The TIM[i]_CH[x](47:24) output line is used by the MAP submodule for further processing (please see [Section 26.15](#)).

Filter Parameter summary for the different Filter Modes

Table 26-19 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/down counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field FLT_CNT_FRQ of register TIMi_CHx_CTRL.

The counter FLT_CNT can either be clock with the CMU_CLK0, CMU_CLK1, CMU_CLK6 or the CMU_CLK7 signal. These signals are coming from the CMU submodule.

The FLT_CNT, FLT_FE and FLT_RE registers are 24-bit width. For example, when the resolution of the CMU_CLK0 signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

26.10.2.2 TIM Filter Modes

Immediate Edge Propagation Mode

In immediate edge propagation mode after detection of an edge the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one TFLT_CLK period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the FLT_RE and FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch GLITCHDET bit in the TIMi_CHx_IRQ_NOTIFY register.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also [Figure 26-25](#)).

Generic Timer Module (GTM)

Figure 26-24 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register FLT_RE.

Immediate Edge Propagation Mode in the case of a rising edge

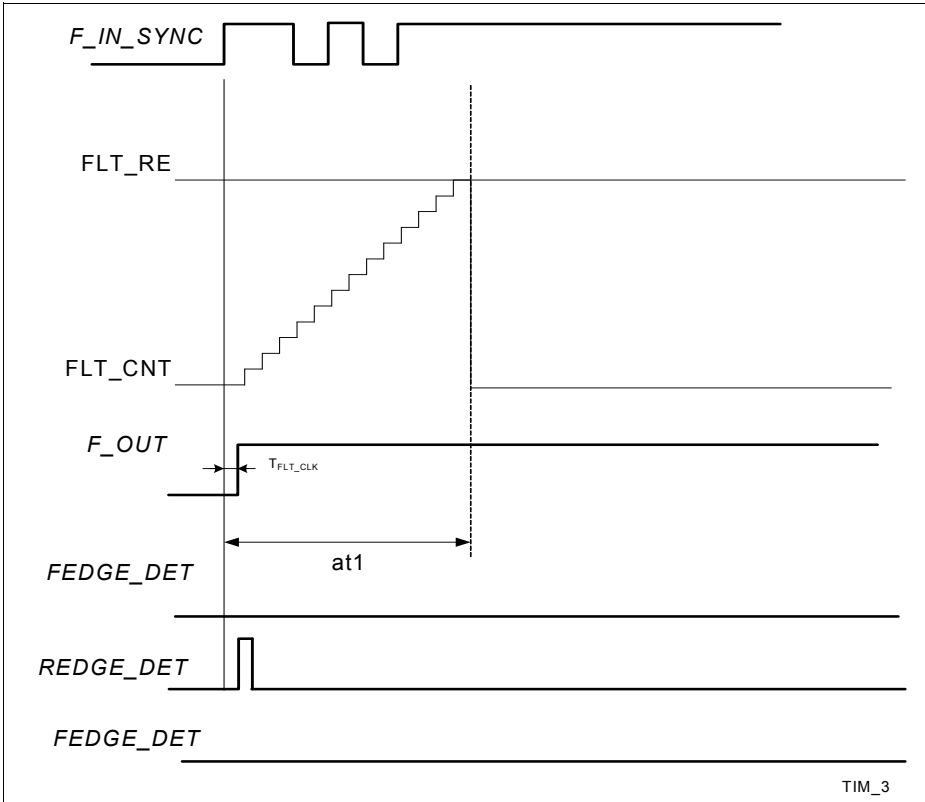

Figure 26-24 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT. The counter FLT_CNT is increment until acceptance time threshold is reached.

Figure 26-25 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

Generic Timer Module (GTM)

Immediate Edge Propagation Mode in the case of a rising and falling edge

Figure 26-25 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. **Figure 26-25** shows this scenario at the detection of the first rising edge and the second falling edge.

Individual De-Glitch Time Mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT. If After FLT_CNT has reached a value of zero during decrease the counter is stopped immediately.

If a glitch is detected a glitch detection bit GLITCHDET is set in the TIMi_CHx_IRQ_NOTIFY register.

Generic Timer Module (GTM)

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 26-26** shows the behaviour of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

Figure 26-26 Individual Deglitch Time Mode (up/down counter) in the case of a rising edge

Individual De-Glitch Time Mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is increment when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the TIMi_CHx_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 26-27** shows the behaviour of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

Individual Deglitch Time Mode (hold counter) in the case of a rising edge

Figure 26-27 Individual Deglitch Time Mode (hold counter) in the case of a rising edge

Immediate Edge Propagation and Individual De-Glitch Mode

As already mentioned, the three different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter or hold counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in [Figure 26-28](#).

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter can not measure the time **TERROR**, as shown in [Figure 26-28](#).

Mixed mode measurement

Figure 26-28 Mixed mode measurement

26.10.2.3 TIM Filter reconfiguration

If FLT_EN=1 a change of FLT_RE or FLT_FE will take place immediately. If FLT_EN=1 a change of FLT_MODE_RE or FLT_FE will be used with the next occurring corresponding edge. If mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If FLT_EN=1 a change of FLT_DTR_RE or FLT_CTR_FE will take place immediately.

26.10.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM submodule has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

The TDU architecture is shown in [Figure 26-29](#).

26.10.3.1 Architecture of the TDU Subunit

Figure 26-29 Architecture of the TDU Subunit

It is possible to detect timeouts with the resolution of the specified CMU_CLKx input signal selected with the bit field TCS of the register $TIMi_CHx_TDU$. The individual timeout values have to be specified in number of ticks of the selected input clock signal and have to be specified in the field TOV of timeout value register $TIMi_CHx_TDUV$ of the TIM channel x ($x:0...7$).

The exact time out value $TTDU$ can be calculated with:

$$T_{TDU} = (TOV + 1) * T_{CMU_GCLKx}$$

whereas T_{CMU_GCLKx} is the clock period of the selected CMU clock signal.

Timeout detection can be enabled or disabled individually inside the $TIMi_CHx_CTRL$ register by setting/resetting the TO_CTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field $TOCTRL$.

The counter TO_CNT is reset by each detected input edge coming either from the filtered input signal or when the timeout value TOV is reached by the counter TO_CNT .

After such a reset or by enabling the channel inside the $TIMi_CHx_CTRL$ register the counter TO_CNT starts counting again with the specified clock input signal.

Generic Timer Module (GTM)

Otherwise, timeout measurements starts immediately after the TO_CTRL bit inside the TIMi_CHx_CTRL register is written (enabled).

The TDU generates an interrupt signal TIM_TODETx_IRQ whenever a timeout is detected for an individual input signal, and the TODET bit is set inside the TIMi_CHx_IRQ_NOTIFY register.

In addition, when the ARU access is enabled with the ARU_EN bit inside the TIMi_CHx_CTRL register, the actual values stored inside the registers TIM[i]_CHx_GPR0 and TIM[i]_CHx_GPR1 are sent together with the last stored signal level to the ARU if a timeout event occurs.

To signal that a timeout occurred, the ARU_OUT(50) bit (ACB(2)) is set. The bit ACB(0) will be updated with the timeout event to the signal level on which the timeout was detected.

Thus, a destination could determine if a timeout occurred at the TIM input by evaluating ACB bit 2.

Since the TIM channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid at the ARU. In that case, the new edge associated data is stored inside the registers TIM[i]_CHx_GPR0 and TIM[i]_CHx_GPR1, the GPR overflow detected bit is set together in the ACB field (ACB(1)) with the timeout bit (ACB(2)) and the values are marked as valid to the ARU.

The ACB bit 2 is cleared, when a successful ARU write access by the TIM channel took place.

The ACB bit 1 is cleared, when a successful ARU write access by the TIM channel took place.

When a valid edge initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is set. The bit ACB(0) will be updated to the level on which the timeout occurred.

When a timeout occurred and initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is not set.

The following table clarifies the meaning of the ACB Bits for valid data provided by a TIM channel:

Table 26-20 TIM ARU Control Bits

ACB4/3	ACB2	ACB1	ACB0	Description
dc	0	0	SL	Valid edge detected
dc	0	1	SL	Input edge overwritten by subsequent edge

Generic Timer Module (GTM)

Table 26-20 TIM ARU Control Bits (cont'd)

ACB4/3	ACB2	ACB1	ACB0	Description
dc	1	0	SL	Timeout detected without valid edge
dc	1	1	SL	Timeout detected with subsequent valid edge detected

26.10.4 TIM Channel Architecture

26.10.4.1 Overview

Each TIM channel consist of an input edge counter ECNT, a Signal Measurement Unit (SMU) with a counter CNT, a counter shadow register CNTS for SMU counter and two general purpose registers GPR0 and GPR1 for value storage.

The value TOV of the timeout register TIMi_CHx_TDU is provided to TDU subunit of each individual channel for timeout measurement. The architecture of the TIM channel is depicted in [Figure 26-30](#).

TIM Channel Architecture

Generic Timer Module (GTM)

Figure 26-30 TIM Channel Architecture

Each TIM channel receives both input trigger signals REDGE_DET_x and FEDGE_DET_x, generated by the corresponding filter module in order to signalize a detected echo of the input signal F_IN_x. The signal F_OUT_x shows the filtered signal of the channel's input signal F_IN_x.

The edge counter ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates ECNT by composing the ECNT[n:1] bits with F_OUT_x as bit 0).

Thus, the whole counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current ECNT[7:0] register content is made visible on the bits 31 down to 24 of the registers GPR0, GPR1 and CNTS. This allows the software to detect inconsistent read accesses to registers GPR0, GPR1, and CNTS. However, the update strategy of these

Generic Timer Module (GTM)

registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field FR_ECNT_OFL when an ECNT overflow is signaled on ECNTOFL. An ECNT overflow can be signaled on 8 bit or full range resolution.

While reading the register TIMi_CHx_ECNT the bit ECNT[0] shows the input signal value F_OUTx independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of TIMi_CHx_ECNT will be frozen until a read of the register takes place. This read will reset the ECNT counter. Continuing reads will show the input signal in bit ECNT[0] again.

When new data is written into GPR0 and GPR1 the NEWVAL bit is set in TIMi_CHx_IRQ_NOTIFY register and depending on corresponding enable bit value the NEWVALx_IRQ interrupt is raised.

Each TIM input channel has an ARU connection for providing data via the ARU to the other GTM submodules. The data provided to the ARU depends on the TIM channel mode and its corresponding adjustments (e.g. multiplexer configuration).

The bit ARU_EN of register TIMi_CHx_CTRL decides, whether the measurement results of registers GPR0 and GPR1 are consumed by another submodule via ARU (ARU_EN = 1) or the CPU via AEI (ARU_EN = 0).

To guarantee a consistent delivery of data from the GPR0 and GPR1 registers to the ARU or the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit NEWVAL is set inside TIMi_CHx_IRQ_NOTIFY register) while the old data is not consumed by the ARU (ARU_EN = 1) or CPU (ARU_EN = 0), the TIM channel sets the GPROFL bit inside the status register TIMi_CHx_IRQ_NOTIFY and it overwrites the data inside the GPR registers GPR0 and GPR1. In addition when ARU_EN=1 the bit ACB(1) is set to 1 to indicate the overflow in the ARU data.

If the CPU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 0), the acknowledge for reading out data is performed by a read access to the register GPR0. Thus, register GPR1 should be read always before GPR0.

If the ARU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 1), the acknowledge for reading out data is performed by the ARU itself. However, the registers GPR0 and GPR1 could be read by CPU without giving an acknowledge.

26.10.4.2 TIM Channel Modes

The TIM provides six different measurement modes that can be configured with the bit field TIM_MODE of register TIMi_CHx_CTRL. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register TIMi_CHx_CTRL for a more detailed controlling of each mode. The meanings of these bits are as follows:

Generic Timer Module (GTM)

- DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured).
- EGPR0_SEL, GPR0_SEL and EGPR1_SEL, GPR1_SEL: control the actual content of the registers GPR0 and GPR1 after a measurement has finished.
- CNTS_SEL: control the content of the registers CNTS. The actual time for updating the CNTS register is mode dependent.
- OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.
- NEWVAL: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signalling that the registers GPR0 and GPR1 are updated.
- ARU_EN: enables sending of the registers GPR0 and GPR1 together with the actual signal level (in bit 48) and the overflow signal GPROFL (in bit 49), and the timeout status information (bit 50) to the ARU.
- EXT_CAP_EN: forces an update of the registers GPR0 and GPR1 and CNTS (TIM channel mode dependant) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields EXT_CAP_SRC in the register TIMi_CHx_ECTRL.

TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, DSL=1), the channel starts measuring after the first rising edge is detected by the filter.

Measurement is done with the CNT register counting with the configured clock coming from CMU_CLKx until a falling edge is detected.

Then the counter value is stored inside the shadow register CNTS (if CNTS_SEL = 0) and the counter CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CNTS register is transferred to GPR0 and the content of CNT register is transferred to GPR1, assuming settings for the selectors GPR0_SEL=11 and GPR1_SEL=11. By this, GPR0 contains the duty cycle length and GPR1 contains the period. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

In addition the CNT register is cleared NEWVAL status bit inside of TIMi_CHx_IRQ_NOTIFY status register and depending on corresponding interrupt enable condition TIM_NEWVALx_IRQ interrupt is raised.

Generic Timer Module (GTM)

The CNTS register update is not performed until measurement is started (first edge defined by DSL is detected). Afterwards each edge leaving the level defined by DSL is performing a CNTS register update.

If a PWM with a low level duty cycle should be measured (DSL = 0), the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in CNTS and then finally in GPR0 and the period is stored in GPR1.

When a PWM period was successfully measured, the data in registers GPR0 and GPR1 is marked as valid for reading by the ARU when the ARU_EN bit is set inside TIMi_CHx_CTRL register, the NEWVAL bit is set inside the TIMi_CHx_IRQ_NOTIFY register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader attached to the ARU (ARU_EN bit enabled) or by the CPU the TIM channel set GPROFL status bit in TIMi_CHx_IRQ_NOTIFY and depending on corresponding interrupt enable bit value raises a GPROFL_IRQ and overwrites the old values in GPR0 and GPR1. A new measurement is started afterwards.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled, the pwm measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

Operation is done depending on cmu clock, ISL, DSL bit and the input signal value defined in the next table:

Table 26-21 TIM PWM Measurement Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
rising edge	-	0	0	0	capture CNT value in CNTS
falling edge	-	0	0	0	CNT = 0
rising edge	-	0	1	0	no
falling edge	-	0	1	0	capture CNT value in CNTS; CNT = 0

Generic Timer Module (GTM)
Table 26-21 TIM PWM Measurement Mode (cont'd)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
1	1	0	-	1	CNT++
0	1	0	-	1	no
falling edge	-	0	0	1	capture CNT value in CNTS
rising edge	-	0	0	1	CNT = 0
falling edge	-	0	1	1	no
rising edge	-	0	1	1	capture CNT value in CNTS; CNT = 0
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

The CNTS register update is not performed until measurement is started (first edge defined by DSL is detected). Afterwards the update of the CNTS register is defined by ISL, DSL combinations in the table above.

TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit DSL of register TIMi_CHx_CTRL register.

The pulse times are measured by incrementing the TIM channel counter CNT whenever the pulse has the specified signal level DSL. The counter is stopped whenever the input signal has the opposite signal level.

The counter CNT counts with the CMU_CLKx clock specified by the CLK_SEL bit field of the TIMi_CHx_CTRL register.

The CNT register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Whenever the counter is stopped, the registers CNTS, GPR0 and GPR1 are updated according to settings of its corresponding input multiplexers, using the bits GPR0_SEL, EGPR0_SEL, EGPR1_SEL, GPR1_SEL, and CNTS_SEL. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

When the ARU_EN bit is set inside the TIMi_CHx_CTRL register the measurement results of the registers GPR0 and GPR1 can be send to subsequent submodules attached to the ARU.

Generic Timer Module (GTM)
External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled, the pulse integration is done until next external capture event occurs.

Operation is done depending on CMU clock, DSL bit and the input signal value defined in the next table:

Table 26-22 TIM integration Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	-	0	CNT++
1	1	0	-	0	no
1	1	0	-	1	CNT++
0	1	0	-	1	no
-	-	rising edge	-	-	do GPRx capture; issue NEWVAL_IRQ
-	0	0	-	-	no

TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields DSL and ISL in TIMi_CHx_CTRL register.

In addition, a TIM[i]_NEWVAL[x]_IRQ interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CNT is used to count the number of edges, and the bit fields EGPR0_SEL, EGPR1_SEL, GPR0_SEL, GPR1_SEL, and CNTS_SEL can be used to configure the desired update values for the registers GPR0, GPR1 and CNTS. These register are updated whenever the edge counter CNT is increment due to the arrival of a desired edge.

If the preceding data was not consumed by a reader attached to the ARU or by the CPU the TIM channel sets GPROFL status bit and raises a GPROFL[x]_IRQ if it was enabled in TIMi_CHx_IRQ_EN register and overwrites the old values in GPR0 and GPR1 with the new ones.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

Generic Timer Module (GTM)

The TIM Input Event Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on ISL, DSL bit and the input signal value defined in the next table:

Table 26-23 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	-	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a TIM[i]_NEWVAL[x]_IRQ is raised is programmable. In this mode it must be specified in the CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CNTS means that after one edge an interrupt is raised, and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields DSL and ISL of register TIMi_CHx_CTRL.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL and GPR1_SEL.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

Generic Timer Module (GTM)
External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on DSL, ISL bit and the input signal value defined in the next table:

Table 26-24 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
-	0	1	-	no
1	rising edge	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	-	0	1	no
0	rising edge	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	-	0	0	no

TIM Bit Compression Mode (TBCM)

The TIM Bit Compression Mode can be used to combine all filtered input signals of a TIM submodule to a parallel 8 bit data word, which can be routed to the ARU.

Since this mode uses all eight input signals with its input filters, it is only available within TIM channel 0 of each TIM submodule. [Figure 26-31](#) gives an overview of the TIM bit compression mode.

TIM Bit Compression Mode

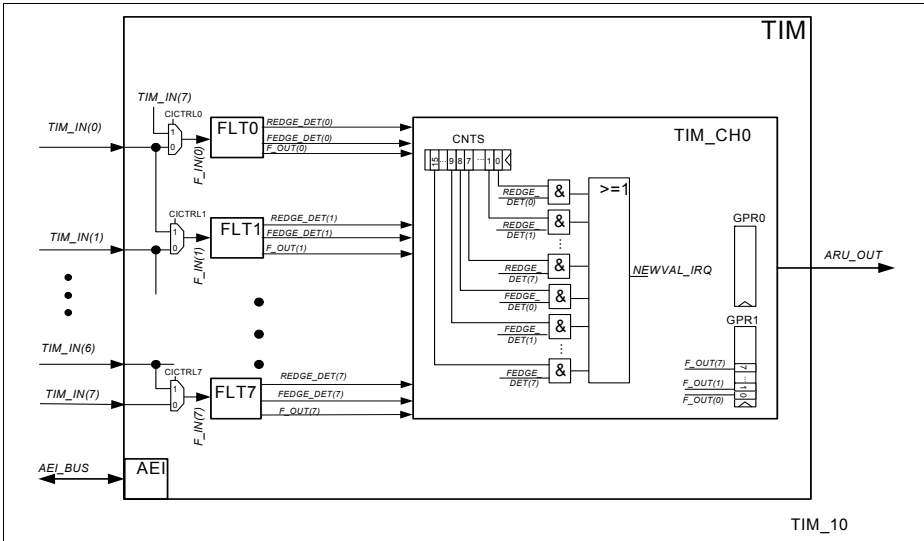

Figure 26-31 TIM Bit Compression Mode

The register CNTS of TIM channel 0 is used to configure the event that releases the NEWVAL_IRQ and samples the input signals F_IN(0) to F_IN(7) in ascending order as a parallel data word in GPR1.

The bits 0 to 7 of the CNTS register are used to select the REDGE_DET signals of the TIM filters 0 to 7 as a sampling event, and the bits 8 to 15 are used to select the FEDGE_DET signals of the TIM filters 0 to 7, respectively. If multiple events are selected, the events are OR-combined (see also [Figure 26-31](#)).

EGPR0_SEL, GRP0_SEL selects the timestamp value, which is routed through the ARU. GRP1_SEL is not applicable in TBCM mode.

If the bit ARU_EN of register TIMi_CH0_CTRL is set, the sampled data of register GPR1 is routed together with a time stamp of register GPR0 to the ARU, whenever the NEWVAL_IRQ is released.

In TIM Bit compression mode, the register ECNT increments on with each NEWVAL_IRQ, which means that the value of ECNT may depend on all eight input signals. Consequently, the LSB of ECNT does not reflect the actual level of the input signal TIM_IN0.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Bit Compression Mode does not depend on the bit field CLK_SEL of register TIMi_CHx_CTRL.

Generic Timer Module (GTM)
External capture Bit Compression Mode (TBCM)

If external capture is enabled, capturing is done depending on DSL, ISL bit and the input signal value defined in the next table:

Table 26-25 TIM Input Event Mode

Input signal F_OUTx	External capture	ISL	DSL	Action description
-	rising edge	1	-	do capture; issue NEWVAL_IRQ; CNT++
-	0	1	-	no
1	rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	-	0	1	no
0	rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	-	0	0	no

TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and rising TIMi_NEWVALx_IRQ is programmable. In this mode it must be specified in the CNTS register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in TIMi_CHx_CNTS means that after one CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the TIMi_CHx_CNT register the elapsed cycles were incremented and compared against TIMi_CHx_CNTS. If TIMi_CHx_CNT is greater or equal to TIMi_CHx_CNTS a trigger will be raised. This allows by writing a value to TIMi_CHx_CNTS that the actual period time can be changed on the fly.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 26-26 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no

In this mode the TIMi_CHx_GPR1 operates as a shadow register for TIMi_CHx_CNTS. This would allow that the period for the next sampling period could be specified. The update of TIMi_CHx_CNTS will only take place once on a trigger if the TIMi_CHx_GPR1 was written by the CPU. This means that the capture value from the previous trigger can be read by the CPU from TIMi_CHx_GPR1 and afterwards the new sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

When selecting ECNT as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture. Selecting GPR0_SEL = 11_B and EGPR0_SEL = 0_B for TIM channel 0 all 8 TIM input signals will captured to GPR[7:0].

In the TGPS Mode the bit field CLK_SEL of register TIMi_CHx_CTRL will define the selected CMU clock which will be used.

The behaviour of the ECNT counter is configurable by ECNT_RESET. If set to 1 on each interrupt (period expired) the ECNT will be reset. Otherwise it operates in wrap around mode.

Generic Timer Module (GTM)

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIMi_CHx_IRQ_NOTIFY and interrupt TIM_ECNTOFLx_IRQ is raised depending on corresponding interrupt enable condition.

External capture Bit Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter CNT and issue a NEWVAL_IRQ.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in the next table:

Table 26-27 TIM Gated Periodic Sampling Mode

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
-	1	0	1	-	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
0	0	-	0	1	no
0	1	0	0	0	if CNT == CNTS then do capture; issue NEWVAL_IRQ; CNT = 0; else CNT++ endif
1	0	0	0	0	no
-	0	0	-	-	no
-	-	rising edge	-	-	do capture; issue NEWVAL_IRQ; CNT = 0

26.10.5 MAP Submodule Interface

The GTM provides one dedicated TIM submodule TIM0 where channels zero (0) to five (5) are connected to the MAP submodule described in [Section 26.15](#). There, the TIM0 submodule channels provide the input signal level together with the actual filter value and the annotated time stamp for the edge together in a 49 bit wide signal to the MAP

Generic Timer Module (GTM)

submodule. This 49 bit wide data signal is marked as valid with a separate valid signal `tim0_map_dval[x]` (`x:0...5`).

Table 26-28 TIM0 to MAP Interface

tim0_map_data[x](48)	signal level bit from tim0_ch[x]
<code>tim0_map_data[x](47:24)</code>	actual filter value <code>TIM0_CHx_FLT_RE/TIM0_CHx_FLT_FE</code> if corresponding channel <code>x</code> bit field <code>FLT_MODE_RE/FLT_MODE_FE</code> is 1 else 0 is assigned.
<code>tim0_map_data[x](23:0)</code>	time stamp value selected by <code>TBU0_SEL</code> , <code>GRP0_SEL</code> , <code>EGPR0_SEL</code> , <code>CNTS_SEL</code> if channel <code>x</code> if bit field <code>TIM_EN=1</code>
<code>tim0_map_dval[x]</code>	mark <code>tim0_map_data[x]</code> valid for one clock cycle

Note: With `TIM_EN=1` the MAP interface starts operation, it is not dependent on the setting of the bit fields `TIM_MODE`, `ISL`, and `DSL`.

Note: While the MAP interface is in the use the following guidelines have to be fulfilled, otherwise inconsistent filter values can be transferred.

Change `TIM0_CHx_FLT_RE` only between occurrence of rising and falling edge.

Change `TIM0_CHx_FLT_FE` only between occurrence of falling and rising edge.

26.10.6 TIM Interrupt Signals

TIM provides 6 interrupt lines per channel. These interrupts are shown below:

Table 26-29 TIM Interrupt Signals

Signal	Description
<code>TIM[i]_NEWVAL[x]_IRQ</code>	New measurement value detected by SMU of channel <code>x</code> (<code>x:0...7</code>)
<code>TIM[i]_ECNTOFL[x]_IRQ</code>	ECNT counter overflow of channel <code>x</code> (<code>x:0...7</code>)
<code>TIM[i]_CNTOFL[x]_IRQ</code>	SMU CNT counter overflow of channel <code>x</code> (<code>x:0...7</code>)
<code>TIM[i]_GPROF[x]_IRQ</code>	GPR0 and GPR1 data overflow, old data was not read out before new data has arrived at input pin (<code>x:0...7</code>)
<code>TIM[i]_TODET[x]_IRQ</code>	Time out reached for input signal of channel <code>x</code> (<code>x:0...7</code>)
<code>TIM[i]_GLITCHDET_IRQ</code>	A glitch was detected by the TIM filter of channel (<code>x: 0...7</code>).

26.10.7 TIM Configuration Registers Overview

TIM contains following configuration registers:

Table 26-30 TIM Configuration Registers Overview

Register Name	Description	Detail in Section
TIMi_CHx_CTRL	TIM channel x control register (x:0...7)	Section 26.10.8.1 Section 26.10.8.2
TIMi_CHx_ECTRL	TIM channel x (x:0...7) extended control	Section 26.10.8.2 0
TIMi_CHx_FLT_RE	TIM channel x filter parameter 0 register (x:0...7)	Section 26.10.8.3
TIMi_CHx_FLT_FE	TIM channel x filter parameter 1 register (x:0...7)	Section 26.10.8.4
TIMi_CHx_TDUV	TIM channel x TDU control register (x:0...7)	Section 26.10.8.1 7
TIMi_CHx_TDUC	TIM channel x TDU counter register (x:0...7)	Section 26.10.8.1 8
TIMi_CHx_GPR0	TIM channel x general purpose 0 register (x:0...7)	Section 26.10.8.6
TIMi_CHx_GPR1	TIM channel x general purpose 1 register (x:0...7)	Section 26.10.8.7
TIMi_CHx_CNT	TIM channel x SMU counter register (x:0...7)	Section 26.10.8.8
TIMi_CHx_ECNT	TIM channel x (x:0...7) SMU edge counter	Section 26.10.8.1 9
TIMi_CHx_CNTS	TIM channel x SMU shadow counter register (x:0...7)	Section 26.10.8.9
TIMi_CHx_IRQ_NOTIFY	TIM channel x interrupt notification register (x:0...7)	Section 26.10.8.1 0
TIMi_CHx_IRQ_EN	TIM channel x interrupt enable register (x:0...7)	Section 26.10.8.1 1
TIMi_CHx_EIRQ_EN	TIM channel x (x:0...7) error interrupt enable	Section 26.10.8.1 6
TIMi_CHx_IRQ_FORCINT	TIM channel x software interrupt force register (x:0...7)	Section 26.10.8.1 2
TIMi_CHx_IRQ_MODE	TIM IRQ mode configuration register (x=0...7)	Section 26.10.8.1 3

Generic Timer Module (GTM)**Table 26-30 TIM Configuration Registers Overview (cont'd)**

Register Name	Description	Detail in Section

Generic Timer Module (GTM)

26.10.8.3 Register TIMi_CHx_FLT_RE (i:0...2)(x:0...7)

GTM_TIM0_CHx_FLT_RE (x=0-7)

GTM_TIM0 Channel x Filter Parameter 0 Register
(0101C_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM1_CHx_FLT_RE (x=0-7)

GTM_TIM1 Channel x Filter Parameter 0 Register
(0181C_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM2_CHx_FLT_RE (x=0-7)

GTM_TIM2 Channel x Filter Parameter 0 Register
(0201C_H+x*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
FLT_RE	[23:0]	rw	Filter parameter for rising edge Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for rising edge Individual deglitch time mode = deglitch time for rising edge
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero

26.10.8.4 Register TIMi_CHx_FLT_FE (i:0...2)(x:0...7)

GTM_TIM0_CHx_FLT_FE (x=0-7)

TIM0 Channel x Filter Parameter 1 Register

(01020_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM1_CHx_FLT_FE (x=0-7)

TIM1 Channel x Filter Parameter 1 Register

(01820_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM2_CHx_FLT_FE (x=0-7)

TIM2 Channel x Filter Parameter 1 Register

(02020_H+x*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
FLT_FE	[23:0]	rw	Filter parameter for falling edge Note: This register has different meanings in the various filter modes. Immediate edge propagation mode = acceptance time for falling edge Individual deglitch time mode = deglitch time for falling edge
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero

26.10.8.5 Register TIMi_CHx_TDU (i:0...2)(x:0...7)

Functionality is replaced by register TIMi_CHx_TDUV, TIMi_CHx_TDUC and bit field TOCTRL in Register TIMi_CHx_CTRL

Generic Timer Module (GTM)

26.10.8.6 Register TIMi_CHx_GPR0 (i:0...2)(x:0...7)

GTM_TIM0_CHx_GPR0 (x=0-7)

TIM0 Channel x General Purpose 0 Register

(01000_H+x*80_H)

Reset Value: 0X000000_H

GTM_TIM1_CHx_GPR0 (x=0-7)

TIM1 Channel x General Purpose 0 Register

(01800_H+x*80_H)

Reset Value: 0X000000_H

GTM_TIM2_CHx_GPR0 (x=0-7)

TIM2 Channel x General Purpose 0 Register

(02000_H+x*80_H)

Reset Value: 0X000000_H

Field	Bits	Type	Description
GPR0	[23:0]	r	<p>Input signal characteristic parameter 0</p> <p>Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR0_SEL, GPR0_SEL of register TIMi_CHx_CTRL.</p>
ECNT	[31:24]	r	<p>Edge counter</p> <p>Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT.</p> <p>Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.</p>

Generic Timer Module (GTM)

26.10.8.7 Register TIMi_CHx_GPR1 (i:0...2)(x:0...7)

GTM_TIM0_CHx_GPR1 (x=0-7)
 TIM0 Channel x General Purpose 1 Register
 (01004_H+x*80_H) Reset Value: 0X000000_H

GTM_TIM1_CHx_GPR1 (x=0-7)
 TIM1 Channel x General Purpose 1 Register
 (01804_H+x*80_H) Reset Value: 0X000000_H

GTM_TIM2_CHx_GPR1 (x=0-7)
 TIM2 Channel x General Purpose 1 Register
 (02004_H+x*80_H) Reset Value: 0X000000_H

Field	Bits	Type	Description
GPR1	[23:0]	r	<p>Input signal characteristic parameter 1</p> <p>Note: The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR1_SEL, GPR1_SEL of register TIMi_CHx_CTRL.</p> <p>Note: In TBCM mode if EGPR1_SEL=1, GPR1_SEL=01 then TIM_INP_VAL is used as input in all other cases TIM filter F_OUT is used as input and bits GPR1(23:8)=0.</p> <p>Note: The content of this register can only be written in TIM channel mode TGPS.</p>
ECNT	[31:24]	r	<p>Edge counter</p> <p>Note: The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT.</p> <p>Note: The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.</p>

Generic Timer Module (GTM)

26.10.8.8 Register TIMi_CHx_CNT (i:0...2)(x:0...7)

GTM_TIM0_CHx_CNT (x=0-7)

TIM0 Channel x SMU Counter Register

(01008_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM1_CHx_CNT (x=0-7)

TIM1 Channel x SMU Counter Register

(01808_H+x*80_H)

Reset Value: 00000000_H

GTM_TIM2_CHx_CNT (x=0-7)

TIM2 Channel x SMU Counter Register

(02008_H+x*80_H)

Reset Value: 00000000_H

26.11 Timer Output Module (TOM)

26.11.1 Overview

The Timer Output Module (TOM) offers 16 independent channels to generate simple PWM signals at each output pin TOM[i]_CH[x]_OUT (i=0...1; x=0...15).

Additionally, at TOM output TOM[i]_CH15_OUT a pulse count modulated signal can be generated.

The architecture of the TOM submodule is depicted in [Figure 26-32](#).

Some useful indices are defined as:

y=0,1

z=0...7

26.11.1.1 TOM Block diagram

Figure 26-32 TOM Block diagram

The two submodules TGC0 and TGC1 are global channel control units that control the enabling/disabling of the channels and their outputs as well as the update of their period and duty cycle register.

Generic Timer Module (GTM)

The module TOM receives two (three) timestamp values TBU_TS0, TBU_TS1 (and TBU_TS2) in order to realize synchronized output behaviour on behalf of a common time base.

The 5 dedicated clock line inputs CMU_FXCLK are providing divided clocks that can be selected to clock the output pins.

26.11.2 TOM Global Channel Control (TGC0, TGC1)

26.11.2.1 Overview

There exist two global channel control units (TGC0 and TGC1) to drive a number of individual TOM channels synchronously by external or internal events.

Each TGC[y] can drive up to eight TOM channels where TGC0 controls TOM channels 0 to 7 and TGC1 controls TOM channels 8 to 15.

The TOM submodule supports four different kinds of signalling mechanisms:

- Global enable/disable mechanism for each TOM channel with control register TOMi_TGCy_ENDIS_CTRL and status register TOMi_TGCy_ENDIS_STAT
- Global output enable mechanism for each TOM channel with control register TOMi_TGCy_OUTEN_CTRL and status register TOMi_TGCy_OUTEN_STAT
- Global force update mechanism for each TOM channel with control register TOMi_TGCy_FUPD_CTRL
- Update enable of the register CM0, CM1 and CLK_SRC_STAT for each TOM channel with the control bit field UPEN_CTRL[z] of TOMi_TGCy_GLB_CTRL

26.11.2.2 TGC Subunit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are:

- the host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL)
- the TBU time stamp (signal TBU_TS0., TBU_TS1, TBU_TS2)
- the internal trigger signal TRIG (bunch of trigger signals TRIG_[x])

Note: The trigger signal is only active for one configured CMU clock period.

As a consequence, if the configured CMU clock period of the channel generating the trigger TRIG_[X] is smaller than the CMU clock period of triggered channel, the triggered channel may not recognize the trigger signal TRIG_[X].

Thus, it is recommended to configure all channels connected via the trigger TRIG_[x] to the same CMU clock period.

Generic Timer Module (GTM)

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register TOMi_TGCy_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register TOMi_TGCy_ACT_TB.

Note, a signed compare of ACT_TB and selected TBU_TS[x] with x=0,1,2 is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIG_[x]) coming from the TOM channels 0 to 7 / 8 to 15.

The corresponding trigger signal TRIG_[x] coming from channel [x] can be masked by the register TOMi_TGCy_INT_TRIG.

To enable or disable each individual TOM channel, the registers TOMi_TGCy_ENDIS_CTRL and/or TOMi_TGCy_ENDIS_STAT have to be used.

The register TOMi_TGCy_ENDIS_STAT controls directly the signal ENDIS. A write access to this register is possible.

The register TOMi_TGCy_ENDIS_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_ENDIS_STAT if one of the three trigger conditions matches.

TOM Global channel control mechanism

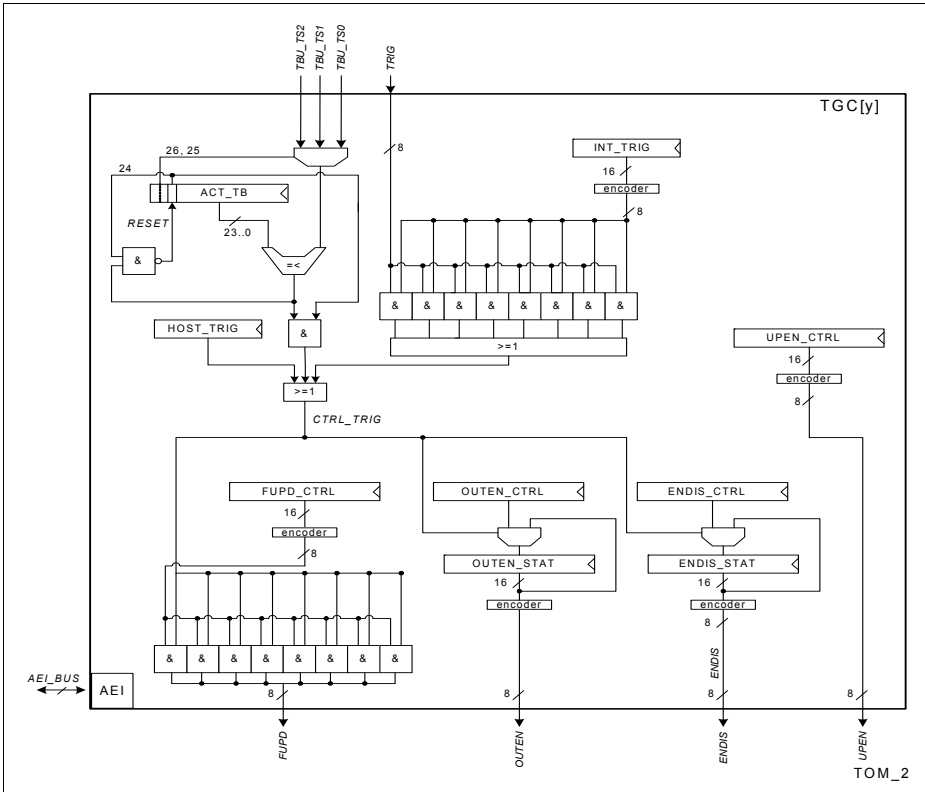

Figure 26-33 TOM Global channel control mechanism

The output of the individual TOM channels can be controlled using the register TOMi_TGCy_OUTEN_CTRL and TOMi_TGCy_OUTEN_STAT.

The register TOMi_TGCy_OUTEN_STAT controls directly the signal OUTEN. A write access to this register is possible.

The register TOMi_TGCy_OUTEN_CTRL is a shadow register that overwrites the value of register TOMi_TGCy_OUTEN_STAT if one of the three trigger conditions matches.

If a TOM channel is disabled by the register TOMi_TGCy_OUTEN_STAT, the actual value of the channel output at TOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register TOMi_CHx_CTRL.

If the output is enabled, the output at TOM_CH[x]_OUT depends on value of FlipFlop SOUR.

Generic Timer Module (GTM)

The register TOMi_TGCy_FUPD_CTRL defines which of the TOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

The register bits UPEN_CTRL[z] defines for which TOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see [Figure 26-34](#) and [Figure 26-35](#)).

26.11.3 TOM Channel (TOM_CH[x])

Each individual TOM channel comprises a Counter Compare Unit 0 (CCU0), a Counter Compare Unit 1 (CCU1) and the Signal Output Generation Unit (SOU). The architecture is depicted in [Figure 26-34](#) for channels 0 to 7 and in [Figure 26-35](#) for channels 8 to 15.

26.11.3.1 TOM Channel 0...7 architecture

Figure 26-34 TOM Channel 0...7 architecture

26.11.3.2 TOM Channel 8...14 architecture

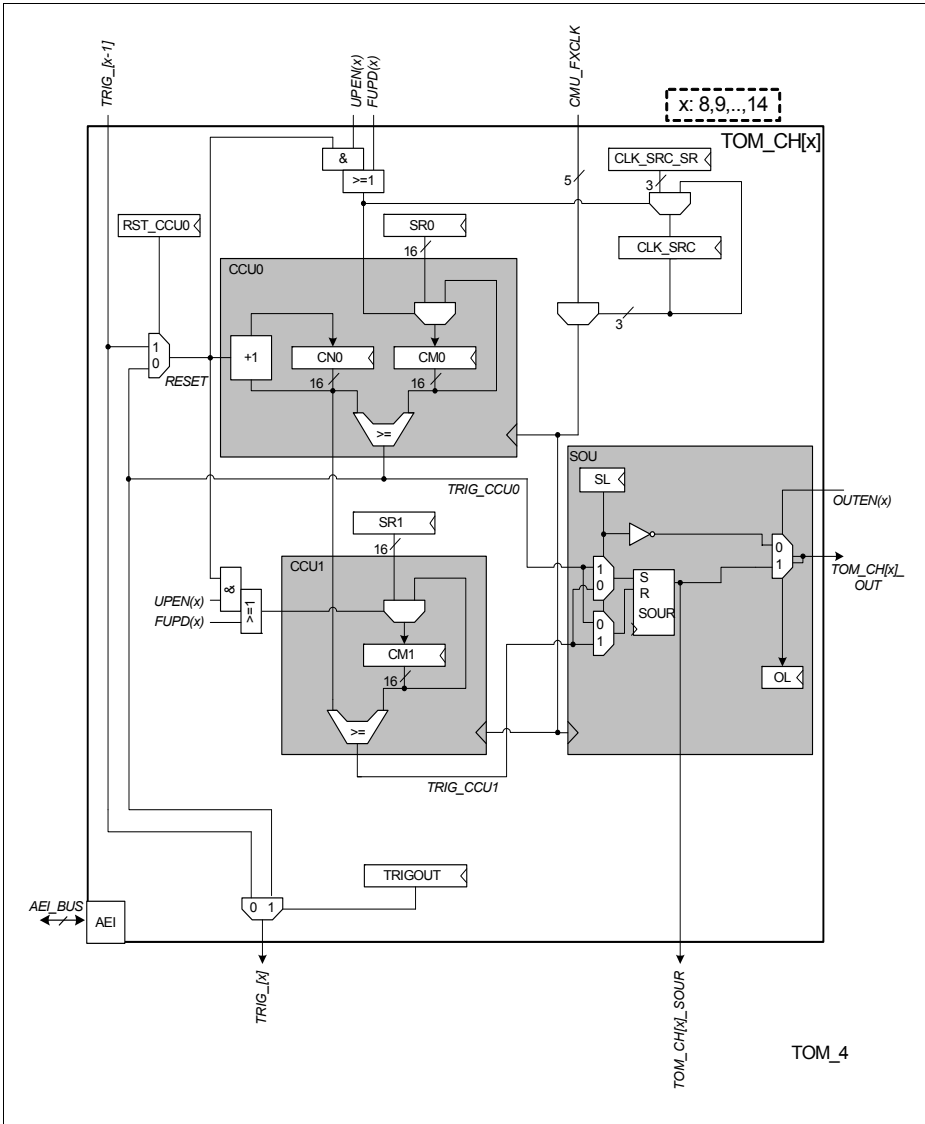

Figure 26-35 TOM Channel 8...14 architecture

26.11.3.3 TOM Channel 15 architecture for PCM generation

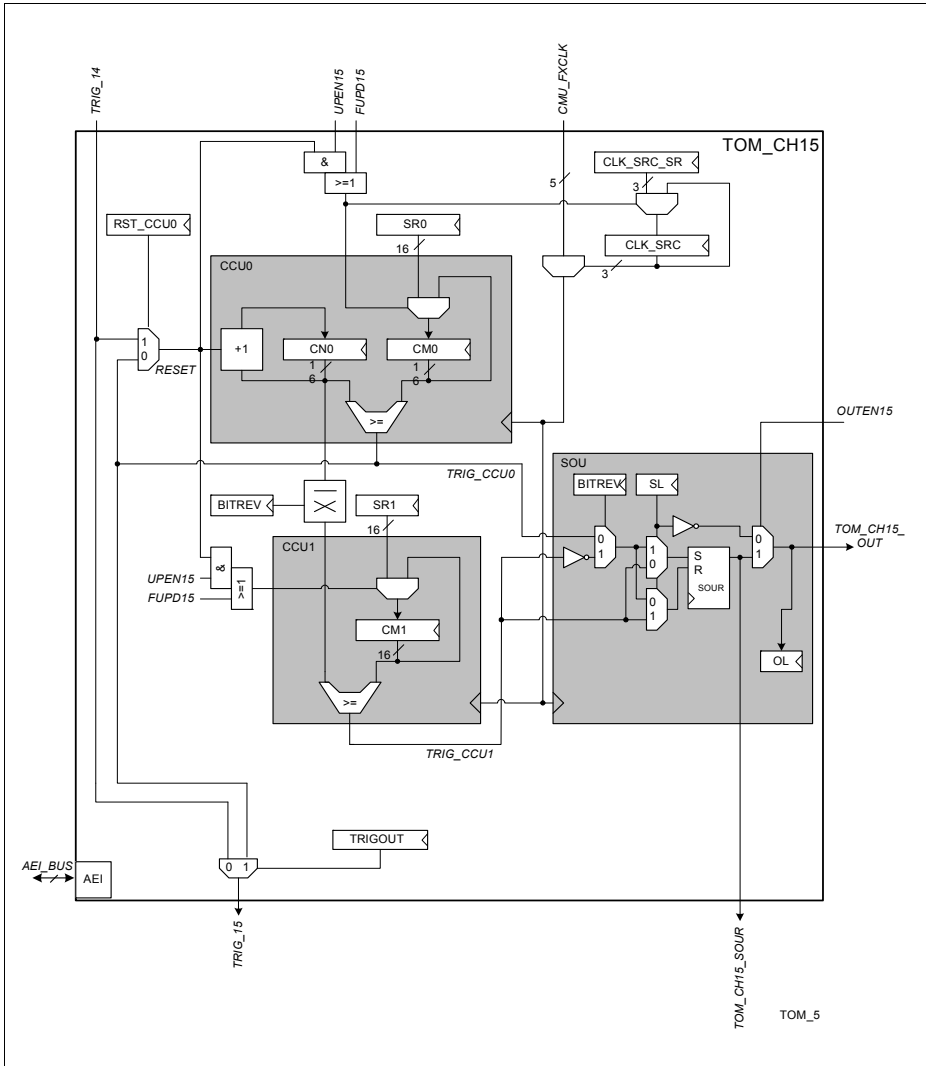

Figure 26-36 TOM Channel 15 architecture for PCM generation

Generic Timer Module (GTM)

The CCU0 contains a counter CN0 which is clocked with one of the selected input frequencies (CMU_FXCLK) provided from outside of the submodule.

Depending on configuration bits RST_CCU0 of register TOMi_CHx_CTRL the counter can be reset either when the counter value is equal to the compare value CM0 or when signalled by the TOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]).

When the counter register CN0 is greater or equal than the register CM0, the subunit CCU0 triggers the SOU subunit and the succeeding TOM submodule channel (signal TRIG_CCU0).

In the subunit CCU1 the counter register CN0 is compared with the value of register CM1. If CN0 is greater or equal than CM1 the subunit CCU1 triggers the SOU subunit (signal TRIG_CCU1).

If counter register CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of $CN0 \geq CM0$ configured by RST_CCU0=0), following statements are valid:

- if $CM0=0$ or $CM0=1$, 0% duty cycle ($=\overline{SL}$) is generated independent of CM1. The counter CN0 is not counting.
- the configuration of $CM1=0$ represents 0% duty cycle ($=\overline{SL}$) at the output
- the configuration of $CM1 \geq CM0$ represents 100% duty cycle ($=SL$)

If counter register CN0 of x channel is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0=1), following statements are valid:

- CM0 defines the edge to SL value, CM1 defines the edge to \overline{SL} value
- if $CM0=CM1$, the output is 100% SL (CM0 has higher priority)
- if $CM0=0$, the output stays at its last value (CN0 stops counting)

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the TOM channel.

The SOU subunit is responsible for output signal generation. On a trigger TRIG_CCU0 from subunit CCU0 or TRIG_CCU1 from subunit CCU1 a SR-FlipFlop of subunit SOU is either set or reset. If it is set or reset depends on the configuration bit SL of the control register TOMi_CHx_CTRL. The initial signal output level for the channel is the erse value of the bit SL.

Figure 26-39 clarifies the PWM output behaviour with respect to the SL bit definition.

The output level on the TOM channel output pin TOM[i]_CH[x]_OUT is captured in bit OL of register TOMi_CHx_STAT.

26.11.3.4 Duty cycle, period and selected counter clock frequency update mechanisms

The two action registers CM0 and CM1 can be reloaded with the content of the shadow registers SR0 and SR1. The register CLK_SRC that determines the clock frequency of

Generic Timer Module (GTM)

the counter register CN0 can be reloaded with its shadow register CLK_SRC_SR (bit field in register TOMi_CHx_CTRL)

The update of the register CM0, CM1 and CLK_SRC with the content of its shadow register is done when the reset of the counter register CN0 is requested (via signal RESET). This reset of CN0 is done if the comparison of CN0 greater or equal than CM0 is true or when the reset is triggered by another TOM channel [x-1] via the signal TRIG_[x-1].

For TOM0 channel 0 TRIG_[1] is '0' hard coded.

With the update of the register CLK_SRC at the end of a period a new counter CN0 clock frequency can easily be adjusted.

An update of duty cycle, period and counter CN0 clock frequency becoming effective synchronously with start of a new period can easily be reached by performing following steps:

1. disable the update of the action register with the content of the corresponding shadow register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '0'.
2. write new desired values to SR0, SR1, CLK_SRC_SR
3. enable update of the action register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOMi_TGCy_GLB_CTRL to '1'.

synchronous update of duty cycle only

A synchronous update of only the duty cycle can be done by simply writing the desired new value to register SR1 without preceding disable of the update mechanism (as described in the section above). The new duty cycle is then applied in the period following the period where the update of register SR1 was done.

synchronous update of duty cycle

Figure 26-37 synchronous update of duty cycle

asynchronous update of duty cycle only

If the update of the duty cycle should be performed independent of the start of a new period (asynchronous), the desired new value can be written directly to register CM1. In this case it is recommended to additionally either disable the synchronous update mechanism as a whole (i.e. clearing bits UPEN_CTRL[z] of corresponding channel [x] in register TOMi_TGXy_GLB_CTRL) or updating SR1 with the same value as CM1 before writing to CM1.

Depending on the point of time of the update of CM1 in relation to the actual value of CN0 and CM1, the new duty cycle is applied in the current period or the following period (see [Figure 26-38](#)). In any case the creation of glitches are avoided. The new duty cycle may jitter from update to update by a maximum of one period (given by CM0). However, the period remains unchanged.

asynchronous update of duty cycle

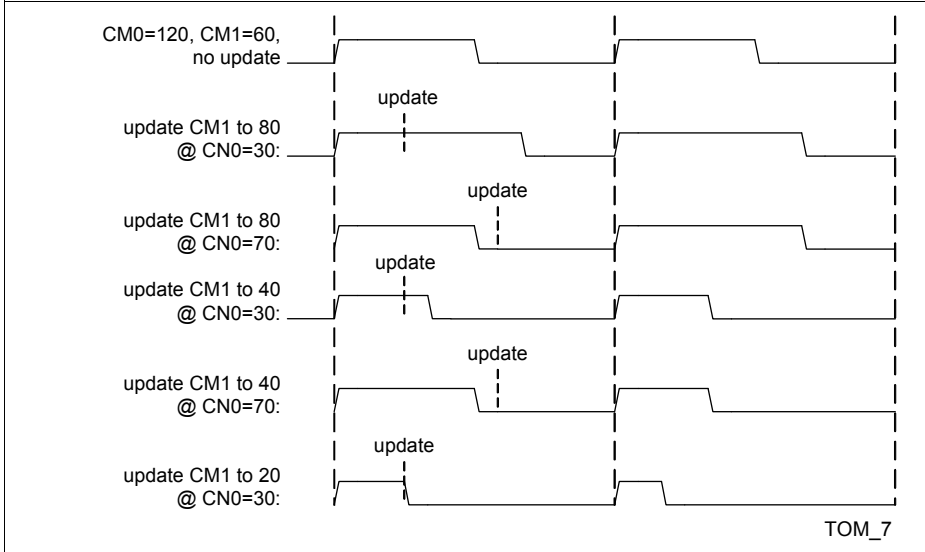

Figure 26-38 asynchronous update of duty cycle

26.11.3.5 TOM continuous mode

In continuous mode the TOM channel starts incrementing the counter register CN0 once it is enabled by setting the corresponding bits in register TOMi_TGCy_ENDIS_STAT (refer to [Section 26.11.2.2](#) for details of enabling a TOM channel).

The signal level of the generated output signal can be configured with the configuration bit SL of the channel configuration register TOMi_CHx_CTRL.

If the counter CN0 is reset from CM0 back to zero, the first edge of a period is generated at TOM[i]_CH[x]_OUT.

The second edge of the period is generated if CN0 has reached CM1.

Every time the counter CN0 has reached the value of CM0 it is reset back to zero and proceeds with incrementing.

PWM Output with respect to configuration bit SL in continuous mode

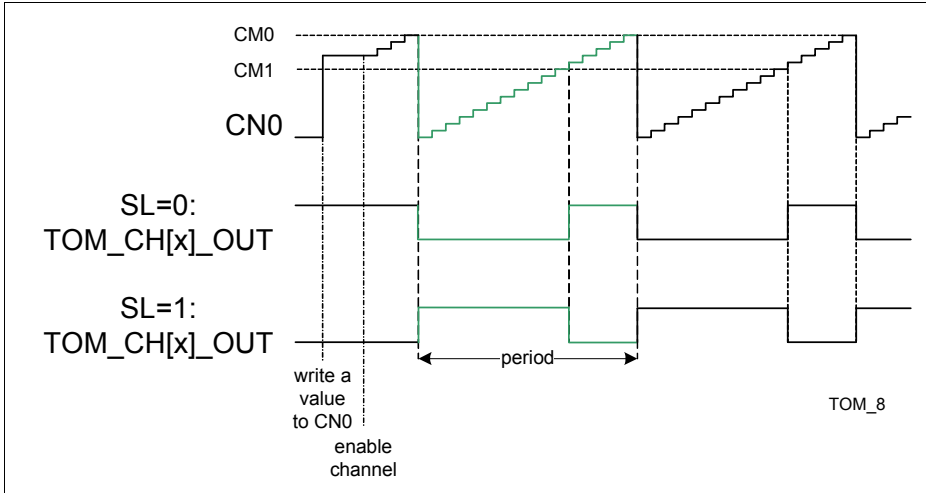

Figure 26-39 PWM Output with respect to configuration bit SL in continuous mode

26.11.3.6 TOM One shot mode

In One-shot mode, the TOM channel generates one pulse with a signal level specified by the configuration bit SL in the channel [x] configuration register TOMi_CHx_CTRL.

First the channel has to be enabled by setting the corresponding TOMi_TGCy_ENDIS_STAT value and the one-shot mode has to be enabled by setting bit OSM in register TOMi_CHx_CTRL.

In one-shot mode the counter CN0 will not be increment once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If SPE mode of TOM[i] channel 2 is enabled (set bit SPEM of register TOMi_CH2_CTRL), also the trigger signal SPE[i]_NIPD can trigger the reset of register CN0 to zero and a start of the pulse generation.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by $(CM0 - CN0)$ multiplied with period defined by current value of CLK_SRC.

If the counter CN0 is reset from CM0 back to zero, the first edge at TOM[i]_CH[x]_OUT is generated.

Generic Timer Module (GTM)

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRLx = 00 (in register TOMi_CHx_CTRL).

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was increment until it has reached CM1 or CN0 is greater than CM1 after an update of CM1). If the counter CN0 has reached the value of CM0 a second time, the counter stops.

PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

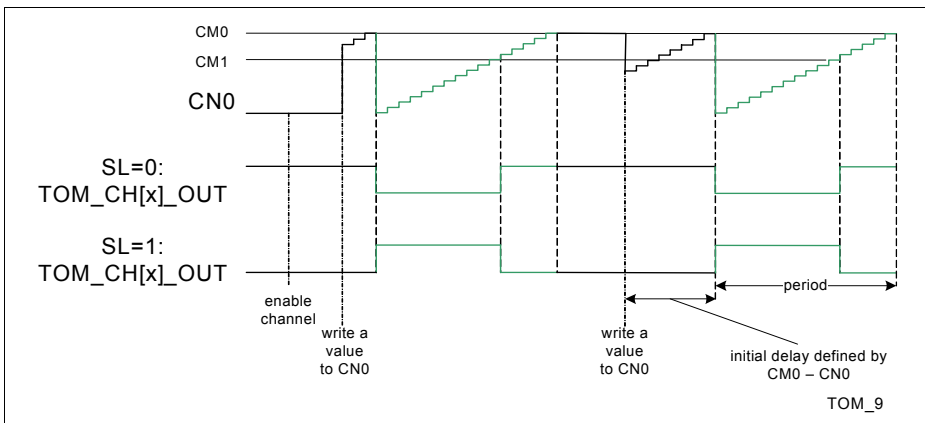

Figure 26-40 PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

Further output of single periods can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value $CN0_{start} < CM0$), the affect of a second write access to CN0 depends on the phase of CN0:

phase 1: update of CN0 before CN0 reaches first time CM0

phase 2: update of CN0 after CN0 has reached first time CM0 but less than CM1

phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value $CN0_{new} < CM0$ leads to shift of first edge (generated if CN0 reaches CM0 first time) by the time $CM0 - CN0_{new}$.

In phase 2: writing to incrementing counter CN0 a value $CN0_{new} < CM1$ while $CN0_{old}$ is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

Generic Timer Module (GTM)

In phase 3: writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

26.11.3.7 Pulse count modulation

At the output TOM[i]_CH15_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal.

Figure 26-36 outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit BITREV to 1.

With the configuration bit BITREV=1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 26-41**.

Bit reversing of counter

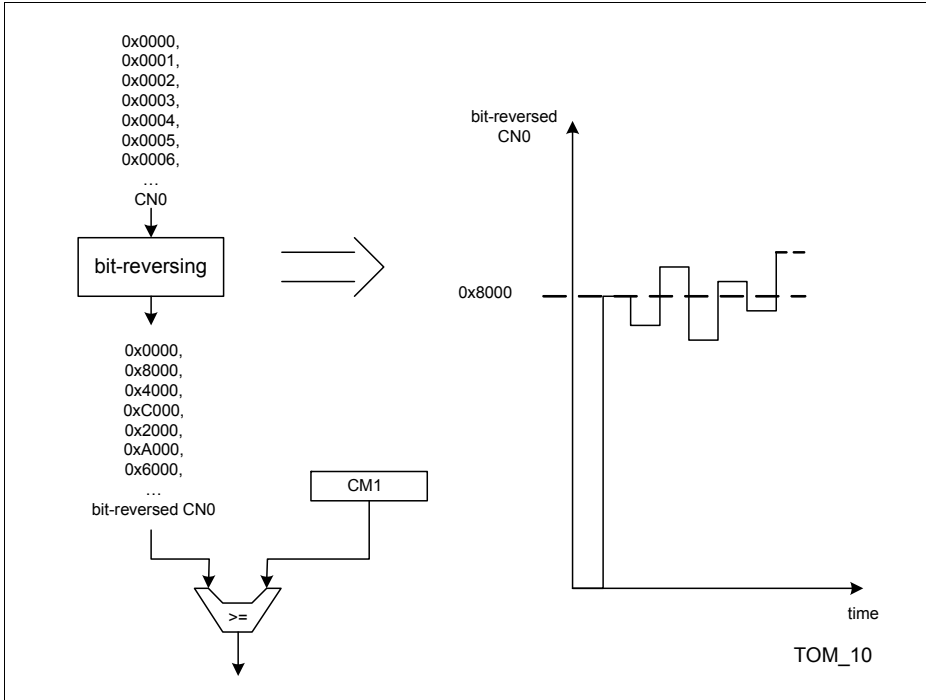

Figure 26-41 Bit reversing of counter

In the PCM mode the counter register CN0 is increment by every clock tick depending on configured CMU clock (CMU_FXCLK).

The output of counter register CN0 is first bit-reversed and than compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater than CM1, the SR-FlipFlop of submodule SOU is set (depending on configuration register SL) otherwise the SR-FlipFlop is reset. This generates at the output TOM[i]_CH15_OUT a pulse count modulated signal.

In PCM mode the CM0 register - in which the period id defined - normally has to be set to its maximum value 0xFFFF.

Note: In this mode the interrupt CCU1TC (see register ATOMi_CHx_IRQ_NOTIFY) is set every time if bitreserve values of CN0 is greater than or equal CM1 which may

Generic Timer Module (GTM)

be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

26.11.4 TOM BLDC Support

The TOM submodule offers in combination with the SPE submodule a BLDC support. To drive a BLDC engine TOM channels 0 to 7 can be used.

The BLDC support can be configured by setting the SPEM bit inside the TOM_i_CH_[z]_CTRL register. When this bit is set the TOM channel output is controlled through the SPE_OUT_(z) signal coming from the SPE submodule (see [Figure 26-34](#)). Please refer to [Section 26.17](#) for a detailed description of the SPE submodule.

The TOM_[i]_CH₂ can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register after new input pattern detected by SPE (signalled by SPE_[i]_NIPD). This feature is configured on TOM_[i]_CH₂ by setting SPEM=1 and OSM=1. For details please refer to section of SPE submodule description.

26.11.5 TOM Gated Counter Mode

Each TOM - SPE module combination provides also the feature of a gated counter mode. This is reached by using the FSOI input of a TIM module to gate the clock of a CCU0 submodule.

To configure this mode, registers of module SPE should be set as following:

- the SPE should be enabled (bit SPE_EN = 1),
- all three TIM inputs should be disabled (SIE0 = SIE1 = SIE2 = 0),
- SPE_i_OUT_CTRL should be set to 00005555h (set SPE_OUT() to '0'),
- mode FSOM should be enabled (FSOM=1),
- set in bit field FSOL bit c if channel c of module TOM is chosen for gated counter mode

Additionally in module TOM

- the SPE mode should be disabled (SPEM=0) and
- the gated counter mode should be enabled (GCM=1)

As a result of this configuration, the counter CN0 in submodule CCU0 of TOM channel c counts as long as input FSOI is '0'.

26.11.6 TOM Interrupt signals

The following table describes TOM interrupt signals:

Table 26-31 TOM Interrupt signals

Signal	Description
TOM_CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
TOM_CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

26.11.7 TOM Configuration Register overview

The following table gives an overview of the TOM configuration registers.

Table 26-32 TOM Configuration Register overview

Register name	Description	Details in Section

TOMi TGC0 Action Time Base Register

 $(0D04C_H + i * 800_H)$

 Reset Value: 00000000_H

Field	Bits	Type	Description
ACT_TB	[23:0]	rw	Time base value specifies the signed compare value with selected signal TBU_TCx (x=0...2). If selected TBU_TSx value is in the interval [ACT_TB-007FFFFFFF _H ,ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TSx is equal to ACT_TB.
TB_TRIG	24	rwh	Set trigger request 0 _B no trigger request 1 _B set trigger request Note: This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.

Generic Timer Module (GTM)

Field	Bits	Type	Description
TBU_SEL	[26:25]	rw	Selection of time base used for comparison 00 _B TBU_TS0 selected 01 _B TBU_TS1 selected 10 _B TBU_TS2 selected 11 _B Reserved; same as 00 _B Note: The bit combination “10” is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Please refer to GTM Architecture block diagram on page 3 to determine the number of channels for TBU of this device.
Reserved	[31:27]	r	Reserved Read as zero, should be written as zero

26.11.8.5 Register TOMi_TGC0_OUTEN_CTRL

GTM_TOMi_TGC0_OUTEN_CTRL (i=0-1)

TOMi TGC0 Output Enable Control Register

(08078_H+i*800_H)

Reset Value: 00000000_H

GTM_TOMi_TGC1_OUTEN_CTRL (i=0-1)

TOMi TGC1 Output Enable Control Register

(08278_H+i*800_H)

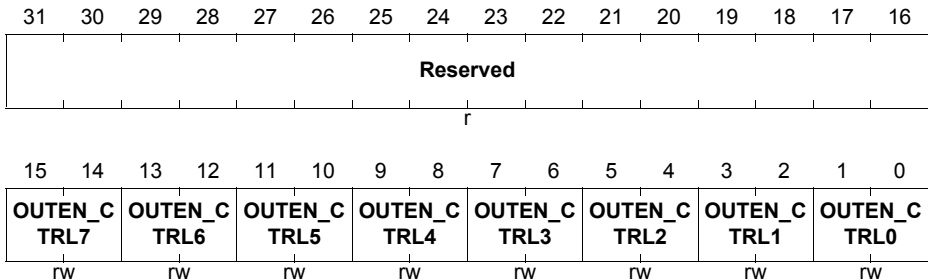

Reset Value: 00000000_H

GTM_ATOMi_AGC_OUTEN_CTRL (i=0-3)

ATOMi AGC Output Enable Control Register

(0D050_H+i*800_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
OUTEN_C TRL0	[1:0]	rw	Output (A)TOM_OUT(0) enable/disable update value Write of following double bit values is possible: 00 _B don't care, bits 1:0 of register OUTEN_STAT will not be changed on an update trigger 01 _B disable channel output on an update trigger 10 _B enable channel output on an update trigger 11 _B don't change bits 1:0 of this register Note: if the channel is disabled (ENDIS[0]=0) or the output is disabled (OUTEN[0]=0), the TOM channel 0 output TOM_OUT[0] is the inverted value of bit SL.
OUTEN_C TRL1	[3:2]	rw	Output (A)TOM_OUT(1)enable/disable update value See bits 1:0
OUTEN_C TRL2	[5:4]	rw	Output (A)TOM_OUT(2) enable/disable update value See bits 1:0
OUTEN_C TRL3	[7:6]	rw	Output (A)TOM_OUT(3) enable/disable update value See bits 1:0
OUTEN_C TRL4	[9:8]	rw	Output (A)TOM_OUT(4) enable/disable update value See bits 1:0

26.12 ARU-connected Timer Output Module (ATOM)

26.12.1 Overview

The ARU-connected Timer Output Module (ATOM) is able to generate complex output signals without CPU interaction due to its connectivity to the ARU. Typically, output signal characteristics are provided over the ARU connection through submodules connected to ARU like e.g. the MCS, DPLL or PSM. Each ATOM submodule contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the ATOM submodule is depicted in [Figure 26-42](#).

26.12.1.1 ATOM Block diagram

Figure 26-42 ATOM Block diagram

The architecture of the ATOM submodule is similar to the TOM submodule, but there are some differences. First, the ATOM integrates only eight output channels. Hence, there exists one ATOM Global Control subunit (AGC) for the ATOM channels. The ATOM is

Generic Timer Module (GTM)

connected to the ARU and can set up individual read requests from the ARU and write requests to the ARU. Furthermore, the ATOM channels are able to generate signals on behalf of time stamps and the ATOM channels are able to generate a serial output signal on behalf of an internal shift register.

Each ATOM channel provides four modes of operation:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)

These modes are described in more detail in [Section 26.12.3](#).

The ATOM channels' operation registers (e.g. counter, compare registers) are 24 bit wide. Moreover, the input clocks for the ATOM channels come from the configurable CMU_CLKx signals of the CMU submodule. This gives the freedom to select a programmable input clock for the ATOM channel counters. The ATOM channel is able to generate a serial bit stream, which is shifted out at the ATOM[i]_CH[x]_OUT output. When configured in this serial shift mode (SOMS) the selected CMU clock defines the shift frequency.

Each ATOM channel provides a so called operation and shadow register set. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over CPU and/or ARU.

When update via ARU is selected, it is possible to configure if both shadow registers are updated via ARU or only one of the shadow registers is updated for SOMP mode.

On the other hand, the shadow registers can be used to provide data to the ARU when one or both of the compare units inside an ATOM channel match. This feature is only applicable in SOMC mode.

In TOM channels it is possible to reload the content of the operation registers with the content of the corresponding shadow registers and change the clock input signal for the counter register simultaneously. This simultaneous change of the input clock frequency together with reloading the operation registers is also implemented in the ATOM channels.

In addition to the feature that the CPU can select another CMU_CLKx during operation (i.e. updating the shadow register bit field CLK_SRC_SR of the ATOMi_CHx_CTRL register), the selection can also be changed via the ARU. Then, for the clock source update, the ACBI register bits of the ATOMi_CHx_STAT register are used as a shadow register for the new clock source.

In general, the behaviour of the compare units CCU0 and CCU1 and the output signal behaviour is controlled with the ACB bit field inside the ATOMi_CHx_CTRL register when the ARU connection is disabled and the behaviour is controlled via ARU through the ACBI bit field of the ATOMi_CHx_STAT register, when the ARU is enabled.

Generic Timer Module (GTM)

Since the ATOM is connected to the ARU, the shadow registers of an ATOM channel can be reloaded via the ARU connection or via CPU over its AEI interface. When loaded via the ARU interface, the shadow registers act as a buffer between the ARU and the channel operation registers. Thus, a new parameter set for a PWM can be reloaded via ARU into the shadow registers, while the operation registers work on the actual parameter set.

26.12.1.2 ATOM Global control (AGC)

Synchronous start and stop of more than one output channel is possible with the AGC subunit. This subunit has the same functionality as the TGC subunit of the TOM submodule. For a description of the AGC subunit functionality, please refer therefore to [Section 26.11.2](#).

26.12.1.3 ATOM Channel mode overview

Each ATOM channel offers the following different operation modes.

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channels generate an output signal immediately after receiving an ARU word according to the two signal level output bits of the ARU word received through the ACBI bit field. Due to the fact, that the ARU destination channels are served in a round robin order, the output signal can jitter in this mode with a jitter of the ARU round trip time.

In ATOM Signal Output Mode Compare (SOMC), the ATOM channel generates an output signal on behalf of time stamps that are located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new time stamps either by CPU or via the ARU. The new time stamps are directly loaded into the channels operation register. The shadow registers are used as capture registers for the two time base values, when a compare match of the channels operation registers occurs.

In ATOM Signal Output Mode PWM (SOMP), the ATOM channel is able to generate simple and complex PWM output signals like the TOM submodule by comparing its operation registers with a submodule internal counter. In difference to the TOM, the ATOM shadow registers can be reloaded by the CPU and by the ARU in the background, while the channel operates on the operation registers.

In ATOM Signal Output Mode Serial (SOMS), the ATOM channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the CMU_CLKx clock signals. Please refer to [Section 26.12.3.4](#) for further details.

26.12.2 ATOM Channel architecture

Each ATOM channel is able to generate output signals according to four operation modes. The architecture of the ATOM channels is similar to the architecture of the TOM channels. The general architecture of an ATOM channel is depicted in **Figure 26-43**.

26.12.2.1 ATOM Channel architecture

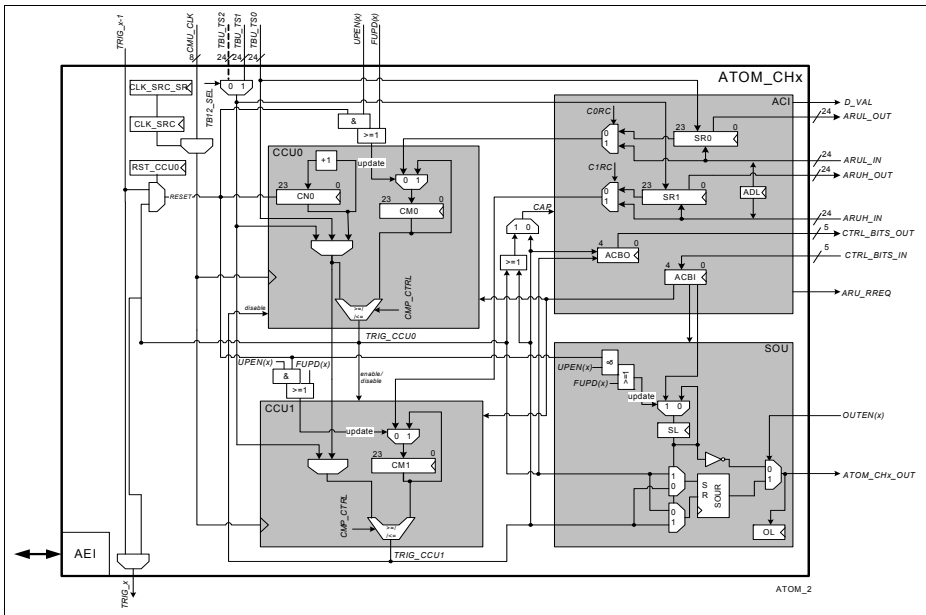

Figure 26-43 ATOM Channel architecture

For all ATOM channels the bit width is 24 of the operation register CN0, CM0 and CM1 and the shadow register SR0 and SR1. The comparators inside CCU0 and CCU1 provide a selectable signed greater/equal or less/equal comparison to compare against the GTM time bases TBU_TS0 and TBU_TS1. If there is a third time base TBU_TS2 implemented inside the GTM, this time base can also be selected inside the ATOM channel with the TB12_SEL bit inside the ATOMi_CHx_CTRL register for comparison. Please refer to TBU **Section 26.9** for further details. For an overview of the implemented TBU submodule version please refer to **Section 26.2.1.1**. The CCU0 and CCU1 units have different tasks for the different ATOM channel modes.

The signed compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first

Generic Timer Module (GTM)

overflow and then reach the compare value. Please note, that for a correct behaviour of this signed compare, the new compare value must not be specified larger/smaller than half of the range of the total time base value (0x7FFFFFFF).

In SOMC mode, the two compare units CCUx can be used in combination to each other. When used in combination, the trigger lines TRIG_CCU0 and TRIG_CCU1 can be used to enable/disable the other compare unit on a match event. Please refer to [Section 26.12.3.2](#) for further details.

The Signal Output Unit (SOU) generates the output signal for each ATOM channel. This output signal level depends on the ATOM channel mode and on the SL bit of the ATOMi_CHx_CTRL register in combination with the two control bits. These two control bits ACB(1) and ACB(0) can either be received via CPU in the ACB register field of the ATOMi_CHx_CTRL register or via ARU in the ACBI bit field of the ATOMi_CHx_STAT register.

The SL bit in the ATOMi_CHx_CTRL register defines in all modes the operational behaviour of the ATOM channel.

When the channel and its output is disabled, the output signal level of the channel is the inverse of the SL bit.

In SOMI and SOMC mode the output signal level depends on the SL, ACB0 and ACB1 bits. In SOMP mode the output signal level depends on the two trigger signals TRIG_CCU0 and TRIG_CCU1 since these two triggers define the PWM timing characteristics and the SL bit defines the level of the duty cycle. In SOMS mode the output signal level is defined by the bit pattern that has to be shifted out by the ATOM channel. The bit pattern is located inside the CM1 register.

The ARU Communication Interface (ACI) subunit is responsible for requesting data routed through ARU to the ATOM channel in SOMI, SOMP and SOMS modes, and additionally for providing data to the ARU in SOMC mode.

In SOMC mode the ACI shadow registers have a different behaviour and are used as output buffer registers for data send to ARU.

26.12.2.2 ARU Communication Interface

The ATOM channels have an ARU Communication Interface (ACI) subunit. This subunit is responsible for data exchange from and to the ARU. This is done with the two implemented registers SR0, SR1, and the ACBI and ACBO bit fields that are part of the ATOMi_CHx_STAT register. The ACI architecture is shown in [Figure 26-44](#).

If the ARU_EN bit is set inside the ATOMi_CHx_CTRL register, the ATOM channel is enabled by setting the enable bits inside the ATOMi_AGC_ENDIS_STAT register and the CPU hasn't written data not equal to zero into the CM0, CM1, SR0, SR1 register, the ATOM channel will first request data from the ARU before the signal generation starts in SOMP, SOMS and SOMC mode.

Generic Timer Module (GTM)

Note: if in SOMP mode there is data inside the CM0 or SR0 register not equal to '0' the channel counter CN0 will start counting immediately, regardless whether the channel has received ARU data yet.

Note: if in SOMS mode there is data inside the CM0 or SR0 register not equal to '0' the channel will start shifting immediately, regardless whether the channel has received ARU data yet.

ACI Architecture overview

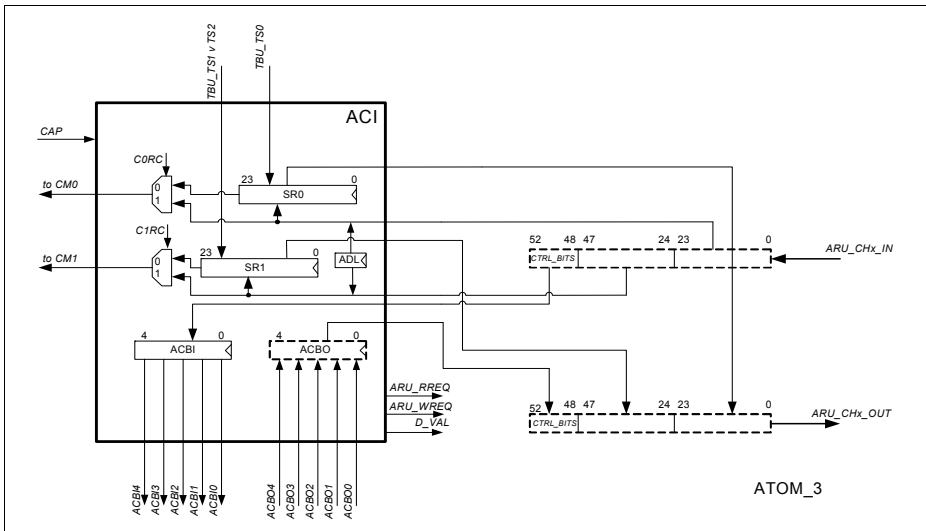

Figure 26-44 ACI Architecture overview

Incoming ARU data (53 bit width signal ARU_CHx_IN) is split into three parts by the ACI and communicated to the ATOM channel registers. In SOMI, SOMP and SOMS modes incoming ARU data ARU_CHx_IN is split in a way that the lower 24 bits of the ARU data (23 down to 0) are stored in the SR0 register, the upper bits (47 down to 24) are stored in the SR1 register and the bits 52 down to 48 (CTRL_BITS) are stored in the ACBI bit field of the register ATOMi_CHx_STAT.

The ATOM channel has to ensure, that in a case when the channel operation registers CM0 and CM1 are updated with the SR0 and SR1 register content and an ARU transfer to these shadow registers happens in parallel that either the old data in both shadow registers is transferred into the operation registers or both new values from the ARU are transferred.

Generic Timer Module (GTM)

In SOMC mode incoming ARU data ARU_CHx_IN is written directly to the ATOM channel operation register in the way that the lower 24 bits (23 down to 0) are written to CM0, and the bits 47 down to 24 are written to register CM1. The bits 52 down to 48 are stored in the ACBI bit field of the ATOMi_CHx_STAT register and control the behaviour of the compare units and the output signal of the ATOM channel.

In SOMC mode the SR0 and SR1 registers serve as capture registers for the time stamps coming from TBU whenever a compare match event is signalled by the CCU0 and/or CCU1 subunits via the CAP signal line. These two time stamps are then provided together with actual ATOM channel status information located in the ACBO bit field to the ARU at the dedicated ARU write address of the ATOM channel when the ARU is enabled.

The encoding of the ARU control bits in the different ATOM operation modes is described in more detail in the following sections.

26.12.3 ATOM Channel modes

As described above, each ATOM channel can operate independently from each other in one of four dedicated output modes:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)

The Signal Output Mode PWM (SOMP) is principally the same like the output mode for the TOM submodule except the bit erase mode which is not included in the ATOM. In addition, it is possible to reload the shadow registers over the ARU without the need of a CPU interaction. The three other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

26.12.3.1 ATOM Signal Output Mode Immediate (SOMI)

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channel generates output signals on the ATOM[i]_CH[x]_OUT output port immediate after update of the bit ACBI(0) of register ATOMi_CHx_STAT or ACB(0) bit of register ATOMi_CHx_CTRL.

If ARU access is enabled by setting bit ARU_EN in register ATOMi_CHx_CTRL, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACBI(0) of register ATOMi_CHx_STAT received at the ACI subunit and the bit SL bit of register ATOMi_CHx_CTRL. The remaining 48 ARU bits (47 down to 0) have no meaning in this mode.

If ARU access is disabled, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACB(0) and the bit SL of register ATOMi_CHx_CTRL.

The initial ATOM channel port pin ATOM[i]_CH[x]_OUT signal level has to be specified by the SL bit field (

Generic Timer Module (GTM)

=0 defined in this mode, see [Figure 26-43](#)) of the ATOMi_CHx_CTRL register when OUTEN_CTRL register bit field OUTEN_CTRLx is disabled (see [Chapter 26.11.8.9](#)) for details.

In SOMI mode the output behaviour depends on the SL bit of register ATOMi_CHx_CTRL and the bit ACBI(0) of the ATOMi_CHx_STAT register or the bit ACB0 of register ATOMi_CHx_CTRL:

Table 26-33 Signal Output Mode Immediate Status information

SL	ACBI(0)/ ACB(0)	Output behaviour
0	0	Set output to inverse of SL (1)
0	1	Set output to SL (0)
1	0	Set output to inverse of SL (0)
1	1	Set output to SL (1)

The signal level bit ACBI(0) is transferred to the SOU subunit of the ATOM and made visible at the output port according to the table above immediately after the data was received by the ACI. This can introduce a jitter on the output signal since the ARU channels are served in a time multiplexed fashion.

26.12.3.2 ATOM Signal Output Mode Compare (SOMC)

Overview

In ATOM Signal Output Mode Compare (SOMC) the output action is performed in dependence of the comparison between input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation please refer to the TBU specification in [Section 26.9](#). It is configurable, which of the two (three) time bases is to be compared with one or both values in CM0 and CM1.

The behaviour of the two compare units CCU0 and CCU1 is controlled either with the bits 4 down to 2 of ACB bit field inside the ATOMi_CHx_CTRL register, when the ARU connection is disabled or with the ACBI bit field of the ATOMi_CHx_STAT register, when

Generic Timer Module (GTM)

the ARU is enabled. In that case the ACB bit field is updated via the ARU control bits 52 down to 48.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 always create edges, dependent on the predefined signal level in SL bit in combination with two control bits that can be specified by either ARU or CPU within the aforementioned ATOMi_CHx_CTRL or ATOMi_CHx_STAT registers.

In SOMC mode the channel is always disabled after the specified compare match event occurred. The shadow registers are used to store two time stamp values at the match time. The channel can be enabled again by first reading the shadow registers, either by CPU or ARU and by providing new data for CMx registers through CPU or ARU. For a detailed description please refer to [SOMC Mode under CPU control](#) and [SOMC Mode under ARU control](#).

If three time bases exist for the GTM-IP there must be a preselection between TBU_TS1 and TBU_TS2 for the ATOM channel. This can be done with TB12_SEL bit in the ATOMi_CHx_CTRL register.

The comparison in CCU0/1 with time base TBU_TS1 or TBU_TS2 can be done on a greater/equal or less/equal compare according to the CMP_CTRL bit. This control bit has no effect to a compare unit CCU0 or CCU1 that compares against TBU_TS0. In this case always a greater/equal compare is done. The bit CMP_CTRL is part of the ATOMi_CHx_CTRL register.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the ATOM channel is determined by the SL bit in the ATOMi_CHx_CTRL register. If the output is disabled, the signal level is set to the inverse level of the SL bit.

If the channel is disabled, the register SOUR is set to the SL bit in the ATOMi_CHx_CTRL register.

On a compare match event the shadow register SR0 and SR1 are used to capture the TBU time stamp values. SR0 always holds TBU_TS0 and SR1 either holds TBU_TS1 or TBU_TS2 dependent on the TB12_SEL bit in the ATOMi_CHx_CTRL register.

Please note, that when the channel is disabled and the compare registers are written, the compare registers CMx are loaded with the written value and the channel starts with the comparison on behalf of this values, when the channel is enabled.

SOMC Mode under CPU control

As already mentioned above the ATOM channel can be controlled either by CPU or by ARU. When the channel should be controlled by CPU, the ARU_EN bit inside the ATOMi_CHx_CTRL register has to be reset.

The output of the ATOM channel is set on a compare match event depending on the ACB10 bit field in combination with the SL bit both located in the ATOMi_CHx_CTRL

Generic Timer Module (GTM)

register. The output behaviour according to the ACB10 bit field in the control register is shown in the following table:

Table 26-34 SOMC Output behaviour

SL	ACB10(5)	ACB10(4)	Output behaviour
0	0	0	No signal level change at output (exception in Figure 26-45 mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in Figure 26-45 mode ACB42=001)
1	0	0	No signal level change at output (exception in Figure 26-45 mode ACB42=001)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in Figure 26-45 mode ACB42=001)

The capture/compare strategy of the two CCUx units can be controlled with the ACB42 bit field inside the ATOMi_CHx_CTRL register. The meaning of these bits is shown in the following table:

Table 26-35 Bit definitions for Capture / Compare operation

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see Figure 26-45
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see Figure 26-45

Generic Timer Module (GTM)
Table 26-35 Bit definitions for Capture / Compare operation (cont'd)

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACB10(5) and ACB10(4).
1	1	1	Not used when ARU disabled.

The behaviour of the ACBI/ACB42 bit combinations '000' and '001' is described in more detail in [Figure 26-45](#).

Figure 26-45 ATOM CCUx Serve first definition

Generic Timer Module (GTM)

If the ATOM channel is enabled, the CM0 and/or CM1 registers and the ACB42 bit field of the ATOMi_CHx_CTRL register can be updated by the CPU as long as the first match event occurs in case of a serve last compare strategy or as long as the overall match event in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers SR0/SR1 and before reading the SR0 and/or SR1 register via ARU, the update of the registers CM0 and/or CM1 is possible but has no effect.

To set up a new compare action, first the SR0 and/or SR1 register containing captured values have to be read and then new compare values have to be written into the register CM0 and/or CM1.

Which CMx register has to be updated depends on the compare strategy defined in the ACB42 bit field of the channel control register. Since the channel immediately starts with the comparison after the CMx register was/were written, the compare strategy has to be updated before the CMx registers are written.

For the serve last compare strategies, if the register CM0 and CM1 are updated, it can happen that one or both compare values are already located in the past. In any way the ATOM channel will first wait until both compare values are written, before it starts the time base comparisons to avoid a deadlock.

The CPU can check at any time if at least one of the ATOM channels' capture compare registers contains valid data and waits for a compare event to happen. This is signalled by the DV bit inside the ATOMi_CHx_STAT register.

Note: For serve last compare strategies, if DV bit is currently not set, writing to CM0 or CM1 sets immediately the DV bit although the compare is only started if both values are written.

In SOMC mode and CCUx control mode 'serve last' exist an exception for update of register CM0/CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU is blocked until the CCU1 compare match event.

In the serve last mode (ACB42="100" or ACB42="101") it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACB10(5) and ACB10(4) bits in the ACB10 bit field of the ATOMi_CHx_CTRL register on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

In addition to storing the captured time stamps in the shadow registers, the ATOM channel provides the result of the compare match event in the ACBO(4) and ACBO(3)

Generic Timer Module (GTM)

bits of the ATOMi_CHx_STAT register. The meaning of the bits is shown in the following table:

Table 26-36 ACBO3 / 4 Bit encoding

ACBO(4)	ACBO(3)	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the SLA-bit in the ATOMi_CHx_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

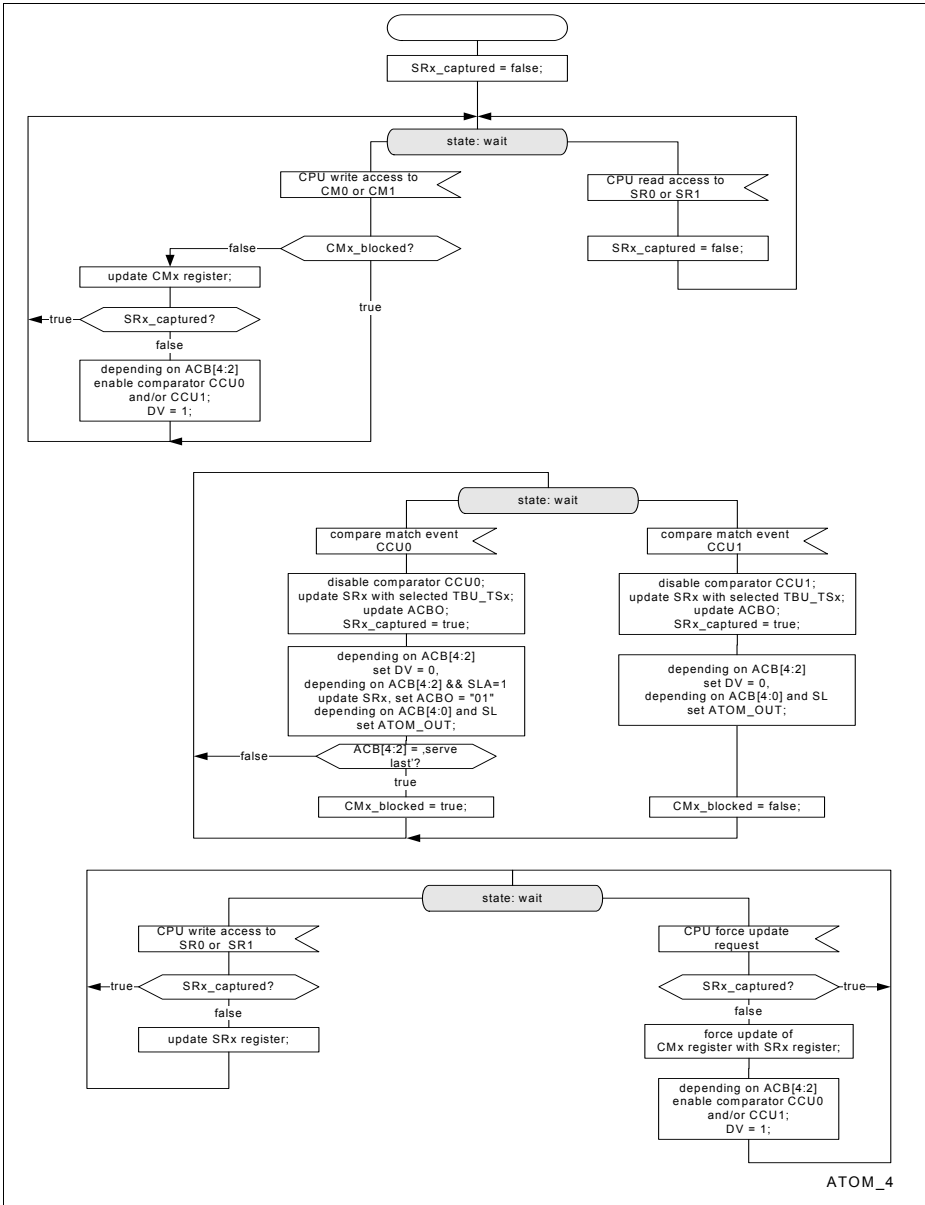

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

The behaviour of an ATOM channel in SOMC mode under CPU control is visualized in [Figure 26-46](#).

SOMC state diagram for channel under CPU control

Generic Timer Module (GTM)

ATOM_4

Figure 26-46 SOMC state diagram

Generic Timer Module (GTM)
SOMC Mode under ARU control

When the channel should be controlled by ARU, the ARU_EN bit inside the ATOMi_CHx_CTRL register has to be set.

In case, the ATOM channel is under ARU control the content for the compare registers CM0 and CM1 as well as the update of the compare strategy can be loaded via the 53 bit ARU word.

The ARU word 23 to 0 is loaded into the CM0 register while the ARU word 47 to 24 is loaded into the CM1 register. The five ARU control bits 52 to 48 are loaded into the ACBI bit field of the ATOMi_CHx_STAT register and control the channel compare strategy as well as the output behaviour in case of compare match events.

For the five ARU control bits 52 to 48 the bits 49 and 48 are loaded into the ACBI bits 1 and 0. The output behaviour also depends on the setting of the SL bit inside of the ATOMi_CHx_CTRL register and is shown in the following table:

Table 26-37 SL Bit encoding

SL	ACBI(1)	ACBI(0)	Output behaviour
0	0	0	No signal level change at output (exception in Figure 26-45 mode ACB42=001)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in Figure 26-45 mode ACB42=001)
1	0	0	No signal level change at output (exception in Figure 26-45 mode ACB42=001)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in Figure 26-45 mode ACB42=001)

For the five ARU control bits 52 to 48 the bits 52 to 50 are loaded into the ACBI bits 4 to 2. With these three bits the capture/compare units CCUX can be controlled as shown in the following table:

Table 26-38 CCU control via ACBI[4:2] control bits

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see Figure 26-45
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see Figure 26-45
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI(1) and ACBI(0).
1	1	1	Change ARU read address to ATOM_RDADDR1 DV flag is not set. Neither ACBI(1) nor ACBI(0) is evaluated.

Generic Timer Module (GTM)

It is important to note that the bit combination "111" for the ACBI(4), ACBI(3) and ACBI(2) bits forces the channel to request new compare values from another destination read address defined in the ATOM_RDADDR1 bit field of the ATOMi_CHx_RDADDR register. After data was successfully received and the compare event occurred the ATOM channel switches back to ATOM_RDADDR0 to receive the next data from there.

After the specified compare match event, the captured time stamps are stored in SR0 and SR1 and the compare result is stored in the ACBO bit field of the ATOMi_CHx_STAT register. The meaning of the ACBO(4) and ACBO(3) bits of the ATOMi_CHx_STAT is shown in the following table:

Table 26-39 ACBO[4:3] bid encoding

ACBO(4)	ACBO(3)	Return value to ARU
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the 'serve last' compare strategy, when the SLA-bit in the ATOMi_CHx_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

When CCU0 and CCU1 is used for comparison it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACBI(0) and ACBI(1) bits in the ACBI bit field of the ATOMi_CHx_STAT register on the first match event and the output will toggle on the second match event.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

For compare strategy 'serve last' the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to registers CM0 and CM1 and the WR REQ are depicted in the following figure.

Generic Timer Module (GTM)

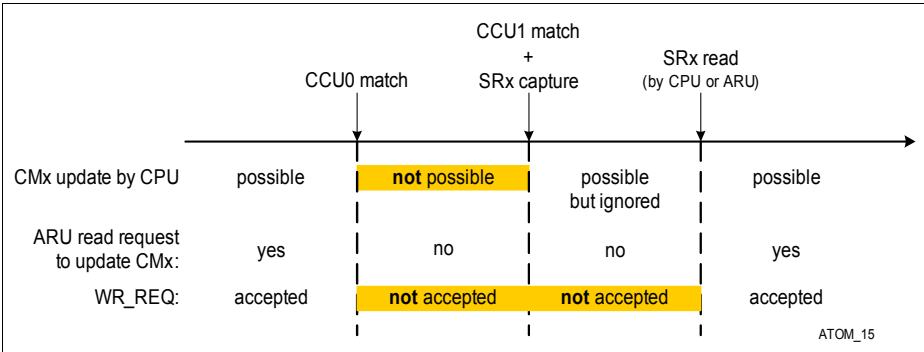

Figure 26-47 CPU access rights in case of compare strategy 'serve last'

ARU Non-Blocking mode

When the compare registers are updated via ARU the update behaviour of the channel is configurable with the ABM bit inside the ATOMi_CHx_CTRL register. When the ABM bit is reset, the ATOM channel is in ARU non-blocking mode.

In this ARU non-blocking mode, data received via ARU is continuously transferred to the registers CM0 and CM1 and the bit field ACBI of register ATOMi_CHx_STAT as long as no specified compare match event occurs.

After a compare match event that causes an update of the shadow register SR0/SR1 and before reading the SR0/SR1 register via CPU or ARU, the update of the registers CM0/ CM1 via CPU or ARU is possible but has no effect.

To set up a new compare action, first the SR0/SR1 registers containing captured values have to be read and then new compare values have to be written into the register CM0/CM1. This can be done either by ARU or by CPU.

When the CPU does the register accesses, only one of the shadow registers has to be read. Dependent on the compare strategy, the CPU has to write one or both of the compare registers.

In SOMC mode and CCUx control mode 'serve last' exist an exception for update of register CM0/CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU or ARU is blocked until the CCU1 compare match event occurs.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by the DV bit inside the ATOMi_CHx_STAT register.

The behaviour of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is disabled is shown in [Figure 26-48](#).

SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

Generic Timer Module (GTM)

Figure 26-48 SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

Generic Timer Module (GTM)**ARU Blocking mode**

When the compare registers are updated by ARU, the ATOM channel can be configured to receive ARU data in a blocking manner. This can be configured by setting the ABM bit in the ATOMi_CHx_CTRL register.

If the ABM and ARU_EN bits are set, the (one) two compare values for CM0 and/or CM1 can be provided by ARU or CPU. If the compare registers CM0 and/or CM1 are/is updated, the ATOM channel waits for the compare match event to happen. No further data is requested from the ARU.

When the specified compare match event happens, the shadow registers SR0 and SR1 are updated together with the ACBO bits in the ATOMi_CHx_STAT register. The data in the shadow registers is marked as valid for the ARU and the DV bit is reset inside the ATOMi_CHx_CTRL register.

If the register SR0 and SR1 holding the captured TBU time stamp values are read by either the ARU or the CPU, the next write access to or update of the register CM0 or CM1 via ARU or the CPU enables the new compare match check again.

At least one of the registers SR0 or SR1 has to be read, before new data is requested from ARU.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by a set DV bit inside the ATOMi_CHx_STAT register.

The behaviour of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is enabled is shown in [Figure 26-49](#).

SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

Generic Timer Module (GTM)

Figure 26-49 SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

Generic Timer Module (GTM)**ATOM SOMC Late update mechanism**

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the ATOMi_CHx_CTRL register. By doing this, the ATOM will request no further data from ARU (if ARU access was enabled). The channel will in any case continue to compare against the values stored inside the compare registers (if bit DV was set). The CPU can now update the new compare values until the compare event happens by writing to the shadow registers, and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

If the WR_REQ bit is set and a compare match event happens, any further access to the shadow registers SR0, SR1 is blocked and the force update of this channel is blocked. In addition, the WRF bit is set in the ATOMi_CHx_STAT register. Thus, the CPU can determine that the late update failed by reading the WRF bit.

If a compare match event already happened, the WR_REQ bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the WRF bit is set if the CPU tries to write the WR_REQ bit in that case.

If between a correct WR_REQ bit set, a correct shadow register write, and before the force update is requested by the AGC a match event occurs on the old compare values, the WRF bit will be set.

The WRF bit will be set in any case if the CPU tries to write to a blocked shadow register.

The WR_REQ bit and the DV bit will be reset on a compare match event.

A blocked force update mechanism will be enabled again after a read access to the register SR0 or SR1 by either the ARU or the CPU.

The ATOM SOMC late update mechanism from CPU is shown in [Figure 26-50](#).

26.12.3.3 ATOM Signal Output Mode PWM (SOMP)

In ATOM Signal Output Mode PWM (SOMP) the ATOM submodule channel is able to generate complex PWM signals with different duty cycles and periods. Duty cycles and periods can be changed synchronously and asynchronously. Synchronous change of the duty cycle and/or period means that the duty cycle or period duration changes after the end of the preceding period. An asynchronous change of period and/or duty cycle means that the duration changes during the actual running PWM period.

The signal level of the pulse generated inside the period can be configured inside the channel control register (SL bit of ATOMi_CHx_CTRL register). The initial signal output level for the channel is the erase pulse level defined by the SL bit. [Figure 26-51](#) clarifies this behaviour.

In SOMP mode, depending on configuration bits RST_CCU0 of register ATOMi_CHx_CTRL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 or when signaled by the ATOMi trigger signal TRIG [x-1] of the preceding channel.

In this case, if UPEN_CTRLx=1, also the working register CM0, CM1 and CLK_SRC are updated.

PWM Output behaviour with respect to the SL bit in the ATOMi_CHx_CTRL register

Figure 26-51 PWM Output behaviour with respect to the SL bit in the ATOMi_CHx_CTRL register

On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers. The behaviour of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in [Figure 26-52](#).

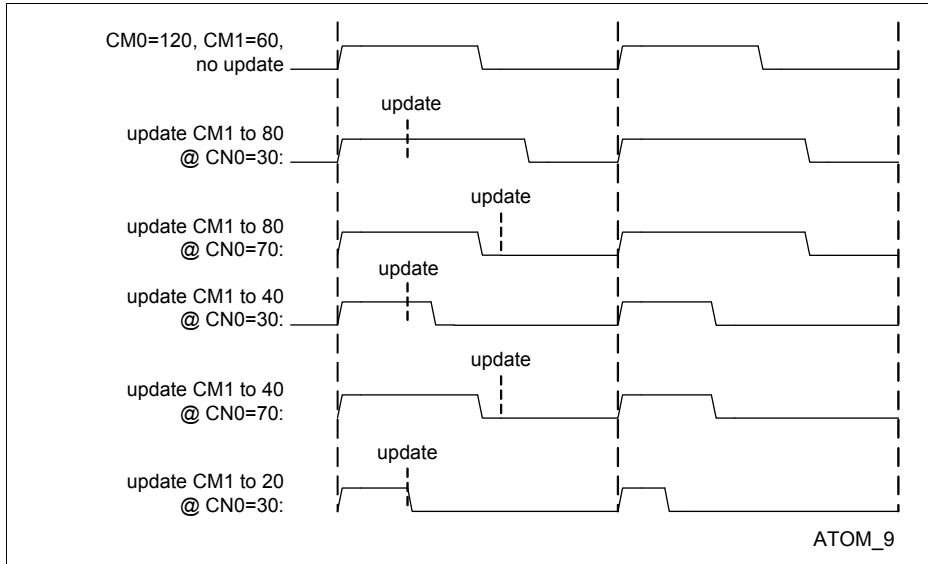

PWM Output behaviour in case of an asynchronous update of the duty cycle

Figure 26-52 PWM Output behaviour in case of an asynchronous update of the duty cycle

The duration of the pulse high or low time and period is measured with the counter in subunit CCU0. The trigger of the counter is one of the eight CMU clock signals configurable in the channel control register `ATOMi_CHx_CTRL`. The register `CM0` holds the duration of the period and the register `CM1` holds the duration of the duty cycle in clock ticks of the selected CMU clock.

If counter register `CN0` of channel `x` is reset by its own CCU0 unit (i.e. the compare match of $CN0 \geq CM0$ configured by `RST CCU0=0`), following statements are valid:

- if $CM0=0$ or $CM0=1$, 0% duty cycle ($=\overline{SL}$) is generated independent of `CM1`. The counter `CN0` is not counting.
- the configuration of `CM1=0` represents 0% duty cycle ($=\overline{SL}$) at the output
- the configuration of $CM1 \geq CM0$ represents 100% duty cycle ($=SL$)

If counter register `CN0` of `x` channel is reset by the trigger signal coming from another channel or the assigned TIM module (configured by `RST CCU0=1`), following statements are valid:

- `CM0` defines the edge to `SL` value, `CM1` defines the edge to \overline{SL} value
- if $CM0=CM1$, the output is 100% `SL` (`CM0` has higher priority)

Generic Timer Module (GTM)

- if CM0=0, the output stays at its last value (CN0 stops counting)

In case the counter value CN0 reaches the compare value in register CM0 or the channel receives an external update trigger via the FUPD(x) signal, a synchronous update is performed. A synchronous update means that the registers CM0 and CM1 are updated with the content of the shadow registers SR0 and SR1 and the CLK_SRC register is updated with the value of the CLK_SRC_SR register.

The clock source for the counter can be changed synchronously at the end of a period. If ARU access is disabled, this is done by using the bit field CLK_SRC_SR of register ATOMi_CHx_CTRL as shadow registers for the next CMU clock source.

If ARU access is enabled, the bits ACBI(4), ACBI(3) and ACBI(2) received via ARU and stored in register ATOM_i_CHx_STAT are used as shadow register for the update of the CMU clock source register CLK_SRC.

For the synchronous update mechanism the generation of a complex PWM output waveform is possible without CPU interaction by reloading the shadow registers SR0, SR1 and the ACBI bit field over the ACI subunit from the ARU, while the ATOM channel operates on the CM0 and CM1 registers.

This internal update mechanism is established, when the old PWM period ends. The shadow registers are loaded into the operation registers, the counter register is reset, the new clock source according to the CLK_SRC_SR or ACBI(4), ACBI(3) and ACBI(2) bits is selected and the new PWM generation starts.

In parallel, the ATOM channel issues a read request to the ARU to reload the shadow registers with new values while the ATOM channel operates on the operation registers. To guarantee the reloading, the PWM period must not be smaller than the worst case ARU round trip time and source for the PWM characteristic must provide the new data within this time. Otherwise, the old PWM values are used from the shadow registers.

When updated over the ARU the user has to ensure that the new period duration is located in the lower (bits 23 to 0) and the duty cycle duration is located in the upper (bits 47 to 24) ARU data word and the new clock source is specified in the ARU control bits 52 to 50.

This pipelined data stream character is shown in [Figure 26-53](#).

ARU Data input stream pipeline structure for SOMP mode

Generic Timer Module (GTM)

Figure 26-53 ARU Data input stream pipeline structure for SOMP mode

When an ARU transfer is in progress which means the ARU_RREQ is served by the ARU, the ACI locks the update mechanism of CM0, CM1 and CLK_SRC until the read request has finished. The CCU0 and CCU1 operate on the old values when the update mechanism is locked.

The shadow registers SR0 and SR1 can also be updated over the AEI bus interface. When updated via the AEI bus the CM0 and CM1 update mechanism has to be locked via the AGC_GLB_CTRL register with the UPENx signal in the AGC subunit. To select the new clock source in this case, the CPU has to write to the CLK_SRC_SR bit field of the ATOMi_CHx_CTRL register.

For an asynchronous update of the duty cycle and/or period the new values must be written directly into the compare registers CM0 and/or CM1 while the counter CN0 continues counting. This update can be done only via the AEI bus interface immediately by the CPU or by the FUPD(x) trigger signal triggered from the AGC global trigger logic. Values received through the ARU interface are never loaded asynchronously into the operation registers CM0 and CM1. Therefore, the ATOM channel can generate a PWM signal on the output port pin ATOM[i]_CH[x]_OUT on behalf of the content of the CM0 and CM1 registers, while it receives new PWM values via the ARU interface ACI in its shadow registers.

On a compare match of CN0 and CM0 or CM1 the output signal level of ATOM[i]_CH[x]_OUT is toggled according to the signal level output bit SL in the ATOMi_CHx_CTRL register.

Thus, the duty cycle output level can be changed during runtime by writing the new duty cycle level into the SL bit of the channel configuration register. The new signal level becomes active for the next trigger CCU_TRIGx (since bit SL is written).

Since the ATOM[i]_CH[x]_OUT signal level is defined as the erse duty cycle output level when the ATOM channel is enabled, a PWM period can be shifted earlier by writing an initial offset value to CN0 register. By doing this, the ATOM channel first counts until CN0 reaches CM0 and then it toggles the output signal at ATOM[i]_CH[x]_OUT.

SOMP One-shot mode

The ATOM channel can operate in One-shot mode when the OSM bit is set in the channel control register. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding `ENDIS_STAT` value.

In One-shot mode the counter `CN0` will not be increment once the channel is enabled.

A write access to the register `CN0` triggers the start of pulse generation (i.e. the increment of the counter register `CN0`).

If the counter `CN0` is reset from `CM0` back to zero, the first edge at `ATOM[i]_CH[x]_OUT` is generated.

To avoid an update of `CMx` register with content of `SRx` register at this point in time, the automatic update should be disabled by setting `UPEN_CTRLx = 00` (in register `ATOMi_CHx_CTRL`).

The second edge is generated if `CN0` is greater or equal than `CM1` (i.e. `CN0` was increment until it has reached `CM1` or `CN0` is greater than `CM1` after an update of `CM1`).

If the counter `CN0` has reached the value of `CM0` a second time, the counter stops.

The new value of `CN0` determines the start delay of the first edge. The delay time of the first edge is given by $(CM0 - CN0)$ multiplied with period defined by current value of `CLK_SRC`.

Figure 26-54 clarifies the pulse generation in SOMP One-shot mode.

PWM Output with respect to configuration bit `SL` in One-shot mode: trigger by writing to `CN0`

Figure 26-54 PWM Output with respect to configuration bit `SL` in One-shot mode:

Generic Timer Module (GTM)**trigger by writing to CN0**

Further output of single pulses can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value $CN0_{start} < CM0$), the affect of a second write access to CN0 depends on the phase of CN0:

phase 1: update of CN0 before CN0 reaches first time CM0

phase 2: update of CN0 after CN0 has reached first time CM0 but less than CM1

phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value $CN0_{new} < CM0$ leads to shift of first edge (generated if CN0 reaches CM0 first time) by the time $CM0 - CN0_{new}$.

In phase 2: writing to incrementing counter CN0 a value $CN0_{new} < CM1$ while $CM0_{old}$ is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: writing to incrementing counter CN0 a value $CN0_{new}$ while $CN0_{old}$ is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial defined by $CM0 - CN0_{new}$.

26.12.3.4 ATOM Signal Output Mode Serial (SOMS)

In ATOM Signal Output Mode Serial (SOMS) the ATOM channel acts as a serial output shift register where the content of the CM1 register in the CCU1 unit is shifted out whenever the unit is triggered by the selected CMU_CLK input clock signal. The shift direction is configurable with the ACB(0) bit inside the ATOM_i_CH_x_CTRL register when ARU is disabled and the ACBI(0) bit inside the ATOM_i_CH_x_STAT register when ARU is enabled.

The data inside the CM1 register has to be aligned according to the selected shift direction in the ACB(0)/ACBI(0) bit. This means that when a right shift is selected, that

Generic Timer Module (GTM)

the data word has to be aligned to bit 0 of the CM1 register and when a left shift is selected, that the data has to be aligned to bit 23 of the CM1 register.

SOMS Mode output generation

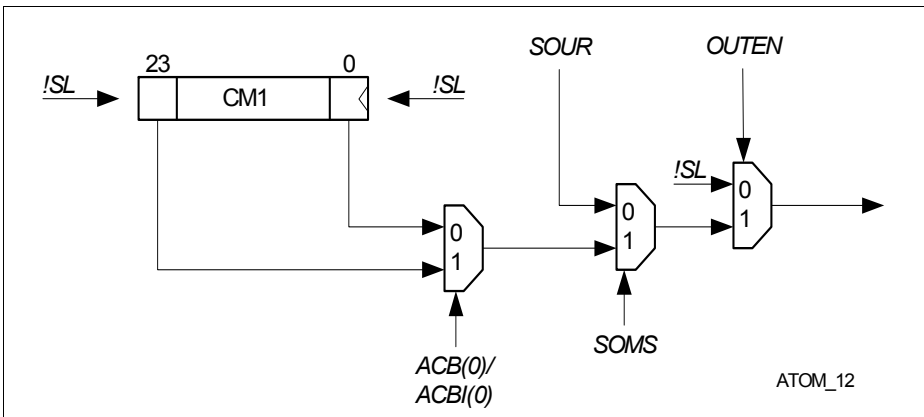

Figure 26-55 SOMS Mode output generation

Figure 12.3.4.1 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as CM0. The total number of bits that are visible at ATOM_OUT is CM0+1.

When the output is disabled the ATOM_OUT is set to the inverse SL bit definition.

When the content of the CM1 register is shifted out, the inverse signal level is shifted into the CM1 register.

When the output is enabled while UPEN_CTRL[x] is disabled, the ATOM_OUT signal level is defined by CM1 bit 0 or 23, dependent on the shift direction defined by ACB(0) or ACBI(0) register setting. Figure 12.3.4.2 should clarify the ATOM channel startup behaviour in this case for right shift. For left shift the CM1 bit 0 in 12.3.4.2 has to be replaced by CM1 bit 23.

SOMS Output signal level at startup, UPEN_CTRL[x] disabled

Generic Timer Module (GTM)

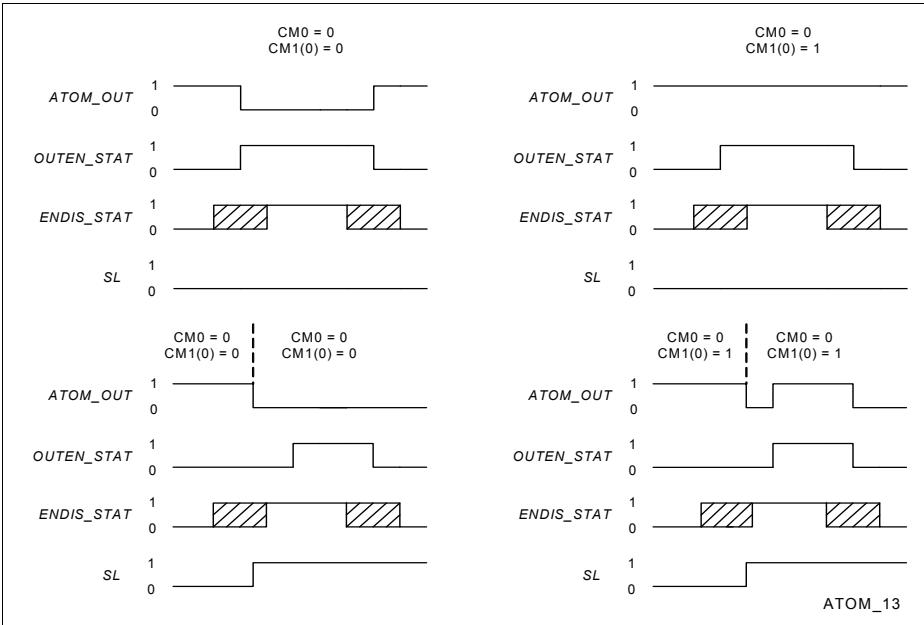

Figure 26-56 SOMS Output signal level at startup, `UPEN_CTRL[x]` disabled

If `UPEN_CTRL[x]` is set and the channel is enabled, the output level is defined by bit 0 or 23 of `CM1` register dependent on the shift direction. Figure 12.3.4.3 shows the output behaviour in that case.

SOMS Output signal level at startup, `UPEN_CTRL[x]` enabled

Generic Timer Module (GTM)

Figure 26-57 SOMS Output signal level at startup, UPEN_CTRL[x] enabled

When the serial data to be shifted is provided via ARU the number of bits that should be shifted has to be defined in the lower 24 bits of the ARU word (23 to 0) and the data that is to be shifted has to be defined in the ARU bits 47 to 24 aligned according to the shift direction. This shift direction has to be defined in the ARU word bit 48 (SL0 bit).

If bit UPEN_CTRL[x] of a channel x is set, after update of CM0/CM1 register with the content of the SR0/SR1 register, a new ARU read request is set up.

If bit UPEN_CTRL[x] of a channel x is not set, no (further) ARU read request is set up (because the SR0/SR1 register are never used for update) and the ATOM may stop shifting after CN0 has reached CM0. Note, that in this case also no automatic restart of shifting is possible.

If a channel is enabled with the settings SOMS mode and ARU_EN = 1, the first received values from ARU are stored in register SR0 and SR1. If CN0 and CM0 are 0 (i.e. CN0 is not counting) and the update of channel x is enabled (UPEN_CTRL[x]=1), an immediate update of the register CM0 and CM1 is also done. This update of CM0 and CM1 triggers the start of shifting.

It is recommended to configure the ATOM channel in One-shot mode when the ARU_EN bit is not set, since the ATOM channel would reload new values from the shadow registers when CN0 reaches CM0.

SOMS mode with ARU_EN = 1 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is not set, the channel is running in the SOMS continuous mode. Then, if the content of the CM0 register equals the counter CN0, the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If the update of the shadow registers does not happen before

Generic Timer Module (GTM)

CN0 reaches CM0 the old values of SR0 and SR1 are used to reload the operation registers.

In contrast to controlling the channel via AEI, the shift direction defined by ARU word bit 48 has only effect after the update of CMx operation registers from the SRx registers.

SOMS mode with ARU_EN = 1 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is set, the channel is running in the SOMS one-shot mode. Then, if the content of the CM0 register equals the counter CN0 and if new values are available in SR0 and SR1 (bit DV set), the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If no new values are available in SR0 and SR1, the register CM0 and CM1 will not be updated, the counter CN0 stops and the ATOM channel continues to request new data from ARU. A later reception of new ARU data in SR0 and SR1 will immediately force the update of the register CM0 and CM1 and restart the counter CN0.

SOMS mode with ARU_EN = 0 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is not set, the ATOM channel updates its CM0/CM1 register with the content of the SR0/SR1 register and restarts shifting immediately. The first bit of new CM1 register value will be applied at the output without any gap to the last bit of the previous CM1 register value.

SOMS mode with ARU_EN = 0 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is set, the ATOM channel stops shifting when CN0 reaches CM0 and no update of CM0 and CM1 is performed.

Then, the shifting of the channel can be restarted again by writing a zero (0) to the CN0 register again. Please note, that the CN0 register should be written with a zero since the CN0 register counts the number of bits shifted out by the ATOM channel.

The writing of a zero to CN0 causes also an immediate update of CM0/CM1 register with the content of SR0/SR1 register.

Interrupts in SOMS mode

In ATOM Signal Output Mode Serial only the interrupt CCU0TC (ATOM[i]_CH[x]_IRQ_NOTIFY) in case of CN0 >= CM0 is generated. The interrupt CCU1TC has no meaning and is not generated.

Generic Timer Module (GTM)

Field	Bits	Type	Description
MODE	[1:0]	rw	ATOM channel mode select 00 _B ATOM Signal Output Mode Immediate (SOMI) 01 _B ATOM Signal Output Mode Compare (SOMC) 10 _B ATOM Signal Output Mode PWM (SOMP) 11 _B ATOM Signal Output Mode Serial (SOMS)
TB12_SEL	2	rw	Select time base value TBU_TS1 or TBU_TS2. 0 _B TBU_TS1 selected for comparison 1 _B TBU_TS2 selected for comparison Note: this bit is only applicable in SOMC mode.
ARU_EN	3	rw	ARU Input stream enable 0 _B ARU Input stream disabled 1 _B ARU Input stream enabled
ACB	[8:4]	rw	ATOM Mode control bits Note: These bits have different meaning in the different ATOM channel modes. Please refer to the mode description sections. Note: These bits are only applicable when ARU_EN = '0'.
CMP_CTR L	9	rw	CCUx compare strategy select 0 _B Greater/equal compare against TBU time base values (TBU_TSx >= CMx) 1 _B Less/equal compare against TBU time base values (TBU_TSx <= CMx) Note: this bit is only applicable in SOMC mode.
Reserved	10	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

Field	Bits	Type	Description
SL	11	rw	<p>Initial signal level</p> <p>0_B Low signal level 1_B High signal level</p> <p>Note: If the output is disabled, the output ATOM_OUT[x] is set to inverse SL independent of ATOM channel mode.</p> <p>Note: In SOMP, SOMI, and SOMS mode, if the channel is disabled, the internal register SOUR inside ATOM sub unit SOU is set to inverse value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled afterwards, the output ATOM_OUT[x] is the inverse value of SL.</p> <p>Note: In SOMC mode, if the channel is disabled, the internal register SOUR inside ATOM sub unit SOU is set to value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled and the channel is disabled, the output ATOM_OUT[x] is the value of SL.</p> <p>Note: In SOMS mode, this bit is only applicable when the channel and its outputs are disabled.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
CLK_SRC CLK_SRC _SR	[14:12]	rw	<p>actual CMU clock source (SOMS)/ shadow register for CMU clock source (SOMP)</p> <p>000_B CMU_CLK0 selected 001_B CMU_CLK1 selected 010_B CMU_CLK2 selected 011_B CMU_CLK3 selected 100_B CMU_CLK4 selected 101_B CMU_CLK5 selected 110_B CMU_CLK6 selected 111_B CMU_CLK7 selected</p> <p>Note: This register is a shadow register for the CMU_CLKx select. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a FORCE_UPDATE.</p> <p>Note: After (channel) reset the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use in SOMP mode one of the CMU_CLKx, it is required to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel.</p>
Reserved	15	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>
WR_REQ	16	rw	<p>CPU Write request bit for late compare register update</p>
Reserved	[19:17]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>
RST_CCU 0	20	rw	<p>Reset source of CCU0</p> <p>0_B Reset counter register CN0 to 0 on matching comparison with CM0 1_B Reset counter register CN0 to 0 on trigger TRIG[x-1]</p> <p>Note: If RST_CCU0=1 and UPEN_CTRLx=1 are set , TRIG[x-1] triggers also the update of work register (CM0, CM1, and CLK_SRC).</p>
Reserved	[23:21]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRIGOUT	24	rw	<p>Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx.</p> <p>0_B TRIG_x[is TRIG_x-1]</p> <p>1_B TRIG_x[is TRIG_CCU0</p> <p>Note: this bit is only applicable in SOMC and SOMP mode.</p>
SLA	25	rw	<p>Serve last ARU communication strategy</p> <p>0_B Capture SRx time stamps after CCU0 match event not provided to ARU</p> <p>1_B Capture SRx time stamps after CCU0 match event provided to ARU</p> <p>Note: This bit is only applicable in SOMC mode.</p> <p>Note: Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy ("100", "101", or "110").</p> <p>Note: When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return "10" in that case.</p> <p>Note: By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to "01" in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to "10". When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.</p>
OSM	26	rw	<p>One-shot mode</p> <p>0_B Continuous PWM generation after channel enable</p> <p>1_B A single pulse is generated</p> <p>Note: this bit is only applicable in SOMP and SOMS modes.</p>

Generic Timer Module (GTM)

26.13 Multi Channel Sequencer (MCS)

26.13.1 Overview

The Multi Channel Sequencer (MCS) submodule is a generic data processing module that is connected to the ARU.

One of its major applications is to calculate complex output sequences that may depend on the time base values of the TBU and are processed in combination with the ATOM submodule.

Other applications can use the MCS submodule to perform extended data processing of input data resulting from the TIM submodule that are provided to the CPU (e.g. using the PSM submodule).

Moreover, some applications may process data provided by the CPU within the MCS submodule, and the calculated results are sent to the outputs using the ATOM submodules.

26.13.1.1 Architecture

Figure 26-58 gives an overview of the MCS architecture.

MCS architecture

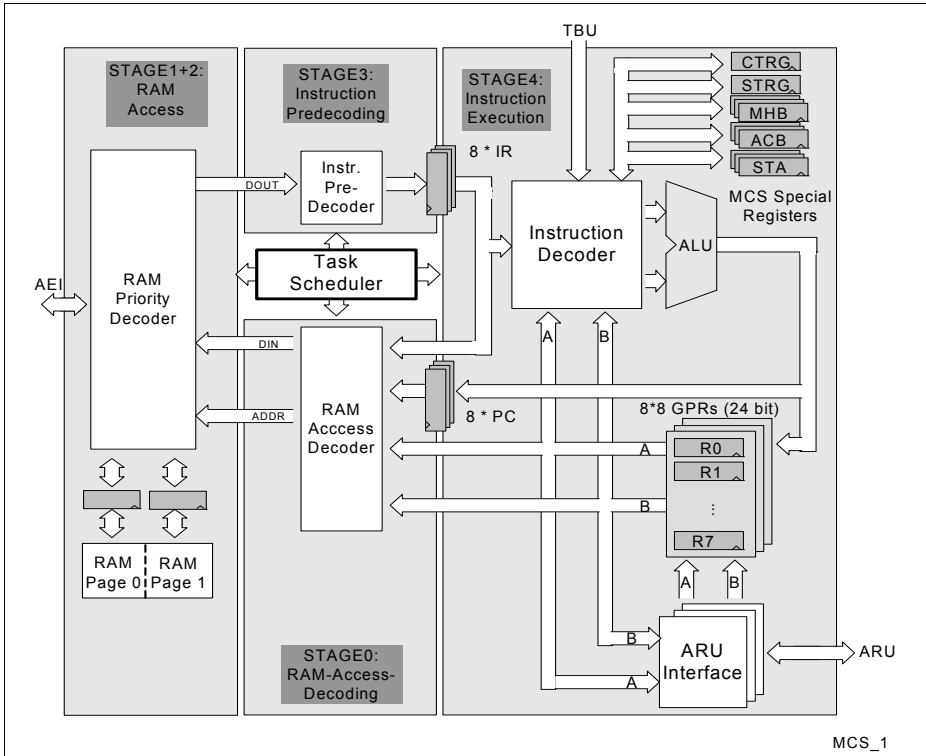

Figure 26-58 MCS architecture

The MCS submodule mainly embeds a single data path with five pipeline stages, consisting of a simple 24-bit Arithmetic Logic Unit (ALU), several decoders, and a connection to two RAM pages located outside of the MCS submodule.

The data path of the MCS is shared by eight so called MCS-channels, whereas each MCS-channel executes a dedicated micro-program that is stored inside the RAM pages connected to the MCS submodule. The execution of the different MCS-channels is controlled by a central task scheduler.

Both RAM pages may contain arbitrary sized code and data sections that are accessible by all MCS-channels and the CPU via AEI.

The MCS submodule supports a memory layout of up to 2^{12} memory locations each 32 bit wide leading to a maximum address range from 0 to $2^{14}-4$.

Generic Timer Module (GTM)

This address space of the MCS is divided into two seamless memory pages.

Memory page 0 begins from address 0 and ranges to address MP0-[i] and memory page 1 ranges from MP0 to MP1-[i].

The parameters MP0 and MP1 are defined externally by the memory configuration submodule MCFG of [Section 26.14](#).

If an ECC Error occurs while an MCS-channel reads data from a memory page, the corresponding MCS-channel is disabled and the ERR bit in register STA is raised.

After a resetting the MCS submodule, the content of both memory pages is initialized with zeros.

An MCS-channel can also be considered as an individual task of a processor that is scheduled at a specific point in time.

A more detailed description of the scheduling can be found in [Section 26.13.1.2](#).

Moreover, each MCS-channel has a dedicated ARU interface for communication with other ARU connected modules, an Instruction Register (IR), a Program Counter Register (PC), a Status Register (STA), an ARU Control Bit Register (ACB), a Memory High Byte Register (MHB) and a Register Bank with eight 24 bit general purpose registers (R0, R1, ...R7).

All the registers, mentioned above, are only visible within its dedicated MCS-channel and thus the MCS-channels cannot exchange data using registers.

The only exception is the common 16 bit wide trigger register that can be accessed by all MCS channels in order to trigger other MCS-channels located in the same submodule. STRG is used to set a bits and CTRG is used to clear bits in the trigger register.

To enable triggering of MCS-channels by CPU, it can set bits in the common trigger register by writing to MCS[i]_STRG and clear bits by writing to MCSi_CTRG.

Whenever data has to be exchanged between different MCS-channels, the connected RAM pages, which are accessible by all MCS-channels, must be used.

However, since the data registers are writable by the CPU, an MCS channel may also exchange data with the CPU using its data registers.

The main actions of the different pipeline stages are as follows:

Pipeline stage 0 performs a setup of address, input data, and control signals for the next RAM access of a specific MCS-channel.

The actual RAM access of a specific MCS-channel is executed in pipeline stage 1 and 2, assuming an external connection of a synchronous RAM with a latency of one clock cycle.

The RAM priority decoder arbitrates RAM accesses that are requested by the CPU via AEI and by the active MCS-channel.

Generic Timer Module (GTM)

If both, CPU and an MCS-channel request a memory access to the same memory page the MCS-channel is prioritized.

Pipeline stage 3 performs pre-decoding of instruction and data resulting from the RAM.

Finally, in pipeline stage 4 the current instruction is executed.

Since the internal registers of the MCS can be updated by different sources (MCS write access, AEI write access and ARU read access) a write conflict occurs if more than one source wants to write to the same register. In this cascade the result of the register is unpredictable.

However, the software should setup its application in a way that such conflicts do not occur.

One exception is the common trigger register which may be written by multiple sources (different MCS channels and AEI) in order to enable fast triggering of different MCS channels. Typically, the software should setup its application in a manner that different sources should not write the same bits in the trigger register.

26.13.1.2 Scheduling

The MCS submodule provides two different scheduling schemes: round-robin schedule and accelerated schedule.

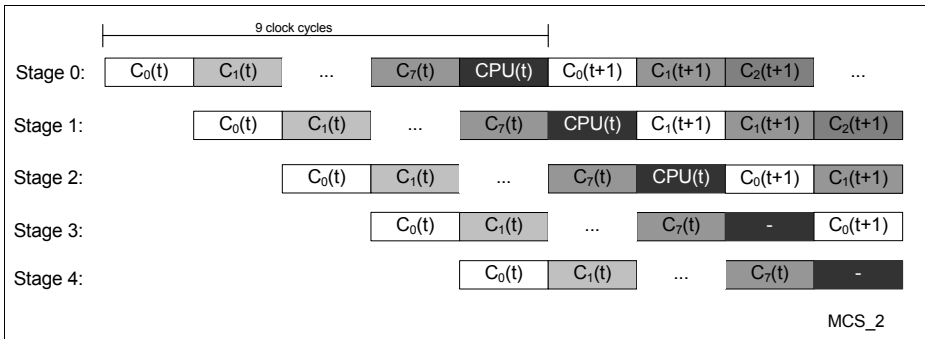

The scheduling scheme can be selected by the SCHED bit in the global MCSi_CTRL register.

The round-robin order scheduling assigns all MCS-channels an equal amount of time slices.

In addition, the scheduler also assigns one time slice to the CPU, in order to guarantee at least one memory access by the CPU within each round-trip cycle.

Figure 26-59 shows the round-robin scheduling with 8 MCS-channels (C_0 to C_7) that are scheduled together with a single CPU access.

Scheduling

Generic Timer Module (GTM)

Figure 26-59 Scheduling

The figure also shows which MCS-channel is activated in specific pipeline stage at a specific point in time.

The execution time of an MCS-channel in a specific pipeline stage is always one clock cycle.

The index t marks all instruction parts of the corresponding MCS-channels belonging to the same round-trip cycle.

Consequently, a single cycle instruction of an MCS-channel requires an effective execution time of 9 clock cycles, ignoring the five clock cycles of pipeline latency.

To improve memory bandwidth between CPU and MCS memory, the time slices of any suspended MCS-channel is also granted to the CPU.

An MCS-channel can be suspended due to the following reasons:

- An MCS-channel is executing a blocking read or write request to an ARU connected submodule (instruction ARD, AWR, ARDI, AWRI).
- An MCS-channel waits on a register match event (instruction WURM), in order to wait on a time base value or a trigger event from another MCS channel.
- An MCS-channel is disabled.

The round-robin scheduling leads to a deterministic round trip time for the whole submodule, however it may waste clock cycles by scheduling MCS-channels that are not able to run at a specific point in time assuming that there is no high CPU bandwidth required.

The second scheduling mode, the accelerated scheduling mode, improves the computational performance of the MCS in the following way:

Initially, the accelerated scheduling mode behaves similar to round-robin scheduling mode.

Whenever the scheduler detects an MCS-channel that is suspended, due to its suspended state (or it is already scheduled in stage 0, 1, 2, or 3), the scheduler is

Generic Timer Module (GTM)

selecting the next non-suspended MCS-channel that would follow if round-robin scheduling is continued.

Considering the timing of [Figure 26-59](#) in conjunction with the accelerated scheduling scheme, a single cycle instruction of an MCS-channel requires an effective execution time between 5 and 9 clock cycles, depending on the number of suspended MCS-channels.

In summary, the round-robin scheduling mode grants time slices of suspended MCS-channels to the CPU and the accelerated scheduling mode grants time slices of suspended MCS-channels to non-suspended MCS-channels.

26.13.2 Instruction Set

This section describes the entire instruction set of the MCS submodule.

After the introduction of the different instruction formats in [Section 26.13.2.1](#), the individual instructions are described in [Section](#) to [Section 26.13.2.7](#).

In general, each instruction is 32 bit wide but the duration of each instruction varies between several instruction cycles. An instruction cycle is defined as the time in SYS_CLK clock cycles that rest between two consecutive instructions of a channel.

As already described in [Section 26.13.1.2](#), the number of required clock cycles for a single instruction cycle can vary in the range of 5 to 9 clock cycles, depending on the number suspended MCS-channels, when the accelerated scheduling scheme is selected inside the MCSi_CTRL register.

In the round robin scheduling scheme, each single cycle instruction takes exactly 9 clock cycles.

Before the instruction formats and the actual instructions are described, some commonly used terms, abbreviations and expressions are introduced:

OREG: The operation register set $OREG = \{R0, R1, R2, \dots, R7, STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, MHB\}$ includes all MCS accessible internal registers, as well as the global time bases TBU_TS0, TBU_TS1, and TBU_TS2 that are provided by the submodule TBU.

AREG: The ARU register set $AREG = \{R0, R1, R2, \dots, R7, ZERO\}$ includes the all registers that can be written by incoming ARU transfers (ARD, ARDI instructions). These registers include all eight general purpose registers. The dummy register ZERO may be used to discard an incoming 24 bit ARU word.

LIT4: The set $LIT4 = \{0, 1, \dots, 15\}$ is an unsigned 4 bit literal.

LIT16: The set $LIT16 = \{0, 1, \dots, 2^{16} - 1\}$ is an unsigned 16 bit literal.

LIT24: The set $LIT24 = \{0, 1, \dots, 2^{24} - 1\}$ is an unsigned 24 bit literal.

BIT SELECTION: The expression $VAR[i]$ represents the i-th bit of a variable VAR.

Generic Timer Module (GTM)

BIT RANGE SELECTION: The expression VAR[m:n] represents the bit slice of variable VAR that is ranging from bit n to bit m.

MEMORY ADDRESSING: The expression MEM(X) represents the 32 bit value at address X of the memory.

Address X ranges between 0 and $2^{14}-4$, whereas X must be an integral multiple of 4.

The expression MEM(X)[m:n] represents the bit slice ranging from bit n to m of the 32 bit word at memory location X.

ARU ADDRESSING: In the case of ARU reading, the expression ARU(X) represents the 53 bit ARU word of ARU channel at address X.

The read address X ranges between 0 and 2^9-1 .

In the case of ARU writing, the expression ARU(X) represents a 53 bit ARU word that is written to an ARU channel indexed by the index X.

The index X selects a single ARU write channel from the pool of the MCS submodule's allocated ARU write channels.

An MCS submodule has 24 ARU write channels, indexed by values 0 to 23.

The expression ARU(X)[m:n] represents the bit slice ranging from bit n to m of the 53 bit ARU word.

26.13.2.1 Instruction Format

The first instruction format, called literal instruction format, embeds a primary 4 bit opcode OPC0, a 24 bit literal value $C \in \text{LIT}_{24}$, and a 4 bit value A, which may be an element of set OREG or AREG, depending on the actual instruction.

Figure 26-60 shows the bit alignment of the literal instruction format.

Literal Instruction format

Figure 26-60 Literal Instruction format

The literal instruction format is primarily used for instructions that are accessing a 24 bit literal and a single 24 bit register as operands.

Generic Timer Module (GTM)

In the following subsections the binary codes of a 24 bit literal instruction is defined as "xxxxaaaaccccccccccccccccccccc", whereas the digits 'x' encode the field OPC0, the digits 'a' encode the operand field A, and the digits 'c' encode the 24 bit literal field C.

If an instruction ignores several bits of field, the bits are defined as '-' in its code.

The second instruction format, called double operand instruction format, embeds a 4 bit primary opcode OPC0, a 4 bit secondary opcode OPC1, a 16 bit literal C ∈ LIT16 and two 4 bit values A and B, which may be an element of set OREG, AREG, or LIT4 depending on the actual instruction.

Figure 26-61 shows the bit alignment of the double operand instruction format.

Double Operand Instruction format

Figure 26-61 Double Operand Instruction format

The double operand instruction format is primarily used for instructions that are accessing two operands stored in the 24 bit registers.

In the following subsections the binary codes of a 16 bit literal instruction is defined as "xxxxaaaabbbbyyycccccccccccccc", whereas the digits 'x' encode the bit field OPC0, 'y' the digits of field OPC2, the digits 'a' encode the operand field A, the digits 'b' the operand field B, and the digits 'c' encode the 16 bit literal field C.

If an instruction ignores several bits of field, the bits are defined as '-' in its code.

26.13.2.2 Data Transfer Instructions

MOVL Instruction

Syntax: MOVL A, C

Operation: A ← C

Status: Z

Duration: 1 instruction cycle

Code: 0001aaaaccccccccccccccccccccc

Description: Transfer literal value C (C ∈ LIT24) to register A (A ∈ OREG).

Generic Timer Module (GTM)

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

MOV Instruction

Syntax: MOV A, B

Operation: $A \leftarrow B$

Status: Z

Duration: 1 instruction cycle

Code: 1010aaaabbbb0000-----

Description: Transfer value B ($B \in \text{OREG}$) to register A ($A \in \text{OREG}$).

The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

MRD Instruction

Syntax: MRD A, C

Operation: $A \leftarrow \text{MEM}(C[13:0])[23:0]$;
 $\text{MHB} \leftarrow \text{MEM}(C[13:0])[31:24]$

Status: Z

Duration: 2 instruction cycles

Code: 1010aaaa---0001--cccccccccccc

Description: Transfer the lower 24 bits of memory content at address C ($C \in \text{LIT16}$) to register A ($A \in \text{OREG}$). The upper 8 bits of the memory content at address C are transferred to MHB register.

The zero bit Z of status register STA is set, if the lower 24 bits of the transferred value are zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A ($A \in \text{OREG}$), the bits 0 to 7 of the referred memory location are transferred to MHB.

The program counter PC is increment by the value 4.

MWR Instruction

Syntax: MWR A, C

Operation: $\text{MEM}(C[13:0])[23:0] \leftarrow A$;
 $\text{MEM}(C[13:0])[31:24] \leftarrow \text{MHB}$

Status: -

Generic Timer Module (GTM)

Duration: 2 instruction cycles

Code: 1010aaaa----0010--cccccccccccccc

Description: Transfer 24 bit value of register A ($A \in \text{OREG}$) together with the MHB register to the memory location at address C ($C \in \text{LIT16}$).

The 24 bit value of register A is stored in the lower significant bits (bit 0 to 23) of the memory location and the MHB register is stored in bits 24 to 31.

The program counter PC is increment by the value 4.

MWR24 Instruction

Syntax: MWR24 A, C

Operation: $\text{MEM}(C[13:0])[23:0] \leftarrow A$

Status: -

Duration: 3 instruction cycles

Code: 1010aaaa----0111--cccccccccccccc

Description: Transfer 24 bit value of register A ($A \in \text{OREG}$) to memory at address C ($C \in \text{LIT16}$).

The 24 bit value of register A is stored in the lower significant bits (bit 0 to 23) of the memory location and the bits 24 to 31 are left unchanged.

The program counter PC is increment by the value 4.

It should be noted that this operation is not an atomic instruction.

MRDI Instruction

Syntax: MRDI A, B

Operation: $A \leftarrow \text{MEM}(B[13:0])[23:0]$

$\text{MHB} \leftarrow \text{MEM}(B[13:0])[31:24]$

Status: Z

Duration: 2 instruction cycles

Code: 1010aaaabbbb0011-----

Description: Transfer the lower 24 bits of a memory location to register A ($A \in \text{OREG}$) using indirect addressing. The upper 8 bits of the memory location are transferred to MHB register.

The memory location where to read from is defined by the bits 0 to 15 of register B ($B \in \text{OREG}$).

The 24 bit value is received from the lower significant bits (bit 0 to 23) of the memory location.

Generic Timer Module (GTM)

The zero bit Z of status register STA is set, if the lower 24 bit of the transferred value is zero, otherwise the zero bit is cleared.

If the MHB register is selected as destination register A (A ? OREG), the bits 0 to 7 of the referred memory location are transferred to MHB.

The program counter PC is increment by the value 4.

MWRI Instruction

Syntax: MWRI A, B

Operation: MEM(B[13:0])[23:0] ← A;
MEM(B[13:0])[31:24] v MHB

Status: -

Duration: 2 instruction cycles

Code: 1010aaaabbbb0100-----

Description: Transfer 24 bit value of register A ($A \in \text{OREG}$) together with the MHB register to the memory using indirect addressing.

The memory location where to write to is defined by the bits 0 to 15 of register B ($B \in \text{OREG}$).

The 24 bit value is stored in the lower significant bits (bit 0 to 23) of the memory location and the MHB register is stored in bits 24 to 31.

The program counter PC is increment by the value 4.

MWRI24 Instruction

Syntax: MWRI24 A, B

Operation: MEM(B[13:0])[23:0] ← A;

Status: -

Duration: 3 instruction cycles

Code: 1010aaaabbbb1000-----

Description: Transfer 24 bit value of A ($A \in \text{OREG}$) to memory using indirect addressing.

The memory location where to write to is defined by the bits 0 to 15 of register B ($B \in \text{OREG}$).

The 24 bit value is stored in the lower significant bits (bit 0 to 23) of the memory location and the bits 24 to 31 are left unchanged.

The program counter PC is increment by the value 4.

It should be noted that this operation is not an atomic instruction.

POP Instruction
Syntax: POP A

Operation: $A \leftarrow \text{MEM}(\text{R7}[13:0])[23:0]$;
 $\text{MHB} \leftarrow \text{MEM}(\text{R7}[13:0])[31:24]$;
 $\text{R7} \leftarrow \text{R7} - 4$;
 $\text{SP_CNT} \leftarrow \text{SP_CNT} - 1$
Status: Z, EN

Duration: 2 instruction cycles

Code: 1010aaaa---0101-----

Description: Transfer the lower significant bits (bit 0 to 23) from the top of stack to register A ($A \in \text{OREG}$), followed by decrementing the stack pointer register R7 with the value 4. The upper 8 bits (bit 24 to 31) from the top of the stack are transferred to register MHB.

If the MHB register is selected as destination register A ($A \neq \text{OREG}$), the bits 0 to 7 from the top of the stack are transferred to MHB.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register R7.

The zero bit Z of status register STA is set, if the lower 24 bit of the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is decremented.

If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFLO of register MCSi_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

PUSH Instruction
Syntax: PUSH A

Operation: $\text{R7} \leftarrow \text{R7} + 4$;
 $\text{SP_CNT} \leftarrow \text{SP_CNT} + 1$;
 $\text{MEM}(\text{R7}[13:0])[23:0] \leftarrow A$;
 $\text{MEM}(\text{R7}[13:0])[31:24] \leftarrow \text{MHB}$
Status: EN

Duration: 2 instruction cycles

Code: 1010aaaa---0110-----

Description: Increment the stack pointer register R7 with the value 4, followed by transferring a 24 bit value of operand A ($A \in \text{OREG}$) together with a MHB register to the

Generic Timer Module (GTM)

new top of the stack. The 24 bit value of A is stored in the bits 0 to 23 and content of the MHB register is stored in the bit 24 to 31 of the memory location.

The memory location for the top of the stack is addressed by the bits 0 to 15 of the stack pointer register.

The program counter PC is increment by the value 4.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is increment.

If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the memory write operation for the A and MHB is discard.

26.13.2.3 ARU Instructions

ARD Instruction

Syntax: ARD A, B, C

Operation: $A \leftarrow \text{ARU}(C[8:0])[23:0];$
 $B \leftarrow \text{ARU}(C[8:0])[47:24];$
 $\text{ACB}[4:0] \leftarrow \text{ARU}(C[8:0])[52:48]$

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0000-----cccccccc

Description: Perform a blocking read access to the ARU and transfer both 24 bit values received at the ARU port to the registers A and B ($A \in \text{AREG}$, $B \in \text{AREG}$), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register $\text{ZERO} \in \text{AREG}$ can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The received ARU control bits are stored in the register ACB.

The lower significant bits of the literal C ($C \in \text{LIT16}$) define the ARU address where to read from.

Generic Timer Module (GTM)

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1). The program counter PC is increment by the value 4.

ARDI Instruction

Syntax: ARDI A, B

Operation: $A \leftarrow \text{ARU}(\text{R6}[8:0])[23:0];$
 $B \leftarrow \text{ARU}(\text{R6}[8:0])[47:24];$
 $\text{ACB}[4:0] \leftarrow \text{ARU}(\text{R6}[8:0])[52:48]$

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0100-----

Description: Perform a blocking read access to the ARU and transfer both 24 bit values received at the ARU port to the registers A and B ($A \in \text{AREG}$, $B \in \text{AREG}$), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register $\text{ZERO} \in \text{AREG}$ can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The received ARU control bits are stored in the register ACB.

The read address is obtained from the bits 0 to 8 of the channels register R6.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

AWR Instruction

Syntax: AWR A, B, C

Operation: $\text{ARU}(\text{C}[4:0])[23:0] \leftarrow A;$
 $\text{ARU}(\text{C}[4:0])[47:24] \leftarrow B;$
 $\text{ARU}(\text{C}[4:0])[52:48] \leftarrow \text{ACB}[4:0];$

Status: CAT

Duration: suspends current MCS-channel

Generic Timer Module (GTM)

Code: 1011aaaabbbb0001-----cccc

Description: Perform a blocking write access to the ARU and transfer two 24 bit values to the ARU port using the registers A and B ($A \in \text{OREG}$, $B \in \text{OREG}$), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

The ARU control bits to be sent are taken from the register ACB.

The lower significant bits (bit 0 to bit 4) of the literal C ($C \in \text{LIT16}$) define an index into the pool of ARU write address that is used for writing data.

Each MCS submodule has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

AWRI Instruction

Syntax: AWRI A, B

Operation: ARU(R6[4:0])[23:0] ← A;
ARU(R6[4:0])[47:24] ← B;
ARU(R6[4:0])[52:48] ← ACB[4:0];

Status: CAT

Duration: suspends current MCS-channel

Code: 1011aaaabbbb0101-----

Description: Perform a blocking write access to the ARU and transfer two 24 bit values to the ARU port using the registers A and B ($A \in \text{OREG}$, $B \in \text{OREG}$), whereas A holds the lower 24 bit ARU word and B holds the upper 24 bit ARU word.

The ARU control bits to be sent are taken from the register ACB.

The bits 0 to 4 of the register R6 define an index into the pool of ARU write address that is used for writing data.

Each MCS submodule has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.

At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).

The program counter PC is increment by the value 4.

NARD Instruction

Syntax: NARD A, B, C

Operation: A ? ARU(C[8:0])[23:0];
B ? ARU(C[8:0])[47:24];
ACB[4:0] ? ARU(C[8:0])[52:48]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Code: 1011aaaabbbb0010-----cccccccc

Description: Perform a non-blocking read access to the ARU trying to transfer both 24 bit values received at the ARU port to the registers A and B (A ? AREG, B ? AREG), whereas A holds the lower 24 bit ARU word, B holds the upper 24 bit ARU word, and the ACB register holds the received ARU control bits.

The lower significant bits of the literal C (C ? LIT16) define the ARU address where to read from.

If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ? AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The program counter PC is incremented by the value 4.

NARDI Instruction

Syntax: NARDI A, B

Operation: A ? ARU(R6[8:0])[23:0];
B ? ARU(R6[8:0])[47:24];
ACB[4:0] ? ARU(R6[8:0])[52:48]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Code: 1011aaaabbbb0011-----

Description: Perform a non-blocking read access to the ARU trying to transfer both 24 bit values received at the ARU port to the registers A and B (A ? AREG, B ? AREG),

Generic Timer Module (GTM)

whereas A holds the lower 24 bit ARU word, B holds the upper 24 bit ARU word, and the ACB register holds the received ARU control bits.

The read address is obtained from the bits 0 to 8 of the channels register R6.

If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.

If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.

If A and B refer to the same register, only the upper 24 bit ARU word is stored and the lower 24 bit ARU word is discard.

If any transferred 24 bit value from the ARU should not stored in a register, the dummy register ZERO ? AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.

The program counter PC is incremented by the value 4.

26.13.2.4 Arithmetic Logic Instructions

ADDL Instruction

Syntax: ADDL A, C

Operation: $A \leftarrow A + C$

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 0010aaaaccccccccccccccccccccccccc

Description: Perform addition operation of a register A ($A \in \text{OREG}$) with a 24 bit literal value C ($C \in \text{LIT24}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred, when the result of the operation cannot be represented in the interval $[0; 2^{24}-1]$, assuming that both operands A and C are unsigned values within the interval $[0; 2^{24}-1]$.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval $[-2^{23}; 2^{23}-1]$, assuming that both operands A and C are signed values within the interval $[-2^{23}; 2^{23}-1]$.

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative ($N=1$) or positive ($N=0$), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

ADD Instruction

Syntax: ADD A, B

Operation: $A \leftarrow A + B$

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 1100aaaabbbb0000-----

Description: Perform addition operation of a register A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

Generic Timer Module (GTM)

The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred, when the result of the operation cannot be represented in the interval $[0; 2^{24}-1]$, assuming that both operands A and B are unsigned values within the interval $[0; 2^{24}-1]$.

The overflow bit V of status register STA is set, if a signed overflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval $[-2^{23}; 2^{23}-1]$, assuming that both operands A and B are signed values within the interval $[-2^{23}; 2^{23}-1]$.

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

SUBL Instruction

Syntax: SUBL A, C

Operation: $A \leftarrow A - C$

Status: Z, CY, N, V

Duration: 1 instruction cycle

Code: 0011aaaaccccccccccccccccccccccccc

Description: Perform subtraction operation of a register A ($A \in \text{OREG}$) with a 24 bit literal value C ($C \in \text{LIT24}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred, when the result of the operation cannot be represented in the interval $[0; 2^{24}-1]$, assuming that both operands A and C are unsigned values within the interval $[0; 2^{24}-1]$.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval $[-2^{23}; 2^{23}-1]$, assuming that both operands A and C are signed values within the interval $[-2^{23}; 2^{23}-1]$.

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

SUB Instruction**Syntax:** SUB A, B**Operation:** $A \leftarrow A - B$ **Status:** Z, CY, N, V**Duration:** 1 instruction cycle**Code:** 1100aaaabbbb0001-----**Description:** Perform subtraction operation of a register A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred, when the result of the operation cannot be represented in the interval $[0; 2^{24}-1]$, assuming that both operands A and B are unsigned values within the interval $[0; 2^{24}-1]$.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval $[-2^{23}; 2^{23}-1]$, assuming that both operands A and B are signed values within the interval $[-2^{23}; 2^{23}-1]$.

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative ($N=1$) or positive ($N=0$), assuming that no overflow/underflow occurred.

The program counter PC is increment by the value 4.

NEG Instruction**Syntax:** NEG A, B**Operation:** $A \leftarrow -B$ **Status:** Z, N, V**Duration:** 1 instruction cycle**Code:** 1100aaaabbbb0010-----**Description:** Perform negation operation (2's Complement) with an operand B ($B \in \text{OREG}$) and store the result in a register A ($A \in \text{OREG}$).

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred, when the result of the operation cannot be represented in the interval $[-2^{23}; 2^{23}-1]$.

Generic Timer Module (GTM)

1], assuming that both operands A and B are signed values within the interval $[-2^{23}, 2^{23}-1]$.

The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.

The program counter PC is incremented by the value 4.

ANDL Instruction

Syntax: ANDL A, C

Operation: $A \leftarrow A \text{ AND } C$

Status: Z

Duration: 1 instruction cycle

Code: 0100aaaacccccccccccccccccccccccc

Description: Perform bitwise AND conjunction of a register A ($A \in \text{OREG}$) with a 24 bit literal value C ($C \in \text{LIT24}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

AND Instruction

Syntax: AND A, B

Operation: $A \leftarrow A \text{ AND } B$

Status: Z

Duration: 1 instruction cycle

Code: 1100aaaabbbb0011-----

Description: Perform bitwise AND conjunction of a register A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.

ORL Instruction

Syntax: ORL A, C

Operation: $A \leftarrow A \text{ OR } C$

Status: Z

Duration: 1 instruction cycle

Generic Timer Module (GTM)

Code: 0101aaaaccccccccccccccccccccccccc

Description: Perform bitwise OR conjunction of a register A ($A \in \text{OREG}$) with a 24 bit literal value C ($C \in \text{LIT24}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

OR Instruction

Syntax: OR A, B

Operation: $A \leftarrow A \text{ OR } B$

Status: Z

Duration: 1 instruction cycle

Code: 1100aaaabbbb0100-----

Description: Perform bitwise OR conjunction of a register A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

XORL Instruction

Syntax: XORL A, C

Operation: $A \leftarrow A \text{ XOR } C$

Status: Z

Duration: 1 instruction cycle

Code: 0110aaaaccccccccccccccccccccccccc

Description: Perform bitwise XOR conjunction of a register A ($A \in \text{OREG}$) with a 24 bit literal value C ($C \in \text{LIT24}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

XOR Instruction

Syntax: XOR A, B

Operation: $A \leftarrow A \text{ XOR } B$

Status: Z

Duration: 1 instruction cycle

Generic Timer Module (GTM)

Code: 1100aaaabbbb0101-----

Description: Perform bitwise XOR conjunction of a register A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$) and store the result in register A.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

SHR Instruction

Syntax: SHR A, C

Operation: $A \leftarrow A \gg C$

Status: Z, CY

Duration: 1 instruction cycle

Code: 1100aaaa----0110-----cccc

Description: Perform right shift operation C ($C \in \text{LIT16}$) times of register A ($A \in \text{OREG}$), whereas C must be in the range [0; 24]. The most significant bits that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the last LSB that is shifted out of the register.

The program counter PC is increment by the value 4._

SHL Instruction

Syntax: SHL A, C

Operation: $A \leftarrow A \ll C$

Status: Z, CY

Duration: 1 instruction cycle

Code: 1100aaaa----0111-----cccc

Description: Perform left shift operation C ($C \in \text{LIT16}$) times of register A ($A \in \text{OREG}$), whereas C must be in the range [0; 24]. The lower significant bits that are shifted into A are cleared.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The carry bit CY of status register STA is updated to the last MSB that is shifted out of the register.

The program counter PC is increment by the value 4.

26.13.2.5 Test Instructions

ATUL Instruction

Syntax: ATUL A, C

Operation: A - C

Status: Z, CY

Duration: 1 instruction cycle

Code: 0111aaaacccccccccccccccccccccccc

Description: Arithmetic Test with an unsigned operand A ($A \in \text{OREG}$) and an unsigned 24 bit literal value C ($C \in \text{LIT24}$).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned literal C.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is increment by the value 4.

ATU Instruction

Syntax: ATU A, B

Operation: A - B

Status: Z, CY

Duration: 1 instruction cycle

Code: 1101aaaabbbb0000-----

Description: Arithmetic Test with an unsigned operand A ($A \in \text{OREG}$) and an unsigned operand B ($B \in \text{OREG}$).

The carry bit CY of status register STA is set if unsigned operand A is less than unsigned operand B.

Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is increment by the value 4.

ATSL Instruction**Syntax:** ATSL A, C**Operation:** A - C**Status:** Z, CY**Duration:** 1 instruction cycle**Code:** 1000aaaaccccccccccccccccccccccccc**Description:** Arithmetic Test with a signed operand A ($A \in \text{OREG}$) and a signed 24 bit literal value C ($C \in \text{LIT24}$).

The carry bit CY of status register STA is set if signed operand A is less than signed literal C.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed literal C.

The zero bit Z of status register STA is set, if A equals to C.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.

The program counter PC is increment by the value 4.

ATS Instruction**Syntax:** ATS A, B**Operation:** A - B**Status:** Z, CY**Duration:** 1 instruction cycle**Code:** 1101aaaabbbb0001-----**Description:** Arithmetic Test with a signed operand A ($A \in \text{OREG}$) and a signed operand B ($B \in \text{OREG}$).

The carry bit CY of status register STA is set if signed operand A is less than signed operand B.

Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed operand B.

The zero bit Z of status register STA is set, if A equals to B.

Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B.

The program counter PC is increment by the value 4.

BTL Instruction**Syntax:** BTL A, C**Operation:** A AND C

Generic Timer Module (GTM)**Status:** Z**Duration:** 1 instruction cycle**Code:** 1001aaaaccccccccccccccccccccccc**Description:** Bit test of an operand A ($A \in \text{OREG}$) with a 24 bit literal bit mask C ($C \in \text{LIT24}$).

The bit test is performed by applying a bitwise logical AND operation with operand A and the bit mask C without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

BT Instruction**Syntax:** BT A, B**Operation:** A AND B**Status:** Z**Duration:** 1 instruction cycle**Code:** 1101aaaabbbb0010-----**Description:** Bit test of an operand A ($A \in \text{OREG}$) with an operand B ($B \in \text{OREG}$), whereas usually one of the operands is a register holding a bit mask.

The bit test is performed by applying a bitwise logical AND operation with register A and register B without storing the result.

The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.

The program counter PC is increment by the value 4.

26.13.2.6 Control Flow Instructions**JMP Instruction****Syntax:** JMP C**Operation:** $\text{PC} \leftarrow \text{C}[13:0]$ **Status:** -**Duration:** 1 instruction cycle**Code:** 1110-----0000--cccccccccccc**Description:** Execute unconditional jump to the memory location C ($C \in \text{LIT16}$).

The program counter PC is loaded with literal C.

JBS Instruction**Syntax:** JBS A, B, C[13:0]**Operation:** $PC \leftarrow C$ if A[B] is set**Status:** -**Duration:** 1 instruction cycle**Code:** 1110aaaabbbb0001--cccccccccccc**Description:** Execute conditional jump to the memory location C ($C \in \text{LIT16}$).

The program counter PC is loaded with literal C, if the bit at position B ($B \in \text{LIT4}$) of operand A ($A \in \text{OREG}$) is set.

Otherwise, if the bit is cleared, the program counter PC is increment by the value 4.

JBC Instruction**Syntax:** JBC A, B, C[13:0]**Operation:** $PC \leftarrow C$ if A[B] is cleared**Status:** -**Duration:** 1 instruction cycle**Code:** 1110aaaabbbb0010--cccccccccccc**Description:** Execute conditional jump to the memory location C ($C \in \text{LIT16}$).

The program counter PC is loaded with literal C, if the bit at position B ($B \in \text{LIT4}$) of operand A ($A \in \text{OREG}$) is cleared.

Otherwise, if the bit is set, the program counter PC is increment by the value 4.

CALL Instruction**Syntax:** CALL C**Operation:** $R7 \leftarrow R7 + 4;$ $\text{MEM}(R7[15:0])[15:0] \leftarrow PC + 4;$ $PC \leftarrow C[13:0];$ $SP_CNT \leftarrow SP_CNT + 1$ **Status:** EN**Duration:** 2 instruction cycles**Code:** 1110-----0011--cccccccccccc**Description:** Call subprogram at memory location C ($C \in \text{LIT16}$).

The stack pointer register R7 is increment by the value 4.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register.

Generic Timer Module (GTM)

After the stack pointer is increment, the increment value of the PC is transferred to the top of the stack.

The program counter PC is loaded with literal C.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is increment.

If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the memory write operation of the increment PC is discarding.

RET Instruction

Syntax: RET

Operation: PC ← MEM(R7[15:0])[15:0];

R7 ← R7 - 4;

SP_CNT ← SP_CNT - 1

Status: EN

Duration: 2 instruction cycles

Code: 1110-----0100-----

Description: Return from subprogram.

The program counter PC is loaded with current value on the top of the stack.

Finally, the stack pointer register R7 is decremented by the value 4.

The memory location for the top of the stack is identified by the bits 0 to 15 of the stack pointer register.

The SP_CNT bit field inside the MCSi_CHx_CTRL register is decremented.

If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.

If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCSi_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

26.13.2.7 Other Instructions**WURM Instruction**

Syntax: WURM A B C

Operation: Wait until register match

Generic Timer Module (GTM)

Status: CWT

Duration: suspends current MCS-channel

Code: 1111aaaabbbb0000cccccccccccccccc

Description: Suspend current MCS-channel until the following register match condition occurs:

$A = (B \text{ AND } \text{MASK})$

whereas $A \in \text{OREG}$, $B \in \text{OREG}$, AND is a bitwise AND operation with bitmask MASK. The bits 16 to 23 of MASK are set to true and the bits 0 to 15 are copied from the instructions literal $C \in \text{LIT16}$.

If the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is increment by the value 4.

This instruction can be used to wait for one or more trigger events generated by other MCS-channels or the CPU. In this case register B is the trigger register STRG, A is a general purpose register holding the bits with the trigger condition to wait for and C is the bitmask that enables trigger bits of interest.

The trigger bits can be set by other MCS channels with a write access (e.g. using a MOVL instruction) to the STRG register or the CPU with a write access to the MCSi_STRG register.

The trigger bits are not cleared automatically by hardware after resuming an MCS-channel, but they have to be cleared explicitly with a write access to the register CTRG by the MCS-channel or with a write access to the register MCSi_CTRG by the CPU.

Please note that more than one channel can wait for the same trigger bit to continue.

The instruction can also be used to wait on a specific time/angle event provided by the TBU. In this case register B is the interesting TBU register TBU_TS0, TBU_TS1, or TBU_TS2, register A is a general purpose register holding the value to wait for and bitmask C should be set to 0xFFFF.

At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully ($\text{CWT} = 0$) or it was cancelled by the CPU ($\text{CWT} = 1$).

If the CWT bit is set simultaneously with the occurrence of the register match condition, the register match condition is prioritized resulting in a cleared CWT bit.

The program counter PC is increment by the value 4, when the trigger bit is set and the channel continues its operation.

NOP Instruction

Syntax: NOP

Operation: -

Status: -

Duration: 1 instruction cycle

Code: 0000-----

Description: No operation is performed.

The program counter PC is increment by the value 4.

26.13.3 MCS Internal Registers

This section describes MCS internal registers which are partly only accessible by the corresponding MCS-channel itself and partly global to all channels. Please see [Table 26-42](#) for clarification.

These registers can be directly accessed with the entire MCS instruction set, e.g. using the ORL instruction to set a specific bit.

26.13.3.1 MCS Internal Registers Overview

The table describes the MCS internal registers. Only parts of this register set can be accessed by the CPU:

Table 26-42 MCS Internal Registers Overview

Register Name	Description	Details in Section
Rx	General purpose register x (x: 0...7), MCS Task internal register	Section 26.13.3.2
STA	Status register, MCS Task internal register	Section 26.13.3.3
ACB	ARU Control Bit register, MCS Task internal register	Section 26.13.3.4
CTRG	Clear Trigger Bits register, MCS Global register from task view	Section 26.13.3.5
STRG	Set Trigger Bits register, MCS Global register from task view	Section 26.13.3.6
TBU_TS0	TBU Timestamp TS0 register, MCS Global register from task view	Section 26.13.3.7
TBU_TS1	TBU Timestamp TS1 register, MCS Global register from task view	Section 26.13.3.8
TBU_TS2	TBU Timestamp TS2 register, MCS Global register from task view	Section 26.13.3.9
MHB	Memory High Byte register, MCS Task internal register	Section 26.13.3.10

Generic Timer Module (GTM)

26.13.3.2 General purpose register Rx (x:0...7)

Rx (x=0-7)

General Purpose Register x (0 + x_H) Reset Value: 000000_H

Field	Bits	Type	Description
DATA	[23:0]	rw	Data field of general purpose register Note: Register R7 is also used as stack pointer register, if stack operations are used in the MCS micro program. Note: Register R6 used also as index/address register for indirect ARU addressing instructions.
n/a	[31:24]	rw	Not applicable

Generic Timer Module (GTM)
26.13.3.3 Register STA

Note: If both, the CPU and the MCS-channel are writing to the same register at the clock cycle, the value of the CPU is written to the register and the value of the MCS-channel is discarding.

STA
Status Register
(8_H)
Reset Value: 00000XX_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
n/a								Reserved				SP_CNT				
r								r				r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved						SAT	CWT	CAT	N	V	Z	CY	MCA	ERR	IRQ	EN
r						r	r	r	r	r	r	rh	rwh	rwh	rw	rw

Field	Bits	Type	Description
EN	0	rw	Enable current MCS-channel 0 _B Disable current MCS-channel. 1 _B Enable current MCS-channel.
IRQ	1	rw	Trigger IRQ 0 _B No triggered IRQ signal. 1 _B Trigger IRQ signal. Note: An MCS-channel trigger an IRQ by writing value 1 to bit IRQ. Writing a value 0 to this bit does not cancel the IRQ, and thus has no effect. Note: An MCS-channel can read the IRQ bit in order to determine the current state of the IRQ handling. The MCS-channel reads a value 1 if an IRQ was released but not cleared by CPU. If an MCS-channel reads a value 0 no IRQ was released or it has been cleared by CPU. Note: The IRQ bit can only be cleared by CPU, by writing a 1 to the corresponding MCSi_CHx_NOTIFY register (see Section 26.13.4.6).

Generic Timer Module (GTM)

Field	Bits	Type	Description
ERR	2	rwh	<p>Set Error Signal</p> <p>0_B No Error occurred 1_B Error occurred</p> <p>Note: The ERR signal of an MCS-channel reflects Error status that may be caused by one of the following conditions:</p> <ul style="list-style-type: none"> • MCS-channel program sets the ERR signal by writing to this bit • ?ECC RAM Error occurred while accessing the connected RAM pages (also disables MCS-channel by clearing bit EN) • Decoding an instruction with an invalid opcode (also disables MCS-channel by clearing bit EN) <p>Note: If the GTM includes a MON submodule, the ERR signal is always captured by this module.</p> <p>Note: An MCS-channel releases an error signal by writing value 1 to bit ERR. Writing a value 0 to this bit does not cancel the error signal, and thus has no effect.</p> <p>Note: An MCS-channel can read the ERR bit in order to determine the current state of the error signal. The MCS-channel reads a value 1 if an ERR occurred previously, but not cleared by CPU. If an MCS-channel reads a value 0 no error was set or it has been cleared by CPU.</p> <p>Note: The ERR bit can only be cleared by CPU, by writing a 1 to the MCSi_ERR register (see Register MCSi_ERR).</p>
MCA	3	rwh	<p>MON Activity signalling for MCS channel</p> <p>0_B No activity signalled to submodule MON. 1_B Activity signalled to submodule MON.</p> <p>Note: When this bit is set the corresponding channel in the MON submodule register MON_ACTIVITY is set (see Section 26.20.8.2. This bit is automatically cleared after writing it by the MCS channel program.</p>
CY	4	rh	<p>Carry bit</p> <p>The carry bit is updated by several arithmetic and logic instructions. In arithmetic operations, the carry bit indicates an unsigned under/overflow.</p>
Z	5	r	<p>Zero bit</p> <p>The zero bit is updated by several arithmetic, logic and data transfer instructions to indicate a result of zero.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
V	6	r	Overflow bit The overflow bit is updated by arithmetic instructions in order to indicate a signed under/overflow.
N	7	r	Negative bit The negative bit is updated by arithmetic instructions in order to indicate a negative result.
CAT	8	r	Cancel ARU transfer bit 0 _B Last ARU transfer was not cancelled. 1 _B CPU cancelled last ARU transfer. <i>Note: This bit is updated after each ARU transfer and it should be evaluated immediately after the ARU instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.</i>
CWT	9	r	Cancel WURM instruction bit 0 _B Last WURM instruction was not cancelled. 1 _B CPU cancelled last WURM instruction of channel. <i>Note: This bit is updated after each WURM instruction and it should be evaluated immediately after the WURM instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.</i>
SAT	10	r	Successful ARU transfer bit 0 _B Non-blocking ARU transfer failed due to missing data 1 _B Non-blocking ARU transfer finished successfully
Reserved	[15:11]	r	Reserved Read as zero, should be written as zero
SP_CNT	[18:16]	r	Stack pointer counter value Actual stack depth of channel. The bit field is increment on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
Reserved	[23:19]	r	Reserved Read as zero, should be written as zero
n/a	[31:24]	r	Not applicable

Generic Timer Module (GTM)

Note: Writing to bits of the register STA with instructions that do implicitly a read-modify-write operation (e.g. "ANDL STA, 0xFFFFFE" or "OR STA, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing of bits of the register STA is to use instructions that do not read the content of STA (e.g. "MOVL STA, 0x0" or "MOV STA, R1").

26.13.3.4 Register ACB
ACB
ARU Control Bit Register
(9_H)
Reset Value: 01FE00XX_H

Field	Bits	Type	Description
ACB0	0	rw	ARU Control bit 0 Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 48 of the ARU word.
ACB1	1	rw	ARU Control bit 1 Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 49 of the ARU word.
ACB2	2	rw	ARU Control bit 2 Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 50 of the ARU word.
ACB3	3	rw	ARU Control bit 3 Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 51 of the ARU word.
ACB4	4	rw	ARU Control bit 4 Note: This bit is updated by each ARU read access and its value is sent to ARU by each ARU write access on bit 52 of the ARU word.
Reserved	[23:5]	rw	Reserved Read as zero, should be written as zero
n/a	[31:24]	r	Not applicable

TRG7	7	rw	Trigger bit 7 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG8	8	rw	Trigger bit 8 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG9	9	rw	Trigger bit 9 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG10	10	rw	Trigger bit 10 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG11	11	rw	Trigger bit 11 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG12	12	rw	Trigger bit 12 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG13	13	rw	Trigger bit 13 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit
TRG14	14	rw	Trigger bit 14 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRG15	15	rw	Trigger bit 15 0_B READ: trigger bit is cleared / WRITE: do nothing 1_B READ: trigger bit is set / WRITE: clear trigger bit Note: The trigger bits TRGx (x = 0...15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCSi_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCSi_CTRG register in the case of the CPU. Trigger bits can be used for signaling specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
Reserved	[23:16]	rw	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRG13	13	rw	Trigger bit 13 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: set trigger bit
TRG14	14	rw	Trigger bit 14 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: set trigger bit
TRG15	15	rw	Trigger bit 15 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: set trigger bit Note: The trigger bits TRGx (x = 0...15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCSi_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCSi_CTRG register in the case of the CPU. Trigger bits can be used for signaling specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
Reserved	[23:16]	rw	Reserved Read as zero, should be written as zero
n/a	[31:24]	r	Not applicable

26.13.3.7 Register TBU_TS0
TBU_TS0
TBU Timestamp TS0 Register
(C_H)
Reset Value: XXXXXXXX_H

Field	Bits	Type	Description
TS	[23:0]	r	Current TBU time stamp 0

Generic Timer Module (GTM)

Field	Bits	Type	Description
n/a	[31:24]	r	Not applicable Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

26.13.3.8 Register TBU_TS1
TBU_TS1
TBU Timestamp TS1 Register
(D_H)
Reset Value: XXXXXXXX_H

Field	Bits	Type	Description
TS	[23:0]	r	Current TBU time stamp 1
n/a	[31:24]	r	Not applicable Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

26.13.3.9 Register TBU_TS2
TBU_TS2
TBU Timestamp TS2 Register
(E_H)
Reset Value: XXXXXXXX_H

Field	Bits	Type	Description
TS	[23:0]	r	Current TBU time stamp 2

Generic Timer Module (GTM)

Field	Bits	Type	Description
n/a	[31:24]	r	Not applicable Note: Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

26.13.3.10 Register MHB
MHB
Memory High Byte Register
(F_H)
Reset Value: XX000000_H

Field	Bits	Type	Description
DATA	[7:0]	rw	High Byte of a memory transfer
Reserved	[23:8]	rw	Reserved Read as zero, should be written as zero
n/a	[31:24]	r	Not applicable

26.13.4 MCS Configuration Registers

This section describes the configuration registers of the MCS submodule.

These registers can only be accessed by the CPU using AEI, but not within the MCS-channel using MCS instructions.

26.13.4.1 MCS Configuration Registers Overview

The table describes the MCS registers that are visible and accessible by the CPU:

Table 26-43 MCS Configuration Registers Overview

Register Name	Description	Details in Section
MCSi_CHx_CTRL	MCS Channel control register (x: 0...7)	Section 26.13.4.2
MCSi_CHx_PC	MCS Channel Program counter register (x: 0...7)	Section 26.13.4.3
MCSi_CHx_Ry	MCS Channel GPRz registers (x: 0...7; y: 0...7)	Section 26.13.4.4
MCSi_CHx_ACB	MCS Channel ACB register (x: 0...7)	Section 26.13.4.5
MCSi_CHx_IRQ_NOTIFY	MCS Channel x interrupt notification register (x: 0...7)	Section 26.13.4.6

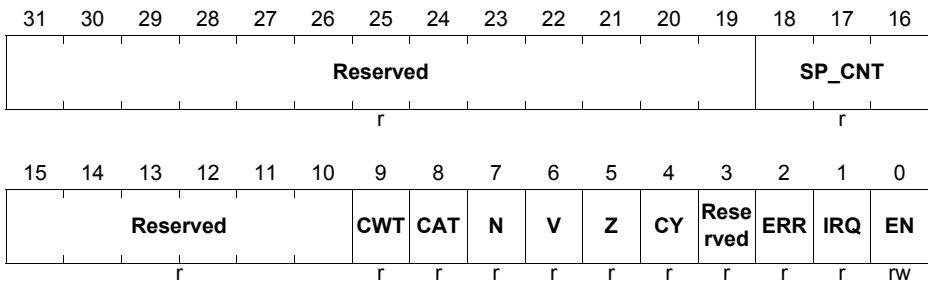

Generic Timer Module (GTM)
Table 26-43 MCS Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section
MCSi_CHx_IRQ_EN	MCS Channel x interrupt enable register (x: 0...7)	Section 26.13.4.7
MCSi_CHx_IRQ_FORCINT	MCS Channel x software interrupt generation register (x: 0...7)	Section 26.13.4.8
MCSi_CHx_IRQ_MODE	IRQ mode configuration register (x=0...7)	Section 26.13.4.9
MCSi_CHx_EIRQ_EN	MCS Channel x error interrupt enable register (x=0...7)	Section 26.13.4.10
MCSi_CTRL	MCS Control register	Section 26.13.4.11
MCSi_CTRG	MCS Clear trigger control register	Section 26.13.4.12
MCSi_STRG	MCS Set trigger control register	Section 26.13.4.13
MCSi_RST	MCS Channel reset register	Section 26.13.4.14
MCSi_ERR	MCS Error register	Section 26.13.4.15

Generic Timer Module (GTM)

26.13.4.2 Register MCSi_CHx_CTRL (x:07)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_CTRL (x=0-7)
MCS0 Channel Control Register (30020_H+x*80_H)
Reset Value: 00000000_H
GTM_MCS1_CHx_CTRL (x=0-7)
MCS1 Channel Control Register (31020_H+x*80_H)
Reset Value: 00000000_H
GTM_MCS2_CHx_CTRL (x=0-7)
MCS2 Channel Control Register (32020_H+x*80_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
EN	0	rw	<p>Enable MCS-channel</p> <p>0_B Disable current MCS-channel. 1_B Enable current MCS-channel.</p> <p>Note: Enabling or disabling of an MCS-channel is synchronized to the ending of an instruction and thus it may take several clock cycles, e.g. active memory transfers or pending WURM transfers have to be finished before disabling the MCS-channel. The internal state of a channel can be obtained by reading the bit EN.</p> <p>Note: In order to disable an MCS channel reliably the EN bit should be cleared following by setting the CAT and CWT bit in order to cancel any pending WURM or ARU instructions.</p> <p>Note: The EN bit is write protected during RAM reset phase.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
IRQ	1	r	Interrupt state 0_B No interrupt pending in MCS-channel x. 1_B Interrupt is pending in MCS-channel x. Note: This bit is read only and it mirrors the internal IRQ state.
ERR	2	r	Error state 0_B No error signal pending in MCS-channel x. 1_B Error signal is pending in MCS-channel x. Note: This bit is read only and it mirrors the internal error state.
Reserved	3	r	Reserved Read as zero, should be written as zero
CY	4	r	Carry bit state Note: This bit is read only and it mirrors the internal carry flag CY.
Z	5	r	Zero bit state Note: This bit is read only and it mirrors the internal zero flag Z.
V	6	r	Overflow bit state Note: This bit is read only and it mirrors the internal carry flag V.
N	7	r	Negative bit state Note: This bit is read only and it mirrors the internal zero flag N.
CAT	8	r	Cancel ARU transfer state Note: This bit is read only and it mirrors the internal cancel ARU transfer status flag CAT.
CWT	9	r	Cancel WURM instruction state Note: This bit is read only and it mirrors the internal cancel WURM instruction status flag CWT.
Reserved	[15:10]	r	Reserved Read as zero, should be written as zero
SP_CNT	[18:16]	r	Stack pointer counter value Actual stack depth of channel. The bit field is increment on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:19]	r	Reserved Read as zero, should be written as zero

26.13.4.3 Register MCSi_CHx_PC (x:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCSi_CH0_PC (i=0-2) MCSi Channel 0 Program Counter Register (30040 _H +i*1000 _H)	Reset Value: 00000000_H
GTM_MCSi_CH1_PC (i=0-2) MCSi Channel 1 Program Counter Register (300C0 _H +i*1000 _H)	Reset Value: 00000004_H
GTM_MCSi_CH2_PC (i=0-2) MCSi Channel 2 Program Counter Register (30140 _H +i*1000 _H)	Reset Value: 00000008_H
GTM_MCSi_CH3_PC (i=0-2) MCSi Channel 3 Program Counter Register (301C0 _H +i*1000 _H)	Reset Value: 0000000C_H
GTM_MCSi_CH4_PC (i=0-2) MCSi Channel 4 Program Counter Register (30240 _H +i*1000 _H)	Reset Value: 00000010_H
GTM_MCSi_CH5_PC (i=0-2) MCSi Channel 5 Program Counter Register (302C0 _H +i*1000 _H)	Reset Value: 00000014_H
GTM_MCSi_CH6_PC (i=0-2) MCSi Channel 6 Program Counter Register (30340 _H +i*1000 _H)	Reset Value: 00000018_H
GTM_MCSi_CH7_PC (i=0-2) MCSi Channel 7 Program Counter Register (303C0 _H +i*1000 _H)	Reset Value: 0000001C_H

Field	Bits	Type	Description
PC	[13:0]	rw	Current Program Counter Note: The program counter is only writable if the corresponding MCS-channel is disabled. The bits 0 and 1 are always written as zeros.
Reserved	[31:14]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.13.4.4 Register MCSi_CHx_Ry (x:0...7, y:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CH0_Ry (y=0-7)

MCS0 Channel 0 Program Counter Register y

(30000_H+y*04_H)

Reset Value: 00000000_H

GTM_MCS1_CH0_Ry (y=0-7)

MCS1 Channel 0 Program Counter Register y

(31000_H+y*04_H)

Reset Value: 00000000_H

GTM_MCS2_CH0_Ry (y=0-7)

MCS2 Channel 0 Program Counter Register y

(32000_H+y*04_H)

Reset Value: 00000000_H

GTM_MCS0_CH1_Ry (y=0-7)

MCS0 Channel 1 Program Counter Register y

(30080_H+y*04_H)

Reset Value: 00000000_H

GTM_MCS1_CH1_Ry (y=0-7)

MCS1 Channel 1 Program Counter Register y

(31080_H+y*04_H)

Reset Value: 00000000_H

GTM_MCS2_CH1_Ry (y=0-7)

MCS2 Channel 1 Program Counter Register y

(32080_H+y*04_H)

Reset Value: 00000000_H

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Field	Bits	Type	Description
DATA	[23:0]	rw	Data of MCS general purpose register ry
Reserved	[31:24]	r	Read as zero, should be written as zero Note: This register is the same as described in Section 26.13.2 .

Generic Timer Module (GTM)

GTM_MCS0_CH2_Ry (y=0-7)		
MCS0 Channel 2 Program Counter Register y	(30100_H+y*04_H)	Reset Value: 00000000_H
GTM_MCS1_CH2_Ry (y=0-7)		
MCS1 Channel 2 Program Counter Register y	(31100_H+y*04_H)	Reset Value: 00000000_H
GTM_MCS2_CH2_Ry (y=0-7)		
MCS2 Channel 2 Program Counter Register y	(32100_H+y*04_H)	Reset Value: 00000000_H
GTM_MCS0_CH3_Ry (y=0-7)		
MCS0 Channel 3 Program Counter Register y	(30180_H+y*04_H)	Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[23:0]	rw	Data of MCS general purpose register ry
Reserved	[31:24]	r	Read as zero, should be written as zero Note: This register is the same as described in Section 26.13.2 .

26.13.4.5 Register MCSi_CHx_ACB (x:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_ACB (x=0-7)
MCS0 Channel ACB Register (30024_H+x*80_H) Reset Value: 00000000_H
GTM_MCS1_CHx_ACB (x=0-7)
MCS1 Channel ACB Register (31024_H+x*80_H) Reset Value: 00000000_H
GTM_MCS2_CHx_ACB (x=0-7)
MCS2 Channel ACB Register (32024_H+x*80_H) Reset Value: 00000000_H

Field	Bits	Type	Description
ACB0	0	r	ARU Control bit 0 Note: This bit is read only and it mirrors the internal state.
ACB1	1	r	ARU Control bit 1 Note: This bit is read only and it mirrors the internal state.
ACB2	2	r	ARU Control bit 2 Note: This bit is read only and it mirrors the internal state.
ACB3	3	r	ARU Control bit 3 Note: This bit is read only and it mirrors the internal state.
ACB4	4	r	ARU Control bit 4 Note: This bit is read only and it mirrors the internal state.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.13.4.6 Register MCSi_CHx_IRQ_NOTIFY (x:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_NOTIFY (x=0-7)

MCS0 Channel x interrupt notification register

$$(30044_H + x * 80_H)$$

Reset Value: 00000000_H

GTM_MCS1_CHx_IRQ_NOTIFY (x=0-7)

MCS1 Channel x interrupt notification register

$$(31044_H + x * 80_H)$$

Reset Value: 00000000_H

GTM_MCS2_CHx_IRQ_NOTIFY (x=0-7)

MCS2 Channel x interrupt notification register

$$(32044_H + x * 80_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
MCS_IRQ	0	rwh	<p>Interrupt request by MCS-channel x</p> <p>0_B No IRQ released 1_B IRQ released by MCS-channel</p> <p>Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged. Note: By writing a '1' to this register, the IRQ flag in the MCS channel status register STA is cleared.</p>
STK_ERR_IRQ	1	rwh	<p>Stack counter overflow/underflow of channel x</p> <p>0_B No IRQ released 1_B A stack counter overflow or underflow occurred</p> <p>Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
MEM_ERR_IRQ	2	rwh	<p>Memory access out of range in channel x</p> <p>0_B No IRQ released 1_B MCS-channel request a memory location out of range 0 to MP1-4.</p> <p>Note: This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged. Note: In the case of a memory overflow, any read or write access to the RAM is always blocked. The read data is unpredictable. Note: It should be noted that in case of a memory overflow, the MSC channel will continue. Thus it is recommended that the CPU immediately stops the MSC channel.</p>
Reserved	[31:3]	r	<p>Reserved Read as zero, should be written as zero</p>

26.13.4.7 Register MCSi_CHx_IRQ_EN (x:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_EN (x=0-7)

MCS0 Channel x Interrupt Enable Register

(30048_H+x*80_H)

Reset Value: 00000000_H

GTM_MCS1_CHx_IRQ_EN (x=0-7)

MCS1 Channel x Interrupt Enable Register

(31048_H+x*80_H)

Reset Value: 00000000_H

GTM_MCS2_CHx_IRQ_EN (x=0-7)

MCS2 Channel x Interrupt Enable Register

(32048_H+x*80_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
MCS_IRQ_EN	0	rw	MCS channel x MCS_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
STK_ERR_IRQ_EN	1	rw	MCS channel x STK_ERR_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
MEM_ERR_IRQ_EN	2	rw	MCS channel x MEM_ERR_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
Reserved	[31:3]	r	Reserved Read as zero, should be written as zero

26.13.4.8 Register MCSi_CHx_IRQ_FORCINT (x:0...7)

All of the following registers are 32-bit accessible.

Generic Timer Module (GTM)

GTM_MCS0_CHx_IRQ_FORCINT (x=0-7)
 MCS0 Channel x Software Interrupt Generation Register
 (3004C_H+x*80_H) Reset Value: 00000000_H

GTM_MCS1_CHx_IRQ_FORCINT (x=0-7)
 MCS1 Channel x Software Interrupt Generation Register
 (3104C_H+x*80_H) Reset Value: 00000000_H

GTM_MCS2_CHx_IRQ_FORCINT (x=0-7)
 MCS2 Channel x Software Interrupt Generation Register
 (3204C_H+x*80_H) Reset Value: 00000000_H

Field	Bits	Type	Description
TRG_MCS_IRQ	0	w	Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software 0 _B No interrupt triggering 1 _B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_STK_ERR_IRQ	1	w	Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software 0 _B No interrupt triggering 1 _B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRG_MEM_ERR_IRQ	2	w	Trigger IRQ bit in MCS_CH_x_IRQ_NOTIFY register by software 0 _B No interrupt triggering 1 _B Assert corresponding field in MCSi_CHx_IRQ_NOTIFY register Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:3]	r	Reserved Read as zero, should be written as zero

26.13.4.9 Register MCSi_CHx_IRQ_MODE (x:0...7)

All of the following registers are 32-bit only accessible.

GTM_MCS0_CHx_IRQ_MODE (x=0-7)
MCS0 IRQ Mode Configuration Register
 $(30050_H + x * 80_H)$
Reset Value: 00000000_H
GTM_MCS1_CHx_IRQ_MODE (x=0-7)
MCS1 IRQ Mode Configuration Register
 $(31050_H + x * 80_H)$
Reset Value: 00000000_H
GTM_MCS2_CHx_IRQ_MODE (x=0-7)
MCS2 IRQ Mode Configuration Register
 $(32050_H + x * 80_H)$
Reset Value: 00000000_H

Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	IRQ mode selection 00 _B Level mode 01 _B Pulse mode 10 _B Pulse-Notify mode 11 _B Single-Pulse mode Note: The interrupt modes are described in Section 26.2.5 .

Generic Timer Module (GTM)

Field	Bits	Type	Description

Generic Timer Module (GTM)

26.13.4.10 Register MCSi_CHx_EIRQ_EN (x:0...7)

GTM_MCS0_CHx_EIRQ_EN (x=0-7)

 MCS0_Channel x Error Interrupt Enable Register
 (30054_H+x*80_H)

 Reset Value: 00000000_H

GTM_MCS1_CHx_EIRQ_EN (x=0-7)

 MCS1_Channel x Error Interrupt Enable Register
 (31054_H+x*80_H)

 Reset Value: 00000000_H

GTM_MCS2_CHx_EIRQ_EN (x=0-7)

 MCS2_Channel x Error Interrupt Enable Register
 (32054_H+x*80_H)

 Reset Value: 00000000_H

Field	Bits	Type	Description
MCS_EIRQ_EN	0	rw	MCS channel x MCS_EIRQ error interrupt enable 0 _B Disable error interrupt 1 _B Enable error interrupt
STK_ERR_IRQ_EN	1	rw	MCS channel x STK_ERR_IRQ error interrupt enable 0 _B Disable error interrupt 1 _B Enable error interrupt
MEM_ERR_IRQ_EN	2	rw	MCS channel x MEM_ERR_IRQ error interrupt enable 0 _B Disable error interrupt 1 _B Enable error interrupt
Reserved	[31:3]	r	Reserved Read as zero, should be written as zero

26.13.4.11 Register MCSi_CTRL

All of the following registers are 32-bit only accessible.

GTM_MCSi_CTRL (i=0-2)

MCSi Control Register (30074_H+i*1000_H) **Reset Value: 00010000_H**

Field	Bits	Type	Description
SCHED	0	rw	MCS submodule scheduling scheme 0 _B Accelerated scheduling scheme. 1 _B Round-Robin scheduling scheme.
HLT_SP_OFL	1	rw	Halt on stack pointer overflow 0 _B No halt on MCS-channel stack pointer counter over/underflow. 1 _B MCS-channel is disabled if a stack pointer counter over/underflow occurs.
Reserved	[15:2]	r	Reserved Read as zero, should be written as zero
RAM_RST	16	r	RAM reset bit 0 _B READ: no RAM reset is active / WRITE: do nothing. 1 _B READ: MCS currently resets RAM content / WRITE: trigger RAM reset. Note: The RAM reset initializes the memory content with zeros. RAM access and enabling of MCS channels is disabled during active RAM reset. Note: This bit is only writable if the bit RF_PROT in register GTM_CTRL is cleared and all MCS-channels are disabled.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:17]	r	Reserved Read as zero, should be written as zero

26.13.4.12 Register MCSi_CTRG

All of the following registers are 32-bit only accessible.

GTM_MCSi_CTRG (i=0-2)

MCSi Clear Trigger Control Register(30028_H+i*1000_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
TRG0	0	rw	Trigger bit 0 0 _B READ: trigger bit is cleared / WRITE: do nothing 1 _B READ: trigger bit is set / WRITE: clear trigger bit

CAT3	11	rwh	Cancel ARU transfer for channel 3 0 _B Do nothing. 1 _B Cancel any pending ARU read or write transfer.
CAT4	12	rwh	Cancel ARU transfer for channel 4 0 _B Do nothing. 1 _B Cancel any pending ARU read or write transfer.
CAT5	13	rwh	Cancel ARU transfer for channel 5 0 _B Do nothing. 1 _B Cancel any pending ARU read or write transfer.
CAT6	14	rwh	Cancel ARU transfer for channel 6 0 _B Do nothing. 1 _B Cancel any pending ARU read or write transfer.

Generic Timer Module (GTM)

Field	Bits	Type	Description
CAT7	15	rwh	<p>Cancel ARU transfer for channel 7</p> <p>0_B Do nothing. 1_B Cancel any pending ARU read or write transfer. This bit is cleared if no read or write is performed actually or with the next read or write after the currently performed read or write is cancelled.</p> <p><i>Note: The CATx (x = 0 ...7) bit inside the STA register of the corresponding MCS-channel is set and any pending ARU read or write request is cancelled. The MCS-channel resumes with the instruction after the ARU transfer instruction.</i></p> <p><i>Note: Note: The CATx (x = 0 ...7) bit is cleared by the corresponding MCS channel, when the channel reaches an ARU read or write instruction.</i></p>
CWT0	16	rwh	<p>Cancel WURM instruction for channel 0</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT1	17	rwh	<p>Cancel WURM instruction for channel 1</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT2	18	rwh	<p>Cancel WURM instruction for channel 2</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT3	19	rwh	<p>Cancel WURM instruction for channel 3</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT4	20	rwh	<p>Cancel WURM instruction for channel 4</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT5	21	rwh	<p>Cancel WURM instruction for channel 5</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>
CWT6	22	rwh	<p>Cancel WURM instruction for channel 6</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
CWT7	23	rwh	<p>Cancel WURM instruction for channel 7</p> <p>0_B Do nothing. 1_B Cancel any pending WURM instruction. This bit is cleared if no WURM is performed actually or with the next WURM after the currently performed WURM is cancelled.</p> <p><i>Note:</i> The CWT_x (x = 0 ...7) bit inside the STA register of the corresponding MCS-channel is set and any pending WURM instruction is cancelled. The MCS-channel resumes with the instruction after the WURM instruction.</p> <p><i>Note:</i> <i>Note:</i> The CWT_x (x = 0 7) bit is cleared by the corresponding MCS channel, when the channel reaches a WURM instruction.</p>
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero</p>

26.13.4.15 Register MCSi_ERR

All of the following registers are 32-bit only accessible.

GTM_MCSi_ERR (i=0-2)

MCSi Error Register (3007C_H+i*1000_H) Reset Value: 00000000_H

Field	Bits	Type	Description
ERR0	0	rwh	Error State of MCS-channel 0 0 _B No error signal. 1 _B Error signal is pending.
ERR1	1	rwh	Error State of MCS-channel 1 0 _B No error signal. 1 _B Error signal is pending.
ERR2	2	rwh	Error State of MCS-channel 2 0 _B No error signal. 1 _B Error signal is pending.
ERR3	3	rwh	Error State of MCS-channel 3 0 _B No error signal. 1 _B Error signal is pending.
ERR4	4	rwh	Error State of MCS-channel 4 0 _B No error signal. 1 _B Error signal is pending.
ERR5	5	rwh	Error State of MCS-channel 5 0 _B No error signal. 1 _B Error signal is pending.
ERR6	6	rwh	Error State of MCS-channel 6 0 _B No error signal. 1 _B Error signal is pending.

Generic Timer Module (GTM)

Field	Bits	Type	Description
ERR7	7	rwh	Error State of MCS-channel 7 0 _B No error signal. 1 _B Error signal is pending. Note: The CPU can read the ERRx (x = 07) bits in order to determine the current error state of the corresponding MCS-channel x. The error state is also evaluated by the module MON, if this module is available. Note: Writing a value 1 to this bit resets the corresponding error state and resets the channel internal ERR bit in the STA and channel CTRL registers.
Reserved	[31:8]	r	Reserved Read as zero, should be written as zero

26.14 Memory Configuration (MCFG)

26.14.1 Overview

The Memory Configuration submodule (MCFG) is an infrastructure module that organizes physical memory blocks and maps them to the instances of Multi Channel Sequencer (MCS) submodules.

The default configuration maps a memory of size $1K \times 32 \text{ bit} = 4\text{KB}$ to MCS memory page 0 and a memory of size $0.5K \times 32 \text{ bit} = 2 \text{KB}$ to MCS memory page 1.

In order to support different memory size for different MCS instances, the MCFG module provides two additional layout configurations for reorganization of memory pages between neighboring MCS modules. [Figure 26-63](#) shows all layout configurations.

The layout configurations SWAP is swapping the 2KB memory page of the current MCS instance with the 4KB memory page of the successive MCS instance. Thus the memory of the current MCS module is increased by 2KB but the memory of the successor is decreased by 2KB.

The layout configurations BORROW is borrowing the 4KB memory page of the successive MCS instance for the current instance. Thus the memory of the current MCS module is increased by 4KB but the memory of the successor is decreased by 4KB.

It should be noted that the successor of the last MCS instance $MCS[i]$ is the first MCS instance $MCS0$.

The actual size of the memory pages for an MCS instance depends on the layout configuration for the current instance $MCS[i]$ and the layout configuration of the preceding memory instance $MCS[i-1]$.

[Figure 26-62](#) summarizes the layout parameters $MP0$ and $MP1$ for MCS instance $MCS[i]$.

The addressing of memory page 0 ranges from 0 to $MP0-[i]$ and the addressing of memory page 1 ranges from $MP0$ to $MP1-[i]$.

Besides these software related layout configurations, the MCFG submodule has an additional input port $MCS_RAM1_EN_ADDR_MSB$ which is routed to the top level of the GTM.

The above mentioned behaviour of the MCFG submodule is applied if this port is connected to a constant logic level of zero (0).

If a constant logic level of one (1) is applied to this port, the MCFG submodule assumes that a memory of size $1K \times 32 \text{ bit} = 4\text{KB}$ is also mapped to MCS memory page 1.

In this case the memory layout configurations of the MCFG submodule change as shown in [Figure 26-64](#) and the memory layout parameters are modified according to [Figure 26-65](#).

26.15 TIM0 Input Mapping Module (MAP)

26.15.1 Overview

The MAP submodule generates the two input signals TRIGGER and STATE for the submodule DPLL by evaluating the output signals of the channel 0 up to channel 5 of submodule TIM0. By using the TIM as input submodule, the filtering of the input signals can be done inside the TIM channels themselves. The MAP submodule architecture is depicted in [Figure 26-66](#).

26.15.1.1 MAP Submodule architecture

Figure 26-66 MAP Submodule architecture

Generally, the MAP submodule can route the channel signals coming from TIM0 in three ways. First, it is possible to route the whole 49 bits of data coming from channel 0 of

Generic Timer Module (GTM)

module TIM0 (TIM0_CH0) to the TRIGGER signal which is then provided to the DPLL together with the T_VALID signal.

Second, the MAP module can route one of the five signals coming from the module TIM0 (i.e. the signals coming from channel 1 up to channel 5) to the output signal STATE which is then provided to the module DPLL together with the S_VALID signal.

Third, the TRIGGER, T_VALID, STATE and S_VALID signals can be generated out of the TIM Signal Preprocessing (TSPP) subunits. This is done in combination with the Sensor Pattern Evaluation (SPE) submodule described in [Section 26.17](#).

There, the signal TRIGGER is generated in subunit TSPP0 out of the TIM0 signals coming from channel 0 up to 2.

The signal STATE is generated in subunit TSPP1 out of the TIM signals coming from channel 3 up to channel 5.

This is only be done, when the TSSPx subunits are enabled and when the SPEx_NIPD signal is raised by the SPE submodule. The SPEx_NIPD_NUM signal encodes, which of the 3 TIMx_CHy input signals has been changed. The SPEx_DIR signal is routed through the TSSPx subunit and implements the T_DIR or S_DIR signal.

A third method to provide a direction signal to DPLL is to use TIM0 channel 6 input (TIM0_IN6) and to route it instead of the DIR signal coming from TSSOP0 to the MAP output T_DIR (set TSEL=0)

26.15.2 TIM Signal Preprocessing (TSPP)

The TSPP combines the three 49 bit input streams coming from the TIM0 submodule and generates one combined 49 bit output stream TSPPO. The input stream combination is done in the unit Bit Stream Combination (BSC). The architecture of the TSPP is shown in [Figure 26-67](#).

26.15.2.1 TIM Signal Preprocessing (TSPP) subunit architecture

Figure 26-67 TIM Signal Preprocessing (TSPP) subunit architecture

26.15.2.2 Bit Stream Combination

The BSC subunit is used to xor-combine the three most significant bits TIM0_CHx(48), TIM0_CHy(48) and TIM0_CHz(48) of the TIM0 inputs. The xor-combined signal is merged with the remaining 48 bits of one of the three input signals TIM0_CHx(47...0), TIM0_CHy(47...0) or TIM0_CHz(47...0) the TSPPO signal. The selection is done with the SPEx_NIPD_NUM input signal coming from the SPE submodule. The action, when the 49 bits are transferred to the TSPPO and the T_VALID or S_VALID signal is raised is determined by the SPEx_NIPD signal coming from the SPE submodule. The TSPPO output signal generation is shown in the example in [Chapter 26.17.3](#).

TSPPO Signal generation for signal TSPPO

Figure 26-68 TSPPO Signal generation for signal TSPPO

The SPEX_NIPD_NUM input signal determines, which data is routed to the TSPPO signal. At the first edge of TIM0_CHx(48) the new data X11 and X12 are routed to TSPPO(47:0). The values X11 and X12 are the two 24 bit values coming from the TIM input channel TIM0_CHx. The next edge is at time t1 on signal TIM0_CHy(48). Therefore, at time t1 the TSPPO(48) signal level changes and the TSPPO(47:0) is set to Y11 and Y12 and so forth.

26.16 Digital PLL Module (DPLL)

26.16.1 Overview

The digital PLL (DPLL) submodule is used for frequency multiplication. The purpose of this module is to get a higher precision of position or value information also in the case of applications with rapidly changed input frequencies. There are two input signals TRIGGER and STATE for which periodic events are processed. The time period between two valid events is called an increment. Each increment is divided into a given number of subincrements by pulses called SUB_INC. The resolution of the generated pulses is restricted by the period of the CMU_CLK0 clock or the TS_CLK respectively (see description of the modules TBU, CMU). The input signals TRIGGER and STATE can have the meaning of position information of linear or angle motions, mass flow values, temperature, pressure or level of liquids.

By means of the DPLL the load of the CPU can be reduced essentially by relieving it from repeated or periodic standard tasks.

The DPLL has to perform the following tasks:

- prediction of the duration of the current increment in [Section 26.16.8](#)
- synchronization of the actual position (under CPU control, see [Synchronization description](#))
- possibility of seamless switch to emergency mode and back under CPU control, see configuration register DPLL_CTRL_0 at [Section 26.16.11](#)
- prediction of position and time related events in [Section 26.16.7](#)

26.16.2 Requirements and demarcation

The two input signals TRIGGER and STATE can be sensor signals from the same device or from two independent devices. When they come from the same device the TRIGGER input is typically a more frequent signal and STATE is a less frequent signal. In such a case the STATE signal can support an emergency mode, when no TRIGGER signal is available. There are also applications supported when STATE and TRIGGER are independent signals from different devices. Both input signals are combined with a validation signal T_VALID or S_VALID respectively, which shows the appearance of new data and must result in a data fetch and a start of the correspondent state machine to perform the calculations (see explanation below).

When STATE is a redundant signal of the same device only the TRIGGER input is used to generate the SUB_INC1 pulses in normal mode. There is a configuration possible, called emergency mode, for which the SUB_INC1 pulses are generated using the STATE input signal.

The decision to switch in the emergency mode and back is made outside the DPLL. The CPU must switch the configuration bit RMO (reference mode) in the DPLL_CTRL_0

Generic Timer Module (GTM)

register (see [Section 26.16.11](#)). Because a switch in emergency mode can appear suddenly, the information of the last increment durations of the STATE input up to FULL_SCALE should be stored always as a precaution.

The filtering as well as the combination or choice of the input signals is made in the TIM submodule (see [Section 26.10](#)) by use of a configurable filter algorithm for each slope and signal as well as in the MAP module (see [Section 26.15](#)) the right TRIGGER or STATE signal is selected by a multiplexer or in the SPE module (see [Section 26.18](#)) different signals are combined to a TRIGGER or STATE signal by using an antivalence operation.

The filter delay value of the signal is transmitted from the TIM module in the FT part of the corresponding signal, because the delay conditions of the signals can change during application.

The filter delays depend also on the filter algorithms used. Only the effective filter delay can be considered in the DPLL.

In order to provide the timing conditions to the DPLL the input trigger signals should have a time stamp (and optional in addition a filter value and a signal level value, as stated above) with an appropriate resolution. The resolution of the time stamps can be either the same resolution as the input time base TBU_TS0 (see [Section 26.16.4.1](#)) or 8 times higher, selected by configuration bits in the DPLL_CTRL_1 register (see [Section 26.16.11.2](#)). The time base TBU_TS0 is used to predict events in the future, called actions.

At the SUB_INCx outputs a predefined number of pulses between each active slope of the TRIGGER/STATE signal is generated, when the correspondent pulse generator is enabled by the enable bits SGEx=1 in the DPLL_CTRL_1 register (see [Section 26.16.11.2](#)).

Dependent on configuration different strategies can be used to correct a wrong pulse number.

The FULL_SCALE range is divided into a fix number of nominal increments. Nominal increments do have the same size. The number of nominal increments in HALF_SCALE is specified in the DPLL_CTRL_0 register (see [Section 26.16.11](#)).

For synchronization purposes some TRIGGER/STATE input signals can be suppressed in dependency on the current position. Therefore an increment as duration between two valid input events can be either a nominal increment or it can consist of more then one nominal increment.

While a true nominal increment starts with a valid event a virtual increment (of always nominal size) is an increment which starts with a missing event. Each increment which represents a gap (e.g. for synchronization purposes) consists of exactly one true nominal increment and at least one virtual increment, each of them having the same nominal duration (see figure below).

26.16.3 Input signal courses

Typical input signal courses are shown in the figure below.

Figure 26-69 Input signal courses

26.16.4 Block and interface description

The block description of the DPLL is shown in the following figure.

26.16.4.1 DPLL Block diagram

Figure 26-70 DPLL Block diagram

Table 26-46 summarizes the interface signals of the DPLL shown by the block diagram above.

26.16.4.2 Interface description of DPLL
Table 26-46 Interface description of DPLL

Name	Width	I/O	Description	Comment
TRIGGER	49	I	Normal Signal for triggering DPLL by positions/values Bit(48)= TRIGGER_S Bits(47:24)= TRIGGER_FT Bits(23:0)= TRIGGER_TS	one bit signal value (SV), 24 bits filter delay value info and 24 bits time stamp, filtered in different modes.
T_VALID	1	I	The values of TRIGGER are valid	Announces the arrival of a new TRIGGER value
STATE	49	I	Assistance signal for synchronisation STATE(48)= STATE_S STATE(47:24)= STATE_FT STATE(23:0)= STATE_TS	Replacement of signal TRIGGER for emergency situations, or signal from an independent device; bits like above, corresponding
S_VALID	1	I	The values of STATE are valid	Announces the arrival of a new STATE value
PMTR_D	53	I	Position minus time request data, delivered by ARU on request for up to 24 requests PMTR_RR; SV _i =PMTR_D(52:48): ACB bits, directly written to the correspondent DPLL_ACB _j registers PSA _i =PMTR_D(47:24): position value for action DLA _i =PMTR_D(23:0) time delay value for action	Data values for calculation of actual ACTIONS; the values are requested by AEN _i =11 ¹⁾ and CAIP=02 ²⁾ ; a served request is shown by PMTR_V which signals that valid PMTR data arrived and they are written immediately after that to the corresponding RAM regions and registers; The DLA _i values must have the same resolution as the TBU_TS0 input.

Generic Timer Module (GTM)
Table 26-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
PMTR_V	1	I	signals a valid PMTR_D value, that means data is delivered on request	when valid: PMTR_D overwrites data in the PSAi and DLAi registers, also when the corresponding ACT_Ni ³⁾ bit =1;
ARU_CA	9	I	Channel address; for valid PMTR addresses: demand data by setting PMTR_RR=1 when enabled by AENi=11 ¹⁾ and CAIP=02 ²⁾ ;	counter value of ARU selects PMTR_RA and PMTR_RR when a valid address
PMTR_RA	9	O	read address of PMTR access	reflects ID_PMTR_i according to the selected channel address
PMTR_RR	1	O	read request of PMTR access; suppressed for CAIPi=1 (see DPLL_STATUS register)	reflects the value of the corresponding AENi ¹⁾ bit while the correspondent bit CAIPi=0 ²⁾
ACT_D	53	O	Output of a time stamp, a position and a control signal for a calculated action; SV_i=ACT_D(52:48): ACB bits, directly written from the correspondent PMTR_D signals; ACT_D(47:24) is the calculated position value PSACi for the action in relation to TBU_TS1 or 2 ⁴⁾ and ACT_D(23:0) is the time stamp value TSACi for the action in relation to TBU_TS0 ⁴⁾	Future time stamp with the resolution as TBU_TS0 input, additional position information and additional control bits;

Generic Timer Module (GTM)
Table 26-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
ACT_V	1	O	ACT_D value is available and valid; blocking read access	for a valid action address: ACT_V reflects the shadow value of ACT_Ni ³⁾ (ACT_Ni is 1 when new PMTR values are available and the shadow register is updated, when a calculation of the actual PMTR values was done); reset after reading of the ACT_D values
ACT_RA	9	I	ACTION read address;	address bits for selection of all 24 action channels
ACT_RR	1	I	read request of selected action	the action data is demanded from an other module
IRQ	27	O	Interrupt request output	Interrupts of DPLL
SUB_INC1	1	O	Pulse output for TRIGGER input filter	sub-position increment provided continuously
SUB_INC2	1	O	Pulse output for STATE input filter (when TRIGGER and STATE are used for 2 independent devices)	sub-position increment provided continuously
SUB_INC1c	1	O	Pulse output for time base unit 1 in compensation mode (can stop in automatic end mode)	sub-position increment related to TRIGGER input
SUB_INC2c	1	O	Pulse output for time base unit 2 in compensation mode (can stop in automatic end mode)	sub-position increment related to STATE input (when TRIGGER and STATE are used for 2 independent devices)
TS_CLK	1	I	Time stamp clock	used for generation of the time stamps; this clock is used to generate the SUB_INC1,2 pulses

Generic Timer Module (GTM)
Table 26-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
CMU_CLK0	1	I	CMU clock 0	used for rapid pulse correction of SUB_INC1,2
SYS_CLK	1	I	System clock	High frequency clock
RESET_N	1	I	Asynchronous reset signal	Low active; After Reset the DPLL is available only after performing the RAM reset procedures by the DPLL hardware.
LOW_RES	1	I	low resolution of TBU_TS0 selected; shows which of the 27 bits of TBU_TS0 are connected to the DPLL	LOW_RES=0: TBU_TS0(DPLL)= lower 24 Bits of TBU_TS0(TBU); LOW_RES=1: TBU_TS0(DPLL)= higher 24 Bits of TBU_TS0(TBU); In the case LOW_RES=1 the TS0_HRT and/or TS0_HRS bits can be set 5)
TBU_TS0	24	I	Actual time stamp from TBU; is needed to decide, if a calculated action is already in the past	24 bit time input, with a resolution of the time stamp clock
TBU_TS1	24	I	Actual position/value stamp 1; for calculation of position stamps (TRIGGER/STATE)	24 bit pos./val. input, with a resolution of the SUB_INC1 pulses
TBU_TS2	24	I	Actual position/value stamp 2; to be implemented for an additional independent position	ditto for SUB_INC2 for calculation of position stamps (STATE) for $SMC^{(6)}=RMO^{(7)}=1$

Generic Timer Module (GTM)
Table 26-46 Interface description of DPLL (cont'd)

Name	Width	I/O	Description	Comment
TDIR	1	I	Direction of TRIGGER input values (TDIR=0 does mean a forward direction and TDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC ⁶⁾ =1 or IDDS ⁸⁾ = 1
SDIR	1	I	Direction of STATE input values (SDIR=0 does mean a forward direction and SDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC ⁶⁾ =1
DIR1	1	O	Direction information of SUB_INC1 (count forwards for DIR1=0 and backwards for DIR1=1)	count direction of TBU_TS1; DIR1 changes always after the evaluation of the corresponding valid TRIGGER slope and after incrementing/decremented of the address pointer
DIR2	1	O	Direction information of SUB_INC2 (count forwards for DIR2=0 and backwards for DIR2=1)	count direction of TBU_TS2; DIR2 changes always after the evaluation of the corresponding valid STATE slope and after incrementing/decremented of the address pointer

26.16.5 DPLL Architecture

26.16.5.1 Purpose of the module

The DPLL generates a predefined number of incremental signal pulses within the period between two events of an input TRIGGER or STATE signal, when the corresponding pulse generator is enabled. The resolution of the pulses is restricted by the frequency of the time stamp clock (TS_CLK). Changes in the period length of the predicted time period of the current increment will result in a change of the pulse frequency in order to get the same number of pulses. This adoption can be performed by DPLL hardware, software or with support of DPLL hardware in different modes.

The basic part of a DPLL is to make a prediction of the current period between two TRIGGER and/or STATE signal edges. Disturbances and systematic failures must be considered as well as changes of increment durations caused by acceleration and deceleration of the supervised process. Therefore, a good estimation is to be done using some measuring values from the past. When the process to be predicted takes a steady and differentiable course not only the current increment but also some more increments for the future can be predicted. In utilisation of such calculations actions for the future can be predicted.

26.16.5.2 Explanation of the prediction methodology

As already shown in [Section 26.16.1](#) the DPLL has to perform different tasks. The basic function for all these tasks is the prediction of the current increment which is based on a relation between increments in the past. Because the relation between two succeeding intervals at a fixed position remains also valid in the case of acceleration or deceleration the prediction of the duration of the current time interval is done by a similarity transformation. Having a good estimation of the current time interval, all the other tasks can be done easily by calculations explained in [Section 26.16.6](#).

26.16.5.3 Clock topology

All registers are read using the system clock SYS_CLK. The SUB_INC1,2 pulses generated have the highest frequency not higher than CMU_CLK0 or TS_CLK respectively. All operations can be performed using the system clock.

26.16.5.4 Clock generation

The clock is generated outside the DPLL.

26.16.5.5 Typical frequencies

For system clock a reasonable clock frequency should be applied to give the DPLL module sufficient computational power to calculate all needed values (prediction of next increment, actions) in time.

26.16.5.6 Time stamps and systematic corrections

The time stamps for the input signals TRIGGER and STATE have 24 bits each. These bits represent the value of the 24 bit free running counter running with a clock frequency selected by the configuration of the TBU. Using a typical frequency of 20 MHz the time stamp represents a relative value of time with a resolution of 50 ns.

The input signals have to be filtered. The filter is not part of the DPLL. The time stamps can have a delay caused by the filter algorithm used. There are delayed and undelayed filter algorithms available and the delay value can depend on a time or a position value.

Systematic deviations of TRIGGER inputs can be corrected by a profile, which also considers systematic missing TRIGGERS. The increments containing missing TRIGGERS are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increment durations.

For each increment this number of enclosed nominal increments is stored in a profile as NT value for TRIGGER. When the increment is a nominal increment the NT value is 1.

For the TRIGGER input the value NT is stored in the ADT_T field in RAM region 2C.

In the case of $AMT^4) = 1$ the ADT_Ti values in the RAM region 2C must also contain the adapting information for the TRIGGER signal, which considers for each increment a systematic physical deviation PD from the perfect increment value with a resolution according to the chosen value of $MLT+1$, which describes the number of SUB_INC1 pulses for a nominal increment.

The value PD for the TRIGGER describes the amount of missing or surplus pulses with a sint13 value, to be added to $MLT+1$ directly. The correction value is in this way also applicable in the case of missing TRIGGER inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment ($MLT+1$) is multiplied by NT first before the PD value is added.

The NT value of the current increment is stored in the variable SYN_T (see NUTC register in [Section 26.16.11.13](#)).

In the case of $RMO^4) = 1$ for $SMC^5) = 0$ (emergency mode) the time stamp of STATE is used to generate the output signal SUB_INC1.

More inaccuracy should be accepted in emergency mode because usually there are only fewer events available for FULL_SCALE according to the value $SNU^4)$.

For the STATE signal the systematic deviations of the increments can be corrected in the same way as for TRIGGER by profile and adaptation information as described below.

Generic Timer Module (GTM)

Systematic deviations of STATE inputs can be corrected by a profile, which also considers systematic missing STATE events. The increments containing missing STATES are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increment durations.

For each increment this number of enclosed nominal increments is stored in a profile as NS value for STATE. When the increment is a nominal increment the NS value is 1.

For the STATE input the value NS is stored in the ADT_S field in RAM region 1C3.

In the case of $AMS^4) = 1$ the ADT_Si values in the RAM region 1C3 must contain the adapting information for the STATE signal, which considers for each increment a systematic physical deviation PD_S from the perfect increment value with a resolution according to the chosen value of MLS1, which describes the number of SUB_INC1 pulses for a nominal increment (see below).

The number of pulses SUB_INC1 for a nominal STATE increment in emergency mode (for SMC=0) is given by the value of $MLS1 = (MLT + 1) * (TNU + 1) / (SNU + 1)$ in order to get the same number of pulses in FULL_SCALE for normal and emergency mode. This value has to be configured by the CPU.

The value PD_S for the STATE describes the amount of missing or surplus pulses with a sint16 value, to be added to MLS1 directly. The correction value is in this way also applicable in the case of missing STATE inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment MLS1 is multiplied by NS first before the PD_S value is added.

The current NS value is stored in the variable SYN_S (see NUSC register in [Section 26.16.11.14](#)).

26.16.5.7 DPLL Architecture overview

As shown in [Section 26.16.4.1](#) the DPLL can process different input signals. The signal TRIGGER is the normal input signal which gives the detailed information of the supervised process. It can be for instance the information of water or other liquid level representing the volume of the liquid, where each millimeter increasing results in a TRIGGER signal generation. In order to get a predefined filling level, without overflow also the inertia of the system must be taken into account. Hence, some delay for closing

Generic Timer Module (GTM)

the inlet valve and also the remaining water amount in the pipe must be considered in order to start the closing action earlier as the filling level will be reached.

A second input signal STATE sends an additional (redundant) information for instance at some centimeters and because of intervals with different distances it gives also information about the system state with the direction of the water flow (in or out), while the TRIGGER signal must not contain information concerning the flow direction. In some applications the inactive slope of TRIGGER can be utilized to transmit a direction information. In the case of faults in the TRIGGER signal the STATE signal is to be processed in order to reach the desired value nevertheless, maybe with some loss of accuracy.

The measuring scale can have some systematic failures, because not all millimeter or centimeter distances measured mean the same value. This could be due to changes in the thickness of the measuring cylinder or the inaccurate position of the marks. These systematic failures are well known by the system and for improvement of the prediction the signals ADT_T and ADT_S for the correction of the systematic failures of TRIGGER and STATE respectively are stored in the internal RAM.

The input signals TRIGGER and STATE are represented as a time stamp signal each, which is stored in the 24 bit TS-part of the corresponding signal.

Information concerning the delay of this signal by filtering of disturbances is stored in the 24 bit FT-part of the signal.

In order to establish the relation of time stamps to the actual time the TBU_TS0⁶⁾ value is also provided showing the actual time value used for prediction of actions in the future.

After reaching the desired water level the water is filled in a bottle by draining. After that the water filling is repeated. The water level at draining is observed by the same sensor signals (the same number of TRIGGER pulses), but the duration of the draining could be different from the filling time. Both times together form the FULL_SCALE region, while one of them is a HALF_SCALE region, which can differ in time but not in the number of pulses, especially for TRIGGER.

For synchronisation purposes some TRIGGER marks can be omitted in order to set the system to a proper synchronisation value (maybe before the upper filling value is reached).

In emergency situations, when the TRIGGER signals are missed the STATE signal is used instead of.

The PMTR_⁶⁾ signals announce the request for a position minus time calculation for up to 24 events.

All 24 events can be activated using the 24 AENi¹⁾ (action enable) bits. Each of these enable bits are asked by the routing engine for a read access. The corresponding read request is generated by the AENi bit while CAIPx is zero. CAIP1 and CAIP2 are two bits of the DPLL_STATUS register for 12 actions each with the meaning "calculation of

Generic Timer Module (GTM)

actions in progress”, controlled by the state machine (see [Chapter 26.16.2](#)) for scheduling the operations.

When such a request is serviced by the ARU (in the case CAIPx=0) the values for position and time are written in the corresponding RAM 1A region (0x0200... 0x025C for the position value and 0x0260... 0x02BC for the delay value), the control bits for the corresponding action are set accordingly. When a new PMTR value arrives, an old value is overwritten without notice and the shadow bit of ACT_Ni is cleared while the ACT_Ni (new action) bit in the DPLL_ACT_STA register is set. The ACT_Ni is cleared, when the currently calculated action value is in the past. Overwriting of old information is possible without data inconsistency because the read request to ARU is suppressed during action calculations by the CAIP1,2 bits. In this way always the last possible PMTR value is used consistently.

- 5) see DPLL_CTRL_1 register
- 6) see DPLL input signal description

26.16.5.8 DPLL Architecture description

The DPLL block diagram [Chapter 26.16.4.1](#) will now be explained in detail in combination with some example configurations of the control registers. There are different configuration bits available which can adopt the DPLL to the use case (see [Chapter 26.16.11](#)).

Let for example in HALF_SCALE the TRIGGER number TNU⁴) be 0x3B (which is for TNU+1 = 60 decimal that does mean 120 events in FULL_SCALE) and the number of SUB_INC1 pulses between two TRIGGERs MLT⁴) be 0x257 (this means 600 pulses per TRIGGER event). Then the FULL_SCALE region can be divided into 72000 parts each of them associated with its own SUB_INC1 pulse. For a run through FULL_SCALE all 72000 pulses should appear but maybe with a different pulse frequency between two TRIGGER events. For this example after each 600 pulses at the SUB_INC1 output the next TRIGGER event is to be expected with the corresponding new time stamp.

Missing SUB_INC1 pulses due to acceleration have to be taken into account within the next increment. Not one pulse has to be missed or added because of calculation inaccuracy in average for a sufficient number of FULL_SCALE periods. This means that not one pulse is sent in addition and all missing pulses are to be caught up on afterwards.

For the systematic arrangement of TRIGGER inputs the profile (as already mentioned in [Section 26.16.5.6](#) is stored in the RAM region 2C (see [Section 26.16.11.100](#)). In this

Generic Timer Module (GTM)

field the relative position of gaps can be stored in the NT value and also physical deviations in the PD value.

For the consideration of systematic missing TRIGGERS the actual NT value of the profile is stored in the SYN_T bits of the NUTC register (see [Section 26.16.11.13](#)).

In normal mode the physical deviation values PD in the ADT_T field could be used to balance the local systematic inaccuracy of the TRIGGER signal. The value of PD (see [Section 26.16.11.100](#)) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD is a signed integer value using 13 bits: up to +/-4096 pulses can be added for each increment.

The NT value of the profile ADT_T has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NT value is stored in SYN_T of the NUTC register.

Using the STATE input there are similar configuration bits available (see [Section 26.16.11](#)).

Let for example in HALF_SCALE the STATE number SNU⁴) be 0xB (which is for SNU+1 =12 decimal and while SYSF⁴) =0 that does mean 24 events in FULL_SCALE). In order to get the same number of SUB_INC1 pulses for FULL_SCALE as above for TRIGGERS the value (MLT+1)=600 is divided by 2*(SNU+1)=24 and multiplied with 2*(TNU+1)=120. The result 3000 must be stored in MLS1 by the CPU (see [Section 26.16.11.78](#)).

For the systematic arrangement of STATE inputs the profile (as already mentioned in [Section 26.16.5.6](#) is stored in the RAM region 1C3 (see [Section 26.16.11.93](#)). In this field the relative position of gaps can be stored in the NS value and also physical deviations in the PD_S value.

For the consideration of systematic missing TRIGGERS the actual NS value of the profile is stored in the SYN_S bits of the NUSC register (see [Section 26.16.11.14](#)).

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the STATE signal. The value of PD_S (see [Section 26.16.11.93](#)) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD_S is a signed integer value using 16 bits: up to +/-32768 pulses can be added for each increment.

The NS value of the profile ADT_S has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NS value is stored in SYN_S of the NUSC register.

- 6) see DPLL input signal description

26.16.5.9 Block diagrams of time stamp processing.

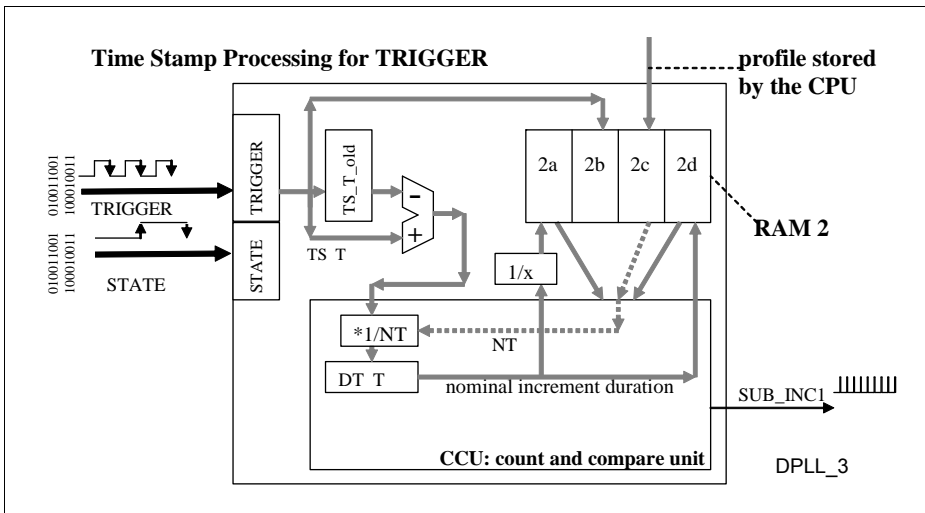

Figure 26-71 Time Stamp Processing

As shown in the block diagram above the time stamp difference of two succeeding input events is calculated. For the prediction of the current increment duration such values from the past are used. For this purpose the measured and calculated values of the last FULL_SCALE period are stored in the RAM. For the TRIGGER input there are 4 different RAM parts in the RAM region 2:

- 2A stores the reciprocals of each nominal increment duration RDT_T
- 2B stores the time stamps of each valid input event TSF_T
- 2C is used for the profile ADT_T and
- 2D for the nominal increment durations DT_T.

Because the prediction is based on the relations of increments in the past this relation can be calculated easily by the multiplication of increment duration values with the reciprocal value of an other increment. In order not to be forced to distinguish between

Generic Timer Module (GTM)

gaps and "normal" increment durations also for gaps only the nominal duration and the correspondent reciprocal values are stored in the RAM field. This is possible by consideration of the NT value in the profile: the measured increment duration is divided by NT.

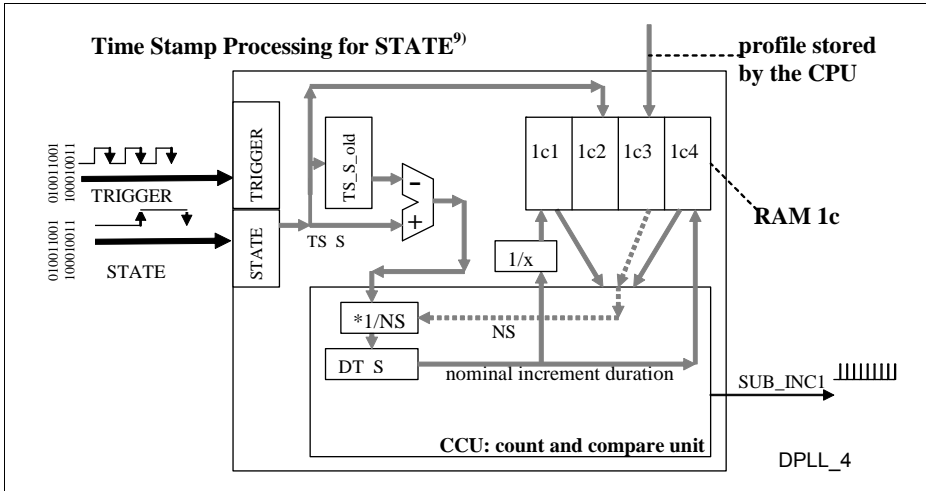

Figure 26-72 Time Stamp Processing for STATE

For the STATE input there are also 4 different RAM parts in the RAM region 1C:

- 1C1 stores the reciprocals of each nominal increment duration RDT_S
- 1C2 stores the time stamps of each valid input event TSF_S
- 1C3 is used for the profile ADT_S and
- 1C4 for the nominal increment durations DT_S.

The calculations are performed similar as for the TRIGGER input. The NS value in the profile shows the appearance of a gap.

26.16.5.10 Register and RAM address overview

The address map of the DPLL is divided into register and memory regions as defined in [Table 26-47](#). The addresses from 0x0000 to 0x00FC are reserved for registers, from 0x0100 to 0x01FC is reserved for action registers to serve the ARU at immediately read request.

The RAM is divided into 3 independent accessible parts 1A, 1B+C and 2.

The part 1A from 0x0200 to 0x037C is used for PMTR values got from ARU and intermediate calculation values; there is no write access from the CPU possible, while the DPLL is enabled.

Generic Timer Module (GTM)

The RAM 1B part from 0x0400 to 0x05FC is reserved for RAM variables and the RAM part 1C from 0x0600 to 0x09FC is used for the STATE signal values.

The RAM region 2 from 0x4000 to 0x4FFC is reserved for the TRIGGER signal values. RAM region 1A has a size of 288 bytes, Ram 1B+C uses 1,125 Kbytes while RAM region 2 3 Kbytes, depending on the number of TRIGGER events in FULL_SCALE. The AOSV_2 register is used to determine the beginning of each part.

The table [Table 26-47](#) in gives the DPLL Address map overview

Register and RAM address map

Registers are used to control the DPLL and to show its status. Also parameters are stored in registers when useful. The table below shows the addresses for status and control registers as well as values stored in additional registers. The register meaning explained in the register overview ([Section 26.16.10](#)) while the bit positions of the status and control registers are described in detail in [Section 26.16.11](#).

Time stamps for TRIGGER and STATE can have either the same resolution as the TBU_TS0 input or 8 times higher. This is configured in the DPLL_CTRL_1 register (see [Section 26.16.11.2](#)). While the TBU_TS0 is used for action predictions the higher resolution of TRIGGER and STATE inputs can be used for a more accurate pulse generation.

The time stamp fields of TRIGGER and STATE are stored in the corresponding RAM regions in such a way, that for a gap also entries for the virtual increments are provided. This is due to the necessity to calculate time differences between a given number of (real and virtual) input events independent of a gap. Therefore the gap is extended in the RAM fields 2B and 1C2.

For all other RAM regions in RAM 2 and RAM 1C the gap is considered as one increment.

For the access to the RAM fields there must be address pointers. When the device starts all address pointers have a zero value and the first measured and calculated values are stored in the beginning of the corresponding RAM field.

Because the position of the device is usually unknown at the beginning no profile information can be used. The profile regions must have their own address pointers each which are set by the CPU as soon as the position is known. By setting the appropriate value to the address pointer APT_2C of the TRIGGER profile or APT_1C3 of the STATE profile respectively the synchronization bits in the DPLL_STATUS register SYT or SYS are set respectively. In the following the gap information can be used.

Because the time stamp fields are extended at the gaps there must be additional address pointers for these regions: APT_2B for TRIGGER time stamps and APT_1C2 for STATE time stamps. These address pointers must be increment by NT or NS respectively when a gap appears.

Table 26-47 DPLL Register and RAM address map

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0000	0x0FC	64	256	Register	used/reserved	0	no RAM
0x100	0x1FC	64	192	ACTION registers	direct read from ARU	0	no RAM
0x0200	0x03FC	128	384	PMTR values RAM 1A	CPU rw access, when DPLL disabled ; ARU has highest priority	1A with own ports	RAM part 1A: 384 bytes
0x0400	0x05FC	128	384	Variables RAM 1B	r and monitored w access by the CPU	1B	RAM part 1B+C: 1,125 Kbytes
0x0600	0x09FC	256	768	STATE data	r and monitored w access by the CPU	1C	
0x0600	0x06FC	64	192	RDT_Si	STATE reciprocal values	1C1	
0x0700	0x07FC	64	192	TSF_Si	STATE TS values	1C2	

Generic Timer Module (GTM)
Table 26-47 DPLL Register and RAM address map (cont'd)

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0800	0x08FC	64	192	ADT_Si	adapt values of STATE	1C3	
0x0900	0x09FC	64	192	DT_Si	nom. STATE inc	1C4

0x4C00	0x57FC	256	768	DT_Ti	nom. TRIGGER increments	2D	

RAM Region 1

RAM region 1 has a size of 1,5 Kbytes and is used to store variables and parameters as well as the measured and calculated values for increments of STATE. The RAM 1 region is divided into two independent accessible RAM parts (A and B+C) with own ports. The address information is shown in the table above and the detailed description is

Generic Timer Module (GTM)

performed in the following sections. The RAM 1A is used to store the PMTR values got from ARU and in addition some intermediate calculation results of actions. RAM region 1B is used for variables needed for the prediction of increments, while RAM 1C is used to store time stamps, profile and durations for all the STATE inputs of the last FULL_SCALE region. All variables and values of RAM 1B+C part use a data width of up to 24 bits.

The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. This is performed when setting The Init_RAM bit in the DPLL_RAM_INI register. The DPLL is only available after finishing this procedure. The initialization progress is shown in the status bits of the same register.

- RAM Region 1A: used for storage of PMTR values got from ARU;
 - read and write access by the CPU is only possible, when the DPLL is disabled.
 - The CPU Address range: 0x0200 – 0x03FC
- RAM Region 1B: usable for intermediate calculations and auxiliary values, data width of 3 bytes used for 24 bit values;
 - A write access to this region results in an interrupt to the CPU, when enabled.
 - Address range: 0x0400 – 0x05FC
- RAM Region 1C: Values of all STATE increments in FULL_SCALE, data width of 3 bytes used for 24 bit values;
 - A write access to this region results in an interrupt to the CPU, when enabled.
 - Address range: 0x0600 – 0x09FC

In RAM region 1C there is a difference in the amount of data. While for the RAM regions 1C1, 1C3 and 1C4 there are $2^*(SNU+1-SYN_NS)$ entries for $SYSF=0$ or $2^*(SNU+1) - SYN_NS$ entries for $SYSF=1$, for the RAM region 1C2 there are $2^*(SNU+1)$ entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_Si values in the RAM region 1C2 before the APS_1C3 is written. The write access to APS_1C3 sets the SYS bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYS bit is set the PMTR values can consider more then the last increment duration for the action prediction by setting NUSE to a corresponding value.

Note: RAM regions 1B and 1C have a common port.

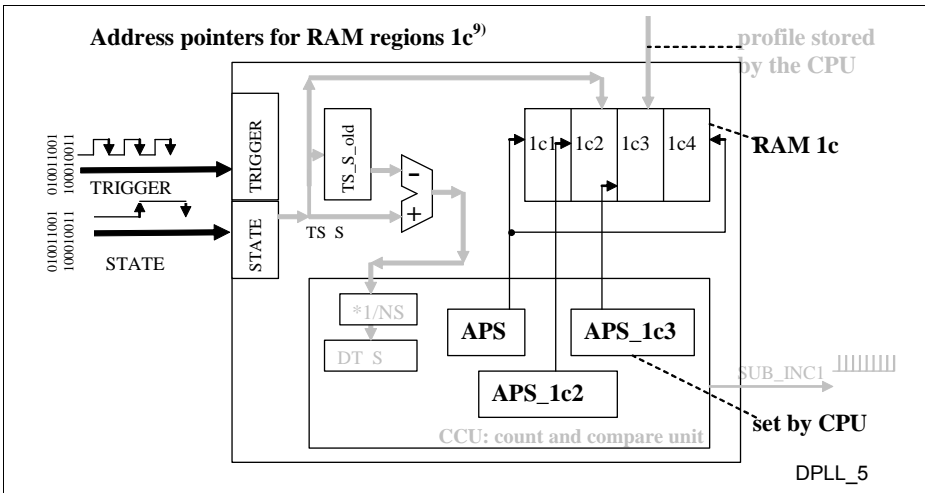

Figure 26-73 Address pointers for RAM regions 1C

The address pointers for RAM region 1C are shown in the diagram above. While the address pointer APS points to the RAM regions 1C1 and 1C4, the address pointer APS_1C2 points to the time stamp field in the region 1C2. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in [Synchronization description](#)).

The address pointer APS_1C3 is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register by the SYS bit.

RAM Region 2

The RAM region 2 has 3 Kbytes and is used to store measured and calculated values for increments of TRIGGER. The address information is explained in [Section 26.16.10](#) while the meaning is explained in this section.

Because of up to 128 TRIGGER events in HALF_SCALE the fields 2A, B C and D must have up to 256 storage places each. For 3 Bytes word size this does mean 3 k Byte of RAM region 2.

In order to save RAM size for configurations with less TRIGGER events the RAM is configurable by the offset switch Register OSW (0x001C) and the address offset value register of RAM region 2 AOSV_2 (0x0020). The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. The DPLL is only available after finishing this procedure.

Generic Timer Module (GTM)

In RAM region 2 there is a difference in the amount of data. While for the RAM regions 2A, 2C and 2D there are $2 \cdot (TNU+1-SYN_NT)$ entries, for the RAM region 2B there are $2 \cdot (TNU+1)$ entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_Ti values in the RAM region 2B before the APT_2C is written.

The write access to APT_2C sets the SYT bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYT bit is set the PMTR values can consider more then the last increment duration for the action prediction by setting NUTE to a value greater then one.

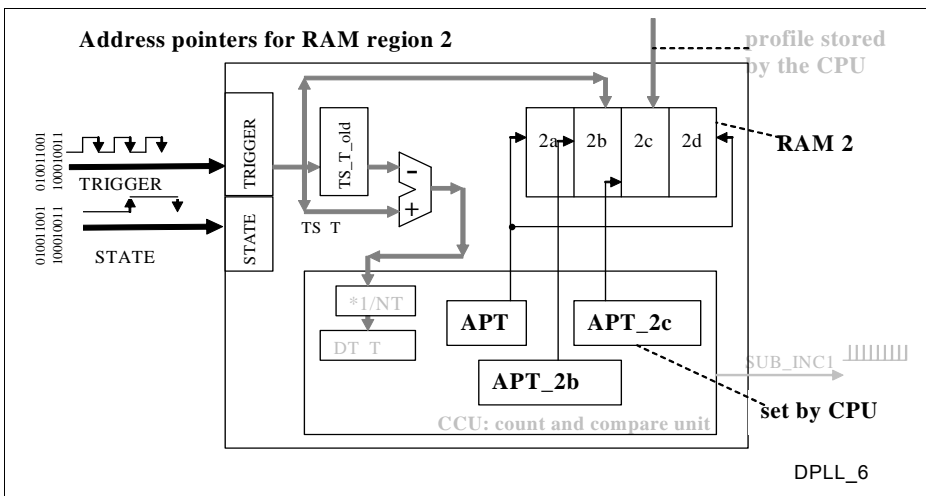

Figure 26-74 Address pointers for RAM region 2

The address pointers for RAM region 2 are shown in the diagram above. While the address pointer APT points to the RAM regions 2A and 2D, the address pointer APT_2B points to the time stamp field in the region 2B. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in [Synchronization description](#)).

The address pointer APT_2C is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register by the SYT bit.

26.16.6 Prediction of the current increment duration

26.16.6.1 The use of increments in the past

Past values to be considered for the prediction of TRIGGER

In order to take into account values of increments for TRIGGERS in the past, the NUTE value is configured to determine the number of past values. In addition the VTN has a value according to the number of virtual increments in the NUTE region. Because gaps come in to the NUTE region or leave it the VTN value must be updated by the CPU until NUTE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 2A and 2D the value NUTE-VTN is to be considered while for the RAM region 2B only the NUTE value is to be considered. This is due to the fact that the time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

Past values to be considered for the prediction of STATE

In order to take into account values of increments for STATE in the past, the NUSE value is configured to determine the number of past values. In addition the VSN has a value according to the number of virtual increments in the NUSE region. Because gaps come in to the NUSE region or leave it the VSN value must be updated by the CPU until NUSE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 1C1 and 1C4 in the past the value NUSE-VSN is to be considered while for the RAM region 1C2 only the NUSE value is to be considered. This is due to the fact that time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

26.16.6.2 Increment prediction in Normal Mode forwards (DIR1=0)

For the prediction of increments and actions in normal mode the values are calculated as described in the following equations.

Please note, that the ascending order of calculation must be hold in order not to lose results still needed. It is important for TRIGGER values to calculate and store in the RAM region 2 all values according to equations up to DPLL-14 before DPLL-1a4...7, DPLL-1b1 and DPLL-1C1, while the last one overwrites DT_Ti when NUTE (see [Section 26.16.11.13](#)) is set to the FULL_SCALE range. Because the old value of DT_Ti is also needed for equation DPLL-10 and DPLL-11 this value is stored temporarily at DT_T_ACT as shown by equation DPLL-1a or DPLL-1b respectively until all prediction calculations are done and after that equation DPLL-1a4...7, DPLL-1b1 and DPLL-1c1 updates DT_Ti: update DT_Ti after calculations of equation DPLL-14. For p=APT calculates in normal mode:

When using filter information of TRIGGER_FT, selected by IDT=1, it must be distinguished by IFP, if this filter information is time or position related:

Generic Timer Module (GTM)

In order to make possible to perform the automatic resolution corrections of equations DPLL-1a1a the filter unit in TIM module must operate using the time stamp clock.

Equations DPLL-1a to calculate TRIGGER time stamps

Equations DPLL-1a to calculate TRIGGER time stamps

For calculation of time stamps use the filter delay information

$$TS_T = TRIGGER_TS \text{ (unchanged for } IDT=0) \quad \text{(DPLL-1a0)}$$

$$TS_T = TS_T - FTV_T \text{ (for } IDT=1 \text{ and } IFP=0) \quad \text{(DPLL-1a1)}$$

with

$$FTV_Tx = FTV_T/8 \quad \text{(for } LOW_RES = 1 \text{ and } TS0_HRT = 0) \quad \text{(DPLL-1a1a)}$$

$$FTV_Tx = FTV_T \quad \text{(for } LOW_RES = 0 \text{ or } TS0_HRT = 1) \quad \text{(DPLL-1a1b)}$$

and

$$TS_T = TS_T - FTV_T * (CDT_TX/NMB_T)_{old}^{(1)} \text{ for } (IDT=1 \text{ and } IFP=1) \quad \text{(DPLL-1a2)}$$

this can be also calculated using the value of ADD_IN_CALN:

$$TS_T = TS_T - FTV_T * (1/ADD_IN_CALN_{old}^{(1)}) \text{ for } (IDT=1 \text{ and } IFP=1) \quad \text{(DPLL-1a3)}$$

- 1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two TRIGGER events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL0 register. The value of 1/ADD_IN_CALN_OLD or (CDT_TX/NMB_T)_old is set to 0xFFFFF in case of an overflow.

Note: CDT_TX is the predicted duration of the last TRIGGER increment and NMB_T the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-5 and DPLL-21 for the current increment after that. Therefore in equation DPLL-1a3 the value ADD_IN of the last increment is used (see equation DPLL-25). SYN_T_OLD is the number of TRIGGER events including missing TRIGGERs as specified in the NUTC register for the last increment, with the initial value of 1.

For storage of time stamps in the RAM see also equations DPLL-1a4 ff. after calculation of actions

Equation DPLL-1b to calculate DT_T_ACT (nominal value)

$$DT_T_ACT = (TS_T - TS_T_OLD) / SYN_T_OLD \quad \text{(DPLL-1b)}$$

For the case SYT=0 (still no synchronization to the profile) the values SYN_T and SYN_T_OLD are still assumed as having the value 1.

Equation DPLL-1c to calculate RDT_T_ACT (nominal value)

$$RDT_T_ACT = 1 / DT_T_ACT \quad \text{(DPLL-1c)}$$

Equation DPLL-2a1 to calculate QDT_T_ACT

Relation of the recent last two increment values for APT=p in forward direction (DIR1=0)

$$QDT_T_ACT = DT_T_ACT * RDT_T[p-1] \quad \text{(DPLL-2a1)}$$

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_T_ACT uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-3 to calculate the error of last prediction

When q = NUTE-VTN considers for the error calculation only the last valid prediction values for DIR1=0:

Calculate the error of the last prediction when using only RDT_T_FS1, DT_T[p-q] and DT_T[p-1] for the prediction of DT_T[p]:

$$EDT_T = DT_T_ACT - (DT_T[p-1] * QDT_T[p-q]) \quad \text{(DPLL-3)}$$

with

$$QDT_T[p-q] = DT_T[p-q] * RDT_T[p-q-1] \text{ for } FST = 0 \quad \text{(DPLL-2b1)}$$

Generic Timer Module (GTM)

$$QDT_T[p-q] = DT_T[p-q] * RDT_T_FS1 \text{ for } FST = 1 \quad \text{(DPLL-2b2)}$$

and

FST has the meaning: NUTE = FULL_SCALE (see NUTC register)

while

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_T[p-q] uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-4 to calculate the weighted average error

for SYT=1 calculate:

$$MEDT_T := (EDT_T + MEDT_T) / 2 \quad \text{(DPLL-4)}$$

Equations DPLL-5 to calculate the current increment value

nominal increment value:

$$CDT_TX_nom = (DT_T_ACT + MEDT_T) * QDT_T[p-q+1] \quad \text{(DPLL-5a)}$$

with (for $q > 1$):

$$QDT_T[p-q+1] = DT_T[p-q+1] * RDT_T[p-q] \quad \text{(DPLL-2c)}$$

and for $q=1$ use equation DPLL-2a1.

while

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next TRIGGER event

$$CDT_TX = CDT_TX_nom * SYN_T \quad \text{(DPLL-5b)}$$

Note: QDT_T[p-q+1] uses a 6 bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-5a or b set the value to 0xFFFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX to 0x0 without any effect to the CTO bit.

26.16.6.3 Increment prediction in Emergency Mode forwards (DIR2=0)

Please note, that the ascending order of calculations for STATE and storage of the values in the RAM region 1C must be hold in order not to lose results still needed. The same considerations as done for DT_T_ACT are valid for DT_S_ACT (equation DPLL-6a4...7, DPLL-6b1 and DPLL-6c1): update TD_Si only after calculations of equation DPLL-14.

When using filter information of STATE_FT, selected by IDS=1, it must be distinguished by IFP, if this filter information is time or position related:

In order to make possible to perform the automatic resolution corrections of equations DPLL-6a1a the filter unit in TIM must operate using the time stamp clock.

Equations DPLL-6a to calculate STATE time stamps

For calculation of time stamps use the filter delay information and use p=APS while DIR2=0:

$$TS_S = STATE_TS \quad (\text{for } IDS=0, \text{ received unchanged value}) \quad (\text{DPLL-6a0})$$

$$TS_S = TS_S - FTV_Sx \quad (\text{for } IDS=1 \text{ and } IFP=0) \quad (\text{DPLL-6a1})$$

with

$$FTV_Sx = FTV_S/8 \quad (\text{for } LOW_RES = 1 \text{ and } TS0_HRS = 0) \quad (\text{DPLL-6a1a})$$

$$FTV_Sx = FTV_S \quad (\text{for } LOW_RES = 0 \text{ or } TS0_HRS = 1) \quad (\text{DPLL-6a1b})$$

and

$$TS_S = TS_S - FTV_S * (CDT_SX/NMB_S)_{old}^{(1)} \quad (\text{for } IDS=1 \text{ and } IFP=1) \quad (\text{DPLL-6a2})$$

this can be also calculated using the value of ADD_IN_CALE:

$$TS_S = TS_S - FTV_S * (ADD_IN_CALE)_{old}^{(1)} \quad (\text{for } IDS=1 \text{ and } IFP=1) \quad (\text{DPLL-6a3})$$

with

see also equations DPLL-6a4 ff. at [Chapter 26.16.6.2](#) for TRIGGER.

- 1) Consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two STATE events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used - for explanation see note 4) at DPLL_CTRL0 register. The value of 1/ADD_IN_CALE_old or (CDT_SX/NMB_S)_old is set to 0xFFFFFFFF in case of an overflow.

Generic Timer Module (GTM)

Note: CDT_SX is the predicted duration of the last STATE increment and NMB_S the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-10 and DPLL-22 respectively for the current increment after that. Therefore in equation DPLL-6a3 the value ADD_IN of the last increment is used (see equation DPLL-26). SYN_S_OLD is the number of increments including missing STATEs as specified in the NUSC register for the last increment with the initial value of 1. The update to the RAM region 1C4 is done after all related calculations (see equation DPLL-6d -after DPLL-14- for this reason).

Equation DPLL-6b to calculate DT_S_ACT (nominal value)

$$DT_S_ACT = (TS_S - TS_S_OLD) / SYN_S_OLD \quad \text{(DPLL-6b)}$$

For the case SYS=0 (still no synchronization to the profile) the values SYN_S and SYN_S_OLD are still assumed as having the value 1.

Equation DPLL-6c to calculate RDT_S_ACT (nominal value)

$$RDT_S_ACT = 1 / DT_S_ACT \quad \text{(DPLL-6c)}$$

Equation DPLL-7a1 to calculate QDT_S_ACT

for APS=p in forward direction (DIR2=0)

$$QDT_S_ACT = DT_S_ACT * RDT_S[p-1] \quad \text{(DPLL-7a1)}$$

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_S_ACT uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-8 to calculate the error of last prediction

with q= NUSE-VSN when using QDT_S[p-q] and DT_S[p-1] for the prediction of DT_S[p]

Generic Timer Module (GTM)

$$\text{EDT_S} = \text{DT_S_ACT} - (\text{DT_S}[p-1] * \text{QDT_S}[p-q]) \quad \text{(DPLL-8)}$$

and with

$$\text{QDT_S}[p-q] = \text{DT_S}[p-q] * \text{RDT_S}[p-q-1] \text{ for FSS} = 0 \quad \text{(DPLL-7b1)}$$

$$\text{QDT_S}[p-q] = \text{DT_S}[p-q] * \text{RDT_S_FS1} \text{ for FSS} = 1 \quad \text{(DPLL-7b1)}$$

and

FSS has the meaning: NUSE = FULL_SCALE (see NUSC register)

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Note: QDT_S[p-q] uses a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-9 to calculate the weighted average error

for SYS=1 calculate:

$$\text{MEDT_S} := (\text{EDT_S} + \text{MEDT_S})/2 \quad \text{(DPLL-9)}$$

Equations DPLL-10 to calculate the current increment (nominal value)

$$\text{CDT_SX_nom} = (\text{DT_S_ACT} + \text{MEDT_S}) * \text{QDT_S}[p-q+1] \quad \text{(DPLL-10a)}$$

with

$$\text{QDT_S}[p-q+1] = \text{DT_S}[p-q+1] * \text{RDT_S}[p-q] \quad (\text{for } q > 1) \quad \text{(DPLL-7c)}$$

see equation DPLL-7a1 for q=1

while

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next STATE event

$$\text{CDT_SX} = \text{CDT_SX_nom} * \text{SYN_S} \quad \text{(DPLL-10b)}$$

Generic Timer Module (GTM)

Note: QDT_S[p-q+1] uses a 6 bit integer part and a 18 bit fractional part.

Note: In the case of an overflow in equations DPLL-10a or b set the value to 0xFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX to 0x0 without any effect to the CSO bit.

All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

26.16.6.4 Increment prediction in Normal Mode backwards (DIR1=1)
Equations DPLL-2a2 to calculate QDT_T_ACT backwards

$$\text{QDT_T_ACT} = \text{DT_T_ACT} * \text{RDT_T}[p+1] \quad \text{(DPLL-2a2)}$$

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-3a to calculate of the error of last prediction

When q = NUTE-VTN and DIR1=1 using only RDT_T[p+q+1], DT_T[p+q] and DT_T[p+1] for the prediction of DT_T[p]

$$\text{EDT_T} = \text{DT_T_ACT} - (\text{DT_T}[p+1] * \text{QDT_T}[p+q]) \quad \text{(DPLL-3a)}$$

with

$$\text{QDT_T}[p+q] = \text{DT_T}[p+q] * \text{RDT_T}[p+q+1] \text{ for FST} = 0 \quad \text{(DPLL-2b3)}$$

$$\text{QDT_T}[p+q] = \text{DT_T}[p+q] * \text{RDT_T_FS1} \text{ for FST} = 1 \quad \text{(DPLL-2b4)}$$

and

FST has the meaning: NUTE = FULL_SCALE (see NUTC register)

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-4 to calculate the weighted average error

For SYT=1 calculate:

$$\text{MEDT_T} := (\text{EDT_T} + \text{MEDT_T})/2 \quad \text{(DPLL-4)}$$

Equation DPLL-5 to calculate the current increment value

$$\text{CDT_TX_nom} = (\text{DT_T_ACT} + \text{MEDT_T}) * \text{QDT_T}[p+q-1] \quad \text{(DPLL-5a1)}$$

with

$$\text{QDT_T}[p+q-1] = \text{DT_T}[p+q-1] * \text{RDT_T}[p+q] \quad (\text{for } q > 1) \quad \text{(DPLL-2c1)}$$

for q=1 use equation DPLL-2a1.

while

QDT_T_ACT as well as QDT_Ti have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

and the expected duration to the next TRIGGER event

$$\text{CDT_TX} = \text{CDT_TX_nom} * \text{SYN_T} \quad \text{(DPLL-5b)}$$

Note: In the case of an overflow (or negative values) in equations DPLL-5a1 or b set the value to 0xFFFFFFFF and the corresponding CTO bit in the DPLL_STATUS register. In case of negative values CDT_TX(_nom) to 0x0.

26.16.6.5 Increment prediction in Emergency Mode backwards (DIR2=1)
Equation DPLL-7a2 to calculate QDT_S_ACT backwards

$$\text{QDT_S_ACT} = \text{DT_S_ACT} * \text{RDT_S}[p+1] \quad \text{(DPLL-7a2)}$$

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Generic Timer Module (GTM)
Equation DPLL-8a to calculate the error of the last prediction

While $q = \text{NUSE-VSN}$, use only $\text{QDT_S}[p+q]$ and $\text{DT_S}[p+1]$ for the prediction of $\text{DT_S}[p]$

$$\text{EDT_S} = \text{DT_S_ACT} - (\text{DT_S}[p+1] * \text{QDT_S}[p+q]) \quad \text{(DPLL-8a)}$$

with

$$\text{QDT_S}[p-q] = \text{DT_S}[p+q] * \text{RDT_S}[p+q+1] \text{ for } \text{FSS} = 0 \quad \text{(DPLL-7b3)}$$

$$\text{QDT_S}[p-q] = \text{DT_S}[p+q] * \text{RDT_S_FS1} \text{ for } \text{FSS} = 1 \quad \text{(DPLL-7b4)}$$

and

FSS has the meaning: $\text{NUSE} = \text{FULL_SCALE}$ (see NUSC register)

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Equation DPLL-9 to calculate the weighted average error

For $\text{SYS}=1$ calculate:

$$\text{MEDT_S} := (\text{EDT_S} + \text{MEDT_S})/2 \quad \text{(DPLL-9)}$$

Equations DPLL-10 to calculate the current increment value

$$\text{CDT_SX_nom} = (\text{DT_S_ACT} + \text{MEDT_S}) * \text{QDT_S}[p+q-1] \quad \text{(DPLL-10a1)}$$

with

$$\text{QDT_S}[p+q-1] = \text{DT_S}[p+q-1] * \text{RDT_S}[p+q] \text{ (for } q > 1) \quad \text{(DPLL-7c1)}$$

for $q=1$ use equation DPLL-7a.

while

QDT_S_ACT as well as QDT_Si have a 24 bit value using a 6 bit integer part and a 18 bit fractional part.

Generic Timer Module (GTM)

and calculate the expected duration to the next STATE event

$$\text{CDT_SX} = \text{CDT_SX_nom} * \text{SYN_S} \quad \text{(DPLL-10b)}$$

Note: In the case of an overflow (or negative values) in equations DPLL-10a1 or b set the value to 0xFFFFFFFF and the corresponding CSO bit in the DPLL_STATUS register. In case of negative values CDT_TX(nom) to 0x0.

All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

26.16.7 Calculations for actions

As already shown for the calculation of the current interval by equations DPLL-1 to DPLL-10 for the prediction of actions a similar calculation is to be done, as shown by the equations DPLL-11. to DPLL-14. The calculation of actions is also needed when the DPLL is used for synchronous motor control applications (SMC=1, see DPLL_CTRL_1 register). For action prediction purposes the measured time periods of the past (one FULL_SCALE back, when the corresponding NUTE or NUSE values are set properly by the CPU) are used. The calculation can be explained by the following assumptions, which are considerably simple:

Take the corresponding increments for prediction in the past and put the sum of it in relation to the increment (DT_T[k], DT_S[k], with $k > 0$, which is represented by the time stamp difference) which is exactly one FULL_SCALE period in the past (DPLL-11 or DPLL-13 respectively). Make a prediction for the coming sum of increments using the current measured increment (DT_T_ACT or DT_S_ACT respectively, that means DPLL-1 or DPLL-6 respectively) and add a weighted average error (DPLL-3 and DPLL-4 or DPLL-8 and DPLL-9 respectively, calculated for one increment prediction) before multiplication with the relation of equation DPLL-11 or DPLL-13 respectively in order to get the result as described by equations DPLL-12 or DPLL-14 respectively.

In order to avoid division operations instead of the increment (DT_T[k], DT_S[k] with $k > 0$) in the past its reciprocal value (RDT_T[k], RDT_S[k] with $k > 0$) is used, which is stored also in RAM.

For the calculation of actions perform always a new refined calculation as long as the resulting time stamp is not in the past. In the other case the tsac/psac values (time/position stamp of action calculated) is set to the time/position stamp of the last input event (TRIGGER/STATE), the ACT_Ni bit in the DPLL_ACT_STA register is reset, while the corresponding ACT_Ni bit in the DPLL_ACT_STA_shadow register is set. Each new PMTR_i value will set this ACT_Ni bit again and reset the correspondent shadow bit until a new calculation is performed.

Generic Timer Module (GTM)**Action updates at highest speed**

Up to 32 action values can be calculated. For the shortest increment durations (23,4 μ s) not all of them can be updated with each valid input event. Please notice the following conditions and parameters for an estimation of possible results.

All time estimation values are given for a system clock frequency of 100 MHz and the assumption, that the calculation of the DPLL is not impeded by a remote read or write access to the DPLL RAMs. Each RAM access is to be considered by an additional delay of about 40 ns (tremote_RAM_access, to be precised later). When using a different system clock frequency the calculation duration is extended accordingly.

1.) Typical time needed for basic operations (RAM update, pointer calculation and SUB_INC generation for normal, emergency mode or one PMSM:

$$t_{basic_0} = 9,9 \mu s$$

2.) Typical time needed basic operations (RAM update, pointer calculation and SUB_INC generation for two PMSMs:

$$t_{basic_1} = 11,0 \mu s$$

3.) Typical time needed to calculate one action

$$t_{action_i} = 3,7 \mu s$$

Please notice that the above mentioned values are observed worst case values, when the two state machines of TRIGGER and STATE are both in operation.

These values allow the calculation of at least 2 action values for each input event for all specified increment durations. The complete time needed for the basic operation, n action calculations and k remote RAM access operations can be calculated as follows

$$t_{complete} = t_{basic_0}/1 + n*t_{action_i} + k*t_{remote_RAM_access}.$$

Typical applications

Normal and emergency mode

For a typical application with the shortest increment duration of 100 μ s in normal or emergency mode the calculation of up to 24 action values can be performed for each valid input event.

One PMSM

For one PMSM and a typical shortest increment time of 39 μ s there is the calculation of up to 7 action values possible for each input event.

Two PMSMs with restricted action calculations

When only one PMSM uses the action calculation service an the shortest increment duration is 39 μ s, there can up to 7 actions served for each valid input event.

Two PMSMs with unrestricted action calculations

Generic Timer Module (GTM)

When 2 PMSMs are used and both use the action calculation service at a minimal increment duration of 39 μ s there are up to 7 action calculations possible for each of the two engines - that means up to 14 action calculations per increment in average.

26.16.7.1 Action calculations for TRIGGER forwards

valid for RMO=0 or for SMC=1 with

p =APT_2B, t =APT, m =NA[i] (part w), mb =NA[i](part b)/1024, NUTE-VTN= q , NUTE= n

Equation DPLL-11a1 to calculate the time prediction for an action

For DIR1=0 and $q>m$ calculate:

$$PDT_T[i] = (TSF_T[p+m-n] - TSF_T[p-n] + mb * DT_Tx[t-q+1]) * RDT_T[t-q] \quad \text{(DPLL-11a1)}$$

with

$$DT_Tx[t-q+1] = DT_T[t-q+1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b2)}$$

or

$$DT_Tx[t-q+1] = DT_T[t-q+1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b3)}$$

and while the multiplication with mb does mean the fractional part of NA[i].

For SMC=0 and RMO=0 calculate for DIR1=0 all 32 actions in forward direction, if requested; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

Equation DPLL-11a2 to calculate the time prediction for an action

For SYT=1, NUTE= 2*(TNU+1), $q>m$ and DIR1=0 equation DPLL-11a2 is equal to

$$PDT_T[i] = (TSF_T[p+m] - TSF_T[p] + mb * DT_Tx[t-q+1]) * RDT_T[t] \quad \text{(DPLL-11a2)}$$

with

$$DT_Tx[t-q+1] = DT_T[t-q+1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b2)}$$

or

$$DT_Tx[t-q+1] = DT_T[t-q+1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b3)}$$

Generic Timer Module (GTM)
Equation DPLL-11b to calculate the time prediction for an action

for DIR1=0, NUTE-VTN=q, q (< or =) m, n>1 and t=APT:

$$PDT_T[i] = (m+mb)*DT_Tx[t-q+1] * RDT_T[t-q] \quad \text{(DPLL-11b)}$$

with

$$DT_Tx[t-q+1] = DT_T[t-q+1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b2)}$$

or

$$DT_Tx[t-q+1] = DT_T[t-q+1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b3)}$$

Note: Note: Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

Equation DPLL-11c to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

$$PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t-1] \quad \text{(DPLL-11c)}$$

with

$$DT_T_ax = DT_T_ACT \text{ for } TS0_HRT=0 \quad \text{(DPLL-1a4a)}$$

or

$$DT_T_ax = DT_T_ACT/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-1a4b)}$$

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

Equation DPLL-12 to calculate the duration value until action

$$DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] \quad \text{(DPLL-12)}$$

Note: All 5 steps in equations DPLL-11 to DPLL-12 are only calculated in normal mode.

26.16.7.2 Action calculations for TRIGGER backwards

valid for RMO=0 or for SMC=1

$p=APS_1C2$, $t=APS$, $m=Nai(part\ w)$ $mb=Nai(part\ b)/1024$, $NUSE-VSN = q \geq m$ and $NUSE=n$

For SMC=0 and RMO=0 calculate for DIR1=1 all 32 actions in backward direction for special purposes; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

Equation DPLL-11a3 to calculate the time prediction for an action

For DIR1= 1 and $q>m$ calculate

$$PDT_T[i] = (TSF_T[p-m+n] - TSF_T[p+n] + mb * DT_Tx[t+q+1]) * RDT_T[t+q] \quad \text{(DPLL-11a3)}$$

with

$$DT_Tx[t+q+1] = DT_T[t+q+1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b4)}$$

or

$$DT_Tx[t+q+1] = DT_T[t+q+1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b5)}$$

Equation DPLL-11a4 to calculate the time prediction for an action

For SYT=1 and $NUTE = 2*(TNU+1)$, $q>m$, $VTN=2*SYN_NT$ and hence $NUTE-VTN = 2*(TNU+1-SYN_NT)$ for DIR1=1 this is equal to

$$PDT_T[i] = (TSF_T[p-m] - TSF_T[p] + mb * DT_Tx[t+q+1]) * RDT_T[t] \quad \text{(DPLL-11a4)}$$

with

$$DT_Tx[t+q+1] = DT_T[t+q+1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b4)}$$

or

$$DT_Tx[t+q+1] = DT_T[t+q+1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b5)}$$

Note: Make the calculations above before updating the $TSF_T[i]$ values according to equations DPLL-1c3 ff.

Generic Timer Module (GTM)
Equation DPLL-11b1 to calculate the time prediction for an action

For NUTE-VTN =q, q (< or =) m the following equation is valid for n>1 and t=APT:

$$PDT_T[i] = (m+mb)*DT_Tx[t+q-1] * RDT_T[t+q] \quad \text{(DPLL-11b1)}$$

with

$$DT_Tx[t+q-1] = DT_T[t+q-1] \text{ for } TS0_HRT=0 \quad \text{(DPLL-11b4)}$$

or

$$DT_Tx[t+q-1] = DT_T[t+q-1]/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-11b5)}$$

Equation DPLL-11c1 to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

$$PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t+1] \quad \text{(DPLL-11c1)}$$

with

$$DT_T_ax = DT_T_ACT \text{ for } TS0_HRT=0 \quad \text{(DPLL-1a4a)}$$

or

$$DT_T_ax = DT_T_ACT/8 \text{ for } TS0_HRT=1 \quad \text{(DPLL-1a4b)}$$

Note: For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

Equation DPLL-12 to calculate the duration value for an action

$$DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] \quad \text{(DPLL-12)}$$

Use the results of equations DPLL-1a, b, DPLL-3 and DPLL-4 for the above calculation

Note: Note: All 5 steps in equations DPLL-11 to DPLL-12 are only calculated in normal mode or when SMC=1.

26.16.7.3 Action calculations STATE forwards

valid for RMO=1

$p=APS_1C2$, $t=APS$, $m=NA[i](part\ w)$ $mb=NA[i9](part\ b)/1024$, $NUSE-VSN = q$ and $NUSE=n>m$

For SMC=0 and RMO=1 calculate for DIR2=0 all 32 actions in forward direction, if requested; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the STATE input.

Equation DPLL-13a1 to calculate the time prediction for an action

For DIR2=0 and $q>m$ calculate:

$$PDT_S[i] = (TSF_S[p+m-n] - TSF_S[p-n] + mb * DT_Sx[t-q+1]) * RDT_S[t-q] \quad \text{(DPLL-13a1)}$$

with

$$DT_Sx[t-q+1] = DT_S[t-q+1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13b2)}$$

or

$$DT_Sx[t-q+1] = DT_S[t-q+1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b3)}$$

Equation DPLL-13a2 to calculate the time prediction for an action

For SYS=1 and $NUSE=2*(SNU+1)$, $q>m$, $SYSF=0$, $VSN=2*SYN_NS$ and hence $NUSE-VSN = 2*(SNU+1-SYN_NS)$ equation DPLL-13a1 is equal to

$$PDT_S[i] = (TSF_S[p+m] - TSF_S[p] + mb * DT_Sx[t-q+1]) * RDT_S[t] \quad \text{(DPLL-13a2)}$$

with

$$DT_Sx[t-q+1] = DT_S[t-q+1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13b2)}$$

or

$$DT_Sx[t-q+1] = DT_S[t-q+1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b3)}$$

Equation DPLL-13b to calculate the time prediction for an action

For $NUSE-VTN = q$, $q (< \text{ or } =) m$ and $n>1$:

Generic Timer Module (GTM)

$$PDT_S[i] = (m+mb)*DT_Sx[t-q+1] * RDT_S[t-q] \quad \text{(DPLL-13b)}$$

with

$$DT_Sx[t-q+1] = DT_S[t-q+1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13b2)}$$

or

$$DT_Sx[t-q+1] = DT_S[t-q+1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b3)}$$

Equation DPLL-13c to calculate the time prediction for an action

for n=1

$$PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t-1] \quad \text{(DPLL-13c)}$$

with

$$DT_S_ax = DT_S_ACT \text{ for } TS0_HRS=0 \quad \text{(DPLL-6a4a)}$$

or

$$DT_S_ax = DT_S_ACT/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-6a4b)}$$

Equation DPLL-14 to calculate the duration value for an action

$$DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] \quad \text{(DPLL-14)}$$

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

Note: All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

26.16.7.4 Action calculations for STATE backwards

valid for RMO=1 with

Generic Timer Module (GTM)

$p=APS_1C2$, $t=APS$, $m=NA[i](part\ w)$ $mb=NA[i](part\ b)/1024$, $NUSE-VSN = q$ and $NUSE=n$

For $SMC=0$ and $RMO=1$ calculate for $DIR1=1$ all 32 actions in backwards mode for special purposes; in the case $SMC=1$ and $RMO=1$ calculate up to 16 actions 16 to 31 in dependence of the STATE input.

Equation DPLL-13a3 to calculate the time prediction for an action

For ($DIR2= 1$ ($SMC=1$) or $DIR1=1$ ($SMC=0$)) and $q>m$ calculate

$$PDT_S[i] = (TSF_S[p-m+n] - TSF_S[p+n] + mb * DT_Sx[p+q-1]) * RDT_S[t+q] \quad \text{(DPLL-13a3)}$$

with

$$DT_Sx[p+q-1] = DT_S[p+q-1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13B4)}$$

or

$$DT_Sx[p+q-1] = DT_S[p+q-1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b5)}$$

Equation DPLL-13a4 to calculate the time prediction for an action

For $SYS=1$, $NUSE=2*(SNU+1)$, $q>m$, $SYSF=0$, $VSN=2*SYN_NS$ and hence $NUSE-VSN = 2*(SNU+1-SYN_NS)$ equation DPLL-13a3 is equal to

$$PDT_S[i] = (TSF_S[p-m] - TSF_S[p] + mb * DT_Sx[p+q-1]) * RDT_S[t] \quad \text{(DPLL-13a4)}$$

with

$$DT_Sx[p+q-1] = DT_S[p+q-1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13b4)}$$

or

$$DT_Sx[p+q-1] = DT_S[p+q-1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b5)}$$

Equation DPLL-13b1 to calculate the time prediction for an action

For $NUSE-VSN =q$, $q (< \text{ or } 0)$ $NUSE=n$ and $n>1$:

$$PDT_S[i] = m * DT_Sx[t+q-1] * RDT_S[t+q] \quad \text{(DPLL-13b1)}$$

with

Generic Timer Module (GTM)

$$DT_Sx[p+q-1] = DT_S[t+q-1] \text{ for } TS0_HRS=0 \quad \text{(DPLL-13b4)}$$

or

$$DT_Sx[p+q-1] = DT_S[t+q-1]/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-13b5)}$$

Equation DPLL-13c1 to calculate the time prediction for an action

for n=1

$$PDT_S[i] = (m+mb) * DT_S_ax * RDT_S[t+1] \quad \text{(DPLL-13c1)}$$

with

$$DT_S_ax = DT_S_ACT \text{ for } TS0_HRS=0 \quad \text{(DPLL-6a4a)}$$

or

$$DT_S_ax = DT_S_ACT/8 \text{ for } TS0_HRS=1 \quad \text{(DPLL-6a4b)}$$

Equation DPLL-14 to calculate the duration value until action

$$DTA[i] = (DT_S_ACT + MEDT_S) * PDT_S[i] \quad \text{(DPLL-14)}$$

Use the results of DPLL-7, DPLL-8 and DPLL-9 for the above calculation

Note: All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

26.16.7.5 Update of RAM in Normal and Emergency Mode

After considering the calculations for up to all 24 actions according to equations (DPLL-11, DPLL-12), only when going back to state 1 or 21 (because of a new TRIGGER or STATE event, that means when no further PMTR values are to be considered) set time stamp values and durations of increments in the RAM.

Equation DPLL-1a4 to update the time stamp values for TRIGGER

Generic Timer Module (GTM)

TSF_T[s]=TS_Tx using the following equations for the determination of TS_Tx	(DPLL-1a4)
For TS0_HRT=0:	
TS_Tx=TS_T	(DPLL-1a4w)
DT_T_ax = DT_T_ACT	(DPLL-1a4a)
For TS0_HRT=1:	
TS_Tx(20:0)=TS_T/8	(DPLL-1a4x)
TS_Tx(23:21)=TBU_TS0_T(23:21)	(DPLL-1a4y)
for TBU_TS0_T(20:0) > or = TS_Tx(20:0)	
TS_Tx(23:21)=TBU_TS0_T(23:21) -1	(DPLL-1a4z)
for TBU_TS0_T(20:0) < TS_Tx(20:0)	
DT_T_ax = DT_T_ACT/8	(DPLL-1a4b)

Note: The combination of values LOW_RES=0 and TS0_HRT=1 is not possible.

Store the time stamp values in the time stamp field according to the address pointer APT_2B=s, but make this update only after the calculation of actions **Section 26.16.7** because the old TSF_T[i] values are still needed for these calculations. Please note that the address pointer after a gap is still increment by SYN_T_OLD in that case (see state machine step 1 in **Section 26.16.8.6**).

Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=0

TSF_T[s-1] = TSF_T[s] -DT_T_ax	(DPLL-1a5)
TSF_T[s-2] = TSF_T[s-1] -DT_T_ax	(DPLL-1a6)

Generic Timer Module (GTM)

until

$$TSF_T[s-r+1] = TSF_T[s-r+2] - DT_T_ax \quad (DPLL-1a7)$$

after the incrementation of the pointer APT_2B by SYN_T_OLD

Equations DPLL-1a5-7 for backward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=1

$$TSF_T[s+1] = TSF_T[s] - DT_T_ax \quad (DPLL-1a5)$$

$$TSF_T[s+2] = TSF_T[s+1] - DT_T_ax \quad (DPLL-1a6)$$

until

$$TSF_T[s+r-1] = TSF_T[s+r-2] - DT_T_ax \quad (DPLL-1a7)$$

after the decrementation of the pointer APT_2B by SYN_T_OLD

Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation

$$DT_T[p] = DT_T_ACT \quad (DPLL-1b1)$$

save old reciprocal value from RAM before overwriting:

$$RDT_T_FS1 = RDT_T[p] \quad (DPLL-1c1)$$

after that store new value in RAM

$$RDT_T[p] = RDT_T_ACT \quad (DPLL-1c2)$$

Store increment duration and reciprocal value in RAM region 2 in normal mode after calculation of actions only when a new valid TRIGGER slope is detected and in emergency mode directly after calculation of DT_T_ACT or RDT_T_ACT respectively.

Equation DPLL-6a4 to update the time stamp values for STATE

Generic Timer Module (GTM)

TSF_S[s]=TS_Sx using the following equations for the determination of TS_Sx	(DPLL-6a4)
For TS0_HRS=0: TS_Sx=TS_S	(DPLL-6a4)
DT_S_ax = DT_S_ACT	(DPLL-6a4a)
For TS0_HRS=1: TS_Sx(20:0)=TS_S/8	(DPLL-6a4x)
TS_Sx(23:21)=TBU_TS0_S(23:21)	(DPLL-6a4y)
for TBU_TS0_S(20:0) > or = TS_Sx(20:0)	
TS_Sx(23:21)=TBU_TS0_S(23:21) -1	(DPLL-6a4z)
for TBU_TS0_S(20:0) < TS_Sx(20:0)	
DT_S_ax = DT_S_ACT/8	(DPLL-6a4b)

Note: The combination of values LOW_RES=0 and TS0_HRS=1 is not possible.

Store the time stamp value in the time stamp field according to the address pointer APS_1C2=s, but make this update only after the calculation of actions (equations DPLL-13a2 or DPLL-13a4, if applicable) because the old TSF_S[i] values are still needed for these calculations. Please note, that the address pointer after a gap is still increment by SYN_S_OLD in that case (see state machine step 21 in [Section 26.16.8.6](#)).

Equations DPLL-6a5-7 to extend the time stamp values for STATE

When SYS=1 and SYN_S_OLD=r>1 and DIR1=0 respectively calculate

TSF_S[s-1] = TSF_S[s] - DT_S_ax	(DPLL-6a5)
TSF_S[s-2] = TSF_S[s-1] - DT_S_ax	(DPLL-6a6)
until	
TSF_S[s- r+1] = TSF_S[s- r+2] - DT_S_ax	(DPLL-6a7)

Generic Timer Module (GTM)

after incrementation of the pointer APS_2B by SYN_S_OLD

Equations DPLL-6a5-7 for backward direction

When SYS=1 and SYN_S_OLD=r>1 and DIR1=1 respectively calculate

$$\text{TSF_S}[s+1] = \text{TSF_S}[s] - \text{DT_S_ax} \quad \text{(DPLL-6a5)}$$

$$\text{TSF_S}[s+2] = \text{TSF_S}[s+1] - \text{DT_S_ax} \quad \text{(DPLL-6a6)}$$

until

$$\text{TSF_S}[s+r-1] = \text{TSF_S}[s+r-2] - \text{DT_S_ax} \quad \text{(DPLL-6a7)}$$

after the incrementation of the pointer APS_1C2 by SYN_S_OLD

Equations DPLL-6b1 and DPLL-6c1 to update the RAM after calculation

$$\text{DT_S}[p] = \text{DT_S_ACT} \quad \text{(DPLL-6b1)}$$

save old reciprocal value from RAM before overwriting:

$$\text{RDT_S_FS1} = \text{RDT_S}[p] \quad \text{(DPLL-6c1)}$$

after that store new value in RAM

$$\text{RDT_S}[p] = \text{RDT_S_ACT} \quad \text{(DPLL-6c2)}$$

when a new valid STATE slope is detected in emergency mode or in normal mode (SMC=RMO=0) directly after calculation of the values above.

Store increment duration and reciprocal value in RAM region 1C in emergency mode after calculation of actions only when a new valid STATE slope is detected and in normal mode directly after calculation of DT_S_ACT or RDT_S_ACT respectively.

26.16.7.6 Time and position stamps for actions in Normal Mode

Equation DPLL-15 to calculate the action time stamp

$$TSAC[i] = DTA[i] - DLA[i] + TS_Tx \text{ (for } DTA[i] > DLA[i] \text{ and } DTA[i] - DLA[i] < 0x800000) \quad \text{(DPLL-15a)}$$

$$TSAC[i] = TS_Tx \text{ (for } DTA[i] < DLA[i]) \quad \text{(DPLL-15b)}$$

$$TSAC[i] = 0x7FFFFFFF + TS_Tx \text{ (for } DTA[i] > DLA[i] \text{ and } DTA[i] - DLA[i] > 0x7FFFFFFF) \quad \text{(DPLL-15c)}$$

Note: For TS_Tx see equations (DPLL-1a4 and following).

The calculation is done after the calculation of the current expected duration value according to equation DPLL-12 at [Section](#). The time stamp of the action can be calculated as shown above in equation DPLL-15 using the delay value of the action and the current time stamp.

Equations DPLL-17 to calculate the position stamp forwards

for DIR1=0 and TS0_HRT=0:

$$PSAC[i] = PSA[i] - (DLA[i] * RCDT_TX_NOM) * (MLT + 1) \quad \text{(DPLL-17)}$$

with

$$RCDT_TX_NOM = RCDT_TX * SYN_T \quad \text{(DPLL-17a)}$$

and

$$RCDT_TX = 1 / CDT_TX \quad \text{(DPLL-17b)}$$

for DIR1=0 and TS0_HRT=1:

$$PSAC[i] = PSA[i] - (8 * DLA[i] * RCDT_TX_NOM) * (MLT + 1) \quad \text{(DPLL-17d)}$$

with

$$RCDT_TX_NOM = RCDT_TX * SYN_T \quad \text{(DPLL-17a)}$$

and

$$\text{RCDT_TX} = 1/\text{CDT_TX} \quad \text{(DPLL-17b)}$$

replace (MLT+1) in equations (DPLL-17) and (DPLL-17d) by MLS1 for SMC=1
 use the calculated value of (DPLL-17b) also for the generation of SUB_INCi
 and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i

The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

Equations DPLL-17 to calculate the position stamp backwards

For DIR1=1 and TS0_HRT=0:

$$\text{PSAC}[i] = \text{PSA}[i] + (\text{DLA}[i] * \text{RCDT_TX_NOM}) * (\text{MLT} + 1) \quad \text{(DPLL-17c)}$$

with

$$\text{RCDT_TX_NOM} = \text{RCDT_TX} * \text{SYN_T} \quad \text{(DPLL-17a)}$$

and

$$\text{RCDT_TX} = 1/\text{CDT_TX} \quad \text{(DPLL-17b)}$$

For DIR1=1 and TS0_HRT=1:

$$\text{PSAC}[i] = \text{PSA}[i] + (8 * \text{DLA}[i] * \text{RCDT_TX_NOM}) * (\text{MLT} + 1) \quad \text{(DPLL-17e)}$$

with

$$\text{RCDT_TX_NOM} = \text{RCDT_TX} * \text{SYN_T} \quad \text{(DPLL-17a)}$$

and

$$\text{RCDT_TX} = 1/\text{CDT_TX} \quad \text{(DPLL-17b)}$$

replace (MLT+1) in equations (DPLL-17c) and (DPLL-17e) by MLS1 for SMC=1

Generic Timer Module (GTM)

use the calculated value of (DPLL-17b) also for the generation of SUB_INCI and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i

The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

26.16.7.7 The use of the RAM

The RAM is used to store the data of the last FULL_SCALE period. The use of single port RAMs is recommended. The data width of the RAM is usual 3 bytes, but could be extended to 4 bytes in future applications. There are 3 different RAMs, each with separate access ports. the RAM 1A is used to store the position minus time requests, got from the ARU. No CPU access is possible to this RAM during operation (when the DPLL is enabled).

Ram 1B is used for configuration parameters and variables needed for calculations. Within RAM 1C the values of the STATE events are stored. RAM 1B and RAM 1C do have a common access port and are also marked as RAM 1BC in order to clarify this fact.

RAM 2 is used for values of the TRIGGER events.

Because of the access of the DPLL internal state machine at the one side and the CPU at the other side the access priority has to be controlled for both RAMs 1BC and 2. The access priority is defined as stated below. The CPU access procedure via AE-interface goes in a wait state (waiting for data valid) while it needs a colliding RAM access during serving a corresponding state machine RAM access. In order not to provoke unexpected behaviour of the algorithms the writing of the CPU to the RAM regions 1B, 1C or 2 will be monitored and results in interrupt requests when enabled.

CPU access is specified at follows:

1. CPU has highest priority for a single read/write access. The DPLL algorithm is stalled during external bus RAM accesses.
2. After serving the CPU access to the RAM the DPLL gets the highest RAM access priority for 8 clock cycles. Afterwards continue with 1.

The RAM address space has to be implemented in the address space of the CPU.

26.16.7.8 Time and position stamps for actions in Emergency Mode

Equation DPLL-18 to calculate the action time stamp

Generic Timer Module (GTM)

TSAC[i]= DTA[i] - DLA[i] + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] < 0x800000) **(DPLL-18a)**

TSAC[i]= TS_Sx (for DTA[i] < DLA[i]) **(DPLL-18b)**

TSAC[i]= 0x7FFFFFF + TS_Sx (for DTA[i] > DLA[i] and DTA[i] - DLA[i] > 0x7FFFFFF) **(DPLL-18c)**

Note: For TS_Sx see equations (DPLL-6a4 and following), [Section](#).

The calculation is done after the calculation of the current expected duration value according to equation DPLL-14 at [Section](#). The time stamp of the action can be calculated as shown in equation DPLL-18 using the delay value of the action and the current time stamp.

Equations DPLL-20 to calculate the position stamp forwards

for DIR1=0 respectively and TS0_HRS=0:

PSAC[i] = PSA[i] - (DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

for DIR2=0 or DIR1=0 respectively and TS0_HRS=1:

PSAC[i] = PSA[i] - (8*DLA[i]*RCDT_SX_NOM)*MLS1 **(DPLL-20d)**

with

RCDT_SX_NOM= RCDT_SX * SYN_S **(DPLL-20a)**

and

RCDT_SX= 1/CDT_SX **(DPLL-20b)**

Generic Timer Module (GTM)

replace MLS1 in equations (DPLL-20) and (DPLL-20d) by MLS2 for (SMC=1 and RMO=1)

use the calculated value of (DPLL-20b) also for the generation of SUB_INCi.

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D.

The action is to be updated for each new STATE event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

Equations DPLL-20 to calculate the position stamp backwards

For DIR2=1 or DIR1=1 respectively and TS0_HRS=0:

$$PSAC[i] = PSA[i] + (DLA[i]*RCDT_SX_NOM)*MLS1 \quad \text{(DPLL-20c)}$$

with

$$RCDT_SX_NOM = RCDT_SX * SYN_S \quad \text{(DPLL-20a)}$$

and

$$RCDT_SX = 1/CDT_SX \quad \text{(DPLL-20b)}$$

For DIR2=1 or DIR1=1 respectively and TS0_HRS=1:

$$PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_SX_NOM)*MLS1 \quad \text{(DPLL-20e)}$$

with

$$RCDT_SX_NOM = RCDT_SX * SYN_S \quad \text{(DPLL-20a)}$$

and

$$RCDT_SX = 1/CDT_SX \quad \text{(DPLL-20b)}$$

replace MLS1 in equations (DPLL-20c) and (DPLL-20e) by MLS2 for (SMC=1 and RMO=1)

use the calculated value of (DPLL-20b) also for the generation of SUB_INCi.

Generic Timer Module (GTM)

and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D.

The action is to be updated for each new STATE event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

26.16.8 Signal processing

26.16.8.1 Time stamp processing

Signal processing does mean the computation of the time stamps in order to calculate at which time the outputs have to appear. For such purposes the time stamp values have to be stored in the RAM and by calculating the difference between old and new values the duration of the last time interval is determined simply. This difference should be also stored in the RAM in order to see the changes between the intervals by changing the conditions and the speed of the observed process.

26.16.8.2 Count and compare unit

The count and compare unit processes all input signals taking into account the configuration values. It uses a state machine and provides the output signals as described above.

26.16.8.3 Sub pulse generation for SMC=0

Equation DPLL-21 to calculate the number of pulses to be sent in normal mode using the automatic end mode condition

For RMO=0, SMC=0 and DMO=0

$$\text{NMB_T} = (\text{MLT}+1) * \text{SYN_T} + \text{MP} + \text{PD_store} + \text{MPVAL1} \quad \text{(DPLL-21)}$$

with

$$\text{PD_store} = \text{ADT_T}[12:0], \text{ prefetched during last increment} \quad \text{(DPLL-21a)}$$

$$\text{SYN_T} = \text{ADT_T}[18:16], \text{ prefetched during last increment}$$

$$\text{MPVAL1} = \text{pulse correction value for PCM1_SHADOW_TRIGGER=1}$$

Generic Timer Module (GTM)

while the value for PD_store is zero for AMT=0

and

the value of MP is zero for COA=0

In order to get a higher resolution for higher speed a generator for the sub-pulses is chosen using an adder. All missing pulses MP are considered using equation DPLL-21 and are determined by counting the number of pulses of the last increment. The value SYN_T is stored from the last increment using NT of the ADT_T[i] value at RAM region 2C.

Equations DPLL-22-24 to calculate the number of pulses to be sent in emergency mode using the automatic end mode condition for SMC=0

For RMO=1, SMC=0 and DMO=0;

the value for PD_S_store is zero for AMS=0

$$\text{NMB_S} = \text{MLS1} * \text{SYN_S} + \text{MP} + \text{PD_S_store} \quad (\text{DPLL-22})$$

with

$$\text{MLS1} = (\text{MLT} + 1) * (\text{TNU} + 1) / (\text{SNU} + 1) \quad (\text{DPLL-23})$$

PD_S_store = ADT_S[15:0], prefetched during last increment

SYN_S = ADT_S[21:16], prefetched during last increment

MPVAL1 = pulse correction value for PCM1_SHADOW_STATE=1

while the value for PD_S_store is zero for AMS=0

and

the value of MP is zero for COA=0

Please note, that these calculations above in equations DPLL-21 and DPLL-22 are only valid for an automatic end mode (DMO = 0).

For calculation of the number of generated pulses a value of 0.5 is added as shown in equations DPLL-25 or DPLL-26 respectively in order to compensate rounding down errors at the succeeding arithmetic operations. Because in automatic end mode the number of pulses is limited by INC_CNT1 it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are caught up for the next increment.

Equation DPLL-25 to calculate ADD_IN in normal mode for SMC=0

In normal mode (for RMO=0) calculate in the case LOW_RES=TS0_HRT

Generic Timer Module (GTM)

$$\text{ADD_IN_CALN} = (\text{NMB_T} + 0.5) * \text{RCDT_TX} \quad (\text{DPLL-25})$$

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b

In normal mode (for RMO=0) calculate in the case LOW_RES=1 and TS0_HRT=0

$$\text{ADD_IN_CALN} = (\text{NMB_T} + 0.5) * (\text{RCDT_TX} / 8) \quad (\text{DPLL-25a})$$

with

RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b

For RMO=0 and SMC=0:

$$\text{ADD_IN_CAL1} = \text{ADD_IN_CALN} \quad (\text{DPLL-25b})$$

LOW_RES=0 and TS0_HRT=1 is not possible. For such a configuration the RCT bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO = 0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Adder for generation of SUB_INCx by the carry Cout**, to be caught up on with CMU_CLK0 (for COA = 0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of TS_CLK. In addition the ADD_IN value should never exceed the value 0x800000. This limitation is only necessary for DMO = 0 and COA = 0 (see DPLL_CTRL_1 register).

For the normal mode replace ADD_IN of the ADDER (see **Figure 26-75**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

Enabling of the compensated output for pulses

The cout of the adder influences directly the SUB_INC1 output of the DPLL (see [Figure 26-75](#)). The compensated output SUB_INCxc is in automatic end mode only enabled by EN_Cxc when INC_CNTx >0.

Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC=0

In emergency mode (RMO=1) calculate in the case LOW_RES=TS0_HRS

$$\text{ADD_IN_CALE} = (\text{NMB_S} + 0.5) * \text{RCDT_SX} \quad (\text{DPLL-26})$$

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b

In emergency mode (RMO=1) calculate in the case LOW_RES=1 and TS0_HRS=0

$$\text{ADD_IN_CALE} = (\text{NMB_S} + 0.5) * \text{RCDT_SX} / 8 \quad (\text{DPLL-26a})$$

while

RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b

For RMO=1 and SMC=0:

$$\text{ADD_IN_CAL1} = \text{ADD_IN_CALE} \quad (\text{DPLL-26b})$$

LOW_RES=0 and TS0_HRS=1 is not possible. For such a configuration the RCS bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO = 0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in [Adder for generation of SUB_INCx by the carry Cout](#), to be caught up on with CMU_CLK0 (for COA = 0).

When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of the system clock. In addition the ADD_IN value should never exceed the value 0x800000 when the TS_CLK frequency exceeds half the frequency of the system clock. This limitation is only necessary for DMO = 0 and COA = 0 (see DPLL_CTRL_1 register).

Generic Timer Module (GTM)

For the emergency mode replace ADD_IN of the ADDER (see [Figure 26-75](#)) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1).

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the output of the adder, stored one time stamp clock before.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

Adder for generation of SUB_INCx by the carry C_{out}

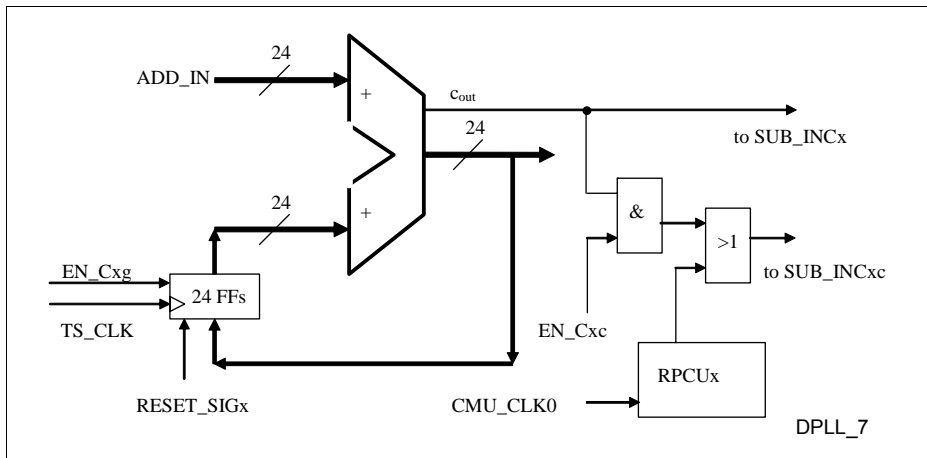

Figure 26-75 Adder for generation of SUB_INCx by the carry C_{out}

Note: The SUB_INC generation by the circuit above has the advantage, that the resolution for higher speed values is better as for a simple down counter.

After RESET and after EN_Cxg=0 the flip-flops (FFs) should have a zero value. EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. This is controlled by the configuration bits SGE1,2 in the DPLL_CONTROL_1 register. The calculated values for the increment prediction using equations DPLL-2c ([Equations DPLL-5 to calculate the current increment value](#)), DPLL-2c1 ([Equation DPLL-5 to calculate the current increment value](#)), DPLL-7c ([Equations DPLL-10 to calculate the current increment \(nominal value\)](#)) or DPLL-7c1 ([Equation DPLL-5 to calculate the current increment value](#)) respectively are valid only when at least NUTE>1 TRIGGER values or at least NUSE>1 STATE values are available. For NUTE =1 or

Generic Timer Module (GTM)

NUSE=1 respectively the equations DPLL-25 ([Equation DPLL-25 to calculate ADD_IN in normal mode for SMC=0](#)) and DPLL-26 ([Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC=0](#)) use the actual increment value subtracted by the weighted average error.

The generation of SUB_INC1 pulses depends on the configuration of the DPLL.

In automatic end mode the counter INC_CNT1 resets the enable signal EN_C1 when the number of pulses desired is reached. In this case only the uncompensated output SUB_INC1 remains active in order to provide pulses for the input filter unit. A new TRIGGER input in normal mode or a new STATE input in emergency mode respectively resets the FFs and also the enable signal EN_Cxg. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event in normal/emergency mode easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. During this time period the EN_Cxg remains cleared. After calculation or providing of a new ADD_IN value the FFs are enabled by EN_Cxg. In this way no pulse is lost. The new pulses are sent out afterwards, when INC_CNT1 is set to the desired value, maybe by adding MLT+1 or MLS1 respectively for the new TRIGGER/STATE event.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation at SUB_INC1 will stop in automatic end mode when the INC_CNT1 register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the lost of pulses can be avoided.

When a new TRIGGER/STATE appears the value of SYN_T*(MLT+1) or SYN_S*MLS1 respectively is added to INC_CNT1, when SGE1=1. Therefore for FULL_SCALE $2*(TNU+1)*(MLT+1)$ pulses SUB_INC1 generated, when INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible. The calculations for the ADD_IN value must be done first. Therefore all values needed for calculation are to be fetched in a forecast.

26.16.8.4 Sub pulse generation for SMC=1

Necessity of two pulse generators

The Adder of [Figure 26-75](#) must be implemented twice in the case of SMC=1: one for SUB_INC1 controlled by the TRIGGER input and (while RMO=1) one for SUB_INC2, controlled by the STATE input. In the case described in the section above for SMC=0 only one Adder is used to generate SUB_INC1 controlled by the TRIGGER in normal mode or by STATE in emergency mode.

Equation DPLL-27 to calculate the number of pulses to be sent for the first device

using the automatic end mode condition

For SMC=1 and DMO=0

$$\text{NMB_T} = \text{MLS1} * \text{SYN_T} + \text{MP} + \text{PD_store} + \text{MPVAL1} \quad (\text{DPLL-27})$$

with

PD_store = ADT_T[12:0], prefetched during last increment

SYN_T = ADT_T[18:16], prefetched during last increment

MPVAL1 = pulse correction value for PCM1_STADOW_TRIGGER=1

while the value for PD_store is zero for AMT=0

and

for COA=0 use zero instead of the value of MP

Equation DPLL-28 to calculate the number of pulses to be sent for the second device using the automatic end mode condition

for RMO=1, SMC=1 and DMO=0

$$\text{NMB_S} = \text{MLS2} * \text{SYN_S} + \text{MP} + \text{PD_S_store} + \text{MPVAL2} \quad (\text{DPLL-28})$$

with

PD_S_store = ADT_S[15:0], prefetched during last increment

SYN_S = ADT_S[21:16], prefetched during last increment

MPVAL2 = pulse correction value for PCM2_SHADOW_TRIGGER=1

while the value for PD_store is zero for AMS=0

and

for COA=0 use zero instead of the value of MP

Please note, that these calculations above in equations DPLL-27 and DPLL-28 are only valid for an automatic end mode (DMO = 0). In addition the number of generated pulses is added by 0.5 as shown in equations DPLL-30 or DPLL-31 respectively in order to compensate rounding down errors at the succeeding division operation. Because in automatic end mode the number of pulses is limited by INC_CNTx it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are made up for the next increment.

Generic Timer Module (GTM)
Equation DPLL-30 to calculate ADD_IN for the first device for SMC=1

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out cout and the following inputs:

- ADD_IN
- the second input is the (delayed) output of the adder, stored with each time stamp clock.

Replace ADD_IN by ADD_IN_CAL1 (when calculated, DLM1=0) or ADD_IN_LD1 (when provided by the CPU, DLM1=1) respectively while:

For SMC=1 and LOW_RES=TS0_HRT

$$\text{ADD_IN_CAL1} = (\text{NMB_T} + 0.5) * \text{RCDT_TX} \quad (\text{DPLL-30})$$

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b.

For SMC=1, LOW_RES= 1 and TS0_HRT=0

$$\text{ADD_IN_CAL1} = (\text{NMB_T} + 0.5) * (\text{RCDT_TX} / 8) \quad (\text{DPLL-30a})$$

When RCDT_TX is the 2^{32} time value of the quotient in equation DPLL-17b.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

ADD_IN_CAL1 is a 24 bit integer value. The CDT_TX is the expected duration of current TRIGGER increment.

The cout of the adder influences directly the SUB_INC1 output of the DPLL (see [Section](#)). The SUB_INC1 output is in automatic end mode only enabled by EN_C1 when INC_CNT1 >0.

Equation DPLL-31 to calculate ADD_IN for the second device for SMC=1

Replace ADD_IN by ADD_IN_CAL2 (when calculated, DLM2=0) or ADD_IN_LD2 (when provided by the CPU, DLM2=1) respectively while:

for SMC=1, RMO=1 and LOW_RES=TS0_HRS:

$$\text{ADD_IN_CAL2} = (\text{NMB_S} + 0.5) * \text{RCDT_SX} \quad (\text{DPLL-31})$$

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b.

for SMC=1, RMO=1, LOW_RES=1 and TS0_HRS=0:

Generic Timer Module (GTM)

$$\text{ADD_IN_CAL2} = (\text{NMB_S} + 0.5) * (\text{RCDT_SX} / 8) \quad (\text{DPLL.3 1a})$$

When RCDT_SX is the 2^{32} time value of the quotient in equation DPLL-20b.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

The cout of the adder2 influences directly the SUB_INC2 output of the DPLL (see [Adder for generation of SUB_INCx by the carry Cout](#)).

The SUB_INC2 output is in automatic end mode only enabled by EN_C2 when INC_CNT2 > 0.

Please note, that after RESET and after EN_Cxc=0 (after stopping in automatic end mode) the flip-flops (FFs) have a zero value and also EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. The calculated values for the increment prediction using equations DPLL-2c [Equations DPLL-5 to calculate the current increment value](#), DPLL-2c1 [Equation DPLL-5 to calculate the current increment value](#), DPLL-7c [Equations DPLL-10 to calculate the current increment \(nominal value\)](#) or DPLL-7c1 [Section](#) respectively are valid only when NUTE > 1 or NUSE > 1 respectively. For NUTE=1 or NUSE=1 respectively the equations DPLL-30 (see [Equation DPLL-30 to calculate ADD_IN for the first device for SMC=1](#)) and DPLL-31 (see [Equation DPLL-31 to calculate ADD_IN for the second device for SMC=1](#)) use the actual increment value subtracted by the weighted average error.

The generation of SUB_INCx pulses depends on the configuration of the DPLL.

In automatic end mode the counter INC_CNTx resets the enable signal EN_Cxcu when the number of pulses desired is reached. In this case only the uncompensated outputs SUB_INCx remain active in order to provide pulses for the input filter units. A new TRIGGER or STATE input respectively can reset the FFs and also ADD_IN, especially when EN_Cxc was zero before. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event easily. For the correction strategy COA = 0 those missing pulses are sent out with maximum frequency as soon they are determined. After that the pulse counter INC_CNTx should be always zero and the new pulses are sent out afterwards, when INC_CNTx is set to the desired value by adding MLS1 or MLS2 for the new TRIGGER or STATE event respectively.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation will stop when the INC_CNTx register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the lost of pulses can be avoided.

When a new TRIGGER appears the value of SYN_T*MLS1 is added to INC_CNT1. Therefore for FULL_SCALE $2 * (\text{TNU} + 1) * \text{MLS1}$ pulses SUB_INC1 generated, when

Generic Timer Module (GTM)

INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible.

When a new STATE appears the value of SYN_S*MLS2 is added to INC_CNT2. Therefore for FULL_SCALE 2*(SNU+1)*MLS2 pulses SUB_INC2 generated, when INC_CNT2 reaches the zero value. The generation of SUB_INC2 pulses has to be done as fast as possible.

26.16.8.5 Calculation of the Accurate Position Values

All appearing TRIGGER and STATE signals do have a time stamp and a position stamp assigned after the input filter procedure. For the calculation of the exact time stamp the filter values are considered in the calculations of equations DPLL-1a [Equations DPLL-1a to calculate TRIGGER time stamps](#) or DPLL-6a [Equations DPLL-6a to calculate STATE time stamps](#) respectively. A corresponding calculation is to be performed for the calculation of position values.

The PSTC and PSSC values can be corrected by the CPU, when needed.

After reset, while FTD=0 and no active TRIGGER slope is detected:

$$\text{PSTC} = 0 \quad (\text{DPLL-32a})$$

Calculate the new Position value for each valid TRIGGER event:

$$\text{PSTC} = \text{PSTC_OLD} + \text{NMB_T_TAR_old} \quad (\text{DPLL-32b})$$

when FTD=1 and SGE1=1

with

PSTC_OLD is the last PSTC value and

NMB_T_old is the number of pulses which are calculated and provided for sending out in the last increment.

After reset, while FTD=0 and no active STATE slope is detected:

$$\text{PSSC} = 0 \quad (\text{DPLL-33a})$$

Calculate the new Position value for each valid STATE event:

PSSC= PSSC_OLD + NMB_S_TAR_old (DPLL-33b)

when FTD=1 and SGE1=1 (SMC=0) or SGE2=1 (SMC=1)

respectively with

PSSC_OLD is the last PSSC value and

NMB_S_old is the number of pulses which are calculated and provided for sending out in the last increment.

26.16.8.6 Scheduling of the Calculation

After enabling the DPLL with each valid TRIGGER or STATE event respectively a cycle of operations is performed to calculate all the results shown in detail in the table below DPLL-2. A state machine controls this procedure and consists of two parts, the first is triggered by a valid slope of the signal TRIGGER, begins at step 1 and ends at step 20 (in normal mode and for SMC=1). The second state machine is controlled by a valid slope of the signal STATE, begins at step 21 and ends at step 40 (in emergency mode and also for SMC=RMO=1). Depending on the mode used all 20 steps are executed or already after 2 steps the jump into the initial state is performed, as shown in the state machine descriptions below. For each new extended cycle (without this jump) all prediction values for actions in the case SMC=0 are calculated once more (with maybe improved accuracy because of better parameters) and all pending decisions are made using these new values when transmitted to the decision device.

In **State description of the State Machine**, the steps of the state machine are described. Please note, that the elaboration of the steps depends on the configuration bits described in the comments. The steps 4 to 17 are only calculated in normal mode (in the state machine explanation below marked yellow in [Section 26.16.2](#)), but steps 24 to 37 are only calculated in emergency mode (in the state machine explanation below marked cyan in [Section 26.16.2](#)) when SMC=0.

State machine partitioning for normal and emergency mode.

Figure 26-76 State machine partitioning for normal and emergency mode

Synchronization description

TRIGGER:

The APT (address pointer for duration and reciprocal duration values of TRIGGER increments) is initially set to zero and increment with each valid TRIGGER event. Therefore data are stored in the RAM beginning from the first available value. The actual duration of the last increment is stored at DT_T_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUTE is one.

A missing TRIGGER is assumed, when at least after $TOV * DT_T_ACT$ no valid TRIGGER event appears.

The data of equations DPLL-1b1 and DPLL-1c2 [Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation](#) are written in the corresponding RAM regions and APT is increment accordingly up to $2 * TNU - 2 * SYN_NT + 1$.

The APT_2B (address pointer for the time stamp field of TRIGGER) is initially set to zero and increment with each valid TRIGGER event. When no gap is detected because of the incomplete synchronization process at the beginning, for all TRIGGER events the time stamp values are written in the RAM up to $2 * (TNU + 1)$ entries, although only $2 * (TNU + 1 - SYN_NT)$ events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Generic Timer Module (GTM)

Before the CPU sets the APT_2C address pointer in order to synchronize to the profile, it writes the corresponding increment value for the necessary extension of the RAM region 2B value APT_2B_EXT into the register APT_2B_sync and sets the status bit APT_2C_status. This value can be e.g. $2 \cdot \text{SYN_NT}$, when all gaps in FULL_SCALE already passed the input data stream of TRIGGER, or less than this value, when up to now e.g. only a single gap is to be considered in the data stream stored already in the RAM region 2B. The number of virtual increments to be considered depends on the number of inputs already got. After writing APT_2C by the CPU, with the next TRIGGER event the APT_2B address pointer is incremented (as usual) and then the additional offset value APT_2B_EXT is added to it once (while APT_2B_STATUS=1 and for forward direction). For that reason the APT_2B_STATUS bit is reset after it. The old APT_2B value before adding the offset is stored in the APT_2B_OLD register as information for the CPU where to start the extension procedure. In the following the CPU fills in the time stamp field around the APT_2B_OLD position taking into account the corresponding number of virtual entries stored in the APT_2B_EXT value and the corresponding NT values in the profile. The extension procedure ends when all gaps considered in the APT_2B_EXT value are treated once. In the consequence all storage locations of RAM region 2B up to now do have the corresponding entries. Future gaps are treated by the DPLL.

For a backward direction the APT_2C_ext value is subtracted accordingly.

When the CPU writes the APT_2C address pointer the SYT bit is set simultaneously. For SYT=1 in normal mode (SMC=0) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing TRIGGER or an additional TRIGGER between two synchronization gaps does reset the LOCK1 bit in normal mode. In that case the CPU must correct the SUB_INC pulse number and maybe correct the APT_2C pointer. For this purpose the LL1I interrupt can be used.

When SYT is set the calculations of equations DPLL-1 to DPLL-5 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.

This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-1a5 to 7 forwards [Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction](#) or backwards [Equations DPLL-1a5-7 for backward direction](#). The APT_2B pointer is for that reason incremented or decremented before this operation considering the virtual increments in addition.

Please note, that for the APT and APT_2C pointers the gap is considered as a single increment.

STATE:

The APS (address pointer for duration and reciprocal duration values of STATE) is initially set to zero and incremented with each valid STATE event. Therefore data are stored in the RAM field beginning at the first location. The ACT duration of the last

Generic Timer Module (GTM)

increment is stored at DT_S_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUSE is one.

A missing STATE is assumed, when at least after $TOV_S * DT_S_actual$ no valid STATE event appears.

The data of equations DPLL-6b1 and DPLL-6c2 **Equations DPLL-6b1 and DPLL-6c1 to update the RAM after calculation** is written in the corresponding RAM regions and APS is increment accordingly up to $2 * SNU - 2 * SYN_NS + 1$ (for $SYSF=0$).

The APS_1C2 (address pointer for the time stamp field of STATE) is initially set to zero and increment with each valid STATE event. When no gap is detected because of the incomplete synchronization process at the beginning, for all STATE events the time stamp values are written in the RAM up to $2 * (SNU + 1)$ entries, although (e.g. for $SYSF=0$) only $2 * (SNU + 1 - SYN_NS)$ events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below:

Before the CPU sets the APS_1C3 address pointer in order to synchronize to the profile, it writes the corresponding increment value APS_1C2_EXT for the necessary extension of the RAM region 1C2 into the register DPLL_APS_SYNC and sets the APS_1C2_STATUS bit there. This value can be e.g. $2 * SYN_NS$ (for $SYSF=0$) or SYN_NS (for $SYSF=1$), when all gaps in FULL_SCALE already passed the input data stream of STATE. Also less than this value can be considered, when up to now only a single gap is to be considered in the data stream stored already in the RAM region 1C2. The number of increments to be considered depends on the number of inputs already got. After writing APS_1C3 by the CPU, with the next valid STATE slope the APS_1C2 address pointer is increment (as usual) and then the additional offset value APS_1C2_EXT is added to it once (while APS_1C2_STATUS=1 and forward direction). For that reason the APS_1C2_STATUS bit is reset after it. The old APS_1C2 value is stored in the APS_1C2_OLD register as information for the CPU where to start the extension procedure. In the following the CPU extends the time stamp field beginning from the APS_1C2_OLD position taking into account the corresponding number of virtual entries according to the APS_1C2_EXT value and also the correspondent NS values in the profile. The extension procedure ends when all gaps considered in the APS_1C2_EXT value are treated once. In the consequence all storage locations of RAM region 1C2 up to now do have the corresponding entries. Future gaps are treated by the DPLL.

For a backward direction the APS_1C2_EXT value is subtracted accordingly.

When the CPU writes the APS_1C3 address pointer the SYS bit is set simultaneously. For $SYS=1$ in emergency mode ($SMC=0$ and $DMO=1$) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing STATE or an additional STATE between two synchronization gaps does reset the LOCK1 bit in emergency mode. In that

Generic Timer Module (GTM)

case the CPU must correct the SUB_INC1 pulse number and maybe correct the APS_1C3 pointer. For this purpose the LL11 interrupt can be used.

When SYS is set the calculations of equations DPLL-5 to DPLL-10 are performed accordingly and the values are stored in (and distributed to) the right RAM positions.

This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-6a5 to 7 forwards [Equations DPLL-6a5-7 to extend the time stamp values for STATE](#) or backwards [Equations DPLL-6a5-7 for backward direction](#). The APS_1C2 pointer is for that reason increment or decremented before this operation considering the virtual increments in addition.

Please note, that for the APS and APS_2C pointers the gap is considered as a single increment.

SMC=1:

For SMC=1 it is assumed, that the starting position is known by measuring the characteristic of the device. In this way the APT and APT_2C as well the APS and APS_1C3 values are set properly, maybe with an unknown repetition rate. When no gap is to be considered for TRIGGER or STATE signals the APT_2B and APS_1C2 address pointers are set equal to APT or APS respectively. It is assumed, that all missing TRIGGERS and missing STATES can be also considered from the beginning, when a valid profile with the corresponding adapt values is written in the RAM regions 1C3 and 2C respectively. In that case the TSF_T[i] and TSF_S[i] must be extended by the DPLL according to the profile. Thus the SYT and SYS bits could be set from the beginning and the LOCK1 and LOCK2 bits are set after recognition of the corresponding gaps accordingly. When no gap exists (SYN_NT=0 or SYN_NS=0), the LOCK bits are set immediately. The CPU can correct the APT_2C and APS_1C3 pointer according to the recognized repetition rate later once more without the loss of Lock1,2.

Operation in backward direction in normal and emergency mode (SMC=0)

When for SMC=0 in normal mode a backwards condition is detected for the TRIGGER input signal (e.g. when THMI is not violated), the LOCK1 bit and the FTD (as well as LOCK2 and FSD) in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1 (the same for NUSE in NUSC). The address pointers APT and APT_2C as described below (and after that decremented for each following valid slope of TRIGGER as long as the DIR1 bit shows the backward direction).

Please notice, that in the case of the change of the direction the ITN and ISN bit in the DPLL_STATUS register are reset.

For this transition to the backward direction no change of address pointer APT and APT_2B is necessary.

profile update for TRIGGER when changing direction

The profile address pointer APT_2C is changed step by step in order to update the profile information in SYN_T, SYN_T_old and PD_store

Generic Timer Module (GTM)

- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T
- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

Note: The update of SYN_T_OLD and the loading of PD_store can be performed in all steps above. The value APT_2B needs not to be corrected. for a direction change from backwards to forwards make the same corrections by incrementing APT_2C.

Make calculations does mean: the operation of the state machine starts in normal mode at step 1 with the calculations and results in an update of the SYN_T value including the automatic update of SYN_T_OLD at state 17 using the actual APT_2C address pointer value, see [Section 26.16.2](#).

The TBU_TB1 value is to be corrected by the number of pulses sent out in the wrong direction mode during the last and current increment. This correction is done by sending out SUB_INC1 pulses for decrementing TBU_TB1 (while DIR1=1).

The amount of pulses is determined by calculation of the difference between NMB_T and INC_CNT1. This difference is multiplied by 2 and added to INC_CNT1. In addition the pulses for the new increment SYN_T_OLD*(MLT+1) are sent. All pulses are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction.

Save inc_cnt1 value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.
2. Set inc_cnt1 to the target value of the last increment
nmb_t_tar_old
3. Add the number of trigger which were calculated for the current increment when this value was already added to inc_cnt1 before the direction change is detected
+ nmb_t
4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)
- inc_cnt1_save
5. Calculate the new target pulses to be sent considering the new values of SYN_T and PD_store and add them:
+ nmb_t_tar_new

This does mean the following equation:

$$\text{inc_cnt1} = \text{nmb_t_tar_old} + \text{nmb_t} - \text{inc_cnt1_save} + \text{nmb_t_tar_new}$$

Generic Timer Module (GTM)

All pulses summarized at `inc_cnt1` are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using `PCM1` of `DPLL_CTRL1` is possible during direction change.

When `PSTC` was incremented/decremented at the active slope and after that the direction change was detected at the same input event, correct `PSTC` once by

- `nmb_t_tar_old` when changed to backwards

+ `nmb_t_tar_old` when changed to forwards

in order to compensate the former operation. When the direction information is known before an intended change of `PSTC`, do not change them.

Store the new calculated value `nmb_t_tar_new` at `nmb_t_tar` for the correct calculation of `PSTC` at the next input event.

consequences for `STATE`

With the next valid `STATE` event the direction information is already given. The profile pointer `APS_1C3` is to be corrected by a two times decrement in order to point to the profile of the next following increment. In the following it is decremented with each `STATE` event while `DIR1=1`. The `SYN_S` and `PD_S_store` values must be updated accordingly, including `SYN_S_OLD` and `PD_S_store_old`.

Because the right direction is already known when an input event appears, make the following corrections:

- decrement `APS_1C3`, load `SYN_S` and `PD_S_store`, update `SYN_S_OLD` and `PD_S_store_old`
- decrement `APS_1C3`, make calculations, load `SYN_S` and `PD_S_store`, update `SYN_S_OLD` and `PD_S_store_old`, wait for a new `STATE` event

Note: The update of `SYN_S_OLD` and the loading of `PD_S_store` can be performed in all steps above. The value of `APS_1C2` needs not to be corrected.

When a new `STATE` event occurs, all address pointers are decremented accordingly as long as `DIR1=1`.

In emergency mode the pulses are corrected as follows:

Save `inc_cnt1` value at direction change to `inc_cnt1_save`.

Calculate the new `inc_cnt1` value as follows:

1. Stop sending pulses and save `inc_cnt1` at the moment of direction change as `inc_cnt1_save`.

2. Set `inc_cnt1` to the target value of the current increment

`nmb_s_tar`

Please notice, that in difference to the normal mode, `nmb_s_tar` is to be used instead of `nmb_s_tar_old`, because direction information in emergency mode is only given from the `TRIGGER` input and occurs independent of a `STATE` event.

Generic Timer Module (GTM)

That means: The calculations at the last STATE event were done for the correct former direction.

3. Do not add the calculated number of state pulses because no new STATE event occurred.

4. Subtract the value of still not sent target pulses (remaining value at `inc_cnt1_save`)
- `inc_cnt1_save`

5. Add the new calculated target pulses for the current increment

+ `nmb_s_tar_new`

when for the calculation all new conditions of `PD_S_store` and `SYN_S` are considered.

`inc_cnt1 = nmb_s_tar_old - inc_cnt1_save + nmb_s_tar_new`

All pulses summarized at `inc_cnt1` are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using `PCM1` of `DPLL_CTRL1` is possible during direction change.

Do not change `PSSC` and suppress incrementing/decrementing of `PSSC` at the event directly following to the direction change information.

Store the new calculated value `nmb_s_tar_new` at `nmb_s_tar` for the correct calculation of `PSTC` at the next input event.

repeated change to forward direction for `TRIGGER`

The `DIR1` bit remains set as long as the `THMI` value remains none violated for the following `TRIGGER` events and is reset when for an invalid `TRIGGER` slope the `THMI` is violated.

Resetting the `DIR1` to 0 results (after repeated reset of `LOCK1`, `NIT`, `NIS`) in the opposite correction of the profile address pointer considered.

This does mean four increment operations of the address pointer `APS_1C3` including the update of `SYN_S` and `PD_S_store` with the automatic update of `SYN_S_OLD` and `PD_S_store_old` four increment operations of the address pointer `APT_2C` including the update of `SYN_T` and `PD_store` with the automatic update of `SYN_S_OLD` and `PD_S_store_old`.

The correction of `TBU_TS1` is done by sending out the correction pulses with the highest possible frequency at `SUB_INC1` while `DIR1=0`. The number of pulses is calculated as shown above.

consequences for `STATE`

For `DIR1=0`: `DIR2` is reset to 0 after the next valid `STATE` event and after a last decrementing of `APS`, `APS_1C3` as well as `APS_1C2`. After that the address pointers are increment again with each following valid `STATE` event as long as `DIR1=0`.

Generic Timer Module (GTM)
Operation in backward direction for TRIGGER (SMC=1)

When for SMC=1 a backwards condition is detected for the TRIGGER input signal (TDIR=1, resulting in DIR1=1), the LOCK1 bit and the FTD in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1. The address pointers APT and APT_2C as well as APT_2B are incremented for a last time (and after that decremented for each following valid slope of TRIGGER as long as the DIR1 bit shows the backward direction).

Please notice, that in the case of the change of the direction the ITN bit in the DPLL_STATUS register is reset.

profile update for TRIGGER

Make the same update steps for the profile address pointer as shown in **Operation in backward direction in normal and emergency mode (SMC=0)**: Decrement APT_2C for 2 times with the update of the SYN_T and PD_store values at each step with an automatic update of SYN_T_OLD and PD_store_old.

- decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
- decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

In the normal case no correction of wrong pulses sent is necessary, because the direction change is detected by the pattern immediately.

Nevertheless a correction is necessary as shown below. In the other case: see treatment of pulses TBU_TS1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

Save inc_cntx value at direction change to inc_cnt1_save.

Calculate the new inc_cnt1 value as follows:

1. Clear inc_cnt1.
2. Set inc_cnt1 to the target value of the last increment

nmb_t_tar

Please notice, that in difference to the normal mode, nmb_t_tar is to be used instead of nmb_t_tar_old, because the direction information is known before the calculation takes place.

3. Do not add the calculated number of trigger pulses because it is not calculated yet before the direction change information is known.

4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)

- inc_cnt1_save

5. Add the new calculated target pulses for the current increment

+ nmb_t_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

Generic Timer Module (GTM)

$inc_cnt1 = nmb_t_tar_old - inc_cnt1_save + nmb_t_tar_new$

All pulses summarized at `inc_cnt1` are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Suppress changing of PSTC for the TRIGGER event when a direction change is detected.

Store the new calculated value `nmb_t_tar_new` at `nmb_t_tar` for the correct calculation of PSTC at the next input event.

repeated change to forward direction for TRIGGER

The DIR1 bit remains set as long as the TDIR bit is set for the following TRIGGER events and is reset when for a valid TRIGGER slope the TDIR is zero.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1 and ITN) in the opposite correction of the address pointer use.

This does mean two increment operations of the address pointer including the update of SYN_T and PD_store.

A complex correction of TBU_TS1 and INC_CNT1 is in the normal case not necessary, when all increments are equal (SYN_NT=0) and no adapt information is used. In this case only the MLS1 value is added to INC_CNT1 in order to backcount the value for the last increment. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at [Operation in backward direction in normal and emergency mode \(SMC=0\)](#).

Operation in backward direction for STATE (SMC=1)

When for SMC=1 a backwards condition is detected for the STATE input signal (SDIR=1, resulting in DIR2=1), the LOCK2 bit and the FSD in the DPLL_STATUS register is reset, the NUSE value in NUSC register is set to 1 and the address pointers APS and APS_1C3_f and APS_1C2 are increment for a last time (and after that decremented for each following valid slope of STATE as long as the DIR2 bit shows the backward direction.

Please notice, that in the case of the change of the direction the ISN bit in the DPLL_STATUS register is reset.

For this transition to the backward direction no change of address pointer APS and APC_1C2 is necessary.

profile update for STATE

Make the same update steps for the profile address pointer as shown in [Operation in backward direction in normal and emergency mode \(SMC=0\)](#): Decrement APS_1C3 for 2 times with the update of the SYN_S, SYN_S_OLD and PD_S_store and PD_S_store_old values at each step:

Generic Timer Module (GTM)

A correction of TBU_TS2 and INC_CNT2 is in the normal case not necessary, because no pulses are sent out with the wrong direction information. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

- decrement APT_1C3, load SYN_S, PD_S_store, update SYN_S_OLD
- decrement APT_1C3, make calculations, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new STATE event.

A complex correction of TBU_TS2 and INC_CNT2 is in the normal case not necessary, when all increments are equal (SYN_NS=0) and no adapt information is used. In this case only the MLS2 value is added to INC_CNT2 in order to backcount the value for the last increment. In the other case: see treatment of pulses TBU_TS1 and ICN_CNT1 in normal mode at **Operation in backward direction in normal and emergency mode (SMC=0)**.

For the second PMSM the pulses are corrected as follows:

Save inc_cnt2 value at direction change to inc_cnt2_save.

Calculate the new inc_cnt2 value as follows:

1. Clear inc_cnt2.
2. Set inc_cnt2 to the target value of the last increment
nmb_s_tar

Please notice, that in difference to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because no new calculation is performed so far.

3. Do not add the calculated number of state pulses because it is not calculated yet before the direction change information is known.
4. Subtract the value of still not sent pulses (remaining value at inc_cnt2_save)
- inc_cnt2_save
5. Add the new calculated target pulses for the current increment
+ nmb_s_tar_new

when for the calculation all new conditions of PD_S_store and SYN_S are considered.

$inc_cnt2 = nmb_s_tar_old - inc_cnt2_save + nmb_s_tar_new$

All pulses summarized at inc_cnt2 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Please notice that no pulse correction using PCM2 of DPLL_CTRL1 is possible during direction change.

Do not change PSSC for a STATE event when a direction change is detected.

Store the new calculated value nmb_s_tar_new at nmb_s_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for STATE

Generic Timer Module (GTM)

The DIR2 bit remains set as long as the SDIR bit is set for the following STATE events and is reset when for a valid STATE slope SDIR is zero.

Resetting the DIR2 to 0 results (after repeated reset of LOCK2 and FSD) in the opposite correction of the address pointer use.

After a last decrementing of all address pointers the APS_1C3 is increment 2 times with a repeated update of SYN_S, SYN_S_OLD and PD_S_store after each increment.

DPLL reaction in the case of non plausible input signals

When the DPLL is synchronized concerning the TRIGGER signal by setting the FTD, SYT and LOCK1 bits in the DPLL_STATUS register, the number of valid TRIGGER events between the gaps is to be checked continuously.

When additional events appear while a gap is expected, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set.

When an unexpected gap appears (missing TRIGGERS), the NUTE value in the NUTC register is set to 1, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set. The address pointers are increment with the next valid TRIGGER slope accordingly.

When the TRIGGER locking range TLR is violated 8),

the state machine 1 will remain in state 1 and the address pointer APT, APT_2B and APT_2C will remain unchanged until the CPU sets the APT_2C accordingly. In this case also the NUTE value in the NUTC register is set to 1. The DPLL stops the generation of the SUB_INC1 pulses and will perform no other actions - remaining in step1 of the first state machine (see [Section 26.16.2](#)).

8) The TOR Bit in the DPLL_STATUS register is set, when the time to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see [Section 26.16.11.75](#)). In this case also the TORI interrupt is generated, when enabled.

When in the following the direction DIR1 changes as described in the sections above the ITN bit in the DPLL_STATUS register is reset, the use of the address pointers APT_2C is switched and the pulse correction takes place as described above.

In all other cases the CPU can interact to leave the instable state. This can be done by setting the APT_2C address pointer which results in a reset of the ITN bit. In the following NUTE can also be set to higher values.

When the DPLL is synchronized concerning the STATE signal by setting the FSD, SYS and LOCK1 (for SMC=0) or LOCK2 (for SMC=1) bits in the DPLL_STATUS register, the number of valid STATE events between the gaps is to be checked continuously.

When additional events appear while a gap is expected or while an unexpected missing STATE event appears, the LOCK1,2 bit is reset and the ISN bit in the DPLL_STATUS register is set.

Generic Timer Module (GTM)

When an unexpected gap appears for $RMO=SMC=1$ (missing STATEs for synchronous motor control), the NUSE value in the NUSC register is set to 1, the LOCK2 bit is reset and the ISN bit in the DPLL_STATUS register is set. The address pointers are incremented with the next valid STATE slope accordingly.

When the STATE locking range SLR is violated 7),

the state machine 2 will remain in state 21 and the address pointer APS, APS_1C2 and APS_1C3 will remain unchanged until the CPU sets the APS_1C3 accordingly. In this case also the NUSE value in the NUSC register is set to 1. The DPLL stops the generation of the SUB_INC1,2 pulses respectively and will perform no other actions - remaining in step21 of the second state machine (see [Section 26.16.2](#)).

7) The SOR Bit in the DPLL_STATUS register is set, when the time to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register (see [Section 26.16.11.76](#)).

In this case also the SORI interrupt is generated, when enabled.

When in the following the direction DIR2 changes as described in the sections above the ISN bit in the DPLL_STATUS register is reset, the use of the address pointers APS_1C3 is switched and the pulse correction takes place as described above. In all other cases the CPU must interact to leave the instable state. This can be done by setting the APS_1C3 address pointers which results in a reset of the ISN bit. In the following NUSE can also be set to higher values.

State description of the State Machine.

Table 26-48 State description of the State Machine

Step	Description	Comments
always for DEN=1	for each inactive TRIGGER slope: generate the TISI interrupt; calculate the time stamp difference ΔT to the last valid event, store this value at THVAL; when THMI >0 is violated ($\Delta T < THMI$): generate TINI interrupt, set DIR1=0 (forwards) set BWD1=0 (see DPLL_STATUS register) else (only for THMI >0): set DIR1= 1 (backwards); set BWD1=1 (see DPLL_STATUS register) after changing the direction correct the pulses WP sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency: WP=NMB_T-DPLL_INC_CNT1; correct INC_CNT1 by addition of 2*WP before sending the correction pulses; check THMA, when THMA is violated, generate the TAXI interrupt; go to step 1 for each inactive STATE slope: set DIR2=DIR1	for SMC=0; set DIR1 always after inc./decr. the address pointers APT, APT_x; go to step 1; stop output of SUB_INC1 and correct pulses after changing DIR1 after incr./decr. of APS_x set DIR2 always after incr./decr. the address pointers APS, APS_x; go to step 1

Generic Timer Module (GTM)

23	<p>send CDSI interrupt; calculate EDT_S and MEDT_S according to equations DPLL-8 and DPLL-9 for RMO=0: go back to step 21 for RMO=0 and update SYN_S and PD_S_store using the current ADT_S[i] values in that case;</p>	<p>Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.</p>
24	<p>calculate CDT_SX according to equation DPLL-10a and b;</p>	<p>only for RMO=1</p>

Generic Timer Module (GTM)
Table 26-48 State description of the State Machine (cont'd)

Step	Description	Comments
25	calculate missing pulses: - for TBU_CH1: $MP1 = INC_CNT1(\text{valid STATE slope})$ - for TBU_CH2: $MP2 = INC_CNT2(\text{valid STATE slope})$ calculate target number of pulses: $NMB_S_TAR = MLS1 * SYN_S + PD_S_store + MPVAL1$ (for SMC=0) $NMB_S_TAR = MLS2 * SYN_S + PD_S_store + MPVAL2$ (for SMC=1) (instead of PD_S_store use zero in the case AMS=0)	only for RMO=1 for SMC=0 instead of MPVAL1=0 use zero for PCM1=0 for SMC=1 instead of MPVAL2=0 use zero for PCM2=0; add MPVAL1/2 once to INC_CNT1/2 and reset PCM1/2 after that
26	sent MPx with highest possible frequency and set $NMB_S = NMB_S_TAR$	only for RMO=1, DMO=0 and COA=0
27	calculate number of pulses to be sent according to DPLL-22 or $NMB_S = NMB_S_TAR + MPx$	only for RMO=1, DMO=0 and COA=1
28	$NMB_S = SYN_S * CNT_NUM1$ (SMC=0) $NMB_S = SYN_S * CNT_NUM2$ (SMC=1)	only for RMO=1, DMO=1
29	update SYN_S and PD_S_store;	Note: There are different behaviours of Reference Model and hardware: For the hardware the values of SYN_T and PD_store are not updated until a new valid TRIGGER slope occurs.

Generic Timer Module (GTM)
Table 26-48 State description of the State Machine (cont'd)

Step	Description	Comments
30	calculate ADD_IN_CAL2 according to equation DPLL-26 and DPLL-26b or DPLL-31 respectively and store this value in RAM use ADD_IN_CAL2 as ADD_IN value for the case DLM=0 use ADD_IN_LD2 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 30); for RMO=1, DMO=DLM=0 and EN_C1u=0 (EN_C1u=0): reset the FlipFlops in the SUB_INC1 or SUB_INC2 generator respectively; start sending SUB_INC1 / SUB_INC2;	only for RMO=1 for DLM=0 for DLM=1
31	calculate $TS_S_CHECK = TS_S + DT_S_ACT * (TOV_S);$	only for RMO=1;
32	automatic setting of actions masking bits in the DPLL_STATUS register: CAIP1 and CAIP2 for SMC=0 only CAIP2 for SMC=1	for RMO=1
33	for all actions with ACT_N[i]=0 calculate: $NA[i] = (PSA[i] - PSSC)/MLS1$ for forward direction with w = integer part and b = remainder of the division (fractional part) for backward direction use $NA[i] = (PSSC - PSA[i])/(MLS1)$ and consider in both cases the time base overflow in order to get a positive difference use MLS2 as divider in the case of SMC=1	for SMC=0: 24 actions, for SMC=1: 12 actions; depending on ACT_Ni in DPLL_ACT_STA register
34	calculate PDT_S[i] and DTA[i] for up to 24 action values according to equations DPLL-13 and DPLL-14;	only for RMO=1; for SMC=0 actions 0...23 for SMC=1 actions 1223
35	calculate TSAC[i] according to equation DPLL-18 and PSAC[i] according to equation DPLL-20	for the relevant actions (see above) and RMO=1

Generic Timer Module (GTM)

Table 26-48 State description of the State Machine (cont'd)

Step	Description	Comments
36	automatic reset of the actions masking bit CAIP in the DPLL_STATUS register: CAIP1=CAIP2=0 for SMC=0 and only CAIP2=0 for SMC=1 set the corresponding ACT_Ni bits in the DPLL_ACT_STA register	for the relevant actions (see above) and RMO=1 Set ACT_Ni and reset ACT_WRi for all enabled actions
37	check the duration of the last increment to its predecessor according to the profile and taking into account TOV_S: set the ISN status bit and reset the corresponding LOCK bit, when not plausible; go to step 38, when no valid STATE appears for all following steps 38 to 40: go immediately back to step 21, when a valid STATE event occurs, interrupt all calculations there and reset all CAIPx in that case; when going back to step 21: store TS_S in RAM 1C2 according to APS_1C2; update RAM 1C1 and RAM 1C4	for all conditions
38	wait for a new PMTR value; set the corresponding CAIPx values and go to step 39 in that case	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs
39	make the requested action calculation according to new PMTR values	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs
40	reset CAIP and go back to step 38	go immediately to step 21 and update the RAM according to step 37 when a valid STATE event occurs

26.16.9 DPLL Interrupt signals

The DPLL provides 27 interrupt lines. These interrupts are shown below.

26.16.9.1 DPLL Interrupt signals

interrupt signals of table

Table 26-49 DPLL Interrupt signals

Signal	Description
DPLL_SORI_IRQ	STATE is out of range
DPLL_TORI_IRQ	TRIGGER is out of range
DPLL_CDSI_IRQ	STATE duration calculated for last increment
DPLL_CDTI_IRQ	TRIGGER duration calculated for last increment
DPLL_TE4_IRQ	TRIGGER event interrupt 4 request ¹⁾
DPLL_TE3_IRQ	TRIGGER event interrupt 3 request ¹⁾
DPLL_TE2_IRQ	TRIGGER event interrupt 2 request ¹⁾
DPLL_TE1_IRQ	TRIGGER event interrupt 1 request ¹⁾
DPLL_TE0_IRQ	TRIGGER event interrupt 0 request ¹⁾
DPLL_LL2_IRQ	Lost of lock interrupt for SUB_INC2 request
DPLL_GL2_IRQ	Get of lock interrupt for SUB_INC2 request
DPLL_E_IRQ	Error interrupt request
DPLL_LL1_IRQ	Lost of lock interrupt for SUB_INC1 request
DPLL_GL1_IRQ	Get of lock interrupt for SUB_INC1 request
DPLL_W1_IRQ	Write access to RAM region 1B or 1C interrupt request
DPLL_W2_IRQ	Write access to RAM region 2 interrupt request
DPLL_PW_IRQ	Plausibility window violation interrupt of TRIGGER request
DPLL_TAS_IRQ	TRIGGER active slope while NTI_CNT is zero interrupt request
DPLL_SAS_IRQ	STATE active slope interrupt request
DPLL_MT_IRQ	Missing TRIGGER interrupt request
DPLL_MS_IRQ	Missing STATE interrupt request
DPLL_TIS_IRQ	TRIGGER inactive slope interrupt request
DPLL_SIS_IRQ	STATE inactive slope interrupt request
DPLL_TAX_IRQ	TRIGGER maximum hold time violation interrupt request
DPLL_TIN_IRQ	TRIGGER minimum hold time violation interrupt request

Generic Timer Module (GTM)

Table 26-49 DPLL Interrupt signals (cont'd)

Signal	Description
DPLL_PE_IRQ	DPLL enable interrupt request
DPLL_PD_IRQ	DPLL disable interrupt request

1) see TINT value in the corresponding ADT_T[i] section of RAM region 2

Note: TEi_IRQ depends on the TINT value in ADT_T[i]¹⁾ and is only active when SYT²⁾

1) see RAM region 2 explanations

2) see DPLL STATUS register

26.16.10 DPLL Register overview
Table 26-50 DPLL register overview

Address offset	Name	Description	Init value	Page
0x0000	DPLL_CTRL_0	DPLL Control Register 0	0x003B_BA57	26-501
0x0004	DPLL_CTRL_1	DPLL Control Register 1	0xB000_0000	26-505
0x0008	DPLL_CTRL_2	DPLL Control Register 2 (actions 0-7 enable)	0x0000_0000	26-513
0x000C	DPLL_CTRL_3	DPLL Control Register 3 (actions 8-15 enable)	0x0000_0000	26-515
0x0010	DPLL_CTRL_4	DPLL Control Register 4 (actions 16-23 enable)	0x0000_0000	26-517
0x0018	DPLL_ACT_STA	DPLL ACTION Status Register with connected shadow register	0x0000_0000	26-519
0x001C	DPLL_OSW	DPLL Offset and switch old/new address register	0x0000_0200	26-521
0x0020	DPLL_AOSV_2	DPLL Address offset register for APT in RAM region 2	0x1810_0800	26-523
0x0024	DPLL_APT	DPLL Actual RAM pointer to RAM regions 2A, b and d	0x0000_0000	26-524
0x0028	DPLL_APS	DPLL Actual RAM pointer to RAM regions 1C1, 1C2 and 1C4	0x0000_0000	26-527
0x002C	DPLL_APT_2C	DPLL Actual RAM pointer to RAM region 2C	0x0000_0000	26-530
0x0030	DPLL_APS_1C3	DPLL Actual RAM pointer to RAM region 1C3	0x0000_0000	26-532
0x0034	DPLL_NUTC	DPLL Number of recent TRIGGER events used for calculations (mod 2*(TNU +1-SYN_NT))	0x0001_2001	26-533

Generic Timer Module (GTM)
Table 26-50 DPLL register overview (cont'd)

Address offset	Name	Description	Init value	Page
0x0038	DPLL_NUSC	Number of recent STATE events used for calculations (e.g. $\text{mod } 2 * (\text{SNU} + 1 - \text{SYN_NS})$ for $\text{SYSF}=0$)	0x0001_2081	26-536
0x003C	DPLL_NTI_CNT	DPLL Number of active TRIGGER events to interrupt	0x0000_0000	26-539
0x0040	DPLL_IRQ_NOTIFY	DPLL Interrupt notification register	0x0000_0000	26-540
0x0044	DPLL_IRQ_EN	DPLL Interrupt enable register	0x0000_0000	26-543
0x0048	DPLL_IRQ_FORCE_CINT	DPLL Interrupt force register	0x0000_0000	26-547
0x004C	DPLL_IRQ_MODE	DPLL Interrupt mode register	0x0000_0000	26-549
0x0050	DPLL_EIRQ_EN	DPLL Error Interrupt enable register	0x0000_0000	
0x00B0	INC_CNT1	DPLL Counter for pulses for TBU_TS1 to be sent in automatic end mode	0x0000_0000	26-554
0x00B4	INC_CNT2	DPLL Counter for pulses for TBU_TS2 to be sent in automatic end mode when $\text{SMC}=\text{RMO}=1$	0x0000_0000	26-555
0x00B8	DPLL_APT_SYNC	DPLL old RAM pointer and offset value for TRIGGER	0x0000_0000	26-556
0x00BC	DPLL_APS_SYNC	DPLL old RAM pointer and offset value for STATE	0x0000_0000	26-559
0x00C0	TBU_TS0_T	DPLL TBU_TS0 value at last TRIGGER event	0x0000_0000	26-562
0x00C4	TBU_TS0_S	DPLL TBU_TS0 value at last STATE event	0x0000_0000	26-562
0x00C8	ADD_IN_LD1	DPLL direct load input value for SUB_INC1	0x0000_0000	26-564

Table 26-50 DPLL register overview (cont'd)

Address offset	Name	Description	Init value	Page
0x00CC	ADD_IN_LD2	DPLL direct load input value for SUB_INC2	0x0000_0000	26-565
0x00FC	DPLL_STATUS	Status register	0x0000_0000	
0x0100 + x * 0x04	DPLL_ID_PMTR_x	DPLL 9-bit ID Information For Input Signal PMT_x[8:0] Register (x:023)	0x0000_01FE	26-573
0x01E0	DPLL_CTRL_0_SHADOW_TRIGGER	shadow register of DPLL_CTRL_0	0x0000_0000	26-574
0x01E4	DPLL_CTRL_0_SHADOW_STATE	shadow register of DPLL_CTRL_0	0x0000_0000	26-576
0x01E8	DPLL_CTRL_1_SHADOW_TRIGGER	shadow register of DPLL_CTRL_1	0x0000_0000	26-577
0x01EC	DPLL_CTRL_1_SHADOW_STATE	shadow register of DPLL_CTRL_1	0x0000_0000	26-578
0x01FC	DPLL_RAM_INI	initialization control and status for RAMs	0x0000_0000	26-580

RAM Region 1 map description.

Table 26-51 RAM Region 1 map description

Name	Description	Address offset in relation to DPLL start address	Page
RAM Region 1A 288 bytes for 96 words of 24 Bits; this RAM is only accessible for DEN = 0		0x0200-0x037C	
PSA[i]	ACTION_i Position/Value action request register (i:023)	0x0200 + i * 0x04	26-581
DLA[i]	ACTION_i time to react before PSAi register (i:023)	0x0280 + i * 0x04	26-581

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
NA[i]	Calculated number of TRIGGER/STATE increments to ACTION_i (i:023)	0x0300 + i * 0x04	26-582
DTA[i]	Calculated Relative Time To ACTION_i Register (i:023)	0x0380 + i * 0x04	26-584
RAM Region 1B		0x0400-0x05FC	
Note: the following registers for variables are located in RAM Region 1B, read access by AEI via bus interface possible, writing results in an interrupt; data width of 3 Bytes used for 24 bit values		288 bytes for 96 words of 24 Bits	
TRIGGER signal information stored			
TS_T	Actual signal TRIGGER time stamp register	0x0400/ 0x0404	26-584
TS_T_OLD	Previous signal TRIGGER time stamp register	0x0404/ 0x0400	26-586
Note: the switch of the LSB address bits is performed using the SWON register at 0x0020		0x0400 ... 0x0404	
FTV_T	Actual signal TRIGGER filter value register	0x0408	26-587
do not use		0x040C	
Note: the switch of the LSB address bits is performed using the SWON register at 0x0020		0x0400 ... 0x040C	
STATE signal information stored			
TS_S	Actual signal TRIGGER time stamp register	0x0410/ 0x0414	26-588
TS_S_OLD	Previous signal STATE time stamp register	0x0414/ 0x0410	26-589

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
	Note: The switch of the LSB address bits is performed using the SWON register at 0x0020.	0x0410 ... 0x0414	
FTV_S	Actual signal STATE filter value register do not use	0x0418 0x041C	26-590
THMI	TRIGGER hold time min value	0x0420	26-591
THMA	TRIGGER hold time max value	0x0424	26-592
THVAL	measured last pulse time from valid to invalid TRIGGER slope do not use	0x0428 0x042C	26-592
TOV	Time out value of TRIGGER, according to the last nominal increment for a missing TRIGGER	0x0430	26-594
TOV_S	Time out value of STATE, according to the last nominal increment for a missing STATE	0x0434	26-595
ADD_IN_C AL1	calculated ADD_IN value for SUB_INC1 generation	0x0438	26-596
ADD_IN_C AL2	calculated ADD_IN value for SUB_INC2 generation	0x043C	26-596
MPVAL1	missing pulses to be added/subtracted directly to SUB_INC1 and INC_CNT1 once	0x0440	26-598
MPVAL2	missing pulses to be added/subtracted directly to SUB_INC2 and INC_CNT2 once	0x0444	26-599
NMB_T_TA R	target number of TRIGGER pulses	0x0448	26-599
NMB_T_TA R_OLD	target number of TRIGGER pulses	0x044C	26-599
NMB_S_TA R	target number of STATE pulses	0x0450	26-599
NMB_S_TA R_OLD	target number of STATE pulses	0x0454	26-599

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
	do not use	0x0458 0x045C	
RCDT_TX	reciprocal value of expected increment duration (T)	0x0460	26-604
RCDT_SX	reciprocal value of expected increment duration (S)	0x0464	26-604
RCDT_TX_NOM	reciprocal value of the expected nominal increment duration (T)	0x0468	26-606
RCDT_SX_NOM	reciprocal value of the expected nominal increment duration (S)	0x046C	26-606
RDT_T_ACT	actual reciprocal value of TRIGGER	0x0470	26-608
RDT_S_ACT	actual reciprocal value of STATE	0x0474	26-608
DT_T_ACT	Duration of last TRIGGER increment	0x0478	26-610
DT_S_ACT	Duration of last STATE increment	0x047C	26-610
	Calculated immediate values (eq. DPLL-1 to DPLL-10)		
EDT_T	Absolute error of prediction for last TRIGGER increment	0x0480	26-612
MEDT_T	Average absolute error of prediction up to the last TRIGGER increment	0x0484	26-612
EDT_S	absolute error of prediction for last STATE increment	0x0488	26-614
MEDT_S	Average absolute error of prediction up to the last STATE increment	0x048C	26-614
CDT_TX	Expected duration of current TRIGGER increment	0x0490	26-616
CDT_SX	Expected duration of current STATE increment	0x0494	26-616
CDT_TX_NOM	Expected nominal duration of current TRIGGER increment (without consideration of missing events)	0x0498	26-617
CDT_SX_NOM	Expected nominal duration of current STATE increment (without consideration of missing events)	0x049C	26-617

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
TLR	TRIGGER locking range value; the TOR bit in the DPLL_STATUS register is set when violated	0x04A0	26-618
SLR	STATE locking range value; the SOR bit in the DPLL_STATUS register is set when violated	0x04A4	26-618
	Relations of the sum of prediction increments to the reference increment in the past (see equations DPLL-11 or DPLL-13 for calculation)		
PDT_Ti	predicted time to Action_i (i:023)	0x0500 + i * 0x04	26-620
MLS1	Calculated number of sub-pulses between two STATE events (to be set by CPU)	0x05C0	26-621
MLS2	Calculated number of sub-pulses between two STATE events (to be set by CPU) for the use when SMC=RMO=1	0x05C4	26-622
CNT_NUM 1	Number of sub-pulses of SUB_INC1 in continuous mode, updated by the host only	0x05C8	26-623
CNT_NUM 2	Number of sub-pulses of SUB_INC2 in continuous mode, updated by the host only	0x05CC	26-623
PVT	Plausibility value of next active TRIGGER slope	0x05D0	26-624
	do not use	0x05D4 0x05DC	
PSTC	Accurate calculated position stamp of last TRIGGER input	0x05E0	26-625
PSSC	Accurate calculated position stamp of last STATE input	0x05E4	26-626
PSTM	Measured position stamp of last TRIGGER input	0x05E8/ 0x05EC	26-627
PSTM_OLD	Measured position stamp of last but one TRIGGER input	0x05EC/ 0x05E8	26-628

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
PSSM	Measured position stamp of last STATE input	0x05F0/ 0x05F4	26-629
PSSM_OL D	Measured position stamp of last but one STATE input	0x05F4/ 0x05F0	26-630
NMB_T	Number of pulses of current increment in normal mode for SUB_INC1(see equation DPLL-21 or for SMC=1 equation DPLL-27 respectively)	0x05F8	26-631
NMB_S	Number of pulses of current increment in emergency mod for SUB_INC1 (see equation DPLL-22) or in the case SMC=1 for SUB_INC2 (see equation DPLL-28)	0x05FC	26-631
RAM Region 1C		0x0600 – 0x09FC	
<p>Note: the following registers for the signal STATE are located in RAM Region 1C, read access by AEI via bus interface possible, writing results in an interrupt; data width of 3 Bytes used for 24 bit values</p>		0,75 Kbytes for 256 words of 24 Bits	
1C1	Reciprocal values of the corresponding successive increments RDT_S[i] (see equations DPLL-6a,b); the values are calculated using the recent NUSE increments (see NUSC register at address 0x0038)		
RDT_Sx	RDT_Sx (x:063)	0x0600 + x* 0x04	26-632
1C2	Time stamp field for STATE events		
TSF_Sx	TSF_Sx (x:063)	0x0700 + x* 0x04	26-633
1C3	Adapt values for the current STATE increment; time stamp values bits 24-27 in addition to the corresponding 24 bit value of TSF_Sx above, stored in bits 23:20 of ADT_S[i];		

Generic Timer Module (GTM)
Table 26-51 RAM Region 1 map description (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
ADT_Sx	ADT_Sx (x:063)	0x0800 + x* 0x04	26-633
1C4	Uncorrected last increment value of STATE (DT_S) for FULL_SCALE; measuring data of increments without corrections used for the CPU to generate ADT_S values		
DT_Sx	DT_Sx (x:063)	0x0900 + x* 0x04	26-634

Table 26-52 Register Region EXT map description

Address offset in relation to DPLL start address	Name	Description	Init value
0x0E00 - 0x0F1C	Register Region EXT	extension of register region in order to allow up to 24 action calculations	
0x0E00 + x * 0x04	DPLL_TSACx	calculated action time stamps for actions (x:023)	0x007F_FFFF
0x0E80 + x * 0x04	DPLL_PSACx	calculated action position stamps for actions (x:023)	0x007F_FFFF
0x0F00	DPLL_ACB_0	control bits for actions 03	0x0000_0000
0x0F04	DPLL_ACB_1	control bits for actions 47	0x0000_0000
0x0F08	DPLL_ACB_2	control bits for actions 811	0x0000_0000

Generic Timer Module (GTM)

Table 26-52 Register Region EXT map description (cont'd)

Address offset in relation to DPLL start address	Name	Description	Init value
0x0F10	DPLL_ACB_4	control bits for actions 1619	0x0000_0000
0x0F14	DPLL_ACB_5	control bits for actions 2023	0x0000_0000

Generic Timer Module (GTM)

RAM Region 2 map description.

Table 26-53 RAM Region 2 Map

Name	Description	Address offset in relation to DPLL start address	Page
RAM Region 2		0x4000-0x4FFC	
	NOTE: the following registers for the signal TRIGGER are located in RAM region 2, read access by AEI via bus interface possible, write access results in an interrupt, when enabled; data width of 3 bytes used for 24 bit values The RAM field part contains 256 values	size 3 Kbytes for word sizes of 24 Bits	
Region 2A	Reciprocal values of the corresponding successive increments RDT_T[i] (see equations DPLL-2a,b); address offsets are given by the AOSV_2A	AOSV_2A values are addresses after shift left by 8	
RDT_Tx	RDT_Tx (x:0255)	AOSV_2A + x*0x04	26-639
Region 2B	Time stamp field for all TRIGGER events in FULL_SCALE; 24 bit time stamp values		
TSF_Tx	TSF_Tx (x:0255)	AOSV_2B + x*0x04	26-639
Region 2C	ADT_T values to correct the measured TRIGGER signal values; time stamp values bits 24-27 in addition to the 24 bit value of TSF_Tx, stored in the bits 23:20 of ADT_T[i]		
ADT_Tx	ADT_Tx (x:0255)	AOSV_2C + x*0x04	26-641

Generic Timer Module (GTM)

Table 26-53 RAM Region 2 Map (cont'd)

Name	Description	Address offset in relation to DPLL start address	Page
Region 2D	Uncorrected last increment values of TRIGGER (DT_T); measuring raw data of increments		
DT_Tx	DT_Tx (x:0255)	AOSV_2 D + x* 0x04	26-642

26.16.11 DPLL Register and Memory description

All of the following registers are 32-bit only accessible.

Description of registers beginning from register DPLL_CTRL_0.

Description of RAM regions beginning from RAM 1A (see below):

Bits 31 down to 24 in each RAM region are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Reserved address regions are not protected against writing.

Description of memory region RAM 1A beginning from memory PSAi

The RAM region 1A is writable only for DEN=0 (see DPLL_CTRL_1 register).

Description of memory region RAM 1B beginning from memory TS_T.

Description of memory region RAM 1C beginning from memory RDT_S.

Description of memory region RAM 2 beginning from memory RDT_T.

26.16.11.1 Register DPLL_CTRL_0

Control register 0.

GTM_DPLL_CTRL_0

DPLL Control Register 0

(28000_H)

Reset Value: 003BBA57_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	SNU				IFP					MLT						
	rw				rw					rw						

Generic Timer Module (GTM)

Field	Bits	Type	Description
MLT¹⁾	[9:0]	rw	<p>Multiplier for TRIGGER</p> <p>MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (1...1024); For emergency mode the number of SUB_INC1 pulses between two STATE events is calculated by the CPU using the formula $MLS1=(MLT+1) * (TNU+1) / (SNU+1)$ in order to get the same number of SUB_INC1 pulses for FULL_SCALE. This value is stored in RAM at 0x05C0. Change of MLT by the CPU must result in the corresponding change of MLS1 by the CPU for SMC=0. Note: The number of MLT events is the binary value plus 1. The value MLT+1 is replaced by MLS1 in the case of SMC=1 (see DPLL_CTRL_1 register) for all relevant calculations.</p>
IFP¹⁾²⁾³⁾	10	rw	<p>Input filter position</p> <p>Value contains position or time related information.</p> <p>0_B TRIGGER_FT and STATE_FT mean time related values, that means the number of time stamp clocks</p> <p>1_B TRIGGER_FT and STATE_FT mean position related values, that means the number of SUB_INC1 (or SUB_INC2 in the case SMC=1) pulses respectively</p>
SNU⁴⁾	[15:11]	rw	<p>STATE number</p> <p>SNU+1 is number of STATE events in HALF_SCALE (1...32). Note: The number of nominal STATE events is the binary value plus 1. Set by DEN=0 only. This value can only be written when the DPLL is disabled.</p>
TNU⁴⁾	[24:16]	rw	<p>TRIGGER number</p> <p>TNU+1 is number of TRIGGER events in HALF_SCALE (1...512). Note: The number of nominal TRIGGER events is the binary value plus 1. Set by DEN=0 only. This value can only be written when the DPLL is disabled.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
AMS²⁾	25	rw	Adapt mode STATE Use of adaptation information of STATE. 0 _B No adaptation information is used for STATE 1 _B Immediate adapting mode; the values ADT_S[i] are considered to calculate SUB_INC1 pulses in emergency mode (SMC=0) or SUB_INC2 pulses for SMC=1
AMT¹⁾	26	rw	Adapt mode TRIGGER Use of adaptation information of TRIGGER. 0 _B No adaptation information for TRIGGER is used 1 _B Immediate adapting mode; the values ADT_T[i] are considered to calculate the SUB_INC1 pulses in normal mode and for SMC=1
IDS²⁾	27	rw	Input delay STATE Use of input delay information transmitted in FT part of the STATE signal. 0 _B Delay information is not used 1 _B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
IDT¹⁾	28	rw	Input delay TRIGGER use of input delay information transmitted in FT part of the TRIGGER signal. 0 _B Delay information is not used 1 _B Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
SEN	29	rw	STATE enable 0 _B STATE signal is not enabled (no signal considered) 1 _B STATE signal is enabled
TEN	30	rw	TRIGGER enable 0 _B TRIGGER signal is not enabled (no signal considered) 1 _B TRIGGER signal is enabled

Generic Timer Module (GTM)

Field	Bits	Type	Description
RMO ¹⁾²⁾	31	rw	<p>Reference mode</p> <p>Selection of the relevant the input signal for generation of SUB_INC1.</p> <p>0_B Normal mode; the signal TRIGGER is used to generate the SUB_INC1 signals</p> <p>1_B Emergency mode for SMC=0; signal STATE is used to generate the SUB_INC1 signals; Double synchronous mode for SMC=1: signal TRIGGER is used to generate the SUB_INC1 signals and STATE is used to generate the SUB_INC2 signals</p> <p>Note: for SMC=0: TRIGGER and STATE are prepared to calculate SUB_INC1. The RMO bit gives a decision only, which of them is used.</p> <p>For changing from normal mode to emergency mode at the following TRIGGER slope (according to the RMO value in the shadow register)1) the PSSC value is calculated by $PSSC = PSSM + \text{correction_value}$ (forward direction) or $PSSC = PSSM - \text{correction_value}$ (backward direction) with the $\text{correction_value} = \text{inc_cnt1} - \text{nmb_t}$.</p> <p>For changing from emergency mode to normal mode at the following STATE slope (according to the RMO value in the shadow register)2) the PSTC value is calculated by $PSTC = PSTM + \text{correction_value}$ (forward direction) or $PSTC = PSTM - \text{correction_value}$ (backward direction) with the $\text{correction_value} = \text{inc_cnt1} - \text{nmb_s}$.</p> <p>In the case of no further TRIGGER or STATE events appearing the CPU has to perform the corrections above accordingly.</p>

- 1) stored in an independent shadow register for a valid TRIGGER event and for DEN = 1.
- 2) stored in an independent shadow register for a valid STATE event and for DEN = 1.
- 3) for IFP=1 the time between two valid TRIGGER or STATE events must be always greater then 2,34 μs and the value x of MLT, MLS1 or MLS2 must be chosen such that the number of time stamps pules between two SUB_INC events must be less then 65536. This is fulfilled when x is greater then 256.
- 4) the time between two valid STATE or TRIGGER events must be always greater then 23,4 ms; in addition the TS_CLK and the resolution must be chosen such that for each nominal increment the time stamps differ at least in the value of 257.

26.16.11.2 Register DPLL_CTRL_1

Control register 1.

GTM_DPLL_CTRL_1
DPLL Control Register 1
(28004_H)
Reset Value: B0000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
DMO ^{1) 2)}	0	rw	DPLL mode select 0 _B Automatic end mode; if the number of pulses for a increment is reached, no further pulse is generated until the next valid TRIGGER/STATE is received; in the case of getting a new valid TRIGGER/STATE before the defined number of pulses is reached, the pulse frequency is changed according to the conditions described below (COA) 1 _B Continuous mode; in this mode a difference between the predefined number of pulses and the actual number of generated pulses can influence the pulse frequency by writing a corresponding pulse number into CNT_NUM1 or CNT_NUM2 respectively in RAM region 1B.

Generic Timer Module (GTM)

Field	Bits	Type	Description
DEN	1	rw	<p>DPLL enable</p> <p>0_B The DPLL is not enabled; Disabling the DPLL will result in a reset state of the DPLL_STATUS register which remains in this state until DEN=1. No DPLL related interrupt will be generated in that case.</p> <p>1_B The DPLL is enabled;</p> <p><i>Note:</i> The bits 31 down to 0 of the DPLL STATUS register are cleared, when the DPLL is disabled. Some bits of the control registers can be set only when DEN=0. The protected bits in the DPLL_CTRL_1 register can not be written when simultaneously DEN is set to 1.</p>
IDDS	2	rw	<p>Input direction detection strategy in case of SMC = 0</p> <p>0_B The input direction is detected comparing the THMI value with the duration between valid and invalid slope of TRIGGER</p> <p>1_B The input direction is detected using TDIR input signal also in the case SMC=0</p> <p><i>Note:</i> This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation. Independent of the value of IDDS is the direction information for TRIGGER in the case SMC=0 always considered at the moment when the invalid slope appears.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
COA ¹⁾²⁾	3	rw	<p>Correction strategy in automatic end mode (DMO=0)</p> <p>0_B The maximum pulse frequency of the system clock will be used to make up for missing pulses from last increment; the output of the calculated new pulses will be delayed accordingly and the FFs in the pulse generation unit will be reset before sending new pulses</p> <p>1_B missing pulses of the last increment are distributed evenly to the next increment, calculations are done when the next valid input event appears. The number of missing sub-pulses will be determined by the pulse counter difference between the last two valid TRIGGER/STATE events respectively; the FFs in the pulse generation unit are not reset before sending new pulses.</p> <p>Note: For SMC=RMO=1: COA is used for SUB_INC1 and SUB_INC2.</p>
PIT ¹⁾	4	rw	<p>Plausibility value PVT to next valid TRIGGER is time related</p> <p>0_B the plausibility value is position related (PVT contains the number of SUB_INC1 pulses)</p> <p>1_B the plausibility value is time related (the PVT value is to be multiplied with the duration of the last increment DT_T_ACT and divided by 1024)</p>
SGE1 ¹⁾²⁾	5	rw	<p>SUB_INC1 generator enable</p> <p>0_B The SUB_INC1 generator is not enabled</p> <p>1_B The SUB_INC1 generator is enabled</p>
DLM1 ¹⁾²⁾	6	rw	<p>Direct Load Mode for SUB_INC1 generation</p> <p>0_B the DPLL uses the calculated ADD_IN_CAL value for the SUB_INC1 generation</p> <p>1_B the ADD_IN_LD value is used for the SUB_INC1 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
PCM1 ¹⁾²⁾³⁾	7	rw	Pulse Correction Mode for SUB_INC1 generation 0 _B the DPLL does not use the correction value stored in MPVAL1 1 _B the DPLL uses the correction value stored in MPVAL1 in normal and emergency mode
SGE2 ²⁾	8	rw	SUB_INC2 generator enable 0 _B The SUB_INC2 generator is not enabled 1 _B The SUB_INC2 generator is enabled
DLM2 ²⁾	9	rw	Direct Load Mode for SUB_INC2 generation 0 _B the DPLL uses the calculated ADD_IN_CAL value for the SUB_INC2 generation 1 _B the ADD_IN_LD value is used for the SUB_INC2 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
PCM2 ²⁾³⁾	10	rw	Pulse Correction Mode for SUB_INC2 generation 0 _B the DPLL does not use the correction value stored in MPVAL2 1 _B the DPLL uses the correction value stored in MPVAL2

Generic Timer Module (GTM)

Field	Bits	Type	Description
SYN_NS	[15:11]	rw	<p>Synchronization number of STATE</p> <p>Summarized number of virtual increments in HALF_SCALE</p> <p>sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL_SCALE (for SYSF=1); the SYN_NS missing STATES can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1C3 as value NS in addition to the adapt values. The number of stored increments in FULL_SCALE must be equal to $2*(SNU+1-SYN_NS)$ for SYSF=0 or $2*(SNU+1)-SYN_NS$ for SYSF=1. This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU.</p> <p>Note: This value can only be written when the DPLL is disabled.</p>
SYN_NT	[20:16]	rw	<p>Synchronization number of TRIGGER</p> <p>Summarized number of virtual increments in HALF_SCALE.</p> <p>Sum of all systematic missing TRIGGER events in HALF_SCALE; the SYN_NT missing TRIGGER can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 2C as value NT in addition to the adapt values. The number of stored increments in FULL_SCALE must be equal to $2*(TNU-SYN_NT)$. This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APT_2C in an appropriate relation to the RAM pointer APT of the actual increment by the CPU.</p> <p>Note: This value can only be written when the DPLL is disabled.</p>
Reserved	21	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
LCD	22	rw	<p>Locking condition definition</p> <p>0_B locking condition definition is one times missing TRIGGERS as expected by the profile in HALF_SCALE (one gap)</p> <p>1_B locking condition definition is n-1 times missing TRIGGERS as expected by the profile in HALF_SCALE (one additional tooth)</p> <p><i>Note: This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation.</i></p>
SWR	23	w	<p>Software Reset</p> <p>resets all register and internal states of the DPLL</p> <p>0_B no software reset enabled</p> <p>1_B software reset enabled</p> <p>Setting the SWR bit results only in a software reset when the DPLL is not enabled (DEN=0). Read as zero.</p>
SYSF	24	rw	<p>SYN_NS for FULL_SCALE</p> <p>The value SYN_NS does mean the sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL_SCALE (for SYSF=1)</p> <p>0_B the SYN_NS value is valid for HALF_SCALE</p> <p>1_B the SYN_NS value is valid for FULL_SCALE</p> <p><i>Note: This value can only be written when the DPLL is disabled.</i></p>
TS0_HRS	25	rw	<p>TS0_HRS</p> <p>0_B the resolution of the used DPLL input TBU_TS0 bits is equal to the STATE input time stamp resolution</p> <p>1_B the STATE input time stamps have a 8 times higher resolution as the TBU_TS0 DPLL input</p> <p><i>Note: This bit can only be written when the DPLL is disabled.</i></p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
TS0_HRT	26	rw	TS0_HRT 0 _B the resolution of the used DPLL input TBU_TS0 bits is equal to the TRIGGER input time stamp resolution 1 _B the TRIGGER input time stamps have a 8 times higher resolution as the TBU_TS0 input Note: This bit can only be written when the DPLL is disabled.
SMC	27	rw	Synchronous Motor Control 0 _B the TRIGGER and STATE inputs are used for a control to SMC 1 _B the TRIGGER input reflects a combined sensor signal for SMC and in the case of RMO=1 also STATE reflects a different combined sensor signal Note: This bit can only be written when the DPLL is disabled.
SSL	[29:28]	rw	STATE slope select Definition of active slope for signal STATE each active slope is an event defined by SNU. Set by DEN=0 only. 00 _B No slope of STATE will be used; this value makes only sense in normal mode 01 _B Low high slope will be used as active slope, only inputs with a signal value of "1" will be considered 10 _B High low slope will be used as active slope, only inputs with a signal value of "0" will be considered 11 _B Both slopes will be used as active slopes Note: This bits can only be written when the DPLL is disabled.
TSL	[31:30]	rw	Definition of active slope for signal TRIGGER each active slope is an event defined by TNU Set by DEN=0 only. 00 _B No slope of TRIGGER will be used; this value makes only sense in emergency mode 01 _B Low high slope will be used as active slope, only inputs with a signal value of "1" will be considered 10 _B High low slope will be used as active slope, only inputs with a signal value of "0" will be considered 11 _B Both slopes will be used as active slopes Note: This bits can only be written when the DPLL is disabled.

Generic Timer Module (GTM)

- 1) stored in an independent shadow register for a valid TRIGGER event and for DEN = 1.
- 2) stored in an independent shadow register for a valid STATE event and for DEN = 1.
- 3) Bit is cleared, when transmitted to shadow register

ACT_Ni	[23:0]	rw	<p>New output data values concerning to action i provided</p> <p>0_B no new output data available after a recent PMT request or actual event value is in the past or invalid</p> <p>1_B new PMTR data received or calculation is to be precise by taking into account new TRIGGER or STATE values</p> <p>Note: ACT_Ni is</p> <ul style="list-style-type: none"> • set (for AENi=1 and a new valid PMTR), that means when new action data are to be calculated for the correspondent action. After each calculation of the new actions values the ACT_Ni bit updates the corresponding bit in the connected shadow register. The status of the ACT_Ni bits in the shadow register is reflected by the corresponding DPLL output signal ACT_V (valid bit). • reset together with the corresponding shadow register bit for AENi=0; • reset without the corresponding shadow register bit when the calculated event is in the past • the corresponding shadow register bit is reset, when new PMTR data are written or when the provided action data are read (blocking read) • writable for debugging purposes together with the corresponding shadow register when DEN=0 <p>Note: This bit can only be written when the DPLL is disabled.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.7 Register DPLL_OSW

Offset and switch old/new address register.

GTM_DPLL_OSW

DPLL Offset And Switch Old/New Address Register

(2801C_H)

Reset Value: 00000200_H

Field	Bits	Type	Description
SWON_S	0	r	<p>Switch of new STATE</p> <p>Switch bit for LSB address of STATE.</p> <p>This bit is changed for each write access to TS_S/TS_S_OLD. Using this unchanged address bit SWON_S for any access to TS_S results always in an access to TS_S_OLD. For writing to this address the former old (TS_S_OLD_OLD) value is overwritten by the new one while the SWON_S bit changes. Thus the former new one is now the old one and the next access is after changing SWON_S directed to this place. Therefore write to TS_S first and after that immediately to FTV_S and PSSM, always before a new TS_S value is to be written.</p> <p>Note: After writing TS_S, FTV_S and PSSM in this order the address pointer AP with LSB(AP)=SWON_S shows for the corresponding address to TS_S_OLD, FTV_S and PSSM while LSB(AP)≠SWON_S results in an access to TS_S, FTV_S_OLD and PSSM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN = 0).</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
SWON_T	1	r	<p>Switch of new TRIGGER</p> <p>Switch bit for LSB address of TRIGGER. This bit is changed for each write access to TS_T/TS_T_OLD. Using this unchanged address bit SWON_T for any access to TS_T results always in an access to TS_T_OLD. For writing to this address the former old (TS_T_OLD_OLD) value is overwritten by the new one while the SWON_T bit changes. Thus the former new one is now the old one and the next access is after changing SWON_T directed to this place. Therefore write to TS_T first and after that immediately to FTV_T and PSTM, always before a new TS_T value is to be written.</p> <p>Note: After writing TS_T, FTV_T and PSTM in this order the address pointer AP with LSB(AP)=SWON_T shows for the corresponding address to TS_T_OLD, FTV_T and PSTM while LSB(AP)=/SWON_T results in an access to TS_T, FTV_T_OLD and PSTM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN = 0).</p>

Generic Timer Module (GTM)

26.16.11.8 Register DPLL_AOSV_2

Address offset register of RAM 2 regions

GTM_DPLL_AOSV_2

DPLL Address Offset Register For APT In RAM Region 2

(28020_H)

Reset Value: 18100800_H

Field	Bits	Type	Description
AOSV_2A	[7:0]	r	Address offset value of the RAM 2A region The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2A. When the APT value is added to this start address, the current RAM cell RDT_Tx is addressed.
AOSV_2B	[15:8]	r	Address offset value of the RAM 2B region The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2B. When the APT value is added to this start address, the current RAM cell TSF_Tx is addressed.
AOSV_2C	[23:16]	r	Address offset value of the RAM 2C region The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2C. When the APT value is added to this start address, the current RAM cell ADT_Tx is addressed.

Generic Timer Module (GTM)

Field	Bits	Type	Description
AOSV_2D	[31:24]	r	<p>Address offset value of the RAM 2D region</p> <p>The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2D. When the APT value is added to this start address, the current RAM cell DT_Tx is addressed.</p> <p>Note: The offset values are needed to support a scalable RAM size of region 2 from 1,5 Kbytes to 12 Kbytes. The values above must be in correlation with the offset size defined in the OSW register. All offset values are set automatically in accordance to the OSS value in the DPLL_OSW register. This value can be set only for DEN=0.</p>

26.16.11.9 Register DPLL_APT

Actual RAM pointer address for TRIGGER.

GTM_DPLL_APT

DPLL Actual RAM Pointer to RAM Regions 2A, B and D (28024_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
APT_2B	[23:14]	rw	<p>Address pointer TRIGGER for RAM region 2B Actual RAM pointer address value for TSF_T[i] Actual RAM pointer address of TRIGGER events in FULL_SCALE for $2*(TNU+1)$ TRIGGER periods; this pointer is used for the RAM region 2B. The RAM pointer is initially set to zero. For SYT = 1: The pointer APT_2B is increment by SYN_T_OLD for each valid TRIGGER event (simultaneously with APT and APT_2C) for DIR1=0 when a valid TRIGGER input appears. For DIR1=1 (backwards) the APT is decremented by SYN_T_OLD. For SYT = 0: APT_2B is incremented or decremented by 1. In addition when the APT_2C value is written by the CPU - in order to synchronize the DPLL- with the next valid TRIGGER event the APT_2B_EXT value is added/subtracted (while APT_2B_STATUS is one; see DPLL_APT_SYNC register at Chapter 26.16.11.23). Note: This value can only be written when the WAPT_2B bit is set.</p>
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.10 Register DPLL_APS

Actual RAM pointer address for STATE.

GTM_DPLL_APS

DPLL Actual RAM Pointer to RAM Regions 1C1, 1C2 and 1C4

(28028_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
Reserved	0	r	Reserved Read as zero, should be written as zero.
WAPS	1	w	Write bit for address pointer APS read as zero 0 _B the APS is not writable 1 _B the APS is writable Note: This bit is cleared automatically after write.

Generic Timer Module (GTM)

Field	Bits	Type	Description
APS	[7:2]	rw	<p>Address pointer STATE Actual RAM pointer address value for DT_S[i] and RDT_S[i] Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to $2^*(SNU+1-SYN_NS)$ in normal and emergency mode for SYSF=0 or to $2^*(SNU+1)-SYN_NS$ for SYSF=1 respectively; this pointer is used for the RAM region 1C1 and 1C4. APS is incremented (decremented) by one for each valid STATE event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. Note: The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after a valid STATE event and the resulting increment/decrement. Note: This value can only be written when the WAPS bit is set.</p>
Reserved	[12:8]	r	<p>Reserved Read as zero, should be written as zero.</p>
WAPS_1C2	13	w	<p>Write bit for address pointer APS_1C2 read as zero 0_B the APS_1C2 is not writable 1_B the APS_1C2 is writable Note: This bit is cleared automatically after write.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
APS_1C2	[19:14]	rw	<p>Address pointer STATE for RAM region 1C2 Actual RAM pointer address value for TSF_S[i] Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to $2*(SNU+1)$ in normal and emergency mode; this pointer is used for the RAM region 1C2. For SYS=1: APS_1C2 is increment (decremented) by SYN_S_OLD for each valid STATE event and DIR2=0 (DIR2=1). The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. For SYS=0: APT_1C2 is incremented or decremented by 1 respectively. In addition when the APS_1C3 value is written by the CPU - in order to synchronize the DPLL- with the next valid STATE event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at Section 26.16.11.24). Note: This value can only be written when the WAPS_1C2 bit is set.</p>
Reserved	[31:20]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.11 Register DPLL_APT_2C

Actual RAM pointer address for region 2C.

GTM_DPLL_APT_2C

DPLL Actual RAM Pointer to RAM Region 2C
(2802C_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
Reserved	[1:0]	r	Reserved Read as zero, should be written as zero.
APT_2C	[11:2]	rw	Address pointer TRIGGER for RAM region 2C Actual RAM pointer address value for ADT_T[i] Actual RAM pointer address value of TRIGGER adapt events in FULL_SCALE for 2*(TNU+1-SYN_NT) TRIGGER periods depending on the size of the used RAM 2; this pointer is used for the RAM region 2 for the subsection 2C only. The RAM pointer is initially set to zero. The APT_2C value is set by the CPU when the synchronization condition was detected. Within the RAM region 2C initially the conditions for synchronization gaps and adapt values are stored by the CPU.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:12]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p> <p>Note: The APT_2C pointer values are directed to the RAM position of the profile element in RAM region 2C, which correspond to the current increment. For DIR1=0 (DIR1=1) the pointers APT_2C_x are increment (decremented) by one simultaneously with APT. For SMC=0 the change of DIR1 takes place always after a valid TRIGGER event (by evaluation of the invalid slope) and the resulting increment/decrement. In the case SMC=1 the direction change is known before the input event is processed.</p> <p>The correction of the APT_2C pointer differs: for SMC=0 correct 4 times and for SMC=1 correct only 2 times.</p> <p>The APT_2C_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.</p>

Generic Timer Module (GTM)

26.16.11.12 Register DPLL_APS_1C3

Actual RAM pointer address for RAM region 1C3.

GTM_DPLL_APS_1C3

DPLL Actual RAM Pointer to RAM Region 1C3
(28030_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
Reserved	[1:0]	r	Reserved Read as zero, should be written as zero.
APS_1C3	[7:2]	rw	Address pointer STATE for RAM region 1C3 Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1)-SYN_NS in normal and emergency mode for SYSF=0 or to 2*(SNU+1)-SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1C3. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected.
Reserved	[31:8]	r	Reserved Read as zero, should be written as zero. Note: The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1C2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before a valid STATE event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction. The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

Generic Timer Module (GTM)

26.16.11.13 Register DPLL_NUTC

number of recent TRIGGER events used for calculations.

GTM_DPLL_NUTC

DPLL Number of Recent TRIGGER Events Used for Calculations

(28034_H)

Reset Value: 00012001_H

Field	Bits	Type	Description
NUTE	[9:0]	rw	<p>Number of recent TRIGGER events used for SUB_INC1 and action calculations modulo 2*(TNUMax+1)</p> <p>NUTE: number of last nominal increments to be considered for the calculations.</p> <p>No gap is considered in that case for this value, but in the VTN value (see below):</p> <p>This register is set by the CPU, but reset automatically to “1” by a change of direction or lost of LOCK. Each other value can be set by the CPU, maybe FULL_SCALE, HALF_SCALE or parts of them. For FULL_SCALE set NUTE=2*(TNU+1) and fir HALF_SCALE NUTE=TNU+1. The relation values QDT_Tx are calculated using NUTE values in the past with its maximum value of 2*(TNU +1). The value zero (in combination with the value FST=1) does mean 211 values in the past.</p> <p>Note: This value can only be written when the WNUT bit is set.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
FST	10	rw	<p>this value is to be set, when NUTE is set to FULL_SCALE</p> <p>0= the NUTE value is less then FULL_SCALE 1= the NUTE value is equal to FULL_SCALE Note: This value can only be written when the WNUT bit is set.</p>
Reserved	[12:11]	r	<p>Reserved Read as zero, should be written as zero.</p>
SYN_T	[15:13]	rw	<p>Number of real and virtual events to be considered for the current increment</p> <p>This value reflects the NT value of the last valid increment, stored in ADT_T[i]; to be updated after all calculations in step 17 of Table 26-48. Note: This value can only be written when the WSYN bit is set.</p>
SYN_T_OL LD	[18:16]	rw	<p>Number of real and virtual events to be considered for the last increment</p> <p>This value reflects the NT value of the last but one valid increment, stored in ADT_T[i]; is updated automatically when writing SYN_T. Note: This value is updated by the SYN_T value when the WSYN bit is set.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
VTN	[24:19]	rw	<p>Virtual TRIGGER number</p> <p>Number of virtual increments in the current NUTE region This value reflects the number of virtual increments in the current NUTE region; for NUTE=1 this value is zero, when the CPU sets NUTE to a value > 1, it must also set VTN to the correspondent value; for NUTE is set to FULL_SCALE including NUTE=zero (211 modulo 211) the VTN is to be set to 2* SYN_NT. the VTN value is subtracted from the NUTE value in order to get the corresponding APT value for the past; the VTN value is not used for the APT_2B pointer. VTN is to be updated by the CPU when a new gap is to be considered for NUTE or a gap is leaving the NUTE region; for this purpose the TINT values in the profile can be used to generate an interrupt for the CPU at the corresponding positions; no further update of VTN is necessary when NUTE is set to FULL_SCALE Note: This value can only be written when the WVTN bit is set.</p>
Reserved	[28:25]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.23 Register DPLL_APT_SYNC

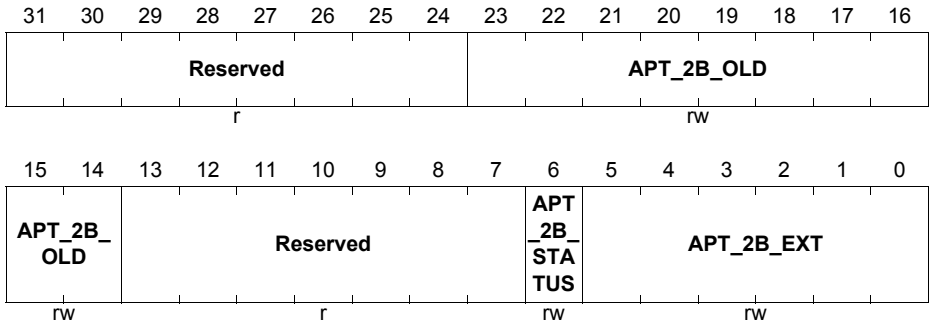

TRIGGER time stamp field offset at synchronisation time.

GTM_DPLL_APT_SYNC

DPLL Old RAM Pointer and Offset Value for TRIGGER

(280B8_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
APT_2B_EXT	[5:0]	rw	<p>Address pointer 2B extension</p> <p>Set by CPU before the synchronization is performed This offset value is the number of virtual increments to be considered for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUTE value to be set and including the next future increment (when SYN_T_OLD is still 1). When the synchronization takes place, this value is to be added to the APT_2B address pointer (for forward direction, DIR1=0) and the APT_2B_STATUS bit is cleared after it. For backward direction subtract APT_2B_EXT accordingly.</p> <p>Note: When the synchronization is intended and the NUTE value is to be set to FULL_SCALE after it, the APT_2B_EXT value must be set to 2*SYN_NT in order to be able to fill all gaps in the extended TSF_T with the corresponding values by the CPU.</p> <p>When still not all values for FULL_SCALE are available, the APT_2B_EXT value considers only a share according to the corresponding NUTE value to be set after the synchronization.</p>
APT_2B_STATUS	6	rwh	<p>Address pointer 2B status</p> <p>Set by CPU before the synchronization is performed The value is cleared when the APT_2B_OLD value is written status bit</p> <p>0_B APT_2B_EXT is not to be considered. 1_B APT_2B_EXT has to be considered for time stamp field extension.</p>
Reserved	[13:7]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
APT_2B_OLD	[23:14]	rw	<p>Address pointer TRIGGER for RAM region 2B at synchronization time</p> <p>This value is set by the current APT_2B value when the synchronization takes place for the first valid TRIGGER event after writing APT_2C but before adding the offset value APT_2B_EXT (that means when APT_2B_STATUS=1)</p> <p>Address pointer APT_2B value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

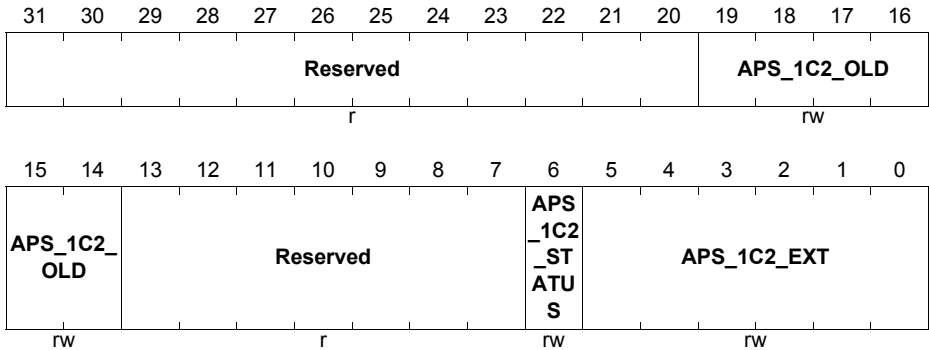

26.16.11.24 Register DPLL_APS_SYNC

STATE time stamp field offset at synchronization time.

GTM_DPLL_APS_SYNC

DPLL Old RAM Pointer and Offset Value for STATE
(280BC_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
APS_1C2_EXT	[5:0]	rw	<p>Address pointer 1C2 extension set by CPU before the synchronization is performed This offset value is the number of virtual increments to be considered for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and include the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1C2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. Note: When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.</p>
APS_1C2_STATUS	6	rwh	<p>Address pointer 1C2 status set by CPU before the synchronization is performed The value is cleared automatically when the APS_1C2_OLD value is written 0_B APT_2B_EXT is not to be considered. 1_B APT_2B_EXT has to be considered for time stamp field extension.</p>
Reserved	[13:7]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
APS_1C2_ OLD	[19:14]	rw	<p>Address pointer STATE for RAM region 1C2 at synchronization time</p> <p>This value is set by the current APS_1C2 value when the synchronization takes place for the first valid STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means when APS_1C2_STATUS=1)</p> <p>Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap</p>
Reserved	[31:20]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.25 Register DPLL_TBU_TS0_T

Time stamp value for the last valid TRIGGER.

GTM_DPLL_TBU_TS0_T

DPLL TBU_TS0 Value at last TRIGGER Event
(280C0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TBU_TS0_T	[23:0]	rw	value of TBU_TS0 at the last TRIGGER event For each T_VALID the value of TBU_TS0 is stored in this register; The register is writable only for test purposes when DEN=0. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.26 Register DPLL_TBU_TS0_S

Time stamp value for the last valid STATE.

GTM_DPLL_TBU_TS0_S

DPLL TBU_TS0 Value at last STATE Event
(280C4_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
TBU_TS0_S	[23:0]	rw	value of TBU_TS0 at the last STATE event For each S_VALID the value of TBU_TS0 is stored in this register; The register is writable only for test purposes when DEN=0. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.27 Register DPLL_ADD_IN_LD1

ADD_IN value in direct load mode for TRIGGER.

GTM_DPLL_ADD_IN_LD1

DPLL Direct Load Input Value for SUB_INC1

(280C8_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
ADD_IN_LD_1	[23:0]	rw	<p>Input value for SUB_INC1 generation given by CPU This value can be used in normal and emergency mode (SMC=0) as well as for SMC=1</p> <p><i>Note: The value is loaded by the CPU but used by the DPLL only for DLM1=1 (see DPLL_CTRL_1 register). When switching DLM1 to 1, the value in the register is used for the SUB_INC1 generation beginning from the next valid TRIGGER or STATE event respectively independently if new values are written by the CPU or not.</i></p> <p><i>Note: When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 10 in the state machine for ADD_in calculations.</i></p> <p><i>Note: If ADD_IN_LD1 value is zero all pulses are sent with the highest possible frequency.</i></p>
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.28 Register DPLL_ADD_IN_LD2

ADD_IN value in direct load mode STATE.

GTM_DPLL_ADD_IN_LD2

DPLL Direct Load Input Value for SUB_INC1

(280CC_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
ADD_IN_LD_2	[23:0]	rw	<p>Input value for SUB_INC2 generation given by CPU This value can be used for SMC=1 while RMO=1</p> <p><i>Note: The value is loaded by the CPU but used by the DPLL only for DLM2=1 (see DPLL_CRTL_1 register). When switching DLM2 to 1, the value in the register is used for the SUB_INC2 generation beginning from the next valid STATE event respectively independently if new values are written by the CPU or not.</i></p> <p><i>Note: When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 30 in the state machine for ADD_in calculations.</i></p> <p><i>Note: If ADD_IN_LD2 value is zero all pulses are sent with the highest possible frequency.</i></p>
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

26.16.11.29 Register DPLL_STATUS

Status register.

The DPLL_STATUS register is reset, when the DPLL is disabled (switching DEN from 1 to 0).

GTM_DPLL_STATUS
DPLL Status Register
(280FC_H)
Reset Value: 00000000_H

Reserved	0	r	Reserved Read as zero, should be written as zero.
CSO	1	rwh	Calculated STATE duration overflow Bit is set when equations DPLL-10a or DPLL-10b lead to an overflow. 0 _B No overflow at equation DPLL-10a or b 1 _B overflow at equation DPLL-10a or b
Reserved	2	r	Reserved Read as zero, should be written as zero.
CTO	3	rwh	Calculated TRIGGER duration overflow Bit is set when equations DPLL-5a or DPLL-5b lead to an overflow. 0 _B No overflow at equation DPLL-5a or b 1 _B overflow at equation DPLL-5a or b <i>Note: When one of the above bits is set the corresponding register contains the maximum value 0xFFFFF.</i>

Generic Timer Module (GTM)

Field	Bits	Type	Description
CRO	4	rwh	<p>Calculated Reciprocal value overflow</p> <p>Bit is set when the calculation of RDT_T_actual or RDT_S_actual leads to an overflow.</p> <p>0_B No overflow at any reciprocal calculation 1_B overflow for at least one reciprocal calculation</p> <p><i>Note: An overflow in calculation of reciprocal values can occur, when the condition of Note 3) to the DPLL_CTRL_0 register is violated (see chapter 16.11.1). Such an overflow can occur according to the calculations in equations (DPLL-1c) or (DPLL-6c).</i></p> <p>The overflow is detected when after the calculation and shifting left 32 bits at least one of the bits 31 to 24 is not zero. In that case the corresponding register is set to 0xFFFFF.</p>
RCS	5	rh	<p>RCS</p> <p>0_B No resolution conflict detected 1_B the TS0_HRT value is set to 1 while LOW_RES=0</p>
RCT	6	rwh	<p>RCT</p> <p>0_B No resolution conflict detected 1_B the TS0_HRS value is set to 1 while LOW_RES=0</p>
PSE	7	rwh	<p>Prediction space configuration error</p> <p>0_B No prediction space error detected 1_B Configured offset value of RAM2 is too small in order to store all TNU+1 values twice in FULL_SCALE</p>
SOR	8	rh	<p>STATE out of range</p> <p>0_B all STATE signal events appear within SLR interval or a direction change was detected 1_B at least one STATE signal event is out of SLR; address pointers APS, APS_1C2, and APS_1C3 are frozen and generated of pulse SUB_INC1,2 respectively is stopped</p> <p>The SOR bit is set, when the time to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register (see chapter 16.13.37) and is reset, when at the current or last valid input event a direction change was detected. the SYS bit is not influenced by setting the SOR bit.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
MS	9	rh	Missing STATE detected according to TOV_S 0 _B No missing STATE detected or a new valid STATE slope occurred 1 _B At least one missing STATE detected after the last valid slope
TOR	10	rh	TRIGGER out of range 0 _B all TRIGGER signal events appear within TLR interval or a direction change was detected 1 _B at least one TRIGGER signal event is out of TLR; address pointers APT, APT_2B, and APT_2C are frozen and generated of pulse SUB_INC1 respectively is stopped The TOR bit is set, when the time to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see chapter 16.13.36) and is reset, when at the current or last valid input event a direction change was detected. The SYT bit is not influenced by setting the TOR bit.
MT	11	rwh	Missing TRIGGER detected according to TOV 0 _B No missing TRIGGER detected or a new valid TRIGGER slope occurred 1 _B At least one missing TRIGGER detected after the last valid slope
RAM2_ER R	12	rwh	DPLL internal access to not configured RAM2 0 _B No access to not configured RAM2 memory space 1 _B access to not configured RAM2 memory space
Reserved	[14:13]	r	Reserved Read as zero, should be written as zero.
LOW_RES	15	rwh	Low resolution of TBU_TS0 is used for DPLL input This value reflects the input signal LOW_RES. 0 _B the lower 24 Bits of TBU_TS0 are used as input for the DPLL 1 _B the higher 24 Bits of TBU_TS0 are used as input for the DPLL
CSVS	16	rh	Current signal value STATE 0 _B the last STATE_S value was 0 1 _B the last STATE_S value was 1
CSVT	17	rh	Current signal value TRIGGER 0 _B the last TRIGGER_S value was 0 1 _B the last TRIGGER_S value was 1

Generic Timer Module (GTM)

Field	Bits	Type	Description
CAIP2	18	rh	Calculation of actions 12 to 23 in progress (2nd part) 0_B currently no action calculation, new data requests possible 1_B action calculation in progress, no new data requests possible
CAIP1	19	rh	Calculation of actions 0 to 11 in progress (1st part) 0_B currently no action calculation, new data requests possible 1_B action calculation in progress, no new data requests possible
ISN	20	rh	Number of STATE is not plausible Bit is set when the number of STATES is different to profile. 0_B the number of STATE events between synchronization gaps is plausible, a direction change is detected or the APS_1C3 pointer is written 1_B after setting LOCK1 in emergency mode (SMC=0 and RMO=1) or LOCK2 for SMC=RMO=1 missing or additional STATE signals detected; bit is cleared when a direction change is detected or the APS_1C3 is written
ITN	21	rh	Increment number of TRIGGER is not plausible Bit is set when the number of TRIGGERS is different to profile. 0_B the number of TRIGGER events between synchronization gaps is plausible, a direction change is detected or the address pointer APT_2C is written 1_B after setting LOCK1 in normal mode (for SMC=0 or SMC=1) or in emergency mode (only for SMC=0) for missing or additional TRIGGER signals detected; bit is cleared when a direction change is detected or the APT_2C is written
BWD2	22	rh	Backwards drive of SUB_INC2 0_B forward direction 1_B backward direction
BWD1	23	rh	Backwards drive of SUB_INC1 0_B forward direction 1_B backward direction
Reserved	24	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

Field	Bits	Type	Description
LOCK2	25	rh	<p>DPLL Lock status concerning SUB_INC2</p> <p>0_B The DPLL is not locked concerning STATE for SMC=1 1_B The DPLL is locked concerning STATE for SMC=1</p> <p><i>Note: Locking of SUB_INC2 appears for RMO=SMC=1: Bit is set, when SYS is set and the number of events between two missing STATES is as expected by the SYN_S values.</i></p> <p><i>Note: LOCK2 is set for SMC=RMO=1: for a valid STATE event when SYS is set and SYN_NS=0 for a valid STATE event when SYS is set and SYN_NS=0 or when SYS is set and the profile stored in the ADT_Si field matches once between two gaps.</i></p> <p><i>Note: LOCK2 is reset: for SMC=RMO=1</i> - when a missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. - when the corresponding input signal STATE is out of locking range SLR.</p>
SYS	26	rh	<p>Synchronization condition of STATE fixed</p> <p>This bit is set when the CPU writes to the APS_1C3 address pointer.</p>
SYT	27	rh	<p>Synchronization condition of TRIGGER fixed</p> <p>This bit is set when the CPU writes to the APT_2C address pointer.</p>
FSD	28	rh	<p>STATE detected</p> <p>0_B Still no valid STATE event was detected after enabling DPLL 1_B At least one valid STATE event was detected after enabling DPLL</p> <p><i>Note: No change of FSD for switching from normal to emergency mode or vice versa.</i></p>
FTD	29	rh	<p>First TRIGGER detected</p> <p>0_B No valid TRIGGER event was detected after enabling DPLL 0_B At least one valid TRIGGER event was detected after enabling DPLL</p> <p><i>Note: No change of FTD for switching from normal to emergency mode or vice versa.</i></p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
LOCK1	30	rh	<p>DPLL Lock status concerning SUB_INC1</p> <p>0_B The DPLL is not locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1)</p> <p>1_B The DPLL is locked for TRIGGER (while SMC=RMO=0 or SMC=1) or for STATE (while SMC=0 and RMO=1)</p> <p>LOCK1 is set:</p> <ul style="list-style-type: none"> - in normal mode (for RMO=SMC=0, LCD=0): Bit is set for a valid TRIGGER event when SYT is set and the number of events between two gaps is as expected by the profile (NT values in the ADT_T[i] field) or when SYN_NT=0 and SYT=1. - in normal mode (for RMO=SMC=0, LCD=1): Bit is set for a valid TRIGGER event when SYT is set and the number of events between two increments without missing TRIGGER (no gap) is as expected by profile (NT values in the ADT_Ti filed). - in emergency mode (for RMO=1 and SMC=0): Bit is set for a valid STATE event, when SYS is set and the received events are in correspondence to the profile (NS values in the ADT_S[i] field) for at least two expected missing STATE events or when SYN_NS=0. - for SMC=1: Bit is set for a valid TRIGGER even when SYT is set and SYN_NT=0 or when SYT is set and the profile stored in the ADT_T[i] field matches once between two gaps. <p>LOCK1 is reset for RMO=SMC=0:</p> <ul style="list-style-type: none"> - when a corresponding missing TRIGGER event occurs while SYN_T=1. this does mean an unexpected missing TRIGGER. - when the corresponding input signal TRIGGER is out of locking range TLR, - when a corresponding direction change is detected for RMO=1 and SMC=0: - when a corresponding missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. - when the corresponding input signal STATE is out of locking range TLR <p>for SMC=1:</p> <ul style="list-style-type: none"> - when a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. - when the corresponding input signal TRIGGER is out of locking range TLR - when a corresponding direction change is detected

Generic Timer Module (GTM)

Field	Bits	Type	Description
ERR	31	rh	Error during configuration or operation resulting in unexpected values 0_{B} when all bits in position 8 to 0 and 10 and 12 are zero 1_{B} when at least one bit in position 8 to 0 or 10 or 12 is one

Generic Timer Module (GTM)

26.16.11.30 Register DPLL_ID_PMTR_x

ID information for input signal PMTRx (position minus time request), x=0...23.

GTM_DPLL_ID_PMTR_x (x=0-23)

DPLL ID Information For Input Signal PMTR x Register
(28100_H+x*04_H)

Reset Value: 000001FE_H

Field	Bits	Type	Description
ID_PMTR_x	[8:0]	rw	<p>ID information to the input signal PMTR_x from the ARU</p> <p><i>Note: The DPLL_ID_PMTR_x can be changed also when the DPLL is enabled.</i></p>
Reserved	[31:9]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)
26.16.11.31 Register DPLL_CTRL_0_SHADOW_TRIGGER

Shadow register of DPLL_CTRL_0 controlled by valid TRIGGER slope.

GTM_DPLL_CTRL_0_SHADOW_TRIGGER
DPLL Control0 Shadow Trigger Register(281E0_H)
Reset Value: 00000257_H

Field	Bits	Type	Description
MLT ¹⁾	[9:0]	r	multiplier for TRIGGER MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (11024).
IFP ¹⁾	10	r	Input filter position Value contains position or time related information.
Reserved	[25:11]	r	Reserved Read as zero, should be written as zero.
AMT ¹⁾	26	r	Adapt mode TRIGGER Use of adaptation information of TRIGGER.
IDS	27	r	Input delay STATE Use of input delay information transmitted in FT part of the STATE signal.
IDT ¹⁾	28	r	Input delay TRIGGER Use of input delay information transmitted in FT part of the TRIGGER signal.
Reserved	[30:29]	r	Reserved Read as zero, should be written as zero.
RMO ¹⁾	31	r	Reference mode; selection of the relevant the input signal for generation of SUB_INC1

Generic Timer Module (GTM)

- 1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

Generic Timer Module (GTM)
26.16.11.32 Register DPLL_CTRL_0_SHADOW_STATE

Shadow register of DPLL_CTRL_0 controlled by a valid STATE slope.

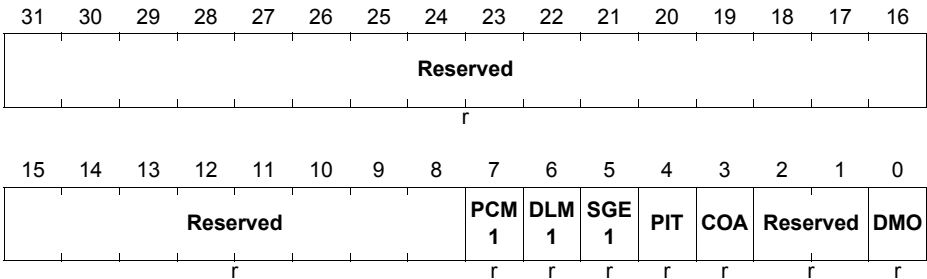

GTM_DPLL_CTRL_0_SHADOW_STATE
DPLL Control 0 Shadow STATE Register(281E4_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
Reserved	[9:0]	r	Reserved Read as zero, should be written as zero.
IFP ¹⁾	10	r	Input filter position Value contains position or position or time related information.
Reserved	[24:11]	r	Reserved Read as zero, should be written as zero.
AMS ¹⁾	25	r	Adapt mode STATE Use of adaptation information of STATE.
Reserved	26	r	Reserved Read as zero, should be written as zero.
IDS ¹⁾	27	r	Input delay STATE Use of input delay information transmitted in FT part of the STATE signal.
Reserved	[30:28]	r	Reserved Read as zero, should be written as zero.
RMO ¹⁾	31	r	Reference mode; selection of the relevant the input signal for generation of SUB_INC1

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

26.16.11.33 Register DPLL_CTRL_1_SHADOW_TRIGGER

Shadow register of DPLL_CTRL_1 controlled by a valid TRIGGER slope.

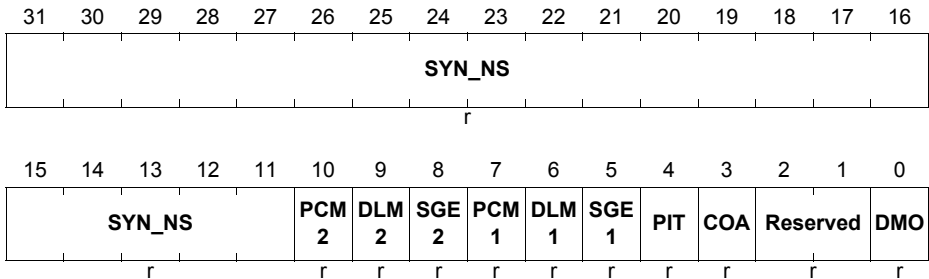

GTM_DPLL_CTRL_1_SHADOW_TRIGGER
DPLL Control 1 Shadow TRIGGER Register(281E8_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
DMO ¹⁾	0	r	DPLL mode select
Reserved	[2:1]	r	Reserved Read as zero, should be written as zero.
COA ¹⁾	3	r	Correction strategy in automatic end mode (DMO=0)
PIT ¹⁾	4	r	Plausibility value PVT to next valid TRIGGER is time related
SGE1 ¹⁾	5	r	SUB_INC1 generator enable
DLM1 ¹⁾	6	r	Direct Load Mode for SUB_INC1 generation
PCM1 ¹⁾	7	r	Pulse Correction Mode for SUB_INC1 generation
Reserved	[31:8]	r	Reserved Read as zero, should be written as zero.

1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_1 are transferred without any input event at the next system clock. This results in the above reset value.

26.16.11.34 Register DPLL_CTRL_1_SHADOW_STATE

Shadow register of DPLL_CTRL_1 controlled by a valid STATE slope.

GTM_DPLL_CTRL_1_SHADOW_STATE
DPLL Control 1 Shadow STATE Register(281EC_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
DMO ¹⁾	0	r	DPLL mode select
Reserved	[2:1]	r	Reserved Read as zero, should be written as zero.
COA ¹⁾	3	r	Correction strategy in automatic end mode (DMO=0)
PIT	4	r	Plausibility value PVT to next valid TRIGGER is time related
SGE1 ¹⁾	5	r	SUB_INC1 generator enable
DLM1 ¹⁾	6	r	Direct Load Mode for SUB_INC1 generation
PCM1 ¹⁾	7	r	Pulse Correction Mode for SUB_INC1 generation
SGE2 ¹⁾	8	r	SUB_INC2 generator enable
DLM2 ¹⁾	9	r	Direct Load Mode for SUB_INC2 generation
PCM2 ¹⁾	10	r	Pulse Correction Mode for SUB_INC2 generation
SYN_NS	[31:11]	r	Synchronization number of STATE Summarized number of virtual increments in HALF_SCALE

Generic Timer Module (GTM)

- 1) Only the values are stored for a valid TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_1 are transferred without any input event at the next system clock. This results in the above reset value.

26.16.11.35 Register DPLL_RAM_INI

Register to control the RAM initialisation.

GTM_DPLL_RAM_INI

DPLL RAM Initatlisation Register (281FC_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
INIT_1A	0	r	<p>RAM region 1A initialization in progress</p> <p>0_B No initialization of considered RAM region in progress</p> <p>1_B Initialization of considered RAM region in progress</p>
INIT_1B	1	r	<p>RAM region 1B initialization in progress</p> <p>see bit 0</p>
INIT_2	2	r	<p>RAM region 2 initialization in progress</p> <p>see bit 0</p>
Reserved	3	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
INIT_RAM	4	w	RAM regions 1A, 1B and 2 are to be initialized 0_B Do not start initialization of all RAM regions 1_B Start initialization of all RAM regions Note: Setting the INIT_RAM bit results only in a RAM reset when the DPLL is not enabled (DEN=0). Note: Depending on the vendor configuration the connected RAM regions are initialized to zero in the case of a module HW reset or for setting the RST bit in the GTM_RST register. Note: In the case of no RAM initialization it must be ensured that all relevant parameters are configured correctly. Otherwise there is no guarantee to get a predictable behaviour.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero.

26.16.11.36 Memory DPLL_PSA[i]

Position request for action i, RAM1A.

GTM_DPLL_PSAi (i=0-23)
DPLL ACTION_i Position/Value Action Request Register
 $(28200_H + i * 04_H)$

 Reset Value: 00000000_H

Field	Bits	Type	Description
PSA	[23:0]	rw	Position information of a desired action (i=0...23) Get position values via ARU Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.37 Memory DPLL_DLA[i]

Time to react for action i, RAM1A

Generic Timer Module (GTM)

GTM_DPLL_DLAI (i=0-23)

DPLL ACTION_i Time To React Before PSA_i Register

$$(28280_H + i * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
DLA	[23:0]	rw	Time to react before the corresponding position value of a desired action is reached In case of LOW_RES=1 (see Chapter 26.16.4.2) this delay value must be also given as low resolution value. Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.38Memory DPLL_NA[i]

Calculated number of TRIGGER / STATE increments to action i, RAM1A.

GTM_DPLL_NAI (i=0-23)

DPLL Calculated Number Of TRIGGER/STATE Increments To ACTION_i

$$(28300_H + i * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
DB	[9:0]	rw	Number of events to Action_i (fractional part) Note: This value can only be written when the DPLL is disabled.
DW	[19:10]	w	Number of events to Action_i (integer part) Note: This value can only be written when the DPLL is disabled.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[23:20]	rw	Reserved Note: must be written as zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero. Note: Use the maximum value for DW=0x3FF in the case of a calculated value which exceeds the representable value.

Generic Timer Module (GTM)

26.16.11.39Memory DPLL_DTA[i]

Calculated relative time to action i, RAM1A.

GTM_DPLL_DTAi (i=0-23)

DPLL Calculated Relative Time To ACTION_i Register
 (28380_H + i * 04_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DTA	[23:0]	rw	Calculated relative time to ACTION_i Note: This value can only be written when the DPLL is disabled. The DTA value is a positive integer value. When calculations using equations DPLL-12 or DPLL-14 result in a negative value, it is replaced by zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.40Memory DPLL_TS_T

Actual TRIGGER time stamp value.

GTM_DPLL_TS_T_0

DPLL Actual Signal TRIGGER Time Stamp Register
 (28400_H)

Reset Value: 00000000_H

GTM_DPLL_TS_T_1

DPLL Actual Signal TRIGGER Time Stamp Register
 (28404_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRIGGER_TS	[23:0]	rw	Time stamp value of the last valid TRIGGER input measured TRIGGER time stamp Note: The LSB address is determined using the SWON_T value in the OSW register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.41 Memory DPLL_TS_T_OLD

Previous TRIGGER time stamp value.

GTM_DPLL_TS_T_OLD_0

DPLL Previous Signal TRIGGER Time Stamp Register
(28400_H)

Reset Value: 00000000_H

GTM_DPLL_TS_T_OLD_1

DPLL Previous Signal TRIGGER Time Stamp Register
(28404_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TRIGGER_TS_old	[23:0]	rw	Time stamp value of the last but one valid TRIGGER input previous measured TRIGGER time stamp Note: The LSB address is determined using the SWON_T value in the OSW register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.42 Memory DPLL_FTV_T

Actual TRIGGER filter value.

GTM_DPLL_FTV_T

DPLL Actual Signal TRIGGER Filter Value Register
(28408_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TRIGGER_FT	[23:0]	rw	Filter value of the last valid TRIGGER input transmitted filter value Note: The LSB address is determined using the SWON_T value in the OSW register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.43 Memory DPLL_TS_S

Actual STATE time stamp register.

GTM_DPLL_TS_S_0

DPLL Actual Signal STATE Time Stamp Register
(28410_H)

Reset Value: 00000000_H

GTM_DPLL_TS_S_1

DPLL Actual Signal STATE Time Stamp Register
(28414_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
STATE_TS	[23:0]	rw	Time stamp value of the last valid STATE input Note: The LSB address is determined using the SWON_S value in the OSW register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.44 Memory DPLL_TS_S_OLD

Previous STATE time stamp register.

GTM_DPLL_TS_S_OLD_0

DPLL Previous Signal STATE Time Stamp Register
(28410_H)

Reset Value: 00000000_H

GTM_DPLL_TS_S_OLD_1

DPLL Previous Signal STATE Time Stamp Register
(28414_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
STATE_T S_OLD	[23:0]	rw	Time stamp value of the last valid STATE input Note: The LSB address is determined using the SWON_S value in the OSW register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.45 Memory DPLL_FTV_S

Actual STATE filter value.

GTM_DPLL_FTV_S

DPLL Actual Signal STATE Filter Value Register (28418_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
STATE_FT	[23:0]	rw	Filter value of the last valid STATE input transmitted filter value Note: The LSB address is determined using the SWON register (see Section 26.16.11.7).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.46 Memory DPLL_THMI

TRIGGER hold time min value.

GTM_DPLL_THMI

DPLL TRIGGER hold time min value (28420_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
THMI	[15:0]	rw	<p>Minimal time between active and inactive TRIGGER slope (uint16)</p> <p>the time value corresponds to the time stamp clock counts; this does mean the clock selected for the TBU_CHO_BASE (see TBU_CHOCTRL register). set min value; generate the TINI interrupt in the case of a violation for THMI>0.</p> <p>Note: Typical retention time values after a valid slope can be e.g. between 45 μs (forwards) and 90 μs (backwards). When THMI is zero, consider always a THMI violation (forwards).</p>
Reserved	[31:16]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.47 Memory DPLL_THMA

TRIGGER hold time max value.

GTM_DPLL_THMA

DPLL TRIGGER Hold Time Max Value(28424_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
THMA	[15:0]	rw	Maximal time between active and inactive TRIGGER slope (uint16) the time value corresponds to the time stamp clock counts; this does mean the clock selected for the TBU_CH0_BASE (see TBU_CH0_CTRL register). max value to be set; generate the TAX interrupt in the case of a violation for THMA>0.
Reserved	[31:16]	r	Reserved Read as zero, should be written as zero.

26.16.11.48 Memory DPLL_THVAL

Measured TRIGGER hold time value.

GTM_DPLL_THVAL

DPLL Measured Last Pulse Time from Valid to Invalid TRIGGER Slope

(28428_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
THVAL	[15:0]	rw	Measured time from the last valid slope to the next inactive TRIGGER slope in time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (uint16) measured value
Reserved	[31:16]	r	Reserved Read as zero, should be written as zero.

Note: In the case of LOW_RES=1 and TBU_HRT=0 the difference between the time stamps of valid and invalid slope is multiplied by 8. The register contains this value.

Generic Timer Module (GTM)

26.16.11.49 Memory DPLL_TOV

Time out value active TRIGGER slope (for missing TRIGGER generation).

GTM_DPLL_TOV

DPLL Time Out Value of active TRIGGER Slope
(28430_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DB	[9:0]	rw	Decision value (fractional part) for missing TRIGGER interrupt
DW	[15:10]	rw	Decision value (integer part) for missing TRIGGER interrupt TOV(15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the timeout time value for a missing trigger event. Note: For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_t_ACT and TOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRT=0: use TBU_TS0 and the estimated time point value unchanged.
Reserved	[23:16]	r	Reserved Must be written as zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)
26.16.11.50 Memory DPLL_TOV_S

Time out value of active STATE slope (for a missing STATE generation).

GTM_DPLL_TOV_S

DPLL Time Out Value of active STATE Slope
(28434_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DB	[9:0]	rw	Decision value (fractional part) for missing STATE interrupt
DW	[15:10]	rw	Decision value (integer part) for missing STATE interrupt TOV_S (15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the timeout time value for a missing STATE event. Note: For the case of LOW_RES=1 (see DPLL_STATUS register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_s_ACT and TOV_S) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRS=0: use TBU_TS0 and the estimated time point value unchanged.
Reserved	[23:16]	r	Reserved Must be written as zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.51 Memory DPLL_ADD_IN_CAL1

Calculated ADD_IN value for SUB_INC1 generation.

GTM_DPLL_ADD_IN_CAL1

DPLL Calculated ADD_IN Value for SUB_INC1 Generation

(28438_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
ADD_IN_CAL_1	[23:0]	rw	Calculated input value for SUB_INC1 generation, calculated by the DPLL calculated value The update of the ADD_IN value by the new calculated value ADD_IN_CAL1 is suppressed for one increment when an unexpected missing TRIGGER (SMC = 1 or RMO = 0) or an unexpected STATE (RMO = 1 and SMC = 0) is detected.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.52 Memory DPLL_ADD_IN_CAL2

Calculated ADD_IN value for SUB_INC2 generation.

GTM_DPLL_ADD_IN_CAL2

DPLL Calculated ADD_IN Value for SUB_INC2 Generation

(2843C_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
ADD_IN_CAL_2	[23:0]	rw	<p>Input value for SUB_INC2 generation, calculated by the DPLL for SMC=RMO=1 calculated value</p> <p>The update of the ADD_IN value by the calculated value ADD_IN_CAL2 is suppressed for one increment when an unexpected missing STATE(RMO = SMC = 1) is detected.</p>
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.53 Memory DPLL_MPVAL1

Missing pluses to be added or subtracted directly.

GTM_DPLL_MPVAL1

DPLL Missing Pulses to be Added/Subtracted Directly to SUB_INC1 and INC_CNT1 Once (28440_H) Reset Value: 00000000_H

Field	Bits	Type	Description
MPVAL1	[15:0]	rw	<p>Missing pulses for direct correction of SUB_INC1 pulses by the CPU (sint16)</p> <p>used only for RMO=0 or SMC=1 for the case PCM1=1. Add MPVAL1 once to INC_CNT1 and reset PCM1 after applying once</p> <p>Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both should not exceed the amount of NT*(MLT+1) or MLS1 respectively.</p>
SIX1	[23:16]	rw	<p>sign extension for MPVAL1</p> <p>0x00 =MPVAL1 is a positive number 0xFF =MPVAL1 is a negative number</p> <p>Note: All bits must be written to either all zeros or all ones.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p> <p>Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both should not exceed the amount of NT*(MLT+1) or MLS1 respectively.</p>

Generic Timer Module (GTM)

26.16.11.54 Memory DPLL_MPVAL2

Missing pulses to be added or subtracted directly.

GTM_DPLL_MPVAL2

DPLL Missing Pulses to be Added/Subtracted Directly to SUB_INC2 and
 INC_CNT2 Once (28444_H) Reset Value: 00000000_H

Field	Bits	Type	Description
MPVAL2	[15:0]	rw	missing pulses for direct correction of SUB_INC2 pulses by the CPU (sint16) used only for SMC=RMO=1 for the case PCM2=1. Add MPVAL2 once to INC_CNT2 and reset PCM2 after applying once Note: Do not provide negative values which exceed the amount of MLS2; when considered negative PD_S values the sum of both should not exceed the amount of MLS2.
SIX2	[23:16]	rw	sign extension for MPVAL2 0x00 =MPVAL2 is a positive number 0xFF =MPVAL2 is a negative number Note: All bits must be written to either all zeros or all ones.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.55 Memory DPLL_NMB_T_TAR

target number of pluses to be sent in normal mode.

GTM_DPLL_NMB_T_TAR

DPLL Target Number of Pulses to be sent in normal mode Register (28448_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
NMB_T_TAR	[15:0]	rw	<p>Target Number of pulses for TRIGGER</p> <p>Calculated number of pulses in normal mode for the current TRIGGER increment without missing pulses. calculated target pulse number</p> <p><i>Note: The LSB address is determined using the SWON_S value in the OSW register (see Chapter 26.16.11.7).</i></p>
Reserved	[23:16]	rw	<p>Reserved</p> <p>Note: must be written to zero.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.56 Memory DPLL_NMB_T_TAR_OLD

Last but one target number of pulses to be sent in normal mode.

GTM_DPLL_NMB_T_TAR_OLD

DPLL Target Number of Pulses to be sent
in normal mode Register (2844C_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
NMB_T_TAR_OLD	[15:0]	rw	<p>Target Number of pulses for TRIGGER</p> <p>Calculated number of pulses in normal mode for the current TRIGGER increment without missing pulses. calculated target pulse number</p> <p><i>Note: The LSB address is determined using the SWON_S value in the OSW register (see Chapter 26.16.11.7).</i></p>
Reserved	[23:16]	rw	<p>Reserved</p> <p>Note: must be written to zero.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.57 Memory DPLL_NMB_S_TAR

Target number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S_TAR
**DPLL Target Number of Pulses to be sent
in emergency mode Register (28450_H)**
Reset Value: 00000000_H

Field	Bits	Type	Description
NMB_S_TAR	[19:0]	rw	Target Number of pulses for STATE Calculated number of pulses in emergency mode for the current STATE increment without missing pulses. calculated target pulse number. <i>Note: The LSB address is determined using the SWON_S value in the OSW register (see Chapter 26.16.11.7).</i>
Reserved	[23:20]	rw	Reserved Note: must be written to zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.58 Memory DPLL_NMB_S_TAR_OLD

Last but one target number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S_TAR_OLD

**DPLL Target Number of Pulses to be sent
in emergency mode Register (28454_H)**

Reset Value: 00000000_H

Field	Bits	Type	Description
NMB_S_TAR_OLD	[19:0]	rw	Target Number of pulses for STATE Calculated number of pulses in emergency mode for the current STATE increment without missing pulses. calculated target pulse number. <i>Note: The LSB address is determined using the SWON_S value in the OSW register (see Chapter 26.16.11.7).</i>
Reserved	[23:20]	rw	Reserved Note: must be written to zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.59 Memory DPLL_RCDT_TX

reciprocal value of the expected increment duration of TRIGGER.

GTM_DPLL_RCDT_TX

DPLL Reciprocal Value of Expected Increment Duration TRIGGER

(28460_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RCDT_TX	[23:0]	rw	Reciprocal value of expected increment duration *2 ³² while only the lower 24 bits are used calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.60 Memory DPLL_RCDT_SX

Reciprocal value of the expected increment duration of STATE.

GTM_DPLL_RCDT_SX

DPLL Reciprocal Value of Expected Increment Duration STATE

(28464_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RCDT_SX	[23:0]	rw	Reciprocal value of expected increment duration *2 ³² while only the lower 24 bits are used calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.61Memory DPLL_RCDT_TX_NOM

Reciprocal value of the expected nominal increment duration of TRIGGER.

GTM_DPLL_RCDT_TX_NOM

DPLL Reciprocal Value of the Expected Nominal Increment Duration TRIGGER
(28468_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
RCDT_TX_NOM	[23:0]	rw	Reciprocal value of nominal increment duration *2 ³² while only the lower 24 bits are used calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.62Memory DPLL_RCDT_SX_NOM

Reciprocal value of the expected nominal increment duration of STATE.

GTM_DPLL_RCDT_SX_NOM

DPLL Reciprocal Value of the Expected Nominal Increment Duration STATE
(2846C_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
RCDT_SX_NOM	[23:0]	rw	Reciprocal value of nominal increment duration *2 ³² while only the lower 24 bits are used calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Note: RCDT_TX_NOM and RCDT_SX_NOM are calculated by the values RCDT_TX and RCDT_SX to be multiplied with SYN_T or SYN_S respectively.

Generic Timer Module (GTM)

26.16.11.63Memory DPLL_RDT_T_ACT

Reciprocal value of the last increment of TRIGGER.

GTM_DPLL_RDT_T_ACT

DPLL Actual Reciprocal Value of TRIGGER

(28470_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RDT_T_A CT	[23:0]	rw	Reciprocal value of last TRIGGER increment *2³² while only the lower 24 bits are used the LSB is rounded up when the next truncated bit is 1. calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF and the CRO bit in the DPLL_STATUS register is set.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.64Memory DPLL_RDT_S_ACT

Reciprocal value of the last increment of STATE.

GTM_DPLL_RDT_S_ACT

DPLL Actual Reciprocal Value of STATE(28474_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
RDT_S_A CT	[23:0]	rw	Reciprocal value of last STATE increment *2³² while only the lower 24 bits are used and the LSB is rounded up when the next truncated bit is 1. calculated value; when an overflow occurs in calculation the value is set to 0xFFFFF and the CRO bit in the DPLL_STATUS register is set.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.65 Memory DPLL_DT_T_ACT

Duration of the last TRIGGER increment.

GTM_DPLL_DT_T_ACT

DPLL Duration of Last TRIGGER Increment (28478_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
DT_T_ACT	[23:0]	rw	Calculated duration of the last TRIGGER increment calculated duration of the last increment; Value will be written into the corresponding RAM field, when all calculations for the considered increment are done and APT is valid.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.66 Memory DPLL_DT_S_ACT

Duration of the last STATE increment.

GTM_DPLL_DT_S_ACT

DPLL Duration of Last STATE Increment
[DT_S_ACT] (2847C_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
DT_S_ACT	[23:0]	rw	Calculated duration of the last STATE increment Calculated increment duration Value will be written into the corresponding RAM field, when all calculations for the considered increment are done and APS is valid.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.67Memory DPLL_EDT_T

Difference of prediction to actual value of the last TRIGGER increment.

GTM_DPLL_EDT_T

DPLL Difference of prediction to actual value of the last TRIGGER increment (28480_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
EDT_T	[23:0]	rw	Signed difference between actual value and a simple prediction of the last TRIGGER increment: sint24 calculated error value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.68Memory DPLL_MEDT_T

Weighted difference of prediction errors of TRIGGER.

GTM_DPLL_MEDT_T

DPLL Weighted difference of Prediction up to the Last TRIGGER Increment (28484_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
MEDT_T	[23:0]	rw	<p>Signed middle weighted difference between actual value and prediction of the last TRIGGER increments: sint24</p> <p>only calculated for SYT=1 calculated medium error value The value is calculated only after synchronization (SYT=1) and the update is suppressed for one increment when an unexpected missing TRIGGER is detected.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.69Memory DPLL_EDT_S

Difference of prediction to actual value of the last STATE increment.

GTM_DPLL_EDT_S

**DPLL Difference of Prediction to actual value
for Last STATE Increment (28488_H)**

Reset Value: 00000000_H

Field	Bits	Type	Description
EDT_S	[23:0]	rw	Signed difference between actual value and prediction of the last STATE increment: sint24 calculated error value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.70Memory DPLL_MEDT_S

Weighted difference of prediction errors of STATE.

GTM_DPLL_MEDT_S

**DPLL Weighted difference of Prediction up to the Last STATE Increment
(2848C_H)**

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
MEDT_S	[23:0]	rw	<p>Signed middle weighted difference between actual value and prediction of the last STATE increments: sint24</p> <p>only calculated for SYS=1 calculated medium error value The value is calculated only after synchronization (SYS=1) and the update is suppressed for one increment when an unexpected missing STATE is detected.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.71 Memory DPLL_CDT_TX

Prediction of the actual TRIGGER duration.

GTM_DPLL_CDT_TX

DPLL Prediction of the actual TRIGGER Increment
(28490_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CDT_TX	[23:0]	rw	Calculated duration of the current TRIGGER increment calculated value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.72 Memory DPLL_CDT_SX

Prediction of the actual STATE increment duration.

GTM_DPLL_CDT_SX

DPLL Prediction of the actual STATE Increment
(28494_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CDT_SX	[23:0]	rw	Calculated duration of the current STATE increment calculated value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.73 Memory DPLL_CDT_TX_NOM

Prediction of the nominal TRIGGER increment duration.

GTM_DPLL_CDT_TX_NOM

DPLL Prediction of the nominal TRIGGER Increment duration

(28498_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CDT_TX_NOM	[23:0]	rw	Calculated duration of the current nominal TRIGGER event calculated value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.74 Memory DPLL_CDT_SX_NOM

Prediction of the nominal STATE increment duration.

GTM_DPLL_CDT_SX_NOM

DPLL Prediction of the nominal STATE increment duration

(2849C_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CDT_SX_NOM	[23:0]	rw	Calculated duration of the current t nominal STATE event calculated value
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.75 Memory DPLL_TLR

TRIGGER locking range.

GTM_DPLL_TLR

DPLL TRIGGER locking range (284A0_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
TLR	[7:0]	rw	Value is to be multiplied with the last nominal TRIGGER duration in order to get the range for the next TRIGGER event without setting TOR in the DPLL_STATUS register multiply value with the last nominal increment duration and check violation; when TLR=0 don't perform the check
Reserved	[31:8]	r	Reserved Read as zero, should be written as zero.

26.16.11.76 Memory DPLL_SLR

STATE locking range.

GTM_DPLL_SLR

DPLL STATE Locking Range (284A4_H) **Reset Value: 00000000_H**

Generic Timer Module (GTM)

Field	Bits	Type	Description
SLR	[7:0]	rw	<p>Value is to be multiplied with the last nominal STATE duration in order to get the range for the next STATE event without setting SOR in the DPLL_STATUS register</p> <p>multiply value with the last nominal increment duration and check violation; when SLR=0 don't perform the check</p>
Reserved	[31:8]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.77 Memory DPLL_PDT[i]

Projected increment sum relations for action i.

GTM_DPLL_PDT_Ti (i=0-23)

DPLL Projected TRIGGER Increment Sum Relations for Action_i

$$(28500_H + i * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
DB	[13:0]	rw	Fractional part of relation between TRIGGER or STATE increments
DW	[23:14]	rw	Integer part of relation between TRIGGER or STATE increments Definition of relation values between TRIGGER or STATE increments PDT[i] according to Equation DPLL-11 or DPLL-13.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.78 Memory DPLL_MLS1

Calculated number of sub-pulses between two STATE events for SMC=0.

GTM_DPLL_MLS1

DPLL Calculated Number of Sub-Pulses between Two STATE Events

(285C0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
MLS1	[17:0]	rw	<p>Number of pulses between two STATE events (to be set and updated by the CPU)</p> <p>For SMC=0 the value of MLS1 is calculated once by the CPU for fixed values in the DPLL_CTRL_0 register by the formula $MLS1 = ((MLT+1)*(TNU+1)/(SNU+1))$ and set accordingly</p> <p>FOR SMC=1 the value of MLS1 represents the number of pulses between two TRIGGER events (to be set and updated by the CPU)</p>
Reserved	[31:18]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.79 Memory DPLL_MLS2

Calculated number of sub-pulses between two STATE events for SMC=1 and RMO=1.

GTM_DPLL_MLS2

DPLL Calculated Number of Sub-Pulses between Two STATE Events

(285C4_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
MLS2	[17:0]	rw	Counter for number of SUB_INC2 pulses Number of pulses between two STATE events (to be set and updated by the CPU). Using adapt information and the missing STATE event information SYN_S, this value can be corrected for each increment automatically.
Reserved	[31:18]	r	Reserved Read as zero, should be written as zero.

26.16.11.80 Memory DPLL_CNT_NUM1

GTM_DPLL_CNT_NUM1

DPLL Number of Sub-Pulses of SUB_INC1 in Continuous Mode

(285C8_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CNT_NUM_1	[23:0]	rw	Counter for number of SUB_INC1 pulses Number of pulses in continuous mode for a nominal increment in normal and emergency mode for SUB_INC1 given and updated by CPU only count value for continuous mode
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.81 Memory DPLL_CNT_NUM2

GTM_DPLL_CNT_NUM2

DPLL Number of Sub-Pulses of SUB_INC2 in Continuous Mode

(285CC_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CNT_NUM_2	[23:0]	rw	Counter for number of SUB_INC2 pulses Number of pulses in continuous mode for a nominal increment in normal and emergency mode for SUB_INC2, given and updated by CPU only count value for continuous mode
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.82 Memory DPLL_PVT

Plausibility value of next TRIGGER slope.

GTM_DPLL_PVT

DPLL Plausibility Value of Next Active TRIGGER Slope

(285D0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PVT	[23:0]	rw	<p>Plausibility value of next valid TRIGGER slope</p> <p>The meaning of the value depends on the value of the PIT value in the DPLL_CTRL_1 register.</p> <p>For PIT=0: the number of SUB_INC1 pulses to be waited for until a next valid TRIGGER event is accepted.</p> <p>For PIT=1: PVT is to be multiplied with the last nominal increment time DT_T_ACT and divided by 1024 and reduced to a 24 bit value in order to get the time to be waited for until the next valid TRIGGER event is accepted. The wait time must be exceeded for a valid slope.</p> <p>Note: When a valid TRIGGER slope is detected while the wait condition is not fulfilled the interrupt PWI is generated. Please note, that the SGE1 must be set, when PIT=0 in order to provide the necessary SUB_INC1 pulses for checking.</p> <p>After an unexpected missing TRIGGER the plausibility check is suppressed for the following increment.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.83 Memory DPLL_PSTC

Actual calculated position stamp of TRIGGER.

GTM_DPLL_PSTC

DPLL Actual Calculated Position Stamp of Last TRIGGER Input

(285E0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSTC	[23:0]	rw	<p>Calculated position stamp of last TRIGGER input value is set by the DPLL and can be updated by the CPU when filter values are to be considered for the exact position (see DPLL_STATUS and DPLL_CTRL registers for explanation of the status and control bits used); For each valid slope of TRIGGER in normal and emergency mode</p> <ul style="list-style-type: none"> • when FTD=0: PSTC is set from actual position value, for the first valid TRIGGER event (no filter delay considered) the CPU must update the value once, taking into account the filter value • when FTD=1: PSTC is increment at each TRIGGER event by • SMC=0: (MLT+1)*(SYN_T) +PD; while PD=0 for AMT=0 • SMC=1: (MLS1)*(SYN_T) +PD; while PD=0 for AMT=0
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.84 Memory DPLL_PSSC

Actual calculated position stamp of STATE.

GTM_DPLL_PSSC

DPLL Accurate Calculated Position Stamp of Last STATE Input

(285E4_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSSC	[23:0]	rw	<p>Calculated position stamp for the last STATE input first value is set by the DPLL and can be updated by the CPU when the filter delay is to be considered. For each valid slope of STATE in normal and emergency mode</p> <ul style="list-style-type: none"> when FSD=0: PSSC is set from actual position value (no filter delay considered), the CPU must update the value once, taking into account the filter value when FSD=1: at each valid slope of STATE (PD_S_store=0 for AMS=0): SMC=0: add $MLS1 * (SYN_S) + PD_S_store$; SMC=1: add $MLS2 * (SYN_S) + PD_S_store$;
Reserved	[31:24]	r	<p>Reserved Read as zero, should be written as zero.</p>

Generic Timer Module (GTM)

26.16.11.85 Memory DPLL_PSTM

Measured position stamp at last TRIGGER input.

GTM_DPLL_PSTM_0

DPLL Measured Position Stamp of Last TRIGGER Input

(285E8_H)

Reset Value: 00000000_H

GTM_DPLL_PSTM_1

DPLL Measured Position Stamp of Last TRIGGER Input

(285EC_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSTM	[23:0]	rw	Position stamp of TRIGGER, measured Measured position stamp of last TRIGGER input, measured at processing the input signal. Store the value TBU_TS1 at the moment when T_VALID is set in an intermediate register, but transmit this value to PSTM only, when the plausibility value (according to PVT) is passed.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Note: The LSB address is determined using the SWON_T value in the OSW register (see [Section 26.16.11.7](#)).

Generic Timer Module (GTM)

26.16.11.86 Memory DPLL_PSTM_OLD

Measured position stamp at last but one TRIGGER input.

GTM_DPLL_PSTM_OLD_0

DPLL Measured Position Stamp of Last But One TRIGGER Input

(285EC_H)

Reset Value: 00000000_H

GTM_DPLL_PSTM_OLD_1

DPLL Measured Position Stamp of Last But One TRIGGER Input

(285E8_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSTM_OL D	[23:0]	rw	Last but one position stamp of TRIGGER, measured Measured position stamp of last but one TRIGGER input, measured at processing the input signal. (because of the input and transmission delay the value of PSTM_OLD can be higher than the exact value PSTC_OLD)
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Note: The LSB address is determined using the SWON_T value in the OSW register (see [Section 26.16.11.7](#)).

26.16.11.87 Memory DPLL_PSSM

Measured position stamp at last STATE input.

GTM_DPLL_PSSM_0

DPLL Measured Position Stamp of Last STATE Input
(285F0_H)

Reset Value: 00000000_H

GTM_DPLL_PSSM_1

DPLL Measured Position Stamp of Last STATE Input
(285F4_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSSM	[23:0]	rw	Position stamp of STATE, measured Measured position stamp of last STATE input, measured at processing the input signal. Store the value TBU_TS1 or TBU_TS2 respectively at the moment when S_VALID is set in PSSM.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Note: The LSB address is determined using the SWON_S value in the OSW register (see [Section 26.16.11.7](#)).

Generic Timer Module (GTM)

26.16.11.88 Memory DPLL_PSSM_OLD

Measured position stamp at last but one STATE.

GTM_DPLL_PSSM_OLD_0

DPLL Measured Position Stamp of Last But One STATE Input

(285F4_H)

Reset Value: 00000000_H

GTM_DPLL_PSSM_OLD_1

DPLL Measured Position Stamp of Last But One STATE Input

(285F0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
PSSM_OLD	[23:0]	rw	Last but one position stamp of STATE, measured Measured position stamp of last but one STATE input, measured at processing the input signal. (because of the input and transmission delay the value of PSSM_OLD can be higher than the exact value PSSC_OLD).
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Note: The LSB address is determined using the SWON_S value in the OSW register (see [Section 26.16.11.7](#)).

Generic Timer Module (GTM)

26.16.11.89 Memory DPLL_NMB_T

Number of pulses to be sent in normal mode.

GTM_DPLL_NMB_T

DPLL Number of Pulses of Current Increment in Normal Mode

(285F8_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
NMB_T	[15:0]	rw	Number of pulses for TRIGGER Calculated number of pulses in normal mode for the current TRIGGER increment. calculated pulse number
Reserved	[23:16]	rw	Reserved Must be written as zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.90 Memory DPLL_NMB_S

Number of pulses to be sent in emergency mode.

GTM_DPLL_NMB_S

DPLL Number of Pulses of Current Increment in Emergency Mode

(285FC_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
NMB_S	[19:0]	rw	Number of pulses for STATE Calculated number of pulses in emergency mode for the current STATE increment. calculated pulse number
Reserved	[23:20]	rw	Reserved Must be written as zero.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.91Memory DPLL_RDT_Sx

Reciprocal values of normal STATE increment durations in FULL_SCALE.

GTM_DPLL_RDT_Sx (x=0-63)
DPLL Nominal STATE x Reciprocal Values in FULL_SCALE

$$(28600_H + x * 04_H) \quad \text{Reset Value: } 00000000_H$$

Field	Bits	Type	Description
RDT_S	[23:0]	rw	Reciprocal difference time of TRIGGER Nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment $*2^{32}$ while only the lower 24 bits are used; no gap considered. The LSB is rounded up when the next truncated bit is 1. Note: There are $2*(SNU+1)-SYN_NS$ entries for $SYSF=0$ or $2*(SNU+1)-SYN_NS$ entries for $SYSF=1$ respectively.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.92Memory DPLL_TSF_S[i]

Time stamp of normal STATE events in FULL_SCALE.

GTM_DPLL_TSF_Sx (x=0-63)

DPLL Time Stamp Field of STATE x Events

$$(28700_H + x * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
TSF_S	[23:0]	rw	Time stamp field of STATE Time stamp value of each valid STATE event. Note: There are 2* (SNU+1) entries.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.93Memory DPLL_ADT_S[i]

Adapt and profile values of the STATE increments in FULL_SCALE

GTM_DPLL_ADT_Sx (x=0-63)

DPLL Adapt Values for All STATE x Increments

$$(28800_H + x * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
PD_S	[15:0]	rw	Physical deviation of STATE Adapt values for each STATE increment in FULL_SCALE (sint16); This value represents the number of pulses to be added to the correspondent increment.

Generic Timer Module (GTM)

Field	Bits	Type	Description
NS	[21:16]	rw	Number of STATES number of nominal STATE parts in the corresponding increment. Note: There are 2* (SNU+1-SYN_NS) entries.
Reserved	[31:22]	r	Reserved Read as zero, should be written as zero.

26.16.11.94Memory DPLL_DT_S[i]

Nominal STATE increment durations in FULL_SCALE.

GTM_DPLL_DT_Sx (x=0-63)

DPLL Nominal STATE x Increment Values for FULL_SCALE

$$(28900_H + x * 04_H) \quad \text{Reset Value: } 00000000_H$$

Field	Bits	Type	Description
DT_S	[23:0]	rw	Difference time of STATE nominal increment duration values for each STATE increment in FULL_SCALE (considering no gap). Note: There are 2* (SNU+1-SYN_NS) entries.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

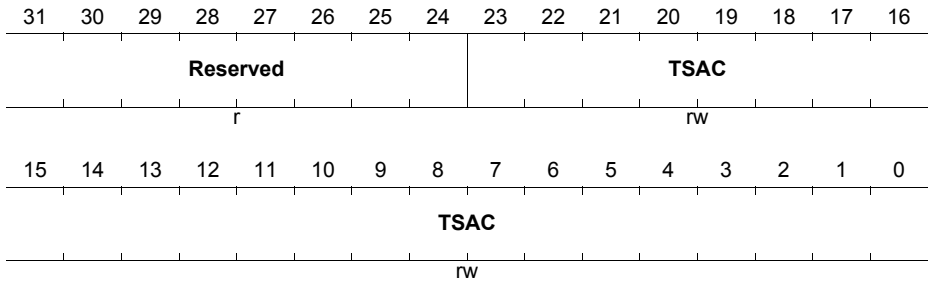

Generic Timer Module (GTM)

26.16.11.95 Memory DPLL_TSAC[i]

Calculated time value to start action i.

GTM_DPLL_TSACi (i=0-23)

DPLL Calculate Time Stamp Register(28E00_H + i * 04_H) Reset Value: 007FFFFF_H

Field	Bits	Type	Description
TSAC	[23:0]	rw	calculated time stamp for ACTION_i Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.96 Memory DPLL_PSAC[i]

Calculated position to start action i.

GTM_DPLL_PSACi (i=0-23)

DPLL Calculated Position Value Register

$$(28E80_H + i * 04_H)$$

Reset Value: 007FFFFFFH

Field	Bits	Type	Description
PSAC	[23:0]	rw	calculated position value for the start of ACTION_i in normal or emergency mode according to equations DPLL-17 or DPLL-20 respectively Note: This value can only be written when the DPLL is disabled.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.97 Memory DPLL_ACBi

Control bits for actions.

GTM_DPLL_ACBi (i=0-5)
DPLL Action Control i Register (28F00_H + i * 04_H)
Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved			ACB_1				Reserved			ACB_0					
r			rw				r			rw					

Field	Bits	Type	Description
ACB_0	[4:0]	rw	Action Control Bits of ACTION_j reflects ACT_D[j](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[7:5]	r	Reserved Read as zero, should be written as zero.
ACB_1	[12:8]	rw	Action Control Bits of ACTION_(j + 1) reflects ACT_D[j+1](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[15:13]	r	Reserved Read as zero, should be written as zero.
ACB_2	[20:16]	rw	Action Control Bits of ACTION_(j + 2) reflects ACT_D[j+2](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.
Reserved	[23:21]	r	Reserved Read as zero, should be written as zero.
ACB_3	[28:24]	rw	Action Control Bits of ACTION_(j + 3) reflects ACT_D[j+3](52:48), j=4*i Note: This value can only be written when the DPLL is disabled.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)
26.16.11.98 Memory DPLL_RDT_T[i]

Reciprocal values of the nominal TRIGGER increment durations in FULL_SCALE.

DPLL_RDT_T_x (x=0-511)

DPLL TRIGGER x Nominal Increment Reciprocals in FULL_SCALE

(AOSV_2A + x * 04_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RDT_T	[23:0]	rw	Reciprocal difference time of TRIGGER 2* (TNU+1- SYN_NT) stored values nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment (which is divided by the number of nominal increments); multiplied by 2 ³² while only the lower 24 bits are used; the LSB is rounded up, when the next truncated bit is 1. Note: There are 2* (TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

26.16.11.99 Memory DPLL_TSF_T[i]

Time stamp values of the nominal TRIGGER increments in FULL_SCALE.

DPLL_TSF_T_x (x=0-511)

DPLL Time Stamp Field of TRIGGER x Events

(AOSV_2B + x * 04_H)

Reset Value: 00000000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
TSF_T	[23:0]	rw	Time stamp field of valid TRIGGER slopes Note: There are 2^* (TNU+1) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero.

Generic Timer Module (GTM)

26.16.11.100 Memory DPLL_ADT_T[i]

Adapt and profile values of the TRIGGER increments in FULL_SCALE.

DPLL_ADT_Tx (x=0-511)

DPLL Adapt Value x for All Increments

$$(AOSV_2C + x * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
PD	[12:0]	rw	Physical deviation Adapt values for each TRIGGER increment in FULL_SCALE (sint13); the PD value does mean the number of SUB_INC1 pulses to be added to NT*(MLT+1); the absolute value of a negative PD must not exceed nt*(MLT+1) or MLS1 respectively; systematic missing TRIGGER events must not be considered for the value of PD;
TINT	[15:13]	rw	TRIGGER Interrupt information depending on the value up to 7 different interrupts can be generated. In the current version the 5 interrupts TE0_IRQ ... TE4_IRQ are supported by TINT="001", "010", "011", "100", "101" respectively. For the values "000", "110" and "111" no interrupt is generated and no other reaction is performed. The corresponding interrupt is activated, when the TINT value is read by the DPLL together with the other values (PD, NT) according to the profile.
NT	[18:16]	rw	Number of TRIGGERS number of nominal TRIGGER parts in the corresponding increment. Note: There are 2* (TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
Reserved	[31:19]	r	Reserved Read as zero, should be written as zero.

26.16.11.101 Memory DPLL_DT_T[i]

Nominal TRIGGER increment durations in FULL_SCALE.

DPLL_DT_Tx (x=0-511)

DPLL Nominal TRIGGER Increment Values for FULL_SCALE

$$(AOSV_2D + x * 04_H)$$

Reset Value: 00000000_H

Field	Bits	Type	Description
DT_T	[23:0]	rw	<p>Difference time of TRIGGER</p> <p>Increment duration values for each TRIGGER increment in FULL_SCALE divided by the number of nominal increments (nominal value).</p> <p>Note: There are 2*(TNU+1- SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero.</p>

26.16.12 Terms and Abbreviations

The following terms and abbreviations are used for DPLL:

- FULL_SCALE; Range in which all positions / values depend on the information of TRIGGER and STATE signals
- HALF_SCALE; Range in which all positions / values depend on the information of TRIGGER signal only, two consecutive HALF_SCALE periods from a FULL_SCALE period
- TS; Time stamp representation
- PS; Position (or value) stamp representation, common description

26.17 Sensor Pattern Evaluation (SPE)

26.17.1 Overview

The Sensor Pattern Evaluation (SPE) submodule can be used to evaluate three hall sensor inputs and together with the TOM module to support the drive of BLDC engines. Thus, the input signals are filtered already in the connected TIM channels. In addition, the SPE submodule can be used as an input stage to the MAP submodule if the DPLL should be used to calculate the rotation speed of one or two electric engine(s). The integration of the SPE submodule into the overall GTM architecture concept is shown in [Figure 26-77](#).

26.17.1.1 SPE Submodule integration concept into GTM

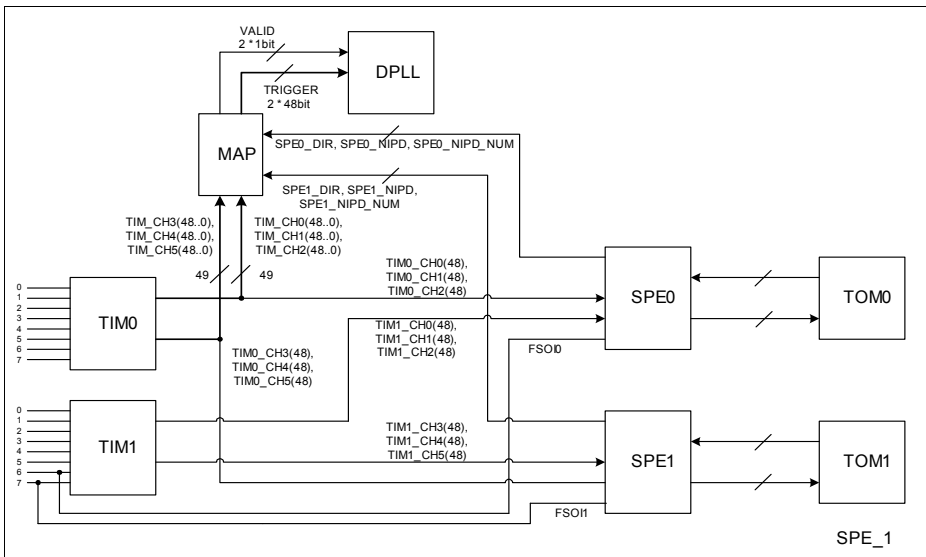

Figure 26-77 SPE integration

As mentioned above, the SPE submodule can determine a rotation direction out of the combined TIM[i]_CHx(48), TIM[i]_CHy(48) and TIM[i]_CHz(48) signals. On this input signals a pattern matching algorithm is applied to generate the SPE_x_DIR signal on behalf of the temporal relation between these input patterns. A possible sample pattern of the three input signals is shown in [Figure 26-78](#). In general, the input pattern is programmable within the SPE submodule.

26.17.1.2 SPE Sample input pattern for

Figure 26-78 SPE sample input pattern

In **Figure 26-78** the input signals define the pattern from the input sensors which have a 50% high and 50% low phase. The pattern according to **Figure 26-79** is as follows:

100 – 110 – 010 – 011 – 001 – 101 – 100

where the first bit (smallest circle) represents $TIM[i]_{CH}[x](48)$, the second bit represents $TIM[i]_{CH}[y](48)$, and the third bit (greatest circle) represents $TIM[i]_{CH}[z](48)$.

Note that the SPE module expects that with every new pattern only one of the three input signals changes its value.

26.17.2 SPE Submodule description

The SPE submodule can handle sensor pattern inputs. Every time if one of the input signals $TIM[i]_{CH}[x](48)$, $TIM[i]_{CH}[y](48)$ or $TIM[i]_{CH}[z](48)$ changes its value, a sample of all three input signals is made. Derived from the sample of the three inputs the encoded rotation direction and the validity of the input pattern sequence can be detected and signalled. When a valid input pattern is detected, the SPE submodule can control the outputs of a dedicated connected TOM submodule. This connection is shown in **Figure 26-79**.

26.17.2.1 SPE to TOM Connections

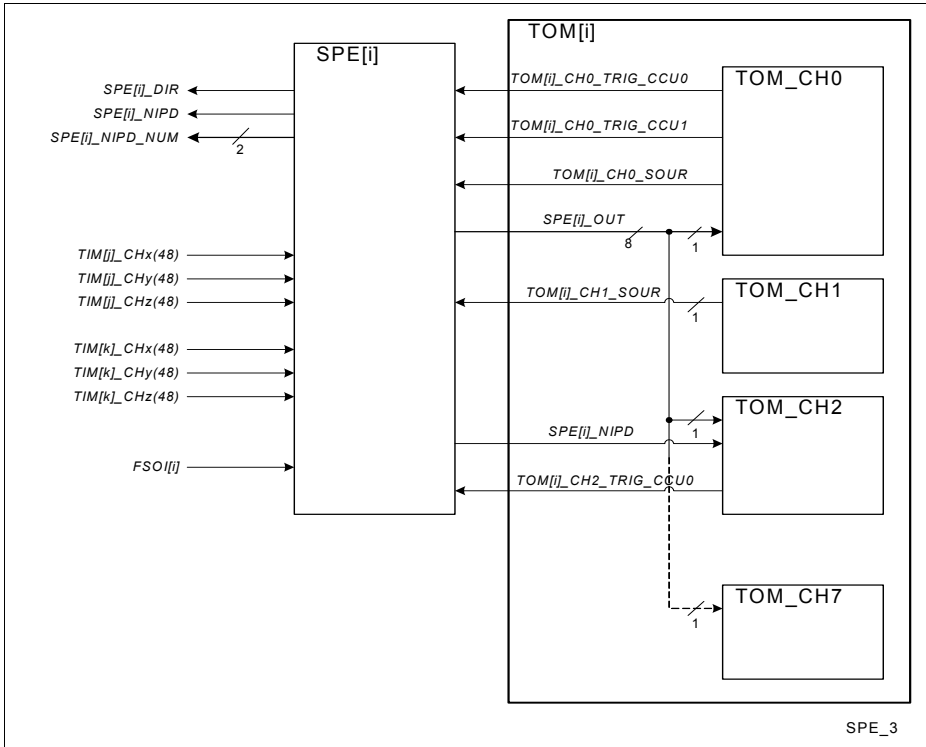

Figure 26-79 SPE to TOM Connections

The TOM[i]_CH0_TRIG_CCU[x] and TOM[i]_CH[x]_SOUR signal lines are used to evaluate the current state of the TOM outputs, whereas the SPE[i]_OUT output vector is used to control the TOM output depending on the new input pattern. The SPE[i]_OUT output vector is defined inside the SPE submodule in a pattern definition table SPEi_OUT_PATx. The internal SPE submodule architecture is shown in [Figure 26-80](#).

26.17.2.2 SPE Submodule architecture

Generic Timer Module (GTM)

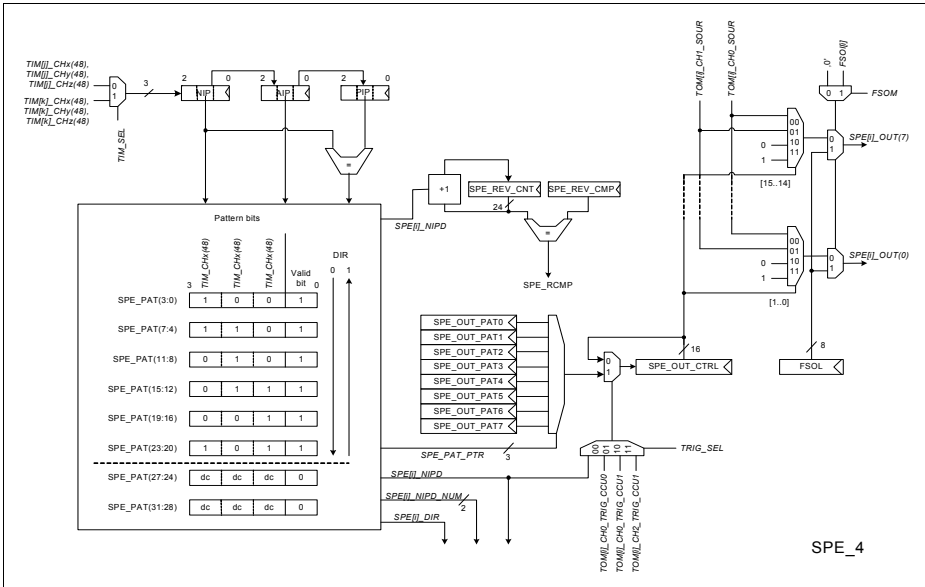

Figure 26-80 SPE Submodule architecture

The SPE_i_PAT register holds the valid input pattern for the three input patterns TIM[i]_CH[x](48), TIM[i]_CH[y](48) and TIM[i]_CH[z](48). The input pattern is programmable. The valid bit shows if the programmed pattern is a valid one. **Figure 26-80** shows the programming of the SPE_i_PAT register for the input pattern defined in **Figure 26-79**.

The rotation direction is determined by the order of the valid input pattern. This rotation direction defines if the SPE_PAT_PTR is incremented (DIR = 0) or decremented (DIR = 1). Whenever a valid input pattern is detected, the NIPD signal is raised, the SPE_PAT_PTR is increment/decremented and a new output control signal SPE_i_OUT(x) is sent to the corresponding TOM submodule.

The TOM[i]_CH2 with i=0...3 can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register after new input pattern detected by SPE (signalled by SPE_i_NIPD).

To do this, the TOM[i]_CH2 has to be configured to work in one-shot mode (set bit OSM in register TOM[i]_CH2_CTRL). The SPE mode of this channel has to be enabled, too (set bit SPEM in register TOM[i]_CH2_CTRL). The SPE module has to be configured to update SPE_OUT_CTRL on TOM[i]_CH2_TRIG_CCUI (set in SPE_i_CTRL_STAT bits TRIG_SEL to '11'). Then, on new input detected by SPE, the signal SPE_i_NIPD triggers the start of the TOM channel 2 to generates one PWM period by resetting CN0 to 0. On

Generic Timer Module (GTM)

second PWM edge triggered by CCU1 of TOM channel 2, the signal TOM[i]_CH2_TRIG_CCU1 triggers the update of SPE_OUT_CTRL.

According to [Figure 26-80](#), the two input patterns "000" and "111" are not allowed combinations and will end in a SPE[i]_PERR interrupt. These two patterns can be used to determine a sensor input error. A SPE[i]_PERR interrupt will also be raised, if the input patterns occur in a wrong order, e.g. if the pattern "010" does not follow the pattern "110" or "011".

The register SPE[i]_IN_PAT bit field inside the SPEi_CTRL_STAT register is implemented, where the input pattern history is stored by the SPE submodule. The CPU can determine a broken sensor when the SPE[i]_PERR interrupt occurs by analyzing the bit pattern NIP inside the SPEi_CTRL_STAT register. The input pattern in the SPEi_CTRL_STAT register is updated whenever a valid edge is detected on one of the input lines TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48). The pattern bit fields are then shifted. The input pattern history generation inside the SPEi_CTRL_STAT register is shown in [Figure 26-81](#).

Additionally to the sensor pattern evaluation the SPE module also provides the feature of fast shut-off for all TOM channels controlled by the SPE module. The feature is enabled by setting bit FSOM in register SPEi_CTRL_STAT. The fast shut-off level itself is defined in the bit field FSOL of register SPEi_CTRL_STAT. The TIM input used to trigger the fast shut-off is either TIM channel 6 or TIM channel 7 depending on the TIM instance connected to the SPE module. For details of connections please refer to [Figure 26-77](#).

26.17.2.3 SPE[i]_IN_PAT register representation

Figure 26-81 Register SPE_IN_PAT implementation

The CPU can disable one of the three input signals, e.g. when a broken input sensor was detected, by disabling the input with the three input enable bits SIE inside the SPE_i_CTRL_STAT register.

Whenever at least one of the input signal TIM_[i]_CH_[x](48), TIM_[i]_CH_[y](48) or TIM_[i]_CH_[z](48) changes the SPE submodule stores the new bit pattern in an internal register NIP (New Input Pattern). If the current input pattern in NIP is the same as in the Previous Input Pattern (PIP) the direction of the engine changed, the SPE_[i]_DCHG interrupt is raised, the direction change is stored internally and the pattern in the PIP bit field is filled with the AIP bit field and the AIP bit field is filled with the NIP bit field. The SPE_[i]_DIR bit inside the SPE_i_CTRL_STAT register is toggled and the SPE_[i]_DIR signal is changed.

If the SPE encounters that with the next input pattern detected new input pattern NIP the direction change again, the input signal is categorized as bouncing and the bouncing input signal interrupt SPE_[i]_BIS is raised.

Immediately after update of register NIP, when the new detected input pattern doesn't match the PIP pattern (i.e. no direction change was detected), the SPE shifts the value of register AIP to register PIP and the value of register NIP to register AIP. The SPE_[i]_NIPD interrupt is raised.

The number of the channel that has been changed and thus leads to the new input pattern is encoded in the signal SPE_[i]_NIPD_NUM.

Generic Timer Module (GTM)

If a sensor error was detected, the CPU has to define upon the pattern in the SPE_i_CTRL_STAT register, which input line comes from the broken sensor. The faulty signal line has to be masked by the CPU and the SPE submodule determines the rotation direction on behalf of the two remaining TIM_[i]_CH_[x] input lines.

The pattern history can be determined by the CPU by reading the two bit fields AIP and PIP of the SPE_i_CTRL_STAT register. The AIP register field holds the actual detected input pattern at TIM_[i]_CH_[x](48), TIM_[i]_CH_[y](48) and TIM_[i]_CH_[z](48) and the PIP holds the previous detected pattern.

After reset the register NIP, AIP and PIP as well as the register SPE_i_PAT_PTR and SPE_i_OUT_CTRL will not contain valid startup values which would allow correct behaviour after enabling SPE and detecting the first input patterns.

Thus, it is necessary to initialize these register to correct values.

To do this, before enabling the SPE, the bit field NIP of register SPE_i_CTRL_STAT can be read and depending on this value the initialization values for the register AIP, PIP, SPT_PAT_PTR and SPE_i_OUT_CTRL can be determined.

26.17.2.4 SPE Revolution detection

The SPE submodule is able to detect and count the number of valid input patterns detected at the specified input ports. This is done with a 24bit revolution counter SPE_CNT. The counter is incremented by a value of one (1) when a new valid input pattern indicating forward direction is detected. The counter is decremented by a value of one (1) when a new valid input pattern indicating backward direction is detected.

In addition there exists a 24 bit SPE_CMP register. The user can initialize this register with a compare value, where an interrupt SPE_i_RCMP is raised, when the revolution counter equals the compare value either in forward or backward direction.

Both register may be written by software at any time.

26.17.3 SPE Interrupt signals

The following table describes SPE interrupt signals:

Table 26-54 SPE Interrupt signals

Signal	Description
SPE _[i] _NIPD	SPE New valid input pattern detected.
SPE _[i] _DCHG	SPE Rotation direction change detected on behalf of input pattern.
SPE _[i] _PERR	SPE Invalid input pattern detected.
SPE _[i] _BIS	SPE Bouncing input signal detected at input.

26.17.4 SPE Register overview

The following table shows an overview about the SPE register set.

Table 26-55 SPE Register overview

Register name	Description	Details in Section
SPEi_CTRL_STAT	SPE Control status register	Section 26.17.5.1
SPEi_PAT	SPE Input pattern definition register	Section 26.17.5.2
SPEi_OUT_PATx	SPE Output definition registers. (x: 07)	Section 26.17.5.3
SPEi_OUT_CTRL	SPE output control register	Section 26.17.5.4
SPEi_CNT	SPE input revolution counter	Section 26.17.5.5
SPEi_CMP	SPE revolution counter compare value	Section 26.17.5.6
SPEi_IRQ_NOTIFY	SPE Interrupt notification register	Section 26.17.5.7
SPEi_IRQ_EN	SPE Interrupt enable register	Section 26.17.5.8
SPEi_EIRQ_EN	SPE Error interrupt enable register.	Section 26.17.5.11
SPEi_IRQ_FORCINT	SPE Interrupt generation by software	Section 26.17.5.9
SPEi_IRQ_MODE	IRQ mode configuration register	Section 26.17.5.10

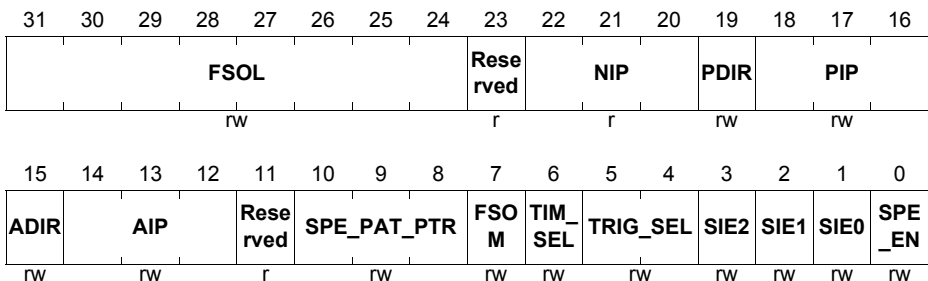

26.17.5 SPE Register description

All of the following registers are 32-bit only accessible.

26.17.5.1 Register SPEi_CTRL_STAT

GTM_SPEi_CTRL_STAT (i=0-1)

SPEi Control Status Register (00800_H+i*80_H) **Reset Value: 00000000_H**

Generic Timer Module (GTM)

Field	Bits	Type	Description
SPE_EN	0	rw	SPE Submodule enable 0 _B SPE disabled. 1 _B SPE enabled.
SIE0	1	rw	SPE Input enable for TIM_CHx(48) 0 _B SPE Input is disabled. 1 _B SPE Input is enabled. Note: When the input is disabled, a '0' signal is sampled for this input. However, the bit field NIP of this register shows the true value of the input signal.
SIE1	2	rw	SPE Input enable for TIM_CHy(48) See bit 1.
SIE2	3	rw	SPE Input enable for TIM_CHz(48) See bit 1.
TRIG_SEL	[5:4]	rw	Select trigger input signal 00 _B SPE[i]_NIPD selected. 01 _B TOM_CH0_TRIG_CCU0 selected. 10 _B TOM_CH0_TRIG_CCU1 selected. 11 _B TOM_CH2_TRIG_CCU1 selected.
TIM_SEL	6	rw	select TIM input signal SPE0: 0 = TIM0_CH0...2 1 = TIM1_CH0...2 SPE1: 0 = TIM0_CH3...5 1 = TIM1_CH3...5 SPE2: 0 = TIM2_CH0...2 1 = unused SPE3: 0 = TIM2_CH3...5 1 = unused
FSOM	7	rw	Fast Shut-Off Mode 0 _B Fast Shut-Off mode disabled 1 _B Fast Shut-Off mode enabled

Generic Timer Module (GTM)

Field	Bits	Type	Description
SPE_PAT_PTR	[10:8]	rw	Pattern selector for TOM output signals Actual index into the SPE _i _OUT_PAT _x register table. Each register SPE _i _OUT_PAT _x is fixed assigned to one bit field IP _x _PAT of register SPE _i _PAT. Thus, the pointer SPE _i _PAT_PTR represents an index to the selected SPE _i _OUT_PAT _x register as well as the actual detected input pattern IP _x _PAT. 000 _B SPE _[i] _OUT_PAT ₀ selected
Reserved	11	r	Reserved Read as zero, should be written as zero
AIP	[14:12]	rw	Actual input pattern that was detected by a regular input pattern change
ADIR	15	rw	Actual rotation direction 0 _B Rotation direction is 0 according to SPE _i _PAT register. 1 _B Rotation direction is 1 according to SPE _i _PAT register.
PIP	[18:16]	rw	Previous input pattern that was detected by a regular input pattern change
PDIR	19	rw	Previous rotation direction 0 _B Rotation direction is 0 according to SPE _i _PAT register. 1 _B Rotation direction is 1 according to SPE _i _PAT register.
NIP	[22:20]	r	New input pattern that was detected Note: This bit field mirrors the new input pattern. SPE internal functionality is triggered on each change of this bit field.
Reserved	23	r	Reserved Read as zero, should be written as zero
FSOL	[31:24]	rw	Fast Shut-Off Level for TOM_[i] channel 0 to 7

26.17.5.2 Register SPE_i_PAT

 GTM_SPE_i_PAT (i=0-1)

 SPE_i Input Pattern Definition Register

 (804_H+i*80_H)

 Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IP7_PAT			IP7_VAL	IP6_PAT			IP6_VAL	IP5_PAT			IP5_VAL	IP4_PAT			IP4_VAL
rw			rw	rw			rw	rw			rw	rw			rw

rw			rw	rw			rw	rw			rw	rw			rw

Field	Bits	Type	Description
IP0_VAL	0	rw	Input pattern 0 is a valid pattern 0 _B Pattern invalid. 1 _B Pattern valid.
IP0_PAT	[3:1]	rw	Input pattern 0 Bit field defines the first input pattern of the SPE input signals. Bit 1 defines the TIM[i]_CHx(48) input signal. Bit 2 defines the TIM[i]_CHy(48) input signal. Bit 3 defines the TIM[i]_CHz(48) input signal.
IP1_VAL	4	rw	Input pattern 1 is a valid pattern See bit 0.
IP1_PAT	[7:5]	rw	Input pattern 1 See bits 3:1.
IP2_VAL	8	rw	Input pattern 2 is a valid pattern See bit 0.
IP2_PAT	[11:9]	rw	Input pattern 2 See bits 3:1.
IP3_VAL	12	rw	Input pattern 3 is a valid pattern See bit 0.
IP3_PAT	[15:13]	rw	Input pattern 3 See bits 3:1.

Generic Timer Module (GTM)

Field	Bits	Type	Description
IP4_VAL	16	rw	Input pattern 4 is a valid pattern See bit 0.
IP4_PAT	[19:17]	rw	Input pattern 4 See bits 3:1.
IP5_VAL	20	rw	Input pattern 5 is a valid pattern See bit 0.
IP5_PAT	[23:21]	rw	Input pattern 5 See bits 3:1.
IP6_VAL	24	rw	Input pattern 6 is a valid pattern See bit 0.
IP6_PAT	[27:25]	rw	Input pattern 6 See bits 3:1.
IP7_VAL	28	rw	Input pattern 7 is a valid pattern See bit 0.
IP7_PAT	[31:29]	rw	Input pattern 7 See bits 3:1.

Note: Only the first block of valid input patterns defines the commutator. All input pattern following the first marked invalid input pattern are ignored.

26.17.5.3 Register SPE_i_OUT_PAT_x (x: 07)

GTM_SPE0_OUT_PAT_x (x=0-7)

SPE0 Output Definition Register x (808_H+x*04_H)

Reset Value: 00000000_H

GTM_SPE1_OUT_PAT_x (x=0-7)

SPE1 Output Definition Register x (888_H+x*04_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
SPE_OUT_PAT	[15:0]	rw	SPE output control value for TOM_CH0 to TOM_CH7 SPE_OUT_PAT[n+1:n] defines output select signal of TOM[i]_CH[n] 00 _B set SPE_OUT(n) to TOM_CH0_SOUR 01 _B set SPE_OUT(n) to TOM_CH1_SOUR 10 _B set SPE_OUT(n) to '0' 11 _B set SPE_OUT(n) to '1' with n = 0...7
Reserved	[31:16]	r	Reserved Read as zero, should be written as zero

Note: Note: Register SPE_i_OUT_PAT_x defines the output selection for TOM[i]_CH0 to TOM[i]_CH7 depending on actual input pattern IP[x]_PAT with x=0-7.

Generic Timer Module (GTM)

26.17.5.4 Register SPE_i_OUT_CTRL

GTM_SPE_i_OUT_CTRL (i=0-1)

SPE_i Output Control Register (828_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
SPE_OUT_CTRL	[15:0]	rw	<p>SPE output control value for TOM_CH0 to TOM_CH7 SPE_OUT_CTRL[n+1:n] defines output select signal of TOM_CHn 00_B set SPE_OUT(n) to TOM_CH0_SOUR 01_B set SPE_OUT(n) to TOM_CH1_SOUR 10_B set SPE_OUT(n) to '0' 11_B set SPE_OUT(n) to '1' with n = 0...7</p>
Reserved	[31:16]	r	<p>Read as zero, should be written as zero Note: Current output control selection for SPE[i]_OUT(0...7).</p>

Generic Timer Module (GTM)

26.17.5.5 Register SPEi_CNT

GTM_SPEi_CNT (i=0-1)

SPEi Revolution Counter Register (840_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CNT	[23:0]	rw	Input signal revolution counter The counter is running if SPE module is enabled (bit SPE_EN). CNT is incrementing if SPE_PAT_PTR is incrementing CNT is decrementing if SPE_PAT_PTR is decrementing
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero

26.17.5.6 Register SPEi_CMP

GTM_SPEi_CMP (i=0-1)

SPEi Revolution Compare Register(844_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
CMP	[23:0]	rw	Input signal revolution counter compare value The interrupt SPEi_RCMP is raised when the SPEi_CNT value equals the SPEi_CMP register. It should be noted that SPEi_RCMP is only raised if an incrementation or decrementation of SPEi_CNT is applied, due to a input signal change. Any update of SPEi_CNT or SPEi_CMP via AEI does not raise an SPEi_RCMP interrupt.
Reserved	[31:24]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.17.5.7 Register SPE_i_IRQ_NOTIFY

GTM_SPE_i_IRQ_NOTIFY (i=0-1)

SPE_i Interrupt Notification Register(82C_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
SPE_NIPD	0	rwh	New input pattern interrupt occurred 0 _B No interrupt occurred. 1 _B New input pattern detected interrupt occurred. Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
SPE_DCHG	1	rwh	SPE_DIR bit changed on behalf of new input pattern See bit 0.
SPE_PERR	2	rwh	Wrong or invalid pattern detected at input See bit 0.
SPE_BIS	3	rwh	Bouncing input signal detected See bit 0.
SPE_RCM_P	4	rwh	SPE revolution counter match event See bit 0.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)
26.17.5.8 Register SPE_i_IRQ_EN
GTM_SPE_i_IRQ_EN (i=0-1)
SPE_i Interrupt Enable Register (830_H+i*80_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
SPE_NIPD_IRQ_EN	0	rw	SPE_NIPD_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM. 1 _B Enable interrupt, interrupt is visible outside GTM.
SPE_DCHG_IRQ_EN	1	rw	SPE_DCHG_IRQ interrupt enable See bit 0.
SPE_PERR_IRQ_EN	2	rw	SPE_PERR_IRQ interrupt enable See bit 0.
SPE_BIS_IRQ_EN	3	rw	SPE_BIS_IRQ interrupt enable See bit 0.
SPE_RCOMP_IRQ_EN	4	rw	SPE_RCOMP_IRQ interrupt enable See bit 0.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero

26.17.5.9 Register SPE_i_IRQ_FORCINT
GTM_SPE_i_IRQ_FORCINT (i=0-1)
SPE_i Interrupt Generation by Software
(834_H+i*80_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
TRG_SPE_NIPD	0	w	Force interrupt of SPE_NIPD 0 _B Corresponding bit in status register will not be forced. 1 _B Assert corresponding field in SPE_IRQ_NOTIFY register. Note: This bit is cleared automatically after interrupt is released Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_SPE_DCHG	1	w	Force interrupt of SPE_DCHG See bit 0.
TRG_SPE_PERR	2	w	Force interrupt of SPE_PERR See bit 0.
TRG_SPE_BIS	3	w	Force interrupt of SPE_BIS See bit 0.
TRG_SPE_RCMP	4	w	Force interrupt of SPE_RCMP See bit 0.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.17.5.10 Register SPEi_IRQ_MODE

GTM_SPEi_IRQ_MODE (i=0-1)

SPEi IRQ Mode Configuration Register(838_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
IRQ_MOD E	[1:0]	rw	IRQ mode selection 00 _B Level mode 01 _B Pulse mode 10 _B Pulse-Notify mode 11 _B Single-Pulse mode Note: The interrupt modes are described in Section 26.2.5 .
Reserved	[31:2]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.17.5.11 Register SPE_i_EIRQ_EN

GTM_SPE_i_EIRQ_EN (i=0-1)

SPE_i Error Interrupt Enable Register(83C_H+i*80_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
SPE_NIPD_EIRQ_EN	0	rw	SPE_NIPD_EIRQ interrupt enable 0 _B Disable error interrupt, error interrupt is not visible outside GTM 1 _B Enable error interrupt, error interrupt is visible outside GTM
SPE_DCHG_EIRQ_EN	1	rw	SPE_DCHG_EIRQ error interrupt enable See bit 0.
SPE_PERR_EIRQ_EN	2	rw	SPE_PERR_EIRQ error interrupt enable See bit 0.
SPE_BIS_EIRQ_EN	3	rw	SPE_BIS_EIRQ error interrupt enable See bit 0.
SPE_RCMP_EIRQ_EN	4	rw	SPE_RCMP_EIRQ error interrupt enable See bit 0.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero

26.18 Interrupt Concentrator Module (ICM)

26.18.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM interrupt lines of the individual submodules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM.

The individual interrupts of the GTM submodules and channels have to be enabled or disabled inside the submodules and channels.

The feed through architecture of bundled interrupt lines is used for the submodules AEI, ARU, BRC, CMP, SPE, PSM, TIM, DPLL, TOM, ATOM and MCS.

To determine the detailed interrupt source the microcontroller has to read the submodule/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

Please note, that the interrupts are only visible inside the ICM and in consequence outside of the GTM, when the interrupt is enabled inside the submodules themselves.

26.18.2 Bundling

The GTM submodule individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signalled to the outside world or bundled a second time into groups and are then signalled to the outside world.

The ICM interrupt bundling is described in the following sections.

26.18.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI, ARU, BRC, PSM, SPE and CMP submodules. In this interrupt group each individual channel of the submodules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM submodule channel that raised the interrupt. The interrupts are also represented in the ICM_IRQG_0 register. This register is typically not read by the CPU, but it is readable.

26.18.2.2 DPLL Interrupt Bundling

The DPLL Interrupt group handles the interrupts coming from the DPLL submodule of the GTM. Each of the individual DPLL interrupt lines has its own dedicated interrupt line to the outside world. The interrupts are additionally identified in the ICM_IRQG_1 interrupt group register. This register is typically not read out by the CPU, but it is readable.

Generic Timer Module (GTM)**26.18.2.3 TIM Interrupt Bundling**

Inside this group submodules which handle GTM input signals are treated. This is the case for the TIM[i] submodules. Each TIM submodule channel is able to generate six (6) individual interrupts if enabled inside the TIM channel. This six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM 24 interrupt lines TIM[i]_IRQ[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the ICM_IRQG_2 register a mirror for the TIM submodule channel interrupts and typically not read out by the CPU, but it is readable.

26.18.2.4 MCS Interrupt Bundling

For complex signal output generation, the MCS submodules are used inside the GTM. Each of these MCS submodules has eight channels with one interrupt line. This interrupt line is connected to the ICM submodule and is feed through directly to the outside world.

In addition the interrupt line status is shown in the ICM_IRQG_4 register. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQ4 register is typically not read out by the CPU, but it is readable.

26.18.2.5 TOM and ATOM Interrupt Bundling

For the TOM and ATOM submodules, the interrupts are bundled within the ICM submodule a second time to reduce external interrupt lines. The interrupts are OR-ed in a manner that one GTM external interrupt line represents two adjacent TOM or ATOM channel interrupts. For TOM[i] and ATOM[i] the bundling is shown in **TOM and ATOM interrupt bundling within ICM**.

TOM and ATOM interrupt bundling within ICM

TOM[i]-input IRQs [i]=0..number of TOM's-1	TOM-output IRQs (OR-ed)	ATOM[i]-input IRQs [i]=0..number of ATOM's-1	ATOM-output IRQs (OR-ed)
TOM[i]_CH0_IRQ	GTM_TOM[i]_IRQ[0]	ATOM[i]_CH0_IRQ	GTM_ATOM[i]_IR Q[0]
TOM[i]_CH1_IRQ		ATOM[i]_CH1_IRQ	
TOM[i]_CH2_IRQ	GTM_TOM[i]_IRQ[1]	ATOM[i]_CH2_IRQ	GTM_ATOM[i]_IR Q[1]

TOM[i]_CH11_IRQ			
TOM[i]_CH12_IRQ	GTM_TOM[i]_IRQ[6]		
TOM[i]_CH13_IRQ			
TOM[i]_CH14_IRQ	GTM_TOM[i]_IRQ[7]		
TOM[i]_CH15_IRQ			

ICM_1

Figure 26-82 TOM and ATOM interrupts

The interrupts coming from the TOM[i] submodules are registered in the ICM_IRQG_6 register. Always two TOM's are bundled in one ICM register, TOM0 and TOM1 are bundled in ICM_IRQG_6. To identify the TOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_6 register first before it goes to the TOM submodule channel itself.

The ICM_IRQG_6 register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

The interrupts coming from the ATOM[i] submodules are registered in the ICM_IRQG_9 register. Always four ATOM's are bundled in one ICM register, ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in ICM_IRQG_9. To identify the ATOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_9 register first before it goes to the ATOM submodule channel itself.

The interrupts coming from the ATOM[i] submodules are registered in the ICM_IRQG_9 register. ATOM0, ATOM1 and ATOM2 are bundled in ICM_IRQG_9. To identify the

Generic Timer Module (GTM)

ATOM submodule channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_9 register first before it goes to the ATOM submodule channel itself.

The ICM_IRQG_9 register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the BRC, FIFO, TIM, MCS, SPE, CMP, DPLL submodules of the GTM. The Module Error interrupts are additionally identified in the ICM_IRQ_MEI error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_MEI register bits are cleared automatically, when their corresponding error interrupt in the submodule is cleared.

FIFO Channel Error Interrupt Bundling

The FIFO Channel Error Interrupt group handles the error interrupts coming from the FIFO channel of the GTM. The FIFO Channel Error interrupts are additionally identified in the ICM_IRQ_CEI0 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI0 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM. The TIM Channel Error interrupts are additionally identified for the submodules TIM0, TIM1, TIM2, and TIM3 in the ICM_IRQ_CEI1 error interrupt group register and for TIM4, TIM5, and TIM6 in the ICM_IRQ_CEI2 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI1 and ICM_IRQG_CEI2 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

MCS Channel Error Interrupt Bundling

The MCS Channel Error Interrupt group handles the error interrupts coming from the MCS channel of the GTM. The MCS Channel Error interrupts are additionally identified for the submodules MCS0, MCS1, MCS2, and MCS3 in the ICM_IRQ_CEI3 error interrupt group register and for MCS4, MCS5, and MCS6 in the ICM_IRQ_CEI4 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI4 and ICM_IRQG_CEI4 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

26.18.3 ICM Interrupt Signals

Following table shows the GTM interrupt lines that are visible at the outside of the GTM.

Table 26-56 ICM Interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_ARU_IRQ[2:0]	[0]: ARU_NEW_DATA0 Interrupt [1]: ARU_NEW_DATA1 Interrupt [2]: ARU_ACC_ACK Interrupt
GTM_BRC_IRQ	BRC Shared interrupt
GTM_CMP_IRQ	CMP Shared interrupt
GTM_SPE[i]_IRQ	SPE Shared interrupt (i: 0...number of SPE's-1)
GTM_PSM[i]_IRQ[x]	PSM Shared interrupts (x: 0...7) (i: 0...number of PSM's-1)
GTM_DPLL_IRQ[0]	DPLL_DCGI: DPLL TRIGGER direction change detected
GTM_DPLL_IRQ[1]	DPLL_EDI: DPLL enable/disable interrupt
GTM_DPLL_IRQ[2]	DPLL_TIN: DPLL TRIG. min. hold time (THMI) viol. detected
GTM_DPLL_IRQ[3]	DPLL_TAX: DPLL TRIG. max. hold time (THMA) viol. detected
GTM_DPLL_IRQ[4]	DPLL_SIS: DPLL STATE inactive slope detected
GTM_DPLL_IRQ[5]	DPLL_TIS: DPLL TRIGGER inactive slope detected
GTM_DPLL_IRQ[6]	DPLL_MSI: DPLL Missing STATE interrupt
GTM_DPLL_IRQ[7]	DPLL_MTI: DPLL Missing TRIGGER interrupt
GTM_DPLL_IRQ[8]	DPLL_SAS: DPLL STATE active slope detected
GTM_DPLL_IRQ[9]	DPLL_TAS: DPLL TRIG. active slope det. while NTI_CNT is 0
GTM_DPLL_IRQ[10]	DPLL_PWI: DPLL Plausibility window (PVT) viol. int. of TRIG
GTM_DPLL_IRQ[11]	DPLL_W2I: DPLL Write access to RAM region 2 interrupt
GTM_DPLL_IRQ[12]	DPLL_W1I: DPLL Write access to RAM region 1B or 1C int
GTM_DPLL_IRQ[13]	DPLL_GLI: DPLL Get of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[14]	DPLL_LLI: DPLL Lost of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[15]	DPLL_EI: DPLL Error interrupt
GTM_DPLL_IRQ[16]	DPLL_GL2I: DPLL Get of lock interrupt for SUB_INC1
GTM_DPLL_IRQ[17]	DPLL_LL2I: DPLL Lost of lock interrupt for SUB_INC2
GTM_DPLL_IRQ[18]	DPLL_TE0: DPLL TRIGGER event interrupt 0

Generic Timer Module (GTM)
Table 26-56 ICM Interrupt Signals (cont'd)

Signal	Description
GTM_DPLL_IRQ[19]	DPLL_TE0: DPLL TRIGGER event interrupt 1
GTM_DPLL_IRQ[20]	DPLL_TE0: DPLL TRIGGER event interrupt 2
GTM_DPLL_IRQ[21]	DPLL_TE0: DPLL TRIGGER event interrupt 3
GTM_DPLL_IRQ[22]	DPLL_TE0: DPLL TRIGGER event interrupt 4
GTM_DPLL_IRQ[23]	DPLL_CDIT: DPLL calculated duration interrupt for trigger
GTM_DPLL_IRQ[24]	DPLL_CDIS: DPLL calculated duration interrupt for state
GTM_DPLL_IRQ[25]	DPLL_TORI: trigger out of range interrupt
GTM_DPLL_IRQ[26]	DPLL_SORI: status out of range interrupt
GTM_TIM[i]_IRQ[x]	TIM Shared interrupts (i: 0...number of TIM's-1) (x: 0...7)
GTM_MCS[i]_IRQ[x]	MCS Interrupt for channel x (x: 0...7) (i: 0...number of MCS's-1)
GTM_TOM[i]_IRQ[x]	TOM Shared interrupts for x:0...7 = {ch0 ch1,,ch14 ch15} (i: 0...number of TOM's-1)
GTM_ATOM[i]_IRQ[x]	ATOM Shared interrupts for x:0...3 = {ch0 ch1,,ch6 ch7} (i: 0...number of ATOM's-1)
GTM_ERR_IRQ	GTM Error Interrupt

26.18.4 ICM Configuration Registers Overview

ICM contains following configuration registers:

Table 26-57 ICM Configuration Registers Overview

Register Name	Description	Details in Section
ICM_IRQG_0	ICM Interrupt group register covering infrastructural and safety components (ARU, BRC, AEI, PSM[i], MAP, CMP,SPE)	Section 26.18.5.1
ICM_IRQG_1	ICM Interrupt group register covering DPLL	Section 26.18.5.2
ICM_IRQG_2	ICM Interrupt group register covering TIM0, TIM1, TIM2	Section 26.18.5.3
ICM_IRQG_4	ICM Interrupt group register covering MCS0 to MCS3 submodules	Section 26.18.5.4
ICM_IRQG_6	ICM Interrupt group register covering GTM output submodules TOM0 and TOM1	Section 26.18.5.5
ICM_IRQG_9	ICM Interrupt group register covering GTM output submodules ATOM0, ATOM1, ATOM2 and ATOM3	Section 26.18.5.6
ICM_IRQG_MEI	ICM Interrupt group register for module error interrupt information	Section 26.18.5.7
ICM_IRQG_CEI0	ICM Interrupt group register 0 for channel error interrupt information	Section 26.18.5.8
ICM_IRQG_CEI1	ICM Interrupt group register 1 for channel error interrupt information	Section 26.18.5.9
ICM_IRQG_CEI3	ICM Interrupt group register 3 for channel error interrupt information	Section 26.18.5.10

26.18.5 ICM Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.18.5.1 Register ICM_IRQG_0

GTM_ICM_IRQG_0

GTM Infrastructure Interrupt Group (600_H)

Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rh	rh	rh	rh	rh	rh	rh	rh
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								SPE 1_IR Q	SPE 0_IR Q	CMP _IRQ	AEL _IRQ	BRC _IRQ	ARU _AC _C_A CK_I RQ	ARU _NE _W_D ATA 1_IR	ARU _NE _W_D ATA 0_IR
r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
ARU_NEW_DATA0_I RQ	0	rh	ARU_NEW_DATA0 interrupt 0 _B no interrupt occurred 1 _B interrupt was raised by the corresponding submodule Note: This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding submodule. The bit is cleared automatically, when the corresponding interrupt in the submodule channels is cleared.
ARU_NEW_DATA1_I RQ	1	rh	ARU_NEW_DATA1 interrupt See bit 0.
ARU_ACC_ACK_IRQ	2	rh	ARU_ACC_ACK interrupt See bit 0.
BRC_IRQ	3	rh	BRC shared submodule interrupt See bit 0.

Generic Timer Module (GTM)

Field	Bits	Type	Description
AEI_IRQ	4	rh	AEI_IRQ interrupt See bit 0.
CMP_IRQ	5	rh	CMP shared submodule interrupt See bit 0.
SPE0_IRQ	6	rh	SPE0 shared submodule interrupt See bit 0.
SPE1_IRQ	7	rh	SPE1 shared submodule interrupt See bit 0.
Reserved	[15:8]	r	Reserved Read as zero, should be written as zero
PSM0_CH 0_IRQ	16	rh	PSM0 shared submodule channel 0 interrupt 0 _B no interrupt occurred 1 _B interrupt was raised by the corresponding submodule Note: This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding submodule. Note: When set this bit represents one of the four interrupt sources FIFO_[x]_EMPTY, FIFO_[x]_FULL, FIFO_[x]_LOWER_WM or FIFO_[x]_UPPER_WM The bit is cleared automatically, when the corresponding interrupt in the submodule channels is cleared.
PSM0_CH 1_IRQ	17	rh	PSM0 shared submodule channel 1 interrupt See bit 16
PSM0_CH 2_IRQ	18	rh	PSM0 shared submodule channel 2 interrupt See bit 16
PSM0_CH 3_IRQ	19	rh	PSM0 shared submodule channel 3 interrupt See bit 16
PSM0_CH 4_IRQ	20	rh	PSM0 shared submodule channel 4 interrupt See bit 16
PSM0_CH 5_IRQ	21	rh	PSM0 shared submodule channel 5 interrupt See bit 16
PSM0_CH 6_IRQ	22	rh	PSM0 shared submodule channel 6 interrupt See bit 16
PSM0_CH 7_IRQ	23	rh	PSM0 shared submodule channel 7 interrupt See bit 16

26.19 Output Compare Unit (CMP)

26.19.1 Overview

The Output Compare Unit (CMP) is designed for the use in safety relevant applications. The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used it is necessary to ensure the total cycle accurate output behaviour of the output modules to be compared. This is given when two ATOM units produce output signals at the same time stamp or when two TOMs have the same configuration and start their output generation at the same time. This is possible by means of the trigger mechanisms TRIG_x provided by the TOMs as shown in the [Section 26.11.1.1](#) (TOM Block Diagram). It is not necessary to compare each output channel with each other.

The CMP enables the comparison of 2x24 channels of the TOM and ATOM units respectively and is restricted to neighbor channels. Thus, channel 0 is compared with channel 1, channel 2 with 3 and so on until the comparison of channel 22 with channel 23.

26.19.1.1 Architecture of the Compare Unit

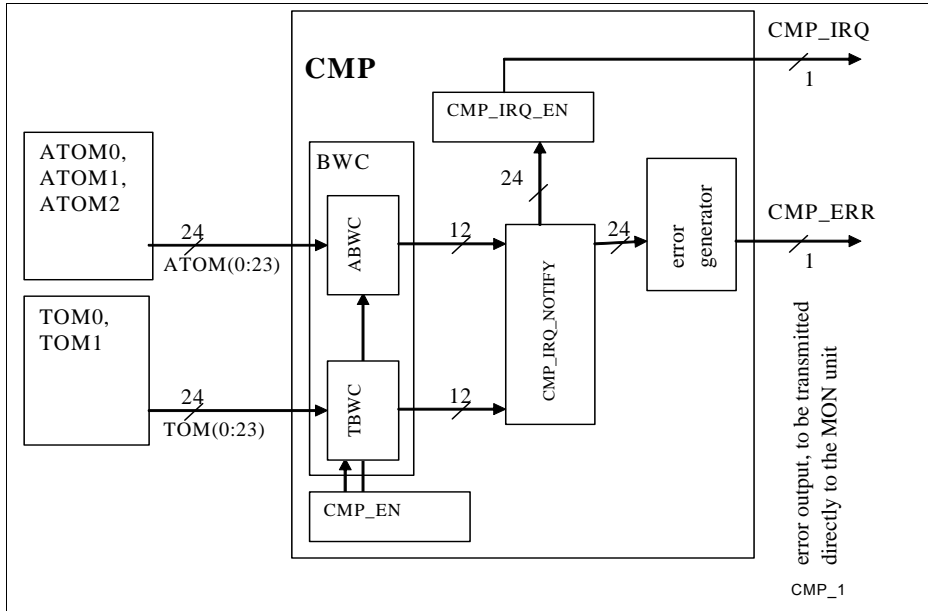

Figure 26-83 Architecture of the Compare Unit

26.19.2 Bitwise Compare Unit (BWC)

The Bitwise Compare Unit compares in pairs the combinations shown in following table

Table 26-58 Bitwise compare

TBWC/ABWC Comparator Number	Compare TOM/ATOM Bit Number one	Compare TOM/ATOM Bit Number Two	Output Number
0	0	1	0
1	2	3	1
2	4	5	2
3	6	7	3
4	8	9	4
5	10	11	5

Generic Timer Module (GTM)
Table 26-58 Bitwise compare (cont'd)

TBWC/ABWC Comparator Number	Compare TOM/ATOM Bit Number one	Compare TOM/ATOM Bit Number Two	Output Number
6	12	13	6
7	14	15	7
8	16	17	8
9	18	19	9
10	20	21	10
11	22	23	11

26.19.3 Configuration of the Compare Unit

Because of the restrictions described in the section above the Compare Unit consists of 24 antivalence (EXOR) elements, a select register CMP_EN which selects the corresponding comparisons and a status register CMP_IRQ_NOTIFY which shows and stores each mismatching result, when selected.

For each with CMP_IRQ_EN enabled mismatching error an interrupt signal on CMP_IRQ is generated.

For each with CMP_EIRQ_EN enabled mismatching error an interrupt signal on CMP_EIRQ is generated.

26.19.4 Error Generator

The error generator generates an error signal to be transmitted directly to the MON unit and independently from the CMP_IRQ and CMP_EIRQ. The error is set when in the CMP_IRQ_NOTIFY register at least one bit is set. The CMP_IRQ_NOTIFY bits are not maskable for this purpose.

The CMP_ERR output reflects its status in the status register of the Monitor Unit, which is to be polled by the CPU.

26.19.5 CMP Interrupt Signal

The CMP submodule has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupts can be determined by reading the CMP_IRQ_NOTIFY register for under consideration of CMP_IRQ_EN register and CMP_EIRQ_EN register. Each source can be forced separately for debug purposes using the interrupt force CMP_IRQ_FORCINT register. CMP_IRQ_MODE configures interrupt output characteristic. All interrupt modes are described in detail in [Section 26.2.5](#).

Table 26-59 CMP interrupt interface

Signal	Description
CMP_EIRQ	Mismatching interrupt of outputs to be compared, when enabled
CMP_IRQ	Mismatching interrupt of outputs to be compared, when enabled

26.19.6 CMP Configuration Registers Overview

CMP contains following configuration registers:

Table 26-60 CMP Configuration Registers Overview

Register Name	Description	Details in Section
CMP_EN	Comparator enable register	Section 26.19.7.1
CMP_IRQ_NOTIFY	Event notification register	Section 26.19.7.2
CMP_IRQ_EN	Interrupt enable register	Section 26.19.7.3
CMP_IRQ_FORCINT	Interrupt force register	Section 26.19.7.4
CMP_IRQ_MODE	IRQ mode configuration register	Section 26.19.7.5
CMP_EIRQ_EN	Error interrupt enable register	Section 26.19.7.6

26.19.7 CMP Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.19.7.1 Register CMP_EN

26.20 Monitor Unit (MON)

26.20.1 Overview

The Monitor Unit (MON) is designed for the use in safety relevant applications. The main idea is to have a possibility to supervise common used circuitry and resources. In this way the activity of the clocks is supervised. In addition the characteristics of output signals can be checked in a MCS channel by a re-read-in via TIM and routing to the MCS. When the comparison fails an error signal is generated in MCS and sent to the monitor unit. One error signal per MCS summarizes the errors of all channels. By generating of an activity signal per channel for each such performed comparison, the activity of TIM, ARU and the used clocks is checked implicitly.

In addition the ARU cycle time could be also compared in a MCS channel to given values.

26.20.1.1 MON Block Diagram

Figure 26-84 MON Block Diagram

26.20.1.2 Realization without Activity Checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore the clock enables are to be checked to have a high value.

26.20.2 Clock Monitoring

The monitor unit has a connection to each of the 8 clocks `CMU_CLK[x]` ($x=0\dots7$), provided by the CMU. Some of these clocks can be used for special tasks (see [Section 26.3](#)).

In addition the 5 clock inputs of the TOMs `CMU_FXCLK[y]` ($y=0\dots4$) are also connected to the MON unit.

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register `MON_STATUS` is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the CMU.

26.20.3 CMP error Monitoring

The signal `CMP_ERR` is to be received directly from module `CMP` and is set if an error occurred.

26.20.4 Checking the Characteristics of Signals by MCS

By use of the MCS some given properties of signals can be checked. Such signals can be generated output signals of TOM or ATOM channels, which are re-read into a TIM and the time stamp information is routed via ARU to the MCS module.

The corresponding MCS signal performs the check according to given properties. In this way signal high or low time as well as signal periods can be checked, also taking into account tolerances. When the check fails a MCS internal error signal is generated and ORed with the error signals of the other channels of the MCS module to an summarized error signal `MCS[z]_ERR` ($z=0\dots235$).

For each MCS a summarized error signal is transmitted to MON and monitored in the `MON_STATUS` register.

In order to check the execution of the comparison for each MCS channel an activity signal is generated. In the `MCA_i_x` ($x=0\dots7$) vector always for each MCS 8 bits for each channels are combined. The activity signals are stored in the `MON_ACTIVITY_0` register

Generic Timer Module (GTM)

for MCS0 to MCS3. The bits are set by a one signal and reset by writing a one to it (preferably after polling the status of the register).

Because the activity signal shows the execution of a comparison, the involved units for providing the signals and execution of comparison (like TIM, ARU and MCS itself) are checked implicitly to work accordingly. Also the involved clocks and time bases are checked in this way.

26.20.5 Checking ARU Cycle Time

The cycle time of the ARU can be checked, when this is essential for safety purposes. This check can be performed by an MCS channel. It should be noted that the MCS program for measuring the ARU round trip time must add a tolerance value.

The resulting error is reported to the MON unit using the summarized error signal MCS[z]_ERR for each MCS module in addition to an interrupt, generated in MCS. The same signals and status bits are used as in the case of checking the signal characteristics.

The corresponding MCS is programmed to get a fixed data value at address 0x1FF. The data value is always zero and is not blocked. When getting the access the time stamp value TBU_TS0 is stored in a register. The next time getting the access the new TBU_TS0 value is stored and the difference between both values is compared with a given value. When the comparison fails, an error flag is set in the MCS internal status register, an interrupt is generated and the error signal MCS[z]_ERR is provided.

When the check is performed, an activity signal MCA_x (x=0...31) is provided for each channel x for each MCSi (i=0...6) together with an summarized interrupt MCS[z]_ERR for each MCS.

The activity signal sets a bit in the MON_ACTIVITY register.

The bits in the MON_ACTIVITY register are reset by writing a one.

When the check fails, an interrupt is generated and the error signal MCS[z]_ERR is provided for the MON unit.

Figure 26-84 shows the block diagram of the Monitor Unit.

26.20.6 MON Interrupt Signals

The MON submodule has no interrupt signals.

26.20.7 MON Registers Overview

Following configuration registers are considered in MON sub module

Table 26-61 MON Registers Overview

Register Name	Description	Details in Section
MON_STATUS	Monitor Status register	Section 26.20.8.1
MON_ACTIVITY_0	Monitor activity register 0	Section 26.20.8.2

26.20.8 MON Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.20.8.1 Register MON_STATUS

Generic Timer Module (GTM)
26.22 GTM Implementation

This chapter describes product specific implementation of the Generic Timer Module (GTM).

Note: After a module reset the outputs of the (A)TOMs are high (see (A)TOMi_CHx_CRTL.SL) and could cause unexpected triggers in other modules.

26.22.1 GTM Registers

1) accesses to address range 0x28380 to 0x283FF cause access errors.

GTM Address Ordering

The GTM address area start at F010 0000_H and ends at F019 FFFF_H. All given address for registers (beside for the DPLL part) are offset addresses to the GTM base address of F010 0000_H and need to be added. DPLL addresses for the CPU access are offset addresses to the DPLL base address of 0x00028000_H, independent if with address is located in a DPLL RAM or not. For the DPLL base address of course the GTM base address have to be added.

Table 26-66 Address Overview

Submodule	Base address (to be added to GTM based address)

Generic Timer Module (GTM)

The clock control register is used to switch the GTM on or off and to control its input clock rate. The GTM can be disabled by setting bit DISR to 1.

CLC
Clock Control Register
(9FD00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the GTM module. 0 _B No disable requested 1 _B Disable requested
DISS	1	r	Module Disable Status Bit Bit indicates the current status of the GTM module. 0 _B GTM module is enabled 1 _B GTM module is disabled
EDIS	3	rw	Sleep Mode Enable Control Used for module sleep mode control.
0	2, [31:4]	r	Reserved Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset and by each System Reset when OCDS is disabled. It is not touched by System Reset when OCDS is enabled.

The OCS register includes the module related control bits for the ODDS Trigger Bus (OTGB).

The OCS control register bits are only effective while the system is in debug mode. While not in debug mode, OCS reset values/modes are effective.

Write access is 32 bit wide only and requires Supervisor Mode.

Generic Timer Module (GTM)

OCS

OCDS Control and Status

 (9FDE8_H)

 Reset Value: 0000 0000_H

SUS	[27:24]	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 _H Will not suspend 1 _H Hard suspend. Clock is switched off immediately. In Hard suspend no registers beside the registers documented in the Implementation section of this chapter could be read or written. 2 _H Soft suspend (GTM Halt Mode). In Soft suspend registers could be read or written, for details see Chapter 26.2.6 . others , reserved
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0.

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Generic Timer Module (GTM)

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, EN31 -> TAG ID 011111_B.

All registers and memories of the GTM are protected beside the following registers:
ACCEN0 and ACCEN1.

ACCEN0
Access Enable Register 0
(9FDFC_H)
Reset Value: FFFF FFFF_H

ENn (n = 0-31)	n	rW	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, EN31 -> TAG ID 111111_B.

All registers and memories of the GTM are protected beside the following registers:
ACCEN0 and ACCEN1.

Generic Timer Module (GTM)
ACCEN1
Access Enable Register 1
(9FDF8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing to it with '1'.

Note: This reset function has the effect as bit RST.RST.

Generic Timer Module (GTM)
KRST0
Kernel Reset Register 0
(9FDF4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the GTM kernel. GTM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the GTM kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

Generic Timer Module (GTM)
KRST1
Kernel Reset Register 1
(9FDF0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to '0') after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR
Kernel Reset Status Clear Register (9FDEC_H)
Reset Value: 0000 0000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

26.22.2 Port Connections

The sections summarize the port connections which defined the boundary of the GTM for the TC26x B-Step.

Generic Timer Module (GTM)

The GTM outputs *cmu_eclk[2:0]* are connected directly to dedicated ports.

Table 26-69 GTM clock to Port Mapping

GTM Clock Output	Alternate Output of Pin
<i>cmu_eclk0</i>	P23.1
<i>cmu_eclk1</i>	P32.4
<i>cmu_eclk2</i>	P11.12

Generic Timer Module (GTM)
26.22.2.1 Port to GTM Control Registers

The inputs to the GTM TIM modules (*gtm_timx_in[7:0]*) are not connected directly to the port input path. Each timed GPIO is connectable to two TIMs via an input multiplexer. In addition the inputs from the on chip peripherals are connected here too.

TIMnINSEL (n = 0-2)
TIMn Input Select Register (9FD10_H+n*4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHxSEL (x = 0-7)	[x*4+3: x*4]	rw	TIM Channel x Input Selection This bit defines which input is connected for TIMn channel x of the GTM. The input is either derived from the a port pad or from a on-chip module.

Generic Timer Module (GTM)

26.22.2.2 GTM to Port Control Registers

The outputs of the GTM TOM and ATOM modules are not connected directly to the port output path. Each TOM and ATOM is connectable to several port alternate inputs via an output multiplexer.

The output signals to the mux are called *gtm_tout_x*, where x is running number.

TOUTSELn (n = 0-9)

26.22.3 MSC Connections

The sections summarize the connections to the MSC modules for the TC26x B-Step. The MSC interfaces (MSC0 and MSC1) provide a serial communication link typically used to connect power switches or other peripheral devices.

The outputs of the signal names are defined in [Table 26-77](#) and [Table 26-78](#).

26.22.4 DSADC Connections

This register defines the DSADC to GTM connections of TC26x B-Step.

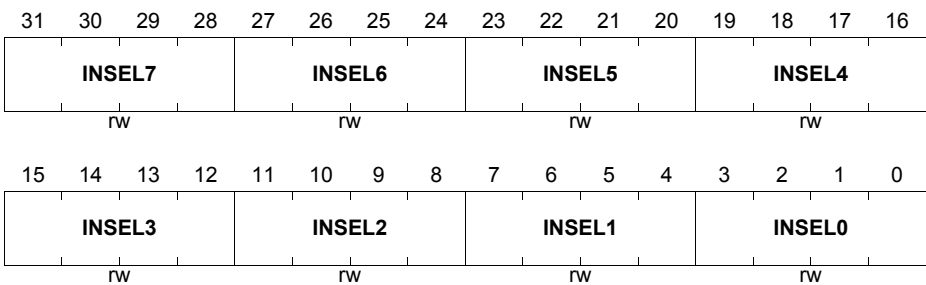

The 16 to 1 multiplexer is implemented once per TIM0 / 1 / 2 module / channel. The input signal from the DSADC is called *dsadc_x_trig_in_y* x = number of DSADC, y = SRM / SAUL / SBLL. The output of the multiplexer is called *timy_muxout_x*, (y = 0,1,2)(x = 0...7).

Register DSADCOUTSELxy defines the GTM to DSADC connections of TC26x B-Step. The DSADC trigger inputs (one per DSADC) 8 to 1 multiplexer is implemented twice per DSADC module / channel. The output signal to the DSADC is called *dsadcx_trig0* and *dsadcx_trig1*, The inputs of the multiplexer are called *dsadc_x_muxin[7:0]*, x = number of DSADCs.

Which of the possible trigger inputs is used by the DSADC can be selected in the VADC module.

0	[31:20]	rw	Reserved Should be written with 0.

26.22.6 SENT Connections

This register defines the GTM to SENT connections of TC26x B-Step.

The trigger generation 16 to 1 multiplexer is implemented twice per ADC module / channel. The output signal to the ADC is called *adcx_trig0* and *adcx_trig1*. As the SENT channels overlay and replace ADC channels the ADC triggers will be also reused for the SENT channels. Therefore no additional outputs for separate operation are defined here.

adcx_trig0 is connected to *sent_trig_x*.

26.22.9 PSI5 Connections

This register defines the GTM to PSI5 connections of TC26x B-Step.

The PSI5 trigger inputs are generated by 16 to 1 multiplexer that are implemented twice per PSI5 module / channel plus 3 combined for all PSI5 channels together. The output signal to the PSI5 is called *psi5x_trig0*, The inputs of the multiplexer are called *psi5_x_muxin[7:0]*, x = number of PSI5 triggers, TC26x B-Step has 6 triggers.

Mapping of PSI5 Triggers

SELx (x = 0-5)	[x*4+3: x*4]	rw	Output Selection for PSI5x GTM connection This bit field defines which TOM / ATOM channel output is used as PSI5x trigger 0. Decoding is defined by Table 26-87 .

Generic Timer Module (GTM)

Field	Bits	Type	Description
0	[31:24]	r	Reserved Read as 0; should be written with 0.

PSI5SOUTSEL
PSI5-S Output Select Register (9FDA8_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SELx (x = 0-2)	[x*4+3: x*4]	rw	Output Selection for PSI5x GTM connection This bit field defines which TOM / ATOM channel output is used as PSI5x trigger 0. Decoding is defined by Table 26-88 .
SELx (x = 4-6)	[x*4+3: x*4]	rw	Output Selection for PSI5x GTM connection This bit field defines which TOM / ATOM channel output is used as PSI5x trigger 0. Decoding is defined by Table 26-88 .
0	[15:12], [31:28]	rw	Reserved Should be written with 0.

26.22.10 GTM Data Exchange Registers

The registers defines additional data exchange and control options for GTM towards the on-chip system of TC26x B-Step.

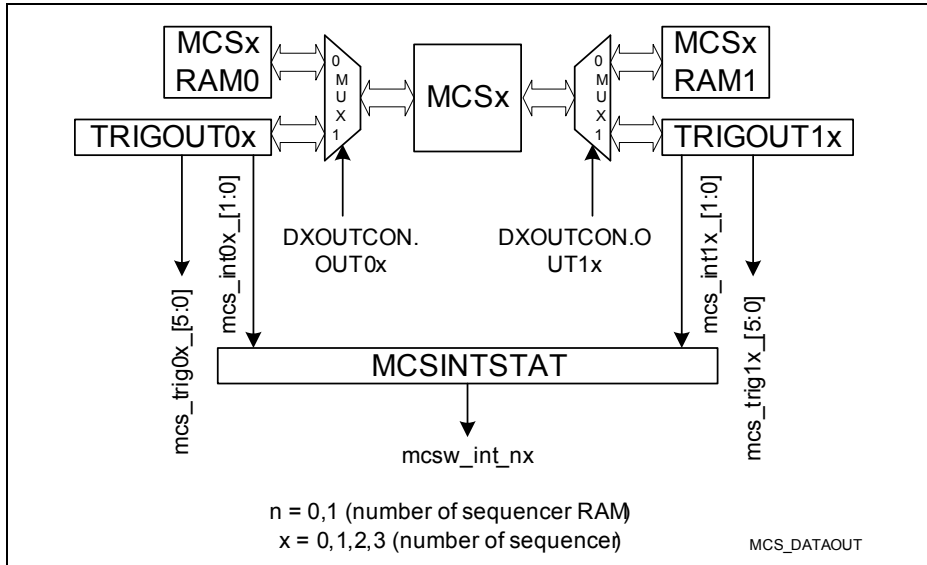

Figure 26-87 MCS Trigger Output Path

The TRIGOUT registers enable the GTM internal sequencers to generate dedicated interrupts or triggers from the sequence flow by writing to this register. The TRIGOUT registers are mirrored to address 0x0000 for each of the two sequencer RAMs. If a write for address 0x0000 updates the RAM or the TRIGOUT register is controlled by the bus accessible register DXOUTCON in central for all sequencers and there RAMs. This need to be configured only once when setting up the GTM with the reminder of the system.

Register MCSINTSTAT contains interrupt status flags and register MCSINTCLR provides the option to clear these status flags from the system bus. Both registers are optional register.

Generic Timer Module (GTM)
DXOUTCON
Data Exchange Output Control Register (9FE00_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
OUT0x (x = 0-2)	x	rw	Output 0x Control This bit defines if register TRIGOUT0x is accessible from the MCS instead the RAM0 or not. 0 _B RAM0 memory is accessed 1 _B Register TRIGOUT0x is accessed
OUT1x (x = 0-2)	x+8	rw	Output 1x Control This bit defines if register TRIGOUT1x is accessible from the MCS instead the RAM1 or not. 0 _B RAM1 memory is accessed 1 _B Register TRIGOUT1x is accessed
0	[7:3],[3 1:11]	r	Reserved Read as 0; should be written with 0.

TRIGOUT0n (n = 0-2)
Trigger Output 0 Register n (9FE04_H+n*4_H)
Reset Value: 0000 0000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
INT0	[1:0]	w	Interrupt Trigger Request 0 This bit field if an interrupt request 0 is generated or not. 00 _B No modification of current state 01 _B Pending interrupt request 0 is cleared 10 _B Interrupt request 0 is set 11 _B No modification of current state
INT1	[3:2]	w	Interrupt Trigger Request 1 This bit field if an interrupt request 1 is generated or not. 00 _B No modification of current state 01 _B Pending interrupt request 1 is cleared 10 _B Interrupt request 1 is set 11 _B No modification of current state
TRIG0	[5:4]	w	Trigger 0 This bit field if an trigger 0 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 0 is cleared 10 _B Trigger 0 is set 11 _B No modification of current state
TRIG1	[7:6]	w	Trigger 1 This bit field if an trigger 1 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 1 is cleared 10 _B Trigger 1 is set 11 _B No modification of current state
TRIG2	[9:8]	w	Trigger 2 This bit field if an trigger 2 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 2 is cleared 10 _B Trigger 2 is set 11 _B Current trigger 2 level is toggled

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRIG3	[11:10]	w	Trigger 3 This bit field if an trigger 3 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 3 is cleared 10 _B Trigger 3 is set 11 _B Current trigger 3 level is toggled
TRIG4	[13:12]	w	Trigger 4 This bit field if an trigger 4 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 4 is cleared 10 _B Trigger 4 is set 11 _B Current trigger 4 level is toggled
TRIG5	[15:14]	w	Trigger 5 This bit field if an trigger 5 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 5 is cleared 10 _B Trigger 5 is set 11 _B Current trigger 5 level is toggled
0	[31:16]	r	Reserved Read as 0; should be written with 0.

TRIGOUT1n (n = 0-2)
Trigger Output 0 Register n (9FE44_H+n*4_H) **Reset Value: 0000 0000_H**

Generic Timer Module (GTM)

Field	Bits	Type	Description
INT0	[1:0]	w	Interrupt Trigger Request 0 This bit field if an interrupt request 0 is generated or not. 00 _B No modification of current state 01 _B Pending interrupt request 0 is cleared 10 _B Interrupt request 0 is set 11 _B No modification of current state
INT1	[3:2]	w	Interrupt Trigger Request 1 This bit field if an interrupt request 1 is generated or not. 00 _B No modification of current state 01 _B Pending interrupt request 1 is cleared 10 _B Interrupt request 1 is set 11 _B No modification of current state
TRIG0	[5:4]	w	Trigger 0 This bit field if an trigger 0 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 0 is cleared 10 _B Trigger 0 is set 11 _B No modification of current state
TRIG1	[7:6]	w	Trigger 1 This bit field if an trigger 1 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 1 is cleared 10 _B Trigger 1 is set 11 _B No modification of current state
TRIG2	[9:8]	w	Trigger 2 This bit field if an trigger 2 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 2 is cleared 10 _B Trigger 2 is set 11 _B Current trigger 2 level is toggled

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRIG3	[11:10]	w	Trigger 3 This bit field if an trigger 3 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 3 is cleared 10 _B Trigger 3 is set 11 _B Current trigger 3 level is toggled
TRIG4	[13:12]	w	Trigger 4 This bit field if an trigger 4 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 4 is cleared 10 _B Trigger 4 is set 11 _B Current trigger 4 level is toggled
TRIG5	[15:14]	w	Trigger 5 This bit field if an trigger 5 request is generated or not. 00 _B No modification of current state 01 _B Pending trigger 5 is cleared 10 _B Trigger 5 is set 11 _B Current trigger 5 level is toggled
0	[31:16]	r	Reserved Read as 0; should be written with 0.

MCS to ADC Triggers

The triggers x0 can be used either as GPIO outputs or a gated trigger inputs for some ADCs.

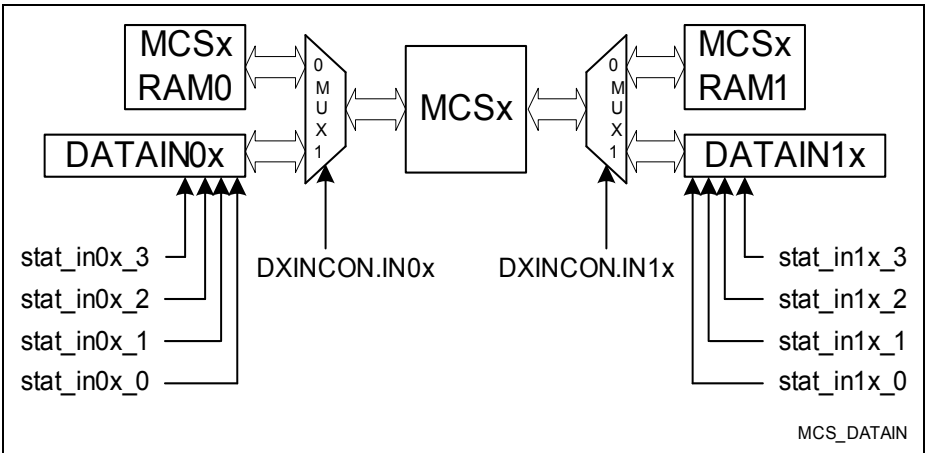

Figure 26-88 MCS Data Input path

The DATAIN registers enable the GTM internal sequencers to access data provided by other masters in the system directly in the sequencer data flow without ARU interaction. In addition the status of dedicated system triggers could also be observed here. The DATAIN registers are mirrored to address 0x0001 for each of the two sequencer RAMs. If a read for address 0x0001 fetch data from the RAM or the DATAIN register is controlled by the bus accessible register DXINCON in central for all sequencers and there RAMs. In addition register DATAIN contains the control if the 4 LSB of the DATAIN register contains data or the status of the four system signals. This need to be configured only once when setting up the GTM with the reminder of the system.

GTM Output	SCU Input
TOM0_12	Input41
TOM1_12	Input51

26.22.12 GTM Debug Interface

OTGB0/1 are 16-bit trigger busses, OTGB2 is 32 bit wide. Further information is available in the OTGM (OCDS Trigger Mux) section of the device specification.

Note: If triggering or tracing is to be used the GTM clock must not be faster than the SPB clock.

26.22.12.1OCDS Trigger Bus (OTGB) Interface

GTM OTGB Features

- IO signals
 - TIM input signals (after filter)
 - TOM output signals
 - ATOM output signals
 - SPE NIPD and DIR signals
 - Groups of 8 signals (e.g. all inputs of a specific TIM, etc.)
 - Two arbitrary groups on one 16 bit OTGB0/1
 - OTGB0 and/or OTGB1 can be used for 2-4 groups in parallel (e.g. both with one TIM 8, one ATOM 8 and one TOM 16)
- MCS
 - Channel number, PC and data access type (read or write)
 - Data value on OTGB2
 - Only one 16 bit OTGB0/1 needed if no data trace. Other free for IO signals.
- ARU
 - ARU_DBG_DATA0/1_H/L on 32 bit OTGB2 (time multiplexed)
- DPLL
 - TASI and SASI signals
 - Accesses to RAM1A/1BC/2 (only one at a time)
- TBUs
 - Trace one selected TBU
 - Trigger signals for individual TBU comparators

The GTM module has five 16 bit and eight 32 bit Trigger Sets ([Table 26-97](#)) which are selected with the **OTSS** register.

Table 26-97 GTM Trigger Sets

Trigger Set	Details
TS16_IOS Trigger Set IO and Other Signals	Table 26-99
TS16_MCA MCS Channel, Address and PC	Table 26-100
TS32_MCD MCS Data	Table 26-101
TS32_ARU Trigger Set ARU	Table 26-102
TS16_DRA1A/1BC/2 DPLL RAM Access Address (3 Sets)	Table 26-103
TS32_DRD1A/1BC/2 DPLL RAM Access Data (3 Sets)	Table 26-104
TS32_TTB0/1/2 TBU Time Stamps (3 Sets)	Table 26-105

Table 26-98 shows all sensible Trigger Set mapping options. Simple permutations of OTGB0/1 are omitted. If OTGB0 and/or OTGB1 is not used for GTM, Trigger Sets of other sources can be added in the OTGM module. The Trigger Sets which will initiate the writing of a 32 or 64 bit data word to the MCDS trace are marked with bold letters. This is by design always the case for OTGB2 Trigger Sets. Independent OTGB0/1 Trigger Sets need an independent own sensitivity to their signal changes, configured in the OTGM module.

Table 26-98 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	TS16_IOS or MCA		
	TS16_IOS or MCA	TS16_IOS	
64 Bit			TS32_ARU or TTB0/1/2
	TS16_IOS or MCA		TS32_MCD
	TS16_IOS or MCA	TS16_IOS	
	TS16_MCA		
	TS16_MCA	TS16_IOS	TS32_DRD1A/1BC/2
	TS16_DRA1A/1BC/2		
	TS16_DRA1A/1BC/2	TS16_IOS	

Generic Timer Module (GTM)

The GTM trigger signals relate to the GTM internal clock, which can be slower or equal to the OTGB/OTGM clock.

IO and Other Signals Trigger Sets

IO Trigger Sets consist of the most important TIM, TOM and ATOM signals in groups of 8. In addition there is a group of SPE signals and one group for miscellaneous signals. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16 bit Trigger Set. In addition it is possible to use one or two 16 bit Trigger Sets with this flexibility. All this is controlled with **OTSC0**.

Table 26-99 TS16_IOS Trigger Set IO and Other Signals

Bits	Name	Description	
[7:0]	SG0	A group of 8 signals from a selected TIM, TOM, ATOM or SPE	
		TIM	All 8 input signals after filter F_OUT
		TOML	Lower 8 output signals TOM_OUT
		TOMH	Higher 8 output signals TOM_OUT
		ATOM	All 8 output signals ATOM_CHx_OUT
		SPE	Bits 0,1: SPE0_NIPD, SPE_DIR0 Bits 2,3: SPE1_NIPD, SPE_DIR1 Bits 4,5: Reserved Bits 6,7: Reserved
[15:8]	SG1	MISC	Bit 0: DPLL TASI Bit 1: DPLL SASI Bit 4: TBU0 trigger (OTBU0T) Bit 5: TBU1 trigger (OTBU1T) Bit 6: TBU2 trigger (OTBU2T) Others: reserved
		Independent selection with same options as for Bits [7:0]	

MCS Trigger Sets

There are two MCS Trigger Sets: TS16_MCA (**Table 26-100**) and TS32_MCD (**Table 26-101**). TS16_MCA allows to observe the PC of all or a selected MCS Channel. If only one Channel is selected, the TS16_MCA value will stay stable until the MCS executes this Channel again. In case of data access by CPU or by a Channel, it represents the data address. With TS32_MCD the associated data value and even the fetched instruction opcode can be traced. Usually the latter is avoided to reduce the trace bandwidth. All this is controlled with **OTSC1**.

Table 26-100 TS16_MCA MCS Channel, Address and PC

Bits	Name	Description
[11:0]	ADDR	PC of MCS Channel or address of data access (32 bit word address)
[15:12]	AQ	Address Qualifier with Channel information 0_H ADDR is PC of MCS Channel 0 H ADDR is PC of MCS Channel 7_H ADDR is PC of MCS Channel 7 C_H reserved D_H reserved E_H ADDR is address of Channel data read access F_H ADDR is address of Channel data write access Others: reserved

Table 26-101 TS32_MCD MCS Data

Bits	Description
[31:0]	Read or written data value of current channel instruction

ARU Trigger Sets

There are four 29 bit ARU data words with debug information (ARU_DBG_DATA0_L/H and ARU_DBG_DATA1_L/H). These words may get valid in the same GTM kernel clock cycle but they will never change in consecutive cycles. This property is used to transmit them with time multiplexing over the OTGB2 bus. ARU_NEW_DATA0/1_IRQ controls the OTGB2 valid signal.

The implementation of TS32_ARU has to capture the ARU_NEW_DATA0/1_IRQ signals and clear these capture bits, when the associated ARU data has been output on OTGB2. The ARU data itself doesn't need to be captured because it will be valid long enough. If both ARU_NEW_DATA0/1_IRQ signals become active in the same cycle, the ARU data is output in four consecutive cycles with the sequence ARU_DBG_DATA0_L, DATA0_H, DATA1_L, DATA1_H.

Table 26-102 TS32_ARU Trigger Set ARU

Bits	Name	Description
[28:0]	DATA	ARU_DBG_DATA

Generic Timer Module (GTM)
Table 26-102 TS32_ARU Trigger Set ARU (cont'd)

DPLL Trigger Sets

The TASI and SASI signals are part of the MISC signal group of TS16_IOS (Table 26-99).

The following tables Table 26-103 and Table 26-104 define six additional DPLL Trigger Sets for observing the DPLL RA

M accesses. Only one of the three DPLL (1A, 1B+C, 2) RAMs can be observed at a time. The Trigger Set selection is done with OTSS.

Table 26-103 TS16_DRA1A/1BC/2 DPLL RAM Access Address

Bits	Name	Description
[13:0]	ADDR	Address of data access. Range starts with address 0 for the selected RAM (1A, 1B+C or 2). Effective width depends on selected RAM
[15:14]	AQ	Address Qualifier 0_H DPLL data read access 1_H DPLL data write access 2_H CPU read access 3_H CPU write access

Table 26-104 TS32_DRD1A/1BC/2 DPLL RAM Access Data

Bits	Name	Description
[23:0]	DATA	Read or written data
[31:24]		Reserved

TBU Trigger Sets

Table 26-105 defines the Trigger Sets for the observation of the different time bases. The Trigger Set selection (one at a time) is done with OTSS.

Table 26-105 TS32_TTB0/1/2 TBU Time Stamps

Bits	Name	Description
[26:0]	TS	Current TBU_TS0/1/2 time stamp. Effective width depends on selected time base.
[31:27]		Reserved

26.22.12.2GTM Debug Registers

All debug control registers are cleared by Debug Reset.

OCDS Trigger Bus (OTGB)

Access are only supported for byte, halfword and word data and requires Supervisor Mode.

OTSS

OCDS Trigger Set Select Register (9FDD0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
OTGB0	[3:0]	rw	Trigger Set for OTGB0 0 _D No Trigger Set selected 1 _D Trigger Set TS16_IOS (Table 26-99) 2 _D Trigger Set TS16_MCA (Table 26-100) 3 _D Trigger Set TS16_DRA1A (Table 26-103) 4 _D Trigger Set TS16_DRA1BC (Table 26-103) 5 _D Trigger Set TS16_DRA2 (Table 26-103) others , reserved
OTGB1	[11:8]	rw	Trigger Set for OTGB1 0 _D No Trigger Set selected 1 _D Trigger Set TS16_IOS (Table 26-99) 2 _D Trigger Set TS16_MCA (Table 26-100) 3 _D Trigger Set TS16_DRA1A (Table 26-103) 4 _D Trigger Set TS16_DRA1BC (Table 26-103) 5 _D Trigger Set TS16_DRA2 (Table 26-103) others , reserved

Generic Timer Module (GTM)

Field	Bits	Type	Description
OTGB2	[19:16]	rw	Trigger Set for OTGB2 0 _H No Trigger Set selected 1 _H Trigger Set TS32_ARU (Table 26-102) 2 _H Trigger Set TS32_MCD (Table 26-101) 3 _H Trigger Set TS32_DRD1A (Table 26-104) 4 _H Trigger Set TS32_DRD1BC (Table 26-104) 5 _H Trigger Set TS32_DRD2 (Table 26-104) 8 _H Trigger Set TS32_TTB0 (Table 26-105) 9 _H Trigger Set TS32_TTB1 (Table 26-105) A _H Trigger Set TS32_TTB2 (Table 26-105) others, reserved
0	[7:4], [15:12], [31:20]	r	Reserved Read as 0; must be written with 0.

OTSC0
OCDS Trigger Set Control 0 Register(9FDD4_H)
Reset Value: 0000 0000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
B1HMI	[31:28]	rw	OTGB1 TS16_IOS High Byte Module Instance Index of the module instance. Index starts with 0, the max. value depends on GTM configuration and module type. For SPE and MISC signals this index is ignored.
0	3, 11, 19, 27	r	Reserved Read as 0; must be written with 0.

OTSC1
OCDS Trigger Set Control 1 Register(9FDD8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
MCS	[3:0]	rw	MCS Channel Select Required by TS16_MCA and TS32_MCD 0000 _B MCS Channel 0 0111 _B MCS Channel 7 1110 _B No MCS Channel (in conjunction with bit MCE set) 1111 _B All MCS Channels others , reserved
MI	[7:4]	rw	MCS Instance Required by TS16_MCA and TS32_MCD Index of the MCS instance. Index starts with 0, the max. value depends on the GTM configuration.
0	8	rw	Reserved Should be written with 0.
MOE	9	rw	MCS Opcode Trace Enable Required by TS32_MCD 0 _B Trigger Set TS32_MCD excludes opcode fetches 1 _B Trigger Set TS32_MCD includes opcode fetches

Generic Timer Module (GTM)

Field	Bits	Type	Description
0	[31:10]	r	Reserved Read as 0; must be written with 0.

ODA

OCDS Debug Access Register (9FDDC_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
DDREN	0	rw	Destructive Debug Read Enable For details see Table 26-106 .
DREN	1	rw	Destructive Read Enable For details see Table 26-106 .
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Table 26-106 Destructive Read Control encoding

ODA.DREN	ODA.DDREN	Description
0	0	Destructive read access are enabled for all masters beside the OCDS master
0	1	Destructive read access are enabled for all masters
1	0	Destructive read access are disabled for all masters
1	1	Destructive read access are disabled for all masters

Generic Timer Module (GTM)
OTBU0T
OCDS TBU0 Trigger Register
(9FDC4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CV	[26:0]	rw	Compare Value This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (Table 26-99) is active.
CM	[29:28]	rw	Compare Mode 0 _H Disabled 1 _H Compare lower 24 bits 2 _H Compare upper 24 bits 3 _H Compare all 27 bits
0	27, [31:30]	r	Reserved Read as 0; must be written with 0.

OTBU1T
OCDS TBU1 Trigger Register
(9FDC8_H)
Reset Value: 0000 0000_H

Generic Timer Module (GTM)

Field	Bits	Type	Description
CV	[23:0]	rw	Compare Value This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (Table 26-99) is active.
EN	28	rw	Enable 0 _B Disabled 1 _B Enabled
0	[27:24], [31:29]	r	Reserved Read as 0; must be written with 0.

OTBU2T
OCDS TBU2 Trigger Register (9FDCC_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CV	[23:0]	rw	Compare Value This value is compared to TBU_CH0_BASE register. As long as both match the associated TS16_IOS.MISC bit (Table 26-99) is active.
EN	28	rw	Enable 0 _B Disabled 1 _B Enabled
0	[27:24], [31:29]	r	Reserved Read as 0; must be written with 0.

26.23 **ision History**

Changes from version 0.3 to 1.0

- 2.2.1 Updated list of registers that drive value “illegal module access”
- 2.5 Fixed bugs in IRQ Specification
- 4.2 Clarified register bit settings in case of Trashbin functionality
- 4.5.2 Clarified register bit settings in case of Trashbin functionality
- 5.5.12,13 Fixed bad naming of register labels
- 10.4.2.5 Clarified modified behaviour of ECNT in mode TBCM
- 10.8.1,2 Clarified behaviour if bad TIM modes are selected
- 11.3.6 Clarified one shot mode in case of writing to CN0 while CN0 is counting
- 12.2.2 Clarified ATOM channel startup behaviour when ARU_EN is set and channel is enabled
- 12.3.1.1, 12.3.2.3, 12.3.3.5, 12.3.4.1 Not used bits can be written in any mode, but should be written as zero when not used
- 12.3.4 Clarified interrupt behaviour in SOMS mode: in SOMS mode only CCU1TC IRQ possible
- 12.6.2 Corrected some bit manipulation properties for bits OSM, TRIGOUT, CLK_SRC/CLK_SRC_SR
- 13.1.1ff Fixed declaration of maximum address range and clarified priorities of register accesses
- 14.1.1ff Documented additional memory layout parameters for the case that two large RAMs are connected to MCS
-
- 16.4.2 LOW_RES options
- 16.7.1 VTN
- 16.8.3ff NMB_T/S: MPVAL1/2 added
- 16.8.5ff PSTC/PSSC = 0 for FTD/FSD=0
- 16.8.6.7ff NMB_T/S calculation and use
- 16.11.1 Note 3): restriction for resolution choices
- 16.11.2 SWR and DEN
- 16.11.6 CRO, PSE, TOR, SOR, LOCK1/2
- 16.11.8/9 OSW and AOSV_2
- 16.11.28/29 old ADD_IN value used
- 16.13 no write protection of available RAM bits
- 16.13.9 THVAL for LOW_RES and !TSO_HRT
- 16.13.16ff all reciprocal values: SHL 32
- 16.14ff resolution of reciprocal values
- 20.1.1ff Activity checker removed
-
- 2.2.1 Updated list of registers that drive value “illegal module access”
- 2.5.4 Changed IRQ behaviour in single pulse mode on simultaneous clear and interrupt event
- 2.9.2 Protected write information

Generic Timer Module (GTM)

- 3.6.1 Clarified usage of ARU_ACCESS register
- 4.5.1 ARU read address only writeable if channel disabled
- 7.4.2 ARU read address only writeable if channel disabled
- 8.3, 8.5, 8.6: Removed confusing reset description
- 12.3 Clarified CN0 behaviour at channel enable
- 12.3.2ff SOMC mode description restructured
- 12.3.4ff SOMS mode description restructured
- 12.6.4 ARU read address only writeable if channel disabled
- 13.2.1 Specified behaviour in the case of bad opcode decoding
- 13.2.3 Added two non blocking ARU read instructions (NARD/NARDI)
- 13.2.4 Clarified behaviour on flags CY and V in arithmetic instructions
- 13.4.5 Added write protection to register MCS[i]_CH[x]_R6
- 16.6.2.1 higher reciprocal resolution TRIGGER
- 16.6.3.1 higher reciprocal resolution STATE
- 16.8.3.6 QDT is zero at the beginning
- 16.8.6.7 Store INC_CNTx when a valid event occurs and use it as MPx in step 5 or 25
- 16.11.1 condition for pulse number per increment
- 16.11.6 refined definitions of CRO, RCS, RCT, MT, MS, FTD, FSD and LOCKx
- 16.11.21 DPLL_ID_PMTR_x is now RPW
- 16.12.3 Bits 24:31 are read only
- 16.13.7ff Bits 24:31 are read only
- 16.13.12ff suppress update for unexpected missing TRIGGER or STATE respectively
- 16.13.16ff calculation of reciprocal values from predicted durations do not influence RCO
- 16.13.32ff Bits 24:31 are read only
- 16.13.43ff minor changes in formulations
- 16.13.47ff Bits 24:31 are read only
- 16.14.3 Bits 24:31 are read only
- 16.15.3 Bits 24:31 are read only
-
- 2.2.1 Updated list of registers that drive value “illegal module access”
- 9.4.3ff Address offset corrected
- 12.3.2ff SOMC mode description restructured
- 16.11.17 refined definitions of TINI and TAXI
-
- 2.2.1 Updated list of registers that may drive an aei_status signal with value “10”
- 2.5.4 Added note in single pulse mode
- 2.6ff Extended description of software debugger support (e.g. added lists of registers with special behaviour in the case of debugger access)
- 2.9.1 ision ID updated
- 2.9.3 Reset force protection includes SW RAM reset

Generic Timer Module (GTM)

- 2.9.9-11 Moved register description of AEI_bridge from module integration guide to this document. Added control and status information for diagnosis of the bridge status.
- 3.3.2 Clarified usage of debug mechanism
- 3.6.1 Extended functionality of ARU_ACCESS register
- 4.5.1 Note added
- 9.4.2 Second note added
- 11.2.2 Note to trigger signal added
- 11.8.2 Meaning of bits in ENDIS_CTRL changed
- 11.8.5 Meaning of bits in OUTEN_CTRL changed
- 12.2.2 Clarified ATOM channel startup behaviour in case of ARU_EN=1
- 12.3.2.1 Added note that less/equal compare only applies for comparisons against TBU_TS1/2
- 12.3.2.2.1 Added ACBI=00111 behaviour in table
- 12.3.2.3.3 Clarified WR_REQ and WRF bit behaviour for ATOM SOMC late update mechanism
- 12.3.2.4 Fixed ACB10 bit description
- 12.3.3.5 Clarified CLK_SRC_SR register description
- 12.3.4 Global ATOM SOMS mode behaviour update
- 12.3.4.6 Update SL and CLK_SRC_SR register description
- 12.6.2 Update SL and CLK_SRC_SR register description
- 13.4.11 Added feature to reset connected RAMs by software
- 15.1.1 Fixed minor specification issues
- 15.4.1 Completed SSL bit field description
- 16.5.10.2 Influence of SYSF to entry number
- 16.6.2.5 New Calculation for FULL_SCALE
- 16.6.2.7 New Meaning of CTO(N)
- 16.6.3.5 New Calculation for FULL_SCALE
- 16.6.3.7 New Meaning of CSO(N)
- 16.6.4.2 New Calculation for FULL_SCALE
- 16.6.5.2 New Calculation for FULL_SCALE
- 16.7ff Handling of actions in the past, considering of VTN, VSN and SYSF for calculations, use of RDT_T_FS1 and RDT_S_FS1
- 16.8.6.7 Use of NMB_T_TAR and NMB_S_TAR
- 16.10 New registers for RAM initialization, NMB_T_TAR and NMB_S_TAR
- 16.11.ff Notes to specify write abilities added. Influence of SYSF, new FST and FSS bits in NUTC/NUSC registers, new DCGI bit in DPLL_IRQ_NOTIFY register; new interrupt line connections; DPPLL_RAM_INI register
- 16.12ff Notes to specify write abilities added
- 16.13.4 NMB_T_TAR explained
- 16.13.8 NMB_S_TAR explained
- 16.13.16 Sign extension
- 16.13.17 Sign extension

Generic Timer Module (GTM)

- 16.14.1ff SYSF influence explained
- 18.5.2 Changed DPLL Interrupt ordering
-
- reworked MSC connection multiplexer structure together with controlling registers
- added forth set for MSC connections
- reworded old sets for MSC connections
- replace MSCxINCONy registers by MSCSETmCONn registers
- add registers MSCxINL/HCON registers
- removed second PSI5 connection register
- add GTM to Port Mapping for BGA-292
- add TIM0 inputs coming from ERU in SCU
- add TIM input connections for BGS-292
- add section for GTM to SENT connections
- add six additional triggers for CAN / TTCAN
- remove GTM to PSI5 trigger 1
- correct the address at the register image for register ADCTRIG0OUT1
- removed function for P32.1 (TOUT37 and TIN37)
- changes access limits for debug register from word to byte limitation

Changes from version 1.0 to 1.1

- add ATOM1 for ADC0 / 1 / 2 Trigger 0
- add ATOM0 for ADC0 / 1 / 2 Trigger 1
- replace ATOM5 with ATOM 3 for ADC5 / 6 / 7 Trigger 0/1
- skip ADC8 triggers
- shift ADC7 triggers to one group for ADC5 / 6 / 7 Triggers
- replace some TOM2 triggers with TOM0 triggers for ADC5 / 6 / 7 Trigger 0 / 1
- removed registers ADCTRIG0OUT1 and ADCTRIG1OUT1
- removed ATOM4 from MSC Set 4
- add register PSI5SOUTSEL
- removed DSADC inputs for TIM1 and TIM2 channels 6 and 7
- add connections from the ADC modules to GTM (end of conversion information)
- add debug improvements for TBU debugging

Changes from version 1.1 to 1.2

- change offset address of register DPLL_RAM_INI in the register image from 283BC_H to 281FC_H
- add debug improvements for TBU debugging
- bring back triggers for ADC 8
-
- 2.1.2 Restricted TOM/ATOM trigger lines to a certain length
- 2.3.1 Changed number of ARU data destinations
- 2.3.2 Introduced formula to determine the device dependent roundtrip time

Generic Timer Module (GTM)

- 2.6.1 Specified register behaviour of GTM_halt more precisely
- 2.9.1 ision ID updated
- 2.9.7 Note about protection included
- 3.6.1 Changed register bit field mode
- 3.6.11 Register bit 0 name corrected
- 3.6.12 Note about protection included
- 4.5.1 Reset value corrected
- 4.5.5 Note about protection included
- 5.1 Fixed specification error, FIFO RAM not initialized with zeros after reset
- 5.5.12 Note cleared automatically included
- 9.1 Specified behaviour of TBU_UPx signals more precisely
- 10ff Clarified indices descriptions of registers and bit fields
- 11.2.2 Added note for signed compare of ACT_TB
- 11.8.4 Changed naming ans description of bit field ACT_TB
- 11.8.27 note about write protection included
- 12.3.2.3.3 Specified behaviour of WR_REQ bit more precisely
- 12.3.4.1ff Specified ATOM SOMS mode more precisely
- 12.6.12 Note about write prtction included
- 13.1.1 Added hint for MCS RAM addresses and changed MCS block diagram
- 13.3.3 Note cleared by CPU included
- 13.4.6 Reset value corrected
- 13.4.9 Note protection included
- 13.4.11 Reset value corrected
- 13.4.11 Note reset values dependencies included
- 14.4.14 Note cleared by MCS channel included
- 16.5.10.1 typo corrected: APS pointer
- 16.7 number of actions calculated per increment in worst case and typical
- 16.5.10.1 typo corrected: APS pointer
- 16.7.1ff calculation of fractional part changed;decision of calculation case is dependent on the relation between q and m
- 16.7.7ff chapter ordering swapped with 16.7.8
- 16.8.4.2ff more detailed description
- 16.8.6.3ff direction change description changed
- 16.8.6.7 changed schedule of RAM update, PSTC and PSSC first value, SGE effect
- 16.10 introduced addresses for shadow registers, changed RAM addresses for calculated target pulse numbers
- 16.11.1 description of change between normal and emergency mode
- 16.11.2 write protection explained, more detailed description of SYN_NT/SYN_NS
- 16.11.12 explained differences for direction change in normal mode (SMC=0) and for SMC=1
- 16.11.13 explained direction change process
- 16.11.19 Note protection and cleared automatically included
- 16.11.24 more detailed explanation of address pointer value extension

Generic Timer Module (GTM)

- 16.11.33 New Register
- 16.11.34 New Register
- 16.11.35 New Register
- 16.11.36 New Register
- 16.12.2 explanation DLA value for low resolution
- 16.13.4 Removed NMB_T_TAR register
- 16.13.8 Removed NMB_S_TAR register
- 16.13.10 explanation TOV value for low resolution
- 16.13.11 explanation TOV_S value for low resolution
- 16.13.16 New RAM storage address
- 16.13.17 New RAM storage address
- 16.13.18 New RAM storage address
- 16.13.19 New RAM storage address
- 16.13.45 mode limited
- 16.13.46 mode limited
- 16.15.1ff start address of RAM2 changed
- SPE: Note about protection included
- 18.5.1ff Register bit mode changed to R
- 18.5.1ff Register bit mode changed to R
- 19.7.4 Note about protection included
- 21.3 Changed reference to address map
-
- 2.2.1 updated list of register which return AEI status of illegal write access
- 2.3.3 (wrong) ARU round trip time calculation removed
- 12.6.6 Note about protection included
- 12.6.8 Note about protection included
- 8.1.1 Added clock source MUX to FXU
- 8.8.ff Added clock selection bit to register CMU_CLK_5_CTRL
- 13.1.1 Updated figure in Architecture section
- 13.3.3 RAM ECC Error disables MCS channel and raises ERR bit
- 13.3.5ff Bit9 naming corrected
- 13.4.12ff Bit9 naming corrected
- 14.1 Reformulated MCFG Spec to be more generic and device independent
- 14.2.1 Reformulated MCFG_CTRL register to be more generic and device independent
- 16.5.10.2 explanation of RAM init procedure
- 16.6.2 explanation of the use of filter values
- 16.7.1ff precise case conditions
- 16.7.5.6ff precise case conditions
- 16.7.8.2ff precise case conditions
- 16.8.5 correct PSTC/PSSC calculation
- 16.11.2 precise SMC bit meaning
- 16.11.23 correct copy/paste error for INC_CNT2

Generic Timer Module (GTM)

- 18.2.3ff number of submodules (TIM, MCS, TOM and ATOM) described generic with “[i]”
- 18.3 Interrupt signals for submodules TIM, MCS, TOM and ATOM described generic with “[i]”
-
- 2.2.1 updated list of register which return AEI status of illegal write access
- 2.3.1ff Table of ARU sources corrected
- 8.5 Added clock selection bit to description
- 8.8.4ff Added clock selection bit to register CMU_CLK_5_CTRL
- 10.7 Corrected link to sub section in overview table
- 11.8.7 Description of bit field FUPD_CTRL
- 12.3.2.2.1 Condition of bit SLA added
- 12.3.2.3 Condition of bit SLA added
- 12.3.2.4 Description of new mode bit SLA
- 12.3.3.5 Bit 16 is not used instead of reserved
- 12.3.4.9 Bit 16 is not used instead of reserved
- 12.6.2 Description of new mode bit SLA added
- 13.1.1 Added ECC Error handling to specification
- 13.3ff Clarified some minor parts of the description
- 13.3.3 Clarified the behaviour of the ERR bit in STA register
- 16.6.2.7 Changed CTO/CTON behaviour in case of negative CDT_TX(_nom) values
- 16.6.3.7 Changed CSO/CSON behaviour in case of negative CDT_SX(_nom) values
- 16.6.4.4 Specified setting of CDT_TX(_nom) in case of negative values
- 16.6.5.4 Specified setting of CDT_SX(_nom) in case of negative values
- 16.7.6.1 Changed calculation of TSAC when action in far future (normal mode)
- 16.7.8.1 Changed calculation of TSAC when action in far future (emergency mode)
- 16.8.3.6 Removed deletion of FF’s in case of new trigger/state event
- 16.8.6.3ff Specify that nmb_t/s_tar_new values replaces nmb_t/s_tar values in case of direction change
- 16.10 reconfiguration of some table elements for better reading
- 16.11.6 Introduced RAM2_ERR status flag, active when access to not configured memory space happened
- 20.4 MON_ACTIVITY_1 register introduced
- 20.7 MON_ACTIVITY_1 register introduced
- 20.8.3 MON_ACTIVITY_1 register introduced
-
- update connection to QSPI
- update bit description for OTSC1.MOE
- remove CPU access to RAM from MCS trigger set TS16_MCA
- correct number of words for DPLL1B RAM in table GTM memory addresses
- add note to warn fro unexpected triggers
- remove bit discriptions in register ODA as explained in seperate table

Changes from version 1.2 to 1.3

- shift ERAY input from TIM channels 0 to channels 7
- update TIM input mapping for TC26x and QFP176
- add note for clock speeds in debug modes
- add information for BGA 416 and BGA 516
- update DSADC to GTM connections
 - add TIM0 inputs
 - move SCU inputs for TIM0 from 1110_B to 1100_B
 - add register DSADCINSEL0
- increase number of bit fields in register DSADCINSELx to 8 for all versions
- add DSADC inputs to all channels of TIM 1 and 2
- shift some DSADC TIM inputs in TIM mapping
-
- 2.1.2 trigger chain length description modified
- 2.3.1 Explain ARU round trip time more precise
- 2.5 ff Typos
- 2.6.1 Typo
- 2.9.9 Register structure updated; introduced Bit field SYNC_INPUT_REG
- 9.1 Removed TBU_TS0 indexing (x)
- 10.1 Removed specific channel number of eight
- 10.1 Removed TBU_TS0 indexing (z)
- 10.2.2 Corrected sentence
- 10.2.2.2.1 Corrected naming of filter mode
- 10.2.2.3.1 Corrected naming of filter mode
- 10.3.1 Corrected timeout calculation formula
- 10.4.2.5 Removed specific channel number of eight
- 10.6 Removed specific channel number of eight
- 10.7 Removed specific channel number of eight
- 10.8.1-13 Removed specific channel number of eight
- 10.8.14 Inserted note on register bit width dependency
- 12.3.2.4 bit ACB10 description
- 12.6.12 bit 1 TRG CCU1TC description
- 16.5.3 declaration of limits for SUB_INC1,2 clocks
- 16.8.3 after eq. 16.25b, 16.26b: explanation of SUB_INC1,2 frequency doubling possibilities
- 16.8.6.3 explanation of “make calculation” steps 3, after 5 : nmb_t replaced by nmb_t_tarin emergency step 2: explanation added at the end of chapter: some corrections
- 16.8.6.4 some corrections like 16.8.3.8 at end
- 16.10 explanation of TBU_TS_x and INC_CNT1,2 RAM Region 2 end depends on device chosen
- 16.11.1 Bits 24:11 explained more detailed

Generic Timer Module (GTM)

- 16.11.3 Bits 3,4: explained more detailed, correction
- 16.11.24,25 heading correction, Bits 5:0 explanation
- 18.3 in table GTM_DPLL_XXX description corrected
- 18.5.1 bit 24 and 25 description corrected
- 18.5.12 description corrected
- 20.8.3 MON_ACTIVITY_1 register at address 0x08
- 2.1.3 new functionality GTM signal multiplexing added
- 2.2.1 CMU_CLK_CTRL, CMU_FXCLK_CTRL, TIM[i]_CH[x]_GPR1 included
- DPLL_PSA, DPLL_DLA, DPLL_NA, DPLL_DTA removed
- 2.5 ff new error interrupt
- 2.8 new address map due to new register
- 2.9.1 bit field YEAR replaced by STEP
- 2.9.9 NOTE text improved
- 2.9.12 new error interrupt
- 2.9.13 new register GTM_TIM[i]_AUX_IN_SRC
- BRC new error interrupt
- 5.4 new error interrupt
- 5.5.14 new error interrupt
- 8.5 selection of clocks for fxclk
- 8.7 new CMU_FXCLK_CTRL
- 8.8.1 clarifying disable/enable functionality
- 8.8.5 no exception for CMU_CLK5_CTRL
- 8.8.9 selection of clocks for fxclk
- 10.1.1 Block diagram updated due to new functionality INPSRC, EXTCAPSRC
- 10.1.2 new functionality INPSRC selection added
- 10.1.3 new functionality EXTCAPSRC selection added
- 10.3 TDU Block diagram and description updated due to new functionality of edge selection
- 10.4.1 TIM channel block diagram and description updated due to new functionality (ECNT increased to 16 bit, ECNT can be captured to GPRx_REG, External_capture)
- 10.4.2ff New functionality External_capture, EGPRx_SEL added to existing TIM modes
- 10.4.2.6 New TIM mode TGPS added
- 10.7 Configuration registers updated due to new added functions
- 10.8.1-2 New bitfields added to support new functionality
- 10.8.5 Register removed, rearranged to TDUV, TDUC register
- 10.8.15-20 Register description for new functions added
- 11.4 TOM_CH2 special mode hint added
- 11.8.17 CLK_SRC_SR bits: description improved
- RST_CCU0 bit: note added
- SPEM bit: note added
- CLK_SRC_SR bits: description improved
- 12.3.2.2.1ff table design corrected

Generic Timer Module (GTM)

- 12.3.2.2.1ff TRIGOUT bit: added
- CLK_SRC_SR bits: NOTE added
- ACBO bits: NOTE added
- 13.1.1 Clarified usage of write accesses to MCS registers in the case of multiple source. Usage of accessing common trigger register is clarified.
- 13.4.11 Added Error interrupt register MCS[i]_CH[x]_EIRQ_EN
- 13.4.13-14 Added Note for writing common trigger bits via AEI
- 15.1.1 figure updated, description of new DIR selection added
- 15.4.1 TSEL bit: TIM0_IN6 feature added
- LSEL bit: new configuration bit
- 16.6.2ff TRIGGER time stamp resolution for filter values considered
- 16.6.3ff STATE time stamp resolution for filter values considered
- 16.7ff up to 32 actions served for device 4
- 16.10 additional registers and address map changed
- 16.11.2 some control bits added
- 16.11.6 control register for 8 additional actions
- 16.11.78 control bits for 8 additional actions
- 16.11.20-21 additional EIRQ enable register
- 16.11.30-35 status register with changed address and omitting CTON/CSON
- up to 32 ID_PMTM register changed SHADOW register bits
- 16.12.1-4 extension to serve 32 actions
- 16.13.38-39 centralization for TRIGGER and STATE calculation
- 16.15ff additional register address range for changed and additional registers to serve up to 32 actions
- 17.2.2 figure updated
- 17.2.4 new chapter for SPE revolution detection
- 17.3 new interrupt SPE_RCMP
- 17.4 new register added
- 17.5.5-6 new register
- 17.5.7 additional IRQ
- 17.5.8 additional IRQ
- 17.5.9 additional IRQ
- 17.5.11 new register
- 18.3 new GTM Error Interrupt
- 18.4 new BRC, FIFO[i]_CH[x], TIM[i]_CH[x], MCS[i]_CH[x], SPE[i], CMP, DPLL, GTM Error Interrupt register
- 18.5.13-18 description of new Error Interrupt Register
- 19.5 new error interrupt
- 19.6 new error interrupt
- 19.7.6 description of new Error Interrupt Register
- 20.5 Note concerning ARU roundtrip time measurement by MCS added
- 10.1.3 EXTCAP_SRC: enhanced functionality description

Generic Timer Module (GTM)

- 10.4.1 new functionality: TIM input signal value available via ECNT[0] if channel is disabled
- 10.4.2 ff EXT_CAP_EN: enhanced functionality description. Added to each TIM channel description of external capture behaviour.
TGPS mode: enhanced functionality description. new functionality: in TGPS mode GPR1 operates as a shadow register for CNTS
- 10.8.7 Register description updated due to added TGPS functionality
- 2.2.1 List of registers and address ranges which return AEI status “10” corrected
- 3.3.1 Note for bit 12 (RREQ) and bit 13 (WREQ) of register ARU_ACCESS added
- 10.8.19 Note added to ECNT register (behaviour of ECNT if channel gets disabled)
- 14ff layout option changed to layout configuration
- 16.4ff clear index 9
- 16.4.2 no hex for width
- 16.5.5 IP like formulation of clock frequency requirements
- 16.5.6 Remove uncleared abbreviation “CDG”
- 16.6.2 Reduction of CTON, CTO function to just CTO flag
- 16.6.3 Reduction of CSON, CSO function to just CSO flag
- 16.11.30 Clarification on SYS/SYT flags, because not influenced for TOR/SOR states
- 18.5.14ff correct naming IRQ to EIRQ
- 19.1.1 include CMP_EIRQ
- 19.3 include CMP_EIRQ_EN
- 19.5 include CMP_EIRQ
- changed reset value for TOM and ATOM CTRL registers SL bits from 0 to 1
-
- changed reset value for TOM and ATOM CTRL registers OL bits from 1 to 0
- update information about access protection

Changes from version 1.3 to 1.4

- correct typo in ADCx Timer Trigger tables so that it matches with the register description
- update GTM connections to ports for TC26x
 - add TOM1_12 and ATOM0_4 for P10.0
 - add TOM1_6 and ATOM1_6 for P10.4
 - add TOM1_8 and ATOM0_0 for P10.7
 - add TOM1_13 and ATOM0_5 for P10.8
 - add TIM2_2, TOM1_4 and ATOM3_4 for P14.10
 - add TOM1_0 and ATOM3_0 for P14.7
 - add TIM2_3 and TOM1_2 for P14.8
 - add TIM2_2 and TOM1_3 for P14.9
 - add TIM0_3 and TOM0_3 for P20.1
 - add TIM0_3 and TOM1_8 for P21.0
 - add TIM0_4 and TOM1_9 for P21.1

Generic Timer Module (GTM)

- add TOM1_2 and ATOM1_2 for P23.5
- update GTM connections to ports for TC29x
 - move timer mapping for P00.13 to P00.15
 - move timer mapping for P00.15 to P00.13
 - update timer mapping for P01.0
 - move timer mapping for P01.09 to P01.1
 - move timer mapping for P01.13 to P01.10
 - move timer mapping for P01.15 to P01.11
 - move timer mapping for P01.08 to P01.12
 - move timer mapping for P01.11 to P01.13
 - move timer mapping for P01.02 to P01.15
 - move timer mapping for P01.01 to P01.2
 - add P01.3 to timer mapping
 - move timer mapping for P01.12 to P01.8
 - move timer mapping for P01.10 to P01.9
 - replace for P02.0 TOM0_12 by TOM0_8 and TOM1_12 by TOM1_8
 - move timer mapping for P02.14 to P02.13
 - move timer mapping for P02.15 to P02.14
 - move timer mapping for P02.13 to P02.15
 - move timer mapping for P10.13 to P10.11
 - move timer mapping for P10.15 to P10.12
 - move timer mapping for P10.12 to P10.13
 - move timer mapping for P10.11 to P10.14
 - move timer mapping for P10.14 to P10.15
 - move timer mapping for P14.15 to P13.14
 - move timer mapping for P14.11 to P13.09
 - move timer mapping for P13.09 to P14.11
 - move timer mapping for P13.12 to P14.12
 - move timer mapping for P13.11 to P14.13
 - move timer mapping for P13.10 to P14.14
 - move timer mapping for P13.14 to P14.15
 - add P26.0 to timer mapping
 - removed P34.0
 - 11.2.1 bit field name CLK_SRC_STAT replaced
 - 11.8.1 bit field name CLK_SRC_STAT replaced
 - 12.6.1 bit field name CLK_SRC_STAT replaced
 - 13.2.2.10 reference to ACB replaced by reference to MHB
 - 16.13.7 more precisely explanation of THMI
 - 16.13.8 more precisely explanation of THMA
 - 16.13.9 more precisely explanation of THVAL
 - 17.5.6 note related to SPEi_RCMP interrupt added
 - remove GTM to QSPI connections
 - change encoding for TS16_DRA1A/1BC/2 DPLL RAM Access Address table

Generic Timer Module (GTM)

- updated register names for ATOMi_CHx_CTRL, TS_T, TS_T_OLD, PSTM, PSTM_OLD, PSSM, and PSSM_OLD for header generation

Changes from version 1.4 to 1.5

- removed second vadc_G6ARBCNT inputs for TIM1 at position 1100
- update end addresses for the DPLL RAMs in the RAM address table
- removed TIM2_5 connection to P34.5
- aligned for TC26x and TC24x the pad to TIM input mapping
- 2.3.3 round trip time advice
- 2.5 correct register name from (...CEI1 to ...CEI5) to (...CEI0 to ...CEI4)
- 2.5.4 exception advice
- 5.1 Explanation of flushing the FIFO after write access to START_ADDR or END_ADDR register
- 5.2.2 Further explanation of ring buffer mode
- 5.5.2ff Note added for further explanation
- 5.5.4ff Note added for further explanation
- 8.3 more precisely explanation of using clocks
- 10.1.2 more precisely explanation of F_{in}(x)
- 10.4.2.5 removed wrong explanation that channels 1 to m-1 have to be disabled
- 10.4.2.6 corrected TGPS mode explanation (counting is done via selected CMU clock)
- 11.1 new indices definition
- 11.3.6 additional one shot mode handling hint
- 12.3.3.4 additional one shot mode handling hint
- 12.6.1 UPEN_CTRL0 Note deleted
- 16.10.5.1ff address relation and names in EXT register region and RAM2 precised
- 16.6.2ff signal names changed
- 16.7 operation times precised for new version
- 16.8.3.4 description of sub_inc generation conditions
- 16.11.2 relation of CMU_CLKo to system clock
- 16.11.3 - 6,8 activity of the enable bits only for DEN=1, reset of SWON_x for DEN=0
- 17.5.4 additional note to SPE_OUT_CTRL
- 182.5ff more precisely explanation of interrupt bundling
- correct typos

Changes from version 1.5 to 1.6

- removed bit OTSC1.MCE as this bit is not required for a correct trace
- correct typos
- replace connections for DSADC1 with DSADC3 for TC26x and TC24x
- removed GxARBCNT for x>3 of TC26x and TC24x
- changed P01.8 TIN158 / TOUT158 to TIN162 / TOUT162
- add ADC output trigger 4 for TC24x

Generic Timer Module (GTM)

- remove connections to and from P10.12
- remove connections to and from P13.8
- remove connections to and from P15.9
- added QFP-144 pinning for TC24x
- remove P00.5 for QFP-80
- remove P00.9 for QFP-100
- and hint for DPLL RAM 1a access errors of TC26x
- added DSADC and ADC connections for TC29x
- add missing bit field for ADC 3 to registers ADCTRIG0OUT0 and ADCTRIG1OUT0 for TC24x
- 2.5 more detailed description of IRQ_NOTIFY
- 2.9.13 bit 0 formula corrected
- 5.5.3 end replaced by start
- 5.5.4 upper replaced by lower
- 5.5.6 EMPTY and FULL description corrected
- 10.2.3 more detailed information about filter reconfiguration
- 10.5 more detailed information about MAP interface
- 10.8.1ff more detailed information about TIM MODE reconfiguration and GELx_SEL
- 10.8.6 additional information about GPR0
- 10.8.7 additional information about GPR1
- 10.8.9 additional information about CNTS
- 10.8.20 additional information about input selection by EXT_CAP_SRC
- 11.3 more detailed specification behavior in case of reset of CN0 by CCU0 compare and trigger
- 12.3.2.3 additional information about compare strategy; figure and description above added
- 12.3.3ff more detailed specification of behavior in case of reset of CN0 by CCU0 compare and by trigger
- 12.3.3.4 figure description corrected
- 12.3.3.5 more detailed information about CLK_SRC_SR and RST_CCU0 in SOMP mode
- 12.6.2 additional / corrected notes for bit SL
- 13.4.1 added missing Note for MEM_ERR_IRQ bit
- 14.1ff new chapter for memory layout configurations and for memory layout parameters
- 16ff all equations numbering transformed from 16.xxx to DPLL-xxx

Changes from version 1.6 to 1.7

- add register MSC0INEXTLCON for TC24x
- removed PSI5 and PSI5-S connections for TC24x
- make some minor correct in the pinning list for TC24x QFP100

Changes from version 1.7 to 1.8

- add register MSC0INEXTLCON for TC26x
- update to Bosch specification version 1.5.5.1:
- 2.2.1 Additional information about status '10'
- 2.4.1 precising the number of generated clocks
- 2.5.1ff corrected signal nmae as same in figure
- 2.9.1 Additional information about bits and values
- 4.5.3 precising information about DID
- 5.5.1 precising information about WULOCK
- 8.3.6 precising the number of generated clocks
- 8.8.1 removed note: Any disabling to EN_ECLKz will be reset internal counters for external clocks
- 10.1.1 replaced GPRz by GPR0 and GPR1
- 10.1.2 state bit VAL_x(1) and MODE_x(1) introduced in diagram and textual description
- 10.1.3.1 precising enable external capture functionality
- 10.3.1 replaced GPRz by GPR0 and GPR1; Extended description of ACB(2:0) bit behavior in case of a timeout event
- 10.4.1 replaced GPRz by GPR0 and GPR1
- 10.4.2 replaced GPRzOFL by GPROFL
- 10.4.2.1 Extended description of CNTS register update
- 10.4.2.3 replaced GPRzOFL by GPROFL
- 10.6 replaced GPRz by GPR0 and GPR1
- 10.6 replaced GPRzOF by GPROFL
- 10.8.2. replaced GPRz by GPR0 and GPR1
- 10.8.10-12 replaced GPRzOFL by GPROFL
- 10.8.15 Description of VAL_0 and MODE_0 enhanced
- 10.8.16 replaced GPRzOFL by GPROFL
- 10.8.20 bit width of EXT_CAP_SRC corrected; new values added
- 11.3.6.1 precising of one shot mode handling
- 11.3.7.1 precising of pulse count modulation mode
- 12.3.2.2 precising description of serve last compare strategy
- 12.3.3.4. precising of one shot mode handling
- 12.6.9 additioanl note for RST_CCU0
- 13.3.3 precising usage of instruction in conjunction with STA
- 16.8.6.7 replaced invalid by inactive
- 16.11 precising section headline and content
- 16.11ff replaced lower case letters in bit fields by upper case letters; added missing prefix DPLL_ to all registers or momory labels
- 16.11.1 precising bit fields 15:11 and 24:16
- 16.11.7 replaced bit field 23:0 by 31:0; additional note for limitations
- 16.11.14 precising NUTE and WNUT definitions

Generic Timer Module (GTM)

- 16.11.17ff replaced lost by loss
- 16.11.30 precisising SOR, MS, TOR, LOCK2, LOCK1 definition
- 16.11.37ff replaced section 16.12ff by 16.11.37-40
- 16.11.41ff replaced section 16.13ff by 16.11.41-91
- 16.11.50 precisising TOV definition
- 16.11.51 precisising TOV_S definition
- 16.11.54 precisising MPVAL1 definition
- 16.11.55 precisising MPVAL2 definition
- 16.11.76 precisising TLR definition
- 16.11.77 precisising SLR definition
- 16.11.92ff replaced section 16.14ff by 16.11.92-95
- 16.11.94 precisising PD_S definition
- 16.11.98ff replaced section 16.15ff by 16.11.96-98
- 16.11.98 replaced ACBj by ACB
- 16.12ff added missing prefix DPLL_ to all register or memory labels
- 16.12.1 precisising RDT_T definition
- 16.12.2 precisising TSF_T definition
- 16.12.3 precisising PD NT definition
- 16.12.4 precisising DT_T definition
- 20.4 replaced MCS[z]_CH[x]_MCA by MCA_i_x
- 20.8.1 replaced MCS[x] by MCSx
- 20.8.2,3 replaced MCS[z]_CH[x]_MCA by MCA_i_x

Changes from version 1.8 to 1.9

- correct error in BGA-416 TOUT numbering for 10.13 and 10.11
- connection shown in figures and register for SET5 and SET6 to MSC2 was corrected
- update description of bit field OCS.SUS
- update description of (A)TOM SOMP Mode
- clarify reset behavior of debug registers
- correct error for 2.11; it is connected to TIM4_4 not to TIM4_7
-

27 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application specific modes, mainly for AC drive control. Special operating modes support the control of Brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported.

It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 kernels.

This chapter is structured as follows:

- Introduction (see [Section 27.1](#))
including register overview (see [Section 27.1.3](#))
- Operating T12 (see [Section 27.2](#))
including T12-related registers (see [Section 27.2.8](#))
and capture/compare control registers (see [Section 27.2.9](#))
- Operating T13 (see [Section 27.3](#))
including T13-related registers (see [Section 27.3.6](#))
- Synchronous start feature (see [Section 27.4](#))
- Trap handling (see [Section 27.5](#))
- Multi-Channel mode (see [Section 27.6](#))
- Hall sensor mode (see [Section 27.7](#))
- Modulation control registers (see [Section 27.8](#))
- Interrupt handling (see [Section 27.9](#))
including interrupt registers (see [Section 27.9.2](#))
- General module operation (see [Section 27.10](#))
including general registers (see [Section 27.10.5](#))
and BPI registers (see [Section 27.10.6](#))
- Module implementation (see [Section 27.11](#))

27.1 Introduction

The CCU6 unit is made up of a Timer T12 Block with three capture/compare channels and a Timer T13 Block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive AC-motors or inverters.

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

*Note: The capture/compare module itself is named CCU6 (capture/compare unit 6).
A capture/compare channel inside this module is named CC6x.*

27.1.1 Feature Set Overview

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Generation of a three-phase PWM supported (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Many interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

Capture/Compare Unit 6 (CCU6)

27.1.2 Block Diagram

The Timer T12 can operate in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel operates in compare mode, whereas another channel operates in capture mode). The Timer T13 can operate in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

Figure 27-1 CCU6 Block Diagram

27.1.3 CCU6 Kernel Registers

For the generation of the overall register table, the prefix “CCU6x_” has to be added to the register names in this table to identify the registers of different CCU6 kernels that are implemented. In this naming convention, x indicates the kernel number.

Table 27-1 shows all registers required for programming of a CCU6. It summarizes the CCU6 kernel registers and defines their offset addresses. BPI registers are listed separately in **Table 27-14**, and Module Output Select registers are listed in **Table 27-16**.

The CCU6 module has no destructive register read mechanisms.

CCU6 Kernel Register Overview

Figure 27-2 CCU6 Registers

Note: In the case of a write access to addresses inside the address range (that is covered by the same chip select signal), but that are not the addresses explicitly mentioned for the module, the write access is not taken into account for the

Capture/Compare Unit 6 (CCU6)

module. The same principle is valid for read accesses. In case of a read access to another address, the module does not react.

Note: The exact register address is given by the relative address of the register (given in [Table 27-1](#)) plus the kernel base address (given in [Table 27-15](#)) of the kernel.

Table 27-1 CCU6 Module Registers

Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
General Registers

27.2 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs. Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see [Section 27.2.1](#))
- Counting scheme (see [Section 27.2.2](#))
- Compare modes (see [Section 27.2.3](#))
- Compare mode output path (see [Section 27.2.4](#))
- Capture modes (see [Section 27.2.5](#))
- Shadow transfer (see [Section 27.2.6](#))
- T12 operating mode selection (see [Section 27.2.7](#))
- T12 register description (see [Section 27.2.8](#))

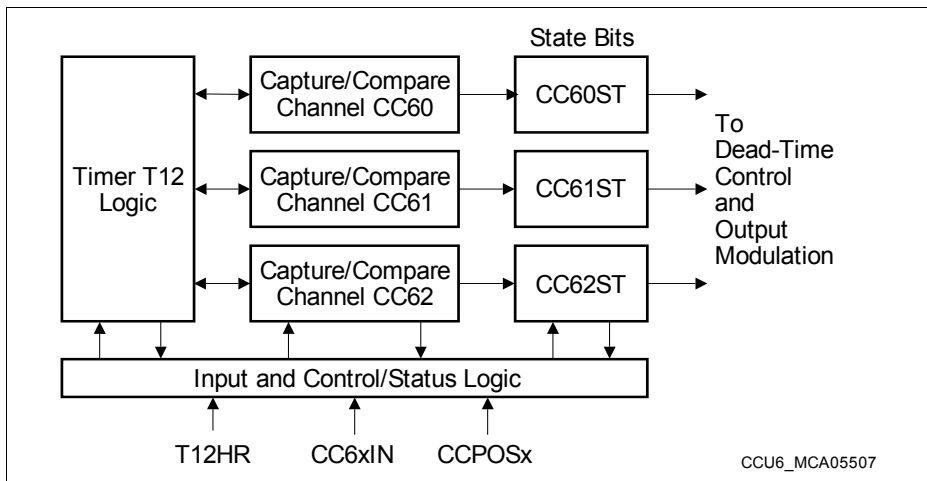

Figure 27-3 Overview Diagram of the Timer T12 Block

27.2.1 T12 Overview

Figure 27-4 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISELO**.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see Table 27-2). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

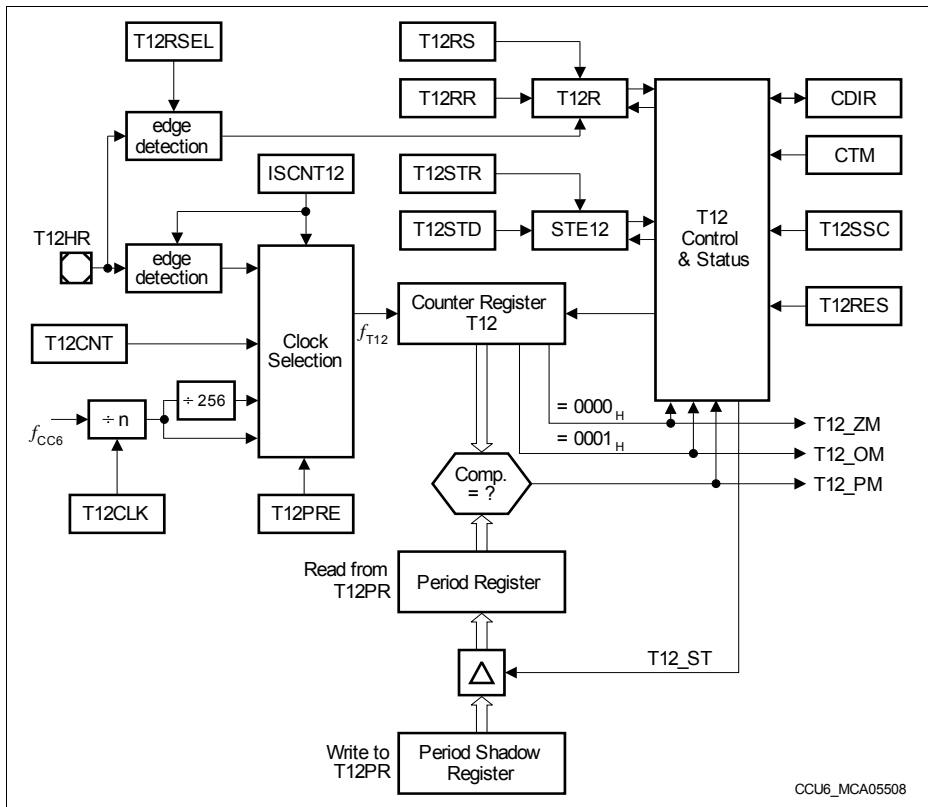

Figure 27-4 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register **T12** is connected to a Period Register **T12PR**. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from 'up' to

Capture/Compare Unit 6 (CCU6)

'down' after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.

A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see [Section 27.2.6](#)) is controlled via the 'T12 Shadow Transfer' control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.

Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode ([Figure 27-5](#)) or Center-Aligned mode ([Figure 27-6](#)), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see [Figure 27-7](#) and [Figure 27-8](#)).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register [TCTR4](#). The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR ([TCTR2.T12RSEL](#)), or it is cleared by hardware according to preselected conditions.

The timer T12 run bit T12R must not be set while the applied T12 period value is zero. Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.

While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

27.2.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

27.2.2.1 Clock Selection

In **Timer Mode** (**PISEL2.ISCNT12** = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 27-2**. The prescaler of T12 is cleared while T12 is not running (**TCTR0.T12R** = 0) to ensure reproducible timings and delays.

Table 27-2 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock f_{T12} Prescaler Off (T12PRE = 0)	Resulting Input Clock f_{T12} Prescaler On (T12PRE = 1)
000 _B	f_{CC6}	$f_{CC6} / 256$
001 _B	$f_{CC6} / 2$	$f_{CC6} / 512$
010 _B	$f_{CC6} / 4$	$f_{CC6} / 1024$
011 _B	$f_{CC6} / 8$	$f_{CC6} / 2048$
100 _B	$f_{CC6} / 16$	$f_{CC6} / 4096$
101 _B	$f_{CC6} / 32$	$f_{CC6} / 8192$
110 _B	$f_{CC6} / 64$	$f_{CC6} / 16384$
111 _B	$f_{CC6} / 128$	$f_{CC6} / 32768$

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to **TCTR4.T12CNT** and **PISEL2.ISCNT12** = 01_B
- If a rising edge of input signal T12HR is detected and **PISEL2.ISCNT12** = 10_B
- If a falling edge of input signal T12HR is detected and **PISEL2.ISCNT12** = 11_B

27.2.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

Figure 27-5 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$$T12_{PER} = \langle \text{Period-Value} \rangle + 1; \text{ in } T12 \text{ clocks } (f_{T12}) \quad (27.1)$$

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.

When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center-Aligned mode, the timer period is given by:

$$T12_{PER} = (\langle \text{Period-Value} \rangle + 1) \times 2; \text{ in } T12 \text{ clocks } (f_{T12}) \quad (27.2)$$

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

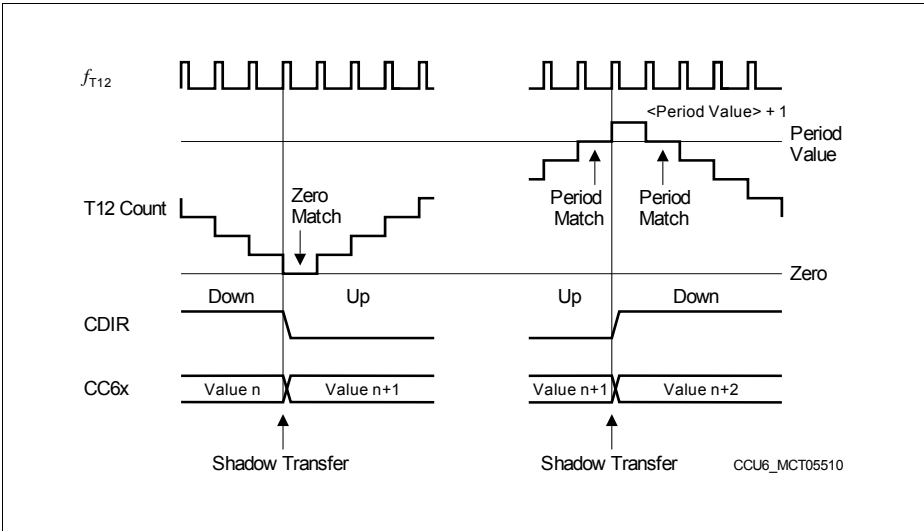

Figure 27-6 T12 Operation in Center-Aligned Mode

Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see [Figure 27-6](#)).

27.2.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see [Figure 27-7](#)).

Figure 27-7 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see [Figure 27-8](#)).

Figure 27-8 Single-Shot Operation in Center-Aligned Mode

27.2.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in [Section 27.2.5](#).

27.2.3.1 Compare Channels

In Compare Mode (see [Figure 27-9](#)), the three individual compare channels CC60, CC61, and CC62 can generate a three-phase PWM pattern.

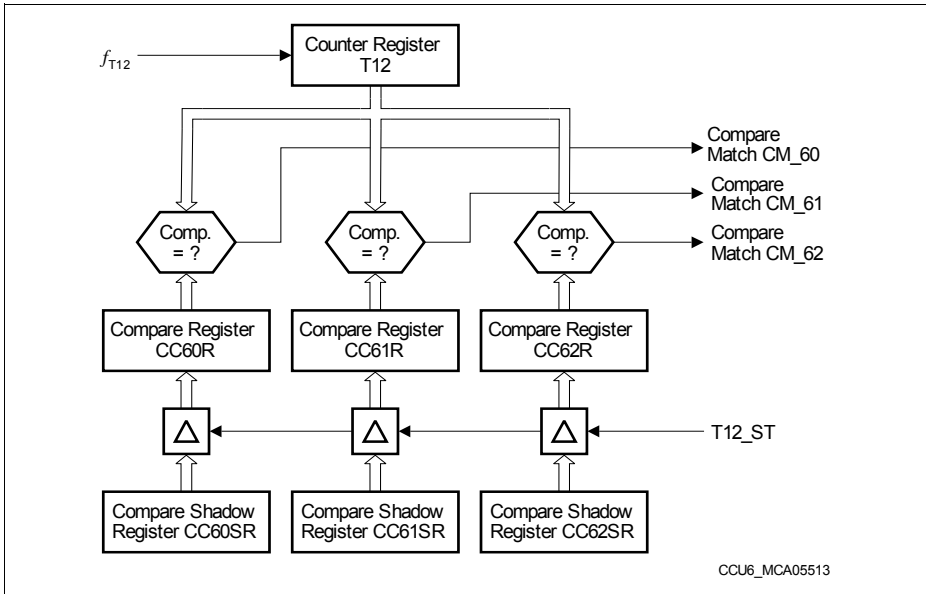

Figure 27-9 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

27.2.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, **CMPSTAT.CC6xST**, holding the status of the compare (or capture) operation (see **Figure 27-10**). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

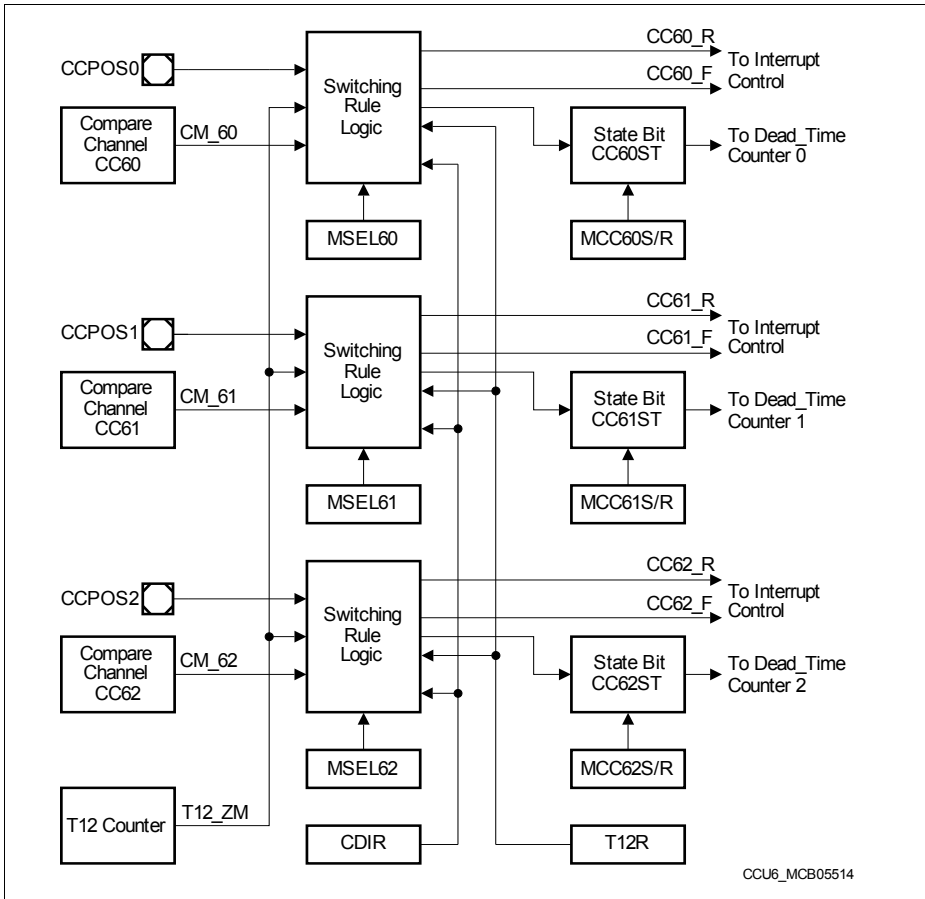

Figure 27-10 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, **T12MSEL.MSEL6x**.

Capture/Compare Unit 6 (CCU6)

In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register **CMPMODIF**, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in **Figure 27-11** and **Figure 27-12**):

A State Bit **CC6xST** is set to 1:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST** is cleared to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

Figure 27-11 Compare Operation, Edge-Aligned Mode

Figure 27-13 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed

Capture/Compare Unit 6 (CCU6)

while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

Figure 27-12 Compare Operation, Center-Aligned Mode

Figure 27-13 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H . Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H . In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule 'zero-match AND compare-match' is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to $\langle \text{Period-Value} \rangle + 1$, and the State Bit CC6ST remains cleared.

Figure 27-14 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

Capture/Compare Unit 6 (CCU6)

Figure 27-14 Three-Channel Compare Waveforms

27.2.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode (**T12MSEL.MSEL6x = 1001_B**) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.

As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see **Figure 27-10** for the state bit logic and **Figure 27-15** for the output paths).

The CCPOSx inputs are evaluated with f_{CC6} .

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

27.2.4 Compare Mode Output Path

Figure 27-15 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to **Section 27.2.4.3** for details on the output modulation.

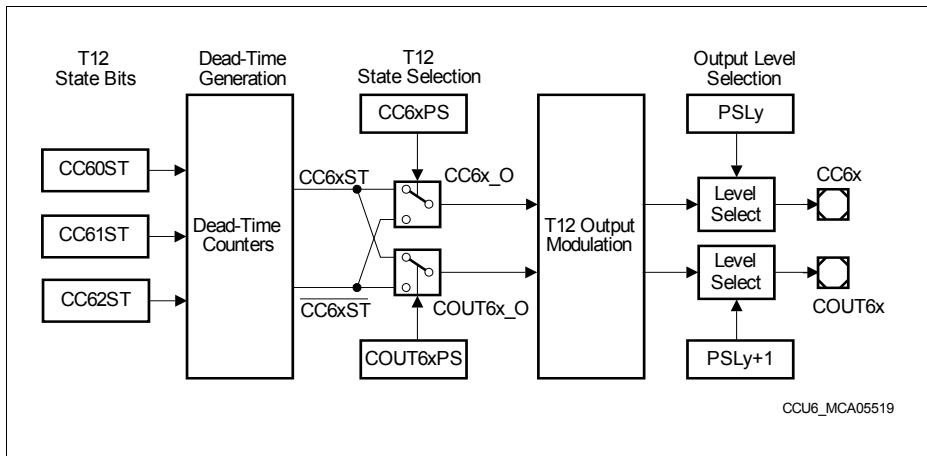

Figure 27-15 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

27.2.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit

Capture/Compare Unit 6 (CCU6)

contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in **Figure 27-16**, is built in a similar way for all three channels of T12. It is controlled by bits in register **T12DTC**. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing **TCTR4.DTRES = 1** sets all dead-times to passive.

Figure 27-16 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTE_x. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6_xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6_xST changes too early. A disabled dead-time counter is always considered as passive and does not delay any edge of CC6_xST.

Based on the State Bits CC6_xST, the Dead-Time Generation Block outputs a direct signal CC6_xST and an inverted signal $\overline{\text{CC6xST}}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in **Figure 27-17**).

Figure 27-17 Dead-Time Generation Waveforms

27.2.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals.

The state selection is based on the signals $\overline{\text{CC6xST}}$ and $\overline{\text{CC6xST}}$ delivered by the dead-time generator (see [Figure 27-15](#)). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit CC6xST .

The user can select independently for each output signal CC6xO and COUT6xO if it should be active before or after the compare value has been reached (see register [CMPSTAT](#)). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal CC6xO can be active before, whereas COUT6xO can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

27.2.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register **MODCTR**). The following signal sources can be combined here **for each T12 output signal** (see **Figure 27-18** for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.

If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register **PSLR**. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Figure 27-18 shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

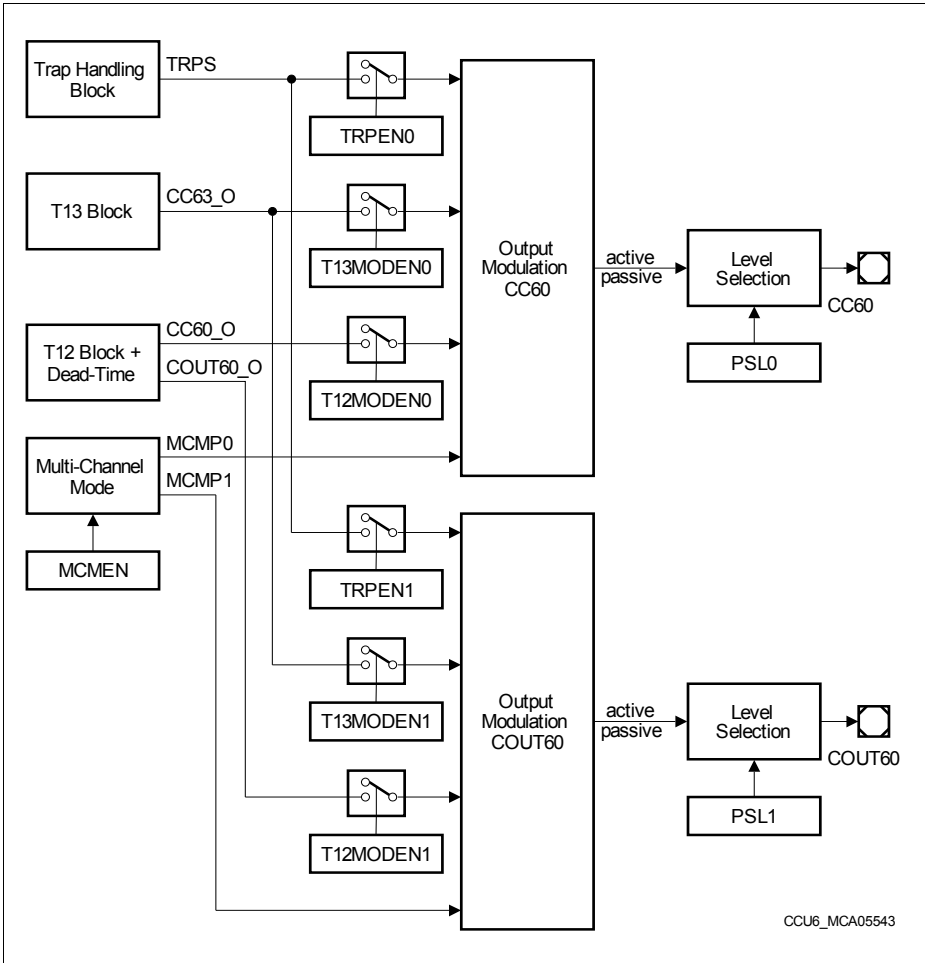

Figure 27-18 Output Modulation for Compare Channel CC60

27.2.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.

In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the **T12MSEL**.MSEL6x bit fields and can be selected individually for each of the channels.

Table 27-3 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6nSR Stored in	T12 Stored in
0100 _B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101 _B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110 _B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111 _B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 27-19 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

Figure 27-19 Capture Mode 1 Block Diagram

Capture/Compare Unit 6 (CCU6)

Capture Modes 2, 3 and 4 are shown in **Figure 27-20**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 27-3**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

Figure 27-20 Capture Modes 2, 3 and 4 Block Diagram

Capture/Compare Unit 6 (CCU6)

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

Figure 27-21 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in [Table 27-4](#).

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also [Section 27.9](#)).

Table 27-4 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010 _B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011 _B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100 _B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR
1101 _B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110 _B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111 _B	–	reserved (no capture or compare action)		

27.2.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0.STE12** (set by writing 1 to the write-only bit **TCTR4.T12STR**, cleared by writing 1 to the write-only bit **TCTR4.T12STD**).

Figure 27-22 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

Figure 27-22 T12 Shadow Register Overview

Capture/Compare Unit 6 (CCU6)

A T12 shadow register transfer takes place (T12_ST active):

- while timer T12 is not running (T12R = 0), or
- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

27.2.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields **T12MSEL.MSEL6x**.

Table 27-5 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000 _B , 1111 _B	Capture/Compare modes switched off
0001 _B , 0010 _B , 0011 _B	Compare mode, see Section 27.2.3 same behavior for all three codings
01XX _B	Double-Register Capture modes, see Section 27.2.5
1000 _B	Hall Sensor Mode, see Section 27.7 In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001 _B	Hysteresis-like compare mode, see Section 27.2.3.3
1010 _B , 1011 _B , 1100 _B , 1101 _B , 1110 _B	Multi-Input Capture modes, see Section 27.2.5

The clocking and counting scheme of the timers are controlled by the timer control registers **TCTR0** and **TCTR2**. Specific actions are triggered by write operations to register **TCTR4**.

27.2.8 T12 related Registers

27.2.8.1 T12 Counter Register

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW.

In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

T12

Timer T12 Counter Register (20_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
T12CV	[15:0]	rwh	Timer 12 Counter Value This register represents the 16-bit counter value of Timer12.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

27.2.8.2 Period Register

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value that is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

T12PR

Timer 12 Period Register

(24_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
T12PV	[15:0]	rwh	T12 Period Value The value T12PV defines the counter value for T12 leading to a period-match. When reaching this value, the timer T12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Capture/Compare Unit 6 (CCU6)

27.2.8.3 Capture/Compare Registers

In compare mode, the registers CC6xR (x = 0 - 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

CC6xR (x = 0-2)

Capture/Compare Register for Channel CC6x

$$(30_H + 4 * x)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCV	[15:0]	rh	Capture/Compare Value In compare mode, the bit fields CCV contain the values, that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Capture/Compare Unit 6 (CCU6)

27.2.8.4 Capture/Compare Shadow Registers

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected capture mode).

CC6xSR (x=0-2)

Capture/Compare Shadow Reg. for Channel CC6x
(40_H+4*x)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCS	[15:0]	rwh	Shadow Register for Channel x Capture/Compare Value In compare mode, the bit fields contents of CCS are transferred to the bit fields CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

27.2.8.5 Dead-time Control Register

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM.

The dead time counters are clocked with the same frequency as T12.

This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead time.

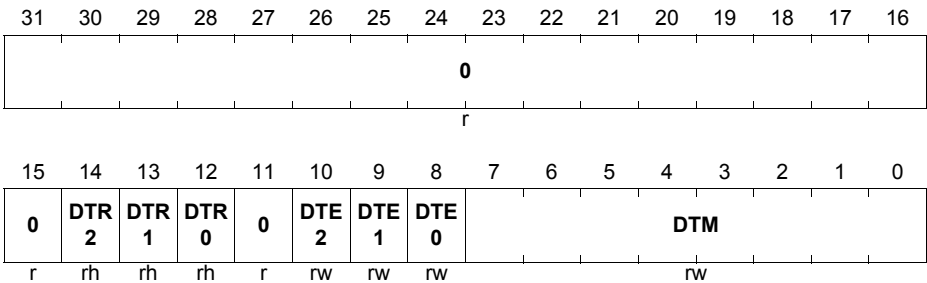

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC

Dead-Time Control Register for Timer12

(28_H)

Reset Value: 0000 0000_H

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
DTM	[7:0]	rw	Dead-Time Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.
DTE2, DTE1, DTE0	10, 9, 8	rw	Dead Time Enable Bits Bits DTE0..DTE2 enable and disable the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1_B Dead-Time Counter x is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTR2, DTR1, DTR0	14, 13, 12	rh	Dead Time Run Indication Bits Bits DTR0..DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12. 0_B Dead-Time Counter x is currently in the passive state. 1_B Dead-Time Counter x is currently in the active state.
0	11, [31:15]	r	Reserved; Returns 0 if read; should be written with 0.

27.2.9 Capture/Compare Control Registers

27.2.9.1 Channel State Bits

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state and control bits defining the active/passive state of the compare channels.

CMPSTAT

Compare State Register (60_H) Reset Value: 0000 0000_H

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
CC60ST, CC61ST, CC62ST, CC63ST ¹⁾	0, 1, 2, 6	rh	Capture/Compare State Bits Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST (x = 0, 1, 2) are related to T12, bit CC63ST is related to T13. 0_B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been cleared by SW the last time. 1_B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.
CCPOS60, CCPOS61, CCPOS62	3, 4, 5	rh	Sampled Hall Pattern Bits Bits CCPOS6x (x = 0, 1, 2) are indicating the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event HCRDY (Hall Compare Ready) occurs. 0_B The input CCPOSx has been sampled as 0. 1_B The input CCPOSx has been sampled as 1.
CC60PS, CC61PS, CC62PS, COOUT60PS, COOUT61PS, COOUT62PS, COOUT63PS ²⁾	8, 10, 12, 9, 11, 13, 14	rwh	Passive State Select for Compare Outputs Bits CC6xPS, COOUT6xPS select the state of the corresponding compare channel, that is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS, COOUT6xPS (x = 0, 1, 2) are related to T12, bit CC63PS is related to T13. 0_B The corresponding compare signal is in passive state while CC6xST is 0. 1_B The corresponding compare signal is in passive state while CC6xST is 1. In capture mode, these bits are not used.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13IM 3)	15	rwh	T13 Inverted Modulation Bit T13IM inverts the T13 signal for the modulation of the CC6x and COU6x (x = 0, 1, 2) signals. 0 _B T13 output CC63_O is equal to <u>CC63ST</u> . 1 _B T13 output CC63_O is equal to <u>CC63ST</u> .
0	7, [31:16]	r	Reserved; Returns 0 if read; should be written with 0.

- 1) These bits are set and cleared according to the T12, T13 switching rules
- 2) These bits have shadow bits and are updated in parallel to the capture/compare registers of T12, T13 respectively. A read action targets the actually used values, whereas a write action targets the shadow bits.
- 3) This bit has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit.

Capture/Compare Unit 6 (CCU6)

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped.

CMPMODIF
Compare State Modification Register
(64_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
MCC60S, MCC61S, MCC62S, MCC63S, MCC60R, MCC61R, MCC62R, MCC63R	0, 1, 2, 6, 8, 9, 10, 14	w	Capture/Compare Status Modification Bits These bits are used to bits to set (MCC6xS) or to clear (MCC6xR) the corresponding bits CC6xST by SW. This feature allows the user to individually change the status of the output lines by SW, e.g. when the corresponding compare timer is stopped. This allows a bit manipulation of CC6xST-bits by a single data write action. The following functionality of a write access to bits concerning the same capture/compare state bit is provided: [MCC6xR, MCC6xS] = 00 _B Bit CC6xST is not changed. 01 _B Bit CC6xST is set. 10 _B Bit CC6xST is cleared. 11 _B reserved
0	[5:3], 7, [13:11], [31:15]	r	Reserved; Returns 0 if read; should be written with 0.

27.2.9.2 T12 Mode Control Register

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of Timer T12.

T12MSEL

T12 Mode Select Register

(68_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
MSEL60, MSEL61, MSEL62	[3:0], [7:4], [11:8]	rw	Capture/Compare Mode Selection These bit fields select the operating mode of the three T12 capture/compare channels. Each channel (x = 0, 1, 2) can be programmed individually for one of these modes (except for Hall Sensor Mode). Coding see Table 27-5 .
HSYNC	[14:12]	rw	Hall Synchronization Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. Coding see Table 27-11 .
DBYP	15	rw	Delay Bypass DBYP controls whether the source signal for the sampling of the Hall input pattern (selected by HSYNC) is delayed by the Dead-Time Counter 0. 0 _B The bypass is not active. Dead-Time Counter 0 is generating a delay after the source signal becomes active. 1 _B The bypass is active. Dead-Time Counter 0 is not used for a delay.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.2.9.3 Timer Control Registers

Register TCTR0 controls the basic functionality of both timers, T12 and T13.

Note: A write action to the bit fields T12CLK or T12PRE is only taken into account while the timer T12 is not running (T12R=0). A write action to the bit fields T13CLK or T13PRE is only taken into account while the timer T13 is not running (T13R=0).

TCTR0
Timer Control Register 0
(70_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
T12CLK	[2:0]	rw	Timer T12 Input Clock Select Selects the input clock for timer T12 that is derived from the peripheral clock according to the equation $f_{T12} = f_{CC6} / 2^{<T12CLK>}$. 000 _B $f_{T12} = f_{CC6}$ 001 _B $f_{T12} = f_{CC6} / 2$ 010 _B $f_{T12} = f_{CC6} / 4$ 011 _B $f_{T12} = f_{CC6} / 8$ 100 _B $f_{T12} = f_{CC6} / 16$ 101 _B $f_{T12} = f_{CC6} / 32$ 110 _B $f_{T12} = f_{CC6} / 64$ 111 _B $f_{T12} = f_{CC6} / 128$
T12PRE	3	rw	Timer T12 Prescaler Bit In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T12. 0 _B The additional prescaler for T12 is disabled. 1 _B The additional prescaler for T12 is enabled.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T12R	4	rh	Timer T12 Run Bit¹⁾ T12R starts and stops timer T12. It is set/cleared by SW by setting bits T12RR or T12RS or it is cleared by HW according to the function defined by bit field T12SSC. 0 _B Timer T12 is stopped. 1 _B Timer T12 is running.
STE12	5	rh	Timer T12 Shadow Transfer Enable Bit STE12 enables or disables the shadow transfer of the T12 period value, the compare values and passive state select bits and levels from their shadow registers to the actual registers if a T12 shadow transfer event is detected. Bit STE12 is cleared by hardware after the shadow transfer. A T12 shadow transfer event is a period-match while counting up or a one-match while counting down. 0 _B The shadow register transfer is disabled. 1 _B The shadow register transfer is enabled.
CDIR	6	rh	Count Direction of Timer T12 This bit is set/cleared according to the counting rules of T12. 0 _B T12 counts up. 1 _B T12 counts down.
CTM	7	rw	T12 Operating Mode 0 _B Edge-aligned Mode: T12 always counts up and continues counting from zero after reaching the period value. 1 _B Center-aligned Mode: T12 counts down after detecting a period-match and counts up after detecting a one-match.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13CLK	[10:8]	rw	Timer T13 Input Clock Select Selects the input clock for timer T13 that is derived from the peripheral clock according to the equation $f_{T13} = f_{CC6} / 2^{<T13CLK>}$. 000 _B $f_{T13} = f_{CC6}$ 001 _B $f_{T13} = f_{CC6} / 2$ 010 _B $f_{T13} = f_{CC6} / 4$ 011 _B $f_{T13} = f_{CC6} / 8$ 100 _B $f_{T13} = f_{CC6} / 16$ 101 _B $f_{T13} = f_{CC6} / 32$ 110 _B $f_{T13} = f_{CC6} / 64$ 111 _B $f_{T13} = f_{CC6} / 128$
T13PRE	11	rw	Timer T13 Prescaler Bit In order to support higher clock frequencies, an additional prescaler factor of 1/256 can be enabled for the prescaler for T13. 0 _B The additional prescaler for T13 is disabled. 1 _B The additional prescaler for T13 is enabled.
T13R	12	rh	Timer T13 Run Bit²⁾ T13R starts and stops timer T13. It is set/cleared by SW by setting bits T13RR or T13RS or it is set/cleared by HW according to the function defined by bit fields T13SSC, T13TEC and T13TED. 0 _B Timer T13 is stopped. 1 _B Timer T13 is running.
STE13	13	rh	Timer T13 Shadow Transfer Enable Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0 _B The shadow register transfer is disabled. 1 _B The shadow register transfer is enabled.
0	[31:14]	r	Reserved; Returns 0 if read; should be written with 0.

1) A concurrent set/clear action on T12R (from T12SSC, T12RR or T12RS) will have no effect. The bit T12R will remain unchanged.

Capture/Compare Unit 6 (CCU6)

- 2) A concurrent set/cleared action on T13R (from T13SSC, T13TEC, T13RR or T13RS) will have no effect. The bit T12R will remain unchanged.

Capture/Compare Unit 6 (CCU6)

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12.

TCTR2
Timer Control Register 2
(74_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
T12SSC	0	rw	Timer T12 Single Shot Control This bit controls the single shot-mode of T12. 0 _B The single-shot mode is disabled, no HW action on T12R. 1 _B The single shot mode is enabled, the bit T12R is cleared by HW if - T12 reaches its period value in edge-aligned mode - T12 reaches the value 1 while down counting in center-aligned mode. In parallel to the clear action of bit T12R, the bits CC6xST (x=0, 1, 2) are cleared.
T13SSC	1	rw	Timer T13 Single Shot Control This bit controls the single shot-mode of T13. 0 _B No HW action on T13R 1 _B The single-shot mode is enabled, the bit T13R is cleared by HW if T13 reaches its period value. In parallel to the clear action of bit T13R, the bit CC63ST is cleared.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13TEC	[4:2]	rw	T13 Trigger Event Control Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000 _B no action 001 _B set T13R on a T12 compare event on channel 0 010 _B set T13R on a T12 compare event on channel 1 011 _B set T13R on a T12 compare event on channel 2 100 _B set T13R on any T12 compare event (ch. 0, 1, 2) 101 _B set T13R upon a period-match of T12 110 _B set T13R upon a zero-match of T12 (while counting up) 111 _B set T13R on any edge of inputs CCPOSx
T13TED	[6:5]	rw	Timer T13 Trigger Event Direction¹⁾ Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00 _B reserved, no action 01 _B while T12 is counting up 10 _B while T12 is counting down 11 _B independent on the count direction of T12
T12RSEL	[9:8]	rw	Timer T12 External Run Selection Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by HW. 00 _B The external setting of T12R is disabled. 01 _B Bit T12R is set if a rising edge of signal T12HR is detected. 10 _B Bit T12R is set if a falling edge of signal T12HR is detected. 11 _B Bit T12R is set if an edge of signal T12HR is detected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13RSEL	[11:10]	rw	Timer T13 External Run Selection Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by HW. 00 _B The external setting of T13R is disabled. 01 _B Bit T13R is set if a rising edge of signal T13HR is detected. 10 _B Bit T13R is set if a falling edge of signal T13HR is detected. 11 _B Bit T13R is set if an edge of signal T13HR is detected.
0	7, [31:12]	r	Reserved; Returns 0 if read; should be written with 0;

1) Example:

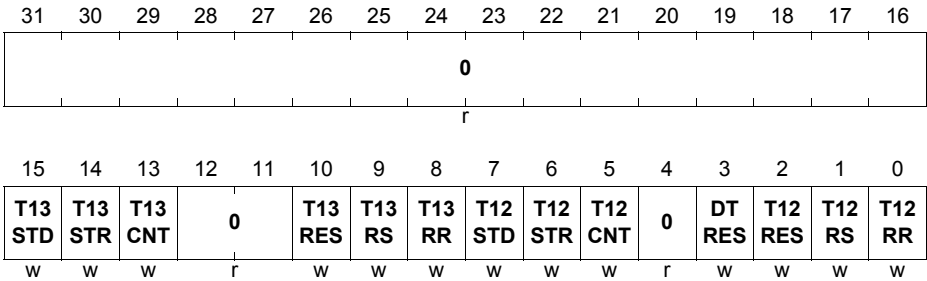

If the timer T13 is intended to start at any compare event on T12 (T13TEC=100) the trigger event direction can be programmed to

- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bit field T13TED=01 or 11.

Capture/Compare Unit 6 (CCU6)

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

TCTR4
Timer Control Register 4
(78_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
T12RR	0	w	Timer T12 Run Reset Setting this bit clears the T12R bit. 0 _B T12R is not influenced. 1 _B T12R is cleared, T12 stops counting.
T12RS	1	w	Timer T12 Run Set Setting this bit sets the T12R bit. 0 _B T12R is not influenced. 1 _B T12R is set, T12 starts counting.
T12RES	2	w	Timer T12 Reset 0 _B No effect on T12. 1 _B The T12 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T12RES has no impact on bit T12R.
DTRES	3	w	Dead-Time Counter Reset 0 _B No effect on the dead-time counters. 1 _B The three dead-time counter channels are cleared to zero.
T12CNT	5	w	Timer T12 Count Event 0 _B No action 1 _B If enabled (PISEL2), timer T12 counts one step.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T12STR	6	w	Timer T12 Shadow Transfer Request 0 _B No action 1 _B STE12 is set, enabling the shadow transfer.
T12STD	7	w	Timer T12 Shadow Transfer Disable 0 _B No action 1 _B STE12 is cleared without triggering the shadow transfer.
T13RR	8	w	Timer T13 Run Reset Setting this bit clears the T13R bit. 0 _B T13R is not influenced. 1 _B T13R is cleared, T13 stops counting.
T13RS	9	w	Timer T13 Run Set Setting this bit sets the T13R bit. 0 _B T13R is not influenced. 1 _B T13R is set, T13 starts counting.
T13RES	10	w	Timer T13 Reset 0 _B No effect on T13. 1 _B The T13 counter register is cleared to zero. The switching of the output signals is according to the switching rules. Setting of T13RES has no impact on bit T13R.
T13CNT	13	w	Timer T13 Count Event 0 _B No action 1 _B If enabled (PISEL2), timer T13 counts one step.
T13STR	14	w	Timer T13 Shadow Transfer Request 0 _B No action 1 _B STE13 is set, enabling the shadow transfer.
T13STD	15	w	Timer T13 Shadow Transfer Disable 0 _B No action 1 _B STE13 is cleared without triggering the shadow transfer.
0	4, [12:11], [31:16]	r	reserved; returns 0 if read; should be written with 0;

Note: A simultaneous write of a 1 to bits that set and clear the same bit will trigger no action. The corresponding bit will remain unchanged.

27.3 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see [Section 27.3.1](#))
- Counting scheme (see [Section 27.3.2](#))
- Compare mode (see [Section 27.3.3](#))
- Compare output path (see [Section 27.3.4](#))
- Shadow register transfer (see [Section 27.3.5](#))
- T13 counter register description (see [Section 27.3.6](#))

Figure 27-23 Overview Diagram of the Timer T13 Block

27.3.1 T13 Overview

Figure 27-24 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers **TCTR0**, **TCTR2**, and **PISEL2**.

Timer T13 receives its input clock, f_{T13} , from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T12).

Via a comparator, the timer T13 Counter Register **T13** is connected to the Period Register **T13PR**. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as

Capture/Compare Unit 6 (CCU6)

well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to [Table 27.3.5](#)). Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM). A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see [Figure 27-26](#)).

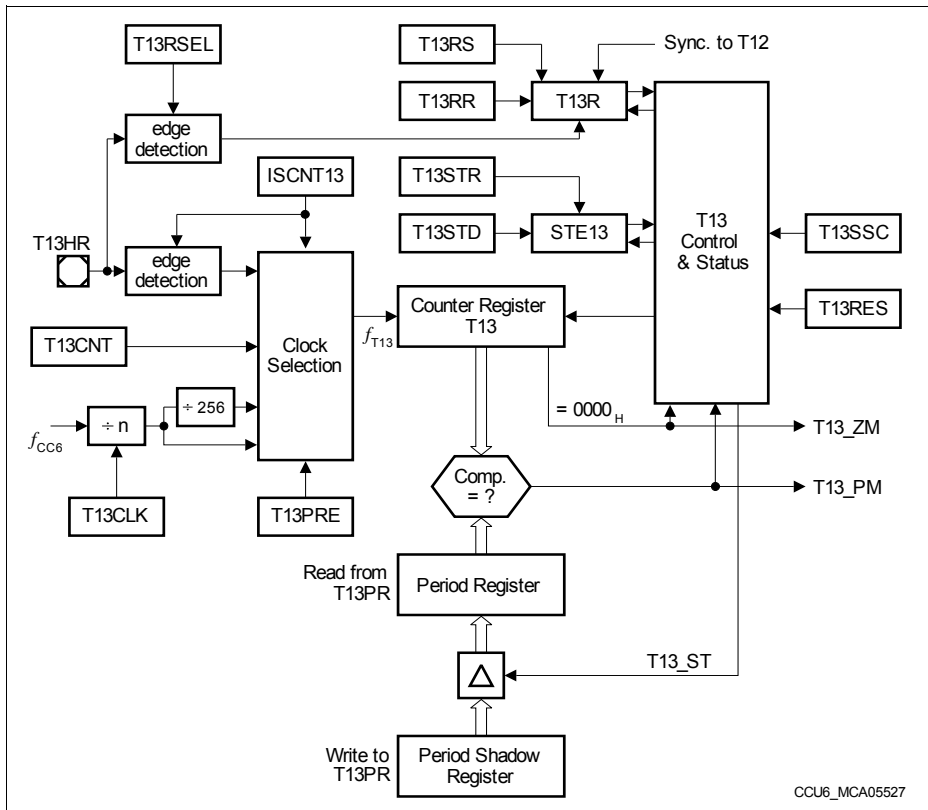

Figure 27-24 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register [TCTR4](#), or it is cleared by hardware according to preselected conditions (single-shot mode). The timer T13 run bit T13R must not be set while the applied T13 period value is zero. Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC

Capture/Compare Unit 6 (CCU6)

conversions).

Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.

While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

27.3.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

27.3.2.1 Clock Selection

In **Timer Mode** (**PISEL2**.ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 27-6**. The prescaler of T13 is cleared while T13 is not running (**TCTR0**.T13R = 0) to ensure reproducible timings and delays.

Table 27-6 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock f_{T13} Prescaler Off (T13PRE = 0)	Resulting Input Clock f_{T13} Prescaler On (T13PRE = 1)
000 _B	f_{CC6}	$f_{CC6} / 256$
001 _B	$f_{CC6} / 2$	$f_{CC6} / 512$
010 _B	$f_{CC6} / 4$	$f_{CC6} / 1024$
011 _B	$f_{CC6} / 8$	$f_{CC6} / 2048$
100 _B	$f_{CC6} / 16$	$f_{CC6} / 4096$
101 _B	$f_{CC6} / 32$	$f_{CC6} / 8192$
110 _B	$f_{CC6} / 64$	$f_{CC6} / 16384$
111 _B	$f_{CC6} / 128$	$f_{CC6} / 32768$

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to **TCTR4**.T13CNT and **PISEL2**.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and **PISEL2**.ISCNT13 = 11_B

27.3.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$$T13_{PER} = \langle \text{Period-Value} \rangle + 1; \text{ in } T13 \text{ clocks } (f_{T13}) \quad (27.3)$$

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple 'counting rule' for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in **Figure 27-25**.

Figure 27-25 T13 Counting Sequence

27.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

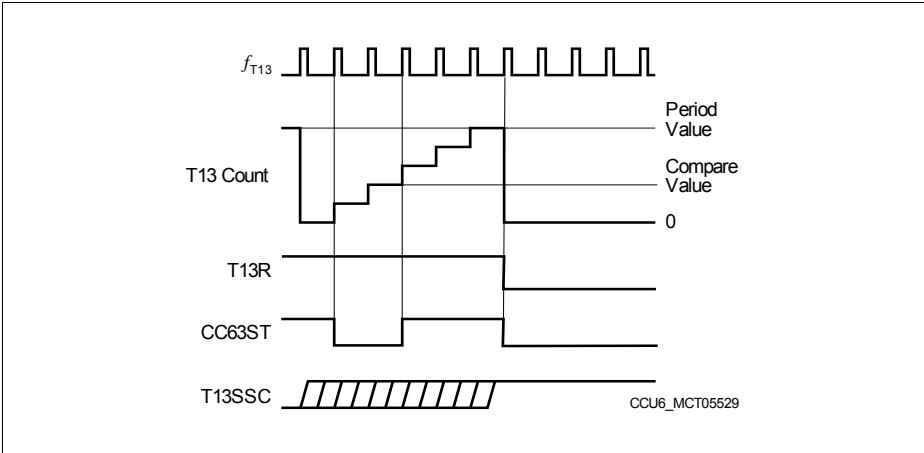

Figure 27-26 Single-Shot Operation of Timer T13

27.3.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 27-27 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

Figure 27-27 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in [Table 27-7](#). Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see [Table 27-8](#)).

Table 27-7 T12 Trigger Event Selection

T13TEC	Selected Event
000 _B	None
001 _B	T12 Compare Event on Channel 0 (CM_CC60)
010 _B	T12 Compare Event on Channel 1 (CM_CC61)
011 _B	T12 Compare Event on Channel 2 (CM_CC62)
100 _B	T12 Compare Event on any Channel (0, 1, 2)
101 _B	T12 Period-Match (T12_PM)
110 _B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111 _B	Any Hall State Change

Table 27-8 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00 _B	Reserved, no action
01 _B	Selected event is active while T12 is counting up (CDIR = 0)
10 _B	Selected event is active while T12 is counting down (CDIR = 1)
11 _B	Selected event is active independently of the count direction of T12

27.3.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 27-23 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, **CC63R**, feeding the comparator, and an associated shadow register, **CC63SR**, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, **CMPSTAT.CC63ST**, holding the status of the compare operation. **Figure 27-28** gives an overview on the logic for the State Bit.

Figure 27-28 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and

Capture/Compare Unit 6 (CCU6)

MCC63R in register **CMPMODIF**.

A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running ($T13R = 1$). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit **CC63ST** is set to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit **CC63ST** is cleared to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

Figure 27-29 T13 Compare Operation

27.3.4 Compare Mode Output Path

Figure 27-30 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to [Section 27.2.4.3](#) for detailed information on the output modulation for T12 signals.

Figure 27-30 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see [Figure 27-31](#)):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit **MODCTR.ECT130**
- The **trap state** TRPS with an individual enable bit **TRPCTR.TRPEN13**

If the modulation input signal COUT63_O is enabled (ECT130 = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.

If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit **PSLR.PSL63**. If the modulated output signal is in the passive

Capture/Compare Unit 6 (CCU6)

state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

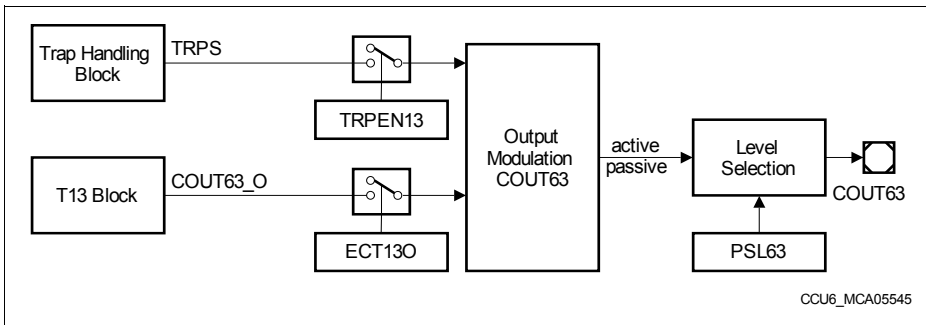

Figure 27-31 T13 Output Modulation

27.3.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit **TCTR0.STE13** (set by writing 1 to the write-only bit **TCTR4.T13STR**, cleared by writing 1 to the write-only bit **TCTR4.T13STD**).

When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer.

A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

Capture/Compare Unit 6 (CCU6)

Figure 27-32 T13 Shadow Register Overview

27.3.6 T13 related Registers

27.3.6.1 T13 Counter Register

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.

Timer T13 only supports compare mode on its compare channel CC63.

Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by SW.

Timer T13 only supports edge-aligned mode (counting up).

T13

Timer T13 Counter Register (50_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
T13CV	[15:0]	rwh	Timer 13 Counter Value This register represents the 16-bit counter value of Timer13.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

27.3.6.2 Period Register

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by SW delivers the value currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

T13PR

Timer 13 Period Register

(54_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
T13PV	[15:0]	rwh	T13 Period Value The value T13PV defines the counter value for T13 leading to a period-match. When reaching this value, the timer T13 is set to zero.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.3.6.3 Compare Register

Registers CC63R is the actual compare register for T13. The values stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register **CMPSTAT**.

CC63R

Compare Register for T13

(58_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCV	[15:0]	rh	Channel CC63 Compare Value The bit field CCV contains the value, that is compared to the T13 counter value.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.3.6.4 Compare Shadow Register

The register CC63R can only be read by SW, the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by SW.

CC63SR

Compare Shadow Register for T13

(5C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCS	[15:0]	rw	Shadow Register for Channel CC63 Compare Value The bit field contents of CCS is transferred to the bit field CCV during a shadow transfer.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.4 Synchronous Start Feature

The T12 and T13 timers can be started synchronously through the T12HR and T13HR inputs of all CCU6x kernels.

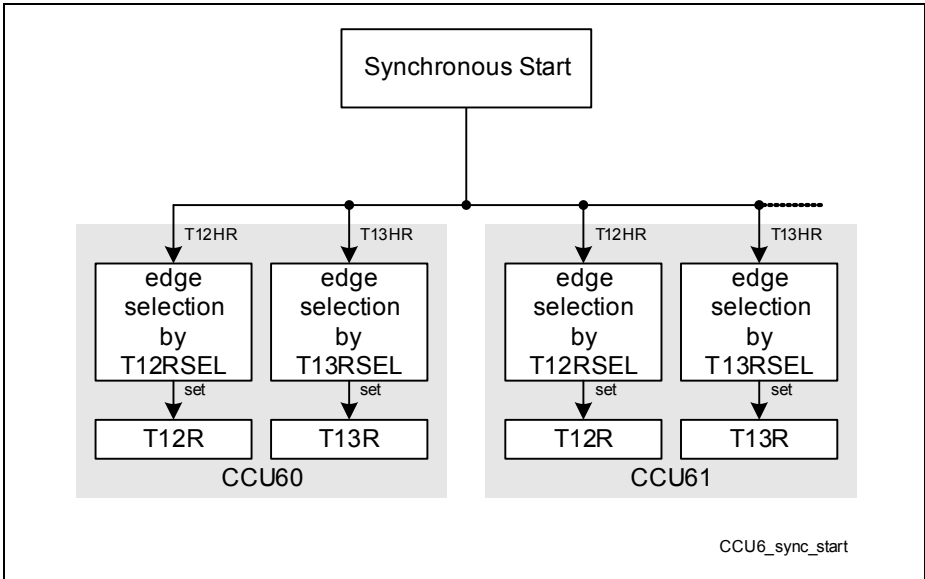

Figure 27-33 Synchronization Concept

27.5 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal $\overline{\text{CTRAP}}$. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register **TRPCTR**. The trap flags TRPF and TRPS are located in register **IS** and can be set/cleared by SW by writing to registers **ISS** and **ISR**.

Figure 27-34 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.

When a trap condition is detected ($\overline{\text{CTRAP}} = 0$) and the input is enabled ($\text{TRPPEN} = 1$), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active). The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}} = 1$ or $\text{TRPPEN} = 0$), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

Figure 27-34 Trap Logic Block Diagram

Capture/Compare Unit 6 (CCU6)

Clearing of TRPF is controlled by the mode control bit TRPM2. If $TRPM2 = 0$, TRPF is automatically cleared by HW when \overline{CTRAP} returns to the inactive level ($\overline{CTRAP} = 1$) or if the trap input is disabled ($TRPPEN = 0$). When $TRPM2 = 1$, TRPF must be reset by SW after \overline{CTRAP} has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. **Figure 27-35** gives an overview on the associated operation.

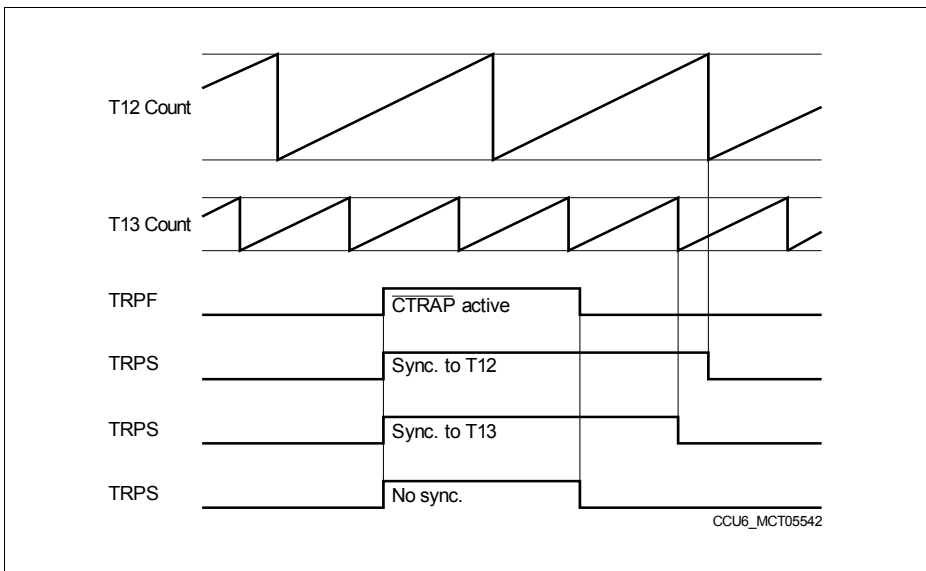

Figure 27-35 Trap State Synchronization (with $TRPM2 = 0$)

27.6 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field **MCMOUT.MCMP** are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit **MODCTR.MCMEN** = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field **MCMP**.

This bit field has its own shadow bit field **MCMOUTS.MCMPS**, that can be written by software. The transfer of the new value in **MCMP** to the bit field **MCMP** can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

Figure 27-36 Multi-Channel Mode Block Diagram

Figure 27-36 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register **MCMCTR**. The event that triggers the update of bit field **MCMP** is chosen by **SWSEL**. In order to synchronize the update of **MCMP** to a PWM generated by T12 or T13, bit field **SWSYN** allows the selection of the synchronization event leading to the transfer from **MCMPS** to **MCMP**. Due to this structure, an update takes place with a new PWM period. A reminder flag **R** is set when the selected switching event occurs

Capture/Compare Unit 6 (CCU6)

(the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit **IS.STR** becomes set and an interrupt can be generated.

In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field MCMPS with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for all settings of SWSEL.

By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 27-9 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000 _B	No automatic event detection
001 _B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010 _B	T13 Period-Match (T13_PM)
011 _B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100 _B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101 _B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110 _B , 111 _B	Reserved, no action

Table 27-10 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00 _B	Direct Mode: the trigger event directly causes the shadow transfer
01 _B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10 _B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11 _B	Reserved, no action

27.7 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register **MCMOUT** holds the actually used values, its shadow register **MCMOUTS** can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.

A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:

CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)

CCPOS1 corresponds to CURH.1 and EXPH.1

CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

27.7.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:

For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated.

Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:

The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

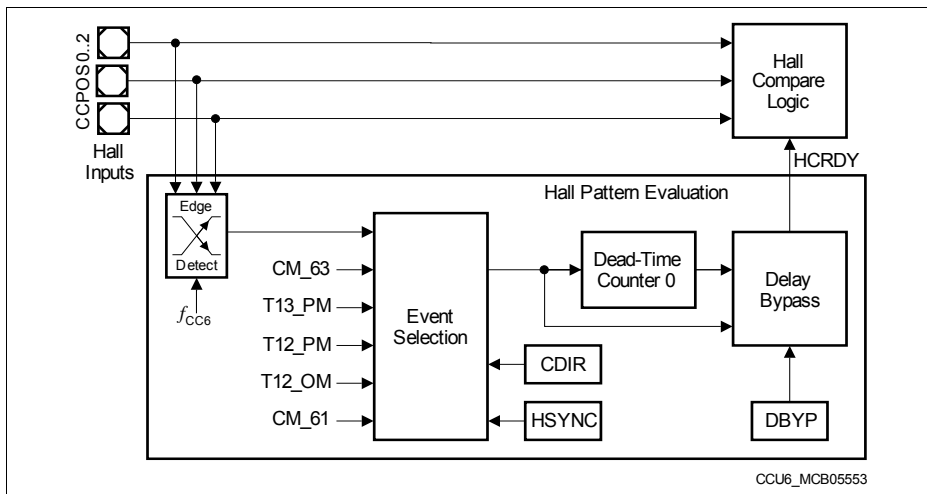

Figure 27-37 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see [Figure 27-38](#)) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

Capture/Compare Unit 6 (CCU6)

Figure 27-37 illustrates the events for Hall pattern evaluation and the noise filter logic, **Table 27-11** summarizes the selectable trigger input signals.

Table 27-11 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000 _B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001 _B	A T13 Compare-Match (CM_63).
010 _B	A T13 Period-Match (T13_PM).
011 _B	Hall sampling triggered by HW sources is switched off.
100 _B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101 _B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110 _B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111 _B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

27.7.2 Hall Pattern Compare Logic

Figure 27-38 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMPS is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register **CMPSTAT**). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

Figure 27-38 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMPS value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

Capture/Compare Unit 6 (CCU6)

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.

Loading this shadow register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCM = 1 (for MCM).

27.7.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag **IS.CHE** (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit **ISS.SCHE** = 1. If enabled by bit **IEN.ENCHE** = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field **INP.INPCHE** defines which service request output becomes activated in case of an interrupt request. To clear flag CHE, SW needs to write **ISR.RCHE** = 1.

Flag **IS.WHE** indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.

The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also [Figure 27-36](#)).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCM is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

Capture/Compare Unit 6 (CCU6)

Figure 27-39 Hall Mode Flags

27.7.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all **T12MSEL.MSEL6x** bit fields of the three T12 Channels to 1000_B. In this mode, illustrated in **Figure 27-40**, channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

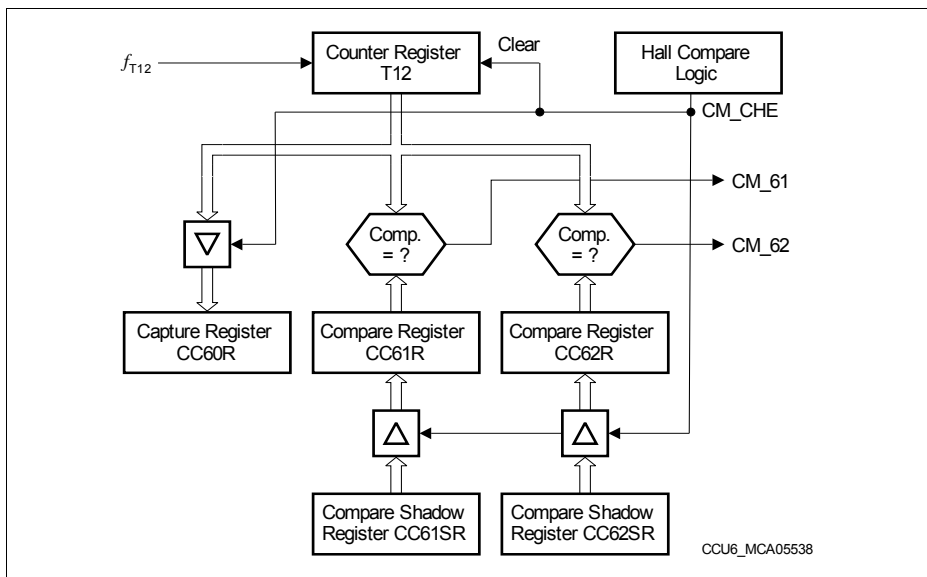

Figure 27-40 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

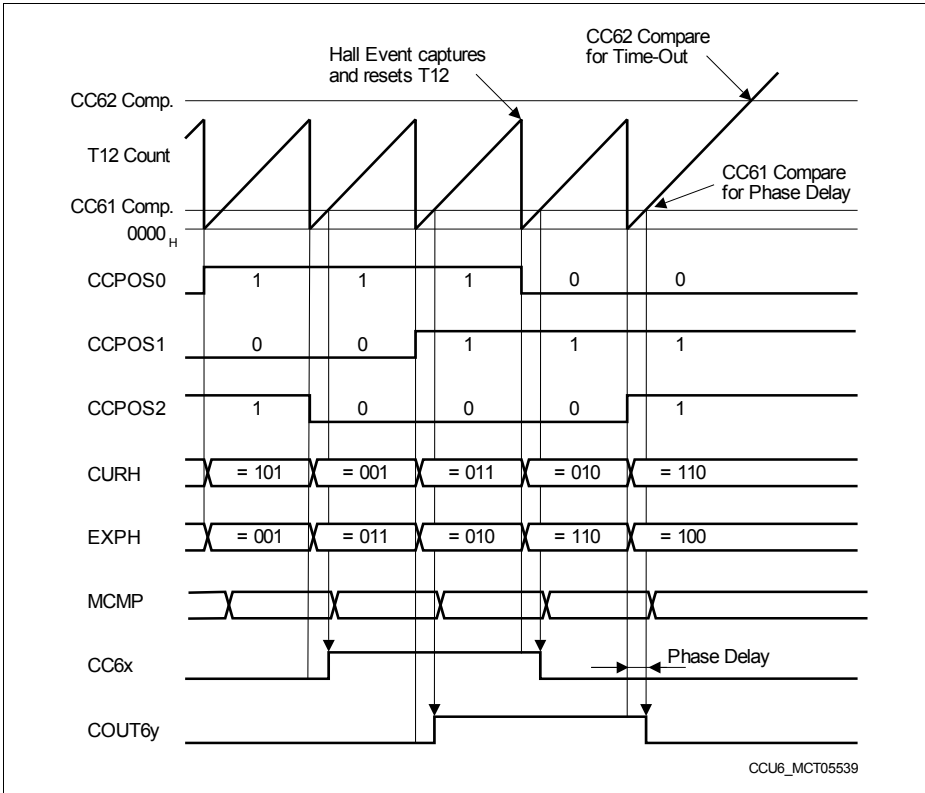

Figure 27-41 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field SWEN). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see Section 27.6). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

27.8 Modulation Control Registers

27.8.1 Modulation Control

This register contains bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

27.8.2 Trap Control Register

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the \overline{CTRAP} input pin, that is monitored (inverted level) by bit IS.TRPF. While TRPF=1 (trap input active), the trap state bit IS.TRPS is set to 1.

27.8.3 Passive State Level Register

Register PSLR defines the passive state level of the PWM outputs of the module. The passive state level is the value that is driven during the passive state of the output. During the active state, the corresponding output pin drives the active state level, that is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute “rh”), whereas the shadow bits can only be written (attribute “w”).

If this mode is enabled by MODCTR.MCMEN = 1, the output state of all T12 related PWM outputs can be modified. This bit field is 0 while IS.IDLE = 1.</p> <p>MCMP0 = MCMOUT.0 for output CC60 MCMP1 = MCMOUT.1 for output COUT60 MCMP2 = MCMOUT.2 for output CC61 MCMP3 = MCMOUT.3 for output COUT61 MCMP4 = MCMOUT.4 for output CC62 MCMP5 = MCMOUT.5 for output COUT62</p> <p>0_B The output is set to the passive state. A PWM generated by T12 or T13 are not taken into account.</p> <p>1_B The output can be in the active state, depending on the enabled PWM modulation signals generated by T12, T13 and the trap state.</p>
R	6	rh	<p>Reminder Flag</p> <p>This flag indicates that the shadow transfer from MCMP5 to MCMP has been requested by the selected trigger source. It is cleared when the shadow transfer takes place or while MCMEN=0.</p> <p>0_B A shadow transfer MCM_ST is not requested.</p> <p>1_B A shadow transfer MCM_ST is requested, but has not yet been executed, because the selected synchronization condition has not yet occurred.</p>
EXPH	[10:8]	rh	<p>Expected Hall Pattern</p> <p>Bit field EXPH is updated by a shadow transfer HP_ST from bit field EXPHS.</p> <p>If HCRDY = 1, EXPH is compared to the sampled CCPOSx inputs in order to detect the occurrence of the next desired (=expected) hall pattern or a wrong pattern. If the sampled hall pattern at the hall input pins is equal to bit field EXPH, a correct Hall event has been detected (CM_CHE).</p>

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
CURH	[13:11]	rh	Current Hall Pattern Bit field CURH is updated by a shadow transfer HP_ST from bit field CURHS. If HCRDY = 1, CURH is compared to the sampled CCPOSx inputs in order to detect a spike. If the sampled Hall pattern at the Hall input pins is equal to bit field CURH, no Hall event has been detected. If the sampled Hall input pattern is neither equal to CURH nor equal to EXPH, the Hall event was not the desired one and may be due to a fatal error (e.g. blocked rotor, etc.). In this case, a wrong Hall event has been detected (CM_WHE).
0	7, [31:14]	r	Reserved; Returns 0 if read; should be written with 0.

27.9 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

27.9.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see [Figure 27-42](#)).

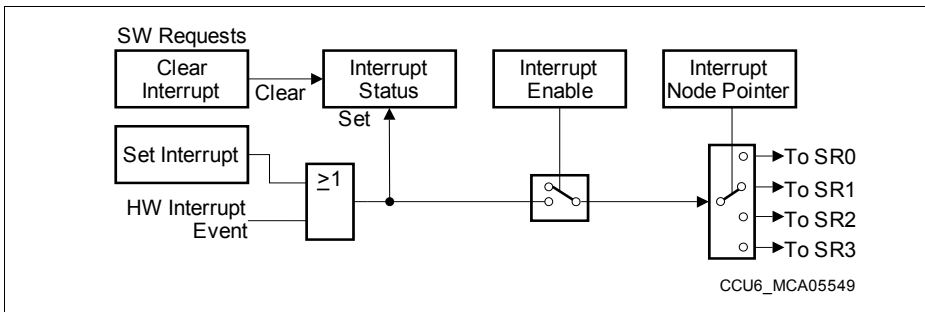

Figure 27-42 General Interrupt Structure

The available interrupt events in the CCU6 are shown in [Figure 27-43](#).

Capture/Compare Unit 6 (CCU6)

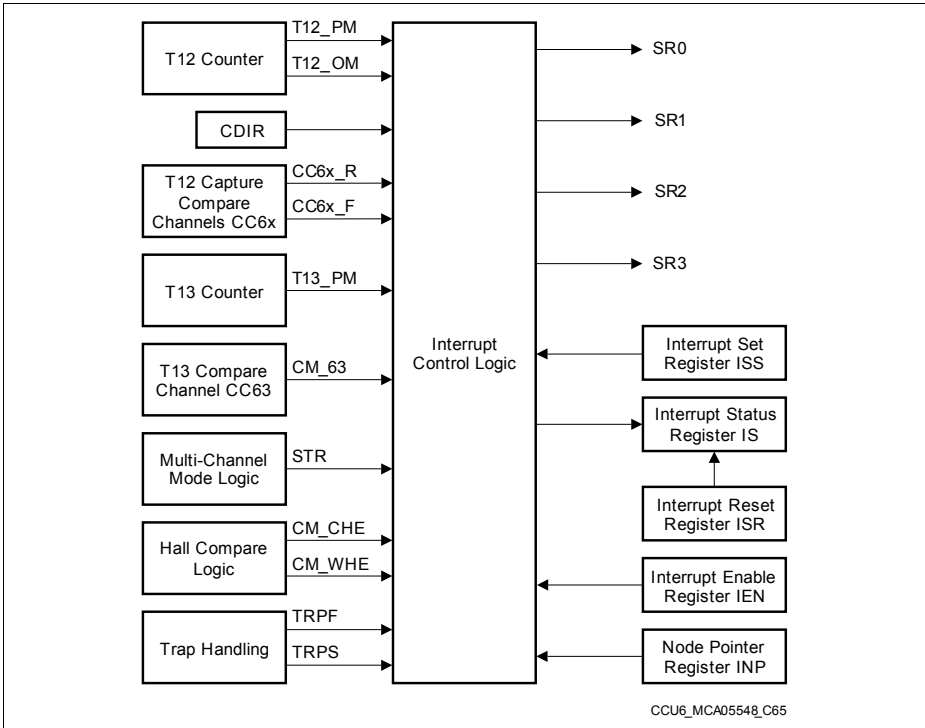

Figure 27-43 Interrupt Sources and Events

27.9.2 Interrupt Registers

27.9.2.1 Interrupt Status Register

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or clear the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to clear the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running ($T1xR=1$). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS

Interrupt Status Register

This event occurs in compare mode when a compare-match is detected while T12 is counting down (CM_6x and CDIR = 1) and in capture mode when a falling edge is detected at the related input CC6xIN. 0 _B The event has not yet been detected. 1 _B The event has been detected.
T12OM	6	rh	Timer T12 One-Match Flag This bit indicates that a timer T12 one-match while counting down (T12_OM and CDIR = 1) has been detected. 0 _B The event has not yet been detected. 1 _B The event has been detected.
T12PM	7	rh	Timer T12 Period-Match Flag This bit indicates that a timer T12 period-match while counting up (T12_PM and CDIR = 0) has been detected. 0 _B The event has not yet been detected. 1 _B The event has been detected.
T13CM	8	rh	Timer T13 Compare-Match Flag This bit indicates that a timer T13 compare-match (CM_63) has been detected. 0 _B The event has not yet been detected. 1 _B The event has been detected.
T13PM	9	rh	Timer T13 Period-Match Flag This bit indicates that a timer T13 period-match (T13_PM) has been detected. 0 _B The event has not yet been detected. 1 _B The event has been detected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
TRPF	10	rh	Trap Flag This bit indicates if a trap condition (input $\overline{\text{CTRAP}} = 0$ or by SW) is / has been detected. If $\text{TRPM2} = 0$, it becomes cleared automatically if $\overline{\text{CTRAP}} = 1$ or $\text{TRPEN} = 0$, whereas if $\text{TRPM2} = 1$, it has to be cleared by writing $\text{RTRPF} = 1$. 0_{B} The trap condition has not been detected. 1_{B} The trap condition is / has been detected.
TRPS	11	rh	Trap State¹⁾ This bit indicates the actual trap state. It is set if $\text{TRPF} = 1$ and becomes cleared according to the mode selected in register TRPCTR . 0_{B} The trap state is not active. 1_{B} The trap state is active.
CHE	12	rh	Correct Hall Event This bit indicates that a correct Hall event (CM_CHE) has been detected. 0_{B} The event has not yet been detected. 1_{B} The event has been detected.
WHE	13	rh	Wrong Hall Event This bit indicates that a wrong Hall event (CM_WHE) has been detected. 0_{B} The event has not yet been detected. 1_{B} The event has been detected.
IDLE	14	rh	IDLE State If enabled by $\text{ENIDLE} = 1$, this bit is set together with bit WHE and it has to be cleared by SW. 0_{B} No action. 1_{B} Bit field MCMP is cleared, the selected outputs are set to passive state.
STR	15	rh	Multi-Channel Mode Shadow Transfer Request This bit indicates that a shadow transfer from MCMPS to MCMP (MCM_ST) has taken place. 0_{B} The event has not yet been detected. 1_{B} The event has been detected.
0	[31:16]	r	Reserved; Returns 0 if read; should be written with 0.

Capture/Compare Unit 6 (CCU6)

- 1) During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register PSLR. Bits TRPS=1 and TRPF=0 can occur if the trap condition is no longer active but the selected synchronization has not yet taken place.

27.9.2.2 Interrupt Status Set Register

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled). All bit positions read as 0.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
ENCHE	12	rw	Enable Interrupt for Correct Hall Event 0_B No interrupt will be generated if the set condition for bit CHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit CHE in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
ENWHE	13	rw	Enable Interrupt for Wrong Hall Event 0_B No interrupt will be generated if the set condition for bit WHE in register IS occurs. 1_B An interrupt will be generated if the set condition for bit WHE in register IS occurs. The service request output that will be activated is selected by bit field INPERR.
ENIDLE	14	rw	Enable Idle This bit enables the automatic entering of the idle state (bit IDLE will be set) after a wrong hall event has been detected (bit WHE is set). During the idle state, the bit field MCMP is automatically cleared. 0_B The bit IDLE is not automatically set when a wrong hall event is detected. 1_B The bit IDLE is automatically set when a wrong hall event is detected.
ENSTR	15	rw	Enable Multi-Channel Mode Shadow Transfer Interrupt 0_B No interrupt will be generated if the set condition for bit STR in register IS occurs. 1_B An interrupt will be generated if the set condition for bit STR in register IS occurs. The service request output that will be activated is selected by bit field INPCHE.
0	11, [31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.9.2.5 Interrupt Node Pointer Register

Register INP contains the interrupt node pointers allowing a flexible interrupt handling. These bit fields define which service request output will be activated if the corresponding interrupt event occurs and the interrupt generation for this event is enabled.

Capture/Compare Unit 6 (CCU6)
INP
Interrupt Node Pointer Register
(AC_H)
Reset Value: 0000 3940_H

Field	Bits	Type	Description
INPCC60, INPCC61, INPCC62	[1:0], [3:2], [5:4]	rw	Interrupt Node Pointer for Channel CC6x Interrupts This bit field defines the service request output activated due to a set condition for bit CC6xR (if enabled by bit ENCC6xR) or for bit CC6xF (if enabled by bit ENCC6xF). 00 _B Service request output SR0 is selected. 01 _B Service request output SR1 is selected. 10 _B Service request output SR2 is selected. 11 _B Service request output SR3 is selected.
INPCHE	[7:6]	rw	Interrupt Node Pointer for the CHE Interrupt This bit field defines the service request output activated due to a set condition for bit CHE (if enabled by bit ENCHE) or for bit STR (if enabled by bit ENSTR). Coding see INPCC6x.
INPERR	[9:8]	rw	Interrupt Node Pointer for Error Interrupts This bit field defines the service request output activated due to a set condition for bit TRPF (if enabled by bit ENTRPF) or for bit WHE (if enabled by bit ENWHE). Coding see INPCC6x.
INPT12	[11:10]	rw	Interrupt Node Pointer for Timer12 Interrupts This bit field defines the service request output activated due to a set condition for bit T12OM (if enabled by bit ENT12OM) or for bit T12PM (if enabled by bit ENT12PM). Coding see INPCC6x.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
INPT13	[13:12]	rw	Interrupt Node Pointer for Timer13 Interrupt This bit field defines the service request output activated due to a set condition for bit T13CM (if enabled by bit ENT13CM) or for bit T13PM (if enabled by bit ENT13PM). Coding see INPCC6x.
0	[31:14]	r	Reserved; Returns 0 if read; should be written with 0.

27.10 General Module Operation

This section provides information about the:

- Input Selection (see [Section 27.10.1](#))
- Input Monitoring (see [Section 27.10.2](#))
- OCDS Suspend Functionality (see [Section 27.10.3](#))
- OCDS Trigger Bus (OTGB) Interface (see [Section 27.10.4](#))
- General Register Description (see [Section 27.10.5](#))
- BPI Register Description (see [Section 27.10.6](#))

27.10.1 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers [PISEL0](#) and [PISEL2](#). This permits to adapt the pin functionality of the device to the application requirements.

The output pins for the module output signals are chosen in the ports.

Naming convention:

The input vector CC60IN[D:A] for input signal CC60IN is composed of the signals CC60INA to CC60IND.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

27.10.2 Input Monitoring

A selected event which occurs at each CCU6 input signal can be monitored through **IMON.x**. Every input signal can be included for the detection of a lost bit event (**IMON.LBE**) if enabled through its individual lost indicator enable bits (**LI.yEN**). The lost bit event occurs if a selected event occurs again with the previous event captured (**IMON.x** remains set) and its lost indicator is enabled for at least one of the monitored input signals. The lost bit event can be enabled (**LI.LBEEN**) for an interrupt to be generated at one of the SRx line, selected through **LI.INPLBE**. The LBE output signal of the kernel can be connected to a capture input to indicate when does the lost bit event happens.

The lost bit event can be used as a kind of interrupt or event watchdog to monitor if an action related to an event has been processed before a second event of the same type occurs. Like this, if a certain event is treated by an interrupt that should be monitored, the related indication flag has to be cleared by SW. If the SW has not yet cleared the flag and the event occurs again, the event is considered as being lost and another interrupt can be generated to inform the system about the loss. This can be also used to indicate that input events occur too often and the main task has not enough time to treat them.

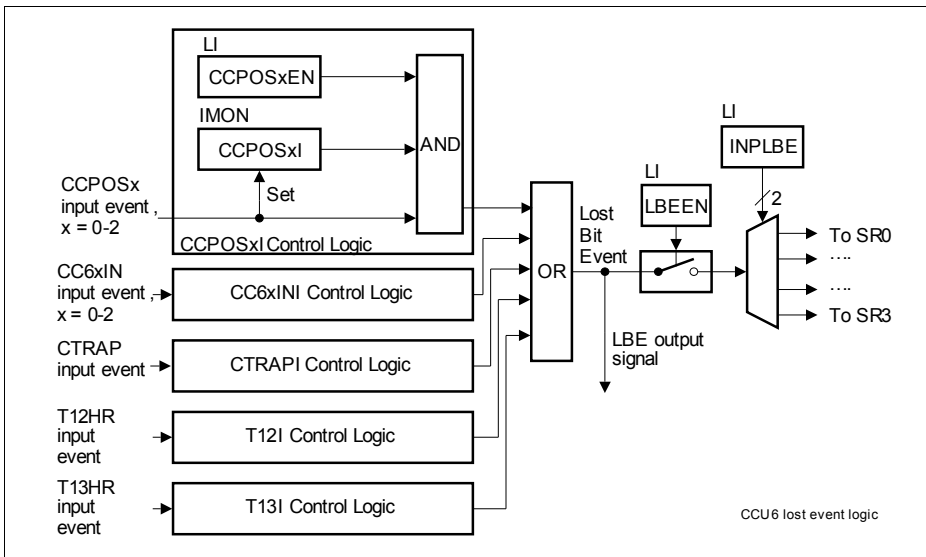

Figure 27-44 Lost Event Logic

27.10.3 OCDS Suspend

The behavior of CCU6 upon an OCDS suspend request is controlled by the **OCS** register. CCU6 supports both Hard Suspend Mode and Soft Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the CCU6 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a CCU6 kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode

In Soft Suspend Mode CCU6 may finalize specific actions before it enters the suspended state with **OCS.SUSSTA** set. This can be advantageous for applications (e.g. motor control) where critical system states could occur if the kernel clock would be switched off immediately upon an OCDS suspend request.

Soft Suspend mode does not influence the kernel clock. Reading and writing of registers is possible without the side effects that may occur when reading/writing registers in Hard Suspend Mode.

For CCU6, two basic soft suspend options (**Stop Mode 0**, **Stop Mode 1**) are available, selected via bit field **OCS.SUS**.

In addition, the internal functional blocks (T12, T13, Hall logic, Trap logic) may individually be programmed via their Sensitivity Bits in register **KSCSR** to accept or ignore a suspend request. If the request sensitivity is disabled, the block continues normal operation. If the request sensitivity is enabled, the block operates as specified for the selected stop mode. The mapping of the CCU6 functional blocks to their Sensitivity Bits is shown in **Table 27-12**.

Stop Mode 0

In Stop Mode 0, if selected to be stopped, the Hall and Trap logic stops immediately, while Timer T12 and/or T13 continues normal operation (if running) until it reaches the end of the PWM period; then it stops (same stop condition as in single shot mode). When Timer T12 stops, the capture inputs CC6xIN are frozen.

Stop Mode 1

In Stop Mode 1, if selected to be stopped, the internal functional blocks (T12, T13, Hall logic, Trap logic) will stop immediately upon a suspend request.

Capture/Compare Unit 6 (CCU6)

If the sensitivity bits for Timer T12 or T13 are set, the corresponding output lines enabled for the trap condition are set to their passive values (similar to a trap condition).

Table 27-12 summarizes the reaction of the CCU6 functional blocks to OCDS suspend requests.

Table 27-12 CCU6 Functional Blocks

Block	Reaction to OCDS Suspend Request	Sensitivity Bit
0	Timer T12: if bit SB0 = 1 _B , - in Stop Mode 0 Timer T12 continues (if running) until the end of the PWM period. Then it stops and the CCxIN input stages are frozen. - in Stop Mode 1 Timer T12 stops immediately and the CC6xIN input stages are frozen. Output lines CC6x, COU6x with enabled trap functionality are set to their passive states.	KSCSR.SB0
1	Timer T13: if bit SB1 = 1 _B , - in Stop Mode 0 Timer T13 continues (if running) until the end of the PWM period. Then it stops. - in Stop Mode 1 Timer T13 stops immediately. If trap functionality for COU63 is enabled, it is set to the passive state.	KSCSR.SB1
2	Hall Logic: if bit SB2 = 1 _B , the hall logic is stopped immediately and the CCPOSx input stages are frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB2
3	Trap Logic: if bit SB3 = 1 _B , the trap logic is stopped immediately and the CTRAP input stage is frozen (same behavior for Stop Mode 0 and 1).	KSCSR.SB3

27.10.4 OCDS Trigger Bus (OTGB) Interface

The CCU6 kernel provides a set of 16 internal status signals that are combined to a Trigger Set. The CCU6 Trigger Set is shown in [Table 27-13](#). It is output on OTGB0 or OTGB1 controlled by the [OCS](#) register.

Table 27-13 TS16_CCU6 Trigger Set CCU6

Bits	Name	Description
0	T12pre	T12 prescaler output
1	T13pre	T13 prescaler output
2	T12_cm0	T12 compare match channel 0
3	T12_cm1	T12 compare match channel 1
4	T12_cm2	T12 compare match channel 2
5	T12_pm	T12 period match
6	T12_om	T12 one match
7	T12_cdir	T12 count direction
8	T12_zm	T12 zero match
9	T13_cm	T13 compare match
10	T13_pm	T13 period match
11	T13_zm	T13 zero match
12	mcm_st	MCM shadow transfer
13	che	Correct Hall event
14	whe	Wrong Hall event
15	trpf	Trap flag

27.10.5 General Registers

27.10.5.1 ID Register

The CCU6 Module Identification Register ID contains read-only information about the module identification number and its revision.

ID

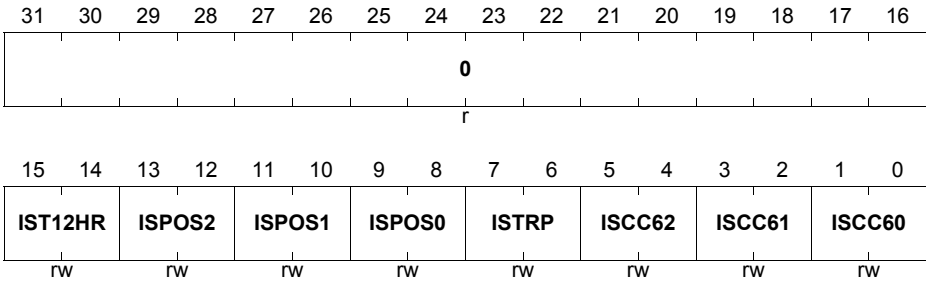

Module Identification Register (08_H) **Reset Value: 0000 54XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number MODREV defines the module revision number. The value of a module revision starts with 01 _H (first revision), 02 _H , 03 _H , ... up to FF _H .
MODNUM	[15:8]	r	Module Number Value This bit field defines the module identification number for the CCU6: 54 _H
0	[31:16]	r	Reserved Read as 0.

27.10.5.2 Port Input Select Registers

Registers PISEL0 and PISEL2 contain bit fields selecting the actual input signal for the module inputs.

PISEL0
Port Input Select Register 0
(10_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ISCC60	[1:0]	rw	Input Select for CC60 This bit field defines the input signal used as CC60 capture input. 00 _B The signal CC60INA is selected. 01 _B The signal CC60INB is selected. 10 _B The signal CC60INC is selected. 11 _B The signal CC60IND is selected.
ISCC61	[3:2]	rw	Input Select for CC61 This bit field defines the input signal used as CC61 capture input. 00 _B The signal CC61INA is selected. 01 _B The signal CC61INB is selected. 10 _B The signal CC61INC is selected. 11 _B The signal CC61IND is selected.
ISCC62	[5:4]	rw	Input Select for CC62 This bit field defines the input signal used as CC62 capture input. 00 _B The signal CC62INA is selected. 01 _B The signal CC62INB is selected. 10 _B The signal CC62INC is selected. 11 _B The signal CC62IND is selected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
ISTRP	[7:6]	rw	Input Select for CTRAP This bit field defines the input signal used as CTRAP input. 00 _B The signal CTRAPA is selected. 01 _B The signal CTRAPB is selected. 10 _B The signal CTRAPC is selected. 11 _B The signal CTRAPD is selected.
ISPOS0	[9:8]	rw	Input Select for CCPOS0 This bit field defines the input signal used as CCPOS0 input. 00 _B The signal CCPOS0A is selected. 01 _B The signal CCPOS0B is selected. 10 _B The signal CCPOS0C is selected. 11 _B The signal CCPOS0D is selected.
ISPOS1	[11:10]	rw	Input Select for CCPOS1 This bit field defines the input signal used as CCPOS1 input. 00 _B The signal CCPOS1A is selected. 01 _B The signal CCPOS1B is selected. 10 _B The signal CCPOS1C is selected. 11 _B The signal CCPOS1D is selected.
ISPOS2	[13:12]	rw	Input Select for CCPOS2 This bit field defines the input signal used as CCPOS2 input. 00 _B The signal CCPOS2A is selected. 01 _B The signal CCPOS2B is selected. 10 _B The signal CCPOS2C is selected. 11 _B The signal CCPOS2D is selected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
IST12HR	[15:14]	rw	Input Select for T12HR This bit field defines the input signal used as T12HR input. 00 _B Either signal T12HRA (if T12EXT = 0) or T12HRE (if T12EXT = 1) is selected. 01 _B Either signal T12HRB (if T12EXT = 0) or T12HRF (if T12EXT = 1) is selected. 10 _B Either signal T12HRC (if T12EXT = 0) or T12HRG (if T12EXT = 1) is selected. 11 _B Either signal T12HRD (if T12EXT = 0) or T12HRH (if T12EXT = 1) is selected.
0	[31:16]	r	Reserved Returns 0 if read, should be written with 0.

PISEL2
Port Input Select Register 2
(14_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13EXT	7	rw	Extension for T13HR Inputs This bit extends the 2-bit field IST13HR. 0 _B One of the signals T13HR[D:A] is selected. 1 _B One of the signals T13HR[H:E] is selected.
0	[31:8]	r	Reserved; Returns 0 if read; should be written with 0.

27.10.5.3 Module Configuration Register

The module configuration register contains bits describing the functionality that is available in the CCU6 module.

MCFG

Module Configuration Register (04_H) **Reset Value: 0000 0007_H**

Field	Bits	Type	Description
T12	0	r	T12 Available This bit indicates if the T12 block is available. 0 _B The T12 block is not available. A write access to T12PR is ignored. 1 _B The T12 block is available. A write access to T12PR is executed.
T13	1	r	T13 Available This bit indicates if the T13 block is available. 0 _B The T13 block is not available. A write access to T13PR is ignored. 1 _B The T13 block is available. A write access to T13PR is executed.
MCM	2	r	Multi-Channel Mode Available This bit indicates if the multi-channel mode functionality is available. 0 _B The multi-channel mode functionality is not available. A write access to MCMOUTS is ignored. 1 _B The multi-channel mode functionality is available. A write access to MCMOUTS is executed.
0	[31:3]	r	Reserved; read as 0; should be written with 0.

27.10.5.4 Input Monitoring Register

The input monitoring register monitors the occurrence of a selected event for the input signals. If a hardware event triggers the setting of bit IMON.x and the same bit is written with 1 via software at the same time, then the corresponding bit is cleared (software overrules hardware). The lost bit event is indicated if an event is detected again at one or more input signals with its lost indicator enabled.

Note: The register is only applicable in capture modes if the edges are selected through T12MSEL.MSEL6x.

IMON

Input Monitoring Register

(98_H)

Reset Value: 0000 0000_H

Capture/Compare Unit 6 (CCU6)

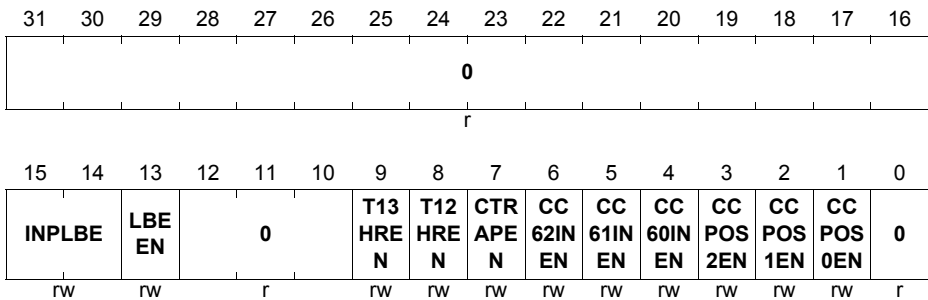

Field	Bits	Type	Description
LBE	0	rwh	<p>Lost Bit Event</p> <p>This bit determines if a lost bit event has occurred. A lost bit event occurs when a selected event occurs again with the previous event captured (IMON.x remains set) and its lost indicator is enabled, for at least one of the monitored input signals. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect.</p> <p>0_B The lost bit event has not occurred. 1_B The lost bit event has occurred.</p>
CCPOSxI (x = 0 -2)	x + 1	rwh	<p>Event indication for input signal CCPOSx</p> <p>The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect.</p> <p>0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.</p> <p><i>Note: The dedicated edge is indicated for a selected event if Hysteretic-like Control or Capture modes are initialized in T12MSEL.MSEL6x. If these modes are not selected, then all edges will be indicated as an event for the inputs.</i></p>
CC6xINI (x = 0 -2)	x + 4	rwh	<p>Event indication for input signal CC6xIN</p> <p>The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect.</p> <p>0_B A selected event has not occurred. 1_B Edge detection indicates a selected event has occurred.</p>
CTRAPI	7	rwh	<p>Event indication for input signal CTRAP</p> <p>The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect.</p> <p>0_B An event has not occurred. 1_B Edge detection indicates an event has occurred.</p>

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T12HRI	8	rwh	Event indication for input signal T12HR The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0 _B An event has not occurred. 1 _B Edge detection indicates an event has occurred.
T13HRI	9	rwh	Event indication for input signal T13HR The bit determines if the selected event has occurred via an edge detection. The bit can be cleared by writing a 1 to the same bit position, while writing a 0 has no effect. 0 _B An event has not occurred. 1 _B Edge detection indicates an event has occurred.
0	[31:10]	r	Reserved; Returns 0 if read; should be written with 0.

27.10.5.5 Lost Indicator Register

The lost indicator register has the lost indicator enable bits for its detected event at the input signals. The lost bit event can then be enabled as an output signal through one of the service request lines.

LI
Lost Indicator Register (9C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCPOSxEN (x = 0 -2)	x + 1	rw	Lost Indicator Enable for input signal CCPOSx This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0 _B Input signal is disabled for a lost bit event detection. 1 _B Input signal is enabled for a lost bit event detection.
CC6xINEN (x = 0 -2)	x + 4	rw	Lost Indicator Enable for input signal CC6xIN This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0 _B Input signal is disabled for a lost bit event detection. 1 _B Input signal is enabled for a lost bit event detection.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
CTRAPEN	7	rw	Lost Indicator Enable for input signal CTRAP This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0 _B Input signal is disabled for a lost bit event detection. 1 _B Input signal is enabled for a lost bit event detection.
T12HREN	8	rw	Lost Indicator Enable for input signal T12HR This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0 _B Input signal is disabled for a lost bit event detection. 1 _B Input signal is enabled for a lost bit event detection.
T13HREN	9	rw	Lost Indicator Enable for input signal T13HR This bit determines if the monitored event at the input signal is enabled for the detection of a lost bit event. 0 _B Input signal is disabled for a lost bit event detection. 1 _B Input signal is enabled for a lost bit event detection.
LBEEN	13	rw	Interrupt Enable for Lost Bit Event This bit determines if a SRx line is activated if lost bit event is detected. 0 _B Lost bit event is disabled for the activation of a SRx line. 1 _B Lost bit event is enabled for the activation of a SRx line.
INPLBE	[15:14]	rw	Interrupt Node Pointer for lost bit event This bit field defines which service request output line is selected to output an lost event alert for an enabled lost bit event. 00 _B Service request output SR0 is selected. 01 _B Service request output SR1 is selected. 10 _B Service request output SR2 is selected. 11 _B Service request output SR3 is selected.
0	0, [12:10], [31:16]	r	Reserved; Returns 0 if read; should be written with 0.

27.10.5.6 Kernel State Control Sensitivity Register

The kernel state control sensitivity register bits define which internal block is affected by Stop Modes 0 and 1, as described in section [Soft Suspend Mode](#).

The Kernel State Control Sensitivity Register (KSCSR) is cleared by Debug Reset.

The register can only be written while the OCDS is enabled (OCDS enable = '1').

KSCSR

Kernel State Control Sensitivity Register

(1C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SB0, SB1, SB2, SB3	0, 1, 2, 3	rw	Sensitivity Block x This bit defines if block x of the CCU6 kernel is sensitive to Stop Mode 0 or Stop Mode 1. The functional definition of the blocks is given in Table 27-12 . 0 _B Block x is not sensitive to Stop Mode 0 or Stop Mode 1. It continues normal operation without respecting the defined stop condition. 1 _B Block x is sensitive to Stop Mode 0 or Stop Mode 1. It is respecting the defined stop condition.
0	[31:4]	r	Reserved; Returns 0 if read; should be written with 0.

27.10.6 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). [Figure 27-45](#) shows all registers associated with the BPI for one CCU6 kernel.

BPI Registers Overview

Figure 27-45 BPI Registers

[Table 27-14](#) gives an overview of the BPI registers, including their access modes and reset class.

Table 27-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00 _H	U, SV	SV, E, P	Application Reset	27-130
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	E8 _H	U, SV	SV, P	Debug Reset	27-131
KRSTCLR	Reset Status Clear Register	EC _H	U, SV	SV, E, P	Application Reset	27-137
KRST1	Reset Control Register 1	F0 _H	U, SV	SV, E, P	Application Reset	27-136
KRST0	Reset Control Register 0	F4 _H	U, SV	SV, E, P	Application Reset	27-135

Table 27-14 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
ACCEN1	Access Enable Register 1	F8 _H	U, SV	SV, SE	Application Reset	27-134
ACCEN0	Access Enable Register 0	FC _H	U, SV	SV, SE	Application Reset	27-133

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

27.10.6.1 System Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the CCU6. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CCU6} module clock signal and Sleep Mode for the module.

CLC

Clock Control Register

(00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable is not requested. 1 _B Module disable is requested.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module. 0 _B Module is enabled. 1 _B Module is disabled.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode. 0 _B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1 _B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	Reserved Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the CCU6 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the CCU6 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register (E8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TGS	[1:0]	rw	Trigger Set for OTGB0/1 0 _H No Trigger Set output 1 _H Trigger Set TS16_CCU6 (Table 27-13) others, reserved
TGB	2	rw	OTGB0/1 Bus Select 0 _B Trigger Set is output on OTGB0 1 _B Trigger Set is output on OTGB1

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
TG_P	3	w	TGS, TGB Write Protection TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	[27:24]	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 _H Will not suspend 1 _H Hard suspend. Clock is switched off immediately. 2 _H Soft suspend, Stop Mode 0 3 _H Soft suspend, Stop Mode 1 others , reserved Effects of soft suspend options on CCU6 Functional Blocks are described in section Soft Suspend Mode
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:4], [31:30]	r	Reserved Read as 0; must be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ..., EN31 -> TAG ID 011111_B.

1) The BPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

ACCEN0
Access Enable Register 0
(FC_H)
Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
ENn (n = 0-31)	n	r/w	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ..., EN31 -> TAG ID 111111_B.

ACCEN1

Access Enable Register 1

(F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers related to the module kernel. The RST bit will be re-set (cleared to '0') by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the CLR bit in the related KRSTCLR register.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge

*Note: A kernel reset, initiated via registers KRST0/KRST1, does not affect the port logic. Because register **PSLR** is set to its default value, the passive level 0 is selected for the outputs CC60..CC62 and COUT60..COUT63 upon a kernel reset. Therefore, software must ensure appropriate levels for the external system at the port pins in case they are different from the default values selected via PSLR.*

KRST0
Kernel Reset Register 0
(F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset. The RST bit will be re-set (cleared to '0') by the BPI with the end of the BPI kernel reset sequence.

Capture/Compare Unit 6 (CCU6)

KRST1

Kernel Reset Register 1

(F0_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers are set.</p> <p>0_B No kernel reset was requested</p> <p>1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to '0') by the BPI after the kernel reset was executed.</p>
0	[31:1]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear Register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Capture/Compare Unit 6 (CCU6)

KRSTCLR

Kernel Reset Status Clear Register (EC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

27.11 Implementation

This chapter describes the implementation of the CCU6 module in the TC26x B-Step device.

- Address map (see [Section 27.11.1](#))
- Module output select (see [Section 27.11.2](#))
- Synchronous start (see [Section 27.11.3](#))
- Digital Connections (see [Section 27.11.4](#))

27.11.1 Address Map

There are two CCU6 kernels in the TC26x B-Step, namely CCU60 and CCU61. The CCU6061 module consists of CCU60 and CCU61 kernels .

Table 27-15 Registers Address Space

Module	Base Address	End Address	Note
CCU60	F000 2A00 _H	F000 2AFF _H	CCU6061 module includes CCU60 and CCU61 kernels
CCU61	F000 2B00 _H	F000 2BFF _H	CCU6061 module includes CCU60 and CCU61 kernels

Table 27-16 Registers Overview - CCU6 Module Registers

Register Short Name	Register Long Name	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CCU6061 Module Registers (only available in the address range of CCU60)						
CCU60_MO SEL	CCU60 Module Output Select Register	0C _H	U, SV	U, SV, P	Application Reset	27-139

27.11.1.1 Module Registers

Module Output Select Register

MOSEL contains bit fields to select the output signal from module CCU6061 for the trigger signals to the A/D converters in the VADC module.

CCU60_MOSEL

CCU60 Module Output Select Register(0C_H)

Reset Value: 0000 0000_H

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
TRIG0SEL	[2:0]	rw	Output Trigger Select for CCU6061 TRIG0 This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000 _B The signal CCU60_COUT63 is selected. 001 _B The signal CCU61_COUT63 is selected. 010 _B The signal CCU60_CC60 is selected. 011 _B The signal CCU61_CC60 is selected. 100 _B The signal CCU60_SR1 is selected. 101 _B The signal CCU61_SR1 is selected. 110 _B The signal CCU60_SR3 is selected. 111 _B The signal CCU61_SR3 is selected.
TRIG1SEL	[5:3]	rw	Output Trigger Select for CCU6061 TRIG1 This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000 _B The signal CCU60_COUT63 is selected. 001 _B The signal CCU61_COUT63 is selected. 010 _B The signal CCU60_CC61 is selected. 011 _B The signal CCU61_CC61 is selected. 100 _B The signal CCU60_SR1 is selected. 101 _B The signal CCU61_SR1 is selected. 110 _B The signal CCU60_SR3 is selected. 111 _B The signal CCU61_SR3 is selected.
TRIG2SEL	[8:6]	rw	Output Trigger Select for CCU6061 TRIG2 This bit field defines the output signal from the CCU6061 module used as the trigger signal to the VADC inputs. 000 _B The signal CCU60_COUT63 is selected. 001 _B The signal CCU61_COUT63 is selected. 010 _B The signal CCU60_CC62 is selected. 011 _B The signal CCU61_CC62 is selected. 100 _B The signal CCU60_SR1 is selected. 101 _B The signal CCU61_SR1 is selected. 110 _B The signal CCU60_SR3 is selected. 111 _B The signal CCU61_SR3 is selected.
0	[31:9]	r	Reserved Returns 0 if read, should be written with 0.

Note: CCU60_MOSEL is located in the address space of kernel CCU60. Therefore, when a reset of kernel CCU60 is triggered via registers CCU60_KRST0 and CCU60_KRST1, register CCU60_MOSEL is also reset.

Capture/Compare Unit 6 (CCU6)

*CCU60_MOSEL is **not** reset when a reset of kernel CCU61 is triggered via registers CCU61_KRST0 and CCU61_KRST1.*

*Because CCU60_MOSEL controls both signals from kernel CCU60 and CCU61, the output signals TRIG0..2 will be set to their inactive levels during **any** kernel reset of CCU60 as well as of CCU61 (see also [Figure 27-46](#)).*

Depending on the application, it may make sense to always reset both kernels in this case.

27.11.2 Module Output Select

For CCU6061 module, there are 3 trigger signals which are selectable from the output signals of the CCU60 and CCU61 kernels.

Each of the trigger signals (TRIG0, TRIG1, TRIG2) of the module is routed to each converter of the VADC module, as follows:

- TRIG0 of CCU6061 is routed to inputs BGREQGTC and GxREQGTC, $x = 0..3$
- TRIG1 of CCU6061 is routed to inputs BGREQGTD and GxREQGTD, $x = 0..3$
- TRIG2 of CCU6061 is routed to inputs BGREQGTE and GxREQGTE, $x = 0..3$

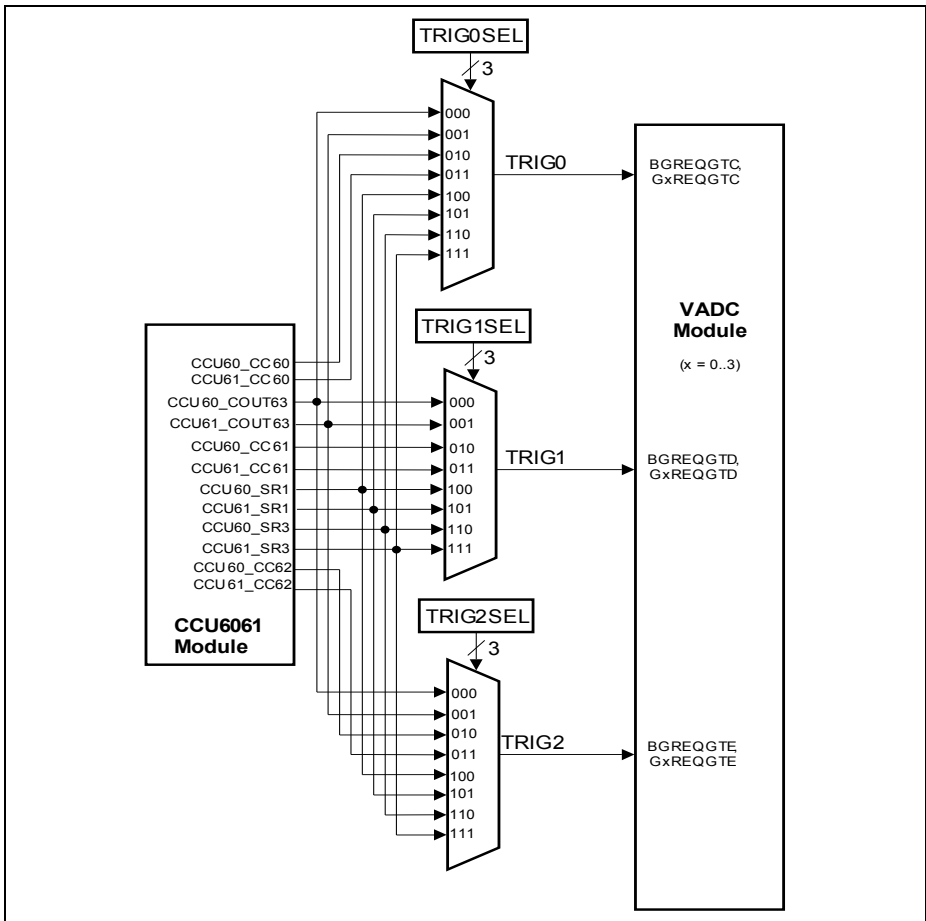

Figure 27-46 Output select trigger TC26x B-Step

27.11.3 Synchronous Start

Synchronous start of the capture/compare timers is supported by control bit `SYSCON.CCTRIG0` in the SCU module. Bit `SYSCON.CCTRIG0` is connected to the `T12HR` and `T13HR` inputs of the `CCU60` and `CCU61` kernels.

Figure 27-47 Synchronization Concept in TC26x B-Step

27.11.4 Digital Connections

The following tables show the digital connections of the CCU6x module with other modules or pins in the TC26x B-Step device.

Each input signal can be selected among 4 or 8 possible input lines, e.g. the input vector for input signal CC60IN is composed of CC60IN[D:A], whereas the input vectors for T12HR and T13HR are composed of T12HR[H:A] and T13HR[H:A]. The following sections refer to the interface signals.

The CCU6x module is clocked with the SPB_Bus clock, so $f_{CC6} = f_{SPB}$.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they can affect the module internal logic. The resulting delay of $2/f_{CC6}$ and an uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation.

An edge of an input signal can only be correctly detected if both, the high phase and the low phase of the input signal are each longer than $1/f_{CC6}$.

27.11.4.1 Connections of CCU60

This table describes the module interconnections of CCU60.

28 General Purpose Timer Unit (GPT12)

The General Purpose Timer Unit blocks GPT1 and GPT2 have very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes.

They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated Timer or Counter Mode, or may be concatenated with another timer of the same block.

Each block has alternate input/output functions and specific interrupts (service requests) associated with it. Input signals can be selected from several sources by register PISEL.

The GPT12 module is clocked with clock f_{GPT} .

Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{\text{GPT}}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in [Section 28.1.6.1](#).

The following list summarizes the supported features:

- $f_{\text{GPT}}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
 - Timer Mode
 - Gated Timer Mode
 - Counter Mode
 - Incremental Interface Mode
- Reload and Capture functionality
- Separate interrupts

Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{\text{GPT}}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in [Section 28.2.7.1](#).

The following list summarizes the supported features:

- $f_{\text{GPT}}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
 - Timer Mode
 - Gated Timer Mode
 - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Separate interrupts

General Purpose Timer Unit (GPT12)

28.1 Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4. When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT1 are signalled on service request lines SR0, SR1, and SR2.

The input and output lines of GPT1 are connected to pins. The control registers for the port functions are located in the respective port modules.

Note: The timing requirements for external input signals can be found in [Section 28.1.5](#), [Section 28.5.2](#) summarizes the module interface signals, including pins and interrupt request signals.

General Purpose Timer Unit (GPT12)

Figure 28-1 GPT1 Block Diagram

28.1.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T3 is configured and controlled via its control register T3CON.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in [Table 28-6](#). The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

General Purpose Timer Unit (GPT12)

Timer T3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 28-2** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL’s output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 28-2**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

Figure 28-2 Block Diagram of the Toggle Latch Logic of Core Timer T3 (x = 3)

General Purpose Timer Unit (GPT12)

28.1.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer T3 in Timer Mode

Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see [Section 28.1.5](#) for details on the input clock options.

Figure 28-3 Block Diagram of Core Timer T3 in Timer Mode

General Purpose Timer Unit (GPT12)

Timer T3 in Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see Section 28.1.5). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).

To enable this operation, the associated pin T3IN must be configured as input.

Figure 28-4 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause a service request via SR1.

General Purpose Timer Unit (GPT12)

Timer T3 in Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see [Table 28-8](#)).

Figure 28-5 Block Diagram of Core Timer T3 in Counter Mode

For Counter Mode operation, pin T3IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 28.1.5](#).

General Purpose Timer Unit (GPT12)
Timer T3 in Incremental Interface Mode

Incremental Interface Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

Figure 28-6 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see [Table 28-10](#)). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The service request generation can be selected: In Rotation Detection Mode (T3M = 110_B), a service request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), a service request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

The incremental encoder can be connected directly to the TC26x B-Step without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, \bar{A}) to digital signals (such as A). This greatly increases noise immunity.

General Purpose Timer Unit (GPT12)

Note: The third encoder output T0, that indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3. If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt (see bit CLRT3EN in register T4CON).

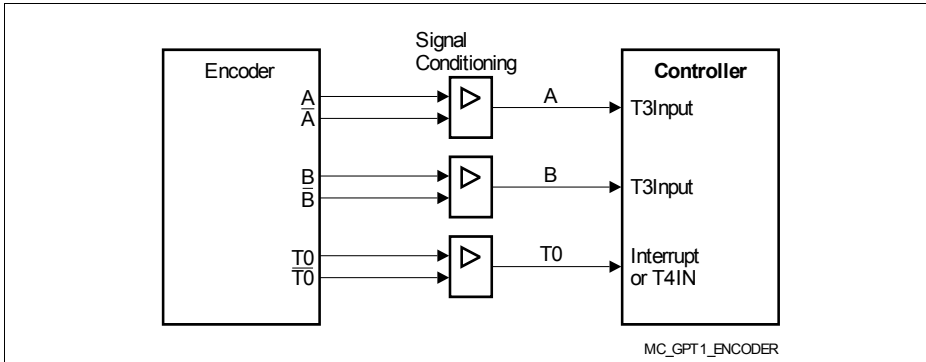

Figure 28-7 Connection of the Encoder to the TC26x B-Step

For Incremental Interface Mode operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B.
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 28.1.5](#).

As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. [Table 28-1](#) summarizes the possible combinations.

Table 28-1 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising ↑	Falling ↓	Rising ↑	Falling ↓
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

General Purpose Timer Unit (GPT12)

Figure 28-8 and Figure 28-9 give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.

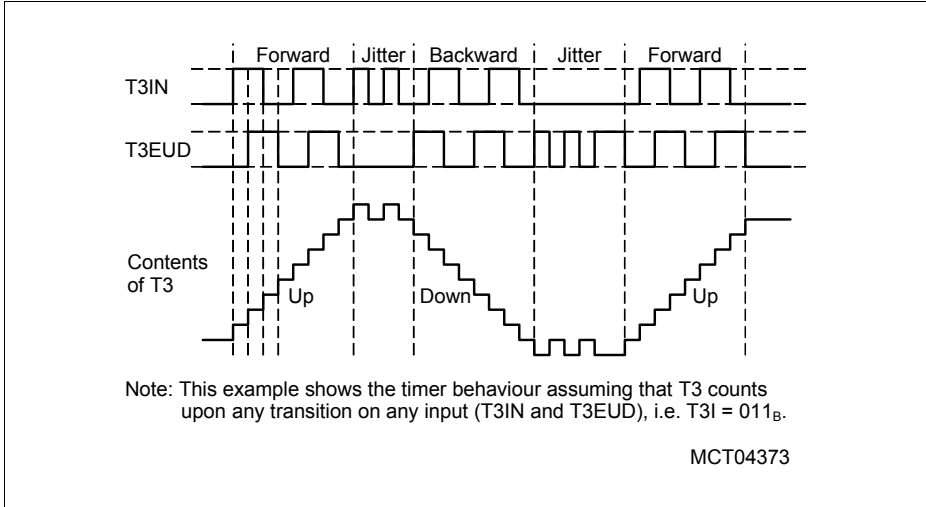

Figure 28-8 Evaluation of Incremental Encoder Signals, 2 Count Inputs

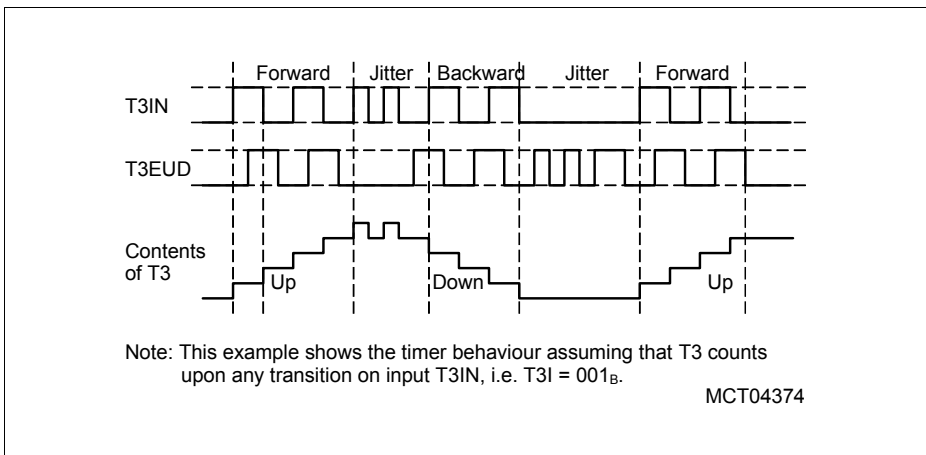

Figure 28-9 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed,

General Purpose Timer Unit (GPT12)

*acceleration, deceleration) may be obtained by measuring the incoming signal periods (see **“Combined Capture Modes”** on **Page 28-58**).*

General Purpose Timer Unit (GPT12)

28.1.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, that are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in [Table 28-6](#).

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

General Purpose Timer Unit (GPT12)

28.1.4 GPT1 Auxiliary Timers T2/T4 Operating Modes

The operation of the auxiliary timers in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timers T2 and T4 in Timer Mode

Timer Mode for an auxiliary timer Tx is selected by setting its bitfield TxM in register TxCON to 000_B.

Figure 28-10 Block Diagram of an Auxiliary Timer in Timer Mode

General Purpose Timer Unit (GPT12)
Timers T2 and T4 in Gated Timer Mode

Gated Timer Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 010_B or 011_B. Bit TxM.0 (TxCON.3) selects the active level of the gate input.

Note: A transition of the gate signal at TxIN does not cause a service request. Service requests of timer T2 are handled via SR0, and service requests of timer T4 are handled via SR2.

Figure 28-11 Block Diagram of an Auxiliary Timer in Gated Timer Mode

Note: There is no output toggle latch for T2 and T4.

Start/stop of an auxiliary timer can be controlled locally or remotely.

General Purpose Timer Unit (GPT12)

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see [Table 28-9](#)).

Figure 28-12 Block Diagram of an Auxiliary Timer in Counter Mode

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 28.1.5](#).

General Purpose Timer Unit (GPT12)

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).

As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

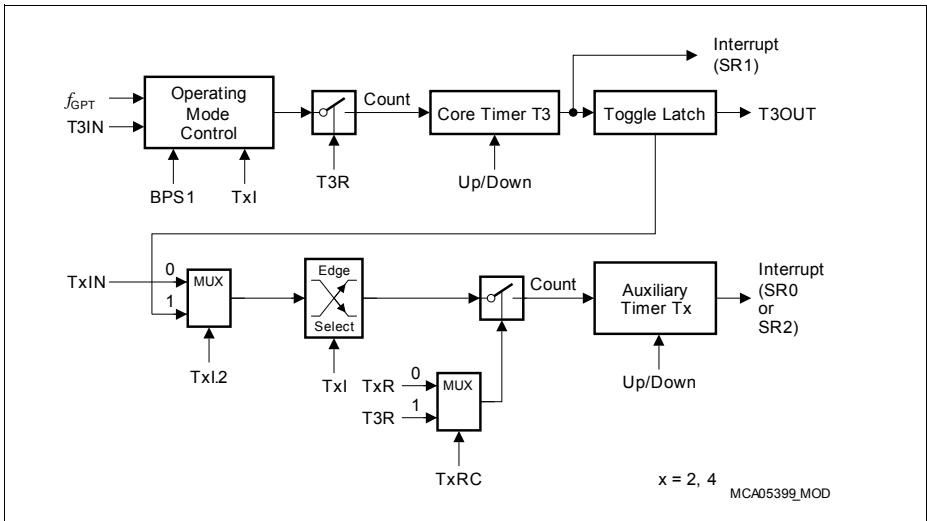

Figure 28-13 Concatenation of Core Timer T3 and an Auxiliary Timer

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

General Purpose Timer Unit (GPT12)

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT1 timers, represented by TIMER_HIGH (for auxiliary timer, here T2) and TIMER_LOW (for core timer T3). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T2
- TIMER_LOW = T3
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see [Table 28-2](#)
- TIMER_HIGH = T2
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T3

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in [Table 28-2](#).

Table 28-2 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS1 = 01 _B	BPS1 = 00 _B	BPS1 = 11 _B	BPS1 = 10 _B
Number of Module clocks	8	16	32	64

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS1 and the Individual Prescalers TXI (see [Table 28-7](#)), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time.

General Purpose Timer Unit (GPT12)

Timers T2 and T4 in Incremental Interface Mode

Incremental Interface Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

Figure 28-14 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see "Combined Capture Modes" on Page 28-58).

General Purpose Timer Unit (GPT12)

Timers T2 and T4 in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In Reload Mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see [Table 28-9](#)), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for Reload Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

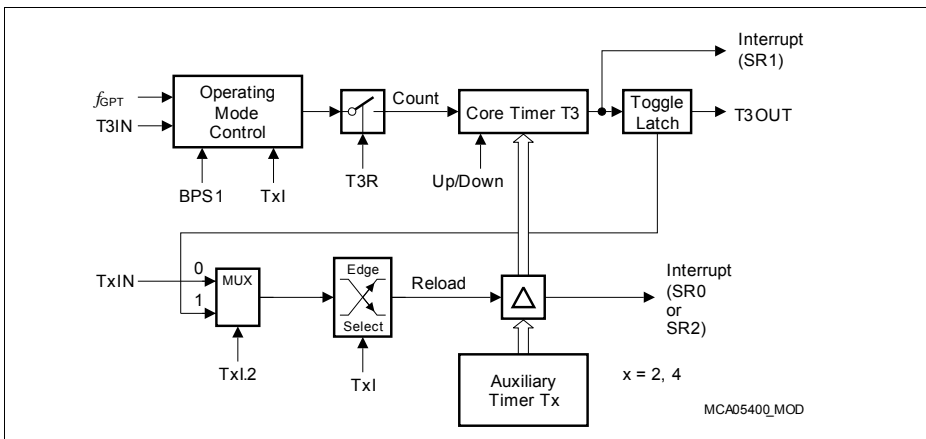

Figure 28-15 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective service request SR0 or SR2 is activated.

Note: When a T3OTL transition is selected for the trigger signal, service request SR1 will also become active, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 28.1.5](#).

The Reload Mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

General Purpose Timer Unit (GPT12)

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard Reload Mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this “single-transition” mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

Figure 28-16 shows an example for the generation of a PWM signal using the “single-transition” reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

Note: The output toggle latch T3OTL is accessible via software and may be changed, if required, to modify the PWM signal.

However, this will NOT trigger the reloading of T3.

General Purpose Timer Unit (GPT12)

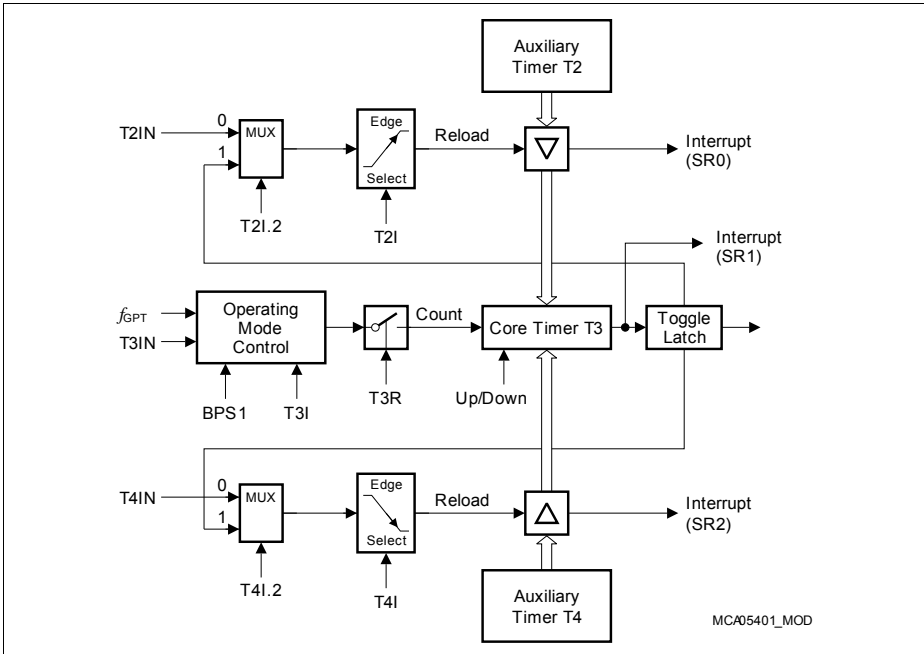

Figure 28-16 GPT1 Timer Reload Configuration for PWM Generation

Note: Although possible, selecting the same reload trigger event for both auxiliary timers should be avoided. In such a case, both reload registers would try to load the core timer at the same time. If this combination is selected, T2 is disregarded and the contents of T4 is reloaded.

The implementation of the GPT1 finite state machine may require special consideration in following cases.

In Case 1, when T2 or T4 are used to reload T3 on overflow/underflow, and T3 is read by software on the fly, the following unexpected values may be read from T3:

- When T3 is counting up, 0000_H or 0001_H may be read from T3 directly after an overflow, although the reload value in T2/T4 is higher (0001_H may be read in particular if BPS1 = 01_B and T3I = 000_B).
- When T3 is counting down, FFFF_H or FFFE_H may be read from T3 directly after an underflow, although the reload value in T2/T4 is lower (FFFE_H may be read in particular if BPS1 = 01_B and T3I = 000_B).

Note: All timings derived from T3 in this configuration (e.g. distance between service requests, PWM waveform on T3OUT, etc.) are accurate except for the specific case described below.

General Purpose Timer Unit (GPT12)

Recommendation:

- When T3 counts up, and T3_value < reload value is read from T3, T3_value should be replaced with the reload value for further calculations.
- When T3 counts down, and T3_value > reload value is read from T3, T3_value should be replaced with the reload value for further calculations.

Alternatively, if the intention is to identify the overflow/underflow of T3, the T3 service request (SR1) may be used.

In Case 2, when T2 is used to reload T3 in the configuration with BPS1 = 01_B and T3I = 000_B (i.e. fastest configuration/highest resolution of T3), the reload of T3 is performed with a delay of one basic clock cycle.

Recommendation:

To compensate the delay and achieve correct timing,

- increment the reload value in T2 by 1 when T3 is configured to count up,
- decrement the reload value in T2 by 1 when T3 is configured to count down.

Alternatively, use T4 instead of T2 as reload register for T3. In this configuration the reload of T3 is not delayed, i.e. the effect described above does not occur with T4.

General Purpose Timer Unit (GPT12)

Timers T2 and T4 in Capture Mode

Capture Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In Capture Mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see [Table 28-9](#)). Bit 2 of TxI is irrelevant for Capture Mode and must be cleared (TxI.2 = 0).

Note: When programmed for Capture Mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

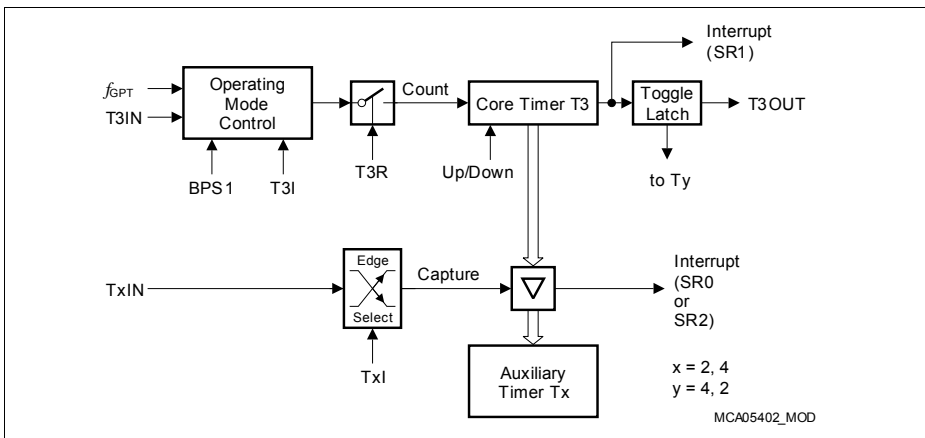

Figure 28-17 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer T3 are loaded into the auxiliary timer register Tx and the associated service request (SR0 or SR2) will be activated.

For Capture Mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 28.1.5](#).

General Purpose Timer Unit (GPT12)
28.1.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see [Figure 28-1](#)). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode or Incremental Interface Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 28-3 Basic Clock Selection for Block GPT1

Block Prescaler ¹⁾	BPS1 = 01 _B	BPS1 = 00 _B ²⁾	BPS1 = 11 _B	BPS1 = 10 _B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$	$f_{GPT}/64$
Input Signal Stable Time	$4 \times t_{GPT}$	$8 \times t_{GPT}$	$16 \times t_{GPT}$	$32 \times t_{GPT}$

1) Please note the non-linear encoding of bitfield BPS1.

2) Default after reset.

Note: The GPT1 block uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T2, T3, T4), these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT1 state machine has 8 states (4 states when BPS1 = 01_B) and processes the timers in the order T3 - T2 (all actions except capture) - T4 - T2 (capture).

Note: When initializing the GPT1 block after reset, and the block prescaler BPS1 in register T3CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, incremental interface, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.

In this case, or when changing BPS1 during operation of the GPT1 block, disable related interrupts before modification of BPS1, and afterwards clear the corresponding service request flags and re-initialize those registers (T2, T3, T4) that might be affected by a count/capture/reload event.

General Purpose Timer Unit (GPT12)
Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS1) \times 2^{<TxI>}} \quad r_{Tx}[\mu s] = \frac{F(BPS1) \times 2^{<TxI>}}{f_{GPT}[\text{MHz}]} \quad (28.1)$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 28-7** summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

Table 28-4 lists GPT1 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor $F(BPS1) \times 2^{<TxI>}$ and the module clock f_{GPT} . Note that some numbers may be rounded.

Table 28-4 GPT1 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock $f_{GPT} = 100 \text{ MHz}$			Example 2: Module Clock $f_{GPT} = 66.5 \text{ MHz}$		
	Frequency	Resolution	Period	Frequency	Resolution	Period
4	25 MHz	40 ns	2.62 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.24 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 μs	83.89 ms	519.53 kHz	1.924 μs	126.1 ms
256	390.6 kHz	2.56 μs	167.8 ms	259.77 kHz	3.850 μs	252.3 ms
512	195.3 kHz	5.12 μs	335.5 ms	129.88 kHz	7.699 μs	504.6 ms
1024	97.7 kHz	10.24 μs	671.1 ms	64.94 kHz	15.398 μs	1.009 s
2048	48.8 kHz	20.48 μs	1.342 s	32.47 kHz	30.797 μs	2.018 s
4096	24.4 kHz	40.96 μs	2.684 s	16.24 kHz	61.594 μs	4.037 s

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see **Figure 28-1**). To ensure that a signal is recognized correctly, its current level (high or

General Purpose Timer Unit (GPT12)

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods is required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 28-5 summarizes the resulting requirements for external GPT1 input signals.

Table 28-5 GPT1 External Input Signal Limits

GPT1 Divider BPS1	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock $f_{GPT} =$ 100 MHz		Example 2: Module Clock $f_{GPT} =$ 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01 _B	$f_{GPT}/8$	$4 \times t_{GPT}$	12.5 MHz	40 ns	8.313 MHz	60.2 ns
00 _B	$f_{GPT}/16$	$8 \times t_{GPT}$	6.25 MHz	80 ns	4.156 MHz	120.3 ns
11 _B	$f_{GPT}/32$	$16 \times t_{GPT}$	3.125 MHz	160 ns	2.078 MHz	240.6 ns
10 _B	$f_{GPT}/64$	$32 \times t_{GPT}$	1.563 MHz	320 ns	1.039 MHz	481.2 ns

These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

General Purpose Timer Unit (GPT12)**28.2 Timer Block GPT2**

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6. When any of the timer registers is written by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupt requests of GPT2 are signalled on service request lines SR3, SR4, and SR5.

The input and output lines of GPT2 are connected to pins. The control registers for the port functions are located in the respective port modules.

Note: The timing requirements for external input signals can be found in [Section 28.2.6](#), [Section 28.5.2](#) summarizes the module interface signals, including pins and interrupt request signals.

General Purpose Timer Unit (GPT12)

Figure 28-18 GPT2 Block Diagram

28.2.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in [Table 28-15](#). The count direction can be changed regardless of whether or not the timer is running.

General Purpose Timer Unit (GPT12)

Timer T6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named ‘Toggle Latch’, shown in the Timer Mode diagrams. **Figure 28-19** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL’s output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timer carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 28-19**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

Figure 28-19 Block Diagram of the Toggle Latch Logic of Core Timer T6 (x = 6)

General Purpose Timer Unit (GPT12)

28.2.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer T6 in Timer Mode

Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see Section 28.2.6 for details on the input clock options.

Figure 28-20 Block Diagram of Core Timer T6 in Timer Mode

General Purpose Timer Unit (GPT12)

Timer 6 in Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see Section 28.2.6). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).

To enable this operation, the associated pin T6IN must be configured as input.

Figure 28-21 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause a service request.

General Purpose Timer Unit (GPT12)

Timer 6 in Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see [Table 28-17](#)).

Figure 28-22 Block Diagram of Core Timer T6 in Counter Mode

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 28.2.6](#).

General Purpose Timer Unit (GPT12)

28.2.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timer can be remotely controlled by the T6 run control bit. Both timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

General Purpose Timer Unit (GPT12)

28.2.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B.

Figure 28-23 Block Diagram of Auxiliary Timer T5 in Timer Mode

General Purpose Timer Unit (GPT12)

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

Note: A transition of the gate signal at line T5IN does not cause a service request.

Figure 28-24 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: There is no output toggle latch for T5.

Start/stop of the auxiliary timer can be controlled locally or remotely.

General Purpose Timer Unit (GPT12)

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see [Table 28-18](#)).

Figure 28-25 Block Diagram of Auxiliary Timer T5 in Counter Mode

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 28.2.6](#).

General Purpose Timer Unit (GPT12)

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).

As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

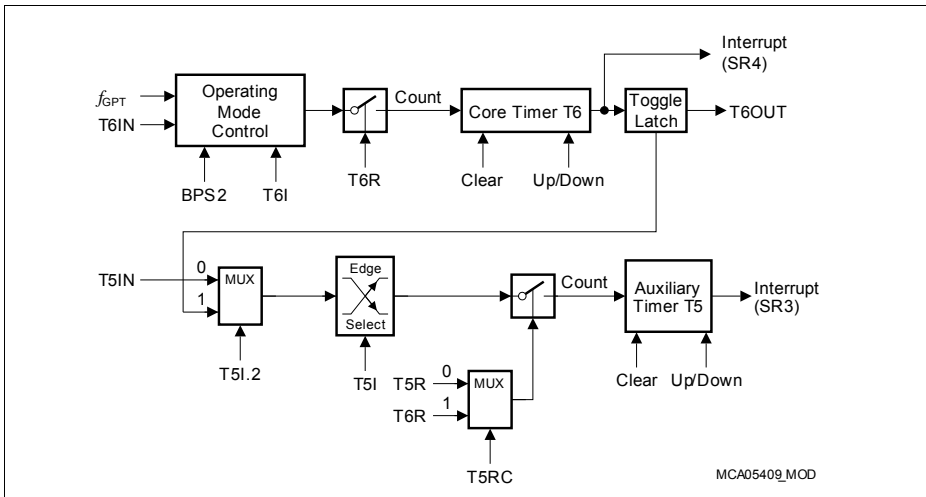

Figure 28-26 Concatenation of Core Timer T6 and Auxiliary Timer T5

When reading the low and high parts of the concatenated timer, care must be taken to obtain consistent values in particular after a timer overflow/underflow (e.g. one part may already have considered an overflow, while the other has not).

General Purpose Timer Unit (GPT12)

Note: This is a general issue when reading multi-word results with consecutive instructions, and not necessarily unique to the GPT12 module architecture.

The following algorithm may be used to read concatenated GPT2 timers, represented by TIMER_HIGH (for auxiliary timer T5) and TIMER_LOW (for core timer T6). The high part is read twice, and reading of the low part is repeated if two different values were read for the high part:

- TIMER_HIGH_TMP = T5
- TIMER_LOW = T6
- Wait two basic clock cycles (to allow increment/decrement of auxiliary timer in case of core timer overflow/underflow) - see [Table 28-11](#)
- TIMER_HIGH = T5
- If TIMER_HIGH is not equal to TIMER_HIGH_TMP then TIMER_LOW = T6

After execution of this algorithm, TIMER_HIGH and TIMER_LOW represent a consistent time stamp of the concatenated timers.

The equivalent number of module clock cycles corresponding to two basic clock cycles is shown in [Table 28-11](#).

Table 28-11 Number of Module Clock Cycles to Wait for Two Basic Clock Cycles

Block Prescaler	BPS2 = 01 _B	BPS2 = 00 _B	BPS2 = 11 _B	BPS2 = 10 _B
Number of module clocks	4	8	16	32

In case the required timer resolution can be achieved with different combinations of the Block Prescaler BPS2 and the Individual Prescalers TxI (see [Table 28-16](#)), the variant with the smallest value for the Block Prescaler may be chosen to minimize the waiting time. E.g. in order to run T6 at $f_{SYS}/512$, select BPS2 = 00_B, T6I = 111_B, and insert 8 NOPs (or other instructions) to ensure the required waiting time before reading TIMER_HIGH the second time.

General Purpose Timer Unit (GPT12)

28.2.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, by GPT1 timer's T3 input lines T3IN and T3EUD, or by read accesses to GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

The capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

Capture/Reload Register CAPREL in Capture Mode

Capture Mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In Capture Mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. [Table 28-19](#) summarizes these options.

General Purpose Timer Unit (GPT12)

Figure 28-27 Capture/Reload Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the service request is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is signalled by the CAPREL interrupt request SR5.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For Capture Mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of

General Purpose Timer Unit (GPT12)

these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 28.2.6](#).

Capture/Reload Register CAPREL in Reload Mode

Reload Mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In Reload Mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the service request SR5 associated with the CAPREL register. However, service request SR4 will be activated, indicating the overflow/underflow of T6.

Figure 28-28 Capture/Reload Register CAPREL in Reload Mode

General Purpose Timer Unit (GPT12)

Capture/Reload Register CAPREL in Capture-And-Reload Mode

Since the reload function and the capture function of register CAPREL can be enabled individually by bits T5SC and T6SR, the two functions can be enabled simultaneously by setting both bits. This feature can be used to generate an output frequency that is a multiple of the input frequency.

Figure 28-29 Capture/Reload Register CAPREL in Capture-And-Reload Mode

This combined mode can be used to detect consecutive external events which may occur aperiodically, but where a finer resolution, that means, more 'ticks' within the time between two external events is required.

For this purpose, the time between the external events is measured using timer T5 and the CAPREL register. Timer T5 runs in Timer Mode counting up with a frequency of e.g. $f_{GPT}/32$. The external events are applied e.g. to pin CAPIN (or other pins supporting

General Purpose Timer Unit (GPT12)

capture mode, see [Table 28-19](#)). When an external event occurs, the contents of timer T5 are latched into register CAPREL and timer T5 is cleared ($T5CLR = 1$). Thus, register CAPREL always contains the correct time between two events, measured in timer T5 increments. Timer T6, which runs in Timer Mode counting down with a frequency of e.g. $f_{GPT}/4$, uses the value in register CAPREL to perform a reload on underflow. This means, the value in register CAPREL represents the time between two underflows of timer T6, now measured in timer T6 increments. Since (in this example) timer T6 runs 8 times faster than timer T5, it will underflow 8 times within the time between two external events. Thus, the underflow signal of timer T6 generates 8 ‘ticks’. Upon each underflow, the interrupt request SR4 will be activated and bit T6OTL will be toggled. The state of T6OTL may be output on pin T6OUT. This signal on T6OUT has 8 times more transitions than the signal which is applied to the selected input (CAPIN in this example).

Note: The underflow signal of Timer T6 can furthermore be used to clock functional units in other modules, e.g. one or more of the timers of the capture/compare units CCU6 (connections see [Section 28.5.2](#)). This gives the user the possibility to set compare events based on a finer resolution than that of the external events. This connection is accomplished via signal T6OFL.

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H , so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

This deviation can be compensated for by using T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition at the selected input pin(s), e.g. on CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H . In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied e.g. at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H . So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two external events, but rather its 2’s complement. Software will have to convert this value, if it is required for the operation.

General Purpose Timer Unit (GPT12)

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

In general, GPT12 has no destructive read mechanisms, except for this special operation mode 'capture on position read operations', where register CAPREL is intentionally updated after a read of T3 or T2/T4 (and T5 or T6 are optionally cleared). In this case, also the associated service request flag in register SRC_GPT120CIRQ is set.

Note: If mode 'capturing on position read operations' is selected, and the corresponding timer (T3, or any of T2, T3, T4) is read by a debugger, a capture event may be triggered (T5 is captured into CAPREL, and T5 or T6 may optionally be cleared (if T5CLR = 1 or T6CLR = 1)).

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

General Purpose Timer Unit (GPT12)
28.2.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see [Figure 28-18](#)). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (Gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 28-12 Basic Clock Selection for Block GPT2

Block Prescaler ¹⁾	BPS2 = 01 _B	BPS2 = 00 _B ²⁾	BPS2 = 11 _B	BPS2 = 10 _B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{GPT}/4$	$f_{GPT}/8$	$f_{GPT}/16$	$f_{GPT}/32$
Input Signal Stable Time	$2 \times t_{GPT}$	$4 \times t_{GPT}$	$8 \times t_{GPT}$	$16 \times t_{GPT}$

1) Please note the non-linear encoding of bitfield BPS2.

2) Default after reset.

Note: The GPT2 module uses a finite state machine to control the actions. Since multiple interactions are possible between the timers (T5, T6) and register CAPREL, these elements are processed sequentially. However, all actions are normally completed within one basic clock cycle. The GPT2 state machine has 4 states (2 states when BPS2 = 01_B) and processes T6 before T5.

Note: When initializing the GPT2 block after reset, and the block prescaler BPS2 in register T6CON needs to be set to a value different from its default value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur during the first basic clock cycle.

In this case, or when changing BPS2 during operation of the GPT2 block, disable related interrupts before modification of BPS2, and afterwards clear the corresponding service request flags and re-initialize those registers (T5, T6, CAPREL) that might be affected by a count/capture/reload event.

General Purpose Timer Unit (GPT12)
Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{Tx} = \frac{f_{GPT}}{F(BPS2) \times 2^{<TxI>}} \quad r_{Tx}[\mu s] = \frac{F(BPS2) \times 2^{<TxI>}}{f_{GPT}[\text{MHz}]} \quad (28.2)$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{<TxI>}$. **Table 28-16** summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

Table 28-13 lists GPT2 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor $F(BPS2) \times 2^{<TxI>}$ and the module clock f_{GPT} . Note that some numbers may be rounded.

Table 28-13 GPT2 Timer Parameters

Overall Prescaler Factor	Example 1: Module Clock $f_{GPT} = 100 \text{ MHz}$			Example 2: Module Clock $f_{GPT} = 66.5 \text{ MHz}$		
	Frequency	Resolution	Period	Frequency	Resolution	Period
2	50 MHz	20 ns	1.311 ms	33.25 MHz	30.1 ns	1.97 ms
4	25 MHz	40 ns	2.621 ms	16.625 MHz	60.2 ns	3.94 ms
8	12.5 MHz	80 ns	5.243 ms	8.313 MHz	120.3 ns	7.88 ms
16	6.25 MHz	160 ns	10.49 ms	4.156 MHz	240.6 ns	15.77 ms
32	3.125 MHz	320 ns	20.97 ms	2.078 MHz	481.2 ns	31.54 ms
64	1.563 MHz	640 ns	41.94 ms	1.039 MHz	962.4 ns	63.07 ms
128	781.25 kHz	1.28 μs	83.89 ms	519.53 kHz	1.924 μs	126.1 ms
256	390.6 kHz	2.56 μs	167.8 ms	259.77 kHz	3.850 μs	252.3 ms
512	195.3 kHz	5.12 μs	335.5 ms	129.88 kHz	7.699 μs	504.6 ms
1024	97.7 kHz	10.24 μs	671.1 ms	64.94 kHz	15.398 μs	1.009 s
2048	48.8 kHz	20.48 μs	1.342 s	32.47 kHz	30.797 μs	2.018 s

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see **Figure 28-18**). To ensure that a signal is recognized correctly, its current level (high or

General Purpose Timer Unit (GPT12)

low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

Table 28-14 summarizes the resulting requirements for external GPT2 input signals.

Table 28-14 GPT2 External Input Signal Limits

GPT2 Divider BPS2	Input Freq. Factor	Input Phase Duration	Example 1: Module Clock $f_{GPT} =$ 100 MHz		Example 2: Module Clock $f_{GPT} =$ 66.5 MHz	
			Max. Input Frequency	Min. Level Hold Time	Max. Input Frequency	Min. Level Hold Time
01 _B	$f_{GPT}/4$	$2 \times t_{GPT}$	25 MHz	20 ns	16.625 MHz	30.1 ns
00 _B	$f_{GPT}/8$	$4 \times t_{GPT}$	12.5 MHz	40 ns	8.313 MHz	60.2 ns
11 _B	$f_{GPT}/16$	$8 \times t_{GPT}$	6.25 MHz	80 ns	4.156 MHz	120.3 ns
10 _B	$f_{GPT}/32$	$16 \times t_{GPT}$	3.125 MHz	160 ns	2.078 MHz	240.6 ns

These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode.

General Purpose Timer Unit (GPT12)

28.4 General Module Operation

This section provides information about the:

- Input Selection (see [Section 28.4.1](#))
- OCDS Suspend Functionality (see [Section 28.4.2](#))
- Miscellaneous GPT12 Register Description (see [Section 28.4.3](#))
- BPI Register Description (see [Section 28.4.4](#))

28.4.1 Input Selection

Each GPT12 input signal can be selected from a vector of two or four possible inputs by programming the port input select register **PISEL**. This permits to adapt the pin functionality of the device to the application requirements.

The output pins for the module output signals are chosen in the ports.

Naming convention (example):

The input vector T3IN[D:A] for input signal T3IN is composed of the signals T3INA to T3IND.

Note: All functional inputs of the GPT12 module are synchronized to the internal basic clock of the GPT1 and GPT2 block, respectively. An edge of an input signal can only be correctly recognized if the high phase and the low phase are longer than one basic clock period. See [Table 28-5](#) for GPT1 external input signal limits, and [Table 28-14](#) for GPT2 external input signal limits.

28.4.2 OCDS Suspend

The behavior of GPT12 upon an OCDS suspend request is controlled by the **OCS** register. GPT12 supports only Hard Suspend Mode.

Hard Suspend Mode

In Hard Suspend Mode the GPT12 kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a GPT12 kernel reset might not be sufficient to bring the system into a defined state.

General Purpose Timer Unit (GPT12)

28.4.3 Miscellaneous GPT12 Registers

28.4.3.1 Port Input Select Register

Register PISEL contains bit fields selecting the actual input signal for the module inputs.

PISEL

28.4.3.2 Identification Register

The GPT12 Module Identification Register ID contains read-only information about the module identification number and its revision.

General Purpose Timer Unit (GPT12)
ID
Identification Register
(08_H)
Reset Value: 0068 C0XX_H

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field indicates the revision number of the TC26x B-Step module (01 _H = first revision).
MODTYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines a 32-bit module
MODNUMBER	[31:16]	r	Module Number This bit field defines the module identification number. For the GPT12 module the module identification number is 68 _H .

General Purpose Timer Unit (GPT12)

28.4.4 BPI Registers

This section describes the registers of the BPI (Bus Peripheral Interface). [Figure 28-30](#) shows all registers associated with the BPI of a GPT12 module.

BPI Registers Overview

Figure 28-30 BPI Registers

[Table 28-21](#) gives an overview of the BPI registers, including their access modes and reset class.

Table 28-21 Registers Overview - BPI Registers

Register Short Name	Description	Offset Addr.	Access Mode		Reset	Page Num.
			Read	Write		
CLC	Clock Control Register	00 _H	U, SV	SV, E, P	Application Reset	28-78
-	Kernel Registers	-	-	-	-	-
OCS	OCDS Control and Status Register	E8 _H	U, SV	SV, P	Debug Reset	28-79
KRSTCLR	Reset Status Clear Register	EC _H	U, SV	SV, E, P	Application Reset	28-84
KRST1	Reset Control Register 1	F0 _H	U, SV	SV, E, P	Application Reset	28-83
KRST0	Reset Control Register 0	F4 _H	U, SV	SV, E, P	Application Reset	28-82
ACCEN1	Access Enable Register 1	F8 _H	U, SV	SV, SE	Application Reset	28-81
ACCEN0	Access Enable Register 0	FC _H	U, SV	SV, SE	Application Reset	28-80

General Purpose Timer Unit (GPT12)

Note: Register bits marked "r" in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

General Purpose Timer Unit (GPT12)
28.4.4.1 System Registers
Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the GPT12 module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{GPT} module clock signal and Sleep Mode for the module.

CLC
Clock Control Register
(00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable is not requested. 1 _B Module disable is requested.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module. 0 _B Module is enabled. 1 _B Module is disabled.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode. 0 _B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1 _B Sleep Mode request is disregarded: Sleep Mode cannot be entered upon a request.

General Purpose Timer Unit (GPT12)

Field	Bits	Type	Description
0	[31:16], [15:4], 2	r	Reserved Read as 0; should be written with 0.

Note: Upon an accepted Sleep Mode request (with EDIS = '1'), or upon a disable request (DISR = '1'), the GPT12 kernel clock is switched off immediately. Therefore, software should ensure that the system controlled by the GPT12 kernel has reached a safe state before triggering a Sleep Mode or module disable request.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set (cleared to '0') by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

28.5 Implementation of the GPT12 Module

This chapter describes the implementation of the GPT12 module in the TC26x B-Step device.

28.5.1 Address Map

There is one GPT12 kernel implemented in the TC26x B-Step, namely GPT120.

Table 28-22 Registers Address Space

Module	Base Address	End Address	Note
GPT120	F000 2E00 _H	F000 2EFF _H	

28.5.2 Module Connections

The following table shows the digital connections of the GPT12 module with other modules or pins in the TC26x B-Step device.

The GPT12 module is clocked with the SPB_Bus clock, so $f_{GPT} = f_{SPB}$.

Note: Signals that are not available in the 144-pin package variant are marked (see footnote ¹⁾).

Versatile Analog-to-Digital Converter (VADC)

29 Versatile Analog-to-Digital Converter (VADC)

The TC26x B-Step provides a series of analog input channels connected to a cluster of Analog/Digital Converters using the Successive Approximation Register (SAR) principle to convert analog input values (voltages) to discrete digital values.

The TC26x B-Step is based on individual SAR converters with dedicated Sample&Hold units.

The number of analog input channels and ADCs depends on the chosen product type (refer to **“Product-Specific Configuration”** on Page 29-147).

Each converter of the ADC cluster can operate independent of the others, controlled by a dedicated set of registers and triggered by a dedicated group request source. The results of each channel can be stored in a dedicated channel-specific result register or in a group-specific result register.

A background request source can access all analog input channels that are not assigned to any group request source. These conversions are executed with low priority. The background request source can, therefore, be regarded as an additional background converter.

Feature List

The following features describe the functionality of the ADC cluster:

- Nominal analog supply voltage 5.0 V, operation at 3.3 V with reduced performance
- Input voltage range from 0 V up to analog supply voltage
- Standard (V_{AREF}) and alternate (CH0) reference voltage source selectable for each channel to support ratiometric measurements and different signal scales
- Up to 4 independent converters with up to 16 analog input channels
- External analog multiplexer control, including adjusted sample time and scan support
- Conversion speed and sample time adjustable to adapt to sensors and reference
- Conversion time below 1 μ s (depending on result width and sample time)
- Flexible source selection and arbitration
 - Programmable arbitrary conversion sequence (single or repeated)
 - Configurable auto scan conversion (single or repeated) on each converter
 - Configurable auto scan conversion (single or repeated) in the background (all converters)
 - Conversions triggered by software, timer events, or external events
 - Cancel-inject-restart mode for reduced conversion delay on priority channels
- Powerful result handling
 - Selectable result width of 8/10/12 bits
 - Fast Compare Mode
 - Independent result registers
 - Configurable limit checking against programmable border values
 - Data rate reduction through adding a selectable number of conversion results
 - FIR/IIR filter with selectable coefficients

Versatile Analog-to-Digital Converter (VADC)

- Flexible service request generation based on selectable events
- Built-in safety features
 - Configurable register access protection supports safety applications
 - Broken wire detection with programmable default levels
 - Multiplexer test mode to verify signal path integrity
- Support of suspend and power saving modes

Table 29-1 Abbreviations used in ADC chapter

Abbreviation	Meaning
ADC	Analog to Digital Converter
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
INL	Integral Non-Linearity (error)
LSB _n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2 ⁿ equally distributed steps)
SCU	System Control Unit of the device
TUE	Total Unadjusted Error

Versatile Analog-to-Digital Converter (VADC)

29.1 Introduction and Basic Structure

The Versatile Analog to Digital Converter module (VADC) of the TC26x B-Step comprises a set of converter blocks that can be operated either independently or via a common request source that emulates a background converter. Each converter block is equipped with a dedicated input multiplexer and dedicated request sources, which together build separate groups, each assigned to a kernel.

Figure 29-2 ADC Kernel Block Diagram

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

A set of functional units (described further down in this section) can be configured according to the requirements of a given application. These units build a path from the input signals to the digital results.

Each kernel provides a dedicated Sample&Hold unit connected to the input multiplexer.

The basic module clock f_{VADC} is connected to the system clock signal f_{SPB} .

Versatile Analog-to-Digital Converter (VADC)

Conversion Modes and Request Sources

Analog/Digital conversions can be requested by several request sources (2 group request sources and the background request source) and can be executed in several conversion modes. The request sources can be enabled concurrently with configurable priorities.

- **Fixed Channel Conversion (single or continuous)**

A specific channel source requests conversions of one selectable channel (once or repeatedly)

- **Auto Scan Conversion (single or continuous)**

A channel scan source (request source 1 or 2) requests auto scan conversions of a configurable linear sequence of all available channels (once or repeatedly)

- **Channel Sequence Conversion (single or continuous)**

A queued source (request source 0) requests a sequence of conversions of up to 8 arbitrarily selectable channels (once or repeatedly)

The conversion modes can be used concurrently by the available request sources, i.e. conversions in different modes can be enabled at the same time. Each source can be enabled separately and can be triggered by external events, such as edges of PWM or timer signals, or pin transitions.

Request Source Control

Because all request sources can be enabled at the same time, an arbiter resolves concurrent conversion requests from different sources. Each source can be triggered by external signals, by on-chip signals, or by software.

Requests with higher priority can either cancel a running lower-priority conversion (cancel-inject-repeat mode) or be converted immediately after the currently running conversion (wait-for-start mode). If the target result register has not been read, a conversion can be deferred (wait-for-read mode).

Certain channels can also be synchronized with other ADC kernels, so several signals can be converted in parallel.

Versatile Analog-to-Digital Converter (VADC)

Figure 29-3 Conversion Request Unit

Input Channel Selection

The analog input multiplexer selects one of the available analog inputs (CH0 - CHx¹) to be converted. Three sources can select a linear sequence, an arbitrary sequence, or a specific channel. The priorities of these sources can be configured.

Additional external analog multiplexers can be controlled automatically, if more separate input channels are required than are built in (see [Section 29.10](#)).

Note: Not all analog input channels are necessarily available in all packages, due to pin limitations. Refer to the implementation description in [Section 29.12](#).

Conversion Control

Conversion parameters, such as sample phase duration or result resolution can be configured for 4 input classes (2 group-specific classes, 2 global classes). Each channel can be individually assigned to one of these input classes.

Each channel can select either the standard reference voltage or the alternate reference voltage (restrictions see [“Product-Specific Configuration” on Page 29-147](#)).

¹ The availability of input channels depends on the package of the used product type. A summary can be found in [Section 29.12.3](#).

Versatile Analog-to-Digital Converter (VADC)

The input channels can, thus, be adjusted to the type of sensor (or other analog sources) connected to the ADC.

This unit also controls the built-in multiplexer and external analog multiplexers, if selected.

Analog/Digital Converter

The selected input channel is converted to a digital value by first sampling the voltage on the selected input and then generating the selected number of result bits.

For 12-bit conversions, post-calibration is executed after converting the channel.

For broken wire detection (see [Section 29.9.1](#)), the converter network can be preloaded before sampling the selected input channel.

Result Handling

The conversion results of each analog input channel can be directed to one of 16 group-specific result registers and one global result register to be stored there. A result register can be used by a group of channels or by a single channel.

The wait-for-read mode avoids data loss due to result overwrite by blocking a conversion until the previous result has been read.

Data reduction (e.g. for digital anti-aliasing filtering) can automatically add up to 4 conversion results before issuing a service request.

Alternatively, an FIR or IIR filter can be enabled that preprocesses the conversion results before sending them to the result register.

Also, result registers can be concatenated to build FIFO structures that store a number of conversion results without overwriting previous data. This increases the allowed CPU latency for retrieving conversion data from the ADC.

Service Request Generation

Several ADC events can issue service requests to CPU or DMA:

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Channel events** indicate the completion of a conversion for a certain channel. This can be combined with limit checking, so interrupts are generated only if the result is within a defined range of values.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of eight service request nodes. This allows grouping the requests according to the requirements of the application.

Versatile Analog-to-Digital Converter (VADC)

Safety Features

Safety-aware applications are supported with mechanisms that help to ensure the integrity of a signal path.

Broken-wire-detection (BWD) preloads the converter network with a selectable level before sampling the input channel. The result will then reflect the preload value if the input signal is no more connected. If buffer capacitors are used, a certain number of conversions may be required to reach the failure indication level.

Pull Down Diagnostics (PDD) connects an additional strong pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper connection of a signal source (sensor) to the multiplexer.

Multiplexer Diagnostics (MD) connects a weak pull-up or pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper operation of the multiplexer.

Converter Diagnostics (CD) connects an alternate signal to the converter. A subsequent conversion can then confirm the proper operation of the converter.

29.2 Electrical Models

Each conversion of an analog input voltage to a digital value consists of two consecutive phases:

- During the sample phase, the input voltage is sampled and stored.
The **Input Signal Path** is a simplified model for this.
- During the conversion phase the stored voltage is converted to a digital result.
The **Reference Voltage Path** is a simplified model for this.

Input Signal Path

The ADC of the TC26x B-Step uses a switched capacitor field represented by C_{AINSW} (small parasitic capacitances are present at each input pin). During the sample phase, the capacitor field C_{AINSW} is connected to the selected analog input CHx via the input multiplexer (modeled by ideal switches and series resistors R_{AIN}).

The switch to CHx is closed during the sample phase and connects the capacitor field to the input voltage V_{AINx} .

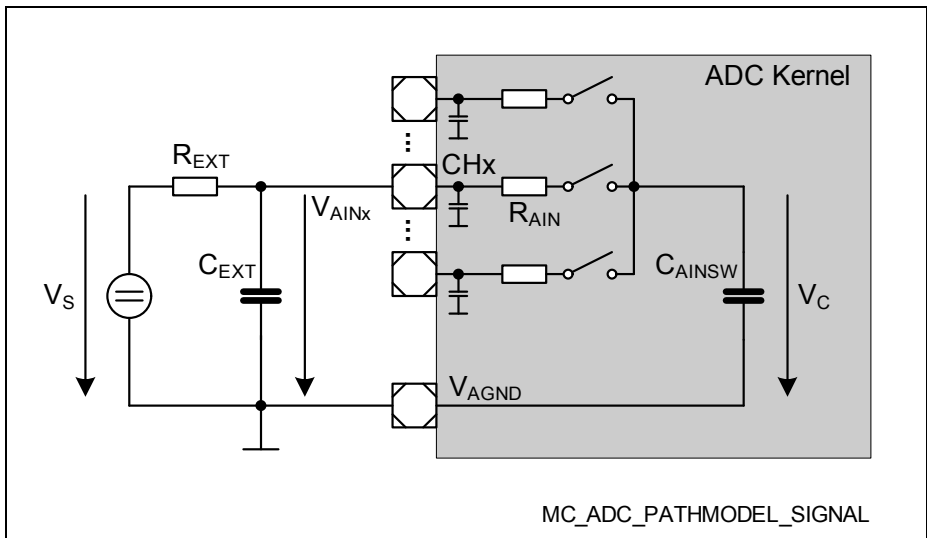

Figure 29-4 Signal Path Model

A simplified model for the analog input signal path is given in **Figure 29-4**. An analog voltage source (value V_S) with an internal impedance of R_{EXT} delivers the analog input that should be converted.

During the sample phase the corresponding switch is closed and the capacitor field C_{AINSW} is charged. Due to the low-pass behavior of the resulting RC combination, the

Versatile Analog-to-Digital Converter (VADC)

voltage V_C to be actually converted does not immediately follow V_S . The value R_{EXT} of the analog voltage source and the desired precision of the conversion strongly define the required length of the sample phase.

To reduce the influence of R_{EXT} and to filter input noise, it is recommended to introduce a fast external blocking capacitor C_{EXT} at the analog input pin of the ADC. Like this, mainly C_{EXT} delivers the charge during the sample phase. This structure allows a significantly shorter sample phase than without a blocking capacitor, because the low-pass time constant defining the sample time is mainly given by the values of R_{AIN} and C_{AINSW} .

The resulting low-pass filter of R_{EXT} (usually a parameter of the signal source) and C_{EXT} should be dimensioned according to the application's requirements:

- For quickly changing dynamic signals, a smaller capacitor allows V_{AINx} to follow V_S between two sample phases of the same analog input channel.
- For high-precision conversions, an external blocking capacitor C_{EXT} in the range of at least $2^n \times C_{AINSW}$ keeps the voltage change of V_{AINx} during the sample phase below 1 LSB_n. This voltage change is due to the charge redistribution between C_{EXT} and C_{AINSW} .

Leakage current through the analog input structure of the ADC can generate a voltage drop over R_{EXT} , introducing an error. The ADC input leakage current increases at high temperature and if the input voltage level is close to the analog supply ground V_{SS} or to the analog power supply V_{DDPA} . The input leakage current of an ADC channel can be reduced by avoiding input voltages close to the supplies.

An overload condition (input voltage exceeds the supply range) at adjacent analog inputs injects an additional leakage current (defined by a coupling factor).

The capacitor C_{AINSW} is automatically precharged to a voltage of approximately half the standard reference voltage V_{AREF} while the converter is idle. Due to varying parameters and parasitic effects, the precharge voltage of C_{AINSW} is typically smaller than $V_{AREF} / 2$.

Note: When conversions are executed in a sequence, or when a conversion cancels a running conversion, the sample phase starts immediately.

The converter does not become idle in this case and C_{AINSW} is not precharged!

Versatile Analog-to-Digital Converter (VADC)

Reference Voltage Path

During the conversion phase, parts of the capacitor field (represented by C_{AREFSW}) are switched to a reference input (V_{AREF} or CH0) or to V_{AGND} . Using CH0 as alternate reference source allows conversions of 5.0 V and 3.3 V based analog input signals with the same ADC kernel.

Stable and noise-free reference and analog supply voltages support accurate conversion results. Because noise can also be introduced from other modules (e.g. switching pins), it is strongly recommended to carefully decouple analog from digital signal domains.

The switching of parts of C_{AREFSW} requires a dynamic current at the selected reference input. The impedance R_{REFEXT} of the reference voltage source V_R has to be low enough to supply the reference current during the conversion phase. An external blocking capacitor C_{REFEXT} can supply the peak currents and minimize the current to be delivered by the reference source.

The reference current I_{AREF} introduces a voltage drop at R_{REFEXT} that should not be neglected for the calculation of the overall accuracy. The average reference current during a conversion depends on the reference voltage level and the time t_{ADC} between two conversion starts: $I_{AREF} = C_{AREFSW} \times V_{AREF} / t_{ADC}$.

The reference current can be reduced by preloading the capacitor field from the supply voltage V_{DDM} . This feature is enabled by setting bit REFPC in register GLOB_CFG. In this case the reference voltage and the supply voltage must be on the same level. The capacitor field is first preloaded from V_{DDM} in a first phase and then adjusted to V_{AREF} in a second phase.

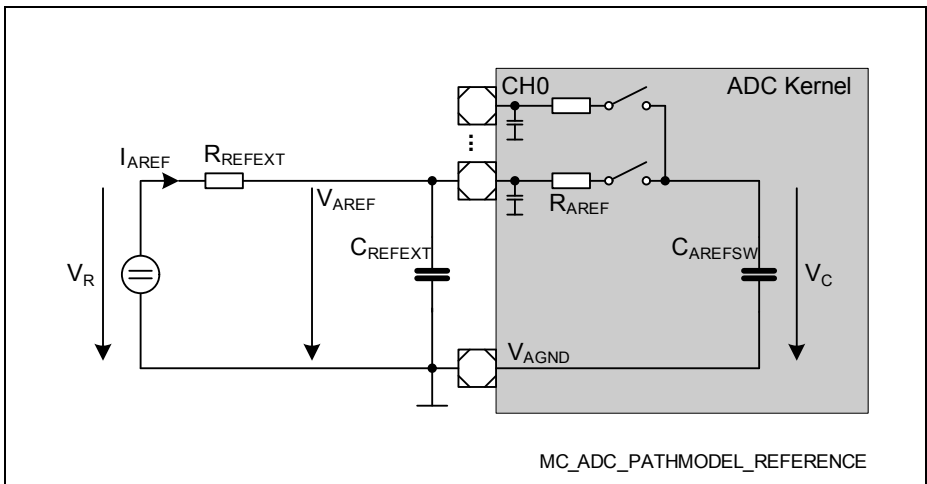

Figure 29-5 Reference Path Model

Versatile Analog-to-Digital Converter (VADC)

Reference Signal Connection

The reference voltages (V_{AREF} , V_{AGND}) have a strong influence on the digital result of a conversion. It is, therefore, recommended to carefully avoid noise of these inputs. The recommended filter structures (see figure) help to cancel high-frequency noise.

- Capacitors (C_{REFEXT}) between corresponding reference pins (V_{AREF} , V_{AGND}) provide peak currents for the conversion steps¹⁾
- Capacitors (C_N) between reference ground and signal ground (V_{AGND} , V_{SS}) and the inductance of the connections attenuate noise
- Use low-ESR capacitors connected closely to the pins
- Connect reference pins via separate lines to star points close to the sensor supply
- Additional resistors in the reference lines (R_F) must be able to carry the average reference current, to avoid inaccuracy due to voltage drop
- The reference ground lines are connected to the signal ground in many applications

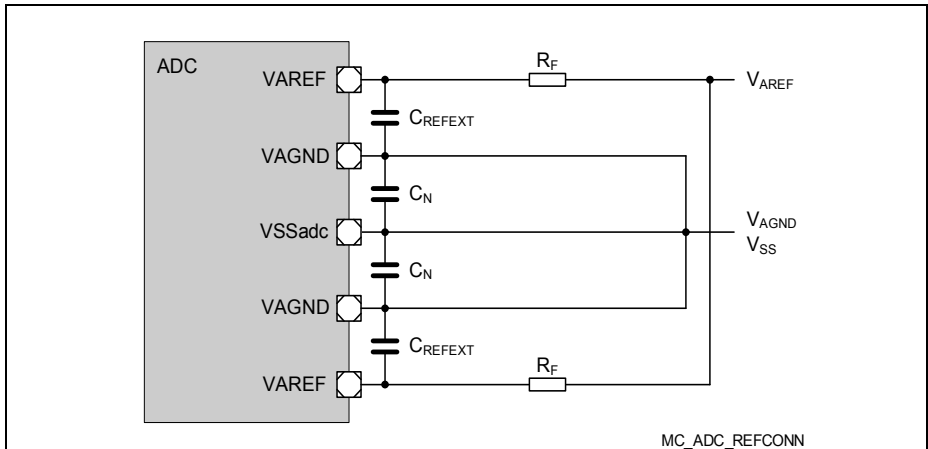

Figure 29-6 Connection of Reference Signals

Due to the charge redistribution between C_{REFEXT} and C_{AREFSW} , the voltage V_{AREF} decreases during the conversion phase. The error introduced by this effect is limited by the external blocking capacitor. $C_{REFEXT} \geq 2^n \times C_{AREFSW}$ limits this error to $1/2 \text{ LSB}_n$ (double C_{REFEXT} to limit the error to $1/4 \text{ LSB}_n$).

Assuming 12-bit conversions and $C_{AREFSW} = 30 \text{ pF}$ leads to:

$C_{REFEXT} > 2^{12} \times 30 \text{ pF} = 123 \text{ nF}$, 100 nF are a good approximation.

The noise filtering capacitor C_N depends on the board properties (e.g. 100 nF).

1) The required capacitor value here depends on the resolution and accuracy.

Versatile Analog-to-Digital Converter (VADC)

Transfer Characteristics and Error Definitions

The transfer characteristic of the ADC describes the association of analog input voltages to the 2^n discrete digital result values (n bits resolution). Each digital result value (in the range of 0 to 2^n-1) represents an input voltage range defined by the reference voltage range divided by 2^n . This range (called quantization step or code width) represents the granularity (called LSB_n) of the ADC. The discrete character of the digital result generates a system-inherent quantization uncertainty of $\pm 0.5 LSB_n$ for each conversion result.

The ideal transfer curve has the first digital transition (between 0 and 1) when the analog input reaches $0.5 LSB_n$. The quantization steps are equally distributed over the input voltage range.

Analog input voltages below or above the reference voltage limits lead to a saturation of the digital result at 0 or 2^n-1 .

The real transfer curve can exhibit certain deviations from the ideal transfer curve:

- The **offset error** is the deviation of the real transfer line from the ideal transfer line at the lowest code. This refers to best-fit lines through all possible codes, for both cases.
- The **gain error** is the deviation of the slope of the real transfer line from the slope of the ideal transfer line. This refers to best-fit lines through all possible codes, for both cases.
- The **differential non-linearity error (DNL)** is the deviation of the real code width (variation of the analog input voltage between two adjacent digital conversion results) from the ideal code width.
- The **integral non-linearity error (INL)** is the deviation of the real transfer curve from an adjusted ideal transfer curve (same offset and gain error as the real curve, but equal code widths).
- The **total unadjusted error (TUE)** describes the maximum deviation between a real conversion result and the ideal transfer characteristics over a given measurement range. Since some of these errors noted above can compensate each other, the TUE value generally is much less than the sum of the individual errors.
The TUE also covers production process variations and internal noise effects (if switching noise is generated by the system, this generally leads to an increased TUE value).

Versatile Analog-to-Digital Converter (VADC)

29.3 Configuration of General Functions

While many parameters can be selected individually for each channel, source, or group, some adjustments are valid for the whole ADC cluster.

29.3.1 Module Identification

The module identification register indicates the version of the ADC module that is used in the TC26x B-Step.

ID

Module Identification Register (0008_H) Reset Value: 00C5 C0XX_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	[15:8]	r	Module Type This internal marker is fixed to C0 _H .
MOD_NUMBER	[31:16]	r	Module Number Indicates the module identification number (00C5 _H = SARADC).

Versatile Analog-to-Digital Converter (VADC)

29.3.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleep mode signal.

CLC
Clock Control Register

 (0000_H)

 Reset Value: 0000 0003_H

Versatile Analog-to-Digital Converter (VADC)

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging) and includes the module-related control bits for the OCDS Trigger Bus (OTGB).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

Individual Module Reset

The Kernel Reset Registers **KRST0/KRST1** are used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. The RST bits will be cleared by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Registers 0 and 1 each include bit RST. To trigger a module reset, both RST bits must be set. They will be cleared automatically with the end of the BPI kernel reset sequence.

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Versatile Analog-to-Digital Converter (VADC)

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

29.3.3 General Clocking Scheme and Control

The A/D Converters of the TC26x B-Step are supplied with a global clock signal from the system f_{VADC} . Two clock signals are derived from this input and are distributed to all converters. The global configuration register defines common clock bases for all converters of the cluster. This ensures deterministic behavior of converters that shall operate in parallel.

The analog converter clock f_{ADCI} determines the performance of the converters and must be selected to comply with the specification given in the Data Sheet.

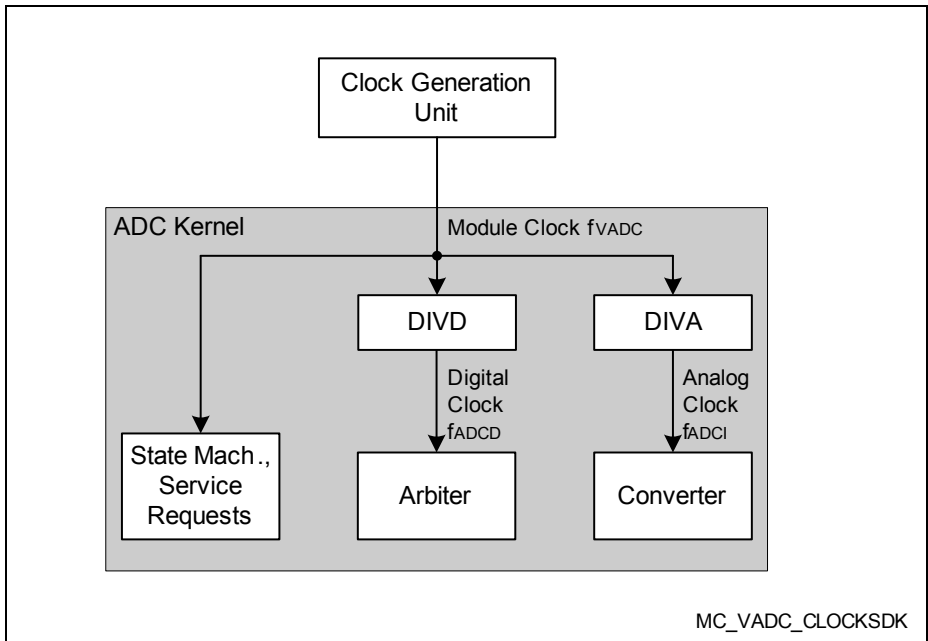

Figure 29-7 Clock Signal Summary

29.3.4 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the VADC.

- The registers of the VADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Registers ACCPROT0/1 allow the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. **Table 29-3** lists the registers that belong to each register group.
Registers ACCPROT0/1 themselves are protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

Valid for TC26/TC24: 4 groups

 Versatile Analog-to-Digital Converter (VADC)

29.4 Analog Module Activation and Control

The analog converter of the ADC is the functional block that generates the digital result values from the selected input voltage. It draws a permanent current during its operation and can be deactivated between conversions to reduce the consumed overall energy.

Note: After reset the analog converters are off. They must be enabled before triggering any action involving a converter.

The accuracy of the conversions is improved by calibrating the analog converter to compensate process, temperature, and voltage variations.

29.4.1 Analog Converter Control

The operating mode is determined by bitfield **GxARBCFG (x = 0 - 3).ANONS**:

- ANONS = 11_B: **Normal Operation**
The converter is active, conversions are started immediately.
Requires no wakeup time.
- ANONS = 10_B or 01_B: **Reserved**
- ANONS = 00_B: **Converter switched Off** (default after reset)
The converter is switched off. Furthermore, digital logic blocks are set to their initial state. If the arbiter is currently running, it completes the actual arbitration round and then stops.
Before starting a conversion, select the active mode for ANONS.
Requires the wakeup time (see below).

Note: Since switching off the analog part requires a wake-up phase, the optimum configuration depends on the actual application.

Entering Power Save Modes

To ensure proper operation of the converter, disable it (ANONS = 00_B) before putting the system into a power save mode. This makes sure that no conversion is disrupted by system activities.

Wakeup Time from Analog Powerdown

When the converter is activated, it needs a certain wakeup time to settle before a conversion can be properly executed. This wakeup time can be established by waiting the required period before starting a conversion, or by adding it to the intended sample time.

The wakeup time is approximately 15 μ s.
Exact numbers can be found in the respective Data Sheets.

Note: The wakeup time is also required after initially enabling the converter.

Versatile Analog-to-Digital Converter (VADC)

29.4.2 Alternate Reference Selection

The VADC control features allow selecting an alternate reference for each channel. This reference signal is taken from channel 0 of a group.

29.4.3 Calibration

Calibration automatically compensates deviations caused by process, temperature, and voltage variations. This ensures precise results throughout the operation time.

An initial start-up calibration is required once after a reset for all converters. All converters must be enabled ($ANONS = 11_B$). The start-up calibration is initiated globally by setting bit SUCAL in register GLOBCFG. By setting bit SUCAL in register CALCTR the start-up calibration can be initiated for the corresponding cluster converter. Conversions may be started after the initial calibration sequence. This is indicated by bit $CALS = 1_B$ AND bit $CAL = 0_B$.

The start-up calibration phase takes 4 352 cycles ($4\ 352 \times 10\text{ ns} = 43.5\ \mu\text{s}$).

After that, calibration cycles will compensate the effects of drifting parameters. The calibration cycles can be executed before or after (user configuration) a conversion sequence or can be disabled.

Note: The ADC error depends on the temperature. Therefore, the calibration must be repeated periodically.

29.5 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests. Three request sources (2 group-specific sources and the background source) can generate requests for the conversion of an analog channel. The arbiter resolves concurrent requests and selects the channel to be converted next.

Upon a trigger event, the request source requests the conversion of a certain analog input channel or a sequence of channels.

- **Software triggers**
directly activate the respective request source.
- **External triggers**
synchronize the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal or from a port pin.

Application software selects the trigger type and source, the channel(s) to be converted, and the request source priority. A request source can also be activated directly by software without requiring an external trigger.

The arbiter regularly scans the request sources for pending conversion requests and selects the conversion request with the highest priority. This conversion request is then forwarded to the converter to start the sampling and conversion of the requested channel.

Each request source can operate in single-shot or in continuous mode:

- **In single-shot mode,**
the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode,**
the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

For each request source of a group, external triggers are generated from one of 15 selectable trigger inputs (REQTRx[O:A]) and from one of 16 selectable gating inputs (REQGTx[P:A])¹⁾. The available trigger signals for the TC26x B-Step are listed in [Section 29.12.4](#).

Note: [Figure 29-3 “Conversion Request Unit” on Page 29-6](#) summarizes the request sources.

¹⁾ The selected gating input can be used as a trigger signal (REQTRxP).

Versatile Analog-to-Digital Converter (VADC)

Two types of request sources are available:

- **A queued source** can issue conversion requests for an arbitrary sequence of input channels. The channel numbers for this sequence can be freely programmed¹⁾. This supports application-specific conversion sequences that cannot be covered by a channel scan source. Also, multiple conversions of the same channel within a sequence are supported.

A queued source converts a series of input channels permanently or on a regular time base. For example, if programmed with medium priority, some input channels can be converted upon a specified event (e.g. synchronized to a PWM). Conversions of lower priority sources are suspended in the meantime.

Request source 0 is a group-specific 8-stage queued source.

- **A channel scan source** can issue conversion requests for a coherent sequence of input channels. This sequence begins with the highest enabled channel number and continues towards lower channel numbers. All available channels¹⁾ can be enabled for the scan sequence. Each channel is converted once per sequence.

A scan source converts a series of input channels permanently or on a regular time base. For example, if programmed with low priority, some input channels can be scanned in a background task to update information that is not time-critical.

- Request source 1 is a group-specific channel scan source.
- Request source 2 is a global channel scan source (background source).

The background source can request conversions of all channels of all groups.

1) The availability of input channels depends on the package of the used product type. A summary can be found in [Section 29.12.3](#).

The background source can only request non-priority channels, i.e. channels that are not selected in registers GxCHASS. Priority channels are reserved for the group-specific request sources 0 and 1.

29.5.1 Queued Request Source Handling

A queued request source supports short conversion sequences (up to 8) of arbitrary channels (contrary to a scan request source with a fixed conversion order for the enabled channels). The programmed sequence is stored in a queue buffer (based on a FIFO mechanism). The requested channel numbers are entered via the queue input, while queue stage 0 defines the channel to be converted next.

A conversion request is only issued to the request source arbiter if a valid entry is stored in queue stage 0.

If the arbiter aborts a conversion triggered by a queued request source due to higher priority requests, the corresponding conversion parameters are automatically saved in the backup stage. This ensures that an aborted conversion is not lost but takes part in the next arbitration round (before stage 0).

The trigger and gating unit generates trigger events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Trigger events start a queued sequence and can be generated either via software or via the selected hardware triggers. The occurrence of a trigger event is indicated by bit QSRx.EV. This flag is cleared when the corresponding conversion is started or by writing to bit QMRx.CEV.

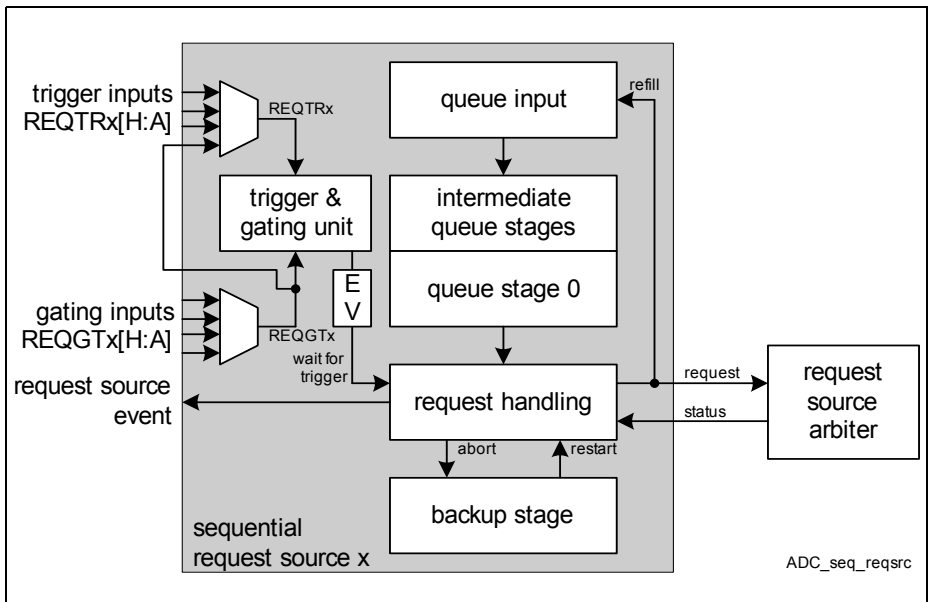

Figure 29-8 Queued Request Source

Versatile Analog-to-Digital Converter (VADC)

A sequence is defined by entering conversion requests into the queue input register (**GxQINR0 (x = 0 - 3)**). Each entry selects the channel to be converted and can enable an external trigger, generation of an interrupt, and an automatic refill (i.e. copy this entry to the top of the queue after conversion). The entries are stored in the queue buffer stages.

The content of stage 0 (**GxQ0R0 (x = 0 - 3)**) selects the channel to be converted next. When the requested conversion is started, the contents of this queue stage is invalidated and copied to the backup stage. Then the next queue entry can be handled (if available).

Note: The contents of the queue stages cannot be modified directly, but only by writing to the queue input or by flushing the queue.

*The current status of the queue is shown in register **GxQSR0 (x = 0 - 3)**.*

If all queue entries have automatic refill selected, the defined conversion sequence can be repeated without re-programming.

Properties of the Queued Request Source

Queued request source 0 provides 8 buffer stages and can handle sequences of up to 8 input channel entries. It supports short application-specific conversion sequences, especially for timing-critical sequences containing also multiple conversions of the same channel.

Queued Source Operation

Configure the queued request source by executing the following actions:

- Define the sequence by writing the entries to the queue input **GxQINR0 (x = 0 - 3)**. Initialize the complete sequence before enabling the request source, because with enabled refill feature, software writes to QINR0 are not allowed.
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper transitions by programming **GxQCTRL0 (x = 0 - 3)**. Enable the trigger and select the gating mode by programming bitfield ENGT in register **GxQMR0 (x = 0 - 3)**.¹⁾
- Enable the corresponding arbitration slot (0) to accept conversion requests from the queued source (see register **GxARBPR (x = 0 - 3)**).

Start a queued sequence by generating a trigger event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software trigger event by setting **GxQMR0.TREV = 1**.

1) If PDOOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid un expected signal transitions.

Versatile Analog-to-Digital Converter (VADC)

- Write a new entry to the queue input of an empty queue. This leads to a (new) valid queue entry that is forwarded to queue stage 0 and starts a conversion request (if enabled by GxQMR0.ENG and without waiting for an external trigger).

Note: If the refill mechanism is activated, a processed entry is automatically reloaded into the queue. This permanently repeats the respective sequence (autoscan). In this case, do not write to the queue input while the queued source is running. Write operations to a completely filled queue are ignored.

Stop or abort an ongoing queued sequence by executing one of the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the queue entries, but only prevents issuing conversion requests to the arbiter.
- Disable the corresponding arbitration slot (0) in the arbiter. This does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the queued source by clearing bitfield ENG = 00_B.
 - Invalidate the next pending queue entry by setting bit GxQMR0.CLRV = 1. If the backup stage contains a valid entry, this one is invalidated, otherwise stage 0 is invalidated.
 - Remove all entries from the queue by setting bit GxQMR0.FLUSH = 1.

Queue Request Source Events and Service Requests

A request source event of a queued source occurs when a conversion is finished. A source event service request can be generated based on a request source event according to the structure shown in [Figure 29-9](#). If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.

The interrupt enable bit is taken from stage 0 for a normal sequential conversion, or from the backup stage for a repeated conversion after an abort.

The service request output line SR_x that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by GxQ0R0.ENS, or GxQBUR0.ENS respectively) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

29.5.2 Channel Scan Request Source Handling

The VADC provides two types of channel scan sources:

- Source 1: Group scan source
This scan source can request all channels of the corresponding group.
- Source 2: Background scan source
This scan source can request all channels of all groups.
Priority channels selected in registers **GxCHASS (x = 0 - 3)** cannot take part in background conversion sequences.

Both sources operate in the same way and provide the same register interface. The background source provides more request/pending bits because it can request all channels of all groups.

Each analog input channel can be included in or excluded from the scan sequence by setting or clearing the corresponding channel select bit in register **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)**. The programmed register value remains unchanged by an ongoing scan sequence. The scan sequence starts with the highest enabled channel number and continues towards lower channel numbers.

Upon a load event, the request pattern is transferred to the pending bits in register **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)**. The pending conversion requests indicate which input channels are to be converted in an ongoing scan sequence. Each conversion start that was triggered by the scan request source, automatically clears the corresponding pending bit. If the last conversion triggered by the scan source is finished and all pending bits are cleared, the current scan sequence is considered finished and a request source event is generated.

A conversion request is only issued to the request source arbiter if at least one pending bit is set.

If the arbiter aborts a conversion triggered by the scan request source due to higher priority requests, the corresponding pending bit is automatically set. This ensures that an aborted conversion is not lost but takes part in the next arbitration round.

The trigger and gating unit generates load events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Load events start a scan sequence and can be generated either via software or via the selected hardware triggers. The request source event can also generate an automatic load event, so the programmed sequence is automatically repeated.

Versatile Analog-to-Digital Converter (VADC)

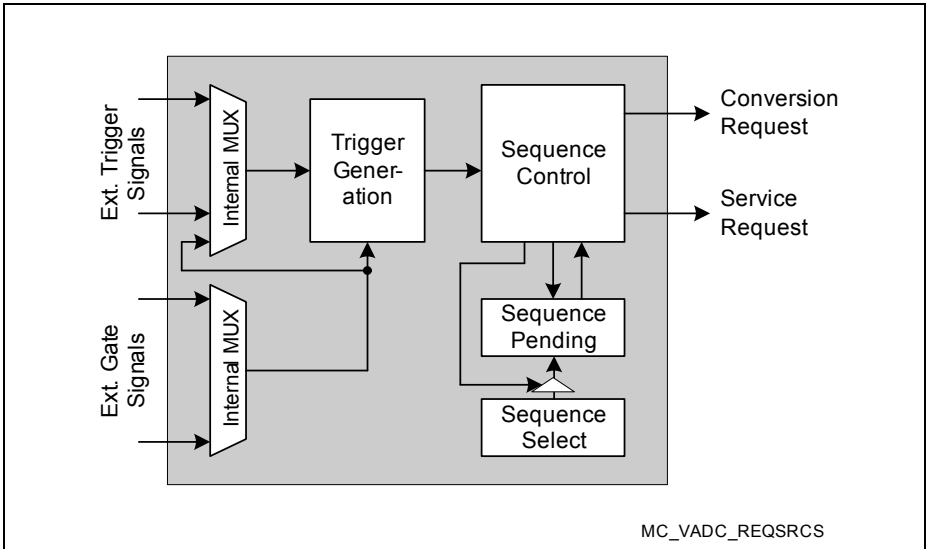

Figure 29-10 Scan Request Source

Versatile Analog-to-Digital Converter (VADC)
Scan Source Operation

Configure the scan request source by executing the following actions:

- Select the input channels for the sequence by programming **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)**
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper signal transitions by programming **GxASCTRL (x = 0 - 3)** or **BRCTRL**. Enable the trigger and select the gating mode by programming **GxASMR (x = 0 - 3)** or **BRSMR**.¹⁾
- Define the load event operation (handling of pending bits, autoscan mode) by programming **GxASMR (x = 0 - 3)** or **BRSMR**.
 A load event with bit LDM = 0 copies the content of **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (overwrite mode). This starts a new scan sequence and aborts any pending conversions from a previous scan sequence.
 A load event with bit LDM = 1 OR-combines the content of **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (combine mode). This starts a scan sequence that includes pending conversions from a previous scan sequence.
- Enable the corresponding arbitration slot (1) to accept conversion requests from the channel scan source (see register **GxARBPR (x = 0 - 3)**).

Start a channel scan sequence by generating a load event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software load event by setting LDEV = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).
- Generate a load event by writing the scan pattern directly to the pending bits in **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)**. The pattern is copied to **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** and a load event is generated automatically.
 In this case, a scan sequence can be defined and started with a single data write action, e.g. under PEC control (provided that the pattern fits into one register).

Note: If autoscan is enabled, a load event is generated automatically each time a request source event occurs when the scan sequence has finished. This permanently repeats the defined scan sequence (autoscan).

Stop or abort an ongoing scan sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the conversion pending bits, but only prevents issuing conversion requests to the arbiter.

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid un expected signal transitions.

Versatile Analog-to-Digital Converter (VADC)

- Disable the corresponding arbitration slot (1 or 2) in the arbiter. This does not modify the contents of the conversion pending bits, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the channel scan source by clearing bitfield ENGT = 00_B. Clear the pending request bits by setting bit CLRPND = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).

Scan Request Source Events and Service Requests

A request source event of a scan source occurs if the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect.

The service request output SR_x that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by ENSI) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.¹⁾

1) Refer to **“Service Request Generation”** on Page 29-133.

Versatile Analog-to-Digital Converter (VADC)
Registers of Group Scan Source

There is a separate register set for each group scan source. These sources can be operated independently.

The control register of the autoscan source selects the external gate and/or trigger signals.

Write control bits allow separate control of each function with a simple write access.

The Channel Select Registers select the channels to be converted by the background request source (channel scan source). Its bits are used to update the pending registers, when a load event occurs.

The number of valid channel bits depends on the channels available in the respective product type (refer to **“Product-Specific Configuration” on Page 29-147**).

*Note: Priority channels selected in registers **GxCHASS (x = 0 - 3)** will not be converted.*

BRSELx (x = 0 - 3)

Background Request Source Channel Select Register, Group x

(0180_H + x * 0004_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHSELGy	[31:0]	rwh	<p>Channel Selection Group x Each bit (when set) enables the corresponding input channel of the respective group to take part in the background scan sequence.</p> <p>0_B Ignore this channel 1_B This channel is part of the scan sequence</p>

Versatile Analog-to-Digital Converter (VADC)

The Channel Pending Registers indicate the channels to be converted in the current conversion sequence. They are updated from the select registers, when a load event occurs.

BRSPNDx (x = 0 - 3)

Background Request Source Pending Register, Group x

(01C0_H + x * 0004_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHPNDGy	[31:0]	rwh	Channels Pending Group x Each bit (when set) request the conversion of the corresponding input channel of the respective group. 0 _B Ignore this channel 1 _B Request conversion of this channel

Note: Writing to any of registers BRSPNDx automatically updates the corresponding register BRSELx and generates a load event that copies all bits from all registers BRSELx to BRSPNDx.

Use this shortcut only when writing the last word of the request pattern.

Versatile Analog-to-Digital Converter (VADC)

29.5.3 Request Source Arbitration

The request source arbiter regularly polls the request sources, one after the other, for pending conversion requests. Each request source is assigned to a certain time slot within an arbitration round, called arbitration slot. The duration of an arbitration slot is user-configurable via register GLOB_CFG, see [Global Configuration](#).

The priority of each request source is user-configurable via register GxARBPR (x = 0 - 3), so the arbiter can select the next channel to be converted, in the case of concurrent requests from multiple sources, according to the application requirements.

An unused arbitration slot is considered empty and does not take part in the arbitration. After reset, all slots are disabled and must be enabled (register GxARBPR (x = 0 - 3)) to take part in the arbitration process.

Figure 29-11 summarizes the arbitration sequence. An arbitration round consists of one arbitration slot for each available request source. The synchronization source is always evaluated in the last slot and has a higher priority than all other sources. At the end of each arbitration round, the arbiter has determined the highest priority conversion request.

If a conversion is started in an arbitration round, this arbitration round does not deliver an arbitration winner. In the TC26x B-Step, the following request sources are available:

- Arbitration slot 0: **Group Queued source**, 8-stage sequences in arbitrary order
- Arbitration slot 1: **Group Scan source**, sequences in defined order within group
- Arbitration slot 2: **Background Scan source**, sequences in defined order, all groups
- Last arbitration slot: **Synchronization source**, synchronized conversion requests from another ADC kernel (always handled with the highest priority in a synchronization slave kernel).

Figure 29-11 Arbitration Round with 4 Arbitration Slots

 Versatile Analog-to-Digital Converter (VADC)

29.5.3.1 Arbiter Operation and Configuration

The timing of the arbiter (i.e. of an arbitration round) is determined by the number of arbitration slots within an arbitration round and by the duration of an arbitration slot.

An arbitration round consist of 4...20 arbitration slots (defined by bitfield **GxARBCFG (x = 0 - 3).ARBRND**). 4 slots are sufficient for the TC26x B-Step, more can be programmed to obtain the same arbiter timing for different products.

The duration of an arbitration slot is configurable $t_{\text{Slot}} = (\text{DIVD}+1) / f_{\text{VADC}}$.

The duration of an arbitration round, therefore, is $t_{\text{ARB}} = 4 \times t_{\text{Slot}}$.

The period of the arbitration round introduces a timing granularity to detect an incoming conversion request signal and the earliest point to start the related conversion. This granularity can introduce a jitter of maximum one arbitration round. The jitter can be reduced by minimizing the period of an arbitration round.

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, mainly the following two options exist. For both options, the converter has to be idle and other conversion requests must not be pending for at least one arbiter round before the trigger event occurs:

- If bit **GxARBCFG (x = 0 - 3).ARBM = 0**, the **arbiter runs permanently**. In this mode, synchronized conversions of more than one ADC kernel are possible.¹⁾
The trigger for a conversion request has to be generated synchronously to the arbiter timing. Incoming triggers should have exactly n-times the granularity of the arbiter ($n = 1, 2, 3, \dots$). In order to allow some flexibility, the duration of an arbitration slot can be programmed in cycles of f_{VADC} .
- If bit **GxARBCFG (x = 0 - 3).ARBM = 1**, the **arbiter stops after an arbitration round** when no conversion request have been found pending any more. The arbiter is started again if at least one enabled request source indicates a pending conversion request. The trigger for a conversion request does not need to be synchronous to the arbiter timing.

In this mode, parallel conversions are not possible for synchronization slave kernels.

Each request source has a configurable priority, so the arbiter can resolve concurrent conversion requests from different sources. The request with the highest priority is selected for conversion. These priorities can be adapted to the requirements of a given application (see register **GxARBPR (x = 0 - 3)**).

The **Conversion Start Mode** determines the handling of the conversion request that has won the arbitration.

1) For more information, refer to **"Synchronization of Conversions" on Page 29-117**.

Versatile Analog-to-Digital Converter (VADC)

The Arbitration Configuration Register selects the timing and the behavior of the arbiter.

Versatile Analog-to-Digital Converter (VADC)

Field	Bits	Type	Description
ARBM	7	rw	Arbitration Mode 0_B The arbiter runs permanently. This setting is required for a synchronization slave (see Section 29.8.1) and for equidistant sampling using the signal ARBCNT (see Section 29.8.2). 1_B The arbiter only runs if at least one conversion request of an enabled request source is pending. This setting ensures a reproducible latency from an incoming request to the conversion start, if the converter is idle. Synchronized conversions are not supported.
0	[15:8]	r	Reserved, write 0, read as 0
ANONS	[17:16]	rh	Analog Converter Control Status Defined by bitfield ANONC in a stand-alone kernel or a kernel in master mode. In slave mode, this bitfield is defined by bitfield ANONC of the respective master kernel. See also Section 29.4.1 . 00_B Analog converter off 01_B Reserved 10_B Reserved 11_B Normal operation (permanently on)
CSRC	[19:18]	rh	Currently Converted Request Source Indicates the arbitration slot number of the current (BUSY = 1) or of the last (BUSY = 0) conversion. This bitfield is updated when a conversion is started. 00_B Current/last conversion for request source 0 01_B Current/last conversion for request source 1 10_B Current/last conversion for background source 11_B Current/last conversion for synchronization request (slave converter)
CHNR	[24:20]	rh	Channel Number Indicates the current or last converted analog input channel. This bitfield is updated when a conversion is started.

Versatile Analog-to-Digital Converter (VADC)

Field	Bits	Type	Description
SYNRUN	25	rh	Synchronous Conversion Running Indicates that a synchronized (= parallel) conversion is currently running. 0_B Normal conversion or no conversion running 1_B A synchronized conversion is running (cannot be cancelled by higher priority requests!)
0	[27:26]	r	Reserved, write 0, read as 0
CAL	28	rh	Start-Up Calibration Active Indication Indicates the start-up calibration phase of the corresponding analog converter. 0_B Completed or not yet started 1_B Start-up calibration phase is active (set one clock cycle after setting bit SUCAL) <i>Note: Start conversions only after the start-up calibration phase is complete.²⁾</i>
CALS	29	rh	Start-Up Calibration Started Indicates that the start-up calibration has begun. 0_B Requested but not yet started 1_B Start-up calibration has begun <i>Note: Bit CALS is cleared when setting bit SUCAL and is set together with bit CAL.</i>
BUSY	30	rh	Converter Busy Flag 0_B Not busy 1_B Converter is busy with a conversion
SAMPLE	31	rh	Sample Phase Flag 0_B Converting or idle 1_B Input signal is currently sampled

- 1) The default setting of 4 arbitration slots is sufficient for correct arbitration. The duration of an arbitration round can be increased if required to synchronize requests.
- 2) The completion of the start-up calibration is indicated by CAL = 0 AND CALS = 1.
 CAL = CALS = 0 indicates that the start-up calibration was requested but has not yet begun.
 CAL = CALS = 1 indicates an ongoing calibration phase.

The Arbitration Priority Register defines the request source priority and the conversion start mode for each request source.

Note: Only change priority and conversion start mode settings of a request source while this request source is disabled, and a currently running conversion requested by this source is finished.

 Versatile Analog-to-Digital Converter (VADC)

29.5.3.2 Conversion Start Mode

When the arbiter has selected the request to be converted next, the handling of this channel depends on the current activity of the converter:

- Converter is currently idle: the conversion of the arbitration winner is started immediately.
- Current conversion has same or higher priority: the current conversion is completed, the conversion of the arbitration winner is started after that.
- Current conversion has lower priority: the action is user-configurable:

- **Wait-for-start mode:** the current conversion is completed, the conversion of the arbitration winner is started after that. This mode provides maximum throughput, but can produce a jitter for the higher priority conversion.

Example in [Figure 29-12](#):

Conversion A is requested (t_1) and started (t_2). Conversion B is then requested (t_3), but started only after completion of conversion A (t_4).

- **Cancel-inject-repeat mode:** the current conversion is aborted, the conversion of the arbitration winner is started after the abortion ($3 f_{VADC}$ cycles).

The aborted conversion request is restored in the corresponding request source and takes part again in the next arbitration round. This mode provides minimum jitter for the higher priority conversions, but reduces the overall throughput.

Example in [Figure 29-12](#):

Conversion A is requested (t_6) and started (t_7). Conversion B is then requested (t_8) and started (t_9), while conversion A is aborted but requested again. When conversion B is complete (t_{10}), conversion A is restarted.

Exception: If both requests target the same result register with wait-for-read mode active (see [Section 29.7.3](#)), the current conversion cannot be aborted.

Note: A cancelled conversion can be repeated automatically in each case, or it can be discarded if it was cancelled. This is selected for each source by bit RPTDIS in the corresponding source's mode register.

Versatile Analog-to-Digital Converter (VADC)

Figure 29-12 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in register **GxARBPR (x = 0 - 3)** and is applied to all channels requested by the source. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

 Versatile Analog-to-Digital Converter (VADC)

29.6 Analog Input Channel Configuration

For each analog input channel a number of parameters can be configured that control the conversion of this channel. The channel control registers define the following parameters:

- **Channel Parameters:** The sample time for this channel and the data width of the result are defined via input classes. Each channel can select one of two classes of its own group or one of two global classes.
- **Reference selection:** an alternate reference voltage can be selected for most channels (exceptions are marked in [Section 29.12.3](#))
- **Result target:** The conversion result values are stored either in a group-specific result register or in the global result register. The group-specific result registers are selected in several ways:
 - channel-specific, selected by bitfield RESREG in register **G0CHCTRY** ($y = 0 - 15$) etc., with bitfield SRCRESREG = 0000_B
 - source-specific, selected by bitfield SRCRESREG in register **GxQCTRL0** ($x = 0 - 3$), **GxASCTRL** ($x = 0 - 3$) or **BRCTRL** with bitfield SRCRESREG $\neq 0000_B$
- **Result position:** The result values can be stored left-aligned or right-aligned. The exact position depends also on the configured result width and on the data accumulation mode.
See also [Figure 29-19 “Result Storage Options” on Page 29-106](#).
- **Compare with Standard Conversions (Limit Checking):** Channel events can be generated whenever a new result value becomes available. Channel event generation can be restricted to values that lie inside or outside a user-configurable band.
In Fast Compare Mode, channel events can be generated depending on the transitions of the (1-bit) result.
- **Broken Wire Detection:** This safety feature can detect a missing connection to an analog signal source (sensor).
- **Synchronization of Conversions:** Synchronized conversions are executed at the same time on several converters.

The **Alias Feature** redirects conversion requests for channels CH0 and/or CH1 to other channels.

29.6.1 Channel Parameters

Each analog input channel is configured by its associated channel control register.

Note: For the safety feature “Broken Wire Detection”, refer to [Section 29.9.1](#).

The following features can be defined for each channel:

- The conversion class defines the result width and the sample time
- Generation of channel events and the result value band, if used
- Target of the result defining the target register and the position within the register

Versatile Analog-to-Digital Converter (VADC)

29.6.2 Alias Feature

The Alias Feature redirects conversion requests for channels CH0 and/or CH1 to other channel numbers. This feature can be used to trigger conversions of the same input channel by independent events and to store the conversion results in different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU/DMA service request latency.
- The sensor signal is connected to only one analog input (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see [Figure 29-13](#)), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, service requests, etc.).

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. [Figure 29-13](#) shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion results can be stored and read out from the result registers RESx (conversion triggered for CHx) and RESy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

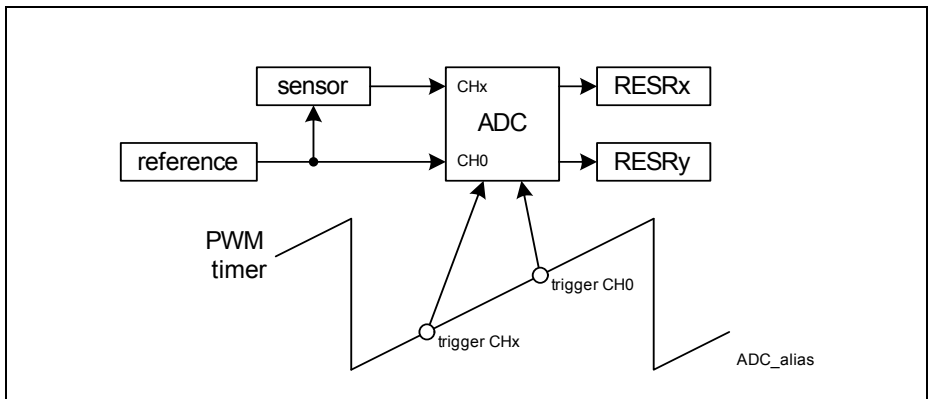

Figure 29-13 Alias Feature

Versatile Analog-to-Digital Converter (VADC)

The alias register can replace the channel numbers of channels CH0 and CH1 with another channel number. The reset value disables this redirection.

0	[31:13]	r	Reserved, write 0, read as 0

Versatile Analog-to-Digital Converter (VADC)

29.6.3 Conversion Modes

A conversion can be executed in several ways. The conversion mode is selected according to the requested resolution of the digital result and according to the acceptable conversion time ([Section 29.6.7](#)).

Use bitfield CMS/CME in register **GxICLASS0 (x = 0 - 3)** etc. to select a mode.

Standard Conversions

A standard conversion returns a result value with a predefined resolution. 8-bit, 10-bit, and 12-bit resolution can be selected.

These result values can be accumulated, filtered, or used for digital limit checking and determination of extrema.

Note: The converters can operate with and without post-calibration.

Fast Compare Mode

In Fast Compare Mode, the selected input voltage is directly compared with a digital value that is stored in the corresponding result register. This compare operation returns a binary result indicating if the compared input voltage is above or below the given reference value. This result is generated quickly and thus supports monitoring of boundary values.

Fast Compare Mode uses a 10-bit compare value stored left-aligned at bit position 11. Separate positive and negative delta values define an arbitrary hysteresis band.

Selecting Compare Values

Values for digital or analog compare operations can be selected from several sources. The separate GxBOUND registers provide software-defined compare values. Compare values can also be taken from a result register where it can be provided by another channel building a reference.

In Fast Compare Mode, the result registers provide the compare value while the bitfields of local GxBOUND registers define positive and negative delta values.

Versatile Analog-to-Digital Converter (VADC)

The local boundary register GxBOUND defines group-specific boundary values or delta limits for Fast Compare Mode.

The global boundary register GLOBBOUND defines general compare values for all channels.

Depending on the conversion width, the respective left 12/10/8 bits of a bitfield are used. For 10/8-bit results, the lower 2/4 bits must be zero!

GxBOUND (x = 0 - 3)

0	[31:28]	r	Reserved, write 0, read as 0

Versatile Analog-to-Digital Converter (VADC)

29.6.4 Compare with Standard Conversions (Limit Checking)

The limit checking mechanism can automatically compare each digital conversion result to an upper and a lower boundary value. A channel event can then be generated when the result of a conversion/comparison is inside or outside a user-defined band (see bitfield CHEVMODE and [Figure 29-14](#)).

This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain predefined conditions.

Note: Channel events can also be generated for each result value (ignoring the band) or they can be suppressed completely.

The boundary values to which results are compared can be selected from several sources (see register GxCHCTRY).

While bitfield BNDSELX = 0000_B, bitfields BNDSELU and BNDSELL select the valid upper/lower boundary value either from the group-specific boundary register **GxBOUND (x = 0 - 3)** or from the global boundary register **GLOBBOUND**. The group boundary register can be selected for each channel of the respective group, the global boundary register can be selected by each available channel.

Otherwise, the compare values are taken from result registers, where bitfield BNDSELX selects the upper boundary value (GxRES1 ... GxRES15), the concatenated bitfields BNDSELU||BNDSELL select the lower boundary value (GxRES0 ... GxRES15).

Figure 29-14 Result Monitoring through Limit Checking

Versatile Analog-to-Digital Converter (VADC)

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:

To select the lower part as valid band, set the lower boundary to the minimum value (000_H) and set the upper boundary to the highest intended value.

To select the upper part as valid band, set the upper boundary to the maximum value (FFF_H) and set the lower boundary to the lowest intended value.

Finding Extrema (Peak Detection)

The limit checking mechanism uses standard conversions and, therefore, always can provide the actual conversion result that was used for comparison. Combining this with a special FIFO mode, that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, provides the usual conversion results and at the same time stores the highest (or lowest) result of a conversion sequence. For this operation the FIFO stage below the standard result must be selected as the compare value. Mode selection is done via bitfield FEN in register GxRCRy.

Before starting a peak detection sequence, write a reasonable start value to the result bitfield in the peak result register (e.g. 0000_H to find the maximum and $FFFF_H$ to find the minimum).

29.6.5 Utilizing Fast Compare Mode

In Fast Compare Mode, the input signal is directly compared to a value stored in bitfield RESULT in the associated result register. This comparison just provides a binary result (above/below), which is available in bit FCR in the same result register. If the exact result value is not required, this saves conversion time. A channel event can then be generated when the input signal becomes higher (or lower) than the compare value (see bitfield CHEVMODE and [Figure 29-15](#)).

The compare value in Fast Compare Mode is taken from the result register. Bitfields BOUNDARY1 and BOUNDARY0 in register **GxBOUND (x = 0 - 3)** define delta limits in this case. These deltas are added to (or subtracted from) the original compare value and allow defining an arbitrary hysteresis band.

The actual used compare value depends on the Fast Compare Result FCR (see registers **GORES_y (y = 0 - 15)**, etc.):

- GxRES_y.FCR = 0: reference value + upper delta
(GxRES_y.RESULT + GxBOUND.BOUNDARY0)
- GxRES_y.FCR = 1: reference value - lower delta
(GxRES_y.RESULT - GxBOUND.BOUNDARY1)

Figure 29-15 Result Monitoring through Compare with Hysteresis

29.6.6 Boundary Flag Control

Both limit checking mechanisms can be configured to automatically control the boundary flags. These boundary flags are also available as control signals for other modules. The flags can be set or cleared when the defined level is exceeded and the polarity of the output signal can be selected. A gate signal can be selected to enable the boundary flag operation while the gate is active.

Each boundary flag is available at group-specific output lines. Node pointers additionally route them to one of four boundary signals or one of the associated common service request lines, see register **GxBFLNP (x = 0 - 3)**.

For standard conversions, a boundary flag will be set/cleared when the conversion result is above the defined band, and will be cleared/set when the conversion result is below the defined band.

The band between the two boundary values defines a hysteresis for setting/clearing the boundary flags.

Using this feature on three channels that monitor linear hall elements can produce signals to feed the three hall position inputs of a unit that generates the corresponding PWM control signals.

In Fast Compare Mode, a boundary flag reflects the result of the comparisons, i.e. it will be set/cleared when the compared signal level is above the compare value, and will be cleared/set when the signal level is below the compare value. The delta values define a hysteresis band around the compare value.

Note: Clear register GxBOUND (i.e. the deltas) if a hysteresis is not wanted.

Figure 29-16 Boundary Flag Switching

Versatile Analog-to-Digital Converter (VADC)

Boundary flags can be switched by each compare operation, or the influence of compare operations can be restricted to the active phases of the corresponding request source gate signal (see **GxBFLC (x = 0 - 3)**).

Note: If a boundary flag is used together with Fast Compare Mode, it is recommended not to direct results from other channels to the corresponding result register.

The output signal derived from a boundary flag can be controlled by other modules. A select input and a data input are available to temporarily replace the boundary flag signal before sending it to the output pin (see **Figure 29-17**).

Figure 29-17 Boundary Flag Control

A boundary flag BFLy is assigned to result register GxRESy and thus to an arbitrary channel.

Versatile Analog-to-Digital Converter (VADC)

The Boundary Flag Register holds the boundary flags themselves together with bits to select the activation condition and the output signal polarity for each flag.

Versatile Analog-to-Digital Converter (VADC)
29.6.7 Conversion Timing

The total time required for a conversion comprises the time from the start of the sample phase¹⁾ until the availability of the result.

The frequency at which conversions are triggered also depends on several configurable factors:

- The selected conversion time, according to the input class definitions. For conversions using an external multiplexer, also the extended sample times count.
- Delays induced by cancelled conversions that must be repeated.
- Delays due to equidistant sampling of other channels.
- The configured arbitration cycle time.
- The frequency of external trigger signals, if enabled.

The conversion timing depends on several user-definable factors:

- The ADC conversion clock frequency, where $f_{\text{ADCI}} = f_{\text{VADC}} / (\text{DIVA} + 1)^2$
- The selected sample time, where $t_{\text{S}} = (2 + \text{STC}) \times t_{\text{ADCI}}$
(STC = additional sample time, see also [Table 29-4](#))
- The selected operating mode (normal conversion / fast compare mode)
- The result width N (8/10/12 bits) for normal conversions
- The post-calibration time PC, if selected (PC = 2, otherwise 0)
- Synchronization steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and synchronization. It can be computed with the following formulas:

Standard conversions: $t_{\text{CN}} = (2 + \text{STC} + \text{N} + \text{PC}) \times t_{\text{ADCI}} + 2 \times t_{\text{VADC}}$

Fast compare mode: $t_{\text{CN}} = (2 + \text{STC} + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{VADC}}$

Timing Examples

System assumptions:

$f_{\text{VADC}} = 100 \text{ MHz}$ i.e. $t_{\text{VADC}} = 10 \text{ ns}$, $\text{DIVA} = 5$, $f_{\text{ADCI}} = 16.67 \text{ MHz}$ i.e. $t_{\text{ADCI}} = 60 \text{ ns}$

According to the given formulas the following minimum conversion times can be achieved:

12-bit calibrated conversion:

$$t_{\text{CN}12\text{C}} = (2 + 12 + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{VADC}} = 16 \times 60 \text{ ns} + 2 \times 10 \text{ ns} = 980 \text{ ns}$$

10-bit uncalibrated conversion:

$$t_{\text{CN}10} = (2 + 10) \times t_{\text{ADCI}} + 2 \times t_{\text{VADC}} = 12 \times 60 \text{ ns} + 2 \times 10 \text{ ns} = 740 \text{ ns}$$

Fast comparison:

$$t_{\text{FCM}} = (2 + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{VADC}} = 4 \times 60 \text{ ns} + 2 \times 10 \text{ ns} = 340 \text{ ns}$$

1) The time from the trigger event that requests the corresponding conversion until the start of the sample phase depends on the arbitration and can, therefore, only be determined when the system setup is known.

2) The minimum prescaler factor for calibrated converters is 2.

Versatile Analog-to-Digital Converter (VADC)

29.7 Conversion Result Handling

The A/D converters can preprocess the conversions result data to a certain extent before storing them for retrieval by the CPU or a DMA channel. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** to user-configurable registers
- **Data Alignment** according to result width and endianness
- **Wait-for-Read Mode** to avoid loss of data
- **Result Event Generation**
- Data reduction or anti-aliasing filtering (see [Section 29.7.6](#))

29.7.1 Storage of Conversion Results

The conversion result values of a certain group can be stored in one of the 16 associated group result registers or in the common global result register (can be used, for example, for the channels of the background source (see [Selecting a Result Register](#)).

This structure provides different locations for the conversion results of different sets of channels. Depending on the application needs (data reduction, auto-scan, alias feature, etc.), the user can distribute the conversion results to minimize CPU load and/or optimize the performance of DMA transfers.

Each result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the corresponding result register and can be read out.

For standard conversions, result values are available in bitfield RESULT. Conversions in Fast Compare Mode use bitfield RESULT for the reference value, so the result of the operation is stored in bit FCR.

Result registers can be read via two different views. These views use different addresses but access the same register data:

- When a result register is read via the **application view**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When a result register is read via the **debug view**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

The application can retrieve conversion results through several result registers:

- Group result register:
Returns the result value and the channel number
- Global result register:
Returns the result value and the channel number and the group number

Versatile Analog-to-Digital Converter (VADC)

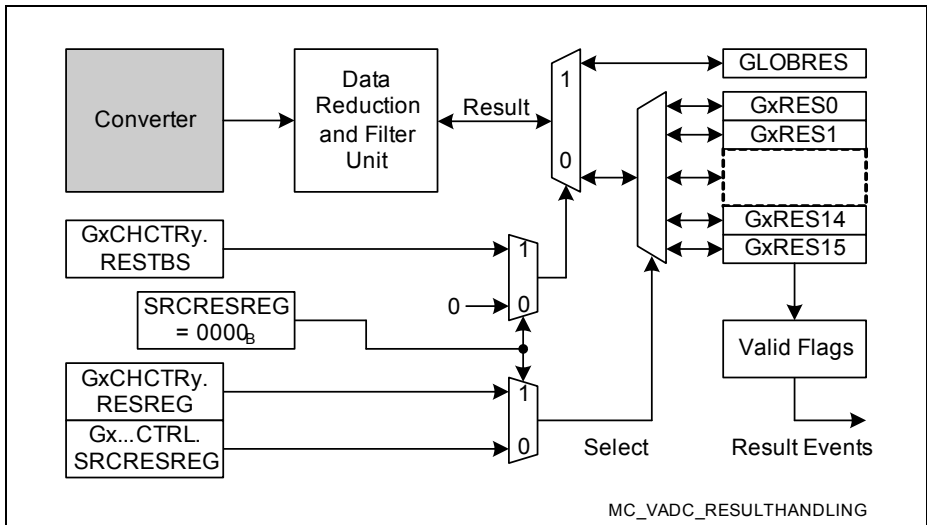

Figure 29-18 Conversion Result Storage

Selecting a Result Register

Conversion results are stored in result registers that can be assigned by the user according to the requirements of the application. The following bitfields direct the results to a register:

- SRCRESREG in register **GxQCTRL0 (x = 0 - 3)**, **GxASCTRL (x = 0 - 3)** or **BRCTRL**
Selects the group-specific result register GxRES1 ... GxRES15 when source-specific result registers are used
- RESTBS in register GxCHCTRY
Selects the global result register for results requested by the background source
- RESREG in register GxCHCTRY
Selects the group-specific result register GxRES0 ... GxRES15 when channel-specific result registers are used (see below).

Using source-specific result registers allows separating results from the same channel that are requested by different request sources. Usually these request sources are used by different tasks and are triggered at different times.

Versatile Analog-to-Digital Converter (VADC)

The group result control registers select the behavior of the result registers of a given group.

Versatile Analog-to-Digital Converter (VADC)

29.7.2 Data Alignment

The position of a conversion result value within the selected result register depends on 3 configurations (summary in **Figure 29-19**):

- The selected result width (12/10/8 bits, selected by the conversion mode)
- The selected result position (Left/Right-aligned)
- The selected data accumulation mode (data reduction)

These options provide the conversion results in a way that minimizes data handling for the application software.

Figure 29-19 Result Storage Options

Bitfield RESULT can be written by software to provide the reference value for Fast Compare Mode. In this mode, bits 11-2 are evaluated, the other bits are ignored.

29.7.3 Wait-for-Read Mode

The wait-for-read mode prevents data loss due to overwriting a result register with a new conversion result before the CPU (or DMA) has read the previous data. For example, auto-scan conversion sequences or other sequences with “relaxed” timing requirements may use a common result register. However, the results come from different input channels, so an overwrite would destroy the result from the previous conversion¹⁾.

Wait-for-read mode automatically suspends the start of a conversion for this channel from this source until the current result has been read. So a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU/DMA capability to read the formerly converted result (latency).

If wait-for-read mode is enabled for a result register (bit GxRCRy.WFR = 1), a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VF = 1) or if a currently running conversion targets the same result register.

If two request sources target the same result register with wait-for-read mode selected, a higher priority source cannot interrupt a lower priority conversion request started before the higher priority source has requested its conversion. Cancel-inject-repeat mode does not work in this case. In particular, this must be regarded if one of the involved sources is the background source (which usually has lowest priority). If the higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

Note: Wait-for-read mode is ignored for synchronized conversions of synchronization slaves (see [Section 29.8](#)).

1) Repeated conversions of a single channel that use a separate result register will not destroy other results, but rather update their own previous result value. This way, always the actual signal data is available in the result register.

Versatile Analog-to-Digital Converter (VADC)

29.7.4 Result FIFO Buffer

Result registers can either be used as direct target for conversion results or they can be concatenated with other result registers of the same ADC group to form a result FIFO buffer (first-in-first-out buffer mechanism). A result FIFO stores several measurement results that can be read out later with a “relaxed” CPU response timing. It is possible to set up more than one FIFO buffer structure with the available result registers.

Result FIFO structures of two or more registers are built by concatenating result registers to their following “neighbor” result register (with next higher index, see [Figure 29-20](#)). This is enabled by setting bitfield GxRCRy.FEN = 01_B.

Conversion results are stored to the register with the highest index of a FIFO structure. Software reads the values from the FIFO register with the lowest index.

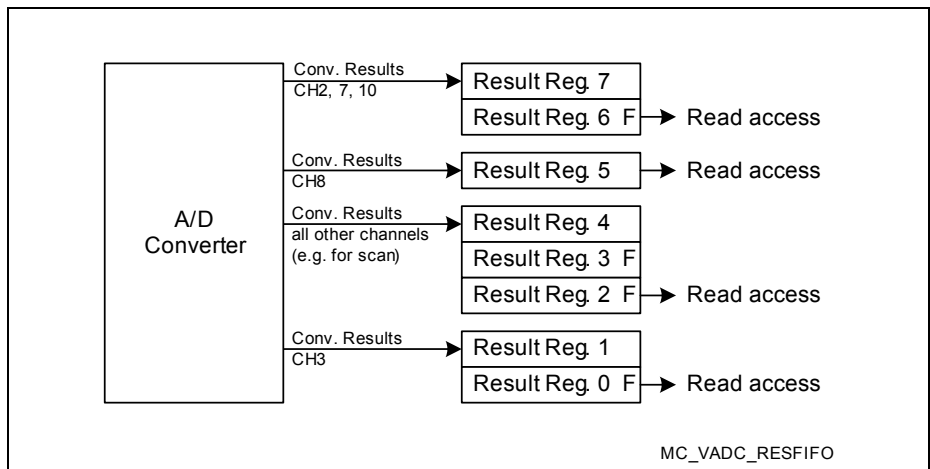

Figure 29-20 Result FIFO Buffers

In the example shown the result registers have been configured in the following way:

- 2-stage buffer consisting of result registers 7-6
- dedicated result register 5
- 3-stage buffer consisting of result registers 4-3-2
- 2-stage buffer consisting of result registers 1-0

[Table 29-5](#) summarizes the required configuration of result registers if they are combined to build result FIFO buffers.

Table 29-5 Properties of Result FIFO Registers

Function	Input Stage	Intermed. Stage	Output Stage
Result target	YES	no	no
Application read	no	no	YES
Data reduction mode	YES	no	no
Wait-for-read mode	YES	no	no
Result event interrupt	no	no	YES
FIFO enable (FEN)	00 _B	01 _B	01 _B
Registers in example	7, 4, 1	3	6, 2, 0

Note: If enabled, a result interrupt is generated for each data word in the FIFO.

29.7.5 Result Event Generation

A result event can be generated when a new value is stored to a result register. Result events can be restricted due to data accumulation and be generated only if the accumulation is complete.

Result events can also be suppressed completely.

Versatile Analog-to-Digital Converter (VADC)
29.7.6 Data Modification

The data resulting from conversions can be automatically modified before being used by an application. Several options can be selected (bitfield DMM in register **G0RCRy (y = 0 - 15)** etc.) which reduce the CPU/DMA load required to unload and/or process the conversion data.

- **Standard Data Reduction Mode (for GxRES0 ... GxRES15):**
Accumulates 2, 3, or 4 result values within each result register before generating a result interrupt. This can remove some noise from the input signal.
- **Result Filtering Mode (FIR, for GxRES7, GxRES15):**
Applies a 3rd order Finite Impulse Response Filter (FIR) with selectable coefficients to the conversion results for the selected result register.
- **Result Filtering Mode (IIR, for GxRES7, GxRES15):**
Applies a 1st order Infinite Impulse Response Filter (IIR) with selectable coefficients to the conversion results for the selected result register.
- **Difference Mode (for GxRES1 ... GxRES15):**
Subtracts the contents of result register GxRES0 from the conversion results for the selected result register. Bitfield DRCTR is not used in this mode.

Table 29-6 Function of Bitfield DRCTR

DRCTR	Standard Data Reduction Mode (DMM = 00_B)	DRCTR	Result Filtering Mode (DMM = 01_B)¹⁾
0000 _B	Data Reduction disabled	0000 _B	FIR filter: a=2, b=1, c=0

Versatile Analog-to-Digital Converter (VADC)

Standard Data Reduction Mode

The data reduction mode can be used as digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 4 conversion values to generate a final result.

Each result register can be individually enabled for data reduction, controlled by bitfield DRCTR in registers **G0RCRy (y = 0 - 15)**ff and **GLOBRCR**. The data reduction counter DRC indicates the actual status of the accumulation.

Note: Conversions for other result registers can be inserted between conversions to be accumulated.

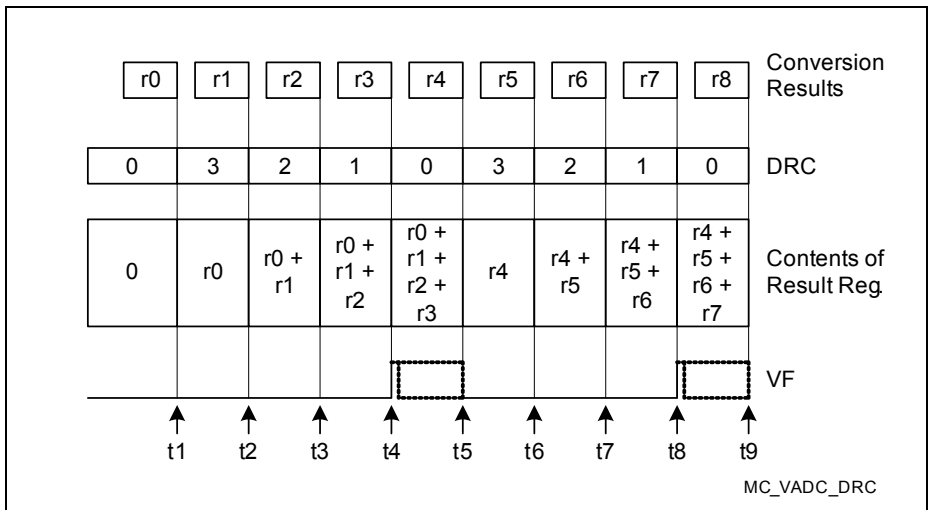

Figure 29-21 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 ... r7) are accumulated and produce 2 final results.

When a conversion is complete and stores data to a result register that has data reduction mode enabled, the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).
- If DRC > 0 (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register. DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.

Versatile Analog-to-Digital Converter (VADC)

The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

*Note: Software can clear the data reduction counter DRC by clearing the corresponding valid Flag (via **GxVFR (x = 0 - 3)**).*

The response time to read the final data reduction results can be increased by associating the adjacent result register to build a result FIFO (see **Figure 29-22**). In this case, the final result of a data reduction sequence is loaded to the adjacent register. The value can be read from this register until the next data reduction sequence is finished (t8 in the 2nd example).

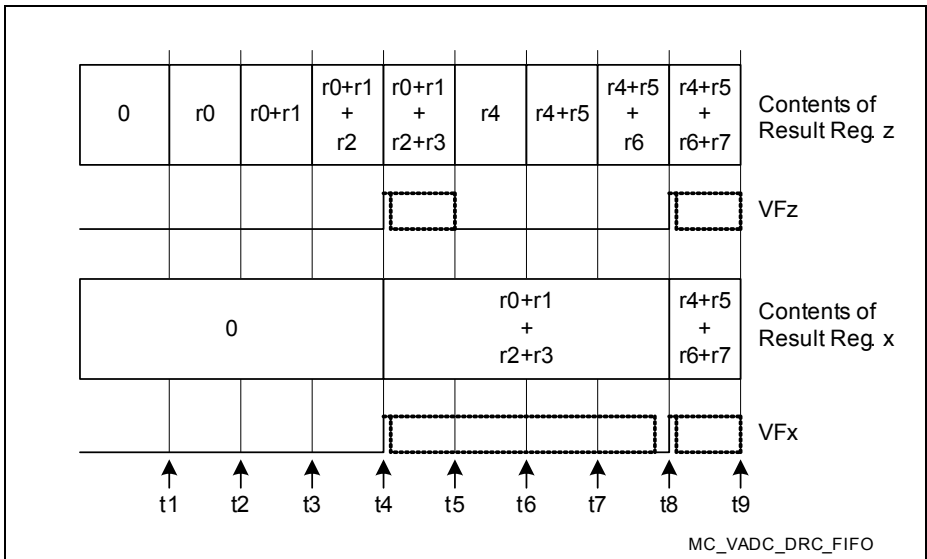

Figure 29-22 Standard Data Reduction Filter with FIFO Enabled

Versatile Analog-to-Digital Converter (VADC)

Finite Impulse Response Filter Mode (FIR)

The FIR filter (see [Figure 29-23](#)) provides 2 result buffers for intermediate results (RB1, RB2) and 3 configurable tap coefficients (a, b, c).

The conversion result and the intermediate result buffer values are added weighted with their respective coefficients to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in [Table 29-6](#)) in registers **G0RCRy** ($y = 0 - 15$)ff and **GLOBRCR**. These coefficients lead to a gain of 3 or 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

Figure 29-23 FIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Versatile Analog-to-Digital Converter (VADC)

Infinite Impulse Response Filter Mode (IIR)

The IIR filter (see [Figure 29-24](#)) provides a result buffer (RB) and 2 configurable coefficients (a, b). It represents a first order low-pass filter.

The conversion result, weighted with the respective coefficient, and a fraction of the previous result are added to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in [Table 29-6](#)) in registers **G0RCRy** ($y = 0 - 15$)ff and **GLOBRCR**. These coefficients lead to a gain of 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

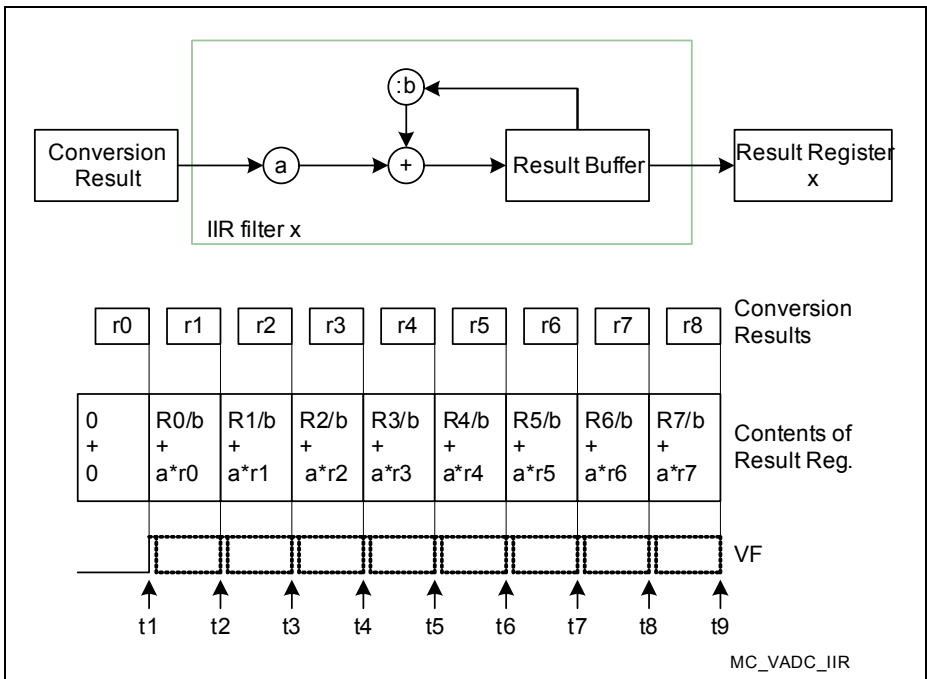

Figure 29-24 IIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Versatile Analog-to-Digital Converter (VADC)

Difference Mode

Subtracting the contents of result register 0 from the actual result puts the results of the respective channel in relation to another signal. No software action is required.

The reference channel must store its result(s) into result register 0. The reference value can be determined once and then be used for a series of conversions, or it can be converted before each related conversion.

Figure 29-25 Result Difference

Versatile Analog-to-Digital Converter (VADC)

29.8 Synchronization of Conversions

The conversions of an ADC kernel can be scheduled either self-timed according to the kernel's configuration or triggered by external (outside the ADC) signals:

Synchronized Conversions for Parallel Sampling support parallel conversion of channels within a synchronization group¹⁾. This optimizes e.g. the control of electrical drives.

Equidistant Sampling supports conversions in a fixed raster with minimum jitter. This optimizes e.g. filter algorithms or audio applications.

29.8.1 Synchronized Conversions for Parallel Sampling

Several independent ADC kernels¹⁾ implemented in the TC26x B-Step can be synchronized for simultaneous measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.

The synchronization mechanism for parallel conversions ensures that the sample phases of the related channels start simultaneously. Synchronized kernels convert the same channel that is requested by the master. Different values for the resolution and the sample phase length of each kernel for a parallel conversion are supported.

A parallel conversion can be requested individually for each input channel (one or more). In the example shown in **Figure 29-26**, input channels CH3 of the ADC kernels 0, 1, 2 are converted synchronously, whereas other input channels do not lead to parallel conversions.

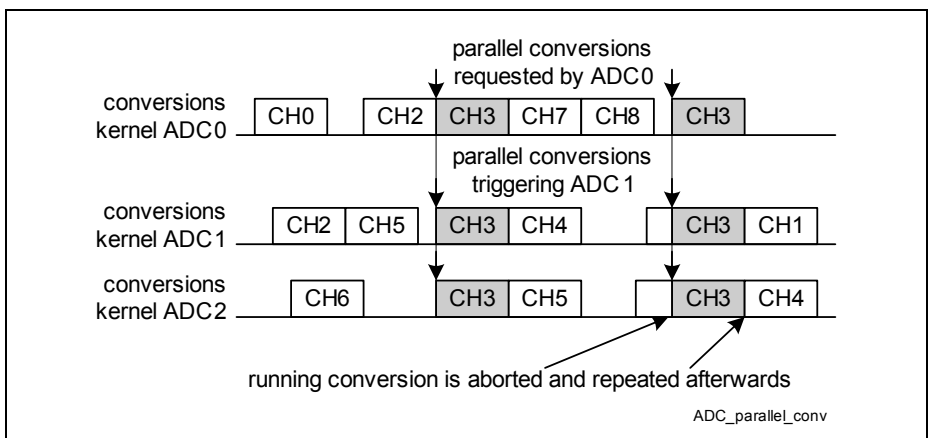

Figure 29-26 Parallel Conversions

1) For a summary, refer to **“Synchronization Groups in the TC26x B-Step”** on **Page 29-148**.

Versatile Analog-to-Digital Converter (VADC)

One kernel operates as synchronization master, the other kernel(s) operate(s) as synchronization slave. Each kernel can play either role. The arbiters of all involved kernels must run synchronously. This is achieved by switching off all involved kernels before the initialization and switching on the master kernel at the end of the initialization sequence.

Master and slave kernels form a “conversion group” to control parallel sampling:

- The arbiters must run permanently (bits **GxARBCFG (x = 0 - 3).ARBM = 0**). Initialize the slave before the master to have the arbiters run synchronously. Set the master’s **GxARBCFG.ANONC** at the end of the initialization.
- **The synchronization master** controls the slave(s) by providing the control information **GxARBCFG (x = 0 - 3).ANONS** (see **Figure 29-27**) and the requested channel number.
 - Bitfield **GxSYNCTR (x = 0 - 3).STSEL = 00_B** selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group.¹⁾
 - The ready signals indicate when a slave kernel is ready to start the sample phase of a parallel conversion.
 - Bit **GxSYNCTR (x = 0 - 3).EVALRy = 1** enables the control by the ready signal (in the example, kernels 1 and 2 are slaves, so **EVALR1 = EVALR2 = 1**).
 - The master requests a synchronized conversion of a certain channel (**SYNC = 1** in the corresponding channel control register **GxCHCTRy**), which is also requested in the connected slave ADC kernel(s).
 - Wait-for-read mode is supported for the master.
- **The synchronization slave** reacts to incoming synchronized conversion requests from the master. While no synchronized conversions are requested, the slave kernel can execute “local” conversions.
 - Bitfield **GxSYNCTR (x = 0 - 3).STSEL = 01_B/10_B/11_B** selects the master’s ANON information as the source of the ANON information for all kernels of the synchronization group¹⁾ (in the example, kernel 0 is the master, so **STSEL = 01_B**).
 - The ready signals indicate when the master kernel and the other slave kernels are ready to start the sample phase of a parallel conversion.
 - Bit **GxSYNCTR (x = 0 - 3).EVALRy = 1** enables the control by the ready signal (in the example, kernel 0 is the master, so **EVALR1 = 1**, kernel 1 and 2 are slaves, so **EVALR2 = 1**).
 - The slave timing must be configured according to the master timing (**ARBRND** in register **GxARBCFG (x = 0 - 3)**) to enable parallel conversions.
 - A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode.

1) **STSEL = 00_B** selects the own ANON information. The other control inputs (**STSEL = 01_B/10_B/11_B**) are connected to the other kernels of a synchronization group in ascending order (see also **Table 29-9 “Synchronization Groups in the TC26x B-Step” on Page 29-148**).

Versatile Analog-to-Digital Converter (VADC)

- Wait-for-read mode is ignored in the slave. Previous results may be overwritten, in particular, if the same result register is used by other conversions.
- Once started, a parallel conversion cannot be aborted.

Note: Synchronized conversions request the same channel number, defined by the master. Using the alias feature (see [Section 29.6.2](#)), analog signals from different input channels can be converted. This is advantageous if e.g. CH0 is used as alternate reference.

Figure 29-27 Synchronization via ANON and Ready Signals

Versatile Analog-to-Digital Converter (VADC)

The Synchronization Control Register controls the synchronization of kernels for parallel conversions.

Note: Program register GxSYNCTR only while bitfield GxARBCFG.ANONS = 00_B in all ADC kernels of the conversion group. Set the master's bitfield ANONC to 11_B afterwards.

29.8.2 Equidistant Sampling

To optimize the input data e.g. for filter or audio applications, conversions can be executed in a fixed timing raster. Conversions for equidistant sampling are triggered by an external signal (e.g. a timer). To generate the trigger signal synchronous to the arbiter, the ADC provides an output signal (ARBCNT) that is activated once per arbitration round and serves as timing base for the trigger timer. In this case, the arbiter must run permanently (**GxARBCFG (x = 0 - 3).ARBM = 0**). If the timer has an independent time base, the arbiter can be stopped while no requests are pending. The preface time (see **Figure 29-28**) must be longer than one arbitration round and the highest possible conversion time.

Select timer mode (TMEN = 1 in register **GxQCTRL0 (x = 0 - 3)** or **GxASCTRL (x = 0 - 3)**) for the intended source of equidistant conversions. In timer mode, a request of this source is triggered and arbitrated, but only started when the trigger signal is removed (see **Figure 29-28**) and the converter is idle.

To ensure that the converter is idle and the start of conversion can be controlled by the trigger signal, the equidistant conversion requests must receive highest priority. The preface time between request trigger and conversion start must be long enough for a currently active conversion to finish.

The frequency of signal REQTRx defines the sampling rate and its high time defines the preface time interval where the corresponding request source takes part in the arbitration.

Depending on the used request source, equidistant sampling is also supported for a sequence of channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

Versatile Analog-to-Digital Converter (VADC)

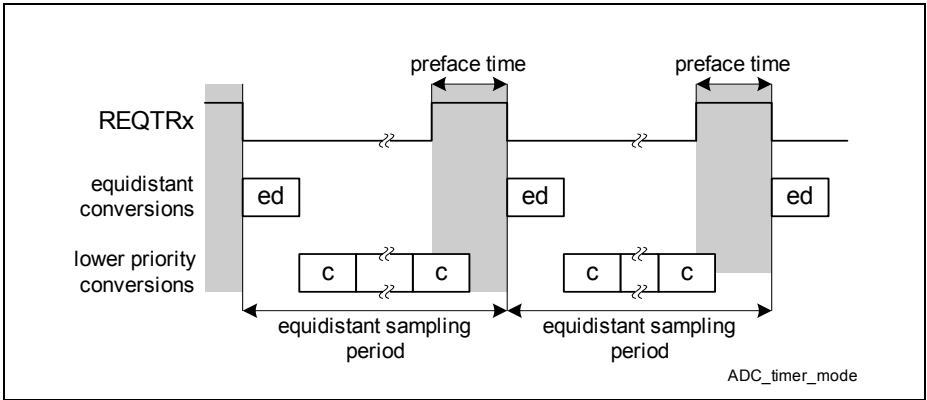

Figure 29-28 Timer Mode for Equidistant Sampling

29.9 Safety Features

Several test features can be enabled to verify the validity of the analog input signals of an application. These test features aim at different sections of the signal flow:

- **Broken Wire Detection** validates the connection from the sensor to the input pin,
- **Multiplexer Diagnostics** validates the operation of the internal analog input multiplexer,
- **Converter Diagnostics** validates the operation of the Analog/Digital converter itself.

29.9.1 Broken Wire Detection

To test the proper connection of an external analog sensor to its input pin, the converter's capacitor can be precharged to a selectable value before the regular sample phase. If the connection to the sensor is interrupted the subsequent conversion value will rather represent the precharged value than the expected sensor result. By using a precharge voltage outside the expected result range (broken wire detection preferably uses V_{AGND} and/or V_{AREF}) a valid measurement (sensor connected) can be distinguished from a failure (sensor detached).

While broken wire detection is disabled, the converter's capacitor is precharged to $V_{AREF}/2$.

Note: The duration of the complete conversion is increased by the preparation phase (same as the sample phase) if the broken wire detection is enabled. This influences the timing of conversion sequences.

Broken wire detection can be enabled for each channel separately by bitfield BWDEN in the corresponding channel control register (GxCHCTRY). Bitfield BWDCH selects the level for the preparation phase.

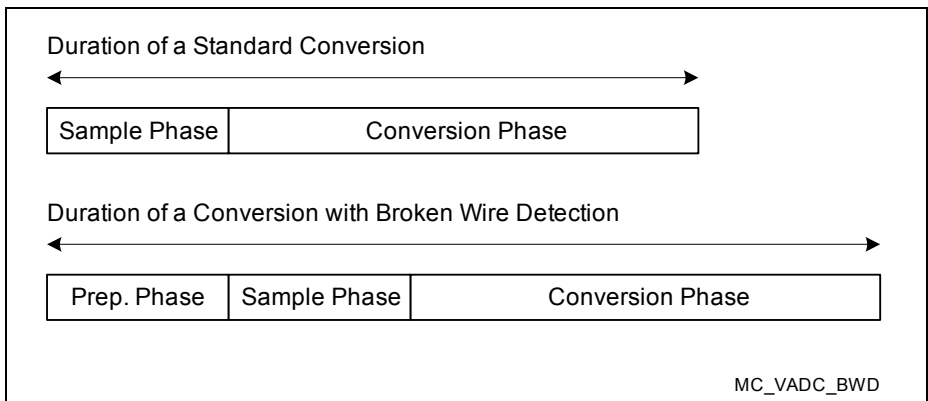

Figure 29-29 Broken Wire Detection

Versatile Analog-to-Digital Converter (VADC)

29.9.2 Signal Path Test Modes

Additional test structures can be activated to test the signal path from the sensor to the input pin and the internal signal path from the input pin through the multiplexer to the converter. These test structures apply additional loads to the signal path (see summary in [Figure 29-30](#)).

Multiplexer Diagnostics

To test the proper operation of the internal analog input multiplexer, additional pull-up and/or pull-down devices can be connected to channels CH1 and CH2. In combination with a known external input signal this test function shows if the multiplexer connects any pin to the converter input and if this is the correct pin.

Pull-Down Diagnostics

One single input channel provides a further strong pull-down (R_{PDD}) that can be activated to verify the external connection to a sensor.

Converter Diagnostics

To test the proper operation of the converter itself, several signals can be connected to the converter input. The test signals can be connected to the converter input either instead of the standard input signal or in parallel to the standard input signal.

To use the converter diagnostic without a connected input, select a non-existent channel number via the alias feature ([Section 29.6.2](#)). Redirect channel 0 or 1 to channel 24 (not connected), the conversion result can then be read from the selected result register for channel 0 or 1.

The test signal can be selected from four different signals as shown in [Figure 29-30](#).

Attention: *If the Multiplexer Diagnostics are used on channels that are overlaid on IO ports, enable these functions by setting the corresponding control bits in registers Pxx_PCSR.*

The corresponding control bits in registers Pxx_PDISC must be cleared for both Multiplexer Diagnostics and Pull-Down Diagnostics.

Versatile Analog-to-Digital Converter (VADC)

Figure 29-30 Signal Path Test

Note: When internal pull devices are activated, they may need some time to pull the input signal to the intended level, depending on the connected external circuitry. This can be accomplished by increasing the sample time for those conversions.

Versatile Analog-to-Digital Converter (VADC)
29.9.3 Configuration of Test Functions

The pull-up and pull-down devices for the test functions can be enabled individually under software control. Various test levels can be applied controlling the devices in an adequate way. Because these test functions interfere with the normal operation of the A/D Converters, they are controlled by a separate register set.

Not all test options are available for each channel. Selecting an unavailable function has no effect.

29.10 External Multiplexer Control

The number of analog input channels can be increased by connecting external analog multiplexers to an input MUX channel. The ADC can be configured to control these external multiplexers automatically.

For each available EMUX interface (see register **EMUXSEL**) one MUX channel or a set of MUX channels from one group can be selected for this operating mode. The ADC supports 1-out-of-8 multiplexers with several control options:

- **Sequence mode** automatically converts all configured external channels when the selected MUX channel is encountered. In the example in **Figure 29-31** the following conversions are done: --4-32-31-30-2-1-0--4-32-31-30-2-1-0--...
- **Single-step mode** converts one external channel of the configured sequence when the selected MUX channel is encountered. In the example in **Figure 29-31** the following conversions are done: --4-32-2-1-0--4-31-2-1-0--4-30-2-1-0--4-32-... (Single-step mode works best with one channel)
- **Steady mode** converts the configured external channel when the selected MUX channel is encountered. In the example in **Figure 29-31** the following conversions are done: --4-32-2-1-0--4-32-2-1-0--4-32-2-1-0--...

*Note: The example in **Figure 29-31** has an external multiplexer connected to MUX channel CH3. The start selection value **EMUXSET** is assumed as 2.*

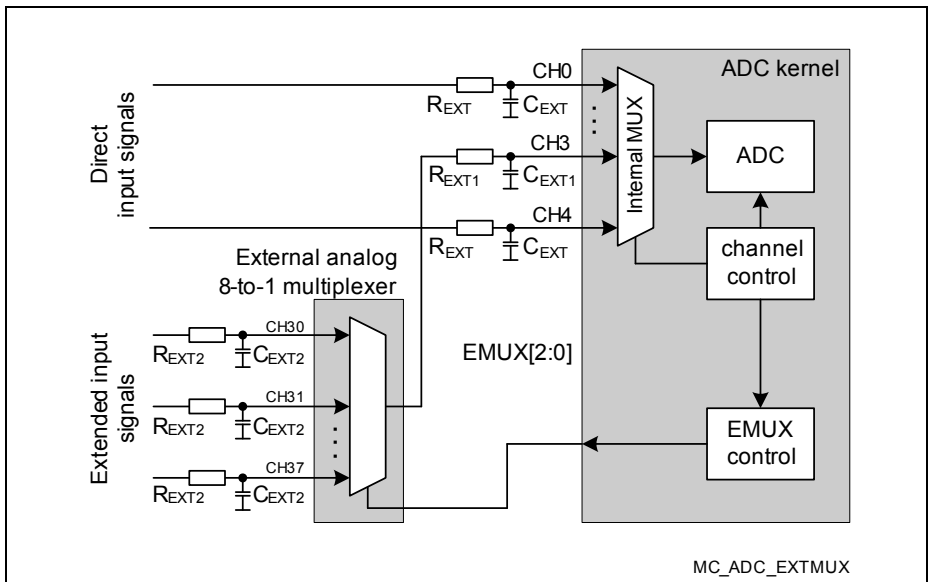

Figure 29-31 External Analog Multiplexer Example

Versatile Analog-to-Digital Converter (VADC)

Bitfield EMUXACT determines the control information sent to the external multiplexer. In single-step mode, EMUXACT is updated after each conversion of an enabled MUX channel. If EMUXACT = 000_B it is reloaded from bitfield EMUXSET, otherwise it is decremented by 1.

Additional external channels may have different properties due to the modified signal path. Local filters may be used at the additional inputs (R_{EXT2} - C_{EXT2} on CH3x in **Figure 29-31**). For applications where the external multiplexer is located far from the ADC analog input, it is recommended to add an RC filter directly at the analog input of the ADC (R_{EXT1} - C_{EXT1} on CH3 in **Figure 29-31**).

Note: Each RC filter limits the bandwidth of the analog input signal.

Conversions for external channels, therefore, use the alternate conversion mode setting CME. This automatically selects a different conversion mode if required.

Switching the external multiplexer usually requires an additional settling time for the input signal. Therefore, the alternate sample time setting STCE is applied each time the external channel is changed. This automatically fulfills the different sampling time requirements in this case.

Control Signals

The external channel number that controls the external multiplexer can be output in standard binary format or Gray-coded. Gray code avoids intermediate multiplexer switching when selecting a sequence of channels, because only one bit changes at a time. **Table 29-7** indicates the resulting codes.

Table 29-7 EMUX Control Signal Coding

Channel	0	1	2	3	4	5	6	7
Binary	000 _B	001 _B	010 _B	011 _B	100 _B	101 _B	110 _B	111 _B
Gray	000	001	011	010	110	111	101	100

Operation Without External Multiplexer

If no external multiplexers are used in an application, the reset values of the control registers provide the appropriate setup.

EMUXMODE = 00_B disables the automatic EMUX control.

Since the control output signals are alternate port output signals, they are only visible at the respective pins if explicitly selected.

Versatile Analog-to-Digital Converter (VADC)

In each group an arbitrary MUX channel or set of MUX channels can be assigned to external multiplexer control (register **GxEMUXCTR** ($x = 0 - 3$)). Each available port interface selects the group whose control lines are output (register **EMUXSEL**).

29.11 Service Request Generation

Each A/D Converter can activate up to 4 group-specific service request output signals and up to 4 shared service request output signals to issue an interrupt or to trigger a DMA channel. Two common service request groups are available, see [“Product-Specific Configuration” on Page 29-147](#).

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events:** indicate that a request source completed the requested conversion sequence and the application software can initiate further actions.
For a scan source (group or background), the event is generated when the complete defined set of channels (pending bits) has been converted.
For a group queue source, the event is generated according to the programming, i.e. when a channel with enabled source interrupt has been converted or when an invalid entry is encountered.
- **Channel events:** indicate that a conversion is finished. Optionally, channel events can be restricted to result values within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Optionally, result events can be generated only at a reduced rate if data reduction is active.
For example, a single DMA channel can read the results for a complete auto-scan sequence, if all channels of the sequence target the same result register and the transfers are triggered by result events.

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of ADC events (the ADC event can generate a service request without the need to clear the indication flag).

Event flag registers indicate all types of events that occur during the ADC's operation. Software can set each flag by writing a 1 to the respective position in register GxCEFLAG/GxRFLAG to trigger an event. Software can clear each flag by writing a 1 to the respective position in register GxCEFCLR/GxREFCLR. If enabled, service requests are generated for each occurrence of an event, even if the associated flag remains set.

Versatile Analog-to-Digital Converter (VADC)

Field	Bits	Type	Description
SEVGLB	0	rwh	Source Event (Background) 0 _B No source event 1 _B A source event has occurred
0	[7:1]	r	Reserved, write 0, read as 0
REVGLB	8	rwh	Global Result Event 0 _B No result event 1 _B New result was stored in register GLOBRES
0	[15:9]	r	Reserved, write 0, read as 0
SEVGLBCLR	16	w	Clear Source Event (Background) 0 _B No action 1 _B Clear the source event flag SEVGLB
0	[23:17]	r	Reserved, write 0, read as 0
REVGLBCLR	24	w	Clear Global Result Event 0 _B No action 1 _B Clear the result event flag REVGLB
0	[31:25]	r	Reserved, write 0, read as 0

Note: Software can set flags REVGLB and SEVGLB and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.

Software can clear these flags by writing 1 to bit REVGLBCLR and SEVGLBCLR, respectively.

Setting both bits (e.g. SEVGLB and SEVGLBCLR) simultaneously clears the corresponding flag (e.g. SEVGLB).

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

Versatile Analog-to-Digital Converter (VADC)
29.12 Implementation into the TC26x B-Step

This section describes the actual implementation of the ADC module into the TC26x B-Step, i.e. the incorporation into the microcontroller system.

The following information is listed:

- [“Product-Specific Configuration” on Page 29-147](#)
- [“Summary of Registers and Locations” on Page 29-149](#)
- [“Analog Module Connections in the TC26x B-Step” on Page 29-154](#)
- [“Digital Module Connections in the TC26x B-Step” on Page 29-157](#)

29.12.1 Product-Specific Configuration

The functional description describes the features and operating modes of the A/D Converters in a general way. This section summarizes the configuration that is available in this product (TC26x B-Step).

Each converter group is equipped with a separate analog converter module and a dedicated analog input multiplexer.

Table 29-8 General Converter Configuration in the TC26x B-Step

Converter Group	Input Channels	Channels w. Altern. Reference	Common Service Req. Group	Associated Standard Reference
G0	0 ... 13	9	C0	V_{AREF1} , V_{AGND1}
G1	0 ... 13	12	C1	V_{AREF1} , V_{AGND1}
G2	0 ... 15	12	C0	V_{AREF1} , V_{AGND1}
G3	0 ... 11	12	C1	V_{AREF1} , V_{AGND1}

Versatile Analog-to-Digital Converter (VADC)
Synchronization Groups in the TC26x B-Step

The converter kernels in the TC26x B-Step can be connected to synchronization groups to achieve parallel conversion of several input channels.

Table 29-9 summarizes which kernels can be synchronized for parallel conversions.

Table 29-9 Synchronization Groups in the TC26x B-Step

ADC Kernel	Synchr. Group	Master selected by control input C1x ¹⁾			
		C10 ²⁾	C11	C12	C13
ADC00	A	ADC00	ADC01	ADC02	ADC03
ADC01	A	ADC01	ADC00	ADC02	ADC03
ADC02	A	ADC02	ADC00	ADC01	ADC03
ADC03	A	ADC03	ADC00	ADC01	ADC02

1) The control input is selected by bitfield STSEL in register **GxSYNCTR (x = 0 - 3)**.

Select the corresponding ready inputs accordingly by bits EVALRx.

2) Control input C10 always selects the own control signals of the corresponding ADC kernel. This selection is meant for the synchronization master or for stand-alone operation.

Versatile Analog-to-Digital Converter (VADC)
29.12.2 Summary of Registers and Locations

The Versatile ADC is built from a series of converter blocks that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see [Table 29-11](#)). The exact register location is obtained by adding the respective register offset to the base address (see [Table 29-10](#)) of the corresponding group.

Due to the regular group structure, several registers appear within each group. Other registers are provided for each channel. This is indicated in the register overview table by placeholders:

- $X###_H$ means: $x \times 0400_H + 0###_H$, for $x = 0 - 3$
- $###Y_H$ means: $###0_H + y \times 0004_H$, for $y = 0 - N$ (depends on register type)

Versatile Analog-to-Digital Converter (VADC)
29.12.3 Analog Module Connections in the TC26x B-Step

The VADC module accepts a number of analog input signals. The analog input multiplexers select the input channels to be converted from the signals available in this product.

Note: If an analog input channel is connected to an I/O port pin, make sure the output driver and/or the digital input path are disabled.

The exact number of analog input channels and the available connection to port pins depend on the employed product type (see also [Section 29.12.1](#)). A summary of channels enclosing all versions of the TC26x B-Step can be found below.

Input channels marked “PDD” provide a pull-down device for pull-down diagnostics.

Input channels marked “MD” can activate the pullup and pulldown devices for multiplexer diagnostics.

Input channels marked “AltRef” can be selected as an alternate reference voltage for conversions on channels of the same group or for conversions on channels of the same cluster.

Input channels marked “noAltref” cannot select an alternate reference voltage, but only the corresponding standard reference voltage.

Table 29-12 Analog Connections in the TC26x B-Step

Signal	Dir.	Source/Destin. ¹⁾	Description
V_{AREF}	I	VAREF1	positive analog reference

Versatile Analog-to-Digital Converter (VADC)
29.12.4 Digital Module Connections in the TC26x B-Step

The VADC module accepts a number of digital input signals and generates a number of output signals. This section summarizes the connection of these signals to other on-chip modules or to external resources via port pins.

Note: The control bitfields for triggers and gates select the corresponding multiplexer input. Values 0000_B ... 1111_B select inputs with suffix -A ... -P.

Table 29-13 Digital Connections in the TC26x B-Step

- 1) Internal signal connection.

Versatile Analog-to-Digital Converter (VADC)

29.13 Use Case Example for VADC

This section provides a code example for the VADC module to give an overview about the core functionality. The code example realizes an event triggered analog to digital conversion. The result is stored as a 12-bit digital value and triggers a result service request.

The VADC contains several ADC groups (G0 ... G3). Each group is connected to up to 8 analog input channels via a multiplexer. The following code example initializes one of the groups and uses one static allocated analog channel as input.

The code example realizes an analog-to-digital conversion by using the background source. The conversion can either run continuously in autoscan mode or can be triggered by an event, like in the following example. This is useful if the conversion needs to be executed at certain times. The result from the most recent conversion is accessible in the global result register **GLOBRES**. A result service request is activated after each conversion. The initialization is done in the following order:

1. Load the global VADC module registers
2. Enable the analog/digital converter 0 (G0)
3. Select channel 0 of G0 as analog input
4. Initialize the conversion result service request
5. Start first conversion

Versatile Analog-to-Digital Converter (VADC)
Step Description to Initialize the VADC Module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection in chapter SCU).

(Line 2) enable control of the module, in clock control register **CLC**.

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) set group 0 to normal operation mode. This activates the converter of group 0. (see also **Section 29.4.1** and **GxARBCFG (x = 0 - 3)**).

(Line 6) load the global configuration register GLOBCFG with the divider factor for the analog internal clock (see also **Figure 29-7**). Set DIVWC[15] to enable write access and initiate the start-up calibration by setting SUCAL[31]. The calibration is necessary to get a precise conversion.

(Line 7) This line enables the arbitration slot 2, that's the background scan source slot which the examples uses. (see also Arbitration Priority Register **GxARBPR (x = 0 - 3)**)

(Line 8) This line sets RESTBS[20], so each conversion result from group 0 input channel 0 is now stored in the global result register GLOBRES. (see also GxCHCTry)

(Line 9) This line selects input channel 0 of group 0 as part of the background scan sequence. (see also **BRSELx (x = 0 - 3)**).

(Line 10) By setting ENGT[0..1]=01 a conversion request can be issued for every channel which was enabled in line 10. here only channel 0. (see also **BRSMR**)

(Line 11) This line enables the group 0 service request in the service request control register SRC_VADCG0SR0 and sets the interrupt priority to VADC0INT (1...255)

(Line 12) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example in chapter IR for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority VADC0INT.

(Line 13) This command enables the result interrupt. It occurs after a result event.

(Line 14) wait until start-up calibration (start in line 6) is done.

(Line 15) setting LDEV=1 generates a load event which starts a conversion.

Note: The conversion result ISR function prototype would be: void VADC_SCAN_irq (void); here could be your ISR code;

Versatile Analog-to-Digital Converter (VADC)
Basic Initialization of the VADC:

```
//=====> Load global module registers
(1) SCU_vResetENDINIT (0); // Access to ENDINIT-prot. reg.
(2) VADC_CLC = 0x0000; // Enable module clock and ctrl.
(3) dummy = VADC_CLC; // Read back ensures write oper.
(4) SCU_vSetENDINIT (0); // Lock ENDINIT-protected reg.
//=====> Enable converter for group 0
(5) VADC_G0ARBCFG = 0x3; // ANONC = 11, analog converter ON
(6) VADC_GLOBCFG = (1<<31) /* SUCAL = 1, start-up calib. */ \
| (1<<15) /* DIVWC = 1, enable write */ \
| 0x9; // DIVA = 9 (clock prescaler)
(7) VADC_G0ARBPR = (1<<26); // AREN2 = 1, enable arb. slot 2
// (= background source)
(8) VADC_G0CHCTR0 = (1<<20); // RESTBS = 1, global result reg.
(9) VADC_BRSSSEL0 = 0x1; // Select CH0 of group 0 for scan
(10) VADC_BRSMR = 0x1; // ENGT = 10B, enable conv. req.
//=====> Init and install service request
(11) SRC_VADCCG0SR0 = (1<<10) /* Enable SR node 0, group 0 */ \
| VADC0INT; // Set prio to <VADC0INT>(1..255)
(12) interruptHandlerInstall (VADC0INT, & VADC_SCAN_irq);
(13) VADC_GLOBRCR = (1<<31); // SRGEN = 1, result service requ.
//=====> Wait for completion of startup cal.
(14) while((VADC_G0ARBCFG.U & 0x30000000) != 0x20000000);
// CALS = 1, CAL = 0: calibr. done
//=====> Start a conversion
(15) VADC_BRSMR |= (1<<9); // LDEV = 1, generate a load event
```

Note: Before a service request can occur, the service request system must be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compilers support the attribute (or similar) to set this bit (see Architecture Manual for more details):
__enable();

30 Delta-Sigma Analog-to-Digital Converter (DSADC)

The Delta-Sigma Analog-to-Digital Converter module (DSADC) of the TC26x B-Step provides a series of analog input channels connected to on-chip modulators using the Delta/Sigma (DS) conversion principle.

The on-chip demodulator channels convert these inputs to discrete digital values.

The number of inputs and DSADC channels depends on the chosen product type (refer to [“Implementation into the TC26x B-Step” on Page 30-85](#)).

Each converter channel can operate independent of the others, controlled by a dedicated set of registers. The results of each channel can be stored in a dedicated channel-specific result register.

The on-chip filter stages generate digital results from the modulator signal. The on-chip modulators accept differential or single-ended input signals.

Features

The following features describe the functionality of a DS Converter:

- Selectable connections for each input line (differential or single-ended inputs)
 - Input multiplexers to select input pins, switching controllable by external triggers
 - Alternate connection to supply voltage, half-scale voltage or reference ground
 - Common mode hold voltage selectable for each individual pin during idle phases
- Differential input amplifier
 - Input voltage range 0...5 V
 - Common mode voltage range selectable
 - Programmable gain (1/2/4/8/16)
 - DC Offset <5 mVDC, gain error < ±1%
 - Input impedance 100 kΩ
 - Calibration for offset and gain
- On-chip 3rd-order modulator
 - Sample frequency 10...20 MHz
 - High-performance and low-power modes
 - External run control
- Main demodulator (concatenated hardware filter stages)
 - Configurable CIC filter with decimation rates of 4...128
 - FIR filter with 8 coefficients (9-bit) with decimation rate 2
 - FIR filter with 28 coefficients (9-bit) with decimation rate 2
 - Optional high-pass filter for DC compensation ($f_{-3dB} = 10^{-5} \times f_d$)
 - Integration stage with external gating
 - Automatic offset correction
 - Time-stamp support
 - Pass Band 10...100 kHz, output sampling rate $f_d = 30...300$ kHz, Pass band ripple $f_d: \pm 1\%$,

Delta-Sigma Analog-to-Digital Converter (DSADC)

Stop band attenuation: $0.5 \dots 1 \times f_d$: >40 dB / $1 \dots 1.5 \times f_d$: >45 dB /
 $1.5 \dots 2 \times f_d$: > 50 dB / $2 \dots 2.5 \times f_d$: >55 dB / $2.5 \dots \text{OSR}/2 \times f_d$: > 60 dB

- Parallel auxiliary demodulator for limit checking
 - Configurable CIC filter with decimation rates of 4...32
 - Two-level boundary comparator
- Built-in support for resolver applications
 - Carrier signal generator
 - Delay compensation for position signals
 - Carrier cancelation by integrator unit
- DMA/Service-requests
 - Result events on new valid results with external gating
 - Alarm events from limit checking

Table 30-1 Abbreviations used in DSADC chapter

Abbreviation	Meaning
ADC	Analog to Digital Converter
CIC	Cyclic Integrating Comb (filter)
DMA	Direct Memory Access (controller)
DNL	Differential Non-Linearity (error)
DSADC	Delta-Sigma (conversion principle) Analog to Digital Converter
FIR	Finite Impulse Response (filter)
INL	Integral Non-Linearity (error)
LSB _n	Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2 ⁿ equally distributed steps)
OSR	Oversampling Ratio
PWM	Pulse Width Modulation
SNR	Signal-Noise Ratio

Delta-Sigma Analog-to-Digital Converter (DSADC)**30.1 Introduction and Basic Structure**

The Delta-Sigma Analog to Digital Converter module of the TC26x B-Step provides several channels with a main and an auxiliary demodulator including configurable filters for decimation (see [Figure 30-2](#)).

The on-chip buffered 3rd order modulator converts an analog input signal to a datastream.

The main chain of digital filters builds the demodulator which produces result values at a configurable output rate. The elements of the filter chain can be selected according to the requirements of the application. The filter chain configuration determines the attenuation and delay properties of the filter. The decimation at a configurable rate reduces the input sampling rate to a lower result data rate.

The configurable CIC filter provides the basic filtering and decimation with a selectable decimation rate.

Two FIR filters, each with a decimation rate of 2, allow effective signal shaping by attenuating the upper frequencies of the signal spectrum.

The high-pass filter provides offset compensation by removing the DC component of the input signal.

The integrator accumulates a configurable amount of result values. The number of samples is programmable or can be controlled by a hardware signal. This function supports resolver applications to get the baseband signal for the motor position calculation. Furthermore, the integrator can be also used in shunt current measurement applications.

A smaller but quicker parallel auxiliary filter with a comparator supports limit checking, e.g. for overcurrent detection. Two limit values can be defined to restrict the generation of service requests to result values within a configurable area. This saves CPU performance and/or DMA bandwidth.

A carrier signal can be generated to support resolver applications.

The on-chip carrier signal generator produces a selectable output signal (sine, triangle, rectangle) which can be used to drive a resolver. Synchronization of each input signal to the carrier signal ensures correct integration of the resolver input signals.

Service requests can be generated to trigger DMA transfers or to request CPU service.

The basic module clock f_{DSD} is connected to the system clock signal f_{SPB} .

Delta-Sigma Analog-to-Digital Converter (DSADC)

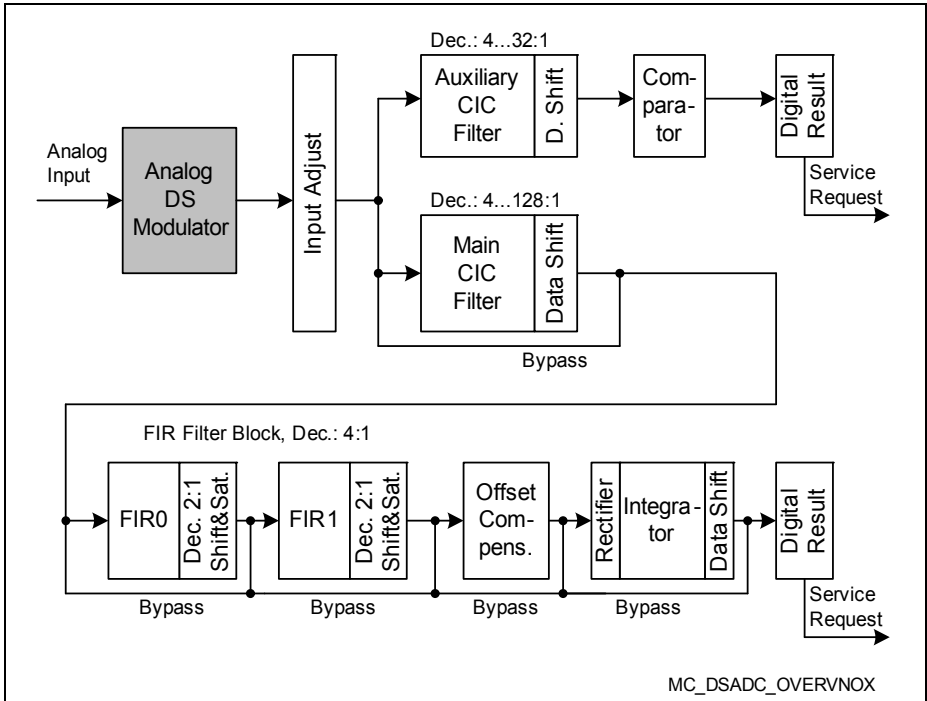

Figure 30-2 DSADC Structure Overview

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.2 Configuration of General Functions

Several parameters can be configured to adapt the functionality of the DSADC to the requirements of the actual application (see [Section 30.2.4](#)).

30.2.1 Module Identification

The module identification register indicates the version of the DSADC module that is used in the TC26x B-Step.

ID

Module Identification Register (0008_H) **Reset Value: 00C6 C0XX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Indicates the revision number of the implementation. This information depends on the design step.
MOD_TYPE	[15:8]	r	Module Type This internal marker is fixed to C0 _H .
MOD_NUMBER	[31:16]	r	Module Number Indicates the module identification number (00C6 _H = DSADC)

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.2.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register **CLC** controls the module clock signal and the reactivity to the sleep signal.

CLC
Clock Control Register (0000_H) Reset Value: 0000 0003_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B On request: enable the module clock 1 _B Off request: stop the module clock
DISS	1	r	Module Disable Status Bit 0 _B Module clock is enabled 1 _B Off: module is not clocked
0	2	r	Reserved, write 0, read as 0
EDIS	3	rw	Sleep Mode Enable Control Used to control module's reaction to sleep mode. 0 _B Sleep mode request is enabled and functional 1 _B Module disregards the sleep mode control signal
0	[31:4]	r	Reserved, write 0, read as 0

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

Delta-Sigma Analog-to-Digital Converter (DSADC)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status Register (0028_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	[31:30]	r	Reserved, write 0, read as 0

Delta-Sigma Analog-to-Digital Converter (DSADC)

Note: Register OCS is cleared by a Debug Reset. While OCDS is disabled, OCS is reset with each system reset. A system reset has no effect while OCDS is enabled. Write access requires supervisor mode.

Delta-Sigma Analog-to-Digital Converter (DSADC)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on-chip bus master TAG IDs 00 0000_B to 01 1111_B (see On-Chip Bus chapter for the mapping of product TAG ID <-> master peripheral). Register ACCEN0 provides one enable bit for each possible TAG ID encoding.

Register ACCEN0 itself is protected by the Safety Endinit feature.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00 0000_B, EN1 -> TAG ID 00 0001_B, ..., EN31 -> TAG ID 01 1111_B (TAG IDs 1X XXXX_B are not used).

1) The Access Enable functionality controls only write transactions to registers CLC, OCS, KRSTx, and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Delta-Sigma Analog-to-Digital Converter (DSADC)

Individual Module Reset

The Kernel Reset Registers **KRST0/KRST1** are used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits in both Kernel Reset Registers. The RST bits will be cleared by the BPI with the end of the BPI kernel reset sequence.

Note: A module kernel reset does not reset registers that do not belong to the module kernel: CLC, OCS, ACCEN0 and, of course, the KRST registers.*

Kernel Reset Registers 0 and 1 each include bit RST. To trigger a module reset, both RST bits must be set. They will be cleared automatically with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set in the same clock cycle the RST bit is cleared. This bit indicates that a kernel reset was processed. Bit RSTSTAT can be cleared by setting bit CLR in register **KRSTCLR**.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0 (0034_H) Reset Value: 0000 0000_H

30.2.3 Register Access Control

Several protection schemes are provided to prevent unintended write access to control bitfields of the DSADC.

- The registers of the DSADC are protected by the general access control mechanism that is configured by register **ACCEN0**.
- A specific register access control scheme provides a versatile protection scheme against unintended corruption of register contents. Register ACCPROT allows the restriction of write accesses for several groups of registers. The registers to be protected can be selected by the user. The table below lists the registers that belong to each register group.
Register ACCPROT itself is protected by the Safety Endinit feature.
- Groups of bitfields within a register may also be protected by an associated write control bit. This write control bit (xxWC) must be written with 1 along with the write access to the intended bitfield(s).

30.2.4 Global Configuration Registers

The global configuration register GLOBCFG selects the source for the internal clock signal which can be used to drive the modulators.

It also selects internal measurement modes.

The global run control register GLOBRC controls the general operation of the available channels.

GLOBCFG

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.3 Input Channel Configuration

The input data for a channel is obtained from the on-chip modulator.

The on-chip modulator can directly convert a differential or single-ended input signal to an input data stream. The performance can be increased by connecting two modulators to a pair. In this case, one of the two channels operates in 4th order mode while the other one operates in 2nd order mode.

The on-chip modulator runs on an internal clock.

The figure below summarizes the data path through the on-chip modulator.

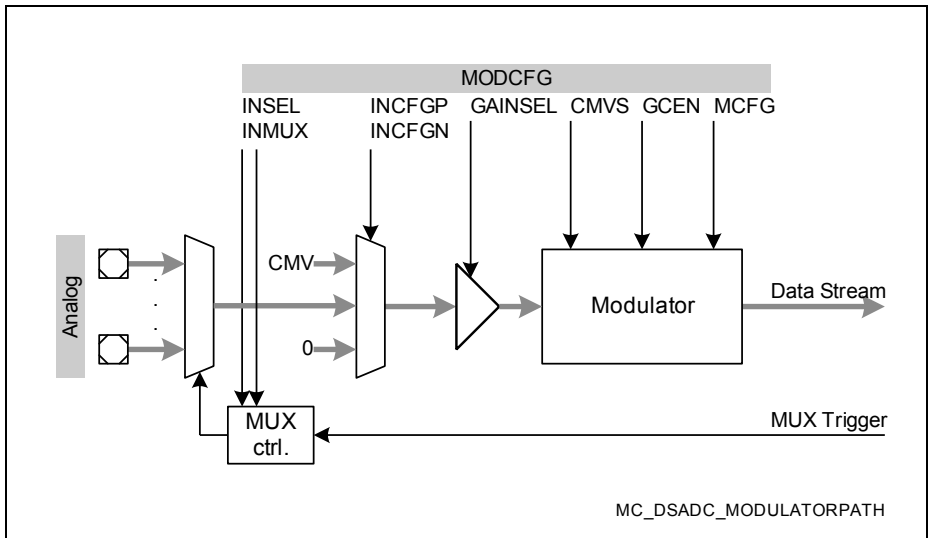

Figure 30-3 Analog Input Path

Delta-Sigma Analog-to-Digital Converter (DSADC)

The modulator clock can be generated in different ways:

- The modulator clock is derived on-chip from the internal clock f_{CLK} (module clock, ERAY PLL clock, oscillator clock).
- The internal clock (f_{CLK}) is also used for the on-chip modulators and for the carrier generator. To ensure a stable modulator clock, it can optionally be derived from the FlexRay clock or directly from oscillator OSC0.
- The used modulator clock also drives the on-chip carrier generator. This enables synchronous operation of carrier generator and integrator.

A trigger signal can be input from a selectable input. These inputs are connected to on-chip peripherals or to pins (see [Section 30.11.4](#)). This trigger signal can be used for different purposes:

- Integration trigger:
The external signal defines the integration window, i.e. the timespan during which result values are integrated.
- Timestamp trigger:
The external signal requests the actualization of the timestamp register.
- Input multiplexer trigger:
The external signal requests the switching of the analog input multiplexer to the next lower input or to the defined start value, respectively.
- Modulator run gate:
The on-chip modulator can be controlled by an external gate signal while it is enabled. In this case it can be disabled temporarily to save power.
- Service request gate:
Service requests for the main filter chain can be restricted to the high or low times of the selected trigger signal.

Note: To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

The figure below summarizes these three signal paths and indicates the source of the corresponding control information.

Delta-Sigma Analog-to-Digital Converter (DSADC)

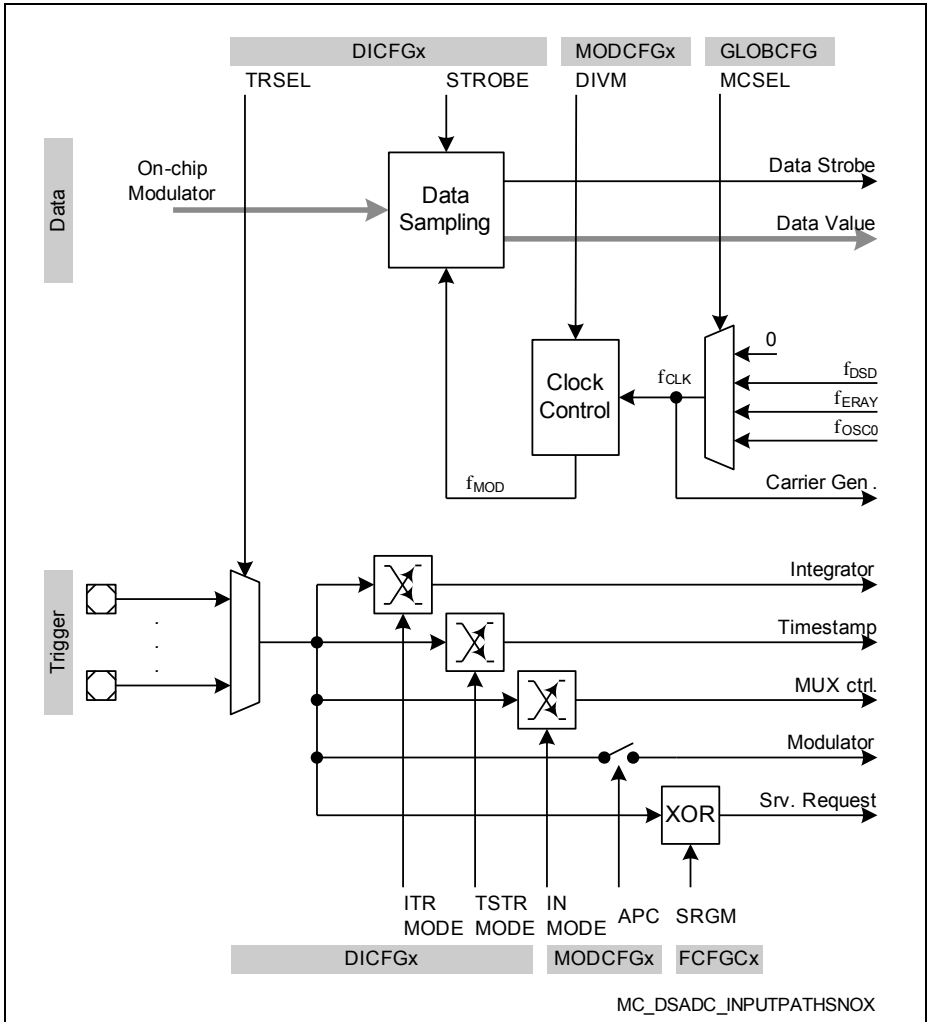

Figure 30-4 Input Path Summary

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.3.1 Modulator Clock Selection and Generation

The modulator clock signal is generated on-chip by a programmable prescaler. The on-chip clock signal is enabled by bitfield MCSEL.

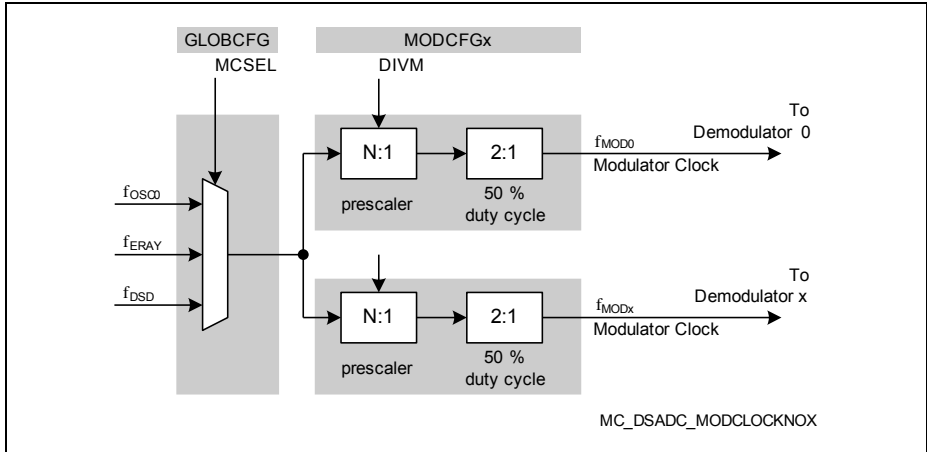

Figure 30-5 Modulator Clock Configuration

The selected clock source (f_{CLK}) is synchronized to the module clock. A configurable edge detector selects the clock signal edges that generate the data strobes which read the next input data and trigger the demodulator (see [Figure 30-6](#)).

Bitfield CSRC in register **DICFGx** ($x = 0, 2, 3$) selects the clock source for each channel. Bitfield STROBE selects the clocking mode, i.e. the clock edges that put a new input data sample into the filter chain.

Delta-Sigma Analog-to-Digital Converter (DSADC)

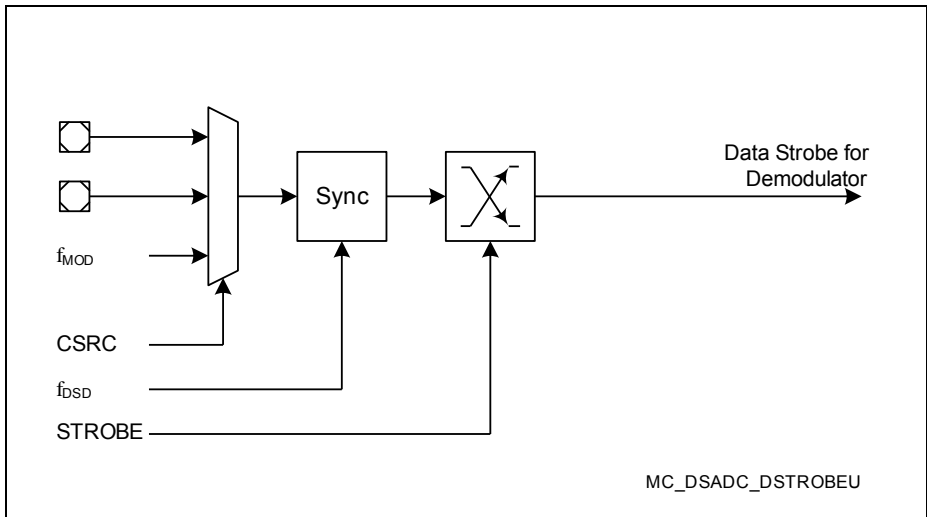

Figure 30-6 Demodulator Data Strobe Selection

Note: The modulator frequency can be selected for each channel separately. To avoid errors caused by cross-coupling, it is recommended to run the on-chip modulator at the same modulator frequency. Using frequencies with a ratio of 2:1 is a compromise.

30.3.2 Input Data Selection

The data stream is generated by the on-chip modulator and is converted to the CIC filter's input format.

Delta-Sigma Analog-to-Digital Converter (DSADC)

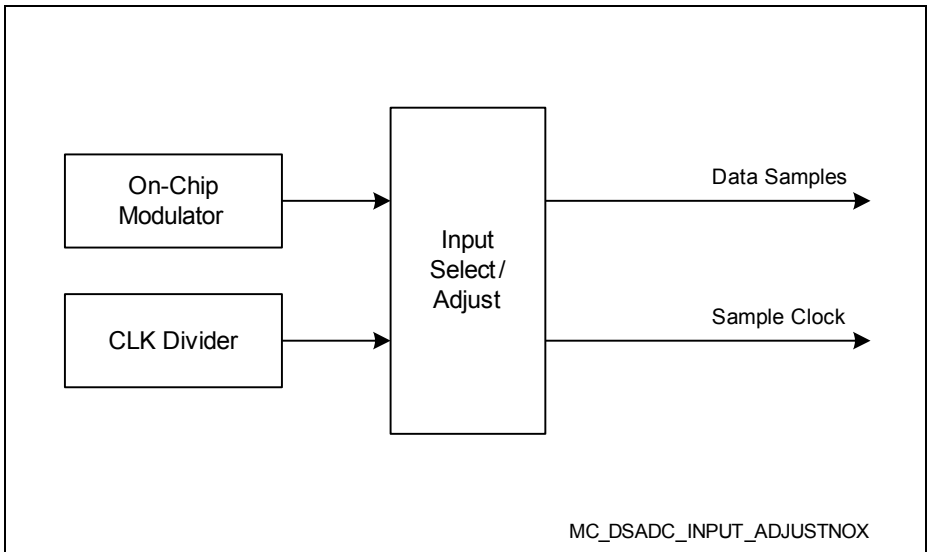

Figure 30-7 Input Control Unit

All options are configured by the demodulator input configuration register **DICFGx (x = 0, 2, 3)**.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.3.3 On-Chip Modulator

The on-chip modulator operates at a frequency range of 10 MHz to 20 MHz. This sample frequency is derived from the actual module frequency (see [“Modulator Clock Selection and Generation” on Page 30-24](#)).

The analog input signal is fed to the sample stage via input resistors and a differential input buffer. This buffer can also operate in single-ended mode with the input signal fed to one input and the other input internally grounded.

Analog input multiplexers connect the input buffer to different pins. Section [“Product-Specific Configuration” on Page 30-85](#) details the available inputs. The input multiplexers are controlled by register [MODCFGx \(x = 0, 2, 3\)](#).

The gain factor of the input stage can be programmed to 1, 2, 4, 8, 16. Three common mode voltages can be selected.

Note: The buffer's feedback path mirrors the selected common mode voltage permanently to the analog signal source through the input resistors.

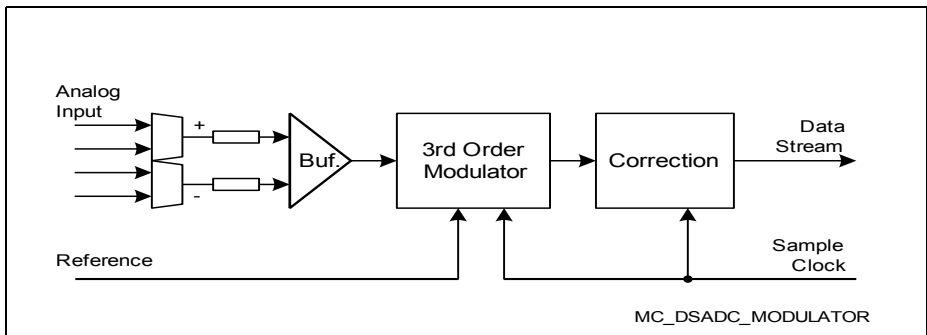

Figure 30-8 Structure of the On-Chip Modulator

Offset correction and gain correction improve the performance of the modulator. Offset measurement mode can be enabled (both inputs to V_{CM} via bitfields INCFGP and INCFGN in register [MODCFGx \(x = 0, 2, 3\)](#)) during the initialization phase and also during operation, e.g. to compensate temperature drift. The measured offset value can be written to register OFFMx for automatic offset correction. Gain correction is accomplished by using a factory-provided compensation value (see [Section 30.3.7](#)).

Operating Modes

The on-chip modulator can run in standard performance mode or in high performance mode. High performance mode achieves the maximum specified SNR, while standard performance mode reduces the power consumption by approx. 2 mA per channel.

Delta-Sigma Analog-to-Digital Converter (DSADC)

The on-chip passive analog anti-alias filter can be enabled to precondition the input signals. The analog anti-alias filter has a typical 3-dB cutoff frequency of approx. 500 kHz.

Both functions are controlled by bitfield MCFG in register **MODCFGx (x = 0, 2, 3)**.

Power Reduction via External Run Control

To reduce the amount of power consumed by the modulator, the modulator can be controlled (enabled/disabled) by an external gate signal (see bit APC in register **MODCFGx (x = 0, 2, 3)**).

Whenever the modulator is enabled, either initially during initialization or repeatedly via automatic power control, it needs a settling time of approx. 1 μ s before delivering proper data.

Make sure to include this settling time in the on-off cycles of the gate signal.

Internal Dithering

Static or low-frequency input signals can generate so-called idle tones which could degrade the SNR. The internal dithering avoids this phenomenon. Internal dithering is enabled by default, see bits DIIEN in register **ICCFGx (x = 0, 2, 3)**.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.3.4 Input Path Control

The input for the DSADC is fed through several stages before being evaluated and filtered. Registers MODCFGx and DICFGx select the available options for these signal stages.

The following features can be configured:

- Signal input pin selection
- Configuration of input buffer and on-chip modulator
- Modulator clock source and/or frequency
- Trigger input pin selection

Signal Input Pin Selection

Some modulator inputs provide analog input multiplexers which connect them to several input pins. These input multiplexers can be controlled directly by software or can be switched triggered by an external control signal. Software selects the desired position via bitfield INSEL, bitfield INMUX indicates the actual setting of the input multiplexer. Bitfield INMODE defines the condition for a trigger event, bitfield INMAC selects the way in which the multiplexer is controlled:

- Software control:
Control bitfield INMUX follows bitfield INSEL, software directly selects the intended input pins.
- Preset mode:
The (software-written) value in bitfield INSEL is copied to bitfield INMUX upon a trigger event. Software can preselect the next intended multiplexer setting which then becomes active when the next trigger event occurs.
- Single-step mode:
Bitfield INMUX is decremented upon each trigger event. If $INMUX = 00_B$ when the trigger occurs, it is loaded from bitfield INSEL instead. In this mode, a predefined sequence of input pins can be scanned automatically.

The trigger signal itself is selected by bitfield TRSEL in register **DICFGx (x = 0, 2, 3)**.

Note: Not all channels provide input multiplexers. Also, the width of the input multiplexers may differ from channel to channel.

*Refer to **“Product-Specific Configuration” on Page 30-85** for a description of the available input paths.*

Delta-Sigma Analog-to-Digital Converter (DSADC)

The modulator configuration register selects the operation mode of the on-chip modulator:

- Input line clamping
- Gain factor of input signal path
- Modulator operating mode
- Divider factor for modulator clock

1) The integration trigger mode controls bit INTEN in register **IWCTR_x** (**x = 0, 2, 3**) and hence the operation of the integrator:

Bit INTEN is set when the selected trigger signal transition occurs (INTEN remains 1 while ITRMODE = 11_B). Bit INTEN is cleared when the inverse trigger signal transition occurs or when the repeat counter expires (INTEN remains 0 while ITRMODE = 00_B). Refer to [“Integrator Stage” on Page 30-54](#) for more information.

2) The timestamp trigger mode controls capturing the timestamp information to register **TSTMP_x** (**x = 0, 2, 3**).

3) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.3.5 Common Mode Voltage

The common mode voltage V_{CM} is derived from the analog reference voltage V_{AREF} . The relational factor, i.e. the V_{CM} level, is selected by bitfield CMVS in register **MODCFGx (x = 0, 2, 3)**.

The optimum choice depends on the application. It is recommended to select $V_{CM} = V_{AREF}/2.27$ to achieve best results for SNR/SFDR. For passive signal sources, the maximum signal amplitude is limited then.

Passive Signal Sources

For passive signal sources the common mode voltage defines the center of the signal range. To avoid non-linearities at the top of the input voltage range, a lower common mode voltage can be selected. This depends on the range of the actual input signal.

For $V_{DDM} = 3.3\text{ V}$, the modulator is supplied directly by the external voltage (bit LOSUP must be set, see **Section 30.2.4**).

For $V_{DDM} = 5.0\text{ V}$, the modulator is supplied by an on-chip regulator.

Active Signal Sources

If the differential signal source itself generates the common mode voltage, there might be a difference between the external and the internal common mode voltage. This voltage difference leads to currents through the external and internal circuitry. An asymmetry of this circuitry can generate an additional gain error.

To limit this effect, select the common mode voltage according to the signal source. The maximum input voltage range depends on the selected common mode voltage.

For single-ended signals the common mode voltage generates an additional error that can be compensated by software (see **“Correction for Single-Ended Operation” on Page 30-45**).

30.3.6 Common Mode Hold Voltage

The input channel's common mode voltage is connected to an input pin while this pin is used for the conversions. It is disconnected from the common mode voltage when

- the modulator is inactive, e.g. when using the automatic power control feature
- the input path is disconnected during calibration phases
- the pin is not currently selected via the analog input multiplexer

Pins that are intended to be used for the DSADC can be connected to the common mode hold voltage V_{CMH} under these circumstances. The connection to the common mode hold voltage ensures that the sensor input does not float away while the respective input line is disconnected.

Registers GLOBVCMH0/GLOBVCMH1/GLOBVCMH2 select the connection to V_{CMH} for each of the possible input pins. Two nibbles are assigned to each channel (positive and

Delta-Sigma Analog-to-Digital Converter (DSADC)

negative inputs) and contain the control bits for each possible input of the respective channel.

Note: Enabling the common mode hold voltage source (GLOBVCMH2.ON = 1) eliminates crosscoupling between inputs of analog input multiplexers.

Bitfield GLOBVCMH2.VCMHS selects the level of the applied common mode hold voltage. The correct setting depends on the available supply voltage and the intended input voltage.

Note: The available channels provide different numbers of input pins. For a summary, refer to “Product-Specific Configuration” on Page 30-85. Only those bits in GLOBVCMHn are valid that correspond to an existing input pin.

A pin is connected to the common mode hold voltage when:

- The common mode hold voltage is selected for this pin (GLOBVCMHn.INxPVCy = 1 or GLOBVCMHn.INxNVCy = 1)
- *AND*
 - The respective pin is not currently connected to the channel (MODCFGx.INMUX)
 - *OR* the respective modulator is disabled (in powerdown)

A pin is disconnected from the common mode hold voltage in other cases.

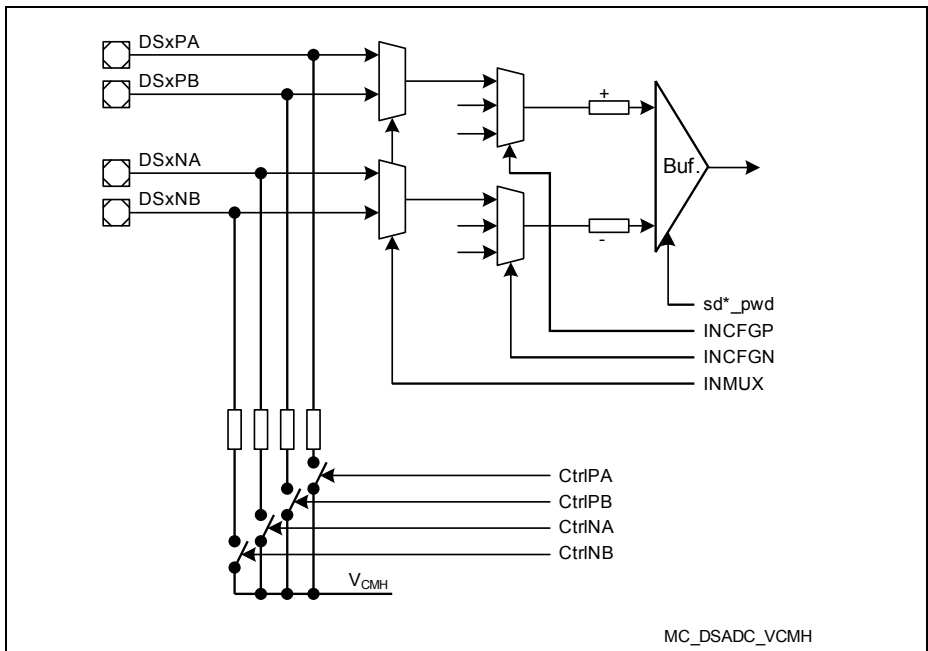

Figure 30-9 Control of VCMH Switches

Delta-Sigma Analog-to-Digital Converter (DSADC)

The common mode hold voltage registers select which input pins are connected to the common mode hold voltage while they are not used for conversions, and which common mode hold voltage is generated:

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.3.7 Calibration Support

The performance of the DSADC can be improved by applying some calibration techniques. Several possibilities are provided:

- Offset compensation can automatically remove the DC component of an AC signal. This is done by the offset compensation filter.
- Offset calibration compensates shifted result values by using results from zero-input measurements.
- Gain calibration uses a calibration factor which is obtained from actual measurements and stored device-specific correction values. The application can multiply the result values by this factor.
- Gain adjustment compensates the variation of the input resistors with stored device-specific correction values.

Note: To compensate temperature effects it is recommended to repeat the calibration sequence when the device temperature has changed by approximately 20 °C.

Offset Calibration Support

The input structures of a channel can shift the input voltage which causes an offset error. This can be compensated by determining the shift by measuring a zero-input. This is done by connecting both input lines to the same signal, e.g. the internal common mode voltage:

- Select the same voltage for both differential input lines (MODCFGx.INCFGP = MODCFGx.INCFGN)
 - For differential operation, select common mode voltage (INCFGP/N = 10_B)
 - For single-ended operation, select reference ground (INCFGP/N = 11_B)
- Calculate the average value from a set of measurements (exclude values that differ more than 10% from the mean value)
- Store the calculated average value in register **OFFMx (x = 0, 2, 3)**

Note: Disable the offset compensation filter for this measurement (FCFGMx.OCEN = 0).

Gain Calibration Support

The overall accuracy can be improved by correcting the specific gain error of a channel via software. This is done by multiplying the result values by a specific gain calibration factor.

Gain calibration is based on a high-precision squarewave generator that generates a reference signal ($V_{\text{AREF}} / 10$) for gain factor measurements. Alternatively, the reference voltage V_{AREF} can be directly selected for a full-scale calibration with an analog gain factor 1.

The digital gain calibration factor (DGCF) for a channel (CHNr) is calculated from the device-specific square wave amplitudes stored in the user Flash area (ASQ) and the actual square wave amplitude value AM measured in the application:

Delta-Sigma Analog-to-Digital Converter (DSADC)

DGCF = (ASQ / 20) / AM [mV] (ASQ is given in steps of 50 μ V).

The actual digital gain correction factor is determined by executing the following sequence:

- Select the intended operating configuration: modulator frequency, decimation rate, data shifter setting, etc.
- Configure the intended (analog) gain factor (MODCFGx.GAINSEL)
Note: Select factors 1...8 (500 mV \times factor 16 leads to overload)
- Select an internal voltage (e.g. MODCFGx.INCFGP = MODCFGx.INCFGN = 01_B, V_{AREF})
- Enable gain calibration mode (MODCFGx.GCEN = 1)
This disconnects the input pins¹⁾ and connects the channel input to an internal square wave signal source with an amplitude of nominally $V_{AREF} / 10$ (exact voltage stored in UCB_IFX) and a frequency of $f_{MOD} / 8192$.
- Determine the actual amplitude by converting the high level and the low level of the square wave signal. Result = AM.
 - Read a sequence of result values.²⁾
 - Ignore the values close to the signal transitions to exclude the overshoots/undershoots caused by the Gibbs phenomenon (see [Figure 30-10](#)).
 - Average the high values and the low values to eliminate noise from this measurement, the difference is the measured amplitude value AM.
- Compute the digital gain calibration factor by dividing the device-specific amplitude by the converted amplitude value:
DGCF [mV/LSB] = (ASQ / 20) / AM.

Note: ASQ is determined with $V_{AREF} = 5.00$ V. If a different reference voltage is used in the application, the full scale value must be scaled accordingly ($V_{AREF} / 5.00$ V).

The result value range for a full-scale input (e.g. ± 5.0 V for an analog gain factor of 1) is, therefore, $AFS = \pm(V_{AREF} / DGCF) = \pm(5\,000 \times AM \times 20 / ASQ)^3$.

Note: Gain calibration can be executed for both modulators of a twin at the same time. It is recommended to use the same modulator frequency in this case.

1) Selecting a pin instead of the internal voltage (INCFGP/INCFGN = 00_B) will connect the square wave signal to the respective pin. In an application this usually must be avoided.

2) The number of result values per period depends on the configured decimation rate. For example, at a decimation rate of 64, 128 values (8192 / 64) cover one period of the square wave signal.

3) Assuming a reference voltage of $V_{AREF} = 5.00$ V. AFS = full-scale amplitude value.

Delta-Sigma Analog-to-Digital Converter (DSADC)

Figure 30-10 Gain Calibration Measurement
Alternate Gain Calibration

For an analog gain factor of 1, the actual digital gain correction factor is alternatively determined by executing the following sequence:

- Select the intended operating configuration: modulator frequency, decimation rate, data shifter setting, etc.
- Select the internal reference voltages as inputs
(MODCFGx.INCFGP = 01_B: V_{AREF}, MODCFGx.INCFGN = 11_B: V_{AGND})
- Determine the actual full-scale value by converting the reference voltage. Average a sequence of values to eliminate noise from this measurement. Result = AM.¹⁾
- Compute the digital gain calibration factor by dividing the full-scale amplitude by the converted full-scale value:
DGCF [mV/LSB] = V_{AREF} / AM = 5 000 / AM.²⁾

The gain calibration sequence must be executed after each startup.

Using the Calibration Values

The offset calibration value is written into **OFFMx (x = 0, 2, 3)** and is subtracted automatically.

With the gain calibration factor the input amplitude A_{IN} can now be computed from the digital result value A_{IN} as:

$$A_{IN} = A_{IN} \times DGCF.$$

The full-range result value is AFS = ±(V_{AREF} / DGCF).

1) Offset calibration must be done before executing this measurement.

2) Assuming a reference voltage of V_{AREF} = 5.00 V.

Delta-Sigma Analog-to-Digital Converter (DSADC)
Gain Adjustment

The input resistors of a channel can cause an additional gain error due to the variation of their values. The actual value of the input resistors is measured during production test. The device-specific 16-bit gain adjustment values (RIN) are stored in the user Flash area (UCB_IFX) at offset $84_H + 8 \times \text{CHNr}$. The respective value of R_{IN} ($R_{IN} [\text{kOhm}] = \text{RIN} / 100$) can then be used together with the sensor impedance to calculate more accurate results.

The actual input resistance depends on the chip temperature. Therefore, RIN calibration values in the user Flash are stored for two temperatures (HOT and COLD). To increase the precision for this parameter, use these values in the following way:

- Compute the linear interpolation factor FLIN:

$$\text{FLIN} = (\text{RIN_COLD} - \text{RIN_HOT}) / (T_{\text{HOT}} - T_{\text{COLD}})$$
- Compute the temperature deviation DT:

$$\text{DT} = T_{\text{HOT}} - T_{\text{ACTUAL}}$$
- Compute the actual resistance value R_{IN} :

$$R_{IN} = (\text{RIN_HOT} + \text{DT} \times \text{FLIN} \times 0.1 + \text{DT}^2 \times \text{FLIN} \times 0.005) / 100 [\text{kOhm}]$$

The temperature during the calibration sequence (T_{ACTUAL}) can be measured via the on-chip die temperature sensor (DTS) or can be estimated according to a known operating condition of the application.

Note: These values are generated at $T_{\text{COLD}} = -40^\circ\text{C}$ and $T_{\text{HOT}} = +125^\circ\text{C}$.

Delta-Sigma Analog-to-Digital Converter (DSADC)

Correction for Single-Ended Operation

The built-in calibration support is optimized for differential operation. Single-ended operation incurs an asymmetry caused by the external circuitry (only attached to one input pin, see R_{EXT} in [Figure 30-11](#)). An additional compensation factor can be calculated from the different resistances present in the analog input path:

R_{FL} = Resistance of the feedback loop

R_{CM} = Resistance of the common mode voltage path

R_{AIN} = Resistance of the analog input line

R_{EXT} = Resistance of the external circuitry.

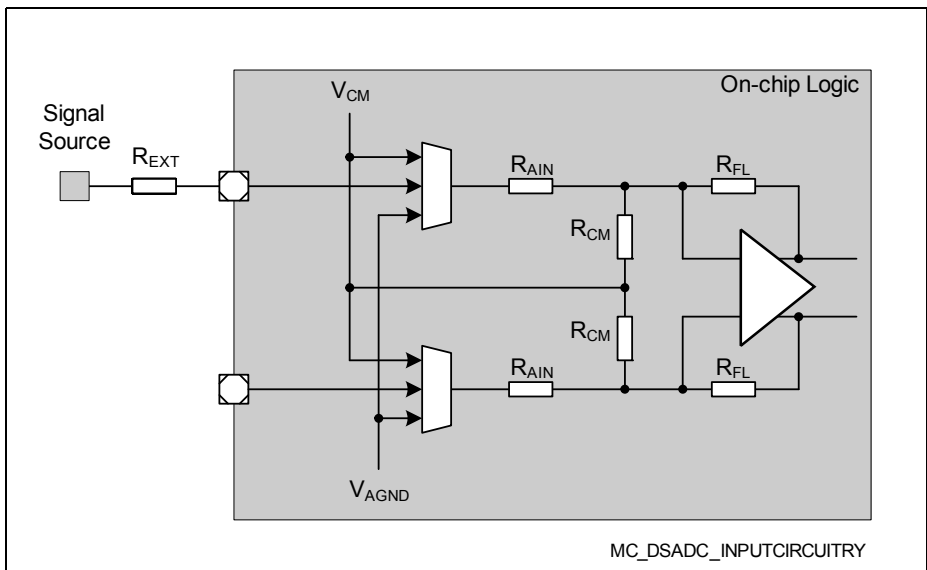

Figure 30-11 Overview of the Input Circuitry of a Channel

Note: This description assumes the sensor signal to be connected to the positive input and the negative input to be grounded internally.

General Algorithm for Resistances of $R_{EXT} \leq 10$ kOhm:

- Calculate auxiliary resistance values:

$$\text{Equivalent input path resistance: } R_{Aequ} = R_{AIN} + R_{EXT} / 2$$

$$\text{Equivalent common mode resistance: } R_{Cequ} = R_{AIN} \times 0.110553$$

- Calculate auxiliary common mode voltage values:

$$\text{Equivalent for low input: } V_{CML} = V_{CM} \times R_{AIN} / (R_{AIN} + R_{Cequ}) = V_{CM} \times 0.900452$$

$$\text{Equivalent for high input: } V_{CMH} = V_{CM} + (V_{AREF} / 2 - V_{CM}) \times R_{Cequ} / (R_{Cequ} + R_{Aequ})$$

Delta-Sigma Analog-to-Digital Converter (DSADC)

- Determine the additional offset value based on the full-scale value

$$\text{OFFS} = \text{AFS} \times (R_{\text{EXT}} / R_{\text{Aequ}}) \times (V_{\text{CML}} / V_{\text{AREF}})$$
 This additional offset value can be added to the value in register OFFMx.
- Determine the additional gain factor based on the various resistances

$$\text{GFS} = R_{\text{Aequ}} / \{R_{\text{AIN}} \times [1 - (R_{\text{EXT}} / R_{\text{Aequ}}) \times (0.5 - V_{\text{CMH}}/V_{\text{AREF}} + V_{\text{CML}}/V_{\text{AREF}})]\}$$
 This additional gain factor can be multiplied with the existing factor DGCF

Note: Using on-chip paths (e.g. the internal grounding of an input line) may incur an inaccuracy due to voltage drops over the on-chip paths.

Example for $R_{\text{AIN}} = 131 \text{ k}\Omega$, $R_{\text{EXT}} = 10 \text{ k}\Omega$, $V_{\text{CM}} = V_{\text{AREF}} / 2.27$, $V_{\text{AREF}} = 5.0 \text{ V}$:

- $R_{\text{Aequ}} = R_{\text{AIN}} + R_{\text{EXT}} / 2 = 131 \text{ k}\Omega + 10 \text{ k}\Omega / 2 = 136 \text{ k}\Omega$
- $R_{\text{Cequ}} = R_{\text{AIN}} \times 0.110553 = 131 \text{ k}\Omega \times 0.110553 = 14.48 \text{ k}\Omega$
- $V_{\text{CML}} = V_{\text{CM}} \times 0.900452 = V_{\text{AREF}} \times 0.396675$
- $V_{\text{CMH}} = V_{\text{CM}} + (V_{\text{AREF}} / 2 - V_{\text{CM}}) \times R_{\text{Cequ}} / (R_{\text{Cequ}} + R_{\text{Aequ}})$
 $= V_{\text{AREF}} / 2.27 + (V_{\text{AREF}} / 2 - V_{\text{AREF}} / 2.27) \times R_{\text{Cequ}} / (R_{\text{Cequ}} + R_{\text{Aequ}})$
 $= 2.202643 \text{ V} + 0.297357 \text{ V} \times 14.48 \text{ k}\Omega / 150.48 \text{ k}\Omega$
 $= 2.231256 \text{ V}$
- $\text{OFFS} = \text{AFS} \times (R_{\text{EXT}} / R_{\text{Aequ}}) \times (V_{\text{CML}} / V_{\text{AREF}})$
 $= \text{AFS} \times 0.029167$
- $\text{GFS} = R_{\text{Aequ}} / \{R_{\text{AIN}} \times [1 - (R_{\text{EXT}} / R_{\text{Aequ}}) \times (0.5 - V_{\text{CMH}}/V_{\text{AREF}} + V_{\text{CML}}/V_{\text{AREF}})]\}$
 $= 136 \text{ k}\Omega / \{131 \text{ k}\Omega \times [1 - 0.073529 \times (0.5 - 0.446251 + 0.396675)]\}$
 $= 136 \text{ k}\Omega / (131 \text{ k}\Omega \times 0.966881)$
 $= 1.073729$

Simplified Algorithm for Resistances of $R_{\text{EXT}} \leq 1 \text{ k}\Omega$:

- Determine the additional offset value based on the full-scale value

$$\text{OFFS} = \text{AFS} \times [R_{\text{EXT}} / (2 \times R_{\text{AIN}} + R_{\text{EXT}})]$$
 This additional offset value can be added to the value in register OFFMx.
- Determine the additional gain factor based on the various resistances

$$\text{GFS} = (R_{\text{AIN}} + R_{\text{EXT}}/2) / [R_{\text{AIN}} \times (1 - R_{\text{EXT}} / 2 \times R_{\text{AIN}})]$$
 This additional gain factor can be multiplied with the existing factor DGCF

Example for $R_{\text{AIN}} = 131 \text{ k}\Omega$, $R_{\text{EXT}} = 1 \text{ k}\Omega$, $V_{\text{CM}} = V_{\text{AREF}} / 2.27$, $V_{\text{AREF}} = 5.0 \text{ V}$:

- $\text{OFFS} = \text{AFS} \times [R_{\text{EXT}} / (2 \times R_{\text{AIN}} + R_{\text{EXT}})]$
 $= \text{AFS} \times 0.003802$
- $\text{GFS} = (R_{\text{AIN}} + R_{\text{EXT}}/2) / [R_{\text{AIN}} \times (1 - R_{\text{EXT}} / 2 \times R_{\text{AIN}})]$
 $= 131.5 \text{ k}\Omega / (131 \text{ k}\Omega \times 0.996183)$
 $= 1.007266$

Delta-Sigma Analog-to-Digital Converter (DSADC)
Range Adaptation

The scaling factor to normalize the result values according to a given format (e.g. $\pm 32\,767$ or 1Q15) is then the relation of the format's limit value and the full scale result (e.g. the scaling factor is $32\,767 / AFS$).

The above calculations result in a gain calibration factor giving the input voltage in millivolts: DGCF [mV/LSB]. If another unit is required by the application, the range adaptation factor can be adjusted accordingly.

Stored Calibration Values

The device-specific calibration values are stored in the User Configuration Block (UCB_IFX) within the on-chip Flash memory. The area assigned to the DSADC begins at offset 80_H and provides records of 2 words per channel. The channel-specific records, therefore, can be read from offset $80_H + 8 \times CHNr$. The table below shows the structure of a record.

Table 30-3 Structure of DSADC Calibration Records

	Halfword 3	Halfword 2	Halfword 1	Halfword 0
Location CH0	86_H	84_H	82_H	80_H
Location CH1	$8E_H$	$8C_H$	$8A_H$	88_H
:	:	:	:	:
Stored value	RIN_HOT	RIN_COLD	Reserved	ASQ

The parameters are stored in the following format:

Resistance = $RIN_* \times 10 \text{ Ohm}$, i.e. $32C8_H = 130 \text{ kOhm}$.

Amplitude = $ASQ \times 50 \mu\text{V}$, i.e. $2710_H = 500 \text{ mV}$.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.4 Main Filter Chain

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio.

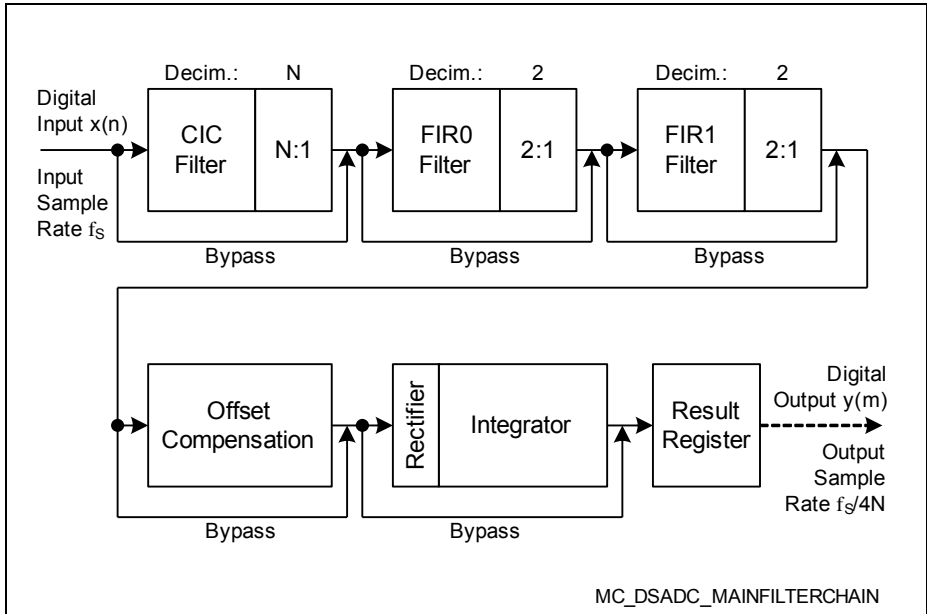

Figure 30-12 Structure of the Main Filter Chain

The elements of the filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application. This comprises the frequency attenuation as well as the total decimation rate.

Note: Only configure or reconfigure filter parameters while the channel is inactive. After the configuration, start the channel by setting the corresponding bit CHxRUN.

30.4.1 CIC Filter

The Cyclic Integrating Comb filter (CIC filter, a.k.a. SINC filter) is a simple but very efficient low-pass filter. Up to three comb filter stages can be cascaded to improve the frequency characteristics. The number of active filter stages can be selected (CIC1, CIC2, CIC3) to find the optimum tradeoff between delay and frequency characteristics.

In addition, a combined mode can be selected (CICF) which represents a compromise between a 2-stage and a 3-stage filter.

Delta-Sigma Analog-to-Digital Converter (DSADC)

To synchronize filters of different channels with fine granularity, the decimation counter starts from an arbitrary start value. This start value can be different from the decimation factor and is loaded only once when the counter is started.

The decimation counter is also restarted (i.e. loaded with the start value) when an integration starts (see [Section 30.4.4](#)).

The decimation factor can be selected in a wide range from 4 to 128.

Table 30-4 Data Shifter Position¹⁾ Dep. on Filter Mode and Decimation

Decimation	CIC1	CIC2	CIC3	CICF
4	17:2	19:4	21:6	20:5

1) * indicates a change. Input data width is 16 bits.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.4.2 FIR Filters

The FIR filter further attenuates the higher frequency bands that pass the CIC filter. This improves the overall frequency response of the main filter chain.

The FIR filter is realized as two subsequent FIR blocks. Each FIR filter block adds a decimation factor of 2, so the total decimation factor (i.e. the oversampling rate, including the CIC filter) is $4 \times N$.

A shift unit at the output of each block (see [Figure 30-13](#)) selects 16 bits from the filter block's output data. This selected portion (usually the upper 16 bits) is used for further processing. To reduce the clipping in case of known limited data values, the selected data portion can be moved down (1 bit after FIR0, up to 3 bits after FIR1). This effectively increases the gain. Bitfields FSH and DSH in register **FCFGMx (x = 0, 2, 3)** select the position of the data portions.

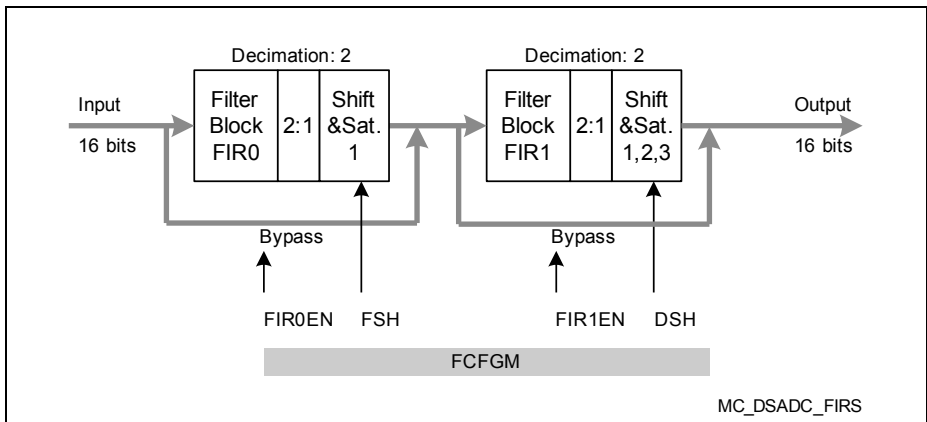

Figure 30-13 FIR Filter Blocks

If an FIR filter block is bypassed, the associated data shifter is also bypassed and its shift control has no effect.

The FIR filters can be described as:

$$y_1(m_1) = \sum_{i=0}^{N_1-1} a_1(i) x(2m_1 - i) \quad y(m) = \sum_{i=0}^{N_2-1} a_2(i) y_1(2m - i)$$

[Figure 30-14](#) shows the FIR filter structure. The first stage FIR has $N_1 = 8$ coefficients, and the second stage has $N_2 = 28$ coefficients.

Delta-Sigma Analog-to-Digital Converter (DSADC)

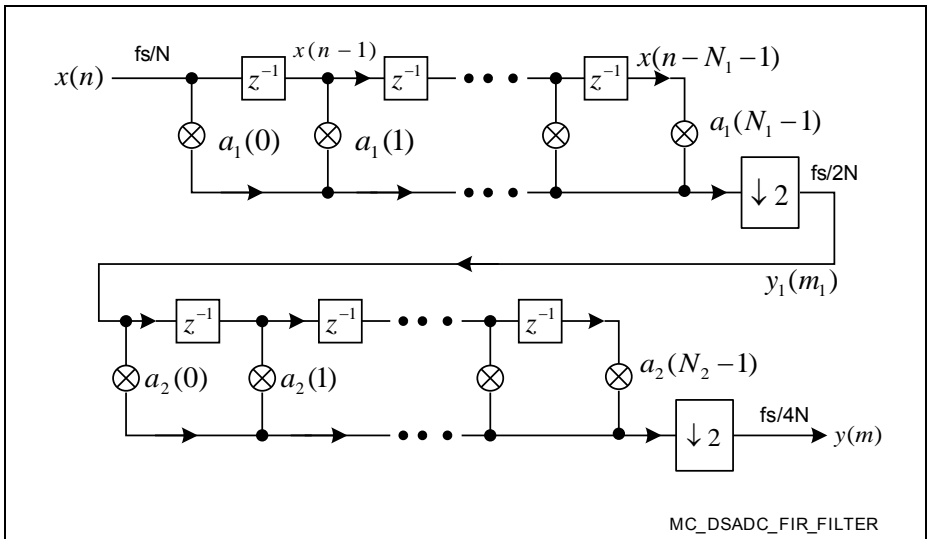

Figure 30-14 FIR Filter Structure

The coefficients of both FIR filters are fixed (see [Table 30-5](#) and [Table 30-6](#)). The filters are symmetric and have linear phase.

Table 30-5 Coefficients of FIR0

a0	a1	a2	a3	a4	a5	a6	a7
-17	-25	83	256	256	83	-25	-17

Table 30-6 Coefficients of FIR1

-3	-2	2	9	-1	-14	-8	19	25	-13	-55	-12	126	256

The resolution of the CIC filter does not represent the resolution of the Delta-Sigma converter. The resolution or the effective number of bits (ENOB) of the Delta-Sigma converter depends on the Signal to Noise Ratio (SNR) of the Delta-Sigma converter including modulator and decimation filter (CIC filter and FIR filter).

The maximum filter output value of a filter depends on the sum of absolute filter coefficients (762 for FIR0, 1090 for FIR1) and the input data width (15-bit + sign), resulting in 24 969 216 for FIR0 and 35 717 120 for FIR1. Therefore, the required data

Delta-Sigma Analog-to-Digital Converter (DSADC)

width of the filters is 26 bits for FIR0 and 27 bits for FIR1. To handle both filters with the same MAC unit, the data width shall be 27 bits + sign.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.4.3 Offset Compensation

The offset compensation stage is a high-pass filter that removes the DC component of the input signal, in particular in case of a differential input signal.

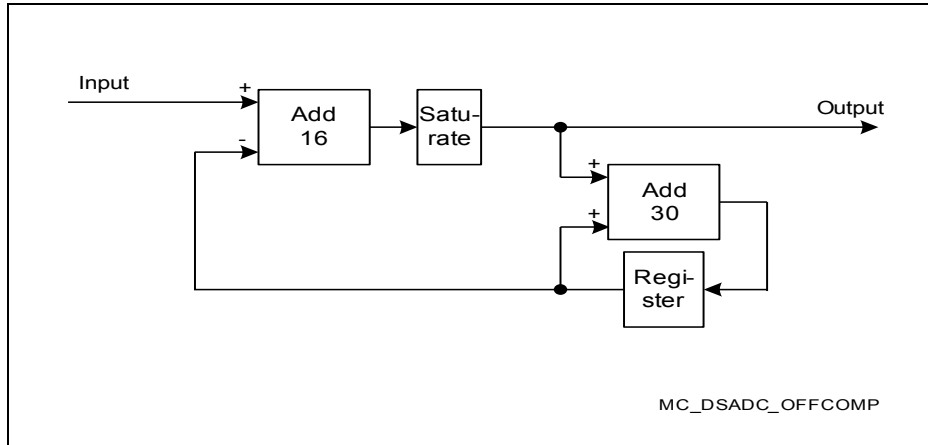

Figure 30-15 Offset Compensation

*Note: When using the offset compensation stage, clear the offset register (**OFFM_x** (**x = 0, 2, 3**)) to avoid over-compensation.*

When running the offset calibration, disable the offset compensation stage to avoid wrong measurements.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.4.4 Integrator Stage

The integrator integrates the result values generated during the defined integration window by adding a configurable number of values to build the final result value. The integration window can be started triggered by an internal or external signal.

A configurable number of values can automatically be discarded after the trigger before the integration window is started. This positions the integration window exactly into a timeframe where the filter is stable or where the signal to be measured is free of system-generated noise.

Integration can be used to measure currents through shunt resistors at defined positions in the signal waveform. It also can remove the carrier signal component in resolver applications. In this case, the values to be integrated can be rectified to yield the maximum amplitude of the receiver signal. The delay between the carrier signal (generated by the on-chip carrier generator) and the received position signals can be compensated automatically. Also refer to [Section 30.9](#).

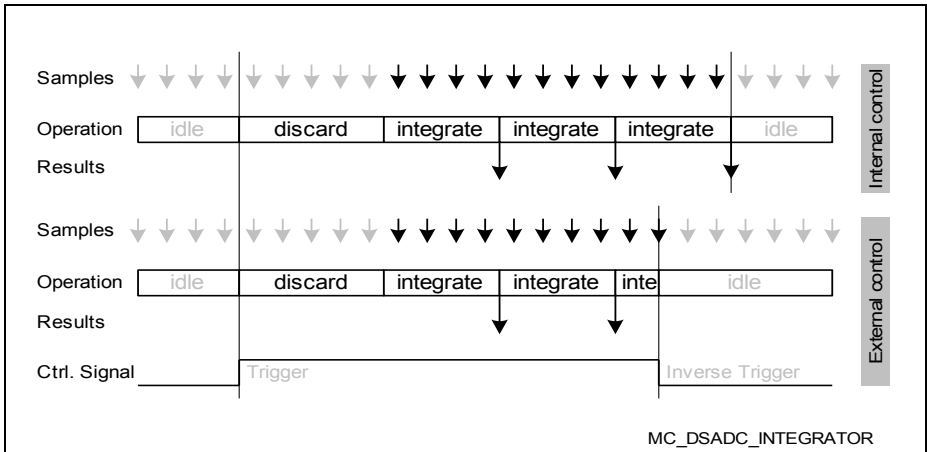

Figure 30-16 Integrator Operation

Note: The integrator can add up to 64 values, while enabled. Its output, therefore, is shifted by 6 bits (1d 64). This leads to reduced result magnitudes when less than 64 values are accumulated.

Delta-Sigma Analog-to-Digital Converter (DSADC)

Starting the Integration Window

The integration window starts when bit INTEN becomes 1:

- **Software-Controlled Mode:**
Select software-controlled integration mode by setting bitfield ITRMODE = 11_B
- **Trigger-Controlled Mode:**
Select trigger-controlled integration mode (ITRMODE = 01_B or 10_B)
and generate the selected trigger edge at the configured trigger input

The external integration trigger signal is selected by bitfield TRSEL in register **DICFGx** (**x = 0, 2, 3**). Bitfield ITRMODE selects the transition of the selected signal to generate the trigger event. Select the trigger source first before enabling it.

Also, the decimation counter of the CIC filter is restarted, i.e. loaded with its start value (see [Section 30.4.1](#)).

When the integration window is started (INTEN becomes 1) the integration counter starts counting. After <NVALDIS> values the counter is reset and the integrator is started (if NVALDIS is zero the integration starts immediately).

Executing Integration Cycles

During an integration cycle <NVALINT+1> input values are integrated. After that, the integration result is stored in the result register and the integrator and the counter are cleared. If bit INTEN = 1 the next integration cycle is started.

Stopping the Integration Window

The integration window stops when bit INTEN becomes 0:

- **Software-Controlled Mode:**
Disable software-controlled integration mode by setting bitfield ITRMODE = 00_B
- **Trigger-Controlled Mode:**
 - Internally controlled end-of-integration (IWS = 0, see upper part of [Figure 30-16](#)):
After <REPVAL+1> integration cycles INTEN is cleared and the integration window closes, after (<NVALINT+1> × <REPVAL+1>) input values
 - Externally controlled end-of-integration (IWS = 1, see lower part of [Figure 30-16](#)):
Generate the selected inverse trigger edge at the configured trigger input (ITRMODE = 01_B or 10_B)
 - Integration may also be stopped by software by setting bitfield ITRMODE = 00_B

Note: When the integration window is closed by an external signal (INTEN cleared by inverse trigger), the integrator and the counter are cleared also.

Delta-Sigma Analog-to-Digital Converter (DSADC)

IWCTR_x (x = 0, 2, 3)
Integration Window Control Register x

$$(x * 0100_H + 0120_H)$$

0	[31:30]	r	Reserved, write 0, read as 0

1) For the control of bit INTEN, see also bitfield ITRMODE in register **DICFGx (x = 0, 2, 3)**.

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.5 Auxiliary Filter

The parallel auxiliary filter uses a CIC filter for decimation, similar to the one used in the main filter chain. The decimation rate is restricted to 32. This also reduces the filter delay, so the auxiliary filter can be used to supervise the input signal and detect abnormal input values earlier than the main filter chain.

The subsequent comparator provides automatic limit checking by comparing each result to two configurable reference values. The comparator can generate a separate service request.

The two values are defined in the boundary select register and determine the valid result value band if limit checking is enabled.

Figure 30-17 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:

To select the lower part as valid band, set the lower boundary to the minimum value (8000_H) and set the upper boundary to the highest intended value.

To select the upper part as valid band, set the upper boundary to the maximum value ($7FFF_H$) and set the lower boundary to the lowest intended value.

The auxiliary filter can generate two types of output:

- Service requests, optionally restricted by the comparators
- Range signals, indicating when the results are above the upper limit (SAULx) or below the lower limit (SBLx)

Delta-Sigma Analog-to-Digital Converter (DSADC)

BOUNDSELx (x = 0, 2, 3)
Boundary Select Register x ($x * 0100_H + 0128_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
BOUNDARYL	[15:0]	rw	Lower Boundary Value for Limit Checking This (two's complement) value is compared to the results of the parallel filter.
BOUNDARYU	[31:16]	rw	Upper Boundary Value for Limit Checking This (two's complement) value is compared to the results of the parallel filter.

An alarm event can be generated when a new conversion result becomes available. Alarm events can be restricted to result values that are inside or outside a user-defined band (see **Figure 30-17**). This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain conditions. For example, an input value can be monitored and an alarm indicates a certain threshold.

Note: Limit checking uses the parallel auxiliary filter at a low decimation rate and, therefore, the alarm is generated earlier than the threshold values are seen at the output of the regular filter chain.

Alarm events can also be suppressed completely (see **FCFGAx (x = 0, 2, 3)**).

The range signals are generated independent of service requests.

Signal SAULx is active while the results are above the upper limit, signal SBLLx is active while the results are below the lower limit.

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.6 Filter Configuration and Control

Both filter chains (main and auxiliary) can be configured for the intended application. The following pages describe the available bitfields in the control registers, [Section 30.6.2](#) provides recommended settings to obtain best results.

Note: The main filter chain, of course, provides more configuration options than the auxiliary filter.

30.6.1 Filter Configuration Options

Both filter paths can be configured according to the requirements of the application. The stages of the main filter chain can be selected.

Delta-Sigma Analog-to-Digital Converter (DSADC)

Field	Bits	Type	Description
EGT	14	rw	Event Gating Defines if events for the auxiliary filter are coupled to the integration window. 0 _B Separate: generate events according to ESEL 1 _B Coupled: generate events only when the integrator is enabled and after the discard phase defined by bitfield NVALDIS ¹⁾
0	15	r	Reserved, write 0, read as 0
AFSC	[17:16]	rw	Auxiliary Filter Shift Control Selects the displacement caused by the data shifter at the auxiliary CIC filter output. 00 _B No shift, use full range 01 _B Shift by 1 10 _B Shift by 2 11 _B Shift by 3
0	[23:18]	r	Reserved, write 0, read as 0
CFADCNT	[31:24]	rh	CIC Filter (Auxiliary) Decimation Counter The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate.

1) While the integrator is bypassed, event gating is disabled, i.e. service requests are generated according to bitfield ESEL. The event gating suppresses service requests, result values are still stored in register RESAx.

30.6.2 Recommended Settings

The digital filters, in particular the main filter chain, provide a number of configuration options to control their operation. However, not all combinations achieve the performance the filters can deliver. The following recommendations describe the dependence of the performance on the configuration settings as well as some standard operating modes.

The digital result values that represent the input signal depend on the configuration of the filter chain, i.e. on the decimation factor, the involved filter elements, and the settings of the data shifters.

Modulator Values

The full-scale values produced by the on-chip modulator are subject to a certain variation due to the involved analog circuitry and also depend on the operating mode:

- $\pm 3 \text{ 600}_D$ as an uncalibrated average value
- $\pm 4 \text{ 096}_D$ in case of an overload condition ($I_{REN} = 1$)

The example calculations below use a full-scale value of $\pm 3 \text{ 800}_D$ ($0ED8_H/F128_H$) to avoid filter overflows.

Note: The modulator output value variation is compensated by the calibration sequence.

Gain Factor of the CIC Filter

The gain factor of the CIC filter is 1.0 for decimation rates of 2^N .

The automatic data shifter after the CIC filter compensates the variation of the result magnitude caused by different decimation factors. This compensation, however, can only be done by powers of 2, while the decimation rate itself can be selected arbitrarily. The gain of the CIC filter, therefore, ranges from 1.0 (decimation rate is 2^N , e.g. 32 or 64) down to approximately 0.5 (decimation rate is $2^N + 1$, e.g. 33 or 65).

The influence of this varying gain on the result magnitude can be computed by using the following approach:

- Compute the factor according to the selected filter configuration and decimation rate (For CIC3 and a decimation rate of 45, the factor is $45^3 = 91 \text{ 125}$)¹⁾
- Determine the next higher power of 2 (e.g. $2^{17} = 131 \text{ 072} > 91 \text{ 125}$)
- Compute the relation of the actual factor and the next power of 2 (e.g. $91 \text{ 125} / 131 \text{ 072} = 0.695228577$)

1) Formula for CIC1: $1 \times N$, for CIC2: N^2 , for CIC3: N^3 , for CICF: $2 \times N^2$.

Delta-Sigma Analog-to-Digital Converter (DSADC)

Gain Factor of FIR Filters and Data Shifters

The gain factor of the FIR filters is defined by their coefficients (see [Section 30.4.2](#)).

For FIR0 the gain factor is:

$$2 \times (-17 - 25 + 83 + 256) / 1\,024 \\ = 0.580078125$$

For FIR1 the gain factor is:

$$2 \times (-3 - 2 + 2 + 9 - 1 - 14 - 8 + 19 + 25 - 13 - 55 - 12 + 126 + 256) / 1\,024 \\ = 0.642578125$$

Shifting the data values by one bit equals a gain factor of 2.0. Therefore, the resulting gain factor is 2^S , where S is the selected value of the respective data shifter.

Avoiding Clipping

To avoid overflow and clipping of values within the filter chain, the magnitude of the result values must not exceed $\pm 2^{15}$ at any stage. This is the basis for selecting the correct settings for the data shifters. See also the example in [Table 30-7](#).

Total Gain Factor of the Digital Filter Chain

Multiplying the gain factors of the individual enabled elements of the filter chain results in the total gain factor:

$$G_{TOT} = G_{CIC} \times G_{SC} \times G_{FIR0} \times G_{SF0} \times G_{FIR1} \times G_{SF1}$$

$$G_{TOT} = G_{CIC} \times 2^{MFSC} \times 0.580078125 \times 2^{FSH} \times 0.642578125 \times 2^{DSH}$$

Note: When defining the settings for the data shifters, try to generate the maximum possible data values without exceeding the limits of the 16-bit data format at each stage. This minimizes errors induced by quantization.

Table 30-7 Example Setup Main Filter Chain, On-chip Modulator

Bitfield	Possible Values	Recommendation ¹⁾	Notes
MODCFGx.GAINSEL	1, 2, 4, 8, 16	1 (0000 _B)	Analog gain factor (valid for this example)
f_{MOD}	10 ... 20 MHz	20 MHz	Modulator sample frequency
FCFGCx.CFMC	CIC1, CIC2, CIC3, CICF	CIC3 (10 _B)	CIC filter grade
FCFGCx.CFMDF	4 ... 128	50 (31 _H)	CIC filter decimation rate (OSR) Gain factor: 125 000 / 131 072 = 0.953674316

Delta-Sigma Analog-to-Digital Converter (DSADC)
Table 30-7 Example Setup Main Filter Chain, On-chip Modulator (cont'd)

Bitfield	Possible Values	Recommendation ¹⁾	Notes
FCFGCx.MFSC	0, 1, 2, 3	3 (11 _B)	Data shifter steps after CIC filter Gain factor: $2^3 = 8.0$ (Magnitude = 28 992: OK)
FCFGMx.FSH	0, 1	0	Data shifter steps after FIR0 Gain factor: 0.580078125 (Magnitude = 16 817: OK; FSH = 1 would lead to 33 635!!)
FCFGMx.DSH	0, 1, 2, 3	1 (01 _B)	Data shifter steps after FIR1 Gain factor: $2^1 = 2.0 \times 0.642578125$ $= 1.28515625$ (Magnitude = 21 613: OK)
Total gain factor	-	-	0.953674316×8.0 $\times 0.580078125 \times 1.28515625$ $= 5.687645168$
RESMx.RESULT	-	-	$\pm 3\ 800_D \times 5.687645168$ $= \pm 21\ 613\ (546D_H)^{2)}$

1) Bitfield values in parentheses.

2) These values are given after offset correction and refer to the nominal modulator output values. The final result values are adjusted by the complete calibration sequence.

Dithering Control

The dithering features reduces the idle tones caused by low-frequency input signals. After reset, dithering is enabled, but the dithering trim value is 000_B. To optimize the effect, set the trim value to 011_B.

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.6.3 Group Delay

Data that enter a digital filter need a certain number of filter clocks before they appear at the filter's output and can be used by the system. The effective group delay depends on the configuration of the filter chain. **Table 30-8** summarizes the delays incurred by the elements of the filter chain. "N" indicates the selected oversampling rate (decimation factor) of the CIC filter. Delays are listed in modulator clock cycles.

Table 30-8 Group Delay Summary

Filter Chain Element	Delay [t_{MOD}]	Notes
On-chip modulator	7	Delay of analog frontend
Input select/adjust unit	1	Synchronization
CIC1	$1 \times (N-1) / 2$	
CIC2	$2 \times (N-1) / 2$	
CIC3	$3 \times (N-1) / 2$	
CICF	$(2 \times N) - 1$	
FIR0	$(3.5 \times N) + C0$	$C0 = 3$ To be added to CIC delay
FIR1	$(27 \times N) + C1$	$C1 = N + 5$ To be added to CIC / FIR0 delay
OC	0	
Integrator	X	Depending on the selected number of discarded and integrated values
Offset correction	0	

Example

$f_{MOD} = 16.66$ MHz, $t_{MOD} = 60$ ns, OSR(CIC3) = 32, FIR active, OC off, no integration.

Group delay:

$$[7 + 1 + (3 \times 31 / 2) + (3.5 \times 32 + 3) + (28 \times 32 + 5)] \times t_{MOD} =$$

$$(7 + 1 + 46.5 + 115 + 901) \times t_{MOD} = 1\,070.5 \times t_{MOD} = 64.23 \mu\text{s}$$

At the given oversampling rate of $32 \times 2 \times 2 = 128$ this equals a delay of $8.36 \times t_D$ (data output rate cycles).

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.7 Conversion Result Handling

The DSADC preprocesses the conversion result data before storing them for retrieval by the CPU or a DMA channel.

Conversion result handling comprises the following functions:

- Filtering and Post-Processing
- Storage of Conversion Results
- Result Event Generation

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio. The selectable integrator can further reduce the output data rate.

The elements of the main filter chain after the initial CIC filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application.

A programmable offset is subtracted automatically from each result value before being stored in the result register. This offset value is stored in the corresponding register OFFMx. It may be an arbitrary value defined by the application.

The offset value can also be obtained by using the offset measurement mode (both inputs to V_{CM} via bitfields INCFGP and INCFGN in register MODCFGx (x = 0, 2, 3)).

The auxiliary filter is fixed. The result values of the auxiliary filter are also available for the application, although in many cases the comparator output signal will be sufficient.

The conversion result values are stored in result register RESMx and RESAx, respectively.

RESMx (x = 0, 2, 3)

Result Register x Main Filter (x * 0100_H + 0130_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RESULT	[15:0]	rh	Result of most recent conversion Signed value (two's complement)
0	[31:16]	r	Reserved, write 0, read as 0

Delta-Sigma Analog-to-Digital Converter (DSADC)

OFFMx (x = 0, 2, 3)
Offset Register x Main Filter ($x * 0100_H + 0138_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
OFFSET	[15:0]	rw	Offset Value This signed value is subtracted from each result before being written to the corresponding result register RESMx.
0	[31:16]	r	Reserved, write 0, read as 0

RESAx (x = 0, 2, 3)
Result Register x Auxiliary Filter ($x * 0100_H + 0140_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RESULT	[15:0]	rh	Result of most recent conversion Signed value (two's complement)
0	[31:16]	r	Reserved, write 0, read as 0

Result Representation

Due to the differential input stage, the results are signed values stored in a 16-bit two's complement format. The CIC filter's output value depends on the selected filter parameters and decimation factor. An automatic data shifter extracts the most significant bits from this filter result.

 Delta-Sigma Analog-to-Digital Converter (DSADC)

30.8 Service Request Generation

The DSADC can activate service request output signals to issue an interrupt, to trigger a DMA channel, or to trigger other on-chip modules.

Service request connections can be found in [Table 30-13 “Digital Connections in the TC26x B-Step” on Page 30-90](#).

Several events can be assigned to each service request output. Service requests can be generated by several types of events:

- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Result events are generated at the output rate of the configured filter chain.
Can be issued via SRAX and SRMx.
- **Alarm events:** indicate that a conversion result value is within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
Can be issued via SRAX.
- **Special events:** indicate specific circumstances of previously configured functions.
 - Timestamp trigger event can generate a service request.
Can be issued via SRMx.
 - Capture event for sign delay measurement can generate a service request.
Can be issued via SRAX.

Each event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of DSADC events (the event can generate a service request without the need to clear the indication flag).

Note: For service request signals to occur, they must be activated via bitfields SRGM and/or SRGA.

Gating Requests of Auxiliary Channel

Result/Alarm events on service request SRAX can be suppressed while the integrator is enabled and is controlled by an external signal. When bit EGT in register **FCFGAx (x = 0, 2, 3)** is set, result events (ESEL = 00_B) or alarm events (ESEL = 01_B or ESEL = 10_B) only generate service requests while the integrator is active after the programmed discard phase.

This prevents alarm requests from being generated while the signal is not evaluated via the main filter chain.

Note: While the integrator is disabled (ITRMODE = 00_B), bit EGT has no effect on the generation of auxiliary service requests.

Delta-Sigma Analog-to-Digital Converter (DSADC)

The following registers provide a set of bits for each available channel.
The number of available channels depends on the chosen device type.

*Note: Software can set flags RESEVx and ALEVx and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.
Software can clear these flags by writing 1 to bit RESECx and ALECx, respectively.*

Delta-Sigma Analog-to-Digital Converter (DSADC)

30.9 Resolver Support

Resolver applications determine the rotation angle by evaluating the signals from two orthogonally placed coils. These coils are excited by the magnetic field of a third coil. The DSADC can read the two return signals using two input channels and can also generate the excitation sine signal (carrier). It also provides synchronization logic to compensate the delay between the generated carrier signal and the received position signals. The integrator stage converts the carrier-based return signals to position-based values (carrier cancellation).

30.9.1 Carrier Signal Generation

The carrier signal generator (CG) is supplied with the selected internal clock signal (f_{CLK}) and outputs a PWM signal that induces a sine signal in the excitation coil of the resolver. Alternatively, it can generate PWM patterns that resemble triangle or square signals (see [Figure 30-20](#)). The polarity of the carrier signal can be selected.

A carrier signal period consists of 32 steps. Each step equals a PWM period of 32 cycles.

Figure 30-19 Carrier Generator Block Diagram

Bit-reverse generation mode increases the frequency spectrum to yield a smoother induced sine signal. This is done by distributing the 0 and 1 bits over the 32 cycles of a PWM period.

The generated pattern is actually a cosine signal, i.e. it starts at the maximum output value. This is advantageous if the output pin is pulled high before the carrier signal is generated. In case of a pull-down the inverted output signal should be selected.

30.9.2 Return Signal Synchronization

In a resolver, the received return signals are induced by the carrier signal and their amplitudes are modulated with the sine and cosine magnitudes corresponding to the current resolver position. These amplitudes are determined by integrating the return signals over a carrier signal period.

To properly integrate their magnitude, the return signals must be rectified. For this purpose the carrier generator provides the sign information of the generated carrier signal (SGNCG in register **CGCFG**).

Alternatively, an external carrier signal generator can be used. If this generator delivers a sign signal, this can be input to a pin and is then used as external carrier sign signal. If no sign signal is available, the carrier signal itself can be converted by the next adjacent input channel and its sign signal is then used as alternate carrier sign signal.

*Note: The resulting sign signal is called SGNCS in **Figure 30-21**.*

The rectification of the received signals must be delayed to compensate the round trip delay through the system (driver, resolver coils, cables, etc.). For the rectification, the received values are multiplied with the delayed carrier sign signal (SGND in register **RECTCFGx (x = 0, 2, 3)**). This synchronization is done for each channel separately, to achieve the maximum possible amplitudes for each signal.

Note: The rectification unit is part of the integrator stage. Therefore, it is only active while the integrator is active.

The delay is realized with the sign delay counter SDCOUNT. SDCOUNT is cleared and started upon a falling edge of the selected sign signal (SGNCS in **Figure 30-21**), i.e. at the begin of the positive halfwave of the carrier signal. After counting SDPOS results from the filter chain, also the rectification signal (SGND) is cleared, indicating positive values from now on. After counting SDNEG values, the rectification signal is set, indicating negative values (see **Figure 30-21**).

The compare values SDPOS and SDNEG are stored by the application software. SDPOS is the delay value that accounts for the resolver signal's round trip delay. This delay is constantly measured by capturing the current counter value into bitfield SDCAP when the first positive result (after negative results) is received in the respective channel. Software can read these value and compute a delay value e.g. by averaging a series of measured values to compensate noise. The delay for the negative halfwave (SGND = 0) is determined by adding the duration of a carrier signal halfwave. This value is written to bitfield SDNEG.

A new captured value is indicated by setting the flag SDCVAL. This flag is cleared when reading register CGSYNCx.

Capturing a new value can trigger a service request. The service request line of the auxiliary channel is used for this purpose. This alternate request source is selected by bitfield SRGA in register **FCFGAx (x = 0, 2, 3)**.

SDNEG	[31:24]	rw	Sign Delay Value for Negative Halfwave Defines the content of SDCOUNT to generate a high delayed sign signal SGND (negative values).

Delta-Sigma Analog-to-Digital Converter (DSADC)

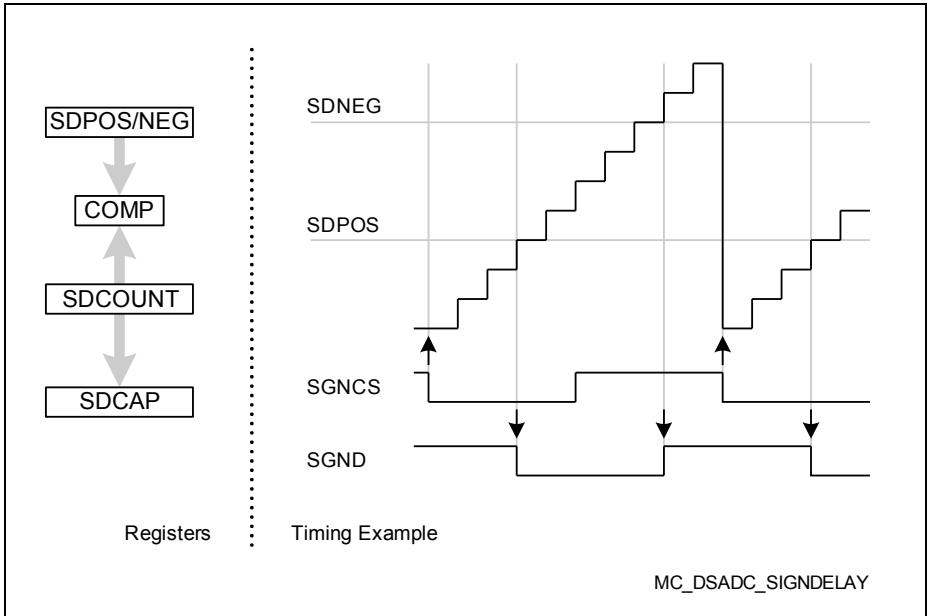

Figure 30-21 Sign Delay Example

Note: Whenever a new result value becomes available from the filter chain, the rectification counter (SDCOUNT) is updated and the rectified value is forwarded to the integrator.

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.10 Time-Stamp Support

Some applications need to determine the result value at certain points of time inbetween two regular output values. The interpolation algorithm needs to determine the position of the required point of time in relation to the regular results.

This interpolation is supported by providing a timestamp that marks the delay since the last regular output value. This timestamp is composed of:

- the last regular result value
- the current decimation counter value
- the current integrator counter value

All timestamp information is combined into one register, so the complete timestamp can easily be stored away by a single DMA transfer. The timestamp information is captured into register TSTMPx upon a hardware trigger. For this purpose, the trigger signal is used, which is selected by bitfield TRSEL in register **DICFGx** (**x = 0, 2, 3**). Bitfield TSTRMODE selects the edge(s) that capture timestamp information.

The valid flag TSVAL is set when timestamp information is stored and is cleared when register TSTMP is read. This indicates to the application software if or not a timestamp trigger has occurred before the corresponding result value was generated.

When timestamp information is stored, a service request can optionally be generated. This allows application software to operate on all result data, even if multiple timestamp triggers occur before a regular result service request.

TSTMPx (x = 0, 2, 3)

30.11 Implementation into the TC26x B-Step

This section describes the actual implementation of the ADC module into the TC26x B-Step, i.e. the incorporation into the microcontroller system.

The following information is listed:

- [“Product-Specific Configuration” on Page 30-85](#)
- [“Summary of Registers and Locations” on Page 30-86](#)
- [“Analog Module Connections in the TC26x B-Step” on Page 30-89](#)
- [“Digital Module Connections in the TC26x B-Step” on Page 30-90](#)

30.11.1 Product-Specific Configuration

The functional description describes the features and operating modes of the DSADC in a general way. This section summarizes the configuration that is available in this product (TC26x B-Step).

The DSADC features a number of twin-modulators that handle 2 input channels each.

Table 30-9 General Converter Configuration in the TC26x B-Step

Channel	Analog Inputs ¹⁾	Reference Voltages	Notes
0	2	V_{AREF1} , V_{AGND1}	2:1 analog multiplexer

2	1	V_{AREF1} , V_{AGND1}	
3	4	V_{AREF1} , V_{AGND1}	4:1 analog multiplexer

1) Differential input pin pairs.

Delta-Sigma Analog-to-Digital Converter (DSADC)
30.11.2 Summary of Registers and Locations

The DSADC is built from a series of channels that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see [Table 30-11](#)). The exact register location is obtained by adding the respective register offset to the base address (see [Table 30-10](#)) of the corresponding channel.

Due to the regular structure, several registers appear within each channel. This is indicated in the register overview table by placeholders:

- $0X##_H$ means: $x \times 0100_H + 01##_H$, for $x = 0, 2, 3$

31 Inter-Integrated Circuit Module (I2C)

This chapter describes the Inter-Integrated Circuit (short I2C) Module of the TC26x B-Step. It contains the following sections:

- Overview (see [Page 31-1](#))
- I2C module functional specification (see [Page 31-4](#)) including:
 - I2C protocol (see [Page 31-4](#))
 - Clock and timing control (see [Page 31-11](#))
 - I2C kernel control logic (see [Page 31-15](#))
 - FIFO operation (see [Page 31-28](#))
 - Service request block operation (see [Page 31-45](#))
- I2C module internal registers (see [Page 31-51](#))
- I2C module implementation (see [Page 31-81](#)).

This specification is fully compliant with the I2C-bus specification version 2.1 [\[3\]](#).

Note: The I2C module register names described in this chapter are referenced in the TC26x B-Step User's Manual by the module name prefix "I2Cm_" with m being the number of the module.

31.1 Overview

This section gives an overview of the I2C-bus and of the I2C module.

31.1.1 I2C-bus Overview

The I2C protocol was developed to provide a simple and efficient data transfer between multiple devices over a short distance. It uses a bidirectional serial bus with two wires.

A serial data line (SDA) and a serial clock line (SCL) carry the information between the devices. These lines are connected to a positive supply voltage via pull-up resistors. In quiescent state, when the bus is free, both lines are high. During communication the lines are alternatively pulled to low. The output stages of devices connected to the bus must have an open-drain (CMOS) or open-collector (bipolar) to perform a wired-AND function.

A device can work as master or as slave. The master initiates the transfer, generates the clock pulses and terminates the transfer; it addresses a slave via a 7-bit or 10-bit address. Data can flow in either direction. In many applications there is only one master, typically a single-chip microcontroller, which communicates with several slaves, e.g. general purpose peripherals or application specific circuits. But also multi-master systems with arbitration and collision detection are possible.

Data on the I2C-bus can be transferred at rates of up to 100 kbit/s in standard mode, up to 400 kbit/s in fast mode and up to 3.4 Mbit/s in high-speed mode. A slow slave may stretch the clock period. The number of devices connected to the same I2C-bus is limited only by a maximum bus capacitance of 400 pF.

Inter-Integrated Circuit Module (I2C)

31.1.2 I2C Module Overview

Figure 31-1 shows a block diagram of the I2C module.

The I2C module works in accordance with I2C-bus specification version 2.1 [3]. It supports master mode, multi-master mode and slave mode. Communication is possible at different speed ranges: standard mode, fast mode and high-speed mode. Not only 7-bit I2C-bus addresses, but also 10-bit addresses can be handled. The module relieves the CPU from many time-critical tasks.

The clock for the kernel of the I2C module is derived from the system clock via a prescaler. An additional fractional divider generates the desired bit rate. The exact timing of the I2C-bus signals can be adjusted.

A FIFO is used for data transfer between CPU and I2C module during transmission and reception. This allows writing and reading of multiple bytes. Data alignment and data sizes can be configured.

Six separate interrupt requests are available: for filling or emptying the FIFO, for reacting on certain protocol events and for handling of errors.

External hardware is connected to the I2C module via a pair of receive and transmit pins.

Figure 31-1 Block Diagram of the I2C Module

Features

- Compatible with I2C-bus specification version 2.1 [3]
- Master mode, multi-master mode and slave mode supported
- Different speed ranges available for data transfer:
 - Standard mode (0-100 kbit/s)
 - Fast mode (0-400 kbit/s)
 - High-speed mode (0-3.4 Mbit/s)
- 7-bit and 10-bit I2C-bus addressing supported
- Automatic execution of low-level tasks like:
 - (De)Serialization of the bus data
 - Generation/detection of start and stop signal
 - Generation/detection of acknowledge signal
 - Bus state detection
 - Bus access arbitration in multi-master mode
 - Recognition of device address in slave mode
 - Configurable detection of general call address
 - Configurable repeated start in master mode
- Flexible clock and timing control:
 - Prescaler for I2C kernel clock
 - Bit rate generation via fractional divider
 - I2C-bus signal timing adjustment
- TX/RX FIFO for buffering data from/to CPU with following features:
 - 8 FIFO stages
 - Configurable data alignment (byte, half word, word)
 - Configurable sizes for burst, transmit and receive package
 - FIFO usable as flow controller
- Advanced interrupt handling:
 - 4 data transfer interrupts (burst, last burst, single, last single)
 - Protocol interrupt with 7 sources (address match, general call, master code, arbitration lost, not-acknowledge received, transmission end, receive mode)
 - Error interrupt with 4 sources (FIFO transmit/receive overflow/underflow)

31.2 I2C Module Functional Specification

This specification is fully compatible with the I2C-bus specification version 2.1 [3].

31.2.1 I2C Protocol

Data is transmitted bit-by-bit on line SDA in conjunction with the clock on line SCL. To start communication, a master device generates a so called start condition. Subsequently data transfer starts. Therefore the data on the SDA line must be stable during the high period of the clock and may only change during SCL low phase. After all data have been transferred, the master closes transmission with a stop condition (see [Figure 31-2](#)).

Figure 31-2 A Complete I2C Data Transfer

Start, Restart and Stop Conditions

A start condition is indicated by a high to low transition on line SDA while SCL remains high, a stop condition is defined by low to high transition under the same condition of high level on line SCL. The bus is considered to be busy after a start condition and to be free again after a stop condition. To allow continuous data transmission or reception without first generating a stop condition, a third condition has been introduced - the restart condition. The bus stays busy if this condition is generated and the same or another slave can be addressed. Start and restart condition are functionally identical.

Address Transmission

After the start condition a slave address is sent. Normally the address is 7 bits long followed by an 8th bit that is a data direction bit (Read/not Write see [Figure 31-3](#)). A zero indicates a transmission (write operation); a one indicates a request to data (read

Inter-Integrated Circuit Module (I2C)

operation). Following the address transmission the addressed device responds with an acknowledge (low on line SDA). If no acknowledge is returned, the master can then generate either a stop condition to abort the transfer or a repeated start condition to start another new transfer.

Figure 31-3 Address Byte Composition

Two groups of eight addresses are reserved for purposes, as shown in [Table 31-1](#). For example the bit combination “11110XX” is reserved for 10-bit addressing mode.

Table 31-1 Reserved I2C-bus Addresses

Address	RnW	Description
0000000	0	General call address
0000000	1	Start byte - no device is allowed to acknowledge
0000001	x	CBUS address - I2C-bus devices may not respond
0000010	x	Reserved for different bus format
0000011	x	Reserved for future use
00001XX	x	High-speed mode master code
11111XX	x	Reserved for future use
11110XX	x	10-bit slave addressing mode

General Call

A general call is characterized by transmission of address “0000000” and RnW bit = 0. It is used for addressing every device connected to the I2C-bus. However, if a device doesn’t need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgement. Otherwise it acknowledges this general call and the following data bytes (if required) and behaves like a slave-receiver. The received data (e.g. programmable part of slave address, address of I2C-bus master) has to be handled by software. For further information the reader is referred to the I2C-bus specification version 2.1 [\[3\]](#).

Inter-Integrated Circuit Module (I2C)

Data Transmission

Each byte transferred over the I2C-bus has to be 8 bits long whereby the number of bytes transmitted per transfer is unrestricted. Bytes are transferred MSB (Most Significant Bit) first. If the slave cannot receive or transmit a data byte until it has performed another function, it can hold the clock line SCL low (wired AND connection) to force the master into a wait state. Data transfer continues when the slave releases the clock line.

Acknowledge

Each transferred respectively received byte has to be followed by an acknowledge bit that is set by the recipient (master or slave depending on the transmission direction) onto the data line SDA. The acknowledge-related clock pulse is generated by the master. The device that has to set the acknowledge bit must pull down the SDA line during the acknowledge clock pulse so that it remains stable low during the high period of this clock pulse. Therefore in case of a slave the clock line may be held low until an acknowledge is released.

When the recipient of data doesn't acknowledge the data, for example because it was unable to receive the data or to transmit any data, the data line must be left high. A master-receiver that does not acknowledge the data from a transmitting slave device thereby tells the slave to stop transmission. The master then generates a stop condition to abort transfer or a repeated start condition to continue.

Clock Synchronization

To transfer messages a master generates its own clock on the SCL line. Data is only valid during the high period of the clock. Therefore data on line SDA has to be stable during this period and may only be changed during the low period of clock.

Two special cases must be considered. First, slave devices (or master devices operating as slaves) never generate clocks but are permitted to delay them. According to [Figure 31-4](#), if device 1 as master device for example sets line SCL to low, device 2 as slave device may extend the low phase by setting its SCL output to low. A device such as a microcontroller with limited hardware for the I2C-bus can thereby slow down the bus clock and adapt the master to the internal operating rate of this device.

Figure 31-4 Clock Synchronization

Second, if several master devices access the I2C-bus at the same time, the SCL line is influenced by more than one device. As shown in the previous example, the SCL line will be held low by the device with the longest SCL low period. Devices with shorter periods enter a wait state during this time. In this way a synchronized SCL clock is generated.

Arbitration

To allow multi-master mode operation, bus arbitration is required. A master may start a transfer only if the bus is free. Two or more masters may generate a defined start condition simultaneously within a minimum hold time.

Arbitration takes place on the SDA line while SCL line is high, when one master transmits a high level while another master transmits a low level. Because of the wired AND functionality, the low level dominates the high level. As result the device that was trying to transmit a high level recognizes a different level on the SDA line and switches off its SDA and SCL output (see [Figure 31-5](#)).

Figure 31-5 Example of an Arbitration Procedure

Arbitration may occur in different stages of transmission. A different level may potentially first appear during comparison of the address bits. If the masters are each trying to address the same device, arbitration continues with comparison of the RnW bit and subsequent data bits (if the masters are transmitting) or acknowledge bits (if the masters are receiving). Because information on the I2C-bus is determined by the winning master, no information is lost during the arbitration process. Since control of the I2C-bus is decided only by comparison of the data transmission stream over line SDA, there is no central master or any order of priority on the bus.

I2C-bus Formats

With the described rule types the formats shown in [Figure 31-6](#) are possible.

- Master-transmitter transmits to slave-receiver and stops after not-acknowledge.
- Master reads slave immediately after transmission of the RnW bit (high level) and the acknowledge from the slave, whereas the master becomes master-receiver and the slave becomes slave-transmitter.
- In combined format the just described regular sequences are handled, except for the repeated start condition instead of the stop condition between two sequences.

Inter-Integrated Circuit Module (I2C)

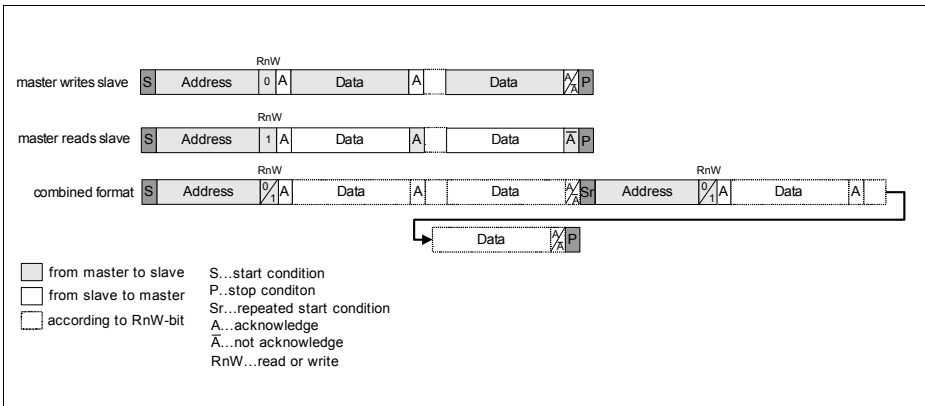

Figure 31-6 Types of I2C-bus Formats

10-bit Addressing Mode

The I2C address area is restricted to 112 applicable addresses with the 7-bit address mechanism described above. It turned out, that more combinations were required to prevent problems with the allocation of slave addresses for new devices. This problem was resolved with the 10-bit addressing scheme that is compatible with 7-bit addressing. Both modes may be used simultaneously. The following formats are possible:

To use 10 bits for addressing, the preamble address “11110XX” with RnW bit = 0 has to be used, including the two most significant bits “XX” of the 10-bit address, followed by an acknowledge from at least one 10-bit address matching slave and the second address byte containing the eight least significant bits. Only the (combined) 10-bit address matching slave now acknowledges. Data packages may now be transmitted to the addressed slave until stop condition or restart condition. If the master needs to read the slave, a combined format with a restart condition is necessary to

- First transmit the 10-bit address (first data package after preamble address contains 2nd address byte, RnW bit is 0) and (after the restart condition)
- Receive the requested data packages. Note that after the restart condition the preamble address “11110XX” has to be sent one more time, now with RnW bit = 1; the matching slave remembers that it was addressed before (see [Figure 31-7](#)). In case of a non matching preamble address, a not-acknowledge is returned.

The slave remains active as slave-transceiver until a stop condition or a restart condition occurs. According to the value of the following RnW bit a new slave may be addressed or the same slave is requested to transmit more data. Additionally the following combined formats (and mixtures of these formats) are allowed ([Figure 31-7](#)):

- A master transmits data to a slave and then reads back data from the same slave. The transfer direction is changed after the restart condition.

Inter-Integrated Circuit Module (I2C)

- A master transmits data to one slave and then transmits data to another slave.
- 10-bit and 7-bit addressing combined in one serial transfer. After restart condition the new addressing mode is selected by the address itself.

Figure 31-7 Types of I2C-bus 10-bit Address Formats

High-speed Mode

To support higher baud rates on the I2C-bus (up to 3.4 Mbaud) the specification introduces the high-speed mode. To communicate at this higher baud rate the protocol uses a so called master code in place of the address byte to indicate that a master wants to change to the high-speed mode.

Inter-Integrated Circuit Module (I2C)

Special attention must be paid to meet the requirements of rise and fall times of the signal edges and other timing characteristics when working in high-speed mode. Also it is necessary to disconnect I2C-bus devices which are not able to follow the fast communication.

After the master sends this master code, no device is allowed to acknowledge it. The involved devices change to high-speed mode and the master starts the communication. The high-speed mode transmission behavior is the same as at lower baud rates with the exception that only restart conditions and stop conditions appear (no start condition). Since the master code determines a unique master device to control the bus, the arbitration process is finished after the master code sequence is put on the bus and must not be continued when working at the new communication speed.

Improvements to the regular I2C-bus specification for high-speed mode are given in section 13.1 of the I2C-bus specification version 2.1 [3].

For high-speed mode there exists a separate configuration register **FDIVHIGHCFG** to program the baud rate; see also **Baudrate Generation**.

31.2.2 Clock and Timing Control

The I2C module offers the following features to control clock and timing:

- Module clock control for integration logic clock and I2C kernel clock (see **Section 31.4.2**)
- Baud rate generation
- I2C signal timing adjustment

31.2.2.1 Baudrate Generation

A baudrate generation unit in the I2C kernel generates the SCL signal from the kernel_clk, controlled by settings of parameters INC, DEC, and FS_SCL_LOW in registers **FDIVCFG** (normal and fast mode), **FDIVHIGHCFG** (high speed mode), and **TIMCFG**.

The I2C standard has some special requirements for the clock, like

- asymmetric duty cycle
- slave or other masters can delay the clock by extending the low period

Therefore, the mechanism of baudrate generation is not quite simple, and needs some explanation, as given hereafter. Please refer also to **Figure 31-8**.

The baudrate generator produces a clock output SCL_OUT, and also uses the feedback clock SCL_IN from the pad. SCL_IN is delayed with respect to SCL_OUT by the chip internal delays, to for SCL_OUT and t_i for SCL_IN, and by the pad rise and fall time. The pad times depend on the pad design, and on the external load and the pullup resistor. Also, the pad times may be different for normal/full speed mode and for high speed mode, if a dedicated high speed pad is being used.

Inter-Integrated Circuit Module (I2C)

SCL is the clock visible on the PCB.

The timing diagram in **Figure 31-8** shows the relations between these 3 clock signals, using nominal low and high times for the clock, as produced internally by the baudrate generator.

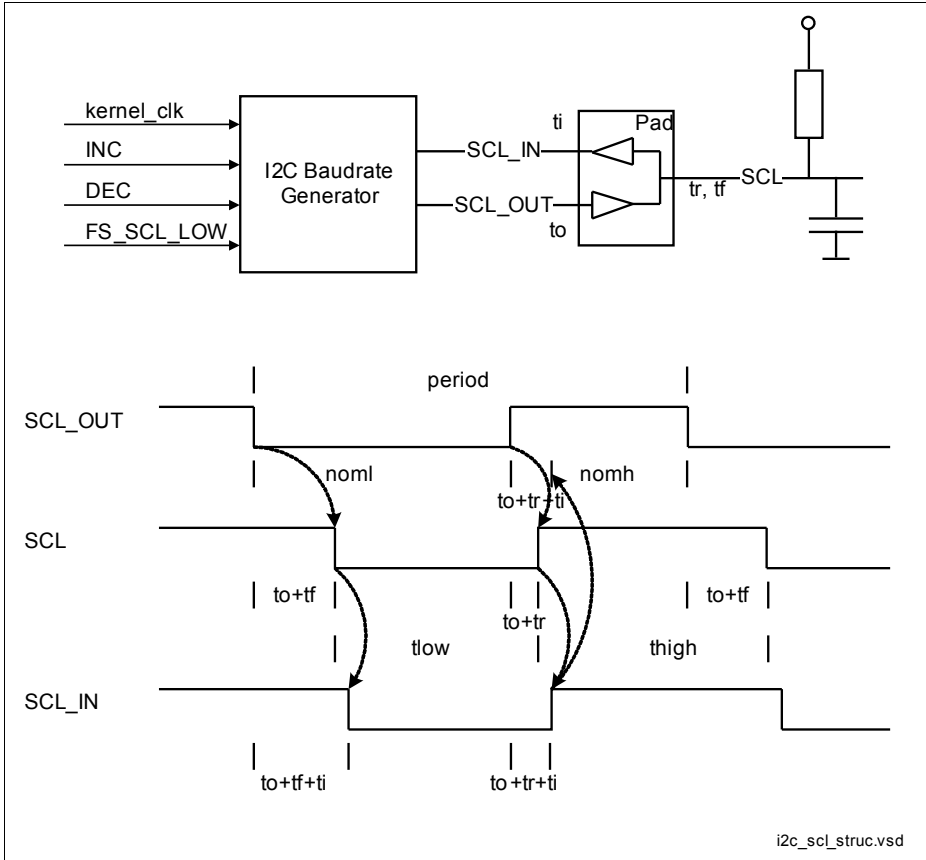

Figure 31-8 SCL Generation

The baudrate generator sets the internal SCL_OUT signal to low for the time noml, with

- Normal and full speed mode:
 - $noml = (DEC + LTC) / INC$ kernel_clk cycles
- High Speed mode:
 - $noml = (5 * DEC - 3 * INC) / INC - 1$ kernel_clk cycles when $DEC \leq 4 * INC$
 - $noml = (4 * DEC + INC) / INC - 1$ kernel_clk cycles when $DEC > 4 * INC$

Inter-Integrated Circuit Module (I2C)

Note: The operator div denotes the integer division: $a \text{ div } b = \text{greatest integer not greater than } a/b$.

Note: These and the following formulas show the mean values over a longer period of time. These may be non-integer multiples of a kernel_clk cycle. The actual value of each clock phase is always an integer multiple of a kernel_clk cycle. It is either the next smaller or the next larger one, compared to the mean value.

When the low time has passed, SCL_OUT is set to high and the baudrate generator waits until the feedback clock SCL_IN goes to high. Next the baudrate generator continues to keep SCL_OUT at high for

- Normal and full speed mode:
 - $\text{nomh} = (\text{DEC} + 3 \cdot \text{INC} - \text{LTC}) / \text{INC}$ kernel_clk cycles
- High Speed mode:
 - $\text{nomh} = 6$ kernel_clk cycles when $\text{DEC} \leq 4 \cdot \text{INC}$
 - $\text{nomh} = (\text{DEC} - 3 \cdot \text{INC}) / \text{INC} + 5$ kernel_clk cycles when $\text{DEC} > 4 \cdot \text{INC}$

Then the next low phase starts.

The Low Time Correction term LTC for normal and fullspeed mode is

- $\text{LTC} = \text{SCL_LOW_LEN}$ when $\text{EN_SCL_LOW_LEN} = 1$
- $\text{LTC} = \text{DEC} \text{ div } 4$ when $\text{EN_SCL_LOW_LEN} = 0$ and $\text{FS_SCL_LOW} = 1$
- $\text{LTC} = \text{DEC} \text{ div } 8$ when $\text{EN_SCL_LOW_LEN} = 0$ and $\text{FS_SCL_LOW} = 0$

In full speed mode, EN_SCL_LOW_LEN should be set to 1 or FS_SCL_LOW should be set to 1 in order to meet the high requirement for the SCL low time in this mode.

SCL_LOW_LEN must not be greater than DEC , when enabled via EN_SCL_LOW_LEN is set to 1.

SCL_LOW_LEN and EN_SCL_LOW_LEN are set in register **TIMCFG**.

This ends up in a period

- Normal and full speed mode:
 - $\text{period} = (2 \cdot \text{DEC} + 3 \cdot \text{INC}) / \text{INC}$ kernel_clk cycles + t_o + t_r + t_i
- High Speed mode:
 - $\text{period} = (5 \cdot \text{DEC} - 3 \cdot \text{INC}) / \text{INC} + 5$ kernel_clk cycles + t_o + t_r + t_i when $\text{DEC} \leq 4 \cdot \text{INC}$
 - $\text{period} = (5 \cdot \text{DEC} - 2 \cdot \text{INC}) / \text{INC} + 4$ kernel_clk cycles + t_o + t_r + t_i when $\text{DEC} > 4 \cdot \text{INC}$

The mechanism to enlarge the SCL_OUT high time by the time needed until the external clock has safely reached the high value ensures, that external slaves or masters can delay the clock, as requested by the standard. As a side effect, it introduces also a frequency reduction even if no external device keeps SCL at low level. This reduction is affected by process/voltage/temperature (PVT) variations on chip, and by the external load and pullup resistor.

Inter-Integrated Circuit Module (I2C)

Therefore, a perfect formula for the baudrate cannot be given. The best settings of INC and DEC for a given system should be found by measurements, taking as a start value the above formula for period with a rough estimate for $t_o + t_r + t_i$. It has to be accepted, that there is some PVT variation.

Note: In normal and full speed mode, the actual low and high times t_{low} and t_{high} of the the external clock SCL are significantly influenced by t_f and t_r . The fall time of the pad is strongly depending on the pad driver characteristic. The rise time is mostly affected by the external circuitry.

In high speed mode, this impact is less critical, due to high speed pad characteristics.

31.2.2.2 I2C Signal Timing Adjustment

The I2C standard includes a number of requirements for the SCL and the SDA timing. These cannot always be fulfilled by the timing of the pads. Therefore, additional timing adjustment options are provided in the controller logic.

Some signal timings can be shifted by multiples of `kernel_clk` cycles, as defined in register **TIMCFG**.

The proper settings have to be determined during chip evaluation.

31.2.3 I2C Kernel Control Logic

The I2C kernel can work in four different modes:

- Master-transmitter
- Master-receiver
- Slave-transmitter
- Slave-receiver

A state machine description can give a good and fast overview of the functionality. Also nearly all possible conditions can be rebuilt by stepping through the state machine and most of the error handling is covered by it. So this method is used to describe the I2C kernel.

Beginning with the top-level state machine, the starting up procedure is covered and together with the slave process and the master process sub-state machines, the active operations are comprehensible. These three state machines and their state transitions are described in the following.

As the I2C-bus working principle is packet orientated, the FIFO is typically configured as flow controller and so it issues the burst- and single-requests. This configuration is established by programming the bits RXFC and TXFC of the **FIFOCFG** register. Writing to the TPS bit-field of the **TPSCTRL** register starts the transfer.

Note: In principle it is possible to use the FIFO in non flow controller mode. When the FIFO is not configured to operate as flow controller, the behavior of the FIFO operation has to be considered. The update of the FIFO fill level is only done when a stage is filled completely. In case of a (not protocol compliant) stopped transfer of the transmitter, the device is not able to evaluate the valid bytes since the FIFO issues interrupts/updates fill level only when a stage is filled completely. To prevent this behavior, the FIFO can be, for example, programmed to word alignment, so every received byte issues an interrupt/update. Anyway the software has to take care of such upcoming not protocol compliant data transmission stops, and has to handle this for example by programming an appropriate time-out.

The Top-level State Machine

Figure 31-9 shows the top-level state machine. There are four states in the top-level state machine:

Figure 31-9 Top-level State Machine

Inter-Integrated Circuit Module (I2C)

CONFIGURATION: The peripheral is inactive; this is indicated by the RUN bit in **RUNCTRL** register, which is set to 0. In this state the peripheral should be configured by software by writing appropriate data words to the **ADDRCFG**, **FDIVCFG**, **FDIVHIGHCFG** and **FIFOCFG** registers. This determines the following features:

- Peripheral is master or slave
- Address when accessed by another device
- Answering behavior to master calls and general calls
- Operating speed on the I2C-bus
- FIFO behavior

LISTENING: The peripheral has been activated by software. This state is entered in master and slave mode. The peripheral has to observe the bus for a certain time¹⁾ to ensure that there is no running transmission on the bus after this state has been entered. If no transitions on the I2C-bus are detected during this time period, the bus is supposed to be free. Otherwise the bit-field BS (bus status) in register **BUSSTAT** is set to 01_B (bus busy). Further functionality depends on the configuration: If the peripheral is a slave, only the slave process can be entered. If the device works as master, slave and master processes can be entered.

SLAVE PROCESS: A Start condition has been detected. The device is waiting for commands from the I2C-bus. This state represents the operation when acting as slave-transmitter or slave-receiver and is itemized in an own sub state machine.

MASTER PROCESS: The device is able to control the bus and work either as master-receiver or master-transmitter. Before the master can control the bus it has to set its clock frequency by programming its fractional divider with the appropriate value by writing it to the **FDIVCFG** register (when the I2C-bus is also operating in high-speed mode the appropriate values for INC and DEC have to be written to **FDIVHIGHCFG**). The master process state is itemized in an own sub state machine.

The transition between the three states on the top-level are:

T1. The RUN bit has been set to 1 by software. The peripheral is activated and ready to observe the I2C-bus or react on transmission start commands.

T2. The RUN bit has been set to 0 again. I.e., because of new configuration effort, the peripheral is switched back to CONFIGURATION mode.

IMPORTANT: When “turning off” the peripheral it must be assured that no I2C-bus control responsibility is owned by the interface! Therefore the shut off process has to change the peripheral into a “secure” state and free the I2C-bus if necessary (generate a stop condition if in master mode). There are signals provided by the interface block which can be used to guarantee a secure shut off when turning off the I2C kernel.

1) One period of 1/100 kHz should be sufficient.

Inter-Integrated Circuit Module (I2C)

Slave Process Sub-state Machine

Figure 31-10 shows the slave process sub-state machine. There are 5 plus 1 (the listening state belongs to master and slave) different states in this sub-state machine:

Figure 31-10 Slave Process Sub-state Machine

LISTENING: This state has been previously described (Figure 31-9). If the device is configured as slave, the module is listening only to the bus activity.

SLAVE RECEIVES ADDRESS: The module is shifting in the serial bits from the I2C-bus and acknowledges if the received byte(s) (first one in 7-bit address mode, first and second one in 10 bit address mode) match the adjusted address. During address matching the slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit, since this can be used as a bit-by-bit handshake procedure.

Note: The address byte(s) is (are) not shifted into the FIFO.

SLAVE RECEIVES BYTES: The module is shifting in the serial bits from the I2C-bus and acknowledges when the whole data byte has been transported to the FIFO. The

Inter-Integrated Circuit Module (I2C)

slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit since this can be used as a bit-by-bit handshake procedure.

SLAVE TRANSMITS BYTES: The slave is allowed to hold down the SCL line when preparing the data for transmission. When valid data is available the slave releases the SCL line and waits for the clock cycles from the master. The interrupt routine which proceeds when entering this state may write to the **TPSCTRL** register to initiate a transmission. This is only allowed if the bit-field BS (bus status) in register **BUSSTAT** in combination with the RnW clearly identifies the slave-transmitter mode of the peripheral. Otherwise writing to this register has no effect. First the I2C kernel gets a byte from the FIFO and puts it into a shift register. The module is then putting single data bits onto the I2C-bus and releases the SDA line after the 8th bit is sent.

*Note: Since the data flow control responsibility is task of the master device the slave should not stop transmitting bytes until the master tells it to do so. Therefore the TPS value in register **TPSCTRL** should be large enough to not run out of data bytes. In case of running out of data, the TRANSMISSION FINISHED state is reentered. The I2C data line is released to high level. The master continues receiving wrong values (0xFF).*

BUS BUSY: The bus is busy and the module is not involved in any data transfer. This is also the entry state when the bus is not free when starting up procedure is taking place (see state S17).

TRANSMISSION FINISHED (BUS BUSY): The module was involved in any data transfer. In distinction to the BUS BUSY state, the slave is still addressed by a master. Every time this state is left, caused due to a stop/restart condition, a TX_END request is generated as indication that the previous transmission has been closed.

The transitions which are connecting the several states are in detail:

S1: The module is detecting a start condition on the bus. It has to set the bit-field BS (bus status) in register **BUSSTAT** to 0_B. When this situation is occurring the I2C kernel is initialized since this indicates a new data transmission.

S2: The address which has been received matches the one stored in the address field in the **ADDRCFG** register. The RnW bit (8th bit in the first received byte) was set to 0. This means that the master wants to write to the slave. The corresponding bit RnW in register **BUSSTAT** is set to 1, i.e. the device continues working as slave-receiver. Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BS (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request.

If the general call (GC) address matching is enabled by setting bit GCE in the **ADDRCFG** register, the device has to react also when it receives a general call (0x00). The GC request is issued and also an acknowledge has to be set on the I2C-bus when the GC is detected.

Inter-Integrated Circuit Module (I2C)

S3: The address which has been received matches the one stored in the address field in the **ADDRCFG** register and the SDA line was at a high level when the RnW bit was sent. This means that the remote master wants to read from the slave. The corresponding bit RnW in the **BUSSTAT** register has to be set to 0 (write). Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BS (bus status) in register **BUSSTAT** to 11_B and generates an AM (address match) request. The device is now working as a slave-transmitter.

S4: The device detects a stop condition on the I2C-bus and switches back to SLAVE LISTENING state. No interrupt is generated after the device was not addressed. The bit-field BS (bus status) in register **BUSSTAT** is set to 00_B (bus free).

S5: If the device is configured via bit MCE (master code enable) in the **ADDRCFG** register to react on a master code, the device can change baud rate to high-speed (Hs) mode when a remote master sends a master code. No device is allowed to acknowledge this master call. The interrupt routine which is called (MC request issued), has to handle the clearing of the interrupt bit in register **PIRQSC**. The LISTENING state is reentered. From now on the device works as slave in high-speed mode until a stop condition occurs.

S6: The slave-transmitter has received an acknowledge from the master-receiver and continues transmission.

S7: After the reception of the address bytes has been finished and no address match has taken place, the device changes to BUS BUSY state.

S8: The device has detected a stop condition on the I2C-bus after/while it was addressed. A TX_END (transmission end) request is generated, the bus is free again respectively the bit-field BS (bus status) in register **BUSSTAT** has to be set to 00_B again. The slave is now in LISTENING state.

S9: The slave has received a restart condition (repeated start condition) after/while it was addressed. A TX_END (transmission end) request is generated, the state switches back to SLAVE RECEIVES ADDRESS. The slave is reset again to a new transmission pending state (bit-field BS in register **BUSSTAT** = 01_B). When the TBAM is activated (configuration register) the slave has to remember that it was addressed before because this event may be followed by a read access of the master to this device. So the address procedure after reset can be shortened and the transition S3 occurs one byte earlier (master sends 10-bit address mode byte with RnW bit = 1 (read)).

S10: A running transmission is ended by a remote master and this device wants to continue without losing control of the I2C-bus. The slave was not in transmission and resets to receive address bytes again since the new data transmission is concerning all connected slaves.

S11: The peripheral has problems to read data bytes from the FIFO (underflow/not ready). This is indicated by generating a TXF_UFL (TX FIFO underflow) request. It also changes to TRANSMISSION FINISHED state.

Inter-Integrated Circuit Module (I2C)

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B) until a stop or restart condition occurs.*

S12: The peripheral has problems to write the received byte into the FIFO (overflow/not ready). This is indicated by generating a RXF_OFL (RX FIFO overflow) request. The slave-transmitter puts a not-acknowledge on the I2C-bus to indicate its situation to the controlling master. This byte is not valid and will be discarded.

*Note: The device is still addressed by a master (bit-field BS in register **BUSSTAT** = 11_B) until a stop or restart condition occurs.*

S13: The remote master wishes to close the connection to this slave and sets a not-acknowledge on the I2C-bus. The device generates a NACK (not-acknowledge) request and changes to TRANSMISSION FINISHED state (bit-field BS in register **BUSSTAT** = 01_B). The interrupt routine can clear the appropriate bit via the corresponding bit in the **PIRQSC** register.

S14: The slave wants to stop the transmission and sets the SETEND bit in register **ENDDCTRL**. It puts a not-acknowledge on the I2C-bus after the next received byte. With this the slave gets the possibility to cancel the transmission via software intervention.

S15: The value of received bytes is equal to bit-field MRPS (maximum receive packet size) of the FIFO register **MRPSCTRL**. The FIFO part of the interface generates the signal MRPS_stop to the I2C kernel, which indicates the end of the received packet capacity. The slave produces a not-acknowledge to the master and changes to TRANSMISSION FINISHED. For more details on FIFO MRPS operation see [Section 31.2.4.5](#).

S16: The number of transmitted bytes is equal to the TPS bit-field of the FIFO register **TPSCTRL**. The FIFO controller generates the EOTXP (end of transmit packet) signal to the I2C kernel, which indicates the last byte to transmit. After the last byte the device changes to TRANSMISSION FINISHED. For more details on FIFO EOTXP operation see [Section 31.2.4.2](#).

Note: The master is not informed about this situation. Since the data flow control responsibility is task of the master device, it may continue receiving wrong values (0xFF).

S17: The module detects bus activity; no start condition has been detected before. A transmission may be currently in progress. The device changes to BUS BUSY state. This transition is performed if a start condition has been missed because the device was not activated (CONFIGURATION state).

Master Process Sub-state Machine

Figure 31-11 shows the master process sub-state machine. There are four different states in this sub-state machine:

Figure 31-11 Master Process Sub-state machine

LISTENING: This state has been previously described (**Figure 31-9**). If the device is configured as master, it is listening to events either from software (writing to **TPSCTRL** register) or from the I2C-bus.

MASTER TRANSMITS BYTES: The device has started a transmission on the I2C-bus by software. The first byte after a start condition contains the address byte including the RnW bit. According to this bit (RnW bit in **BUSSTAT** register is set by hardware) the direction of the following transfer is determined. Bytes are transmitted on the I2C-bus until the FIFO is empty or a stop is initiated by software.

Inter-Integrated Circuit Module (I2C)

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RESTART: The device wants to restart a transmission without losing the control over the I2C-bus. The clock SCL stays low as long as no further communication is requested. The only event that should occur in this state is writing to the **TPSCTRL** register. Nevertheless the device can give up the I2C-bus control by writing to bit SETEND in the **ENDDCTRL** register. Of course, when this situation occurs, the peripheral produces a stop condition on the I2C-bus.

If bit MCE (master code enable) is set in the **ADDRCFG** register, the device has to check if the transmitted address byte is a master code.

MASTER RECEIVES BYTES: The master has ordered bytes from the slave and handles the data transfer from the I2C-bus to the FIFO. This means that the bits are shifted into a buffer register in the I2C kernel and afterwards are passed to the FIFO. Every time a byte was transferred to the FIFO successfully the master-receiver produces an acknowledge in the according position.

The state transitions in the master process are:

M1: The software has written the number of bytes which have to be transmitted over the I2C-bus into the control register **TPSCTRL**. The FIFO generates appropriate data transfer requests which transfers valid data into the FIFO. A start condition is set on the bus and the bit-field BS (bus status) in register **BUSSTAT** is set to 10_B (busy master). The first (the first and the second) byte is (are) the 7-bit (10-bit) address of the slave which shall be accessed.

If the master wishes to initiate a transition to high-speed mode, the transition is only valid in combination with the MCE (master code enable) bit in the **ADDRCFG** register. The software has to write the master code into the FIFO, this means also the value of the **TPSCTRL** is predetermined with 1.

M2: The master receives an acknowledge from slave and the bit RnW in the **BUSSTAT** register was set to 1 during the addressing phase. A slave has been addressed successfully as transmitter, the state moves to MASTER RECEIVES BYTES. An RX (Receive) request is generated to distinguish between transmit- and receive-FIFO requests in non flow controller mode.

M3: The valid data packet from the FIFO was transferred successfully to the I2C-bus and the FIFO indicates this by the EOTXP (end of transmit packet) signal. If the RnW bit was set to 0 (writing to a slave) and bit SOPE (stop on packet end) in register **ADDRCFG** was set to 1, the transfer is closed by putting a stop condition on the bus. After this stop condition has been detected the peripheral indicates this successful transfer to the software via the TX_END (transmission end) request. The bus status bit-field is set to 0x0 (bus free).

Inter-Integrated Circuit Module (I2C)

M4: After the master transmits a byte it releases the SDA line to allow the addressed slave to pull down the SDA line (acknowledge). If this event occurs (and RnW in register **BUSSTAT** was set to 0), the master can continue to transfer bytes on the I2C-bus.

M5: The SDA line level is not equal to the one that is set by the master. This means that another master also tries to control the I2C-bus. This is indicated by the AL (arbitration lost) request and the device switches to the LISTENING state. The interrupt routine has to clear bit AL in the **PIRQSC** register. The Arbitration lost indication is not executable when the device works in high-speed mode (no arbitration procedure in high-speed mode since there is only one master remaining). The arbitration process must be operating at each bit which is sent by the master! Before interrupting the CPU, the bit-field BS (bus status) in register **BUSSTAT** is set to 01_B.

Note: It could be the case that the other master tried to address this device at the same time. Since this device could not check the transmitted address bytes till arbitration lost, no acknowledge is generated. The other master has to address this device once more.

M6: If the master wants to transmit bytes but the FIFO is empty (underflow), it has to generate a TXF_UFL (TX FIFO underflow) request. The bit-field BS (bus status) in register **BUSSTAT** is reset to 00_B, and a TX_END (transmission end) request is generated after the master has put a stop condition on the bus.

M7: The I2C kernel wants to transfer bytes to the FIFO but without success. Then it has to produce an RXF_OFI (RX FIFO overflow) request. The current byte is not-acknowledged and a stop condition is put on the bus (bit-field BS in register **BUSSTAT** is set to 00_B and a TX_END (transmission end) request is generated). (

M8: If master code has been transmitted by the device and a NACK (not-acknowledge) has been received, the MASTER RESTART state is entered. The clock SCL stays low as long as no further communication is requested. This is done by writing bit-field TPS in register **TPSCTRL** (see transition M9).

M9: A new communication in high-speed mode is started by writing bit-field TPS in register **TPSCTRL** when a master code has been previously transmitted (M8). The switch into high-speed mode (MC request) is done as soon as clock and data are released to high (see **Figure 31-12**). State MASTER TRANSMITS BYTES is entered. During high-speed mode, all fast and standard mode devices must be disconnected from the bus. This can be done in the MC request.

M10: Bit SETRSC has been set during the transmission of the data (the software wants to change direction/slave and therefore writes to the **ENDCTRL** register). The I2C kernel resets and changes to MASTER RESTART state and a TX_END (transmission end) request is generated. Therefore, the master does not lose the control of the I2C-bus after the transmission has ended. The master stops transmission after the current byte was acknowledged/not acknowledged. Valid data in the FIFO are discarded. In this situation the FIFO is flushed to produce an initial situation.

Inter-Integrated Circuit Module (I2C)

M11: If the master wants to change direction/slave immediately in this state, it has to write to bit SETRSC in the **ENDCTRL** register. The master puts a not-acknowledge on the appropriate place during the current transmitted byte. This indicates the slave-transmitter to stop transmission. The master switches to MASTER RESTART state; a TX_END (transmission end) request is generated.

M12: By sending a not-acknowledge on the bus, the master indicates the slave an upcoming stop of the transmission. This is established by writing to bit SETEND in register **ENDCTRL**. This end of transmission is indicated to the FIFO which then transports the remaining valid data to the memory (indicating the data end either by a LSREQ or a LBREQ). Stop condition and TX_END (transmission end) request are generated. The LISTENING state is entered; the bit-field BS (bus status) in register **BUSSTAT** is set to 00_B.

M13: If the master is receiving a not-acknowledge and bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 1, it produces a stop condition, resets the bit-field BS (bus status) in register **BUSSTAT** and issues a NACK (not-acknowledge) request and a TX_END (transmission end) request. The FIFO is flushed; remaining data in the FIFO stages are discarded.

M14: If bit SONA (stop on not-acknowledge) in the **ADDRCFG** register is 0, the peripheral wants to remain the controlling master of the I2C-bus after receiving a not-acknowledge. The next state is MASTER RESTART. A NACK (not-acknowledge) request and a TX_END (transmission end) request indicate this event to the software. The FIFO transfers the valid data to the memory.

M15: The master decided to transfer data on the bus again and writes to the **TPSCTRL** register. The first byte is interpreted as address byte (the 8th bit indicates RnW). The appropriate data transfer requests are activated by the FIFO controller. After the SCL line is high again (slave can stretch the low period) the master is allowed to put a restart condition onto the bus and is again in the MASTER TRANSMITS BYTES state starting to transmit bytes again.

M16: The software has written the SETEND bit in the **ENDCTRL** register. The peripheral stops transmission of bytes after the current byte has been written on the bus. The I2C kernel flushes the FIFO since the remaining data in the FIFO is invalid. A TX_END (transmission end) request is generated.

M17: The FIFO indicates the end of the data packet and the peripheral was configured to go into MASTER RESTART state after that event. Since the data transfer has ended as intended a TX_END (transmission end) request is produced.

M18: The master has no data to send anymore but still controls the I2C-bus. Therefore it can use the SETEND bit to give up the I2C-bus control by setting a stop condition. A TX_END (transmission end) request is generated.

M19: A value different to zero is programmed to bit-field MRPS (maximum receive packet size) of the **MRPSCTRL** register. If the number of received bytes is equal to the MRPS bit-field, the FIFO produces the MRPS_stop signal. When bit SOPE (stop on

Inter-Integrated Circuit Module (I2C)

packet end) in the **ADDRCFG** register is set to 0, the master generates a not-acknowledge and changes to MASTER RESTART state, so the master does not lose the control over the I2C-bus. A TX_END (transmission end) request is generated.

M20: (See also M19.) The FIFO produces the MRPS_stop signal which indicates that the desired amount of received data bytes is reached. The peripheral generates a not-acknowledge and changes to LISTENING state because bit SOPE (stop on packet end) in the **ADDRCFG** register is set to 1. Of course, the interface produces a stop condition; so the I2C-bus is free again (change also the bus status bit-field!). A TX_END (transmission end) request is also generated. The LBREQ or the LSREQ indicate the completed reception of data. For more details on FIFO MRPS operation see [Section 31.2.4.5](#).

Inter-Integrated Circuit Module (I2C)

Figure 31-12 Connection Examples including Requests in Master and Slave Mode

Inter-Integrated Circuit Module (I2C)

31.2.4 FIFO Operation

The I2C module uses a FIFO between its kernel and the bus, in order to adapt the character processing speed of the peripheral to the transfer rate of the bus system. The FIFO has a transmission state and a reception state. **Figure 31-13** shows the bidirectional half duplex TX/RX FIFO unit with the input and output lines and with the corresponding FIFO registers.

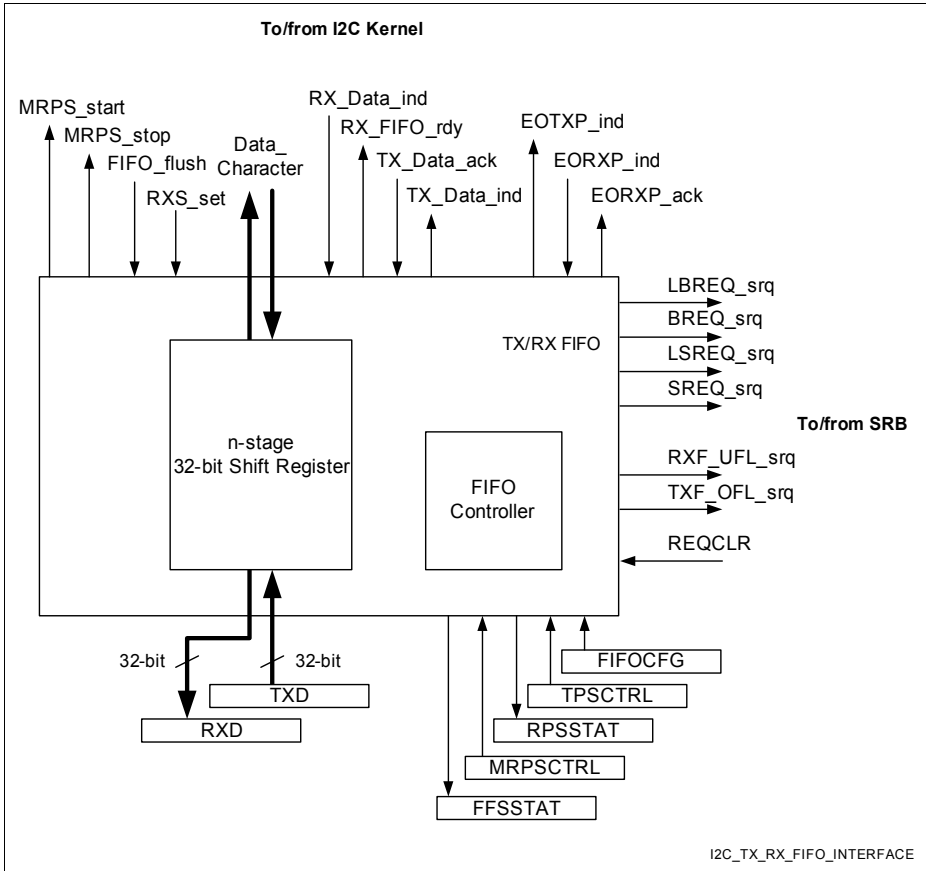

Figure 31-13 Bidirectional Half Duplex TX/RX FIFO

31.2.4.1 Data Transmission

The software can move transmit data to the FIFO by writing to the Transmission Data Register **TXD**. Moving data to the FIFO can be done according to the data transfer request signals generated by the FIFO controller as described in [Section 31.2.4.2](#). But with the register **FFSSTAT**, which indicates the number of full FIFO stages, the data transfer to the FIFO can be handled completely without data transfer requests. The data alignment within the FIFO is described in [Section 31.2.4.3](#). The FIFO shifts data to the I2C kernel by means of the handshake lines `tx_data_ind` and `tx_data_ack`.

With the signal `FIFO_flush` the I2C kernel is able to clear the FIFO content. But if a data transfer request (see [Section 31.2.4.2](#)) is pending, then the FIFO is not cleared until the corresponding signal `REQCLR` has been set by software.

The I2C-bus interface should know when it is receiving the last character of a data packet from the FIFO. Therefore the software should define a transmit packet size in bit-field `TPS` of register **TPSCTRL** and then the FIFO controller indicates the last character of the packet to the I2C kernel by setting the `EOTXP` (end of transmit packet) signal.

Since `TPS` is double buffered the software can write the size of the next packet into `TPS` as soon as the `TPS` value of the current packet has been loaded into the `TPS` counter, i.e. reading `TPS` returns 0. This happens a few clock cycles after the previous packet has been transmitted.

Also the characters of the next packet can be moved to the FIFO immediately after the current packet characters as indicated in [Figure 31-14](#). If byte or half word alignment is used as described in [Section 31.2.4.3](#), then the characters of two different packets must not be aligned in a single stage.

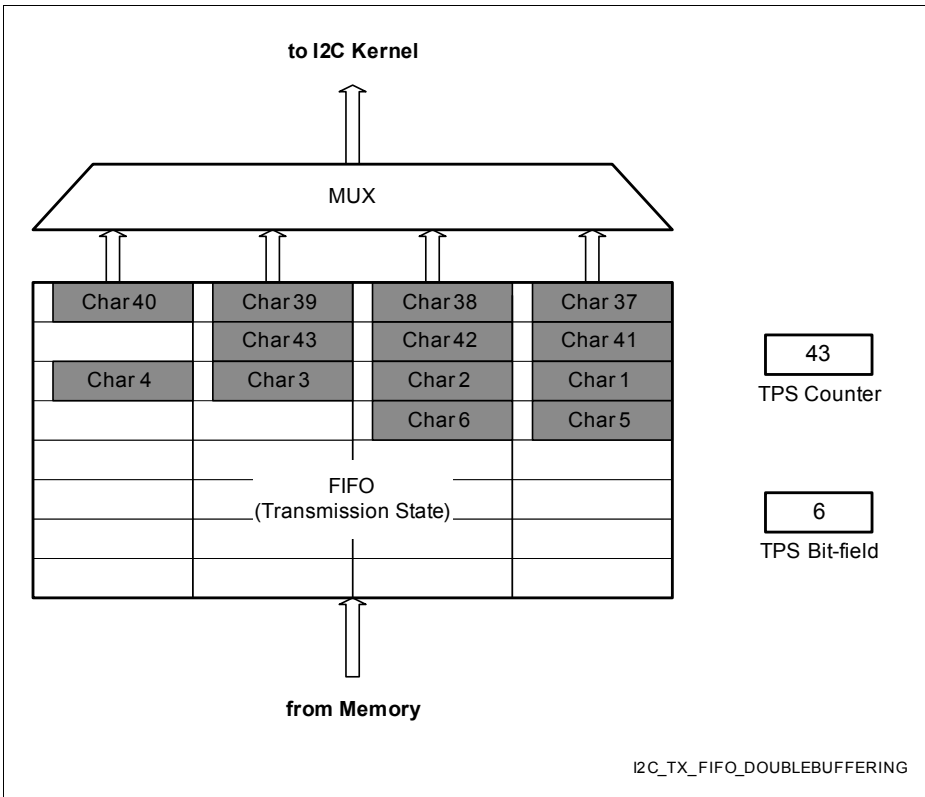

Figure 31-14 FIFO Containing Data of Two Different Transmit Packets

Error Handling

- If a TX FIFO overflow occurs (i.e. the software writes data too fast to the FIFO), then the new incoming character is discarded and a TX FIFO overflow interrupt request is generated.
- If a TX FIFO underflow occurs (i.e. the I2C kernel tries to read from an empty FIFO), then the I2C kernel generates a TX FIFO underflow interrupt request.

31.2.4.2 Transmit Request Generation

For the following it is assumed that the FIFO is used as flow controller, selected via bit TXFC of the **FIFOCFG** register.

In this case the bit-field TPS of the **TPSCTRL** register is not only used for the generation of the EOTXP (end of transmit packet) signal (see **Section 31.2.4.1**), but also to initiate

Inter-Integrated Circuit Module (I2C)

the whole data transfer. I.e. the software indicates that it wants to transmit a data packet by writing the packet size to the bit-field TPS. Then the FIFO unit asserts burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size set in bit-field TXBS of register **FIFOCFG**. At this point, if the remaining data is equal to the burst size, then a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

Notes

1. *The next request is only generated if previous request was cleared.*
2. *Pre-loading TPS with the packet size of the next frame, before the current packet has been transmitted completely, enables a continuous data throughput (e.g. of audio data).*
- 3.
4. *If the FIFO is not used as flow controller, the I2C-bus interface should use bit-field TPS of the TPSCCTRL register to set the EOTXP signal. A burst request BREQ is generated each time the number of empty FIFO stages is equal or greater than the burst size set in bit-field TXBS and the previous request was cleared. No single requests SREQ and LSREQ will be issued.*

31.2.4.3 Transmit Data Alignment

Depending on bit-field TXFA (TX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Note: Byte alignment is synonymous with character alignment, half word alignment with character alignment of two data characters, and word alignment with character alignment of four characters.

Byte Aligned TX Characters

If the TX characters are byte aligned, then the FIFO extracts the bytes and shifts them to the I2C kernel via a multiplexer as it is shown in **Figure 31-15**.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 4, the last word must be filled up with dummy bytes if necessary. The FIFO transmits only the valid bytes of the last word depending on the setting of the bit-field TPS of the **TPSCTRL** register.

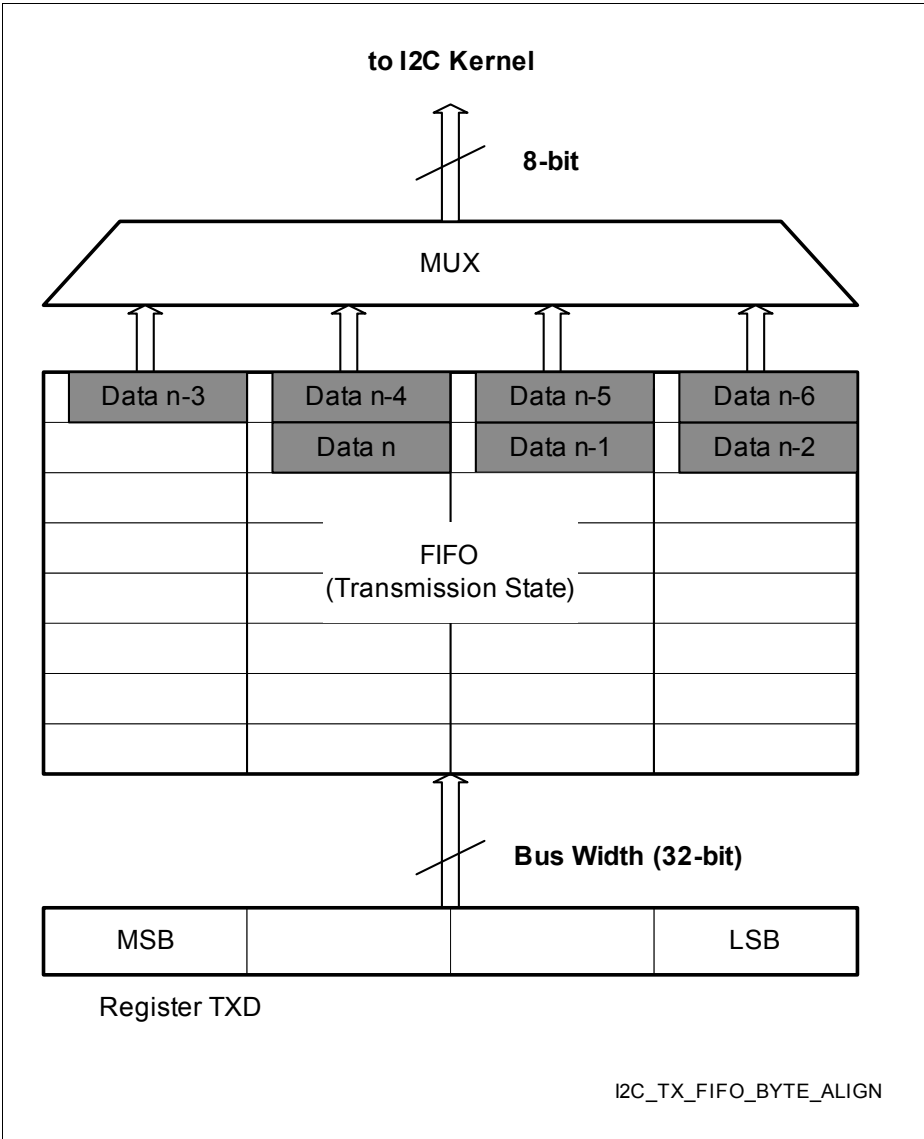

Figure 31-15 FIFO in Transmission State with Byte Aligned Data

Inter-Integrated Circuit Module (I2C)**Half Word Aligned**

If the TX characters are half word aligned, then the FIFO extracts the half words and shifts them to the I2C kernel via a multiplexer as it is shown in [Figure 31-16](#).

Note: The I2C kernel extracts the right data bits from the half word it receives from the FIFO.

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 2, the last word must be filled up with a dummy half word if necessary. The FIFO transmits only the valid half words of the last word depending on the setting of the bit-field TPS.

Figure 31-16 FIFO in Transmission State with Half Word Aligned Data

Inter-Integrated Circuit Module (I2C)

Word Aligned

If the TX characters are word aligned, then the FIFO shifts them to the I2C kernel as it is shown in **Figure 31-17**.

Note: The I2C kernel extracts the right data bits from the word it receives from the FIFO.

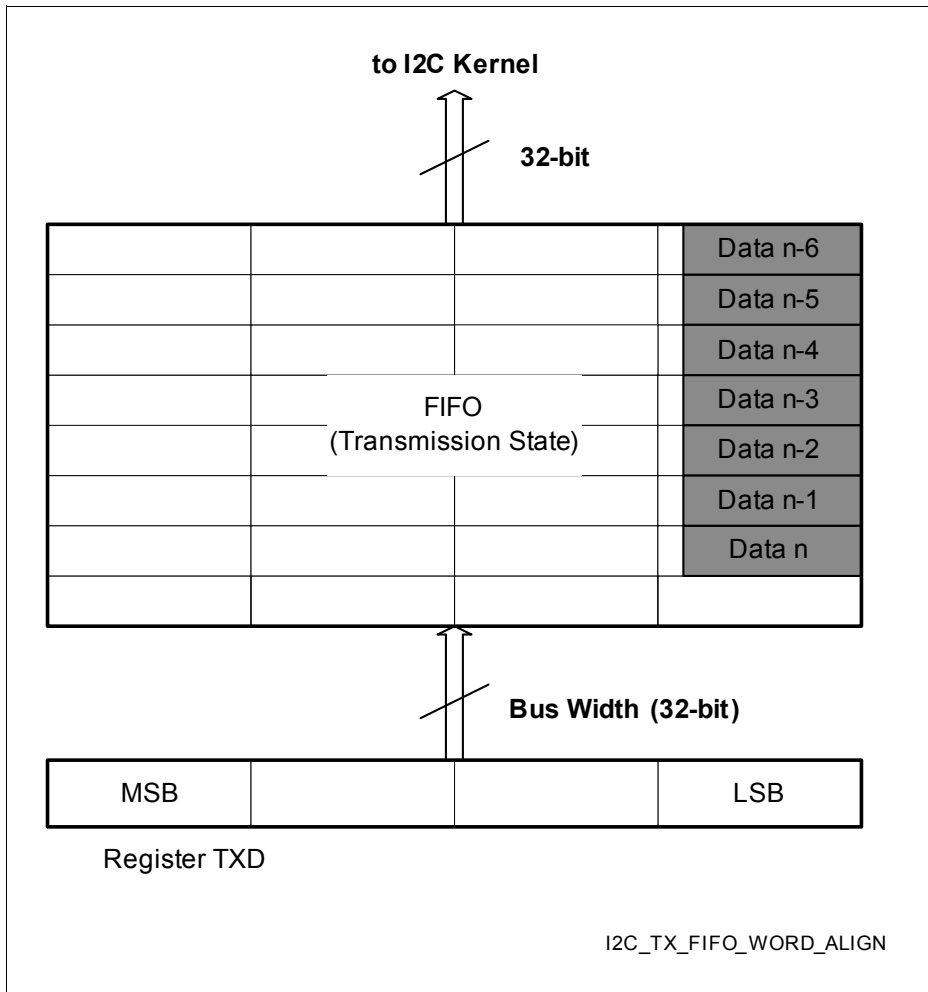

Figure 31-17 FIFO in Transmission State with Word Aligned Data

31.2.4.4 Data Reception

The software can read received data from the FIFO by reading the Reception Data Register **RXD**. Reading data from the FIFO should be done according to the data transfer request signals generated by the FIFO controller. The register **FFSSTAT** indicates the number of filled FIFO stages. The data alignment within the FIFO is described in [Section 31.2.4.6](#). The I2C kernel shifts data into the FIFO by means of the handshake signals **RX_FIFO_rdy** and **RX_Data_ind**.

Before the first reception starts, the I2C kernel has to set the **RXS_set** line. This causes the assertion of **RX_FIFO_rdy** to indicate the I2C kernel that one data character can be written into the FIFO.

With the signal **FIFO_flush** the I2C kernel is able to clear the FIFO content. But if a data transfer request is pending and the FIFO is configured as flow controller, then the FIFO is not cleared until the corresponding signal **REQCLR** has been set by software.

Error Handling

- If the RX FIFO is completely full (i.e. the software reads out the data too slow), then the I2C kernel generates an RX FIFO overflow interrupt request.
- If an RX FIFO underflow occurs (i.e. the software reads from empty FIFO), then an RX FIFO underflow interrupt request is generated.
- If an error (including the FIFO overflow condition described above) is detected in the I2C kernel and the current reception is stopped, then it also has to generate an **EORXP_ind** signal, so that the remaining characters in the FIFO can be moved out by means of data transfer requests.

31.2.4.5 Receive Request Generation

If the whole data of the current received packet has been moved into the buffer, then the I2C kernel will set the **EORXP_ind** (end of receive packet indication) signal. The received characters, which are shifted in the FIFO, are counted by an **RPS** (received packet size) counter. If an **EORXP_ind** occurs, then the content of the **RPS** counter is moved to the register **RPSSTAT** and the counter is reset. If data alignment in the FIFO is used, then the **RPSSTAT** value can be used to check for valid characters in the last read word (see [Section 31.2.4.6](#)).

For the following it is assumed that the FIFO is used as flow controller, selected via bit **RXFC** of the **FIFOCFG** register.

The FIFO unit asserts burst requests **BREQ** each time the FIFO filling level is greater than the burst size set in bit-field **RXBS** of register **FIFOCFG**. An **EORXP_ind** causes the FIFO unit to assert burst requests **BREQ** until the amount of data still to be transferred is less than or equal to the burst size. At this point, if the remaining data is equal to the burst size, a last burst request **LBREQ** is issued. Otherwise, single requests **SREQ** and a last single request **LSREQ** will be issued.

Inter-Integrated Circuit Module (I2C)

When the packet has been shifted out of the FIFO by software, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.

The next received packet may be shifted into FIFO immediately after the current packet, so that the FIFO contains data of two different packets. But the EORXP_ind of the next packet must not be asserted before the EORXP_ind of the current packet has been acknowledged. The RPS counter is counting the characters of the next packet, while in the register **RPSSTAT** the packet size of the current packet remains readable. The first character of the new packet is always shifted in a new FIFO stage as indicated in **Figure 31-18**. (The FIFO data alignment is described in **Section 31.2.4.6**.)

Figure 31-18 FIFO Containing Data of Two Different Receive Packets

If the number of the received characters of one packet is equal to the maximum received packet size, which is defined by bit-field MRPS in register **MRPCTRL**, then the FIFO controller gets into the state, where it generates LBREQ or SREQ and LSREQ. If the I2C

Inter-Integrated Circuit Module (I2C)

kernel generates an EORXP_ind in this state, then this indication is valid for the received packet and the FIFO accepts no more characters from the I2C kernel until the current packet has been moved out of the FIFO or the start of a new packet has been detected by asserting RXS_set.

The bit-field MRPS is double buffered, i.e. the software can write the MRPS value of the next packet as soon as the current MRPS value has been loaded, i.e. reading MRPS returns 0. This happens a few clock cycles after all data of the previous packet have been read from the FIFO. If an MRPS overflow occurs (one character before the last character is received), then the MRPS_stop trigger to the I2C kernel is generated. But if the next MRPS value is written to MRPS before the last data character of current frame has been completely received, then no MRPS_stop is generated. The I2C-bus interface will use the MRPS_stop trigger to stop the reception of the corresponding data packet.

But the MRPS bit-field can also be used to initiate a reception, when the peripheral is master-receiver. Therefore writing to MRPS generates a trigger MRPS_start to the I2C kernel. The next MRPS value written to MRPS generates only an MRPS_start when an MRPS_stop was generated before.

The MRPS features can only be used if the FIFO is the flow controller.

Notes

- 1. When the MRPS control feature of the FIFO is used to limit the packet size of a continuous incoming data stream (MRPS is only written once and left unchanged), characters exceeding MRPS are discarded. The FIFO can not handle more than two packets. When the FIFO is filled with data characters of two packets then a further RXS_set will be overseen by the FIFO. Additionally the FIFO does not set the RX_FIFO_rdy.*
- 2. If the FIFO is not used as flow controller, a single request SREQ is always generated as soon as the readable FIFO stage is filled up with characters. Additionally, a burst request BREQ is generated as soon as the number of filled FIFO stages is equal to or greater than the burst size set in bit-field RXBS of register FIFOCFG. When the I2C kernel sets EORXP_ind, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.*

31.2.4.6 Receive Data Alignment

Depending on bit-field RXFA (RX FIFO Alignment) in register **FIFOCFG**, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Byte Aligned

If the RX data should be byte aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in **Figure 31-19**.

Since the number of characters of the received packet is not necessarily a multiple of 4, the upper bytes of the last word can be invalid. The software has to check for invalid bytes of the last word by means of the bit-field RPS (received packet size) in register **RPSSTAT**.

Figure 31-19 FIFO in Reception State with Byte Aligned Data

Inter-Integrated Circuit Module (I2C)**Half Word Aligned**

If the RX data should be half word aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a demultiplexer as it is shown in [Figure 31-20](#).

Note: The I2C kernel fills up the half words with dummy bits.

Since the number of characters of the received packet is not necessarily a multiple of 2, the upper bytes of the last word can be invalid. The software has to check for invalid half words of the last word by means of the bit-field RPS (received packet size) in register [RPSSTAT](#).

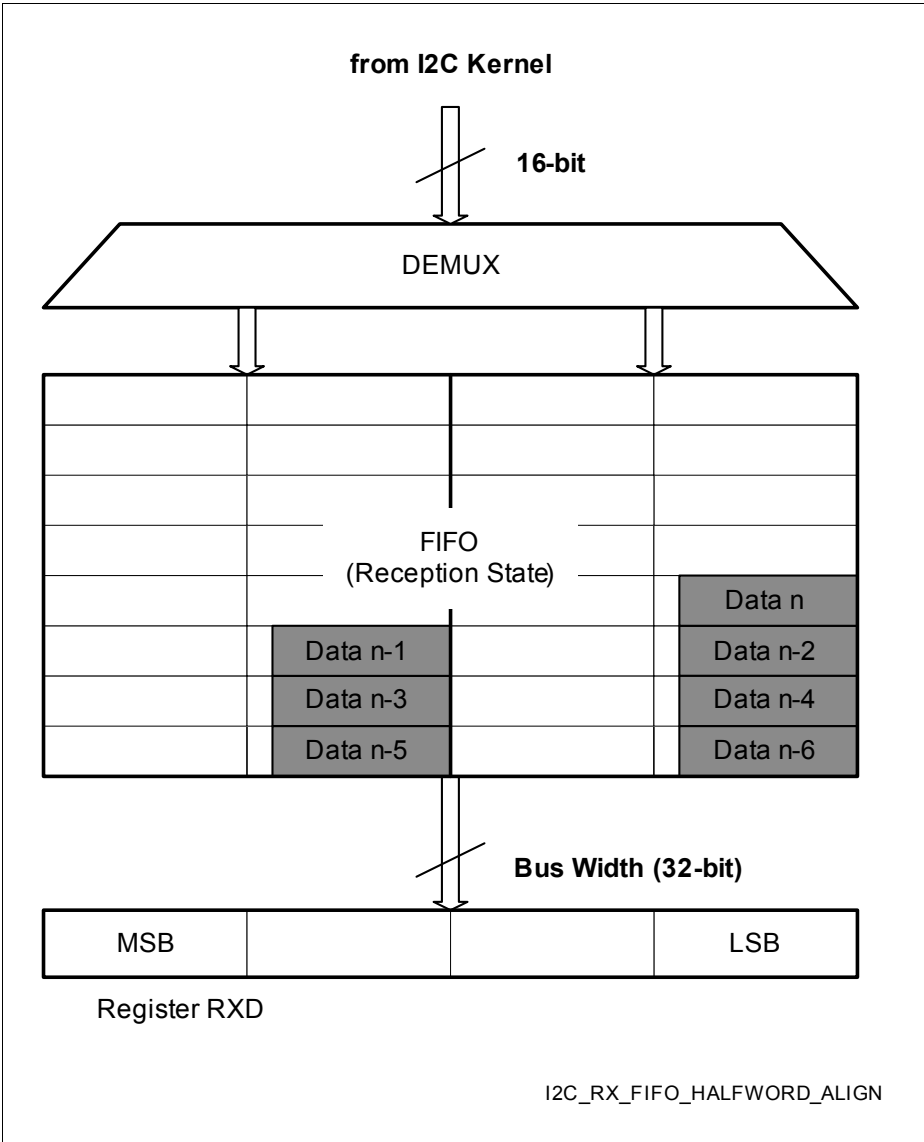

Figure 31-20 FIFO in Reception State with Half Word Aligned Data

Inter-Integrated Circuit Module (I2C)

Word Aligned

If the RX data should be word aligned, then the characters from the I2C kernel are shifted to the FIFO as it is shown in **Figure 31-21**.

Note: The I2C kernel fills up the words with dummy bits.

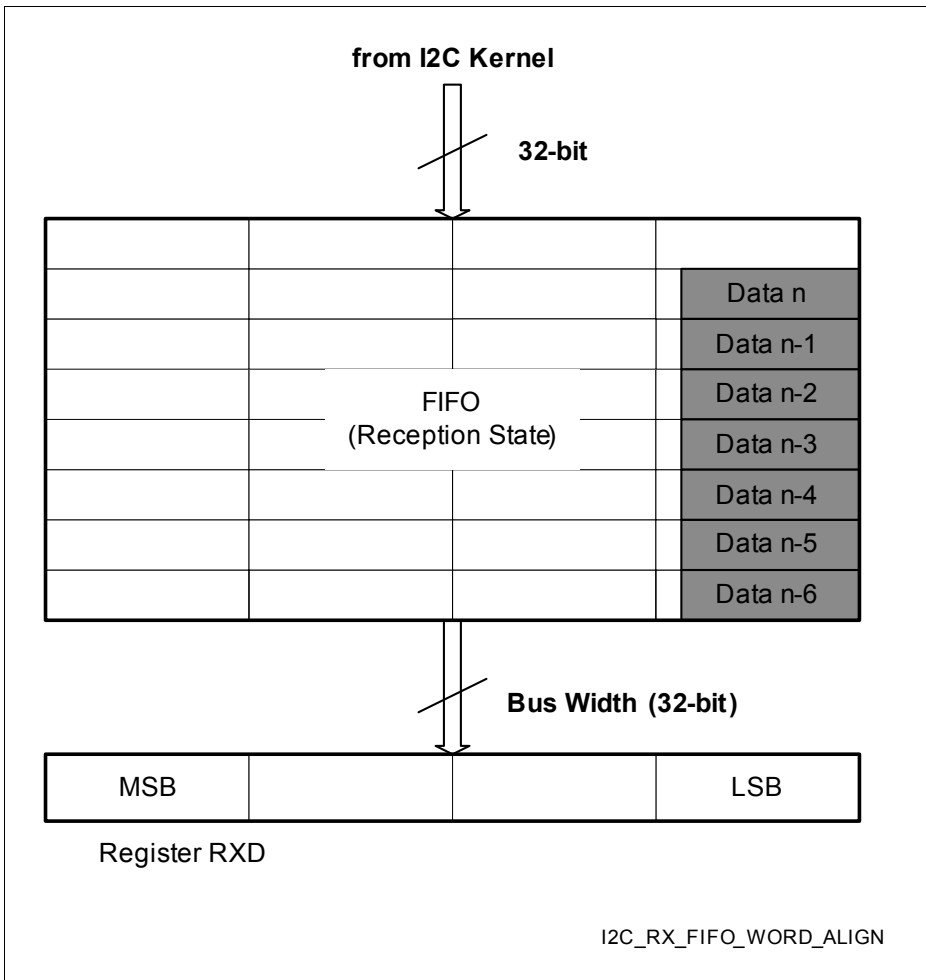

Figure 31-21 FIFO in Reception State with Word Aligned Receive Data

31.2.4.7 Switching between Transmission and Reception

Initially, the FIFO is in the TX state, so that the software can initiate a TX transfer simply by writing data to the bit-field TXD. If the I2C kernel wants the FIFO to switch to the RX state in the meantime, then it can set the RXS_set line and even if transmission is ongoing the TX transfer is aborted. This causes the FIFO to flush its content, switch to the RX state and reset the received packet size counter. If the software wants to write to the register TXD when the FIFO is in RX state, then this causes a bus error. As soon as the FIFO has received an EORXP_ind signal from the kernel and the software has moved all RX characters out of the FIFO via the register RXD, the FIFO automatically switches back into the TX state.

If the software writes to the register TPSCTRL when the FIFO is in the RX state, the TPS value is pending until the FIFO returns to the TX state. Then the transmission is initiated, if the FIFO is the flow controller.

If the FIFO is flow controller and the software writes to the register MRPSCTRL, then an MRPS_start is generated independent of the state of the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (xREQ) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been set by software. If the FIFO has been cleared in the RX state, then it switches back to the TX state afterwards.

31.2.5 Service Request Block Operation

The SRB (Service Request Block) of the I2C module is used to prepare the interrupt and data transfer requests for the interrupt controller.

31.2.5.1 Overview of Service Requests

The I2C service requests are partially combined in the SRB (see [Section 31.3.4](#) and [Section 31.3.5](#)). [Figure 31-22](#) shows an overview of the service requests. [Table 31-2](#) provides a list of all service requests of the I2C module.

Inter-Integrated Circuit Module (I2C)

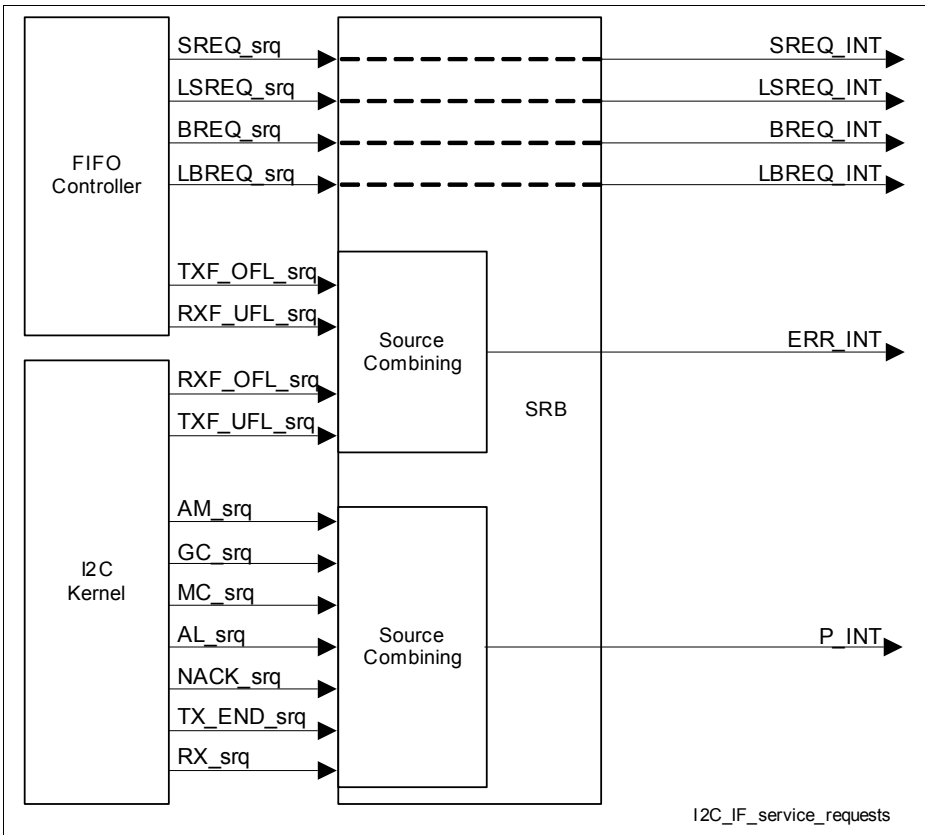

Figure 31-22 Overview of I2C Module Service Requests

Table 31-2 I2C Module Service Requests

Service Request	InterruptRequest	Description
BREQ_srq	BREQ_INT	Burst Data Transfer Request FIFO requests a transfer of a programmed burst number of words from/to the memory.
LBREQ_srq	LBREQ_INT	Last Burst Data Transfer Request FIFO requests a last burst transfer from/to the memory.

Inter-Integrated Circuit Module (I2C)
Table 31-2 I2C Module Service Requests (cont'd)

Service Request	InterruptRequest	Description
SREQ_srq	SREQ_INT	Single Data Transfer Request FIFO requests a single transfer of a word from/to the memory.
LSREQ_srq	LSREQ_INT	Last Single Data Transfer Request FIFO requests a last single transfer from/to the memory.
TXF_OFL_srq	ERR_INT	TX FIFO Overflow Request FIFO has detected a TX FIFO overflow.
TXF_UFL_srq	ERR_INT	TX FIFO Underflow Request I2C kernel has detected a TX FIFO underflow. The transmission is finished after the current byte. A stop condition is generated if the kernel works as master. The kernel changes to listening state.
RXF_OFL_srq	ERR_INT	RX FIFO Overflow Request I2C kernel has detected an RX FIFO overflow and the incoming character is discarded. The kernel puts a not-acknowledge on the bus and changes to listening state. A stop condition is generated if the kernel works as master.
RXF_UFL_srq	ERR_INT	RX FIFO Underflow Request FIFO has detected an RX FIFO underflow.
AM_srq	P_INT	Address Match Request Device (master/slave) has been addressed by a remote master (also indicated in bit-field BS in register BUSSTAT).
GC_srq	P_INT	General Call Request When the general call matching process is activated this interrupt indicates that another master has put a general call on the I2C-bus.
MC_srq	P_INT	Master Code Request When the master code matching process is activated this interrupt indicates the appearing of a master code on the I2C-bus issued by a remote master. The request is generated after a not-acknowledge and the clock is released to high again.

Inter-Integrated Circuit Module (I2C)
Table 31-2 I2C Module Service Requests (cont'd)

Service Request	InterruptRequest	Description
AL_srq	P_INT	Arbitration Lost Request Arbitration is lost after the device has tried to start a transmission on the I2C_bus.
NACK_srq	P_INT	Not-acknowledge Received Request Not-acknowledge received when working as transmitter (i.e. RnW bit is 0).
TX_END_srq	P_INT	Transmission End Request In master mode this event is produced by the I2C kernel to indicate that the transmission of the current packet has ended properly after the stop condition has been put on the I2C-bus or MASTER RESTART state has been entered. (At this point, a restart condition can be generated or the connection can be finished by generating a stop condition). This request is created in master mode at any stop condition to indicate that the bus is free again and it could be obtained. In slave mode this event is produced by the I2C kernel if it was addressed by a master and the current transmission was terminated by a stop or restart condition.
RX_srq	P_INT	Receive Mode Request I2C kernel indicates to the FIFO switching from transmit to receive mode. When FIFO is operating in non flow controller mode, this service request can be used to distinguish between transmit and receive FIFO data requests.

The generation of these events is visualized in the state machine [Figure 31-9](#), [Figure 31-10](#) and [Figure 31-11](#). The timing is shown in [Figure 31-12](#).

31.2.5.2 Interrupt Service Request Structure

The I2C module provides level based service request lines, which can be processed by an interrupt controller. The service requests must be cleared in the interrupt service routine. For test purposes, all service requests can also be set by SW via a register bit. All service requests can be masked within the peripheral. Furthermore, requests that are not necessarily mutually exclusive are combined in order to reduce the number of request lines.

Flow of Data Transfer Requests

Figure 31-23 shows the flow of a data transfer request, which comes from the FIFO controller.

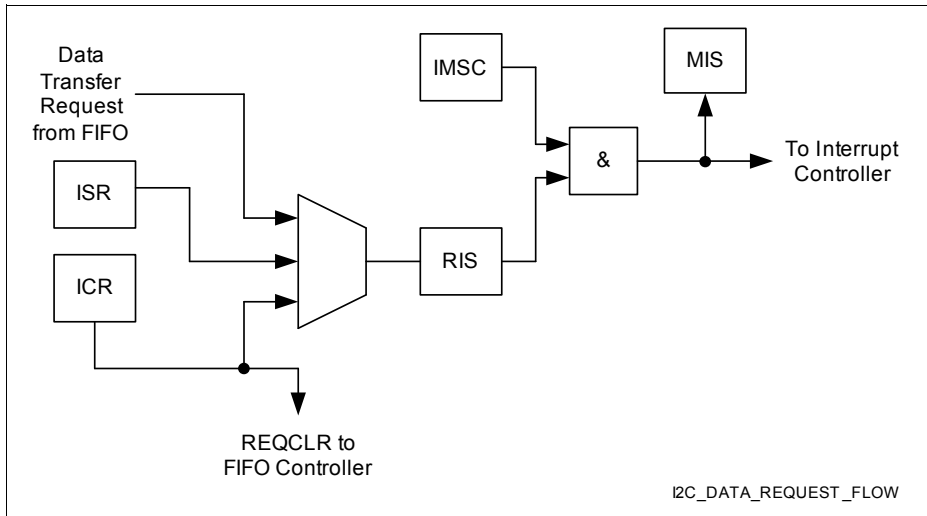

Figure 31-23 Data Transfer Request Flow

A data transfer request sets the corresponding status bit in the Raw Interrupt Status Register **RIS**. The status bit can also be set by writing 1 to the corresponding bit in the Interrupt Set Register **ISR**. It will be cleared by writing 1 to the corresponding bit in the Interrupt Clear Register **ICR**.

The Interrupt Mask Control Register **IMSC** enables or disables the requests to the interrupt controller. The Masked Interrupt Status Register **MIS** contains the current masked values of the requests.

If a request is disabled via register **IMSC** while the request is active, the request will be removed but only until the **IMSC** bit is set again, unless the request has been cleared in the meantime.

If a request is disabled via register **IMSC** and the source becomes active, then the request bit will only be set in the **RIS** register. If the corresponding **IMSC** bit is later enabled, the request will consequently become active in the **MIS** register.

Before enabling a request, it is good practice to always first clear the corresponding bit in the **RIS** register via **ICR**.

Multiple Source Interrupt Requests

For error and protocol interrupt requests which have multiple sources, the interrupt structure is extended. Additional register sets are implemented within the SRB.

Figure 31-24 gives an overview of the combining of several request sources to a single request.

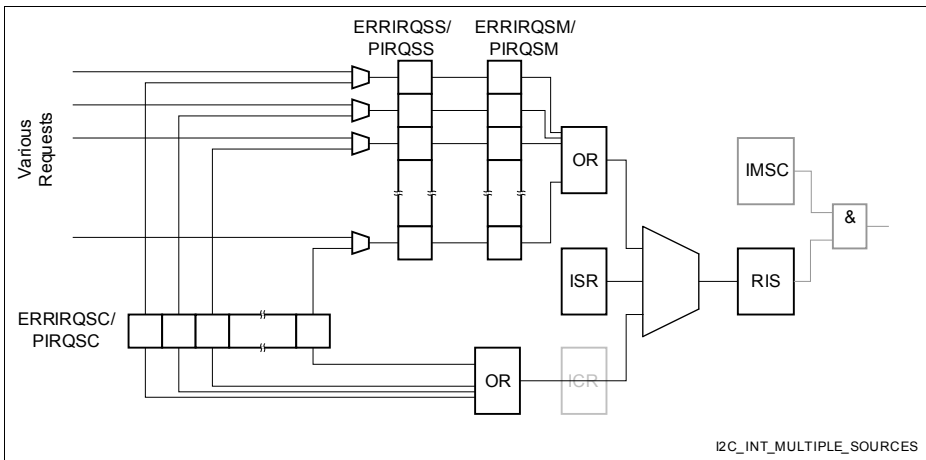

Figure 31-24 Interrupt Request with Multiple Sources

An interrupt request sets the corresponding raw status bit in the Interrupt Request Source Status Register **ERRIRQSS** (for error) or **PIRQSS** (for protocol).

The status bits can be cleared via the Interrupt Request Source Clear Register **ERRIRQSC** (for error) or **PIRQSC** (for protocol). If no further error/protocol request sources are active, the whole error/protocol interrupt request is cleared. This register replaces the functionality of the bit I2C_ERR_INT (for error) or bit I2C_P_INT (for protocol) in the Interrupt Clear Register **ICR**.

The Interrupt Request Source Mask Register **ERRIRQSM** (for error) or **PIRQSM** (for protocol) enables or disables the interrupt requests. The request lines from the enabled sources are combined (OR) to a single level sensitive request line, which acts as input for the corresponding bit I2C_ERR_INT (for error) or I2Cm_bit I2C_P_INT (for protocol) in the Raw Interrupt Status Register **RIS**.

Inter-Integrated Circuit Module (I2C)

31.3 I2C Module Internal Registers

This section describes the internal registers of the I2C module. All register names described in this section are also referenced in other parts of the TC26x B-Step User's Manual by the module name prefix "I2Cm_". For an overview of all module registers, see [Section 31.4.4](#).

31.3.1 Global Module Control Registers

Module Identification Register

This register contains read-only information about the module and its revision.

ID

Module Identification Register (08_H) Reset Value: 0000 5703_H

Field	Bits	Type	Description
MOD_REV	7:0	r	Module Revision Number This bit-field defines the revision number.
MOD_NUMBER	15:8	r	Module Number This bit-field defines the module identification number..
0	31:16	r	Reserved Read as 0; should be written with 0.

RUN Control Register

This register selects configuration mode or run mode.

RUNCTRL

RUN Control Register (10_H) Reset Value: 0000 0000_H

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
RUN	0	rw	Enable I2C-bus Interface 0 _B I2C-bus interface disabled; write access to configuration registers enabled 1 _B Participation in I2C-bus communication enabled (if properly configured); write access to configuration registers disabled
0	31:1	r	Reserved Read as 0; should be written with 0.

End Data Control Register

This register is used to either turn around the data transmission direction or address another slave without sending a stop condition. Also the software can stop the slave-transmitter by sending a not-acknowledge when working as master-receiver or even stop data transmission immediately when operating as master-transmitter. The writing to the bits of this control register is only effective in certain states.

ENDDCTRL

End Data Control Register (14_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SETRSC	0	w	<p>Set Restart Condition</p> <p>This bit is always read as 0.</p> <p>0_B Has no effect.</p> <p>1_B The master wants to restart a data transmission (changing slave/direction). The effect depends on the current state.</p> <p>MASTER RECEIVES BYTES: The master puts a not-acknowledge on the bus and switches to MASTER RESTART state.</p> <p>MASTER TRANSMITS BYTES: After the current byte has been sent, the master switches to MASTER RESTART state.</p>
SETEND	1	w	<p>Set End of Transmission</p> <p>This bit is always read as 0.</p> <p><i>Note: Do not write 1 to this bit when bus is free. This will cause an abort after the first byte when a new transfer is started.</i></p> <p>0_B Has no effect.</p> <p>1_B The effect depends on the current state.</p> <p>MASTER RECEIVES BYTES: After receiving the current byte, the master puts a not-acknowledge on the bus to indicate the transmission end to the slave-transmitter. Next it produces a stop condition on the bus and changes its state to LISTENING.</p> <p>MASTER TRANSMITS BYTES: After sending the current byte and receiving an acknowledge or not-acknowledge from the slave-receiver, the master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING.</p> <p>MASTER RESTART: The master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING.</p> <p>SLAVE RECEIVES BYTES: The slave-receiver puts a not-acknowledge on the bus after the received byte and changes its state to TRANSMISSION FINISHED.</p>

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
0	31:2	r	Reserved Read as 0; should be written with 0.

Fractional Divider Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for standard and fast mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured.

FDIVCFG
Fractional Divider Configuration Register
(18_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
DEC	10:0	rw	Decrement Value of Fractional Divider For standard/fast mode, see Baudrate Generation .
INC	23:16	rw	Increment Value of Fractional Divider For standard/fast mode, see Baudrate Generation .
0	15:11, 31:24	r	Reserved Read as 0; should be written with 0.

Fractional Divider High-speed Mode Configuration Register

This configuration register is used to program the fractional divider of the I2C-bus for high-speed mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured if high-speed mode is used.

Inter-Integrated Circuit Module (I2C)

FDIVHIGHCFG
Fractional Divider High-speed Mode Configuration Register

 (1C_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
DEC	10:0	rw	Decrement Value of Fractional Divider For high-speed mode, see Baudrate Generation .
INC	23:16	rw	Increment Value of Fractional Divider For high-speed mode, see Baudrate Generation .
0	31:24, 15:11	r	Reserved Read as 0; should be written with 0.

Inter-Integrated Circuit Module (I2C)
Address Configuration Register

This configuration register contains the I2C-address (when addressed as a slave) and some bits that control the basic operation of the peripheral.

ADDRCFG
Address Configuration Register
(20_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ADR	9:0	rw	I2C-bus Device Address This bit-field determines the address of the device when addressed as a slave. (Watch out for reserved addresses by referring to I2C-bus spec V2.1.) Depending on setting of TBAM, this is either a 7-bit address (bits [7:1]) or a 10-bit address (bits [9:0]).
TBAM	16	rw	Ten Bit Address Mode <i>Note: When this bit is zero, only bits 7 down to 1 of the ADR field are valid.</i> 0 _B 7-bit address mode enabled. 1 _B 10-bit address mode enabled.
GCE	17	rw	General Call Enable 0 _B Ignore general call occurrence. 1 _B Enable general call detection; when detected, an acknowledge will be put on the bus
MCE	18	rw	Master Code Enable 0 _B Device is not able to get along with high-speed mode 1 _B Device is able to handle master code

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
MnS	19	rw	Master / not Slave 0 _B Peripheral is configured as slave 1 _B Peripheral is configured as master
SONA	20	rw	Stop on Not-acknowledge <i>Note: After successful transmission of a master code (during high-speed mode) SONA is not considered till a stop condition is manually generated by SETEND.</i> 0 _B Device changes to MASTER RESTART state. 1 _B Device puts a stop condition on the bus and changes to LISTENING state.
SOPE	21	rw	Stop on Packet End <i>Note:</i> <ol style="list-style-type: none"> If device works as receiver a not-acknowledge is always generated on package end. After successful transmission of a master code (during high-speed mode) SOPE is not considered till a stop condition is manually generated by SETEND. 0 _B Device enters MASTER RESTART state when the data packet end is indicated by the FIFO. 1 _B Device puts a stop condition on the bus when the data packet end is indicated by the FIFO and changes to MASTER LISTENING state.
0	15:10, 31:22	r	Reserved Read as 0; should be written with 0.

Inter-Integrated Circuit Module (I2C)

Bus Status Register

This register contains status information of the I2C-bus. This additional information can be used by software to start appropriate actions.

BUSSTAT

Bus Status Register

(24_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
BS	1:0	rh	<p>Bus Status</p> <p>Shows the current status on the I2C-bus.</p> <p>00_B I2C-bus is free (no start condition detected).</p> <p>01_B A start condition has been detected on the bus (bus busy).</p> <p>10_B The device is working as master and has claimed the control on the I2C-bus (busy master).</p> <p>11_B A remote master has accessed this device as slave.</p>
RnW	2	rh	<p>Read/not Write</p> <p>Set by hardware automatically after address byte has been sent/received.</p> <p>0_B Working as transmitter (Write to I2C-bus).</p> <p>1_B Working as receiver (Read from I2C-bus).</p>
0	31:3	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Timing Configuration Register

This configuration register adjusts some timings of the I2C-bus signals SCL and SCA. The delays are given in kernel_clk cycles (denoted as stages below).

Inter-Integrated Circuit Module (I2C)

TIMCFG

Timing Configuration Register

(40_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SDA_DEL_HD_DAT	5:0	rw	SDA Delay Stages for Data Hold Time SDA delay stages for data hold time in standard and fast mode. 000000 _B 3 stages delay 000001 _B 4 stages delay XXXXXX _B ... 111111 _B 66 stages delay
HS_SDA_DEL_HD_DAT	8:6	rw	SDA Delay Stages for Data Hold Time in High-speed Mode 000 _B 3 stages delay 001 _B 4 stages delay XXX _B ... 111 _B 10 stages delay
SCL_DEL_HD_STA	11:9	rw	SCL Delay Stages for Hold Time Start (Restart) Bit 000 _B 2 stages delay 001 _B 3 stages delay XXX _B .. 111 _B 9 stages delay

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
EN_SCL_LOW_LEN	14	rw	Enable Direct Configuration of SCL Low Period Length in Fast Mode 0B DIS , SCL low period is a fixed part of the whole period, as defined by FS_SCL_LOW 1B EN , SCL low period is determined by the setting of SCL_LOW_LEN
FS_SCL_LOW	15	rw	Set Fast Mode SCL Low Period Timing 0 _B Standard mode SCL low period timing 1 _B Fast mode SCL low period timing
HS_SDA_DEL	18:16	rw	SDA Delay Stages for Start/Stop bit in High-speed Mode 000 _B 3 stages delay 001 _B 4 stages delay XXX _B ... 111 _B 10 stages delay
SCL_LOW_LEN	31:24	rw	SCL Low Length in Fast Mode If enabled by EN_SCL_LOW_LEN setting, this field determines the extension of the SCL low time. In case of INC = 1, the low time is extended by the number of kernel_clk cycles. In general, there is a more complex formula, as given in the functional specification. The total period time is not changed, i.e., the SCL high period is reduced accordingly. Setting SCL low time to period length or higher is not supported and would lead to unpredictable results. Reset: 00 _H
0	13:12, 23:19	r	Reserved Read as 0; should be written with 0.

The delayed stages may have +/- 1 stage deviation.

31.3.2 FIFO Registers

Transmission Data Register

The software has to write the characters to be transmitted into this register.

A larger address range (8000_H to BFFC_H) is reserved for the FIFO. Accessing any address in the defined range has the same effect as accessing the first address.

A read access to TXD register is not possible, it will return 0 in all cases. Reading has no effect on the FIFO.

When using byte or half word access from the bus, the TX FIFO pointer will only be increased, if one of the following conditions is fulfilled:

- The most significant byte or half word of the FIFO stage is written
- The packet end is reached

TXD

Transmission Data Register (8000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TXD	31:0	rw	Transmission Data Characters to be transmitted

Inter-Integrated Circuit Module (I2C)
Transmit Packet Size Control Register

This register is used to indicate the peripheral the size of the packet to be transmitted. Writing the packet size to this register if the FIFO controller is configured for flow controller mode initiates the data requests (BREQ, SREQ, ...).

Writing to this register in configuration state has no impact.

TPSCTRL
Transmit Packet Size Control Register(34_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TPS	13:0	rwh	Transmit Packet Size Length in characters of the transmit packet, write value range: 1 to 16383 Reading returns the written value as long as it is not loaded to an internal counter. After that, reading returns 0 and a new value can be written.
0	31:14	r	Reserved Read as 0; should be written with 0.

Reception Data Register

The software can read the received characters from this register.

A larger address range (C000_H to FFFC_H) is reserved for the FIFO. Reading from any address in the defined range has the same effect as reading from the first address.

RXD
Reception Data Register
(C000_H)
Reset Value: 0000 0000_H

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
RXD	31:0	rh	Reception Data Received characters

Received Packet Size Status Register

This register indicates the size of the received data packet to the software. The software should read this register after the last request of a packet.

RPSSTAT
Received Packet Size Status Register
(30_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RPS	13:0	rh	Received Packet Size Length in characters of the received packet (0 to 16383)
0	31:14	r	Reserved Read as 0; should be written with 0.

FIFO Configuration Register

This configuration register is used to set up the FIFO before the peripheral is enabled and data is received or transmitted.

Inter-Integrated Circuit Module (I2C)
FIFO CFG
FIFO Configuration Register
(28_H)
Reset Value: 0000 0022_H

Field	Bits	Type	Description
RXBS	1:0	rw	RX Burst Size 00 _B 1 word 01 _B 2 words 10 _B 4 words 11 _B Do not use this combination
TXBS	5:4	rw	TX Burst Size 00 _B 1 word 01 _B 2 words 10 _B 4 words 11 _B Do not use this combination
RXFA	9:8	rw	RX FIFO Alignment Use byte alignment wherever it is possible. 00 _B Byte aligned (character alignment) 01 _B Half word aligned (character alignment of two characters) 10 _B Word aligned (character alignment of four characters) 11 _B Do not use this combination

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
TXFA	13:12	rw	TX FIFO Alignment Use byte alignment wherever it is possible. 00 _B Byte aligned (character alignment) 01 _B Half word aligned (character alignment of two characters) 10 _B Word aligned (character alignment of four characters) 11 _B Do not use this combination
RXFC	16	rw	RX FIFO Flow Control 0 _B RX FIFO not as flow controller 1 _B RX FIFO as flow controller
TXFC	17	rw	TX FIFO Flow Control 0 _B TX FIFO not as flow controller 1 _B TX FIFO as flow controller
0	3:2, 7:6, 11:10, 15:14, 31:18	r	Reserved Read as 0; should be written with 0.

Maximum Received Packet Size Control Register

This register is used to limit the received packet size. The register value may be changed in any state of the FIFO.

MRPSCTRL
Maximum Received Packet Size Control Register
(2C_H)
Reset Value: 0000 0000_H

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
MRPS	13:0	rwh	Maximum Received Packet Size Length in characters of packet to be received; write value range: 0 (unlimited size) to 16383 Reading returns the written value as long as the previous packet has not been read completely from the FIFO. After that, MRPS is loaded to an internal register, reading returns 0 and a new value can be written.
0	31:14	r	Reserved Read as 0; should be written with 0.

Filled FIFO Stages Status Register

This register is used to indicate the number of filled FIFO stages.

FFSSTAT

Filled FIFO Stages Status Register

(38_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
FFS	5:0	rh	Filled FIFO Stages Number of filled FIFO stages (0 to 8)
0	31:6	r	Reserved Read as 0; should be written with 0.

31.3.3 Basic Interrupt Registers

For an overview of the Service Request Block (SRB) see [Section 31.2.5](#).

Raw Interrupt Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the interrupt request sources. One status bit is provided for each request. A write to this register has no effect. The status bits are set by hardware or software (via register [ISR](#)) and can be cleared by software (via register [ICR](#)).

RIS

Raw Interrupt Status Register (80_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
LSREQ_INT	0	rh	Last Single Request Interrupt 0 _B No interrupt request 1 _B Interrupt request pending
SREQ_INT	1	rh	Single Request Interrupt 0 _B No interrupt request 1 _B Interrupt request pending
LBREQ_INT	2	rh	Last Burst Request Interrupt 0 _B No interrupt request 1 _B Interrupt request pending
BREQ_INT	3	rh	Burst Request Interrupt 0 _B No interrupt request 1 _B Interrupt request pending

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
I2C_ERR_INT	4	rh	I2C Error Interrupt This is the combined bit for indication of FIFO errors due to overflow and underflow. 0 _B No interrupt request 1 _B Interrupt request pending
I2C_P_INT	5	rh	I2C Protocol Interrupt This is the combined bit for indication of a protocol event in the I2C kernel. 0 _B No interrupt request 1 _B Interrupt request pending
0	31:6	r	Reserved Read as 0; should be written with 0.

Interrupt Mask Control Register

A write of 1 to a particular bit of this register enables the corresponding interrupt request; a write of 0 disables it. A read to this register returns the current mask bits. After reset all requests are disabled.

IMSC
Interrupt Mask Control Register (84_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
LSREQ_INT	0	rw	Last Single Request Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
SREQ_INT	1	rw	Single Request Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled
LBREQ_INT	2	rw	Last Burst Request Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled
BREQ_INT	3	rw	Burst Request Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled
I2C_ERR_INT	4	rw	I2C Error Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled
I2C_P_INT	5	rw	I2C Protocol Interrupt 0 _B Interrupt request disabled 1 _B Interrupt request enabled
0	31:6	r	Reserved Read as 0; should be written with 0.

Masked Interrupt Status Register

This read-only register returns the masked status value (derived from registers **RIS** and **IMSC**) of the corresponding interrupt requests. A write to this register has no effect.

MIS

Masked Interrupt Status Register (88_H) **Reset Value: 0000 0000_H**

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
LSREQ_INT	0	rh	Last Single Request Interrupt 0_B No interrupt request 1_B Interrupt request pending
SREQ_INT	1	rh	Single Request Interrupt 0_B No interrupt request 1_B Interrupt request pending
LBREQ_INT	2	rh	Last Burst Request Interrupt 0_B No interrupt request 1_B Interrupt request pending
BREQ_INT	3	rh	Burst Request Interrupt 0_B No interrupt request 1_B Interrupt request pending
I2C_ERR_INT	4	rh	I2C Error Interrupt This is the combined bit for indication of FIFO errors due to overflow and underflow. 0_B No interrupt request 1_B Interrupt request pending
I2C_P_INT	5	rh	I2C Protocol Interrupt This is the combined bit for indication of a protocol event in the I2C kernel. 0_B No interrupt request 1_B Interrupt request pending
0	31:6	r	Reserved Read as 0; should be written with 0.

Interrupt Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding interrupt request is cleared; a write of 0 has no effect. Reading the register returns 0.

Inter-Integrated Circuit Module (I2C)
ICR
Interrupt Clear Register
(8C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
LSREQ_INT	0	w	Last Single Request Interrupt 0 _B No change 1 _B Clear interrupt request
SREQ_INT	1	w	Single Request Interrupt 0 _B No change 1 _B Clear interrupt request
LBREQ_INT	2	w	Last Burst Request Interrupt 0 _B No change 1 _B Clear interrupt request
BREQ_INT	3	w	Burst Request Interrupt 0 _B No change 1 _B Clear interrupt request
0	31:4	r	Reserved Read as 0; should be written with 0.

Interrupt Set Register

On a write of 1 to a particular bit of this write-only register, the corresponding interrupt request is set; a write of 0 has no effect. Reading the register returns 0.

Inter-Integrated Circuit Module (I2C)

ISR
Interrupt Set Register
(90_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
LSREQ_INT	0	w	Last Single Request Interrupt 0 _B No change 1 _B Set interrupt request
SREQ_INT	1	w	Single Request Interrupt 0 _B No change 1 _B Set interrupt request

BREQ_INT	3	w	Burst Request Interrupt 0 _B No change 1 _B Set interrupt request
I2C_ERR_INT	4	w	I2C Error Interrupt 0 _B No change 1 _B Set interrupt request
I2C_P_INT	5	w	I2C Protocol Interrupt 0 _B No change 1 _B Set interrupt request
0	31:6	r	Reserved Read as 0; should be written with 0.

31.3.4 Error Interrupt Source Registers

For an overview of the source register operation see [Section 31.2.5.2](#).

Error Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding error interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register [ERRIRQSS](#).

ERRIRQSM

Error Interrupt Request Source Mask Register

(60_H)

Reset Value: 0000 000F_H

Field	Bits	Type	Description
RXF_UFL	0	rw	RX FIFO Underflow 0 _B Interrupt request source disabled 1 _B Interrupt request source enabled
RXF_OFL	1	rw	RX FIFO Overflow 0 _B Interrupt request source disabled 1 _B Interrupt request source enabled
TXF_UFL	2	rw	TX FIFO Underflow 0 _B Interrupt request source disabled 1 _B Interrupt request source enabled
TXF_OFL	3	rw	TX FIFO Overflow 0 _B Interrupt request source disabled 1 _B Interrupt request source enabled
0	31:4	r	Reserved Read as 0; should be written with 0.

Inter-Integrated Circuit Module (I2C)

Error Interrupt Request Source Status Register

This read-only register returns the current raw status value (without reflecting the mask) of the error interrupt request sources. A write to this register has no effect. The error status bits are set by hardware and can be cleared by software (via register **ERRIRQSC**).

ERRIRQSS

Error Interrupt Request Source Status Register (64_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXF_UFL	0	rh	RX FIFO Underflow 0 _B No interrupt request 1 _B Interrupt request pending
RXF_OFL	1	rh	RX FIFO Overflow 0 _B No interrupt request 1 _B Interrupt request pending
TXF_UFL	2	rh	TX FIFO Underflow The I2C kernel has detected a TX FIFO underflow. 0 _B No interrupt request 1 _B Interrupt request pending
TXF_OFL	3	rh	TX FIFO Overflow 0 _B No interrupt request 1 _B Interrupt request pending
0	31:4	r	Reserved Read as 0; should be written with 0.

Inter-Integrated Circuit Module (I2C)
Error Interrupt Request Source Clear Register

On a write of 1 to a particular bit of this write-only register, the corresponding error interrupt request source is cleared and if no further error interrupt request sources are active, the whole error interrupt is cleared. If the corresponding bit is set by SW via the **ISR** register, then it can be cleared by setting any non-reserved bit of the interrupt request source clear register. A write of 0 has no effect. Reading the register returns 0.

The interrupts are explained in detail in description of register **ERRIRQSS**.

ERRIRQSC
Error Interrupt Request Source Clear Register
(68_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXF_UFL	0	w	RX FIFO Underflow 0 _B No change 1 _B Clear interrupt request source
RXF_OFL	1	w	RX FIFO Overflow 0 _B No change 1 _B Clear interrupt request source
TXF_UFL	2	w	TX FIFO Underflow 0 _B No change 1 _B Clear interrupt request source
TXF_OFL	3	w	TX FIFO Overflow 0 _B No change 1 _B Clear interrupt request source
0	31:4	r	Reserved Read as 0; should be written with 0.

31.3.5 Protocol Interrupt Source Registers

For an overview of the source register operation see [Section 31.2.5.2](#).

Protocol Interrupt Request Source Mask Register

A write of 1 to a particular bit of this register enables the corresponding protocol interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register [PIRQSS](#).

PIRQSM

Protocol Interrupt Request Source Mask Register

(70_H)

Reset Value: 0000 007F_H

Field	Bits	Type	Description

Inter-Integrated Circuit Module (I2C)

31.4 I2C Module Implementation

This section describes I2C module interfaces with the clock control, port control and interrupt control. TC26x B-Step provides one module I2C0.

Note: This module may not be available in all marking options. If it is not available then the functionality behind the associated registers is not guaranteed.

31.4.1 Interfaces of the I2C Module(s)

Figure 31-25 shows the TC26x B-Step specific implementation details and interconnections of the I2C module(s):

- A clock control block generates the clock signals required for the module.
- For the I2C-bus lines SCL and SDA, different I/O lines can be selected.
- The interrupt outputs of the module are connected to the interrupt control unit.

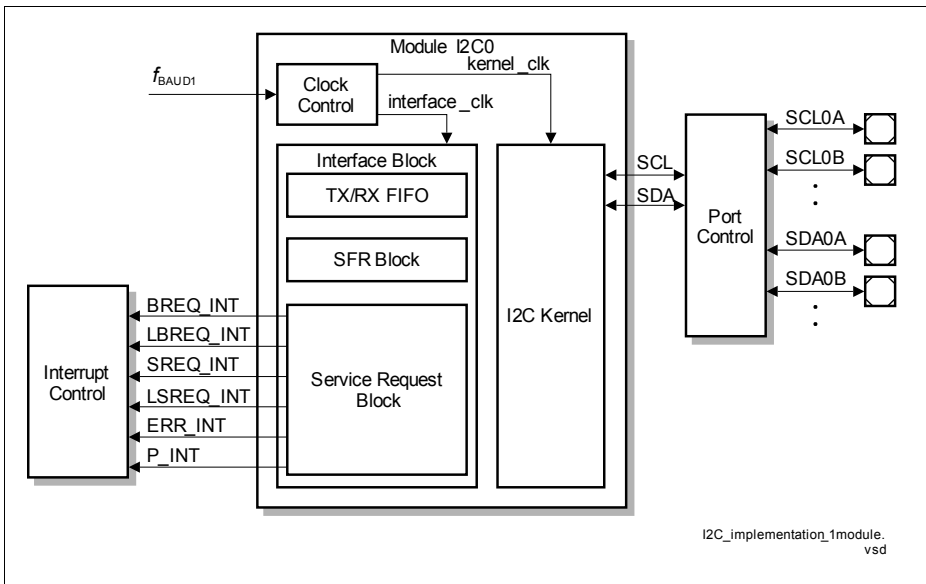

Figure 31-25 I2C Module Implementation and Interconnections

31.4.2 Module Clock Control

The clock control allows the programmer to adapt the peripheral's functionality and power consumption to the application's requirement. The clock f_{BAUD1} is connected to the bus clock, which generates the clock for the interface block, and to the module clock, from which the I2C kernel clock is derived. By programming the kernel's operating frequency, an optimal ratio between power consumption, EMC behavior and functionality can be achieved. Furthermore, for power saving reasons the peripheral can be disabled as a whole by switching off the peripheral's clocks via clock gating cells.

A simplified description of the clock control is shown in [Figure 31-26](#). See register [CLC1](#) for a description of the clock control parameters.

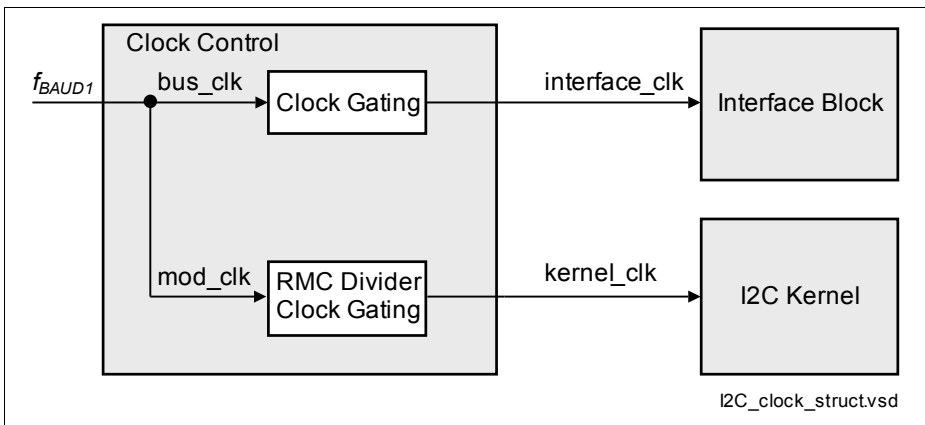

Figure 31-26 Module Clock Control

The following clocking modes are supported for the peripheral:

- Standard run mode
- Disable mode
- OCDS suspend mode

Standard Run Mode

In this mode the module clock is divided by the value of bit-field RMC in register [CLC1](#). The value written to this bit field is equal to the dividing factor (e.g. RMC=04_H is equal to dividing by factor 4). If 00_H is written into RMC, the kernel clock is stopped.

Inter-Integrated Circuit Module (I2C)

Kernel Clock Calculation in Standard Run Mode:

$$f_{kernel_clk} = \frac{f_{mod_clk}}{RMC}; (RMC > 0) \quad (31.1)$$

I2C_FORMULA_RMC

Disable Mode

In this mode the clocks are switched off. It can be entered by either activating the module disable input (if not disabled by setting bit EDIS in register **CLC1**) or by setting bit DISR in register **CLC1**. Note that a secure clock shut off with handshake is performed before it is disabled (see “Secure Clock Shut Off” in **OCDS Suspend Mode**).

Additionally a peripheral can be disabled without handshake (see “Fast Clock Shut Off” in **OCDS Suspend Mode**) by setting the bit field of the clock divider to 00_H.

OCDS Suspend Mode

In this mode the clocks are disabled. If bit SPEN in register **CLC1** is set, the mode can be entered by activating the input module_ocds.

In OCDS suspend mode all registers of the suspended module can be read. Note that each read during disabled clock can not affect hardware. For example multiple reads to FIFO port registers always return the same value as the FIFO control is not working.

No write access to the registers is supported during suspend mode, except writes to the **CLC1** register. For writing other registers the suspend mode for the module has to be removed first by clearing bit SPEN. After the write access is executed, bit SPEN should be set again.

OCDS suspend mode supports two different disable features, selectable by bit FSOE in register **CLC1**:

- **Fast Clock Shut Off**

Selecting the fast clock shut off stops the clock immediately after all pending read and write accesses are finished (including synchronization mechanisms with the I2C kernel). This shut off mode can be activated by setting bit DISR in register **CLC1**.

- **Secure Clock Shut Off**

Disabling the clock via secure clock shut off additionally activates the handshake mechanism with the peripheral. The peripheral is switched to a secure state before disabling the clock.

*Note: To write to SPEN or FSOE, bit SBWE in register **CLC1** must also be set in the same write access.*

31.4.3 Bus Peripheral Interface Registers

This register controls the clock gating and dividing circuitry of the peripheral.

CLC1
Clock Control 1 Register
(00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable not requested 1 _B Module disable requested
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module. 0 _B Module enabled 1 _B Module disabled
SPEN	2	rw	Module Suspend Enable Bit for OCDS 0 _B Module suspend disabled 1 _B Module suspend enabled
EDIS	3	rw	External Request Disable 0 _B External clock disable request is enabled 1 _B External clock disable request is disabled
SBWE	4	w	Module Suspend Bit Write Enable for OCDS This bit is always read as 0. 0 _B Bits SPEN and FSOE are write protected 1 _B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE

Inter-Integrated Circuit Module (I2C)

Field	Bits	Type	Description
FSOE	5	rw	Fast Switch Off Enable 0 _B FSOE Clock switch off in OCDS suspend mode via Disable Control Feature (Secure Clock Switch Off) 1 _B Fast clock switch off in OCDS suspend mode
RMC	15:8	rwh	Clock Divider for Standard Run Mode Max. 8-bit divider value If RMC is set to 0 the module is disabled. <i>Note: As long as the new divider value RMC is not valid, reading register returns 0000 00XX_H</i>
0	7:6, 31:16	r	Reserved Read as 0; should be written with 0.

31.4.4 I2C Module Registers Overview

In the following, the registers of the I2C module are listed. First of all, some explanation on the access conditions is given.

Special I2C Register Access Condition

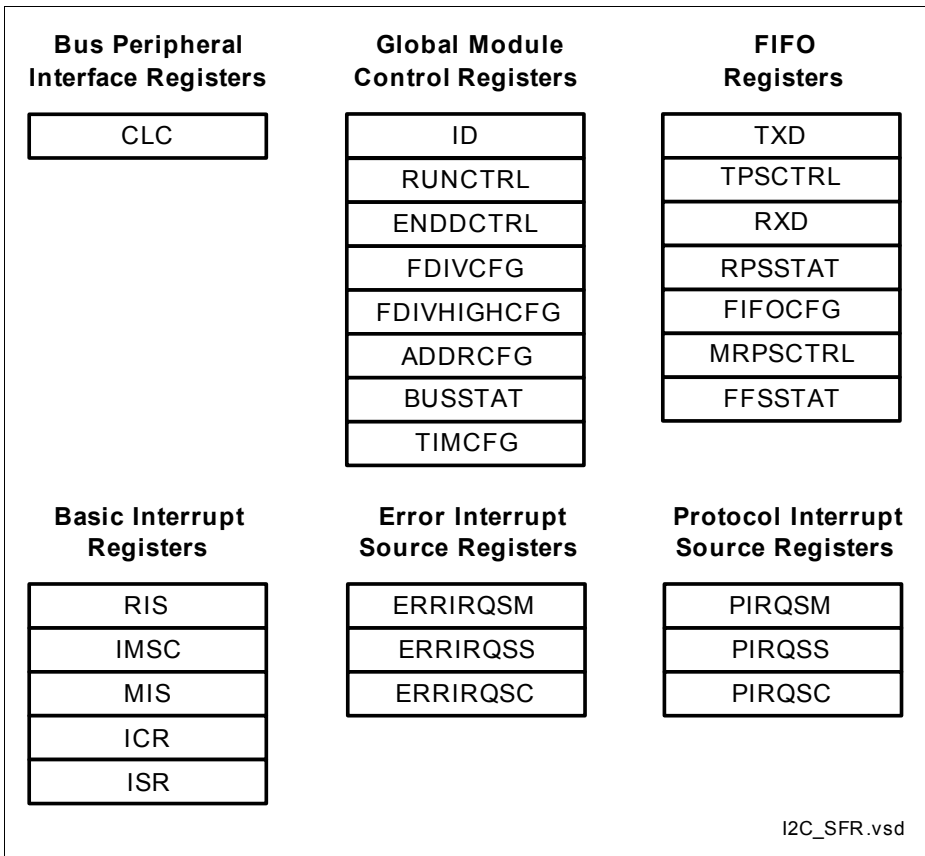

Besides the general register protection, the I2C module has two main modes that must be considered when programming the peripheral:

- **Configuration Mode:** In this mode the peripheral can be prepared for transmission and reception via the configuration registers, which are only writable in this mode. The peripheral is in the configuration mode when bit RUN is set to 0.
- **Run Mode:** In this mode the peripheral is ready to transmit or receive data. Its configuration registers are locked for write access which will generate a bus error. The peripheral is in the run mode when bit RUN is set to 1.

I2C Registers Overview

There are the following blocks of registers (see [Figure 31-27](#)):

- Bus Peripheral Interface Registers
- Global Module Control Registers
- FIFO Registers
- Basic Interrupt Registers
- Error Interrupt Source Registers
- Protocol Interrupt Source Registers

Figure 31-27 I2C Module Registers

The registers address space of the modules is defined in [Table 31-3](#).

The registers overview in [Table 31-4](#) shows the register names of the module instances, the offset addresses and the links to the names used in this specification.

An access to an address in the address range of this module which is not given in the table causes a bus error.

Table 31-3 Registers Address Space of I2C Module

Note: The base address of the I2C0 BPI registers is F00D 0000_H.

Note: All I2C registers are Reset Class 3 registers.

31.4.5 Port and I/O Line Control

Not only the interconnections between the I2C module and the port I/O lines have to be configured, but also the function and the characteristics of the port pins. The following control operations must be executed for the used port pins:

- Selection of I2C module via output port multiplexer
- Configuration of output port function with open drain
- Configuration of pad driver characteristics
- Selection of I2C input lines

31.4.6 Interrupt Control

The interrupt functionality is described in the chapter for the interrupt router (IR).

The signal names used in the interrupt router description are explained in [Table 31-6](#).

Table 31-6 Interrupt Router Signal Names for I2Cm Module (m = 0/1)

Signal Name	Name in Module	Explanation
SRC_I2CmBREQ	BREQ_INT	Burst Data Transfer
SRC_I2CmLBREQ	LBREQ_INT	Last Burst Data Transfer
SRC_I2CmSREQ	SREQ_INT	Single Data Transfer
SRC_I2CmLSREQ	LSREQ_INT	Last Single Data Transfer
SRC_I2CmERR	ERR_INT	Error
SRC_I2CmP	P_INT	Protocol

31.5 Module Integration

This section describes the topics regarding the integration of the module on chip.

31.5.1 Integration Overview

The I2C module consists of a delivery providing an AHB bus interface integrated into the FPI bus system by using an FPI2AHB adapter.

The adapter contains a slave bus interface providing translation between the FPI and the AHB bus protocols. The module supports additionally the following features:

- power saving (sleep mode)
- debug suspend
- local module reset
- PISEL - port input selection regarding the serial data input

The power saving and debug suspend features are supported by the AHB based I2C module itself, and the local module reset and PISEL features are supported by the FPI2AHB adapter, see [Figure 31-28](#).

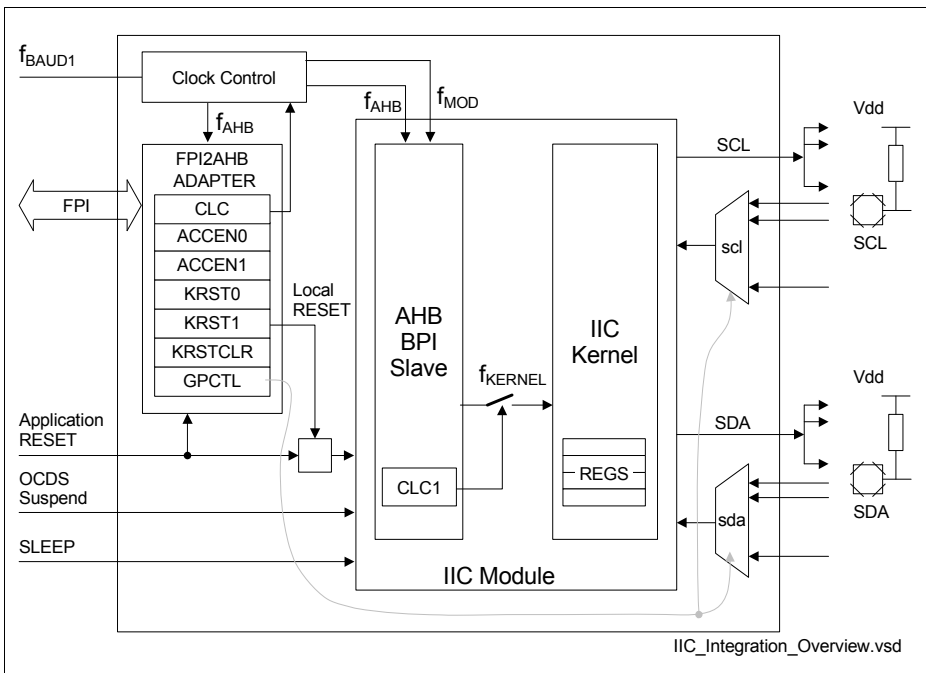

Figure 31-28 Integration Overview

31.5.2 BPI_SPB Module Registers

This section describes the registers implemented in the slave (FPI2AHB) adapter component.

31.5.2.1 System Registers

Figure 31-29 shows all registers associated with the BPI_FPI module, configured for one kernel. See also **Table 31-5** for the address mapping.

BPI_FPI Registers Overview

Figure 31-29 BPI_FPI Registers

Kernel Reset

If a kernel reset is requested, the adapter will synchronously assert the internal kernel reset output and error any ongoing accesses on the FPI bus not addressed to the adapter's internal SFRs.

The method of using the kernel reset output from the adapter to initialise the associated AHB module is module specific and outside the scope of this specification.

Any AHB accesses in progress will be synchronously terminated.

GPCTL

A single, adapter specific, SFR is implemented in the adaptor.

The SFR contains general purpose read/write control bits without ENDINIT protection. All the bits are connected to output ports on the FPI2AHB entity. The SFR will implement no safety requirements and is not be suitable for controlling hardware related to safety functions. The SFR supports, byte, half word and word transactions only. All other transactions are rejected with an FPI error termination.

Note: In the I2C module, this register implements the PISEL functionality. The SDA and SCL input multiplexors are controlled in parallel with each PISEL setting. Since 3 bits are implemented for PISEL, up to 8 sets of SDA and SCL pins can be defined.

Inter-Integrated Circuit Module (I2C)
Principle of Operation

When the controlling state machine detects an FPI access, it compares the address to the address of the SFR. In the case that the address matches the SFR address, the normal state machine transitions are interrupted and the access is not passed to the AHB bus.

If the access opcode is not SDTB, SDTH or SDTW, then the access is terminated with an FPI error. If the opcode is supported, the SFR data will be returned on the FPI bus if the transaction is a read or the appropriate bits of the register will be updated if the access is a write.

Clock Control Register (CLC)

The Clock Control Register, CLC, acts globally and allows the complete AHB module to be disabled to reduce power consumption when the module is not required. When the module is disabled (DISS=1_B), only register accesses to the adapter register address space are permitted. All other accesses to the module address space will be errored.

I2C0_CLC
Clock Control Register
(10000_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Module Identification Register (ID)

The identification register allows the programmer version-tracking of the module.

Inter-Integrated Circuit Module (I2C)

I2C0_MODID

Module Identification Register (10004_H) Reset Value: 00C2 C0XX_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number.

Inter-Integrated Circuit Module (I2C)

General Purpose Control Register

I2C0_GPCTL

General Purpose Control Register (10008_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PISEL	[2:0]	rw	<p>Port Input Select</p> <p>Used to select the input pins providing the serial data and clock input signals, in the range of 0 to 7.</p> <p>000_B SDA0A and SCL0A are selected. 001_B SDA0B and SCL0B are selected. 010_B SDA0C and SCL0C are selected. 011_B SDA0D and SCL0D are selected. 100_B SDA0E and SCL0E are selected. 101_B SDA0F and SCL0F are selected. 110_B SDA0G and SCL0G are selected. 111_B SDA0H and SCL0H are selected.</p> <p><i>Note: In TC26x B-Step, not all PISEL options are available. See the Ports chapter.</i></p>
0	[31:3]	r	<p>reserved</p> <p>Reads 0. Should be written with 0.</p>

Inter-Integrated Circuit Module (I2C)
Access Enable Register 0

The Access Enable Register 0 controls write access¹⁾ for transactions to registers with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The adapter is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

Field	Bits	Type	Description
ENn (n = 0-31)	n	r/w	Access Enable for Master TAG ID n This bit enables write access to the module register addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed. Read accesses will be executed. 1 _B Write and read accesses will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Inter-Integrated Circuit Module (I2C)

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). These tags are not used in this system and so no programmable bits are provided.

I2C0_ACCEN1

Access Enable Register 1

(10010_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	31:0	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset function is used to synchronously reset the AHB module. To activate the kernel reset, it is necessary to set the RST bits by writing with 1_B in both Kernel Reset Registers. The RST bit will be re-set by the adapter with the end of the adapter kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to 1_B in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, write accesses to the module registers will result in an error acknowledge. Adapter registers can still be accessed.

Inter-Integrated Circuit Module (I2C)
I2C0_KRST0
Kernel Reset Register 0
(10014_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (reset to 0 _B) b after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Inter-Integrated Circuit Module (I2C)

I2C0_KRST1

Kernel Reset Register 1

(10018_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set.</p> <p>0_B No kernel reset was requested</p> <p>1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to 0_B) after the kernel reset was executed.</p>
0	[31:1]	r	<p>Reserved</p> <p>Read as 0_B; should be written with 0_B.</p>

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Inter-Integrated Circuit Module (I2C)

I2C0_KRSTCLR

Kernel Reset Status Clear Register (1001C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description

0	[31:1]	r	Reserved Read as 0 _B ; should be written with 0 _B .

32 Input Output Monitor (IOM)

32.1 Overview

The Input Output Monitor (IOM) module serves as a smart I/O comparison unit, observing and checking for the correct operation of system peripheral outputs that may serve and/or control externally-attached hardware, as well as the correct operation of the hardware itself, including any sensors whose signals may serve as an input to the monitoring function.

The monitoring function may be achieved in a number of configurable ways depending upon the application and the type of safety measure to be deployed. (Examples of such measures are included later-on within this chapter). Triggering via software is also permissible in this manner.

Monitor and reference signals (where needed) are taken from applicable system peripherals (i.e. Capture/Compare Units and General Purpose Timer Units) where they connect to internal padlogic (that feeds/controls I/O Ports), which may or may not be driven to the pads (configuration dependent). In this manner connectivity can be made to a signal that is to be driven externally, and to another signal that may serve as a reference, although may not be driven off-chip. A driven signal may also serve as a reference in order to compare against another that may be provided via a GPIO input, e.g. from a sensor external to the device.

Up to 16 monitoring points can be configured, with the capability to generate a system event that may be driven from one individual, several individual or multiple occurrences of a monitored condition, or a combination of several depending upon configuration.

32.2 Features

- 16 Filter & Prescaler Channels, each connected to a specific pad (Pn_IN), the output of which to serve as a monitor or reference signal.
- 16 Logic Analyzer Modules (LAMs), with each channel comprising a mux to independently select monitor and reference signal inputs, with which to undertake the compare. A local event (i.e. internal to IOM) is generated when parity or disparity occurs between the selected monitor and reference signals. Configurable via register settings.
- 1 EXOR combiner, configurable (via register) to select a range of upto 8 GTM inputs in order to generate a combined signal to serve as a reference.
- Event Combiner Module (ECM), that takes the 16 local event signals (1 from each of the LAM modules) and generates a system event signal (connecting to system Safety Management Unit) from a single, combination or multiple local event(s). Configurable via register settings.

Input Output Monitor (IOM)

- System Peripheral Bus (SPB) interface for configuration and status register interaction.

32.3 Interfaces

The IOM features the following interfaces:

- System Peripheral Bus (SPB) - for the configuration of constituent parts of the IOM and the interrogation of associated status registers/bitfields.
- Multiple port logic/module connectivity, serving as reference or monitor signals. See SoC Integration section within this chapter for device-specific connections to GTM, GPT12, QSPI, CCU, GPIO (for GTM, etc.).
- Safety Management Unit (SMU) - a single global event signal used inform the SMU of a generated event within the IOM.
- System Signals - FPI Clock, GTM Clock, System Reset.

Note: The functionality of the IOM is independent from system debug, and no connectivity or mode of operation exists for this purpose.

Input Output Monitor (IOM)

32.4 Kernel Description

In addition to the Logic Analyzer Modules, Filter & Prescaler Blocks and Event Combiner Module, the IOM also features a System Peripheral Bus (SPB) interface for configuration and status register access. Note: All the configuration registers are protected by the register access protection mechanism (global definition).

Figure 32-1 IO Monitor Block Diagram

The operational clock for the IOM is derived by combining the SPB and GTM clocks as a logical OR, the resultant frequency of which is therefore determined to be the higher of the two frequencies (assuming a synchronous relationship between the two, both being derived from the same system-level clock). This provides the capability for the IOM to sample GTM-related signals when the SPB (FPI) clock is lower than that of the GTM within the system.

Input Output Monitor (IOM)

32.5 Filter & Prescaler Channel Description

The IOM instances 16 Filter & Prescaler Channels(FPC's) for the purposes of preconditioning and filtering the signals received from the pads (Pn_IN inputs) that may be used as a reference or monitor.

Figure 32-2 Monitor & Reference Selection logic incorporating Filter and Prescaler channel

As shown in Figure 32-2, each FPC channel (cell) is equipped with an signal input multiplexer, a clock multiplexer, an edge detection circuitry, a 16-bit timer, a 16-bit compare register, a 16-bit comparator, and a FPC control circuitry. The edge detection circuitry detects respective edges for the prescaler modes and detects glitches in all other modes.

FPC Registers

The following registers are assigned to the Filter and Prescaler Cells FPC_k ($k = 0-15$):

- FPCESR = Filter and Prescaler Cells Rising and Falling Edge Status Register.
- FPCCTR_k = Filter and Prescaler Cell Control Register k
- FPCTIM_k = Filter and Prescaler Cell Timer Register k

FPC Operating Modes

Each filter and prescaler cell can be individually configured to operate in one of the following operating modes:

- Delayed Debounce Filter Mode on both edges
- Immediate Debounce Filter Mode on both edges
- Rising edge: Immediate Debounce Filter Mode, falling edge: No filtering
- Rising edge: No filtering, falling edge: Immediate Debounce Filter Mode
- Rising edge: Delayed Debounce Filter Mode, falling edge: Immediate Debounce Filter Mode
- Rising edge: Immediate Debounce Filter Mode, falling edge: Delayed Debounce Filter Mode
- Prescaler Mode (triggered by edge detection circuitry on rising edge)
- Prescaler Mode (triggered by edge detection circuitry on falling edge)

The operation mode is selected by bit field FPCCTR_k.MOD.

FPC Input Signal notes

The maximum FPC input signal frequency must be less than or equal to the sampling rate ($f_{FPI}/2$).

FPC Output Signal notes

A level output, representative signal SOL_k, indicating the direction of the detected signal transition, that can be configured to connect to the Logic Analyzer Module_m.

Delayed Debounce Filter Mode

In Delayed Debounce Filter Mode, the signal input SIN is filtered from all signal transitions and glitches with a width smaller than the selected clock period length multiplied by the compare register value.

The input signal SIN is analyzed at the selected filter clock rate of f_{IOM} . If the state of the input sample differs from the current output signal value, the 16-bit timer is increased by one. When the timer register $FPCTIM_k$ is not in its idle state (0000_H) **and** the state of the input sample matches the current output signal value, the 16-bit timer is decremented by one (see [Figure 32-3](#)); if bit $FPCTR_k.RTG$ is set, the timer will be set to idle state again (see [Figure 32-4](#)). A rising or falling edge, occurring on the signal input line SIN when the timer is greater than zero but less than the compare value, sets the corresponding glitch flag $FPCRES.REG$ (on rising edge glitch) or $FPCFES.FEG$ (on falling edge glitch). When the timer matches the 16-bit compare value stored in $FPCTR_k.CMP$ (timer threshold), the level output signal line SOL_k is inverted, and the timer is reset to 0000_H. The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value $FPCTR_k.CMP$ is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal.

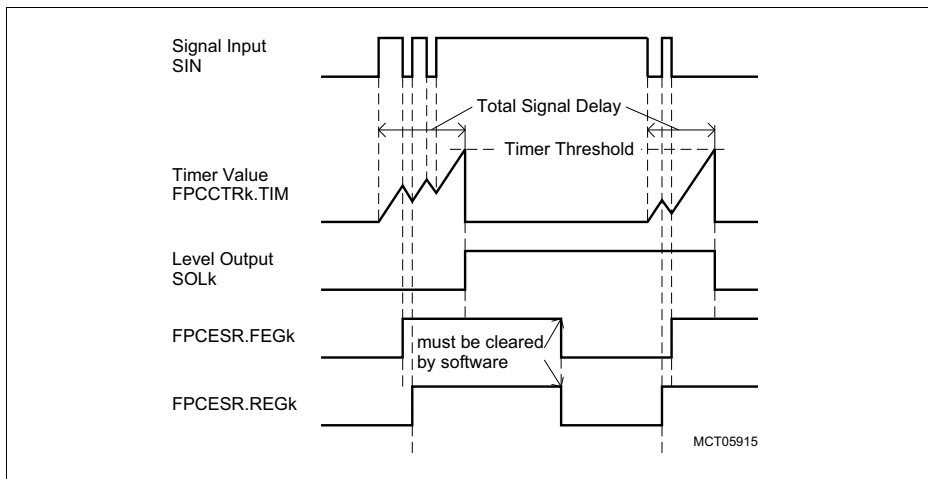

Figure 32-3 FPC Delayed Debounce Filter Algorithm with Timer Decrement

Figure 32-4 FPC Delayed Debounce Filter Algorithm with Timer Reset

The total signal delay from input to output depends on the programmed compare register value, the number of high-frequency pulses (glitches) during the filter operating time, and the timer behaviour in case of a glitch (decrement or reset).

The FPC Delayed Debounce Filter Mode is selected by:

- $FPCCTR_k.MOD = 000_B$

Input Output Monitor (IOM)

Immediate Debounce Filter Mode

In Immediate Debounce Filter Mode, the input signal is filtered from signal transitions and glitches arriving a programmable time after an input signal edge detection (see [Figure 32-5](#)).

The input signal SIN is sampled with f_{FPI} and the input signal SIN edge detection is also performed with f_{FPI} . The further analysis (e.g. filter timer increment, glitch detection) is also achieved with f_{FPI} .

As long as the timer is reset, the FPC control circuitry copies the sampled input value directly to the level output signal line SOLk. When a rising or falling edge occurs on the signal input line SIN and the 16-bit compare value $FPCCTR_k.CMP$ is not zero, the timer is enabled to be increased by the selected clock and the copy mechanism is disabled. When the timer value $FPCTIM_k.TIM$ matches the compare value $FPCCTR_k.CMP$, the timer is reset and the copy mechanism is enabled again. A rising or falling edge, occurring on SIN while the timer is greater than zero but less than the compare value, sets the corresponding glitch flag $FPCRES.REG$ (on rising edge glitch) or $FPCFES.FEG$ (on falling edge glitch). The rising/falling edge glitch flags must be reset by software.

The filter is by-passed if the compare value $FPCCTR_k.CMP$ is programmed to zero (0000_H). In this case, the input signal is directly copied to the output signal without any disable periods.

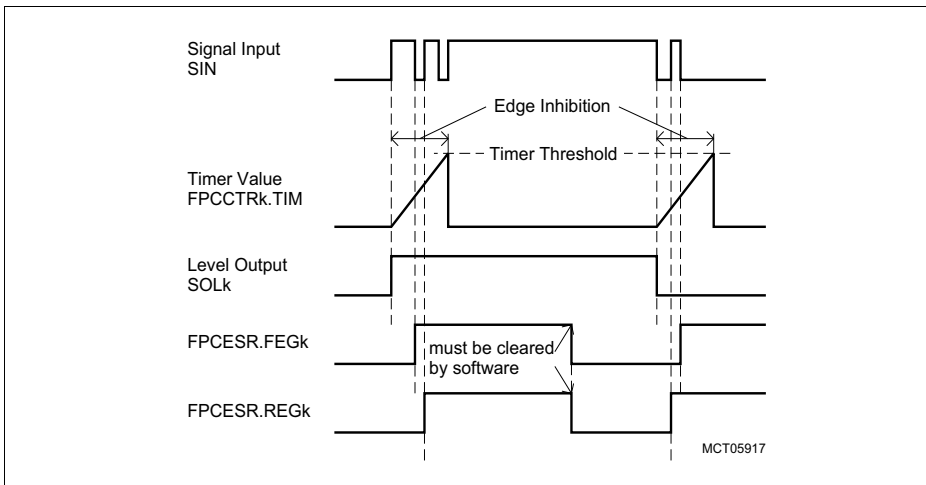

Figure 32-5 FPC Immediate Debounce Filter Algorithm on Both Edges

Note: During the last clock cycle of edge inhibition time (where timer value is equal to the compare value) an input signal glitch will be filtered but the corresponding glitch status flag in register FPCRES/FPCFES is not set.

Input Output Monitor (IOM)

The Immediate Debounce Filter can be enabled only for one edge, either rising or falling. In this case, the signal output follows the signal input value immediately after the timer threshold of the filtered edge is reached, without re-starting the timer (see **Figure 32-6**).

Figure 32-6 FPC Immediate Debounce Filter Algorithm on Rising Edge only

The FPC Immediate Debounce Filter Modes are selected by:

- $FPCCTR_k.MOD = 001_B$: Immediate Debounce Filter Mode on both edges
- $FPCCTR_k.MOD = 010_B$: Immediate Debounce Filter Mode on rising edge only, no filtering on falling edge.
- $FPCCTR_k.MOD = 011_B$: Immediate Debounce Filter Mode on falling edge only, no filtering on rising edge.

Mixed Filter Modes

In the Mixed Filter Modes, one edge of a signal is filtered in the Delayed Debounce Mode, and the other edge is filtered in the Immediate Debounce Mode. The Debounce Mode is switched when the timer threshold is reached. Note that both filter modes use the same timer threshold in this case (see [Figure 32-7](#), demonstrating Delayed Debounce Mode with Timer Decrement on Rising Edge and Immediate Debounce of on Falling Edge).

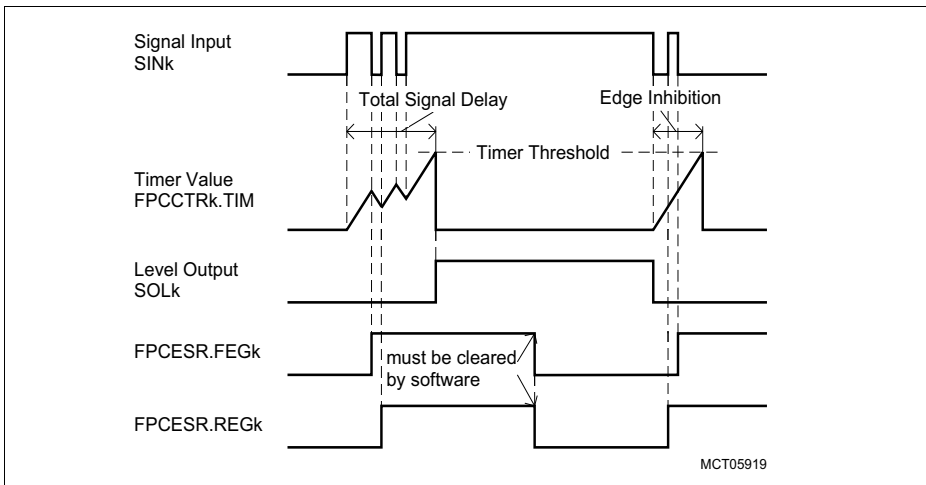

Figure 32-7 FPC Mixed Filter Algorithm

The FPC Mixed Filter Modes are selected by:

- $FPCCTR_k.MOD = 100_B$: Delayed Debounce Filter Mode on rising edge
Immediate Debounce Filter Mode on falling edge
- $FPCCTR_k.MOD = 101_B$: Immediate Debounce Filter Mode on rising edge
Delayed Debounce Filter Mode on falling edge

Prescaler Mode

In Prescaler Mode, the input signal is sampled and analyzed with f_{FPI} . The FPC control circuitry counts each rising (or falling) edge of the input signal. When the timer value matches the compare value:

- one IOM module clock pulse is generated at the level output signal SOL_k
- the timer $FPCTIM_k.TIM$ is reset to 0000_H

Figure 32-8 shows a divide-by-6 operation using the FPC in Prescaler Mode with trigger on rising edge selected.

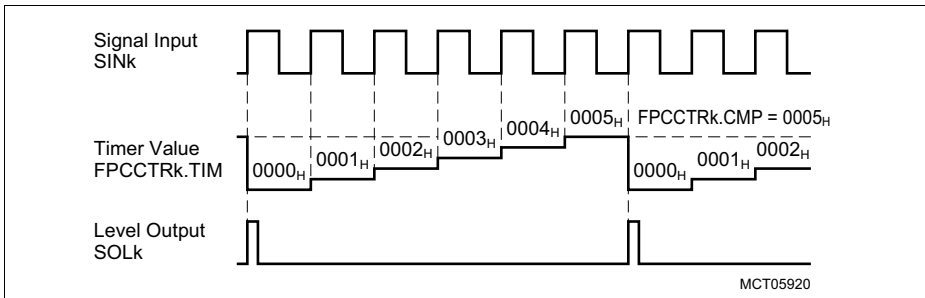

Figure 32-8 FPC Prescaler Mode

For a divide-by-n operation, the compare value $FPCCTR_k.CMP$ must be set to $n - 1$.

The FPC Prescaler Modes are selected by:

- $FPCCTR_k.MOD = 110_B$: Prescaler Mode triggered by edge detection circuitry on rising edge
- $FPCCTR_k.MOD = 111_B$: Prescaler Mode triggered by edge detection circuitry on falling edge

32.6 EXOR Combiner Description

The EXOR Combiner can be configured to accept up to 8 external inputs from GTM module outputs, used to replicate a typical *combined* signal from an automotive multi-phase motor. The output from which can then be used as a reference to monitor such a motor.

Figure 32-9 EXOR Combiner block diagram

EXOR Combiner Registers

The following registers are assigned to the block:

- GTMEXR = GTM Input EXOR Combiner Selection Configuration Register.

EXOR Combiner Input Signals

- 8 inputs from the GTM module(s).

EXOR Combiner Output Signals

- 1 output signal reflecting the combined logical EXOR function on the associated (and enabled) input(s).

32.7 Logic Analyzer Module (LAM) Description

The IOM instances 16 Logic analyzer Modules (LAM's) for the purposes of monitor and reference signal comparison. Each block accepts one monitor and one reference level signal from the 16 monitor & 16 reference signals available, from the FPC/Input selection block. The behaviour of each LAM is set by configuring the associated register settings.

Figure 32-10 Logic Analyzer Module (LAM) block diagram

As shown in Figure 32-9, each Logic Analyzer Module features inputs for the Reference & Monitor points, fed from the requisite Filter & Prescaler block. Depending upon the Logic Analyzer Module configuration register (LAMCFG), and the event window settings register (LAMEWS), the block may be configured to monitor a particular type of signal behaviour, input from sensors external to the device in order to monitor, govern and/or control external application behaviour with particular regard to any given safety requirements.

Input Output Monitor (IOM)

LAM Registers

The following registers are assigned to the Logic Analyzer Module LAM_m (m = 0-15):

- LAMCFG_m = Logic Analyzer Module Configuration Register m
- LAMEWS_m = Logic Analyzer Module Event Window Settings Register m
- LAMEWC_m = Logic Analyzer Module Event Window Count Status Register m

LAM Input Signals

Two inputs exist for each LAM_m:

- Reference signal input, fed from the requisite Filter & Prescaler block.
- Monitor signal input, fed from the requisite Filter & Prescaler block.

Depending upon the required function, both inputs or just the Monitor input may be utilised.

LAM Output Signals

One output is provided by each LAM:

- Event trigger output, configured to be active when a monitored signal falls outside the intended timed and/or periodic behaviour.

32.8 Event Combiner Module (ECM) Description

The IOM instances one Event Combiner Module, which takes the event outputs from each of the 16 Logic Analyzer Modules (LAM's). Some or all of these events can then be combined in a variety of configurable ways in order to generate a single system event.

Figure 32-11 Event Combiner Module (ECM) block diagram

Input Output Monitor (IOM)

Four separate 4bit counters with configurable thresholds are also available to be assigned to count multiple occurring events from any of the 16 available LAM's. The output of these counter units (active once a count threshold has been met/surpassed) can also be included (via configuration) within the generation of the system event. (Note: the alarm output will be connected to the Safety Management Unit, SMU.EMM).

The ECM also includes two Event Trigger History (ETMETH0/1) registers, updated with each system event, used to record the status of the 16 LAM event outputs, thereby identifying which triggers were responsible.

In addition, the ECM incorporates a System Peripheral Bus (SPB) interface for writing configuration and reading status registers appertaining to all subblock within the IOM.

ECM Registers

The following registers are assigned to the ECM:

- ECMCCFG = ECM counter configuration register (for the four 4bit local event counters).
- ECMSELR = ECM global event selection register (for the selection of local events, or multiples thereof, required to generate the global event signal).

ECM Input Signals

- From Logic Analyzer Modules (LAM's)
 - Local event triggers from LAM blocks (0 to 15).
- System Peripheral Bus.

ECM Output Signals

One output is generated by each LAM:

- Global event trigger output, intended to be connected to the Safety Management Unit.
- System Peripheral Bus.

Input Output Monitor (IOM)

32.9 IOM Registers

This section describes the kernel registers of the IOM unit.

All read and write accesses to an undefined address location within the IOM address space will result in a bus error on the System Peripheral Bus (SPB).

IOM Kernel Register Overview

Figure 32-12 IOM Kernel Registers

In the TC26x B-Step, the registers of the IOM units are located in the following address ranges.

32.9.1 IOM Identification Register (IOM_ID)

The IOM Identification Register ID contains read-only information about the module version.

IOM_ID

IOM Identification Register (008_H) Reset Value: 00CC C001_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number MOD_REV defines the Module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Number Value This bit field defines the module as a 32 bit module: C0 _H
MOD_NUM	[31:16]	r	Module Number Value This bit field defines the identification number for the IOM.

32.9.2 Filter & Prescaler Cell (FPC) Registers

IOM Filter and Prescaler Cells Rising & Falling Edge Status Register (IOM_FPCESR)

The Filter and Prescaler Edge Status Register stores the state of detected rising and falling edges from each of the FPC cells.

The register can be written to selectively clear individual bits.

Individual bits are also cleared with a write to the control register (FPCCTRk) or timer register (FPCTIMk).

Input Output Monitor (IOM)
Event Combiner Module Event Trigger History Register (IOM_ECMETH0)

One of two registers (IOM_ECMETH0 and IOM_ECMETH1) that record the status of LAM's 0 to 15 event outputs for the last 4 generated system events.

The generation of a system event will cause the status of the event outputs from LAM blocks 0 to 15 to be recorded in ETA0-15, respectively. Just prior to this happening, the previous status held in ETA0-15 is moved to ETB0-15. Similarly, the previous contents of ETB0-15 and ETC0-15 are moved to ETC0-15 and ETD15-0, respectively. The old contents of ETD15-0, being lost.

At reset (or a register write to either IOM_ECMETH0 or IOM_ECMETH1), all Event Trigger Active flags (ETA, ETB, ETC, ETD) will be cleared.

Input Output Monitor (IOM)

32.9.6 System Registers

IOM Clock Control Register (IOM_CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{clk} module clock signal, sleep mode and disable mode for the module.

IOM_CLC

IOM Clock Control Register (000_H) Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	2	rw	Reserved Read as 0; should be written with 0.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode.
RMC	[15:8]	rw	8-bit Clock Divider Value in RUN Mode
0	[31:16], [7:4]	r	Reserved Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing

Input Output Monitor (IOM)

CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

IOM Access Enable Register (IOM_ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

IOM_ACCEN0

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

IOM Kernel Reset Register 0 (IOM_KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

IOM_KRST0

IOM Kernel Reset Register 0 (024_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set.</p> <p>0_B No kernel reset was requested 1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.</p>

Input Output Monitor (IOM)

IOM_PORTLOGIC_CONN_EXOR

Figure 32-15 EXOR combiner portlogic/block signal connectivity

32.11 Example Monitor/Safety Measures

For each channel the following measurements shall be possible:

- Duty cycle measurement
- Set-up and/or hold time measurement
- Delay window (min,max) with respect to rising or falling edge

The following waveforms provide more examples of typical signal monitoring functionality that could be deployed using the IOM. Some typical configuration settings are also provided on some of the examples.

32.11.1 Example 1 - Pulse or duty cycle too short

Figure 32-16 example 1 - pulse or duty cycle too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum duty cycle length required. If duty cycle is shorter than this value then EVT will trigger)

32.11.2 Example 2 - Pulse or duty cycle too long

Figure 32-17 example 2 - pulse or duty cycle too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal (or invert for non-duty part of period)

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x9 ; CLR on positive edge, EVT on negative edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum duty cycle length required. If duty cycle is longer than this value then EVT will trigger)

32.11.3 Example 3 - Period too short

Figure 32-18 example 3 - period too short

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x1 ; invert window, capture events under the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (minimum period length required. If duty cycle is shorter than this value then EVT will trigger)

32.11.4 Example 4 - Period too long

Figure 32-19 example 4 - period too long

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't care

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x1 ; select monitor signal for event window

LAMCFG.EDS: 0x5 ; CLR on positive edge, EVT on positive edge

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; select appropriate threshold (maximum period length required. If duty cycle is longer than this value then EVT will trigger)

32.11.5 Example 5 - Diagnosis of Command and Feedback - acceptable propagation window and/or signal consistency check

Figure 32-20 example 5 - Diagnosis of Command & Feedback

Using the driven signal (off-chip) as a reference, using a feedback signal (input to device) as the monitor. Checking that the monitored signal shows activity within an acceptable propagation window, and/or that the feedback signal shows the same behaviour as the reference (Command = Feedback).

Example settings for LAM block registers:

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x1 ; (MON xor REF) signal used for event generation

LAMCFG.RMS: 0x0 ; free-running

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xB ; CLR on both edges of REF, EVT on falling edge (of xor'd signal)

LAMCFG.IWW: 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; set to max delay allowed

32.11.6 Example 6 - Diagnosis of Set-up and Hold times

Figure 32-21 example 6 - Diagnosis of Set-up & Hold times

Ensuring that data remains stable within the Set-up and Hold windows, generating an event otherwise, and/or ensuring that data only changes within the specified windows. Note that 2 LAM channels will be required for this purpose, one for set-up, one for hold.

Example settings for LAM block registers for Set-up :

LAMCFG.IVR: 0x0 ; don't invert reference signal

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; run is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xF ; CLR on both edges, EVT on both edges

LAMCFG.IVW : 0x0 ; don't invert window, capture events beyond the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Set-up (ref Threshold 1 on waveforms shown)

Input Output Monitor (IOM)

Example settings for LAM block registers for Hold:

LAMCFG.IVR: 0x0 ; invert reference signal (use for gating)

LAMCFG.IVM: 0x0 ; don't invert monitor signal

LAMCFG.MOS: 0x0 ; monitor signal used for event generation

LAMCFG.RMS: 0x1 ; event window is gated

LAMCFG.EWS: 0x0 ; select reference signal for event window

LAMCFG.EDS: 0xD ; CLR on positive edge (inverted neg. edge), EVT on both edges

LAMCFG.IVW : 0x1 ; invert window, capture events below the threshold

LAMCFG.MCS/RCS ; select according to device configuration

LAMEWS.THR ; Acceptable Hold (ref Threshold 2 on waveforms shown)

33 Peripheral Sensor Interface (PSI5)

This chapter describes the PSI5 Interface of the TC27x. It contains the following sections:

- Functional description of the PSI5 kernel (see **“Overview” on Page 33-2**)
- PSI5 kernel register descriptions (see **“PSI5 Kernel Registers” on Page 33-22**)
- TC27x implementation-specific details and registers of the PSI5 module (port connections and control, interrupt control, address decoding, and clock control) see **“PSI5 Module Implementation” on Page 33-141**

33.1 PSI5 Kernel Description

Figure 33-1 shows a global view of the PSI5 interface.

Figure 33-1 General Block Diagram of the PSI5 Interface

The PSI5 module communicates with the external world via one I/O line for each channel. The PSI5RXx lines are the receive data input signals. If the optional unidirectional mode is used, the signals PSI5TXx are transmitted on separate GPIO ports. Receive and transmit path are always routed to two different ports.

Peripheral Sensor Interface (PSI5)

33.1.1 Overview

The PSI5 IP-module performs communication according to the PSI5 specification V1.3.

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

This module supports many additional features as discussed today in the standard organization.

The PSI5 interface provides a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages protocol handling and data representation to the application. Note that there is no on chip phy, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5 channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a 32-bit buffer register for each channel and an additional 32-bit register containing the 24-bit time stamp and additional status bits. These 64 bits per frame are additionally stored in a buffer of 32 lines per channel.

In Host to sensor communication mode, the module can provide regular sync pulses and select between internal and external timer/trigger resources. It supports as well CPU to sensor communication, e.g. for setting up the sensor and retrieving sensor status information.

The register set of the PSI5 module can be accessed directly by the CPU for configuration, data read out and status query.

The PSI5 module supports the following features:

Features

- Conformance with PSI5 protocol specification V1.3
- Data rates of 125 kbit/s and 189 kbit/s supported
- 2 PSI5 channels working independently in parallel
- Supports 6 sensor slots per channel
- Asynchronous and synchronous data transmission modes (control by micro controller in synchronous mode)
- Decoding manchester protocol
- Error recognition in manchester code
- Configurable data word length 8, 10, 16, 20, 24 bit according to standard (PSI5 V1.3)
- Support of non standard V1.3 frame length: 11... 33 bit
- CRC check of received sensor data implemented but CRC code transparent
- Support of extended serial data messaging according to SENT SAE J2716 JAN 2010

Peripheral Sensor Interface (PSI5)

- 24-Bit time stamp (resolution: 1µs)
- Storage of up to 32 frames per channel with time stamp
- FIFO access and management
- Buffer overrun detection
- Buffer Memory Status Overview Registers
- Support of ECU to Sensor communication
- Three 64-bit downstream data registers for data input, data preparation and data output
- Downstream data transmission by variation of pulse length (2.0)
- Downstream data transmission by leaving out sync pulses (V1.3)
- Staggering Sync Pulses of all channels to avoid too many channels sending sync pulses in parallel
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence and CRC generator for downstream data
- One sum interrupt for general events
- One sum interrupt on selectable errors
- Sticky interrupt flags, error interrupt optional (default disabled)
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting

Configurability

- Number of PSI5 channels working independently in parallel (1 - 5)
- Storage of up to 32 frames per channel with time stamp (w/wo)
 - FIFO access and management
 - Buffer overrun detection
 - Buffer Memory Status Overview, Set and Clear Registers

33.2 General Operation

PSI5 is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 33-2 shows a typical TC27x application in which a PSI5 interface reads a sensor device.

Peripheral Sensor Interface (PSI5)

Figure 33-2 PSI5 to External Device Connection

PSI5 communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage.

Figure 33-3 shows a typical TC27x application in which a PSI5 ECU reads multiple PSI5 sensor devices on a bus.

Figure 33-3 PSI5 Frames with Sync pulses

33.3 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

SOF: Start of Frame

Peripheral Sensor Interface (PSI5)

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

33.4 PSI5 Operation

The Module supports two modes:

Standard PSI5 Mode supports communication fully compliant to V1.3

Extended PSI5 Mode supporting additional bit fields and longer frames. (See below)

In standard V1.3 mode, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for data frames but are interpreted as data. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

In extended Mode (Power Train sub standard), the pulse width is modulated. A standard pulse represents a 0, a longer pulse a 1. This way continuous data transmission can be achieved.

33.5 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5 protocol.

33.5.1 PSI5 V1.3 Frame

Figure 33-4 shows the layout and definitions of a standard PSI5 frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

Figure 33-4 Standard PSI5 Frame

33.5.2 Extended PSI5 Frame (non standard)

Figure 33-5 shows the layout and definitions of an extended PSI5 frame as defined in V2.0 for automotive power train application. Note that the PSI5 standard specifies that the least significant bit is sent out first.

Figure 33-5 Extended PSI5 Frame

Enhanced PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

- 1) 1-bit even parity
- 2) 3-bit CRC

The applied generator polynomial of the CRC is $g(x) = 1 + x + x^3$ with a binary start value (seed) "111". The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

In this implementation the number of elements is configurable and thus longer or shorter than 8 .. 28 bits!

33.5.3 Extended Serial Data Encoding (“Slow Channel”)

The serial data is transmitted bit wise per frame in bits [1:0] of the Messaging bit field of 18 consecutive messages from the transmitter.

33.5.4 Extended Serial Data Frame

Serial data (“Slow Channel”) is communicated in a 18-bit sequence as shown in **Figure 33-6**. The frame start of a serial message is indicated by the unique pattern “01111110” in bit M1. The first “1” in a series of six ones (after a “0”) indicates the first set of a Messaging bits (M1 and M0) of a serial frame. Messaging bit M1 of serial data frames 1 - 6 are set to “1”. Messaging bit M1 of serial communication nibbles 7, 13 and 18 are set to “0”. 18 consecutive PSI5 messages must be successfully transmitted (no errors) for the serial value to be received. The CRC generation is different from the CRC generation on the data nibbles. (See SENT Standard SAE_J2716_201001)

The serial message frame contains 21 bits of message data and a 6-bit frame-check sequence. Two different configurations can be chosen:

- 12-bit data and 8-bit message ID
- 16-bit data and 4-bit message ID

A configuration bit (serial data bit M1, serial communication Messaging bits of frame No. 8) determines the configuration of the enhanced serial message frame. It determines how the PSI5 module automatically interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

Figure 33-6 Extended Serial Data Frame

Figure 33-7 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 0.

Peripheral Sensor Interface (PSI5)

Figure 33-7 Configuration Bit = 0

Figure 33-8 shows in detail the frame structure for Extended Serial Data Frames with Configuration Bit = 1.

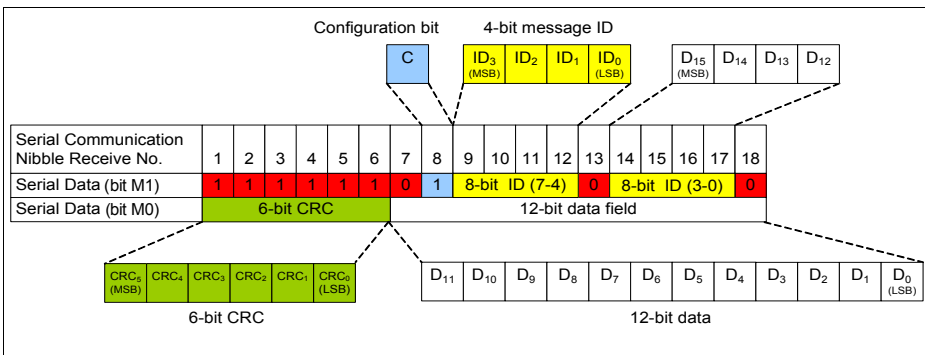

Figure 33-8 Configuration Bit = 1

33.6 Sync Pulses

Sync Pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

33.6.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is forced by the master on the OUT pin. An external phy translates this pulse into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 frame, starting

Peripheral Sensor Interface (PSI5)

with the 2 start bits, data and Parity or CRC . The timing diagram in [Figure 33-9](#) visualizes a synchronous transmission

Figure 33-9 Synchronous Transmission

33.6.2 ECU to Sensor Communication

Two versions are supported: legacy PSI5 V1.3 (see [Figure 33-10](#)) and revised version (see [Figure 33-11](#) and [Figure 33-12](#)) .

The legacy version

uses sync pulses as start condition and start bits to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

Figure 33-10 ECU to Sensor (legacy)

The revised version

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously. Every ECU-to-Sensor frame starts with a nine-bit frame-start-sequence [0 1 1 1 1 1 1 0]. Synchronization is possible at the beginning of each frame.

Sync Bits

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted at every seventh bit position (after every six bits of the sensor address and the payload data). With respect

Peripheral Sensor Interface (PSI5)

to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

Figure 33-11 ECU to Sensor, Bit transmission (revised)

Figure 33-12 ECU to Sensor, Frame format (revised)

Enhanced ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.

The generator polynomial of the CRC is

$$g(x)=x^6 + x^4 +x^3 +1$$

with a binary CRC initialization value "010101".

The transmitter extends the data bits by six zeros (as MSBs).

This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1 .. C5].

In this implementation the number of elements is configurable and thus longer or shorter than 24 bits (standard is 4 address and 20 data bits)!

33.7 Manchester Decoding

Decoding of the Manchester protocol:

- The Manchester decoder uses a nominal 4 MHz / 6.048 MHz sampling clock (32 samples per bit).
- A sampling counter, running at the sampling clock rate controls the sampling of the incoming Manchester encoded data.
- The Manchester signal transition occurring in the middle of the bit time resets the counter, making the counter count from 0-31 (nominally) between successive mid-bit times.
- Detection of the mid-bit transitions uses three consecutive samples (011 = rising edge, 100 = falling edge).
- The maximum value of the 6 bit counter shall be 41, at which point a Manchester error is detected due to lack of a transition, and the counter rolls over to 0. ("Idle Time")
- The value of a Manchester encoded input data bit is determined by proper logic levels before and after a transition and proper timing of the transition.
- Bit-value determination nominally takes place at the 1/4 and 3/4 bit times, with the mid-bit transition occurring at the 1/2 bit time. This is nominally at sampling counter values of 8 (1/4 bit time) and 24 (3/4 bit time).
- Logic levels are determined using a 2 of 3 majority vote of consecutive samples (samples 23, 24, 25 and 7, 8, 9)
 - The combinations 111, 011, 101, 110 indicate a 1
 - The combinations 000, 001, 010, 100 indicate a 0

Manchester-2 is used by standard PSI5 V1.3:

- Start bits = '00'
- Falling edge corresponds to logical '1'
- Rising edge corresponds to logical '0'
- Least significant bit (LSB) is sent out first

Figure 33-13 Manchester-2

Sampling Details

- Recognition of Frame Start
 - Manchester Code requires a deterministic Start of Frame
 - Frame Separation: An "Idle Time" of at least one Bit time is required

Peripheral Sensor Interface (PSI5)

- “Idle Time” is the time without edges on the line that is required to safely determine that no frame is being transceived (1 Bit time + tolerance = > 41 samples)
 The Idle Counter starts counting
 - on a falling edge, after sync pulse or after BOT, if the channel is switched on
 - if the line is low
 - up to 41 and stops and
 - activates the idle flag
 - until the line shows a rising edge, this clears the idle counter
- After this idle time, a determined start bit sequence is required for synchronization of the phase of receiver and transmitter ('0 0' in case of the „Manchester 2“-code employed)
- If no idle time occurs at the end of a frame, bits after the configured length are dropped.
- If a 2nd frame comes too early (collision = no idle time) the 2nd frame is dropped. The decoder waits for an “Idle Time” for re synchronization.
- Idle time is particularly required in case of Manchester Errors and frame collisions for a save re synchronization. Otherwise, two successive zeros in a damaged frame / a second colliding frame could lead to reception of wrong data. Note that back to back transfers of correct frames are forbidden by standard (T_gap required).
- This idle time is required as well after a regular End Of Frame, Sync Pulse or a Blank Out Time to avoid inadvertent synchronization inside frames under transmission.
- Bit sampling
 - After the start of the protocol is detected and an edge on the line signal is detected and the counter is greater 25 the counter is set to '0'
 - If the counter is 41 the counter is set to '0' and stops
 - The counter will be incremented each clock cycle
 - When the sample counter has the value 9, the level is stored in register cnt9_val
 - When the sample counter has the value 25, the level is stored in register cnt25_val
 - This register is reset if no frame is detected. Otherwise a wrong start bit detection could occur.
- Bit evaluation
 - When the sample counter value is 16, the decision is done for the new sample value:
 - Check if the last edge was detected correctly i.e.: edge detected between sample counter value 25 and sample counter value 41
 - If true:
 - Cnt_25_lev = 0 & cnt_9_lev = 1 => new sample = '0'
 - Cnt_25_lev = 1 & cnt_9_lev = 0 => new sample = '1'
 - If the edge check fails or cnt_25_lev = cnt_9_lev, Manchester Error is assumed.

Peripheral Sensor Interface (PSI5)

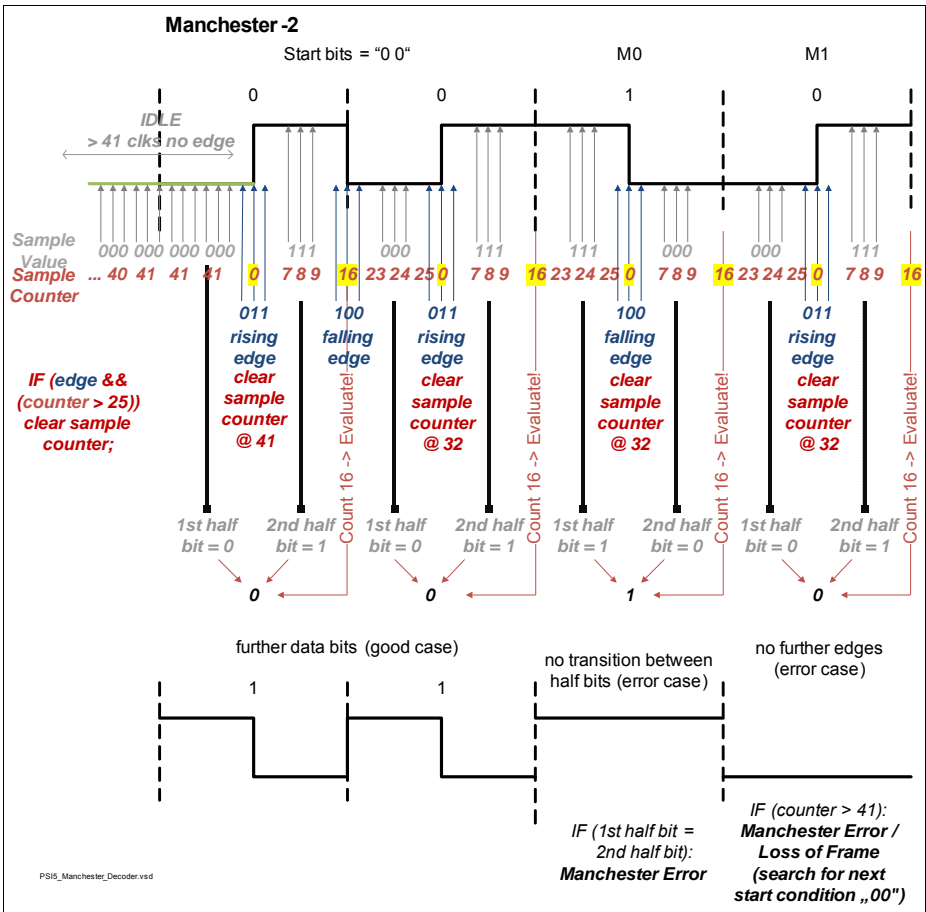

Figure 33-14 Manchester Decoder

Definition of Manchester Error (ME)

- Two half bits have the same value => ME, the decoder waits for an "Idle Time"
- > 41 sample times no edge => ME
- The ME is no dedicated interrupt but will lead to various error responses depending on where it occurs. See [Table 33-1](#).

Table 33-1 Error Responses due to ME

Manchester Error (ME) Case	Response	Comment
First ME in start bits	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of slot where SOF happened. This is true even if these start bits should start before WDL and end after WDL
Start bits cut off by BOT or Sync Pulse (frame starts without leading idle time)	Discard frame	NFI (if FEC is set) and empty frame stored (if FEC and VBS is set)
First ME in Messaging bits	If MSG is set: MEI	Frame is stored, bits after error are lost ("0")
	If MSG cleared: NBI	
First ME in data, parity or CRC / Frame ends too early	NBI	Frame is stored, bits after error are lost ("0")
Frame ends too late (longer than PDL)	no NBI	Bits after PDL are cut off and EOF is detected. Frame is stored.
Collision (Idle Time missing)	Discard 2nd frame	If the 1st frame was too late and running over WDL or If the 2nd frame was too early and running over WDL then for 2nd frame, NFI (if FEC is set) and empty frame stored (if FEC and VBS is set), Time Stamp = end of 2nd slot

In all cases, the receiver waits for an idle time followed by the start bits "00" before a new frame is detected.

33.8 Bit Rate Generation

The bit rate of each channel is individually selectable from the 2 standard bit rates 125 kHz and 189 kHz. The two referring over sampling frequencies are generated centrally.

This chapter shows in detail how the bit rate for each channel is adjusted.

Peripheral Sensor Interface (PSI5)

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different PSI5 channels. Usually this can be left unused.

For each of the two bit rates there is an own fractional divider. Each channel can select one out of the two clock signals f_{125} and f_{189} .

For details on the principles of a fractional divider, please refer to the SCU chapter of TC27x section "Clock Control".

The PSI5 module provides 5 clock signals centrally (Figure 33-15):

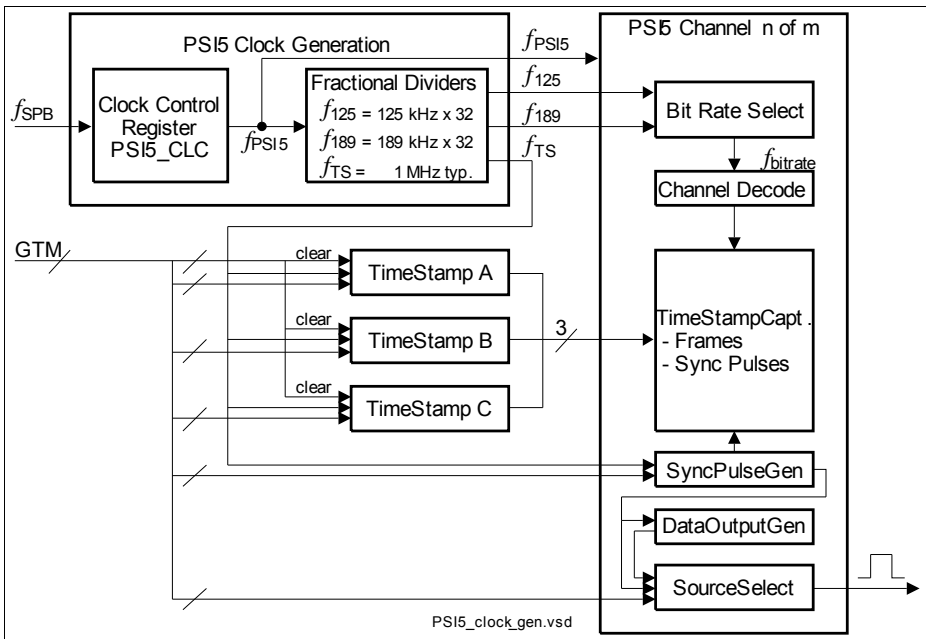

Figure 33-15 PSI5 Module Clock Generation

- f_{PSI5}

This is the module clock that is used inside the PSI5 kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5} is always identical to the system clock frequency f_{SPB} . The clock control register PSI5_CLC makes it possible to enable/disable f_{PSI5} under certain conditions.
- $f_{fracdiv}$

This clock is the module clock that is used inside the PSI5 kernel for bit rate generation of the serial channels. The fractional divider register PSI5_FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1.

Peripheral Sensor Interface (PSI5)

- f_{125}
This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRL controls the frequency of f_{125} . The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency
- f_{189}
This clock is the over sampling clock that can be selected for use inside a PSI5 channel as the bit rate frequency. The fractional divider register PSI5_FDRH controls the frequency of f_{189} . The clock drives the manchester decoder and needs to be 32 times faster than the nominal bus frequency.
- f_{TS}
This clock is used to drive the central time stamp counter. It can be selected to drive the global sync pulse time base and inside the PSI5 channels to drive the local watch dog timers. The fractional divider register PSI5_FDRT controls the frequency of f_{TS} . This is usually adjusted to 1 MHz / 1 μ s period time.

The following two formulas define the frequency of f_{fracdiv} :

$$f_{\text{fracdiv}} = f_{\text{PSI5}} / (1024 - \text{PSI5_FDR.STEP}); \text{FDR.DM} = 01\text{B} \quad (33.1)$$

$$f_{\text{fracdiv}} = f_{\text{PSI5}} \times \text{PSI5_FDR.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDR.DM} = 10\text{B} \quad (33.2)$$

The following two formulas define the frequency of f_{125} .

$$f_{125} = f_{\text{fracdiv}} / (1024 - \text{PSI5_FDRL.STEP}); \text{FDRL.DM} = 01\text{B} \quad (33.3)$$

$$f_{125} = f_{\text{fracdiv}} \times \text{PSI5_FDRL.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDRL.DM} = 10\text{B} \quad (33.4)$$

The following two formulas define the frequency of f_{189} .

$$f_{189} = f_{\text{fracdiv}} / (1024 - \text{PSI5_FDRH.STEP}); \text{FDRH.DM} = 01\text{B} \quad (33.5)$$

$$f_{189} = f_{\text{fracdiv}} \times \text{PSI5_FDRH.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDRH.DM} = 10\text{B} \quad (33.6)$$

The following two formulas define the frequency of f_{TS} :

$$f_{TS} = f_{\text{PSI5}} / (1024 - \text{PSI5_FDRT.STEP}); \text{FDRT.DM} = 01\text{B} \quad (33.7)$$

$$f_{TS} = f_{\text{PSI5}} \times \text{PSI5_FDRT.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDRT.DM} = 10\text{B} \quad (33.8)$$

33.9 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) of Infineons GPTA® in Delayed De-bounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{PSI5} . If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{PSI5} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive/bypassed. Nevertheless, the input signal is sampled with f_{PSI5} .

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes $2 \times T_{PSI5}$ times longer for the internal signal to change value. The filter's principal implies a delay of the signal by $(DEPTH \times T_{PSI5})$.

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 33-16 shows the digital glitch filter:

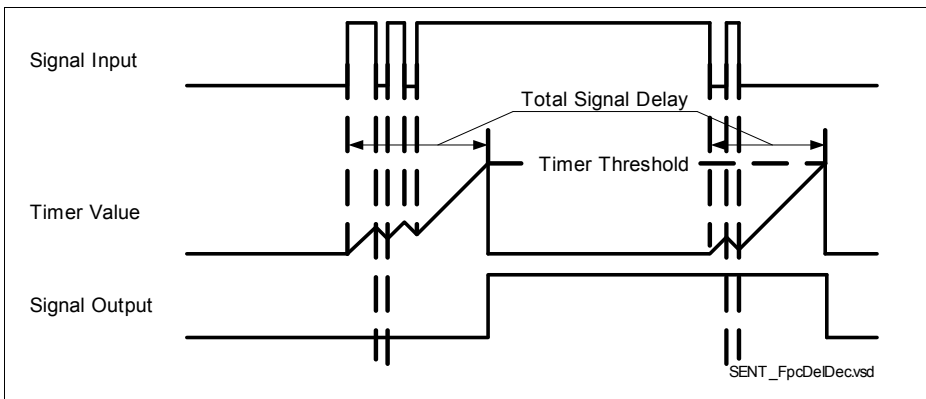

Figure 33-16 Digital Glitch Filter

33.10 Time Stamp Generation

Three time bases can be selected for Time Stamping:

Any of TSRA, TSRB and TSRC provide one time stamp counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by a selectable GTM signal or by SW, single or synchronously.

Two times are captured for each channel:

The last sync pulse sent on this channel is stored in the sync pulse time stamp capture register SPTSCx.

The last start of frame (SOF) on this channel is stored in the SOF capture register SFTSCx.

For each channel the capture time (SPTSC or SFTSC) can be selected, that will be stored in the Receive Data Register and the Receive Data Memory.

Figure 33-17 shows the time stamp generation:

Peripheral Sensor Interface (PSI5)

Figure 33-17 Time Stamp Generation

33.11 Error Detection Capabilities

Each PSI5 channel can detect and signal the following error conditions:

Protocol Level:

- No frame received / Manchester coding error in start bits (NFI)
- Messaging Bits with Manchester coding Error (MEI)
- Number of bits too small / Manchester coding error but messaging bits ok (NBI)
- Checksum error (CRCI)
- Frame not sent in expected time slot (TEI)
- Serial Communication: Wrong Status and Communication bit field (WSI)
- Serial Communication: CRC error (SCRI)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- Receive Data Memory Overrun (RMI)
- FIFO Warning Level (FWI)
- Receive Memory Underrun (RUI)
- ECU to Sensor Data Buffer Underrun (TBI)

33.12 Interrupts

8 Interrupt sources are available for the PSI5 module. For each trigger source of a channel x one interrupt can be selected in register INPx.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. This happens always if at least the start bits were received without Manchester coding error.

RSI indicates a receive frame success interrupt, i.e. non of the interrupts NFI, MEI, NBI, CRCI, TEI, RBI, RMI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. This allows e.g. to use only the Receive data register RDRL/Hx and ignore the Receive Data Memory RDML/Hx. Both RDI and RSI will be issued together in normal use cases where reception is correct.

RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host ("overwrite"), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.

RMI is issued if no memory buffer is available. RMI is set after a frame has been received or a No Frame Received (NFI) message is to be stored while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag RDixWRP and finds any of these two flags already set. The old data is overwritten by the new data in the buffer memory.

FWI is set if the configured warning level of the FIFOx was reached. (See RFCx)

Peripheral Sensor Interface (PSI5)

TPI, TSI and TOI indicate a transmit interrupt. They are activated when data is moved from a SDR to SSR (TPI), from SSR to SOR (TSI) and from SOR to the pulse generator (TOI).

TPOI, TSOI and TOOI indicate a transfer (send) register overrun interrupt. They are set if data is written to one of the registers in the transmission chain while the referring register is locked (occupied). The data written is ignored in this case.

In addition the protocol error interrupts are available:

TEI, NBI, MEI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to standard V1.3. Note that the wrong data is still available in all buffers. In particular, on MEI the wrong data is still fed into the SENT serial data analyzer (slow channel).

NFI is set, if a frame is missing in a slot configured by the watch dog timer. The module can be configured to store a complete message anyhow with flag NFI set. The slot count and the time stamp can be helpful for debugging. This provides a method for easy data handling, e.g. by using DMA transfers only without checking single interrupt bits.

WSI, SDI, SCRI treat the interrupts referring to the Status and Communication nibble.

For acceleration of the interrupt service routine, a Register INTOV is implemented that shows if an interrupt class (RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI) is active on any of the channels. It holds a flag for each class which ORs the states from all channels of each node pointer in interrupt node pointer registers INPx. This flag is automatically set if there is an interrupt pending for the node pointer which is enabled. It is automatically reset, if no more enabled interrupt is pending for interrupt class.

In addition, there are 8 overview registers per channel holding the flags NBI, CRCI, TEI, RMI, RSI, RDI, NFI, MEI for each buffer line: NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx; x = [1 .. 0]. E.g. NBIOV0 holds 32 bits, one for each buffer line of channel 0 reflecting if NBI is set in this buffer line.

The interrupt request or the corresponding interrupt set bit (in register INTSETA/B) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATA/Bx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLRA/B.

If more than one interrupt source is connected to the same interrupt node (in register INPx), the requests are combined to one common line.

33.13 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to the interrupt router. See [Table 33-4 “Service Request Lines of PSI5” on Page 33-142](#).

33.14 PSI5 Kernel Registers

This section describes the kernel registers of the PSI5 module. All PSI5 kernel register names described in this section will be referenced in other parts of the TC27x User's Manual by the module name prefix "PSI5_" for the PSI5 interface.

All registers in the PSI5 address spaces are reset with the application reset (definition see SCU section "Reset Operation").

The complete and detailed address map of the PSI5 module is described in [Table 33-2](#) on [Page 33-22](#).

w can take the values 0 ... 6 (watch dog limit values)

x can take the values 0 ... 1 (PSI5 channels)

y can take the values 0 ... 31

z can take the values 0 ... 5

1) The absolute register address is calculated as follows:

Module Base Address ([Table 33-2](#)) + Offset Address (shown in this column)

33.14.1 Module Control

Module Identification Register

The PSI5 Module Identification Register ID contains read-only information about the module version.

PSI5_ID

Module Identification Register (008_H) **Reset Value: 00C3 C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the PSI5: 00C3 _H

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

Peripheral Sensor Interface (PSI5)
PSI5_CLC
Clock Control Register
(000_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Note: After a hardware reset operation, the f_{PSI5} clock is switched off and the PSI5 module is disabled (DISS set).

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

Peripheral Sensor Interface (PSI5)
PSI5_OCS
OCDS Control and Status
(3CC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SUS	[27:24]	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 _H Will not suspend 1 _H Hard suspend. Clock is switched off immediately. The kernel continues when hard suspend is left. 2 _H Soft suspend option A (Suspend after end of current send or receive transfers, if any are ongoing) others, reserved
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Peripheral Sensor Interface (PSI5)

The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00000B, EN1 -> TAG ID 000001B, ... , EN31 -> TAG ID 011111B.

PSI5_ACCEN0
Access Enable Register 0
(3D0_H)

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... , EN31 -> TAG ID 111111B.

Peripheral Sensor Interface (PSI5)
PSI5_ACCEN1
Access Enable Register 1
(3D4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Peripheral Sensor Interface (PSI5)
PSI5_KRST0
Kernel Reset Register 0
(3D8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Peripheral Sensor Interface (PSI5)
PSI5_KRST1
Kernel Reset Register 1
(3DC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Peripheral Sensor Interface (PSI5)
PSI5_KRSTCLR
Kernel Reset Status Clear Register (3E0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Fractional Divider Register

 The Fractional Divider Register controls the input clock f_{fracdiv} .

PSI5_FDR
PSI5 Fractional Divider Register (00C_H)
Reset Value: 0000 0000_H

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
0	[13:10], [31:26]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)

Fractional Divider Register for Lower Bit Rate

The Fractional Divider Register for lower Bit Rate contains the pre divider that defines the time resolution of the f_{125} . It divides f_{fracdiv} by a factor as given in [Equation \(33.3\)](#) and [Equation \(33.4\)](#) and provides f_{125} to all channels.

FDRL

Fractional Divider Register for Lower Bit Rate (010_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
0	[13:10], [31:26]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)

Fractional Divider Register for Higher Bit Rate

The Fractional Divider Register for Higher Bit Rate contains the pre divider that defines the time resolution of f_{189} . It divides $f_{fracdiv}$ by a factor as given in [Equation \(33.5\)](#) and [Equation \(33.6\)](#) and provides f_{189} to all channels.

FDRH
Fractional Divider Register for Higher Bit Rate (014_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
0	[13:10] , [31:26]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)
Fractional Divider Register for Time Stamp

The PSI5 Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of the Time Stamp Registers TSRA/B/C and the Sync Pulse Time Base Counter SBC. It divides f_{PSI5} by a factor as given in [Equation \(33.7\)](#) and [Equation \(33.8\)](#). It contains as well the bits for reset control of the time stamp counters.

FDRT
Fractional Divider Register for Time Stamp (018_H) Reset Value: 0000 0000_H

ECEB	30	rw	External Time Stamp Clear Enable B Enables the external trigger line selected by ECS to clear the global time stamp counter TSRB.CTS on rising edge of the external trigger. 0 _B disabled 1 _B enabled
ECEC	31	rw	External Time Stamp Clear Enable C Enables the external trigger line selected by ECS to clear the global time stamp counter TSRC.CTS on rising edge of the external trigger. 0 _B disabled 1 _B enabled
0	[13:10]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)
Module Time Stamp Register A

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRA
Time Stamp Register A
(01C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CTS	[23:0]	r	Current Time Stamp for the Module This bit field shows the current time stamp.
ETB	[26:24]	rw	External Time Base Select Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000 _B TRIG0 001 _B TRIG1 ... _B ... 101 _B TRIG5 110 _B reserved, no trigger selected 111 _B reserved, no trigger selected
TBS	27	rw	Time Base Select This bit selects the clock source for CTS 0 _B Internal, CTS counts in clock cycles of f_{TS} 1 _B External, CTS counts in clock cycles of f_{GTM}
ACL	30	w	Clear All Current Time Stamp Counters If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
CLR	31	w	Clear Current Time Stamp for the Module If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)
Module Time Stamp Register B

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRB
Time Stamp Register B
(020_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CTS	[23:0]	r	Current Time Stamp for the Module This bit field shows the current time stamp.
ETB	[26:24]	rw	External Time Base Select Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000 _B TRIG0 001 _B TRIG1 ... _B ... 101 _B TRIG5 110 _B reserved, no trigger selected 111 _B reserved, no trigger selected

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
CLR	31	w	Clear Current Time Stamp for the Module If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)
Module Time Stamp Register C

This PSI5 Module Time Stamp Register contains read-only information about the current time given in clock cycles of f_{TS} or f_{GTM} since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRC
Time Stamp Register C
(024_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CTS	[23:0]	r	Current Time Stamp for the Module This bit field shows the current time stamp.
ETB	[26:24]	rw	External Time Base Select Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000 _B TRIG0 001 _B TRIG1 ... _B ... 101 _B TRIG5 110 _B reserved, no trigger selected 111 _B reserved, no trigger selected
TBS	27	rw	Time Base Select This bit selects the clock source for CTS 0 _B Internal, CTS counts in clock cycles of f_{TS} 1 _B External, CTS counts in clock cycles of f_{GTM}
ACL	30	w	Clear All Current Time Stamp Counters If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
CLR	31	w	Clear Current Time Stamp for the Module If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	[29:28]	r	Reserved Read as 0; should be written with 0.

Peripheral Sensor Interface (PSI5)
Global Control Register

The Global Control Register defines module wide settings.

The first 5 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: NFI, TEI, NBI, MEI, CRCI.

GCR
Global Control Register
(02C_H)
Reset Value: 0000 001F_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NBI	1	rw	NBI is selected if bit is set.
MEI	2	rw	MEI is selected if bit is set.
NFI	3	rw	NFI is selected if bit is set.
TEI	4	rw	TEI is selected if bit is set.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
ETCx (x = 0-4)	8+x	rw	Enable Channel Trigger Counter CTVx.CTC This bit enables CTVx.CTC. The bits ETC0 ..x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTCx counts on, starting from its current value. CTCx can be written only if ETCx is cleared (stopped). In TC27x only ETC0 .. 1 are available. All other must be written with 0, and always read 0.
CENx (x = 0-4)	16+x	rw	Enable Channel This bit enables PSI5 Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel.
0	[31:21], [15:13], [7:5]	r	Reserved Read as 0; should be written with 0.

33.14.2 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCR_x determines for the PSI5 channel x:

for the receiver:

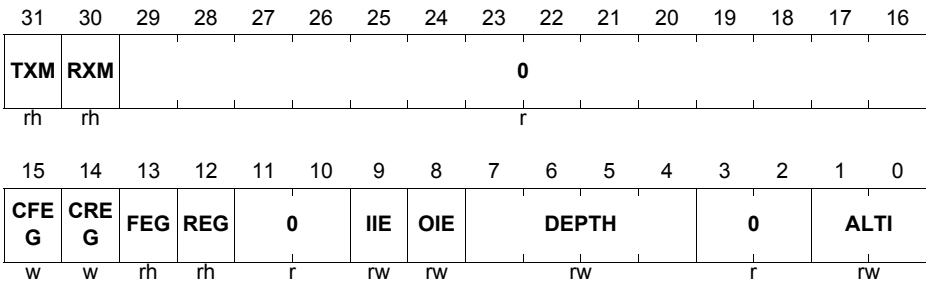

- the alternate input
- the filter depth
- the input signal polarity

for the transmitter

- the output signal polarity

IOCR_x (x = 0-1)

Input and Output Control Register x(030_H+x*36*4) Reset Value: 0000 0000_H

Field	Bits	Type	Description
ALTI	[1:0]	rw	Alternate Input Select Selects the alternate input for channel x: 00 _B Alternate Input 0 selected 01 _B Alternate Input 1 selected 10 _B Alternate Input 2 selected 11 _B Alternate Input 3 selected

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
DEPTH	[7:4]	rw	Digital Glitch Filter Depth DEPTH determines the number of port input samples clocked with f_{PSI5} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 0000 _B off, default 0001 _B 1 T_{PSI5} 0010 _B 2 0011 _B 3 ... _B ... 1111 _B 15
OIE	8	rw	Output Inverter Enable Channel x Selects the Pulse Polarity of the output of channel x 0 _B Pulse polarity is not inverted 1 _B Pulse polarity is inverted
IIE	9	rw	Input Inverter Enable Channel x Selects the Pulse Polarity of the input of channel x 0 _B Pulse polarity is not inverted 1 _B Pulse polarity is inverted
REG	12	rh	Rising Edge Glitch Flag for Channel x Shows the status of the glitch detection of channel x 0 _B No Glitch detected on rising edge 1 _B Glitch detected on rising edge REG is cleared by setting CREG.
FEG	13	rh	Falling Edge Glitch Flag for Channel x Shows the status of the glitch detection of channel x 0 _B No Glitch detected on falling edge 1 _B Glitch detected on falling edge FEG is cleared by setting CFEG.
CREG	14	w	Clear Rising Edge Glitch Flag for Channel x Clears the status flag REG 0 _B REG is not cleared 1 _B REG is cleared CREG always read zero.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
CFEG	15	w	Clear Falling Edge Glitch Flag for Channel x Clears the status flag FEG 0 _B FEG is not cleared 1 _B FEG is cleared CFEG always read zero.
RXM	30	rh	Receive Monitor for Channel x Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0 _B Current signal is low. 1 _B Current signal is high.
TXM	31	rh	Transmit Monitor for Channel x Shows the status of the transmit signal of channel x inverted as specified by OIE. 0 _B Current signal is low. 1 _B Current signal is high.
0	[3:2], [11:10], [29:16]	r	Reserved Read as 0; should be written with 0.

33.14.3 Receiver Control Registers

Receiver Control Register A

The Receiver Control Registers RCRA contains control bits/bit fields that are related to the PSI5 receiver operation. It configures the payload length of the up to 6 frames in the up to 6 slots.

RCRAx (x = 0-1)

Receiver Control Register A x **(034_H+x*36*4)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
PDLy (y = 0-5)	[5*y+4: 5*y]	rw	Payload Data Length PDL determines the number of data bits per frame that the PSI5 channel x is setup for in slot y. PDL does not include the start bits and the Parity/CRC bits. PDL includes the Messaging bits, the Frame Control bits and the Status bits. 0000 _B 0 bit data 0001 _B 1 bit data 00010 _B 2 bit data 00011 _B 3 bit data 11100 _B 28 bit data 11101 _B 0 bit data 11111 _B 0 bit data

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
ASYN	30	rw	Asynchronous Mode If set, <ul style="list-style-type: none"> the watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0 Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. No Sync Pulses generated, TX path is inactive 0_B off (default) 1_B on
AVBS	31	rw	Verbose Mode for Asynchronous Mode If set, and ASYN is set and WDL0 is > 0 an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watch dog timer for the PSI5 channel x without reception of a frame. 0_B off (default) 1_B on

Receiver Control Register B

The Receiver Control Registers RCRBx contains control bits/bit fields that are related to the PSI5 receiver operation. It configures up to 6 frame types in the up to 6 slots.

RCRBx (x = 0-1)

Receiver Control Register B x **(038_H+x*36*4)** **Reset Value: 0000 0000_H**

0	[31:6]	r	Reserved Read as 0; should be written with 0.

Watch Dog Timer Register

Synchronous Mode

Selected with RCRAx.ASYN = 0.

The Watch Dog Timer Registers WDTxy contain 7 time limits defining 6 frame slots.

Peripheral Sensor Interface (PSI5)

The internal Watch Dog timer is started automatically at the start of a sync pulse. The value entered here defines the time in multiples of TTS (defined in FDRT) from the last start of a sync pulse on channel x.

The internal Watch Dog Timer is compared to WDL_x. A match triggers:

- the automatic incrementing of slot counter RDRH.SC_x
- starting from WDL_x1 on: check if a frame with the corresponding SC y has been received or if such a frame is still being received since last WDL_x expired. If this is not the case but a frame was expected in this slot y (configured so in RCRB_x.FEC_y) “No Frame Received” Interrupt NFI is issued. If configured so (in RCRB_x.VBS_y), an empty frame (all data fields are ‘0’) is stored in RDRL/H_x and the referring RDML/H.
- Frames that start before a slot boundary and end after this boundary but are too short and thus discarded will result in an NFI / empty frame as well (if configured).
 - If no frame was received before the SOF in this slot,
SC = slot where SOF happened.
Time Stamp = end of slot where SOF happened.
 - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and if no good frame is received in this next slot:
SC = next slot (SC where SOF happened + 1)
Time Stamp = end of next slot (SC where SOF happened + 1).
 - If a good frame was received in this slot before a second SOF crosses WDL, the parameters for the next slot are taken over already and if a good frame is received in this next slot: no NFI is issued.
- (The remarks about the Time Stamps assume that RCRC_x.TSR selects SFTSC_x.)
- A frame starting before a slot y and ending in slot y will not prevent NFI for slot y.

Detection of Frame Boundaries:

- SOF is the first rising edge of the first start bit after an “Idle Time”, a time stamp is triggered and SC is captured for the frame at this point in time
- EOF is determined based on the configured frame length (RCRAX.PDL_y and RCRC_x.CRC_y). An unexpected “Idle Time” or Manchester Error will result in earlier EOF detection.
- For each frame, the receiver checks if slot counter SC at SOF is equal to SC at EOF. If not, the interrupt TEI is issued. FEC is not relevant for TEI.

If WDL_x is cleared no check is performed but RDRH.SC is still incremented when it is its turn in the sequence of the WDLs. Thus such unconfigured WDL_x must appear only at the end. If an unconfigured WDL_x appears between configured WDL_x, the slot count will be confused.

If a frame is received in a slot where no frame is expected, no dedicated flag is set but the frame is received with the parameters (PDL, SC and on) given for this slot. SW will detect this as SC for this frame is wrong.

Asynchronous Mode

Peripheral Sensor Interface (PSI5)

Selected with RCRAx.ASYN = 1.

The watch dog timers for the PSI5 channel x, slot WDL1 .. 6 are disabled. If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0. Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. If AVBS (verbose mode) is set too, an empty frame is stored in RDRL/Hx and the referring RDML/H.

Channel Configuration at Slot Boundaries / Take over of Slot Parameters

The receiver takes over the parameters for a frame at the beginning of a slot
- with 3 exceptions:

Exception 1)

During SLOT0 (this is the slot after the last configured slot), after the sync pulse, the configuration of SLOT1 is already used. An internal shadow slot count value makes sure, the messaging bits are routed to slow channel for SLOT1. This way, a frame for SLOT1 that is too early will be received correctly, the messaging bits are sorted correctly. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT0) than it ends (SLOT1). SC = 1 will be stored in the receive buffer/memory.

Exception 2)

Frames that come too early could destroy the slow channel of the preceding slot. To prevent this, during SLOT1 .. SLOT5, the configuration of the next slot is loaded immediately after EOF was received. Note that an SOF must be seen first in the same slot before an EOF is looked for. This way, the HW prevents the destruction of a good frame by a preceding frame that is too late. An internal shadow slot count value makes sure, the messaging bits are routed to the slow channel for the following SLOT. This way, a frame for e.g. SLOT3 that is too early will be received correctly, the messaging bits are sorted correctly in SLOT3 and not in SLOT2 where the SOF of this frame is. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT2) than it ends (SLOT3). SC = 3 will be stored in the receive buffer/memory.

Exception 3)

If a frame does not end at the configured end of a slot, the new parameters of the following slot are taken over by the receiver only after the EOF was detected. This allows to receive a frame properly that is too late.

Note that orphan frames, i.e. frames that come with a timely shift of one or more slots can not be detected as such. Thus they will be stored with the SC as they appear.

Notes on Frames coming too early

Peripheral Sensor Interface (PSI5)

A frame may come too early and thus start in a slot that is configured for no frame (FEC = 0).

If the user wants to make sure that this frame is stored in RDR/RDM, the slot with FEC = 0 must be configured in the same way as its follower.

At least, the length field PDL must be set to its maximum value (28) to allow for reception of all frame lengths. This allows to capture such a frame with referring error bits. (TEI, NBI, CRC in most cases)

If this is not done and PDL is (by default) = 0 the following happens:

CASE1: SOF is too early and thus in the slot with FEC = 0, due to PDL = 0 also EOF is detected in the slot with FEC = 0.

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI is issued.

CASE2: SOF is too early and thus in the slot with FEC = 0, although PDL = 0 EOF is detected in the slot FOLLOWING the slot with FEC = 0 (because CRC transmission end here, i.e. the SOF was very close to the end of the slot)

The Frame is stored in RDR/RDM with Time Stamp, 0 bits of data (as configured in PDL), Slot Count of the too early slot (with FEC =0), CRCI is generated as the FSM assumes that no CRC can be checked ok on no data, NBI and TEI bits are set.

WDT0w (w = 0-6)

Watch Dog Timer Register 0w **(040_H+w*4)** **Reset Value: 0000 0000_H**

WDT1w (w = 0-6)

Watch Dog Timer Register 1w **(0D0_H+w*4)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
WDLxw	[15:0]	rw	Watch Dog Timer Limit for channel x limit w.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Usage of the Watch Dog Timer Limits:

The example below shows some use cases.

F1: "Frame too early": Slot Count SC at SOF is 0 and 1 at EOF. Timing Error is issued (TEI). F1 is stored with configuration of Slot 1 and SC = 1.

WDL2: Slot Count SC incremented by HW, no "No Receive Frame" Interrupt as no frame expected (FEC=0)

F3: "Frame too late": Slot Count SC at SOF is 3 and 4 at EOF. Timing Error is issued (TEI). The configuration for Slot 3 is kept until the end of F3 so that it is not destroyed. Note that the EOF of Frame 3 does not lead to take over the configuration of Slot 5! But the EOF of F4 does. This way a F5 coming too early would be received correctly.

WDL5: "Frame missing": No SOF or EOF received since WDL4. A frame was expected (FEC=1), No Receive Frame Interrupt is issued.

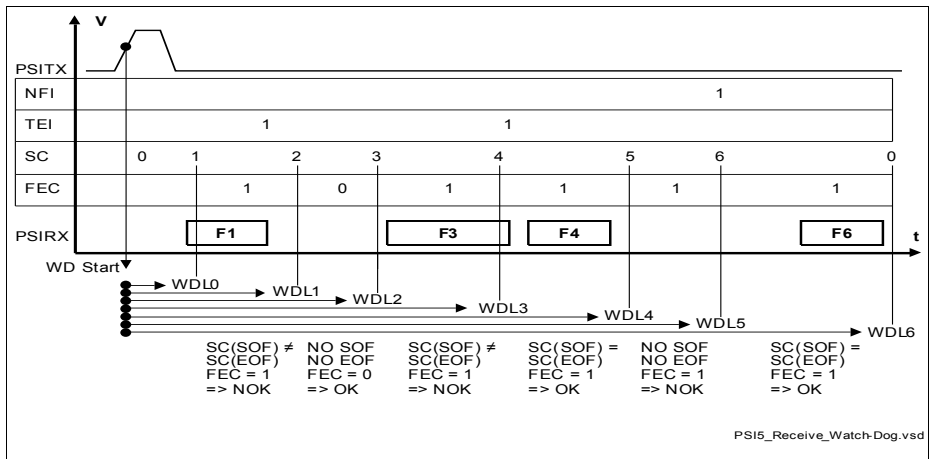

Figure 33-18 Watch Dog Timer Limits

33.14.4 Receive Data and Status Registers

Receiver Status Register

The Receive Status Register provides the status information of channel x.

RSRx (x = 0-1)

Receive Status Register x (05C_H+x*36*4) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CRC	[2:0]	r	CRC of last frame. CRC0 is on bit position 0.
MSG	[9:8]	r	Messaging Bits of last frame. MSG0 is on bit position 8.
0	[7:3], [31:10]	r	Reserved Read as 0; should be written with 0.

Serial Data and Status Register (“Slow Channel”)

The Serial (Receive) Data and Status Register provides the data and status information of channel x slot y. The data is presented in bit field SD independent from the SCRC check result in SCRI.

Peripheral Sensor Interface (PSI5)
SDS0z (z = 0-5)
Serial Data and Status Register 0z (060H+z*4)
Reset Value: 0000 0000_H
SDS1z (z = 0-5)
Serial Data and Status Register 1z (0F0H+z*4)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SD	[15:0]	r	Serial Data of last serial data frame on channel x slot y. SD0 is on bit position 0. If SDS.CON is not set, bits [15:12] are zero.
MID	[23:16]	r	Message ID of last serial data frame. ID0 is on bit position 16. If SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	SCRC CRC of last serial data frame. CRC0 is on position 24.
SCRI	30	r	CRC of Serial Message failed Interrupt Flag. This bit is set if the CRC of the serial message fails. This includes a check of the Messaging bit field for correct 0 values of bit 1 in frames 7, 13 and 18. See INTSTATx.
CON	31	r	Configuration bit of last serial frame. 0 _B 12-bit data and 8-bit message ID 1 _B 16-bit data and 4-bit message ID

Peripheral Sensor Interface (PSI5)
Start of Pulse Time Stamp Capture Register SPTSCx

Each time a sync pulse is sent on channel x, the time stamp is captured in this register. RCRC.TSP selects, if TSRA, B or C is used. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SPTSCx (x = 0-1)
SOP TS Capture Register SPTSCx(078_H+x*36*4)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TS	[23:0]	rh	Time Stamp of the last sync pulse sent on channel x. The Time Stamp is taken at the rising edge of the pulse.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

Start of Frame Time Stamp Capture Register SFTSCx

Each time a start of frame is received on channel x, the time stamp is captured in this register. The first rising edge of the first start bit is captured. Note that a preceding "Idle Time" is required for start bit detection. In case the two start bits should not be received successfully (i.e. without manchester coding errors) the frame is completely dropped and the latest captured value is overwritten with the next SOF or at the referring WDLy for "empty messages" if configured in RCRBx.VBSy. RCRC.TSF selects, if TSRA, B or C is used. RCRCx.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

Peripheral Sensor Interface (PSI5)

SFTSCx (x = 0-1)
SOF TS Capture Register SFTSCx(07C_H+x*36*4)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TS	[23:0]	rh	Time Stamp of the last frame received on channel x. The Time Stamp is taken at the rising edge of the first start bit S1 that was qualified by the receiver.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

Receive Data Registers RDRLx

The Receive Data Register RDRLx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

The bit CRCI reflect, whether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

Peripheral Sensor Interface (PSI5)
RDRLx (x = 0-1)
Receive Data Register Low x (080H+x*36*4) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CRCI	0	rh	CRC Error Flag This bit is set if the CRC or Parity check fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) 0 _B correct CRC/Parity 1 _B wrong CRC/Parity
CRC	[3:1]	rh	CRC CRC/parity bit of last PSI5 frame. CRC0 or Parity bit is on bit position 1. In case of NFI, this field is cleared.
RD	[31:4]	rh	RD Receive data of last PSI5 frame. D0 is on bit position 4. In case of NFI, this field is cleared.

Receive Data Registers RDRHx

The Receive Data Register RDRHx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

The bits RBI, RMI, RSI, NBI and TEI reflect, whether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the the old status of the referring sticky bit in INTSTATA before latest frame reception.

Peripheral Sensor Interface (PSI5)
RDRHx (x = 0-1)
Receive Data Register High x (084H+x*36*4) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TS	[23:0]	rh	Time Stamp of the last received PSI5 frame. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx. (It can be selected if the time stamp of the last sync pulse is stored or the time stamp for the start of frame).
SC	[26:24]	rh	Slot Counter In Synchronous Mode (RCRAx.ASYN=0): Number of the slot the SOF of the frame was received in. In Asynchronous Mode (RCRAx.ASYN=1): revolving frame number between 1 and 6. 000 _B not valid (SOF too early) 001 _B Slot 1 ... _B ... 110 _B Slot 6 111 _B not valid
TEI	27	rh	Time Slot Error Flag In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy). In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. 0 _B no error 1 _B error

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
NBI	28	rh	<p>Number of bits Error Flag</p> <p>This bit is set if the last frame received less bits than expected but no manchester coding error occurred until S1, S2, M0 and M1 where received.</p> <p>Note that the frame after the error might be completely wrong.</p> <p>0_B all bits received 1_B not all bits received</p>
MEI	29	rh	<p>Error in Message Bits Flag</p> <p>This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG)</p> <p>Note that the frame after the error might be completely wrong.</p> <p>0_B frame is correct 1_B frame is not correct</p>
NFI	30	rh	<p>No Frame Received Flag</p> <p>This bit is set at the end of a slot if neither an SOF nor an EOF was received in this slot. If only the two start bits are received and no further data, this "SOF" is discarded completely and treated like no frame received as well.</p> <p>If RCRBx.VBS is set, an empty frame is stored anyhow and RDIX is issued as well. The content of RDRL/Hx / RDML/Hx is valid for SC, TS (captured at the end of the slot) and for this bit (NFI). Bit fields RD and CRC are cleared (all zero).</p> <p>0_B no error 1_B error</p>
RBI	31	rh	<p>Receive Buffer Overflow Flag</p> <p>This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data.</p> <p>0_B No overflow 1_B Overflow</p>

33.14.5 Receive Data Memory

The module design allows for usage in 2 ways without mode selection:

Ring Buffer Usage

The Receive Data Memory x is built as a ring buffer. I.e. the first frame is stored in RDML/Hx0, the next in RDML/Hx1 and so on. At buffer 31 a wrap around is performed automatically. I.e. the next frame is stored in buffer 0. RFCx.WRP is showing the last location written and automatically incremented after write.

Receive Buffer Overrun Interrupt Flag RBI is set, if a buffer is written before the SW cleared Receive Data Interrupt Overview Flag RDIOVx (unchecked or erroneous frame received or No Frame Received (NFI) message to be stored).

FIFO Usage

Writing to the Receive Data Memory by the module moves the write pointer after writing. Reading from RDFx 2 times with a 32 bit word access moves the read pointer to the next younger buffer automatically after the read access. It clears as well all interrupt overview bits for this buffer line in NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx; RDIOVx, NFIOVx, MEIOVx. This allows for fully automatic DMA transfers without CPU intervention. The DMA simply needs to be set up in a way that it reads exactly the number of buffers configured with the FIFO warning level FWL. The application SW configures "FIFO Warning Level Request Interrupt" FWI so that it is routed to the referring DMA channel as trigger source. Note that FWI does not need to be cleared to repetitively trigger the DMA.

If RFCx.WRAP is cleared and the read pointer (after the auto increment said above) equals the write pointer while reading from RDFx, a Receive Memory Underrun Interrupt RUIx is flagged and the read pointer is not moved on automatically even if RDFx is read.

IF RFCx.FRQ is set, the FIFO needs to be flushed by RFCx.FLU.

Peripheral Sensor Interface (PSI5)

Figure 33-19 Receive Data Memory

Receive Data Memory RDMLx_y

The Receive Data Memory RDML_x for channel x shows the data content of up to 32 received data frames.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

Peripheral Sensor Interface (PSI5)
RDML0y (y = 0-31)
Receive Data Memory Low 0y (600H+y*8) Reset Value: 0000 0000_H
RDML1y (y = 0-31)
Receive Data Memory Low 1y (700H+y*8) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CRCI	0	rh	CRC Error Flag Copied from RDRLx at frame end.
CRC	[3:1]	rh	CRC Copied from RDRLx at frame end.
RD	[31:4]	rh	RD Copied from RDRLx at frame end.

Receive Data Memory RDMHxy

The Receive Data Memory RDMHx for channel x shows the data content of up to 32 received data frames.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

Peripheral Sensor Interface (PSI5)
RDMH0y (y = 0-31)
Receive Data Memory High 0y (604H+y*8) Reset Value: 0000 0000_H
RDMH1y (y = 0-31)
Receive Data Memory High 1y (704H+y*8) Reset Value: 0000 0000_H

Field	Bits	Type	Description
TS	[23:0]	rh	Time Stamp Copied from RDRHx at frame end.
SC	[26:24]	rh	Slot Counter Copied from RDRHx at frame end.
TEI	27	rh	Time Slot Error Flag Copied from RDRHx at frame end.
NBI	28	rh	Number of bits Error Flag Copied from RDRHx at frame end.
MEI	29	rh	Error in Messaging Bits Flag Copied from RDRHx at frame end.
NFI	30	rh	No Frame Received Flag Copied from RDRHx at frame end.
RMI	31	rh	Receive Memory Overflow Flag Copied from INTSTATAx at frame end.

Receive FIFO Control Register RFCx

RFCx contains control bits for the FIFO and Ring Buffer operation.

Peripheral Sensor Interface (PSI5)
RFCx (x = 0-1)
Receive FIFO Control Register x (3E4_H+x*4)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
REP	[5:0]	r	FIFO Read Pointer points to the buffer to be read next. Incremented after read. The last bit indicates if RDMxH or RDMxL is read. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI)
WRP	[13:8]	r	FIFO/Ring Buffer Write Pointer points to the buffer written last. Incremented before write. The last bit indicates if RDMxH or RDMxL is written. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI).
FWL	[20:16]	rw	FIFO Warning Level Number of new entries at which the FIFO Warning Interrupt FWIx is set automatically. For calculation WRP and REP are used. I.e. only if the memory is read via RDFx, this works properly.
WRAP	29	r	Write Pointer WRAP Indicator If set, the Write Pointer is one wrap around ahead of the Read Pointer. It is cleared, if the the Read Pointer wraps around too or when FLU is set by SW.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
FRQ	30	r	Flush Request if set, FIFO read and write pointers are not incremented any more due to excessive RMI. (Too many overrun conditions). This bit is cleared when FLU is set.
FLU	31	w	Flush if set, FIFO read and write pointers are cleared. Bits and WRAP are cleared. SW needs to clear interrupts as needed. This bit can only be set and is cleared by HW. Always read as 0.
0	[28:21] , [15:14] , [7:6]	r	Reserved Read as 0; should be written with 0.

Receive Data FIFO RDFx

The Receive Data FIFO RDFx for channel x shows the oldest data content of up to 32 received data frames. I.e. RFCx.REP is pointing at the buffer presented.

Do not set a debugger watch point on this register as any read access will issue a hard ware request for new data (move read pointer REP and present referring memory content in RDFx). A debugger watch point can be set on the RDML/Hx and RFCx to monitor the FIFO behavior.

RDFx (x = 0-1)

Receive Data FIFO x (3F8H+x*4) **Reset Value: 0000 0000_H**

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
RD	[31:0]	rh	RD Shows the content of RDML/Hxy; y = RFCx.REP[5:1]; L/H = RFCx.REP[0]. Reading this register triggers incrementation of REP and presentation of next FIFO value at next read access! Once a complete buffer is read (64 bit, 2 accesses to RDF) all overview flags for this very buffer are cleared automatically.

Peripheral Sensor Interface (PSI5)
RSI Overview Register

The RSI Overview Register RSIOVx contains flags to manage the receive memory of PSI5 channel x.

RSIOVx (x = 0-1)

RSI Overview Register **(40C_H+x*4)** **Reset Value: 0000 0000_H**

33.14.6 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (PSI5 V1.3) (EPS is cleared)
- sync pulses for ECU to Sensor communication (PSI5 enhanced) (EPS is set)
- sync pulses provided by GTM (Bypass BYP set)
- Blank Out (switch off receiver during and after the Sync Pulse)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. If data is available (TOF is set) the pulses will be modulated according to the selected standard. EPS selects between extended standard with pulse length modulation and legacy mode according to PSI5 standard V1.3 with pulse dropping. The minimum pulse length is defined by PGC.PLEN for both standards. For the extended standard, the pulses are prolonged by PGC.DEL if a one is coded. Exception is the bypass path (BYP is set). These pulses are transmitted without any modulation.

Any combination of PTE, ETE and BYP can produce too long pulses!

Peripheral Sensor Interface (PSI5)

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TOF.

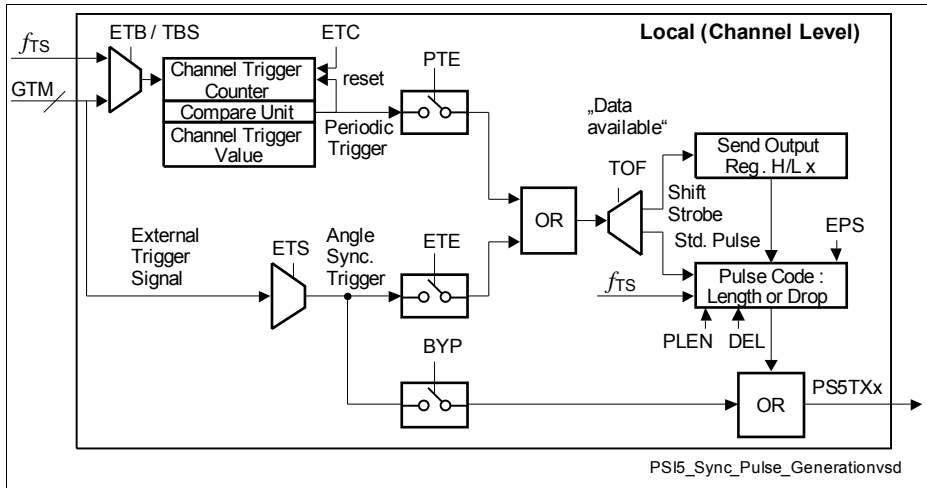

Figure 33-20 PSI5 Sync Pulse Generation

Blank Out Time

BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver.

Peripheral Sensor Interface (PSI5)

Figure 33-21 PSI5 Blank Out Time

Pulse Generation Control Registers PGCx

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

PGCx (x = 0-1)

Pulse Generation Control Register x(088_H+x*36*4) Reset Value: 0000 0000_H

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
PLEN	[5:0]	rw	Pulse Length Defines the length of the pulse in TTS times (defined by FDRT). This is the standard pulse width without data coding into the pulse width or for coding a '0'. 000000 _B Pulse length is 0 TTS 000001 _B Pulse length is 1 TTS 111111 _B Pulse length is 63 TTS
DEL	[13:8]	rw	Delay Length In case data is coded into the pulse length, this defines the ADDITIONAL length of the pulse in TTS times. The resulting sum length is the pulse width for coding a '1' into the pulse width. 000000 _B Pulse length is 0 TTS 000001 _B Pulse length is 1 TTS 111111 _B Pulse length is 63 TTS
TBS	15	rw	Time Base Select This bit selects the clock source for CTVx 0 _B Internal, CTV counts in clock cycles of f_{TS} 1 _B External, CTV counts in clock cycles of f_{GTM}
ETB	[18:16]	rw	External Time Base Select Selects the external clock line for counter CTVx. 000 _B TRIG0 001 _B TRIG1 ... _B ... 101 _B TRIG5 110 _B reserved, no trigger selected 111 _B reserved, no trigger selected
PTE	19	rw	Periodic Trigger Enable Periodic trigger is defined by CTVx. Should be 0 if ETE or BYP is set. 0 _B disabled 1 _B enabled

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
ETS	[22:20]	rw	External Trigger Select Selects the external trigger line for pulse generation (e.g. angle synchronous). 000 _B TRIG0 001 _B TRIG1 ... _B ... 101 _B TRIG5 110 _B reserved, no trigger selected 111 _B reserved, no trigger selected
ETE	23	rw	External Trigger Enable “Angle sync. trigger”, external line is selected by ETS. Should be 0 if PTE or BYP is set. 0 _B disabled 1 _B enabled
BYP	24	rw	Bypass Enable An external signal, selected by ETS directly drives the output of channel x. Should be 0 if PTE or ETE is set. 0 _B disabled 1 _B enabled
BOT	[31:25]	rw	Blank Out Time BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver. 0000000 _B Blank Out Time is 0 TTS 0000001 _B Blank Out Time is 1 TTS 1111111 _B Blank Out Time is 127 TTS
0	14, [7:6]	r	Reserved Read as 0; should be written with 0.

Channel Trigger Value Register x CTVx

The Channel Trigger Value Register x contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

The Channel Trigger Value CTV is the compare value which clears the counter CTC on

Peripheral Sensor Interface (PSI5)

equality and only on equality. At exactly this time, a sync pulse is triggered. The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - "CTC preset value"

I.e. CTC preset is > CTV so that the the time to to roll over is the offset. Of course CTC preset can be < CTV so that this CTC has some advance. Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external phys can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse. For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 .. 1 can be used.

Peripheral Sensor Interface (PSI5)

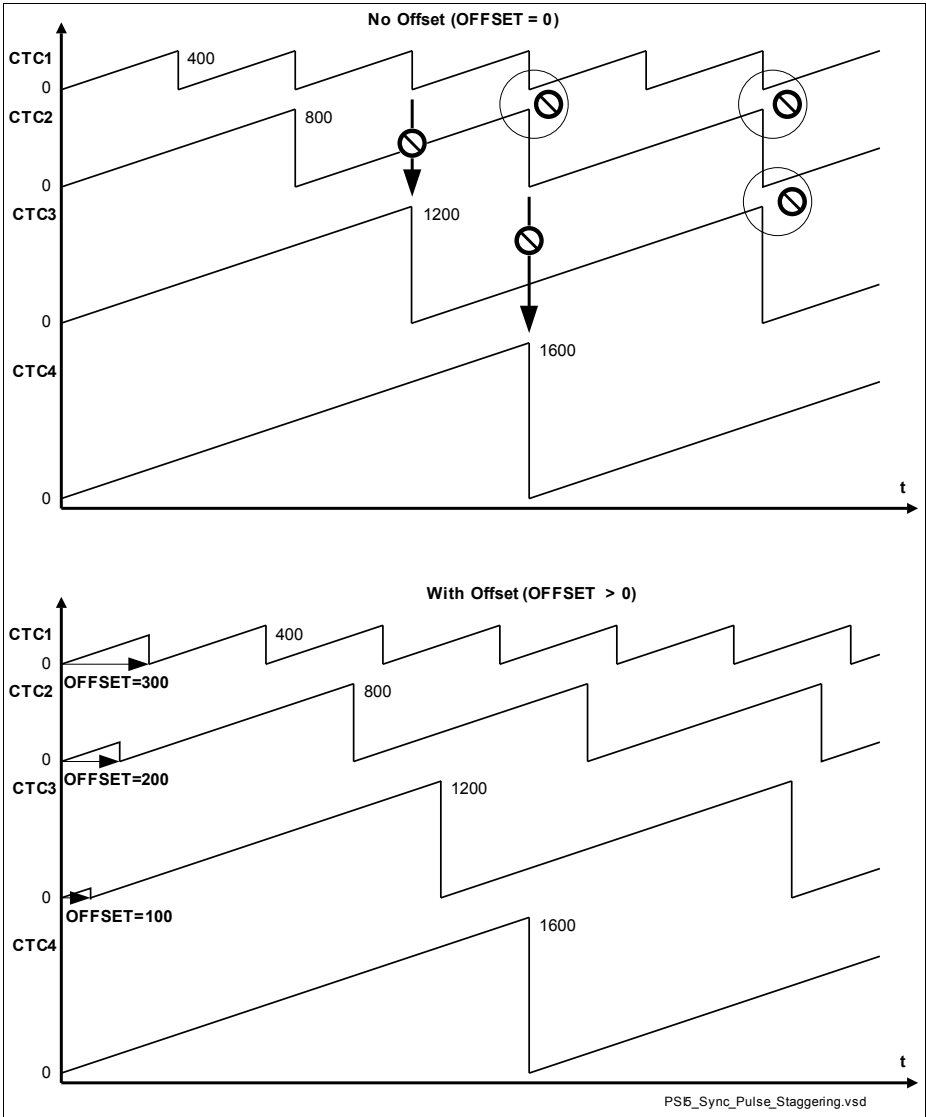

Figure 33-22 PSI5 Pulse Staggering

Peripheral Sensor Interface (PSI5)
CTV_x (x = 0-1)
Channel Trigger Value Register x (08C_H+x*36*4)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CTV	[15:0]	rw	Channel Trigger Value CTV Contains the compare value (exact match) of Channel Trigger CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse is generated.
CTC	[31:16]	rw	Channel Trigger Counter This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

Peripheral Sensor Interface (PSI5)

Send Data Preparation

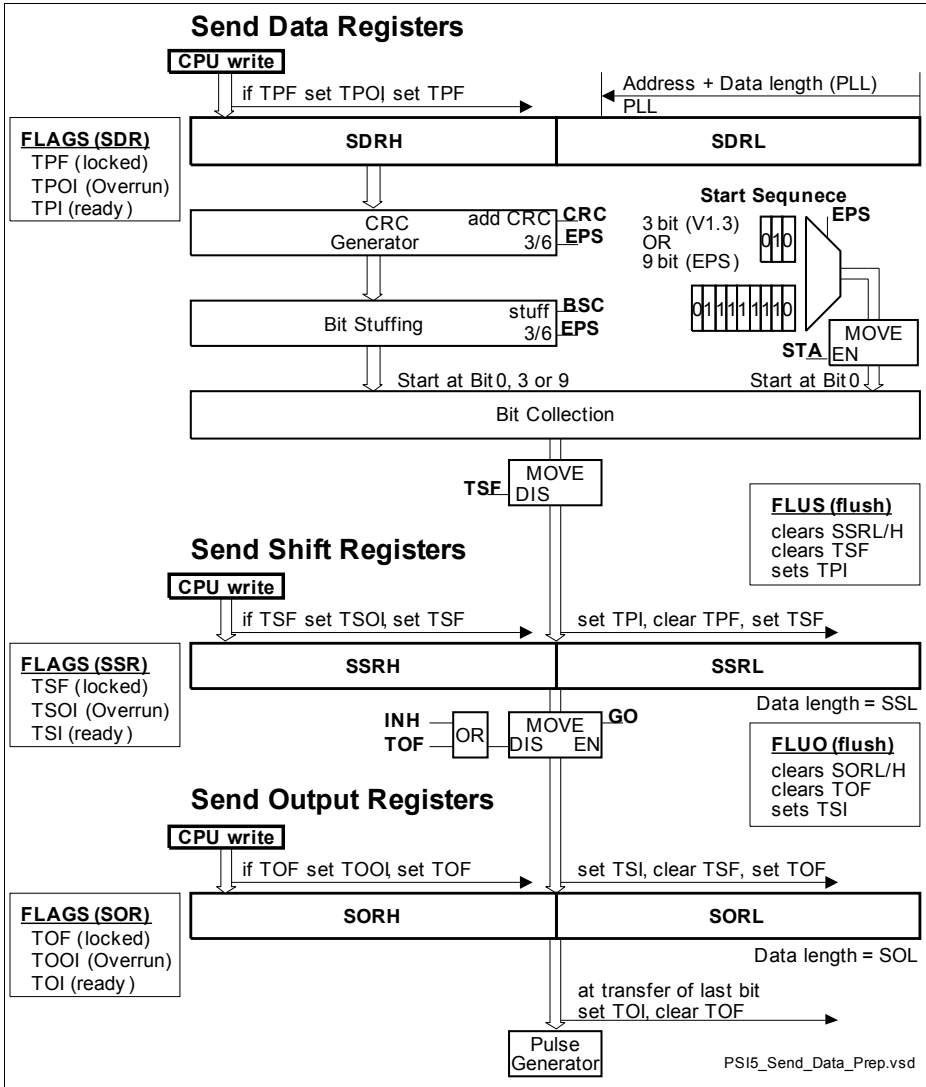

Figure 33-23 PSI5 Send Data Preparation

Peripheral Sensor Interface (PSI5)
Send Control Registers SCR_x

The Send Control Register SCR contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

Data is collected in SDRL/H_x and the control bits are collected in SCR_x.

The send control unit is build to transmit complete ECU to sensor frames.

SCR_x (x = 0-1)

Send Control Register x (090_H+x*36*4) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
PLL	[5:0]	rw	Pay Load Length of Registers SDRL/H Defines the length that is taken into account: 000000 _B length is 1 000001 _B length is 2 ... 111111 _B length is 64 If PLL > 31, SDRH needs to be written to trigger the HW for automatic STA, BSC or CRC generation or just moving data to SSRL/H. Else writing to SDRL is sufficient. PLL needs to be written before SDRL/H is used for proper operation. If insertion of STA, BSC and CRC results in more than 64 bits, the MSBs are truncated in SSR.
EPS	6	rw	Enhanced Protocol Selection 0 _B PSI5 V1.3. No Pulse length extension 1 _B Enhanced Protocol with Pulse length extension.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
BSC	7	rw	Bit Stuffing Control 0 _B No automatic bit stuffing 1 _B Automatic bit stuffing is enabled. Depending from bit EPS after 3 bits a '1' is inserted (V1.3) or after 6 bits a '0' is inserted (enhanced Power Train Mode) Note that this makes the frame longer.
SSL	[13:8]	rw	Pay Load Length of Registers SSRL/H Defines the length that is taken into account. Start Sequence, BSC and CRC need to be added to PLL by SW if SSL is calculated based on PLL. 000000 _B length is 1 000001 _B length is 2 111111 _B length is 64 If SSL > 31, SSRH needs to be written to trigger the HW for automatic moving data to SORL/H. Else writing to SSRL is sufficient. SSL needs to be written before SSRL/H is used for proper operation.
FLUS	14	w	Flush SSRH/Lx Setting this bit stops the shifting process and flushes (clears) SSRH/Lx and TSF. TPIx is issued at the end of successful flushing. Reads always as zero.
FLUO	15	w	Flush SORH/Lx Setting this bit stops the sending process and flushes (clears) SORH/Lx and TOF. TSIx is issued at the end of successful flushing. Reads always as zero.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
SOL	[21:16]	rw	<p>Pay Load Length of Registers SORL/H</p> <p>Defines the length that is taken into account. Start Sequence, CRC and Stuffing needs to be added by SW to PLL if SOL is calculated based on PLL.</p> <p>000000_B length is 1 000001_B length is 2 ... 111111_B length is 64</p> <p>If SOL > 31, SORH needs to be written to trigger the HW for automatic moving data to the pulse generator. Else writing to SORL is sufficient. SOL needs to be written before SORL/H is used for proper operation.</p>
CRC	22	rw	<p>CRC Generation Control</p> <p>0_B CRC is not generated automatically. 1_B CRC is automatically generated and added to the frame by HW (according to EPS). Note that this makes the frame longer. CRC calculation is not performed, if at least 1 CRC bit does not fit into 64 bit, e.g. due to STA or BSC. In this case, one or two zero bits are inserted.</p>
STA	23	rw	<p>Start Sequence Generation Control</p> <p>0_B no start sequence generated, payload starts at bit 0! 1_B automatically generated and added to the frame by HW (according to EPS) payload starts at bit 3/9 (EPS = 0/1). Note that this makes the frame longer.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
INH	24	rw	<p>Inhibit Transfer</p> <p>This inhibits the automatic transfer from the shift registers SSRL/H to SORL/H after the preparation of all automatic bit fields (STA, BSC, CRC). After a write access to SDRL/Hx, the automatic preparation is done by HW if selected. If automatic preparation of the start sequence is not selected, data is moved by HW without change to SSRL/H.</p> <p>When the HW is done with the transfer to the internal shift registers, interrupt TPI is activated, flag TSF is set and flag TPF is cleared automatically. Depending on INH, GO must be set after TPI before transfer to SORL/H takes place: After the transfer to SORL/H, TSI is activated, TOF is set and and TSF is cleared automatically. .</p> <p>INH defines the start mode:</p> <p>0_B automatic transfer 1_B GO bit must be set before transfer</p>
GO	25	w	<p>Release prepared Send data</p> <p>This is only relevant if INH is set It allows for manual control of the transfer from SSRH/L to SORL/H. It is always read as zero and is automatically cleared.</p> <p>0_B no transfer 1_B start transfer</p>
TPF	26	r	<p>Transmit Preparation Flag</p> <p>If set, preparation is in progress: start sequence and/ or CRC and/or stuffing and/or at least copying data from SDRL/H. If set, write access to SDRL/H will not change any data and issue TPOI. It is cleared automatically after preparation is finished.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
TSF	27	r	Transmit Shift Flag If set, data in SSRL/H is waiting to be shifted to SORL/H. This can be caused by an automatic transfer from SDRL/H or from a CPU write access to SSRL/H. If $SSL < 32$ it is sufficient to write SSRL. Else, only writing SSRH will set TSF. If set, write access to SSRL/H will not change any data and issue TSOI. It is cleared automatically after data was shifted to SORL/H or after flushing the register by setting bit FLUS.
TOF	28	r	Transmit Output Flag If set, data in SORL/H is waiting to be transmitted to the sensor. This can be caused by an automatic transfer from SSRL/H or from a CPU write access to SORL/H. If $SOL < 32$ it is sufficient to write SORL. Else, only writing SDRH will set TSF. If set, write access to SORL/H will not change any data and issue TOOI. It is cleared automatically after data was transmitted to the sensor or after flushing the register by setting bit FLUO.
TRQ	31	r	Transfer Request in Progress While a transfer is being sent this bit is set. Write access is ignored.
0	[30:29]	r	Reserved Read as 0; should be written with 0.

Send Data Registers SDRLx

The Send Data Register SDRLx for channel x shows the data content of a data frame to be sent.

Data to be sent must be written while the channel is enabled (GCR.CEN is set). While CEN is cleared the HW can not detect the write access as all state machines are stopped.

Peripheral Sensor Interface (PSI5)
SDRLx (x = 0-1)
Send Data Register Low x **(094_H+x*36*4)** **Reset Value: 0000 0000_H**

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
SDy (y = 63-32)	y-32	rw	SDy Send data of next ECU to Sensor frame. The unused MSBs (bit position SCRx.PLL and higher) must be written with '0'. If PLL is < 32, SDRHx must not be written.

Send Shift Registers SSRLx

The Send Shift Register SSRLx for channel x shows the data that will be shifted to the Send Output Register SORL. It contains as well the stuff bits as specified in PSI5 V1.3 or in the enhancement proposal of PSI5 standard as of July 2010. During transmission, all bits are shifted to LSB with each sync pulse. MSB is filled up with zero.

SSRLx (x = 0-1)

33.14.7 Interrupt Control Registers
INTOV
Interrupt Overview Register
(2F8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RSI	0	rh	Interrupt Pending on any Node Pointer RSI If any interrupt requested flag is set for any Node Pointer RSI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RSI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RDI	1	rh	Interrupt Pending on any Node Pointer RDI If any interrupt requested flag is set for any Node Pointer RDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
RBI	2	rh	Interrupt Pending on any Node Pointer RBI If any interrupt requested flag is set for any Node Pointer RBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.RBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
TDI	3	rh	Interrupt Pending on any Node Pointer TDI If any interrupt requested flag is set for any Node Pointer TDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
TBI	4	rh	Interrupt Pending on any Node Pointer TBI If any interrupt requested flag is set for any Node Pointer TBI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.TBI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
ERRI	5	rh	Interrupt Pending on any Node Pointer ERRI If any interrupt requested flag is set for any Node Pointer ERRI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.ERRI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
SDI	6	rh	Interrupt Pending on any Node Pointer SDI If any interrupt requested flag is set for any Node Pointer SDI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.SDI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
FWI	7	rh	Interrupt Pending on any Node Pointer FWI If any interrupt requested flag is set for any Node Pointer FWI in register INTSTATx AND the referring interrupt is enabled in INTENx then INTOV.FWI is set. It is automatically reset if all flags in INTSTATx are cleared for which the referring interrupt is enabled in INTENx.
0	[31:8]	r	Reserved Read as 0.

Peripheral Sensor Interface (PSI5)
Interrupt Status Registers

The Interrupt Status Registers INTSTATA/Bx contains status bits that show the status of any interrupt of PSI5 channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATAx (x = 0-1)

Interrupt Status Register A x (310_H+x*4) **Reset Value: 0000 0000_H**

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	<p>Receive Success Interrupt Request Flag</p> <p>This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors NFI, TEI, NBI, MEI, CRCI if selected to be taken into account in register GCR.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.RSI.</p> <p>This bit can be set by bit INTSETAX.RSI.</p> <p>This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
RDI	1	rh	<p>Receive Data Interrupt Request Flag</p> <p>RDI is activated when a received frame is moved to a Receive Data Register RDRL/Hx. Both RDI and RSI will be issued together at correct reception.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.RDI. This bit can be set by bit INTSETAX.RDI. This bit is set independently from INTENAX.</p>
RBI	2	rh	<p>Receive Buffer Overflow Interrupt Request Flag</p> <p>This bit is set after a frame has been received while the old one was not read from RDRHx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. Thus, RBI can be ignored if the receive memory is used.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRAX.RBI. This bit can be set by bit INTSETAX.RBI. This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
TEI	3	rh	<p>Time Slot Error Interrupt Request Flag</p> <p>In Synchronous Mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watch dog timer (see WDTxy).</p> <p>In Asynchronous Mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDLO.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.TEI.</p> <p>This bit can be set by bit INTSETAX.TEI.</p> <p>This bit is set independently from INTENAX.</p>
NBI	4	rh	<p>Number of Bits Wrong Request Flag</p> <p>This bit is set if the last frame received less bits than expected but no Manchester coding error occurred until S1, S2, M0 and M1 where received.</p> <p>Note that the frame after the error might be completely wrong.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.NBI.</p> <p>This bit can be set by bit INTSETAX.NBI.</p> <p>This bit is set independently from INTENAX.</p>
MEI	5	rh	<p>Error in Message Bits Flag</p> <p>This bit is set if a manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG)</p> <p>Note that the frame after the error might be completely wrong.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.MEI.</p> <p>This bit can be set by bit INTSETAX.MEI.</p> <p>This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
CRCI	6	rh	<p>CRC Error Request Flag</p> <p>This bit is set if the CRC fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse)</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.CRCI. This bit can be set by bit INTSETAX.CRCI. This bit is set independently from INTENAX.</p>
FWI	7	rh	<p>FIFO Warning Level Request Flag</p> <p>This bit is set after if the configured warning level of the FIFOx was reached. (See RFCx)</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.FWI. This bit can be set by bit INTSETAX.FWI. This bit is set independently from INTENAX.</p>
RUI	8	rh	<p>Receive Memory Underrun Interrupt Request Flag</p> <p>This bit is set after a SPB master reads from FIFO while no new data was available. (See RFCx)</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.RUI. This bit can be set by bit INTSETAX.RUI. This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
RMI	9	rh	<p>Receive Memory Overflow Flag</p> <p>This bit is set after a frame has been received while RDIOVx.RDI[RFCx.WRP] is set. I.e. the kernel wants to set flag RDIxWRP and finds this flag already set. The old data is overwritten by the new data in the buffer memory.</p> <p>0_B No overflow 1_B Overflow</p> <p>This bit can be cleared by bit INTCLRAX.RMIx. This bit can be set by bit INTSETAX.RMIx. This bit is set independently from INTENAX.</p>
TPI	10	rh	<p>Transfer Preparation Interrupt Request Flag</p> <p>This bit is set after data to be transferred has been moved from SDRL/H to SSRL/H. Thus a new value can be written to SDRL/Hx and the prepared data can be checked and modified by SW.</p> <p>0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit is automatically cleared by writing SDRx. This is an exception! It allows for DMA transfers without CPU activity. This bit can be cleared by bit INTCLRAX.TDI. This bit can be set by bit INTSETAX.TDI. This bit is set independently from INTENAX.</p>
TPOI	11	rh	<p>Transmit Preparation Overflow Interrupt Request Flag</p> <p>This bit is set after if SDRL/H is written while TPF is set. The old data is NOT overwritten.</p> <p>0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.TPOI. This bit can be set by bit INTSETAX.TPOI. This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
TSI	12	rh	<p>Transfer Shift Interrupt Request Flag</p> <p>This bit is set after data to be transferred has been moved from SSRL/H to SORL/H. Thus a new value can be written to SSRL/Hx.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit is NOT cleared by writing SSRL/Hx. This bit can be cleared by bit INTCLRAX.TSI. This bit can be set by bit INTSETAX.TSI. This bit is set independently from INTENAX.</p>
TSOI	13	rh	<p>Transmit Shift Overflow Interrupt Request Flag</p> <p>This bit is set after if SSRL/H is written while TSF is set.</p> <p>The old data is NOT overwritten.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.TSOI. This bit can be set by bit INTSETAX.TSOI. This bit is set independently from INTENAX.</p>
TOI	14	rh	<p>Transfer Output Interrupt Request Flag</p> <p>This bit is set after last bit to be transferred has been moved from SORL/H to the pulse generator. Thus a new value can be written to SORL/Hx.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit is NOT cleared by writing SORL/Hx. This bit can be cleared by bit INTCLRAX.TOI. This bit can be set by bit INTSETAX.TOI. This bit is set independently from INTENAX.</p>

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
TOOI	15	rh	<p>Transmit Shift Overflow Interrupt Request Flag</p> <p>This bit is set after if SORL/H is written while TOF is set. The old data is NOT overwritten.</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.TOOI. This bit can be set by bit INTSETAX.TOOI. This bit is set independently from INTENAX.</p>
NFI	16	rh	<p>No Frame Received Interrupt Flag</p> <p>This bit is set at the end of a slot if neither an SOF nor an EOF was received in this slot. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If the “SOF only frame” crosses the WDL, NFI occurs after WDL and EOF detection. If RCRBx.VBS is set, an empty frame is stored anyhow. In this case RDIX is issued as well. The only valid information is SC, TS (captured at the end of the slot) and this bit (NFI).</p> <p>0_B No interrupt was requested since this bit was cleared the last time</p> <p>1_B An interrupt was requested since this bit was cleared the last time</p> <p>This bit can be cleared by bit INTCLRAX.NFI. This bit can be set by bit INTSETAX.NFI. This bit is set independently from INTENAX.</p>
0	[31:17]	r	<p>Reserved</p> <p>Read as 0.</p>

Peripheral Sensor Interface (PSI5)

Interrupt Node Pointer Register

The Interrupt Node Pointer Register INPx contains the node pointers of PSI5 channel x.

Node Pointer ERRI is one single node pointer for the following interrupts:

- TEI
- NFI
- NBI
- MEI
- CRCI
- RUI
- RMI
- WSly
- SOly
- SCRly

Node Pointer TBI is one single node pointer for the following interrupts:

- TPOI
- TSOI
- TOOI

Node Pointer TDI is one single node pointer for the following interrupts:

- TPI
- TSI
- TOI

INPx (x = 0-1)

Interrupt Node Pointer Register x (2FC_H+x*4)

Reset Value: 0000 0000_H

Peripheral Sensor Interface (PSI5)

Field	Bits	Type	Description
ERRI	[23:20]	rw	Interrupt Node Pointer for Interrupt ERRI This bit field defines the interrupt node, that is requested due to the set condition for bit TEI, NFI, NBI, MEI, CRCl, RUI, RMI, CRCl _y , WSly, SOly, SCRly. For bit field definition, see RSI.
SDI	[27:24]	rw	Interrupt Node Pointer for Interrupt SDI This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
FWI	[31:28]	rw	Interrupt Node Pointer for FWI This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FWI. For bit field definition, see RSI.

33.15 PSI5 Module Implementation

This section describes the PSI5 module interface as it is implemented in the TC27x. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

33.15.1 Interface Connections of the PSI5 Module

Figure 33-24 shows the TC26x B-Step-specific implementation details and interconnections of the PSI5 module.

The PSI5 module is supplied with a separate clock control, address decoding, and interrupt control logic. The 8 modules' service request outputs are connected with the interrupt router. Outputs of the GTM module are connected to the timer inputs: 6 configured.

The serial data inputs PSIRXn of the receive channels of the PSI5 module as well as the sender outputs PSITXn are connected to GPIO lines. If the outputs are used, they are mapped to a different port pin than the referring PSI5 data input line as most phys will use separate TX and RX lines.

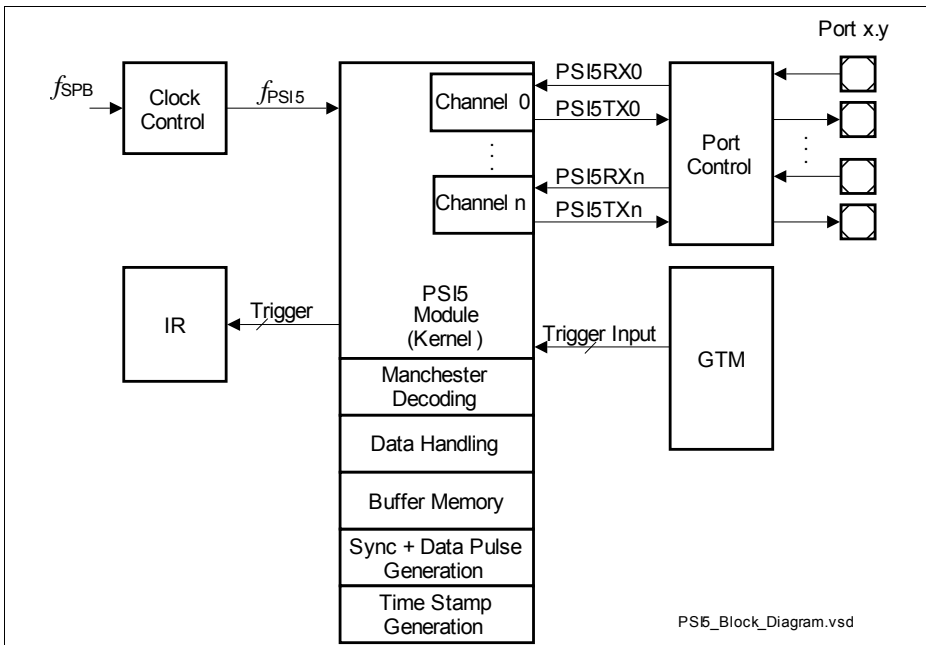

Figure 33-24 PSI5 Module Implementation and Interconnections

33.15.1.1 On-Chip Connections

This section describes the on-chip connections of the PSI5 module.

Interrupt Router Service Requests

The module has 8 Request Trigger outputs connecting it to the interrupt router. The request lines are connected to the IR controller as shown in [Table 33-4](#).

Table 33-4 Service Request Lines of PSI5

INP value	Request Line	Connected to	Description
0000b	TRIGO0	PSI5_SRC0	PSI5 Service Request Node 0
0001b	TRIGO1	PSI5_SRC1	PSI5 Service Request Node 1
0010b	TRIGO2	PSI5_SRC2	PSI5 Service Request Node 2
0011b	TRIGO3	PSI5_SRC3	PSI5 Service Request Node 3
0100b	TRIGO4	PSI5_SRC4	PSI5 Service Request Node 4
0101b	TRIGO5	PSI5_SRC5	PSI5 Service Request Node 5
0110b	TRIGO6	PSI5_SRC6	PSI5 Service Request Node 6
0111b	TRIGO7	PSI5_SRC7	PSI5 Service Request Node 7

Trigger Inputs

The module has 6 trigger inputs which can be randomly chosen by programming IOCRx.ETS, ECS or ETB. The trigger inputs (TRIG[5:0]) of the PSI5 module are connected to the GTM as shown in [Table 33-5](#).

Table 33-5 Trigger Input Lines of PSI5

Request Line	Connected to	Description
TRIG0	gtm.psi5_0_trig_0_o	GTM Trigger Line TRIG0
TRIG1	gtm.psi5_1_trig_0_o	GTM Trigger Line TRIG1
TRIG2	gtm.psi5_2_trig_0_o	GTM Trigger Line TRIG2
TRIG3	gtm.psi5_3_trig_0_o	GTM Trigger Line TRIG3
TRIG4	gtm.psi5_4_trig_0_o	GTM Trigger Line TRIG4
TRIG5	gtm.psi5_5_trig_0_o	GTM Trigger Line TRIG5

33.15.2 PSI5 Module-Related External Registers

The registers listed in [Figure 33-25](#) are not included in the PSI5 module kernel but must be programmed for proper operation of the PSI5 module.

Figure 33-25 PSI5 Implementation-specific Special Function Registers

33.15.2.1 Port Control

The Port Control Registers contain:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

[Table 33-6](#) shows an overview how bits and bit fields must be programmed for the required I/O functionality of the PSI5 I/O lines.

The PSI5 interface input shares its input pins with digital ports.

For one channel the PSI5 output pins and PSI5 input pins are next to each other.

Table 33-6 PSI5 I/O Control Selection and Setup

PSI5 Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
0	P00.1/ PSIRX0A	PSI5_IOCRO.ALT1 = 00 _B	P00_IOCRO.PC1 = 0XXXX _B	I
	P00.2/ PSITX0	not applicable	P00_IOCRO.PC2 = 1X100 _B	O

33.15.2.2 Timing Constraints

Delays and jitter inside the module:

- The time from the detection of the last bit of a frame at the input pin of the controller, to the presentation of the data to the software (including CRC calculation) is $\leq 3 \mu\text{s}$.
- The time from the sync pulse trigger output of the Sync Pulse Generator, to the output of the sync pulse trigger at the data output pin of the controller is $\leq 2 \mu\text{s}$.
- Latency between first high slope of first start bit / sync pulse and time stamp generation will be defined after design started, target is a few module clock cycles

Peripheral Sensor Interface (PSI5)

- Jitter between first high slope of first start bit / sync pulse and time stamp generation is calculated in the following way:
 - each timer in the chain adds its jitter given by the time resolution:
 - the TS counter itself has a resolution of nominally 1 μ s
 - the FDRT driving it has a jitter of one input clock phase (this can be avoided by using normal divider mode which should be default)
 - The PLL driving FDRT has a jitter of one input clock phase due to FM PLL clock clipping, this happens at nominally 600 MHz
 - The PLL driving FDRT has an accumulated jitter of +/- 5 ns (as of today, subject to change after characterization)
 - Thus, the jitter is at least $1\mu + 5$ ns

33.16 Revision History

This Internal Target Specification is based on: "PSI5 Specification **V1.3**".

Table 33-7 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.5D	First Draft with content, Pulse Generation tbd, Implementation details tbd Interrupt Flag Overview Registers for Memory Buffers tbd
Rev_0.9	First version for review Addresses, some implementation details and pictures tbd.
Rev_0.10	Updated Sync Pulse Generator block, added figure Updated ECU to Sensor Communication block, now containing 3 stages, added detailed figure Updated Serial Data (slow data) , added receive registers and memory for raw data Updated Manchester decoder and added figure Updated Watch Dog timer block, added 7th timer, added figure Added Time Stamp Generation and selection logic, added figure Cleaned up Interrupts and Triggers Added Port Mapping (full filling the requirements) Addresses, some implementation details and pictures tbd.
Rev_0.11	Added GTM input to Sync Pulse Generator block, updated figure Added Time Stamp configuration logic to support 3 Timers Updated Watch Dog timer block, added capability to check time windows instead of time outs only, updated figure Updated Time Stamp Generation and selection logic, to contain 3 counters (was 2) with individual selection of input clock (GTM or F_ts), was 2 counters with fixed inputs, updated figure Added interrupt "No Frame Received" and the possibility to store this event in the Receive Memory Added RDIOV, NFIOV and MEIOV and the referring set and clear regs. Added Picture of Receive Data Memory INTOV now shows pending interrupts per Node Pointer Addresses, some implementation details and pictures tbd.

Peripheral Sensor Interface (PSI5)
Table 33-7 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.5	Changed to 5 channels for TC29x
Rev_1.6	Added remarks (to CRC, SCRI, MEI, NBI) for clarity, no functional changes. Changed names of bits in INTOV according to their interrupt class representation (for more clarity) into: RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI instead of INP[7:0]. Changed access restrictions of IOCR.CFEG/CREG from rw to w.
Rev_1.7	Removed CLC.RMC
Rev_1.8	Updated BE behavior
Rev_1.9	Added RFCx.FRQ and WRAP Note on hard suspend
Rev_1.10	Updated description of OCS
Rev_1.11	Updated description (typo) of SFTSCx Updated Port Chapter
Rev_1.12	Idle time mandatory before looking for start bits, also after BOT and Sync Pulse EOF of a dropped frame will not prevent NFI any more Added Manchester Decoder description from Concept Engineering Slide Set. NBI will be issued not only on too short frames but on too long frames as well for safer detection of wrong sensor assembly.
Rev_1.13	Changed Manchester Decoder sample counter max value from 39 to 41 Removed CR: "NBI will be issued not only on too short frames but on too long frames as well for safer detection of wrong sensor assembly."
Rev_1.14	Support for 2 channels implemented
Rev_1.15	Added pin out description to channel 3 and 4

34 Peripheral Sensor Interface with Serial PHY Connection (PSI5-S)

This document contains the following sections:

- Functional description of the PSI5-S kernel (see [Page 34-2](#))
- PSI5-S kernel register descriptions (see [Page 34-58](#))
- TC27x implementation details (see [Page 34-139](#))

34.1 PSI5-S Description

[Figure 34-1](#) shows a global view of the PSI5-S interface.

Figure 34-1 General Block Diagram of the PSI5-S Interface

Peripheral Sensor Interface with Serial PHY Connection

The PSI5-S module communicates with the external world via one ASC interface for all channels. This ASC is built into the PSI5-S module. If the optional bidirectional mode is used, the commands to the external Physical Layer Interface (PHY) are transmitted via this ASC.

34.1.1 Overview

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

The PSI5-S IP-module performs communication according to the PSI5 specification V2.0 2011-6.

PSI5 defines a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages communication with this PHY and the presentation of the data to the application. Note that there is no on chip PHY, i.e. the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5-S channel can be set up according to the underlying application. In particular the number of bits forming one value is configured.

The message storage consists of a set of 3 32-bit registers for all channels: one PSI5-S Message Receive Data Register containing the received sensor data, one time stamp register containing the 24-bit value and one additional register containing status bits.

For synchronous communication mode, the module can consume sync pulses from the external GTM or generate periodic sync pulses by itself. It supports as well ECU to sensor communication by offering a 32-bit register, where messages can be set up by the CPU. All kinds of sync pulses are translated into a referring, programmable Byte to be sent via ASC.

The register set of the PSI5-S module can be accessed directly by the CPU for configuration, data read out and status query.

The PSI5-S module supports the following features:

General Features

- ASC based communication with compatible PSI5-S PHY
- Baud rate Generator (up to 12,5) MHz (@ 200 MHz ASC Sub Module Clock)
- Clock out generator to supply external PHY
- Conformance with PSI5 protocol specification V2.0 2011-6
- Data rates of 125 kbit/s and 189 kbit/s supported (by external PHY already)
- 8 PSI5-S channels sharing one common ASC (incl. channel 0 frame 1 special use)
- Supports 6 sensor slots per channel
- Asynchronous and synchronous PSI5 data transmission modes

Peripheral Sensor Interface with Serial PHY Connection

- 8 Interrupt or DMA triggers

Features of Message Recovery Block

- ASC format 10 Bit: 1 Start Bit, 8 Data bits, 1 Stop Bit (Up Stream)
- Each PSI5 Frame is transported in a Packet Frame consisting of 3 to 6 UART Frames transmitted back to back, i.e. with exactly one stop bit - no additional delay.
- Packet Frames are separated by a programmable idle time (1 .. 16 idle bits)
- Assembly and decoding of Packet frames (envelope)
- Routing of PSI5 Frames to their referring channel receive buffer in system memory by hardware DMA support
- Checking CRC of Packet Frames (XCRC)
- Frames with XCRC NOK will be routed to channel 0 frame 1
- The external PHY sends all Frames of an Asynchronous Channel with FID = 1, all frames of this channel have the same length and structure as defined for FID 1. Thus it is sufficient to configure frame 1 for asynchronous channels.
- Configurable data length 8 .. 28 bit + 3 bit PSI5 CRC or 1 bit PSI5 Parity
- CRC check of received PSI5 sensor data, CRC code still transparent
- NO HW Support of extended serial data messaging according to SENT SAE J2716 JAN 2010. Messaging bits are transported fully transparent for SW decoding
- 24-Bit time stamp on sync pulse request via ASC (resolution: 1µs)
- Two independent time bases for Time Stamp: clocked by GTM (1 out of n GTM signals is selectable) or internal periodic trigger generator
- PHY answers to CPU commands with standard frames of fixed predefined length in channel 0 frame 0.
- Error bits in Packet Frame are presented fully transparent and an interrupt is issued.
- One Interrupt for error free Packet Frame, relevant errors are selectable
- One Interrupt for Packet Frame reception disregarding any error.

Features of Message Generation Block

- Support of ECU to Sensor communication
- One 32-bit send data register per channel for downstream data input
- Data is shifted out LSB first, MSB is filled with '0' or '1' with each shift (depending on bit coding method: Tooth Gap or Pulse Width)
- ASC format 11 Bit: 1 Start Bit, 8 Data bits, 1 Parity, 1 Stop Bit (Down Stream)
- Downstream commands of fixed format (3 MSB = Channel ID, 5 LSB = Command)
- All commands are randomly programmable and thus not interpreted by PSI5-S
- Downstream data transmission by 2 different ASC commands (short/no and long pulse)
- 8 common lines of FIFO for all channels, writable by
- PSI5 Message Generation
- Sync Pulse Generation (pre programmed Bytes for '0' and '1')
- CPU Commands

Peripheral Sensor Interface with Serial PHY Connection

- Direct CPU Write Registers allow for insertion of commands into the FIFO for configuration and debugging
- 6 GTM inputs for Sync Pulse Triggering
- SW configurable staggering of Sync Pulse generation
- Generation of 3 or 6 bit CRC for downstream data
- Start sequence generator for downstream data (can be switched off)
- Bit stuffing generator for downstream data (can be switched off)
- CRC generator for downstream data (can be switched off)
- Internal Loop Back mode for check of CRC generator and SW development

Configurability

- No configuration options planned.

34.2 Definitions

SENT: Single Edge Nibble Transmission

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

PHY: Physical Layer Interface

ECU: Electronic Control Unit

FSM: Finite State Machine

ASIC: Application Specific Integrated Circuit

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SOF: Start of Frame

EOF: End of Frame

STS: Start Sequence

AD: Address Data (e.g. of ECU to Sensor Frame)

SD: Send Data (Payload of ECU to Sensor Frame)

CRC: Cyclic Redundancy Check

UART: Universal Asynchronous Receiver Transmitter

34.3 General Operation

PSI5-S is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the

Peripheral Sensor Interface with Serial PHY Connection

sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 34-2 shows a typical TC27x application in which a PSI5-S interface reads a sensor device.

Figure 34-2 PSI5 to External Device Connection

PSI5-S communication is

- asynchronous, unidirectional from sensor to controller without any synchronization
- synchronous, bidirectional with a sync pulse from the ECU triggering messages
- synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage of the current loop.

Figure 34-3 shows a typical TC27x application in which a PSI5 ECU reads multiple PSI sensor devices on a bus.

Figure 34-3 PSI5 Frames with Sync pulses

34.4 PSI5 ECU to Sensor Operation

ECU to Sensor communication is defined in PSI5 V2.0 2011-06. Data transmission and configuration of the sensor can be done by modulation of the Sync Pulses.

The Module supports two modes:

- Tooth Gap Method
- Pulse Width Method

Peripheral Sensor Interface with Serial PHY Connection

With the Tooth Gap Method, a specific start condition and a start sequence switch the sensor in ECU to Sensor communication mode. In this mode, the sync pulses are no longer used as triggers for PSI5 Frames but are interpreted as data for the sensor. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

With the Pulse Width Method a standard length pulse represents a 0, a longer pulse a 1. This way continuous data transmission can be achieved. The pulses can be non isochronous, e.g. dependent from the angle position of a rotating axis.

34.5 Frame Formats and Definitions

This section describes the frame formats and definitions of the PSI5-S protocol.

34.5.1 Communication between PSI5-S and PHY via UART

This chapter treats the communication on the UART connection.

34.5.1.1 “Packet Frames” received from PHY

Figure 34-4 and **Figure 34-5** show the layout and definitions of the “Packet Frames”. Packet Frames are 3 to 6 “UART Frames” carrying one “PSI5 Frame”. The format accepted by PSI5-S is explained here. A UART frame is one transmission unit on the ASC. On the receive path it consists of one Start Bit, 8 Data Bits and one Stop bit. Parity can be chosen optionally, e.g. for loop back tests. The figures show the minimum and maximum Packet Frame population with data. Where the figures show ‘Res0’ bits, these bits can be crowded by more data bits if configured so.

Detection of Frame Boundaries and Packet Frame Processing

- SOF (Start of Frame) is defined by a start bit detected after idle on ASC.
- Idle equals at least 2 Stop Bits.
 - The required idle time can be configured between 1 and 16 additional Stop Bits.
 - An idle state signal is provided internally by the ASC to the reassembly unit.
 - The idle signal starts on detection of the first stop bit and ends when the first slope of the next start bit has passed the 2 out of 3 majority vote input filter.
- If idle is detected before the minimum of 3 UART Frames was received, these UART Frames are copied to channel 0 frame 1 (non recoverable frames).
- Based on the ChID and FID received in the first UART frame, the module checks
 - If the referring channel is enabled and
 - If the FID is valid and configured (PDL > 0) and
 - What the number is of expected UART frames configured in UFC
 - If at least this number of UART frames is received without idle and
 - If the XCRC is correct
- If these checks pass
 - EOF is detected after the correct number of UART frames

Peripheral Sensor Interface with Serial PHY Connection

- Data is copied to RDR, interrupts, and the status are updated in RDS. In particular CRC/P check is executed. Time Stamp (TSM) and Target address (TAR) are updated. Depending from bit RCRAx.FIDS the FID might be manipulated.
- The message recovery unit does not wait for idle to execute the steps above.
- If these checks fail (“non recoverable frames”)
 - EOF is detected after idle or a maximum of 6 UART Frames
 - The 1 to 6 UART Frames are stored in channel 0 frame 1.
- If more UART frames follow a passing or failing Packet Frame without idle,
 - EOF is detected after idle or a maximum of 6 UART Frames
 - The 1 to 6 UART Frames are stored in channel 0 frame 1
 - Reception is stopped
 - The next UART Frames following without idle time are ignored
 - Reception starts only after the idle time programmed in GCR.IDT is detected (“bubbling idiot” protection)

Non Recoverable Frame Presentation in RDR and RDS

- RDS.FID and ChID are derived from the first UART Frame received.
- RDR.RD[27:0] contains all bits of each UART Frame received after the header. I.e.
 - 0 bits for 1 UART Frame,
 - 8 bits for 2 UART Frames,
 - 16 bits for 3 UART Frames,
 - 24 bits for 4 UART Frames,
 - 28 bits for 5 and 6 UART Frames.
- RDS.CRC is determined as follows:
 - If 6 UART Frames were received: bits [6:4] of the 5th UART Frame.
 - If 1 .. 5 UART Frames where received: determined by PDL
 - PDL may not be reliable, but this way all data is covered either in the data field or in the XCRC field. In case PDL was correct, CRC is shown correctly.
- RDS.XCRC contains always the bits [7:2] of the last UART Frame received. Also if only 1 UART Frame was received.
- Note that XCRCI is always set as either XCRC was wrong or the number of UART frames received was wrong or it could not be determined.

Loop Back support

- Parity and number of stop bits need to be configured the same for sender and receiver in loop back mode. Parity control and polarity of parity can be configured separately each for TX and RX. This can be done before switching on loop back mode. Alternatively the parity control can be adjusted as well in one single register access together with switching the ASC part to loop back mode.
- Both ways are supported: add Parity bit to the receiver or use the transmitter without parity. (Standard use case is to use transmitter with parity)
- Data to be transmitted can be written directly to register CDW
- This way a synthetic Packet Frame can be sent to the reassembly unit for test purposes.

Peripheral Sensor Interface with Serial PHY Connection

- The received loop back data is treated in the same way as the normal receive data. Good frames are received in their referring channel and slot. Frames with wrong XCRC, idle time or UFC are stored in channel 0 frame 1.

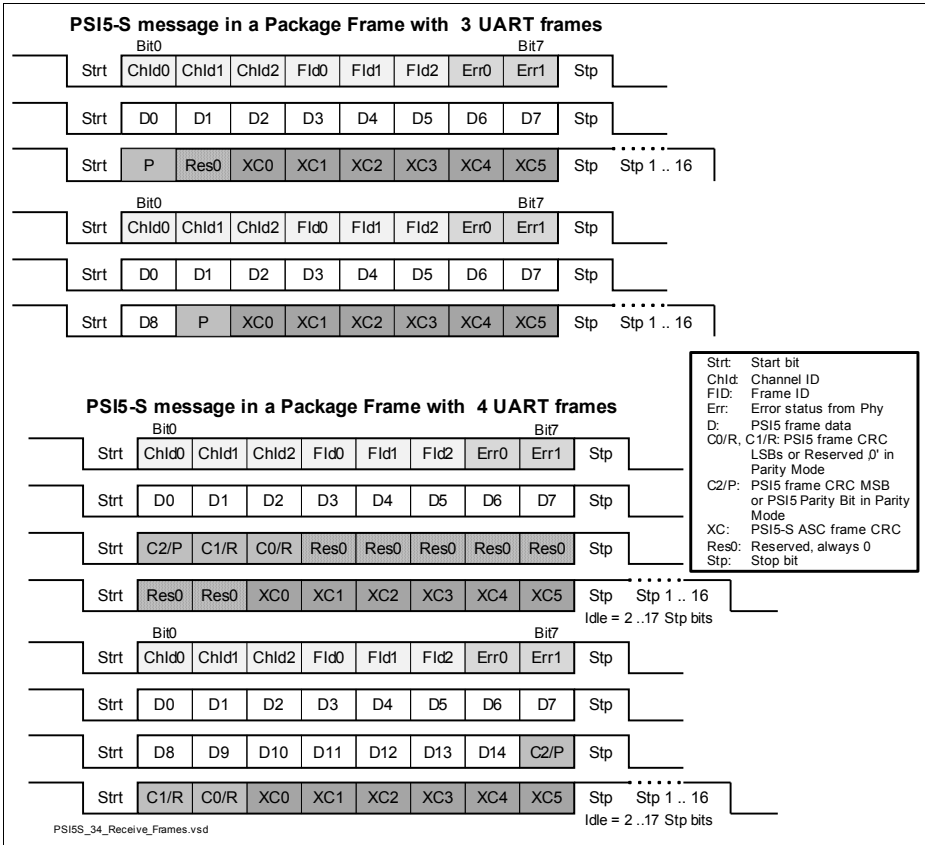

Figure 34-4 PSI5-S 3 + 4 UART Frames per Package Frame received from PHY

Peripheral Sensor Interface with Serial PHY Connection

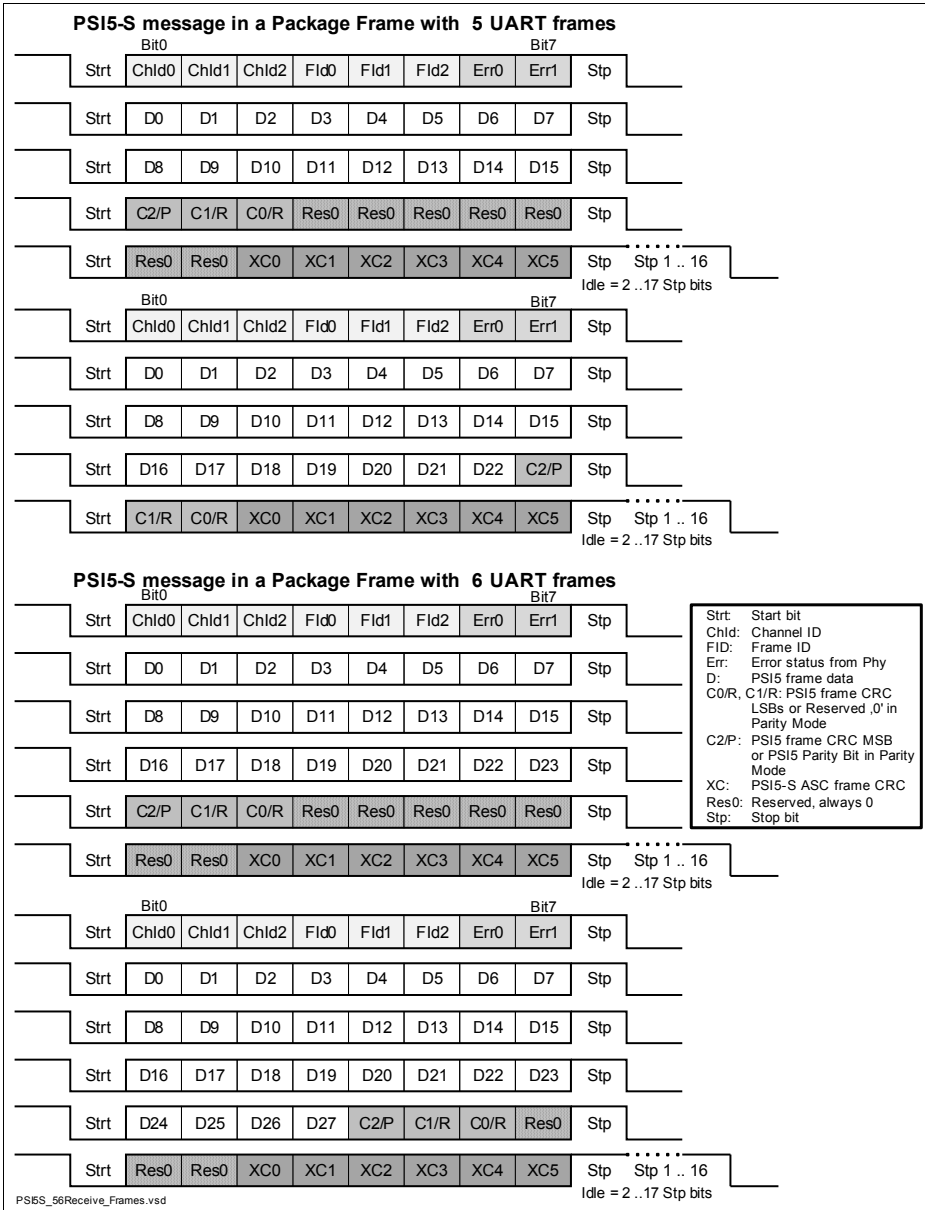

Figure 34-5 PSI5-S 5 + 6 UART Frames per Package Frame received from PHY

Peripheral Sensor Interface with Serial PHY Connection

XCRC Content

XCRC is always sent at the end of the last UART Packet. For XCRC calculation, all bits of the preceding UART Frames that belong to the Packet Frame are relevant including potential stuffing bits (Res0). UART Start / Stop bits are excluded.

In detail the XCRC shall contain the header (ChId, FID, Err0, Err1), PSI5 frame data (D0 .. Dx, PSI5 frame Parity Bit or CRC bits) and potential stuffing bits (Res0) between P/CRC and XCRC. Not included are start and stop bits of the UART packets and the 2 start bits (S0, S1) of the PSI5 frame.

The LSB of the first byte (ChId0) is fed first into the XCRC polynomial.

XCRC Calculation Method

XCRC equals the CRC defined in PSI5 Standard 2.0 “Frame format 4 ECU to Sensor Message CRC”, see **“ECU to Sensor Communication” on Page 34-12**.

34.5.1.2 PSI5-S UART Frames transmitted to PHY

Figure 34-6 shows the layout and definitions of the UART Frames sent by PSI5-S.

Figure 34-6 PSI5-S UART Frames transmitted to the PHY

34.5.2 Communication between PHY and Sensor (PSI5 Standard)

This chapter treats the frame formats on the PSI5 bus as short reference.

34.5.2.1 PSI5 Standard Frame Format

Figure 34-7 shows the principal layout and definitions of a PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and Parity definition.

Peripheral Sensor Interface with Serial PHY Connection

Figure 34-7 Standard PSI5 Frame Format

34.5.2.2 PSI5 Extended Frame Format

Figure 34-8 shows the layout and definitions of an Extended PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first.

Figure 34-8 PSI5 Extended Frame Format

PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

- 1) 1-bit even parity
- 2) 3-bit CRC

The applied generator polynomial of the CRC is $g(x) = 1 + x + x^3$ with a binary start value (seed) "111". The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0)

34.5.2.3 Sync Pulses

Sync Pulses are used for two different purposes:

Peripheral Sensor Interface with Serial PHY Connection

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication.

Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is transmitted via ASC to the external PHY. The external PHY translates this ASC command into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 Frame, starting with the 2 start bits, data and Parity or CRC. The timing diagram in [Figure 34-9](#) visualizes a synchronous transmission

Figure 34-9 Synchronous Transmission

ECU to Sensor Communication

PSI5 V2.0 2011-06 defines 4 principle frame formats. Please refer to this standard document for more details. As the main target application is power train, only frame format 4 is cited here. This is the format for the power train sub standard.

Two methods for the ECU to Sensor Communication are supported:

Tooth Gap Method (see [Figure 34-10](#)) and
Pulse Width Method (see [Figure 34-11](#) and [Figure 34-12](#)).

Tooth Gap Method

uses usually 31 sync pulses as start condition and start bits (0 1 0) to signal the start of the ECU to Sensor Communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and Parity definition.

Peripheral Sensor Interface with Serial PHY Connection

Figure 34-10 ECU to Sensor (Tooth Gap Method)

Pulse Width Method

allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously.

Sync Bits of frame format 4

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted after every six bits of the sensor address and the payload data. With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

Figure 34-11 ECU to Sensor, Bit transmission (Pulse Width Method)

Figure 34-12 ECU to Sensor, Frame format 4 (power train)

Peripheral Sensor Interface with Serial PHY Connection

Frame format 4 ECU to Sensor Message CRC

The ECU-to-Sensor Frame has a 6-bit CRC.

The generator polynomial of the CRC is

$$g(x)=x^6 + x^4 +x^3 +1$$

with a binary CRC initialization value "010101".

The transmitter extends the data bits by six zeros (as MSBs).

This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check.

When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum.

These six check bits shall be transmitted LSB first [C0, C1 .. C5]. This CRC value is computed as a function of the contents of all address and data bits and Sync bits ("0" bits). For purposes of the CRC calculation, the bits shall be ordered: $m = [A0 A1 .. A3 D0 D1 0 D2 .. D19 0]$.

In this implementation the number of elements is configurable. While the standard is 4 address and 20 data bits, the module allows longer or shorter messages too.

34.6 Clock Generation

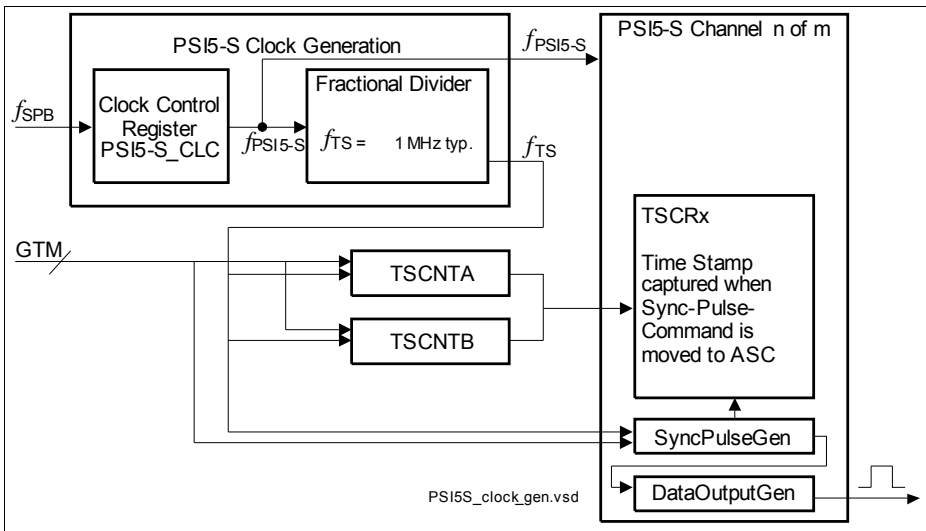

The PSI5-S module provides 2 central Time Stamp Counters and the central Time Stamp Clock f_{TS} to each channel. See [Figure 34-13](#). The clock of each Time Stamp Counter is individually selectable: either f_{TS} or any of the GTM inputs can be selected to drive them.

This chapter shows in detail how f_{TS} is adjusted.

For details on the principles of a fractional divider, please refer to the SCU chapter of TC27x section "Clock Control".

The PSI5-S module provides 2 internal clock signals centrally

Peripheral Sensor Interface with Serial PHY Connection

Figure 34-13 PSI5-S Module Clock Generation

- $f_{\text{PSI5-S}}$
 This is the module clock that is used inside the PSI5-S kernel for control purposes such as clocking of control logic and register operations. The frequency of $f_{\text{PSI5-S}}$ is controlled by register FDR and derived from the system clock frequency f_{SPB} . The clock control register CLC makes it possible to enable/disable $f_{\text{PSI5-S}}$ under certain conditions.
- f_{TS}
 This clock is usually used to drive the central Time Stamp Counters. It can be selected to drive the global sync pulse time base and inside the PSI5-S channels to drive the local sync pulse generators and watch dog timers. The fractional divider register FDRT controls the frequency of f_{TS} . This is usually adjusted to 1 MHz / 1 μ s period time.

The following two formulas define the frequency of f_{TS} :

$$f_{\text{TS}} = f_{\text{PSI5-S}} / (1024 - \text{PSI5-S_FDRT.STEP}); \text{FDRT.DM} = 01\text{B} \quad (34.1)$$

$$f_{\text{TS}} = f_{\text{PSI5-S}} \times \text{PSI5-S_FDRT.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDRT.DM} = 10\text{B} \quad (34.2)$$

34.6.1 Overview on Clocks in the System

To reduce system cost, the external PHY can be supplied with a clock from TC27x. EXTCLK1/2 (SCU), CMU_ECK (GTM) or by PSISCLK (PSI5-S). The range is limited to

Peripheral Sensor Interface with Serial PHY Connection

20 .. 25 MHz maximum for proper clock transmission. The PHY needs to provide 3 clocks from this: Sample clock for 189 kHz, and 125 kHz and the ASC oversampling clock.

A divider by 2 is added between the actual fractional divider block and the output signal f_{PSISCLK} in order to achieve a duty cycle of 50% (plus tolerances due to fractional divider jitter)! This is why the formulas contain the division by 2 at the end.

- f_{PSISCLK}
This clock is used to drive the external PHY.
The fractional divider register **FDO** controls the frequency of f_{PSISCLK} .

The following formula defines the frequency of f_{PSISCLK} :

$$f_{\text{PSISCLK}} = f_{\text{BAUD2}} / (2048 - \text{PSI5-S_FDO.STEP}) / 2; \text{DM} = 01\text{B} \tag{34.3}$$

$$f_{\text{PSISCLK}} = f_{\text{BAUD2}} \times \text{PSI5-S_FDO.STEP} / 2048 / 2 \text{ with STEP} = 0 \dots 2047; \text{DM} = 10\text{B} \tag{34.4}$$

In order to relax the requirements with respect to ASC communication with TC27x while allowing for high bit rates, some additional provisions have been made. The ASC Sub Module is supplied with a higher frequency (f_{BAUD2}) to allow for very high precision at high baud rates (4 - 12,5 MBaud). As a second measure to achieve this, the fractional divider in ASC is longer than in the standard module. **Figure 34-14** illustrates the situation on PCB. Refer to the ASC sub chapter for baud rate calculations.

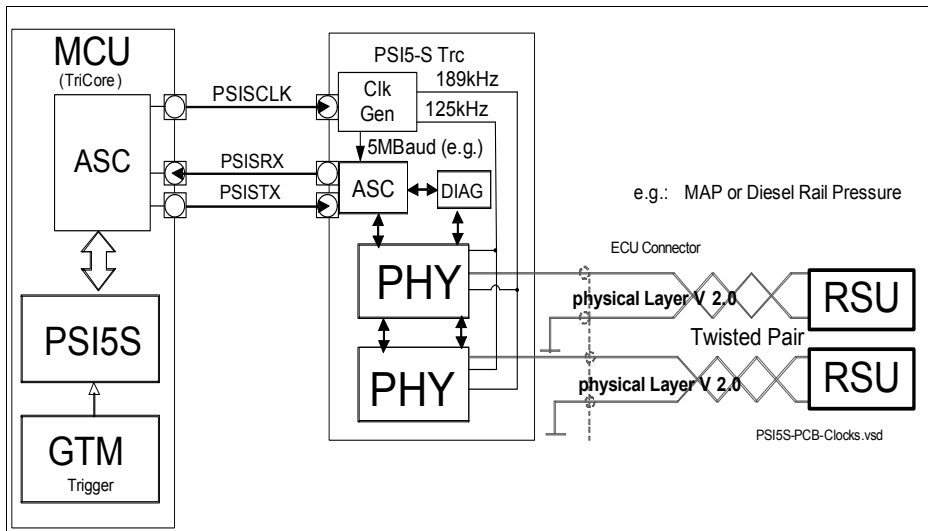

Figure 34-14 PSI5-S Clock Requirements of PHY

Peripheral Sensor Interface with Serial PHY Connection

34.7 Time Stamp Generation

Two time bases can be selected for Time Stamping:

Any of TSCNTA and TSCNTB provide one Time Stamp Counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, i.e. one of the GTM inputs. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by SW single or synchronously.

The last sync pulse sent on a channel is stored in the sync pulse time stamp capture register TSCRx. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture. Non recoverable Packet Frames will be stored with the current value of TSCNTA/B directly copied to TSM. See RCRAx on [Page 34-83](#) and on for more details.

For each channel the capture time (TSCRx) is stored.

Figure 34-15 shows the time stamp generation:

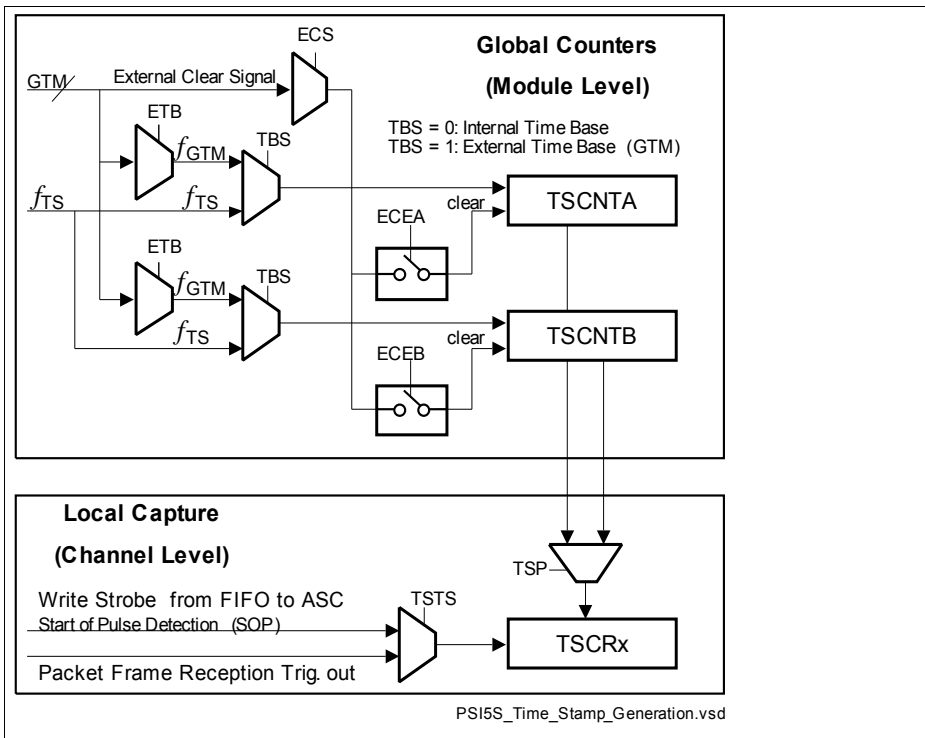

Figure 34-15 Time Stamp Generation

Peripheral Sensor Interface with Serial PHY Connection

34.8 Watch Dog Timers

The value entered in WDTx.WDL defines the time in multiples of TTS (defined in FDRT) until expiry of the watch dog.

There are two modes of operation that can be selected with bit RCRAx.WDMS.

In normal operation an interrupt (TEI) is issued if the distance between two RDIs is longer than specified in WDL. In this mode, The internal watch dog timer is started automatically when the channel is enabled.

In synchronous mode, TEI is issued if the watch dog timer expires without reception of CHCI in time. I.e. the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long.

In both modes, only completely and correctly received Packet Frames on channel x can qualify, i.e. Packet Frames with XCRC checked ok. Otherwise the channel number can not be determined - the referring WDLx not be selected.

The internal watch dog timer is compared to WDL. A match

- triggers a TEI.
- restarts the watch dog timer. I.e. it clears the internal watch dog timer and it counts on from zero. TEI is repeated if no recoverable frames are received.

If no watch dog is needed, WDL is cleared, the internal watch dog timer is stopped and no check is performed.

Asynchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is cleared the internal watch dog timer y is restarted on reception of a new recoverable frame (RDIx) for the referring channel. It is not restarted by a sync pulse and not stopped by a certain number of received Packet Frames.

The example below shows the use of the watch dog. The sync pulse is completely ignored by the watch dog system.

F2 is the only frame coming too late. All others start before the expiry of the watch dog.

Peripheral Sensor Interface with Serial PHY Connection

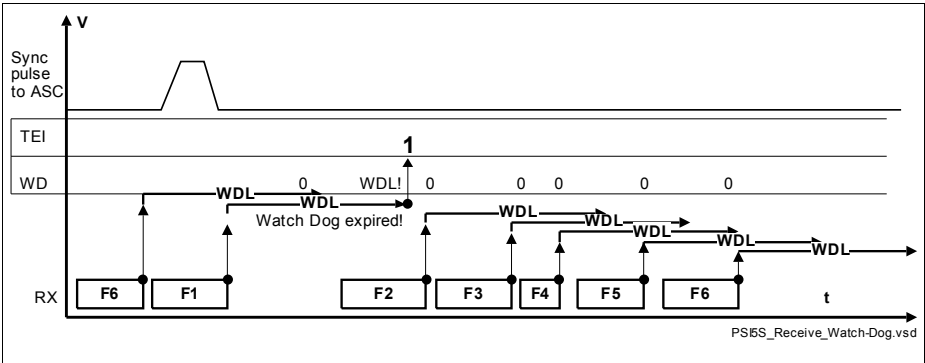

Figure 34-16 Watch Dog Timers

Synchronous mode of the Watch Dog Timers:

If RCRAx.WDMS is set the WDT is restarted on sync pulse and stopped at reception of the last frame configured in NFx. Register NFCx contains the bit fields NFx which configure the number of Packet Frames expected after the sync pulse. FCNT.FCx is the counter that is compared with NFx.

Peripheral Sensor Interface with Serial PHY Connection

The Watch Dog Timer is restarted (cleared and set to run), each time a Sync Pulse is transferred for the referring channel from FIFO to ASC. The Watch Dog Timer of this channel is forced to stop if the number of a received Packet Frames (counted in FCNT.FCx) matches the number configured in NFC.NFx. This supports in particular angle synchronous channels where the distance of packets can vary strongly with e.g. the roundings per minute of an axis.

The WDT can not stop in time if a non recoverable (and thus not countable) Packet Frame is received! If more than the configured number of Packet Frames are received, no dedicated interrupt is issued for this but the frame is still received correctly.

RCRAx.WDMS should be 0 on asynchronous channels. Otherwise, the internal Watch Dog Timer will be stopped after reception of the number of configured frames but never be restarted due to the lack of a Sync Pulse!

If a sensor is not present in a special configuration, NFx must be reduced accordingly! E.g. if out of F1 .. F6 the F2 is missing, only 5 frames are configured.

Please refer to register **"NFC"** on [Page 34-79](#) for detailed description.

Peripheral Sensor Interface with Serial PHY Connection

Figure 34-17 Watch Dog Timers in synchronous mode

34.9 Send Data

This chapter contains the details of how data to be sent is prepared. The scope extends to:

- Periodic Triggers
- Angle Synchronous Triggers
- ECU to Sensor communication

34.9.1 Channel Trigger

Peripheral Sensor Interface with Serial PHY Connection

The Channel Trigger Value Register CTVx contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

The Channel Trigger Value CTV is the compare value which restarts the counter CTC on equality and only on equality. At exactly this time, a sync pulse is triggered.

The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (e.g. same frequency, double etc.).

In this document OFFSET = 65535 - "CTC preset value"

I.e. CTC preset is > CTV so that the the time to to roll over is the offset.

Of course CTC preset can be < CTV so that this CTC has some advance.

Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external PHYs can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.

For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 .. 7 can be used.

Peripheral Sensor Interface with Serial PHY Connection

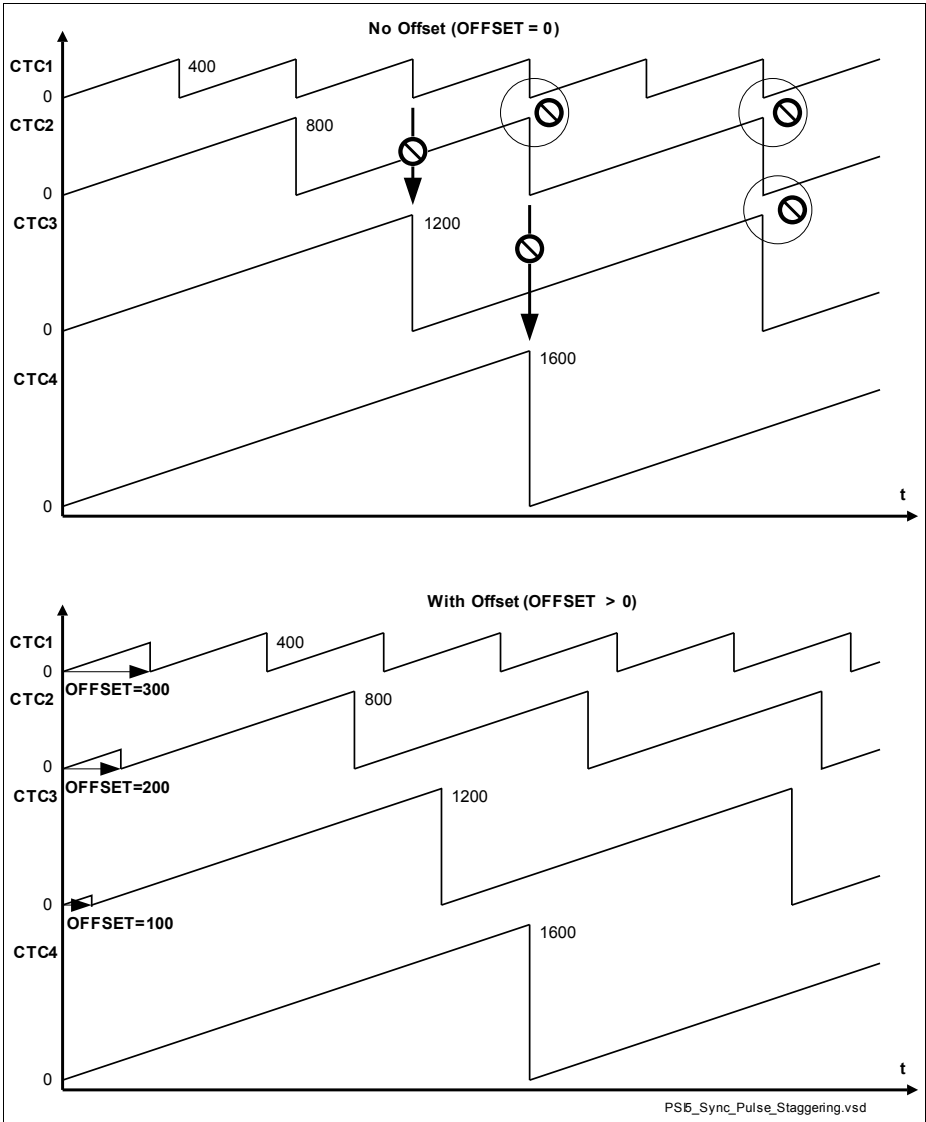

Figure 34-18 PSI5-S Pulse Staggering

Peripheral Sensor Interface with Serial PHY Connection

34.9.2 Sync Pulse Control

The sync pulse generation provides the following functionality:

- periodic sync pulses, driven by a common module time base (PTE is set)
- angle synchronous sync pulses, driven by GTM (ETE is set)
- sync pulses for ECU to Sensor communication (Tooth Gap Method, EPS[0]=0)
- sync pulses for ECU to Sensor communication (PWM Method, EPS[0]=1)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. The pulses will be modulated according to the selected standard. EPS selects between PWM method and Tooth Gap Method with pulse dropping.

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TPF.

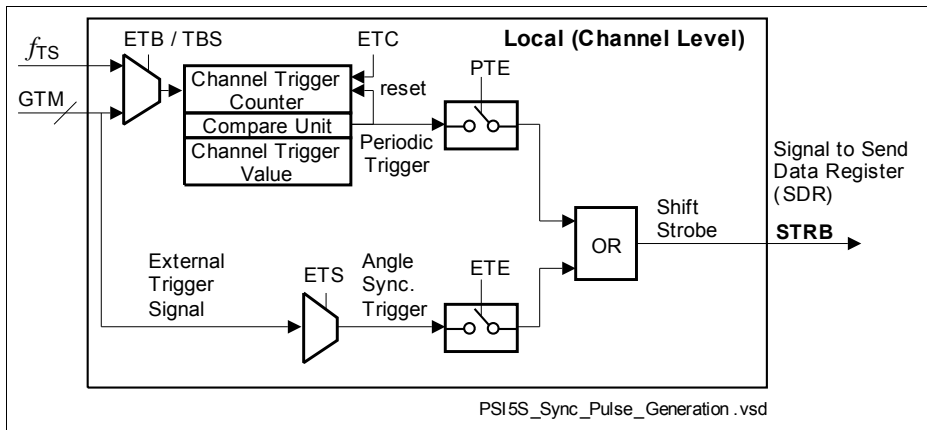

Figure 34-19 PSI5-S Sync Pulse Generation

34.9.3 Send Data Preparation

Figure 34-20 shows the mechanisms how ECU to sensor communication data is treated:

Peripheral Sensor Interface with Serial PHY Connection

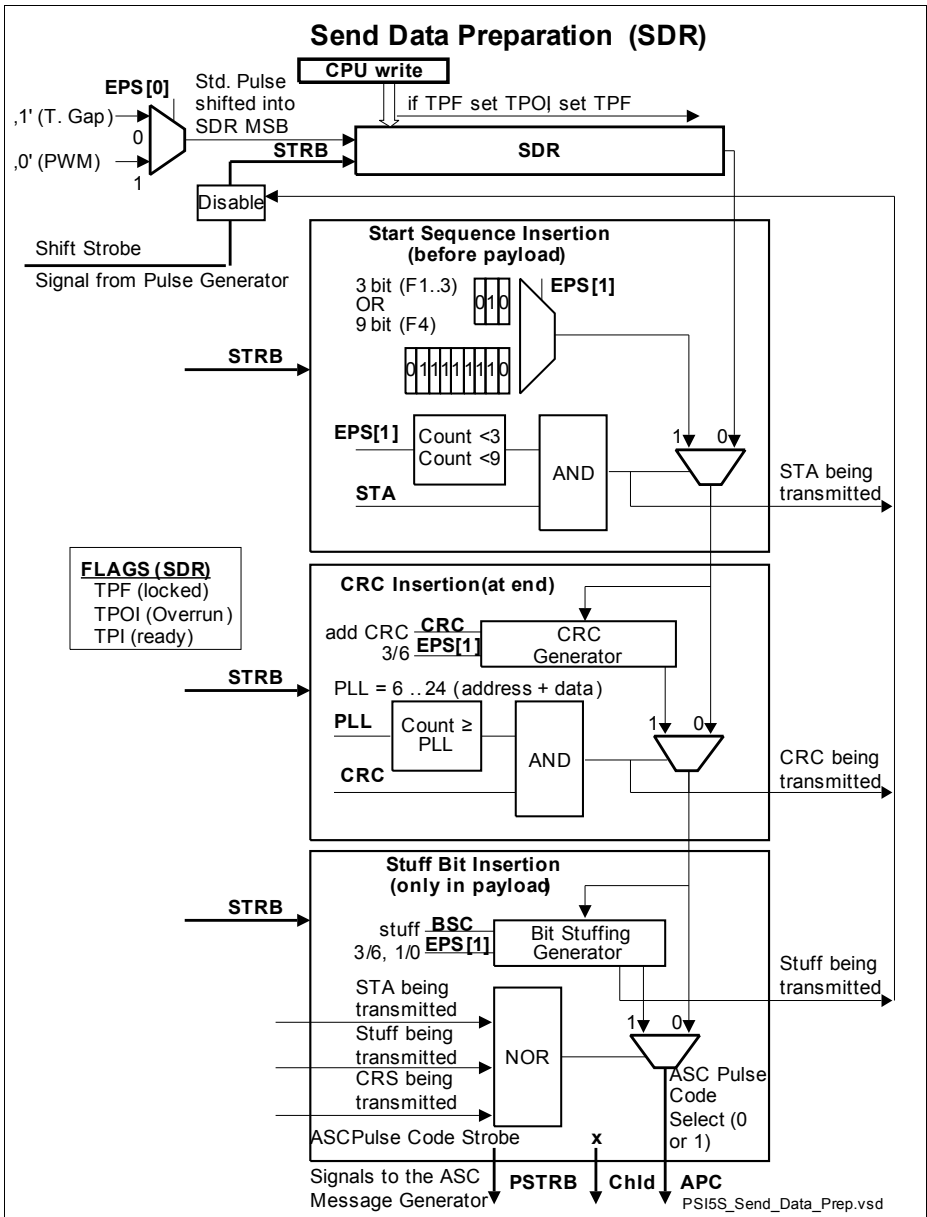

Figure 34-20 PSI5-S Send Data Preparation

Peripheral Sensor Interface with Serial PHY Connection

34.10 Message Generation

Figure 34-21 shows the message generation logic. The generated ASC commands are sorted into an internal FIFO of 8 entries of 9 bits width. The MSB stores the information, if a command is generated from the sync pulse generation (ASC Pulse Code Strobe issued the write into FIFO) or if the CPU wrote a command. This is important for the Time Stamp generation. Usually the Time Stamp is captured when a Sync Pulse Command leaves the FIFO i.e. is copied to the ASC TX buffer. Commands stored in the FIFO can only trigger a Time Stamp capture if they are marked as Sync Pulse in bit 8. Nevertheless, the CPU can set MSB (bit 8) in Register CDW if the command is to be treated like a Sync Pulse Command and a Time Stamp should be captured. Note that if RCRAx.TSTS is set, the Sync Pulses do not trigger the Time stamp capture. In this case, the Packet Frame reception triggers the capture and bit 9 is ignored.

There is no further arbitration of the CPU and Message Generation Unit. The PHY answers CPU commands with standard frames of fixed predefined length in channel 0 frame 0.

Interrupt FOI is issued if a transfer to the FIFO was generated by the message generation unit or by CDW (CPU direct write register) while the FIFO was full. In a correct setup, this will never be the case as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays. In most cases too many write accesses to CDW will be the root cause. This exceptional condition can be handled either by waiting until the FIFO has transferred at least one command or by a module reset by SW. It should not occur in the application but FOI should help SW generation and debugging.

The transfer path of a command to the ASC could add jitter to sync pulses.

In case several channels request a pulse at exactly the same time, the channel with the lower channel number is served first and CDW has highest priority.

Peripheral Sensor Interface with Serial PHY Connection

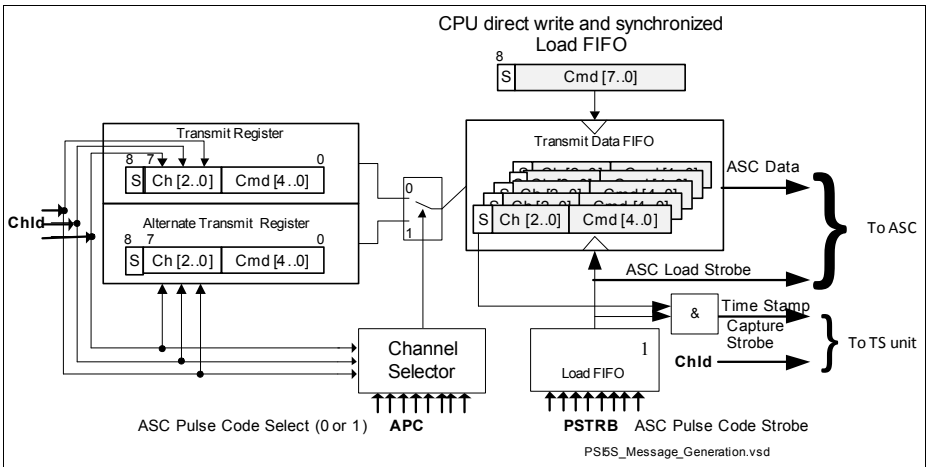

Figure 34-21 PSI5-S Message Generation Logic

34.11 DMA Support

The received frames come in sequentially and are XCRC checked. The complete reassembled frame including Channel Id (ChId), Frame ID (FId) and status are available at RDR and RDS. TSM shows the latest time stamp of the currently received channel.

RDR, RDS and TSM are located in 3 sequentially addressed registers. This way, they are easily readable by DMA. See [Figure 34-22](#).

34.11.1 Single DMA, 8 dedicated DMAs

With one single DMA channel, one common frame buffer in the system memory can be build up. All frames can be collected from RDR, RDS and TSM. The DMA source address is programmed to be always RDS, block transfer is set to 3 words with auto address increment. The target is set to be automatically incremented. This results in one buffer in system memory with all frames from all channels.

Individual buffers for each channel can be build up if more DMA channels are used. Each channel can generate its own receive triggers RDI and RSI. Thus individual DMAs can be set up for each channel similarly to the single DMA use case but with individual target addresses for each channel.

Peripheral Sensor Interface with Serial PHY Connection

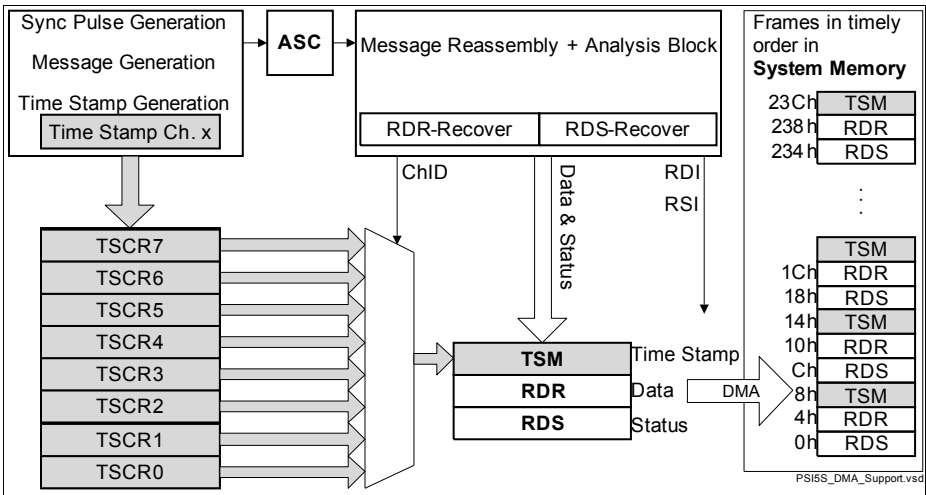

Figure 34-22 PSI5-S Single DMA Support

34.11.2 Two daisy chained DMAs

The PSI5-S supports sorting by channel with only two DMA channels. Register TAR contains the target address that is to be copied by the first DMA into the target address register of the second DMA. Source and target of the first DMA are fixed (DMA register SADR and DADR). The target address offered in TAR is calculated by PSI5-S by adding an offset value to the programmable base address defined in BAR. This allows for locating the channel buffers at any location in system memory.

The resulting base + offset is presented in TAR. The target address depends on:

- BAR (base address)
- ChID: offset of channel number currently received (channel number x 6 (buffer lines) x 3 (words per frame) x 4 Bytes per word = 72 Bytes x channel number. This allows to receive 6 frames per channel which equals the maximum number of PSI5 Frames per Sync Pulse.
- FID: offset of frame ID currently received. (3 words i.e. 12 Bytes per frame)
Note that the frame ID used for this sorting depends from RCRAx.FIDS! In particular in asynchronous mode, FIDS needs to be set so that the FID from the Packet Frame is replaced by a rolling number.
- Note that the message reassembly unit forces non recoverable messages to be stored at the address for ChID = 0, FID = 1 but with original ChID and FID! I.e. RDS contains the CHID and FID as received in the first UART Frame for better debugging!
- The source address of the second DMA needs to be programmed to be fixed to the address of RDS. Use shadow control to “wrap around” the source address.

Peripheral Sensor Interface with Serial PHY Connection

(DMA_MExADICR.SHCT must be set to 0x0101b).

Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see DMA chapter, DMA_MExCHCR.BLKM) 32 bit (the data width is defined in DMA_MExCHCR.CHDW) accesses.

Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).

Peripheral Sensor Interface with Serial PHY Connection

The source address of the second DMA needs to be programmed to be fixed (see DMA chapter, register ADRCR_{xz}) to the address of RDS.

Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see DMA chapter, DMA_MExCHCR.BLKM) 32 bit (the data width is defined in DMA_MExCHCR.CHDW) accesses.

Use shadow control to “wrap around” the source address. (DMA_MExADICR.SHCT must be set to 0x0101b).

Peripheral Sensor Interface with Serial PHY Connection

The second DMA must be of the next lower priority than the first. Selecting hardware request input via $CHCRxz.PRSEL$ allows for daisy chaining the two DMA channels. See **Figure 34-23**.

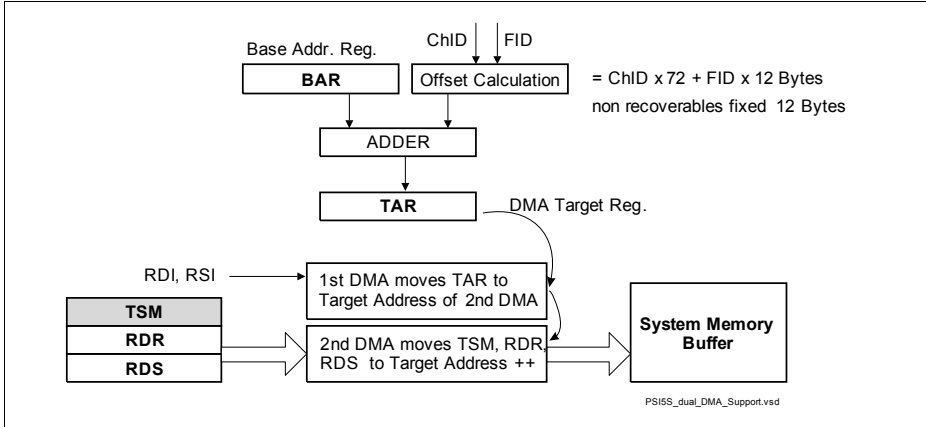

Figure 34-23 PSI5-S Dual DMA Support (daisy chained)

34.11.3 Interrupts for DMA support

Interrupts for Single DMA usage

Interrupts RDI or RSI can be used as trigger for the DMA transfer from TSM/RDS/RDR.

Interrupts for two daisy chained DMA usage

If one of the buffers is full, this is signalled to SW by interrupt CHCI. The “status buffer full” is defined as follows: current number of received frames counted in FCNT.FCx equals the number of expected frames configured in NFC.NFx. In synchronous mode this is the case, if all expected PSI5 frames after a Sync Pulse are received by PSI5-S. The number of expected frames is looked up in register NFC.NFx for channel x. In Asynchronous mode, NFC.NFx should be programmed to 6 while RCRAx.FIDS is set. This way the FID for an asynchronous channel is a rolling number 0 .. 5 and the 6 buffer locations are used completely before CHCI is issued. See [Figure 34-24](#).

Peripheral Sensor Interface with Serial PHY Connection

There is a delay between CHCI and the completion of the DMA transfer of the last set of RDS, RDR and TSM to the system memory! SW needs special checks to grant data consistency, e.g. evaluating the DMA interrupts or comparison of the Time Stamps in the System Memory!

CHCI is not granting that all data is completely moved to system memory by DMA!

Improved Data Consistency with Packet Frame Count (PFC)

For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

Figure 34-24 PSI5-S Generation of Interrupt CHCI

34.12 Error Detection Capabilities

Each PSI5-S channel can detect and signal the following error conditions:

Protocol Level:

- Packet Frame CRC Error (XCRC)
- PSI5 Frame Checksum error (CRCI)
- Frame not sent in time / UART Frames missing (TEI)
- Error Bits Set in Packet Frame (HDI)
- Errors Signalled by ASC Sub Module (i.e. PE, FE, OE)

Peripheral Sensor Interface with Serial PHY Connection

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- ECU to Sensor Data Buffer Underrun (TBI)

34.13 Special use of Channel 0

Note that data that is received in incomplete or too long Packet Frames is always copied - as is - to Channel 0 Frame ID 1. This can happen, if UART Frames are lost, the PHY sends non allowed data or idle before the actual end of the Packet Frame. See [““Packet Frames” received from PHY” on Page 34-6](#).

This is the only actual reservation / limitation in functionality of Channel 0. I.e. all frames can be received and sorted correctly in Channel 0 as long as the Packet Frame is configured with: ChID = 0. It is recommended not to use ChID = 0 AND FID = 1 for normal sensor frames but to keep FID = {2, 3, 4, 5}.

The target application assumes, that the PHY sends messages for its own house keeping with ChID = 0, FID = 0. This is assumed in this document and e.g. shown in [Table 34-1 “Frame Mapping” on Page 34-31](#). Nevertheless, a different application may not have this functionality or may use a different ChID / FID configuration.

34.14 ASC Kernel Description

[Figure 34-25](#) shows a global view of the ASC interface. The ASC is fully integrated into the PSI5-S module. It can be switched to dedicated internal use of the PSI5-S module or to ASC only mode where all PSI5 functionality is disabled. In the last case, the whole PSI5-S module represents one additional ASC in the system.

Peripheral Sensor Interface with Serial PHY Connection

Figure 34-25 General Block Diagram of the ASC Interface

The ASC module communicates with the external world via two I/O lines. The RXD line is the receive data input signal (and also output signal in Synchronous Mode), and TXD is the transmit output signal.

Clock control, address decoding, and interrupt service request control are managed outside the ASC module kernel.

34.14.1 Overview

The ASC provides serial communication between the TC27x and other micro controllers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered in ASC only mode. During internal PSI5-S mode, double-buffering is switched off for the transmitter. The receiver stays double buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a

Peripheral Sensor Interface with Serial PHY Connection

separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

Features

- Full-duplex asynchronous operating modes
 - 8-bit or 9-bit data frames, LSB first
 - Parity-bit generation/checking
 - Separate Parity control for receive and transmit
 - One or two stop bits
 - Baud rate from 12,5 Mbit/s to 3 bit/s (@ 200 MHz module clock)
 - Multiprocessor mode for automatic address/data Byte detection
 - Loop-back capability
- Half-duplex 8-bit synchronous operating mode
 - Baud rate from 25 Mbit/s to 2034,5 bit/s (@ 200 MHz module clock)
- Double-buffered transmitter (in ASC-only mode)/receiver
- Interrupt generation
 - On a transmit buffer empty condition
 - On a transmit last bit of a frame condition
 - On a receive buffer full condition
 - On an error condition (frame, parity, overrun error)
- Implementation features
 - Connections to DMA Controller
 - Connections of receiver input to GTM for baud rate detection and LIN break signal measuring

Peripheral Sensor Interface with Serial PHY Connection

34.14.2 General Operation

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous Mode, data is transmitted or received synchronously to a shift clock generated by the microcontroller. In Asynchronous Mode, 8-bit or 9-bit data transfer, parity generation, and the number of stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data are double-buffered. For multiprocessor communication, a mechanism is included to distinguish address Bytes from data Bytes. Testing is supported by a loop-back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

A transmission is started by writing to the Transmit Buffer Register, TBUF. Only the number of data bits determined by the selected operating mode will actually be transmitted; that is, bits written to positions 9 through 15 of register TBUF are always insignificant. Data transmission is double-buffered, so a new character may be written to TBUF before the transmission of the previous character is complete. This allows a back-to-back transmission of characters to take place without gaps.

Data reception is enabled by the receiver enable bit CON.REN. After a reception has been completed, the received data and, if provided by the selected operating mode, the received parity bit can be read from the (read-only) receive buffer register RBUF. Unused bits in the upper half of RBUF that are not required in the selected operating mode will be read as zeros.

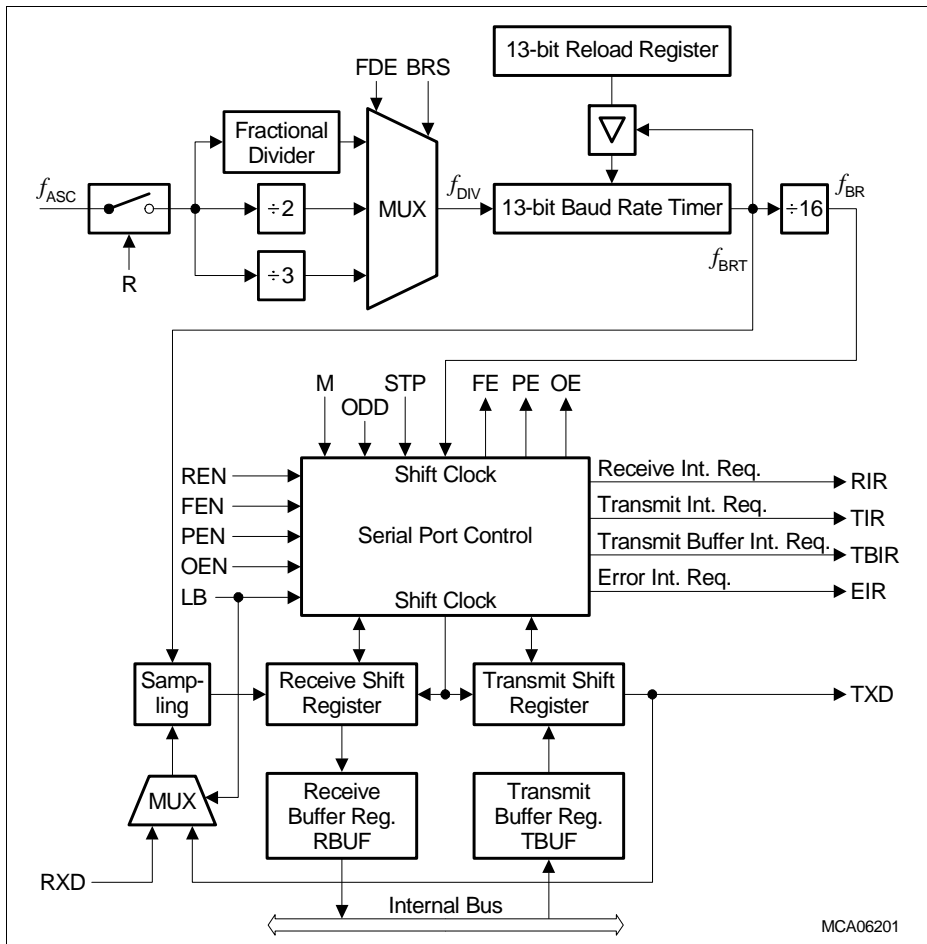

Data reception is double-buffered, so that reception of a second character may already begin before the previously received character has been read out of the receive buffer register. During the exclusive use by the PSI5-S, double buffering is switched off. The PSI5-S internal output FIFO is used instead. As commands for sync pulses are time stamped inside PSI5-S as they leave the internal FIFO, the double buffering would add unwanted jitter. In all modes, receive buffer overrun error detection can be selected through bit CON.OEN. When enabled, the overrun error status flag CON.OE and the error interrupt request line EIR will be activated when the receive buffer register has not been read by the time reception of a second character is complete. In this case, the previously received character in the receive buffer is overwritten.

The loop-back option (selected by bit CON.LB) allows the data currently being transmitted to be received simultaneously in the receive buffer. This may be used to test serial communication routines at an early stage without having to provide an external network. In loop-back mode, the alternate input/output function of port pins is not required.

Peripheral Sensor Interface with Serial PHY Connection

34.14.3 Asynchronous Operation

Asynchronous Mode supports full-duplex communication, in which both transmitter and receiver use the same data frame format and have the same baud rate. Data is transmitted on pin TXD and received on pin RXD. **Figure 34-26** shows the block diagram of the ASC when operating in Asynchronous Mode.

Peripheral Sensor Interface with Serial PHY Connection

34.14.3.1 Asynchronous Data Frames

Asynchronous data frames can consist of 8-bit or 9-bit data frames.

8-bit Data Frames

The 8-bit data frames consist of either eight data bits D7 ... D0 (CON.M = 001_B), or of seven data bits D6 ... D0 plus an automatically generated parity bit (CON.M = 011_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2 sum of the seven data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 8-bit data mode). The parity error flag CON.PE will be set, along with the error interrupt request flag, if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

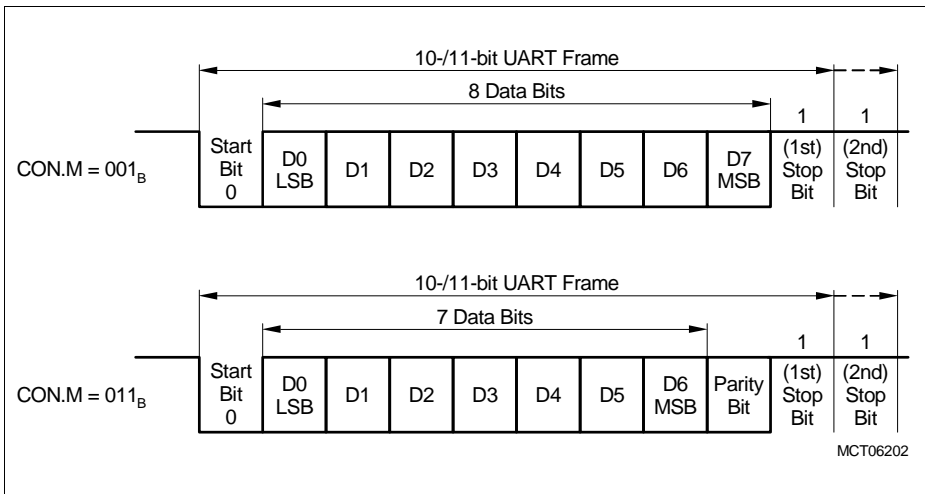

Figure 34-27 Asynchronous 8-bit Frames

Peripheral Sensor Interface with Serial PHY Connection

9-bit Data Frames

The 9-bit data frames consist of nine data bits D8 ... D0 (CON.M = 100_B), or of eight data bits D7 ... D0 plus an automatically generated parity bit (CON.M = 111_B) or of eight data bits D7 ... D0 plus wake-up bit (CON.M = 101_B). Parity may be odd or even, depending on bit CON.ODD. An even parity bit will be set if the modulo-2-sum of the eight data bits is 1. An odd parity bit will be cleared in this case. Parity checking is enabled via bit CON.PEN (always OFF in 9-bit data and wake-up mode). The parity error flag CON.PE will be set along with the error interrupt request flag if a wrong parity bit is received. The received parity bit itself will be stored in RBUF too.

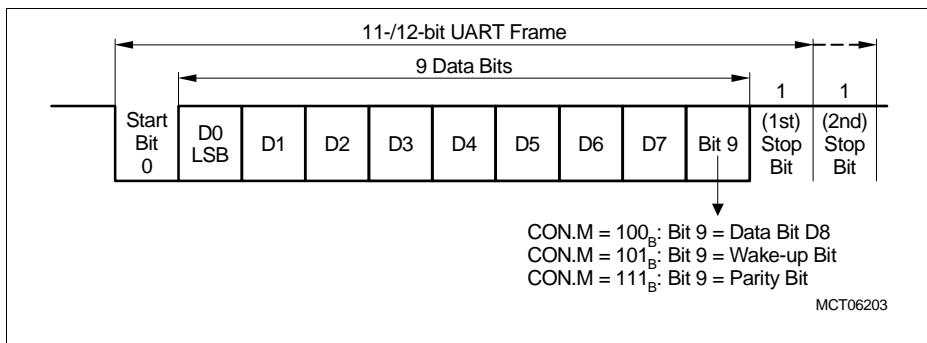

Figure 34-28 Asynchronous 9-bit Frames

In Wake-up Mode (CON.M = 101_B), received frames are transferred to the receive buffer register only if the 9th bit (the wake-up bit) of the frame is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.
