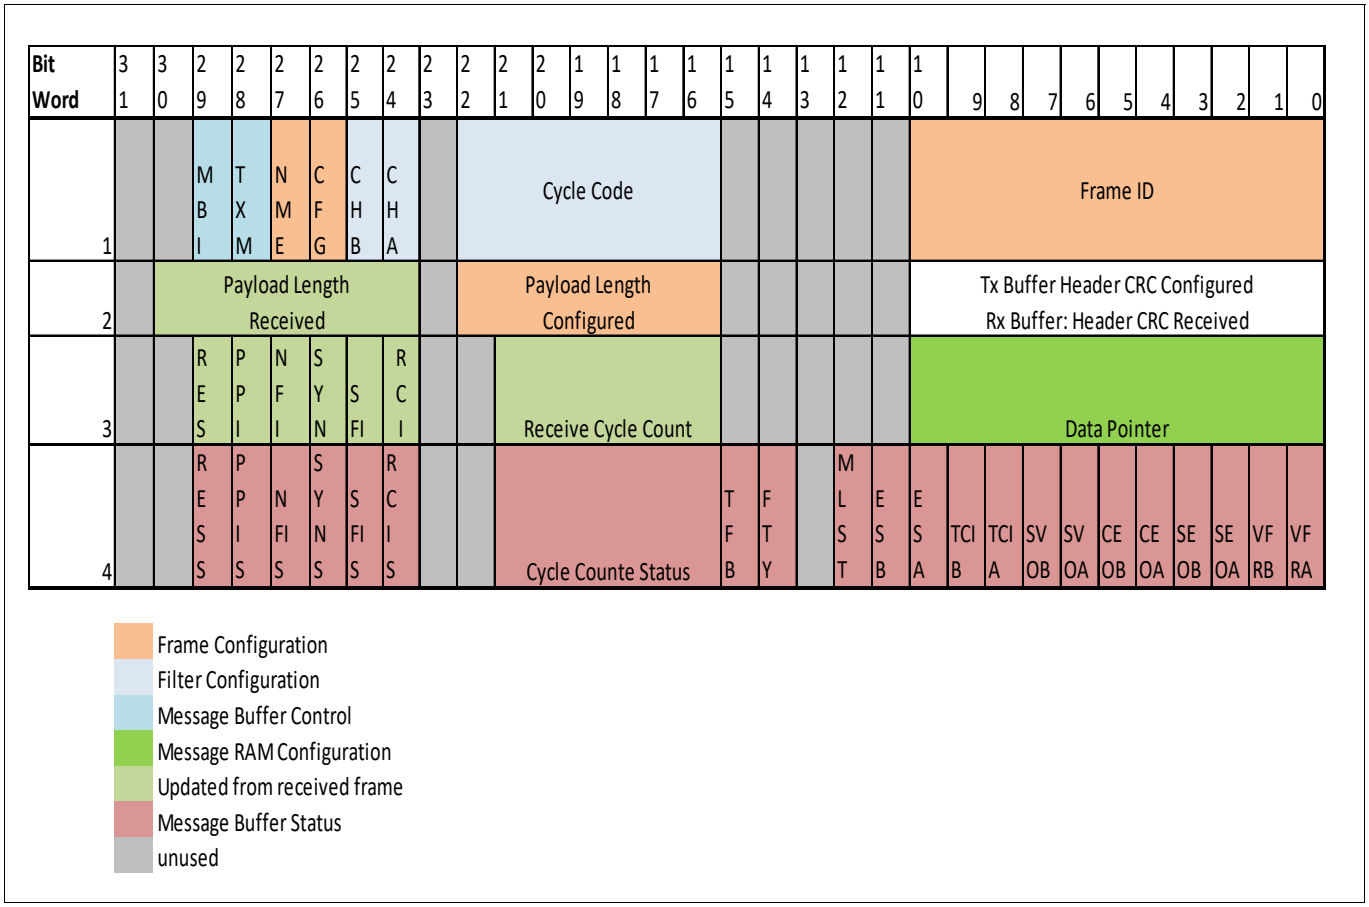

Figure 630 Header Section of a Message Buffer in the Message RAM

Header 1 (word 0)

Write access via WRHS1, read access via RDHS1:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive / transmit
- PPIT: Payload Preamble Indicator Transmit
- XMI: Transmit mode configuration: single-shot / continuous
- MBI: Message Buffer receive / transmit service request enable

Header 2 (word 1)

Write access via WRHS2, read access via RDHS2:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
  - Receive Buffer: Updated from received Frame
- Payload Length Configured
  - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of Payload Segment (2-byte words) stored from received Frame

Header 3

Write access via WRHS3, read access via RDHS3:

- Data Pointer
  - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access via RDHS3, valid for receive buffers only, updated from received Frames:

- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Startup Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message Buffer Status MBS (word 3)

Read access via MBS, updated by the Communication Controller at the end of the configured slot.

- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

41.3.13.2 Data Partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition. **Table 403** below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section, respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see Table below)

Table 403 Example for Structure of the Data Section in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
…	unused								unused								unused								unused

2047	unused								unused								**MB80** Data5								**MB80** Data4							

41.3.13.3 ECC Check

There is an ECC checking mechanism implemented in the E-Ray module to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator / checker attached as shown in **Figure 631**. When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and the faulty Message Buffer indicators MHDS.FMBD, MHDS.MFMB, MHDS.FMB are located in the Message Handler Status register. These error flags control the error interrupt flag EIR.EERR.

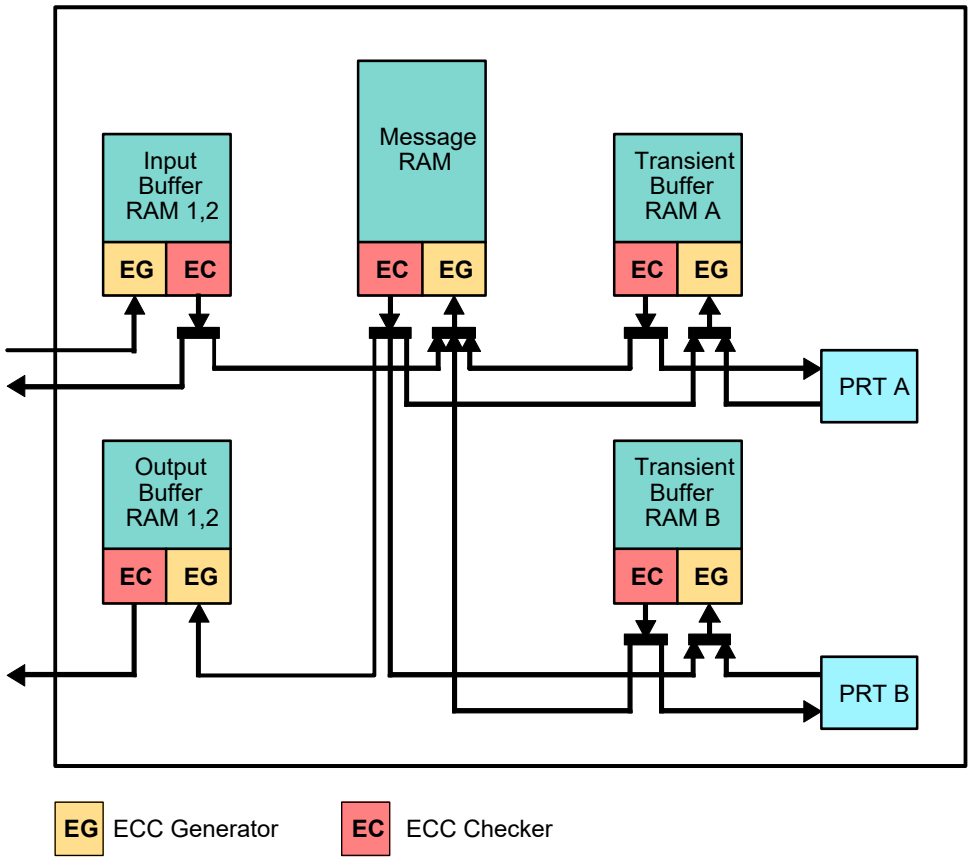

Figure 631 ECC Generation and Check

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status MHDS register is set
- The ECC error flag EIR.EERR in the Error Service Request Register is set, and if enabled, a module service request to the Host will be generated.

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM
   (Transfer of Header and Data Section)
   a) MHDS.EIBF bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB has been updated
   c) MHDS.FMB indicates the number of the faulty Message Buffer
   d) Transmit buffer: Transmission request for the respective Message Buffer is not set
2. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM
   (Transfer of Data Section only)
   a) MHDS.EMR bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer

c) MHDS.FMB indicates the number of the faulty Message Buffer
d) The Data Section of the respective Message Buffer is not updated
e) Transmit buffer: Transmission request for the respective Message Buffer is not set

3. ECC error during host reading Input Buffer RAM
   a) • MHDS.EIBF bit is set
4. ECC error during scan of Header Sections in Message RAM
   a) MHDS.EMR bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c) MHDS.FMB indicates the number of the faulty Message Buffer
   d) Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
   a) MHDS.EMR bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c) MHDS.FMB indicates the number of the faulty Message Buffer
   d) Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
   a) MHDS.ETBF1, MHDS.ETBF2 bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM
   (ECC error when reading Header Section of respective Message Buffer from Message RAM)
   a) MHDS.EMR bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c) MHDS.FMB indicates the number of the faulty Message Buffer
   d) The Data Section of the respective Message Buffer is not updated
8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM
   (ECC error when reading Transient Buffer RAM A, B)
   a) MHDS.ETBF1, MHDS.ETBF2 bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c) MHDS.FMB indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
   a) MHDS.EMR bit is set
   b) MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c) MHDS.FMB indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
    a) • MHDS.EOBF bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

41.3.14 Host Handling of Errors

An ECC error caused by transient bit flips can be fixed by:

41.3.14.1 Self-Healing

ECC errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

41.3.14.2 CLEAR_RAMS Command

After Power-On Reset, the E-Ray RAMs hold arbitrary values which causes ECC errors (MHDS) when a read operation is performed in a E-Ray RAM location. Hence the ERAY RAMs should be initialized always after a Power-On reset. When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to zero. Inorder to perform a safe initialization of RAM blocks, the following programming sequence is suggested:

1. Remove EINIT protection for the writing of the CLC register
2. Enable the clock in the CLC register
3. Read the CLC register back to ensure that the clocks are enabled
4. Enable the EINIT protection
5. Enable the test mode. Take care of the unlock sequence. Refer to description of LCK.TMK and TEST1.WRTEN
6. Check if CCSV.POCS is either 0x0 (DEFAULT_CONFIG) or 0xF (CONFIG). If not in any of these states, perform the according command to get to CONFIG state
7. Check if SUCC1.PBSY is equal to 0x0. If 0x1 wait until 0x0.
8. Set SUCC1.CMD to 0xC meaning that the CLEAR_RAMS command is entered
9. Read SUCC1.CMD. If 0x0 the command has not been accepted. Repeat up from step 7. Otherwise continue.
10. Wait for 1024 module cycles.
11. Enable RAM Test mode: TEST1.TMC = 01b. This mode enables access of all RAM blocks in E-Ray module to host.
12. CUST1.IBF1PAG = 1b
13. CUST1.IBF2PAG = 1b
14. Repeat steps 7 to 10 and then proceed to step 15
15. Read atleast one address in all the E-Ray RAM blocks
16. Switch off Test Mode: TEST1.WRTEN = 0b
17. Clear ECC error flags in MHDS and EIR registers

41.3.14.3 Temporary Unlocking of Header Section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see “Lock Register”).For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

41.3.15 Module Service Request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable / enable controls for each individual service request source separately.

An service request may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register EIR and the Status Service Request SIR Register.

Table 404 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFCL	Receive FIFO Critical Level
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1

Table 404 Module Service Request Flags and Service Request Line Enable (cont'd)

Register	Bit	Function
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	EERR	ECC Error
	RFO	Receive FIFO Overrun
EIR	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host INT0SR and INT1SR are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/ INT1SRC.SRE.

The interrupt lines to the Host NDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (NDIC1 to NDIC4). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled message buffer status changed interrupts (MSIC1 to MSIC4). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured via the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered via input pin **STPWn**.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on signals IBUSY and OBUSY. When a transfer has completed bit SIR.TIBC or SIR.TOBC is set.

41.3.16 Restrictions

The following restrictions have to be considered when programming the E-Ray IP-module. A violation of these restrictions may lead to an erroneous behavior of the E-Ray IP-module.

41.3.16.1 Message Buffers with the same Frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.

41.3.16.2 Data Transfers between IBF / OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the setup time to start the first transfer, the number of 4-byte words to be transferred, and the number of concurrent tasks to be managed by the Message Handler. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX / RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that e.g. a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

cyclestrans = (remaining cycles of transfer running) + (cycles of requested transfer)

cyclestrans = cyclesrem + cyclesreq

cyclesrem = (number of concurrent tasks) * (setup time + (number of 4-byte words)rem)

cyclesreq = (number of concurrent tasks) * (setup time + (number of 4-byte words)req)

setup time = 2 f_{CLC_ERAY} cycles

Under worst case conditions a transfer is requested directly after the previous transfer started:

Max. number of f_{CLC_ERAY} cycles: cyclestrans = (3 * (2 + 68)) + (3 * (2 + 68)) = 420

Worst case timing: timetrans(40MHz) = 420 * 25ns = 10.5 µs

41.3.17 E-Ray Module Implementation

This section describes the E-Ray interfaces as implemented in AURIX™ TC3xx Platform with the clock control, port and DMA connections, interrupt control, and address decoding.

Figure below shows a detailed view of the E-Ray interface.

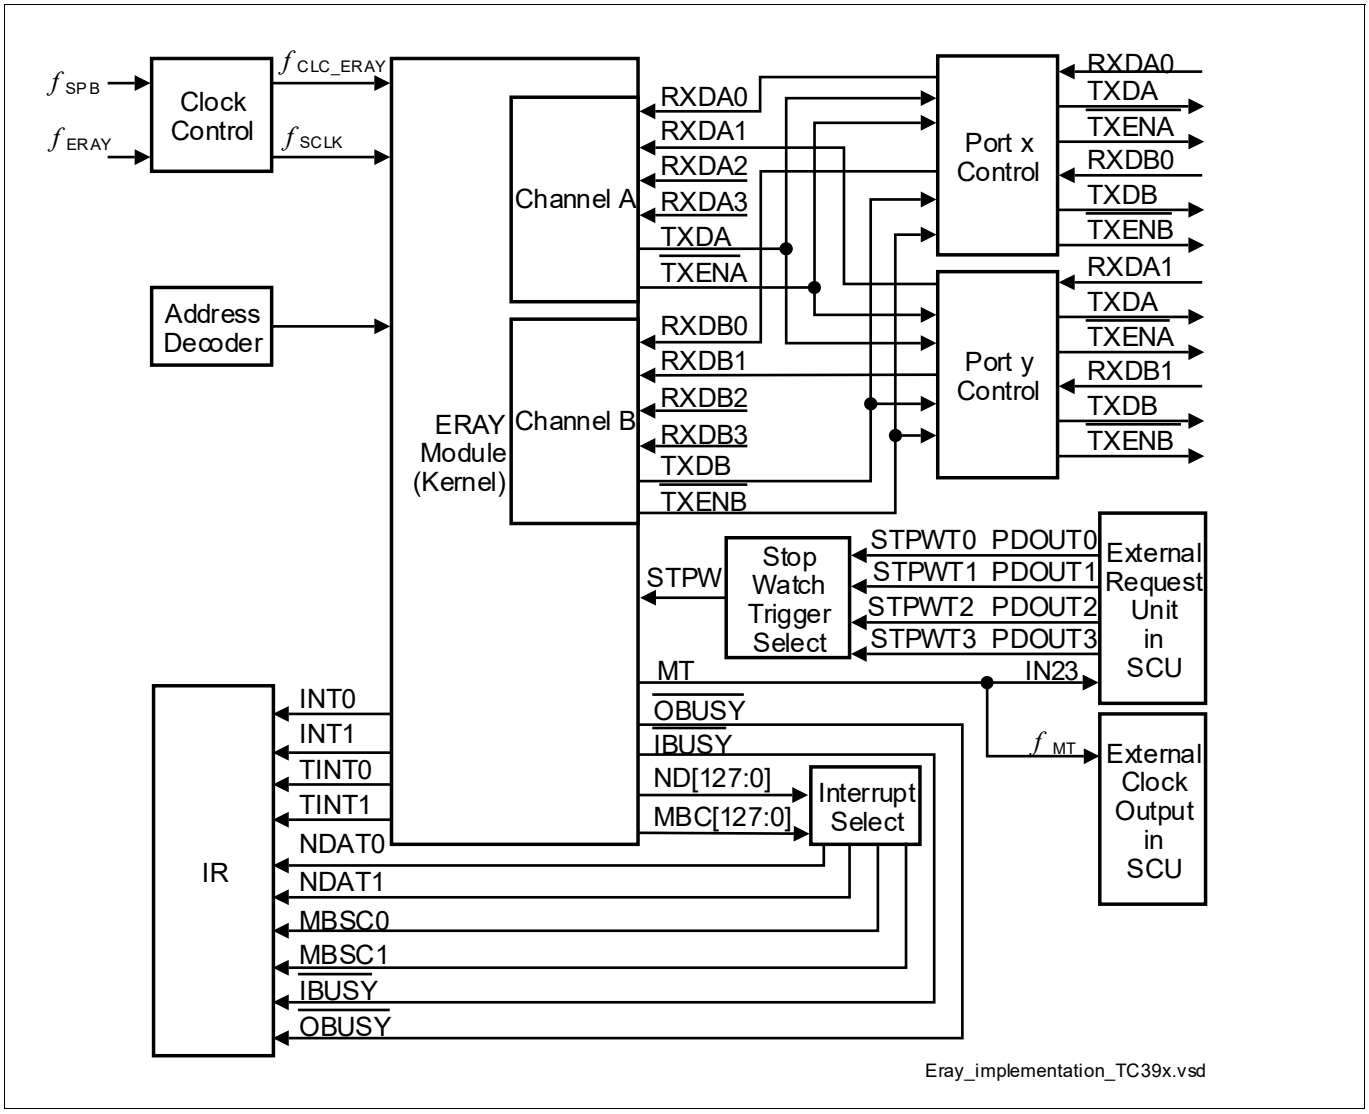

Figure 632 Detailed Block Diagram of the E-Ray Interface

41.3.17.1 Interconnections of the E-Ray Module

The E-Ray module has 2 FlexRay™ communication channels, channel A and channel B. Each channel provides a set of signals to drive a bus driver. The E-Ray module requires two different clocks, a sampling clock of the FlexRay™ bus f_{SCLK}. f_{SCLK} has to be 8 times the baud rate of the FlexRay™ communication. A second clock f_{CLC_ERAY} is used for the main protocol controller state machine and the customer interface logic. To enable deactivation of the E-Ray Module, f_{CLC_ERAY} and f_{SCLK} may be disabled (clock gated) by the CLC.DISR Enable E-Ray (Clock Gating) bit.The following items are described in this section:

- E-Ray module (kernel) external registers
- Port control and connections
  - I/O port line assignment
  - I/O function selection

  - Pad driver characteristics selection
- On-chip connections
  - SCU Connections
  - DMA connections
- Module clock generation
- Interrupt registers
- E-Ray address map

41.3.17.2 Port Control and Connections

This section describes the I/O connections of the E-Ray module.

41.3.17.2.1 Input/Output Function Selection

Table below shows how bits and bit fields must be programmed for the required I/O functionality of the E-Ray I/O lines. This table also shows the values of the peripheral input select registers.

Table 405 E-Ray I/O Control Selection and Setup

Port Lines	Input Select Register	Input/Output Control Register Bits	I/O

41.3.17.3 On-Chip Connections

This section describes all on-chip interconnections of the E-Ray modules except the connections to I/O ports.

41.3.17.3.1 E-Ray Connections with IR

The E-Ray module of the AURIX™ TC3xx Platform has several on-chip interconnections to the IR. Table below shows these interconnections. These enable the IR to handle different service request of E-Ray module via the DMA or Interrupt Service Routine.

Table 406 Request Assignment for IR

Line #	ERAY Output Signal	IR Request Input Line
00	INT0	SRC_ERAY0INT0
01	INT1	SRC_ERAY0INT1
02	TINT0	SRC_ERAY0TINT0
03	TINT1	SRC_ERAY0TINT1
04	NDAT0	SRC_ERAY0NDAT0
05	NDAT1	SRC_ERAY0NDAT1
06	MBSC0	SRC_ERAY0MBSC0
07	MBSC1	SRC_ERAY0MBSC1
08	OBUSY	SRC_ERAY0OBUSY
09	IBUSY	SRC_ERAY0IBUSY
10	INT0	SRC_ERAY1INT0
11	INT1	SRC_ERAY1INT1
12	TINT0	SRC_ERAY1TINT0
13	TINT1	SRC_ERAY1TINT1
14	NDAT0	SRC_ERAY1NDAT0
15	NDAT1	SRC_ERAY1NDAT1
16	MBSC0	SRC_ERAY1MBSC0
17	MBSC1	SRC_ERAY1MBSC1
18	OBUSY	SRC_ERAY1OBUSY
19	IBUSY	SRC_ERAY1IBUSY

41.3.17.3.2 E-Ray Connections with SMU

The E-Ray module of the AURIX™ TC3xx Platform provides to the SMU the following alarms (ALMx): SRAM ECC single bit correction, SRAM ECC uncorrectable error, SRAM address error, SRAM buffer address error.

41.3.17.3.3 E-Ray Connections with the External Request Unit of SCU

The E-Ray module of the AURIX™ TC3xx Platform has several on-chip interconnections to the External Request Unit (ERU) in the SCU to externally trigger stop watch events and to provide a global time e.g. to the on chip timers. Table 24-29 and Table below show these interconnections.

STPWT0_ are the inputs of ERAY0, STPWT1_ of ERAY1.

Table 407 External Stop Watch Request Assignment

ERAY Input Signal	ERU Request Output Line	Selected by
STPWT0_0/1_0	ERU_PDOUT0	CUST1.STPWTS = 00_B
STPWT0_1/1_1	ERU_PDOUT1	CUST1.STPWTS = 01_B
STPWT0_2/1_2	ERU_PDOUT2	CUST1.STPWTS = 10_B
STPWT0_3/1_3	ERU_PDOUT3	CUST1.STPWTS = 11_B

Table 408 Global Macrotick Connection to ERU

ERAY Output Signal	ERU Request Input Line	Selected by
MT0 (from ERAY0)	ERU_IN23	ERU_EICR1.EXIS0 = 11_B
MT1 (from ERAY1)	ERU_IN73	ERU_EICR3.EXIS1 = 11_B

41.3.17.3.4 E-Ray Connections to GTM

The E-Ray module of the AURIX™ TC3xx Platform has several on-chip interconnections to the Generic Timer Module (GTM). Table below show these interconnection s.

Table 409 Global Macrotick Connection to GTM

ERAY Output Signal	TIM Input Line
MT0	TIM0_7
MT0	TIM1_7
MT0	TIM2_7
MT0	TIM3_7
MT1	TIM4_7
MT1	TIM5_7

41.3.17.3.5 E-Ray Connections with the External Clock Output of SCU

The E-Ray module of the AURIX™ TC3xx Platform has one on-chip interconnections to the External Clock Output Unit in the SCU to distribute externally as also internally the Macro Tick as time base for distributed system control. Table below shows this interconnection.

Table 410 Global Macrotick Connection to External Clock Output

ERAY Output Signal	External Clock Output	Selected by
MT0 (from ERAY0)	f_{MT0}	SCU_EXTCON.SEL0 = 1111_B

41.3.17.4 OCDS Trigger Bus (OTGB) Interface

The E-Ray module has two 16 bit and one 32 bit Trigger Sets (**Table 411**) which are selected with the OTSS register.

Table 411 E-Ray Trigger Sets

Trigger Set	Details
TS16_SEP Service Requests, Errors and POC State	**Table 413**

Table 411 E-Ray Trigger Sets (cont'd)

Trigger Set	Details
TS16_MC Macrotick Counter	Table 414
TS32_SCSC State, Cycle and Slot Counter	Table 415

Table 412 shows all possible Trigger Set mapping options. If OTGB0 and/or OTGB1 is not used for E-Ray, Trigger Sets of other sources can be added in the OTGM module.

Table 412 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	TS16_SEP/MC		
		TS16_SEP/MC	
	TS16_SEP/MC	TS16_SEP/MC	
64 Bit			TS32_SCSC
	TS16_SEP/MC		TS32_SCSC
		TS16_SEP/MC	TS32_SCSC
	TS16_SEP/MC	TS16_SEP/MC	TS32_SCSC

Table 413 TS16_SEP Service Requests, Errors and POC State

Bits	Description
0	Interrupt 0 Service Request (INT0SRC)
1	Interrupt 1 Service Request (INT1SRC)
2	Timer Interrupt 0 Service Request (TINT0SRC)
3	Timer Interrupt 1 Service Request (TINT1SRC)
4	New Data 0 Service Request (NDAT0SRC)
5	New Data 1 Service Request (NDAT1SRC)
6	Message Buffer Status Changed 0 Service Request (MBSC0SRC)
7	Message Buffer Status Changed 1 Service Request (MBSC1SRC)
8	Output Buffer Busy Service Request (OBUSYSRC)
9	Input Buffer Busy Service Request (IBUSYSRC)
10	Reserved
11	Error on Channel A (EIR.EDA)
12	Error on Channel B (EIR.EDB)
[15:13]	POC State bits[2:0] (CCSV.POCS)

Table 414 TS16_MC Macrotick Counter

Bits	Description
[13:0]	Macrotick Value (MTCCV.MTV)
[15:14]	Reserved

Table 415 TS32_SCSC State, Cycle and Slot Counter

Bits	Description
[10:0]	Slot Counter Channel A (SCV.SCCA)
[22:12]	Slot Counter Channel B (SCV.SCCB)
[29:24]	Cycle Counter Value (MTCCV.CCV)
30	Transfer Input Buffer Completed (SIR.TIBC)
31	Transfer Output Buffer Completed (SIR.TOBC)
11,23	Reserved

TS32_SCSC becomes valid (posedge on otgb2_valid_o) on a change of any Slot Counter or Transfer Buffer state. This covers also the Cycle Counter which will always change with a slower rate.

41.3.17.5 OTGB E-Ray Registers

41.3.17.5.1 OCDS Trigger Bus (OTGB)

The OTGB control register is cleared by Debug Reset. Write access is 32 bit wide only and requires Supervisor Mode.

OCDS Trigger Set Select

OTSS
OCDS Trigger Set Select **(0870_H)** **Application Reset Value: $0000\ 0000_H$**

41.3.17.6 BPI_FPI Module Registers

Note: Register bits marked “r” in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

CLC
Clock Control Register **(0000_H)** **Application Reset Value: $0000\ 0003_H$**

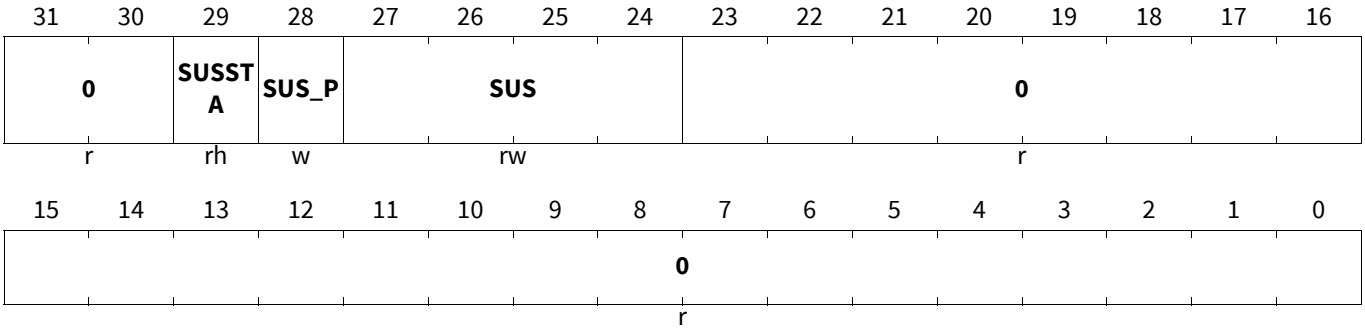
0	2, 7:4, 15:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS
OCDS Control and Status **($08E8_H$)** **Debug Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0_H Will not suspend 1_H Hard suspend. Clocks f_{CLC_ERAY} and the sampling clock f_{SCLK} are switched off immediately. No read or write access to any registers. 2_H Soft suspend. This bit forces the module into freeze state. **others**, reserved

Field	Bits	Type	Description
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; must be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access. [1]for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus Master TAG Assignments Chapter). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, … , EN31 -> TAG ID 011111B.

Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers.The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to ´1´ by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to ´0´ by writing ´1´ to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

KRST0

Kernel Reset Register 0 **(08F4$_H$)** **Application Reset Value: 0000 0000$_H$**

0														RSTSTAT	RST
r														rh	rwh

Field	Bits	Type	Description
RST	0	rwh	**Kernel Reset** This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	1	rh	**Kernel Reset Status** This bit indicates wether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with ´1´ to the CLR bit in the related KRSTCLR register. 0_B No kernel reset was executed 1_B Kernel reset was executed
0	31:2	r	**Reserved** Read as 0; should be written with 0.

Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers (KRST1.RST and KRST0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 **(08F0$_H$)** **Application Reset Value: 0000 0000$_H$**

0	31:1	r	**Reserved** Read as 0; should be written with 0.

41.3.17.7 Interrupt Registers

Two different type of Interrupt Registers are described within this chapter.
The Interrupt Control register enable the selection of the Service Request used to signal an event. The Interrupt Control registers NDIC1 to NDIC4 select the service request node used for New Data Events.The Interrupt Control registers MSIC1 to MSIC4 select the service request node used for Message Buffer Status Changed Events.
The Interrupt Service Request Control Registers control the eight service request nodes.

New Data Interrupt Control 1

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

41.4 Registers

The programmer's model of the E-Ray module follows the principle of memory mapped peripheral. Some portion of the memory follows the principle of segmented/paged memory organization.

41.4.1 Register Map

The E-Ray module allocates an address space of 4 Kbyte (000_H to $FFFF_H$). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer specific purposes. All functions related to these addresses are located in the Customer Host Interface. The test registers located on address 0010_H and 0014_H are writable only under the conditions described in **Special Registers**.

The assignment of the Message Buffers is done according to the scheme shown in **Table 416** below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit / Receive Buffers assigned to static segment
- Static and Dynamic Buffers: Transmit / Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

The Message Buffer separation configuration can be changed only in "DEFAULT_CONFIG" or "CONFIG" state only by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup / SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM in the SUC Configuration Register 1 (SUCC1). In addition, Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

Table 416 Assignment of Message Buffers

Message Buffer 0	⇓ Static Buffers	
Message Buffer 1		
…		
	⇓ Static + Dynamic Buffers	⇐ **FDB**
	⇓ FIFO	⇐ **FFB**
Message Buffer N-1		
Message Buffer N		⇐ **LCB**

41.4.2 E-Ray Kernel Registers

This chapter describes all registers of the E-Ray kernel.

All registers in the E-Ray address spaces are reset with the application reset with one exception: OCS is reset with debug reset only.

41.4.2.1 Customer Registers

The addresses 0004_H - $000F_H$,$03C8_H$ - $03EC_H$ and 0800_H - $0FFF_H$ are reserved for customer-specific registers.

Module Identification Register

This register contains bit fields identifying the E-Ray module in Infineon's Module portfolio and is read only.

ID
Module Identification Register (0008_H) Application Reset Value: 0044 C0XX$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MOD_NUMBER															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** MOD_REV defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	15:8	r	**Module Type** The value of this bit field is $C0_H$. It defines the module as a 32-bit module.
MOD_NUMBER	31:16	r	**Module Number Value** This bit field defines a module identification number. For the E-Ray module the module identification number is 44_H.

Busy and Input Buffer Control Register

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme. IBFS changes 2 clock cycles after any reset to '1'. Thus the application will read this bit as '1' already at first access after any reset.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

CUST1
Busy and Input Buffer Control Register (0004_H) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TO															
rw															

Field	Bits	Type	Description
TO	31:0	rw	**CIF Timeout Reload Value** The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

Automatic Delayed Write Access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter preluded with the 32-bit value specified in the bit field CUST3.TO. If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, e.g. to set OBCR.VIEW will lead to a canceled read or write operation, e.g. OBCR.VIEW remains cleared, and an error is signalled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer (MBF⇒ OBF) is completed. During this time span all read and write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal TOBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, e.g. to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time, e.g. OBCR.VIEW remains cleared, and an error is signalled by setting EIR.IOBA) or the read or write completes normally, e.g. set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer (MBF⇒ OBF) is finalized. During this time the bus is locked and no further access to the E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TOBC or due to other not processed read or write accesses to the E-Ray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF (IBF⇒ MBF), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF⇒ MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signalled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer (IBFÞMBF) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is

cleared. Additionally signal TIBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA) or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF$\Rightarrow$ MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TIBC or due to other not processed read or write accesses to the E-Ray module.

So setting CUST3.TO = $FFFFFFFF_H$, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

41.4.2.2 Special Registers

Test Register 1

The Test Register 1 holds the control bits to configure the test modes of the E-Ray module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the E-Ray IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register. In CERA and CERB, Coding errors are also signalled when the Communication Controller is in "MONITOR_MODE". The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.

TEST1
Test Register 1 **(0010_H)** **Application Reset Value: $0000\ 0300_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CERB				CERA				0		TXENB	TXENA	TXB	TXA	RXB	RXA

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						AOB	AOA	0		TMC		0		ELBE	WRTEN
r						rh	rh	r		rw		r		rw	rw

Field	Bits	Type	Description
WRTEN	0	rw	**Write Test Register Enable** Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on “Lock Register”. The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0_B Write access to test registers disabled. 1_B Write access to test registers enabled.

Field	Bits	Type	Description
ELBE	1	rw	**External Loop Back Enable** There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	5:4	rw	**Test Multiplexer Control** 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	**Activity on A** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	**Activity on B** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	**Read Channel A Receive Pin** This bit field shows the current logic state of RXDA. 0_B RXDA = 0 1_B RXDA = 1
RXB	17	rh	**Read Channel B Receive Pin** This bit field shows the current logic state of RXDB. 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	**Read or Write to Channel A Transmit Pin** A write to this bit field sets the TXDA to corresponding logic state. A read from this bit field shows the current logic state of TXDA. 0_B TXDA = 0 1_B TXDA = 1

Field	Bits	Type	Description
TXB	19	rwh	**Read or Write to Channel B Transmit Pin** A write to this bit field sets the TXDB to corresponding logic state. A read from this bit field shows the current logic state of TXDB. 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	**Read or Write to Channel A Transmit Enable Pin** A write to this bit field sets the TXENA to corresponding logic state. A read from this bit field shows the current logic state of TXENA. 0_B $\overline{\text{TXENA}}$= 0 1_B $\overline{\text{TXENA}}$= 1
TXENB	21	rwh	**Read or Write to Channel B Transmit Enable Pin** A write to this bit field sets the TXENB to corresponding logic state. A read from this bit field shows the current logic state of TXENB. 0_B $\overline{\text{TXENB}}$ = 0 1_B $\overline{\text{TXENB}}$= 1
CERA	27:24	rh	**Coding Error Report Channel A** Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. Other combinations are reserved. 0_H No coding error detected 1_H Header CRC error detected 2_H Frame CRC error detected 3_H Frame Start Sequence FSS too long 4_H First bit of Byte Start Sequence BSS seen LOW 5_H Second bit of Byte Start Sequence BSS seen HIGH 6_H First bit of Frame End Sequence FES seen HIGH 7_H Second bit of Frame End Sequence FES seen LOW 8_H CAS / MTS symbol seen too short 9_H CAS / MTS symbol seen too long
CERB	31:28	rh	**Coding Error Report Channel B** Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. Other combinations are reserved. 0_H No coding error detected 1_H Header CRC error detected 2_H Frame CRC error detected 3_H Frame Start Sequence FSS too long 4_H First bit of Byte Start Sequence BSS seen LOW 5_H Second bit of Byte Start Sequence BSS seen HIGH 6_H First bit of Frame End Sequence FES seen HIGH 7_H Second bit of Frame End Sequence FES seen LOW 8_H CAS / MTS symbol seen too short 9_H CAS / MTS symbol seen too long

Field	Bits	Type	Description
0	3:2, 7:6, 15:10, 23:22	r	**Reserved** Returns 0 if read; should be written with 0.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the E-Ray module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

The cycle counter value of Frames send in ATM mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show $0000\ 1101_H$ while the E-Ray module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back via physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels’s Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The E-Ray cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

The cycle counter value of Frames used in loop back mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

Test Register 2

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the E-Ray module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2
Test Register 2 **(0014_H)** **Application Reset Value: $0000\ 0000_H$**

WRECC	14	rw	**Write ECC Data Enable** Content of ECCW is transferred to the RAM: *Note: Test mode must be entered. See "Test Register 1"* 0_B disabled 1_B enabled
0	3, 13:7, 15, 31:16	r	**Reserved** Returns 0 if read; should be written with 0.

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to $7FF_H$ (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

In RAM test mode the memory must be accessed with 32Bit accesses only.

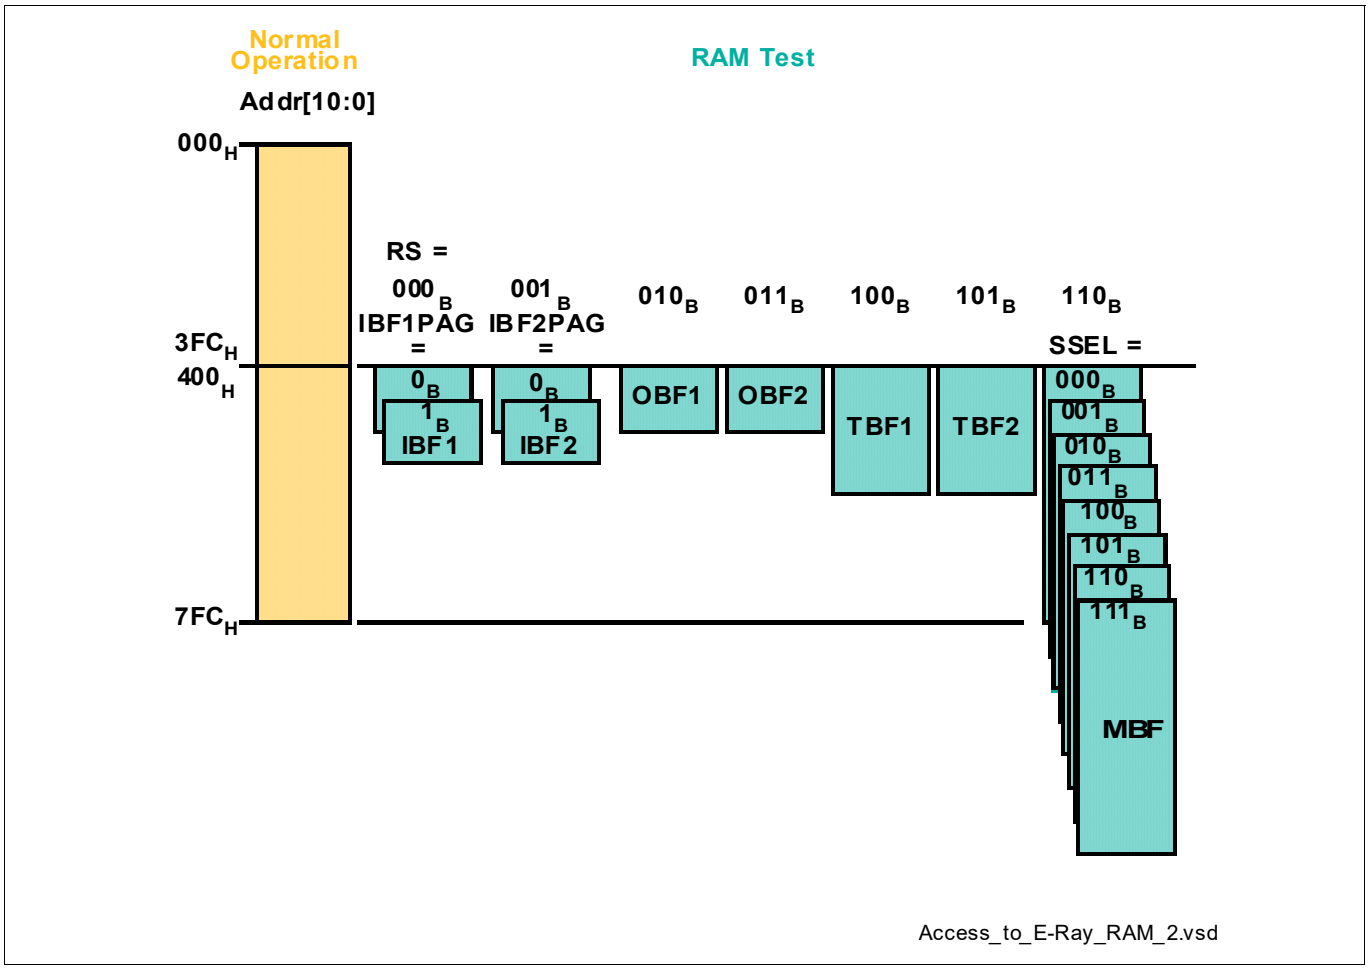

Figure 633 RAM test mode Access to E-Ray RAM Blocks

Lock Register

The Lock Register is write-only. Reading the register will return $0000\ 0000_H$.

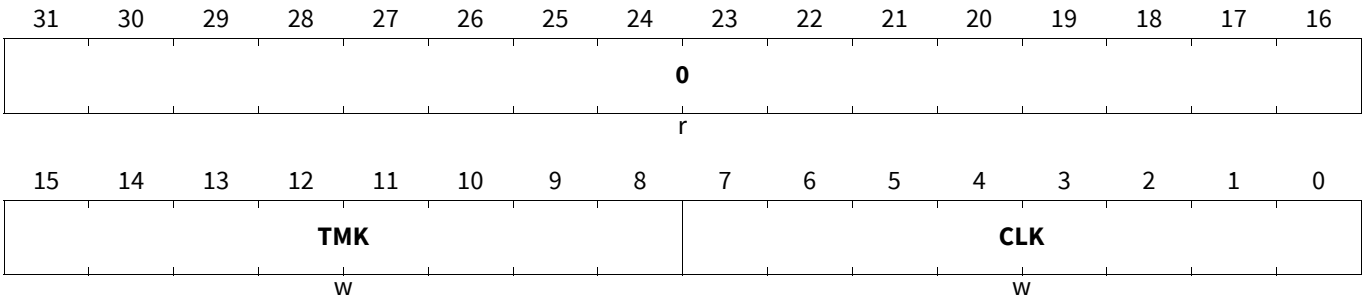
Note: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

To exit "CONFIG" state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated.

First write: LCK.CLK = CE_H = $1100\ 1110_B$

Second write: LCK.CLK = 31_H = 0011 0001_B

LCK
Lock Register **($001C_H$)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
CLK	7:0	w	**Configuration Lock Key** To leave “CONFIG” state by writing to SUCC1.CMD commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated. First write: LCK.CLK = CE_H = 1100 1110_B Second write: LCK.CLK = 31_H = 0011 0001_B Third write: SUCC1.CMD Returns 0 if read
TMK	15:8	w	**Test Mode Key** To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75_H = 0111 0101_B Second write: LCK.TMK = $8A_H$ = 1000 1010_B Second write: TEST1.WRTEN = 1 Returns 0 if read
0	31:16	r	**Reserved** Returns 0 if read; should be written with 0.

41.4.2.3 Service Request Registers

The address space from 0020_H to $007F_H$ is reserved for service request registers.

Error Service Request Select Register

The flags are set when the Communication Controller detects one of the listed error conditions. They remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

EIR
Error Service Request Select Register (0020_H) Application Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					TABB	LTVB	EDB	0					TABA	LTVA	EDA

r				rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
PEMC	0	rwh	**POC Error Mode Changed** This flag is set whenever the error mode signalled by CCEV.ERRM in the Communication Controller Error Vector register has changed. This flag is cleared by writing a 1. 0_B Error mode has not changed 1_B Error mode has changed
CNA	1	rwh	**Command Not Accepted** The flag signals that the write access to the CHI command vector SUCC1.CMD in the SUC Configuration Register 1 was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = 1). This flag is cleared by writing a 1. 0_B CHI command accepted 1_B CHI command not accepted
SFBM	2	rwh	**SYNC Frames Below Minimum** This flag signals that the number of SYNC Frames received during the last communication cycle was below the limit required by the FlexRay™ protocol. May be set during startup and therefore should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. This flag is cleared by writing a 1. 0_B Sync node: 1 or more SYNC Frames received Non-sync node: 2 or more SYNC Frames received 1_B Less than the required minimum of SYNC Frames received

Field	Bits	Type	Description
SFO	3	rwh	**SYNC Frame Overflow** Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC02.SNM in the GTU Configuration Register 2. This flag is cleared by writing a 1. 0_B Number of received SYNC Frames ≤ GTUC02.SNM 1_B More SYNC Frames received than configured by GTUC02.SNM
CCF	4	rwh	**Clock Correction Failure** This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing offset and / or rate correction • Clock Correction limit reached The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit CCF should be cleared by the Host after the Communication Controller entered "NORMAL_ACTIVE" state. This flag is cleared by writing a 1. 0_B Clock correction successful so far 1_B Clock correction failed
CCL	5	rwh	**CHI Command Locked** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit EIR.CNA is also set to 1. This flag is cleared by writing a 1. 0_B CHI command accepted 1_B CHI command not accepted
EERR	6	rh	**ECC Error** The flag signals an ECC error to the Host. It is set whenever one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1. See also "Message Handler Status". This bit must be cleared at initialization of the module! 0_B No error detected 1_B Error detected
RFO	7	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected

Field	Bits	Type	Description
EFA	8	rwh	**Empty FIFO Access** This flag is set by the Communication Controller when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty. 0_B No Host access to empty FIFO occurred 1_B Host access to empty FIFO occurred
IIBA	9	rwh	**Illegal Input Buffer Access** This flag is set by the Communication Controller when the Host wants to modify a Message Buffer via Input Buffer while the Communication Controller is not in “CONFIG” or “DEFAULT_CONFIG” state and one of the following conditions applies: 1. The Host writes to the Input Buffer Command Request register to modify the: a) Header Section of Message Buffer 0, 1 if configured for transmission in key slot b) Header Section of static Message Buffers with buffer number < MRC.FDB while MRC.SEC = 01_B c) Header Section of any static or dynamic Message Buffer while MRC.SEC = $1x_B$ d) Header and / or Data Section of any message buffer belonging to the receive FIFO 2. The Host writes to any register of the Input Buffer while IBCR.IBSYS is set. 0_B No illegal Host access to Input Buffer occurred 1_B Illegal Host access to Input Buffer occurred
IOBA	10	rwh	**Illegal Output Buffer Access** This flag is set by the Communication Controller when the Host requests the transfer of a Message Buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1. 0_B No illegal Host access to Output Buffer occurred 1_B Illegal Host access to Output Buffer occurred
MHF	11	rwh	**Message Handler Constraints Flag** The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.TNSA, MHDF.TNSB, MHDF.WAHP changes from 0 to 1. 0_B No Message Handler failure detected 1_B Message Handler failure detected
EDA	16	rwh	**Error Detected on Channel A** This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from 0 to 1. This flag is cleared by writing a 1. 0_B No error detected on channel A 1_B Error detected on channel A

Field	Bits	Type	Description
LTVA	17	rwh	**Latest Transmit Violation Channel A** The flag signals a latest transmit violation on channel A to the Host. This flag is cleared by writing a 1. 0_B No latest transmit violation detected on channel A 1_B Latest transmit violation detected on channel A
TABA	18	rwh	**Transmission Across Boundary Channel A** The flag signals to the Host that a transmission across a slot boundary occurred for channel A. This flag is cleared by writing a 1. 0_B No transmission across slot boundary detected on channel A 1_B Transmission across slot boundary detected on channel A
EDB	24	rwh	**Error Detected on Channel B** This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from 0 to 1. This flag is cleared by writing a 1. 0_B No error detected on channel B 1_B Error detected on channel B
LTVB	25	rwh	**Latest Transmit Violation Channel B** The flag signals a latest transmit violation on channel B to the Host. This flag is cleared by writing a 1. 0_B No latest transmit violation detected on channel B 1_B Latest transmit violation detected on channel B
TABB	26	rwh	**Transmission Across Boundary Channel B** The flag signals to the Host that a transmission across a slot boundary occurred for channel B. This flag is cleared by writing a 1. 0_B No transmission across slot boundary detected on channel B 1_B Transmission across slot boundary detected on channel B
0	15:12, 23:19, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

Status Service Request Register

The flags are set whenever the Communication Controller detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

SIR

Status Service Request Register **(0024_H)** **Application Reset Value: $0000\ 0000_H$**

Field	Bits	Type	Description
WST	0	rwh	**Wakeup Status** This flag is set when the wakeup status vector CCSV.WSV in the Communication Controller Status Vector register changes to a value other than UNDEFINED. This flag is cleared by writing a 1. 0_B Wake-up status unmodified 1_B Wake-up status modified (and not UNDEFINED)
CAS	1	rwh	**Collision Avoidance Symbol** This flag is set by the Communication Controller during STARTUP state when a CAS or potential CAS was received. This flag is cleared by writing a 1. 0_B No bit pattern matching the CAS symbol received 1_B Bit pattern matching the CAS symbol received
CYCS	2	rwh	**Cycle Start Service Request** This flag is set by the Communication Controller when a communication cycle starts This flag is cleared by writing a 1. 0_B No communication cycle started 1_B Communication cycle started
TXI	3	rwh	**Transmit Service Request** This flag is set by the Communication Controller at the end of Frame transmission if bit WRHS1.MBI in the respective Message Buffer is set. This flag is cleared by writing a 1. 0_B No Frame transmitted from a transmit buffer with WRHS1.MBI = 1 1_B At least one Frame was transmitted from a transmit buffer with WRHS1.MBI = 1
RXI	4	rwh	**Receive Service Request** This flag is set by the Communication Controller whenever the set condition of a Message Buffer ND flag is fulfilled and if bit WRHS1.MBI of that Message Buffer is set to 1. This flag is cleared by writing a 1. 0_B No ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 1_B At least one ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1

Field	Bits	Type	Description
RFNE	5	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame was stored into the empty receive FIFO.m The actual state of the receive FIFO is monitored in register FSR 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	6	rh	**Receive FIFO Critical Level** This flag is set when a valid receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
NMVC	7	rwh	**Network Management Vector Changed** This service request flag signals a change in the Network Management Vector visible to the Host. This flag is cleared by writing a 1. 0_B No change in the Network Management vector 1_B Network Management vector changed
TI0	8	rwh	**Timer Service Request 0** This flag is set whenever timer 0 matches the conditions configured in the Timer Service Request 0 Configuration Register T0C. A Timer Service Request 0 is also signalled by TINT0SRC. This flag is cleared by writing a 1. 0_B No Timer Service Request 0 1_B Timer Service Request 0 occurred
TI1	9	rwh	**Timer Service Request 1** This flag is set whenever the conditions programmed in the Timer Service Request 1 Configuration Register T1C are met. A Timer Service Request 1 is also signalled by TINT1SRC. This flag is cleared by writing a 1. 0_B No Timer Service Request 1 1_B Timer Service Request 1 occurred
TIBC	10	rwh	**Transfer Input Buffer Completed** This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit IBCR.IBSYS in the Input Buffer Command Request register has been reset by the Message Handler. This flag is cleared by writing a 1. 0_B No transfer completed 1_B Transfer between Input Buffer and Message RAM completed
TOBC	11	rwh	**Transfer Output Buffer Completed** This flag is set whenever a transfer from Message RAM to the Output Buffer has completed and bit OBCR.OBSYS in the Output Buffer Command Request register has been reset by the Message Handler. This flag is cleared by writing a 1. 0_B No transfer completed 1_B Transfer between Message RAM and the Output Buffer completed

Field	Bits	Type	Description
SWE	12	rwh	**Stop Watch Event** This flag is set after a stop watch activation when the current cycle counter and Macrotick value are stored in the Stop Watch Register 1 (STPW1). This flag is cleared by writing a 1. 0_B No Stop Watch Event 1_B Stop Watch Event occurred
SUCS	13	rwh	**Startup Completed Successfully** This flag is set whenever a startup completed successfully and the Communication Controller entered “NORMAL_ACTIVE” state. This flag is cleared by writing a 1. 0_B No startup completed successfully 1_B Startup completed successfully
MBSI	14	rwh	**Message Buffer Status Service Request** This flag is set by the Communication Controller when the Message Buffer status MBS has changed and if bit RDHS1.MBI of that Message Buffer is set. This flag is cleared by writing a 1. 0_B No Message Buffer status change of Message Buffer with RDHS1.MBI= 1 has changed 1_B Message Buffer status of at least one Message Buffer with RDHS1.MBI= 1 has changed
SDS	15	rwh	**Start of Dynamic Segment** This flag is set by the Communication Controller when the dynamic segment starts. 0_B Dynamic segment not yet started 1_B Dynamic segment started
WUPA	16	rwh	**Wakeup Pattern Channel A** This flag is set by the Communication Controller when a wakeup pattern was received on channel A. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. This flag is cleared by writing a 1. 0_B No wake-up pattern received on channel A 1_B Wake-up pattern received on channel A
MTSA	17	rwh	**MTS Received on Channel A(vSS!ValidMTSA)** Media Access Test symbol received on channel A during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. This flag is cleared by writing a 1. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A

Field	Bits	Type	Description
WUPB	24	rwh	**Wakeup Pattern Channel B** This flag is set by the Communication Controller when a wakeup pattern was received on channel B. Only set when the Communication Controller is in “WAKEUP”, “READY”, or “STARTUP” state, or when in Monitor mode. This flag is cleared by writing a 1. 0_B No wake-up pattern received on channel B 1_B Wake-up pattern received on channel B
MTSB	25	rwh	**MTS Received on Channel B** Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. This flag is cleared by writing a 1. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B
0	23:18, 31:26	r	**Reserved** Returns 0 if read; should be written with 0.

Error Service Request Line Select

The Error Service Request Line Select register assigns a service request generated by a specific error service request flag from register EIR to one of the two module service request lines INT0SRC or INT1SRC:

0 = Interrupt assigned to interrupt line (INT0SRC)

1 = Interrupt assigned to interrupt line (INT1SRC)

Error Service Request Enable Set

The settings in the Error Service Request Enable register determine which status changes in the Error Service Request Register will result in an service request. The enable bits are set by writing to EIES and reset by writing to EIER. Writing a 1 sets the specific enable bit, a 0 has no effect.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

EIES
Error Service Request Enable Set (0030$_H$) Application Reset Value: 0000 0000$_H$

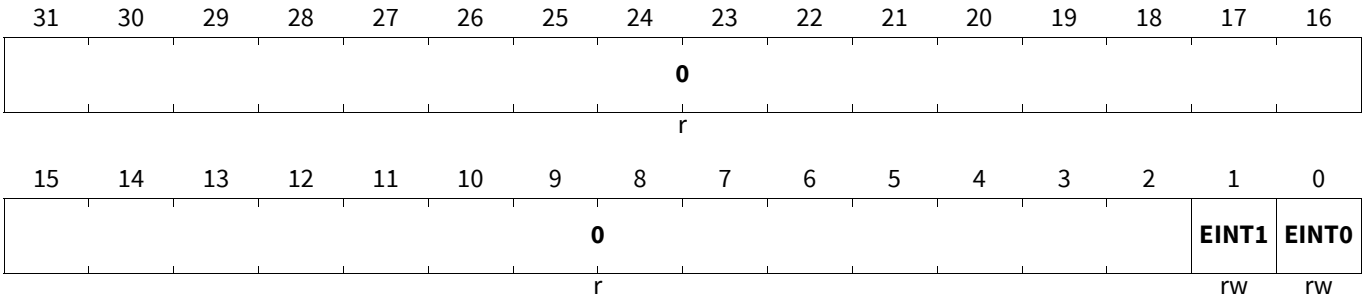
Service Request Line Enable

Each of the two service request lines to the Host INT0SRC, INT1SRC can be enabled / disabled separately by programming bit EINT0 and EINT1.

ILE

Service Request Line Enable **(0040_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
EINT0	0	rw	**Enable Service Request Line 0(INT0SRC)** 0_B Service Request line disabled 1_B Service Request line enabled
EINT1	1	rw	**Enable Service Request Line 1(INT1SRC)** 0_B Service Request line disabled 1_B Service Request line enabled
0	31:2	r	**Reserved** Returns 0 if read; should be written with 0.

Timer 0 Configuration

Absolute timer. Specifies in terms of cycle count and Macrotick the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one Macrotick and SIR.TI0 is set to 1.

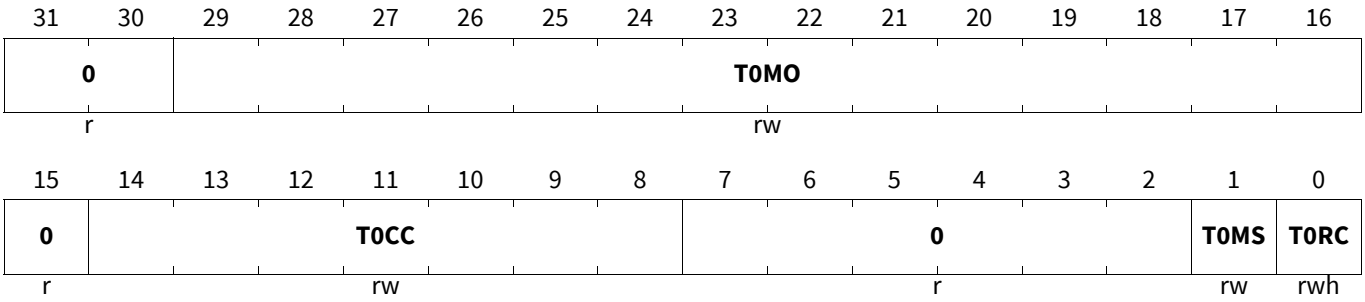
Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 0 is halted by Host command, output signal TINT0SR is reset to 0 immediately.

T0C

Timer 0 Configuration **(0044_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
T0RC	0	rwh	**Timer 0 Run Control** 0_B Timer 0 halted 1_B Timer 0 running
T0MS	1	rw	**Timer 0 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T0CC	14:8	rw	**Timer 0 Cycle Code** The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see “Cycle Counter Filtering”.
T0MO	29:16	rw	**Timer 0 Macrotick Offset** Configures the Macrotick offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.
0	7:2, 15, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Timer 1 Configuration

Relative timer. After the specified number of Macroticks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one Macrotick and SIR.TI1 is set to 1.

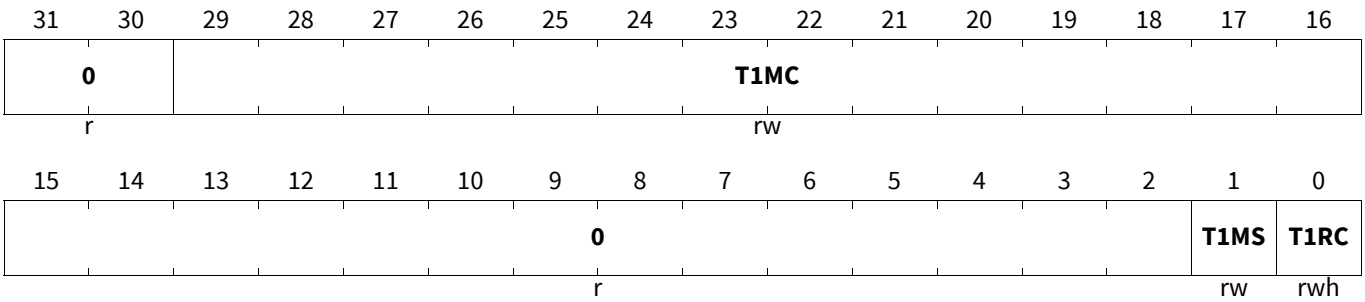
Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

Note: In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 1 is halted by Host command, output signal TINT1SR is reset to 0 immediately.

T1C

Timer 1 Configuration (0048$_H$) Application Reset Value: 0002 0000$_H$



Field	Bits	Type	Description
T1RC	0	rwh	**Timer 1 Run Control** 0_B Timer 1 halted 1_B Timer 1 running

Field	Bits	Type	Description
T1MS	1	rw	**Timer 1 Mode Select** 0_B Single-shot mode 1_B Continuous mode
T1MC	29:16	rw	**Timer 1 Macrotick Count** When the configured Macrotick count is reached the timer 1 service request is generated. Valid values are: 2_H …$3FFF_H$ Macroticks in continuous mode 1_H …$3FFF_H$ Macroticks in single-shot mode
0	15:2, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Stop Watch Register 1

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the Macrotick counter increment following next to the stop watch activation the actual cycle counter and Macrotick value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

Note: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.

STPW1

Stop Watch Register 1 **($004C_H$)** **Application Reset Value: $0000\ 0000_H$**

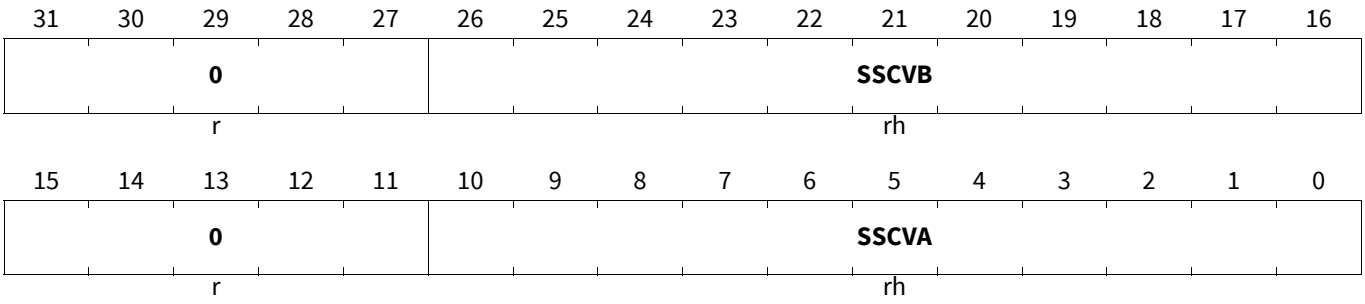
Stop Watch Register 2 **(0050_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
SSCVA	10:0	rh	**Stop Watch Captured Slot Counter Value Channel A** State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
SSCVB	26:16	rh	**Stop Watch Captured Slot Counter Value Channel B** State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	15:11, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

41.4.2.4 Communication Controller Control Registers

This section describes the registers provided by the Communication Controller to allow the Host to control the operation of the Communication Controller. The FlexRay™ protocol specification requires the Host to write application configuration data in “CONFIG” state only. Please consider that the configuration registers are not locked for writing in “DEFAULT_CONFIG” state.

The configuration data is reset when “DEFAULT_CONFIG” state is entered from application reset. To change POC state from “DEFAULT_CONFIG” to “CONFIG” state the Host has to apply CHI command “CONFIG”. If the Host wants the Communication Controller to leave “CONFIG” state, the Host has to proceed as described on **LCK** Register.

SUC Configuration Register 1

Note:

3. *This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!*
4. *The protocol requires that both bits TXST and TXSY are set for coldstart nodes.*
5. *MTSA and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command “SEND_MTS”. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000B.*

SUCC1

SUC Configuration Register 1 **(0080_H)** **Application Reset Value: $0C40\ 1000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				CCHB	CCHA	MTSB	MTSA	HCSE	TSM	WUCS	PTA				
r				rw	rw	rw	rw	rw	rw	rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSA					0	TXSY	TXST	PBSY	0			CMD			
rw					r	rw	rw	rh	r			rwh			

Field	Bits	Type	Description
CMD	3:0	rwh	**CHI Command Vector** The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”, and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored. Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions. 0_H COMMAND_NOT_ACCEPTED” 1_H CONFIG 2_H READY 3_H WAKEUP 4_H RUN 5_H ALL_SLOTS 6_H HALT 7_H FREEZE 8_H SEND_MTS 9_H ALLOW_COLDSTART A_H RESET_STATUS_INDICATORS B_H MONITOR_MODE C_H CLEAR_RAMS D_H Reserved … F_H Reserved
PBSY	7	rh	**POC Busy** Signals that the POC is busy and cannot accept a command from the Host. SUCC1.CMD is locked against write accesses. Set to 1 after hard reset during initialization of internal RAM blocks. 0_B POC not busy, SUCC1.CMD writable 1_B POC is busy, SUCC1.CMD locked

Field	Bits	Type	Description
TXST	8	rw	**Transmit Startup Frame in Key Slot (pKeySlotUsedForStartup)** Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No Startup Frame transmission in key slot, node is non-coldstarter 1_B Key slot used to transmit startup Frame, node is leading or following coldstarter
TXSY	9	rw	**Transmit SYNC Frame in Key Slot (pKeySlotUsedForSync)** Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. [1) 2)] 0_B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1_B Key slot used to transmit SYNC Frames, node is sync node
CSA	15:11	rw	**Cold Start Attempts (gColdStartAttempts)** Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	20:16	rw	**Passive to Active (pAllowPassiveToActive)** Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 00000_B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.
WUCS	21	rw	**Wakeup Channel Select (pWakeupChannel)** With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B

Field	Bits	Type	Description
TSM	22	rw	**Transmission Slot Mode (pSingleSlotEnabled)** Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM. 0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)
HCSE	23	rw	**Halt due to Clock Sync Error (pAllowHaltDueToClock)** Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state
MTSA	24	rw	**Select Channel A for MTS Transmission** The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission
MTSB	25	rw	**Select Channel B for MTS Transmission** The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel B disabled for MTS transmission 1_B Channel B selected for MTS transmission
CCHA	26	rw	**Connected to Channel A (pChannels)** Configures whether the node is connected to channel A. 0_B Not connected to channel A 1_B Node connected to channel A (default after application reset)
CCHB	27	rw	**Connected to Channel B (pChannels)** Configures whether the node is connected to channel B. 0_B Not connected to channel B 1_B Node connected to channel B (default after application reset)
0	6:4, 10, 31:28	r	**Reserved** Returns 0 if read; should be written with 0.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes COMMAND_NOT_ACCEPTED
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state “CONFIG” when called in POC states “DEFAULT_CONFIG“, “READY“, or in “MONITOR_MODE“. When called in “HALT” state transits to POC state “DEFAULT_CONFIG“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

READY

Go to POC state “READY” when called in POC states “CONFIG”, “NORMAL_ACTIVE”, “NORMAL_PASSIVE”, “STARTUP”, or “WAKEUP”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

WAKEUP

Go to POC state WAKEUP when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

RUN

Go to POC state “STARTUP” when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state “HALT” at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state “HALT” immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state “NORMAL_ACTIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALLOW_COLDSTART

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG“, “CONFIG”, “HALT”, or “MONITOR_MODE“. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see “MONITOR_MODE”.

CLEAR_RAMS

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the E-Ray internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMS. Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

Note: All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks f_{CLC_ERAY} and f_{SCLK}, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time Frame. Reading register CCSV will show data that is delayed by synchronization from f_{SCLK} to f_{CLC_ERAY} domain and by the Host-specific CPU interface.

Table below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.

Table 418 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART

Table 418 Reference to CHI Host command summary from FlexRay™ protocol specification (cont'd)

CHI Command	Where processed (POC State)	CHI Command Vector CMD
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

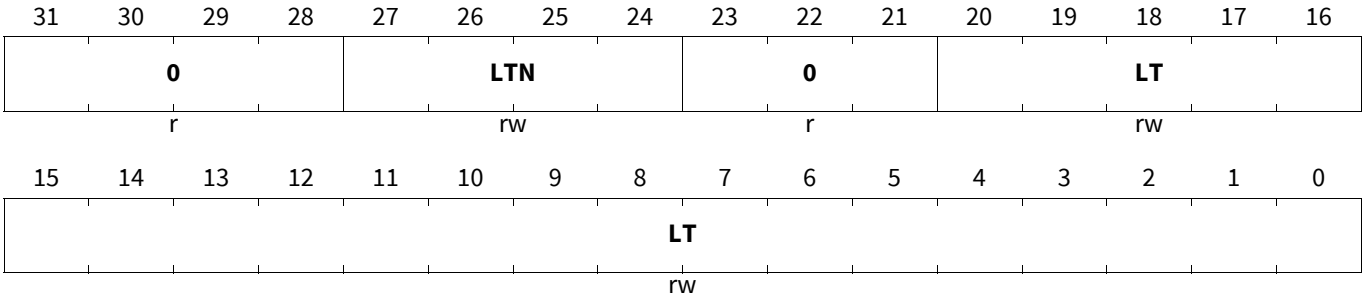
SUC Configuration Register 2

The Communication Controller accepts modifications of the register in "DEFAULT_CONFIG" or "CONFIG" state only.

Note: The wakeup / startup noise time-out is calculated as follows: The wakeup / startup noise time-out = pdListenTimeout • gListenNoise = LT • (LTN+ 1)

SUCC2

SUC Configuration Register 2 (0084_H) Application Reset Value: $0100\ 0504_H$



Field	Bits	Type	Description
LT	20:0	rw	**Listen Timeout(pdListenTimeout)** Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504_H to 139706_H) Microticks

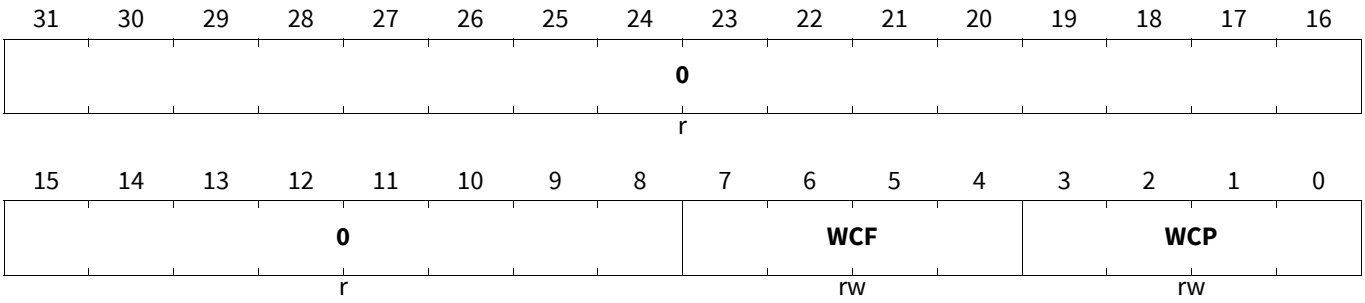
Field	Bits	Type	Description
LTN	27:24	rw	**Listen Time-out Noise (gListenNoise - 1)** Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. This bit can be updated in "DEFAULT_CONFIG" or "CONFIG" state only. 1_H Listen Time-out Noise is equal 2 2_H Listen Time-out Noise is equal 3 3_H … E_H Listen Time-out Noise is equal 3 … 15 F_H Listen Time-out Noise is equal 16
0	23:21, 31:28	r	**Reserved** Returns 0 if read; should be written with 0.

SUC Configuration Register 3

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC3

SUC Configuration Register 3 (0088_H) Application Reset Value: $0000\ 0011_H$

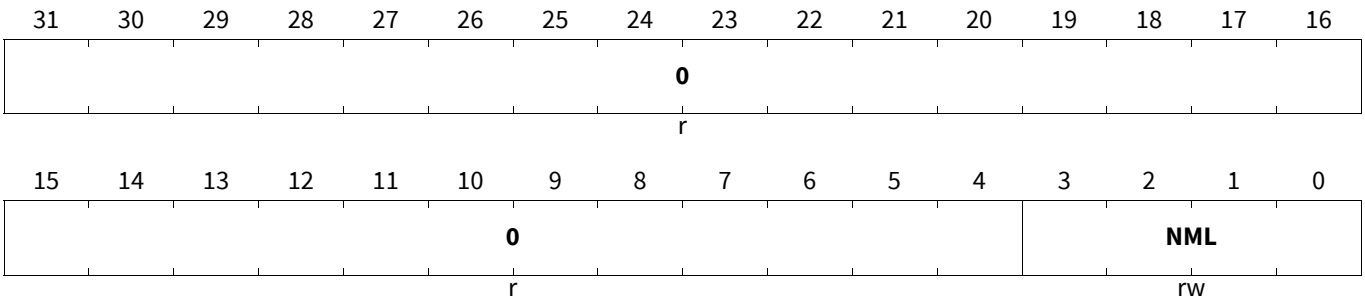


Field	Bits	Type	Description
WCP	3:0	rw	**Maximum Without Clock Correction Passive(gMaxWithoutClockCorrectionPassive)** Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs.
WCF	7:4	rw	**Maximum Without Clock Correction Fatal (gMaxWithoutClockCorrecti on Fatal)** Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to “HALT” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H)cycle pairs.
0	31:8	r	**Reserved** Returns 0 if read; should be written with 0.

NEM Configuration Register

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC
NEM Configuration Register **($008C_H$)** **Application Reset Value: $0000\ 0000_H$**

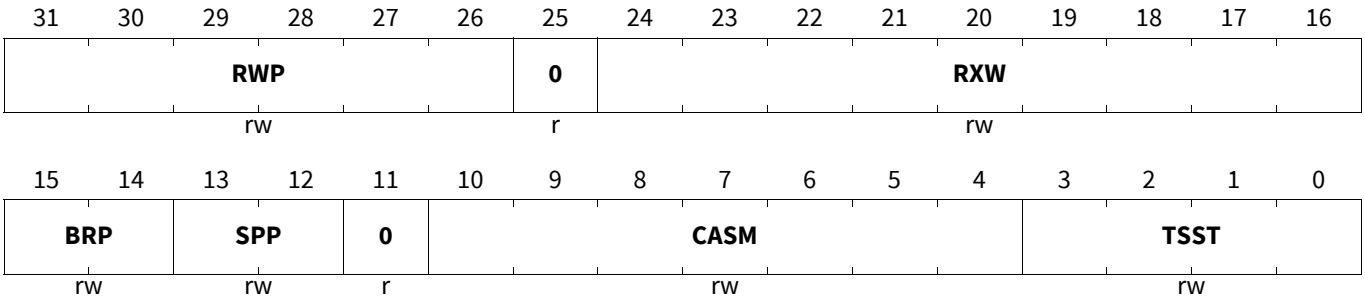


Field	Bits	Type	Description
NML	3:0	rw	**Network Management Vector Length(gNetworkManagementVectorLength)** These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0_H to C_H) bytes.
0	31:4	r	**Reserved** Returns 0 if read; should be written with 0.

PRT Configuration Register 1

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1
PRT Configuration Register 1 **(0090_H)** **Application Reset Value: $084C\ 0633_H$**



Field	Bits	Type	Description
TSST	3:0	rw	**Transmission Start Sequence Transmitter(gdTSSTransmitter)** Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100ns at 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3_H to F_H) Bit Times.

Field	Bits	Type	Description
CASM	10:4	rw	**Collision Avoidance Symbol Maximum (gdCASRxLowMax)** Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43_H to 63_H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	13:12	rw	**Strobe Point Position** Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. *Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.* 00_B Sample 5 (default) 01_B Sample 4 10_B Sample 6 11_B Reserved; should not be used.
BRP	15:14	rw	**Baud Rate Prescaler (gdSampleClockPeriod, pSamplePerMicrotick)** The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock f_{SCLK}= 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate. 00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = 1 / $f_{SCLK\ pSamplesPerMicrotick = 2}$ 01_B 5 Mbit/s (1 Microtick= 25ns; single sampled with f_{SCLK} / 2) gdSampleClockPeriod = 25 ns = 2 / $f_{SCLK\ pSamplesPerMicrotick = 1}$ 10_B 2.5 Mbit/s (1 Microtick = 50ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / $f_{SCLK\ pSamplesPerMicrotick = 1}$ 11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1
RXW	24:16	rw	**Wakeup Symbol Receive Window Length (gdWakeupSymbolRxWindow)** Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 ($4C_H$ to $12D_H$) Bit Times.
RWP	31:26	rw	**Repetitions of Tx Wakeup Pattern (pWakeupPattern)** Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to $3F_H$).
0	11, 25	r	**Reserved** Returns 0 if read; should be written with 0.

PRT Configuration Register 2

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC2

PRT Configuration Register 2 **(0094_H)** **Application Reset Value: $0F2D\ 0A0E_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		**TXL**						**TXI**							
r		rw						rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		**RXL**						**0**		**RXI**					
r		rw						r		rw					

Field	Bits	Type	Description
RXI	5:0	rw	**Wakeup Symbol Receive Idle(gdWakeupSymbolRxIdle)** Configures the number of Bit Times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 (E_H to $3B_H$) Bit Times.
RXL	13:8	rw	**Wakeup Symbol Receive Low (gdWakeupSymbolRxLow)** Configures the number of Bit Times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 (A_H to 37_H) Bit Times.
TXI	23:16	rw	**Wakeup Symbol Transmit Idle (gdWakeupSymbolTxIdle)** Configures the number of Bit Times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 ($2D_H$ to $B4_H$)Bit Times.
TXL	29:24	rw	**Wakeup Symbol Transmit Low (gdWakeupSymbolTxLow)** Configures the number of Bit Times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 (F_H to $3C_H$) Bit Times.
0	7:6, 15:14, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

MHD Configuration Register

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

MHDC

MHD Configuration Register **(0098_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			**SLT**												
r			rw												

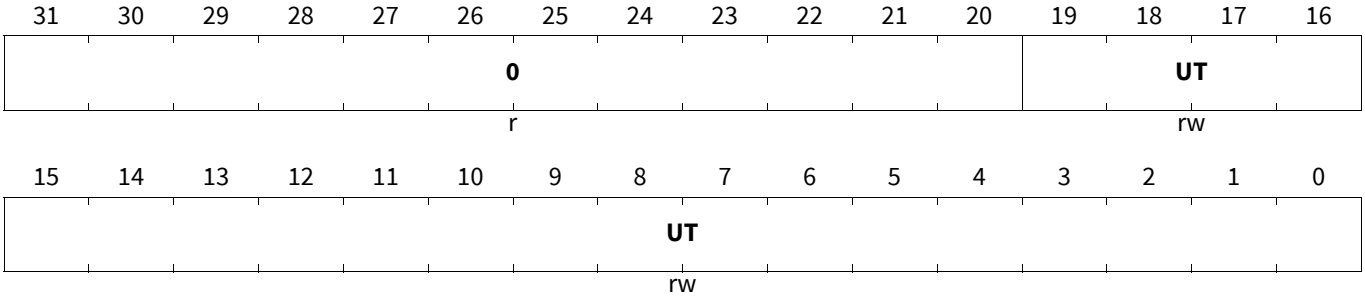
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									**SFDL**						
r									rw						

Field	Bits	Type	Description
SFDL	6:0	rw	**Static Frame Data Length(gPayloadLengthStatic)** Configures the cluster-wide payload length for all Frames sent in the static segment in double byte. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127 (0 to $7F_H$).
SLT	28:16	rw	**Start of Latest Transmit(pLatestTx)** Configures the maximum minislot value allowed before inhibiting Frame transmission in the dynamic segment of the cycle. There is no transmission dynamic segment if SLT is reset to zero. Valid values are 0 to 7981 (0 to $1F2D_H$) minislots.
0	15:7, 31:29	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 1

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC01
GTU Configuration Register 1 **($00A0_H$)** **Application Reset Value: $0000\ 0280_H$**



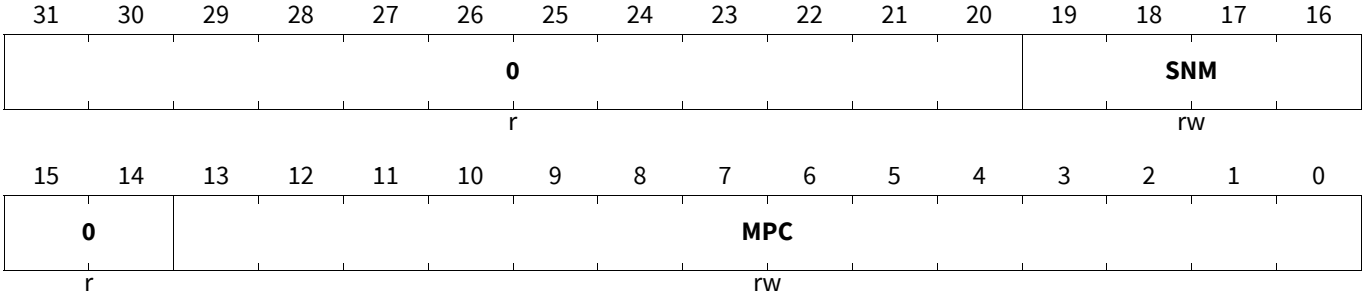
Field	Bits	Type	Description
UT	19:0	rw	**Microtick per Cycle(pMicroPerCycle)** Configures the duration of the communication cycle in Microticks. Valid values are 640 to 640000 (280_H to $9C400_H$) Microticks.
0	31:20	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 2

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC02

GTU Configuration Register 2 ($00A4_H$) Application Reset Value: $0002\ 000A_H$



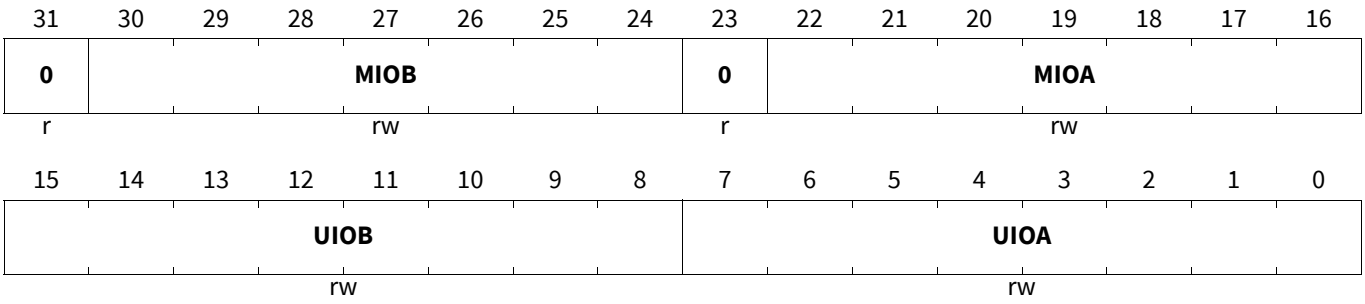
Field	Bits	Type	Description
MPC	13:0	rw	**Macrotick Per Cycle(gMacroPerCycle)** Configures the duration of one communication cycle in Macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 (A_H to $3E80_H$) Macroticks.
SNM	19:16	rw	**Sync Node Max(gSyncNodeMax)** Maximum number of Frames within a cluster with SYNC Frame indicator bit SYN set to 1. Must be identical in all nodes of a cluster. Valid values are 2 to 15 (2_H to F_H).
0	15:14, 31:20	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 3

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC03

GTU Configuration Register 3 ($00A8_H$) Application Reset Value: $0202\ 0000_H$



Field	Bits	Type	Description
UIOA	7:0	rw	**Microtick Initial Offset Channel A(pMicroInitialOffset[A])** Configures the number of Microticks between the actual time reference point on channel A and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.

Field	Bits	Type	Description
UIOB	15:8	rw	**Microtick Initial Offset Channel B (pMicroInitialOffset[B])** Configures the number of Microticks between the actual time reference point on channel B and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
MIOA	22:16	rw	**Macrotick Initial Offset Channel A(gMacroInitialOffset[A])** Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
MIOB	30:24	rw	**Macrotick Initial Offset Channel B(gMacroInitialOffset[B])** Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
0	23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 4

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only. For details about configuration of NIT and OCS see “Configuration of Network Idle Time (NIT) Start and Offset Correction Start”.

GTUC04

GTU Configuration Register 4 **($00AC_H$)** **Application Reset Value: $0008\ 0007_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		**OCS**													
r		rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		**NIT**													
r		rw													

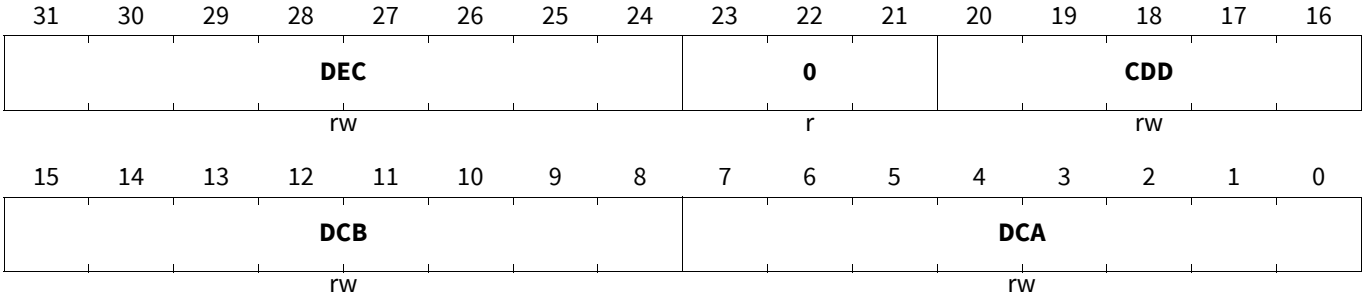
Field	Bits	Type	Description
NIT	13:0	rw	**Network Idle Time Start(gMacroPerCycle - gdNIT - 1)** Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of Macroticks from the beginning of the cycle. The start of network idle time (NIT) is recognized if Macrotick = gMacroPerCycle - gdNIT -1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 (7_H to $3E7D_H$) Macroticks.

Field	Bits	Type	Description
OCS	29:16	rw	**Offset Correction Start (gOffsetCorrectionStart - 1)** Determines the start of the offset correction within the network idle time (NIT) phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of E-Ray implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 (8_H to $3E7E_H$) Macroticks.
0	15:14, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 5

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC05
GTU Configuration Register 5 **($00B0_H$)** **Application Reset Value: $0E00\ 0000_H$**



Field	Bits	Type	Description
DCA	7:0	rw	**Delay Compensation Channel A(pDelayCompensation[A])** Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 µs to 0.05 µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
DCB	15:8	rw	**Delay Compensation Channel B (pDelayCompensation[B])** Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 to 0.05 µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
CDD	20:16	rw	**Cluster Drift Damping(pClusterDriftDamping)** Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to 20 (0_H to 14_H) Microticks.
DEC	31:24	rw	**Decoding Correction(pDecodingCorrection)** Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143 (E_H to $8F_H$) Microticks.

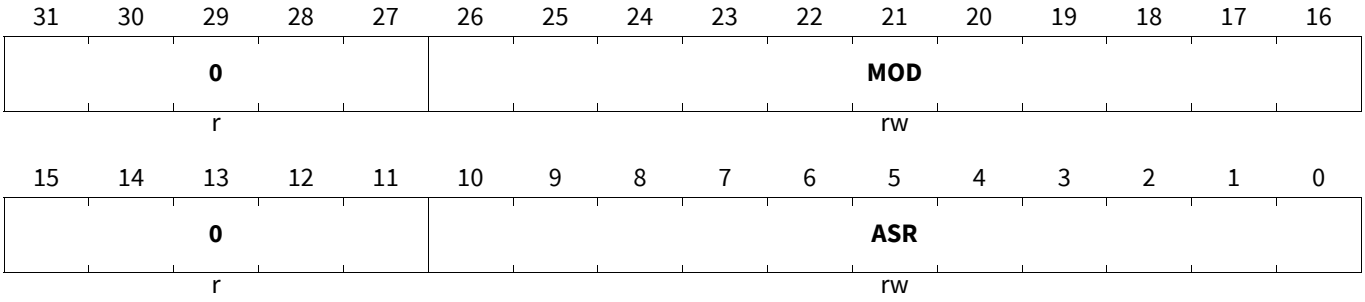
Field	Bits	Type	Description
0	23:21	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 6

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC06

GTU Configuration Register 6 (00B4$_H$) Application Reset Value: 0002 0000$_H$



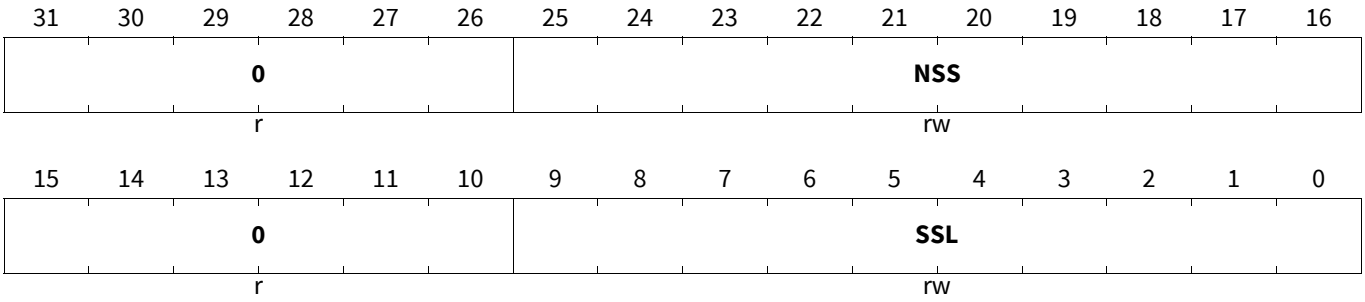
Field	Bits	Type	Description
ASR	10:0	rw	**Accepted Startup Range(pdAcceptedStartupRange)** Number of Microticks constituting the expanded range of measured deviation for startup Frames during integration. Valid values are 0 to 1875 (0_H to 753_H) Microticks.
MOD	26:16	rw	**Maximum Oscillator Drift(pdMaxDrift)1)** Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in Microticks. Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	15:11, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 7

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC07

GTU Configuration Register 7 (00B8$_H$) Application Reset Value: 0002 0004$_H$



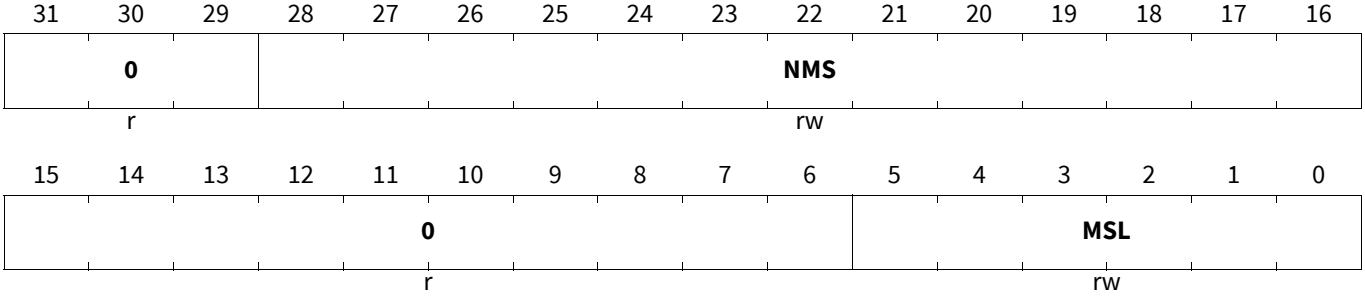
Field	Bits	Type	Description
SSL	9:0	rw	**Static Slot Length(gdStaticSlot)** Configures the duration of a static slot in Macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 (4_H to 293_H) Macroticks.
NSS	25:16	rw	**Number of Static Slots(gNumberOfStaticSlots)** Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay™ network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023 (2_H to $3FF_H$).
0	15:10, 31:26	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 8

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC08

GTU Configuration Register 8 ($00BC_H$) Application Reset Value: $0000\ 0002_H$



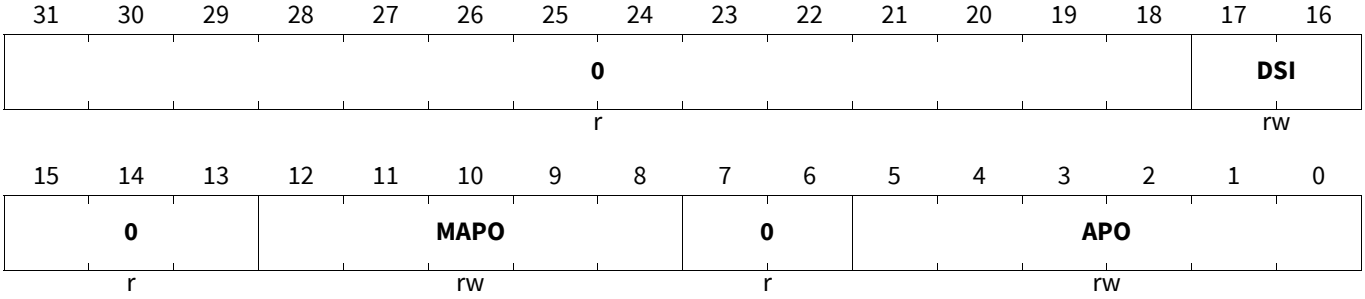
Field	Bits	Type	Description
MSL	5:0	rw	**Minislot Length(gdMinislot)** Configures the duration of a minislot in Macroticks. The minislot length must be identical in all nodes of a cluster. Valid values are 2 to 63 (2_H to $3F_H$) Macroticks.
NMS	28:16	rw	**Number of Minislots(gNumberOfMinislots)** Configures the number of minislots within the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster. Valid values are 0 to 7986 (0_H to $1F32_H$).
0	15:6, 31:29	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 9

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC09

GTU Configuration Register 9 ($00C0_H$) Application Reset Value: $0000\ 0101_H$



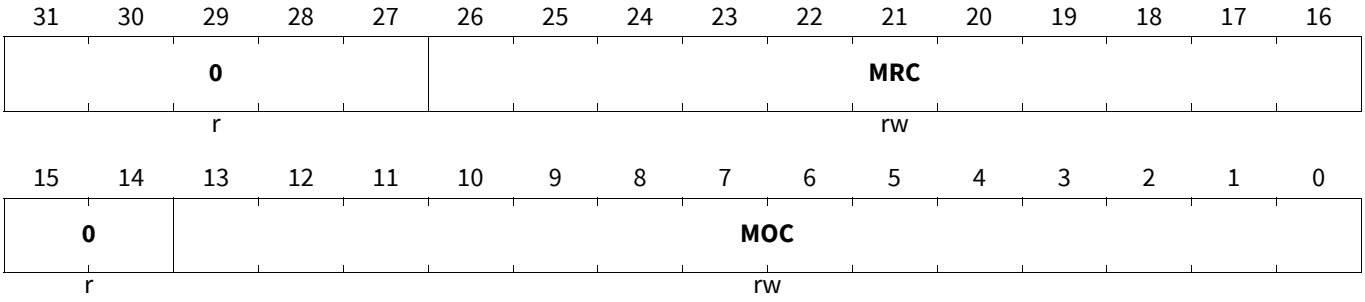
Field	Bits	Type	Description
APO	5:0	rw	**Action Point Offset(gdActionPointOffset)** Configures the action point offset in Macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 (1_H to $3F_H$) Macroticks.
MAPO	12:8	rw	**Minislot Action Point Offset (gd Minislot Action Point Offset)** Configures the action point offset in Macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 (1_H to $1F_H$) Macroticks.
DSI	17:16	rw	**Dynamic Slot Idle Phase (gdDynamicSlotIdlePhase)** The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.
0	7:6, 15:13, 31:18	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 10

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC10

GTU Configuration Register 10 ($00C4_H$) Application Reset Value: $0002\ 0005_H$



Field	Bits	Type	Description
MOC	13:0	rw	**Maximum Offset Correction(pOffsetCorrectionOut)** Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The Communication Controller checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266 (5_H to $3BA2_H$) Microticks.
MRC	26:16	rw	**Maximum Rate Correction (pRateCorrectionOut)** Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The communication controller checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	15:14, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

GTU Configuration Register 11

GTUC11
GTU Configuration Register 11 ($00C8_H$) Application Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0						ERCC		0						EOCC	
r						rw		r						rw	

Field	Bits	Type	Description
EOCC	1:0	rw	**External Offset Correction Control(pExternOffsetControl)** By writing to EOCC the external offset correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external clock correction 01_B No external clock correction 10_B External offset correction value subtracted from calculated offset correction value 11_B External offset correction value added to calculated offset correction value

Field	Bits	Type	Description
ERCC	9:8	rw	**External Rate Correction Control(pExternRateControl)** By writing to ERCC the external rate correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external rate correction 01_B No external rate correction 10_B External rate correction value subtracted from calculated rate correction value 11_B External rate correction value added to calculated rate correction value
EOC	18:16	rw	**External Offset Correction(pExternOffsetCorrection)** Holds the external clock offset correction value in Microticks to be applied by the internal synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
ERC	26:24	rw	**External Rate Correction (pExternRateCorrection)** Holds the external rate correction value in Microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during network idle time (NIT). Can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
0	7:2, 15:10, 23:19, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

41.4.2.5 Communication Controller Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the Communication Controller between two accesses (non-atomic read accesses). The status vector may change faster than the Host can poll the status vector, depending on f_{CLC_ERAY} frequency.

Communication Controller Status Vector

CCSV

Communication Controller Status Vector **(0100_H)** **Application Reset Value: $0010\ 4000_H$**

r	rh	rh	rh	r		rh		rh	rh	rh					

Field	Bits	Type	Description
POCS	5:0	rh	**Protocol Operation Control Status** 00_H ... 05_H, $0F_H$ Indicates the actual state of operation of the Communication Controller Protocol Operation Control 06_H … 14_H are reserved. 10_H ... 13_H Indicates the actual state of operation of the POC in the wakeup path 14_H … $1F_H$ are reserved. 20_H ... $2B_H$ Indicates the actual state of operation of the POC in the startup path $2C_H$ … $3F_H$ are reserved. 00_H “DEFAULT_CONFIG” state 01_H “READY” state 02_H “NORMAL_ACTIVE” state 03_H “NORMAL_PASSIVE” state 04_H “HALT” state 05_H “MONITOR_MODE” state $0F_H$ “CONFIG” state 10_H WAKEUP_STANDBY state 11_H “WAKEUP_LISTEN” state 12_H “WAKEUP_SEND” state 13_H “WAKEUP_DETECT” state 20_H “STARTUP_PREPARE” state 21_H “COLDSTART_LISTEN” state 22_H “COLDSTART_COLLISION_RESOLUTION state 23_H “COLDSTART_CONSISTENCY_CHECK” state 24_H “COLDSTART_GAP state 25_H “COLDSTART_JOIN” State 26_H “INTEGRATION_COLDSTART_CHECK” state 27_H “INTEGRATION_LISTEN” state 28_H “INTEGRATION_CONSISTENCY_CHECK” state 29_H “INITIALIZE_SCHEDULE” state $2A_H$ “ABORT_STARTUP” state $2B_H$ “STARTUP_SUCCESS” state
FSI	6	rh	**Freeze Status Indicator(vPOC!Freeze)** Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	**Halt Request(vPOC!CHIHaltRequest)** Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

Field	Bits	Type	Description
SLM	9:8	rh	**Slot Mode(vPOC!SlotMode)** Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00_B SINGLE 01_B Reserved 10_B ALL_PENDING 11_B ALL
CSNI	12	rh	**Coldstart Noise Indicator(vPOC!ColdstartNoise)** Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	**Coldstart Abort Indicator** Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSI	14	rh	**Cold Start Inhibit(vColdStartInhibit)** Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B). 0_B Cold starting of node enabled 1_B Cold starting of node disabled

Field	Bits	Type	Description
WSV	18:16	rh	**Wakeup Status(vPOC!WakeupStatus)** Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state. 000_B UNDEFINED. Wakeup not yet executed by the Communication Controller. 001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state. 010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state. 011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel. 100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel. 101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header. 110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern. 111_B Reserved
RCA	23:19	rh	**Remaining Coldstart Attempts(vRemainingColdstartAttempts)** Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.
PSL	29:24	rh	**POC Status Log** Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.
0	11:10, 15, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Communication Controller Error Vector

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

CCEV

Communication Controller Error Vector **(0104_H)** **Application Reset Value: $0000\ 0000_H$**

0			PTAC					ERRM		0		CCFC			
r			rh					rh		r		rh			

Field	Bits	Type	Description
CCFC	3:0	rh	**Clock Correction Failed Counter(vClockCorrectionFailed)** The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	7:6	rh	**Error Mode(vPOC!ErrorMode)** Indicates the actual error mode of the POC. 00_B “ACTIVE” (green) 01_B “PASSIVE” (yellow) 10_B “COMM_HALT” (red) 11_B Reserved
PTAC	12:8	rh	**Passive to Active Count(vAllowPassiveToActive)** Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA-1.
0	5:4, 31:13	r	**Reserved** Returns 0 if read; should be written with 0.

Slot Counter Value

SCV

Slot Counter Value **(0110_H)** **Application Reset Value: $0000\ 0000_H$**

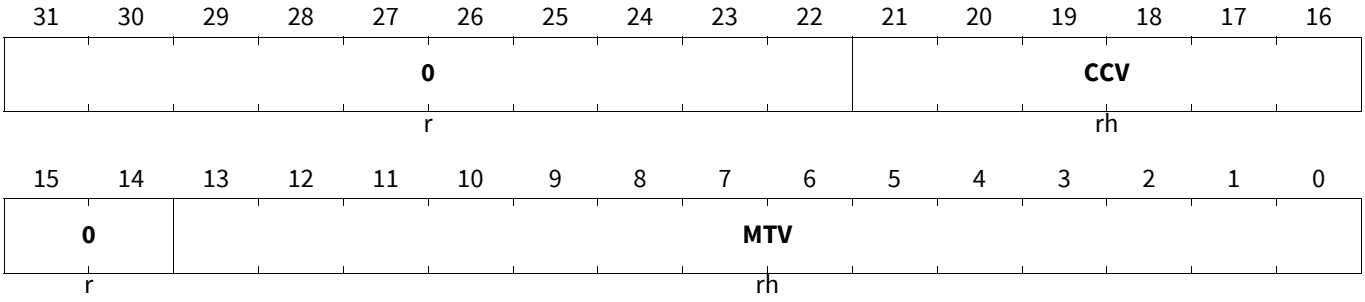
0					SCCA										
r					rh										

Field	Bits	Type	Description
SCCA	10:0	rh	**Slot Counter Channel A(vSlotCounter[A])** Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FF_H$).
SCCB	26:16	rh	**Slot Counter Channel B(vSlotCounter[B])** Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	15:11, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

Macrotick and Cycle Counter Value

MTCCV

Macrotick and Cycle Counter Value (0114_H) Application Reset Value: $0000\ 0000_H$

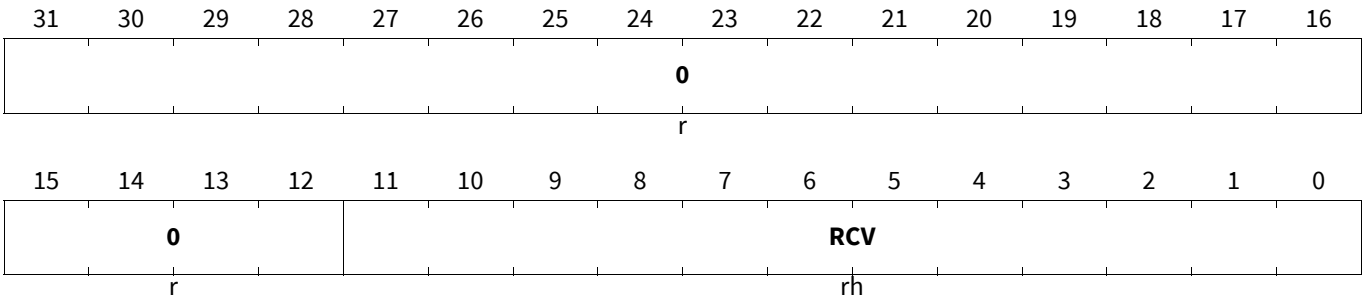


Field	Bits	Type	Description
MTV	13:0	rh	**Macrotick Value(vMacrotick)** Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0_H to $3E80_H$).
CCV	21:16	rh	**Cycle Counter Value(vCycleCounter)** Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0_H to $3F_H$).
0	15:14, 31:22	r	**Reserved** Returns 0 if read; should be written with 0.

Rate Correction Value

RCV

Rate Correction Value **(0118_H)** **Application Reset Value: $0000\ 0000_H$**



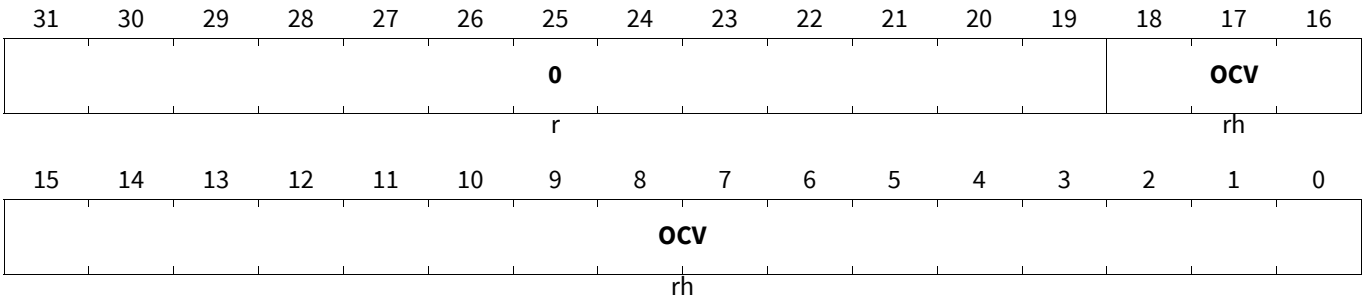
Field	Bits	Type	Description
RCV	11:0	rh	**Rate Correction Value(vRateCorrection)** Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	31:12	r	**Reserved** Returns 0 if read; should be written with 0.

Offset Correction Value

Note: The external rate / offset correction value is added to the limited rate / offset correction value.

OCV

Offset Correction Value **($011C_H$)** **Application Reset Value: $0000\ 0000_H$**



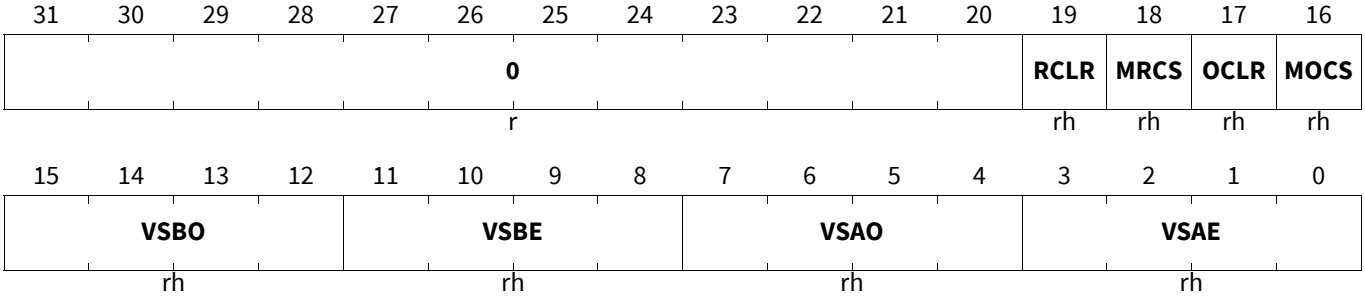
Field	Bits	Type	Description
OCV	18:0	rh	**Offset Correction Value(vOffsetCorrection)** Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	31:19	r	**Reserved** Returns 0 if read; should be written with 0.

SYNC Frame Status

The maximum number of valid SYNC Frames in a communication cycle is 15.

SFS

SYNC Frame Status **(0120_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
VSAE	3:0	rh	**Valid SYNC Frames Channel A, even communication cycle** Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSAO	7:4	rh	**Valid SYNC Frames Channel A, odd communication cycle** Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSBE	11:8	rh	**Valid SYNC Frames Channel B, even communication cycle** Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
VSBO	15:12	rh	**Valid SYNC Frames Channel B, odd communication cycle** Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	**Missing Offset Correction Signal** The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction signal valid 1_B Missing offset correction signal

Field	Bits	Type	Description
OCLR	17	rh	**Offset Correction Limit Reached** The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction below limit 1_B Offset correction limit reached
MRCS	18	rh	**Missing Rate Correction Signal** The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction signal valid 1_B Missing rate correction signal
RCLR	19	rh	**Rate Correction Limit Reached** The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit.as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction below limit 1_B Rate correction limit reached
0	31:20	r	**Reserved** Returns 0 if read; should be written with 0.

Symbol Window and Network Idle Time Status

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

Note: MTSA and MTSB may be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in "Lock Register". This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B

SWNIT

Symbol Window and Network Idle Time Status (0124_H) **Application Reset Value: $0000\ 0000_H$**

Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSA is set to 1. 0_B No MTS symbol received on channel A 1_B MTS symbol received on channel A
MTSB	7	rh	**MTS Received on Channel B(vSS!ValidMTSB)** Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSB is set to 1. 0_B No MTS symbol received on channel B 1_B MTS symbol received on channel B
SENA	8	rh	**Syntax Error during network idle time (NIT) Channel A(vSS!SyntaxErrorA)** Updated by the Communication Controller channel A at the end of the NIT. 0_B No syntax error detected 1_B Syntax error during network idle time (NIT) detected on channel A

Field	Bits	Type	Description
SBNA	9	rh	**Slot Boundary Violation during network idle time (NIT) Channel A(vSS!BViolationA)** Updated by the Communication Controller channel A at the end of the NIT. 0_B No slot boundary violation detected 1_B Slot boundary violation during network idle time (NIT) detected on channel A
SENB	10	rh	**Syntax Error during network idle time (NIT) Channel B(vSS!SyntaxErrorB)** Updated by the Communication Controller channel B at the end of the NIT. 0_B No syntax error detected 1_B Syntax error during network idle time (NIT) detected on channel B
SBNB	11	rh	**Slot Boundary Violation during network idle time (NIT) Channel B(vSS!BViolationB)** Updated by the Communication Controller channel B at the end of the NIT. 0_B No slot boundary violation detected 1_B Slot boundary violation during network idle time (NIT) detected on channel B
0	31:12	r	**Reserved** Returns 0 if read; should be written with 0.

Aggregated Channel Status

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1.When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1. LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.

ACS

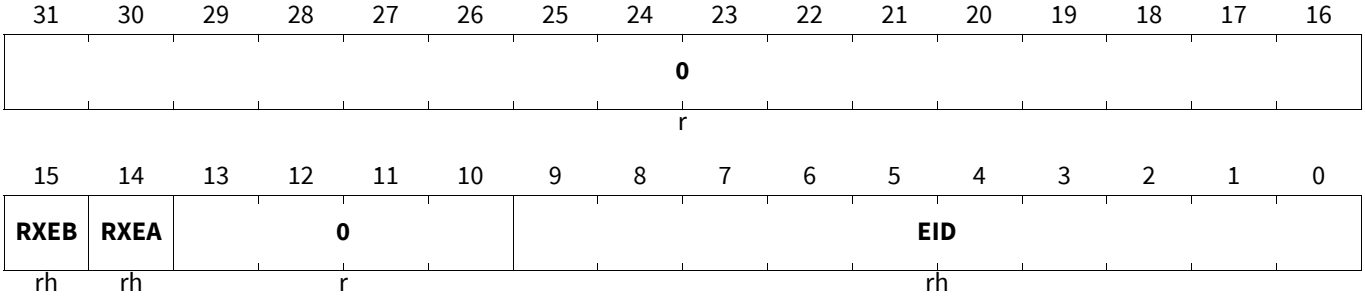
0	7:5, 31:13	r	**Reserved** Returns 0 if read; should be written with 0.

Even Sync ID Symbol Window n

Registers Even Sync ID nn (ESIDn, n=01-15) hold the Frame IDs of the SYNC Frames received in **even** communication cycles, sorted in ascending order, with register ESID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an even communication cycle, register ESID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and the flags RXEA, RXEB are set. The value is updated during the network idle time (NIT) of each even communication cycle.

ESIDn (n=01-15)

Even Sync ID Symbol Window n **(0130_H+(n-1)*4)** **Application Reset Value: 0000 0000_H**



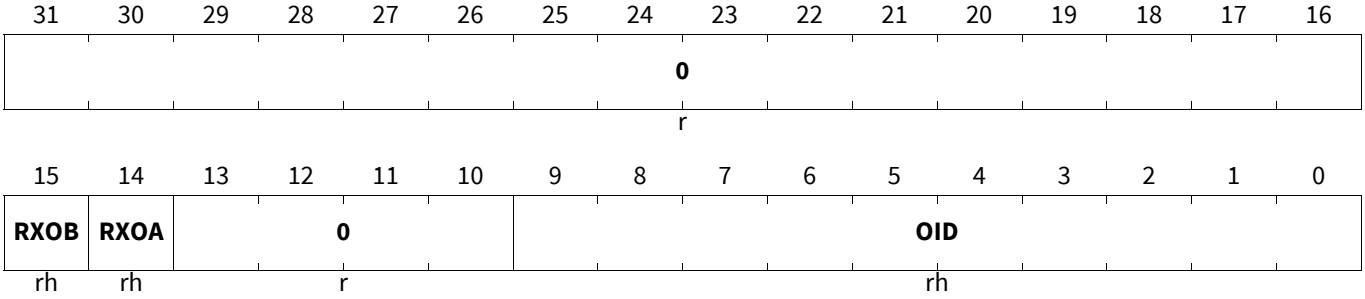
Field	Bits	Type	Description
EID	9:0	rh	**Even Sync ID(vsSyncIDListA,B even)** SYNC Frame ID even communication cycle.
RXEA	14	rh	**Received/Configured Even Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel A / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXEB	15	rh	**Received/Configured Even Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0_B SYNC Frame not received on channel B / node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B / node not configured to transmit SYNC Frames
0	13:10, 31:16	r	**Reserved** Returns 0 if read; should be written with 0.

Odd Sync ID Symbol Window n

he Odd Sync ID nn (OSIDn, n=01-15) hold the Frame IDs of the SYNC Frames received in **odd** communication cycles, sorted in ascending order, with register OSID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an odd communication cycle, register OSID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set. The value is updated during the network idle time (NIT) of each odd communication cycle.

OSIDn (n=01-15)

Odd Sync ID Symbol Window n **(0170_H+(n-1)*4)** **Application Reset Value: 0000 0000_H**



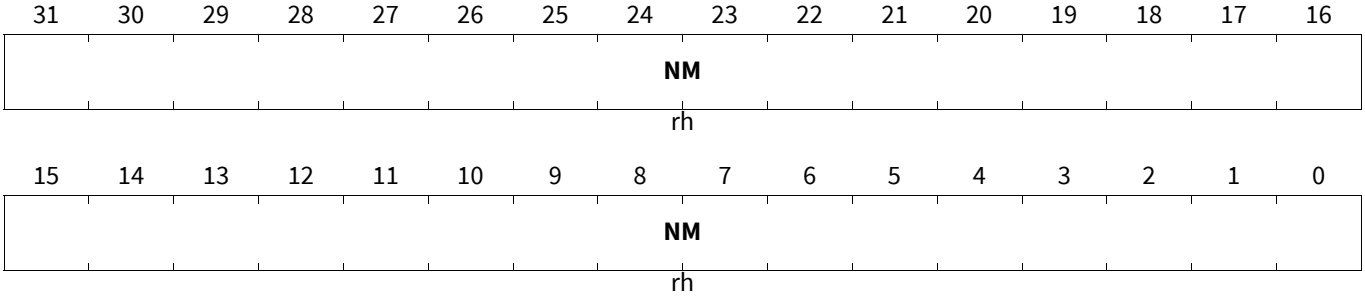
Field	Bits	Type	Description
OID	9:0	rh	**Odd Sync ID(vsSyncIDListA,B odd)** SYNC Frame ID even communication cycle.
RXOA	14	rh	**Received Odd Sync ID on Channel A** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID (OSID1 only). 0_B SYNC Frame not received on channel A/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel A/ node not configured to transmit SYNC Frames
RXOB	15	rh	**Received Odd Sync ID on Channel B** Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = OID (OSID1 only) 0_B SYNC Frame not received on channel B/ node configured to transmit SYNC Frames 1_B SYNC Frame received on channel B/ node not configured to transmit SYNC Frames
0	13:10, 31:16	r	**Reserved** Returns 0 if read; should be written with 0.

Network Management Vector x

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see “Network Management”). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x=1-3)

Network Management Vector x **($01B0_H$+(x-1)*4)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description

41.4.2.6 Message Buffer Control Registers

Message RAM Configuration

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC

Message RAM Configuration (0300_H) Application Reset Value: $0180\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					SPLM	SEC		LCB							
r					rw	rw		rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FFB								FDB							
rw								rw							

Field	Bits	Type	Description
FDB	7:0	rw	**First Dynamic Buffer** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H No group of Message Buffers exclusively for the static segment configured 01_H …$7F_H$ Message Buffers 0 to FDB-1 reserved for static segment 80_H …FF_H No dynamic Message Buffers configured
FFB	15:8	rw	**First Buffer of FIFO** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H …$7E_H$ Message Buffers from FFB to LCB assigned to the FIFO $7F_H$ All Message Buffers assigned to the FIFO 80_H …FF_H No Message Buffers assigned to the FIFO
LCB	23:16	rw	**Last Configured Buffer** May be only modified in “DEFAULT_CONFIG” or “CONFIG” state. 01_H …$7F_H$ Number of Message Buffers is LCB + 1 80_H …FF_H No Message Buffer configured

Field	Bits	Type	Description
SEC	25:24	rw	**Secure Buffers** Not evaluated when the Communication Controller is in "DEFAULT_CONFIG" or "CONFIG" state. For temporary unlocking see "Host Handling of Errors". *Note: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked* 00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled. 01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled 10_B Reconfiguration of all Message Buffers locked 11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled
SPLM	26	rw	**SYNC Frame Payload Multiplex** This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly. 0_B Only Message Buffer 0 locked against reconfiguration 1_B Both Message Buffers 0 and 1 are locked against reconfiguration
0	31:27	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.

Table 420 Usage of the three Message Buffer Pointer

Message Buffer 0	⇓ Static Buffers		
Message Buffer 1			
…			
	⇓ Static + Dynamic	⇐ **FDB**	
			FIFO configured: **FFB** > **FDB**
	⇓ FIFO	⇐ **FFB**	No FIFO configured: **FFB** ≥ 128

Table 420 Usage of the three Message Buffer Pointer (cont'd)

Message Buffer N-1		**LCB ≥ FDB, LCB ≥ FFB**
Message Buffer N		⇐ **LCB**

The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations!**

Note: The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see "Message RAM". In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section. The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in "DEFAULT_CONFIG" or "CONFIG" state reconfiguration of Message Buffers belonging to the FIFO is locked.

FIFO Rejection Filter

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during "DEFAULT_CONFIG" or "CONFIG" state only.

FRF

FIFO Rejection Filter **(0304_H)** **Application Reset Value: $0180\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							**RNF**	**RSS**	**CYF**						
r							rw	rw	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			**FID**											**CH**	
r			rw											rw	

Field	Bits	Type	Description
CH	1:0	rw	**Channel Filter** May be modified in "DEFAULT_CONFIG" or "CONFIG" state only. 00_B receive on both channels[1)] 01_B receive only on channel B 10_B receive only on channel A 11_B no reception
FID	12:2	rw	**Frame ID Filter** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000_H …$7FF_H$ Frame ID filter values

Field	Bits	Type	Description
CYF	22:16	rw	**Cycle Counter Filter** The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see “Cycle Counter Filtering”. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	**Reject in Static Segment** If this bit is set, the FIFO is used only be used in dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B FIFO also used in static segment 1_B Reject messages for static segment
RNF	24	rw	**Reject NULL Frames** If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B NULL Frames are stored in the FIFO 1_B Reject all NULL Frames
0	15:13, 31:25	r	**Reserved** Returns 0 if read; should be written with 0.

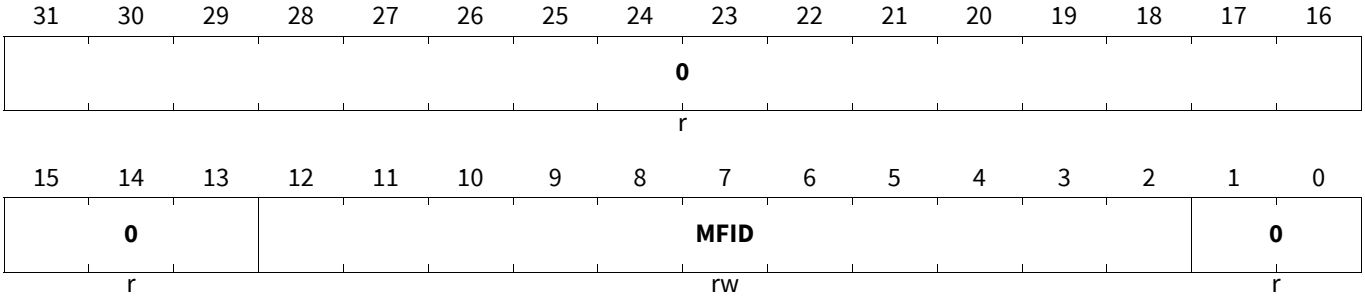
1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

FIFO Rejection Filter Mask

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM

FIFO Rejection Filter Mask **(0308_H)** **Application Reset Value: $0000\ 0000_H$**

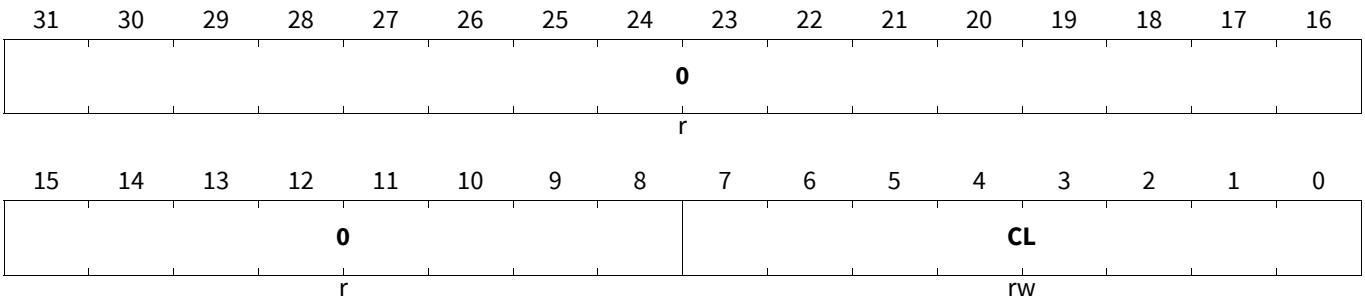


Field	Bits	Type	Description
MFID	12:2	rw	**Mask Frame ID Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. When '0' written in a bit position, the corresponding Frame ID filter bit is used for rejection filtering. When '1' written in a bit position, the corresponding Frame ID filter bit is ignored. Valid values are from 0x000 - 0x3FF.
0	1:0, 31:13	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Critical Level

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL
FIFO Critical Level **($030C_H$)** **Application Reset Value: $0000\ 0080_H$**



Field	Bits	Type	Description
CL	7:0	rw	**Critical Level** When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, a service request is generated.
0	31:8	r	**Reserved** Returns 0 if read; should be written with 0.

41.4.2.7 Message Buffer Status Registers

Message Handler Status

The Message Handler Status register gives the Host access to the current state of the Message Handler. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register. If one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1 EIR.EERR is set.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

MHDS

Message Handler Status **(0310_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				**MBU**				**0**	**MBT**						
r				rh				r	rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				**FMB**				**CRAM**	**MFMB**	**FMBD**	**ETBF2**	**ETBF1**	**EMR**	**EOBF**	**EIBF**
r				rh				rh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
EIBF	0	rwh	**ECC Error Input Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Input Buffer RAM 1 or Input Buffer RAM 2
EOBF	1	rwh	**ECC Error Output Buffer RAM 1,2** 0_B No error 1_B Error occurred when reading Output Buffer RAM 1 or Output Buffer RAM 2
EMR	2	rwh	**ECC Error Message RAM** 0_B No error 1_B Error occurred when reading the Message RAM
ETBF1	3	rwh	**ECC Error Transient Buffer RAM A** 0_B No error 1_B Error occurred when reading Transient Buffer RAM A
ETBF2	4	rwh	**ECC Error Transient Buffer RAM B** 0_B No error 1_B Error occurred when reading Transient Buffer RAM B
FMBD	5	rwh	**Faulty Message Buffer Detected** 0_B No faulty Message Buffer 1_B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error

Field	Bits	Type	Description
MFMB	6	rwh	**Multiple Faulty Message Buffers detected** 0_B No additional faulty Message Buffer 1_B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
CRAM	7	rh	**Clear all internal RAM's** Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by CHI command CLEAR_RAMS. 0_B No execution of the CHI command CLEAR_RAMS 1_B Execution of the CHI command CLEAR_RAMS ongoing
FMB	14:8	rh	**Faulty Message Buffer** ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	22:16	rh	**Message Buffer Transmitted** Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	30:24	rh	**Message Buffer Updated** Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127)and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
0	15, 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Last Dynamic Transmit Slot

The Last Dynamic Transmit Slot Register stores the Slot Counter value at the time of the last Frame transmission in the dynamic segment. This register is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.

LDTS

Last Dynamic Transmit Slot **(0314_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					**LDTB**										
r					rh										

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					**LDTA**										
r					rh										

Field	Bits	Type	Description
LDTA	10:0	rh	**Last Dynamic Transmission Channel A** Value of (vSlotCounter[A]) at the time of the last Frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
LDTB	26:16	rh	**Last Dynamic Transmission Channel B** Value of (vSlotCounter[B]) at the time of the last Frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
0	15:11, 31:27	r	**Reserved** Returns 0 if read; should be written with 0.

FIFO Status Register

The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

FSR

FIFO Status Register **(0318_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RFFL								**0**					**RFO**	**RFCL**	**RFNE**
rh								r					rh	rh	rh

Field	Bits	Type	Description
RFNE	0	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame (data or NULL Frame depending on rejection mask) was stored in the FIFO. In addition, service request flag SIR.RFNE is set. The bit is reset after the Host has read all message from the FIFO. 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	1	rh	**Receive FIFO Critical Level** This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by FCL.CL. The flag is cleared by the Communication Controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, an service request is generated. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
RFO	2	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set.The flag is cleared by the next FIFO read access issued by the Host. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
RFFL	15:8	rh	**Receive FIFO Fill Level** Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	7:3, 31:16	r	**Reserved** Returns 0 if read; should be written with 0.

Message Handler Constraints Flags

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. Software write of '1' when a flag is already cleared has no effect. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

Note: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.

MHDF

Message Handler Constraints Flags **(031C$_H$)** **Application Reset Value: 0000 0000$_H$**

Field	Bits	Type	Description
SNUA	0	rwh	**Status Not Updated Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel A. 0_B No overload condition occurred when updating MBS for channel A 1_B MBS for channel A not updated
SNUB	1	rwh	**Status Not Updated Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel B. 0_B No overload condition occurred when updating MBS for channel B 1_B MBS for channel B not updated
FNFA	2	rwh	**Find Sequence Not Finished Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0_B No find sequence not finished for channel A 1_B Find sequence not finished for channel A
FNFB	3	rwh	**Find Sequence Not Finished Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0_B No find sequence not finished for channel B 1_B Find sequence not finished for channel B
TBFA	4	rwh	**Transient Buffer Access Failure A** This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0_B No TBF A access failure 1_B TBF A access failure

Field	Bits	Type	Description
TBFB	5	rwh	**Transient Buffer Access Failure B** This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0_B No Transient Buffer B access failure 1_B Transient Buffer B access failure
TNSA	6	rwh	**Transmission Not Started Channel A** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0_B No transmission not started on channel A 1_B Transmission not started on channel A
TNSB	7	rwh	**Transmission Not Started Channel B** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0_B No transmission not started on channel B 1_B Transmission not started on channel B
WAHP	8	rwh	**Write Attempt to Header Partition** Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses. 0_B No write attempt to Header Partition 1_B Write attempt to Header Partition
0	31:9	r	**Reserved** Returns 0 if read; should be written with 0.

Transmission Request Register 1

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1
Transmission Request Register 1 **(0320_H)** **Application Reset Value: $0000\ 0000_H$**

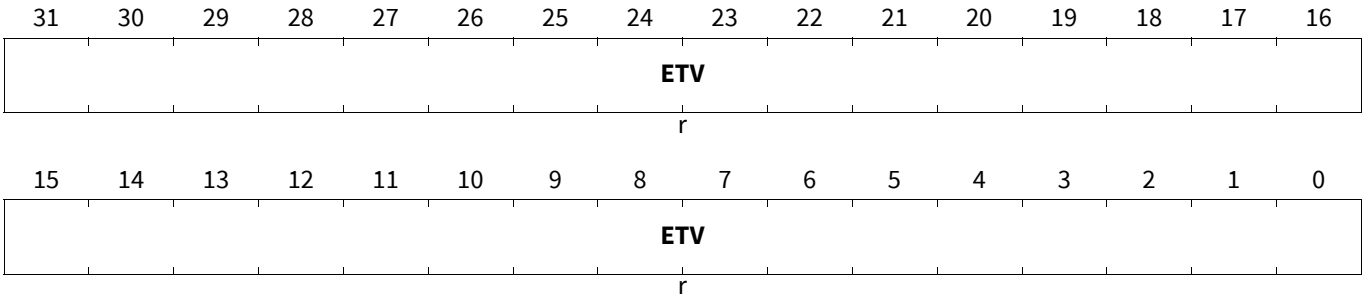
1	0	2	Release 1.0.2	31.10.2007

Endian Register

This register may be used to check, if the data of the E-Ray is handled by a host with the correct endian format. It is read only.

ENDN

Endian Register **(03F4$_H$)** **Application Reset Value: 8765 4321$_H$**



Field	Bits	Type	Description
ETV	31:0	r	**Endianness Test Value** The endianness test value.

41.4.2.9 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the Header and Data Sections to be transferred to the selected Message Buffer in the Message RAM. It is used to configure the Message Buffers in the Message RAM and to update the Data Sections of transmit buffers.

When updating the Header Section of a Message Buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in “Message Buffer Status” is automatically reset to zero.

The Header Sections of Message Buffers belonging to the receive FIFO can only be (re)configured when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For those Message Buffers only the payload length configured and the data pointer need to be configured via WRHS2.PLC and WRHS2.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in “Data Transfer from Input Buffer to Message RAM”.

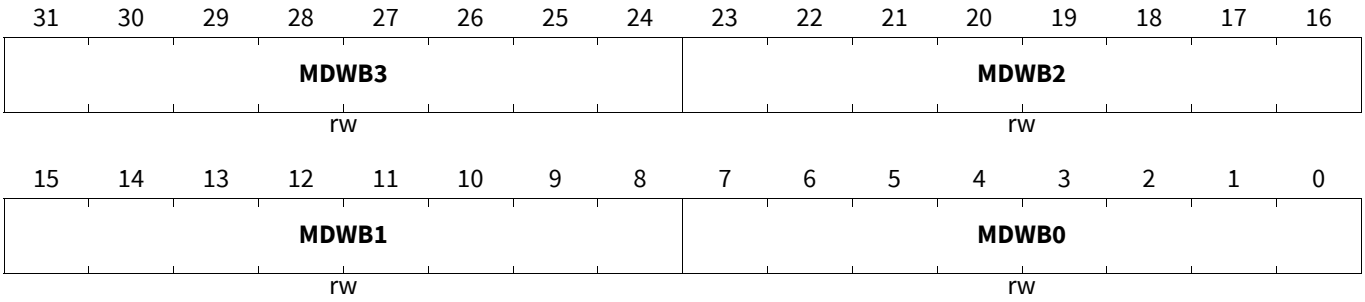
Write Data Section n

The Write Data Section (WRDSn, n = 01-64) holds the data words to be transferred to the Data Section of the addressed Message Buffer. The data words (DW_n) are written to the Message RAM in transmission order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the payload length configured by WRHS2.PLC).

Notes

1. *16-bit Word 127 is located on WRDS64.MDW. In this case WRDS64.MDW is unused (no valid data). The Input Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS.*
2. *When writing to the WRDSnn (nn = 01-64), each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started by writing the number of the target Message Buffer in the Message RAM to the Input Buffer Command Request register. If a 32-bit word of the Input Buffer has been filled with less then two consecutive 16-bit accesses OR four consecutive 8-bit accesses (less then 32-bit), random data is transferred into the Input buffer for every not written 16-bit or 8-bit of a 32-bit word.*

WRDSn (n=01-64)
Write Data Section n **(0400_H+(n-1)*4)** **Application Reset Value: 0000 0000_H**



Field	Bits	Type	Description
MDWB0	7:0	rw	**32-Bit Word nn, Byte 0**
MDWB1	15:8	rw	**32-Bit Word nn, Byte 1**
MDWB2	23:16	rw	**32-Bit Word nn, Byte 2**
MDWB3	31:24	rw	**32-Bit Word nn, Byte 3**

Write Header Section 1

WRHS1

Write Header Section 1 **(0500_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		MBI	TXM	PPIT	CFG	CHB	CHA	0	CYC

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					FID										
r					rw										

Field	Bits	Type	Description
FID	10:0	rw	**Frame ID** Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	22:16	rw	**Cycle Code** The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see Section "Cycle Counter Filtering".
CHA	24	rw	**Channel Filter Control A** The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	**Channel Filter Control B** The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	**Message Buffer Direction Configuration Bit** This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0_B The corresponding buffer is configured as Receive Buffer 1_B The corresponding buffer is configured as Transmit Buffer
PPIT	27	rw	**Payload Preamble Indicator Transmit** This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the E-Ray module, but can be done by the Host. 0_B Payload Preamble Indicator not set 1_B Payload Preamble Indicator set

Field	Bits	Type	Description
TXM	28	rw	**Transmission Mode** This bit is used to select the transmission mode (see “Transmit Buffers”). 0_B Continuous mode 1_B Single-shot mode
MBI	29	rw	**Message Buffer Service Request** This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and /or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0_B The corresponding Message Buffer service request is disabled 1_B The corresponding Message Buffer service request is enabled
0	15:11, 23, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Note: The Input Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.

Table 422 Channel Filter Control Bits

CHA	CHB	Transmit Buffertransmit Frame on	Receive Bufferstore Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Write Header Section 2

WRHS2
Write Header Section 2 **(0504_H)** **Application Reset Value: $0000\ 0000_H$**

r					rw										

Field	Bits	Type	Description
DP	10:0	rw	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	31:11	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Mask

Configures how the Message Buffer in the Message RAM selected by the Input Buffer Command Request register IBCR is updated. If IBF Host and IBF Shadow are swapped, also masked bits IBCM.LHSH, IBCM.LDSH, and IBCM.STXRH are swapped with bits IBCM.LHSS, IBCM.LDSS, and IBCM.STXRS to keep them attached to the respective Input Buffer transfer.

IBCM

Input Buffer Command Mask **(0510_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													STXRS	LDSS	LHSS

0													STXRH	LDSH	LHSH
r													rwh	rwh	rwh

Field	Bits	Type	Description
LHSH	0	rwh	**Load Header Section Host** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM
LDSH	1	rwh	**Load Data Section Host** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM
STXRH	2	rwh	**Set Transmission Request Host** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission
LHSS	16	rh	**Load Header Section Shadow** 0_B Header Section is not updated 1_B Header Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
LDSS	17	rh	**Load Data Section Shadow** 0_B Data Section is not updated 1_B Data Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)

Field	Bits	Type	Description
STXRS	18	rh	**Transmission Request Shadow** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing of finalized)
0	15:3, 31:19	r	**Reserved** Returns 0 if read; should be written with 0.

Input Buffer Command Request

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also “Data Transfer from Input Buffer to Message RAM”).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR

Input Buffer Command Request (0514_H) Application Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
IBRH	6:0	rwh	**Input Buffer Request Host** Selects the target Message Buffer in the Message RAM for data transfer from Input Buffer. Valid values are 00_H to $7F_H$ (0…127).

Field	Bits	Type	Description
IBSYH	15	rh	**Input Buffer Busy Host** Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the IBSYH is set back to 0. 0_B No request pending 1_B Request while transfer between IBF Shadow and Message RAM in progress
IBRS	22:16	rh	**Input Buffer Request Shadow** Number of the target Message Buffer actually updated/lately updated. Valid values are 00_H to $7F_H$ (0…127).
IBSYS	31	rh	**Input Buffer Busy Shadow** Set to 1 after writing IBRH. When the transfer between IBF Shadow and the Message RAM has completed, IBSYS is set back to 0. 0_B Transfer between IBF Shadow and Message RAM completed 1_B Transfer between IBF Shadow and Message RAM in progress
0	14:7, 30:23	r	**Reserved** Returns 0 if read; should be written with 0.

41.4.2.10 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out Message Buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected Message Buffer from Message RAM to the respective Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in “Data Transfer from Message RAM to Output Buffer”.

Read Data Section n

The Read Data Section nn (RDDSn, n = 01-64) holds the data words read from the Data Section of the addressed Message Buffer. The data words are read from the Message RAM in reception order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the Payload Length).

Note: DW127 is located on RDDS64.MDW. In this case RDDS64.MDW is unused (no valid data). The Output Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS.

RDDSn (n=01-64)
Read Data Section n **(0600_H+(n-1)*4)** **Application Reset Value: 0000 0000_H**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					FID										
r					rh										

Field	Bits	Type	Description
FID	10:0	rh	**Frame ID**
CYC	22:16	rh	**Cycle Code**
CHA	24	rh	**Channel Filter Control A**
CHB	25	rh	**Channel Filter Control B**
CFG	26	rh	**Message Buffer Direction Configuration Bit**
PPIT	27	rh	**Payload Preamble Indicator Transmit**
TXM	28	rh	**Transmission Mode**
MBI	29	rh	**Message Buffer Service Request**
0	15:11, 23, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Note: In case that the Message Buffer read from the Message RAM belongs to the receive FIFO, FID holds the received Frame ID, while CYC, CHA, CHB, CFG, PPIT, TXM, and MBI are reset to zero.

Table 423 Channel Filter Control Bits

CHA	CHB	Transmit Buffertransmit Frame on	Receive Bufferstore Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

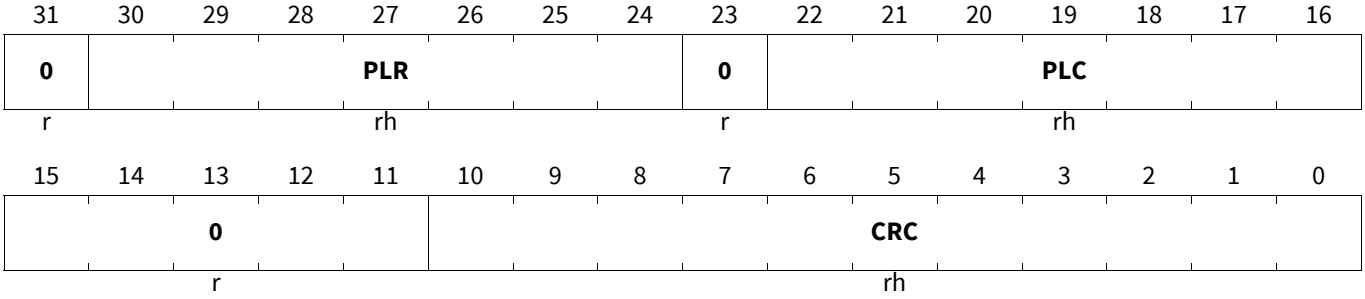
Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Read Header Section 2

Note: The Message RAM is organized in 4-byte words. When received data is stored into a Message Buffer's Data Section, the number of 2-byte data words written into the Message Buffer is PLC rounded to the next even value. PLC should be configured identical for all Message Buffers belonging to the receive FIFO. Header 2 is updated from Data Frames only.

RDHS2

Read Header Section 2 **(0704_H)** **Application Reset Value: $0000\ 0000_H$**



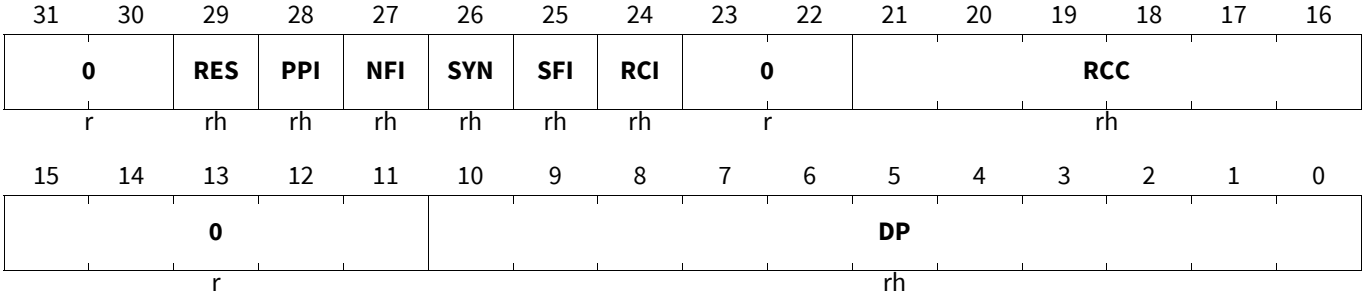
Field	Bits	Type	Description
CRC	10:0	rh	**Header CRC(vRF!Header!HeaderCRC)** Receive Buffer: Configuration not required. Header CRC updated from receive Data Frames. Transmit Buffer: Header CRC calculated and configured by the Host
PLC	22:16	rh	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host.
PLR	30:24	rh	**Payload Length Received(vRF!Header!Length)** Payload length value updated from received Data Frame (exception: if Message Buffer belongs to the receive FIFO PLR is also updated from received NULL Frames). When a message is stored into a Message Buffer the following behavior with respect to payload length received and payload length configured is implemented: • **PLR > PLC:** The payload data stored in the Message Buffer is truncated to the payload length configured for even PLC or else truncated to PLC + 1. • **PLR ≤ PLC:** The received payload data is stored into the Message Buffers Data Section. The remaining data bytes of the Data Section as configured by PLC are filled with undefined data. • **PLR = 0:** The Message Buffer's Data Section is filled with undefined data. • **PLC = 0:** Message Buffer has no Data Section configured. No data is stored into the Message Buffer's Data Section.
0	15:11, 23, 31	r	**Reserved** Returns 0 if read; should be written with 0.

Read Header Section 3

Note: Header 3 is updated from Data Frames only.

RDHS3

Read Header Section 3 **(0708_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
DP	10:0	rh	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	21:16	rh	**Receive Cycle Count(vRF!Header!CycleCount)** Cycle counter value updated from received Data Frame.
RCI	24	rh	**Received on Channel Indicator(vSS!Channel)** Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0_B Frame received on channel B 1_B Frame received on channel A
SFI	25	rh	**Startup Frame Indicator(vRF!Header!SuFIndicator)** A Startup Frame is marked by the Startup Frame indicator. 0_B The received Frame is not a startup Frame 1_B The received Frame is a startup Frame
SYN	26	rh	**SYNC Frame Indicator(vRF!Header!SyFIndicator)** A SYNC Frame is marked by the SYNC Frame indicator. 0_B The received Frame is not a SYNC Frame 1_B The received Frame is a SYNC Frame
NFI	27	rh	**NULL Frame Indicator(vRF!Header!NFIndicator)** Is set to 1 after storage of the first received Data Frame. 0_B Up to now no Data Frame has been stored into the respective Message Buffer 1_B At least one Data Frame has been stored into the respective Message Buffer
PPI	28	rh	**Payload Preamble Indicator(vRF!Header!PPIndicator)** The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1_B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload

Field	Bits	Type	Description
RES	29	rh	**Reserved Bit(vRF!Header!Reserved)** Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	15:11, 23:22, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Message Buffer Status

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see “Filtering and Masking”, “Transmit Process”, and “Receive Process”.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

MBS

VFRB	1	rh	**Valid Frame Received on Channel B(vSS!ValidFrameB)** A valid Frame indication is set if a valid Frame was received on channel B. 0_B No valid Frame received on channel B 1_B Valid Frame received on channel B
SEOA	2	rh	**Syntax Error Observed on Channel A(vSS!SyntaxErrorA)** A syntax error was observed in the assigned slot on channel A. 0_B No syntax error observed on channel A 1_B Syntax error observed on channel A

Field	Bits	Type	Description
SEOB	3	rh	**Syntax Error Observed on Channel B(vSS!SyntaxErrorB)** A syntax error was observed in the assigned slot on channel B. 0_B No syntax error observed on channel B 1_B Syntax error observed on channel B
CEOA	4	rh	**Content Error Observed on Channel A(vSS!ContentErrorA)** A content error was observed in the assigned slot on channel A. 0_B No content error observed on channel A 1_B Content error observed on channel A
CEOB	5	rh	**Content Error Observed on Channel B(vSS!ContentErrorB)** A content error was observed in the assigned slot on channel B. 0_B No content error observed on channel B 1_B Content error observed on channel B
SVOA	6	rh	**Slot Boundary Violation Observed on Channel A(vSS!BViolationA)** A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A. 0_B No slot boundary violation observed on channel A 1_B Slot boundary violation observed on channel A
SVOB	7	rh	**Slot Boundary Violation Observed on Channel B(vSS!BViolationB)** A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B. 0_B No slot boundary violation observed on channel B 1_B Slot boundary violation observed on channel B
TCIA	8	rh	**Transmission Conflict Indication Channel A(vSS!TxConflictA)** A transmission conflict indication is set if a transmission conflict has occurred on channel A. 0_B No transmission conflict occurred on channel A 1_B Transmission conflict occurred on channel A
TCIB	9	rh	**Transmission Conflict Indication Channel B(vSS!TxConflictB)** A transmission conflict indication is set if a transmission conflict has occurred on channel B. 0_B No transmission conflict occurred on channel B 1_B Transmission conflict occurred on channel B
ESA	10	rh	**Empty Slot Channel A** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel A 1_B No bus activity detected in the assigned slot on channel A
ESB	11	rh	**Empty Slot Channel B** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel B 1_B No bus activity detected in the assigned slot on channel B

Field	Bits	Type	Description
MLST	12	rh	**Message Lost** The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame. Not affected by reception of NULL Frames except for Message Buffers belonging to the receive FIFO. The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF. 0_B No message lost 1_B Unprocessed message was overwritten
FTA	14	rh	**Frame Transmitted on Channel A** Indicates that this node has transmitted a Data Frame in the assigned slot on channel A. *Note: The FlexRay™ protocol specification requires that FTA can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1* 0_B No transmission transmitted on channel A 1_B Data Frame transmitted on channel A in cycle defined by CCS bit field
FTB	15	rh	**Frame Transmitted on Channel B** Indicates that this node has transmitted a Data Frame in the assigned slot on channel B. *Note: The FlexRay™ protocol specification requires that FTB can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1* 0_B No transmission transmitted on channel B 1_B Data Frame transmitted on channel B in cycle defined by CCS bit field
CCS	21:16	rh	**Cycle Count Status** Cycle Count when status (MBS register) has been updated.
RCIS	24	rh	**Received on Channel Indicator Status(vSS!Channel)** Indicates the channel on which the Frame was received. *Note: For receive buffers (CFG = 0) the RCIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B Frame received on channel B 1_B Frame received on channel A

Field	Bits	Type	Description
SFIS	25	rh	**Startup Frame Indicator Status(vRF!Header!SuFIndicator)** A Startup Frame is marked by the Startup Frame indicator. *Note: For receive buffers (CFG = 0) the SFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B No Startup Frame received 1_B The received Frame is a startup Frame
SYNS	26	rh	**SYNC Frame Indicator Status(vRF!Header!SyFIndicator)** A SYNC Frame is marked by the SYNC Frame indicator. *Note: For receive buffers (CFG = 0) the SYNS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B No SYNC Frame received 1_B The received Frame is a SYNC Frame
NFIS	27	rh	**NULL Frame Indicator Status(vRF!Header!NFIndicator)** If reset to 0 the Payload Segment of the received Frame contains no usable data. *Note: For receive buffers (CFG = 0) the NFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B Received Frame is a NULL Frame 1_B Received Frame is not a NULL Frame
PPIS	28	rh	**Payload Preamble Indictor Status(vRF!Header!PPIndicator)** The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. *Note: For receive buffers (CFG = 0) the PPIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B Static Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID Dynamic Segment: The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Static Segment: Network Management vector at the beginning of the payload Dynamic Segment: Message ID at the beginning of the payload

Field	Bits	Type	Description
RESS	29	rh	**Reserved Bit Status(vRF!Header!Reserved)** Reflects the state of the received reserved bit. The reserved bit is transmitted as 0. *Note: For receive buffers (CFG = 0) the RESS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
0	13, 23:22, 31:30	r	**Reserved** Returns 0 if read; should be written with 0.

Output Buffer Command Mask

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

Note: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.

OBCM

Output Buffer Command Mask (0710_H) Application Reset Value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														RDSH	RHSH

RDSS	1	rwh	**Read Data Section Shadow** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer

Field	Bits	Type	Description
RHSH	16	rh	**Read Header Section Host** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	**Read Data Section Host** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
0	15:2, 31:18	r	**Reserved** Returns 0 if read; should be written with 0.

Output Buffer Command Request

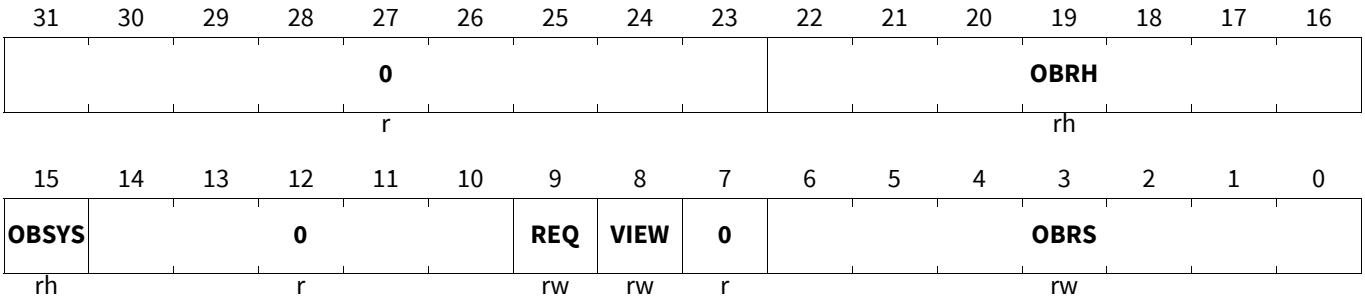
The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also “Data Transfer from Message RAM to Output Buffer”).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

OBCR

Output Buffer Command Request **(0714_H)** **Application Reset Value: $0000\ 0000_H$**



Field	Bits	Type	Description
OBRS	6:0	rw	**Output Buffer Request Shadow** Number of source Message Buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 00_H to $7F_H$ (0 to 127). If the number of the first Message Buffer of the receive FIFO is written to this register the Message Handler transfers the Message Buffer addressed by the GET Index Register (GIDX, “FIFO Function”) to OBF Shadow.

Field	Bits	Type	Description
VIEW	8	rw	**View Shadow Buffer** Toggles between OBF Shadow and OBF Host. Only writeable while OBCR.OBSYS = 0. 0_B No action 1_B Swap OBF Shadow and OBF Host
REQ	9	rw	**Request Message RAM Transfer** Requests transfer of Message Buffer addressed by OBCR.OBRS from Message RAM to OBF Shadow. Only writeable while OBCR.OBSYS = 0. 0_B No request 1_B Transfer to OBF Shadow requested
OBSYS	15	rh	**Output Buffer Busy Shadow** Set to 1 after setting bit OBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, OBCR.OBSYS is cleared again. 0_B No transfer in progress 1_B Transfer between Message RAM and OBF Shadow in progress
OBRH	22:16	rh	**Output Buffer Request Host** Number of Message Buffer currently accessible by the Host via RDHS1 to RDHS3, MBS, and RDDSnn (nn = 01-64). By setting OBCR.VIEW OBF Shadow and OBF Host are swapped and the transferred Message Buffer is accessible by the Host. Valid values are 00_H to $7F_H$ (01 to 127).
0	7, 14:10, 31:23	r	**Reserved** Returns 0 if read; should be written with 0.

41.5 Destructive Debug

On destructive debug entry ie., when DMU_SP_PROCONHSMCFG.DESTDBG = 11b and DMU_HF_PROCONDBG.EDM = 11b, the ERAY Transmit Data and transmit enable for Channel A and Channel B (TXDA, TXDB, TXENA and TXENB) are tied to logic ‘1b’. This blocks any further ERAY transmission when AURIX™ TC3xx Platform has entered the Destructive Debug state.

42 Peripheral Sensor Interface (PSI5)

The PSI5 module communicates with the external world via one I/O line for each channel. The PSI5RXx lines are the receive data input signals. If the optional unidirectional mode is used, the signals PSI5TXx are transmitted on separate GPIO ports. Receive and transmit path are always routed to two different ports.

Figure 634 shows a global view of the PSI5 interface.

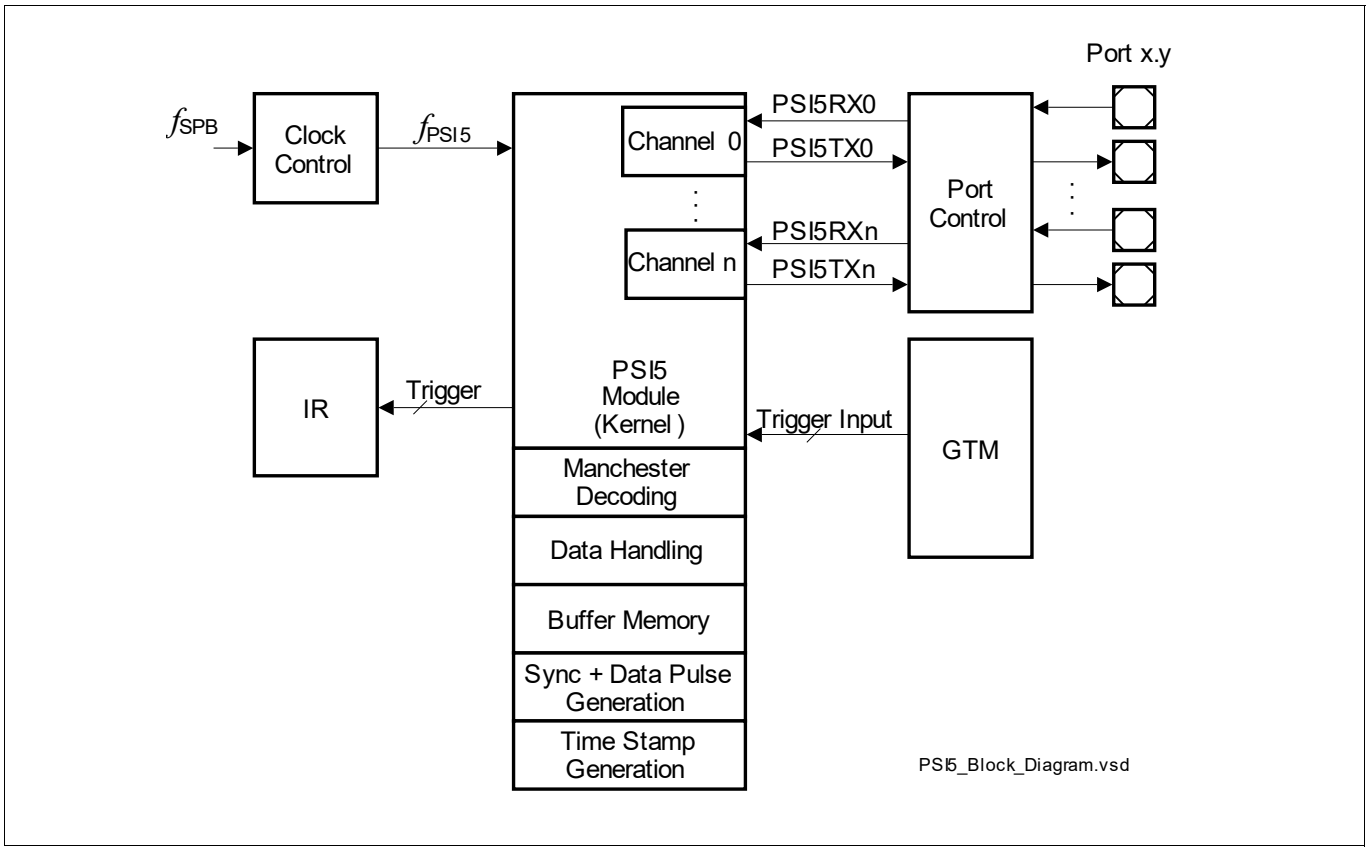

Figure 634 General Block Diagram of the PSI5 Interface

42.1 Feature List

FEATURE LIST

- Conformance with PSI5 protocol specification V1.3
- Data rates of 125 kbit/s and 189 kbit/s supported
- 4 PSI5 channels implemented
- All implemented channels are working independently in parallel
- Supports 6 sensor slots per channel
- Asynchronous and synchronous data transmission modes
  (control by micro controller in synchronous mode)
- Decoding manchester protocol
- Error recognition in manchester code
- Configurable data word length 8, 10, 16, 20, 24 bit according to standard (PSI5 V1.3)
- Support of non standard V1.3 frame length: 11… 33 bit
- CRC check of received sensor data implemented but CRC code transparent
- Support of Enhanced Serial Messages according to SENT SAE J2716 JAN 2010
- 24-Bit time stamp (resolution: 1µs)
- Storage of up to 32 frames per channel with time stamp
- FIFO access and management
- Buffer overrun detection
- Buffer Memory Status Overview Registers
- Support of ECU to Sensor communication
- Three 64-bit downstream data registers for data input, data preparation and data output
- Downstream data transmission by variation of pulse length (2.0)
- Downstream data transmission by leaving out sync pulses (V1.3)
- Staggering Sync Pulses of all channels to avoid too many channels sending sync pulses in parallel
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence and CRC generator for downstream data
- One sum interrupt for general events
- One sum interrupt on selectable errors
- Sticky interrupt flags, error interrupt optional (default disabled)
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting

42.2 Overview

The PSI5 IP-module performs communication according to the PSI5 specification V1.3.

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

This module supports many additional features as discussed today in the standard organization.

The PSI5 interface provides a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages protocol handling and data representation to the application. Note that there is no on chip phy, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5 channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a 32-bit buffer register for each channel and an additional 32-bit register containing the 24-bit time stamp and additional status bits. These 64 bits per frame are additionally stored in a buffer of 32 lines per channel.

In Host to sensor communication mode, the module can provide regular sync pulses and select between internal and external timer/trigger resources. It supports as well CPU to sensor communication, e.g. for setting up the sensor and retrieving sensor status information.

The register set of the PSI5 module can be accessed directly by the CPU for configuration, data read out and status query.

The PSI5 module supports the following features:

42.3 Functional Description

42.3.1 General Operation

PSI5 is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 635 shows a typical device application in which a PSI5 interface reads a sensor device.

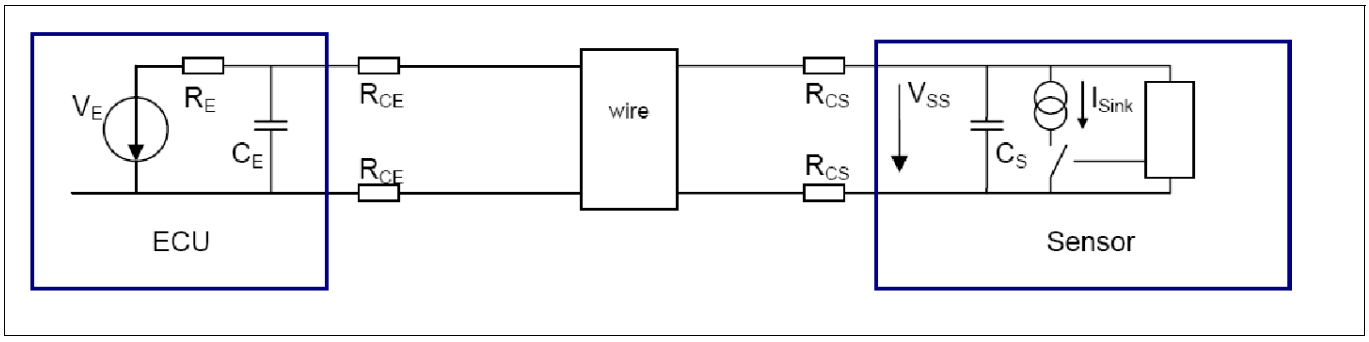

Figure 635 PSI5 to External Device Connection

PSI5 communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage.

Figure 636 shows a typical device application in which a PSI5 ECU reads multiple PSI5 sensor devices on a bus.

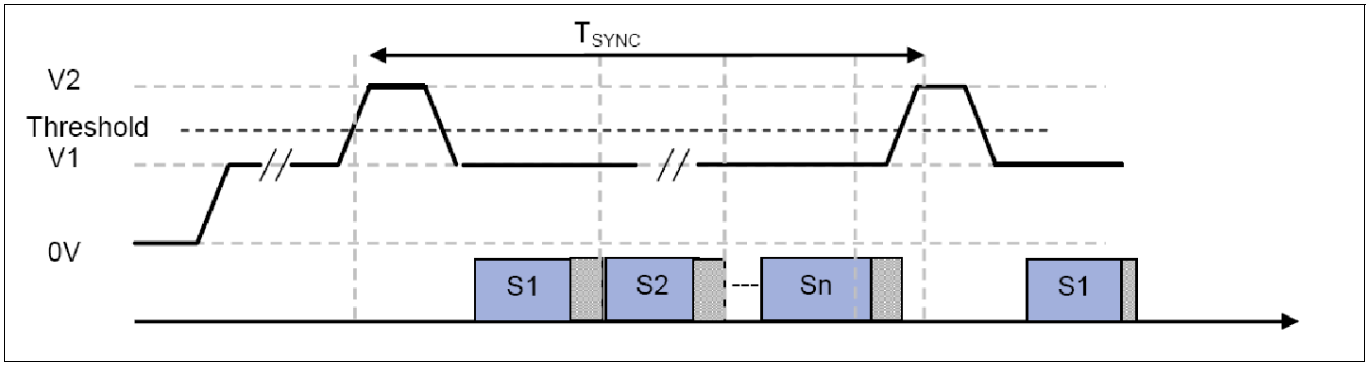

Figure 636 PSI5 Frames with Sync pulses

42.3.2 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

SOF: Start of Frame

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

42.3.3 PSI5 Operation

The Module supports two modes:

Standard PSI5 Mode supports communication fully compliant to V1.3

Extended PSI5 Mode supporting additional bit fields and longer frames. (See below)

In standard V1.3 mode, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for data frames but are interpreted as data. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

In extended Mode (Power Train sub standard), the pulse width is modulated. A standard pulse represents a 0, a longer pulse a 1. This way continuos data transmission can be achieved.

42.3.4 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5 protocol.

42.3.4.1 PSI5 V1.3 Frame

Figure 637 shows the layout and definitions of a standard PSI5 frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

Example: 16 Bit Data Word „0xAD2C“ with 3-Bit CRC

S1	S2	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14	D15	C2	C1	C0
0	0	0	0	1	1	0	1	0	0	1	0	1	1	0	1	0	1	1	0	0
		C = „1100“				2 = „0010“				D = „1101“				A = „1010“						

Figure 637 Standard PSI5 Frame

42.3.4.2 Extended PSI5 Frame (non standard)

Figure 638 shows the layout and definitions of an extended PSI5 frame as defined in V2.0 for automotive power train application. Note that the PSI5 standard specifies that the least significant bit is sent out first.

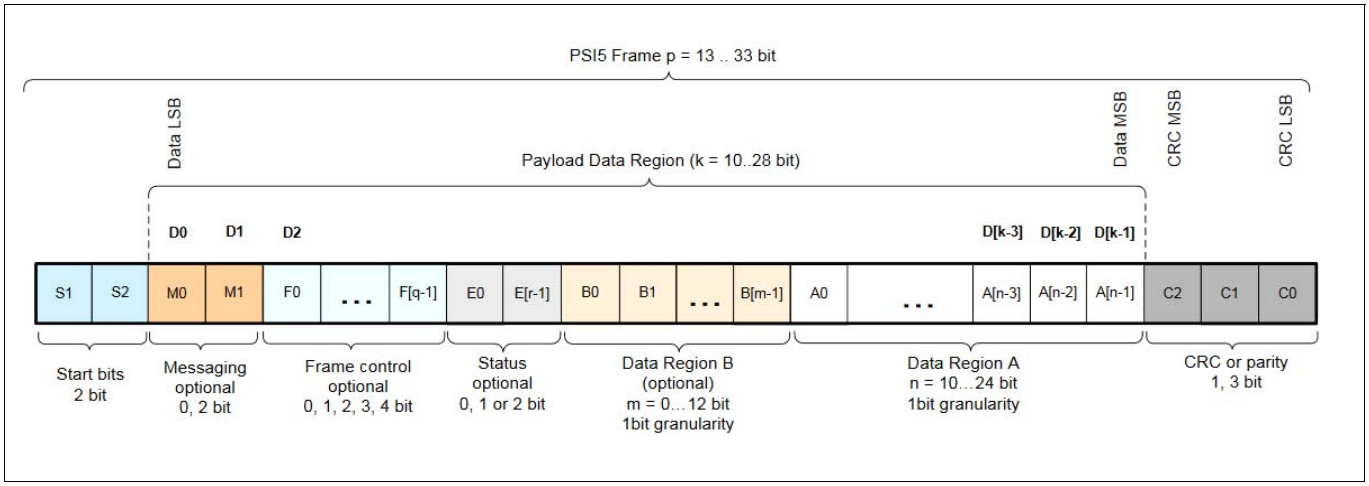

Figure 638 Extended PSI5 Frame

Enhanced PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1) 1-bit even parity

2) 3-bit CRC

The applied generator polynomial of the CRC is g(x) = 1 + x + x3 with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

In this implementation the number of elements is configurable and thus longer or shorter than 8…28 bits!

42.3.4.3 Enhanced Serial Message (“Slow Channel”)

The serial data is transmitted bit wise per frame in bits [1:0] of the Messaging bit field of 18 consecutive messages from the transmitter.

42.3.4.4 Enhanced Serial Data Frame

Serial data (“Slow Channel”) is communicated in an 18 frame sequence as shown in **Figure 639**. The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit M1 constructed across 7 consecutive PSI5 messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive PSI5 messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The CRC generation is different from the CRC generation on the data nibbles. (See SENT Standard SAE_J2716_201001)

The serial message frame contains 21 bits of message data and a 6-bit frame-check sequence. Two different configurations can be chosen:

- 12-bit data and 8-bit message ID
- 16-bit data and 4-bit message ID

A configuration bit (serial data bit M1, serial communication Messaging bits of frame No. 8) determines the configuration of the enhanced serial message frame. It determines how the PSI5 module automatically interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

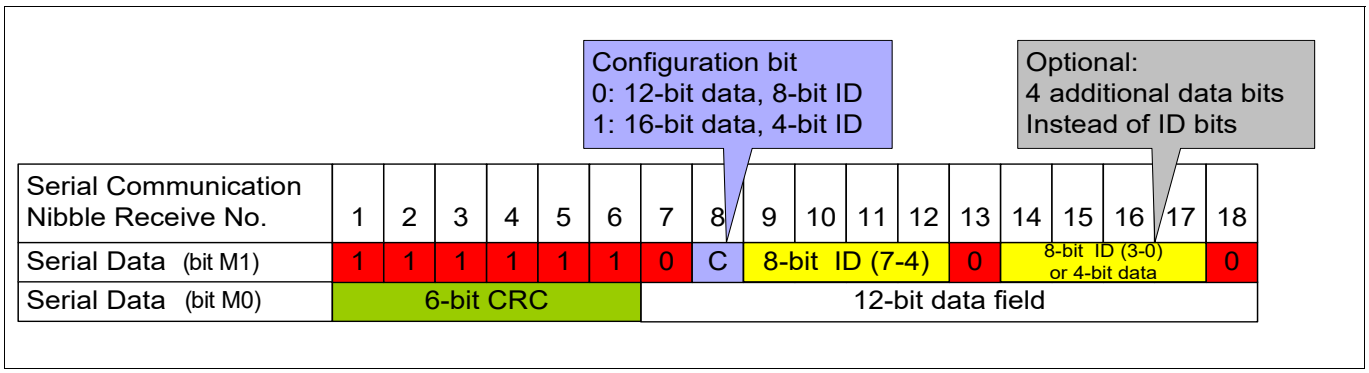

Figure 639 Enhanced Serial Data Frame

Figure 640 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

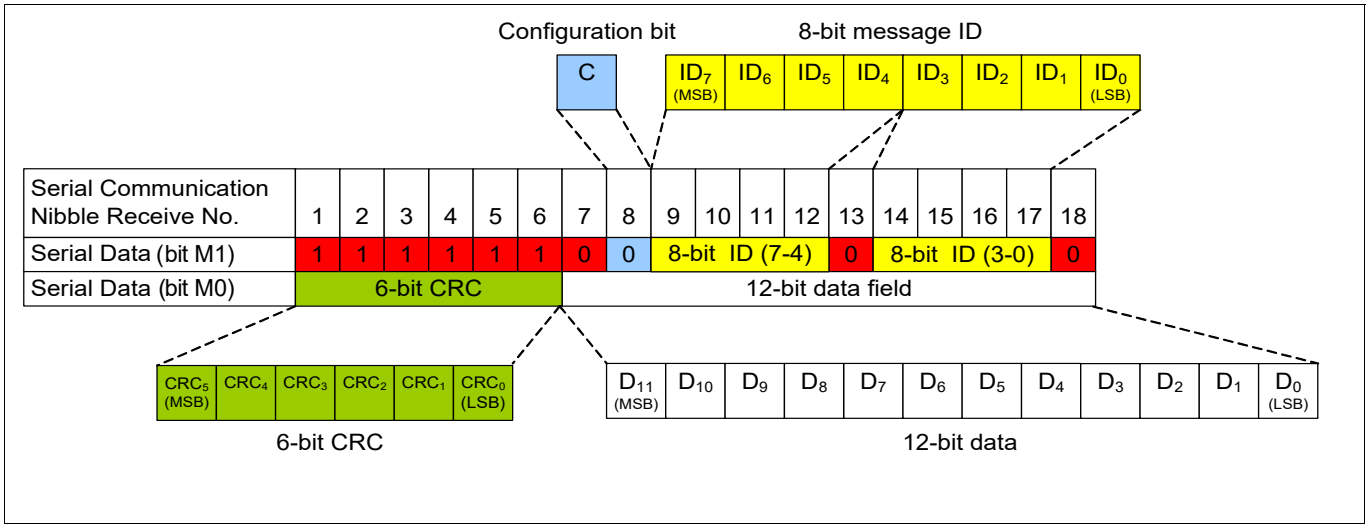

Figure 640 Configuration Bit = 0

Figure 641 shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

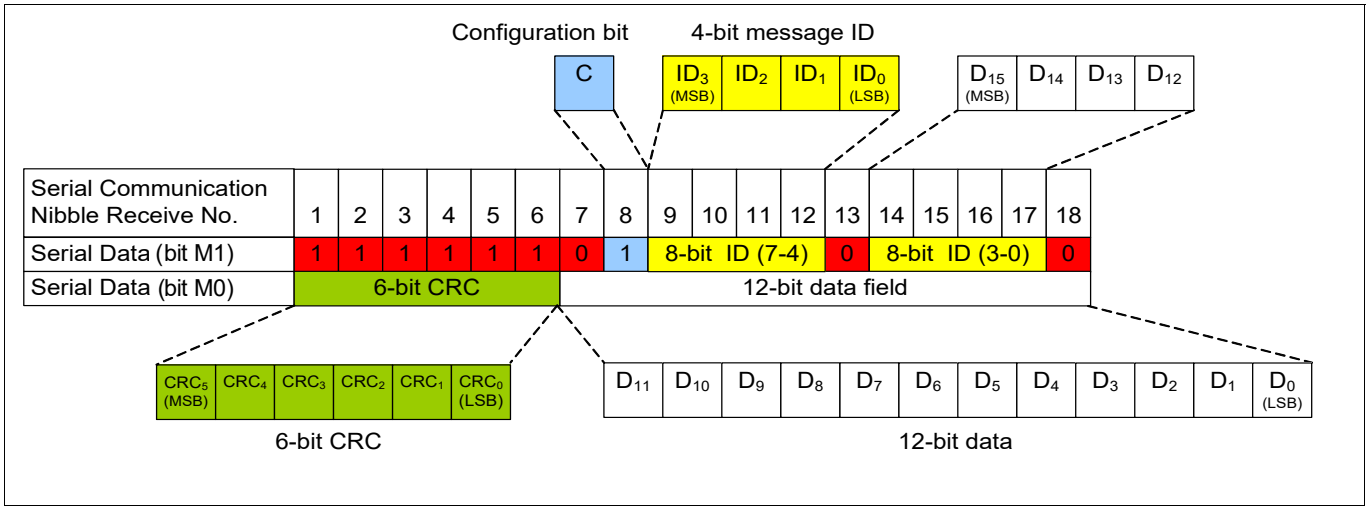

Figure 641 Configuration Bit = 1

42.3.5 Sync Pulses

Sync Pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

42.3.5.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is forced by the master on the OUT pin. An external phy translates this pulse into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 frame, starting with the 2 start bits, data and Parity or CRC. The timing diagram in **Figure 642** visualizes a synchronous transmission

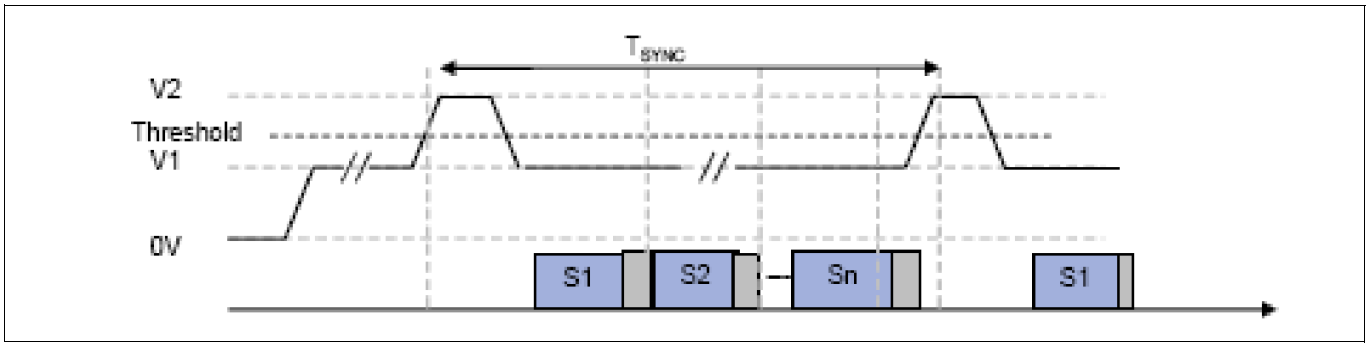

Figure 642 Synchronous Transmission

42.3.5.2 ECU to Sensor Communication

Two versions are supported:
legacy PSI5 V1.3 (see **Figure 643**) and
revised version (see **Figure 644** and **Figure 645**).

The legacy version

uses sync pulses as start condition and start bits to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

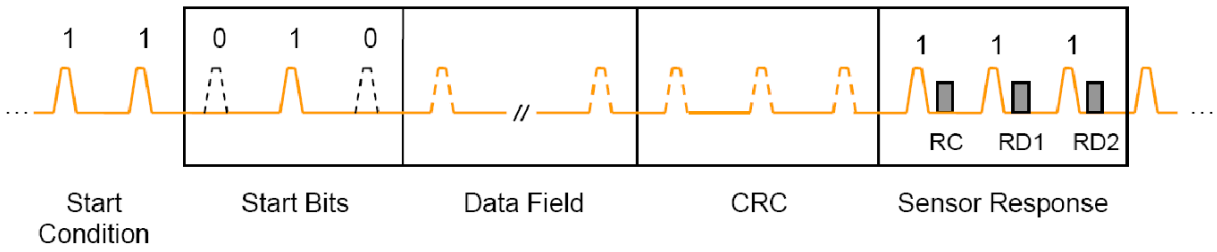

Figure 643 ECU to Sensor (legacy)

The revised version

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously. Every ECU-to-Sensor frame starts with a nine-bit frame-start-sequence [0 1 1 1 1 1 1 1 0]. Synchronization is possible at the beginning of each frame.

Sync Bits

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted at every seventh bit position (after every six bits of the sensor address and the payload data). With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

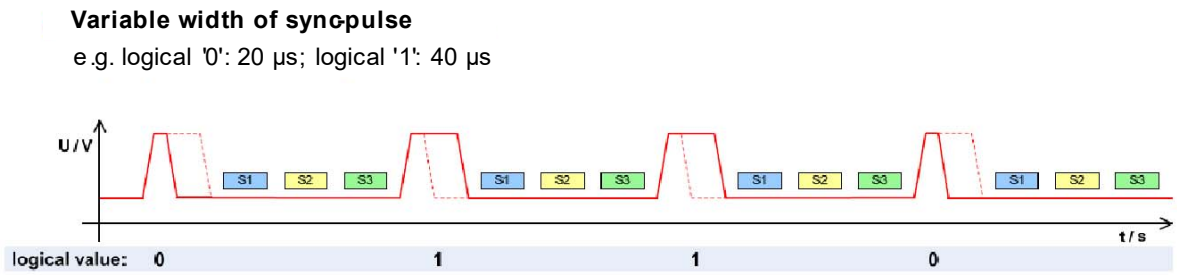

Figure 644 ECU to Sensor, Bit transmission (revised)

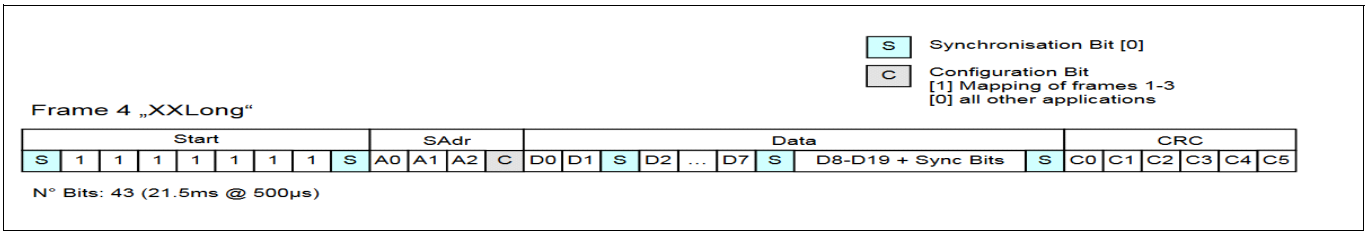

Figure 645 ECU to Sensor, Frame format (revised)

Enhanced ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.
The generator polynomial of the CRC is
g(x)=x6 + x4 +x3 +1
with a binary CRC initialization value “010101”.
The transmitter extends the data bits by six zeros (as MSBs).

This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1…C5].

In this implementation the number of elements is configurable and thus longer or shorter than 24 bits (standard is 4 address and 20 data bits)!

42.3.6 Manchester Decoding

Decoding of the Manchester protocol:

- The Manchester decoder uses a nominal 4 MHz / 6.048 MHz sampling clock (32 samples per bit).
- A sampling counter, running at the sampling clock rate controls the sampling of the incoming Manchester encoded data.
- The Manchester signal transition occurring in the middle of the bit time resets the counter, making the counter count from 0-31 (nominally) between successive mid-bit times.
- Detection of the mid-bit transitions uses three consecutive samples (011 = rising edge, 100 = falling edge).
- The maximum value of the 6 bit counter shall be 41, at which point a Manchester error is detected due to lack of a transition, and the counter rolls over to 0. (“Idle Time”)
- The value of a Manchester encoded input data bit is determined by proper logic levels before and after a transition and proper timing of the transition.
- Bit-value determination nominally takes place at the 1/4 and 3/4 bit times, with the mid-bit transition occurring at the 1/2 bit time. This is nominally at sampling counter values of 8 (1/4 bit time) and 24 (3/4 bit time).
- Logic levels are determined using a 2 of 3 majority vote of consecutive samples (samples 23, 24, 25 and 7, 8, 9)
  - The combinations 111, 011, 101, 110 indicate a 1
  - The combinations 000, 001, 010, 100 indicate a 0

Manchester-2 is used by standard PSI5 V1.3:

- Start bits = ‘00’
- Falling edge corresponds to logical ‘1’
- Rising edge corresponds to logical ‘0’
- Least significant bit (LSB) is sent out first

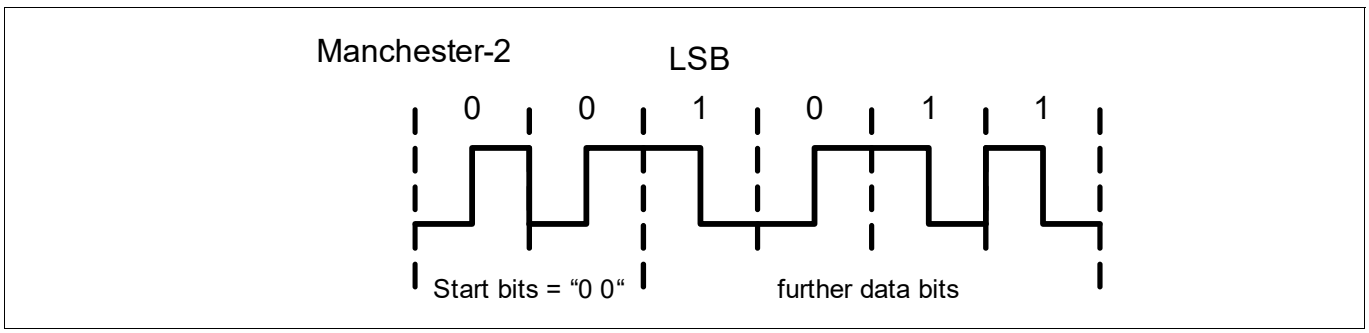

Figure 646 Manchester-2

Sampling Details

- Recognition of Frame Start

  - Manchester Code requires a deterministic Start of Frame
  - Frame Separation: An “Idle Time” of at least one Bit time is required
  - “Idle Time” is the time without edges on the line that is required to safely determine that no frame is being transferred (1 Bit time + tolerance = > 41 samples)
    The Idle Counter starts counting
    - on a falling edge, after sync pulse or after BOT, if the channel is switched on
    - if the line is low
    - up to 41 and stops and
    - activates the idle flag
    - until the line shows a rising edge, this clears the idle counter
  - After this idle time, a determined start bit sequence is required for synchronization of the phase of receiver and transmitter (‘0 0’ in case of the „Manchester 2“-code employed)
  - If no idle time occurs at the end of a frame, bits after the configured length are dropped.
  - If a 2nd frame comes too early (collision = no idle time) the 2nd frame is dropped. The decoder waits for an “Idle Time” for re synchronization.
  - Idle time is particularly required in case of Manchester Errors and frame collisions for a save re synchronization. Otherwise, two successive zeros in a damaged frame / a second colliding frame could lead to reception of wrong data. Note that back to back transfers of correct frames are forbidden by standard (T_gap required).
  - This idle time is required as well after a regular End Of Frame, Sync Pulse or a Blank Out Time to avoid inadvertent synchronization inside frames under transmission.
- Bit sampling
  - After the start of the protocol is detected and an edge on the line signal is detected and the counter is greater 25 the counter is set to ‘0’
  - If the counter is 41 the counter is set to ‘0’ and stops
  - The counter will be incremented each clock cycle
  - When the sample counter has the value 9, the level is stored in register cnt9_val
  - When the sample counter has the value 25, the level is stored in register cnt25_val
  - This register is reset if no frame is detected. Otherwise a wrong start bit detection could occur.
- Bit evaluation
  - When the sample counter value is 16, the decision is done for the new sample value:
  - Check if the last edge was detected correctly i.e.: edge detected between sample counter value 25 and sample counter value 41
  - If true:
  - Cnt_25_lev = 0 & cnt_9_lev = 1 => new sample = ‘0’
  - Cnt_25_lev = 1 & cnt_9_lev = 0 => new sample = ‘1’
  - If the edge check fails or cnt_25_lev = cnt_9_lev, Manchester Error is assumed.

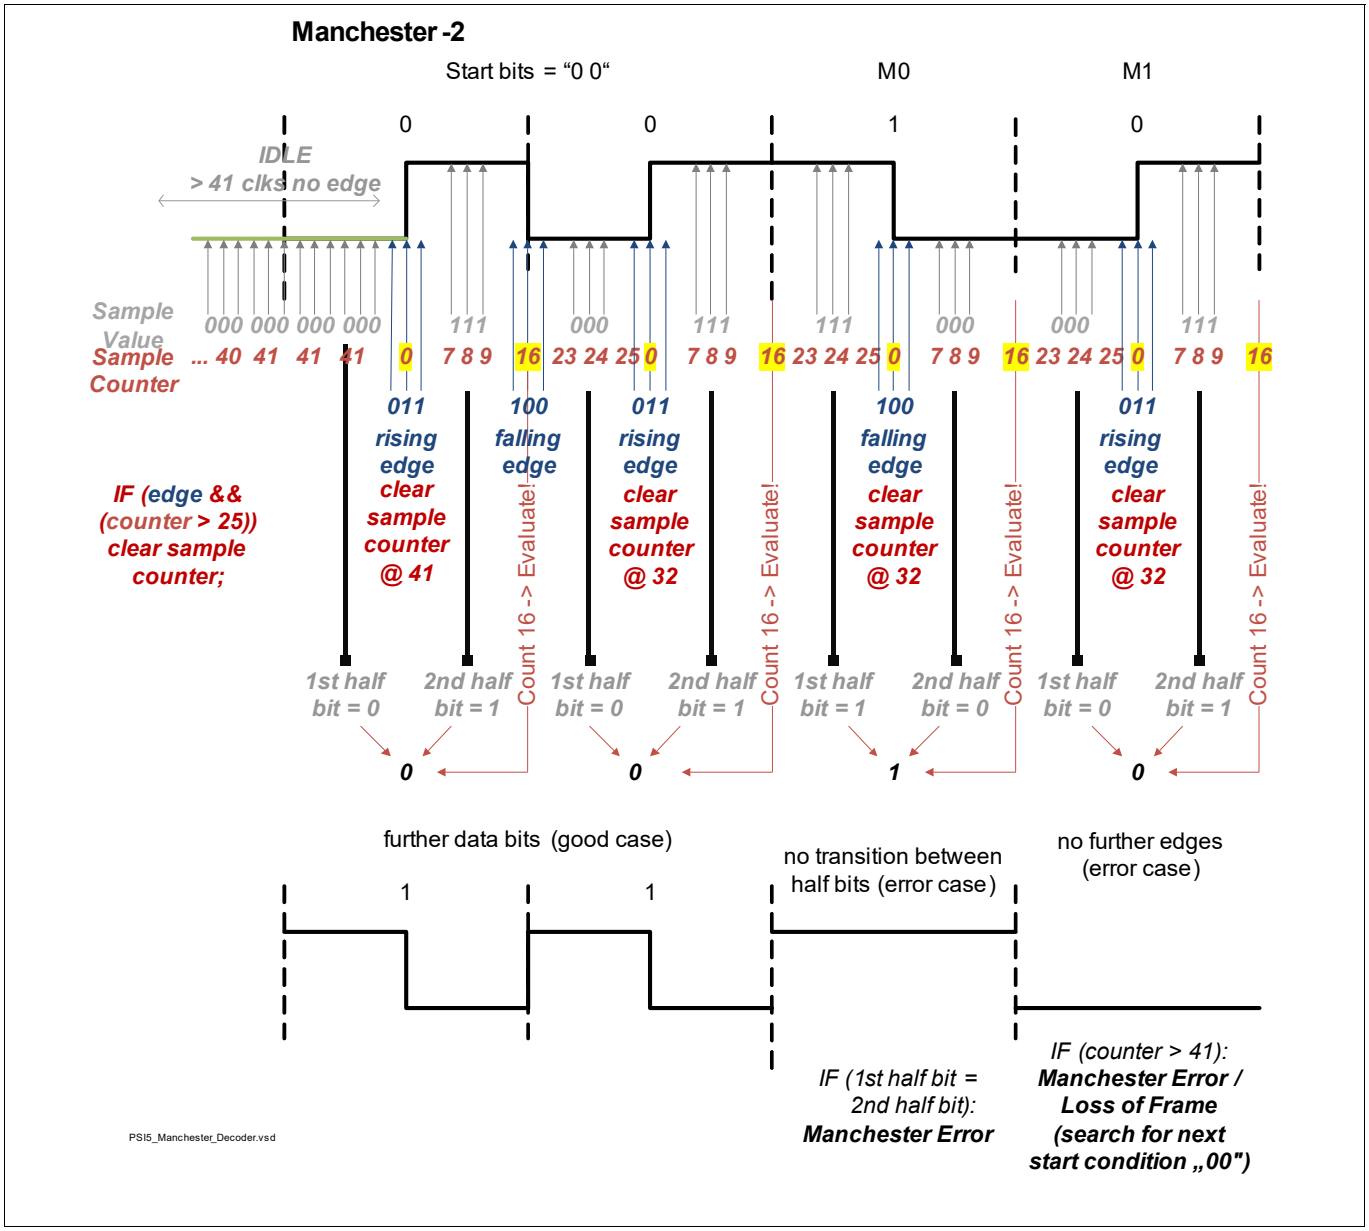

Figure 647 Manchester Decoder

Definition of Manchester Error (ME)

- Two half bits have the same value => ME, the decoder waits for an "Idle Time"
- > 41 sample times no edge => ME
- The ME is no dedicated interrupt but will lead to various error responses depending on where it occurs. See **Table 426**.

Table 426 Error Responses due to ME

Manchester Error (ME) Case	Response	Comment
First ME in start bits	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of slot where SOF happened. This is true even if these start bits should start before WDL and end after WDL
Start bits cut off by BOT or Sync Pulse (frame starts without leading idle time)	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set)
First ME in Messaging bits	If MSG is set: MEI	Frame is stored, bits after error are lost (“0”)
	If MSG cleared: NBI	
First ME in data, parity or CRC / Frame ends too early	NBI	Frame is stored, bits after error are lost (“0”)
Frame ends too late (longer than PDL)	no NBI	Bits after PDL are cut off and EOF is detected. Frame is stored.
Collision (Idle Time missing)	Discard 2nd frame	If the 1st frame was too late and running over WDL or If the 2nd frame was too early and running over WDL then for 2nd frame, NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of 2nd slot
In all cases, the receiver waits for an idle time followed by the start bits “00” before a new frame is detected.		

42.3.7 Bit Rate Generation

The bit rate of each channel is individually selectable from the 2 standard bit rates 125 kHz and 189 kHz. The two referring over sampling frequencies are generated centrally.

This chapter shows in detail how the bit rate for each channel is adjusted.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different PSI5 channels. Usually this can be left unused.

For each of the two bit rates there is an own fractional divider. Each channel can select one out of the two clock signals f_{125} and f_{189}.

For details on the principles of a fractional divider, please refer to the SCU chapter of the device section “Clock Control”.

The PSI5 module provides 5 clock signals centrally (**Figure 648**):

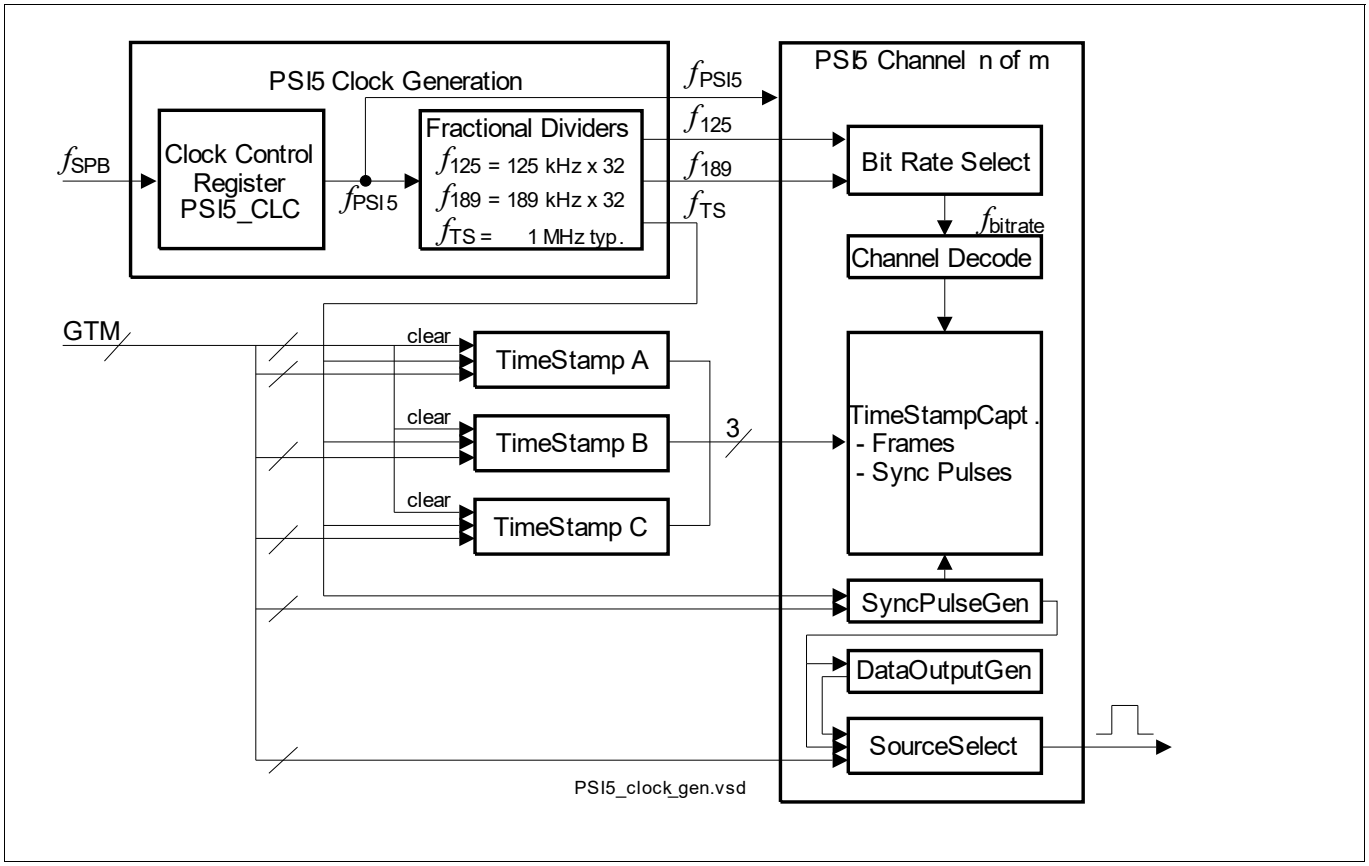

Figure 648 PSI5 Module Clock Generation

- f_{PSI5}
  This is the module clock that is used inside the PSI5 kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5} is always identical to the system clock frequency f_{SPB}. The clock control register PSI5_CLC makes it possible to enable/disable f_{PSI5} under certain conditions.
- $f_{fracdiv}$
  This clock is the module clock that is used inside the PSI5 kernel for bit rate generation of the serial channels. The fractional divider register PSI5_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.
- f_{125}
  This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRL controls the frequency of f_{125}.The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency
- f_{189}
  This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRH controls the frequency of f_{189}.The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency.
- f_{TS}
  This clock is used to drive the central time stamp counter.
  It can be selected to drive the global sync pulse time base and
  inside the PSI5 channels to drive the local watch dog timers. The fractional divider register PSI5_FDRT controls the frequency of f_{TS}.This is usually adjusted to 1 MHz / 1 µs period time.

The following two formulas define the frequency of $f_{fracdiv}$:

$f_{fracdiv} = f_{PSI5}$ / (1024 - PSI5_FDR.STEP); FDR.DM = 01B (42.1)

$f_{fracdiv} = f_{PSI5}$ x PSI5_FDR.STEP / 1024 with STEP = 0 … 1023; FDR.DM = 10B (42.2)

The following two formulas define the frequency of f_{125}.

$f_{125} = f_{fracdiv}$ / (1024 - PSI5_FDRL.STEP); FDRL.DM = 01B (42.3)

$f_{125} = f_{fracdiv}$ x PSI5_FDRL.STEP / 1024 with STEP = 0 … 1023; FDRL.DM = 10B (42.4)

The following two formulas define the frequency of f_{189}.

$f_{189} = f_{fracdiv}$ / (1024 - PSI5_FDRH.STEP); FDRH.DM = 01B (42.5)

$f_{189} = f_{fracdiv}$ x PSI5_FDRH.STEP / 1024 with STEP = 0 … 1023; FDRH.DM = 10B (42.6)

The following two formulas define the frequency of f_{TS}:

$f_{TS} = f_{PSI5}$ / (1024 - PSI5_FDRT.STEP); FDRT.DM = 01B (42.7)

$f_{TS} = f_{PSI5}$ x PSI5_FDRT.STEP / 1024 with STEP = 0 … 1023; FDRT.DM = 10B (42.8)

42.3.8 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) of Infineons GPTA® in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{PSI5}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{PSI5} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive/bypassed. Nevertheless, the input signal is sampled with f_{PSI5}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes 2 x T_{PSI5} times longer for the internal signal to change value. The filters principal implies a delay of the signal by (DEPTH x T_{PSI5}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 649 shows the digital glitch filter:

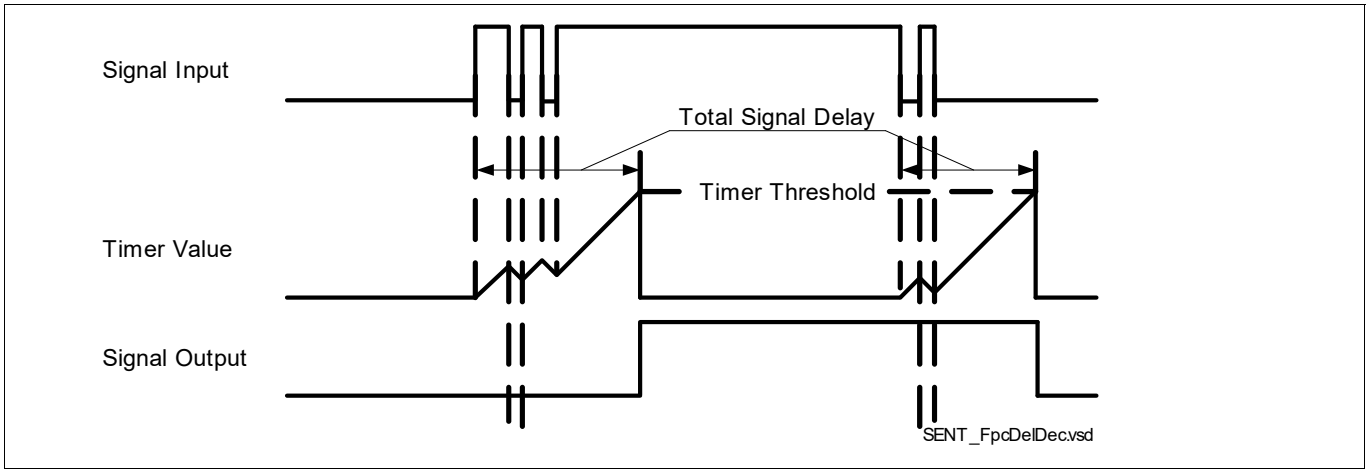

Figure 649 Digital Glitch Filter

42.3.9 Time Stamp Generation

Three time bases can be selected for Time Stamping:

Any of TSRA, TSRB and TSRC provide one time stamp counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by a selectable GTM signal or by SW, single or synchronously.

Two times are captured for each channel:

The last sync pulse sent on this channel is stored in the sync pulse time stamp capture register SPTSCx.

The last start of frame (SOF) on this channel is stored in the SOF capture register SFTSCx.

For each channel the capture time (SPTSC or SFTSC) can be selected, that will be stored in the Receive Data Register and the Receive Data Memory.

Figure 650 shows the time stamp generation:

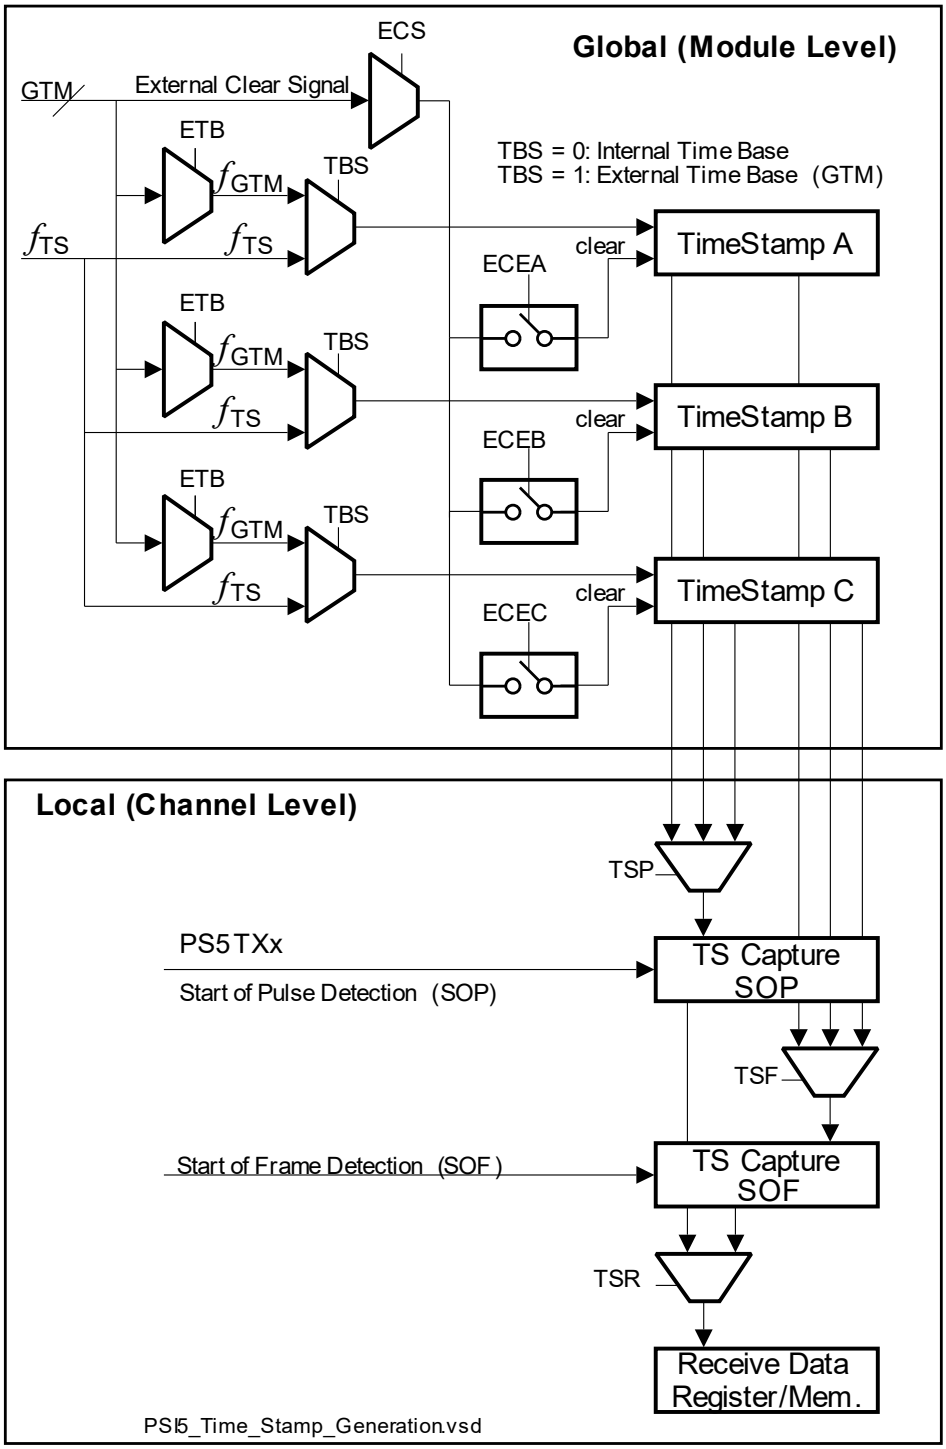

Figure 650 Time Stamp Generation

42.3.10 Watch Dog Timer

Synchronous Mode

Selected with RCRAx.ASYN = 0.

The Watch Dog Timer Registers WDTxy contain 7 time limits defining 6 frame slots.

The internal Watch Dog timer is started automatically at the start of a sync pulse. The value entered here defines the time in multiples of TTS (defined in FDRT) from the last start of a sync pulse on channel x.

The internal Watch Dog Timer is compared to WDLxy. A match triggers:

- the automatic incrementing of slot counter RDRH.SCx
- starting from WDLx1 on: check if a frame with the corresponding SC y has been received or if such a frame is still being received since last WDLxy expired. If this is not the case but a frame was expected in this slot y (configured so in RCRBx.FECy) “No Frame Received” Interrupt NFI is issued. If configured so (in RCRBx.VBSy), an empty frame (all data fields are ‘0’) is stored in RDRL/Hx and the referring RDML/H.
- Frames that start before a slot boundary and end after this boundary but are too short and thus discarded will result in an NFI / empty frame as well (if configured).
  - If no frame was received before the SOF in this slot,
    SC = slot where SOF happened.
    Time Stamp = end of slot where SOF happened.
  - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and
    if no good frame is received in this next slot:
    SC = next slot (SC where SOF happened + 1)
    Time Stamp = end of next slot (SC where SOF happened + 1).
  - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and
    if a good frame is received in this next slot: no NFI is issued.
- (The remarks about the Time Stamps assume that RCRCx.TSR selects SFTSCx.)
- A frame starting before a slot y and ending in slot y will not prevent NFI for slot y.

Detection of Frame Boundaries:

- SOF is the first rising edge of the first start bit after an “Idle Time”, a time stamp is triggered and SC is captured for the frame at this point in time
- EOF is determined based on the configured frame length (RCRAx.PDLy and RCRCx.CRCy). An unexpected “Idle Time” or Manchester Error will result in earlier EOF detection.
- For each frame, the receiver checks if slot counter SC at SOF is equal to SC at EOF. If not, the interrupt TEI is issued. FEC is not relevant for TEI.

If WDLxy is cleared no check is performed but RDRH.SC is still incremented when it is its turn in the sequence of the WDLs. Thus such unconfigured WDLxy must appear only at the end. If an unconfigured WDLxy appears between configured WDLxy, the slot count will be confused.

If a frame is received in a slot where no frame is expected, no dedicated flag is set but the frame is received with the parameters (PDL, SC and on) given for this slot. SW will detect this as SC for this frame is wrong.

Asynchronous Mode

Selected with RCRAx.ASYN = 1.
The watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled. If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0. Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. If AVBS (verbose mode) is set too, an empty frame is stored in RDRL/Hx and the referring RDML/H.

Channel Configuration at Slot Boundaries / Take over of Slot Parameters

The receiver takes over the parameters for a frame at the beginning of a slot
- with 3 exceptions:

Exception 1)

During SLOT0 (this is the slot after the last configured slot), after the sync pulse, the configuration of SLOT1 is already used. An internal shadow slot count value makes sure, the messaging bits are routed to slow channel for SLOT1. This way, a frame for SLOT1 that is too early will be received correctly, the messaging bits are sorted correctly. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT0) than it ends (SLOT1). SC = 1 will be stored in the receive buffer/memory.

Exception 2)

Frames that come too early could destroy the slow channel of the preceding slot. To prevent this, during SLOT1 .. SLOT5, the configuration of the next slot is loaded immediately after EOF was received. Note that an SOF must be seen first in the same slot before an EOF is looked for. This way, the HW prevents the destruction of a good frame by a preceding frame that is too late. An internal shadow slot count value makes sure, the messaging bits are routed to the slow channel for the following SLOT. This way, a frame for e.g. SLOT3 that is too early will be received correctly, the messaging bits are sorted correctly in SLOT3 and not in SLOT2 where the SOF of this frame is. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT2) than it ends (SLOT3). SC = 3 will be stored in the receive buffer/memory.

Exception 3)

If a frame does not end at the configured end of a slot, the new parameters of the following slot are taken over by the receiver only after the EOF was detected. This allows to receive a frame properly that is too late.

Note that orphan frames, i.e. frames that come with a timely shift of of one ore more slots can not be detected as such. Thus they will be stored with the SC as they appear.

Notes on Frames coming too early

A frame may come too early and thus start in a slot that is configured for no frame (FEC = 0).

If the user wants to make sure that this frame is stored in RDR/RDM, the slot with FEC = 0 must be configured in the same way as its follower.

At least, the length field PDL must be set to its maximum value (28) to allow for reception of all frame lengths. This allows to capture such a frame with referring error bits. (TEI, NBI, CRC in most cases)

If this is not done and PDL is (by default) = 0 the following happens:

CASE1: SOF is too early and thus in the slot with FEC = 0, due to PDL = 0 also EOF is detected in the slot with FEC = 0.

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI is issued.

CASE2: SOF is too early and thus in the slot with FEC = 0, although PDL = 0 EOF is detected in the slot FOLLOWING the slot with FEC = 0 (because CRC transmission end here, i.e. the SOF was very close to the end of the slot)

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI and TEI bits are set.

Usage of the Watch Dog Timer Limits

The example below shows some use cases.

F1: “Frame too early”: Slot Count SC at SOF is 0 and 1 at EOF. Timing Error is issued (TEI). F1 is stored with configuration of Slot 1 and SC = 1.

WDL2: Slot Count SC incremented by HW, no “No Receive Frame” Interrupt as no frame expected (FEC=0)

F3: “Frame too late”: Slot Count SC at SOF is 3 and 4 at EOF. Timing Error is issued (TEI). The configuration for Slot 3 is kept until the end of F3 so that it is not destroyed. Note that the EOF of Frame 3 does not lead to take over the configuration of Slot 5! But the EOF of F4 does. This way a F5 coming too early would be received correctly.

WDL5: “Frame missing”: No SOF or EOF received since WDL4. A frame was expected (FEC=1), No Receive Frame Interrupt is issued.

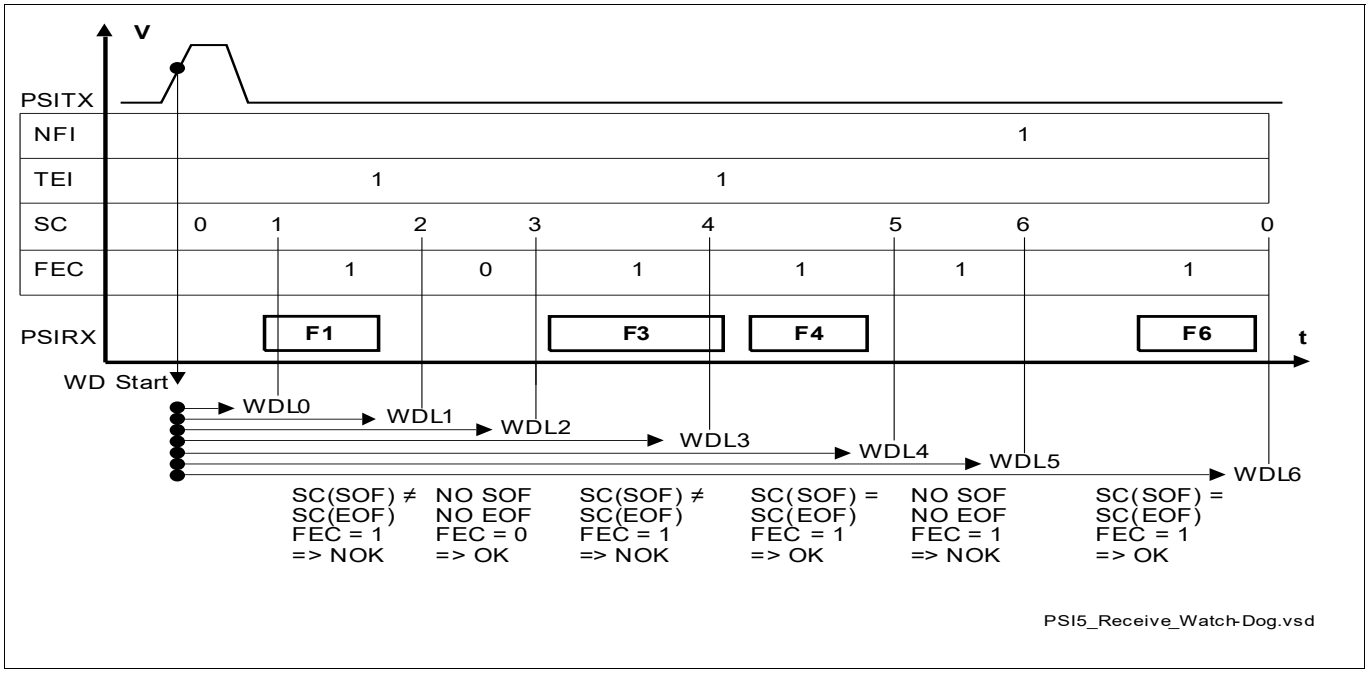

Figure 651 Watch Dog Timer Limits

42.3.11 Receive Data Memory

The module design allows for usage in 2 ways without mode selection:

Ring Buffer Usage

The Receive Data Memory x is built as a ring buffer. I.e. the first frame is stored in RDML/Hx0, the next in RDML/Hx1 and so on. At buffer 31 a wrap around is performed automatically. I.e. the next frame is stored in buffer 0. RFCx.WRP is showing the last location written and automatically incremented after write.

Receive Buffer Overrun Interrupt Flag RBI is set, if a buffer is written before the SW cleared Receive Data Interrupt Overview Flag RDIOVx (unchecked or erroneous frame received or No Frame Received (NFI) message to be stored).

FIFO Usage

Writing to the Receive Data Memory by the module moves the write pointer after writing.
Reading from RDFx 2 times with a 32 bit word access moves the read pointer to the next younger buffer automatically after the read access. It clears as well all interrupt overview bits for this buffer line in NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx. This allows for fully automatic DMA transfers without CPU intervention. The DMA simply needs to be set up in a way that it reads exactly the number of buffers configured with the FIFO warning level FWL. The application SW configures “FIFO Warning Level Request Interrupt” FWI so that it is routed to the referring DMA channel as trigger source. Note that FWI does not need to be cleared to repetitively trigger the DMA.

If RFCx.WRAP is cleared and the read pointer (after the auto increment said above) equals the write pointer while reading from RDFx, a Receive Memory Underrun Interrupt RUIx is flagged and the read pointer is not moved on automatically even if RDFx is read.

IF RFCx.FRQ is set, the FIFO needs to be flushed by RFCx.FLU.

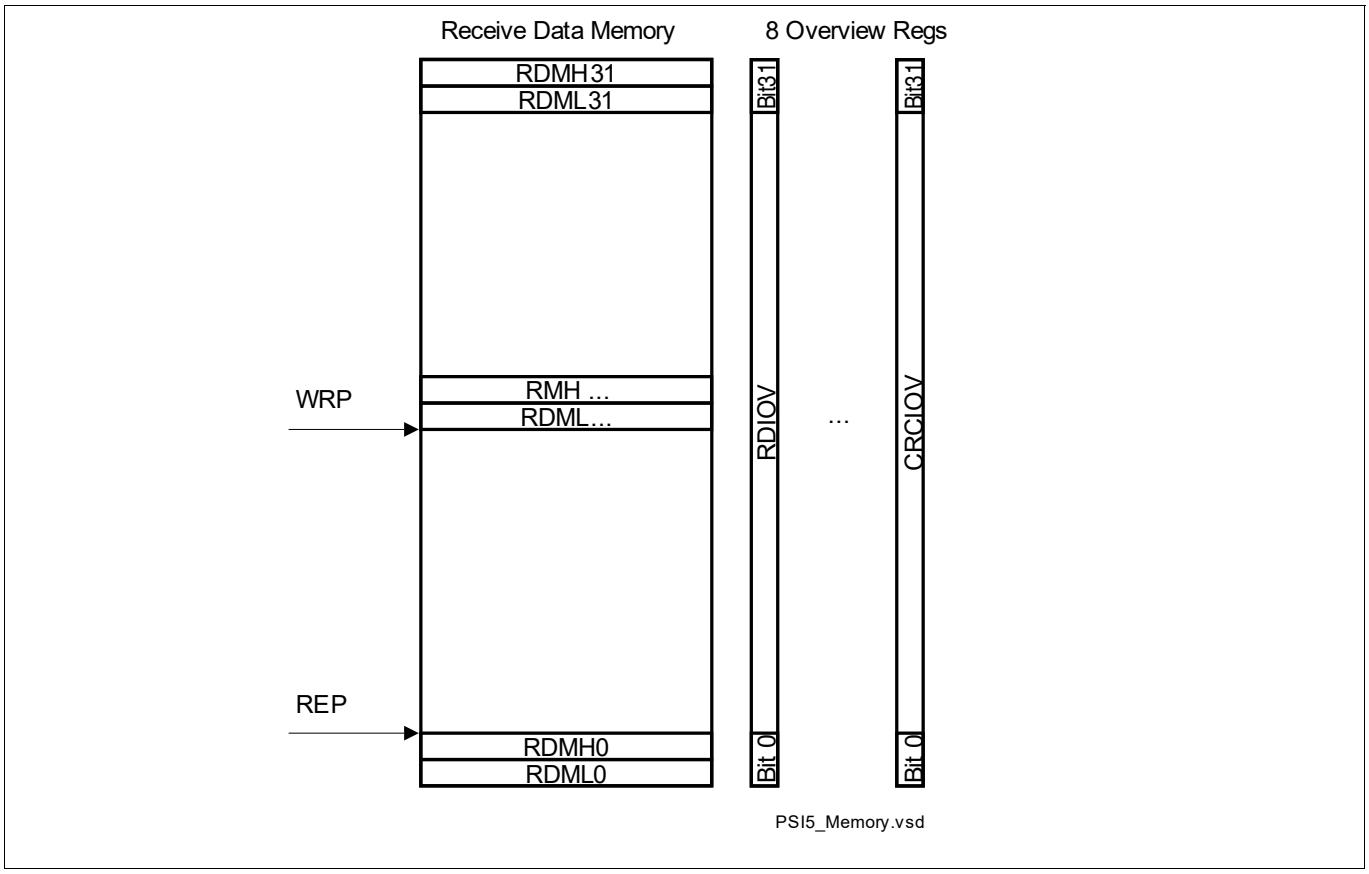

Figure 652 Receive Data Memory

42.3.12 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (PSI5 V1.3) (EPS is cleared)
- sync pulses for ECU to Sensor communication (PSI5 enhanced) (EPS is set)
- sync pulses provided by GTM (Bypass BYP set)
- Blank Out (switch off receiver during and after the Sync Pulse)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. If data is available (TOF is set) the pulses will be modulated according to the selected standard. EPS selects between extended standard with pulse length modulation and legacy mode according to PSI5 standard V1.3 with pulse dropping (“tooth gap”). The minimum pulse length is defined by PGC.PLEN for both standards. For the extended standard, the pulses are prolonged by PGC.DEL if a one is coded. Exception is the bypass path (BYP is set). These pulses are transmitted without any modulation.

Any combination of PTE, ETE and BYP can produce too long pulses!

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TOF.

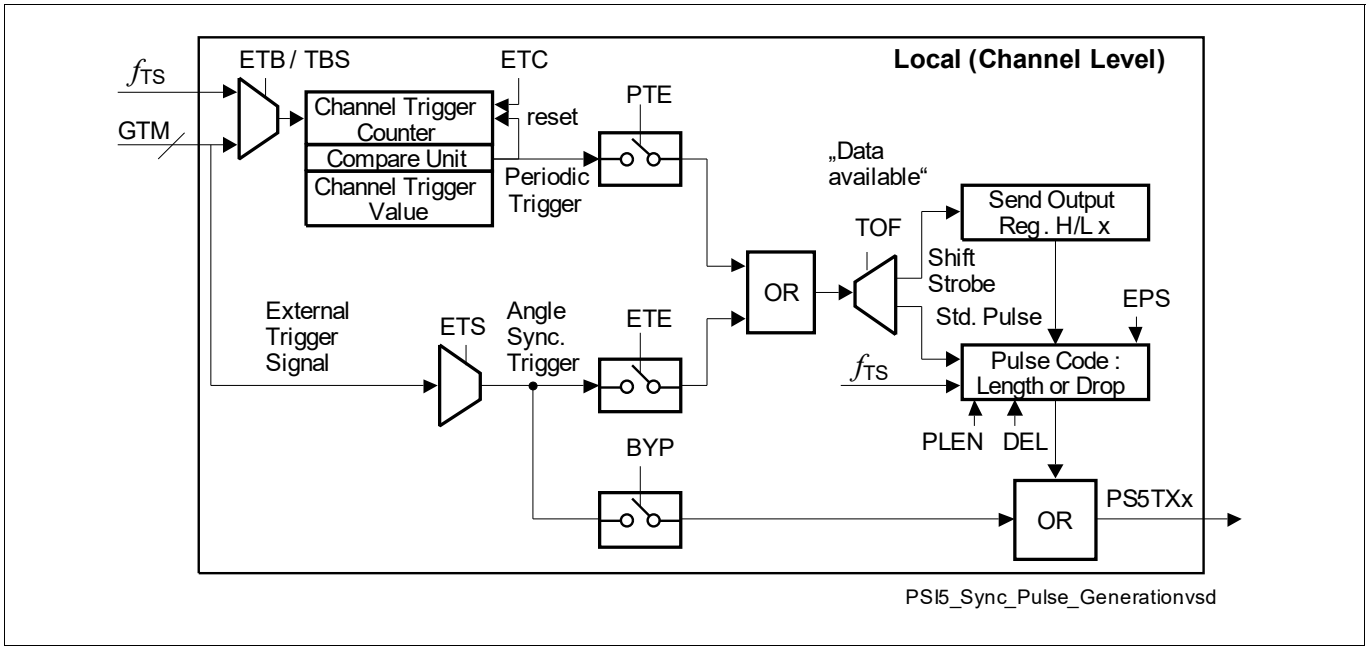

Figure 653 PSI5 Sync Pulse Generation

Blank Out Time

BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver.

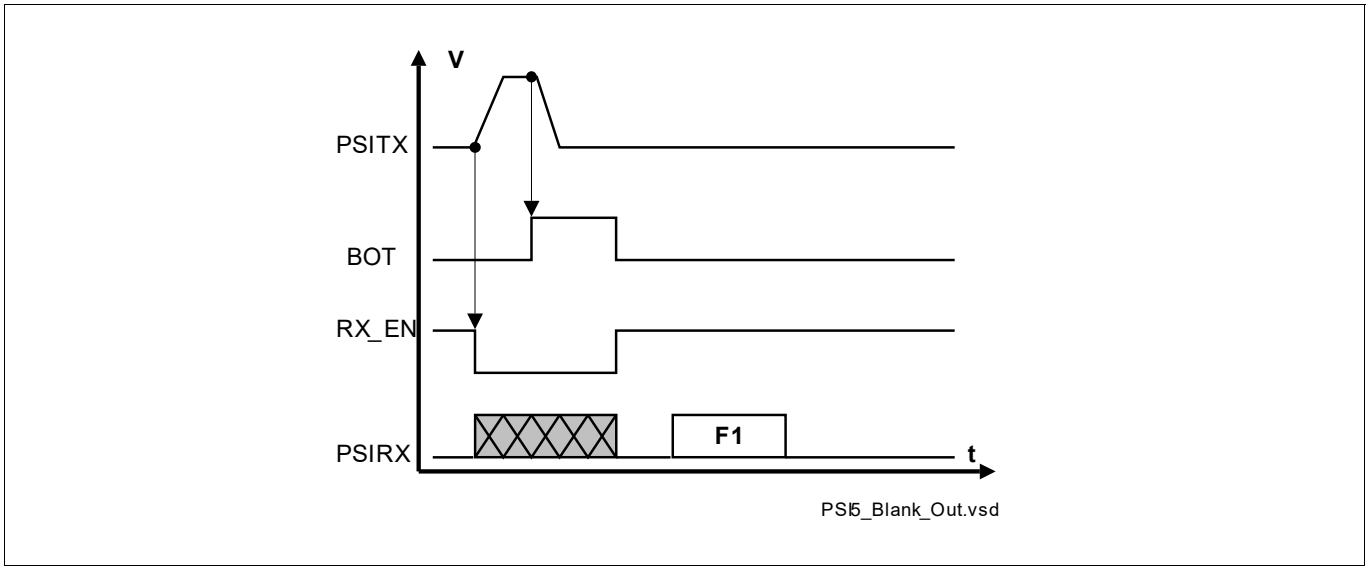

Figure 654 PSI5 Blank Out Time

42.3.13 Channel Trigger

The Channel Trigger Value Register x contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

The Channel Trigger Value CTV is the compare value which clears the counter CTC on equality and only on equality. At exactly this time, a sync pulse is triggered.

The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows

for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - “CTC preset value”

I.e. CTC preset is > CTV so that the time to to roll over is the offset.
Of course CTC preset can be < CTV so that this CTC has some advance.
Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external phys can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.
For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 .. 4 can be used.

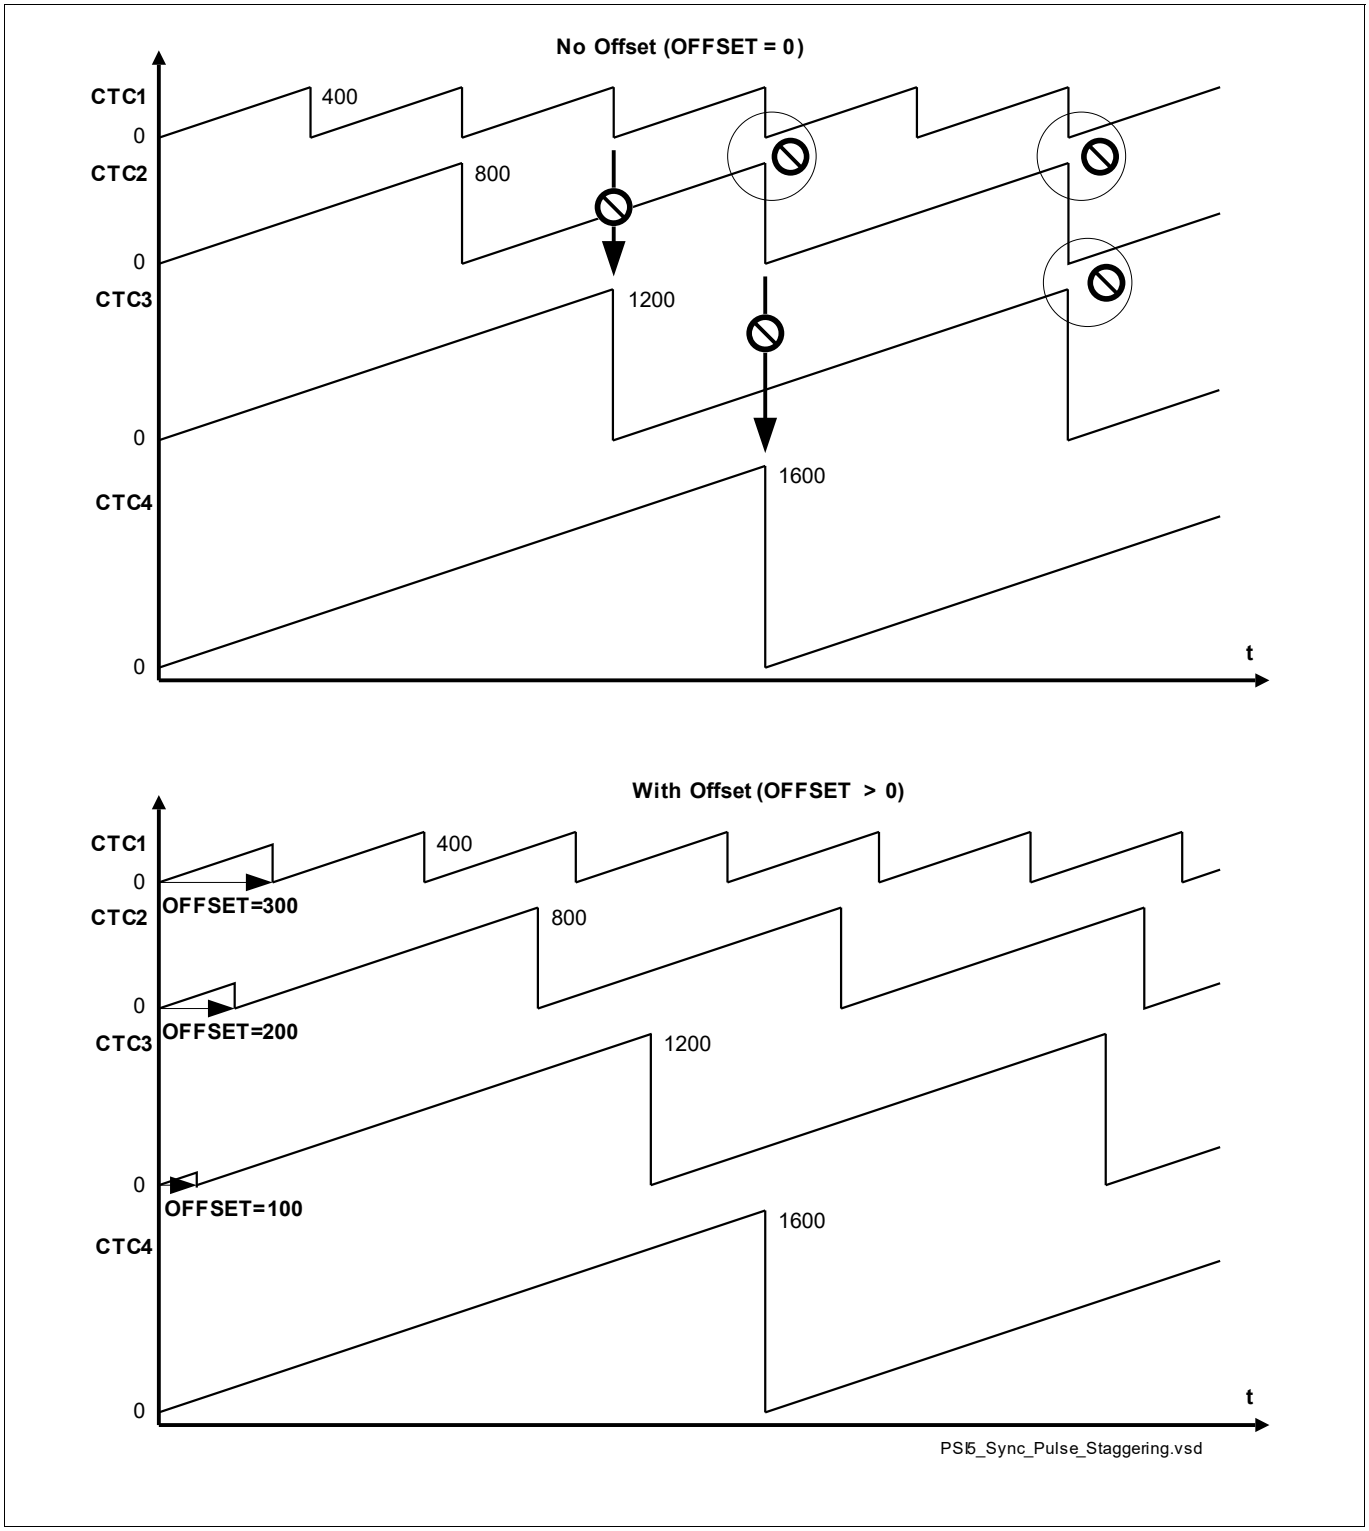

Figure 655 PSI5 Pulse Staggering

42.3.14 Send Control

The Send Control Register SCR contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

Data is collected in SDRL/Hx and the control bits are collected in SCRx.

The send control unit is build to transmit complete ECU to sensor frames.

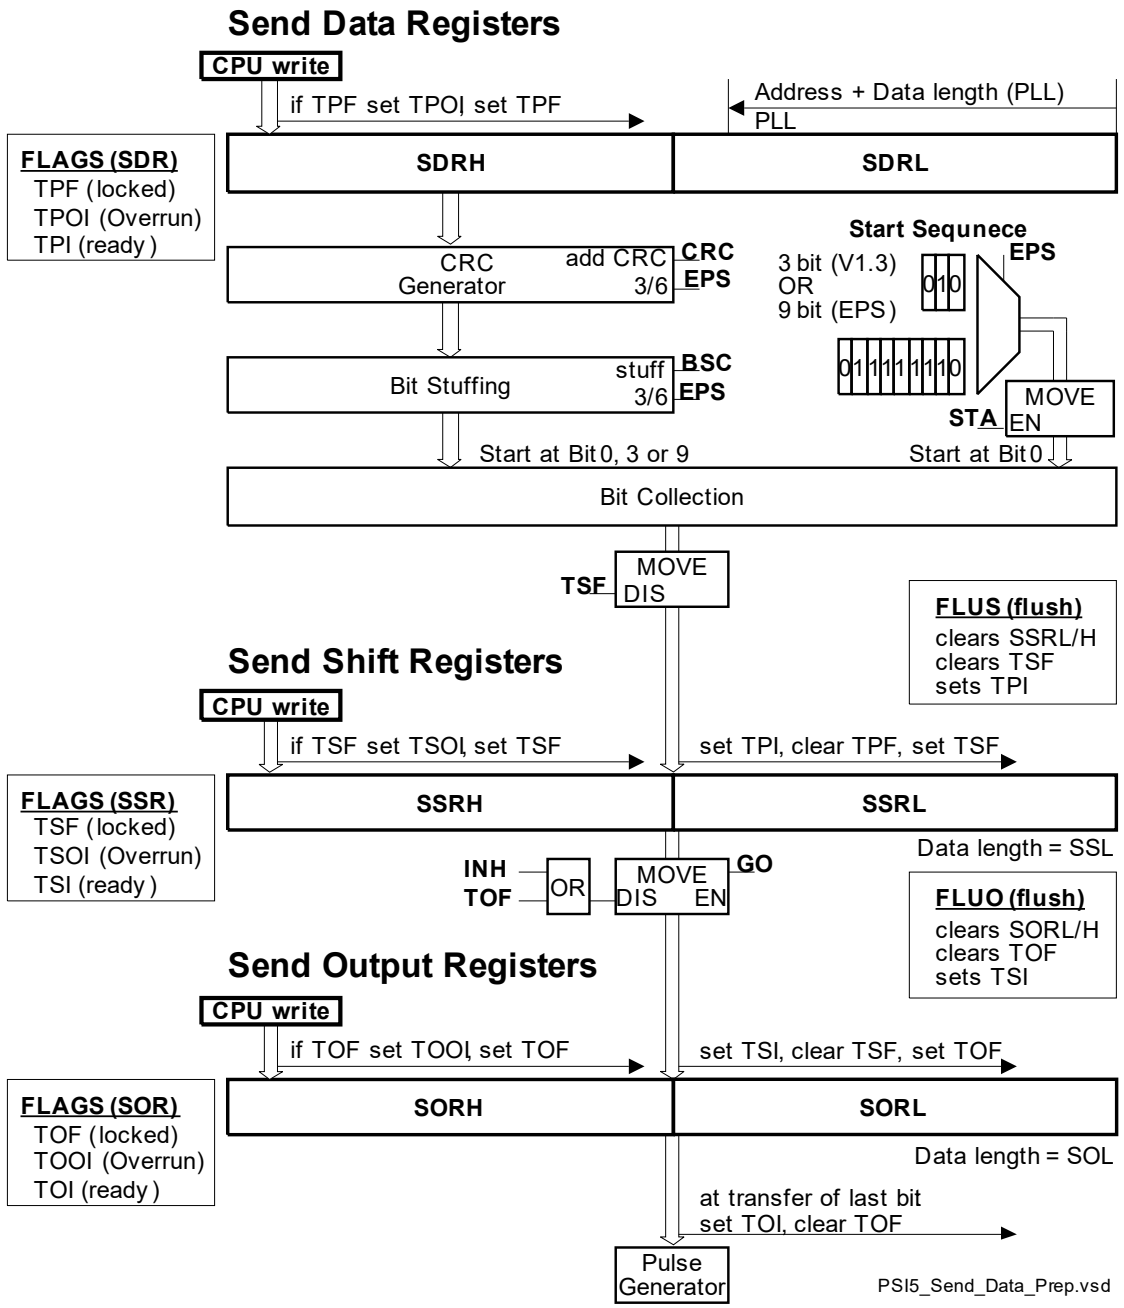

Figure 656 PSI5 Send Data Preparation

42.3.15 Error Detection Capabilities

Each PSI5 channel can detect and signal the following error conditions:

Protocol Level:

- No frame received / Manchester coding error in start bits (NFI)
- Messaging Bits with Manchester coding Error (MEI)
- Number of bits too small / Manchester coding error but messaging bits ok (NBI)
- Checksum error (CRCI)
- Frame not sent in expected time slot (TEI)
- Serial Communication: Wrong Status and Communication bit field (WSI)
- Serial Communication: CRC error (SCRI)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- Receive Data Memory Overrun (RMI)
- FIFO Warning Level (FWI)
- Receive Memory Underrun (RUI)
- ECU to Sensor Data Buffer Underrun (TBI)

42.3.16 Interrupts

8 Interrupt sources are available for the PSI5 module. For each trigger source of a channel x one interrupt can be selected in register INPx.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. This happens always if at least the start bits were received without Manchester coding error.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts NFI, MEI, NBI, CRCI, TEI, RBI, RMI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. This allows e.g. to use only the Receive data register RDRL/Hx and ignore the Receive Data Memory RDML/Hx. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.

RMI is issued if no memory buffer is available. RMI is set after a frame has been received or a No Frame Received (NFI) message is to be stored while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag INTSTATAx.RDI[RFCx.WRP] and finds this flag already set. The old data is overwritten by the new data in the buffer memory.

FWI is set if the configured warning level of the FIFOx was reached. (See RFCx)

TPI, TSI and TOI indicate a transmit interrupt. They are activated when data is moved from a SDR to SSR (TPI), from SSR to SOR (TSI) and from SOR to the pulse generator (TOI).

TPOI, TSOI and TOOI indicate a transfer (send) register overrun interrupt. They are set if data is written to one of the registers in the transmission chain while the referring register is locked (occupied). The data written is ignored in this case.

In addition the protocol error interrupts are available:

TEI, NBI, MEI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to standard V1.3. Note that the wrong data is still available in all buffers. In particular, on MEI the wrong data is still fed into the serial data analyzer (slow channel).

NFI is set, if a frame is missing in a slot configured by the watch dog timer. The module can be configured to store a complete message anyhow with flag NFI set. The slot count and the time stamp can be helpful for debugging. This provides a method for easy data handling, e.g. by using DMA transfers only without checking single interrupt bits.

WSI, SDI, SCRI treat the interrupts referring to the Status and Communication nibble.

For acceleration of the interrupt service routine, a Register INTOV is implemented that shows if an interrupt class (RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI) is active on any of the channels. It holds a flag for each class which ORs the states from all channels of each node pointer in interrupt node pointer registers INPx. This flag is automatically set if there is an interrupt pending for the node pointer which is enabled. It is automatically reset, if no more enabled interrupt is pending for interrupt class.

In addition, there are 8 overview registers per channel holding the flags NBI, CRCI, TEI, RMI, RSI, RDI, NFI, MEI for each buffer line: NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx; x = [3…0]. E.g. NBIOV0 holds 32 bits, one for each buffer line of channel 0 reflecting if NBI is set in this buffer line.

The interrupt request or the corresponding interrupt set bit (in register INTSETA/B) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATA/Bx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLRA/B.
If more than one interrupt source is connected to the same interrupt node (in register INPx), the requests are combined to one common line.

42.3.17 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router.

42.4 Registers

This section describes the kernel registers of the PSI5 module. All PSI5 kernel register names described in this section will be referenced in other parts of the document by the module name prefix “PSI5_” for the PSI5 interface.

All registers in the PSI5 address spaces are reset with the application reset with one exception: OCS is reset with debug reset only. (Definition see SCU section “Reset Operation”)

w can take the values 0 … 6 (watch dog limit values)

x can take the values 0 … 3 (PSI5 channels)

y can take the values 0 … 31

z can take the values 0 … 5

Note:

3. *All registers belong to Application Reset except OCS, which belongs to Debug Reset.*
4. *Access to reserved addresses delivers bus error (BE).*
5. *Registers RDFx, RDMLxy, RDMHxy reflect RAM content, so reset does not change the content.*

42.4.1 Detailed Register Description

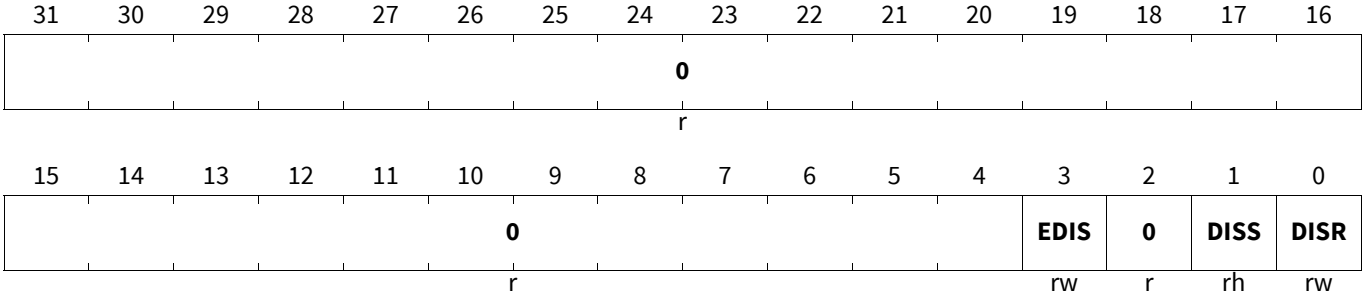
Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

Note: After a hardware reset operation, the f_{PSI5} clock is switched off and the PSI5 module is disabled (DISS set).

CLC

Clock Control Register **(000_H)** **Application Reset Value: 0000 0003_H**



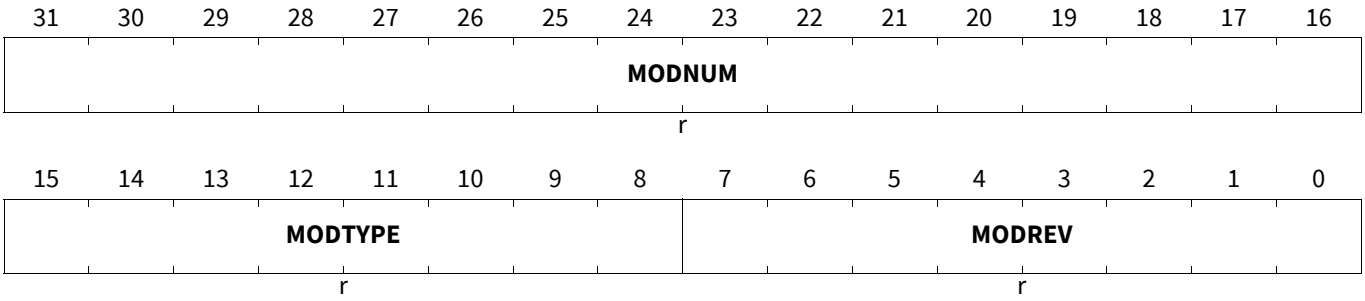
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module.
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module.
EDIS	3	rw	**External Sleep Mode Request Disable Bit** Used to control module's sleep mode. *Note: If this bit is cleared the kernel clock f_{PSI5} is disabled during System Sleep Mode.*
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

Module Identification Register

The PSI5 Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register **(008_H)** **Application Reset Value: 00C3 $C0XX_H$**



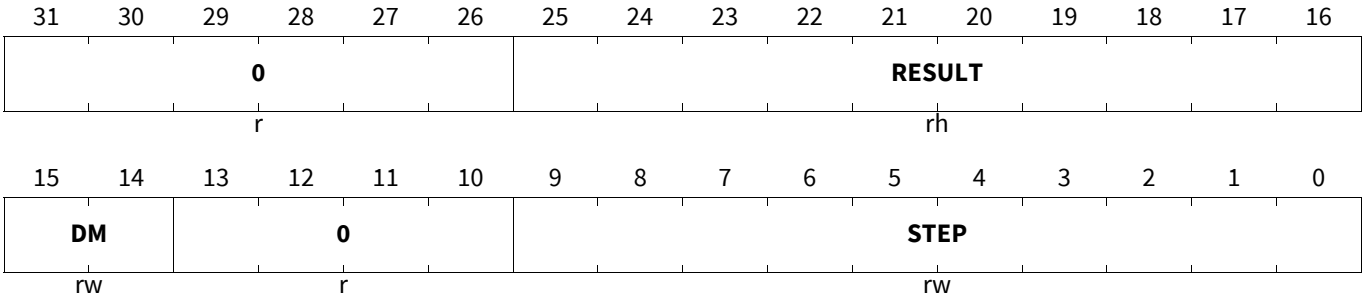
Field	Bits	Type	Description
MODREV	7:0	r	**Module Revision Number** This bit field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MODTYPE	15:8	r	**Module Type** This bit field defines the module as a 32-bit module: $C0_H$

Field	Bits	Type	Description
MODNUM	31:16	r	**Module Number Value** This bit field defines the module identification number for the PSI5: $00C3_H$

PSI5 Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$.

FDR
PSI5 Fractional Divider Register ($00C_H$) Application Reset Value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Lower Bit Rate

The Fractional Divider Register for lower Bit Rate contains the pre divider that defines the time resolution of the f_{125}. It divides $f_{fracdiv}$ by a factor as given in **Equation (42.3)** and **Equation (42.4)** and provides f_{125} to all channels.

FDRL

Fractional Divider Register for Lower Bit Rate (010$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DM		0				STEP									
rw		r				rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Higher Bit Rate

The Fractional Divider Register for Higher Bit Rate contains the pre divider that defines the time resolution of f_{189}. It divides $f_{fracdiv}$ by a factor as given in **Equation (42.5)** and **Equation (42.6)** and provides f_{189} to all channels.

FDRH

Fractional Divider Register for Higher Bit Rate (014$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DM		0				STEP									
rw		r				rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.

Field	Bits	Type	Description
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Fractional Divider Register for Time Stamp

The PSI5 Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of the Time Stamp Registers TSRA/B/C and the Sync Pulse Time Base Counter SBC. It divides f_{PSI5} by a factor as given in **Equation (42.7)** and **Equation (42.8)**. It contains as well the bits for reset control of the time stamp counters.

FDRT

Fractional Divider Register for Time Stamp (018$_H$) Application Reset Value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECEC	ECEB	ECEA	ECS			RESULT

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		0				STEP									
rw		r				rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.

Field	Bits	Type	Description
ECS	28:26	rw	**External Time Stamp Clear Source Select** Selects the external trigger line that clears the global time stamp counters TSRA/B/C.CTS if this is enabled by ECEA/ECEB/ECEC. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
ECEA	29	rw	**External Time Stamp Clear Enable A** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRA.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEB	30	rw	**External Time Stamp Clear Enable B** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRB.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
ECEC	31	rw	**External Time Stamp Clear Enable C** Enables the external trigger line selected by ECS to clear the global time stamp counter TSRC.CTS on rising edge of the external trigger. 0_B disabled 1_B enabled
0	13:10	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register A

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRA

Module Time Stamp Register A **($01C_H$)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTS															
r															

Field	Bits	Type	Description
CTS	23:0	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	29:28	r	**Reserved** Read as 0; should be written with 0.

Time Stamp Register B

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRB

Time Stamp Register B **(020_H)** **Application Reset Value: 0000 0000$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CLR	**ACLR**	**0**		**TBS**	**ETB**			**CTS**							
w	w	r		rw	rw			r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTS															
r															

Field	Bits	Type	Description
CTS	23:0	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.

Field	Bits	Type	Description
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	29:28	r	**Reserved** Read as 0; should be written with 0.

Module Time Stamp Register C

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRC

Module Time Stamp Register C **(024_H)** **Application Reset Value: $0000\ 0000_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CLR	**ACLR**	**0**		**TBS**	**ETB**			**CTS**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTS															
r															

Field	Bits	Type	Description
CTS	23:0	r	**Current Time Stamp for the Module** This bit field shows the current time stamp.

Field	Bits	Type	Description
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B reserved, no trigger selected 111_B reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM}
ACLR	30	w	**Clear All Current Time Stamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
CLR	31	w	**Clear Current Time Stamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	29:28	r	**Reserved** Read as 0; should be written with 0.

Global Control Register

The Global Control Register defines module wide settings.

The first 5 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: NFI, TEI, NBI, MEI, CRCI.

GCR
Global Control Register **(02C$_H$)** **Application Reset Value: 0000 001F$_H$**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											CEN4	CEN3	CEN2	CEN1	CEN0
r											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			ETC4	ETC3	ETC2	ETC1	ETC0	0			TEI	NFI	MEI	NBI	CRCI
r			rw	rw	rw	rw	rw	r			rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCI	0	rw	**CRCI** is selected if bit is set.
NBI	1	rw	**NBI** is selected if bit is set.
MEI	2	rw	**MEI** is selected if bit is set.

Field	Bits	Type	Description
NFI	3	rw	**NFI** is selected if bit is set.
TEI	4	rw	**TEI** is selected if bit is set.
ETCx (x=0-4)	x+8	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0 ..x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTCx counts on, starting from its current value. CTCx can be written only if ETCx is cleared (stopped). In the device only ETC0…3 are available. All other must be written with 0, and always read 0.
CENx (x=0-4)	x+16	rw	**Enable Channel** This bit enables PSI5 Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. In the device only CEN0…3 are available. All other must be written with 0, and always read 0.
0	7:5, 15:13, 31:21	r	**Reserved** Read as 0; should be written with 0.

Input and Output Control Register x

The Input and Output Control Register IOCRx determines for the PSI5 channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the transmitter

- the output signal polarity

IOCRx (x=0-3)

Input and Output Control Register x **(030_H+x*90_H)** **Application Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXM	**RXM**	**0**													
rh	rh	r													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CFEG	**CREG**	**FEG**	**REG**	**0**		**IIE**	**OIE**	**DEPTH**				**0**		**ALTI**	
w	w	rh	rh	r		rw	rw	rw				r		rw	

Field	Bits	Type	Description
ALTI	1:0	rw	**Alternate Input Select** Selects the alternate input for channel x: 00_B Alternate Input 0 selected 01_B Alternate Input 1 selected 10_B Alternate Input 2 selected 11_B Alternate Input 3 selected
DEPTH	7:4	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with *f*PSI5 that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0_H off, default 1_H 1 T_{PSI5} 2_H 2 … F_H 15
OIE	8	rw	**Output Inverter Enable Channel x** Selects the Pulse Polarity of the output of channel x 0_B Pulse polarity is not inverted 1_B Pulse polarity is inverted
IIE	9	rw	**Input Inverter Enable Channel x** Selects the Pulse Polarity of the input of channel x 0_B Pulse polarity is not inverted 1_B Pulse polarity is inverted
REG	12	rh	**Rising Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x REG is cleared by setting CREG. 0_B No Glitch detected on rising edge 1_B Glitch detected on rising edge
FEG	13	rh	**Falling Edge Glitch Flag for Channel x** Shows the status of the glitch detection of channel x FEG is cleared by setting CFEG. 0_B No Glitch detected on falling edge 1_B Glitch detected on falling edge
CREG	14	w	**Clear Rising Edge Glitch Flag for Channel x** Clears the status flag REG CREG always read zero. 0_B REG is not cleared 1_B REG is cleared
CFEG	15	w	**Clear Falling Edge Glitch Flag for Channel x** Clears the status flag FEG CFEG always read zero. 0_B FEG is not cleared 1_B FEG is cleared

Field	Bits	Type	Description
RXM	30	rh	**Receive Monitor for Channel x** Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor for Channel x** Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high.
0	3:2, 11:10, 29:16	r	**Reserved** Read as 0; should be written with 0.

Receiver Control Register A x

The Receiver Control Registers RCRA contains control bits/bit fields that are related to the PSI5 receiver operation. It configures the payload length of the up to 6 frames in the up to 6 slots.

RCRAx (x=0-3)
Receiver Control Register A x **(034_H+x*90_H)** **Application Reset Value: 0000 0000_H**
