This feature can be used to control communication in multi-processor systems, for example:

When the master processor aims to transmit a block of data to one of several slaves, it first sends out an address 'Byte' (in this case, a 'Byte' consists of nine bits) that identifies the target slave. An address 'Byte' differs from a data 'Byte' in that the additional 9th bit is a 1 for an address 'Byte' but is a 0 for a data 'Byte', so, no slave will be interrupted by a data 'Byte'. An address 'Byte' will interrupt all slaves (operating in 8-bit data + wake-up bit mode), so each slave can examine the eight LSBs of the received character (the address). The addressed slave will switch to 9-bit data mode (for example, by clearing bit CON.M[0]), which enables it to also receive the data Bytes that will be coming (having the wake-up bit cleared). The slaves that were not being addressed remain in 8-bit data + wake-up bit mode, ignoring the following data 'Bytes'.

Peripheral Sensor Interface with Serial PHY Connection

34.14.3.2 Asynchronous Transmission

Asynchronous transmission begins when the next overflow of the divide-by-16 baud rate timer (transition of the baud rate clock f_{BR}) occurs, if bit CON.R is set and data has been loaded into TBUF. The transmitted data frame consists of three elements:

1. The start bit
2. The data field (8 or 9 bits, LSB first, including a parity bit, if selected)
3. The delimiter (1 or 2 stop bits)

Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register; thus, freeing TBUF for the next transmit data to be loaded. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may then be loaded with the next transmit data while transmission of the previous one continues.

The Transmit Interrupt Request line TIR will be activated before the last bit of a frame is transmitted, that is, before the first or the second stop bit is shifted out of the transmit shift register.

Note: A dedicated GPIO device pin which is connected to the module output pin TXD must be configured by software as alternate data output for asynchronous transmission.

34.14.3.3 Asynchronous Reception

Asynchronous reception is initiated by a falling edge (1-to-0 transition) on pin RXD, on the condition that bits CON.R and CON.REN are set. The receive data input pin RXD is sampled at sixteen times the rate of the selected baud rate. A majority decision of the 7th, 8th and 9th sample determines the effective sampled bit value. This avoids erroneous results that may be caused by noise.

If the detected value is not a 0 when the start bit is sampled, the receive circuit is reset and waits for the next 1-to-0 transition at pin RXD. If the start bit proves valid, the receive circuit continues sampling and shifts the incoming data frame into the receive shift register.

When the last stop bit has been received, the contents of the receive shift register are transferred to the Receive Data Buffer Register RBUF. Simultaneously, the receive interrupt request line RIR is activated after the 9th sample in the last stop bit time-slot (as programmed), regardless whether valid stop bits have been received or not. The receive circuit then waits for the next start bit (1-to-0 transition) at the receive data input line.

Note: A dedicated GPIO pin that is connected to the module input pin RXD must be configured by software as input for asynchronous reception.

Asynchronous reception is stopped by clearing bit CON.REN. A currently received frame is completed including generation of the receive interrupt request and an error interrupt request, if appropriate. Start bits that follow this frame will not be recognized.

Peripheral Sensor Interface with Serial PHY Connection

Note: In wake-up mode, received frames are transferred to the receive buffer register only if the 9th bit (the wake-up bit) is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

34.14.3.4 RXD/TXD Data Path Selection in Asynchronous Modes

The data paths for the serial input and output data in Asynchronous Modes are affected by control bit CON.LB (loop-back) as shown in [Figure 34-29](#).

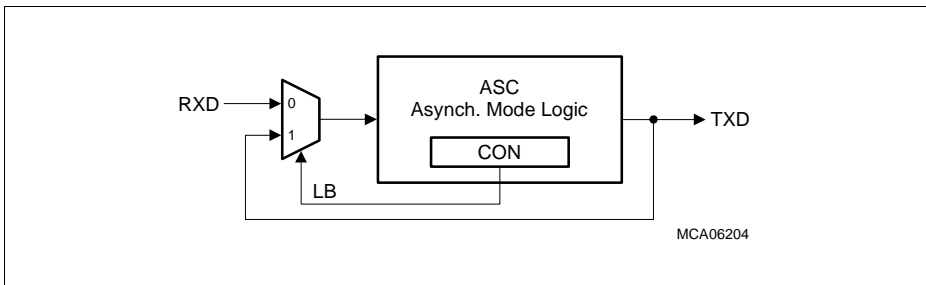

Figure 34-29 RXD/TXD Data Path Selection in Asynchronous Modes

Peripheral Sensor Interface with Serial PHY Connection

34.14.4 Synchronous Operation

Synchronous Mode supports half-duplex communication, usable for simple I/O expansion via shift registers. Data is transmitted and received via pin RXD while pin TXD outputs the shift clock. These signals are typically connected as alternate functions with GPIO port pins. Synchronous Mode is selected with CON.M = 000_B.

Eight data bits are transmitted or received synchronous to a shift clock generated by the internal baud rate generator. The shift clock is active only as long as data bits are transmitted or received.

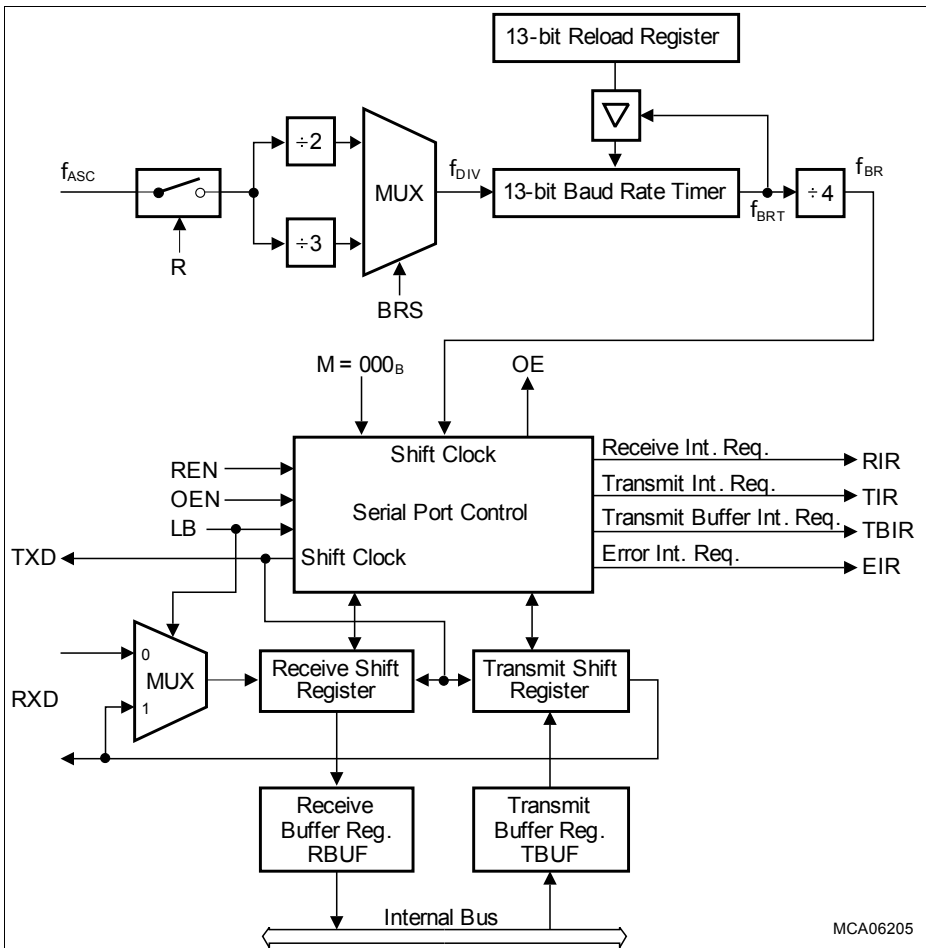

Figure 34-30 Synchronous Mode of Serial Channel ASC

Peripheral Sensor Interface with Serial PHY Connection

34.14.4.1 Synchronous Transmission

Synchronous transmission begins after data has been loaded into TBUF, provided that CON.R is set and CON.REN = 0 (half-duplex, no reception), with one exception: in asynchronous Loop-back Mode (bit CON.LB set), CON.REN must be set for reception of the transmitted Byte. In synchronous Loop-back Mode, the transmitted Byte can still be received if CON.REN=0. Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register, thus freeing TBUF for the next data to be sent. This is indicated by the transmit buffer interrupt request line TBIR being activated. TBUF may now be loaded with the next data, while transmission of the previous one continues. The data bits are transmitted synchronously with the shift clock. After the bit time for the 8th data bit, both TXD and RXD will be set to high level, the transmit interrupt request line TIR is activated, and serial data transmission stops.

Note: The dedicated GPIO device pins that are connected to TXD and RXD must be configured by software as alternate data outputs in order to provide the shift clock and the output data during synchronous transmission.

34.14.4.2 Synchronous Reception

Synchronous reception is initiated by setting bit CON.REN = 1. If bit CON.R = 1, the data applied at RXD is clocked into the receive shift register synchronously to the clock which is output at TXD. After the 8th bit has been shifted in, the contents of the receive shift register are transferred to the receive data buffer RBUF, the receive interrupt request line RIR is activated, the receiver enable bit CON.REN is reset, and serial data reception stops.

Synchronous reception is stopped by clearing bit CON.REN. Any Byte that is currently being received is completed, including the generation of the receive interrupt request and an error interrupt request, if appropriate. Writing to the transmit buffer register while a reception is in progress has no effect on reception and will not start a transmission.

If a previously received Byte has not been read out of the receive buffer register by the time the reception of the next Byte is complete, both the error interrupt request line EIR and the overrun error status flag CON.OE will be activated/set, provided that the overrun check has been enabled by bit CON.OEN.

Note: The dedicated GPIO device pin that is connected to TXD must be configured by software as alternate data output in order to provide the shift clock. The dedicated GPIO device pin that is connected to RXD must be configured by software as input during synchronous reception.

Peripheral Sensor Interface with Serial PHY Connection

34.14.4.3 Synchronous Timing

Figure 34-31 shows timing diagrams of the ASC Synchronous Mode data reception and data transmission. In idle state, the shift clock is at high level. With the beginning of a synchronous transmission of a data Byte, the data is shifted out at RXD with the falling edge of the shift clock. If a data Byte is received through RXD, data is latched with the rising edge of the shift clock.

One shift clock cycle (f_{BR}) delay is inserted between two consecutive receive or transmit data Bytes.

Figure 34-31 ASC Synchronous Mode Waveforms

Peripheral Sensor Interface with Serial PHY Connection

34.14.5 Baud Rate Generation

The ASC has its own dedicated 13-bit baud rate generator with 13-bit reload capability, allowing baud rate generation independent of other timers.

The baud rate generator is clocked with a clock (f_{DIV}) which is derived via a prescaler from the ASC module clock f_{ASC} . The baud rate timer is counting downwards and can be started or stopped through the baud rate generator run bit CON.R. Each underflow of the timer generates one clock pulse to the serial channel. The timer is reloaded with the value stored in its 13-bit reload register at each underflow. The resulting clock f_{BRT} is again divided by a factor for the baud rate clock ($\div 16$ in asynchronous operating modes and $\div 4$ in synchronous operating mode). The prescaler is selected by the bits CON.BRS and CON.FDE. In the asynchronous operating modes, a fractional divider prescaler unit is available (in addition to the two fixed dividers) that allows selection of prescaler divider ratios of $n/2048$ with $n = 0-2047$. Therefore, the baud rate of ASC is determined by the module clock, the content of register FDV, the reload value in register BG, and the operating mode (asynchronous or synchronous).

Register BG is the dual-function baud rate generator/reload register. Reading BG returns the contents of the timer in bit field BR_VALUE (bits 31:13 return zero), while writing to BG always updates the reload register (bits 31:13 are insignificant).

An auto-reload of the timer with the contents of the reload register is performed each time BG is written to. However, if CON.R = 0 at the time the write operation to BG is performed, the timer will not be reloaded until the first instruction cycle after CON.R = 1. For a clean baud rate initialization, BG should only be written if CON.R = 0. If BG is written with CON.R = 1, an unpredictable behavior of the ASC may occur during running transmit or receive operations.

Peripheral Sensor Interface with Serial PHY Connection

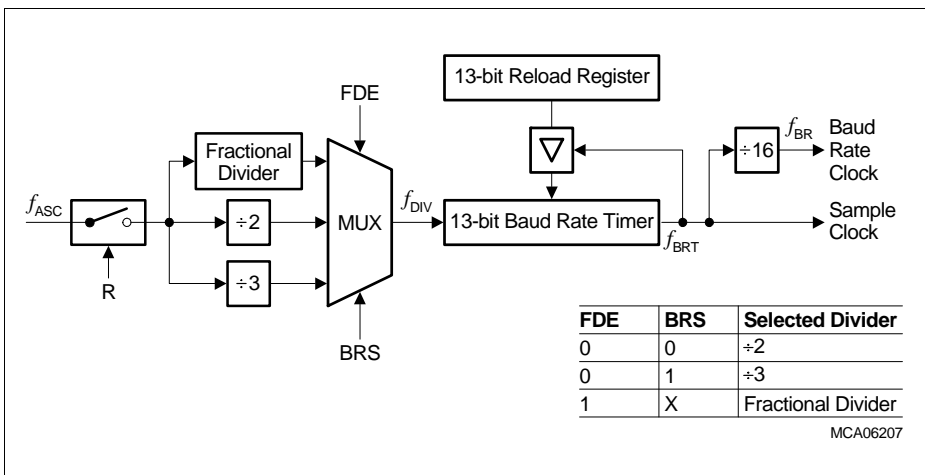

34.14.5.1 Baud Rates in Asynchronous Mode

For asynchronous operation, the baud rate generator provides a clock f_{BRT} with sixteen times the rate of the established baud rate. Every received bit is sampled on the 7th, 8th and 9th cycle of this clock. The clock divider circuitry, which generates the input clock f_{DIV} for the 13-bit baud rate timer, is extended by a fractional divider circuitry that allows the adjustment of more accurate baud rates and the extension of the baud rate range.

The baud rate of the baud rate generator depends on the settings of the following bits and register values:

- Input clock f_{ASC}
- Selection of the baud rate timer input clock f_{DIV} by bits CON.FDE and CON.BRS
- If bit CON.FDE = 1 (fractional divider): value of register FDV
- Value of the 13-bit reload register BG

The output clock of the baud rate timer with the reload register is the sample clock in the asynchronous operating modes of the ASC. For baud rate calculations, this baud rate clock f_{BR} is derived from the sample clock f_{BRT} by a division of sixteen.

Figure 34-32 ASC Baud Rate Generator Circuitry in Asynchronous Modes

Peripheral Sensor Interface with Serial PHY Connection
Using the Fixed Input Clock Divider

The baud rate for asynchronous operation of the serial channel ASC when using the fixed input clock divider ratios (CON.FDE = 0) and the required BG reload value for a given baud rate can be determined by the following formulas:

Table 34-2 Asynchronous Baud Rate Formulas using the Fixed Input Clock Dividers

FDE	BRS	BG	Formula
0	0	0 ... 8191	Baud rate = $f_{ASC} / (32 \times (BG + 1))$ BG = $f_{ASC} / (32 \times \text{Baud rate}) - 1$
	1		Baud rate = $f_{ASC} / (48 \times (BG + 1))$ BG = $f_{ASC} / (48 \times \text{Baud rate}) - 1$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved for the asynchronous operating modes when using the two fixed clock dividers and a module clock of 200 MHz is 6.25 Mbit/s.

Peripheral Sensor Interface with Serial PHY Connection
Using the Fractional Divider

When the fractional divider is selected, the input clock f_{DIV} for the baud rate timer is derived from the module clock f_{ASC} by a programmable fractional divider. If $CON.FDE = 1$, the fractional divider is activated. It divides f_{ASC} by a fraction of $n/2048$ for any value of n from 0 to 2047. If $n = 0$, the divider ratio is 1, which means that $f_{DIV} = f_{ASC}$. In general, the fractional divider allows the baud rate to be programmed with much better accuracy than with the two fixed prescaler divider stages.

Note: In fractional divider mode, the clock f_{DIV} can have a maximum period jitter of one f_{ASC} clock period.

Table 34-3 Asynchronous Baud Rate Formulas using the Fractional Input Clock Divider

FDE	BRS	BG	FDV	Formula
1	–	0 ... 8191	1 ... 2047	Baud rate = $(FDV / 2048) \times (f_{ASC} / (16 \times (BG + 1)))$
			0	Baud rate = $f_{ASC} / (16 \times (BG + 1))$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer. FDV represents the contents of the fractional divider register bit field FDV.FD_VALUE, taken as an unsigned 11-bit integer.

Peripheral Sensor Interface with Serial PHY Connection

34.14.5.2 Baud Rates in Synchronous Mode

For synchronous operation, the baud rate generator provides a clock f_{BRT} that runs with four times the established baud rate (see [Figure 34-33](#)).

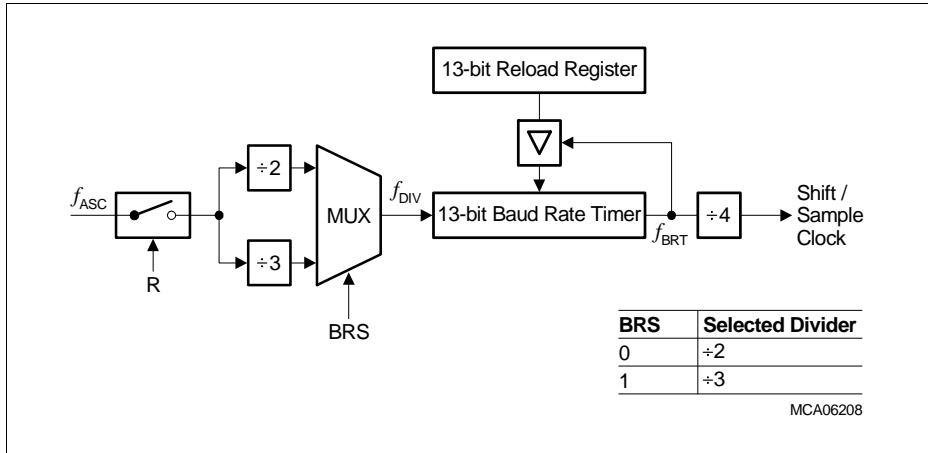

Figure 34-33 ASC Baud Rate Generator Circuitry in Synchronous Mode

The baud rate for synchronous operation of the serial channel ASC can be determined by the formulas as shown in [Table 34-4](#).

Table 34-4 Synchronous Baud Rate Formulas

BRS	BG	Formula
0	0 ... 8191	Baud rate = $f_{ASC} / (8 \times (BG + 1))$ BG = $f_{ASC} / (8 \times \text{Baud rate}) - 1$
1		Baud rate = $f_{ASC} / (12 \times (BG + 1))$ BG = $f_{ASC} / (12 \times \text{Baud rate}) - 1$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

Peripheral Sensor Interface with Serial PHY Connection

34.14.6 Hardware Error Detection Capabilities

To improve the reliability of serial data exchange, the serial channel ASC provides an error interrupt request flag that indicates the presence of an error and three (selectable) error status flags in register CON that indicate which error has been detected during reception. Upon completion of a reception, the error interrupt request line EIR will be activated simultaneously with the receive interrupt request line RIR, if one or more of the following conditions are met:

- If the framing error detection enable bit CON.FEN is set and any of the expected stop bits is not high, the framing error flag CON.FE is set, indicating that the error interrupt request is due to a framing error (asynchronous operating modes only).
- If the parity error detection enable bit CON.PEN is set in the modes where a parity bit is received and the parity check on the received data bits proves false, the parity error flag CON.PE is set, indicating that the error interrupt request is due to a parity error (asynchronous operating modes only).
- If the overrun error detection enable bit CON.OEN is set and the last character received was not read out of the receive buffer by software or DMA transfer at the time the reception of a new frame is complete, the overrun error flag CON.OE is set indicating that the error interrupt request is due to an overrun error (Asynchronous and Synchronous Modes).

34.14.7 Interrupts

Four interrupt sources are provided for serial channel ASC. Line TIR indicates a transmit interrupt, TBIR indicates a transmit buffer interrupt, RIR indicates a receive interrupt, and EIR indicates an error interrupt of the serial channel. The interrupt output lines TBIR, TIR, RIR, and EIR are synchronized to the PSI5-S kernel and routed by the INPs to the trigger output lines.

The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE.

Note: By contrast to the error interrupt request line EIR, the error status flags CON.FE/CON.PE/CON.OE are not reset automatically but must be cleared by software.

For normal operation (that is, other than error interrupt), the ASC provides three interrupt requests to control data exchange via this serial channel:

- TBIR is activated when data is moved from TBUF to the transmit shift register.
- TIR is activated before the last bit of an asynchronous frame is transmitted, or after the last bit of a synchronous frame has been transmitted.
- RIR is activated when the received frame is moved to RBUF.

While the task of the receive interrupt handler is quite clear, the transmitter is serviced by two interrupt handlers. This provides advantages for the servicing software.

Peripheral Sensor Interface with Serial PHY Connection

For single transfers, it is sufficient to use the transmitter interrupt (TIR), which indicates that the previously loaded data has been transmitted, except for the last bit of an asynchronous frame.

For multiple back-to-back transfers, it is necessary to load the following piece of data at least before the last bit of the previous frame has been transmitted. In Asynchronous Mode, this leaves just one bit-time for the handler to respond to the transmitter interrupt request; in Synchronous Mode, it is entirely impossible.

Using the Transmit Buffer Interrupt (TBIR) to reload transmit data provides the time necessary to transmit a complete frame for the service routine, as TBUF may be reloaded while the previous data is still being transmitted.

Figure 34-34 ASC Interrupt Generation

As shown in [Figure 34-34](#), TBIR is an early trigger for the reload routine, while TIR indicates the completed transmission. Software using handshake should, therefore, rely on TIR at the end of a data block to ensure that all data has been transmitted.

34.15 Interrupts

8 Interrupt sources are available for the PSI5-S module. For each trigger source of a channel x one interrupt can be selected in register INPx.

Peripheral Sensor Interface with Serial PHY Connection

RDI indicates a receive data interrupt. It is activated when a received frame is moved to Receive Data Register RDR.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts/errors XCRCI, CRCI, TEI, PE, FE, OE, RBI or HDI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host ("overwrite"), i.e. the kernel wants to set interrupt RDI and finds RDI already set.

TPI indicates a transmit interrupt. It is activated when data is completely moved from a SDR to ASC (TPI). Thus it can be used to trigger the next write access to SDR.

TPOI indicates a transfer (send) register (SDR) overrun interrupt. It is set if data is written to SDR while the referring register is locked (occupied), signalled by TPF. The data written is ignored in this case. FOI indicates that the output FIFO was overrun.

In addition the protocol error interrupts are available:

CRCI, XCRC. If CRC interrupt is activated, data is to be treated as invalid according to standard V2.0 2011-06. Note that the wrong data is still available in all buffers. For XCRCI, these frames are always stored in Channel 0 Frame 1.

TEI is issued by the watch dog timer if the timely distance between two frames is too long.

CHCI indicates that the last frame expected for a channel is received.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.

If more than one interrupt source is connected to the same interrupt node pointer (in register INPx all node pointer point to the same line), the requests are combined to one common line.

34.16 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router. See [Table 34-7 "Service Request Lines of PSI5-S" on Page 34-140](#).

Peripheral Sensor Interface with Serial PHY Connection
34.17 PSI5-S Kernel Registers

This section describes the kernel registers of the PSI5-S module. All PSI5-S kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "PSI5S_" for the PSI5-S interface.

All registers in the PSI5-S address spaces are reset with the application reset (definition see SCU section "Reset Operation").

The complete and detailed address map of the PSI5-S module is described in [Table 34-5](#) on [Page 34-58](#).

x can take the values 0 ... 7 (PSI5-S channels)

List of Access Protection Abbreviations

- U - User Mode
- SV - Supervisor Mode
- BE - Bus Error
- nBE - no Bus Error
- P - Access Protection, as defined by the ACCEN Register
- E - ENDINIT
- SE - Safety ENDINIT

Reset Classes

All registers belong to reset class 3 except OCS, which belongs to reset class 1.

 Module Base Address ([Table 34-5](#)) + Offset Address (shown in this column)

34.17.1 Module Control

Peripheral Sensor Interface with Serial PHY Connection
Module Identification Register

The PSI5-S Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register (008_H) **Reset Value: 00D3 C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the PSI5-S: 00D3 _H

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. <i>Note: This bit disables the kernel clocks f_{CLC_PSI5-S} and the ASC clock f_{BAUD2}.</i>
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	External Sleep Mode Request Disable Bit Used to control module's sleep mode. <i>Note: If this bit is cleared the kernel clock f_{CLC_PSI5-S} and the ASC clock f_{BAUD2} are disabled during System Sleep Mode.</i>
0	[31:4], 2	r	Reserved Read as 0; should be written with 0.

Note: After a hardware reset operation, the clocks f_{PSI5-S} and f_{BAUD2} are switched off and the PSI5-S module and the included ASC module are disabled (DISS set).

Fractional Divider Register

The Fractional Divider Register controls the clock f_{PS5-S} .

This bit field only controls the kernel clock f_{PSI5-S} and not the sampling clock f_{BAUD2} .

Peripheral Sensor Interface with Serial PHY Connection
FDR
PSI5-S Fractional Divider Register
(00C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
0	[13:10], [31:26]	r	Reserved Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

Peripheral Sensor Interface with Serial PHY Connection

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

Peripheral Sensor Interface with Serial PHY Connection

ACCEN1

Access Enable Register 1

(3D4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Peripheral Sensor Interface with Serial PHY Connection
KRST0
Kernel Reset Register 0
(3D8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Peripheral Sensor Interface with Serial PHY Connection
KRST1
Kernel Reset Register 1
(3DC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Peripheral Sensor Interface with Serial PHY Connection

XCRCI	1	rw	XCRCI is selected if bit is set.
TEI	2	rw	TEI is selected if bit is set.
PE	3	rw	PE is selected if bit is set.
FE	4	rw	FE is selected if bit is set.
OE	5	rw	OE is selected if bit is set.
RBI	6	rw	RBI is selected if bit is set.
HDI	7	rw	HDI is selected if bit is set.

Peripheral Sensor Interface with Serial PHY Connection

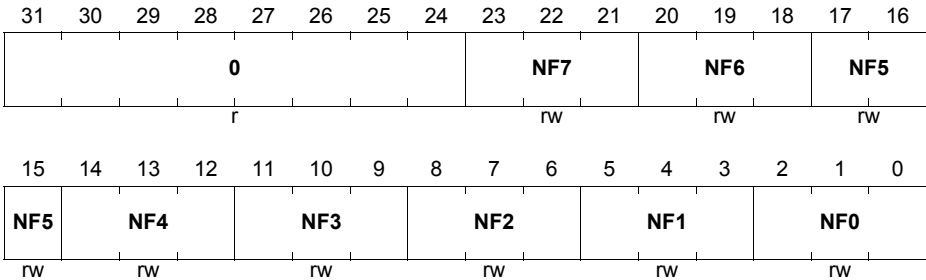

Field	Bits	Type	Description
ETC_x (x = 0-7)	8+x	rw	Enable Channel Trigger Counter CTV_x.CTC This bit enables CTV _x .CTC. The bits ETC0 ..x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTC _x counts on, starting from its current value. CTC _x can be written only if ETC _x is cleared (stopped).
CEN_x (x = 0-7)	16+x	rw	Enable Channel x This bit enables PSI5-S Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. Frames received for a disabled channel are copied to ChID 0, FID 1 with original IDs.
IDT	[27:24]	rw	Idle Time (GLOBAL VALUE FOR ALL CHANNELS) determines the number of stop bits in addition to the stop bit of the last UART Frame that is required for SOF detection. (IDT-1) idle bit times are allowed/tolerated within one Packet Frame. Default is IDT = 0, i.e. back to back transfer. 0000 _B 1 bit time idle 0001 _B 2 bit times idle 1111 _B 16 bit times idle
ASC	31	rw	ASC only Mode is selected if bit is set. The ASC registers are fully controllable by SW via SPB. If cleared, the ASC is controlled by the message reassembly unit and the message generation unit. RBUF and TBUF are no longer writable by SW and interrupts are handled by the message reassembly block automatically.
0	[30:28]	r	Reserved Read as 0; should be written with 0.

Number of Frames Control Register

Peripheral Sensor Interface with Serial PHY Connection

This register contains the number of Packet Frames expected after a Sync Pulse. It stores the compare values for the counters in register FCNT.

See **“FCNT” on Page 34-80**.

NFC
Number of Frames Control Register (020_H)
Reset Value: 0024 9249_H

Field	Bits	Type	Description
NF_x (x = 0-7)	[3*x+2: 3*x]	rw	Number of expected Frames on Channel x 000 _B reserved, do not use! Reads back 1. 001 _B 1 ... _B ... 110 _B 6 111 _B reserved, do not use! Reads back 6.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

Number of Frames Count Register

Peripheral Sensor Interface with Serial PHY Connection

This register contains the number of Packet Frames actually received after the last Sync Pulse. A Sync Pulse on channel x will clear FCx.

If FCNT.FCx equals NFC.NFx interrupt CHCI is issued and FCNT.FCx will roll over to '1' with the reception of the next recoverable message on channel x. The roll over happens in any case, even if no Sync Pulse clears FCx after CHCI.

If RCRAx.WDMS is set, NFC and FCNT affect the operation of the watch dog timer. See ["Watch Dog Timers" on Page 34-18](#).

NFC and FCNT also affect the generation of interrupt CHCI. See ["Interrupts for DMA support" on Page 34-36](#).

FCNT

Frame Counter Register (024_H) Reset Value: 0000 0000_H

r				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Field	Bits	Type	Description
CRCy (y = 0-5)	y	rw	CRC or Parity Selection If set, a 3 bit CRC checksum is expected for the PSI5-S channel x in slot y. Else, 1 bit Parity is assumed. This bit field is looked up before potential modification of FID according to FIDS. 0 _B 1 Parity Bit is configured (default) 1 _B 3 CRC bits are configured
TSEN	6	rw	Time Stamp Enable Enables the time stamping for channel x 0 _B off (default) TSCRx and thus TSM are forced to 0x0000 0000! 1 _B on, see TSP and TSTS
TSP	7	rw	Time Stamp Select For non recoverable Packets (stored in ChID '0', FID '1' with original IDs); TSCNTA is captured in TSM and not in TSCR0 (independent from TSP). 0 _B TSCNTA.CTS is captured in TSCRx 1 _B TSCNTB.CTS is captured in TSCRx

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
TSTS	8	rw	<p>Time Stamp Trigger Select</p> <p>0_B On Sync Pulse. TSCRx is updated on Sync Pulse. TSM is updated from TSCRx on Packet Frame reception after ChID extraction. For non recoverable Packets (stored in ChID '0', FID '1' with original IDs); TSCR0 is not updated and TSM is updated with the current value of TSCNTA (independent from TSP). This happens at the time the FSM assumes the Packet Frame to be non recoverable. This allows following good packets to be time stamped correctly.</p> <p>1_B On any Frame. TSCRx and TSM are updated simultaneously with the current value of TSCNTA/B depending from RCRAx.TSP on Packet Frame reception after ChID extraction. (RDI) This allows SW to read the time of reception on the referring channel from TSCRx. For non recoverable Packets (stored in ChID '0', FID '1' with original IDs), TSM is updated with the current value of TSCNTA (independent from TSP and TSEN). This happens at the time the FSM assumes the Packet Frame to be non recoverable. TSCR0 is updated only if RCRA0.TSTS is set ('1')</p>
FIDS	9	rw	<p>Frame ID Select</p> <p>0_B Frame ID is updated from Packet Frame Header (sync mode). Channel 0 should have FIDS cleared. This avoids that the module overwrites non recoverable messages with Transceiver Messages. Note that non recoverable messages are always stored in ChID '0', FID '1' with original IDs.</p> <p>1_B Frame ID is a rolling number 0 .. 5 copied from FCNT.(FCx-1) (async mode) Non recoverable messages are still stored in ChID '0', FID '1' with original IDs.</p>

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
WDMS	10	rw	Watch Dog Timer Mode Select 0 _B Watch Dog Timer is restarted on reception of each recoverable frame on Channel x (async mode). 1 _B Watch Dog Timer is restarted on Sync Pulse and stopped at reception of the last frame configured in NFC.NFx.(sync mode)
UFCy (y = 0-5)	[2*y+17 :2*y+16]	rw	UART Frame Count per Packet Frame in Slot y This bit field defines the number of UART Frames per Packet Frame that are expected for Slot y. This bit field is looked up before potential modification of FID according to FIDS. 00 _B 3 UART Frames 01 _B 4 UART Frames 10 _B 5 UART Frames 11 _B 6 UART Frames
0	[31:28], [15:11]	r	Reserved Read as 0; should be written with 0.

Receiver Control Register Bx

The Receiver Control Registers RCRBx configures the number of payload bits and implicitly the number of UART Frames (Bytes) each of the up to 6 slots in channel x. CENx must be clear for write access.

RCRBx (x = 0-7)

Receiver Control Register Bx (050_H+x*4) Reset Value: 0000 0000_H

PDL3		PDL2				PDL1				PDL0					
rw		rw				rw				rw					

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
PDL_y (y = 0-5)	[5*y+4: 5*y]	rw	Payload Data Length PDL determines the number of bits in a Packet Frame frame for Slot y. It also determines the position of the CRC/Parity bit. E.g. 8 defines 8 data bits on position [7:0]. On bit position 8 the CRC/Parity is located. See Figure 34-4 . If PDL _y is cleared ('0') no frame is expected for this slot. Packet Frames received for a slot with PDL = '0' are copied to ChID 0, FID 1 with original IDs without further processing. This bit field is looked up before potential modification of FID according to RCRAx.FIDS. 00000 _B No Frame expected! 00001 _B 8 bits 01000 _B 8 bits 01001 _B 9 bits 11100 _B 28 bits 11111 _B 28 bits
0	[31:30]	r	Reserved Read as 0; should be written with 0.

Watch Dog Timer Register
WDTx (x = 0-7)
Watch Dog Timer Register x (070_H+x*4) Reset Value: 0000 0000_H

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
WDL	[23:0]	rw	Watch Dog Timer Limit for channel x. If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed. CENx must be clear for write access.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

34.17.4 Receive Data and Status Registers

Start of Pulse Time Stamp Capture Register TSCRx

Peripheral Sensor Interface with Serial PHY Connection

If RCRAx.TSEN is set, the time stamp is captured in this register each time a sync pulse is sent from the ASC FIFO to the ASC TX buffer for channel x. RCRAx.TSP selects, if TSCNTA or B is used.

TSCRx (x = 0-7)
Capture Register TSCRx **(090_H+x*4)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TS	[23:0]	r	Time Stamp of the last sync pulse sent for channel x.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

Receive Status Registers RDS

Peripheral Sensor Interface with Serial PHY Connection

The Receive Status Register RDS shows the status of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

The bits CRCl, XCRCI, HDI, PE, FE, OE, TEI and RBI reflect, whether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTAT or CON (ASC sub module) for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTAT or CON before latest frame reception.

RDS

Receive Status Register (0B0H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
XCRCy (y = 0-5)	y	r	XCRC CRC of last Packet Frame. XCRC0 is on bit position 0.
XCRCI	6	r	XCRC Error Flag This bit is set if the CRC check on the enveloping Packet Frame fails including the case where XCRC check can not be performed (non recoverable frames) see Chapter 34.5.1.1 . 0 _B correct XCRC 1 _B wrong XCRC
CRCy (y = 0-2)	7+y	r	CRC of last frame. CRC0 / Parity is on bit position 7. If Parity is used, CRC1/2 are always 0.

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
CRCI	10	r	CRC Error Flag This bit is set if the CRC or Parity check on the transported PSI5 frame fails. 0 _B correct CRC/Parity 1 _B wrong CRC/Parity
ERR0	11	r	Error signalling Flag 0 This bit represents the status of the error signalling flag Err0 in the enveloping Packet Frame.
ERR1	12	r	Error signalling Flag 1 This bit represents the status of the error signalling flag Err1 in the enveloping Packet Frame.
HDI	13	r	Header Error Signalled Flag This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. 0 _B (Err0 OR Err1) = false (0) 1 _B (Err0 OR Err1) = true (1)
PE	14	r	ASC Parity Error Flag This bit is set if the error flag signalling a parity error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
FE	15	r	ASC Framing Error Flag This bit is set if the error flag signaling a framing error was set during reception of one of the ASC Bytes transporting this PSI5 frame.
OE	16	r	ASC Overrun Error Flag This bit is set if the error flag signaling an overrun error was set during reception of one of the ASC Bytes transporting this PSI5 frame.

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
TEI	17	r	<p>Time Error Flag</p> <p>This bit is set if the watch dog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long.</p> <p>If WDMS is in synchronous mode, all frames after TEI have TEI set in RDS until either CHCI is issued or INSTATx.TEI is cleared by SW. RDS.TEI flag is independently from INTENx.TEI.</p> <p>0_B no error 1_B error</p>
RBI	18	r	<p>Receive Buffer Overflow Flag</p> <p>This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds RDI already set. The old data is overwritten by the new data.</p> <p>0_B No overflow 1_B Overflow</p>
FID	[21:19]	r	<p>Frame ID (Frame Number)</p> <p>See bit RCRAx.FIDS for actual content.</p> <p>000_B Slot 0 001_B Slot 1 ..._B ... 101_B Slot 5 110_B not valid, frame is copied to ChID 0, FID 1 with original IDs 111_B not valid, frame is copied to ChID 0, FID 1 with original IDs</p>
CID	[24:22]	r	<p>Channel ID (Channel Number)</p> <p>000_B channel 0 001_B channel 1 ..._B ... 110_B channel 6 111_B channel 7</p>
AFC	[27:25]	r	<p>Actual UART Frame Count</p> <p>This bit field shows the number of UART frames actually received. This is used to further analyze non recoverable frames by SW or during debugging.</p>

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
PFC	[31:28]	r	<p>Packet Frame Count</p> <p>For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.</p>

Receive Data Registers RDR

Peripheral Sensor Interface with Serial PHY Connection

The Receive Data Register RDR shows the data content of a received data frame. If Messaging bits are used, they are located on bit position [1:0].

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

RDR
Receive Data Register
(0B4H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDy (y = 0-27)	y	r	PSI5 Receive Data of last frame. D0 is on bit position 0.
PFC	[31:28]	r	Packet Frame Count For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Time Stamp Mirror Register TSM

Peripheral Sensor Interface with Serial PHY Connection

Each time a new frame is received, the value from TSCRx for the referring channel is mirrored here. This register is updated, after XCRC was checked ok, as the referring channel number can not be securely determined before.

TSM
Time Stamp Mirror Register TSM (0B8_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TS	[23:0]	r	Time Stamp of the last sync pulse sent on channel x.
PFC	[31:28]	r	Packet Frame Count For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.
0	[27:24]	r	Reserved Read as 0; should be written with 0.

Target Address Registers TAR

Peripheral Sensor Interface with Serial PHY Connection

TAR contains the address that is to be copied by the first DMA into the target address register of the second DMA. This is required for the use case with 2 DMAs. See **“DMA Support” on Page 34-27**

TAR

Target Address Register (0D0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[1:0]	r	Reserved Read as 0; should be written with 0.
TA	[31:2]	r	Target Address Contains the upper 30 bit of the target address for the next DMA transfer. The 32 bit target address must be word aligned. Thus the 2 LSBs are fixed to 0. It is updated each time a new Packet Frame is received completely.

Base Address Registers BAR

Peripheral Sensor Interface with Serial PHY Connection

BAR contains the address in the system memory where the PSI5-S buffer for all channels is built up.

BAR must be configured by the application for an address space that is big enough for all channels that are enabled. TAR will wrap around after the upper limit (0xFFFF FFFF) if adding the offsets (based on ChID and FID) exceeds this limit.

BAR
Base Address Register (0D4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[1:0]	r	Reserved Read as 0; should be written with 0.
BA	[31:2]	rw	Base Address Contains the upper 30 bits of the base address for the DMA transfers. The 32 bit base address must be word aligned. Thus the 2 LSBs are fixed to 0.

34.17.5 Sync Pulse Control
Pulse Generation Control Registers PGCx

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5-S module to the sensor / external PHY.

Peripheral Sensor Interface with Serial PHY Connection
PGCx (x = 0-7)
Pulse Generation Control Register x(0F0_H+x*4)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								ETE	ETS			PTE		ETB	
r								rw	rw			rw		rw

TBS		0		ATXCMD				0			TXCMD				
rw		r		rw				r			rw				

Field	Bits	Type	Description
TXCMD	[4:0]	rw	TX Command Defines the value that is copied to the ASC FIFO for coding a '0'.
ATXCMD	[12:8]	rw	Alternate TX Command Defines the value that is copied to the ASC FIFO for the alternate pulse width i.e. for coding a '1'.
TBS	15	rw	Time Base Select This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{TRIGx} according to the setting of bit ETB.
ETB	[18:16]	rw	External Time Base Select Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 \dots_B \dots 111_B TRIG7
PTE	19	rw	Periodic Trigger Enable Periodic trigger is defined by CTVx. Should be 0 if ETE is set. 0_B disabled 1_B enabled

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
ETS	[22:20]	rw	External Trigger Select Selects the external trigger line for pulse generation (e.g. angle synchronous). 000 _B TRIG0 001 _B TRIG1 ... _B ... 111 _B TRIG7
ETE	23	rw	External Trigger Enable "Angle sync. trigger", external line is selected by ETS. Should be 0 if PTE is set. 0 _B disabled 1 _B enabled
0	[31:24], [14:13], [7:5]	r	Reserved Read as 0; should be written with 0.

Channel Trigger Value Register CTVx

CTV contains the value that determines the period of periodic triggers for each channel. It contains as well the counter that can be initialized with an offset so that the phase of harmonic trigger frequencies on different channels can be staggered.

CTVx (x = 0-7)

Channel Trigger Value Register x ($110_H + x \cdot 4$) **Reset Value: 0000 0000_H**

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
CTV	[15:0]	rw	Channel Trigger Value CTV Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse triggered.
CTC	[31:16]	rw	Channel Trigger Counter This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Send Control Registers SCR_x

The Send Control Register SCR_x contains control data bits required for sending data from the PSI5-S module to the sensor / external PHY.

Data is collected in SDR_x and the control bits are collected in SCR_x.

The send control unit is build to transmit complete ECU to sensor frames.

SCR_x (x = 0-7)
Send Control Register x (130_H+x*4) Reset Value: 0000 0000_H

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
PLL	[4:0]	rw	Pay Load Length of Registers SDRx Defines the length that is taken into account: 00000 _B length is 6 00001 _B length is 6 00110 _B length is 6 11000 _B length is 24 11111 _B length is 24 PLL needs to be written before SDRx is used for proper operation.
EPS	[7:6]	rw	Enhanced Protocol Selection EPS[0] controls the Bit Format and MSB Fill bit. (0: Tooth Gap, MSB Fill 1) (1: PWM, MSB Fill 0) EPS[1] controls the Frame Format (0: Frame Format 1 - 3) (1: Frame Format 4) 00 _B Tooth Gap Method, '1' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 01 _B Pulse Width Method, '0' for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, '1' for stuffing, 3 bit CRC). 10 _B reserved, do not use! 11 _B Pulse Width Method, '0' for filling the shift register from MSB; Frame Format 4 (9 bit start sequence, 6 bit stuffing distance, '0' for stuffing, 6 bit CRC).
BSC	8	rw	Bit Stuffing Control 0 _B No automatic bit stuffing 1 _B Automatic bit stuffing is enabled. Depending from bit EPS[1] after 3 bits a '1' is inserted (Frame Format 1 -3) or after 6 bits a '0' is inserted (Frame Format 4)

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
FLUS	14	w	Flush SDRx Setting this bit stops shifting out the data in SDRx, the start sequence or CRC if any and clears the referring FSMs and counters, if EPS[0]=0 SDRx is flushed by setting all bits if EPS[0]=1 SDRx is flushed by clearing all bits clears TPF TPIx is issued at the end of successful flushing. Reads always as zero.
CRC	22	rw	CRC Generation Control 0 _B CRC is not generated automatically, it still can be written by SW together with the data (e.g. to test the remote CRC) 1 _B CRC is automatically generated by HW (according to EPS[1])
STA	23	rw	Start Sequence Generation Control 0 _B no start sequence generated, shifting out payload starts at bit 0! 1 _B automatically generated by HW (according to EPS[1]) shifting out payload starts after 3/9 bits (EPS[1] = 0/1)
TPF	26	r	Transmit in Progress Flag If set, data preparation and transmission is in progress: start sequence or CRC or stuffing bits or data from SDRx are being transferred. It is cleared automatically after preparation and transmitting is finished. If set, write access to SDRx will not change any data and issue TPOI.
0	[31:27],[25:24],[21:15],[13:9],5	r	Reserved Read as 0; should be written with 0.

Send Data Registers SDRx

Peripheral Sensor Interface with Serial PHY Connection

The Send Data Register SDR_x shows the data content of a data frame to be sent. CEN_x must be set for write access. For initialization SCR_x.FLUS can be used.

SDR_x (x = 0-7)

Send Data Register x (150_H+x*4) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SD2 3	SD2 2	SD2 1	SD2 0	SD1 9	SD1 8	SD1 7	SD1 6
r								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SD_y (y = 0-23)	y	rw	SD_y Send data of next ECU to Sensor frame. Each time a bit is shifted out, the whole content is shifted right by 1 position and the MSB is filled with '1' or '0' depending from EPS[0]. This allows to read back SDR and determine the status of the shift process by SW. The unused MSBs (bit position SCR _x .PLL and higher) must be written with '0' if EPS[0] is set (PWM Method) and with '1' if EPS[0] is cleared (Tooth Gap Method). This is required, as the respective standard value is shifted into the register from MSB during shift out operation. SDR _x will be filled with this value after shift out process.
0	[31:24]	r	Reserved Read as 0.

CPU Direct Write Registers CDW

Peripheral Sensor Interface with Serial PHY Connection

The CPU Direct Write Register CDW allows the CPU to insert a command into the ASC FIFO. Note that Bits SD[7:5] select the channel for which the time stamp is captured. These bits are copied to the UART Frame Bit positions [2:0] (ChID) while SD[4:0] are copied to UART Frame Bit positions [7:3] (Command). See [Figure 34-6](#).

CDW
CPU Direct Write Register (170_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SDy (y = 0-7)	y	rw	SDy Send data of next ECU to Sensor frame.
TSI	8	rw	Trigger Pulse Indicator If this bit is set, a sync pulse is assumed and thus a time stamp is captured when the command leaves the FIFO and is written to ASC TX Register. Bits SD[7:5] select the channel for which the time stamp is captured. RCRAx.TSTS must be cleared. If set, the time stamp is captured on Packet Frame reception only.
0	[31:9]	r	Reserved Read as 0.

34.17.6 ASC Registers

Peripheral Sensor Interface with Serial PHY Connection

The serial operating modes of the ASC module are controlled by its Control Register CON. This register contains control bits for mode and error check selection, and status flags for error identification.

CON
Control Register
(210_H)
Reset Value: 0000 0000_H

SETOE	13	w	Set Overrun Error Flag 0 _B No effect 1 _B Bit CON.OE is set. Bit is always read as 0.
0	[3:0], [7:6], [31:14]	r	Reserved Read as 0; should be written with 0.

Note: When the set and clear bits for an error flag are set at the same time during a WHBCON write operation (e.g SETPE = CLRPE = 1), the error flag in CON is not affected.

Peripheral Sensor Interface with Serial PHY Connection

The Baud Rate Timer Reload Register BG of the ASC module contains the 13-bit reload value for the baud rate timer in Asynchronous and Synchronous Modes.

BG

Baud Rate Timer/Reload Register (214_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
BR_VALUE	[12:0]	rwh	Baud Rate Timer/Reload Register Value Reading BR_VALUE returns the 13-bit content of the baud rate timer. Writing BR_VALUE loads the baud rate timer reload register. BG should only be written if CON.R = 0.
0	[31:13]	r	Reserved Read as 0; should be written with 0.

The Fractional Divider Register FDV of the ASC module contains the 11-bit divider value for the fractional divider (asynchronous mode only).

FDV

Fractional Divider Register (218_H) **Reset Value: 0000 0000_H**

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
FD_VALUE	[10:0]	rw	Fractional Divider Register Value FD_VALUE contains the 11-bit value n of the fractional divider which determines the fractional divider ratio $n/2048$ ($n = 0-2047$). With $n = 0$, the fractional divider is switched off (divider ratio = 1).
0	[31:1 1]	r	Reserved Read as 0; should be written with 0.

The Fractional Divider Register FDO contains the 11-bit divider value for the fractional divider that is generating f_{PSISCLK} from f_{BAUD2} . PSISCLK is a clock that can be used on a pin to drive the external PHY.

FDO
Fractional Divider for Output CLK Register (21C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
STEP	[10:0]	rw	Step Value Reload or addition value for internal accumulator.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. (default after System Reset). 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated.

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
0	[31:16], [13:11]	r	Reserved Read as 0; should be written with 0.

The Transmit Buffer Register TBUF of the ASC module contains the transmit data value in Asynchronous And Synchronous Modes. If GCR.ASC is cleared, TBUF is no longer writable by SW and interrupts are handled by the message reassembly block automatically.

TBUF
Transmit Buffer Register (220_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TD_VALUE	[8:0]	rw	Transmit Data Register Value TBUF contains the data to be transmitted in the asynchronous and synchronous operating modes of the ASC. Data transmission is double-buffered; therefore, a new value can be written to TBUF before the transmission of the previous value is complete.
0	[31:9]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface with Serial PHY Connection

The receive buffer register RBUF of the ASC module contains the receive data value in Asynchronous and Synchronous Modes.

RBUF
Receive Buffer Register
(224_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD_VALUE	[8:0]	rh	Receive Data Register Value RBUF contains the received data bits and, depending on the selected mode, the parity bit in the asynchronous and synchronous operating modes of the ASC. In Asynchronous Mode, with CON.M = 011 _B (7-bit data + parity), the received parity bit is written into RBUF.7. In Asynchronous Mode, with CON.M = 111 _B (8-bit data + parity), the received parity bit is written into RBUF.8.
0	[31:9]	r	Reserved Read as 0.

Peripheral Sensor Interface with Serial PHY Connection

0	[31:27]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface with Serial PHY Connection
Interrupt Status Registers Global

The Interrupt Status Registers INTSTATG contains status bits that show the status of any global interrupt, i.e. of the ASC inside PSI5-S and XCRCI indicating a non recoverable message is received. On XCRCI, the non recoverable message is stored in ChID '0', FID '1' with original IDs. INTSTATG contains as well FOI indicating a FIFO overrun condition. In a correct setup, this will never be set as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays.

The bits are set independently from the referring Interrupt Enable in Register INTENG. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATG
Interrupt Status Register G (304_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TIR	0	rh	Transmit Interrupt Request Flag 0 _B No interrupt was requested since this bit was cleared the last time 1 _B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRG.TIR. This bit can be set by bit INTSETG.TIR. This bit is set independently from INTENG.
RIR	1	rh	Receive Interrupt Request Flag 0 _B No interrupt was requested since this bit was cleared the last time 1 _B An interrupt was requested since this bit was cleared the last time This bit can be cleared by bit INTCLRG.RIR. This bit can be set by bit INTSETG.RIR. This bit is set independently from INTENG.

Peripheral Sensor Interface with Serial PHY Connection

Field	Bits	Type	Description
EIR	2	rh	<p>Error Interrupt Request Flag</p> <p>The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE,</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRG.EIR. 34.18 PSI5-S Module Implementation

This section describes the PSI5-S module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

34.18.1 Interface Connections of the PSI5-S Module

Figure 34-35 shows the TC26x B-Step-specific implementation details and interconnections of the PSI5-S module.

The PSI5-S module is supplied with a separate clock control, address decoding, and interrupt control logic. The 8 modules' service request outputs are connected with the interrupt router. 6 outputs of the GTM module are connected to the timer inputs.

The serial data inputs PSISRxn of the receive channels of the PSI5-S module as well as the sender output PSISTX are connected to GPIO lines. If the output is used, it is mapped to a different port pin than the referring PSI5-S data input line.

Figure 34-35 PSI5-S Module Implementation and Interconnections

Peripheral Sensor Interface with Serial PHY Connection
34.18.1.1 On-Chip Connections

This section describes the on-chip connections of the PSI5-S module.

Interrupt Router Service Requests

The module has 8 Request Trigger outputs connecting it to the interrupt router (IR). The request lines are connected to the IR controller as shown in [Table 34-7](#). Interrupt node pointers (INPx) select the line for each trigger source. Multiple nodes may point to the same line. In this case the triggers are combined with a simple OR logic.

Table 34-7 Service Request Lines of PSI5-S

INP value	Request Line	Connected to	Description
000b	TRIGO0	PSI5S_SRC0	PSI5-S Service Request Node 0
001b	TRIGO1	PSI5S_SRC1	PSI5-S Service Request Node 1
010b	TRIGO2	PSI5S_SRC2	PSI5-S Service Request Node 2
011b	TRIGO3	PSI5S_SRC3	PSI5-S Service Request Node 3
100b	TRIGO4	PSI5S_SRC4	PSI5-S Service Request Node 4
101b	TRIGO5	PSI5S_SRC5	PSI5-S Service Request Node 5
110b	TRIGO6	PSI5S_SRC6	PSI5-S Service Request Node 6
111b	TRIGO7	PSI5S_SRC7	PSI5-S Service Request Node 7

Trigger Inputs

The module has 8 PSI5-S Channels and 6 trigger inputs which can be randomly chosen by programming PGCx.ETS/ETB, FDRT.ECS and TSCNTA/B.ETB. The trigger inputs (TRIG[7:0]) of the PSI5-S module are connected to the GTM as shown in [Table 34-8](#).

Table 34-8 Trigger Input Lines of PSI5-S

Request Line	Connected to	Description
TRIG0	gtm.psi5_0_trig_0_o	GTM Trigger Line TRIG0
TRIG1	gtm.psi5_1_trig_0_o	GTM Trigger Line TRIG1
TRIG2	gtm.psi5_2_trig_0_o	GTM Trigger Line TRIG2
TRIG3	GND	not connected to GTM
TRIG4	gtm.psi5_4_trig_0_o	GTM Trigger Line TRIG4
TRIG5	gtm.psi5_5_trig_0_o	GTM Trigger Line TRIG5
TRIG6	gtm.psi5_6_trig_0_o	GTM Trigger Line TRIG6
TRIG7	GND	not connected to GTM

Peripheral Sensor Interface with Serial PHY Connection

34.18.2 PSI5-S Module-Related External Registers

The registers listed in [Figure 34-36](#) are not included in the PSI5-S module kernel but must be programmed for proper operation of the PSI5-S module.

Figure 34-36 PSI5-S Implementation-specific Special Function Registers

34.18.2.1 Port Control

The Port Control Registers contain:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

[Table 34-9](#) shows an overview how bits and bit fields must be programmed for the required I/O functionality of the PSI5-S I/O lines.

The PSI5-S interface input shares its input pins with digital ports.

For one PSI5-S module the output and input pins are next to each other. Not connected inputs are tied internally on chip.

The Module can be used as ASC only. PSI5-S message reassembly unit, message generation and pulse generation are not available in this mode.

If in this use case the module is switched to SSC mode, the port wiring is switched automatically in the following way:

- RXD line remains receive data input,
- CLK provides the synchronous transmit clock coming from the internal TXD signal and
- TXD provides the output data coming from the internal RXD signal.

This way the wiring is compatible with the wiring of other UART modules of the product family. See [Figure 34-37](#).

Version Number	Changes to Previous Version
Rev_1.0	<p>Frame Buffer in System Memory: Removed double buffer concept and replaced it by memory mapped concept.</p> <p>Removed registers for SW swapping and data consistency (ABAR, SWAP, BSRA, BSRB)</p> <p>Removed BFI</p> <p>Added CHCI</p> <p>Changed NFC.NFx definitions and added RCRAx.WDMS controlling the Watch Dog Timer behavior.</p> <p>Swapped addresses of RDS and TSM. Having the TS written at the end of a DMA transfer allows a simple check: all data in a buffer is consistent if the TS are strictly monotonic increasing from FID1 .. FID6 - within senseful boundaries. This does not work for extreme use cases.</p> <p>Added CLC.RMC and CLC.EDIS</p> <p>Removed automatic clear of TPI by writing SDRx.</p> <p>Moved XCRC to INTSTATG as it is not available for each channel but for Ch 0 only.</p> <p>Reduced INP bit field to 3 bit</p> <p>Added INTSTATx.HDI and INPx.HDI</p> <p>Removed RCRAx.EN (local channel enable), function is in GCR</p> <p>Added RCRAx.TSEN (Time Stamp enable)</p> <p>Removed TSCNTA/B.ACLR, CLR, TBE</p> <p>Added TSCNTA. CLRA, CLRB, TBEA, TBEB for simultaneous start/stop and clear of both timers.</p> <p>Removed bit SCR.TRQ, redundant with TPF.</p>
Rev_1.1	<p>Updated OCS description.</p> <p>Changed FID from 1 .. 6 to 0 .. 5; non recoverable frames ChID 0, FID 1, transceiver messages ChID 0, FID 0, rolling number FID for asynchronous frames is 0 .. 5</p> <p>Change to TSP: for non recoverable messages, TSP is not relevant but TSCNTA is used always.</p> <p>Changed RDS.CRC to reverse order</p> <p>Changed RDS.HDI bit position to 13, ERR0/1 moved to 11/12</p> <p>Added PFC to RDR, RDS, TSM</p> <p>Detailed definition of XCRC</p> <p>In Tooth Gap Method all commands are transferred to the UART even if it is a command for '0' i.e. for "no pulse"</p> <p>Replaced CLC.RMC by new register FDR.</p> <p>FIFO overrun condition is signalled by INSTATG.FOI</p>

Peripheral Sensor Interface with Serial PHY Connection

Table 34-10 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.2	Added INTOV.FOI corrected typos
Rev_1.3	Added paragraph on wrap around of BAR to register description of BAR. RBI depends on RDI only (no dependency on RSI any more) due to conflicts with GCR.RBI (loop back timing loop) R/TBUF are readable while GCR.ASC is cleared Added clarification: RDS.TEI is set for all frames till CHCI
Rev_1.4	Typo corrected in description of BAR.
Rev_1.5	Added FDO providing PSISCLK, clock out for PHY. Updated Pinning Table
Rev_1.6	Removed FDO.RESULT Removed GTC.ETC typo. Clarified that non recoverable messages are always stored in ChID '0', FID '1' but with original IDs as received. Updated pinning Added clarification to RDS.FID: Frames with FID [6:7] are copied to ChID 0, FID 1 with original IDs Added hint: CON.M and CON.MTX need to be cleared both for sync mode Added mux on port wiring for "ASC only in SSC mode" use case
Rev_1.7	Typo corrections Clarification added in NFC.FCx: FC is cleared with Sync Pulse only in Sync Mode (WDMS is set) Clarification added in RDS.TEI: when TEI is cleared in INTSTATx, it is no longer shown in RDS. Added hint to CDW clarifying the relation between layout of CDW and actual frame (updated Figure 34-6 accordingly) Changed chapter “Packet Frames” received from PHY on Page 34-6 to allow reception of good frames w/o correct idle at the end
Rev_1.8	Correction of feature list entry on asynchronous channels Added RDS.AFC for debugging. Corrected CLC.EDIS description. Added section "Non Recoverable Frame Presentation in RDR and RDS" Moved PSISCLK from P02.2 O2 to P02.4 O4
Rev_1.9	Changed number of GTM inputs depending on product implementation
Rev_1.10	Updated details on DMA programming

35 Ethernet MAC (ETH)

This chapter describes the Ethernet MAC ^{1) 2)} of the TC26x B-Step.

35.1 Overview

Figure 35-1 shows the basic structure of the module:

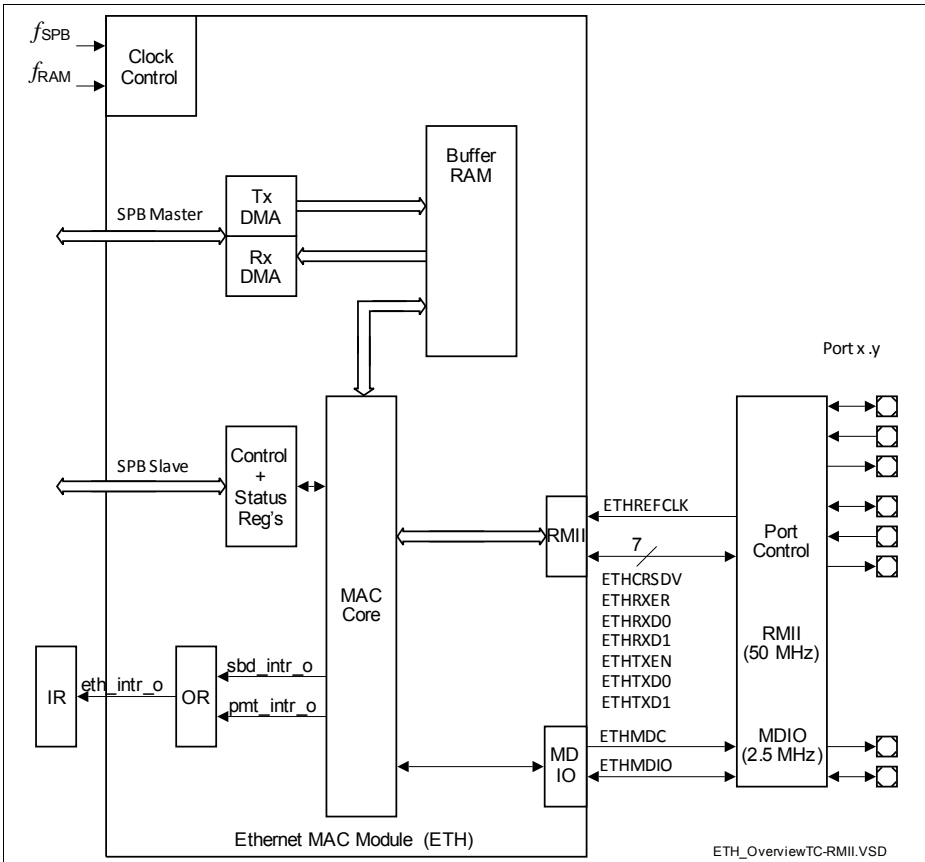

Figure 35-1 Ethernet MAC Module Overview

- 1) Excerpted portions are Synopsys Proprietary. Used with permission.
- 2) Module is not available in some variants. In these variants registers are still accessible but functionality cannot be guaranteed.

35.1.1 General Module Description

The DWC Ether MAC 10/100/1000 Universal, V3.7a, commonly referred to as GMAC-UNIV in this document, enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard. In TC26x B-Step it is configured to support 10 and 100 Mbit modes. Note that Gigabit mode is not configured, nevertheless the core is referred to as GMAC to avoid confusion with other cores.

The GMAC-UNIV provides an optimized (with respect to gate count and latency), configurable, flexible product to meet the needs of various applications and customers, and supports a industry standard interface to the PHY: Reduced Media Independent Interface (RMII). The GMAC-AHB is designed to interface to the industry standard AMBA High-Performance Bus (AHB) on the application side. In TC26x B-Step an adaptation logic interfaces to the SPB bus.

The GMAC-UNIV is compliant to the following standards:

- IEEE 802.3-2002 for Ethernet MAC
- IEEE 1588-2008 standard for precision networked clock synchronization
- RMII specification from RMII consortium

Note: Although the naming convention used in this databook and the source code indicate "GMAC," the databook is also applicable to the 10/100 Universal product.

35.1.2 System Overview

35.1.2.1 System-Level Block Diagram

A system-level block diagram is shown in **Figure 35-2**.

Figure 35-2 GMAC-UNIV Block Diagram

35.1.2.2 Interfaces

The GMAC-AHB transfers data to system memory through the AHB master interface. The host CPU uses the default 32-bit AHB Slave interface to access the GMAC subsystem’s Control and Status registers (CSRs).

The GMAC-UNIV supports the following PHY interface:

- Reduced MII (RMII)

35.1.2.3 Transmit and Receive FIFOs

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the GMAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by

Ethernet MAC (ETH)

the DMA. These are asynchronous FIFOs, as they also transfer the data between the application clock and the GMAC line clocks.

Tx/Rx FIFOs are 32 bits wide and 4/4 kByte deep.

35.1.3 Features List

The GMAC-UNIV includes the following features, listed by category.

35.1.3.1 GMAC Core Features

- Supports 10/100-Mbit/s data transfer rates with the following PHY interfaces
 - RMIi interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operation
 - Supports CSMA/CD Protocol for half-duplex operation
 - Supports IEEE 802.3x flow control for full-duplex operation
 - Optional forwarding of received pause control frames to the user application in full-duplex operation
 - Back-pressure support for half-duplex operation
 - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for Automatic Pad/CRC Stripping on receive frames
- Programmable frame length to support Standard or Jumbo Ethernet frames with sizes up to 16 KB
- Programmable InterFrameGap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
 - Up to 31 additional 48-bit perfect (DA) address filters with masks for each byte
 - Up to 31 48-bit SA address comparison check with masks for each byte
 - 64-bit Hash filter (optional) for multicast and uni-cast (DA) addresses
 - Option to pass all multicast addressed frames
 - Promiscuous mode support to pass all frames without any filtering for network monitoring
 - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports 32-bit data transfer interface on the system-side
- Complete network statistics (optional) with RMON/MIB Counters (RFC1757/RFC2819/RFC2665). It is completely under control of higher protocol level (SW) to make use of these counters.
- MDIO Master interface for PHY device configuration and management, e.g. for switching the PHY in external loopback mode.
- Optional module for detection of LAN wake-up frames and AMD Magic Packet frames

Ethernet MAC (ETH)

- Optional Receive module for checksum off-load for received IPv4 and TCP packets encapsulated by the Ethernet frame
- Optional Enhanced Receive module for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams.
- Optional module to support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status.

35.1.3.2 DMA Block Features

The DMA block exchanges data between the MTL block and host memory. A set of registers (DMA CSR) to control DMA operation is accessible by the host.

DMA features include:

- 32-bit data transfers
- Single-channel Transmit and Receive engines
- Fully synchronous design operating on a single system clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention; each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size (SINGLE, INCR4/8, not supported by the System: INCR of undefined length) for Transmit and Receive DMA Engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Separate ports for host CSR access and host data interface

35.1.3.3 Transaction Layer (MTL) Features

The MTL block consists of two sets of FIFOs: a Transmit FIFO with programmable threshold capability, and a Receive FIFO with a configurable threshold (default of 64 bytes).

MTL features include:

- 32-bit Transaction Layer block providing a bridge between the application and the GMAC-CORE
- Single-channel Transmit and Receive engines
- Data transfers executed using simple FIFO-protocol

Ethernet MAC (ETH)

- Synchronization for all clocks in the design (Transmit, Receive and system clocks)
- Optimization for packet-oriented transfers with frame delimiters
- Four Separate ports for system-side and GMAC-CORE-side transmission and reception
- Two RAM-based asynchronous FIFOs with synchronous/asynchronous Read and Write operation with respect to the Read and Write clocks (one for transmission and one for reception)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status.
- Configurable Receive FIFO threshold (default fixed at 64 bytes) in Cut-Through mode
- Option to filter all error frames on reception and not forward them to the application in Store-and-Forward mode
- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the GMAC core
- Supports threshold control for transmit buffer management
- Supports configurable number of frames to be stored in FIFO at any time. The default is up to 8 frames in GMAC-MTL configuration.
- Automatic generation of PAUSE frame control or backpressure signal to the GMAC core based on Receive FIFO-fill (threshold configurable) level.
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Data FIFO RAM chip-select disabled when inactive, to reduce power consumption
- Optional module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode.

35.1.3.4 Monitoring, Test, and Debugging Support Features

- Supports internal loopback on the MII for debugging
- external loopback is supported via the integrated MDIO controlling the PHY
- DMA states (Tx and Rx) given as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data-paths and FIFO fill-levels.
- Application Abort status bits
- MMC (RMON) module in the GMAC core
- Current Tx/Rx Buffer pointer as status registers
- Current Tx/Rx Descriptor pointer as status registers

35.2 Architecture

35.2.1 Introduction

The GMAC-UNIV is a highly configurable product with multiple interfaces to the system side or the PHY side. Major modules and functions are only selected when required. A block diagram of the GMAC-UNIV's system configuration is provided in [Figure 35-3](#).

Figure 35-3 GMAC-UNIV Block Diagram

The following sections describe the functionality of the major blocks and timing behavior of the interfaces.

- [Section 35.2.2](#) provides an overview of precision network time synchronization using the Precision Time Protocol established under the IEEE 1588 standard.
- [Section 35.2.3](#) describes the functionality of the AHB interfaces in GMAC-AHB configuration
- [Section 35.2.4](#) describes the functioning of the DMA.
- [Section 35.2.5](#) explains the functioning of the MAC Transaction Layer (MTL) module which controls the Receive and Transmit FIFO memories.
- [Section 35.2.6](#) describes the functionality of the (G)MAC core transmitter and receiver.
- [Section 35.2.7](#), [Section 35.2.8](#), and [Section 35.2.8](#) describe the optional RMON, Power Management, and SMA interface modules.
- [Section 35.2.11](#) describes the Interrupt signal structure in the (G)MAC core.

35.2.2 IEEE 1588-2002 Overview

The IEEE 1588 standard defines a protocol enabling precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The protocol applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The message-based protocol, named Precision Time Protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is depicted in [Figure 35-4](#).

Figure 35-4 Networked Time Synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 and must, for Ethernet ports, be captured at the MII.
2. A slave receives the Sync message and also captures the exact time, t_2 , using its timing reference.
3. The master then sends the slave a Follow_up message, which contains t_1 information for later use.
4. The slave sends the master a Delay_Req message, noting the exact time, t_3 , at which this frame leaves the MII.

Ethernet MAC (ETH)

5. The master receives this message, capturing the exact time, t_4 , at which it enters its system.
6. The master sends the t_4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.

35.2.2.1 Reference Timing Source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32-bits providing time in seconds, and the lower 32-bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

Internal Reference Time

This takes only the reference clock input and uses it to generate the Reference time (also called the System Time) internally and use it to capture time stamps. The generation, update, and modification of the System Time are described in [System Time Register Module](#).

35.2.2.2 Transmit Path Functions

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which capturing a time stamp is required are controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether or not a time stamp must be captured for that frame.

No snooping or processing of the transmitted frames is performed to identify PTP frames. Frame-wise control is exercised through control bits in the transmit descriptor (as described in [Descriptor Format With IEEE 1588 Time Stamping Enabled](#)).

Captured time stamps are returned to the application in a manner similar to that in which status is provided for frames. The time stamp is returned to software inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2 and TDES3 fields, with TDES2 holding the time stamp's 32 least significant bits, except as described in [Transmit Time Stamp Field](#).

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in TDES6 and TDES7, respectively

35.2.2.3 Receive Path Functions

When the IEEE 1588 time-stamping feature is selected and enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. No snooping or processing of the received frames is performed to identify PTP frames in the default mode (Advanced Time Stamp feature is not selected).

The core returns the time-stamp to the software in the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits, except as mentioned in [Receive Time Stamp](#). The time stamp is only written to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the time stamp is not available (for example, due to an RxFIFO overflow) an all-ones pattern is written to the descriptors (RDES2 and RDES3), indicating that time stamp is not correct. If the software uses a control register bit to disable time stamping, the DMA does not alter RDES2 or RDES3.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in RDES6 and RDES7, respectively. RDES0[7] will indicate whether the time-stamp is updated in RDES6/7 or not.

35.2.2.4 Time Stamp Error Margin

According to the IEEE 1588 specifications, the time stamp must be captured at the SFD of transmitted and received frames at the MII interface. Since the reference timing source (the PTP clock, `clk_ptp_ref_i`) is different from the MII clocks, a small error margin is introduced, due to the transfer of information across asynchronous clock domains.

In the transmit path, the captured and reported time stamp has a maximum error margin of 2 PTP clocks. In other words, the captured time stamp has the value of the reference time source given within 2 clocks after the SFD has been transmitted on the MII.

Similarly, on the receive path, the error margin is 3 MII clocks, plus up to 2 PTP clocks. You can ignore the error margin due to the 3 MII clocks by assuming that this constant delay is present in the system (or link) before the SFD data reaches the GMAC's MII interface.

35.2.2.5 Frequency Range of Reference Timing Clock

Because asynchronous logic is in place for time stamp information transfers across clock domain, a minimum delay is required between two consecutive time stamp captures. This delay is 3 clock cycles of both the MII and PTP clocks. If the gap is shorter, the GMAC does not take a time stamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time and the timing constraints achievable for logic operating on the PTP clock. Another factor to consider is that the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Hence, a higher PTP clock

Ethernet MAC (ETH)

frequency gives better system performance. The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the MII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends on the core's operating mode and operating speed.

For example, in 100 Mbit/s full-duplex operation, the minimum gap between two SFDs is 160 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 8 clocks of preamble).

In the example, $(3 \times \text{PTP}) + (3 \times \text{MII}) \leq 160 \times \text{MII}$; thus, the minimum PTP clock frequency is about 0.5 MHz ($((160 - 3) \times 40 \text{ ns} / 3 = 2.093 \text{ ns period})$)

35.2.2.6 Advanced Time Stamp Feature Support

In addition to the basic features for time stamp mentioned in [IEEE 1588-2002 Overview](#), the advanced time stamp option has the following features.

- Support for the IEEE 1588-2008 (Version 2) timestamp format.
- Option to take snapshot for all frames or for PTP type frames.
- Option for taking snapshot for event messages only.
- Option to take the snapshot based on the clock type (ordinary, boundary, end-to-end and peer-to-peer)
- Option to select the node to be a Master or Slave for ordinary and boundary clock.
- Identification of PTP message type, version, and PTP payload sent directly over Ethernet given as status.
- Option to measure time in digital or binary format.

Peer-to-Peer PTP (Pdelay) Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Pdelay message in addition to SYNC, Delay Request, Follow-up and Delay Response messages. [Figure 35-5](#) shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 35-5 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

The link delay measurement starts with port-1 issuing a “Pdelay_Req” message and generating a timestamp, for the Pdelay_Req message. Port-2 receives the “Pdelay_Req” message and generates a timestamp, t_2 , for this message. Port-2 returns a Pdelay_Resp message and generates a timestamp, t_3 , for this message. To minimize errors due to any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message.

Port-2 either:

Ethernet MAC (ETH)

- Returns the difference between the timestamps t2 and t3 in the Pdelay_Resp message,
- Returns the difference between the timestamps t2 and t3 in a Pdelay_Resp_Follow_Up message, or
- Returns the timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.

Port-1 generates a timestamp, t4, upon receiving the Pdelay_Resp message. Port-1 then uses these four timestamps to compute the mean link delay.

Clock Types

The type of clock nodes supported in IEEE 1588-2008 is described in this section. The corresponding support provided by the advanced time stamp feature for each of the clock type is also mentioned.

1. Ordinary clock support: In this type the clock can be a grandmaster or a slave clock. This clock has a single PTP state.

Table 35-1 shows the messages for which time-stamp snapshot is taken on the receive side for Master and Slave nodes.

The ordinary clock in the domain supports a single copy of the protocol and has a single PTP state and will typically be a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as sensors and actuators. In telecom applications, the ordinary clock may be associated with a timing demarcation device.

Typically for ordinary clock, you will need to take snapshot for only one type of PTP messages. For e.g. you will require supporting either version 1 or 2 PTP messages, not both.

The following features are supported.

- a) Sends and receives PTP messages. The time stamp snapshot can be controlled as described in **32-bit Register - Timestamp_Control**.
 - b) Maintains the data sets (e.g., time stamp values).
2. Boundary clock support: This type of clock is similar to the ordinary clock except for the following.

Hence the features of ordinary clock holds good for the boundary clock also.

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the core (refer to **Receive Path Functions**) will help you to quickly identify the type of message and take appropriate action.

- a) The clock data sets are common to all ports of the boundary clock
 - b) The local clock is common to all ports of the boundary clock.
3. End to end transparent clock support: The end-to-end transparent clock forwards all messages like normal bridge, router or repeater. The resident time needs to be

Ethernet MAC (ETH)

computed to update the correctionField. Hence snapshot needs to be taken for the messages mentioned in [Table 35-2](#).

In the end-to-end transparent clock, the residence times are accumulated in a special field (correctionField) of the PTP event (SYNC) message or the associated Follow-up (FOLLOW_UP) Message. Hence it is important to take a snapshot for these messages alone. This can be quickly done by setting the control bit (TSEVNTENA), which enables snapshot to be taken for event messages and also selecting the type of clock in the “Time Stamp Control Register”.

The residence time is also corrected for Delay_Req messages (but snapshot of the timestamp is not required). The message type statuses provided helps you to quickly identify the message and update the correctionField.

The message type status provided will also help in taking appropriate action depending on the type of PTP message received.

4. Peer to peer transparent clock support: In this type of clock the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp and Pdelay_Resp_Follow_Up messages with the link peer. Hence support for taking snapshot for the event messages related to Pdelay is added. [Table 35-3](#).

The transparent clock corrects only the SYNC and Follow-up message. As discussed earlier this can be achieved using the message status provided.

The type of clock to be implemented will be configurable through control register, as mentioned in [32-bit Register - Timestamp_Control](#). To ensure that the snapshot is taken only for the messages indicated in the table for the corresponding clock type, the “TSEVNTENA: Enable Time Stamp Snapshot for Event Messages” bit has to be set.

PTP Processing and Control

The common message header for PTP messages is shown below. This format is taken from IEEE standard 1588-2008 (Revision of IEEE Std. 1588-2002).

Table 35-4 Message Format Defined in IEEE 1588-2008

BITS		OCTETS	OFFSET
transportSpecific	messageType	1	0
Reserved	versionPTP	1	1
messageLength		2	2
domainNumber		1	4
Reserved		1	5
flagField		2	6
correctionField		8	8
Reserved		4	16
sourcePortIdentity		10	20
sequenceId		2	30
controlField ¹⁾		1	32
logMessageInterva		1	33

1) controlField is used in version 1. For version 2, messageType field will be used for detecting different message types.

There are some fields in the PTP frame that are used to detect the type and control the snapshot to be taken. This is different for PTP frames sent directly over Ethernet, PTP frames sent over UDP / IPv4 and PTP frames that are sent over UDP / IPv6. The following sections provide information on the fields that are used to control taking the snapshot.

PTP Frame Over IPv4

Table 35-5 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv4 for IEEE 1588 version 1 and 2. Note that the octet positions

Ethernet MAC (ETH)

for tagged frames will be offset by 4. This is based on Appendix-D of the IEEE 1588-2008 standard and the message format defined in [Table 35-4](#).

Table 35-5 IPv4-UDP PTP Frame Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Frame type	12, 13	0x0800	IPv4 datagram
IP Version and Header Length	14	0x45	IP version is IPv4
Layer-4 protocol	23	0x11	UDP
IP Multicast address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0,0x00, 0x01,0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-primary multicast address: 224.0.1.129 PTP-Pdelay multicast address: 224.0.0.107
UDP destination port	36, 37	0x013F, 0x0140	0x013F – PTP event message ¹⁾ 0x0140 – PTP general messages
PTP control field (IEEE version 1)	74	0x00/0x01/0x02 /0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req, 0x02 – Follow_Up 0x03 – Delay_Resp 0x04 – Management

Ethernet MAC (ETH)
Table 35-5 IPv4-UDP PTP Frame Fields Required for Control and Status (cont'd)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE version 2)	42 (nibble)	0x0/0x1/0x2/0x3/0x8/0x9/0xB/0xC/0xD	0x0 – SYNC 0x1 – Delay_Req 0x2 – Pdelay_Req 0x3 – Pdelay_Resp 0x8 – Follow_Up 0x9 – Delay_Resp 0xA – Pdelay_Resp_Follow_Up 0xB – Announce 0xC – Signaling 0xD – Management

MAC Destination multicast address ¹⁾	0-5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All except peer delay messages - 01-1B-19-00-00-00 Pdelay messages - 01-80-C2-00-00-0E
PTP version field	15 (nibble)	0x1 or 0x2	0x1 – Supports PTP version 1 0x2 – Supports PTP version 2

1) In addition, the address match of destination addresses (DA) programmed in MAC address 1 to 31 will be used, if the control bit 18 (TSENMACADDR: Enable MAC address for PTP frame filtering) of the Time Stamp Control register is set.

Reference Timing Source (for Advance Timestamp Feature)

The updated functionality for advanced timestamp support is mentioned in the following points.

1. The IEEE 1588-2008 standard defines the seconds field of the time to be 48 bits wide. The fields to time-stamp will be the following.

- a) UInteger48- seconds field
- b) UInteger32-nanoseconds field

The “seconds” field is the integer portion of the timestamp in units of seconds. The

Ethernet MAC (ETH)

“nanoseconds” field is the fractional portion of the timestamp in units of nanoseconds. E.g. 2.000000001 seconds is represented as secondsField = 0x0000_0000_0002 and nanoSeconds = 0x0000_0001. Thus the maximum value in nanoseconds field in this format will be 0x3B9A_C9FF value (i.e (10e9-1) nanoseconds). This is defined as digital rollover mode of operation. It will also support the older mode in which the nano-seconds field will roll-over and increment the seconds field after the value of 0x7FFF_FFFF. (Accuracy is ~0.466 ns per bit). This is defined as the binary rollover mode. The modes can be controlled using the “TSCTRLSSR: Time Stamp Digital or Binary rollover control” bit of the time stamp control register.

2. When the Advanced IEEE 1588 time-stamp feature is selected time maintained in the core will still be 64-bit wide, as the overflow to the upper 16-bits of seconds register happens once in 130 years. The value of the upper 16-bits of the seconds field can only be obtained from the CSR register. This is optional and can be controlled by the coreKit parameter “IEEE1588 Higher Word Register Enable” described in Chapter 6. A CSR status bit which indicates if the 32-bit “seconds” field has overflowed is also provided.
3. There is also a pulse-per-second output given to indicate 1 second interval (default). Option is provided to change the interval. Refer [32-bit Register - Timestamp_Control](#) for more information.
4. Option to take auxiliary time-stamp snapshot with an external event is supported. Refer to section [Auxiliary Snapshot](#) for details.

Transmit Path Functions

There are no changes in the transmit path functions for GMAC-CORE and GMAC-MTL configuration for the Advanced time stamp option.

The structure of the descriptor changes when Advanced IEEE 1588 version support is enabled. The IEEE 1588 timestamp feature is supported using Alternate (Enhanced) descriptors format only. The descriptor is 32-bytes long (8 DWORDS) and the snapshot of the timestamp is written in descriptor 6 and 7.

Receive Path Functions

When the advanced time stamp feature is selected, processing of the received frames to identify valid PTP frames is done. The snapshot of the time to be sent to the application can be controlled.

The following options are provided in the time stamp control register to control the snapshot.

1. Option to enable snapshot for all frames.
2. Enable snapshot for IEEE 1588 version 2 or version 1 time stamp.
3. Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.

Ethernet MAC (ETH)

4. Enable time stamp snapshot for the received frame for IPv4 or IPv6.
5. Enable time stamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ or PDELAY_RESP) only.
6. Enable the node to be a Master or Slave. This will control the type of messages for which snap-shot will be taken (this depends on the type of clock that is selected and is valid for ordinary or boundary clock only).

Note that PTP messages over VLAN frames are also supported.

The time stamp is returned to the software inside the corresponding Transmit and Receive Descriptor. The Advanced time stamp feature is supported using Alternate (Enhanced) descriptors only which is 32-bytes long. Extended status containing the time stamp message status and the IPC offload status is written back in descriptor 4 and the snapshot of the time stamp is written back in descriptor 6 and 7. The complete details on the descriptors when the advanced time stamping is enabled are provided in [Alternate or Enhanced Descriptors](#).

Auxiliary Snapshot

The auxiliary snap shot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i`. This feature is independent of whether the system time is generated internally or given as input (on `ptp_timestamp_i` bus). Such snap-shots are stored in a 4-deep FIFO. Only 64-bit of the time will be stored in the FIFO. The upper 16-bits of the seconds register can be read from “Time Stamp Higher Word Register” when it is present.

The storing of the snapshot can be indicated to the host with an interrupt. The value of the snapshot is read out through a FIFO register access (see [32-bit Register - Timestamp Control](#)). When the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status is set in the Time Stamp Status Register. This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot will not be written to the FIFO when it is full. When the host reads the 64-bit timestamp from the FIFO, space is available to store the next snapshot. This FIFO can be cleared using the control bit “ATSFC: Auxiliary Snapshot FIFO clear” defined in the Time Stamp Control Register. When multiple snapshots are present in the FIFO, the count is indicated in the “ATSNS: Auxiliary Time Stamp Number of Snapshots” bits of the Time Stamp Status Register.

35.2.3 AHB Application Host Interface

In the GMAC-AHB core, the DMA Controller interfaces with the Host through the AMBA AHB Interface. The AHB Master Interface controls data transfers while the AHB Slave interface accesses CSR space. The DMA can be used in embedded applications where DMA is required to optimize data transfer between the GMAC and system memory.

The AHB Master interface converts the internal DMA request cycles into AHB cycles.

Characteristics of this interface include the following:

- Fully AMBA 2.0-compliant AHB Master: with restrictions
- You can choose fixed burst length only (SINGLE, INCR4, INCR8) by programming the FB in the DMA Bus Mode register (see [Register Description](#)).
 - When fixed burst length is chosen, the AHB master always initiates a burst with SINGLE or INCR4/8type. But when such a burst is responded with SPLIT/RETRY/early burst termination, the AHB master will re-initiate the pending transfers of the burst with INCR or SINGLE burst-length type. It will terminate such INCR bursts when the original requested fixed-burst is transferred. In Fixed Burst-Length mode, if the DMA requests a burst transfer that is not equal to INCR4/8, the AHB Host interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the AHB interface splits it into multiple transfers of INCR8 and INCR4 and 3 SINGLE transactions.
- The AHB slaves interfaced to the GMAC-AHB must support SINGLE and INCR transfers, at a minimum.
- Takes care of AHB SPLIT, RETRY, and ERROR conditions. Any ERROR response will halt all further transactions for that DMA, and indicate the error as fatal through the CSR and interrupt. The application must give a hard or soft reset to the module to restart the operation.
- Takes care of AHB 1K boundary breaking
- Handles all data transfers (according to the data bus width configuration), except for Descriptor Status Write accesses (which are always 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.

All AHB burst transfers can be aligned to an address value by enabling the DMA Bus Mode register's AAL bit. If both the FB and AAL bits are set to 1, the AHB interface and the DMA together ensure that all initiated beats are aligned to the address, completing the frame transfer in the minimum number of required beats.

For example, in 32-bit data bus mode, if a data buffer transfer's start address is 0xF000_0008 and the DMA is configured for a maximum beat size of 8, the AHB transfers occur in the following sequence:

- 2 SINGLE transfers at addresses 0xF000_0008 and 0xF000_000C
- 1 INCR4 transfer at address 0xF000_0010
- All subsequent beats are INCR8 transfers starting from address 0xF000_0020. For an address-aligned INCR8 transfer, the 5 least-significant bits of the address must be 0.
- The DMA Controller requests an AHB Burst Read transfer only when it can accept the received burst data completely. Data read from the AHB is always pushed into the DMA without any delay or BUSY cycles.
- The DMA requests an AHB Burst Write transfer only when it has the sufficient data to transfer the burst completely. The AHB interface always assumes that it has data available to push into the AHB bus. However, the DMA can prematurely indicate end-

Ethernet MAC (ETH)

of-valid data (due to the transfer of end-of-frame of an Ethernet frame) during the burst. In Fixed Burst Length mode, the AHB Master interface continues the burst with dummy data until the specified length is completed.

The AHB 32-bit Slave interface provides access to the DMA and GMAC CSR space. Characteristics of this interface include the following:

- Fully AMBA 2.0 Compliant AHB Slave—no restrictions
- Supports single and INCR4/8 transfers
- Supports busy and early terminations
- Supports 32-bit, 16-bit, and 8-bit write/read transfers to the CSR; 32-bit access to the CSR are recommended to avoid any SW synchronization problems.
- Generates OKAY only response; does not generate SPLIT, RETRY, or ERROR responses.

35.2.4 DMA Controller

The DMA has independent Transmit and Receive engines, and a CSR space. The Transmit Engine transfers data from system memory to the device port (MTL), while the Receive Engine transfers data from the device port to system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The DMA and the Host driver communicate through two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

Control and Status registers are described in detail in [Chapter 35.3.1.1](#). Descriptors are described in detail in [Chapter 35.4](#).

The DMA transfers data frames received by the core to the Receive Buffer in the Host memory, and Transmit data frames from the Transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.

There are two descriptor lists; one for reception, and one for transmission. The base address of each list is written into DMA Registers 3 and 4, respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both Receive and Transmit descriptors (RDES1[24] and TDES1[24]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer

Ethernet MAC (ETH)

status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA will skip to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.

The descriptor ring and chain structure is shown in **Figure 35-6**.

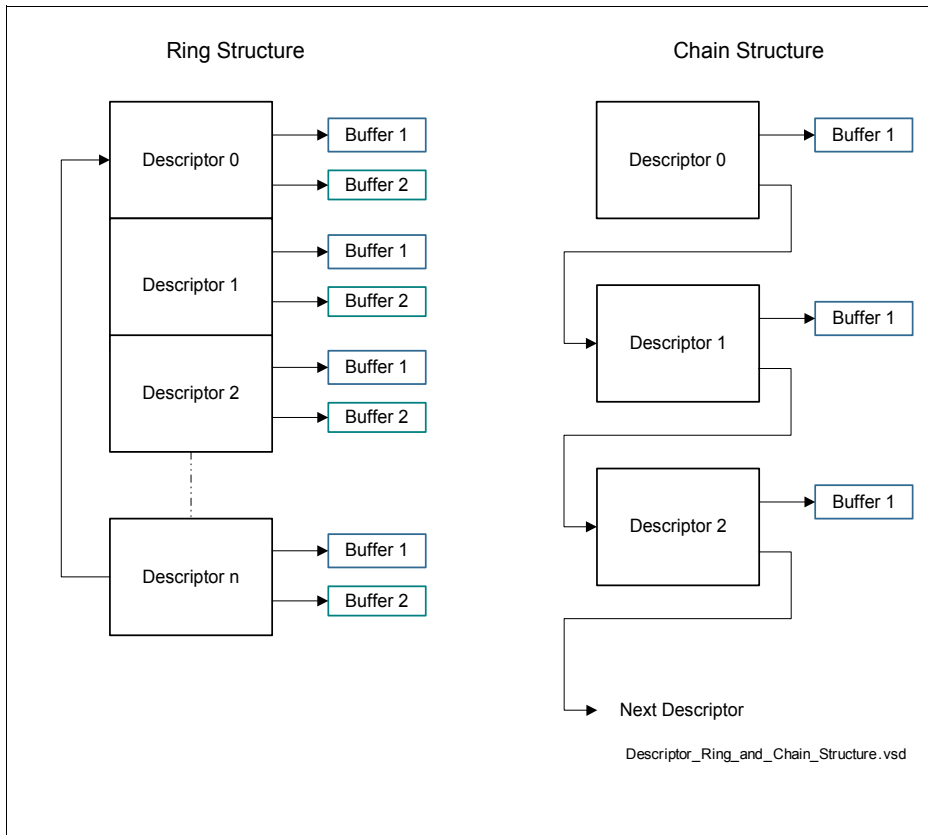

Figure 35-6 Descriptor Ring and Chain Structure

35.2.4.1 Initialization

Initialization for the GMAC is as follows.

1. Write to DMA Register 0 to set Host bus access parameters.
2. Write to DMA Register 7 to mask unnecessary interrupt causes.

Ethernet MAC (ETH)

3. The software driver creates the Transmit and Receive descriptor lists. Then it writes to both DMA Register 3 and DMA Register 4, providing the DMA with the starting address of each list.
4. Write to GMAC Registers 1, 2, and 3 for desired filtering options.
5. Write to GMAC Register 0 to configure and enable the Transmit and Receive operating modes. The PS and DM bits are set based on the auto-negotiation result (read from the PHY).
6. Write to DMA Register 6 to set bits 13 and 1 to start transmission and reception.
7. The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

Host Bus Burst Access

The DMA will attempt to execute fixed-length Burst transfers on the AHBMaster interface if configured to do so (FB bit of DMA Register 0). The maximum Burst length is indicated and limited by the PBL field (DMA Register 0[13:8]). The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL or $16 * 8/\text{bus width}$) burst-size for the 16-bytes to be read.

The Transmit DMA will initiate a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions.

The Receive DMA will initiate a data transfer only when sufficient data to accommodate the configured burst is available in MTL Receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the Receive FIFO. The DMA will indicate the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions. If the end-of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in-order to complete the fixed-burst.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 8 (for $\text{PBL} > 8$), because the AHB interface does not support more than INCR8.

Host Data Buffer Alignment

The Transmit and Receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example - Buffer Read

If the Transmit buffer address is 32'h0000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, then the DMA will read five full words from address 32'h0000FF0, but when transferring data to the MTL Transmit FIFO, the extra bytes (the first two bytes) will be dropped or ignored. Similarly, the last 3 bytes of the last transfer will also be ignored. The DMA always ensures it transfers a full 32-bit data to the MTL Transmit FIFO, unless it is the end-of-frame.

Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the GMAC core. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The Receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the system bus's data width, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1.024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual

Ethernet MAC (ETH)

useful space in this buffer is 1.022 bytes, even though the buffer size is programmed as 1.024 bytes, due to the start address offset.

DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses to the AHB Master interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (DA bit of DMA Register 0 is reset), the arbiter allocates the data bus in the ratio set by the PR bits of DMA Register 0, when both Transmit and Receive DMAs are requesting for access simultaneously. When the DA bit is set, the Receive DMA always gets priority over the Transmit DMA for data access.

35.2.4.2 Transmission**TxDMA Operation: Default (Non-OSF) Mode**

The Transmit DMA engine in default mode proceeds as follows:

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Frame data.
2. Once the ST bit (DMA Register 6[13]) is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host, or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (DMA Register 5[2]) and Normal Interrupt Summary (DMA Register 5[16]) bits are set. The Transmit Engine proceeds to Step 8.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1'b1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the Transmit data from the Host memory and transfers the data to the MTL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps Step 2, Step 3, and Step 4 are repeated until the end-of-Ethernet-frame data is transferred to the MTL.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time-stamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this

Ethernet MAC (ETH)

descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.

8. Transmit Interrupt (DMA Register 5[0]) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last Descriptor. The DMA engine then returns to Step 2.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to Step 2) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared.

The TxDMA transmission flow in default mode is shown in [Figure 35-7](#).

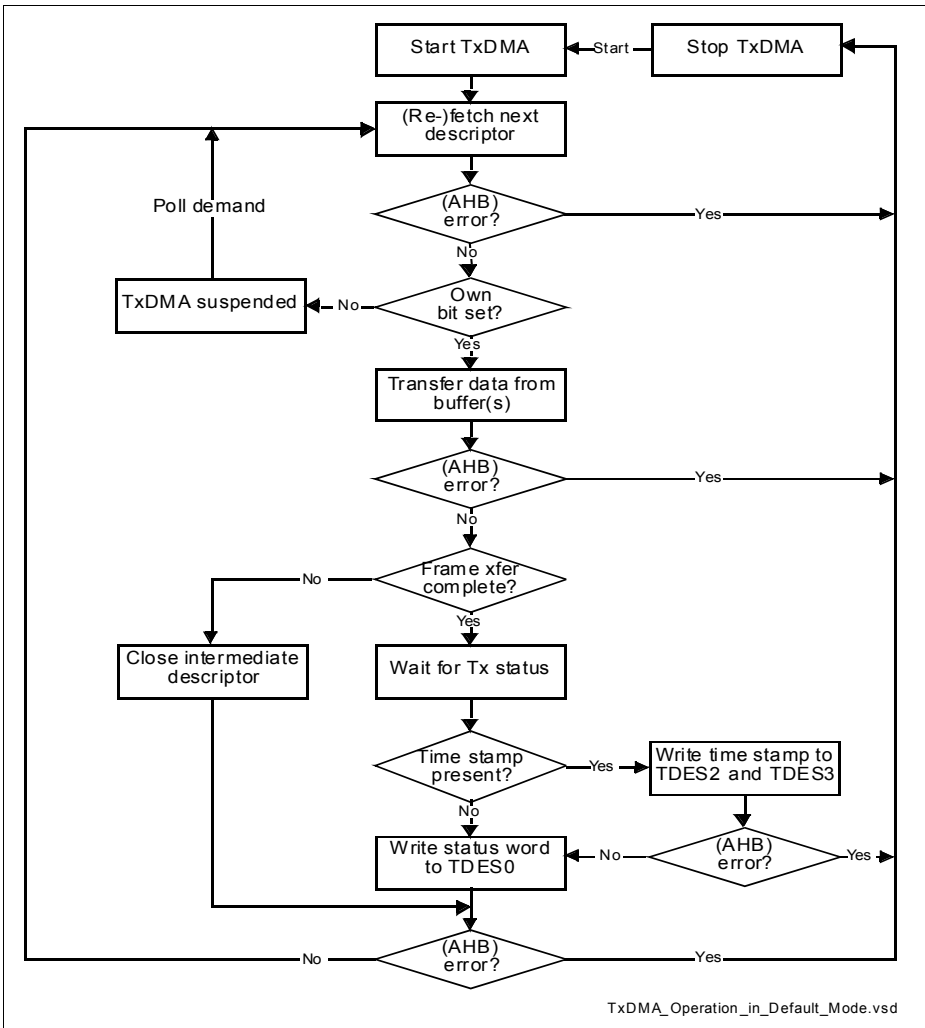

Figure 35-7 TxDMA Operation in Default Mode

TxDMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in DMA Register 6[2]). As the transmit process finishes transferring the first frame, it immediately polls the

Ethernet MAC (ETH)

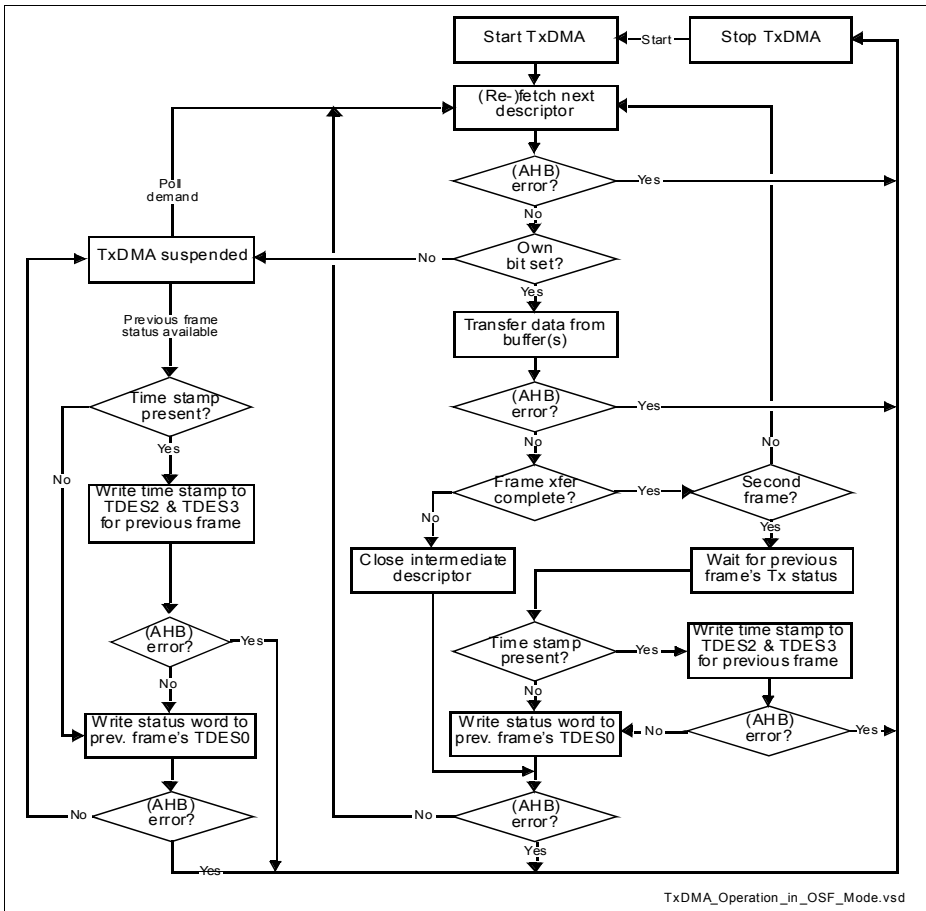

Transmit Descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In OSF mode, the Run state Transmit DMA operates in the following sequence:

1. The DMA operates as described in Step 1–Step 5 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 6.
4. The DMA fetches the Transmit frame from the Host memory and transfers the frame to the MTL until the End-of-Frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and time stamp. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 2 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 6).
7. In Suspend mode, if a pending status and time stamp are received from the MTL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (DMA Register 1).

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than 2 different descriptors for correct and proper operation.

The basic flow is charted in [Figure 35-8](#).

Figure 35-8 TxDMA Operation in OSF Mode

Transmit Frame Processing

The Transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields contain valid data. If the Transmit Descriptor indicates that the MAC core must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively.

Ethernet MAC (ETH)

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL Transmit FIFO. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the Transmit Process attempts to acquire the Next Descriptor. The Transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) was set, Transmit Interrupt (DMA Register 5[0]) is set, the Next Descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MTL Transmit FIFO has reached either a programmable transmit threshold (DMA Register 6[16:14]), or a full frame is contained in the FIFO. There is also an option for Store and Forward Mode (DMA Register 6[21]). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the second condition occur, both Abnormal Interrupt Summary (DMA Register 5[15]) and Transmit Underflow bits (DMA Register 5 [5]) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into SUSPEND state due to the first condition, then both Normal Interrupt Summary (DMA Register 5 [16]) and Transmit Buffer Unavailable (DMA Register 5 [2]) are set.

In both cases, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA.

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

35.2.4.3 Reception

The Receive DMA engine's reception sequence is depicted in [Figure 35-9](#) and proceeds as follows:

1. The host sets up Receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).

Ethernet MAC (ETH)

2. Once the SR (DMA Register 6[1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to Step 8.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 6. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to Step 7. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 3.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.
8. The Receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 1'b0) the Receive Buffer Unavailable bit (Register 5[7]) is set and the DMA Receive engine enters the Suspended state (Step 8). If the DMA owns the descriptor, the engine returns to Step 3 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (You can control flushing using Bit 24 of DMA Register 6).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's Receive FIFO. The engine proceeds to Step 1 and refetches the next descriptor.

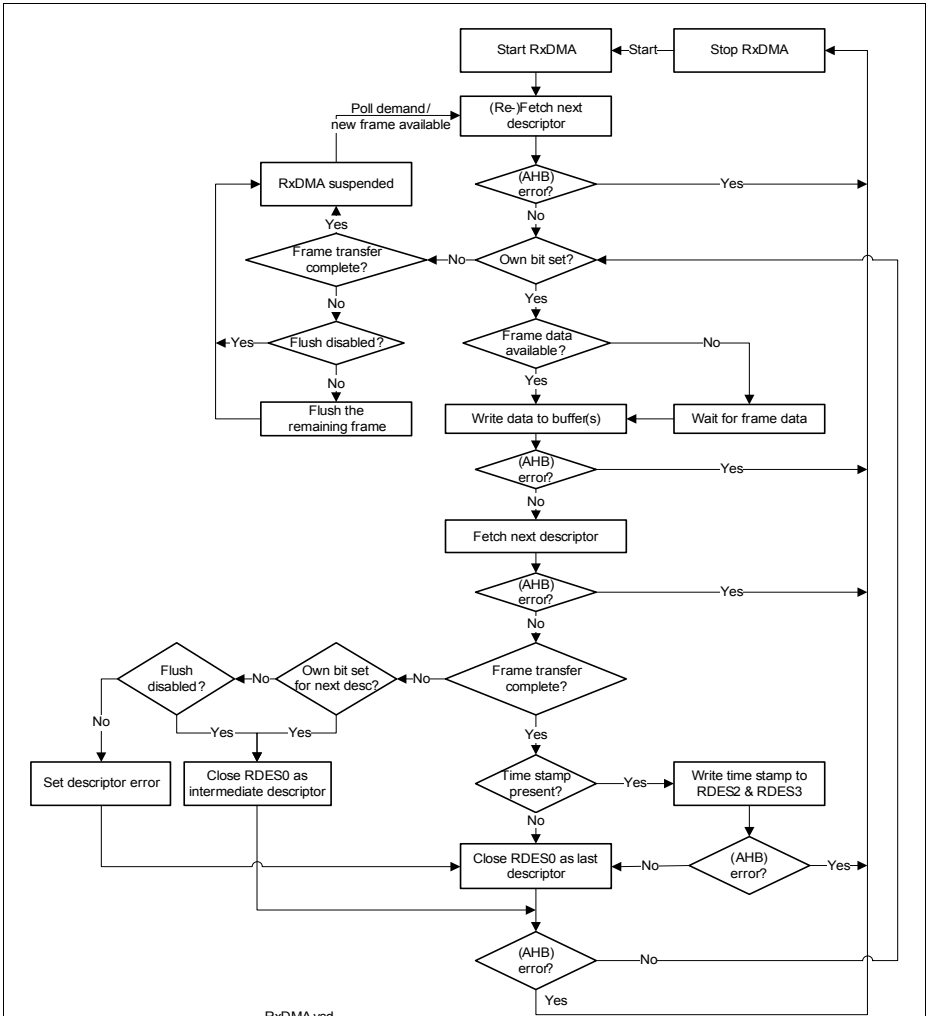

Figure 35-9 Receive DMA Operation

The DMA does not acknowledge accepting the status from the MTL until it has completed the time stamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled time stamping through CSR, when a valid time stamp value is not available for the frame (for example, because the receive FIFO was full before the time stamp could be written to it), the DMA writes all-ones to RDES2 and RDES3.

Ethernet MAC (ETH)

Otherwise (that is, if time stamping is not enabled), the RDES2 and RDES3 remain unchanged.

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The receive Start/Stop bit (Register 6[1]) has been set immediately after being placed in the Run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current Receive Descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received.
- A Receive poll demand has been issued.

Receive Frame Processing

The GMAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to configurable threshold bytes set for the Receive FIFO of MTL, or when the complete frame is written to the FIFO in Store-and-Forward mode.

If the frame fails the address filtering, it is dropped in the GMAC block itself (unless Receive All GMAC Register 1[31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the MTL Receive FIFO.

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the Receive Buffer pointed to by the current descriptor. The DMA sets First Descriptor (RDES0[9]) after the DMA Host Interface (AHB/AXI or MDC) becomes ready to receive a data transfer (if DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is reset to 1'b0, either as the Data buffer fills up or as the last segment of the frame is transferred to the Receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES[8]) and First Descriptor (RDES[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets Receive Interrupt (Register 5[6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the Receive Process sets Receive Buffer Unavailable (Register 5[7]) and then enters the Suspend state. The position in the receive list is retained.

Receive Process Suspended

If a new Receive frame arrives while the Receive Process is in Suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the Receive Process re-enters the Run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL Rx FIFO and increments the missed frame counter. If more than one frame is stored in the MTL Rx FIFO, the process repeats.

The discarding or flushing of the frame at the top of the MTL Rx FIFO can be avoided by setting Operation Mode register bit 24 (DFF). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state.

35.2.4.4 Interrupts

Interrupts can be generated as a result of various events. DMA Register 5 contains all the bits that might cause an interrupt. DMA Register 7 contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in DMA Register 5. Interrupts are cleared by writing a 1'b1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal `sbd_intr_o` is deasserted. If the GMAC core is the cause for assertion of the interrupt, then any of the GLI, GMI, or GPI bits of DMA Register 5 will be set high.

Note: DMA Register 5 is the (interrupt) status register. The interrupt pin (`sbd_intr_o`) will be asserted due to any event in this status register only if the corresponding interrupt enable bit is set in DMA Register 7.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Receive Interrupt (DMA Register 5[6]) indicates that one or more frames was transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan DMA Register 5 for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in DMA Register 5. For example, the controller generates a Receive interrupt (DMA Register 5[6]) and the driver begins reading DMA Register 5. Next, Receive Buffer Unavailable (DMA Register 5[7]) occurs. The driver clears the Receive interrupt. Even then, the `sbd_intr_o` signal is not deasserted, due to the active or pending Receive Buffer Unavailable interrupt.

An interrupt timer is given for flexible control of Receive Interrupt (DMA register 5[6]). When this Interrupt timer is programmed with a non-zero value, it will get activated as soon as the RxDMA completes a transfer of a received frame to system memory without

asserting the Receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31] in Table 7-3). When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RI is enabled in DMA Register 7. This timer gets disabled before it runs out, when a frame is transferred to memory and the RI is set because it is enabled for that descriptor.

35.2.5 MAC Transaction Layer (MTL)

The MAC Transaction Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the GMAC core. It also enables the data to be transferred between the application clock domain and the GMAC clock domains. The MTL layer has 2 data paths, namely the Transmit path and the Receive Path. The data path for both directions is 32-bit wide and operates with a simple FIFO protocol.

The GMAC-MTL communicates with the application side with the Application Transmit Interface (ATI), Application Receive Interface (ARI), and the MAC Control Interface (MCI).

35.2.5.1 Transmit Path

The DMA controls all transactions for the transmit path through the ATI. Ethernet frames read from the system memory is pushed into the FIFO by the DMA. The frame is then popped out and transferred to the GMAC core when triggered. When the end-of-frame is transferred, the status of the transmission is taken from the GMAC core and transferred back to the DMA.

The Transmit FIFO has a depth of 4K bytes. 4FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the AHB interface. The data from the AHB Master interface is pushed into the FIFO with the appropriate byte lanes qualified by the DMA. The DMA also indicates the start-of-frame (SOF) and end-of-frame (EOF) transfers along with a few sideband signals controlling the pad-insertion/CRC generation for that frame in the GMAC core.

Per-frame control bits, such as Automatic Pad/CRC Stripping disable, time stamp capture, and so forth are taken as sideband control inputs on the ATI, stored in a separate register FIFO, and passed on to the core transmitter when the corresponding frame data is read from the Transmit FIFO.

There are two modes of operation for popping data towards the GMAC core. In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the GMAC core. The threshold level is configured using the TTC bits of DMA Register 0. In store-and-forward mode, the MTL pops the frame towards the GMAC core only when one or more of the following conditions are true:

- When a complete frame is stored in the FIFO

Ethernet MAC (ETH)

- When the TX FIFO becomes almost full
- When the ATI watermark becomes low. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst-length on the ATI.

Therefore, the MTL never stops in the store-and-forward mode even if the Ethernet frame length is bigger than the Tx FIFO depth.

The application can flush the Transmit FIFO of all contents by setting the FTF (DMA Register 6[20]) bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer from the MTL to the GMAC core, then the MTL stops further transfer as the FIFO is considered to be empty. Hence an underflow event occurs at the GMAC transmitter and the corresponding Status word is forwarded to the DMA.

Initialization through **Transmit Status Word** detail initialization and transmit operations for the MTL Layer.

Initialization

Upon reset, the MTL is ready to manage the flow of data to and from the DMA and the GMAC.

There are no requirements for enabling the MTL. However, the GMAC block and the DMA controller must be enabled individually through their respective CSRs.

Single-Packet Transmit Operation

During a transmit operation, the MTL block is slaved to the DMA controller. The general sequence of events for a transmit operation is as follows.

1. If the system has data to be transferred, the DMA controller, if enabled, fetches data from the Host through the AHB/AXI Master interface and starts forwarding it to the MTL. The MTL pushes the data received from the DMA into the FIFO. It continues to receive the data until the end-of frame of the frame is transferred.
2. The data is taken out of the FIFO and sent to the MAC by the FIFO controller engine. When the threshold level is crossed or a full packet of data is received into the FIFO, the MTL pops out the frame data and drives them to the GMAC core. The engine continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the MTL receives the Status from the GMAC and then notifies the DMA controller

Transmit Operation—Two Packets in the Buffer

1. Because the DMA must update the descriptor status before releasing it to the Host, there can be at the most two frames inside a transmit FIFO. The second frame will be fetched by the DMA and put into the FIFO only if the OSF (Operate on Second

Ethernet MAC (ETH)

Frame bit is set). If this bit is not set, the next frame will be fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The MTL, in the meantime, receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the MTL pushes it to the DMA. If the DMA has already completed sending the second packet to the MTL, it must wait for the status of the first packet before proceeding to the next frame.

Transmit Operation—Multiple Packets in Buffer

In GMAC-MTL configuration, the transmit FIFO can be configured to accept more than 2 packets at a time. This option limits the number of status words that can be stored in the MTL before it is transferred to the DMA/host. By default, this number is limited to 2 but can be configured for 4 or 8 as well. Once the MTL FIFO accepts the number of frames equal to the status FIFO depth, it will stop accepting further frames unless the transmit Status that is given out and accepted by the host/DMA thus freeing up the space in this small FIFO.

Retransmission During Collision

While a frame is being transferred from the MTL to the GMAC, a collision event occurs on the GMAC line interface in Half-Duplex mode. The GMAC then indicates a retry attempt to the MTL by giving the status even before the end-of-frame is transferred from MTL. Then the MTL will enable the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes are popped towards the GMAC core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the GMAC core indicates a late-collision event.

Transmit FIFO Flush Operation

The GMAC provides a control to the software to flush the Transmit FIFO in the MTL layer through the use of Bit 20 of the Operation Mode register. The Flush operation is immediate and the MTL clears the Tx FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the GMAC Core. The data which is already accepted by the MAC transmitter will not be flushed. It will be scheduled for transmission and will result in underflow as Tx FIFO does not complete the transfer of rest of the frame. As in all underflow conditions, a runt frame will be transmitted and observed on the line. The status of such a frame will be marked with both Underflow and Frame Flush events (TDES0 bits 13 and 1).

Ethernet MAC (ETH)

The MTL layer also stops accepting any data from the application (DMA) during the Flush operation. It will generate and transfer Transmit Status Words to the application for the number of frames that is flushed inside the MTL (including partial frames). Frames that are completely flushed in the MTL will have the Frame Flush Status bit (TDES0 13) set. The MTL completes the Flush operation when the application (DMA) accepts all of the Status Words for the frames that were flushed, and then clears the Transmit FIFO Flush control register bit. At this point, the MTL starts accepting new frames from the application (DMA).

Transmit Status Word

At the end of transfer of the Ethernet frame to the GMAC core and after the core completes the transmission of the frame, the MTL outputs the transmit status to the application. The detailed description of the Transmit Status is the same as for bits [23:0] of TDES0, given in [Table 35-28](#).

If IEEE 1588 time stamping is enabled, the MTL returns specific frame's 64-bit time stamp, along with the ATI's transmit status.

Transmit Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the GMAC-UNIV has an Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the Checksum Offload Engine for transmitted frames.

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-Forward mode (that is, when the TSF bit is set in DMA Register 6). If the core is configured for Threshold (cut-through) mode, the Transmit COE is bypassed.

Note: You must make sure that the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the GMAC Core transmitter. The reason being that when space is not available to accept the programmed burst length of the data, then the MTL TxFIFO starts reading to avoid dead-lock. Once reading starts, then checksum insertion engine fails and consequently all succeeding frames may get corrupted due to improper recovery. Therefore, you must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):

FIFO Depth – PBL – 3 FIFO Locations

The PBL is the programmed burst-length.

Ethernet MAC (ETH)

This module supports two types of checksum calculation and insertion. This checksum engine can be controlled for each frame by setting the CIC bits (Bits 28:27 of TDES1, described in **Transmit Descriptor 1 (TDES1)**) in GMAC-AHB or GMAC-DMA configurations.

Note: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field; thus, the COE does not modify IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in **Table 35-28**). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field.

In other words, this bit is set when an IP header error is asserted under the following circumstances:

For IPv4 datagrams

- The received Ethernet type is 0x0800, but the IP header's Version field does not equal 0x4
- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
- The total frame length is less than the value given in the IPv4 Header Length field

For IPv6 datagrams

- The Ethernet type is 0x86dd but the IP header Version field does not equal 0x6
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

Even when the COE detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

TCP/UDP/ICMP Checksum Engine

Ethernet MAC (ETH)

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

Note: For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

Note: Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are not processed by this engine, and therefore must be bypassed. In other words, payload checksum insertion must not be enabled for such frames.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's Checksum field. This engine includes the Checksum field in the checksum calculation, then replaces the Checksum field with the final calculated checksum.
- In the second mode, the engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in [Table 35-28](#)). This engine sets the Payload Checksum Error status bit when it detects that the frame has been forwarded to the MAC Transmitter engine in Store-and-Forward mode without the end-of-frame being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

35.2.5.2 Receive Path

This module receives the frames given out by the GMAC core and pushes them into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured Receive threshold (RTC of DMA Register 6). The MTL also indicates the FIFO fill level so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

Receive Operation through **Receive Status Word** detail receive operations for the MTL Layer.

Receive Operation

During an Rx operation, the MTL is slaved to the GMAC. The general sequence of Receive operation events is as follows:

1. When the GMAC receives a frame, it pushes in data along with byte enables. The GMAC also indicates the SOF and EOF. The MTL accepts the data and pushes it into the Rx FIFO. After the EOF is transferred, the GMAC drives the status word, which is also pushed into the same Rx FIFO by the MTL.
2. When IEEE 1588 time stamping is enabled and the 64-bit time stamp is available along with the receive status, it is appended to the frame received from the GMAC and is pushed into the Rx FIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing the time stamp in the Rx FIFO.
3. The MTL_RX engine takes the data out of the FIFO and sends it to the DMA. In the default Cut-Through mode, when 64 bytes (configured with RTC bits of DMA Register 6) or a full packet of data are received into the FIFO, the MTL_RX engine pops out the data and indicates its availability to the DMA. Once the DMA initiates the transfer to the AHBinterface, the MTL_RX engine continues to transfer data from the FIFO until a complete packet has been transferred. Upon completion of the EOF frame transfer, the MTL pops out the status word and sends it to the DMA controller.
4. In Rx FIFO Store-and-Forward mode (configured by the RSF bit of DMA Register 6), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only valid frames are read out and forwarded to the application. In Cut-Through mode, some error frames are not dropped, because the error status is received at the end-of-frame, by which time the start of that frame has already been read out of the FIFO.

Note: In 32-bit data bus mode, the time-stamp transfer takes two clock cycles and the lower 32-bit of the time-stamp is given out first. The status also may be extended to two cycles when Advanced Time-stamp feature is enabled.

Receive Operation Multiframe Handling

Since the status is available immediately following the data, the MTL is capable of storing any number of frames into the FIFO, as long as it is not full.

GMAC Flow Control

The flow control operation of the GMAC can also be enabled (EFC bit of DMA Register 6) by the Rx FIFO control logic. The flow control signal to the GMAC is asserted whenever the Rx FIFO fill level crosses the configured threshold (RFA bits of DMA Register 6). This flow control signal is deasserted once the FIFO fill-level falls below the

Ethernet MAC (ETH)

configured threshold (RFD bits). This operation is independent of whether the GMAC is configured for full-duplex or half-duplex.

The above hardware flow control operation is applicable only when the Rx FIFO is 4.096 or more bytes deep. A separate sideband flow control signal (sbd_flowctrl_i) is optionally provided at the top-level I/O for all GMAC-AHB, GMAC-AXI, GMAC-DMA and GMAC-MTL configurations. For 4.096-byte or larger Rx FIFOs, this sideband signal is logically ORed with the hardware flow control signal. Thus, flow control is enabled when either of these signals is asserted and disabled when both these signals are deasserted.

Error Handling

If the MTL Rx FIFO is full before it receives the EOF data from the GMAC, an overflow is declared, the whole frame (including the status word) is dropped, and the overflow counter in the DMA (Register 8) is incremented. This is true even if the Forward Error Frame (FEF bit of DMA Register 6) is set. If the start address of such a frame has already been transferred to the Read Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status will indicate a partial frame due to overflow. In such frames, the Frame Length field is invalid.

The MTL Rx Control logic can filter error and undersized frames, if enabled (using the DMA Register 6 FEF and FUF bits). If the start address of such a frame has already been transferred to the Rx FIFO Read Controller, that frame is not filtered. The start address of the frame is transferred to the Read Controller after the frame crosses the receive threshold (set by the DMA Register 6 RTC bits).

If the MTL Receive FIFO is configured to operate in Store-and-Forward mode, all error frames can be filtered and dropped.

Receive Status Word

At the end of the transfer of the Ethernet frame to the host, the MTL outputs the receive status to the Application. The detailed description of the receive status is the same as for Bits[31:0] of RDES0, given in [Table 35-23](#), except that Bits 31, 14, 9, and 8 are reserved and have a reset of 1'b0 by default. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

Note: When Advanced Time Stamp feature is enabled, the status is composed of two parts - normal (default [31:0]), and extended. The extended status[63:32] gives the information about the received ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. In 32-bit data-bus, these are transferred over two clock cycles. The detailed description of the receive status is the same as described in RDES0 and RDES4 in [Receive Descriptor](#), except that bits 31, 14, 9, and 8 of normal status is reserved and have a reset value of 1'b0. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

35.2.6 GMAC Core

The GMAC core supports many interfaces towards the PHY chip. In TC26x B-Step RMII is implemented. The PHY interface can be selected only once after reset. The GMAC core communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI) and the MAC Control Interface (MCI).

35.2.6.1 Transmission

Transmission is initiated when the MTL Application pushes in data with the SOF . When the SOF signal is detected, the GMAC accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the RMII/MII after the Application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-Duplex mode. Until then, the GMAC does not accept the data received from MTL.

After the EOF is transferred to the GMAC Core, the core complete normal transmission and then gives the Status of Transmission back to the MTL. If a normal collision (in Half-duplex mode) occurs during transmission, the GMAC core makes valid the Transmit Status to the MTL. It then accepts and drops all further data until the next SOF is received. The MTL block should retransmit the same frame from SOF on observing a Retry request (in the Status) from the GMAC.

The GMAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. During the normal transfer of a frame from MTL, if the GMAC receives a SOF without getting an EOF for the previous frame, then it (the SOF) is ignored and the new frame is considered as continuation of the previous frame.

The following six modules constitute the transmission function of the GMAC:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module

This module interfaces the transmit path of the GMAC core with the external frame with a FIFO interface.

This module also outputs the (32-bit) Transmit Status to the application at the end of normal transmission or collision.

Additionally, this module outputs the Transmit Snapshot register value.

Transmit Frame Controller Module

The Transmit Frame Controller (TFC) consists of two registers to hold data, byte enables, and the last data control received from the TBU. The register provides a buffer between the Application and the TPE to regulate data flow as well as converts the input data into an 8-bit bus towards the TPE.

When the number of bytes received from the Application falls below 60 (DA+SA+LT+DATA), the state machine that interfaces with the TBU automatically appends zeros to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The GMAC can be programmed not to append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by CTX module. The TFC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the GMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the GMAC is programmed to append pads for frames (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TFC module will append the CRC at the end of padded frame.

The TFC converts the data received on the 32/64/128-bit interface from the TBU into 8-bit data for the TPE module.

Transmit Protocol Engine Module

The Transmit Protocol Engine (TPE) module consists of a transmit state machine that controls the operation of Ethernet frame transmission. The module's transmit state machine performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates jam pattern in Half-Duplex mode
- Jabber timeout
- Flow control for Half-Duplex mode (back pressure)
- Generates transmit frame status
- Contains time stamp snapshot logic for IEEE 1588 support

When a new frame transmission from the TFC is requested, the transmit state machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 8'b10101010 pattern, and the SFD is defined as 1 byte of 8b'10101011 pattern.

The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-Duplex mode, not to Full-Duplex mode. In Full-Duplex mode, the transmit state machine ignores the phy_col_i signal from the PHY.

Ethernet MAC (ETH)

In MII mode, if a collision occurs any time from the beginning of the frame to the end of the CRC field, the transmit state machine sends a 32-bit jam pattern of 32'h55555555 on the MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the transmit state machine completes the transmission of preamble and SFD and then sends the jam pattern.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Frame Burst mode is enabled), the transmit state machine sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status.

The TPE module maintains a jabber timer (only in 10/100-Mbit/s mode) to cut off the transmission of Ethernet frames if the TFC module transfers more than 2.048 (default) bytes. The time-out is changed to 10.240 bytes when the Jumbo frame is enabled.

The Transmit state machine uses the deferral mechanism for the flow control (Back Pressure) in Half-Duplex mode. When the Application requests to stop receiving frames, the Transmit state machine sends a JAM pattern of 32 bytes whenever it senses a reception of a frame, provided the transmit flow control is enabled. This will result in a collision and the remote station will back off. The Application requests the flow control by setting BPA bit of Register6. If the application requests a frame to be transmitted, then it will be scheduled and transmitted even when the backpressure is activated. Note that if the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations will abort their transmissions due to excessive collisions.

If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus. The system time source is either an external input or internally generated, according to the configuration selected.

Transmit Scheduler Module

The Transmit Scheduler (STX) module is responsible for scheduling the frame transmission on the MII. The two major functions of this module are to maintain the inter-frame gap between two transmitted frames and to follow the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode. This module provides an enable signal to the TPE module after satisfying the IFG and Back-off delays.

The STX module maintains an idle period of the configured inter-frame gap (IFG bits of Register 0 between any two transmitted frames. If frames from the TFC arrive at the TPE module sooner than the configured IFG time, the TPE module waits for the enable signal from the STX module before starting the transmission on the MII. The STX module starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of programmed IFG value, the module issues an enable signal to the TPE module in Full-Duplex mode. In Half-Duplex mode and when IFG is configured for 96 bit times, the STX module follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3

Ethernet MAC (ETH)

specification. The module resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the STX module continues the IFG count and enables the transmitter after the IFG interval.

The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in Half-Duplex mode.

Transmit CRC Generator Module

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet frame. The TFC module sends the frame data and any necessary padding to the CTX module through an 8-bit interface.

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The module gets the Ethernet frame's byte data from the TFC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TFC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming frame. The TFC module issues the start command before sending the new frame data for calculation. The calculated CRC is valid on the next clock after the data is received.

Transmit Flow Control Module

The Transmit Flow Control (FTX) module generates Pause frames and transmit them to the TFC module as necessary, in Full-Duplex mode. The TFC module receives the Pause frame from the FTX module, appends the calculated CRC, and sends the frame to the TPE module. Pause frame generation can be initiated in two ways. The Application can request the FTX module to send a Pause frame either by setting the FCB bit in the Flow Control register Register 6 or by asserting the `mti_flowctrl_i` signal in response to the receive FIFO full conditions (packet buffer).

If the Application has requested the flow control by setting the FCB bit of Register 6, the FTX module will generate and transmit a single Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in Register 6. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time register with appropriate value.

If the Application has requested the flow control by asserting the `mti_flowctrl_i` signal, the FTX module will generate and transmit a Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in the Register 6. The FTX module monitors the `mti_flowctrl_i` signal. If it remains asserted at a configurable number of slot-times (PLT bits of GMAC Register 6) before this Pause-

Ethernet MAC (ETH)

time runs-out, a second Pause frame will be transmitted to the TFC module. The process will be repeated as long as the `mti_flowctrl` signal remains asserted.

If the `mti_flowctrl_i` signal goes inactive prior to the sampling time, the FTX module will transmit a Pause frame with zero Pause Time to indicate to the remote end that the receive buffer is ready to receive new data frames.

35.2.6.2 MAC Transmit Interface Protocol

The MAC Transmit Interface (MTI) connects the application (MTL module in the GMAC) with the GMAC to provide the Ethernet data for transmission.

The application initiates the Ethernet frame transmission by writing the first data of the frame to the GMAC, provided the GMAC is ready to accept data. The Application can push-in data as long as the GMAC core is ready to accept it.

If the frame transmission is not successful (due to underflow, collision, jabber timeout, excessive deferral events), the GMAC core will assert the transmit status even before the EOF is received. The Application will have to take the appropriate action as per the status. The GMAC will drop all further data input to it until the next SOF.

35.2.6.3 Reception

A receive operation is initiated when the GMAC detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The received frame is stored in a shallow buffer until the address filtering is performed. The frame is dropped in the core if it fails the address filter.

The following are the functional blocks in the Receive path of the GMAC core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Frame Controller Module (RFC)
- Receive Flow Control Module (FRX)
- Receive IP Checksum checker (IPC)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module

The RPE consists of the receive state machine which strips the preamble and SFD. Once the `phy_rxdv_i` signal of the MII becomes active, the RPE's receive state machine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, the state machine begins sending the data of the Ethernet frame to the RFC module, beginning with the first byte following the SFD (destination address).

Ethernet MAC (ETH)

If IEEE 1588 time stamping is enabled, the RPE takes a snapshot of the system time when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

In MII mode, the RPE converts the received nibble data into bytes, then forwards the valid frame data to the RFC module

The receive state machine of the RPE module decodes the Length/Type field of the receiving Ethernet frame. If the Length/Type field is less than 600 (hex) and if the MAC is programmed for the auto crc/pad stripping option, the state machine sends the data of the frame up to the count specified in the Length/Type field, then starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the Length/Type field and checks for the Length interpretation.

If the Length/Type field is greater than or equal to 600 (hex), the RPE module will send all received Ethernet frame data to the RFC module, irrespective of the value on the programmed auto-CRC strip option.

As a default, the GMAC is programmed for watchdog timer to be enabled, that is, frames above 2.048 (10.240 if Jumbo Frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. This feature can be disabled by programming the GMAC Configuration register, Watchdog Disable. However even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog time-out status is given.

The GMAC supports loopback of transmitted frames onto its receiver. As a default, the GMAC loopback function is disabled, but this feature can be enabled by programming the GMAC Configuration register, Loopback bit. The transmit and receive clocks can have an asynchronous timing relationship, so an asynchronous FIFO is used to make the loopback path of the phy_txd_o data onto the receive path. The asynchronous FIFO is 10 bits (6 bits in 10/100 Mbit/s mode) wide to accommodate phy_txd_o, phy_txen_o, and phy_txer_o. The FIFO is nine deep in 10/100 Mbit/s mode and free-running to write on the write clock (clk_tx_i) and read on every read clock (clk_rx_i).

The write and read pointers get re-initialized to have an offset of 2 (4 in 10/100 Mbit/s mode) at the start of each frame read out of the FIFO. This helps to avoid overflow/underflow during the transfer of a frame, and ensures that the overflow/underflow occurs only during the IFG period between the frames. Please note that the FIFO depth of nine is sufficient to prevent data corruption for frame sizes up to 9.022 bytes with a difference of 200 ppm between the MII Transmit and Receive clock frequencies. Hence, bigger frames should not be looped back, as they may get corrupted in this loopback FIFO.

At the end of every received frame, the RPE module generates received frame status and sends it to the RFC module. Control, missed frame, and filter fail status are added to the receive status in the RFC module.

Receive CRC Module

The Receive CRC (CRX) interfaces to the RPE module to check for any CRC error in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following generating polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The module gets the data from the RPE module (DA+SA+LT+DATA+PAD+FCS). The RPE module also sends a control signal that indicates the validity of the data. Irrespective of the auto pad/CRC strip, the CRX module receives the entire frame to compute the CRC check for received frame. As a note on the auto pad/CRC strip settings, the entire frame is not transferred between the RPE and RFC 8-bit interface.

Receive Checksum Offload Engine

The Checksum Offload engine is optional (not available in the default configuration) and selectable during configuration. Two types of Receive Checksum Offload engine are available for configuration. Full Checksum Offload, the Type 2 engine is instantiated.

Type 2

In this mode, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. You can enable this module by setting the IPC bit in the GMAC Configuration register. The GMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frames' Type field. This identification applies to VLAN-tagged frames as well.

The Receive Checksum Offload engine calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

Ethernet MAC (ETH)

As mentioned in [TCP/UDP/ICMP Checksum Engine](#), this engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP.

In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

Receive Frame Controller Module

The Receive Frame Controller (RFC) receives the Ethernet frame data and status from the RPE module. The RFC module consists of a FIFO of parameterized depth (default set to 4 deep and 37 bits wide) and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet frame data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a frame buffering for the receiving Ethernet frame from the RPE module. The main functions of the RFC module are:

- Data path conversion, which converts the 8-bit data to 32-bit data to the RBU module.
- Frame filtering
- Attaching the calculated IP Checksum input from IPC.
- Update the Receive Status and forward to RBU.

If the RA bit of the GMAC CSR Frame Filter register is set, the RFC module initiates the data transfer to the RBU module as soon as 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RFC module sends out the received frame status that includes the frame filter bits (SA Filterfail and DAFilterfail) and status from the RFC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the Application whether the received frame has passed the filter controls (both address filter and Frame Filter controls from CSR). The RFC module will not drop any frame on its own in this mode.

If the RA bit is reset, the RFC module performs frame filtering based on the destination/source address (the Application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc. The RFC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module will not initiate any transfers to the RBU module. After receiving the destination/source address bytes, the RFC checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFB, the frame is dropped at the RFC module and not transferred to the Application.

On a delayed filter response from the AFM (this can only occur if you change the AFM logic), the RFC module waits until the FIFO is full, and then proceeds with the frame transfer to the RBU module. However, it will still take the delayed response from the AFM module and if it is a (DA/SA) filter failure, then it will drop the rest of the frame and send the Rx Status Word (with zero frame-length, CRC Error and Runt Error bits set) immediately indicating the filter-fail. If there is no response from the AFM until the end of frame is transmitted, the filter fail status in the Rx Status Word is updated accordingly.

Ethernet MAC (ETH)

When the PMT module is configured for power-down mode, all received frames are dropped by this block, and are not forwarded to the application.

Receive Flow Control Module

The Receive Flow Controller (FRX) detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame. The FRX module is enabled only in Full-Duplex mode. The Pause frame detection function can be enabled or disabled with the RFE bit of GMAC CSR Register 6.

Once the receive flow control is enabled, the FRX module begins monitoring the received frame destination address for any match with the multicast address of the control frame (48'h0180C200001). If a match is detected, the FRX module indicates to the RFC module, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether or not to transfer the received control frame to the Application, based on the (PCF) bit setting of GMAC CSR Register 1 (Filter register).

The FRX module also decodes the Type, Op-code, and Pause Timer field of the receiving control frame. At the end of received frame, the FRX module gets the received frame status from RPE. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the FRX module requests the MAC transmitter to pause the transmission of any data frame for the duration of the decoded Pause Time value, multiplied by the slot time (64 byte times). Meanwhile, if another Pause frame is detected with a zero Pause Time value, the FRX module resets the Pause Time and gives another pause request to the Transmitter. If the received control frame matches neither the Type field (16'h8808), Opcode (16'h00001), nor byte length (64 bytes), or if there is a CRC error, the FRX module does not generate a Pause request to Transmitter.

In the case of a pause frame with a multicast destination address, the RFC filters the frame based on the address match from the FRX module. For a pause frame with a unicast destination address, the filtering in the FRX module depends on whether the DA matched the contents of the MAC Address Register 0 and the UP Bit of GMAC Core Register 6 is set (detecting a pause frame even with a unicast destination address). The PCF register bits (Bit [7:6] of GMAC Register 1) controls the filtering for control frames in addition to the Address filter module.

Receive Bus Interface Unit Module

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RFC module into a 32-bit FIFO protocol on the Application side. The RBU module interfaces with the Application through the MAC receive interface (MRI).

If IEEE 1588 time stamping is enabled, the RBU also outputs the time stamp captured from the received frame.

Address Filtering Module

The Address Filtering (AFM) module performs the destination and source address checking function on all received frames and reports the address filtering status to the RFC module. The address checking is based on different parameters (Frame Filter register) chosen by the Application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive frames by itself, but reports the status of the address filtering (whether to drop the frame or not) to the RFC module. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. In Mill mode the module takes 14/26 clocks (from the start of frame) to compare the destination/ source address of the receiving frame. The AFM module gets the station's physical (MAC) address and the Multicast Hash table from CSR module for address checking. The CSR module provides the Frame Filter register parameters to AFM.

Unicast Destination Address Filter

The AFM supports up to 32 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Frame Filter register is reset), the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr31 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr31) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA.

In Hash filtering mode (When HUC bit is set), the AFM performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register, and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Multicast Destination Address Filter

The GMAC can be programmed to pass all multicast frames by setting the PM bit in the Frame Filter register. If the PM bit is reset, the AFM performs the filtering for multicast addresses based on the HMC bit of Frame Filter register. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

Ethernet MAC (ETH)

In Hash filtering mode, the AFM performs imperfect filtering using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register and a value of 111111 selects Bit 63 of the Hash Table register.

If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Hash or Perfect Address Filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the HPF bit of the Frame Filter register and setting the corresponding HUC or HMC bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

Broadcast Address Filter

The AFM doesn't filter any broadcast frames in the default mode. However, if the GMAC is programmed to reject all broadcast frames by setting the DBF bit in the Frame Filter register, the DAF module asserts the Filter fail signal to RFC, whenever a broadcast frame is received. This will tell the RFC module to drop the frame.

Unicast Source Address Filter

The GMAC can also perform a perfect filtering based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC Address registers [1:31] can be configured to contain SA instead of DA for comparison, by setting Bit 30 of the corresponding Register. Group filtering with SA is also supported. The frames that fail the SA Filter are dropped by the GMAC if the SAF bit of Frame Filter register is set.

When SAF bit is set, the result of SA Filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result will drop the frame and both filters have to pass in-order to forward the frame to the application.

Inverse Filtering Operation

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits of the Frame Filter register respectively. The DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 35-8 and **Table 35-9** summarize the Destination and Source Address filtering based on the type of frames received.

Table 35-8 Destination Address Filtering Table

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames.
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match.
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match.
	0	0	1	0	X	X	X	Pass on Hash filter match.
	0	0	1	1	X	X	X	Fail on Hash filter match.
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match.
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match.
Multicast	1	X	X	X	X	X	X	Pass all frames.
	X	X	X	X	X	1	X	Pass all frames.
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	0	X	0	1	0	X	Pass on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 35-8 Destination Address Filtering Table (cont'd)

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DB	DA Filter Operation
	0	0	X	1	1	0	X	Fail on Hash filter match and drop PAUSE control frames if PCF = 0x.
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.

Table 35-9 Source Address Filtering Table

Frame Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all frames.
	0	0	0	Pass status on Perfect/Group filter match but do not drop frames that fail.
	0	1	0	Fail status on Perfect/Group filter match but do not drop frame.
	0	0	1	Pass on Perfect/Group filter match and drop frames that fail.
	0	1	1	Fail on Perfect/Group filter match and drop frames that fail.

35.2.6.4 System Time Register Module

64-bit time is maintained in this module and updated using the input reference clock. This time is the source for taking snapshots (time stamps) of Ethernet frames being transmitted or received at the MII.

The System Time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Time Stamp Update register. For initialization, the System Time counter is written with the value in the Time Stamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, a slave clock's frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in

Figure 35-10. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider. This algorithm is depicted in **Figure 35-10**:

Figure 35-10 System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is, for example, 66 MHz, this ratio is calculated as $66 \text{ MHz} / 50 \text{ MHz} = 1.32$. Hence, the default addend value to be set in the register is $2^{32} / 1.32$, `0xC1F07C1F`.

Ethernet MAC (ETH)

If the reference clock drifts lower, to 65 MHz for example, the ratio is $65 / 50$, or 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F ($2^{32} / 1.32$) must be programmed.

In **Figure 35-10**, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps). Two different methods are used to update the System Time register, depending on which configuration you choose (See **Architecture**).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue}_0 = 2^{32} / \text{FreqDivisionRatio}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time MasterSyncTime_n the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime_n and computes MasterClockTime_n as:

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n$$
- The master clock count for current Sync cycle, MasterClockCount_n is given by:

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$
 (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, SlaveClockCount_n is given by:

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}$$
- The difference between master and slave clock counts for current Sync cycle, ClockDiffCount_n is given by:

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n$$
- The frequency-scaling factor for slave clock, FreqScaleFactor_n is given by:

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n$$
- The frequency compensation value for Addend register, FreqCompensationValue_n is given by:

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n * \text{FreqCompensationValue}_{n-1}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm will correct it at the cost of more Sync cycles.

35.2.7 MAC Management Counters

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32 bits wide. The write data is qualified with the corresponding `mci_be_i` signals. Thus, non-32-bit accesses are allowed as long as the address is word-aligned.

The organization of these registers is shown in [Table 1-17](#). The MMCs are accessed using transactions, in the same way the CSR address space is accessed. The following sections in the chapter describe the various counters and list the address for each of the statistics counters. This address will be used for Read/Write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that are passed by the Address Filter (AFM) block. Statistics of frames that are dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes (DA bytes are not received fully).

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet frames. This gathering is only enabled when Full Checksum Offload Engine is selected during RTL configuration. The address map of the corresponding registers, 0x0200–0x02FC, is given in [Table 1-17](#).

35.2.7.1 Address Assignments

The MMC register naming convention is as follows.

- “tx” as a prefix or suffix indicates counters associated with transmission
- “rx” as a prefix or suffix indicates counters associated with reception
- “_g” as a suffix indicates registers that count good frames only
- “_gb” as a suffix indicates registers that count frames regardless of whether they are good or bad

The following explanations pertain to terminology used in [Table 1-17](#) through [Table 1-24](#).

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- Jabber Timeout

- No Carrier/Loss of Carrier
- Late Collision
- Frame Underflow
- Excessive Deferral
- Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- CRC error
- Runt Frame (shorter than 64 bytes)
- Alignment error (in 10/100 Mbit/s only)
- Length error (non-Type frames only)
- Out of Range (non-Type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN Frame maxsize = 1522
- Jumbo Frame maxsize = 9018
- JumboVLAN Frame maxsize = 9022

Table 35-10 MMC Register Map

GMAC CSR Register No.	Address Offset	Register Name	Register Description
64	0x0100	mmc_cntrl	MMC Control establishes the operating mode of MMC. For more details, refer to Table 1-18 .
65	0x0104	mmc_intr_rx	MMC Receive Interrupt maintains the interrupt generated from all of the receive statistic counters. For more details, refer to Table 1-19 .
66	0x0108	mmc_intr_tx	MMC Transmit Interrupt maintains the interrupt generated from all of the transmit statistic counters. For more details, refer to Table 1-20 .
67	0x010C	mmc_intr_mask_rx	MMC Receive Interrupt mask maintains the mask for the interrupt generated from all of the receive statistic counters. For more details, refer to Table 1-21 .

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
68	0x0110	mmc_intr_mask_tx	MMC Transmit Interrupt Mask maintains the mask for the interrupt generated from all of the transmit statistic counters. For more details, refer to Table 1-22 .
69	0x0114	txoctetcount_gb	Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames.
70	0x0118	txframecount_gb	Number of good and bad frames transmitted, exclusive of retried frames.
71	0x011C	txbroadcastframes_g	Number of good broadcast frames transmitted.
72	0x0120	txmulticastframes_g	Number of good multicast frames transmitted.
73	0x0124	tx64octets_gb	Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames.
74	0x0128	tx65to127octets_gb	Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.
75	0x012C	tx128to255octets_gb	Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.
76	0x0130	tx256to511octets_gb	Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.
77	0x0134	tx512to1023octets_g	Number of good and bad frames transmitted with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble and retried frames.

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
78	0x0138	tx1024tomaxoctets_gb	Number of good and bad frames transmitted with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
79	0x013C	txunicastframes_gb	Number of good and bad unicast frames transmitted.
80	0x0140	txmulticastframes_gb	Number of good and bad multicast frames transmitted.
81	0x0144	txbroadcastframes_gb	Number of good and bad broadcast frames transmitted.
82	0x0148	txunderflowerror	Number of frames aborted due to frame underflow error.
83	0x014C	txsinglecol_g	Number of successfully transmitted frames after a single collision in Half-duplex mode.
84	0x0150	txmulticol_g	Number of successfully transmitted frames after more than a single collision in Half-duplex mode.
85	0x0154	txdeferred	Number of successfully transmitted frames after a deferral in Half-duplex mode.
86	0x0158	txlatecol	Number of frames aborted due to late collision error.
87	0x015C	txexesscol	Number of frames aborted due to excessive (16) collision errors.
88	0x0160	txcarriererror	Number of frames aborted due to carrier sense error (no carrier or loss of carrier).
89	0x0164	txoctetcount_g	Number of bytes transmitted, exclusive of preamble, in good frames only.
90	0x0168	txframecount_g	Number of good frames transmitted.
91	0x016C	txexcessdef	Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times).

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
92	0x0170	txpauseframes	Number of good PAUSE frames transmitted.
93	0x0174	txvlanframes_g	Number of good VLAN frames transmitted, exclusive of retried frames.
94	0x0178	Reserved	
95	0x017C	Reserved	
96	0x0180	rxframecount_gb	Number of good and bad frames received.
97	0x0184	rxoctetcount_gb	Number of bytes received, exclusive of preamble, in good and bad frames.
98	0x0188	rxoctetcount_g	Number of bytes received, exclusive of preamble, only in good frames.
99	0x018C	rxbroadcastframes_g	Number of good broadcast frames received.
100	0x0190	rxmulticastframes_g	Number of good multicast frames received.
101	0x0194	rxrcrcerror	Number of frames received with CRC error.
102	0x0198	rxalignmenterror	Number of frames received with alignment (dribble) error.
103	0x019C	rxrunterror	Number of frames received with runt (<64 bytes and CRC error) error.
104	0x01A0	rxjabbererror	Number of giant frames received with length (including CRC) greater than 1.518 bytes (1.522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.
105	0x01A4	rxundersize_g	Number of frames received with length less than 64 bytes, without any errors.
106	0x01A8	rxoversize_g	Number of frames received with length greater than the maxsize (1.518 or 1.522 for VLAN tagged frames), without errors.

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
107	0x01AC	rx64octets_gb	Number of good and bad frames received with length 64 bytes, exclusive of preamble.
108	0x01B0	rx65to127octets_gb	Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.
109	0x01B4	rx128to255octets_gb	Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble.
110	0x01B8	rx256to511octets_gb	Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble.
111	0x01BC	rx512to1023octets_gb	Number of good and bad frames received with length between 512 and 1.023 (inclusive) bytes, exclusive of preamble.
112	0x01C0	rx1024tomaxoctets_gb	Number of good and bad frames received with length between 1.024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
113	0x01C4	rxunicastframes_g	Number of good unicast frames received.
114	0x01C8	rxlengtherror	Number of frames received with length error (Length type field $\frac{1}{4}$ frame size), for all frames with valid length field.
115	0x01CC	rxoutofrangetype	Number of frames received with length field not equal to the valid frame size (greater than 1.500 but less than 1.536).
116	0x01D0	rxpauseframes	Number of good and valid PAUSE frames received.
117	0x01D4	rxfifooverflow	Number of missed received frames due to FIFO overflow.
118	0x01D8	rxvlanframes_gb	Number of good and bad VLAN frames received.

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
119	0x01DC	rxwatchdogerror	Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2.048 bytes).
120:127	0x01E0–0x01FC	Reserved	
128	0x0200	mmc_ipc_intr_mask_rx	MMC IPC Receive Checksum Offload Interrupt Mask maintains the mask for the interrupt generated from the receive IPC statistic counters. See Table 1-23 for further detail.
129	0x0204	Reserved	
130	0x0208	mmc_ipc_intr_rx	MMC Receive Checksum Offload Interrupt maintains the interrupt that the receive IPC statistic counters generate. See Table 1-24 for further detail.
131	0x020C	Reserved	
132	0x0210	rxipv4_gd_frms	Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload
133	0x0214	rxipv4_hdrerr_frms	Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors
134	0x0218	rxipv4_nopay_frms	Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine
135	0x021C	rxipv4_frag_frms	Number of good IPv4 datagrams with fragmentation
136	0x0220	rxipv4_udtbl_frms	Number of good IPv4 datagrams received that had a UDP payload with checksum disabled
137	0x0224	rxipv6_gd_frms	Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
138	0x0228	rxipv6_hdrerr_frms	Number of IPv6 datagrams received with header errors (length or version mismatch)
139	0x022C	rxipv6_nopay_frms	Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers
140	0x0230	rxudp_gd_frms	Number of good IP datagrams with a good UDP payload. This counter is not updated when the rxipv4_udtbl_frms counter is incremented.
141	0x0234	rxudp_err_frms	Number of good IP datagrams whose UDP payload has a checksum error
142	0x0238	rttcp_gd_frms	Number of good IP datagrams with a good TCP payload
143	0x023C	rttcp_err_frms	Number of good IP datagrams whose TCP payload has a checksum error
144	0x0240	rxicmp_gd_frms	Number of good IP datagrams with a good ICMP payload
145	0x0244	rxicmp_err_frms	Number of good IP datagrams whose ICMP payload has a checksum error
146:147	0x0248–0x024C	Reserved	
148	0x0250	rxipv4_gd_octets	Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. (Ethernet header, FCS, pad, or IP pad bytes are not included in this counter or in the octet counters listed below).
149	0x0254	rxipv4_hdrerr_octets	Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter.

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
150	0x0258	rxipv4_nopay_octets	Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 header's Length field is used to update this counter.
151	0x025C	rxipv4_frag_octets	Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 header's Length field is used to update this counter.
152	0x0260	rxipv4_udtbl_octets	Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes.
153	0x0264	rxipv6_gd_octets	Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data
154	0x0268	rxipv6_hdrerr_octets	Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 header's Length field is used to update this counter.
155	0x026C	rxipv6_nopay_octets	Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 header's Length field is used to update this counter.
156	0x0270	rxudp_gd_octets	Number of bytes received in a good UDP segment. This counter (and the counters below) does not count IP header bytes.
157	0x0274	rxudp_err_octets	Number of bytes received in a UDP segment that had checksum errors
158	0x0278	rtcp_gd_octets	Number of bytes received in a good TCP segment

Table 35-10 MMC Register Map (cont'd)

GMAC CSR Register No.	Address Offset	Register Name	Register Description
159	0x027C	rxtcp_err_octets	Number of bytes received in a TCP segment with checksum errors
160	0x0280	rxicmp_gd_octets	Number of bytes received in a good ICMP segment
161	0x0284	rxicmp_err_octets	Number of bytes received in an ICMP segment with checksum errors
162:191	0x0288–0x02FC	Reserved	

35.2.7.2 MMC Register Description

MMC Control Register

The MMC Control register establishes the operating mode of the management counters.

Table 35-11 MMC Control Register

Bit	Access Type	Reset Value	Description
31:6	R	0000_000H	Reserved
5	rw	0	Full-Half preset When low and bit4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16) When high and bit4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16)

Table 35-11 MMC Control Register (cont'd)

Bit	Access Type	Reset Value	Description
4	rwh	0	Counters Preset When set, all counters will be initialized or preset to almost full or almost half as per Bit5 above. This bit will be cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts due to MMC counter becoming half-full or full.
3	rw	0	MMC Counter Freeze When set, this bit freezes all the MMC counters to their current value. (None of the MMC counters are updated due to any transmitted or received frame until this bit is reset to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)
2	rw	0	Reset on Read When set, the MMC counters will be reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
1	rw	0	Counter Stop Rollover When set, counter after reaching maximum value will not roll over to zero.
0	rwh	0	Counters Reset When set, all counters will be reset. This bit will be cleared automatically after 1 clock cycle

Note: When Bit 0 and Bit 4 are set in the same cycle, Counters get preset immediately after getting cleared.

MMC Receive Interrupt Register

The MMC Receive Interrupt register maintains the interrupts generated when the receive statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 35-12 MMC Receive Interrupt Register

Bit	Access Type	Reset Value	Description
31:24	r	00H	Reserved
23	rh	0	The bit is set when the rxwatchdog error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the rxvlanframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the rxfifooverflow counter reaches half the maximum value, and also when it reaches the maximum value.
20	rh	0	The bit is set when the rxpauseframes counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the rxoutofrangetype counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the rxlengtherror counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the rxunicastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the rx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the rx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the rx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the rx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 35-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
12	rh	0	The bit is set when the rx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the rx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the rxoversize_g counter reaches half the maximum value, and also when it reaches the maximum value.
9	rh	0	The bit is set when the rxundersize_g counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the rxjabbererror counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the rxrunterror counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the rxalignmenterror counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the rxrcerror counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the rxmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the rxbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the rxoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 35-12 MMC Receive Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rh	0	The bit is set when the rxoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the rxframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Note: rh means that this register bit is set internally and is cleared when the Counter register is read.

MMC Transmit Interrupt Register

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000), and when they cross their maximum values (0xFFFF_FFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Note: Access restriction applies: Any read access to the register clears this register!

Table 35-13 MMC Transmit Interrupt Register

Bit	Access Type	Reset Value	Description
31:25	r	00 _H	Reserved
24	rh	0	The bit is set when the txvlanframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
23	rh	0	The bit is set when the txpauseframes error counter reaches half the maximum value, and also when it reaches the maximum value.
22	rh	0	The bit is set when the txoexcessdef counter reaches half the maximum value, and also when it reaches the maximum value.
21	rh	0	The bit is set when the txframecount_g counter reaches half the maximum value, and also when it reaches the maximum value.

Table 35-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
20	rh	0	The bit is set when the txoctetcount_g counter reaches half the maximum value, and also when it reaches the maximum value.
19	rh	0	The bit is set when the txcarriererror counter reaches half the maximum value, and also when it reaches the maximum value.
18	rh	0	The bit is set when the txexesscol counter reaches half the maximum value, and also when it reaches the maximum value.
17	rh	0	The bit is set when the txlatecol counter reaches half the maximum value, and also when it reaches the maximum value.
16	rh	0	The bit is set when the txdeferred counter reaches half the maximum value, and also when it reaches the maximum value.
15	rh	0	The bit is set when the txmulticol_g counter reaches half the maximum value, and also when it reaches the maximum value.
14	rh	0	The bit is set when the txsinglecol_g counter reaches half the maximum value, and also when it reaches the maximum value.
13	rh	0	The bit is set when the txunderflowerror counter reaches half the maximum value, and also when it reaches the maximum value.
12	rh	0	The bit is set when the txbroadcastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
11	rh	0	The bit is set when the txmulticastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.
10	rh	0	The bit is set when the txunicastframes_gb counter reaches half the maximum value, and also when it reaches the maximum value.

Table 35-13 MMC Transmit Interrupt Register (cont'd)

Bit	Access Type	Reset Value	Description
9	rh	0	The bit is set when the tx1024tomaxoctets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
8	rh	0	The bit is set when the tx512to1023octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
7	rh	0	The bit is set when the tx256to511octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
6	rh	0	The bit is set when the tx128to255octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
5	rh	0	The bit is set when the tx65to127octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
4	rh	0	The bit is set when the tx64octets_gb counter reaches half the maximum value, and also when it reaches the maximum value.
3	rh	0	The bit is set when the txmulticastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
2	rh	0	The bit is set when the txbroadcastframes_g counter reaches half the maximum value, and also when it reaches the maximum value.
1	rh	0	The bit is set when the txframecount_gb counter reaches half the maximum value, and also when it reaches the maximum value.
0	rh	0	The bit is set when the txoctetcount_gb counter reaches half the maximum value, and also when it reaches the maximum value.

MMC Receive Interrupt Mask Register

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Table 35-14 MMC Receive Interrupt Mask Interrupt Register

Bit	Access Type	Reset Value	Description

35.2.8 Power Management Block

This section describes the power management (PMT) mechanisms supported by the GMAC. PMT supports the reception of network (remote) wake-up frames and Magic Packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and Magic Packets received by the GMAC. The PMT block sits on the receiver path of the GMAC and is enabled with remote wake-up frame enable and Magic Packet enable. These enables are in the PMT Control and Status register and are programmed by the Application. You can include the optional PMT module by selecting it in the coreKit during configuration. You have the option to select either or both types of power-management frames (remote wake-up and Magic Packet)

PMT registers are accessed in the same manner as with GMAC-CSR registers. Refer to registers 10 and 11, for mapping information.

When the power down mode is enabled in the PMT, then all received frames are dropped by the core and they are not forwarded to the application. The core comes out of the power down mode only when either a Magic Packet or a Remote Wake-up frame is received and the corresponding detection is enabled.

35.2.8.1 PMT Block Description

PMT Control and Status Register

The PMT CSR program the request wake-up events and monitor the wake-up events.

Note: Access restriction applies: Any read access to the register clears this register!

Table 35-18 PMT Control and Status Register

Bit	Access Type	Reset Value	Description
31	rwh	0	Wake-Up Frame Filter Register Pointer Reset When set, resets the Remote Wake-up Frame Filter register pointer to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies: setting sets + clearing has no effect.
30:10	R	0000_00 _H	Reserved
9	rw	00	Global Unicast When set, enables any unicast packet filtered by the GMAC (DAF) address recognition to be a wake-up frame.
8:7	R	0	Reserved
6	rh	0	Wake-Up Frame Received When set, this bit indicates the power management event was generated due to reception of a wake-up frame. This bit is cleared by a Read into this register.
5	rh	0	Magic Packet Received When set, this bit indicates the power management event was generated by the reception of a Magic Packet. This bit is cleared by a Read into this register.
4:3	R	00	Reserved
2	rw	0	Wake-Up Frame Enable When set, enables generation of a power management event due to wake-up frame reception.

Table 35-18 PMT Control and Status Register (cont'd)

Bit	Access Type	Reset Value	Description
1	rw	0	Magic Packet Enable When set, enables generation of a power management event due to Magic Packet reception.
0	rwh	0	Power Down When set, all received frames will be dropped. This bit is cleared automatically when a magic packet or Wake-Up frame is received, and Power-Down mode is disabled. Frames received after this bit is cleared are forwarded to the application. This bit must only be set when either the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Access restriction applies: setting sets + clearing has no effect.

Remote Wake-Up Frame Filter Register

The register `wkupmfilter_reg`, address (028_H), loads the Wake-up Frame Filter register. To load values in a Wake-up Frame Filter register, the entire register (`wkupmfilter_reg`) must be written. The `wkupmfilter_reg` register is loaded by sequentially loading the eight register values in address (028) for `wkupmfilter_reg0`, `wkupmfilter_reg1`,... `wkupmfilter_reg7`, respectively. `wkupmfilter_reg` is read in the same way.

Note: The internal counter to access the appropriate `wkupmfilter_reg` is incremented when `lane3` is accessed by the CPU. This should be kept in mind if you are accessing these registers in byte or half-word mode.

wkupfilter_reg0	Filter 0 Byte Mask							
wkupfilter_reg1	Filter 1 Byte Mask							
wkupfilter_reg2	Filter 2 Byte Mask

wkupfilter_reg5	Filter 3 Offset		Filter 2 Offset		Filter 1 Offset		Filter 0 Offset	
wkupfilter_reg6	Filter 1 CRC - 16				Filter 0 CRC - 16			
wkupfilter_reg7	Filter 3 CRC - 16				Filter 2 CRC - 16			

Wake_Up_Frame_Filter_Register.vsd

Figure 35-11 Wake-Up Frame Filter Register

Filter i Byte Mask

This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wake-up frame. The MSB (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.

Filter i Command

This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame. Bit 2 and Bit 1 are reserved. Bit 0 is the enable for filter i; if Bit 0 is not set, filter i is disabled.

Filter i Offset

This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern-offset is the offset for the filter i first byte to be examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).

Filter i CRC-16

This register contains the CRC_16 value calculated from the pattern, as well as the byte mask programmed to the wake-up filter register block.

35.2.8.2 Remote Wake-Up Frame Detection

When the GMAC is in sleep mode and the remote wake-up bit is enabled in PMT Control and Status register (002C), normal operation is resumed after receiving a remote wake-up frame. The Application writes all eight wake-up filter registers, by performing a sequential Write to address (0028). The Application enables remote wake-up by writing a 1 to Bit 2 of the PMT Control and Status register.

PMT supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, GMII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT Control and Status register for every remote Wake-up frame received. A PMT interrupt to the Application triggers a Read to the PMT Control and Status register to determine reception of a wake-up frame.

35.2.8.3 Magic Packet Detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The GMAC receives a specific packet of information, called a Magic Packet, addressed to the node on the network.

Only Magic Packets that are addressed to the device or a broadcast address will be checked to determine whether they meet the wake-up requirements. Magic Packets that pass the address filtering (unicast or broadcast) will be checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a GMAC Address appearing 16 times.

The application enables Magic Packet wake-up by writing a 1 to Bit 1 of the PMT Control and Status register. The PMT block constantly monitors each frame addressed to the node for a specific Magic Packet pattern. Each frame received is checked for a 48'hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the GMAC address without

Ethernet MAC (ETH)

any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 48'hFF_FF_FF_FF_FF_FF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (48'hFF_FF_FF_FF_FF_FF). The device will also accept a multicast frame, as long as the 16 duplications of the GMAC address are detected.

If the MAC address of a node is 48'h00_11_22_33_44_55, then the GMAC scans for the data sequence:

```
Destination Address Source Address ..... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
...CRC
```

Magic Packet detection is updated in the PMT Control and Status register for Magic Packet received. A PMT interrupt to the Application triggers a read to the PMT CSR to determine whether a Magic Packet frame has been received.

35.2.8.4 System Considerations During Power-Down

GMAC-UNIV neither gates nor stops clocks when Power-Down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with clk_rx_i during Power-Down mode, because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during Power-Down mode.

The pmt_intr_o signal is asserted when a valid wake-up frame is received. This signal is generated in the clk_rx_i domain.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when Transmit Interrupt (TI-DMA Register 5[0]) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC Configuration register.
3. Wait until the Receive DMA empties all the frames from the Rx FIFO (a software timer may be required).
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter Power-Down mode.

Ethernet MAC (ETH)

6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid wake-up frame, the GMAC-UNIV asserts the pmt_intr_o signal and exits Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

35.2.9 Station Management Agent

The Station Management Agent (SMA) module allows the Application to access any PHY registers through a 2-wire Station Management interface (MIM). The interface supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time. For more details on the communication from the Application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications section of the IEEE 802.3z specification, 1000BASE Ethernet. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in [Figure 35-12](#).

Figure 35-12 SMA Interface Block

35.2.9.1 Functions

The GMAC initiates the Management Write/Read operation. The clock gmii_mdc_o is a divided clock from the Application clock clk_csr_i. The divide factor depends on the clock range setting in the GMII Address register. Clock range is set as follows:

Selection	clk_csr_i	MDC Clock
0000	60-100 MHz	clk_csr_i/42
0001	100-150 MHz	clk_csr_i/62
0010	20-35 MHz	clk_csr_i/16

Ethernet MAC (ETH)

Selection	clk_csr_i	MDC Clock
0011	35-60 MHz	clk_csr_i/26
0100	150-250 MHz	clk_csr_i/102
0101	250-300 MHz	clk_csr_i/124
0110, 0111	Reserved	

The gmii_mdc_o is the derivative of the Application clock clk_csr_i. The Management operation is performed through the gmii_md_i, gmii_mdo_o and gmii_mdo_o_e signals. A three-state buffer is implemented outside the GMAC to interface with an external PHY.

The frame structure on the MDIO line is shown below.

IDLE The mdio line is three-state; there is no clock on gmii_mdc_o

PREAMBLE 32 continuous bits of value 1

START Start-of-frame is 2'01

OPCODE 2'b10 for Read and 2'b01 for Write

PHY ADDR 5-bit address select for one of 32 PHYs

REG ADDR Register address in the selected PHY

TA Turnaround is 2'bZ0 for Read and 2'b10 for Write

DATA Any 16-bit value. In a Write operation, the GMAC drives mdio; in a Read operation, PHY drives it.

35.2.9.2 MII Management Write Operation

When the user sets the GMII Write and Busy bits (see GMII Address Register, **“32-bit Register - GMII_Address” on Page 1-309**), the GMAC CSR module transfers the PHY address, the register address in PHY, and the write data (GMII Data Register) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or the GMII Data Register during this period are ignored (the Busy bit is high), and the transaction is completed without any error on the MCI interface.

Ethernet MAC (ETH)

After the Write operation has completed, the SMA indicates this to the CSR which then resets the Busy bit. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame. The frame format for the Write operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	01	AAAAA	RRRRR	10	DDDDDD	Z

Figure 35-13 Management Write Operation

Figure 35-13 is a reference for the Write operation.

35.2.9.3 MII Management Read Operation

When the user sets the GMII Busy bit (see GMII Address Register, **“32-bit Register - GMII Address” on Page 1-309**) with the GMII Write bit as 0, the GMAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the GMII Management Interface using the Management Frame Format specified in the GMII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII Address register contents or the GMII Data register while the transaction is ongoing. Write operations to the GMII Address register or GMII Data Register during this period are ignored (the Busy bit is high) and the transaction completed without any error on the MCI interface.

After the Read operation has completed, the SMA indicates this to the CSR, which then resets the Busy bit and updates the GMII Data register with the data read from the PHY. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of GMII Address Register) to generate the MDC clock for this interface. The GMAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. The frame format for the Read operation is as follows:

IDLE	PREAMBLE	START	OPCODE	PHY ADDR	REG ADDR	TA	DATA	IDLE
Z	1111...11	01	10	AAAAA	RRRRR	Z0	DDD... .DDD	Z

Figure 35-14 is a reference for the read operation.

Figure 35-14 Management Read Operation

35.2.10 Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs (only in 10/100 mode). According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

- The RMII module is instantiated between the GMAC and the PHY. This helps translation of the MAC’s MII into the RMII. The RMII block has the following characteristics:
- Supports 10 Mbit/s and 100 Mbit/s operating rates.
- Two clock references are sourced externally, providing independent, 2-bit wide transmit and receive paths.

35.2.10.1 Block Diagram

Figure 35-15 shows the position of the RMII block relative to the Ethernet MAC and RMII PHY. The RMII block is placed in front of the Ethernet MAC to translate the MII signals to RMII signals.

Figure 35-15 RMII Block Diagram

35.2.10.2 Block Overview

The following list describes the RMII’s hardware components, which are shown in [Figure 35-16](#). Each of these blocks is briefly described in the following sections.

MII-RMII Transmit (MRT) Block: This block translates all MII transmit signals to RMII transmit signals. All RMII signals are synchronous to `clk_rmii_i`.

MII-RMII Receive (MRR) Block: This block translates all RMII receive signals to MII receive signals. All MII signals are synchronous to `clk_rx_i`. You must ensure that the same clock is connected to both `clk_tx_i` and `clk_rx_i` clock input ports in RMII mode. This is required because clock-MUXing logic is avoided inside the GMAC core.

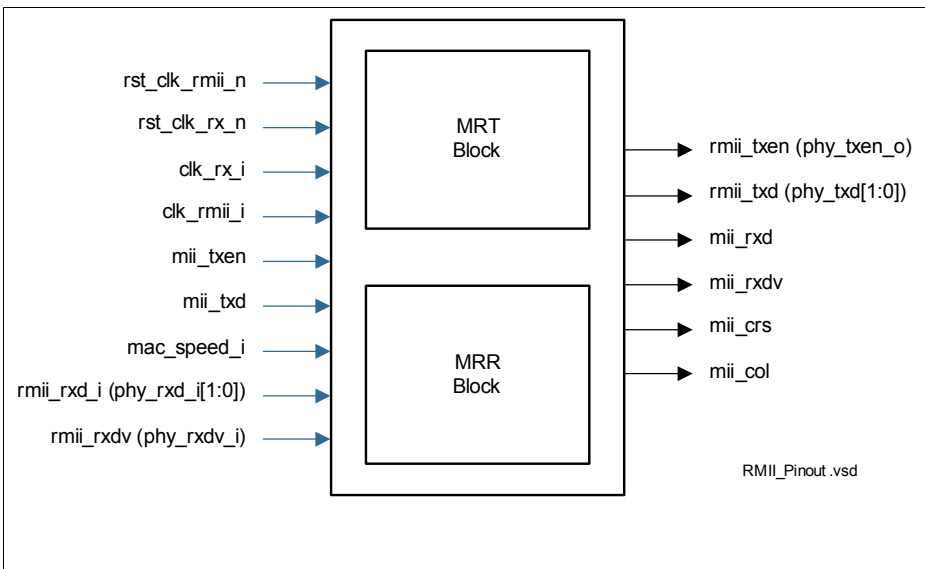

Figure 35-16 RMII Pinout

Ethernet MAC (ETH)

Note: The `mac_speed_i` signal configures the RMII to operate at 10 Mbit/s or 100 Mbit/s. This signal is driven from the MAC Configuration register's FES bit.

35.2.10.3 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMII a di-bit at a time with the order of di-bit transmission shown in [Figure 35-17](#). The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

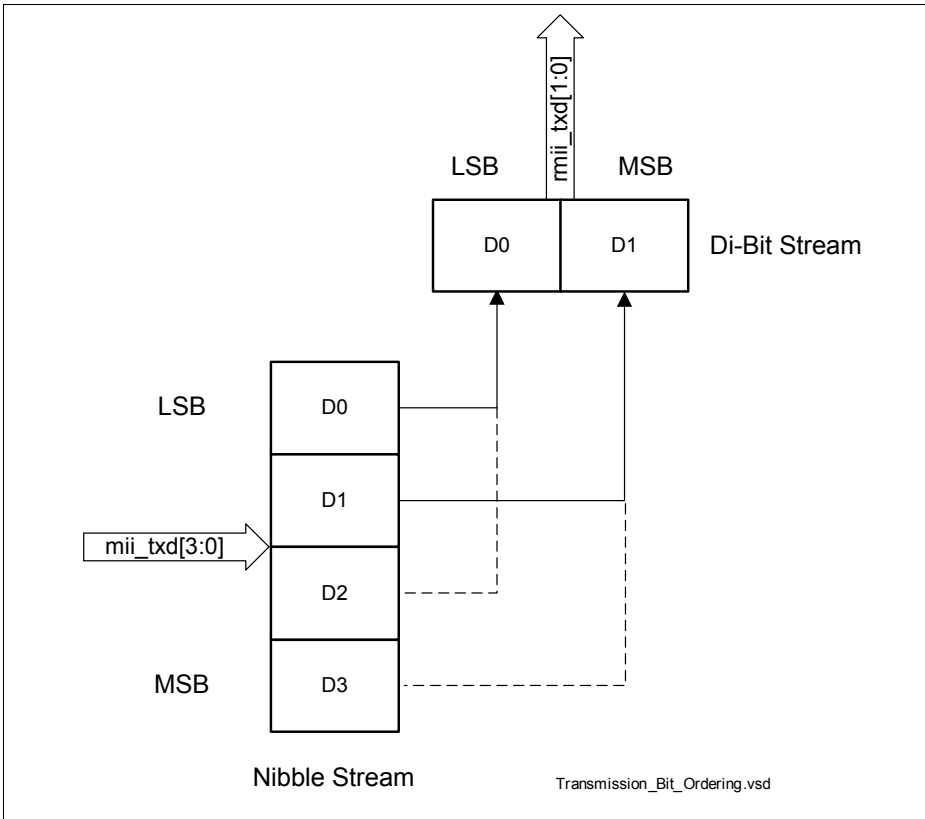

Figure 35-17 Transmission Bit Ordering

35.2.10.4 RMII Transmit Timing Diagrams

[Figure 35-18](#) through [Figure 35-21](#) show MII-to-RMII transaction timing.

Ethernet MAC (ETH)

Figure 35-18 shows the start of MII transmission and the following RMII transmission in 100 Mbit/s mode.

Figure 35-18 Start of MII and RMII Transmission in 100 Mbit/s Mode

Figure 35-19 shows the end of frame transmission for MII and RMII in 100 Mbit/s mode.

Figure 35-19 End of MII and RMII Transmission in 100 Mbit/s Mode

Figure 35-20 shows the start of MII transmission and the following RMII transmission in 10 Mbit/s mode.

Figure 35-20 Start of MII and RMII Transmission in 10 Mbit/s Mode

Figure 35-21 shows the end of MII transmission and RMII transmission in 10 Mbit/s mode.

Figure 35-21 End of MII and RMII Transmission in 10 Mbit/s Mode

Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in **Figure 35-22**. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

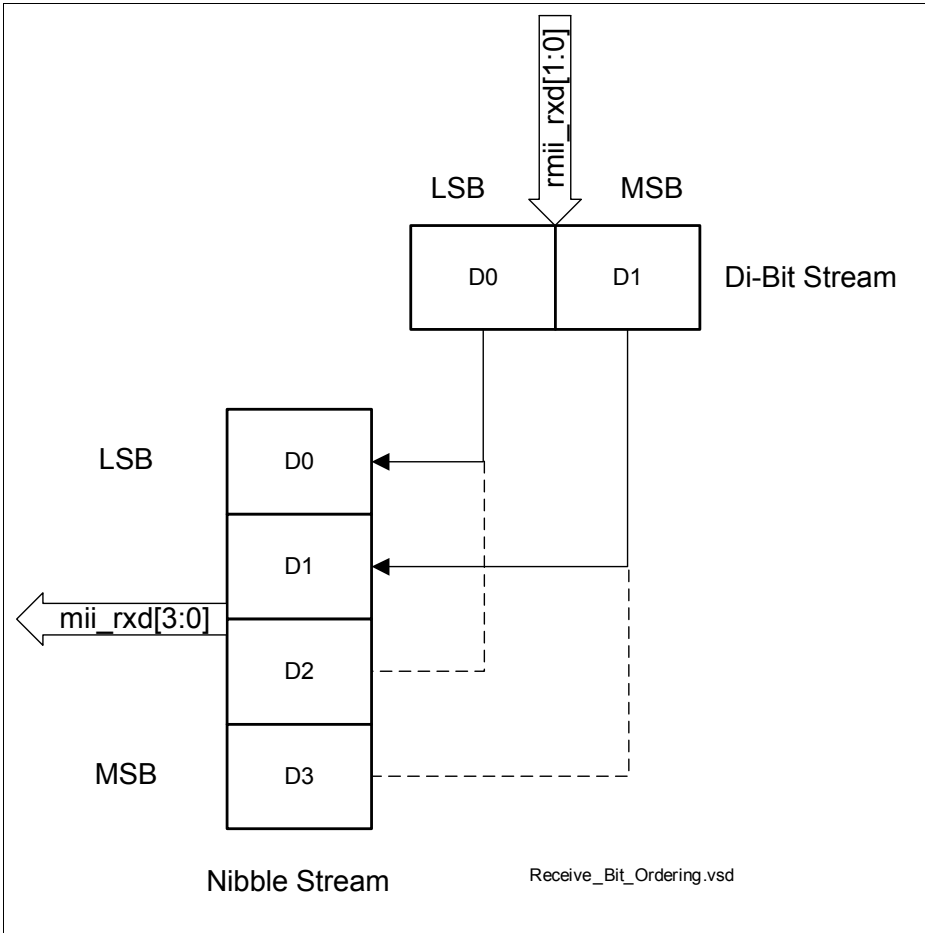

Figure 35-22 Receive Bit Ordering

35.2.11 Interrupts From the GMAC Core

Interrupts can be generated from the GMAC core as a result of various events in the optional modules in it.

The Interrupt Status register in the GMAC Register Map ([“GMAC Register Map” on Page 1-281](#)) describes the events that can cause an interrupt from the GMAC core. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the Interrupt Mask register.

Ethernet MAC (ETH)

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt. For example, Bit 0 of the Interrupt register, set high, indicates that the link status on the RGMII interface has changed. You must read Register 54 (the RGMII Status register) to clear this interrupt event.

The interrupts from the RGMII and PCS blocks are combined (OR'ed) and given as the GLI bit in the DMA Status register. The TTI, GPI, and GMI signals in [Figure 35-23](#) refer to the bits that can be read in the DMA Status register.

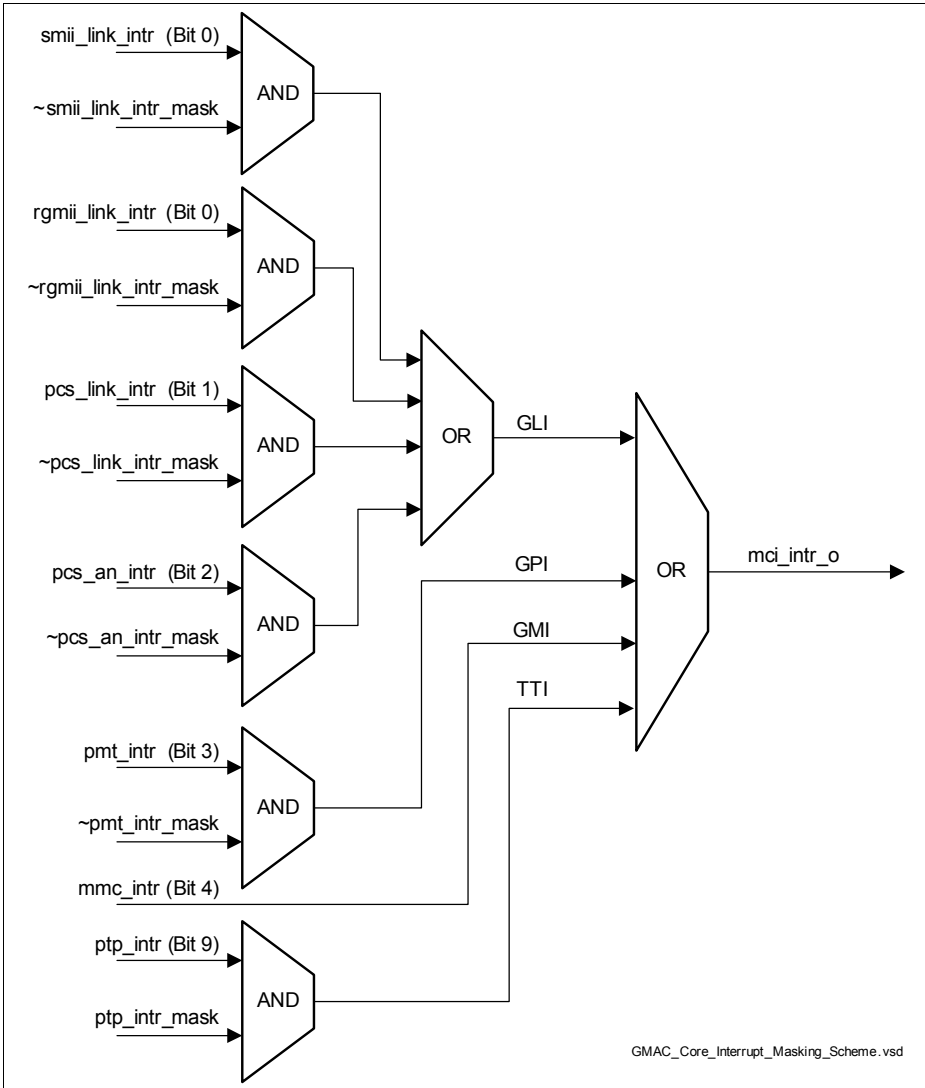

Figure 35-23 GMAC Core Interrupt Masking Scheme

35.3 Register

General notes on registers:

Ethernet MAC (ETH)

- All CSRs are implemented as 32-bit registers and can be accessed in 1 read/write cycle with a 32-bit MCI interface (or 32-bit AHB slave port). If you initiate a non-32-bit register access, the byte enable signals (mci_be_i[3:0]) qualify the corresponding register bytes. Only write operations are qualified with byte enables, while read operations are always 32-bit, unless the register is affected by a read operation. Byte enable signals qualify reads to such registers as, for example, the MMC counter registers.
- The transfer of particular register contents (e.g., MAC DA address register) to the Transmit or Receive clock domains are initiated when a particular byte is written. This is indicated in the register descriptions, where applicable.
- When any Register content is being transferred to a different clock domain after a write operation, there should not be any further writes to the same location until the first write is updated. Otherwise, the second write operation will not get updated to the destination clock domain. Thus the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock or PHY transmit clock).

35.3.1 Register Maps

The register maps in this section provide high-level summaries of each register or group of registers. The detailed register descriptions in [“Register Description” on Page 1-292](#).

Reserved address space (marked as “do not use”) will generate no bus error (nBE).

All registers in the DMA and MAC Registers map (1000_H - 2058_H) are P = ACCEN protected. The registers for additional Module Control are ACCEN protected according to [Figure 35-22](#).

35.3.1.1 Register Overview

Table 35-19 Registers Address Space - ETH Module

Module	Base Address	End Address	Note
ETH	F001 D000 _H	F001 F0FF _H	-

35.3.1.2 DMA Register Map

Table 35-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
0	2000 _H	DMA Register 0 (Bus Mode Register) Controls the Host Interface Mode.
1	2004 _H	DMA Register 1 (Transmit Poll Demand Register) Used by the host to instruct the DMA to poll the Transmit Descriptor List.
2	2008 _H	DMA Register 2 (Receive Poll Demand Register) Used by the Host to instruct the DMA to poll the Receive Descriptor List.
3	200C _H	DMA Register 3 (Receive Descriptor List Address Register) Points the DMA to the start of the Receive Descriptor list.
4	2010 _H	DMA Register 4 (Transmit Descriptor List Address Register) Points the DMA to the start of the Transmit Descriptor List.
5	2014 _H	DMA Register 5 (Status Register) The Software driver (application) reads this register during interrupt service routine or polling to determine the status of the DMA.
6	2018 _H	DMA Register 6 (Operation Mode Register) Establishes the Receive and Transmit operating modes and command.
7	201C _H	DMA Register 7 (Interrupt Enable Register) Enables the interrupts reported by the Status Register.
8	2020 _H	DMA Register 8 (Missed Frame and Buffer Overflow Counter Register) Contains the counters for discarded frames because no host Receive Descriptor was available, and discarded frames because of Receive FIFO Overflow.
9	2024 _H	DMA Register 9 (Receive Interrupt Watchdog Timer Register) Watchdog time-out for Receive Interrupt (RI) from DMA
12-17	2030 _H - 2044 _H	Do not use

Table 35-20 DMA Register Map

DMA Register No.	Offset Address	Register Name and Description
18	2048 _H	DMA Register 18 (Current Host Transmit Descriptor Register) Points to the start of current Transmit Descriptor read by the DMA.
19	204C _H	DMA Register 19 (Current Host Receive Descriptor Register) Points to the start of current Receive Descriptor read by the DMA.
20	2050 _H	DMA Register 20 (Current Host Transmit Buffer Address Register) Points to the current Transmit Buffer address read by the DMA.
21	2054 _H	DMA Register 21 (Current Host Receive Buffer Address Register) Points to the current Receive Buffer address read by the DMA.
22	2058 _H	DMA Register 22 (HW Feature Register) Indicates the presence of the optional features of the core.
23-63	205C _H - 20FC _H	Do not use

35.3.1.3 GMAC Register Map

Table 1-59 provides the address map of the GMAC core registers.

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
0	1000 _H	GMAC Register 0 (MAC Configuration Register) This is the operation mode register for the MAC.
1	1004 _H	GMAC Register 1 (MAC Frame Filter) Contains the frame filtering controls.

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
2	1008 _H	GMAC Register 2 (Hash Table High Register) Contains the higher 32 bits of the Multicast Hash table. This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
3	100C _H	GMAC Register 3 (Hash Table Low Register) Contains the lower 32 bits of the Multicast Hash table. This register is present only when the Hash filter function is selected in coreConsultant. (See Table ??)
4	1010 _H	GMAC Register 4 (GMII Address Register) Controls the management cycles to an external PHY. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
5	1014 _H	GMAC Register 5 (GMII Data Register) Contains the data to be written to or read from the PHY register. This register is present only when the Station Management (MDIO) feature is selected in coreConsultant. (See Table ??)
6	1018 _H	GMAC Register 6 (Flow Control Register) Controls the generation of control frames.
7	101C _H	GMAC Register 7 (VLAN Tag Register) Identifies IEEE 802.1Q VLAN type frames.
8	1020 _H	GMAC Register 8 (Version Register) Identifies the version of the Core
9	1024 _H	GMAC Register 9 (Debug Register) Gives the status of various internal blocks for debugging

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
10	1028 _H	<p>Remote Wake-Up Frame Filter</p> <p>This is the address through which the remote Wake-up Frame Filter registers (wkupfilter_reg) are written/read by the Application. wkupfilter_reg is actually a pointer to eight (not transparent) such wkupfilter_reg registers. Eight sequential Writes to this address (028) will write all wkupfilter_reg registers. Eight sequential Reads from this address (028) will read all wkupfilter_reg registers.</p> <p>This register contains the higher 16 bits of the 7th MAC address.</p> <p>This register is present only when the PMT module Remote Wake-up feature is selected in coreConsultant. (See Table ??) Refer to “Remote Wake-Up Frame Filter Register” on page ?? for additional information.</p>
11	102C _H	<p>PMT Control and Status</p> <p>This register is present only when the PMT module is selected in coreConsultant. (See Table ??) Refer to “PMT Control and Status Register” on page ?? for additional information.</p>
12-13	1030 _H - 1034 _H	Do not use
14	1038 _H	<p>GMAC Register 14 (Interrupt Status Register)</p> <p>Contains the interrupt status.</p>
15	103C _H	<p>GMAC Register 15 (Interrupt Mask Register)</p> <p>Contains the masks for generating the interrupts.</p>
16	1040 _H	<p>GMAC Register 16 (MAC Address 0 High Register)</p> <p>Contains the higher 16 bits of the first MAC address.</p>
17	1044 _H	<p>GMAC Register 17 (MAC Address 0 Low Register)</p> <p>Contains the lower 32 bits of the first MAC address.</p>
18	1048 _H	<p>GMAC Register 18 (MAC Address 1 High Register)</p> <p>Contains the higher 16 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).</p>

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
19	104C _H	GMAC Register 19 (MAC Address 1 Low Register) Contains the lower 32 bits of the second MAC address. This register is present only when Enable MAC Address 1 is selected in coreConsultant. (See Table ??).
20	1050 _H	MAC Address 2 High Register Contains the higher 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
21	1054 _H	MAC Address 2 Low Register Contains the lower 32 bits of the third MAC address. This register is present only when Enable MAC Address 2 is selected in coreConsultant. (See Table ??).
22	1058 _H	MAC Address 3 High Register Contains the higher 16 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
23	105C _H	MAC Address 3 Low Register Contains the lower 32 bits of the fourth MAC address. This register is present only when Enable MAC Address 3 is selected in coreConsultant. (See Table ??).
55-63	10DC _H - 10FC _H	Do not use
64-191	1100 _H - 12FC _H	MMC Register Map See Table 1-17 “MMC Register Map” on Page 1-131 .
192-447	1300 _H - 16FC _H	Do not use
448	1700 _H	Register 448 (Time Stamp Control Register) Controls the time stamp generation and update logic.
449	1704 _H	Register 449 (Sub-Second Increment Register) Contains the 8-bit value by which the Sub-Second register is incremented. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
450	1708 _H	Register 450 (System Time - Seconds Register) Contains the lower 32 bits of the seconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
451	170C _H	Register 451 (System Time - Nanoseconds Register) Contains 32 bits of the nanoseconds field of the system time. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
452	1710 _H	Register 452 (System Time - Seconds Update Register) Contains the lower 32 bits of the seconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
453	1714 _H	Register 453 (System Time - Nanoseconds Update Register) Contains 32 bits of the nanoseconds field to be written to, added to, or subtracted from the System Time value. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
454	1718 _H	Register 454 (Time Stamp Addend Register) This register is used by the software to readjust the clock frequency linearly to match the master clock frequency. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
455	171C _H	Register 455 (Target Time Seconds Register) Contains the higher 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.
456	1720 _H	Register 456 (Target Time Nanoseconds Register) Contains the lower 32 bits of time to be compared with the system time for interrupt event generation. This register is only present when IEEE1588 time stamping is enabled without an external time stamp input.

Table 35-21 GMAC Register Map

GMAC Register No.	Offset Address	Register Name and Description
457	1724 _H	Register 457 (System Time - Higher Word Seconds Register) Contains the most significant 16-bits of the time stamp seconds value. This register is optional and can be selected using the coreKit parameter identified in "IEEE 1588 Time Stamp Block" on page ??.
458	1728 _H	Register 458 (Time Stamp Status Register) Contains the PTP status. This register is available only when the advanced IEEE 1588 timestamp feature is selected.
459	172C _H	Register 459 (PPS Control Register) This register is used to control the interval of the PPS signal output, such that a duration of less than 1 second can be achieved between pulses.
460	1730 _H	Register 460 (Auxiliary Time Stamp - Nanoseconds Register) Contains the lower 32 bits (nanoseconds field) of the auxiliary time stamp register.
461	1734 _H	Register 461 (Auxiliary Time Stamp - Seconds Register) Contains the upper 32 bits (seconds field) of the auxiliary time stamp register.
462-511	1738 _H - 17FC _H	Do not use
512-511	1738 _H - 17FC _H	Do not use

35.3.1.4 Ethernet MAC Additional Module Control Registers

This section describes the additional module control registers of the Ethernet MAC module. All Ethernet MAC register names described in this section will be referenced in other parts of the TC26x B-Step User's Manual by the module name prefix "Ethernet MAC_" for the Ethernet MAC interface.

All registers in the Ethernet MAC address spaces are reset with the application reset (definition see SCU section "Reset Operation"). P = ACCEN protection

Table 35-22 Register Overview - ETH Add. Mod. Contr. Registers

r	rw	rw	rw	rw	rw	rw	r	rw	rw		rw	rw	rw	rw	rw

Field	Bits	Type	Description
PRELEN	[1:0]	rw	<p>Preamble Length for Transmit Frames</p> <p>These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.</p> <ul style="list-style-type: none"> * 2'b00: 7 bytes of preamble * 2'b01: 5 byte of preamble * 2'b10: 3 bytes of preamble * 2'b11: reserved
RE	2	rw	<p>Receiver Enable</p> <p>When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
TE	3	rw	<p>Transmitter Enable</p> <p>When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.</p>
DC	4	rw	<p>Deferral Check</p> <p>When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Deferral time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts.</p> <p>When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
BL	[6:5]	rw	<p>Back-Off Limit</p> <p>The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration.</p> <p>* 00: $k = \min(n, 10)$ * 01: $k = \min(n, 8)$ * 10: $k = \min(n, 4)$ * 11: $k = \min(n, 1)$</p> <p>where n = retransmission attempt. The random integer r takes the value in the range $0 \leq r < k$th power of 2</p>
ACS	7	rw	<p>Automatic Pad or CRC Stripping</p> <p>When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.</p> <p>When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host.</p>
LUD	8	r	<p>Link Up or Down</p> <p>This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface:</p> <p>* 0: Link Down * 1: Link Up</p> <p>This bit is reserved (RO with default value) and is enabled when the RGMII, SGMII, or SMII interface is enabled during core configuration.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
DR	9	rw	<p>Disable Retry</p> <p>When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status.</p> <p>When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode and is reserved (RO with default value) in the full-duplex-only configuration.</p>
IPC	10	rw	<p>Checksum Offload</p> <p>When this bit is set, the MAC calculates the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected).</p> <p>When this bit is reset, this function is disabled.</p> <p>When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared.</p> <p>If the IP Checksum Offload feature is not enabled during core configuration, this bit is reserved (RO with default value).</p>
DM	11	rw	<p>Duplex Mode</p> <p>When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configuration.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
LM	12	rw	<p>Loopback Mode</p> <p>When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input (clk_rx_i) is required for the loopback to work properly, because the Transmit clock is not looped-back internally.</p>
DO	13	rw	<p>Disable Receive Own</p> <p>When this bit is set, the MAC disables the reception of frames when the gmii_txen_o is asserted in the half-duplex mode.</p> <p>When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting.</p> <p>This bit is not applicable if the MAC is operating in the full-duplex mode. This bit is reserved (RO with default value) if the MAC is configured for the full-duplex-only operation.</p>
FES	14	rw	<p>Speed</p> <p>This bit selects the speed in the MII, RMII, SMII, RGMII, SGMII, or RevMII interface:</p> <ul style="list-style-type: none"> * 0: 10 Mbps * 1: 100 Mbps <p>This bit is reserved (RO) by default and is enabled only when the RMII, SMII, RGMII, SGMII, or RevMII interface is enabled during core configuration. This bit generates link speed encoding when TC (Bit 24) is set in the RGMII, SMII, or SGMII mode.</p> <p>This bit is always driven for RevMII. If the MAC is configured with an RMII, SMII, SGMII, or RGMII PHY interface, this bit can optionally be driven as an output signal (mac_speed_o[0]) to reflect the value of this bit in the mac_speed_o signal.</p> <p>In addition, this bit is reserved when RMII is enabled without enabling the <i>Output Port for speed selection</i> option during core configuration.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
PS	15	r	<p>Port Select</p> <p>This bit selects between GMII and MII: * 0: GMII (1000 Mbps) * 1: MII (10/100 Mbps)</p> <p>In the 10 or 100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only with the appropriate value. In the default 10/100/1000 Mbps configurations, this bit is R_W. The mac_portselect_o signal reflects the value of this bit.</p>
DCRS	16	rw	<p>Disable Carrier Sense During Transmission</p> <p>When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. This bit is reserved (and RO) in the full-duplex-only configurations.</p>
IFG	[19:17]	rw	<p>Inter-Frame Gap</p> <p>These bits control the minimum IFG between frames during transmission.</p> <ul style="list-style-type: none"> * 000: 96 bit times * 001: 88 bit times * 010: 80 bit times * ... * 111: 40 bit times <p>In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 64 bit times (and above) in the GMAC-CORE configuration and 80 bit times (and above) in other configurations.</p>
JE	20	rw	<p>Jumbo Frame Enable</p> <p>When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
BE	21	r	Frame Burst Enable When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. This bit is reserved (and RO) in the 10/100 Mbps only or full-duplex-only configurations.
JD	22	rw	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission.
WD	23	rw	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes.
TC	24	r	Transmit Configuration in RGMII, SGMII, or SMII When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII, SMII, or SGMII port. When this bit is reset, no such information is driven to the PHY. This bit is reserved (and RO) if the RGMII, SMII, or SGMII PHY port is not selected during core configuration.
CST	25	rw	CRC Stripping of Type Frames When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.
SFTERR	26	r	SMII Force Transmit Error When set, this bit indicates to the PHY to force a transmit error in the SMII frame being transmitted. This bit is reserved if the SMII PHY port is not selected during core configuration.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TWOKPE	27	rw	<p>IEEE 802.3as support for 2K packets Enable</p> <p>When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames.</p> <p>When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames.</p> <p>When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
SARC	[30:28]	r	<p>Source Address Insertion or Replacement Control</p> <p>This field controls the source address insertion or replacement for all transmitted frames. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits [29:28]:</p> <ul style="list-style-type: none"> * 2'b0x: The input signals mti_sa_ctrl_i and ati_sa_ctrl_i control the SA field generation. * 2'b10: <ul style="list-style-type: none"> - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC inserts the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. * 2'b11: <ul style="list-style-type: none"> - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (registers 16 and 17) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC replaces the content of the MAC Address 1 registers (registers 18 and 19) in the SA field of all transmitted frames. <p>Note:</p> <ul style="list-style-type: none"> - Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value. - These bits are reserved and RO when the Enable SA, VLAN, and CRC Insertion on TX feature is not selected during core configuration.
RESERVE D_31	31	r	RESERVED_31

32-bit Register - MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

ETH_MAC_FRAME_FILTER
Register 1 - MAC Frame Filter

32-bit Register - Hash_Table_High

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (Hash Table High or Hash Table Low), and the other 5 bits determine which bit within the register. A hash value of 5b'00000 selects Bit 0 of the selected register, and a value of 5b'11111 selects Bit 31 of the selected register. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
 2. Perform bitwise reversal for the value obtained in Step 1.
 3. Take the upper 6 bits from the value obtained in Step 2.
 For example, if the DA of the incoming frame is received as 0x1F52419CB6AF (0x1F is the first byte received on GMII interface), then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of Hash Table High register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering. Note: To help you program the hash table, a sample C routine that generates a DA's 6-bit hash is included in the /sample_codes/ directory of your workspace. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the PM (Pass All Multicast) bit is set in Register 1, then all multicast frames are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table High or Low registers are written. Consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain when double-synchronization is enabled. The Hash Table High register contains the higher 32 bits of the Hash table.

ETH_HASH_TABLE_HIGH
Register 2 - Hash Table High Register (1008_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
HTH	[31:0]	rw	Hash Table High This field contains the upper 32 bits of the Hash table.

32-bit Register - Hash_Table_Low

The Hash Table Low register contains the lower 32 bits of the Hash table. Both Register 2 and Register 3 are reserved if the Hash Filter Function is disabled or the 128-bit or 256-bit Hash Table is selected during core configuration.

ETH_HASH_TABLE_LOW

Register 3 - Hash Table Low Register (100C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
HTL	[31:0]	rw	Hash Table Low This field contains the lower 32 bits of the Hash table.

32-bit Register - GMII_Address

The GMII Address register controls the management cycles to the external PHY through the management interface.

ETH_GMII_ADDRESS

Register 4 - GMII Address Register (1010_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
GB	0	rw	<p>GMII Busy</p> <p>This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress.</p> <p>The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared.</p> <p>The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present.</p>
GW	1	rw	<p>GMII Write</p> <p>When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
CR	[5:2]	rw	<p>CSR Clock Range</p> <p>The CSR Clock Range selection determines the frequency of the MDC clock according to the clk_csr_i frequency used in your design. The suggested range of clk_csr_i frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz.</p> <ul style="list-style-type: none"> - 0000: The frequency of the clk_csr_i clock is 60-100 MHz and the MDC clock is clk_csr_i/42. - 0001: The frequency of the clk_csr_i clock is 100-150 MHz and the MDC clock is clk_csr_i/62. - 0010: The frequency of the clk_csr_i clock is 20-35 MHz and the MDC clock is clk_csr_i/16. - 0011: The frequency of the clk_csr_i clock is 35-60 MHz and the MDC clock is clk_csr_i/26. - 0100: The frequency of the clk_csr_i clock is 150-250 MHz and the MDC clock is clk_csr_i/102. - 0100: The frequency of the clk_csr_i clock is 250-300 MHz and the MDC clock is clk_csr_i/124. - 0110 and 0111: Reserved <p>When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when clk_csr_i is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Program the following values only if the interfacing chips support faster MDC clocks:</p> <ul style="list-style-type: none"> - 1000: clk_csr_i/4 - 1001: clk_csr_i/6 - 1010: clk_csr_i/8 - 1011: clk_csr_i/10 - 1100: clk_csr_i/12 - 1101: clk_csr_i/14 - 1110: clk_csr_i/16 - 1111: clk_csr_i/18 <p>These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
GR	[10:6]	rw	GMII Register These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.
PA	[15:11]	rw	Physical Layer Address This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII module.
RESERVE D_31_16	[31:16]	r	RESERVED_31_16

32-bit Register - GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

ETH_GMII_DATA

Register 5 - GMII Data Register (1014_H) **Reset Value: 0000 0000_H**

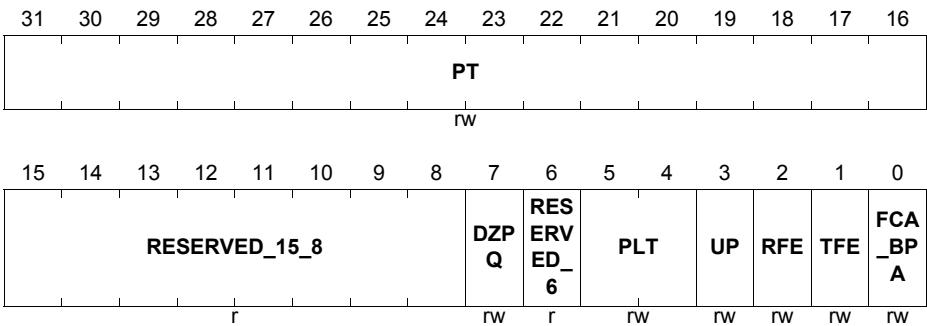

Field	Bits	Type	Description
GD	[15:0]	rw	GMII Data This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.
RESERVE D_31_16	[31:16]	r	RESERVED_31_16

32-bit Register - Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control module. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

ETH_FLOW_CONTROL

Register 6 - Flow Control Register (1018_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
FCA_BPA	0	rw	<p>Flow Control Busy or Backpressure Activate</p> <p>This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set.</p> <p>In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared.</p> <p>In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.</p>
TFE	1	rw	<p>Transmit Flow Control Enable</p> <p>In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames.</p> <p>In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.</p>
RFE	2	rw	<p>Receive Flow Control Enable</p> <p>When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
UP	3	rw	<p>Unicast Pause Frame Detect</p> <p>When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.</p>
PLT	[5:4]	rw	<p>Pause Low Threshold</p> <p>This field configures the threshold of the PAUSE timer at which the input flow control signal <code>mti_flowctrl_i</code> (or <code>sbd_flowctrl_i</code>) is checked for automatic retransmission of PAUSE Frame.</p> <p>The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if <code>PT = 100H</code> (256 slot-times), and <code>PLT = 01</code>, then a second PAUSE frame is automatically transmitted if the <code>mti_flowctrl_i</code> signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted.</p> <p>The following list provides the threshold values for different values:</p> <ul style="list-style-type: none"> - 00: The threshold is Pause time minus 4 slot times (PT - 4 slot times). - 01: The threshold is Pause time minus 28 slot times (PT - 28 slot times). - 10: The threshold is Pause time minus 144 slot times (PT - 144 slot times). - 11: The threshold is Pause time minus 256 slot times (PT - 256 slot times). <p>The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
DZPQ	7	rw	<p>Disable Zero-Quanta Pause</p> <p>When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal <code>sbd_flowctrl_i/mti_flowctrl_i</code>).</p> <p>When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled.</p>
RESERVE D_15_8	[15:8]	r	RESERVED_15_8
PT	[31:16]	rw	<p>Pause Time</p> <p>This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.</p>

Ethernet MAC (ETH)

32-bit Register - VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. If the VLAN Tag register is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

ETH_VLAN_TAG

Register 7 - VLAN Tag Register (101C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
VL	[15:0]	rw	<p>VLAN Tag Identifier for Receive Frames</p> <p>This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field:</p> <ul style="list-style-type: none"> * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field <p>When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison.</p> <p>If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
ETV	16	rw	<p>Enable 12-Bit VLAN Tag Comparison</p> <p>When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering.</p> <p>When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering.</p>
VTIM	17	rw	<p>VLAN Tag Inverse Match Enable</p> <p>When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched.</p> <p>When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.</p>
ESVL	18	rw	<p>Enable S-VLAN</p> <p>When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.</p>
VTHM	19	r	<p>VLAN Tag Hash Table Match Enable</p> <p>When set, the most significant four bits of the VLAN tag;Cs CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison.</p> <p>When reset, the VLAN Hash Match operation is not performed. If the VLAN Hash feature is not enabled during core configuration, this bit is reserved (RO with default value).</p>

32-bit Register - Remote_Wake_Up_Frame_Filter

This is the address through which the application writes or reads the remote wake-up frame filter registers (wkupfilter_reg). The wkupfilter_reg register is a pointer to eight wkupfilter_reg registers. The wkupfilter_reg register is loaded by sequentially loading the eight register values. Eight sequential writes to this address (0x0028) writes all wkupfilter_reg registers. Similarly, eight sequential reads from this address (0x0028) read all wkupfilter_reg registers. This register contains the higher 16 bits of the seventh MAC address. This register is present only when you select the PMT module Remote Wake-up feature in coreConsultant.

ETH_REMOTE_WAKE_UP_FRAME_FILTER

Register 10 - Remote Wake-Up Frame Filter Register (1028_H) **Reset Value: 0000 0000_H**

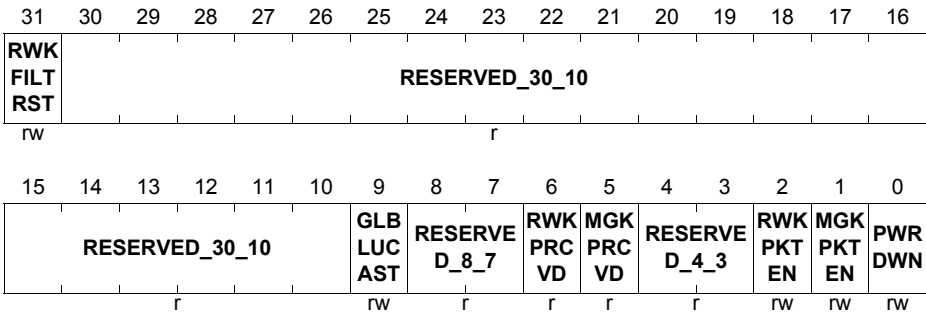

Field	Bits	Type	Description
WKUPFR MFTR	[31:0]	rw	WKUPFRMFTR Remote Wake-Up Frame Filter

32-bit Register - PMT_Control_Status

This register is present only when you select the PMT module in the coreConsultant.

ETH_PMT_CONTROL_STATUS

Register 11 - PMT Control and Status Register (102C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
PWRDWN	0	rw	Power Down When set, the MAC receiver drops all received frames until it receives the expected magic packet or wake-up frame. This bit is then self-cleared and the power-down mode is disabled. The Software can also clear this bit before the expected magic packet or wake-up frame is received. The frames, received by the MAC after this bit is cleared, are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
MGKPKTEN	1	rw	Magic Packet Enable When set, enables generation of a power management event because of magic packet reception.
RWKPKTEN	2	rw	Wake-Up Frame Enable When set, enables generation of a power management event because of wake-up frame reception.

Ethernet MAC (ETH)

Field	Bits	Type	Description
RESERVE D_4_3	[4:3]	r	RESERVED_4_3

TSIM	9	rw	Timestamp Interrupt Mask When set, this bit disables the assertion of the interrupt signal because of the setting of Timestamp Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when IEEE1588 timestamping is enabled. In all other modes, this bit is reserved.
LPIIM	10	r	LPI Interrupt Mask When set, this bit disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Register 14 (Interrupt Status Register). This bit is valid only when you select the Energy Efficient Ethernet feature during core configuration. In all other modes, this bit is reserved.
RESERVE D_31_11	[31:11]	r	RESERVED_31_11

32-bit Register - MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS0_HIGH

MBC	[29:24]	rw	Mask Byte Control These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address14 registers. Each bit controls the masking of the bytes as follows: * Bit 29: Register 18[15:8] * Bit 28: Register 18[7:0] * Bit 27: Register 19[31:24] * ... * Bit 24: Register 19[7:0]

Ethernet MAC (ETH)

Field	Bits	Type	Description
SA	30	rw	<p>Source Address</p> <p>When this bit is set, the MAC Address14[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address14[47:0] is used to compare with the DA fields of the received frame.</p>
AE	31	rw	<p>Address Enable</p> <p>When this bit is set, the address filter module uses the 15th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.</p>

Ethernet MAC (ETH)

32-bit Register - MAC_Address14_Low

The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station.

ETH_MAC_ADDRESS14_LOW

Register 45 - MAC Address14 Low Register (10B4_H) **Reset Value: FFFF FFFF_H**

Field	Bits	Type	Description
ADDRLO	[31:0]	rw	MAC Address14 [31:0] This field contains the lower 32 bits of the 15th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MAC_Address15_High

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address15 Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH_MAC_ADDRESS15_HIGH
Register 46 - MAC Address15 High Register (10B8_H) Reset Value: 0000 FFFF_H

Field	Bits	Type	Description
ADDRHI	[15:0]	rw	ADDRHI MAC Address15 [47:32] This field contains the upper 16 bits (47:32) of the 16th 6-byte MAC address.
RESERVE D_23_16	[23:16]	r	RESERVED_23_16

32-bit Register - MAC_Address15_Low

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station.

ETH_MAC_ADDRESS15_LOW

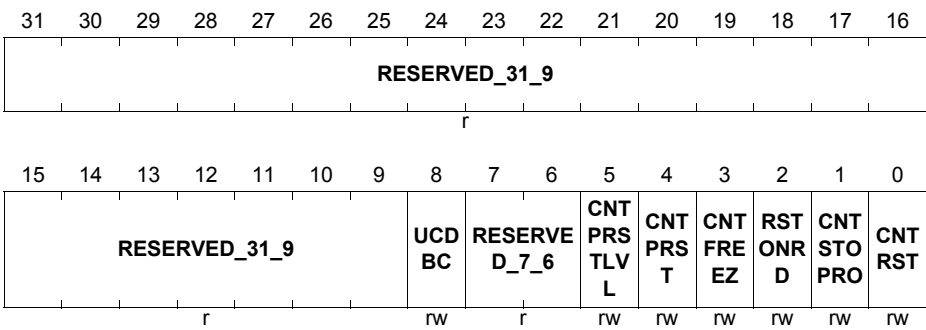

Register 47 - MAC Address15 Low Register (10BC_H) Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
ADDRLO	[31:0]	rw	MAC Address15 [31:0] This field contains the lower 32 bits of the 16th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

32-bit Register - MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

ETH_MMC_CONTROL
Register 64 - MMC Control Register (1100_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CNTRST	0	rw	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle.
CNTSTOPRO	1	rw	Counters Stop Rollover When this bit is set, after reaching maximum value, the counter does not roll over to zero.
RSTONRD	2	rw	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.
CNTFREEZ	3	rw	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.

Ethernet MAC (ETH)

Field	Bits	Type	Description
CNTPRST	4	rw	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.
CNTPRST LVL	5	rw	Full-Half Preset When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFFF0.
RESERVE D_7_6	[7:6]	r	RESERVED_7_6
UCDBC	8	rw	Update MMC Counters for Dropped Broadcast Frames When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.
RESERVE D_31_9	[31:9]	r	RESERVED_31_9

32-bit Register - MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Field	Bits	Type	Description
TXGBOCTIM	0	rw	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value.
TXGBFRMIM	1	rw	MMC Transmit Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txframecount_gb counter reaches half of the maximum value or the maximum value.
TXBCGFI M	2	rw	MMC Transmit Broadcast Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastframes_g counter reaches half of the maximum value or the maximum value.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TXMCGFIM	3	rw	MMC Transmit Multicast Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastframes_gb counter reaches half of the maximum value or the maximum value.
TX64OCTGBFIM	4	rw	MMC Transmit 64 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value.
TX65T127OCTGBFIM	5	rw	MMC Transmit 65 to 127 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value.
TX128T255OCTGBFIM	6	rw	MMC Transmit 128 to 255 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value.
TX256T511OCTGBFIM	7	rw	MMC Transmit 256 to 511 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value.
TX512T1023OCTGBFIM	8	rw	MMC Transmit 512 to 1023 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value.
TX1024TMAXOCTGBFIM	9	rw	MMC Transmit 1024 to Maximum Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TXUCGBF IM	10	rw	MMC Transmit Unicast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastframes_gb counter reaches half of the maximum value or the maximum value.
TXMCGBF IM	11	rw	MMC Transmit Multicast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticastframes_gb counter reaches half of the maximum value or the maximum value.
TXBCGBF IM	12	rw	MMC Transmit Broadcast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcastframes_gb counter reaches half of the maximum value or the maximum value.
TXUFLOW ERFIM	13	rw	MMC Transmit Underflow Error Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value.
TXSCOLG FIM	14	rw	MMC Transmit Single Collision Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value.
TXMCOLG FIM	15	rw	MMC Transmit Multiple Collision Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value.
TXDEFFIM	16	rw	MMC Transmit Deferred Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value.

Field	Bits	Type	Description
TXLATCO LFIM	17	rw	MMC Transmit Late Collision Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value.
TXEXCOL FIM	18	rw	MMC Transmit Excessive Collision Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value.
TXCARER FIM	19	rw	MMC Transmit Carrier Error Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value.
TXGOCTI M	20	rw	MMC Transmit Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value.
TXGFRMI M	21	rw	MMC Transmit Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txframecount_g counter reaches half of the maximum value or the maximum value.
TXEXDEF FIM	22	rw	MMC Transmit Excessive Deferral Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value.
TXPAUSFI M	23	rw	MMC Transmit Pause Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txpauseframes counter reaches half of the maximum value or the maximum value.
TXVLANG FIM	24	rw	MMC Transmit VLAN Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txvlanframes_g counter reaches half of the maximum value or the maximum value.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TXOSIZEG FIM	25	rw	MMC Transmit Oversize Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value.
RESERVE D_31_26	[31:26]	r	RESERVED_31_26

32-bit Register - Tx_Octet_Count_Good_Bad

This register maintains the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

ETH_TX_OCTET_COUNT_GOOD_BAD

Register 69 - Transmit Octet Count for Good and Bad Frames (1114_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXOCTGB	[31:0]	r	TXOCTGB This field indicates the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

Ethernet MAC (ETH)

32-bit Register - Tx_Frame_Count_Good_Bad

This register maintains the number of good and bad frames transmitted, exclusive of retried frames.

ETH_TX_FRAME_COUNT_GOOD_BAD

Register 70 - Transmit Frame Count for Good and Bad Frames (1118_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXFRMGB	[31:0]	r	TXFRMGB This field indicates the number of good and bad frames transmitted, exclusive of retried frames

32-bit Register - Tx_Broadcast_Frames_Good

This register maintains the number of transmitted good broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD

Register 71 - Transmit Frame Count for Good Broadcast Frames (111C_H) **Reset Value: 0000 0000_H**

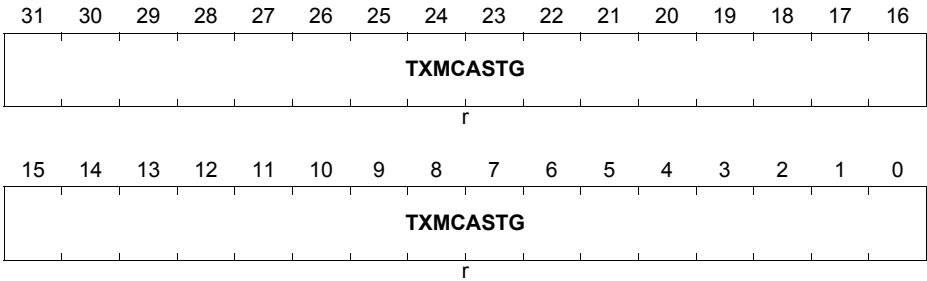

Field	Bits	Type	Description
TXBCASTG	[31:0]	r	TXBCASTG This field indicates the number of transmitted good broadcast frames.

32-bit Register - Tx_Multicast_Frames_Good

This register maintains the number of transmitted good multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD

Register 72 - Transmit Frame Count for Good Multicast Frames (1120_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXMCASTG	[31:0]	r	TXMCASTG This field indicates the number of transmitted good multicast frames.

32-bit Register - Tx_64Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

ETH_TX_64OCTETS_FRAMES_GOOD_BAD

Register 73 - Transmit Octet Count for Good and Bad 64 Byte Frames (1124_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TX64OCTGB	[31:0]	r	TX64OCTGB This field indicates the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_65To127Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_65TO127OCTETS_FRAMES_GOOD_BAD

Register 74 - Transmit Octet Count for Good and Bad 65 to 127 Bytes Frames

(1128_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TX65_127 OCTGB	[31:0]	r	TX65_127OCTGB This field indicates the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

Ethernet MAC (ETH)

32-bit Register - Tx_128To255Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_128TO255OCTETS_FRAMES_GOOD_BAD

Register 75 - Transmit Octet Count for Good and Bad 128 to 255 Bytes Frames (112C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TX128_255OCTGB	[31:0]	r	TX128_255OCTGB This field indicates the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_256To511Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_256TO511OCTETS_FRAMES_GOOD_BAD

Register 76 - Transmit Octet Count for Good and Bad 256 to 511 Bytes Frames (1130_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TX256_511OCTGB	[31:0]	r	TX256_511OCTGB This field indicates the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_512To1023Octets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_512TO1023OCTETS_FRAMES_GOOD_BAD

Register 77 - Transmit Octet Count for Good and Bad 512 to 1023 Bytes Frames (1134_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TX512_1023OCTGB	[31:0]	r	TX512_1023OCTGB This field indicates the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

Ethernet MAC (ETH)

32-bit Register - Tx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of transmitted good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

ETH_TX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

Register 78 - Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes

Frames (1138_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TX1024_M AXOCTGB	[31:0]	r	TX1024_MAXOCTGB This field indicates the number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Tx_Unicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad unicast frames.

ETH_TX_UNICAST_FRAMES_GOOD_BAD

Register 79 - Transmit Frame Count for Good and Bad Unicast Frames (113C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXUCASTGB	[31:0]	r	TXUCASTGB This field indicates the number of transmitted good and bad unicast frames.

32-bit Register - Tx_Multicast_Frames_Good_Bad

This register maintains the number of transmitted good and bad multicast frames.

ETH_TX_MULTICAST_FRAMES_GOOD_BAD

Register 80 - Transmit Frame Count for Good and Bad Multicast Frames (1140_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXMCASTGB	[31:0]	r	TXMCASTGB This field indicates the number of transmitted good and bad multicast frames.

32-bit Register - Tx_Broadcast_Frames_Good_Bad

This register maintains the number of transmitted good and bad broadcast frames.

ETH_TX_BROADCAST_FRAMES_GOOD_BAD

Register 81 - Transmit Frame Count for Good and Bad Broadcast Frames (1144_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXBCAST GB	[31:0]	r	TXBCASTGB This field indicates the number of transmitted good and bad broadcast frames.

32-bit Register - Tx_Underflow_Error_Frames

This register maintains the number of frames aborted because of frame underflow error.

ETH_TX_UNDERFLOW_ERROR_FRAMES

Register 82 - Transmit Frame Count for Underflow Error Frames (1148_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXUNDRFLW	[31:0]	r	TXUNDRFLW This field indicates the number of frames aborted because of frame underflow error.

32-bit Register - Tx_Single_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after a single collision in the half-duplex mode.

ETH_TX_SINGLE_COLLISION_GOOD_FRAMES

Register 83 - Transmit Frame Count for Frames Transmitted after Single Collision (114C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXSNGLCOLG	[31:0]	r	TXSNGLCOLG This field indicates the number of successfully transmitted frames after a single collision in the half-duplex mode.

32-bit Register - Tx_Multiple_Collision_Good_Frames

This register maintains the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

ETH_TX_MULTIPLE_COLLISION_GOOD_FRAMES

Register 84 - Transmit Frame Count for Frames Transmitted after Multiple

Collision

(1150_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXMULTCOLG	[31:0]	r	TXMULTCOLG This field indicates the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

32-bit Register - Tx_Deferred_Frames

This register maintains the number of successfully transmitted frames after a deferral in the half-duplex mode.

ETH_TX_DEFERRED_FRAMES

Register 85 - Transmit Frame Count for Deferred Frames (1154_H)

Reset Value:

0000 0000_H

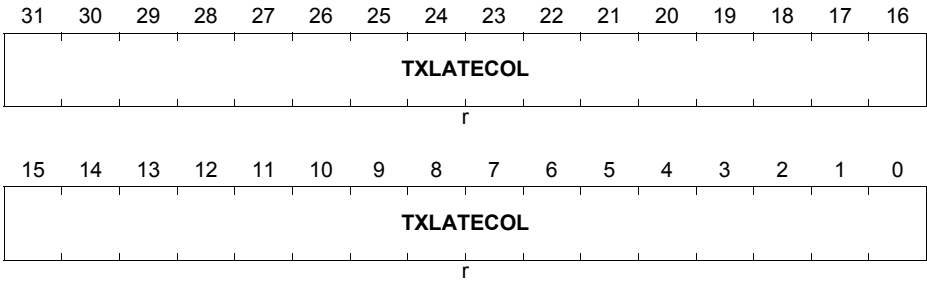

Field	Bits	Type	Description
TXDEFRD	[31:0]	r	TXDEFRD This field indicates the number of successfully transmitted frames after a deferral in the half-duplex mode.

32-bit Register - Tx_Late_Collision_Frames

This register maintains the number of frames aborted because of late collision error.

ETH_TX_LATE_COLLISION_FRAMES

Register 86 - Transmit Frame Count for Late Collision Error Frames (1158_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXLATECOL	[31:0]	r	TXLATECOL This field indicates the number of frames aborted because of late collision error.

32-bit Register - Tx_Excessive_Collision_Frames

This register maintains the number of frames aborted because of excessive (16) collision error.

ETH_TX_EXCESSIVE_COLLISION_FRAMES

Register 87 - Transmit Frame Count for Excessive Collision Error Frames

(115C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXEXSCOL	[31:0]	r	TXEXSCOL This field indicates the number of frames aborted because of excessive (16) collision error.

32-bit Register - Tx_Carrier_Error_Frames

This register maintains the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

ETH_TX_CARRIER_ERROR_FRAMES

Register 88 - Transmit Frame Count for Carrier Sense Error Frames (1160_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXCARR	[31:0]	r	TXCARR This field indicates the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

32-bit Register - Tx_Octet_Count_Good

This register maintains the number of bytes transmitted, exclusive of preamble, in good frames.

ETH_TX_OCTET_COUNT_GOOD

Register 89 - Transmit Octet Count for Good Frames (1164_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXOCTG	[31:0]	r	TXOCTG This field indicates the number of bytes transmitted, exclusive of preamble, in good frames.

32-bit Register - Tx_Frame_Count_Good

This register maintains the number of transmitted good frames, exclusive of preamble.

ETH_TX_FRAME_COUNT_GOOD

Register 90 - Transmit Frame Count for Good Frames (1168_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXFRMG	[31:0]	r	TXFRMG This field indicates the number of transmitted good frames, exclusive of preamble.

32-bit Register - Tx_Excessive_Deferral_Error

This register maintains the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

ETH_TX_EXCESSIVE_DEFERRAL_ERROR

Register 91 - Transmit Frame Count for Excessive Deferral Error Frames (116C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXEXSDEF	[31:0]	r	<p>TXEXSDEF</p> <p>This field indicates the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.</p>

32-bit Register - Tx_Pause_Frames

This register maintains the number of transmitted good PAUSE frames.

ETH_TX_PAUSE_FRAMES

Register 92 - Transmit Frame Count for Good PAUSE Frames (1170_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXPAUSE	[31:0]	r	TXPAUSE This field indicates the number of transmitted good PAUSE frames.

32-bit Register - Tx_VLAN_Frames_Good

This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

ETH_TX_VLAN_FRAMES_GOOD

Register 93 - Transmit Frame Count for Good VLAN Frames (1174_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXVLANG	[31:0]	r	<p>TXVLANG This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.</p>

32-bit Register - Tx_OSize_Frames_Good

This register maintains the number of transmitted good Oversize frames, exclusive of retried frames.

ETH_TX_OSIZG_FRAMES_GOOD

Register 94 - Transmit Frame Count for Good Oversize Frames (1178_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TXOSIZG	[31:0]	r	TXOSIZG This field indicates the number of frames transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged frames; 2000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_Frames_Count_Good_Bad

This register maintains the number of received good and bad frames.

ETH_RX_FRAMES_COUNT_GOOD_BAD

Register 96 - Receive Frame Count for Good and Bad Frames (1180_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXFRMGB	[31:0]	r	RXFRMGB This field indicates the number of received good and bad frames.

Ethernet MAC (ETH)

32-bit Register - Rx_Octet_Count_Good_Bad

This register maintains the number of bytes received, exclusive of preamble, in good and bad frames.

ETH_RX_OCTET_COUNT_GOOD_BAD

Register 97 - Receive Octet Count for Good and Bad Frames (1184_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXOCTGB	[31:0]	r	RXOCTGB This field indicates the number of bytes received, exclusive of preamble, in good and bad frames.

Ethernet MAC (ETH)

32-bit Register - Rx_Octet_Count_Good

This register maintains the number of bytes received, exclusive of preamble, only in good frames.

ETH_RX_OCTET_COUNT_GOOD

Register 98 - Receive Octet Count for Good Frames (1188_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXOCTG	[31:0]	r	RXOCTG This field indicates the number of bytes received, exclusive of preamble, only in good frames.

32-bit Register - Rx_Broadcast_Frames_Good

This register maintains the number of received good broadcast frames.

ETH_RX_BROADCAST_FRAMES_GOOD

Register 99 - Receive Frame Count for Good Broadcast Frames (118C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXBCASTG	[31:0]	r	RXBCASTG This field indicates the number of received good broadcast frames.

32-bit Register - Rx_Multicast_Frames_Good

This register maintains the number of received good multicast frames.

ETH_RX_MULTICAST_FRAMES_GOOD

Register 100 - Receive Frame Count for Good Multicast Frames (1190_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXMCASTG	[31:0]	r	RXMCASTG This field indicates the number of received good multicast frames.

32-bit Register - Rx_CRC_Error_Frames

This register maintains the number of frames received with CRC error.

ETH_RX_CRC_ERROR_FRAMES

Register 101 - Receive Frame Count for CRC Error Frames (1194_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXCRCERR	[31:0]	r	RXCRCERR This field indicates the number of frames received with CRC error.

32-bit Register - Rx_Alignment_Error_Frames

This register maintains the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

ETH_RX_ALIGNMENT_ERROR_FRAMES

Register 102 - Receive Frame Count for Alignment Error Frames (1198_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXALGNERR	[31:0]	r	RXALGNERR This field indicates the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.

32-bit Register - Rx_Runt_Error_Frames

This register maintains the number of frames received with runt error(<64 bytes and CRC error).

ETH_RX_RUNT_ERROR_FRAMES

Register 103 - Receive Frame Count for Runt Error Frames (119C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXRUNTE RR	[31:0]	r	RXRUNTERR This field indicates the number of frames received with runt error(<64 bytes and CRC error).

32-bit Register - Rx_Jabber_Error_Frames

This register maintains the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

ETH_RX_JABBER_ERROR_FRAMES

Register 104 - Receive Frame Count for Jabber Error Frames (11A0_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXJABERR	[31:0]	r	RXJABERR This field indicates the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

32-bit Register - Rx_Undersize_Frames_Good

This register maintains the number of frames received with length less than 64 bytes and without errors.

ETH_RX_UNDERSIZE_FRAMES_GOOD

Register 105 - Receive Frame Count for Undersize Frames (11A4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXUNDER SZG	[31:0]	r	RXUNDERSZG This field indicates the number of frames received with length less than 64 bytes and without errors.

32-bit Register - Rx_Oversize_Frames_Good

This register maintains the number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames) and without errors.

ETH_RX_OVERSIZE_FRAMES_GOOD

Register 106 - Receive Frame Count for Oversize Frames (11A8_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXOVERSZG	[31:0]	r	RXOVERSZG This field indicates the number of frames received without errors, with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames; 2,000 bytes if enabled in bit 27 of Register 0 (MAC Configuration Register)).

32-bit Register - Rx_64Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length 64 bytes, exclusive of preamble.

ETH_RX_64OCTETS_FRAMES_GOOD_BAD

Register 107 - Receive Frame Count for Good and Bad 64 Byte Frames (11AC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX64OCTGB	[31:0]	r	RX64OCTGB This field indicates the number of received good and bad frames with length 64 bytes, exclusive of preamble.

32-bit Register - Rx_65To127Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

ETH_RX_65TO127OCTETS_FRAMES_GOOD_BAD

Register 108 - Receive Frame Count for Good and Bad 65 to 127 Bytes Frames (11B0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX65_127 OCTGB	[31:0]	r	RX65_127OCTGB This field indicates the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

Ethernet MAC (ETH)

32-bit Register - Rx_128To255Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

ETH_RX_128TO255OCTETS_FRAMES_GOOD_BAD

Register 109 - Receive Frame Count for Good and Bad 128 to 255 Bytes Frames (11B4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX128_255OCTGB	[31:0]	r	RX128_255OCTGB This field indicates the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

Ethernet MAC (ETH)

32-bit Register - Rx_256To511Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

ETH_RX_256TO511OCTETS_FRAMES_GOOD_BAD

Register 110 - Receive Frame Count for Good and Bad 256 to 511 Bytes Frames (11B8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX256_511OCTGB	[31:0]	r	RX256_511OCTGB This field indicates the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

Ethernet MAC (ETH)

32-bit Register - Rx_512To1023Octets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

ETH_RX_512TO1023OCTETS_FRAMES_GOOD_BAD

Register 111 - Receive Frame Count for Good and Bad 512 to 1,023 Bytes Frames (11BC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX512_1023OCTGB	[31:0]	r	RX512_1023OCTGB This field indicates the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

Ethernet MAC (ETH)

32-bit Register - Rx_1024ToMaxOctets_Frames_Good_Bad

This register maintains the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble.

ETH_RX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

Register 112 - Receive Frame Count for Good and Bad 1,024 to Maxsize Bytes Frames (11C0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RX1024_MAXOCTGB	[31:0]	r	RX1024_MAXOCTGB This field indicates the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

32-bit Register - Rx_Unicast_Frames_Good

This register maintains the number of received good unicast frames.

ETH_RX_UNICAST_FRAMES_GOOD

Register 113 - Receive Frame Count for Good Unicast Frames (11C4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXUCASTG	[31:0]	r	RXUCASTG This field indicates the number of received good unicast frames.

32-bit Register - Rx_Length_Error_Frames

This register maintains the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

ETH_RX_LENGTH_ERROR_FRAMES

Register 114 - Receive Frame Count for Length Error Frames (11C8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXLENER R	[31:0]	r	RXLENERR This field indicates the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

32-bit Register - Rx_Out_Of_Range_Type_Frames

This register maintains the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

ETH_RX_OUT_OF_RANGE_TYPE_FRAMES

Register 115 - Receive Frame Count for Out of Range Frames (11CC_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXOUTOFRNG	[31:0]	r	RXOUTOFRNG This field indicates the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

32-bit Register - Rx_Pause_Frames

This register maintains the number of received good and valid PAUSE frames.

ETH_RX_PAUSE_FRAMES

Register 116 - Receive Frame Count for PAUSE Frames (11D0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXPAUSE FRM	[31:0]	r	RXPAUSEFRM This field indicates the number of received good and valid PAUSE frames.

32-bit Register - Rx_FIFO_Overflow_Frames

This register maintains the number of received frames missed because of FIFO overflow.

ETH_RX_FIFO_OVERFLOW_FRAMES

Register 117 - Receive Frame Count for FIFO Overflow Frames (11D4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXFIFOVFL	[31:0]	r	RXFIFOVFL This field indicates the number of received frames missed because of FIFO overflow.

32-bit Register - Rx_VLAN_Frames_Good_Bad

This register maintains the number of received good and bad VLAN frames.

ETH_RX_VLAN_FRAMES_GOOD_BAD

Register 118 - Receive Frame Count for Good and Bad VLAN Frames (11D8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXVLANFRGB	[31:0]	r	RXVLANFRGB This field indicates the number of received good and bad VLAN frames.

32-bit Register - Rx_Watchdog_Error_Frames

This register maintains the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

ETH_RX_WATCHDOG_ERROR_FRAMES

Register 119 - Receive Frame Count for Watchdog Error Frames (11DC_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXWDGERR	[31:0]	r	RXWDGERR This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Receive_Error_Frames

This register maintains the number of frames received with error because of the GMII/MII RXER error.

ETH_RX_RECEIVE_ERROR_FRAMES

Register 120 - Receive Frame Count for Receive Error Frames (11E0_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXRCVERR	[31:0]	r	RXRCVERR This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - Rx_Control_Frames_Good

This register maintains the number of good control frames received.

ETH_RX_CONTROL_FRAMES_GOOD

Register 121 - Receive Frame Count for Good Control Frames (11E4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXCTRLG	[31:0]	r	RXCTRLG This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

32-bit Register - MMC_IPC_Receive_Interrupt_Mask

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. This register is 32-bits wide. This register is present only when any one of the MMC Receive IPC Counters is selected during core configuration.

ETH_MMC_IPC_RECEIVE_INTERRUPT_MASK
Register 128 - MMC Receive Checksum Offload Interrupt Mask Register (1200_H)
Reset Value: 0000 0000_H

32-bit Register - RxIPv4_Good_Frames

This register maintains the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

ETH_RXIPV4_GOOD_FRAMES

Register 132 - Receive IPV4 Good Frame Counter Register (1210_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4GDFRM	[31:0]	r	RXIPV4GDFRM This field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

32-bit Register - RxIPv4_Header_Error_Frames

This register maintains the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

ETH_RXIPV4_HEADER_ERROR_FRAMES

Register 133 - Receive IPV4 Header Error Frame Counter Register (1214_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4HDRERRFRM	[31:0]	r	RXIPV4HDRERRFRM This field indicates the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

32-bit Register - RxIPv4_No_Payload_Frames

This register maintains the number of received IPv4 datagram frames without a TCP, UDP, or ICMP payload processed by the Checksum engine.

ETH_RXIPV4_NO_PAYLOAD_FRAMES

Register 134 - Receive IPV4 No Payload Frame Counter Register (1218_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4NO PAYFRM	[31:0]	r	RXIPV4NOPAYFRM This field indicates the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine.

32-bit Register - RxIPv4_Fragmented_Frames

This register maintains the number of good IPv4 datagrams received with fragmentation.

ETH_RXIPV4_FRAGMENTED_FRAMES

Register 135 - Receive IPV4 Fragmented Frame Counter Register (121C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4FRAGFRM	[31:0]	r	RXIPV4FRAGFRM This field indicates the number of good IPv4 datagrams received with fragmentation.

Ethernet MAC (ETH)

32-bit Register - RxIPv4_UDP_Checksum_Disabled_Frames

This register maintains the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLED_FRAMES

Register 136 - Receive IPV4 UDP Checksum Disabled Frame Counter Register (1220_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4UDSBLFRM	[31:0]	r	RXIPV4UDSBLFRM This field indicates the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

32-bit Register - RxIPv6_Good_Frames

This register maintains the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

ETH_RXIPV6_GOOD_FRAMES

Register 137 - Receive IPV6 Good Frame Counter Register (1224_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV6GDFRM	[31:0]	r	RXIPV6GDFRM This field indicates the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

32-bit Register - RxIPv6_Header_Error_Frames

This register maintains the number of IPv6 datagrams received with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_FRAMES

Register 138 - Receive IPV6 Header Error Frame Counter Register (1228_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV6HDRERRFRM	[31:0]	r	RXIPV6HDRERRFRM This field indicates the number of IPv6 datagrams received with header errors (length or version mismatch).

32-bit Register - RxIPv6_No_Payload_Frames

This register maintains the number of received IPv6 datagram frames without a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

ETH_RXIPV6_NO_PAYLOAD_FRAMES

Register 139 - Receive IPV6 No Payload Frame Counter Register (122C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXIPV6NO PAYFRM	[31:0]	r	RXIPV6NOPAYFRM This field indicates the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

32-bit Register - RxUDP_Good_Frames

This register maintains the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

ETH_RXUDP_GOOD_FRAMES

Register 140 - Receive UDP Good Frame Counter Register (1230_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXUDPGDFRM	[31:0]	r	RXUDPGDFRM This field indicates the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

32-bit Register - RxUDP_Error_Frames

This register maintains the number of good IP datagrams whose UDP payload has a checksum error.

ETH_RXUDP_ERROR_FRAMES

Register 141 - Receive UDP Error Frame Counter Register (1234_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXUDPER RFRM	[31:0]	r	RXUDPERFRM This field indicates the number of good IP datagrams whose UDP payload has a checksum error.

32-bit Register - RxTCP_Good_Frames

This register maintains the number of good IP datagrams with a good TCP payload.

ETH_RXTCP_GOOD_FRAMES

Register 142 - Receive TCP Good Frame Counter Register (1238_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXTCPGD FRM	[31:0]	r	RXTCPGDFRM This field indicates the number of good IP datagrams with a good TCP payload.

32-bit Register - RxTCP_Error_Frames

This register maintains the number of good IP datagrams whose TCP payload has a checksum error.

ETH_RXTCP_ERROR_FRAMES

Register 143 - Receive TCP Error Frame Counter Register (123C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXTCPERRFRM	[31:0]	r	RXTCPERRFRM This field indicates the number of good IP datagrams whose TCP payload has a checksum error.

32-bit Register - RxICMP_Good_Frames

This register maintains the number of good IP datagrams with a good ICMP payload.

ETH_RXICMP_GOOD_FRAMES

Register 144 - Receive ICMP Good Frame Counter Register (1240_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXICMPGDFRM	[31:0]	r	RXICMPGDFRM This field indicates the number of good IP datagrams with a good ICMP payload.

32-bit Register - RxICMP_Error_Frames

This register maintains the number of good IP datagrams whose ICMP payload has a checksum error.

ETH_RXICMP_ERROR_FRAMES

Register 145 - Receive ICMP Error Frame Counter Register (1244_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXICMPERRFRM	[31:0]	r	RXICMPERRFRM This field indicates the number of good IP datagrams whose ICMP payload has a checksum error.

32-bit Register - RxIPv4_Good_Octets

This register maintains the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

ETH_RXIPV4_GOOD_OCTETS

Register 148 - Receive IPV4 Good Octet Counter Register (1250_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4GD OCT	[31:0]	r	This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv4_Header_Error_Octets

This register maintains the number of bytes received in IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of the IPv4 header is used to update this counter.

ETH_RXIPV4_HEADER_ERROR_OCTETS

Register 149 - Receive IPV4 Header Error Octet Counter Register (1254_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXIPV4HDRERROCT	[31:0]	r	This field indicates the number of bytes received in the IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of IPv4 header is used to update this counter. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

Ethernet MAC (ETH)

32-bit Register - RxIPv4_No_Payload_Octets

This register maintains the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_NO_PAYLOAD_OCTETS

Register 150 - Receive IPV4 No Payload Octet Counter Register (1258_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXIPV4NO PAYOCT	[31:0]	r	This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

Ethernet MAC (ETH)

32-bit Register - RxIPv4_Fragmented_Octets

This register maintains the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.

ETH_RXIPV4_FRAGMENTED_OCTETS

Register 151 - Receive IPV4 Fragmented Octet Counter Register (125C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV4FRAGOCT	[31:0]	r	This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

Ethernet MAC (ETH)

32-bit Register - RxIPv4_UDP_Checksum_Disable_Octets

This register maintains the number of bytes received in a UDP segment that had the UDP checksum disabled.

ETH_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS

Register 152 - Receive IPV4 Fragmented Octet Counter Register (1260_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXIPV4UDSBLOCT	[31:0]	r	RXIPV4UDSBLOCT This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

Ethernet MAC (ETH)

32-bit Register - RxIPv6_Good_Octets

This register maintains the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.

ETH_RXIPV6_GOOD_OCTETS

Register 153 - Receive IPV6 Good Octet Counter Register (1264_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV6GD OCT	[31:0]	r	<p>This field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.</p> <p>This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.</p>

32-bit Register - RxIPv6_Header_Error_Octets

This register maintains the number of bytes received in IPv6 datagrams with header errors (length or version mismatch).

ETH_RXIPV6_HEADER_ERROR_OCTETS

Register 154 - Receive IPv6 Header Error Octet Counter Register (1268_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXIPV6HDRERROCT	[31:0]	r	This field indicates the number of bytes received in IPv6 datagrams with header errors (length or version mismatch). The value in the IPv6 headers Length field is used to update this counter. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxIPv6_No_Payload_Octets

This register maintains the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload.

ETH_RXIPV6_NO_PAYLOAD_OCTETS

Register 155 - Receive IPv6 No Payload Octet Counter Register (126C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXIPV6NO PAYOCT	[31:0]	r	This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Good_Octets

This register maintains the number of bytes received in a good UDP segment.

ETH_RXUDP_GOOD_OCTETS

Register 156 - Receive UDP Good Octet Counter Register (1270_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXUDPGD OCT	[31:0]	r	RXUDPGDOCT This field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxUDP_Error_Octets

This register maintains the number of bytes received in a UDP segment with checksum errors.

ETH_RXUDP_ERROR_OCTETS

Register 157 - Receive UDP Error Octet Counter Register (1274_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXUDPERROCT	[31:0]	r	RXUDPERROCT This field indicates the number of bytes received in a UDP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Good_Octets

This register maintains the number of bytes received in a good TCP segment.

ETH_RXTCP_GOOD_OCTETS

Register 158 - Receive TCP Good Octet Counter Register (1278_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXTCPGD OCT	[31:0]	r	RXTCPGDOCT This field indicates the number of bytes received in a good TCP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxTCP_Error_Octets

This register maintains the number of bytes received in a TCP segment with checksum errors.

ETH_RXTCP_ERROR_OCTETS

Register 159 - Receive TCP Error Octet Counter Register (127C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXTCPERROCT	[31:0]	r	RXTCPERROCT This field indicates the number of bytes received in a TCP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Good_Octets

This register maintains the number of bytes received in a good ICMP segment.

ETH_RXICMP_GOOD_OCTETS

Register 160 - Receive ICMP Good Octet Counter Register (1280_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXICMPG DOCT	[31:0]	r	RXICMPGDOCT This field indicates the number of bytes received in a good ICMP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

32-bit Register - RxICMP_Error_Octets

This register maintains the number of bytes received in a ICMP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

ETH_RXICMP_ERROR_OCTETS

Register 161 - Receive ICMP Error Octet Counter Register (1284_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXICMPERROCT	[31:0]	r	RXICMPERROCT Number of bytes received in an ICMP segment with checksum errors

Ethernet MAC (ETH)
32-bit Register - Timestamp_Control

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver. Note: * Bits[5:1] are reserved when External Timestamp Input feature is enabled. * Bits[19:8] are reserved and read-only when Advanced Timestamp feature is not enabled. * Bits[28:24] are reserved and read-only when Auxiliary Snapshot feature is not enabled. * Release 3.60a onwards, the functions of Bits 17 and 16 (SNAPTYPSEL) have changed. These functions are not backward compatible with the functions described in release 3.50a.

ETH_TIMESTAMP_CONTROL
Register 448 - Timestamp Control Register (1700_H) **Reset Value: 0000 2000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	r	rw	rw	rw	rw	rw	rw	

Field	Bits	Type	Description
TSENA	0	rw	Timestamp Enable When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set.
TSCFUPDT	1	rw	Timestamp Fine or Coarse Update When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TSINIT	2	rw	<p>Timestamp Initialize</p> <p>When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized.</p>
TSUPDT	3	rw	<p>Timestamp Update</p> <p>When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated.</p>
TSTRIG	4	rw	<p>Timestamp Interrupt Trigger Enable</p> <p>When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt.</p>
TSADDRE G	5	rw	<p>Addend Reg Update</p> <p>When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it.</p>
RESERVE D_7_6	[7:6]	r	RESERVED_7_6
TSENALL	8	rw	<p>Enable Timestamp for All Frames</p> <p>When set, the timestamp snapshot is enabled for all frames received by the MAC.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
TSCTRLS SR	9	rw	Timestamp Digital or Binary Rollover Control When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit.
TSVER2E NA	10	rw	Enable PTP packet Processing for Version 2 Format When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format.
TSIPENA	11	rw	Enable Processing of PTP over Ethernet Frames When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets.
TSIPV6EN A	12	rw	Enable Processing of PTP Frames Sent Over IPv6-UDP When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.
TSIPV4EN A	13	rw	Enable Processing of PTP Frames Sent over IPv4-UDP When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default.
TSEVNT NA	14	rw	Enable Timestamp Snapshot for Event Messages When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling.
TSMSTRE NA	15	rw	Enable Snapshot for Messages Relevant to Master When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Ethernet MAC (ETH)

Field	Bits	Type	Description
SNAPTYP SEL	[17:16]	rw	Select PTP packets for Taking Snapshots These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.
TSENMAC ADDR	18	rw	Enable MAC address for PTP Frame Filtering When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet.
RESERVE D_23_19	[23:19]	r	RESERVED_23_19
ATSFC	24	r	Auxiliary Snapshot FIFO Clear When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. This bit is reserved when the Add IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN0	25	r	Auxiliary Snapshot 0 Enable This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration.
ATSEN1	26	r	Auxiliary Snapshot 1 Enable This field controls capturing the Auxiliary Snapshot Trigger 1. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than two.

Ethernet MAC (ETH)

Field	Bits	Type	Description
ATSEN2	27	r	<p>Auxiliary Snapshot 2 Enable</p> <p>This field controls capturing the Auxiliary Snapshot Trigger 2. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than three.</p>
ATSEN3	28	r	<p>Auxiliary Snapshot 3 Enable</p> <p>This field controls capturing the Auxiliary Snapshot Trigger 3. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored. This bit is reserved when the IEEE 1588 Auxiliary Snapshot option is not selected during core configuration or the selected number in the Number of IEEE 1588 Auxiliary Snapshot Inputs option is less than four.</p>
RESERVE D_31_29	[31:29]	r	RESERVED_31_29

32-bit Register - Sub_Second_Increment

This register is present only when the IEEE 1588 timestamp feature is selected without an external timestamp input. In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

ETH_SUB_SECOND_INCREMENT

Register 449 - Sub-Second Increment Register (1704_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SSINC	[7:0]	rw	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of <code>clk_ptp_i</code>) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.
RESERVE D_31_8	[31:8]	r	RESERVED_31_8

32-bit Register - System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to clk_csr_i). These registers (450 and 451) are present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS

Register 450 - System Time - Seconds Register (1708_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSS	[31:0]	r	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

Ethernet MAC (ETH)

32-bit Register - System_Time_Nanoseconds

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set, each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.

ETH_SYSTEM_TIME_NANOSECONDS

Register 451 - System Time - Nanoseconds Register (170C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSSS	[30:0]	r	Timestamp Sub Seconds The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TSCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.
RESERVED_31	31	r	RESERVED_31

32-bit Register - System_Time_Seconds_Update

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_SECONDS_UPDATE

Register 452 - System Time - Seconds Update Register (1710_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSS	[31:0]	rw	Timestamp Second The value in this field indicates the time in seconds to be initialized or added to the system time.

32-bit Register - System_Time_Nanoseconds_Update

This register is present only when IEEE 1588 timestamp feature is selected without external timestamp input.

ETH_SYSTEM_TIME_NANOSECONDS_UPDATE

Register 453 - System Time - Nanoseconds Update Register (1714_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSSS	[30:0]	rw	Timestamp Sub Second The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When bit 9 (TCTRLSSR) is set in Register 448 (Timestamp Control Register), each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF.
ADDSUB	31	rw	Add or subtract time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

32-bit Register - Timestamp_Addend

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

ETH_TIMESTAMP_ADDEND

Register 454 - Timestamp Addend Register (1718_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSAR	[31:0]	rw	Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

32-bit Register - Target_Time_Seconds

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers. This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_SECONDS

Register 455 - Target Time Seconds Register (171C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TSTR	[31:0]	rw	Target Time Seconds Register This register stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, then based on Bits [6:5] of Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled).

32-bit Register - Target_Time_Nanoseconds

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

ETH_TARGET_TIME_NANOSECONDS

Register 456 - Target Time Nanoseconds Register (1720_H)

Reset Value: 0000

0000_H

Field	Bits	Type	Description
TTSLO	[30:0]	rw	<p>Target Timestamp Low Register</p> <p>This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
TRGTBUSY	31	r	<p>Target Time Register Busy</p> <p>The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain.</p> <p>The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.</p>

32-bit Register - System_Time_Higher_Word_Seconds

This register is present only when the IEEE 1588 Advanced Timestamp feature is selected without an external timestamp input.

ETH_SYSTEM_TIME_HIGHER_WORD_SECONDS

Register 457 - System Time - Higher Word Seconds Register (1724_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TSHWR	[15:0]	rw	Timestamp Higher Word Register This field contains the most significant 16-bits of the timestamp seconds value. This register is optional and can be selected using the Enable IEEE 1588 Higher Word Register option during core configuration. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the System Time - Seconds register.
RESERVE D_31_16	[31:16]	r	RESERVED_31_16

32-bit Register - Timestamp_Status

This register is present only when Advanced IEEE 1588 Timestamp feature is selected. All bits except Bits[27:25] gets cleared when the host reads this register.

ETH_TIMESTAMP_STATUS
Register 458 - Timestamp Status Register (1728_H)
Reset Value: 0000 0000_H

Ethernet MAC (ETH)

Field	Bits	Type	Description
PPSCTRL _PPSCMD	[3:0]	rw	<p>PPSCTRL0 or PPSCMD0</p> <p>PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:</p> <ul style="list-style-type: none"> -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. <p>Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:</p> <ul style="list-style-type: none"> * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: <ul style="list-style-type: none"> - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: <ul style="list-style-type: none"> - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) <p>This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register).</p> <p>Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is</p>

Field	Bits	Type	Description
SWR	0	rw	<p>Software Reset</p> <p>When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the DWC_gmac clock domains. Before reprogramming any register of the DWC_gmac, you should read a zero (0) value in this bit .</p> <p> Note:
</p> <p>* The Software reset function is driven only by this bit. Bit 0 of Register 64 (Channel 1 Bus Mode Register) or Register 128 (Channel 2 Bus Mode Register) has no impact on the Software reset function.</p> <p>* The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
DA	1	rw	<p>DMA Arbitration Scheme</p> <p>This bit specifies the arbitration scheme between the transmit and receive paths of Channel 0.</p> <ul style="list-style-type: none"> * 0: Weighted round-robin with Rx:Tx or Tx:Rx. <p>The priority between the paths is according to the priority specified in bits 15:14 (PR) and priority weights specified in Bit 27 (TXPR).</p> <ul style="list-style-type: none"> * 1: Fixed priority. <p>The transmit path has priority over receive path when Bit 27 (TXPR) is set. Otherwise, receive path has priority over the transmit path.</p> <p>In the GMAC-AXI configuration, these bits are reserved and read-only (RO).</p>
DSL	[6:2]	rw	<p>Descriptor Skip Length</p> <p>This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
ATDS	7	rw	<p>Alternate Descriptor Size</p> <p>When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory. This bit is present only when you select the Alternate Descriptor feature and any one of the following features during core configuration:</p> <ul style="list-style-type: none"> * Advanced Timestamp feature * IPC Full Checksum Offload Engine (Type 2) feature <p>Otherwise, this bit is reserved and read-only. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
PBL	[13:8]	rw	<p>Programmable Burst Length</p> <p>These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions.</p> <p>If the number of beats to be transferred is more than 32, then perform the following steps:</p> <ol style="list-style-type: none"> 1. Set the PBLx8 mode.
 2. Set the PBL.
 <p>For example, if the maximum number of beats to be transferred is 64, then first set PBLx8 to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.</p> <p>For different data bus widths and FIFO sizes, the valid PBL range (including x8 mode) is provided in the following list. If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered.</p> <p>Note: In the half-duplex mode, the valid PBL range specified in the following list is applicable only for Tx FIFO.</p> <p>* 32-Bit Data Bus Width</p> <p>- 2 KB and Higher FIFO Depth: All PBL values are supported in the full-duplex mode and half-duplex modes.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
PR	[15:14]	rw	<p>Priority Ratio</p> <p>These bits control the priority ratio in the weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when Bit 1 (DA) is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether Bit 27 (TXPR) is reset or set.</p> <ul style="list-style-type: none"> * 00: The Priority Ratio is 1:1. * 01: The Priority Ratio is 2:1. * 10: The Priority Ratio is 3:1. * 11: The Priority Ratio is 4:1. <p>In the GMAC-AXI configuration, these bits are reserved and read-only (RO).</p>
FB	16	rw	<p>Fixed Burst</p> <p>This bit controls whether the AHB or AXI Master interface performs fixed burst transfers or not. When set, the AHB interface uses only SINGLE, INCR4, INCR8, or INCR16 during start of the normal burst transfers. When reset, the AHB or AXI interface uses SINGLE and INCR burst transfer operations.</p> <p>For more information, see Bit 0 (UNDEF) of the AXI Bus Mode register in the GMAC-AXI configuration.</p>
RPBL	[22:17]	rw	<p>Rx DMA PBL</p> <p>This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write.</p> <p>The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high.</p>
USP	23	rw	<p>Use Separate PBL</p> <p>When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
PBLx8	24	rw	<p>PBLx8 Mode</p> <p>When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.</p> <p>Note: This bit function is not backward compatible. Before release 3.50a, this bit was 4xPBL.</p>
AAL	25	rw	<p>Address Aligned Beats</p> <p>When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address.</p> <p>This bit is valid only in the GMAC-AHB and GMAC-AXI configuration and is reserved (RO with default value 0) in all other configurations.</p>
MB	26	rw	<p>Mixed Burst</p> <p>When this bit is set high and the FB bit is low, the AHB Master interface starts all bursts of length more than 16 with INCR (undefined burst) whereas it reverts to fixed burst transfers (INCRx and SINGLE) for burst length of 16 and less.</p> <p>This bit is valid only in the GMAC-AHB configuration and reserved in all other configuration.</p>
TXPR	27	rw	<p>Transmit Priority</p> <p>When set, this bit indicates that the transmit DMA has higher priority than the receive DMA during arbitration for the system-side bus. In the GMAC-AXI configuration, this bit is reserved and read-only (RO).</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
PRWG	[29:28]	r	Channel Priority Weights This field sets the priority weights for Channel 0 during the round-robin arbitration between the DMA channels for the system bus. * 00: The priority weight is 1. * 01: The priority weight is 2. * 10: The priority weight is 3. * 11: The priority weight is 4. This field is present in all DWC_gmac configurations except GMAC-AXI when you select the AV feature. Otherwise, this field is reserved and read-only (RO).
RESERVE D_31_30	[31:30]	r	RESERVED_31_30

32-bit Register - Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

ETH_TRANSMIT_POLL_DEMAND

Register 1 - Transmit Poll Demand Register (2004_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TPD	[31:0]	rw	Transmit Poll Demand When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.

32-bit Register - Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

ETH_RECEIVE_POLL_DEMAND

Register 2 - Receive Poll Demand Register (2008_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RPD	[31:0]	rw	<p>Receive Poll Demand</p> <p>When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.</p>

32-bit Register - Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_RECEIVE_DESCRIPTOR_LIST_ADDRESS

Register 3 - Receive Descriptor List Address Register (200C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RESERVE D_1_0	[1:0]	r	RESERVED_1_0
RDESLA	[31:2]	rw	Start of Receive List This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH_TRANSMIT_DESCRIPTOR_LIST_ADDRESS

Register 4 - Transmit Descriptor List Address Register (2010_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RESERVE D_1_0	[1:0]	r	RESERVED_1_0
TDESLA	[31:2]	rw	Start of Transmit List This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).

32-bit Register - Status

The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

ETH_STATUS
Register 5 - Status Register

Field	Bits	Type	Description
TI	0	rw	Transmit Interrupt This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.
TPS	1	rw	Transmit Process Stopped This bit is set when the transmission is stopped.
TU	2	rw	Transmit Buffer Unavailable This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.

Ethernet MAC (ETH)

Field	Bits	Type	Description
TJT	3	rw	<p>Transmit Jabber Timeout</p> <p>This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled). When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.</p>
OVF	4	rw	<p>Receive Overflow</p> <p>This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].</p>
UNF	5	rw	<p>Transmit Underflow</p> <p>This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.</p>
RI	6	rw	<p>Receive Interrupt</p> <p>This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.</p>
RU	7	rw	<p>Receive Buffer Unavailable</p> <p>This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.</p>
RPS	8	rw	<p>Receive Process Stopped</p> <p>This bit is asserted when the Receive Process enters the Stopped state.</p>

Ethernet MAC (ETH)

Field	Bits	Type	Description
RWT	9	rw	Receive Watchdog Timeout This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).
ETI	10	rw	Early Transmit Interrupt This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.
RESERVE D_12_11	[12:11]	r	RESERVED_12_11
FBI	13	rw	Fatal Bus Error Interrupt This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.
ERI	14	rw	Early Receive Interrupt This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.
AIS	15	rw	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): <ul style="list-style-type: none"> * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.

Ethernet MAC (ETH)

Ethernet MAC (ETH)

32-bit Register - Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

ETH_MISSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER

Register 8 - Missed Frame and Buffer Overflow Counter Register (2020_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MISFRMCNT	[15:0]	r	MISFRMCNT This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read with mci_be_i[0] at 1'b1.
MISCNTOVF	16	r	MISCNTOVF Overflow bit for Missed Frame Counter
OVFFRMCNT	[27:17]	r	OVFFRMCNT This field indicates the number of frames missed by the application. This counter is incremented each time the MTL asserts the sideband signal mtl_rxoverflow_o. The counter is cleared when this register is read with mci_be_i[2] at 1'b1.

Ethernet MAC (ETH)

Field	Bits	Type	Description
OVFCNTOVF	28	r	OVFCNTOVF Overflow bit for FIFO Overflow Counter

Ethernet MAC (ETH)

32-bit Register - Receive_Interrupt_Watchdog_Timer

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

ETH_RECEIVE_INTERRUPT_WATCHDOG_TIMER

Register 9 - Receive Interrupt Watchdog Timer Register (2024_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RIWT	[7:0]	rw	RI Watchdog Timer Count This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.
RESERVE D_31_8	[31:8]	r	RESERVED_31_8

32-bit Register - AHB_or_AXI_Status

This register provides the active status of the AHB master interface or AXI interface's read and write channels. This register is present and valid only in the GMAC-AHB and GMAC-AXI configurations. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

ETH_AHB_OR_AXI_STATUS

Register 11 - AHB or AXI Status Register (202C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
AXWHSTS	0	r	AXI Master Write Channel or AHB Master Status When high, it indicates that AXI Master's write channel is active and transferring data in the GMAC-AXI configuration. In the GMAC-AHB configuration, it indicates that the AHB master interface FSMs are in the non-idle state.
AXIRDSTS	1	r	AXI Master Read Channel Status When high, it indicates that AXI Master's read channel is active and transferring data.
RESERVE D_31_2	[31:2]	r	RESERVED_31_2

32-bit Register - Current_Host_Transmit_Descriptor

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_DESCRIPTOR

Register 18 - Current Host Transmit Descriptor Register (2048_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CURTDES APTR	[31:0]	r	Host Transmit Descriptor Address Pointer Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Descriptor

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

ETH_CURRENT_HOST_RECEIVE_DESCRIPTOR

Register 19 - Current Host Receive Descriptor Register (204C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CURRDES APTR	[31:0]	r	Host Receive Descriptor Address Pointer Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Transmit_Buffer_Address

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

ETH_CURRENT_HOST_TRANSMIT_BUFFER_ADDRESS

Register 20 - Current Host Transmit Buffer Address Register (2050_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CURTBUF APTR	[31:0]	r	Host Transmit Buffer Address Pointer Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - Current_Host_Receive_Buffer_Address

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

ETH_CURRENT_HOST_RECEIVE_BUFFER_ADDRESS

Register 21 - Current Host Receive Buffer Address Register (2054_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CURRBUF APTR	[31:0]	r	Host Receive Buffer Address Pointer Cleared on Reset. Pointer updated by the DMA during operation.

32-bit Register - HW_Feature

This register indicates the presence of the optional features or functions of the DWC_gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset as per the selection of features during the DWC_gmac configuration.

35.4 Descriptors

This chapter comprises the following subsections:

- **Normal Descriptor Formats**
- **Alternate or Enhanced Descriptors**

*Note: The Ethernet MAC in TC26x B-Step does not support Normal Descriptor Format as it is configured to support IEEE1588 PTP time stamping! Nevertheless parts of the explanations in the chapter **Chapter 1.7.1** are required for complete understanding.*

35.4.1 Normal Descriptor Formats

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors, as explained in **DMA Controller**. The default descriptor formats (common for both Receive and Transmit Descriptors) are shown in **Figure 35-24**, and field descriptions are provided in **Chapter 1.7.1.1** to **Chapter 1.7.1.2**.

Note:

3. All descriptions in **Chapter 1.7.1.1** and **Chapter 1.7.1.2** correspond to the default descriptor format. The alternate enhanced descriptor format is discussed in **Chapter 1.7.2** “Alternate or Enhanced Descriptors” on **Page 1-680**.
4. Changes to the default descriptor format when IEEE1588 time stamping is enabled are described in **Chapter 1.7.1.3** “Descriptor Format With IEEE 1588 Time Stamping Enabled” on **Page 1-676**.

Each descriptor contains two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory management schemes.

The descriptor addresses must be aligned to the bus width used (Word/Dword/Lword for 32-bit buses).

Figure 35-24 shows the descriptor format in a 32-bit data bus.

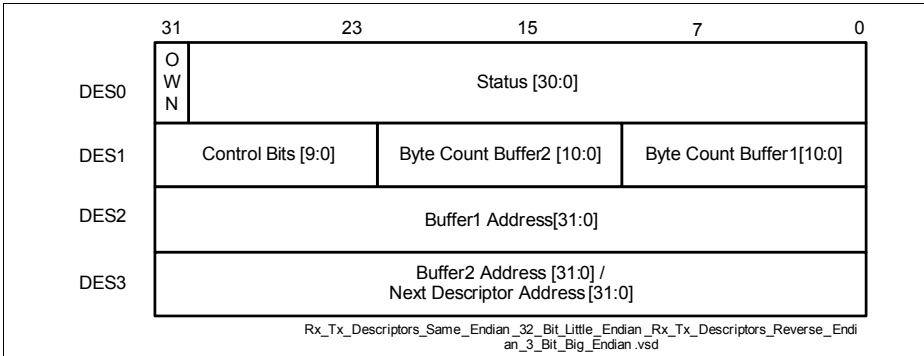

Figure 35-24 Rx/Tx Descriptors for 32-Bit Data Bus

35.4.1.1 Receive Descriptor

The GMAC Subsystem requires at least two descriptors when receiving a frame. The Receive state machine of the DMA (in the GMAC Subsystem) always attempts to acquire an extra descriptor in anticipation of an incoming frame. (The size of the incoming frame is unknown). Before the RxDMA closes a descriptor, it will attempt to acquire the next descriptor even if no frames are received.

In a single descriptor (receive) system, the subsystem will generate a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA. Thus, the Host is forced to increase either its descriptor pool or the buffer size. Otherwise, the subsystem starts dropping all incoming frames.

Figure 35-25 Receive Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Receive Descriptor 0 (RDES0)

RDES0 contains the received frame status, the frame length, and the descriptor ownership information. The descriptions in the following tables (Table 1-83 through Table 1-91) are for the default mode of a Little-Endian 32-bit data bus with Same Endian descriptors, or Big-Endian data bus with Reverse-Endian descriptors. If the DUT is configured for Big-Endian mode, 32-bit data bus with Same Endian descriptors or Little-Endian data bus with Reverse Endian descriptors, then byte lanes 3 and 0 are swapped while byte lanes 1 and 2 are swapped, that is, bits [31:24] will be available on data bus [7:0], and vice-versa.

Table 35-23 Receive Descriptor 0

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM: Destination Address Filter Fail When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.

Table 35-23 Receive Descriptor 0 (cont'd)

Bit	Description
29:1 6	<p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame.</p> <p>This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • RDES0[0]: Payload Checksum Error • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: IPC Checksum (Type 2) / Giant Frame • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
14	<p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
13	<p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.</p>
12	<p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.</p>
11	<p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.</p>

Table 35-23 Receive Descriptor 0 (cont'd)

Bit	Description
10	VLAN: VLAN Tag When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.
9	FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame
7	IPC Checksum Error/Giant Frame When IP Checksum Engine (Type 1) is enabled, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. The Error Summary bit[15] is NOT set when this bit is set in this mode. If this bit is set when Full Checksum Offload Engine (Type 2) is enabled, it indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. Refer to Table 1-84 for more details. If you do not select IP Checksum Module during core configuration, this bit, when set, indicates that the received frame was a Giant Frame. Giant frames are larger-than-1.518-byte (or 1.522-byte for VLAN) normal frames and larger-than-9,018-byte (9.022-byte for VLAN) frame when Jumbo Frame processing is enabled.
6	LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.
5	FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. Refer to Table 1-84 for more details.
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.

Table 35-23 Receive Descriptor 0 (cont'd)

Bit	Description
3	RE: Receive Error When set, this bit indicates that the gmii_rxr_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	CE: CRC Error When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	Rx MAC Address/Payload Checksum Error When set, this bit indicates that the Rx MAC Address registers value (1 to 15) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field. If Full Checksum Offload Engine is enabled, this bit, when set, indicates the TCP, UDP, or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP, or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. Refer to Table 1-84 for more details.

When the Full Checksum Offload Engine (Type 2) is enabled, the permutations of bits 5, 7, and 0 reflect the conditions discussed in [Table 1-84](#).

Table 35-24 Receive Descriptor 0 When COE (Type 2) Is Enabled

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	Frame Status
0	0	0	IEEE 802.3 Type frame (Length field value is less than 0600 _H)
1	0	0	IPv4/IPv6 Type frame, no checksum error detected
1	0	1	IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected

Table 35-24 Receive Descriptor 0 When COE (Type 2) Is Enabled (cont'd)

Bit 5: Frame Type	Bit 7: IPC Checks um Error	Bit 0: Payload Checks um Error	Frame Status
1	1	0	IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected
1	1	1	IPv4/IPv6 Type frame with both IP header and payload checksum errors detected
0	0	1	IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload
0	1	1	A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.)
0	1	0	Reserved

Note: The first five conditions are backward-compatible to versions 3.30a and previous. The last two conditions (001, 011), which had been reserved, are not backward-compatible, because the Frame Type (FT) bit is reset during bypasses, even for valid Type frames.

Receive Descriptor 1 (RDES1)

RDES1 contains the buffer sizes and other bits that control the descriptor chain/ring.

Note: See [Buffer Size Calculations](#) for further detail on calculating buffer sizes.

Table 35-25 Receive Descriptor 1

Bit	Description
31	Disable Interrupt on Completion When set, this bit will prevent the setting of the RI (CSR5[6]) bit of the Status Register for the received frame that ends in the buffer pointed to by this descriptor. This, in turn, will disable the assertion of the interrupt to Host due to RI for that frame.
30:26	Reserved
25	RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.

Table 35-25 Receive Descriptor 1 (cont'd)

Bit	Description
24	RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] is set, RBS2 (RDES1[21-11]) is a “don't care” value. RDES1[25] takes precedence over RDES1[24].
23:22	Reserved
21:11	RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. This field is not valid if RDES1[24] is set.
10:0	RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4/8/16 depending upon the bus widths (32/64/128), even if the value of RDES2 (buffer1 address pointer) is not aligned. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24).

Receive Descriptor 2 (RDES2)

RDES2 contains the address pointer to the first data buffer in the descriptor.

Note: See [Host Data Buffer Alignment](#) for further detail on buffer address alignment.

Table 35-26 Receive Descriptor 2 (Default Operation)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

Receive Descriptor 3 (RDES3)

RDES3 contains the address pointer either to the second data buffer in the descriptor or to the next descriptor.

Table 35-27 Receive Descriptor 3

Bit	Description
31:0	<p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present.</p> <p>If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.</p>

35.4.1.2 Transmit Descriptor

The descriptor addresses must be aligned to the bus width used (32). [Figure 35-26](#) shows the transmit descriptor format in Little-Endian mode with a 32-bit data bus.

Each descriptor is provided with two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory-management schemes.

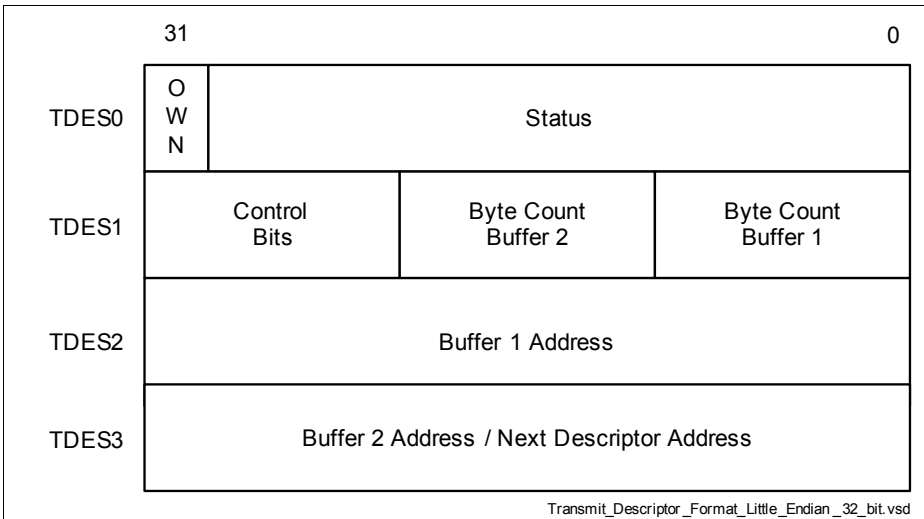

Figure 35-26 Transmit Descriptor Format in Little-Endian Mode With a 32-bit Data Bus

Transmit Descriptor 0 (TDES0)

TDES0 contains the transmitted frame status and the descriptor ownership information.

Table 35-28 Transmit Descriptor 0

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.</p>
30:18	Reserved

Table 35-28 Transmit Descriptor 0 (cont'd)

Bit	Description
17	<p>TTSS: Tx Time Stamp Status</p> <p>This status bit indicates that a time stamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 and TDES3 have time stamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]) in a descriptor is set. This bit is valid only when IEEE1588 time stamping feature is enabled; otherwise, it is reserved.</p>
16	<p>IHE: IP Header Error</p> <p>When set, this bit indicates that the Checksum Offload engine detected an IP header error and consequently did not modify the transmitted frame for any checksum insertion. This bit is valid only when Full Checksum Offload is enabled; otherwise, it is reserved.</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error
14	<p>JT: Jabber Timeout</p> <p>When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.</p>
13	<p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA/MTL flushed the frame due to a SW flush command given by the CPU.</p>

Table 35-28 Transmit Descriptor 0 (cont'd)

Bit	Description
12	<p>PCE: Payload Checksum Error</p> <p>This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either due to insufficient bytes, as indicated by the IP Header's Payload Length field, or the MTL starting to forward the frame to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet frame being transmitted: to avoid deadlock, the MTL starts forwarding the frame when the FIFO is full, even in Store-and-Forward mode.</p> <p>When the Full Checksum Offload engine is not enabled during configuration, this bit is reserved.</p>
11	<p>LC: Loss of Carrier</p> <p>When set, this bit indicates that Loss of Carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision and when the GMAC operates in Half-Duplex Mode.</p>
10	<p>NC: No Carrier</p> <p>When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.</p>
9	<p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode and 512 byte times including Preamble and Carrier Extension in GMII Mode). Not valid if Underflow Error is set.</p>
8	<p>EC: Excessive Collision</p> <p>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration Register is set, this bit is set after the first collision and the transmission of the frame is aborted.</p>
7	<p>VF: VLAN Frame</p> <p>When set, this bit indicates that the transmitted frame was a VLAN-type frame.</p>
6:3	<p>CC: Collision Count</p> <p>This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.</p>

Table 35-28 Transmit Descriptor 0 (cont'd)

Bit	Description
2	<p>ED: Excessive Deferral</p> <p>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode, or in Jumbo Frame enabled mode) if the Deferral Check (DC) bit is set high in the GMAC Control Register.</p>
1	<p>UF: Underflow Error</p> <p>When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).</p>
0	<p>DB: Deferred Bit</p> <p>When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.</p>

Transmit Descriptor 1 (TDES1)

TDES1 contains the buffer sizes and other bits which control the descriptor chain/ring and the frame being transferred.

Note: See [Buffer Size Calculations](#) for further detail on calculating buffer sizes.

Table 35-29 Transmit Descriptor 1

Bit	Description
31	<p>IC: Interrupt on Completion</p> <p>When set, this bit sets Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.</p>
30	<p>LS: Last Segment</p> <p>When set, this bit indicates that the buffer contains the last segment of the frame.</p>
29	<p>FS: First Segment</p> <p>When set, this bit indicates that the buffer contains the first segment of a frame.</p>

Table 35-29 Transmit Descriptor 1 (cont'd)

Bit	Description
28:27	<p>CIC: Checksum Insertion Control</p> <p>These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6 as described below.</p> <ul style="list-style-type: none"> • 2'b00: Do nothing. Checksum Engine is bypassed • 2'b01: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. • 2'b10: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. • 2'b11: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. In other words, the TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. <p>The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.</p>
26	<p>DC: Disable CRC</p> <p>When set, the GMAC does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29]).</p>
25	<p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The returns to the base address of the list, creating a descriptor ring.</p>
24	<p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES1[24] is set, TBS2 (TDES1[21–11]) are “don't care” values. TDES1[25] takes precedence over TDES1[24].</p>
23	<p>DP: Disable Padding</p> <p>When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC (TDES1[26]) bit. This is valid only when the first segment (TDES1[29]) is set.</p>

Table 35-29 Transmit Descriptor 1 (cont'd)

Bit	Description
22	TTSE: Transmit Time Stamp Enable When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES1[29]) is set.
21:11	TBS2: Transmit Buffer 2 Size These bits indicate the Second Data Buffer in bytes. This field is not valid if TDES1[24] is set.
10:0	TBS1: Transmit Buffer 1 Size These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24).

Transmit Descriptor 2 (TDES2)

TDES2 contains the address pointer to the first buffer of the descriptor.

Table 35-30 Transmit Descriptor 2

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See Host Data Buffer Alignment for further detail on buffer address alignment.

Transmit Descriptor 3 (TDES3)

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor.

Table 35-31 Transmit Descriptor 3

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

35.4.1.3 Descriptor Format With IEEE 1588 Time Stamping Enabled

The default descriptor format (as described in **“Receive Descriptor” on Page 1-677** and **“Transmit Descriptor” on Page 1-669**), and field descriptions remain unchanged when created by software (Own bit is set in DES0). However, if the software has enabled IEEE 1588 functionality, the DES2 and DES3 descriptor fields (see **Figure 35-27**) take on a different meaning when the DMA closes the descriptor (own bit in DES0 is cleared). The DMA updates the DES2 and DES3 with the time stamp value before clearing the Own bit in DES0.

When the core is operating in 32-bit mode (**Figure 35-24**), DES2 is updated with the lower 32 time stamp bits (the Sub-Second field, called TSL in subsequent sections) and DES3 is updated with the upper 32 time stamp bits (the Seconds field, called TSH in subsequent sections).

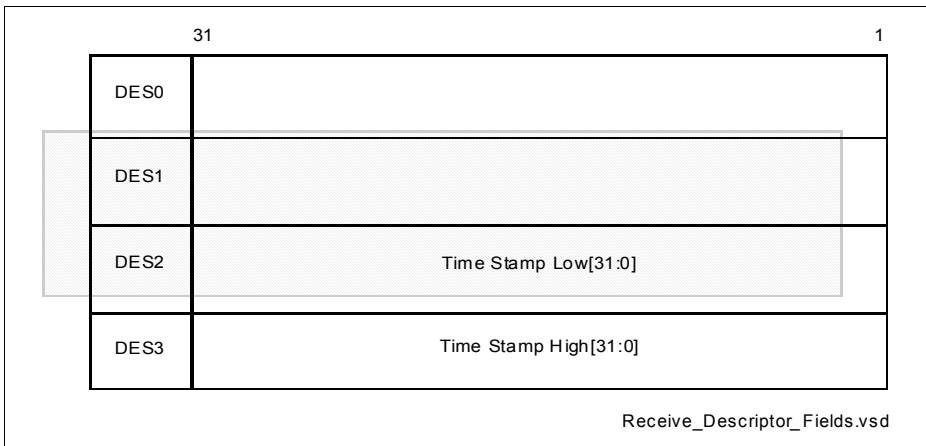

Figure 35-27 Receive Descriptor Fields When DMA Clears the Own Bit

The following sections describe the details specific to receive and transmit descriptors in this mode.

Receive Descriptor

Receive Time Stamp

The tables below describe the fields that have different meaning for RDES2 and RDES3 when the receive descriptor is closed and time stamping is enabled.

Note: When software disables the time stamping feature (the TSENA bit in Register 448 is low), the DMA does not update the descriptor's RDES2/RDES3 fields before closing the RDES0.

Table 35-32 Receive Descriptor Fields (RDES2)

Bit	Description
31:0	<p>RTSL: Receive Frame Time Stamp Low</p> <p>The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES3 show an all-ones value, the time stamp must be treated as corrupt.</p>

Table 35-33 Receive Descriptor Fields (RDES3)

Bit	Description
31:0	<p>RTSH: Receive Frame Time Stamp High</p> <p>The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]).</p> <p>When this field and RDES2's RTSL field show all-ones values, the time stamp must be treated as corrupt.</p>

Transmit Descriptor

In addition to the changes described in [“Descriptor Format With IEEE 1588 Time Stamping Enabled” on Page 1-676](#), the Transmit descriptor has additional control and status bits (TTSE and TTSS, respectively) for time stamping, as shown in [Figure 35-28](#). Software sets the TTSE bit (when the Own bit is set), instructing the core to generate a time stamp for the corresponding Ethernet frame being transmitted. The DMA sets the TTSS bit if the time stamp has been updated in the TDES2 and TDES3 fields when the descriptor is closed (Own bit is cleared).

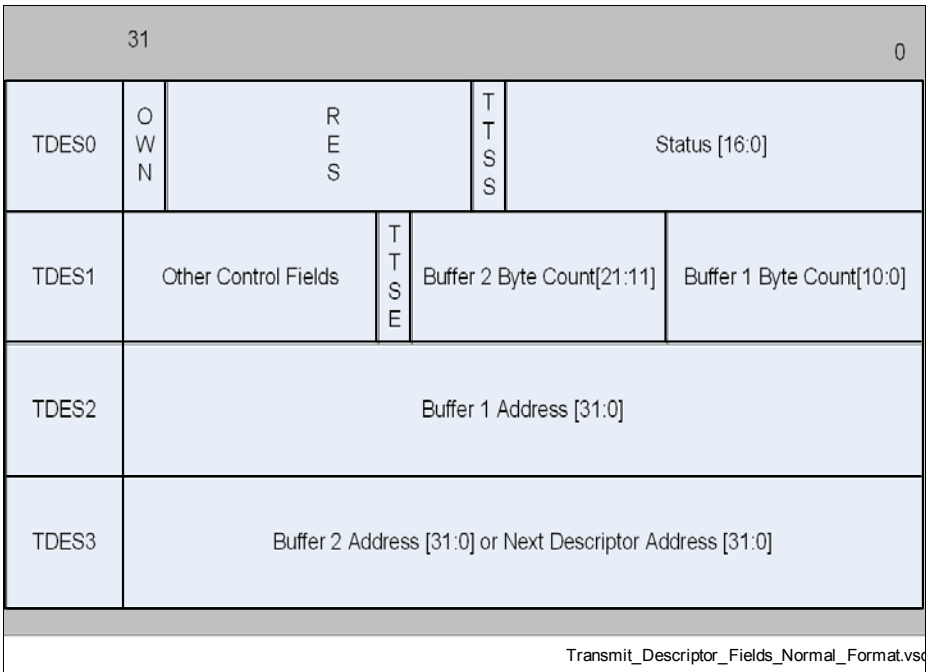

Figure 35-28 Transmit Descriptor Fields– Normal Format

Transmit Time Stamp Control and Status Fields

The position of these fields is different for normal transmit descriptor and enhanced format transmit descriptor. The value of this field in both the cases shall be preserved by the DMA at the time of closing the descriptor.

Updates to [Table 1-87](#) and [Table 1-88](#) for the default (normal) descriptor format are described below.

Table 35-34 Transmit Time Stamp Status – Normal Descriptor Format Case (TDES0)

Bit	Description
17	<p>TTSS: Transmit Time Stamp Status</p> <p>This field is a status bit indicating that a time stamp was captured for the corresponding transmit frame. When this bit is set, both TDES2 and TDES3 have a time stamp value that was captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30] in the descriptor) is set.</p>

Table 35-35 Transmit Time Stamp Control – Normal Descriptor Format Case (TDES1)

Bit	Description
22	<p>TTSE: Transmit Time Stamp Enable</p> <p>When set, this field enables IEEE1588 hardware time stamping for the transmit frame described by the descriptor.</p> <p>This field is valid only when the First Segment control bit (TDES1[29] in the descriptor) is set.</p>

Transmit Time Stamp Field

The transmit descriptor format and field descriptions remain unchanged when they are created by software (when the Own bit is set). However, when the DMA closes the last descriptor (marked, in the alternative descriptor format, by the LS bit in TDES1 or TDES0) and IEEE 1588 functionality is enabled (the Own bit is cleared), the TDES2 and TDES3 descriptor fields are updated with the time stamp, if taken, for that frame.

The fields in TDES2 and TDES3 are swapped when the core operates in 64- or 128-bit and with the descriptor in Reverse-Endian mode

[Table 1-96](#) and [Table 1-97](#) describe the fields that have different meaning when the descriptor is closed.

Table 35-36 Transmit Descriptor Fields (TDES2)

Bit	Description
31:0	<p>TTSL: Transmit Frame Time Stamp Low</p> <p>This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.</p>

Table 35-37 Transmit Descriptor Fields (TDES3)

Bit	Description
31:0	<p>TTSH: Transmit Frame Time Stamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set.</p>

35.4.2 Alternate or Enhanced Descriptors

The alternate (or enhanced) descriptor structure can have 8 DWORDS (32-bytes) instead of the 4 DWORDS as in the case of normal descriptor format. The features of the alternate descriptor structure are

- The normal descriptor structure allows data buffers of up to 2.048 bytes. The alternative descriptor structure has been implemented to support buffers of up to 8 KB (useful for Jumbo frames).
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (Advanced time stamp or IPC full offload configuration), RDES1.
- The transmit descriptor stores the time stamp in TDES6 and TDES7 when advanced time stamp feature is selected.
- This receive descriptor structure is also used for storing the extended status (RDES4) and time stamp (RDES6 and RDES7) when advanced time stamp feature or IPC full offload is selected.
- When alternate descriptor mode is selected, and Time-stamping feature is enabled, the software needs to allocate 32-bytes (8 DWORDS) of memory for every descriptor. When Time-stamping or Receive IPC FullOffload engine are not enabled, the extended descriptors are not required and the SW can use alternate descriptors with the default size of 16 bytes. The core also needs to be configured for this change using the DMA Bus Mode Register[7].
- When alternate descriptor is chosen without Time Stamp or Full IPC Offload feature, the descriptor size is always 4 DWORDS (DES0-DES3).

The description or bit-mapping alternate descriptor structure (in Little Endian mode) is given below.

*Note: The effect of Big Endian mode (byte-swap) explained in **“Normal Descriptor Formats” on Page 1-658** apply to this descriptor structure as well.*

When alternate descriptor with only Full IPC Offload (Type 2) is selected, it is not backward compatible to the previous release 3.4x with respect to status bits[7,5,0] in RDES0. In this mode, you should enable the extended descriptor mode (8 DWORDS) to get the IPC checksum engine status in RDES4.

35.4.2.1 Transmit Descriptor

The transmit descriptor structure is shown in **Figure 35-29**. The application software must program the control bits TDES0[31:20] during descriptor initialization. When the DMA updates the descriptor, it write backs all the control bits except the OWN bit (which it clears) and updates the status bits[19:0]. The contents of the transmitter descriptor word 0 (TDES0) through word 3 (TDES3) are given in **Table 1-98** through **Table 1-101**, respectively.

With the advance time stamp support, the snapshot of the time stamp to be taken can be enabled for a given frame by setting the “TTSE: Transmit Time Stamp Enable” (bit-25 of TDES0). When the descriptor is closed (i.e. when the OWN bit is cleared), the time-

Ethernet MAC (ETH)

stamp is written into TDES6 and TDES7. This is indicated by the status bit “TTSS: Transmit Time Stamp Status” (bit-17 of TDES0). This is shown in **Figure 35-29**. The contents of TDES6 and TDES7 are mentioned in **Table 1-102** and **Table 1-103**.

Note: When either of Advanced Time Stamp or IPC Offload (Type 2) features is enabled, the SW should set the DMA Bus Mode register[7], so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space are not valid.

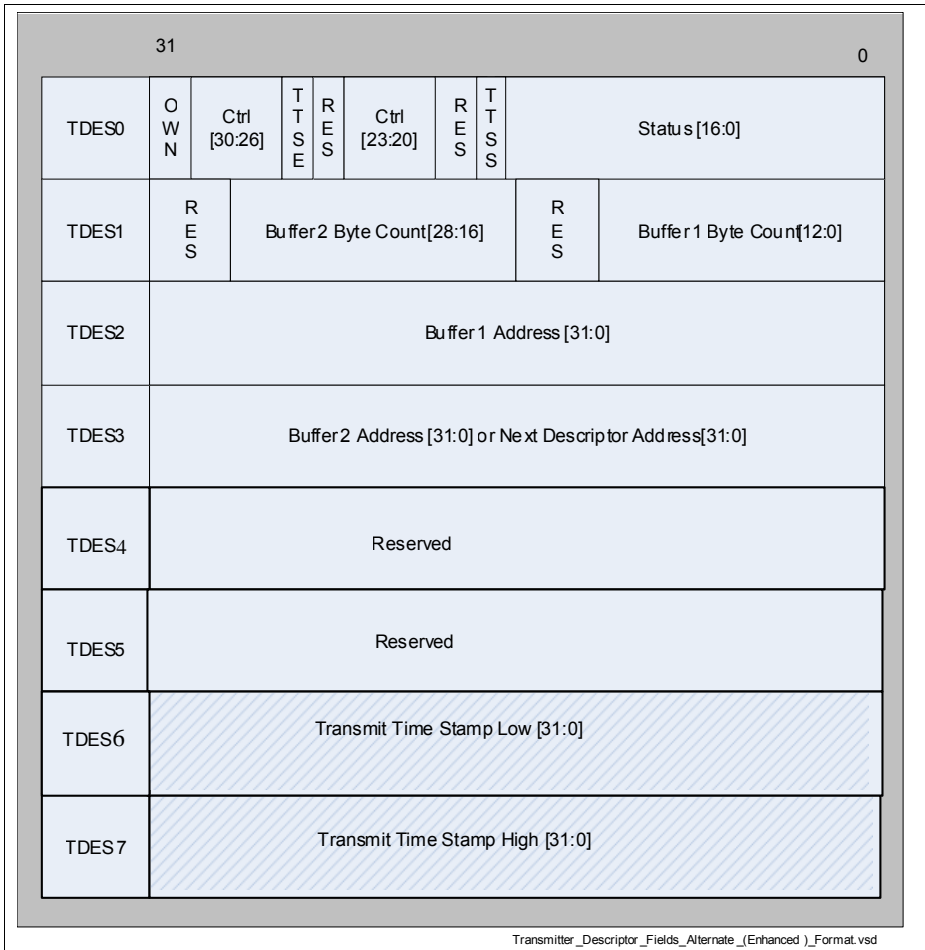

Figure 35-29 Transmitter Descriptor Fields - Alternate (Enhanced) Format

Table 35-38 Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.</p>
30	<p>IC: Interrupt on Completion</p> <p>When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.</p>
29	<p>LS: Last Segment</p> <p>When set, this bit indicates that the buffer contains the last segment of the frame.</p>
28	<p>FS: First Segment</p> <p>When set, this bit indicates that the buffer contains the first segment of a frame.</p>
27	<p>DC: Disable CRC</p> <p>When this bit is set, the GMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.</p>
26	<p>DP: Disable Pad</p> <p>When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.</p>
25	<p>TTSE: Transmit Time Stamp Enable</p> <p>When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.</p>
24	<p>Reserved</p>

Table 35-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
23:22	<p>CIC: Checksum Insertion Control</p> <p>These bits control the checksum calculation and insertion. Bit encodings are as shown below.</p> <ul style="list-style-type: none"> • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. <p>This field is reserved when the IPC_FULL_OFFLOAD configuration parameter is not selected.</p>
21	<p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p>
20	<p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a “don't care” value. TDES0[21] takes precedence over TDES0[20].</p>
19:18	<p>Reserved</p>
17	<p>TTSS: Transmit Time Stamp Status</p> <p>This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set.</p>
16	<p>IHE: IP Header Error</p> <p>When set, this bit indicates that the GMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.</p>

Table 35-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
15	<p>ES: Error Summary Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error • TDES0[16]: IP Header Error • TDES0[12]: IP Payload Error
14	<p>JT: Jabber Timeout When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set.</p>
13	<p>FF: Frame Flushed When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU.</p>
12	<p>IPE: IP Payload Error When set, this bit indicates that GMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.</p>
11	<p>LC: Loss of Carrier When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the GMAC operates in Half-Duplex mode.</p>
10	<p>NC: No Carrier When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission.</p>
9	<p>LC: Late Collision When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set.</p>

Table 35-38 Transmit Descriptor Word 0 (TDES0) (cont'd)

Bit	Description
8	EC: Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.
7	VF: VLAN Frame When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	CC: Collision Count This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.
2	ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbit/s mode or if Jumbo Frame is enabled) if the Deferral Check (DC) bit in the GMAC Control register is set high.
1	UF: Underflow Error When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]).
0	DB: Deferred Bit When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.

Table 35-39 Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	TBS2: Transmit Buffer 2 Size These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set. See Buffer Size Calculations for further detail on calculating buffer sizes.

Table 35-39 Transmit Descriptor Word 1 (TDES1) (cont'd)

Bit	Description
15:13	Reserved
12:0	TBS1: Transmit Buffer 1 Size These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 35-40 Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See Host Data Buffer Alignment for further detail on buffer address alignment.

Table 35-41 Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.)

Table 35-42 Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	TTSL: Transmit Frame Time Stamp Low This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.

Table 35-43 Transmit Descriptor 7 (TDES7)

Bit	Description
31:0	<p>TTSH: Transmit Frame Time Stamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set.</p>

35.4.2.2 Receive Descriptor

The structure of the received descriptor is shown in [Figure 35-30](#). This can have 32 bytes of descriptor data (8 DWORDs) when Advanced Time Stamping or IPC Full Offload feature is selected.

Note: When either of these features is enabled, the SW should set the DMA Bus Mode register[7] so that the DMA operates with extended descriptor size. When this control bit is reset, RDES0[7] and RDES0[0] will be always cleared and the RDES4-RDES7 descriptor space are not valid

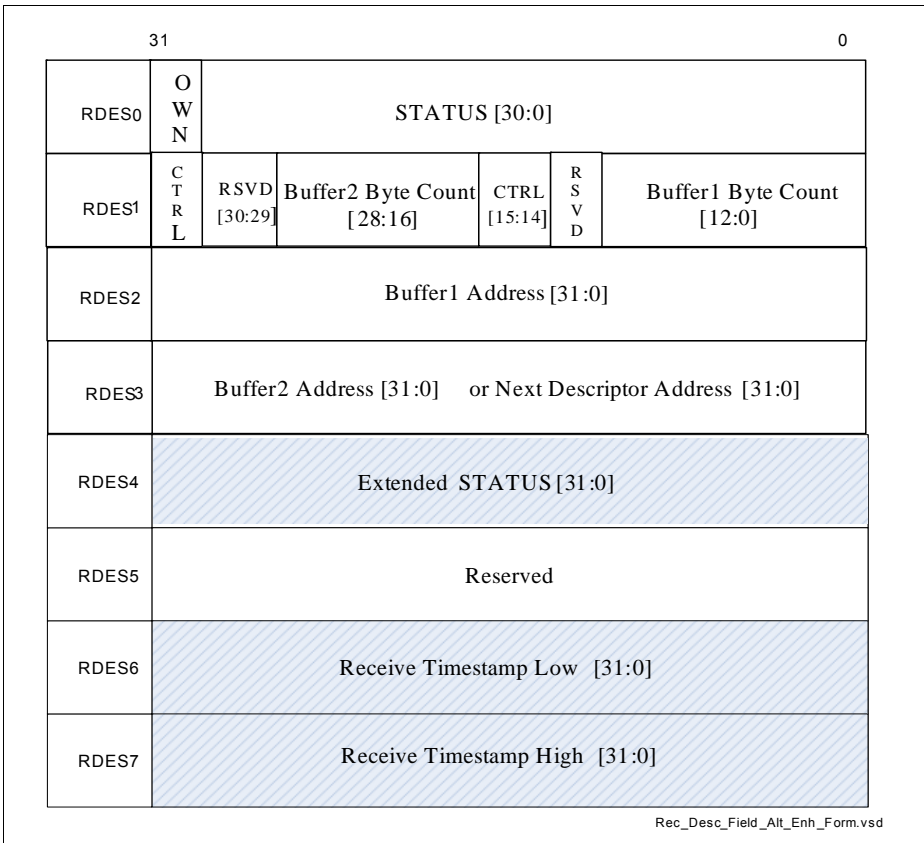

Figure 35-30 Receive Descriptor Fields - Alternate (Enhanced) Format

The contents of RDES0 are identified in [Table 1-104](#). The contents of RDES1 through RDES3 are identified in [Table 1-105](#) through [Table 1-107](#), respectively.

Note: Some of the bit functions of RDES0 are not backward compatible to Release 3.41a and previous versions. These bits are Bit[7], Bit[0] and Bit[5]. The function of Bit[5] is backward compatible to Release 3.30a and previous versions.

Table 35-44 Receive Descriptor Fields (RDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.</p>
30	<p>AFM: Destination Address Filter Fail</p> <p>When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core.</p>
29:16	<p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame.</p> <p>This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header/Payload Error • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
14	<p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
13	<p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core.</p>

Table 35-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
12	<p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset.</p>
11	<p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.</p>
10	<p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core.</p>
9	<p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.</p>
8	<p>LS: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame</p>
7	<p>Time Stamp Available/IP Checksum Error (Type1) /Giant Frame</p> <p>When Advanced Time Stamp feature is present, this bit, when set, indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When IP Checksum Engine (Type 1) is selected, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes.</p> <p>Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger-than-1,518-byte (or 1,522-byte for VLAN) normal frames and larger-than-9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled.</p>
6	<p>LC: Late Collision</p> <p>When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.</p>
5	<p>FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.</p>

Table 35-44 Receive Descriptor Fields (RDES0) (cont'd)

Bit	Description
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.
3	RE: Receive Error When set, this bit indicates that the gmii_rxr_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	CE: CRC Error When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.
0	Extended Status Available/Rx MAC Address When either Advanced Time Stamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When Advance Time Stamp Feature or IPC Full Offload is not selected, this bit indicates Rx MAC Address status. When set, this bit indicates that the Rx MAC Address registers value (1 to 31) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field.

Table 35-45 Receive Descriptor Fields 1 (RDES1)

Bit	Description
31	DIC: Disable Interrupt on Completion When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RI for that frame.
30:29	Reserved

Table 35-45 Receive Descriptor Fields 1 (RDES1) (cont'd)

Bit	Description
28:16	<p>RBS2: Receive Buffer 2 Size</p> <p>These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64, or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. See Buffer Size Calculations for further details on calculating buffer sizes.</p>
15	<p>RER: Receive End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p>
14	<p>RCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is cleared, RBS2 (RDES1[28:16]) is a “don’t care” value. RDES1[15] takes precedence over RDES1[14].</p>
13	<p>Reserved</p>
12:0	<p>RBS1: Receive Buffer 1 Size</p> <p>Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8, or 16, depending upon the bus widths (32, 64, or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8, or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 14). See Buffer Size Calculations for further details on calculating buffer sizes.</p>

Table 35-46 Receive Descriptor Fields 2 (RDES2)

Bit	Description
31:0	<p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored. See Host Data Buffer Alignment for further details on buffer address alignment.</p>

Table 35-47 Receive Descriptor Fields 3 (RDES3)

Bit	Description
31:0	<p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present.</p> <p>If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.</p>

The extended status written is as shown in [Table 1-108](#). The extended status is written only when there is status related to IPC or Time Stamp available. The availability of extended status is indicated by bit-0 of RDES0. This status is available only when Advance Time Stamp or IPC Full Offload feature is selected.

Table 35-48 Receive Descriptor Fields 4 (RDES4)

Bit	Description
31:14	Reserved
13	<p>PTP Version</p> <p>When set, indicates that the received PTP message is having the IEEE 1588 version 2 format. When reset, it has the version 1 format. This is valid only if the message type is non-zero. This bit is available only if Advance Time Stamp feature is selected else it is reserved</p>
12	<p>PTP Frame Type</p> <p>When set, this bit that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7. This bit is available only if Advanced Time Stamp feature is selected</p>

Table 35-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
11:8	<p>Message Type</p> <p>These bits are encoded to give the type of the message received.</p> <ul style="list-style-type: none"> • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1111: Reserved <p>These bits are valid only when you select the Advance Time Stamp feature.</p>
7	<p>IPv6 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv6 packet.</p>
6	<p>IPv4 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv4 packet.</p>
5	<p>IP Checksum Bypassed</p> <p>When set, this bit indicates that the checksum offload engine is bypassed.</p>
4	<p>IP Payload Error</p> <p>When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.</p>

Table 35-48 Receive Descriptor Fields 4 (RDES4) (cont'd)

Bit	Description
3	<p>IP Header Error</p> <p>When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.</p>
2:0	<p>IP Payload Type</p> <p>These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE also sets these bits to 2'b00 if it does not process the IP datagram's payload due to an IP header error or fragmented IP.</p> <ul style="list-style-type: none"> • 3'b000: Unknown or did not process IP payload • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b1xx: Reserved

RDES6 and RDES7 contain the snapshot of the time-stamp. The availability of the snapshot of the time-stamp in RDES6 and RDES7 is indicated by bit-7 in the RDES0 descriptor. The contents of RDES6 and RDES7 are identified in [Table 1-109](#) and [Table 1-110](#), respectively.

Table 35-49 Receive Descriptor Fields 6 (RDES6)

Bit	Description
31:0	<p>RTSL: Receive Frame Time Stamp Low</p> <p>This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p>

Table 35-50 Receive Descriptor Fields 7 (RDES7)

Bit	Description
31:0	<p>RTSH: Receive Frame Time Stamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p>

35.5 Ethernet MAC Module Implementation

This section describes the Ethernet MAC module interface as it is implemented in the TC26x B-Step. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

35.5.1 Interface Connections of the Ethernet MAC Module

The Ethernet MAC module is supplied with a separate clock control, address decoding, and interrupt control logic. The modules' service request outputs are connected with one interrupt node.

Ethernet MAC (ETH)

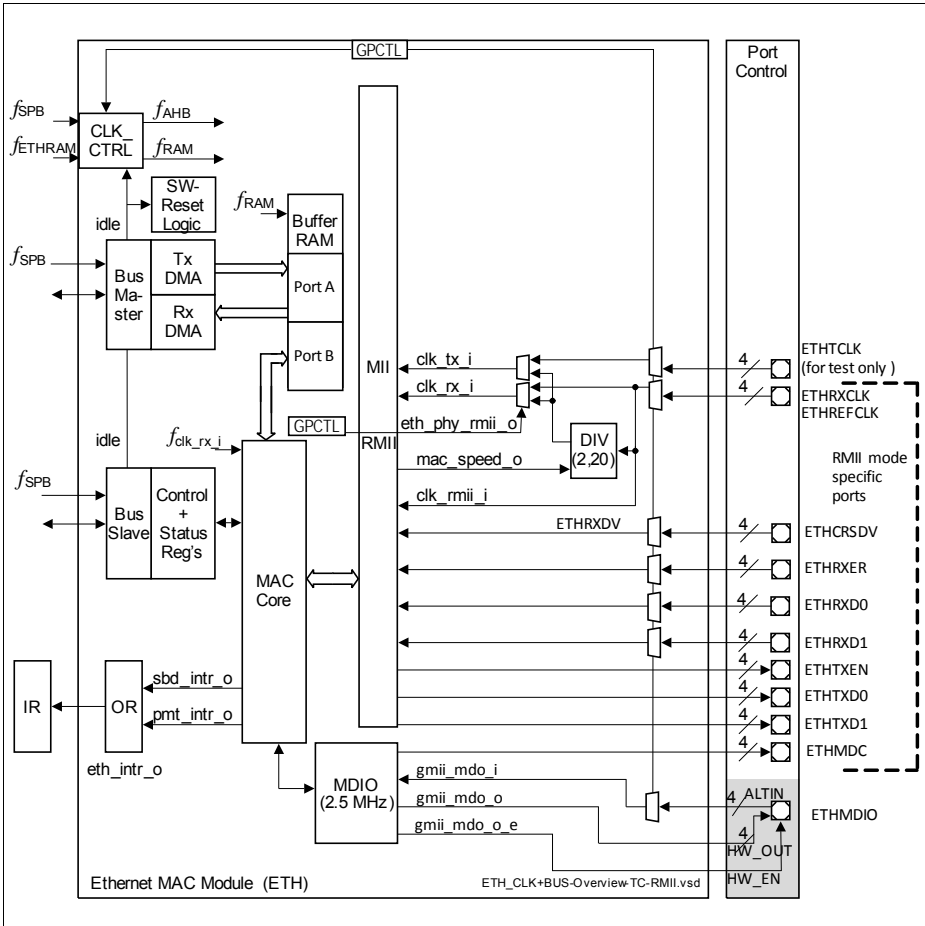

Figure 35-31 Ethernet MAC Module Implementation and Interconnections

35.5.1.1 On-Chip Connections

This section describes the on-chip connections of the Ethernet MAC module.

Interrupt Service Requests

The module has one Service Request Node connecting it to the interrupt system. The interrupt request line is connected to the interrupt controller as shown in [Table 1-112](#).

Table 35-51 Service Request Lines of Ethernet MAC

Request Line	Connected to	Description
ETH_SRC0	eth_intr_o	DMA functions (sbd_intr_o), this internal line is connected via OR gate to ETH.SR0
ETH_SRC0	eth_intr_o	wake up on LAN (pmt_intr_o), this internal line is connected via OR gate to ETH.SR0

35.5.1.2 Clocks

The module has multiple clock inputs connecting it to the system. They are connected to the system as shown in [Table 1-113](#).

Table 35-52 Clock Lines of Ethernet MAC

Clock Line	Connected to	Description
hclk_i / f_{AHB}	f_{SPB}	AHB Master Interface Clock, divided by 2 if GPCTL.DIV is set
clk_ram_i / f_{RAM}	f_{ETHRAM}	RAM Clock (separate clock from SCU.CGU) <ul style="list-style-type: none"> it is by default $2 \times f_{\text{SPB}}$ must always be 2, 3, 4 ... (natural number) times higher than f_{SPB} it must be $\geq 4 \times \text{clk_tx_i} / \text{clk_rx_i}$ (Both are 25 MHz for 100 MBit/s and 2.5 MHz for 10 MBit/s) divided by 2 if GPCTL.DIV is set
clk_csr_i	f_{SPB}	AHB Slave Interface Clock
clk_tx_i	ETHTXCLK (port pin)	Transmission Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_rx_i	ETHRXCLK (port pin)	Reception Clock from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)

Ethernet MAC (ETH)

Table 35-52 Clock Lines of Ethernet MAC (cont'd)

Clock Line	Connected to	Description
clk_rmii_i	ETHREFCLK (port pin)	50-MHz clock used by the RMII from Phy needs a clock input during SW reset (ETH_BUS_MODE.SWR)
clk_ptp_ref_i	f_{SPB}	Reference Clock for the Time Stamp Update Logic

35.5.2 Ethernet MAC Module-Implementation Related Registers

The registers listed in [Figure 35-32](#) Ethernet MAC must be programmed for proper operation of the Ethernet MAC module.

Figure 35-32 Ethernet MAC Implementation-specific Special Function Registers

35.5.2.1 Port Control

The Ethernet MAC is connected to general purpose I/O lines. Each line is connected to up to four different general purpose I/O lines that can be chosen alternatively. The selection from one of these alternatives is done by application SW by programming ETH_GPCTL.ALTIx respectively.

For MDIO, ALTIx selects the direction control signal (“HW_OUT control”) gmii_mdo_o_e_[x] as well. The signals gmii_mdo_o_e_[n] that are not selected are forced passive.

The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

[Table 35-53](#) shows an overview how bits and bit fields must be programmed for the required I/O functionality of the Ethernet MAC I/O lines.

Note: Some PHYs provide an interrupt output, signalling e.g. line activity. It might be useful to connect this to an interrupt input on system level. This signal is not connected to the Ethernet MAC!

Table 35-53 Ethernet MAC I/O Control Selection and Setup

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P02.8	ETHMDC		na	P02_IOCR8.PC8 = 1X110 _B	O

Ethernet MAC (ETH)
Table 35-53 Ethernet MAC I/O Control Selection and Setup (cont'd)

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P21.0	ETHMDC		na	P21_IOCRO.PC0 = 1X110 _B	O
P21.2	ETHMDC		na	P21_IOCRO.PC2 = 1X101 _B	O
P00.0	ETHMDIOA		ETH_GPCTL.ALTIO = 00 _B	P00_IOCRO.PC0 = 0XXX _B	I/ O
	gmii_mdo_o_e_0 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P21.1	ETHMDIOB		ETH_GPCTL.ALTIO = 01 _B	P21_IOCRO.PC1 = 1X110 _B	I/ O
	No support of I/O direction control by HW. Unidirectional input or output only as configured in P21_IOCRO.PC1 by SW.				
P21.3	ETHMDIOD		ETH_GPCTL.ALTIO = 11 _B	P21_IOCRO.PC3 = 0XXX _B	I/ O
	gmii_mdo_o_e_3 (I/O direction control of MDIO) connected to HW_DIR and HW_EN input of this port; choose Single EN - the pin is controlled by its own, dedicated, single HW_EN signal; gmii_mdo_o is connected to HW_OUT of the port, gmii_mdo_i is connected to ALTIN of the port (via input demultiplexer controlled by ALTI).				
P11.12	ETHREFCLKA	R	ETH_GPCTL.ALT11 = 00 _B	P11_IOCRO.PC12 = 0XXX _B	I
	RMII: EXTCLK1 can be selected as output (P11_IOCRO.PC12 = 1X110 _B) while ETH_GPCTL.ALT11 selects this pin as input. This setting supplies both: external PHY and this module with ETHREFCLK. Note that the jitter requirement of IEEE802.3 can not be met with this internal clock. If used as REFCLK, use fast input mode (P11_PDR1.PD12 = X00 _B and P11_IOCRO.PC12 = 0XXXX _B)				
P11.12	ETHXCLKB	R	ETH_GPCTL.ALT110 = 01 _B	P11_IOCRO.PC12 = 0XXX _B	I
	Not for application but for SW development and test. This allows to use MII loop back without external circuit if TXCLK and RXCLK are clocked with EXTCLK1.				

Ethernet MAC (ETH)
Table 35-53 Ethernet MAC I/O Control Selection and Setup (cont'd)

Port	MAC signals	R/ Mii	Input Select Register	Input/Output Control Register Bits	I/ O
P11.11	ETHCRSDVA	R	ETH_GPCTL.ALT14 = 00 _B	P11_IOC8.PC11 = 0XXX _B	I
P21.7	ETHRXERB	R	ETH_GPCTL.ALT15 = 01 _B	P21_IOC4.PC7 = 0XXX _B	I
P11.10	ETHRXD0A	R	ETH_GPCTL.ALT16 = 00 _B	P11_IOC8.PC10 = 0XXX _B	I
P11.9	ETHRXD1A	R	ETH_GPCTL.ALT17 = 00 _B	P11_IOC8.PC9 = 0XXX _B	I
P11.6	ETHTXEN	R	na	P11_IOC4.PC6 = 1X110 _B P11_PCSR.SEL6 = 1 _B	O
P11.3	ETHTXD0	R	na	P11_IOC0.PC3 = 1X110 _B P11_PCSR.SEL3 = 1 _B	O
P11.2	ETHTXD1	R	na	P11_IOC0.PC2 = 1X110 _B P11_PCSR.SEL2 = 1 _B	O

35.5.2.2 Clock Control

The master interface (DMAs) of the Ethernet MAC is connected to f_{SPB} via a clock control in register GPCTL.

Note: The RAM frequency needs to run at double the application clock!

35.5.2.3 Additional Register

Module Identification Register

The Ethernet MAC Module Identification Register ID contains read-only information about the module version.

ETH_ID

Module Identification Register (0004_H) **Reset Value: 00BF C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the Ethernet MAC: 00BF _H

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock for the module.

ETH_CLC

Clock Control Register

(0000_H)

Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. The disable request is delayed internally until all pending transactions on the master and slave interface to the SPB are completed.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Note: After a hardware reset operation, the $f_{Ethernet\ MAC}$ clock is switched off and the Ethernet MAC module is disabled (DISS set).

Input and Output Control Register Functions

The Input and Output Control Register GPCTLx determines for the Ethernet MAC which alternate input is to be used and selects the phy interface.

This register is reset by power on reset and hardware reset.

Note: This register is not affected by the local module reset!

ETH_GPCTL

Input and Output Control Register (0008_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						DIV	EPR	0		ALT10	ALT9	ALT8			
r						rw	rw	r		rw	rw	rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALT17		ALT16		ALT15		ALT14		ALT13		ALT12		ALT11		ALT10	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
ALT _y (y = 0-10)	[2*y+1: 2*y]	rw	Alternate Input Select Selects the alternate input for channel y. If no signal is connected to an alternate input, it is connected to GND. 0000 _B Alternate Input 0 selected 0001 _B Alternate Input 1 selected ... _B ... 0011 _B Alternate Input 3 selected

Ethernet MAC (ETH)

Field	Bits	Type	Description
EPR	24	rw	External Phy Interface RMMI Mode Bit Used to select the phy interface during module reset of MAC triggered by setting SWR bit of DMA Register 0. If set during this reset, RMI is selected and an internal predivider divides the clock clk_rmii_i from pin ETHRXC by 2 or 20 and provides it to the internal signals clk_tx_i and clk_rx_i . The division factor depends from the signal mac_speed_o , controlled by bit FES in Register 0 (MAC Configuration Register). If cleared during the module reset said above, MII is selected and the divider is not active but the clock signals clk_tx_i and clk_rx_i are connected directly to the referring port pins. Note that the status of this bit is latched in during module reset only.
DIV	25	rw	Module Clock Divider Request Bit If set, f_{AHB} and f_{RAM} will be divided by 2.
0	[31:26] , [23:22]	r	Reserved Read as 0; should be written with 0.

Note: After a hardware reset, all clocks are switched off and the Ethernet module is disabled (DISS set). In this case, only register CLC is accessible for configuration.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B , EN1 -> TAG ID 000001_B , ... , EN31 -> TAG ID 011111_B .

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

ETH_ACCEN0
Access Enable Register 0
(000C_H)
Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
ENn (n = 0-31)	n	r/w	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ETH_ACCEN1

Access Enable Register 1

(0010_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

ETH_KRST0
Kernel Reset Register 0
(0014_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set and both: master and slave interface are idle. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is

Ethernet MAC (ETH)

necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

ETH_KRST1
Kernel Reset Register 1
(0018_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set and both: master and slave interface are idle. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

ETH_KRSTCLR

Kernel Reset Status Clear Register (001C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Advanced Driver Assistance Subsystem (ADAS)**36 Advanced Driver Assistance Subsystem (ADAS)**

Some product derivatives include hardware support for Advanced Driver Assistance Systems (See Introduction chapter).

In ADAS derivative products the following additional hardware is present:

- Camera and RADAR Interface (CIF) (TC26x and TC29x only)
 - Parallel interface
 - On-the-fly JPEG encoding of camera signals
 - De-interleaving of external ADC radar signals
- Fast Fourier Transform Accelerator (FFT)
Integrated windowing support and up to 1024 point FFTs
- Extended Memory
- A high speed Backbone Bus
- Additional ADC channels (TC23x only)
 - Supports 4 channel concurrent sampling throughout all ADAS products
- A high speed input capture unit
 - For high precision frequency measurements of low speed signals
 - See QSPI module, section “High Speed Input Capture”

This chapter describes these peripherals in the context of radar and video based applications for Advanced Driver Assistance Systems

Figure 36-1 shows an overview of the ADAS subsystem.

Advanced Driver Assistance Subsystem (ADAS)

Figure 36-1 Block Diagram of the ADAS Subsystem

36.1 Camera and ADC Interface (CIF)

36.1.1 Introduction

The Camera and ADC Interface (CIF) represents a complete video and still picture input interface transferring data from an image sensor into EMEM. Furthermore several hardware blocks - performing image processing operations on the incoming data - are provided.

36.1.1.1 Camera and ADC Interface Functional Overview

Apart from providing the physical interfacing to various types of camera sensor modules, the CIF block implements image processing and encoding functionality. The integrated image processing unit supports image sensors with integrated YC_bC_r processing. Additionally the CIF also supports transfer of RAW (e.g. Bayer Pattern) images and non frame synchronized data packets.

The CIF block features a 16 bit parallel interface.

All output data is transmitted via the memory interface to a BBB system using the master interface.

Programming of the CIF is done by register read/write transactions using a BBB slave interface.

The following list summarizes the CIF's features:

- Throughput up to 96 MPixel/s
- 32-bit BBB slave programming interface
- BBB master interface
- ITU-R BT 601 compliant video interface supporting YC_bC_r and RAW data transfer
- ITU-R BT 656 compliant video interface supporting YC_bC_r and RAW data transfer
- Non line/frame aligned data transfer (data mode)
- 16-bit parallel camera and ADC interface
- YC_bC_r 4:2:2 processing
- Hardware JPEG encoder (supporting images up to a horizontal resolution of 1280 pixel) incl. JFIF1.02 stream generator and programmable quantization and Huffman tables
- Windowing and frame synchronization
- 1 Main and 5 Extra Image Cropping units allowing parallel transfer and position adjustment of up to 6 subregions
- Path from Main Image Stabilization or from one Extra Image Cropping unit to AGBT debug interface including a Metasymbol Generation unit inserting frame start and timing information into the stream
- Programmable watchdog timer to detect abortion/breaks in frame transmission

- Linear downscaling for the first extra path, supporting a mode for RGB Bayer Pattern
- Frame skip support for video (e.g. MPEG-4) encoding
- Macro block line, frame end, capture error, data loss interrupts and synchronization (h_start, v_start) interrupts
- Programmable polarity for synchronization signals
- Luminance/chrominance and chrominance blue/red swapping for YC_bC_r input signals
- Maximum input resolution of 4095x4095 pixels
- Buffer in EMEM organized as ring-buffer, supporting up to 2x8 Beat Bursts (2x32 Bytes)
- Buffer overflow protection for RAW data transfer and JPEG files
- Asynchronous reset input, software reset for the entire IP and separate software resets for all sub-modules
- Support of planar, semi planar and interleaved storage format (main path)
- Power management by software controlled clock disabling of currently not needed sub-modules

36.1.1.2 Camera and ADC Interface Block Diagram

Figure 36-2 shows the Camera and ADC Interface Block Diagram (top level view).

The BBB interface is divided into a master and a slave interface with their own clock domains. These clock domains may be asynchronous to the CIF Module Clock. To avoid data loss the frequency of the BBB clocks need to fulfill the following requirements:

- BBB Interface Master Clock (DMA) \geq CIF Module Clock
- BBB Interface Master Clock (DMA) $\leq 2 * \text{CIF Module Clock}$
- CIF Module Clock \geq Pixel Clock (PCLK)

Figure 36-2 Camera and ADC Interface Block Diagram

36.1.2 Camera and ADC Interface Functional Specification

This chapter describes the CIF's functionality.

36.1.2.1 Target Applications

The CIF is targeted on various applications requiring a mega pixel still image and/or video input (e.g.: mobile devices, automotive or industrial vision, ...).

Camera Interface Example

A target application example is shown in [Figure 36-3](#).

Figure 36-3 Target application example

The CIF provides a sensor/camera interface for a wide variety of video applications and it is optimized for high speed data transmission under terms of low power consumption.

This module is designed to be used for the following use cases:

- Video capturing/encoding
- Still image capturing in $YCbCr$ with on-the-fly JPEG encoding
- RAW frame data capturing
- Simple non line/frame aligned data reception (data mode) used for example for connecting to external ADCs

The CIF requires fast system memory for image storage in either planar/semi-planar/interleaved $YCbCr$ or RAW planar format or as JPEG compressed data. The integrated JPEG encoding engine is able to generate a full JFIF 1.02 compliant JPEG file that can be displayed directly by any image viewer.

All important YC_bC_r formats - which are used for video compression (e.g. MPEG4) for instance - are supported. For on-the-fly encoding macro block line interrupts are generated to trigger video encoding.

Connecting External ADC

The CIF provides a parallel interface that can be used to connect external ADC converters. In order to connect to one or more external ADCs, the CIF module requires a timer module capable of generating the appropriate clock and select signals, like the Generic Timer Module (GTM). The [Figure 36-4](#) shows an example of a connection between a single ADC and the CIF module.

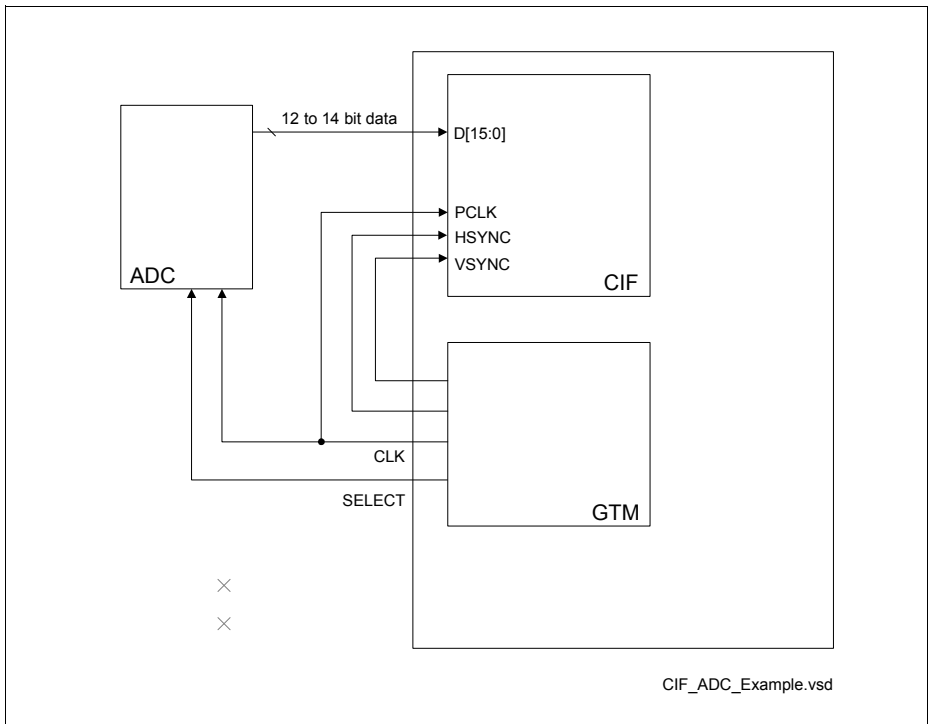

Figure 36-4 Example of a Connection to an External ADC

Connecting multiple ADCs to the CIF module may require an external multiplexer, and additional control signals to control it. Using twin or quad ADCs avoids the need for an external multiplexer.

The ADC data has to be connected MSB aligned to the CIF input pins. The **Figure 36-5** shows examples of data connections between a 12-bit or 14-bit ADC and the CIF module.

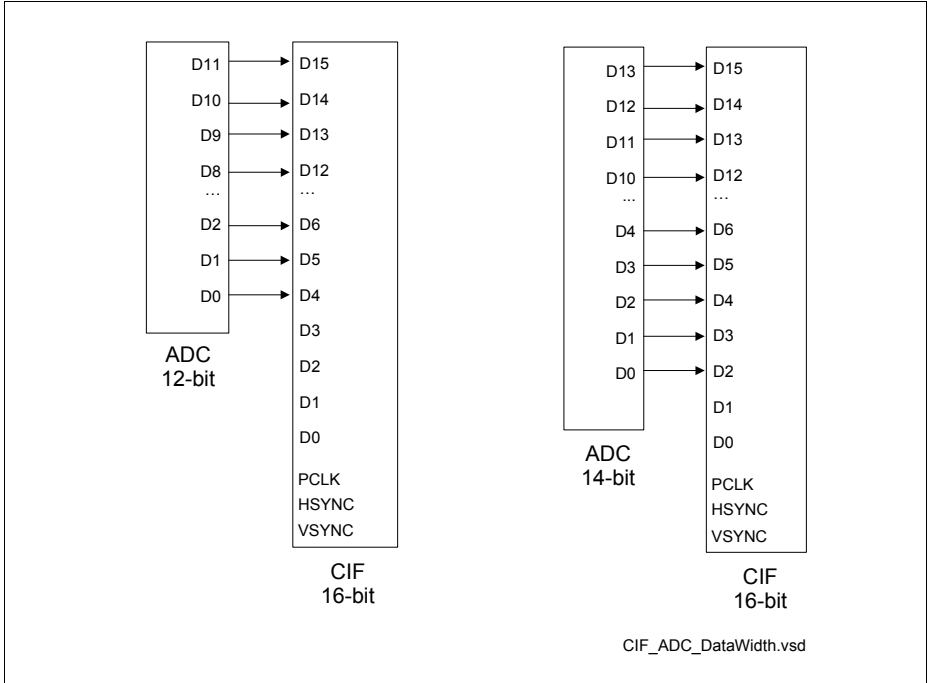

Figure 36-5 External ADC Data Alignment

The pixel clock PCLK controls the data transfer. The first edge of the clock signal can initiate the ADC to provide the data; the second edge can trigger the CIF to latch the data. In the [Figure 36-6](#) the providing of the next parallel data is referred to as “shifting”, which is what happens if the ADC has a data FIFO. The clock polarity can be programmed both in the GTM and in the CIF module. In the CIF module, the PCLK polarity is configured in by the bit field `CIFISP_ACQ_PROP.SAMPLE_EDGE`.

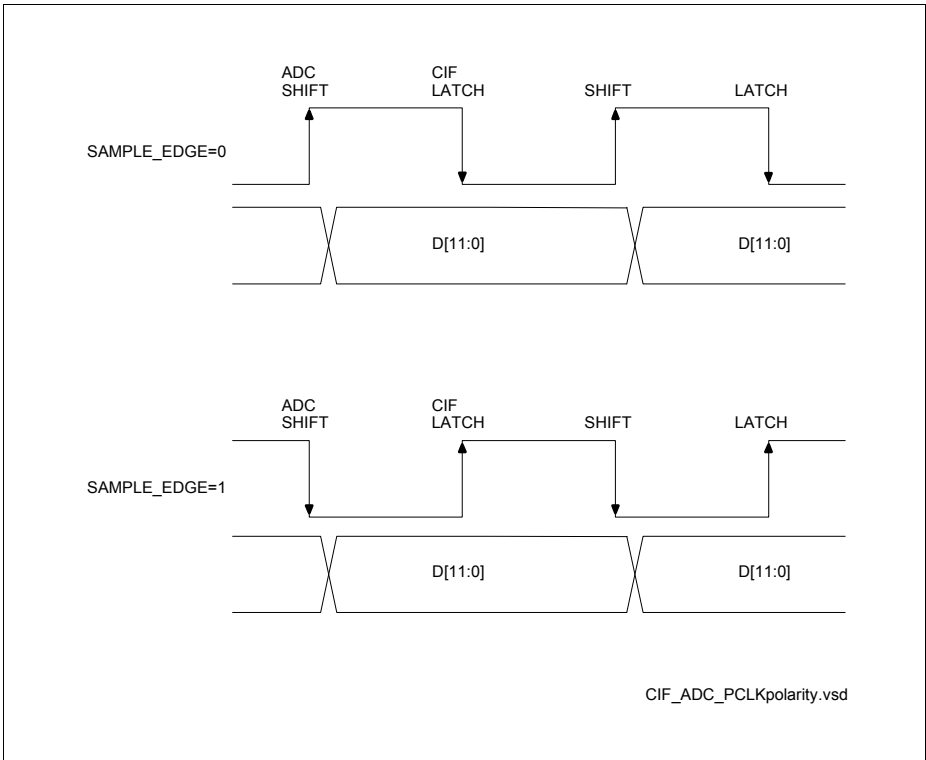

Figure 36-6 PCLK Clock Polarity and Data Transfer (12-bit ADC)

The polarity of the signals HSYNC and VSYNC can also be configured by using the bit fields `CIFISP_ACQ_PROP.HSYNC_POL` and `CIFISP_ACQ_PROP.VSYNC_POL`.

36.1.2.2 Functional Description

The CIF forms a complete video and still picture input interface solution for SoCs for various applications.

It is widely programmable and therefore very flexible to use. It supports input frame resolutions up to 4095x4095 pixels.

It consists of a Video Image Signal Processing unit (ISP), a Security Watchdog unit, luminance/chrominance splitter (Y/C Split), a linear downscaling unit, main and several extra cropping units, debug path, JPEG encoder, output unit, control unit (Ctrl) and a BBB slave interface for programming purposes.

All data transfer between EMEM and CIF is handled via the memory interface block.

For more information and a block diagram please refer to the sub module descriptions below and to [Section 36.1.1.1](#).

Sub Module ISP

The ISP is the interface to the attached sensor device. It accepts either ITU-R BT.601 YCbCr or RAW RGB Bayer data, or ITU-R BT.656 YCbCr or RAW RGB Bayer data. Furthermore a so called "data mode" is supported which accepts non line or frame organized data. In this mode the states of the hsync and vsync hardware lines are considered as "enable" and "transfer indicator". This mode allows connecting the CIF to any source delivering a parallel data stream (e.g. camera sensor including a JPEG encoder).

The input part of the ISP is fully programmable in terms of signal polarities, active video data positions, and luminance/chrominance order.

A handshake based mechanism is used for data qualification. As the sensor device can not be stopped from delivering data, a pipeline stall leads to an error if it occurs within an active video line.

The ISP also contains its own programming registers to be accessed by a 32 bit handshake interface.

Figure 36-7 Block Diagram of the ISP Sub Module

The following features are implemented:

- CCIR656/601 compatible 16-bit video interface
- Input sampling on positive or negative sample clock
- Cropping of the output picture (to crop interpolation artifacts), also used for windowing

Sub Module Security Watchdog

The Security Watchdog unit is used to monitor the incoming image data. Specifically it can be used to detect and report irregularities or interruptions in the data stream. To do so the horizontal and vertical synchronization signals in the input formatter unit are observed and are compared to programmable time-out frames. When a time-out frame gets violated an interrupt is generated to immediately report this event.

The timing information is retrieved via 16-bit counters. There are two separate counters to measure horizontal and vertical timeframes in parallel. To enhance the configurability of the timing information an additional 16-bit prescaler controls the speed of the counter units, enabling a timing unit granularity from $1 \cdot T_{\text{cif_clk}}$ to $2^{16} \cdot T_{\text{cif_clk}}$.

Figure 36-8 Block diagram of the Security Watchdog sub module

As can be seen in [Figure 36-9](#) there are four time frames of interest to be watched. The time between:

- Start and End of a frame (t_{VSE})
- End and Start of the next frame (t_{VES})
- Start and End of a line (t_{HSE})
- End and Start of the next line (t_{HES})

Figure 36-9 Programmable time-outs for the Security Watchdog

All those time-outs are programmable 16 bit values which can be set via the following registers: **“Watchdog Vertical Timeout Register”** on [Page 36-161](#) and **“Watchdog Horizontal Timeout Register”** on [Page 36-162](#). So as soon as the corresponding

counter reaches the programmed value an interrupt is triggered. A programmed value of zero means the time-out is not configured to trigger an event.

It is possible to completely disable the Security Watchdog unit by setting the corresponding bit of its (“**Watchdog Control Register**” on Page 36-160) or by disabling the clock of this sub module in the “**CIF Internal Clock Control Register**” on Page 36-51.

Sub Module Y/C-Split

This module contains a data path splitter separating luminance (Y) and chrominance (C) information of a 16 bit YCbCr 4:2:2. Independent 8 bit Y and C channels are the result of this operation.

The Y/C Splitter must ensure that the output Y and C data streams are fully aligned, i.e. if Y data are processed in one clock cycle only, the Y channel has to be stalled until the C component belonging to the processed Y component has been taken. **Figure 36-10** gives a coarse overview of the data flow from/to the sub-module.

Figure 36-10 Block Diagram of the Y/C-Splitting Sub Module

Sub Module JPEG Encoder

The baseline JPEG encoder module consists of a JPEG encoder pipeline. The pipeline - which is shown in **Figure 36-11 “Block Diagram of the JPEG Encoder Sub Module” on Page 36-14** - is controlled by a register interface that is accessed via handshake interface. The following description gives an overview of the general functionality of the JPEG encoder.

Figure 36-11 Block Diagram of the JPEG Encoder Sub Module

The encoding process starts with a raster to block conversion of the $YCbCr$ 4:2:2 pixel data provided e.g. by an imaging device. The incoming line oriented pixel data is reordered into 8x8 pixel blocks, one for each component.

Every 8x8 pixel block undergoes a baseline DCT computation, a zigzag reordering, a quantization and a variable length encoding (Huffman based). Last encoding step is the generation of the JFIF 1.02 compliant data stream by inserting markers and tables.

The encoder needs two clock cycles per pixel for processing, if $YCbCr$ 4:2:2 data is used, which is the normal mode of the JPEG encoder.

Sub Module Linear Downscaler

The first extra path includes a simple scaling unit which allows to reduce the size of the transferred image by simply skipping lines and columns of a frame. The amount of horizontal (columns) and vertical (lines) data reduction can be programmed separately. The module supports four modes:

- Single skip
- Double or RGB Bayer skip
- Single pass
- Double pass

The single skip mode simply skips every n^{th} line or column, but since this would destroy the integrity of a regular RGB Bayer pattern - see [Figure 36-12](#) - there is also the possibility to use the double skip mode which preserves the pattern.

Since skipping leads to a maximum data reduction of 50% at best there are corresponding pass modes to the skip modes. The difference of these modes is that only every n^{th} pixel (or ever n^{th} two pixels) get(s) passed to the following processing unit, all other pixels get skipped. In other words: The pass mode can downscale the image data at rates $\geq 50\%$, whereas the skip mode allows scaling at rates $\leq 50\%$.

Regarding the single/double pass modes it is also important to mention that whether the bayer pattern stays preserved or not is here only dependant on the pass-value. Odd values of n will destroy the bayer pattern integrity, whereas even values will preserve it.

Figure 36-12 Single vs. RGB Bayer mode

It's further worth mentioning that the linear downscaler - like any other image processing unit - can be set to a bypass mode where data is passed on unprocessed to the next module.

Sub Module Extra Path Units

In addition to the main path, the CIF allows to define and transfer up to 5 additional image regions into memory. Those extra paths all have their own image cropping unit¹⁾ which allows to crop a separate sub-region of the image. Furthermore it is possible to utilize the displacement and recenter functionality of the image cropping unit to adjust the position of the cropping window (e.g. tracking a moving object). For details about the functionality of the image stabilization unit see the corresponding section in the CIF Programmer's Manual.

1) In the main path the Image Cropping unit is referred to as Image Stabilization unit, since in YCbCr video mode it may be used to compensate camera shakes.

Figure 36-13 shows the function of the main and extra path units: The main path may capture the full incoming frame utilizing it's downscaling unit to keep the output size - and hence the computational effort for ongoing image processing by the system - low.

In parallel up to 5 (the example below shows four) sub images may be cropped from the same input image. Those images are stored and handled independent of the main path and also independent of each other.

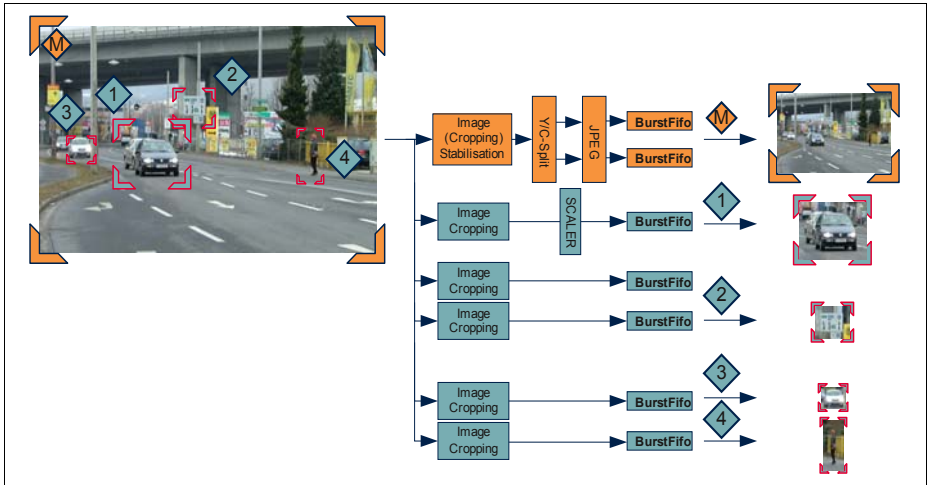

Figure 36-13 Example: Main and four active Extra Paths

Since the Y/C-Split unit is not present in the extra paths, the following restriction is given:

- only one receive buffer (no support for planar/semi-planar storage)

Nevertheless every extra path has it's own storage ring buffer and it's own distinct interrupt generation unit for those. Those separate interrupts of the distinct extra paths are then again merged in a single multiple source interrupt register to a single separate extra path interrupt line.

Only the first extra path has a downscaling unit, so for the other paths (including the main path) it is not possible to reduce the image dimension further after the cropping stages.

Every present extra path can be en/disabled via a programmable control register.

Parallel use of several extra paths

Using multiple overlapping or nested cropping windows leads to parallel activation of several extra paths generating bus load that could overload the memory interface and the back bone bus in case high baud rates are used. More then two nested windows is not recommended. Extra care should be taken when using overlapped cropping windows to keep the peak BBB bus load low. For example, use cropping windows widths which are multiple of the burst size configured in the MI (Memory Interface) block. This allows the cropped regions to be transferred to memory using only bursts on the BBB bus, without a need for single moves to transfer the pixels at the end of a line that do not

make a whole burst. For burst of four 32-bit moves, resulting in 16 bytes per burst, the optimal cropping window width is multiple of 16 pixels (1 byte per pixel). CIF single move takes 8 BBB clock cycles (0.5 bytes/clock cycle), burst of four 12 (1.33 bytes/clock cycle), and burst of eight 16 clock cycles (2 bytes/clock cycle). Burst of eight results in 200 Mbytes/sec for 100MHz BBB bus clock, which is the theoretical maximum if the CIF module is the only master on the BBB bus.

Debug Path

The debug path is used to transfer data from one of the CIF paths (main or extra) to an Aurora Gigabit Trace (AGBT) debug interface. To do so the data from one of the paths - which may also still be passed on to the memory interface - is additionally routed to the debug unit. Despite simply passing this data on to the AGBT interface, the CIF debug path also inserts meta information and CRC checksums to the stream. This helps to ease, enhance and secure the analysis of the retrieved data.

As can be seen in the [Figure 36-14](#) it is possible to select - via a MUX - from which path the data to send via the Aurora interface is taken. The selected data is then transferred into a latency compensation FIFO. This is needed to let the Metastream Generator send several additional information symbols before the received data stream, which shall not block the transfer of this stream to memory meanwhile.

Figure 36-14 Debug Path block diagram

Those additionally inserted symbols are:

- Metasymbol marker
- Metastream type information
- a 30-bit timestamp
- a Frame-/Linenumber
- up to eight 15-bit user defined symbols
- Payload length Information
- Header & Payload checksum

Figure 36-15 shows an example of a pixel line as transferred over the debug interface. The pixel debug stream consists of 16-bit symbols, where the value $FFFF_H$ shall be a reserved value - the so called Metasymbol marker - which distinctly marks the start of a debug frame. This leads to some obvious restrictions in other symbols. The general rule reads as follows: In every symbol despite the Metasymbol marker the highest bit (MSB) has to be 0_B .

The currently supported Metastream types are:

- Start of Frame (SoF) Code 00_H
- Start of Line (SoL) Code 01_H

SoF is a simple Marker which only consists of the type and length information, timestamp, framenumber, user symbols and CRC. The SoF has no payload attached and hence no corresponding information like payload length or payload-CRC. Like the name suggests the SoF is sent only once at the beginning of an image frame. It has to be followed by - depending on the image size - several SoL packets.

Figure 36-15 shows an example of a SoL packet. Basically it contains the same information like a SoF packet, just with a linenumber instead of a framenumber and additional payload information.

As can be also seen in the example the payload symbols - which are the image pixels of a line - are right shifted by one & stuffed with zero on the high significant end. In case of 16 bit data this means that the least significant bit of the payload gets lost. In 14 bit data mode, the data is right-shifted for 1 bit, but the two LSB bits are always zero, so there is no data loss. In YUV16 mode the module shifts right and the chrominance LSB is lost. In RAW16 mode the module does not shift and the LSB bit is lost.

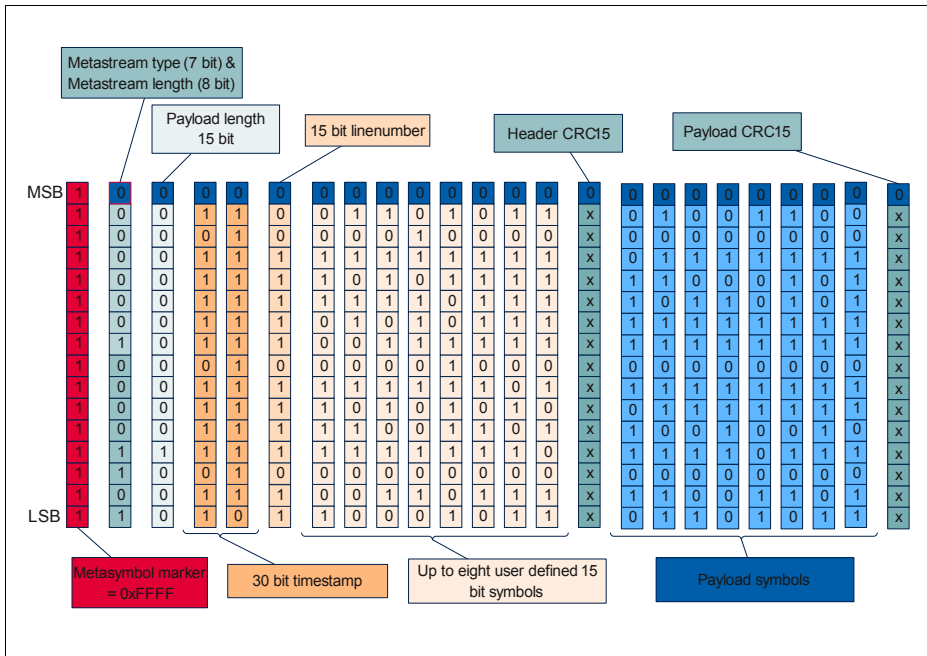

Figure 36-15 Line debug packet

The header length which is always included in a packet and the payload length which is additionally included in SoL packets can be used as additional security measures to quickly identify transmission gaps or similar issues. All given length information in the debug stream is referring to symbols. So in the example of **Figure 36-15** the payload length of 8 means that exactly 8 symbols of payload have to follow the header. The header length symbol gives the length of the header excluding the Metasymbol marker. For both values, header and payload - the CRC is not included.

The timestamp is a simple free running 30 bit counter and can be used to introduce quite accurate timing information to the stream. To enhance the flexibility of this counter a preceding prescaler unit is included which is clocked by the CIF module clock. This unit allows to configure the granularity of the timestamp to be between $1 \cdot T_{\text{cif module clk}}$ to $2^{32} \cdot T_{\text{cif module clk}}$.

User defined symbols are a way to insert/feed back software dependant information into the data stream. One possible application could be the insertion of coarse time/date information which supplements the internally generated timestamp.

The eight user defined symbols are freely programmable registers which can be included into the stream on a per symbol basis. Per default after reset no user defined symbols will be sent in the debug data stream.

Linenumber and framenumber are simple counters which can be reset by software at any time. The framenumber will run free and simply overflow starting again from zero, whereas the linenumber will be reset internally with every new SoF packet.

As CRC a 15 bit version using the same polynomial as the CAN-bus CRC is used. The input to this CRC is a full 16 bit symbol. The header CRC covers all symbols from the Metasymbol marker up to the last active user defined symbol. Whereas the payload CRC covers all payload symbols from the first after the header CRC up to the last.

If it is not needed it is possible to deactivate the whole debug path by disabling it's clock via the **“CIF Internal Clock Control Register” on Page 36-51**.

Note: The CIF module shifts the pixel data to the right when transferring via AGBT, in order to guarantee data symbol MSB of zero. Therefore, the LSB bit is lost in case the data is LSB aligned. This is valid for YUV data and 16-bit radar data. The raw RGB data is 14-bit MSB aligned and no LSB loss occurs.

Sub Module Memory Interface (MI)

The Memory Interface module - shown as in **Figure 36-16** - has the following tasks:

- It collects the CIF internal data streams and writes them into the EMEM.
- It decouples the BBB master clock from the CIF module clock.

Attention: In order to configure the CIF BBB master to access the EMEM, see the dedicated address map for BBB master accesses in the EMEM chapter.

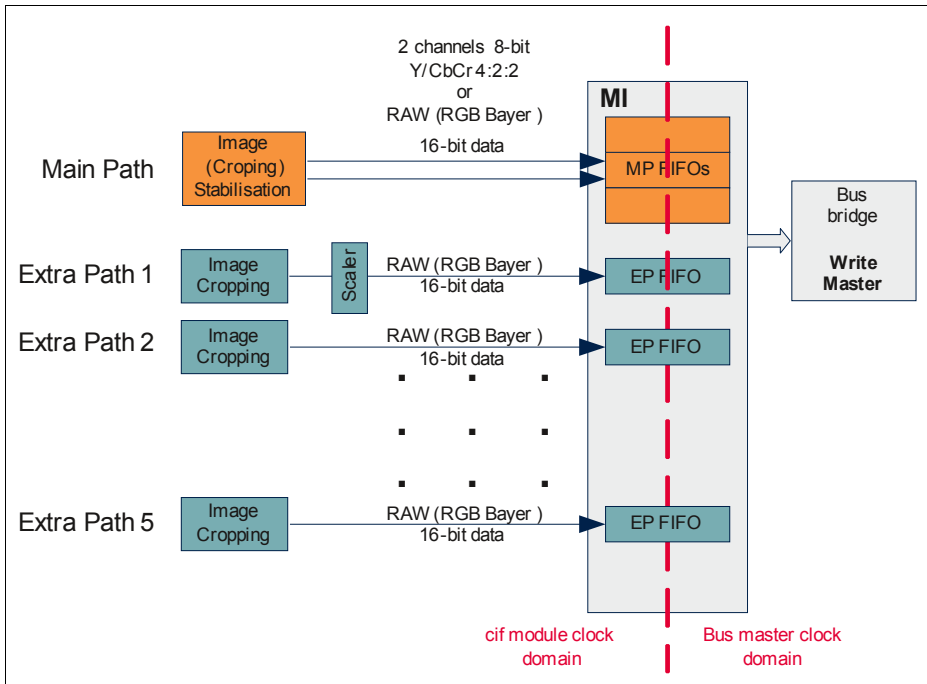

Figure 36-16 Overview Memory Interface connections

The MI supports storage of main picture YCbCr, JPEG and RAW data (up to 16 bit). Y, Cb and Cr data is stored in EMEM supporting the following modes:

- separate buffers (planar)
- two buffers (semi planar)
- one buffer (interleaved)

Figure 36-17 gives an overview of those three modes, but also shows the effect of the byte swapping option which effects the endianness of the output format.

All FIFOs used in MI are synchronization FIFOs which handle the task of decoupling the different clock domains.

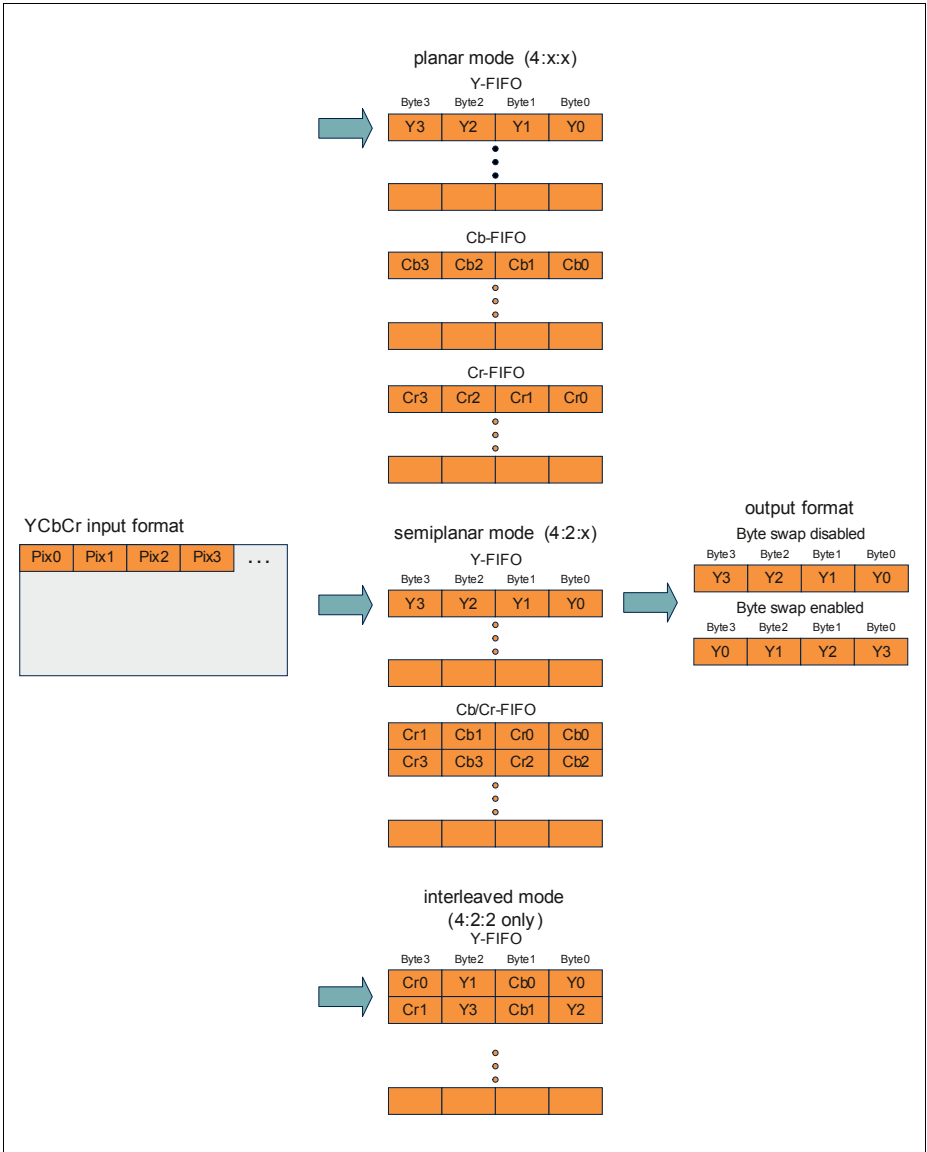

Figure 36-17 Storage scheme YCbCr in MI

For storage of RAW data only one FIFO buffer is supported/needed. If more than 8 bits data are required in RAW mode, then the data bits are stored as 16-bit words in memory. Usually these bits are stored MSB aligned, meaning the unused least significant bits remain zero or become a replica of the RAW data most significant bits (see **“INPUT_SELECTION” on Page 36-58**). It is also possible to disable this MSB alignment (**“INPUT_SELECTION_NO_APP” on Page 36-57**) leading to LSB aligned data values. This especially makes sense for non image RAW data (e.g. data mode). **Figure 36-18** visualizes the previously mentioned facts.

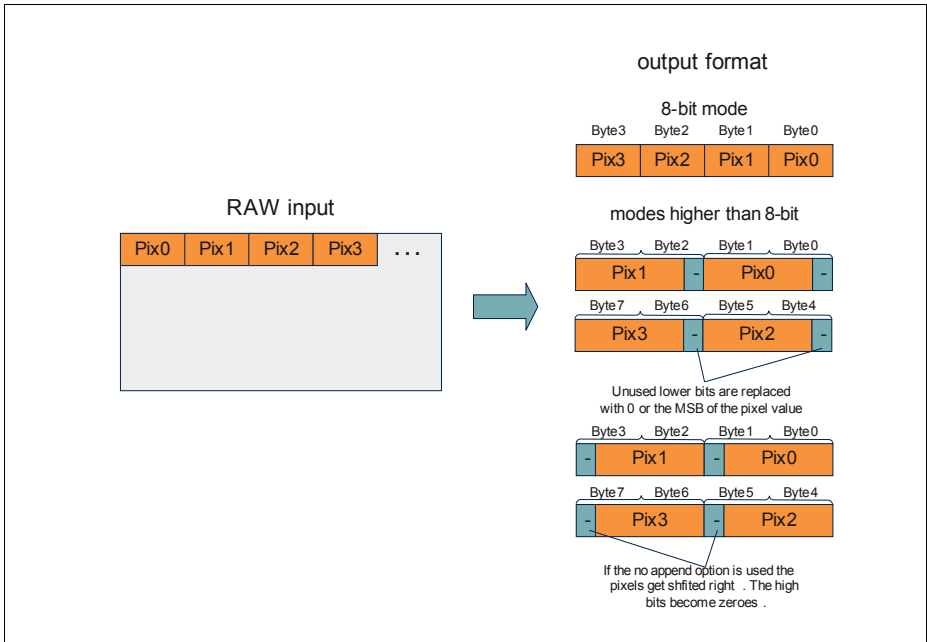

Figure 36-18 RAW data storage scheme in MI

Unlike the main path the extra paths support interleaved storage mode only. This is given by the fact that extra paths only have a single component FIFO.

Write to EMEM

The following **Figure 36-19** shows the basic building blocks of the unit. As can be seen there are several input port handshake interfaces:

- 2 x 8 bit Y, Cb/Cr main picture data or up to 16 bit RAW data
- 64 bit JPEG data
- For every extra path 2 x 8 bit Y, Cb/Cr extra picture data¹⁾ or up to 16 bit RAW data

The following modes of operation are supported:

- image data only
- JPEG data only
- RAW data only

The interface to the EMEM is a simple handshake oriented protocol, which is connected to the BBB master via a bridge. Three kinds of bus accesses are supported, 8-beat bursts, 4-beat bursts and single transfers, all with a data width of 32 bit. The storage areas, which are located in the EMEM, are organized as ring buffers.

Interrupts are generated for the following events:

- picture end of frame
- macro block line (16 lines of Y data and 8 lines of Cb and Cr data of the picture are written to the EMEM)
- programmed fill level of picture Y data reached
- wrap around of the programmed address range separately for Y, Cb and Cr of the picture
- BBB write error propagated by the handshake target interface

Each FIFO can store at least two 8-beat bursts.

Figure 36-19 Block Diagram of the Memory Interface write path

BBB Master Interface

The BBB Master Interface connects the Memory Interface to the BBB.

1) YCbCr data is handled interleaved as 16 bit data extra paths.

- Unique TAG
- Word Access only
- Priority relative to CPU access via EMEM
- Bandwidth on bus
- RAM arbitration inside EMEM
- Reset behavior
- Bus error handling

BBB Slave Interface

The BBB Slave Interface connects the Control Unit to the BBB system. Internally it represents an AHB-Slave-to-handshake-Initiator block, while from the BBB a standard SPB_BPI is used.

- No safety features.
- No OCDS functionality (Request: Add monitoring via OTGM for the next product!).
- No ENDINT/OEN/... protection
- Standard CLC register.
- Allowed access width is 32-bit only.
8-bit and 16-bit accesses are treated as 32-bit and the content of all 32 data signals of the bus is written to the register.
- Error handling - no notification of the read and write accesses to reserved locations

Control Unit

The Control Unit serves two purposes:

- Interface from BBB Slave Interface to the local configuration register blocks of the other modules
- Clock and reset control registers for the CIF

The Control Unit has one 32 bit handshake input interface, three 16 bit handshake output interfaces, and two 32 bit handshake output interfaces.

As all transfers from the handshake input interface are 32 bit wide, these accesses have to be mapped accordingly to the 16 bit handshake interfaces, e.g. ignoring the upper 16 bits or filling them with zeros respectively.

Each block inside the CIF uses a dedicated clock signal that can be controlled by a programmable register inside the Control Unit.

Existing software resets in the CIF blocks can also be controlled by a programmable register inside the Control Unit. An asynchronous reset for the sensor clock domain has to be generated from the system reset. A soft reset for all registers in the CIF is provided. It behaves like the asynchronous hardware reset.

Shadow Registers

A distinctive feature of the local configuration registers are so called shadow registers. Because it can not be ensured that the complete re-programming of the CIF can be done during the vertical blanking period between two frames shadow registers have been introduced. These shadow registers hold the configuration values that are actually used for processing and are only updated with the latest written configuration values after a special update signal is triggered. This update signal may be generated after a frame has ended but in order to allow a fast configuration it may also be forced to trigger immediately.

36.1.3 CIF Registers Description

The following section describes the CIF registers on bit level.

36.1.3.1 CIF Registers Overview

The communication and control flow to and from the CIF module is realized via internal registers. Access to the registers will be provided via an BBB slave interface. Each access is 32 bit aligned.

The CIF uses a distributed configuration register scheme. So there is no central unit containing all programming registers, but all CIF sub-modules contain their own programming registers.

Note: Write accesses to reserved access locations are ignored. Read access deliver all zeros. No traps are triggered. Accesses of bus masters not enabled with the ACCENx registers cause acknowledge error.

The register set is divided into the following register types:

- Control registers
- Configuration setting registers
- Shadow configuration setting registers
- Interrupt registers

Shadow registers are used to support dynamic data path re-programming. The next programming values are written into the configuration setting registers of a local configuration unit of a CIF internal block. Shadow registers are used for the processing part of the sub-modules to keep the current values for processing. Updating of these shadow registers can be triggered by either the configuration update bits in the sub-module control registers in terms of immediate update, or by triggering the “generate configuration update” bit in the ISP control register to automatically update all shadow registers in the whole data processing pipeline after the last pixel of a processed frame.

All defined configuration register addresses of the CIF are offset addresses. The CIF base address is defined by the external BBB address decoder.

Note: The table below shows the base addresses as seen by the CPUs, after the address translation done by the BBB bridge. On the BBB bus itself the base addresses start with F00E instead of F90E.

Table 36-1 Registers Address Space

Module	Base Address	End Address	Note
CIF	F90E 2000 _H	F90E 201B _H	Base = CIF_CONTROL_BASE
CIFISP	F90E 2400 _H	F90E 2647 _H	Base = CIF_ISP_BASE
CIFMI	F90E 3400 _H	F90E 3513 _H	Base = CIF_MI_BASE
CIFJPE	F90E 3800 _H	F90E 388F _H	Base = CIF_JPE_BASE

Table 36-1 Registers Address Space (cont'd)

Module	Base Address	End Address	Note
CIFISPIS	F90E 4300 _H	F90E 4333 _H	Base = CIF_IS_BASE
CIFWD	F90E 4400 _H	F90E 441F _H	Base = CIF_WATCHDOG_BASE
CIFLDS	F90E 4500 _H	F90E 4507 _H	Base = CIF_LIN_DSCALE_BASE
CIFDP	F90E 4700 _H	F90E 4733 _H	Base = CIF_DEBUG_PATH_BASE
CIFEP	F90E 4900 _H	F90E 5333 _H	Base = CIF_EP_IC_BASE
CIFMIEP	F90E 5400 _H	F90E 592F _H	Base = CIF_EXTRA_PATH_BASE
CIFBBB	F90E 1F00 _H	F90E 1FFF _H	Base = CIF_SPB_BASE

Table 36-2 Registers Overview (in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number

CIFMIEP_k_SIZE_INIT (k=1-5)	Memory Interface Size of Extra Path 5 Data Buffer Register	050C _H	36-201

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFMIEP_z_OFFS_CNT_INIT (z=1-5)	Memory Interface Offset Counter Init Value For Extra Path 5 Data Buffer Register	0510 _H	36-202
CIFMIEP_z_OFFS_CNT_START (z=1-5)	Memory Interface Offset Counter Start Value For Extra Path 5 Data Buffer Register	0514 _H	36-203
CIFMIEP_z_IRQ_OFFS_INIT (z=1-5)	Memory Interface Fill Level Interrupt Offset Value For Extra Path 5 Data Buffer Register	0518 _H	36-204
Extra Path Programming Registers, Extra Path Memory Interface Shadow Registers			
CIFMIEP_z_CTRL_SHD (z=1-5)	Memory Interface Extra Path 1 Control Internal Shadow Register	011C _H	36-205
CIFMIEP_z_BASE_AD_SHD (z=1-5)	Memory Interface Extra Path 1 Control Internal Shadow Register	0120 _H	36-206
CIFMIEP_k_SIZE_SHD (k=1-5)	Memory Interface Extra Path 1 Base Address Shadow Register	0124 _H	36-206
CIFMIEP_z_OFFS_CNT_SHD (z=1-5)	Memory Interface Extra Path 1 Current Offset Counter Shadow Register	0128 _H	36-207
CIFMIEP_z_IRQ_OFFS_SHD (z=1-5)	Memory Interface Extra Path 1 Fill Level Interrupt Offset Value Shadow Register	012C _H	36-208
CIFMIEP_z_CTRL_SHD (z=1-5)	Memory Interface Extra Path 2 Control Internal Shadow Register	021C _H	36-205
CIFMIEP_z_BASE_AD_SHD (z=1-5)	Memory Interface Extra Path 2 Base Address Shadow Register	0220 _H	36-206
CIFMIEP_k_SIZE_SHD (k=1-5)	Memory Interface Extra Path 2 Size Shadow Register	0224 _H	36-206
CIFMIEP_z_OFFS_CNT_SHD (z=1-5)	Memory Interface Extra Path 2 Current Offset Counter Shadow Register	0228 _H	36-207
CIFMIEP_z_IRQ_OFFS_SHD (z=1-5)	Memory Interface Extra Path 2 Fill Level Interrupt Offset Value Shadow Register	022C _H	36-208

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFMIEP_z_CTRL_SHD (z=1-5)	Memory Interface Extra Path 3 Control Internal Shadow Register	031C _H	36-205
CIFMIEP_z_BASE_AD_SHD (z=1-5)	Memory Interface Extra Path 3 Base Address Shadow Register	0320 _H	36-206
CIFMIEP_k_SIZE_SHD (k=1-5)	Memory Interface Extra Path 3 Size Shadow Register	0324 _H	36-206
CIFMIEP_z_OFFS_CNT_SHD (z=1-5)	Memory Interface Extra Path 3 Current Offset Counter Shadow Register	0328 _H	36-207
CIFMIEP_z_IRQ_OFFS_SHD (z=1-5)	Memory Interface Extra Path 3 Fill Level Interrupt Offset Value Shadow Register	032C _H	36-208
CIFMIEP_z_CTRL_SHD (z=1-5)	Memory Interface Extra Path 4 Control Internal Shadow Register	041C _H	36-205
CIFMIEP_z_BASE_AD_SHD (z=1-5)	Memory Interface Extra Path 4 Base Address Shadow Register	0420 _H	36-206
CIFMIEP_k_SIZE_SHD (k=1-5)	Memory Interface Extra Path 4 Size Shadow Register	0424 _H	36-206
CIFMIEP_z_OFFS_CNT_SHD (z=1-5)	Memory Interface Extra Path 4 Current Offset Counter Shadow Register	0428 _H	36-207
CIFMIEP_z_IRQ_OFFS_SHD (z=1-5)	Memory Interface Extra Path 4 Fill Level Interrupt Offset Value Shadow Register	042C _H	36-208
CIFMIEP_z_CTRL_SHD (z=1-5)	Memory Interface Extra Path 5 Control Internal Shadow Register	051C _H	36-205
CIFMIEP_z_BASE_AD_SHD (z=1-5)	Memory Interface Extra Path 5 Base Address Shadow Register	0520 _H	36-206
CIFMIEP_k_SIZE_SHD (k=1-5)	Memory Interface Extra Path 5 Size Shadow Register	0524 _H	36-206
CIFMIEP_z_OFFS_CNT_SHD (z=1-5)	Memory Interface Extra Path 5 Current Offset Counter Shadow Register	0528 _H	36-207

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFMIEP_z_IRQ_OFFS_SHD (z=1-5)	Memory Interface Extra Path 5 Fill Level Interrupt Offset Value Shadow Register	052C _H	36-208
Extra Path Programming Registers, Extra Path Image Cropping Control Registers			
CIFEP_z_IC_CTRL (z=1-5)	Extra Path 1 Image Cropping Control Register	0000 _H	36-209
CIFEP_z_IC_RECENTER (z=1-5)	Extra Path 1 Image Cropping Recenter Register	0004 _H	36-210
CIFEP_z_IC_H_OFFS (z=1-5)	Extra Path 1 Image Cropping Horizontal Offset of Output Window Register	0008 _H	36-210
CIFEP_z_IC_V_OFFS (z=1-5)	Extra Path 1 Image Cropping Vertical Offset Of Output Window Register	000C _H	36-212
CIFEP_z_IC_H_SIZE (z=1-5)	Extra Path 1 Image Cropping Output Horizontal Picture Size Register	0010 _H	36-213
CIFEP_k_IC_V_SIZE (k=1-5)	Extra Path 1 Image Cropping Output Vertical Picture Size Register	0014 _H	36-214
CIFEP_k_IC_MAX_DX (k=1-5)	Extra Path 1 Image Cropping Maximum Horizontal Displacement Register	0018 _H	36-214
CIFEP_z_IC_MAX_DY (z=1-5)	Extra Path 1 Image Cropping Maximum Vertical Displacement Register	001C _H	36-216
CIFEP_z_IC_DISPLACE (z=1-5)	Extra Path 1 Image Cropping Camera Displacement Register	0020 _H	36-216
CIFEP_z_IC_CTRL (z=1-5)	Extra Path 2 Image Cropping Control Register	0100 _H	36-209
CIFEP_z_IC_RECENTER (z=1-5)	Extra Path 2 Image Cropping Recenter Register	0104 _H	36-210
CIFEP_z_IC_H_OFFS (z=1-5)	Extra Path 2 Image Cropping Horizontal Offset Register	0108 _H	36-210
CIFEP_z_IC_V_OFFS (z=1-5)	Extra Path 2 Image Cropping Vertical Offset Register	010C _H	36-212

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFEP_z_IC_H_SIZE (z=1-5)	Extra Path 2 Image Cropping Horizontal Picture Size Register	0110 _H	36-213
CIFEP_k_IC_V_SIZE (k=1-5)	Extra Path 2 Image Cropping Vertical Picture Size Register	0114 _H	36-214
CIFEP_k_IC_MAX_DX (k=1-5)	Extra Path 2 Image Cropping Maximum Horizontal Displacement Register	0118 _H	36-214
CIFEP_z_IC_MAX_DY (z=1-5)	Extra Path 2 Image Cropping Maximum Vertical Displacement Register	011C _H	36-216
CIFEP_z_IC_DISPLACE (z=1-5)	Extra Path 2 Image Cropping Displacement Register	0120 _H	36-216
CIFEP_z_IC_CTRL (z=1-5)	Extra Path 3 Image Cropping Control Register	0200 _H	36-209
CIFEP_z_IC_RECENTER (z=1-5)	Extra Path 3 Image Cropping Recenter Register	0204 _H	36-210
CIFEP_z_IC_H_OFFS (z=1-5)	Extra Path 3 Image Cropping Horizontal Offset Register	0208 _H	36-210
CIFEP_z_IC_V_OFFS (z=1-5)	Extra Path 3 Image Cropping Vertical Offset Register	020C _H	36-212
CIFEP_z_IC_H_SIZE (z=1-5)	Extra Path 3 Image Cropping Horizontal Picture Size Register	0210 _H	36-213
CIFEP_k_IC_V_SIZE (k=1-5)	Extra Path 3 Image Cropping Vertical Picture Size Register	0214 _H	36-214
CIFEP_k_IC_MAX_DX (k=1-5)	Extra Path 3 Image Cropping Maximum Horizontal Displacement Register	0218 _H	36-214
CIFEP_z_IC_MAX_DY (z=1-5)	Extra Path 3 Image Cropping Maximum Vertical Displacement Register	021C _H	36-216
CIFEP_z_IC_DISPLACE (z=1-5)	Extra Path 3 Image Cropping Displacement Register	0220 _H	36-216
CIFEP_z_IC_CTRL (z=1-5)	Extra Path 4 Image Cropping Control Register	0300 _H	36-209

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFEP_z_IC_RECENTER (z=1-5)	Extra Path 4 Image Cropping Recenter Register	0304 _H	36-210
CIFEP_z_IC_H_OFFSETS (z=1-5)	Extra Path 4 Image Cropping Horizontal Offset Register	0308 _H	36-210
CIFEP_z_IC_V_OFFSETS (z=1-5)	Extra Path 4 Image Cropping Vertical Offset Register	030C _H	36-212

CIFEP_k_IC_V_OFFS_S HD (k=1-5)	Extra Path 5 Image Cropping Current Vertical Offset of Output Window Shadow Register	0428 _H	36-218
CIFEP_k_IC_H_SIZE_S HD (k=1-5)	Extra Path 5 Image Cropping Current Output Horizontal Picture Size Shadow Register	042C _H	36-218
CIFEP_k_IC_V_SIZE_SHADOW (k=1-5)	Extra Path 5 Image Cropping Current Output Vertical Picture Size Shadow Register	0430 _H	36-219
Debug Path Programming Registers, Debug Path Control Registers			
CIFDP_CTRL	Debug Path Control Register	0000 _H	36-221

Table 36-2 Registers Overview (cont'd)(in alphabetical order)

Register Short Name	Register Long Name	Offset Address	Page Number
CIFDP_PDIV_CTRL	Debug Path Predivider Control Register	0004 _H	36-224
Debug Path Programming Registers, Debug Path Status Registers			
CIFDP_FLC_STAT	Debug Path Frame/Line Counter Status Register	0008 _H	36-225
CIFDP_PDIV_STAT	Debug Path Predivider Counter Status Register	000C _H	36-226
CIFDP_TSC_STAT	Debug Path Timestamp Counter Status Register	0010 _H	36-226
Debug Path Programming Registers, Debug Path User Defined Symbols Registers			
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 1 Register	0014 _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 2 Register	0018 _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 3 Register	001C _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 4 Register	0020 _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 5 Register	0024 _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 6 Register	0028 _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 7 Register	002C _H	36-227
CIFDP_UDS_x (x=1-8)	Debug Path User Defined Symbol 8 Register	0030 _H	36-227

The register is addressed wordwise.

Table 36-3 Registers Access Types

Mode	Symbol	Description Hardware (HW)	Description Software (SW)
Basic Access Types			
read/write	rw	Register is used as input for the HW	Register is read and writable by SW
read	r	Register is written by HW (register between input and output -> one cycle delay)	Value written by SW is ignored by HW; that is, SW may write any value to this field without affecting HW behavior
write	w	Register is written by software and affects hardware behavior with every write by software.	Register is writable by SW. When read, the register does not return the value that has been written previously, but some constant value instead.

36.1.3.2 CIF Control Registers

The address of each CIF control register is evaluated as CIF_CONTROL_BASE + Offset.

CIF Clock Control Registers

CIF Clock Control Register

CIF_CCL

Clock Control Register (0000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CIF_CCLFDS	2	rw	Clock Control Logic disable 0 _B processing/cfg-clocks for all CIF sub modules enabled 1 _B processing/cfg-clocks for all CIF sub modules disabled w/o access to ID and CIF_CCL register Reset: 0 _B
CIF_CCLDISS	1	r	Status of cif_ccl[2] bit (copy of cif_ccl[2]) Reset: 0 _B
0	31:3, 0	r	Reserved Read as 0, should be written with 0.

CIF Custom Registers

CIF Revision Identification Register

CIF_ID

CIF Revision Identification Register (0008_H)

Reset Value: 00B3 C002_H

Field	Bits	Type	Description
MODNUM	31:16	r	Module Number Value This bit field defines the module as a CIF. Reset: B3 _H
MODTYPE	15:8	r	Module Type This bit field defines the module as a 32-bit module. Reset: C0 _H
MODREV	7:0	r	Module Revision Number This bit field defines the module revision number. Reset: 02 _H

CIF Internal Control Registers
CIF Internal Clock Control Register
CIF_ICCL
CIF Internal Clock Control Register (0010_H)
Reset Value: 000F 0061_H

Field	Bits	Type	Description
CIF_DEBUG_PATH_CLK_EN	19	rw	Debug Path clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
CIF_EXTRA_PATHS_CLK_ENABLE	18	rw	Extra Paths clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
CIF_LIN_DSCALER_CLK_ENABLE	17	rw	Linear Downscaler clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
CIF_WATCHDOG_CLK_ENABLE	16	rw	Security Watchdog clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B

Field	Bits	Type	Description
CIF_MI_CLK_ENABLE	6	rw	Memory interface clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
CIF_JPEG_CLK_ENABLE	5	rw	JPEG encoder clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
CIF_ISP_CLK_ENABLE	0	rw	ISP processing clock enable 0 _B power safe 1 _B processing mode Reset: 1 _B
0	31:20, 15:7, 4:1	r	Reserved Read as 0, should be written with 0.

Internal Reset Control Register

CIF_IRCL

CIF Internal Reset Control Register (0014_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r											rw	rw	rw	r	rw	r	rw

Field	Bits	Type	Description
CIF_DEBUG_PATH_RST	19	rw	Debug Path software reset 0 _B processing mode 1 _B reset state
CIF_EXTRA_PATHS_RST	18	rw	Extra Paths software reset 0 _B processing mode 1 _B reset state
CIF_LIN_DSCALE_R_RST	17	rw	Linear Downscaler software reset 0 _B processing mode 1 _B reset state
CIF_WATCHDOG_RST	16	rw	Security Watchdog software reset 0 _B processing mode 1 _B reset state
CIF_GLOBAL_RST	7	rw	Soft reset of entire CIF 0 _B processing mode 1 _B reset state
CIF_MI_SOFT_RST	6	rw	Memory interface software reset 0 _B processing mode 1 _B reset state
CIF_JPEG_SOFT_RST	5	rw	JPEG encoder software reset 0 _B processing mode 1 _B reset state
CIF_YCS_SOFT_RST	2	rw	Y/C splitter software reset 0 _B processing mode 1 _B reset state
CIF_ISP_SOFT_RST	0	rw	Isp software reset 0 _B processing mode 1 _B reset state
0	31:20, 15:8, 4:3, 1	r	Reserved Read as 0, should be written with 0.

CIF Data Path Control Register

For configuration of the Extra Data Paths see [“Extra Path Programming Registers” on Page 36-180](#).

CIF_DPCL

CIF Data Path Control Register (0018_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
IF_SELECT	9:8	rw	Selects input interface 0 _D parallel interface Other values are reserved. Reset: 0 _D
CIF_CHAN_MODE	3:2	rw	Y/C splitter channel mode 0 _D disabled 1 _D main path and RAW data mode Other values are reserved. Reset: 0 _D
CIF_MP_MUX	1:0	rw	Data path selector for main path 00 _B disabled 01 _B data to MI uncompressed 10 _B data to JPEG encoder Other values are reserved. Reset: 00 _B
0	31:10, 7:4	r	Reserved Read as 0, should be written with 0.

36.1.3.3 ISP Programming Registers

The address of each CIF ISP programming register is evaluated as CIF_ISP_BASE + Offset.

ISP Control Registers

ISP Global Control Register

CIFISP_CTRL

ISP Global Control Register (0000_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	rw	rw	r	w	w			r			rw	rw		rw	

Field	Bits	Type	Description
ISP_CSM_C_RANGE	14	rw	Color Space Matrix chrominance clipping range for ISP output 0 _B CbCr range 16..240 according to ITU-R BT.601standard 1 _B full UV range 0..255
ISP_CSM_Y_RANGE	13	rw	Color Space Matrix luminance clipping range for ISP output 0 _B Y range 16..235 according to ITU-R BT.601standard 1 _B full Y range 0..255

Field	Bits	Type	Description
ISP_GEN_CFG_UPD	10	w	ISP Generate Config Update 1 _B generate frame synchronous configuration signal at the output of ISP for shadow registers of the following processing modules 0 _B no effect Reset: 0 _B
ISP_CFG_UPD	9	w	ISP Config Update 1 _B immediately configures (update) shadow registers 0 _B no effect Reset: 0 _B
ISP_INFORM_ENABLE	4	rw	ISP Input Formater Enable Controls input formater frame synchronously, if <code>isp_gen_cfg_upd</code> is used to activate this bit. For immediate update <code>isp_cfg_upd</code> must be used 1 _B Input Formater is active 0 _B Input Formater is in deactivated Reset: 0 _B
ISP_MODE	3:1	rw	ISP Mode Unused values are reserved. 000 _B RAW picture 001 _B ITU-R BT.656 (YUV with embedded sync) 010 _B ITU-R BT.601 (YUV input with H and Vsync signals) 100 _B datamode (ISP bypass, sync signals interpreted as data enable) 110 _B RAW picture mode with ITU-R BT.656 synchronization Reset: 000 _B
ISP_ENABLE	0	rw	ISP output enable Controls output formater frame synchronously, if <code>isp_gen_cfg_upd</code> is used to activate this bit. For immediate update <code>isp_cfg_upd</code> must be used. 0 _B ISP output OFF 1 _B ISP output ON Reset: 0 _B

Field	Bits	Type	Description
0	31:15, 12:11, 8:5	r	Reserved Read as 0, should be written with 0.

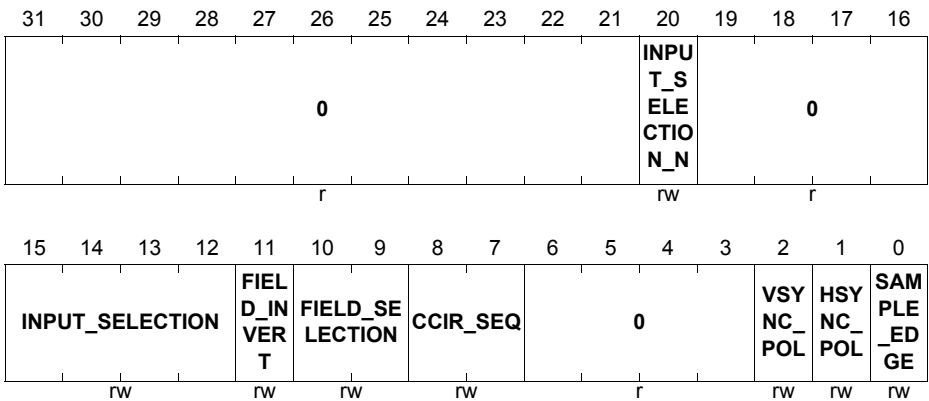

ISP Acquisition Registers

ISP Acquisition Properties Register

CIFISP_ACQ_PROP

ISP Acquisition Properties Register (0004_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
INPUT_SELECTION_NO_APP	20	rw	Input Selection No Append This field controls if the input of an external Interface gets appended with zeroes or it MSBs or shifted right to be LSB aligned. 0 _B append enabled 1 _B append disabled

Field	Bits	Type	Description
INPUT_SELECTIO N	15:12	rw	Input Selection 0000 _B 8-bit external Interface if enabled append 8 MSBs as LSBs 0001 _B 8-bit external Interface if enabled append 8 zeroes as LSBs 0010 _B 10-bit external Interface if enabled append 6 MSBs as LSBs 0011 _B 10-bit external Interface if enabled append 6 zeroes as LSBs 0100 _B 12-bit external Interface if enabled append 4 MSBs as LSBs 0101 _B 12-bit external Interface if enabled append 4 zeroes as LSBs 0110 _B 14-bit external Interface if enabled append 2 MSBs as LSBs 0111 _B 14-bit external Interface if enabled append 2 zeroes as LSBs 1000 _B 16-bit external Interface Reset: 0000 _B
FIELD_INVERT	11	rw	Field Invert If set to 1 _B the field-id will be inverted (even fields will become odd ones and vice versa). Reset: 0 _B
FIELD_SELECTIO N	10:9	rw	Field Selection 00 _B sample all fields (don't care about fields) 01 _B sample only even fields 10 _B sample only odd fields 11 _B reserved Reset: 00 _B
CCIR_SEQ	8:7	rw	CCIR Sequence This bit field defines the output sequence of the Acquisition Format block. 00 _B YCbYCr 01 _B YCrYCb 10 _B CbYCrY Reset: 00 _B

Field	Bits	Type	Description
VSYNC_POL	2	rw	Vertical sync polarity 0 _B high active 1 _B low active Reset: 0 _B
HSYNC_POL	1	rw	Horizontal sync polarity 0 _B high active 1 _B low active Reset: 0 _B
SAMPLE_EDGE	0	rw	Sample Edge 0 _B negative edge sampling 1 _B positive edge sampling Reset: 0 _B
0	31:21, 19:16, 6:3	r	Reserved Read as 0, should be written with 0.

ISP Acquisition Horizontal Offset Register
CIFISP_ACQ_H_OFFS
ISP Acquisition Horizontal Offset Register
(0008_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ACQ_H_OF FS	12:0	rw	Horizontal sample offset In sensor data samples (yuv: 4 samples=2pix) Reset: 0000 _H
0	31:13	r	Reserved Read as 0, should be written with 0.

ISP Acquisition Vertical Offset Register

CIFISP_ACQ_V_OFFS

ISP Acquisition Vertical Offset Register

(000C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ACQ_V_OF FS	11:0	rw	Vertical sample offset In lines Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Acquisition Horizontal Size Register

CIFISP_ACQ_H_SIZE

ISP Acquisition Horizontal Size Register

(0010H)

Reset Value: 0000 0A28_H

Field	Bits	Type	Description
ACQ_H_SIZE E	12:0	rw	Horizontal sample size In sensor data samples YUV input: 2 samples=1 pixel, else 1 sample=1 pixel; So in YUV mode ACQ_H_SIZE must be twice as large as horizontal image size Horizontal image size must always be even except in RAW picture mode; if an odd size is programmed the value will be truncated to even size Reset: 0A28 _H
0	31:13	r	Reserved Read as 0, should be written with 0.

ISP Acquisition Vertical Size Register

CIFISP_ACQ_V_SIZE

ISP Acquisition Vertical Size Register

(0014_H)

Reset Value: 0000 0800_H

Field	Bits	Type	Description
ACQ_V_SIZE E	11:0	rw	Vertical sample size In lines Reset: 800 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Acquisition Number of Frames Register

CIFISP_ACQ_NR_FRAMES

**ISP Acquisition Number of Frames Register
(0018_H)**

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ACQ_NR_FRAME S	9:0	rw	Number of Input Frames To be sampled (0 = continuous) Reset: 000 _H
0	31:10	r	Reserved Read as 0, should be written with 0.

ISP Output Control Registers

ISP Output Window Horizontal Offset Register

CIFISP_OUT_H_OFFS

ISP Output Window Horizontal Offset Register

(0194_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_H_OFFS	11:0	rw	Horizontal Picture Offset Unit = pixel Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Output Window Vertical Offset Register

CIFISP_OUT_V_OFFS

ISP Output Window Vertical Offset Register

(0198_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_V_OFFS	11:0	rw	Vertical Picture Offset Unit = lines Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Output Horizontal Picture Size Register

CIFISP_OUT_H_SIZE

**ISP Output Horizontal Picture Size Register
(019C_H)**

Reset Value: 0000 0A28_H

Field	Bits	Type	Description
ISP_OUT_H_SIZE	11:0	rw	Horizontal picture size in pixel. If ISP_MODE is set to ... <ul style="list-style-type: none"> • 001_B : ITU-R BT.656 YUV • 010_B : ITU-R BT.601 YUV ... only even numbers are accepted, because complete quadruples of YUYV(YCbYCr) are needed for the 422 output. (if an odd size is programmed the value will be truncated to even size) Reset: 0A28 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Output Vertical Picture Size Register

CIFISP_OUT_V_SIZE

ISP Output Vertical Picture Size Register

(01A0_H)

Reset Value: 0000 0800_H

Field	Bits	Type	Description
ISP_OUT_V_SIZE	11:0	rw	Vertical picture size In lines Reset: 800 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Shadow Flags Register

CIFISP_FLAGS_SHD

ISP Shadow Flags Register

(01A8_H)

Reset Value: FFFF C000_H

Field	Bits	Type	Description
S_HSYNC	31	r	State of ISP input port s_hsync For test purposes Reset: 0 _B
S_VSYNC	30	r	State of ISP input port s_vsync For test purposes Reset: 0 _B
S_DATA	29:14	r	State of ISP input port s_data For test purposes Reset: 000 _H
INFORM_FIELD	2	r	Current field information 0 _B = odd 1 _B = even Reset: 0 _B
ISP_INFORM_ENAB LE_SHD	1	r	Input formatter enable shadow register Reset: 0 _B
ISP_ENABLE_SHD	0	r	ISP enable shadow register 0 _B no output of data 1 _B ISP currently outputs data Reset: 0 _B
0	13:3	r	Reserved Read as 0.

ISP Output Window Horizontal Offset Register

Current horizontal offset of output window (shadow register).

CIFISP_OUT_H_OFFS_SHD
ISP Output Window Horizontal Offset Shadow Register
(01AC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_H_OFFS_SHD	11:0	r	Current horizontal picture offset In lines Reset: 000 _H
0	31:12	r	Reserved Read as 0.

ISP Output Window Vertical Offset Register

Current vertical offset of output window (shadow register).

CIFISP_OUT_V_OFFS_SHD
ISP Output Window Vertical Offset Shadow Register
(01B0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_V_OFFSET_SH D	11:0	r	Current vertical picture offset In lines Reset: 000 _H
0	31:12	r	Reserved Read as 0.

ISP Output Horizontal Picture Size Shadow Register

Current output horizontal picture size (shadow register)

CIFISP_OUT_H_SIZE_SHD

ISP Output Horizontal Picture Size Shadow Register

(01B4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_H_SIZE_SHD	12:0	r	Current horizontal picture size In pixels Reset: 0000 _H
0	31:13	r	Reserved Read as 0.

ISP Output Vertical Picture Size Shadow Register

Current output vertical picture size (shadow register).

CIFISP_OUT_V_SIZE_SHD

ISP Output Vertical Picture Size Shadow Register

(01B8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISP_OUT_V_SIZE_S HD	11:0	r	Current vertical pic size In lines Reset: 000 _H
0	31:12	r	Reserved Read as 0.

ISP Interrupt Control Registers

ISP Interrupt Mask Register

CIFISP_IMSC

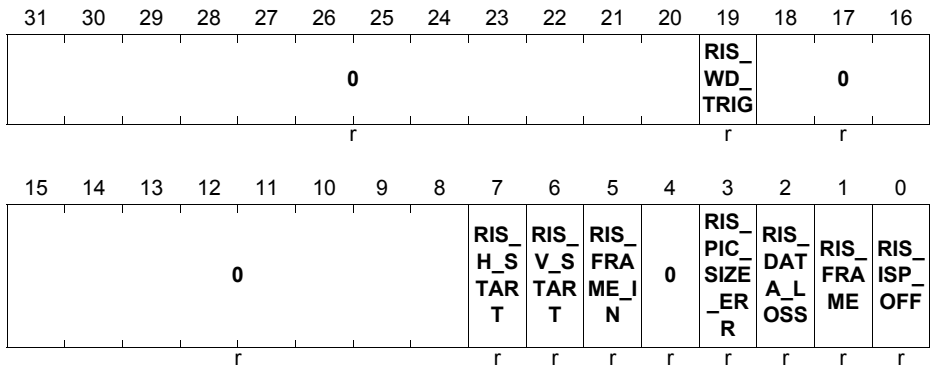

ISP Interrupt Mask Register

 (01BC_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
IMSC_WD_TRIG	19	rw	A watchdog timeout was triggered at the ISP input 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_H_START	7	rw	Start Edge of h_sync 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_V_START	6	rw	Start Edge of v_sync 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_FRAME_IN	5	rw	Sampled Input Frame is Complete 0 _B mask out 1 _B enable interrupt Reset: 0 _B

Field	Bits	Type	Description
IMSC_PIC_SIZE_ER R	3	rw	Pic Size Violation Occurred Programming seems wrong 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_DATA_LOSS	2	rw	Loss of Data Within a line, processing failure 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_FRAME	1	rw	Frame was Completely Put Out 0 _B mask out 1 _B enable interrupt Reset: 0 _B
IMSC_ISP_OFF	0	rw	Isp was Turned Off (vsynced) Due to f_cnt reached or manual 0 _B mask out 1 _B enable interrupt Reset: 0 _B
0	31:20, 18:8, 4	r	Reserved Read as 0, should be written with 0.

ISP Raw Interrupt Status Register
CIFISP_RIS
ISP Raw Interrupt Status Register (01C0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RIS_WD_TRIG	19	r	A watchdog timeout was triggered at the ISP input Reset: 0 _B
RIS_H_START	7	r	Start Edge of h_sync Reset: 0 _B
RIS_V_START	6	r	Start Edge of v_sync Reset: 0 _B
RIS_FRAME_IN	5	r	Sampled Input Frame is Complete Reset: 0 _B
RIS_PIC_SIZE_ERR	3	r	Pic Size Violation Occurred Programming seems wrong Reset: 0 _B
RIS_DATA_LOSS	2	r	Loss of Data Within a line, processing failure Reset: 0 _B
RIS_FRAME	1	r	Frame was Completely Put Out Reset: 0 _B
RIS_ISP_OFF	0	r	Isp was Turned Off (vsynced) Due to f_cnt reached or manual Reset: 0 _B

Field	Bits	Type	Description
0	31:20, 18:8, 4	r	Reserved

Miscellaneous ISP Registers
ISP Error Register
CIFISP_ERR
ISP Error Register
(023C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
OUTFORM_SIZE_ERR	2	r	Size error is generated in outmux submodule Reset: 0 _B
IS_SIZE_ERR	1	r	Size error is generated in image stabilization submodule Reset: 0 _B
INFORM_SIZE_ERR	0	r	Size error is generated in inform submodule Reset: 0 _B
0	31:3	r	Reserved Read as 0.

CIFISP_ERR and CIFISP_ERR_CLR

For debug purposes the **CIFISP_ERR** and **CIFISP_ERR_CLR** are implemented. In the case a PIC_SIZE_ERR interrupt is signalled the SW is able to see in which submodule this error was generated. Writing to the **CIFISP_ERR_CLR** register clears this bit.

ISP Error Clear Register

CIFISP_ERR_CLR

ISP Error Clear Register

(0240_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
OUTFORM_SIZE_ERR_CLR	2	w	Size error is cleared Reset: 0 _B
IS_SIZE_ERR_CLR	1	w	Size error is cleared Reset: 0 _B
INFORM_SIZE_ERR_CLR	0	w	Size error is cleared Reset: 0 _B
0	31:3	r	Reserved Read as 0, should be written with 0.

ISP Frame Counter Register

CIFISP_FRAME_COUNT

ISP Frame Counter Register

(0244_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
FRAME_COUNTER	9:0	r	<p>Current Frame Count of Processing</p> <p>In the ISP_FRAME_COUNT register the number of processed frames are displayed. For example: If a 8 is programmed into the ISP_ACQ_NR_FRAMES register, a read access to the ISP_FRAME_COUNT register during processing of the first picture shows a 7.</p> <p>After the entire frames are processed the ISP_OFF interrupt is generated and the ISP_FRAME_COUNT has the count zero. In case a '0' is programmed into the ISP_ACQ_NR_FRAMES register (continues mode) the ISP_FRAME_COUNT register keeps the value '0'. Reset: 000_H</p>
0	31:10	r	<p>Reserved</p> <p>Read as 0.</p>

36.1.3.4 Linear Downscaler Programming Registers

The address of each CIF Linear Downscaler register is evaluated as CIF_LIN_DSCALE_BASE + Offset.

Linear Downscaler Configuration Registers

Linear Downscaler Control Register

CIFLDS_CTRL

Linear Downscaler Control Register (0000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
LDS_H_MODE	9:8	rw	Horizontal scaling mode 00 _B Single skip 01 _B Double skip 10 _B Single pass 11 _B Double pass Reset: 00 _B
LDS_V_MODE	5:4	rw	Vertical scaling mode 00 _B Single skip 01 _B Double skip 10 _B Single pass 11 _B Double pass Reset: 00 _B
LDS_H_EN	1	rw	Horizontal scaling enable 0 _B Horizontal downscaling is disabled 1 _B Horizontal downscaling is enabled Reset: 0 _B

Field	Bits	Type	Description
LDS_V_EN	0	rw	Vertical scaling enable 0 _B Vertical downscaling is disabled 1 _B Vertical downscaling is enabled Reset: 0 _B
0	31:10, 7:6, 3:2	r	Reserved Read as 0, should be written with 0.

Linear Downscaler Factor Register

CIFLDS_FAC

Linear Downscaler Factor Register (0004_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
LDS_H_FAC	23:16	rw	Horizontal scaling factor Depending on the configured mode every lds_h_fac+1th pixel (or double pixel) will be skipped or passed on to the next module. Reset: 00 _H
LDS_V_FAC	7:0	rw	Vertical scaling factor Depending on the configured mode every lds_v_fac+1th line (or double line) will be skipped or passed on to the next module. Reset: 00 _H
0	31:24, 15:8	r	Reserved Read as 0, should be written with 0.

36.1.3.5 Memory Interface Programming Registers

The address of each CIF memory interface register is evaluated as CIF_MI_BASE + Offset.

Memory Interface Control Registers

Memory Interface Global Control Register

CIFMI_CTRL

Memory Interface Global Control Register

(0000_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							r/w	r		r/w	r/w	r	r/w		

Field	Bits	Type	Description
MP_WRITE_FORMAT	23:22	rw	<p>Main Picture YCbCr Write Format Defines how YCbCr main picture data is written to memory. Ignored if JPEG data is chosen. The description listed first in the table below indicates the write format as used in YCbCr mode, the second one is valid for RAW data mode only.</p> <p><i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent to the path.</i></p> <p>00_B planar (YCbCr mode) / RAW & data mode (8 bit) 01_B semi-planar for YCbCr 4:2:x / RAW 8 bit 10_B interleaved_combined for YCbCr 4:2:2 only / RAW & data mode (greater 8 up to 16 bit) 11_B reserved / RAW greater 8 up to 16 bit Reset: 00_B</p>
INIT_OFFSET_EN	21	rw	<p>Init Offset Counter Enable Enables updating of the offset counters shadow registers for picture to the programmed register init values. MI_MP_Y/CB/CR_OFFS_CNT_INIT -> MI_MP_Y/CB/CR_OFFS_CNT_SHD The update will be executed either when a forced software update occurs (in register MI_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected. After a picture skip has been performed init_offset_en selects between skip restart and skip init mode (see bit skip in register MI_INIT). Reset: 0_B</p>

Field	Bits	Type	Description
INIT_BASE_EN	20	rw	<p>Init Base Address Enable</p> <p>Enables updating of the base address and buffer size shadow registers for picture to the programmed register init values.</p> <p>MI_MP_Y/CB/CR_BASE_AD_INIT -> MI_MP_Y/CB/CR_BASE_AD_SHD</p> <p>MI_MP_Y/CB/CR_SIZE_INIT -> MI_MP_Y/CB/CR_SIZE_SHD</p> <p>The update will be executed either when a forced software update occurs (in register MI_INIT bit <code>cfg_upd = 1</code>) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected.</p> <p>Reset: 0_B</p>
BURST_LEN_CHROM	18	rw	<p>Chrominance Burst Length</p> <p>Burst length for Cb or Cr data affecting write port.</p> <p>Ignored if 8-beat bursts not supported.</p> <p><i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent .</i></p> <p>0_B 4-beat bursts 1_B 8-beat bursts</p> <p>Reset: 0_B</p>
BURST_LEN_LUM	16	rw	<p>Luminance Burst Length</p> <p>Burst length for Y, JPEG, or RAW data affecting write port.</p> <p>Ignored if 8-beat bursts not supported.</p> <p>This burst configuration is also applied to the Extra Paths.</p> <p><i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent .</i></p> <p>0_B 4-beat bursts 1_B 8-beat bursts</p> <p>Reset: 0_B</p>

Field	Bits	Type	Description
BYTE_SWAP	7	rw	<p>Byte Swap Enable Enables change of byte order of the 32 bit output word at write port.</p> <p><i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</i></p> <p>0_B no byte mirroring 1_B byte order is mirrored but the bit order within one byte doesn't change</p> <p>Reset: 0_B</p>
RAW_ENABLE	3	rw	<p>Enables RAW mode Programmed value becomes effective (visible in control shadow register) after a soft reset or a forced software update. Affects MI_IN and MI_OUT module.</p> <p>Reset: 0_B</p>
JPEG_ENABLE	2	rw	<p>Enables JPEG mode Programmed value becomes effective (visible in control shadow register) after a soft reset or a forced software. Affects MI_IN and MI_OUT module.</p> <p>Reset: 0_B</p>
MP_ENABLE	0	rw	<p>Enables main picture data path, YCbCr mode Programmed value becomes effective (visible in control shadow register) after a soft reset, a forced software update or an automatic config update. Affects MI_IN and MI_OUT module.</p> <p>Reset: 0_B</p>
0	31:24, 19, 17, 15:8, 6:4, 1	r	<p>Reserved Read as 0, should be written with 0.</p>

Note: In order to select the appropriate mode, set one bit from RAW_ENABLE, JPEG_ENABLE and MP_ENABLE to 1, and set the the others to 0.

Memory Interface Control Register For Address Init And Skip Function Register

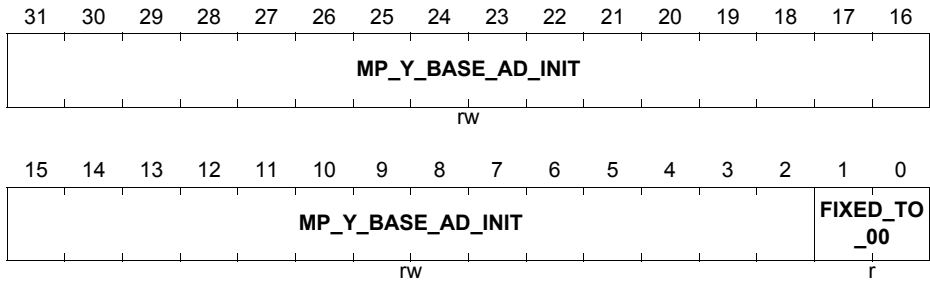

CIFMI_INIT

**Memory Interface Control Register For Address Init And Skip Function Register
(0004_H) Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MI_CFG_UPDATE	4	w	Forced Configuration Update Leads to an immediate update of the shadow registers. Depending on the two init enable bits in the MI_CTRL register (init_offset_en and init_base_en) the offset counter, base address and buffer size shadow registers are also updated. Reset: 0 _B

Field	Bits	Type	Description
MI_SKIP	2	w	<p>Skip Picture Skip of current or next starting main picture: Aborts writing of main picture image data of the current frame to RAM (after the current burst transmission has been completed). Further main picture data up to the end of the current frame are discarded. No further macroblock line interrupt (<code>_line</code>), no wrap around interrupt for main picture (<code>wrap_mp_y/cb/cr</code>) and no fill level interrupt (<code>fill_mp_y</code>) are generated. Skip does not affect the generation of the main path frame end interrupt (<code>mp_frame_end</code>). The byte counter (register <code>MI_BYTE_CNT</code>) is not affected. It produces the correct number of JPEG or RAW data bytes at the end of the current (skipped) frame. After a skip has been performed the offset counter for the main picture at the start of the following frame are set depending on the bit <code>init_offset_en</code> in register <code>MI_CTRL</code>:</p> <p>A) Skip restart mode (<code>init_offset_en = 0</code>) The offset counters of the main picture are restarted at the old start value of the previous skipped frame.</p> <p>B) Skip init mode (<code>init_offset_en = 1</code>) The offset counters of the main picture are initialized with the register contents of the offset counter init registers without any additional forced software update or automatic config update.</p> <p>Reset: 0_B</p>
0	31:5, 3, 1:0	r	<p>Reserved Read as 0, should be written with 0.</p>

Memory Interface Base Address For Main Picture Y Component, JPEG or RAW Data Register
CIFMI_MP_Y_BASE_AD_INIT
Memory Interface Base Address For Main Picture Y Component, JPEG or RAW Data Register (0008_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
MP_Y_BASE_AD_INIT	31:2	rw	Main Picture Y Base Address Init Base address of main picture Y component ring buffer, JPEG ring buffer or RAW data ring buffer. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update. <i>Note: Set control bit <code>init_base_en</code> before updating so that a forced or automatic update can take effect.</i> Reset: 0 _D
FIXED_TO_00	1:0	r	Bits [1:0] are set to “00” (word aligned value). Reset: 00 _B

Memory Interface Size Of Main Picture Y Component, JPEG or RAW Data Register
CIFMI_MP_Y_SIZE_INIT
**Memory Interface Size of main picture Y component, JPEG or RAW data Register
(000C_H) Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MP_Y_SIZE_INIT	23:2	rw	Main Picture Y Size Init Size of main picture Y component ring buffer, JPEG ring buffer or RAW data ring buffer. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update. <i>Note: Set control bit <code>init_base_en</code> before updating so that a forced or automatic update can take effect.</i> Reset: 0 _D
FIXED_TO_00	1:0	r	Bits [1:0] are set to “00” (word aligned value). Reset: 00 _B
0	31:24	r	Reserved Read as 0, should be written with 0.

Memory Interface Offset Counter Init Value For Main Picture Y, JPEG or RAW Data Register
CIFMI_MP_Y_OFFSETS_CNT_INIT
Memory Interface Offset Counter Init Value For Main Picture Y, JPEG or RAW Data Register

 (0010_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
MP_Y_OFFSETS_CNT_INIT	23:2	rw	<p>Main Picture Y Offset Counter Init Offset counter init value of main picture Y component ring buffer, JPEG ring buffer or RAW data ring buffer.</p> <p>Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update.</p> <p><i>Note: Set control bit <code>init_base_en</code> before updating so that a forced or automatic update can take effect. Check exceptional handling in skip modes.</i></p> <p>Reset: 0_D</p>
FIXED_TO_00	1:0	r	<p>Bits [1:0] are set to “00” (word aligned value). Reset: 00_B</p>
0	31:24	r	<p>Reserved Read as 0, should be written with 0.</p>

Memory Interface Offset Counter Start Value For Main Picture Y, JPEG or RAW Data Register
CIFMI_MP_Y_OFFS_CNT_START
Memory Interface Offset Counter Start Value For Main Picture Y, JPEG or RAW Data Register
 (0014_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
MP_Y_OFFS_CNT_S TART	23:2	r	Main Picture Y Offset Counter Start Offset counter value which points to the start address of the previously processed picture (main picture Y component, JPEG or RAW data). Updated at frame end. Note: A soft reset resets the contents to the reset value. Reset: 0 _D
FIXED_TO_00	1:0	r	Bits [1:0] are set to “00” (word aligned value). Reset: 00 _B
0	31:24	r	Reserved Read as 0.

Memory Interface Fill Level Interrupt Offset Value For Main Picture Y, JPEG or RAW Data Register

Register 236

CIFMI_MP_Y_IRQ_OFFS_INIT
Memory Interface Fill Level Interrupt Offset Value For Main Picture Y, JPEG or RAW Data Register (0018_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
MP_Y_IRQ_OFFS_INIT	23:2	rw	Main Picture Y IRQ Offset Init Reaching this programmed value by the current offset counter for addressing main picture Y component, JPEG or RAW data leads to generation of fill level interrupt fill_mp_y. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update. Reset: 0 _D
FIXED_TO_00	1:0	r	Bits [1:0] are set to “00” (word aligned value). Reset: 00 _B
0	31:24	r	Reserved Read as 0, should be written with 0.

Memory Interface Base Address For Main Picture Cb Component Ring Buffer Register

CIFMI_MP_CB_BASE_AD_INIT

Memory Interface Base Address For Main Picture Cb Component Ring Buffer Register (001C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
MP_CB_BASEAD_INIT	31:2	rw	<p>Main Picture Cb Base Address Init Base address of main picture Cb component ring buffer. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update.</p> <p><i>Note: Set control bit <code>init_base_en</code> before updating so that a forced or automatic update can take effect.</i></p> <p>Reset: 0_D</p>

BUS_WRITE_ERROR	8	w	Bus Write Error Clear status of Bus write error flag Reset: 0 _B
MP_CR_FIFO_FULL	2	w	Main Picture Cr FIFO Full Clear status of Cr FIFO full flag in main path Reset: 0 _B
MP_CB_FIFO_FULL	1	w	Main Picture Cb FIFO Full Clear status of Cb FIFO full flag in main path Reset: 0 _B
MP_Y_FIFO_FULL	0	w	Main Picture Y FIFO Full Clear status of Y FIFO full flag in main path Reset: 0 _B
0	31:29, 23:9, 7:3	r	Reserved Read as 0, should be written with 0.

36.1.3.6 JPEG Encoder Programming Registers

The address of each CIF JPEG encoder register is evaluated as CIF_JPE_BASE + Offset.

JPEG Encoder Control Registers

JPE Command To Start Stream Header Generation Register

Register 305

CIFJPE_GEN_HEADER

JPE Command To Start Stream Header Generation Register

(0000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER	0	w	Generate Header 1 _B Start command to generate stream header ; auto reset to zero after one clock cycle Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

JPE Start Command To Start JFIF Stream Encoding Register

CIFJPE_ENCODE

JPE Start Command To Start JFIF Stream Encoding Register

(0004_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CONT_MODE	5:4	rw	Encoder continuous mode "00": encoder stops at frame end (corresponds to former behavior)"01": encoder starts automatically to encode the next frame"10": unused"11": encoder first generates next header and then encodes automatically the next frame These settings are checked after encoding one frame. They are not auto-reset by hardware. Reset: 00 _B
ENCODE	0	w	Encode 1 _B Start command to start JFIF stream encoding; auto reset to zero after one clock cycle Reset: 0 _B
0	31:6, 3:1	r	Reserved Read as 0, should be written with 0.

JPE Automatic Configuration Update (INIT) Register

CIFJPE_INIT

**JPE Automatic Configuration Update Register
(0008_H)**

Reset Value: 0000 0000_H

Field	Bits	Type	Description
JP_INIT	0	w	JPEG Init This bit has to be set after “Encode” to start the JPEG encoder. The “Encode” command becomes active either with JP_INIT or with the input signal “CFG_UPD” auto reset to zero after one clock cycle !!! 1 _B Immediate start of JPEG encoder. Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

JPE Y Value Scaling Control Register
CIFJPE_Y_SCALE_EN
JPE Y Value Scaling Control Register(000C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
Y_SCALE_EN	0	rw	Y scale flag 0 _B no Y input scaling 1 _B scaling Y input from [16..235] to [0..255] Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

JPE Cb/Cr Value Scaling Control Register

CIFJPE_CBCR_SCALE_EN

JPE Cb/Cr Value Scaling Control Register

(0010_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CBCR_SCALE_EN	0	rw	Cb/Cr scale flag 0 _B no Cb/Cr input scaling 1 _B scaling Cb/Cr input from [16..240] to [0..255] Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

JPE Header Generation Debug Register

CIFJPE_TABLE_FLUSH

JPE Header Generation Debug Register

(0014_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TABLE_FLUSH	0	rw	Header generation debug control flag (controls transmission of last header bytes if the 64 bit output buffer is not completely filled) 0 _B wait for encoded image data to fill output buffer 1 _B immediately transmit last header bytes Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

JPEG Codec Horizontal Image Size For Encoding Register

CIFJPE_ENC_HSIZE

JPEG Codec Horizontal Image Size For Encoding Register

(0018_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ENC_HSIZE	11:0	rw	Horizontal Size JPEG codec horizontal image size for R2B and SGEN blocks Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

JPEG Codec Vertical Image Size For Encoding Register

CIFJPE_ENC_VSIZE

JPEG Codec Vertical Image Size For Encoding Register

(001C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ENC_VSIZE	11:0	rw	Vertical Size JPEG codec vertical image size for R2B and SGEN blocks Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

JPEG Picture Encoding Format Register

Register 313

CIFJPE_PIC_FORMAT

JPEG Picture Encoding Format Register

(0020_H)

Reset Value: 0000 0001_H

Field	Bits	Type	Description
ENC_PIC_FORMAT	2:0	rw	Picture Encoding Format 001 _B 4:2:2 format 1XX _B 4:0:0 format Reset: 001 _B
0	31:3	r	Reserved Read as 0, should be written with 0.

JPE Restart Marker Insertion Register

CIFJPE_RESTART_INTERVAL

JPE Restart Marker Insertion Register

(0024_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RESTART_INTERVAL	15:0	rw	Restart Interval No of MCU in reset interval via host Reset: 0000 _H
0	31:16	r	Reserved Read as 0, should be written with 0.

Q- table Selector 0, Quant. Table For Y Component

CIFJPE_TQ_Y_SELECT

**Q- table Selector 0 Quant Table For Y Component
(0028_H)**

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TQ0_SELECT	1:0	rw	Q-Table Selector Y Q-table selector 0, Quant. For Y component. 00 _B Q-Table 0 01 _B Q-Table 1 10 _B Q-Table 2 11 _B Q-Table 3 Reset: 00 _B
0	31:2	r	Reserved Read as 0, should be written with 0.

Q- table selector 1, quant. table for U component

CIFJPE_TQ_U_SELECT

**Q- table Selector 1, Quant. Table For U Component
(002C_H)**

Reset Value: 0000 0001_H

Field	Bits	Type	Description
TQ1_SELECT	1:0	rw	Q-Table Selector U Q-table selector 1, Quant. For U component. 00 _B Q-Table 0 01 _B Q-Table 1 10 _B Q-Table 2 11 _B Q-Table 3 Reset: 00 _B
0	31:2	r	Reserved Read as 0, should be written with 0.

Q- table selector 2, quant. table for V component

CIFJPE_TQ_V_SELECT

**Q- table Selector 2 Quant Table For V Component
(0030_H)**

Reset Value: 0000 0001_H

Field	Bits	Type	Description
TQ2_SELECTOR	1:0	rw	Q-Table Selector V Q-table selector 2, Quant. For V component. 00 _B Q-Table 0 01 _B Q-Table 1 10 _B Q-Table 2 11 _B Q-Table 3 Reset: 00 _B
0	31:2	r	Reserved Read as 0, should be written with 0.

JPE Huffman Table Selector For DC Values

CIFJPE_DC_TABLE_SELECT

JPE Huffman Table Selector For DC Values Register
(0034_H)

Reset Value: 0000 0006_H

Field	Bits	Type	Description
DC_TABLE_SELECTOR	2:0	rw	DC Table Selector XX0 _B dc table 0; component 0 XX1 _B dc table 1; component 0 X0X _B dc table 0; component 1 X1X _B dc table 1; component 1 0XX _B dc table 0; component 2 1XX _B dc table 1; component 2 Reset: 110 _B
0	31:3	r	Reserved Read as 0, should be written with 0.

JPE Huffman Table Selector For AC Values Register

CIFJPE_AC_TABLE_SELECT

JPE Huffman Table Selector For AC Values Register
(0038_H)

Reset Value: 0000 0006_H

Field	Bits	Type	Description
AC_TABLE_SELECT	2:0	rw	AC Table Selector "xx0" = dc table 0; component 0 "xx1" = dc table 1; component 0 "x0x" = dc table 0; component 1 "x1x" = dc table 1; component 1 "0xx" = dc table 0; component 2 "1xx" = dc table 1; component 2 Reset: 110 _B
0	31:3	r	Reserved Read as 0, should be written with 0.

JPE Table Programming Register

CIFJPE_TABLE_DATA

JPE Table Programming Register (003C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TABLE_WDAT A _H	15:8	w	Table data MSB Reset: 00 _H
TABLE_WDAT A _L	7:0	w	Table data LSB Reset: 00 _H
0	31:16	r	Reserved Read as 0, should be written with 0.

JPE Table Programming Select Register

CIFJPE_TABLE_ID

JPE Table Programming Select Register

(0040_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TABLE_ID	3:0	rw	JPE Table ID Select table according to the following list. Values 8 _H through F _H are reserved for debug purposes. 0 _H Q-Table 0 1 _H Q-Table 1 2 _H Q-Table 2 3 _H Q-Table 3 4 _H VLC DC Table 0 5 _H VLC AC Table 0 6 _H VLC DC Table 1 7 _H VLC AC Table 1 Reset: 0000 _B
0	31:4	r	Reserved Read as 0, should be written with 0.

JPE Huffman AC Table 0 Length Register
CIFJPE_TAC0_LEN
JPE Huffman AC Table 0 Length Register
(0044_H)
Reset Value: 0000 00B_H

Field	Bits	Type	Description
TAC0_LEN	7:0	rw	AC Table 0 Length Huffman table length for ac0 table Reset: B2 _H
0	31:8	r	Reserved Read as 0, should be written with 0.

JPE Huffman DC Table 0 Length Register
CIFJPE_TDC0_LEN
JPE Huffman DC Table 0 Length Register
(0048_H)
Reset Value: 0000 001C_H

Field	Bits	Type	Description
TDC0_LEN	7:0	rw	DC Table 0 Length Huffman table length for dc0 table Reset: 1C _H
0	31:8	r	Reserved Read as 0, should be written with 0.

JPE Huffman AC Table 1 Length Register
CIFJPE_TAC1_LEN
JPE Huffman AC Table 1 Length Register
(004C_H)
Reset Value: 0000 00B_H

Field	Bits	Type	Description
TAC1_LEN	7:0	rw	AC Table 1 Length Huffman table length for ac1 table Reset: B2 _H
0	31:8	r	Reserved Read as 0, should be written with 0.

JPE Huffman DC Table 1 Length Register
CIFJPE_TDC1_LEN
JPE Huffman DC Table 1 Length Register
(0050_H)
Reset Value: 0000 001C_H

Field	Bits	Type	Description
TDC1_LEN	7:0	rw	DC Table 1 Length Huffman table length for dc1 table Reset: $1C_H$
0	31:8	r	Reserved Read as 0, should be written with 0.

JPE Encoder Status Flag Register

CIFJPE_ENCODER_BUSY

JPE Encoder Status Flag Register (0058_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CODEC_BUSY	0	r	Codec Busy 0 _B Codec is free (not busy) 1 _B JPEG codec in process Reset: 0 _B
0	31:1	r	Reserved Read as 0.

JPE Header Mode Definition Register

CIFJPE_HEADER_MODE

JPE Header Mode Definition Register

(005C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
HEADER_MODE	1:0	rw	Header Mode 00 _B no APPn header 01 _B don't use this setting 10 _B JFIF header 11 _B don't use this setting Reset: 00 _B
0	31:2	r	Reserved Read as 0, should be written with 0.

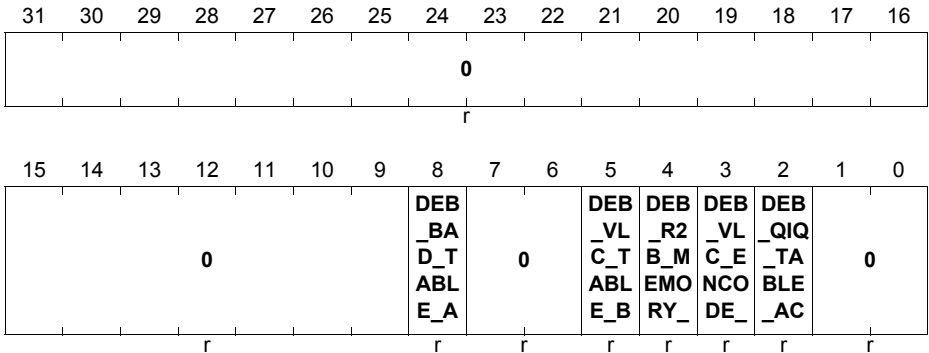

JPE Encode Mode Register

CIFJPE_ENCODE_MODE

JPE Encode Mode Register (0060_H) Reset Value: 0000 0001_H

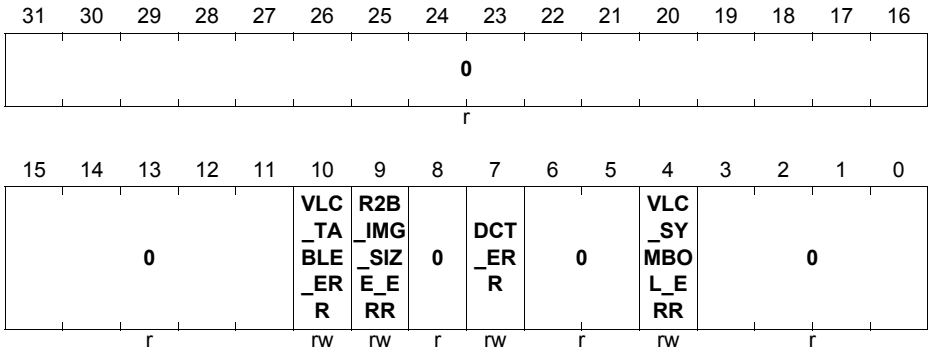

Field	Bits	Type	Description
ENCODE_MODE	0	r	Encode Mode Always 1, because this is the encoder only edition Reset: 1 _B
0	31:1	r	Reserved Read as 0.

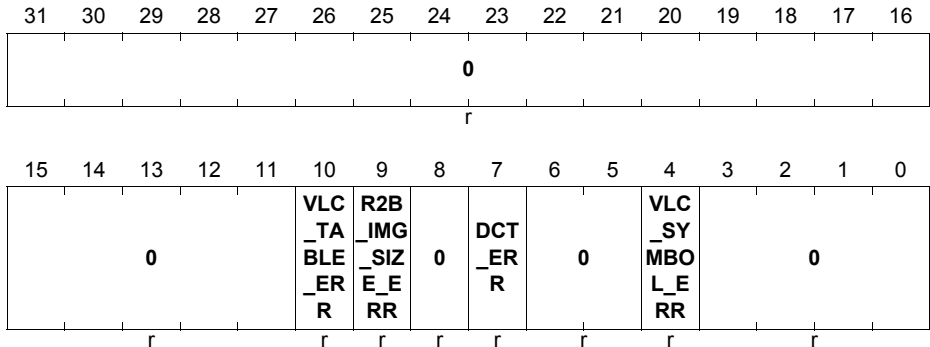

JPE Debug Information Register
CIFJPE_DEBUG
JPE Debug Information Register
(0064_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
DEB_BAD_TABLE_ACCESS	8	r	Debug Bad Table Access Debug signal only (set if an access to the TABLE_DATA or to the TABLE_ID register is performed, when the JPEG_ENCODER is busy. In this case a default handshake acknowledge is generated. Thus the configuration bus is not blocked) Reset: 0 _B
DEB_VLC_TABLE_BUSY	5	r	Debug VLC Table Busy Debug signal only (vlc access to huff-tables) Unit will initialize huff tables internally, busy for ~400 cycles after reset. Reset: 0 _B
DEB_R2B_MEMORY_FULL	4	r	R2B Memory Full Debug signal only (line memory status of r2b) Reset: 0 _B

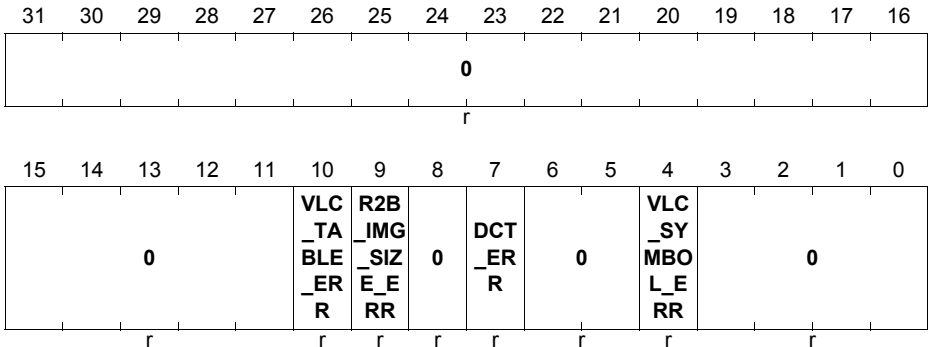

Field	Bits	Type	Description
DEB_VLC_ENCODE_B USY	3	r	VLC Encode Busy Debug signal only (vlc encode processing active) Reset: 0 _B
DEB_QIQ_TABLE_AC C	2	r	QIQ Table Access Debug signal only (QIQ table access) Reset: 0 _B
0	31:9, 7:6, 1:0	r	Reserved Read as 0.

JPEG Encoder Interrupt Registers
JPE Error Interrupt Mask Register
CIFJPE_ERROR_IMR
JPE Error Interrupt Mask Register (0068_H)
Reset Value: 0000 0000_H

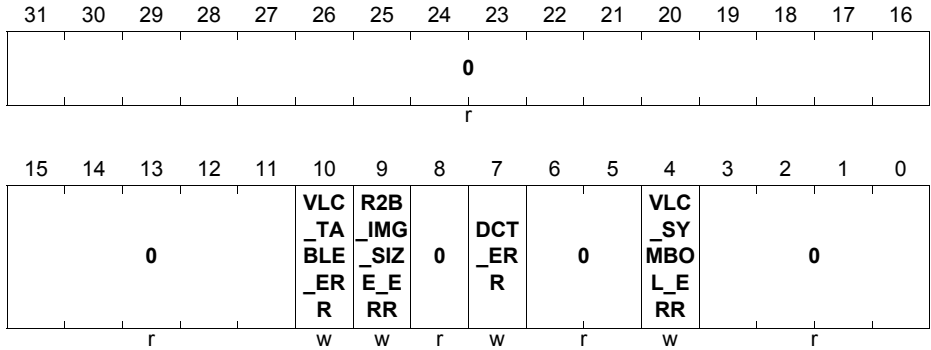

Field	Bits	Type	Description
VLC_TABLE_ERR	10	rw	VLC Table Error 1 _B interrupt is activated (masked in) Reset: 0 _B
R2B_IMG_SIZE_ERR	9	rw	R2B Image Size Error 1 _B interrupt is activated (masked in) Reset: 0 _B
DCT_ERR	7	rw	DC Table Error 1 _B interrupt is activated (masked in) Reset: 0 _B
VLC_SYMBOL_ERR	4	rw	VLC Symbol Error 1 _B interrupt is activated (masked in) Reset: 0 _B
0	31:11, 8, 6:5, 3:0	r	Reserved Read as 0, should be written with 0.

JPE Error Raw Interrupt Status Register
CIFJPE_ERROR_RIS
JPE Error Raw Interrupt Status Register
(006C_H)
Reset Value: 0000 0000_H

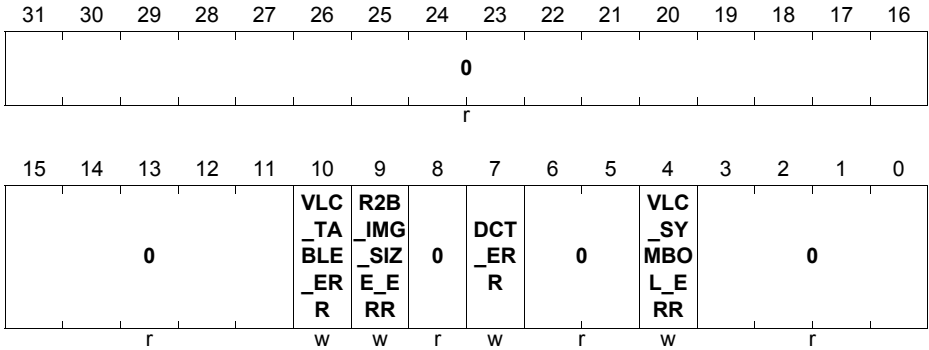

Field	Bits	Type	Description
VLC_TABLE_ERR	10	r	VLC Table Error 1 _B illegal table detected
R2B_IMG_SIZE_ERR	9	r	R2B Image Size Error 1 _B mismatch of predefined h_size and v_size values with calculated values (encode mode)
DCT_ERR	7	r	DC Table Error 1 _B block start mismatch
VLC_SYMBOL_ERR	4	r	VLC Symbol Error 1 _B illegal symbol detected (encoding)
0	31:11, 8, 6:5, 3:0	r	Reserved Read as 0

JPE Error Masked Interrupt Status Register
CIFJPE_ERROR_MIS
**JPE Error Masked Interrupt Status Register
(0070_H)**
Reset Value: 0000 0000_H

Field	Bits	Type	Description
VLC_TABLE_ERR	10	r	VLC Table Error 1 _B illegal table detected Reset: 0 _B
R2B_IMG_SIZE_ERR	9	r	R2B Image Size Error 1 _B mismatch of predefined h_size and v_size values with calculated values (encode mode) Reset: 0 _B
DCT_ERR	7	r	DC Table Error 1 _B block start mismatch Reset: 0 _B
VLC_SYMBOL_ERR	4	r	VLC Symbol Error 1 _B illegal symbol detected (encoding) Reset: 0 _B
0	31:11, 8, 6:5, 3:0	r	Reserved Read as 0.

JPE Error Interrupt Set Register
CIFJPE_ERROR_ISR
JPE Error Interrupt Set Register
(0078_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
VLC_TABLE_ERR	10	w	VLC Table Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
R2B_IMG_SIZE_ERR	9	w	R2B Image Size Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
DCT_ERR	7	w	DC Table Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
VLC_SYMBOL_ERR	4	w	VLC Symbol Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
0	31:11, 8, 6:5, 3:0	r	Reserved Read as 0, should be written with 0.

JPE Error Interrupt Clear Register
CIFJPE_ERROR_ICR
JPE Error Interrupt Clear Register (0074_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
VLC_TABLE_ERR	10	w	VLC Table Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
R2B_IMG_SIZE_ERR	9	w	R2B Image Size Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
DCT_ERR	7	w	DC Table Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
VLC_SYMBOL_ERR	4	w	VLC Symbol Error 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
0	31:11, 8, 6:5, 3:0	r	Reserved Read as 0, should be written with 0.

JPEG Status Interrupt Mask Register

CIFJPE_STATUS_IMR

JPEG Status Interrupt Mask Register

(007C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER_DONE	5	rw	Header Generation Complete 1 _B interrupt is activated (masked in) Reset: 0 _B
ENCODE_DONE	4	rw	Encoding Complete 1 _B interrupt is activated (masked in) Reset: 0 _B
0	31:6, 3:0	r	Reserved Read as 0, should be written with 0.

JPEG Status Raw Interrupt Status Register
CIFJPE_STATUS_RIS
JPEG Status Raw Interrupt Status Register
(0080_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER_DONE	5	r	Header Generation Complete 1 _B Stream header generation finished Reset: 0 _B
ENCODE_DONE	4	r	Encoding Complete 1 _B Encode processing finished Reset: 0 _B
0	31:6, 3:0	r	Reserved Read as 0.

JPEG Status Masked Interrupt Status Register
CIFJPE_STATUS_MIS
**JPEG Status Masked Interrupt Status Register
(0084_H)**
Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER_DONE	5	r	Header Generation Complete 1 _B Stream header generation finished Reset: 0 _B
ENCODE_DONE	4	r	Encoding Complete 1 _B Encode processing finished Reset: 0 _B
0	31:6, 3:0	r	Reserved Read as 0.

JPEG Status Interrupt Clear Register
CIFJPE_STATUS_ICR
JPEG Status Interrupt Clear Register
(0088_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER_DONE	5	w	Header Generation Complete 1 _B clear status bit, bit is reset to zero after 1 clk Reset: 0 _B
ENCODE_DONE	4	w	Encoding Complete 1 _B clear status bit, bit is reset to zero after 1 clk Reset: 0 _B
0	31:6, 3:0	r	Reserved Read as 0, should be written with 0.

JPEG Status Interrupt Set Register
CIFJPE_STATUS_ISR
JPEG Status Interrupt Set Register (008C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
GEN_HEADER_DONE	5	w	Header Generation Complete 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
ENCODE_DONE	4	w	Encoding Complete 1 _B set error bit, bit is reset to zero after 1 clk Reset: 0 _B
0	31:6, 3:0	r	Reserved Read as 0, should be written with 0.

36.1.3.7 Security Watchdog Programming Registers

The address of each CIF Security Watchdog register is evaluated as CIF_WATCHDOG_BASE + Offset.

Watchdog Configuration Registers

Watchdog Control Register

CIFWD_CTRL

Watchdog Control Register (0000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
WD_PREDIV	31:16	rw	Watchdog Counter Predivider A value of 0 means that the Watchdog Counters are increased with every CIF clock cycle. Every other value N leads to an increment at every N+1th cycle. Reset: 00 _H
RST_PD_CNT	3	w	Reset Predivider Counter 0 _B nothing happens 1 _B reset counter
RST_V_CNT	2	w	Reset Vertical Counter 0 _B nothing happens 1 _B reset counter
RST_H_CNT	1	w	Reset Horizontal Counter 0 _B nothing happens 1 _B reset counter

Field	Bits	Type	Description
WD_EN	0	rw	Enable Security Watchdog 0 _B unit is disabled 1 _B enables the watchdog unit
0	15:4	r	Reserved Read as 0, should be written with 0.

Watchdog Vertical Timeout Register

CIFWD_V_TIMEOUT

Watchdog Vertical Timeout Register

(0004_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
WD_VES_T O	31:16	rw	Watchdog Vertical End Start Timeout A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the vertical counter reaches the value in the vertical End Start phase. Reset: 00 _H
WD_VSE_T O	15:0	rw	Watchdog Vertical Start End Timeout A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the vertical counter reaches the value in the vertical Start End phase. Reset: 00 _H

Watchdog Horizontal Timeout Register

CIFWD_H_TIMEOUT

Watchdog Horizontal Timeout Register

(0008_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
WD_HES_TO	31:16	rw	Watchdog Horizontal End Start Timeout A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the horizontal counter reaches the value in the horizontal End Start phase. Reset: 00 _H
WD_HSE_TO	15:0	rw	Watchdog Horizontal Start End Timeout A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the horizontal counter reaches the value in the horizontal Start End phase. Reset: 00 _H

Watchdog Interrupt Registers

Watchdog Interrupt Mask Register

CIFWD_IMSC

Watchdog Interrupt Mask Register (000C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IMSC_WD_VES_TO	3	rw	Vertical End Start Timeout Enable interrupt (1) or mask out (0) Reset: 0 _B
IMSC_WD_VSE_TO	2	rw	Vertical Start End Timeout Enable interrupt (1) or mask out (0) Reset: 0 _B
IMSC_WD_HES_TO	1	rw	Horizontal End Start Timeout Enable interrupt (1) or mask out (0) Reset: 0 _B
IMSC_WD_HSE_TO	0	rw	Horizontal Start End Timeout Enable interrupt (1) or mask out (0) Reset: 0 _B
0	31:4	r	Reserved Read as 0, should be written with 0.

Watchdog Raw Interrupt Status Register
CIFWD_RIS
Watchdog Raw Interrupt Status Register
(0010_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RIS_WD_VES_TO	3	r	Vertical End Start Timeout The counter reached the programmed timeout. Reset: 0 _B
RIS_WD_VSE_TO	2	r	Vertical Start End Timeout The counter reached the programmed timeout. Reset: 0 _B
RIS_WD_HES_TO	1	r	Horizontal End Start Timeout The counter reached the programmed timeout. Reset: 0 _B
RIS_WD_HSE_TO	0	r	Horizontal Start End Timeout The counter reached the programmed timeout. Reset: 0 _B
0	31:4	r	Reserved Read as 0.

Watchdog Masked Interrupt Status Register
CIFWD_MIS
**Watchdog Masked Interrupt Status Register
(0014_H)**
Reset Value: 0000 0000_H

Field	Bits	Type	Description
MIS_WD_VES_TO	3	r	Vertical End Start Timeout The counter reached the programmed timeout. Reset: 0 _B
MIS_WD_VSE_TO	2	r	Vertical Start End Timeout The counter reached the programmed timeout. Reset: 0 _B
MIS_WD_HES_TO	1	r	Horizontal End Start Timeout The counter reached the programmed timeout. Reset: 0 _B
MIS_WD_HSE_TO	0	r	Horizontal Start End Timeout The counter reached the programmed timeout. Reset: 0 _B
0	31:4	r	Reserved Read as 0.

Watchdog Interrupt Clear Register
CIFWD_ICR
Watchdog Interrupt Clear Register (0018_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ICR_WD_VES_T O	3	w	Vertical End Start Timeout 0 _B nothing happens 1 _B clear interrupt
ICR_WD_VSE_T O	2	w	Vertical Start End Timeout 0 _B nothing happens 1 _B clear interrupt
ICR_WD_HES_T O	1	w	Horizontal End Start Timeout 0 _B nothing happens 1 _B clear interrupt
ICR_WD_HSE_T O	0	w	Horizontal Start End Timeout 0 _B nothing happens 1 _B clear interrupt
0	31:4	r	Reserved Read as 0, should be written with 0.

Watchdog Interrupt Set Register
CIFWD_ISR
Watchdog Interrupt Set Register
(001C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISR_WD_VES_TO	3	w	Vertical End Start Timeout 0 _B nothing happens 1 _B set interrupt
ISR_WD_VSE_TO	2	w	Vertical Start End Timeout 0 _B nothing happens 1 _B set interrupt
ISR_WD_HES_TO	1	w	Horizontal End Start Timeout 0 _B nothing happens 1 _B set interrupt
ISR_WD_HSE_TO	0	w	Horizontal Start End Timeout 0 _B nothing happens 1 _B set interrupt
0	31:4	r	Reserved Read as 0, should be written with 0.

36.1.3.8 ISP Image Stabilization Registers

The address of each CIF image stabilization register is evaluated as CIF_IS_BASE + Offset.

Image Stabilization Control Registers

ISP Image Stabilization Control Register

CIFISPIS_CTRL

ISP Image Stabilization Control Register

(0000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_EN	0	rw	Image Stabilization Enable 0 _B image stabilization switched off 1 _B image stabilization switched on Reset: 0 _B
0	31:1	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Recenter Register

CIFISPIS_RECENTER

ISP Image Stabilization Recenter Register

(0004_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RECENTER	2:0	rw	Recenter 000 _B recenter feature switched off For all other values recentering is active (cur_h/v_offs-H/V_OFFS)/2 pöower(recenter) Reset: 000 _B
0	31:3	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Horizontal Offset Of Output Window Register

CIFISPIS_H_OFFS

ISP Image Stabilization Horizontal Offset Of Output Window Register

(0008_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_H_OFFS	11:0	rw	Horizontal Picture Offset Horizontal picture offset in pixel Reset: 0000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Vertical Offset Of Output Window Register

CIFISPIS_V_OFFS

ISP Image Stabilization Vertical Offset Of Output Window Register

(000C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_V_OFFS	11:0	rw	Vertical Picture Offset Vertical picture offset in lines Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Output Horizontal Picture Size Register

CIFISPIS_H_SIZE

ISP Image Stabilization Output Horizontal Picture Size Register

(0010_H)

Reset Value: 0000 0A28_H

Field	Bits	Type	Description
IS_H_SIZE	11:0	rw	<p>Horizontal Picture Size Horizontal picture size in pixel Only even numbers are accepted, because complete quadruples of YUYV(YCbYCr) are needed for the following modules. If an odd size is programmed the value will be truncated to even size. If ISP_MODE is set to 001_B (ITU-R BT.656 YUV) 010_B (ITU-R BT.601 YUV) 011_B (ITU-R BT.601 Bayer RGB) 101_B (ITU-R BT.656 Bayer RGB) Reset: A28_H</p>
0	31:12	r	<p>Reserved Read as 0, should be written with 0.</p>

ISP Image Stabilization Output Vertical Picture Size Register

CIFISPIS_V_SIZE

ISP Image Stabilization Output Vertical Picture Size Register

(0014_H)

Reset Value: 0000 0800_H

Field	Bits	Type	Description
IS_V_SIZE	11:0	rw	Vertical Picture Size Vertical picture size in lines Reset: 800 _H
0	31:12	r	Reserved

ISP Image Stabilization Maximum Horizontal Displacement Register

CIFISPIS_MAX_DX

ISP Image Stabilization Maximum Horizontal Displacement Register

(0018_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_MAX_DX	11:0	rw	Maximum Horizontal Displacement Maximum allowed accumulated horizontal displacement in pixels Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Maximum Vertical Displacement Register

CIFISPIS_MAX_DY

ISP Image Stabilization Maximum Vertical Displacement Register

(001C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_MAX_DY	11:0	rw	Maximum Vertical Displacement Maximum allowed accumulated vertical displacement in lines Reset: 000 _H
0	31:12	r	Reserved Read as 0, should be written with 0.

ISP Image Stabilization Camera Displacement Register

CIFISPIS_DISPLACE

ISP Image Stabilization Camera Displacement Register

(0020_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DY	27:16	rw	Camera Displacement ISP_IS will compensate for vertical camera displacement of DY pixels in the next frame Reset: 000 _H
DX	11:0	rw	Camera Displacement ISP_IS will compensate for horizontal camera displacement of DX pixels in the next frame Reset: 000 _H
0	31:28, 15:12	r	Reserved Read as 0, should be written with 0.

Image Stabilization Shadow Registers

ISP Image Current Horizontal Offset Of Output Window (Shadow Register) Register

CIFISPIS_H_OFFS_SHD

SP Image Current Horizontal Offset Of Output Window Shadow Register

(0024_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IS_H_OFFS_S HD	12:0	r	Horizontal Picture Offset Current horizontal picture offset in lines Reset: 0000 _H
0	31:13	r	Reserved Read as 0

ISP Image Current Vertical Offset Of Output Window (Shadow Register) Register

CIFISPIS_V_OFFS_SHD

ISP Image Current Vertical Offset Of Output Window Shadow Register
(0028_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
IS_V_OFFS_SHD	11:0	r	Vertical Picture Offset Current vertical picture offset in lines Reset: 000 _H
0	31:12	r	Reserved Read as 0.

ISP Image Current Output Horizontal Picture Size (Shadow Register) Register

CIFISPIS_H_SIZE_SHD

ISP Image Current Output Horizontal Picture Size Shadow Register

(002C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description

0							BYT_ES_WAP	0						EP_ENABLE	
r							rw	r						rw	

Field	Bits	Type	Description
EP_WRITE_FOR MAT	23:22	rw	<p>Extra Path Write Format Defines how Extra Path data is written to memory.</p> <p><i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent to the path.</i></p> <p>00_B RAW & data mode (8 bit) 01_B RAW 8 bit 10_B RAW & data mode (greater 8 up to 16 bit) 11_B YCbCr 16 bit; YCbCr data is handled interleaved as 16 bit data in extra paths. Reset: 00_B</p>
INIT_OFFSET_E N	21	rw	<p>Init Offset Counter Enable Enables updating of the offset counters shadow registers for Extra Path to the programmed register init values. MI_EP_OFFS_CNT_INIT -> MI_EP_OFFS_CNT_SHD The update will be executed either when a forced software update occurs (in register MI_EP_n_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected. After a picture skip has been performed init_offset_en selects between skip restart and skip init mode (see bit skip in register MI_EP_INIT). Reset: 0_B</p>

Field	Bits	Type	Description
INIT_BASE_EN	20	rw	<p>Init Base Address Enable Enables updating of the base address and buffer size shadow registers for picture to the programmed register init values. MI_EP_BASE_AD_INIT -> MI_EP_BASE_AD_SHD MI_EP_SIZE_INIT -> MI_EP_SIZE_SHD The update will be executed either when a forced software update occurs (in register MI_EP_n_INIT bit <code>cfg_upd = 1</code>) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected. Reset: 0_B</p>
BYTE_SWAP	7	rw	<p>Byte Swap Enable Enables change of byte order of the 32 bit output word at write port. <i>Note: Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</i> 0_B no byte mirroring 1_B byte order is mirrored but the bit order within one byte doesn't change Reset: 0_B</p>
EP_ENABLE	0	rw	<p>Enables enable ep picture data path Programmed value becomes effective (visible in control shadow register) after a soft reset, a forced software update or an automatic config update. Affects MI_IN and MI_OUT module. Reset: 0_B</p>
0	31:24, 19:8, 6:1	r	<p>Reserved Read as 0, should be written with 0.</p>

Memory Interface Control Register For Address Init And Skip Function Register

CIFMIEP_z_INIT (z=1-5)

Memory Interface Extra Path z Control Register For Address Init And Skip Function Register

(z*0100_H+4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
MI_EP_CFG_UPD	4	w	Forced Configuration Update Leads to an immediate update of the shadow registers. Depending on the two init enable bits in the MI_EP_n_CTRL register (init_offset_en and init_base_en) the offset counter, base address and buffer size shadow registers are also updated. Reset: 0 _B

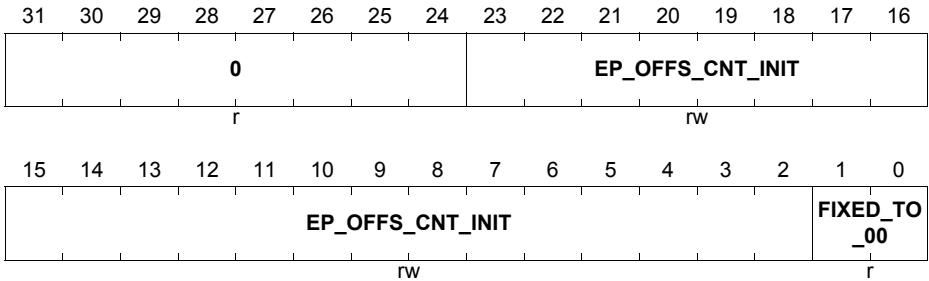

Field	Bits	Type	Description
MI_EP_SKIP	2	w	<p>Skip Picture</p> <p>Skip of current or next starting main picture: Aborts writing of main picture image data of the current frame to RAM (after the current burst transmission has been completed). Further picture data up to the end of the current frame are discarded. No further macroblock line interrupt (mblk_line), no wrap around interrupt for picture (wrap_ep_n) and no fill level interrupt (fill_ep_n) are generated. Skip does not affect the generation of the extra path frame end interrupt (ep_frame_end). The byte counter (register MI_EP_BYTE_CNT) is not affected. It produces the correct number of RAW data bytes at the end of the current (skipped) frame. After a skip has been performed the offset counter for the main picture at the start of the following frame are set depending on the bit init_offset_en in register MI_CTRL:</p> <p>A) Skip restart mode (init_offset_en = 0) The offset counters of the Extra Path are restarted at the old start value of the previous skipped frame.</p> <p>B) Skip init mode (init_offset_en = 1) The offset counters of the Extra Path are initialized with the register contents of the offset counter init registers without any additional forced software update or automatic config update.</p> <p>Reset: 0_B</p>
0	31:5, 3, 1:0	r	<p>Reserved</p> <p>Read as 0, should be written with 0.</p>

Memory Interface Base Address for Extra Path Buffer Register
CIFMIEP_z_BASE_AD_INIT (z=1-5)
Memory Interface Base Address For Extra Path z Data Buffer Register
 (z*0100_H+8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
EP_BASE_AD_INIT	31:2	rw	Extra Path Base Address Init Base address of Extra Path ring buffer. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update. <i>Note: Set control bit <code>init_base_en</code> before updating so that a forced or automatic update can take effect.</i> Reset: 0 _D
FIXED_TO_00	1:0	r	Bits [1:0] are set to "00" (word aligned value). Reset: 00 _B

36.1.4 CIF Module Implementation

This section describes the implementation and integration details of the CIF module.

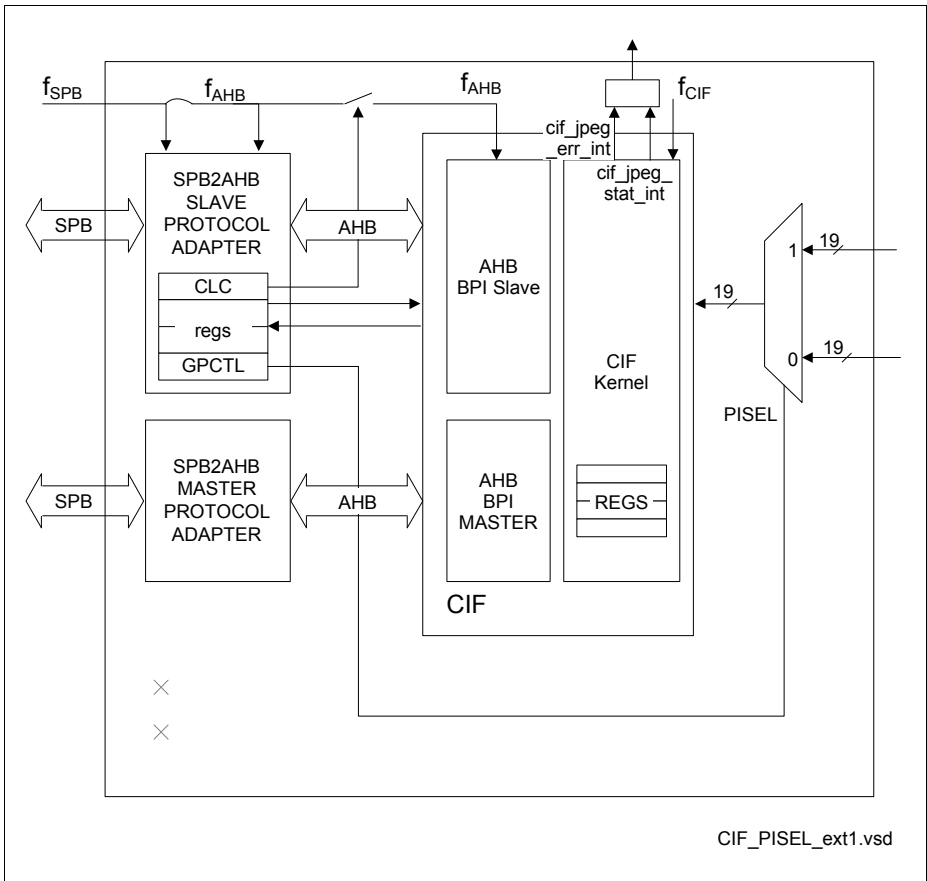

Figure 36-20 Overview of the SPB2AHB adapter

*Note: Normally only one pin mapping of CIF signals to pins is available, selected by **CIFBBB_GPCTL**. PISEL default value of 0. The second selection is tied to low.*

36.1.4.1 BPI_SPB Module Registers

This section describes the registers implemented in the slave (SPB2AHB) adapter component.

In this specification release it is assumed that the BPI_SPB registers will use reserved addresses in the module address space, and not separate address page. This issue is subject of discussion and may change.

System Registers

Figure 36-21 shows all registers associated with the BPI_SPB module, configured for one kernel. The Offset Address in the following BPI_SPB register table and in the BPI_SPB register descriptions are proposals. In a standard 32 bit peripheral the CLC is mapped to offset address 00h, module ID to 08h.

BPI_SPB Registers Overview

Figure 36-21 BPI_SPB Registers

Standard Registers

The adapter will implement the following standard registers as defined in the specification for the SPB BPI:

- MODID, Module ID¹⁾
- CLC, Clock Control
- ACCEN0, Access Enable 0
- ACCEN1, Access Enable 1
- KRST0, Kernel Reset 0
- KRST1, Kernel Reset 1
- KRSTCLR, Kernel Reset Clear
- GPCTL Register

Instantiation of the CLC register is controlled by a VHDL generic. Instantiation of the KRST0, KRST1, and KRSTCLR registers is controlled by a second VHDL generic. The MODID, ACCEN0 and ACCEN1 registers will always be present.

If a particular register is not instantiated then any associated output ports on the adapter entity will be driven to a constant logic value.

1) It is possible to set the fields of the module ID register without altering the adapter RTL by setting VHDL generics on the adapter instantiation

Kernel Reset

If a kernel reset is requested, the adapter will synchronously assert the internal kernel reset output and error any ongoing accesses on the SPB bus not addressed to the adapter's internal SFRs.

The method of using the kernel reset output from the adapter to initialise the associated AHB module is module specific and outside the scope of this specification.

Any AHB accesses in progress will be synchronously terminated.

GPCTL

There is a single adapter specific SFR implemented in the adaptor.

The SFR contains 32 general purpose read/write control bits without ENDINIT protection. All the bits are connected to output ports on the SPB2AHB entity. The SFR will implement no safety requirements and is not be suitable for controlling hardware related to safety functions. The SFR supports, byte, half word and word transactions only. All other transactions are rejected with an SPB error termination.

Note: In the CIF module, this register is reserved.

Principle of Operation

When the controlling state machine detects an SPB access, it compares the address to the address of the SFR. This address is configurable via VHDL generic when instantiating the adaptor. In the case that the address matches the SFR address, the normal state machine transitions are interrupted and the access is not passed to the AHB bus.

If the access opcode is not SDTB, SDTH or SDTW, then the access is terminated with an SPB error. If the opcode is supported, the SFR data will be returned on the SPB bus if the transaction is a read or the appropriate bits of the register will be updated if the access is a write.

Clock Control Register (CLC)

The Clock Control Register, CLC, acts globally and allows the complete AHB module to be disabled to reduce power consumption when the module is not required. When the module is disabled ($DISS=1_B$), only register accesses to the adapter register address space are permitted. All other accesses to the module address space will be errored.

CIFBBB_CLC

Clock Control Register

(00_H)

Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Module Identification Register (ID)

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the DMA module.

CIFBBB_MODID

Module Identification Register

(04_H)

Reset Value: 00B3 C0XX_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number.

General Purpose Control Register

CIFBBB_GPCTL

General Purpose Control Register (08_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PISEL	0	r	Port Input Select Bit Selects between two pin mappings of the CIF interface. 0 _B pin mapping 0 selected (default) 1 _B pin mapping 1 selected
0	[31:1]	r	reserved Reads 0. Should be written with 0.

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions to registers with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The adapter is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

CIFBBB_ACCEN0

Access Enable Register 0

RES	31:0	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset function is used to synchronously reset the AHB module. To activate the kernel reset, it is necessary to set the RST bits by writing with 1_B in both Kernel Reset Registers. The RST bit will be re-set by the adapter with the end of the adapter kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, write accesses to the module registers will result in an error acknowledge. Adapter registers can still be accessed.

CIFBBB_KRST0
Kernel Reset Register 0

 (14_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (reset to 0 _B) b after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

CIFBBB_KRST1

Kernel Reset Register 1

(18_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set.</p> <p>0_B No kernel reset was requested</p> <p>1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to 0_B) after the kernel reset was executed.</p>
0	[31:1]	r	<p>Reserved</p> <p>Read as 0_B; should be written with 0_B.</p>

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

CIFBBB_KRSTCLR

0	[31:1]	r	Reserved Read as 0 _B ; should be written with 0 _B .

36.1.5 CIF Programming Hints

36.1.5.1 Configuration and Shadow Registers

Most of the configuration registers inside the CIF hold static programming information (e.g. horizontal and vertical synchronization polarities at the sensor interface). But, in some cases it is required to dynamically re-program the active processing data path with new parameters (e.g. for zooming by re-defining the window). All of these new parameters must not be changed during the processing of a frame, but between frames or at the end of a frame.

Re-programming is done by a CPU attached to the Bus slave interface. Because it can not be ensured that the complete re-programming can be done during the vertical blanking period between two frames shadow registers have been introduced. These shadow registers hold the configuration values that are actually used for processing. Their corresponding configuration registers (e.g. ISP_OUT_H_OFFSETS_SHD and ISP_OUT_H_OFFSETS) store the new values until the configuration update is triggered.

For initial programming after reset or for complete re-programming of the CIF (e.g. changing from viewfinder mode to snapshot mode and vice versa) there exists a `cfg_upd` trigger bit in the main control register of each sub-module making use of shadow registers. Writing a 1 into this field copies the configuration register value into the shadow register. Mostly the main control register also has a shadow register. Other control bits set during the same write transfer as the `cfg_upd` bit are also copied to the shadow register.

Another method of shadow register update is used for dynamically re-programming the data path (see [Figure 36-22 “Automatic Data Path Re-Programming” on Page 36-239](#)). In this case the ISP, which is always the first part of the pipeline, triggers the configuration update for the whole pipeline by setting the `gen_cfg_upd` bit in the ISP main control register `ISP_CTRL`. This causes a configuration update pulse to be sent through the pipeline together with the last pixel of a frame. Each sub-module of the active processing pipeline updates its shadow registers after processing the last pixel of a frame and sends the configuration update pulse to the next stage of the pipeline.

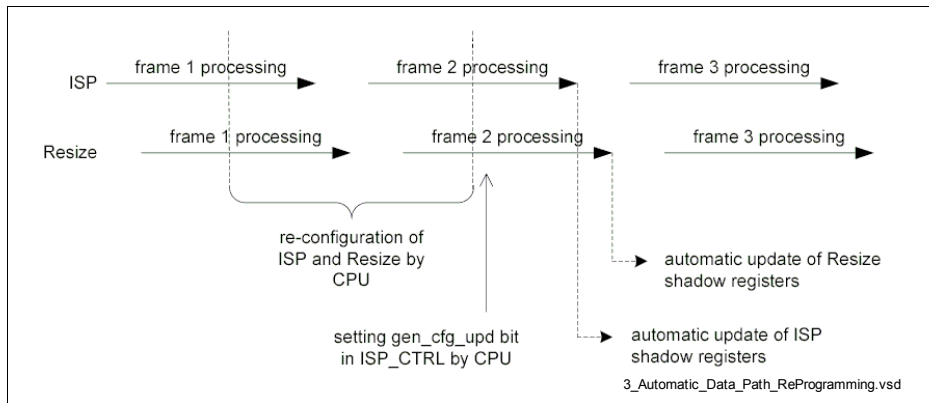

Figure 36-22 Automatic Data Path Re-Programming

Some configuration registers exist that can be changed during processing without use of shadow registers. These are for example adjustment registers in the ISP or the color processing unit which have immediate influence of the processing in terms of pixel calculations. But, no processing errors or unknown formats will result in re-programming of these register. So it is safe to modify them at any time.

36.1.5.2 General Setup for Operation

The basic configuration of the CIF must be done in idle mode. This mode can be entered by either:

- Applying the asynchronous system reset

- Software reset which is combined with the asynchronous system reset
- Applying software resets to all CIF sub-modules (refer to VI_IRCL register)
- Disabling the ISP by setting `isp_en` in `ISP_CTRL` to 0 and waiting for “isp_off” IRQ

In idle mode the following sub-modules must be configured: ISP, memory interface and control unit for image capturing to memory.

The configuration steps, which are performed by register accesses via the Bus slave interface, are the following:

- Set CIF to idle state
- Image acquisition configuration:
 - Set the input acquisition window depending on the attached camera device (`ISP_ACQ_H_OFFS`, `ISP_ACQ_V_OFFS`, `ISP_ACQ_H_SIZE`, `ISP_ACQ_V_SIZE`)
 - Define synchronization signal mode and polarity, data sample edge referring to the sensor clock (`ISP_ACQ_PROP`), and number of frames to be captured (`ISP_NR_FRAMES`)
- Image windowing setup:
 - Define the ISP output window (`ISP_OUT_H_OFFS`, `ISP_OUT_V_OFFS`, `ISP_OUT_H_SIZE`, `ISP_OUT_V_SIZE`)
- Immediate ISP configuration update (`cfg_upd = 1` in `ISP_CTRL`)
- Data path configuration:
 - Depending on the use case the data path must be configured for the desired operation (`VI_DPCL`)
- Main picture memory buffer configuration:
 - Define luminance (Y) buffer base address and size in system memory (`MI_MP_Y_BASE_ADDR`, `MI_MP_Y_SIZE`)
 - Define Y data start offset relative to the Y buffer (`MI_MP_Y_OFFS`)
 - Define chrominance blue (C_B) buffer base address and size in system memory (`MI_MP_CB_BASE_ADDR`, `MI_MP_CB_SIZE`)
 - Define C_B data start offset relative to the C_B buffer (`MI_MP_CB_OFFS`)
 - Define chrominance red (C_R) buffer base address and size in system memory (`MI_MP_CR_BASE_ADDR`, `MI_MP_CR_SIZE`)
 - Define C_R data start offset relative to the C_R buffer (`MI_MP_CR_OFFS`)
- Immediate memory interface configuration update:
 - Define to update base and offset shadow registers (`init_base = 1` and `init_offset = 1` in `MI_INIT`)
 - Update shadow registers for video (in) and Bus part (out) (`cfg_upd_mi_in = 1` and `cfg_upd_mi_out = 1` in `MI_CTRL`)
- Enable/disable interrupts (`ISP_IMSC`, `MI_IMSC`)

Now the basic setup of all necessary registers is done.

For programming a specific use case the data path needs to be configured in the right way (please refer to chapter **“Use Case Description” on Page 36-262**). Additionally not

active sub-modules can be switched off as described in chapter **“Power Management”** on Page 36-265.

36.1.5.3 Start-Stop Programming

Data capturing controlled by the ISP

Data capturing is controlled by the ISP only. All the other sub-modules in the processing pipeline automatically stop processing if no video data is available.

The CIF starts and stops video data capturing in a frame synchronized way. So the time of enabling data capturing is not important as the ISP waits for the beginning of a frame before sampling data. The same applies for stopping video data capturing. Regardless of the current pixel position in the frame or outside the frame the current frame is always captured completely before disabling the ISP.

The ISP contains an input acquisition and an output formatting unit. Both units are able to start and stop video processing frame synchronously. For video capturing both units must be enabled, but for disabling capturing at least one of them must be switched off.

Note: It is highly recommended to use the output formatter of the ISP for controlling video processing, because this unit is able to generate an “isp off” interrupt based on the ISP output frame after windowing.

Additionally it is possible to specify the number of frames to be captured by writing this number into ISP_NR_FRAMES. Continuous capturing is enabled by writing a 0 into this register.

So to enable the ISP input_en in ISP_CTRL must be set to 1 first. At this point the ISP starts capturing data but does not provide them at its output interface. The output interface is part of the output formatter which also does the output windowing. It is enabled setting isp_en in ISP_CTRL to 1.

To stop video capturing it is sufficient to disable the ISP output formatter by setting isp_en in ISP_CTRL to 0, or if a certain number of frames to be captured have been specified, the ISP automatically disables its output formatter. Then the “isp off” interrupt is generated after putting out the last pixel of the last frame.

Note: After stopping data capturing at the ISP the processing pipeline is still working for a while because of the pipeline delay of some pixel lines. This delay depends on the mode of operation. The maximum delay is about 11 lines.

The pipeline is clean after either applying the software reset to the involved sub-modules (resulting in loss of data in memory), or it must be waited until the complete frame has been written into system memory. The latter is done by waiting for the “frame end” interrupt of the output unit.

36.1.5.4 Abort of Processing

Complete abort of processing can be either done by applying the asynchronous system reset to the CIF, the software reset for the entire CIF or by applying the software resets to all involved sub-modules which is the preferred method.

Frame Skip

For the main picture data path another way of discarding pixel data exist: frame skipping. This can be used if e.g. the video encoding device can not keep up with the frame rate provided by the CIF. In this case the system controller has to set the skip bit in the MI_INIT register of the memory interface.

For frame skipping the memory interface discards all remaining pixels of the current frame at its main picture input ports. It only completes the current burst transfer and flushes all main picture internal data FIFOs. Resetting of the related offset data pointers for the buffers depends on the value of `init_offset` in `MI_CTRL`. If `init_offset` is set to 1 the buffer offset counters are reset to the programmed values in `MI_MP_Y/CB/CR_OFFS`. If `init_offset` is set to 0 the offset counters for all buffers are set to the beginning of the current (skipped) frame.

Frame skipping does not affect "frame end" interrupt generation.

Handling Picture Size Error

Aborting the ISP processing becomes necessary, if an input picture size violation is detected by the hardware. In this case the interrupt `PIC_SIZE_ERR` is raised, and the ISP does not generate a frame end interrupt, even if the picture size is corrected. To recover from this condition, a software reset of the ISP is necessary. After a reset the picture size needs to be programmed to the appropriate values and processing can be started again.

To find the reason behind the picture size error the register `ISP_ERR` might be helpful. This register provides the information about where exactly the size error occurred.

36.1.5.5 Interrupt Handling

The CIF provides two programmable level active interrupt outputs driven by the ISP and memory interface sub-modules. Interrupt control and status registers are located locally in their originating sub-modules. All sub-module masked interrupts are ORed together to drive the interrupt line.

Five interrupt registers are provided for each interrupt line per block able to generate interrupts:

- Interrupt mask register (IMSC)
- Raw interrupt status register (RIS)
- Masked interrupt status register (MIS)

- Interrupt clear register (ICR)
- Interrupt set register (ISR)

The IMSC register defines if the events actually generate an interrupt. If a mask bit is set, the corresponding event is allowed to generate an interrupt. Per default all mask bits are set to 0 to prevent interrupt generation.

The RIS register shows the status of all sub-module internal events without effect of the mask register IMSC.

The MIS register shows the status of the events allowed to trigger an interrupt (MIS = RIS AND IMSC). If an interrupt has been thrown the MIS register must be read for locating the accountable event.

The ICR register is used for clearing interrupts by resetting the event. Writing a 1 into a interrupt bit resets the respective event. Reading of this register always returns "00_H".

The ISR register is used to trigger events for debug and test purposes. Writing a 1 into an interrupt bit activates the associated event and an interrupt will be thrown if the mask register is set accordingly. Reading this register always returns "00_H".

ISP Events

The ISP generates events at several positions during input and output data formatting. **Figure 36-23** shows the trigger points for the following events:

- ISP returns to idle state (isp_off)
- Output frame end reached (out_frame_end)
- Input frame end reached (in_frame_end)

Figure 36-23 Frame Based ISP Events

Additionally the following error events may be generated:

- Input picture size violation detected (`pic_err`)
- Loss of data detected during an active (`data_loss`)

These two events are immediately triggered as they occur. For more information on ISP events please refer to chapter **“ISP Programming” on Page 36-246**.

Memory Interface (MI) Events

The MI provides events from several internal sources (see **Figure 36-24 “Memory Interface Events” on Page 36-245**) supporting video encoding as well as signalling error and transfer end conditions:

- Bus write error detected (`write_err`)
- Main picture buffer wrap-around occurred for Y, C_b , C_r buffers (`wrp_m_y`, `wrp_m_cb`, `wrp_m_cr`)
- Programmed fill level reached in main Y buffer (`fill_m_y`)
- Next macro-block line stored (`mblk_line`)
- Last pixel of image or RAW data stream is written into memory (`frame_end`)

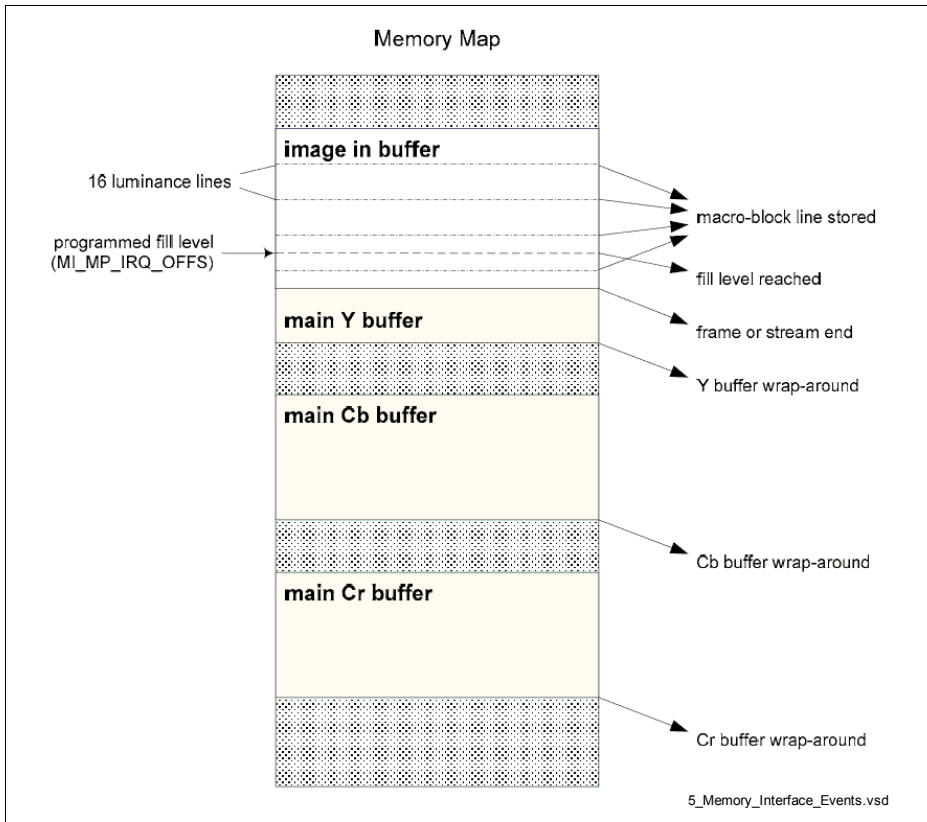

Figure 36-24 Memory Interface Events

The “macro block line” and “frame end” events not only depend on the Y buffer, but also on C_b and C_r buffers because all pixel components have to be written to memory before triggering the appropriate event. For “frame end” this synchronization works for all supported YC_bC_r formats (4:2:2, 4:2:0). The “macro-block line” event relies on 16 luminance and 8 chrominance lines, which are in YC_bC_r 4:2:0 format.

For better debugging in MI an additional status register is implemented. The MI shows status information of the FIFOs in the MI_STATUS register and if a read or write Bus error occurred. This registers can be cleared with the according MI_STATUS_CLR register. Usage of this register should be as follows: If an error interrupt was triggered from the sensor FIFO of the ISP (DATA_LOSS interrupt), then the MI_STATUS register should be checked to find out the reason for the error. One reason could be the latency of the Bus bus, which results in FIFO full bits set in the MI_STATUS register.

36.1.5.6 Reset Handling

Three types of resets are supported by the CIF:

- Asynchronous system reset
- Software reset for the entire CIF
- Independent software resets for each sub-module

The asynchronous reset is a low active system reset for resetting all flip-flops inside the CIF. After an asynchronous reset no processing, status, or configuration information is kept.

The same behaviour as for “asynchronous system reset” is true for the software reset bit of the entire CIF. All status and configuration register information is reset. After applying this reset the software must wait at least 10 module clock cycles before the CIF can be reprogrammed.

The independent software resets for each sub-module are meant for just resetting processing and status information, but not configuration register content. So, the software reset is first choice if a processing error occurs and the system should be re-initialized without need to fully re-program the device. It is triggered by single bits for all CIF sub-modules in VI_IRCL.

36.1.5.7 Programming Guide

This chapter gives a detailed overview about programming of the particular CIF sub-modules.

ISP Programming

The ISP sub-module contains input acquisition, output formatting, as well as status and error interrupt generation.

An overview of the internal processing blocks of the ISP is given in the figure **“Block Diagram of the ISP Sub Module” on Page 36-11** .

Error Handling

If an input picture size violation was detected and reported (interrupt) by the ISP, then the ISP needs to be reseted (soft-reset) in order to do the processing of the following frames. Without reset the frame end interrupt will not work correctly for the following frames, even if the picture size is correct then.

Input Acquisition

The input formatter is responsible for sampling data from the sensor device and providing it to the other blocks in the processing pipelines.

As the clock provided by the image sensor is used for data sampling, the sample edge can be selected depending on the phase shift between data and pixel clock. If `sample_edge` in `ISP_ACQ_PROP` is set to 1 the rising edge of the pixel clock is used,

otherwise the falling edge. The sample edge selection depends on the phase relationship between pixel clock and image data.

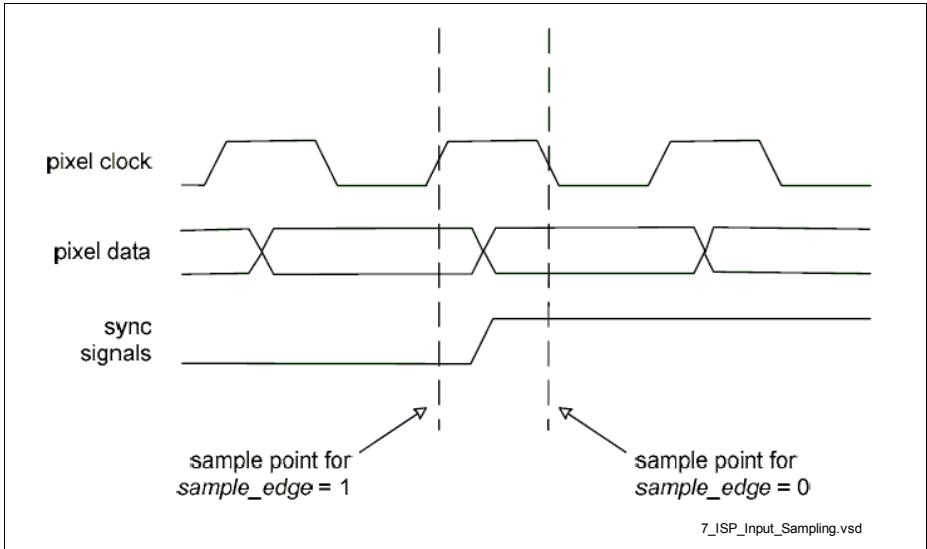

Figure 36-25 ISP Input Sampling

The input acquisition has to be adapted to the specifics of the attached sensor device in terms of image resolution, color space format, black pixel regions, etc.

In addition please make sure that the sensor device delivers at least 2 lines of vertical blanking and at least 5 pixels horizontal blanking in its video timing. This is needed for the CIF ISP to function properly.

The input acquisition window has to be defined using the registers

ISP_ACQ_H_OFFS,
 ISP_ACQ_V_OFFS,
 ISP_ACQ_H_SIZE,
 ISP_ACQ_V_SIZE.

In addition the sample window can be further cropped for the following processing chains by the registers

ISP_OUT_H_OFFS,
 ISP_OUT_V_OFFS,
 ISP_OUT_H_SIZE,
 ISP_OUT_V_SIZE.

This is necessary, because processing blocks must not be fed with images containing black pixel areas. These areas have to be cut off before the image data is transferred to the CIF's ISP.

Furthermore the polarity of the horizontal and vertical synchronization signals in ITU-R BT.601 mode have to be defined using `hsync_pol` and `vsync_pol` in `ISP_ACQ_PROP`.

Limited support for capturing of interlaced video is available. So either odd or even, or both fields can be sampled (`field_sel` in `ISP_ACQ_PROP`).

In the `ISP_CTRL` programming register the operating mode for the ISP must be selected with `isp_mode` (also refer to the following chapters).

Input formatter enabling and disabling is described in chapter [“Start-Stop Programming” on Page 36-241](#).

Output Formatting and Image Stabilization

At the output of the ISP sub module the image data may be cropped a third time by using the registers

`ISP_IS_H_OFFS`,

`ISP_IS_V_OFFS`,

`ISP_IS_H_SIZE`,

`ISP_IS_V_SIZE`.

These registers should be used, if digital zoom features shall be implemented in the system software.

Figure 36-26 illustrates the different possible regions which can be defined by the corresponding register settings. Some of these regions may have the same size and offset (settings), if a differentiation is not needed.

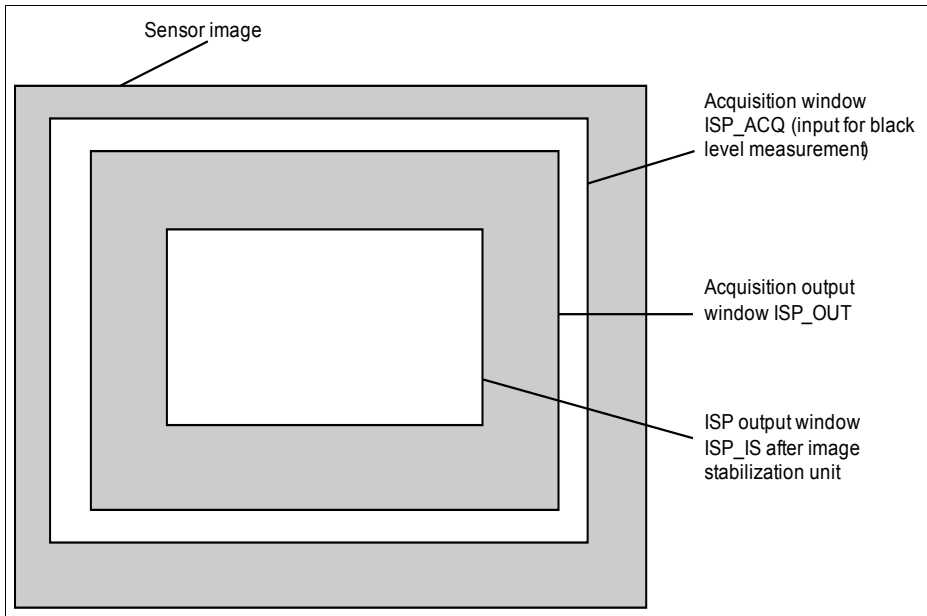

Figure 36-26 Possible cropping regions of ISP

In addition the output cropping module is designed to support image stabilization features for video capturing.

For image stabilization a sub frame must be chosen from the input frame, because a certain border around the output image is needed to have some margin for correcting the position of the image. Based on externally generated camera global motion data, image stabilization offers the functionality to compensate for that camera motion by moving the chosen sub frame across the input frame according to the signalled camera motion. The information source for global motion may be a motion sensor or extracted from the image content by a video encoder. The global motion vector has to be written into the configuration register `ISP_IS_DISPLACE` by software for each frame. To prevent the sub frame from running out of the input frame, the sub frame is re-centered at a programmable rate that is proportional to its distance from the center of the input frame. The rate is programmed by setting the register `ISP_IS_RECENTER` with appropriate values.

In addition, the maximum allowed displacement of the sub window is programmable by using `ISP_IS_MAX_DX` and `ISP_IS_MAX_DY` registers. The output picture size is using shadow registers. If the programmed size can't be reached due to incorrect register programming or wrong input formats, a picture size error interrupt is triggered.

In standard mode (image stabilization switched off: `is_en=0` in `ISP_IS_CTRL`), the registers `ISP_IS_H_OFFS`, `ISP_IS_V_OFFS`, `ISP_IS_H_SIZE`, and `ISP_IS_V_SIZE` are used to cut a programmable sub frame out of the input frame as described above.

If image stabilization is switched on, the horizontal and vertical offset of the chosen sub frame is automatically updated. This automatic update according to camera displacements `dx` and `dy` programmed to the `ISP_IS_DISPLACE` register is implemented as described below.

Instead of using the values programmed to the configuration registers `ISP_IS_H_OFFS` and `ISP_IS_V_OFFS`, (which are now used to configure the initial position of the chosen sub frame) two new internal registers `cur_h_offs` and `cur_v_offs` are used to dynamically choose the sub frame sent to the output interface. These are updated with each frame in the following way:

if `IS_RECENTER != 0`

$$\text{cur_h_offs} = (\text{cur_h_offs} - \text{dx}) - ((\text{cur_h_offs} - \text{IS_H_OFFS}) / 2^{\text{IS_RECENTER}})$$

else

$$\text{cur_h_offs} = (\text{cur_h_offs} - \text{dx})$$

`cur_h_offs` is clipped to the range

`[IS_H_OFFS - IS_MAX_DX ... IS_H_OFFS + IS_MAX_DX]`.

The system software has to ensure that `IS_H_OFFS` is greater or equal `IS_MAX_DX` and that `IS_H_SIZE + IS_H_OFFS + IS_MAX_DX` does not exceed the horizontal size of the input frame. Recommended value for `IS_MAX_DX` is equal to `IS_H_OFFS`.

if `IS_RECENTER != 0`

$$\text{cur_v_offs} = (\text{cur_v_offs} - \text{dy}) - ((\text{cur_v_offs} - \text{IS_V_OFFS}) / 2^{\text{IS_RECENTER}})$$

else

$$\text{cur_v_offs} = (\text{cur_v_offs} - \text{dy})$$

`cur_v_offs` is clipped to the range

`[IS_V_OFFS - IS_MAX_DY ... IS_V_OFFS + IS_MAX_DY]`.

The system software has to ensure that `IS_V_OFFS` is greater or equal `IS_MAX_DY` and that `IS_V_SIZE + IS_V_OFFS + IS_MAX_DY` does not exceed the vertical size of the input frame. Recommended value for `IS_MAX_DY` is equal to `IS_V_OFFS`.

The system software has to ensure that the dx and dy values in ISP_IS_DISPLACE register are always up to date. Especially when no movement was detected the values have to be set to zero.

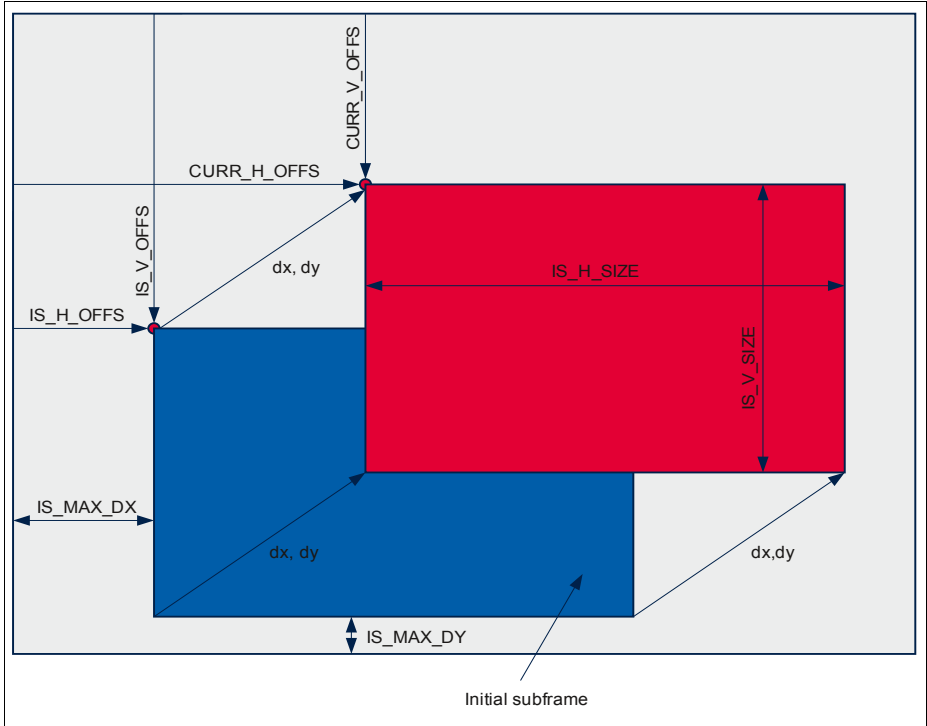

Figure 36-27 Illustration of image stabilization parameters

Data Mode

In data mode all input data are considered as bytes. No line or frame organization is expected any more, so the states of the hsync and vsync hardware lines are considered as "byte enable" and "transfer indicator". This mode allows connecting the CIF to any source delivering a data stream (e.g. camera sensor including a JPEG encoder). This mode is selected by programming a "4" into the `isp_mode` field of `ISP_CTRL`. In this mode no limitation for the amount of data exists. The data will be stored in system memory in the region "main Y buffer".

As the synchronization signal polarities are programmable, the same applies to byte enable and transfer indicator as well. Also the sample edge can be selected by programming the register `ISP_ACQ_PROP` accordingly.

To start a transfer sequence, the transfer indicator (vsync) and byte enable (hsync) may be asserted (driven to an active level, usually low) at the same time or one after another in the following order: first assert vsync, then assert hsync. The transfer end condition is detected by the CIF when these signals are de-asserted as shown in [Figure 36-28](#). Detecting the transfer end condition will lead to a main-path frame-end interrupt as soon as the last byte of this transfer is written to the system memory. During a transfer sequence, sampling of the input data can be paused by de-asserting the hsync for the desired amount of clock cycles.

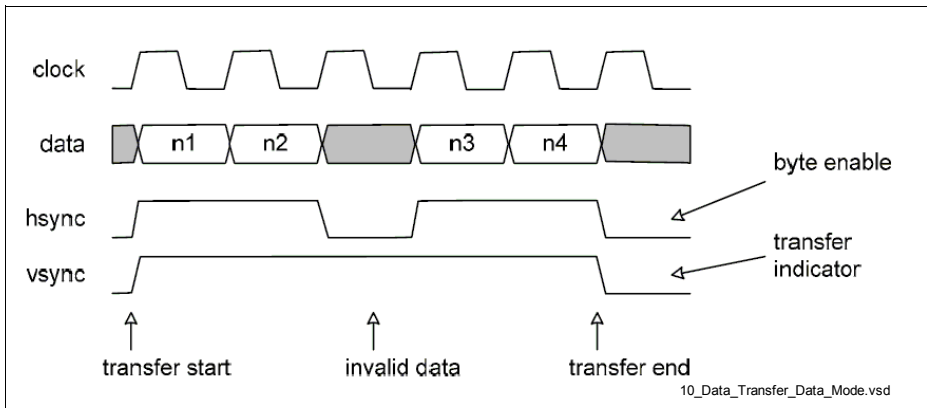

Figure 36-28 Data Transfer in Data Mode with Active High Level

Note that because there are no line and frame structures in the data mode any more, there is also no frame synchronized start mechanism as described above. Thus, the time of enabling the ISP is important here, because if the transfer indicator line

Is asserted at the moment of enabling the ISP, data capturing would start right away. If the entire amount of bytes of a transfer sequence is to be captured, the ISP must be enabled while the transfer indicator is de-asserted.

In situations with periodically repeated transfer sequences, the suggested strategy of capturing one entire sequence is as follows:

- Setup the complete processing chain including input acquisition, data path and output buffer size and address.
- Setup the memory interface to skip the next incoming frame (i.e. suppress the actual writing in system memory)
- Start the ISP for one frame only and wait for the frame-end interrupt. Because starting the ISP was done unsynchronized with the transfer sequence repetition, the CIF usually won't sample the entire number of bytes of this sequence. But this is not important, because we have suppressed writing to memory anyway, and are only interested in the frame-end-notification interrupt.

- As soon as the frame-end interrupt occurs, we know for sure that the last transfer sequence has just been completed. Now re-program the output buffer address, start the ISP for another single frame, and wait again for the frame-end notification.
- Upon occurrence of the frame-end interrupt, the entire number of data bytes from the last transfer sequence can be found in the output buffer.

In data mode, the values of the registers `ISP_ACQ_V_OFF`, `ISP_ACQ_H_OFF`, `ISP_ACQ_H_SIZE` and `ISP_ACQ_V_SIZE` are irrelevant.

RAW Picture Mode

RAW picture mode allows sampling of the input image according to the setting of the BT.601 sync signals and providing it directly at the output of the ISP. No data processing is done at all allowing to store the 8 up to 16-bit data samples from the sensor device directly in system memory. No luminance/chrominance separation and re-ordering are done. After writing a 0 into the `isp_mode` field of `ISP_CTRL` the ISP is set to RAW picture mode.

The maximum size of data is limited by the offset and size counters. This means a maximum of 4095x4095 bytes are possible. The image data will be stored in the main Y buffer. In case of more than 8 bits data, the data bits are stored in 16-bit words in memory. The bits are stored MSB aligned.

ITU-R BT 601/656 YCbCr4:2:2 Mode

This ITU-R BT 601/656 mode allows the connection of an image sensor with integrated ISP functionality. In this case $YCbCr$ data is expected at the sensor interface. In ITU-R BT 656 mode the synchronization signals are not considered as all timing reference data are encoded into the data stream (SAV and EAV codes). For ITU-R BT 601 mode the vertical and horizontal synchronization signals are sampled together with the image data. The synchronization signals can be interpreted as synchronization pulses, or as reference signals to be seen in the following figure.

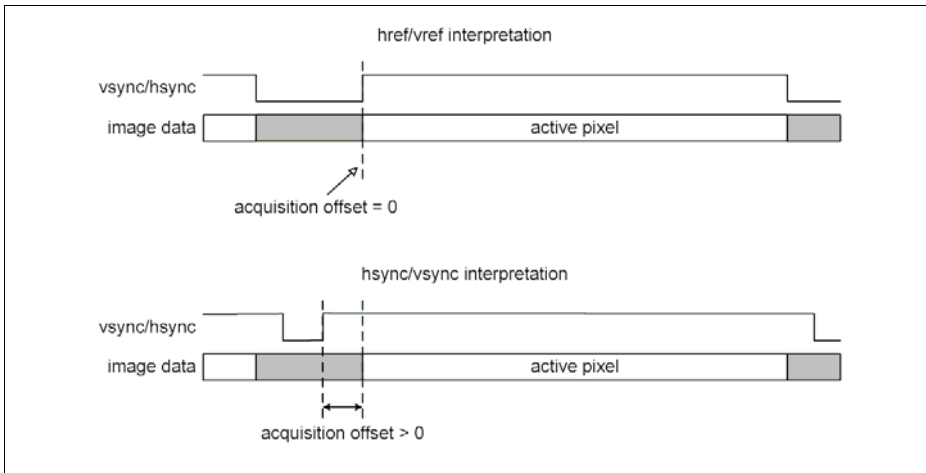

Figure 36-29 Reference and Synchronization Signals for ITU-R BT 601 Mode

Memory Interface Programming

The CIF memory interface unit (MI) is responsible for reading/writing image data from/to the system memory. As shown in Figure [“Memory Interface Unit overview” on Page 36-255](#), the MI has three main tasks, which can operate independently:

- Take image data from the main path, either in YCbCr or RAW format and write it into certain data buffers located in the system memory.

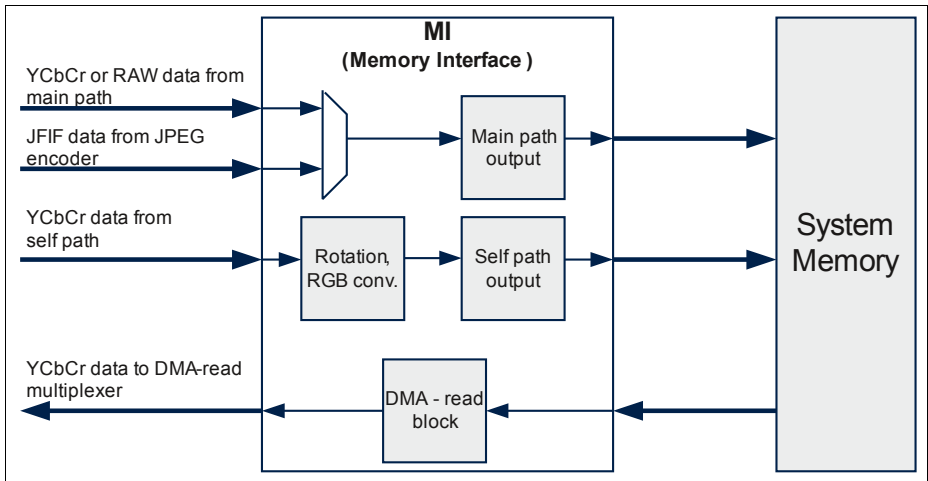

Figure 36-30 Memory Interface Unit overview

External Output Buffers

Depending on which paths are enabled and which output format is selected, the MI unit can simultaneously output image data to up to 6 independent buffers. The buffers are named according to their relation to the main data path and their usage in the (most common) YCbCr planar output format: main-Y-buffer, main-Cb-buffer, main-Cr-buffer.

The buffers itself are not part of the CIF IP; they are system memory areas accessible from the bus that is also connected to the CIF. One can think of the MI as a kind of DMA controller, which writes to the configured memory locations without any CPU assistance. To configure the memory locations, each of the buffers mentioned earlier has a set of registers assigned to it.

- MI_xx_xx_BASE_AD_INIT
 - This is the base address of the memory area to use for that buffer. (e.g. the lowest address of that buffer) Note that buffer base addresses must be 4-byte-aligned. In case the target system uses some kind of PMMU, the physical address must be specified, because virtual-to-physical translation is not possible for this kind of DMA-like transfer.
- MI_xx_xx_SIZE_INIT
 - This is the size of the memory area in bytes. Note that the size is also required to be a multiple of 4. It is ensured that for write operations in this particular buffer, the MI will only write to memory locations from the base address to the base address + the size - 1. If the MI reaches the end of the memory area while continuously writing data, the buffer "wraps around" and it proceeds to write starting from the

base address again. This wrap around event can also be used to trigger an interrupt. See the MI_RIS register for details.

- MI_xx_xx_OFFS_CNT_INIT
 - This is the initial offset (in bytes) for writing to the buffer after e.g. a soft reset. Usually, to write to the buffer from the very beginning, an offset of zero is to be programmed into this register.
- MI_xx_xx_OFFS_CNT_START
 - This is a read-only register, which holds the offset at which the MI had written the last processed frame. This register is updated at frame end, so at any given time, it contains always the starting offset of the last completely processed frame.

One of the buffers, the main-Y-buffer, is additionally able to trigger an interrupt as soon as a particular filling level is reached. This level can be configured in terms of an offset count (in bytes) from the base address using the MI_MP_Y_IRQ_OFFS_INIT register.

Further, the MI supports updating the buffer configuration seamlessly between two consecutive frames without dropping a frame by using the shadow register concept described in chapter **“Configuration and Shadow Registers” on Page 36-238**. Two bits in the MI_CTRL register (init_offset_en and init_base_en) can be used to select whether the base address and size, or the offset counters, or both are being updated at the next configuration update pulse. It should be noted that it is only possible to update the selected parts of all the buffers at once. It is not possible to re-configure only specific buffers and leave the others left untouched.

As mentioned earlier, there are some restrictions permitting only 4-byte-alignment buffer base addresses, and both sizes and offsets also need to be a multiple of 4. This is because the MI writes the data to the memory areas in 4-byte-accesses. It is possible to change the endianness of these accesses with the byte_swap bit in the MI_CTRL register. **Figure 36-31** illustrates this with the example use case of writing 8-bit Y-samples from a frame with a width of 5 pixels. The setting of the byte_swap bit affects the write accesses to all buffers regardless of whether YCbCr or RAW data is to be written. Note that "addr" is a 4-byte aligned address in this example. For all other output schemes illustrated and discussed in this chapter, a setting of byte_swap = 0 is assumed.

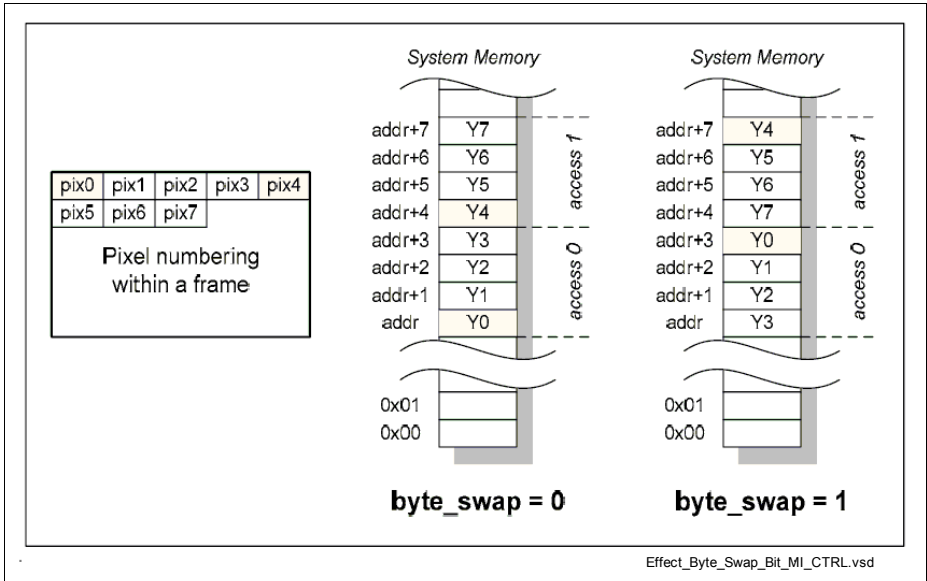

Figure 36-31 Effect of the byte_swap bit in MI_CTRL

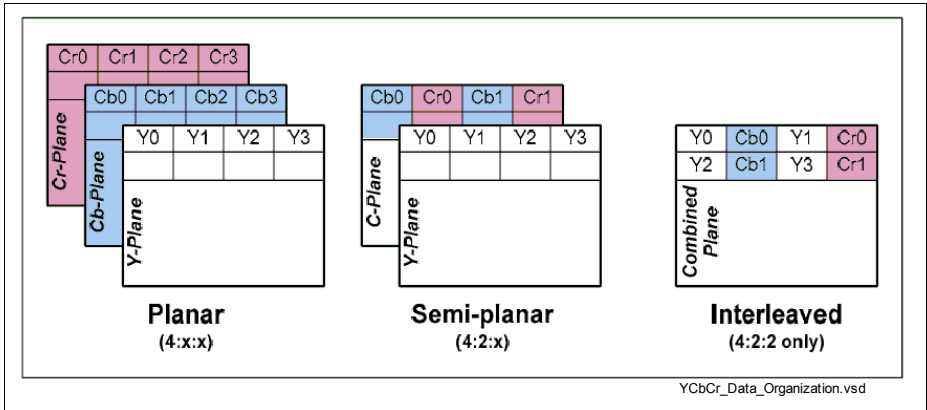

Figure 36-32 YCbCr Data organization

Main Path output programming

The main path output sub-module of the MI is intended to be used for video stream generation (YCbCr for further compressing via software encoders), or high resolution still

image snapshot . To achieve this, it can be configured to output one out of the following data sources:

- YCbCr data from the main path scaler
 - To enable this, bit `mp_enable` in the `MI_CTRL` register is to be set. The data can be output in planar, semi-planar or interleaved format, as shown in [Figure 36-32](#). The selection is done with the bits `mp_write_format` in the `MI_CTRL` register. In semi-planar mode, the main-Cb-buffer is used for the multiplexed Cb/Cr values and the main-Cr-buffer remains unused. In interleaved mode, only the main-Y-buffer is used for all the multiplexed values.
- RAW data from the main path scaler.
 - This mode is enabled by setting the bit `raw_enable` in the `MI_CTRL` register. RAW data is assumed to be received via the same way as YCbCr data, but is written to the main-Y-buffer only. in RAW mode, the `mp_write_format` bits of the `MI_CTRL` register are used to select between 8-bit mode (which will write only the 8 most significant bits of every sample) up to 16-bit mode (which will e.g. write the full 16-bit msb-aligned into 2 bytes of the output buffer). This implies that for the higher than 8-bit modes, a buffer size twice as much is necessary as for the 8-bit mode, and the least significant bits of every 16-bit value are unused and remain zero.

In some RAW data modes the actual number of bytes to write per frame depends on the input signal and/or the compression ratio, and is not known in advance. Thus, this number is given in the read-only `MI_BYTE_CNT` register, which is updated at frame end only. So this register always shows the number of bytes written to the main-Y-buffer for last completely processed frame.

It is assumed that all the sub-modules within the CIF's processing chain located in front of the MI are configured in a way that the input data to the MI main path corresponds to what it is configured for. If this is not the case, the behavior of the MI is not predictable.

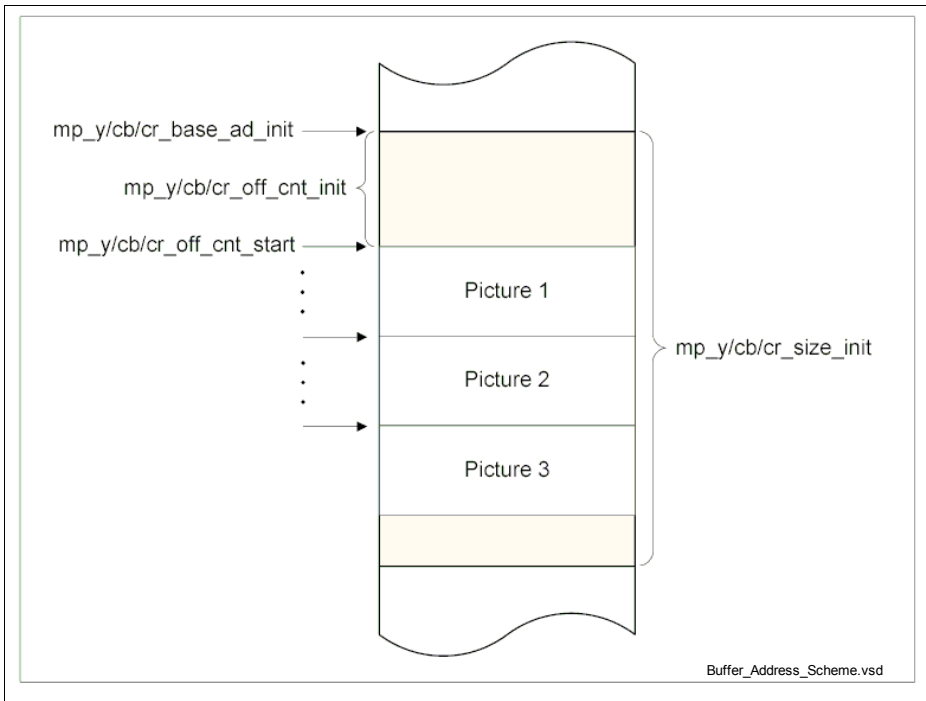

Figure 36-33 Buffer address scheme, valid for main picture buffers

Getting Started - First steps for startup

This chapter describes the first steps to startup the CIF in YCbCr mode. The procedure and the register contents are presented. Generally, all sub modules (like MI, EP, LDS) within CIF can be configured in arbitrary order but the ISP sub module must be enabled last.

General Hints

Activity of the input port (data and sync lines) can be observed through register ISP_FLAGS_SHD.

Recipe 1: YCbCr Bypass Mode

In YCbCr Bypass mode the image sensor is expected to deliver pre-processed image data in YCbCr format at its parallel output port. Because of the pre-processing, most of the CIF's ISP functionality can be bypassed, so only a small number of registers must be programmed to put this mode into operation. The Main Scaler unit will also be bypassed, so that the incoming data will be presented almost unmodified at the output. All that's left to do in the processing chain is YC-sequence reordering.

Requirements / Preconditions

In this example, we assume a sensor delivering VGA-sized (640x480) frames continuously using YCbCr data format with 4:2:2 color sub sampling. Synchronization is assumed to be done according to ITU.BT601 (i.e. using separate wires carrying hsync and vsync signals, both active high in this example).

It is further assumed that the sensor is already up and running and that it is configured to the mode described above. Its pixel clock is running and meets the CIF's AC-requirements, and the sync signals and image sensor data bus are routed to the CIF's input ports.

Basic Initialization

1. Enable the main clock in VI_CCL VI_CCL = 0000 0000_H
2. Enable all clocks of all sub-modules VI_ICCL = FFFF FFFF_H
3. Trigger the asynchronous system reset of the CIF
Typically the asynchronous reset line is connected to a central module of your SOC, handling resets for all components. Usually there is one bit reserved for this purpose. There may be some delay required in the software before the following access to the CIF (time until the central module clears reset, time until the reset signal is synchronized to the sensor clock domain of the CIF).

ISP input acquisition

1. Switch to ITU.BT601 compatible mode (ISP still disabled yet) ISP_CTRL = 0000 0004_H
2. Set the input acquisition properties according to what is delivered by the sensor: sampling at falling edge of pixel clock; h- and v-sync high active; sample sequence Y-Cb-Y-Cr; don't care about odd or even fields; 8-bit data interface.
ISP_ACQ_PROP = 0000 0300_H
3. Set the input acquisition window according to what is delivered by the sensor.(here, we assume no delay between the sync signals and the active pixel data, that's why the offset values can remain zero. Horizontal size is twice the image width, because for every 2 incoming pixels, there are also 2 chrominance values):
ISP_ACQ_H_SIZE = 0000 0500_H(2*640 = 1280)
ISP_ACQ_H_OFS = 0
ISP_ACQ_V_SIZE = 0000 01E0_H(480)
ISP_ACQ_V_OFS = 0

ISP output formatter

1. We want to output the complete incoming frame from the sensor (no cropping) so the whole sensor resolution need to be programmed in the output window
ISP_OUT_H_SIZE = 0000 0280_H(640)
ISP_OUT_V_SIZE = 0000 01E0_H(480)
ISP_OUT_H_OFFS = 0 ISP_OUT_V_OFFS = 0

Data Path

1. Select parallel interface and main data path, enable output of main data path
 $VI_DPCL = 0000\ 0001_H$ $MI_CTRL = 0000\ 0001_H$

Memory Interface

1. Set Y, Cb and Cr buffer position and size (32bit aligned). Update shadow registers with next configuration update:

```

MI_MP_Y_BASE_AD_INIT = <Y base address>
MI_MP_Y_SIZE_INIT = <sizeY>
MI_MP_CB_BASE_AD_INIT = <Cb base address>
MI_MP_CB_SIZE_INIT = <sizeC>
MI_MP_CR_BASE_AD_INIT = <Cr base address>
MI_MP_CR_SIZE_INIT = <sizeC>

```

Set to main picture data mode (do not swap bytes, do not mirror) and update shadow register immediately. (This also transfers the base address and the size to their respective shadow registers).

```

MI_CTRL = 0030\ 0001_H      MI_INIT = 0000\ 0010_H

```

Interrupt Processing

1. Setup interrupt service routines, clear and enable interrupts if needed, e.g. frame end interrupt of memory interface:

```

MI_ICR = 0000\ 0001_H  MI_IMSC = 0000\ 0001_H

```

Start the CIF

1. Enable input acquisition and output formatter (to start the output formatter there is no configuration update necessary). As soon as the CIF is started the lower two bits of ISP_FLAGS_SHD are set.

$ISP_CTRL = ISP_CTRL | 00000011_H$ With the initialization sequence above, the CIF is set to sample all incoming frames and presents them at the output. If this is not the desired use case and e.g. a single frame is to be captured instead, this can be configured using the input acquisition register $ISP_ACQ_NR_FRAM$. If this register is nonzero, only the given number of frames is being captured after the CIF has been started.

36.1.5.8 Use Case Description

The CIF is designed to support for example the following mobile phone use cases:

- Data transfer from external devices into system memory
- Viewfinder mode for still image capture
- Still image capture
- Video encoding

The above mentioned use cases are described in detail in the following chapters. Furthermore information about power management and configuration accesses are also given in this section.

Data Transfer

This use case transfers byte data, like JPEG compressed data from a camera sensor with integrated JPEG encoder, into system memory (main Y buffer). Further processing must not be done as these data are no plain image or video data. The **Figure 36-34** shows the blocks active during data transfer. The inactive blocks are bypassed or disabled.

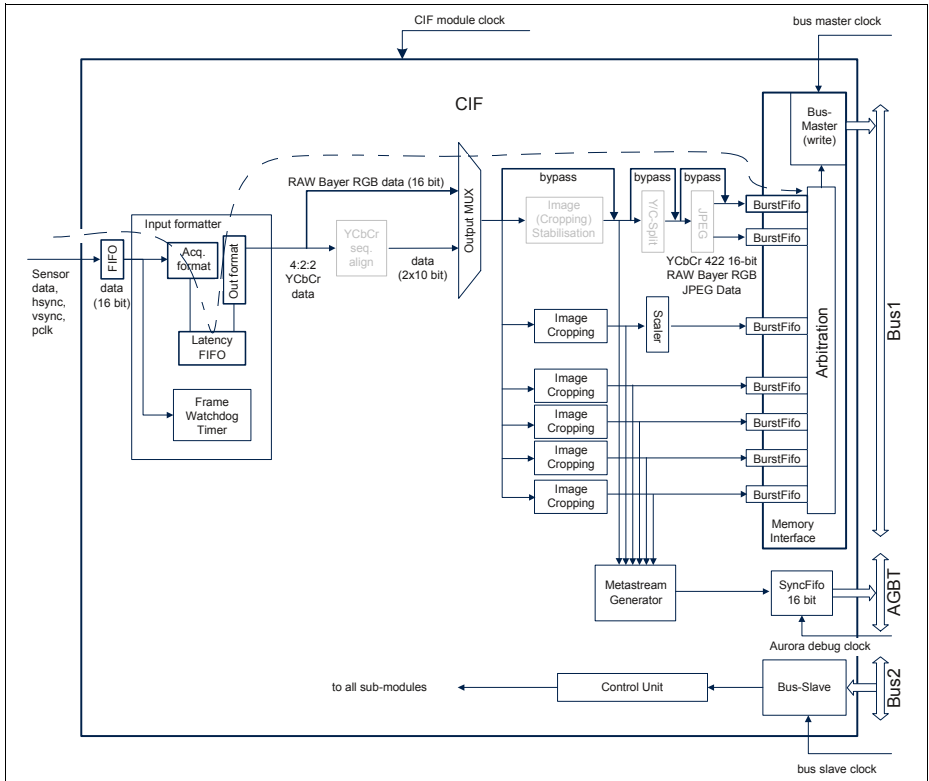

Figure 36-34 Active Blocks for Use Case Data Transfer

A transfer indicator and a byte valid signal (refer to **Figure 36-28**) are used to identify transfer start and stop as well as to identify valid data bytes. The ISP has to be set to data mode (mode field in ISP_CTRL), all other functions (e.g. offset and size registers) are not used. The data path must be switched to 8 bit data/RAW data mode (VI_DPCL).

At the memory interface the Y buffer must be defined (MI_MP_Y_BASE_ADR, MI_MP_Y_SIZE) and the RAW data port must be enabled (raw_data_en in MI_CTRL).

After transfer being indicated by the “frame end” interrupt of the memory interface the number of transferred bytes can be read from MI_BYTE_CNT.

Viewfinder Mode

This use case is to be used for displaying a video stream at an attached LCD. The CIF is responsible for capturing the video data at the sensor interface and transferring a continuous image data stream to the system memory.

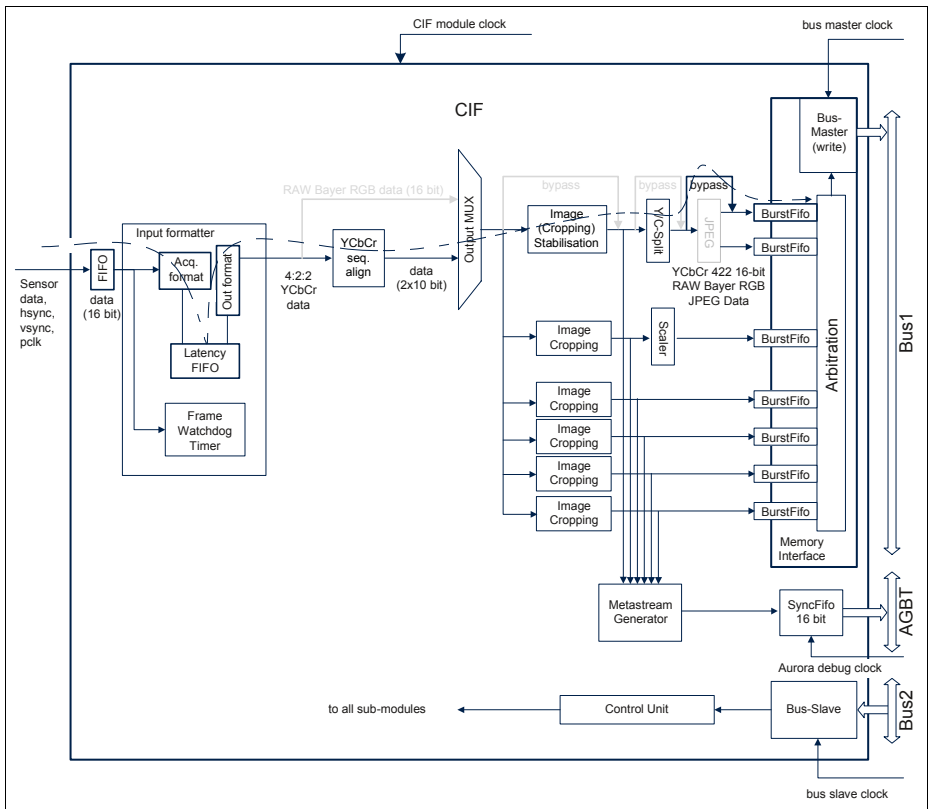

Figure 36-35 Active Blocks for Use Case Viewfinder

Image data are captured at the ISP. The mode depends on the camera sensor being used and can be YCbCr 4:2:2 with embedded timing control signals or external synchronization signals (selected by the `isp_mode` field in `ISP_CTRL`).

Still Image Capture

This use case is meant for capturing a still image.

The use case viewfinder always precedes the capturing use case.

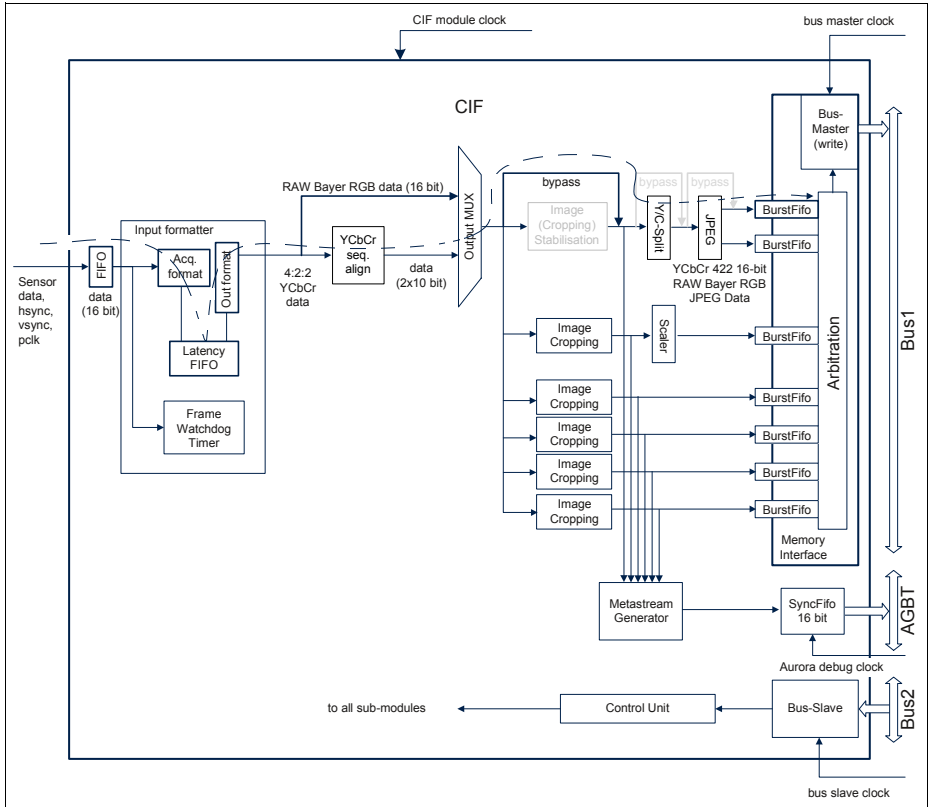

Figure 36-36 Active Blocks for Use Case Still Image Capture

In this use case the ISP samples the image and color processing can be done. The data path must be set to main 8bit luminance and chrominance processing format.

36.1.5.9 Power Management

There are two main power modes for the CIF: running and switched-off. In running mode the master clock provided at the Bus interface is passed to the CIF blocks. In switched-off mode the master clock is disabled (gated) in the CIF control unit. So only register

accesses are possible, but no processing. Controlling the main power modes is done using the VI_CCL configuration register.

In running mode a further method exists to minimize power consumption of the CIF. Separate clock gating exists for all blocks inside the CIF (except the Y/C-splitter). This is controlled by the VI_ICCL configuration register. For each module that is not needed for the actual processing (bypassed or disabled) the module clock can be disabled by clock gating as shown in Figure **“Clock Gating Scheme for the CIF” on Page 36-266**.

Clock gating for static configuration registers is handled automatically. Their clocks are enabled during read or write accesses via the Bus slave interface only, otherwise they are switched off.

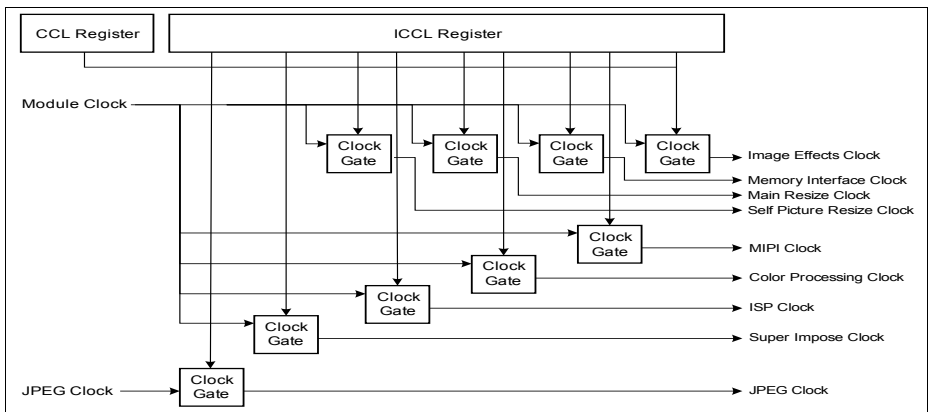

Figure 36-37 Clock Gating Scheme for the CIF

36.1.5.10 Basics on Configuration Access

Configuration accesses are done by using the Bus slave interface. Single beat transactions with a data width of 32 bits are supported.

Each CIF sub-module contains its own local configuration registers. For optimized power consumption these registers are clocked during read/write data transfers only. This clock gating is handled automatically by the control unit and is fully transparent to the application.

36.2 Extended Memory (EMEM)

The Extended Memory (EMEM) contains RAM blocks (Tiles) which can be used as global memory. It has interfaces to the LMU and the BBB. The EMEM architecture is similar to the EMEM of the Emulation Devices (ED).

Applications:

- Data and program code storage
- FFT data buffering
- Image buffering

Features:

- 512 Kbyte RAM in total
- Concurrent access from LMU and BBB to different tiles possible
- BBB burst transfers supported
- ECC with SECCDED (Single Error Correction, Double Error Detection)

36.2.1 Block Diagram

The Extended Memory consists of a regular memory array (ADM - Application Data Memory) build out of 64 Kbyte RAM Tiles. Additionally on certain products of the family the optional extension memories XAM is offered.

The Extended Memory provides two internal interfaces:

- LMU Interface
- BBB Interface with master and slave interface

The two interfaces allow a concurrent access to two different Tiles.

36.2.1.1 Extended Application Memory (XAM)

The XAM feature is a family concept for products, which require more than 1 MB Application RAM. The first EMEM RAM block (ADM) is partitioned into 16 Tiles. The following XAM EMEM block is without partitioning. A wrapper routes the accesses to ADM or XAM as a single continuous address range. The availability of XAM for different members of the product family is listed in [Table 36-4](#).

36.2.1.2 Family Overview

[Figure 36-38](#) shows an EMEM configuration example and [Table 36-4](#) the Extension Memory configurations for the different products of the family.

Figure 36-38 EMEM Configuration Example with ADM, XAM Tiles
Table 36-4 Extension Memory availability for the Product Family

Product	Total RAM Size	ADM Size	XAM Size	XAM Addr. LMU/BBB
TC29x	2048 KB	1 MB	1 MB	xx10 0000 ¹⁾
TC27x	1024 KB	1 MB	-	-
TC26x	512 KB	512 KB	-	-
TC24x	256 KB	256 KB	-	-
TC23x	512 KB	512 KB	-	-

1) More information can be found in [Table 36-6](#).

36.2.2 Operational Overview

The Extended Memory as a whole can be in Standby Locked Mode or in Enabled Mode. Immediately after Power On Reset, the entire Extended Memory is in Unused Mode, thus the Tiles are not yet reserved for application mode. At any time, each Tile can be individually assigned to Application or again Unused Memory by setting its mode.

If a Tile has to be configured to Application Mode to activate the Extended Memory for the application.

This two step approach with selecting the global assignment for the Extended Memory of a Tile first and then operating it supports a safe operation.

Note: Before using the EMEM the boundary to this memory must be enabled by de-asserting the OSCU control bit OSTATE.EECDIS. Failing to do so will result in a hang-up of the CPU/DMA on the first read access to the EMEM.

Tile in Unused Mode

After Power On Reset, the Tiles are still in Unused Mode and are not yet reserved. They cannot be accessed before being assigned to Extended Memory by software. Later on, each Tile can be individually returned to Unused Memory space.

Tile in Application Mode

A RAM Tile in Application Mode can be accessed from the LMU or the BBB. The arbitration for concurrent accesses is done within the Extended Memory by delaying the BBB access.

Simultaneous Accesses

Up to two different Tiles can be accessed in parallel via the two interfaces, if these Tiles are configured in Application mode.

36.2.3 Extended Memory

By writing to Register **TILECONFIG**, unused Tiles can be assigned to Extended Memory. In Application Mode, write and read accesses can be performed by the LMU or BBB interfaces in arbitrary sequence. The arbitration is done internally with higher priority for the LMU interface.

36.2.4 Access Error Generation

If a Tile is accessed over an interface which is not supported in the current mode of the Tile, an error is signalled to the access initiator.

Any access attempt to RAM or a register during Standby Locked Mode is answered with an access error.

Table 36-5 Error Signaling for RAM Accesses

	LMU I/F	BBB I/F
Application Mode	Ok ¹⁾	Ok ¹⁾

1) If an ECC error is detected, an access error is signalled to the corresponding interface. If the width of a write access is smaller than the addressed memory word, an internal read-modify-write access is performed which potentially results in an ECC error for the read part. An ECC error is also generated, if a RAM location was not initialized before!

In Locked Mode, the registers **CLC**, **ID**, and **SBRCTR** are accessible via the LMU through the BBB master interface, access to other registers raises an error.

36.2.5 Tiles and RAM Address Ranges

The Extended Memory (ADM RAM area) can be accessed from two interfaces:

- LMU Interface
- BBB Interface

Accesses to the Extended Memory via the LMU are done by one of the CPUs or other SRI bus masters. To cater for cached/non-cached access the Extended Memory is mapped to two segments by the LMU.

The addressing of ADM and XAM depends on the interface. LMU and BBB have the same addressing view, just with a different base address.

The LMU/BBB addressing is based on the 1 MB ADM address area, followed by XAM always starting at the 1 MB address.

Assignment of Tiles to Trace Memory usually starts with Index 0 ([Table 36-6](#)).

Table 36-6 EMEM Tiles and Address Ranges

Tile	LMU ¹⁾ TC26x	BBB	SBDAP Address
t; (ADM) t=0...7	sF0t0000 _H sF0tFFFF _H	AF0t0000 _H AF0tFFFF _H	000t0000 _H 000tFFFF _H

1) s = B_H: non-cached access by CPU, s = 9_H: cached access by CPU

For register accesses see [Table 36-7](#).

[Figure 36-39](#) shows TC29x and TC26x as an example.

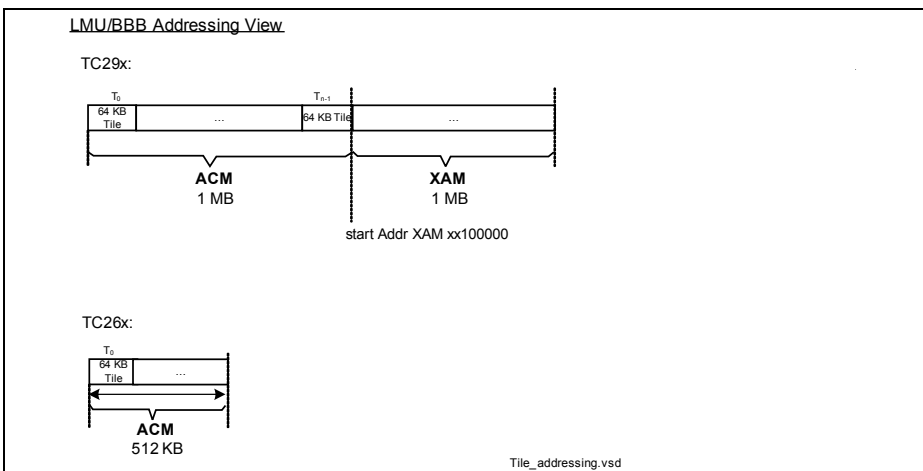

Figure 36-39 TCM and AXM interface addressing view.

More details about ADM and XAM addressing can be found in [Table 36-6](#).

36.2.6 EMEM Initialization

After Power-on Reset the EMEM is locked and requires an unlock sequence similar to the EMEM of Emulation Device to get the memory initialized.

Unlocking the EMEM

To unlock EMEM, the following sequence is written to the [SBRCTR](#) register.

1. 0000 0002_H,
2. 0000 0006_H,
3. 0000 000E_H

Writing any other value to [SBRCTR](#) before the complete sequence was written will reset the state machine, i.e. the sequence must be started again from the beginning. Writing to other registers however does not influence the sequence checker state machine.

The current state is signalled with bit [SBRCTR.STBLOCK](#).

36.2.7 Usage Constraints

In this section assumptions are listed for using the EMEM module.

36.2.7.1 Clock Constraints

The clock for the BBB must not be faster than the EMEM clock. For the TC26x B-Step the LMU clock is equal to SRI clock.

36.2.7.2 BBB Interface

The BBB slave interface supports burst transfers, e.g. for image buffering.

36.2.8 Power Saving

In order to minimise power consumption, the clocks of inactive Tiles can be gated.

If clock gating is enabled ([SBRCTR.ACGEN](#)), all Tiles in Unused Mode are no longer clocked.

Tiles in Application are not gated directly. For this purpose they can first be set to Unused Mode.

The current clock gating status is individually indicated for each Tile ([SBRCTR.ACGSTi](#)).

36.2.9 EMEM Configuration

For power saving reasons, each tile is initially in unused mode. The register bits **TILECONFIG** allow to allocate the specific tiles as application memory. The configuration state of each Tile is indicated in register **TILESTATE**.

36.2.10 EMEM Interfaces

As each Tile is arbitrated individually, transactions from the different interfaces into different Tiles are handled concurrently, i.e. up to two.

According to the word-lengths of the addressed RAM blocks, measures are taken for optimizing RAM accesses. Internal read-modify-write transactions are only required (due to ECC) if the word-length of data for the physical write access is smaller than the word-length of the memory.

36.2.10.1 LMU Interface

Read and write transactions are initiated by the LMU. Burst and read-modify-write transactions are not supported, but are split into basic and concatenated transactions.

Wide Read Transactions

Read accesses wider than the read-data word-length at the LMU are transformed into multi-beat transactions in subsequent cycles, taking into account wrapping around for unaligned addresses.

Concatenated read accesses of small words are not expected due to the wide-read access feature. If concatenated read accesses should occur anyhow, the EMEM processes them just like sequences of single read accesses without waiting for the master request to become inactive in between.

Concatenated Write Transactions

For write-widths smaller than the word-width of the memory, generally a complete memory word has to be synthesized before physically writing to memory, due to the required ECC which refers to complete memory words only. Whenever a write access is received from the LMU, a speculative read is immediately started and a ready signal returned to the LMU. In the next cycle, the read data is updated with the previous write data and written back, if the first write access is single. If instead another concatenated write transaction is received, the just obtained read data is not used, but the two subsequent write data portions are combined and written to memory. Thus, for a concatenated write, only the first of two consecutive write accesses causes a speculative internal read, because the protocol does not yet allow to decide for a first write, whether a second concatenated one is about to follow.

36.2.10.2 BBB Slave Interface

Transactions from the BBB to EMEM memory are initiated by any BBB master. In order to avoid internal read-modify-write accesses to EMEM-RAM, BBB write data received by the EMEM slave interface in burst operations is accumulated before being written into the memory. The EMEM control decides from the FPI opcode and the given memory word size whether a combination is possible or an internal read is required. These optimizations include unaligned burst transfers.

36.2.11 Feed-Through Transactions

The EEC must also be accessed from the product chip part. For this purpose, the EMEM feeds through transactions received from the LMU to the BBB Master Interface, if none of the EMEM's RAMs is addressed. Thus LMU and EMEM jointly act as bus-bridge between the SRI bus and the Backbone bus.

When acting as BBB Bus Master the EMEM tag and Supervisor Mode (SVM) is used.

36.2.11.1 EMEM Register Accesses

The SFRs of the EMEM are accessed via the BPI part of the BBB Slave Interface by any component connected to the BBB through a master interface, such as IOC32, and also the EMEM itself.

A register access from the product side is performed via LMU, the BBB Master Interface to the BBB, and from there via the BBB Slave Interface.

36.2.12 Address Map

All EMEM registers are prefixed "EMEM_" in the register map of the device.

EMEM occupies an address window of 256 bytes. The relative register addresses in the register descriptions below are given as offset addresses to the base address of the window.

The base addresses for register accesses are identical for LMU and BBB. Internally in the EMEM, a window of 2 MB, `addr[21:0]` is available for addressing registers via BBB.

Note: This window is mapped to another segment when accessed via the SRI. Please, check production device address mapping to find the correct offset.

Access rights within the address range of EMEM:

- Read access to defined register addresses: U, SV
- Write access to defined register addresses: U, SV (no BE even if read-only register)
- Read access to empty addresses: No error (returns 0)
- Write access to empty addresses: BE
- Read or write when the kernel clock is turned off: BE (unless **CLC**)

Table 36-7 Registers Address Space

36.2.13 EMEM Register Description

As detailed in the OCDS chapter, several reset domains exist on TC26x B-Step. All registers of the EMEM module belong to the Power On Reset domain and are reset by PORST. The **CLC** register additionally belongs to the EEC Reset domain.

TILECONFIG

Tile Configuration Register (20_H) **Reset Value: 0000 0000_H**

DISS	1	rh	Disable Status Bit 0 _B Module enabled 1 _B Module disabled
0	[31:2]	r	Reserved returns 0 if read; should be written with 0

The clock control register allows to switch the memory subsystem on or off. After Power On Reset the memory subsystem is disabled. The memory subsystem can be enabled by clearing bit DISR. It is ensured that the **CLC** is still writable when the clock is switched off.

36.3 FFT Engine (FFT)

This chapter describes the FFT Engine, an algorithm specific accelerator. The FFT Engine is not available in all devices and only those with the ADAS feature set.

The FFT Engine utilises the SRI connectivity of the LMU. The FFT Engine is clocked at the same frequency as the SRI and all cycle counts are in terms of SRI clocks.

Figure 36-40 FFT Engine Integration into the LMU

36.3.1 Overview

The FFT Engine calculates forward and inverse FFTs of lengths 8 to 1024 (powers of 2 only). It operates on real and complex data which can have co-efficients of 16 or 32-bits in length.

The actual forward and inverse transforms calculated by this core are given by

$$X[k] = \frac{1}{N} \sum_{n=0}^{N-1} x[n] \exp(-j2\pi kn/N) \quad \text{Forward}$$

$$x[n] = \frac{1}{N} \sum_{k=0}^{N-1} X[k] \exp(j2\pi kn/N) \quad \text{Inverse}$$

In usual DSP literature the forward transform is not divided by N, but this is performed in hardware for consistency between transforms and to implement a transform that cannot overflow.

36.3.2 Feature List

General features:

- Per transform selection of FFT or inverse FFT (IFFT).
- Per transform selection of FFT/IFFT size from 8, 16, 32, 64, 128, 256, 512 or 1024 points.
- Per transform selection of real or complex input operands.
- Per transform selection of input operands with 16-bit or 32-bit precision.
- Per transform selection of output results with 16-bit or 32-bit precision.
- Internal calculation to 32-bits of precision.

In addition to standard FFT calculations, the FFT Engine also supports a window function to be applied to input operands. The window function utilises a window RAM to hold coefficients which allows any real symmetrical function to be used. Use of this features is described in [Section 36.3.7](#). Another important performance enhancement is the use of double buffering to support the overlap of loading and unloading the FFT Engine while computation continues

Input operands for FFT or inverse FFT calculations which are loaded with 16-bits of precision are converted to 32-bits prior to storage inside the FFT engine. Calculations are carried out to 32-bits of precision using block floating point and adaptive scaling to ensure there is no loss of dynamic range during the intermediate calculations. Results are adjusted to natural scaling for software convenience before being read out. Output results which are unloaded with 16-bits of precision are converted from the 32-bit internal result by rounding (to nearest even) with saturation as they are transferred out.

36.3.3 FFT Engine Performance

After operands are loaded into the FFT Engine, the number of cycles the engine takes to complete a computation is a function of the length of the transform it has been programmed to execute. If N is the length of the transform, then the number of clock cycles to complete is:

$$(N+15) * \text{ceil}(\log_4(N))$$

The cycle count till availability of results for the supported FFT/IFFT lengths is show in [Table 36-9](#).

Table 36-9 FFT Engine Execution Times

Transform Length	Cycles	Transform Length	Cycles
8	46	128	572
16	62	256	1084
32	141	512	2635
64	237	1024	5195

36.3.4 System Performance

The complete steps required for the execution of an FFT/IFFT are:

- writing to the FFT_CSR to configure the required operation (input format, length, window operation, output format, start) with a single write
- transferring the required number of operands into the FFT Engine
- waiting for the engine to complete (or being interrupted)
- unloading the results from the FFT Engine

Total execution time for an FFT/IFFT calculation must take into consideration the time for storing of operands into the FFT Engine, and reading of the results out as well as the calculation time shown in the table FFT Engine Execution Times.

36.3.4.1 Data Movement Optimisation

The loading and unloading cycles will be a significant part of the total execution time required and is one of the major optimisation opportunities. Using the minimum operand size for input or output (16-bit versus 32-bit) can halve the amount of time in loading and unloading.

FFT transforms based on real operands only, could be calculated by loading complex values with imaginary components of zero along with real component values. However the FFT Engine supports optimising out this unnecessary transfer, and setting FFT_CSR.IN_FMT appropriately for real operands will halve the loading time. Both these transform options will significantly reduce the end to end cycle count for an operation, despite the fact that they have no effect on the transform calculation time.

Programmed loading and unloading by TriCore CPUs can transfer 64-bits at a time. For smaller transform lengths this may be most efficient. For longer transforms, the optimum bandwidth to load and unload the FFT Engine is obtained using the DMA to transfer bursts of four 64-bit words at a time.

36.3.4.2 Double Buffering Optimisation

As well as the opportunity to optimise the data movement time, the FFT Engine also provides the mechanisms to overlap FFT/IFFT execution with loading and unloading results. The FFT Engine is provided with two buffers each capable of supporting a maximum length FFT/IFFT transform. These two buffers are operated in a ping-pong arrangement and allow the overlap of transfer in and out of the FFT Engine, with the calculation of a transform with an earlier loaded set of operands. Thus, the throughput of FFT/IFFT operations is higher than determined by the total latency (loading, execution, unloading) of an individual transform.

36.3.5 Address Spaces and Access Protection

The FFT Engine responds to three address spaces in the system address map:

- a register space located from F870_0C00h to F870_0CFFh,
- a data space located at BE00_0000h to BE07_FFFFh,
- a window coefficient space located at BE10_0000h to BE17_FFFFh.

All three address spaces within the FFT Engine are protected by the access enable registers of the LMU which protects the resources against writes from unauthorised SoC masters.

36.3.5.1 Register Address Space

The FFT register space consists of 32-bit registers that only respond correctly to 32-bit read and write operations.

- any read from register space which is an 8-, 16- or 64-bit operation will result in an undefined value,
- any read from register space which is a burst transfer will result in a transaction error,
- any write to register space which is a burst transfer or an 8-, 16- or 64-bit operation will result in a transaction error,
- any atomic operation to register space will result in a transaction error.

36.3.5.2 Data Space

The data space only supports 64-bit and burst-4 transfers. Accesses that are 8-, 16- or 32-bit or burst-2 transfers to the data space will have undefined results.

The data space does not have standard memory characteristics. Instead this region operates as access to two separate FIFOs. Write accesses (regardless of addresses used) will place operands in order into one of the ping-pong buffers; for example for a 512 length FFT, the first data transferred will be 'sample 0', and the 512th sample transferred will be 'sample 511' regardless of the addresses used (provided they are all

within the FFT Engine data space). There is no ability to direct accesses to either of the ping-pong buffers, this is purely controlled by the FFT Engine.

Read accesses to the data space will return results out of one of the FIFOs in the same manner. The first read of a completed transform will receive 'result 0', and the Nth read will receive 'result N-1', again the addresses used will not influence the result element returned.

Bit FFTPFDIS should be cleared (0) in register LMU_MEMCON (see Local Memory Unit chapter) before accessing the data space.

Intermixing single transfers of 64-bits or burst-4 transfers during the same loading phase, or same unloading phase will have undefined results.

36.3.5.3 Window Coefficient Space

The window coefficient space only supports 64-bit and burst-4 transfers. Accesses that are 8-, 16- or 32-bit or burst-2 transfers to the window space will have undefined results. Within the window coefficient address space is a RAM holding the window coefficients - the window RAM.

The window RAM occupies 1-KByte (with corresponding aliases) of the window address space. Read and writes to this 1-KByte RAM will have standard memory characteristics only when validly accessed.

Accesses to the window RAM are only well behaved (reads to an address will return the same data last written) when

- the FFT Engine is idle,
- the FFT Engine does not have any results to be unloaded and
- bit FFTPFDIS should be set (1) in register LMU_MEMCON (see Local Memory Unit chapter).

For this reason writing to the window RAM should only be performed when the three conditions above have been met.

Note: The entire window RAM must be initialised before the FFT Engine can run a transform. This requirement is regardless of whether the window function is enabled or not for the transform.

36.3.6 Data Value Formats

The data formats supported by the FFT Engine for operands are identical to the corresponding TriCore architecture fractional formats for ease of manipulation. While, the window coefficient format which is manipulated less frequently uses a different format to slightly enhance precision.

36.3.6.1 Time and Frequency Sample Format

Data with 16-bit precision corresponds to TriCore signed fractional data with 16-bits (also known as 1.15 or Q15 format). Data with 32-bit precision corresponds to TriCore signed fractional data with 32-bits (also known as 1.31 or Q31 format).

Data values in this format have a single high-order sign bit, where 0 represents positive (+) and 1 represents negative (-), followed by an implied binary point and fraction. Their values are therefore in the range $[-1, 1)$.

Complex data corresponds to an array of two elements in little-endian order, where the first element (index 0 in 'C' notation) is the real coefficient, and the second element (index 1 in 'C' notation) is the imaginary coefficient.

36.3.6.2 Window Coefficient Format

A valid window function will have coefficients in the range $[0, 1]$. However, strictly only the central window coefficient requires to be 1.0 and the remainder are in the range $[0, 1)$. If the 1.15 or Q15 format was used for window coefficients, then as all the coefficients are positive, the MSBs of co-efficients stored in the window RAM (the central coefficient is not loaded), would be redundant.

To take advantage of this fact, the FFT Engine calculate with unsigned window coefficients and the stored values to the window RAM are the 16 fractional bits of a nominal 1.16 format.

36.3.7 Window Usage

The window RAM allows the user to load a window function of their choice and apply it (or not) to subsequent transforms. The parameters in the window RAM are only changed when the window function is required to be changed, they otherwise persist between transform operations (i.e. have standard memory characteristics).

The window RAM only contains half the maximum length transform entries (see [Section 36.3.6.2](#) for the format) and exploits symmetry to generate a complete window for that length of transform. If a window function is to be used for any length transform, it must be fully loaded and the FFT Engine will select the appropriate coefficients.

The expected usage is that a window function will be selected for a good match to the system and application properties, loaded at system initialisation, and then either applied or not (using FFT_CSR.WIN_BYN clear or set respectively) to subsequent FFT operations. While the window function can be changed during system operation, any change must respect the requirements listed in [Section 36.3.5.3](#). Thus, any change will incur some latency till the next transform operation is possible; either with or without the new window function applied.

Note: As specified in [Section 36.3.5.3](#) the window RAM must be initialised before any FFT Engine transform operation.

36.3.7.1 Window Parameters

If the window function is to be used, the coefficients for a maximum length transform must be computed. First generate a window of odd length and with a central maximum value of 1.0. For example if using MATLAB then this command

```
w = hamming(1024, 'periodic');
```

or

```
w = hamming(1025, 'symmetric');
```

will return the first 1024 points of a 1025 point periodic window. Next select the first 512 values of w and scale them up and round to an unsigned 16-bit integer

```
wi = round(65536*w(1:512));
```

These are the values to load into the window RAM. Note that this procedure is generic for any window, always start with a length 1025 symmetric or 1024 period variant. A common window in radar is Blackman-Harris, which would be generated in MATLAB with

```
w = blackmanharris(1025);  
wi = round(65536*w(1:512));
```

Note that the 1.0 central coefficient is internally generated by the hardware so it is essential that the window is correctly scaled to 1.0.

For FFT transform sizes less than the maximum the hardware will index the full window table to generate the correct coefficients for a smaller FFT size.

Although the hardware will not stop you applying a window in the frequency domain it may not be desirable.

36.3.8 Interrupt and DMA Operation

As well as inspecting the CSR register to determine when FFT/IFFT operations may be commenced, the FFT Engine allows interrupt driven data movement. There are two SRC registers in the IR connected to triggers from the FFT Engine. These are SRC_FFTRFS and SRC_FFTDONE. As is standard, each of these SRCs can select either a CPU or DMA channel to service the event.

A trigger will be sent to SRC_FFTRFS whenever FFT_CSR.RFS transitions from 0 to 1, this alerts the system to the fact the FFT_ENGINE can be loaded with another transform. Since there are two (ping-pong) buffers, this event means the FFT Engine may still be busy computing a previously loaded transform.

A trigger will be sent to SRC_FFTDONE whenever a transform calculation has completed and the unload operation can be performed.

A possible operational sequence utilising both of these trigger conditions is described below

1. A CPU reads the FFT_CSR register and looks for RFS bit to be set. Software then writes to the FFT_CSR register with START set to 1, and the desired values for IFFT, LENGTH, WIN_BY, IN_FMT, OUT_FMT.
2. The same CPU programs DMA channel(s) to send data to the FFT Engine, and configures the service request control (SRC) registers in the interrupt router SRC_FFTRFS and SRC_FFTDONE as required.
At this stage the CPU could return to some other task (perhaps preparing operands or examining results).
3. A CPU receiving the interrupt corresponding to SRC_FFTRFS, can write the next START command and initiate the DMA to transfer the next transforms operands to the FFT Engine.
Again at this stage the CPU is then free to return to some other task.
4. An interrupt corresponding to SRC_FFTDONE can trigger an already configured DMA channel to read back data from the FFT Engine, which when it has unloaded the results can then trigger a CPU to inform it of the unload completion.
5. Loop back to 3

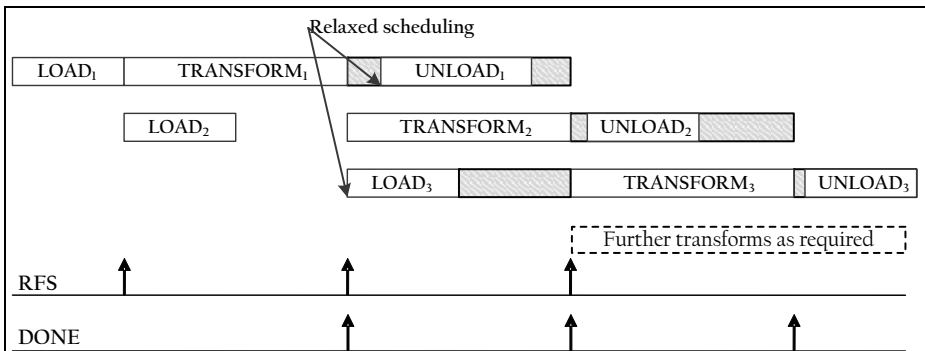

Figure 36-41 Three Consecutive Transforms

The double buffer architecture allows overlapping FFT execution with the DMA load/unload operation. This is illustrated in [Figure 36-41](#) where this example shows three transforms. The use of two memory buffers allows more relaxed scheduling of the DMA load/unload during overlapped transforms as shown by the unload operation being delayed until after the load operation for the third transform has commenced.

36.3.9 FFT Engine Registers

This section described the register interface to the FFT Engine. This address region should not be unintentionally read or written because this might cause side effects on FFT Engine state.

All registers are reset by the application reset apart from **FFT_ODA** and **FFT_OCS**. These registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. They are not changed by System Reset when OCDS is enabled.

Where a register is defined as "ACCEN Enable Protected" (designated with "P" for writes), then the LMU ACCEN settings will be used.

Table 36-10 Registers Address Space

Module	Base Address	End Address	Note
FFT	F870 0C00 _H	F870 0CFF _H	-

Table 36-11 Registers Overview

36.3.9.1 FFT Clock Control Register

FFT Clock Control Register (FFT_CLC)

The FFT Clock Control Register, FFT_CLC, acts globally and allows the complete FFT Engine to be disabled to reduce power consumption when the FFT is not required. When the FFT Engine is disabled (DISS=1_B), only register accesses to the FFT Engine are permitted. All other accesses to the FFT address space will receive a transaction error.

FFT_CLC

FFT Clock Control Register (0000_H) **Reset Value: 0000 0002_H**

Field	Bits	Type	Description
DISR	0	rw	FFT Disable Request Bit Used for enable/disable control of the FFT Engine.
DISS	1	rh	FFT Disable Status Bit Bit indicates the current status of the FFT Engine. DISABLED after reset.
0	31:2	r	Reserved Read as 0; should be written with 0.

36.3.9.2 FFT Module Identification Register

FFT Identification Register (FFT_ID)

The FFT identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the FFT Engine.

FFT_ID
FFT Identification Register
(0008_H)
Reset Value: 00E2 C001_H

Field	Bits	Type	Description
MOD_REV	7:0	r	Module Revision Number This bit field defines the module revision number. 01 _H : the value for max. 1K point engine 02 _H : the value for max. 2K point engine.
MOD_TYPE	15:8	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	31:16	r	Module Number Value This bit field defines a module identification number. The value for the FFT Engine is 00E2 _H .

36.3.9.3 FFT Control and Status Register

FFT Control and Status Register (FFT_CSR)

This is the main register to control FFT/IFFT operation and provide feedback on the current state of the FFT Engine.

FFT_CSR
FFT Control and Status Register
(0040_H)
Reset Value: 0010 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											RFS	BUS Y	OUT _FM T	IN_FMT	
r											rh	rh	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		WIN _BY P	IFFT	LENGTH				0				STA RT			
r		rw	rw	rw				r				rwh			

Field	Bits	Type	Description
START	0	rwh	Start Transform Start a new transform - cleared by hardware.
LENGTH	11:8	rw	Length of Transform Log base 2 of the required transform size. Length must be between 3 (transform of 8) and 10 (transform of 1024).
IFFT	12	rw	Inverse FFT 0 _B perform FFT. 1 _B perform IFFT.
WIN_BYP	13	rw	Window Bypass 0 _B use window function 1 _B bypass window function
IN_FMT	17:16	rw	Input Format 0 _D 1 complex 32-bit datum per 64-bit word 1 _D 2 real 32-bit data per 64-bit word 2 _D 2 complex 16-bit data per 64-bit word 3 _D 4 real 16-bit data per 64-bit word
OUT_FMT	18	rw	Output Format 0 _D 1 complex 32-bit datum per 64-bit word 1 _D 2 complex 16-bit data per 64-bit word
BUSY	19	rh	FFT Engine Busy 0 _D : FFT Engine Idle - no pending transforms 1 _D : FFT Engine has at least one transform in operation.

Field	Bits	Type	Description
RFS	20	rh	Ready For Start 0_D : cannot accept a START operation 1_D : can accept a START operation.
0	31:21, 15:14, 7:1	r	Reserved Read as 0; should be written with 0

This register may be written at any time without setting the START bit, but this will have no effect on the FFT Engine. Only updates with the START bit set will change the FFT Engine state, and must be done before data can be loaded into the FFT Engine, to inform it of the input data formats and operational mode for that transform.

However the FFT Engine must be ready to accept a new START request. This register can be read and the RFS - ready for start - bit examined. If the RFS is true then a new transform can be started. A trigger will be sent to SRC_FFERR if START is set when the FFT Engine is not ready. The commencement of new transforms in an interrupt driven manner is described in [Section 36.3.8](#).

The IN_FMT field determines how data on the little-endian 64-bit data bus is loaded into the FFT Engine.

Table 36-12 Input Data Formats

IN_FMT	Halfword[3]	Halfword[2]	Halfword[1]	Halfword[0]
0	imag[0]		real[0]	
1	real[1]		real[0]	
2	imag[1]	real[1]	imag[0]	real[0]
3	real[3]	real[2]	real[1]	real[0]

The OUT_FMT field determines how data on the little-endian 64-bit data bus is unloaded from the FFT Engine.

Table 36-13 Output Data Formats

OUT_FMT	Halfword[3]	Halfword[2]	Halfword[1]	Halfword[0]
0	imag[0]		real[0]	
1	imag[1]	real[1]	imag[0]	real[0]

The BUSY bit reports the status of the FFT engine. If BUSY is set then at least one transform has either been requested with a START or is executing or is waiting for unloading

36.3.9.4 FFT History Registers

History registers allow the last few commands issued to the CSR to be retained for debug, the registers have no other effect upon the FFT Engine. They are reset to 0, and contain a non-zero value whenever they have been loaded by performing a write to the CSR register with START set. This write may or may not have setup a transform operation correctly depending upon the state of CSR.RFS at the time the START was issued.

FFT History Register 0 (FFT_HISTORY0)

The value of FFT CSR control fields when START was last issued.

FFT_HISTORY0

FFT History0 Register

(0060_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
LENGTH	11:8	rh	Length of Transform value of FFT_HISTORY0.LENGTH when START command was last issued.
IFFT	12	rh	Inverse FFT value of FFT_HISTORY0.IFFT when START command was last issued.

Field	Bits	Type	Description
WIN_BYP	13	rh	Window Bypass value of FFT_HISTORY0.WIN_BYP when START command was last issued.
IN_FMT	17:16	rh	Input Format value of FFT_HISTORY0.IN_FMT when START command was last issued.
OUT_FMT	18	rh	Output Format value of FFT_HISTORY0.OUT_FMT when START command was last issued.
BUSY	19	rh	FFT Engine Busy value of FFT_HISTORY0.BUSY when START command was last issued.
RFS	20	rh	Ready For Start value of FFT_HISTORY0.RFS when START was last issued.
0	31:21, 15:14, 7:0	r	Reserved Always read as 0.

36.3.9.5 FFT Debug Control Registers

FFT OCDS Debug Access Register (FFT_ODA)

The FFT OCDS Debug Access (FFT_ODA) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not affected by System Reset when OCDS is enabled.

This register is used to control whether or not register bits which change state on read do so when read by the on-chip debug system.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_ODA
FFT OCDS Debug Access Register (00E4_H)
Reset Value: 0000 0000_H

Table 36-14 Destructive Read Control encoding

DRDIS	DDREN	Description
0	0	Destructive read access are enabled for all masters except the OCDS master.
0	1	Destructive read access are enabled for all masters
1	-	Destructive read access are disabled for all masters

FFT OCDS Control and Status Register (FFT_OCS)

The FFT OCDS Control and Status (FFT_OCS) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not affected by System Reset when OCDS is enabled (signal eec_reset_n_i).

The FFT_OCS control register bits are only effective while the system is in debug mode. While not in debug mode, OCS reset values/modes are effective.

When a triggered by a high level on the suspend signal, the FFT/IFFT calculation will be halted as soon as practicable. Operation should resume when the suspend input is cleared.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_OCS

FFT OCDS Control and Status (00E8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SUS	27:24	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS). 0 _H Will not suspend 1 _H Reserved for Hard suspend which is not implemented. 2 _H Soft suspend (Halt Mode) others , reserved
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended

Field	Bits	Type	Description
0	23:0, 31:30	r	Reserved Read as 0; must be written with 0.

36.3.9.6 FFT Kernel Reset Registers

FFT Kernel Reset Status Clear Register (FFT_KRSTCLR)

The FFT Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRSTCLR

FFT Kernel Reset Status Clear Register(00EC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear <i>Note: Read always as 0_B.</i> 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT
0	31:1	r	Reserved Read as 0 _B ; should be written with 0 _B .

FFT Kernel Reset Register 1 (FFT_KRST1)

The FFT Kernel Reset function is used to synchronously reset all the FFT Engine registers (except those connected to Debug reset) and the FFT Engine operation. To activate the kernel reset, it is necessary to set the RST bits by writing the value 1_B in both Kernel Reset Registers. The RST bit will be reset by hardware at the end of the kernel reset sequence.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRST1
FFT Kernel Reset Register 1
(00F0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers are set. The RST bit will be cleared (re-set to 0 _B) after the kernel reset is executed. 0 _B No kernel reset was requested 1 _B A kernel reset was requested
0	31:1	r	Reserved Read as 0 _B ; should be written with 0 _B .

FFT Kernel Reset Register 0 (FFT KRST0)

The FFT Kernel Reset function is used to synchronously reset all the FFT Engine registers (except those connected to Debug Reset) and the FFT Engine operation. To activate the kernel reset, it is necessary to set the RST bits by writing the value 1_B in both Kernel Reset Registers. The RST bit will be reset by hardware at the end of the kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

During the execution of the kernel reset; until RSTSTAT is set, all write accesses to the kernel registers will result in an error acknowledge.

Write access is 32 bit wide only and requires Supervisor Mode.

FFT_KRST0
FFT Kernel Reset Register 0
(00F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to 0 _B) b after the kernel reset was executed. 0 _B No kernel reset was requested 1 _B A kernel reset was requested
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits are cleared (FFT_KRST0.RST and FFT_KRST1.RST). This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register. 0 _B No kernel reset was executed 1 _B Kernel reset was executed
0	31:2	r	Reserved Read as 0; should be written with 0.
