P14_ACCEN1	Port 14 Access Enable Register 1	00F8 _H	Page 14-54
P14_ACCEN0	Port 14 Access Enable Register 0	00FC _H	Page 14-53

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

- 1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))
- 2) These registers are listed and noted here in the Port 14 section because they differ from the general port register description given in [Section 14.3](#).

14.9.3.1 Port 14 Output Register

The basic P14_OUT register functionality is described on [Page 14-36](#). Port lines P14.[15:11] are not connected. Reading the P14_OUT bits P[15:12] always return 0. Reading P11 returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P14_OMR, P14_OMSR, P14_OMCR, P14_OMSRx (x=0,4,8), P14_OMCRx (x=0,4,8).

14.9.3.2 Port 14 Output Modification Register

The basic P14_OMR register functionality is described on [Page 14-38](#). However, port lines P14.[15:11] are not connected. The P14_OMR bits PS11 and PCL11 has no direct effect on port lines but only on register bits P14_OUT.P11.

14.9.3.3 Port 14 Output Modification Set Register

The basic P14_OMSR register functionality is described on [Page 14-40](#). However, port lines P14.[15:11] are not connected. The P14_OMSR bits PS11 has no direct effect on port lines but only on register bits P14_OUT.P11.

14.9.3.4 Port 14 Output Modification Set Register 8

The basic P14_OMSR8 register functionality is described on [Page 14-43](#). However, port lines P14.11 is not connected. The P14_OMSR8 bit PS11 has no direct effect on port line but only on register bit P14_OUT.P11.

14.9.3.5 Port 14 Output Modification Clear Register

The basic P14_OMCR register functionality is described on [Page 14-45](#). However, port lines P14.11 are not connected. The P14_OMCR bits PCL11 has no direct effect on port lines but only on register bits P14_OUT.P11.

14.9.3.6 Port 14 Output Modification Clear Register 8

The basic P14_OMCR8 register functionality is described on [Page 14-48](#). However, port lines P14.11 is not connected. The P14_OMCR8 bit PCL11 has no direct effect on port lines but only on register bit P14_OUT.P11.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.9.3.7 Port 14 Input/Output Control Register 8

The PC11 bit field in register P14_IOC8 is not connected.

P14_IOC8
Port 14 Input/Output Control Register 8

 (18_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC11	[31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC8, PC9, PC10	[7:3], [15:11], [23:19]	rw	Port Control for Port 14 Pin 8 to 10 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P14_IOC8
Port 14 Input/Output Control Register 8

 (18_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC11	[31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC8, PC9, PC10	[7:3], [15:11], [23:19]	rw	Port Control for Port 14 Pin 8 to 10 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.9.3.8 Port 14 Input Register

The basic P14_IN register functionality is described on [Page 14-52](#). However, port lines P14.[15:11] are not connected. Therefore, bits P[15:11] in register P14_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.9.3.9 Port 14 Pad Driver Mode 1 Register

P14_PDR1
Port 14 Pad Driver Mode 1 Register (44_H)
Reset Value: 0000 3333_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL15	PD15		PL14	PD14		PL13	PD13		PL12	PD12

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL11	PD11		PL10	PD10		PL9	PD9		PL8	PD8					
rw	rw		rw	rw		rw	rw		rw	rw		rw			

Field	Bits	Type	Description
PD8, PD9, PD10	[2:0], [6:4], [10:8]	rw	Pad Driver Mode for Port 14 Pin 8 to 10
PL8, PL9, PL10	3, 7, 11	rw	Pad Level Selection for Port 14 Pin 8 to 10
PD11	[14:12]	rw	Reserved Read as 000 _B after reset; returns value that was written.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	Reserved Read as 000 _B after reset; should be written with 0.
PL11	15	rw	Reserved Read as 0 _B after reset; returns value that was written.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	Reserved Read as 0 _B after reset; should be written with 0.

14.9.3.10 Port 14 Emergency Stop Register

The basic P14_ESR register functionality is described on [Page 14-50](#). Port lines P14.[15:11] are not connected. Reading the P14_ESR bits EN[15:12] always returns 0. Reading P14_ESR bits EN11 returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.10 Port 15

This section describes the Port 15 functionality.

14.10.1 Port 15 Configuration

Port 15 is a 9-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, ASCLIN, MultiCAN+, SCU, QSPI, CCU6 and I2C functions.

14.10.2 Port 15 Function Table

Table 14-22 summarizes the I/O control selection functions of each Port 15 line.

Table 14-22 Port 15 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P15.0	I	General-purpose input	P15_IN.P0	P15_IOCRO. PC0	0XXXX _B
		GTM input	TIN71

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

- 1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))
- 2) These registers are listed and noted here in the Port 15 section because they differ from the general port register description given in [Section 14.3](#).

14.10.3.1 Port 15 Output Register

The basic P15_OUT register functionality is described on [Page 14-36](#). Port lines P15.[15:9] are not connected. Reading the P15_OUT bits P[15:12] always return 0, reading P[11:9] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P15_OMR, P15_OMSR, P15_OMCR, P15_OMSRx (x=0,4,8), P15_OMCRx (x=0,4,8).

14.10.3.2 Port 15 Output Modification Register

The basic P15_OMR register functionality is described on [Page 14-38](#). However, port lines P15.[15:9] are not connected. The P15_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.3.3 Port 15 Output Modification Set Register

The basic P15_OMSR register functionality is described on [Page 14-40](#). However, port lines P15.[15:9] are not connected. The P15_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.3.4 Port 15 Output Modification Set Register 8

The basic P15_OMSR8 register functionality is described on [Page 14-43](#). However, port lines P15.[11:9] are not connected. The P15_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.3.5 Port 15 Output Modification Clear Register

The basic P15_OMCR register functionality is described on [Page 14-45](#). However, port lines P15.[15:9] are not connected. The P15_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

14.10.3.6 Port 15 Output Modification Clear Register 8

The basic P15_OMCR8 register functionality is described on [Page 14-48](#). However, port lines P15.[11:9] are not connected. The P15_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P15_OUT.P[11:9].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.10.3.7 Port 15 Input/Output Control Register 8

The PC[11:9] bit fields in register P15_IOC8 are not connected.

P15_IOC8
Port 15 Input/Output Control Register 8

 (18_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC8	[7:3]	rw	Port Control for Port 15 Pin 8 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P15_IOC8
Port 15 Input/Output Control Register 8

 (18_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC8	[7:3]	rw	Port Control for Port 15 Pin 8 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.10.3.8 Port 15 Input Register

The basic P15_IN register functionality is described on [Page 14-52](#). However, port lines P15.[15:9] are not connected. Therefore, bits P[15:9] in register P15_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.10.3.9 Port 15 Pad Driver Mode 1 Register

P15_PDR1

 Port 15 Pad Driver Mode 1 Register (44_H)

 Reset Value: 0000 3333_H

PL11	PD11		PL10	PD10		PL9	PD9		PL8	PD8					
rw	rw		rw	rw		rw	rw		rw	rw		rw			

Field	Bits	Type	Description
PD8	[2:0]	rw	Pad Driver Mode for Port 15 Pin 8
PL8	3	rw	Pad Level Selection for Port 15 Pin 8
PD9, PD10, PD11	[6:4], [10:8], [14:12]	rw	Reserved Read as 000 _B after reset; returns value that was written, have to be written with 0.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	Reserved Read as 000 _B after reset; should be written with 0.
PL9, PL10, PL11	7, 11, 15	rw	Reserved Read as 0 _B after reset; returns value that was written, have to be written with 0.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	Reserved Read as 0 _B after reset; should be written with 0.

14.10.3.10 Port 15 Emergency Stop Register

The basic P15_ESR register functionality is described on [Page 14-50](#). Port lines P15.[15:9] are not connected. Reading the P15_ESR bits EN[15:12] always returns 0 and should be written with 0. Reading the P15_ESR bits EN[11:9] returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.11 Port 20

This section describes the Port 20 functionality.

14.11.1 Port 20 Configuration

Port 20 is a 13-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, MultiCAN+, SCU, OCDS, ASCLIN, HSCT, CCU6, and QSPI functions.

14.11.2 Port 20 Function Table

Table 14-24 summarizes the I/O control selection functions of each Port 20 line.

Table 14-24 Port 20 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P20.0	I	General-purpose input	P20_IN.P0	P20_IOCRO.PC0	0XXXX _B

P20_ACCEN0	Port 20 Access Enable Register 0	00FC _H	Page 14-53

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 20 section because they differ from the general port register description given in [Section 14.3](#).

14.11.3.1 Port 20 Output Register

The basic P20_OUT register functionality is described on [Page 14-36](#). Port line P20.[5:4] and P20.15 are not connected. Reading the P20_OUT bits P[5:4] and P15 returns the value that was last written (0 after reset). These connected bits can be also set/reset by the corresponding bits in P20_OMR, P20_OMSR, P20_OMCR, P20_OMSRx (x=4,12), P20_OMCRx (x=4,12). P20_OUT.P2 does not determine the level at P20.2, returns the value that was last written.

14.11.3.2 Port 20 Output Modification Register

The basic P20_OMR register functionality is described on [Page 14-38](#). However, port lines P20.[5:4] and P20.15 are not connected. The P20_OMR bits PS[5:4], PS15 and PCL[5:4], PCL15 have no direct effect on port lines but only on register bits P20_OUT P[5:4] and P15. P20_OMR bit PS2 and PCL2 has no effect on P20_OUT.P2.

14.11.3.3 Port 20 Output Modification Set Register

The basic P20_OMSR register functionality is described on [Page 14-40](#). However, port lines P20.15 is not connected. The P20_OMSR bits PS15 has no direct effect on port line but only on register bits P20_OUT.P15. P20_OMSR bit PS2 has no effect on P20_OUT.P2.

14.11.3.4 Port 20 Output Modification Set Register 0

The basic P20_OMSR0 register functionality is described on [Page 14-41](#). P20_OMSR0 bit PS2 has no effect on P20_OUT.P2.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.11.3.5 Port 20 Output Modification Set Register 4

The basic P20_OMSR4 register functionality is described on [Page 14-42](#). However, port lines P20.[5:4] are not connected. The P20_OMSR4 bits PS[5:4] has no direct effect on port lines but only on register bits P20_OUT.P[5:4].

14.11.3.6 Port 20 Output Modification Set Register 12

The basic P20_OMSR12 register functionality is described on [Page 14-44](#). However, port lines P20.15 is not connected. The P20_OMSR12 bits PS15 has no direct effect on port lines but only on register bits P20_OUT.P15.

14.11.3.7 Port 20 Output Modification Clear Register

The basic P20_OMCR register functionality is described on [Page 14-45](#). However, port lines P20.[5:4] and P20.15 are not connected. The P20_OMCR bits PCL[5:4], PCL15 has no direct effect on port lines but only on register bits P20_OUT.P[5:4] and P15. P20_OMCR bit PCL2 has no effect on P20_OUT.P2.

14.11.3.8 Port 20 Output Modification Clear Register 0

The basic P20_OMCR0 register functionality is described on [Page 14-46](#). P20_OMCR0 bit PCL2 has no effect on P20_OUT.P2.

14.11.3.9 Port 20 Output Modification Clear Register 4

The basic P20_OMCR4 register functionality is described on [Page 14-47](#). However, port lines P20.[5:4] are not connected. The P20_OMCR4 bits PCL[5:4] has no direct effect on port lines but only on register bits P20_OUT.P[5:4].

14.11.3.10Port 20 Output Modification Clear Register 12

The basic P20_OMCR12 register functionality is described on [Page 14-49](#). However, port lines P20.15 are not connected. The P20_OMCR12 bits PCL15 has no direct effect on port lines but only on register bits P20_OUT.P15.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.11.3.11 Port 20 Input/Output Control Register 0

The PC2 bit field in register P20_IOCRO is not connected.

P20_IOCRO

Port 20 Input/Output Control Register 0

(10_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC0	[7:3]	rw	Port Control for Port n Pin 0
PC1	[15:11]	rw	Port Control for Port n Pin 1
PC3	[31:27]	rw	Port Control for Port n Pin 3
PC2	[23:19]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.11.3.17 Port 20 Emergency Stop Register

The basic P20_ESR register functionality is described on [Page 14-50](#). Port lines P20.2, P20.[5:4] and P20.15 are not connected. Reading the EN2, EN[5:4], EN15 returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.12 Port 21

This section describes the Port 21 functionality.

Port 21 is an 8-bit GPIO port. Pins associated to it be used in two ways:

- as a CMOS Port where each pin outputs one signal, as any other port (only exception - no open drain mode available), and
- as an output LVDS port

The switching between the CMOS/LVDS modes is done via the P21_LPCR_x register.

The switching between Input/Output and Pull-Up/Pull-Down control is done via the IOCR register.

Attention: *In the LVDS mode the IOCR.PC_x bit field of each pin of the LVDS pair must be programmed as output, that is 1xxxx_B.*

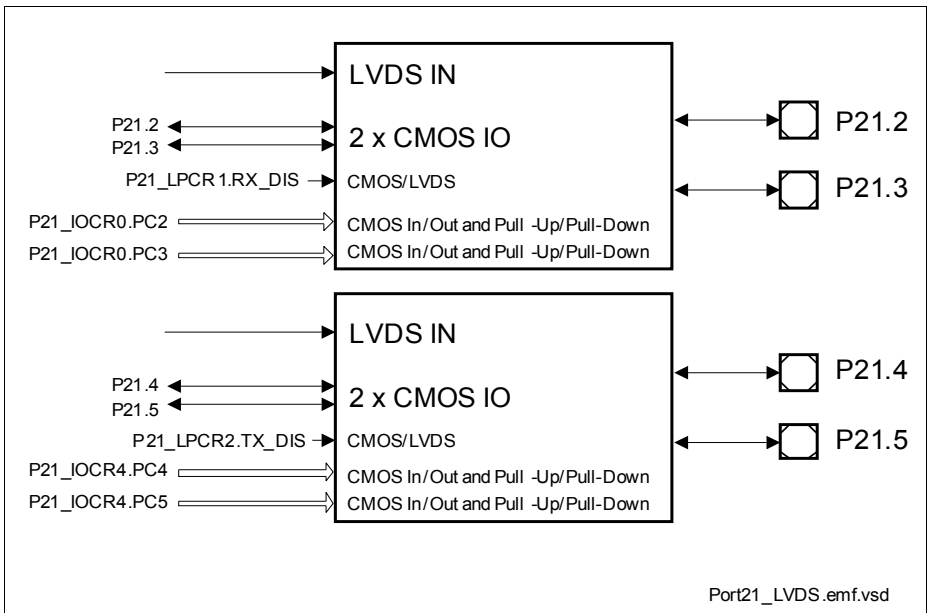

Figure 14-4 Port 21 Pad Connections

14.12.1 Port 21 Configuration

Port 21 is a 8-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, Ethernet, ASCLIN, QSPI, SCU, CCU6, HSCT, OCDS and GPT12 functions.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.12.2 Port 21 Function Table

Table 14-26 summarizes the I/O control selection functions of each Port 21 line.

P21_ACCEN1	Port 21 Access Enable Register 1	00F8 _H	Page 14-54
P21_ACCEN0	Port 21 Access Enable Register 0	00FC _H	Page 14-53

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 21 section because they differ from the general port register description given in [Section 14.3](#).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.12.3.1 Port 21 Output Register

The basic P21_OUT register functionality is described on [Page 14-36](#). Port line P21.[15:8] are not connected. Reading the P21_OUT bit P[15:8] always return 0. These connected bits can be also set/reset by the corresponding bits in P21_OMR, P21_OMSR, P21_OMCR, P21_OMSRx (x=0,4), P21_OMCRx (x=0,4).

14.12.3.2 Port 21 Output Modification Register

The basic P21_OMR register functionality is described on [Page 14-38](#). However, port lines P21.[15:8] are not connected.

14.12.3.3 Port 21 Output Modification Set Register

The basic P21_OMSR register functionality is described on [Page 14-40](#). However, port lines P21.[15:8] is not connected.

14.12.3.4 Port 21 Output Modification Clear Register

The basic P21_OMCR register functionality is described on [Page 14-45](#). However, port lines P21.[15:8] are not connected.

14.12.3.5 Port 21 Input Register

The basic P21_IN register functionality is described on [Page 14-52](#). However, port lines P21.[15:8] are not connected. Therefore, bits P[15:8] in register P21_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.12.3.6 P21 LVDS Pad Control Register

For configuration of LVDSH mode in LPCR_x registers, the LVDS function need to be selected (CMOS function disabled).

If port-controlled, the receive or transmit enabling of the LVDS path is controlled by the respective RX_{_}DIS and TX_{_}DIS bits in the P21_LPCR_x registers. Otherwise, this is handled by the equivalent control bit via the HSCT module. If LVDS mode is disabled, the respective functions of the control bits of the register are not activated, except TX_{_}PD bit which needs to be additionally configured, if desired.

P21_LPCR1 register controls the functions of the LVDSH RX pads for P21.[3:2].

P21_LPCR1
Port 21 LVDS Pad Control Register 1(00A4_H)
Reset Value: 0000 0046_H

Field	Bits	Type	Description
RDIS_CTRL	0	rw	LVDS RX__DIS controller The LVDS RX __ DIS control function can be selected from the Port (default) or HSCT module. 0 _B Port controlled 1 _B HSCT controlled
RX__DIS	1	rw	Disable Receive LVDS Disable the receive LVDS / enable CMOS path. If this bit is set to 1 - no transfer from the LVDS sender can be received and the receiver LVDS is in low power state. 0 _B enable LVDS / disable CMOS mode 1 _B disable LVDS / enable CMOS mode

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
TERM	2	rw	Select Receiver Termination Mode Selects a suitable internal load capacitance. 0 _B external termination - on the PCB 1 _B 100 Ω Receiver internal termination
LRXTERM	[7:3]	rw	LVDS RX Poly-resistor configuration value Programming bits for the on die poly resistor termination. The value is configured during production test. Each chip configuration on this bit field is unique and configured during production testing. <i>Note: The configuration value shall not be changed by user after start-up for a guaranteed behavior.</i>
0	[15:12], [9:8]	rw	Reserved Read as 0; should be written with 0.
0	[31:16], [11:10]	r	Reserved Read as 0; should be written with 0.

P21_LPCR2 register controls the functions of the LVDS TX pad for P21.[5:4].

P21_LPCR2
Port 21 LVDS Pad Control Register 2(00A8_H)
Reset Value: 0000 6000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TX_PWD PD	TX_PD	TX_DIS	TDIS _CT RL	0		LVD SRL	LVD SR					0			
rw	rw	rw	rw	r		rw	rw					rw			

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
LVDSR	8	rw	Special reduced LVDS electrical signaling mode LVDSR = 1 and LVDSRL = 0 activates LVDSR electrical. LVDSR = 1 and LVDSRL = 1 Not allowed - Software must prevent this situation! <i>Note: LVDSR = 1 and LVDSRL = 1 the special reduced electrical LVDS signaling is enabled.</i>
LVDSRL	9	rw	LVDS IEEE electrical signaling mode LVDSR = 0 and LVDSRL = 1 activates the IEEE reduced LVDS link electrical signaling specification LVDSR = 0 and LVDSRL = 0 activates the IEEE general purpose link.
TDIS_CTRL	12	rw	LVDS TX_DIS controller The LVDS TX_DIS control function can be selected from the Port (default) or HSCT module. 0 _B Port controlled 1 _B HSCT controlled
TX_DIS	13	rw	Disable Transmit LVDS Disable the transmit LVDS / enable CMOS path. If this bit is set to 1 - no transfer on LVDS data path can be initiated and the LVDS driver is disabled. 0 _B enable LVDS / disable CMOS mode 1 _B disable LVDS / enable CMOS mode
TX_PD	14	rw	LVDS Power Down 0 _B LVDS power on 1 _B LVDS power down (default)
TX_PWDPD	15	rw	Disable TX Power down pull down. This function disables or enables the LVDS pull down resistor. The application code must disable TX power down pull down resistor with a power up. With a LVDS Power Down configuration the pull down function must be enabled, if required. 0 _B disabled TX Power down pull down resistor. 1 _B enabled TX Power down pull down resistor.
0	[7:0]	rw	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
0	[31:16], [11:10]	r	Reserved Read as 0; should be written with 0.

14.12.3.7 Port 21 Emergency Stop Register

The basic P21_ESR register functionality is described on [Page 14-50](#). Port lines P21.[15:8] are not connected. Reading the P15_ESR bits EN[15:8] always returns 0. EN2 is reserved and has no influence on the emergency control function of P21.2, should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.13 Port 22

This section describes the Port 22 functionality.

Port 22 is an 4-bit GPIO port. Pins associated to it be used in two ways:

- as a CMOS Port where each pin outputs one signal, as any other port (only exception - no open drain mode available), and
- as an output LVDS port where a pin pair (two pins) outputs one differential MSC signal.

The switching between the CMOS/LVDS modes is done via the P22_PDR0 registers.

The switching between Input/Ouput and Pull-Up/Pull-Down control is done via the IOCR register.

Attention: In the LVDS mode the IOCR.PCx bit field of each pin of the LVDS pair must be programed as output, that is 1xxxx_b.

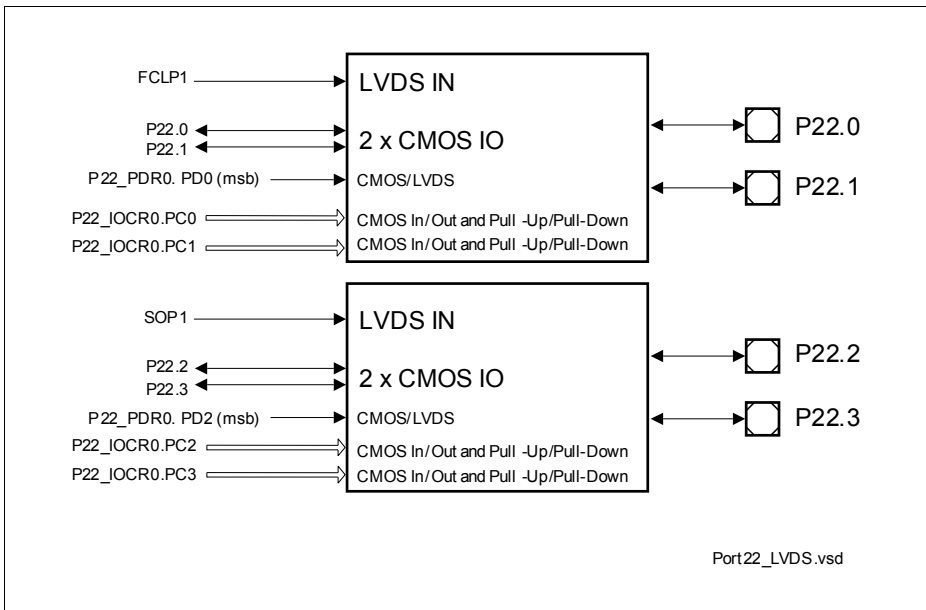

Figure 14-5 Port 22 Pad Connections

14.13.1 Port 22 Configuration

Port 22 is a 4-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, QSPI, CCU6 and MSC functions.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.13.2 Port 22 Function Table

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 22 section because they differ from the general port register description given in [Section 14.3](#).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.13.3.1 Port 22 Output Register

The basic P22_OUT register functionality is described on [Page 14-36](#). Port line P22.[15:4] are not connected. Reading P22_OUT bit P[15:4] always return 0. These connected bits can be also set/reset by the corresponding bits in P22_OMR, P22_OMSR, P22_OMCR, P22_OMSR0, P22_OMCR0.

14.13.3.2 Port 22 Output Modification Register

The basic P22_OMR register functionality is described on [Page 14-38](#). However, port lines P22.[15:4] are not connected.

14.13.3.3 Port 22 Output Modification Set Register

The basic P22_OMSR register functionality is described on [Page 14-40](#). However, port lines P22.[15:4] are not connected.

14.13.3.4 Port 22 Output Modification Clear Register

The basic P22_OMCR register functionality is described on [Page 14-45](#). However, port lines P22.[15:12] are not connected.

14.13.3.5 Port 22 Input Register

The basic P22_IN register functionality is described on [Page 14-52](#). However, port lines P22.[15:12] are not connected. Therefore, bits P[15:12] in register P22_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.13.3.6 Port 22 Pad Driver Mode 0 Register

The basic P22_PDR0 register functionality is described on [Page 14-25](#).

P22_PDR0
Port 22 Pad Driver Mode 0 Register (40_H)
Reset Value: 3333 3333_H

rw	rw		rw	rw		rw	rw		rw	rw					

Field	Bits	Type	Description
PD0	[2:0]	rw	Pad Driver Mode for Port 22 Pin [1:0] The MSB of PDx switches between CMOS (default) and LVDS modes. 0XX _B CMOS input or output (depending on IOCRx setting). 1XX _B LVDS output (pull-up or pull-down must be switched off via IOCRx)
PD2	[10:8]	rw	Pad Driver Mode for Port 22 Pin [3:2] The MSB of PDx switches between CMOS (default) and LVDS modes. 0XX _B CMOS input or output (depending on IOCRx setting). 1XX _B LVDS output (pull-up or pull-down must be switched off via IOCRx)
PD1	[6:4]	rw	Pad Driver Mode for Port 22 Pin 1
PD3	[14:12]	rw	Pad Driver Mode for Port 22 Pin 3
PD4	[18:16]	rw	Pad Driver Mode for Port 22 Pin 4
PD5	[22:20]	rw	Pad Driver Mode for Port 22 Pin 5
PL0	3	rw	Pad Level Selection for Port 22 Pin 0
PL1	7	rw	Pad Level Selection for Port 22 Pin 1
PL2	11	rw	Pad Level Selection for Port 22 Pin 2
PL3	15	rw	Pad Level Selection for Port 22 Pin 3

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
PL4	19	rw	Pad Level Selection for Port 22 Pin 4
PL5	23	rw	Pad Level Selection for Port 22 Pin 5
PD6, PD7	[26:24], [30:28]	rw	Reserved Read as 000 _B after reset; returns value that was written.
PL6, PL7	27, 31	rw	Reserved Read as 0 _B after reset; returns value that was written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.13.3.7 Port 22 LVDS Pad Control Register

For P22_LPCR_x($x=0-1$), PS1 needs to be configured to the intended pad supply level before the LVDSM function is enabled.

P22_LPCR0

Port 22 LVDS Pad Control Register 0 (A0_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PS1	1	rw	Pad Supply for pins [1:0] Selects between 5V or 3.3V supply on V_{EXT} for the LVDSM pad-pair. 0 _B 5V supply 1 _B 3.3V supply
0	[3:2], 0	rw	Reserved Read as 0; must be written with 0.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P22_LPCR1
Port 22 LVDS Pad Control Register 1 (A4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PS1	1	rw	Pad Supply for pins [3:2] Selects between 5V or 3.3V supply on V_{EXT} for the LVDSM pad-pair. 0 _B 5V supply 1 _B 3.3V supply
0	[3:2], 0	rw	Reserved Read as 0; must be written with 0.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

14.13.3.8 Port 22 Emergency Stop Register

The basic P22_ESR register functionality is described on [Page 14-50](#). Port lines P22.[15:4] are not connected. Reading EN[15:4] always returns 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.14 Port 23

This section describes the Port 23 functionality.

14.14.1 Port 23 Configuration

Port 23 is a 6-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, MSC, QSPI, ASCLIN, SCU and CCU6 functions.

14.14.2 Port 23 Function Table

Table 14-30 summarizes the I/O control selection functions of each Port 23 line.

Table 14-30 Port 23 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 23 section because they differ from the general port register description given in [Section 14.3](#).

14.14.3.1 Port 23 Output Register

The basic P23_OUT register functionality is described on [Page 14-36](#). Port line P23.[15:6] are not connected. Reading the P23_OUT bits P[15:8] always return 0, reading P[7:6] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P23_OMR, P23_OMSR, P23_OMCR, P23_OMSRx (x=0,4), P23_OMCRx (x=0,4).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.14.3.2 Port 23 Input/Output Control Register 4

The PC[7:6] bit fields in register P23_IOCRA are not connected.

P23_IOCRA

Port 23 Input/Output Control Register 4

(14_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC4	[7:3]	rw	Port Control for Port 23 Pin 4
PC5	[15:11]	rw	Port Control for Port 23 Pin 5
PC6, PC7	[23:19], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

PL6, PL7	27, 31	rw	Reserved Read as 0 _B after reset; returns value that was written.

14.14.3.4 Port 23 Output Modification Register

The basic P23_OMR register functionality is described on [Page 14-38](#). However, port lines P23.[15:6] are not connected. The P23_OMR bits PS[7:6] and PCL[7:6] have no direct effect on port lines but only on register bits P23_OUT.P[7:6].

14.14.3.5 Port 23 Output Modification Set Register

The basic P23_OMSR register functionality is described on [Page 14-40](#). However, port lines P23.[15:6] is not connected. The P23_OMSR bits PS[7:6] have no direct effect on port lines but only on register bits P23_OUT.P[7:6].

14.14.3.6 Port 23 Output Modification Set Register 4

The basic P23_OMSR4 register functionality is described on [Page 14-42](#). However, port lines P23.[7:6] are not connected. The P23_OMSR4 bits PS[7:6] have no direct effect on port lines but only on register bits P23_OUT.P[7:6].

14.14.3.7 Port 23 Output Modification Clear Register

The basic P23_OMCR register functionality is described on [Page 14-45](#). However, port lines P23.[15:6] are not connected. The P23_OMCR bits PCL[7:6] have no direct effect on port lines but only on register bits P23_OUT.P[7:6].

14.14.3.8 Port 23 Output Modification Clear Register 4

The basic P23_OMCR4 register functionality is described on [Page 14-47](#). However, port lines P23.[7:6] are not connected. The P23_OMCR4 bits PCL[7:6] have no direct effect on port lines but only on register bits P23_OUT.P[7:6].

14.14.3.9 Port 23 Input Register

The basic P23_IN register functionality is described on [Page 14-52](#). However, port lines P23.[15:6] are not connected. Therefore, bits P[15:6] in register P23_IN are always read as 0.

14.14.3.10 Port 23 Emergency Stop Register

The basic P23_ESR register functionality is described on [Page 14-50](#). Port lines P23.[15:6] are not connected. Reading the EN[15:8] always returns 0. Reading the P15_ESR bits EN[7:6] returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.15 Port 32

This section describes the Port 32 functionality.

14.15.1 Port 32 Configuration

Port 32 is a 6-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, ASCLIN, MultiCAN+, SCU, CCU6, PMU, OCDS and MSC functions.

14.15.2 Port 32 Function Table

Table 14-32 summarizes the I/O control selection functions of each Port 32 line.

Table 14-32 Port 32 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

- 2) These registers are listed and noted here in the Port 32 section because they differ from the general port register description given in [Section 14.3](#).

14.15.3.1 Port 32 Output Register

The basic P32_OUT register functionality is described on [Page 14-36](#). Port lines P32.1, P32.5, P32.[15:8] are not connected. Reading the P32_OUT bits P1, P5 returns the value that was last written. Reading P[15:8] always return 0. These connected bits can be also set/reset by the corresponding bits in P32_OMR, P32_OMSR, P32_OMCR, P32_OMSRx (x=0,4), P32_OMCRx (x=0,4).

14.15.3.2 Port 32 Output Modification Register

The basic P32_OMR register functionality is described on [Page 14-38](#). However, port lines P32.1, P32.5, P32.[15:8] are not connected. The P32_OMR bits PS1, PS5, and PCL1, PCL5 have no direct effect on port lines but only on register bits P32_OUT.P1, P5.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.15.3.3 Port 32 Input/Output Control Register 0

The PC1 bit field in register P32_IOCRO is not connected.

P32_IOCRO

Port 32 Input/Output Control Register 0

(10_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC0	[7:3]	rw	Port Control for Port n Pin 0
PC2	[23:19]	rw	Port Control for Port n Pin 2
PC3	[31:27]	rw	Port Control for Port n Pin 3
PC1	[15:11]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P32_IOCR0
Port 32 Input/Output Control Register 0

 (10_H)

 Reset Value: 0000 0000_H

PL1, PL5	7, 23	rw	Reserved Read as 0 _B after reset; returns value that was written.

14.15.3.6 Port 32 Output Modification Set Register

The basic P32_OMSR register functionality is described on [Page 14-40](#). However, port lines P32.1, P32.5, P32.[15:8] are not connected. The P32_OMSR bits PS1, PS5 have no direct effect on port lines but only on register bits P32_OUT.P1, P5.

14.15.3.7 Port 32 Output Modification Set Register 0

The basic P32_OMSR0 register functionality is described on [Page 14-41](#). However, port lines P32.1 is not connected. The P32_OMSR0 bits PS1 has no direct effect on port lines but only on register bits P32_OUT.P1.

14.15.3.8 Port 32 Output Modification Set Register 4

The basic P32_OMSR4 register functionality is described on [Page 14-42](#). However, port lines P32.5 is not connected. The P32_OMSR4 bits PS5 has no direct effect on port lines but only on register bits P32_OUT.P5.

14.15.3.9 Port 32 Output Modification Clear Register

The basic P32_OMCR register functionality is described on [Page 14-45](#). However, port lines P32.1, P32.5, P32.[15:8] are not connected. The P32_OMCR bits PCL1, PCL5 have no direct effect on port lines but only on register bits P32_OUT.P32_OUT.P1, P5.

14.15.3.10 Port 32 Output Modification Clear Register 0

The basic P32_OMCR0 register functionality is described on [Page 14-46](#). However, port lines P32.1 are not connected. The P32_OMCR0 bits PCL1 has no direct effect on port lines but only on register bits P32_OUT.P1.

14.15.3.11 Port 32 Output Modification Clear Register 4

The basic P32_OMCR4 register functionality is described on [Page 14-47](#). However, port lines P32.5 are not connected. The P32_OMCR4 bits PCL5 has no direct effect on port lines but only on register bits P32_OUT.P5.

14.15.3.12 Port 32 Input Register

The basic P32_IN register functionality is described on [Page 14-52](#). However, port lines P32.1, P32.5, P32.[15:8] are not connected. Therefore, bits P1, P5, P[15:8] in register P32_IN are always read as 0.

14.15.3.13 Port 32 Emergency Stop Register

The basic P32_ESR register functionality is described on [Page 14-50](#). Port lines P32.1, P32.5, P32.[15:8] are not connected. Reading EN1, EN5 returns the value that was last written, reading EN[15:8] always returns 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.16 Port 33

This section describes the Port 33 functionality.

14.16.1 Port 33 Configuration

Port 33 is a 16-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, CCU6, PSI5, PSI5-S, SENT, DSADC, ASCLIN, VADC, GPT12, QSPI, MultiCAN+, SCU, SMU, OCDS and MSC functions.

14.16.2 Port 33 Function Table

Table 14-34 summarizes the I/O control selection functions of each Port 33 line.

Table 14-34 Port 33 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P33.0	I	General-purpose input	P33_IN.P0	P33_IOCRO. PC0	0XXXX _B
		GTM input	TIN22

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

14.16.3.1 Port 33 Emergency Stop Register

The basic P33_ESR register functionality is described on [Page 14-50](#). EN8 is reserved and has no influence on the emergency control function of P33.8, should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)**14.17 Port 40**

This section describes the Port 40 functionality in detail.

14.17.1 Port 40 Configuration

Port 40 is a 8-bit input port.

Table 14-36 summarizes the input control selection functions of each Port 40 line.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.17.2 Port 40 Function Table

Table 14-36 summarizes the input control selection functions of each Port 40 line. If digital input functionality is selected, the digital input needs to meet the criteria defined for the Class S pads.

Field	Bits	Type	Description
PC10, PC11	[23:19], [31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC8, PC9	[7:3], [15:11]	rw	Port Control for Port 40 Pin 8 to 9 (coding see Table 14-5 , only input selection apply.)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.17.5 Port 40 Pin Function Decision Control Register

P40_PDISC

Port 40 Pin Function Decision Control Register(60_H) Reset Value: 0000 03CF_H

Field	Bits	Type	Description
PDIS0	0	rw	Pin Function Decision Control for Pin 0 The bit selects the function of P40.0 The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 0. 1 _B Pad is used for ADC analog input x.
PDIS1	1	rw	Pin Function Decision Control for Pin 1 The bit selects the function of P40.1 The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 1. 1 _B Pad is used for ADC analog input x.
PDIS2	2	rw	Pin Function Decision Control for Pin 2 The bit selects the function of P40.2. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 2 1 _B Pad is used for ADC analog input x.
PDIS3	3	rw	Pin Function Decision Control for Pin 3 The bit selects the function of P40.3. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 3. 1 _B Pad is used for ADC analog input x.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
PDIS6	6	rw	Pin Function Decision Control for Pin 6 The bit selects the function of P40.6. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 6. 1 _B Pad is used for ADC analog input x.
PDIS7	7	rw	Pin Function Decision Control for Pin 7 The bit selects the function of P40.7. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 7. 1 _B Pad is used for ADC analog input x.
PDIS8	8	rw	Pin Function Decision Control for Pin 8 The bit selects the function of P40.8. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 8. 1 _B Pad is used for ADC analog input x.
PDIS9	9	rw	Pin Function Decision Control for Pin 9 The bit selects the function of P40.9. The default state of the pad selects the ADC analog input. 0 _B Pad is used for digital input 9. 1 _B Pad is used for ADC analog input x.
0	[15:10]	rw	Reserved Read as 0; should be written with 0.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.17.6 Port 40 Pin Controller Select Register

P40_PCSR enables or disables the VADC Multiplexer Diagnostics (MD) feature.

P40_PCSR
Port 40 Pin Controller Select Register (64_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SELx (x = 2-1)	0 + x	rw	Pin Controller Select for Pin x This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature. For the respective analog signal connection, see analog connections table in VADC chapter. 0 _B Disables VADC MD feature. 1 _B Enables VADC MD feature.
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect. 0 _B The register is unlocked and can be updated. 1 _B The register is locked and can not be updated.
0	0, [11:3]	rw	Reserved Read as 0; returns value last written, must be written with 0.
0	[30:12]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

15 Direct Memory Access (DMA)

This chapter describes the DMA Controller. It contains the following sections:

- Features (see [Section 15.2](#))
- Block Diagram (see [Section 15.3](#))
- Functional Description (see [Section 15.4](#))
- Power Modes (see [Section 15.5](#))
- Functional Safety Features (see [Section 15.6](#))
- Debug Features (see [Section 15.7](#))
- Register Description (see [Section 15.8](#))
- Use Cases (see [Section 15.9](#))

Note: The DMA kernel register names described in [Section 15.8](#) are referenced in the TC26x B-Step User's Manual by the module name prefix "DMA_".

15.1 What is new

Major differences of the RAM based AURIX DMA compared to the register based AURIX DMA are

- Any DMA move engine can service a DMA request from any DMA channel. There is no fixed mapping of DMA channels to move engines. DMA requests from the highest number DMA channel are serviced first by the DMA controller. The DMA move engine is the module that executes DMA channel requests.
- The DMA channel transaction control set is stored in the DMARAM. The move engines use a copy of the DMARAM channel transaction control set to service DMA requests.
- DMA channels can be assigned to one of four hardware resource partitions that determine access protection of the DMARAM channel transaction control set.
- DMA channels can be daisy chained. On completing a DMA transaction a DMA channel can initiate a DMA transaction in the immediate next lower priority channel.
- DMA channel source and address pointers are 32-bit wide address counters. The source and destination wrap buffers are optionally selectable.
- Support for DMA Linked Lists. The current DMA transaction can load the next DMA transaction control set into the DMARAM by overwriting the existing channel transaction control set. It can optionally auto start the next DMA transaction.
- Support for DMA Double Buffering. The DMA transaction can execute read or fill DMA transfer from one of two source or destination buffers. A control bit allows the re-direction of DMA transfers from the one buffer to the other buffer.
- All DMA channels support safe DMA operation by the addition of logic to calculate checksums during DMA Moves.
- The move engine supports 64-bit data transfers to SRI addresses. Each move engine has its own 256-bit read buffer to access resources in the cached address ranges.
- The DMA kernel is clocked at the SRI clock frequency.

15.2 Features

The DMA controller is a fast and flexible DMA controller that has the following features:

- The DMA controller supports 48 DMA channels:
 - DMA channel 047 has the highest priority.
 - DMA channel 000 has the lowest priority.
- DMA channel hardware requests are sourced from the Interrupt Router (IR) Interrupt Control Unit (ICU). The system architecture defines a dedicated ICU to arbitrate between peripheral interrupt triggers and generate a DMA hardware request.
 - Any peripheral that can trigger an interrupt can initiate a DMA transfer.
- DMA channel software requests.
- The DMA controller supports 2 move engines for the parallel execution of DMA requests:
 - 1 X DMA sub-block (move engine) services 1 X active DMA channel.
 - DMA sub-blocks (move engines) work in parallel.
- The DMA can be hardware configured to support three programmable levels of System Peripheral Bus (SPB) bus priority through the single on chip bus data path to support the optional addition of a Debug Interface.
 - Setting high priority supports enhanced debug access. The debugger wins arbitration at the internal DMA bus switch and over all other bus master requests in order to gain immediate access to the SPB. There is a potential impact on performance.
 - Setting low priority supports non intrusive debugging. The debugger only wins arbitration when no other DMA access requesters or bus masters are requesting access to the bus. There is minimal performance impact.
- Individually programmable operation modes for each DMA channel
- Full 32-bit addressing capability of each DMA channel
 - 4 Gbyte address range.
 - Circular buffer addressing mode with flexible circular buffer sizes
- Data block move throughput
 - DMA transaction moving data from an SRI-source to an SRI-destination supports >8 Mbyte moves per DMA transaction.
 - DMA transaction moving data either from an FPI-source or to an FPI-destination supports >1 Mbyte moves per DMA transaction.
- The DMA transaction control set is stored in the DMARAM.
- DMA read move and DMA write moves are directed by the DMA switch to different sources and destinations depending on the source or destination address.
- Buffer capability for move actions on the buses (at least 1 move per bus is buffered)
- Programmable data width of DMA moves:
 - SPB master interface: 8-bit, 16-bit, or 32-bit.
 - SRI master interface: 8-bit, 16-bit, 32-bit, 64-bit, 128-bit or 256-bit.
- Interrupt Triggers:

Direct Memory Access (DMA)

- Each DMA channel generates one traffic management interrupt trigger with an unique interrupt vector and priority level.
- The DMA generates one error interrupt trigger.
- Operating frequencies:
 - The DMA controller kernel (active channel, move engine and SRI master interface) work at the SRI clock frequency in order to maximise the data throughput for DMA moves from SRI source addresses to SRI destination addresses.
 - The DMA controller configuration sector (slave interface, DMARAM, ICU interface and SPB Master interface) work at the SPB clock frequency.
- Slave based access protection:
 - DMA channel transaction control sets are access protected.
 - Each DMA channel is assigned to a hardware resource partition.
 - Access control to a hardware partition is via enabling of individual Master TAG IDs to have write access to the hardware partition.
 - Each DMA hardware resource partition has an unique Master TAG IDs and is configured to make accesses in supervisor or user mode.

Direct Memory Access (DMA)

15.3 Block Diagram

The DMA Controller transfers data from data source locations to data destination locations without intervention of the CPU or other on chip devices. One data move operation is controlled by an active DMA channel. A DMA sub-block can service DMA requests from any of the DMA channels. The Bus Switch provides the connection between a DMA sub-block and on chip bus interfaces.

Figure 15-1 DMA Block Diagram

Programming of the DMA transaction control sets is via a bus slave interface. The slave interface supports clock control and access protection to the DMA controller. The Access

Direct Memory Access (DMA)

Enable registers are safe endinit protected and support register monitoring safety measures.

Address decoding and DMA request wiring are managed outside the DMA controller.

15.4 Functional Description

15.4.1 Definition of Terms

Some basic terms must be defined for the functional description of the DMA controller.

DMA Move

A DMA move is an operation that always consists of two parts:

1. A read move that loads data from a data source into the DMA controller
2. A write move that puts data from the DMA controller to a data destination

Within a DMA move, data is always moved from the data source via the DMA controller to the data destination. Data is temporarily stored in the DMA controller. The data widths of read move and write move are typically identical (8-bit, 16-bit, 32-bit, 64-bit, 128-bit or 256-bit).

Figure 15-2 DMA Definition of Terms

DMA Transfer

A DMA transfer can be composed of 1, 2, 3, 4, 5, 8, 9 or 16 DMA moves.

DMA Transaction

A DMA transaction is composed of several (at least one) DMA transfers. The Transfer Count determines the number of DMA transfers within one DMA transaction.

Example:

1024 word (32-bit wide) transactions can be composed of 256 transfers of four DMA word moves, or 128 transfers of eight DMA word moves.

Linked List

A linked list is a series of DMA transactions executed in the same DMA channel.

15.4.2 DMA Principles

The DMA controller supports DMA moves from one address location to another location.

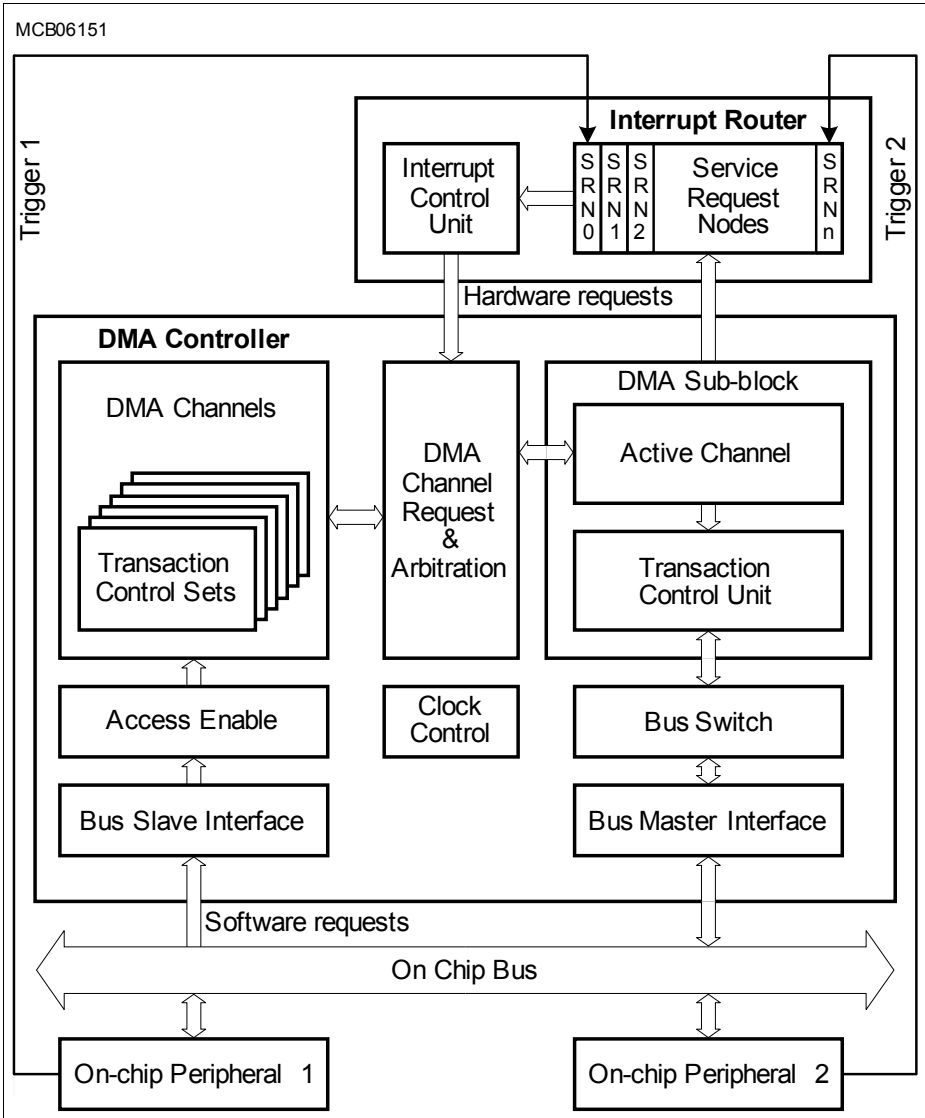

Figure 15-3 DMA System Overview

Direct Memory Access (DMA)

DMA moves can be requested either by hardware or by software. DMA hardware requests are triggered by specific request lines from the Interrupt Control Unit (ICU) or from other DMA channels (see [Figure 15-3](#)). Typically, the parallel occurrence of DMA requests and interrupts requests for DMA channels is possible. Therefore, the ICU and the DMA controller can react independently to interrupt DMA requests that have been generated by one source.

The DMA controller primarily consists of DMA channels, sub-blocks (move engines) and a bus switch. Once configured, the DMA sub-blocks are able to act as a master on the SPB Bus and on the SRI Bus.

15.4.3 DMA Channel Functionality

The transaction control set of each DMA channel is stored in the DMARAM in an array of 8 X 32-bit words. When a DMA request is serviced the associated transaction control set is copied from the DMARAM to the active DMA channel register set within a DMA sub-block. The transaction control set of a DMA channel includes functionality to support the calculation of Cyclic Redundancy Checker (CRC) checksums for source and destination addresses and read data to support enhanced data integrity checking. The index “z” refers to the channel number (z = 000 to a maximum of z = 047) within the DMA controller.

DMA channels are associated with a hardware resource partition. The index “y” refers to the hardware resource number (y = 0-3). The move engine and error registers located in the DMA sub-block use the index “x” to refer to the DMA sub-block number (x = 0-1).

When a DMA sub-block x services a DMA request from DMA channel z then the transaction control set (8 X 32-bit words) is copied from the DMARAM to the following active channel register set in DMA sub-block x:

- Channel x Status Register MExCHSR (for details, see [Page 15-108](#))
- Channel x Control Register MExCHCR (for details, see [Page 15-112](#))
- Channel x Address and Interrupt Control Register MExADICR (for details, see [Page 15-116](#))
- Channel x Shadow Address Register MExSHADR (for details, see [Page 15-111](#))
- Channel x Destination Address Register MExDADR (for details, see [Page 15-126](#))
- Channel x Source Address Register MExSADR (for details, see [Page 15-127](#))
- Channel x Source and Destination Address CRC Register MExSDCRC (for details, see [Page 15-128](#))
- Channel x Read Data CRC Register MExRDCRC (for details, see [Page 15-129](#))

15.4.3.1 Shadowed Source or Destination Address

As a typical application, an ASC module that receives data (fixed source address) has to deliver it to a memory buffer using a DMA transaction (variable destination address). After a certain amount of data has been transferred, a new DMA transaction should be

Direct Memory Access (DMA)

initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running DMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new destination address is written into a buffer register, i.e. the shadow address register. At the start of the next DMA transaction, the new address is transferred from this shadow address register to the destination address register without CPU intervention. This shadow mechanism avoids the CPU having to check for the end of a DMA transaction before reprogramming address registers.

The shadow address register can be used also to store a source address. However, it cannot store source and destination address at the same time. This means that the shadow mechanism makes it possible to automatically update either a new source address, or a new destination address at the start of a DMA transaction. If both address registers (for source and destination address) have to be updated for the next DMA transaction, a running DMA transaction for this channel must be finished. After that, source and destination address registers can be written before the next DMA transaction is started.

Only one address register can be shadowed while a transaction is running, because the shadow register can only be assigned either to the source or to the destination address. Note that the shadow address transfer mechanism has the same behavior in Single and Continuous Mode.

When the shadow mechanism is disabled the DMA sub-block active channel shadow address register MExSHADR is always read as 0000 0000_H.

DMA Channel Idle

If no DMA transaction is running and a new source or destination address is written to DMA channel z then the new address value is directly written into the DMARAM source address word (SADRz) or destination address word (DADRz). Writes to the shadow address word (SHADRz) are as follows:

- Read Only Mode: the shadow address is not writable (ADICRz.SHCT = 0001_B or 0010_B) and a write to the shadow address word SHADRz will result in a bus error.
- Direct Write Mode: the shadow address is directly writable (ADICRz.SHCT = 0101_B or 0110_B) and the shadow address word SHADRz is updated.

DMA Channel Active

In the case when move engine x is servicing a DMA request from DMA channel z and a DMA transfer is in progress then address updates are dependent on the shadow control settings:

- Read Only Mode: [Figure 15-4](#) shows the actions that take place when a source address register is updated (destination register update happens in an equivalent

Direct Memory Access (DMA)

manner). The shadow address is not directly writable ($ADICRz.SHCT = 0001_B$ or 0010_B).

- For source shadow addressing ($ADICRz.SHCT = 0001_B$) the new source address is written to the shadow address register $MExSHADR$ in DMA sub-block x .
- For destination shadow addressing ($ADICRz.SHCT = 0010_B$) the new destination address is written to the shadow address register $MExSHADR$ in DMA sub-block x .
- Direct writes to the shadow address register will result in a bus error.
- When the current DMA transaction completes and the final write back to DMARAM occurs the $MExSHADR$ value is written to either $SADRz$ or $DADRz$ and the $SHADRz$ is set to 00000000_H .
- Direct Write Mode: the shadow address is directly writable ($ADICRz.SHCT = 0101_B$ or 0110_B) and the shadow address register $MExSHADR$ in DMA sub-block x is directly written.
 - The $SHADRz$ value stored in the DMARAM is updated to the $MExSHADR$ value on the write back.
 - At the start of a new DMA transaction the source address register ($MExSADR$) or the destination address register ($MExDADR$) is updated with the $SHADRz$ value. $MExADICR.SHCT$ must be set accordingly.
 - The shadow transfer will be repeated until DMA channel z is reset or until the value in $MExSHADR$ is $0000\ 0000_H$.

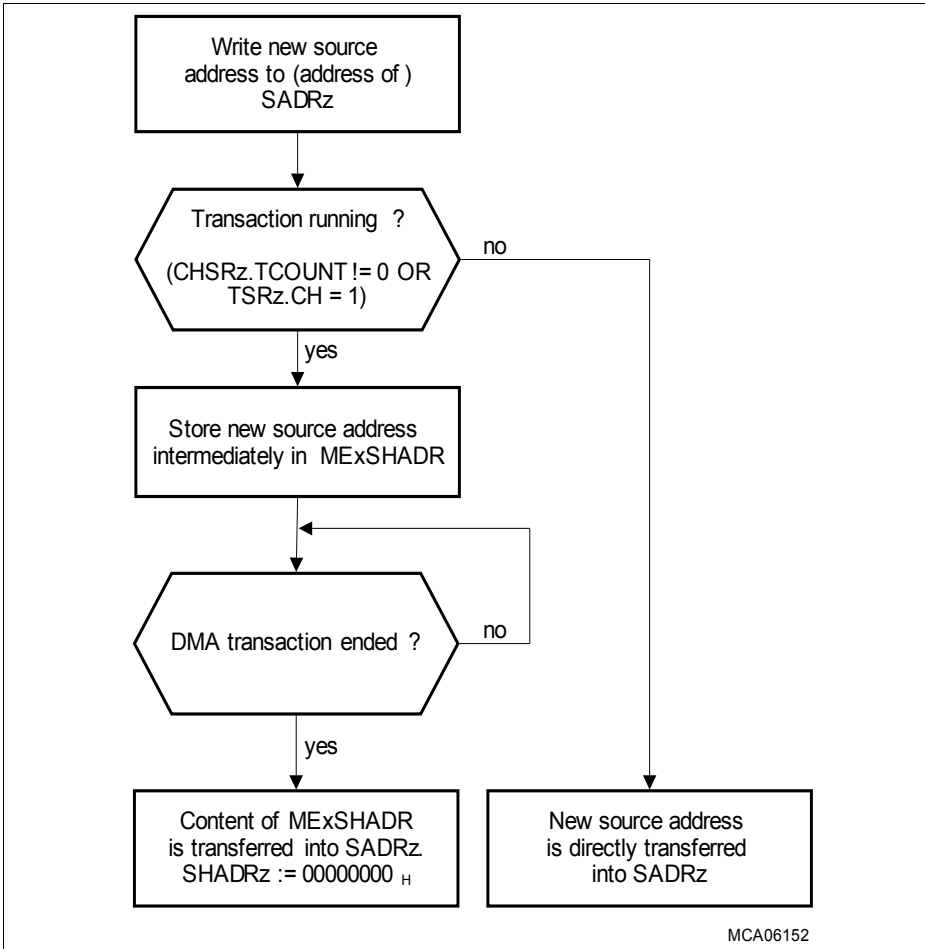

Figure 15-4 Source Address Update (ADICRz.SHCT = 0001_B)

Transfer Count Update

The transfer count of a DMA transaction, stored in bit field CHCFGRz.TREL, can also be programmed if the DMA transaction is running. At the start of a DMA transaction, CHCFGRz.TREL is transferred to bit field MExCHSR.TCOUNT. TCOUNT is updated during the DMA transaction.

No reload of address or counter will be done if MExCHSR.TCOUNT is not equal to 0.

Direct Memory Access (DMA)

The reprogramming of channel specific values (except for the selected shadow address register) must be avoided while a DMA channel is active as the data transfer maybe corrupted.

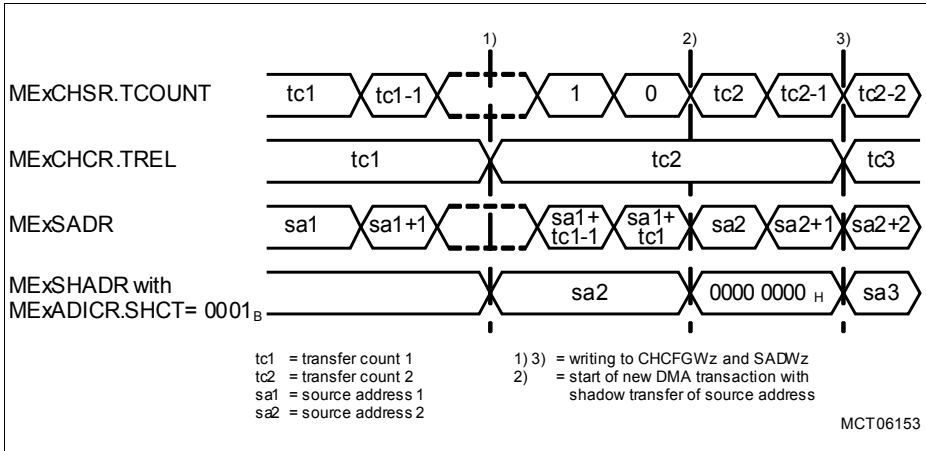

Figure 15-5 Shadow Source Address and Transfer Count Update with MExADICR.SHCT = 0001_B (Shadow Read Only Mode)

Figure 15-5 shows how the contents of the source address register MExSADR and the transfer count MExCHSR.TCOUNT are updated during two DMA transactions with a shadowed source address and transfer count update.

At reference point 2) the DMA transaction 1 is finished and DMA transaction 2 is started. At 1) the DMA channel is reprogrammed with two new parameters for the next DMA transaction: Transfer count $tc2$ and source address $sa2$. Source address $sa2$ is buffered in MExSHADR and transferred to MExSADR when the new DMA transaction is started at 2). At this time, transfer count $tc2$ is also transferred to MExCHSR.TCOUNT. Note that the shadow address register is only reset by hardware to $0000\ 0000_H$ as shown in this example, if the write enable bit is set to 0 (ADICRz.SHCT = 0001_B or 0010_B).

In the event that CHCFGz.TREL is written while DMA channel z is active:

- A write to CHCFGz.TREL will update the MExCHCR.TREL value in the DMA sub-block x.
- On write back CHCFGz.TREL is updated with the latest MExCHCR.TREL value.
- MExCHSR.TCOUNT is updated to the new CHCFGz.TREL value at the start of the next DMA transaction.

15.4.3.2 DMA Channel Request Control

Figure 15-6 shows the control logic for DMA requests that is implemented for each DMA channel.

Figure 15-6 Channel Request Control

Two different types of DMA requests are possible:

- Hardware DMA requests
- Software DMA requests

DMA hardware requests (CHz_REQ) are triggered by the Interrupt Control Unit (ICU).

If CHCFGRz.PRSEL = 1 in the current DMA channel z can bypass the ICU and trigger a DMA hardware request in the next lower DMA channel z-1. The latency to service a DMA channel z-1 request is reduced. DMA channel z interrupt service requests are disabled.

Direct Memory Access (DMA)

Hardware requests are enabled/disabled by status bit TSRz.HTRE. HTRE can be set/reset by software or by hardware in Single Mode at the end of a DMA transaction. A software request can be generated by setting bit CHCSRz.SCH.

Status flag TSRz.CH indicates whether or not a software or hardware generated DMA request for DMA channel z is pending. TSRz.CH is cleared when the DMA transfer starts (RROAT = 0) or at the end of a DMA transaction (RROAT = 1).

If a software or a hardware DMA request is detected for channel z while TSRz.CH is set, a request lost event occurs. This error event indicates that the DMA is already processing a transfer and that another transfer has been requested before the end of the previous one. In this case, bit TSRz.TRL will be set. If ADICRz.ETRL is set then a transfer lost interrupt trigger will be generated when DMA channel z becomes active.

15.4.3.3 DMA Channel Operation Modes

The operation mode of a DMA channel is individually programmable for each DMA channel z. In basic terms, a DMA channel can operate in the following modes:

- Software controlled mode
- Hardware controlled mode, in Single Mode, Continuous Mode or Linked List.

In software-controlled mode, a DMA channel request is generated by setting a control bit. In hardware-controlled mode, a DMA channel request is generated by the ICU servicing an interrupt trigger generated by an on chip peripheral unit.

In hardware-controlled Single Mode, a DMA channel z becomes disabled by hardware after the last DMA transfer of its DMA transaction. In hardware-controlled Continuous Mode, a DMA channel z remains enabled after the last DMA transfer of its DMA transaction.

In linked list mode the DMA channel is loaded with the new transaction control set on completion of the current DMA transaction. The next DMA transaction can optionally be auto started by a software request.

In hardware- and software-controlled mode, a DMA request signal can be configured to trigger a complete DMA transaction or one single transfer.

Software-controlled Modes

In software-controlled mode, one software request starts one complete DMA transaction or one single DMA transfer. Software-controlled modes are selected by writing TSRz.DCH = 1. This forces status flag TSRz.HTRE = 0 (hardware request of DMA channel z is disabled).

The software-controlled mode that initiates one complete DMA transaction to be executed is selected for DMA channel z by the following write operations:

- CHCFGRz.RROAT = 1
- CHCSRz.SCH = 1

Direct Memory Access (DMA)

Setting CHCSRz.SCH to 1 (this is the software request) causes the DMA transaction of DMA channel z to be started and TSRz.CH to be set. At the start of the DMA transaction, the value of CHCFGRz.TREL is loaded into MExCHSR.TCOUNT (transfer count or tc) and the DMA transfers are executed. After each DMA transfer, TCOUNT becomes decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, DMA channel z becomes disabled and status flag TSRz.CH is reset. Setting CHCSRz.SCH again starts a new DMA transaction of DMA channel z with the parameters as currently defined in the channel register set.

Figure 15-7 Software Controlled Mode Operation

Direct Memory Access (DMA)

The software-controlled mode that initiates a single DMA transfer to be executed is selected for DMA channel z by the following write operations:

- CHCFGRz.RROAT = 0
- CHCSRz.SCH = 1, repeated for each DMA transfer

When CHCFGRz.RROAT = 0, TSRz.CH is cleared when a DMA transfer starts and a new software request (writing CHCSRz.SCH = 1) must be generated for starting the next DMA transfer.

Hardware-controlled Modes

In hardware-controlled modes, a hardware request signal starts a DMA transaction or a single DMA transfer. There are two hardware-controlled modes available:

- **Single Mode:**
Hardware requests are disabled by hardware after a DMA transaction
- **Continuous Mode:**
Hardware requests are not disabled by hardware after a DMA transaction

Hardware-controlled Single Mode

In hardware-controlled Single Modes, one hardware request starts one complete DMA transaction or one single DMA transfer. The hardware-controlled Single Mode that initiates one complete DMA transaction to be executed for DMA channel z is selected by the following operations:

- CHCFGRz.CHMODE = 0
- CHCFGRz.RROAT = 1
- CHCFGRz.PRSEL = 0
- TSRz.ECH = 1

Setting TSRz.ECH to 1 enables hardware transfer requests (TSRz.HTRE = 1) for DMA channel z. When the ICU generates a DMA hardware request CHz_REQ then TSRz.CH is set high. If DMA channel z wins channel arbitration then DMA channel z becomes a move engine active channel. The value of CHCFGRz.TREL is loaded into MEXCHSR.TCOUNT and the DMA transaction is started by executing its first DMA transfer. After each DMA transfer, TCOUNT is decremented and next source and destination addresses are calculated. When TCOUNT reaches the 0, DMA channel z becomes disabled and status flags TSRz.CH and TSRz.HTRE are reset. In order to start a new hardware-controlled DMA transaction, hardware requests must be enabled again by setting TSRz.HTRE through TSRz.ECH = 1. The hardware request disable function in Single Mode is typically needed when a reprogramming of the DMA channel register set (addresses, transfer count) is required before the next hardware triggered DMA transaction is started.

Direct Memory Access (DMA)

The hardware-controlled Single Mode in which each single DMA transfer has to be requested by a hardware request signal is selected as described above, with one difference:

- $CHCFGRz.RROAT = 0$

In this operation mode, $TSRz.CH$ is cleared when a new DMA transfer starts, and a new hardware request at CHz_REQ must be generated for starting the next DMA transfer.

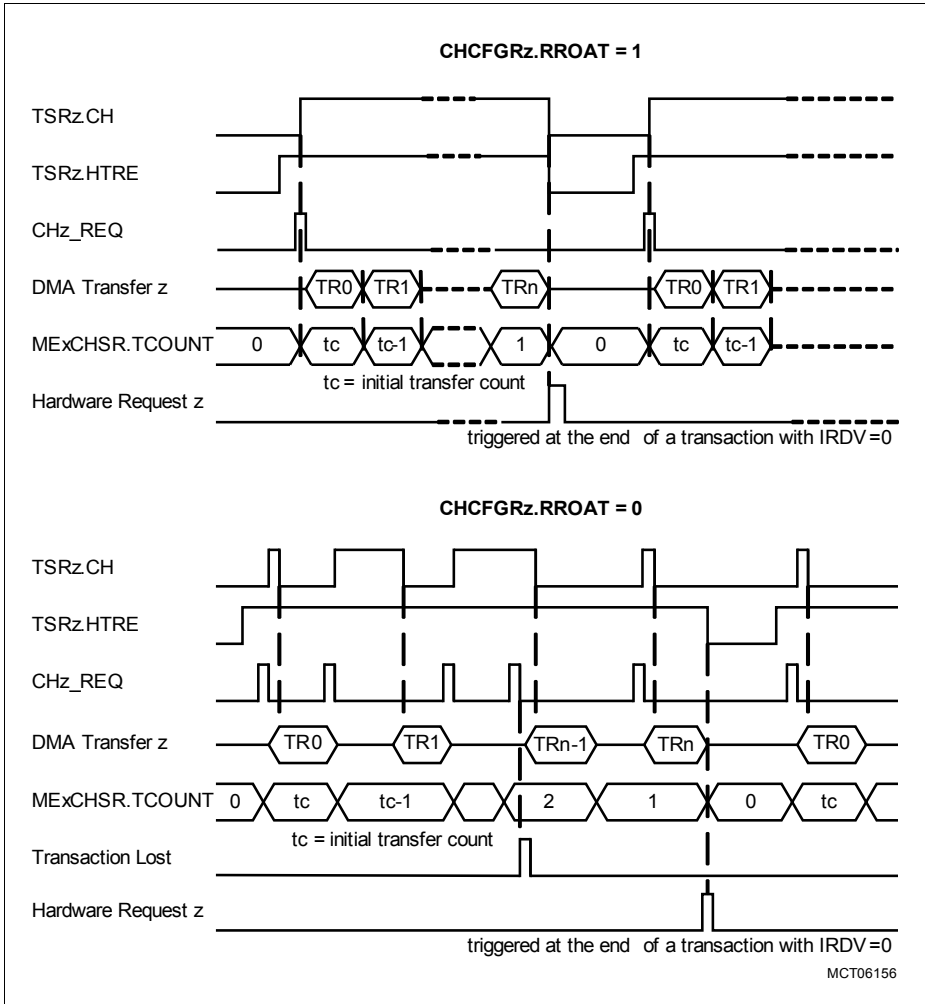

Figure 15-8 Hardware-controlled Single Mode Operation

Direct Memory Access (DMA)

Hardware-controlled Continuous Mode

In hardware-controlled Continuous Mode (CHCFGRz.CHMODE = 1), the hardware transaction request enable bit TSRz.HTRE is not reset at the end of a DMA transaction. A new transaction of DMA channel z with the parameters actually stored in the transaction control set of DMA channel z is started each time when CHCSRz.TCOUNT = 0 at the end of the DMA transaction. No software re-enable for a hardware request at CHz_REQ is required.

Combined Software/Hardware-controlled Mode

Figure 15-9 shows how software- and hardware-controlled modes can be combined. In the example, the first DMA transfer is triggered by software when setting CHCSRz.SCH. Hardware requests are still disabled. After hardware requests have been enabled by setting TSRz.ECH, subsequent DMA transfers are triggered now by hardware request coming from the CHz_REQ line.

In the example, DMA channel z operates in Single Mode (CHCFGRz.CHMODE = 0). In this mode, TSRz.HTRE becomes reset by hardware when CHCSRz.TCOUNT = 0 at the end of the DMA transaction.

Figure 15-9 Transaction Start by Software, Continuation by Hardware

If a DMA channel is configured to be triggered by parallel hardware and software requests then if the requests collide in the same clock cycle the DMA move will be executed and a Transaction/Transfer Request Lost event will be flagged in the TSRz.TRL bit.

15.4.3.4 DMA Service Requests

Interrupt Requests are prioritized by the Interrupt Router and processed by one of the Service Providers (CPU or DMA). Each DMA peripheral interfaces to a dedicated Interrupt Control Unit (ICU) instantiated in the Interrupt Router (IR).

DMA channels are associated with the Service Request Priority Number bit field programmed in the Service Request Control Register SRC.SRPN. For example:

- DMA Channel 000 equates to SRC.SRPN = 0 programmed in IR.
- DMA Channel 001 equates to SRC.SRPN = 1 programmed in IR.
- DMA Channel 002 equates to SRC.SRPN = 2 programmed in IR.
- DMA Channel 003 equates to SRC.SRPN = 3 programmed in IR.
- DMA Channel 004 equates to SRC.SRPN = 4 programmed in IR.

The routing of a hardware Service Request to a service provider destination is determined by the IR Type of Service Control bit field SRC.TOS. The DMA will acknowledge all Service Requests. If the value programmed in the SRC.SRPN is for an Invalid Channel then the DMA Controller will take no action.

The user must programme valid SRC.SRPN values for a DMA peripheral.

Daisy Chain

DMA Channels can be daisy chained by setting the bit CHCFGRz.PRSEL.

When a higher priority DMA channel completes a DMA transaction then it will initiate a DMA transaction on the next lower priority DMA channel by setting the access pending bit TSRz.CH bit. Daisy chaining is limited to a higher priority DMA channel initiating the next lower priority DMA Channel.

Enabling the daisy chain disables the channel transfer interrupt trigger in the next higher priority channel. In a typical DMA daisy chain application only the lowest priority DMA channel is required to generate a channel transfer interrupt trigger. When the sequence of DMA transactions from the highest to lowest priority DMA channel has completed then the lowest priority DMA channel in the daisy chain will generate a channel transfer interrupt trigger to signal the end of the DMA operation.

Only the Service Request for the highest priority DMA Channel in the daisy chain is initiated by the ICU. The lower priority Service Requests bypass the ICU in order to improve interrupt latency.

15.4.3.5 Channel Reset Operation

A DMA transaction of DMA channel z can be stopped (channel is reset) by setting bit TSRz.RST. If a read or write on chip bus access of DMA channel z is executed at the time when TSRz.RST is set then the On Chip Bus access is finished normally. This behavior guarantees data consistency.

When a channel reset is applied to an active DMA channel, the on-going DMA transfer executing in the move engine will complete before the DMA channel transitions to the reset state. A pending DMA channel must become active and service its pending request before making a transition to the channel reset state.

DMA Channel Reset State

On completion of a DMA channel reset:

- Bits TSRz.HTRE, TSRz.CH, TSRz.TRL, CHCSRz.ICH, CHCSRz.IPM, CHCSRz.WRPD, CHCSRz.WRPS, CHCSRz.LXO, and bit field CHCSRz.TCOUNT are reset.
- If a circular buffer ADICRz.SCBE and/or ADICRz.DCBE is enabled then the source and/or destination address register will be set to the wrap boundary else the address registers are cleared. SHADRz will be cleared.
- All automatic functions are stopped for channel z.

Resetting a DMA Channel

A user program must execute the following steps to reset a DMA channel:

1. If hardware requests are enabled for the DMA channel z, disable the DMA channel z hardware requests by setting TSRz.DCH = 1.
2. Writing a 1 to TSRz.RST.
3. Waiting (polling) until TSRz.RST = 0 to indicate the reset has completed.

During a DMA channel reset operation, software requests must not be initiated by setting CHCSRz.SCH = 1.

Restarting a DMA Channel

A user program must execute the following steps for restarting a DMA channel after it was reset:

1. Optionally (re-)configuring the address and other channel registers.
2. Restarting the DMA channel z by setting TSRz.ECH = 1 for hardware requests or CHCSRz.SCH = 1 for software requests.

15.4.3.6 Channel Halt Operation

A DMA channel can be halted during a DMA transaction and the state frozen to allow a background RAM test to be run over a destination memory in order to detect stuck bits and distinguish between static errors and transient errors. On completion of the RAM test the DMA channel can be re-started and the DMA transaction completed.

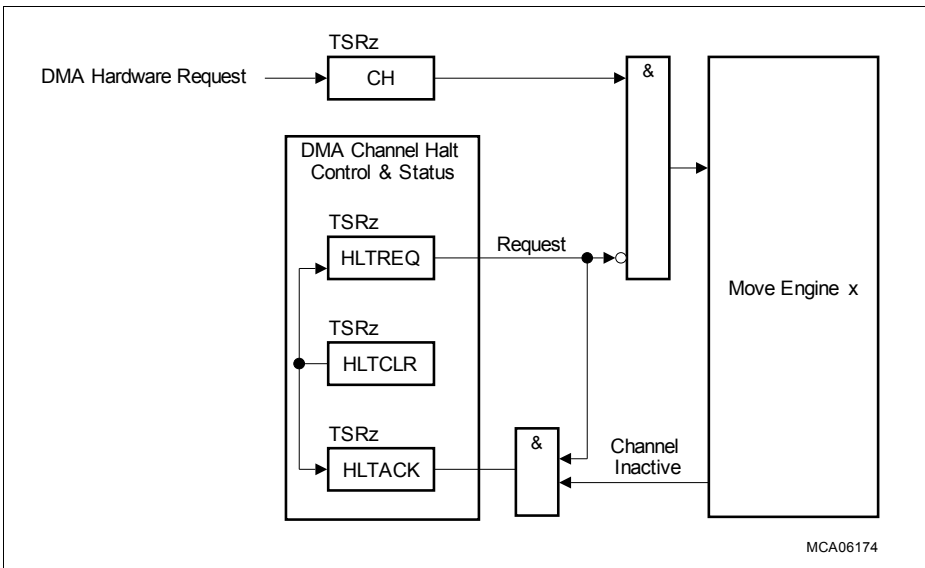

Figure 15-10 DMA Channel Halt Control

The halt control utilizes a set/clear mechanism to request the channel transitions to and from the HALT state on completion of the current DMA transfer. Only writing a logic '1' to set or clear a halt request to a DMA channel has an effect and the status of other channels can be ignored.

The DMA channel halt operation is shown in [Figure 15-11](#).

Entering DMA Channel Halt

Channel Halt Mode of DMA channel z is entered if the halt request bit `TSRz.HLTREQ` is set by software. The DMA channel enters the halt state mode automatically after the current DMA transfer is completed. The DMA channel z halt state is signalled by the halt acknowledge status flag `TSRz.HLTACK`.

When the DMA channel is in the halt state the transaction control set can be modified. These modifications are taken into account for further DMA transactions or DMA transfers of the related DMA channel after Halt Mode has been left again.

Direct Memory Access (DMA)

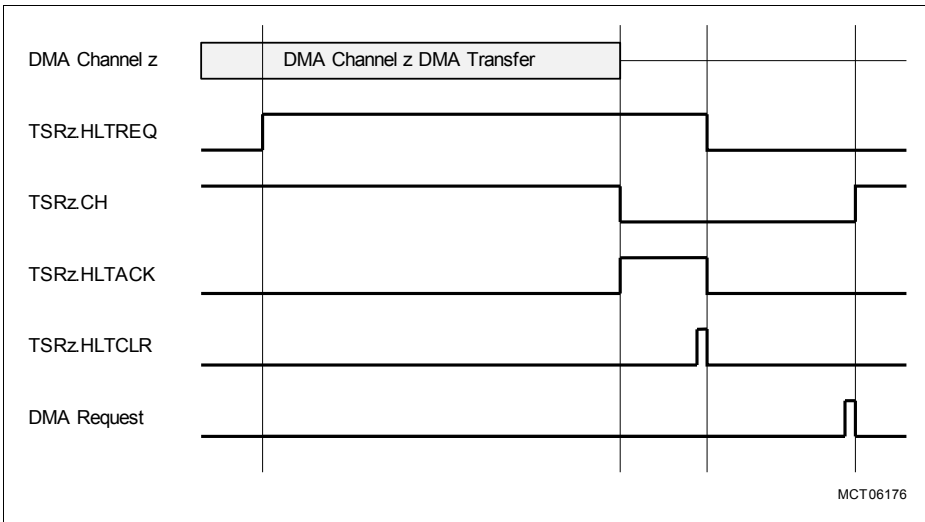

Figure 15-11 DMA Channel Halt Operation

Exiting Channel Halt Mode

DMA channel z is released from the halt state by software setting the halt clear bit TSRz.HLTCLR. Normal DMA operation is resumed.

DMA Hardware Request during Channel Halt Mode

If DMA channel z is in the halt state (TSRz.HLTACK = 1_B) and the hardware transaction request enable bit TSRz.HTRE is set then the DMA channel z will respond to DMA hardware request service requests as follows:

- Idle channel (TSRz.CH = 0_B): the access pending bit will be set and the DMA hardware request will be serviced when DMA channel z exits halt mode.
- Active channel (TSRz.CH = 1_B): the TSRz.TRL bit is set as the transaction will be lost. If the enable transaction request lost interrupt bit ADICRz.ETRL is set then an interrupt will be generated for a transaction request lost event.

Direct Memory Access (DMA)

15.4.3.7 Transfer Count and Move Count

The move count determines the number of moves (consisting of one read and one write each) to be done in each DMA transfer. It allows the user to indicate to the DMA the number of moves to be done after one request. The number of DMA moves per DMA transfer is selected by the block mode settings (CHCFGRz.BLKM).

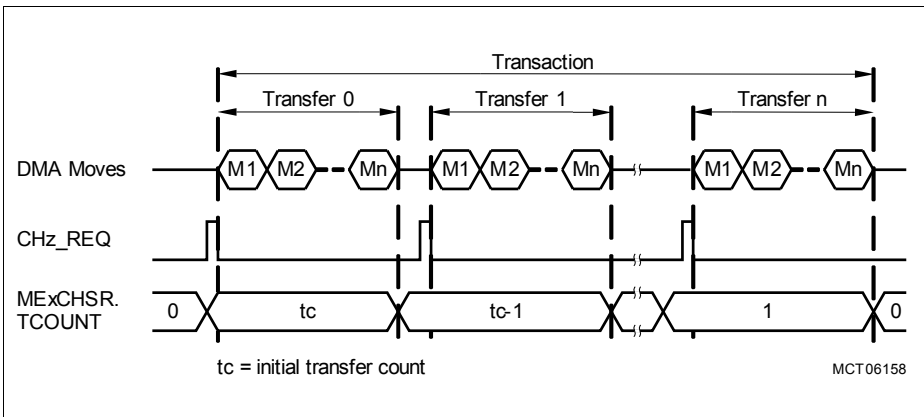

Figure 15-12 Transfer and Move Count

After a DMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters can be selected:

- The address offset, which is a multiple of the selected data width
- The offset direction: addition, subtraction, or none (unchanged address)

Control bits in address and interrupt control word ADICRz determine how the addresses are incremented/decremented. Further, the data width as defined in CHCFGRz.CHDW is taken into account for the address calculation.

Figure 15-13 and Figure 15-14 show two examples of address calculation. In both examples, a data width of 16-bit (CHCFGRz.CHDW = 001_B) is assumed.

Direct Memory Access (DMA)

Programmable Address Modification - Example 1

In **Figure 15-13**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H.

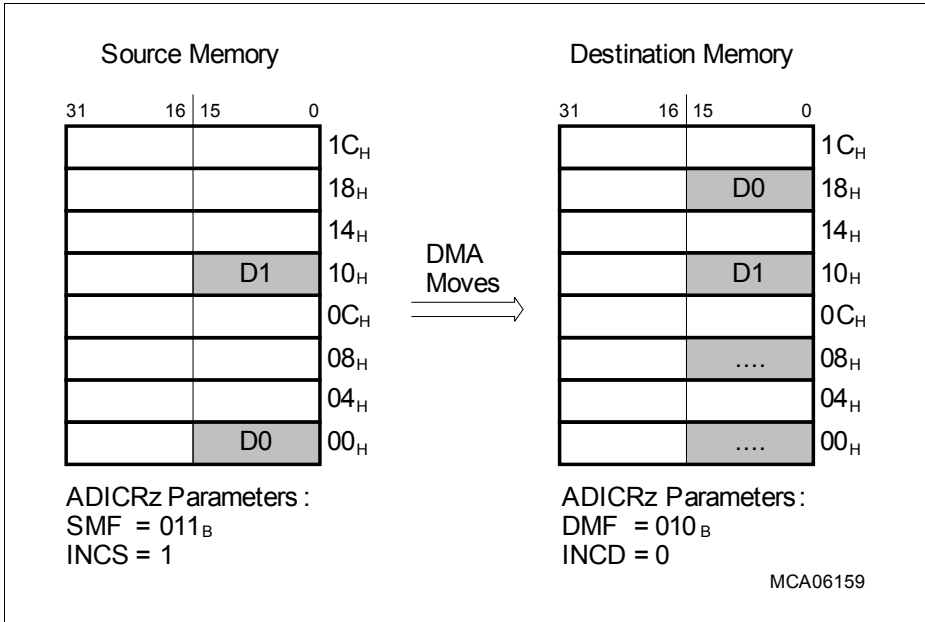

Figure 15-13 Programmable Address Modification - Example 1

Direct Memory Access (DMA)

Programmable Address Modification - Example 2

In **Figure 15-14**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with incrementing destination addresses offset of 04_H .

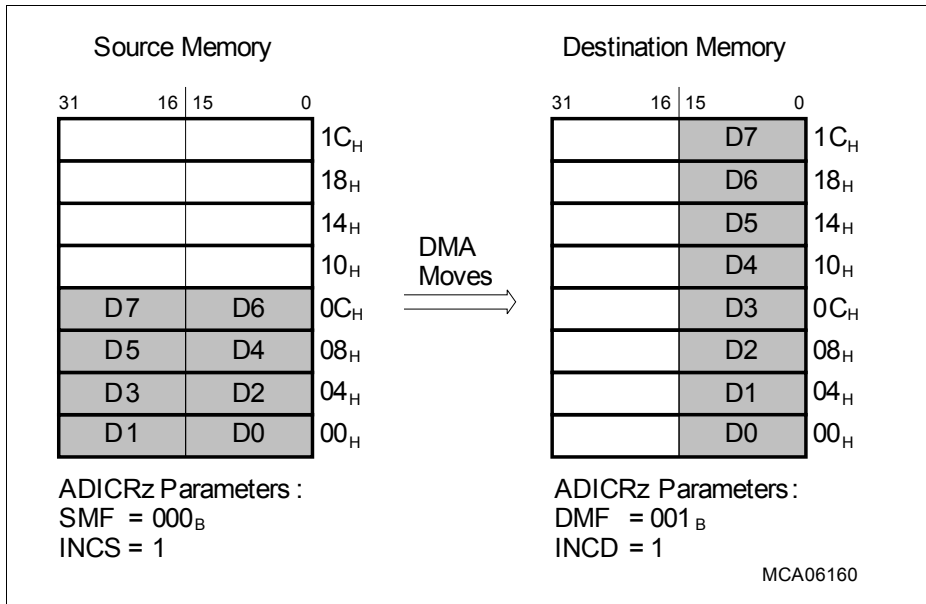

Figure 15-14 Programmable Address Modification - Example 2

15.4.3.8 Circular Buffer

Destination and source address can be configured to build a circular buffer separately for source and destination data. Within this circular buffer, addresses are updated as defined in **Figure 15-13** and **Figure 15-14** with a wrap-around at the buffer limits. The circular buffer length is determined by bit fields ADICRz.CBLS (for the source buffer) and ADICRz.CBLD (for the destination buffer). These 4-bit wide bit fields determine which bits of the 32-bit address remain unchanged at an address update. Possible buffer sizes of the circular buffers can be 2^{CBLS} or 2^{CBLD} bytes (= 1, 2, 4, 8, 16, ... up to 64k bytes).

Source and destination addresses are updated (incremented or decremented) during a DMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS-1:0] or [CBLD-1:0] occurred. This address-freezing mechanism always causes the circular buffers to be aligned to a multiple integer value of its size.

Direct Memory Access (DMA)

If the circular buffer size is less or equal than the selected address offset (see **Figure 15-13**), the same circular buffer address will always be accessed.

The source and destination circular buffers are enabled by setting the circular buffer enable bits ADICRz.SCBE and ADICRz.DCBE respectively.

15.4.3.9 Address Counter

If ADICRz.SCBE = 0 then the source circular buffer is not enabled and the address will increment/decrement determined by ADICRz.INCS across the entire 32-bit address field. The address offset is determined by CHCFGRz.CHDW. The source address will wrap around on the 32-bit address boundary:

- If incrementing will wrap from FFFFFFFF_H to 00000000_H.
- If decrementing will wrap from 00000000_H to FFFFFFFF_H.

15.4.3.10 Flow Control

A timestamp can optionally be attached at the end a DMA transaction to record the occurrence of the event. The timestamp is the time at which the event was recorded by the DMA controller and not the real time.

Timestamp Generation

The timestamp is generated from a 32-bit binary upwards synchronous counter clocked by the SPB clock divided by 8 as shown in **Figure 15-15**. The counting starts automatically after an application reset. It is not possible to affect the counter during normal operation.

Figure 15-15 Timestamp Generation

The current 32-bit count value can be read through the DMA_TIME register.

Timestamp Appendage

The appendage of a timestamp to the destination data at the end of a DMA transaction is controlled by the ADICRz.STAMP bit. If enabled then a 32-bit timestamp will be appended by a DMA write move to the next word aligned address in the destination data

Direct Memory Access (DMA)

sequence. If the address control increment of destination address bit $ADICRz.INCD = 1_B$ then the timestamp will be written at the next higher word aligned destination address and if $ADICRz.INCD = 0_B$ then the timestamp will be written at the next lower word aligned destination address.

If a DMA channel is configured to support circular buffer operation then the timestamp must be appended at the next word aligned address above the circular buffer ($ADICRz.INCD = 1_B$) or below the circular buffer ($ADICRz.INCD = 0_B$). The appendage of the timestamp must not overwrite or change the destination address of circular buffer DMA move data.

Direct Memory Access (DMA)

Appendage of Timestamp - Example 1

In **Figure 15-16**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 10_H to a destination memory with decrementing destination addresses offset of 08_H .

The destination address is incrementing ($ADICRz.INCD = 1_B$) and the timestamp is appended above the destination data.

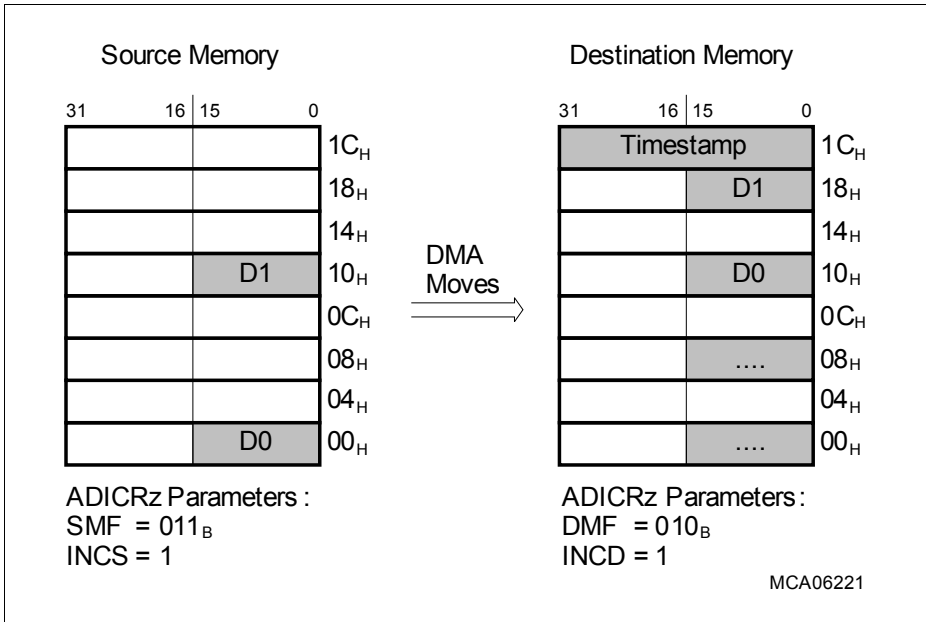

Figure 15-16 Appendage of Timestamp - Example 1 ($ADICRz.INCD = 1$)

Appendage of Timestamp - Example 2

In **Figure 15-17**, 16-bit half-words are transferred from a source memory with an incrementing source address offset of 02_H to a destination memory with decrementing destination addresses offset of 04_H .

The destination address is decrementing ($ADICRz.INCD = 0$) and the timestamp is appended below the destination data.

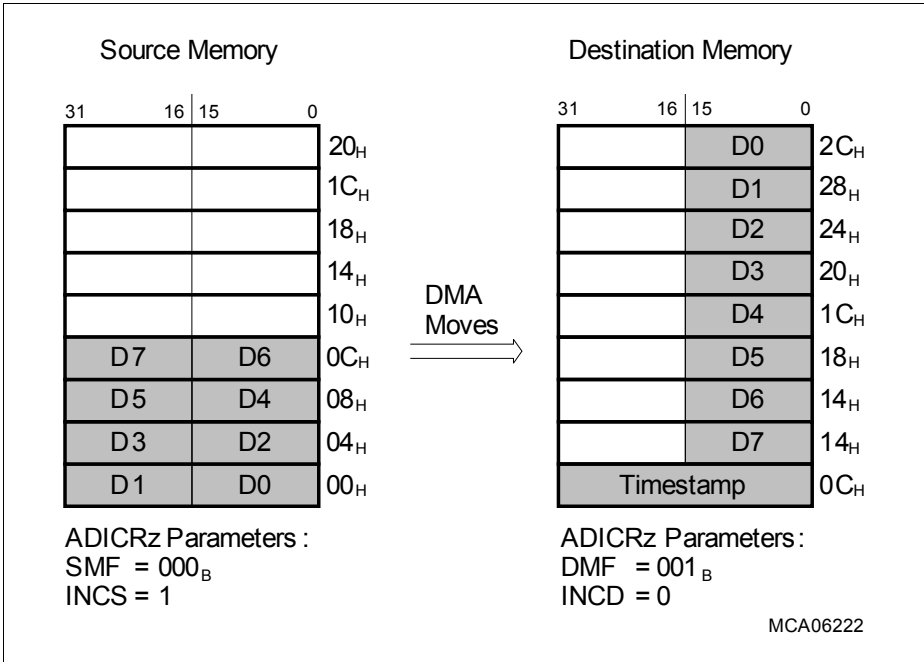

Figure 15-17 Appendage of Timestamp - Example 2 (ADICRz.INCD = 0)

Flow Control

The appendage of timestamps to the end of DMA transactions support flow control. The relative count value of the timestamp can be used to determine the sequence of DMA writes to different destination addresses.

15.4.3.11 Double Buffering Operation

The DMA supports double buffering [Figure 15-18](#) shows an example of double destination buffering. DMA read moves transfer a continuous data stream from a peripheral to the DMA controller and DMA write moves transfer the read data from the DMA controller to one of two destination buffers stored in memory. The data stream can be re-directed via a software switch. The dormant data buffer can be frozen and be available for cyclic software tasks while the other data buffer continues to be filled.

Direct Memory Access (DMA)

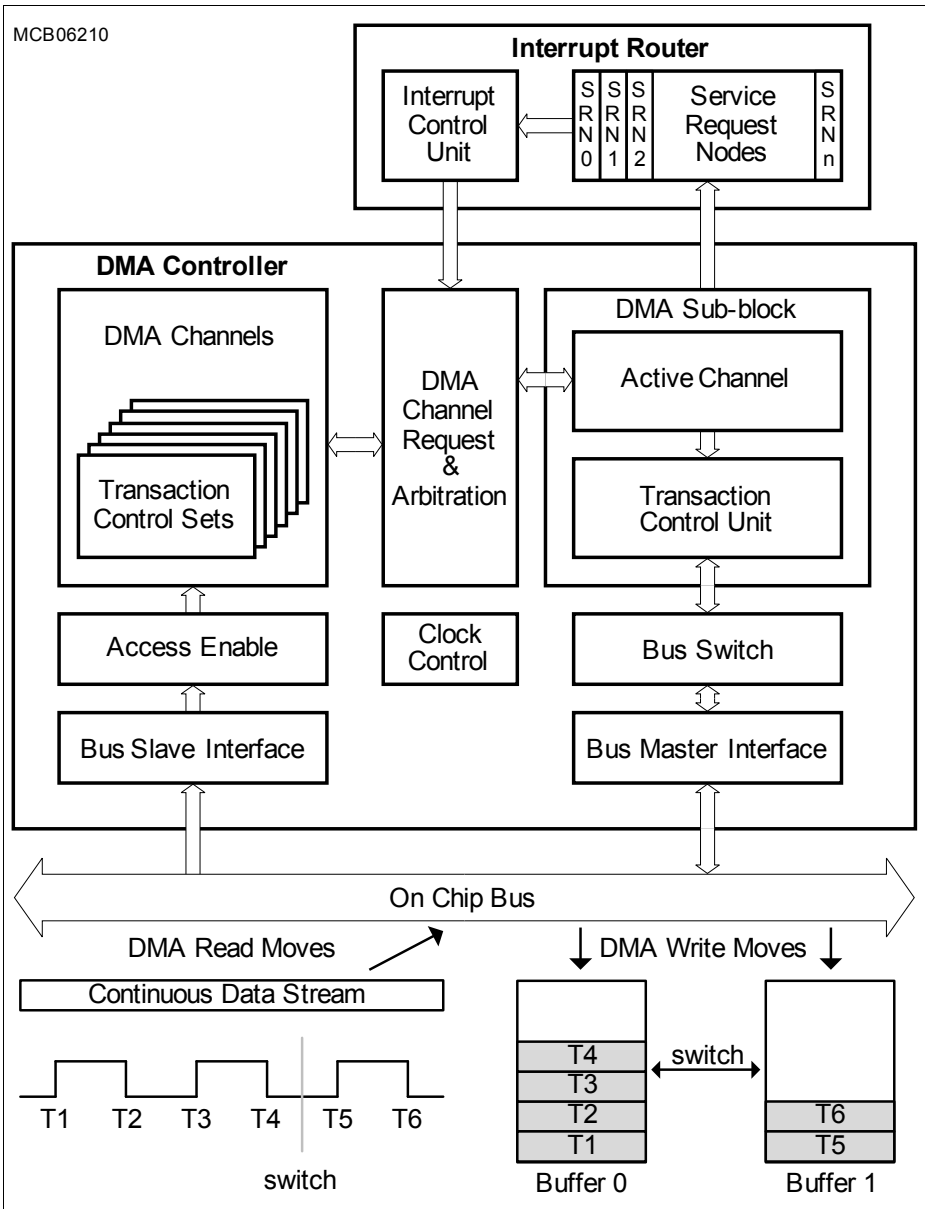

Figure 15-18 DMA Double Buffering

Direct Memory Access (DMA)**Double Source Addressing**

A DMA Channel can be configured to support double source addresses (ADICRz.SHCT[3:1] = 100_B).

Data is streamed by the DMA from one of two data buffers (buffer 0 and buffer 1) stored in memory to a continuous output data stream. Double buffer source addresses:

- The source address SADRz is used to address buffer 0.
- The shadow address SHADRz is used as a source address to address buffer 1.

The size of the two source double buffers is equal and determined by the following DMA transaction control parameters:

- The channel data width (CHCFGRz.CHDW).
- The source circular buffer enable/disable control (ADICRz.SCBE).
- The source address modification factor (ADICRz.SMF).
- The increment of the source address (ADICRz.INCS).
- The block mode value (CHCFGRz.BLKM).
- The transfer reload value (CHCFGRz.TREL).

The size of one source buffer is equal to the size of one DMA transaction.

Double Destination Addressing

A DMA Channel can be configured to support double destination addresses (ADICRz.SHCT[3:1] = 101_B).

A continuous input data stream is directed by the DMA to one of two data buffers (buffer 0 and buffer 1) stored in memory. Double buffer destination addresses:

- The destination address DADRz is used to address buffer 0.
- The shadow address SHADRz is used as a destination address to address buffer 1.

The size of the two destination double buffers is equal and determined by the following DMA transaction parameters:

- The channel data width (CHCFGRz.CHDW).
- The destination circular buffer enable/disable control (ADICRz.DCBE).
- The destination address modification factor (ADICRz.DMF).
- The increment of the destination address (ADICRz.INCD).
- The block mode value (CHCFGRz.BLKM).
- The transfer reload value (CHCFGRz.TREL).

The size of one destination buffer is equal to the size of one DMA transaction.

Active Buffer

During DMA double buffering the CHCSRz.BUFFER status bit is used to indicate which buffer is active.

- MExCHSR.BUFFER = 0_B: buffer 0 is read or filled by the DMA.

Direct Memory Access (DMA)

- MExCHSR.BUFFER = 1_B: buffer 1 is read or filled by the DMA.

Buffer Switching

The re-direction of the data stream from one buffer to the other can be controlled by software and additionally automatically by hardware. Automatic hardware switching is selected by setting ADICRz.SHCT[0] = 1_B. The different DMA double buffering modes are shown in [Table 15-1](#).

Table 15-1 DMA Double Buffering Modes

SHCT	Description
1000 _B	DMA Double Source Buffering Software Switch Only Switching from the current source buffer to the other source buffer is controlled by the software switch CHCSRz.SWB
1001 _B	DMA Double Source Buffering Automatic Hardware and Software Switch DMA controller automatically switches source buffers when current source buffer is emptied. Software source buffer switching controlled by CHCSRz.SWB
1010 _B	DMA Double Destination Buffering Software Switch Only Switching from the current destination buffer to the other destination buffer is controlled by the software switch CHCSRz.SWB
1011 _B	DMA Double Destination Buffering Automatic Hardware and Software Switch DMA controller automatically switches destination buffers when current destination buffer is full. Software destination buffer switching controlled by CHCSRz.SWB

Software Buffer Switch

Before a DMA transaction completes and the active buffer is full software can re-direct the data stream from the active buffer to the other buffer by setting CHCSRz.SWB. If a move engine is actively servicing a DMA channel z configured for double buffering then the current DMA transfer completes before the buffer switch is made.

On completion of the DMA transfer the DMA controller will:

- Automatically re-load MExCHSR.TCOUNT with CHCFGRz.TREL
- Switch the address pointer between the source/destination address and the shadow
 - Buffer 0 address pointer (source or destination address).
 - Buffer 1 address pointer (shadow address).

Direct Memory Access (DMA)

The address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

During a software buffer switch no DMA requests are lost by the DMA controller and there is no loss, duplication or split of data across the two buffers.

Buffer Empty or Full

If the current buffer is emptied (in the case of DMA double source buffering) or filled (in the case of DMA double destination buffering) before a software buffer switch is received then the DMA channel will stop and no more DMA transfers are made. The transaction control set is frozen. The transfer count status (MExCHSR.TCOUNT and CHCSRz.TCOUNT) when the DMA channel is stopped is equal to 0000_H.

The signalling of a buffer empty or full event can be generated by using the DMA channel traffic interrupt service request. The interrupt control ADICRz.INTCT is set to 10_B and the interrupt raise detect value ADICRz.IRDV set to 0000_B. When the transfer count equals zero then the DMA channel will raise a DMA channel interrupt service request.

The DMA channel interrupt handler can interrogate the DMA channel transaction control set to identify which empty or full buffer generated the interrupt. Software can reset the channel ready to restart DMA double buffering operations.

Fast Data Rate

If the data rate is faster than the DMA controller is able to transfer the data to one of the buffers then a transaction request lost event will occur.

If the DMA controller is servicing a DMA access pending request (TSRz.CH = 1_B) and a DMA hardware request is detected then the transaction request lost bit TSRz.TRL will be set. If the enable transaction request lost bit is set (ADICRz.ETRL = 1_B) then a DMA error interrupt service request will be generated.

The DMA error interrupt handler can interrogate the DMA channels and identify the source of the error. Software can reset the DMA channel and restart DMA double buffer operations.

Automatic Hardware Buffer Switch

The DMA controller will automatically switch from the active buffer to the other buffer when the DMA transaction reading or filling the active buffer completes. On switching buffers the MExCHSR.FROZEN bit is set to indicate that one buffer is frozen and available for cyclic software tasks. The interrupt control bits ADICRz.INTCT and interrupt raise detect value MExADICR.IRDV can be used to generate a DMA channel interrupt service request.

On completion of the DMA transaction when MExCHSR.TCOUNT equals 0000_H the DMA controller will:

Direct Memory Access (DMA)

- Automatically re-load MExCHSR.TCOUNT with CHCFGRz.TREL
- Switch the address pointer between the source/destination address and the shadow address:
 - Buffer 0 address pointer (source or destination address).
 - Buffer 1 address pointer (shadow address).

The address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

During an automatic hardware buffer switch no DMA requests are lost by the DMA controller and there is no loss, duplication or split of data across the two buffers.

Frozen Buffer

When the DMA controller switches buffer the frozen bit MExCHSR.FROZEN is set. The frozen buffer is then available for a cyclic software task. On completion of the software task the status bit MExCHSR.FROZEN is cleared by software and the buffer address pointer is re-programmed to the start address ready for the next DMA transaction that reads/fills the buffer.

Transaction Request Lost

If MExCHSR.FROZEN is equal to 1_B then the automatic hardware switch buffer will not occur and the DMA controller will stop. If a DMA hardware request is detected before MExCHSR.FROZEN is cleared then the transaction request lost bit TSRz.TRL is set and a DMA error interrupt service request will be generated if ADICRz.ETRL is 1_B.

Direct Memory Access (DMA)**DMA Double Buffer Operation**

A typical DMA double buffer application is shown in [Figure 15-19](#):

- A DMA read move loads a continuous stream of 32-bit data words from an SPB connected peripheral into the DMA controller.
- A DMA write move stores the data from the DMA controller into one of two destination data buffers connected to the SRI-XBAR.

Double destination buffering with software buffer switch only is selected by using the shadow operation control bits (ADICRz.SHCT = 1010_B) as shown in [Table 15-1](#). The shadow mechanism is not available.

Transaction Control Set

The DMA active channel points at the two buffers as follows:

- The destination address register MExDADR.DADR is the address pointer to buffer 0.
- The shadow address register MExSHADR.SHADR is the address pointer to buffer 1.

The transfer count (CHCFGRz.TREL), block mode (CHCFGRz.BLKM) and address modification factors (CHCFGRz.CHDW, ADICRz.DCBE, ADICRz.DMF and ADICRz.INCD) are the same for the two buffers.

The buffer depth of the two data buffers is identical and is equal to one DMA transaction. The size of the buffer depth is a multiple of the address modification factors, the DMA transfer block mode and the DMA transaction transfer count.

DMA Operation

The DMA channel z configured for double destination buffering is programmed to execute DMA transfers of 2 X 32-bit words from a source peripheral to one of two destination buffers.

The DMA channel receives a DMA request and on winning arbitration executes a DMA transfer. During the second DMA transfer, the DMA channel z receives a swap buffer command. On completion of the current DMA transfer the frozen buffer bit MExCHSR.FROZEN is set.

At the start of the next DMA transfer the incoming data stream is re-directed to buffer 1. No data is lost, duplicated or split between the buffers. MExCHSR.TCOUNT is reloaded with CHCFGRz.TREL and executes DMA moves to the buffer 1 starting at the address stored in MExSHADR. The status bit MExCHSR.BUFFER switches state to indicate that the DMA controller is filling buffer 1. The cyclic software task operates on buffer 0 and on completion clears MExCHSR.FROZEN and re-programmes the destination address register to the buffer 0 start address. Buffer 0 is now available to receive data and the software will issue a switch buffer instruction and in turn buffer 1 will become available for a cyclic software task.

Direct Memory Access (DMA)

Figure 15-19 DMA Double Destination Buffering

Direct Memory Access (DMA)**15.4.3.12 Linked Lists**

Linked lists are an extension of the DMA channel functionality. Linked lists consist of a series of DMA transactions executed by the same DMA channel z. Each DMA transaction has a unique transaction control set. The source and destination areas do not have to exist in contiguous areas of memory. The new DMA transaction can issue a DMA software request and auto start the DMA transaction bypassing the Interrupt Router and so reducing the cumulative latency over a number of DMA transactions.

In a linked list, the current DMA channel transaction control set defines the shadow register as an address pointer to read the next 32-byte transaction control set from anywhere in memory and overwrite the current transaction control set in the DMARAM.

The following types of linked lists are supported:

- DMA Linked List (see [Section 15.4.3.13](#))
- Accumulated Linked List (see [Section 15.4.3.14](#))
- Safe Linked List (see [Section 15.4.3.15](#))
- Conditional Linked List (see [Section 15.4.3.16](#))

Linked lists support greater flexibility in the use of the DMA controller.

Circular Operation of Linked List

Linked lists may be configured for circular operation when the same series of DMA transactions in the linked list are endlessly repeated.

Pattern Detection During a Linked List

If a DMA transaction in a DMA, Accumulated or Safe Linked List is configured for pattern detection then a pattern match (see [Section 15.4.7](#)) will terminate linked list operation. If the pattern match occurs during the last DMA move of the DMA transaction then the current DMA move status is preserved and the next transaction control set is not loaded. Software must reconfigure the DMA channel.

Software Termination of a Linked List

If the linked list is terminated by software then the current DMA transaction is completed and the linked list is disabled.

Direct Memory Access (DMA)**15.4.3.13 DMA Linked List**

A DMA channel z supports a DMA linked list consisting of 32-Byte transaction control sets by using the shadow operation control bits (ADICRz.SHCT = 1100_B) as shown in [Table 15-15](#).

If DMA channel z is configured to support a DMA linked list then when the DMA move engine x completes the servicing of a DMA request from DMA channel z it will read the next transaction control set from memory and overwrite the DMARAM channel z with the new transaction control set. The current DMA transaction uses the shadow address as an address pointer to the next transaction control set. The address pointer to the next transaction control set must be mapped to a 32-byte aligned address in either internal or external memory and configured as shown in [Figure 15-20](#). A BTR4 access can be used to read the new transaction control set. The DMA controller will start reading the new transaction control set from the RDCRCRz word upwards. The last word to be read is CHCSRz.

If CHCSRz.SCH is set to 1 then the new transaction control set will auto start and initiate a new transaction request for DMA channel z. The access pending bit TSRz.CH will be set. The DMA controller will arbitrate against other pending requests on completion of the current DMA transfer. When DMA channel z wins arbitration the new DMA transaction will be serviced. There is no limit to the number of DMA transactions in a DMA linked list.

The DMA transactions in the linked list can be started by hardware or software requests. Auto start of a new DMA channel z transaction control set is limited to software requests.

Last DMA Transaction in DMA Linked List

The DMA traffic management interrupt service requests may be used to signal the completion of the last DMA transaction in the DMA linked list. The last DMA transaction will load a new transaction control set. The auto start is not to be set.

Loading Non Linked List Transaction Control Set

If a DMA linked list loads a non linked list transaction control set then the DMA channel exits linked list mode. The non linked list transaction control set will not auto start.

Direct Memory Access (DMA)

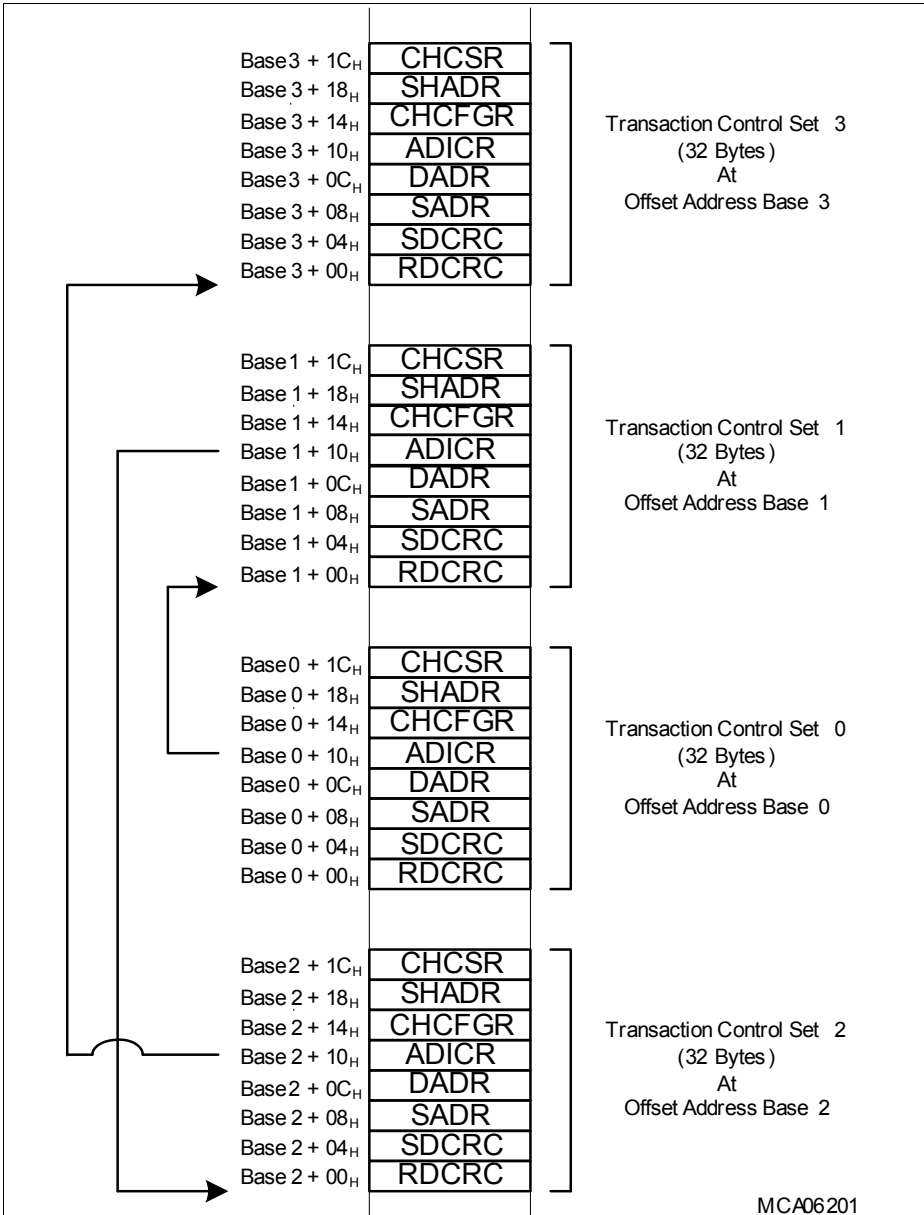

Figure 15-20 DMA Linked List

15.4.3.14 Accumulated Linked List

A DMA channel z supports an accumulated linked list by using the shadow operation control bits ($ADICRz.SHCT = 1101_B$) as shown in [Table 15-15](#). The accumulated linked list is a variant of the DMA linked list and has an identical footprint in memory (size and structure). The $SDCRCRz$ and $RDCRCRz$ words are not overwritten when the new transaction control set is written into the DMARAM channel z and are accumulated across DMA transactions.

SDCRC & RDCRC Checksums

The SDCRC and RDCRC checksums are not overwritten when the new transaction control set is loaded into the DMA channel. On completion of the linked list operation (on completion of the last DMA transaction) the SDCRC and RDCRC checksums are the values calculated across all DMA transactions.

15.4.3.15 Safe Linked List

A Safe linked list provides protection against software errors. If the shadow address in the linked list is incorrectly written then a link address pointer could point to any random area of memory and load a new transaction control set and execute it. A DMA channel z supports a safe linked list by using the shadow operation control bits ($ADICRz.SHCT = 1110_B$) as shown in [Table 15-15](#).

Proceeding from one DMA transaction to the next DMA transaction in the linked list sequence is dependent on the current SDCRC checksum matching the expected SDCRC checksum stored in the next transaction control set.

SDCRC Checksum

The user is required to load the SDCRC word with an expected CRC checksum value. When the safe link list reads the new transaction control set from memory the SDCRC checksum generated by the running DMA transaction is compared against the new expected SDCRC checksum. If the checksums match then the DMA controller proceeds with the execution of the new transaction control set. And if not then a DMA error service interrupt request is triggered, error flag $ERRxSR.SLLER$ set and the DMA stops the execution of the linked list. Assuming all the SDCRC checksum values match at the end of the linked list then the checksum is the value calculated across all DMA transactions.

RDCRC Checksum

The RDCRC checksum word is not overwritten when the new transaction control set is loaded into the DMA channel. The RDCRC checksum value at the end of the linked list is the accumulated checksum across the read data for all DMA transactions.

Direct Memory Access (DMA)

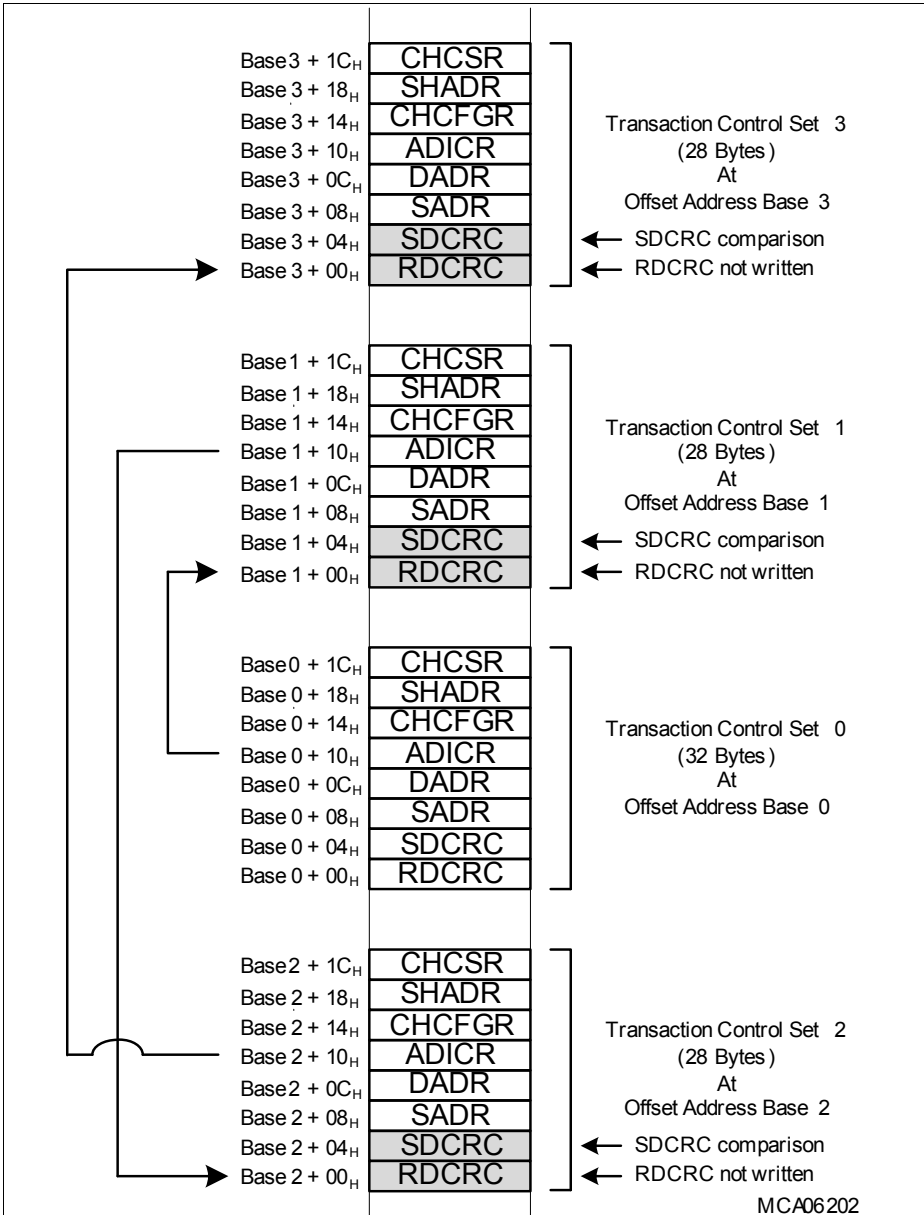

Figure 15-21 Safe Linked List

15.4.3.16 Conditional Linked List

A special use of linked lists is the Conditional Linked Lists (CLL) as shown in **Figure 15-22**. Selection of the address pointer is determined by a conditional state.

A DMA channel supports a Conditional Linked List by using the shadow operation control bits ($ADICRz.SHCT = 1111_B$) as shown in **Table 15-15**. DMA usage of CLL is limited to 8-bit DMA read moves ($CHCFGRz.CHDW = 000_B$). CLL does not support the appendage of timestamps ($ADICRz.STAMP = 0_B$).

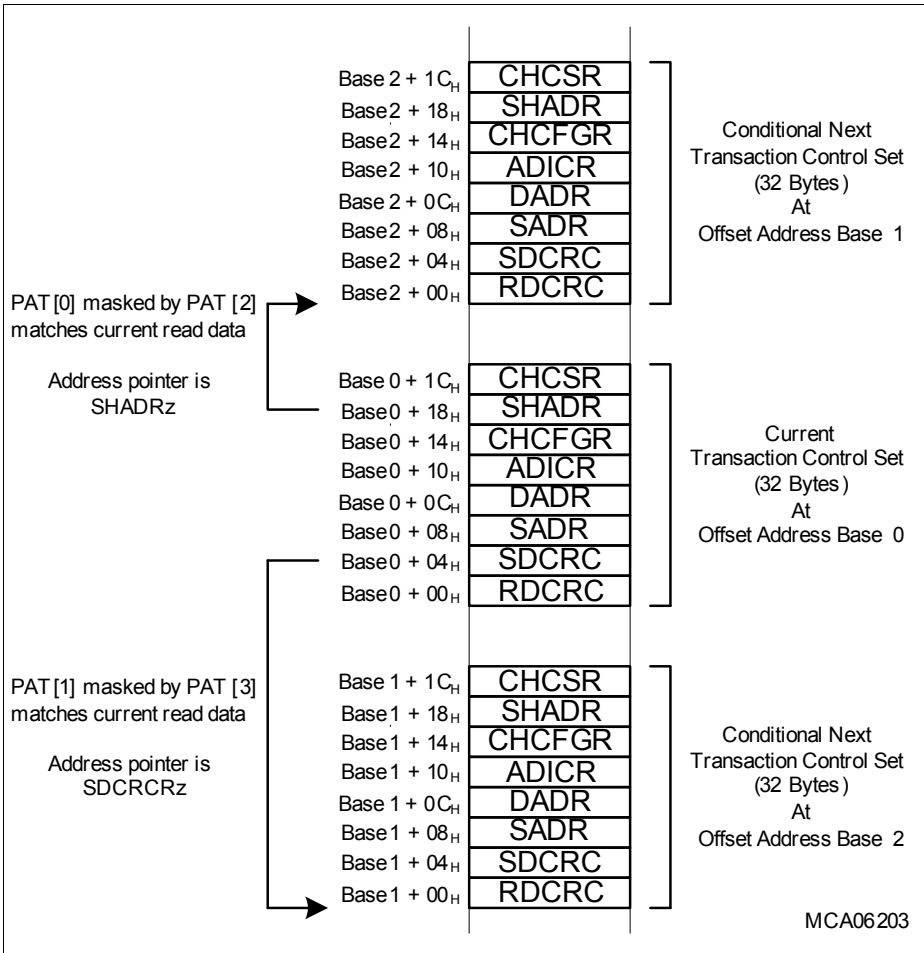

Figure 15-22 Conditional Linked List

Direct Memory Access (DMA)

In addition to using the shadow address as an address pointer CLL utilizes the source and destination address CRC checksum register SDCRCRz as a second address pointer.

CLL Pattern Detection

The DMA channel must be programmed to select one of the pattern read registers:

- PRR0 is selected if CHCFGRz.PATSEL = 000_B
- PRR1 is selected if CHCFGRz.PATSEL = 100_B

Note: If a DMA channel is configured for CLL then CHCFGRz.PATSEL[1:0] = 00_B

The configuration of the pattern detection logic to support conditional linked lists is shown in **Figure 15-23**.

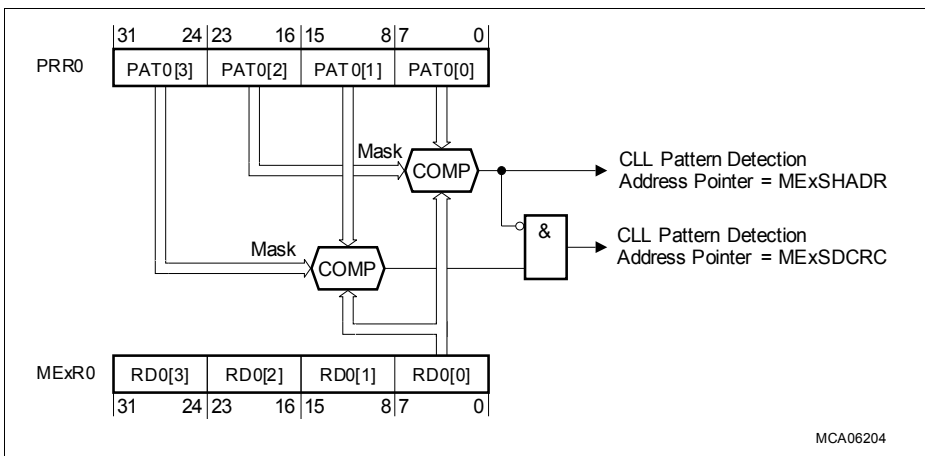

Figure 15-23 Conditional Linked List and Pattern Detection Logic

During each DMA move the pattern detection logic is used to determine the selection of the address pointer:

- If PAT[0] masked by PAT[2] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.
- If PAT[1] masked by PAT[3] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The source and destination address CRC checksum register MExSDCRC stores the address pointer to the next transaction control set in the linked list.
- If both PAT[0] masked by PAT[2] and PAT[1] masked by PAT[3] are matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed

Direct Memory Access (DMA)

load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.

- If there is no match then continue with the DMA transaction.

If a pattern match is detected then:

- The DMA transaction ends with the current DMA move.
- TSRz.CH will clear when the DMA write move has completed.

Completion of Current DMA Transaction

If the current DMA transaction completes when MExCHSR.TCOUNT = 0 and there is no pattern match then the conditional linked list will load a new transaction control set. The shadow address register MExSHADR stores the address pointer to the next transaction control set in the linked list.

Multiple Pattern Detection Conditions

The user may intentionally program PAT[0] masked by PAT[2] not to match with the current read data MEx0R.RD0[0] and transition across a series of DMA transactions in the Conditional Linked List. In each DMA transaction the user may programme a series of different PAT[1] masked by PAT[3] values and test if each value matches with the current read data MEx0R.RD0[0].

If PAT[1] masked by PAT[3] is matching with the current read data MEx0R.RD0[0] then when the current DMA move is completed load a new transaction control set. The source and destination address CRC checksum register MExSDCRC stores the address pointer to the next transaction control set in the linked list.

15.4.4 Transaction Control Engine

Each DMA sub-block has a Transaction Control Unit. The Transaction Control Unit in the DMA sub-block, as shown in the DMA Controller block diagram in [Figure 15-24](#), contains the transaction control set stored in the active channel register set and a move engine.

Figure 15-24 Transaction Control Engine

Any move engine can service hardware or software requests from any DMA channel.

DMA Channel Arbitration

The DMA channel arbitrator continuously monitors DMA channel transfer access pending requests. The highest number DMA channel with an access pending wins the DMA channel arbitration. On winning arbitration the transaction control set is read from the

Direct Memory Access (DMA)

DMARAM and written to the DMA sub-block active channel register set. The DMA channel parameters are passed to the move engine and a DMA transfer composed of a number of DMA moves is processed.

On completion of each DMA transfer the move engine re-arbitrates for the highest priority DMA channel and services the next DMA transfer request. If there is a higher priority DMA transfer request then the current lower priority DMA channel transaction control set is copied to the DMARAM and the active channel register set overwritten with the parameters of the higher priority DMA channel.

If the DMA channel is halted, suspended or has finished the DMA transaction then the move engine will also re-arbitrate for the highest priority DMA request.

DMA Read Buffer

Each DMA move engine includes a 256-bit buffer to store read data from DMA read moves. The read buffer supports the reading of four double words (=256-bit) of data.

A read move to a cached area of memory (Segments 8 and 9) will be translated into an SRI-Bus BTR4 transaction. The 256-bit read data will be stored together with the related 64-bit aligned address in the move engine. If the next and subsequent read access to a segment 8 or 9 address is identical (64-bit aligned) to the current read buffer contents, the requested read data will be read from the read buffer instead of from the SRI-Bus.

If the next read from a segment 8 or 9 address is not identical (64-bit alignments) to the current read buffer contents, the content of the read buffer is invalidated. A BTR4 read request is generated, the read buffer will be updated with the new 256-bit data and its related addresses.

The loading of a new DMA transfer into the move engine or a DMA write to a segment 8 or 9 address invalidates the DMA read buffer.

Address range of segments 8 & 9 is 8000 0000_H - 9FFF FFFF_H.

DMA Move Engine

The move engine requests the required buses and loads or stores data according to the parameters of a DMA transfer. It is able to wait if a targeted bus is not available.

The processing of a DMA transfer (composed of several DMA moves) of a DMA transaction by the move engine cannot be interrupted and is always completed. A DMA channel interrupt, reset, halt request or debug suspend only becomes active when the DMA channel completes the current DMA transfer.

On completion of a DMA transfer the move engine will send back the updated address register information to the active channel register set. If the current DMA channel continues to win arbitration then the move engine will continue processing DMA transfers until the DMA transaction is completed.

Possible source and destination error conditions are also reported.

15.4.4.1 Error Conditions

The DMA move engine reports bus error and source/destination error status. In the case of multiple errors, the error bits are set according to the error conditions. This means that more than one bus error flag and source/destination flag can be set.

The DMA channel should be configured to generate an error interrupt service request.

Bus Errors

The bus error flag ERRSRx.SPBER indicates an SPB Bus error occurred during a move (read or write) of a DMA module transaction.

The bus error flag ERRSRx.SRIER indicates an SRI Bus error that occurred during a move (read or write) of a DMA module transaction.

Source and Destination Errors

The source error flags ERRSRx.SER indicate that an error occurred during a DMA read move from a source address during a DMA transaction of DMA sub-block x.

The destination error flags ERRSRx.DER indicate that an error occurred during a DMA write move to a destination address during a DMA transaction of DMA sub-block x.

If a source or destination error is reported then the DMA transaction completes. If a source error is reported during a DMA read move then the DMA write move is not executed, but the destination address is updated.

Source and destination errors include unsupported types of bus transaction.

Source and Destination Errors in a Linked List

If a DMA channel is configured as a linked list and a source or destination error is reported then the current DMA transaction must complete. In the case of the Conditional Linked List pattern matches will be disabled. The new transaction control set must not be loaded and the linked list stops to allow debug of the current DMA transaction.

Transaction Control Set Load Error in a Linked List

During all linked list operations (DMA, Accumulated, Safe and Conditional) if an error is reported during the loading of a next transaction control set then the error flag ERRSRx.DLLER is set, the last error channel ERRSRx.LEC is recorded and the source of the error is set. The linked list operation will be aborted and the transaction request state bit TSRz.CH bit cleared.

Safe Linked List SDCRC Errors

A Safe Linked List must confirm that the calculated SDCRC checksum matches the expected SDCRC checksum before the next transaction control set is loaded. If the

Direct Memory Access (DMA)

SDCRC checksum does not match then a Safe Linked List error ERRSRx.SLLER is reported.

RAM Errors

When a DMA channel wins arbitration the transaction control set is copied from the DMARAM to the DMA sub-block active channel register set. If an ECC error is signalled during the DMARAM read then the error flag ERRSRx.RAMER is set and the last error channel ERRSRx.LEC recorded. The DMA transfer will be aborted and the transaction request state bit TSRz.CH bit cleared.

Transaction Request Lost

The transaction request lost error flag TSRz.TRL indicates if a DMA request for DMA channel z has been lost.

15.4.5 Bus Switch, Bus Switch Priorities

The bus switch of the DMA controller provides the connection from the DMA sub-blocks and system peripheral masters to on chip bus master interfaces (see [Figure 15-25](#)). One access can be buffered in the bus interfaces.

The Bus Switch supports Switch Address Routing to the whole memory range.

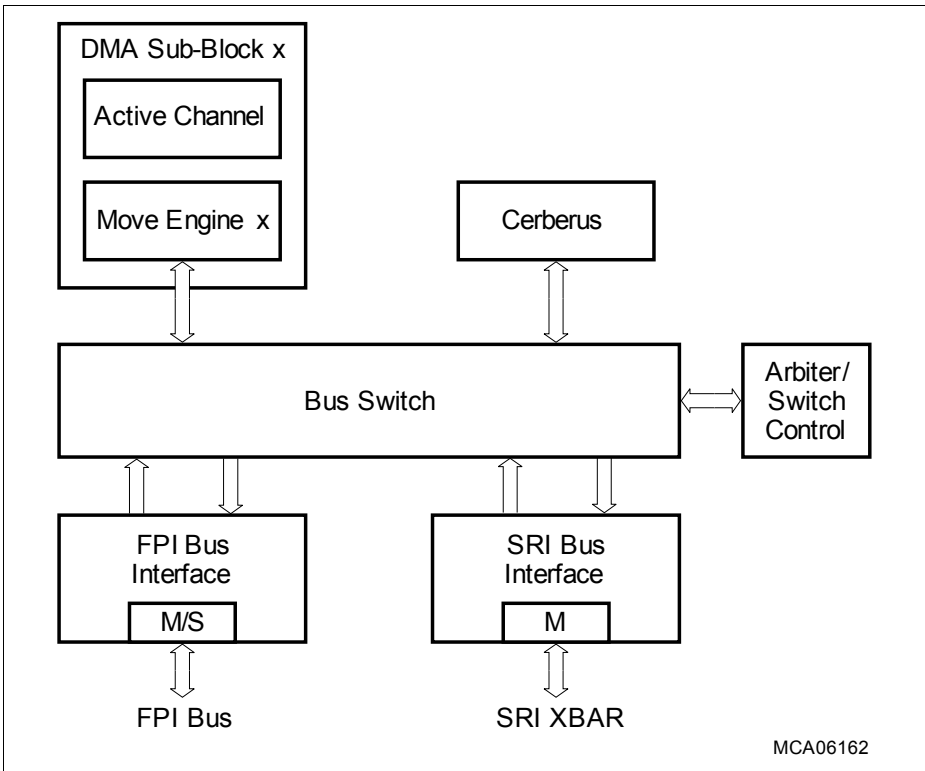

Figure 15-25 Bus Switch

Note: The accesses of the DMA Move Engine’s bus interfaces to the On Chip Bus interfaces are always done in Supervisor Mode.

The arbiter/switch control unit arbitrates the requests from the connected active interfaces (DMA move engines and Cerberus) and grants the buses connected to the switch for data transfers. [Table 15-2](#) and [Table 15-3](#) defines the Bus Switch priorities for requests to the same on chip bus interface. The arbitration scheme is valid in case of a collision of requests from active peripherals connected to the DMA bus switch (move engines) for the same resource (SPB Bus Interface, SRI Bus Interface). The arbitration is done for each bus switch request.

In case of a collision between DMA move engine requests and a Cerberus request on the DMA bus switch for the same resource, the priorities are as given in [Table 15-2](#).

Direct Memory Access (DMA)
Table 15-2 DMA Bus Switch Priorities

Priority	Agent Requests	Comment
Highest	Cerberus to On Chip Bus High	Priority selection by software in Cerberus.
	DMA move engine write	-The detailed Bus Switch priorities for the two engines with concurrent reads or concurrent writes are listed in Table 15-3 .
	DMA move engine read	-The detailed Bus Switch priorities for the two engines with concurrent reads or concurrent writes are listed in Table 15-3 .
Lowest	Cerberus to On Chip Bus Low	Priority selection by software in Cerberus.

Concurrent SRI Accesses

In case of a collision of both move engines with concurrent read requests or concurrent write requests for the SRI resource, the highest channel wins.

Concurrent SPB Accesses

In case of a collision of both move engines with concurrent read requests or concurrent write requests for the SPB resource, the move engine with the highest DMA priority determined by MExCHCR.DMAPRIO determines the winning arbitration on the DMA bus switch (see [Table 15-3](#)).

Table 15-3 DMA SPB Resource Switch Priorities of DMA Move Engines

Priority	DMA Move Engine Request	Comment
Highest	Move Engine x MExCHCR.DMAPRIO = "11"	Move engine with high DMA priority.
	Move Engine x MExCHCR.DMAPRIO = "10"	Move engine with medium DMA priority.
	Move Engine x MExCHCR.DMAPRIO = "01"	Move engine with medium DMA priority.
Lowest	Move Engine x MExCHCR.DMAPRIO = "00"	Move engine with low DMA priority.

If the move engines are processing DMA moves with concurrent read requests or concurrent write requests of equal DMA priority then the move engine processing the highest DMA channel number wins the arbitration at the DMA bus switch.

Direct Memory Access (DMA)**15.4.6 DMA Module Priorities on On Chip Busses**

Every active peripheral connected to the DMA bus switch that requests for access to SPB Bus or SRI Bus has to go through two arbitration stages before accessing the on chip bus: DMA internal arbitration at the DMA bus switch and DMA module external arbitration at the on chip bus.

The DMA can be connected to the SPB Bus and to the SRI Bus with master interfaces.

- The complete list of SPB master priorities can be found in the SPB Bus Control Unit Chapter.
- The complete list of SRI master priorities can be found in the Shared Resource Interconnect Chapter.

15.4.6.1 On Chip Bus Access Rights, RMW support

All accesses triggered by the DMA Move Engines are always done in SV mode.

The DMA module does not support read/modify write instructions.

15.4.6.2 On Chip Bus Master Interfaces

This chapter describes the features of the DMA on chip bus master interfaces to the SPB Bus and to the SRI Bus.

The DMA SPB master interface supports:

- single data read and write transactions (8-bit, 16-bit, 32-bit)
- generation of interleaved FPI transactions from different sources (move engines)
- de-assertion of request after retry in order to prevent bus blocking.
- out of order transactions from different sources in order to avoid side effects (blocking) between the different sources (move engines)
- three dedicated SPB requests (low, medium, high priority)¹⁾.

A single move engine supports only one DMA transaction from one DMA channel at a time and generates a sequence of read - write sequences. The DMA sub-block will not generate permanent, pipelined, high priority requests.

The DMA SRI master interface supports:

- single data read and write transactions (8-bit, 16-bit, 32-bit, 64-bit)²⁾
- block transfer read and write transactions (128-bit, 256-bit)³⁾
- generation of interleaved SRI transactions from different sources (move engines)

1) The complete list of SPB master priorities can be found in the SPB Bus Control Unit Chapter.

2) 64-bit DMA move supported for DMA read move from SRI source to DMA write move to SRI destination

3) Block transfer DMA move supported for DMA read move from SRI source to DMA write move to SRI destination

Direct Memory Access (DMA)

A single move engine supports only one DMA transaction from one DMA channel at a time and generates a sequence of read - write sequences. The DMA sub-block will not generate permanent, pipelined, high priority requests.

15.4.7 Pattern Detection

Pattern detection is only supported for 8-bit, 16-bit and 32-bit channel data width. Only the read data in MEx0R is compared with the value in one of the pattern read registers.

After a DMA read move, read data in the move engine least significant word read register MEx0R can be compared with data stored in one of the pattern read registers. Any move engine can service any DMA channel request. If pattern detection is selected then the DMA channel must be configured to select one of the pattern read registers (PRR0 or PRR1) for the pattern compare.

The result of a pattern compare match is always stored in a bit (MExCHSR.LXO) of the channel status register of the active DMA channel in the move engine x that is currently executing the DMA move. Therefore, the pattern match result LXO of the previous read move can also be combined together with the pattern match result of the actual read move. Move engine x read register MEx0R is overwritten with each read move.

The configuration and capabilities of the pattern detection logic further depends on the settings of MExCHCR.CHDW. CHDW determines the data width for the DMA read and write moves for each individual DMA channel z. The control bits, MExCHCR.PATSEL, selects among the different pattern detection modes for a specific value of CHDW.

If a DMA channel z is configured for pattern detection then the appendage of timestamps is not supported (ADICRz.STAMP = 0_B).

Interrupt Service Request

If MExCHCR.PATSEL[1:0] is not equal to 00_B and a pattern match is detected then:

- The DMA transaction ends with the current DMA move.
- TSRz.HTRE is cleared to stop DMA transfers on the current active channel z.
- TSRz.CH will clear when the DMA write move has completed.
- A pattern detection interrupt service request will be raised corresponding to the current active DMA channel z except in the case that a source error is reported.

The value of MExCHSR.TCOUNT and MEx0R can be read out by the interrupt software.

If MExCHCR.PATSEL=000_B or 100_B then no action will be taken when a pattern match is detected. A wrap interrupt can be used.

The software will have to service the interrupt and to activate the channel again.

15.4.7.1 Pattern Compare Logic

Read move data and compare match patterns are compared on a bit-wise level. The logic as shown in [Figure 15-26](#) is implemented in each COMP block of [Figure 15-27](#), [Figure 15-28](#), and [Figure 15-29](#). One COMP block controls either 8 bits or 16 bits of data and makes it possible to mask each data bit for the compare operation.

In the compare logic for one bit of the COMP block, a data bit from register MEx0R is compared to the corresponding pattern bit stored in a pattern read register. If both bits

Direct Memory Access (DMA)

are equal and a pattern mask bit stored in another part of pattern read register is 0, the compare matched condition becomes active. When the pattern mask bit is set to 1, the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within a COMP block are true, the compare match output line of the COMP block becomes active.

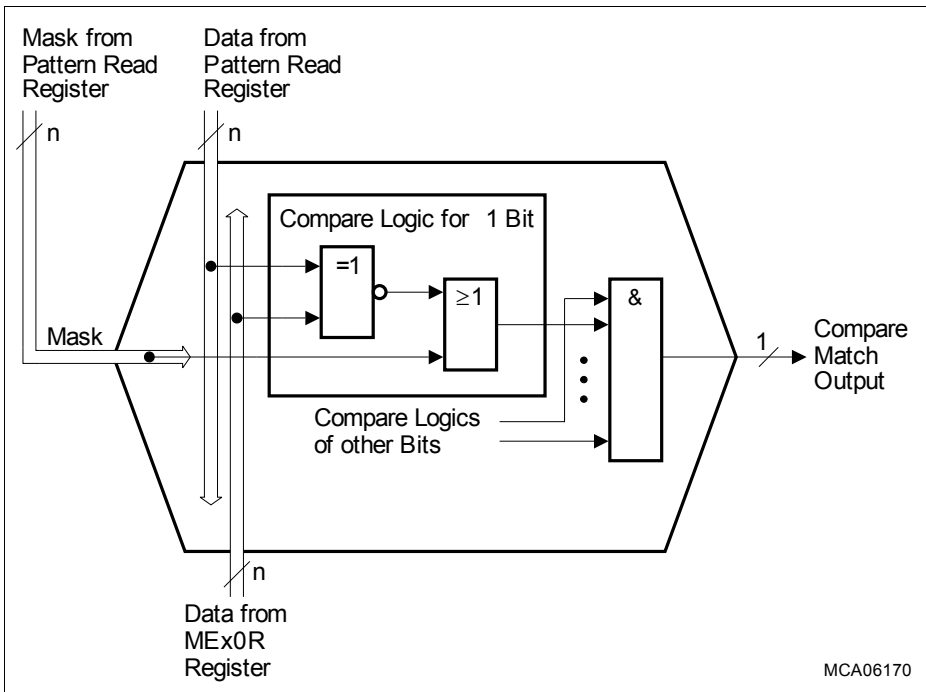

Figure 15-26 Pattern Compare Logic (COMP Block)

15.4.7.2 Pattern Detection for 8-bit Data Width

When 8-bit channel data width is selected ($MExCHCR.CHDW = 000_B$) and the channel is configured to select PRR0 ($MExCHCR.PATSEL[2] = 0_B$), the pattern detection logic is configured as shown in [Figure 15-27](#).

Direct Memory Access (DMA)

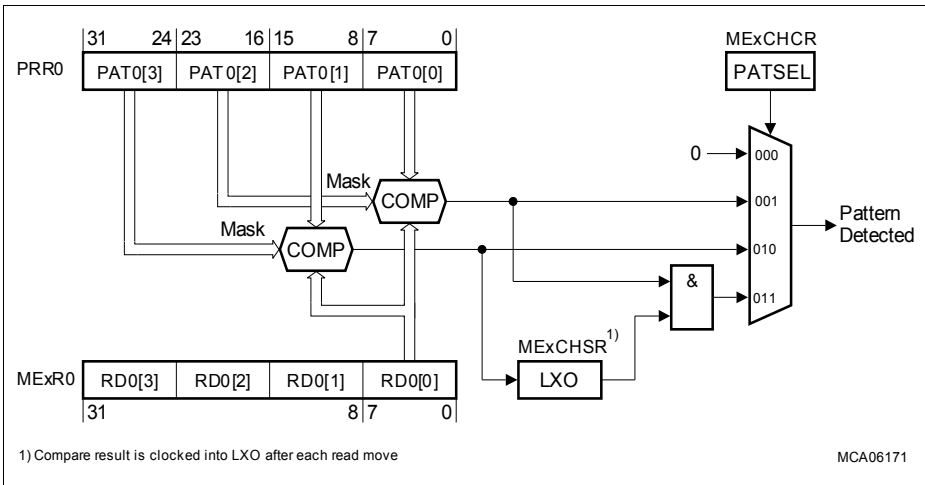

Figure 15-27 Pattern Detection for 8-bit Data Width (MExCHCR.CHDW = 000_B)

When 8-bit channel data width is selected, the pattern detection logic allows the byte of a DMA read move to be compared with two different patterns. Three compare match configurations are possible (see [Table 15-4](#)). A mask operation of each compared bit is possible.

Table 15-4 Pattern Detection for 8-bit Data Width

MExCHCR.PATSEL	Pattern Detection Operating Modes
000 _B	Pattern detection disabled
001 _B	Pattern compare of MExR.RD0[0] to PAT0[0], masked by PAT0[2]
010 _B	Pattern compare of MExR.RD0[0] to PAT0[1], masked by PAT0[3]
011 _B	Pattern compare of MExR.RD0[0] to PAT0[0], masked by PAT0[2] of the <u>actual</u> DMA read move and Pattern compare of MExR.RD0[0] to PAT0[1], masked by PAT0[3] of the <u>previous</u> DMA read move of DMA channel z
100 _B	Pattern detection disabled
101 _B	Pattern compare of MExR.RD0[0] to PAT1[0], masked by PAT1[2]

Direct Memory Access (DMA)

Table 15-4 Pattern Detection for 8-bit Data Width

MExCHCR.PATSEL	Pattern Detection Operating Modes
110 _B	Pattern compare of MExR.RD0[0] to PAT1[1], masked by PAT1[3]
111 _B	Pattern compare of MExR.RD0[0] to PAT1[0], masked by PAT1[2] of the <u>actual</u> DMA read move and Pattern compare of MExR.RD0[0] to PAT1[1], masked by PAT1[3] of the <u>previous</u> DMA read move of DMA channel z

Two Byte Pattern Detection Sequence

If the DMA channel pattern selection is configured to select a two byte sequence (MExCHCR.PATSEL[1:0] = 11_B) against PRR0 (MExCHCR.PATSEL[2] = 0_B) then after each DMA read move the pattern match result "MExOR.RD0[0] with PRR0.PAT0[1], masked by PRR0.PAT0[3]" is stored in bit MExCHSR.LXO.

This operating mode allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial peripheral unit with 8-bit data width (e.g.: recognition of carriage-return, line-feed characters).

15.4.7.3 Pattern Detection for 16-bit Data Width

When 16-bit channel data width is selected (MExCHCR.CHDW = 001_B) and the DMA channel is configured to select to PRR0 (MExCHCR.PATSEL[2] = 0_B), the pattern detection logic can be configured as shown in [Figure 15-28](#).

Direct Memory Access (DMA)

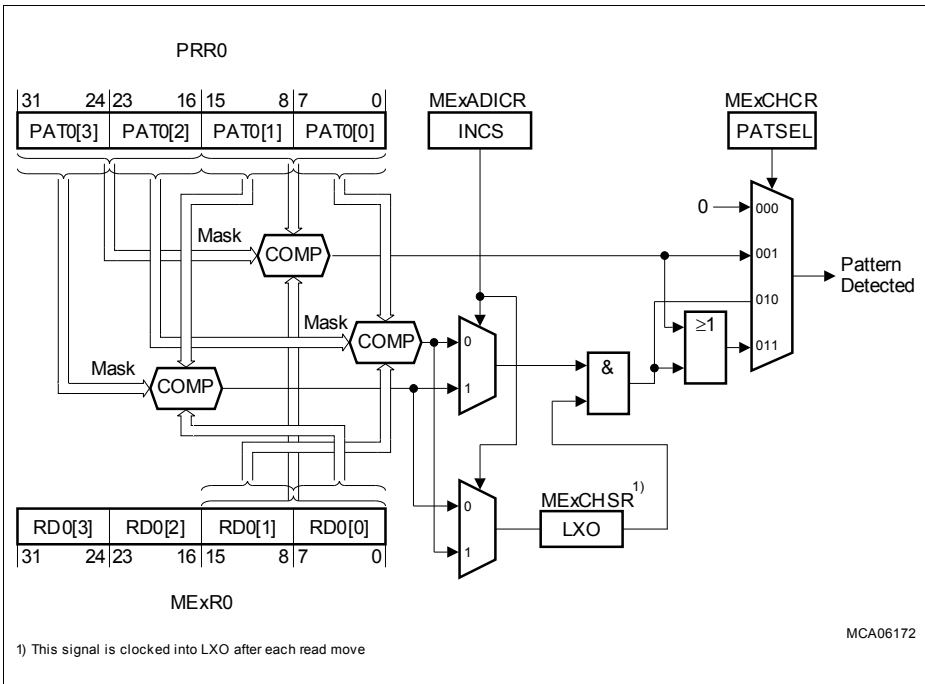

Figure 15-28 Pattern Detection for 16-bit Data Width (CHCFGRz.CHDW = 001_B)

When 16-bit channel data width is selected, the pattern detection logic makes it possible to compare the complete half-word of one read move only (aligned mode) or to compare upper and lower byte of two consecutive read moves (unaligned modes). Both modes can be combined (combined mode) too. Three compare match configurations are possible (see [Table 15-5](#)). A mask operation of each compared bit is possible.

Table 15-5 Pattern Detection for 16-bit Data Width

MExCHCR. PATSEL	MExADICR. INCS	Pattern Detection Operating Modes
000 _B	—	Pattern detection disabled
001 _B	—	Aligned Mode: Pattern compare of MEx0R.RD0[1:0] to PAT0[1:0], masked by PAT0[3:2]

Direct Memory Access (DMA)

Table 15-5 Pattern Detection for 16-bit Data Width (cont'd)

MExCHCR. PATSEL	MExADICR. INCS	Pattern Detection Operating Modes
010 _B	0	Unaligned Mode 1 (Source Address Decrement): Pattern compare of MEx0RMEx1R.RD0[1] to PAT0[0], masked by PAT0[2] of the <u>actual</u> DMA read move and Pattern compare of MEx0R.RD0[0] to PAT0[1], masked by PAT0[3] (LXO) of the <u>previous</u> DMA read move of DMA channel z
	1	Unaligned Mode 2 (Source Address Increment): Pattern compare of MEx0R.RD0[0] to PAT0[1], masked by PAT0[3] of the <u>actual</u> DMA read move and Pattern compare of MEx0R.RD0[1] to PAT0[0], masked by PAT0[2] (LXO) of the <u>previous</u> DMA read move of DMA channel z
011 _B	0 or 1	Combined Mode: Pattern compare for aligned mode (PATSEL = 001 _B) or unaligned modes (PATSEL = 010 _B)
100 _B	–	Pattern detection disabled
101 _B	–	Aligned Mode: Pattern compare of MEx0R.RD0[1:0] to PAT1[1:0], masked by PAT1[3:2]
110 _B	0	Unaligned Mode 1 (Source Address Decrement): Pattern compare of MEx0R.RD0[1] to PAT1[0], masked by PAT1[2] of the <u>actual</u> DMA read move and Pattern compare of MEx0R.RD0[0] to PAT1[1], masked by PAT1[3] (LXO) of the <u>previous</u> DMA read move of DMA channel z
	1	Unaligned Mode 2 (Source Address Increment): Pattern compare of MEx0R.RD0[0] to PAT1[1], masked by PAT1[3] of the <u>actual</u> DMA read move and Pattern compare of MEx0R.RD0[1] to PAT1[0], masked by PAT1[2] (LXO) of the <u>previous</u> DMA read move of DMA channel z
111 _B	0 or 1	Combined Mode: Pattern compare for aligned mode (PATSEL = 101 _B) or unaligned modes (PATSEL = 110 _B)

Unaligned Mode 1

In unaligned mode 1 (source address decremented), the high byte (MEx0R.RD01) of the current and the low byte (MEx0R.RD00) of the previous 16-bit DMA read move are compared.

Unaligned Mode 2

In unaligned mode 2 (source address incremented), the low byte (MEx0R.RD00) of the current and the high byte (MEx0R.RD01) of the previous 16-bit DMA read move are compared.

Combined Mode

If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the combined mode must be used. This mode is the most flexible mode that combines the pattern search capability for aligned and unaligned 16-bit data searches.

15.4.7.4 Pattern Detection for 32-bit Data Width

When 32-bit channel data width is selected (MExCHCR.CHDW = 010_B) the pattern detection logic and the DMA channel is configured to select to PRR0 (MExCHCR.PATSEL[2] = 0_B), is configured as shown in [Figure 15-29](#).

Figure 15-29 Pattern Detection for 32-bit Data Width (MExCHCR.CHDW = 010_B)

In 32-bit channel data width mode, the pattern detection logic makes it possible to compare the lower half-word only, the upper half-word only, or the complete 32-bit word

Direct Memory Access (DMA)

with a pattern stored in the pattern read register. Three compare match configurations are possible (see [Table 15-6](#)). A mask operation is not possible.

Table 15-6 Pattern Detection for 32-bit Data Width

MExCHCR.PATSEL	Pattern Detection Operating Modes
000 _B	Pattern detection disabled
001 _B	Unmasked pattern compare of RD0[1:0] to PAT0[1:0]
010 _B	Unmasked pattern compare of RD0[3:2] to PAT0[3:2]
011 _B	Unmasked pattern compare of RD0[3:0] to PAT0[3:0]
100 _B	Pattern detection disabled
101 _B	Unmasked pattern compare of RD0[1:0] to PAT1[1:0]
110 _B	Unmasked pattern compare of RD0[3:2] to PAT1[3:2]
111 _B	Unmasked pattern compare of RD0[3:0] to PAT1[3:0]

Direct Memory Access (DMA)**15.4.8 DMA Configuration Interface**

The DMA controller implements a standard FPI slave interface compliant with the FPI bus protocol on the SPB bus. The SPB slave interface supports the following functions:

- Control of the DMA general control registers to support clock control, power management, debug, etc.
- Reading and writing DMA registers that manage DMA transactions.
- Reading and writing the transaction control set for each DMARAM channel z.
- Reading the active channel transaction registers in the DMA sub-block.
- Configuring and reading the move engine and error registers.

The DMA controller supports single data transfers and does not support block transfers.

15.4.8.1 DMARAM Channel Control and Status Word

The DMARAM Control and Status Word CHCSRz supports two functions:

- Storing channel status bits including the transfer count status. The status is updated when the active channel is written back on completion of a DMA transaction or on completion of a DMA transfer on losing channel arbitration.
- Write only triggers to set and clear state in the channel configuration and status.

The write only control and clear triggers (CHCSRz.SCH, TSRz.ECH, TSRz.DCH, CHCSRz.SWB, CHCSRz.CICH, CHCSRz.CWRP and CHCSRz.SIT) can be written independently of the channel transaction state (active, pending or idle).

15.4.8.2 DMA Active Channel Write Back

A DMA channel is active when a move engine services a hardware or software request. When a pending DMA channel request wins arbitration the transaction control set is copied from the DMARAM and loaded into the DMA sub-block active channel registers and the active channel field MExSR.CH is updated. The DMA channel is defined to be active.

The point at which transaction control set is written back to the DMARAM is dependent on the MExCHCR.RROAT:

- MExCHCR.RROAT = 0, the transaction control set is written back on completion of each DMA transfer.
- MExCHCR.RROAT = 1, the transaction control set is written back when the DMA channel loses channel arbitration and completes the current DMA transfer.

If a write back has occurred then the transaction control set stored in the DMARAM will not match the transaction control set held in the DMA sub-block active channel registers.

Direct Memory Access (DMA)

15.4.8.3 DMA Active Channel Shadow Control

An SPB write to a DMARAM channel z addresses other than the CHCSRz word when DMA channel z transaction request state bit TSRz.CH has an access pending will result in a bus error with the following shadow address source or destination address buffering exceptions as defined in [Table 15-7](#).

Table 15-7 DMA Active Channel SPB Write Shadow Control Exceptions

SHCT	Description
0001 _B	<p>Source Address Buffering (Read Only)</p> <p>Active DMA channel z SPB writes to the source address SADRz are permitted. Direct Memory Access (DMA)

15.4.8.4 DMARAM Write Back During Linked List Execution

When a linked list is executed by move engine x the contents of the move engine read register are selectively written back to the DMARAM transaction control set as defined in [Table 15-8](#).

Table 15-8 Linked List Write Backs

SHCT	Description
1100 _B	<p>DMA Linked List</p> <p>The DMA controller reads a DMA channel transaction control set and overwrites 8 X words in the DMARAM.</p> <p><i>Note: The SDCRC and RDCRC checksums are unique for each DMA transaction in the DMA Linked List.</i></p>
1101 _B	<p>Accumulated Linked List</p> <p>The DMA controller reads a DMA channel transaction control set and overwrites 6 X words in the DMA RAM. The SDCRC and RDCRC words are not overwritten.</p> <p><i>Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the DMA Linked List.</i></p>
1110 _B	<p>Safe Linked List</p> <p>The DMA controller reads a DMA channel transaction control set. The Linked List only proceeds with the next DMA transaction if the existing SDCRC checksum matches the expected SDCRC checksum in the loaded from the new DMA transaction control set.</p> <p><i>Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the DMA Linked List.</i></p>
1111 _B	<p>Conditional Linked List</p> <p>Shadow address register (MExSHADR) and source and destination address CRC register (MExSDCRC) are used as address pointers to a DMA linked lists. The selection of the address pointer is determined by DMA channel pattern detection conditions.</p> <p><i>Note: Calculation of SDCRC checksums is not supported.</i></p>

15.4.9 Interrupt Service Requests

The interrupt structure of the DMA controller is very flexible. There are five different types of interrupt events. The service control registers are located in the Interrupt Router.

- Each DMA channel has its own interrupt service request that covers DMA channel traffic management events:
 - Channel transfer interrupt service request
 - Channel pattern detection interrupt service request
 - Channel source and destination wrap buffer interrupt service requests
- The DMA controller has one interrupt service request covering all error events:
 - Channel transaction request lost interrupt service request
 - Channel safe linked list SDCRC checksum comparison error
 - Move engine source and destination error interrupt service request
 - Read DMARAM ECC error interrupt service request
 - DMA linked list transaction control set load error interrupt service request

The DMA controller interrupt service requests are shown in [Figure 15-30](#). The number of interrupt service requests in the DMA controller is one greater than the number of DMA channels.

The channel interrupt service requests detect normal DMA traffic events and raise an interrupt request via the shared DMA channel interrupt service request output. The interrupt event is internally generated as a request pulse and always stored in the active DMA Channel Status Register MEXCHSR.

The move engine interrupt service requests detect error conditions and raise an interrupt request via the shared error interrupt service request output. Source and destination errors are stored in the move engine error status register ERRSRx. The transaction request lost condition is stored in the channel status register TSRz.TRL. A transaction request lost error interrupt service request is generated if ADICRz.ETRL enables the service request when channel z becomes an active DMA channel.

The routing of both channel transaction request lost and move engine source and destination error conditions via the error interrupt service request centralizes the reporting of all errors in each DMA sub-block to one interrupt service request. In the event that a DMA error interrupt request is raised then the error handler will read the contents of the move engine error status register ERRSRx and all the TSRz.TRL bits to identify the source of the error.

Software Activation of Interrupt Service Requests

Each channel interrupt service request can be activated by programming CHCSRz.SIT. The error interrupt service request can be activated by programming ERRINTR.SIT.

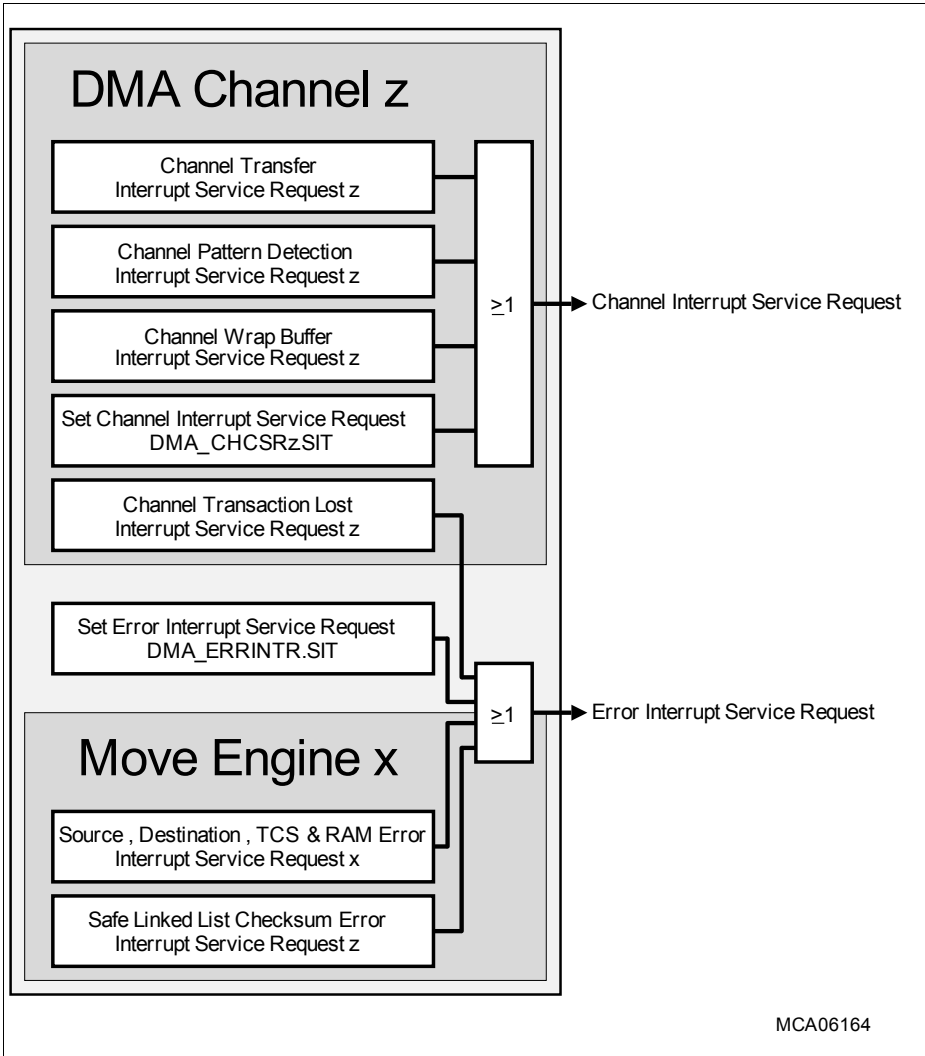

Figure 15-30 DMA Controller Interrupt Service Requests

The following sections describe each of the interrupt service request types in detail.

15.4.9.1 Channel Transfer Interrupt Service Request

The channel transfer interrupt service request is always activated after a DMA transfer, or when MExCHSR.TCOUNT matches with the value of bit field MExADICR.IRDV after it has been decremented after a DMA transfer. A channel transfer interrupt is indicated when status flag MExCHSR.ICH (CHCSRz.ICH) is set. The status flag can be reset together by software when setting bit CHCSRz.CICH (or TSRz.RST). The channel interrupt of DMA channel z is enabled when bit ADICRz.INTCT[1] is set.

Bit MExADICR.INTCT[0] selects one of two types of interrupt source. For the compare operation, bit field MExADICR.IRDV (4-bit) is zero-extended to 14-bit and then compared with the 14-bit TCOUNT value. This means that a TCOUNT match interrupt can be generated after one of the last 16 DMA transfers of a DMA transaction. Note that with $IRDV = 0000_B$, the match interrupt is generated at the end of a DMA transaction (after the last DMA transfer).

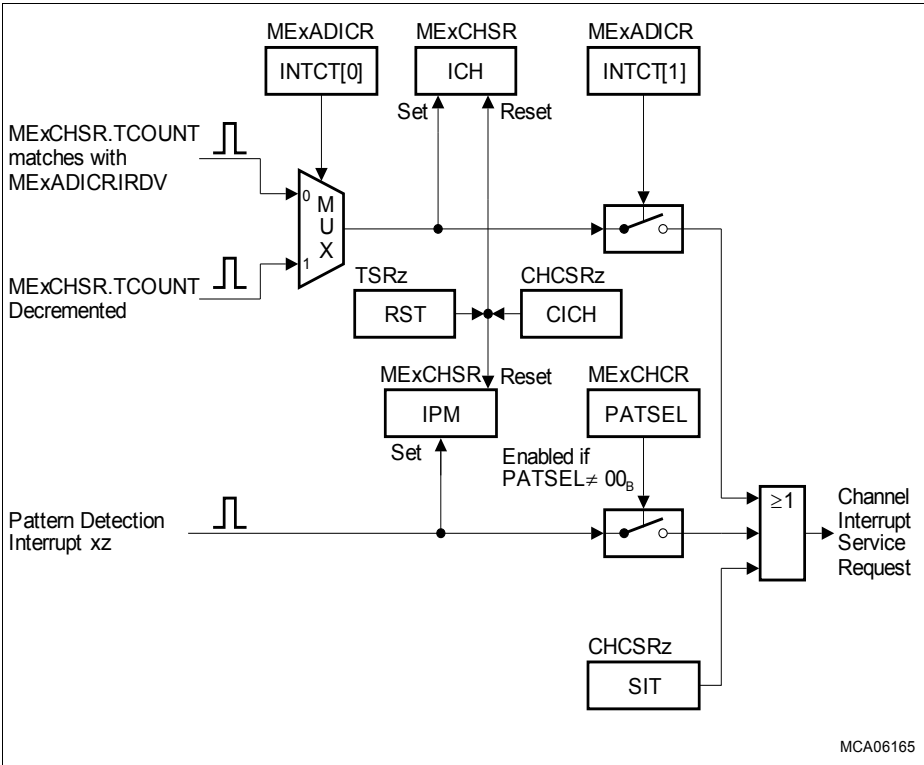

If MExCHCR.PRSEL = 1B for DMA channel z then the channel transfer service request interrupt is masked and the access pending bit is set in the next lower priority DMA channel z-1.

15.4.9.2 Channel Pattern Detection Interrupt Service Request

The channel pattern detection interrupt service request is enabled when MExCHCR.PATSEL[1:0] is not equal 00_B . The pattern detection interrupt is indicated when status flag MExCHSR.IPM is set. The status flag MExCHSR.IPM can be reset together by software when setting bit CHCSRz.CICH (or TSRz.RST).

Further details on the pattern detection are described in [Section 15.4.7](#).

Direct Memory Access (DMA)

MCA06165

Figure 15-31 Channel Transfer and Pattern Detection Interrupt Service Requests

Figure 15-31 shows the implementation of the channel transfer interrupt service request, the pattern detection interrupt service request and the channel set interrupt service request functions.

15.4.9.3 Channel Wrap Buffer Interrupt Service Request

Each DMA channel z is able to generate a wrap buffer interrupt for source buffer or destination buffer overflow.

A wrap source buffer interrupt of DMA channel z is indicated by status flag MExCHSR.WRPS. A wrap destination buffer interrupt of DMA channel z is indicated by the status flag MExCHSR.WRPD. Both interrupt status flags can be reset by software when bit CHCSRz.CWRP (or TSRz.RST) becomes set. The wrap source buffer interrupt is enabled when bit MExADICR.WRPSE is set. The wrap destination buffer interrupt is enabled when bit MExADICR.WRPDE is set. The two interrupts for wrap source buffer and wrap destination buffer are OR-ed together with other channel interrupt service requests to form one common channel interrupt service request.

The channel pattern match detection must not be enabled while a wrap interrupt is enabled for the same channel.

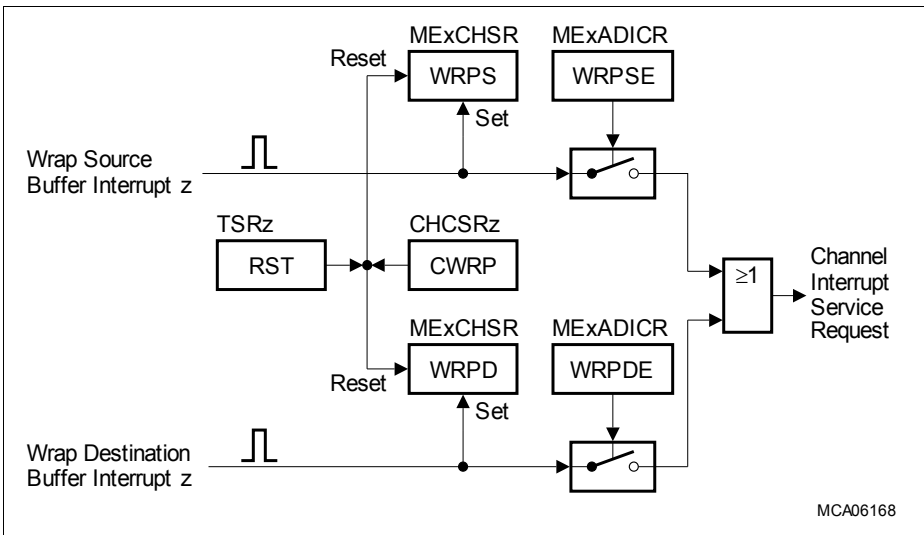

Figure 15-32 Channel Wrap Buffer Interrupt Service Requests

15.4.9.4 Transaction Request Lost Interrupt Service Request

Each DMA channel z is able to detect a transaction request lost condition. This condition becomes true when a new hardware or software DMA request occurs while the previous transaction or transfer on DMA channel z is not finished, indicated by TSRz.CH is still set. If such a transaction request lost condition occurs then bit TSRz.TRL is set.

A transaction request lost condition of DMA channel z is indicated by status flag TSRz.TRL, which can be reset by setting bit TSRz.CTL or TSRz.RST.

Figure 15-33 Transaction Request Lost Interrupt Service Requests

Interrupt Service Request

The transaction request lost interrupt service request for DMA channel z is enabled when bit ADICRz.ETRL is set. The interrupt service request is routed via the DMA error service request.

15.4.9.5 Source and Destination Error Interrupt Service Requests

The Move Engine is able to detect error conditions that occur during accesses to the bus interfaces of the Bus Switch (see [Figure 15-25](#)). Two error conditions can be detected:

- Source error indicates a bus error occurred during a read move from the data source.
- Destination error indicates a bus error that occurred during a write move to the data destination.

A source error of Move Engine x is indicated by the status flag ERRSRx.SER. Status flag ERRSRx.SER can be reset by software when setting bit CLREx.CSER. The source error interrupt of Move Engine x is enabled when bit EERx.ESER is set. Separate reset, status, and enable bits are available in the Move Engines for source error condition, as well as for destination error condition.

Note that in case of a read move error, the write move is not executed but the destination address is updated.

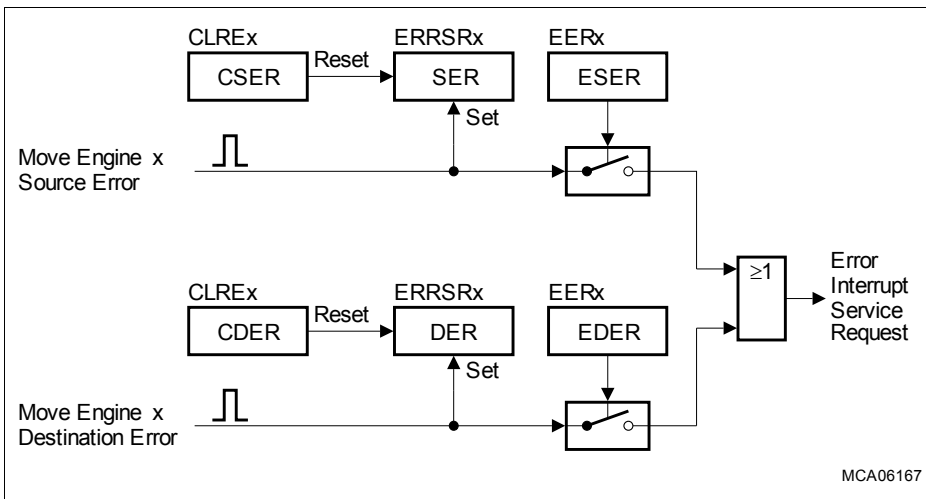

Figure 15-34 Move Engine Interrupt Service Requests

When a move engine source or destination error occurs, additional status bits and bit fields are provided in the error status register ERRSRx to indicate the following two status conditions:

- At which on chip bus interface a move engine error occurred.
- For which DMA channel z a move engine read or write move error was reported (ERRSRx.LEC).

Direct Memory Access (DMA)

These error status bits and bit fields are required by error handler software to detect in detail at which on chip bus interface and DMA channel z the move engine error has been generated.

- ERRSRx.SPBER is reset when bit CLREx.CSPBER is set.
- ERRSRx.SRIER is reset when bit CLREx.CSRIER is set.

The move engine interrupt service request can be activated by programming ERRINTR.SIT.

15.4.9.6 DMA Linked List Error Interrupt Service Request

During all DMA linked list operations the move engine is able to detect an error if the next transaction control set is not loaded correctly. This condition becomes true when a bus error is reported.

A DMA linked list error is indicated by the error status flag ERRSRx.DLLER. Status flag ERRSRx.DLLER can be reset by software when setting bit CLREx.CDLLER. Additional status bits are provided to indicate the following:

- At which on chip bus interface a move engine error occurred.
- For which DMA channel z the error was reported (ERRSRx.LEC).

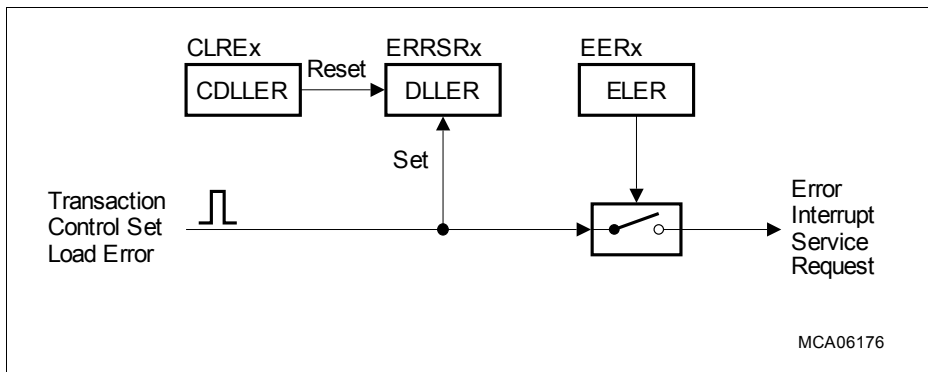

Figure 15-35 DMA Linked List Error Interrupt Service Requests

Interrupt Service Request

The DMA linked list error interrupt service request is enabled when bit EERx.ELER is set. The interrupt service request is routed via the DMA error service request.

15.5 Power Modes

15.5.1 Sleep Mode

Sleep Mode is enabled by the DMA Clock Control Register active low Sleep Mode Enable Control bit DMA_CLC.EDIS. If the enable bit is active when the sleep request input is activated then the DMA clock will be switched off when the move engines have completed any pending DMA transfers.

15.6 Functional Safety Features

15.6.1 Access Protection

A slave destination controls access to its bus peripheral interfaces and kernel address registers. Each on chip resource with bus master capability has a unique master tag identifier that is used to identify the source of an on chip bus transaction. The master tag identifier based access protection is used to enable write accesses to individual slave address ranges. There is no master tag identifier access control associated with read accesses.

Each DMA channel *z* including its transaction control set stored in DMARAM is assigned to one of *y* hardware resource partitions (default 0) and is write access control protected. Write accesses to DMA channel *z* control registers are only possible if the on chip bus master performing the write access has its master tag identifier enabled by the assigned hardware resource partition. Groups of DMA channels can be assigned to a hardware resource and write accesses are limited to individual on chip bus masters.

DMA Master Tag Identifiers

Each hardware resource partition supports a unique master tag identifier as shown in [Table 15-9](#). The master tag identifier is driven onto the bus during a read or write access and allows the bus controller to identify the hardware resource requesting the access.

Table 15-9 Bus Master Tag Identifiers

Hardware Partition	Master Tag Identifier
DMA Hardware Resource 0	000110
DMA Hardware Resource 1	000111
DMA Hardware Resource 2	001000
DMA Hardware Resource 3	001001

Direct Memory Access (DMA)**DMA Supervisor/User Mode**

The supervisor or user mode setting for a hardware resource is determined by the control bit `MODEy.MODE`. All the DMA channels assigned to a hardware resource assume the hardware resource supervisor or user mode setting. If the DMA bus master accesses a supervisor mode protected slave interface in user mode then the slave will reply with `ERR` acknowledge. The response will be recorded in the Move Engine x Error Status Register.

DMA Write Move

A DMA channel is programmed to read data from a source address and write the data to a destination address. For a DMA write move operation to successfully complete the slave access control logic must enable write accesses to the destination address for the bus master tag identifier of the requesting DMA hardware resource.

15.6.2 Data Integrity

The following data integrity error conditions are detected in the DMA and reported to the SMU:

- Error Correcting Code (ECC) errors generated by the DMARAM.
- Error Correcting Code (ECC) errors generated from SRI data.

15.6.2.1 DMARAM

The DMA controller detects several different classes of ECC error. These errors will set a status flag in the `MEMCON` register and send a trigger to the SMU for the processing of the error condition. ECC errors are reported for the following error conditions:

Internal ECC Error

The DMARAM is accessed by the internal DMA controller logic during the loading of the transaction control set into the DMA sub-block. If an ECC error occurs then the `MEMCON.INTERR` is set and a trigger is sent to the SMU. The DMA transaction will not take place and the channel number will be recorded in the move engine last error channel bit field `ERRSRx.LEC` and the error status bit `ERRSRx.RAMER` set.

SPB Read Access

If an ECC error is signalled during an SPB read access to the DMARAM then the `MEMCON.DATAERR` status bit will be set and a trigger sent to the SMU.

SPB Write Access

An SPB write access will require the DMARAM to perform an internal Read Modify Write (iRMW). If an ECC error is reported by the DMARAM during the read phase then the

Direct Memory Access (DMA)

MEMCON.RMWERR bit will be set and a trigger sent to the SMU. The write phase of the iRMW will not take place.

15.6.2.2 DMA SRI Read and Write Data

The SRI Bus protocol supports the reliable delivery of data between sources and destinations by extending the protocol to include ECC. The ECC word is generated across the address and data words. The DMA read move supports data integrity checking for data sourced from SRI Bus destinations. The ECC word is recoded for a subsequent DMA Write Move to an SRI Bus destination address.

ECC errors can be generated at two locations in the DMA:

- The DMA checks the integrity of read data received across the SRI Bus from SRI sources during a DMA read move.
- Write data to SRI destinations will be sourced from the Move Engine Read Register and is checked for data integrity during a DMA write move.

System Peripheral Bus

The SPB-Bus protocol does not support data integrity checking. ECC extensions will be generated when the read data is stored in the Move Engine Read Register. The integrity of SPB sourced data will be checked when it is written to the SRI Bus.

Data Integrity Testing

The alarm can also be triggered by software. The MBIST is used to generate an ECC error condition in a memory used as a DMA source. When the data is passed through the DMA it will generate an ECC error condition. See MTU chapter for details.

15.7 Debug Features

The DMA controller supports the following debugging capabilities:

- Channel suspend
- OCDS Trigger Bus
- MCDS Trace Interface

15.7.1 Channel Suspend Mode

The on chip debug control unit is able to generate a channel suspend mode request (SUSREQ) for the DMA controller. When this channel suspend request becomes active, the state of a DMA channel becomes frozen regarding hardware changes to ensure that the state of the DMA channels can be analyzed by reading the register contents. Pending transfers in the DMA module on chip Bus master interfaces (SPB master interface, SRI master interface) are completed. The DMA controller signals its channel suspend mode back to the on chip debug control via a suspend acknowledge.

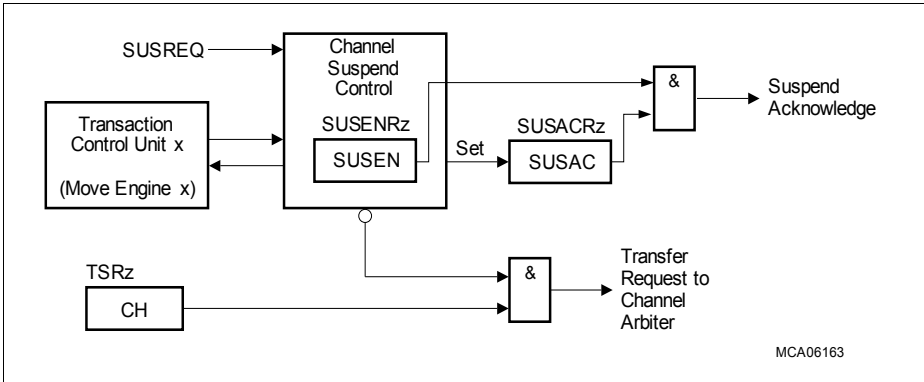

Figure 15-36 Channel Suspend Mode Control

Entering Channel Suspend Mode

Channel suspend mode of DMA channel z is entered if its suspend enable bit in the Suspend Mode Enable Register SUSENRz.SUSEN is set. When SUSREQ becomes active, the operation of all DMA channels enabled for channel suspend mode is stopped automatically after their current DMA transfer has finished in the transaction control unit. Afterwards, the suspend active status flag SUSACRz.SUSAC is set, indicating that DMA channel z is in channel suspend mode.

The DMA suspend acknowledge becomes active when all DMA channels z that are enabled for the Channel Suspend Mode have set their suspend active status flag SUSACRz.SUSAC. In Channel Suspend Mode, register contents can be modified. These modifications are taken into account for further DMA transactions or DMA transfers of the related DMA channel after Suspend Mode has been left again.

DMA channels that are disabled for Suspend Mode (SUSENRz.SUSEN = 0) continue with its normal operation.

Exiting Channel Suspend Mode

Channel suspend mode of DMA channel z is left and its normal operation continues if either the SUSREQ signal becomes inactive, or if the enable bit SUSENRz.SUSEN is reset by software.

15.7.2 OCDS Trigger Bus (OTGB) Interface

A Trigger Set is a collection of signals which supports a specific debug use case. The OCDS Trigger Set Select Register controls which Trigger Set is applied to the bus. The register is cleared by Debug Reset and by each System Reset when OCDS is disabled.

Direct Memory Access (DMA)

It is not touched by the System Reset when OCDS is enabled. The trigger sets are routed by the OCDS Trigger Mux (OTGM) to the OCDS Trigger Switch (OTGS) and the MCDS. A DMA Trigger Set is unique to each DMA module dependent on the number of channels and move engines.

15.7.3 MCDS Trace Interface

The DMA module provides two 8 bit vectors for debug and trace signal generation purposes that are used for OCDS Level 3 and for OCDS Level 1:

- One 8 bit vector from SPB master interface via BCU_SPB to BAL_SPB inside MCDS (i.e. spb_clk domain).
- One 8 bit vector from SRI master interface via SRI_XBAR to BAL_SRI inside MCDS (i.e. sri_clk domain).

For each DMA master interface trace is captured to identify the DMA move engine and channel making the request.

Table 15-10 Trace Vector Definition

Bit	Trace
[6:0]	DMA Channel
[7]	DMA Move Engine 0 _B Move Engine 0 1 _B Move Engine 1

DMA Trace Signal Generation for OCDS Level 3

The trace mechanism allows the identity of the DMA move engine and channel accessing the on chip bus to be determined. The mechanism enables the MCDS system to trace transactions on the on chip bus generated by one or a group of dedicated DMA internal sources.

DMA Trace Signal Generation for OCDS Level 1

For OCDS Level 1 purposes the DMA provides two 8 bit vectors.

15.8 Register Description

Figure 15-37 and **Table 15-12** show all registers associated with the DMA Controller Kernel. All DMA kernel register names described in this section are also referenced in other parts of the TC26x B-Step User's Manual by the module name prefix "DMA_".

DMA Register Index

The following index numbers are used:

- Index "x" is used to refer to the DMA sub-block (x = 0-1).
- Index "y" is used to refer to the hardware resource partitions (y = 0-3).
- Index "z" is used to refer to the DMA channel (z = 000-047).

DMA Register Classes

The registers fall into the following distinctive classes:

- Control registers that support clock control and the access protection to all registers and the DMARAM.
- Channel control registers are DMA channel control bits directly written into registers:
 - Channel reset
 - Hardware transfer request enable
 - Access pending set by either hardware triggers or software transfer requests
 - Transaction request lost status
 - Suspend enable
 - Suspend acknowledge
 - 2-bit hardware resource to partition channels across DMA partitions
- Active channel control read only registers store DMA channel control and status information for the current DMA move performed by the sub-block move engine.
- Move engine and error registers store control, status and read data for the current DMA transaction.

DMA Registers Overview

Clock Control Register	OCDS Trigger Select Register	Hardware Resource Partition	Sub-block Error Registers

-	Reserved (ch = 48)	2000 _H + (ch * 0020 _H)- 3FFC _H	BE	BE	-	-

- 1) The absolute register address is calculated as follows:
Module Base Address ([Table 15-11](#)) + Offset Address (shown in this column)
Further, the following ranges for parameters x, y, and z are valid: x = 0-1, y = 0-3, z = 000-047.
- 2) Registers (addresses) protected by the default Hardware Resource Partition 0 Access Enable Registers ACCEN00 and ACCEN01 are marked P00 and P01.
- 3) In shadow address modes write access to DMA_SHADRz is controlled by the register bit DMA_ADICRz.SHCT[2]. If DMA_ADICRz.SHCT = '0001' or '0010' then Access Mode Write for DMA_SHADRz is BE. If DMA_ADICRz.SHCT = '0101' or '0110' then Access Mode Write for DMA_SHADRz is SV.

Direct Memory Access (DMA)

15.8.1 DMA General Module Control Registers

DMA Clock Control Register

The Clock Control Registers DMA_CLC controls the internal f_{DMA} clock signal and sleep mode in order to control the power consumption.

DMA_CLC

DMA Clock Control Register

 (0000_H)

 Reset Value: 0000 0008_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module
EDIS	3	rw	Sleep Mode Enable Control Used for module sleep mode control. 0 _B Sleep mode request is regarded. Module is enabled to go into sleep mode. 1 _B Sleep mode request is disregarded. Sleep mode cannot be entered on a request.
RES	2, [31:4]	r	Reserved Read as 0; must be written with 0.

Note: After a hardware reset operation, the DMA module is enabled.

Note: The sleep mode does not modify any of the registers.

Direct Memory Access (DMA)

DMA Module Identification Register

DMA_ID
Module Identification Register (0008_H) **Reset Value: 0087 C003_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number.
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. The value for the DMA module is 0087 _H .

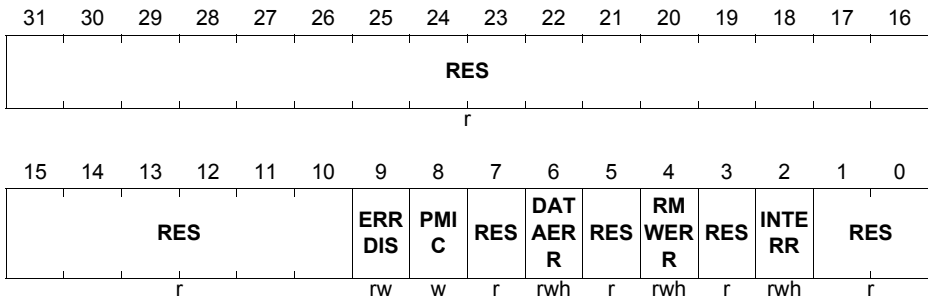

Direct Memory Access (DMA)

DMA Memory Control Register

Provides control of the memory integrity error checking, error signalling to the SMU and error injection for ECC logic test. The register is cleared by an Application Reset.

DMA_MEMCON

DMA Memory Control Register (0020_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
INTERR	2	rwh	Internal ECC Error Flag set by hardware when the DMA logic detects an ECC error while accessing the RAM. This bit is cleared by writing 0 _B but cannot be set by software. 0 _B No error has occurred 1 _B An error has been observed during a RAM access.
RMWERR	4	rwh	Internal Read Modify Write Error Flag set by hardware when the DMA logic detects an ECC error on the read phase of an internal RMW operation. This bit is cleared by writing 0 _B but cannot be set by software. 0 _B No error has occurred 1 _B An error has been observed during an internal RMW operation.

Direct Memory Access (DMA)

Field	Bits	Type	Description
DATAERR	6	rwh	SPB Data Phase ECC Error Flag set by hardware when the SPB interface detects an ECC error during the data phase of an incoming read transaction. This bit is cleared by writing 0 _B but cannot be set by software. 0 _B No error has occurred 1 _B An ECC error has been observed on an SPBI transaction addressed to the DMARAM
PMIC	8	w	Protection Bit for Memory Integrity Control Bit Will always return 0 _B when read 0 _B Bit Protection: Bit 9 remains unchanged after DMA_MEMCON write. 1 _B Bit 9 will be updated by the current write to DMA_MEMCON
ERRDIS	9	rw	ECC Error Disable When set SPB bus errors caused by ECC errors in data read from the SRAM will be disabled 0 _B Normal behavior. SPB bus error will occur on SRAM ECC errors. Default after reset 1 _B Test Mode. SPB bus errors will not be generated on an SRAM ECC error. This does not affect the generation of interrupts.
RES	[1:0],3,5,7,[31:10]	r	Reserved Read as 0; must be written with 0.

DMARAM Physical Implementation

If the number of DMA channels is small then the DMARAM may be implemented using logic. A logic implementation shall not generate ECC errors (MEMCON.INTERR = 0_B, MEMCON.RMWERR = 0_B and MEMCON.DATAERR = 0_B).

Direct Memory Access (DMA)
15.8.2 DMA Access Protection Registers

Write access to each DMA channel z transaction control set is controlled by the respective pair of Access Control Registers for the Hardware Resource assigned to the DMA channel z.

DMA Hardware Resource y Access Enable Register 0

The DMA Access Enable Register 0 controls read / write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B. Each register bit enables one possible 6 bit TAG ID coding.

Mapping of TAG IDs to DMA_ACCEN0.ENn:

- EN0 -> TAG ID 000000_B
- EN1 -> TAG ID 000001_B
- ...
- EN31 -> TAG ID 011111_B

DMA_ACCENy0 (y = 0-3)
DMA Hardware Resource y Access Enable Register 0

(0040_H + y * 8_H)

Reset Value: FFFF FFFF_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN3	EN3	EN2	EN2	EN2	EN2	EN2	EN2	EN2	EN2	EN2	EN2	EN1	EN1	EN1	EN1
1	0	9	8	7	6	5	4	3	2	1	0	9	8	7	6
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN1	EN1	EN1	EN1	EN1	EN1	EN9	EN8	EN7	EN6	EN5	EN4	EN3	EN2	EN1	EN0
5	4	3	2	1	0										
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	Access Enable for Master TAG ID n This bit enables read / write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

The DMA Hardware Resource y Access Enable Register 0 is safe endinit protected.

Direct Memory Access (DMA)

DMA Hardware Resource y Access Enable Register 1

The DMA Access Enable Register y1 controls read / write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B. Each register bit enables one possible 6 bit TAG ID coding.

Mapping of TAG IDs to DMA_ACCENx1.ENn:

- EN0 -> TAG ID 100000_B
- EN1 -> TAG ID 100001_B
- ...
- EN31 -> TAG ID 111111_B

DMA_ACCENy1 (y = 0-3)

DMA Hardware Resource y Access Enable Register 1

$$(0044_H + y * 8_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	[31:0]	r	Reserved Read as 0; must be written with 0.

The DMA Hardware Resource y Access Enable Register 1 is safe endinit protected.

15.8.3 DMA Sub-block Error Registers

DMA Enable Error Register

The Enable Error Register describes how the DMA controller reacts to errors. It enables the interrupts for Move Engine errors.

DMA_EERx (x = 0-1)

DMA Enable Error Register x

(0120_H + x * 1000_H)

Reset Value: 0503 0000_H

Field	Bits	Type	Description
RES	[15:0]	r	Reserved Read as 0; must be written with 0.
ESER	16	rw	Enable Move Engine x Source Error This bit enables the generation of a Move Engine x source error interrupt. 0 _B Move Engine x source error interrupt is disabled. 1 _B Move Engine x source error interrupt is enabled.
EDER	17	rw	Enable Move Engine x Destination Error This bit enables the generation of a Move Engine x destination error interrupt. 0 _B Move Engine x destination error interrupt is disabled. 1 _B Move Engine x destination error interrupt is enabled.
RES	[23:18]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

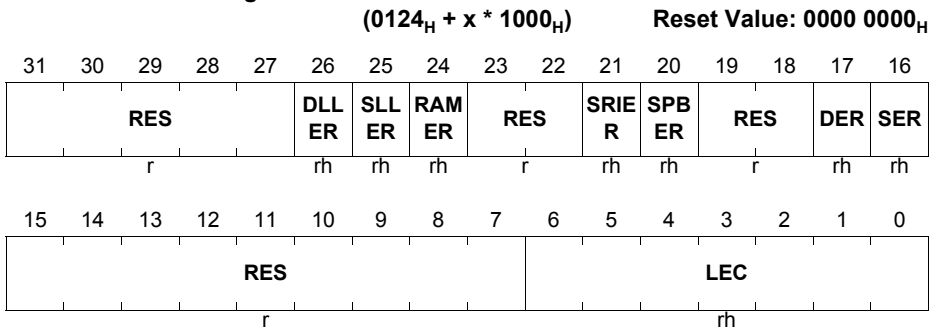

Field	Bits	Type	Description
ERER	24	rw	Enable Move Engine x RAM Error This bit enables the generation of a Move Engine x RAM error interrupt. 0 _B Move Engine x RAM error interrupt is disabled. 1 _B Move Engine x RAM error interrupt is enabled.
RES	25	r	Reserved Read as 0; must be written with 0.
ELER	26	rw	Enable Move Engine x DMA Linked List Error This bit enables the generation of a Move Engine x DMA Linked List error interrupt. 0 _B Move Engine x DMA Linked List error interrupt is disabled. 1 _B Move Engine x DMA Linked List error interrupt is enabled.
RES	[31:27]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

DMA Error Status Register

The Error Status Register indicates if the DMA controller could not answer to a request because the previous request was not terminated (see [Section 15.4.4.1](#)).

It indicates that an SPB Bus access or an SRI Bus access has terminated with errors.

DMA_ERRSRx (x = 0-1)
DMA Error Status Register x

Field	Bits	Type	Description
LEC	[6:0]	rh	Move Engine x Last Error Channel This bit field indicates the channel number of the last channel of Move Engine x leading to an On Chip Bus error that has occurred. <i>Note: Last Error Channel DMA_ERRSRx.LEC is not set on RAM error DMA_ERRSRx.RAMER or Safe Linked List error DMA_ERRSRx.SLLER</i>
RES	[15:7]	r	Reserved Read as 0; must be written with 0.
SER	16	rh	Move Engine x Source Error This bit is set whenever a Move Engine x error occurred during a source (read) move of a DMA transfer, or a request could not be serviced due to the access protection. 0 _B No Move Engine x source error has occurred. 1 _B A Move Engine x source error has occurred.

Direct Memory Access (DMA)

Field	Bits	Type	Description
DER	17	rh	Move Engine x Destination Error This bit is set whenever a Move Engine x error occurred during a destination (write) move of a DMA transfer, or a request could not be serviced due to the access protection. 0 _B No Move Engine x destination error has occurred. 1 _B A Move Engine x destination error has occurred.
RES	[19:18]	r	Reserved Read as 0; must be written with 0.
SPBER	20	rh	Move Engine x SPB Bus Error This bit is set whenever a Move Engine x DMA Move that has been started by the DMA SPB master interface leads to an error on the SPB Bus. 0 _B No error occurred. 1 _B An error occurred on SPB Bus interface.
SRIER	21	rh	Move Engine x SRI Bus Error This bit is set whenever a Move Engine x DMA Move that has been started by the DMA SRI master interface leads to an error on the SRI Bus. 0 _B No error occurred. 1 _B An error occurred on SRI Bus interface.
RES	[23:22]	r	Reserved Read as 0; must be written with 0.
RAMER	24	rh	Move Engine x RAM Error This bit is set whenever a Move Engine x error occurred during the loading of a transaction control set from the DMARAM to the DMA sub-block x channel registers. 0 _B No error occurred. 1 _B An error occurred during the load of a transaction control set.
SLLER	25	rh	Move Engine x Safe Linked List Error This bit is set whenever a Move Engine x error occurred during the comparison of a SDCRC checksums during a safe linked list. 0 _B No error occurred. 1 _B An error occurred during the SDCRC checksum comparison.

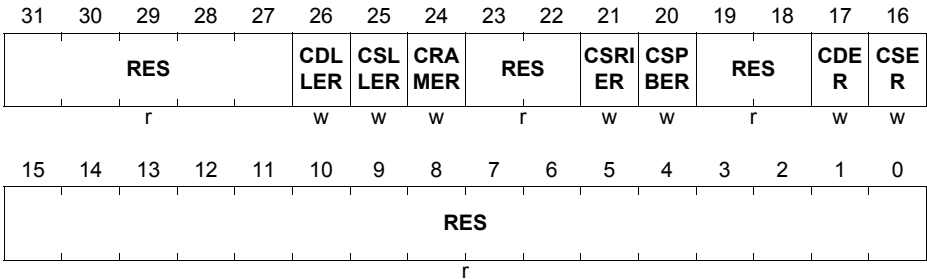

Direct Memory Access (DMA)

Field	Bits	Type	Description
DLLER	26	rh	<p>Move Engine x DMA Linked List Error</p> <p>This bit is set whenever a Move Engine x error occurred during the loading of a new transaction control set from anywhere in memory to overwrite the current transaction control set stored in the DMARAM.</p> <p>0_B No error occurred. 1_B An error occurred during the loading of a new transaction control set.</p> <p><i>Note: Error reporting includes all DMA Linked List operations included Accumulated Linked List, Safe Linked List and Conditional Linked List.</i></p>
RES	[31:27]	r	<p>Reserved</p> <p>Read as 0; must be written with 0.</p>

Direct Memory Access (DMA)
DMA Clear Error Register

The Clear Error contains bits to clear the corresponding Move Engine error flags.

DMA_CLRE_x (x = 0-1)

DMA Clear Error Register x
(0128_H + x * 1000_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	[15:0]	r	Reserved Read as 0; must be written with 0.
CSER	16	w	Clear Move Engine x Source Error 0 _B No action 1 _B Clear source error flag DMA_ERRSRx.SER.
CDER	17	w	Clear Move Engine x Destination Error 0 _B No action 1 _B Clear destination error flag DMA_ERRSRx.DER.
RES	[19:18]	r	Reserved Read as 0; must be written with 0.
CSPBER	20	w	Clear SPB Error 0 _B No action 1 _B Clear error flag DMA_ERRSRx.SPBER.
CSRIER	21	w	Clear SRI Error 0 _B No action 1 _B Clear error flag DMA_ERRSRx.SRIER.
RES	[23:22]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

Field	Bits	Type	Description
CRAMER	24	w	Clear RAM Error 0 _B No action 1 _B Clear error flag DMA_ERRSRx.RAMER.
CSLLER	25	w	Clear SLL Error 0 _B No action 1 _B Clear error flag DMA_ERRSRx.SLLER.
CDLLER	26	w	Clear DLL Error 0 _B No action 1 _B Clear error flag DMA_ERRSRx.DLLER.
RES	[31:27]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

15.8.4 DMA Sub-block Move Engine Registers

DMA Move Engine Status Register

The Move Engine Status Register is a read-only register that holds status information about the transaction handled by the Move Engines.

DMA_MExSR ($x = 0-1$)

DMA Move Engine x Status Register

($0130_H + x * 1000_H$)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RS	0	rh	Move Engine x Read Status 0 _B Move Engine x is not performing a read. 1 _B Move Engine x is performing a read.
RES	[3:1]	r	Reserved Read as 0; must be written with 0.
WS	4	rh	Move Engine x Write Status 0 _B Move Engine x is not performing a write. 1 _B Move Engine x is performing a write.
RES	[15:5]	r	Reserved Read as 0; must be written with 0.
CH	[22:16]	rh	Active Channel z in Move Engine x This bit field indicates the number of the DMA Channel z currently being processed by the Move Engine x.
RES	[31:23]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 0

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

The value in the Read Register is compared to the bits in Move Engine Pattern Register depending on the pattern detection configuration and the channel data width.

DMA_MEx0R (x = 0-1)

DMA Move Engine x Read Register 0

(0140_H + x * 1000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD00, RD01, RD02, RD03	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD0[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA Sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 1

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx1R (x = 0-1)
DMA Move Engine x Read Register 1
(0144_H + x * 1000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD10, RD11, RD12, RD13	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD1[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA Sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 2

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx2R (x = 0-1)
DMA Move Engine x Read Register 2
(0148_H + x * 1000_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD20, RD21, RD22, RD23	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD2[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 3

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx3R (x = 0-1)
DMA Move Engine x Read Register 3
(014C_H + x * 1000_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD30, RD31, RD32, RD33	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD3[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 4

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx4R (x = 0-1)
DMA Move Engine x Read Register 4
 $(0150_H + x * 1000_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD40, RD41, RD42, RD43	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD4[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 5

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx5R (x = 0-1)
DMA Move Engine x Read Register 5
 $(0154_H + x * 1000_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD50, RD51, RD52, RD53	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD5[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 6

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx6R (x = 0-1)
DMA Move Engine x Read Register 6
 $(0158_H + x * 1000_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD60, RD61, RD62, RD63	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD6[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)
DMA Move Engine x Read Register 7

The Move Engine x Read Register indicate the value that has just been read by Move Engine x.

DMA_MEx7R (x = 0-1)
DMA Move Engine x Read Register 7
(015C_H + x * 1000_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD70, RD71, RD72, RD73	[7:0], [15:8], [23:16], [31:24]	rh	Read Value for Move Engine x Contains the 32-bit read data (four bytes RD7[3:0]) that is stored in the Move Engine x after each read move. The content of MExR is overwritten after each read move of a DMA channel belonging to DMA sub-block x.

Direct Memory Access (DMA)

15.8.5 DMA Move Engine Active Channel Registers

DMA Move Engine Channel Status Register

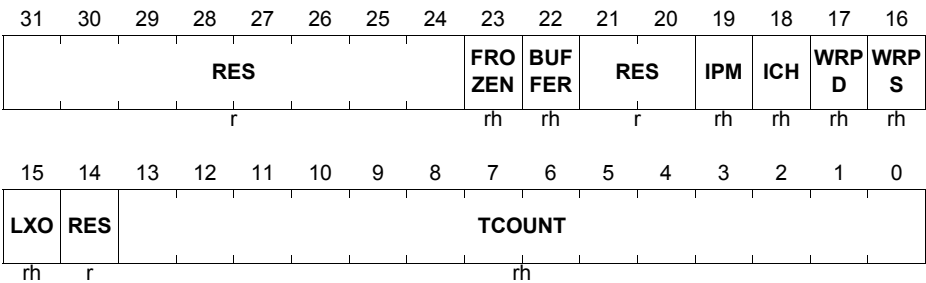

The read only DMA active channel Channel Status Register contains the current transfer count, pattern detection compare result and the status of traffic management interrupt triggers.

DMA_MExCHSR (x = 0-1)

DMA Move Engine x Channel Status Register

(019C_H + x * 1000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TCOUNT	[13:0]	rh	<p>Transfer Count Status</p> <p>TCOUNT holds the actual value of the DMA transfer count for DMA channel z.</p> <p>TCOUNT is loaded with the value of CHCFGRz.TREL when TSRz.CH becomes set (and TCOUNT = 0).</p> <p>After each DMA transfer, TCOUNT is decremented by 1.</p>
RES	14	r	<p>Reserved</p> <p>Read as 0; must be written with 0.</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
LXO	15	rh	<p>Old Value of Pattern Detection</p> <p>This bit contains the compare result of a pattern compare operation when 8-bit or 16-bit data width is selected.</p> <p>8-bit data width: see Table 15-4 and Figure 15-27</p> <p>16-bit data width: see Table 15-5 and Figure 15-28</p> <p>0_B The corresponding pattern compare operation did not find a pattern match during the previous DMA read move</p> <p>1_B The corresponding pattern compare operation found a pattern match during the previous DMA read move</p>
WRPS	16	rh	<p>Wrap Source Buffer</p> <p>Indicates a wrap-around of source buffer.</p> <p>0_B No wrap-around occurred for channel z.</p> <p>1_B A wrap-around occurred for channel z.</p> <p>This bit is reset by software by writing a 1 to CHCSRz.CWRP or TSRz.RST.</p>
WRPD	17	rh	<p>Wrap Destination Buffer</p> <p>Indicates a wrap-around of destination buffer.</p> <p>0_B No wrap-around occurred for channel z.</p> <p>1_B A wrap-around occurred for channel z.</p> <p>This bit is reset by software by writing a 1 to CHCSRz.CWRP or TSRz.RST.</p>
ICH	18	rh	<p>Interrupt from Channel</p> <p>This bit indicates that channel z has raised an interrupt for TCOUNT = IRDV or if TCOUNT has been decremented (depending on ADICRz.INTCT[0]. This bit (and IPM) is reset by software when writing a 1 to ADICRz.CICH or by a channel reset (writing TSRz.RST = 1).</p> <p>0_B A channel interrupt has not been detected.</p> <p>1_B A channel interrupt has been detected.</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
IPM	19	rh	Pattern Detection from Channel This bit indicates that a pattern has been detected for channel z while the pattern detection has been enabled. This bit (and ICH) is reset by software when writing a 1 to ADICRz.CICH or by a channel reset (writing TSRz.RST = 1). 0 _B A pattern has not been detected. 1 _B A pattern has been detected.
RES	[21:20]	r	Reserved Read as 0; must be written with 0.
BUFFER	22	rh	DMA Double Buffering Active Buffer This bit is active during DMA double buffering and indicates which buffer is read or filled. 0 _B Buffer 0 read or filled by DMA. 1 _B Buffer 1 read or filled by DMA.
FROZEN	23	rh	DMA Double Buffering Frozen Buffer This bit is active during DMA double buffering and indicates that one of the double buffers is frozen and available for a cyclic software task. 0 _B Buffer is not frozen. 1 _B Buffer is frozen.
RES	[31:24]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

DMA Move Engine Channel Shadow Address Register

The read only DMA active channel Shadow Address Register holds the 32-bit shadow address.

DMA_MExSHADR (x = 0-1)

DMA Move Engine x Channel Shadow Address Register

(0198_H + x * 1000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SHADR	[31:0]	rh	<p>Shadowed Address</p> <p>This bit field holds the 32-bit shadow address of the active DMA channel. The function of the shadow address is set by the shadow control settings. See Table 15-15 for a description.</p>

Direct Memory Access (DMA)
DMA Move Engine Channel Control Register

The read only DMA active channel Channel Control Register contains the configuration and control bits.

DMA_MExCHCR (x = 0-1)
DMA Move Engine x Channel Control Register
 $(0194_H + x * 1000_H)$
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAprio		RES	PRSEL	RES	PATSEL			CHDW			CHMODE	RROAT	BLKM		
rh		r	rh	r	rh			rh			rh	rh	rh		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES		TREL													
r		rh													

Field	Bits	Type	Description
TREL	[13:0]	rh	Transfer Reload Value This bit field contains the number of DMA transfers for a DMA transaction of DMA channel z. This 14-bit transfer count value is loaded into MExCHSR.TCOUNT at the start of a DMA transaction (when TSRz.CH becomes set and CHCSRz.TCOUNT = 0). A write to CHCFGz.TREL during a running DMA transaction has no influence to the running DMA transaction. If CHCFGRz.TREL = 0 or if CHCFGRz.TREL = 1 then MExCHSR.TCOUNT will be loaded with 1 when a new transaction is started (at least one DMA transfer must be executed per DMA transaction).

Direct Memory Access (DMA)

Field	Bits	Type	Description
BLKM	[18:16]	rh	<p>Block Mode</p> <p>BLKM determines the number of DMA moves executed during one DMA transfer.</p> <p>000_B One DMA transfer has 1 DMA move 001_B One DMA transfer has 2 DMA moves 010_B One DMA transfer has 4 DMA moves 011_B One DMA transfer has 8 DMA moves 100_B One DMA transfer has 16 DMA moves 101_B One DMA transfer has 3 DMA moves 110_B One DMA transfer has 5 DMA moves 111_B One DMA transfer has 9 DMA moves</p> <p>See also Figure 15-12 on Page 15-23.</p>
RROAT	19	rh	<p>Reset Request Only After Transaction</p> <p>RROAT determines whether or not the TSRz.CH transfer request state flag is reset after each transfer.</p> <p>0_B TSRz.CH is reset after each transfer. A transfer request is required for each transfer. 1_B TSRz.CH is reset when CHSRz.TCOUNT = 0 after a transfer. One transfer request starts a complete DMA transaction</p>
CHMODE	20	rh	<p>Channel Operation Mode</p> <p>CHMODE determines the reset condition for control bit TSRz.HTRE of the DMA channel.</p> <p>0_B Single Mode operation is selected for DMA channel. After a transaction, DMA channel is disabled for further hardware requests (TSRz.HTRE is reset by hardware) TSRz.HTRE must be set again by software for starting a new transaction. 1_B Continuous Mode operation is selected for DMA channel z. After a transaction, bit TSRz.HTRE remains set</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
CHDW	[23:21]	rh	<p>Channel Data Width</p> <p>CHDW determines the data width for the read and write moves of DMA channel z.</p> <p>000_B 8-bit data width for moves selected <i>Note: Single Data Transfer Byte (SDTB)</i></p> <p>001_B 16-bit data width for moves selected <i>Note: Single Data Transfer Half-Word (SDTH)</i></p> <p>010_B 32-bit data width for moves selected <i>Note: Single Data Transfer Word (SDTW)</i></p> <p>011_B 64-bit data width transaction selected <i>Note: SRI-Bus: Single Data Transfer Double Word (SDTD)</i> <i>Note: SPB-Bus: not supported.</i></p> <p>100_B 128-bit data width transaction selected <i>Note: SRI-Bus: Block Transfer Request - 2 Transfers (BTR2)</i> <i>Note: SPB-Bus: not supported.</i></p> <p>101_B 256-bit data width transaction selected <i>Note: SRI-Bus: Block Transfer Request - 4 Transfers (BTR4)</i> <i>Note: SPB-Bus: not supported.</i></p> <p>110_B Reserved</p> <p>111_B Reserved</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
PATSEL	[26:24]	rh	<p>Pattern Select</p> <p>This bit field selects the mode of the pattern detection logic. Depending on the channel data width, PATSEL[1:0] selects different pattern detection configurations.</p> <p>If pattern detection is enabled (PATSEL[1:0] not equal 00_B), the pattern detection interrupt line will be activated on the selected pattern match.</p> <p>PATSEL[2] selects the pattern read register.</p> <p>0_B Pattern Read Register 0 1_B Pattern Read Register 1</p> <p>8-bit channel data width (CHDW = 000_B): Selected pattern detection configuration see Table 15-4 on Page 15-55.</p> <p>16-bit channel data width (CHDW = 001_B): Selected pattern detection configuration see Table 15-5 on Page 15-57.</p> <p>32-bit channel data width (CHDW = 010_B): Selected pattern detection configuration see Table 15-6 on Page 15-60.</p>
PRSEL	28	rh	<p>Peripheral Request Select</p> <p>This bit field controls the hardware request input multiplexer of DMA channel z-1 (see Figure 15-6 on Page 15-13).</p> <p>0_B Hardware trigger selected 1_B Daisy chain selected</p>
DMAPRIO	[31:30]	rh	<p>DMA Priority</p> <p>This bit determines the DMA the request priority that is used when a move operation related to channel z is requesting SPB-Bus. This bit has no effect in channel prioritization inside the Move Engine x in.</p> <p>00_B Low priority selected 01_B Medium priority selected 10_B Medium priority selected 11_B High priority selected</p>
RES	[15:14], 27, 29	r	<p>Reserved</p> <p>Read as 0; must be written with 0.</p>

Direct Memory Access (DMA)

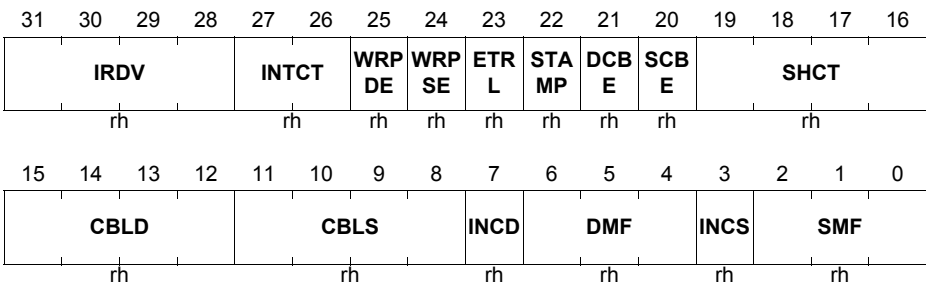

DMA Move Engine Channel Address and Interrupt Control Register

The read only DMA active channel Address and Interrupt Control Register controls how source and destination addresses are updated after a DMA move. Furthermore, it determines whether or not a source or destination address register update is shadowed. The interrupt control bits enable the generation of DMA traffic interrupt triggers.

DMA_MExADICR (x = 0-1)

DMA Move Engine x Channel Address and Interrupt Control Register

(0190_H + x * 1000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description																
SMF	[2:0]	rh	<p>Source Address Modification Factor</p> <p>This bit field and the data width as defined in MExCHCR.CHDW determine an address offset value by which the source address is modified after each DMA move. See also Table 15-13.</p> <table style="width:100%; border-collapse: collapse;"> <tr><td style="width: 50px;">000_B</td><td>Address offset is 1 x MExCHCR.CHDW</td></tr> <tr><td>001_B</td><td>Address offset is 2 x MExCHCR.CHDW</td></tr> <tr><td>010_B</td><td>Address offset is 4 x MExCHCR.CHDW</td></tr> <tr><td>011_B</td><td>Address offset is 8 x MExCHCR.CHDW</td></tr> <tr><td>100_B</td><td>Address offset is 16 x MExCHCR.CHDW</td></tr> <tr><td>101_B</td><td>Address offset is 32 x MExCHCR.CHDW</td></tr> <tr><td>110_B</td><td>Address offset is 64 x MExCHCR.CHDW</td></tr> <tr><td>111_B</td><td>Address offset is 128 x MExCHCR.CHDW</td></tr> </table>	000 _B	Address offset is 1 x MExCHCR.CHDW	001 _B	Address offset is 2 x MExCHCR.CHDW	010 _B	Address offset is 4 x MExCHCR.CHDW	011 _B	Address offset is 8 x MExCHCR.CHDW	100 _B	Address offset is 16 x MExCHCR.CHDW	101 _B	Address offset is 32 x MExCHCR.CHDW	110 _B	Address offset is 64 x MExCHCR.CHDW	111 _B	Address offset is 128 x MExCHCR.CHDW

101 _B	Address offset is 32 x MExCHCR.CHDW																		
110 _B	Address offset is 64 x MExCHCR.CHDW																		
111 _B	Address offset is 128 x MExCHCR.CHDW																		

Direct Memory Access (DMA)

Field	Bits	Type	Description
INCS	3	rh	<p>Increment of Source Address</p> <p>This bit determines whether the address offset as selected by SMF will be added to or subtracted from the source address after each DMA move. The source address is not modified if CBL5 = 0000_B.</p> <p>0_B Address offset will be subtracted 1_B Address offset will be added.</p>
DMF	[6:4]	rh	<p>Destination Address Modification Factor</p> <p>This bit field and the data width as defined in MEXCHCR.CHDW determines an address offset value by which the destination address is modified after each DMA move. The destination address is not modified if CBLD = 0000_B. See also Table 15-13.</p> <p>000_B Address offset is 1 x MEXCHCR.CHDW 001_B Address offset is 2 x MEXCHCR.CHDW 010_B Address offset is 4 x MEXCHCR.CHDW 011_B Address offset is 8 x MEXCHCR.CHDW 100_B Address offset is 16 x MEXCHCR.CHDW 101_B Address offset is 32 x MEXCHCR.CHDW 110_B Address offset is 64 x MEXCHCR.CHDW 111_B Address offset is 128 x MEXCHCR.CHDW</p>
INCD	7	rh	<p>Increment of Destination Address</p> <p>This bit determines whether the address offset as selected by DMF will be added to or subtracted from the destination address after each DMA move. The destination address is not modified if CBLD = 0000_B.</p> <p>0_B Address offset will be subtracted 1_B Address offset will be added</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
CBLS	[11:8]	rh	<p>Circular Buffer Length Source</p> <p>This bit field determines which part of the 32-bit source address register remains unchanged and is not updated after a DMA move operation (see also Section 15.4.3.8).</p> <p>Therefore, CBLS also determines the size of the circular source buffer.</p> <p>0000_B Source address SADR[31:0] is not updated 0001_B Source address SADR[31:1] is not updated 0010_B Source address SADR[31:2] is not updated 0011_B Source address SADR[31:3] is not updated ..._B ... 1110_B Source address SADR[31:14] is not updated 1111_B Source address SADR[31:15] is not updated</p>
CBLD	[15:12]	rh	<p>Circular Buffer Length Destination</p> <p>This bit field determines which part of the 32-bit destination address register remains unchanged and is not updated after a DMA move operation (see also Page 15-25). Therefore, CBLD also determines the size of the circular destination buffer.</p> <p>0000_B Destination address DADR[31:0] is not updated 0001_B Destination address DADR[31:1] is not updated 0010_B Destination address DADR[31:2] is not updated 0011_B Destination address DADR[31:3] is not updated ..._B ... 1110_B Destination address DADR[31:14] is not updated 1111_B Destination address DADR[31:15] is not updated</p>
SHCT	[19:16]	rh	<p>Shadow Control</p> <p>This bit field determines the function of the shadow address register. See Table 15-15.</p>
SCBE	20	rh	<p>Source Circular Buffer Enable</p> <p>0_B Source circular buffer disabled 1_B Source circular buffer enabled</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
DCBE	21	rh	Destination Circular Buffer Enable 0 _B Destination circular buffer disabled 1 _B Destination circular buffer enabled
STAMP	22	rh	Time Stamp This bit enables the appendage of a timestamp after the end of the last DMA Move during a DMA transaction. 0 _B No action. 1 _B Enable the appendage of a 32-bit timestamp.
ETRL	23	rh	Enable Transaction Request Lost Interrupt This bit enables the generation of an interrupt when TSRz.TRLz is set. 0 _B The interrupt generation for a request lost event for channel z is disabled. 1 _B The interrupt generation for a request lost event for channel z is enabled.
WRPSE	24	rh	Wrap Source Enable 0 _B Wrap source buffer interrupt trigger disabled 1 _B Wrap source buffer interrupt trigger enabled
WRPDE	25	rh	Wrap Destination Enable 0 _B Wrap destination buffer interrupt trigger disabled 1 _B Wrap destination buffer interrupt trigger enabled
INTCT	[27:26]	rh	Interrupt Control 00 _B No interrupt trigger will be generated on changing the TCOUNT value. The bit CHSRz.ICH is set when TCOUNT equals IRDV. 01 _B No interrupt trigger will be generated on changing the TCOUNT value. The bit CHSRz.ICH is set when TCOUNT is decremented 10 _B Interrupt trigger is generated and bit CHSRz.ICH is set on changing the TCOUNT value and TCOUNT equals IRDV 11 _B Interrupt trigger is generated and bit CHSRz.ICH is set each time TCOUNT is decremented <i>Note: see Figure 15-31.</i> <i>Note: If DMA_CHCFGRz.PRSEL = 1_B for the next lower priority channel then the channel transfer trigger interrupt is disabled.</i>

Direct Memory Access (DMA)

Field	Bits	Type	Description
IRDV	[31:28]	rh	Interrupt Raise Detect Value Defines the Threshold Limit of CHSRz.TCOUNT for which a channel interrupt trigger will be raised.

Direct Memory Access (DMA)
Address Offset Calculation Tables

Table 15-13 and **Table 15-14** show the offset values that are added or subtracted to/from a source or destination address register after a DMA move.

Bit field SMF and bit INCS determine the offset value for the source address.

Bit field DMF and bit INCD determine the offset value for the destination address.

Table 15-13 Address Offset Calculation Table (8-bit, 16-bit and 32-bit)

CHCFGRz.CHDW = 000 _B (8-bit Data Width)			CHCFGRz.CHDW = 001 _B (16-bit Data Width)			CHCFGRz.CHDW = 010 _B (32-bit Data Width)

Direct Memory Access (DMA)

Shadow Control Table

Table 15-15 defines the functionality of the shadow address register control bits.

Table 15-15 Shadow Control Table

SHCT	Description
0000 _B	Source and destination registers written directly. <i>Note: Shadow address register is not used and set to 00000000_H.</i>
0001 _B	Source Address Buffering (Read Only) Shadow address used for source buffering. When writing to SADRz, the address is buffered in SHADRz and transferred to SADRz with the start of the next DMA transaction. <i>Note: Shadow address register is read only and is automatically set to 00000000_H when the shadow transfer takes place (equal to AudoNG).</i>
0010 _B	Destination Address Buffering (Read Only) Shadow address used for destination buffering. When writing to DADRz, the address is buffered in SHADRz and transferred to DADRz with the start of the next DMA transaction. <i>Note: Shadow address register is read only and is automatically set to 00000000_H when the shadow transfer takes place (equal to AudoNG).</i>
0011 _B	Reserved. <i>Note: Shadow address register is not used and set to 00000000_H.</i>
0100 _B	Reserved. <i>Note: Shadow address register is not used and set to 00000000_H.</i>
0101 _B	Source Address Buffering (Direct Write) Shadow address used for source buffering. Shadow address register can be read and can be directly written. The value stored in SHADRz is not automatically modified when the shadow transfer takes place.
0110 _B	Destination Address Buffering (Direct Write) Shadow address used for destination buffering. Shadow address register can be read and can be directly written. The value stored in SHADRz is not automatically modified when the shadow transfer takes place.
0111 _B	Reserved. <i>Note: Shadow address register is not used and set to 00000000_H.</i>
1000 _B	Double Source Buffering Software Switch Only Shadow address used for double buffering

Direct Memory Access (DMA)

Table 15-15 Shadow Control Table (cont'd)

SHCT	Description
1001 _B	Double Source Buffering Automatic Hardware and Software Switch Shadow address used for double buffering
1010 _B	Destination Double Destination Buffering Software Switch Only Shadow address used for double buffering
1011 _B	Destination Double Destination Buffering Automatic Hardware and Software Switch Shadow address used for double buffering
1100 _B	DMA Linked List The DMA controller reads a DMA channel transaction control set and overwrites 8 X words in the corresponding DMARAM channel z. <i>Note: The SDCRC and RDCRC checksums are unique for each DMA transaction in the DMA Linked List. RDCRCRz and SDCRCRz are overwritten after each DMA transaction in the DMA Linked List.</i>
1101 _B	Accumulated Linked List The DMA controller reads a DMA channel transaction control set and overwrites 6 X words in the corresponding DMARAM channel z. <i>Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the Accumulated Linked List. RDCRCRz and SDCRCRz are not overwritten</i>
1110 _B	Safe Linked List The DMA controller reads a DMA channel transaction control set. The Linked List only proceeds with the next DMA transaction if the existing SDCRC checksum matches the expected SDCRC checksum in the loaded from the new DMA transaction control set. <i>Note: The SDCRC and RDCRC checksums are accumulated across all DMA transactions of the Safe Linked List. RDCRCRz is not overwritten.</i>
1111 _B	Conditional Linked List Shadow address register (MExSHADR) and source and destination address CRC register (MExSDCRC) are used as address pointers to a Linked List. The selection of the address pointer is determined by DMA channel pattern detection conditions. <i>Note: Calculation of SDCRC checksums is not supported.</i>

Direct Memory Access (DMA)**Shadow Address used for Source or Destination Buffering**

The Shadow Address Register holds the shadowed source or destination address before it is written into the source or destination address register.

Shadow Address used for DMA Double Buffering

The Shadow Address Register holds a second source or destination address used to store data in a second source or destination location.

Shadow Address used for DMA Linked Lists

The Shadow Address Register holds an address pointer to the next DMA transaction control set.

Direct Memory Access (DMA)

DMA Move Engine Channel Destination Address Register

The read only DMA active channel Destination Address Register holds the 32-bit destination address. If a DMA channel is active, MExDADR is updated continuously (if programmed) and shows the actual destination address that is used for write moves within DMA transfers.

DMA_MExDADR (x = 0-1)

DMA Move Engine x Channel Destination Address Register x

(018C_H + x * 1000_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DADR	[31:0]	rh	Destination Address This bit field holds the actual 32-bit destination address of the active DMA channel that is used for write moves.

Direct Memory Access (DMA)

DMA Move Engine x Channel Source Address Register

The read only DMA active channel Source Address Register holds the 32-bit source address. If a DMA channel is active, MExSADR is updated continuously (if programmed) and shows the actual source address that is used for read moves within DMA transfers.

DMA_MExSADR (x = 0-1)

DMA Move Engine x Channel Source Address Register

$$(0188_H + x * 1000_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SADR	[31:0]	rh	<p>Source Start Address</p> <p>This bit field holds the actual 32-bit source address of the active DMA channel that is used for read moves.</p>

Direct Memory Access (DMA)

DMA Channel Source and Destination Address CRC Register

The read only DMA active channel Source and Destination Address CRC Register will store one polynomial calculation during each DMA read and each DMA write move provided there is no retry or error condition flagged.

DMA_MExSDCRC (x = 0-1)

DMA Move Engine x Channel Source and Destination Address CRC Register

(0184_H + x * 1000_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SDCRC	[31:0]	rh	Source and Destination Address CRC This bit field contains the working CRC32 ethernet polynomial checksum for the source and destination address.

Direct Memory Access (DMA)

DMA Move Engine Channel Read Data CRC Register

The read only DMA active channel Read Data CRC Register will store one polynomial calculation during each DMA read move provided that there is no retry or error condition flagged. In order to start a CRC32 sequence the MExRDCRC must be initialized (e.g. written with 00000000_H or with a desired start value) and an DMA transaction must be set up (start address, length, etc.).

DMA_MExRDCRC (x = 0-1)

DMA Move Engine x Channel Read Data CRC Register

$$(0180_H + x * 1000_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDCRC	[31:0]	rh	Read Data CRC This bit field contains the working CRC32 ethernet polynomial checksum for read data.

15.8.6 DMA OCDS Registers

DMA OCDS Trigger Set Select Register

The selection of the OCDS Trigger Bus (OTGB) is controlled by the OTSS register.

The OTSS register is cleared by Debug Reset and it is cleared by each System Reset when OCDS is disabled. The OTSS Register is not touched by the System Reset when OCDS is enabled.

Write access requires OCDS to be enabled and Supervisor mode.

DMA_OTSS

DMA OCDS Trigger Set Select (1200_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TGS	[3:0]	rw	Trigger Set (Table 15-16) for OTGB0/1 0 _D No Trigger Set selected 1 _D Trigger Set 1 2 _D Trigger Set 2 8 _D Trigger Set 8 9 _D Trigger Set 9 10 _D Trigger Set 10 others reserved
BS	7	rw	OTGB0/1 Bus Select 0 _B Trigger Set is output on OTGB0 1 _B Trigger Set is output on OTGB1
RES	[6:4], [31:8]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

OCDS Trigger Bus Interface

Table 15-16 lists the Trigger Sets, which are selected with the DMA_OTSS register for the 16 bit OCDS Trigger Bus (OTGB0/1) interface. Only one Trigger Set can be output at a time either on OTGB0 or on OTGB1.

The OCDS Trigger Bus has no dependency on the OCDS enabled state.

Table 15-16 DMA Trigger Sets

Index	Description	Details
0	No Trigger Set selected	
1	Channels (TS16_PF) Active channels	Table 15-17
2	Channels (TS16_ERR) Error channel number and flags	Table 15-18
8	Transaction Request State (TS16_C15) Transaction Request State Channel [15:0]	
9	Transaction Request State (TS16_C31) Transaction Request State Channel [31:16]	
10	Transaction Request State (TS16_C47) Transaction Request State Channel [47:32]	
Other	Reserved. No Trigger Set selected	

Performance Trigger Set
Table 15-17 TS16_PF Trigger Set Channels

Bits	Name	Description
[6:0]	CH0	Channel number active in move engine 0
7	ME0	Move engine 0 idle/active 0_B Move engine 0 is idle 1_B Move engine 0 is active
[14:8]	CH1	Channel number active in move engine 1
15	ME1	Move engine 1 active 0_B Move engine 1 is idle 1_B Move engine 1 is active

The performance trigger set continuously monitors the activity in the move engines. While the move engine is servicing a DMA request from DMA channel z the move engine idle/active bit TS16_PF.MEx is set and the TS16_PF.CHx bit field is set to the DMA channel number z. When the move engine is idle the idle/active bit TS16_PF.MEx goes low. The TS16_PF.CHx bit field retains the value of the last active DMA channel.

Error Trigger Set
Table 15-18 TS16_ERR Trigger Set Channels

Bits	Name	Description
[6:0]	LEC	Last error channel number
[11:7]		Reserved
12	ME0SE	Source Error
13	ME0DE	Destination Error
14	ME1SE	Source Error
15	ME1DE	Destination Error

If a move engine x source or destination error occurs then the respective CH.MExSE or TS16_CH.MExDE gets set. The TS16_CH.LEC returns the last error channel. If both move engines generate an error condition in the same clock cycle then the TS16_CH.LEC will record the last error channel for move engine 0.

The TS16_ERR trigger set retains its value until there is a new move engine source or destination error. The MCDS must be able to sample the source or destination occurrence and the DMA error channel.

Direct Memory Access (DMA)

DMA Error Interrupt Set Register

The Error Interrupt Set Register allows the DMA error interrupt service request to be activated by software.

DMA_ERRINTR

DMA Error Interrupt Set Register

(1204_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SIT	0	w	Set Error Interrupt Service Request 0 _B No action 1 _B DMA error interrupt service request will be activated. Reading this bit returns a 0
RES	[31:1]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

15.8.7 DMA Pattern Detection Registers

Pattern Read Register 0

The Pattern Read Register 0 contains the patterns (mask and/or compare bits) to be processed by the Move Engine pattern detection logic.

DMA_PRR0

Pattern Read Register 0

(1208_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PAT00, PAT01, PAT02, PAT03	[7:0], [15:8], [23:16], [31:24]	rw	Pattern for Move Engine Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in the Move Engine. Depending on the pattern detection configuration (MEXCHCR.PATSEL) and channel data width (MEXCHCR.CHDW), the patterns are processed as bytes or half-words.

Direct Memory Access (DMA)

Pattern Read Register 1

The Pattern Read Register 1 contains the patterns (mask and/or compare bits) to be processed by the Move Engine pattern detection logic.

DMA_PRR1

Pattern Read Register 1

(120C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PAT10, PAT11, PAT12, PAT13	[7:0], [15:8], [23:16], [31:24]	rw	Pattern for Move Engine Determines up to four 8-bit compare patterns/mask patterns to be processed by the pattern detection logic in the Move Engine. Depending on the pattern detection configuration (MEXCHCR.PATSEL) and channel data width (MEXCHCR.CHDW), the patterns are processed as bytes or half-words.

15.8.8 DMA Flow Control Registers

Time Register

The Time Register contains the 32-bit count value used for the appendage of DMA timestamps.

DMA_TIME

Time Register

(1210_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
COUNT	[31:0]	r	Timestamp Count This bit field provides the count value used for the appendage of DMA timestamps.

Direct Memory Access (DMA)

15.8.9 DMA Channel Hardware Resource Registers

DMA Mode Registers

The DMA Mode Registers control whether hardware resources access the on chip buses in supervisor mode or user mode.

DMA_MODEy (y = 0-3)

DMA Mode Register y

$$(1300_H + y * 4_H)$$

Reset Value: 0000 0001_H

Field	Bits	Type	Description
MODE	0	rw	Hardware Resource Supervisor Mode Bit determines if a hardware resource 0 makes bus accesses in supervisor mode or user mode. 0 _B Bus master is in user mode. 1 _B Bus master is in supervisor mode.
RES	[31:1]	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)
DMA Channel Hardware Resource Register z

The Hardware Resource Register assigns DMA channels to one of the four hardware resource partitions.

Initially all DMA channels are assigned to Hardware Resource 0 and read/write accesses are controlled by the ACCEN00 and ACCEN01 registers. If a DMA channel z is assigned to one of the other Hardware Resource Partitions then access control will change to the corresponding pair of access enable registers.

Each hardware resource partition supports a unique bus Master Tag Identifier (TAGID).

DMA_HRRz (z = 000-047)

DMA Channel Hardware Resource Register z

($1800_H + z * 0004_H$)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
HRP	[1:0]	rw	Hardware Resource Partition y 00 _B Hardware Resource Partition 0. 01 _B Hardware Resource Partition 1. 10 _B Hardware Resource Partition 2. 11 _B Hardware Resource Partition 3.
RES	[31:2]	r	Reserved Read as 0; must be written with 0.

15.8.10 DMA Channel Suspend Registers

DMA Channel Suspend Enable Register z

The Suspend Enable Register enables/disables soft suspend mode capability.

DMA_SUSENRz (z = 000-047)

DMA Suspend Enable Register z

(1A00_H + z * 0004_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SUSEN	0	rw	<p>Channel Suspend Enable for DMA Channel z</p> <p>This bit enables the channel suspend capability individually for each DMA channel z.</p> <p>0_B DMA channel z is disabled for channel suspend mode. The DMA channel z does not react on an active suspend request signal SUSREQ</p> <p>1_B DMA channel z is enabled for Soft-suspend Mode. If the suspend request signal SUSREQ becomes active, a DMA transaction of DMA channel z is stopped after the current DMA transfer has been finished</p> <p>Channel suspend mode can be terminated when SUSENz is written with 0.</p>
RES	[31:1]	r	<p>Reserved</p> <p>Read as 0; must be written with 0.</p>

Note: Register is only reset by the Debug Reset.

Direct Memory Access (DMA)
DMA Suspend Acknowledge Register z

The Suspend Acknowledge Register indicates the DMA Channel soft suspend status.

DMA_SUSACRz (z = 000-047)

DMA Suspend Acknowledge Register z

($1C00_H + z * 0004_H$)

Reset Value: $0000\ 0000_H$

Field	Bits	Type	Description
SUSAC	0	rh	Channel Suspend Mode or Frozen State Active for DMA Channel z This status bit indicates whether or not DMA channel z is in channel suspend mode or in the frozen state. 0_B DMA channel z is not in channel suspend mode, frozen state or internal actions are not yet finished after the channel suspend mode or frozen state was requested. 1_B DMA channel z is in channel suspend mode or frozen state.
RES	[31:1]	r	Reserved Read as 0; must be written with 0.

Note: This register is only reset by the Debug Reset.

15.8.11 DMA Transaction State Registers

DMA Channel Transaction State Register z

The Transaction State Register supports:

- The enabling and assertion of DMA channel hardware requests.
- The recording of a transaction request lost event for the channel.
- The setting, reporting and clearing of a DMA channel halt.
- The assertion of a DMA channel reset.

DMA_TSRz (z = 000-047)

DMA Transaction State Register z

(1E00_H + z * 0004_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES						HLT CLR	RES						CTL	DCH	ECH
r						w	r						w	w	w

RES						HLT ACK	HLT REQ	RES				CH	TRL	HTR E	RST
r						rh	rwh	r				rh	rh	rh	rwh

Field	Bits	Type	Description
RST	0	rwh	<p>DMA Channel Reset</p> <p>These bits force the DMA channel z to stop its current DMA transaction. Once set by software, this bit will be automatically cleared when the channel has been reset. Writing a 0 to RST has no effect.</p> <p>0_B No action (write) or the requested channel reset has been reset (read).</p> <p>1_B DMA channel z is stopped. More details see Page 15-20.</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
HTRE	1	rh	<p>Hardware Transaction Request Enable State</p> <p>0_B Hardware transaction request for DMA Channel is disabled. An input DMA request will not trigger the channel.</p> <p>1_B Hardware transaction request for DMA Channel is enabled. The transfers of a DMA transaction are controlled by the corresponding channel request line of the DMA requesting source.</p> <p><i>Note: HTRE Operation</i></p> <p>4. <i>Single Mode: HTRE is set to 0 when MExCHSR.TCOUNT is decremented and MExCHSR.TCOUNT = 0.</i></p> <p>5. <i>HTRE can be enabled and disabled with TSRz.ECH and TSRz.DCH.</i></p> <p>6. <i>HTRE is reset when a pattern match is detected.</i></p>
TRL	2	rh	<p>Transaction/Transfer Request Lost of DMA Channel</p> <p>0_B No request lost event has been detected for channel z.</p> <p>1_B A new DMA request was detected while TSRz.CH=1 (request lost event).</p> <p>This bit is reset by software when writing a 1 to TSRz.CTL or by a channel reset (writing TSRz.RST = 1).</p>
CH	3	rh	<p>Transaction Request State</p> <p>0_B No DMA request is pending for channel.</p> <p>1_B A DMA request is pending for channel.</p> <p>CH is reset when a pattern match is detected.</p>
HLTREQ	8	rwh	<p>Halt Request</p> <p>The halt request is a status bit that remains active until it is cleared by TSRz.HALTCLR</p> <p>0_B No action.</p> <p>1_B Halt request.</p>
HLTACK	9	rh	<p>Halt Acknowledge</p> <p>Halt acknowledge status from DMA channel.</p>
ECH	16	w	<p>Enable Hardware Transfer Request</p> <p>see table below</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
DCH	17	w	Disable Hardware Transfer Request see table below
CTL	18	w	Clear Transaction Request Lost for DMA Channel z Software clear of the DMA channel transaction request lost interrupt flag TSRz.TRL 0 _B No action 1 _B Clear DMA channel transaction request lost flag TSRz.TRL Reading this bit returns a 0.
HLTCLR	24	w	Clear Halt Request and Acknowledge Software write only active high clear of halt request TSRz.HALTREQ and halt acknowledge status bit TSRz.HALTACK 0 _B No action. 1 _B Halt clear. Reading this bit returns a 0.
RES	[7:4], [15:10], [23:19], [31:25]	r	Reserved Read as 0; must be written with 0.

Note: The DMA channel transaction/transfer request lost of a DMA channel is permanently available state that detects the loss of a DMA service request. If a transaction/transfer request lost is detected then an error interrupt trigger will be generated when the DMA channel z becomes active in a DMA sub-block x and if DMARAM bit ADICRz.ETRL enable bit is high.

DMA Channel Hardware Transaction/Transfer Request Conditions
Table 15-19 Conditions to Set/Reset the Bits TSRz.HTRE

TSRz.ECH	TSRz.DCH	Transaction Finishes ¹⁾ for Channel z	Modification of TSRz.HTRE
0	0	0	unchanged
1	0	0	set
X	1	X	reset
X	X	1	reset

Direct Memory Access (DMA)

1) In Single Mode only. In Continuous Mode, the end of a transaction has no impact.

15.8.12 DMA Transaction Control Set

The composition of a DMA transaction for each DMA channel is defined the transaction control set stored in the DMARAM. Each transaction control set consists of 8 X 32-bit words:

- DMA_RDCRCRz, DMA_SDCRCRz¹⁾, DMA_SADRz, DMA_DADRz and DMA_SHADRz store 32-bit CRC or address values.
- DMA_ADICRz and DMA_CHCFGRz store DMA channel configuration control bits.
- DMA_CHCSRz stores active channel status and write only active triggers.

DMA Channel Read Data CRC Register

DMA_RDCRCRz (z = 000-047)

DMA Channel Read Data CRC Register z

($2000_H + z * 20_H$)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDCRC	[31:0]	rwh	Read Data CRC This bit field stores the CRC32 ethernet polynomial checksum for read data of an inactive DMA channel.

1) The Source and Destination Address CRC can detect failures in the DMA fetch configuration information and updates to the dynamic channel information.

Direct Memory Access (DMA)

DMA Channel Source and Destination Address CRC Register

DMA_SDCRCRz (z = 000-047)

DMA Channel Source and Destination Address CRC Register z
 (2004_H + z * 20_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SDCRC	[31:0]	rwh	Source and Destination Address CRC This bit field stores the CRC32 ethernet polynomial checksum for the source and destination address of an inactive DMA channel.

Direct Memory Access (DMA)

DMA Channel Source Address Register

The Source Address Register stores the source address of an inactive DMA channel.

DMA_SADRz (z = 000-047)

DMA Channel Source Address Register z

$$(2008_H + z * 20_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SADR	[31:0]	rwh	Source Address This bit field holds the actual 32-bit source address of an inactive DMA channel.

Note: If a DMA channel is configured to execute 16-bit DMA moves then the source address register should be aligned to a 16-bit start source address.

Direct Memory Access (DMA)

DMA Channel Destination Address Register

The Destination Address Register stores the destination address of an inactive DMA channel.

DMA_DADRz (z = 000-047)

DMA Channel Destination Address Register x

$$(200C_H + z * 20_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DADR	[31:0]	rwh	Destination Address This bit field holds the actual 32-bit destination address of an inactive DMA channel.

Note: If a DMA channel is configured to execute 16-bit DMA moves then the destination address register should be aligned to a 16-bit start destination address.

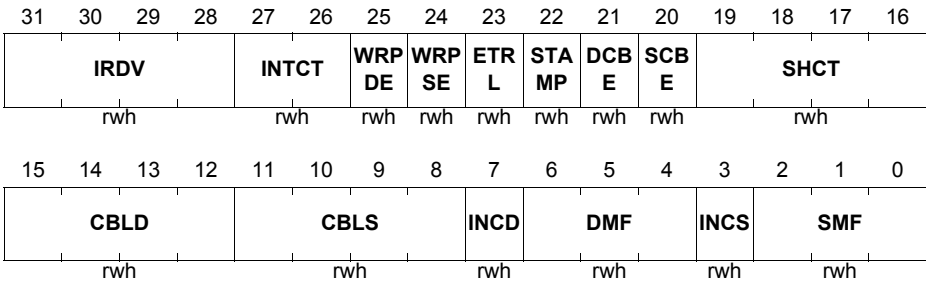

Direct Memory Access (DMA)
DMA Channel Address and Interrupt Control Register

The Address and Interrupt Control Register stores bits to update source and destination addresses and the generation of DMA channel traffic management interrupt triggers.

DMA_ADICRz (z = 000-047)

DMA Channel Address and Interrupt Control Register x

$$(2010_H + z * 20_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SMF	[2:0]	rwh	Source Address Modification Factor This bit field stores the Source Address Modification Factor of an inactive DMA channel.
INCS	3	rwh	Increment of Source Address This inactive DMA channel control bit determines if the source address is decremented or incremented.
DMF	[6:4]	rwh	Destination Address Modification Factor This bit field stores the Destination Address Modification Factor of an inactive DMA channel.
INCD	7	rwh	Increment of Destination Address This bit field stores the Destination Address Modification Factor for an inactive DMA channel.
CBLS	[11:8]	rwh	Circular Buffer Length Source This bit field stores circular buffer address update control of an inactive DMA channel.
CBLD	[15:12]	rwh	Circular Buffer Length Destination This bit field stores circular buffer address update control of an inactive DMA channel.
SHCT	[19:16]	rwh	Shadow Control Inactive DMA channel shadow control.

Direct Memory Access (DMA)

Field	Bits	Type	Description
SCBE	20	rwh	Source Circular Buffer Enable Inactive DMA channel source circular buffer enable.
DCBE	21	rwh	Destination Circular Buffer Enable Inactive DMA channel destination circular buffer enable.
STAMP	22	rwh	Time Stamp Enable appendage of time stamp.
ETRL	23	rwh	Enable Transaction Request Lost Interrupt Inactive DMA channel bit to enable the generation of an error interrupt service request.
WRPSE	24	rwh	Wrap Source Enable Inactive DMA channel source buffer interrupt trigger enable/disable.
WRPDE	25	rwh	Wrap Destination Enable Inactive DMA channel destination buffer interrupt trigger enable/disable.
INTCT	[27:26]	rwh	Interrupt Control Inactive DMA channel interrupt control.
IRDV	[31:28]	rwh	Interrupt Raise Detect Value Inactive DMA channel interrupt threshold value.

Shadow Address Register Read Only Mode

If $ADICRz.SHCT = 0001_B$ or $ADICRz.SHCT = 0010_B$ then source or destination address buffering is selected and SHADRz is written when a transaction is running. The SHADRz is automatically set to $0000\ 0000_H$ when the shadow transfer takes place. The user can read the shadow register in order to detect if the shadow transfer has already taken place. If the value in SHADRz is $0000\ 0000_H$, no shadow transfer can take place and the corresponding address register is modified according to the circular buffer rules.

Shadow Address Register Write Enable Mode

If $ADICRz.SHCT = 0101_B$ or $ADICRz.SHCT = 0110_B$ then the shadow register SHADRz can be directly written. The value stored in the MExSHADR is not modified when the shadow transfer takes place, the shadow mechanism remains active and the shadow transfer will be repeated until Channel z is reset or until the value in SHADRz is $0000\ 0000_H$, is written into the shadow register.

Direct Memory Access (DMA)
DMA Channel Configuration Register

The Channel Configuration Register stores control and configuration data.

DMA_CHCFGRz (z = 000-047)

DMA Channel Configuration Register z

($2014_H + z * 20_H$)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RES		TREL													
r		rwh													

Field	Bits	Type	Description
TREL	[13:0]	rwh	Transfer Reload Value Inactive DMA channel transfer reload value.
BLKM	[18:16]	rwh	Block Mode Inactive DMA channel block mode control bit field.
RROAT	19	rwh	Reset Request Only After Transaction Inactive DMA channel control bit to reset the request state flag.
CHMODE	20	rwh	Channel Operation Mode Inactive DMA channel control bit to reset condition of the hardware transaction request enable bit.
CHDW	[23:21]	rwh	Channel Data Width Inactive DMA channel data width bit field.
PATSEL	[26:24]	rwh	Pattern Select Inactive DMA channel pattern select bit field.
PRSEL	28	rwh	Peripheral Request Select Inactive DMA channel hardware request trigger control.
DMAprio	[31:30]	rwh	DMA Priority Inactive DMA channel priority bit field.

Direct Memory Access (DMA)

Field	Bits	Type	Description
RES	[15:14], 27, 29	r	Reserved Read as 0; must be written with 0.

Direct Memory Access (DMA)

DMA Channel Shadow Address Register

The Shadow Address Register stores the 32-bit shadow address of an inactive DMA channel.

DMA_SHADR_z (z = 000-047)

DMA Channel Shadow Address Register z

$$(2018_H + z * 20_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SHADR	[31:0]	rwh	Shadowed Address This bit field stores the 32-bit shadow address of an inactive DMA channel.

Direct Memory Access (DMA)
DMA Channel Control and Status Register

The Channel Control and Status Register contains the current transfer count, channel reset, pattern detection compare result and the status of traffic management interrupt triggers.

DMA_CHCSRz (z = 000-047)
DMARAM Channel Control and Status Register z
(201C_H + z * 20_H)
Reset Value: 0000 0000_H

LXO	RES	TCOUNT													
rh	r	rh													

Field	Bits	Type	Description
TCOUNT	[13:0]	rh	Transfer Count Status DMA transfer count for an inactive DMA channel.
LXO	15	rh	Old Value of Pattern Detection Inactive DMA channel compare result.
WRPS	16	rh	Wrap Source Buffer Inactive DMA channel wrap-around of source buffer interrupt trigger flag.
WRPD	17	rh	Wrap Destination Buffer Inactive DMA channel wrap-around of destination buffer interrupt trigger flag.
ICH	18	rh	Interrupt from Channel Inactive DMA channel interrupt trigger flag.
IPM	19	rh	Pattern Detection from Channel Inactive DMA channel pattern detection flag.
BUFFER	22	rh	DMA Double Buffering Active Buffer This bit is active during DMA double buffering and indicates which buffer is read or filled. 0 _B Buffer 0 read or filled by DMA. 1 _B Buffer 1 read or filled by DMA.

Direct Memory Access (DMA)

Field	Bits	Type	Description
FROZEN	23	rwh	<p>DMA Double Buffering Frozen Buffer</p> <p>This bit is active during DMA double buffering and indicates that one of the double buffers is frozen and available for a cyclic software task.</p> <p>0_B Buffer is not frozen. 1_B Buffer is frozen.</p> <p><i>Note: FROZEN bit must only be cleared by software.</i></p>
SWB	24	w	<p>DMA Double Buffering Switch Buffer</p> <p>When double buffering is selected by programming ADICRz.SHCT then the control bit is used to re-direct data from one buffer to the other buffer.</p> <p>0_B No action. 1_B Switch from buffer.</p> <p><i>Note: If a Linked List mode (ADICRz.SHCT[3:2] = 11) is configured then SWB must be 0.</i></p>
CWRP	25	w	<p>Clear Wrap Buffer Interrupt z</p> <p>Software clear of both the DMA channel source and destination wrap buffer interrupts stored in DMARAM at locations CHSRz.WRPS and CHSRz.WRPD</p> <p>0_B No action. 1_B Bits CHSRz.WRPS and CHSRz.WRPD are reset.</p> <p><i>Note: If DMA channel z is active in Move Engine x then clear bit fields MExCHSR.WRPS and MExCHSR.WRPD</i></p> <p>Reading this bit returns a 0.</p>
CICH	26	w	<p>Clear Interrupt for DMA Channel z</p> <p>Software clear of the DMA channel interrupt flags stored in DMARAM locations CHSRz.ICH and CHSRz.IPM</p> <p>0_B No action. 1_B Bits MExCHSR.ICH and MExCHSR.IPM are reset.</p> <p><i>Note: If DMA channel z is active in Move Engine x then clear bit fields MExCHSR.ICH and MExCHSR.IPM</i></p> <p>Reading this bit returns a 0.</p>

Direct Memory Access (DMA)

Field	Bits	Type	Description
SIT	27	w	Set Interrupt Trigger for DMA Channel z 0 _B No action. 1 _B Channel z interrupt trigger will be activated. Reading this bit returns a 0. <i>Note: If a Linked List mode (ADICRz.SHCT[3:2] = 11) is configured then SIT must be 0.</i>
SCH	31	w	Set Transaction Request for DMA Channel 0 _B No action. 1 _B A transaction for DMA channel z is requested. When setting SCH, TSRz.CH becomes set to indicate that a DMA request is pending for DMA channel z.
RES	14, [21:20], [30:28]	r	Reserved Read as 0; must be written with 0.

15.9 Use Cases

This section provides a code example for the DMA module to give an overview about the core functionality. The example realizes a one word (32 bit-length) single data transfer from a data source location to a data destination location without intervention of the CPU. The transfer gets triggered by software in this example. The module also supports hardware triggering, please see [Chapter 15.4.3.3](#) for more details.

There will be no interrupt or further functions created in this example, please see the respective registers for more details on that. The examples uses DMA channel 000 (z=000).

Step description to initialize and trigger a data transfer via DMA:

(Line 1) The 32-bit data source address (DMA_SADR000_ADD) gets stored in the source address register SADR000 (see register definition [DMA_SADR](#)).

(Line 2) The 32-bit data destination address (DMA_DADR000_ADD) gets stored in the destination address register DADR000 (see register definition [DMA_DADR](#)).

(Line 3) The channel data width is defined in the channel configuration register CHCR000 (see register definition [DMA_CHCFGR](#)). Setting DMA_CHCFGR000.[23:21] = 010_B sets the channel data width to 32 bit.

(Line 4) DMA hardware transfer requests are disabled in the transaction state register TSR000 (see register definition [DMA_TSR](#)). Writing DMA_TSR000.[17] = 1 disables the hardware transfer requests.

(Line 5) This line starts the data transfer between the source and destination memory address.

Note: the declaration of DMA_SADR000_ADD and DMA_DADR000_ADD must be done by the user.

Initialization Code for 1 ms timer interrupt

```
(1) DMA_SADR000 = DMA_SADR000_ADD; //data source add
(2) DMA_DADR000 = DMA_DADR000_ADD; //data destination add
(3) DMA_CHCFGR000.U |= (010 << 21);
(4) DMA_TSR000.U |= (1 << 17); //disable hardware requests
(5) DMA_CHCSR000.U |= (1 << 31); //start transfer
```

Note: The transfer can be started everywhere in the program.

16 Flexible CRC Engine (FCE)

This document describes the Flexible CRC Engine (FCE) module. The FCE provides a parallel implementation of Cyclic Redundancy Code (CRC) algorithms. The current FCE version for the TC26x B-Step microcontroller implements the IEEE 802.3 ethernet CRC32, the CCITT CRC16 and the SAE J1850 CRC8 polynomials. FCE's generic structure enables it to be extended with multiple independent CRC polynomials. The primary target of FCE is to be used as an hardware acceleration engine for software applications or operating systems services (compatible with Autosar CRC "specification of CRC Routines") using CRC signatures. CRC algorithms are commonly used to calculate message signatures that can be used to check message integrity during transport over communication channels like internal busses or interfaces between micro-controllers. CRC signatures are also suitable to sign blocks of data residing in variable or invariable storage elements.

The FCE operates as a standard peripheral bus slave and is fully controlled through a set of configuration and control registers. The different CRC algorithms are independent from each other, they can be used concurrently by different software tasks.

This chapter is structured as follows:

- **"Features" on Page 16-3**
- **"Operational overview" on Page 16-4**
- **"FCE Functional Description" on Page 16-5**
- **"FCE Module Registers" on Page 16-13**
- **"Interfaces of the FCE Module" on Page 16-12**
- **"Programming Guide" on Page 16-37**
- **"Properties of CRC code" on Page 16-40**

*Note: The FCE kernel register names described in **"FCE Module Registers" on Page 16-13** are referenced in a product User's Manual by the module name prefix "FCE_".*

16.2 Features

The FCE provides the following features:

- The FCE implements the following CRC polynomials:
 - IEEE 802.3 CRC32 ethernet polynomial: $0x04C11DB7^{1)}$ (crc kernel 0 and 1)
 - CCITT CRC16 polynomial: $0x1021$ (crc kernel 2)
 - SAE J1850 CRC8 polynomial: $0x1D$ (crc kernel 3)
- Parallel CRC implementation
 - Data blocks to be computed by FCE shall be a multiple of the polynomial degree
 - Start address of Data blocks to be computed by FCE shall be aligned to the polynomial degree
- Register Interface compliant with Autosar specification for CRC routines:
 - Input Register
 - CRC Register
 - Configuration Registers enabling to control the CRC operation and perform automatic checksum checks at the end of a message.
 - Extended register interface to control reliability of FCE execution in safety applications.
- FCE can be reset independently by a module reset controlled by software. The reset affects all CRC engines.
- Error notification scheme via dedicated interrupt node for:
 - Transient error detection: error interrupt generation (maskable) with local status register (cleared by software)
 - Checksum failure: error interrupt generation (maskable) with local status register (cleared by software)
- FCE implements provides one interrupt line to the interrupt system. Each CRC engine has its own set of flag registers.

1) The polynomial hexadecimal representation covers the coefficients degree - 1 down to 0.

16.3 Operational overview

The FCE is a standard peripheral slave module. The FCE is fully synchronous with the peripheral bus clock and runs with a 1:1 clock ratio.

The FCE operation is controlled over a set of memory mapped registers. The main purpose is to serve as hardware acceleration for software applications requiring CRC checksum computation. The register set has been designed to enable the FCE. Depending on the hardware configuration the FCE may implement more crc kernels with different CRC polynomials. The specific configuration for a product will be described into the product customizing chapter. Every crc kernel will present the same hardware and software architecture. The rest of this document will focus only on the description of the generic CRC kernel architecture. The **Figure 16-1 “FCE system integration” on Page 16-4** shows the kernel configuration for the TC26x B-Step microcontroller.

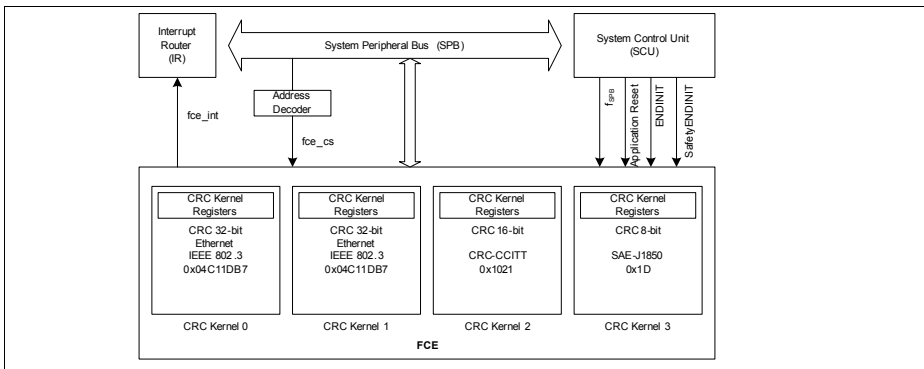

Figure 16-1 FCE system integration

In a multi-kernel implementation the interrupt lines are ored together, the FCE only present a single interrupt node to the system. Each crc kernel implements a status register that enables the software to identify which interrupt source is active. Please refer to the **STSm (m = 0-3)** register for a detailed description of the status and interrupt handling.

16.4 FCE Functional Description

16.4.1 Overview

The generic CRC kernel structure is presented in **Figure 16-2 “CRC kernel architecture”** on Page 16-5.

Figure 16-2 CRC kernel architecture

A checksum algorithm based on CRC polynomial division is characterized by the following properties:

Flexible CRC Engine (FCE)

- [1] polynomial degree (e.g. 32, that represents the highest power of two of the polynomial)
- [2] polynomial (e.g. 0x04C11DB7: the 33rd bit is omitted because always equal to 1)
- [3] init value: the initial value of the CRC register
- [4] input data reflected: indicates if each byte of the input parallel data is reflected before being used to compute the CRC
- [4] result data reflected: indicates if the final CRC value is reflected or not
- [5] XOR value: indicates if a final XOR operation is done before returning the CRC result

All the properties are static once a polynomial has been chosen. However the FCE provides the capability to control the two reflection steps and the final xor as depicted in [Figure 16-2 “CRC kernel architecture” on Page 16-5](#) through the CFG register. The reset values are compatible with the implemented algorithm. The final xor control enables to select either 0xFFFFFFFF or 0x00000000 to be xored with the POST_CRC1 (see [Figure 16-2 “CRC kernel architecture” on Page 16-5](#)) value. These two values are those used by the most common CRC polynomials.

Note: The reflection steps and final XOR do not modify the properties of the CRC algorithm in terms of error detection, only the CRC final signature is affected.

16.4.2 CRC Operation

Software must first ensure that the CRC kernel is properly configured, especially the initial CRC register value written via the **CRC** register. If the software wishes to use the automatic signature check at the end of a message, the **LENGTH** register and **CHECK** registers must be configured with respectively the length as number of words of the message and the expected signature (**CHECK**). The word length is defined by the degree of the polynomial used. The **CHECK** value takes into account the final CRC reflection and XOR operation. The self check is enable by the **CFG.CCE** bit field.

CRC Kernel access rules:

Depending on the CRC kernel accesses by software the following rules apply:

- When accessing a CRC kernel of degree $\langle N \rangle$ only the bits $N-1$ down to 0 are used by the CRC kernel. The upper bits are ignored on write. When reading from a CRC kernel register the non-used upper bits are set to 0.

Property:

If the input message $M1$ consists of a message $M0$ appended with the CRC signature of $M0$, then the CRC signature of $M1$ shall be 0.

The software writes as many times as necessary into the **IR** register according to the length of the message. If **CFG.CCE** bit field is set, every time the **IR** register is written, the **LENGTH** register is decremented by one. In the case the Automatic Length Reload feature is not enabled (see **CFGm (m = 0-3)** register), if **LENGTH** is already at zero but software still writes to **IR** (by mistake) every bit of the **LENGTH** should be set to 1 and hold this value until software initializes it again for the processing of a new message. In such case the **STS.LEF** (Length Error Flag) should be set and an interrupt generated if the **CFG.LEI** (Length Error Interrupt) is set.

The hardware monitors the transition of the **LENGTH** register from 1 to 0 to detect the end of the message and proceed with the comparison of the **POST_CRC2** (see **Figure 16-2**) value with the **CHECK** register value. If the Automatic Length Reload feature is enabled the **LENGTH** register is reinitialized with the previously configured value. This feature is especially suited when the FCE is used in combination with a DMA engine.

The next two figures provides an overview of the control and status features of a CRC kernel.

Flexible CRC Engine (FCE)

Figure 16-3 CRC kernel configuration register

Figure 16-4 CRC kernel status register

16.4.3 Register protection and monitoring methods

Register Monitoring: applied to CFG and CHECK registers

Because CFG and CHECK registers are critical to the CRC operation, some mechanisms to detect and log transient errors are provided. Early detection of transient failures enables to improve the failure detection time and assess the severity of the failure. The monitoring mechanisms are implemented using two redundant instances as presented in [Figure 16-5](#).

Figure 16-5 Register monitoring scheme

Let <REG> designate either CFG or CHECK registers. When a write to <REG> takes place a copy of the redundant register is also updated. **Redundant registers are not visible to software.** Bits of <REG> reserved have no storage and are not used for redundancy. A compare logic continuously compares the two stored values and provides a signal that indicates if the compare is successful or not. The result of all compare blocks are ored together to provide a single flag information. If a mismatch is detected the **STS.CEF** (Configuration Error Flag) bit is set. For run-time validation of the compare logic a Force Register Mismatch bit field (**CTR.FRM_<REG>**) is provided. When set to 1 by software the contents of the redundant register is shifted left by one bit position (redundant bit 0 position is always replaced by a logical 0 value) and is given to the compare logic instead of the redundant register value. This enables to check the compare logic is functional. Using a walking bit pattern, the software can completely check the full operation of the compare logic. Software needs to clear the **CTR.FRM_<REG>** bit to '0' to be able to trigger again a new comparison error interrupt.

Register Access Protection: applies to LENGTH and CHECK registers

In order to reduce the probability of a mis-configuration of the CHECK and LENGTH registers (in the case the automatic check is used), the write access to the CHECK and LENGTH registers must follow the procedure depicted in [Figure 16-6](#):

Figure 16-6 Access control to CHECK register

Let <REG> designate **CHECK** or **LENGTH** registers. Before being able to configure a new <value> value into the <REG> register of a crc kernel, software must first write the 0xFACECAFE value to the <REG> address. The 0xFACECAFE is not written into the CHECK register. The next write access will proceed as a normal bus write access. The write accesses shall use full 32-bit access only. This procedure will then be repeated every time software wants to configure a new <REG> value. If software reads the CHECK register just after writing 0xFACECAFE it returns the current <REG> contents and not 0xFACECAFE. **A read access to <REG> has no effect on the protection mechanism.**

16.4.4 FCE interrupts

Each FCE crc kernel provides one internal interrupt source. The interrupt lines from each crc kernel are ored together to be sent to interrupt system. The system interrupt is an active high pulse with the duration of one cycle (of the peripheral clock). The FCE interrupt handler can use the status information located within the **STS** status register of each crc kernel.

Flexible CRC Engine (FCE)

Each crc kernel provides the following interrupt sources:

- CRC Mismatch Interrupt controlled by **CFG.CMI** bit field and observable via the status bit field **STS.CMF** (CRC Mismatch Flag).
- Configuration Error Interrupt controlled by **CFG.CEI** bit field and observable via the status bit field **STS.CEF** (Configuration Error Flag).
- Length Error Interrupt controlled by **CFG.LEI** bit field and observable via the status bit field **STS.LEF** (Length Error Flag).
- Bus Error Interrupt controlled by **CFG.BEI** bit field and observable via the status bit field **STS.BEF** (Bus Error Flag).

Interrupt generation rules

- A status flag shall be cleared by software by writing a **1** to the corresponding bit position.
- If an status flag is set and a new hardware condition occurs, no new interrupt is generated by the kernel: the STS.<FLAG> bit field masks the generation of a new interrupt from the same source. If a SW access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration.

As all the interrupts are caused by an error condition, the interrupt shall be handled by a Error Management software layer. The software services using the FCE as acceleration engine may not directly deal with error conditions but let the upper layer using the service to deal with the error handling.

16.5 Interfaces of the FCE Module

The interfaces of the FCE module shall be described in the module design specification.

16.6 FCE Module Registers

Figure 16-7 and **Table 16-2** show all registers associated with a FCE crc-kernel. All FCE kernel register names are described in this section. They should get the prefix “FCE_” when used in the context of a product specification.

The registers are numbered by one index to indicate the related FCE CRC Kernel ($m = 0-3$). Some kernel registers are adapted to the degree of the polynomial implemented by the kernel.

FCE Registers Overview

1) The absolute register byte address for each crc kernel m is calculated as follows:
 CRC kernel register base Address ([Table 16-1](#)) + m*20H, m = 0-3

Access Mode Rules

The [Table 16-2 “Registers Overview - CRC Kernel Registers” on Page 16-14](#) uses the standard access mode conventions.

- E indicates that an access is only possible if the **end of initialization** signal is active. In this case Supervisor Mode (SV) is also mandatory.
- SE indicates that an access is only possible if the **safety end of initialization** signal is active. In this case Supervisor Mode (SV) is also mandatory.
- When U, SV are both listed it means that a read or write access can be done either in user mode (U) or supervisor mode (SV).
- BE stands for Bus Error, NSC stands for No Special Condition.
- P indicates that the register is protected by ACCEN0/1.

Disabling the FCE

The FCE module can be disabled using the **CLC** register.

When the disable state is requested all pending transactions running on the bus slave interface must be completed before the disabled state is entered. The CLC Register Module Disable Bit Status CLC.DISS indicates whether the module is currently disabled (DISS == 1). Any attempt to write any of the BPI writable registers with the exception of the CLC Register will generate a bus error. A read operation of BPI registers is allowed and does not generate a bus error.

Resetting the FCE

The FCE module can be reset using the **KRST0**, **KRST1**, and **KRSTCLR** registers. This action affects all the CRC kernels.

To reset the FCE it is necessary to set the RST bits by writing with '1' in both Reset Registers **KRST0**, **KRST1**. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Reset Register 0 includes a reset status bit that is set to '1' by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a reset was processed. The bit can be re-set to '0' by writing to it with '1'.

16.6.1 System Registers description

This section describes the registers related to the product system architecture.

Clock Control Register (CLC)

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

CLC

Clock Control Register (00_H) **Reset Value: 0000 0003_H**

Field	Bits	Type	Description
DIRS	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Note: The features related to the pre-defined FDIS, EDIS and RMC fields are not supported by the FCE. Therefore the corresponding fields have been removed from the CLC register.

Module Identification Register
ID
Module Identification Register (08_H) Reset Value: 00CA C002_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision). The current revision number is 02 _H .
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. The value for the FCE module is 00CA _H .

Kernel Reset Clear Register (KRSTCLR)

Refer to **“Resetting the FCE” on Page 16-16** for the usage of the register.

KRSTCLR

Kernel Reset Status Clear Register (EC_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

 Refer to **“Resetting the FCE” on Page 16-16** for the usage of the register.

KRST1
Kernel Reset Register 1
(F0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

Refer to **“Resetting the FCE” on Page 16-16** for the usage of the register.

KRST0

Kernel Reset Register 0 (F4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set.</p> <p>0_B No kernel reset was requested 1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.</p>
RSTSTAT	1	rw	<p>Kernel Reset Status</p> <p>This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits.</p> <p>0_B No kernel reset was executed 1_B Kernel reset was executed</p> <p>This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.</p>
0	[31:2]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B.

ACCEN1

Access Enable Register 1

(F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 00000_B to 011111_B.

ACCEN0
Access Enable Register 0
(FC_H)
Reset Value: FFFF FFFF_H

16.6.2 CRC Kernel Control/Status Registers

CRC Engine Input Register

IR_m (m = 0-1)

Input Register m

(20_H + m*20_H)

Reset Value: 0000 0000_H

31

0

Field	Bits	Type	Description
IR	[31:0]	rw	Input Register This bit field holds the 32-bit data to be computed

A write to IR_m triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Only 32-bit write transactions are allowed to this IR_m registers, any other bus write transaction will lead to a Bus Error.

CRC Engine Input Register

IR_m (m = 2-2)

Input Register m

(20_H + m*20_H)

Reset Value: 0000 0000_H

31

0

Field	Bits	Type	Description
IR	[15:0]	rw	Input Register This bit field holds the 16-bit data to be computed
0	[31:16]	r	Reserved Read as 0; should be written with 0.

A write to IR_m triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Only 32-bit or 16-bit write

Flexible CRC Engine (FCE)

transactions are allowed to this IRm register, any other bus write transaction will lead to a Bus Error. Only the lower 16-bit of the write transactions will be used.

CRC Engine Input Register

IRm (m = 3-3)

Input Register m

(20_H + m*20_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IR	[7:0]	rw	Input Register This bit field holds the 8-bit data to be computed
0	[31:8]	r	Reserved Read as 0; should be written with 0.

A write to IRm triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Any write transaction is allowed to this IRm register. Only the lower 8-bit of the write transactions will be used.

CRC Engine Result Register
RES_m (m = 0-1)
CRC Result Register m
(24_H + m*20_H)
Reset Value: FFFF FFFF_H

31

0

Field	Bits	Type	Description
RES	[31:0]	rh	Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect.

CRC Engine Result Register
RES_m (m = 2-2)
CRC Result Register m
(24_H + m*20_H)
Reset Value: 0000 FFFF_H

31

0

Field	Bits	Type	Description
RES	[15:0]	rh	Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

CRC Engine Result Register

RESm (m = 3-3)

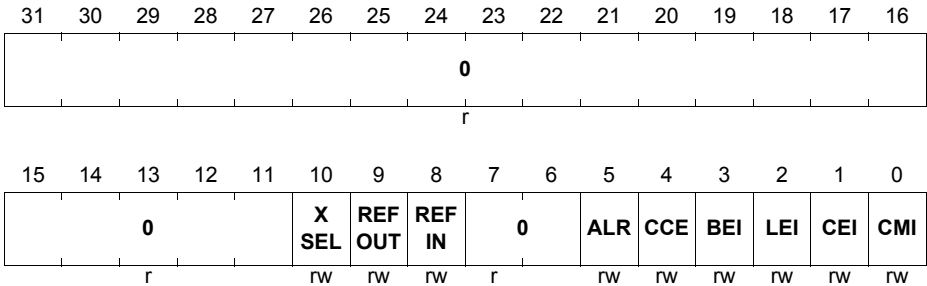

CRC Result Register m

(24_H + m*20_H)

Reset Value: 0000 00FF_H

Field	Bits	Type	Description
RES	[7:0]	rh	Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect.
0	[31:8]	r	Reserved Read as 0; should be written with 0.

CRC Engine Configuration Register
CFGm (m = 0-3)
CRC Configuration Register m
(28_H + m*20_H)
Reset Value: 0000 0700_H

Field	Bits	Type	Description
CMI	0	rw	CRC Mismatch Interrupt 0 _B CRC Mismatch Interrupt is disabled 1 _B CRC Mismatch Interrupt is enabled
CEI	1	rw	Configuration Error Interrupt When enabled, a Configuration Error Interrupt is generated whenever a mismatch is detected in the CFG and CHECK redundant registers. 0 _B Configuration Error Interrupt is disabled 1 _B Configuration Error Interrupt is enabled
LEI	2	rw	Length Error Interrupt When enabled, a Length Error Interrupt is generated if software writes to IR register with LENGTH equal to 0 and CFG.CCE is set to 1. 0 _B Length Error Interrupt is disabled 1 _B Length Error Interrupt is enabled
BEI	3	rw	Bus Error Interrupt When enabled, an interrupt is generated if a bus write transaction with an access width smaller than the kernel width is issued to the input register. 0 _B Bus Error Interrupt is disabled 1 _B Bus Error Interrupt is enabled

Flexible CRC Engine (FCE)

Field	Bits	Type	Description
CCE	4	rw	CRC Check Comparison 0 _B CRC check comparison at the end of a message is disabled 1 _B CRC check comparison at the end of a message is enabled
ALR	5	rw	Automatic Length Reload 0 _B Disables automatic reload of the LENGTH field. 1 _B Enables automatic reload of the LENGTH field at the end of a message.
REFIN	8	rw	IR Byte Wise Reflection 0 _B IR Byte Wise Reflection is disabled 1 _B IR Byte Wise Reflection is enabled
REFOUT	9	rw	CRC 32-Bit Wise Reflection 0 _B CRC 32-bit wise is disabled 1 _B CRC 32-bit wise is enabled
XSEL	10	rw	Selects the value to be xored with the final CRC 0 _B 0x00000000 1 _B 0xFFFFFFFF
0	[7:6], [31:11]	r	Reserved Read as 0; should be written with 0.

CRC Engine Status Register
STSm (m = 0-3)
CRC Status Register m ($2C_H + m \cdot 20_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CMF	0	rwh	CRC Mismatch Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect.
CEF	1	rwh	Configuration Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect.
LEF	2	rwh	Length Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect.
BEF	3	rwh	Bus Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

Flexible CRC Engine (FCE)

CRC Engine Length Register

LENGTH_m (m = 0-3)

CRC Length Register m (30_H + m*20_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
LENGTH	[15:0]	rwh	Message Length Register Number of 32-bits words building the message over which the CRC checksum is calculated. This bit field is modified by the hardware: every write to the IR register decrements the value of the LENGTH bit field. If the CFG.ALR field is set to 1, the LENGTH field shall be reloaded with its configuration value at the end of the cycle where LENGTH reaches 0.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Flexible CRC Engine (FCE)

CRC Engine Check Register

CHECK_m (m = 0-1)

CRC Check Register m (34_H + m*20_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHECK	[31:0]	rw	CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field

CRC Engine Check Register

CHECK_m (m = 2-2)

CRC Check Register m (34_H + m*20_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHECK	[15:0]	rw	CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field
0	[31:16]	r	Reserved Read as 0; should be written with 0.

CRC Engine Check Register

CHECK_m (m = 3-3)

CRC Check Register m

(34_H + m*20_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CHECK	[7:0]	rw	CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field
0	[31:8]	r	Reserved Read as 0; should be written with 0.

16.8 Properties of CRC code

Hamming Distance

The Hamming distance defines the error detection capability of a CRC polynomial. A cyclic code with a Hamming Distance of D can detect all D-1 bit errors. [Table 16-3 “Hamming Distance as a function of message length \(bits\)” on Page 16-40](#) shows the dependency of the Hamming Distance with the length of the message.

17 Interrupt Router (IR)

The chapter describes the Interrupt Router (IR) module that schedules on TC26x B-Step Interrupts (here called service requests) from external resources, internal resources and SW to the TriCore CPU and to the DMA modules (here called service provider).

Topics covered include the architecture of the interrupt system, interrupt system configuration, and the interrupt operations of the TC26x B-Step peripherals.

17.1 Overview

An interrupt request can be serviced either by one of the CPUs or by the DMA module. Interrupt requests are called “service requests” rather than “interrupt requests” in this document because they can be serviced by either one of the service providers.

The interrupt system in the TC26x B-Step is realized in the Interrupt Router module which includes the Service Request Nodes (SRNs), the Interrupt Control Units (ICUs) and additional functionality for SW development support.

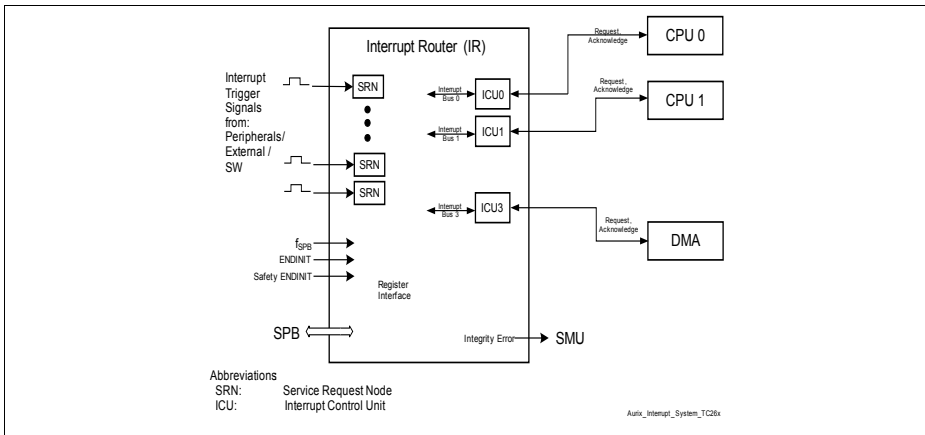

As shown in [Figure 17-1](#), each TC26x B-Step module that can generate service requests is connected to one or more Service Request Nodes (SRNs) in the central Interrupt Router module. The Interrupt Router module includes also several general purpose Service Request Nodes (SRNs) that can be used for software (SW) triggered service requests.

Each SRN contains a Service Request Control Register (SRC) to configure the service request regarding e.g. priority, mapping to one of the available service providers.

Each SRN is connected to all ICUs in the interrupt router module where the SRNs control register setting defines the target service provider and the priority of the service request.

Each ICU handles the interrupt arbitration among competing service requests from SRNs that are mapped to the ICU.

Each ICU is connected to one service provider (CPU or DMA module) where the ICU offers the valid winning service request/SRN of an arbitration round and the service provider signals back to the ICU when and which service request it is processing.

Interrupt Router (IR)

Figure 17-1 Block Diagram of the TC26x B-Step Interrupt System

17.2 Features

- Interrupt System with support of up to 512 / 1024 service requests
- Support of up to 255 service request priority levels per ICU¹⁾ / Service Provider
- Support of up to 16 ICU / service provider
- Each CPU and DMA module with an dedicated ICU
- ICU service request arbitration independent from other ICUs
- Low latency arbitration - three / four clocks²⁾ from receipt of an service request to sending it to the service provider
- Each Service Request with a dedicated Service Request Node (SRN)
- Each SRN with a programmable 8-bit priority vector¹⁾
- Each SRN can be mapped to one of the implemented ICUs / Service Providers
- SRNs are cleared automatically by hardware on interrupt acknowledge by the configured service provider
- Interrupt System Integrity support
- Four General Purpose Service Requests (GPSR) per CPU that can be used as Software Interrupts (not assigned to peripherals or external interrupts)
- Mechanism to signal General Purpose Service Requests (Software Interrupts) simultaneously to multiple Service Providers (Service Request Broadcast Registers, SRB)

1) Max. 255 of the implemented service requests can be mapped to one CPU

2) Depends on the complexity and the clock frequency of the Interrupt Router. Details for the implementation are described in the chapter Module Implementation

Interrupt Router (IR)

- Priority dependent masking of service requests (for CPUs, related control registers included in the CPUs)
- External Interrupts with filter modes and trigger modes (to e.g. falling edge, rising edge, high or low level). Modes can be configured during runtime¹⁾
- CPU wake up support (service request to CPUx is signalled to SCU to wake up CPUx in case CPUx is in IDLE state)

17.3 Service Request Nodes (SRN)

Each Service Request node (SRN) inside the Interrupt Router module contains a Service Request Control (SRC) Register and interface logic that connects it to the triggering unit outside the Interrupt Router module and to the interrupt arbitration buses inside the Interrupt Router (see also: [Figure 17-1](#)).

17.3.1 Service Request Control Registers

All Service Request Control Registers in the Interrupt Router module have the same format. In general, these registers contain:

- Enable/disable information
- Service Request Set bit and Service Request Clear bit
- Service Request Priority Level vector (8-bit)
- Service provider destination
- Service request status bit
- Software-initiated service request set and reset bits
- Integrity errors signalled to the Safety Monitor Unit (SMU)
- Interrupt Sticky and Overflow bits

Besides being activated by the associated triggering unit through hardware, each SRN can also be set or reset by software via two software-initiated service request control bits.

The description given in this chapter characterizes all Service Request Control Registers of the TC26x B-Step. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

17.3.1.1 General Service Request Control Register Format

Service Request Control Register (SRC)

The description given in this chapter characterizes all Service Request Control Registers of the TC26x B-Step. Information on peripheral module interrupt functions such as enable or request flags is provided in the corresponding sections of the module chapters.

1) External Interrupt logic and related control registers are described in the System Control Unit (SCU) chapter, External Request Unit (ERU)

Interrupt Router (IR)

Field	Bits	Type	Description
IOV	27	rh	Interrupt Trigger Overflow Bit The IOV bit is set by HW if a new service request was triggered via interrupt trigger or SETR bit while the SRN has still an pending service request. 0_B No Interrupt Trigger Overflow detected 1_B Interrupt Overflow Detected.
IOVCLR	28	w	Interrupt Trigger Overflow Clear Bit IOVCLR is required to reset IOV. 0_B No action 1_B Clear IOV; bit value is not stored; read always returns 0.
SWS	29	rh	SW Sticky Bit The Software Sticky Bit is set when the SRR bit has been set via the SETR (Request Set Bit). 0_B No interrupt was initiated via SETR 1_B Interrupt was initiated via SETR This bit can be cleared by writing with 1. Writing with 0 has no effect.
SWSCLR	30	w	SW Sticky Clear Bit SWSCLR is required to reset SWS. 0_B No action 1_B Clear SWS; bit value is not stored; read always returns 0.
Reserved	31	rh	Reserved Read as 0 or 1; should be written with 0.
0	[23:22], [15:13], [9:8]	r	Reserved Read as 0; should be written with 0.

17.3.1.2 Changing the SRN configuration

All Service Request Nodes are disabled per default. To use a Service Request Node, it has to be configured and enabled by setting the SRC.SRE bit='1'.

The Service Request Nodes can be configured regarding the interrupt service provider target (SRC.TOS) and regarding the service request priority number (SRC.SRPN).

Once an SRN is enabled, the TOS and/or SRPN bit fields can be changed by using the following sequence:

- disable the SRN (SRC.SRE='0') (write to SRC.SRE)
- check that the SRN is disabled (read back SRC.SRE and check for SRE='0')
- check the register LWSRx (read/poll LWSRx, see note below):
- if LWSRx.STAT='1' and LWSRx.SRPN and LWSRx.ECC are equal to the (old) SRC value check again
- if LWSRx.STAT='0' or LWSRx.SRPN or LWSRx.ECC are not equal to the old SRC values anymore go on with the next step (change SRC value)
- change the SRC.TOS and/or SRC.SRPN bit field
- enable the SRN (SRC.SRE='1') (write to SRC.SRE)

The read/poll of LWSRx is mandatory before changing SRC.TOS and/or SRC.SRPN. Otherwise the last interrupt before the SRN disabling could still be taken (enter) for execution in the CPU. It could be acknowledged later by the CPU with the side effect that the first interrupt of the just re-configured SRN can get lost. The time between enter and acknowledge is not deterministic if the ISP is a TriCore. If the ISP is the DMA module, enter and acknowledge are signalled in the same cycle. The 'x' in LWSRx means that the LWSR register related to the TOS setting has to be checked (TOS=0 -> LWSR0, TOS=1 -> LWSR1, ...).

17.3.1.3 Protection of the SRC Registers

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see [Chapter 17.6.1](#)). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

- SRC[31:16] is write protected by ACCEN00
- SRC[15:0] is write protected by ACCEN10

This implementation allows to define a first group of TAG ID(s) that are allowed to modify the configuration of the Service Request Nodes (TOS, SRPN, SRE), and a second group of TAG IDs that are allowed to modify the Service Request Nodes control bits (set/clear of SW Interrupts, clear of Sticky and Overflow bits)

Write access to SRC[31:16] with access protection violation

When an SRC register is written with a 32 bit data access, only the SRC register parts without ACCEN protection violation will be updated:

Interrupt Router (IR)

- Violation for SRC[31:16] (ACCEN00) and SRC[15:0] (ACCEN10)
- no update of the SRC register, Alarm send to SMU
- Violation for SRC[31:16] (ACCEN00)
- no update of SRC[31:16], SRC[15:0] updated, Alarm send to SMU
- Violation for SRC[31:16] (ACCEN10)
- SRC[31:16] updated, no updated of SRC[15:0], Alarm send to SMU

17.3.1.4 Request Set and Clear Bits (SETR, CLRR)

The SETR and CLRR bits allow software to set or clear the service request bit SRR.

- Writing a 1 to SETR causes bit SRR to be set to 1
- Writing a 1 to CLRR causes bit SRR to be cleared to 0
- Writing a 1 to SETR and CLRR at the same time, SRR is not changed
- The value written to SETR or CLRR is not stored
- Writing a 0 to these bits has no effect
- These bits always return 0 when read

17.3.1.5 Enable Bit (SRE)

The SRE bit enables an interrupt to take part in the arbitration for the selected service provider. It does not enable or disable the setting of the request flag SRR; the request flag can be set by hardware or by software (via SETR) independent of the state of the SRE bit. This allows service requests to be handled automatically by hardware or through software polling.

If SRE = 1, pending service requests are passed on to the designated service provider for interrupt arbitration. The SRR bit is automatically set to 0 by hardware when the service request is acknowledged by the Interrupt Service Provider. It is recommended that in this case, software should not modify the SRR bit to avoid unexpected behavior due to the hardware controlling this bit.

If SRE = 0, pending service requests are not passed on to service providers. Software can poll the SRR bit to check whether a service request is pending. To acknowledge the service request, the SRR bit must then be reset by software by writing a 1 to CLRR.

Note: In this document, 'active source' means an SRN whose Service Request Control Register has its request enable bit SRE set to 1 to allow its service requests to participate in interrupt arbitration.

17.3.1.6 Service Request Flag (SRR)

When set, the SRR flag indicates that a service request is pending. It can be set or reset directly by hardware or indirectly through software using the SETR and CLRR bits. Writing directly to this bit via software has no effect.

Interrupt Router (IR)

SRR can be set or cleared either by hardware or by software regardless of the state of the enable bit SRE. However, the request is only forwarded for service if the enable bit is set. If SRE = 1, a pending service request takes part in the interrupt arbitration of the service provider selected by the device's TOS bit field. If SRE = 0, a pending service request is excluded from interrupt arbitrations.

SRR is automatically reset by hardware when the service request is acknowledged and serviced. Software can poll SRR to check for a pending service request. SRR must be reset by software in this case by writing a 1 to CLRR.

Note: Clearing a pending service request flag SRR and enabling the corresponding service request node (SRN) should be done in two steps / two writes: first clear the SRR flag (SRC.CLRR), then enable the (SRC.SRE).

17.3.1.7 Type-Of-Service Control (TOS)

There are multiple service providers for service requests in the TC26x B-Step, e.g. two CPU and the DMA module. The TOS bit field is used to select to which of the available interrupt service provider an service request has to be forwarded.

Note: Before modifying an TOS or an SRPN bit field, the corresponding SRN must be disabled (SRE = 0).

17.3.1.8 Service Request Priority Number (SRPN)

The 8-bit Service Request Priority Number (SRPN) indicates the priority of a service request with respect to other sources requesting service from the same service provider, and with respect to the priority of the service provider itself.

SRPN Rules:

- Each active source selecting the same service provider must have a unique SRPN value to differentiate its priority
- Active sources selecting different service provider could use same SRPN values
- If a source is not active – meaning its SRE bit is 0 – no restrictions are applied to the service request priority number
- The SRPN is used by service providers to select an Interrupt Service Routine (ISR) or DMA channel to service the request

Service Provider is a CPU:

ISRs are associated with Service Request Priority Numbers by an Interrupt Vector Table located in each CPU. This means that the CPU Interrupt Vector Table is ordered by priority number. This is unlike traditional interrupt CPU architectures in which their interrupt vector tables are ordered by the source of the interrupt. The CPU Interrupt Vector Tables allow a single peripheral to have multiple priorities for different purposes.

Interrupt Router (IR)

Note: For a CPU, the SRPN value of 00_H is a special value and must not be used for service requests mapped to a CPU.

Note: TC1.6E and TC1.6P CPUs are providing a flexible interrupt table alignment with a configurable vector spacing of 8 byte or 32 byte. Pls. see also CPU chapter.

Service Provider is the DMA:

The complete SRPN number is used for the arbitration of service requests the DMA module. Within the module, the DMA channels are associated with the Service Request Priority Number by the SRPN LSBs of the SRPN.

Only the SRPN numbers 0 ... max_channel_number will result in a trigger of the related DMA channel. SRPN numbers > max_channel_number do not result in a DMA channel trigger nor any other signalling.

Examples:

- In case of an 16 channel DMA module the SRPN number 00H will trigger the channel 0, 07H will trigger the channel 7. All SRPN > 0FH will not result in a channel trigger.
- In case of an 64 channel DMA module the SRPN number 00H will trigger the channel 0, 17H will trigger the channel 23 an 3FH. will trigger channel 64. All SRPN > 3FH will not result in a channel trigger.

17.3.1.9 ECC Encoding (ECC)

The SRC.ECC bit field will be updated by the SRN under the following conditions:

- write or Read-Modify-Write to SRC[31:0]
- write to SRC[15:0] (16-bit write)
- write to SRC[15:8] or write to SRC[7:0] (byte write)

In case of a 32-bit write or a Read-Modify-Write to the SRC, the ECC bit field will be updated with the calculated ECC, the data written to ECC bit field will be ignored.

ECC encoding covers the new values of SRC.SRPN, SRC.TOS, SRC.SRE and the internal 10 bit index number of the written SRN.

There is no permanent ECC check. ECC check will be checked whenever the SRN with an pending service request was accepted by the selected (TOS) service provider as next service request to be processed.

For a check of the error detection mechanisms ECC errors can be inserted (ECC bit field modified) by:

- writing to SRC[23:16] (byte write)
- writing to SRC[31:16] (16-bit write)

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

ECC Code

The ECC code used for the IR Error Detection mechanism is a Hsiao 22_5 code with DED (double error detection) capability:

```
GEN_ENC22_5 : if (word_width_g/(nb_mems_g*ecc_granularity_g)) =
22 and (nb_check_bits_g = 5) generate
    cmr22_5: for i in 0 to nb_check_bits_g - 1 generate
        CODE_MATRIX_ROWS(i)    <= code_rows_22_5(i);
    end generate;
end generate;
```

```
type rows_22_5_t is array (4 downto 0) of std_ulogic_vector(21
downto 0);
constant code_rows_22_5 : rows_22_5_t :=
("0001001011001011011011",
"0010010101010101101101",
"0100100110100110110110",
"1000111000111000111111",
"1111000000111111000111");
```

17.3.1.10 Interrupt Trigger Overflow Bit (IOV)

The IOV bit is set by HW if both conditions are true:

- service request is pending
- a new service request is triggered via interrupt trigger or SETR bit

17.3.1.11 Interrupt Trigger Overflow Clear Bit (IOVCLR)

The Interrupt Trigger Overflow Clear Bit can be used to clear the IOV bit. The IOV bit is cleared by writing a '1' to the IOVCLR bit.

17.3.1.12 SW Sticky Bit (SWS)

The Software Sticky Bit is set when the SETR (Request Set Bit) is written with 1.

17.3.1.13 SW Sticky Clear Bit (SWSCLR)

The Software Sticky Clear Bit can be used to clear the SWS bit. The SWS bit is cleared by writing a '1' to the SWSCLR bit.

17.4 Interrupt Control Unit (ICU)

The Interrupt Router module includes one ICU per service provider (CPUs and DMA module) where each ICU is related to one service provider. SRNs can be mapped to one of the ICUs via the SRNs SRCx.TOS register bit field (see also: [Figure 17-1](#)).

The Interrupt Control Units (ICU):

- Manages the arbitration among competing service requests from SRNs that are mapped to the ICU
- Provides the winner of the arbitration round to the service provider
- Receives the information from the service provider which service request was accepted
- Checks the accepted service request information (ECC check)
- Signals integrity errors to the Safety Monitor Unit (SMU)
- Manages the clearing of acknowledged service requests in the related SRNs

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

17.4.1 ICU Control Registers

This section describes the Interrupt Control Unit (ICU) registers. Each ICU includes two control registers:

- Latest Winning Service Request register (LWSR) provides information about the winner of the last service request arbitration round
- Last Acknowledged Service Request register (LASR) provides information about the last service request that was accepted by the service provider

17.4.1.1 Latest Winning Service Request Register (LWSR)

Latest Winning Service Request (LWSR)

The Latest Winning Service Request register provides information about the winner of the last arbitration round. The register bit fields are representing what is provided by the ICU to the Interrupt Service Provider.

LWSR

Latest Winning Service Request (xx_H) **Reset Value: 0000 0000_H**

ECC	[15:10]	r	Latest Winner ECC This bit field shows the ECC field (SRN.ECC) that was transferred from the last winning SRN to the ICU. This bit field is only valid if STAT is set to 1. <i>Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.</i>
ID	[25:16]	r	Latest Winner ID This bit field shows the ID number of the last winning SRN. This bit field is only valid if STAT is set to 1

Interrupt Router (IR)

Field	Bits	Type	Description
STAT	31	r	<p>LWSR Register Status</p> <p>The STAT register indicates if the PN, ECC and ID bit fields are still valid. They are still valid if the interrupt from the SRN identified by ID is still pending. If the ICU does not have a winner because no interrupt is pending or not yet arbitrated than it clears the STAT bit.</p> <p>0_B LWSR bit fields are not valid 1_B LWSR bit fields are valid</p>
0	[30:26] , [9:8]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

17.4.1.2 Last Acknowledged Service Request Register (LASR)

Last Acknowledged Service Request (LASR)

The Last Acknowledged Service Request register is representing the information that was sent by the Interrupt Service Provider together with the last acknowledge.

LASR

Last Acknowledged Service Request (xx_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PN	[7:0]	r	Last Acknowledged Service Request Priority Number This bit field shows the Priority Number of the last acknowledged service request
ECC	[15:10]	r	Last Acknowledged Interrupt ECC This bit field shows the ECC value of the last acknowledged service request, as send by the service provider with acknowledge <i>Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.</i>
ID	[25:16]	r	Last Acknowledged Interrupt SRN ID This bit field shows the ID number of the last acknowledged service request, as send by the service provider with acknowledge
0	[31:26], [9:8]	r	Reserved Read as 0; should be written with 0.

17.4.1.3 Error Capture Register (ECR)

Error Capture Register (ECR)

The Error Capture Register captures the Last Acknowledged Service Request (LASR) register contents when an ECC error was detected by the ICU. The ECR shows always the last ECR contents where an ECC error was detected. Software can clear the ECR contents by writing to the ECR. Error Status (STAT) and Error Overflow (EOV) bits can be used as error handling mechanism and indication that error information where lost.

If ECR.EOV is cleared by SW, ECR.EOV must be cleared together with ECR.STAT. If a new error is detected in parallel to the ECR.EOV clear than ECR.EOV is set again by hardware while ECR.STAT is cleared.

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

ECR

Error Capture Register

 (xx_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PN	[7:0]	rwh	Service Request Priority Number This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
ECC	[15:10]	rwh	Service Request ECC This bit field shows the ECC of the last service request where an error was detected. Bit field can be modified by writing to it. This bit field can be modified by: <ul style="list-style-type: none"> • writing to SRC[23:16] (byte write) • writing to SRC[31:16] (16-bit write)

Interrupt Router (IR)

Field	Bits	Type	Description
ID	[25:16]	rwh	Service Request Node ID This bit field shows the ID of the last service request where an error was detected. Bit field can be modified by writing to it
EOV	30	rwh	Error Overflow Bit The bit is set if an ECC error was detected by the ICU while ECR.STAT='1' (Error Overflow situation). 0 _B No Error Overflow situation detected 1 _B Error Overflow situation detected This bit can be cleared by writing with 1. Writing with 0 has no effect. If this bit is cleared, it must be cleared together with the STAT bit.
STAT	31	rwh	Error Status Bit The Error Status Bit is set whenever an ECC was detected by the ICU. 0 _B No ECC error detected 1 _B ECC error detected This bit can be cleared by writing with 1. Writing with 0 has no effect.
0	[29:26] , [9:8]	r	Reserved Read as 0; should be written with 0.

17.5 General Purpose Service Requests, Service Request Broadcast

The Interrupt Router module provides multiple groups of General Purpose Service Requests (GPSR) and a mechanism to trigger multiple Service Requests of a GPSR group in parallel, by software. The GPSR can be used as Software Interrupt.

Figure 17-2 Structure of a General Purpose Service Request Group and the related Broadcast register (Example for SRC_GPSRx0, SRB0)

17.5.1 General Purpose Service Requests (GPSRxy)

The Interrupt Router module provides multiple groups of General Purpose Service Requests:

- Each General Purpose Service Request Group consists of four Service Request Nodes. Nodes that can be used as Software Interrupt
- The General Purpose Service Requests can be configured and controlled via the related Service Request Control registers SRC_GPSRxy¹⁾
- The GPSR are not mapped to module service request triggers so they can only be used a SW trigger
- A General Purpose Service Request xy can only be triggered by writing '1' to the related SRC_GPSRxy.SETR¹⁾ bit or by writing a '1' to the related Service Request Broadcast register bit SRBx[y]

17.5.2 Service Request Broadcast Registers (SRBx)

There is one Service Request Broadcast register (SRBx) implemented for each General Purpose Service Request Group (GPSRxy¹⁾).

The Service Request Broadcast register x can be used to trigger multiple Service Requests within the SRC_GPSRxy¹⁾ group in parallel.

- SRBx is always read as 0
- Writing '1' to SRBx[y] triggers the service request GPXRxy (y=3:0)
- Writing '1' to SRBx[31:4] has no effect.

1) SRC_GPSRxy: x = group number; y= number of interrupt within the group, y=0:3

17.6 System Registers

The Interrupt Router module includes the standard set of TC26x B-Step system registers. **Figure 17-3** shows these system registers which include registers for:

- Register access protection
- Module Clock Control¹⁾
- Module Kernel Reset¹⁾
- OCDS Control and Status Register

Figure 17-3 Interrupt Router System Registers

17.6.1 Register Access Protection (ACCEN1/0)

The Interrupt Router module provides a master TAG ID based write access protection as part of the AURIX safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see **Chapter 17.6.1**). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

TAG ID based protection means that the support of write transactions to the Interrupt Router control registers can be enabled / disabled for each master TAG ID individually. For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed (see also **Figure 17-3**).

¹⁾ The Interrupt Router module does not support the features of this system register

Interrupt Router (IR)

The register access protection is controlled via the registers INT_ACCEN1 and INT_ACCEN0 where each bit is related to one encoding of the 6 bit On Chip Master TAG ID.

The INT_ACCEN1/0 access protection controls the write access to all Interrupt Router control and system registers with the exception of INT_ACCEN1/0. INT_ACCEN1/0 are only Safety Endinit protected.

After reset, all access enable bits and access control bits are enabled. INT_ACCEN1/0 have to be configured and checked to bring the system into a safe state.

17.6.2 Kernel Reset Registers (KRST1/0, KRSTCLR)

The Interrupt Router module does not include the kernel reset registers (KRST1, KRST0, KRSTCLR).

Note: The Interrupt Router module does not support a module kernel reset.

17.6.3 Clock Control Register (CLC)

The Interrupt Router module does not include the module clock control (CLC).

Note: The Interrupt Router module does not support the Clock Control register functionality which means that the Interrupt Router module clock can not be disabled by the CLC register.

17.6.4 OCDS Control and Status Register (OCS)

The Interrupt Router module does not include OCDS Control and Status (OCS) register.

Note: The Interrupt Router module does not support the OCS register functionality.

17.7 Arbitration Process

Each ICU in the interrupt module has its own interrupt bus. Each Service Request Node (SRN) can be directed to one service provider by mapping it via the SRC.TOS bit field setting to the related ICU / Interrupt Bus.

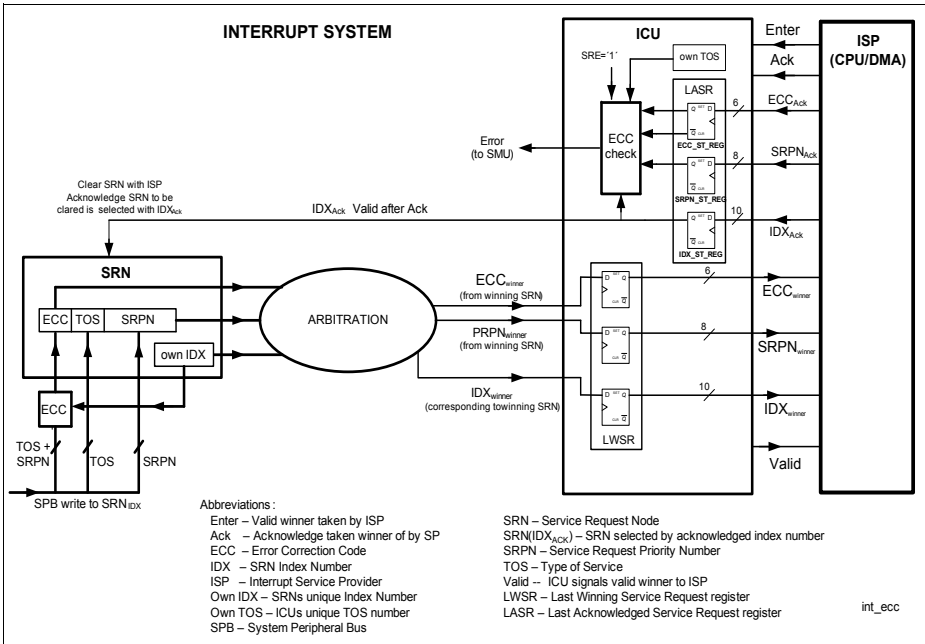

Figure 17-4 Interrupt System Arbitration Scheme Overview

With a first pending service request, an interrupt bus is starting a first arbitration process. The arbitration process on one interrupt bus is repeated as long at least one service request is pending. The related Interrupt Control Unit provides the service request that won the last arbitration process.

This means: when the ICU provides a service request to the service provider, and a new service request with a higher priority comes in, the ICU will offer the new service request after the next arbitration process.

The arbitration process implemented in the TC26x B-Step uses 3 system peripheral bus clock cycles to determine the pending service request with the highest priority number, SRPN. The exact number of the implementation is described in the Module Implementation chapter.

In an arbitration process, the interrupt bus compares the SRC.SRPN bit fields of all pending Service Request Nodes, mapped to this interrupt bus via SRC.TOS setting.

Interrupt Router (IR)

During the arbitration process, the pending service request with the highest priority number is identified as winner and the related SRN Service Request Control register bit field values SRPN, ECC and the Index of the SRN are provided to the ICU. The ICU provides these (SRPN, ECC, SRN Index) to the service provider. The ICU does an ECC check when it gets these information back from the service provider with an acknowledge. The ECC check is done with the received values: ECC, SRPN, SRN Index Number, SRE bit assumed to be '1' (SRN enabled) and the TOS number of the ICU.

The Interrupt Router module signals detected errors to the Safety Management Unit (one bit in the SMU, covers errors from all SRN and ICUs).

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

17.7.1 Number of Clock Cycles per Arbitration Process

The Interrupt Router implementation is can be configured regarding the number of:

- supported service requests (Service Request Nodes, SRN, up to 1024)
- supported service providers (Interrupt Control Units, ICUs)
- clock cycles per service request arbitration (3 SPB clock cycles)

The characteristics of the Interrupt Router module implemented in an AURIX product is described in the Module Implementation sub-chapter.

Figure 17-5 Interrupt System Timing (Schematic Overview, 3 Cycle Arbitration)

Figure 17-5 shows the interrupt timing of an Interrupt Router implementation with 3 cycle arbitration.

Cycle 1: No service request for the ICU is pending (therefore no arbitration round)

Cycle 2: One module is triggering a service request by sending a pulse to the related SRN in the Interrupt Router module.

Interrupt Router (IR)

Cycle 3-5: Arbitration among all pending service requests to the ICU

Cycle 6: ICU provides winning service request to the service provider (SRPN, ECC, SRN Index)

Cycle 7 - n-1: ICU re-arbitrates whenever a new service request from another SRN is pending, provides new winning service request to ICU if there is a new pending one with a higher SRPN number (higher priority)

Cycle 6- n-1: Interrupt Service Provider takes the information of the latest winning SRN (Enter)

Cycle n: Service provider acknowledges service request (provides SRPN, ECC, SRN Index informations of the acknowledged service request). ICU changes signals to ICU to 'no valid service request available' in the same clock cycle.

Cycle n+1: ICU does an ECC check of the acknowledge information (SRPN, ECC, SRN Index, SRE='1', TOS number of the ICU. If mismatch -> Integrity Error signalled to SMU/ SRPN, ECC and Index are captured in the ECR)

Cycle n+2: ICU selects the acknowledged SRN (selected by SRN Index). Selected SRN checks acknowledged SRPN and ECC with own SRC SRPN/ECC values (if mismatch -> Integrity Error signalled to SMU)

Cycle n+3: If at least one service request to the ICU is pending: new arbitration among all pending service request to the ICU

17.7.2 Service Request Acknowledge

When a Service Provider starts with the execution of a service request that was provided by the ICU, the Service Provider sends an acknowledge to the ICU. In parallel to the acknowledge, the Service Provider sends the informations about the executed service request back to the ICU (SRPN, ECC, SRN Index Number).

In the same clock cycle, the Service Provider sends an acknowledge, the ICU changes to 'no service request available': the ICU does not provide an arbitration winner to the service provider. This behavior of the ICU ensures that a just acknowledged service request is not provided again before the SRN was re-set (see [Figure 17-5](#)).

17.7.3 Handling of detected ECC Errors

The ICU does an ECC check of the informations it receives with the acknowledge from the Service Provider and the TOS number of the ICU itself. Assumption for the SRE bit is '1' (SRN was enabled). ECC in the SRN is covering the SRC bit field values: SRC.SRPN, SRC.SRN Index, SRC.SRE and SRC.TOS. (see [Figure 17-5](#))

Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.

If the ICUx detects an ECC error:

Interrupt Router (IR)

- ICUx captures the ECC, SRPN and the Index that showed an ECC error in the Error capture registers (ECRx), sets the ECRx.STAT bit and the ECRx.EOV bit if the STAT bit is still set.
- ICU signals the error via the IR error signal to the TC26x B-Step Safety Management Unit (SMU). SMU forwards this information to a CPU (if enabled).
- ICUx clears the service request in the SRN (selected by the Index)
- The CPU that received the 'ECC error detected in Interrupt Router' information via SMU can identify the ICU via the Error Status bits (ECRx.STAT='1'), read out the related service request information and clear the ECRx.STAT bit by writing with '1'. The CPU can also identify if one or multiple ECC errors were detected by this ICU via the Error Overflow bit (ECRx.EOV='1').

17.8 Usage of the TC26x B-Step Interrupt System

The following sections provide a short description of the Service Provider interfaces to the Interrupt Router ICUs.

Note: All ICU sub-modules in the Interrupt Router have the same functionality.

17.8.1 CPU to ICU Interface

Each CPU has one Interface is connected to one ICU of the Interrupt Router module. The CPU ICU interface consists of a register set where it takes over the informations of a service request provided by the ICU (SRPN, SRN Index, ECC). The informations will be send back to the ICU when the CPU acknowledges the provided service request.

The CPU ICU interface contains an Interrupt Control Register (ICR) that holds the current CPU priority number (CCPN), the global interrupt enable/disable bit (IE) and the pending interrupt priority number (PIPn). Further details of the CPU ICU interface and the CPU handling of interrupts can be found in the CPU chapter.

17.8.2 DMA to ICU Interface

The DMA module has one interface where it is connected to one ICU of the Interrupt Router module.

The DMA takes over the service request informations for the ICU, triggers internally the addressed channel and acknowledge it immediately to the ICU where the related SRN is cleared.

The DMA to ICU interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, SRN Index, ECC), The DMA sends them back to the ICU in the next clock cycle with an acknowledge.

The DMA channel priority scheme is identical to the scheme of the interrupt system: higher SRPN number -> higher service request priority, higher DMA channel number -> higher priority of the DMA channels where channel 0 has the lowest priority within the DMA.

17.8.3 Software-Initiated Interrupts

Software can set the service request bit (SRR) in any SRN by writing to its Service Request Control Register. Thus, software can initiate service requests that are handled by the same mechanism as hardware initiated service requests.

After the SRR bit is set in an SRN, there is no way to distinguish between a software initiated service request and a hardware initiated service request. For this reason, software should only use SRNs and interrupt priority numbers that are not being used for hardware initiated service requests.

Interrupt Router (IR)

The TC26x B-Step contains groups of General Purpose Service Request SRNs per CPU that support software-initiated interrupts. One group per implemented TriCore CPU, each group including four SRNs. These SRNs are not connected to internal or external hardware trigger signals and can only be used as software interrupts / software initiated service requests. These SRNs are called General Purpose Service Requests Nodes (SRC_GPSRxy, x=group number, y=0-3).

Additionally, any otherwise unused SRN can be employed to generate software interrupts.

17.8.4 External Interrupts

Four SRNs (Int_SCUSRC[3:0]) are reserved to handle external interrupts. The setup for external GPIO port input signals (edge/level triggering, gating etc.) that are able to generate an interrupt request is controlled in the External Request Unit (ERU). The ERU functionality is described in detail in the SCU chapter.

17.9 Use Case Examples

This section shows a use case for the interrupt system and a use case for the OTGS.

17.9.1 Use Case Example Interrupt Handler

This section explains how to organize the TriCore interrupt vector table. When an interrupt is accepted by the TriCore, the entry address into the interrupt vector table is calculated by the base interrupt vector table pointer TriCore register BIV and the priority number of that interrupt (PIPn). The TriCore TC1.6P and TC1.6E architecture offers the possibility to configure the vector spacing per entry to either 32 Byte (see Figure below a (Figure 17-6) or 8 Byte (see Figure below b (Figure 17-6)). As a third option the vector table can be reduced to a single entry by masking the PIPn (see Figure below c (Figure 17-6)).

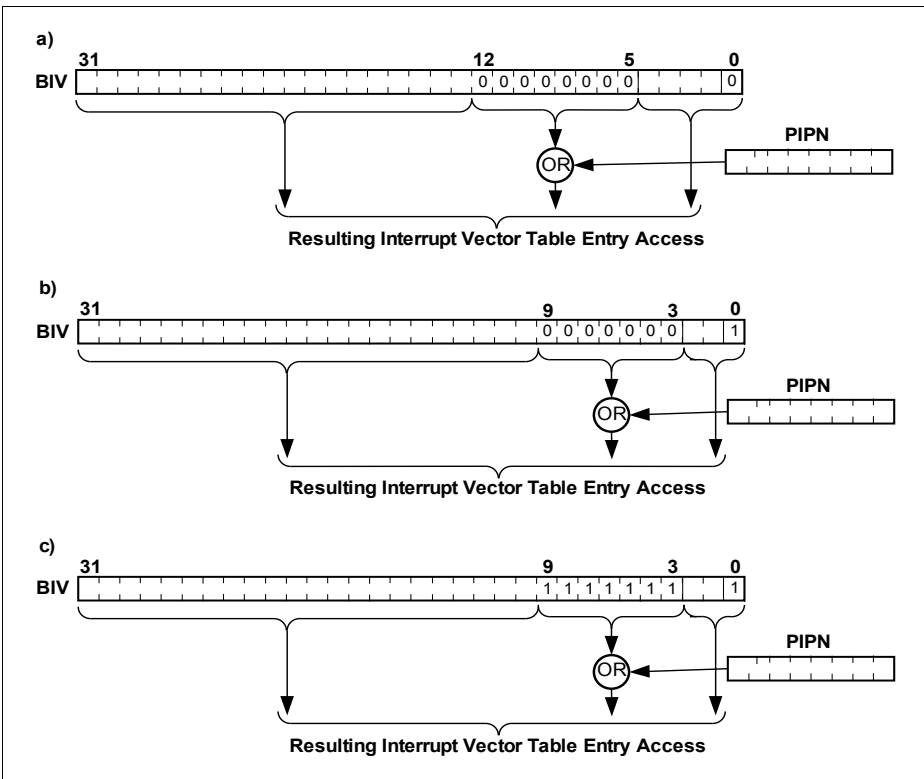

Figure 17-6 Interrupt Vector Table Address Calculation for a) 32 Byte b) 8 Byte vector entry or c) single entry

By using the 32 Byte configuration small interrupt routines can be implemented directly into the vector table. They can even span multiple vector entries (see also TriCore Architecture Manual). This type of fast interrupt handling is useful, if the vector table can

Interrupt Router (IR)

be located into the TriCore program side memory. The 8 Byte configuration reduces the vector table size. Each vector entry contains only a jump instruction or a call and return as 16-bit opcode instruction. The TriCore compiler supports this kind of interrupt vector table generation by keywords or functions. A minimum vector table can be configured if the BIV mask the PIPN so that any interrupt address calculation results in the same address. E.g.

```
__mtcr(BIV,0x80000001 | 0xFF<<3); // move to core register BIV
```

This configures the BIV register to use a common, single entry where a function interruptHandler is located to branch to the specific interrupt routine by using an array of function pointers. If a pointer to the array is used the array could be switched quickly.

Step description to initialize and install interrupts:

(Line 1) define ISR pointer array. Max. 255 interrupts possible.

(Line 2) define pointer which points to the start of the isr_pointer_array.

(Line 3) start of function interruptHandlerInstall. This function installs the interrupts in the array. Necessary information are the interrupt priority and ISR entry address.

(Line 4) This line stores the ISR entry address in the array.

(Line 5 and 6) This function branches to the specific interrupt routine and gets called immediately after an interrupt occurs.

(Line 7) This line gives the return command, after the ISR has been processed.

C Code Example to initialize and install interrupts:

```
(1) void (*isr_pointer_array[256])(void);
(2) void (**isr)(void) = isr_pointer_array;
(3) void interruptHandlerInstall(long int SRprio, long int addr){
(4) *isr_pointer_array[SRprio]=addr;
}
(5) void interruptHandler(void){
(6) isr[__mtcr(ICR) & 0xFF]();
(7) asm (" rfe"); // return from event
}
```

The interrupt entry addresses are stored in a data array instead of encoding the values into the instructions. The function interruptHandlerInstall organizes the installation of the interrupts in that array (see the application of this interrupt handler in a module e.g. use case example in STM chapter). This kind of vector table generation offers sometimes more flexibly than the 8 Byte configuration and does not require any specific compiler support for interrupts.

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit

Interrupt Router (IR)

(ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):

`__enable();`

to set this bit. (See also Architecture Manual for more details)

17.10 Module Implementation

17.10.1 Characteristics of TC26x B-Step Interrupt Router Module

The Interrupt Router module is implemented with the following characteristics:

- Number of clock cycles per arbitration process: 3
- Number of Interrupt Control Units (ICU): 3
- Number of General Purpose Service Request groups: 2

17.10.2 Mapping of TC26x B-Step Module Service Request Triggers to SRNs

All TC26x B-Step module service requests are mapped to one Service Request Node in the Interrupt Router.

Each SRN has one unique SRN Index Number within the Interrupt Router module.

The Interrupt Router module has one 511 / 1024 interrupt trigger input vector where the interrupt trigger input vector bit [x] is related to the SRN with the SRN Index Number x¹⁾. This means that a trigger pulse on interrupt trigger input vector bit [x] will trigger the SRN [x].

1) The Interrupt Router register overview table shows for all TC26x B-Step module service requests the SRC registers with its address offset and the related SRN Index number

Figure 17-7 Mapping of Module Interrupt Trigger to SRN (Index Numbers)

17.10.2.1 Mapping of Service Request Control Registers

The address of SRC registers related to one module instance is identical over the whole Aurix family (e.g. interrupts of SPI0).

Each SRN has one unique SRN Index Number within the Interrupt Router module.

The number of the implemented SRNs for each Aurix device is adapted the devices feature set. All SRNs in an Interrupt Router module have consecutive Index Numbers (e.g.: if 256 SRNs are implemented, Index Numbers are 0 - 255). Each SRN has one unique SRN Index Number within the Interrupt Router module.

Example:

In a high end device with many modules/module instances SPI0 interrupts might be mapped to the SRNs with Index Numbers 180 to 185, related SRC can be accessed with address offset 0x2F0 to 0x2F5

In order to fulfill both requirements (same address for SPI0 related SRCs in all AURIX devices but reduced number of SRNs in smaller family devices with consecutive Index Numbers, the Interrupt Router module includes an address mapping shell (**Figure 17-8**). This address mapping shell re-maps the fixed SRC addresses of e.g. SPI0 of the above example to the SRN in the Interrupt Router module¹⁾.

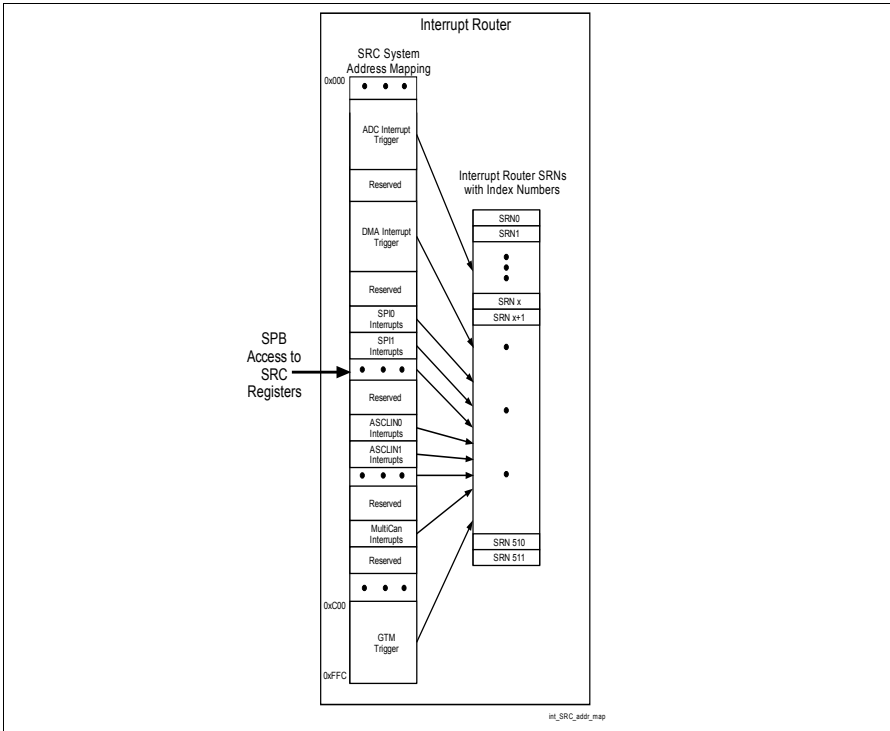

Figure 17-8 Mapping of SRC System Address to SRNs

17.10.2.2 Interrupts related to the Debug Reset

For software debug purposes the AURIX devices require some service request nodes related only to the Debug Reset. These SRNs keep its SRC register contents and the pending service request status in case of a non Debug Reset (e.g. an Application Reset). In combination with other debug reset related debug logic (e.g. breakpoint logic) this allows customer SW to debug situations that result in an application reset and after an application reset.

17.10.2.3 Timing characteristics of Service Request Trigger Signals

The Interrupt Router is clocked with the System Peripheral Bus (SPB) clock

Rules for the TC26x B-Step module interrupt / Service Request trigger signals to the IR:

- Trigger signals must be synchronous to SPB clock
- IR trigger inputs re edge sensitive (positive clock edge)

Interrupt Router (IR)

- Trigger signal pulse with min. high length of one SPB clock cycle, high pulse length can be > 1 SPB clock cycle
- Debug related trigger signal pulse should be kept high by the related TC26x B-Step module until the trigger was processed

Interrupt Router (IR)

17.11 Interrupt Router System and Module Registers

Figure 17-9 shows all registers associated with the Interrupt Router module in the TC26x B-Step device. The Interrupt Router allocates two address ranges:

- 2 * 256 byte address range covering the Interrupt Router system registers, ICU control registers and OTGM registers (Table 17-1)
- 8 KByte address range covering the Service Request Control registers (Table 17-3)

List of used Reset Class abbreviations:

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Application Reset (see description in the chapter SCU / Reset Types)

Note: A violation of the access protection will not be executed (e.g. a write to a 'Px'/ACCEN protected register from a disabled master). In this case an access protection error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

17.11.1 System and ICU Control Registers

Module Identification Register (ID)

Interrupt Router Module Identification Register.

INT_ID

Module Identification Register (008_H) **Reset Value: 00B9 C0XX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. The value for the Interrupt Router module is 0087H.

Service Request Broadcast Register (SRB0 / SRB1)

Interrupt Service Request Broadcast Registers can be used to trigger multiple Service Requests of a General Purpose Service Request Group in parallel.

Interrupt Router (IR)
INT_SRB0
Service Request Broadcast Register 0(010_H)
Reset Value: 0000 0000_H
INT_SRB1
Service Request Broadcast Register 1(014_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TRIG0	0	w	General Purpose Service Request Trigger 0 Writing with '1' SRBx.TRIG0 triggers the General Purpose Service Request 0 in group x (GPSRx0). Writing with 0 has no effect. This bit is always read as 0.
TRIG1	1	w	General Purpose Service Request Trigger 1 Writing with '1' SRBx.TRIG1 triggers the General Purpose Service Request 0 in group x (GPSRx1). Writing with 0 has no effect. This bit is always read as 0.
TRIG2	2	w	General Purpose Service Request Trigger 2 Writing with '1' SRBx.TRIG2 triggers the General Purpose Service Request 0 in group x (GPSRx2). Writing with 0 has no effect. This bit is always read as 0.
TRIG3	3	w	General Purpose Service Request Trigger 3 Writing with '1' SRBx.TRIG3 triggers the General Purpose Service Request 0 in group x (GPSRx3). Writing with 0 has no effect. This bit is always read as 0.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

Interrupt Router (IR)
Access Enable Register 0 (ACCEN0/10)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The registers ACCEN00 / ACCEN01 are providing one enable bit for each 6-bit On Chip Bus Master TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

INT_ACCEN00

Access Enable Register 0 (0F4_H) **Reset Value: FFFF FFFF_H**

INT_ACCEN10

Kernel 1 Access Enable Register 0 (0FC_H) **Reset Value: FFFF FFFF_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register 1 (ACCEN11/01)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN11/01 are not implemented with register bits as the related On Chip Bus Master TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

Interrupt Router (IR)

INT_ACCEN01

Kernel 0 Access Enable Register 1 (0F0_H) **Reset Value: 0000 0000_H**

INT_ACCEN11

Kernel 1 Access Enable Register 1 (0F8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Latest Winning Service Request (LWSR)

The Latest Winning Service Request register provides informations about the winner of the last arbitration round. The register bit fields are representing what is provided by the ICU to the Interrupt Service Provider.

INT_LWSRx (x = 0-1)

Latest Winning Service Request Register x (100_H+x*10_H) **Reset Value: 0000 0000_H**

INT_LWSR3

Latest Winning Service Request Register 3 (130_H) **Reset Value: 0000 0000_H**

Interrupt Router (IR)

Field	Bits	Type	Description
PN	[7:0]	r	Latest Winner Priority Number This bit field shows the Priority Number of a pending service request that won the last arbitration round. This bit field is only valid if STAT is set to 1
ECC	[15:10]	r	Latest Winner ECC This bit field shows the ECC field (SRN.ECC) that was transferred from the last winning SRN to the ICU. This bit field is only valid if STAT is set to 1.
ID	[25:16]	r	Latest Winner Index Number This bit field shows the index number of the last winning SRN. This bit field is only valid if STAT is set to 1
STAT	31	r	LWSR Register Status The STAT register indicates if the PN, ECC and ID bit fields are still valid. They are still valid if the interrupt from the SRN identified by ID is still pending. If the ICU does not have a winner because no interrupt is pending or not yet arbitrated than it clears the STAT bit. 0 _B LWSR bit fields are not valid 1 _B LWSR bit fields are valid
0	[30:26] , [9:8]	r	Reserved Read as 0; should be written with 0.

Last Acknowledged Service Request (LASR)

The Last Acknowledged Service Request register provides informations about the last service request that was acknowledged by the Interrupt Service Provider. The register bit fields are representing what was sent by the Interrupt Service Provider together with the latest acknowledge.

Interrupt Router (IR)

INT_LASRx (x = 0-1)

Last Acknowledged Service Request Register x ($104_H + x \cdot 10_H$)

Reset Value:

0000 0000_H

INT_LASR3

Last Acknowledged Service Request Register 3 (134_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PN	[7:0]	r	Last Acknowledged Service Request Priority Number This bit field shows the Priority Number of the last acknowledged service request
ECC	[15:10]	r	Last Acknowledged Interrupt ECC This bit field shows the ECC value of the last acknowledged service request, as send by the service provider with acknowledge
ID	[25:16]	r	Last Acknowledged Interrupt SRN Index Number This bit field shows the index number of the SRN, related to the last acknowledged service request, as send by the service provider with acknowledge
0	[31:26], [9:8]	r	Reserved Read as 0; should be written with 0.

Error Capture Register (ECR)

The Error Capture Register captures the Last Acknowledged Service Request (LASR) register contents when an ECC error was detected by the ICU. The ECR shows always the last ECR contents where an ECC error was detected. Software can clear the ECR contents by writing to the ECR.

Interrupt Router (IR)
INT_ECR_x (x = 0-1)
Error Capture Register x
(108_H+x*10_H)
Reset Value: 0000 0000_H
INT_ECR3
Error Capture Register 3
(138_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PN	[7:0]	rwh	Service Request Priority Number This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
ECC	[15:10]	rwh	Service Request ECC This bit field shows the ECC of the last service request where an error was detected. Bit field can be modified by writing to it.
ID	[25:16]	rwh	Service Request Node Index Number This bit field shows the index number of the last service request where an error was detected. Bit field can be modified by writing to it
EOV	30	rwh	Error Overflow Bit The bit is set if an ECC error was detected by the ICU while ECR.STAT='1' (Error Overflow situation). 0 _B No Error Overflow situation detected 1 _B Error Overflow situation detected This bit can be cleared by writing with 1. Writing with 0 has no effect. If this bit is cleared, it must be cleared together with the STAT bit.

Interrupt Router (IR)

Field	Bits	Type	Description
STAT	31	rwh	Error Status Bit The Error Status Bit is set whenever an ECC was detected by the ICU. 0 _B No ECC error detected 1 _B ECC error detected This bit can be cleared by writing with 1. Writing with 0 has no effect.
0	[29:26], [9:8]	r	Reserved Read as 0; should be written with 0.

17.12 OTGM Registers

All OTGM registers are cleared by Debug Reset and by each System Reset when OCDS is disabled. They are not touched by System Reset when OCDS is enabled.

Write access is 32 bit wide only and requires Supervisor Mode and OCDS enabled.

17.12.1 Status and Control
INT_OOBS

OTGM OTGB0/1 Status (80_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
OTGB0	[15:0]	rh	Status of OTGB0
OTGB1	[31:16]	rh	Status of OTGB1

Note: OTGB0/1 value is sampled not captured. A capture register is available in OTGS.

Interrupt Router (IR)

INT_OSSIC

OTGM SSI Control

 (84_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
TGS	[1:0]	rw	Trigger Set for OTGB0/1 0 _H No Trigger Set output 1 _H Trigger Set TS16_SSI (Table 1-1) others, reserved
TGB	2	rw	OTGB0/1 Bus Select 0 _B Trigger Set is output on OTGB0 1 _B Trigger Set is output on OTGB1
0	[31:3]	r	Reserved Read as 0; must be written with 0.

17.12.2 IRQ MUX Control

INT_OIXTS

OTGM IRQ MUX Trigger Set Select

 (88_H)

 Reset Value: 0000 0000_H

Interrupt Router (IR)

Field	Bits	Type	Description
TGS	[1:0]	rw	Trigger Set Select for OTGB0/1 Overlay 0 _D No overlay 1 _D Trigger Set TS8_IS (Table 1-2) 2 _D Trigger Set TS8_SPA (Table 1-3) 3 _D reserved
OBS	[9:8]	rw	Overlay Byte Select 0 _D OTGB0 [7:0] 1 _D OTGB0 [15:8] 2 _D OTGB1 [7:0] 3 _D OTGB1 [15:8]
0	[7:2], [31:10]	r	Reserved Read as 0; must be written with 0.

INT_OIXMS
OTGM IRQ MUX Missed IRQ Select (8C_H) **Reset Value: 0000 0000_H**

0						MIRQ									
r						rw									

Field	Bits	Type	Description
MIRQ	[9:0]	rw	SRN Index for Missed Interrupt Trigger
0	[31:10]	r	Reserved Read as 0; must be written with 0.

Interrupt Router (IR)

INT_OIXS0

OTGM IRQ MUX Select 0

(90_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IRQ0	[9:0]	rw	SRN Index for Interrupt Trigger 0
IRQ1	[25:16]	rw	SRN Index for Interrupt Trigger 1
0	[31:26], [15:10]	r	Reserved Read as 0; must be written with 0.

INT_OIXS1

OTGM IRQ MUX Select 1

(94_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IRQ2	[9:0]	rw	SRN Index for Interrupt Trigger 2
IRQ3	[25:16]	rw	SRN Index for Interrupt Trigger 3
0	[31:26], [15:10]	r	Reserved Read as 0; must be written with 0.

17.12.3 Interrupt System Trace

INT_OIT

OTGM IRQ Trace

 (A0_H)

 Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Interrupt Router (IR)

17.12.4 MCDS Interface

INT_OMISP

OTGM MCDS I/F Sensitivity Posedge (A4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
OTGB0	[15:0]	rw	Bitwise Posedge Sensitivity for OTGB0 If a bit is set an OTGB value will be written to MCDS on a rising edge of the associated OTGB0 bit.
OTGB1	[31:16]	rw	Bitwise Posedge Sensitivity for OTGB1 If a bit is set an OTGB value will be written to MCDS on a rising edge of the associated OTGB1 bit.

INT_OMISN

OTGM MCDS I/F Sensitivity Negedge (A8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
OTGB0	[15:0]	rw	Bitwise Negedge Sensitivity for OTGB0 If a bit is set an OTGB value will be written to MCDS on a falling edge of the associated OTGB0 bit.

Interrupt Router (IR)

Field	Bits	Type	Description
OTGB1	[31:16]	rw	Bitwise Negedge Sensitivity for OTGB1 If a bit is set an OTGB value will be written to MCDS on a falling edge of the associated OTGB1 bit.

17.13 Interrupt Router SRC Registers

Figure 17-9 shows all registers associated with the Interrupt Router module in the TC26x B-Step device. This chapter describes the Service Request Control registers including:

- Mapping of Aurix module interrupt triggers to SRC
- SRC offsets
- SRN Index numbers

List of used Reset Class abbreviations:

- Reset Class 1 -> Debug Reset (see description in the chapter SCU / Reset Types)
- Reset Class 3 -> Application Reset (see description in the chapter SCU / Reset Types)

Note: A violation of the access protection will not be executed (e.g. a write to a 'Px'ACCEN protected register from a disabled master). In this case an access protection error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

Table 17-3 Registers Address Space - Service Request Control Registers (SRC)

18 System Timer (STM)

This chapter describes the System Timer (STM). The TC26x B-Step's STM is designed for global system timing applications requiring both high precision and long period.

18.1 Overview

The STM has the following features:

- Free-running 64-bit counter
- All 64 bits can be read synchronously
- Different 32-bit portions of the 64-bit counter can be read synchronously
- Flexible service request generation based on compare match with partial STM content
- Counting starts automatically after an Application Reset
- STM registers are reset by an Application Reset if bit ARSTDIS.STMxDIS is cleared. If bit ARSTDIS.STMxDIS is set, the STM registers are not reset.

Special STM register semantics provide synchronous views of the entire 64-bit counter, or 32-bit subsets at different levels of resolution.

18.2 Operation

The STM is an upward counter, running at frequency f_{STM} . In case of an Application Reset, the STM is reset if bit SCU_ARSTDIS.STMxDIS is cleared. After reset, the STM is enabled and immediately starts counting up. It is not possible to affect the content of the timer during normal operation. The timer registers can only be read but not written to.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes. In suspend mode, the STM clock is stopped but all registers are still readable.

Due to the 64-bit width of the STM, it is not possible to read its entire content with one instruction. It needs to be read with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to possible overflow from the low part of the timer to the high part between the two read operations). To enable a synchronous and consistent reading of the STM content, a capture register (CAP) is implemented. It latches the content of the high part of the STM each time when one of the registers TIM0 to TIM5 is read. Thus, CAP holds the upper value of the timer at exactly the same time when the lower part is read. The second read operation would then read the content of the CAP to get the complete timer value.

The STM can also be read in sections from seven registers, TIM0 through TIM6, that select increasingly higher-order 32-bit ranges of the STM. These can be viewed as individual 32-bit timers, each with a different resolution and timing range.

System Timer (STM)

The content of the 64-bit System Timer can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

Figure 18-1 provides an overview on the STM module. It shows the options for reading parts of the STM content.

Figure 18-1 General Block Diagram of the STM Module

18.2.1 Compare Register Operation

The content of the 64-bit STM can be compared against the content of two compare values stored in the CMP0 and CMP1 registers. Service requests can be generated on a compare match of the STM with the CMP0 or CMP1 registers.

Two parameters are programmable for the compare operation:

1. The width of the relevant bits in registers CMP0/CMP1 (compare width MSIZE_x) that is taken for the compare operation can be programmed from 0 to 31.
2. The first bit location in the 64-bit STM that is taken for the compare operation can be programmed from 0 to 31.

These programming capabilities make compare functionality very flexible. It even makes it possible to detect bit transitions of a single bit n ($n = 0$ to 31) within the 64-bit STM by setting $MSIZE = 0$ and $MSTART = n$.

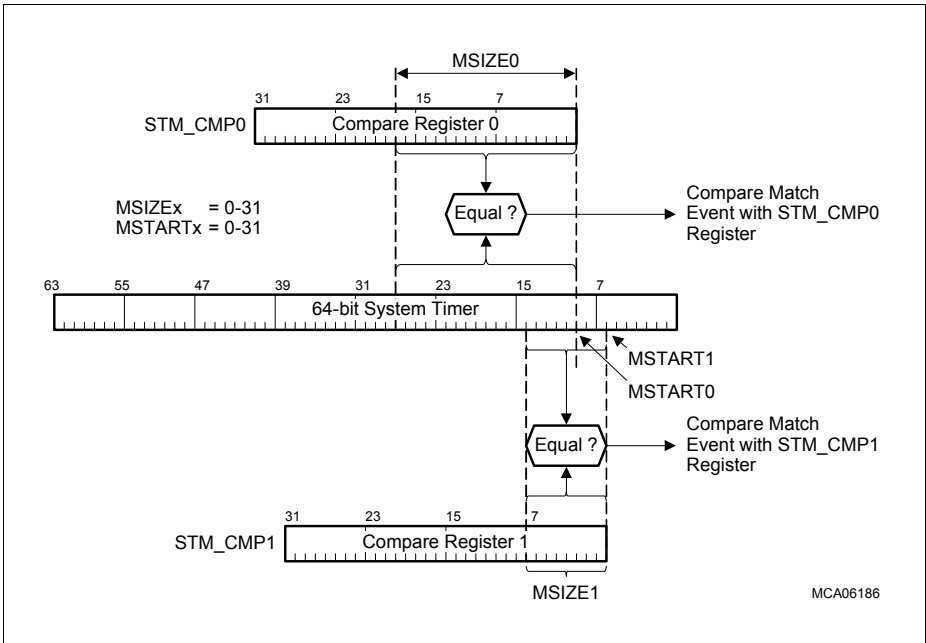

Figure 18-2 Compare Mode Operation

Figure 18-2 shows an example of the compare operation. In this example the following parameters are programmed:

- $MSIZE0 = 10001_B = 17_D$; $MSTART0 = 01010_B = 10_D$
- $MSIZE1 = 00111_B = 7_D$; $MSTART1 = 00111_B = 7_D$

System Timer (STM)

A compare operation with MSIZE not equal 11111_B always implies that the compared value as stored in the CMP register is right-extended with zeros. This means that in the example of **Figure 18-2**, the compare register content CMP0[17:0] plus ten zero bits right-extended is compared with STM[27:0] with STM[9:0] = 000_H. In case of register CMP1, STM[14:0] with STM[6:0] = 00_H are compared with CMP1[9:0] plus seven zero bits right-extended.

18.2.2 Compare Match Interrupt Control

The compare match interrupt control logic is shown in **Figure 18-3**. Each CMPx register has its compare match interrupt request flag (ICR.CMPxIR) that is set by hardware on a compare match event. The interrupt request flags can be set (ISSR.CMPxIRS) or cleared (ISSR.CMPxIRR) by software. Note that setting ICR.CMPxIR by writing a 1 into ISSR.CMPxIRS does not generate an interrupt at STMIRx. The compare match interrupts from CMP0 and CMP1 can be further directed by ICR.CMPxOS to either output signal STMIR0 or STMIR1.

Figure 18-3 STM Interrupt Control

The compare match interrupt flags ICR.CMPxIR are immediately set after an STM reset operation, caused by a compare match event with the reset values of the STM and the compare registers CMPx. This setting of the CMPxIR flags does not directly generate compare match interrupts because the compare match interrupts are automatically disabled after a STM reset operation (CMPxEN = 0). Therefore, before enabling a

System Timer (STM)

compare match interrupt after a STM Application Reset, the CMPxIR flags should be cleared by software (writing register ISSR with CMPxIRR set). Otherwise, undesired compare match interrupt events are triggered.

18.2.3 Using Multiple STMs

For systems that include multiple CPUs there are also multiple STMs available. Each STM is aimed to serve as time base for one individual CPU operating system main scheduler clock trigger. This is done by the usage of one compare register and the associated interrupt generating the trigger.

All STM modules are connected and controlled by f_{STM} and can therefore operate on the same frequency if desired.

Note: For synchronisation of CPUs they contain timer called temporal protection system.

18.2.4 STM as Reset Trigger

A compare match triggered by an CMP0 event can generate a reset in the system. The reset has to be enable for each STM module individually in register SCU_RSTCON.

18.3 STM Registers

This section describes the STM registers of the STM.

Table 18-1 Registers Address Space

Module	Base Address	End Address	Note
STM0	F000 0000 _H	F000 00FF _H	STM for CPU0

1) These registers are reset by an application reset if bit ARSTDIS.STMxDIS is cleared.

System Timer (STM)

18.3.1 Clock Control Register

The STM clock control register is used to switch the STM on or off and to control its input clock rate. After reset, the STM is always enabled and starts counting. The STM can be disabled by setting bit DISR to 1.

CLC

Clock Control Register

 (00_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the STM module. 0 _B No disable requested 1 _B Disable requested <i>Note: f_{STM} is generated by the CCU.</i>
DISS	1	r	Module Disable Status Bit Bit indicates the current status of the STM module. 0 _B STM module is enabled 1 _B STM module is disabled
EDIS	3	rw	Sleep Mode Enable Control Used for module sleep mode control.
0	[10:8]	rw	Reserved Should be written with 0.
0	2, [7:4], [31:11]	r	Reserved Read as 0; should be written with 0.

The STM Module Identification Register ID contains read-only information about the module version.

System Timer (STM)

ID
Module Identification Register (08_H) **Reset Value: 0000 C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number MODREV defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the STM: 0000 _H

System Timer (STM)

18.3.2 Timer/Capture Registers

Registers TIM0 to TIM6 provide 32-bit views at varying resolutions of the underlying STM counter.

Register TIM0SV address the STM[31:0] bits at a second optional address as TIM0.

TIM0

Timer Register 0 (10_H) **Reset Value: 0000 0000_H**

TIM0SV

Timer Register 0 Second View (50_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
STM[31:0]	[31:0]	r	System Timer Bits [31:0] This bit field contains bits [31:0] of the 64-bit STM.

TIM1

Timer Register 1 (14_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
STM[35:4]	[31:0]	r	System Timer Bits [35:4] This bit field contains bits [35:4] of the 64-bit STM.

System Timer (STM)

TIM2

Timer Register 2

 (18_H)

 Reset Value: 0000 0000_H

31

0

Field	Bits	Type	Description
STM[39:8]	[31:0]	r	System Timer Bits [39:8] This bit field contains bits [39:8] of the 64-bit STM.

TIM3

Timer Register 3

 (1C_H)

 Reset Value: 0000 0000_H

31

0

Field	Bits	Type	Description
STM[43:12]	[31:0]	r	System Timer Bits [43:12] This bit field contains bits [43:12] of the 64-bit STM.

TIM4

Timer Register 4

 (20_H)

 Reset Value: 0000 0000_H

31

0

Field	Bits	Type	Description
STM[47:16]	[31:0]	r	System Timer Bits [47:16] This bit field contains bits [47:16] of the 64-bit STM.

System Timer (STM)

TIM5

Timer Register 5

(24_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
STM[51:20]	[31:0]	r	System Timer Bits [51:20] This bit field contains bits [51:20] of the 64-bit STM.

TIM6

Timer Register 6

(28_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
STM[63:32]	[31:0]	r	System Timer Bits [63:32] This bit field contains bits [63:32] of the 64-bit STM.

System Timer (STM)

CAP

Timer Capture Register (2C_H) Reset Value: 0000 0000_H

CAPSV

Timer Capture Register Second View (54_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
STMTCAP[63:32]	[31:0]	rh	<p>Captured System Timer Bits [63:32] The capture register STMTCAP always captures the STM bits [63:32] when one of the registers TIM0 to TIM5 and TIMOSV is read. This capture operation is performed in order to enable software to operate with a coherent value of all the 64 STM bits at one time stamp. This bit field contains bits [63:32] of the 64-bit STM.</p> <p><i>Note: Reading register TIMOSV capture also the read value for register TIM6. In this way reading TIMOSV followed by CAP6SV delivers the timer values for the first read request.</i></p>

18.3.3 Compare Registers

The compare register CMPx holds up to 32-bits; its value is compared to the value of the STM.

CMPx (x = 0-1)

Compare Register x (30_H+x*4_H) Reset Value: 0000 0000_H

System Timer (STM)

Field	Bits	Type	Description
CMPVAL	[31:0]	rw	Compare Value of Compare Register x This bit field holds up to 32 bits of the compare value (right-adjusted).

System Timer (STM)

The STM Compare Match Control Register controls the parameters of the compare logic.

CMCON

Compare Match Control Register

(38_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
MSIZE0	[4:0]	rw	<p>Compare Register Size for CMP0</p> <p>This bit field determines the number of bits in register CMP0 (starting from bit 0) that are used for the compare operation with the System Timer.</p> <p>00000_B CMP0[0] used for compare operation 00001_B CMP0[1:0] used for compare operation ... 11110_B CMP0[30:0] used for compare operation 11111_B CMP0[31:0] used for compare operation</p>
MSTART0	[12:8]	rw	<p>Start Bit Location for CMP0</p> <p>This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP0 bit 0. The number of bits to be compared is defined by bit field MSIZE0.</p> <p>00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 11110_B STM[30] is the lowest bit number 11111_B STM[31] is the lowest bit number</p>

System Timer (STM)

Field	Bits	Type	Description
MSIZE1	[20:16]	rw	<p>Compare Register Size for CMP1</p> <p>This bit field determines the number of bits in register CMP1 (starting from bit 0) that are used for the compare operation with the System Timer.</p> <p>00000_B CMP1[0] used for compare operation 00001_B CMP1[1:0] used for compare operation ... 11110_B CMP1[30:0] used for compare operation 11111_B CMP1[31:0] used for compare operation</p>
MSTART1	[28:24]	rw	<p>Start Bit Location for CMP1</p> <p>This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP1 bit 0. The number of bits to be compared is defined by bit field MSIZE1.</p> <p>00000_B STM[0] is the lowest bit number 00001_B STM[1] is the lowest bit number ... 11110_B STM[30] is the lowest bit number 11111_B STM[31] is the lowest bit number</p>
0	[7:5], [15:13], [23:21], [31:29]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

18.3.4 Interrupt Registers

The two compare match interrupts of the STM are controlled by the STM Interrupt Control Register.

ICR

Interrupt Control Register (3C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CMP0EN	0	rw	<p>Compare Register CMP0 Interrupt Enable Control This bit enables the compare match interrupt with compare register CMP0.</p> <p>0_B Interrupt on compare match with CMP0 disabled 1_B Interrupt on compare match with CMP0 enabled</p>
CMP0IR	1	rh	<p>Compare Register CMP0 Interrupt Request Flag This bit indicates whether or not a compare match interrupt request of compare register CMP0 is pending. CMP0IR must be cleared by software.</p> <p>0_B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1_B A compare match interrupt has been detected. CMP0IR must be cleared by software and can be set by software, too (see CMPISCR register). After a STM reset operation, CMP0IR is immediately set as a result of a compare match event with the reset values of the STM and the compare registers CMP0.</p>

System Timer (STM)

Field	Bits	Type	Description
CMP0OS	2	rw	Compare Register CMP0 Interrupt Output Selection This bit determines the interrupt output that is activated on a compare match event of compare register CMP0. 0 _B Interrupt output STMIR0 selected 1 _B Interrupt output STMIR1 selected
CMP1EN	4	rw	Compare Register CMP1 Interrupt Enable Control This bit enables the compare match interrupt with compare register CMP1. 0 _B Interrupt on compare match with CMP1 disabled 1 _B Interrupt on compare match with CMP1 enabled
CMP1IR	5	rh	Compare Register CMP1 Interrupt Request Flag This bit indicates whether or not a compare match interrupt request of compare register CMP1 is pending. CMP1IR must be cleared by software. 0 _B A compare match interrupt has not been detected since the bit has been cleared for the last time. 1 _B A compare match interrupt has been detected. CMP1IR must be cleared by software and can be set by software, too (see CMPISCR register). After a STM reset, CMP1IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP1.
CMP1OS	6	rw	Compare Register CMP1 Interrupt Output Selection This bit determines the interrupt output that is activated on a compare match event of compare register CMP1. 0 _B Interrupt output STMIR0 selected 1 _B Interrupt output STMIR1 selected
0	3, [31:7]	r	Reserved Read as 0; should be written with 0.

System Timer (STM)

The bits in the STM Interrupt Set/Clear Register make it possible to set or cleared the compare match interrupt request status flags of register ICR.

ISCR
Interrupt Set/Clear Register
(40_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CMP0IRR	0	w	Reset Compare Register CMP0 Interrupt Flag 0 _B Bit ICR.CMP0IR is not changed. 1 _B Bit ICR.CMP0IR is cleared.
CMP0IRS	1	w	Set Compare Register CMP0 Interrupt Flag 0 _B Bit ICR.CMP0IR is not changed. 1 _B Bit ICR.CMP0IR is set. The state of bit CMP0IRR is "don't care" in this case.
CMP1IRR	2	w	Reset Compare Register CMP1 Interrupt Flag 0 _B Bit ICR.CMP1IR is not changed. 1 _B Bit ICR.CMP1IR is cleared.
CMP1IRS	3	w	Set Compare Register CMP1 Interrupt Flag 0 _B Bit ICR.CMP1IR is not changed. 1 _B Bit ICR.CMP1IR is set. The state of bit CMP1IRR is "don't care" in this case.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

Note: Reading register ISCR always returns 0000 0000_H.

18.3.5 Interface Registers

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status (E8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SUS	[27:24]	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 _H Will not suspend 1 _H Reserved, do not use this combination 2 _H 64-bit counter will be stopped others , Reserved, do not use this combination <i>Note:</i> For details see the OCDS chapter.
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0.

System Timer (STM)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 00000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00000_B, EN1 -> TAG ID 00001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0
(FC_H)

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID master peripheral mapping).

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1

Access Enable Register 1

(F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

The Kernel Reset Register 0 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing to it with '1'.

KRST0

Kernel Reset Register 0

(F4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the STM kernel. STM kernel registers related to the Debug Reset (Class 1) are not influenced. To reset the STM kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be cleared with the end of the BPI kernel reset sequence.

KRST1

Kernel Reset Register 1 (F0_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to '0') after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)

19 Asynchronous/Synchronous Interface (ASCLIN)

The main purpose of the ASCLIN module is to provide asynchronous serial communication with external devices using only data-in, data-out signals.

The focus of the module is set to fast and flexible communication: either fast point-to-point or master-to-many slaves communication using the LIN protocol.

Additionally, the module supports the synchronous SPI communication.

Figure 19-1 shows an overview of the ASCLIN module.

Note: The RX, TX, RTS, CTS, SCLKO, SLISO signal names are prefixed with "A" in order to achieve unique names on chip level, distinct from signal names of other communication modules.

Figure 19-1 Block Diagram of the ASCLIN module.

>> [Registers Overview](#)

>> [BPI_FPI Module Registers](#)

Asynchronous/Synchronous Interface (ASCLIN)

19.1 Feature List

This section describes the features of the ASCLIN module.

General Features

- 16 bytes TxFIFO
- 16 bytes RxFIFO
- Pack / unpack capabilities of the Tx and Rx FIFO
- Interrupt generation
 - On a configurable transmit FIFO level
 - On a configurable receive FIFO level
 - On an error condition (frame, parity, overrun error)
 - On various module internal events (end of ASC/SPI frame, LIN events)
- Interrupt signals capable of triggering either a CPU or a DMA
- Programmable oversampling of 4 to 16 times per bit
- Programmable sampling point position
- Programmable digital glitch filter and median filter for incoming bit stream
- Shift direction LSB first
- Internal loop-back mode

Standard ASC Features

- Full-duplex asynchronous operating modes
 - 7-bit, 8-bit or 9-bit (or up to 16-bit) data frames, LSB first
 - Parity-bit generation/checking
 - One or two stop bits
 - Max baud rate $f_A / 16$ (6.25 MBaud @ 100 MHz f_A module clock)
 - Min. baud rate $f_A / 268\ 435\ 456$ (0.37 Baud @ 100 MHz f_A module clock)
- Optional RTS / CTS handshaking
- Support of
 - JASO D 903

Extended ASC Features

- Programmable oversampling of 4 to 16 times per bit
 - module capability of up to 4 times higher baud rates ($f_A / 4$) then the standard ASC
 - system considerations like pad type, incoming signal quality and accumulated PLL jitter can lead to constraints regarding the usable oversampling ratios (for example $f_A / 8 = 200\text{MHz} / 8 = 25\ \text{MBaud}$)
- Programmable sampling point position

LIN Features

- Support of

Asynchronous/Synchronous Interface (ASCLIN)

- LIN version 1.3
- LIN version 2.0
- LIN version 2.1 and
- J2602
- Break detection
- Break injection
- Sync field generation
- Auto baud detection based on Sync Field measurement
- Optional Collision detection, required for LIN version 2.1
- LIN Watchdogs
 - Header time-out
 - Frame or Response time-out
- Stuck at zero/one monitoring
- Bus idle time monitoring
- Wake-Up
- Minimum CPU load in master mode
 - Single interrupt indicating the end of the frame
- Minimum CPU load in slave mode
 - Single interrupt at the end of the header reception
 - Single interrupt at the end of the response or end of frame
- Standard operation with one interrupt per transmitted or received byte supported

SPI Features

- SPI master modes (slave mode not supported):
 - Four-wire or three-wire (with / without slave select output signal)
- Up to 16-bit data width
- Full-duplex and half-duplex
 - Min. baud rate $f_A / 268\,435\,456$ MBaud (= 0.37 Baud @ 100 MHz f_A module clock)
 - Max. baud rate $f_A / 4$ MBaud (= 25 MBaud @ 100 MHz f_A module clock)
- Programmable leading and trailing delays

Asynchronous/Synchronous Interface (ASCLIN)

19.2 Overview

This section shows the essential sub blocks of the module when used as standard ASC, as LIN or as SPI master.

Figure 19-2 Architecture Overview

Note: Collision detection is mandatory only in the LIN specification V2.1.

Note: In LIN mode, both ARX and ATX signal must be connected to the LIN bus in order ASCLIN module to work properly.

Asynchronous/Synchronous Interface (ASCLIN)

19.3 External Signals

The ASCLIN module provides the following external signals:

- Serial clock output ASCLK
- Receive data input ARX (Master Receive MR input in SPI mode)
- Transmit data output ATX (Master Transmit MT output in SPI mode)
- Slave select signal output ASLSO
- Request to send handshake output ARTS
- Clear to send handshake input ACTS

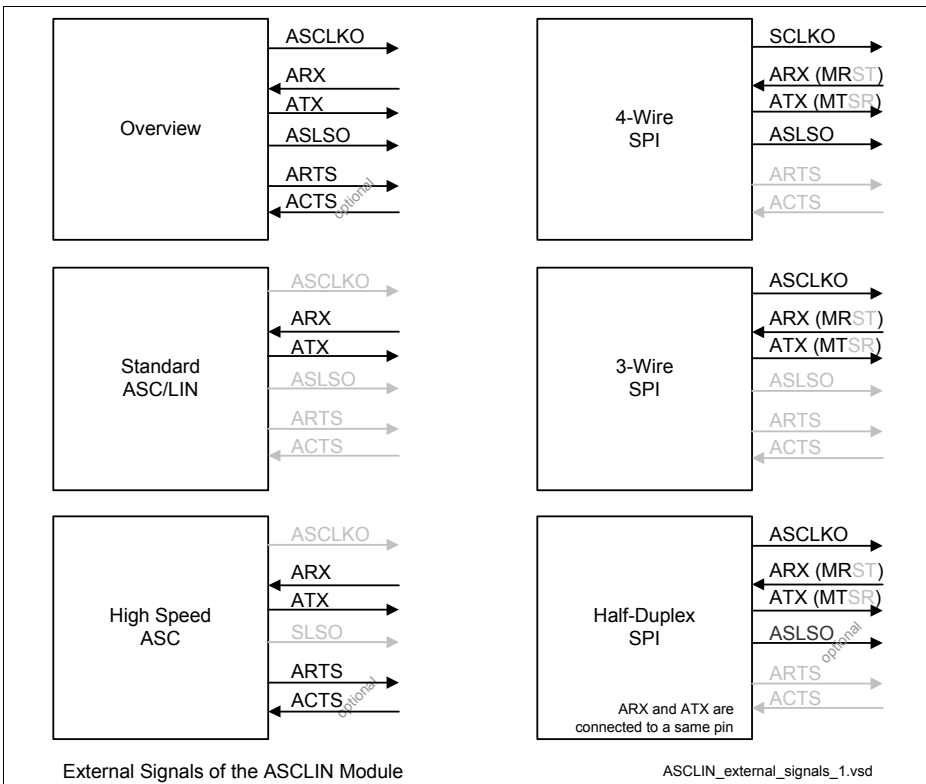

Figure 19-3 External Signals of the ASCLIN Module in Different Modes

Asynchronous/Synchronous Interface (ASCLIN)

19.4 User Interface

The user interface contains a Tx FIFO and an Rx FIFO.

They provide the following services: takes data packets with width optimal for the FPI¹⁾ bus and packs them to serial frames, buffers the FPI bus data, manages handshaking. These features are designed to optimize the use of the module in LIN, high-speed ASC and SPI mode. They also optimize the use of the module in standard ASC mode.

19.4.1 TxFIFO Overview

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame. It also has the ability to pack 32-bit writes from the FPI bus to four up-to-8-bit or two up-to-16-bit frames.

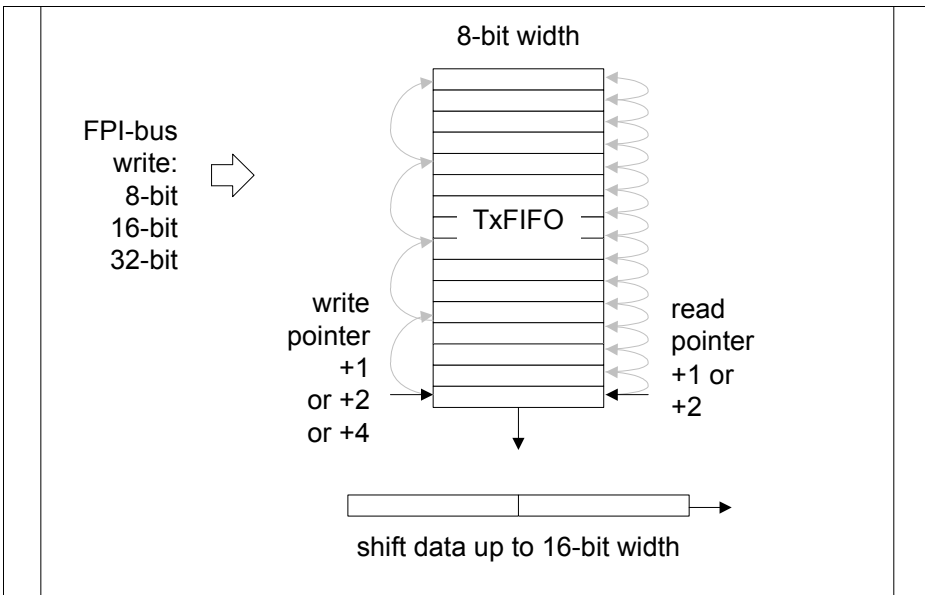

Figure 19-4 TxFIFO Overview

The number of bytes written to the TxFIFO is always defined with the **TXFIFOCON.INW**, does not depend on the SPB write width, and should be equal to it.

If the SPB write width is shorter than INW, then the missing part is padded with zeros.

If the SPB write width is longer than INW, then the excessive part is lost.

1) FPI is the protocol used on the System Peripheral Bus (SPB).

Asynchronous/Synchronous Interface (ASCLIN)

On the shift register side, the TxFIFO is always emptied by a number of bytes as needed for the data width field **DATCON.DATLEN**.

The **Table 19-1** describes all the possible write (fill) combinations. The bytes which will be filled into the TXFIFO are labeled as A, B, C, D and 0.

Table 19-1 Inlet Width versus SPB Write Width

TxFIFO Contents		SPB Bus Write Width		
		8-Bit A	16-Bit BA	32-Bit DCBA
Inlet Width INW	8-Bit	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

19.4.2 Using the TxFIFO

The Tx FIFO has the ability to pack 16-bit writes from the FPI bus to two up-to-8-bit frames or one up-to-16-bit frame.

Note: Some (but not all) use-cases are described in the sections below. The software can always access the TXFIFO 8, 16 or 32 bit wide, according to its requirements.

19.4.2.1 Standard ASC Mode

The most standard usage of the ASC module is to transmit 7 or 8-bit values, and to fill the FIFO with 8-bit wide FPI-bus accesses. The FPI bus access is 8-bit wide, and there is only BS0 (Byte Select 0) signal active.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 8-bit, and the Tx_Outlet_Width is 8-bit.

Asynchronous/Synchronous Interface (ASCLIN)

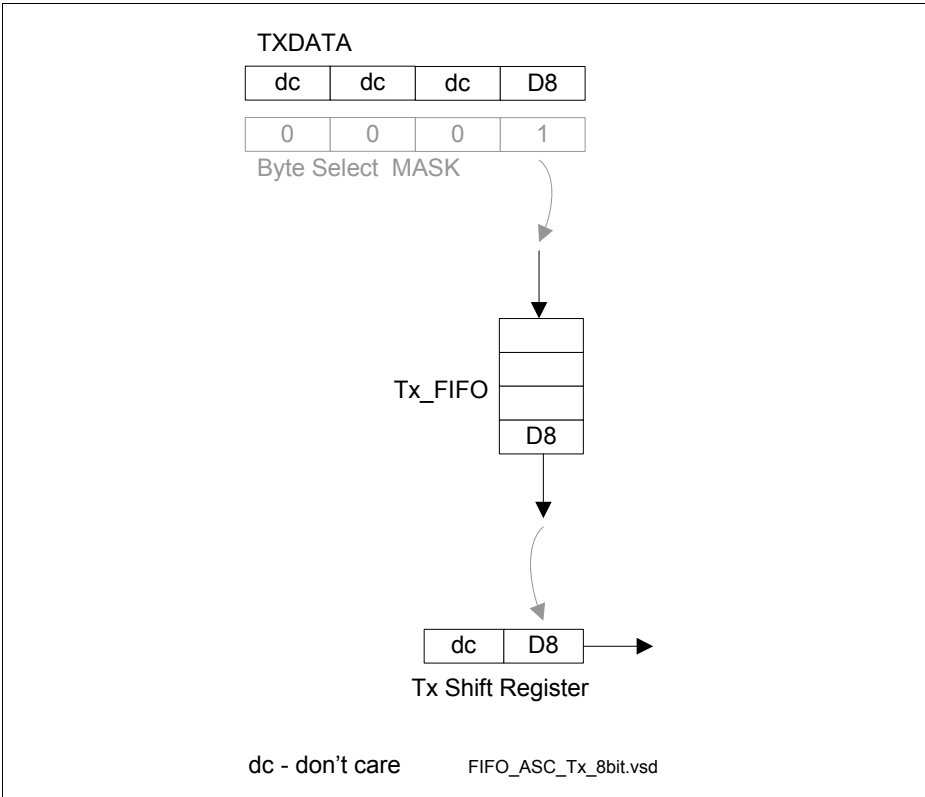

Figure 19-5 FIFO Operation in 7- or 8-Bit ASC Mode, with or without Parity

A less common mode of operation of the ASC module is to transmit 9-bit values, containing either 9-bit data or 8-bit data. The FPI bus access should be 16-bit wide, and there are BS0 and BS1 (Byte Select 0 and 1) signals active. The shift register is filled with two 8-bit values at the location read pointer and read pointer + 1.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 16-bit, and the Tx_Outlet_Width is 16-bit.

Asynchronous/Synchronous Interface (ASCLIN)

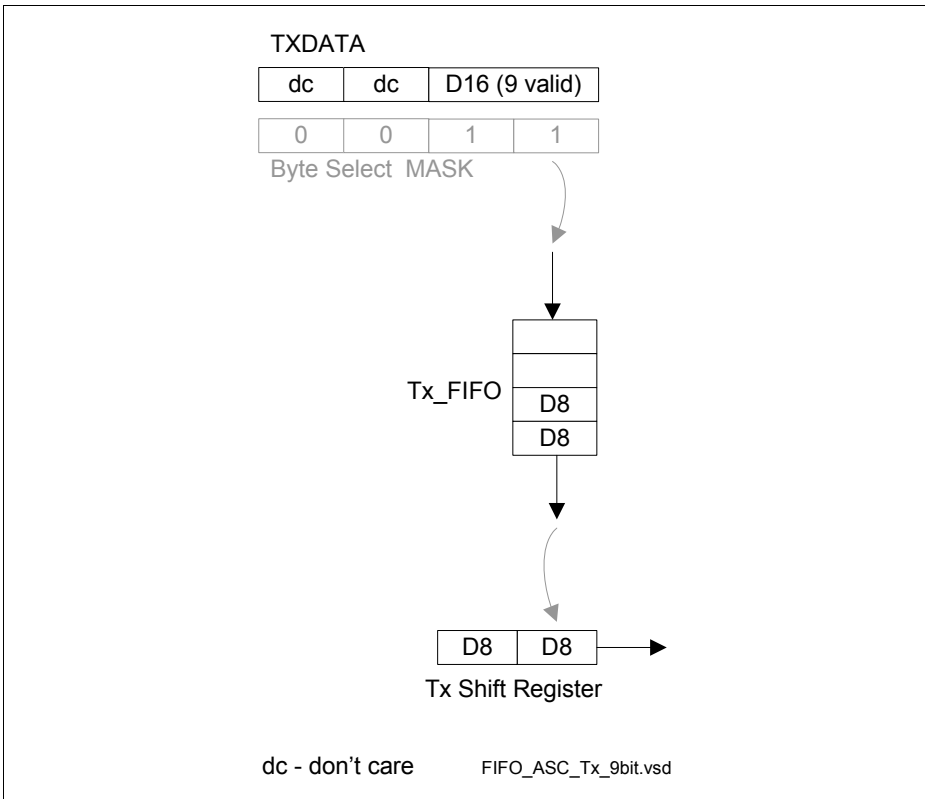

Figure 19-6 FIFO Operation in 9-Bit ASC Mode

19.4.2.2 High Speed ASC Mode

In order to reduce the FPI bus load by not using a 32-bit move for 7 or 8-bit values, one option is to fill the FIFO with 32-bit wide accesses containing four 8-bit wide values. All Byte Select signals BS[3:0] are active, and all four bytes are written in the TX FIFO in one cycle. At the same time, the write pointer of the TXFIFO jumps by the amount of four. The transmit data is written to the address TXDATA. The Tx_Inlet_Width is 32-bit, and the Tx_Outlet_Width is 8-bit.

Asynchronous/Synchronous Interface (ASCLIN)

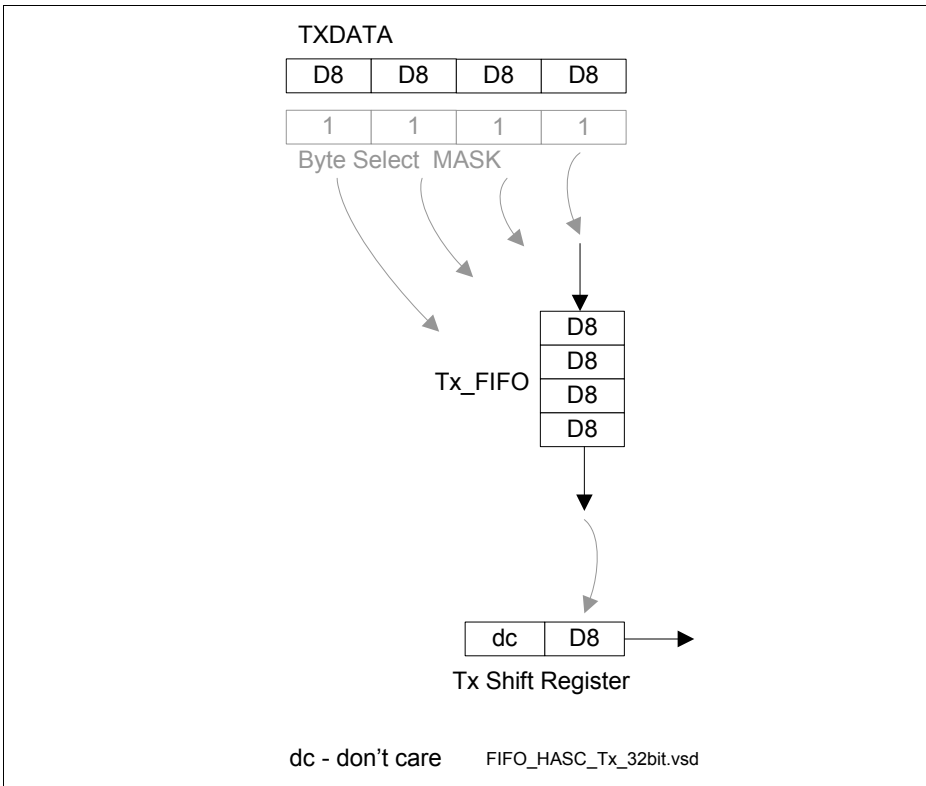

Figure 19-7 High-Speed Communication Scenario

Asynchronous/Synchronous Interface (ASCLIN)

19.4.2.3 LIN Mode

In LIN mode, several 8-bit frames are preceded by a low break pulse.

The generation of the break pulse is programmable with an 8 bit timer in units of bits, where the wide range of break pulses can be generated, for example in a range between 13 and 26 bits and beyond (up to 256 bits, but these lengths would violate the maximum LIN header length). The detection of the break pulse is programmable with an 8 bit timer in units of bits. Among others, the standard thresholds of 10 and 11 bit times can be set. .

The pulse is generated by an module internal timer. The transmit sequence consists of filling the stopped TXFIFO with the appropriate bytes, and then starting the break pulse, which activates the TxFIFO.

The transmit data is written to the address TXDDATA. The Tx_Inlet_Width can be 8-bit (or 16-bit, or 32-bit), and the Tx_Outlet_Width is 8-bit.

19.4.2.4 SPI Mode

SPI mode is used most often to send or receive data of 8 or 16-bits length, or some length in between. Therefore the reading out of the Tx FIFO must be 8 or 16-bit wide, and write could be 16-bit wide, or even 32-bit wide if two frames are packed in one FPI bus access.

The transmit data is written to the address TXDATA. The Tx_Inlet_Width is up to 32-bit, and the Tx_Outlet_Width is up to 16-bit.

Asynchronous/Synchronous Interface (ASCLIN)

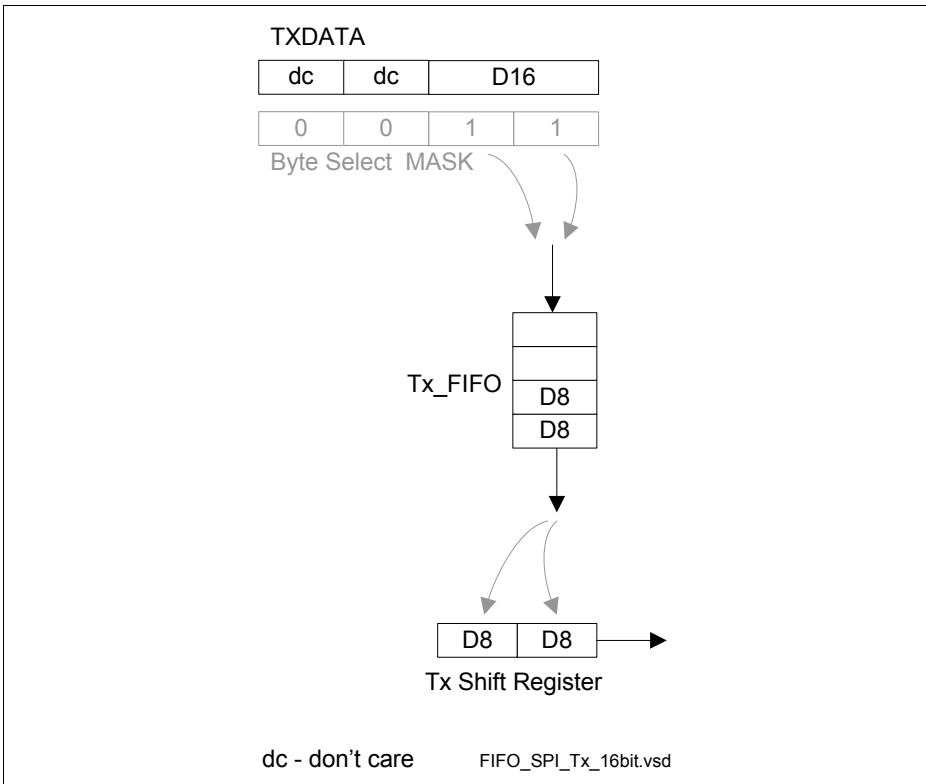

Figure 19-8 TXFIFO Operation in SPI Mode

19.4.3 RxFIFO Overview

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus. It also has the ability to pack four up-to-8-bit 2-up-to-16-bit frames to one 32-bit write to the FPI bus.

Figure 19-9 RxFIFO Overview

The number of bytes taken out of the RxFIFO is always **RXFIFOCON.OUTW**, does not depend on the SPB bus read width, which should be normally equal to OUTW.

If the SPB read width is shorter than the OUTW, then the missing part is filled with zeros.

If the SPB read width is longer than OUTW width, then the excessive part is lost.

On the shift register side, the RxFIFO is always filled with a number of bytes as needed for the data width field **DATCON.DATLEN**.

The **Table 19-2** describes all the possible combinations. The bytes in the RxFIFO are named A, B, C and D, A being the first one to take out. The padding byte is 0.

*Note: In case of an underflow, i.e. when a read access is performed to RXDATA and the number of bytes to be taken out of the FIFO as given by the setting of **RXFIFOCON.OUTW** exceeds the number of bytes that are actually stored in the FIFO, as indicated by **RXFIFOCON.FILL**, then the RxFIFO delivers the available data padded with zeros up to the read access width. However, the data remain in the FIFO and the filling level **RXFIFOCON.FILL** is not changed. To remove the data, the user software must flush the RxFIFO. The bit **FLAGS.RFU** is set.*

Asynchronous/Synchronous Interface (ASCLIN)

Table 19-2 Outlet Width versus SPB Read Width

SPB-Read Data, taken from the RxFIFO		SPB Bus Read Width		
		8-Bit	16-Bit	32-Bit
Outlet Width OUTW	8-Bit	A	A	A
	16-Bit	0A	BA	BA
	32-Bit	000A	00BA	DCBA

Asynchronous/Synchronous Interface (ASCLIN)

19.4.4 Using the Rx FIFO

The Rx FIFO has the ability to pack two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the FPI bus.

19.4.4.1 Standard ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address delivers one byte and empties the FIFO for one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

In case of data width of 9 bits, one read on this address delivers two byte and empties the FIFO for two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

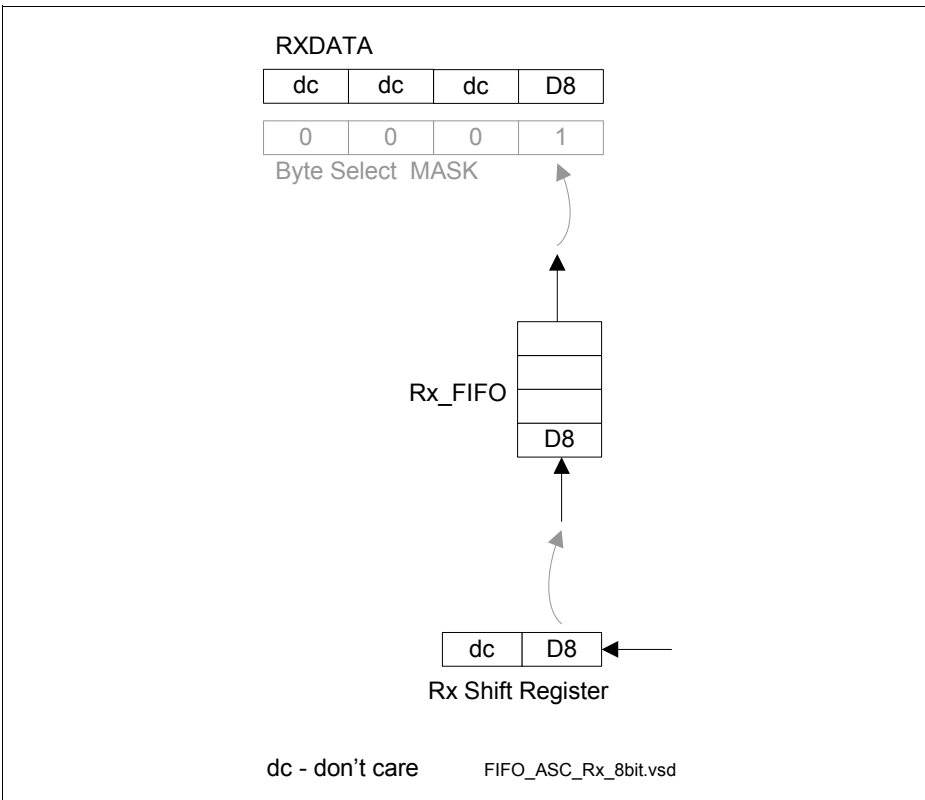

Figure 19-10 8-Bit ASC Reception

Asynchronous/Synchronous Interface (ASCLIN)

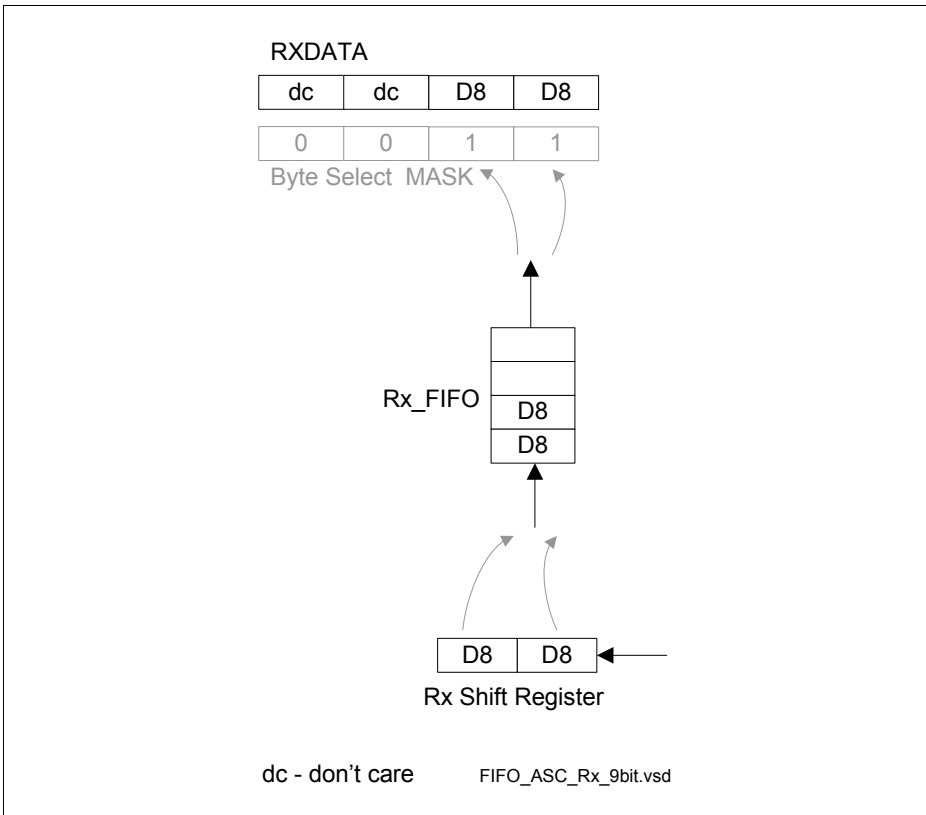

Figure 19-11 9-Bit ASC Reception

Asynchronous/Synchronous Interface (ASCLIN)

19.4.4.2 High Speed ASC Mode

The received data is read from the address RXDATA.

In case of data width of 7 or 8 bits, one read on this address can deliver (one or two or) four bytes and empties the FIFO by four elements, if the Rx_Outlet_Width is 32-bit. The Rx_Inlet_Width is 8-bit.

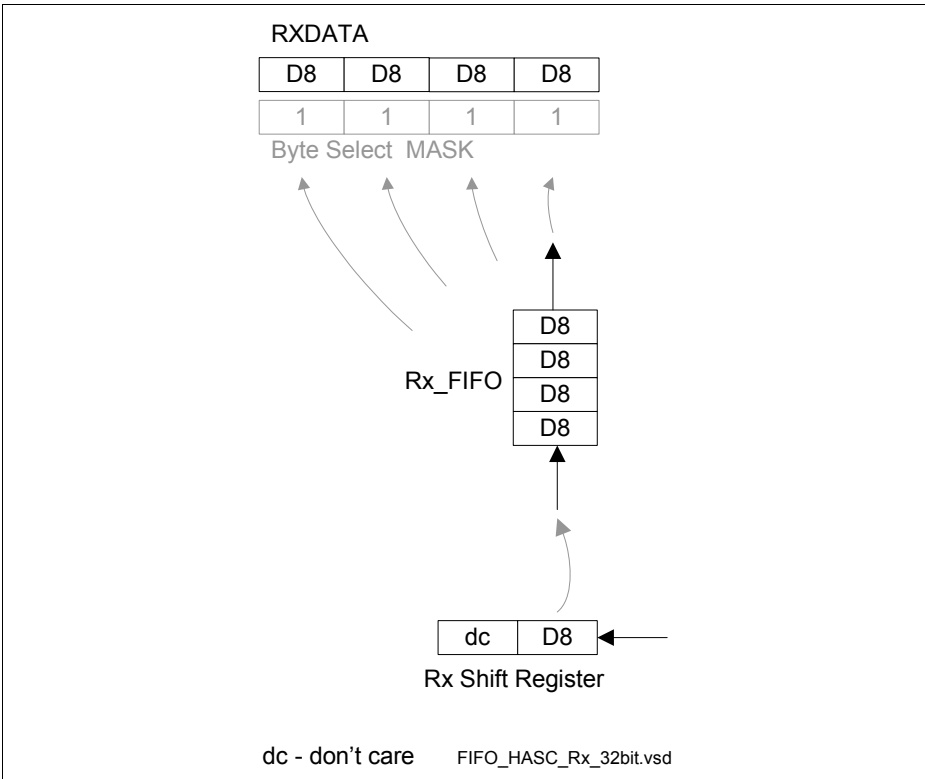

Figure 19-12 High Speed ASC Communication

19.4.4.3 LIN Mode

The received data is read from the address RXDATA.

The read data width is 8 bits (or 16 bit or 32 bit), one read on this address delivers one byte and empties the FIFO by one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit

Asynchronous/Synchronous Interface (ASCLIN)

Figure 19-13 RXFIFO Operation in LIN Mode

Asynchronous/Synchronous Interface (ASCLIN)

19.4.4.4 SPI Mode

The received data is read from the address RXDATA.

In case of data width of 16 bits, one read on this address delivers two bytes and empties the FIFO by two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit

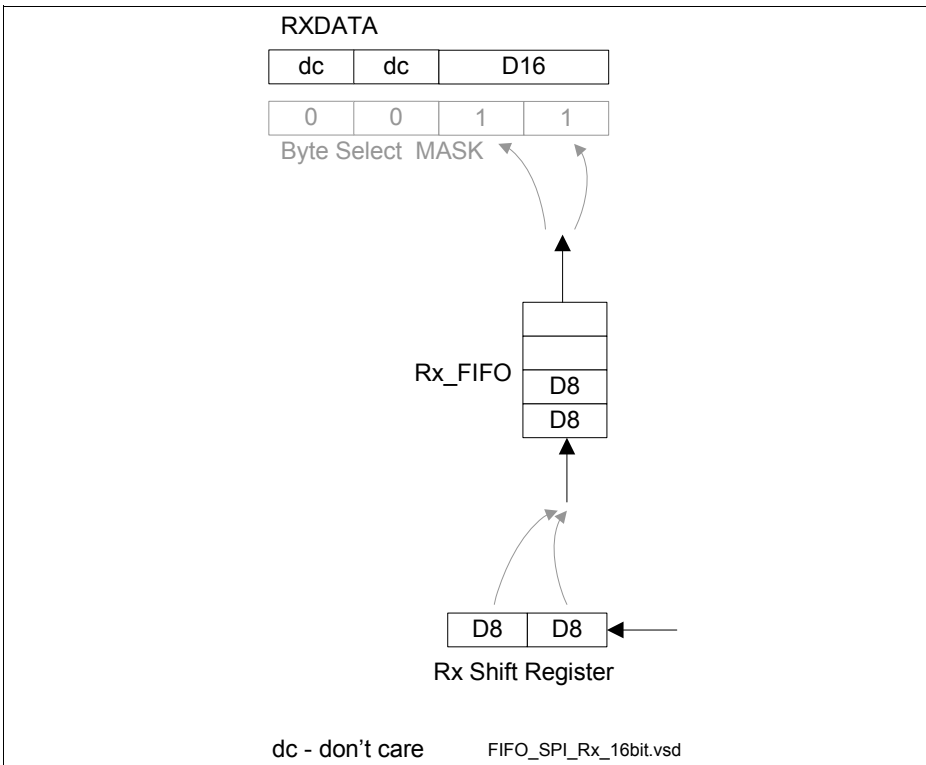

Figure 19-14 RXFIFO Operation in SPI Mode

19.4.5 RTS / CTS Handshaking

A receiver deactivates the RTS (Request to Send) output signal when the RXFIFO is almost full, in order to avoid its overload. When the emptying of the RXFIFO starts, for example by a DMA, and the filling level falls below the threshold level, the RTS output is activated again. The threshold level is fixed to RXFIFO size minus four, in order to support byte, two bytes and four bytes DMA transfers.

The transmitter receives the RTS output of the receiver on its CTS input and accordingly pauses and resumes the transmission.

Asynchronous/Synchronous Interface (ASCLIN)

19.5 Clock System

The clock system generates all the clocks needed for the proper operation of the ASCLIN module: digital filter clock, oversampling clock, bit time and serial SPI clock.

The clock used for the clock system f_A is independent from the SPB bus clock and remains constant if the SPB bus clock changes, for example in power saving scenarios. The bit field **CSR.CLKSEL** selects the clock source for the f_A frequency, which can be synchronous or asynchronous, higher or lower than the SPB bus frequency.

19.5.1 Baud Rate Generation

Fractional Divider, n-divider and oversampling divider with configurable sample point.

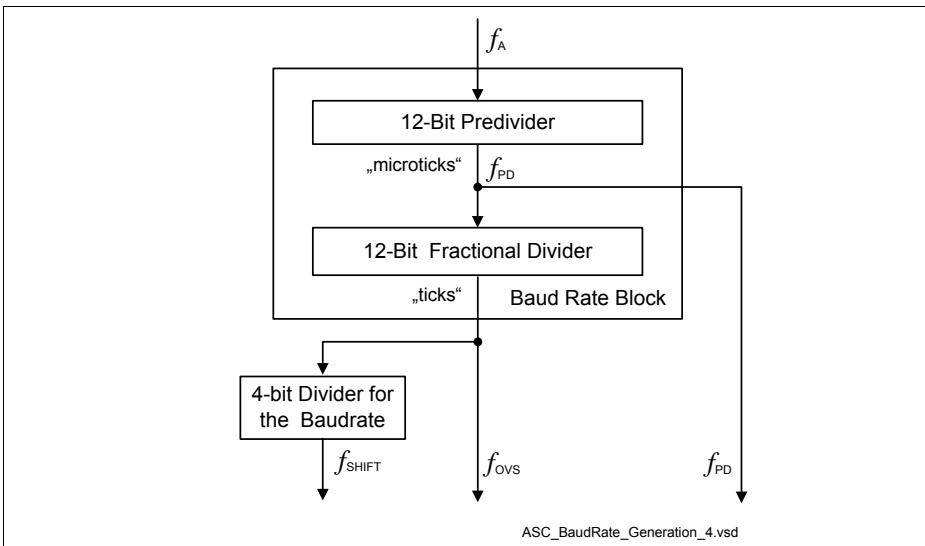

Figure 19-15 Baud Rate Generation

The following bit fields are available for configuring of the 28-bit baud rate divider chain:

- **BITCON.PRESCALER** - the division ratio of the predivider
- **BRG.NUMERATOR** - the nominator of the fractional divider
- **BRG.DENOMINATOR** - the denominator of the fractional divider
- **BITCON.OVERSAMPLING** - the division ratio of the baudrate post divider

The chain of the generated frequencies from f_A down to the f_{SHIFT} (the baudrate) is calculated as follows:

$$f_{PD} = f_A / (\mathbf{BITCON.PRESCALER} + 1)$$

$$f_{OVS} = f_{PD} * \mathbf{BRG.NUMERATOR} / \mathbf{BRG.DENOMINATOR},$$

Asynchronous/Synchronous Interface (ASCLIN)

$$f_{\text{SHIFT}} = f_{\text{OVS}} / (\text{BITCON.OVERSAMPLING} + 1)$$

*Note: Fractional division requires that **BRG.NUMERATOR** is less or equal than the **BRG.DENOMINATOR**.*

The overall formula is given as follows:

(19.1)

$$\text{BAUDRATE} = \frac{f_A \times \text{NUMERATOR}}{(\text{PRESCALER} + 1) \times \text{DENOMINATOR} \times (\text{OVERSAMPLING} + 1)}$$

19.5.2 Bit Timing Properties

The ASCLIN module provides flexible programming of the bit oversampling, sampling point and input signal filtering properties.

The oversampling factor for the incoming bit-stream is configurable from 4 to 16 ticks (or time quanta) per bit.

At the same time, using the oversampling frequency, a digital median filter can be enabled to filter the incoming bit stream. The filtering uses the standard majority out of three procedure. If the filter is disabled, then each bit is sampled only once.

The sampling point is also configurable and should be used in conjunction with the oversampling factor. One standard setting is 16x oversampling and using the samples 7, 8 and 9 for the data. Another possible setting could be 8x oversampling and using the samples 3, 4, and 5 for data.

The following bitfields are available for configuring the bit properties:

- **BITCON.PRESCALER** - the twelve bit integer divider defining the microtick used by the fractional divider to generate the baud rate, and by the digital filter for the deglitching of the RX input signal.
- **BITCON.SAMPLEPOINT** - the bit field defining the sampling point position, and the duty cycle in the SPI mode.
- **BITCON.SM** - the bit enables the digital median filter (majority out of three): 1 or 3 samples per bit.
- **IOCR.DEPTH** - the bitfield defining the floating average filter depth: off or 1 to 63 microticks
- **BITCON.OVERSAMPLING** - the bitfield defining the number of ticks per bit, in the range of 4 to 16. This is a post-divider located after the fractional divider.

Asynchronous/Synchronous Interface (ASCLIN)

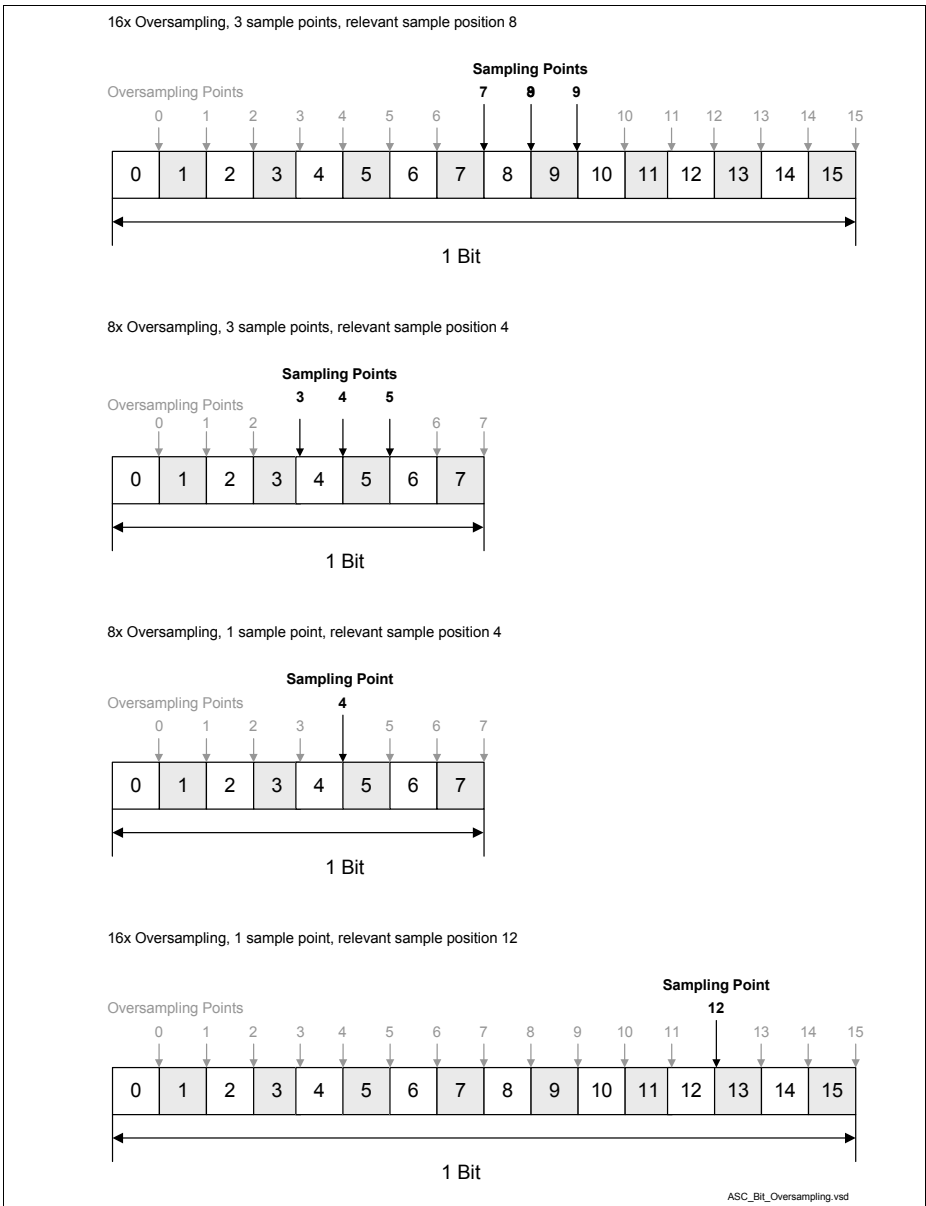

Figure 19-16 ASCLIN Bit Structure

Asynchronous/Synchronous Interface (ASCLIN)

Generally, the sampling point should be placed in the middle of the bit. This position is optimal in case the baud rate (the oscillator frequency) is not very precise and stable.

If the oscillator precision is very high, which is usually the case when two microcontrollers driven by quartz oscillators communicate, but the signal edges are very unsymmetrical, which is the case if open drain half-duplex connection is used, it can be of advantage to move the sample point somewhere in the second half of the bit. Open drain connection usually causes the “0” bits to be longer than the “1” bits. In such a case, optimizing the sampling point would mean placing it in the middle of the shorter “1” bit.

At the end, different combinations of oscillator precision, asymmetry of the edges, and loop-delays for collision detection result in different optimal positions of the sampling point.

Figure 19-17 Bit Length Asymmetry and the Sampling Point

Asynchronous/Synchronous Interface (ASCLIN)

19.6 Data Frame Configuration

Applicable as transmitter and receiver, the parity scheme is configured in the bit fields **FRAMECON**.ODD, the data length in the bit fields **DATCON**.DATLEN and the stop bits in the bit fields **FRAMECON**.STOP.

19.7 Miscellaneous Configuration

Loop - back

Asynchronous/Synchronous Interface (ASCLIN)

19.8 Synchronous Mode

In synchronous mode the module supports the SPI setting of shift edge first, than the latch edge, see [Figure 19-18](#). The module is set in synchronous mode by using the bit field [FRAMECON.MODE](#).

Figure 19-18 SPI Timing

19.8.1 Baud Rate and Clock Generation

The baud rate and clock generation in the synchronous mode uses generally the same counters and principles as in the asynchronous mode. It uses the same prescaler, fractional divider, and oversampling divider with configurable sample point. The only difference is that the shift clock is driven as output signal at the pin SCLKO. If a symmetrical shift clock is required, the oversampling ratio should be an even number, and the sampling point should be set to one half of the oversampling ratio (see the [BITCON](#) register).

The clock polarity is configured in the bit [IOCR.CPOL](#).

Asynchronous/Synchronous Interface (ASCLIN)

19.8.2 Data Frame Configuration

The leading and trailing delays are configured in the bit fields **FRAMECON.LEAD** and **FRAMECON.STOP**. The IDLE phase duration is configured using the bit field **FRAMECON.IDLE**. The data length of 2 to 16 bit is defined in the bit field **DATCON.DATLEN**.

19.8.3 Slave Selects Configuration

The SPI master activates automatically the slave select output signal for each data word. The polarity of the slave select can be configured by using **IOCR.SPOL**.

19.8.4 Miscellaneous Configuration

Loop - back

Asynchronous/Synchronous Interface (ASCLIN)**19.9 LIN Support**

The ASCLIN module provides hardware support for the LIN protocol.

It supports all four elementary LIN transactions:

- TxH - Transmission of Header
- TxR - Transmission of Response
- RxH - Reception of Header
- RxR - Reception of Response

By supporting additionally the combinations of these elementary transactions, the module actually supports all LIN use cases: sending and receiving headers and responses as

- LIN master or
- LIN slave

A LIN master is engaged in three elementary transactions: TxH, TxR, RxR. It never engages in RxH, because a master never receives a header, it only transmits a header.

A LIN slave engages also in three elementary transactions: RxH, TxR, RxR. It never engages in TxH, because a slave never transmits a header, it only receives a header.

Each elementary transaction needs some hardware resources in order to be completed with minimum CPU intervention. Here is a list of tasks per transaction, supported by hardware, and the required hardware resources:

- TxH - Transmission of Header - master mode only
 - break generation: 8-bit bit-field defining the break length in units of bits
 - sync-field generation: hard coded 55H byte
 - ID transmission with interrupt generation
- TxR - Transmission of Response - master and slave mode
 - number of bytes parameter: bit-field of length 4
 - checksum generation: hardware engine, supporting classic and enhanced checksum, which can be enabled or disabled
- RxH - Reception of Header - slave mode only
 - optional auto-baud detection: fractional divider with programmable nominator and denominator
 - number of bytes parameter: bit-field of length 4
 - checksum detection: hardware that supports classic and enhanced checksum, which can be enabled or disabled; a checksum error is flagged, and an error interrupt can be triggered, if enabled
 - interrupt at end of header (necessary to set the number of bytes for the RxR phase)
 - timeout on overflow: 8-bit timer
 - break detection: 8 bit timer with programmable threshold in units of bits
- RxR - Reception of Response - master and slave mode
 - number of bytes parameter: bit-field of length 4

Asynchronous/Synchronous Interface (ASCLIN)

- checksum: the received checksum is optionally delivered in the RXFIFO
- timeout on overflow: 8-bit timer

The break detection feature is always active.

Wake-up signal generation in both slave and master mode

For many LIN configuration parameters, the hardware of the ASCLIN module provides wider ranges than the LIN standard parameters. Therefore the application software shall take care that appropriate LIN standard values are used to configure the module. Such configuration parameters are:

- break length
- data width
- break threshold
- wake-up length
- header, frame and response timeout
- idle time

Figure 19-19 Overview of the elementary LIN transactions

Asynchronous/Synchronous Interface (ASCLIN)

19.9.1 LIN Watchdog

The LIN watchdog monitors the duration of the header, the frame or the response, and appearance of break pulses. It checks against the pre-defined time limits. If the limits are violated, timeout interrupts are generated.

The LIN watchdog is necessary in slave mode.

The wake pulse generation is performed using the shift register and an appropriate data byte containing several consecutive zero bits. The wake pulse detection is done using falling edge detection.

For monitoring the bus for long idle or zero states flags for rising and falling edge are available. These flags can be polled with some appropriate time raster (in microseconds or milliseconds range).

The header timeout value is known at module initialization time and remains constant for all frames.

The frame or response timeout value depends on the length of the response (1 to 8 bytes) and must be set by software depending on the received ID, after the header has been received. The initial value of this timeout should be set by software to the maximum allowed by the timer, that is 256.

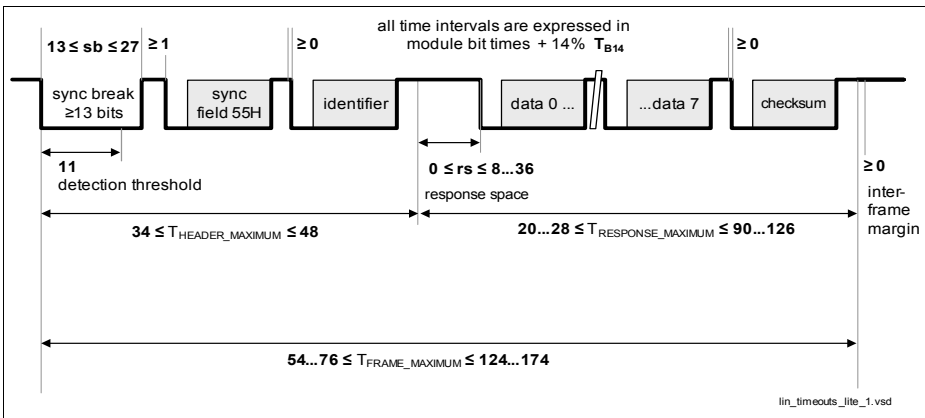

Figure 19-20 Duration of the Elements of a LIN Frame

The module provides timer blocks running in parallel, performing watchdog functions on specific timing requirements of the LIN protocol.

Asynchronous/Synchronous Interface (ASCLIN)

19.9.1.1 LIN Break, Wake, Stuck Handling

This subsection describes:

- the monitoring of the LIN Bus
- Break Pulse detection and generation and
- Wake Pulse detection and generation.

Monitoring the Bus

Figure 19-21 LIN Bus View as Sequence of Sequences of Zeros and Ones

Monitoring the bus for long idle periods (or stuck periods) is supported by providing the bit fields **FLAGS.RED** and **FLAGS.FED**. Polling these fields periodically within some time raster defined by the operating system or timer for example each 1ms or each 10 ms can be used for detecting very long inactive periods in the range, for example, of 150 ms to 10s. Additionally, an interrupt on edge can be enabled by using the corresponding enable bits in the **FLAGSENABLE** registers. Setting and clearing the flags can be done by software by using the **FLAGSET** and **FLAGSCLEAR** register.

Note: The low break or wake up pulses do not cause a dummy byte to be transferred to the receive FIFO and do not cause a frame violation error interrupt. After the pulse the shift register goes into initial state and waits for the falling edge of the start bit of the next frame.

Break and Wake Pulse Detection

The detection of the break pulse, which is defined as low pulse with a minimum duration of 13 bit times, is performed using a threshold of either 10 or 11 bit times. The break detection threshold is set using the bitfield **LINBTIMER.BREAK**.

Detecting a break pulse anywhere in the frame resets the LIN state machine to the "Break Delimiter Detected" state BDD and the whole sequence inclusive the watchdog timeout counting starts from the beginning .

Note: Detecting a break pulse anywhere in the frame could result in setting the Frame Error Flag (FE)

Wake low-pulse detection is done by monitoring the bus for a falling edge in sleep mode. If an early wake-up shall be suppressed, the parameter **IOCR.DEPTH** (gliche filter) may be used.

Asynchronous/Synchronous Interface (ASCLIN)

Break and Wake Pulse Generation

The generated break low-pulse duration is defined by the bit field **LINBTIMER.BREAK** in the range of 1 to 64 bits.

Wake low-pulse is nominal 5 bit times long, but can be set to any value between 1 and 9, by writing the appropriate character in the TXFIFO and requesting its transmission as the wake pulse by setting **FLAGS.TWRQ**.

Note: Injecting the low pulse disables the reception with the shift register, so that this low pulse is not detected or treated as a normal ASC frame.

Asynchronous/Synchronous Interface (ASCLIN)

19.9.1.2 LIN Header and Response Timers

The LIN header and response times can be monitored separately.

(>>LINHTIMER, DATCON description)

- Header duration measurement
 - In master mode starting point of the time measurement is falling edge of the break pulse.
 - In slave mode starting point of the time measurement is the moment of detecting that there is a break pulse going on, that is the moment of detection of a low pulse longer than either 10 or 11 bit times, as configured in the LINBTIMER register.
- Response duration measurement
 - In both master and slave modes the response duration measurement starts with the end of the header and ends with the end of the response. “End” means end of the last bit of the last byte (of the checksum byte).

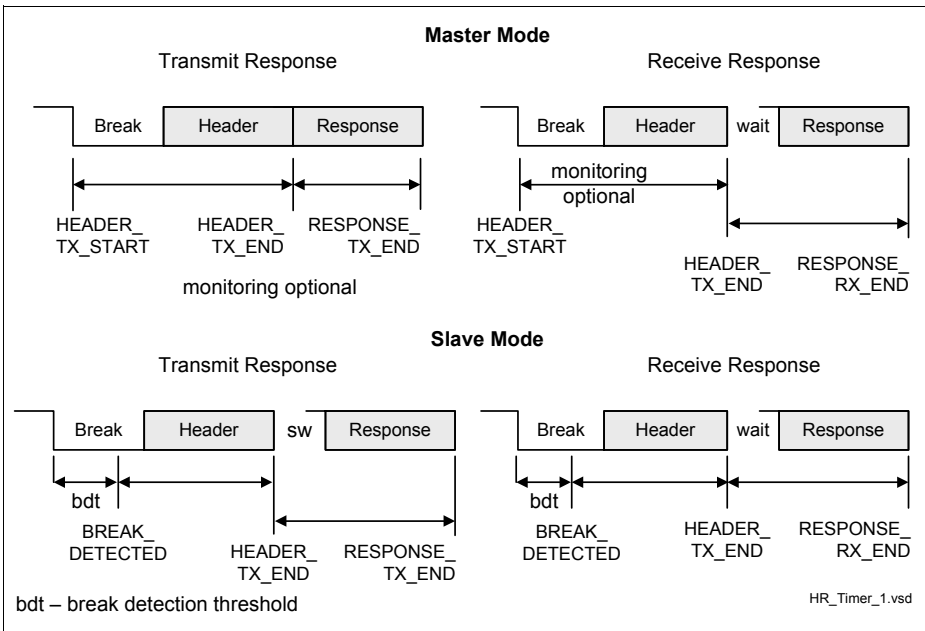

Figure 19-22 Duration Measurement of the Header and Response

Note: Transmitting master node can optionally monitor its own header or response timeouts, in order to detect some error conditions, like TXFIFO not containing the ID or data to be transmitted. However, these error conditions can be detected also in other ways.

Asynchronous/Synchronous Interface (ASCLIN)

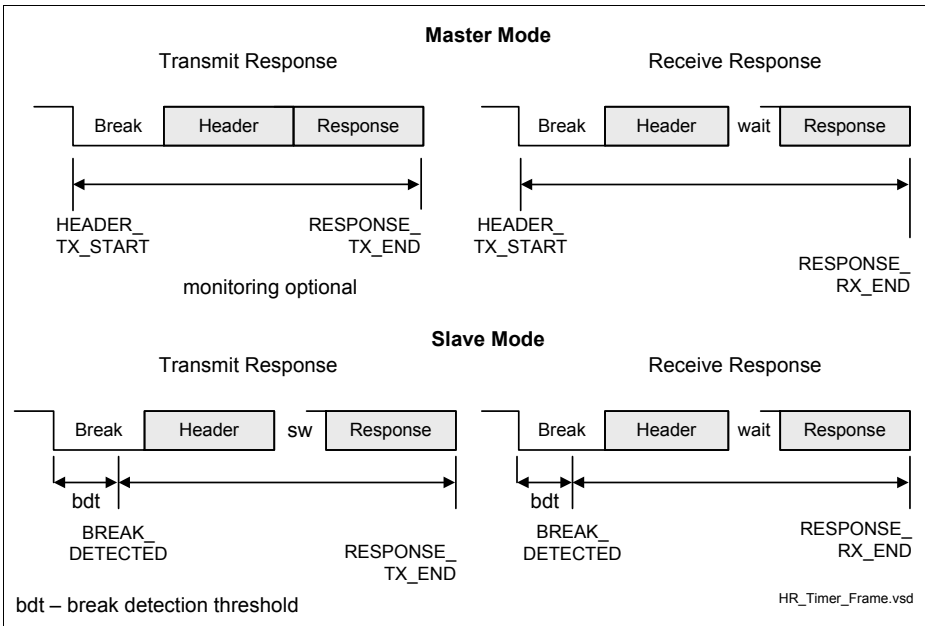

Figure 19-23 Duration Measurement of the Response or Frame

According to the setting of the bit `DATCON.RM`, the `DATCON.RESPONSE` bit field defines response or frame duration threshold.

Asynchronous/Synchronous Interface (ASCLIN)
19.9.2 LIN Master Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in LIN master mode:

- deactivate the clock source : **CSR.CLKSEL** = 0 (off)
- wait or poll for **CSR.CON** = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON.MODE** = INIT
- activate the clock source : set **CSR.CLKSEL**
- wait or poll for **CSR.CON** = 1
- deactivate the clock source : **CSR.CLKSEL** = 0 (off)
- wait or poll for **CSR.CON** = 0
- select the operation mode : **FRAMECON.MODE** = 3 (LIN)
- configure the master mode : **LINCON.MS** = 1
- configure the baud rate : **BRG**
- configure the bit timing : **BITCON.PRESCALER** and **OVERSAMPLING**
- configure the bit sampling : **IOCR.DEPTH**, **BITCON.SM**, **SAMPLEPOINT**
- configure the frame parameter : **FRAMECON.PEN**=0 (no parity), **STOP** = 1
- configure the break length : **LINBTIMER.BREAK** = 13 (typ)
- configure the delay parameter : **FRAMECON.LEAD**, **FRAMECON.IDLE**
- configure the checksum mode : **LINCON.CSEN**, **LINCON.CSI**
- activate the clock source : set **CSR.CLKSEL**
- wait or poll for **CSR.CON** = 1

Send only a header [master task]:

- configure the watchdog timer : **DATCON.RESPONSE** =256 (max)
- configure the RXFIFO : **RXFIFOCON.ENI** = 0 (or 1), **OUTW**, **BUF**=0, flush
- configure the TXFIFO : **TXFIFOCON.ENO** = 0, **INW**, flush
- clear the event flags : **FLAGSCLEAR**.**THC**, **TRC**, **RRC**, **CEC**, **FEC**, **HTC**, **RTC**, **LPC**, **LC**, **TFOC/LC**, **RFOC/UC/LC**
- enable the TX interrupt event : **FLAGSENABLE**.**THE**
- enable the EX interrupt events : **FLAGSENABLE**.**HTE**, **CEE**, (**FEE**, **LPE**)
- write into the TXFIFO : **TXDATA** = ID byte
- start the header transmission : **FLAGSET**.**THRQS** = 1
- configure the TXFIFO : **TXFIFOCON.ENO** = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case

Asynchronous/Synchronous Interface (ASCLIN)

after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

React to the interrupt(s) indicating the end of transmission (and reception) of the ID byte:

- check the error flags : **FLAGS**.HT, CE (FE, LP)
- read from the RXFIFO : **RXDATA**=received ID, if no error has been detected

Check the transmitted / received ID to determine with which response sequence: transmit, receive or ignore to continue (same procedure as in the slave mode).

Send a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCN**.ENI = 0
- configure the TXFIFO : **TXFIFOCN**.ENO = 1
- clear the event flags : **FLAGSCLEAR**.TRC, TFOC/UC, CEC, RTC, BDC
- enable the TX interrupt event : **FLAGSENABLE**.TRE
- enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE (RTE), BDE
- write into the TXFIFO : **TXDATA** = data bytes D0, D1, ... (and optionally the checksum byte if the hardware checksum generation is disabled)
- start response transmission : **FLAGSET**.TRRQS = 1
- the corresponding interrupts signal an error or the end of the response transmission

Receive a response to the latest header [slave task]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode: **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCN**.ENI = 1
- clear the event flags : **FLAGSCLEAR**.RRC, RFOC/UC, FEC, LCC, RTC, FEDC, REDC, BDC
- enable the RX interrupt event : **FLAGSENABLE**.RRE
- enable the EX interrupt events: **FLAGSENABLE**.RFOE/UE, FEE, (LCE), RTE, BDE
- The corresponding interrupts signal that the whole response has been received (= end of the frame) or an error has occurred.

Note: If checksum injection has been enabled, the received (custom) checksum is also written into the RXFIFO and should be taken into account.

- Fetch from the RXFIFO : **RXDATA** = received data, if no error occurred

*Note: The hardware checksum check can be enabled using the bit **LINCON**.CSEN. The received checksum write to the RXFIFO can be enabled using the **LINCON**.CSI.*

Asynchronous/Synchronous Interface (ASCLIN)
Ignore the latest header [slave task]:

- configure the RXFIFO : **RXFIFOCON**.ENI = 0
- set the header only mode : **DATCON**.HO = 1
- clear the event flags : **FLAGSCLEAR**.FEDC, REDC, BDC

The LIN master always knows if the header is followed by a response transmission (by himself) or a response reception (by a slave) or the response transmission is from slave to slave, except in case of a slave that does not respond always, but driven by internal events.

In case of addressing an always responding slave, it is recommended first to configure the header and response (transmission or reception), and afterwards to start the header transmission and optionally, at the same time, the response transmission.

To start a transaction consisting of sending a header and sending or receiving a response, which makes one whole LIN frame [master node]:

- configure the response count : **DATCON**.DATLEN
- configure the watchdog timer : **DATCON**.RESPONSE
- configure the checksum mode : **DATCON**.CSM
- configure the RXFIFO : **RXFIFOCON**.BUF = 0, flush, ENI = 0
- configure the TXFIFO : **TXFIFOCON** flush, ENO = 0
- clear the interrupt event flags : **FLAGSCLEAR**.THC, TRC, RRC, CEC, FEC, HTC, RTC, LPC, LCC, TFOC/UC/LC, RFOC/UC/LC, FEDC, REDC, BDC
- send case
 - enable the TX interrupt event : **FLAGSENABLE**.TRE, (THE, HTE)
 - enable the EX interrupt events: **FLAGSENABLE**.TFOE, CEE, (FEE, RTE, LPE, BDE)
- receive case
 - enable the RX interrupt event: **FLAGSENABLE**.RRE. (THE, HTE)
 - enable the EX interrupt events: **FLAGSENABLE**.RFOE/UEE, CEE, FEE, RTE, (LCE, BDE)
- write into the TXFIFO : **TXDATA** = ID byte
- send case
 - write to TXFIFO : **TXDATA** = data bytes (and optionally checksum byte if the hardware checksum is disabled)
- start the header transmission : **FLAGSSET**.THRQS = 1
- configure the TXFIFO : **TXFIFOCON**.ENO = 1

Note: If the software needs the sent ID in the RXFIFO, it should add the setting of ENI=1 to the sequence above - before triggering the header transmission. In such a case after the header has been transmitted the ID byte will be available in the RXFIFO, but not the sync byte.

- send case
 - start transmit response : also set **FLAGSSET**.TRRQS = 1

Asynchronous/Synchronous Interface (ASCLIN)

- the corresponding interrupt signals an error or the end of the response transmission
- read from the RXFIFO : if no error detected, **RXDATA** = received ID
- receive case
 - fetch from the RXFIFO : if no error has been detected, **RXDATA** = received data bytes and optionally the checksum byte

Asynchronous/Synchronous Interface (ASCLIN)
19.9.3 LIN Slave Sequences

The sequences described below are examples how the elementary LIN transactions can be executed. There exist other ways to do them, for example by using other events to control the protocol flow: fifo level events instead of end of header / response events. Some alternatives are indicated in the lists below with brackets.

Initialize the module in slave mode:

- deactivate the clock source : **CSR.CLKSEL** = 0 (off)
- wait or poll for **CSR.CON** = 0 (see also **Clock Reconfiguration**)
- enter the INIT mode : **FRAMECON.MODE** = INIT
- activate the clock source : set **CSR.CLKSEL**
- wait or poll for **CSR.CON** = 1
- deactivate the clock source : **CSR.CLKSEL** = 0 (off)
- wait or poll for **CSR.CON** = 0
- select the operation mode : **FRAMECON.MODE** = 3 (LIN)
- configure the slave mode : **LINCON.MS** = 0
- configure the baud rate : **BRG**, autobaud detection enable, **BRD.UPPER** / **LOWERLIMIT**
- configure the bit timing : **BITCON.PRESCALER** and **OVERSAMPLING**
- configure the bit sampling : **IOCR.DEPTH**, **BITCON.SM**, **SAMPLEPOINT**
- configure the frame parameter : **FRAMECON.PEN** = 0 (no parity), **STOP**= 1
- configure the break length : **LINBTIMER.BREAK** = 11 (typ)
- configure the header timeout : **LINHTIMER.HEADER**
- configure the delay parameter : **FRAMECON.IDLE**
- configure the checksum mode : **LINCON.CSEN**, **LINCON.CSI**
- activate the clock source : set **CSR.CLKSEL**
- wait or poll for **CSR.CON** = 1

In slave mode, the module waits for a header from the master, that is, it waits for a break pulse followed by the sync byte and the ID.

Configure for header reception [slave task]:

- configure the watchdog timer : **DATCON.RESPONSE** =256 (max)
- configure the RXFIFO : **RXFIFOCON** bufmode = 0, flush, **ENI** = 0
- clear the interrupt flags : **FLAGSCLEAR.RHC**, **TRC**, **RRC**, **FEC**, **HTC**, **RTC**, **BDC**, **LPC**, **LAC**, **LCC**, **TFOC/UC/LC**, **RFOC/UC/LC**
- enable the RX interrupt event : **FLAGSENABLE.RHE**
- enable the EX interrupt event : **FLAGSENABLE.HTE**, **CEE**, **FEE**, **LAE**, **LPE**

React to the interrupt(s) generated after receiving the ID byte:

- check error flags : **FLAGS.HT**, **FE**, **LA**, **LP**
- read from the RXFIFO : if no error detected, **RXDATA** = received ID

Asynchronous/Synchronous Interface (ASCLIN)

Check the received ID to determine which response sequence (send, receive or ignore header) to use next.

The LIN slave does not know in advance if it will respond to the header with a transmission himself or it will receive a response by another slave. It looks up the received ID and decides if this ID is associated with a transmit or receive response or if it doesn't care (it is for some other slave). This look-up and the subsequent configuration of the module must be performed by software within the allowed response time.

Send a response to the latest header [slave task]:

(same sequence as in master mode)

Receive a response to the latest header [slave task]:

(same sequence as in master mode)

Ignore the latest header (if the received ID contains an error or is not for this slave) [slave task]:

(same sequence as in master mode)

19.9.4 Using the ENI and HO Bits

Both the ENI (Enable Input) and HO (Header Only) bits affect the reception of the various byte types in the LIN frame.

The HO bit is normally used in cases where the response part of a frame should be ignored; the module waits for the next break signal. The ENI bit can be set by the user software, but is also set by the hardware in slave mode after the sync byte reception, in order to enable the transfer of the ID byte of the header in the RXFIFO.

Asynchronous/Synchronous Interface (ASCLIN)

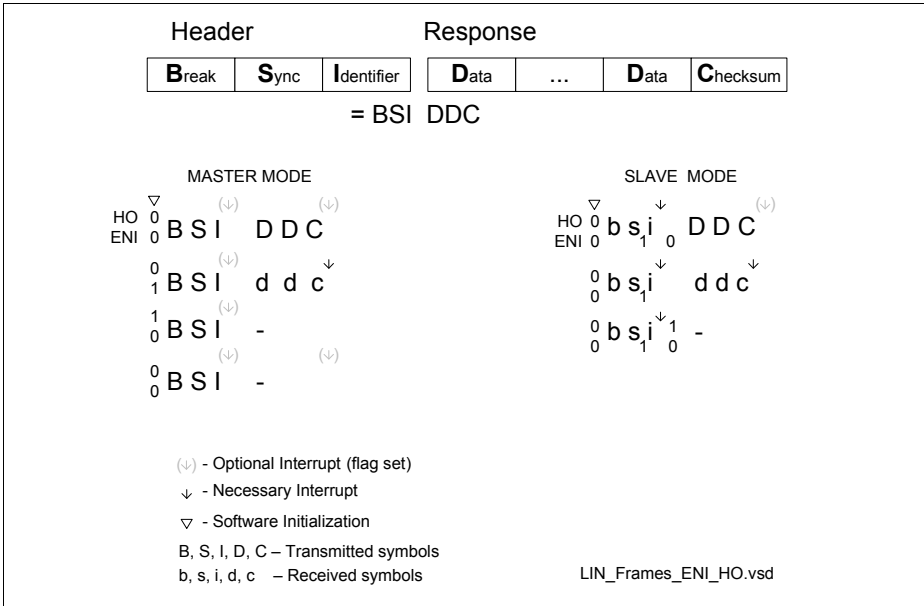

Figure 19-24 ENI and HO bits

19.9.5 LIN Error Recovery

This section describes the behavior of the module in case of errors detected during reception and during transmission of a LIN frame.

Reception Related Errors

In case of an reception error, the receive state machine goes into the state for waiting for break, and the corresponding interrupt is triggered.

ID Parity error

Checksum error

Timeout error

Framing error

Baud Rate error

Asynchronous/Synchronous Interface (ASCLIN)

Transmission Related Errors

Collision error (LIN2.1 mandatory). If the collision detection mechanism is enabled **FLAGSENABLE.CEN**, the frame will be aborted and the transmitter state machine goes to the idle state.

19.9.6 LIN Sleep and LIN Wake-Up

Wake up low pulse in duration of 250us to 5ms can be generated by the module.

Wake up low pulse in duration longer than 150us wakes up a sleeping module.

A master node which has received a wake up pulse can start polling the slaves, that is it can start sending break pulses and headers, and sending or receiving corresponding responses.

A slave which has been woken up shall be capable of receiving LIN headers after a wake-up time of maximum 100ms. A slave issuing a wake-up pulse expects to receive a header within 150ms to 250ms after the end of the wake-up pulse. If the header does not come, the slave issues a wake up pulse again.

Asynchronous/Synchronous Interface (ASCLIN)

19.10 Auto Baud Rate Detection

Auto baud rate detection is active in slave mode during the reception of the sync field in the LIN header. It measures the longest time interval between two falling edges in the 55H sync field. The measured value is loaded in the denominator of the fractional divider and used afterwards for generating the baudrate for the remainder of this frame if the auto baud rate usage is enabled (**LINCON.ABD** = 1).

Figure 19-25 Measurement of the Sync field

The following bitfields are available for monitoring the autobaud detection:

- **BRD.MEASURED** - the measured time interval between the first and the fifth falling edge of the sync byte
- **BRD.UPPERLIMIT** - In case the LIN autobaud detection measures a baud rate 14% lower than the nominal one, that is measures a time interval longer than the UPPERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.
- **BRD.LOWERLIMIT** - In case the LIN autobaud detection measures a baud rate 14% higher than the nominal one, that is measures a time interval shorter than the LOWERLIMIT, a baud rate error event is triggered that, if enabled, generates an interrupt.

Auto Baud Rate Operation

The **BRD.UPPERLIMIT** defines the maximum allowed duration for 8 bits in microticks, and therefore the minimum allowed baud rate. In order to define 14% lower baud rate, 8-bit duration 16% longer than the nominal must be entered in the UPPERLIMIT bit field. This is due to the fact that $BaudRate = 1 / BitTime$, and UPPERLIMIT defines the time.

The **BRD.LOWERLIMIT** defines the minimum allowed duration for 8 bits in microticks, and therefore the maximum allowed baud rate. In order to define 14% higher baud rate, 8-bit duration 12% shorter than the nominal must be entered in the LOWERLIMIT bit

Asynchronous/Synchronous Interface (ASCLIN)

field. This is due to the fact that $BaudRate = 1 / BitTime$, and LOWERLIMIT defines the time.

If the autobaud is activated, the fractional divider uses a numerator value of $8 \times (BITCON.OVERSAMPLING + 1)$ and ignores the bit field BRG.NUMERATOR. For the standard LIN protocol oversampling of 16 ($BITCON.OVERSAMPLING = 15$), the numerator value used internally is 128, ignoring the bit field BRG.NUMERATOR. Nevertheless, programming 128, or $8 \times (OVERSAMPLING + 1)$ in BRG.NUMERATOR may increase the clarity of the software.

Regarding the denominator of the fractional divider, defined in BRG.DENOMINATOR, its initial value is the nominal value and is set by the application software. During the operation of the module, the BRD.MEASURED value is automatically loaded into the BRG.DENOMINATOR, as long as it is within the limits.

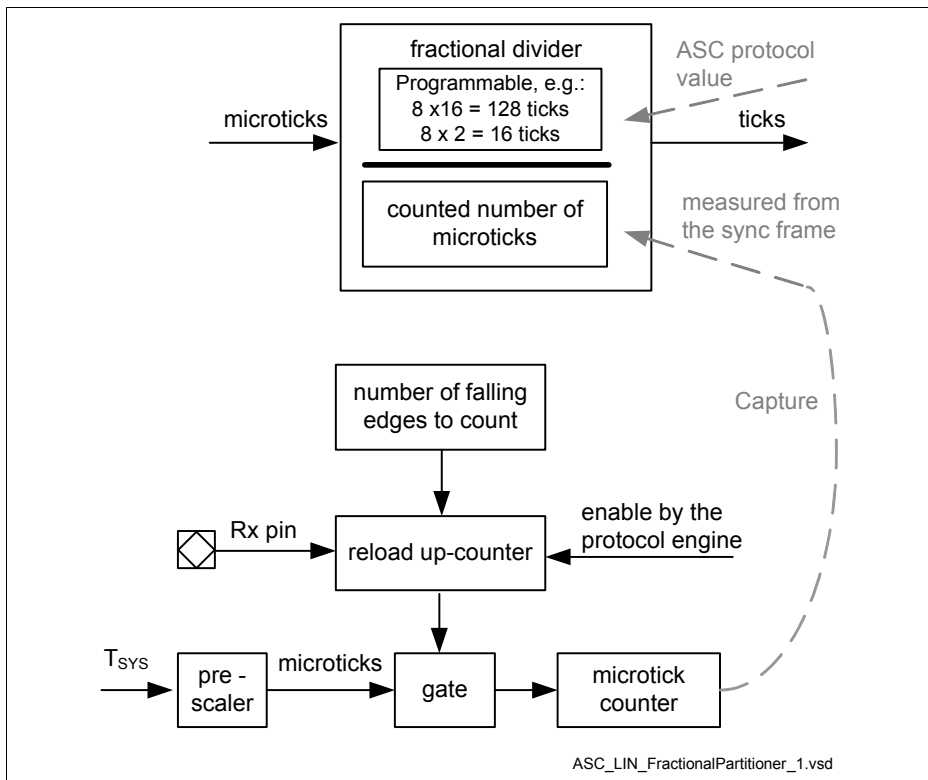

Figure 19-26 Overview of the LIN Auto Baud Detection Principle

Asynchronous/Synchronous Interface (ASCLIN)

Auto baud rate detection measures the time between the first and the fifth falling edge of the sync field in T_{SYS} units and loads this number in the denominator. The LIN protocol uses baud rates in a range between 2400 Baud to 19200 Baud. The expected time at 19.2 KBaud is $8 * 52.1 \text{ us} = 416.8 \text{ us}$ and the expected denominator value at $T_{SYS} = 10\text{ns}$ is in the range of $417\text{us} / 10\text{ns} = 41700$.

The numerator operates internally with the quantum for 8 bits, 16 times oversampling for LIN protocol: $8 * 16 = 128$. The bit field **BRG.NUMERATOR** is ignored.

19.11 Collision Detection

Collision detection monitors the consistency of transmitted and the echoed received bytes in LIN mode and half duplex SPI mode.

Asynchronous/Synchronous Interface (ASCLIN)

19.12 LIN Protocol Control

There is a central LIN protocol state machine. It is connected to the receiver and the transmitter shift registers, the Tx and Rx FIFOs, the checksum logic and the watchdog timers. The machine takes care of generating the sync byte of 55_H and the automatic handling of the checksum. Both the classic LIN V1.3 and the enhanced LIN V2.0 / V2.1 checksum are supported (>> **LINCON** register). The hardware checksum feature is switchable on and off, and the choice between using the classical and the enhanced checksum is done by software with the **DATCON.CSM** bit on a frame by frame basis. As can be seen in the **Figure 19-28**, for the LIN version 2.0 and 2.1, the enhanced checksum is calculated for the identifiers 0...59, and the classical checksum for the identifiers 60...63.

Additionally, the parity of the ID field is generated in master mode, and checked in slave mode. In slave mode, in case of a mismatch between the received and the calculated parity, an error interrupt is raised.

In receive case, if **LINCON.CSI** = 1, the received checksum byte is written to the RXFIFO after the last data byte.

Figure 19-27 Block Diagram of the LIN Control Subsystem

Asynchronous/Synchronous Interface (ASCLIN)

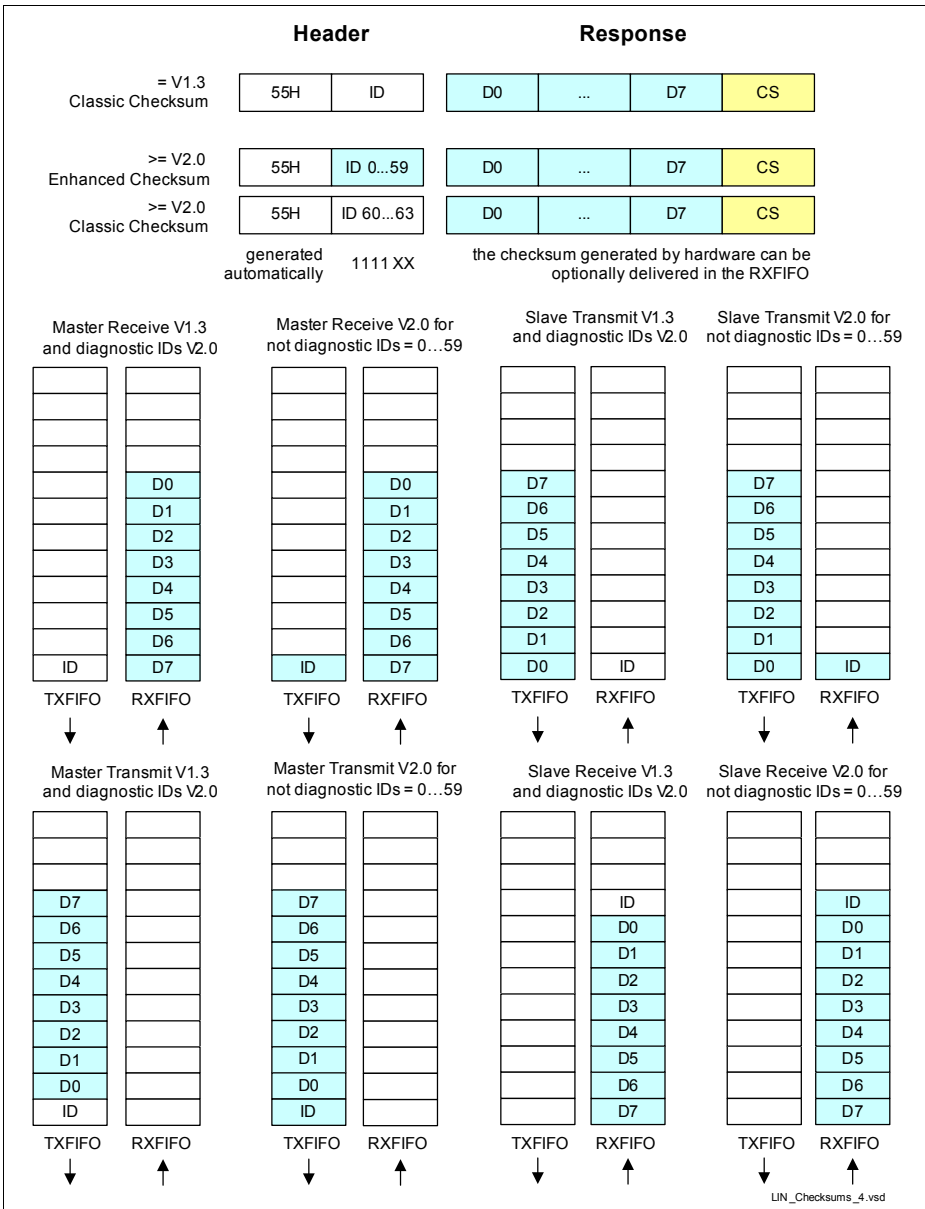

Figure 19-28 Coverage of the Checksum in Different Use Cases

Asynchronous/Synchronous Interface (ASCLIN)

19.13 Interrupts

The ASCLIN module generates three interrupts:

- TX - Transmit Interrupt
 - signals the TxFIFO level event (**FLAGS.TFL**)
- RX - Receive Interrupt
 - signals the RxFIFO level event (**FLAGS.RFL**)
- EX - Extended Error Interrupt
 - signals every error (**FLAGS.PE**, FE, CE, RFO, RFU, TFO) and
 - some additional events (**FLAGS.FED**, RED)

The LIN events related to transmission and reception of header and response are mapped to the corresponding transmit, receive and extended error interrupts

- TX:
 - transmission of the header in master mode completed (**FLAGS.TH**)
 - transmission of a response completed (**FLAGS.TR**)
- RX:
 - reception of the header in a slave mode completed (**FLAGS.RH**)
 - reception of the response completed (**FLAGS.RR**)
- EX:
 - LIN protocol (**FLAGS.BD**, TC) and
 - LIN error events (**FLAGS.HT**, RT, LP, LA, LC)

In order to determine which event is the source of a LIN interrupt, the **FLAGS** register must be polled.

Triggering a DMA

The interrupt signals are used also as DMA trigger signals. The interrupt signals are connected to the Interrupt Router Module, which routes the interrupts either to a CPU or to a DMA. There are no separate DMA trigger signals.

Asynchronous/Synchronous Interface (ASCLIN)

Relationship between the Service Request Nodes and the Event Nodes

There are several events mapped to each service request node.

Each service request (interrupt) node contains an SRC (Service Request Control) register containing a sticky flag bit and the associated set, clear and enable bits. The SRC registers are located in the IR (Interrupt Router) module.

The service request flags in the SRC registers are set by hardware, and if the enable bit is set, will be cleared by hardware when the interrupt servicing starts.

One interrupt node may be triggered by more than one events. Each event which causes an interrupt also has a sticky flag bit and associated set, clear and enable bits. These bits are distributed in four registers: **FLAGS**, **FLAGSET**, **FLAGSCLEAR**, and **FLAGSENABLE** located in the ASCLIN module. Each set of four bits associated to one event builds a virtual “event node”, see **Figure 19-29**.

The event flags are set by hardware and if enabled, trigger an interrupt. They are not cleared by hardware. They are cleared only by software in the corresponding interrupt service routine, which usually polls the flags to find the cause for the interrupts. The event flags can be also set by software for test purposes.

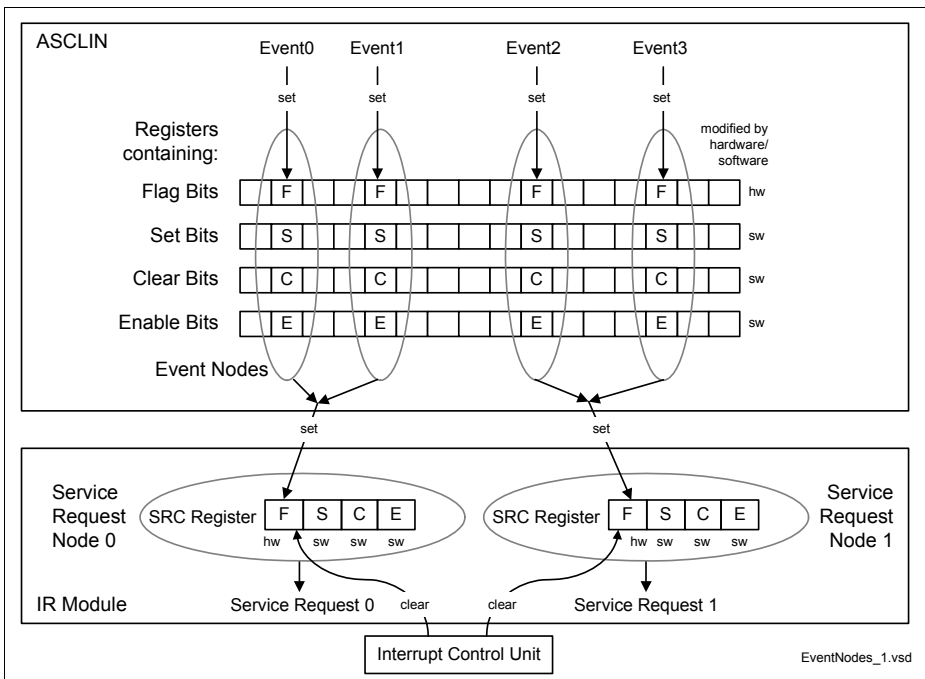

Figure 19-29 Relationship between Event Nodes and Service Request Nodes

Asynchronous/Synchronous Interface (ASCLIN)

Some flags do not generate interrupts and do not have enable bits. They are used either for issuing requests, which are subsequently acknowledged by hardware, or only for polling by software, see **Figure 19-30**.

Clearing an request / acknowledge flag by software is ignored (for example **FLAGS.TRRQ**, **THRQ**, **TWRQ**).

There are no pure polled only flags in the ASCLIN module, although by letting the enable bits disabled, all interrupt event flags can be used as polled only (for example idle and stuck monitoring by using **FLAGS.FED**, **RED**). Setting such bits per software in such a case is meaningless, except for test purposes.

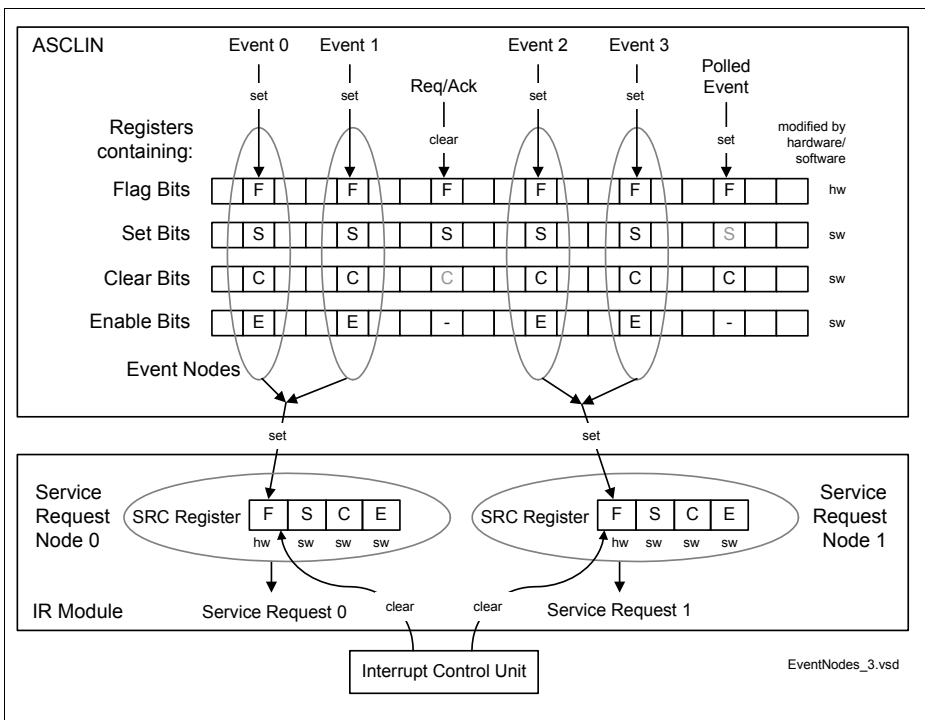

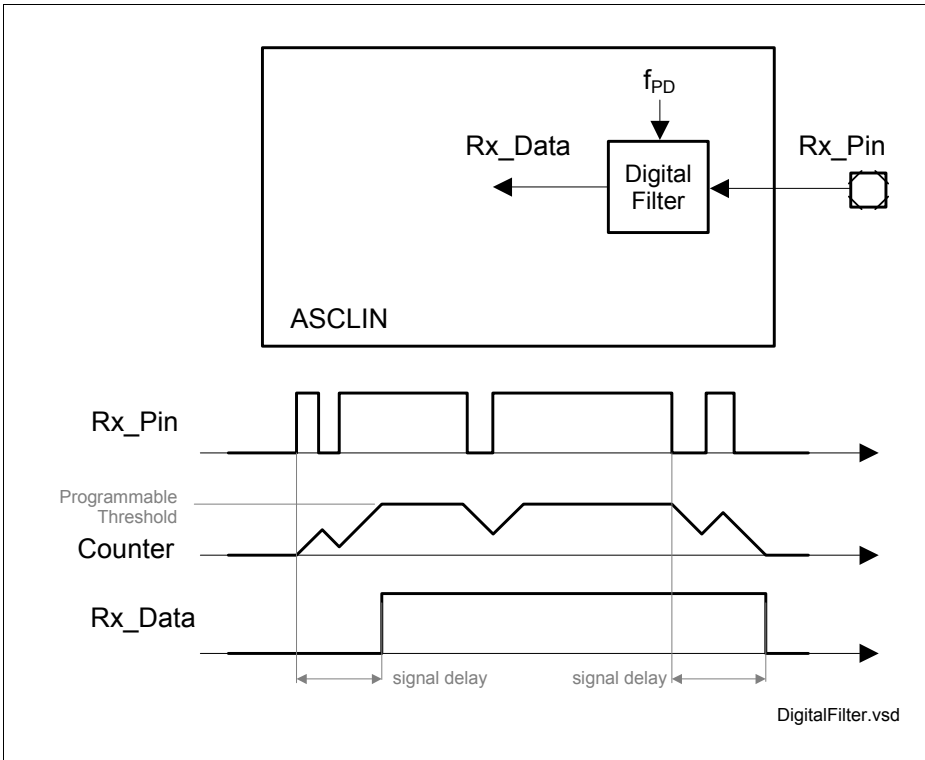

Figure 19-30 Acknowledge Flags and Polled Flags

Asynchronous/Synchronous Interface (ASCLIN)

19.14 Digital Glitch Filter

The digital glitch filter removes short glitches from the input data signal by using an increment / decrement counter with programmable threshold. On the other hand, the filter introduces a delay into the signal path, depending on the digital filter sampling frequency f_{PD} and the threshold programmed in the bit field **IOCR.DEPTH**.

Figure 19-31 Digital Filter

Asynchronous/Synchronous Interface (ASCLIN)

19.15 Suspend, Sleep and Power-Off Behavior

Generally, the ASCLIN module transmits short data frames, not longer than 16 bits, mostly 8 bit long, sometimes with very low baud rates, down to few KBaud. In LIN mode, the data frames build LIN frames.

Simply freezing the module in the middle of an asynchronous ASC frame mostly results in an erroneous data at the receiver side, depending on the data content.

Freezing the module inside the LIN frame transmission, but between the transmission of single bytes results in a timeout error at the receiver side.

If the ASCLIN module gets a request for switching off the clock, it disables immediately all request lines towards the DMA in order to stop further DMA transfers.

In order to power down the module in a well defined way, the user software must take care that the power down request is issued when there is no ongoing single frame or LIN frame transfer and that both FIFOs are empty.

19.15.1 OCDS Suspend

OCDS soft suspend request suspends the module activity at the end of the current transaction. In ASC and SPI cases, this is the end of the current frame. In LIN case, this is the end of the current LIN frame (regular end of response, header timeout, or response timeout).

OCDS hard suspend request, for debugging purposes, immediately freezes the ASCLIN module in the current state. The SPB clock feeding the kernel clock f_{CLC} is immediately switched off. If f_{CLC} is selected for f_A (by using the **CSR.CLKSEL** bit field), the asynchronous clock f_A is also immediately switched off.

*Note: The asynchronous clock f_A remains switched on if a clock source other than f_{CLC} is selected for f_A (by using the **CSR.CLKSEL** bit field).*

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a ASCLIN kernel reset might not be sufficient to bring the system into a defined state.

19.15.2 Sleep Mode

Going into sleep mode implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a sleep request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur.

The ASCLIN module behaves in the same way as in case of disable request..

Asynchronous/Synchronous Interface (ASCLIN)

19.15.3 Disable Request (Power-Off)

Going into power off implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a power-off request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur. This is no issue if the power-off procedure is one-way, that is no continuation of operation without reinitialization of the module is expected.

The ASCLIN module sets immediately all outputs to inactive, stops reacting to inputs, the internal state machines go to initial state, the registers remain unchanged, and then the module acknowledges the request. All clocks to the module are switched off.

19.16 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bit in the kernel register KRSTx0.RST and KRSTx1.RST.

Both sources reset the ASCLIN module. They execute an Application Reset, which resets all the registers except the OCS register. All output signals get the reset value.

The **OCS** register is reset by the Debug Reset.

Asynchronous/Synchronous Interface (ASCLIN)
19.17 Use Case Example ASC Interface

This section explains the core functionality of the ASCLIN interface with a code example. The example uses the ASC feature of the module to transmit and receive a data set via loop back mode (see also figure 21-2 (LINK!)). The following settings are used:

- Data length: 8 bit
- Baud rate: 9600 Bd
- One stop bit, parity bit checking, oversampling factor 16, sampling points 7,8 and 9
- Rx and Tx interrupt

Step description to initialize the ASC module with the settings from above:

(Line 1) reset ENDINIT to get access to ENDINIT protected register, here ASCLIN0_CLC. (see also ENDINIT protection chapter 8.9.3(LINK))

(Line 2) enable the control of the module in the clock control register CLC (LINK)

(Line 3) store CLC register in a dummy variable (has to be defined before). Read back to avoid pipeline effects.

(Line 4) set ENDINIT to lock the protected register again.

(Line 5) The clk source gets set in the clock selection register CSR (LINK). Before setting a source, no clk supply ([3:0]=0) must be set. Final clk selection in Line 20.

(Line 6) This line sets the loop back mode in the input and output control register IOCR (LINK). (see also figure 21-2 (LINK))

(Line 7) This line clears and enables the Tx FIFO and also defines the writing size of 1 byte per clk. The Tx FIFO filling level to trigger an interrupt gets set to 0 ([11:8] =0). The Tx FIFO triggers a Tx interrupt, if the Tx FIFO filling level falls to or below that defined level. The Tx interrupt get enabled in Line 14. (see also chapter 21.4.1 TxFIFO Overview (LINK) and TXFIFOCON (LINK) register)

(Line 8) This line installs the Rx FIFO identically like the Tx FIFO from the line above. (see also RXFIFOCON (LINK) and chapter 21.4.2 RxFIFO Overview (LINK))

(Line 9) The oversampling factor (here 16), the sample points (here 7,8 and 9) and the prescaler for the baudrate (here 10) gets configured in the bit configuration register BITCON (LINK). (see also section 21.5. Clock System (LINK))

(Line 10) One stop bit and initialize mode as basic operation mode (necessary before switching to another mode) are getting configured in the FRAMECON (LINK) register. The parity bit feature with parity type even gets also enabled.

(Line 11) The data length of 8 bits gets set in the DATCON (LINK) register.

(Line 12) the clk divider for the baud rate gets set to 48/3125 in the baud rate generation register BRG (LINK) (see also 21.5. Clock System (LINK))

*Note: assuming $f_{clk} = 100$ MHz and (defined in line 8) $prescaler = 10$, $oversampling = 16$:
 $f_{shift} = (f_{clk}/prescaler * 48/3125) / oversampling = 9600$ Bd*

Asynchronous/Synchronous Interface (ASCLIN)

(Line 13) Clear all interrupt flags in the FLAGSCLEAR (LINK) register. Before setting the respective interrupt flags in Line 14

(Line 14) enable the Tx and Rx interrupts in the FLAGSENABLE (LINK) register. The interrupts getting triggered by the FIFO's (see Line 6/7).

(Line 15) This line enables the Tx interrupt in the service request control register SRC_ASCLIN0TX (LINK) and sets the interrupt priority to ASC0TX_PRIO (1...255).

(Line 16) This line enables the Rx interrupt in the service request control register SRC_ASCLIN0RX (LINK) and sets the interrupt priority to ASC0RX_PRIO (1...255).

(Line 17 and 18) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (LINK) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority ASC0TX_PRIO respectively ASC0RX_PRIO.

(Line 19) setting operating mode finally to ASC (see also Line 9).

(Line 20) setting clk source finally to fclk (see also Line 4).

Note: your Tx ISR function prototype would be: void ASC0_TX_irq (void); here could be your ISR code;

Initialization of the ASC interface:

```

(1)  SCU_vResetENDINIT (0);           // enable ENDINIT register
(2)  ASCLIN0_CLC = 0x000;             // disable module control
(3)  dummy = ASCLIN0_CLC;             //read back
(4)  SCU_vSetENDINIT (0);             // lock ENDINIT register
(5)  ASCLIN0_CSR = 0;                 // clk source, no clk
(6)  ASCLIN0_IOCR = 0x10000001;       // Loopback
(7)  ASCLIN0_TXFIFOCON = 0x00000043;  // init TXFIFO
(8)  ASCLIN0_RXFIFOCON = 0x00000043;  // init RXFIFO
(9)  ASCLIN0_BITCON = 0x830F0009;     // OS 16, SP 7,8,9, PS 10
(10) ASCLIN0_FRAMECON = 0x40000200;   // 1 Stop, Init Mode, P
(11) ASCLIN0_DATCON = 0x7;            //8 Data Bits
(12) ASCLIN0_BRG = 0x00300C35;        // divider for Baudrate
(13) ASCLIN0_FLAGSCLEAR = 0xFFFFFFFF; // Clear all Flags
(14) ASCLIN0_FLAGSENABLE = 0xF0000000; // Enable TX/RX Int.

(15) SRC_ASCLIN0TX = (1 << 10) | ASC0TX_PRIO;
(16) SRC_ASCLIN0RX = (1 << 10) | ASC0RX_PRIO;

```

Asynchronous/Synchronous Interface (ASCLIN)

```
(17) interruptHandlerInstall (ASC0TX_PRI0, & ASC0_TX_irq);  
(18) interruptHandlerInstall (ASC0RX_PRI0, & ASC0_RX_irq);  
  
(19) ASCLIN0_FRAMECON |= 0x00010000; // Mode ASC  
(20) ASCLIN0_CSR = 1; //clk source CLC
```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):

```
__enable();
```

to set this bit. (See also Architecture Manual for more details)

Asynchronous/Synchronous Interface (ASCLIN)

19.18 Kernel Registers

This section describes the kernel registers of the ASCLIN module. All ASCLIN kernel register names described in this section will be referenced in other parts of the TC26x B-Step User’s Manual by the module name prefix “ASCLIN0_” for the ASCLIN0 interface and “ASCLIN1_” for the ASCLIN1 interface.

All registers in the ASCLIN address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

Asynchronous/Synchronous Interface (ASCLIN)

- 1) All registers have read access mode U, SV. Read access from reserved addresses delivers bus error (BE). All registers belong to application (class 3) reset except OCS, which belongs to debug (class 1) reset.
- 2) This register is writable only if **CSR.CLKSEL=0**.

List of Access Protection Abbreviations

U	- User Mode
SV	- Supervisor Mode
BE	- Bus Error
nBE	- no Bus Error
P	- Access Protection, as defined by the ACCEN Register
E	- ENDINIT
SE	- Safety ENDINIT

Asynchronous/Synchronous Interface (ASCLIN)

19.18.1 Kernel Registers

IOCR

The Input and Output Control Register IOCRx determines several properties of the RX and TX signal path:

for the RX signal:

- the alternate input
- the filter depth

for the TX signal

- the trigger source

r	r/w		r/w		r/w		r								

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
IDLE	[8:6]	rw	<p>Duration of the IDLE delay Defines the duration of the IDLE delay in bit times. If more characters are available in the TXFIFO, this is the pause inserted between the characters. In the SPI mode, this is the idle time between the frames. In the ASC and LIN mode, this is the pause inserted between transmission of bytes. Idle also applies to the pause between the header and the response (response space).</p> <p><i>Note: The collision detection runs in parallel to the idle delay and in LIN mode may extend the time between two bytes for one bit length. This effect may occur if the the round trip delay including the digital filter delay is longer than the idle delay.</i></p> <p>000_B 0 001_B 1 ..._B ... 111_B 7</p>
STOP	[11:9]	rw	<p>Number of Stop Bits Defines the number of stop bits in ASC and LIN mode, or the trailing delay in SPI mode. In ASC mode, standard values are 1 and 2. In LIN mode, standard value is 1. In SPI mode there is no standard value. Nevertheless, all settings are possible in all modes.</p> <p>000_B 0 (not allowed in ASC and LIN modes) 001_B 1 ..._B ... 111_B 7</p>
LEAD	[14:12]	rw	<p>Duration of the Leading Delay Defines the leading delay in bit times in SPI mode. Has no meaning in the ASC mode. In LIN mode, this is a delay inserted between the end of the break and the start of the sync character.</p> <p>000_B 0 (not allowed in LIN mode) 001_B 1 ..._B ... 111_B 7</p>

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
MODE	[17:16]	rw	<p>Mode Selection</p> <p>This bit field defines the basic operating mode of the module.</p> <p>In initialize mode, all outputs are at inactive level, and the module does not respond to the input signals. Changing the mode of the module must be done by switching first to initialize mode, and then to the other mode.</p> <p>The SCLK signal generated by the module is active only in the SPI mode.</p> <p>The CTS output generated by the module is active only in the ASC mode.</p> <p>00_B Initialize mode 01_B ASC mode 10_B SPI mode 11_B LIN mode</p>
MSB	28	rw	<p>Shift Direction</p> <p>Defines the shift direction of the shift register. Relevant for the SPI mode. In ASC and LIN modes, should be set to zero. Parity bit is shifted out last independently of the shift direction.</p> <p>0_B LSB first 1_B MSB first</p>
CEN	29	rw	<p>Collision Detection Enable</p> <p>Enables the collision detection mechanism.</p> <p>0_B Disabled 1_B Enabled</p>
PEN	30	rw	<p>Parity Enable</p> <p>Enables the parity bit attached to the data bits. Parity bit can be used for ASC and SPI protocols. The standard LIN bytes do not use this parity bit.</p> <p>0_B Disabled 1_B Enabled</p>

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
ODD	31	rw	Parity Type Defines the type of parity bit attached to the data bits. This setting is valid for all modes of operation (ASC, LIN, SPI). 0 _B Even 1 _B Odd
0	[5:0], 15, [27:18]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
DATCON

DATCON register defines the number of bits in the ASC (affecting the LIN protocol, if used) and SPI frames, data length or the number of data bytes in a LIN response (if any) and the checksum mode. It additionally defines the time window for the LIN response.

In case the whole LIN response does not fit in this time window, an error interrupt is generated. The measurement starts at the end of the last bit of the header, and ends at the end of the last bit of the response.

(>> [Table 19-4](#))

DATCON

Data Configuration Register (1C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RESPONSE	[23:16]	rw	Response Timeout Threshold Value Defines the timer limit in the range of 1 to 256 bit times.
HO	13	rw	Header Only Defines if the LIN frame shall consist of a header and response or of a header only. 0 _B Header and response expected 1 _B Header only expected, response ignored
RM	14	rw	Response Mode Defines if the RESPONSE bit field defines a LIN Response or LIN Frame timeout threshold. See Figure 19-23 . 0 _B Frame 1 _B Response

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
CSM	15	rw	Checksum Mode Defines if the classic or the enhanced checksum will be calculated by the checksum block. 0 _B Classic 1 _B Enhanced
DATLEN	[3:0]	rw	Data Length Defines the number of bits in a character. In the ASC mode, standard length is 7, 8, or 9 bits. In the SPI mode, there is no standard length. In ASC and SPI modes, any length from 2 to 16 bits is possible, although not standard for some protocols. In LIN mode, standard length is 8 bits per character. Therefore, this field defines the number of data bytes of the response. 0000 _B 1 0001 _B 2 0010 _B 3 0011 _B 4 ... _B ... 1111 _B 16
0	[31:24], [12:4]	r	Reserved

Asynchronous/Synchronous Interface (ASCLIN)

BRD

The BRD defines the properties specific for the automatic baud rate detection when the module operates as a LIN slave.

(>> [Table 19-4](#) register overview)

(>> [Auto Baud Rate Detection](#))

BRD

Baud Rate Detection Register (24_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
LOWER LIMIT	[7:0]	rw	Lower Limit This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000 _B . See Auto Baud Rate Detection .
UPPER LIMIT	[15:8]	rw	Upper Limit This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000 _B . See Auto Baud Rate Detection .
MEASURED	[27:16]	rh	Measured Value of the Denominator This bit field contains the measured value of the duration of 8-bits form the sync field of the LIN header in microtics. It is automatically loaded in the denominator of the fractional divider, in case of LIN slave operation with autobaud detection.
0	[31:28]	r	Reserved

Asynchronous/Synchronous Interface (ASCLIN)

LINCON

LINCON contains bits that control LIN specific features of the module.

(>> [Table 19-4](#) register overview)

(>> [LIN Protocol Control](#) chapter)

(>> [LIN Master Sequences](#), [LIN Slave Sequences](#))

LINCON

LIN Control Register (28_H) Reset Value: 0000 0000_H

Asynchronous/Synchronous Interface (ASCLIN)

LINBTIMER

This register defines

- break detection limit if the module operates as LIN slave or
- length of the generated break pulse if the module operates as LIN master.

The break timer, if enabled, monitors the bus continuously.

(>> [Table 19-4](#) register overview)

(>> [LIN Break, Wake, Stuck Handling](#))

(>> [LIN Master Sequences, LIN Slave Sequences](#))

LINBTIMER

LIN Break Timer Register

(2C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
BREAK	[5:0]	rw	Break Pulse Generation and Detection In LIN slave mode, this bit field defines the duration of the detection threshold for the break pulse. In LIN master mode, this bit field defines the duration of the transmitted break pulse. The time unit is bit time.
0	[31:6]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)

LINHTIMER

LINHTIMER register defines the time windows for the header of a LIN frame.

In master mode, the timer starts counting at the falling edge of the break pulse, and stops counting when the last bit of the header (including the stop bits) has been transmitted. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

In slave mode, the timer starts counting when the break pulse has been detected, after a low time of 10 or 11 bit times, and stops counting when the last bit of the header has been received. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

(>> [Table 19-4](#) register overview)

LINHTIMER

LIN Header Timer Register (30_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
HEADER	[7:0]	rw	Header Timeout Threshold Value Defines the timer limit in the range of 1 to 256 bit times.
0	[31:8]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
FLAGS

The FLAGS register contains all the flag bits of the ASCLIN module: the LIN phase flags (header and response transmit and receive), the overflow flags of the LIN timers, and the standard ASC error flags.

A corresponding interrupt triggering can be enabled using the **FLAGSENABLE** register.

(>> **Table 19-4** register overview)

(>> **LIN Master Sequences, LIN Slave Sequences**)

Asynchronous/Synchronous Interface (ASCLIN)

TXDATA

Writing data to this register enters the data to the TXFIFO.

(>> [Table 19-4](#))

TXDATA

Transmit Data Register

(44_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DATA	[31:0]	w	Data Writing to this bit field writes the content to the TXFIFO, depending on the write width - 8, 16 or 32 bit. read from this register returns 0.

Asynchronous/Synchronous Interface (ASCLIN)

RXDATA

Reading data from this register takes data from the RXFIFO.

(>> [Table 19-4](#))

RXDATA

Receive Data Register

(48_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DATA	[31:0]	rh	Data Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit. Write to this register has no effect.

Asynchronous/Synchronous Interface (ASCLIN)
CSR

This register is used to select the clock source for the baud rate generation, detection, timeouts and the SPI delays.

(>> [Table 19-4](#))

CSR

Clock Selection Register (4C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLKSEL	[4:0]	rw	Baud Rate Logic Clock Select 00000 _B No clock supplied 00001 _B f_{CLC} 00010 _B XTAL Oscillator Clock f_{OSCO} 00100 _B f_{ERAY} 01000 _B $f_{ASCLINF}$ 10000 _B $f_{ASCLINS}$... _B not allowed
CON	31	rh	Clock On Flag Shows if the clock in the bit time domain is switched on or off. Many configuration registers can be written only if this bit shows 0 (see Table 19-4). 0 _B clock is off 1 _B clock is on
0	[30:5]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
RXDATAD

Reading data from this register takes data from the RXFIFO, but does not influence the read pointer. This virtual register provides non-destructive read to the RXFIFO.

(>> [Table 19-4](#))

RXDATAD
Receive Data Debug Register
(50_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
DATA	[31:0]	rh	Data Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit, but does not influence the read pointer of the RXFIFO. Write to this register has no effect.

Clock Reconfiguration

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum $T_W \geq 4 * (1/f_A) + 2 * (1/f_{CLC})$ must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that the f_{CLC} is selected as a baud rate and bit timing logic clock (CSR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Additionally, always activate the asynchronous clock for at least two f_A cycles:

- after entering the INIT state and
- after device reset

This is an example of a correct sequence:

- CSR.CLKSEL = No_Clock (equals the reset state)
- Wait T_W or poll for CSR.CON = 0

Asynchronous/Synchronous Interface (ASCLIN)

- FRAMECON.MODE = INIT
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1
- CSR.CLKSEL = No_Clock
- Wait T_W or poll for CSR.CON = 0
- FRAMECON.MODE = ASC (or SPI or LIN)
- CSR.CLKSEL = Clock_On
- Wait T_W or poll for CSR.CON = 1

See also [LIN Master Sequences](#)

See also [LIN Slave Sequences](#)

Abort Sequence

If a header has been transmitted in ASCLIN master mode, and the corresponding response does not come, the waiting for the response can be aborted by first entering the INIT mode and then entering the LIN mode. The sequence is identical with the example sequence above.

Asynchronous/Synchronous Interface (ASCLIN)

19.19 Implementation

This section describes the product specific configuration of the ASCLIN module and its interconnection with the rest of the system. The TC26x B-Step contains 4 interfaces, ASCLIN0 to ASCLIN3.

19.19.1 BPI_FPI Module Registers

19.19.1.1 System Registers

Figure 19-33 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

Figure 19-33 BPI_FPI Registers

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_A module clock signal, sleep mode and disable mode for the module.

(>> Table 19-4 register overview)

Asynchronous/Synchronous Interface (ASCLIN)

CLC

Clock Control Register

(00_H)

Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode, that is if the sensitivity of the module to the sleep signal is enabled to react to it or disabled to ignore it. 0 _B Enabled 1 _B Disabled
0	[31:4], 2	r	Reserved Read as 0; must be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

(>> [Table 19-4](#) register overview)

OCS
OCDS Control and Status
(E8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description

SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

(>> [Table 19-4](#) register overview)

ACCEN0

Field	Bits	Type	Description
ENn (n = 0-31)	n	rW	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Asynchronous/Synchronous Interface (ASCLIN)

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 10000_B to 11111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 10000_B, EN1 -> TAG ID 10001_B, ... , EN31 -> TAG ID 11111_B.

(>> [Table 19-4](#) register overview)

ACCEN1

Access Enable Register 1

(F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0_B No kernel reset was executed 1_B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

(>> [Table 19-4](#) register overview)

KRST1

Kernel Reset Register 1

(F0_H)

Reset Value: 0000 0000_H

Asynchronous/Synchronous Interface (ASCLIN)

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0_B No kernel reset was requested 1_B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

(>> [Table 19-4](#) register overview)

KRSTCLR

Kernel Reset Status Clear Register (EC_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0_B No action 1_B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Asynchronous/Synchronous Interface (ASCLIN)
19.20 On-Chip Connections

This section describes the on-chip connections of the ASCLINx module instances.

Port/Pin Connections

The connections of the ASCLIN modules to the pins / ports is described in the chapters regarding the pinning and the ports.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected ARX signals in the lower half range (RHA to RXD) are connected to (active) low level, “0”
- The unconnected ARX signals in the upper half range (RXE to RXH) are connected to (inactive) high level, “1”
- The unconnected ACTS signals are connected to low level “0”, which is after reset the inactive level (but disabled via **IOCR**.CTSEN bit field, meaning don't care)

Table 19-5 shows an overview for TC26x how bits and bit fields must be programmed for the required I/O functionality of the ASCLIN I/O lines.

Table 19-5 ASCLIN I/O Control Selection and Setup

ASCLIN Connection to Itself

the following connection is defined for each ASCLIN instance:

ARTS -> ACTSD

This connection can be useful in the SPI mode, where frequently the transmission and the reception of data are performed in parallel. If this connection is selected by using

Asynchronous/Synchronous Interface (ASCLIN)

IOCR.CTS, the TXFIFO will deliver data for transmission only if there is a free space in the RXFIFO. If not, the TXFIFO will wait for emptying of the RXFIFO by software and then automatically continue the transmission.

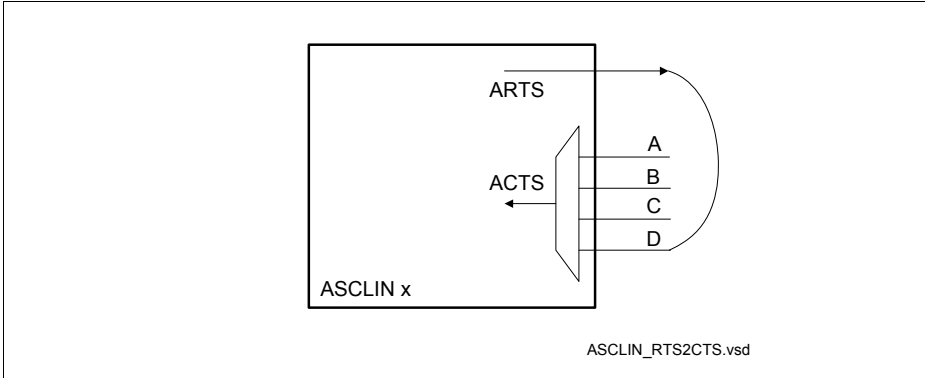

Figure 19-34 ASCLIN ARTS to ACTS Connection

19.21 ASC at CAN Support

The ASC Tx and Rx signals are overlaid with CAN Rx and Tx signal. See the Ports chapter and the Pinning chapter for the particular pin assignments.

A virgin device with a completely erased flash memory can be booted via ASC at CAN pins. See the Boot chapter for details on the implementation.

Queued Synchronous Peripheral Interface (QSPI)

20 Queued Synchronous Peripheral Interface (QSPI)

The main purpose of the QSPI module is to provide synchronous serial communication with external devices using clock, data-in, data-out and slave select signals. The focus of the module is set to fast and flexible communication: either point-to-point or master-to-many slaves communication.

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

>> [Registers Overview](#)

>> [BPI_FPI Module Registers](#)

20.1 Feature List

This section describes the features of the QSPI module.

- Master and Slave Mode operation
 - Full-duplex operation
 - Half-duplex operation
 - Automatic slave select control
 - Four-wire and three-wire type of connection
- Flexible data format
 - Programmable number of data bits: 2 to 32 data bits (plus parity: 3 to 33 bits)
 - 4 to 32 data bits possible for 50 Mbit/s
 - Programmable shift direction: LSB or MSB shift first
 - Programmable clock polarity: Idle low or idle high state for the shift clock
 - Programmable clock phase: data shift with leading or trailing edge of the shift clock
- Baud rate generation
 - Flexible baud rate and delays (leading, trailing, idle) generation
- Interrupt generation
 - On a transmitter FIFO event
 - On a receiver FIFO event
 - On an error condition (receive, baud rate, transmit error, parity error)
 - On a phase transition (start of frame, end of frame ...)
- QSPI supports control and data handling by the DMA controller
- Flexible QSPI pin configuration
- Hardware supported parity mode
 - Odd / even / no parity
- Seven slave select inputs SLSIB..H in Slave Mode
- Sixteen programmable slave select outputs SLISO[15:0] in Master Mode
 - Automatic SLISO generation with programmable timing
 - Programmable active level and enable control

Queued Synchronous Peripheral Interface (QSPI)

- External demultiplexing of the slave select outputs support
- Several module reset options
 - State machine reset per software (only the state machine)
 - Module reset per software (both FIFOs, all registers and the state machine)
 - Automatic stop option of the state machine in slave mode after baud rate error
- Loop-Back mode
- Interoperability with SSC and USIC modules of Infineon microcontroller families, and with popular (Q)SPI interfaces of multiple suppliers
- Communication stop on RxFIFO full
 - Shift register full and RxFIFO full can pause the communication
 - Interrupt generation
- High Speed Input Capture (HSIC)
 - Provides input capture functionality for ADAS applications
 - 15-bit counter with resolution of $f_{\text{BAUD}2}$

Queued Synchronous Peripheral Interface (QSPI)

20.2 Overview

This section gives a top-level overview of the QSPI.

20.2.1 External Signals

The communication between two devices using QSPI generally uses four signals:

- serial clock SCLK
- data in master to slave direction MTSR (Master Transmit Slave Receive)
- data in slave to master direction MRST (Master Receive Slave Transmit)
- slave select signal SLS

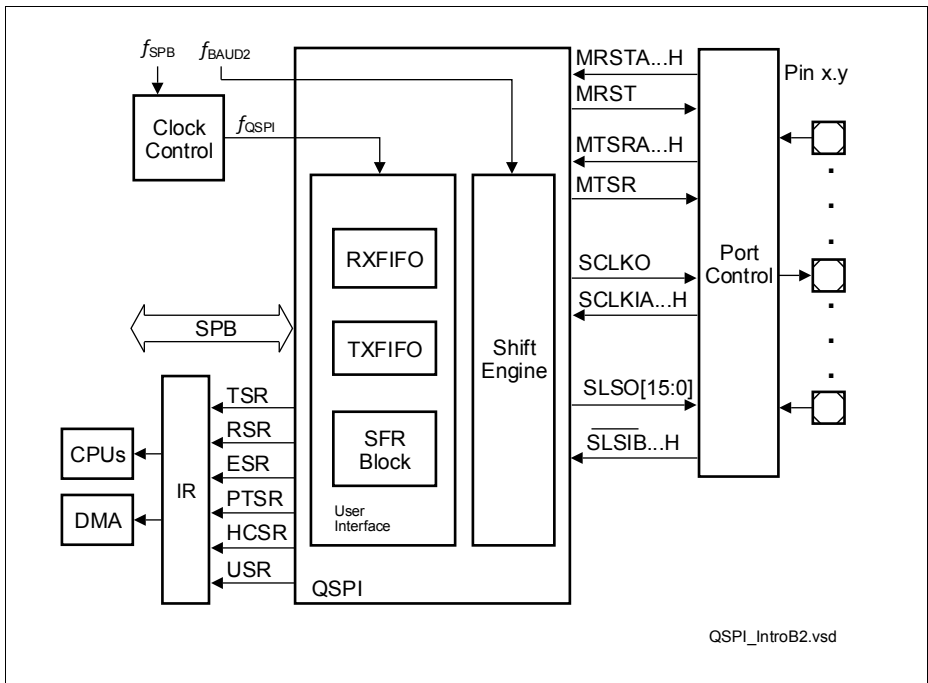

Figure 20-1 External Signals of the QSPI Module

Queued Synchronous Peripheral Interface (QSPI)

20.2.2 Operating Modes

The QSPI operates in one of two modes regarding the generation of the serial clock and slave select signals: master or slave mode. The master generates and drives the clock and select signals, the slave receives these signals.

The QSPI operates in one of three modes regarding the direction of the communication and depending whether the transmission and the reception appear simultaneously or not: duplex, half-duplex and simplex mode.

This gives six possible combinations for the operating mode of the QSPI: master duplex, half-duplex, and simplex; slave duplex, half-duplex, and simplex.

Note: The half-duplex mode can be implemented either by short-cut connection between two different pins on the pcb, one data output and one data input pin, or by using single pins mapped to both data input and data output signals. See the pinning and port chapters for the pinning definition of a particular product. The module itself does not differentiate between the full-duplex, half-duplex or simplex connection.

Queued Synchronous Peripheral Interface (QSPI)

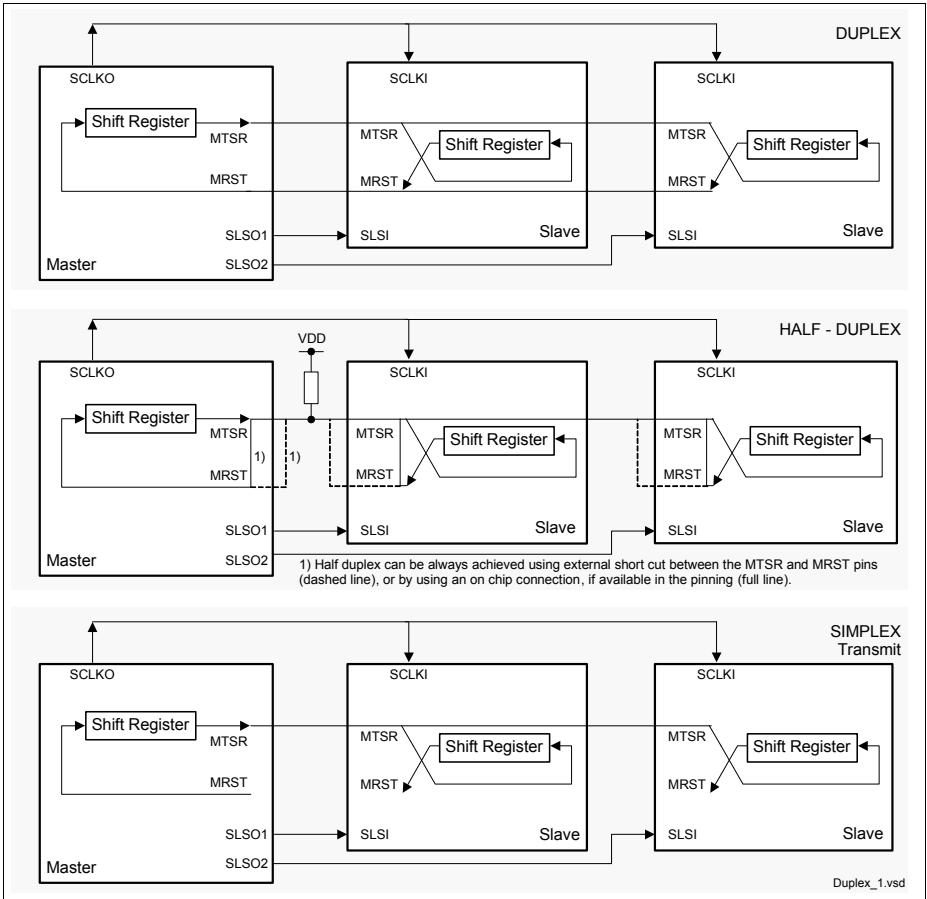

Figure 20-2 Operating Modes and Types of Connections

Queued Synchronous Peripheral Interface (QSPI)

20.2.3 Queue Support Overview

The term "Queue Support" is used in this context to describe the functionality implemented for comfortable switching of the timing configuration of the QSPI frames, depending on the slave select signal which is to be activated. The main feature of the module is the possibility to take both the configuration and data to the TXFIFO, and to track down which TXFIFO entry is configuration, and which data. The QSPI module expects 32 basic configuration bits to be moved with one move (for example DMA move) from some on-chip general purpose RAM to the TXFIFO. These 32 configuration bits from the TXFIFO and the configuration bits from the 8 configuration extension registers **ECONz** contained in the QSPI module, define together the full configuration of the module (see **Figure 20-3**). One extension register is used for two slave selects: ECON0 for SLSO0 and SLSO8, ECON1 for SLSO1 and SLSO9 ...

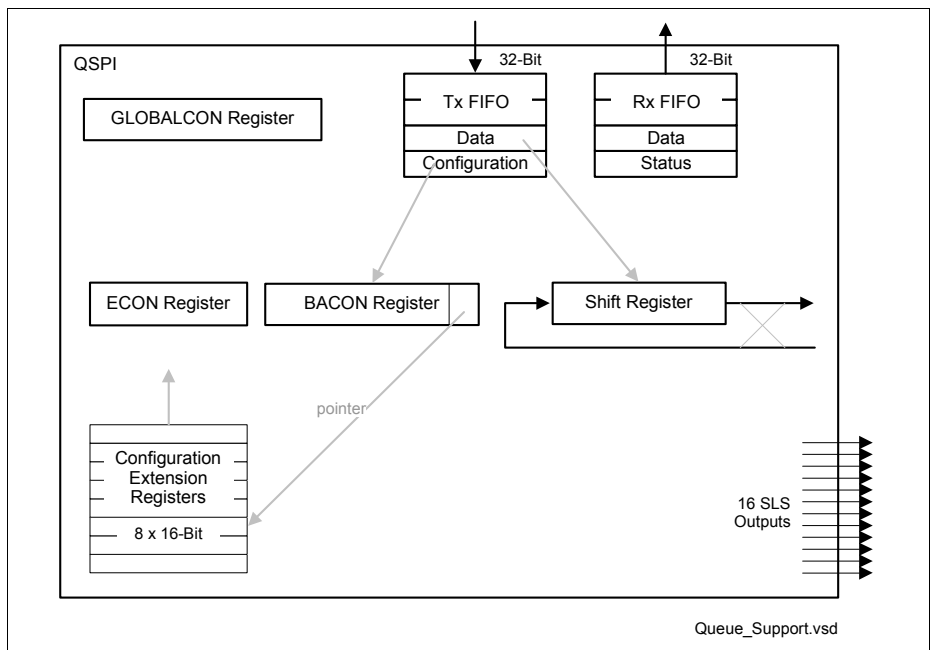

Figure 20-3 Queue Support Overview

Queued Synchronous Peripheral Interface (QSPI)

20.2.4 Architecture Overview

The **Figure 20-4** shows the main blocks of the QSPI module. The Tx FIFO and Rx FIFO provide the user interface. The Shift Register and the “Miscellaneous Logic” block build the state machine of the module. The “Configuration Extensions” block provides comprehensive capabilities for configuring the QSPI frames.

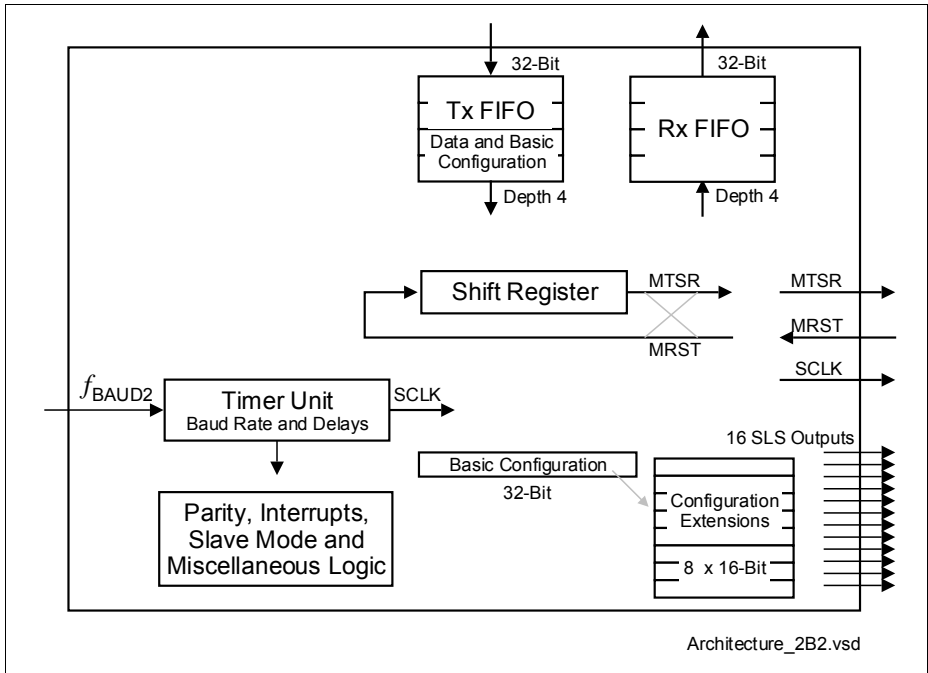

Figure 20-4 QSPI - Architecture Overview

Queued Synchronous Peripheral Interface (QSPI)

20.2.5 Three Wire Connection

The term "Three Wire Connection" is used in this context to describe a connection without slave select signal. This connection relies solely on counting bits for determining the end of the current frame and resetting the shift register state machine, instead of using the slave select signal for this purpose. This way of communication is less robust than communication with slave select, but it saves a pin on both master and slave device.

The name "three wire connection" is true only in case of full-duplex connection, where exactly three signals (clock, data-in, data-out) are needed. In case of half-duplex and simplex connections only two signals (clock, data-in/data-out common data line) are necessary.

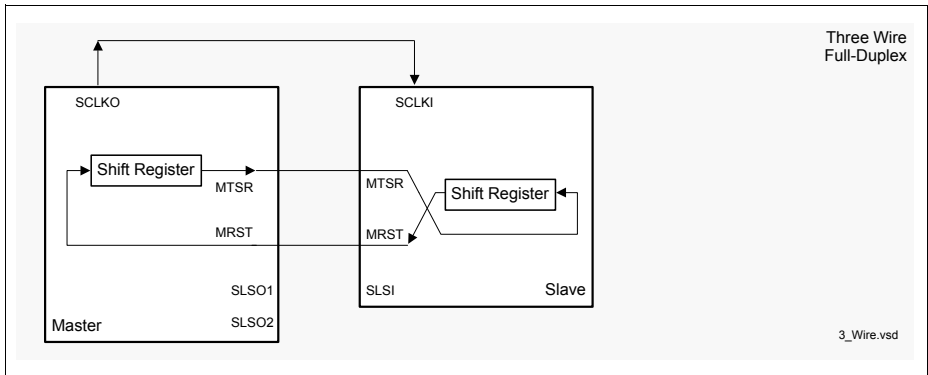

Figure 20-5 Three Wire Connection

Queued Synchronous Peripheral Interface (QSPI)

20.3 Abstract Overview

An abstract overview of the QSPI module is shown in **Figure 20-6**. This document describes the QSPI module according to this view: the State Machine with its configuration and status capabilities, the User Interface, and the Interrupts (in this order).

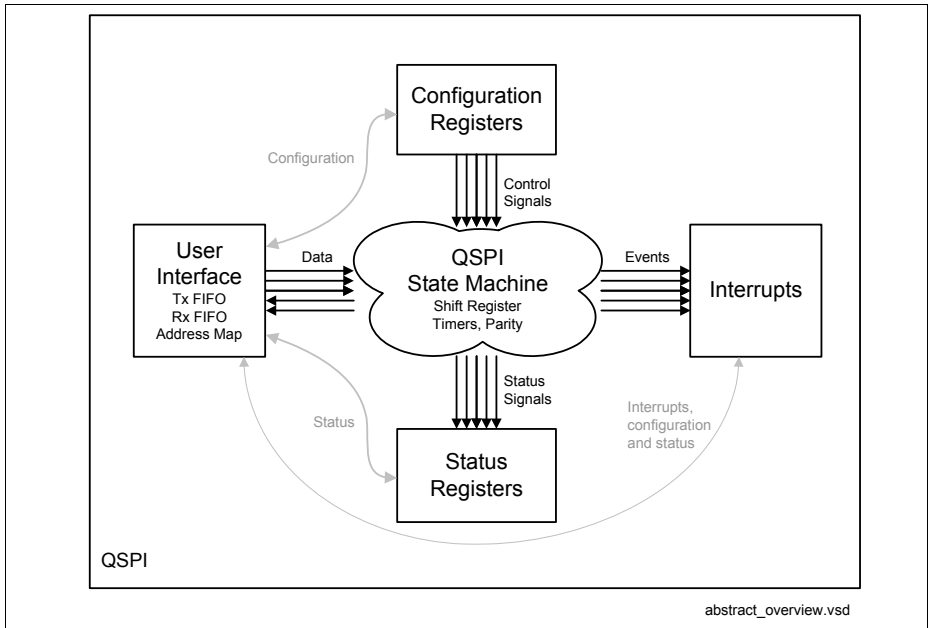

Figure 20-6 QSPI - Abstract Overview

Queued Synchronous Peripheral Interface (QSPI)

20.4 Frequency Domains

The state machine of the QSPI is placed in a separate frequency domain operating with a frequency f_{BAUD2} which can be:

- integer multiple of the SPB bus frequency
- equal to the SPB frequency
- lower than the SPB frequency, derived by integer division

The baud rate is determined by the f_{BAUD2} frequency divided by an integer equal or greater than four.

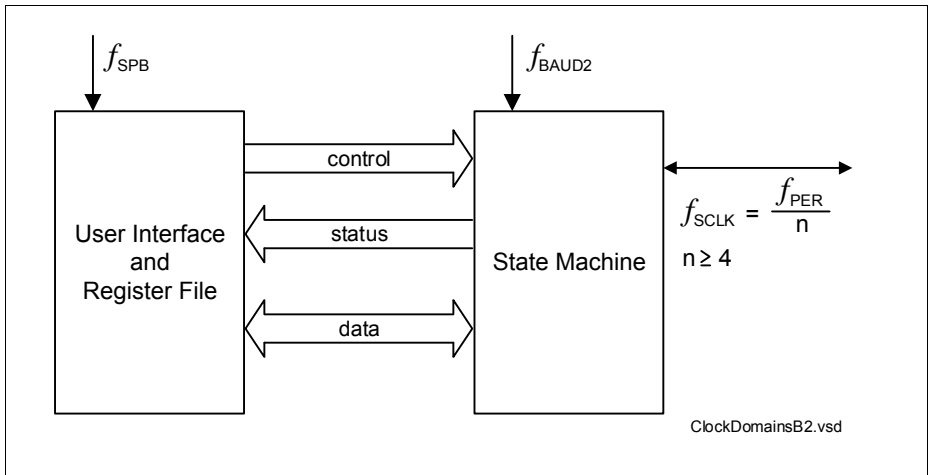

Figure 20-7 QSPI - Frequency Domains

Queued Synchronous Peripheral Interface (QSPI)

20.5 Master Mode State Machine

In master mode, the QSPI module generates the timings, the serial clock, and the slave select signals.

20.5.1 Phases of one Communication Cycle

This section describes the possibilities available for configuring the length of the phases of the QSPI communication: timing delays, data length, duty cycle and data sampling.

A QSPI frame starts with activating a slave select signal SLSO (at transition from idle to leading delay phase), and ends with its deactivation (at transition from trailing delay to wait or idle phase). It is a sequence of five phases: idle delay, leading delay, data phase, trailing delay and an optional wait phase. The idle phase is subdivided in two phases of equal length: idle A and idle B.

Figure 20-8 shows a full and a compressed view of a QSPI frame and its phases. The full view shows all four signals needed for a QSPI connection. The compressed view represents the phases in a single row, in a way suitable to discuss their properties.

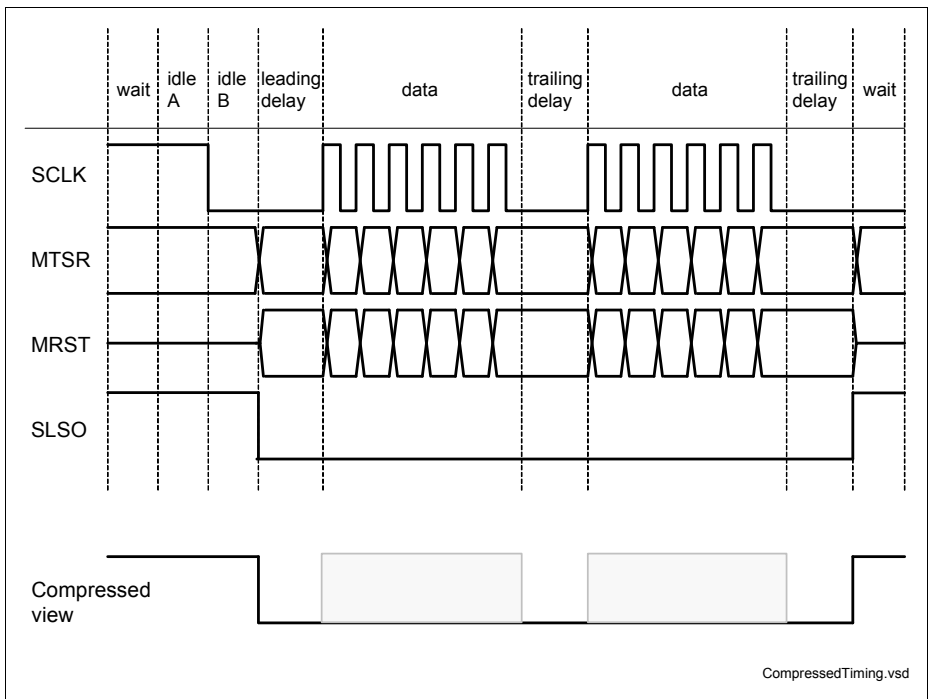

Figure 20-8 Phases of a QSPI Frame (Example for Data Length of 5 Bits)

Queued Synchronous Peripheral Interface (QSPI)

The flexible timing control of the QSPI allows to program each phase in a very wide time range, with sufficient precision. Some examples of QSPI frames, in compressed view, with different lengths of the phases, are shown in **Figure 20-9**.

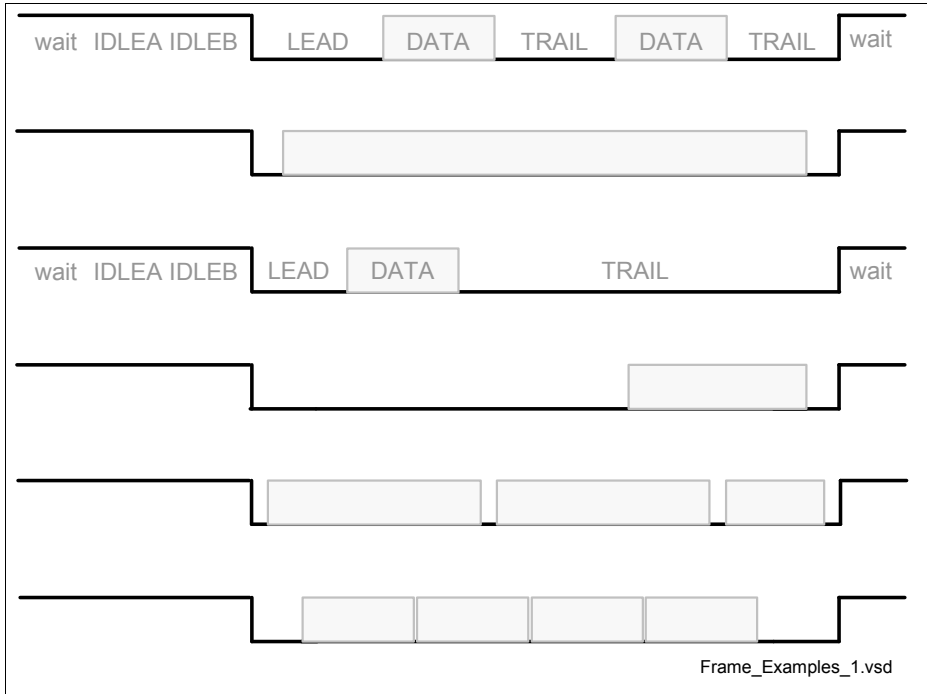

Figure 20-9 Examples of QSPI Frames in Compressed View

The length of the phases is programmed using the corresponding bit fields in the register **BACON**. There are four main bit fields defining the length of the phases in t_Q units and several modifier bit fields defining their range and granularity:

- IDLE
- LEAD
- DATA
- TRAIL

The WAIT phase is simply a loop waiting for a write to the Tx FIFO, without predefined duration, and consequently without a defining bit field.

The IDLE bit field defines two sub-phases with the same length IDLEA and IDLEB. At the transition between them the polarity of the serial clock signal for the next slave is set / changed.

Queued Synchronous Peripheral Interface (QSPI)

In addition, the flexible timing control allows to program the duty cycle and the sampling point properties of the serial clock. This allows to improve to a certain extent the achievable baud rate taking into account the clock asymmetries and the loop-delay.

The **ECON** bit fields A, B and C define the length of the corresponding bit segments.

Figure 20-10 Control of the Duty Cycle and the Sampling Point of the Serial Clock

Queued Synchronous Peripheral Interface (QSPI)

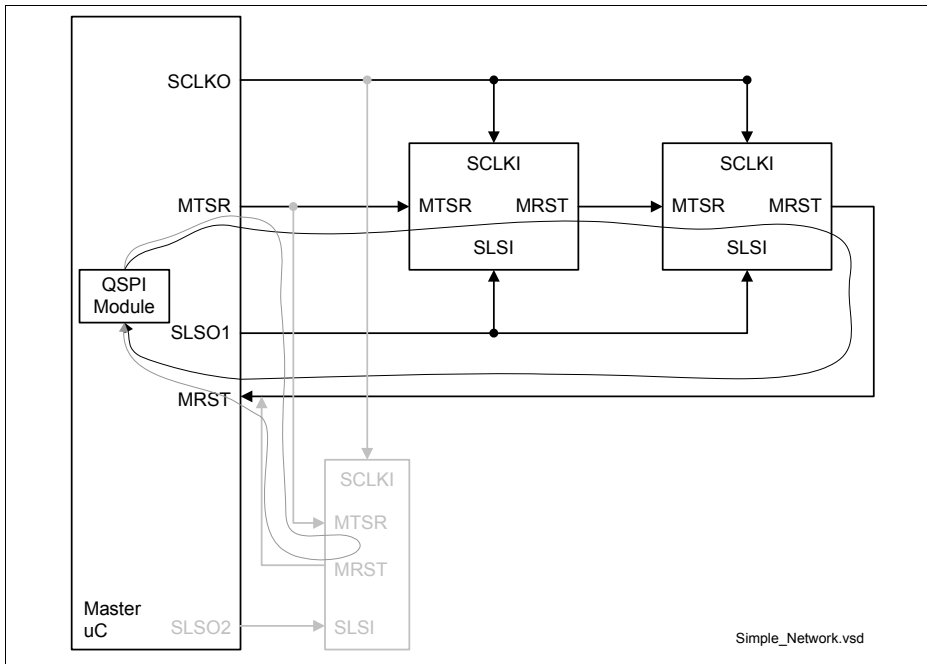

Figure 20-11 Closed-loop delays in a simple network consisting of one daisy-chain and one point to point connection in parallel

The purpose of the duty cycle control is:

- to compensate the influence of the path and pad asymmetry on the duty cycle
- to compensate the considerable asymmetry of the edges in case of half-duplex connection implemented as open-drain driver with pull-up resistor
- to adjust the duty cycle optimally to the timing properties of the master and slave, and to the properties of the connection (distance and capacitive load)
- to help achieve optimal baud rate, especially at higher baud rates which need an odd division factor (for example $5 = 3 \text{ high time} + 2 \text{ low time}$ or $5 = 2 \text{ high time} + 3 \text{ low time}$)

The purpose of the sampling point control is to allow reliable reception of the data transmitted by the slave, at as high as possible baud rates.

In master receive direction the slave transmitted data reaches the master considerably late relative to the shift edge of the serial clock. This is caused by the loop delay consisting of:

- the traveling time of the shift clock edge from the master to the slave
- the reaction time of the slave
- the traveling time of the data from the slave to the master

Queued Synchronous Peripheral Interface (QSPI)

Last but not least, the flexible timing control allows to control the phase and the polarity of the shift clock.

The clock polarity is configured by bit field **ECONz.CPOL**. This bit field sets the clock idle polarity to low or high.

The clock phase is configured by bit field **ECONz.CPH**. This bit field sets the initial clock delay to 0 or Bit Segment A, as defined by the bit field **ECONz.A**.

The CPOL and CPH settings control the master mode. The slave mode timing behavior is fixed to CPOL=0 and CPH=1, and these values must be programmed in the **ECON** register pointed by **BACON.CS**.

The **Figure 20-12** shows the QSPI timings for clock phase CPH = 0.

ECON.CPH = 0 is used when communicating with a slave that delivers a valid value of the first bit immediately after being selected with an SLS signal. In such a case the first clock edge in a frame is used to latch the first bit. The second edge delivers the second bit value, and so on. The last edge in a frame delivers a bit with don't care value.

Figure 20-12 Timing of a transfer with CPH = 0 (Example for Data Length of 4 Bits)

The trailing delay starts after the last shift clock period of a data block and is followed either by the deactivating edge of SLSO, or a new data block in continuous mode.

Attention: If CPH = 0, then the total delay between the SLSO activating edge and the first edge of the serial clock SCLKO is LEAD + **ECONz.A**

Queued Synchronous Peripheral Interface (QSPI)

Figure 20-13 shows the QSPI timings for clock phase CPH = 1.

ECON.CPH = 1 is used when communicating with a slave that delivers a bit with a random or don't care value immediately after being selected with the SLSO signal. In such a case the first clock edge in a frame is used by the slave to shift out the first valid data bit. The second edge latches this bit value, and so on. The last edge in a frame is used to latch the last valid data bit, which normally remains driven until the end of the frame.

Figure 20-13 Timing of a transfer with CPH = 1 (Example for Data Length of 4 Bits)

The leading delay lasts between the active edge of the SLSO and the first shift clock edge.

Attention: If CPH = 1, then the total delay between the last edge of the SCLKO and the SLSO deactivating edge is $TRAIL + ECONz.B + ECONz.C$

Queued Synchronous Peripheral Interface (QSPI)

20.5.2 Configuration Extensions

This section describes the possibilities available for configuring the phases of the QSPI communication: timing delays, data lengths, their ranges and granularity.

The QSPI module controls 16 communication channels, which are individually programmable. Each channel is associated to one slave select output and to the corresponding timing and other properties (baud rate, delays, data width, parity...).

The 16 slave select channels of the QSPI module are subdivided in two groups of 8 slave select channels:

- Channels 0 to 7
- Channels 8 to 15, channel 8 having the same **ECON** settings as channel 0, channel 9 as channel 1, and so on.

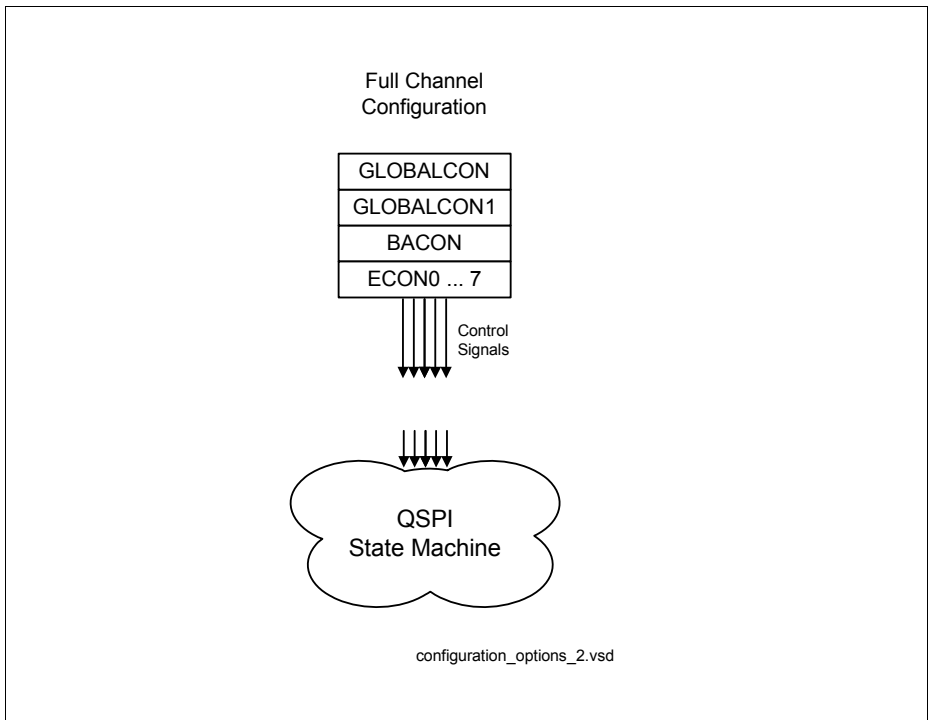

Figure 20-14 Flexible Configuration Concept

Queued Synchronous Peripheral Interface (QSPI)

20.5.3 Details of the Baud Rate and Phase Duration Control

The QSPI phases correspond to states of a simple state machine defining a sequence of simple states and loops. Due to the strict sequential nature of the communication cycle one timer is enough to define the length of each phase. The length of each phase is defined in time quanta, and the length of a time quantum is defined by a time quantum timer. Each QSPI slave select channel has its own time quantum length, based on the module time quantum length:

T_{BAUD2} clock period → one module time quantum → one channel time quantum

Each QSPI module generates a module time quantum which is further downscaled to a channel quantum. This affects both the delays and the baud rates. The assumption is that the pad strength setting, the capacitive load and the corresponding QSPI network layout properties do not allow extreme differences in the baud rates for the different slaves connected to one module. They all have similar speed range: high speed, or medium speed, or low speed. Mixing very high speed and very low speed slaves does not make much sense. Many slaves produce high accumulated capacitive load on the clock and data outputs, which influences the possible baud rates for all slaves. Variations in the baud rates of the slaves of one module in the range of 6:1 is possible by varying the bit segment phases in each channel. Additional two-bit counter per slave allows for additional scaling of 1, 2, 4, or 8, making a total bit-time variation of 48:1 between the channels in one module possible.

Each QSPI slave select channel has its own set of phase lengths, depending on $T_{\text{BAUD2}} = 1 / f_{\text{BAUD2}}$

- $T_{\text{SCLKz}} = T_{\text{BAUD2}} * \text{GLOBALCON.TQ} * \text{ECONz.Q} * (A + B + C)$
- $T_{\text{LEAD}} = T_{\text{BAUD2}} * \text{BACON.LPRE} * \text{BACON.LEAD}$
- $T_{\text{TRAIL}} = T_{\text{BAUD2}} * \text{BACON.TPRE} * \text{BACON.TRAIL}$
- $T_{\text{IDLEA,B}} = T_{\text{BAUD2}} * \text{BACON.IPRE} * \text{BACON.IDLE}$
- $T_{\text{STROBE}} = T_{\text{BAUD2}} * \text{GLOBALCON.TQ} * \text{ECONz.Q} * \text{GLOBALCON.STROBE}$

Note: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value. For the formulas using the actual binary values of the bit-fields, see [Figure 20-16](#) and [Figure 20-17](#).

Queued Synchronous Peripheral Interface (QSPI)

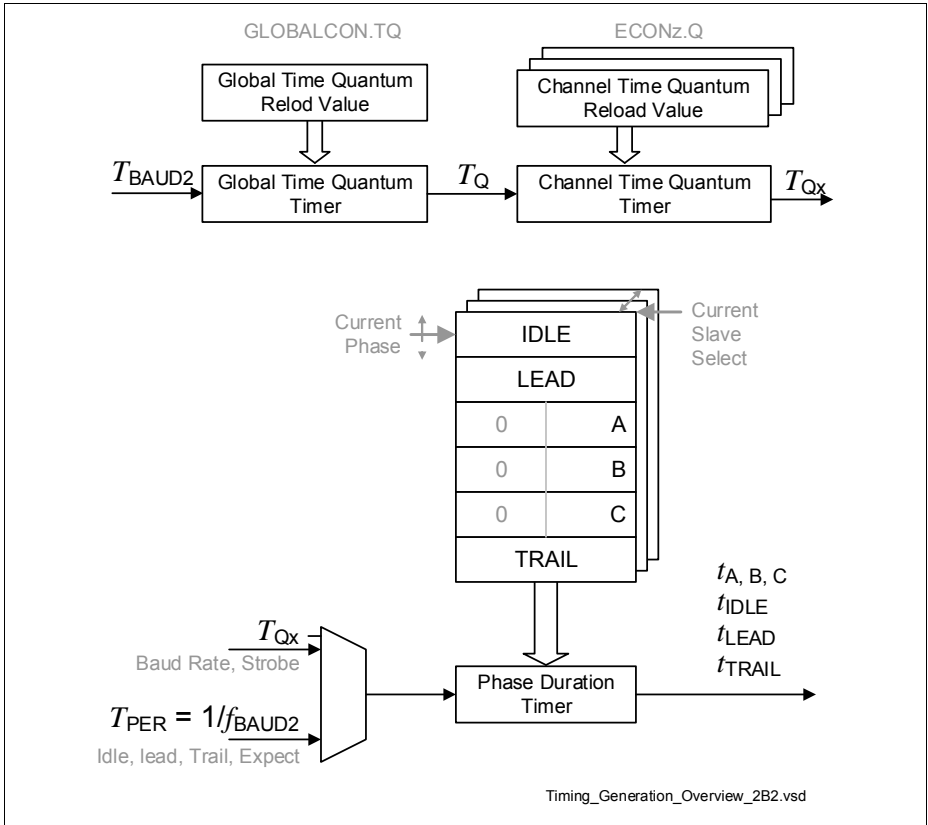

Figure 20-15 Phase Duration Control, Overview

Queued Synchronous Peripheral Interface (QSPI)

20.5.4 Calculation of the Baud Rates and the Delays

This section gives another alternative view to the calculation of the baud rate and the duration of the delays.

The baud rate generation chain for a channel starts with a common TQ divider. The resulting global time quantum is used by the dedicated Q and A,B,C dividers to generate the baud rates per channel (slave select). See [Figure 20-16](#).

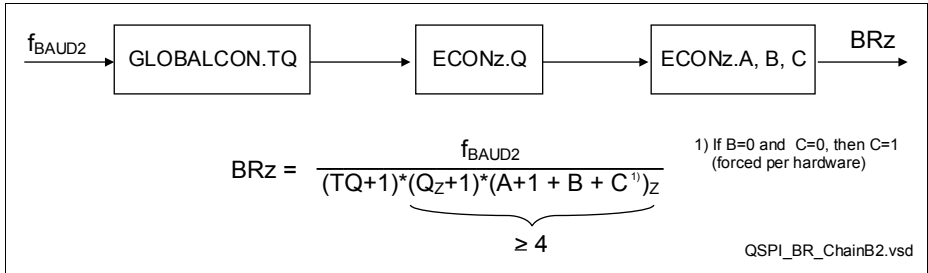

Figure 20-16 Baud Rate Calculation

Attention: The following condition must be satisfied: $(Q+1) \cdot (A+1 + B + C) \geq 4$. Or alternatively formulated: bit length must be at least $4 \cdot T_Q$.

Each delay of an active channel (slave select) has a separate and independent divider chain starting with a power-of-four prescaler and an n-divider. See [Figure 20-17](#).

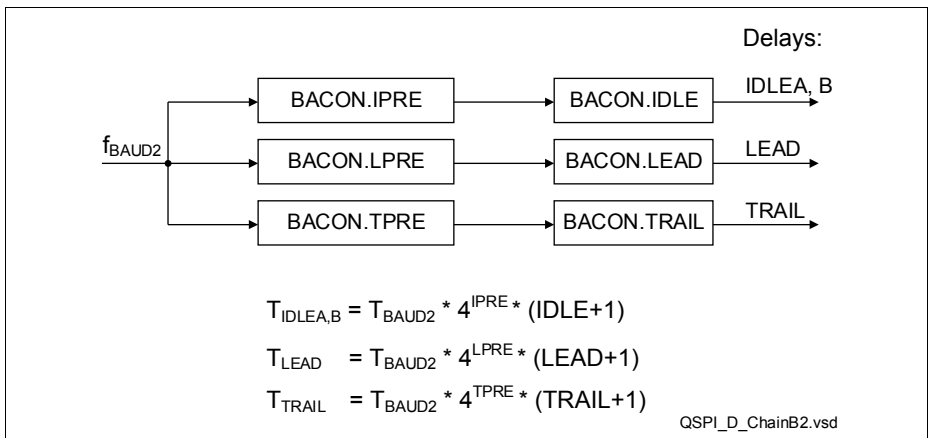

Figure 20-17 Calculation of the delays

Queued Synchronous Peripheral Interface (QSPI)

20.5.5 State Diagram of Standard Communication Cycle

Figure 20-18 shows the top view of the standard communication cycle of the QSPI state machine in a hierarchical way. The “Data” state consists of a loop of several “Bit” states, where the number of repetitions is defined with the data width bit field. Each “Bit” state consists of a simple sequence of “A”, “B”, and “C” states.

A complete (or standard) communication cycle containing all phases, starting with activating the slave select and ending with its deactivation, is executed only if the bit **BACON.LAST = 1**. Otherwise, the slave select remains active and the module waits for more FIFO data entries.

The Phase Transition Interrupt PT (events PTI1 and PTI2) signal one out of all phase transitions which are shown in **Figure 20-18**, selected by the bit fields **GLOBALCON.PT1** and **PT2**.

20.5.6 Expect Phase

Figure 20-21 shows the EXPECT state in the QSPI state machine diagram. This state can be entered in the long data mode and in the continuous mode, where one frame consists of more than one TXFIFO entries. Its purpose is to provide monitoring of the latencies on the FPI bus. In this case, after one FIFO entry has been shifted out and the module expects more bits to shift, according to the BACON.DL, a time-out counting starts. If the expected FIFO entry does not come in time, a time-out occurs.

The duration of the EXPECT state is zero if at the end of the current DATA state the new data is already available in the FIFO.

The duration of the EXPECT state can be anywhere between zero and the programmed upper limit, if the next data is written into the TXFIFO any time within the allowed time window. In this case the current frame continues with the SLSO signal remaining active.

The duration of the EXPECT state is exactly maximum if the data did not come in time. Then the current frame is stopped, but the SLSO is not deactivated. A TO (Time - Out) interrupt is raised. The state machine continues the EXPECT state in a loop, waiting for the software intervention, generating an interrupt signal after each expect time interval.

Figure 20-21 EXPECT Cycles of the QSPI State Machine

Queued Synchronous Peripheral Interface (QSPI)

20.5.7 External Slave Select Expansion

In this mode the bit field **BACON**.CS drives directly the SLSO1 to SLSO4 signals, not demultiplexed by the QSPI, but chip-externally. **SSOC**.AOL bits can invert the SLSO0...4 signal levels individually; **SSOC**.OEN bits enable them. See also **GLOBALCON**.DEL0.

Figure 20-22 Demultiplexing the Slave Select Signals Externally

In order to ensure glitch free selection, a strobe signal is provided, driven at SLSO0 pin. This signal is delayed relative to the SLSO1...4 signals for LS (Lead Strobe) and TS (Trail Strobe) delays, equal in duration and configurable in the range of 1 to 16* f_{BAUD2}. The duration of the LS and TS delays is set in the **GLOBALCON**.STROBE.

Queued Synchronous Peripheral Interface (QSPI)

20.6 User Interface

This section describes the possibilities available for transferring data between the on-chip RAM memories and the QSPI module using the transmit and receive FIFOs. The QSPI features one 4 x 32-bit Tx FIFO and one 4 x 32-bit Rx FIFO. The address ranges for writing data and configuration to the Tx FIFO and for reading data and configuration from the Rx FIFO consist of address locations with special properties:

- Tx FIFO
 - DATA_ENTRY - writes to any of these eight functionally identical locations are always interpreted as data
 - BACON_ENTRY - writes to this location are always interpreted as configuration
 - MIX_ENTRY - writes to this location are interpreted as data or configuration, based on a set of rules
- Rx FIFO
 - RX_EXIT - reads from this location deliver either data or data and status, based on a set of rules.

Queued Synchronous Peripheral Interface (QSPI)

20.6.1 Transmit and Receive FIFOs

The Tx_FIFO is filled with both configuration and data entries, which are distributed to the **BACON** and the shift register at the exit of the Tx_FIFO. The Tx_FIFO keeps track if an entry is configuration or data. The control and the data elements are automatically distributed to the **BACON** and shift register. If no data is available, the new **BACON** is pending.

If a frame is finished and there is data in the FIFO

- in short mode, a new frame starts automatically with the same configuration as the last one.
- in long mode, the extra data are ignored.

TX_FIFO error conditions:

- FPI bus write to a full TX_FIFO generates an overflow interrupt. The write is ignored.
- In case of slave mode, (**GLOBALCON.MS** = 1X), in case of an underflow, only "1" are delivered.

RX_FIFO error conditions:

- FPI bus read from an empty RX_FIFO generates an underflow interrupt, and delivers only "1" bits.
- Hardware attempt to write a full RX_FIFO with data or status generates an overflow interrupt. The write attempt is ignored by the RX_FIFO.
- If the **GLOBALCON.SRF** bit is set, the communication is stopped in case of full FIFO in master mode. In slave mode, the bit is ignored, no stop can be done.
- If the FPI bus frequency is very slow, and the baud rate very high, it can happen that some data is lost on the way between the shift register and a not full RX_FIFO. In such a case, an overflow interrupt is generated, although the RX_FIFO is not full.

The Rx_FIFO can be filled with both status and received data entries, depending on **GLOBALCON.SI**.

Note: If a 8-bit or 16-bit write is executed to the TX_FIFO entry addresses, the data is mapped 1:1 to its location within the 32-bit wide TX_FIFO entry, and the rest is padded with zeros.

Queued Synchronous Peripheral Interface (QSPI)

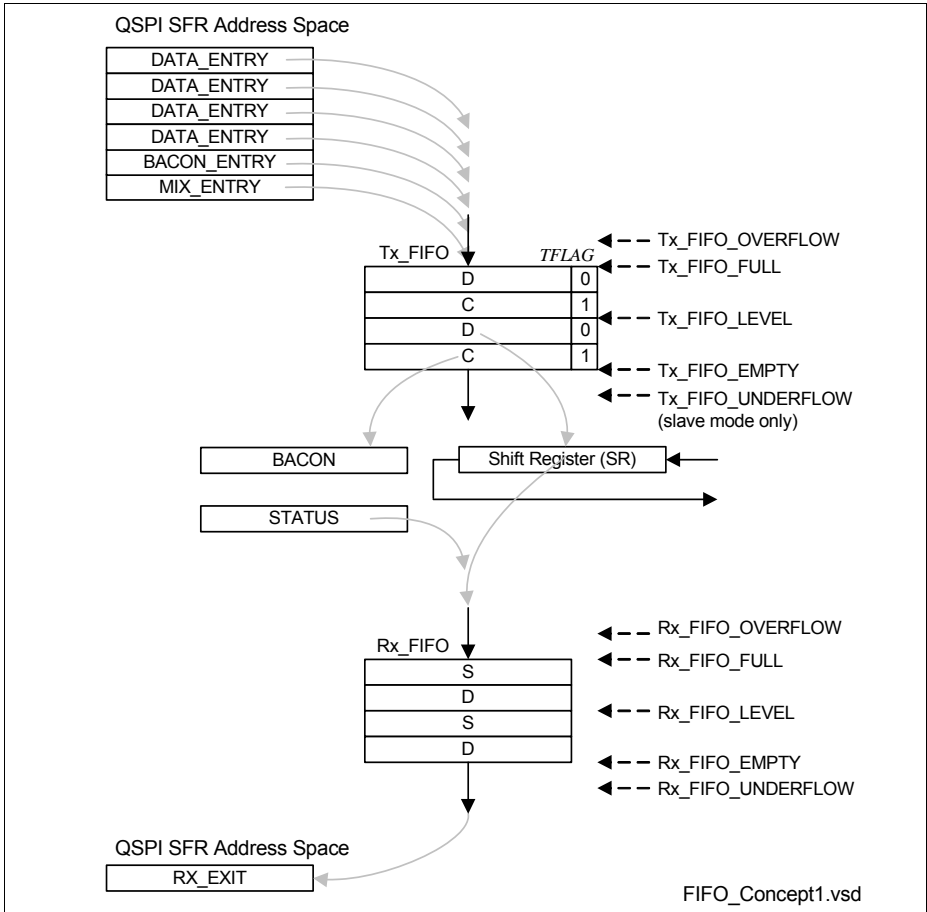

Figure 20-24 Architecture of the Tx and Rx FIFOs

(>>Interrupts)

Queued Synchronous Peripheral Interface (QSPI)

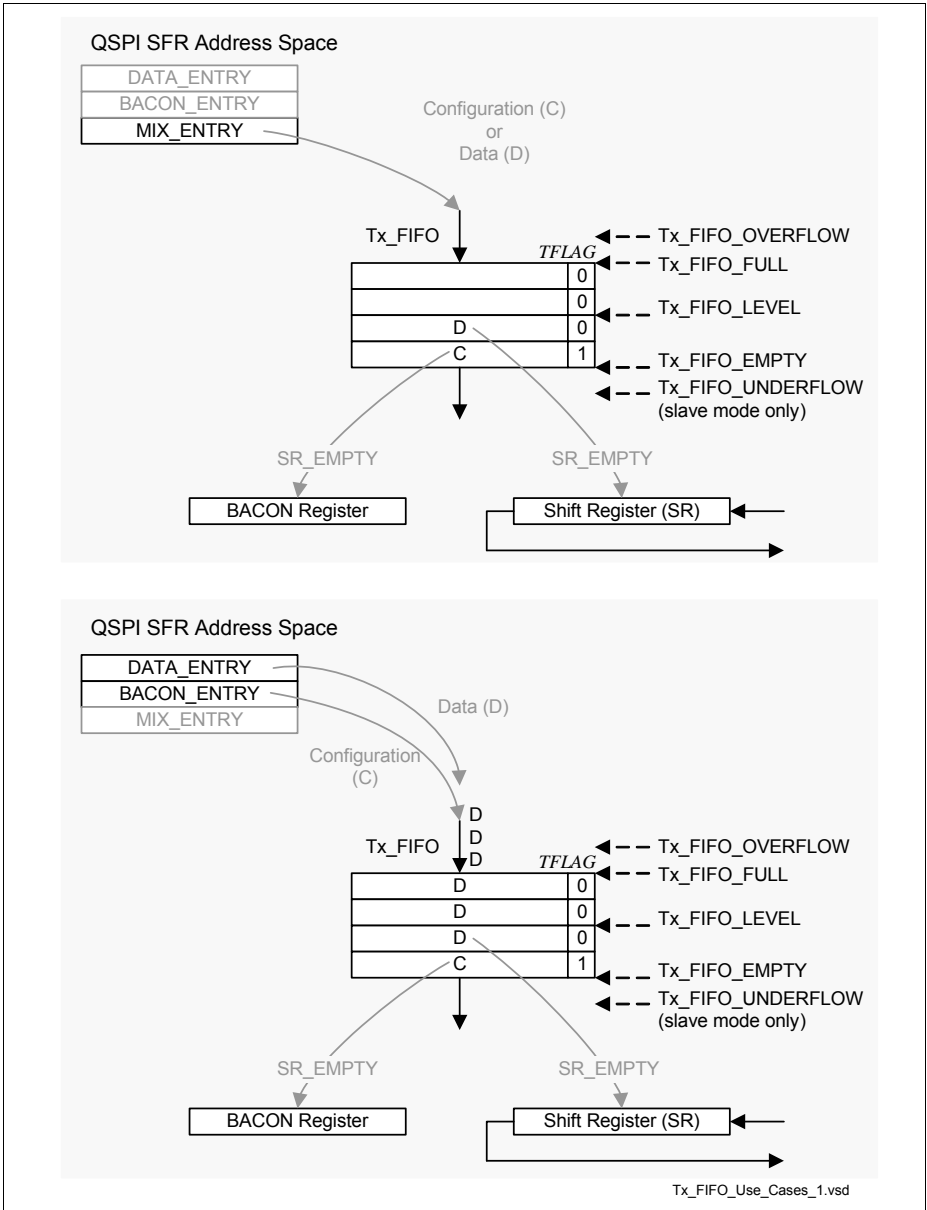

Figure 20-25 Using Tx FIFO Mix and Bacon / Data Entries

Queued Synchronous Peripheral Interface (QSPI)

20.6.1.1 Short Data Mode

In Short Data Mode, the QSPI module transmits single data with a length of 2 to 32 bits in one frame. This mode is defined by **BACON.LAST** = 1 and **BACON.BYTE** = 0.

The transfer cycle is a sequence of the following phases: W?_I_L_D_T. The symbol “?” means that the phase is optional (duration of 0 allowed).

For example, a Tx_FIFO event can be used to trigger one DMA transfer (consisting of two 32-bit moves) to transfer both the BACON and DATA entries from an on-chip RAM memory to the QSPI module.

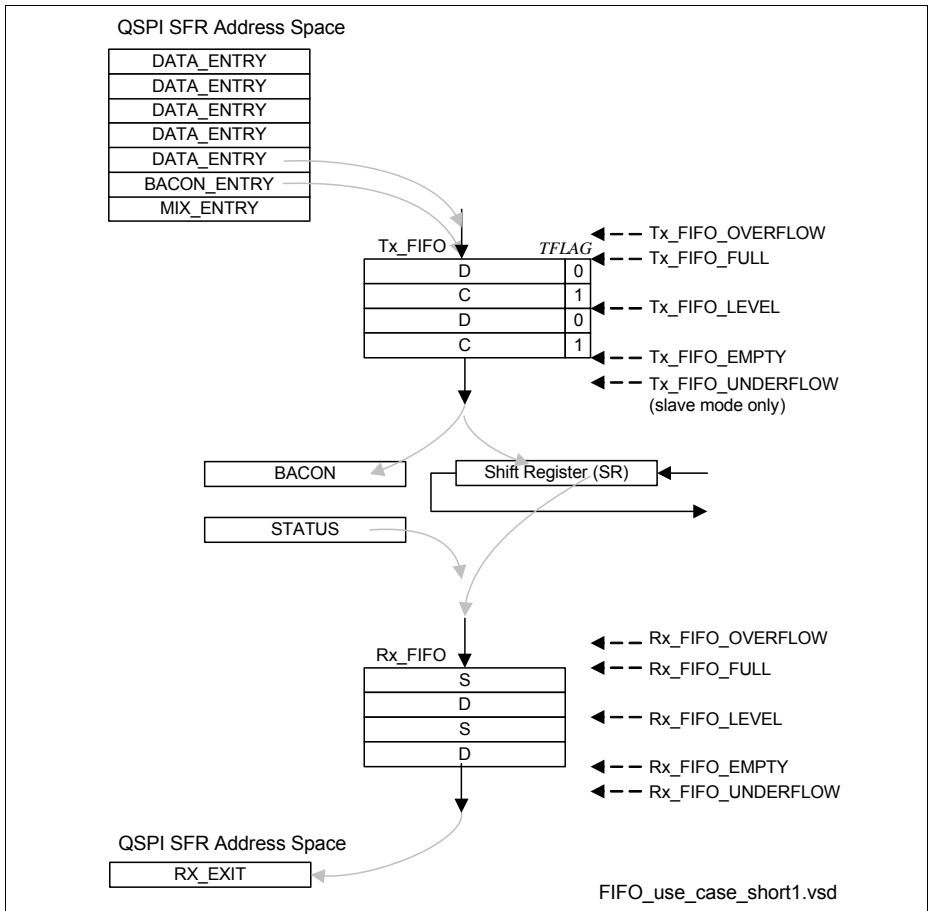

Figure 20-26 User Interface in Short Data Mode

Queued Synchronous Peripheral Interface (QSPI)

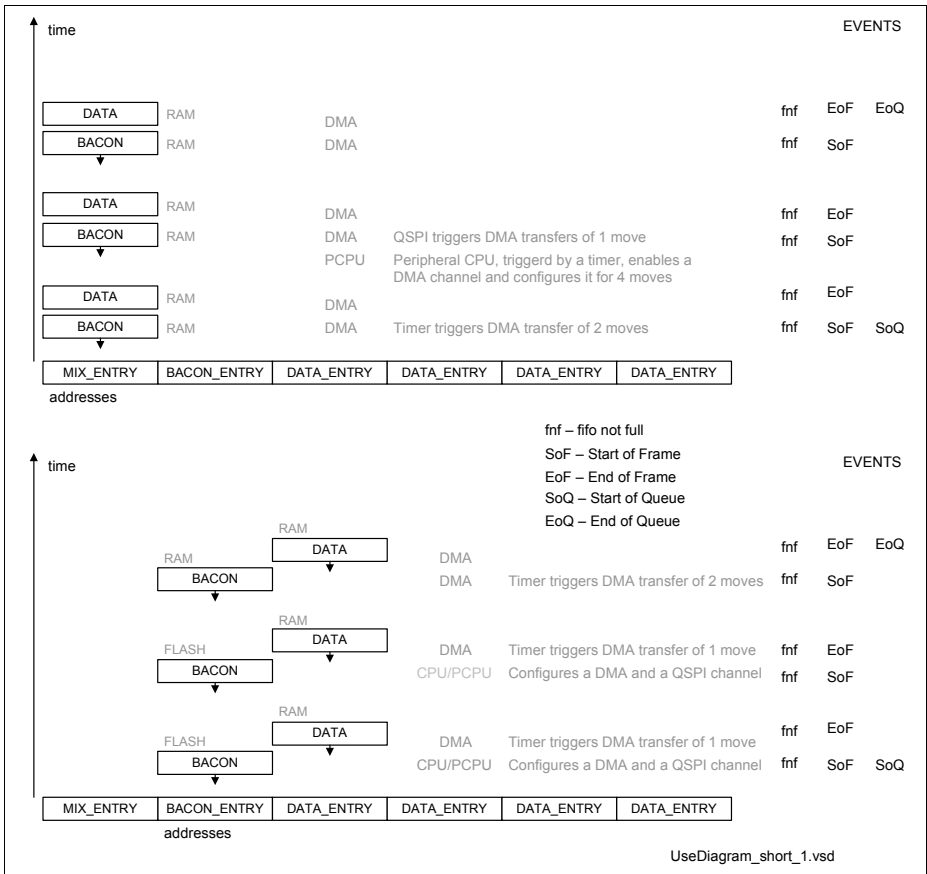

Figure 20-27 Use Diagram of the User Interface in Short Data Mode

Queued Synchronous Peripheral Interface (QSPI)

20.6.1.2 Long Data Mode

In Long Data Mode, the QSPI module transmits bursts of up to 32 bytes (256 bits) in one frame. This mode is defined by programming **BACON.LAST** = 1 and **BACON.BYTE** = 1. One transfer cycle in long data mode is a sequence of the following phases: W?_I_L_D_T. The W_I_L_D_T_I_L_D_T sequence is possible. The symbol “?” indicates that the phase is optional (duration of 0 allowed). Each “D” indicates a data length as defined with **BACON.DL** and **BACON.BYTE**, that is, up to 256 bits. One “D” is made of a number of 32-bit TXFIFO entries “d” and one rest at the end “b”, which can be written as D=dddddb.

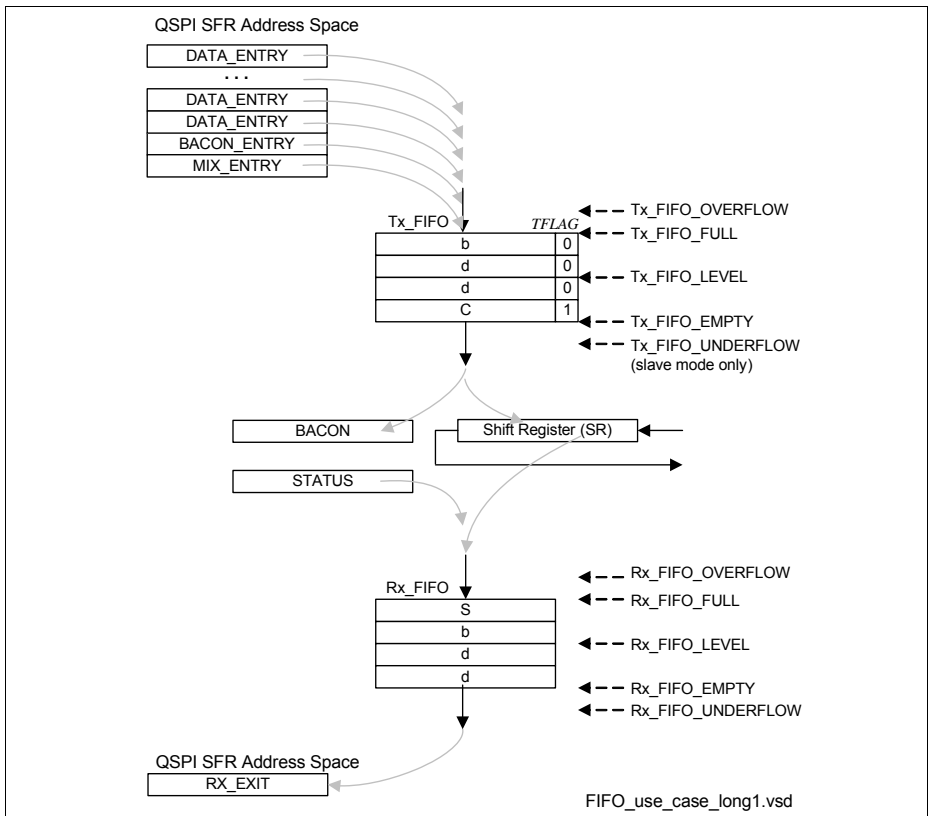

Figure 20-28 User Interface in Long Data Mode

In a DMA transfer example, a Tx_FIFO_EMPTY event can be used to trigger one DMA transfer (consisting of, for example, four 32-bit moves) to transfer the BACON and three DATA entries from RAM memory to the QSPI module. The three data words could

Queued Synchronous Peripheral Interface (QSPI)

contain 80 bits (10 bytes) of data. The three data words could also contain 40 bits (5 bytes), 64 bits (8 bytes) plus one dummy word. In this way short bursts of up to 96 bits can be transmitted.

In such 4 words DMA transfer example, the Tx_FIFO event can be used to transfer two 32-bit words per transfer.

If a configuration word is written when a data word is expected, the configuration word is ignored, and an Unexpected Configuration Error is raised.

Queued Synchronous Peripheral Interface (QSPI)

Figure 20-29 Use Diagram of the User Interface in Long Data Mode

Queued Synchronous Peripheral Interface (QSPI)

20.6.1.3 Continuous Data Mode

In Continuous Data Mode, the QSPI transmits a stream of data with an arbitrary length with an active slave select signal. It can be used with both short and long data.

This mode starts by programming a control word containing **BACON**.LAST = 0 and the first data. The communication continues with the subsequent data entries written. The mode ends with a control word containing **BACON**.LAST = 1 and the last data. If LAST = 0, then TRAIL is a delay between data blocks. The W_I_L_D_T_D_T_D_T sequence appears. Each "D" represents data block as defined with **BACON**.DL and **BACON**.BYTE (up to 256 bits). If LAST = 1 then TRAIL is trailing delay, see [Figure 20-9](#).

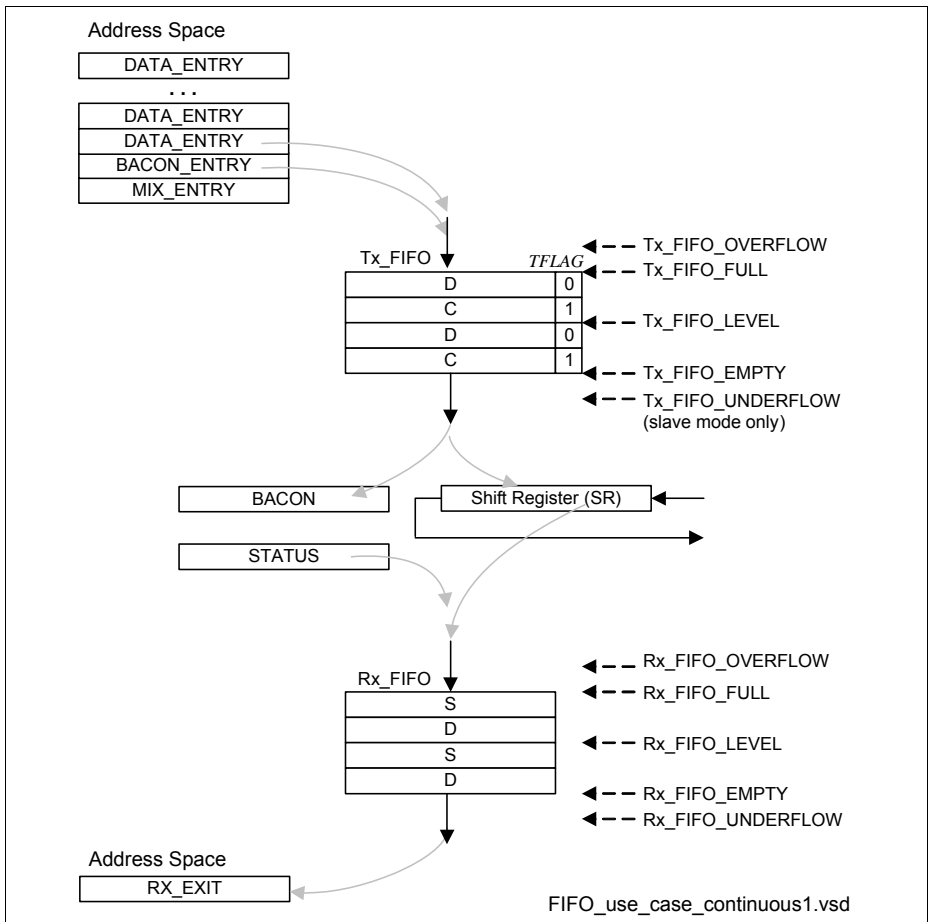

Figure 20-30 User Interface in Continuous Data Mode

Queued Synchronous Peripheral Interface (QSPI)

The **Figure 20-31** shows an example of continuous data mode using short data. Here, the CPU starts the stream by writing BACON to the BACON_ENTRY address, and afterwards a DMA transfers the whole stream except the last BACON and DATA.

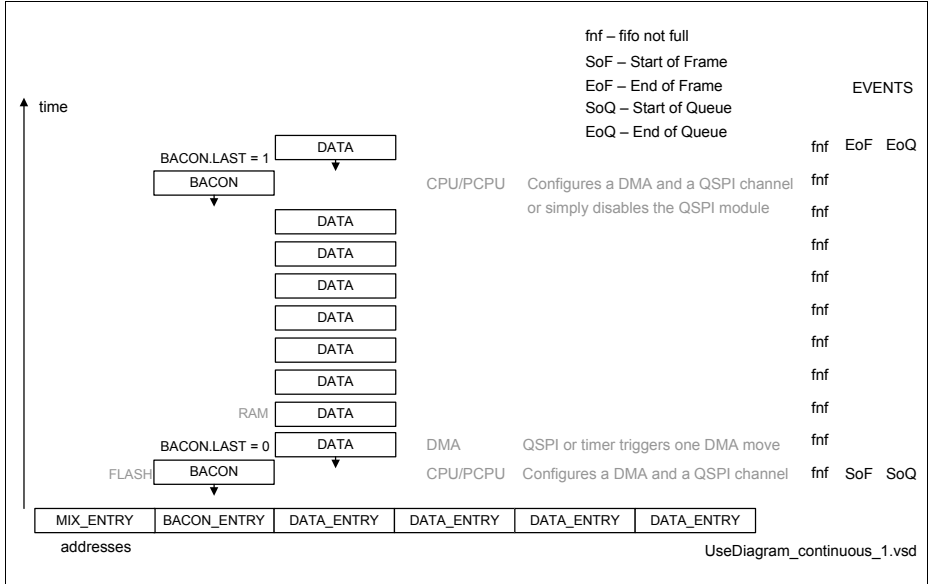

Figure 20-31 Use Diagram of Continuous Data Mode with Short Data

Queued Synchronous Peripheral Interface (QSPI)

The **Figure 20-32** shows an example of continuous data mode using long data. Here, the first BACON must be repeated after each data block, but on the other hand, the whole transfer can be done using only the MIX entry and one single DMA channel, without CPU involvement. The loss of efficiency because of the unnecessary extra BACONS can be minimized by using long data blocks.

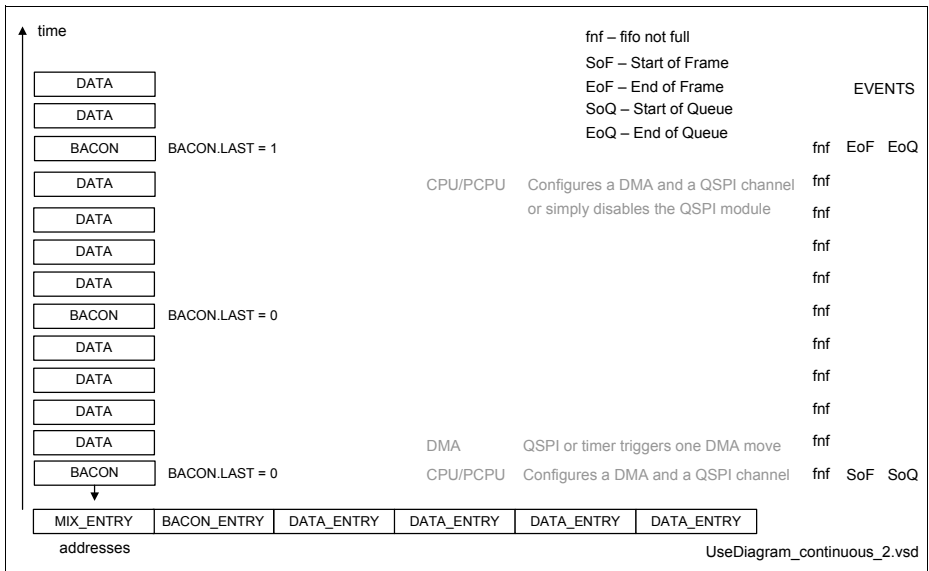

Figure 20-32 Use Diagram of Continuous Data Mode with Long Data

Queued Synchronous Peripheral Interface (QSPI)

20.6.1.4 Single Configuration - Multiple Frames Behavior

If longer sequences of data with length of up to 16 bit have to be sent to single slave in separate frames, then the DMA move for the repeating configuration word can be saved. An example of a TxFIFO contents and the resulting message sequence is shown in Figure 20-33.

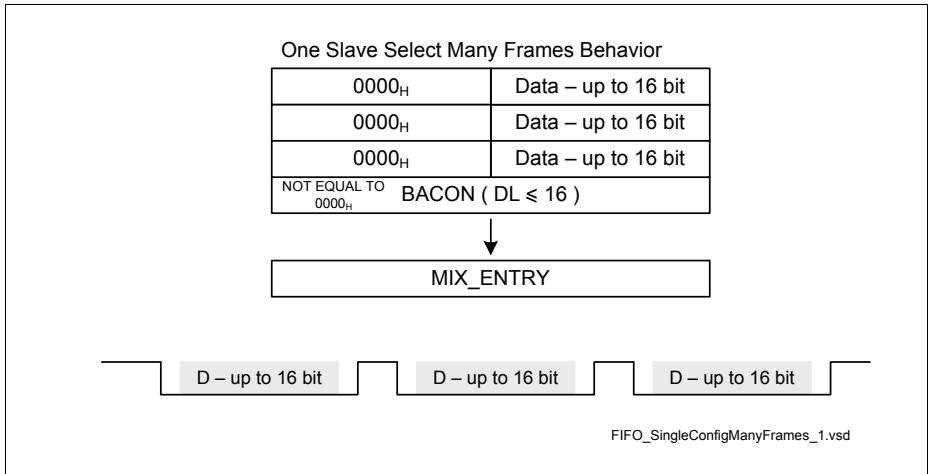

Figure 20-33 Multiple Frames to One Channel (Example of up to 16 Bit Data)

In order to support sending short multiple frames to single channel without having to send the same configuration each time, the TXFIFO follows this rule:

- If **BACON.DL** less or equal 15 (up to 16 bit data length)
- if **MIX_ENTRY** address is used
- then if the upper 16 bit of a 32-bit **MIX_ENTRY** are 0, the entry is considered data, else configuration. Note that there is no valid configuration word with upper 16 bits equal to 0.
- In such a case the TXFIFO marks the entry as data.

*Note: In case the **BACON.LAST** = 0, the slave select remains active between the frames. The behavior is equal to the continuous mode. The disadvantage of this method is that only up to 16 bits data can be transferred with one FPI bus move. The advantage is that continuous mode is possible using the mix entry.*

20.6.1.5 Big Endian Data Format

The bit-field **ECON.BE** activates the permutation of the data bytes written to the shift register and read from it to the big endian format and back.

ECON.BE allows for switching between big and little endian per slave (SLSO signal).

Queued Synchronous Peripheral Interface (QSPI)

See [Figure 20-34](#) and [Figure 20-35](#).

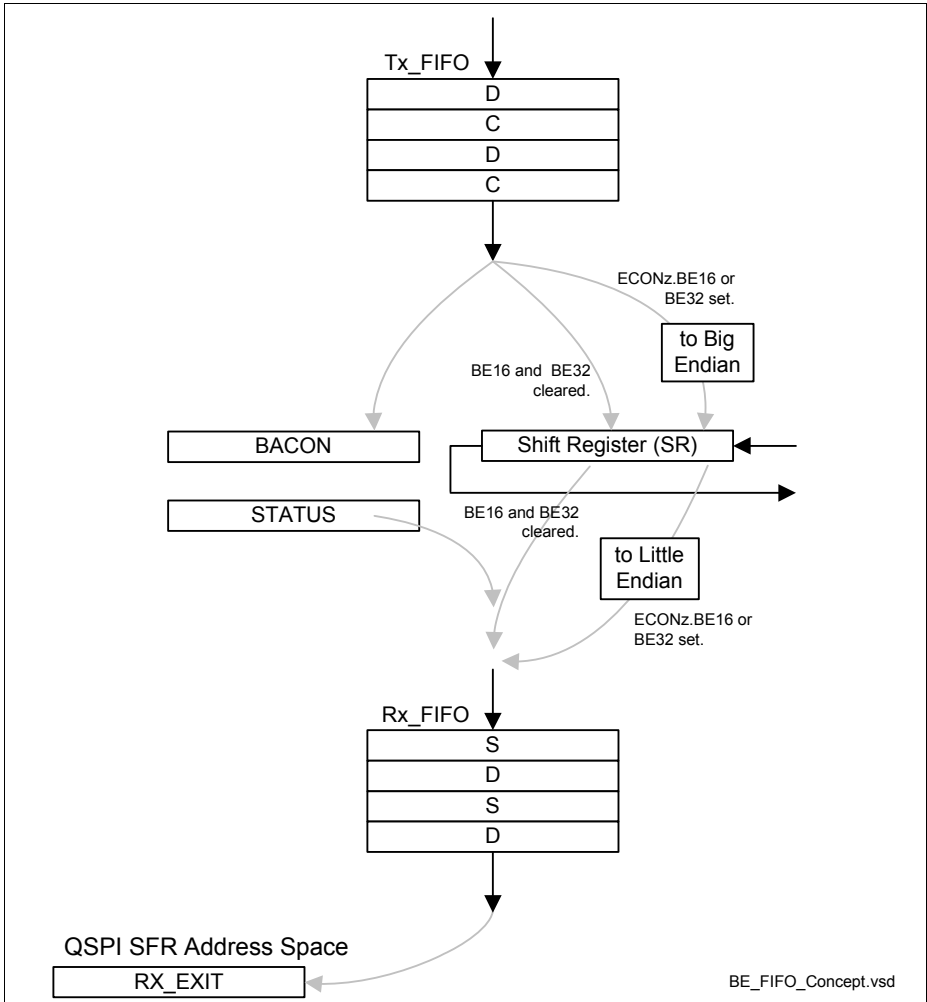

Figure 20-34 Big Endian Data Path

Converting data from little to big endian and other way around requires one and the same permutation of the data bytes, as shown in [Figure 20-34](#). One permutation block is located before and one after the shift register, so that only data can be permuted, and not **BACON** or **STATUS**.

Queued Synchronous Peripheral Interface (QSPI)

Figure 20-35 Endianness Byte Permutation

The endianness byte permutation should be used only for 16-bit and 32-bit data (and multiples of it), and not for other data lengths.

20.6.2 Loop-Back Mode

Loop Back mode is a master mode test feature used for establishing a module internal connection between the transmit and the receive signal, the same as if the transmit and receive pins would be short connected. It is activated by setting the **GLOBALCON.LB** bit.

Queued Synchronous Peripheral Interface (QSPI)

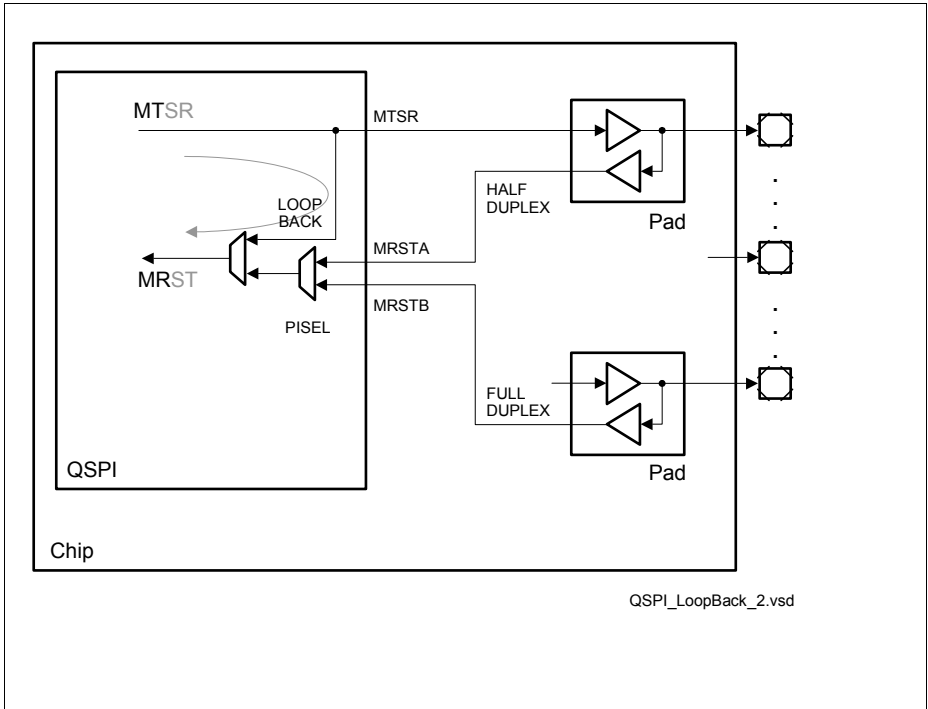

Figure 20-36 Loop-Back Mode

Queued Synchronous Peripheral Interface (QSPI)

20.7 Interrupts

There are several types of interrupts:

- Interrupts related to the user interface
 - FIFO related interrupts
- Interrupts related to the shift engine (state machine)
 - error interrupts
 - phase transition interrupts

According to this classification, here follows the complete list of all the interrupts:

- FIFO related interrupts
 - TX - Transmit FIFO Interrupt, requests feeding of the TXFIFO, but does not signal the error events of overflow and underflow (see [Figure 20-24](#))
 - RX - Receive FIFO Interrupt, requests emptying of the RxFIFO, but does not signal the error events of overflow and underflow (see [Figure 20-24](#))
- ERR Error Interrupt
 - signals every error condition
 - signals TX_FIFO_OVERFLOW, TX_FIFO_UNDERFLOW
 - signals RX_FIFO_OVERFLOW, RX_FIFO_UNDERFLOW
- PT - Phase transition interrupt, signalling two out of all phase transitions in the QSPI communication cycle (see [Figure 20-18](#) and [Figure 20-21](#))
 - PT1 event
 - PT2 event
- U - User Interrupt
 - triggered by the PT1 event during the time [BACON.UINT](#) bit keeps this event enabled.

Queued Synchronous Peripheral Interface (QSPI)

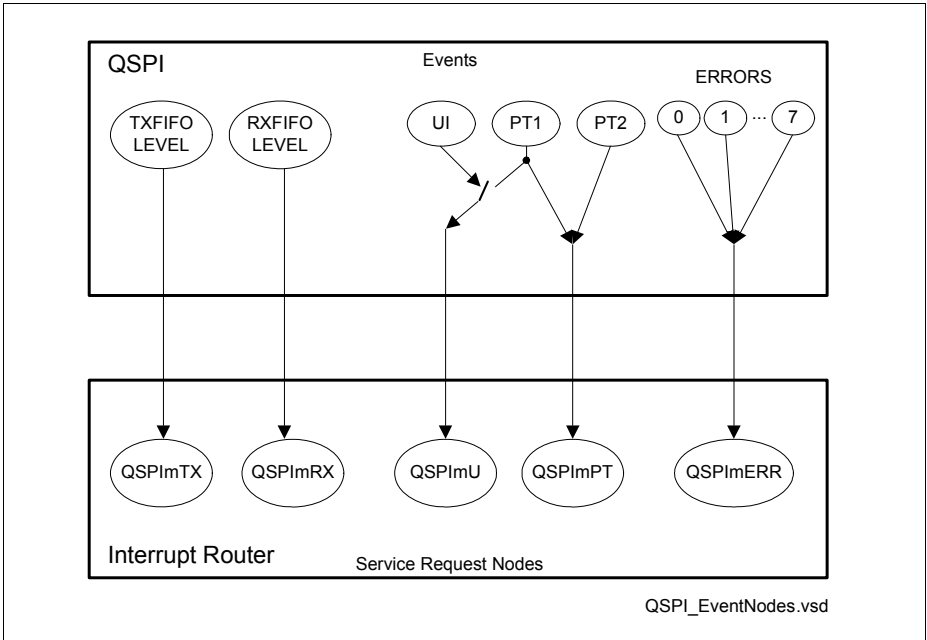

Figure 20-37 Events and Interrupts Overview

20.7.1 Slave Mode SLSI Interrupt

In slave mode, deactivating the SLSI signal (SLSI rising edge) triggers the PT interrupt, if PT2 enabled.

Queued Synchronous Peripheral Interface (QSPI)

20.7.2 Interrupt Flags Behavior

An state of an event flag (low or high) does not influence the flow of its event signal. If an event occurs recurrently, and the event flag remains set (if not cleared by the software interrupt handler), the interrupt flag (which is cleared by hardware, by an ICU, when the interrupt wins an arbitration round) would receive recurrent triggers, and the flag would be constantly set all the time.

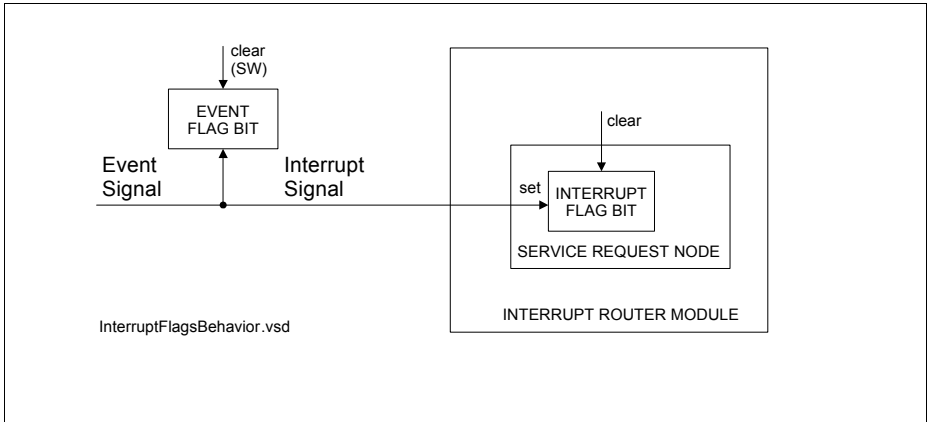

Figure 20-38 Events and Interrupts Overview

Queued Synchronous Peripheral Interface (QSPI)

20.7.3 TXFIFO Interrupt Generation

The TXFIFO provides two interrupt generation modes, selected by the bit-field **GLOBALCON1.TXFM**:

- Single Move Mode
- Batch Move Mode
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single Move Mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

The single move mode supports primarily a DMA operation using single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available. If the write makes the TXFIFO full (no more empty elements), an interrupt is not generated in order to prevent overflow. It is generated later when the shift register (or BACON) reads one element from the TXFIFO, making it not full.

The **Figure 20-39**, shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

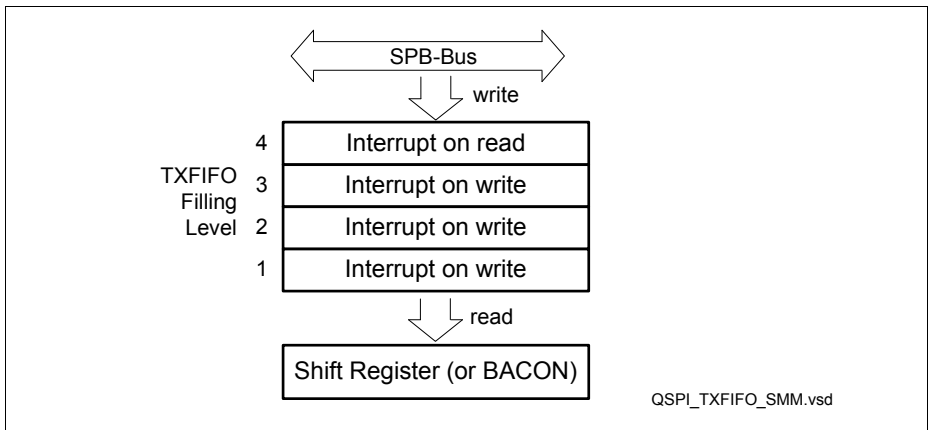

Figure 20-39 Interrupt Generation in the Single Move Mode

Queued Synchronous Peripheral Interface (QSPI)

Batch Move Mode

Batch Move Mode supports the following use case:

- CPU servicing the TXFIFO

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more than one TXFIFO elements are empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

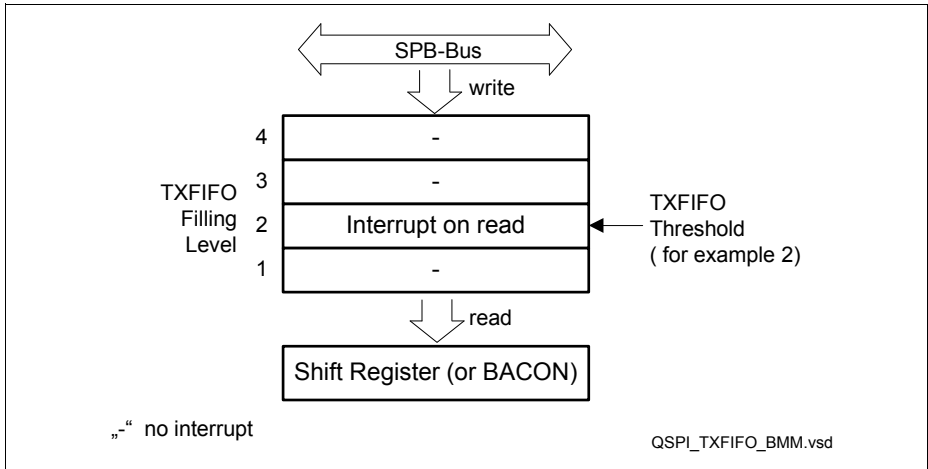

Figure 20-41 TXFIFO - Interrupt Generation in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls below the programmed threshold, implying that there are at least the predefined number of empty TXFIFO elements available.

Attention: *The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.*

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted (or frame and BACON), the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Queued Synchronous Peripheral Interface (QSPI)

Combined Mode

TXFIFO generates interrupt each time a data is fetched from it below the pre-programmed threshold, as defined in the **GLOBALCON1.TXFIFOINT**. Consequently, it generates two close interrupts when delivering BACON and the first following data. If the BACON TX interrupt is not serviced until the DATA1 TX interrupt comes, which will always be the case due to their time proximity, the BACON TX interrupt will be lost. Therefore, it is recommended that a DMA should always perform two moves per interrupt trigger (transfer size of two). Otherwise, the TXFIFO average filling level will go down with the time and at the end remain oscillating between zero and one (except in continuous mode). The DMA transaction loss event that may be raised by the DMA should be ignored.

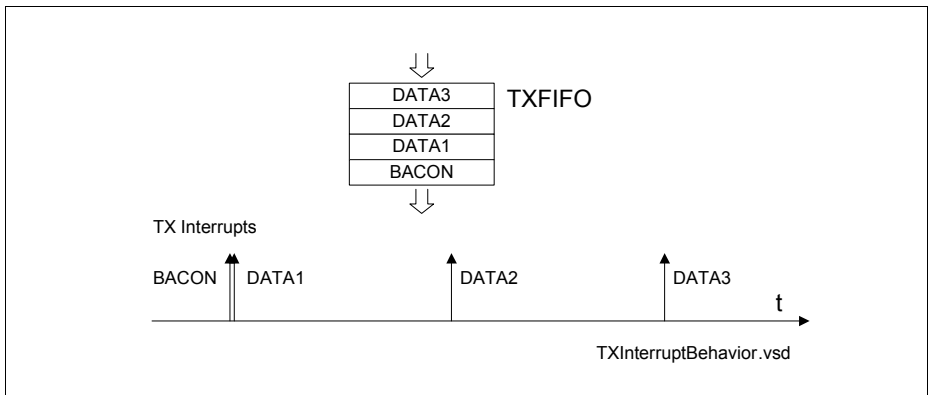

Figure 20-42 Events and Interrupts Overview

Queued Synchronous Peripheral Interface (QSPI)

20.7.4 RXFIFO Interrupt Generation

The RXFIFO provides two interrupt generation modes, selected by the bit field **GLOBALCON1.RXFM**:

- Single Move Mode
- Batch Move Mode
- Combined Mode

Single Move Mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

The single move mode supports primarily a DMA operation using single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty. If the read makes the RXFIFO empty, an interrupt is not generated in order to prevent underflow. It is generated later when the shift register (or STATUS) writes new element to the empty RXFIFO.

The **Figure 20-39**, shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

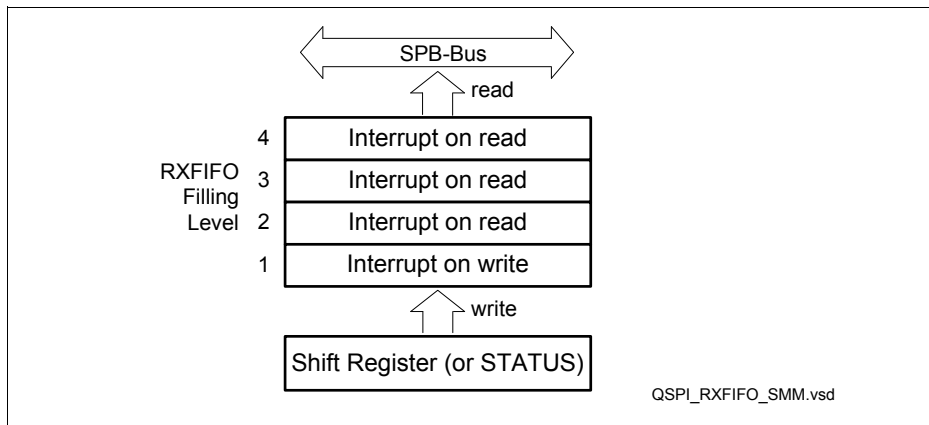

Figure 20-43 RXFIFO - Interrupt Triggering in the Single Move Mode

Queued Synchronous Peripheral Interface (QSPI)

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of refetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention: *In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.*

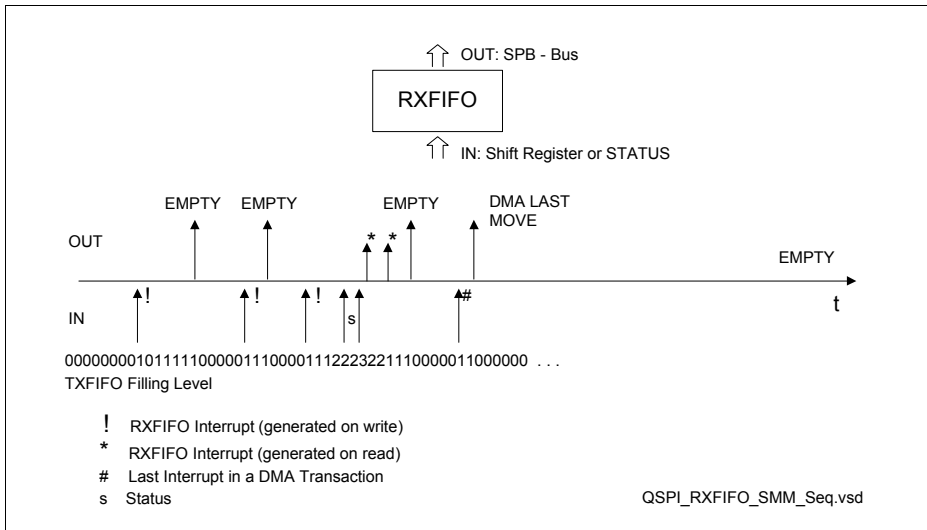

Figure 20-44 RXFIFO - Interrupt Operation in Single Move Mode

Queued Synchronous Peripheral Interface (QSPI)

Batch Move Mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more than one RXFIFO elements are full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

Batch Move Mode supports the following use case:

- CPU servicing the RXFIFO

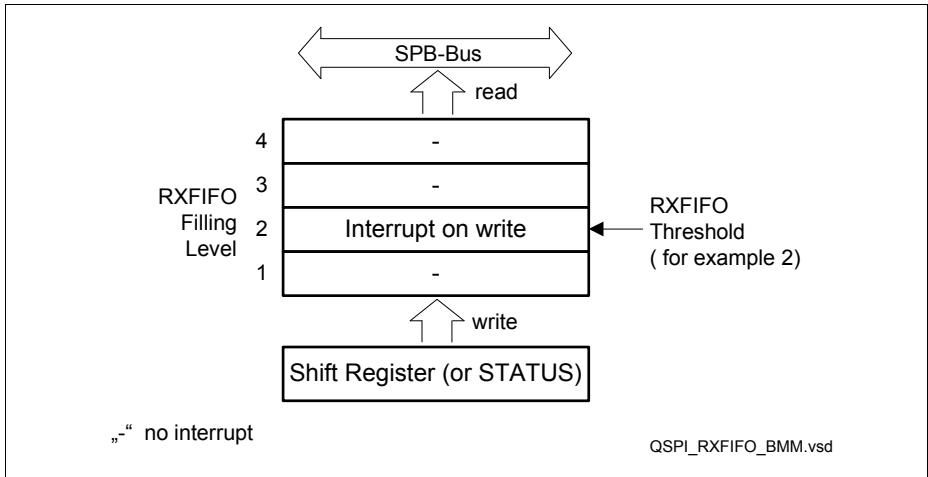

Figure 20-45 RXFIFO - Interrupt Triggering in the Batch Move Mode

In Batch Move Mode, an interrupt is generated only at one point in the RXFIFO, when the filling level rises above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available.

Attention: It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frames have been received until the moment the RXFIFO is reempted. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames has been received (or a frame and STATUS), the RXFIFO will become full, and reempty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect can not occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Queued Synchronous Peripheral Interface (QSPI)

Combined Mode

RXFIFO generates interrupt each time a data is written to it above the preprogrammed level, as defined in the [GLOBALCON1.RXFIFOINT](#). Consequently, it generates two close interrupts when filled with data and STATUS. If the data RX interrupt is not serviced until the STATUS RX interrupt comes, which will always be the case due to their time proximity, the STATUS RX interrupt will be lost. In such a case, it is recommended that the DMA performs two moves per interrupt trigger (transfer size of two). Otherwise, the RXFIFO average filling level will go up with the time and at the end overflow.

20.7.5 DMA Transfer Example

Transmitting one compact RAM queue using DMA could consist of the following steps:

- The user software configures one appropriate DMA channel (source address, destination address, one move per transfer, number of transfers per transaction, gating mode, single mode, interrupt at the end of the transaction etc...)
- A not full Tx FIFO from some QSPI module constantly generates pending DMA request
- A timer triggers a software routine that enables the DMA channel
- The DMA channel reads the queue elements from some on-chip general purpose RAM and writes them to the QSPI, one element at a time. One DMA transfer is one move long. One whole queue takes one transaction.
- The DMA channel generates an interrupt at the end of the transaction
- The DMA channel disables itself at the end of the transaction (single mode) and waits for further software actions.

The sequence is identical for the receive direction.

Queued Synchronous Peripheral Interface (QSPI)

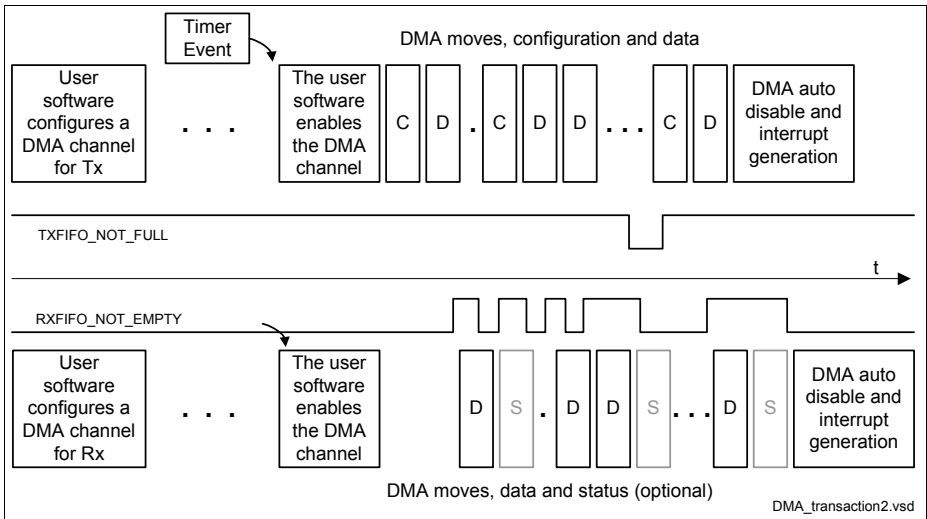

Figure 20-46 Example of transmitting a compact RAM Queue per DMA

20.8 Slave Mode

The slave mode is entered by setting the bit field GLOBALCON.MS to value 1x. Before entering the slave mode, the related parameters must be configured, including pin selection for SCLKI, SLSI and MTSR, pin input level, and pull-up/pull-down configuration. Subsequently state machine reset should be performed and afterwards the slave mode should be entered.

In slave mode data is being pushed into or out of the module through the serial pins by an external master. The RXFIFO must be regularly emptied by the system in order to avoid data loss, and the TXFIFO must be regularly fed by the system to avoid delivering all "1" data in case of empty TXFIFO.

If the slave mode relies on a slave select signal to mark the start and, in parallel to the bit counting, the end of a frame, then deactivating the slave signal by the master automatically resets the shift register state machine to wait state.

If the slave mode relies solely on bit counting for determining the frame end, then any SCLKI clock period longer than two bit times is treated as an end of a frame and simultaneously as a baud rate error.

In slave mode, the module simply immediately responds to external clock edges. Therefore, the settings for the leading, trailing, idle delays, and duty cycle and sampling point are irrelevant. From all timing settings, only the data length and the baud rate divider setting are relevant. The baud rate setting is important because of its role of watchdog timer of the incoming serial clock.

Queued Synchronous Peripheral Interface (QSPI)

Generally, the slave mode supports the same user interface as the master mode. This means the BACON-Data sequences remain the same. The SRF bit is ignored.

Limit the data length setting in the slave mode to the range of 2 to 32 bits. The byte setting **BACON.BYTE** is to be set to zero, that is, it always defines bits.

In case of receive only (simplex receive) the user software must reset the module in order to switch to transmit and receive mode (full duplex). Generally, mode reconfiguration (slave mode to master mode) requires module reset which resets the internal state machines and counters.

In case of slave transmit, the user software must write data to the TXFIFO before the first SCLKI edge of a frame arrives. If the TXFIFO is empty at this point of time, an underflow occurs, all "1" data is delivered, and underflow error interrupt is triggered if enabled. If the TXFIFO is written at the same time when the first SCLKI edge starts the shifting, the underflow occurs, interrupt will be triggered and data from the TXFIFO will be transmitted possibly corrupted - the first bit will be "1".

In case of TXFIFO / RXFIFO underflow the fifos deliver all "1" data .

In case of TXFIFO / RXFIFO overflow, the last data is lost. In such case data or optionally status in the RXFIFO can be lost.

The bit counting in the slave mode operates according to the following rules:

- The incoming bits (or shift clock shift edges) are counted and when the number defined in the **BACON.DL** is reached, the bits are transferred in the RXFIFO
- If the SLSI input is deactivated, the internal bit counter is reseted.

In slave mode, sleep requests may be enabled only when there is no pending transmit queue and no pending transmission and the TXFIFO is empty.

20.8.1 Shift Clock Phase and Polarity in Slave Mode

In slave mode the shift clock phase and polarity are fixed to CPH=1 and CPOL=0 (have to be programmed accordingly in the **ECON** register selected by **BACON.CS**) and slave select polarity is fixed to low active. The baud rate that the slave expects is defined in the **ECON** register pointed at by the **BACON.CS**.

Queued Synchronous Peripheral Interface (QSPI)

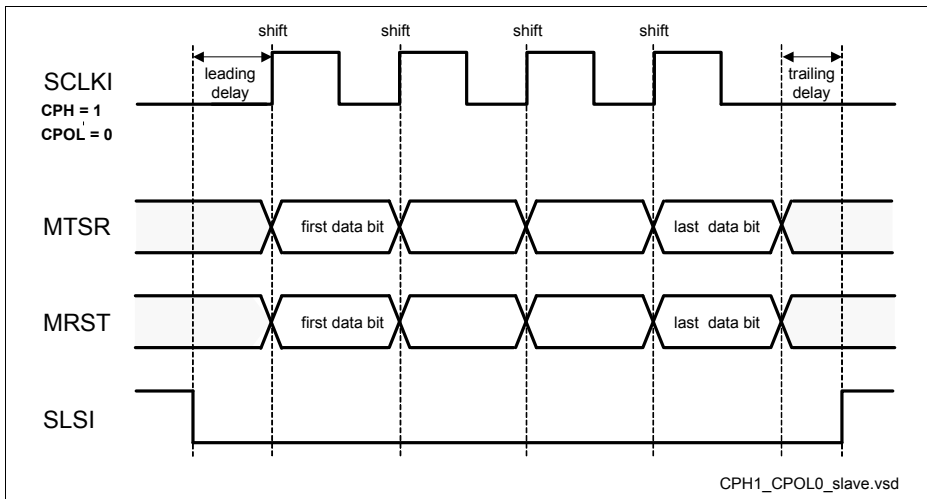

Figure 20-47 Slave transfer, CPH = 1, CPOL = 0

20.8.2 Shift Clock Monitoring

The QSPI module provides two mechanisms for monitoring the shift clock input signal in slave mode. These mechanisms monitor:

- if the receiving shift clock frequency (baud rate) lies within a certain range and
- if there are spikes on the shift clock input.

In case such disturbances are detected, the reaction is always the same:

- the corresponding error flags in **STATUS.ERRORFLAGS** are set, which can be cleared with **FLAGSCLEAR.ERRORCLEARS**
- the common error interrupt is raised if enabled in **GLOBALCON1.ERRORENS** and
- the bit **GLOBALCON.EN** is automatically cleared, if this feature is enabled by the bit **GLOBALCON.AREN**. The user software can activate a reset afterwards

In case of too high baud rate error, baud rate detection and spike detection both react, where spike detection is more effective. Spike detection reacts immediately, baud rate detection requires several bits with higher baud rate. Baud rate detection uses a window two nominal bit times wide and counts the real bit times: double baud rate error requires at least four real shift clock pulses to be detected, triple baud rate error requires six and so on. Baud rate detection does not react to all spikes smaller than one kernel clock period.

In case of too low baud rate error, baud rate detection reacts immediately, spike detection ignores this case.

Queued Synchronous Peripheral Interface (QSPI)
20.8.2.1 Baud Rate Error Detection

If the shift clock has less than half or more than double the expected baud rate, then:

- the corresponding flag is set in **STATUS.ERRORFLAGS**
- error interrupt is raised if enabled in **GLOBALCON1.ERRORENS**
- automatic clear of **GLOBALCON.EN** follows, if enabled by **GLOBALCON.AREN**.

20.8.2.2 Spike Detection

Short spikes on the clock line due to ground bouncing or clock ringing due to over/undershoots would cause one or more extra bits to be written to the front end receive fifo of the slave. This extra bit, if no measures are taken by the software, would cause all the subsequent received frames to be corrupted (shifted).

The spike detection mechanism operates up to 50MBaud and checks if a bouncing spike has occurred on the clock line near to the correct receiving clock edges.

If a spike is detected, the software should use **GLOBALCON.RESETS** bitfield, and should clear the corresponding status flags. Alternatively a complete module reset may be performed via registers **KRST0/KRST1**.

The spike detection is based on two mechanisms:

- detection of two close writes to the front end receive FIFO by detecting filling level of two
- using an inverted watchdog set to ca. 75% to 80% SCLKI clock period, which is the optimal range.

The inverted watchdog is a timer which starts to count triggered on the write event to the front-end receive fifo of the slave. During the time the watchdog counts, no edge is allowed to occur. An edge in the forbidden time raises a spike error event.

If a spike occurs in the last 25% of the SCLKI period, when the watchdog has stopped counting, the watchdog will be triggered to count by the spike. The next regular edge will violate the forbidden time and raise a spike event.

The watchdog counts **ECON.B + ECON.C** time quantas. The following constraint applies: $50\% * T_{SCLKI} < \mathbf{ECON.B} + \mathbf{ECON.C} < 100\% * T_{SCLKI}$

Queued Synchronous Peripheral Interface (QSPI)

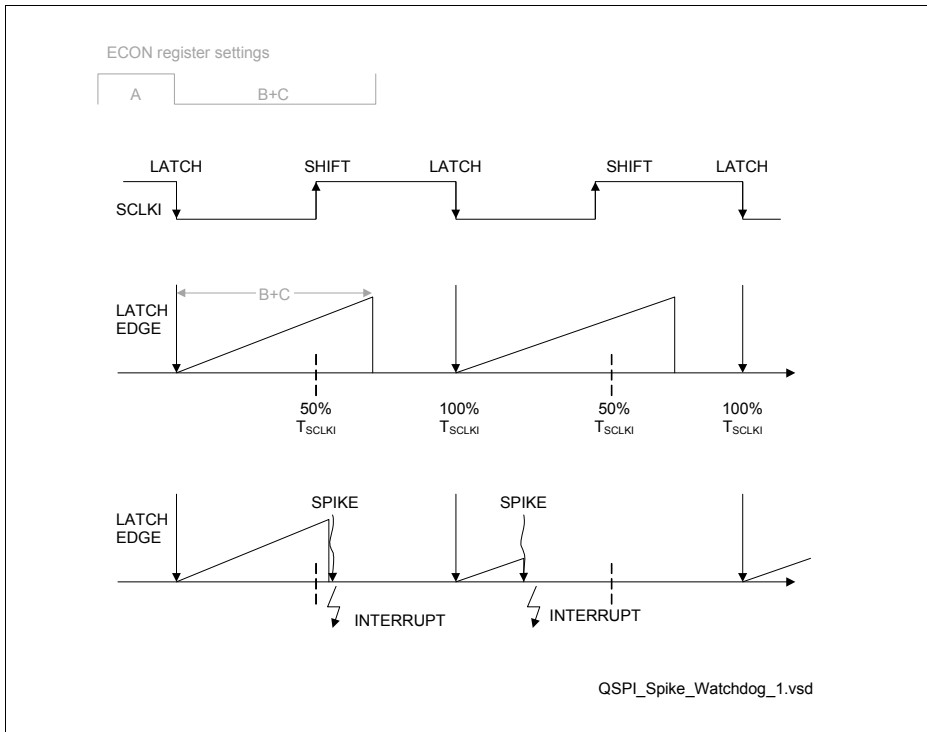

Figure 20-48 Spike Watchdog

20.8.2.3 Shift Clock Monitor Flags

The spike detection mechanism sets the flag **STATUS1.SPD** if it has detected a spike. The baud rate error detection mechanism sets the flag **STATUS1.BRD** if it has detected excessive baud rate deviation.

Writing 1 to SPD and BRD sets the bit and causes an interrupt if enabled. Writing 0 has no effect.

Both signals are ORed. This combined signal is shown in **STATUS.ERRORFLAGS** and raises an interrupt if enabled in **GLOBALCON1.ERRORENS**. Automatic clear of **GLOBALCON.EN** follows, if enabled by **GLOBALCON.AREN**.

If the **STATUS.ERRORFLAGS[2]** bit is cleared via **FLAGSCLEAR.ERRORCLEARS[2]**, the both flags SPD and BRD are automatically cleared.

Queued Synchronous Peripheral Interface (QSPI)

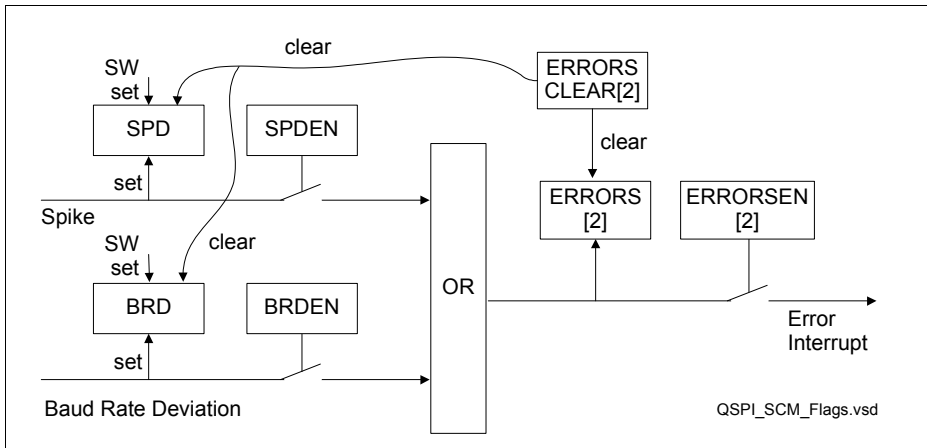

Figure 20-49 Shift Clock Monitor Flags

20.8.3 Parity

Parity settings for transmit and receive are defined by the corresponding bit fields in the **BACON** register.

The parity bit is concatenated to the data bits at transmission time. That means that a frame containing 16 bit data is 17 bits long (data + 1 parity). The transmitted parity bit can be read from the **STATUS.TPV** bit.

The parity bit is removed from the received bits at receive time automatically. The received parity bit can be read from the **STATUS.RPV** bit.

Attention: Parity is available only if the bit field **BACON.BYTE = 0**, that is, only for data of up to 32 bits length, that is, only in short mode.

Attention: The parity bit is concatenated to the data at the **LSB** location. If the bit field **BACON.MSB = 0** it is shifted out first, else it is shifted out last.

Queued Synchronous Peripheral Interface (QSPI)

20.9 Kernel Registers

This section describes the kernel registers of the QSPI module. All QSPI kernel register names described in this section will be referenced in other parts of the TC26x B-Step User’s Manual by the module name prefix “QSPI0_” for the QSPI0 interface, “QSPI1_” for the QSPI1 interface and so on.

All registers in the QSPI address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

QSPI Kernel Register Overview

Figure 20-50 QSPI Kernel Registers

The following tables give the overview of the QSPI base addresses and registers.

Table 20-1 Registers Address Space

Module	Base Address	End Address	Note
QSPI0	F0001C00 _H	F0001CFF _H	–
QSPI1	F0001D00 _H	F0001DFF _H	–

Queued Synchronous Peripheral Interface (QSPI)

- 1) The absolute register address is Module Base Address ([Table 20-1](#)) + Offset Address (shown in this column)
- 2) All registers have read access mode U, SV. Read access to reserved addresses delivers bus error (BE).
All registers belong to application reset except OCS, which belongs to debug reset.

List of Access Protection Abbreviations

U	- User Mode
SV	- Supervisor Mode
BE	- Bus Error
nBE	- no Bus Error
P	- Access Protection, as defined by the ACCEN Register
E	- ENDINIT
SE	- SafetyENDINIT

Queued Synchronous Peripheral Interface (QSPI)

20.9.1 Kernel Registers

PISEL

The PISEL register controls the input signal selection of the SSC module.

(>> [Table 20-2](#) register overview)

PISEL

Port Input Select Register (04_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
MRIS	[2:0]	rw	Master Mode Receive Input Select MRIS selects one out of eight MRST receive input lines (0 to 7 correspondingly), used in Master Mode. The signal suffixes "A" to "H" correspond to the bit field values of 0 to 7: MRSTxA ->0, MRSTxB->1 ...
SRIS	[6:4]	rw	Slave Mode Receive Input Select SRIS selects one out of eight MTSR receive input lines (0 to 7 correspondingly), used in Slave Mode. The signal suffixes "A" to "H" correspond to the bit field values of 0 to 7: MTSRxA ->0, MTSRxB->1 ...
SCIS	[10:8]	rw	Slave Mode Clock Input Select SCIS selects one out of eight module kernel SCLK input lines (0 to 7 correspondingly) that is used as clock input line in slave mode. The signal suffixes "A" to "H" correspond to the bit field values of 0 to 7: SCLKIxA ->0, SCLKIxB->1 ...

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
SLSIS	[14:12]	rw	Slave Mode Slave Select Input Selection 000 _B Slave select input lines are deselected; QSPI is operating without slave select input functionality. 001 _B <u>SLSI</u> input line A is selected for operation 010 _B <u>SLSI</u> input line B is selected for operation 011 _B <u>SLSI</u> input line C is selected for operation 100 _B <u>SLSI</u> input line D is selected for operation 101 _B <u>SLSI</u> input line E is selected for operation 110 _B <u>SLSI</u> input line F is selected for operation 111 _B <u>SLSI</u> input line G is selected for operation The SLSIS must be programmed properly before the slave mode is set with GLOBALCON.MODE and the module is set to RUN mode.
0	[31:15], 11, 7, 3	r	Reserved Read as 0; should be written with 0.

Queued Synchronous Peripheral Interface (QSPI)

ID

The Module Identification Register ID contains read-only information about the module version.

(>> [Table 20-2](#) register overview)

ID

Module Identification Register (08_H) **Reset Value: 00C0 C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number MODREV defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines a 32-bit module.
MOD NUMBER	[31:16]	r	Module Number Value This bit field together with MODTYPE uniquely identifies a module.

Queued Synchronous Peripheral Interface (QSPI)

GLOBALCON

GLOBALCON contains configuration parameters which affect all channels.

(>> [Table 20-2](#) register overview)

GLOBALCON

Global Configuration Register

(10_H)

Reset Value: 000F 30FF_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESETS				AR EN	MS	EN	0	STIP	SRF	STROBE

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DEL 0	LB	EXPECT				SI	0	TQ							
rw	rw	rw				rw	r	rw							

Field	Bits	Type	Description
TQ	[7:0]	rw	Global Time Quantum Length Common n-divider scaling the baud rates of all channels in direction of higher or lower baud rates. Must not be changed during a running transaction. 0 _D division by 1 1 _D division by 2 ... _D ... 255 _D division by 256
SI	9	rw	Status Injection Selects if the status register content injection into the RxFIFO is enabled or disabled. The status injections, if enabled, is performed after each data block, depending on the BACON.DL and BYTE setting. 0 _B disabled 1 _B enabled
EXPECT	[13:10]	rw	Time-Out Value for the Expect Phase expressed in T_{QSPI} units 0 _D 64 (2 ⁶) 1 _D 128(2 ⁷) ... _D ... 15 _D 2097152 (2 ²¹ = 2 Mega)

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
LB	14	rw	Loop-Back Control Selects if the transmit output is internally connected to the receive input for test purposes. 0 _B Loop-Back inactive 1 _B Loop-Back active For detailed description, see the Loop-Back Mode section.
DELO	15	rw	Delayed Mode for SLSO0 Switches the delayed mode for external multiplexer enabling on and off 0 _B Delayed mode off 1 _B Delayed mode on
STROBE	[20:16]	rw	Strobe Delay for SLSO0 in Delayed Mode Defines the length of the SLSO0 delay in T_Q time units as defined for channel z (T_Q units) selected by the current BACON.CS , if GLOBALCON.DELO = 1. 00000 _B 1 00001 _B 2 ... _B ... 11111 _B 32
SRF	21	rw	Stop on RxFIFO Full If this bit is set, the data fetching out of the TxFIFO by the shift register stops when the RxFIFO is full, in order to prevent RxFIFO overflow. Master mode only. 0 _B Feature disabled 1 _B Feature enabled
STIP	22	rw	Slave Transmit Idle State Polarity This bit determines the logic level of the Slave Mode transmit signal MRST when the QSPI slave select input signals are inactive ($PISEL.SLSIS \neq 000_B$). 0 _B MRST = 0 when QSPI is deselected in Slave Mode. 1 _B MRST = 1 when QSPI is deselected in Slave Mode

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
EN	24	rwh	<p>Enable Bit</p> <p>Used to request transition between PAUSE and RUN mode per software. Cleared by hardware automatically at leaving the following states: disabled, suspend and sleep.</p> <p>In order to determine if the requested state has actually been reached, the STATUS.PHASE bit field should be polled. See also Operation Modes.</p> <p>0_B PAUSE requested 1_B RUN requested</p>
MS	[26:25]	rw	<p>Master Slave Mode</p> <p>Selects if the module operates in master or slave mode. This bit field must be configured before the first write to the TXFIFO.</p> <p>00_B Master Transmit and Receive 01_B Reserved 10_B Slave Transmit and Receive 11_B Slave Transmit and Receive</p>
AREN	27	rw	<p>Automatic Reset Enable</p> <p>Enables the reset of the GLOBALCON.EN on baud rate and spike error in slave mode.</p> <p>0_B disabled 1_B enabled</p>
RESETS	[31:28]	w	<p>Bits for resetting sub-modules per software</p> <p>Write to this bit field triggers a reset operation. The reset operation is not a single cycle operation, but takes several clock cycles, not more than the least common multiple of CCUCON0.SPBDIV and CCUCON0.BAUD2DIV (the configured division ratios, not the content of the bit fields).</p> <p>0000_B No reset triggered 0111_B State Machine, TXFIFO and RXFIFO reset, registers not reset 1111_B Module reset others, reserved</p> <p>For resetting the whole module, use KRST0 / KRST1 reset mechanism.</p>

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
0	8, 23	r	Reserved Read as 0; should be written with 0.

Note: If the EN bit is cleared first, and then the partial state machine reset activated, then the state machine goes into PAUSE state.

Queued Synchronous Peripheral Interface (QSPI)
GLOBALCON1

GLOBALCON1 contains bit fields for control of the extension of the slave select signals by using an external demultiplexer.

(>> [Table 20-2](#) register overview)

GLOBALCON1
Global Configuration Register 1
(14_H)
Reset Value: 0005 0000_H

TPRE	[15:13]	rh	Prescaler for the Trailing Delay Length in T_{BAUD2} units 000 _B 1 001 _B 4 010 _B 16 ... _B ... 111 _B 16384
TRAIL	[18:16]	rh	Trailing Delay Length Defines the length of the leading delay, in T_{BAUD2} units pre scaled with TPRE 0 _D 1 units 1 _D 2 unit ... _D ... 7 _D 8 units
PARTYP	19	rh	Parity Type Valid for both receive and transmit direction 0 _B Even parity 1 _B Odd parity

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
UINT	20	rh	<p>User Interrupt at the PT1 Event in the Subsequent Frames</p> <p>This bit is an enable signal for the PT1 event routed to the User Interrupt Service Request. The interrupt signals are generated until disabled with the next BACON.</p> <p>0_B Disabled 1_B Enabled</p>
MSB	21	rh	<p>Shift MSB or LSB First</p> <p>This bit sets the shift direction of the shift register. If the MSB option is set, and the data is a block longer than 32 bits, the block must be fed into the TXFIFO in reverse direction, from the end of the block until its beginning.</p> <p>0_B Shift LSB first 1_B Shift MSB first</p>
BYTE	22	rh	<p>Byte</p> <p>Defines if data length is expressed in bits or bytes</p> <p>0_B DL defines the data length in bits 1_B DL defines the data length in bytes</p>
DL	[27:23]	rh	<p>Data Length</p> <p>Defines the data length in bits or bytes of one data block, depending on the setting of the bit field BYTE</p> <p>0_D 2 bits if BYTE=0; XXL mode if BYTE=1 1_D 2 bits or bytes ..._D ... 31_D 32 bits or bytes</p> <p>For the maximum baud rate of 50 MBaud, the minimum data length possible is four.</p>
CS	[31:28]	rh	<p>Channel Select</p> <p>Selects the channel to which the subsequent data entry belongs (channel = the SLSO signal to be activated and the corresponding ECON configuration extension)</p> <p>This bit field selects one slave in a range of 0 to 15, by driving one SLSO signal out of 16 available.</p> <p>In case of an external demux mode, this bit field appears on the lines SLS01 to SLS04 as it is, additionally inverted or not, as defined in the SSOC register.</p>

Queued Synchronous Peripheral Interface (QSPI)

If an application does not use the SLSO signals of the QSPI module, but uses software channel selection, then the alternate function multiplexer in the ports must be configured so that the signal SLSO is not selected, but the corresponding bit Pn.OUT.

Alternatively, to emulate SLSO functionality, the software can disable (low) all the **SSOC**.OEN bits, and then toggle the **SSOC**.AOL bits.

Queued Synchronous Peripheral Interface (QSPI)

ECON

Configuration extensions for channels 0 to 15. Register x defines several timing characteristics for two channels: z and z+8.

(>> [Table 20-2](#) register overview)

(>> [Figure 20-12](#), [Figure 20-13](#) timing diagrams)

ECONz (z = 0 - 7)

Configuration Extension z (20_H + z*4_H) **Reset Value: 0000 1450_H**

Field	Bits	Type	Description
Q	[5:0]	rw	Time Quantum Defines the time quantum length used by A, B, and C to define the baud rate and duty cycle by. This prescaler cascades the prescaler GLOBALCON.TQ . 000000 _B 1 000001 _B 2 ... _B ... 111111 _B 64
A	[7:6]	rw	Bit Segment 1 Length expressed in time quantums of ECONz.Q . 00 _B 1 01 _B 2 10 _B 3 11 _B 4

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
B	[9:8]	rw	Bit Segment 2 Length expressed in time quanta of ECONz.Q. 00 _B 0 01 _B 1 10 _B 2 11 _B 3
C	[11:10]	rw	Bit Segment 3 Length expressed in time quanta of ECONz.Q. 00 _B 0 (if B=0, then C is minimum 1 per hardware) 01 _B 1 10 _B 2 11 _B 3
CPH	12	rw	Clock Phase Delay of one half SCLK clock cycle. 0 _B Disabled 1 _B Enabled
CPOL	13	rw	Clock Polarity Idle level of the shift clock signal at the SCLK pin 0 _B Idle level low 1 _B Idle level high
PAREN	14	rw	Enable Parity Check This bit field enables both the parity generation in transmit and parity check in receive direction. 0 _B Disabled 1 _B Enabled
BE	[31:30]	rw	Permutate bytes to / from Big Endian 00 _B Disabled 01 _B 16-bit big endian 10 _B 32-bit big endian 11 _B Disabled
0	[29:15]	r	reserved

Queued Synchronous Peripheral Interface (QSPI)

STATUS

Status register contains bits flagging the current status of the module and its sub-modules.

Note: It is not recommended to set the STATUS register flags per software for purposes other than testing. In such cases, use write instructions only, not read-modify-write instructions or bit instructions which compile to read-modify-write instructions.

Note: When using the RXFIFO status injection feature, only bits 22 to 31 reflect the status at the moment of injection, that is for the latest frame. Due to pipeline effects, the other bits contain not-latest information.

(>> [Table 20-2](#) register overview)

STATUS

Status Register (40_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
TXF	9	rwh	Transmit Interrupt Request Flag Flags an occurrence of a request to feed the TXFIFO, which is generated when an element is fetched from the FIFO, and the FIFO filling level is equal or less than the set threshold level. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.TXEN = 1 . Writing 0 has no effect.
RXF	10	rwh	Receive Interrupt Request Flag Flags an occurrence of a request to empty the RXFIFO, which is generated when an element is written into the FIFO, and the FIFO filling level is equal or greater than the set threshold level. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.RXEN = 1 . Writing 0 has no effect.
PT1F	11	rwh	Phase Transition 1 Flag Flags an occurrence of a PT1 event, as selected with the GLOBALCON1.PT1 , and triggers an interrupt if GLOBALCON1.PT1EN = 1 . Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
PT2F	12	rwh	Phase Transition 2 Flag In master mode, flags an occurrence of a PT2 event, as selected with the GLOBALCON1.PT2 , and triggers an interrupt if GLOBALCON1.PT2EN = 1 . In slave mode, set by the SLSI deactivated event. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
USRF	15	rwh	User Interrupt Request Flag Flags an occurrence of an USR event. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.USREN = 1 . Writing 0 has no effect.

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
TXFIFO LEVEL	[18:16]	rh	TXFIFO Filling Level Shows how many entries in the TXFIFO are waiting for transmission 000 _B 0 001 _B 1 010 _B 2 011 _B 3 100 _B 4 ... _B reserved
RXFIFO LEVEL	[21:19]	rh	RXFIFO Filling Level Shows how many entries in the RXFIFO are waiting for software to move them to RAM 000 _B 0 001 _B 1 010 _B 2 011 _B 3 100 _B 4 ... _B reserved
SLAVESEL	[25:22]	rh	Currently Active Slave Select Flag Displays the currently active slave select.
RPV	26	rh	Received Parity Value Displays the last received parity bit, if parity was enabled. Else if the parity is disabled, reads 0.
TPV	27	rh	Transmitted Parity Value Displays the last transmitted parity bit, if parity was enabled. Else 0.

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
PHASE	[31:28]	rh	Flags the ongoing phase Displays the current phase number. Relevant only in master mode. In slave mode this bit field indicates always 0. 0000 _B Wait 0001 _B Idle A 0010 _B Idle B 0011 _B Lead 0100 _B Data 0101 _B Trail 0110 _B Expect 0111 _B Lead Strobe 1000 _B Trail Strobe Not 0 means busy.
0	13, 14	r	Reserved Read as 0; should be written with 0.

Note: Slave TXFIFO underflow error is activated if the transmission has been started by the master at the time when the slave FIFO was empty, or at the same moment updated. In the second case inconsistent data will be transmitted.

Note: Reading the TXFIFO filling level bit field returns a value which can be used to calculate how many writes can be performed by a CPU without causing an overflow (in case no DMA is programmed to access the TXFIFO in parallel). For example, if the TXFIFO level was one, maximum three (TXFIFO depth of four minus one) write accesses are possible. Due to the volatility of the bit field, the filling level can go down in some nanoseconds after the read.

Note: Reading the RXFIFO filling level bit field returns a value which shows directly how many reads can be performed by a CPU without causing an underflow. Due to the volatility of the bit field, the filling level can go up in some nanoseconds after the read.

Note: Reading the PHASE bit field shows a previous phase of the frame, and a PT1F and PT2F flags indicate previous phase transitions. If the communication speed is not too high or the phases duration not very short compared to the software latency delays, which would normally be the case, these would be the latest completed phase and the latest phase transitions. Nevertheless, in case of high baud rates, the duration of the phases must be taken

Queued Synchronous Peripheral Interface (QSPI)

into consideration, but only if these bit fields are used in an application, and not only for debugging purposes.

Queued Synchronous Peripheral Interface (QSPI)

STATUS1

 (>> [Table 20-2](#) register overview)

STATUS1
Status Register 1

 (44_H)

 Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SPD	SPD	BRD	BRD							0					
rw	rw	rw	rw							r					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0										
r		r		r		r								rh	

Field	Bits	Type	Description
BITCOUNT	[7:0]	r	Number of the bit shifted out Supports up to 256 bits. BITCOUNT = 0 indicates two states: no transmission and transmission of the first bit. The differentiation can be made by reading the phase information. BITCOUNT = 1 indicates transmission of the second bit and so on until 256. After transmission of the last bit the counter goes to zero.
BRDEN	28	rw	Baud Rate Deviation Enable Enables the signal path. 0 _B disabled 1 _B enabled
BRD	29	rw	Baud Rate Deviation Flag Shows if baud rate deviation has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0 _B no event 1 _B event detected
SPDEN	30	rw	Spike Detection Enable Enables the signal path. 0 _B disabled 1 _B enabled

 Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
SPD	31	rwh	Spike Detection Flag Shows if spike has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0 _B no event 1 _B event detected
0	[27:8]	r	Reserved Read as 0; should be written with 0.

If the **STATUS.ERRORFLAGS[2]** bit is cleared via **FLAGSCLEAR.ERRORCLEARS[2]**, the both flags SPD and BRD are automatically cleared.

Queued Synchronous Peripheral Interface (QSPI)

SSOC

SSOC controls the level of each slave select and enables/disables each one individually.
 (>> [Table 20-2](#) register overview)

SSOC

Slave Select Output Control Register (48_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
OEN	[31:16]	rw	Enable Bits for the SLSO Outputs In disabled state the SLSO output drives the idle level as defined by the AOL bit field. "0" at certain position means that the corresponding SLSO is disabled. "1" means enabled.
AOL	[15:0]	rw	Active Output Level for the SLSO Outputs The idle level is the inverted one. "0" at certain position means active low level for the corresponding SLSO. "1" means active high.

Queued Synchronous Peripheral Interface (QSPI)

FLAGSCLEAR

(>> [Table 20-2](#) register overview)

FLAGSCLEAR

Flags Clear Register (54_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
ERROR CLEARS	[8:0]	w	<p>Write Only Bits for Clearing the Error Flags Writing 1 clears the corresponding error flag in the ERORRFLAGS bit field. Reading returns 0.</p> <p>00000000_B No clear 00000001_B Parity Error clear 00000010_B Unexpected Configuration Error clear 00000100_B Baud Rate Error clear 00001000_B TXFIFO overflow clear 00010000_B TXFIFO underflow clear 00100000_B RXFIFO overflow clear 00100000_B RXFIFO underflow clear 01000000_B EXPECT time out clear 10000000_B SLSI misplaced inactivation clear</p>
TXC	9	w	<p>Transmit Event Flag Clear Write of 1 clears the STATUS.TXF bit. Write of 0 has no effect. Read delivers 0.</p> <p>0_B no action 1_B clear</p>

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
RXC	10	w	Receive Event Flag Clear Write of 1 clears the STATUS .RXF bit. Write of 0 has no effect. Read delivers 0. 0 _B no action 1 _B clear
PT1C	11	w	PT1 Event Flag Clear Write of 1 clears the STATUS .PT1F bit. Write of 0 has no effect. Read delivers 0. 0 _B no action 1 _B clear

USRC	15	w	User Event Flag Clear Write of 1 clears the STATUS .USRF bit. Write of 0 has no effect. Read delivers 0. 0 _B no action 1 _B clear
0	13, 14	rw	Reserved Read as 0; should be written with 0.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Queued Synchronous Peripheral Interface (QSPI)

XXLCON

The XXLCON register provides counter for sending frames with very long blocks of data by extending the long data mode. It avoids a need for further BACON entries, like those needed in continuous mode.

Data length in this register overrides the **BACON.DL** setting in XXL mode, when **BACON.BYTE=1** and **BACON.DL=0**. The data is sent to the slave as defined by **BACON.CS** bit field.

(>> **Table 20-2** register overview)

XXLCON

Extra Large Data Configuration Register(58_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
XDL	[15:0]	rw	<p>Extended Data Length Defines the length of the data block in bytes in range of 2 to 65536. Overrides BACON.DL when BACON.BYTE=1 and BACON.DL=0.</p> <p>0_D 2 bytes 1_D 2 bytes ..._D ... 65535_D 65536 bytes</p>

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
BYTECOUNT	[31:16]	r	<p>Extended Data Length</p> <p>In the XXL mode, shows the current state of the internal byte down counter (bytes remaining to be sent). In short and long modes, the value of this bit field is don't care.</p> <p>0_D zero bytes</p> <p>1_D two bytes</p> <p>..._D ...</p> <p>65535_D 65536 bytes</p>

Queued Synchronous Peripheral Interface (QSPI)

MIXENTRY

(>> [Table 20-2](#) register overview)

MIXENTRY

MIX_ENTRY Register (5C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
E	[31:0]	w	Entry Point to the TxFIFO

BACONENTRY

(>> [Table 20-2](#) register overview)

BACONENTRY

BACON_ENTRY Register (60_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
E	[31:0]	w	Entry Point to the TxFIFO

Queued Synchronous Peripheral Interface (QSPI)

DATAENTRY

(>> [Table 20-2](#) register overview)

DATAENTRY_x (x=0-7)

DATA_ENTRY Register x (64_H + x*4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
E	[31:0]	w	Entry Point to the TxFIFO

RXEXIT

(>> [Table 20-2](#) register overview)

RXEXIT

RX_EXIT Register (90_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
E	[31:0]	r	Read Point from the RxFIFO

Note: The RXFIFO has a property that a read access from an empty RXFIFO generates an underflow interrupt, and delivers only "1" bits, which overrules the reset value. Therefore reading from a non initialized RXFIFO delivers all "1" and not all "0".

Queued Synchronous Peripheral Interface (QSPI)

RXEXITD

The register **RXEXITD** provides a non-destructive address, showing the next available value in the RXFIFO.

(>> **Table 20-2** register overview)

RXEXITD

RX_EXIT Debug Register (94_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
E	[31:0]	r	Read Point from the RxFIFO

*Note: This register provides a non-volatile access to the RXFIFO. It delivers the same value as **RXEXIT**, but without affecting read pointer and the filling level of the RXFIFO.*

Queued Synchronous Peripheral Interface (QSPI)

20.10 Operation Modes

Generally, the QSPI module transmits a RAM queue of an arbitrary length, fed by a DMA module, and makes pauses between the queues. The QSPI module does not know anything about the queue length or the current position within the queue or the future schedule of the messages that may come.

If the QSPI module gets a request for switching off the clock or pausing the module, it disables all service request lines.

The QSPI module provides two options for switching off the clocks or pausing the module: hard suspend (as soon as possible regarding for example the length of interrupt request pulses), and soft suspend (transition to the PAUSE state with finishing the current frame). The requests can be triggered by hardware signals (disable, suspend, sleep) or by software write to **GLOBALCON.EN** bit.

Disable, Pause and Run

After being enabled by clearing the **CLC.DISR** bit, the QSPI enters the PAUSE state. In this state, the QSPI module can be initialized, the TXFIFO pre-filled, and then, by setting the **GLOBALCON.EN** bit, put into a RUN state.

The software requests PAUSE state of the running module by clearing the **GLOBALCON.EN** bit. The software can detect that the QSPI module has reached the PAUSE state by polling for the **GLOBALCON.EN=0** and **STATUS.PHASE=0** (indicating WAIT state, master mode only).

In PAUSE state, the user interface of the module is active. The registers and the FIFOs can be read and written. However, both the receive and transmit state machines are inactive, in master as well as in the slave mode. This allows for reconfiguration of the module without affecting the serial bus.

Queued Synchronous Peripheral Interface (QSPI)

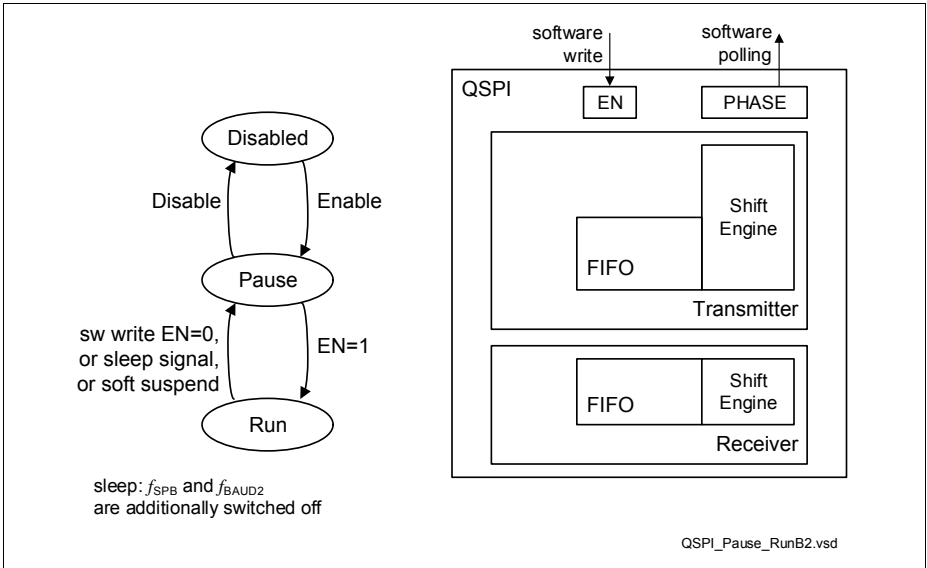

Figure 20-51 Pause and Run Overview

The concept of the PAUSE state is reused for handling the soft OCDS suspend and Sleep requests. In contrast to active Pause state and OCDS suspend, the sleep state has the special property that (due to the low power requirement) both FPI and QSPI clocks are switched off.

Queued Synchronous Peripheral Interface (QSPI)

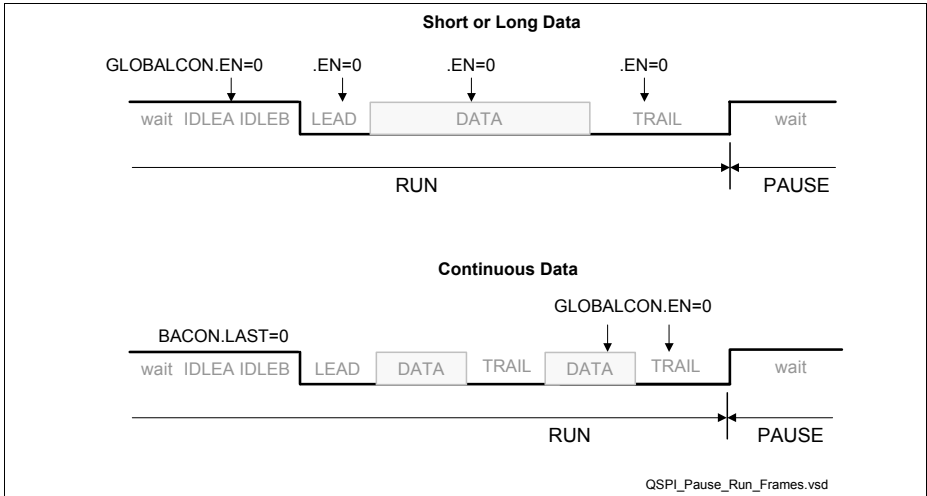

Figure 20-52 Entering the Pause State

If a running module receives a request to PAUSE, it waits for the end of the TRAIL phase. For all modes (Short, Long and Continuous), the PAUSE state is indicated by **GLOBALCON.EN=0** and **STATUS.PHASE=0**, master mode only.

Queued Synchronous Peripheral Interface (QSPI)

20.10.1 OCDS Suspend

The OCDS hard suspend request, for debugging purposes, simply freezes the QSPI module in the current state. No signal is changed including the service request lines, which remain frozen in the current state.

The QSPI responds to an OCDS soft suspend request by entering the PAUSE state immediately after the subsequent end of a trail phase, and then sending acknowledge (see [Figure 20-53](#)). The behavior is the same as for entering the **Sleep Mode**.

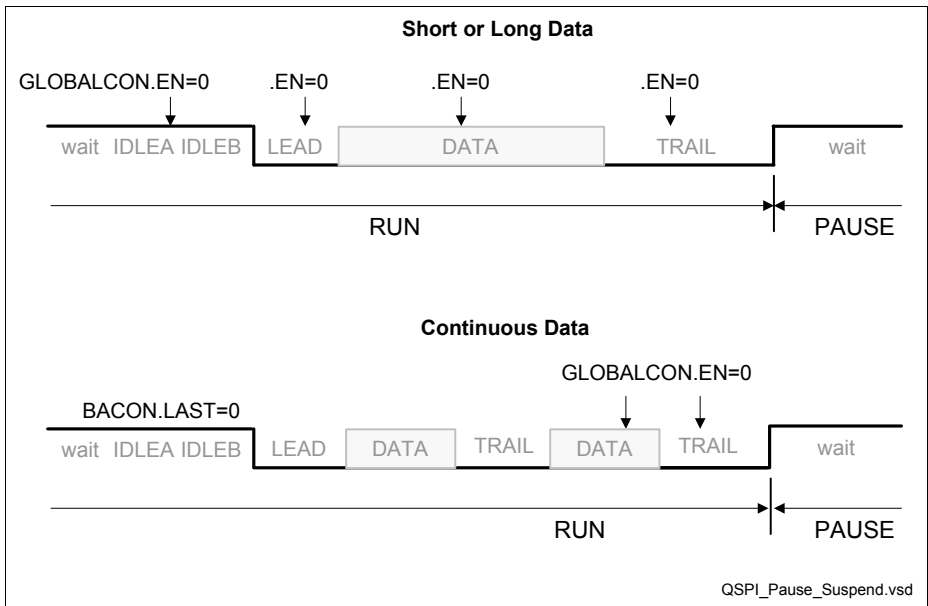

Figure 20-53 Entering the Sleep, Soft Suspend, and Disable State

Reading the FIFO entries by the Cerberus (detected by the FPI master tag) does not modify the FIFO content nor the read and write pointers.

Queued Synchronous Peripheral Interface (QSPI)

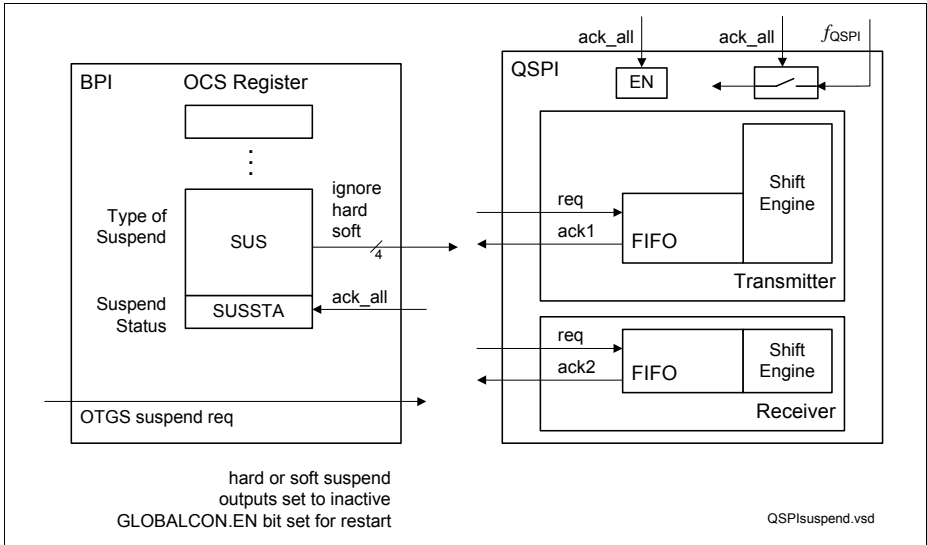

Figure 20-54 Suspend Overview

Note: In Hard Suspend Mode the QSPI kernel clock is switched off immediately. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a QSPI kernel reset might not be sufficient to bring the system into a defined state.

Queued Synchronous Peripheral Interface (QSPI)

20.10.2 Sleep Mode

Sleep signal is a system wide hardware signal requesting from all modules to go to low power saving state as soon as possible. For the QSPI module, going to sleep mode can be disabled or enabled by setting or clearing the CLC.EDIS bit. The module enters the sleep as soon as possible and remains in this state as long as the hardware sleep signal is active. Upon deactivation of the sleep signal, the QSPI wakes in PAUSE state (**GLOBALCON.EN** bit is cleared by the QSPI module) and waits for the software to enable the **GLOBALCON.EN** bit.

If CLC.EDIS bit is cleared, the sleep mode is enabled and the module enters the sleep state:

in master mode

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields.
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty
- or immediately if the SLSI is inactive (the one selected by PISEL)

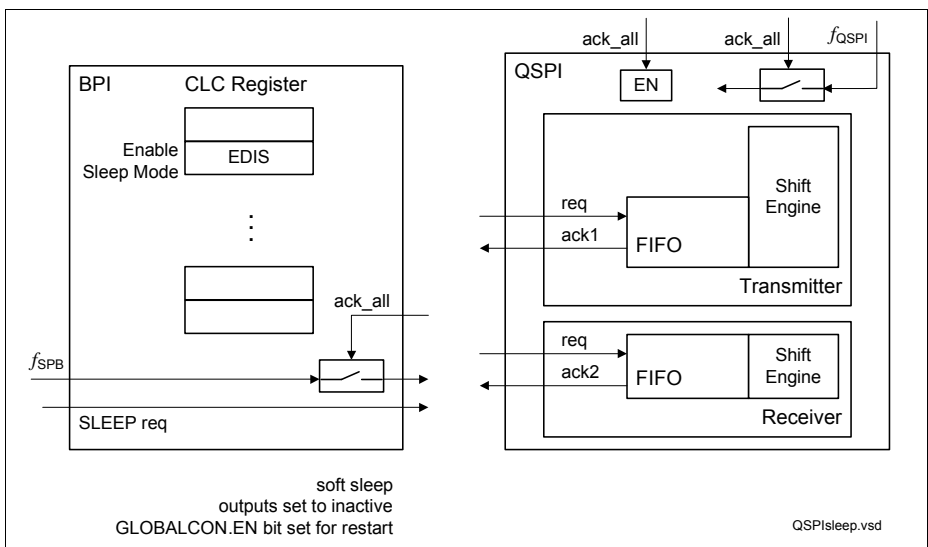

Figure 20-55 Sleep Overview

Queued Synchronous Peripheral Interface (QSPI)

It is responsibility of the user software to have the sleep enabled in a safe time intervals, where no race conditions or pipeline effects between the QSPI module and the DMA can occur in case of sleep request.

Note: CLC disable request and sleep request block immediately kernel register write accesses. This includes also the TXFIFO access. Therefore if the module expects more data (like in long or continuous mode), it will enter the expect phase and remain there and never do an acknowledge and enter the required state. Periodic timeout interrupts will be generated. Therefore it is not recommended to request a sleep or disable during an ongoing long or continuous transfer.

20.10.3 Disabling the QSPI

The software can switch off the QSPI module by setting the CLC.DISR bit. It is responsibility of the user software to issue a disable request in a safe time interval, where no race conditions or pipeline effects between the QSPI module and the DMA can occur. This is no issue if the switch-off procedure is one-way, that is no continuation of operation without reinitialization/reset of the module is expected. **GLOBALCON.EN** bit is cleared.

The QSPI module itself behaves in the following way.

in master mode like entering the sleep mode:

- after ending the TRAIL delay if a transmission is in progress
- or immediately if the module is in WAIT state

in slave mode

- after the bit counter has counted the full predefined number of bits as defined in GLOBALCON.DL and BYTE bit fields, if a transmission is ongoing or
- immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty

Queued Synchronous Peripheral Interface (QSPI)

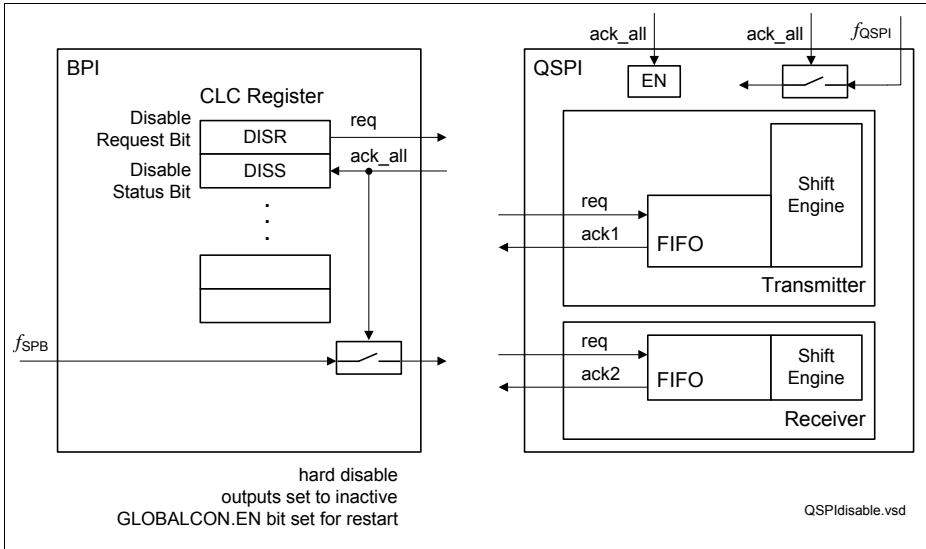

Figure 20-56 Disable Overview

20.11 Reset Behavior

There are two sources of reset:

- BPI (Bus Peripheral Interface)
- Reset bits in the kernel register - **GLOBALCON.RESETS**

BPI reset puts the whole QSPI module in reset state. All outputs get the reset value.

Software writing the **GLOBALCON.RESETS** bit field contains bits for resetting: TXFIFO, RXFIFO, shift state machine, register file. Setting all the bits in a single write resets the whole module.

Queued Synchronous Peripheral Interface (QSPI)

20.12 QSPI Module Implementation

This section describes the interfaces of the QSPI module instances with the clock control, port connections, interrupt control, and address decoding. There are 4 module instances, QSPI0 to QSPI3.

20.12.1 Module Identification Registers

The reset values of the QSPIx_ID module identification registers are 00C0 C0XX_H.

20.12.2 Interfaces of the QSPI Modules

Figure 20-57 shows the implementation details and interconnections of the QSPI module.

Each of the QSPI modules is supplied with a separate clock control, interrupt control, and address decoding logic. Two interrupt outputs can be used to generate DMA requests. The QSPIx I/O lines are connected to the ports as described in the pinning and ports chapters.

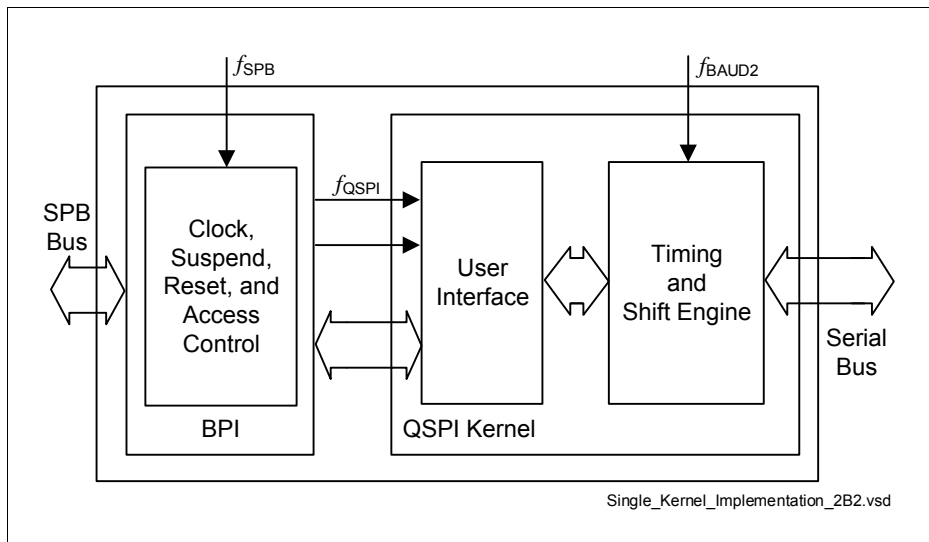

Figure 20-57 Module Implementation Overview

Queued Synchronous Peripheral Interface (QSPI)

20.12.3 On-Chip Connections

This section describes the on-chip connections of the QSPIx module instances.

SCU Connections

Wake-up from sleep is done by the SCU.ERU triggering a software interrupt on a programmable edge on SLSI pin.

DMA Requests

There are no dedicated DMA request lines. The interrupt or service request signals are general purpose request signals that can be routed to each service provider.

Port/Pin Connections

The connections of the QSPI modules to the pins / ports is described in the chapters regarding the pinning and the ports.

The MTSR and MRST signals are also mapped to LVDS output and input pads. For details see the Ports chapter and the Pinning chapter.

Note: If LVDSH receiver pad is used, the software must take into account the corresponding control and configuration bits, located in the HSCT module and in the corresponding port registers.

Input signals not connected to ports/pins are connected to the following voltage levels:

- The unconnected SCLKI signals are connected to low level "0"
- The unconnected SLSI signals are connected to (inactive) high level "1"
- The unconnected MRST input signals are connected to low level "0".

Queued Synchronous Peripheral Interface (QSPI)

20.12.4 QSPI Related External Registers

Figure 20-58 summarizes the module-related external registers which are required for QSPI programming. These are:

- port registers and
 - service request node registers,
- described in the corresponding chapters.

Figure 20-58 Implementation-specific Special Function Registers

Queued Synchronous Peripheral Interface (QSPI)

20.12.4.1 BPI_FPI Module Registers

System Registers

Figure 20-59 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC should be mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_FPI register is to map them to the end of the peripheral address range.

BPI_FPI Registers Overview

Figure 20-59 BPI_FPI Registers

The writes of the bus masters to the QSPI module is controlled by Access Protection registers ACCENx.

The QSPI implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{clk} module clock signal, sleep mode and disable mode for the module.

Queued Synchronous Peripheral Interface (QSPI)
CLC
Clock Control Register
(00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	Sleep Mode Enable Control Used to enable the module's sleep mode. 0 _B Enabled 1 _B Disabled
0	[31:4]	r	Reserved Read as 0; should be written with 0.
0	2	rw	Reserved Should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

Queued Synchronous Peripheral Interface (QSPI)
OCS
OCDS Control and Status
(E8_H)

0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0. The bits [4:0] are rw (readable and writable).

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Queued Synchronous Peripheral Interface (QSPI)

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

Queued Synchronous Peripheral Interface (QSPI)

ACCEN1

Access Enable Register 1

(F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Queued Synchronous Peripheral Interface (QSPI)

KRST0
Kernel Reset Register 0
(F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST

Queued Synchronous Peripheral Interface (QSPI)

bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1
(F0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Status Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

Queued Synchronous Peripheral Interface (QSPI)

KRSTCLR
Kernel Reset Status Clear Register (EC_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Queued Synchronous Peripheral Interface (QSPI)

20.12.4.2 Interrupt Control Registers

The interrupts of the QSPI module are controlled by six service request control registers, located in the IR (Interrupt Router) module:

- QSPIxTX Transmit Interrupt
- QSPIxRX Receive Interrupt
- QSPIxERR Error Interrupt
- QSPIxPT Phase Transition Interrupt
- QSPIxHC High Speed Capture Interrupt
- QSPIxU User Interrupt

Queued Synchronous Peripheral Interface (QSPI)

20.13 High Speed Input Capture

The HSIC sub-module provides high precision measurement of relatively low speed input signals. It contains 15-bit timer can be configured to continuously measure:

- whole period (rising edge to rising edge),
- high time (rising edge to falling edge) or
- low time (falling edge to rising edge)
- whole period (falling edge to falling edge)

The resolution of the counter is f_{BAUD2}^{-1} . The result is provided in a capture register and an interrupt is raised after each capture.

Figure 20-60 HSIC Modes of Operation

Each capture event causes the content of a 15-bit counter to be captured to the CAPCON.CAP bit field, see Figure 20-61.

Queued Synchronous Peripheral Interface (QSPI)

Figure 20-61 Capture Timer Architecture

The interrupt raised by the capture event is routed to the HC interrupt, see [Figure 20-62](#). The flag bit, set, clear and select bits are located in the **CAPCON** register.

The first interrupt after enabling the HSIC block by setting **CAPCON.EN** may deliver random **CAPCON.CAP** value, depending on the level of the input signal at the moment of enabling. Therefore, the software should discard the first value captured immediately after enabling the HSIC block.

Figure 20-62 HSIC Interrupt Path

Queued Synchronous Peripheral Interface (QSPI)

Disable Request

Clearing the disable request bit **CLC.DISR** switches the clock of the whole QSPI module including the HSIC block on.

Setting the bit **QSPI2_CAPCON.EN** enables the HSIC sub-module. The counter first enters wait state, waiting for the first start edge as defined in the **QSPI2_CAPCON.EDGECON**. Afterwards, it operates according to the **Figure 20-60**.

If **CLC.DISR** is cleared when **QSPI2_CAPCON.EN = 1**, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON.EDGECON**) to start counting, and continues operating according to the **Figure 20-60**.

Debug Suspend

Suspend of the QSPI module causes suspend of the HSIC; separate suspend is not possible. Nevertheless, the targeted use cases are either HSIC timer active, or QSPI communication, but not both.

Active and enabled hard debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter continues counting. Writing to a register in hard suspend state causes the HSIC block to receive a couple of clock cycles, which causes the counter to increase its value.

Active and enabled soft debug suspend signal stops the HSIC block immediately (QSPI kernel disabled). After the suspend signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON.EDGECON**) to start counting, and continues operating according to the **Figure 20-60**.

Sleep Mode

Active and enabled sleep signal stops the HSIC block. After the sleep signal is deactivated, the counter is cleared to zero, waits for the next start edge (as defined in **QSPI2_CAPCON.EDGECON**) to start counting, and continues operating according to the **Figure 20-60**.

Reset

Each reset of the QSPI module causes reset of the HSIC sub-module; separate reset is not possible.

Queued Synchronous Peripheral Interface (QSPI)

20.13.1 HSIC Registers

20.13.1.1 Register Description

CAPCON

CAPCON is the only control register for the HSIC sub-module. It contains the configuration, control bits and the captured value of the counter.

(>> [Table 20-2](#) register overview)

QSPI2_CAPCON

Capture Control Register (A0_H) Reset Value: 0000 0000_H

QSPI3_CAPCON

Capture Control Register (A0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CAP	[14:0]	rh	Captured Value Provides the latest capture value from the capture timer.
OVF	15	rh	Overflow Flag Signals if an overflow event of the capture timer occurred in the latest measurement. Shows a value of 1 if one or more overflows of the capture timer occurred during the latest measurement. Each capture event refreshes this bit with the new value.

Queued Synchronous Peripheral Interface (QSPI)

Field	Bits	Type	Description
EDGECON	[17:16]	rw	Edge Configuration Configure the capture mode of the counter, defining which edge starts the counting, which edge captures its contents. 00 _B RR mode (rising edge to rising edge) 01 _B RF mode (rising edge to falling edge) 10 _B FR mode (falling edge to rising edge) 11 _B FF mode (falling edge to falling edge)
INS	[19:18]	rw	Input Selection Selects one of four input lines for the capture signal. 00 _B INA selected 01 _B INB selected 10 _B INC selected 11 _B IND selected
EN	20	rw	Enable Bit of the Capture Timer Enables the capture timer clock. Enabled timer waits for the next start edge as defined in EDGECON, before it starts counting. 0 _B disabled 1 _B enabled
CAPC	28	w	Capture Flag Clear Writing 1 to this bit clears the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPS	29	w	Capture Flag Set Writing 1 to this bit sets the flag CAPF. Writing 0 has no effect. Returns 0 on read.
CAPF	30	rh	Capture Flag Indicates if a capture event has occurred since the last clear event by the bit CAPC.
CAPSEL	31	rw	Capture Interrupt Select Bit Select if the capture events are routed to the HC interrupt line. 0 _B not routed (capture interrupt disabled) 1 _B routed (capture interrupt enabled)
0	[27:21]	r	reserved

20.13.2 HSIC Implementation

HSIC block is available in the QSPI2 and QSPI3.

Queued Synchronous Peripheral Interface (QSPI)**20.13.2.1 Connection to the pins**

For the connections to the pins, see the pinning chapter.

The unconnected input lines are tied to zero.

Queued Synchronous Peripheral Interface (QSPI)

21 High Speed Serial Link (HSSL)

The HSSL module provides point-to-point communication of both single data values and of large data blocks, called streams. The communicating devices can be complex microcontrollers, or a microcontroller and a device with only basic execution capabilities. There are four channels to transfer single values to/from target. They support direct writing of 8/16/32 bit data from the initiator into a target's register, as well as reading a value from a target, performed by a modules internal master on the target side. For transferring large data blocks there is a channel containing FIFOs. The HSSL module implements Transport Layer tasks and hands over the data to another module which provides Data Link Layer and Physical Layer services, data serialization and transmission. All transfers are protected by safety features like CRC and timeout.

Figure 21-1 Block Diagram HSSL

High Speed Serial Link (HSSL)**Features**

- Connects microcontroller to microcontroller or to any digital device
- Writing a single 8 / 16 / 32 bit data value into the register of a target device
- Reading single data from an 8 / 16 / 32 bit register of a target device
- Support of 32-bit address range
- Transfers protected by CRC16
- Programmable time outs for detection of blocked answer transfers
- Automatic frame transfer ID generation for detection of dropped frames
- Support of DMA driven multiple register write / read transfers
- Efficient transmission and reception of large data blocks / streams
- Acknowledge for command and stream frames to reduce latency of error detection
- Two stage FIFOs for transmitting and receiving streaming data
- Automatic FIFO flush when entering the run mode, for error handling
- Write protection by an external Memory Protection Unit MPU
- Remote trigger of event / interrupt in the target device by the initiator
- Identification of the target by the JTAG ID number
- Feature set identification of the HSSL module possible by using the JTAG ID number
- Access protection from an external master

Description

The HSSL module generates all necessary protocol formats in order to enable two devices to communicate to each other. Two basic modes are supported.

In register transfer mode the transmitter (“sending device”) provides an address and a data value by writing them into dedicated registers of the HSSL module. The HSSL module puts it into an envelope (called frame) and forwards it via physical layer to the target device. The target takes the information out of the frame and writes the received data into the address which came in the same frame as the data. If the sender wants to read the content of a register or a memory location, it simply sends only the address. The target device reads the value from the specified location and replies it to the sender by transferring it through an answer frame, which has a format of it’s own.

The transfer of register / memory contents is protected by several security levels. A 16 bit CRC value (called CRC16) is attached to the end of each frame. Each transfer process triggers a watchdog, which makes sure that the communication happens within a deterministic schedule. The target device itself offers the capability to define access windows, which allow reading or writing only from / into certain address ranges.

Each frame must be acknowledged by the target by sending an appropriate response frame. If the response frame does not come inside a predefined time window, the initiator module triggers a timeout interrupt.

In data stream mode data blocks of user defined size can moved from the memory of the sending device into the memory of the target device. A DMA master, which can be configured with any source address and source length, autonomously fetches data, breaks it into smaller blocks of programmable size, and puts it into a FIFO. The lower level companion module of the HSSL module empties the FIFO from the “other side” to the physical lines, which connect two devices. In the target device receives a structure, which is inverse to the sender system, the data blocks, puts them into a FIFO, which is in turn emptied by a DMA master into the target memory.

All streaming data transfers are subject to the protection features which are available for the register transfer mode.

After module reset, most registers are only released for read for remote access. They have to be unlocked by the local SW.

In order to ensure consistent initialization of the communication channel there is a possibility to determine the feature set of the module by using the JTAG ID of the device, which uniquely identifies the available HW options of the module. ASIC versions of the HSSL interface may only employ stripped down instances.

High Speed Serial Link (HSSL)

21.1 Lower communication layers module (HSCT)

The lower level companion module/logic controls the lower communication layers positioned between two devices, the data and the physical level.

The chip to chip interface employs a digital interface for inter chip communication between a master IC and a slave IC. The interface is capable of running in a master or in a slave mode. During configuration phase the role of the Interface (master or slave) has to be defined. It is not intended to change the system role during an application.

The interface consists of a full-duplex RX and TX high-speed data interface based on double ended differential signals (in total 4 lines) and a master clock interface (SYS_CLK). The master IC owns the crystal and provides the clock to the slave. The interface reset is derived from the System reset and provided by chip internal reset signaling.

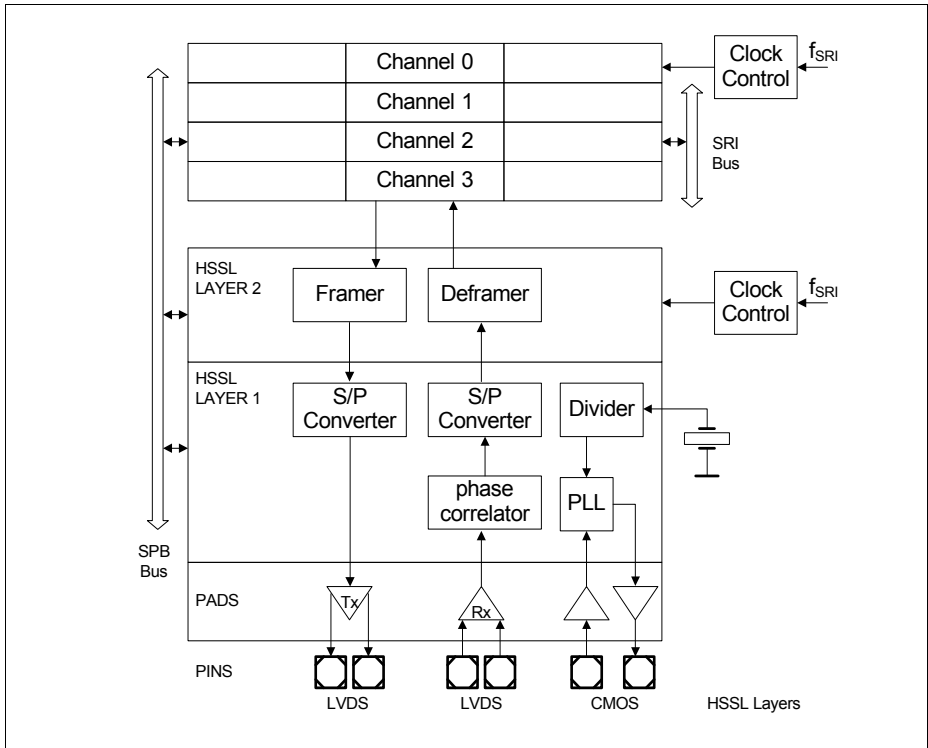

Figure 21-2 Physical Layer

High Speed Serial Link (HSSL)**Features:**

- Transmission of symbol information from the master IC to the slave IC
- Receive symbol information sent from the slave IC to the master IC
- System Clock provided by the master IC (crystal owner) to the slave IC
- Exchange of control information in both directions
- Clear To Send indication in both directions
- Unsolicited status in both directions
- Regular data transfer in both directions based on data channels
- Master IC data transfer speed 5 MBaud and 320 MBaud
- Three slave IC data transfer speeds available based on 20 MHz SYS_Clk:
 - 5 MBaud (low speed)
 - 20 MBaud (medium speed)
 - 320 MBaud (high speed)
- Two slave IC data transfer speeds available based on 10 MHz SYS_Clk (lower EMI):
 - 5 MBaud (low speed)
 - 320 MBaud (high speed)
- The interface is based on IEEE 1596.3 LVDS IOs
- To reduce the voltage swing a configuration option is available

21.2 HSSL Protocol Definition

This section describes the high level protocol definition of the HSSL interface.

The HSSL communication normally consists of two stage transactions, sending a command and an receiving a response. It involves two participants:

- an initiator, which starts a transaction by sending a command
- a target, which responds to the command

21.2.1 List of Abbreviations, Acronyms, and Term Definitions

ACK - Acknowledge Frame

NACK - Not Acknowledge Frame (Target Error Frame)

CRC - Cyclic Redundancy Check

HSSL - High Speed Serial Link

TO - Time Out

TT - Transaction Tag

TTERR - Transaction Tag Error

SPB - Serial Peripheral Bus

SRI - Shared Resource Interconnection

SoC - System on Chip

Initiator - Device that starts a HSSL transaction by sending a command frame

Target - Device that responds to a command frame sent by an initiator

21.2.2 Frame Types

The HSSL module generates a serial frame by:

- taking the payload delivered by a CPU or a DMA
- first wrapping it in a HSSL frame by adding header and CRC fields, and then
- wrapping the HSSL frame in a HSCT frame by adding Sync, Header and End bit fields (see [Figure 21-3](#))

High Speed Serial Link (HSSL)

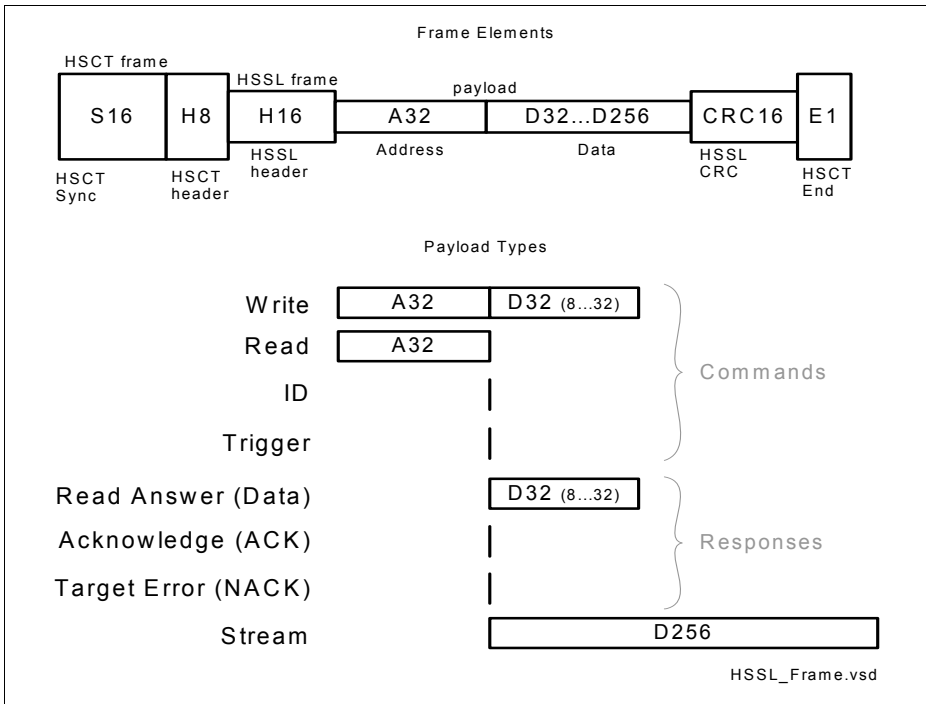

Figure 21-3 HSSL Frame Types

There are several types of frames:

Command Frames

Command frames are sent by the initiator to request an action by the target. There are four types of command frames:

- **Write Frame**
 - Used by the initiator to request the target controller to write the data to the address, both provided by the initiator.
- **Read Frame**
 - Used by the initiator to request the target controller to read and deliver a content from an address from its address space.
- **Read ID Frame**
 - Used by the initiator to request the target controller to read and deliver a content uniquely defining the target device. The answer is a standard Read Data Answer Frame.
- **Trigger Frame**

High Speed Serial Link (HSSL)

- Used by the initiator to trigger the trigger interrupt in the target module.

In this document, the command frames are sometimes referred to as WRT frames.

Response Frames

Response frames are sent by the target either to deliver the requested data or to report a successful or unsuccessful completion of a request. There are three types of response frames:

- **Read Data Answer Frame**
 - Used by the target to deliver the data, requested by the initiator with a read command frame. It is frequently referred to as a Data frame.
- **Acknowledge Frame**
 - Used by the target to confirm the completion of a write or trigger command. It is frequently referred to as an ACK frame.
- **Target Error Frame**
 - Used by the target to report the unsuccessful attempt to complete a write or read command. It is frequently referred to as a NACK frame.

Stream Frame

Used by the initiator controller for sending data streams. It behaves similar to a write command frame which contains long 256-bit data block, is acknowledged in the same way, but the acknowledge uses sliding window with depth of 2 (instead of 1 as for the simple command frames).

21.2.2.1 Frame and Payload Lengths

Each type of frame has a single data length associated with it. The length of the frame depends on the length of the payload. Different frame types have different payload lengths, but the payload length for one type is constant for all variations of the frame type. For example all data frames have the same length, although they can carry 8, 16 or 32 bit data. This is due to the fact that the data field in the frame is always 32 bit long, and if the data itself is shorter, it is copied several times to fill in the whole field. The same behavior is valid for the read answer frames.

The rest of the frame, consisting of sync and header fields, has always the same length (see [Figure 21-7](#)).

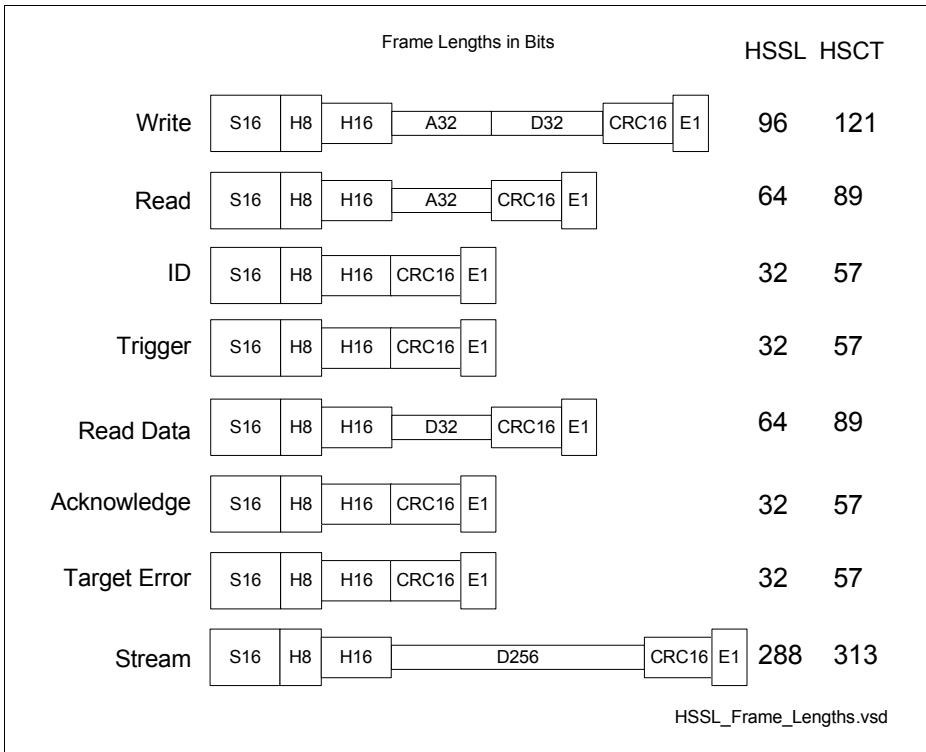

Figure 21-4 Frame Lengths

21.2.2.2 Data Types

There are four types of HSSL data:

- 8-bit
- 16-bit
- 32-bit
- 256-bit stream block

In the case of 8/16/32 bit data types, the transmitted number of bits is always 32, where the shorter data types are copied several times to fill up this length (see [Figure 21-5](#)).

High Speed Serial Link (HSSL)

Figure 21-5 Data Types

21.2.2.3 Cyclic Redundancy Check Field - CRC

The HSSL protocol uses the CRC-16-CCITT polynomial: $x^{16} + x^{12} + x^5 + 1$ with the following standard properties:

- seed: 0xFFFF
- calculation direction: MSB first (header msb to lsb, then payload msb to lsb)
- CRC result direction: MSB first

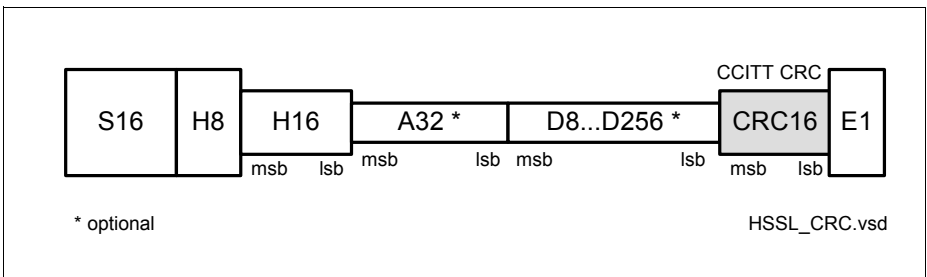

Figure 21-6 CRC Field

21.2.2.4 Header Structure

The HSSL header contains the protocol information that is required additionally to the raw payload data. The HSSL header describes the payload data regarding the length and the type, and carries additional information like channel number code and transaction tag. It also carries stand-alone information in case of frames without payload, like acknowledge and trigger frames.

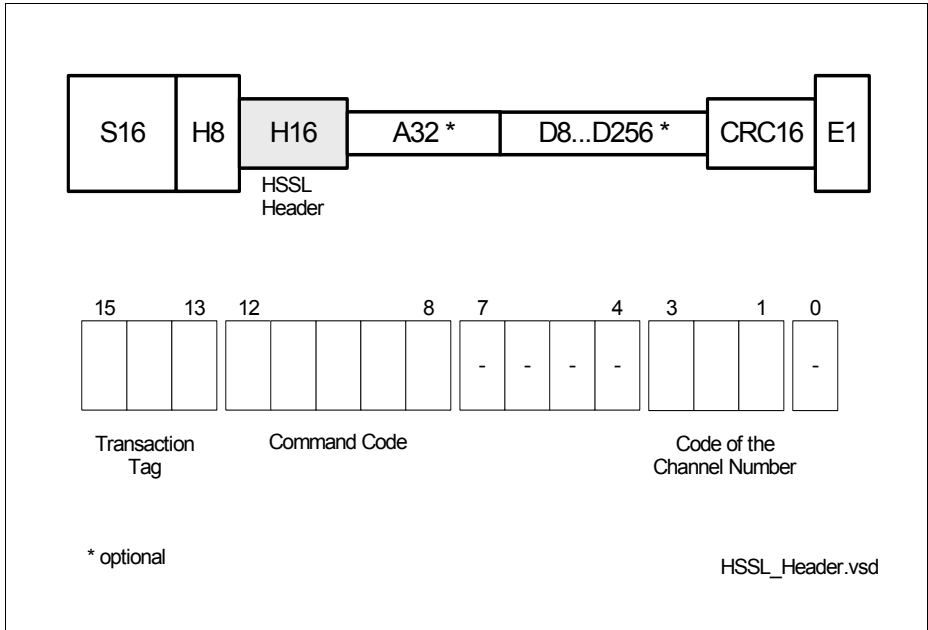

Figure 21-7 Header Types

Note: The unused bits in the header are padded with 0.

Table 21-1 Mapping of HSSL to HSCT channel codes

HSSL Channel Number	HSSL Channel Number, Binary Code	HSSL Channel Number, Special Code	HSCT Channel	HSCT Channel Code
0	000	100	A	0100
1	001	101	B	0101
2	010	110	C	0110
3	011	111	D	0111
4 (reserved)	100	000	E	1000
5 (reserved)	101	001	F	1001
6 (reserved)	110	010	G	1010
7 (reserved)	111	011	H	1011

Note: The HSSL module supports four channels, 0 to 3.

Table 21-2 List of Command Codes

Command Code	Command Description	HSSL Frame Size
00000	Read 8 bit	64
00001	Read 16 bit	64
00010	Read 32 bit	64
00011	RFU (Reserved for Future Use)	-
00100	Write 8 bit with ACK (Acknowledge)	96
00101	Write 16 bit with ACK	96
00110	Write 32 bit with ACK	96
00111	RFU	-
01000	ACK OK	32
01001	ACK Target Error	32
01010	Read Answer OK	64
01011	RFU	-
01100	Trigger with ACK	32
01101	RFU	-
01110	RFU	-

10111	Stream Data with ACK (32 Byte Data)	288
11000	RFU	-
11001	RFU	-
11010	RFU	-
11011	RFU	-
11100	RFU	-
11101	RFU	-
11110	RFU	-
11111	RFU	-

21.2.3 Single and Block Transfers

Single frame transfers are always performed expecting an acknowledge.

21.2.4 Streaming Interface

Stream frame transfers are always performed with acknowledge.

There are only write streams possible. Read streams are not possible.

21.2.5 Sliding Window Protocol

For flow control the HSSL module implements two variants of the “Sliding Window” protocol regarding the sliding window depth:

- depth of one used for command frames
 - The depth of one means that a single timer tracks the arrival of the corresponding response frame. A new command can be sent only after the response to the previous command has been received, or a timeout occurred

High Speed Serial Link (HSSL)

- depth of two used for streaming frames
 - the depth of two means that there are two timers tracking the acknowledge times for the two latest streaming frames. In this case, a second stream frame can be sent although an acknowledge / timeout to the previous stream frame has not been received yet. After the second stream frame, no third stream frame can be sent before the first one has been acknowledged

An example of communication using sliding window with depth of one protocol is shown in **Figure 21-8**. Here, the initiator sends commands originating from one and the same channel, for example channel 0 (labeled with the capital letter “A”), and the corresponding acknowledge frames from the target are labeled with the small letter “a”.

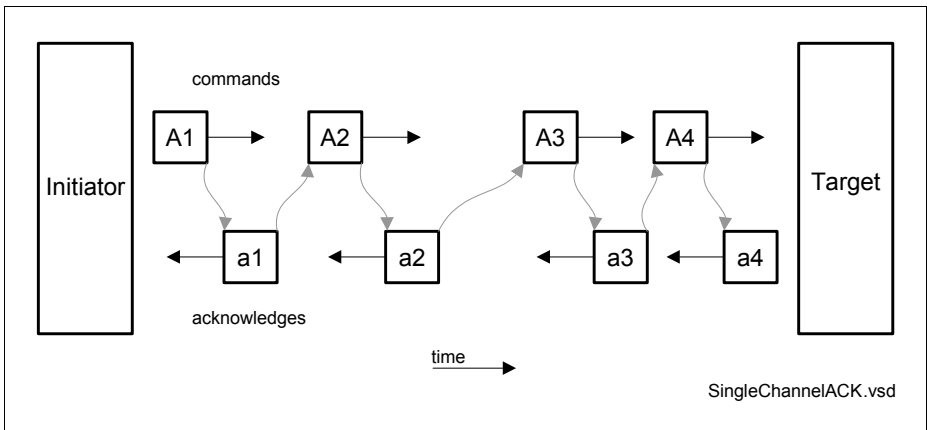

Figure 21-8 Flow Control, Single Channel, Sliding Window With Depth of One

The sliding window protocol requires capability of sending acknowledge frames in the target and timeout timers in the initiator. Every time the target receives a frame without detecting an error, it sends a response / acknowledge to the initiator. If the target detects a frame with a CRC error, it does not send an acknowledge. The missing acknowledge causes a timeout event in the initiator channel.

If the command frames are longer than the acknowledge frames plus the reaction time, like for example in case of streaming, back to back transfers are easily possible, see **Figure 21-9**.

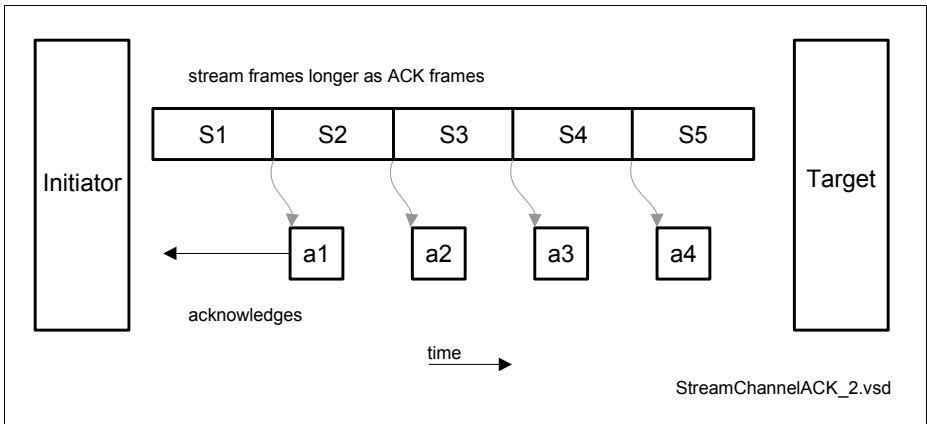

Figure 21-9 Flow Control, Streaming Frames

21.2.6 Error Management

The HSSL protocol defines four types of errors:

- Time Out
- Transaction Tag Error
- CRC Error
- Target Error

Time Out Error

A time out error is detected at the initiator side, if the expected ACK frame was not received within the expected time window. This can occur if a frame had been sent by the initiator, and the target detected an CRC error and did not answer with an acknowledge, or the connection between the initiator and the target is physically damaged in one or the other direction.

Transaction Tag Error

A transaction tag error occurs at the initiator side, if instead the expected ACK frame with the expected TAG number, an acknowledge with an unexpected transaction tag was received. This would indicate a missing frame or missing acknowledge. Transaction tag error generate frames that pass the CRC checking stage.

CRC Error

A CRC Error can occur:

- at the target side, in which case:

High Speed Serial Link (HSSL)

- the CRC error flag is set
- the received command frame with a CRC error is discarded
- no acknowledge frame is sent and
- a channel unspecific EXI error interrupt is generated, if enabled.
- at the initiator side, in which case:
 - the CRC error flag is set
 - the received response frame with a CRC error is discarded
 - a channel unspecific EXI error interrupt is generated, if enabled

Both scenarios lead to a time out at the initiator side.

In both cases the CRC error flag is set at the side receiving the erroneous frame (either initiator or target) and an interrupt is generated, if enabled.

For the purpose of CRC error injection, a bit field with an XOR mask used for toggling the bits of the calculated CRC is provided, see **CRC.XORMASK**. In order to switch on this feature, the E (Endinit) protected bit must be set by the application software. The error injection only influences the generation of the transmitted CRC.

Target Error

A Target Error can occur at the target side, when accessing the target memory a bus error or memory protection error occurs. In such a case, the target responds with an NACK frame indicating the error.

21.2.7 Shift Direction

In general, the HSSL interface makes a copy of a memory location or block from the address space of one microcontroller into the address space of the other microcontroller.

The HSSL module delivers 32-bit parallel data.

The transfer over HSCT serial link is done by using MSB first shifting at 32-bit level.

The overview of the path from the memory to the serial bus is shown in the **Figure 21-10**.

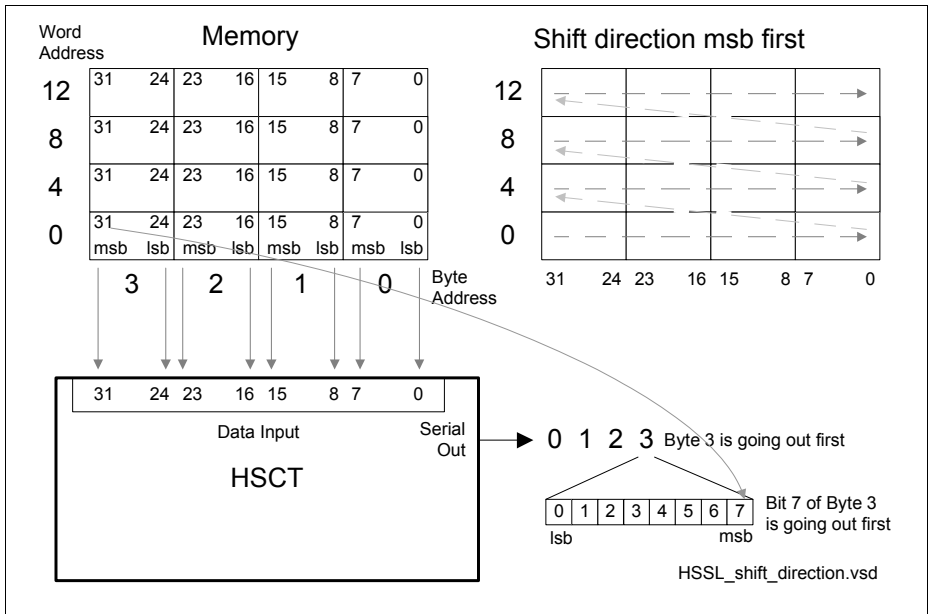

Figure 21-10 Shift Direction in Case of HSCT Layer

Figure 21-11 Stream Frame in Case of HSCT Layer

High Speed Serial Link (HSSL)

21.3 HSSL Implementation

This section describes the implementation of the HSSL protocol.

21.4 Overview

The HSSL module is connected to the SRI bus using a master interface and to the SPB bus using a BPI slave interface.

Additionally, it is connected to the SPB bus using a master interface.

The SRI master interface is capable of performing single and burst reads and writes on the SRI bus. Additionally, the HSSL kernel provides logic for performing streaming communication. The write and read accesses are always performed in User Mode.

The SPB BPI slave interface is used by an SPB master (DMA, CPU, HSSL SPB Master) for writing the HSSL registers, thus configuring the module and performing single read and write operations.

The SPB master interface is capable of performing single read operations, write operations, and streaming communication using BTR4 burst accesses on the SPB bus. The SPB master accesses are always performed in User Mode.

The HSSL module to use the SRI or the SPB master depending on the address of the access. Accesses to the SPB address space are automatically routed to the SPB master, accesses to the SRI address space are automatically routed to the SRI master. The address window $F000\ 0000_H - F7FF\ FFFF_H$ is used for the SPB bus, otherwise SRI.

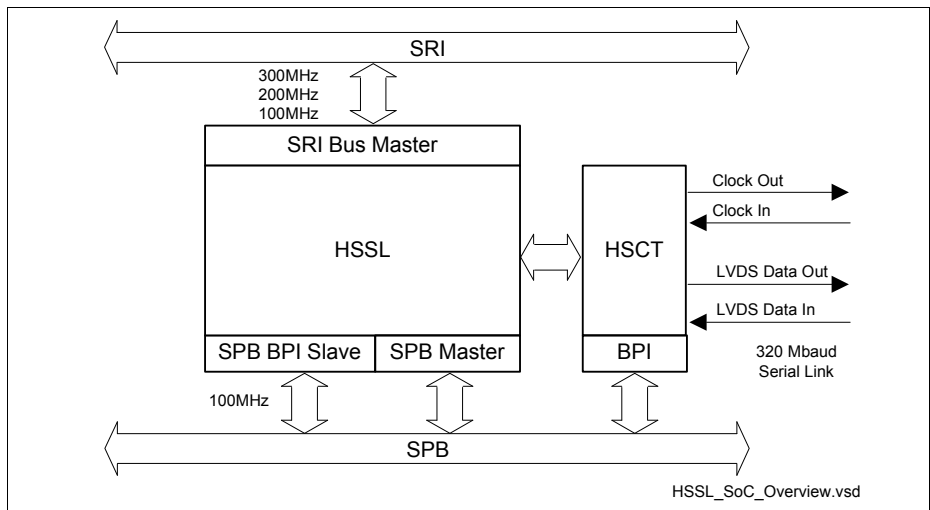

Figure 21-12 HSSL Subsystem Overview

High Speed Serial Link (HSSL)

21.4.1 HSSL Module Operation

The HSSL module consists of separate transmitter and receiver, each containing four channels.

The transmitter contains an arbiter block and a wrapper block, which are common for all channels. The arbiter provides fixed arbitration between the channels which are ready to send when the serial link is available, with channel 0 having the highest priority, and the channel 3 having the lowest priority. The wrapper block generates the CRC.

The receiver unwraps the HSSL frame, discards the frames with a CRC error, and distributes the error free commands and acknowledges to the channels.

A common prescaler generates the time basis for all channels, in particular for their timeout timers.

Figure 21-13 HSSL Layer Architecture

21.4.1.1 Frame Transmission Prioritisation

When more than one frames are pending, an arbitration is performed between them.

Each channel activates two flags: initiator command flag and response flag: channel 0 I0 and R0, channel 1 I1 and R1...

Between the response and command frame request types, the response request type has higher priority. Among the requests of a same type, lower channel number has higher priority, see **Figure 21-14**. A pending frame is indicated with a corresponding request flag in the register **QFLAGS**.

The SRI/SPB bus master sets the response requests ("R" flags).

The software write accesses via the SPB bus set the initiator requests ("I" flags).

The transmit arbiter clears the "I" and "R" flags of the arbitration winner.

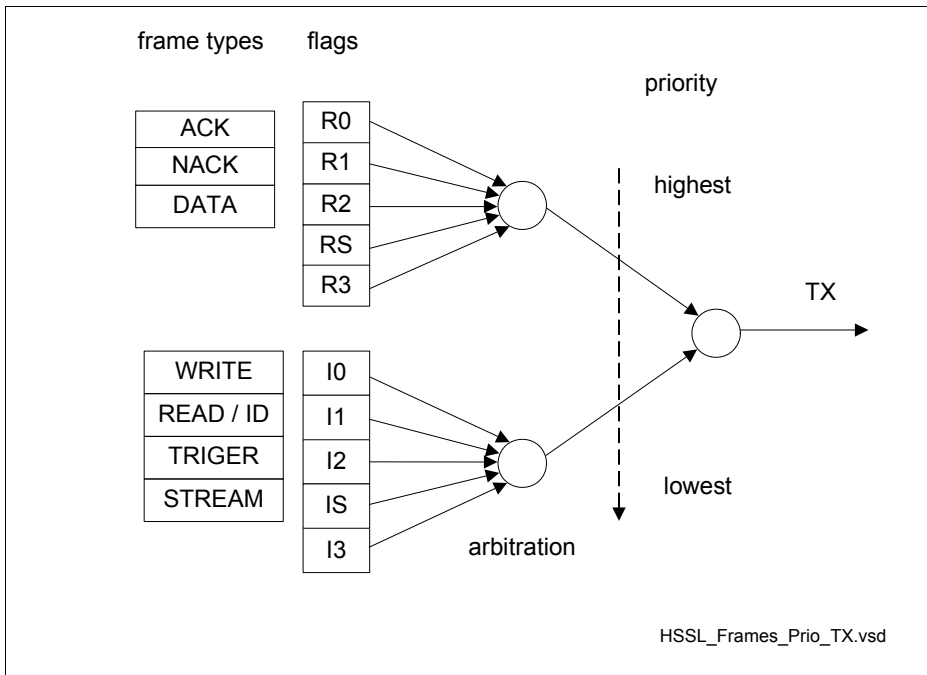

Figure 21-14 Frame Priorities in the HSSL module

21.4.1.2 Received Frame Management and Command Execution

After a frame passes the CRC check, it is checked for its type. A received command frame sets a request flag for the SRI/SPB master, a received response frame resets the expect flag and stops the appropriate channel timeout, see [Figure 21-15](#).

The target flags “T” are set by the frame distributor, and cleared by the arbiter of the SRI/SPB master.

The expect flags “E” are set by the Tx arbiter, and reset by the Rx distributor.

The ISB and ISF flags operate together to control the streaming process. The ISB flag (Initiator Stream Block flag) is set by the software to enable the streaming. The ISF flag (Initiator stream FIFO flag) is set/cleared by the TXFIFO according to its filling level.

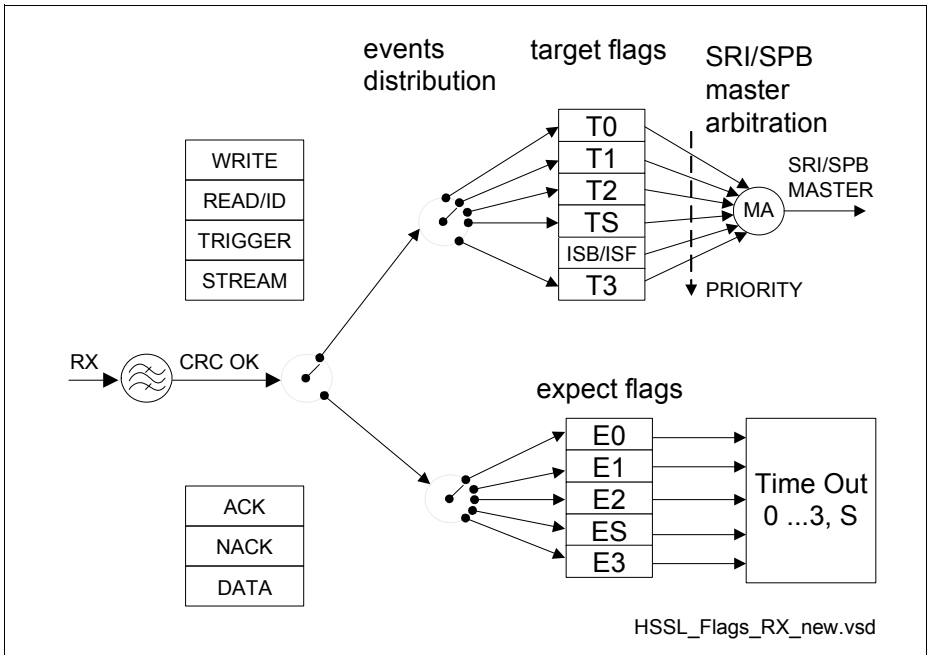

Figure 21-15 Received Frames Management

The CRC and Transaction Tag error flags are located in the **MFLAGS** register.

An overview of a full communication cycle over all sections of a channel (initiator, target or receive, transmit) is shown in [Figure 21-16](#).

See also the **QFLAGS** register description.

If the channel does not have a command pending and does not expect a response, it is ready.

High Speed Serial Link (HSSL)

Note: In case of a trigger command frame, the target command distributor sets the corresponding Rx flag, and not the corresponding Tx flag, due to the fact that the service request is triggered directly, and not by the SRI/SPB master.

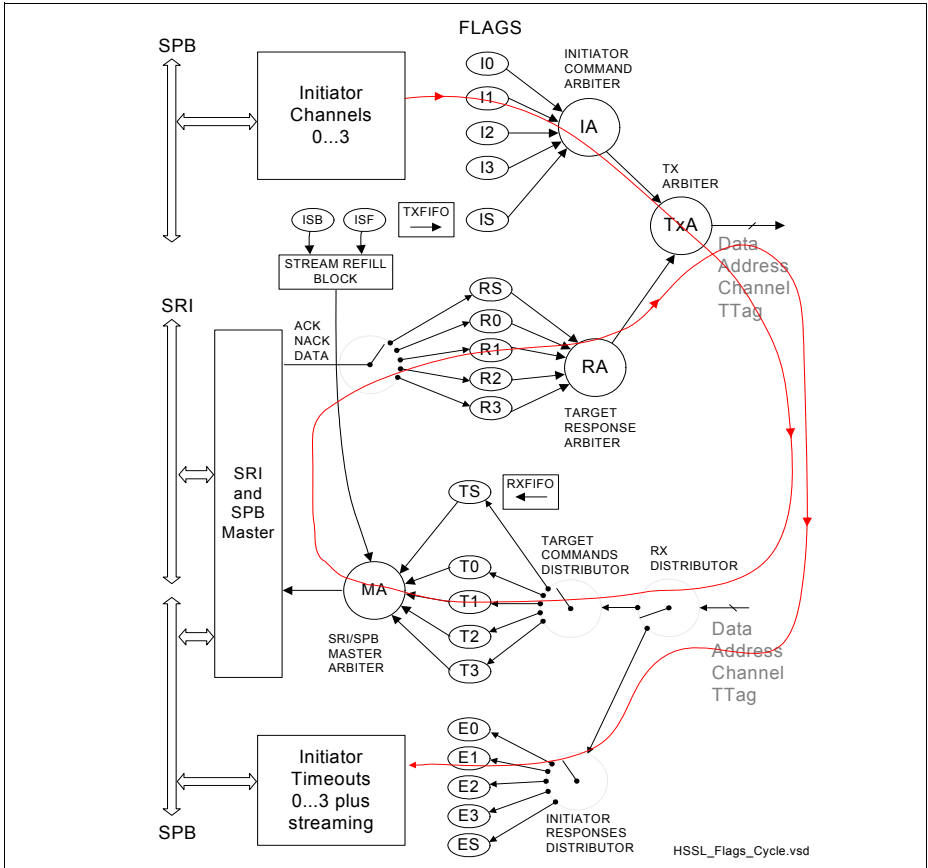

Figure 21-16 Request Flags Overview and a Communication Cycle Example

Table 21-3 Set and Clear of Request Flags

	I	R	T	E	ISB	ISF
SPB Software Write	set	-	-	-	set	-
Tx Arbiter	clear	clear	-	set	-	-
Rx Distributor	-	- ¹⁾	set	clear	-	-

High Speed Serial Link (HSSL)

Table 21-3 Set and Clear of Request Flags

	I	R	T	E	ISB	ISF
SRI / SPB Master	-	set	clear	-	-	-
Stream Refill Block	-	-	-	-	clear	clear
TXFIFO	-	-	-	-	-	set

- 1) In case of a trigger command, an R flag is set by the Rx Distributor instead of a T Flag, because a trigger command is not executed by the SRI/SPB master.

21.4.2 HSSL Channel Architecture

The HSSL module contains four channels. The functionality of each channel can be subdivided in two ways:

- transmitter and receiver functionality
 - The transmit functionality generates an appropriate header for each frame
 - The receiver generates an appropriate acknowledge header with the tag and channel number code. The read and writes are performed by the SRI/SPB master. Therefore, the module can send back to the transmitter a target error frame if an SRI/SPB bus error occurs and the transfer on the bus can not be executed.
 - The timeout monitoring on one hand and the acknowledge management on the other hand involve both the transmitter and receiver channels
- initiator and target functionality
 - The initiator functionality transmits write, read or trigger command frames in random sequence, after the previous command has been responded to.
 - Generation/comparison of a Transaction Tag per channel is an initiator functionality
 - The timeout management is a pure initiator functionality.
 - The target functionality is to receive commands, executes them, and generates and transmits responses.

Figure 21-17 Architecture of Channels 0,1, 3 and Channel 2 in Command Mode

Channel 2 can be switched between command and streaming mode of operation. In single mode a single data register is used and in streaming mode a FIFO is used.

Channel 2 contains one initiator and one target address counter which are used to fill a memory range with data. Each counter contains two start address registers and one stream frame count register.

At reaching the predefined frame count, a wrap around is automatically executed.

High Speed Serial Link (HSSL)

The granularity of the start address is 256-bit.

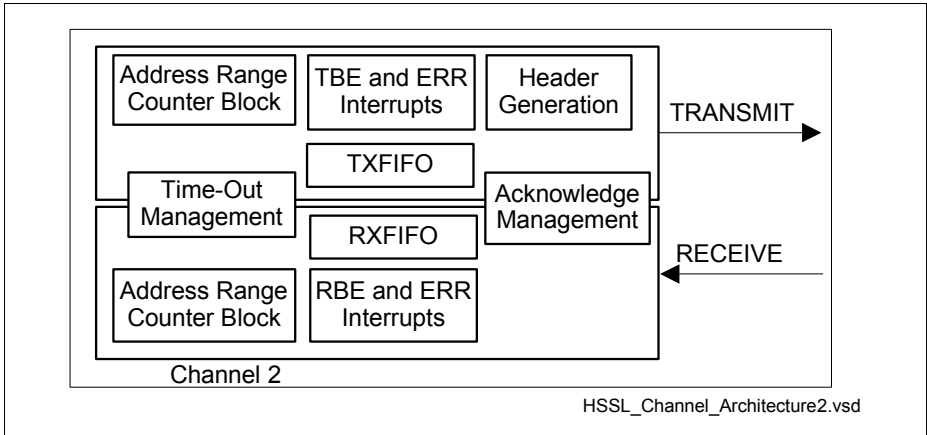

Figure 21-18 HSSL Architecture of Channel 2

A classification of the various channel functions is shown in [Figure 21-19](#).

Figure 21-19 Overview of Channel Functions

High Speed Serial Link (HSSL)

21.4.3 Acknowledge Responses

A read or write command is executed by the SRI / SPB master. The SRI / SPB master reads or writes to the SRI / SPB bus and signals either a successful transaction or an error. The are the following cases:

- When the SRI master writes or reads an SRI memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.
- When the SPB master writes or reads an SPB module or memory, both cases are acknowledged so that the HSSL module receives a feedback in any case.

Figure 21-20 Bus Error Feedback Paths

21.4.4 Cross Dependencies Between the Frame Types

For a channel in a target role, there are cross-dependencies between command frame arrival and triggering of an ACK or NACK frame for a channel. Each command frame received with correct CRC of types Write, Stream, or Trigger Frame will result in either ACK or NACK (target error) response frame. Each Read Frame received with correct CRC will result either with Data Frame (Read Response Frame) or with NACK (Target Error Frame), see [Figure 21-21](#).

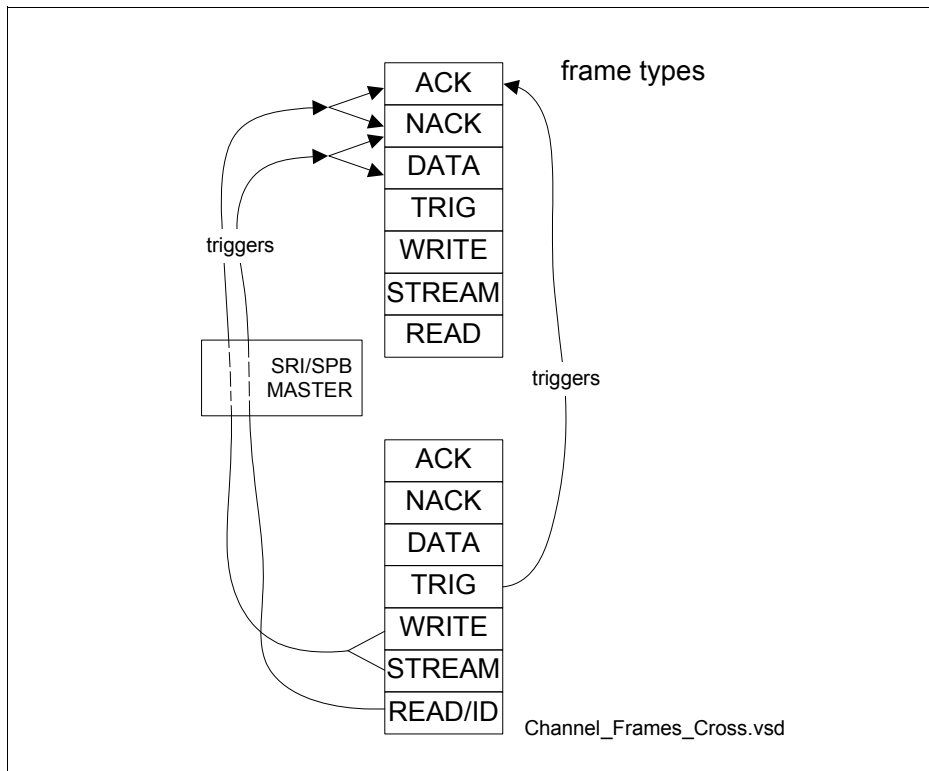

Figure 21-21 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in a Target Role

Additionally, generating a response frame involves copying of the transaction tag of the command frame into the response frame. The response frame is triggered by an SRI/SPB master signalling either a successful SRI/SPB bus transaction or an SRI/SPB bus error. Only a Trigger Command Frame triggers immediate acknowledge, because it results in an interrupt flag being set, and not in a bus transaction.

High Speed Serial Link (HSSL)

On the initiator side, there is a forward looking cross dependency between a command frame and the expected response, see **Figure 21-22**. Setting a transmission request flag for a certain command is accompanied in parallel with:

- capturing the current transaction tag in the bit field **ICONx (x=0-3).CETT**.
- generating the next transaction tag by incrementing a three bit counter per channel, the **ICONx (x=0-3).ITTAG**.
- starting the timeout counter at the moment when the command wins the arbitration
- setting an expect tag indicating that the timeout is running and a response frame is expected. See **MFLAGS.Ex** bit fields.

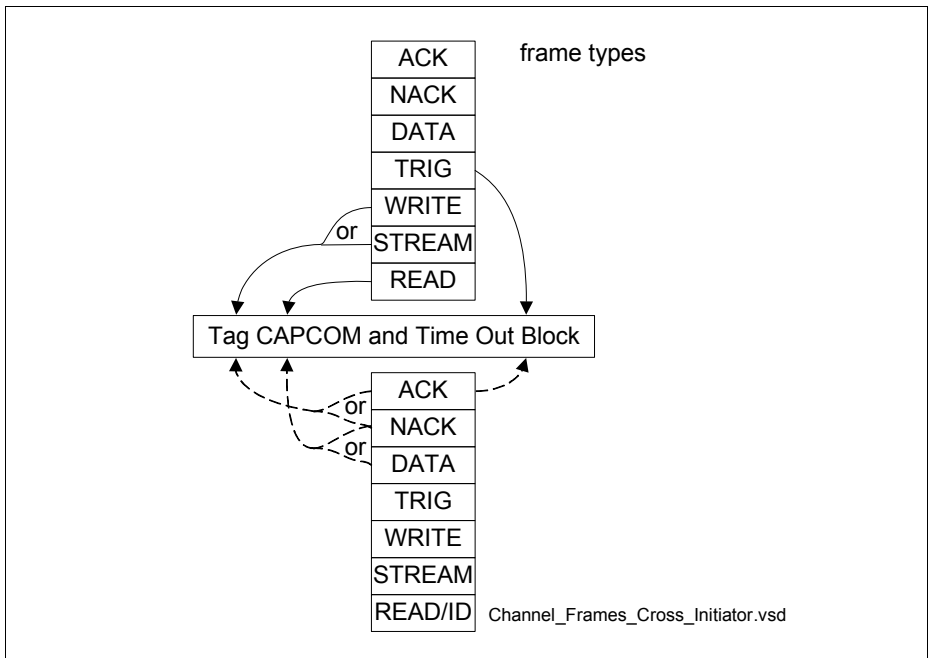

Figure 21-22 Channel 2 Cross Dependencies Between Stream and Command Frames and their Responses in an Initiator Role

21.4.5 Command Timeout

A timeout timer is started when a frame wins the arbitration and is delivered by the channel for transmission. The timeout timer is stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, and the timeout timer reaches zero, the timer is stopped, a timeout error is triggered and the expect flag is cleared.

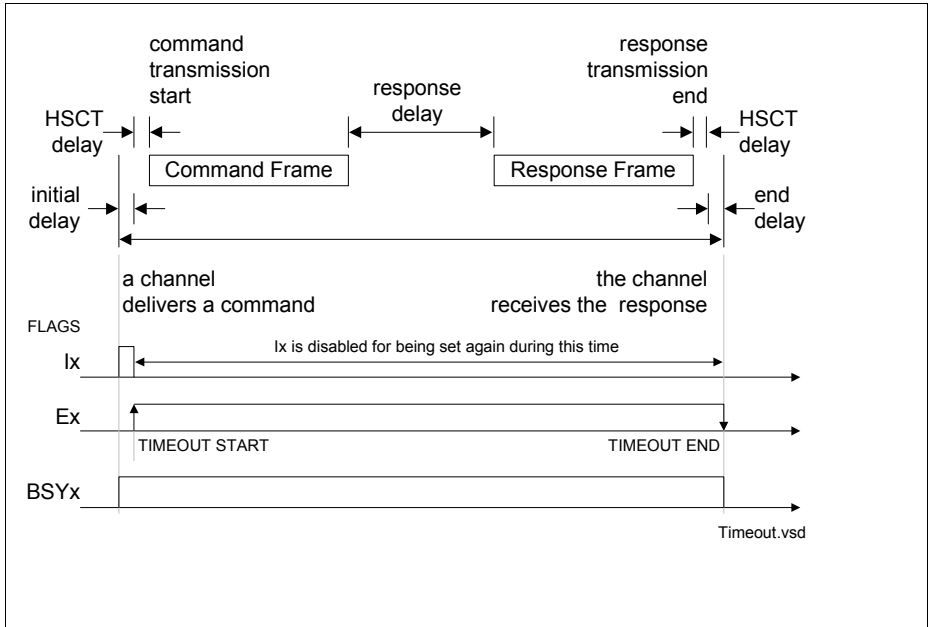

Figure 21-23 Command Timeout Measurement

21.4.5.1 Command Timeout Operation

The HSSL module contains one prescaler common to all channels, and one channel specific timer block per channel. The timer block generates the transaction tag for the channel by incrementing a three bit counter, captures the current transaction tag and compares it with the arrived response. In case of an error sequence CRC and timeout error, the timeout block generates a timeout signal. The timeout timer is reloaded and starts down-counting when the command transmission process starts.

The current timeout timer current value is indicated in the bit field **ICON.TOCV**, and the timeout reload value is configured in the bit field **ICON.TOREL**.

High Speed Serial Link (HSSL)

The currently expected transaction tag is indicated in the bit field **ICON.CETT**, the captured value of the latest erroneous transaction tag is indicated in the bit field **ICON.LETT**.

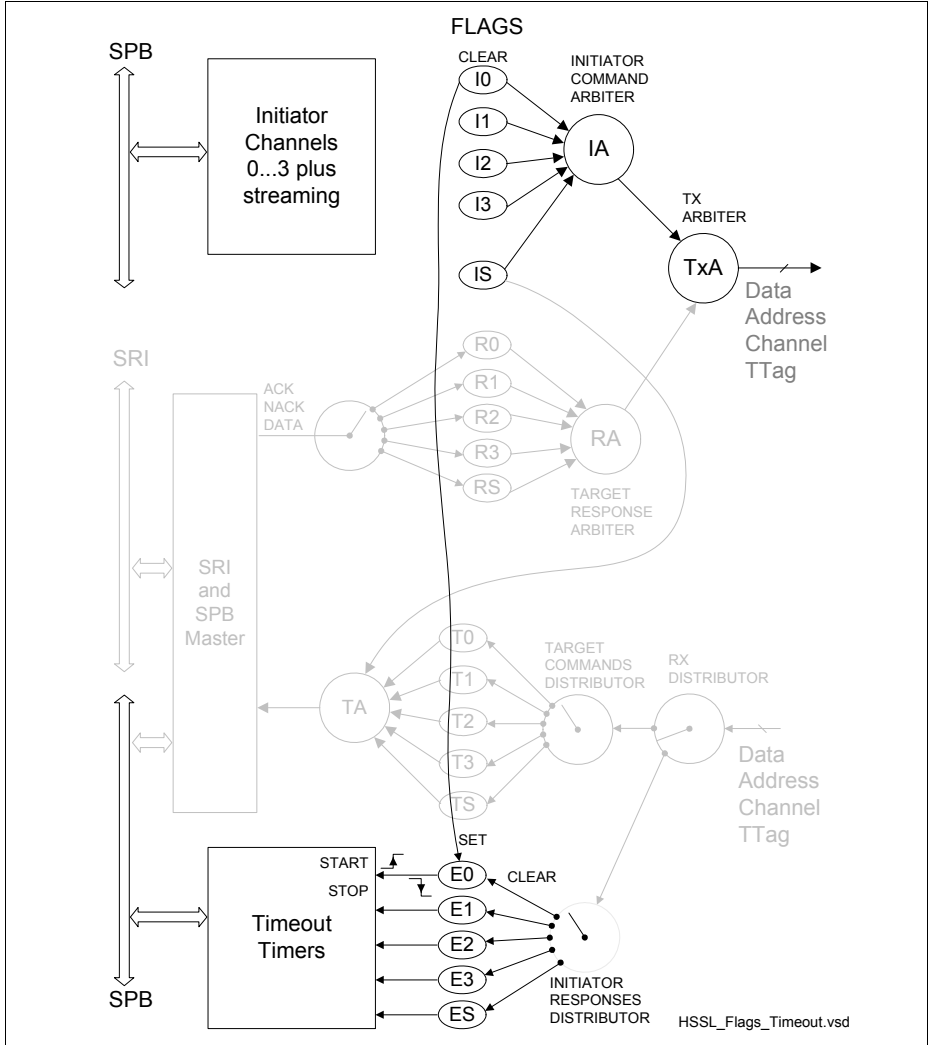

Figure 21-24 Request Flags Overview and a Communication Cycle Example

High Speed Serial Link (HSSL)

From the point of view of the flags, the timeout starts with the rising edge of the **QFLAGS**.Ex flag and ends with its falling edge, see **Figure 21-22**. The Ex flag is set by the falling edge of the lx flag, which is reset when its command request wins the transmit arbitration, see **Figure 21-24**.

21.4.6 Stream Timeout

A free timeout timer block is started when a frame wins an arbitration round and is delivered by the channel for transmission. The timeout timer block is reset to zero and stopped if an appropriate response frame has arrived in time (without a CRC error). If an appropriate response has not arrived, a timeout error is triggered and the timeout timer block is reset.

The stream initiator keeps track of the expected acknowledges using a virtual expect fifo having a virtual filling level EXFL. Each new stream frame transmission increment the EXFL, receiving a correct acknowledge decreases the EXFL. As long as the expect fifo is full (filling level 2) no new transmit request can be issued. In order a new stream frame request to be issued, which means the flag IS to be set by the module, three conditions must be met:

- $EXFL < 2$ - the expect level must be below two,
- $TXFL > 0$ - the TXFIFO must be not-empty and
- $ISB = 1$ - the bit ISB bit must have been set by the software.

High Speed Serial Link (HSSL)

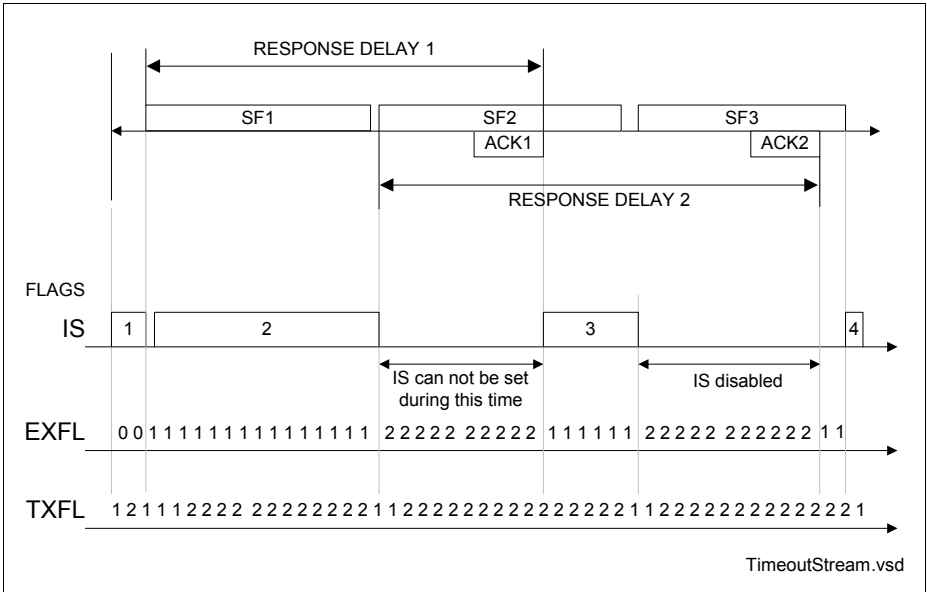

Figure 21-25 Stream Timeout Measurement

21.4.6.1 Stream Timeout Operation

The stream channel monitors the arrivals of the stream frame responses by using two timeout timer blocks. A single timer block is shown in **Figure 21-26**.

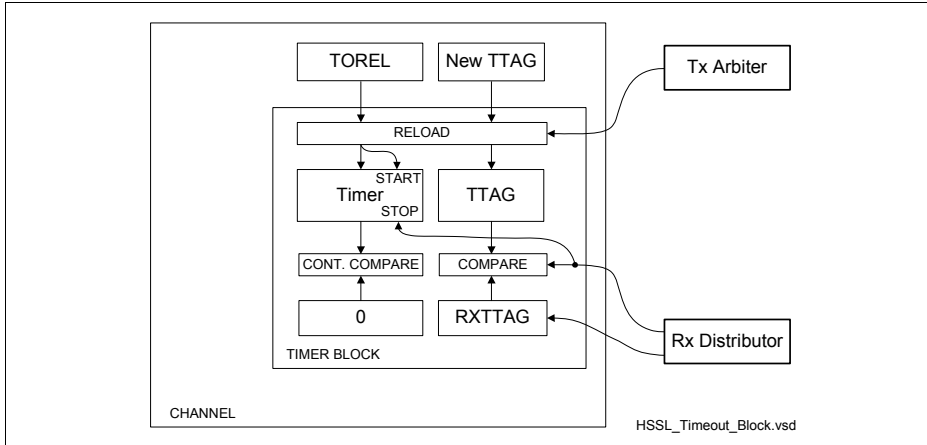

Figure 21-26 Single Timeout Block

The new initiator TTAG value which will be used for the next frame is visible in the bit field **ICONx.ITTAG**. The **ICONx** register also contains the TOREL and the TOCV bit fields.

High Speed Serial Link (HSSL)

The streaming functionality uses two timers sharing the same reload value, as defined by the **ICON2.TOREL**. The timeout timer blocks simulate the behavior of a FIFO (named Expect FIFO), by having additionally a “write” and “read” pointer:

- the “write” or transmit pointer points to the timer block where the next command frame will trigger the writing of the timer reload value and the transaction tag,
- the “read” or receive pointer points to the block which performs the transaction tag comparison with the currently arrived stream acknowledge TTAG.
- The EXFL or virtual filling level indicating how many timers are active 0, 1 or 2

The EXFL is visible in the register **SFSFLAGS**.

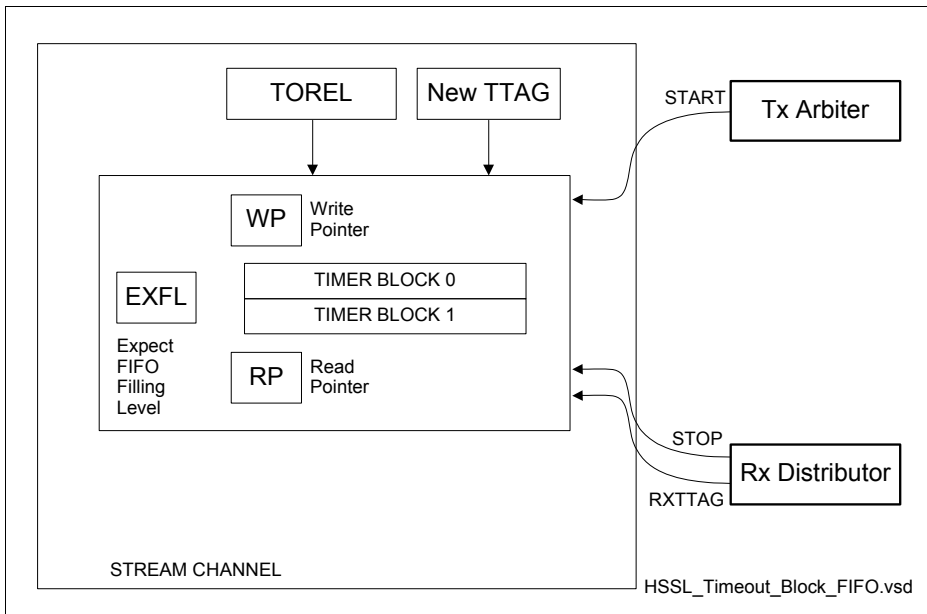

Figure 21-27 Stream Timeout Block

21.4.7 Data FIFOs of the Streaming Channel 2

Each stream frame delivers 256 bit data. This data is transferred by the SRI/SPB bus master in a memory by using BTR4 bursts. The start address and the end address is aligned at 256-bit block border, see **ISSAx (x=0-1)**, **ISFC**, **TSSAx (x=0-1)**, **TSFC**.

The channel expects one full streaming frame of 256 bit to be delivered before triggering either the SRI/SPB master or the HSCT module for fetching the data. The streaming is full duplex capable, which means one FIFO for each direction is available, and also Prioritisation for the requests to the SRI/SPB master.

Emptying the RXFIFO has higher priority than filling the TXFIFO.

A service request to the SRI/SPB master is generated when the complete payload of a streaming frame is available in a FIFO.

Figure 21-28 Streaming FIFO

21.5 Modes of Operation

The HSSL module has the following modes:

- Disabled mode (software controlled via DISR bit)
- Initialize mode (software via INI bit, sleep & suspend signals)
- Run mode (INI bit, sleep and suspend signals)
- OCDS soft suspend mode (OCDS suspend signal)
- Sleep mode (sleep signal)

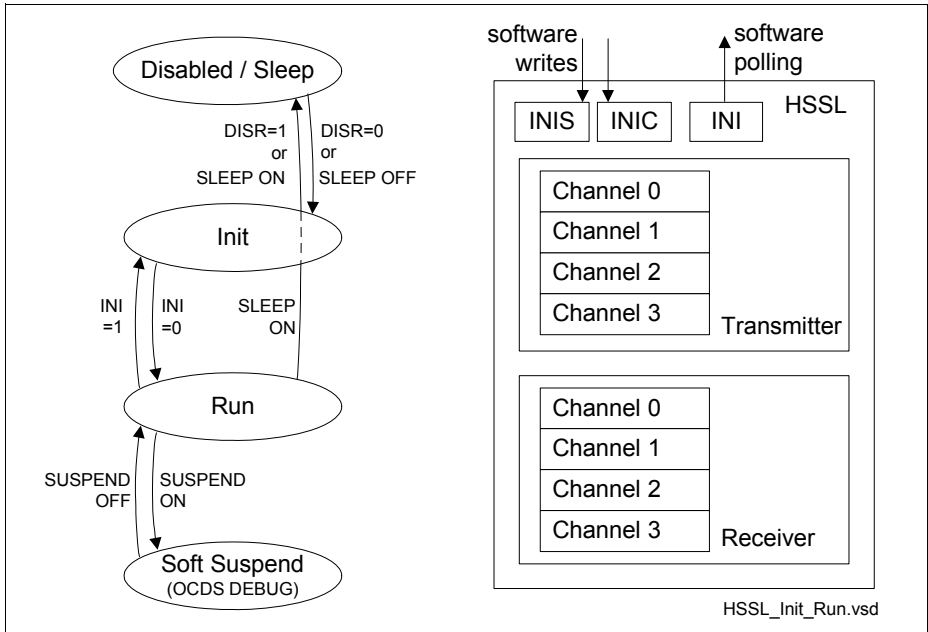

Figure 21-29 Modes of operation

After Init state has been requested by using the **MFLAGSSET.INIS** bit, the HSSL module immediately stops starting new SRI/SPB transactions and new command, response and stream frame transmissions by resetting all request bits (I, T and R) in the **QFLAGS** register and disabling these bits for being set again. The already started transactions/transmissions will be finished. Afterwards, it waits for all pending response frames to arrive or the corresponding timeout events to be raised. This condition is achieved when all expect bits in the **QFLAGS** register has been cleared by the hardware, and there are no ongoing transmission and SRI/SPB master activities. Subsequently the module enters the Init state and the **MFLAGS.INI** flag is set. The CTS signal is deactivated in order to inform the peer module about the Init state.

High Speed Serial Link (HSSL)

During the transition from run to sleep state, triggered by the sleep signal, the **MFLAGS.INI** bit is automatically set by the hardware (behaves as INI bit was set by software). When the sleep period is over and the sleep signal is deactivated, the module goes into the Init state and must be set to Run state by software, by writing **MFLAGSC.L.INIC=1**.

At the state transition of Init -> Run the timeout timers and all the flags are reset. The RUN state starts with all channels inactive.

At the state transition SoftSuspend -> Run the timers are not reset but continue to run and the flags states are preserved, because the module continues operating from the point at which it was suspended.

When leaving the Run state towards Sleep the CTS signal is deactivated and the transmission of the pending commands is stopped.

When a soft suspend is requested, the module stops the transmission of the pending command and stream frames, waits until all expect flags are cleared, then deactivates the CTS signal and at the end acknowledges the soft suspend request and sets the bit **OCS.SUSSTA**. Incoming target frames are served until the CTS signal stops the other side from sending new command and stream frames.

Hard Suspend request causes immediate switching off of the module clocks. After ending the Hard Suspend state both HSSL and HSCT modules must be reset by the application software and communication restarted from reset state.

Note: Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles. Attention: register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a HSSL kernel reset might not be sufficient to bring the system into a defined state.

Figure 21-30 Actions on State Transitions

21.6 Interrupts

The HSSL module generates four types of interrupts per channel and one channel unspecific module interrupt.

Command Channel Interrupts

Each HSSL command channel generates four interrupts:

- Command OK interrupt COK
- Read Data interrupt RDI
- Error interrupt ERR
- Trigger interrupt, triggered by a trigger command frame TRG

An arrival of an error free frame response (ACK frame) triggers a COK interrupt, otherwise an ERR interrupt is triggered. An arrival of a read response frame triggers at the initiator side, additionally to the COK interrupt, an RDI interrupt.

An arrival of a trigger frame at the target side triggers a TRG interrupt there.

ERR interrupt is disjunct to COK and RDI interrupts, meaning that for one frame, either ERR or COK and optionally RDI can occur. After an ERR interrupt, normal transmission must be resumed by software, because an optional DMA would remain not retriggered and would wait for COK indefinitely.

Stream Channel Interrupts

The HSSL stream transmit sub-channel generates three interrupts:

- TBE - Transmit Block End interrupt, shared with the COK interrupt of the command mode of the channel 2
- error interrupt ERR, shared with the ERR interrupt of the command mode of the channel 2
- RBE - Receive Block End interrupt, shared with the TRG interrupt of the command mode of the channel 2.

Exception Interrupt EXI

If the receive stage of the HSSL module detects a CRC error or any inconsistency in the received data the global EXI Interrupt is activated, which is not channel specific.

Note: The HSCT module uses channels A to D for the HSSL channels 0 to 3. So, HSCT channel 0100_B corresponds to 000_B (binary code) or 100_B (special code) in the HSSL header.

The EXI interrupt is also raised on an edge of the TEI signal (HSCT CTS output).

In total, the HSSL module provides $4 \cdot 4 + 1 = 17$ interrupt lines.

21.7 Operating a Command Channel

All HSSL command channel provide identical functionality.

21.7.1 Initiating a Single Write Command

In order to initiate a write command, the software must

- configure the data width and the type of the request which will follow (read or write)
- provide the new data (most frequently, but not necessary)
- provide new address

Write to the address register requests the predefined type of the transfer

21.7.2 Initiating a Single Read Command

In order to initiate a read command, the software must

- configure the data width and the type of the request which will follow (read or write)
- skip providing of the data step, or provide dummy data
- provide new address

Write to the address register requests the predefined type of the transfer

21.7.3 Initiating a Single Trigger Command

In order to initiate a trigger command, the software can either

- request a trigger type of frame and provide dummy data and address
- directly request a trigger frame by writing **ICONx (x=0-3).TQ**

21.7.4 DMA Operated Command Queues

It is possible to use DMA to initiate lists of commands, by moving memory blocks containing the command lists to the HSSL module. In order to support such a way of operation, each channel provides three registers arranged in a particular way: first **IWD**, followed by **ICON** and **IRWA** at the end. For executing a list of write commands all three registers must be written for each command; for executing a list of read commands the first register **IWD** is optional (dummy write possible) but the last two **ICON** and **IRWA** are mandatory; for executing a trigger command only writing **ICON.TQ** is mandatory, but optionally even all three registers can be written: dummy write to **IWD**, write to **ICON.RWT** and write to **IRWA** to issue the request.

The answer data to a read command is available in the **IRD** register.

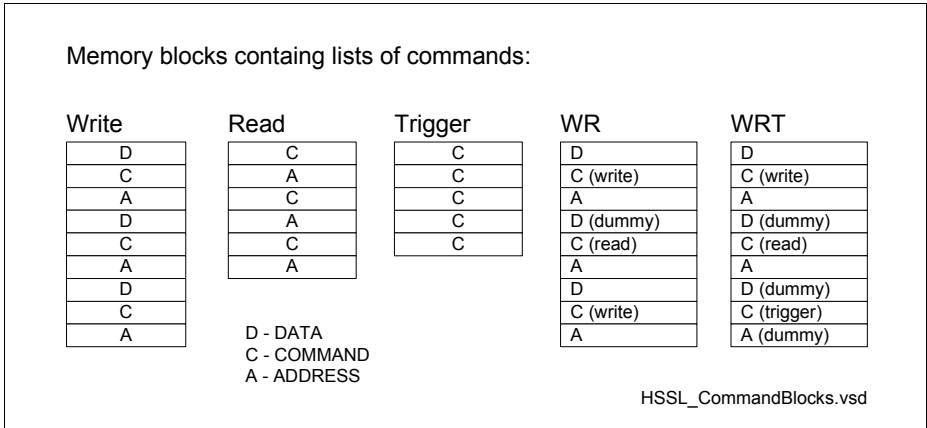

Figure 21-31 Command Queues

21.7.5 Receiver Error Handling

The HSSL receiver generates three error signals, two channel specific and one general:

- channel specific timeout and transaction tag errors and
- channel unspecific CRC error
- command frames, which pass the CRC check, containing an RFU command code are ignored
- Command frames, which pass the CRC check, containing invalid (greater than 3) channel number are ignored.
- If a command frame is received and the acknowledge of the previous command has not been sent yet, the new command frame is discarded.
- If a response frame comes, and the channel does not expect any more a response (the E flag is 0), than an incoming response is discarded without any error interrupts, additional to the timeout interrupt. This scenario can occur if a response is received after a timeout, and before the next command has been sent.
- If a channel in command mode receives a stream frame, the stream frame will be ignored.
- if a channel in streaming mode receives a command frame, the command frame will be ignored.

21.7.5.1 Timeout Error

Error triggered by the initiator.

21.7.5.2 Transaction Tag Error

Error triggered by the initiator.

21.7.6 Global Error

Global, channel not specific error is triggered if a CRC error, inconsistency between the HSCT and HSSL header, and SRI/SPB error occurs.

CRC error is triggered:

- by the target: when erroneous command frames has been received and
- by the initiator for erroneous response frames.

There is a dedicated interrupt named EXI which signals the CRC error. There is no indication if the CRC error was caused by a command or response frame. The CRC error caused by a response frame will be followed by a timeout interrupt. The received data is discarded; it is not available for the software in any register(s).

Additionally, the CRC error interrupt signals an inconsistency between the data length and channel number code delivered by the HSCT module and the information contained in the HSSL header. The differentiation between the two types of error can be done by reading the **MFLAGS**.CRCE, PIE1 and PIE2 flags. All three error types can occur and are detected independently of each other, so that more than one flag can be set at the same time.

An SRI error interrupt (EXI) is triggered if there was a transaction ID error, ECC error or SRI error acknowledge on the SRI bus. The flag **MFLAGS**.SRIE indicates this type of error. In case of an SRI read data ECC error, this event is additionally signalled to the SMU module.

An SPB error also triggers the global error interrupt (EXI) and sets the **MFLAGS**.SRIE flag.

21.8 Memory Block Transfer Modes of the Stream Channel

HSSL streaming channel is capable of transmitting one stream and receiving one stream in parallel. Streaming operates either in single block mode or continuous mode.

In single block mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives the preconfigured memory block, generates an interrupt signal and waits for the next trigger.

In continuous mode, after triggering/enabling the streaming by using the **MFLAGS**.ISB/TSE bit, the SRI/SPB master of the HSSL module transmits/receives two memory blocks of the same size in a round robin fashion indefinitely, or after being stopped by the software.

The streaming mode of the initiator/transmitter is configured by using the **CFG**.SMT bit. The streaming mode of the target/receiver is configured by using the **CFG**.SMR bit.

High Speed Serial Link (HSSL)

Triggering/enabling a block or continuous stream is done by using the Stream Block Request bit **MFLAGS.ISB/TSE** bit. In single block mode, the hardware resets this bit after performing a block transfer. In continuous mode, the transfer is ongoing continuously (**MFLAGS.ISB/TSE** remains set) and a stop of the transfer must be requested by writing one to **MFLAGSCL.ISBC/TSEC** bit.

On the initiator side, after completing the transfer of the current memory block that is currently read from the memory, the transmitter will be stopped and the **MFLAGS.ISB** will be cleared.

On the target side, after completing the transfer of the current memory block that is currently written to the memory, the receiver will be stopped and the **MFLAGS.TSE** will be cleared.

SRI/SPB error on the target triggers an error interrupt and the hardware stops. The TSE bit (and the RXFIFO) will be cleared by the hardware and the incoming frames are ignored.

Any error on the initiator side (like SRI/SPB error, target error, timeout, transaction tag error) triggers an error interrupt and the hardware stops streaming. The bit ISB (and the TXFIFO) will be cleared by hardware. All the incoming frames will be ignored, including the acknowledge frames of the previous frames.

Error can also occur at the beginning of a new memory block, while the last frames of the previous memory block are still in the TXFIFO. These frames are also lost, and the previous memory block remains incompletely received.

After an error while streaming in one direction the software must restart the streaming in that direction at both sides. The streaming will restart with a new block.

An error while streaming in most cases leaves the target waiting in the middle of a block. The target receiver can be stopped immediately (and afterwards restarted) by clearing the **MFLAGS.TSE** only when **TSFC.CURCOUNT** equals **TSFC.RELCOUNT**. Normally, **CURCOUNT** equals **RELCOUNT** before the start of a transfer of a block or between block transfers. Otherwise, while waiting in the middle of a block transfer, **RELCOUNT** can be made equal to **CURCOUNT** by writing the **CURCOUNT** value to **RELCOUNT**. This can be done either locally, by the target itself, or remotely, by the initiator using HSSL command frames.

The two initiator start addresses are configured in **ISSAx (x=0-1)**. The single block size is configured in the **ISFC** register. The current address being transferred is indicated in the read only (rh) **ISCA** register. The bit **MFLAGS.IMB** selects the corresponding **ISSAx (x=0-1)** register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **ISSAx (x=0-1)** is copied to the **ISCA** register.

The two target start addresses are configured in **TSSAx (x=0-1)**. The single block size is configured in the **TSFC** register. The current address being transferred is indicated in the read only (rh) **TSCA** register. The bit **MFLAGS.TMB** selects the corresponding

High Speed Serial Link (HSSL)

TSSAx (x=0-1) register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address **TSSAx (x=0-1)** is copied to the **TSCA** register.

The HSSL stream transmitter generates one dedicated interrupt and several error events:

- transmit block end interrupt, generated after the acknowledge of the last frame has been received.
- error events that can trigger a channel error interrupt (target, timeout, transaction tag, unexpected error)
- a global SRI/SPB error interrupt (check if the ISB bit is cleared by hardware)

The HSSL stream receiver generates one dedicated interrupt and several error events:

- receive block end interrupt event, generated after the last stream frame in a block has been written to the memory and the SRI/SPB master has received a confirmation (an acknowledge, but not an error).
- error event (target error that triggers a NACK frame)
- a SRI/SPB global error interrupt (check if the TSE bit is cleared by hardware)

As long as the ISB bit is low, the TXFIFO and the expect FIFO are cleared and kept in the empty state.

As long as the TSE bit is low, the RXFIFO is cleared and kept in the empty state.

High Speed Serial Link (HSSL)

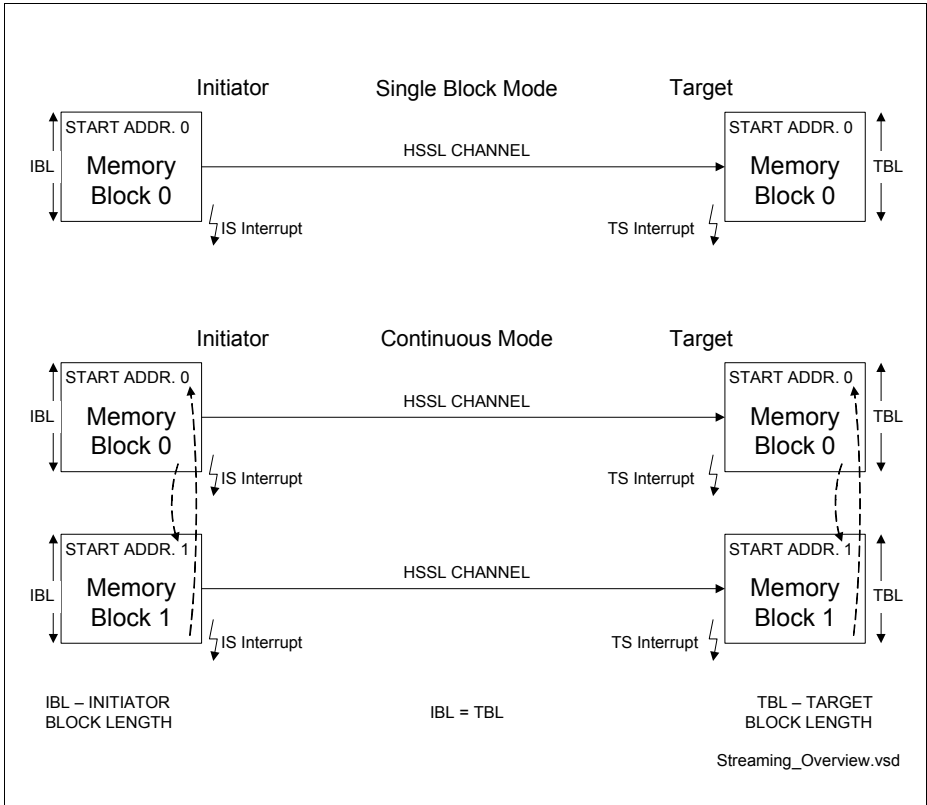

Figure 21-32 Stream Modes of Operation

21.9 HSSL Reset

Both HSCT and the HSSL modules must be reset together.

21.10 OCDS SRI / SPB Master Suspend

The SRI /SPB master access on the bus can be suspended by using the OCDS suspend request. When the master reaches idle state the suspend acknowledge signal is activated.

High Speed Serial Link (HSSL)

21.11 OCDS Trigger Sets

In order to support the debugging activities, the HSSL module provides a set of internal signals to the on-chip debug system OCDS. An overview of this feature is shown in **Figure 21-33**. Its configuration is done by using the bits **OC.S.TGS** and **TGB**.

An edge on any module internal signal belonging to the selected set going out on one of the two OTGB busses triggers an action of the OCDS system.

Figure 21-33 Overview of the Trigger Sets and Busses

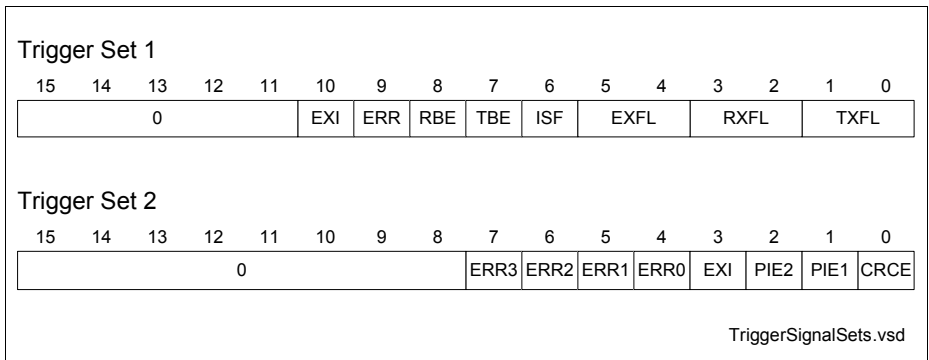

Figure 21-34 Overview of the Trigger Signal Sets

Table 21-4 HSSL Trigger Sets

Name	Description
TS16_STR	Streaming Channel Trigger Set (Trigger Set 1)
TS16_ERR	Error Trigger Set (Trigger Set 2)

High Speed Serial Link (HSSL)

The trigger sets 1 and 2 are used, the set 3 is not used (padded with 0).

Set 1, streaming channel debugging:

- 2 bits: TXFIFO filling level **SFSFLAGS.TXFL**
- 2 bits: RXFIFO filling level **SFSFLAGS.RXFL**
- 2 bits: Expect FIFO filling level **SFSFLAGS.EXFL**
- 1 bit: Initiator Stream Frame Request **SFSFLAGS.ISF**
- 4 bits: streaming channel interrupt signals TBE, RBE, ERR, EXI, see **Interrupts**.
- others: not used

Set 2, timeout errors caused by unspecific errors debugging:

- 1 bit: CRC error **MFLAGS.CRCE**
- 1 bit: Phy Inconsistency error, inconsistent channel number code, **MFLAGS.PIE1**
- 1 bit: Phy Inconsistency error, inconsistent data length, **MFLAGS.PIE2**
- 5 bits: error interrupt signals 1 x EXI and 4 x ERR, see **Interrupts**.
- others: not used

Note: The signal lists from above are mapped to the trigger sets in the following way: first item from the list to the trigger signal 0,... to 15.

21.12 Access Protection

The HSSL module provides memory access protection in form of four memory access windows. Each window can be located anywhere within the address space, having an arbitrary size with the granularity of 256 bytes.

Each window defines a memory range where an access is allowed. All four windows create a sort of an access filter that protects the memory from external writing or reading. A window can be a read only, write only or read and write window.

Each window is defined with:

- window start address, see register **AWSTART_x (x=0-3)**
- window end address, see register **AWEND_x (x=0-3)** and
- access rule: read only, write only or read and write, see register **AR**

If two access windows overlap, one read only and one write only, the common address range is read and write accessible. If no access window overlaps with r, w or rw window, the r, w or rw window wins. No access window means window disabled.

Figure 21-35 HSSL Access Windows

Normally, it is expected that the End Address is higher then or equal to the Start Address. Otherwise, the window is invalid and no commands can pass through the up-side-down range.

The **AWSTART_x (x=0-3)** registers define the first address of the first 256-byte block of an address window. The **AWEND_x (x=0-3)** registers define the first address of the last

High Speed Serial Link (HSSL)

256-byte block of an address window. The following diagram shows the details of the address window definition.

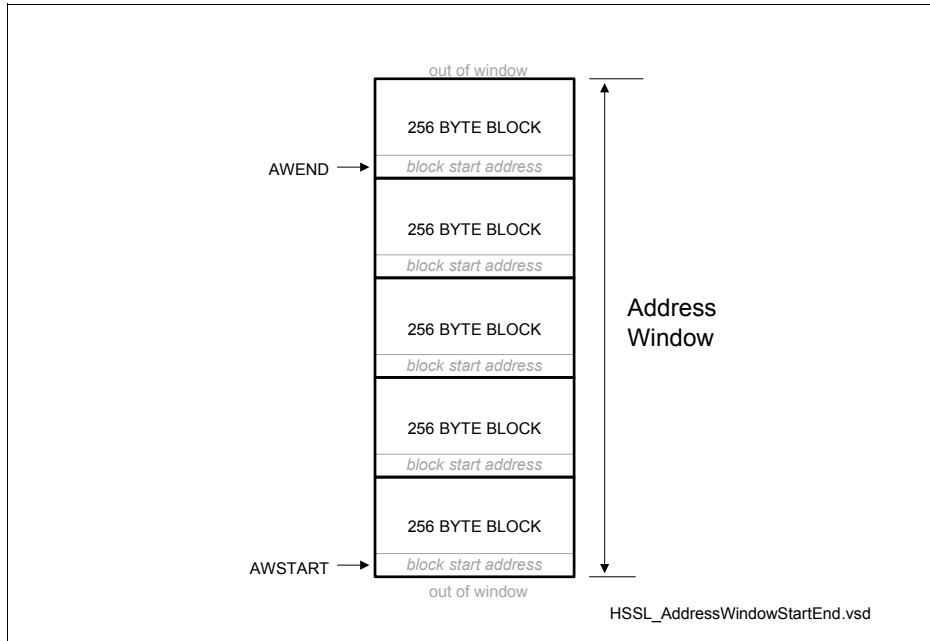

Figure 21-36 Access Windows Definition

These command frames are subject to filtering:

- Register Read
- Register Write and
- Stream Frame

These command always pass through:

- Read Answer
- ACK
- NACK
- Trigger
- ID Request

Command Frames Access Protection

If a HSSL target receives a read or write command frame with an address which passes through one of the windows, the command is executed and a response frame is sent back.

High Speed Serial Link (HSSL)

If a HSSL target receives a command frame with an address which does not pass through any windows, the command is not executed, a NACK response is sent back. The memory access violation flag **MFLAGS.MAV** is set, the access violating channel is captured in the bit field **AR.MAVCH**, and the EXI interrupt is triggered in the target.

Streaming Access Protection

In contrast to the read and write command frames, the stream frames do not contain an address information. There are two cases to distinguish, target side and initiator side.

At the target side, when the streaming starts, the initiator has already programmed the target addresses in the **TSSAx (x=0-1)** registers by using write frames, which pass through and carry the stream address in their data field. Therefore, the memory filtering uses the current access address, visible in the **TSCA** register, and if the current streaming address passes through the access protection filter, the read or write is executed, else a NACK frame is sent as a response.

If a HSSL target receives a stream frame and the current access address does not pass through any windows, the access is not executed, a NACK response is sent back, . The TSE bit will be cleared by hardware and the incoming frames will be ignored. The memory access violation flag **MFLAGS.MAV** is set, the access violating channel is captured in the bit field **AR.MAVCH**, and the EXI interrupt is triggered in the target.

At the initiator side, the **ISSAx (x=0-1)** registers, which are externally accessible, define the memory range to be transmitted. Therefore, the access filtering at the initiator side covers the streaming read accesses by using the current access address, visible in the **ISCA** register.

At the initiator side, access violation stops the streaming, and the ISB bit is cleared by hardware. The memory access violation flag **MFLAGS.MAV** is set, the access violating channel is captured in the bit field **AR.MAVCH**, and the EXI interrupt is triggered.

Public and Private Registers

The HSSL module contains two types of registers:

- public registers, which can be both read and written by the HSSL module itself
- private registers, which can be only read by the HSSL module itself

This behavior of the HSSL module registers is implemented by using the User Mode (U) and Supervisor Mode (SV) of writing registers. The private registers are writable in SV mode, the public registers are writable in U and SV mode.

The memory access protection registers **AWSTARTx (x=0-3)**, **AWENDx (x=0-3)** and **AR** including the **TIDADD** register are all writable only in Supervisor Mode, and are consequently private. The HSSL itself makes only User Mode accesses, so that it can not write these registers.

Figure 21-37 HSSL access to its own registers

21.13 Kernel Registers

This section describes the registers of the HSSL module.

Note: The HSSL module occupies 1KByte of address space, although only the first 256 bytes are used. Accessing a not used address location generates a bus error.

There are no registers in the HSSL with the destructive read property, where a read access would generate some action in the hardware.

Table 21-5 Registers Address Space

1) All registers have read access mode U, SV, except the access protection registers AWSTART, AWEND and AR, which have read access mode SV.

Read access from reserved addresses delivers bus error (BE).

All registers belong to reset class 3 except OCS, which belongs to reset class 1.

2) Read access mode: SV only.

This register delivers 0 to a read access in User Mode, but BE is not triggered.

List of Access Protection Abbreviations

U - User Mode

SV - Supervisor Mode

BE - Bus Error

nBE - no Bus Error

P - Access Protection, as defined by the ACCEN Register

E - ENDINIT

SE - Safety ENDINIT

21.13.1 Global Registers

ID

The Module Identification Register ID contains read-only information about the module version.

(>> [Table 21-6](#) register overview)

ID

Module Identification Register (08_H) **Reset Value: 00CB C0XX_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number MODREV defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines a 32-bit module.
MOD NUMBER	[31:16]	r	Module Number Value This bit field together with MODTYPE uniquely identifies a module.

High Speed Serial Link (HSSL)

CRC

(>> [Table 21-6](#) register overview)

This register only influences the generation of the CRC in the transmit direction.

CRC

CRC Control Register

(0C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
XORMASK	[15:0]	rw	Value to be XORed with the Calculated CRC Used for error injection / test purposes.
XEN	16	rw	Enable the Error Injection via XORMASK 0 _B disabled 1 _B enabled
0	[31:17]	r	reserved

High Speed Serial Link (HSSL)

CFG

The CFG register is used to configure the HSSL module. It shall only be written in the Initialize Mode.

(>> **Table 21-6** register overview)

Note: The duration of a timeout interval may vary for an amount of one predivider clock period. Therefore the predivider should be set as low as possible, and the timeout length as many predivider periods as possible.

CFG

Configuration Register (10_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
PREDIV	[13:0]	rw	Global Predivider Defines the down-scaled module clock to be used by all channel timeout timers. 0 _D 1 1 _D 2 2 _D 3 others , corresponding down-scale factor
SMT	16	rw	Streaming Mode Transmitter 0 _B Continuous 1 _B Single
SMR	17	rw	Streaming Mode Receiver 0 _B Continuous 1 _B Single

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
SCM	18	rw	Streaming Channel Mode Defines if the channel 2 is used in a streaming or command mode. 0 _B Command 1 _B Streaming
CCC	19	rw	Channel Code Control Defines the coding of the channel number in the HSSL header. 0 _B Binary 1 _B Special
0	[31:20], [15:14]	r	reserved

21.13.2 Channel.Flags Registers

QFLAGS

This register contains flags indicating if an appropriate action request is pending or not. The action request can be pending in different stages of a communication cycle, see [Figure 21-16](#).

(>> [Table 21-6](#) register overview)

QFLAGS

Request Flags Register (14_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
I	[3:0]	rh	<p>Request Flags for Initiated Commands</p> <p>These flags are set by the corresponding channel when a WRTS command is initiated. The WRT commands are initiated via the SPB bus. The S(tream) commands are initiated by the module internally, by the TXFIFO, except for the first stream frame start, which is done via the SPB bus. See MFLAGS.ISB and ISF flags.</p> <p>0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending others, corresponding combination of requests</p>

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
T	[7:4]	rh	<p>Request Flags for Commands Arrived at Target These flags are set by the hardware according to the header information of a frame arrived at the target without a CRC error. They are used by the arbiter of the SRI/SPB master and cleared when the appropriate command is executed.</p> <p>0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending others, corresponding combination of requests</p>
R	[11:8]	rh	<p>Request Flags for Response Frames at the Target After a command has been executed by the SRI/SPB master, an appropriate flag is being set which indicates that an ACK/NACK/DATA is pending.</p> <p>0000_B No request pending 0001_B Channel 0 request pending 0010_B Channel 1 request pending 0100_B Channel 2 request pending 1000_B Channel 3 request pending others, corresponding combination of requests</p>
E0	[17:16]	rh	<p>Expect Flags for Activated Timeout Timer 0 An appropriate two bit flag is set by the hardware when a timeout timer for a channel is started. The hardware clears the appropriate flag when any response frame arrives at the initiator. In case of an unexpected response the flag UNEXPECTED is additionally set.</p> <p>00_B No request pending 01_B write request pending 10_B read request pending 11_B trigger request pending</p>
E1	[19:18]	rh	Expect Flags for Activated Timeout Timer 1
E2	[21:20]	rh	Expect Flags for Activated Timeout Timer 2
E3	[23:22]	rh	Expect Flags for Activated Timeout Timer 3

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
IS	28	rh	I Flag for Stream Frames See the “I” flag description above. 0 _B No request pending 1 _B Request pending
RS	29	rh	R Flag for Stream Frames See the “R” flag description above. 0 _B No request pending 1 _B Request pending
TS	30	rh	T Flag for Stream Frames See the “T” flag description above. 0 _B No request pending 1 _B Request pending
ES	31	rh	E Flag for Stream Frames See the “E” flag description above. 0 _B No request pending 1 _B Request pending
0	[27:24], [15:12]	r	reserved

MFLAGS

 (>> [Table 21-6](#) register overview)

 (>> [Memory Block Transfer Modes of the Stream Channel](#))

MFLAGS
Miscellaneous Flags Register
(18_H)
Reset Value: 8000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INI	TEO	TEI	TSE	0	0	CRC E	PIE2	PIE1	SRIE	MAV	ISB	IMB	TMB	0	
rh	rh	rh	rh	r	r	rh	rh	rh	rh	rh	rh	rh	rh	rh	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNEXPECTED				TIMEOUT				TTE				NACK			
rh				rh				rh				rh			

Field	Bits	Type	Description
NACK	[3:0]	rh	Not Acknowledge Error - Target Error Indicates that a target error frame has been received.
TTE	[7:4]	rh	Transaction Tag Error Indicates for each channel if a CRC correct acknowledge frame with an unexpected transaction tag number has been received.
TIMEOUT	[11:8]	rh	Timeout Error Indicates for each channel if an timeout event has occurred.
UNEXPECTED	[15:12]	rh	Unexpected Type of Frame Error Indicates for each channel if an unexpected or inappropriate response is received. For example a NACK for a Trigger frame or DATA for WRITE frame.

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
TMB	18	rh	<p>Target Memory Block Selects the currently active memory block used by the target as a target for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed.</p> <p>0_B Memory block 0 1_B Memory block 1</p>
IMB	19	rh	<p>Initiator Memory Block Selects the currently active memory block used by the initiator as a source for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed.</p> <p>0_B Memory block 0 1_B Memory block 1</p>
ISB	20	rh	<p>Initiator Stream Block Request Indicates if stream block request is pending. Set by the software to start a stream block transfer by using the MFLAGSSET.ISBS bit; clear by the software possible (if needed) by using the MFLAGSCL.ISBC bit; cleared by hardware at the end of the current block transfer in single mode, but not in continuous mode.</p> <p>0_B No request or streaming ongoing 1_B Streaming ongoing</p>
MAV	21	rh	<p>Memory Access Violation Indicates a memory access violation.</p> <p>0_B No violation 1_B Violation</p>
SRIE	22	rh	<p>SRI/SPB Bus Access Error Indicates an error on the SRI bus - transaction ID, ECC error or error acknowledge. Indicates an error on the SPB bus, error acknowledge or timeout.</p> <p>0_B No error 1_B Error</p>

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
PIE1	23	rh	PHY Inconsistency Error 1 Indicates if HSCT to HSSL channel number code comparator has detected an inconsistency error. 0 _B No error 1 _B Error
PIE2	24	rh	PHY Inconsistency Error 2 Indicates if HSCT to HSSL data length comparator has detected an inconsistency error. 0 _B No error 1 _B Error
CRCE	25	rh	CRC Error Indicates if CRC checker has detected a CRC error. 0 _B No error 1 _B Error
TSE	28	rh	Target Stream Enable Used by the hardware to handle the single and continuous streaming. In single mode, cleared by hardware after the current block transfer ends. The module ignores afterwards the incoming steam frames. 0 _B Disabled 1 _B Enabled
TEI	29	rh	Transmit Enable Input Indicates the state of the TEI input signal of the HSSL module, which is driven by the CTS output signal of the HSCT module. Any edge on this signal triggers an EXI interrupt. This low level signal stops the transmission of both command and response frames.
TEO	30	rh	Transmit Enable Output Indicates the state of the TEO output signal of the HSSL module, which drives thee CTS input signal of the HSCT module. This bit is cleared by hardware at entering the INIT and Soft Suspend state.
INI	31	rh	Initialize Mode Indicates if the module is in the Initialize or Run mode. 0 _B Run mode 1 _B Initialize mode

SFSFLAGS
Stream FIFOs Status Flags Register (28_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RXFL	[1:0]	rh	Stream RxFIFO Filling Level Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00 _B 0 01 _B 1 10 _B 2 11 _B reserved (not possible)
TXFL	[3:2]	rh	Stream TxFIFO Filling Level Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00 _B 0 01 _B 1 10 _B 2 11 _B reserved (not possible)
EXFL	[5:4]	rh	Stream Expect FIFO Filling Level Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00 _B 0 01 _B 1 10 _B 2 11 _B reserved (not possible)

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
ISF	15	rh	Initiator Stream Frame Request Indicates if stream TXFIFO request is pending. Set and cleared by the TXFIFO. 0 _B TXFIFO fill request not pending 1 _B TXFIFO fill request pending
0	[31:16], [14:6]	r	reserved

21.13.3 Channel.Initiator Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions. In order to support command queues, the addresses of the **IWD**, **ICON**, **IRWA**, and **IRD** registers are ordered in a sequence of IWD0, ICON0, IRWA0, IRD0, IWD1, ICON1, IRWA1, IRD1, IWD2, ICON2, IRWA2, IRD2, IWD3, ICON3, IRWA3, IRD3, see **DMA Operated Command Queues**. For the timeout handling description, see **Command Timeout Operation**.

IWD

The IWD register contains the data part of a write command.

(>> **Table 21-6** register overview)

IWDx (x=0-3)

Initiator Write Data Register x ($30_H + x*10_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DATA	[31:0]	rw	Data Part of the Payload of a Write Frame For 8-bit and 16-bit write command frames, the whole frame payload width of 32-bit is automatically filled with copies of the lower 8-bits or 16-bits of the register.

High Speed Serial Link (HSSL)
ICON

The ICON register contains the control and the configuration bits of a channel.

Bitfields TOREL and ITTAG are used for command frames, and also reused for streaming frames in channel 2. All other bit fields are used only for command frames.

(>> [Table 21-6](#) register overview)

ICONx (x=0-3)

Initiator Control Data Register x ($34_H + x*10_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
IDQ	0	w	Read ID Request This bit provides the only way to request a read ID frame. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No read ID request 1_B Read ID frame request
TQ	1	w	Trigger Request This bit provides an alternative way to request a trigger frame, without having to write to the channel address register. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No trigger request 1_B Trigger frame request
LETT	[4:2]	rh	Last Error Transaction Tag
CETT	[7:5]	rh	Currently Expected Transaction Tag
TOCV	[15:8]	rh	Time Out Current Value

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
DATLEN	[17:16]	rw	Data Length Defines the length of the data in bits of the write and read command. 00 _B 8-bit 01 _B 16-bit 10 _B 32-bit 11 _B reserved (implemented as 32-bit)
BSY	20	rh	Channel Busy
RWT	[19:18]	rw	Read Write Trigger Command Type Defines if the write to the IRWA register will trigger read, write or trigger request. 00 _B No action 01 _B Read Frame 10 _B Write Frame 11 _B Trigger Frame
ITTAG	[23:21]	rh	Initiator Transaction Tag This bit displays the current value of the three bit counter generating the new transaction tag value.
TOREL	[31:24]	rw	Time Out Reload Value Defines the duration of the timeout in units of prescaled clock periods. This parameter is valid both in command and stream mode of the channel 2.

IRWA

The IRWA register contains the address part of a write command. Writing the IRWA register triggers a transmit request for the appropriate channel.

(>> [Table 21-6](#) register overview)

IRWAx (x=0-3)

Initiator Read Write Address Register(38_H + x*10_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
ADDRESS	[31:0]	rw	Address Part of the Payload of a Write Frame Writing to this registers triggers transmission of a Write Frame. The address must be aligned according to the data width: byte addresses for 8-bit data, word addresses for 16-bit data, double word addresses for 32-bit data.

IRD

The IRD register contains the data read from the target, which has been fed back as a response to a read command.

(>> [Table 21-6](#) register overview)

IRD_x (x=0-3)

Initiator Read Data Register ($3C_H + x*10_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DATA	[31:0]	rh	Data Delivered by a Read Response Frame

21.13.4 Channel.Target Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions.

TCD

The TCD register contains the data part of a write command which is currently being processed by the channel on the target side, or the latest data which has been read by the SRI/SPB master in case of a read command.

(>> [Table 21-6](#) register overview)

TC Dx (x=0-3)

Target Current Data Register x ($70_H + x*8_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
D	[31:0]	rh	Data Part of the Payload of a Write Command Frame or Read Data of a Read Command Frame

TCA

The TCA register contains the address part of a read or write command which is currently being processed by the channel on the target side.

In case of Read ID frame, the address is copied from the register [TIDADD](#).

(>> [Table 21-6](#) register overview)

TC Ax (x=0-3)

Target Current Address Register x ($74_H + x*8_H$) **Reset Value: 0000 0000_H**

High Speed Serial Link (HSSL)

Field	Bits	Type	Description
A	[31:0]	rh	Address Part of the Payload of a Write Command Frame or a Read Command Frame or ID Frame

TSTAT

The TSTAT register contains the status bits of the common target functionality.

(>> [Table 21-6](#) register overview)

TSTAT
Target Status Register
(90_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
LASTCCx (x=0-3)	[8*x+4: 8*x]	rh	Last Command Code Indicates the latest command code from the header for the corresponding channel.
LASTTTx (x=0-3)	[8*x+7: 8*x+5]	rh	Last Transaction Tag Indicates the transaction tag of the latest command or stream frame for the corresponding channel.

High Speed Serial Link (HSSL)

TIDADD

The TIDADD register contains the address from which the target ID is fetched.

(>> [Table 21-6](#) register overview)

TIDADD

Target ID Address Register (94_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
A	[31:0]	rw	Address Pointer Address pointer containing the address of the memory location containing the unique ID data.

High Speed Serial Link (HSSL)

ISFC

Initiator Stream Frame Count Register(AC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELCOUNT	[15:0]	rw	<p>Reload Count Number Contains the number of frames to transfer per memory block. Bit field length depends on application requirements.</p> <p>0_D 1 1_D 1 2_D 2 3_D 3 others, corresponding number of frames</p>
CURCOUNT	[31:16]	rh	<p>Current Count Number Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.</p>

21.13.6 Target Stream Registers

(>> [Table 21-6](#) register overview)

(>> [Memory Block Transfer Modes of the Stream Channel](#))

TSSAx (x=0-1)

Target Stream Start Address Register x(B0_H + x*4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
ADDR	[31:5]	rw	Start Address for the Memory Range Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	[4:0]	r	reserved

TSCA

Target Stream Current Address Register (B8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CURR	[31:5]	rh	Address of the Memory Location for the Current Transfer Aligned on 256-bit (or 32 byte) limit (stream frame payload size).
0	[4:0]	r	reserved

High Speed Serial Link (HSSL)

TSFC

Target Stream Frame Count Register (BC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELCOUNT	[15:0]	rw	<p>Reload Count Number Contains the number of frames to transfer per memory block. Bit field length depends on application requirements.</p> <p>0_D 1 1_D 1 2_D 2 3_D 3 others, corresponding number of frames</p>
CURCOUNT	[31:16]	rh	<p>Current Count Number Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.</p>

21.13.7 Access Protection Registers

This sub section describes the registers defining the access windows where the HSSL accesses are allowed. These registers are writable only in supervisor mode, which makes them not writable by the HSSL itself.

(>> [Table 21-6](#) register overview)

AWSTARTx

AWSTARTx (x=0-3)

Access Window Start Register x ($C0_H + x*8_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
AWS	[31:8]	rw	Access Window Start Address This bit field defines the upper 24 bits of the start address of the corresponding access window. This results in a granularity of 256 bytes for the start address.
0	[7:0]	r	reserved

AWENDx

AWENDx (x=0-3)

Access Window End Register x ($C4_H + x*8_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
AWE	[31:8]	rw	Access Window End Address This bit field defines the upper 24 bits of the end address of the corresponding access window. This results in a granularity of 256 bytes for the end address.
0	[7:0]	r	reserved

High Speed Serial Link (HSSL)

AR

AR

Access Rules Register

(E0_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ARWx (x=0-3)	[1+2*x: 0+2*x]	rw	Access Rule for Window x 00 _B No access (window disabled) 01 _B Read access allowed 10 _B Write access allowed 11 _B Read and write access allowed
MAVCH	[17:16]	rh	Memory Access Violation Channel This bit field shows the number of the latest channel that attempted a not allowed access. 00 _B Channel 0 01 _B Channel 1 10 _B Channel 2 11 _B Channel 3
0	[31:18], [15:8]	r	reserved

21.14 Module Implementation

The following section describes the topics regarding the integration of the module on chip.

21.14.1 BPI_SPB Module Registers

21.14.1.1 System Registers

Figure 21-38 shows all registers associated with the BPI_FPI module, configured for one kernel. The Offset Address in the following BPI_FPI register table and in the BPI_FPI register descriptions are proposals. In a standard 32 bit peripheral the CLC is mapped to offset address 00h, module ID to 08h. The proposal for the new BPI_SPB register is to map them to the end address of the peripheral address range together with the peripherals SRNs.

BPI_FPI Registers Overview

Figure 21-38 BPI_FPI Registers

The writes of the bus masters to the HSSL module is controlled by Acces Protection registers ACCENx.

The HSSL implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{\leftarrow} module clock signal, sleep mode and disable mode for the module.

High Speed Serial Link (HSSL)

CLC

Clock Control Register

(00_H)

Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode.
0	[31:4], 2	r	Reserved Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode

High Speed Serial Link (HSSL)
OCS
OCDS Control and Status

High Speed Serial Link (HSSL)

Note: The bit *SUSSTA* is set only at entering the suspend state from the run state, according to the [Figure 21-29](#). It will not be set if the soft suspend request comes in any other state than run state, like init or disabled/sleep state.

Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B,..., EN31 -> TAG ID 011111B.

ACCEN0

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

High Speed Serial Link (HSSL)

TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ..., EN31 -> TAG ID 111111B.

ACCEN1
Access Enable Register 1
(F8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0
Kernel Reset Register 0
(F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST

High Speed Serial Link (HSSL)

bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

0	[31:1]	r	Reserved Read as 0; should be written with 0.

21.15 High Speed Communication Tunnel (HSCT)

This chapter describes the High Speed Communication Tunnel interface for the Microcontroller high speed data communication including the physical layer and the control (link) layer.

21.15.1 Overview

The HSCT chip to chip communication interface employs an interface for inter chip communication between a master interface and a slave interface. The interface is based on LVDS IO technology and developed to function as a master or a slave interface. During initialization phase the role of the Interface (master or slave) must to be defined. It is not intended to change the system role during an application.

The interface is a full-duplex interface for TX and RX data transfer. The data transfer speed can be configured to function in low or high speed and allows to configure in each transfer direction an independent transfer speed in order to reduce power and EMI, based on transfer speed requirements. A sleep mode for the LVDS IO's is implemented, which reduces power on the IO, if the interface is not in use.

The master interface is defined to own the crystal and provides the clock (**SysClik**) to the slave interface. The slave interfaces allows a master interface generated SysClik routing through the SysClik IO or the XTAL1 IO. The second one allows to use SysClik as reference clock for the System PLL. The HSCT Master/Slave interface in the system allows one crystal only. The interface reset is derived from the System reset and provided by chip internal reset signaling.

In **Figure 21-39** a system level view of the interface and interface connection is shown.

Figure 21-39 Overview of Interface Signals.

Note: The HSCT SysClk path from Master to Slave device can be done using Master Port 20.0 (5 V) or using Port 21.6 (3.3V). Only one of this two signal path shall be used on a PCB design. It is recommended to use P20.0 signaling path. HSCT SysClk connection to XTAL1 is not supported by FlexRay PLL.

21.15.1.1 Features

The HSCT interface is intended to carry:

- Transmit Symbol information from the master interface to the slave interface
- Receive Sample information from the slave interface to the master interface
- System Clock provided by the master interface (crystal owner) to the slave interface
- Control information on Master TX link and RX link
- Clear To Send indication in both directions
- Unsolicited Status in both directions
- Regular data transfer in both directions based on data channels
- Master interface data transfer speed 5 MBaud and 320 MBaud.
- Three slave interface data transfer speeds available based on 20 MHz SysClk:
 - 5 MBaud (low speed)
 - 20 MBaud (medium speed)
 - 320 MBaud (high speed)
- Two slave interface data transfer speeds available based on 10 MHz SysClk:
 - 5 MBaud (low speed)
 - 320 MBaud (high speed)
- The interface is based on IEEE 1596.3 LVDS IO's
- To reduce the voltage swing a configuration option is available

21.15.2 Functional Description

21.15.2.1 Introduction

The first HSCT communication is always established from master interface. The LVDS IO's are based on standard IO technology following IEEE 1596.3 specification. The HSCT LVDS IO common voltage is defined to be a 1.2V. Compared to IEEE 1596.3 the differential voltage level can be reduced via configuration option to reduce EMI. Additionally the HSCT SysClk can be configured to run at Crystal/2 to reduce EMI instead of Crystal frequency used as single ended clock.

The intention is to implement the interface either as a master interface or as a slave interface. So the interface is able to handle both roles (master or slave). The following detailed description should describe both roles. This requires the following definitions:

- TX line or TxData link (TX_DAT, TX_DATX) defines the data transfer from the master interface to the slave interface.
- RX line or RxData link (RX_DAT, RX_DATX) defines the data transfer from the slave interface to the master interface.
- Transmit direction, outbound data (or transmission) describes to send out data independent of the role the interface does have.
- Receive direction, inbound data (or receiving) describes to receive data independent of the role the interface does have.

21.15.2.2 Physical Layer

RX / TX Data Interface

During initialization the associated TxData link starts in low-speed mode, with the high-speed clock generators turned off and the RxData Link disabled. An interface control sequence, initiated by software, allows to switch the interface in high-speed mode.

The data interface can transmit up to 320 Mbit/s in the RX and the TX direction (full-duplex). The data is recovered from RX data stream (RX_DAT, RX_DATX) in the master interface and from TX (TX_DAT, TX_DATX) data stream in the slave interface.

Table 21-7 shows the interconnects of the differential data lines for control and data transfer between the master interface and the slave interface.

In transmit direction a 320 Mbit/s data signal is transmitted from the master interface to the slave interface. Proper phase selection is processed at receiver side via six different phases of a 320 MHz clock.

In RxData direction a 320 Mbit/s differential data signal is supplied from the slave interface to the master interface. A proper phase selection is processed for data recovery at the master receiver path via six different phases of a 320 MHz clock. The slave interface reference clock must be the SysClk, driven by the interface Master. The Slave must receive the SysClk from the master interface to be enabled to transfer data. In the slave interface the 320 MHz data clock is generated internally from the SysClk. The slave interface PLL reference clock is based on the **SysClk** interface signaling or on a clock provided via the Oscillator input. The selection can be done via configuration register setting. Also the slave receiver path is using the six different phases of a 320 MHz clock to recover the data.

Note: A local crystal at the slave interface taken as reference clock for the interface PLL is not allowed as the data recovery based on clock phase shift does work on a common reference clock source! It is allowed to use the oscillator input of the chip and connect the master interface SysClk to it. In this case also other chip internal PLL's can be supplied with the SysClk master interface reference clock.

Table 21-7 Physical Interconnects

Direction	Name	Description
Transmit	TX_DAT, TX_DATX	Channel TX data and control information at a max rate of 320 Mbit/s from the master interface to the slave interface
Receive	RX_DAT, RX_DATX	Channel RX data and control information at a max rate of 320 Mbit/s from the slave interface to the master interface

The interface driver in shutdown mode provides a pull-down to 0V on both differential pins to ensure that the signals are held in a defined state. The RxDAT link enters shutdown mode by Interface control logical channel command and exit shutdown mode by control command, again. The slave transmission line is disabled by default and must be enabled by the master. The master is using control commands to link operation modes.

Payload content is transferred most significant bit first. For example, if a 32-bit payload contains a message that is built in a 32-bit register in the sending interface, b31 of the register (the MSb) shall be the first bit of payload transmitted and b0 (LSb) shall be the last. Larger payloads should be built up according to the same principle.

Differential Signaling Principle Based on LVDS

The voltage at the termination resistor of the receiver is either positive or negative, which depends on the direction of the current flowing through it. This is determined by the state of the switches at the transmit stage. The voltage V_{OD} should be evaluated by a comparator with hysteresis.

Figure 21-40 Pad Driver and Pad Receive

The HSCT interface does not define specific test for an error-free transmission, although the signal quality of course suffers from attenuation and noise and in particular it depends on proper wave propagation. Therefore the interconnect lines need to have a characteristic wave impedance Z_L equal to $100\ \Omega$ differential, corresponding to the termination resistor R_T at the receiver side.

Note: Due to the nature of wave propagation a termination other than with the characteristic line impedance leads to inevitable signal degradations. Therefore any operation mode other than $100\ \Omega$ termination is only supported from a functional point of view (i.e. the corresponding electrical configuration is possible) without any further guarantee of an error-free transmission.

Note: The interface receiver provide an input termination impedance of $100\ \Omega \pm 20\%$ at the IO. If a more precise termination is required the design offers to disable the internal termination impedance and allow an external termination on the PCB.

The differential output voltage V_{OD} is defined as the difference of the voltages V_{dP} and V_{dN} at the receiver input pins.

$$V_{OD} = V_{dP} - V_{dN} \quad (21.1)$$

The common-mode voltage V_{OS} is defined as the arithmetic mean value of the voltages at the receiver input pins:

(21.2)

$$V_{OS} = \frac{V_{dP} + V_{dN}}{2}$$

V_{OD} , V_{OS} , and the corresponding minimum differential eye opening V_{eye} considering LVDS transmitter jitter are graphically shown in [Figure 21-41](#) and [Figure 21-42](#) for ideal signals.

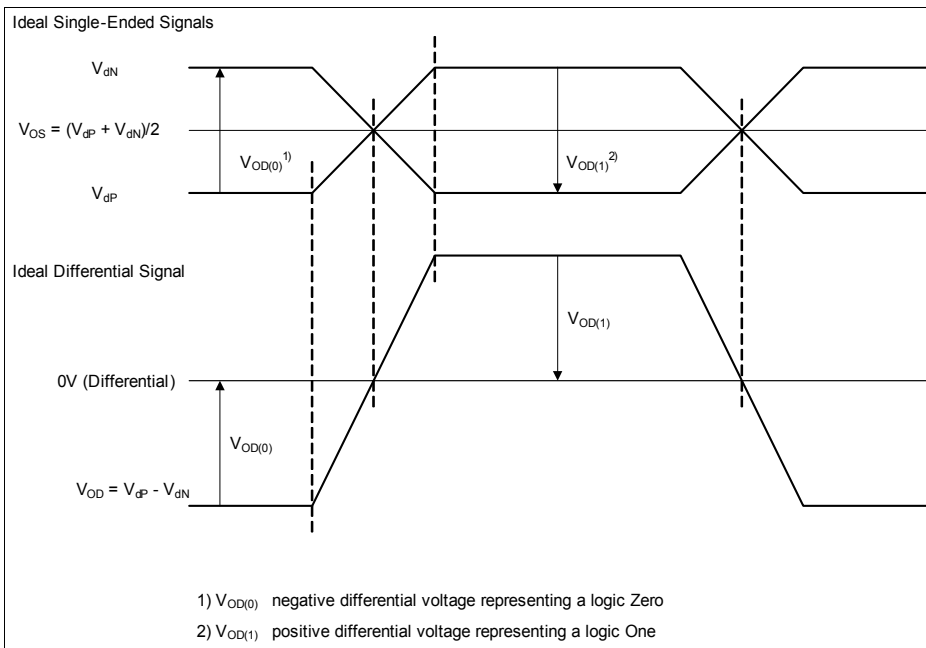

Figure 21-41 Ideal Single-Ended and Ideal Differential Signals

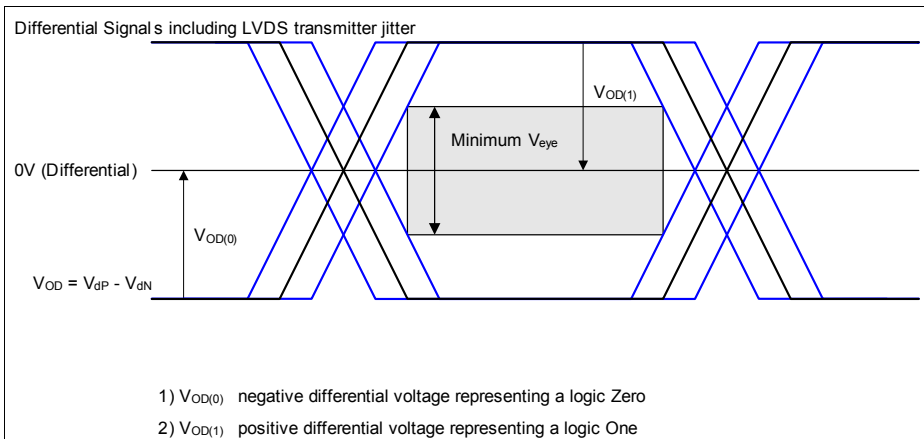

Figure 21-42 Differential Eye Opening

21.15.2.3 Electrical Characteristics Based on LVDS for Reduced Link trace length

The characteristics are based on the LVDS standard IEEE P1596.3-1995. It is adapted for low power consumption and lower supply voltages for short ranges. It is assumed that the master interface and the slave interface may have different supply voltages, but common mode voltage for the differential signaling is based on 1.2V.

Operating Modes

The HSCT interface comprises the following operating modes:

- Terminated Mode:** The data transmitter requires a 100 Ω external termination at the pins **TX_DAT** and **TX_DATX**. The termination is given by a 100 Ω resistor at the receiver input, of the opposite LVDS device, for matching the differential characteristic impedance of the line with the impedance of the receiver. PCB design has to follow guidelines on differential signal routing. The PCB placed termination resistor can be chosen very precise. Via configuration option an 100 Ω LVDS receiver internal resistor can be enabled with a +/- 20% tolerance.
- Power up:** The line receiver shall always be enabled after power up and SysClk is active. The data decoder behind the receiver is not enabled at this point. It is enabled when the first transition on the data lines is detected by the line receiver. The line driver must be enabled on the master side via SW control. On the slave side the line driver must be enabled by sending interface message control commands from the master. After power up the link starts in low speed mode. After line driver enable some time is required to power up the LVDS transmitter line. The LVDS driver will be activated after a startup time of max. 3 ms. The data link in RX and TX direction is ready to transmit and receive data after the defined setup time.

- **Sleep mode:** In terminated operation the differential voltage across the resistor will be reduced to nominally zero (-5mV to 20mV at 100 Ω +/- 20%) and hence, the line driver current requirement will reduce to internal bias currents. The common-mode voltage, however, should be maintained. Also the PLL is not switched off during sleep mode and being in high speed mode.
- **Power down:** When any interface driver supply voltage is removed, the driver shall provide a weak pull-down to 0 V to ensure that the signals are held in a well-defined state. It is a requirement to be free of cross- and bias current during power down.

Note: The line driver in the master interface shall be turned on before the line driver in the slave interface is activated, i.e. before sending the transmitter activation command to the slave interface, in order to avoid receiving undefined data in the slave interface.

The implementation of the output driver is based on a bridge topology of current sources. Accordingly the equivalent differential source impedance is high-ohmic (>10k Ω). This mismatch with regards to the immediate termination at the Microcontroller chip edge (100 Ω line) is common practice among LVDS interface designs.

Due to the strong dependency on link length and layout, as well as the susceptibility to noise and interference, it is recommended, to have the termination available on the PCB:

- Receiver **internal termination mode** not active (PCB termination): can be programmed in register **INIT**. The data transmitter is operated without a termination inside the differential receiver pair.
- Receiver **internal termination mode** active: allows to have a 100 Ω resistor internally with a +/-20% tolerance. Programming via the same register bit as PCB termination (in register **INIT**).

Data Rates

Both, master and slave interface shall be ready to receive frames whenever the SysClk is running. The link shall initialize in low-speed mode with the high-speed clock generators turned off and the RxData link disabled. Subsequent speed and mode changes shall be commanded by the master interface, except sleep mode on the RxData link, which is controlled by the slave interface. Except when using sleep mode, both links shall default to the logic zero state, while dormant and between frames. This is required, to ensure that data will not be lost during a speed change.

Interface data rate change on both the TxData and the RxData link shall be possible without losing data. It is highly recommended to keep the link quiet during the time the interface transfer speed is changed. Changing transfer data rate on an active link does not guarantee stable data transfer.

The HSCT standard defines three different data speed modes:

- Low speed mode
- Medium speed mode
- High speed mode

Additionally the HSCT standard defines the different data speed modes to be derived from the crystal frequency. Taking the Automotive common crystal frequency of 20 MHz the following data rates can be produced based on the available multiplication factors.

SysClk; RefClk = Crystal frequency = 20 MHz:

- 5 MHz = Crystal frequency / 4 (Low Speed)
- 20 MHz = Crystal frequency (Medium Speed)
- 320 MHz = Crystal frequency * 16 (High Speed)

SysClk; RefClk = Crystal frequency / 2 = 10 MHz:

- 5 MHz = SysClk frequency / 2 (Low Speed)
- 20 MHz = Medium Speed - **not available**
- 320 MHz = SysClk frequency * 32 (High Speed)

Low Speed mode and Medium Speed mode frequencies are generated directly out of the Crystal frequency. High Speed mode frequency requires a PLL, which takes the Crystal clock as reference clock.

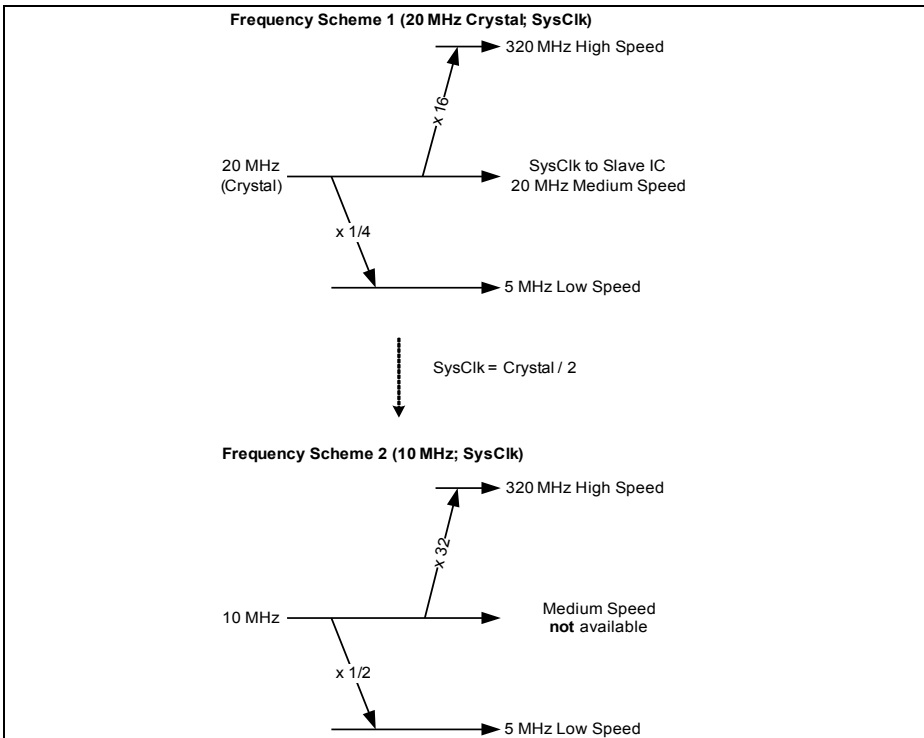

Figure 21-43 Frequency Scheme

Connecting a 20 MHz Crystal to the system allows to generate the Automotive frequency scheme.

The following table (Table 21-8) shows the data transfer direction and the available Automotive transfer speed based on Crystal clock frequency.

Table 21-8 HSCT Data Rates

Direction	Data Rate	Operating Mode
Master interface to Slave interface	5 Mbit/s	“low speed mode” for startup / fallback
Master interface to Slave interface	320 Mbit/s	“high speed mode”
Slave interface to Master interface	5 Mbit/s	“low speed mode” for startup / fallback

Table 21-8 HSCT Data Rates (cont'd)

Direction	Data Rate	Operating Mode
Slave interface to Master interface	20 Mbit/s	“medium speed mode” <i>Note: only available, if reference clock; SysClk is at 20 MHz (Crystal)</i>
Slave interface to Master interface	320 Mbit/s	“high speed mode”

*Note: To fulfill the requirement - having reduced EMI on the single ended **SysClk** - the interface can be configured to operated on a **SysClk = Crystal/2** frequency. Choosing the **crystal/2** mode excludes the medium speed mode available in slave to master data transfer direction (receiver line). Low speed mode devices divide SysClk by 2 to achieve the low speed clock. Another possibility to reduce EMI is reducing SysClk driver strength based on the 20 MHz clock, which is the recommended way as BER is better than using 10 MHz.*

PLL configuration and Baud Rates

The PLL supports different speed modes and frequency modes, which will be described in this section in detail. Each mode and transfer direction can be configured separately.

Table 21-9 High Speed Mode selection

PLL Speed [MHz]	320	320	280	280	240	240	200	200
PLL reference frequency [MHz]	20	10	20	10	20	10	20	10
PLLWMF [hex]	10	20	0E	1C	0C	18	0A	14
TXHD 1/1 [MBaud]	320	320	280	280	240	240	200	200
TXHD 1/2 [MBaud]	160	160	140	140	120	120	100	100
TXHD 1/4 [MBaud]	80	80	70	70	60	60	50	50
TXHD 1/8 [MBaud]	40	40	35	35	30	30	25	25
TXHD 1/16 [MBaud]	20	20	17.5	17.5	15	15	12.5	12.5

PLL reference frequency and PLL frequency control word Multiplication factor (PLLWMF) defines the PLL speed and are used to configure the output frequency of the PLL. The interface baud rate can be configured separately in TX direction (TXHD) and RX direction (RXHD). The table above exemplarily shows the TX direction.

Correlator

Data transfer from the master interface to the slave interface can either be in “high speed mode” or “low speed mode” (**Crystal**/4 at 20 MHz SysClk or SysClk/2 at 10 MHz SysClk). A correlator is used for finding the optimum sample phase for the transfer. The correlator configuration differs in high speed and low speed mode.

Phase Selection

Every frame starts with a 16-bit sync field (see [Figure 21-44](#)) containing a synchronization pattern. Note that the sync pattern starts with 1, so a new frame always starts on the rising edge. In between frames, there is always at least one bit 0 in normal mode. By sending 1 immediately after the last bit in a frame, the master interface controller demands sleep mode as described in Section Sleep Mode. Neither the master interface nor the slave interface may assume that the other side will maintain data phasing between frames. The receiving interface shall use the sync pattern to determine the start time of the frame relative to the local clock.

Figure 21-44 Synchronization Pattern

The synchronization pattern is only needed for selecting the optimum sample phase, so it is not feed through to the output register of the correlator.

Payload Size Decoding

Every frame consists of three parts: a 16-bit synchronization pattern, an 8-bit header and the payload field which can be 8, 32, 64, 96, 128, 256 or 512 bits. The header contains information about payload size and logical channel type. Although decoding the header is task of the deframer, the payload size shall also be evaluated inside the correlator for finding the end of a frame.

The header is sent most significant bit first. The first 3 bits (bit5, bit6 and bit7) contain the payload size of this frame (see [Table 21-10](#)).

Table 21-10 Payload Size Coding

b7 ... b5	Payload Size (bits)	Total Frame Size (bits)
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152

Table 21-10 Payload Size Coding (cont'd)

b7 ... b5	Payload Size (bits)	Total Frame Size (bits)
101	256	280
110	512	536 (not supported)
111	288	312

Note: In a harsh Automotive environment a payload of 512 bit may cause increased error bit streams, due to the long distance from one synchronization pattern to the next. This is the reason why this data transfer length is not supported.

The correlator shall decode the payload size field and count the number of received bytes. After the last byte in a frame has been fed through to the correlator output register, the tuning of the multiplexer unit becomes invalid. In between frames at least one bit 0 shall be transmitted. The comparison procedure is started again as soon as there is a 1 at the MSB position in the shift registers.

The 8-bit header and the payload are used as input for the deframer block.

Note: The sync pattern and inter-frame bits are not passed to the deframer. An error in the sync pattern generates an error and is detected by the Physical layer.

Transmission initiated Sleep Mode - bringing receiver path into sleep mode.

By sending a 1 immediately after the last bit in a frame, the interface indicates that its LVDS line driver is sent to sleep mode, and suggests sleep mode to the receiver LVDS.

To leave sleep mode, the master interface shall send 8 bits of 0. This is performed in high speed mode and in low speed mode.

Jitter Budget

The system clock is distributed directly from the master interface to the slave interface.

Subsequently, all jitter investigations considered in the following sections are referenced to the system clock, i.e., 20 MHz as the base oscillator frequency or 10 MHz as the base oscillator frequency divided by 2.

Each system clock distribution has an associated filter function that comprehends the worst case combination of PLL bandwidth/peaking and equivalent jitter. The effective jitter seen at the LVDS receivers clock-data recovery inputs is a function of the difference in LVDS receiver and LVDS transmitter PLL bandwidth and peaking convolved with the jitter spectrum of the system clock.

System Clock variations contain jitter over a wide range of frequencies, some of which will be tracked by the LVDS receiver or otherwise removed by the combination of the LVDS transmitter and the LVDS receiver PLLs. Consequently, the nature of the filter functions is in part dependent on the way of how the system clock is distributed. In general, the system clock jitter is filtered by the PLL difference function which

comprehends the “mismatch” between LVDS transmitter and LVDS receiver PLL and also accounts for the impact of the transport delay.

Direct System Clock Distribution

This architecture implies direct distribution of the crystal clock as system clock from the master interface to the slave interface. Hence, the system clock is directly supplied to both LVDS transmitter PLL and LVDS receiver PLL. Hence, a major part of the clock jitter is sourced equally through LVDS transmitter and LVDS receiver PLLs. The amount of jitter appearing at the data recovery block is then defined by the transfer function difference of the LVDS transmitter and LVDS receiver PLLs, and by the sum of the clock jitter of the LVDS transmitter PLL, $X_{\text{clkMaster}}(s)$, and the LVDS receiver PLL, $X_{\text{clkSlave}}(s)$.

Based on the above clock architecture, a difference function may be defined that describes the “mismatch” between LVDS transmitter and LVDS receiver PLLs. As a first approximation second order transfer functions are assumed.

The jitter of the direct system clock distribution is described by the phase noise power spectral density function as the absolute square of $X_d(s)$, as follows.

$$|X_d(s)|^2 = |X(s)|^2 |H_1(s)e^{-sT} - H_2(s)|^2 + |X_{\text{clkMaster}}(s)|^2 + |X_{\text{clkSlave}}(s)|^2 \quad (21.3)$$

where

$$H_1(s) = \frac{2s \zeta_1 \omega_{n1} + \omega_{n1}^2}{s^2 + 2s \zeta_1 \omega_{n1} + \omega_{n1}^2} \quad (21.4)$$

and

$$H_2(s) = \frac{2s \zeta_2 \omega_{n2} + \omega_{n2}^2}{s^2 + 2s \zeta_2 \omega_{n2} + \omega_{n2}^2} \quad (21.5)$$

Conversion between the natural PLL frequency ω_n and the -3 dB point is given by the following expression.

$$\omega_{3dB} = \omega_n \sqrt{1 + 2\zeta^2 + \sqrt{(1 + 2\zeta^2)^2 + 1}} \quad (21.6)$$

Under the assumption that crystal clock jitter can be ignored, i.e.,

$$X(s) \approx 0 \quad (21.7)$$

and LVDS transmitter to LVDS receiver transport delay can be neglected, i.e.,

$$e^{sT} \approx 1 \quad (21.8)$$

the phase noise power spectral density of the direct system clock distribution can be simplified, as follows.

$$|X_d(s)|^2 = |X_{clkMaster}(s)|^2 + |X_{clkSlave}(s)|^2 \quad (21.9)$$

Note: The slave interface requires a SysClk from the master always as reference clock. It is not supported by the interface to have a separate crystal connected to the SysClk input as reference clock at the slave interface. The master interface generated SysClk needs to be enabled.

Jitter Budgeting

To estimate the total rms jitter of LVDS transmitter PLL and LVDS receiver PLL for data recovery the following procedure has to be followed.

- Piece wise linear integration of the additive SSB (Single Sideband) phase noise for direct clock distribution to obtain the total phase noise power of the LVDS transmitter PLL.
- Calculation of the rms jitter of the LVDS transmitter PLL as shown in [Figure 21-45](#).
- Calculation of the total rms jitter RJ as the square root of the sum of the squares of the rms jitter from the LVDS transmitter PLL and the LVDS receiver PLL.
- Calculation of total jitter, i.e., random and deterministic, considering duty-cycle distortion and other effects to guarantee minimum eye opening at the interface.

Figure 21-45 Calculation of Jitter from SSB Phase Noise

Calculation of Total Jitter Budget

To estimate the total jitter budget allowed for the random rms jitter *RJ* as described in the sections before, the following procedure for direct clock distribution has to be followed.

- Calculation of the jitter headroom available for the ideal jitter-free case given by the minimum eye opening, i.e., 55% of a 320 MHz period.
- Calculation of the total jitter headroom required under the assumption that the total long-term jitter *TJ* will not exceed the maximum peak-to-peak jitter specified.
- Subtraction of two phases of the oversampling frequency used for data recovery taking into account the data-recovery uncertainty in multiples of phases of the oversampling frequency. The data-recovery uncertainty is implementation specific

and determined by the data-recovery oversampling factor DR_{OS} . **Figure 21-46** depicts the case where the selected sampling phase of the data recovery is almost one sample phase away from the ideal sampling point. Thus, the budget left for the peak jitter is reduced by almost one sample phase and hence, the peak-to-peak jitter is reduced by almost two phases.

- The remaining sum represents the jitter budget which is the upper limit for the peak-to-peak jitter calculated from the random rms jitter distribution RJ described in the sections before. Given a required *bit error rate* $BER = 10^{-12}$ for *SysClk* 20 MHz, and $BER = 10^{-9}$ for *SysClk* 10 MHz.

The jitter budget is given by the following equation.

$$TJ_{pp} = DJ_{pp} + RJ_{pp} = (DJ_{TX} + DJ_{RX}) + 2 * Q * \sqrt{J_{ABS}^2 + J_{ACC}^2} \quad (21.10)$$

Figure 21-46 Sampling Point Selection

21.15.2.4 Protocol Layer

The protocol layer is between the higher layer protocol (HSSL) and the physical layer. The protocol Layer is performing the frame generation in transmit direction and extracts the payload out of a frame in receive direction, called deframing.

Deframer

The deframer's tasks are decoding the 8-bit header and separating the data stream according to the logical channel type.

During Microcontroller reset, the deframer shall ignore all data coming in from the correlator. This is a precaution measure to eliminate possible malfunctions due to floating HSCT lines.

Additionally the deframer does check the header for potential errors, e.g. size is matching received data or size is allowed and received type is allowed. An error in the header discards the received data.

Header Decoding

The first 8-bit in a frame, after the sync pattern has been filtered out by the correlator, is the header or frame type field. It contains information about the payload size and logical channel type coding (see [Figure 21-11](#)). Please note again that all transfers are most significant bit first.

Figure 21-47 Header (Frame Type Field)

- The payload size coding can be seen in [Table 21-10](#) in the previous.
- Bits 1 to 4 define the logical channel type. See [Table 21-11](#) for details on the logical channel type coding. Note that some kinds of transfer are exclusively used from the master interface to the slave interface or from the slave interface to the master interface.
- Bit 0 is used as Clear To Send bit CTS for transfers from the slave interface to the master interface (Requires an enable via configuration). For transfers from the master interface to the slave interface also the master interface can send CTS, which must also be enabled via configuration before. Also CTS from master interface indicates the master to the slave, no more data can be accepted. This feature requires for the master interface as well as for the slave interface that higher layer FIFO provides a configuration watermark allowing to tune the CTS signaling - dependant on the transferred payload size.

Table 21-11 Logical Channel Type Coding

b4 ... b1	Logical Channel Type Master interface to Slave interface (TX Link)	Logical Channel Type Slave interface to Master interface (RX Link)
0000	Interface Control	Interface Control (PING answer, 32-bit value)
0001	Master interface Unsolicited Status (32-bit only)	Slave interface Unsolicited Status (32-bit only)
0010	Slave interface Control (not supported, receiver generates an error) ¹⁾	Slave interface Solicited Read (not supported, receiver error) ²⁾
0011	CTS Transfers	CTS Transfer
0100	Data Channel A	Data Channel A
0101	Data Channel B	Data Channel B
0110	Data Channel C	Data Channel C
0111	Data Channel D	Data Channel D
1000	Data Channel E (not supported, receiver generates an error interrupt)	Data Channel E (receiver error interrupt)
1001	Data Channel F (not supported, receiver error interrupt)	Data Channel F (receiver error interrupt)
1010	Data Channel G (not supported, receiver error interrupt)	Data Channel G (receiver error interrupt)
1011	Data Channel H (not supported, receiver generates an error interrupt)	Data Channel H (receiver error interrupt)
1100	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1101	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1110	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1111	Reserved - receiver error interrupt	Reserved - receiver error interrupt

1) Solicited control command for slave interface control is not supported - instead a higher layer two-way protocol is available.

2) Solicited read command for slave interface read is not supported - instead a higher layer two-way protocol is available.

Note: A logical channel type TX transfer request of not supported or reserved types is not stopped or prevented to be send out. Receiver side is expected to react with an error indication.

*Note: The received header information can be checked by SW reading Header status register (**STAT**). An error in the header is a severe error in a running system. Application SW must handle the situation by interface link checks (PING). Additionally it is suggested to restart a running stream, if data loss cannot be tolerated. Received header frames are discarded, the same as the CTS information inside this error frame.*

Payload Size for transmission Data

For a transmission data transfer it is recommended to use max 288-bit payload size.

Logical Channel Separation

Reflecting the logical channel type to the higher level interface, the deframer sends the frame payload. The payload, as all other parts in a frame, is sent most significant bit first.

- All data received on and decoded as channel A to D data are sent via an 32-bit data interface to the RX-FIFO.
- Data from one HSCT interface to the other can be sent using the 32-bit, 64-bit, 96-bit or 288-bit payload size.

Note: Receiving a 8-bit header size on a logical channel results in an header error.

Framer

The framer combines data and control information from the higher layer protocol to the frame payload. Note that the payload again is sent most significant bit first. The framer codes the logical channel type and the payload size in the header according to the HSCT header format (see [Figure 21-47](#)). Then a complete frame consisting of 16-bit synchronization pattern (see [Figure 21-44](#)), 8-bit header and payload field is put together.

The following logical channels are used for transmissions between master interface and slave interface:

- Data from the transmit Unit: The frame will be sent to the receiving interface side as soon as the transmit FIFO contains enough data for the required payload size. The appropriate values will be signaled with the payload size signal and in the logical channel type field in the header. For data transfer, only the logical channel types Data Channel A to D are be used! Receiving a header type reflecting the type Data Channel E to H generates an error.
- Slave interface control (at TX link) and Slave interface read (at RX link), identified by logical channel type encoding of Hex 2, is not supported.
- Unsolicited status information can be send by master interface and slave interface based on a 32-bit payload size. An unsolicited status can be used to send an unexpected and urgent message to the other side. Receiving an unsolicited message results in an interrupt at the receiving side.

Note: The Slave interface (RX link) can send out a control command (channel type encoding Hex 0), which is the predefined PING answer having a defined 32-bit payload. All other control commands are not available for the RX link to send. Slave interface solicited read (RX link, channel type encoding Hex 2) and Master interface control (TX link, channel type encoding Hex 2) are not supported by the HSCT automotive module. Receiving a header type reflecting these types on the RX link or TX link generates an error.

The handling of all frame parts is done by the framer. For determining the end of a frame, the framer shall count the number of payload bits sent to the receiver side. In between frames bits 0 shall be transmitted.

Clear to Send (CTS)

The HSCT interface is able to use “data pull” in both directions (master interface to slave interface and slave interface to master interface) to perform flow control on the transmission FIFO's. Therefore the CTS bit in the header is asserted, when the other side is allowed to send more data, and it is negated when the other side should stop transferring data.

A CTS deactivation can be send out in a “normal” transmit frame, indicated by the header bit. The following payload is not discarded at receiving interface side and processed normally. CTS deactivation can be send out in a CTS type transmit frame, if no actual transmit data is available. The clear to send information is indicated by the header CTS bit deactivation. Following payload is discarded at receiving side. A received clear to send deactivation requires to stop the transmission immediately after the actual frame being in transmission or prevent to send a new frame, if currently no transmission is active. Control frames can still be send.

The clear to send is independent of the channel having caused the back pressure. It simply stops the data channel transfer. As soon as the traffic jam is resolved the CTS bit in the next transmitted frame is activated again, or a separate CTS frame is send with the CTS bit activated.

Higher Layer software must analyze which channel caused the traffic jam and can send the information to the other side.

The usage of the CTS signaling is optional. CTS signaling can be disabled by disabling the CTS_FRAME **CTSCTRL**.

Per default the CTS bit in the header is set to 1. When the threshold value in the receive FIFO is reached, the CTS bit shall be reset to 0 in the header of the next frame sent. If there are currently no data in the higher layer module transmission FIFO to be sent in a new frame, a dedicated CTS transfer according to the logical channel type in **Table 21-11** is generated. This transfer always uses the 8-bit payload size containing dummy bits. The payload in a CTS transfer will be discarded by the receiving side.

Generation of dedicated CTS frames can be disabled by resetting bit **CTS_FRAME** in register **CTSCTRL** to 0.

The CTS bit is set to 1 again when the receive FIFO fill level in the higher layer module is below the threshold value. This is reflected by activating the CTS signal again.

The CTS signals are full duplex signals and are side information in the transferred data frame. The deframer filters the TXCTS information from the received frame header. The TXCTS is presented to the higher layer TX interface frame based. Changes within a frame is not intended. At the higher layer receiver side the higher layer does activate the RXCTS signal, if no more data can be received. The Framers sends the RXCTS information with the header of the next frame.

Sleep Mode for line driver path

The HSCT interface offers an optional transmission sleep mode in between frames. Whether the move to the transmission sleep mode can be performed, depends on the actual symbol rate, as well as the protocol payload size, because it takes the LVDS line driver about 60 ns to wake up from sleep mode. In sleep mode, the transmitting line suggests sleep mode to the other side by sending an 1 immediately after the last bit in a frame. Setting the SLPEN bitfield to 1 enables Transmission sleep mode.

If enabled, Transmission sleep mode shall be triggered after every frame, in case there is no data or CTS frame due to be sent. When Transmission sleep mode shall be triggered to the opposite receiving side, the P/S converter inserts a 1 after the last bit in a frame, and asserts the sleep signal to the transmission LVDS driver.

The sleep signal is reset as soon as the transmission FIFO wake-up threshold value is reached, or when control information shall be sent to the slave interface from the master interface. These events trigger the wake-up counter which ensures that the LVDS line driver becomes ready for operation within 60 ns. After the wake-up time the framer starts sending eight bits 0 for signalling the start of a new frame to the receiving side. Subsequently the framer generates the new frame to be sent to the receiving side.

The transmission FIFO threshold value at the higher level protocol module can be programmed depending on the payload size and data rate in order to ensure that no additional latency in the data stream is generated due to the wake-up time for the LVDS line driver.

Interface Control

The master interface is configured via a CPU based configuration. The Slave interface can be configured by sending an interface control command from the master interface. The interface control command is used to configure the slave interface into the defined mode. The receiving slave interface shall take no action, if a reserved payload value is received. Instead it generates an error interrupt. HW reacts on the received control command.

After startup the interface is enabled to work at low speed (**SysClk/4** or **SysClk/2**) and the PLL is off, no matter of the mode it had been before. Therefore shutting down the interface by chip internal control mechanism causes the interface to leave loopback-mode, clock test mode and sleep mode, if it was previously in any of these modes, and forces the receiver and transmitter to power down mode.

The interface transmitter path is disabled per default. It shall be enabled by using the appropriate interface control, which is a payload command for the slave interface and a control via SW for the master interface.

Note: No data can be transferred to the other side as long as the transmitter is disabled. In this case all data in TX direction are discarded!

The Interface Control Logical Channel transfer command always uses the 8-bit payload size and is send by the master interface only. Payload is send MSb first. The interface control payload values are shown in **Table 21-12**. All other payload values are reserved for future use. Whenever a reserved payload value is received it shall be ignored and reported by an error.

Table 21-12 Interface Control Payload Values

Value (hex)	Function
00 _H	“ping” (send by master interface. Slave interface sends back a fixed 32-bit payload result.)
01 _H	Reserved
02 _H	Slave interface clock multiplier start (in preparation for high speed mode)
04 _H	Slave interface clock multiplier stop (after fallback from high speed mode)
08 _H	Select low speed mode for transfers from the Master interface to the Slave interface
10 _H	Select high speed mode for transfers from the Master interface to the Slave interface
20 _H	Select low speed mode for transfers from the Slave interface to the Master interface
40 _H	Select medium speed mode for transfers from the Slave interface to the master interface <i>Note:</i> Not allowed, if SysClk = Crystal/2 (10 MHz) at Slave interface.
80 _H	Select high speed mode for transfers from the Slave interface to the master interface
31 _H	Enable Slave interface transmitter
32 _H	Disable Slave interface transmitter

Table 21-12 Interface Control Payload Values (cont'd)

Value (hex)	Function
34 _H	Turn on clock test mode (Send 101010... on Rx line continuously using currently configured Rx line rate; cancelled by issuing the “test mode off” command. Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the “test mode off” function, which in should not loop back and re-initialize itself for normal operation, retaining whichever interface clock rate are currently configured.)
38 _H	Turn off test mode (cancel clock test mode and payload loopback)
FF _H	Turn on payload loopback (incoming frames at Slave interface are looped back until cancelled by a Frame containing “test mode off”.) <i>Note: Requires same speed configuration for RX- and TX-link.</i>

Note: Before changing the speed mode SW has to take care that data Transmission on both links is stopped and the interface remains quiet.

As a general principle, after a mode change the master interface should request a data transfer from the slave interface to stimulate a frame, which confirms the correct reception and the mode change was successful. The PING function, available in the interface control logical channel shall be used to verify a successful speed change. The master interface generated PING has to be send in system defined time intervals, to verify the link is still alive. Sending out a ping requires system SW to activate a system timer. Not receiving the PING answer within the system defined time, the link cannot be considered as stable and a new initialization is required. The Slave interface sends back a fixed, known response based on a control command, at the currently configured link rate on RxData line.

Slow to Fast:

The slow to fast interface speed change can apply to only one of the interfaces data transfer directions or to both at the same time. At both sides Clock multipliers are needed, when either interface is to run at high speed. If the RXData link is not enabled, but needs to be, the master interface sends “Enable Slave Interface transmitter”. If the slave interface clock multiplier is not already running the master interface sends “Slave interface clock multiplier start” to the slave interface at low speed. The master interface enables its own clock multiplier, if it is not already running. After the proper settling time, the master interface sends “select high speed” to the slave interface at the currently configured speed for the TXData link. The slave interface switches the requested interface to high speed. The master interface switches the requested interface to high speed. The master interface sends a frame to the slave interface requiring a response at the currently configured speed for the TxData Link. The slave interface responds with a frame to confirm the mode change has worked. In order to select high speed for both

RXData and TXData links the master interface sends “select high speed” for the RxData link first and then for the TxData link. As described before it is suggested to send the PING for verifying a successful speed change.

Fast to Slow:

The fast to slow interface speed change is the converse of the slow-to-fast transition. Both clock multipliers must be running for either interface to operate in high-speed mode. Once both interfaces no longer require the clock multipliers they can be turned off, using the appropriate interface control payload values to command the switch in the slave interface.

Before entering high speed mode it shall be assured that the high speed clock is available by sending the interface control value 0x02.

Figure 21-48 shows the TX transmission state machine, which controls transfers from the master interface to slave interface. The interface control value `int_ctrl` represents the received interface control payload value according to **Table 21-12**.

Note: Application Software has to ensure, that no data communication is active on RX-link or TX-link during the time the interface speed is changed. Otherwise a save speed change without data loss can not be guaranteed interface.

Figure 21-48 TX link State Machine

The loopback mode is used for test and verification to identify BER. When the master interface demands loopback mode, the slave interface internally loops back all received payload values in the following frames using the currently configured clock speed on the receive data link, without applying further processing internally. (Transmit and receive chains internally shall be disabled.) The header configuration is the same as in the incoming frame and the CTS bit in the header shall be asserted. Payload contents are ignored at slave interface in loopback mode, except for the “turn off test mode” interface control value, which ends loopback mode. The “turn off test mode” frame shall not be looped back to the master interface. After leaving loopback mode, the interface is prepared for normal operation at the previously used clock speed.

Note: The “loopback on” function has been intentionally coded at a large Hamming distance from the other codes (minimum of 5, usually 7, thus requiring at least five bit-errors in the Header field for another function to be corrupted into “loopback on”.

The RX link state machine, which is responsible for controlling transfers from slave interface to the master interface, can be seen in [Figure 21-49](#). The state machine is implemented on slave interface at transmitting path. The interface control value `int_ctrl` represents the received interface control payload value according to [Table 21-12](#).

Figure 21-49 RX link State Machine

*Note: The **Medium speed mode** is only available, if the reference clock (SysClk) is running at **Crystal speed (20 MHz)**. For Crystal/2 medium speed mode is not available. A configuration of medium speed at Crystal/2 = SysClk causes low speed mode.*

In clock test mode the transmitter sends '101010 ...' continuously using the currently configured clock speed. Clock test mode can be left by sending the interface control value "turn off test mode".

The ping function in the slave interface always uses the 32-bit payload size sending back the value 0xABCDEF01 (see [Figure 21-50](#)) using the logical channel type Hex 0 (PING Status - on RX link).

Figure 21-50 The Slave interface “ping” Response

The Interface control commands to configure the slave interface have to be written into the master interface register **IFCTRL.IFCVS**. For sending the control frame a logic 1 needs to be written to the **IFCTRL.SIFCV** register to trigger the frame transfer. The 8 register bits **IFCTRL.IFCVS** represent the same functionality as defined for the interface control payload values. Coding is as shown in **Table 21-12**. The register field **IFCTRL.IFCVS** shall be written with the appropriate interface control payload value for every state transition shown in **Figure 21-48** and **Figure 21-49**. The interface control in the slave interface can alternatively be performed by programming the **IFCTRL.IFCVS**. This allows controllability of the Slave interface besides the frame based configuration. The Master interface is controlled by register configuration of physical layer only.

In **Table 21-13** the processing times for the time consuming interface control transitions (defined in **Table 21-12**) are listed.

Table 21-13 Processing Times for Interface Control

IFCVS (hex)	Transition Description	Processing Time
02 _H	Slave interface clock multiplier off to Slave interface high speed clock avail.	80 µs
04 _H	Slave interface clock multiplier on to Slave interface clock multiplier off	2 µs
08 _H	TX high speed mode to TX low speed mode	600 ns
10 _H	TX low speed mode to TX high speed mode	400 ns
20 _H	RX high or medium speed to RX low speed mode	400 ns
40 _H	RX high or low speed to RX medium speed mode	400 ns
80 _H	RX low or medium speed to RX high speed mode	400 ns
31 _H	RX disabled to RX low speed mode	500 ns

Note: The physical layer requires about 20 µs to power up, including bandgap. Afterwards the PLL Reset is allowed to be release. After PLL reset removal it takes about 50 µs to get the PLL into a locked state.

Power up sequence

The power up sequence of the HSCT Physical Layer and the LVDS IO requires to have the BandGap enabled and stable before the Bias distributor and LVDS power can be enabled. Bias distributor and LVDS power on are enabled in Master interface mode by disabling the TX_PD at LVDS PAD Control register. The required time to power up is about 500 ns. In Slave interface mode the TX_PD at LVDS PAD Control register needs to be enabled by startup software during initialization process.

21.15.3 Use Cases

The following section describes the chip to chip communication requirements based on a HSCT interface connection. The Micro Controller (MC) is from a system point of view intended to be the master interface of the chip to chip communication. Application SW has to consider power up time of companion chip during the bringup of the link.

21.15.3.1 MC to ASIC

The MC (master) is connected to the ASIC (slave) which allows to perform data streaming in both directions and register control (read/write) by the MC, which allows to use ASIC defined ASIC functions.

21.15.3.2 MC to FPGA

The MC (master) is connected to the FPGA (slave), which allows to perform data streaming in both directions.

21.15.3.3 MC to MC

This use case allows to connect two MC's together, whereas one of them gets, from the Interface point of view, the master function and the other the slave function. Potential application would be register control or data streaming. After the interface role (master or slave) definition, the role is not allowed to change. In this case only the master interface does have the crystal connected. The slave interface does use the SysClk as reference clock for the existing PLL's. The reference clock at the slave interface is used to clock the HSCT PLL and additionally as clock source for the system PLL.

The HSCT analog part is per default in power down mode. Application SW is required to enable power supply for the analog part. Only after the power is on for the analog part, communication via the HSCT interface is possible.

21.15.4 HSCT Register Description

21.15.4.1 Registers Definition

This section describes the kernel registers of the HSCT module and the System related register in single kernel configuration. All HSCT kernel register will be referenced in other parts of the TC26x B-Step User's Manual by the module name prefix "HSCT_".

HSCT Kernel Register Overview

Figure 21-51 HSCT Register Overview

The complete and detailed address map of the HSCT modules is described in the next chapter.

Address Map

Note: The absolute register address is calculated as follows: Module Base Address ([Table 21-14](#)) + Offset Address

A register is addressed word wise.

Note: Register bits marked reserved in the following register description are virtual registers and do not contain flip-flops. They are always read as 0.

HSCT Kernel Register Definitions

ID

The Module Identification Register ID contains read-only information about the module version. For a register overview, see the [Table 21-15](#).

ID

Module Identification Register (08_H) **Reset Value: 00B4 C001_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number 01 _H The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Number Type C0 _H 32 bit peripheral
MOD_NUM	[31:16]	r	Module Number for module identification 00B4 _H Is the module identification number for the HSCT interface.

INIT
INIT
Initialization register (10_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SYS_CLK_EN	1	rw	Enable SysClk in Master interface SysClk enable activates the SysClk. 0 _B disable (default) 1 _B enabled <i>Note: This feature is only available in the master interface. In slave interface mode the register setting does not have an effect.</i>
SRCF	2	rw	Select SysClk / Reference Clock Frequency rate For master interface defines Reference frequency. For slave interface frequency defines SysClk frequency. Has an effect for Low Speed only. 0 _B SysClk; RefClk is 20 MHz (Divider 1/1) 1 _B SysClk; RefClk is 10 MHz (Divider 1/2)
IFM	3	rw	Select Interface Mode Select the Interface Mode (master IF or slave IF). 0 _B master IF 1 _B slave IF

Field	Bits	Type	Description
LHLR	10	rw	<p>Loopback path at Slave interface side at higher layer system RAM.</p> <p>Disable of the LVDS IO loopback when the bit is set. The function allows to loop back data at a higher layer in HW or by SW using a RAM area.</p> <p>0_B Loopback path performed at LVDS IO 1_B Loopback path at higher layer RAM area</p>
TXHD	[18:16]	rw	<p>Transmit High Speed Divider.</p> <p>The Transmit High Speed data rate can be reduced by dividing factors. The Transmit High Speed data rate is separated from the Receive High Speed data rate.</p> <p>000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. 110_B For future use. 111_B For future use.</p>
RXHD	[21:19]	rw	<p>Receive High Speed Divider.</p> <p>The Receive High Speed data rate can be reduced by dividing factors. The Receive High Speed data rate is separated from the Transmit High Speed data rate.</p> <p>000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. 110_B For future use. 111_B For future use.</p> <p><i>Note: For future use configuration leads to no output clock delivered to the correlator.</i></p>
0	[31:22], [15:11], [9:4], 0	r	Reserved

IFCTRL

This register allows to configure the transfer Speed of the Master Interface and is also used to send the command frame to the slave.

Note: The Master interface link speed configuration immediately takes place. Therefore the Master interface speed transition must not be changed with a Slave interface command send activity.

IFCTRL
CPU transfer control register
(14_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
IFCVS	[7:0]	rw	Master Mode - Interface Control Value to be send to Slave interface See Table 21-12 . <i>Note:</i> 7. <i>Master IF: The value is taken as control frame value send as payload to the slave IF.</i> 8. <i>Slave IF: The value is a new configuration of the slave IF.</i>

Field	Bits	Type	Description
SIFCV	8	w	<p>Master Mode - Slave IF control frame trigger</p> <p>0_B The IFCVS field configured value does not have an effect (default).</p> <p>1_B Writing a one to the register bit sends the control frame configured in register field IFCVS, if the interface is configured as master. In slave interface configuration the trigger has an effect and takes the IFCTRL.IFCVS value. In slave mode this is not the usual control flow. A frame based configuration shall be used instead. A control frame has higher priority than a register control. At a simultaneous occurrence of both configuration source the register configuration in slave mode is lost.</p> <p><i>Note: Changing the interface configuration, software must guarantee not having transfers active on the interface.</i></p> <p><i>Note: The register bit reads back a zero always.</i></p>
MRXSPEED	[17:16]	rw	<p>Master Mode RX speed</p> <p>00_B Low Speed</p> <p>01_B Medium Speed</p> <p>10_B High Speed</p> <p>11_B for future use</p> <p><i>Note: Register setting only valid in interface master mode.</i></p>
MTXSPEED	[19:18]	rw	<p>Master Mode TX speed</p> <p>00_B Low Speed</p> <p>01_B for future use</p> <p>10_B High Speed</p> <p>11_B for future use</p> <p><i>Note: Register setting only valid in interface master mode.</i></p>

Field	Bits	Type	Description
IFTESTMD	20	rw	<p>Master Mode Interface Test Mode</p> <p>0_B Test Mode disabled</p> <p>1_B Test Mode enabled - send out 101010101.. test pattern continuously.</p> <p><i>Note: Register setting only valid in interface master mode. Slave interface does send out the 101010101.. sequence on RX link by receiving the Turn clock test mode on interface Control logical channel command.</i></p>
0	[15:9],[31:21]	r	Reserved

SLEEPCTRL
SLEEPCTRL
Sleep Control Register
(18_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SLPEN	0	rw	Sleep mode enabled Sleep mode is enabled and performed after receiving a 1 at the end of a received frame or in transmission direction, if a empty is received from HSSL FIFO. 0 _B Sleep mode disabled. 1 _B Sleep mode enabled.
SLPCLKG	1	rw	Clock Gating in Sleep Mode During transmission in sleep mode the clock for HSCT (framer, deframer) can be gated in order to minimize power consumption. <i>Note: Clock gating: Receiving path and transmitting path is separated.</i> 0 _B Clock gating in transmission sleep mode disabled. 1 _B Clock gating in transmission sleep mode enabled.
0	[31:2]	r	Reserved

CTSCTRL
CTSCTRL
Clear To Send Control Register
(1C_H)
Reset Value: 0000 0001_H

IRQCLR

This register is the Interrupt clear register. By writing a logic 1 to the register the interrupt in the IRQ register is cleared by a clear pulse. This means the interrupt clear methodology is write one to clear. Reading from this register presents the logic value 0 to software.

IRQCLR
Interrupt clear register
(48_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
HERCLR	1	w	Header error detected interrupt clear
PYERCLR	2	w	Payload error detected interrupt clear
CERCLR	3	w	HSCT command error interrupt clear
IFCFSCCLR	4	w	HSCT interface control command send interrupt clear
SMERCLR	5	w	Speed Mode Switch Error interrupt clear
USMSFCLR	6	w	Unsolicited message frame send finished interrupt clear
PLERCLR	7	w	PLL lost lock error interrupt clear
USMCLR	8	w	Unsolicited Message received clear
PARCLR	9	w	PING Answer received clear
TXTECLR	10	w	TX disable error interrupt clear
SFOCLR	11	w	Synchronization FIFO overflow (in RX direction) interrupt clear
SFUCLR	12	w	Synchronization FIFO underflow (in TX direction) interrupt clear

Field	Bits	Type	Description
0	[31:13], 0	r	Reserved

USMR

The Unsolicited Status message register is available to capture unsolicited messages received with the logical channel command encoding in the header of the frame (Logical Channel Type Hex 1).

USMR

Unsolicited Status Message Received (50_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
USMR	[31:0]	rh	Unsolicited status message received The register contains the last received unsolicited status message.

USMS

A write to the register does activate the interface to send out an unsolicited status message to the other interface side. The Logical Channel Type reflected in the header is Hex 1 and the Payload is 32-bit always. An unsolicited frame has a higher priority than a Frame based on a data channel. In between frames the USMS gets higher priority than the data transfer requested by the HSSL.

USMS

Unsolicited Status Message Send (54_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
USMS	[31:0]	rw	Unsolicited status message send Writing to the register triggers a unsolicited status message to be send to the other interface side.

BPI_FPI Module Registers (Single Kernel Configuration)

Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the HSCT module. Where a module kernel is connected to the CLC clock control interface, CLC register controls the module clock, sleep mode and disable mode for the module.

CLC

Clock Control Register

(00_H)

Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control (clock and local access) of the module. The disable is performed after an acknowledge signal from the core logic is received.
DISS	1	r	Module Disable Status Bit Bit indicates the current status of the module and is set after the requested disable is active.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode. A system sleep mode request only becomes active, if enabled by this bit. If sleep request is active, no writes to the module kernel are possible anymore.

Field	Bits	Type	Description
0	[31:4], 2	r	Reserved Read as 0; should be written with 0.

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = '1'). While OCDS is not enabled, OCS reset values/modes are effective.

OCS

OCDS Control and Status (FFE8_H) **Reset Value: 0000 0000_H**

Access Enable Register 1

(FFF8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

0	[31:1]	r	Reserved Read as 0; should be written with 0.

21.15.5 Suspend, Sleep and Power-Off Behavior

Generally, the HSCT module transmits and receives data and control information via the differential signal interface.

A power down of the module can be done in any situation of the transmission. After Power up the interfaces is in low speed mode, again. It is strongly recommended to have the transfers stopped from the higher layer protocol before sending the HSCT layer into power off state. In order to power down the module in a well defined way, the user software must take care that the power down request is issued after ongoing transfers or stop the transfers before. Issuing an power down within a transfer - all data is lost.

21.15.5.1 OCDS Suspend

OCDS suspend request, for debugging purposes, simply freezes the HSCT module in the current state. This corresponds to the hard suspend of the whole module, that is both the transmitter and the receiver. After the end of the suspend state, the receive data will be most probably corrupted. Therefore, the whole interface must be reset, re initialized and reactivated.

21.15.5.2 Sleep Mode

Going into sleep mode implies that the HSCT module has finished all activities and that the HSSL TX FIFOs are empty and the last data of the frame are send. It is responsibility of the user software to enable sleep mode SLEEPCTRL.SLPEN.

21.15.5.3 Disable Request (Power-Off)

Going into power off implies that the HSCT module has finished all activities.

22 Micro Second Channel (MSC)

This chapter describes the Micro Second Channel Interfaces , MSC0 and MSC1 of the TC26x B-Step. It contains the following sections:

- Functional description of the MSC kernel (see [Page 22-3](#))
- MSC kernel register descriptions (see [Page 22-50](#))
- TC26x B-Step implementation-specific details and registers of the MSC module (port connections and control, interrupt control, address decoding, and clock control, see [Page 22-92](#))
- >> [Registers Overview](#)

Note: The MSC kernel register names described in [Section 22.3](#) are also referenced in the TC26x B-Step User's Manual by the module name prefix "MSC0_" for the MSC0 module and by "MSC1_" for the MSC1 module.

Micro Second Channel (MSC)

MSC Applications

The MSC is a serial interface that is especially designed to connect external power devices to the TC26x B-Step. The serial data transmission capability minimizes the number of pins required to connect such external power devices. Parallel data information (coming from the timer units) or command information is sent out to the power device via a high- speed synchronous serial data stream (downstream channel). The MSC receives data and status back from the power device via a low-speed asynchronous serial data stream (upstream channel).

Parallel requests from on chip bus masters to a module will be executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

Figure 22-1 shows a typical TC26x B-Step application in which an MSC interface controls two power devices. Output data is provided by the module.

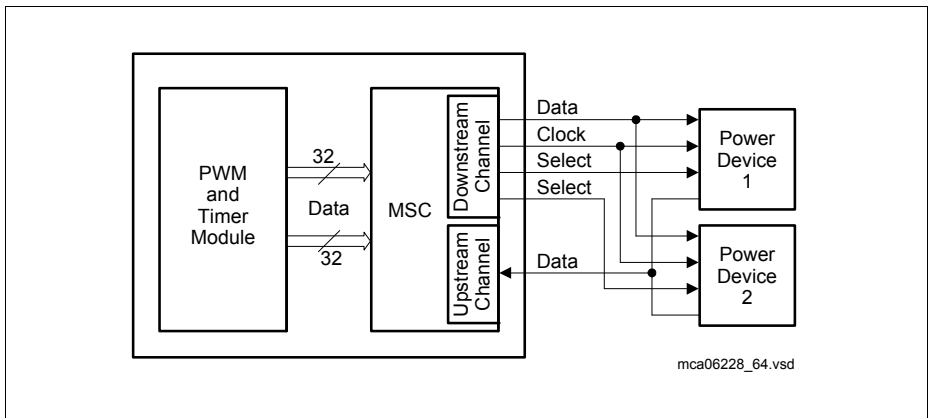

Figure 22-1 MSC to External Power Device Connection

Some applications are:

- Control of the external power switching unit via the downstream channel
- Receiving information back from power switching unit
- Serial connections of the TC26x B-Step to other peripheral devices

22.1 MSC Kernel Description

This section describes the functionality of the MSC kernel.

22.1.1 Overview

The MSC interface provides a serial communication link typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel. **Figure 22-2** shows a global view of the MSC interface signals.

The MSC module features functional extensions, but is compatible to the MSC interface of the TC17xx devices.

Figure 22-2 General Block Diagram of the MSC Interface

The downstream and upstream channels of the MSC module communicate with the external world via nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data, and enable signals). One out of eight input lines $SDI[7:0]$ is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC

Micro Second Channel (MSC)

register contents or data that is provided at the ALTINL/ALTINH input lines. These input lines are typically connected to other on-chip peripheral units (for example with a timer unit like the GTM). An emergency stop input signal makes it possible to set bits of the serial data stream to dedicated values in emergency case.

Clock control, address decoding, and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

Features

- Fast synchronous serial interface to connect power switches in particular, or other peripheral devices via serial buses
- High-speed synchronous serial transmission on downstream channel
 - Serial output clock frequency: $f_{FCL} = f_{MSC}/2$ ($f_{MSCmax} = 100$ MHz)
 - Fractional clock divider for precise frequency control of serial clock f_{MSC}
 - Command, data, and passive frame types
 - Start of serial frame: Software-controlled, timer-controlled, or free-running
 - Transmission with or without SEL bit
 - Flexible chip select generation indicates status during serial frame transmission
 - Emergency stop without CPU intervention
- Low-speed asynchronous serial reception on upstream channel
 - Baud rate: f_{MSC} divided by 4, 8, 16, 32, 64, 128, or 256 ($f_{MSCmax} = 100$ MHz)
 - Standard asynchronous serial frames
 - Programmable upstream data frame length (16 or 12 bits)
 - Parity error checker
 - 8-to-1 input multiplexer for SDI lines
 - Built-in spike filter on SDI lines
 - Programmable delay of the receive interrupt after the last stop bit (0 or 1 bit time)
- Selectable pin types of downstream channel interface:
four LVDS differential output drivers or four digital GPIO pins
- Module reset available
- Advanced features:
 - Asynchronous Baud Rate Adjustment Block
 - one extra interrupt
 - 64-bit data frames extension
 - fully compatible with the 32-bit data frames module version

22.1.2 Downstream Channel

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 64-bit shift register is divided into two 32-bit parts, SRL and SRH. Each bit of SRL and SRH can be selected to be delivered by the downstream data register DD, by the Downstream Command Register DC, or by two 16-bit wide input signal buses ALTINL and ALTINH.

Figure 22-3 is a diagram of the MSC downstream channel.

Figure 22-3 Downstream Channel Block Diagram

The enable signals ENL, ENH, and ENC indicate certain phases of the serial transmission in relation to the serial clock FCL. In the I/O control logic, these signals can be combined to four enable/select outputs EN[3:0]. For supporting differential output

Micro Second Channel (MSC)

drivers, the serial clock output FCL and the serial data output SO are available in both polarities, indicated by the signal name suffix “P” and “N”.

The emergency stop input line EMGSTOPMSC is used to indicate an emergency stop condition of a power device. In emergency case, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL and ALTINH buses.

22.1.2.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the MSC.

Basic Definitions

Figure 22-4 shows the layout and definitions of a downstream frame. A downstream frame is composed of an active phase and a passive phase. During the active phase, data transmission takes place and during the passive phase no data is transmitted at SO. The active phase is split into two parts: The SRL active phase in which the content of the shift register low part SRL is transmitted, and the SRH active phase in which the content of the shift register high part SRH is transmitted. At the beginning of the SRL and SRH active phase, a selection bit (SELL) can be optionally inserted into the serial data stream. In the frame shown in **Figure 22-4**, SELL is generated at the beginning of the SRL active phase (not for the SRH active phase). The least significant bits of SRL and SRH are sent out first.

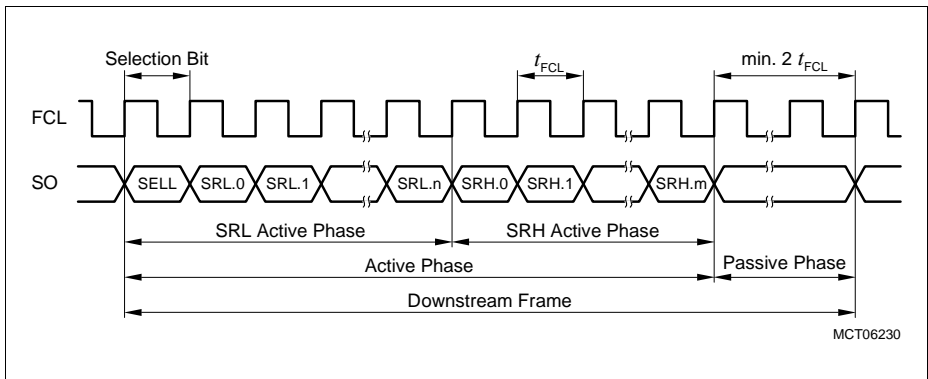

Figure 22-4 Downstream Channel Frame

The MSC downstream channel uses three types of frame formats for operation:

- Command frames, indicated by SELL = 1
- Data frames, indicated by SELL = 0 or SELL bit insertion disabled
- Passive time frame, indicated by ENL = ENH = 0

Micro Second Channel (MSC)

Command Frames

A command frame has two active phase parts, SRL active phase and SRH active phase. The command frame always starts with a high-level selection bit, independently whether the selection bit insertion (as defined by bit DSC.ENSELL) is enabled or not. The number of the bits transmitted during SRL and SRH active phases (except the selection bit) is defined by bit field DSC.NBC. SRL and SRH are combined to a value up to 64-bit whose length can be selected from 0 up to 32 bits. In other words, whenever bits of SRH are transmitted, they are always preceded by the transmission of the complete SRL content.

During the active phase of a command frame, the enable output signal ENC becomes active. The enable output signals ENL and ENH remain inactive.

The passive phase of a command frame always has a fixed length of $2 \times t_{FCL}$. The diagram shown in **Figure 22-5** assumes that the FCL clock is only generated during the active phase of the command frame (OCR.CLKCTRL = 0).

Figure 22-5 Command Frame Layout

Micro Second Channel (MSC)

Table 22-1 shows the programming of the bits to be transmitted and the resulting length of the complete command frame.

Table 22-1 Command Frame Length

DSC.NBC	SRL/SRH Bits that are Transmitted in Active Phase	Command Frame Length in t_{FCL} Periods
000000 _B	No bit shifted out	$1 + 0 + 2 = 3$
000001 _B	SRL[0] shifted out	$1 + 1 + 2 = 4$
000010 _B	SRL[1:0] shifted out	$1 + 2 + 2 = 5$
000011 _B	SRL[2:0] shifted out	$1 + 3 + 2 = 6$
...
001111 _B	SRL[14:0] shifted out	$1 + 15 + 2 = 18$
010000 _B	SRL[15:0] shifted out	$1 + 16 + 2 = 19$
010001 _B	SRL[15:0] and SRH[0] shifted out	$1 + 17 + 2 = 20$
010010 _B	SRL[15:0] and SRH[1:0] shifted out	$1 + 18 + 2 = 21$
010011 _B	SRL[15:0] and SRH[2:0] shifted out	$1 + 19 + 2 = 22$
...
011111 _B	SRL[15:0] and SRH[14:0] shifted out	$1 + 31 + 2 = 34$
100000 _B	SRL[15:0] and SRH[15:0] shifted out	$1 + 32 + 2 = 35$
Other NBC combinations	Reserved; do not use these bit combinations.	

Micro Second Channel (MSC)

Data Frames

A data frame has two active phase parts, SRL active phase and SRH active phase. The number of bits that are transmitted can be programmed separately for each of these two phases. Bit field DSC.NDBL determines the number of SRL bits that are transmitted during the SRL active phase and DSC.NDBH determines the number of SRH bits that are transmitted during the SRH active phase.

SRL and SRH active phases can start with a low-level selection bit when enabled by bits DSC.ENSELL or DSC.ENSELH.

During the SRL active phase of a data frame, the enable output signal ENL becomes active and during the SRH active phase of a data frame, the enable output signal ENH becomes active. The enable output signal ENC remains inactive.

The length of the data frame's passive phase is variable and is defined by bit field DSC.PPD. It can be within a range of $2 \times t_{FCL}$ up to $31 \times t_{FCL}$. The diagram shown in Figure 22-6 assumes that the FCL clock is only generated during the active phase of the data frame (OCR.CLKCTRL = 0).

Table 22-2, Table 22-3, and Table 22-5 show the definitions of the five data frame parameters that determine the layout of the data frame.

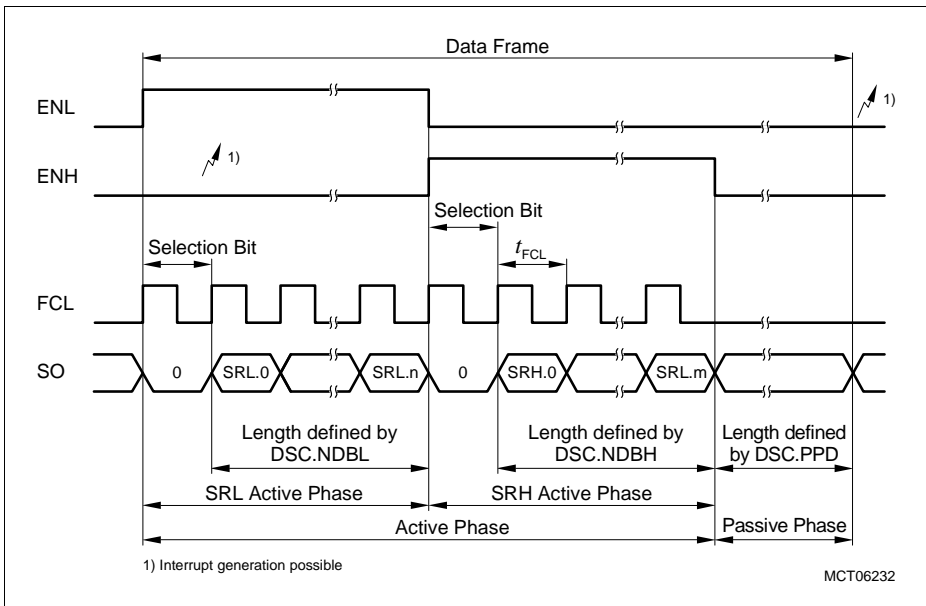

Figure 22-6 Data Frame Layout

Table 22-2 Data Frame Selection Bit Parameters

DSC.ENSELL	Selection Bit	DSC.ENSELH	Selection Bit
0	No selection bit inserted at the beginning of the SRL active phase	0	No selection bit inserted at the beginning of the SRH active phase
1	A low level selection bit is inserted at the beginning of the SRL active phase	1	A low level selection bit is inserted at the beginning of the SRH active phase

*Note: The MSC module can operate in two modes: standard (up to 32 data bits) or extended (up to 64 data bits). The mode is selected by using the bit **DSCE.EXEN**.*

Table 22-3 Data Frame SRL/SRH Length Parameters, Standard Mode

DSCE.NDBLE=0 and DSC.NDBL	SRL Bits Transmitted in SRL Active Phase	DSCE.NDBHE=0 and DSC.NDBH	SRH Bits Transmitted in SRH Active Phase
0 0000 _B	No SRL bit transmitted	0 0000 _B	No SRH bit transmitted

...
1 01111 _B	SRL[30:0]	1 01111 _B	SRH[30:0]

Micro Second Channel (MSC)

Table 22-4 Data Frame SRL/SRH Length Parameters, Extended Mode (cont'd)

DSCE.NDBLE=1 and DSC.NDBL	SRL Bits Transmitted in SRL Active Phase	DSCE.NDBHE=1 and DSC.NDBH	SRH Bits Transmitted in SRH Active Phase
1 10000 _B	SRL[31:0]	1 10000 _B	SRH[31:0]
Other bit combinations	Reserved; do not use these bit combinations.	Other bit combinations	Reserved; do not use these bit combinations.

Table 22-5 Data Frame Passive Phase Length

DSC.PPD	Passive Phase Length
00000 _B	$2 \times t_{FCL}$
00001 _B	$2 \times t_{FCL}$
00010 _B	$2 \times t_{FCL}$
00011 _B	$3 \times t_{FCL}$
...	...
11110 _B	$30 \times t_{FCL}$
11111 _B	$31 \times t_{FCL}$

The following formula determines the number of t_{FCL} cycles of an up to 32-bit data frame: All parameters (bits and bit fields) are located in register DSC.

$$N_{cycles} = ENSELL + NDBL + ENSELH + NDBH + PPD \quad (22.1)$$

Note that in the formula above, PPD must be set to 2 when $DSC.PPD \leq 00010_B$.

The following formula determines the number of t_{FCL} cycles of an extended, up to 64-bit data frame, in case DSC.NDBL and DSC.NDBH are not equal to zero:

$$N_{cycles} = ENSELL + NDBL + NDBLE \cdot EXEN \cdot 16 + ENSELH + NDBH + NDBHE \cdot EXEN \cdot 16 + PPD + PPDE \cdot 32 \quad (22.2)$$

Otherwise, the corresponding factor $NDBLE \cdot EXEN \cdot 16$ or $NDBHE \cdot EXEN \cdot 16$ must be taken as zero (see [Table 22-4](#)).

Note that in the formula above, PPD must be set to 2 when $DSC.PPD \leq 00010_B$.

The parameters (bits and bit fields) are located in registers DSC and DSCE.

Attention: *In order to calculate the time between two consecutive TRPs, always use $ENSELL=1$ in the formulas above. $ENSELL$ does not influence the time between two consecutive TRPs, but only the length of a data*

Micro Second Channel (MSC)

frame. The difference in the starting point of a frame with ENSELL=0 and 1 is shown in the [Figure 22-13](#) and [Figure 22-14](#).

Passive Time Frames

A passive time frame has the length defined by the five data frame parameters according [Equation \(22.1\)](#). They are generated only in Data Repetition Mode. Under special conditions (command frame insertion), passive time frames can be shortened (see [Figure 22-10](#)).

During passive time frames, the data output SO have to be considered as invalid at the receiving device and the clock output FCL may toggle or not (as selected by bit OCR.CLKCTRL). The ENL and ENH enable signals remain at low level during a passive time frame.

22.1.2.2 Shift Register Operation

This section describes the SRL and SRH shift register loading.

SRL Shift Register Loading

During the SRL/SRH shift register load operation at the beginning of each downstream frame transmission, several parameters determine which information is loaded into the bits of the shift register. **Figure 22-7** shows the logic that is implemented for the SRL shift register loading operation. The logic for the SRH shift register loading operation is equivalent to the one for the SRL register. Its differences in data sources and register controls are described later in this section.

Figure 22-7 SRL Shift Register Data Loading Control

Micro Second Channel (MSC)

Four data sources can be selected for each SRL bit by using several control bits and one control signal:

- ALTINL input line (non-inverted)
- ALTINL input line (inverted)
- Bit of DD.DDL (downstream data register)
- Bit of DC.DCL (downstream control register)

When SRL is loaded for data frame transmission (DSC.CP = 0), bit fields DSDSL.SLx determine bit-wise which data is loaded into SRL bit x. The data source selection as controlled by DSDSL.SLx will only be effective when EMGSTOPMSC is inactive (at low level). When EMGSTOPMSC = 1 (active) during the load operation, all SRL[x] bits that are enabled for the emergency stop feature (bit ESR.ENLx = 1) are loaded directly with the corresponding bit DDL[x] of the downstream data register DD.

When SRL is loaded for command frame transmission (DSC.CP = 1), always the lower 16-bit part DCL of the downstream control register is loaded completely into SRL.

Table 22-6 summarizes all SRL data source selection capabilities (x = 0-31):

- in standard mode, **DSCE.EXEN** = 0, the selection configuration of up to 16 bits (x = 0-15) is taken into account
- in extended mode, **DSCE.EXEN** = 1, the selection configuration of up to 32 bits (x = 0-31) is taken into account

Table 22-6 SRL Data Source Selection Capabilities

DSC. CP	DSDSL. SLx DSDSLE.SLx	ESR. ENLx	EMGSTOP MSC	Selection
0	00 _B	0	–	Bit DD.DDL[x] is loaded into SRL[x].
	01 _B			Reserved.
	10 _B			State of ALTINL[x] input is loaded into SRL[x].
	11 _B			Inverted state of ALTINL[x] input is loaded into SRL[x].
	XX _B	1	1	Bit DD.DDL[x] is loaded into SRL[x].
1	XX _B	X	X	Bit fields DCL and DCH are completely loaded into SRL and SRH, respectively.

*Note: The data signals can be overruled by injected pin signals INJ0 and INJ1. See **DSCE** register.*

SRH Shift Register Loading

The SRH shift register load operation is equivalent to the SRL shift register load operation. The following differences must be taken into account for SRH shift register loading:

- Input lines ALTINH are connected instead of ALTINL input lines.
- DSDSH register bits control data source selection instead of DDSL register.
- Emergency stop is enabled by ESR.ENHx bits instead of ESR.ENLx bits.
- Bits of the downstream data register high part DDH are selected instead of DDL.
- Downstream control register high part DCH is selected instead of DCL.

22.1.2.3 External Signal Injection

Input signals from two pins can be independently injected at two data bit positions in a data frame. The injection takes place both in normal and in extended mode. The external signals are always injected at the defined position, and if the data frame is shorter than this position, then these signals remain unused. For example, if **DSCE**.INJPOS0 defines injection the position 14 of the SRL, and the **DSC**.NBDL=12, then all the data bits from position 12 and up remain unused, including the injected signal.

In normal mode the bits are counted from 0 to 31 from LSB to MSB, and in extended mode the bits are counted from 0 to 63 from LSB to MSB, see [Figure 22-8](#). The injection position is always counted as if the frame has the maximal length. In the first step of the preparation for a transmission the injection takes place, and then in the second step, if some fields are configured to be shorter or omitted (for example DDLE or DDH or any other), the unused bits are discarded and only the remaining valid bits are shifted out.

Figure 22-8 External Signal Injection

22.1.2.4 Transmission Modes

The downstream channel of the MSC makes it possible to select between two transmission modes:

- Triggered Mode, selected by $DSC.TM = 0$, or
- Data Repetition Mode, selected by $DSC.TM = 1$

Triggered Mode

In Triggered Mode, command frames or data frames are sent out as a result of a software event. When a frame transmission has been finished and no further frame transmission has been requested, the downstream channel returns to idle state and waits for the next frame transmission to be triggered by software.

Setting the $DSC.TM$ bit triggers immediately a frame transmission using the values existing at that moment.

When the Downstream Command Register DC is written, the command pending bit $DSC.CP$ becomes set and a command frame will be immediately started and sent out if the downstream channel is idle. If a data or command frame is currently processed and output, the command frame transmission is delayed, and started when the active downstream frame has been finished. The command pending bit $DSC.CP$ becomes cleared by hardware when the first bit of the command frame is sent out.

If the downstream channel is idle and the data pending bit $DSC.DP$ is set by writing $ISC.SDP$ with 1, a data frame will be immediately started and sent out if the downstream channel is idle. If a data frame or a command frame is currently processed and output, the data frame transmission is delayed and started when the active downstream frame has been finished. The data pending bit $DSC.DP$ becomes cleared by hardware when the first bit of the data frame is sent out.

A command frame always has priority over the data frame. This means that if both frame pending bits are set ($DSC.DP = DSC.CP = 1$), the command frame will always be sent first. Therefore, a pending data frame transmission will be delayed as long as no further command frame transmission is running or requested.

Figure 22-9 is a flow diagram of the Triggered Mode. This diagram especially shows the behavior of the data and command pending bits $DSC.DP$ and $DSC.CP$. If both frame pending bits are set ($DSC.DP = DSC.CP = 1$), the command frame will always be sent first, followed by the data frame (assuming no further command frame has been requested).

The type of the active frame that is currently processed and output is indicated by two status flags: $DSS.DFA$ is set during a data frame transmission and $DSS.CFA$ is set during a command frame transmission. Further, the downstream counter $DSS.DC$ indicates the number of shift clock periods that have been elapsed since the start of the current frame.

Micro Second Channel (MSC)

In Triggered Mode, the shift register loading event as described in [Section 22.1.2.2](#) occurs just before a command or data frame transmission is started.

Figure 22-9 Triggered Mode Flow Diagram

Data Repetition Mode

In Data Repetition Mode, data frames are sent out continuously without any software interaction. In the time gap between two consecutive data frames, passive time frames can be inserted. The number of passive time frames to be inserted (0 to 15) is defined by bit field DSS.NPTF. The duration of data frame (t_{DF}) and passive time frames (t_{PTF}) is determined by the five data frame parameters (see [Equation \(22.1\)](#)). These parameters determine the time reference points (TRP) at which a data, command or passive time frames is started (see diagram A in [Figure 22-10](#)).

The automatic data frame generation is controlled by the data pending bit DSC.DP. This bit is set at the end of the last passive data frame if a command frame is running or starts at this TRP, overruling a data frame. DSC.DP is cleared by hardware when the pending data frame starts with transmission at the next TRP. Data Frames are always aligned to time reference points. This means they always start at a TRP. Passive time frames can be shortened. This is especially the case when command frames are inserted.

Continuous data frame transmission can be interrupted by insertion of command frames. Command frames are initiated by software. When the downstream command register DC is written, the command pending bit DSC.CP is set by hardware. CP = 1 indicates that the MSC starts a command frame at the next TRP, independently of whether a data

Micro Second Channel (MSC)

frame (indicated by DSC.DP = 1) or passive time frame should be started with the next TRP. This means also that command frames are always aligned to time reference points.

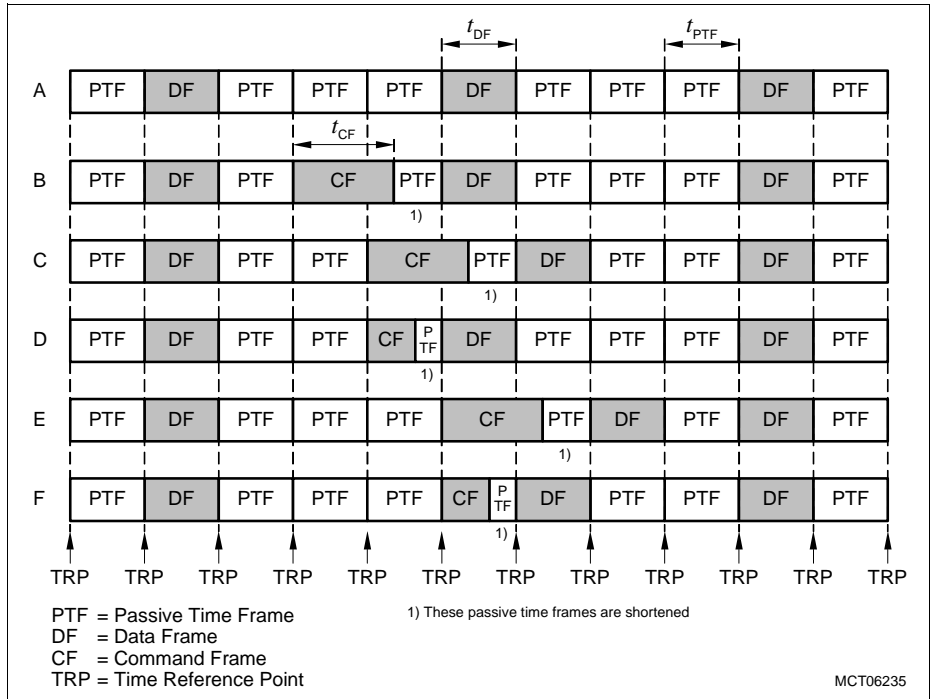

Figure 22-10 Data Repetition Mode Frame Examples with DSS.NPTF = 0011_B

Diagrams B to F in Figure 22-10 show the command frame insertion in Data Repetition Mode.

In diagram B, a command frame has been requested during the first passive time frame after the data frame, and is inserted at the next TRP. In diagrams C and D, a command frame has been requested during the second passive time frame, and is inserted at the time reference point of the last nominal passive time frame.

When the command frame and data frame is not of the same length (this is the case in diagram B to F), a shortened passive time frame is inserted until the next TRP is reached. This ensures that the next data or normal passive time frame is again aligned to a TRP.

Figure 22-11 is a flow diagram of the Data Repetition Mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP = DSC.CP = 1), the command frame will always be

Micro Second Channel (MSC)

sent first, followed by the data frame when the next TRP is reached (assuming no further command frame has been requested).

When the last passive frame is transmitted, DSC.DP becomes set by hardware. This triggers the start of a data frame when the next TRP is reached.

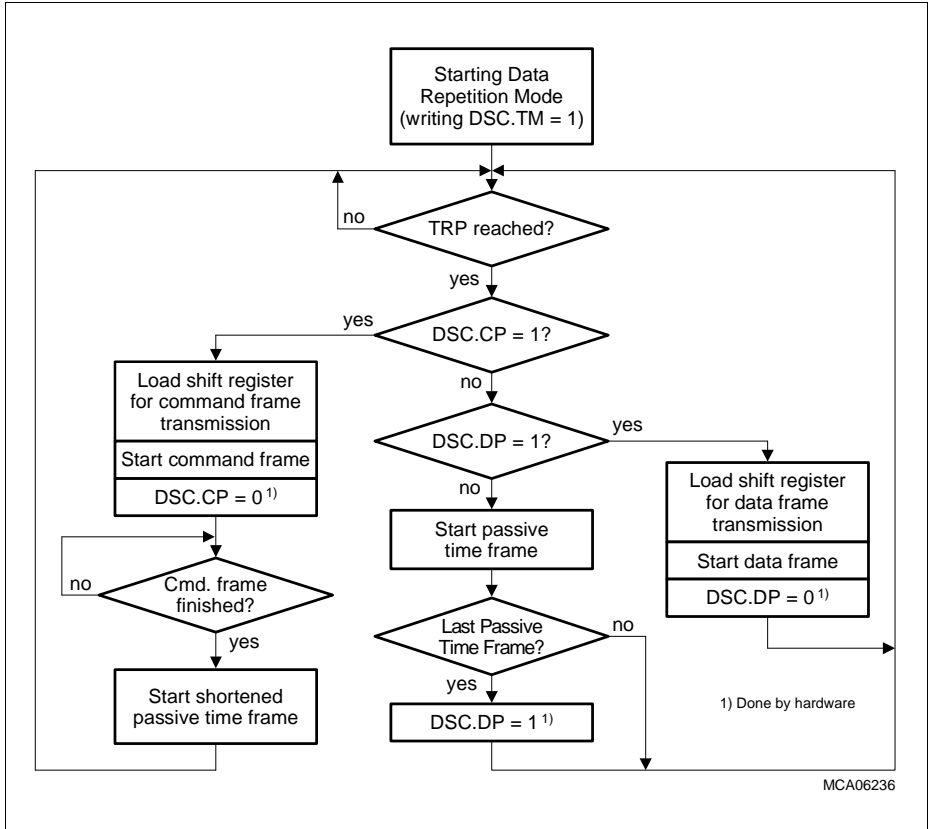

Figure 22-11 Data Repetition Mode Flow Diagram

The type of the active frame (data or command frame) that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current data, command, or passive time frame.

Micro Second Channel (MSC)

As in Triggered Mode, the shift register loading event as described in [Section 22.1.2.2](#) occurs in Data Repetition Mode just before a TRP, this means shortly before a command or data frame transmission is started.

Passive Frame Counter in Data Repetition Mode

In Data Repetition Mode, a passive time frame counter DSS.PFC indicates how many time frames have been already transmitted after the last regular data frame occurrence. The passive time frame counter counts up from 0000_B to the value which has been written into bit field DSS.NPTF (number of passive time frames). DSS.PFC = 0000_B indicates that a data frame is requested for transmission.

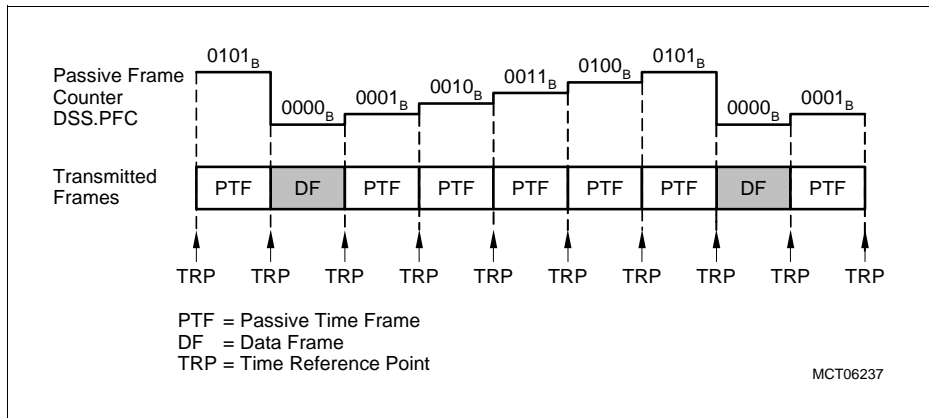

Figure 22-12 Passive Frame Counter Operation (with DSS.NPTF = 0101_B)

22.1.2.5 Downstream Counter and Enable Signals

During downstream channel operation, a 8-bit downstream counter DSS.DC is counting FCL shift clock periods. With the loading of the shift register, the downstream counter is reset to 00_H and started for counting up to the end of the downstream frame (end of passive phase).

In Triggered Mode, the downstream counter stops counting at the end of the passive phase and waits until a new downstream frame is started.

In Repetition Mode, the downstream counter does not stop at the end of the passive phase but is reset and starts counting up again with the next frame, independently whether a data frame, command frame, or passive time frame is started as next frame.

Figure 22-13 shows an example of downstream channel data frame transmission. In this example, the selection bit for the SRL active frame is enabled (ENSELL = 1), and the selection bit for the SRH active frame is disabled (ENSELH = 0). With loading of the shift register SRL/SRH, the downstream counter is reset and then starts counting up with each FCL clock until the end of the passive phase. ENL is set to high level at the beginning of the SRL active frame selection bit.

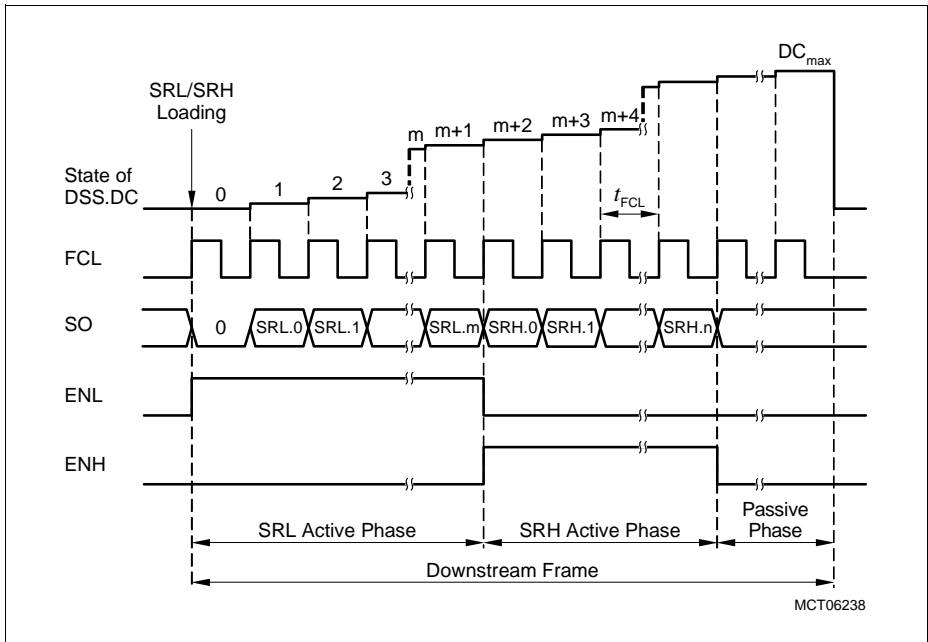

Figure 22-13 Shift Clock Counting: Data Frame with ENSELL = 1 and ENSELH = 0

Micro Second Channel (MSC)

When the selection bit for the SRL active frame is disabled (ENSELL = 0, see [Figure 22-14](#)), the loading of the shift register SRL/SRH (and reset of the downstream counter) occurs one FCL clock cycle before the first data bit SRL.0 is output. ENL is set to high level with the beginning of the first data bit SRL.0.

Figure 22-14 Shift Clock Counting: Data Frame with ENSELL = 0 and ENSELH = 0

22.1.2.6 Baud Rate

The baud rate of the downstream channel's serial transmission is defined by the frequency of the serial clock FCL, and is always $f_{MSC}/2$. The f_{MSC} generation is device specific and depends on the implementation of the MSC module. The TC26x B-Step specific clock generation is described on [Page 22-103](#).

22.1.2.7 Abort of Frames

Only a reset condition of the device can abort a current transmission. The MSC module does not start a new frame transmission when the downstream channel becomes disabled, the suspend mode is requested, or the sleep mode is entered. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no time frame finished interrupt is generated any more.

Micro Second Channel (MSC)

22.1.3 Upstream Channel

The MSC upstream channel is an asynchronous serial receiver based on the standard asynchronous data transfer protocol. It is dedicated to receive a serial data stream from a peripheral device via its serial data input SDI, using two specific data frame formats.

Figure 22-15 is a block diagram of the MSC upstream channel.

Figure 22-15 Upstream Channel Block Diagram

The incoming data at SI is sampled after it has been filtered for spikes. The detected logic states of the serial input are clocked into a shift register. After the complete reception of the serial data frame, the content of the shift register is transferred into one of the four data registers, and an interrupt can be generated optionally.

The reception baud rate is directly coupled to the module clock f_{MSC} , and can be within a range of $f_{MSC}/4$ up to $f_{MSC}/256$.

*Note: If the ABRA block is used with a fractional divider with a fractional ratio generating the upstream baud rate, and in order to compensate the additional fractional divider jitter, the reception baud rate must be less than $f_{MSC}/10$, or $f_{MSC}/(8 \text{ to } 256) * n/1024 < f_{MSC}/10$.*

22.1.3.1 Data Frames

The asynchronous data frames used by the upstream channel include four basic parts:

1. One start bit, always at low level
2. An 8-bit data field D[7:0] with LSB first
3. An optional 4-bit address field A[3:0] with LSB first
4. One parity bit and two stop bits, that are always at high level

As shown in [Figure 22-16](#), the 16-bit upstream data frame includes an additional 4-bit address field. The upstream frame type is selected by bit USR.UFT.

- USR.UFT = 0: 12-bit upstream data frame selected
- USR.UFT = 1: 16-bit upstream data frame with 4-bit address field selected

Figure 22-16 Upstream Channel Frame Types

22.1.3.2 Parity Checking

The incoming parity bit of the data frames can be checked by the upstream channel. When a parity error is detected, the parity error flag PERR in the related Upstream Data Register UDx is set. Note that a setting of the parity error flag PERR does not generate an interrupt. The PERR bits must be checked by software. The UDx registers also store the parity bit of the incoming data frame (UDx.P) and the parity bit that is generated internally (UDx.IPF).

Bit USR.PCTR determines the parity mode, even or odd, that is selected for parity checking. With USR.PCTR = 0, even parity mode is selected. Even parity means that the parity bit is set on an odd number of 1s in the data field (12-bit upstream data frame) or in the address plus data field (16-bit upstream data frame). With USR.PCTR = 1, odd parity mode is selected. In odd parity mode, the parity bit is set on an even number of 1s of the related data.

Micro Second Channel (MSC)

The parity checking logic in the upstream channel also controls whether start bit and the two stop bits of the upstream data frame are at correct logic level. If the start bit is not at low level and the two stop bits are not at high level at the end of the frame reception, the parity error flag UDx.PERR is set, too.

22.1.3.3 Data Reception

The reception of the upstream frame is started with a falling edge (1-to-0 transition) on the SI line. When the start bit is detected, serial reception is enabled and the receive circuit begins to sample the incoming serial data and to buffer it in the receive buffer. After the second stop bit has been detected, the content of the receive buffer is transferred to one of four upstream data registers UDx. The receive circuit then waits for the next start bit (1-to-0 transition) at the SI line. When the content of the receive buffer has been transferred to UDx, the valid bit UDx.V is set by hardware, and a receive interrupt can be generated.

The data reception mechanism does not involve destructive read mechanisms.

Note: The SI input line is the filtered non-inverted (OCR.ILP = 0) or inverted (OCR.ILP = 1) SDI input signal. The SI input signal selection is described on [Page 22-34](#).

Frame Reception with Address Field

Frame reception for a 16-bit data frame (see [Figure 22-17](#)) is selected by USR.UFT = 1. When the content of the receive buffer has been received completely, it is transferred to one of the four UDx registers. The two most significant address bits A[3:2] of the received 4-bit address field select the number x of register UDx in which the received frame content is stored. Register UDx is loaded with the two least significant address bits A0 and A1 (UDx.LABF), the 8-bit data (UDx.DATA), the received parity bit (UDx.P), the calculated parity bit (UDx.IPF), and the parity checking result (UDx.PERR). Finally, the valid bit UDx.V is set to indicate that the UDx register contains valid data.

The current state of the frame reception is indicated by the content of an upstream counter that is readable via bit field USR.UC. The upstream counter is a 5-bit counter that counts the upstream frame bits during reception. As shown in [Figure 22-17](#), the upstream counter is loaded with 10000_B at the detection of a start bit. It counts down and is again at 00000_B when the second stop bit has been detected and the frame reception is finished.

The state of the serial input data line SI is sampled in the middle of a bit cell and shifted into the receive buffer at the end of the bit cell. The frequency of the shift clock f_{SHIFT} depends the selected baud rate (see [Page 22-28](#)).

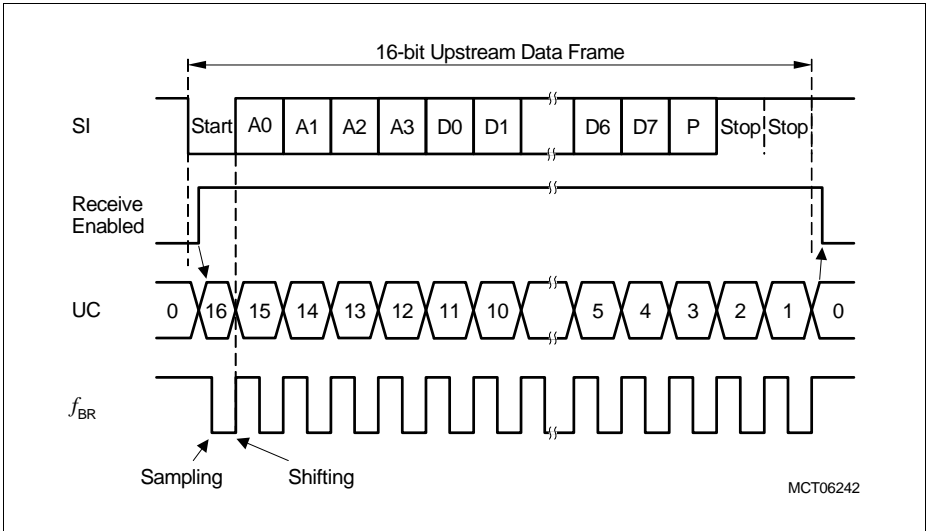

Figure 22-17 16-bit Upstream Reception

Data Reception without Address Field

Frame reception for a 12-bit data frame is selected by $USR.UFT = 0$. The reception scheme is comparable with that of the 16-bit data frame reception but there are a few differences:

- The upstream counter is initially loaded with 01100_B .
- The received frame content is always stored in register UD0.
- Bit field UD0.LABF is always loaded with 00_B when the frame is stored.

Micro Second Channel (MSC)

22.1.3.4 Baud Rate

The baud rate of the upstream channel is derived from the MSC module clock f_{MSC} . **Figure 22-18** shows the configuration of the upstream channel clock circuitry.

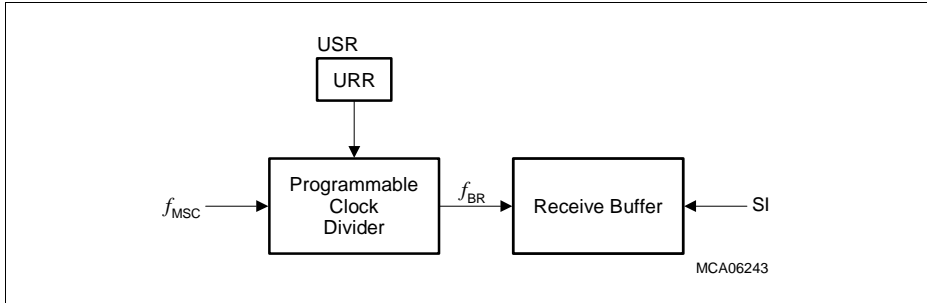

Figure 22-18 Upstream Channel Clock Circuitry

The serial data input SI is evaluated with the baud rate clock f_{BR} in the middle of each bit cell, and latched in case of a data bit. The baud rate clock f_{BR} is derived from f_{MSC} by a programmable clock divider. The frequency of f_{BR} determines the width of a received bit cell and therefore the baud rate for the received data. The content of bit field USR.URR selects the baud rate according **Table 22-7**. The resulting baud rate formula is:

$$\text{Baud rate}_{\text{MSC Upstream Channel}} = \frac{f_{\text{MSC}}}{\text{DF}} \quad (22.3)$$

Table 22-7 Upstream Channel Divide Factor DF Selection & Baud Rate

USR.URR	Divide Factor DF	Baud Rate
000 _B	reception disabled	–
001 _B	4	$f_{\text{MSC}}/4$
010 _B	8	$f_{\text{MSC}}/8$
011 _B	16	$f_{\text{MSC}}/16$
100 _B	32	$f_{\text{MSC}}/32$
101 _B	64	$f_{\text{MSC}}/64$
110 _B	128	$f_{\text{MSC}}/128$
111 _B	256	$f_{\text{MSC}}/256$

Note: With the USR.URR = 000_B the upstream channel is disabled and data reception is not possible.

Micro Second Channel (MSC)

The content of bit field USR.URR determines the operation of an internal sampling reload counter that is clocked with f_{MSC} . **Figure 22-19** shows the operation of the sampling counter at the beginning of an upstream frame with a divide factor DF of 8 (USR.URR = 010_B is equal to DF = 8) which means eight sampling clocks per each frame bit cell.

When the upstream channel is in idle state, it waits for a falling edge (1-to-0 transition) at SI. Therefore, the sample counter starts counting up and is reset when the selected divide factor DF as shown in **Table 22-7** is reached. In the middle of the sampling counter's count range, the logic state at SI is evaluated and, in case of a data bit, latched in the receive buffer's shift register. With the reload of the sampling counter, the shift register is shifted by one bit position.

Figure 22-19 Upstream Channel Sampling with URR = 010_B

22.1.3.5 Spike Filter

The upstream channel input line SDI is sampled using a built-in spike filter with synchronization stage, both clocked with f_{MSC} . The spike filter is a chain of flip-flops with a majority decision logic (2 out of 3). A sampled value that is found at least twice in three samples is taken as data input value for SI.

22.1.3.6 Upstream Timer

The upstream timer monitors the time interval between two subsequent upstream frames. The timer reloads its starting values from the register **USCE** and starts counting downwards. If the time interval between two frames is longer than allowed, the counter reaches the value of zero, raises an upstream timer interrupt and stops counting. The counter reloads and starts counting on four events:

- Enabling of the MSC module after reset via **CLC.DISR**
- Resetting the module
- Writing the bit fields **USCE.USTOPRE** or **USCE.USTOVAL** per software
- Detecting the falling edge of the start bit of a frame

Figure 22-20 Upstream Timer Operation

The upstream watchdog timer counts bit times. The time window in which the next upstream frame must occur can be calculated according to the formula:

$$\text{TimeOut} = \text{BitTime} * 2^{(\text{USTOPRE}+1)} * (\text{USTOVAL}+1)$$

22.1.4 I/O Control

The types of I/O control logic for the MSC module I/O lines are shown in [Figure 22-21](#). The downstream channel generates five output signals that control eight MSC module outputs, split into four chip select outputs, two clock outputs, and two serial data outputs. The upstream channel has one input signal.

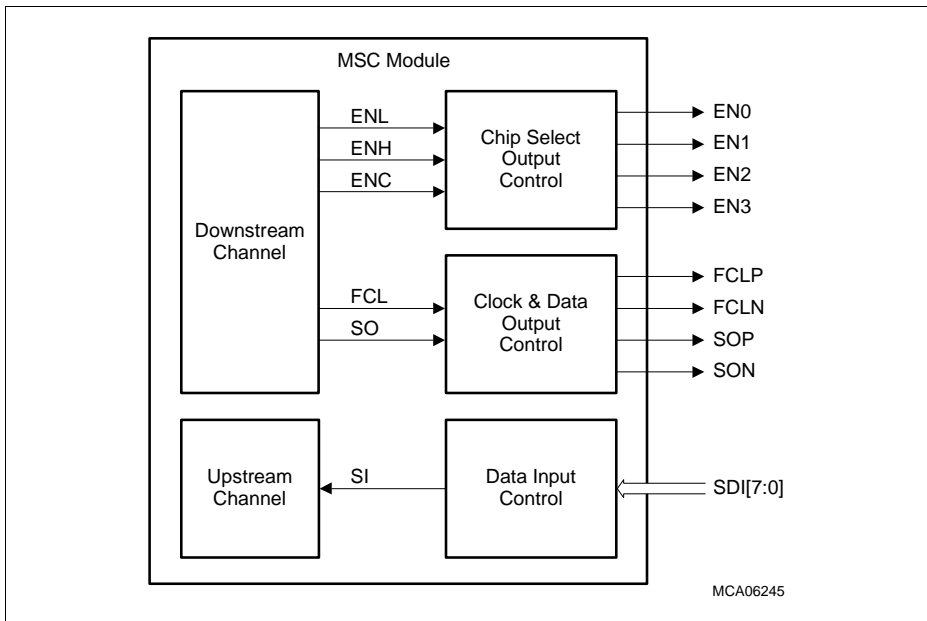

Figure 22-21 I/O Control

The MSC module I/O signals is controlled by bit fields that are located in the Output Control Register OCR.

22.1.4.1 Downstream Channel Output Control

As shown in [Figure 22-5](#) and [Figure 22-6](#), the active phases during downstream channel operation are indicated by three enable signals:

- ENL indicates the SRL active phase of a data frame
- ENH indicates the SRH active phase of a data frame
- ENC indicates the active phase of a command frame

The chip select output control logic of the MSC uses a signal compressing scheme (similar to the interrupt request compressing scheme in [Figure 22-29](#)) that allows each of the three enable signals to be directed via a 2-bit selector to one of the four chip enable

Micro Second Channel (MSC)

outputs EN[3:0]. This also makes it possible to connect more than one internal enable signal (ENL, ENH, ENC) to one chip enable output ENx. Three bit fields in register OCR (CSL, CSH, and CSC) determine which chip enable output becomes active on a valid internal enable signal.

In the MSC, enable signals are high-level active signals. If required in a specific application, all chip enable outputs ENx can be assigned for low-level active polarity by setting bit OCR.CSLP.

Figure 22-22 Downstream Channel: Chip Enable Output Control

Micro Second Channel (MSC)

At the MSC downstream channel, the internal serial clock output FCL and data output line SO are available outside the MSC module as two signal pairs with inverted signal polarity, FCLP/FCLN and SOP/SON. Both, clock and data outputs, are generated from the module internal signals FCL and SO according to [Figure 22-23](#).

Figure 22-23 Downstream Channel: Clock and Data Output Control

With `OCR.CLP = 0`, FCLP has identical and FCLN has inverted polarity compared to FCL. Setting `OCR.CLP`, exchanges the signal polarities of FCLP and FCLN. An equivalent control capability is available for the SOP and SON data outputs (controlled by `OCR.SLP`).

One additional control capability not shown in [Figure 22-23](#) is available for the FCL signal. With `OCR.CLKCTRL = 1`, the FCL clock signal will always be generated, independently whether a downstream frame is currently transmitted or not. If `OCR.CLKCTRL = 0`, FCL becomes only active during the active phases of data or command frames (not during passive time frames).

22.1.4.2 Upstream Channel

As shown in **Figure 22-24**, the MSC upstream channel can be connected to up to eight SDI[7:0] serial inputs. Bit field OCR.SDISEL selects one out of these input lines (input signal SDI). If OCR.ILP = 0, SDI is directly connected to the serial receive buffer input SI. If OCR.ILP = 1, SDI is connected to input SI via an inverter.

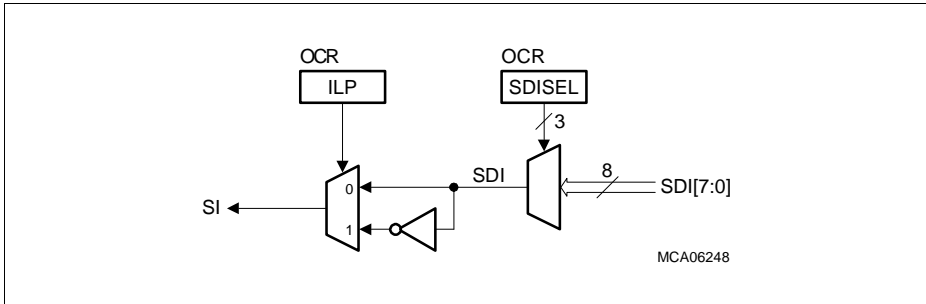

Figure 22-24 Upstream Channel Serial Data Input Control

22.1.5 MSC Interrupts

The MSC module has seven interrupt sources and five service request outputs. A service request output is able to generate interrupts (controlled by a service request control register) or DMA requests. The service request output assignment, interrupt or DMA request, is specific for each microcontroller that is using the MSC. In this section, the term “interrupt request” has the meaning of “service request” that is able to handle interrupt or DMA requests.

Each interrupt source is provided with a status flag, enable bit(s) with software set/clear capability, and an interrupt node pointer. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag that is located in the Interrupt Status Register ISR. All interrupt status flag can be set or cleared individually by software via the interrupt Set Clear Register ISC. Software-controlled interrupt generation can be initiated by setting the interrupt status flag of the corresponding interrupt. Each interrupt source can be enabled or disabled individually. When an interrupt event is enabled, a 2-bit interrupt node pointer determines which of the service request outputs will be activated. See [Figure 22-29](#).

[Table 22-8](#) shows the seven MSC interrupt sources.

Table 22-8 MSC Interrupt Sources

Interrupt Type	Generated by
Data frame interrupt	Downstream Channel
Command frame interrupt	
Time frame finished interrupt	
Receive data interrupt	Upstream Channel
Upstream Timeout Interrupt	
Sync FIFO overflow	ABRA Block
Sync FIFO underflow	

22.1.5.1 Data Frame Interrupt

A data frame interrupt can be generated when either the first or the last data bit of the downstream channel is shifted out and becomes available at the SO output line (see also [Figure 22-6](#)). Bit ICR.EDIE selects which case is selected.

Note: If ICR.EDIE = 10_B, an interrupt at the first data bit is only generated if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active.

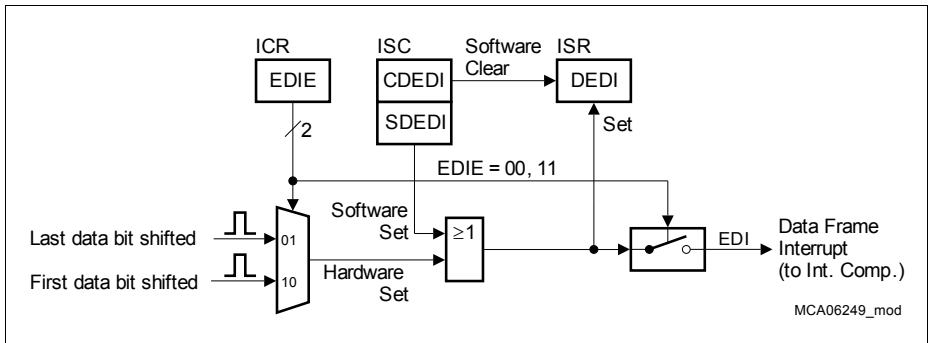

Figure 22-25 Data Frame Interrupt Control

22.1.5.2 Command Frame Interrupt

A command frame interrupt can be generated at the end of a downstream channel command frame (see also [Figure 22-5](#)).

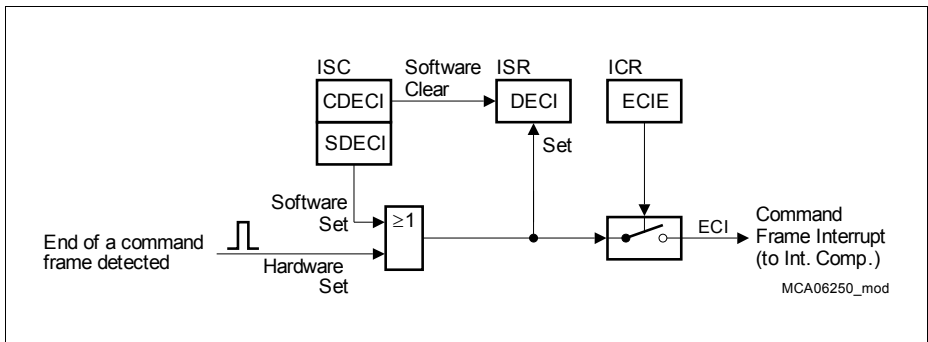

Figure 22-26 Command Frame Interrupt Control

22.1.5.3 Time Frame Finished Interrupt

A time frame finished interrupt can be generated at the end of a downstream channel passive time phase.

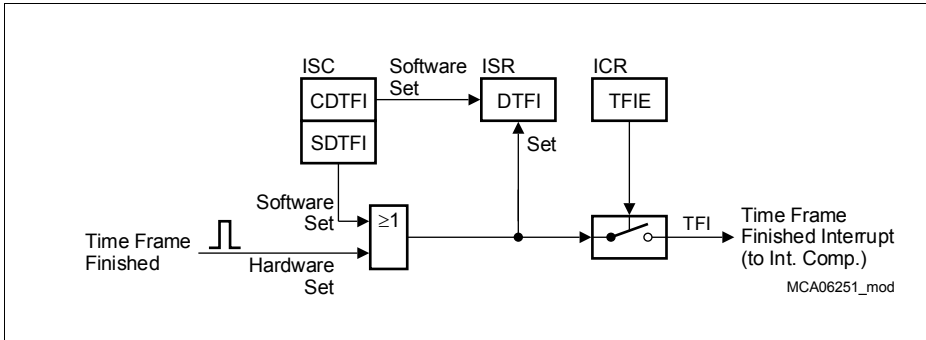

Figure 22-27 Time Frame Interrupt Control

22.1.5.4 Receive Data Interrupt

Whenever the upstream channel receives data in registers UDx (x = 0-3), the MSC is able to generate an interrupt. Three interrupt generation conditions can be selected for the receive data interrupt:

- Each update of UDx (x = 0-3) generates a receive data interrupt.
- Each update of UDx (x = 0-3) generates a receive data interrupt when the updated value is not equal 00_H.
- Only an update of register UD3 generates a receive data interrupt.

The selection of the interrupt generation condition is controlled by bit field ICR.RDIE. Setting ICR.RDIE = 0 disables the receive data interrupt in general. ISR.URDI is the interrupt status flag that can be set or clear when writing bits ISC.CURDI or ISC.SURDI with a 1. If the fractional divider is used, then the software should clear the URDI flag by using ISC.CURDI with a delay of one bit time after the interrupt signal has been generated. The same applies to clearing the UDx.V flag via UDx.C. Otherwise, due to the latencies introduced by the fractional divider, the clear may fail.

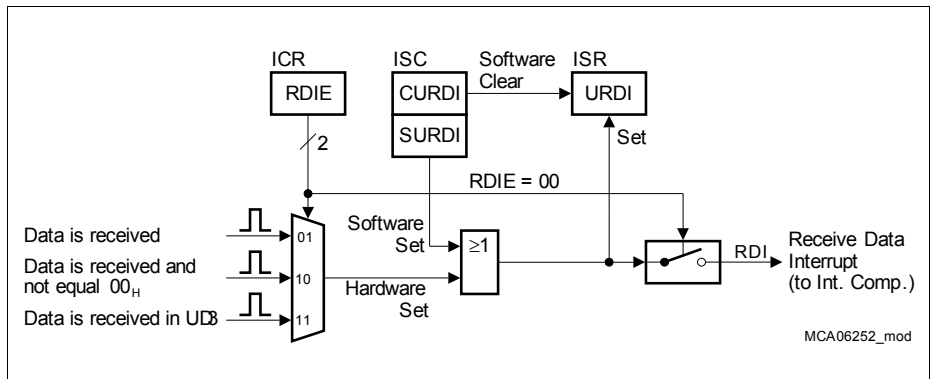

Figure 22-28 Receive Data Interrupt Control

The upstream receive interrupt can be optionally delayed for 1 bit time by setting the **USR.SRDC** bit.

Micro Second Channel (MSC)

22.1.5.5 Interrupt Request Compressor

The interrupt control logic of the MSC uses a flexible interrupt compressing scheme. Seven interrupt sources can be directed via a 2-bit interrupt node pointer to one of the four service request outputs SR[3:0], and three of them additionally to SR4. This makes it possible to connect more than one interrupt source to one interrupt output SRx.

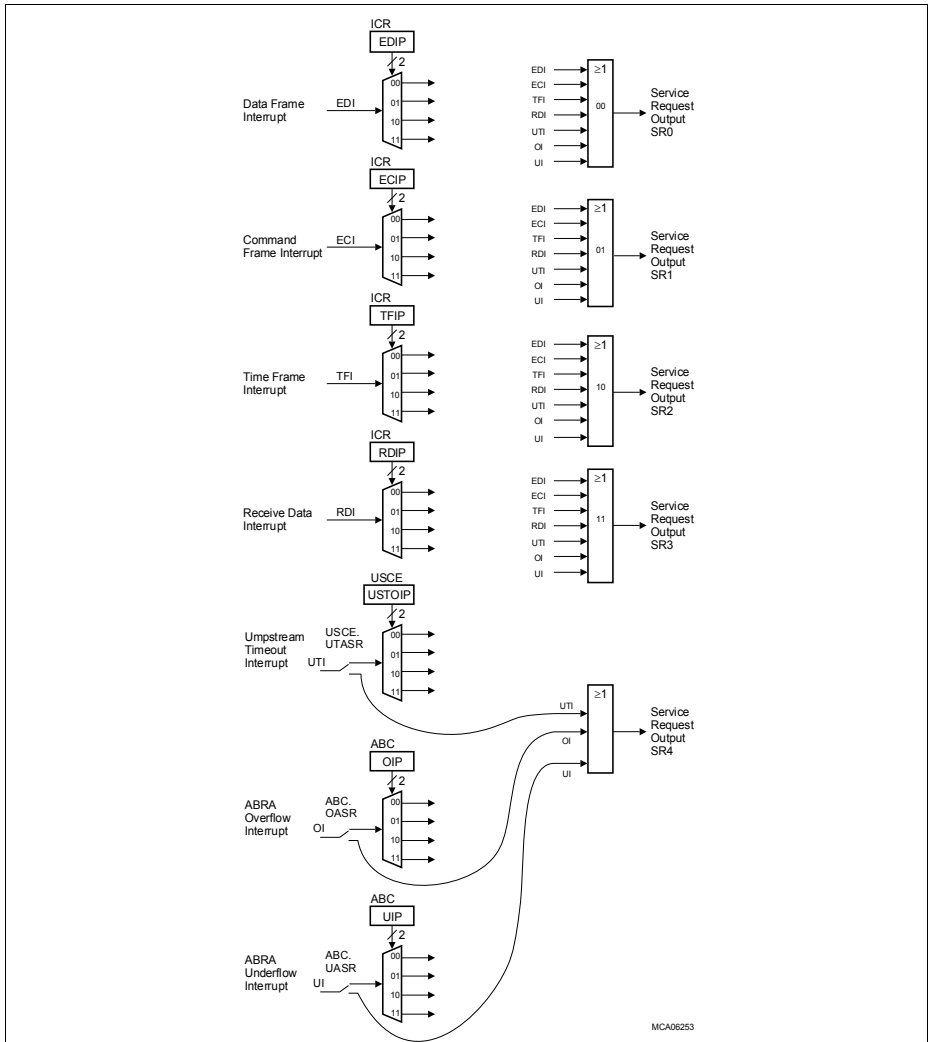

Figure 22-29 MSC Interrupt Request Compressor

22.2 ABRA (Asynchronous Baud Rate Adjustment Block)

The Asynchronous Baud Rate Adjustment Block (ABRA) takes as an input a serial MSC stream with one baud rate and outputs the same serial stream with another baud rate, asynchronous to the input one. The input signal bundle consists of serial clock, data and select signal, and the output signal bundle consists of the same signals.

Additionally, the output clock of an MSC without ABRA can be only set to 50% duty cycle, while with the ABRA block, other duty cycles are also possible.

22.2.1 Overview

The ABRA block is located between the MSC kernel and the output pins.

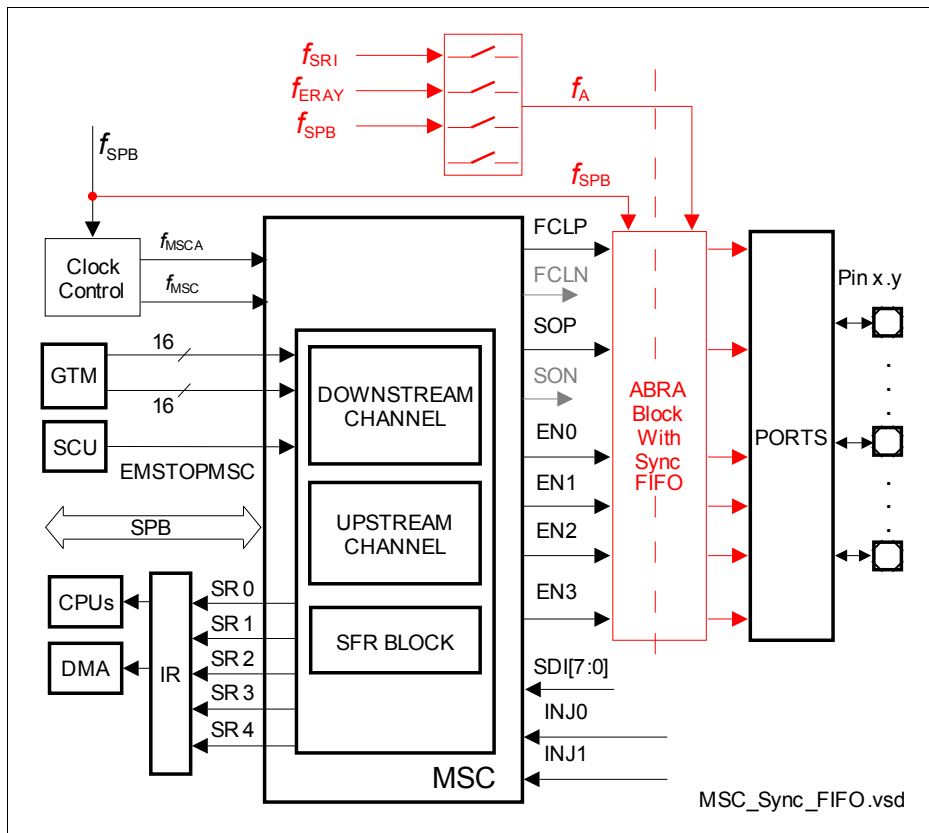

Figure 22-30 ABRA Overview

Micro Second Channel (MSC)

The user has two possibilities: either to use the ABRA block, or to bypass it. In case of using ABRA, additional delay in the signal path between the module and the pins of up to three f_A periods is to be taken into account. Additionally, some margin between the input frame length and the output frame length must be guaranteed by the customer, in order to avoid overflow of the ABRA block.

If the ABRA is not used, the behavior of the MSC module is identical with the previous implementations. The user can also choose between using the 64-bit extension or not, which makes 4 combinations in total, as shown in **Figure 22-31**

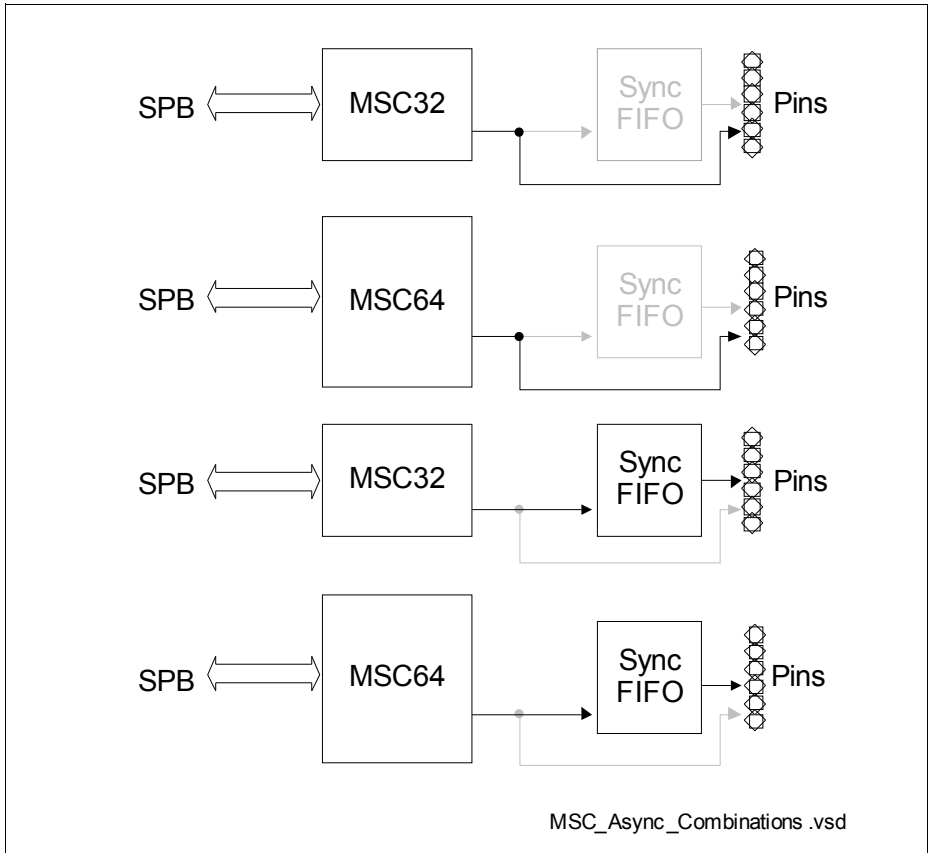

Figure 22-31 Use-Case Combinations

All configuration parameters related to the ABRA block are located in the ABC (Asynchronous Block Configuration) register.

22.2.2 Timings Issues

The ABRA block introduces a delay in the signal path from the MSC module to the pins. However it does not influence significantly the timings between the signals themselves. The output delays between the shift clock, data and enable signals remain approximately the same as if the ABRA block is not used, except for small differences that may appear due to the different routes that the signals take inside the chip, but these differences are included in the one common timing of the MSC module.

22.2.3 Adjusting the Passive Phase of a Frame

The main purpose of the Asynchronous Baud Rate Adjustment block is to transform a frame going in with a higher baud rate (for example 50Mbaud), to a frame going out with a lower baud rate (for example 40Mbaud). Therefore, the duration of the outgoing frame is longer then the duration of the incoming frame. In order not to overflow the ABRA block with too many incoming frames, there must be a pause between them, which is adjusted by configuring the passive phase of the frames. This pause plus the incoming frame duration must be longer or equal to the outgoing frame duration plus some margin.

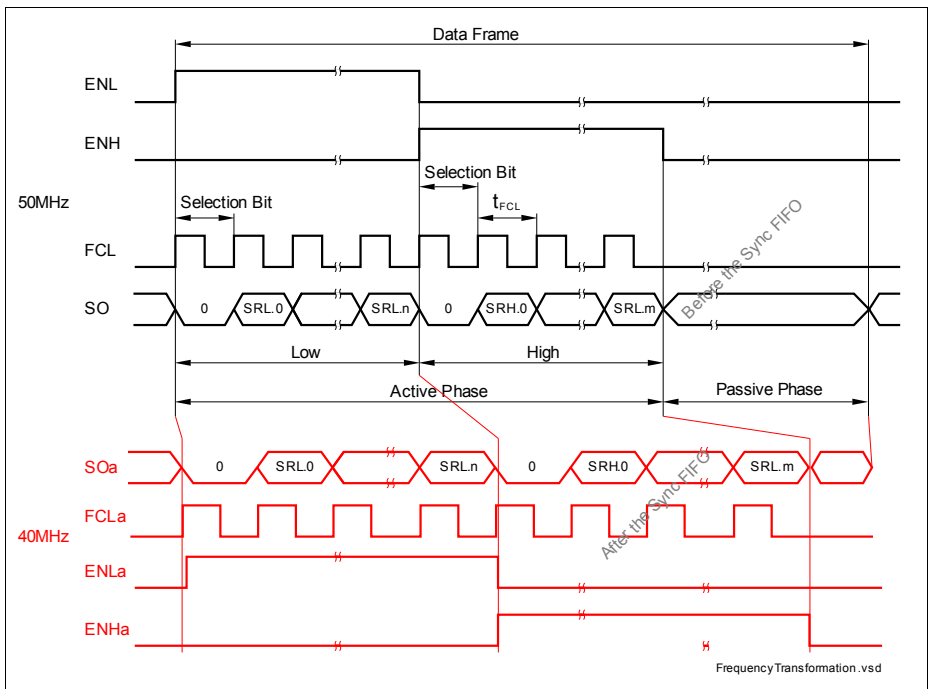

Figure 22-32 Passive Phase Adjustment

Micro Second Channel (MSC)

In order to allow for frame length adjustments:

- for command frames, the bit field **DSTE.PPCE** defines a programmable passive phase in a range of 2 to 65 input frequency cycles, and
- for data frames, the bit field **DSTE.PPDE** extends the passive phase from 0 to 32 to 0 to 128 bit times.

The length of the frame in the MSC domain (data and passive bits) must be longer than the length of the frame in the asynchronous domain, in order to prevent overload in case of back to back transmission:

$$(N_D + N_P) * T_{FCL} > (N_D + N_{PA}) * T_{FCLA}$$

which results to the the following inequality for setting the length of the passive phase in the MSC domain:

$$N_P > [N_D * (T_{FCLA} - T_{FCL}) + N_{PA} * T_{FCLA}] / T_{FCL}$$

Where:

T_{FCL} :

serial clock period in the MSC domain with activated ABRA: $T_{FCL} = 1 / \text{BaudRate}_{\text{MSCA}}$, $\text{BaudRate}_{\text{MSCA}} = f_{\text{SPB}} / (2^m)$, see **Intermedate Downstream Channel Baud Rate** with ABRA block.

T_{FCLA} :

serial clock period of the ABRA block $T_{FCLA} = 1 / \text{BaudRate}_{\text{ABRA}}$, $\text{BaudRate}_{\text{ABRA}} = f_A / (\text{ABC.NDA} * (\text{ABC.LOW}+1 + \text{ABC.HIGH}+1))$

N_P : number of the passive bits in the MSC domain (see **DSTE.PPDE** and **DSC.PPD**)

N_{PA} : number of the targeted passive bits in the asynchronous domain

N_D : number of data bits **DSC.NDBH+NDBL+SELH+SELL+DSCE.NDBLE+NDBHE** in both domains.

Note: If the passive phase settings in the MSC module are not correctly configured in such a way that two frames merge, that is, there is no passive phase on the pins at all, an overflow interrupt is triggered. If the passive phase is wrongly shorter, no error signal is generated.

Input/Output Baud Rate Ratio

The ABRA output baud rate going to the pins must be lower than the input baud rate coming from the MSC module and higher then roughly half of the input baud rate (more precisely higher than 57% of the input baud rate in worst-case, due to the fact that in worst-case MSC data frame can contain 64 data bits plus additionally two select bits).

22.2.4 Jitter of the Downstream Frames

This section describes the jitter effects affecting the starting point of the downstream frames, depending on the setting of the serial clock - serial clock only during the active phase of a frame, or continuous clock.

Note: If the asynchronous frequency f_A is a multiple of f_{SPB} , derived from the same PLL, there is no jitter of the downstream frames, only delay. This applies to the cases where f_A is f_{SPB} or f_{SRI} (for example 200MHz or 300MHz).

22.2.4.1 Jitter in Active Phase Clock Mode

The active phase clock mode is set when **OCR.CLKCTRL** = 0. In this mode the serial clock is generated only during the transmission of the data bits. The ABRA outgoing frame is delayed relative to the incoming frame for three to four f_A cycles. This implies passive phase duration jitter of +/- one f_A cycle. The example in the **Figure 22-33** assumes 50MBaud input and 40MBaud output baud rate, $f_A = 80\text{MHz}$, back to back frames.

Figure 22-33 Frame Jitter in Active Phase Clock Mode

22.2.4.2 Jitter in Continuous Clock Mode

Continuous clock mode is set when **OCR.CLKCTRL** = 1. In this mode the serial clock is always on. The ABRA output frame is delayed relative to the input frame first for two to three f_A cycles, and then it is shifted out with the first available outgoing rising edge of the serial clock. This implies total delay of three to four f_A cycles plus zero to one half output bit time, and a jitter of one output bit time.

The average length of the output frames is equal to the length of the input frames. The ABRA block generates an averaging effect similar to that of a fractional divider. It introduces occasionally jitter of one bit time in the output frame length, in the passive phase of the frame, in order to adjust the average output time raster to the ideal input time raster. The granularity of the input time raster is one input bit time (for example 20ns at 50MBaud), the granularity of the output time raster is one output bit time (for example 25ns at 40MBaud).

The example in the **Figure 22-34** assumes 50MBaud input baud rate and 40MBaud output baud rate, $f_A = 80\text{MHz}$, back to back frames.

Figure 22-34 Frame Jitter in Continuous Clock Mode

22.2.5 Interrupt Position with the ABRA Block

The position of the MSC interrupts within a frame depends only on the internal time schedule of the MSC module in both use cases with and without ABRA block. Therefore the interrupt position in the internal time raster is constant and is the same as in the previous versions of the MSC module, and does not depend on the asynchronous baud rate which is seen on the pins. This behavior affects only the downstream interrupts, which are:

- Data Frame Interrupt
- Command Frame Interrupt
- Time Frame Finished Interrupt

Figure 22-35 Interrupt Position with the ABRA Block

The downstream interrupts can be used for updates of the shadowed rw bit fields for the next frame transmission. Such bit fields are located in the Data Register **DD**, Command Register **DC**, Data Control **DSC** and Data Status **DSS**. Due to the next-frame-update effect, the small jitter and delay effects of the frames as seen on the pins is not relevant, as well as the position of the interrupt in the asynchronous frame.

22.2.6 Configuring the ABRA block

This section describes all the configurable parameters of the ABRA block. They are located in the **ABC** (Asynchronous Block Configuration) register.

Output Baud Rate

The ABRA block shifts out the data with a baud rate generated by dividing the clock f_A in the range of 2 to 32.

The high and the low time of the shift clock are generated by a separate 4-bit n-divider, each operating in the range of 1 to 16. Therefore the duty cycle can be finely configured to be 50% or any other ratio. This may provide some advantages when the communicating devices have asymmetrical timings (output delays or set-up/hold times). See the description of the bit-fields **ABC.HIGH** and **ABC.LOW**

The output baud rate of the ABRA block is defined with the formula:

$$\text{Baud Rate} = f_A / (\text{ABC.NDA} * (\text{ABC.LOW} + 1 + \text{ABC.HIGH} + 1))$$

Continuous Shift Clock

As defined in the bit field **ABC.CC**, the shift clock signal can be active either:

- only during the data transmission time
- continuously

Overflow and Underflow Interrupts

If the input and the output timings of the ABRA block are not adjusted to each other, an overflow of the ABRA block will occur and an error interrupt will be triggered on line X.

Overflow occurs either if the input data rate is too high or the output data rate is too low.

The corresponding bit fields are **ABC.OF**, **OFM**, **OIE**.

Underflow occurs either if the input data rate is too low or the output data rate is too high.

The corresponding bit fields are **ABC.UF**, **UFM**, **UIE**

See also **Interrupt Request Compressor**.

This feature can not guarantee protection against software errors like reconfiguring the baud rates in the middle of a frame.

The configuration of the ABRA block and the MSC kernel is static and the time behavior is deterministic and calculable. Therefore, an overflow/underflow event always signals some configuration error resulting in unadjusted input/output baud rate ratio (see **Input/Output Baud Rate Ratio**). In normal operation and with correctly configured baud rates (clocks and clock dividers) these events do not occur.

Micro Second Channel (MSC)

In case of underflow/overflow event the output frame will be corrupt. The simplest solution to a sporadic event caused by a transient (noise, alpha particle) is to reset the module, reconfigure and restart the communication.

Bypass Mode

If the ABRA block is not used, it is disabled and bypassed via the bit field **ABC.ABB**.

22.2.7 Implementation Issues

The ABRA block operates using synchronization FIFO. The MSC module writes its serial stream to the synchronization FIFO with its serial shift clock, and the same data is read out of the FIFO by using the ABRA serial shift clock, generating out of the f_A .

Three signals are being transformed: the serial shift clock, the serial data stream and the enable (chip select) signals.

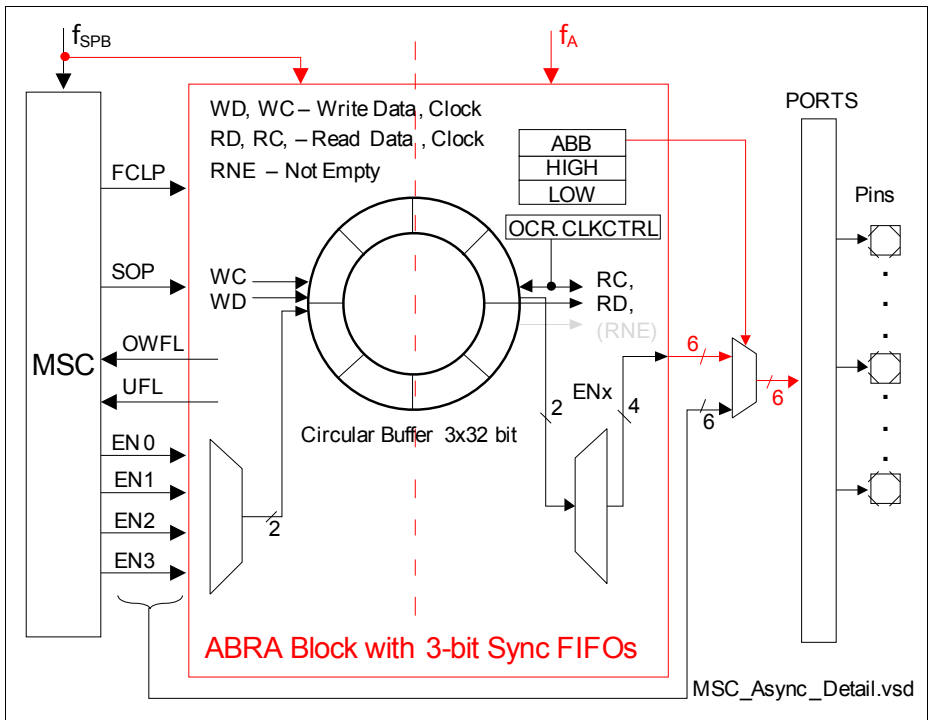

Figure 22-36 Implementation Details of the ABRA Block

22.2.8 ABRA Disable, Sleep and Suspend Behavior

This section describes the behavior of the MSC module in case of:

- switching the module on/off - disable behavior
- power saving - sleep mode
- debugging - OCDS suspend mode

The main concept is to provide as similar behavior as the behavior of the MSC module without the ABRA block, as much as possible.

22.2.8.1 Disable and Sleep Behavior

There is no difference in the behavior of the module in case of entering / leaving the disable and sleep state. Disable state is controlled by a bit set / cleared by software, sleep state is controlled by a hardware signal which can be disabled or enabled.

On disable/sleep state request, the module finishes the possibly ongoing frames (downstream or upstream), then acknowledges the request and the module clock is switched off.

On leaving the disable/sleep state, the module continues with the operation at the same point where it entered the corresponding state.

22.2.8.2 OCDS Suspend Behavior

In case of Hard Suspend, the clock is switched off immediately. A running frame will not be finished.

In case of Soft Suspend, the state is entered after the following two conditions are met:

- any ongoing upstream reception is completed, and
- any ongoing downstream frame transmission is completed, both from the MSC kernel and the ABRA block side

22.3 MSC Kernel Registers

This section describes the kernel registers of the MSC module. All MSC kernel register names described in this section will be referenced in other parts of the TC26x B-Step User's Manual by the module name prefix "MSCx_".

All registers in the MSC address spaces are reset with the application reset (definition see SCU section "Reset Operation").

1) The absolute register address is calculated as follows:

Module Base Address ([Table 22-9](#)) + Offset Address (shown in this column)

2) All registers have read access mode U, SV. Read access to reserved addresses delivers bus error (BE) except 50H and 54H.

All registers belong to reset class 3 except OCS, which belongs to reset class 1.

22.3.1 Module Identification Register

ID

The MSC Module Identification Register ID contains read-only information about the module version.

>> [Registers Overview](#)

ID

Module Identification Register (08_H) **Reset Value: 0028 C01X_H**

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the MSC: 0028 _H

22.3.2 Status and Control Registers
USR

The Upstream Status Register is used to configure the upstream channel data format, baud rate, and parity type. It also provides the status information of the upstream counter (UC).

>> [Registers Overview](#)

USR

Upstream Status Register (10_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
UFT	0	rw	Upstream Channel Frame Type This bit determines the frame type used by the upstream channel for data reception. 0 _B 12-bit upstream frame selected 1 _B 16-bit upstream frame selected (with 4-bit address field)
URR	[3:1]	rw	Upstream Channel Receiving Rate This bit field determines the baud rate for the upstream channel. 000 _B Upstream channel disabled; no reception is possible 001 _B Baud rate = $f_{MSC}/4$ 010 _B Baud rate = $f_{MSC}/8$ 011 _B Baud rate = $f_{MSC}/16$ 100 _B Baud rate = $f_{MSC}/32$ 101 _B Baud rate = $f_{MSC}/64$ 110 _B Baud rate = $f_{MSC}/128$ 111 _B Baud rate = $f_{MSC}/256$

Micro Second Channel (MSC)

Field	Bits	Type	Description
PCTR	4	rw	Parity Control This bit determines the parity mode used by the upstream channel for data reception. 0_B Even parity mode is selected. A parity bit is set on an odd number of 1s in the serial address/data stream. 1_B Odd parity mode is selected. A parity bit is set on an even number of 1s in the serial address/data stream.
SRDC	5	rw	Service Request Delay Control This bit determines the additional delay inserted by the upstream channel when triggering the receive interrupt. Only the hardware generated interrupt can be delayed. The software generated interrupt by writing the ISC.SURDI bit is never delayed. 0_B No delay 1_B Delay of 1 bit time
UC	[20:16]	rh	Upstream Counter This bit field indicates the content of the upstream counter that counts the bits during upstream channel reception.
0	[15:6], [31:21]	r	Reserved Read as 0; shall be written with 0.

Micro Second Channel (MSC)
DSC

The Downstream Control Register is used to control the operation mode and frame layout of the downstream channel transmission. It also contains the two pending status bits.

Micro Second Channel (MSC)

USCE

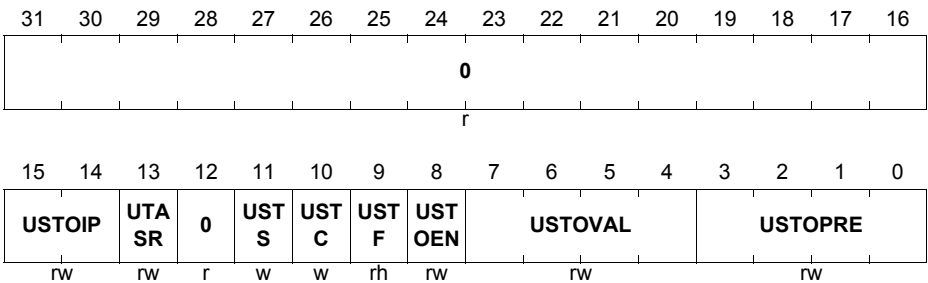

The Upstream Control Enhanced Register is used to control the upstream channel timeout feature.

>> [Registers Overview](#)

USCE

Upstream Control Enhanced Register 1(5C_H)

Reset Value: 0000 00FF_H

Field	Bits	Type	Description
USTOPRE	[3:0]	rw	Upstream Timeout Prescaler Prescaler for the upstream time-out limit. Expressed in upstream bit times. 2 ^N divider in the range of 1 to 32768. Write to this bit field triggers new start of the watchdog timer. 0000 _B 1 0001 _B 2 0010 _B 4 ... _B ... 1110 _B 32768 1111 _B reserved
USTOVAL	[7:4]	rw	Upstream Timeout Value Upstream timeout value for the N-divider in the range of 1 to 16, expressed in number of upstream bit time lengths (the upstream bit time is the reciprocal value of the upstream baud rate). TimeOut = BitTime * 2 ^(USTOPRE+1) * (USTOVAL+1). Write to this bit field triggers new start of the watchdog timer.

Micro Second Channel (MSC)

Field	Bits	Type	Description
USTOEN	8	rw	Upstream Timeout Interrupt Enable Enable bit for the upstream timeout interrupt. The timeout counter runs continuously independently of the USTOEN bit. The USTOEN enables only the interrupt generation. 0_B Disabled 1_B Enabled
USTF	9	rh	Upstream Timeout Flag Signals an upstream timer event. If set by software, the interrupt is also triggered, if enabled. The watchdog timer runs continuously and sets the USTF flag at overflow, independently from the enable bit. Therefore this bit must be cleared with the same write access which enables the interrupt. 0_B Disabled 1_B Enabled
USTC	10	w	Upstream Timeout Clear Clears the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Clear
USTS	11	w	Upstream Timeout Set Sets the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Set
UTASR	13	rw	Upstream Timeout Alternate Service Request Selects if the interrupt signal is routed to the alternate service request node. See Figure 22-29 . 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
USTOIP	[15:14]	rw	Upstream Timeout Interrupt Node Pointer USTOIP selects the service request output line SR _n (n = 0-3) for the data frame interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
0	[31:16], 12	r	Reserved Read as 0; shall be written with 0.

TFIE	11	rw	Time Frame Interrupt Enable This bit enables the time frame interrupt. 0 _B Interrupt generation disabled. 1 _B Interrupt generation enabled.
RDIP	[13:12]	rw	Receive Data Interrupt Pointer RDIP selects the service request output line SRn (n = 3-0) for the receive data interrupt. 00 _B Service request output SR0 selected 01 _B Service request output SR1 selected 10 _B Service request output SR2 selected 11 _B Service request output SR3 selected

Micro Second Channel (MSC)

Field	Bits	Type	Description
RDIE	[15:14]	rw	Receive Data Interrupt Enable This bit field determines the enable conditions for the receive data interrupt. 00 _B Interrupt generation disabled. 01 _B An interrupt is generated when data is received and written into the upstream data registers UD _x (x = 0-3). 10 _B An interrupt is generated as with RDIE = 01 _B but only if the received data is not equal to 00 _H . 11 _B An interrupt is generated when data is received and written into register UD3.
0	6, 10, [31:16]	r	Reserved Read as 0; shall be written with 0.

Micro Second Channel (MSC)

ISR

The Interrupt Status Register ISR holds the interrupt status flags that indicate an interrupt occurrence in downstream and upstream channels.

>> [Registers Overview](#)

ISR

Interrupt Status Register (44_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
DEDI	0	rh	Data Frame Interrupt Flag This flag is always set by hardware when a downstream channel data frame interrupt is generated. DEDI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SDEDI or ISC.CDEDI set.
DECI	1	rh	Command Frame Interrupt Flag This flag is always set by hardware when a downstream channel command frame interrupt is generated, whether or not it is enabled. DECI can be set or cleared by software when writing to register ISC with the appropriate bits SDECI or CDECI set.
DTFI	2	rh	Time Frame Interrupt Flag This flag is always set by hardware when a downstream channel time frame interrupt is generated, whether or not it is enabled. DTFI can be set or cleared by software when writing to register ISC with the appropriate bits SDTFI or CDTFI set.

Micro Second Channel (MSC)

Field	Bits	Type	Description
URDI	3	rh	Receive Data Interrupt Flag This flag is always set by hardware when an upstream channel receive data interrupt is generated, whether or not it is enabled. URDI can be set or cleared by software when writing to register ISC with the appropriate bits SURDI or CURDI set.
0	[31:4]	r	Reserved Read as 0; shall be written with 0.

Micro Second Channel (MSC)
ISC

The Interrupt Set Clear Register ISC is used to set or clear the MSC interrupt flags located in the Interrupt Status Register ISR. Reading ISC always returns 0000 0000_H.

Note: When the ISC register is written with both bits (set and reset bit) for a specific interrupt flag, the clear operation takes place and the set operation is ignored.

Micro Second Channel (MSC)
OCR

The Output Control Register OCR determines the MSC input/output signal polarities, the chip select output signal assignment, and the serial output clock generation.

>> [Registers Overview](#)

OCR

Output Control Register (4C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLP	0	rw	FCLP Line Polarity 0 _B FCLP and FCL signal polarity is identical. FCLN signal has inverted FCL signal polarity. 1 _B FCLP signal has inverted FCL signal polarity. FCLN and FCL signal polarities are identical.
SLP	1	rw	SOP Line Polarity 0 _B SOP and SO signal polarity is identical. SON signal has inverted SO signal polarity. 1 _B SOP signal has inverted SO signal polarity. SON and SO signal polarities are identical.
CSLP	2	rw	Chip Selection Lines Polarity 0 _B EN[3:0] and ENL, ENH, ENC signal polarities are identical (high active). 1 _B EN[3:0] signal polarities are inverted (low active) to the ENL, ENH, ENC signal polarities. Bit CSLP is buffered during a frame transmission. This means that any change of CSLP becomes valid first with the start of the next frame transmission.

Micro Second Channel (MSC)

Field	Bits	Type	Description
ILP	3	rw	SDI Line Polarity 0 _B SDI and SI signal polarities are identical. 1 _B SDI and SI signal polarities are inverted.
CLKCTRL	8	rw	Clock Control This bit determines the activation of clock output FCL. 0 _B FCL is activated only during the active phases of data or command frames (not during passive time frames). 1 _B FCL is always active whether or not a downstream frame is currently transmitted.
CSL	[10:9]	rw	Chip Enable Selection for ENL This bit field selects the chip enable output ENx that becomes active during the SRL active phase (ENL = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00 _B EN0 line is selected for ENL. 01 _B EN1 line is selected for ENL. 10 _B EN2 line is selected for ENL. 11 _B EN3 line is selected for ENL.
CSH	[12:11]	rw	Chip Enable Selection for ENH This bit field selects the chip enable output ENx that becomes active during the SRH active phase (ENH = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00 _B EN0 line is selected for ENH. 01 _B EN1 line is selected for ENH. 10 _B EN2 line is selected for ENH. 11 _B EN3 line is selected for ENH.
CSC	[14:13]	rw	Chip Enable Selection for ENC This bit field selects the chip enable output ENx that becomes active during the active phase (ENC = 1) of a command frame. The active level of ENx is defined by bit CSLP. 00 _B EN0 line is selected for ENC. 01 _B EN1 line is selected for ENC. 10 _B EN2 line is selected for ENC. 11 _B EN3 line is selected for ENC.

Micro Second Channel (MSC)

Field	Bits	Type	Description
SDISEL	[18:16]	rw	Serial Data Input Selection This bit field selects the source for the serial data input SDI of the upstream channel. 000 _B SDI0 input is selected for SDI. 001 _B SDI1 input is selected for SDI. 010 _B SDI2 input is selected for SDI. 011 _B SDI3 input is selected for SDI. 100 _B SDI4 input is selected for SDI. 101 _B SDI5 input is selected for SDI. 110 _B SDI6 input is selected for SDI. 111 _B SDI7 input is selected for SDI.
0	[7:4], 15, [31:19]	r	Reserved Read as 0; shall be written with 0.

Micro Second Channel (MSC)

DSDSLE

The bit fields of the Downstream Select Data Low Register DSDSL determine the data source for the upper 16 bits in the shift register SRL.

>> [Registers Overview](#)

DSTE

The Downstream Control Enhanced Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

>> [Registers Overview](#)

DSTE
Downstream Timing Extension Register (74_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PPDE	[1:0]	rw	Passive Phase Length at Data Frames Extension Additional MSB bits extension of the PPD bit field.
PPCE	[7:2]	rw	Passive Phase Length at Control Frames Extension Additional MSB bits extension of the fixed length of 2 of the command frames passive phase. The final length is 2 + PPCE resulting in a range of 2 to 65. 000000 _B 2 000001 _B 3 ... _B ... 111111 _B 65
NDD	[11:8]	rw	N Divider Downstream Defines the division ratio in the range of 1 to 16. 0000 _B 1 0001 _B 2 ... _B ... 1111 _B 16
0	[31:12]	r	Reserved Read as 0; shall be written with 0.

22.3.3 Data Registers

DD

The Downstream Data Register DD contains data to be transmitted during data frames.

>> [Registers Overview](#)

DD

Downstream Data Register (1C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DDL	[15:0]	rw	Downstream Data for SRL Shift Register Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDH	[31:16]	rw	Downstream Data for SRH Shift Register Contains the data bits to be transmitted during the SRH active phase of a data frame.

DC

The Downstream Command Register DC contains command information to be transmitted during command frames.

>> [Registers Overview](#)

DC

Downstream Command Register (20_H) **Reset Value: 0000 0000_H**

Micro Second Channel (MSC)

Field	Bits	Type	Description
DCL	[15:0]	rw	Downstream Command for SRL Shift Register Contains the data bits to be transmitted during the SRL active phase of a command frame.
DCH	[31:16]	rw	Downstream Command for SRH Shift Register Contains the data bits to be transmitted during the SRH active phase of a command frame.

Micro Second Channel (MSC)
UDx

The four Upstream Data Registers UDx store the content (data, addresses, received and calculated parity bit, parity error bit) of a received upstream channel data frame.

>> [Registers Overview](#)

UDx (x = 0-3)

Upstream Data Register x **(30_H+x*4_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DATA	[7:0]	rh	Received Data This bit field contains the 8-bit receive data.
V	16	rh	Valid Bit This bit is set by hardware when the received data is written to UDx. Writing bit C = 1 clears V. If hardware setting and software clearing of the valid bit occur simultaneously, bit V will be cleared.
P	17	rh	Parity Bit This flag contains the parity bit that has been received with the data frame.
C	18	w	Clear Bit 0 _B No operation. 1 _B Bit V is cleared. C is always read as 0.
LABF	[20:19]	rh	Lower Address Bit Field This bit field contains the two address bits A[1:0] of the 4-bit address field (16-bit data frame). If 12-bit data frame is selected, LABF is always set to 00 _B .

Micro Second Channel (MSC)

Field	Bits	Type	Description
IPF	21	rh	Internal Parity Flag This bit contains the parity bit that has been calculated in the MSC during data frame reception.
PERR	22	rh	Parity Error This bit indicates if a start bit error, parity error, or stop bit error occurred during frame reception. 0 _B No error detected. 1 _B Error detected.
0	[15:8], [31:23]	r	Reserved Read as 0; shall be written with 0.

22.3.4 Extension Registers

This sub-chapter describes the registers related to 64-bit extension of the MSC module.

ESRE

The Emergency Stop Extension Register ESRE determines which bits of SRL and SRH are enabled for emergency operation.

>> [Registers Overview](#)

ESRE

Emergency Stop Extension Register (68_H) **Reset Value: 0000 0000_H**

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Field	Bits	Type	Description
ENLx (x = 16-31)	x-16	rw	Emergency Stop Enable for Bit x in SRL This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit of the data register DD.DDL[x] is used for the shift register load operation. 0 _B Emergency stop feature for bit SRL[x] is disabled. 1 _B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x = 16-31)	x	rw	Emergency Stop Enable for Bit x in SRH This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DD.DDH[x] is used for the shift register load operation. 0 _B Emergency stop feature for bit SRH[x] is disabled. 1 _B The emergency stop feature for bit SRH[x] is enabled.

Micro Second Channel (MSC)

DDE

The Downstream Data Extension Register DDE contains data to be transmitted during data frames.

>> [Registers Overview](#)

DDE

Downstream Data Extension Register (6C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DDLE	[15:0]	rw	Downstream Data Extension for SRL Shift Register Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHE	[31:16]	rw	Downstream Data Extension for SRH Shift Register Contains the data bits to be transmitted during the SRH active phase of a data frame.

Micro Second Channel (MSC)

DDM

The Downstream Data Mirror Register DDM provides alternative address for the DD register. The purpose of this alternative address is to provide convenient way to write up to 64 bit data blocks to the MSC module by using DMA with automatic address increment and wrap around. The DMA writes first to the DDE register, and then to the DDM register, which triggers the data transfer in the same way as a write to the DD register.

>> [Registers Overview](#)

DDM

Downstream Data Mirror Register (70_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DDL M	[15:0]	w	Downstream Data Mirror for SRL Shift Register Contains the data bits to be transmitted during the SRL active phase of a data frame.
DD H M	[31:16]	w	Downstream Data Mirror for SRH Shift Register Contains the data bits to be transmitted during the SRH active phase of a data frame.

22.3.5 Asynchronous Block Registers

ABC

The Asynchronous Block Configuration register ABC contains all the bit fields related to the ABRA block.

>> [Registers Overview](#)

>> [Configuring the ABRA block](#)

ABC

Asynchronous Block Configuration Register (80_H) **Reset Value: 0000 0000_H**

UNF	23	r	Underflow Flag Indicates if overflow error has occurred. 0 _B No overflow error 1 _B Overflow error
UFM	[25:24]	w	Underflow Flag Modify Sets or clears the overflow flag UF. 00 _B No action 01 _B Set (also triggers the underflow interrupt if enablede) 10 _B Clear (additionally flushes the ABRA FIFO and resets the bit counter) 11 _B No action
UIE	26	rw	Underflow Interrupt Enable Enables or disables the path of the interrupt signal towards the interrupt node. If enabled, an overflow event triggers an interrupt, and if disabled then not. The UF flag always indicates the occurrence of an overflow event, independently of UIE. 0 _B Overflow interrupt disabled 1 _B Overflow interrupt enabled
CLKSEL	[29:27]	rw	Clock Select Selects the clock source for the ABRA block. 000 _B no clock 001 _B f_{SPB} 010 _B f_{SRI} 100 _B f_{ERAY} others , reserved (no clock)

Micro Second Channel (MSC)

Field	Bits	Type	Description
ABB	31	rw	Asynchronous Block Bypass Defines if the asynchronous block and the n-divider of the MSC downstream path (located parallel to the fractional divider) are used or not. If bypassed, then also disabled. 0_B Bypassed and disabled 1_B Not bypassed and active
0	11, 22, 30	r	Reserved Read as 0; shall be written with 0.

*Note: The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bitfield, and then a second write defining the new clock source. Between the first and the second write a delay of minimum $4 * (1/f_A) + 2 * (1/f_{CLC})$ must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that the f_{CLC} is selected as f_A (CSR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.*

22.4 MSC Module Implementation

This section describes the MSC module interface as implemented in the TC26x B-Step. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

22.4.1 Module Identification Registers

The reset value of the ID module identification register is 0028 C01X_H.

22.4.2 BPI_FPI Module Registers (Single Kernel Configuration)

22.4.2.1 System Registers

Figure 22-38 shows all registers associated with the BPI_FPI module, configured for one kernel.

BPI_FPI Registers Overview

Figure 22-38 BPI_FPI Registers

The writes of the bus masters to the MSC module is controlled by Acces Protection registers ACCENx.

The MSC implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

Micro Second Channel (MSC)
Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{\leftarrow} module clock signal, sleep mode and disable mode for the module.

>> [Registers Overview](#)

CLC
Clock Control Register

0	[31:1]	r	Reserved Read as 0; shall be written with 0.

22.4.3 Interface Connections of the MSC Module

The MSC module is supplied with a separate clock control, address decoding, and interrupt control logic. The service request outputs are connected with the interrupt nodes in the Interrupt Router module. Outputs of the GTM module are connected to the alternate input buses ALTINL/ALTINH. The emergency stop output from the SCU controls the corresponding inputs of MSC0 module.

The serial data and clock outputs of the downstream channels of the MSC module are connected to combined GPIO/LVDS differential output drivers. Details about these four pins are defined in the ports chapter.

22.4.4 MSC Module-Related External Registers

Figure 22-39 summarizes the module-related external registers which are required for MSC programming (see also **Figure 22-37** for the module kernel specific registers). Generally, additionally to programming the MSC kernel and BPI registers, the Fractional Divider, the ports registers located in the Ports module and interrupt registers located in the Interrupt Router module.

Figure 22-39 MSC Implementation-specific Special Function Registers

22.4.5 Clock Control

The following section describes the clock control and the baud rate generation of the MSC module.

The MSC module is provided with two independent clock signals (**Figure 22-40**):

- f_{CLC}
 This is the module clock that is used inside the MSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is always identical to the system clock frequency f_{SPB} . The clock control register MSC_CLC makes it possible to enable/disable f_{CLC} under certain conditions.
- f_{MSC}
 This clock is the module clock that is used inside the MSC for baud rate generation of the serial upstream and downstream channel. The fractional divider register MSC_FDR controls the frequency of f_{MSC} and makes it possible to enable/disable it independent of f_{CLC} .
- f_{MSCA}
 This clock is the downstream clock which is used together with the ABRA block. In this case, the upstream baud rate can be fine-tuned with the fractional divider, and the downstream channel frequency is configured with an n-divider.

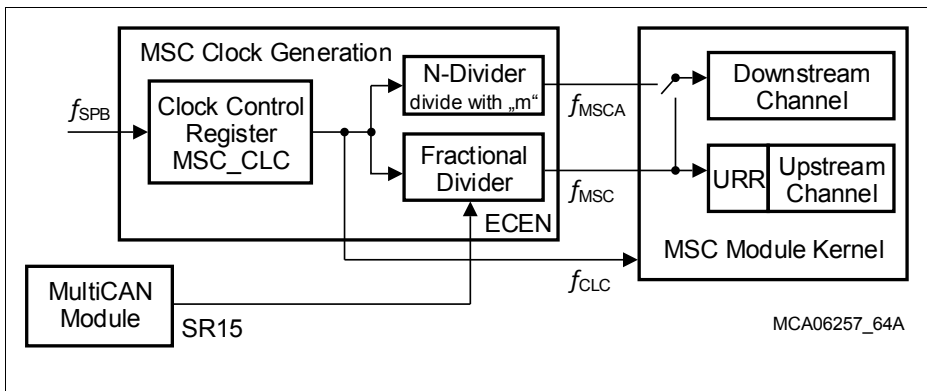

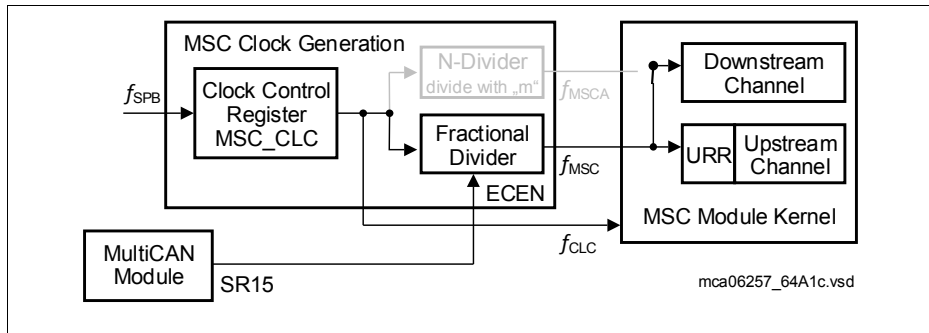

Figure 22-40 MSC Module Clock Generation

Micro Second Channel (MSC)

22.4.5.1 Clock Control Without the ABRA Block

Not using the ABRA block is the standard, compatibility use-case, which guarantees the full compatibility with the standard MSC module not containing the ABRA block. The clock generation is therefore identical with the standard MSC clock generation. The additional N-Divider (dividing with the division factor named “m”) is not used. Only the fractional divider is used (using the factor named “n” in the formulas below).

Figure 22-41 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC} :

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \text{ with } n = 1024 - \text{MSC.FDR.STEP} \quad (22.4)$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \text{ with } n = 0-1023 \quad (22.5)$$

Micro Second Channel (MSC)
Downstream Channel Baud Rate

As the clock signal FCL of the synchronous downstream channel is always half the frequency of f_{MSC} , the resulting downstream channel baud rate is defined by:

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{2 \times (1024 - \text{MSC.FDR.STEP})} \quad (22.6)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{2 \times 1024} \quad (22.7)$$

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field USR.URR (see also [Equation \(22.3\)](#) on [Page 22-28](#)). The divide factor DF can be at minimum 4 and at maximum 256.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - \text{MSC.FDR.STEP})} \quad (22.8)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{DF \times 1024} \quad (22.9)$$

[Equation \(22.4\)](#), [Equation \(22.6\)](#), and [Equation \(22.8\)](#) are valid for normal divider mode (FDR.DM = 01_B). [Equation \(22.5\)](#), [Equation \(22.7\)](#), and [Equation \(22.9\)](#) are valid for fractional divider mode (FDR.DM = 10_B).

Micro Second Channel (MSC)

22.4.5.2 Clock Control when using the ABRA Block

Using the ABRA block makes additional considerations regarding the baud-rate adjustments necessary.

An additional N-Divider **DSTE.NDD** is used for configuring the intermediate downstream baud rate the MSC module is using for writing to the ABRA block (dividing the f_{SPB} with the integer division factor named “m” in the formulas below). The final output downstream baud rate is configured in the ABRA block itself. The following restriction applies: the ABRA output downstream baud rate is between half and whole intermediate baud rate.

When ABRA block is active, the fractional divider **FDR.STEP** is used only for adjusting the upstream baud rate (using the factor named “n” in the formulas below).

Attention: The following restriction applies: the upstream baud rate must be less than one tenth of the f_{SPB} . See also [Upstream Channel](#).

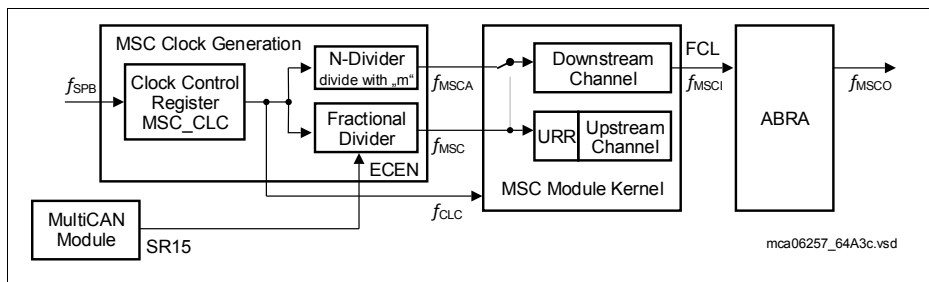

Figure 22-42 MSC Module Clock Generation

The following two formulas define the frequency of f_{MSC} :

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{MSC.FDR.STEP} \quad (22.10)$$

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \quad \text{with } n = 0-1023 \quad (22.11)$$

The following formula defines the frequency of f_{MSCA} :

$$f_{MSCA} = f_{SPB} \times \frac{1}{m} \quad \text{with } m = 1 - 16 \quad (22.12)$$

Micro Second Channel (MSC)
Intermediate Downstream Channel Baud Rate

When the ABRA block and the downstream N-divider are enabled with **ABC.ABB**, the intermediate clock signal FCL of the synchronous downstream channel going into the ABRA block is always half the frequency of f_{MSCA} :

$$\text{Baud rate}_{MSCA} = f_{SPB} \times \frac{1}{2 \times m} \quad (22.13)$$

The final output baud rate f_{MSCO} can be calculated as described in **Output Baud Rate**.

Upstream Channel Baud Rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit field **USR.URR** (see also **Equation (22.3)** on **Page 22-28**). The divide factor DF can be at minimum 4 and at maximum 256. Nevertheless, the minimum DF factor when using ABRA block should be 8. See the note on **Page 22-24**.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - MSC.FDR.STEP)} \quad (22.14)$$

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{MSC.FDR.STEP}{DF \times 1024} \quad (22.15)$$

Equation (22.10), **Equation (22.11)**, and **Equation (22.14)** are valid for normal divider mode (**FDR.DM** = 01_B). **Equation (22.11)** and **Equation (22.15)** are valid for fractional divider mode (**FDR.DM** = 10_B).

Example for Setting the Fractional Divider

This example shows how to receive upstream frames generated from 40MHz downstream clock, when the module baud-rate frequency is 100MHz/2=50MHz. The fractional divider is used to adjust the FCL clock of 50MHz to FCL clock of 40MHz, that is, it multiplies with 4/5. The best approximation of 4/5 with x/1024 is for x=819, giving an error of 0.025%. So in this case, the optimal setting for **FDR.STEP** is 819. In the next stage of the divider cascade, the DF power-of-two-divder divides the clock further to the final baud rate, matching the baud rate generated by the MSC slave device.

22.4.5.3 Fractional Divider Register

FDR

The Fractional Divider Register controls the clock rate of the shift clock f_{MSC} .

>> [Registers Overview](#)

FDR

Fractional Divider Register (0C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
ENHW	30	rw	Enable Hardware Clock Control Controls operation of ECEN input and DISCLK bit.
DISCLK	31	rwh	Disable Clock Hardware controlled disable for f_{MSC} signal.
0	10, [27:26], 28, 29	r	Reserved Read as 0; shall be written with 0.
0	11, [13:12]	rw	Reserved rw bit with no function. Read as 0; shall be written with 0.

22.4.6 Port Control

MSC clock and data output lines are connected to dedicated LVDS differential output drivers. Some of the MSC module I/O lines are connected to I/O ports and therefore controlled in the port logic.

The following port control operations selections must be executed for these I/O lines:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

22.4.7 On-Chip Connections

This section describes the on-chip connections of the MSCx modules.

22.4.7.1 EMGSTOPMSC Signal (from SCU)

The emergency stop input signal EMGSTOPMSC of the MSCx modules is connected to the output signal of the emergency stop input control logic. This logic is located in the SCU. Its functionality is controlled by the SCU emergency stop register.

Note: If the emergency stop signal is used by the MSC module, setting the SCU.EMSR.MODE=0 is mandatory. MODE=1 is not allowed to be used with the MSC module.

22.4.7.2 Interrupt Service Requests

All five service request outputs SR[4:0] are connected to the Interrupt Router Module. There they are routed further to a CPU or a DMA. The MSCx_SRCy registers are also located in the IR (Interrupt Router) Module.

22.4.7.3 Connections to Ports / Pins

These connections are described in the chapters regarding the ports and the pinning. Unused SDI signal are tied high.

Micro Second Channel (MSC)

22.4.7.4 GTM Connections

Each MSC module is connected to up to 64 TOM or ATOM outputs of the GTM module. For more detailed description of the connections for each derivative, see the section “MSC Connections” in the GTM chapter.

Table 22-11 GTM to MSC Connections

MSC Input	GTM Output
MSC0_ALTINL[15:0]	GTM_MSC0ALTINL[15:0]

MSC1_ALTINLE[15:0]	GTM_MSC1ALTINH[15:0]
MSC1_ALTINH[15:0]	GTM_MSC1ALTINH[15:0]
MSC1_ALTINHE[15:0]	GTM_MSC1ALTINL[15:0]

22.5 Use Case Example Micro Second Channel (MSC)

This section provides a code example for the MSC module to give an overview about the core functionality. It describes how to send data frames continuously without any software interaction, called data repetition mode. The MSC module contains two MSC serial interfaces, MSC 0 and MSC 1, each is able to connect up to four external power devices. This examples uses interface MSC 0.

Each interface can send command and data frames (see also 25.1.2.1 Frame Formats and Definitions(LINK)) via downstream channel. Between each data frame one or more passive frames can be inserted (see also Figure 25-9, Data Repetitions Mode Frame Examples (LINK)). This example realizes sending out only data frames in repetition mode with one passive frame in between. The module has more features than the example shows. For further details please see user's manual.

The MSC module can also receive frames with the upstream channel. These frames are usually status frames from the external devices. The example keeps the focus on sending out via downstream channel so the upstream channel is not part of this chapter. The initialization process follows the following order:

1. Enable MSC 0
2. Initialize MSC 0 for down streaming
3. Start sending

Step description to initialize the MSC module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter 8.9.3(LINK)).

(Line 2) enable control of the module, in clock control register CLC (LINK).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) This line loads the fractional divider register FDR(LINK). DM=01 sets the module to normal divider mode while STEP defines the Baudrate.

Note: Assuming $f_{clk}=100\text{MHz}$ and $STEP=3FE \rightarrow \text{Baudrate} = 25 \text{ Mbaud}$

(Line 5) set ENDINIT to lock the protected register again.

(Line 6) This line loads the downstream control register DSC (LINK). TM=1 sets the module to data repetition mode, NDBL and NDBH are defining the length of the SRL and SRH active phase, here set to 15 bit(see also Figure 25-6(LINK)). PPD=2 sets the length of the passive frame to $2 \times t_{FCL}$ and DIDIS=1 disables sending. Sending will be enabled after initialization.

(Line 7) This line set the number of passive time frames in the downstream status register DSS (LINK). NPTF=1 \rightarrow one passive time frame gets inserted.

Micro Second Channel (MSC)

(Line 8) The data gets loaded in the downstream data register DD (LINK). The data itself is here just an example.

(Line 9) This line resets DIDIS, so the module starts sending out data and passive time frames.

Initialization of the MSC module:

```
// enable MSC 0
(1) SCU_vResetENDINIT (0); // enable ENDINIT reg
(2) MSC0_CLC = 0x000; // disable module control
(3) dummy = MSC0_CLC; // read to check the made changes
(4) MSC0_FDR = (1 << 14) | 0x3FE; // DM=01, STEP=3FE
(5) SCU_vSetENDINIT (0); // lock ENDINIT reg
// Initialize MSC 0 for down streaming
(6) MSC0_DSC = 0x02009081; //PPD=2,DSDIS=1,NDBH=16,NDBL=16,TM=1
(7) MSC0_DSS = (1 << 8); // NPTF=1
(8) MSC0_DD = 0x5555AAAA; // downstream data (example)
// Start sending
(9) MSC0_DSC |= (1 << 15); // DIDIS=0
```

23 Controller Area Network Controller (MultiCAN+)

This chapter describes the MultiCAN+ controller of the TC26x B-Step. It contains the following sections:

- CAN basics (see [Page 23-2](#))
- Overview of the CAN Module in the TC26x B-Step (see [Page 23-12](#))
- CAN Flexible Data Rate in TC26x B-Step (see [Page 23-15](#))
- Functional description of the MultiCAN+ Kernel (see [Page 23-17](#))
- MultiCAN+ Kernel register description (see [Page 23-71](#))
- TC26x B-Step implementation-specific details (port connections and control, interrupt control, address decoding, clock control, see [Page 23-149](#)).

Table 23-1 Fixed Module Constants

Constant	Description
n_objects	Number of Message Objects available.
n_interrupts	Number of Interrupt Output Lines available.
n_pendings n_pendingregs	Number of Message Pending Bits available. There are n_pendings/32 message pending registers.
n_lists	Number of Lists available for allocation of Message Objects.
n_nodes	Number of CAN Nodes available As each CAN node has its own list in addition to the list of un-allocated elements, the relation n_nodes < n_lists is true.

Controller Area Network Controller (MultiCAN+)**23.1 CAN Basics**

CAN is an asynchronous serial bus system with one logical bus line. It has an open, linear bus structure with equal bus participants called nodes. A CAN bus consists of two or more nodes.

The bus logic corresponds to a “wired-AND” mechanism. Recessive bits (equivalent to the logic 1 level) are overwritten by dominant bits (logic 0 level). As long as no bus node is sending a dominant bit, the bus is in the recessive state. In this state, a dominant bit from any bus node generates a dominant bus state. The maximum CAN bus speed is, by definition, 1 Mbit/s. This speed limits the CAN bus to a length of up to 40 m. For bus lengths longer than 40 m, the bus speed must be reduced.

The binary data of a CAN frame is coded in NRZ code (Non-Return-to-Zero). To ensure re-synchronization of all bus nodes, bit stuffing is used. This means that during the transmission of a message, a maximum of five consecutive bits can have the same polarity. Whenever five consecutive bits of the same polarity have been transmitted, the transmitter will insert one additional bit (stuff bit) of the opposite polarity into the bit stream before transmitting further bits. The receiver also checks the number of bits with the same polarity and removes the stuff bits from the bit stream (= destuffing).

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC Sequence. The stuff bits will be inserted at fixed positions.

23.1.1 Addressing and Bus Arbitration

In the CAN protocol, address information is defined in the identifier field of a message. The identifier indicates the contents of the message and its priority. The lower the binary value of the identifier, the higher is the priority of the message.

For bus arbitration, CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) is used. If bus node A attempts to transmit a message across the network, it first checks that the bus is in the idle state (“Carrier Sense”) i.e. no node is currently transmitting. If this is the case (and no other node wishes to start a transmission at the same moment), node A becomes the bus master and sends its message. All other nodes switch to receive mode during the first transmitted bit (Start-Of-Frame bit). After correct reception of the message (acknowledged by each node), each bus node checks the message identifier and stores the message, if required. Otherwise, the message is discarded.

If two or more bus nodes start their transmission at the same time (“Multiple Access”), bus collision of the messages is avoided by bit-wise arbitration (“Collision Detection / Non-Destructive Arbitration” together with the “Wired-AND” mechanism, dominant bits override recessive bits). Each node that sends also reads back the bus level. When a recessive bit is sent but a dominant one is read back, bus arbitration is lost and the transmitting node switches to receive mode. This condition occurs for example when the message identifier of a competing node has a lower binary value and therefore sends a

Controller Area Network Controller (MultiCAN+)

message with a higher priority. In this way, the bus node with the highest priority message wins arbitration without losing time by having to repeat the message. Other nodes that lost arbitration will automatically try to repeat their transmission once the bus returns to idle state. Therefore, the same identifier can be sent in a Data Frame only by one node in the system. There must not be more than one node programmed to send Data Frames with the same identifier.

Standard message identifier has a length of 11 bits. CAN specification 2.0B extends the message identifier lengths to 29 bits, i.e. the extended identifier.

23.1.2 CAN Frame Formats

Four different data frame formats are supported which differ in the length of the Arbitration Field and Control Field:

- Classical CAN Base format: 11-bit long identifier, constant bit rate
- Classical CAN Extended format: 29-bit long identifier, constant bit rate
- CAN FD Base format: 11-bit long identifier, dual bit rate
- CAN FD Extended format: 29-bit long identifier, dual bit rate

In addition for Classical CAN remote frames exist, for 11-bit and 29bit identifiers.

23.1.3 CAN Frame Types

There are three types of CAN frames:

- Data Frames
- Remote Frames
- Error Frames

A Data Frame contains a Data Field of 0 to 8 bytes in length. A Remote Frame contains no Data Field and is typically generated as a request for data (e.g. from a sensor). Data and Remote Frames can use an 11-bit “Standard” identifier or a 29-bit “Extended” identifier. An Error Frame can be generated by any node that detects a CAN bus error.

23.1.3.1 Data Frames

There are four types of Data Frames defined (see [Figure 23-1](#)):

- Standard Data Frame Classical CAN Format
- Extended Data Frame Classical CAN Format
- Standard Data Frame CAN FD Format
- Extended Data Frame CAN FD Format

11-bit Data Frame (CAN Format)

A Data Frame begins with the Start-Of-Frame bit (SOF = dominant level) for hard synchronization of all nodes. The SOF is followed by the Arbitration Field consisting of 12 bits, the 11-bit identifier (reflecting the contents and priority of the message), and the

Controller Area Network Controller (MultiCAN+)

RTR (Remote Transmission Request for Classical CAN) bit. With RTR at dominant level, the frame is marked as Data Frame. With RTR at recessive level, the frame is defined as a Remote Frame.

The next field is the Control Field consisting of 6 bits. The first bit of this field is the IDE (Identifier Extension) bit and is at dominant level for the Standard Data Frame. The following bit is reserved and defined as a dominant bit. The remaining 4 bits of the Control Field are the Data Length Code (DLC) that specifies the number of bytes in the Data Field. The Data Field can be 0 to 8 bytes wide. The Cyclic Redundancy (CRC) Field that follows the data bytes is used to detect possible transmission errors. It consists of a 15-bit CRC sequence completed by a recessive CRC delimiter bit.

The final field is the Acknowledge Field. During the ACK Slot, the transmitting node sends out a recessive bit. Any node that has received an error free frame acknowledges the correct reception of the frame by sending back a dominant bit, regardless of whether or not the node is configured to accept that specific message. This behavior assigns the CAN protocol to the “in-bit-response” group of protocols. The recessive ACK delimiter bit, which must not be overwritten by a dominant bit, completes the Acknowledge Field.

Seven recessive End-of-Frame (EOF) bits finish the Data Frame. Between any two consecutive frames, the bus must remain in the recessive state for at least 3 bit times (called Inter Frame Space). If after the Inter Frame Space, no other nodes attempt to transmit the bus remains in idle state with a recessive level.

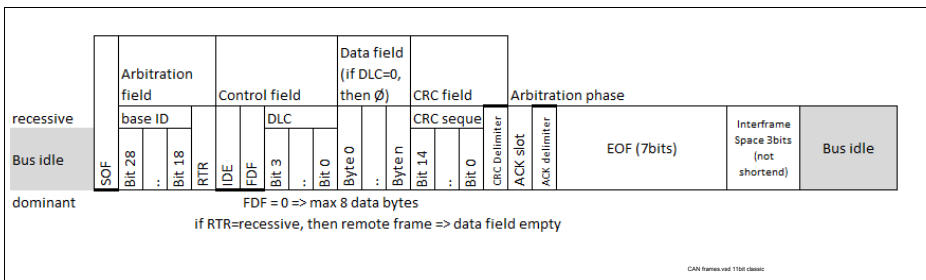

Figure 23-1 Classical 11bit ID CAN Data Frame

Extended Data Frame (Classical CAN Format)

In the Extended CAN Data Frame, the message identifier of the standard frame has been extended to 29-bit. A split of the extended identifier into two parts, an 11-bit least significant section (as in classical CAN frame) and an 18-bit most significant section, ensures that the Identifier Extension bit (IDE) can remain at the same bit position in both standard and extended frames.

In the Extended CAN Data Frame, the SOF bit is followed by the 32-bit Arbitration Field. The first 11 bits are the least significant bits of the 29-bit Identifier (“Base-ID”). These 11 bits are followed by the recessive Substitute Remote Request (SRR) bit. The SRR is

Controller Area Network Controller (MultiCAN+)

further followed by the recessive IDE bit, which indicates the frame to be an Extended CAN frame. If arbitration remains unresolved after transmission of the first 11 bits of the identifier, and if one of the nodes involved in arbitration is sending a classical CAN frame, then the CAN frame will win arbitration due to the assertion of its dominant IDE bit. Therefore, the SRR bit in an Extended CAN frame is recessive to allow the assertion of a dominant RTR bit by a node that is sending a CAN Remote Frame. The SRR and IDE bits are followed by the remaining 18 bits of the extended identifier and the RTR bit. Control field and frame termination is identical to the Classical Data Frame.

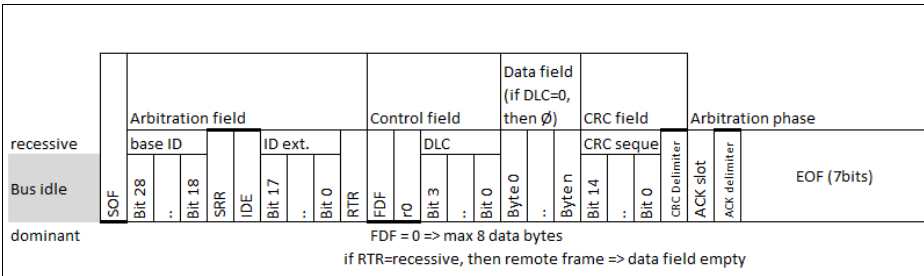

Figure 23-2 Classical 29 bit ID CAN Data Frame

Standard and Extended Data Frame (CAN FD Format)

Data frames for CAN FD with 11bit identifier are shown in [Figure 23-3](#).

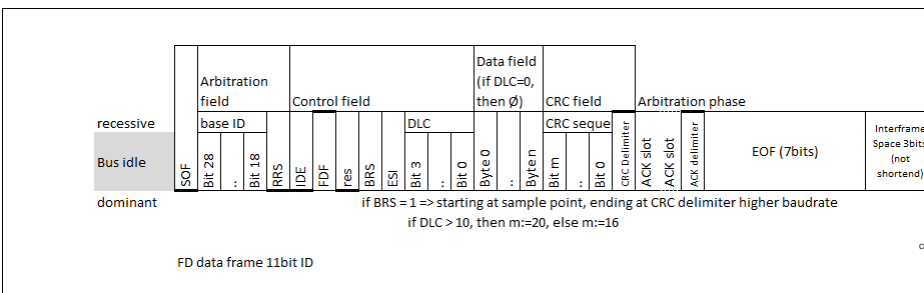

Figure 23-3 CAN FD 11bit ID Data Frames

Extended data frames for CAN FD are shown in [Figure 23-4](#).

Controller Area Network Controller (MultiCAN+)

Figure 23-4 CAN FD 29bit ID Data Frames

The difference between Standard / Extended Data Frames in CAN and CAN FD format are highlighted below:

1. In the Arbitration Field:
 - a) CAN Format Frames contain the RTR bit, where in CAN FD Format it is replaced with the dominant r1(reserved) bit.
 - b) The reserved r0, r1 (bits) are sent dominant. Receivers accept dominant and recessive bits.
2. In the Control Field:
 - a) CAN FD Format Frames consists of the additional (FDF) CAN FD format bit, (BRS) bit rate switch bit and (ESI) error state indicator bit.
 - b) CAN FD format (FDF) bit comes after the IDE bit for frames with 11-bit identifier and it comes after the r1 (reserved) bit with 29-bit identifier. FDF is the new name for the previous r0 bit.
 - c) Bit Rate Switch (BRS) bit switches the bit rate from standard bit rate of Arbitration Phase to preconfigured bit rate of the Data Phase when the bit is transmitted recessive. The bit rate is not switched when BRS bit is transmitted dominant.
 - d) Error State Indicator (ESI) bit is transmitted dominant by error active nodes and recessive by error passive nodes.
 - e) Data Length Code (DLC) bits indicates the number of bytes in the Data Field.
3. In the CRC Field:
 - a) CRC sequence bits for CAN FD uses CRC_17 for data field up to sixteen bytes long and CRC_21 for data field longer than sixteen bytes. CRC calculation consists of the SOF, Arbitration Field, Control Field and (if present) Data field, supplemented with nCRC bits of '0'.
 Stuff-bits are included in CRC calculation. All CRC sequences (CRC_15, 17, 21) are calculated for all nodes, where the node that wins the arbitration send the CRC sequence selected by values of the FDF bit and DLC. Receivers only consider the selected CRC polynomial to check for CRC error
 - b) CRC Delimiter for CAN FD consists of one or two recessive bits that has the function of switching the Data phase to Arbitration phase when the sample point reaches the first bit of the CRC Delimiter.
 Transmitter sends only one recessive bit as CRC delimiter, but accepts two

Controller Area Network Controller (MultiCAN+)

recessive bits before the edge from recessive to dominant of the Acknowledge slot. Receiver sends Acknowledge bit after the first CRC Delimiter.

- c) Due to a weakness of the CRC in a certain situation, and additional checksum is needed. For example a software checksum inside the last data byte. This is a weakness in the standard and not of the module. Therefore with DIS2015 the CRC field of CAN FD will be changed.
4. In the ACK Field:
 - a) For ACK slot, CAN FD nodes accept a two bit long dominant phase of overlapping ACK bits as a valid ACK, to compensate for phase shifts between Receivers.

23.1.3.2 Remote Frames

Normally, data transmission is performed on an autonomous basis with the data source node (e.g. a sensor) sending out a Data Frame. It is also possible, however, for a destination node (or nodes) to request the data from the source. For this purpose, the destination node sends a Remote Frame with an identifier that matches the identifier of the required Data Frame. The appropriate data source node will then send a Data Frame as a response to this remote request.

There are 2 differences between a Remote Frame and a Data Frame.

- The RTR bit is in the recessive state in a Remote Frame.
- There is no Data Field in a Remote Frame.

If a Data Frame and a Remote Frame with the same identifier are transmitted at the same time, the Data Frame wins arbitration due to the dominant RTR bit following the identifier. In this way, the node that transmitted the Remote Frame receives the requested data immediately.

Remote frames are only defined in Classical CAN format. Remote frames and the corresponding RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e. FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).

23.1.3.3 Error Frames

An Error Frame is generated by any node that detects a bus error. An Error Frame consists of two fields, an Error Flag field followed by an Error Delimiter field. The Error Delimiter Field consists of 8 recessive bits and allows the bus nodes to restart bus communications after an error. There are, however, two forms of Error Flag fields. The form of the Error Flag field depends on the error status of the node that detects the error.

When an error-active node detects a bus error, the node generates an Error Frame with an active-error flag. The error-active flag is composed of six consecutive dominant bits that actively violate the bit-stuffing rule. All other stations recognize a bit-stuffing error and generate Error Frames themselves. The resulting Error Flag field on the CAN bus

Controller Area Network Controller (MultiCAN+)

therefore consists of six to twelve consecutive dominant bits (generated by one or more nodes). The Error Delimiter field completes the Error Frame. After completion of the Error Frame, bus activity returns to normal and the interrupted node attempts to re-send the aborted message.

If an error-passive node detects a bus error, the node transmits an error-passive flag followed, again, by the Error Delimiter field. The error-passive flag consists of six consecutive recessive bits, and therefore the Error Frame (for an error-passive node) consists of 14 recessive bits (i.e. no dominant bits). Therefore, the transmission of an Error Frame by an error-passive node will not affect any other node on the network, unless the bus error is detected by the node that is actually transmitting (i.e. the bus master). If the bus master node generates an error-passive flag, this may cause other nodes to generate Error Frames due to the resulting bit-stuffing violation. After transmission of an Error Frame an error-passive node must wait for 6 consecutive recessive bits on the bus before attempting to rejoin bus communications.

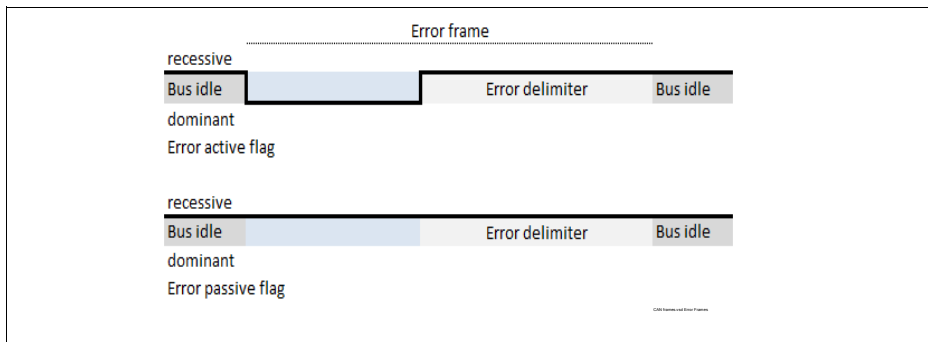

Figure 23-5 CAN Error Frames

A CAN FD node operating in the Data-Phase will switch back to the Arbitration Phase when starting an Error Flag.

23.1.3.4 Overload Frame

The Overload Frame consists of two bit fields which are Overload Flag and Overload Delimiter.

Overload conditions

If a CAN FD node samples a dominant bit at the eight bit (last bit) of an Error Delimiter or Overload Delimiter, or if a CAN FD Receiver samples a dominant bit at the last bit of End of Frame, it will start transmitting an Overload Frame (not an Error Frame). The Error Counters will not be incremented.

Controller Area Network Controller (MultiCAN+)
23.1.4 The Nominal Bit Time

One bit cell (this means one high or low pulse of the NRZ code) is composed by four segments. Each segment is an integer multiple of Time Quanta t_Q . The Time Quanta is the smallest discrete timing resolution used by a CAN node. The nominal bit time definition with its segments is shown in [Figure 23-6](#).

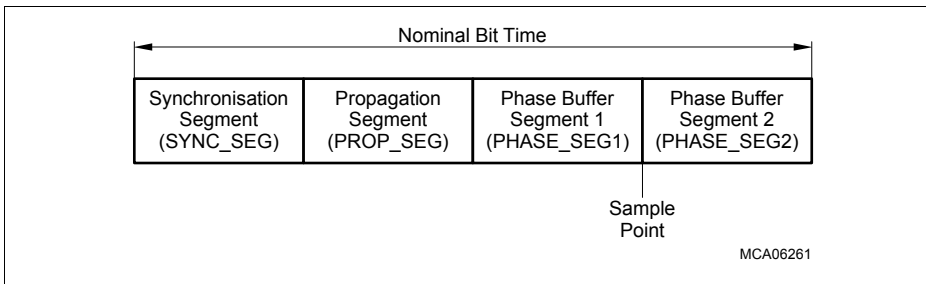

Figure 23-6 Partition of Nominal Bit Time

The Synchronization Segment (SYNC_SEG) is used to synchronize the various bus nodes. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment. The length of this segment is always $1 t_Q$.

The Propagation Segment (PROP_SEG) is used to compensate for signal delays across the network. These delays are caused by signal propagation delay on the bus line and through the electronic interface circuits of the bus nodes.

The Phase Segments 1 and 2 (PHASE_SEG1, PHASE_SEG2) are used to compensate for edge phase errors. These segments can be lengthened or shortened by re-synchronization. PHASE_SEG2 is reserved for calculation of the subsequent bit level, and is $\geq 2 t_Q$. At the sample point, the bus level is read and interpreted as the value of the bit cell. It occurs at the end of PHASE_SEG1.

The total number of t_Q in a bit time is between 8 and 25.

As a result of re-synchronization, PHASE_SEG1 can be lengthened or PHASE_SEG2 can be shortened. The amount of lengthening or shortening the phase buffer segments has an upper limit given by the re-synchronization jump width. The re-synchronization jump width may be between 1 and $4 t_Q$, but it may not be longer than PHASE_SEG1.

23.1.4.1 CAN FD bit timing

The first part of a CAN FD frame until the BRS bit is transmitted with the Nominal Bit Rate. The bit rate is switched if the BRS bit is recessive, until the CRC Delimiter is reached or until the CAN FD controller sees an error condition that results in the starting

Controller Area Network Controller (MultiCAN+)

of an Error Frame. CAN FD Error Frames, as well as ACK Field, End of Frame, Overload Frames and all in CAN Format are transmitted with the Nominal Bit Rate

Synchronization Rules

Hard synchronization and Resynchronization are the two forms of synchronization. They obey the following rules,

- Hard synchronization is performed whenever there is a recessive to dominant edge during Bus Idle, Suspend Transmission, and second or third bits of Intermission. Hard synchronization is also performed at the recessive to the dominant edge from FDF to r0 in CAN FD format frames
- A transmitter shall not resynchronize while it transmits in the CAN FD data phase

23.1.5 Error Detection and Error Handling

The CAN protocol has sophisticated error detection mechanisms. The following errors can be detected:

- **Cyclic Redundancy Check (CRC) Error**

With the CRC, the transmitter calculates special check bits for the bit sequence from the start of a frame until the end of the Data Field. This CRC sequence is transmitted in the CRC Field. The receiving node also calculates the CRC sequence using the same formula, and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an Error Frame is generated. The message is repeated.

- **Acknowledge Error**

In the Acknowledge Field of a message, the transmitter checks whether a dominant bit is read during the Acknowledge Slot (that is sent out as a recessive bit). If not, no other node has received the frame correctly, an Acknowledge Error has occurred, and the message must be repeated. No Error Frame is generated.

- **Form Error**

If a transmitter detects a dominant bit in one of the four segments End of Frame, Interframe Space, Acknowledge Delimiter, or CRC Delimiter, a Form Error has occurred, and an Error Frame is generated. The message is repeated.

- **Bit Error**

A Bit Error occurs if a) a transmitter sends a dominant bit and detects a recessive bit or b) if the transmitter sends a recessive bit and detects a dominant bit when monitoring the actual bus level and comparing it to the just transmitted bit. In case b), no error occurs during the Arbitration Field (ID, RTR, IDE) and the Acknowledge Slot.

- **Stuff Error**

If between Start of Frame and CRC Delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an Error Frame is generated. The message is repeated.

Controller Area Network Controller (MultiCAN+)

Detected errors are made public to all other nodes via Error Frames (except Acknowledge Errors). The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states (error-active, error-passive or bus-off) according to the value of the internal error counters. The error-active state is the usual state where the bus node can transmit messages and active-error frames (made of dominant bits) without any restrictions. In the error-passive state, messages and passive-error frames (made of recessive bits) may be transmitted. The bus-off state makes it temporarily impossible for the node to participate in the bus communication. During this state, messages can be neither received nor transmitted.

Basic CAN, Full CAN

There is one more CAN characteristic that is related to the interface of a CAN module (controller) and the host CPU: Basic-CAN and Full-CAN functionality.

In Basic-CAN devices, only basic functions of the protocol are implemented in hardware, such as the generation and the check of the bit stream. The decision, whether a received message has to be stored or not (acceptance filtering), and the complete message management must be done by software.

Full-CAN devices (this is the case for the MultiCAN+ controller as implemented in TC26x B-Step) manage the whole bus protocol in hardware, including the acceptance filtering and message management. Full-CAN devices contain message objects that handle autonomously the identifier, the data, the direction (receive or transmit) and the information of CAN operation. During the initialization of the device, the host CPU determines which messages are to be sent and which are to be received. The host CPU is informed by interrupt if the identifier of a received message matches with one of the programmed (receive-) message objects. The CPU load of Full-CAN devices is greatly reduced. When using Full-CAN devices, high baud rates and high bus loads with many messages can be handled.

Controller Area Network Controller (MultiCAN+)**23.2 Overview**

The MultiCAN+ module provides a communication interface which is fully compliant with CAN specification V2.0B (active) and to CAN FD ISO11898-1 DIS version 2014, providing communications at up to 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode and/or CAN FD until 5 MBaud dataspeed (dependent on frequency and nodes)).

The MultiCAN+ module for the TC26x B-Step consists of module (i.e MultiCAN with 5 CAN nodes), representing serial communication interfaces. Each CAN node communicates over two pins (TXD and RXD). The device ports which are used for TXD and RXD may be individually configured within the PORTS block. Several port configuration options are available to provide application-specific flexibility.

The MultiCAN+ module contains 5 independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

All CAN nodes share a common set of 256 message objects. Each message object can be individually allocated to one of the CAN nodes. Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}) and are programmable up to a data rate of 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode or up to 5 MBaud in CAN FD mode. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

23.2.1 Features List

The MultiCAN+ module provides the following features:

- Compliant with ISO 11898 and SAE J 1939
- CAN functionality according to CAN specification V2.0 B active
- Supports CAN with Flexible Data-Rate Specification CAN FD DIS version ISO11898-1 2014 with max. 64 data bytes¹⁾
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/s when operating in Classical CAN mode per ISO 11898-1:2003(E)

1) At time of release of this document ISO 11898-1 (Classical CAN and CAN FD) is in working draft mode, an errata sheet will document differences when ISO 11898-1 has been finalized.

Controller Area Network Controller (MultiCAN+)

- Supports up to 5MBaud, when operating in CAN FD mode.
- Support for asynchronous clock sources for baud rate generation by providing separate frequency domain and input:
 - System frequency clock f_{CLC}
 - Low-jitter E-Ray PLL clock
 - Direct oscillator clock (e.g. from ceramic resonator)
- Frequency jitter calibration based on external CAN messages during runtime
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of 256 message objects can be individually
 - Allocated (assigned) to any CAN node
 - Configured as transmit or receive object
 - Setup to handle frames with 11-bit or 29-bit identifier
 - Identified by a timestamp via a frame counter
 - Configured to remote monitoring mode
- Advanced Acceptance Filtering
 - Each message object provides an individual acceptance mask to filter incoming frames
 - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
 - Message objects can be grouped into different priority classes for transmission and reception
 - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or on its order in the list
- Advanced CAN node features
 - Analyzer Mode supports monitoring of bus traffic without actively participating on the bus
 - Internal Loop-Back Mode is available for test purposes
 - An internal timer is provided that can detect a receive or remote frame time-out; the message objects to be supervised are selectable
 - Data transmission from a node can be stopped without affecting reception
 - Programmable minimum delay between two consecutive messages
- Advanced message object functionality
 - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
 - Message objects can be linked to form a gateway that automatically transfers frames between 2 different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined
- Advanced data management
 - The message objects are organized in double-chained lists

Controller Area Network Controller (MultiCAN+)

- List reorganizations can be performed at any time, even during full operation of the CAN nodes
- A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list
- Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
- Advanced interrupt handling
 - Message interrupts, node interrupts can be generated
 - Interrupt requests can be routed individually to one of the 16 interrupt output lines
 - Message post-processing notifications can be combined flexibly into a dedicated register field of 256 notification bits
- Module internal SRAM with ECC protection
- Pretended Networking Operation for energy saving purposes
 - If direct oscillator clock is selected for baud rate generation, CPU clock can be slowed down or CPU Idle Mode can be entered
 - Three selectable message object can be transmitted periodically without CPU involvement, triggered by a CAN node timer or by STM or GTM modules.
 - Message objects are received without CPU involvement and can wake up the system via receive interrupt

AUTOSAR optimized and backward compatible with existing MultiCAN software

Controller Area Network Controller (MultiCAN+)**23.3 CAN Flexible Data-Rate (CAN FD)**

CAN Flexible Data-Rate (CAN FD) builds on existing CAN (ISO 11898-1) specifications allowing higher data rates and larger payloads. This is achieved with a new CAN FD frame format different from existing Classical CAN format, both frame formats can coexist within the same network. Classical CAN nodes and CAN FD nodes can communicate with each other as long as CAN FD frame format is not being used.

CAN FD functionality is available on all nodes of MultiCAN+ module.

Feature Lists

- Supports CAN Flexible Data-Rate Specification V1.0

23.3.1 Transmitter Delay Compensation

The CAN protocol requires that transmitted data be compared with the received data from its local CAN transceiver to determine if there are any transmit errors. In the case of CAN FD data phase when a faster bit rate is used, resulting in shorter bit timing, the delay caused by the local transmitting loop delay will be greater than TSEG1 (time segment before sample point) causing a bit error to be detected. The transmitter loop delay limits the bit rate in the data phase of a CAN FD frame.

Thus to overcome this limitation, a Transmitter Delay Compensation feature is introduced where a new sample point (Secondary Sample Point) shall be used by transmitters in the data phase of a CAN FD frame, the sample point which does not account for the transceiver loop delay is ignored.

The Secondary Sample Point consists of the transmitter loop delay and a configurable Transmitter Delay Compensation offset (NTDCRx.TDCO). (i.e The secondary sample point is reached by counting the total delay consisting of the compensation offset and measured transceiver loop delay.)

The Transmitter loop delay is measured in each transmitted frame at the edge from the FDF bit to the following bit r0, between the edge of the transmitted bit and the edge of the received bit. (see [Figure 23-7](#)) The count down is started with the begin of the bit time (transmit point).

Controller Area Network Controller (MultiCAN+)

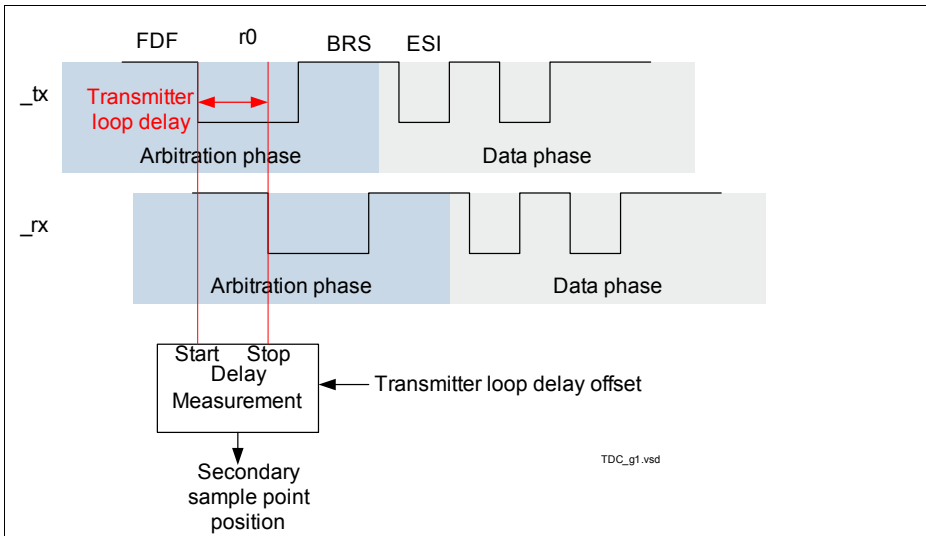

Figure 23-7 Transmitter Delay Loop measurement

Transmitter Delay compensation offset (NTDCRx.TDCO) is used to adjust the secondary sample point inside the bit time (e.g half of the bit time in the data phase). Finally the resulting Secondary Sample Point is rounded down to the next integer number of time quanta t_q and placed after the end of the transmitted bit. If a bit error is detected at the Secondary Sample Point, the transmitter will react to this bit error at the next sample point.

(i.e When a bit error is detected by the Transmitter Delay compensation unit, the error is reported at the next sample point and becomes visible (in error active case) at the transmit point that follows the regular sample point.)

Secondary Sample Point is used in the Data Phase of CAN FD and Sample Point is used in the Arbitration Phase of CAN FD. The Transmitter Delay compensation which determines the secondary sample point is able to handle a total delay (measured transceiver loop delay + compensation offset) which goes beyond the current bit time.

MultiCAN+ module allows the secondary sample point to be placed anywhere within the current and next 3 bit times (i.e covers up to 4 data phase bit rate). The maximum delay which can be compensated by MultiCAN+ delay compensation during the data phase is 4 bit times.

Note:

9. CAN receive input line contributes to the measured loop delay.
10. Measurement granularity of the Transmitter Delay compensation is the fast time quantum given by the fast baud rate prescaler.

Controller Area Network Controller (MultiCAN+)

23.4 MultiCAN+ Kernel Functional Description

This section describes the functionality of the MultiCAN+ module.

23.4.1 Module Structure

Figure 23-8 shows the general structure of the MultiCAN+ module.

Figure 23-8 MultiCAN+ Block Diagram

CAN Nodes

Each CAN node consists of several sub-units.

- Bitstream Processor**
 The Bitstream Processor performs data, remote, error and overload frame processing according to the ISO 11898 standard. This includes conversion between the serial data stream and the input/output registers.
- Bit Timing Unit**
 The Bit Timing Unit determines the length of a bit time and the location of the sample point according to the user settings, taking into account propagation delays and phase shift errors. The Bit Timing Unit also performs resynchronization.

Controller Area Network Controller (MultiCAN+)

- **Error Handling Unit**

The Error Handling Unit manages the receive and transmit error counter. Depending on the contents of both counters, the CAN node is set into an error-active, error passive or bus-off state.

- **Node Control Unit**

The Node Control Unit coordinates the operation of the CAN node:

- Enable/disable CAN transfer of the node
- Enable/disable and generate node-specific events that lead to an interrupt request (CAN bus errors, successful frame transfers etc.)
- Administration of the frame counter and of the node timers

- **Interrupt Control Unit**

The Interrupt Control Unit in the CAN node controls the interrupt generation for the different conditions that can occur in the CAN node.

Message Controller

The Message Controller handles the exchange of CAN frames between the CAN nodes and the message objects that are stored in the Message RAM. The Message Controller performs several functions:

- Receive acceptance filtering to determine the correct message object for storing of a received CAN frame
- Transmit acceptance filtering to determine the message object to be transmitted first, individually for each CAN node
- Transfer contents between message objects and the CAN nodes, taking into account the status/control bits of the message objects
- Handling of the FIFO buffering and gateway functionality
- Aggregation of message-pending notification bits

List Controller

The List Controller performs all operations that lead to a modification of the double-chained message object lists. Only the list controller is allowed to modify the list structure. The allocation/deallocation or reallocation of a message object can be requested via a user command interface (command panel). The list controller state machine then performs the requested command autonomously.

Interrupt Control

The general interrupt structure is shown in [Figure 23-9](#). The interrupt event can trigger the interrupt generation. The interrupt pulse is generated independently of the interrupt flag in the interrupt status register. The interrupt flag can be reset by software by writing a 0 to it.

Controller Area Network Controller (MultiCAN+)

If enabled by the related interrupt enable bit in the interrupt enable register, an interrupt pulse can be generated at one of the 16 interrupt output lines INT_0m of the MultiCAN+ module. If more than one interrupt source is connected to the same interrupt node pointer (in the interrupt node pointer register), the requests are combined to one common line.

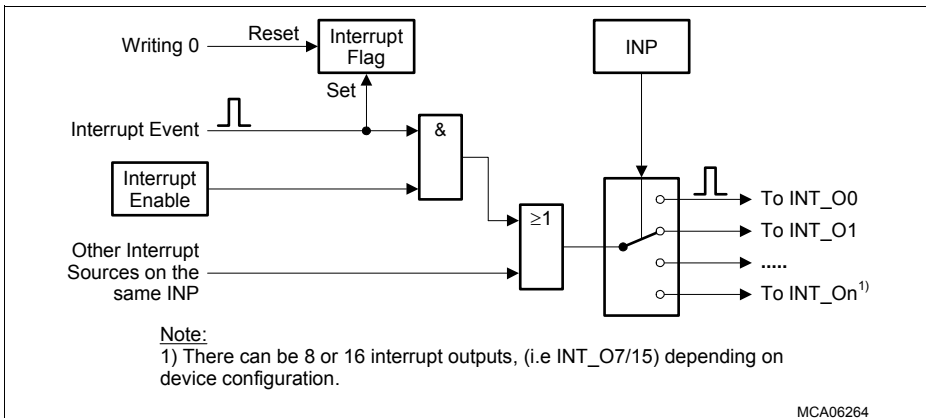

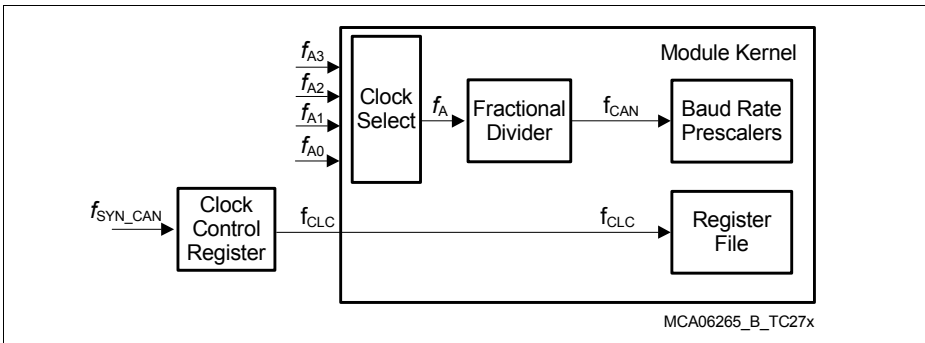

Figure 23-9 General Interrupt Structure

23.4.2 Clock Control

The CAN module timer clock f_{CAN} of the functional blocks of the MultiCAN+ module is derived from the asynchronous, higher precision clock f_A or from the synchronous clock source. The Fractional Divider is used to generate f_{CAN} used for bit timing calculation, The frequency of f_{CAN} is identical for all CAN nodes. The register file operate with the module control clock f_{CLC} . See also **“MultiCAN+ Clock Generation” on Page 23-20**.

The output clock f_{CAN} of the Fractional Divider is based on the clock f_A , but only every nth clock pulse is taken. The suspend signal (coming as acknowledge from the MultiCAN+ module in response to a OCDS suspend request) freezes or resets the Fractional Divider. The clock select and fractional divider are reset together with the CAN module kernel when the module kernel reset is triggered.

Controller Area Network Controller (MultiCAN+)

Figure 23-10 MultiCAN+ Clock Generation

The $f_{\text{SYN_CAN}}$ is identical to f_{SPB} . f_{Ai} is the asynchronous clock input.

Table 23-2 indicates the minimum operating frequencies in MHz for f_{CLC} that are required for a baud rate of 1 Mbit/s for the active CAN nodes. If a lower baud rate is desired, the values can be scaled linearly (e.g. for a maximum of 500 kbit/s, 50% of the indicated value are required).

For CAN FD operations, please refer to **Table 23-3** for the minimum operating frequency in MHz for f_{CLC} that are required.

The values imply that the CPU (or DMA) executes maximum accesses to the MultiCAN+ module. The values may contain rounding effects.

Controller Area Network Controller (MultiCAN+)
Table 23-2 Minimum Operating Frequencies¹⁾²⁾ [MHz]

Number of allocated message objects MO ³⁾ ,	Number of Active CAN Nodes				
	1	2	3	4	5
16 MO	12	19	26	33	40
32 MO	15	23	30	37	44
64 MO	21	28	37	46	53
128 MO	40	45	50	55	61
256 MO	72	77	82	88	93

1) In the case of 15 time quanta, the minimum operating frequency required is 15MHz.

2) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

3) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

Controller Area Network Controller (MultiCAN+)
Table 23-3 Minimum Operating Frequencies for CAN FD [MHz]

No. of allocated MO ¹⁾	No. of Active CAN Nodes	Acceleration Factor ²⁾³⁾				
		1	2	3	4	5
16 MO	1	20	40	60	80	100
	2	39	48	72	96	-
	3	58	58	84	-	-
	4	77	77	96	-	-
	5	96	96	-	-	-

	5	96	96	-	-	-
64 MO	1	27	40	60	80	100
	2	39	51	72	96	-
	3	58	65	84	-	-
	4	77	79	96	-	-
	5	96	96	-	-	-
128 MO	1	47	65	75	81	100
	2	57	79	91	99	-
	3	67	93	-	-	-
	4	77	-	-	-	-
	5	96	-	-	-	-

1) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See [Section 23.4.12.5](#)

2) Acceleration Factor is the ratio of the Data Bit Rate to Nominal Bit Rate. The Nominal Bit Rate is taken as 1Mbit/s in table above. As an example, an acceleration factor(A.F) of 4 refers to a Data Bit Rate of 4Mbit/s and Nominal Bit Rate is 1Mbit/s.

Only the node operating with the highest baudrate need to be considered when several nodes operate at different acceleration factor. e.g When 1node operate at A.F of 3 and 3 nodes operate at A.F of 2, the minimum operating frequency required is determined by the node operate at A.F of 3.

3) Please note that other combinations of acceleration factor are possible, values here are for illustrative purposes only. Values with dash '-' indicates required f_{CLC} exceeding the maximum frequency capability of product SCU typically at 100MHz.

Controller Area Network Controller (MultiCAN+)

The baud rate generation of the MultiCAN+ being based on f_A , this frequency has to be chosen carefully to allow correct CAN bit timing. The required value of f_A is given by an integer multiple (n) of the CAN baud rate multiplied by the number of time quanta per CAN bit time. For example, to reach 1 Mbit/s with 20 tq per bit time, possible values of f_A are given by formula $[n \times 20]$ MHz, with n being an integer value, starting at 1.

In order to minimize jitter, it is not recommended to use the fractional divider mode for high baud rates.

Additionally, for correct operation of the MultiCAN, the following conditions have to be fulfilled,

$$\text{Baudrate}_{\max} = [(8 \times T_{\text{CAN}}) + (8 \times T_{\text{CLC}}) + (4 \times \text{No. of active CAN nodes} \times T_{\text{CLC}})] \quad (23.1)$$

also

$$\text{NBTR.SJW} < \text{NBTR.TSEG1}$$

As an example, when $f_{\text{CLC}} = 10\text{MHz}$, $f_{\text{CAN}} = 20\text{MHz}$, No of active CAN nodes =2,

$$\text{Baudrate}_{\max} = [(8 \times 50\text{ns}) + (8 \times 100\text{ns}) + (4 \times 2 \times 100\text{ns})] = 2000\text{ns} = 500 \text{KBaud}$$

Table 23-4 below illustrates the minimum CAN module timer clock f_{CAN} and Module Control Clock f_{CLC} that's required to support a baudrate generation of 500KBaud. If a higher baudrate is desired, the values need to be calculated as per **Equation (23.1)**.

Table 23-4 Minimum Operating Frequencies [MHz] required for 500KBaud

No. of active CAN nodes	$f_{\text{CAN}} = f_{\text{CLC}}$ (MHz)	$f_{\text{CAN}} \neq f_{\text{CLC}}$ (MHz) ¹⁾

Table 23-4 Minimum Operating Frequencies [MHz] required for 500KBaud

4	16	16	16
		20	15
		24	15
		80	13

1) To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e. when frequency of f_{SPB} is reduced), f_{SYN_CAN} and f_{CLC} are switched from f_{SPB} to f_{CAN} when SCU register CCUCON.LPDIV>0.

23.4.3 Port Input Control

It is possible to select the input lines for the RXDCANx inputs for the CAN nodes. The selected input is connected to the CAN node and is also available to wake-up the system. More details are defined in [Section 23.7.5.2](#) on [Page 23-166](#).

23.4.4 OCDS Suspend

The OCDS suspend of MultiCAN+ is controlled with the **OCS** register. MultiCAN+ module provides the following Suspend Modes:

Hard Suspend Mode (VERSION: RW ACCESS NEEDS KERNEL CLOCKING) (All actions are immediately stopped)

The Hard Suspend mode is not to be used in normal CAN applications, this mode is meant for debugging the peripheral IP within a controlled environment.

In Hard Suspend Mode, the MultiCAN+ module clocks f_{CLC} and f_{CAN} are switched off. Reading and writing of registers is possible but will enable the kernel clock for a few cycles. In this mode, there is a very high probability that the communication with other CAN devices is made impossible and that the CAN bus is blocked (e.g. if the suspended CAN module just sends a dominant level). A reset operation must be executed to leave Hard Suspend Mode.

Attention: Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a MultiCAN+ kernel reset might not be sufficient to bring the system into a defined state.

Soft Suspend Mode (The current action is finished)

In Soft Suspend Mode, the MultiCAN+ module clock f_{CLC} is kept running. Module functions are stopped automatically after internal actions have been finished before it enters the suspended state with **OCS.SUSSTA** set (for example, after a CAN frame has been sent out). Due to this behavior, the communication network is not blocked. All registers are accessible for read and write actions. As a result, the debugger can stop

Controller Area Network Controller (MultiCAN+)

the module actions and modify registers. These modifications are taken into account after the Suspend Mode is left. Soft Suspend mode does not influence the kernel clock. The Hard Suspend Mode can be enabled/disabled only for the complete MultiCAN+ module. The Soft Suspend Mode can be individually enabled for each CAN node.

The user has to be aware that the Soft Suspend Mode can corrupt the TTCAN timing values, because the counter clock can be disabled. In order to guarantee correct TTCAN behavior, a TTCAN node should not enter any Suspend Mode if the consistency of the timing data must be ensured.

Note: During suspend mode, kernel registers may be accessed only when the kernel clock is running.

23.4.5 OCDS Trigger Bus (OTGB) Interface

The MultiCAN Trigger Set is shown in [Table 23-5](#). Its output is on OTGB0 or OTGB1 controlled by the **OCS** register.

Table 23-5 TS16_CAN Trigger Set MultiCAN

Bits	Name	Description
[7:0]	MON	Message Object Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
[11:8]	NN	Node Number for transmit and receive direction. Only valid when TT or RT is active and FMI is inactive.
12	TT	Transmit Trigger. Active for one clock cycle when the transmit message is setup.
13	RT	Receive Trigger. Active for one clock cycle after End-of-Frame (EOF) processing for a receive message.
14	FMI	Foreign Message Indicator. The received message will not be copied to any message object. Only valid when RT is active.
15		Reserved

MCDS Trigger Setup

[Table 23-6](#) lists the qualification methods for TC16_CAN with MCDS. The methods are not exclusive and can be combined.

Controller Area Network Controller (MultiCAN+)

Table 23-6 TS16_CAN MCDS Trigger Setup

Qualification	Method
Transmit and/or receive messages	Positive edge sensitivity on TS16_CAN.TT and/or RT. Configured in the OTGM MCDS I/F.
No foreign messages.	MCDS data value condition $TS16_CAN < 4000_H$
Specific message object	MCDS masked data value comparison. $TS16_CAN \& 00FF_H ==$ message object number
Specific node	MCDS masked data value comparison. $TS16_CAN \& 0F00_H ==$ (node number) $<< 8$

Controller Area Network Controller (MultiCAN+)**23.4.6 CAN Node Control**

Each CAN node may be configured and run independently of the other CAN node. Each CAN node is equipped with its own node control logic to configure the global behavior and to provide status information.

Note: In the following descriptions, index “x” stands for the node number and index “n” represents the message object number.

Configuration Mode is activated when bit NCRx.CCE is set to 1. This mode allows CAN bit timing parameters and the error counter registers to be modified.

CAN Analyzer Mode

CAN Analyzer Mode is activated when bit NCRx.CALM is set to 1. In this operation mode, Data And Remote Frames are monitored without active participation in any CAN transfer (CAN transmit pin is held on recessive level). Incoming Remote Frames are stored in a corresponding transmit message object, while arriving data frames are saved in a matching receive message object.

In CAN Analyzer Mode, the entire configuration information of the received frame is stored in the corresponding message object, and can be evaluated by the CPU to determine their identifier, IDE bit information and data length code (ID and DLC optionally if the Remote Monitoring Mode is active, bit MOFCRn.RMM = 1). Incoming frames are not acknowledged, and no Error Frames are generated. If CAN Analyzer Mode is enabled, Remote Frames are not responded to by the corresponding Data Frame, and Data Frames cannot be transmitted by setting the transmit request bit MOSTATn.TXRQ. Receive interrupts are generated in CAN Analyzer Mode (if enabled) for all error free received frames.

The node-specific interrupt configuration is also defined by the Node Control Logic via the NCRx register bits TRIE, ALIE and LECIE:

- If control bit TRIE is set to 1, a transfer interrupt is generated when the NSRx register has been updated (after each successfully completed message transfer).
- If control bit ALIE is set to 1, an alert interrupt is generated when a “bus-off” condition has been recognized or the Error Warning Level has been exceeded or under-run. Additionally, list or object errors lead to this type of interrupt.
- If control bit LECIE is set to 1, a last error code interrupt is generated when an error code > 0 is written into bit field NSRx.LEC by hardware.

Setting bit TXDIS in register NCRx stops the transmit activity of this node without affecting reception; bit CANDIS disables the node completely.

The Node x Status Register NSRx provides an overview about the current state of the respective CAN node x, comprising information about CAN transfers, CAN node status, and error conditions.

Controller Area Network Controller (MultiCAN+)

The CAN frame counter can be used to check the transfer sequence of message objects or to obtain information about the instant a frame has been transmitted or received from the associated CAN bus. CAN frame counting is performed by a 16-bit counter, controlled by register NFCRx. Bit fields NFCRx.CFMOD and NFCRx.CFSEL determine the operation mode and the trigger event incrementing the frame counter.

23.4.6.1 Bit Timing Unit

According to the ISO 11898 standard, a CAN bit time is subdivided into different segments (**Figure 23-11**). Each segment consists of multiples of a time quantum t_q . The magnitude of t_q is adjusted by Node x Bit Timing Register bit fields NBTRx.BRP and NBTRx.DIV8, both controlling the baud rate prescaler (register NBTRx is described on **Page 23-105**). The baud rate prescaler is driven by the module timer clock f_{CAN} (generation and control of f_{CAN} is described on **Page 23-162**).

Figure 23-11 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows a phase synchronization between transmitter and receiver time base. The Synchronization Segment length is always one t_q . The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver on the CAN bus line and in the transceiver circuit. For a working collision detection mechanism, T_{Prop} must be two times the sum of all propagation delay quantities rounded up to a multiple of t_q . The phase buffer segments 1 and 2 (T_{b1} , T_{b2}) before and after the signal sample point are used to compensate for a mismatch between transmitter and receiver clock phases detected in the synchronization segment.

The maximum number of time quanta allowed for re-synchronization is defined by bit field NBTRx.SJW. The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter T_{Seg1} , which is defined by the value NBTRx.TSEG1. A minimum of 3 time quanta is demanded by the ISO standard. Parameter T_{Seg2} , which is defined by the value of NBTRx.TSEG2, covers the Phase Buffer Segment 2. A minimum of 2 time

Controller Area Network Controller (MultiCAN+)

quanta is demanded by the ISO standard. According to ISO standard, a CAN bit time, calculated as the sum of T_{Sync} , T_{Seg1} and T_{Seg2} , must not fall below 8 time quanta.

Calculation of the bit time:

$$\begin{aligned}
 t_q &= (\text{BRP} + 1) / f_{\text{CAN}} && \text{if DIV8} = 0 \\
 &= 8 \times (\text{BRP} + 1) / f_{\text{CAN}} && \text{if DIV8} = 1 \\
 T_{\text{Sync}} &= 1 \times t_q \\
 T_{\text{Seg1}} &= (\text{TSEG1} + 1) \times t_q && (\text{min. } 3 t_q) \\
 T_{\text{Seg2}} &= (\text{TSEG2} + 1) \times t_q && (\text{min. } 2 t_q) \\
 \text{bit time} &= T_{\text{Sync}} + T_{\text{Seg1}} + T_{\text{Seg2}} && (\text{min. } 8 t_q)
 \end{aligned}$$

To compensate phase shifts between clocks of different CAN controllers, the CAN controller must synchronize on any edge from the recessive to the dominant bus level. The hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the re-synchronization jump width T_{SJW} defines the maximum number of time quanta, a bit time may be shortened or lengthened by one re-synchronization. The value of SJW is defined by bit field NBTRx.SJW.

$$\begin{aligned}
 T_{\text{SJW}} &= (\text{SJW} + 1) \times t_q \\
 T_{\text{Seg1}} &\geq T_{\text{SJW}} + T_{\text{prop}} \\
 T_{\text{Seg2}} &\geq T_{\text{SJW}}
 \end{aligned}$$

The maximum relative tolerance for f_{CAN} in classical CAN format and CAN FD format depends on the Phase Buffer Segments, re-synchronization jump width and the bit time.

Classical CAN Format

$$\begin{aligned}
 df_{\text{CAN}} &\leq \min(T_{b1}, T_{b2}) / [2 \times (13 \times \text{bit time} - T_{b2})] && \text{AND} \\
 df_{\text{CAN}} &\leq T_{\text{SJW}} / 20 \times \text{bit time}
 \end{aligned}$$

CAN FD Format

$$\begin{aligned}
 df_{\text{CAN}} &\leq \min(T_{b1(N)}, T_{b2(N)}) / [2 \times (13 \times \text{bit time}_{(N)} - T_{b2(N)})] && \text{AND} \\
 df_{\text{CAN}} &\leq T_{\text{SJW}(N)} / 20 \times \text{bit time}_{(N)} && \text{AND} \\
 df_{\text{CAN}} &\leq T_{\text{SJW}(D)} / 20 \times \text{bit time}_{(D)} && \text{AND}
 \end{aligned}$$

Controller Area Network Controller (MultiCAN+)

$$df_{CAN} \leq \min(T_{b1(D)}, T_{b2(D)}) / (2 \times [(6 \times \text{bit time}_{(D)} - T_{b2(D)}) \times BRP_{(D)} / BRP_{(N)} + (7 \times \text{bit time}_{(N)})]) \quad \text{AND}$$

$$df_{CAN} \leq [T_{S,JW(D)} - (BRP_{(N)} / BRP_{(D)} - 1)] / (2 \times [(2 \times \text{bit time}_{(N)} - T_{b2(N)}) \times BRP_{(N)} / BRP_{(D)} + T_{b2(D)} + 4 \times \text{bit time}_{(D)}])$$

A valid CAN bit timing must be written to the CAN Node Bit Timing Register NBTR and Fast Node Bit Timing Register before resetting the INIT bit in the Node Control Register, i.e. before enabling the operation of the CAN node.

The Node Bit Timing Register may be written only if bit CCE (Configuration Change Enable) is set in the corresponding Node Control Register.

23.4.6.2 Bitstream Processor

Based on the message objects in the message buffer, the Bitstream Processor generates the remote and Data Frames to be transmitted via the CAN bus. It controls the CRC generator and adds the checksum information to the new remote or Data Frame. After including the SOF bit and the EOF field, the Bitstream Processor starts the CAN bus arbitration procedure and continues with the frame transmission when the bus was found in idle state. While the data transmission is running, the Bitstream Processor continuously monitors the I/O line. If (outside the CAN bus arbitration phase or the acknowledge slot) a mismatch is detected between the voltage level on the I/O line and the logic state of the bit currently sent out by the transmit shift register, a CAN LEC error interrupt request is generated, and the error code is indicated by the Node x Status Register bit field NSRx.LEC.

The data consistency of an incoming frame is verified by checking the associated CRC field. When an error has been detected, a CAN LEC error interrupt request is generated and the associated error code is presented in the Node x Status Register NSRx. Furthermore, an Error Frame is generated and transmitted on the CAN bus. After decomposing a faultless frame into identifier and data portion, the received information is transferred to the message buffer executing remote and Data Frame handling, interrupt generation and status processing.

23.4.6.3 Error Handling Unit

The Error Handling Unit of a CAN node x is responsible for the fault confinement of the CAN device. Its two counters, the Receive Error Counter REC and the Transmit Error Counter TEC (bit fields of the Node x Error Counter Register NECNTx, see [Page 23-112](#)) are incremented and decremented by commands from the Bitstream Processor. If the Bitstream Processor itself detects an error while a transmit operation is running, the Transmit Error Counter is incremented by 8. An increment of 1 is used when the error condition was reported by an external CAN node via an Error Frame generation. For error analysis, the transfer direction of the disturbed message and the

Controller Area Network Controller (MultiCAN+)

node that recognizes the transfer error are indicated for the respective CAN node x in register NECNT x . Depending on the values of the error counters, the CAN node is set into error- active, error-passive, or bus-off state.

The CAN node is in error-active state if both error counters are below the error-passive limit of 128. The CAN node is in error-passive state, if at least one of the error counters is equal to or greater than 128.

The bus-off state is activated if the Transmit Error Counter is equal to or greater than the bus-off limit of 256. This state is reported for CAN node x by the Node x Status Register flag NSRx.BOFF. The device remains in this state, until the “bus-off” recovery sequence is finished. Additionally, Node x Status Register flag NSRx.EWRN is set when at least one of the error counters is equal to or greater than the error warning limit defined by the Node x Error Count Register bit field NECNT x .EWRNLVL. Bit NSRx.EWRN is reset if both error counters fall below the error warning limit again (see [Page 23-95](#)).

23.4.6.4 CAN Frame Counter

Each CAN node is equipped with a frame counter that counts transmitted/received CAN frames or obtains information about the time when a frame has been started to transmit or be received by the CAN node. CAN frame counting/bit time counting is performed by a 16-bit counter that is controlled by Node x Frame Counter Register NFCRx (see [Page 23-113](#)). Bit field NFCRx.CFSEL determines the operation mode of the frame counter:

- **Frame Count Mode:**
After the successful transmission and/or reception of a CAN frame, the frame counter is copied into the CFCVAL bit field of the MOIPR n register of the message object involved in the transfer. Afterwards, the frame counter is incremented.
- **Time Stamp Mode:**
The frame counter is incremented with the beginning of a new bit time. When the transmission/reception of a frame starts, the value of the frame counter is captured and stored to the CFC bit field of the NFCRx register. After the successful transfer of the frame the captured value is copied to the CFCVAL bit field of the MOIPR n register of the message object involved in the transfer.
- **Bit Timing Mode:**
Used for baud rate detection and analysis of the bit timing ([Chapter 23.4.8.3](#)).
- **Error Count Mode:**
The frame counter is incremented when an error frame is received or an error is detected by the node (010_B to 110_B) (see [Table 23-12](#) for [Encoding of the LEC Bit field](#)). If the NFCRx.CFCIE interrupt bit is enabled, the NFCRx.CFCOV overflow flag will be set when the frame counter overflows.

23.4.6.5 Node Timing Functions

A CAN node offers the following timing functions:

- A receive time-out mode that can detect reception of message objects; the message objects to be supervised are selectable.
- Without CPU involvement, a selectable message object can be transmitted periodically, triggered by a timer, a System Timer (STM) or General Timer Module (GTM).

The clocking options for the node timer is controlled by Node Timer Clock Control Register, **CAN_NTCCR_x (x = 0-4)**, the node timing functions for Receive Timeout Mode is controlled by Node x Timer Receive Timeout Register, **CAN_NTRTR_x (x = 0-4)** and for Transmit Trigger Mode is controlled by Node x Timer A/B/C Transmit Trigger Registers, **CAN_NTATTR_x (x = 0-4)**, **CAN NTBTR_x (x = 0-4)**, **CAN_NTCTTR_x (x = 0-4)**.

Modes with Timer Usage

A CAN node timer is driven by the CAN bit time clock, divided by a prescaler selected via bit field TPSC in the corresponding timer control register. The timers are enabled by writing to the RELOAD bits in the relevant node timer registers; then it decrements from its initial value. The further behavior depends on the selected timer mode:

- **Receive Timeout Mode:**
By setting bit MOFCR_n.RXTOE, a receive time-out check is enabled for message object n, which may be a receive or remote data object. If any of the participating message objects is received before the timer is 0, the timer will be reloaded. When the timer reaches 0, it will stop. Bit TE in NTRTR_x register will be set. With bit TEIE = 1, a node interrupt will be generated.
- **Transmit Trigger Mode:**
When the timer reaches 0, Bit MOSTAT_n.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Transmit Trigger by System Timer or General Timer Module

For Node x Timer the trigger for transmission of a message can also be set by a System Timer (STM) trigger event or General Timer Module (GTM) trigger event. See **Figure 23-12**.

Bit NTCCR_x.TRIGSRC in the timer clock control register enables this feature and the timer is started once values are written to the RELOAD bits of the relevant NTATT_x, NTBTT_x, or NTCTT_x registers. In transmit trigger mode, when a trigger event occurs (STM or GTM), the node timer will be decremented per trigger event timing prescaled by (TPSC+1) till it reaches zero where Bit MOSTAT_n.TXRQ of the message object n selected by bit field TXMO in the timer control register will be set.

Controller Area Network Controller (MultiCAN+)

Note: The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes.

Figure 23-12 CAN Node Timing Modes

23.4.6.6 CAN Node Interrupts

Each CAN node has five hardware triggered interrupt request types that are able to generate an interrupt request upon:

- The successful transmission or reception of a frame
- A CAN protocol error with a last error code
- An alert condition: Transmit/receive error counters reach the warning limit, bus-off state changes, a List Length Error occurs, or a List Object Error occurs
- An overflow of the frame counter
- A node timer A, C or D event

Besides the hardware generated interrupts, software initiated interrupts can be generated using the Module Interrupt Trigger Register MITR. Writing a 1 to bit n of bit field MITR.IT generates an interrupt request signal on the corresponding interrupt output line INT_On. When writing MITR.IT more than one bit can be set resulting in activation of multiple INT_On interrupt output lines at the same time. See also **“Interrupt Control” on Page 23-170** for further processing of the CAN node interrupts.

Controller Area Network Controller (MultiCAN+)

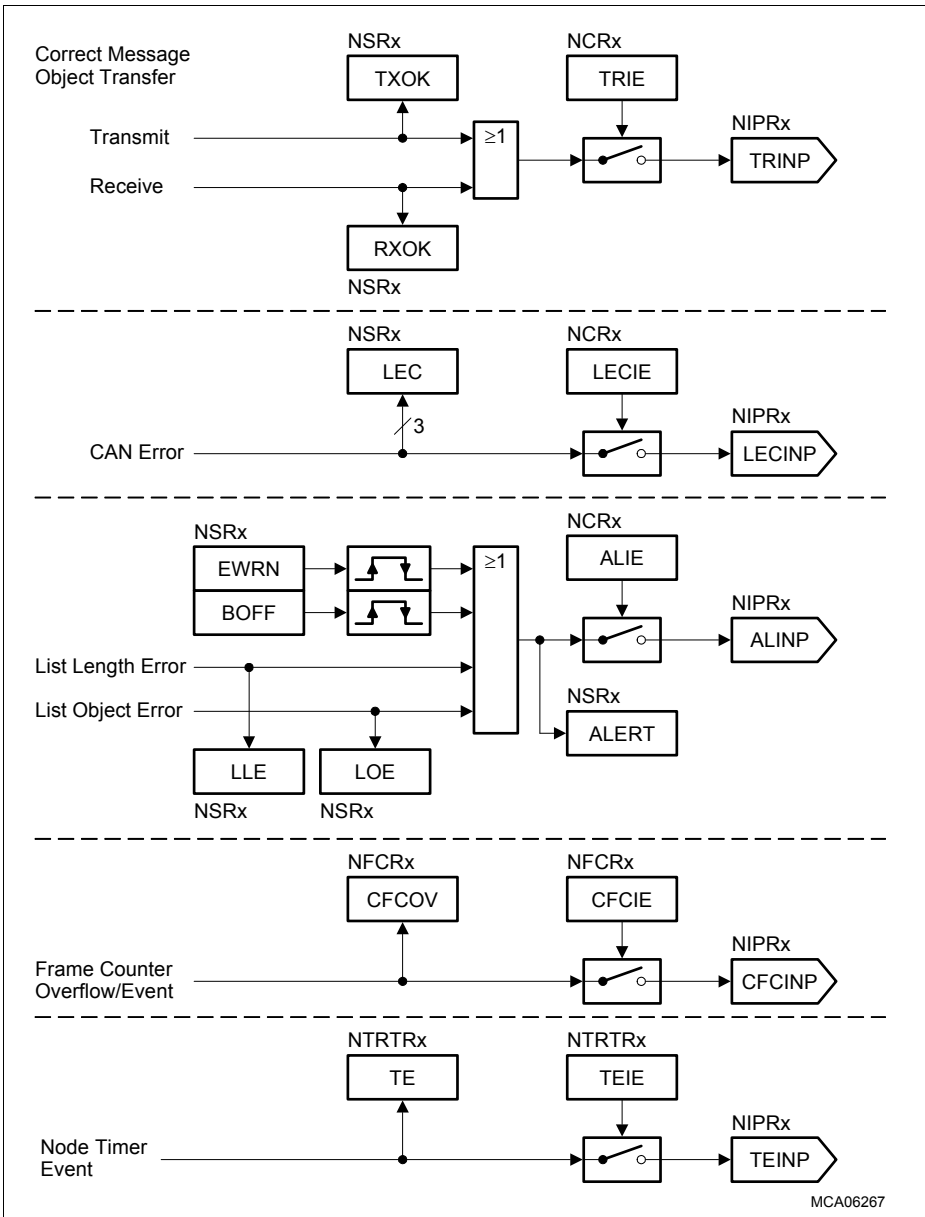

Figure 23-13 CAN Node Interrupts

Controller Area Network Controller (MultiCAN+)

23.4.7 Message Object List Structure

This section describes the structure of the message object lists in the MultiCAN+ module.

23.4.7.1 Basics

The message objects of the MultiCAN+ module are organized in double-chained lists, where each message object has a pointer to the previous message object in the list as well as a pointer to the next message object in the list. The MultiCAN+ module provides 16 lists. Each message object is allocated to one of these lists. In the example in [Figure 23-14](#), the three message objects (3, 5, and 16) are allocated to the list with index 2 (List Register LIST2).

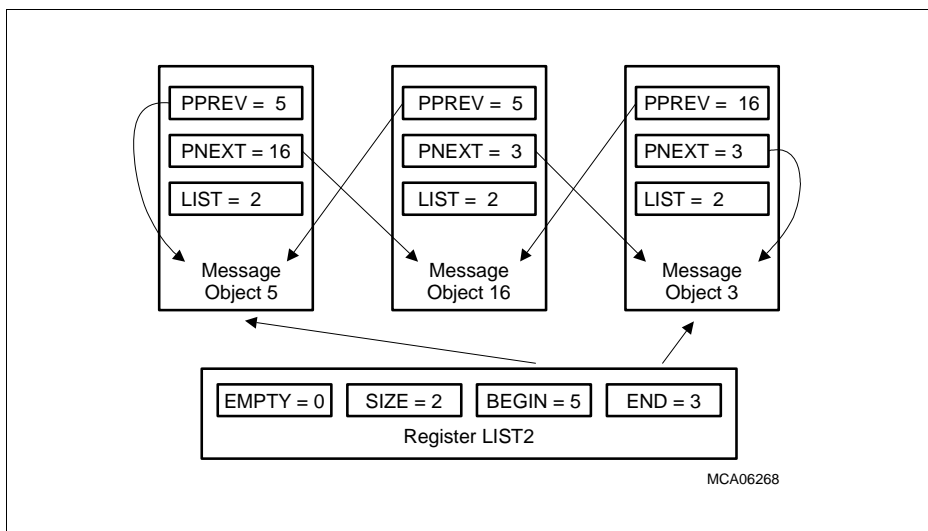

Figure 23-14 Example Allocation of Message Objects to a List

Bit field BEGIN in the List Register (for definition, see [Page 23-86](#)) points to the first element in the list (object 5 in the example), and bit field END points to the last element in the list (object 3 in the example). The number of elements in the list is indicated by bit field SIZE of the List Register (SIZE = number of list elements - 1, thus SIZE = 2 for the 3 elements in the example). The EMPTY bit of the List Register indicates whether or not a list is empty (EMPTY = 0 in the example, because list 2 is not empty).

Each message object n has a pointer PNEXT in its Message Object n Status Register MOSTAT n (see [Page 23-126](#)) that points to the next message object in the list, and a pointer PPREV that points to the previous message object in the list. PPREV of the first message object points to the message object itself because the first message object has

Controller Area Network Controller (MultiCAN+)

no predecessor (in the example message object 5 is the first message object in the list, indicated by PPREV = 5). PNEXT of the last message object also points to the message object itself because the last message object has no successor (in the example, object 3 is the last message object in the list, indicated by PNEXT = 3).

Bit field MOSTATn.LIST indicates the list index number to which the message object is currently allocated. The message object of the example are allocated to list 2. Therefore, all LIST bit fields for the message objects assigned to list 2 are set to LIST = 2.

23.4.7.2 List of Unallocated Elements

The list with list index 0 has a special meaning: it is the list of all unallocated elements. An element is called unallocated if it belongs to list 0 (MOSTATn.LIST = 0). It is called allocated if it belongs to a list with an index not equal to 0 (MOSTATn.LIST > 0).

After reset, all message objects are unallocated. This means that they are assigned to the list of unallocated elements with MOSTATn.LIST = 0. After this initial allocation of the message objects caused by reset, the list of all unallocated message objects is ordered by message number (predecessor of message object n is object n-1, successor of object n is object n+1).

23.4.7.3 Connection to the CAN Nodes

Each CAN node is linked to one unique list of message objects. A CAN node performs message transfer only with the message objects that are allocated to the list of the CAN node. This is illustrated in [Figure 23-15](#). Frames that are received on a CAN node may only be stored in one of the message objects that belongs to the CAN node; frames to be transmitted on a CAN node are selected only from the message objects that are allocated to that node, as indicated by the vertical arrows.

There are more lists (16) than CAN nodes (5). This means that some lists are not linked to one of the CAN nodes. A message object that is allocated to one of these unlinked lists cannot receive messages directly from a CAN node and it may not transmit messages.

FIFO and gateway mechanisms refer to message numbers and not directly to a specific list. The user must take care that the message objects targeted by FIFO/gateway belong to the desired list. The mechanisms make it possible to work with lists that do not belong to the CAN node.

Controller Area Network Controller (MultiCAN+)

Figure 23-15 Message Objects Linked to CAN Nodes

23.4.7.4 List Command Panel

The list structure cannot be modified directly by write accesses to the LIST registers and the PPREV, PNEXT and LIST bit fields in the Message Object Status Registers, as they are read only. The list structure is managed by and limited to the list controller inside the MultiCAN+ module. The list controller is controlled via a command panel allowing the user to issue list allocation commands to the list controller. The list controller has two main purposes:

1. Ensure that all operations that modify the list structure result in a consistent list structure.
2. Present maximum ease of use and flexibility to the user.

The list controller and the associated command panel allows the programmer to concentrate on the final properties of the list, which are characterized by the allocation of message objects to a CAN node, and the ordering relation between objects that are allocated to the same list. The process of list (re-)building is done in the list controller.

Controller Area Network Controller (MultiCAN+)

Table 23-7 gives an overview on the available panel commands while **Table 23-11** on **Page 23-80** describes the panel commands in more detail.

Table 23-7 Panel Commands Overview

Command Name	Description
No Operation	No new command is started.
Initialize Lists	Run the initialization sequence to reset the CTRL and LIST field of all message objects.
Static Allocate	Allocate message object to a list.
Dynamic Allocate	Allocate the first message object of the list of unallocated objects to the selected list.
Static Insert Before	Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object.
Dynamic Insert Before	Insert a new message object before a given destination object.
Static Insert Behind	Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object.
Dynamic Insert Behind	Insert a new message object behind a given destination object.

A panel command is started by writing the respective command code into the Panel Control Register bit field PANCTR.PANCMD (see **Page 23-79**). The corresponding command arguments must be written into bit fields PANCTR.PANAR1 and PANCTR.PANAR2 before writing the command code, or latest along with the command code in a single 32-bit write access to the Panel Control Register.

With the write operation of a valid command code, the PANCTR.BUSY flag is set and further write accesses to the Panel Control Register are ignored. The BUSY flag remains active and the control panel remains locked until the execution of the requested command has been completed. After a reset and resetting the CLC.DISR (see **Page 23-164**) register, the list controller builds up list 0. Afterwards the BUSY bit is set, dependent on core speed this might be visible. During list controller initialization, BUSY is set and other accesses to the CAN RAM are forbidden. The CAN RAM can be accessed again when BUSY becomes inactive.

Note: The CAN RAM is automatically initialized after reset by the list controller in order to ensure correct list pointers in each message object. The end of this CAN RAM initialization is indicated by bit PANCTR.BUSY becoming inactive.

Controller Area Network Controller (MultiCAN+)

In case of a dynamic allocation command that takes an element from the list of unallocated objects, the PANCTR.RBUSY bit is also set along with the BUSY bit (RBUSY = BUSY = 1). This indicates that bit fields PANAR1 and PANAR2 are going to be updated by the list controller in the following way:

1. The message number of the message object taken from the list of unallocated elements is written to PANAR1.
2. If ERR (bit 7 of PANAR2) is set to 1, the list of unallocated elements was empty and the command is aborted. If ERR is 0, the list was not empty and the command will be performed successfully.

The results of a dynamic allocation command are written before the list controller starts the actual allocation process. As soon as the results are available, RBUSY becomes inactive (RBUSY = 0) again, while BUSY still remains active until completion of the command. This allows the user to set up the new message object while it is still in the process of list allocation. The access to message objects is not limited during ongoing list operations. However, any access to a register resource located inside the RAM delays the ongoing allocation process by one access cycle.

As soon as the command is finished, the BUSY flag becomes inactive (BUSY = 0) and write accesses to the Panel Control Register are enabled again. Also, the “No Operation” command code is automatically written to the PANCTR.PANCMD field. A new command may be started any time when BUSY = 0.

All fields of the Panel Control Register PANCTR except BUSY and RBUSY may be written by the user. This makes it possible to save and restore the Panel Control Register if the Command Panel is used within independent (mutually interruptible) interrupt service routines. If this is the case, any task that uses the Command Panel and that may interrupt another task that also uses the Command Panel should poll the BUSY flag until it becomes inactive and save the whole PANCTR register to a memory location before issuing a command. At the end of the interrupt service routine, the task should restore PANCTR from the memory location.

Before a message object that is allocated to the list of an active CAN node shall be moved to another list or to another position within the same list, bit MOSTATn.MSGVAL (“Message Valid”) of message object n must be cleared.

23.4.8 CAN Node Analyzer Mode

The chapter describes the CAN node analyzer capabilities of the MultiCAN+ module.

23.4.8.1 Analyzer Mode

The CAN Analyzer Mode makes it possible to monitor the CAN traffic for each CAN node individually without affecting the logical state of the CAN bus. The CAN Analyzer Mode for CAN node x is selected by setting Node x Control Register bit NCRx.CALM.

Controller Area Network Controller (MultiCAN+)

In CAN Analyzer Mode, the transmit pin of a CAN node is held at a recessive level permanently. The CAN node may receive frames (Data, Remote, and Error Frames) but is not allowed to transmit. Received Data/Remote Frames are not acknowledged (i.e. acknowledge slot is sent recessive) but will be received and stored in matching message objects as long as there is any other node that acknowledges the frame. The complete message object functionality is available, but no transmit request will be executed. CAN Analyzer mode works for both Classical CAN format and CAN FD format.

23.4.8.2 Loop-Back Mode

The MultiCAN+ module provides a Loop-Back Mode to enable an in-system test of the MultiCAN+ module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MultiCAN+ module) and a bus select switch for each CAN node (see [Figure 23-16](#)). With the switch, each CAN node can be connected either to the internal CAN bus (Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Loop-Back Mode is selected for CAN node *x* by setting the Node *x* Port Control Register bit NPCRx.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

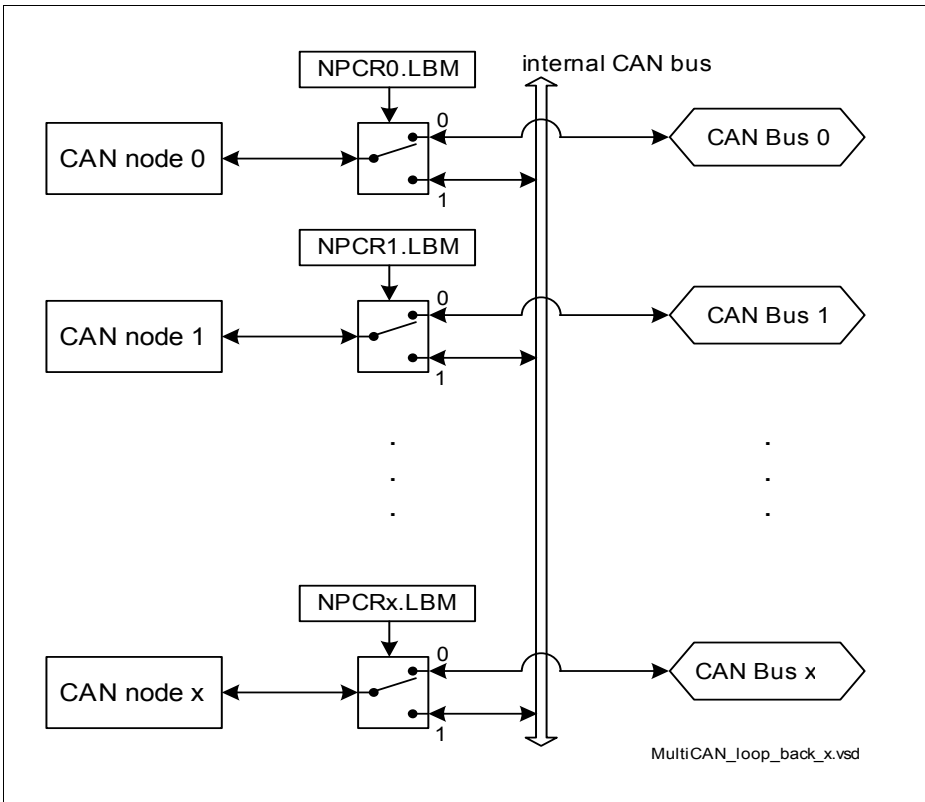

Figure 23-16 Loop-Back Mode

23.4.8.3 Bit Timing Analysis

Detailed analysis of the bit timing can be performed for each CAN node using the analysis modes of the CAN frame counter. The bit timing analysis functionality of the frame counter may be used for automatic detection of the CAN baud rate, as well as to analyze the timing of the CAN network.

Bit timing analysis for CAN node x is selected when bit field $NFCRx.CFMODE = 10_B$. Bit timing analysis does not affect the operation of the CAN node.

The bit timing measurement results are written into the $NFCRx.CFC$ bit field. Whenever $NFCRx.CFC$ is updated in bit timing analysis mode, bit $NFCRx.CFCOV$ is also set to indicate the CFC update event. The value of $NFCRx.CFC$ is valid one module cycle later when $NFCRx.CFCOV$ is set. If $NFCRx.CFCIE$ is set, an interrupt request can be generated (see [Figure 23-13](#)).

Controller Area Network Controller (MultiCAN+)

Automatic Baud Rate Detection

For automatic baud rate detection, the time between the observation of subsequent dominant edges on the CAN bus must be measured. This measurement is automatically performed if bit field `NFCRx.CFSEL = 000B`. With each dominant edge monitored on the CAN receive input line, the time (measured in f_{CAN} clock cycles) between this edge and the most recent dominant edge is stored in the `NFCRx.CFC` bit field.

Synchronization Analysis

The bit time synchronization is monitored if `NFCRx.CFSEL = 010B`. The time between the first dominant edge and the sample point is measured and stored in the `NFCRx.CFC` bit field. The bit timing synchronization offset may be derived from this time as the first edge after the sample point triggers synchronization and there is only one synchronization between consecutive sample points.

Synchronization analysis can be used, for example, for fine tuning of the baud rate during reception of the first CAN frame with the measured baud rate.

Driver Delay Measurement

The delay between a transmitted edge and the corresponding received edge is measured when `NFCRx.CFSEL = 011B` (dominant to dominant) and `NFCRx.CFSEL = 100B` (recessive to recessive). These delays indicate the time needed to represent a new bit value on the physical implementation of the CAN bus.

23.4.9 Message Acceptance Filtering

The chapter describes the Message Acceptance Filtering capabilities of the MultiCAN+ module.

23.4.9.1 Receive Acceptance Filtering

When a CAN frame is received by a CAN node, a unique message object is determined in which the received frame is stored after successful frame reception. A message object is qualified for reception of a frame if the following six conditions are met.

- The message object is allocated to the message object list of the CAN node by which the frame is received.
- Bit `MOSTATn.MSGVAL` in the Message Object Status Register (see [Page 23-126](#)) is set.
- Bit `MOSTATn.RXEN` is set.
- Bit `MOSTATn.DIR` is equal to bit `RTR` of the received frame.
If bit `MOSTATn.DIR = 1` (transmit object), the message object accepts only Remote Frames. If bit `MOSTATn.DIR = 0` (receive object), the message object accepts only Data Frames.

Controller Area Network Controller (MultiCAN+)

- If bit MOAMRn.MIDE = 1, the IDE bit of the received frame becomes evaluated in the following way: If MOARn.IDE = 1, the IDE bit of the received frame must be set (indicates extended identifier). If MOARn.IDE = 0, the IDE bit of the received frame must be cleared (indicates standard identifier).
If bit MOAMRn.MIDE = 0, the IDE bit of the received frame is “don’t care”. In this case, message objects with standard and extended frames are accepted.
- The identifier of the received frame matches the identifier stored in the Arbitration Register of the message object as qualified by the acceptance mask in the MOAMRn register. This means that each bit of the received message object identifier is equal to the bit field MOARn.ID, except those bits for which the corresponding acceptance mask bits in bit field MOAMRn.AM are cleared. These identifier bits are “don’t care” for reception. **Figure 23-17** illustrates this receive message identifier check.

Among all messages that fulfill all six qualifying criteria the message object with the highest receive priority wins receive acceptance filtering and becomes selected to store the received frame. All other message objects lose receive acceptance filtering.

The following priority scheme is defined for the message objects:

A message object a (MOa) has higher receive priority than a message object b (MOb) if the following two conditions are fulfilled (see **Page 23-143**):

1. MOa has a higher priority class than MOb. This means, the 2-bit priority bit field MOARa.PRI must be equal or less than bit field MOARb.PRI.
2. If both message objects have the same priority class (MOARa.PRI = MOARb.PRI), MOb is a list successor of MOa. This means that MOb can be reached by means of successively stepping forward in the list, starting from a.

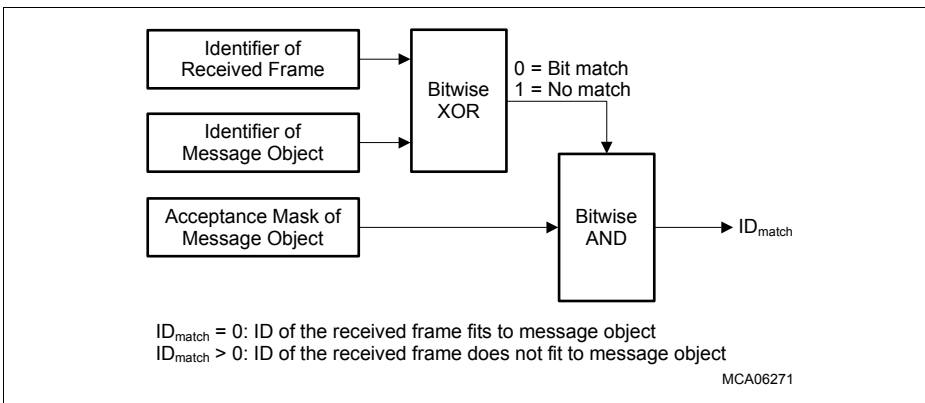

Figure 23-17 Received Message Identifier Acceptance Check

23.4.9.2 Transmit Acceptance Filtering

A message is requested for transmission by setting a transmit request in the message object that holds the message. If more than one message object have a valid transmit request for the same CAN node, one of these message objects is chosen for transmission, because only a single message object can be transmitted at one time on a CAN bus.

A message object is qualified for transmission on a CAN node if the following four conditions are met (see also [Figure 23-18](#)).

1. The message object is allocated to the message object list of the CAN node.
2. Bit MOSTATn.MSGVAL is set.
3. Bit MOSTATn.TXRQ is set.
4. Bit MOSTATn.TXEN0 and MOSTATn.TXEN1 are set.

A priority scheme determines which one of all qualifying message objects is transmitted first. It is assumed that message object a (MOa) and message object b (MOb) are two message objects qualified for transmission. MOb is a list successor of MOa. For both message objects, CAN messages CANa and CANb are defined (identifier, IDE, and RTR are taken from the message-specific bit fields and bits MOARn.ID, MOARn.IDE and MOSTATn.DIR).

If both message objects belong to the same priority class (identical PRI bit field in register MOARn), MOa has a higher transmit priority than MOb if one of the following conditions is fulfilled.

- $PRI = 10_B$ and CAN message MOa has higher or equal priority than CAN message MOb with respect to CAN arbitration rules (see [Table 23-19](#) on [Page 23-144](#)).
- $PRI = 01_B$ or $PRI = 11_B$ (priority by list order).

The message object that is qualified for transmission and has highest transmit priority wins the transmit acceptance filtering, and will be transmitted first. All other message objects lose the current transmit acceptance filtering round. They get a new chance in subsequent acceptance filtering rounds.

Controller Area Network Controller (MultiCAN+)

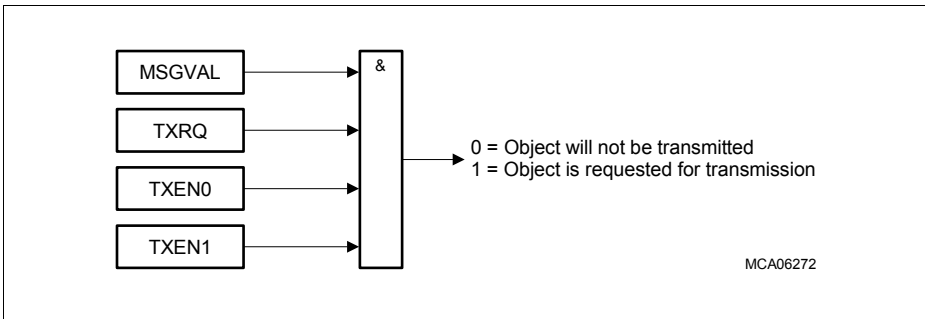

Figure 23-18 Effective Transmit Request of Message Object

23.4.10 Message Postprocessing

After a message object has successfully received or transmitted a frame, the CPU can be notified to perform a postprocessing on the message object. The postprocessing of the MultiCAN+ module consists of two elements:

1. Message interrupts to trigger postprocessing.
2. Message pending registers to collect pending message interrupts into a common structure for postprocessing.

23.4.10.1 Message Object Interrupts

When the storage of a received frame into a message object or the successful transmission of a frame is completed, a message interrupt can be issued. For each message object, a transmit and a receive interrupt can be generated and routed to one of the sixteen CAN interrupt output lines (see [Figure 23-19](#)). A receive interrupt occurs also after a frame storage event that has been induced by a FIFO or a gateway action. The status bits TXPND and RXPND in the Message Object n Status Register are always set after a successful transmission/reception, whether or not the respective message interrupt is enabled.

A third FIFO full interrupt condition of a message object is provided. If bit field MOFCRn.OVIE (Overflow Interrupt Enable) is set, the FIFO full interrupt will be activated depending on the actual message object type.

In case of a Receive FIFO Base Object (MOFCRn.MMC = 0001_B), the FIFO full interrupt is routed to the interrupt output line INT_Om as defined by the transmit interrupt node pointer MOIPRn.TXINP.

In case of a Transmit FIFO Base Object (MOFCRn.MMC = 0010_B), the FIFO full interrupt becomes routed to the interrupt output line INT_Om as defined by the receive interrupt node pointer MOIPRn.RXINP.

Controller Area Network Controller (MultiCAN+)

See also **“Interrupt Control” on Page 23-170** for further processing of the message object interrupts.

Figure 23-19 Message Interrupt Request Routing

Controller Area Network Controller (MultiCAN+)

23.4.10.2 Pending Messages

When a message interrupt request is generated, a message pending bit is set in one of the Message Pending Registers. There are 8 Message Pending Registers, MSPNDk (k = 0-7) with 32 pending bits available each. The general Figure 23-20 shows the allocation of the message pending bits in case that the maximum possible number of eight Message Pending Registers are implemented and available on the chip.

Figure 23-20 Message Pending Bit Allocation

Controller Area Network Controller (MultiCAN+)

The location of a pending bit is defined by two demultiplexers selecting the number k of the MSPNDk registers (3-bit demux), and the bit location within the corresponding MSPNDk register (5-bit demux).

Allocation Case 1

In this allocation case, bit field MCR.MPSEL = 0000_B (see [Page 23-83](#)). The location selection consists of 2 parts:

- The upper three bits of MOIPRn.MPN (MPN[7:5]) select the number k of a Message Pending Register MSPNDk in which the pending bit will be set.
- The lower five bits of MOIPRn.MPN (MPN[4:0]) select the bit position (0-31) in MSPNDk for the pending bit to be set.

Allocation Case 2

In this allocation case, bit field MCR.MPSEL is taken into account for pending bit allocation. Bit field MCR.MPSEL makes it possible to include the interrupt request node pointer for reception (MOIPRn.RXINP) or transmission (MOIPRn.TXINP) for pending bit allocation in such a way that different target locations for the pending bits are used in receive and transmit case. If MPSEL = 1111_B, the location selection operates in the following way:

- At a transmit event, the upper 3 bits of TXINP determine the number k of a Message Pending Register MSPNDk in which the pending bit will be set. At a receive event, the upper 3 bits of RXINP determine the number k .
- The bit position (0-31) in MSPNDk for the pending bit to be set is selected by the lowest bit of TXINP or RXINP (selects between low and high half-word of MSPNDk) and the four least significant bits of MPN.

General Hints

The Message Pending Registers MSPNDk can be written by software. Bits that are written with 1 are left unchanged, and bits which are written with 0 are cleared. This makes it possible to clear individual MSPNDk bits with a single register write access. Therefore, access conflicts are avoided when the MultiCAN+ module (hardware) sets another pending bit at the same time when software writes to the register.

Each Message Pending Register MSPNDk is associated with a Message Index Register MSIDk (see [Page 23-89](#)) which indicates the lowest bit position of all set (1) bits in Message Pending Register k . The MSIDk register is a read-only register that is updated immediately when a value in the corresponding Message Pending Register k is changed by software or hardware.

23.4.11 Message Object Data Handling

This chapter describes the handling capabilities for the Message Object Data of the MultiCAN+ module.

23.4.11.1 Frame Reception

After the reception of a message, it is stored in a message object according to the scheme shown in [Figure 23-21](#). The MultiCAN+ module not only copies the received data into the message object, and it provides advanced features to enable consistent data exchange between MultiCAN+ and CPU.

MSGVAL

Bit MSGVAL (Message Valid) in the Message Object n Status Register MOSTATn is the main switch of the message object. During the frame reception, information is stored in the message object only when MSGVAL = 1. If bit MSGVAL is reset by the CPU, the MultiCAN+ module stops all ongoing write accesses to the message object. Now the message object can be re-configured by the CPU with subsequent write accesses to it without being disturbed by the MultiCAN+.

RTSEL

When the CPU re-configures a message object during CAN operation (for example, clears MSGVAL, modifies the message object and sets MSGVAL again), the following scenario can occur:

1. The message object wins receive acceptance filtering.
2. The CPU clears MSGVAL to re-configure the message object.
3. The CPU sets MSGVAL again after re-configuration.
4. The end of the received frame is reached. As MSGVAL is set, the received data is stored in the message object, a message interrupt request is generated, gateway and FIFO actions are processed, etc.

After the re-configuration of the message object (after step 3 above) the storage of further received data may be undesirable. This can be achieved through bit MOSTATn.RTSEL (Receive/Transmit Selected) that makes it possible to disconnect a message object from an ongoing frame reception.

When a message object wins the receive acceptance filtering, its RTSEL bit is set by the MultiCAN+ module to indicate an upcoming frame delivery. The MultiCAN+ module checks RTSEL whether it is set on successful frame reception to verify that the object is still ready for receiving the frame. The received frame is then stored in the message object (along with all subsequent actions such as message interrupts, FIFO & gateway actions, flag updates) only if RTSEL = 1.

When a message object is invalidated during CAN operation (resetting bit MSGVAL), RTSEL should be cleared before setting MSGVAL again (latest with the same write

Controller Area Network Controller (MultiCAN+)

access that sets MSGVAL) to prevent the storage of a frame that belongs to the old context of the message object. Therefore, a message object re-configuration should consist of the following steps:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL bit and set MSGVAL again

RXEN

Bit MOSTATn.RXEN enables a message object for frame reception. A message object can receive CAN messages from the CAN bus only if RXEN = 1. The MultiCAN+ module evaluates RXEN only during receive acceptance filtering. After receive acceptance filtering, RXEN is ignored and has no further influence on the actual storage of a received message in a message object.

Bit RXEN enables the “soft phase out” of a message object: after clearing RXEN, a currently received CAN message for which the message object has won acceptance filtering is still stored in the message object but for subsequent messages the message object no longer wins receive acceptance filtering.

RXUPD, NEWDAT and MSGLST

An ongoing frame storage process is indicated by the RXUPD (Receive Updating) flag in the MOSTATn register. RXUPD is set with the start and cleared with the end of a message object update, which consists of frame storage as well as flag updates.

After storing the received frame (identifier, IDE bit, DLC; including the Data Field for Data Frames), the NEWDAT (New Data) bit of the message object is set. If NEWDAT was already set before it becomes set again, bit MSGLST (Message Lost) is set to indicate a data loss condition.

The RXUPD and NEWDAT flags can help to read consistent frame data from the message object during an ongoing CAN operation. The following steps are recommended to be executed:

1. Clear NEWDAT bit.
2. Read message content (identifier, data etc.) from the message object.
3. Check that both, NEWDAT and RXUPD, are cleared. If this is not the case, go back to step 1.
4. When step 3 was successful, the message object contents are consistent and has not been updated by the MultiCAN+ module while reading.

Bits RXUPD, NEWDAT and MSGLST have the same behavior for the reception of Data as well as Remote Frames.

Controller Area Network Controller (MultiCAN+)

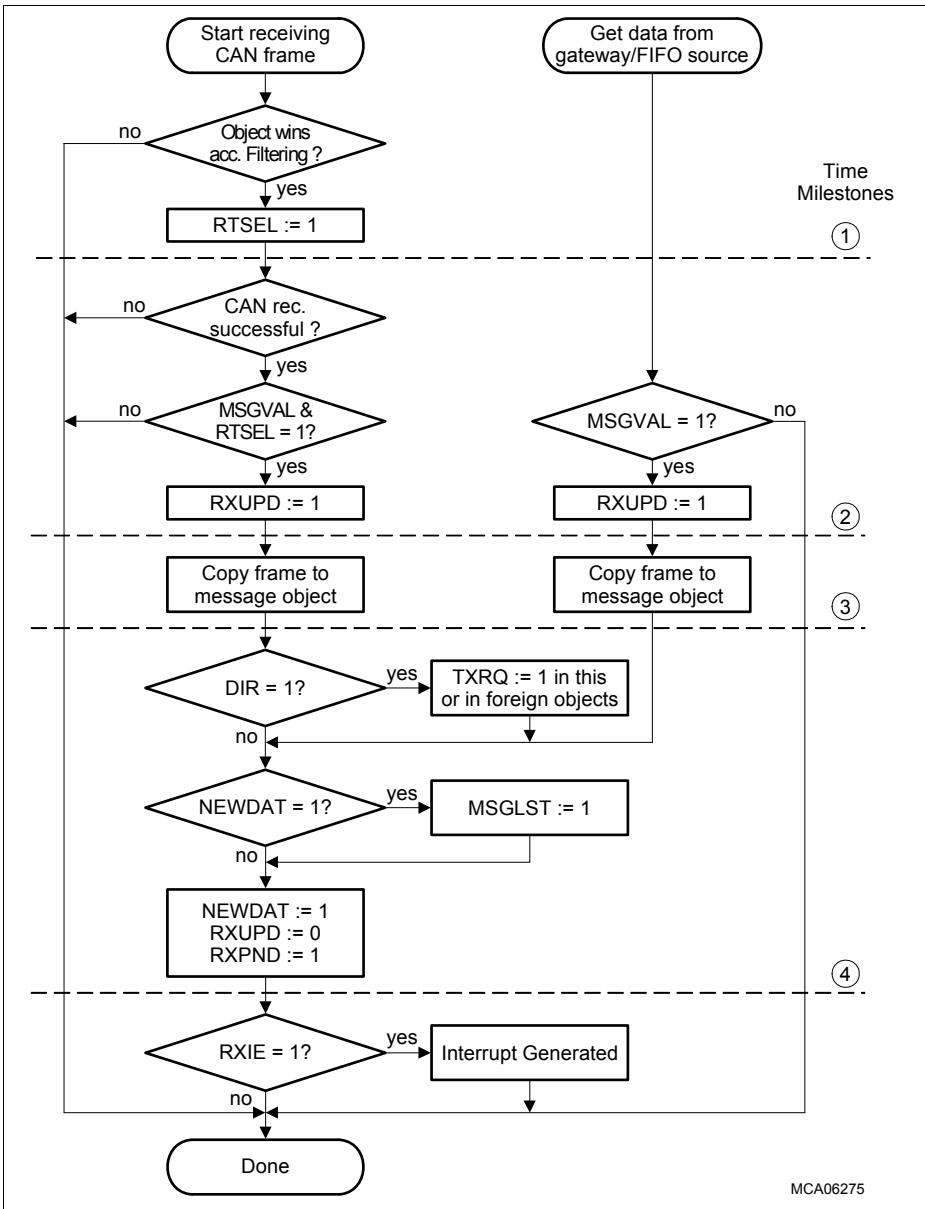

Figure 23-21 Reception of a Message Object

Controller Area Network Controller (MultiCAN+)
23.4.11.2 Frame Transmission

The process of a message object transmission is shown in [Figure 23-22](#). Along with the copy of the message object content to be transmitted (identifier, IDE bit, RTR = DIR bit, DLC, including the Data Field for Data Frames) into the internal transmit buffer of the assigned CAN node, several status flags are also served and monitored to control consistent data handling.

The transmission process of a message object starting after the transmit acceptance filtering is identical for Remote and Data Frames.

MSGVAL, TXRQ, TXEN0, TXEN1

A message can only be transmitted if all four bits in registers MOSTATn, MSGVAL (Message Valid), TXRQ (Transmit Request), TXEN0 (Transmit Enable 0), TXEN1 (Transmit Enable 1) are set as shown in [Figure 23-18](#). Although these bits are equivalent with respect to the transmission process, they have different semantics:

Table 23-8 Message Transmission Bit Definitions

Bit	Description
MSGVAL	Message Valid This is the main switch bit of the message object.
TXRQ	Transmit Request This is the standard transmit request bit. This bit must be set whenever a message object should be transmitted. TXRQ is cleared by hardware at the end of a successful transmission, except when there is new data (indicated by NEWDAT = 1) to be transmitted. When bit MOFCRn.STT (“Single Transmit Trial”) is set, TXRQ becomes already cleared when the contents of the message object are copied into the transmit frame buffer of the CAN node. A received remote request (after a Remote Frame reception) sets bit TXRQ to request the transmission of the requested data frame.
TXEN0	Transmit Enable 0 This bit can be temporarily cleared by software to suppress the transmission of this message object when it writes new content to the Data Field. This avoids transmission of inconsistent frames that consist of a mixture of old and new data. Remote requests are still accepted when TXEN0 = 0, but transmission of the Data Frame is suspended until transmission is re-enabled by software (setting TXEN0).

Controller Area Network Controller (MultiCAN+)
Table 23-8 Message Transmission Bit Definitions (cont'd)

Bit	Description
TXEN1	<p>Transmit Enable 1</p> <p>This bit is used in transmit FIFOs to select the message object that is transmit active within the FIFO structure.</p> <p>For message objects that are not transmit FIFO elements, TXEN1 can either be set permanently to 1 or can be used as a second independent transmission enable bit.</p>

RTSEL

When a message object has been identified to be transmitted next after transmission acceptance filtering, bit MOSTATn.RTSEL (Receive/Transmit Selected) is set.

When the message object is copied into the internal transmit buffer, bit RTSEL is checked, and the message is transmitted only if RTSEL = 1. After the successful transmission of the message, bit RTSEL is checked again and the message postprocessing is only executed if RTSEL = 1.

For a complete re-configuration of a valid message object, the following steps should be executed:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL and set MSGVAL

Clearing of RTSEL ensures that the message object is disconnected from an ongoing/scheduled transmission and no message object processing (copying message to transmit buffer including clearing NEWDAT, clearing TXRQ, time stamp update, message interrupt, etc.) within the old context of the object can occur after the message object becomes valid again, but within a new context.

NEWDAT

When the contents of a message object have been transferred to the internal transmit buffer of the CAN node, bit MOSTATn.NEWDAT (New Data) is cleared by hardware to indicate that the transmit message object data is no longer new.

When the transmission of the frame is successful and NEWDAT is still cleared (if no new data has been copied into the message object meanwhile), TXRQ (Transmit Request) is cleared automatically by hardware.

If, however, the NEWDAT bit has been set again by the software (because a new frame should be transmitted), TXRQ is not cleared to enable the transmission of the new data.

Controller Area Network Controller (MultiCAN+)

Figure 23-22 Transmission of a Message Object

23.4.12 Message Object Functionality

This chapter describes the functionality of the Message Objects in the MultiCAN+ module.

23.4.12.1 Standard Message Object

A message object is selected as standard message object when bit field MOFCRn.MMC = 0000_B (see [Page 23-113](#)). The standard message object can transmit and receive CAN frames according to the basic rules described in the previous sections. Additional services such as Single Data Transfer Mode or Single Transmit Trial (see following sections) are available and can be individually selected.

23.4.12.2 Single Data Transfer Mode

Single Data Transfer Mode is a useful feature in order to broadcast data over the CAN bus without unintended duplication of information. Single Data Transfer Mode is selected via bit MOFCRn.SDT.

Message Reception

When a received message stored in a message object is overwritten by a new received message, the contents of the first message are lost and replaced with the contents of the new received message (indicated by MSGLST = 1).

If SDT is set (Single Data Transfer Mode activated), bit MSGVAL of the message object is automatically cleared by hardware after the storage of a received Data or Remote Frame. This prevents the reception of further messages.

Message Transmission

When a message object receives a series of multiple remote requests, it transmits several Data Frames in response to the remote requests. If the data within the message object has not been updated in the time between the transmissions, the same data can be sent more than once on the CAN bus.

In Single Data Transfer Mode (SDT = 1), this is avoided because MSGVAL is automatically cleared after the successful transmission of a Data or Remote Frame.

23.4.12.3 Single Transmit Trial

If the bit STT in the message object function register is set (STT = 1), the transmission request is cleared (TXRQ = 0) when the frame contents of the message object have been copied to the internal transmit buffer of the CAN node. Thus, the transmission of the message object is not tried again when it fails due to CAN bus errors.

23.4.12.4 Message Object Format (Classical CAN & CAN FD)

Message objects are used for transmission or reception of CAN data frames. The transmit and receive behavior of a Classical CAN node in Classical CAN (ISO 11898-1:2003(E)) or CAN FD (ISO 11898-1 DIS version 2014) are determined by a node control register bit (i.e. NCRx.FDEN) and two message object function control register bits (i.e. MOFCRn.FDF and MOFCRn.BRS) as shown in [Table 23-18](#).

A CAN node which has been set to work in Classical CAN mode i.e. (NCRx.FDEN = 0) would be able to transmit message objects programmed for Classical CAN Frames (i.e. MOFCRn.FDF = 0, MOFCRn.BRS = 0/1) only. When receiving Classical CAN data frames in a node that works in Classical CAN mode the message object function control register bits (i.e. MOFCRn.FDF and MOFCRn.BRS) are not used and not updated.

In the case when a CAN node set to work in a particular mode (e.g. Classical CAN mode) and receives a message object request for transmission or reception that does not correspond with the CAN mode (i.e. MOFCRn.FDF = 1, MOFCRn.BRS = 0/1), the transmission would be cancelled (i.e. corresponding MOSTATn.TXRQ cleared) and CAN frame not received in message object. The CAN node is not blocked and able to transmit or receive other message objects.

However a CAN node that has been set to work in CAN FD mode i.e. (NCRx.FDEN = 1) is able to transmit and receive Classical CAN Data Frames, Long Data Frames or Long + Fast Data Frames. For message object transmission, message object function control bits (i.e. MOFCRn.FDF & MOFCRn.BRS) determines the CAN frame format to be used and functions as status register bits during message reception.

Note: Remote Frame Requests do not change MOFCRn.FDF and MOFCRn.BRS bits.

23.4.12.5 Message Object FIFO Structure

In case of high CPU load it may be difficult to process a series of CAN frames in time. This may happen if multiple messages are received or must be transmitted in short time.

Therefore, a FIFO buffer structure is available to avoid loss of incoming messages and to minimize the setup time for outgoing messages. The FIFO structure can also be used to automate the reception or transmission of a series of CAN messages and to generate a single message interrupt when the whole CAN frame series is done.

There can be several FIFOs in parallel. The number of FIFOs and their size are limited only by the number of available message objects. A FIFO can be installed, resized and de-installed at any time, even during CAN operation.

The basic structure of a FIFO is shown in [Figure 23-23](#). A FIFO consists of one base object and n slave objects. The slave objects are chained together in a list structure (similar as in message object lists). The base object may be allocated to any list. Although [Figure 23-23](#) shows the base object as a separate part beside the slave objects, it is also possible to integrate the base object at any place into the chain of slave objects. This means that the base object is slave object, too (not possible for gateways).

Controller Area Network Controller (MultiCAN+)

The absolute object numbers of the message objects have no impact on the operation of the FIFO.

The base object does not need to be allocated to the same list as the slave objects. Only the slave object must be allocated to a common list (as they are chained together). Several pointers (BOT, CUR and TOP) that are located in the Message Object n FIFO/Gateway Pointer Register MOFGPRn link the base object to the slave objects, regardless whether the base object is allocated to the same or to another **list** than the slave objects.

The smallest FIFO would be a single message object which is both, FIFO base and FIFO slave (not very useful). The biggest possible FIFO structure would include all message objects of the MultiCAN+ module. Any FIFO sizes between these limits are possible.

In the FIFO base object, the FIFO boundaries are defined. Bit field MOFGPRn.BOT of the base object points to (includes the number of) the bottom slave object in the FIFO structure. The MOFGPRn.TOP bit field points to (includes the number of) the top slave object in the FIFO structure. The MOFGPRn.CUR bit field points to (includes the number of) the slave object that is actually selected by the MultiCAN+ module for message transfer. When a message transfer takes place with this object, CUR is set to the next message object in the list structure of the slave objects (CUR = PNEXT of current object). If CUR was equal to TOP (top of the FIFO reached), the next update of CUR will result in CUR = BOT (wrap-around from the top to the bottom of the FIFO). This scheme represents a circular FIFO structure where the bit fields BOT and TOP establish the link from the last to the first element.

Bit field MOFGPRn.SEL of the base object can be used for monitoring purposes. It makes it possible to define a slave object within the list at which a message interrupt is generated whenever the CUR pointer reaches the value of the SEL pointer. Thus SEL makes it possible to detect the end of a predefined message transfer series or to issue a warning interrupt when the FIFO becomes full.

Controller Area Network Controller (MultiCAN+)

Figure 23-23 FIFO Structure with FIFO Base Object and n FIFO Slave Objects

23.4.12.6 Receive FIFO

The Receive FIFO structure is used to buffer incoming (received) Remote or Data Frames.

A Receive FIFO is selected by setting $\text{MOFCRn.MMC} = 0001_{\text{B}}$ in the FIFO base object. This MMC code automatically designates a message object as FIFO base object. The message modes of the FIFO slave objects are not relevant for the operation of the Receive FIFO.

When the FIFO base object receives a frame from the CAN node it belongs to, the frame is not stored in the base object itself but in the message object that is selected by the base object's MOFGPRn.CUR pointer. This message object receives the CAN message as if it is the direct receiver of the message. However, $\text{MOFCRn.MMC} = 0000_{\text{B}}$ is implicitly assumed for the FIFO slave object, and a standard message delivery is performed. The actual message mode (MMC setting) of the FIFO slave object is ignored. For the slave object, no acceptance filtering takes place that checks the received frame for a match with the identifier, IDE bit, and DIR bit.

With the reception of a CAN frame, the current pointer CUR of the base object is set to the number of the next message object in the FIFO structure. This message object will then be used to store the next incoming message.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer MOFGPRn.CUR becomes equal to MOFGPRn.SEL , a FIFO overflow interrupt request is generated. This interrupt request is generated on interrupt node TXINP of the base object immediately after the storage of the received frame in the slave object. Transmit interrupts are still generated if TXIE is set.

A CAN message is stored in FIFO base and slave object only if $\text{MSGVAL} = 1$.

In order to avoid direct reception of a message by a slave message object, as if it was an independent message object and not a part of a FIFO, the bit RXEN of each slave object must be cleared. The setting of the bit RXEN is "don't care" only if the slave object is located in a list not assigned to a CAN node.

23.4.12.7 Transmit FIFO

The Transmit FIFO structure is used to buffer a series of Data or Remote Frames that must be transmitted. A transmit FIFO consists of one base message object and one or more slave message objects.

A Transmit FIFO is selected by setting $\text{MOFCRn.MMC} = 0010_{\text{B}}$ in the FIFO base object. Unlike the Receive FIFO, slave objects assigned to the Transmit FIFO must explicitly set their bit fields $\text{MOFCRn.MMC} = 0011_{\text{B}}$. The CUR pointer in all slave objects must point back to the Transmit FIFO Base Object (to be initialized by software).

Controller Area Network Controller (MultiCAN+)

The MOSTATn.TXEN1 bits (Transmit Enable 1) of all message objects except the one which is selected by the CUR pointer of the base object must be cleared by software. TXEN1 of the message (slave) object selected by CUR must be set. CUR (of the base object) may be initialized to any FIFO slave object.

When tagging the message objects of the FIFO as valid to start the operation of the FIFO, then the base object must be tagged valid (MSGVAL = 1) first.

Before a Transmit FIFO becomes de-installed during operation, its slave objects must be tagged invalid (MSGVAL = 0).

The Transmit FIFO uses the TXEN1 bit in the Message Object Status Register of all FIFO elements to select the actual message for transmission. Transmit acceptance filtering evaluates TXEN1 for each message object and a message object can win transmit acceptance filtering only if its TXEN1 bit is set. When a FIFO object has transmitted a message, the hardware clears its TXEN1 bit in addition to standard transmit postprocessing (clear TXRQ, transmit interrupt etc.), and moves the CUR pointer in the next FIFO base object to be transmitted. TXEN1 is set automatically (by hardware) in the next message object. Thus, TXEN1 moves along the Transmit FIFO structure as a token that selects the active element.

If bit field MOFCRn.OVIE (“Overflow Interrupt Enable”) of the FIFO base object is set and the current pointer CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. The interrupt request is generated on interrupt node RXINP of the base object after postprocessing of the received frame. Receive interrupts are still generated for the Transmit FIFO base object if bit RXIE is set.

23.4.12.8 Gateway Mode

The Gateway Mode makes it possible to establish an automatic information transfer between two independent CAN buses without CPU interaction.

The Gateway Mode operates on message object level. In Gateway mode, information is transferred between two message objects, resulting in an information transfer between the two CAN nodes to which the message objects are allocated. A gateway may be established with any pair of CAN nodes, and there can be as many gateways as there are message objects available to build the gateway structure.

Gateway Mode is selected by setting MOFCRs.MMC = 0100_B for the gateway source object s. The gateway destination object d is selected by the MOFGPRd.CUR pointer of the source object. The gateway destination object only needs to be valid (its MSGVAL = 1). All other settings are not relevant for the information transfer from the source object to the destination object.

Controller Area Network Controller (MultiCAN+)

Gateway source object behaves as a standard message object with the difference that some additional actions are performed by the MultiCAN+ module when a CAN frame has been received and stored in the source object (see [Figure 23-24](#)):

1. If bit MOFCRs.DLCC is set, the data length code MOFCRs.DLC is copied from the gateway source object to the gateway destination object.
2. If bit MOFCRs.IDC is set, the identifier MOARs.ID and the identifier extension MOARs.IDE are copied from the gateway source object to the gateway destination object.
3. If bit MOFCRs.DATC is set, the data bytes stored in the two data registers MODATALs and MODATAHs are copied from the gateway source object to the gateway destination object. All 8 data bytes are copied, even if MOFCRs.DLC indicates less than 8 data bytes.
4. If bit MOFCRs.GDFS is set, the transmit request flag MOSTATd.TXRQ is set in the gateway destination object.
5. The receive pending bit MOSTATd.RXPND and the new data bit MOSTATd.NEWDAT are set in the gateway destination object.
6. A message interrupt request is generated for the gateway destination object if its MOSTATd.RXIE is set.
7. The current object pointer MOFGPRs.CUR of the gateway source object is moved to the next destination object according to the FIFO rules as described on [Page 23-57](#).
A gateway with a single (static) destination object is obtained by setting MOFGPRs.TOP = MOFGPRs.BOT = MOFGPRs.CUR = destination object.

The link from the gateway source object to the gateway destination object works in the same way as the link from a FIFO base to a FIFO slave. This means that a gateway with an integrated destination FIFO may be created; in [Figure 23-23](#), the object on the left is the gateway source object and the message object on the right side is the gateway destination objects.

The gateway operates equivalent for the reception of data frames (source object is receive object, i.e. DIR = 0) as well as for the reception of Remote Frames (source object is transmit object).

Controller Area Network Controller (MultiCAN+)

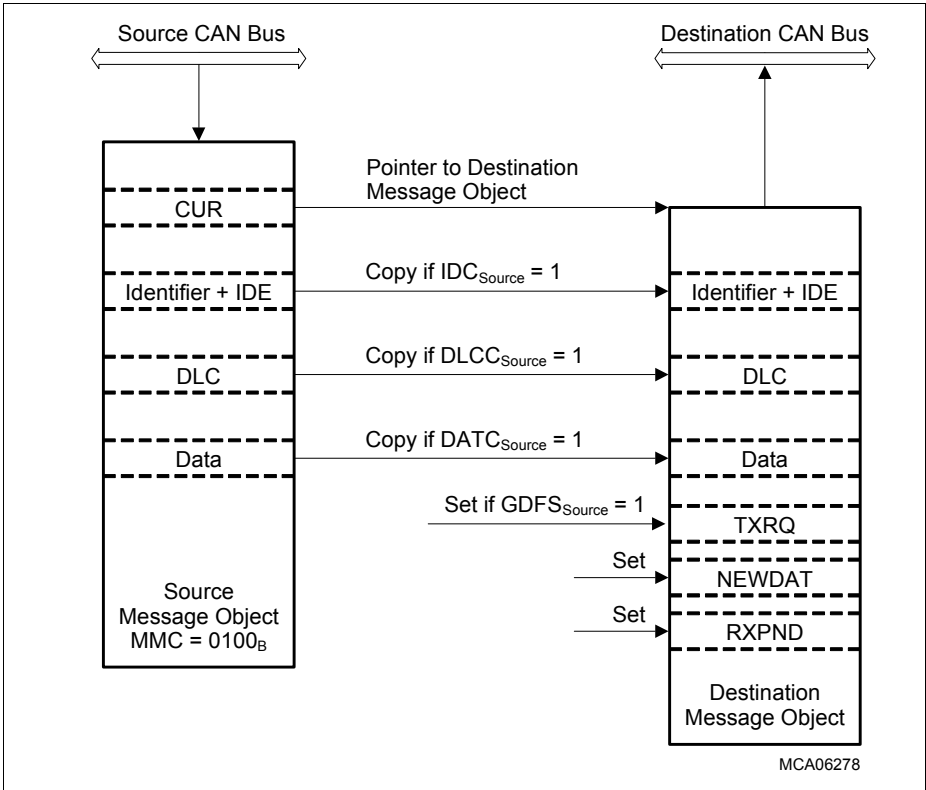

Figure 23-24 Gateway Transfer from Source to Destination

23.4.12.9 Foreign Remote Requests

When a Remote Frame has been received on a CAN node and is stored in a message object, a transmit request is set to trigger the answer (transmission of a Data Frame) to the request or to automatically issue a secondary request. If the Foreign Remote Request Enable bit MOFCRn.FRREN is cleared in the message object in which the remote request is stored, MOSTATn.TXRQ is set in the same message object.

If bit FRREN is set (FRREN = 1: foreign remote request enabled), TXRQ is set in the message object that is referenced by pointer MOFGPRn.CUR. The value of CUR is, however, not changed by this feature.

Although the foreign remote request feature works independently of the selected message mode, it is especially useful for gateways to issue a remote request on the source bus of a gateway after the reception of a remote request on the gateway destination bus. According to the setting of FRREN in the gateway destination object, there are two capabilities to handle remote requests that appear on the destination side (assuming that the source object is a receive object and the destination is a transmit object, i.e. $DIR_{source} = 0$ and $DIR_{destination} = 1$):

FRREN = 0 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway destination object.
3. A Data Frame with the current data stored in the destination object is transmitted on the destination bus.

FRREN = 1 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway source object (must be referenced by CUR pointer of the destination object).
3. A remote request is transmitted by the source object (which is a receive object) on the source CAN bus.
4. The receiver of the remote request responds with a Data Frame on the source bus.
5. The Data Frame is stored in the source object.
6. The Data Frame is copied to the destination object (gateway action).
7. TXRQ is set in the destination object (assuming $GDFS_{source} = 1$).
8. The new data stored in the destination object is transmitted on the destination bus, in response to the initial remote request on the destination bus.

23.4.12.10 CAN FD - 64 byte Messages

In order to support higher than 8 data bytes payload (e.g 64bytes data payload) using current message object structure the data byte buffer (MODATALn and MODATAHn) has to be extended.

Controller Area Network Controller (MultiCAN+)

Thus an additional CAN FD 64 bytes message mode, MOFCR.MMC=5 is added. When CAN FD 64 bytes message mode is selected, additional message objects are used to store the extra data bytes.

The additional message objects used are specified by the pointer on MOFGPR.BOT and MOFGPR.TOP register bits. (i.e those message object registers (MOFCR, MOFGPR, MOIPR, MOAMR, MODATAL, MODATAH and MOAR) are used to store the extra data bytes with their alternate register view on EMOzDATA_n at the same address location. MOCTR is the only register that is not used for data storage it retains its original function.

As an example for a 64 byte message, data bytes 0-7 are stored in the message object, similar to a standard message object, data bytes 8-35 are stored in the message object to which MOFGPR.BOT refers to and data bytes 36-63 are stored in the message object to which MOFGPR.TOP refers to. Data byte 0 refers to the first byte transferred within a CAN frame. For shorter than 64 bytes messages, unused data bytes are padded upon reception and ignored upon transmission.

The additional message objects chosen to store the extra data bytes must not take part in CAN communication i.e either they are allocated to a list that does not belong to an active CAN node or have that particular message object MOCTR register bits MOCTR_n.RXEN, MOCTR_n.TXEN0 (and/or TXEN1, TXRQ) cleared, i.e (RXEN=0, TXEN0=0, TXEN1=0 and TXRQ=0). MOCTR.MSGVAL remains the same, data is stored in the extra message objects when MSGVAL is set. When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.

For optimum performance it is recommended to place the extra message objects outside active CAN node lists, so they do not take part in CAN acceptance filtering.

23.4.13 Measurement for Oscillator Calibration

The chip can be driven by an oscillator which is less accurate than required by the CAN specification, if it is possible to detect the deviation and to change the oscillator frequency during runtime. The MultiCAN module can measure the time interval between the start of a CAN frame and a certain edge on the bus. The timer hardware is accessed via Measurement Control Register MECR (see [Page 23-91](#)) and Measurement Status Register MESTAT (see [Page 23-93](#)).

A 16-bit timer is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node (selected by MECR.NODE). The timer is incremented by the module control clock f_{CLC} . The timer content is captured when an edge specified by MECR.ANYED is detected on the input line of the CAN node. However, the timer must have reached threshold MECR.TH before; so edges occurring earlier cannot cause a capture. Only the first edge after threshold is considered, and the node itself may not be sending. Bit field CAPT in the status register contains the captured timer value, and bit CAPRED indicates the type of edge that caused the capture. On a capture event, bit

Controller Area Network Controller (MultiCAN+)

CAPE in the same register will be set. If bit MECR.CAPEIE = 1, a node interrupt will be generated. With the starting edge of the following CAN frame, a new measurement cycle begins. To avoid an overflow on the measurement and to get a measurement result MESTAT.CAPE bit has to be cleared before the measurement end condition occurs.

To avoid wrong capture results due to timer overflow, the timer will be stopped when $FFFF_H$ is reached. If MECR.TH = 0000_H , the timer is always stopped and the capture function is disabled.

Some important issues should be mentioned:

- The timing of the measured CAN frame should be as exact as possible.
- No unadjusted CAN stations - including the selected MultiCAN node - should participate actively in the communication. The selected node can be set to Analyzer Mode.
- When setting the timer threshold and evaluating the capture result, the tolerances including the oscillator deviation must be considered.
- It may not be possible to use a well-defined CAN message for measurement. Then worst-case-scenarios according to the CAN protocol must be observed. E.g. in a data or remote frame, the first rising (recessive) edge might occur after five bit times, and the next falling one after additional five bit times.
- Also error and overload frames which may lead to unexpected capture results should be taken into account.
- Edges occurring a considerable time after the start of a CAN frame will yield good resolution but may produce ambiguous results if the oscillator is not yet sufficiently adjusted. Therefore, only one step for measurement and calibration may not be sufficient.
- As there is only one oscillator on the chip, its calibration influences the timing of the whole system and particularly the timing of other CAN nodes.

Controller Area Network Controller (MultiCAN+)
23.5 Use Case Example MultiCAN+

This section explains the core functionality of the MultiCAN+ module with a code example. The example realizes sending a CAN message via internal CAN-bus from node 0 to node 1.

The MultiCAN+ module for the TC26x B-Step consists of module (i.e MultiCAN with 5 CAN nodes), representing serial communication interfaces. Each CAN node can either be connected to a port or to the internal CAN bus (see). So a maximum of CAN channels can be realized with the MultiCAN+ module (For more information and further functions see [Section 23.2](#)).

All CAN nodes share a common set of 256 message objects. A message object function like a container for a specific CAN message; both transmitting and receiving of CAN messages can be realized. The message objects are organized in double-chained lists, each list is dedicated to a certain CAN node (list 1 is node 0, list 2 is node 1, etc.). After a reset, all message objects are unallocated and therefore assigned to list 0, this list does not belong to a CAN node. During initialization it is possible to allocate the message objects individually to certain CAN node lists. Each allocated message object can be set up with all necessary information like the message ID etc. (see chapter 26.2 and following for further explanations of the CAN module).

In the use case example CAN node 0 will send a CAN message via internal CAN bus to CAN node 1. The transmitting message object (MO) will be MO 0 and the receiving message object will be MO 1. As soon as the CAN frame successfully receives at MO 1 a receive interrupt will occur. The initialization process follows the following order:

1. Load global MultiCAN+ module registers
2. Initialize the CAN nodes
3. Allocate the message objects to the CAN nodes
4. Initialize the message objects
5. Start the CAN nodes
6. Start transmit request for CAN message from node 0 to node 1.
7. Receive message at node 1, Rx interrupt occurs.

Step description to initialize the MultiCAN+ module:

(Line 1) reset ENDINIT to get access to ENDINIT protected registers. (see also ENDINIT protection chapter 8.9.3(LINK)).

(Line 2) enable control of the module, in clock control register CLC (**CLC**).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) load fractional divider to $f_{CAN} = f_{ASYN_CAN}$ (see also 26.3.2 Clock Control (**Fractional Divider**), f_{ASYN_CAN} see **MCR**).

(Line 5) set ENDINIT to lock the protected register again.

Controller Area Network Controller (MultiCAN+)

(Line 6) set clk source to f_{ASYN_CAN} in module control register MCR(**MCR**).

Note: The reconfiguration of the clk source must be done by two writes and a certain delay between these. See MCR for more details.

(Line 7) The setting of protection CCE[6] and INIT[0] activates the initialization and configuration mode for CAN node 0. This is necessary for the upcoming changes in CAN node 0. (see also node configuration register NCRn (**CAN_NCRx (x = 0-4)**))

(Line 8) This example uses the internal loop-back mode, so this line connects CAN node 0 to the internal CAN Bus. (see also Figure 26-13(**Figure 23-16**) and node port control register NPCR(**CAN_NPCRx (x = 0-4)**))

(Line 9) The CAN bit time is subdivided into different segments. (see also 26.3.6.1 Bit Timing Unit(**Bit Timing Unit**)). Assuming $f_{CAN} = 100\text{MHz}$ this line then sets the baudrate to 500kBaud and the sample point to 80% in the node bit timing register NBTR (**CAN_NBTRx (x = 0-4)**).

Note: The FM PLL should be off. Otherwise a stable CAN communication is not ensured

(Line 10 - 12) same as line 7 - 9 but with node 1.

(Line 13) The allocation of the message objects to certain CAN node lists function via a list command panel. The panel control register PANCTR(**PANCTR**) can only be written if both busy flags are reseted. Therefore this while loop waits until the register is ready.

(Line 14) This line allocates message object 0 to list 1 (belongs to CAN node 0).

(Line 15) see line 13.

(Line 16) This line allocates message object 1 to list 2 (belongs to CAN node 0).

(Line 17) Initialize MO 0 in the message object register MOCTR(**CAN_MOCTRz (z = 0-254)**) as transmit MO by setting bits [27:25]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 18) this line sets the message data length of MO 0 to 8 bytes.(see also message object function control register MOFCR (**CAN_MOFCRn (n = 0-255)**)).

(Line 19) the message ID of MO 0 gets set to standard message (11 bit length) with a message ID of 0xFF in the Message object arbitration register MOAR (**CAN_MOARn (n = 0-255)**).

(Line 20) Initialize MO 1 in the message object register MOCTR as receive MO by setting bit RXEN[23]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 21) the receive interrupt gets enabled in the message object function control register MOFCR .

(Line 22) same as Line 19 but for MO 1. The same message ID is necessary to receive CAN messages from the bus with this specific ID.

(Line 23) the Rx interrupt gets connected to the CAN interrupt output line 1.(see also MOIPR(**CAN_MOIPRn (n = 0-255)**))

Controller Area Network Controller (MultiCAN+)

(Line 24) This line enables the Rx interrupt in the service request control register SRC_CANINT1 and sets the interrupt priority to CAN_SR1INT (1...255)

(Line 25) The interruptHandlerInstall function gets called (this function has to be written first, see interrupt handler example (Chapter 17.10.1) for more details). This function installs the interrupt service routine (ISR) entry address in the interrupt vector array with the priority CAN_SR1INT.

(Line 26) The 4 lower data bytes are getting loaded in the MODATAL(**CAN_MODATALn (n = 0-255)**) register. the data itself is here just an example.

(Line 27) The 4 higher data bytes are getting loaded in the MODATAH(**CAN_MODATAHn (n = 0-255)**) register. (just an data example as well)

(Line 28) This line resets INIT[0] and CCE[6] bit in the node control register from node 0. The node is now synchronizing itself to the bus.

(Line 29) same as line 28, but with node 1.

(Line 30) The NEWDATA bit gets set in the MOCTR register, this should always be done after a write process in the data registers from line 26/27. The transmit request bit TXRQ gets set, this starts the transmission of the CAN message. The RTSEL gets reset to ensure the transmission.

(Line 31) If the message is received the MOCTR.NEWDAT[19] bit in the receive MO 1 is set. This line just waits for the reception. The occurrence of the Rx interrupt can also be used as a proof that the message arrived.

Note: The Rx ISR function prototype would be: void CAN1_Rx_irq (void); here could be your ISR code;

Initialization of the MultiCAN+ module:

```
// Load global MultiCAN+ registers:
(1)  SCU_vResetENDINIT (0);    // enable ENDINIT reg
(2)  CAN_CLC = 0x000;         // disable module control
(3)  dummy = CAN_CLC;        //read to check the made changes
(4)  CAN_FDR = (1 << 14) | 0x3FF;    //DM=1,STEP=1023
(5)  SCU_vSetENDINIT (0);    // lock ENDINIT reg
(6)  CAN_MCR = 0x1;         // CLKSEL=1

//Init CAN nodes 0 and 1:
(7)  CAN_NCR0 = (1 << 6) | 1;    // CCE=1,INIT=1
(8)  CAN_NPCR0 = (1 << 8);    // LBM=1
(9)  CAN_NBTR0 = 0x3EC9;    //set bit segments
(10) CAN_NCR1 = (1 << 6) | 1;    // CCE=1,INIT=1
(11) CAN_NPCR1 = (1 << 8);    // LBM=1
```

Controller Area Network Controller (MultiCAN+)

```

(12) CAN_NBTR1 = 0x3EC9;          //set bit segments
//Allocate message objects to CAN nodes:
(13) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(14) CAN_PANCTR = (1 << 24)|(0 << 16)| 2; // MO 0 to list 1
(15) while(CAN_PANCTR.U & (0x00000100 | 0x00000200)); // busy?
(16) CAN_PANCTR = (2 << 24)|(1 << 16)| 2; // MO 1 to list 2
//Init MO_0 (list 1, node 0)
(17) CAN_MOCTR0 = (1<<27)|(1<<26)|(1<<25)|(1<<21); // set to Tx
(18) CAN_MOFCR0 = (8 << 24);          // DLC=8
(19) CAN_MOAR0 = (1 << 30)|(0xFF << 18); // PRI=01, ID=0xFF
//Init MO_1 (list 2, node 1)
(20) CAN_MOCTR1 = (1 << 23)|(1 << 21); // set to Rx
(21) CAN_MOFCR1 = (1 << 16);          // RXIE=1
(22) CAN_MOAR1 = (1 << 30)|(0xFF << 18); // PRI=01, ID=0xFF
(23) CAN_MOIPR1 = 0x1;              // RXINP=1 -> select INT_01
(24) SRC_CANINT1 = (1 << 10) | CAN_SRN1INT; // enable INT_01
(25) interruptHandlerInstall (CAN_SRN1INT, & CAN1_Rx_irq);
// Load Data, Start CAN nodes
(26) CAN_MODATAL0 = 0x0D0D0D0D; // load data, lower 4 Bytes
(27) CAN_MODATAH0 = 0x0E0E0E0E; // load data, higher 4 Bytes
(28) CAN_NCR0 &= ~(1<<6)| 1; // reset CCE and INIT
(29) CAN_NCR1 &= ~(1<<6)| 1; // reset CCE and INIT
// set transmit request to send message
(30) CAN_MOCTR0 = (1<<24)|(1<<19)|(1<<6); //TXRQ=1,NEWDAT=1
(31) while((CAN_MOSTAT1.B.NEWDAT) != 1); //check if Rx

```

Note: Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):

__enable();

to set this bit. (See also Architecture Manual for more details)

Controller Area Network Controller (MultiCAN+)

23.6 MultiCAN+ Kernel Registers

This section describes the kernel registers of the MultiCAN+ module. All MultiCAN+ kernel register names described in this section are also referenced in other parts of the TC26x B-Step User’s Manual by the module name prefix “CAN_”.

MultiCAN+ Kernel Register Overview

The MultiCAN+ Kernel include three blocks of registers:

- Global Module Registers
- Node Registers, for each CAN node *x*
- Message Object Registers, for each message object *n*

Figure 23-25 MultiCAN+ Kernel Registers

The registers of the MultiCAN+ module kernel are listed below.

Table 23-9 Registers Address Space - MultiCAN+ Kernel Registers

Figure 23-26 MultiCAN+ Register Address Map

23.6.1 Global Module Registers

All list operations such as allocation, de-allocation and relocation of message objects within the list structure are performed via the Command Panel. It is not possible to modify the list structure directly by software by writing to the message objects and the LIST registers.

Module Identification Register.

Controller Area Network Controller (MultiCAN+)

ID

Module Identification Register (008_H) Reset Value: 00B5 C0XX_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number MOD_REV defines the revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type C0 _H Define the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines the MultiCAN+ module identification number (=00B5H)

Controller Area Network Controller (MultiCAN+)

The Panel Control Register PANCTR is used to start a new command by writing the command arguments and the command code into its bit fields.

PANCTR
Panel Control Register
(1C4_H)
Reset Value: 0000 0301_H

Field	Bits	Type	Description
PANCMD	[7:0]	rwh	Panel Command This bit field is used to start a new command by writing a panel command code into it. At the end of a panel command, the NOP (no operation) command code is automatically written into PANCMD. The coding of PANCMD is defined in Table 23-11 .
BUSY	8	rh	Panel Busy Flag 0 _B Panel has finished command and is ready to accept a new command. 1 _B Panel operation is in progress.
RBUSY	9	rh	Result Busy Flag 0 _B No update of PANAR1 and PANAR2 is scheduled by the list controller. 1 _B A list command is running (BUSY = 1) that will write results to PANAR1 and PANAR2, but the results are not yet available.
PANAR1	[23:16]	rwh	Panel Argument 1 See Table 23-11 .
PANAR2	[31:24]	rwh	Panel Argument 2 See Table 23-11 .
0	[15:10]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)
Panel Commands

A panel operation consists of a command code (PANCMD) and up to two panel arguments (PANAR1, PANAR2). Commands that have a return value deliver it to the PANAR1 bit field. Commands that return an error flag deliver it to bit 31 of the Panel Control Register, this means bit 7 of PANAR2.

Table 23-11 Panel Commands

PANCMD	PANAR2	PANAR1	Command Description
00 _H	–	–	No Operation Writing 00 _H to PANCMD has no effect. No new command is started.
01 _H	Result: Bit 7: ERR Bit 6-0: undefined	–	Initialize Lists Run the initialization sequence to reset the CTRL and LIST fields of all message objects. List registers LIST[7:0] are set to their reset values. This results in the de-allocation of all message objects. The initialization command requires that bits NCRx.INIT and NCRx.CCE are set for all CAN nodes. Bit 7 of PANAR2 (ERR) reports the success of the operation: 0 _B Initialization was successful 1 _B Not all NCRx.INIT and NCRx.CCE bits are set. Therefore, no initialization is performed. The initialize lists command is automatically performed with each reset of the MultiCAN+ module, but with the exception that all message object registers are reset, too.
02 _H	Argument: List Index	Argument: Message Object Number	Static Allocate Allocate message object to a list. The message object is removed from the list that it currently belongs to, and appended to the end of the list, given by PANAR2. This command is also used to deallocate a message object. In this case, the target list is the list of unallocated elements (PANAR2 = 0).

Controller Area Network Controller (MultiCAN+)

Table 23-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
03 _H	Argument: List Index Result: Bit 7: ERR Bit 6-0: undefined	Result: Message Object Number	Dynamic Allocate Allocate the first message object of the list of unallocated objects to the selected list. The message object is appended to the end of the list. The message number of the message object is returned in PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty.
04 _H	Argument: Destination Object Number	Argument: Source Object Number	Static Insert Before Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. The source object thus becomes the predecessor of the destination object.
05 _H	Argument: Destination Object Number Result: Bit 7: ERR Bit 6-0: undefined	Result: Object Number of inserted object	Dynamic Insert Before Insert a new message object before a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as a result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty.

Controller Area Network Controller (MultiCAN+)

Table 23-11 Panel Commands (cont'd)

PANCMD	PANAR2	PANAR1	Command Description
06 _H	Argument: Destination Object Number	Argument: Source Object Number	Static Insert Behind Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. The source object thus becomes the successor of the destination object.
07 _H	Argument: Destination Object Number Result: Bit 7: ERR Bit 6-0: undefined	Result: Object Number of inserted object	Dynamic Insert Behind Insert a new message object behind a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty.
08 _H - FF _H	–	–	Reserved

Controller Area Network Controller (MultiCAN+)

The Module Control Register MCR contains basic settings that determine the operation of the MultiCAN+ module.

The write access to the lowest byte of the MCR register is possible only if the CCE bits of all CAN nodes are set (NCRx.CCE bits). The NCRx.INIT bits will be automatically set when the lowest byte of the MCR register is written, independent of the setting of the CCE bits. The INIT bits have to be reset by software in order to activate the CAN nodes.

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write defining the new clock source. Between the first and the second write a delay of $4 / f_A + 2 / f_{CAN}$ number of cycles must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that f_{ASYN_CAN} is selected as the baud rate logic clock (MCR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Note: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.

MCR
Module Control Register
(1C8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLKSEL	[3:0]	rw	Baud Rate Logic Clock Select 0000 _B No clock supplied 0001 _B f_{ASYN_CAN} 0010 _B Oscillator Clock 0100 _B E-Ray clock (f_{ERAY}) 1000 _B hard wired to 0 ... _B not allowed
0	8	rw	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
MPSEL	[15:12]	rw	<p>Message Pending Selector</p> <p>Bit field MPSEL makes it possible to select the bit position of the message pending bit after a message reception/transmission by a mixture of the MOIPRn register bit fields RXINP, TXINP, and MPN. Selection details are given in Figure 23-20 on Page 23-48.</p>
0	[31:16], [11:9],[7:4]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Controller Area Network Controller (MultiCAN+)

The Interrupt Trigger Register ITR is used to trigger interrupt requests on each interrupt output line by software.

MITR

Module Interrupt Trigger Register (1CC_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
IT	[15:0]	w	Interrupt Trigger Writing a 1 to IT[m] (m = 0-15) generates an interrupt request on interrupt output line INT_O[m]. Writing a 0 to IT[m] has no effect. Bit field IT is always read as 0. Multiple interrupt requests can be generated with a single write operation to MITR by writing a 1 to several bit positions of IT.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

List Pointer and List Register

Each CAN node has a list that determines the allocated message objects. Additionally, a list of all unallocated objects is available. Furthermore, general purpose lists are available which are not associated to a CAN node. The List Registers are assigned in the following way:

- LIST0 provides the list of all unallocated objects
- LIST1 provides the list for CAN node 0
- LIST2 provides the list for CAN node 1
- ...
- LIST $\underline{5}$ provides the list for CAN node $\underline{4}$

LIST0

List Register 0 (100_H) **Reset Value: 00FF FF00_H**

LISTn (n = 1-15)

List Register n (100_H+n*4_H) **Reset Value: 0100 0000_H**

Field	Bits	Type	Description
BEGIN	[7:0]	rh	List Begin BEGIN indicates the number of the first message object in list i.
END	[15:8]	rh	List End END indicates the number of the last message object in list i.
SIZE	[23:16]	rh	List Size SIZE indicates the number of elements in the list i. SIZE = number of list elements - 1 SIZE = 0 indicates that list i is empty.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
EMPTY	24	rh	List Empty Indication 0 _B At least one message object is allocated to list i. 1 _B No message object is allocated to the list i. List i is empty.
0	[31:25]	r	Reserved Read as 0.

Controller Area Network Controller (MultiCAN+)

Message Notifications

When a message object n generates an interrupt request upon the transmission or reception of a message, then the request is routed to the interrupt output line selected by the bit field MOIPRn.TXINP or MOIPRn.RXINP of the message object n. As there are more message objects than interrupt output lines, an interrupt routine typically processes requests from more than one message object. Therefore, a priority selection mechanism is implemented in the MultiCAN+ module to select the highest priority object within a collection of message objects.

The Message Pending Register MSPNDk contains the pending interrupt notification of list i.

MSPNDk (k = 0-7)

Message Pending Register k **(140_H+k*4_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
PND	[31:0]	rwh	Message Pending When a message interrupt occurs, the message object sets a bit in one of the MSPND register, where the bit position is given by the MPN[4:0] field of the IPR register of the message object. The register selection n is given by the higher bits of MPN. The register bits can be cleared by software (write 0). Writing a 1 has no effect.

Controller Area Network Controller (MultiCAN+)

Each Message Pending Register has a Message Index Register MSIDk associated with it. The Message Index Register shows the active (set) pending bit with lowest bit position within groups of pending bits.

MSIDk (k = 0-7)
Message Index Register k **(180_H+k*4_H)** **Reset Value: 0000 0020_H**

Field	Bits	Type	Description
INDEX	[5:0]	rh	Message Pending Index The value of INDEX is given by the bit position i of the pending bit of MSPNDk with the following properties: <ol style="list-style-type: none"> MSPNDk[i] & IM[i] = 1 i = 0 or MSPNDk[i-1:0] & IM[i-1:0] = 0 If no bit of MSPNDk satisfies these conditions then INDEX reads 100000 _B . Thus INDEX shows the position of the first pending bit of MSPNDk, in which only those bits of MSPNDk that are selected in the Message Index Mask Register are taken into account.
0	[31:6]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Message Index Mask Register MSIMASK selects individual bits for the calculation of the Message Pending Index. The Message Index Mask Register is used commonly for all Message Pending registers and their associated Message Index registers.

MSIMASK

Message Index Mask Register (1C0_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
IM	[31:0]	rw	Message Index Mask Only those bits in MSPNDk for which the corresponding Index Mask bits are set contribute to the calculation of the Message Index.

Controller Area Network Controller (MultiCAN+)

The Measurement Control Register MECR controls the CAN edge timing measurement function for calibration purposes.

MECR
Measurement Control Register (1D0_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TH	[15:0]	rw	Threshold This bit field contains the threshold value for the measurement timer. If TH = 0000 _H , the timer is stopped and the capture function is disabled.
INP	[19:16]	rw	Interrupt Node Pointer INP selects the interrupt output line INT_O _m (m = 0-15) for a capture event interrupt. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
NODE	[22:20]	rw	Node This bit field determines the CAN node x whose input line RXDCAN _x is used for start and capture of the measurement timer. 000 _B Node 0 001 _B Node 1 ... _B ... 100 _B Node 4

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
ANYED	24	rw	Any Edge This bit enables capture on any edge of CAN input line specified by NODE. 0_B Capture on falling (dominant) edge only 1_B Capture on rising (recessive) or falling (dominant) edge
CAPEIE	25	rw	Capture Event Interrupt Enable This bit enables the capture event interrupt. 0_B Capture event interrupt is disabled 1_B Capture event interrupt is enabled Bit field INP selects the interrupt output line which becomes activated at this type of interrupt.
DEPTH	[29:27]	rw	Digital Glitch Filter Depth DEPTH determines the number of input samples clocked with f_{CLC} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000_B off, default 001_B Filter depth of 8 cycles 010_B Filter depth of 16 cycles 011_B Filter depth of 32 cycles 100_B Filter depth of 64 cycles 101_B Filter depth of 128 cycles 110_B Filter depth of 255 cycles 111_B not allowed, reserved
SOF	30	rw	Start Of Frame This bit selects falling edge or any edge as measurement for start of frame detection. 0_B Measurement starts with any falling edge 1_B Measurement starts with falling Start of Frame edge. i.e any falling edge that occurs while the CAN node is in idle state
0	23, 26, 31	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Measurement Status Register MESTAT contains the status information of the CAN edge timing measurement.

MESTAT

Measurement Status Register (1D4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CAPT	[15:0]	rh	<p>Captured Timer</p> <p>This bit field contains the captured measurement timer content.</p> <p>The timer itself is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node specified by MECR.NODE. The timer is incremented by the module control clock f_{CLC} and will be stopped when FFFF_H is reached. If MECR.TH = 0000_H, the timer is always stopped.</p> <p>A capture will take place if all the following conditions are met:</p> <ol style="list-style-type: none"> MECR.TH > 0000_H Timer is cleared and started by new frame Timer reaches MECR.TH This node is not sending and first edge (as specified by MECR.ANYED) after 3. occurs on input line <p>Capture will be repeated for the following CAN frames until MECR.TH is cleared.</p>
CAPRED	16	rh	<p>Captured Rising Edge</p> <p>This bit indicates the type of edge that caused the last capture event.</p> <p>0_B Capture occurred on falling (dominant) edge</p> <p>1_B Capture occurred on rising (recessive) edge</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
CAPE	17	rwh	Capture Event This flag is set on a capture event. It must be reset by software. 0_B No capture event has occurred since last flag reset 1_B Capture event has occurred since last flag reset An interrupt request is generated if MECR.CAPEIE = 1. If CAPE=1 then no further measurement results are posted to MESTAT.CAPT and MESTAT.CAPRED. CAPE bit has to be cleared to re-enable update of MESTAT.CAPT and MESTAT.CAPRED.
0	[31:18]	r	Reserved Read as 0; should be written with 0.

23.6.2 CAN Node Registers

The CAN node registers are built in for each CAN node of the MultiCAN+ module. They contain information that is directly related to the operation of the CAN nodes and are shared among the nodes.

The Node Control Register contains basic settings that determine the operation of the CAN node.

CAN_NCRx (x = 0-4)
Node x Control Register ($200_H + x * 100_H$) **Reset Value: 0000 0041_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						FD EN	SUS EN	CAL M	CCE	TXDI S	CAN DIS	ALIE	LECI E	TRIE	INIT
r						rw	rw	rw	rw	rw	rw	rw	rw	rw	rwh

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
INIT	0	rwh	<p>Node Initialization</p> <p>0_B Resetting bit INIT enables the participation of the node in the CAN traffic. If the CAN node is in the bus-off state, the ongoing bus-off recovery (which does not depend on the INIT bit) is continued. With the end of the bus-off recovery sequence the CAN node is allowed to take part in the CAN traffic. If the CAN node is not in the bus-off state, a sequence of 11 consecutive recessive bits must be detected before the node is allowed to take part in the CAN traffic.</p> <p>1_B Setting this bit terminates the participation of this node in the CAN traffic. Any ongoing frame transfer is cancelled and the transmit line goes recessive. If the CAN node is in the bus-off state, then the running bus-off recovery sequence is continued. If the INIT bit is still set after the successful completion of the bus-off recovery sequence, i.e. after detecting 128 sequences of 11 consecutive recessive bits (11 × 1), then the CAN node leaves the bus-off state but remains inactive as long as INIT remains set.</p> <p>Bit INIT is automatically set when the CAN node enters the bus-off state (see Page 23-30).</p>
TRIE	1	rw	<p>Transfer Interrupt Enable</p> <p>TRIE enables the transfer interrupt of CAN node x. This interrupt is generated after the successful reception or transmission of a CAN frame in node x.</p> <p>0_B Transfer interrupt is disabled. 1_B Transfer interrupt is enabled.</p> <p>Bit field NIPRx.TRINP selects the interrupt output line which becomes activated at this type of interrupt.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
LECIE	2	rw	<p>LEC Indicated Error Interrupt Enable</p> <p>LECIE enables the last error code interrupt of CAN node x. This interrupt is generated with each hardware update of bit field NSRx.LEC with LEC > 0 (CAN protocol error).</p> <p>0_B Last error code interrupt is disabled. 1_B Last error code interrupt is enabled.</p> <p>Bit field NIPRx.LECINP selects the interrupt output line which becomes activated at this type of interrupt.</p>
ALIE	3	rw	<p>Alert Interrupt Enable</p> <p>ALIE enables the alert interrupt of CAN node x. This interrupt is generated by any one of the following events:</p> <ul style="list-style-type: none"> • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE <p>0_B Alert interrupt is disabled. 1_B Alert interrupt is enabled.</p> <p>Bit field NIPRx.ALINP selects the interrupt output line which becomes activated at this type of interrupt.</p>
CANDIS	4	rw	<p>CAN Disable</p> <p>Setting this bit disables the CAN node. The CAN node first waits until it is bus-idle or bus-off. Then bit NSRx.SUSACK and NCRx.INIT is automatically set, and an alert interrupt is generated if bit ALIE is set.</p>
TXDIS	5	rw	<p>Transmit Disable</p> <p>Setting this bit disables the transmission on CAN node x as soon as bus-idle is reached. Reception and bits in MOSTATn, e.g. TXRQ, will not be influenced.</p>
CCE	6	rw	<p>Configuration Change Enable</p> <p>0_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may only be read. All attempts to modify them are ignored.</p> <p>1_B The Bit Timing Register, the Port Control Register, Error Counter Register and NCRx.FDEN bit may be read and written.</p>

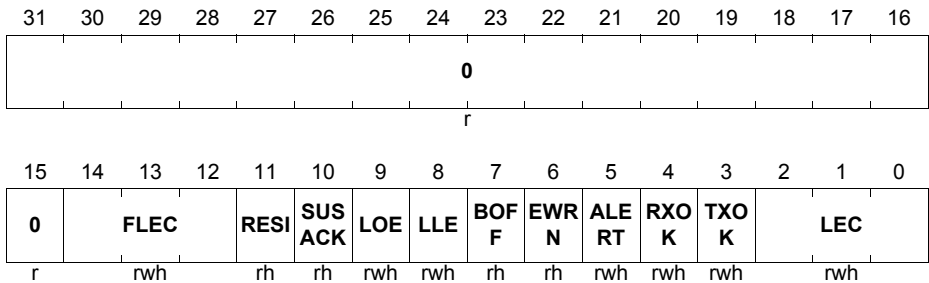

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
CALM	7	rw	<p>CAN Analyzer Mode</p> <p>If this bit is set, then the CAN node operates in Analyzer Mode. This means that messages may be received, but not transmitted. No acknowledge is sent on the CAN bus upon frame reception. Active-error flags are sent recessive instead of dominant. The transmit line is continuously held at recessive (1) level.</p> <p>Bit CALM can be written only while bit INIT is set.</p>
SUSEN	8	rw	<p>Suspend Enable</p> <p>This bit makes it possible to set the CAN node into Suspend Mode via OCDS (on chip debug support):</p> <p>0_B An OCDS suspend trigger is ignored by the CAN node.</p> <p>1_B An OCDS suspend trigger disables the CAN node: As soon as the CAN node becomes bus-idle or bus-off, bit INIT is internally forced to 1 to disable the CAN node. The actual value of bit INIT remains unchanged.</p> <p>Bit SUSEN is reset via OCDS Reset.</p>
FDEN	9	rw	<p>CAN Flexible Data-Rate Enable</p> <p>This bit enables the CAN FD feature:</p> <p>0_B CAN FD disabled. Message transfer for CAN frames using classical CAN Format.</p> <p>1_B CAN FD enabled. Message transfer for CAN frames using CAN FD Format¹⁾.</p> <p>Bit FDEN is protected by CCE and INIT bit. Please see Section 23.4.12.4 and Table 23-18</p>
0	[31:10]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

1) Message transmission in Classical CAN, Long Frame or Long + Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e Able to Receive Classical CAN Format Frames ISO11898-1 Long Frame and Long + Fast CAN FD Frames)

Controller Area Network Controller (MultiCAN+)

The Node Status Register NSRx reports errors as well as successfully transferred CAN frames.

CAN_NSRx (x = 0-4)
Node x Status Register
(204_H+x*100_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
LEC	[2:0]	rwh	Last Error Code This bit field indicates the type of the last (most recent) CAN error. The encoding of this bit field is described in Table 23-12 .
TXOK	3	rwh	Message Transmitted Successfully 0 _B No successful transmission since last (most recent) flag reset. 1 _B A message has been transmitted successfully (error-free and acknowledged by at least another node). TXOK must be reset by software (write 0). Writing 1 has no effect.
RXOK	4	rwh	Message Received Successfully 0 _B No successful reception since last (most recent) flag reset. 1 _B A message has been received successfully. RXOK must be reset by software (write 0). Writing 1 has no effect.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
ALERT	5	rwh	Alert Warning The ALERT bit is set upon the occurrence of one of the following events (the same events which also trigger an alert interrupt if ALIE is set): <ul style="list-style-type: none"> • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE ALERT must be reset by software (write 0). Writing 1 has no effect.
EWRN	6	rh	Error Warning Status 0 _B No warning limit exceeded. 1 _B One of the error counters REC or TEC reached the warning limit EWRNLVL.
BOFF	7	rh	Bus-off Status 0 _B CAN controller is not in the bus-off state. 1 _B CAN controller is in the bus-off state.
LLE	8	rwh	List Length Error 0 _B No List Length Error since last (most recent) flag reset. 1 _B A List Length Error has been detected during message acceptance filtering. The number of elements in the list that belongs to this CAN node differs from the list SIZE given in the list termination pointer. LLE must be reset by software (write 0). Writing 1 has no effect.
LOE	9	rwh	List Object Error 0 _B No List Object Error since last (most recent) flag reset. 1 _B A List Object Error has been detected during message acceptance filtering. A message object with wrong LIST index entry in the Message Object Status Register has been detected. LOE must be reset by software (write 0). Writing 1 has no effect.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
SUSACK	10	rh	Suspend Acknowledge 0 _B The CAN node is not in Suspend Mode or a suspend request is pending, but the CAN node has not yet reached bus-idle or bus-off. 1 _B The CAN node is in Suspend Mode: The CAN node is inactive (bit NCR.INIT internally forced to 1) due to an OCDS suspend request.
RESI	11	rh	Received Error State Indicator Flag This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set. 0 _B Last received CAN FD message did not have its ESI flag set. 1 _B Last received CAN FD message had its ESI flag set.
FLEC	[14:12]	rwh	Fast Last Error Code This bit field indicates the type of the last (most recent) CAN error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. The encoding of this bit field is described in Table 23-12 . This field will be cleared to zero when a CAN FD frame with its BRS flag set has been transferred (reception or transmission) without error.
0	[31:15]	r	Reserved Read as 0; should be written with 0.

Encoding of the LEC Bit field
Table 23-12 Encoding of the LEC Bit field

LEC Value	Signification
000 _B	No Error: No error was detected for the last (most recent) message on the CAN bus.
001 _B	Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
010 _B	Form Error: A fixed format part of a received frame has the wrong format.

Controller Area Network Controller (MultiCAN+)
Table 23-12 Encoding of the LEC Bit field (cont'd)

LEC Value	Signification
011 _B	Ack Error: The transmitted message was not acknowledged by another node.
100 _B	Bit1 Error: During a message transmission, the CAN node tried to send a recessive level (1) outside the arbitration field and the acknowledge slot, but the monitored bus value was dominant.
101 _B	Bit0 Error: Two different conditions are signaled by this code: <ol style="list-style-type: none"> 1. During transmission of a message (or acknowledge bit, active-error flag, overload flag), the CAN node tried to send a dominant level (0), but the monitored bus value was recessive. 2. During bus-off recovery, this code is set each time a sequence of 11 recessive bits has been monitored. The CPU may use this code as indication that the bus is not continuously disturbed.
110 _B	CRC Error: The CRC checksum of the received message was incorrect.
111 _B	CPU write to LEC: Whenever the CPU writes the value 111 to LEC, it takes the value 111. Whenever the CPU writes another value to LEC, the written LEC value is ignored.

Note: When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error. Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate.

Controller Area Network Controller (MultiCAN+)

The five interrupt pointers in the Node Interrupt Pointer Register NIPRx select one out of the sixteen interrupt outputs individually for each type of CAN node interrupt. See also [Page 23-34](#) for more CAN node interrupt details.

CAN_NIPRx (x = 0-4)
Node x Interrupt Pointer Register (208_H+x*100_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ALINP	[3:0]	rw	Alert Interrupt Node Pointer ALINP selects the interrupt output line INT_0m (m = 0-15) for an alert interrupt of CAN Node x. 0000 _B Interrupt output line INT_00 is selected. 0001 _B Interrupt output line INT_01 is selected. ... _B ... 1110 _B Interrupt output line INT_014 is selected. 1111 _B Interrupt output line INT_015 is selected.
LECINP	[7:4]	rw	Last Error Code Interrupt Node Pointer LECINP selects the interrupt output line INT_0m (m = 0-15) for an LEC interrupt of CAN Node x. 0000 _B Interrupt output line INT_00 is selected. 0001 _B Interrupt output line INT_01 is selected. ... _B ... 1110 _B Interrupt output line INT_014 is selected. 1111 _B Interrupt output line INT_015 is selected.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
TRINP	[11:8]	rw	Transfer OK Interrupt Node Pointer TRINP selects the interrupt output line INT_Om (m = 0-15) for a transfer OK interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
CFCINP	[15:12]	rw	Frame Counter Interrupt Node Pointer CFCINP selects the interrupt output line INT_Om (m = 0-15) for a frame counter overflow interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
TEINP	[19:16]	rw	Timer Event Interrupt Node Pointer TEINP selects the interrupt output line INT_Om (m = 0-15) for a timer event interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
0	[31:20]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node Port Control Register NPCRx configures the CAN bus transmit/receive ports. NPCRx can be written only if bit NCRx.CCE is set.

CAN_NPCRx (x = 0-4)
Node x Port Control Register (20C_H+x*100_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RXSEL	[2:0]	rw	Receive Select RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed only through the selected input. <i>Note: In TC26x B-Step, only specific combinations of RXSEL are available (see also “Node Receive Input Selection” on Page 23-166 for description and the page before for RXSEL selections).</i>
LBM	8	rw	Loop-Back Mode 0 _B Loop-Back Mode is disabled. 1 _B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
0	[7:3], [31:9]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node Bit Timing Register NBTRx contains all parameters to set up the bit timing for the CAN transfer. NBTRx can be written only if bit NCRx.CCE is set. Please note that NBTRx is a register with two views, depending on NCRx.FDEN settings different view applies. (i.e When NCRx.FDEN=0, CAN_NBTRx view applies and when NCRx.FDEN=1, CAN_NBTEVRx applies)

CAN_NBTRx (x = 0-4)
Node x Bit Timing Register $(210_H + x * 100_H)$ **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
BRP	[5:0]	rw	Baud Rate Prescaler The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[7:6]	rw	(Re) Synchronization Jump Width (SJW + 1) time quanta are allowed for re-synchronization.
TSEG1	[11:8]	rw	Time Segment Before Sample Point (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
TSEG2	[14:12]	rw	Time Segment After Sample Point (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 7.
DIV8	15	rw	Divide Prescaler Clock by 8 0 _B A time quantum lasts (BRP+1) clock cycles. 1 _B A time quantum lasts 8 × (BRP+1) clock cycles.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node Bit Timing Extended View Register NBTEVRx is applicable only when NCRx.FDEN=1 (CAN FD enabled). NBTEVRx contains all parameters to set up CAN bit timing for Nominal Bit Rate. NBTRx register can be written only if bit NCRx.CCE is set.

CAN_NBTEVRx (x = 0-4)

Node x Bit Timing Extended View Register(210_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
BRP	[5:0]	rw	Baud Rate Prescaler The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1.
SJW	[11:8]	rw	(Re) Synchronization Jump Width (SJW + 1) time quanta are allowed for re-synchronization.
DIV8	15	rw	Divide Prescaler Clock by 8 0 _B A time quantum lasts (BRP+1) clock cycles. 1 _B A time quantum lasts 8 × (BRP+1) clock cycles.
TSEG2	[20:16]	rw	Time Segment After Sample Point (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 31.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
TSEG1	[27:22]	rw	Time Segment Before Sample Point (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 63.
0	[7:6], [14:12], 21, [31:28]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Fast Node Bit Timing Register, FNBTRx contains all parameters to set up CAN bit timing for Data Bit Rate. FNBTRx can be written only if bit NCRx.CCE is set.

CAN_FNBTRx (x = 0-4)
Fast Node x Bit Timing Register (238_H+x*100_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
FBRP	[5:0]	rw	Fast Baud Rate Prescaler The duration of one time quantum is given by (BRP + 1) clock cycles.
FSJW	[7:6]	rw	Fast (Re) Synchronization Jump Width (SJW + 1) time quanta are allowed for re-synchronization.
FTSEG1	[11:8]	rw	Fast Time Segment Before Sample Point (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization.
FTSEG2	[14:12]	rw	Fast Time Segment After Sample Point (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization.
0	[31:15]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Transmitter Delay Compensation Register, TDCRx contains all parameters to setup the Transmitter Delay Compensation Feature and the corresponding status bits. NTDCRx register can be written only if bit NCRx.CCE is set.

CAN_NTDCRx (x = 0-4)
Node x Transmitter Delay Compensation Register
 $(23C_H + x * 100_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
TDCV	[4:0]	r	Transmitter Delay Compensation Value This bit field shows the secondary sample point which is the sum of the measured Transmitter Delay (from CAN Transmit to Receive) and Transmitter Delay compensation offset, NTDCRz.TDCO. Valid values for TDCV are 0 to 31 times of time quanta t_Q .
TDCO	[11:8]	rw	Transmitter Delay Compensation Offset This bit field defines the Transmitter Delay compensation offset that is added to the measured Transmitter Delay (from CAN Transmit to Receive) which forms the secondary sample point. Valid values for TDCO are 0 to 15 times of time quanta t_Q .
TDC	15	rw	Transmitter Delay Compensation Enable This bit enables the Transmitter Delay Compensation feature: 0 _B Transmitter Delay Compensation disabled. 1 _B Transmitter Delay Compensation enabled.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
0	[7:5], [14:12], [31:16]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node Error Counter Register NECNTx contains the CAN receive and transmit error counter as well as some additional bits to ease error analysis. NECNTx can be written only if bit NCRx.CCE is set.

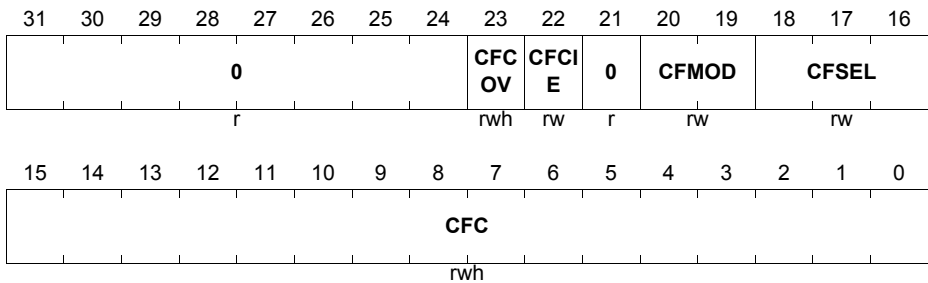

CAN_NECNTx (x = 0-4)
Node x Error Counter Register (214_H+x*100_H) **Reset Value: 0060 0000_H**

Field	Bits	Type	Description
REC	[7:0]	rwh	Receive Error Counter Bit field REC contains the value of the receive error counter of CAN node x.
TEC	[15:8]	rwh	Transmit Error Counter Bit field TEC contains the value of the transmit error counter of CAN node x.
EWRNLVL	[23:16]	rw	Error Warning Level Bit field EWRNLVL determines the threshold value (warning level, default 96) to be reached in order to set the corresponding error warning bit EWRN.
LETD	24	rh	Last Error Transfer Direction 0 _B The last error occurred while the CAN node x was receiver (REC has been incremented). 1 _B The last error occurred while the CAN node x was transmitter (TEC has been incremented).
LEINC	25	rh	Last Error Increment 0 _B The last error led to an error counter increment of 1. 1 _B The last error led to an error counter increment of 8.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
0	[31:26]	r	Reserved Read as 0; should be written with 0.

The Node Frame Counter Register NFCRx contains the actual value of the frame counter as well as control and status bits of the frame counter.

CAN_NFCRx (x = 0-4)
Node x Frame Counter Register (218_H+x*100_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CFC	[15:0]	rwh	CAN Frame Counter In Frame Count Mode (CFMOD = 00 _B), this bit field contains the frame count value. In Time Stamp Mode (CFMOD = 01 _B), this bit field contains the captured bit time count value, captured with the start of a new frame. In all Bit Timing Analysis Modes ¹⁾ (CFMOD = 10 _B), CFC always displays the number of f_{CAN} clock cycles (measurement result) minus 1. Example: a CFC value of 34 in measurement mode CFSEL = 000 _B means that 35 f_{CAN} clock cycles have been elapsed between the most recent two dominant edges on the receive input. In Error Count Mode (CFMOD = 11 _B), this bit field contains the total amount of error frames received or error detected by the node.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
CFSEL	[18:16]	rw	<p>CAN Frame Count Selection</p> <p>This bit field selects the function of the frame counter for the chosen frame count mode.</p> <p>Frame Count Mode</p> <p>Bit 0 If Bit 0 of CFSEL is set, then CFC is incremented each time a foreign frame (i.e. a frame not matching to a message object) has been received on the CAN bus.</p> <p>Bit 1 If Bit 1 of CFSEL is set, then CFC is incremented each time a frame matching to a message object has been received on the CAN bus.</p> <p>Bit 2 If Bit 2 of CFSEL is set, then CFC is incremented each time a frame has been transmitted successfully by the node.</p> <p>Time Stamp Mode</p> <p>The frame counter is incremented (internally) at the beginning of a new bit time. The value is sampled during the SOF bit of a new frame. The sampled value is visible in the CFC field.</p> <p>Bit Timing Mode</p> <p>The available bit timing measurement modes are shown in Table 23-13. If CFCIE is set, then an interrupt on request node x (where x is the CAN node number) is generated with a CFC update.</p> <p>Error Count Mode</p> <p>The frame counter is incremented when an error frame is received or an error is detected by the node. (001_B to 110_B) (see Table 23-12 for Encoding of the LEC Bit field).</p>
CFMOD	[20:19]	rw	<p>CAN Frame Counter Mode</p> <p>This bit field determines the operation mode of the frame counter.</p> <p>00_B Frame Count Mode: The frame counter is incremented upon the reception and transmission of frames.</p> <p>01_B Time Stamp Mode: The frame counter is used to count bit times.</p> <p>10_B Bit Timing Mode: The frame counter is used for analysis of the bit timing.</p> <p>11_B Error Count Mode: The frame counter is used for counting when an error frame is received or an error is detected by the node.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
CFCIE	22	rw	CAN Frame Count Interrupt Enable CFCIE enables the CAN frame counter overflow interrupt of CAN node x. 0 _B CAN frame counter overflow interrupt is disabled. 1 _B CAN frame counter overflow interrupt is enabled. Bit field NIPRx.CFCINP selects the interrupt output line that is activated at this type of interrupt.
CFCOV	23	rwh	CAN Frame Counter Overflow Flag Flag CFCOV is set upon a frame counter overflow (transition from FFFF _H to 0000 _H). In bit timing analysis mode, CFCOV is set upon an update of CFC. An interrupt request is generated if CFCIE = 1. 0 _B No overflow has occurred since last flag reset. 1 _B An overflow has occurred since last flag reset. CFCOV must be reset by software.
0	21, [31:24]	r	Reserved Read as 0; should be written with 0.

1) The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set.

Bit Timing Analysis Modes
Table 23-13 Bit Timing Analysis Modes (CFMOD = 10)

CFSEL	Measurement
000 _B	Whenever a dominant edge (transition from 1 to 0) is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
001 _B	Whenever a recessive edge (transition from 0 to 1) is monitored on the receive input the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC.
010 _B	Whenever a dominant edge is received as a result of a transmitted dominant edge, the time (clock cycles) between both edges is stored in CFC.
011 _B	Whenever a recessive edge is received as a result of a transmitted recessive edge, the time (clock cycles) between both edges is stored in CFC.
100 _B	Whenever a dominant edge that qualifies for synchronization is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent sample point is stored in CFC.

Controller Area Network Controller (MultiCAN+)
Table 23-13 Bit Timing Analysis Modes (CFMOD = 10) (cont'd)

CFSEL	Measurement
101 _B	<p>With each sample point, the time (measured in clock cycles) between the start of the new bit time and the start of the previous bit time is stored in CFC[11:0].</p> <p>Additional information is written to CFC[15:12] at each sample point: CFC[15]: Transmit value of actual bit time CFC[14]: Receive sample value of actual bit time CFC[13:12]: CAN bus information (see Table 23-14)</p>
110 _B	Reserved, do not use this combination.
111 _B	Reserved, do not use this combination.

Table 23-14 CAN Bus State Information

CFC[13:12]	CAN Bus State
00 _B	<p>NoBit</p> <p>The CAN bus is idle, performs bit (de-) stuffing or is in one of the following frame segments: SOF, SRR, CRC, delimiters, first 6 EOF bits, IFS.</p>
01 _B	<p>NewBit</p> <p>This code represents the first bit of a new frame segment. The current bit is the first bit in one of the following frame segments: Bit 10 (MSB) of standard ID (transmit only), RTR, reserved bits, IDE, DLC(MSB), bit 7 (MSB) in each data byte and the first bit of the ID extension.</p>
10 _B	<p>Bit</p> <p>This code represents a bit inside a frame segment with a length of more than one bit (not the first bit of those frame segments that is indicated by NewBit). The current bit is processed within one of the following frame segments: ID bits (except first bit of standard ID for transmission and first bit of ID extension), DLC (3 LSB) and bits 6-0 in each data byte.</p>
11 _B	<p>Done</p> <p>The current bit is in one of the following frame segments: Acknowledge slot, last bit of EOF, active/passive-error frame, overload frame. Two or more directly consecutive Done codes signal an Error Frame.</p>

Controller Area Network Controller (MultiCAN+)

The Node x Timer Clock Control, Node x Timer Receive Timeout and Node x Timer A/B/C Transmit Trigger Registers offer additional timing functions for the node.

The Node x Timer Clock Control Register NTCCR_x controls the functions of the node timer.

CAN_NTCCR_x (x = 0-4)
Node x Timer Clock Control Register (21C_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[7:0]	r	Reserved Read as 0; should be written with 0.
TPSC	[11:8]	rw	Timer Prescaler The duration of one timer clock is given by (TPSC + 1) CAN bit times for all NTCCR _x .TRIGSRC settings.
0	[17:12]	r	Reserved Read as 0; should be written with 0.
TRIGSRC	[20:18]	rw	Trigger Source This bit selects the trigger source for the different modes in the node timer. 000 _B Node x Timer is decremented per f_{CLC} timing to 0. 001 _B System Timer (STM) trigger event enabled. Node x Timer is decremented per STM trigger event prescaled by (TPSC + 1). 010 _B General Timer (GTM) trigger event enabled. Node x Timer is decremented per GTM trigger event prescaled by (TPSC + 1). 011 _B Reserved, do not use. ... _B ... 111 _B Reserved, do not use.

Controller Area Network Controller (MultiCAN+)

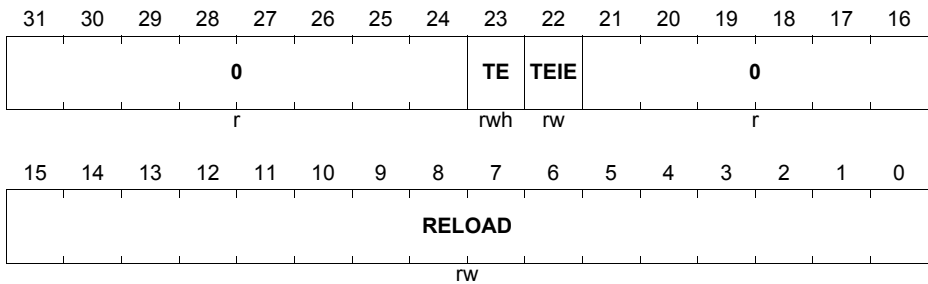

Field	Bits	Type	Description
0	[31:21]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node x Timer Receive Timeout Register NTRTx controls the node timing functions for Receive Timeout Mode.

CAN_NTRTRx (x = 0-4)

Node x Timer Receive Timeout Register (220_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELOAD	[15:0]	rw	Reload Value This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
0	[21:16]	r	Reserved Read as 0; should be written with 0.
TEIE	22	rw	Timer Event Interrupt Enable This bit enables the node timer event interrupt of CAN node x. 0 _B Timer event interrupt is disabled 1 _B Timer event interrupt is enabled Bit field NIPRx.TEINP selects the interrupt output line which becomes activated at this type of interrupt.
TE	23	rwh	Timer Event This flag is set on a node timer transition from 1 to 0 in Receive Timeout Mode. This bit must be reset (i.e Write to '0') by software, writing a '1' has no effect. 0 _B No timer event has occurred since last flag reset 1 _B Timer event has occurred since last flag reset An interrupt request is generated if TEIE = 1.
0	[31:24]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node x Timer A Transmit Trigger Register NTATTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTATTRx (x = 0-4)

Node x Timer A Transmit Trigger Register (224_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELOAD	[15:0]	rw	Reload Value This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	Transmit Message Object On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTATTRx.START timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTATTR.START=0 2) Program NTATTR.TXMO with new value
STRT	24	rw	Timer Start This bit field controls the operation of the timer. 0 _B Timer is stopped. 1 _B Timer is started.
0	[31:25]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node x Timer B Transmit Trigger Register NTBTTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTBTTRx (x = 0-4)

Node x Timer B Transmit Trigger Register (228_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELOAD	[15:0]	rw	Reload Value This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	Transmit Message Object On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTBTTRx.START timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTBTTRx.START=0 2) Program NTBTTRx.TXMO with new value
STRT	24	rw	Timer Start This bit field controls the operation of the timer. 0 _B Timer is stopped. 1 _B Timer is started.
0	[31:25]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

The Node x Timer C Transmit Trigger Register NTCTTx controls the node timing functions for Transmit Trigger Mode.

CAN_NTCTTRx (x = 0-4)

Node x Timer C Transmit Trigger Register (22C_H+x*100_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RELOAD	[15:0]	rw	Reload Value This bit field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	[23:16]	rw	Transmit Message Object On a transmit trigger event selected by bit TRIGSRC, the transmit request bit MOSTATn.TXRQ of message object number n will be set. Note: The NTCTTRx.START timer has to be stopped before a new value can be programmed into TXMO, i.e 1) Program NTCTTR.START=0 2) Program NTCTTR.TXMO with new value
STRT	24	rw	Timer Start This bit field controls the operation of the timer. 0 _B Timer is stopped. 1 _B Timer is started.
0	[31:25]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

23.6.3 Message Object Registers

The Message Object Control Register MOCTR_n and the Message Object Status Register MOSTAT_n are located at the same address offset within a message object address block (offset address 1C_H). The MOCTR_n is a write-only register that makes it possible to set/reset CAN transfer related control bits through software. Therefore the reset value is written as 0x0, even though the read part of the register has a different reset value.

CAN_MOCTR_z (z = 0-254)

Message Object z Control Register(101C_H+z*20_H)

Reset Value: 00000000_H

CAN_MOCTR255

Message Object 255 Control Register(FFC_H)

Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				SET DIR	SET TXE N1	SET TXE N0	SET TXR Q	SET RXE N	SET RTS EL	SET MSG VAL	SET MSG LST	SET NEW DAT	SET RXU PD	SET TXP ND	SET RXP ND
w				w	w	w	w	w	w	w	w	w	w	w	w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

w				w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RESRXPND, SETRXPND	0, 16	w	Reset/Set Receive Pending These bits control the set/reset condition for RXPND (see Table 23-15).
RESTXPND, SETTXPND	1, 17	w	Reset/Set Transmit Pending These bits control the set/reset condition for TXPND (see Table 23-15).
RESRXUPD, SETRXUPD	2, 18	w	Reset/Set Receive Updating These bits control the set/reset condition for RXUPD (see Table 23-15).
RESNEWDAT, SETNEWDAT	3, 19	w	Reset/Set New Data These bits control the set/reset condition for NEWDAT (see Table 23-15).

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
RESMSGST, SETMSGST	4, 20	w	Reset/Set Message Lost These bits control the set/reset condition for MSGST (see Table 23-15).
RESMSGVAL, SETMSGVAL	5, 21	w	Reset/Set Message Valid These bits control the set/reset condition for MSGVAL (see Table 23-15).
RESRTSEL, SETRTSEL	6, 22	w	Reset/Set Receive/Transmit Selected These bits control the set/reset condition for RTSEL (see Table 23-15).
RESRXEN, SETRXEN	7, 23	w	Reset/Set Receive Enable These bits control the set/reset condition for RXEN (see Table 23-15).
RESTXRQ, SETTXRQ	8, 24	w	Reset/Set Transmit Request These bits control the set/reset condition for TXRQ (see Table 23-15).
RESTXEN0, SETTXEN0	9, 25	w	Reset/Set Transmit Enable 0 These bits control the set/reset condition for TXEN0 (see Table 23-15).
RESTXEN1, SETTXEN1	10, 26	w	Reset/Set Transmit Enable 1 These bits control the set/reset condition for TXEN1 (see Table 23-15).
RESDIR, SETDIR	11, 27	w	Reset/Set Message Direction These bits control the set/reset condition for DIR (see Table 23-15).
0	[15:12], [31:28]	w	Reserved Should be written with 0.

Table 23-15 Reset/Set Conditions for Bits in Register MOCTRn

RESy Bit ¹⁾	SETy Bit	Action on Write
Write 0	Write 0	Leave element unchanged
	No write	
No write	Write 0	
Write 1	Write 1	

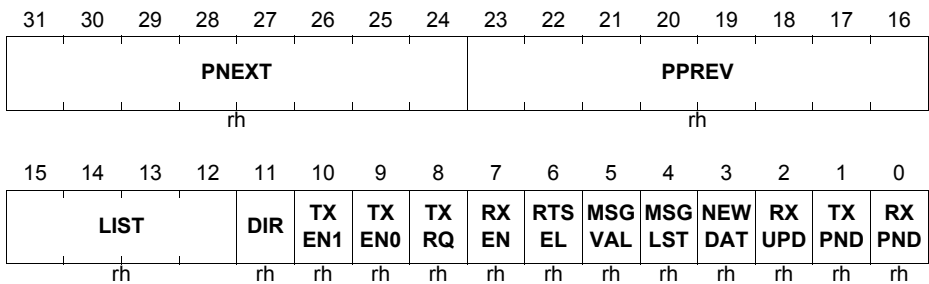

Controller Area Network Controller (MultiCAN+)
Table 23-15 Reset/Set Conditions for Bits in Register MOCTRn (cont'd)

RESy Bit¹⁾	SETy Bit	Action on Write
Write 1	Write 0	Reset element
	No write	
Write 0	Write 1	Set element
No write		

1) The parameter “y” stands for the second part of the bit name (“RXPND”, “TXPND”, ... up to “DIR”).

Controller Area Network Controller (MultiCAN+)

The MOSTATn is a read-only register that indicates message object list status information such as the number of the current message object predecessor and successor message object, as well as the list number to which the message object is assigned.

CAN_MOSTAT0
Message Object 0 Status Register (101C_H)
Reset Value: 0100 0000_H
CAN_MOSTATn (n = 1-254)
Message Object n Status Register(101C_H+n*20_H)
Reset Value: ((n+1)*01000000_H)+((n-1)*00010000_H)
CAN_MOSTAT255
Message Object 255 Status Register (2FFC_H)
Reset Value: FFFE0000_H

Field	Bits	Type	Description
RXPND	0	rh	Receive Pending 0 _B No CAN message has been received. 1 _B A CAN message has been received by the message object n, either directly or via gateway copy action. RXPND is set by hardware and must be reset by software.
TXPND	1	rh	Transmit Pending 0 _B No CAN message has been transmitted. 1 _B A CAN message from message object n has been transmitted successfully over the CAN bus. TXPND is set by hardware and must be reset by software.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
RXUPD	2	rh	Receive Updating 0 _B No receive update ongoing. 1 _B Message identifier, DLC, and data of the message object are currently updated.
NEWDAT	3	rh	New Data 0 _B No update of the message object n since last flag reset. 1 _B Message object n has been updated. NEWDAT is set by hardware after a received CAN frame has been stored in message object n. NEWDAT is cleared by hardware when a CAN transmission of message object n has been started. NEWDAT should be set by software after the new transmit data has been stored in message object n to prevent the automatic reset of TXRQ at the end of an ongoing transmission.
MSGLST	4	rh	Message Lost 0 _B No CAN message is lost. 1 _B A CAN message is lost because NEWDAT has become set again when it has already been set.
MSGVAL	5	rh	Message Valid 0 _B Message object n is not valid. 1 _B Message object n is valid. Only a valid message object takes part in CAN transfers.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
RTSEL	6	rh	<p>Receive/Transmit Selected</p> <p>0_B Message object n is not selected for receive or transmit operation.</p> <p>1_B Message object n is selected for receive or transmit operation.</p> <p>Frame Reception: RTSEL is set by hardware when message object n has been identified for storage of a CAN frame that is currently received. Before a received frame becomes finally stored in message object n, a check is performed to determine if RTSEL is set. Thus the CPU can suppress a scheduled frame delivery to this message object n by clearing RTSEL by software.</p> <p>Frame Transmission: RTSEL is set by hardware when message object n has been identified to be transmitted next. A check is performed to determine if RTSEL is still set before message object n is actually set up for transmission and bit NEWDAT is cleared. It is also checked that RTSEL is still set before its message object n is verified due to the successful transmission of a frame. RTSEL needs to be checked only when the context of message object n changes, and a conflict with an ongoing frame transfer shall be avoided. In all other cases, RTSEL can be ignored. RTSEL has no impact on message acceptance filtering. RTSEL is not cleared by hardware.</p>
RXEN	7	rh	<p>Receive Enable</p> <p>0_B Message object n is not enabled for frame reception.</p> <p>1_B Message object n is enabled for frame reception.</p> <p>RXEN is evaluated for receive acceptance filtering only.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
TXRQ	8	rh	<p>Transmit Request</p> <p>0_B No transmission of message object n is requested.</p> <p>1_B Transmission of message object n on the CAN bus is requested.</p> <p>The transmit request becomes valid only if TXRQ, TXEN0, TXEN1 and MSGVAL are set. TXRQ is set by hardware if a matching Remote Frame has been received correctly. TXRQ is reset by hardware if message object n has been transmitted successfully and NEWDAT is not set again by software.</p>
TXEN0	9	rh	<p>Transmit Enable 0</p> <p>0_B Message object n is not enabled for frame transmission.</p> <p>1_B Message object n is enabled for frame transmission.</p> <p>Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set.</p> <p>The user may clear TXEN0 in order to inhibit the transmission of a message that is currently updated, or to disable automatic response of Remote Frames.</p>
TXEN1	10	rh	<p>Transmit Enable 1</p> <p>0_B Message object n is not enabled for frame transmission.</p> <p>1_B Message object n is enabled for frame transmission.</p> <p>Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set.</p> <p>TXEN1 is used by the MultiCAN+ module for selecting the active message object in the Transmit FIFOs.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
DIR	11	rh	Message Direction 0_B Receive Object selected: With TXRQ = 1, a Remote Frame with the identifier of message object n is scheduled for transmission. On reception of a Data Frame with matching identifier, the message is stored in message object n. 1_B Transmit Object selected: If TXRQ = 1, message object n is scheduled for transmission of a Data Frame. On reception of a Remote Frame with matching identifier, bit TXRQ is set.
LIST	[15:12]	rh	List Allocation LIST indicates the number of the message list to which message object n is allocated. LIST is updated by hardware when the list allocation of the object is modified by a panel command.
PPREV	[23:16]	rh	Pointer to Previous Message Object PPREV holds the message object number of the previous message object in a message list structure.
PNEXT	[31:24]	rh	Pointer to Next Message Object PNEXT holds the message object number of the next message object in a message list structure.

Table 23-16 MOSTATn Reset Values

Message Object	PNEXT	PPREV	Reset Value
0	1	0	0100 0000 _H
1	2	0	0200 0000 _H
2	3	1	0301 0000 _H
3	4	2	0402 0000 _H
...
<u>255</u>	<u>255</u>	<u>254</u>	<u>FFFE</u> 0000 _H

The Message Object Interrupt Pointer Register MOIPRn holds the message interrupt pointers, the message pending number, and the frame counter value of message object n.

Controller Area Network Controller (MultiCAN+)
CAN_MOIPRn (n = 0-255)
Message Object n Interrupt Pointer Register
(1008_H+n*20_H)
Reset Value: 0000 0000_H

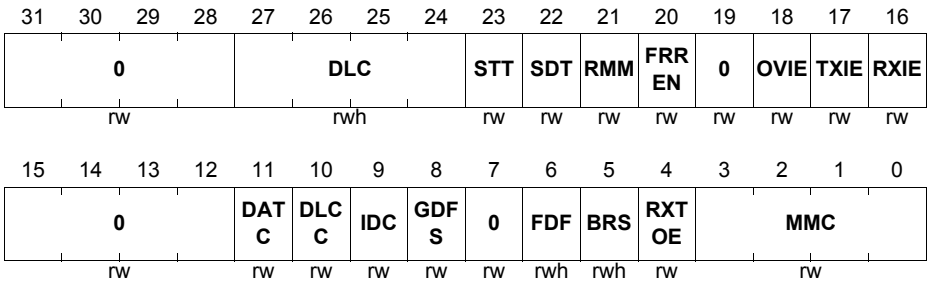

Field	Bits	Type	Description
RXINP	[3:0]	rw	Receive Interrupt Node Pointer RXINP selects the interrupt output line INT_Om (m = 0-15) for a receive interrupt event of message object n. RXINP can also be taken for message pending bit selection (see Page 23-48). 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
TXINP	[7:4]	rw	Transmit Interrupt Node Pointer TXINP selects the interrupt output line INT_Om (m = 0-15) for a transmit interrupt event of message object n. TXINP can also be taken for message pending bit selection (see Page 23-48). 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... _B ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected.
MPN	[15:8]	rw	Message Pending Number This bit field selects the bit position of the bit in the Message Pending Register that is set upon a message object n receive/transmit interrupt.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
CFCVAL	[31:16]	rwh	CAN Frame Counter Value When a message is stored in message object n or message object n has been successfully transmitted, the CAN frame counter value NFCRx.CFC is then copied to CFCVAL.

Controller Area Network Controller (MultiCAN+)

The Message Object Function Control Register MOFCR_n contains bits that select and configure the function of the message object. It also holds the CAN data length code.

CAN_MOFCR_n (n = 0-255)
Message Object n Function Control Register
(1000_H+n*20_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
MMC	[3:0]	rw	Message Mode Control MMC controls the message mode of message object n. 0000 _B Standard Message Object 0001 _B Receive FIFO Base Object 0010 _B Transmit FIFO Base Object 0011 _B Transmit FIFO Slave Object 0100 _B Gateway Source Object 0101 _B CANFD 64 bytes Message Mode ... _B ... 1111 _B Do not use
RXTOE	4	rw	Receive Time-Out Enable RXTOE enables participation of message in receive time-out check which is performed via a Timer controlled by the register NTRTR of the corresponding node. 0 _B Message does not take part in receive time-out check 1 _B Message takes part in receive time-out check Applicable to receive messages and to transmit messages waiting for remote frames.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
BRS	5	rwh	Bit Rate Switch 0 _B Message Object transmission/reception without bit rate switching. 1 _B Message Object transmission/reception with bit rate switching. Please see Section 23.4.12.4 and Table 23-18
FDf	6	rwh	CAN FD Frame Format 0 _B Message Object transmission/reception in Classical CAN Frame Format. 1 _B Message Object transmission/reception in CAN FD Format (new DLC coding and CRC) Please see Section 23.4.12.4 and Table 23-18
GDFS	8	rw	Gateway Data Frame Send 0 _B TXRQ is unchanged in the destination object. 1 _B TXRQ is set in the gateway destination object after the internal transfer from the gateway source to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
IDC	9	rw	Identifier Copy 0 _B The identifier of the gateway source object is not copied. 1 _B The identifier of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.
DLCC	10	rw	Data Length Code Copy 0 _B Data length code is not copied. 1 _B Data length code of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
DATC	11	rw	<p>Data Copy</p> <p>0_B Data fields are not copied.</p> <p>1_B Data fields in registers MODATALn and MODATAHn of the gateway source object (after storing the received frame in the source) are copied to the gateway destination.</p> <p>Applicable only to a gateway source object; ignored in other nodes.</p>
RXIE	16	rw	<p>Receive Interrupt Enable</p> <p>RXIE enables the message receive interrupt of message object n. This interrupt is generated after reception of a CAN message (independent of whether the CAN message is received directly or indirectly via a gateway action).</p> <p>0_B Message receive interrupt is disabled.</p> <p>1_B Message receive interrupt is enabled.</p> <p>Bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt.</p>
TXIE	17	rw	<p>Transmit Interrupt Enable</p> <p>TXIE enables the message transmit interrupt of message object n. This interrupt is generated after the transmission of a CAN message.</p> <p>0_B Message transmit interrupt is disabled.</p> <p>1_B Message transmit interrupt is enabled.</p> <p>Bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
OVIE	18	rw	<p>Overflow Interrupt Enable</p> <p>OVIE enables the FIFO full interrupt of message object n. This interrupt is generated when the pointer to the current message object (CUR) reaches the value of SEL in the FIFO/Gateway Pointer Register.</p> <p>0_B FIFO full interrupt is disabled. 1_B FIFO full interrupt is enabled.</p> <p>If message object n is a Receive FIFO base object, bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. If message object n is a Transmit FIFO base object, bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. For all other message object modes, bit OVIE has no effect.</p>
FRREN	20	rw	<p>Foreign Remote Request Enable</p> <p>Specifies whether the TXRQ bit is set in message object n or in a foreign message object referenced by the pointer CUR.</p> <p>0_B TXRQ of message object n is set on reception of a matching Remote Frame. 1_B TXRQ of the message object referenced by the pointer CUR is set on reception of a matching Remote Frame.</p>
RMM	21	rw	<p>Transmit Object Remote Monitoring</p> <p>0_B Remote monitoring is disabled: Identifier, IDE bit, and DLC of message object n remain unchanged upon the reception of a matching Remote Frame. 1_B Remote monitoring is enabled: Identifier, IDE bit, and DLC of a matching Remote Frame are copied to transmit object n in order to monitor incoming Remote Frames. Bit RMM applies only to transmit objects and has no effect on receive objects.</p>

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
SDT	22	rw	<p>Single Data Transfer</p> <p>If SDT = 1 and message object n is not a FIFO base object, then MSGVAL is reset when this object has taken part in a successful data transfer (receive or transmit).</p> <p>If SDT = 1 and message object n is a FIFO base object, then MSGVAL is reset when the pointer to the current object CUR reaches the value of SEL in the FIFO/Gateway Pointer Register.</p> <p>With SDT = 0, bit MSGVAL is not affected.</p>
STT	23	rw	<p>Single Transmit Trial</p> <p>If this bit is set, then TXRQ is cleared on transmission start of message object n. Thus, no transmission retry is performed in case of transmission failure.</p>
DLC	[27:24]	rwh	<p>Data Length Code</p> <p>Bit field determines the number of data bytes for message object n.</p> <p>In Classical CAN Format: A value of DLC > 8 results in a data length of 8 data bytes. If a frame with DLC > 8 is received, the received value is stored in the message object.</p> <p>In CAN FD format, valid values for DLC are 0 to 15. See Table 23-17</p>
0	7, [15:12], 19, [31:28]	rw	<p>Reserved</p> <p>Read as 0 after reset; value last written is read back; should be written with 0.</p>

Coding of DLC in CAN FD
Table 23-17 Coding of DLC in CAN FD

DLC Value	Description
0000 _B	0 Data Byte for Message Object n.
... _B	...
1000 _B	8 Data Byte for Message Object n.
1001 _B	12 Data Byte for Message Object n.
1010 _B	16 Data Byte for Message Object n.

Controller Area Network Controller (MultiCAN+)
Table 23-17 Coding of DLC in CAN FD (cont'd)

DLC Value	Description
1011 _B	20 Data Byte for Message Object n.
1100 _B	24 Data Byte for Message Object n.
1101 _B	32 Data Byte for Message Object n.
1110 _B	48 Data Byte for Message Object n.
1111 _B	64 Data Byte for Message Object n.

CAN FD Transmit And Receive Behavior

Message transmission and reception behavior of CAN data frames is summarized at **Table 23-18** below.

Table 23-18 CAN FD Transmit And Receive Behavior

FDEN	FDF¹⁾	BRS¹⁾	Transmit Behavior
0 _B	0 _B	0 _B	Classical CAN Frames (ISO 11898-1)
0 _B	0 _B	1 _B	Classical CAN Frames (ISO 11898-1)
0 _B	1 _B	0 _B	Transmission Cancelled ²⁾ (i.e TXRQ bit cleared)
0 _B	1 _B	1 _B	Transmission Cancelled ²⁾ (i.e TXRQ bit cleared)
1 _B	0 _B	0 _B	Classical CAN Frames (ISO 11898-1)
1 _B	0 _B	1 _B	Classical CAN Frames (ISO 11898-1)
1 _B	1 _B	0 _B	Long Frame (i.e CAN FD frame with BRS = 0, whole frame transmitted with slow baudrate)
1 _B	1 _B	1 _B	Long + Fast Frame (i.e CAN FD frame with BRS = 1, switching fast baudrate for dataphase)
FDEN	FDF³⁾	BRS³⁾	Receive Behavior⁴⁾
0 _B	0/1 _B	0/1 _B	- Classical CAN Frames
1 _B	0/1 _B	0/1 _B	- Classical CAN Frames - Long Frames - Long + Fast Frames

1) User writes

2) TXRQ in message object is cleared upon transmit setup and transmit setup cancelled. CAN node is not blocked and able to transmit other message objects.

3) Hardware writes

4) Please note that Remote Frames Request do not change BRS and FDF bits.

Controller Area Network Controller (MultiCAN+)

The Message Object FIFO/Gateway Pointer register MOFGPRn contains a set of message object link pointers that are used for FIFO and gateway operations.

CAN_MOFGPRn (n = 0-255)
Message Object n FIFO/Gateway Pointer Register
 $(1004_H + n * 20_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
BOT	[7:0]	rw	Bottom Pointer Bit field BOT points to the first element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 8-35 are stored in the message object.
TOP	[15:8]	rw	Top Pointer Bit field TOP points to the last element in a FIFO structure. Or in the case when MOFCR.MMC=5, CAN FD 64 bytes message mode, BOT points to where Data bytes 36-63 are stored in the message object.
CUR	[23:16]	rwh	Current Object Pointer Bit field CUR points to the actual target object within a FIFO/Gateway structure. After a FIFO/gateway operation CUR is updated with the message number of the next message object in the list structure (given by PNEXT of the Message Object Status Register) until it reaches the FIFO top element (given by TOP) when it is reset to the bottom element (given by BOT).

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
SEL	[31:24]	rw	Object Select Pointer Bit field SEL is the second (software) pointer to complement the hardware pointer CUR in the FIFO structure. SEL is used for monitoring purposes (FIFO interrupt generation).

Controller Area Network Controller (MultiCAN+)

Message Object n Acceptance Mask Register MOAMRn contains the mask bits for the acceptance filtering of the message object n.

CAN_MOAMRn (n = 0-255)
Message Object n Acceptance Mask Register
 $(100C_H + n * 20_H)$
Reset Value: 3FFF FFFF_H

Field	Bits	Type	Description
AM	[28:0]	rw	Acceptance Mask for Message Identifier Bit field AM is the 29-bit mask for filtering incoming messages with standard identifiers (AM[28:18]) or extended identifiers (AM[28:0]). For standard identifiers, bits AM[17:0] are “don’t care”.
MIDE	29	rw	Acceptance Mask Bit for Message IDE Bit 0 _B Message object n accepts the reception of both, standard and extended frames. 1 _B Message object n receives frames only with matching IDE bit.
0	[31:30]	rw	Reserved Read as 0 after reset; value last written is read back; should be written with 0.

Controller Area Network Controller (MultiCAN+)

Message Object n Arbitration Register MOARn contains the CAN identifier of the message object.

CAN_MOARn (n = 0-255)

Message Object n Arbitration Register

$(1018_H + n * 20_H)$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
ID	[28:0]	rwh	CAN Identifier of Message Object n Identifier of a standard message (ID[28:18]) or an extended message (ID[28:0]). For standard identifiers, bits ID[17:0] are “don’t care”.
IDE	29	rwh	Identifier Extension Bit of Message Object n 0 _B Message object n handles standard frames with 11-bit identifier. 1 _B Message object n handles extended frames with 29-bit identifier.

Controller Area Network Controller (MultiCAN+)

Field	Bits	Type	Description
PRI	[31:30]	rw	<p>Priority Class</p> <p>PRI assigns one of the four priority classes 0, 1, 2, 3 to message object n. A lower PRI number defines a higher priority. Message objects with lower PRI value always win acceptance filtering for frame reception and transmission over message objects with higher PRI value. Acceptance filtering based on identifier/mask and list position is performed only between message objects of the same priority class. PRI also determines the acceptance filtering method for transmission:</p> <p>00_B Reserved.</p> <p>01_B Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) somewhere before this object in the list.</p> <p>10_B Transmit acceptance filtering is based on the CAN identifier. This means, message object n is considered for transmission only if there is no other message object with higher priority identifier + IDE + DIR (with respect to CAN arbitration rules) somewhere in the list (see Table 23-19).</p> <p>11_B Transmit acceptance filtering is based on the list order (as PRI = 01_B).</p>

Controller Area Network Controller (MultiCAN+)

Transmit Priority of Msg. Objects based on CAN Arbitration Rules

Table 23-19 Transmit Priority of Msg. Objects Based on CAN Arbitration Rules

Settings of Arbitrarily Chosen Message Objects A and B, (A has higher transmit priority than B)	Comment
A.MOAR[28:18] < B.MOAR[28:18] (11-bit standard identifier of A less than 11-bit standard identifier of B)	Messages with lower standard identifier have higher priority than messages with higher standard identifier. MOAR[28] is the most significant bit (MSB) of the standard identifier. MOAR[18] is the least significant bit of the standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = 0 (send Standard Frame) B.MOAR.IDE = 1 (send Extended Frame)	Standard Frames have higher transmit priority than Extended Frames with equal standard identifier.
A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = B.MOAR.IDE = 0 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Fame)	Standard Data Frames have higher transmit priority than standard Remote Frames with equal identifier.
A.MOAR[28:0] = B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Frame)	Extended Data Frames have higher transmit priority than Extended Remote Frames with equal identifier.
A.MOAR[28:0] < B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 (29-bit identifier)	Extended Frames with lower identifier have higher transmit priority than Extended Frames with higher identifier. MOAR[28] is the most significant bit (MSB) of the overall identifier (standard identifier MOAR[28:18] and identifier extension MOAR[17:0]). MOAR[0] is the least significant bit (LSB) of the overall identifier.

Controller Area Network Controller (MultiCAN+)

Message Object n Data Register Low MODATALn contains the lowest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

CAN_MODATALn (n = 0-255)
Message Object n Data Register Low
 $(1010_H + n * 20_H)$
Reset Value: 0000 0000_H

Field	Bits	Type	Description
DB0	[7:0]	rwh	Data Byte 0 of Message Object n

Controller Area Network Controller (MultiCAN+)

23.7 MultiCAN+ Module Implementation

This section describes CAN module interfaces with the clock control, port connections, interrupt control, and address decoding.

23.7.1 Interfaces of the MultiCAN+ Module

shows the TC26x B-Step specific implementation details and interconnections of the MultiCAN+ module. The I/O lines of the MultiCAN+ module (two I/O lines of each CAN node) are connected to the Ports listed in. The MultiCAN+ module is also supplied by clock control, interrupt control, and address decoding logic. MultiCAN+ interrupts can be directed to the DMA, CPU, GTM modules which are able to trigger DMA transfers and GTM, CPU operations.

Controller Area Network Controller (MultiCAN+)

23.7.2 MultiCAN+ Module External Registers

The registers listed in [Figure 23-27](#) are not included in the MultiCAN+ module kernel, some registers must be programmed for proper operation of the MultiCAN+ module.

Controller Area Network Controller (MultiCAN+)

23.7.2.1 System Registers

OCDS Trigger Bus (OTGB)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS
OCDS Control and Status (0E8_H) **Reset Value: 0000 0000_H**

(0F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing to it with '1'.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

KRST0

Kernel Reset Register 0

(0F4_H)

0	[31:1]	r	Reserved Read as 0; should be written with 0.

Controller Area Network Controller (MultiCAN+)

23.7.3 MultiCAN+ Clock Interconnects With SCU

The MultiCAN+ module clock inputs are connected to System Control Unit (SCU) clock control unit (CCU) as shown in Figure 23-28 and Table 23-21 below.

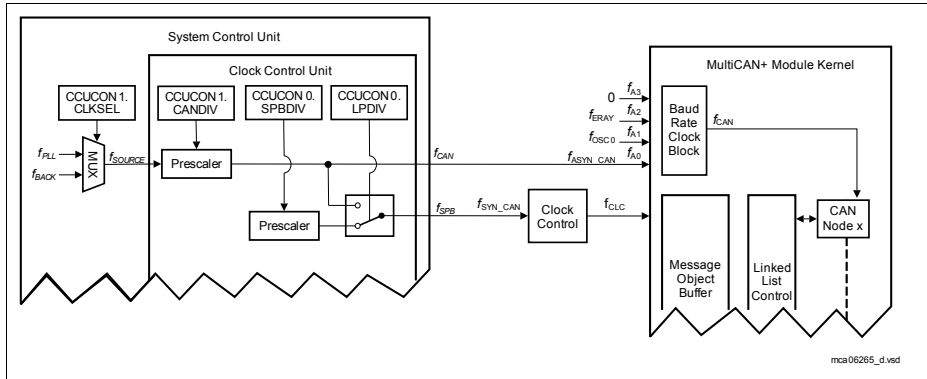

Figure 23-28 MultiCAN+ Clock Interconnects with SCU

Table 23-21 MultiCAN+ Clock Interconnects

CAN Clock Inputs	Connected to	Description
f_{ASYN_CAN}	SCU	f_{ASYN_CAN} of the MultiCAN+ module is one of the clock inputs of the Baud Rate Clock Block, providing the MultiCAN+ module timer clock f_{CAN} . f_{ASYN_CAN} connects to SCU CCU f_{CAN} and is controlled by CCUCON1.CANDIV. The CCUCON1.CANDIV is able to select different values of prescalers based on a selectable f_{PLL} or f_{BACK} source.
f_{SYN_CAN}	SCU	f_{SYN_CAN} of the MultiCAN+ module is the clock input of the Clock Control Register Block, providing the main kernel clock f_{CLC} . f_{SYN_CAN} connects to SCU CCU and is multiplexed between f_{SPB} and f_{CAN} . In normal mode, f_{SYN_CAN} is connected to f_{SPB} where else in pretended networking mode (CCUCON0.LP DIV > 0), f_{SYN_CAN} connects to f_{CAN} of SCU CCU.

Note: The f_{CAN} mentioned on the SCU chapter does not refer to the same f_{CAN} that is mentioned on the MultiCAN+ chapter.

Controller Area Network Controller (MultiCAN+)

11. The f_{CAN} mentioned on the SCU chapter refers in general to connection for MultiCAN+ clocking inputs f_{ASYN_CAN} and f_{SYN_CAN} . Depending on the settings of CCUCON1.CANDIV and CCUCON0.LPDIV different clock sources are connected (See [Table 23-21](#)).
12. The f_{CAN} mentioned on the MultiCAN+ chapter refers to the module timer clock (See [Section 23.7.4.2](#)).

Controller Area Network Controller (MultiCAN+)

23.7.4 Module Clock Generation

This chapter describes the way the module get's its clock.

23.7.4.1 Clock Selection

The bit timing machine and the rest of the MultiCAN+ module are separate frequency domains and can be driven by separate independent frequencies. The bit timing unit can be driven by the SPB bus clock or with the direct oscillator clock, and the rest of the chip is driven only by the SPB bus clock.

The purpose of supplying the bit timing unit with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of by high precision quartz crystal.

Selecting the clock source for the bit timing unit is done by programming the bit-field MCR.CLKSEL.

Enabling and disabling the clock of the module by using CLC.DISR affects always both frequency domains, so that when f_{CLC} is switched off, f_A is also switched off.

23.7.4.2 Fractional Divider

As shown in [Figure 23-29](#), the clock signals for the MultiCAN+ module are generated and controlled by a clock control unit. This clock generation unit is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. This unit includes two registers:

- CAN_CLC: generation of the module control clock f_{CLC}
- CAN_FDR: frequency control of the module timer clock f_{CAN}

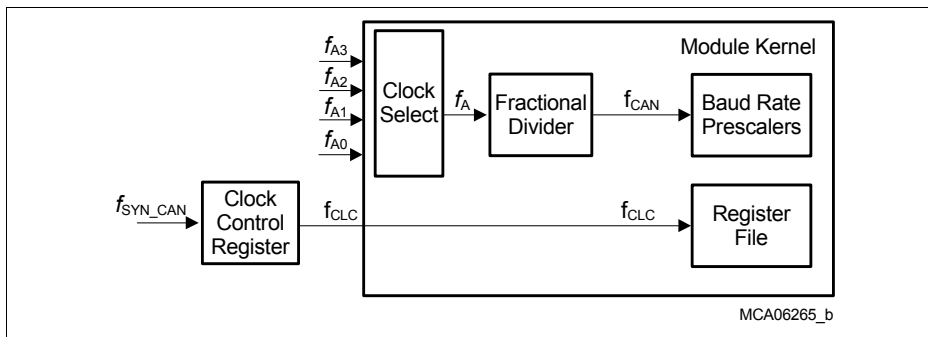

Figure 23-29 MultiCAN+ Module Clock Generation

The f_{SYN_CAN} is identical to f_{SPB} .

Controller Area Network Controller (MultiCAN+)

The module control clock f_{CLC} is used inside the MultiCAN+ module for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the system clock frequency f_{SPB} . The clock control register CAN_CLC makes it possible to enable/disable f_{CLC} under certain conditions.

The module timer clock f_{CAN} is used inside the MultiCAN+ module as input clock for all timing relevant operations (e.g. bit timing). The settings in the CAN_FDR register determine the frequency of the module timer clock f_{CAN} according the following two formulas:

$$f_{CAN} = f_A \times \frac{1}{n} \quad \text{with } n = 1024 - \text{CAN_FDR.STEP} \quad (23.2)$$

$$f_{CAN} = f_A \times \frac{n}{1024} \quad \text{with } n = 0-1023 \quad (23.3)$$

Equation (23.2) applies to normal divider mode (CAN_FDR.DM = 01_B) of the fractional divider. **Equation (23.3)** applies to fractional divider mode (CAN_FDR.DM = 10_B).

Note: The CAN module is disabled after reset. In general, after reset, the module control clock f_{CLC} must be switched on (writing to register CAN_CLC) before the frequency of the module timer clock f_{CAN} is defined (writing to register CAN_FDR).

Controller Area Network Controller (MultiCAN+)
CAN Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the f_{CAN} module clock signal, sleep mode and fast shut-off mode for the module.

CLC
CAN Clock Control Register
(000_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. Note that no register access is possible to any register while module is disabled.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode.
0	[31:4], 2	r	Reserved Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency.

The fractional divider register allows the programmer to control the clock rate of the module timer clock f_{CAN} .

Controller Area Network Controller (MultiCAN+)
FDR
CAN Fractional Divider Register
(00C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for the result.
DM	[15:14]	rw	Divider Mode This bit field selects normal divider mode, fractional divider mode, and off-state.
0	[13:10], [31:16]	r	Reserved Read as 0; should be written with 0.

23.7.5 Port and I/O Line Control

The interconnections between the MultiCAN+ module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

23.7.5.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MultiCAN+ module are controlled by the port input/output control registers, which are described in the port chapter. In case of discrepancies between port chapter and CAN chapter, the description in the port chapter is correct.

shows the corresponding pins, sorted by node. Even though the table is pair wise, it is possible to select a different pairing for RXD and TXD. In addition the RXSEL value to be programmed for the Receive Pins is part of this table. For more information on RXSEL please see [Chapter 23.7.5.2](#).

23.7.5.2 Node Receive Input Selection

Additionally to the I/O control selection, as defined in the port chapter, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register NPCRx must be set according to . Values for NPCRx.RXSEL other than those of the table mentioned above will result in a recessive receive input for node x. As a hint A results in 0x0, B in 0x1 until H resulting in the value of 0x7.

This feature allows, for example, a CAN node which operates in analyzer mode to monitor the receive operations of its neighbor CAN node.

Controller Area Network Controller (MultiCAN+)

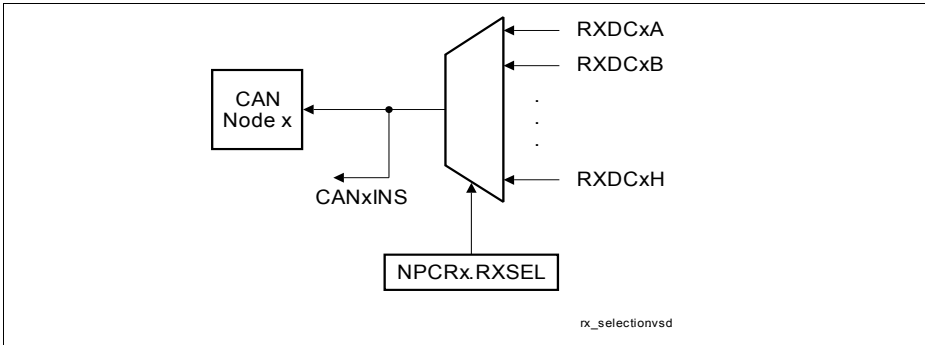

Figure 23-30 CAN Module Receive Input Selection

23.7.5.3 CAN Transmit Trigger Inputs

The CAN transmit trigger inputs of MultiCAN are used to trigger for transmission of a message. In the TC26x B-Step, these input lines are connected as shown in [Table 23-22](#). For the TC26x device the 5th node has no trigger inputs.

Table 23-22 CAN Transmit Trigger Inputs

Receive Input	Connected to	From / to Module
CAN Node 0		
STM_N0_TRIG	stm0.system_irq_o(0)	System Timer Module (STM)
GTM_N0_TRIG	gtm.can_trig_0_o	General Timer Module (GTM)
...		
...
CAN Node 4		
STM_N4_TRIG	stm0.system_irq_o(0)	System Timer Module (STM)
GTM_N4_TRIG	gtm.can_trig_4_o	General Timer Module (GTM)

23.7.5.4 Connections to Interrupt Router Inputs

The interrupt output line INT_O0-15 is connected to the Interrupt Router module, see [Table 23-23](#).

Controller Area Network Controller (MultiCAN+)
Table 23-23 Interrupt Router Inputs

Interrupt Router Input	Connected to CAN Interrupt Output

Timer input (gtm.tim_1_muxin_4_i(13))	
Timer input (gtm.tim_2_muxin_4_i(13))	

23.7.6 Interrupt Control

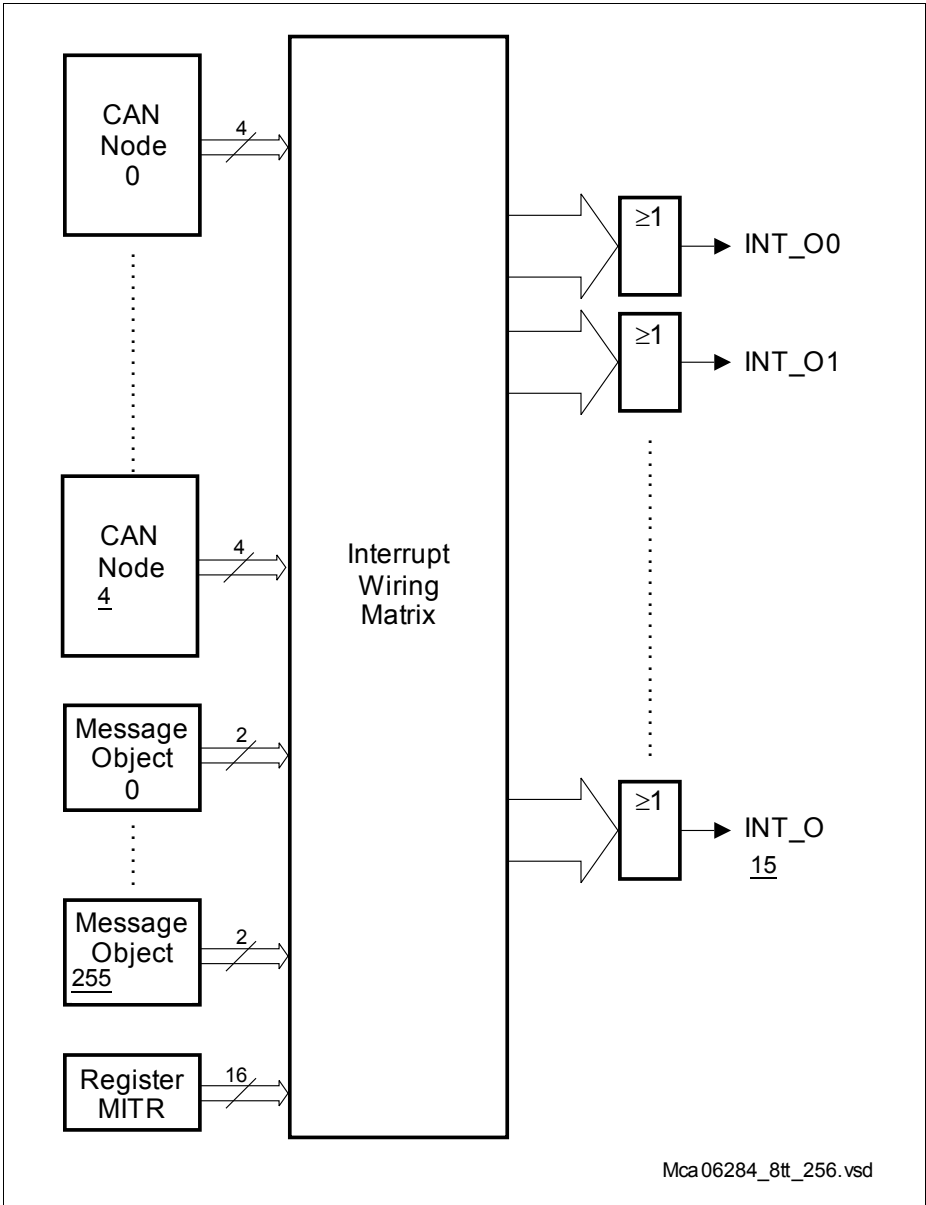

The interrupt control logic in the MultiCAN+ module uses an interrupt compressing scheme that allows high flexibility in interrupt processing. There are hardware and software interrupt sources available:

- CAN node interrupts:
 - Five different interrupt sources for each of the 5 CAN nodes = $5 * \underline{5}$ interrupt sources
- Message object interrupts:
 - Two interrupt source for each message object = $2 * \underline{256}$ interrupt sources
- One register (MITR) to initiate 16 interrupts via software

Each of the hardware initiated interrupt sources is controlled by a 4-bit interrupt pointer that directs the interrupt source to one of the 16 interrupt outputs INT_Om ($m = 0\text{-}15$). This makes it possible to connect more than one interrupt source (between one and all) to one interrupt output line. The interrupt wiring matrix shown in **Figure 23-31** is built up according to the following rules:

- Each output of the 4-bit interrupt pointer demultiplexer is connected to exactly one OR-gate input of the INT_Om line. The number “m” of the corresponding selected INT_Om interrupt output line is defined by the interrupt pointer value.
- Each INT_Om output line has an input OR gate which is connected to all interrupt pointer demultiplexer outputs which are selected by an identical 4-bit pointer value.

Controller Area Network Controller (MultiCAN+)

Mca06284_8tt_256.vsd

Figure 23-31 Interrupt Compressor

Controller Area Network Controller (MultiCAN+)**23.8 MultiCAN+ Soft Configuration**

There is one property of the MultiCAN+ module that can be configured via external signals. The MultiCAN+ module reads the configuration of these properties from PERCFG register.

- CAN FD on/off for the device is configured in PERCFG.CANFDEN (which is bit 8 of the corresponding register).

MultiCAN+ Soft Configuration can only restrict the module. That means that only the numbers equal or smaller than the number of physically available resources in the module may be used. Otherwise, an unpredictable behavior occurs.

23.9 Revision history

External revision history only shows major changes of MultiCAN+ module versions.

External Revision History (from MultiCAN+ v3.0 to MultiCAN+ v3.1)

- As per review meeting on 4Sep12 with designer, Removed for below:
 - Section 1.1.3.5 on Intermission removed as same as CAN V2.0B Bosch specs, under Section 9.1 Protocol Modifications, point 2.
 - Section 1.1.3.5 on Suspend transmission removed as same as CAN V2.0B Bosch specs, under Section 3.1.5 Interframe Spacing, Suspend Transmission.
 - Section 1.1.4.1 on Resynchronization removed as same as CAN V2.0B Bosch specs, under Section 8 Bit timing requirements, Resynchronization.
 - Section 1.1.4.1 on Synchronization rules, removed point 1,2 and 4. Point 3 and 5 are kept as new requirements in CAN FD.
 - Section 1.5.2 on Integrating mode, removed as same as CAN V2.0B Bosch specs, under Section 2 Sleep Mode / Wake-up.
- As per review meeting on 4Sep12 with designer, Added for below:
 - Additional text under MOFCRn.DLC, “Also if DLC>8 is programmed for message transmission, message transmit will be disabled.”
- Added at Section 1.6.4 OCDS suspend, Note on “During suspend mode, kernel registers may be accessed only when the kernel clock is running”

External Revision History (from MultiCAN+ v3.1 to MultiCAN+ v3.2)

- As per AURIX JF on 1oct12, after bosch meeting on discussion of baudrates, request for below:
 - Modified on Section 1.1.3.1 on Fig1-2 CAN FD data frames changed to 64 data bytes and removed footnote on “Current design supports up to 8 data bytes payload only”
 - Removed on Section 1.3.1 footnote on “supports message transfer of data length code 0 to 8 data bytes with no Transmitter Delay compensation”
 - Removed on Section 1.5 “8 data bytes, no Transmitter Delay compensation “
 - Modified on Section 1.5.1, table 1-3, point 4 on Transmitter Delay compensation from “not implemented” to “implemented”
 - Removed on Section 1.6.8.1 on CAN Restricted operation mode.
 - Modified on MOFCR.DLC bit to support for more than 8 data bytes, have included 12, 16, 20, 24, 32, 48, 64 data bytes option.
 - Added Section 1.5.2 Transmitter Delay Compensation and FNBTRx.TDC, FNBTRx.TDCO, FNBSTATx.TDCV.
-

External Revision History (from MultiCAN+ v3.2 to MultiCAN+ v3.3)

- Modified MultiCAN+ clocking from SCU for below

Controller Area Network Controller (MultiCAN+)

- Various diagrams and text that refers “ $f_{MULTICAN}$ ” to “ f_{ASYN_CAN} ” and “ f_{SYN_CAN} ”. Also added Section 1.13.3 MultiCAN+ Clock Interconnects with SCU
- Section 1.6.2 Table 1-5 footnote changed from “To guarantee the minimum operating frequencies when low power mode is enabled, fCLC is switched in fMULTICAN to a operating clock source, when SCU register CCUCON.” to “To guarantee the minimum operating frequencies when low power mode (pretended networking mode) is enabled (i.e when frequency of fSPB is reduced), fSYN_CAN and fCLC are switched from fSPB to fCAN when SCU register CCUCON0.LPDIV>0.”
- Renamed Fast Node x Bit Timing Status Register to Node x Transmitter Delay Compensation Register and moved FNBTRx.TDC, FNBTRx.TDCO to NTDCRx.TDC, NTDCRx.TDCO.

External Revision History (from MultiCAN+ v3.3 to MultiCAN+ v3.4)

- As per mail on “Widening of NBTR register field while maintaining compatibility and more” modified for below:
- - Rearranged FNBTRx register bits to use same layout as NBTRx for lowest 16bits and empty for upper 32bits
 - Changed address of FNBTRx to 0x0238 and NTDCRx to 0x23C
 - Swapped on NTDCRx register bits on TDC =Bit 15 and TDCO= Bits 11-8
 - Added NBTEVRx, Node Bit Timing Extended View Register. NBTEVRx view applies when NCRx.FDEN=1 and NBTRx view applies when NCRx.FDEN=0.
 - NBTEVRx. TSEG1 is 6 bits, valid values from 2 to 63
 - NBTEVRx. TSEG2 is 4 bits, valid values are 1 to 15
 - NBTEVRx.SJW is 4 bits, valid values are 1 to 15

External Revision History (from MultiCAN+ v3.4 to MultiCAN+ v3.5)

- As per review feedback on V3.3 CANFD specs review modified for below:
 - Removed on Section 1.1.3.1 text on point 2e “In current CAN FD implementation, up to 8 data bytes payload are supported only”
 - Added on Table 1-4 Minimum Operating Frequencies, footnote “To guarantee the minimum operating frequencies when low power mode.”
 - Removed on Section 1.4.12.4 “vice versa”
 - Update of Table 1-24 MultiCAN+ Clock Interconnects
- Additional modifications for below:
 - Added on NCRx.FDEN footnote on “Message transmission in Long & Fast CAN FD Frames. Message Reception according to CAN FD Protocol Specification, (i.e Able to Receive Classical CAN Format Frames ISO11898-1 and Long + Fast CAN FD Frames)”
 - Added on Table 1-8 Coding of DLC in CAN FD and MOFCRx.DLC

Controller Area Network Controller (MultiCAN+)

- Added MOFCR.FDF, MOFCR.BRS bit to indicate message format reception when MOFCRx.MOFM =1 (CAN FD enabled) (i.e received frame in classical CAN or CAN FD format)
- Added on NSRx.FLEC, fast last error code to indicate the error code during the fast bit rate.
- Added note on Table 1-13 Encoding of LEC bit field, “When a frame in CAN FD format reached data phase with BRS flag set, the next CAN event (error/valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of CAN FD CRC will be shown as Form and not Stuff Error.”

External Revision History (from MultiCAN+ v3.5 to MultiCAN+ v3.6)

-
-

External Revision History (from MultiCAN+ v3.6 to MultiCAN+ v3.7)

- As per mail on “Message Mode proposal for CAN FD 64 data bytes” modified for below.
 - Added [Section 23.4.12.10](#) on CAN FD 64 byte Message Mode
 - Added [CAN_EMOzDATA0 \(z = 0-255\)](#) Extended Message Object Data Register and on Table 1-11
 - Modified on MOFCR.MMC bit 101 to CAN FD 64 bytes message mode.
- As per TC24x_tag_coverage.xls added tags AURIX_GEN1:5246, 5396, 5373, 5374:
- As per CAN FD weekly meeting on 21Nov12, modified for MOFCR.BRS and MOFCR.FDF bit from rh to rwh.

External Revision History (from MultiCAN+ v3.7 to MultiCAN+ v3.8)

- Added note on [Section 23.4.6.5](#) “The transmit request bits (i.e NTATTx.TXMO / NTBTTx.TXMO / NTCTTx.TXMO) in the timer control register of a node is able to trigger transmit request (MOSTATn.TXRQ) of message object in a list belonging to any other CAN nodes”.
- As per MultiCAN+ V3.7 feedback review
 - Modified on CAN_NBTEVRx text to “NBTEVRx contains all parameters to setup CAN bit timing for Nominal Bit Rate”.
 - Modified on CAN_FNBTRx text to “FNBTRx contains all parameters to setup CAN bit timing for Data Bit Rate”.
 - Modified on CAN_FNBTRx register bits name to FTSEG1, FTSEG2, FSJW and FBRP.
 - Modified on CAN_NBTEVRx.TSEG2 to 5bits, bit20 to bit16.

Controller Area Network Controller (MultiCAN+)
External Revision History (from MultiCAN+ v3.8 to MultiCAN+ v3.9)

- As per MultiCAN+ V3.7 feedback review.
 - As per mail “CCE protection of register tdcrc” added on CAN_NTDCR register “NTDCRx register can be written only if bit NCRx.CCE is set.”. Removed on NTDCR.TDC text on “this bit is CCE and INIT protected”.
 - Added on soft configuration section a footnote on CAN FD “When CAN FD is disabled by PRDCFG, access to CAN FD registers do not generate a bus error. To verify CAN FD is disabled, try to set NCRx.FDEN bit and read back the NCRx register values, the NCRx.FDEN bits remain cleared.”
 - Modified on NTDCR.TDCV text from fcan/fclc to time quanta “Valid values for TDCV are 0 to 31 times of time quanta t_Q ”
 - Modified on NTDCR.TDCO text from fcan/fclc to time quanta “Valid values for TDCO are 0 to 15 times of time quanta t_Q .”
 - Added text under Section CAN FD 64 bytes Message Mode “When MSGVAL of the base object is cleared, an ongoing data transfer to TOP and BOT objects are aborted, thereby freeing objects BOT and TOP. Clearing MSGVAL bits of BOT, TOP objects and the extra message objects do not stop an ongoing data transfer and are not considered at all.”
 - Added text on NCRx.FDEN, MOFCR.MOFM, MOFCR.BRS and MOFCR.FDF bits “Please see Table 1-19 CAN FD Transmit and Receive Behavior.”

External Revision History (from MultiCAN+ v3.9 to MultiCAN+ v3.10)

- As per MultiCAN+ V3.7 feedback review
 - Updated Table 1-19 CAN FD Transmit and Receive Behavior, corrected for transmit behavior “Classical CAN Frames” FDEN from 0_B to X_B .

External Revision History (from MultiCAN+ v3.10 to MultiCAN+ v3.11)

- As per MultiCAN+ V3.7 feedback review
 - Updated Table 1-30 MultiCAN+ I/O control Selection and Setup and Table 1-36 Receive Input Selection
 - Added Table 1-9 “Minimum Operating Frequencies for CAN FD [MHz]”
- Updated on Section 1.6.2 Clock Control on example of equation 1.1 to “As an example, when $f_{CLC} = 10\text{MHz}$, $f_{CAN} = 20\text{MHz}$, No of active CAN nodes =2, $\text{Baudratemax} = [(8 \times 50\text{ns}) + (8 \times 100\text{ns}) + (4 \times 2 \times 100\text{ns})] = 2000\text{ns} = 500 \text{KBaud}$ ”

External Revision History (from MultiCAN+ v3.11 to MultiCAN+ v3.12)

- Modified on Section 1.1.3.2 Remote Frames, paragraph from “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format.”

Controller Area Network Controller (MultiCAN+)

In a CAN FD node, Remote frames request are always replied back in CAN format and will never receive replies in CAN FD format.” to “Remote frames is only defined in CAN format, Remote frames and RTR bit do not exist for CAN FD format. Remote frame requests do not change the format of the preconfigured reply data frames (i.e FDF and BRS bits of preconfigured data frames are not changed on remote frame requests, reply data frames may be in CAN base/extended or CAN FD base/extended).”

- Modified on Table 1-20 CAN FD Transmit and Receive Behavior on receive behavior to FDEN=0, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, FDEN=1, MOFM=X, BRS=0/1, FDF=0/1- Classical CAN Frames, Long Frames, Long + Fast Frames.
- Added on Table 1-20 CAN FD Transmit and Receive Behavior, footnote on receive behavior “Please note that Remote Request Frames do not change BRS and FDF bits.”

External Revision History (from MultiCAN+ v3.12 to MultiCAN+ v3.13)

- Modified for below
 - Added on MCR.CLKSEL bit option 0100_B E-Ray clock “(Feray)”.
 - Added Fig1-52 MultiCAN+ Interconnects with SCU on section 1.13.3 MultiCAN+ Clock Interconnects With SCU.
-

External Revision History (from MultiCAN+ v3.13 to MultiCAN+ v3.14)

- Removed NSRx.RESI bit would generate interrupt on NSRx.ALERT and NCRx.ALIE. Also modified NSRx.RESI bit to ‘rh’ changed description to “This bit is an error flag that is set when the ESI flag in a received CAN FD frame is set.” and “0_b-Last received CAN FD message did not have its ESI flag set. 1_b-Last received CAN FD message had its ESI flag set.”
- Addition to note on Table 1-13 Encoding of LEC bit field, “Correspondingly CAN event (error/valid frame) will be shown back at LEC after the first bit of the CRC delimiter when CAN FD switches from Data bit rate to Nominal bit rate”.

External Revision History (from MultiCAN+ v3.14 to MultiCAN+ v3.15)

- Removal of MOFCR.MOFM bit. Update of Table 1-20 CAN FD Transmit and Receive Behaviour.
- Update of Table 1-5 Minimum Operating Frequencies for CAN FD [MHz].
 - Addition of Acceleration Factor rows for values from 1 to 8
 - Modified on Footnote 3) with addition of Base Nominal Bit Rate is 1Mbit/s and addition “when several nodes operate at different acceleration factor A.F, only the node operating the highest acceleration factor need to be considered for the required minimum operating frequency requirement.”

Controller Area Network Controller (MultiCAN+)**External Revision History (from MultiCAN+ v3.15 to MultiCAN+ v3.16)**

- Section 1.6.12.4 Message Object Format updated with removal of MOFCR.MOFM and replaced with description of NCRx.FDEN and MOFCRn.FDF, MOFCRn.BRS bits.
- CAN FD feature added for TC27x C-step, TC26x B-step, TC29x B-step.
- Updated on features list, with bullet item “Supports an acceleration factor of 8 when operating in CAN FD mode per Bosch CAN FD V1.0 April17th 2012”

External Revision History (from MultiCAN+ v3.16 to MultiCAN+ v3.17)

-
- Updated Table 1-5 Minimum Operating Frequencies for CAN FD [MHz], with corrected values from multican_performance_canfd_16apr13.xls
 - Modified Acceleration Factor rows for values from 1 to 5 and at various places that mentions AF to 1 to 5.

External Revision History (from MultiCAN+ v3.17 to MultiCAN+ v3.18)

- Added additional text on Section 1.5.2 Transmitter Delay Compensation to describe more details on secondary sample point implementation.
- Added on footnote of Table 1-5 Minimum Operating Frequencies for CAN FD “When message objects are configured as transmit or receive FIFO structures i.e MOFCRn.MMC = 0001/0010, only the base object of 1 is counted towards the minimum frequency requirement, all other slave objects on the FIFO do not count towards the minimum frequency requirement. See Section 1.6.12.5.
- Relabel tags CAN_NUMBER_NODES to CAN1_NUMBER_NODES on Table1-2.

External Revision History (from MultiCAN+ v3.18 to MultiCAN+ v3.19)

- Text enhancements below:
 - Under Section 1.1.3.1, abbreviation added for FDF, BRS, ESI bit
 - Under Section 1.1.3.3, amended from “shall switch back” to “will switch back”
 - Under Section 1.3, amended from “on every nodes” to “on all nodes”
 - Under Section 1.3.1, amended from “measured Transmitter Delay” to measured loop delay”
 - Under CAN_MOFCR on CAN FD Transmit and Receive Behavior, added text “Message transmission and reception behavior of CAN data frames is summarized at Table 1-20 below.”
 - Under CAN_MOFGPR.TOP/BOT added text MOFGPR.BOT points to data byte 8-35 and MOFGPR.TOP points to 36-63.

External Revision History (from MultiCAN+ v3.19 to MultiCAN+ v3.20)

- All reference to EDL is renamed to FDF, register bit MOFCR.EDL is renamed to MOFCR.FDF, functionality remains the same.

Controller Area Network Controller (MultiCAN+)**External Revision History (from MultiCAN+ v3.20 to MultiCAN+ v3.21)**

-

External Revision History (from MultiCAN+ v3.21 to MultiCAN+ v3.22)

- Changed CAN FD descriptions to customer relevant information.

External Revision History (from MultiCAN+ v3.22 to MultiCAN+ v3.23)

- Corrected spelling bugs

External Revision History (from MultiCAN+ v3.23 to MultiCAN+ v3.24)

- Changes for XMC device frequencies, not applying for AURIX devices

External Revision History (from MultiCAN+ v3.24 to MultiCAN+ v3.25)

- Changes for XMC port naming. Correcting XMC specification by removing AURIX relevant issues.

External Revision History (from MultiCAN+ v3.25 to MultiCAN+ v3.26)

- Corrected memory space for XCM1000.
- Fixed pad naming for all devices.
- CLC and FDR are existing on all modules, which are existent in one microcontroller.

External Revision History (from MultiCAN+ v3.26 to MultiCAN+ v3.27)

- Corrected interrupt mapping for XCM1000.

External Revision History (from MultiCAN+ v3.27 to MultiCAN+ v3.28)

- CRC issue of CAN FD documented.

External Revision History (from MultiCAN+ v3.28 to MultiCAN+ v3.29)

- MCR register, formula for clock switching mathematically not correct. As no clock cycles were calculated. Exchanged to clock cycles..

24 Single Edge Nibble Transmission (SENT)

This chapter describes the SENT Interface of the TC26x B-Step. It contains the following sections:

- Functional description of the SENT kernel (see **“Overview” on Page 24-2**)
- SENT kernel register descriptions (see **“SENT Kernel Registers” on Page 24-22**)
- TC26x B-Step implementation-specific details and registers of the SENT module (port connections and control, interrupt control, address decoding, and clock control, see **“SENT Module Implementation” on Page 24-70**)

24.1 SENT Kernel Description

Figure 24-1 shows a global view of the SENT interface.

Figure 24-1 General Block Diagram of the SENT Interface

The SENT module communicates with the external world via one I/O line for each channel. The STx lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. This way the optional SPC data can be transmitted and the line is used bidirectionally. In case of an external transceiver, receive and transmit path can be routed to two different ports.

Single Edge Nibble Transmission (SENT)

24.1.1 Overview

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the SENT module kernel.

The SENT IP-module performs communication according to the SENT specification J2716 JAN2010.

While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized SENT protocol defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a SENT channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is support.

The register set of the SENT module can be accessed directly by the CPU for configuration, data read out and status query.

The SENT IP-module supports the following features:

Single Edge Nibble Transmission (SENT)

Features

- Conformance with SENT protocol specification J2716 JAN2010
- Data rates of up to 65,8 kbit/s at 3 μ s tick length and 6 data nibbles on each channel
- Support of standard tick times (3 μ s through 90 μ s) and
- Message tick time programmable between 0.2 μ s and 90 μ s
- 6 SENT channels working independently in parallel
- Status nibble optionally included in the checksum (default not included)
- Sticky interrupt flags, error interrupt optional (default disabled)
- Configurable frame length (default is 24 bit), max data size is 32 bits
- Serial data processing optional (default: disabled)
- Option for bigger frame lengths (must still be fix for each application)
- transparent mode (nibble CRCs are written to the receive control register for SW processing)
- Support of SPC
- Support of trailing Pause Nibble of any length (even longer than 70 ticks)
- Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
- The receiver module will monitor the message for the following error conditions:
 - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
 - Too many or too few nibbles between calibration pulses.
 - Checksum error.
 - Successive calibration pulse differ by more than 1.5625%
 - Any nibble data values measured as < 0 or >15.
- When any of those errors is detected, the receiver module shall declare that a message error has occurred and ignore the entire message.
- Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to re synchronize.
- Option to enable/disable the check of the next calibration pulse before validation of received data
- Digital Glitch filter suppressing noise
- Buffer overrun detection
- Optional output inversion for use of external open drain transistor
- Optional input inversion for use of external open transistor for level shifting
- Interrupt on status nibble violation
- Programmable Nibble sorting to support LSN or HSN first and relief CPU
- Time stamp generation
- Watch Dog on incoming frames

Single Edge Nibble Transmission (SENT)

24.1.2 General Operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

Figure 24-3 shows a typical TC26x B-Step application in which a SENT interface reads a sensor device.

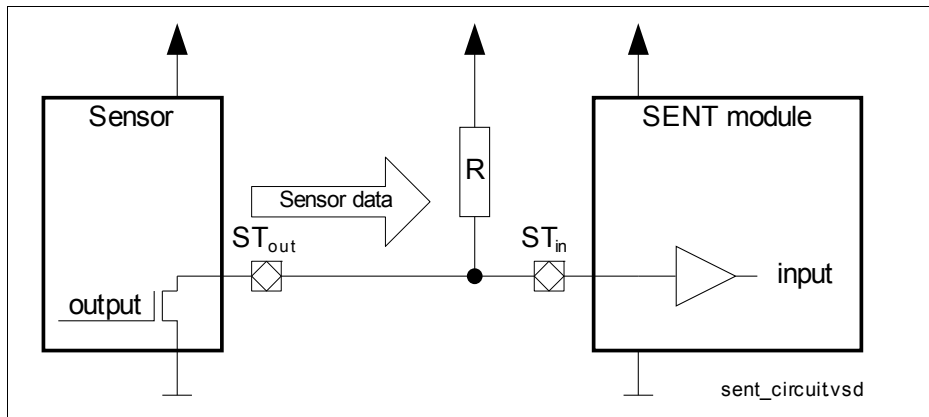

Figure 24-2 SENT to External Device Connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of unidirectionality as said above while keeping conformance to the standard.

Figure 24-3 shows a typical TC26x B-Step application in which an SPC enabled SENT ECU reads an SPC enabled SENT sensor device.

Single Edge Nibble Transmission (SENT)

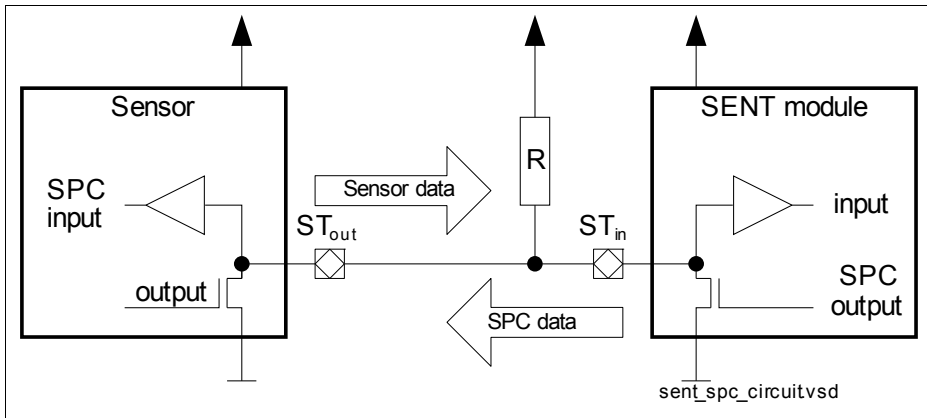

Figure 24-3 SENT SPC to External Device Connection

Some applications are:

- Read out of the external throttle position sensor (e.g. SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel.
- Serial connections of the TC26x B-Step to other peripheral devices

24.1.2.1 Definitions

SENT: Single Edge Nibble Transmission

Nibble: Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)

SPC: Short PWM Code

PWM: Pulse Width Modulation

ASIC: Application Specific Integrated Circuit

CAN: Controller Area Network

LIN: Local Interconnect Network

ISO: International Organization for Standardization

ECU: Electronic Control Unit

FSM: Finite State Machine

Single Edge Nibble Transmission (SENT)

24.1.3 Standard SENT Operation

Standard SENT Mode supports communication fully compliant to J2716 JAN2010, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. **Figure 24-4** shows the block diagram of the SENT Module when operating in Standard SENT Mode.

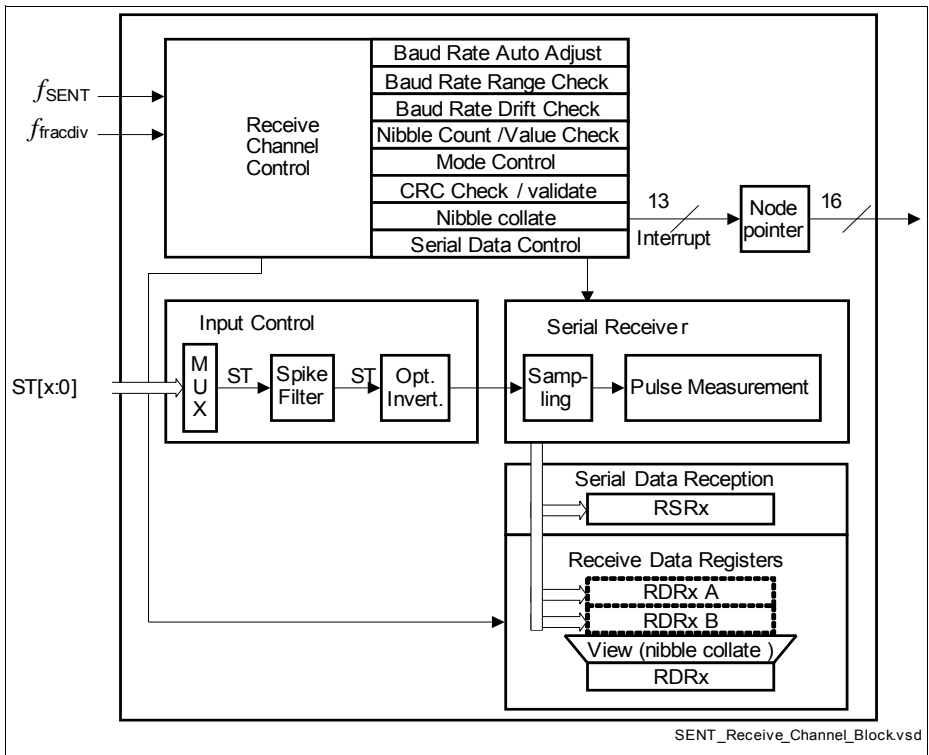

Figure 24-4 Standard SENT Mode Operation

Single Edge Nibble Transmission (SENT)

24.1.3.1 Frame Formats and Definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic Definitions

Figure 24-5 shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

Figure 24-5 Standard Encoding Frame

Serial Data Encoding in Status and Communication Nibble

The Status and Communication nibble is used by sensors that transmit extra serial data such as part numbers or diagnostic information. Data bits from this nibble are constructed across multiple SENT messages to form a Short Serial Message or an Enhanced Serial Message. These messages are alternately referred to as “Slow Channel” data in the J2716 specification.

Table 24-1 Short Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

Single Edge Nibble Transmission (SENT)

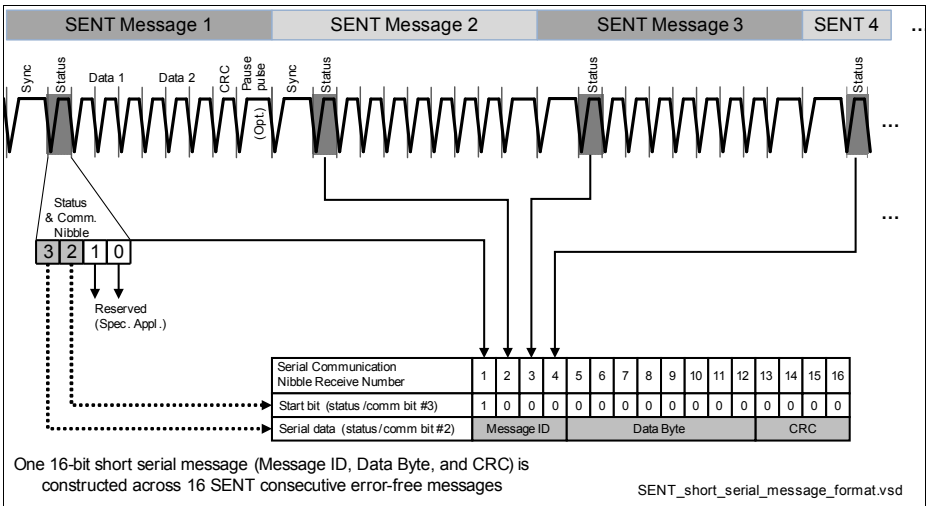

Figure 24-6 Short Serial Message, Serial Data Encoding over 16 messages

Short Serial Message Format

The SENT kernel supports the Short Serial Message Format defined in the J2716 specification. The Short Serial Message Format provides 16 bits of data, constructed across 16 SENT messages. Each of the 16 messages contains one bit of Short Serial Message data in Status and Communication nibble bit 2.

Serial data is communicated in a 16-bit sequence as shown in Table 24-2. The start of a Short Serial Message is indicated by a 1 in bit 3 of the Status and Communication nibble. That SENT message and the next 15 must be successfully received (no errors) for the Short Serial Message data to be received. The CRC generation is identical to the CRC generation on the data nibbles. Short Serial Message data is provided in the SDSx register.

Table 24-2 Short Serial Message Format

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Startbit (bit # 3)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Serial Data (bit # 2)	Message ID			Data Byte									CRC			

CRC Calculation

SENT signal data and Short Serial Message data is secured with a 4 bit CRC. The standard CRC calculation method is defined in the J2716 JAN2010 specification.

Single Edge Nibble Transmission (SENT)

RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial $x^4 + x^3 + x^2 + 1$ with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used e.g. in the sensor TLE4998 for the signal data. See [Figure 24-7](#) for details.

```
// Fast way for any µC with low memory and compute capabilities
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {...};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15,
2, 8, 5};
CheckSum= 5; // initialize checksum with seed "0101"
for (i=0; i<7; i++) {
    CheckSum = CheckSum ^ Data[i];
    CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

Note: For the “Enhanced Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

Single Edge Nibble Transmission (SENT)

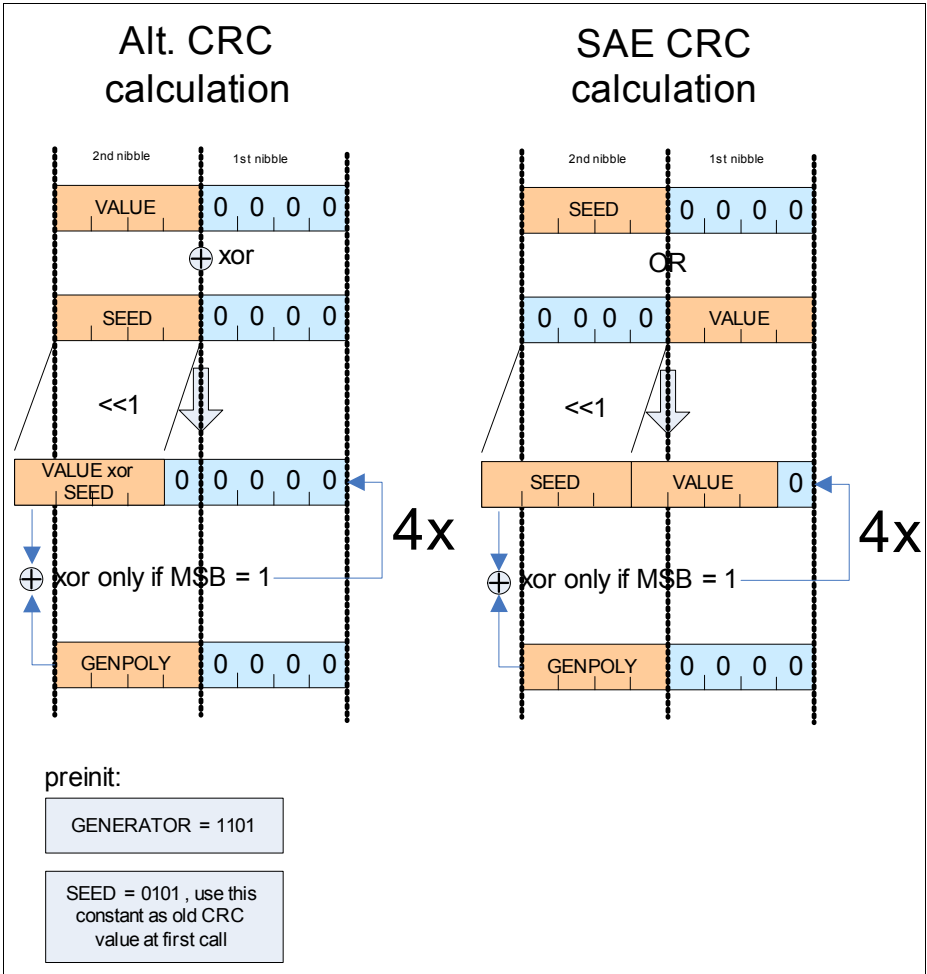

Figure 24-7 Alternate vs. SAE CRC Calculation

Single Edge Nibble Transmission (SENT)

Enhanced Serial Message Format

The SENT kernel supports the Enhanced Serial Message Format defined in the J2716 specification. The Enhanced Serial Message Format provides 21 bits of message data and a 6-bit CRC, constructed across 18 SENT messages. The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

Table 24-3 Enhanced Serial Data Encoding

Bit Number	Bit Function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1 1 1 1 1 1 0

Enhanced Serial Message Frame

Serial data is communicated in an 18 frame sequence as shown in [Table 24-4](#). The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit #3 of the status and communication nibble, constructed across 7 SENT messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive SENT messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The 6-bit Enhanced Serial Message CRC is different from the 4-bit CRC on SENT (fast channel) messages. (See SENT Standard)

An Enhanced Serial Message contains 21 bits of message data and a 6-bit frame-check sequence. A configuration bit (serial data bit #3 of the 8th SENT message's Serial Communication Nibble) determines how the SENT module interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID, see [Table 24-5](#)
- Configuration bit = 1: 16-bit data and 4-bit message ID, see [Table 24-6](#)

Enhanced Serial Message data is provided in the SDSx register.

Table 24-4 Enhanced Serial Data Frame

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	C	8-bit ID (7-4)				0	8-bit ID (3-0) or 4-bit data			0	
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Note:

Single Edge Nibble Transmission (SENT)

13. Message 8 Status Nibble bit # 3 is Configuration Bit C that defines the Enhanced Serial Data format:

0: 12-bit data, 8-bit ID, see [Table 24-5](#)

1: 16-bit data, 4-bit ID, see [Table 24-6](#)

14. Messages 17-14 Status Nibble bit # 3 contain either the lower 4 bits (Bit 3-0) of 8bit ID or 4 additional data bits.

[Table 24-5](#) shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

Table 24-5 Configuration Bit = 0

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	0	8-bit ID (7-4)				0	8-bit ID (3-0)			0	
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

[Table 24-6](#) shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

Table 24-6 Configuration Bit = 1

Serial Communication Nibble Receive No.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial Data (bit # 3)	1	1	1	1	1	1	0	1	4-bit ID (3-0)				0	4-bit data (15-12)			0	
Serial Data (bit # 2)	6-bit CRC						12-bit data field											

Single Edge Nibble Transmission (SENT)

24.1.4 SPC Operation

The module supports a SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by J2716 JAN2010. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

24.1.4.1 Synchronous Transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin. This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble decoding and indicates that the data line is idle again. The timing diagram in [Figure 24-8](#) visualizes a synchronous transmission

Figure 24-8 Synchronous Transmission (SPC)

24.1.4.2 Range Selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

Single Edge Nibble Transmission (SENT)

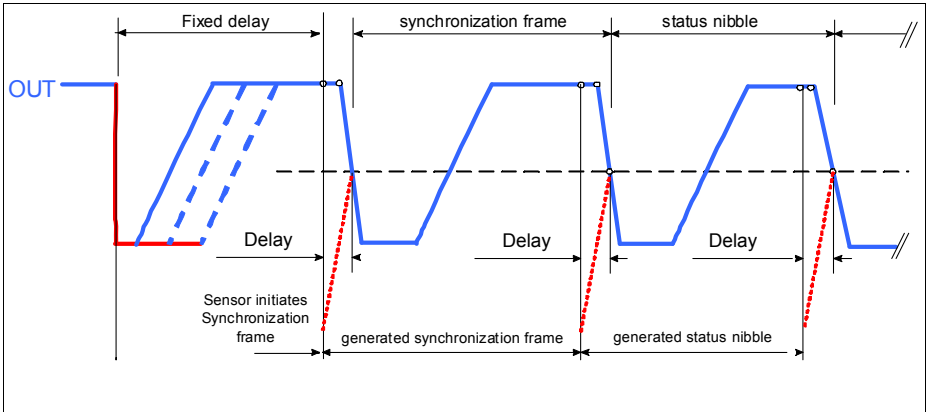

Figure 24-9 Range (SPC)

24.1.4.3 ID Selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in [Figure 24-10](#).

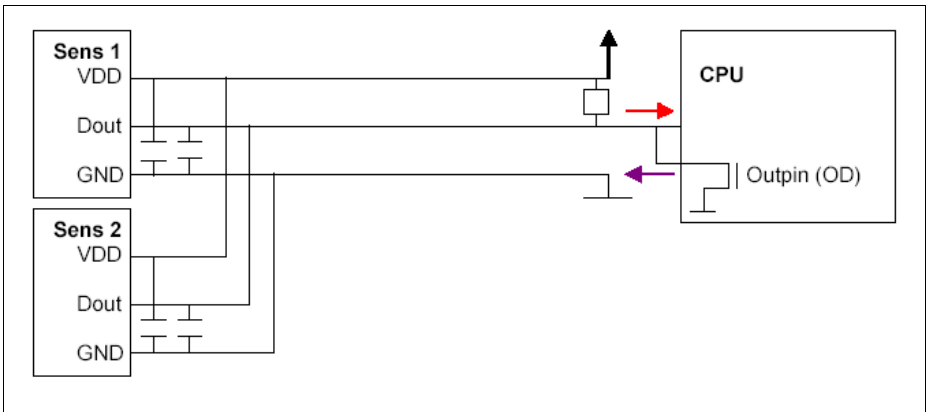

Figure 24-10 ID Selection (SPC)

Single Edge Nibble Transmission (SENT)

24.1.4.4 Bidirectional Transmit Mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in [Figure 24-11](#).

Figure 24-11 Bidirectional Transmit Mode (SPC)

24.1.4.5 SPC Timing

An SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold V_{thf} . The sensor detects that the OUT line has been released as soon as V_{thr} is crossed. [Figure 24-12](#) shows the timing definitions for the master pulse. The master low time t_{mlow} as well as the total trigger time t_{mtr} are individual for the different SPC modes and are given in the sensors specifications. It is recommended to choose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: $t_{mlow,typ} = (t_{mlow,min} + t_{mlow,max}) / 2$.

Single Edge Nibble Transmission (SENT)
24.1.5 Baud Rate Generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending from the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +- 25% as specified in J2716 JAN2010.

Chapter 24.1.5 shows in detail how the baud rate for each channel is adjusted. $1 / f_{\text{tick}_x}$ defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency f_{fracdiv} can be set up so that it is handy as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization / Calibration pulses of 1.5625% (1/64) and adapt the own baud rate. The tick time is typically 3 μs but can vary by standard and take values up to 10 μs . Future application might require even shorter tick times for higher repetition rates. This is why this implementation allows for an even extended range of 0.2 ... 90 μs . To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency. For details on the principles of a fractional divider, please refer to the SCU chapter of TC26x B-Step section "Clock Control".

The SENT module provides two clock signals to the channels (**Figure 24-13**):

- f_{SENT}
This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{SYS} . The clock control register SENT_CLC makes it possible to enable/disable f_{SENT} under certain conditions.
- f_{fracdiv}
This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of f_{fracdiv} . Usually not required and set to 1.

The channels generate two local clock signals:

- f_{pdiv_x}
This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx controls the frequency of f_{pdiv_x} .
- f_{tick_x}
This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx controls the frequency of

Single Edge Nibble Transmission (SENT)

f_{tick_x} . The higher the value of DIV the higher the precision with which the Synchronization / Calibration pulse and the deviation in the length of 2 consecutive Synchronization / Calibration pulses (drift) can be measured.

DIV must be set in an interval of [560, 3276].

Each time a Synchronization / Calibration pulse starts DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x} . At the end of the Synchronization / Calibration pulse this value is taken as new divider of the CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with $\text{DIVM} / 2$. This is required to center the data eye and to make the margin symmetrical.

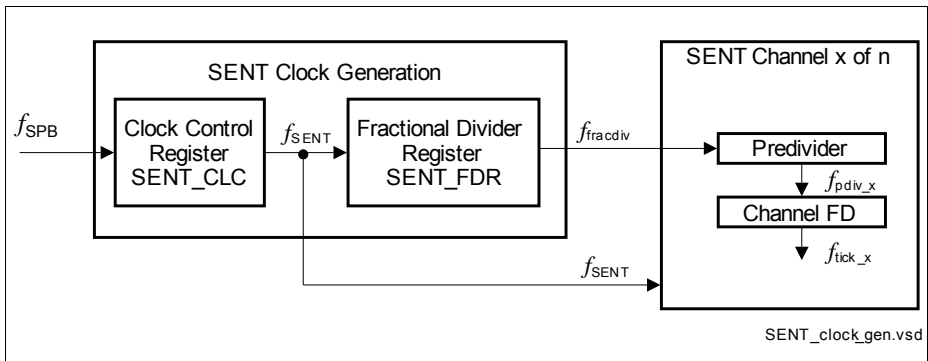

Figure 24-13 SENT Module Clock Generation

The following two formulas define the frequency of f_{fractdiv} :

$$f_{\text{fractdiv}} = f_{\text{SENT}} / (1024 - \text{SENT_FDR.STEP}); \text{FDR.DM} = 01_{\text{B}} \quad (24.1)$$

$$f_{\text{fractdiv}} = f_{\text{SENT}} \times \text{SENT_FDR.STEP} / 1024 \text{ with STEP} = 0 \dots 1023; \text{FDR.DM} = 10_{\text{B}} \quad (24.2)$$

The following formula defines the frequency of f_{pdiv_x} :

$$f_{\text{pdiv}_x} = f_{\text{fractdiv}} / (\text{SENT_CPDRx.PDIV} + 1) \quad (24.3)$$

The following formula defines the nominal frequency of f_{tick_x} . For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$$f_{\text{tick}_x} = f_{\text{pdiv}_x} \times 56 / \text{SENT_CFDRx.DIV} \text{ with DIV} = 560 \dots 3276 \quad (24.4)$$

Single Edge Nibble Transmission (SENT)

24.1.6 Error Detection Capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol Level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or > 15
- Wrong Status and Communication nibbles
- Serial Communication CRC error

Transfer Management Level:

- Receive Data Buffer Overrun
- SPC Data Buffer Underrun

Single Edge Nibble Transmission (SENT)

24.1.7 Digital Glitch Filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. Thus it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv} . If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv} .

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes $2 \times T_{pdiv}$ times longer for the internal signal to change value. The filters principal implies a delay of the signal by $(DEPTH \times T_{pdiv})$.

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

Figure 24-14 shows the digital glitch filter:

Figure 24-14 Digital Glitch Filter

Single Edge Nibble Transmission (SENT)

24.1.8 Interrupts

4 Interrupt request lines are available for the SENT module.

RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. RSI indicates a receive frame success interrupt, i.e. the CRC was successful. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host ("overwrite"), i.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. TDI indicates a transmit interrupt. It is activated when data is moved from a SCR to a transmit shift register. TBI indicates a transfer buffer under run interrupt. It is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. In addition the protocol error interrupts are available: FRI, FDI, NNI, NVI, CRCI. If one of the protocol interrupts is activated, data is to be treated as invalid according to J2716 JAN2010. WSI, SDI SCRI treat the interrupts referring to the Status and Communication nibble. WDI is the Watch Dog Error Interrupt. It is issued if the time between two frames is too long.

For acceleration of the interrupt service routine, a Register INTOV is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR. If more than one interrupt source is connected to the same interrupt node pointer (in register INPx), the requests are combined to one common line.

24.1.9 Trigger Outputs

Any interrupt source can be used as trigger output TRIGO outside the module. Each TRIGO is connected to a IR input. See [Table 24-9 "Service Request Lines of SENT" on Page 24-71](#).

Single Edge Nibble Transmission (SENT)

24.2 SENT Kernel Registers

This section describes the kernel registers of the SENT module. All SENT kernel register names described in this section will be referenced in other parts of the TC26x B-Step User’s Manual by the module name prefix “SENT_” for the SENT interface.

All registers in the SENT address spaces are reset with the application reset (definition see SCU section “Reset Operation”).

SENT Kernel Register Overview

Figure 24-15 SENT Kernel Registers

The complete and detailed address map of the SENT module is described in [Table 24-7](#) on [Page 24-22](#).

Note: x can take the values 0 ... 5

Single Edge Nibble Transmission (SENT)

24.2.1 Module Control

Module Identification Register

The SENT Module Identification Register ID contains read-only information about the module version.

ID

Module Identification Register (08_H) Reset Value: 0080 C0XX_H

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MODTYPE	[15:8]	r	Module Type This bit field defines the module as a 32-bit module: C0 _H
MODNUM	[31:16]	r	Module Number Value This bit field defines the module identification number for the SENT: 0080 _H

Fractional Divider Register

The Fractional Divider Register controls the input clock f_{fracdiv} of all SENT channels.

Single Edge Nibble Transmission (SENT)

SENT_FDR
SENT Fractional Divider Register
(0C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
STEP	[9:0]	rw	Step Value Reload or addition value for RESULT.
DM	[15:14]	rw	Divider Mode DM selects normal or fractional divider mode. 00 _B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01 _B Normal Divider Mode selected. 10 _B Fractional Divider Mode selected. 11 _B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	[25:16]	rh	Result Value Bit field for the addition result.
0	[13:10], [31:26]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

Module Time Stamp Register

The SENT Module Time Stamp Register contains read-only information about the current time given in clock cycles generated from TPD since last reset while module was clocked. Writing to TPD clears this register.

TSR

Time Stamp Register (18_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CTS	[31:0]	r	Current Time Stamp for the Module This bit field shows the current time stamp.

Single Edge Nibble Transmission (SENT)

Module Time Stamp Pre Divider Register

The SENT Module Time Stamp Predivider Register contains the pre divider that defines the time resolution of TSR. Writing to TPD clears register TSR.

TPD

Time Stamp Predivider Register (1C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
TDIV	[19:0]	rw	Divider Factor of Pre Divider for TSR Divides $f_{fracdiv}$ by (TDIV + 1) and drives TSR.
0	[31:20]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

24.2.2 Channel Baud Rate Registers

Channel Pre Divider Register

The Channel Pre Divider Register CPDRx contains the pre divider that is related to the SENT channel baud rate.

See [Equation \(24.3\)](#)

CPDRx (x = 0-5)

Channel Pre Divider Register x (100_H+40_H*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
PDIV	[11:0]	rw	Divider Factor of Pre Divider for Channel x Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	[31:12]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

Channel Fractional Divider Register

The Channel Fractional Divider Register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See [Equation \(24.4\)](#) in [Chapter 24.1.5](#) for a detailed description.

CFDRx (x = 0-5)

Channel Fractional Divider Register x(104_H+40_H*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
DIV	[11:0]	rw	Divider Value Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
DIVM	[27:16]	rh	Measured Divider Value DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.
0	[15:12], [31:28]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)
24.2.3 Receiver Control and Status Registers
Receiver Control Register

The Receiver Control Register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x = 0-5)

Receiver Control Register x (108_H+40_H*x) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CEN	0	rw	Channel Enable When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0 _B channel x disabled (default) 1 _B channel x enabled
IEP	1	rw	Ignore End Pulse When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. 0 _B End Pulse not ignored (default) 1 _B End Pulse ignored For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range.

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
ACE	2	rw	<p>Alternative CRC Mode Enable</p> <p>When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path.</p> <p><i>Note: If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored.</i></p> <p>0_B Serial CRC calculation as specified in J2716 JAN2010 (default)</p> <p>1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.</p>
SNI	3	rw	<p>Status Nibble Included in CRC</p> <p>When SNI is set, the status Nibble is included in (signal data) CRC.</p> <p>0_B Status Nibble not included in CRC (default)</p> <p>1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).</p>
SDP	4	rw	<p>Serial Data Processing Mode</p> <p>This bit switches automatic serial data processing on.</p> <p>0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default)</p> <p>1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.</p>
SCDIS	5	rw	<p>CRC for Serial Data Disabled Mode</p> <p>This bit selects the CRC disabled mode.</p> <p>00_B CRC is enabled (default)</p> <p>01_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.</p>

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
CDIS	6	rw	CRC Disabled Mode This bit selects the CRC disabled mode. 00 _B CRC is enabled (default) 01 _B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
CFC	7	rw	<p>Consecutive Frame Check This bit determines the way the most recently received frame buffer is indicated as valid.</p> <p>0_B Check against Past Sync Pulse The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued.</p> <p>1_B Check against Future Sync Pulse The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.</p>

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
FRL	[15:8]	rw	<p>Frame Length</p> <p>FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC.</p> <p>00000000_B No data nibble 00000001_B 1 data nibble 00000010_B 2 data nibbles 00000011_B 3 nibbles 00001000_B 8 nibbles Maximum in normal length mode 11111111_B 255 nibbles</p> <p>If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong.</p>

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
CRZ	16	rw	<p>CRC with Zero Nibble for Serial Data</p> <p>This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles)</p> <p>00_B Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) (default)</p> <p>01_B Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames).</p> <p>The enhanced serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard.</p>
ESF	17	rw	<p>Enhanced Serial Frame Mode</p> <p>This bit selects the serial frame structure.</p> <p>0_B short (16 frames, 4 bit ID, 8 bit data, 4 bit CRC)</p> <p>1_B enhanced (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)</p>
IDE	18	rw	<p>Ignore Drift Error Mode</p> <p>This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated.</p> <p>Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful.</p> <p>0_B Drift Errors enabled (default)</p> <p>1_B Drift Errors disabled</p>
SUSEN	19	rw	<p>Suspend Enable</p> <p>This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support):</p> <p>0_B An OCDS suspend trigger is ignored by this SENT channel.</p> <p>1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded.</p> <p>Bit SUSEN is reset via OCDS Reset.</p>

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
0	[31:20]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

Watch Dog Timer Register

The Watch Dog Timer Register WDTx contains the time out value for channel x. The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0. The value entered here defines the time in multiples of T_{tick_x} (defined in CFDR) from the last RDI on channel x.

The internal Watch Dog Timer is compared to WDLx.

A match triggers interrupt WDI and stops the internal Watch Dog Counter x.

After such a match, the Watch Dog Timer will be cleared and started automatically with clearing bit WDI (by setting INTCLR.WDI). I.e. the Watch Dog Counter is running only if interrupt flag WDI is cleared.

If WDL is cleared, the WDTx is stopped/disabled.

WDTx (x = 0-5)

Watch Dog Timer Register x $(134_H + x * 40_H)$ **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
WDLx	[15:0]	rw	Watch Dog Timer Limit for channel x .
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Receiver Status Register

The Receive Status Register provides the status information of channel x.

Single Edge Nibble Transmission (SENT)

RSRx (x = 0-5)
Receive Status Register x ($10C_H + 40_H * x$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CRC	[3:0]	r	CRC of last frame. CRC ₀ is on bit position 0.
CST	[5:4]	r	Channel Status CST shows the current status of channel x. 00 _B STOP Channel is disabled and can be configured 01 _B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10 _B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11 _B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	[11:8]	r	Status and Communication Nibble of last frame. SCN ₀ is on bit position 8.
0	[7:6], [31:12]	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)
Serial Data and Status Register

The Serial (Receive) Data and Status Register provides the data and status information of channel x.

SDSx (x = 0-5)
Serial Data and Status Register x (110_H+40_H*x)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SD	[15:0]	r	Serial Data of last serial data frame. SD ₀ is on bit position 0. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.
MID	[23:16]	r	Message ID of last serial data frame. ID ₀ is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	[29:24]	r	SCRC CRC of last serial data frame. CRC ₀ is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	Configuration bit of last serial frame. 0 _B 12-bit data and 8-bit message ID 1 _B 16-bit data and 4-bit message ID
0	30	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

24.2.4 Input and Output Control

Input and Output Control Register Functions

The Input and Output Control Register IOCRx determines for the SENT channel x:

for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit

- the trigger source
- the output signal polarity

IOCRx (x = 0-5)

Input and Output Control Register x(114_H+40_H*x)

Reset Value: X000 0000_H

CREG	14	rw	Clear Rising Edge Glitch Flag for Channel x Clears the status flag REG 0 _B REG is not cleared 1 _B REG is cleared CREG always read zero.

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
CFEG	15	rw	Clear Falling Edge Glitch Flag for Channel x Clears the status flag FEG 0 _B FEG is not cleared 1 _B FEG is cleared CFEG always read zero.
ETS	[19:16]	rw	External Trigger Select Selects the external trigger line if SCR _x .TRIG is programmed to 11 _B . 0000 _B TRIG0 0001 _B TRIG1 5 _D TRIG5 1111 _B reserved
EC	[27:20]	rh	Edge Counter This bit field contains a counter with saturation (stops at 0xFF). It is incremented with any falling edge that appears on the input pin selected by IOCR.ALTI. Note that this holds true in all states (STOP, INITIALIZED, RUNNING, SYNCHRONIZED). It is intended for debugging, in particular to find a bubbling idiot that sends before enabling the module.
CTR	28	rw	Clear Trigger Monitor Flag for Channel x Clears the status flag TRM 0 _B TRM is not cleared 1 _B TRM is cleared CTR always read zero. Reset value of CTR is 0.
TRM	29	rh	Trigger Monitor Flag for Channel x Shows the status of the trigger detection of channel x 0 _B No Trigger detected 1 _B Trigger detected (one or several) TRM is cleared by setting CTR. Reset value of TRM is 0.
RXM	30	rh	Receive Monitor for Channel x Shows the status of the receive signal of channel x after glitch filtering and inverted as specified by IIE. 0 _B Current signal is low. 1 _B Current signal is high. Reset value of RXM is X.

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
TXM	31	rh	Transmit Monitor for Channel x Shows the status of the transmit signal of channel x inverted as specified by OIE. 0_B Current signal is low. 1_B Current signal is high. Reset value of TXM is X.
0	[3:2], 11	r	Reserved Read as 0; should be written with 0.

Single Edge Nibble Transmission (SENT)

24.2.5 Receive Data Registers

Receive Data Registers RDRx

The Receive Data Registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

*Note: Register VIEW must be set up correctly to see all data nibbles of the frame!
By default the application software set VIEW to 7654 3210_H.*

*Note: The internal receive buffer is always cleared (0x0000 0000_H) at each frame start.
Thus unused nibbles are always read as zero.*

RDRx (x = 0-5)

Receive Data Register x (80_H+x*4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDRy (y = 0-7)	[4*y+3 : 4*y]	rh	Receive Data Nibble y RDRy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000 _H . I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

Single Edge Nibble Transmission (SENT)
Channel Receive Time Stamp Register

The SENT Channel x Receive Time Stamp Register contains read-only information about the time the last frame for channel x was received. Time is captured with the second falling edge, i.e. at the Status/Communication data pulse.

RTSx (x=0-5)

Receive Time Stamp Register x ($A80_H + x * 4_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
LTS	[31:0]	r	Last Receive Time Stamp for Channel x This bit field shows the time stamp of the last frame on channel x.

Receive Data View Register VIEWx

The Receive Data View Registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles.

The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7.

If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones.

Example: two 12 bit values are transmitted. One with highest significant nibble first and one with lowest significant nibble first. The frame looks like this: 456321_H. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble.

The actual signal values are 0x123_H and 0x456_H. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: 73 654 012_H. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: 0x0456 0123_H to the host.

In the example RDR nibbles 3 and 7 contain 0x0000_B as the Receive Buffer is always cleared (0x0000 0000_H) before new data is received.

Single Edge Nibble Transmission (SENT)

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. 7654 3210_H.

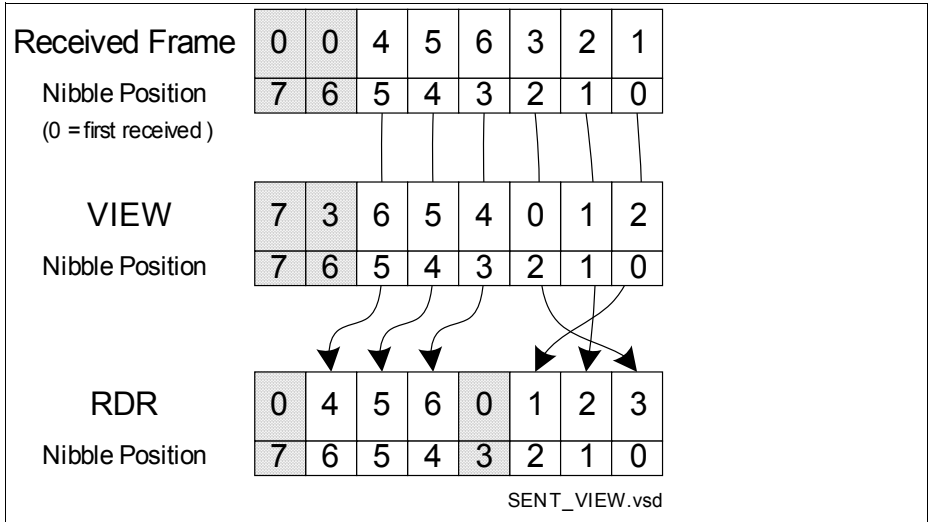

Figure 24-16 Functionality of VIEW Register

VIEW_x (x = 0-5)

Receive Data View Register x (11C_H+40_H*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RDNP_y (y = 0-7)	[4*y+2 :4*y]	rw	<p>Receive Data Target Nibble Pointer y</p> <p>RDNP_y points to the Nibble in Receive Data Register RDR_x where the nibble y from the received frame is sorted to. Nibble 0 is the first data nibble in the frame. It gets moved to the position defined in RDNP0. And on.</p> <p>000_B Nibble 0 selected 001_B Nibble 1 selected ..._B ... 111_B Nibble 7 selected</p> <p><i>Note: RDNP_y must be written before first frame reception. All RDNP_y must have different values. (Higher RDNP_y overwrite lower RDNP_y.)</i></p>
0	3, 7, 11, 15, 19, 23, 27, 31	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Single Edge Nibble Transmission (SENT)

24.2.6 SPC Control

SPC Control Registers SCR_x

The SPC Control Register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is build to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode "Bidirectional transmit". Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal can be sufficient and no further SW intervention is required. Here the data can be changed ("ID-Selection" Mode) or simply left constant ("Sync" Mode). Only a HW trigger needs to be set up.

In Mode 0, SPC is deactivated for this channel. A write access to SCR_x does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCR_x is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TB_{ix} is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCR_x. After the data was transferred to the internal transmission register, interrupt TD_{ix} signals that a new value can be written. INTSTAT_x.TD_{ix} must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse.

This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode "Bidirectional Transmit" this mode is useful to synchronize the transmission. TD_{ix} and TB_{ix} work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCR_x.ETS). This is most useful in SPC "sync" mode. TD_{ix} and TB_{ix} work as in Mode 1.

Single Edge Nibble Transmission (SENT)

SCRx (x = 0-5)

SPC Control Register x

(118_H+40_H*x)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PLEN	[5:0]	rw	<p>Pulse Length</p> <p>Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used.</p> <p>000000_B Pulse length is 0 ticks 000001_B Pulse length is 1 tick 111111_B Pulse length is 63 ticks</p>

Single Edge Nibble Transmission (SENT)

Field	Bits	Type	Description
TRIG	[7:6]	rw	Trigger Source and Mode Selection Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00 _B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01 _B Pulse starts immediately (no auto repetition) 10 _B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11 _B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	[13:8]	rw	Delay Length Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 000000 _B Pulse is not delayed 000001 _B Pulse is delayed by 1 tick ... 111111 _B Pulse is delayed by 63 ticks
BASE	14	rw	Time Base Selects the Pulse Time Base 0 _B Pulse is based on measured frequency of last Synchronization/Calibration Pulse 1 _B Pulse is based on nominal frequency
TRQ	15	r	Transfer Request in Progress While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

WDI	[31:28]	rw	Interrupt Node Pointer for Interrupt WDI This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.WDI (if enabled by bit INTENx.WDI). For bit field definition, see RSI.

Single Edge Nibble Transmission (SENT)

24.3 SENT Module Implementation

This section describes the SENT module interface as it is implemented in the TC26x B-Step. It especially covers clock control, port and on-chip connections, interrupt control, and address decoding.

24.3.1 Interface Connections of the SENT Module

Figure 24-17 shows the TC26x B-Step-specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. Outputs of the GTM module are connected to the 6 timer inputs.

The serial data inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are used, they are usually mapped to the same port pin like the referring SENT data input line as this minimizes the pin count requirement.

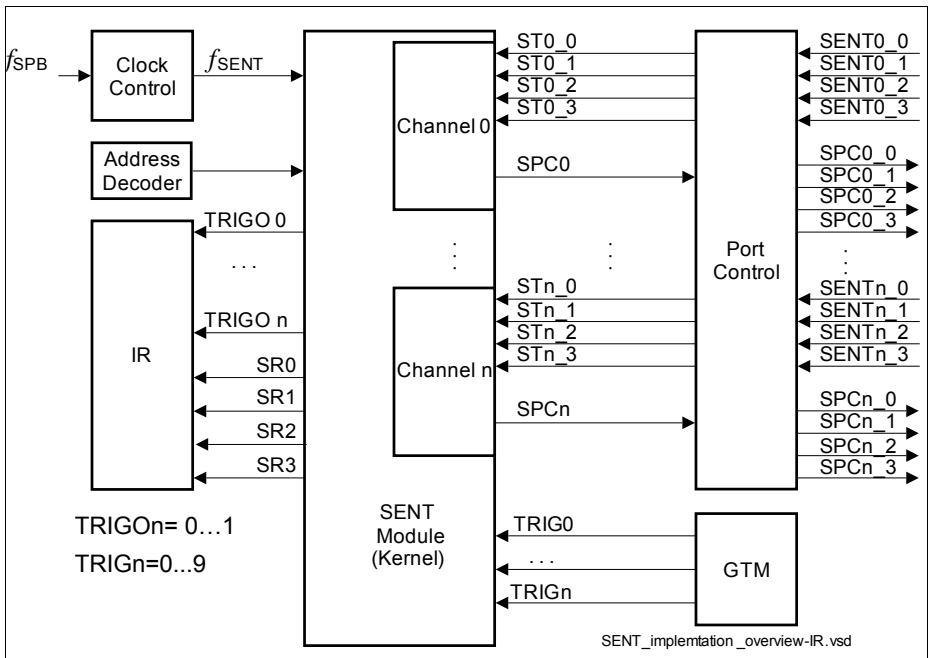

Figure 24-17 SENT Module Implementation and Interconnections

Single Edge Nibble Transmission (SENT)
24.3.1.1 On-Chip Connections

This section describes the on-chip connections of the SENT module.

24.3.1.2 Interrupt and DMA Controller Service Requests

The trigger outputs of the SENT module are connected via the Interrupt router. The request lines are connected as shown in [Table 24-9](#).

Table 24-9 Service Request Lines of SENT

INP value	Request Line	Connected to	Description
0000 _b	SR0	SRC_SENT0	Interrupt Router SENT Request 0
0001 _b	SR1	SRC_SENT1	Interrupt Router SENT Request 1
0010 _b	SR2	SRC_SENT2	Interrupt Router SENT Request 2
0011 _b	SR3	SRC_SENT3	Interrupt Router SENT Request 3
0100 _b	TRIGO0	SRC_SENT4	Interrupt Router SENT Request 4
0101 _b	TRIGO1	SRC_SENT5	Interrupt Router SENT Request 4
0110 _b	TRIGO2	SRC_SENT6	Not Connected
0111 _b	TRIGO3	SRC_SENT7	Not Connected
1000 _b	TRIGO4	SRC_SENT8	Not Connected
1001 _b	TRIGO5	SRC_SENT9	Not Connected
1010 _b	TRIGO6	SRC_SENT10	Not Connected
...
1111 _b	TRIGO11	SRC_SENT15	Not Connected

Trigger Inputs

The module has 6 Sent Channels and the same number of trigger inputs which can be randomly chosen by programming IOCRx.ETS. The trigger inputs (TRIG[5:0]) of the SENT module are connected to the GTM as shown in [Table 24-10](#). n = [0 .. 5]

Table 24-10 Trigger Input Lines of SENT

Request Line	Connected to	Description
TRIG0	TRIG0	GTM.ADC_0_TRIG_0
TRIG1	TRIG1	GTM.ADC_1_TRIG_0
...

Single Edge Nibble Transmission (SENT)**Table 24-10 Trigger Input Lines of SENT**

Request Line	Connected to	Description
TRIG4	TRIG4	GTM.ADC_4_TRIG_0
TRIG5	TRIG5	GTM.DSADC_0_TRIG_0

Single Edge Nibble Transmission (SENT)

24.3.2 SENT Module-Related External Registers

The registers listed in [Figure 24-18](#) are external of the SENT module kernel but must be programmed for proper operation of the SENT module.

Figure 24-18 SENT Implementation-specific Special Function Registers

24.3.2.1 Port Control

The SENT input channels are overlaid with standard ADC channels as they are replacing former analog signals. Each channel is connected to two ADC channels that can be chosen alternatively. In addition each channel is connected to general purpose I/O lines as well. Each channel is connected to two different general purpose I/O lines that can be chosen alternatively. The selection from on of these 4 alternatives is done by application SW by programming SENT_IOCRx.ALTi respectively.

The SPC output lines are connected to the same I/O ports as the referring input channel. The ADC channels do not provide output functionality. The SPC I/O ports are controlled in the port logic (see also [Figure 24-17](#)). The following port control operations and selections must be executed for these I/O lines:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

Input/Output Function Selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlaid with SENT digital input and no output option on this pin.
- SENT configured digital I/O lines (open drain, no push/pull, uses SDIR, single pin hardware direction control HW_DIR, SDIR is controlled by the data value: 0 = active out, 1 = passive/open drain, input)

Single Edge Nibble Transmission (SENT)

- Standard general purpose input/output function on two lines for each channel (input on ADC alternative 1 or 2, or on I/O port alternative 1 while the output is chosen to be on I/O ports alternative 2).

The SENT module overlays dedicated analog to digital converter (ADC) pins as digital input port.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. V_{ddm} must be supplied with 5V for SENT operation.

SENT physical layer uses 5V signal voltage levels. All SENT inputs are mapped to 5V compatible ADC pads. V_{ddm} must be supplied with 5V for SENT operation.

The SENT module can be configured to use input/output ports configured for use with SENT. These control settings for the port pins differ from the standard general purpose I/O lines in so far as

- they are controlled by the SENT module output data via their HW_DIR line
- they are configured to use no push/pull devices and to work in open drain mode if the output function is selected by the HW_DIR line of the port

The SENT module can be configured to use standard (push pull) general purpose I/O lines as well. Different port pins can be selected for input and for output. This allows the use of external transceiver devices.

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as port direction (input/output) with alternate output selection, pull-up/down devices, and open-drain selections. The I/O lines for the SENT module are controlled by the Port input/output control registers shown below.

Table 24-11 shows an overview how bits and bit fields must be programmed for the required I/O functionality of the SENT I/O lines.

Table 24-11 SENT I/O Control Selection and Setup

SENT Channel	Port Lines	Input Select Register	Input/Output Control Register Bits	I/O

Single Edge Nibble Transmission (SENT)
24.3.3 BPI_FPI Module Registers
Clock Control Register (CLC)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock, sleep mode and disable mode for the module.

SENT_CLC
Clock Control Register
(00_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module.
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode.
RMC	[15:8]	rw	8-bit Clock Divider Value in RUN Mode
0	[31:16], [7:4], 2	r	Reserved Read as 0; should be written with 0.

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

Single Edge Nibble Transmission (SENT)

15. After a hardware reset operation, the f_{SENT} and $f_{fracdiv}$ clocks are switched off and the SENT module is disabled (DISS set).

OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status (E8_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SUS	[27:24]	rw	OCDS Suspend Control Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 _H Will not suspend 1 _H Hard suspend. Clock is switched off immediately. (SPC low pulse breaks immediately, Port Pin keeps the last value if suspend state is entered) 2 _H Soft suspend (SPC low pulse will be finished before suspend state is entered) others , reserved
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	Suspend State 0 _B Module is not (yet) suspended 1 _B Module is suspended
0	[23:0], [31:30]	r	Reserved Read as 0; must be written with 0.

Single Edge Nibble Transmission (SENT)
Access Enable Register (ACCEN0)

The Access Enable Register 0 controls write access¹⁾ for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... , EN31 -> TAG ID 011111_B.

ACCEN0
Access Enable Register 0
(FC_H)

Field	Bits	Type	Description
ENn (n = 0-31)	n	rW	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

Single Edge Nibble Transmission (SENT)

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 10000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1
(F8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

Single Edge Nibble Transmission (SENT)
KRST0
Kernel Reset Register 0
(F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rh	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

24.4 Revision History

This User's Manual is based on: SAE Standard "SENT Revision J2716 JAN2010".

Table 24-12 Revision History

Version Number	Changes to Previous Version
Rev_0.1D	First Draft (Bullet Points ++)
Rev_0.2D	Second Draft (Bullet Points ++)
Rev_0.3D	First Review Version
Rev_0.4D	<ul style="list-style-type: none"> • RCRx.NINT removed as unnecessary FIFO support • Spelling Checked • Renamed INTNP to INP (request DE) • One common error node pointer in INP for FRI, FDI, NNI, NVI, CRCI, WSI, SCRI (reduce DE effort) • Interrupt Node Pointer in INPx increased from 2 bit to 4 bit • Renamed PVAL to PDIV in register CPDRx • RCRx.ASP "Additional Sync/Cal Pulse expected" deleted, not required • RCRx.ACE "Alternate CRC Mode" added, request customer • cleanup Register SCR • ISR0 (Input select register) deleted • AltIn and Filter DEPTH moved to IOCRx • SCRx.DEL moved to SDRx • SCRx deleted, BASE and TRQ moved to SDR • Restructured Chapters (interrupts after functional registers, implementation chapter cleaned up) • Simplified Baud rate generation (Fdtick removed)
Rev_0.5D	<ul style="list-style-type: none"> • Clean up Glitch filter Chapter • Detailed Baud Rate Generation • Added Address overview table

Single Edge Nibble Transmission (SENT)

Table 24-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_0.6D	<ul style="list-style-type: none"> • Channel Fractional Divider with variable divider instead of variable dividend • Glitch filter based on F_pdiv and no longer on F_sent • Glitch detection added • Pre divider = PDIV and no longer PDIV + 1 • Compressed address overview table • Interrupt generation updated with figure • Trigger outputs renamed (RSI and SDI, no more TRIGO) and completed • RDI simplified - now independent from RSI • ETS wording corrected • INTOV now only updated for enabled interrupts (before: any change) • Renamed "SPC Data Register SDR" to "SPC Control Register SCR", it contains both data and control information • TDI wording optimized • External Registers Overview corrected • KSCCFG removed
Rev_1.0D	First complete revision (To be done)
Rev_1.1D	<ul style="list-style-type: none"> • Moved Base Address to F032_1000 - F032_19FF (10x256 bytes) • Serial message ID added. SDSx.SCN moved to [19:16], SDSx.SCRC moved to [15:12], SDSx.MID placed at [11:8]. • RSI and TDI as trigger outputs replaced by 8 Trigger Outputs programmable in the INPs. • implemented first port mapping proposal from product
Rev_1.2	<ul style="list-style-type: none"> • Added hint to RCR.CEN that FSMs are initialized during enable • Port mapping updated to latest changes of CW08/47

Single Edge Nibble Transmission (SENT)
Table 24-12 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.3	<ul style="list-style-type: none"> • Fixed INTENx Bit descriptions: all bits are rw and high active (typo) • added to feature list: “Programmable Nibble sorting to support LSN or HSN first and relief CPU” (was missing) • SENT_FDR.DM[1:0] added description of all 4 states of this bit field. (same as system level) • IOCR.DEPTH corrected f_{SENT} sent to f_{pdiv} (longer glitch tolerance) • Add Freeze-Disable Bit [10] to SENT_FDR (system requirement) • Pre divider factor is (PDIV + 1) and no longer PDIV (ease design) • Resulting Channel Fractional Divider is (DIV + 1) and no longer DIV • Add IOCR.TXM, RXM and TRM monitor bits (ease of validation) • RDRx added explanation: unused nibbles are shown as '0' (for clarity) • RDI and RSI: Read clears these bits NOT (request from AE) • Renamed Transmit Buffer Overflow to UNDER-Flow with change to respective functionality (data completely transmitted without new write) • RCRx.CFC: Wording improved and details added
Rev_1.4	<ul style="list-style-type: none"> • Added column Access Modes to Register Table • Updated Figure 24-2, Figure 24-3, Figure 24-4 (beautification) • The clock signal f_{pdiv} of a channel must always be at least 20 (old value 10) times the nominal tick frequency, to cater for worst case. • INPx: Added reserved values • Corrected interrupt structure figure, no more separate DMA TRIGO lines. • RCRx, VIEWx and CFDRx Reset value corrected to 0x0000 0000 hex • Added explanations to RDRx and VIEWx • AI00050230 - SENT_FDR register located at “unusual” address: Moved CLC to offset 0x0Ch for consistency with other modules • Reduced ETS to 3 bit and ALTI to 2 bit width • “Zero Nibble Insertion in CRC” covered. See RCR.CRZ. • UTP AI00050205 - “Extended Serial Frame” covered. Added description of extended serial frame. • SDS.SCN moved to RSR.SCN (Allows for an aligned representation of ID and Data as well as a fixed position for SCN) • SDS.SD, SDS.MID, SDS.SCRC enlarged (to 16, 8 and 6 bit width) • SDS.CON and RCR.ESF added • Resulting Channel Fractional Divider is DIV and no longer (DIV + 1)

Single Edge Nibble Transmission (SENT)

25 FlexRay™ Protocol Controller (E-Ray)

The E-Ray IP-module performs communication according to the FlexRay™ ¹⁾ protocol specification v2.1, developed for automotive applications. With maximum specified clock the bitrate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

25.1 E-Ray Kernel Description

Figure 25-1 shows a global view of the E-Ray interface.

Figure 25-1 General Block Diagram of the E-Ray Interface

The E-Ray module communicates with the external world via three I/O lines each channel. The RXDA_x and RXDB_x lines are the receive data input signals, TXDA and

1) Infineon®, Infineon Technologies®, are trademarks of Infineon Technologies AG. FlexRay™ is a trademark of FlexRay Consortium.

FlexRay™ Protocol Controller (E-Ray)

TXDB lines are the transmit output signals, $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the E-Ray module kernel.

25.2 Overview

For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 Message Buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay™ Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay™ Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Service Request Control, and to access the Message RAM via Input / Output Buffer.

The E-Ray IP-module supports the following features:

- Conformance with FlexRay™ protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 Message Buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 Message Buffers with max. 48 byte data field or up to 30 Message Buffers with 254 byte Data Sections
- Configuration of Message Buffers with different payload lengths possible
- One configurable receive FIFO
- Each Message Buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to Message Buffers via Input and Output Buffer.
Input Buffer: Holds message to be transferred to the Message RAM
Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module service requests
- Network Management supported
- Four service request lines
- Automatic delayed read access to Output Command Request Register (OBCR) if a data transfer from Message RAM to Output Shadow Buffer (initiated by a previous write access to the OBCR) is ongoing.
- Automatic delayed read access to Input Command Request Register (IBCR) if a data transfer from Input Shadow Buffer to Message RAM to (initiated by a previous write access to the IBCR) is ongoing.

FlexRay™ Protocol Controller (E-Ray)

- Four Input Buffer for building up transmission Frames in parallel.
- Flag indicating which Input Buffer is currently accessible by the host.

25.3 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

25.4 Block Diagram

The E-Ray is built up by the following main submodules:

Figure 25-2 E-Ray Block Diagram

Customer Host Interface (CIF)

Connects the FPI Bus to the E-Ray IP-module via the Generic Host Interface.

Generic Host Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic Host Interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed via the Generic Host Interface.

FlexRay™ Protocol Controller (E-Ray)**Input Buffer (IBF)**

For write access to the Message Buffers configured in the Message RAM, the Host can write the Header and Data Section for a specific Message Buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected Message Buffer in the Message RAM.

Because the Input Buffer (IBF) Scheme does only allow to write the entire Message Frame, not only parts of it, the number of IBF has been increased from originally 2 to 4. This enables to fill the buffer partly and at the end request transfer into Message RAM. Therefore 2 extra bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for Host writes.

Output Buffer (OBF)

For read access to a Message Buffer configured in the Message RAM the Message Handler transfers the selected Message Buffer to the Output Buffer. After the transfer has completed, the Host can read the Header and Data Section of the transferred Message Buffer from the Output Buffer.

Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay™ Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ Message Buffers together with the related configuration data (Header and Data Partition).

Transient Buffer RAM (TBF 1/2)

Stores the Data Section of two complete messages.

FlexRay™ Channel Protocol Controller (PRT A/B)

The FlexRay™ Channel Protocol Controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ Frames and symbols
- Check of Header CRC
- Generation / check of Frame CRC

FlexRay™ Protocol Controller (E-Ray)

- Interfacing to bus driver

The FlexRay™ Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Service Request Control

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by FTM algorithm
 - Rate correction
 - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislottng)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of Frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network Management (NEM)

Handles of the Network Management vector

Service Request Control (INT)

The Service Request Controller performs the following functions:

- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

25.5 Programmer's Model

The programmer's model of the E-Ray module follows the principle of memory mapped peripheral. Some portion of the memory follows the principle of segmented/paged memory organization.

25.5.1 Register Map

The E-Ray module allocates an address space of 4 Kbyte (000_H to FFFF_H). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0004_H - 000F_H, 03C8_H - 03EC_H and 0800_H - 0FFF_H are reserved for customer specific purposes. All functions related to these addresses are located in the Customer Host Interface. The test registers located on address 0010_H and 0014_H are writable only under the conditions described in [“Special Registers” on Page 25-22](#).

The assignment of the Message Buffers is done according to the scheme shown in [Table 25-1](#) below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit / Receive Buffers assigned to static segment
- Static and Dynamic Buffers: Transmit / Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

The Message Buffer separation configuration can be changed only in “DEFAULT_CONFIG” or “CONFIG” state only by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup / SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY, and SUCC1.TSM

FlexRay™ Protocol Controller (E-Ray)

in the SUC Configuration Register 1 (SUCC1). In addition, Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

Table 25-1 Assignment of Message Buffers

Message Buffer 0	↓ Static Buffers	
Message Buffer 1		
...		
	↓ Static + Dynamic Buffers	← FDB
	↓ FIFO	← FFB
Message Buffer N-1		
Message Buffer N		← LCB

25.5.2 E-Ray Kernel Registers

This chapter describes all registers of the E-Ray kernel.

All registers in the E-Ray address spaces are reset with the application reset with one exception: OCS is reset with debug reset only. (Definition see SCU section “Reset Operation”)

Table 25-2 Registers Address Space E-Ray Kernel Register Address Space

FlexRay™ Protocol Controller (E-Ray)

- 1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

Note: Registers covered by the ACCENx write protection mechanism are marked with 'P' in Access Mode, Write.

25.5.2.1 Customer Registers

The addresses 0004_H - 000F_H, 03C8_H - 03EC_H and 0800_H - 0FFF_H are reserved for customer-specific registers.

Module Identification Register (ID)

This register contains bit fields identifying the E-Ray module in Infineons Module portfolio and is read only.

ID

Module Identification Register (0008_H) **Reset Value: 0044 C0XX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type The value of this bit field is C0 _H . It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. For the E-Ray module the module identification number is 44 _H .

FlexRay™ Protocol Controller (E-Ray)

Busy Control Register (CUST1)

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme. IBFS changes 2 clock cycles after any reset to '1'. Thus the application will read this bit as '1' already at first access after any reset.

CUST1

Busy and Input Buffer Control Register

FlexRay™ Protocol Controller (E-Ray)

Customer Interface Time-out Counter Register (CUST3)

The Time-out Counter Register is realizing the time-out counter reload (startup) value for the automatic delay scheme (not the time-out down counter itself).

CUST3

Customer Interface Timeout Counter (000C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TO	[31:0]	rw	CIF Timeout Reload Value The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

Automatic Delayed Write Access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter precluded with the 32-bit value specified in the bit field CUST3.TO. If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, e.g. to set OBCR.VIEW will lead to a canceled read or write operation, e.g. OBCR.VIEW remains cleared, and an error is signalled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is completed. During this time span all read and

FlexRay™ Protocol Controller (E-Ray)

write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal TOBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, e.g. to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is cancelled after the stall time, e.g. OBCR.VIEW remains cleared, and an error is signalled by setting EIR.IOBA) or the read or write completes normally, e.g. set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer (MBF⇒OBF) is finalized. During this time the bus is locked and no further access to the E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TOBC or due to other not processed read or write accesses to the E-Ray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF (IBF⇒MBF), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF⇒MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signalled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is cleared. Additionally signal TIBC may be used, e.g. for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay

FlexRay™ Protocol Controller (E-Ray)

time elapsed (in this case the read or write operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA) or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF⇒MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to E-Ray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the E-Ray module, read or write stall may only be detected through the signal TIBC or due to other not processed read or write accesses to the E-Ray module.

So setting CUST3.TO = FFFFFFFF_H, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

25.5.2.2 Special Registers

Test Register 1 (TEST1)

The Test Register 1 holds the control bits to configure the test modes of the E-Ray module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the E-Ray IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

TEST1

Test Register 1

Field	Bits	Type	Description
WRTEN	0	rw	Write Test Register Enable Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on “Lock Register (LCK)” on Page 25-30 . The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0 _B Write access to test registers disabled. 1 _B Write access to test registers enabled.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
ELBE	1	rw	External Loop Back Enable There are two possibilities to perform a loop back test. External loop back via physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	[5:4]	rw	Test Multiplexer Control 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	Activity on A The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannellIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	Activity on B The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannellIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	Read Channel A Receive Pin 0_B RXDA = 0 1_B RXDA = 1

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
RXB	17	rh	Read Channel B Receive Pin 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	Read or Write to Channel A Transmit Pin 0_B TXDA = 0 1_B TXDA = 1
TXB	19	rwh	Read or Write to Channel B Transmit Pin 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	Read or Write to Channel A Transmit Enable Pin 0_B TXENA = 0 1_B TXENA = 1
TXENB	21	rwh	Read or Write to Channel B Transmit Enable Pin 0_B TXENB = 0 1_B TXENB = 1
CERA	[27:24]	rh	Coding Error Report Channel A¹⁾ Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. 0000_B No coding error detected 0001_B Header CRC error detected 0010_B Frame CRC error detected 0011_B Frame Start Sequence FSS too long 0100_B First bit of Byte Start Sequence BSS seen LOW 0101_B Second bit of Byte Start Sequence BSS seen HIGH 0110_B First bit of Frame End Sequence FES seen HIGH 0111_B Second bit of Frame End Sequence FES seen LOW 1000_B CAS / MTS symbol seen too short 1001_B CAS / MTS symbol seen too long Other combinations are reserved.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CERB	[31:28]	rh	Coding Error Report Channel B¹⁾ Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. 0000 _B No coding error detected 0001 _B Header CRC error detected 0010 _B Frame CRC error detected 0011 _B Frame Start Sequence FSS too long 0100 _B First bit of Byte Start Sequence BSS seen LOW 0101 _B Second bit of Byte Start Sequence BSS seen HIGH 0110 _B First bit of Frame End Sequence FES seen HIGH 0111 _B Second bit of Frame End Sequence FES seen LOW 1000 _B CAS / MTS symbol seen too short 1001 _B CAS / MTS symbol seen too long Other combinations are reserved.
0	[3:2], [7:6], [15:10], [23:22]	r	Reserved Returns 0 if read; should be written with 0.

1) Coding errors are also signalled when the Communication Controller is in "MONITOR_MODE". The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in "CONFIG" state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED". CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the E-Ray module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: "CONFIG") to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

FlexRay™ Protocol Controller (E-Ray)

The cycle counter value of Frames send in ATM mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show $0000\ 1101_H$ while the E-Ray module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back via physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins TXENA, TXENB are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels’s Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The E-Ray cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

The cycle counter value of Frames used in loop back mode can be programmed via MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

FlexRay™ Protocol Controller (E-Ray)
Test Register 2 (TEST2)

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the E-Ray module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2
Test Register 2
(0014_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RS	[2:0]	rw	RAM Select In RAM Test mode the RAM blocks selected by RS are mapped to module address 0000 0400 _H to 0000 07FF _H (1024 byte addresses). 000 _B Input Buffer RAM 1 (IBF1) 001 _B Input Buffer RAM 2 (IBF2) 010 _B Output Buffer RAM 1 (OBF1) 011 _B Output Buffer RAM 2 (OBF2) 100 _B Transient Buffer RAM A (TBF1) 101 _B Transient Buffer RAM B (TBF2) 110 _B Message RAM (MBF) 111 _B Reserved; should not be used.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
SSEL	[6:4]	rw	Segment Select To enable access to the complete Message RAM (8192 byte addresses) the Message RAM is segmented. 000 _B access to RAM byte 0000 _H to 03FF _H enabled 001 _B access to RAM byte 0400 _H to 07FF _H enabled 010 _B access to RAM byte 0800 _H to 0BFF _H enabled 011 _B access to RAM byte 0C00 _H to 0FFF _H enabled 100 _B access to RAM byte 1000 _H to 11FF _H enabled 101 _B access to RAM byte 1400 _H to 17FF _H enabled 110 _B access to RAM byte 1800 _H to 1BFF _H enabled 111 _B access to RAM byte 1C00 _H to 1FFF _H enabled

0	3, [13:7], 15, [31:16]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to 7FF_H (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

In RAM test mode the memory must be accessed with 32Bit accesses only.

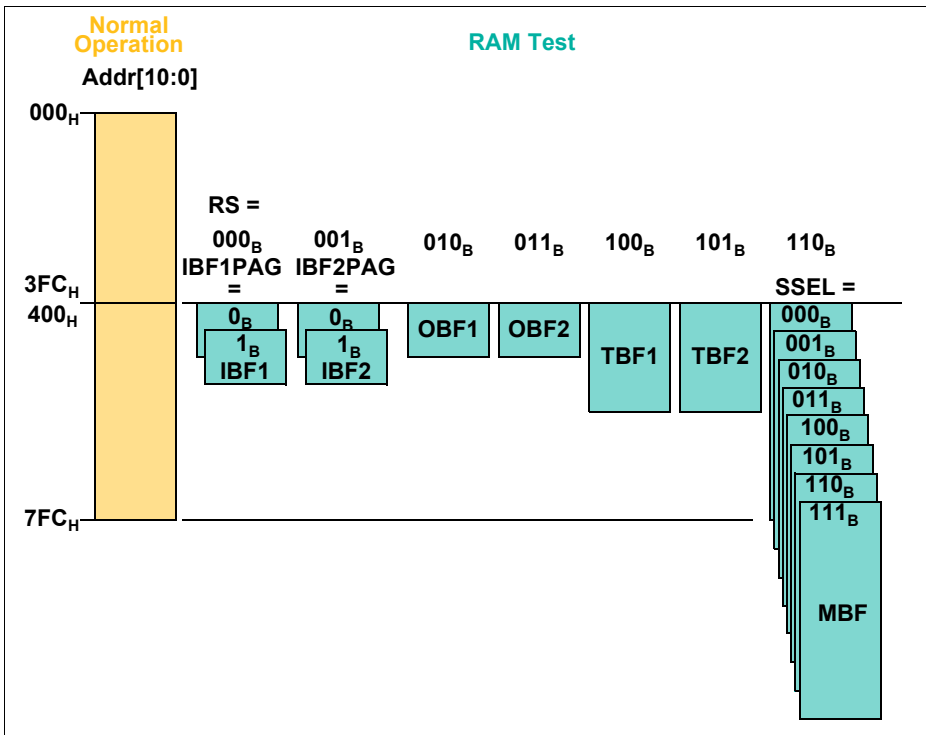

Figure 25-3 RAM test mode Access to E-Ray RAM Blocks

FlexRay™ Protocol Controller (E-Ray)

Lock Register (LCK)

The Lock Register is write-only. Reading the register will return 0000 0000_H.

LCK

Field	Bits	Type	Description
CLK	[7:0]	w	<p>Configuration Lock Key</p> <p>To leave “CONFIG” state by writing to SUCC1.CMD commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated.</p> <p>First write: LCK.CLK = CE_H = 1100 1110_B</p> <p>Second write: LCK.CLK = 31_H = 0011 0001_B</p> <p>Third write: SUCC1.CMD</p> <p>Returns 0 if read</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
TMK	[15:8]	w	Test Mode Key To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75 _H = 0111 0101 _B Second write: LCK.TMK = 8A _H = 1000 1010 _B Second write: TEST1.WRTEN = 1 Returns 0 if read
0	[31:16]	r	Reserved Returns 0 if read; should be written with 0.

Note: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no “dummy accesses” e.g. to the remaining register bytes / words are inserted by the compiler.

To exit “CONFIG” state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in “CONFIG” state and the sequence has to be repeated.

First write: LCK.CLK = CE_H = 1100 1110_B

Second write: LCK.CLK = 31_H = 0011 0001_B

FlexRay™ Protocol Controller (E-Ray)

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	[23:18], [31:26]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Service Request Line Enable (ILE)

Each of the two service request lines to the Host INT0SRC, INT1SRC can be enabled / disabled separately by programming bit EINT0 and EINT1.

ILE

Service Request Line Enable (0040_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
EINT0	0	rw	Enable Service Request Line 0 (INT0SRC) 0 _B Service Request line disabled 1 _B Service Request line enabled
EINT1	1	rw	Enable Service Request Line 1 (INT1SRC) 0 _B Service Request line disabled 1 _B Service Request line enabled
0	[31:2]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Timer 0 Configuration (T0C)

Absolute timer. Specifies in terms of cycle count and MacroTICK the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one MacroTICK and SIR.TI0 is set to 1.

Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

T0C
Timer 0 Configuration (0044_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		T0MO

0		T0CC					0					T0M	T0R		
r		rw					r					rw	rwh		

Field	Bits	Type	Description
T0RC	0	rwh	Timer 0 Run Control 0 _B Timer 0 halted 1 _B Timer 0 running
T0MS	1	rw	Timer 0 Mode Select 0 _B Single-shot mode 1 _B Continuous mode
T0CC	[14:8]	rw	Timer 0 Cycle Code The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see “Cycle Counter Filtering” on Page 25-215 .
T0MO	[29:16]	rw	Timer 0 MacroTICK Offset Configures the MacroTICK offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	[7:2], 15, [31:30]	r	Reserved Returns 0 if read; should be written with 0.

Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves "NORMAL_ACTIVE" or "NORMAL_PASSIVE" state, or if timer 0 is halted by Host command, output signal TINT0SR is reset to 0 immediately.

FlexRay™ Protocol Controller (E-Ray)
Timer 1 Configuration (T1C)

Relative timer. After the specified number of MacroTicks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one MacroTick and SIR.T11 is set to 1.

Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

T1C
Timer 1 Configuration (0048_H)
Reset Value: 0002 0000_H

T1MC	[29:16]	rw	Timer 1 MacroTick Count When the configured MacroTick count is reached the timer 1 service request is generated. Valid values are: 2 _H ... 3FFF _H MacroTicks in continuous mode 1 _H ... 3FFF _H MacroTicks in single-shot mode
0	[15:2], [31:30]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Note: In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 1 is halted by Host command, output signal TINT1SR is reset to 0 immediately.

FlexRay™ Protocol Controller (E-Ray)
Stop Watch Register 1 (STPW1)

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the MacroTICK counter increment following next to the stop watch activation the actual cycle counter and MacroTICK value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

STPW1
Stop Watch Register 1
(004C_H)
Reset Value: 0000 0000_H

EDGE	2	rw	Stop Watch Trigger Edge Select 0 _B Falling Edge 1 _B Rising Edge

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
SSWT	3	rwh	Software Stop Watch Trigger When the Host writes this bit to 1 the stop watch is activated. After the actual cycle counter and Macrotick value are stored in the Stop Watch register this bit is reset to 0. The bit is only writeable while ESWT = 0. 0 _B Software trigger reset 1 _B Stop watch activated by software trigger
EETP	4	rw	Enable External Trigger Pin Enables stop watch trigger event via signal STPW if ESWT = 1. 0 _B Stop watch trigger via signal STPW disabled 1 _B Edge on signal STPW triggers stop watch
EINT0	5	rw	Enable Service Request 0 Trigger Enables stop watch trigger by service request 0 event if ESWT = 1. 0 _B Stop watch trigger by service request 0 disabled 1 _B Service Request 0 event triggers stop watch
EINT1	6	rw	Enable Service Request 1 Trigger Enables stop watch trigger by service request 1 event if ESWT = 1. 0 _B Stop watch trigger by service request 1 disabled 1 _B Service Request 1 event triggers stop watch
SCCV	[13:8]	rh	Stopped Cycle Counter Value State of the cycle counter when the stop watch event occurred. Valid values are: 0...3F _H Valid Values
SMTV	[29:16]	rh	Stopped Macrotick Value State of the Macrotick counter when the stop watch event occurred. Valid values are: 0...3F _H Valid Values
0	7, [15:14], [31:30]	r	Reserved Returns 0 if read; should be written with 0.

Note: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.

FlexRay™ Protocol Controller (E-Ray)

Stop Watch Register 2 (STPW2)

STPW2

Stop Watch Register 2 (0050_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SSCVA	[10:0]	rh	Stop Watch Captured Slot Counter Value Channel A State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047 (0 _H to 7FF _H).
SSCVB	[26:16]	rh	Stop Watch Captured Slot Counter Value Channel B State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047 (0 _H to 7FF _H).
0	[15:11], [31:27]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CMD	[3:0]	rwh	<p>CHI Command Vector</p> <p>The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = "COMMAND_NOT_ACCEPTED", and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored.</p> <p>0000_B COMMAND_NOT_ACCEPTED" 0001_B CONFIG 0010_B READY 0011_B WAKEUP 0100_B RUN 0101_B ALL_SLOTS 0110_B HALT 0111_B FREEZE 1000_B SEND_MTS 1001_B ALLOW_COLDSTART 1010_B RESET_STATUS_INDICATORS 1011_B MONITOR_MODE 1100_B CLEAR_RAMs 1101_B Reserved 1110_B Reserved 1111_B Reserved</p> <p>Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions.</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
TXST	8	rw	Transmit Startup Frame in Key Slot^{1) 2)} (pKeySlotUsedForStartup) Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0 _B No Startup Frame transmission in key slot, node is non-coldstarter 1 _B Key slot used to transmit startup Frame, node is leading or following coldstarter
TXSY	9	rw	Transmit SYNC Frame in Key Slot^{1) 2)} (pKeySlotUsedForSync) Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0 _B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1 _B Key slot used to transmit SYNC Frames, node is sync node
CSA	[15:11]	rw	Cold Start Attempts¹⁾ (gColdStartAttempts) Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	[20:16]	rw	Passive to Active¹⁾ (pAllowPassiveToActive) Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 0000 _B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
WUCS	21	rw	<p>Wakeup Channel Select¹⁾ (pWakeupChannel) With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state.</p> <p>0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B</p>
TSM	22	rw	<p>Transmission Slot Mode¹⁾ (pSingleSlotEnabled) Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM.</p> <p>0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)</p>
HCSE	23	rw	<p>Halt due to Clock Sync Error¹⁾ (pAllowHaltDueToClock) Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only.</p> <p>0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state</p>
MTSA	24	rw	<p>Select Channel A for MTS Transmission^{1) 3)} The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state.</p> <p>0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
MTSB	25	rw	Select Channel B for MTS Transmission^{1) 3)} The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0 _B Channel B disabled for MTS transmission 1 _B Channel B selected for MTS transmission
CCHA	26	rw	Connected to Channel A¹⁾ (pChannels) Configures whether the node is connected to channel A. 0 _B Not connected to channel A 1 _B Node connected to channel A (default after application reset)
CCHB	27	rw	Connected to Channel B¹⁾ (pChannels) Configures whether the node is connected to channel B. 0 _B Not connected to channel B 1 _B Node connected to channel B (default after application reset)
0	[6:4], 10, [31:28]	r	Reserved Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

2) The protocol requires that both bits TXST and TXSY are set for coldstart nodes.

3) MTSa and MTSB may also be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command “SEND_MTS”. If both bits MTSa and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_g.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes command_not_accepted
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state “CONFIG” when called in POC states “DEFAULT_CONFIG“, “READY“, or in “MONITOR_MODE“. When called in “HALT” state transits to POC state

FlexRay™ Protocol Controller (E-Ray)

“DEFAULT_CONFIG“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

READY

Go to POC state “READY” when called in POC states “CONFIG”, “NORMAL_ACTIVE”, “NORMAL_PASSIVE”, “STARTUP”, or “WAKEUP”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

WAKEUP

Go to POC state WAKEUP when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

RUN

Go to POC state “STARTUP” when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state “HALT” at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state “HALT” immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state “NORMAL_ACTIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FlexRay™ Protocol Controller (E-Ray)**ALLOW_COLDSTART**

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG”, “CONFIG”, “HALT”, or “MONITOR_MODE”. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see [“MONITOR_MODE” on Page 25-199](#).

CLEAR_RAMs

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMs need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMs.

The initialization of the E-Ray internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMs. Before asserting CHI command CLEAR_RAMs the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

FlexRay™ Protocol Controller (E-Ray)

Note: All accepted commands with exception of CLEAR_RAMs and SEND_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks f_{CLC_ERAY} and f_{SCLK} , assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time Frame. Reading register CCSV will show data that is delayed by synchronization from f_{SCLK} to f_{CLC_ERAY} domain and by the Host-specific CPU interface.

Table 25-4 below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.]

Table 25-4 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

FlexRay™ Protocol Controller (E-Ray)
SUC Configuration Register 2 (SUCC2)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC2

SUC Configuration Register 2 (0084_H) Reset Value: 0100 0504_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		LTN				0		LT																							
r		rw				r		rw																							

Field	Bits	Type	Description
LT	[20:0]	rw	Listen Timeout¹⁾ (pdListenTimeout) Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504 _H to 139706 _H) Microticks
LTN	[27:24]	rw	Listen Time-out Noise¹⁾ (gListenNoise - 1) Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. 1 _H Listen Time-out Noise is equal 2 2 _H Listen Time-out Noise is equal 3 ... _H ... F _H Listen Time-out Noise is equal 16
0	[23:21], [31:28]	r	Reserved Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

*Note: The wakeup / startup noise time-out is calculated as follows:
The wakeup / startup noise time-out = pdListenTimeout • gListenNoise
= LT • (LTN+ 1)*

FlexRay™ Protocol Controller (E-Ray)

NEM Configuration Register (NEMC)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC

NEM Configuration Register (008C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
NML	[3:0]	rw	Network Management Vector Length¹⁾ (gNetworkManagementVectorLength) These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0 _H to C _H) bytes.
0	[31:4]	r	Reserved Returns 0 if read; should be written with 0.

1) This bit can be updated in “DEFAULT_CONFIG” or “CONFIG” state only!

FlexRay™ Protocol Controller (E-Ray)
PRT Configuration Register 1 (PRTC1)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1

PRT Configuration Register 1 (0090_H) Reset Value: 084C 0633_H

Field	Bits	Type	Description
TSST	[3:0]	rw	Transmission Start Sequence Transmitter¹⁾ (gdTSSTransmitter) Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100ns at 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3 _H to F _H) Bit Times.
CASM	[10:4]	rw	Collision Avoidance Symbol Maximum¹⁾ (gdCASRxLowMax) Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43 _H to 63 _H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	[13:12]	rw	Strobe Point Position¹⁾ Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. 00 _B Sample 5 (default) 01 _B Sample 4 10 _B Sample 6 11 _B Reserved; should not be used. <i>Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.</i>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
BRP	[15:14]	rw	<p>Baud Rate Prescaler¹⁾ (gdSampleClockPeriod, pSamplePerMicrotick) The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock $f_{SCLK} = 80$ MHz. One bit time always consists of 8 samples independent of the configured baud rate.</p> <p>00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = $1 / f_{SCLK}$ pSamplesPerMicrotick = 2</p> <p>01_B 5 Mbit/s (1 Microtick= 25ns; single sampled with $f_{SCLK} / 2$) gdSampleClockPeriod = 25 ns = $2 / f_{SCLK}$ pSamplesPerMicrotick = 1</p> <p>10_B 2.5 Mbit/s (1 Microtick = 50ns; single sampled with $f_{SCLK} / 4$) gdSampleClockPeriod = 50 ns = $4 / f_{SCLK}$ pSamplesPerMicrotick = 1</p> <p>11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with $f_{SCLK} / 4$) gdSampleClockPeriod = 50 ns = $4 / f_{SCLK}$ pSamplesPerMicrotick = 1</p>
RXW	[24:16]	rw	<p>Wakeup Symbol Receive Window Length¹⁾ (gdWakeupSymbolRxWindow) Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 (4C_H to 12D_H) Bit Times.</p>
RWP	[31:26]	rw	<p>Repetitions of Tx Wakeup Pattern¹⁾ (pWakeupPattern) Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to 3F_H).</p>
0	11, 25	r	<p>Reserved Returns 0 if read; should be written with 0.</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
FSI	6	rh	Freeze Status Indicator (vPOC!Freeze) Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	Halt Request (vPOC!CHIHaltRequest) Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.
SLM	[9:8]	rh	Slot Mode (vPOC!SlotMode) Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00 _B SINGLE 01 _B Reserved 10 _B ALL_PENDING 11 _B ALL
CSNI	12	rh	Coldstart Noise Indicator (vPOC!ColdstartNoise) Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	Coldstart Abort Indicator Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CSI	14	rh	<p>Cold Start Inhibit (vColdStartInhibit)</p> <p>Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B).</p> <p>0_B Cold starting of node enabled 1_B Cold starting of node disabled</p>
WSV	[18:16]	rh	<p>Wakeup Status (vPOC!WakeupStatus)</p> <p>Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state.</p> <p>000_B UNDEFINED. Wakeup not yet executed by the Communication Controller.</p> <p>001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state.</p> <p>010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state.</p> <p>011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel.</p> <p>100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.</p> <p>101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header.</p> <p>110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern.</p> <p>111_B Reserved</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
RCA	[23:19]	rh	<p>Remaining Coldstart Attempts (vRemainingColdstartAttempts)</p> <p>Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.</p>
PSL	[29:24]	rh	<p>POC Status Log</p> <p>Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.</p>
0	[11:10], 15, [31:30]	rh	<p>Reserved</p> <p>Returns 0 if read; should be written with 0.</p>

FlexRay™ Protocol Controller (E-Ray)
Communication Controller Error Vector (CCEV)

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

CCEV
Communication Controller Error Vector (0104_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CCFC	[3:0]	rh	Clock Correction Failed Counter (vClockCorrectionFailed) The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	[7:6]	rh	Error Mode (vPOC!ErrorMode) Indicates the actual error mode of the POC. 00 _B “ACTIVE” (green) 01 _B “PASSIVE” (yellow) 10 _B “COMM_HALT” (red) 11 _B Reserved
PTAC	[12:8]	rh	Passive to Active Count (vAllowPassiveToActive) Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA.
0	[5:4], [31:13]	r	Reserved Returns 0 if read; should be written with 0.

Slot Counter Value (SCV)
SCV
Slot Counter Value (0110_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SCCA	[10:0]	rh	Slot Counter Channel A (vSlotCounter[A]) Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0 _H to 7FD _H).
SCCB	[26:16]	rh	Slot Counter Channel B (vSlotCounter[B]) Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0 _H to 7FD _H).
0	[15:11], [31:27]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Macrotick and Cycle Counter Value (MTCCV)
MTCCV
Macrotick and Cycle Counter Value (0114_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
MTV	[13:0]	rh	Macrotick Value (vMacrotick) Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0 _H to 3E80 _H).
CCV	[21:16]	rh	Cycle Counter Value (vCycleCounter) Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0 _H to 3F _H).
0	[15:14], [31:22]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Rate Correction Value (RCV)

RCV

Rate Correction Value (0118_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RCV	[11:0]	rh	Rate Correction Value (vRateCorrection) Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	[31:12]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Offset Correction Value (OCV)

OCV

Offset Correction Value (011C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
OCV	[18:0]	rh	Offset Correction Value (vOffsetCorrection) Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	[31:19]	r	Reserved Returns 0 if read; should be written with 0.

Note: The external rate / offset correction value is added to the limited rate / offset correction value.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
VSBO	[15:12]	rh	Valid SYNC Frames Channel B, odd communication cycle Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	Missing Offset Correction Signal The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0 _B Offset correction signal valid 1 _B Missing offset correction signal
OCLR	17	rh	Offset Correction Limit Reached The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0 _B Offset correction below limit 1 _B Offset correction limit reached
MRCS	18	rh	Missing Rate Correction Signal The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0 _B Rate correction signal valid 1 _B Missing rate correction signal
RCLR	19	rh	Rate Correction Limit Reached The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit.as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0 _B Rate correction below limit 1 _B Rate correction limit reached
0	[31:20]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Symbol Window and network idle time (NIT) Status (SWNIT)

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

Note: MTS_A and MTS_B may be changed outside “DEFAULT_CONFIG” or “CONFIG” state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in “Lock Register (LCK)” on Page 25-30. This may be combined with CHI command SEND_MTS. If both bits MTS_A and MTS_B are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B

SWNIT

Symbol Window and Network Idle Time Status

(0124_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description

SBSA	1	rh	Slot Boundary Violation in Symbol Window Channel A (vSS!BViolationA) 0 _B No slot boundary violation detected 1 _B Slot boundary violation during symbol window detected on channel A

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
TCSA	2	rh	Transmission Conflict in Symbol Window Channel A (vSSI!TxConflictA) 0 _B No transmission conflict detected 1 _B Transmission conflict in symbol window detected on channel A
SESB	3	rh	Syntax Error in Symbol Window Channel B (vSSI!SyntaxErrorB) 0 _B No syntax error detected 1 _B Syntax error during symbol window detected on channel B
SBSB	4	rh	Slot Boundary Violation in Symbol Window Channel B (vSSI!BViolationB) 0 _B No slot boundary violation detected 1 _B Slot boundary violation during symbol window detected on channel B
TCSB	5	rh	Transmission Conflict in Symbol Window Channel B (vSSI!TxConflictB) 0 _B No transmission conflict detected 1 _B Transmission conflict in symbol window detected on channel B
MTSA	6	rh	MTS Received on Channel A (vSSI!ValidMTSA) ¹⁾ Media Access Test symbol received on channel A during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSA is set to 1. 0 _B No MTS symbol received on channel A 1 _B MTS symbol received on channel A
MTSB	7	rh	MTS Received on Channel B (vSSI!ValidMTSB) ¹⁾ Media Access Test symbol received on channel B during the proceeding symbol window. Updated by the Communication Controller for each channel at the end of the symbol window. When this bit is set to 1, also interrupt flag SIR.MTSB is set to 1. 0 _B No MTS symbol received on channel B 1 _B MTS symbol received on channel B

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
SENA	8	rh	Syntax Error during network idle time (NIT) Channel A (vSSI!SyntaxErrorA) Updated by the Communication Controller channel A at the end of the NIT. 0 _B No syntax error detected 1 _B Syntax error during network idle time (NIT) detected on channel A
SBNA	9	rh	Slot Boundary Violation during network idle time (NIT) Channel A (vSSI!BViolationA) Updated by the Communication Controller channel A at the end of the NIT. 0 _B No slot boundary violation detected 1 _B Slot boundary violation during network idle time (NIT) detected on channel A
SENB	10	rh	Syntax Error during network idle time (NIT) Channel B (vSSI!SyntaxErrorB) Updated by the Communication Controller channel B at the end of the NIT. 0 _B No syntax error detected 1 _B Syntax error during network idle time (NIT) detected on channel B
SBNB	11	rh	Slot Boundary Violation during network idle time (NIT) Channel B (vSSI!BViolationB) Updated by the Communication Controller channel B at the end of the NIT. 0 _B No slot boundary violation detected 1 _B Slot boundary violation during network idle time (NIT) detected on channel B
0	[31:12]	r	Reserved Returns 0 if read; should be written with 0.

- 1) MTSA and MTSB may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in "Lock Register (LCK)". This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_g.

FlexRay™ Protocol Controller (E-Ray)
Aggregated Channel Status (ACS)

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

ACS
Aggregated Channel Status (0128_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
VFRA	0	rwh	Valid Frame Received on Channel A (vSS!ValidFrameA) One or more valid Frames were received on channel A in any static or dynamic slot during the observation period. 0 _B No valid Frame received 1 _B Valid Frame(s) received on channel A
SEDA	1	rwh	Syntax Error Detected on Channel A (vSS!SyntaxErrorA) One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel A. 0 _B No syntax error observed 1 _B Syntax error(s) observed on channel A
CEDA	2	rwh	Content Error Detected on Channel A (vSS!ContentErrorA) One or more Frames with a content error were received on channel A in any static or dynamic slot during the observation period. 0 _B No Frame with content error received 1 _B Frame(s) with content error received on channel A

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CIA	3	rwh	<p>Communication Indicator Channel A</p> <p>One or more valid Frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation.</p> <p>0_B No valid Frame(s) received in slots containing any additional communication</p> <p>1_B Valid Frame(s) received on channel A in slots containing any additional communication</p>
SBVA	4	rwh	<p>Slot Boundary Violation on Channel A (vSSI!BViolationA)</p> <p>One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT).</p> <p>0_B No slot boundary violation observed</p> <p>1_B Slot boundary violation(s) observed on channel A</p>
VFRB	8	rwh	<p>Valid Frame Received on Channel B (vSSI!ValidFrameB)</p> <p>One or more valid Frames were received on channel B in any static or dynamic slot during the observation period.</p> <p>0_B No valid Frame received</p> <p>1_B Valid Frame(s) received on channel B</p>
SEDB	9	rwh	<p>Syntax Error Detected on Channel B (vSSI!SyntaxErrorB)</p> <p>One or more syntax errors in static or dynamic slots, symbol window, and network idle time (NIT) were observed on channel B.</p> <p>0_B No syntax error observed</p> <p>1_B Syntax error(s) observed on channel B</p>
CEDB	10	rwh	<p>Content Error Detected on Channel B (vSSI!ContentErrorB)</p> <p>One or more Frames with a content error were received on channel B in any static or dynamic slot during the observation period.</p> <p>0_B No Frame with content error received</p> <p>1_B Frame(s) with content error received on channel B</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CIB	11	rwh	Communication Indicator Channel B One or more valid Frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid Frame AND had any combination of either syntax error OR content error OR slot boundary violation. 0_B No valid Frame(s) received in slots containing any additional communication 1_B Valid Frame(s) received on channel B in slots containing any additional communication
SBVB	12	rwh	Slot Boundary Violation on Channel B (vSS!BViolationB) One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and network idle time NIT). 0_B No slot boundary violation observed 1_B Slot boundary violation(s) observed on channel B
0	[7:5], [31:13]	r	Reserved Returns 0 if read; should be written with 0.

Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1. When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1.

FlexRay™ Protocol Controller (E-Ray)
Even Sync ID [01...15] (ESIDnn)

Registers Even Sync ID nn (ESIDnn, nn=01-15) hold the Frame IDs of the SYNC Frames received in **even** communication cycles, sorted in ascending order, with register ESID01 holding the lowest received SYNC Frame ID. If the node itself transmits a SYNC Frame in an even communication cycle, register ESID01 holds the respective SYNC Frame ID as configured in Message Buffer 0 and the flags RXEA, RXEB are set. The value is updated during the network idle time (NIT) of each even communication cycle.

ESIDnn (nn = 01-15)
Even Sync ID Symbol Window nn

Field	Bits	Type	Description
EID	[9:0]	rh	Even Sync ID (vsSyncIDListA,B even) SYNC Frame ID even communication cycle.
RXEA	14	rh	Received/Configured Even Sync ID on Channel A Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0 _B SYNC Frame not received on channel A / node configured to transmit SYNC Frames 1 _B SYNC Frame received on channel A / node not configured to transmit SYNC Frames
RXEB	15	rh	Received/Configured Even Sync ID on Channel B Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID (ESID1 only). 0 _B SYNC Frame not received on channel B / node configured to transmit SYNC Frames 1 _B SYNC Frame received on channel B / node not configured to transmit SYNC Frames

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	[13:10], [31:16]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	[13:10], [31:16]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Network Management Vector [1...3] (NMVx)

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see **“Network Management” on Page 25-213**). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x = 1-3)

Network Management Vector x

$$(01AC_H + x * 4)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
NM	[31:0]	rh	Network Management Vector

Table 25-5 below shows the assignment of the received payload's data byte to the Network Management vector.

Table 25-5 Assignment of Data Byte to Network Management Vector

NM3	Data11			Data10			Data9			Data8																						

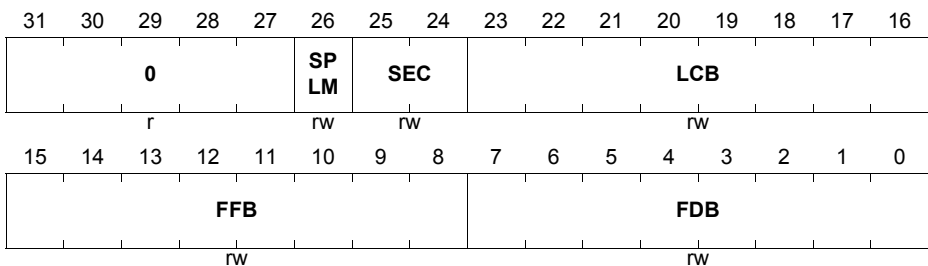

25.5.2.6 Message Buffer Control Registers

Message RAM Configuration (MRC)

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC

Message RAM Configuration (0300_H) **Reset Value: 0180 0000_H**

Field	Bits	Type	Description
FDB	[7:0]	rw	First Dynamic Buffer May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00 _H No group of Message Buffers exclusively for the static segment configured 01 _H ...7F _H Message Buffers 0 to FDB-1 reserved for static segment 80 _H ...FF _H No dynamic Message Buffers configured
FFB	[15:8]	rw	First Buffer of FIFO May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00 _H ...7E _H Message Buffers from FFB to LCB assigned to the FIFO 7F _H All Message Buffers assigned to the FIFO 80 _H ...FF _H No Message Buffers assigned to the FIFO

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
LCB	[23:16]	rw	<p>Last Configured Buffer May be only modified in “DEFAULT_CONFIG” or “CONFIG” state.</p> <p>01_H ...7F_H Number of Message Buffers is LCB + 1</p> <p>80_H ...FF_H No Message Buffer configured</p>
SEC	[25:24]	rw	<p>Secure Buffers Not evaluated when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For temporary unlocking see “Host Handling of Errors” on Page 25-248.</p> <p>00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled.</p> <p><i>Note: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked</i></p> <p>01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled</p> <p>10_B Reconfiguration of all Message Buffers locked</p> <p>11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled</p>
SPLM	26	rw	<p>SYNC Frame Payload Multiplex This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly.</p> <p>0_B Only Message Buffer 0 locked against reconfiguration</p> <p>1_B Both Message Buffers 0 and 1 are locked against reconfiguration</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	[31:27]	r	Reserved Returns 0 if read; should be written with 0.

Note: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.

Table 25-6 Usage of the three Message Buffer Pointer

Message Buffer 0	↓ Static Buffers		
Message Buffer 1			
	↓ Static + Dynamic Buffers	← FDB	
...			FIFO configured: FFB > FDB
	↓ FIFO	← FFB	No FIFO configured: FFB ≥ 128
Message Buffer N-1			LCB ≥ FDB, LCB ≥ FFB
Message Buffer N		← LCB	

The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations!**

*Note: The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see **“Message RAM” on Page 25-239**.*

In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “Static Buffers” or at the beginning of the “Static + Dynamic Buffers” section.

The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in “DEFAULT_CONFIG” or “CONFIG” state reconfiguration of Message Buffers belonging to the FIFO is locked.

FlexRay™ Protocol Controller (E-Ray)
FIFO Rejection Filter (FRF)

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRF
FIFO Rejection Filter (0304_H) **Reset Value: 0180 0000_H**

Field	Bits	Type	Description
CH	[1:0]	rw	Channel Filter May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00 _B receive on both channels ¹⁾ 01 _B receive only on channel B 10 _B receive only on channel A 11 _B no reception
FID	[12:2]	rw	Frame ID Filter Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000 _H ... 7FF _H Frame ID filter values

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
CYF	[22:16]	rw	Cycle Counter Filter The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see “Cycle Counter Filtering” on Page 25-215 . May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	Reject in Static Segment If this bit is set, the FIFO is used only be used in dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0 _B FIFO also used in static segment 1 _B Reject messages for static segment
RNF	24	rw	Reject NULL Frames If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0 _B NULL Frames are stored in the FIFO 1 _B Reject all NULL Frames
0	[15:13], [31:25]	r	Reserved Returns 0 if read; should be written with 0.

- 1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

FlexRay™ Protocol Controller (E-Ray)

FIFO Rejection Filter Mask (FRFM)

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM

FIFO Rejection Filter Mask (0308_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
MFID	[12:2]	rw	Mask Frame ID Filter May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0 _B Corresponding Frame ID filter bit is used for rejection filtering. 1 _B Ignore corresponding Frame ID filter bit.
0	[1:0], [31:13]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

FIFO Critical Level (FCL)

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL

FIFO Critical Level (030C_H) Reset Value: 0000 0080_H

Field	Bits	Type	Description
CL	[7:0]	rw	<p>Critical Level</p> <p>When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1 bit SIR.RFCL is set to 1, and if enabled, a service request is generated.</p>
0	[31:8]	r	<p>Reserved</p> <p>Returns 0 if read; should be written with 0.</p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
FMBD	5	rwh	Faulty Message Buffer Detected 0 _B No faulty Message Buffer 1 _B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error
MFMB	6	rwh	Multiple Faulty Message Buffers detected 0 _B No additional faulty Message Buffer 1 _B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
GRAM	7	rh	Clear all internal RAM's Signals that execution of the CHI command CLEAR_RAMs is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by CHI command CLEAR_RAMs. 0 _B No execution of the CHI command CLEAR_RAMs 1 _B Execution of the CHI command CLEAR_RAMs ongoing
FMB	[14:8]	rh	Faulty Message Buffer ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	[22:16]	rh	Message Buffer Transmitted Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	[30:24]	rh	Message Buffer Updated Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127) and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
0	15, 23, 31	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
RFO	2	rh	Receive FIFO Overrun The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set. The flag is cleared by the next FIFO read access issued by the Host. 0 _B No receive FIFO overrun detected 1 _B A receive FIFO overrun has been detected
RFFL	[15:8]	rh	Receive FIFO Fill Level Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	[7:3], [31:16]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

MHDF
Message Handler Constraints Flags (031C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SNUA	0	rwh	Status Not Updated Channel A This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel A. 0 _B No overload condition occurred when updating MBS for channel A 1 _B MBS for channel A not updated
SNUB	1	rwh	Status Not Updated Channel B This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel B. 0 _B No overload condition occurred when updating MBS for channel B 1 _B MBS for channel B not updated

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
FNFA	2	rwh	Find Sequence Not Finished Channel A This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0 _B No find sequence not finished for channel A 1 _B Find sequence not finished for channel A
FNFB	3	rwh	Find Sequence Not Finished Channel B This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0 _B No find sequence not finished for channel B 1 _B Find sequence not finished for channel B
TBFA	4	rwh	Transient Buffer Access Failure A This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0 _B No TBF A access failure 1 _B TBF A access failure
TBFB	5	rwh	Transient Buffer Access Failure B This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0 _B No Transient Buffer B access failure 1 _B Transient Buffer B access failure
TNSA	6	rwh	Transmission Not Started Channel A This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0 _B No transmission not started on channel A 1 _B Transmission not started on channel A
TNSB	7	rwh	Transmission Not Started Channel B This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0 _B No transmission not started on channel B 1 _B Transmission not started on channel B

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
WAHP	8	rwh	<p>Write Attempt to Header Partition</p> <p>Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses.</p> <p>0_B No write attempt to Header Partition 1_B Write attempt to Header Partition</p>
0	[31:9]	r	<p>Reserved</p> <p>Returns 0 if read; should be written with 0.</p>

FlexRay™ Protocol Controller (E-Ray)
Transmission Request 1 (TXRQ1)

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1
Transmission Request Register 1 (0320_H) **Reset Value: 0000 0000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
TXRn (n = 96-127)	n - 96	rh	Transmission Request n (n = 96-127) If the flag is set, the respective Message Buffer 96 to 127 is ready for transmission respectively transmission of this Message Buffer is in progress. In single-shot mode the flags are reset after transmission has completed.

FlexRay™ Protocol Controller (E-Ray)
New Data Register 1 (NDAT1)

This register reflect the state of the ND flags of all configured Message Buffers 0 to 31. ND flags assigned to transmit buffers are meaningless. If the number of configured Message Buffers is less than 31, the remaining NDn flags have no meaning. The registers are reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

NDAT1
New Data Register 1
(0330_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ND 31	ND 30	ND 29	ND 28	ND 27	ND 26	ND 25	ND 24	ND 23	ND 22	ND 21	ND 20	ND 19	ND 18	ND 17	ND 16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
NDn (n = 0-31)	n	rh	New Data n (n = 0-31) The flags are set when a valid received Data Frame matches the Message Buffer’s filter configuration, independent of the payload length received or the payload length configured for that Message Buffer. The flags are not set after reception of NULL Frames except for Message Buffers belonging to the receive FIFO. An ND flag is reset when the Header Section of the corresponding Message Buffer is reconfigured or when the Data Section has been transferred to the Output Buffer.

FlexRay™ Protocol Controller (E-Ray)
New Data Register 2 (NDAT2)

This register reflect the state of the ND flags of all configured Message Buffers 32 to 63. ND flags assigned to transmit buffers are meaningless. If the number of configured Message Buffers is less than 63, the remaining NDn flags have no meaning. The registers are reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

NDAT2
New Data Register 2
(0334_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FlexRay™ Protocol Controller (E-Ray)

Endian Register (ENDN)

This register may be used to check, if the data of the E-Ray is handled by a host with the correct endian format. It is read only.

ENDN

Endian Register (003F4_H) Reset Value: 8765 4321_H

Field	Bits	Type	Description
ETV	[31:0]	r	Endianness Test Value The endianness test value.

25.5.2.9 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the Header and Data Sections to be transferred to the selected Message Buffer in the Message RAM. It is used to configure the Message Buffers in the Message RAM and to update the Data Sections of transmit buffers.

When updating the Header Section of a Message Buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **“Message Buffer Status (MBS)” on Page 25-176** is automatically reset to zero.

The Header Sections of Message Buffers belonging to the receive FIFO can only be (re)configured when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For those Message Buffers only the payload length configured and the data pointer need to be configured via WRHS2.PLC and WRHS2.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **“Data Transfer from Input Buffer to Message RAM” on Page 25-224**.

Write Header Section 1 (WRHS1)
WRHS1
Write Header Section 1 (0500_H) Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		MBI	TXM	PPIT	CFG	CHB	CHA	0		CYC

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				FID											
r				rw											

Field	Bits	Type	Description
FID	[10:0]	rw	Frame ID Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	[22:16]	rw	Cycle Code The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see Section 25.6.7.3 .
CHA	24	rw	Channel Filter Control A The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	Channel Filter Control B The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	Message Buffer Direction Configuration Bit This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0 _B The corresponding buffer is configured as Receive Buffer 1 _B The corresponding buffer is configured as Transmit Buffer

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
PPIT	27	rw	Payload Preamble Indicator Transmit This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the E-Ray module, but can be done by the Host. 0 _B Payload Preamble Indicator not set 1 _B Payload Preamble Indicator set
TXM	28	rw	Transmission Mode This bit is used to select the transmission mode (see “Transmit Buffers” on Page 25-217). 0 _B Continuous mode 1 _B Single-shot mode
MBI	29	rw	Message Buffer Service Request This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and /or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0 _B The corresponding Message Buffer service request is disabled 1 _B The corresponding Message Buffer service request is enabled
0	[15:11], 23, [31:30]	r	Reserved Returns 0 if read; should be written with 0.

Note: The Input Buffer RAMs are initialized to zero when leaving application reset or by CHI command CLEAR_RAMs. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMs need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.

Table 25-8 Channel Filter Control Bits

CHA	CHB	Transmit Buffer transmit Frame on	Receive Buffer store Frame received from
1 ¹⁾	1 ¹⁾	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

1) If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

FlexRay™ Protocol Controller (E-Ray)
Write Header Section 2 (WRHS2)
WRHS2
Write Header Section 2
(0504_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
CRC	[10:0]	rw	Header CRC (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC calculated and configured by the Host. For calculation of the Header CRC the payload length of the Frame send on the bus has to be considered. In static segment the payload length of all Frames is configured by MHDC.SFDL.
PLC	[22:16]	rw	Payload Length Configured Length of Data Section (number of 2-byte words) as configured by the Host. During static segment the static Frame payload length as configured by MHDC.SFDL in the MHD Configuration Register defines the payload length for all static Frames. If the payload length configured by PLC is shorter than this value padding byte are inserted to ensure that Frames have proper physical length. The padding pattern is logical zero.
0	[15:11], [31:23]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Write Header Section 3 (WRHS3)

WRHS3

Write Header Section 3

(0508_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
DP	[10:0]	rw	Data Pointer Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	[31:11]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
LHSS	16	rh	Load Header Section Shadow 0 _B Header Section is not updated 1 _B Header Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
LDSS	17	rh	Load Data Section Shadow 0 _B Data Section is not updated 1 _B Data Section selected for transfer from Input Buffer to the Message RAM (transfer is ongoing of finalized)
STXRS	18	rh	Transmission Request Shadow If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 0-31) are evaluated for transmit buffer only. 0 _B Reset Transmission Request flag 1 _B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing of finalized)
0	[15:3], [31:19]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Input Buffer Command Request (IBCR)

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also [“Data Transfer from Input Buffer to Message RAM” on Page 25-224](#)).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR
Input Buffer Command Request (0514_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
DP	[10:0]	rh	Data Pointer Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	[21:16]	rh	Receive Cycle Count (vRF!Header!CycleCount) Cycle counter value updated from received Data Frame.
RCI	24	rh	Received on Channel Indicator (vSS!Channel) Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0 _B Frame received on channel B 1 _B Frame received on channel A
SFI	25	rh	Startup Frame Indicator (vRF!Header!SuFIndicator) A Startup Frame is marked by the Startup Frame indicator. 0 _B The received Frame is not a startup Frame 1 _B The received Frame is a startup Frame
SYN	26	rh	SYNC Frame Indicator (vRF!Header!SyFIndicator) A SYNC Frame is marked by the SYNC Frame indicator. 0 _B The received Frame is not a SYNC Frame 1 _B The received Frame is a SYNC Frame
NFI	27	rh	NULL Frame Indicator (vRF!Header!NFIndicator) Is set to 1 after storage of the first received Data Frame. 0 _B Up to now no Data Frame has been stored into the respective Message Buffer 1 _B At least one Data Frame has been stored into the respective Message Buffer

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
PPI	28	rh	Payload Preamble Indicator (vRF!Header!PPIndicator) The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0 _B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1 _B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload
RES	29	rh	Reserved Bit (vRF!Header!Reserved) Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	[15:11], [23:22], [31:30]	r	Reserved Returns 0 if read; should be written with 0.

Note: Header 3 is updated from Data Frames only.

FlexRay™ Protocol Controller (E-Ray)
Message Buffer Status (MBS)

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see **“Filtering and Masking” on Page 25-213**, **“Transmit Process” on Page 25-217**, and **“Receive Process” on Page 25-220**.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.</i></p>

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
0	13, [23:22], [31:30]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

OBCM
Output Buffer Command Mask (0710_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RHSS	0	rwh	Read Header Section Shadow 0 _B Header Section is not read 1 _B Header Section selected for transfer from Message RAM to Output Buffer
RDSS	1	rwh	Read Data Section Shadow 0 _B Data Section is not read 1 _B Data Section selected for transfer from Message RAM to Output Buffer
RHSH	16	rh	Read Header Section Host 0 _B Header Section is not read 1 _B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	Read Data Section Host 0 _B Data Section is not read 1 _B Data Section selected for transfer from Message RAM to Output Buffer
0	[15:2], [31:18]	r	Reserved Returns 0 if read; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Note: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.

Output Buffer Command Request (OBCR)

The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also [“Data Transfer from Message RAM to Output Buffer” on Page 25-226](#)).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

FlexRay™ Protocol Controller (E-Ray)

OBCR
Output Buffer Command Request (0714_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
OBSRS	[6:0]	rw	Output Buffer Request Shadow Number of source Message Buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 00 _H to 7F _H (0 to 127). If the number of the first Message Buffer of the receive FIFO is written to this register the Message Handler transfers the Message Buffer addressed by the GET Index Register (GIDX, “FIFO Function” on Page 25-221) to OBF Shadow.
VIEW	8	rw	View Shadow Buffer Toggles between OBF Shadow and OBF Host. Only writeable while OBCR.OBSYS = 0. 0 _B No action 1 _B Swap OBF Shadow and OBF Host
REQ	9	rw	Request Message RAM Transfer Requests transfer of Message Buffer addressed by OBCR.OBSRS from Message RAM to OBF Shadow. Only writeable while OBCR.OBSYS = 0. 0 _B No request 1 _B Transfer to OBF Shadow requested
OBSYS	15	rh	Output Buffer Busy Shadow Set to 1 after setting bit OBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, OBCR.OBSYS is cleared again. 0 _B No transfer in progress 1 _B Transfer between Message RAM and OBF Shadow in progress

FlexRay™ Protocol Controller (E-Ray)

0	7, [14:10], [31:23]	r	<p>Reserved</p> <p>Returns 0 if read; should be written with 0.</p>

25.6 Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

25.6.1 Communication Cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized MacroTICK.

Figure 25-4 Structure of Communication Cycle

25.6.1.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all Frames on both channel

FlexRay™ Protocol Controller (E-Ray)

Parameters: Number of Static Slots **GTUC07.NSS**, Static Slot Length **GTUC07.SSL**, Payload Length Static **MHDC.SFDL**, Action Point Offset **GTUC09.APO**.

25.6.1.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots **GTUC08.NMS**, Minislot Length **GTUC08.MSL**, Minislot Action Point Offset **GTUC09.MAPO**, Start of Latest Transmit (last minislot) **MHDC.SLT**.

25.6.1.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are sent in "NORMAL_ACTIVE" state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset **GTUC09.APO** (same as for static slots), Network Idle Time Start **GTUC04.NIT**.

25.6.1.4 Network Idle Time (NIT)

During network idle time the Communication Controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple MacroTicks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start **GTUC04.NIT**, Offset Correction Start **GTUC04.OCS**.

25.6.1.5 Configuration of Network Idle Time (NIT) Start and Offset Correction Start

The number of MacroTicks per cycle (gMacroPerCycle) is assumed to be m . It is configured by programming **GTUC02.MPC** = m .

Figure 25-5 Configuration of network idle time (NIT) start and offset correction start

The static / dynamic segment starts with Macrotick 0 and ends with Macrotick n:
 $n = \text{static segment length} + \text{dynamic segment offset} + \text{dynamic segment length} - 1 \text{ Macrotick}$

$$n = g\text{NumberOfStaticSlots} \cdot g\text{dStaticSlot} + \text{dynamic segment offset} + g\text{NumberOfMinislots} \cdot g\text{dMinislot} - 1 \text{ Macroticks}$$

The static segment length is configured by [GTUC07.SSL](#) and [GTUC07.NSS](#).
 The dynamic segment length is configured by [GTUC08.MSL](#) and [GTUC08.NMS](#).

The dynamic segment offset is:

If $g\text{dActionPointOffset} \leq g\text{dMinislotActionPointOffset}$:

$$\text{dynamic segment offset} = 0 \text{ MT}$$

Else if $g\text{dActionPointOffset} > g\text{dMinislotActionPointOffset}$:

$$\text{dynamic segment offset} = g\text{dActionPointOffset} - g\text{dMinislotActionPointOffset}$$

The network idle time (NIT) starts with Macrotick k+1 and ends with the last Macrotick of cycle m-1. It has to be configured by setting [GTUC04.NIT](#) = k.

For the E-Ray the offset correction start is required to be

$$\text{GTUC04.OCS} \geq \text{GTUC04.NIT} + 1 = k+1.$$

The length of symbol window results from the number of Macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by $k - n$.

25.6.2 Communication Modes

The FlexRay™ Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static:** minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic:** minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

25.6.3 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC Frames from other nodes.

25.6.3.1 Global Time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

25.6.3.2 Local Time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

FlexRay™ Protocol Controller (E-Ray)

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

25.6.3.3 Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of **every** communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: "NORMAL_ACTIVE" → "NORMAL_PASSIVE" → "HALT")
- Correction value is an integer number of Microticks
- Correction done in **odd** numbered cycles, distributed over the Macroticks beginning at offset correction start up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened / shortened)

Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of **odd** numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value

FlexRay™ Protocol Controller (E-Ray)

- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next **even / odd** cycle pair (Macroticks lengthened / shortened)

Synchronization Process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Max. one SYNC Frame per node in one communication cycle
- Max. 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

SYNC Frame Transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames **SUCC1.TXSY** must be set to 1.

25.6.3.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

25.6.4 Error Handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit **EIR.PEMC** in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signalled by **CCEV.ERRM** in the Communication Controller Error Vector register.

Table 25-10 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE (green)	Full operation , State: "NORMAL_ACTIVE" The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR .
PASSIVE (yellow)	Reduced operation , State: "NORMAL_PASSIVE", Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR .
COMM_HALT (red)	Operation halted , State: "HALT", Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macro-tick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers EIR and SIR . The bus drivers are disabled.

25.6.4.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the maximum "without clock correction passive" limit defined by **SUCC3.WCP**, the POC transits from "NORMAL_ACTIVE" to "NORMAL_PASSIVE" state. When it reaches the "maximum without clock correction fatal" limit defined by **SUCC3.WCF**, it transits "NORMAL_ACTIVE" or "NORMAL_PASSIVE" to the "HALT" state. Both limits are defined in the SUC Configuration Register 3.

FlexRay™ Protocol Controller (E-Ray)

The Clock Correction Failed Counter **CCEV.CCFC** allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any **odd** numbered communication cycle where either the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set. The two flags are located in the SYNC Frame Status register, while the Clock Correction Failed Counter is located in the Communication Controller Error Vector register.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the Missing Offset Correction signal **SFS.MOCS** nor the Missing Rate Correction signal **SFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value **SUCC3.WCF** as defined in the SUC Configuration Register 3 is reached (i.e. incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The Clock Correction Failed Counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

25.6.4.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. **SUCC1.PTA** in the SUC Configuration Register 1 defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If **SUCC1.PTA** is reset to zero the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

25.6.4.3 HALT Command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing **SUCC1.CMD** = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state **SUCC1.CMD** will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit **EIR.CNA** in the Error Service Request Register is set to 1. If enabled an service request to the Host is generated.

25.6.4.4 FREEZE Command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing **SUCC1.CMD** = 0111_B in the SUC Configuration Register 1. The FREEZE

FlexRay™ Protocol Controller (E-Ray)

command triggers the entry of the "HALT" state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

25.6.5 Communication Controller States

This chapter introduces the states of the Communication Controller.

25.6.5.1 Communication Controller State Diagram

State transitions are controlled by external the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector **SUCC1.CMD** located in the SUC Configuration Register 1.

Figure 25-6 Overall State Diagram of E-Ray Communication Controller

The Communication Controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 25-11 State Transitions of E-Ray Overall State Machine

T#	Condition	From	To
1	application reset	HW Reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001 _B	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011 _B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001 _B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010 _B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001 _B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011 _B	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010 _B	WAKEUP	READY
9	Command RUN, SUCC1.CMD = 0100 _B	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010 _B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY

FlexRay™ Protocol Controller (E-Ray)
Table 25-11 State Transitions of E-Ray Overall State Machine (cont'd)

T#	Condition	From	To
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110 _B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110 _B	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD = 0111 _B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001 _B	HALT	DEFAULT_CONFIG

25.6.5.2 DEFAULT_CONFIG State

In “DEFAULT_CONFIG” state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The Communication Controller enters this state

- When leaving application reset
- When exiting from “HALT” state

To leave “DEFAULT_CONFIG” state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to “CONFIG” state.

CONFIG State

In “CONFIG” state, the Communication Controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the Communication Controller configuration.

FlexRay™ Protocol Controller (E-Ray)

The Communication Controller enters this state

- When exiting from “DEFAULT_CONFIG” state
- When exiting from “MONITOR_MODE” or “READY” state

When the state has been entered via “HALT” and “DEFAULT_CONFIG” state, the Host can analyze status information and configuration. Before leaving “CONFIG” state the Host has to assure that the configuration is fault-free.

To leave “CONFIG” state, the Host has to perform the unlock sequence as described on **“LCK” on Page 25-30**. Directly after unlocking the “CONFIG” state the Host has to write **SUCC1.CMD** in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves “CONFIG”.

*Note: The Message Buffer Status Registers (**MHDS**, **TXRQ1** to **TXRQ4**, **NDAT1** to **NDAT4**, **MBSC1** to **MBSC4**) and status data stored in the Message RAM and are not affected by the transition of the POC from “CONFIG” to “READY” state.*

When the Communication Controller is in “CONFIG” state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK} , f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

25.6.5.3 MONITOR_MODE

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0011_B the Communication Controller enters “MONITOR_MODE”. In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions in Monitor Mode (FRF.RSS will be ignored, filtering not functional). This mode can be used for debugging purposes in case e.g. that startup of a FlexRay™ network fails. After writing **SUCC1.CMD** = 0001_B the Communication Controller transits back to “CONFIG” state.

In MONITOR_MODE the pick first valid mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits **MBS.VFRA**, **MBS**, **MBS.MLST**, **MBS.RCIS**, **MBS.SFIS**, **MBS.SYNS**, **MBS.NFIS**, **MBS.PPIS**, **MBS.RESS** have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags **SIR.MTSA** resp. **SIR.MTSB** are set. **SIR.CAS** has no function in “MONITOR_MODE”.

25.6.5.4 READY State

After unlocking “CONFIG” state and writing **SUCC1.CMD** = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to WAKEUP state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state

- When exiting from “CONFIG”, “WAKEUP”, “STARTUP”, “NORMAL_ACTIVE”, or “NORMAL_PASSIVE” state by writing **SUCC1.CMD** = 0010_B (READY command).

The Communication Controller exits from this state

- To “CONFIG” state by writing **SUCC1.CMD** = 0001_B (CONFIG command)
- To “WAKEUP” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command)
- To “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

*Note: Status bits **MHDS**, registers **TXRQ1** to **TXRQ4**, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.*

25.6.5.5 WAKEUP State

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.1.

The Communication Controller enters this state

- When exiting from “READY” state by writing **SUCC1.CMD** = 0011_B (WAKEUP command).

The Communication Controller exits from this state to “READY” state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing **SUCC1.CMD** = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian

FlexRay™ Protocol Controller (E-Ray)

(if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit **SUCC1.WUCS** in the SUC Configuration Register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit **SIR.WST** in the Status Service Request Register. The wakeup status vector can be read from the Communication Controller Status Vector register **CCSV.WSV**. If a valid wakeup pattern was received also either flag **SIR.WUPA** or flag **SIR.WUPB** in the Status Service Request Register is set.

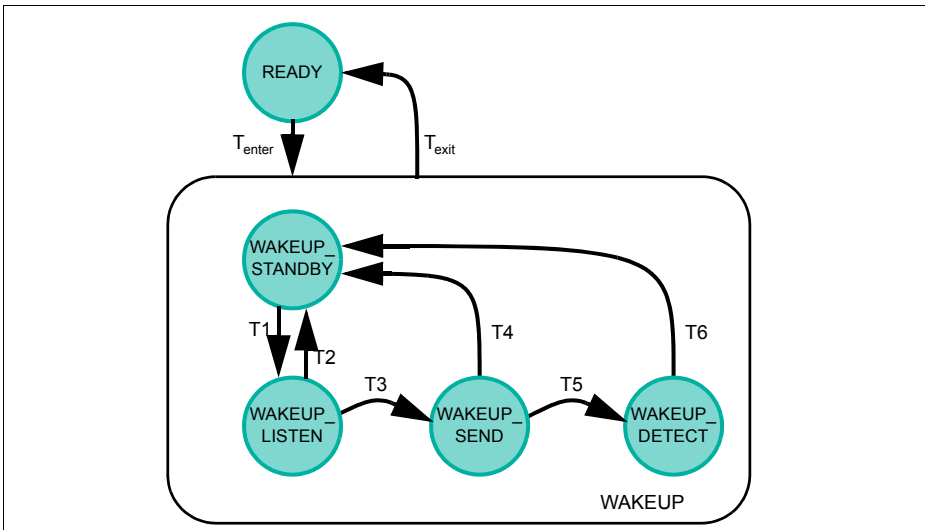

Figure 25-7 Structure of POC State WAKEUP

Table 25-12 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to "WAKEUP" state by writing SUCC1.CMD = 0011 _B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to "WAKEUP_LISTEN" state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY

FlexRay™ Protocol Controller (E-Ray)
Table 25-12 State Transitions WAKEUP (cont'd)

T#	Condition	From	To
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration Register 1 OR Frame Header received on either available channel	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to “READY” state by writing SUCC1.CMD = 0010 _B (READY command). This command also resets the wakeup FSM to “WAKEUP_STANDBY” state	WAKEUP	READY

The “WAKEUP_LISTEN” state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out **SUCC2.LT** and listen time-out noise **SUCC2.LTN**. Both values can be configured in the SUC Configuration Register 2. listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In “WAKEUP_SEND” state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into “STARTUP” state by CHI command RUN.

In “WAKEUP_DETECT” state the Communication Controller attempts to identify the reason for the wakeup collision detected in “WAKEUP_SEND” state. The monitoring is bounded by the expiration of listen time-out as configured by **SUCC2.LT** in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to “READY” state. Otherwise WAKEUP_DETECT is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in “CONFIG” state
 - Select wakeup channel by programming bit **SUCC1.WUCS**
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command Communication Controller to start wakeup on the configured channel by writing **SUCC1.CMD** = 0011_B
 - Communication Controller enters “WAKEUP”
 - Communication Controller returns to “READY” state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
 - In a dual channel cluster wait for WUP on the other channel
 - Reset coldstart inhibit flag **CCSV.CSI** by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command))
- Reset Coldstart Inhibit flag **CCSV.CSI** in the CCSV register by writing **SUCC1.CMD** = 1001_B (ALLOW_COLDSTART command), coldstart node only
- Command Communication Controller to enter startup by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter “STARTUP” state by writing **SUCC1.CMD** = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT Configuration Registers **PRTC1** and **PRTC2**.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time

FlexRay™ Protocol Controller (E-Ray)

- Wakeup symbol collision resilient for up to two sending nodes (two overlapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by **PRTC2.TXL**
- Wakeup symbol idle time used to listen for activity on the bus, configured by **PRTC2.TXI**
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by **PRTC1.RWP** (2 to 63 repetitions)
- Wakeup symbol receive window length configured by **PRTC1.RXW**
- Wakeup symbol receive low time configured by **PRTC2.RXL**
- Wakeup symbol receive idle time configured by **PRTC2.RXI**

Figure 25-8 Timing of Wakeup Pattern

25.6.5.6 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state via (see **Figure 25-9**):

FlexRay™ Protocol Controller (E-Ray)

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit SYNC Frame in Key Slot bits **SUCC1.TXST** and **SUCC1.TXSY** in the SUC Configuration Register 1 set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **SUCC1.CSA** in the SUC Configuration Register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive SYNC Frames from which to derive the TDMA schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

Figure 25-9 State Diagram Time-Triggered Startup

Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **CCSV.CSI** in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **CCSV.CSI** is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command **ALLOW_COLDSTART (SUCC1.CMD = 1001_B)**

25.6.5.7 Startup Time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the “COLDSTART_LISTEN” state. The expiration of either of these timers causes the node to leave the initial sensing phase (“COLDSTART_LISTEN” state) with the intention of starting up communication.

*Note: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **SUCC2.LT** and **SUCC2.LTN** from the SUC Configuration Register 2.*

Startup Time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming **SUCC2.LT** (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Both channels reaching idle state while in “COLDSTART_LISTEN” state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the “COLDSTART_LISTEN” state
- When the “COLDSTART_LISTEN” state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup Noise Time-out

At the same time the startup timer is started for the first time (transition from “STARTUP_PREPARE” state to “COLDSTART_LISTEN” state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming **SUCC2.LTN** (gListenNoise - 1) in the SUC Configuration Register 2 (see “**SUC Configuration Register 2 (SUCC2)**” on **Page 25-87**).

The startup noise time-out is:

$\text{pdListenTimeout} \cdot \text{gListenNoise} = \text{SUCC2.LT} \cdot (\text{SUCC2.LTN} + 1)$

The startup noise timer is restarted upon:

- Entering the “COLDSTART_LISTEN” state
- Reception of correctly decoded Headers or CAS symbols while the node is in “COLDSTART_LISTEN” state

The startup noise timer is stopped when the “COLDSTART_LISTEN” state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

25.6.5.8 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by **SUCC1.CSA** in the SUC Configuration Register 1. The number of remaining coldstarts attempts **CCSV.RCA** can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

FlexRay™ Protocol Controller (E-Ray)**Path of following Coldstart Node (responding to leading Coldstart Node)**

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

FlexRay™ Protocol Controller (E-Ray)

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

25.6.5.9 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering “STARTUP” via coldstart path) and one additional node have entered the “NORMAL_ACTIVE” state, the startup phase for the cluster has finished. In the “NORMAL_ACTIVE” state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “ACTIVE” to “COMM_HALT”
- “NORMAL_PASSIVE” state due to change of the error state from “ACTIVE” to “PASSIVE”
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

25.6.5.10 NORMAL_PASSIVE State

“NORMAL_PASSIVE” state is entered from “NORMAL_ACTIVE” state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In “NORMAL_PASSIVE” state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the “NORMAL_ACTIVE” state the node does not actively participate in communication, i.e. neither symbols nor Frames are transmitted.

FlexRay™ Protocol Controller (E-Ray)

In “NORMAL_PASSIVE” state

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- “HALT” state by writing **SUCC1.CMD** = 0110_B (HALT command, at the end of the current cycle)
- “HALT” state by writing **SUCC1.CMD** = 0111_B (FREEZE command, immediately)
- “HALT” state due to change of the error state from “PASSIVE” to “COMM_HALT”
- “NORMAL_ACTIVE” state due to change of the error state from “PASSIVE” to “ACTIVE”. The transition takes place when **CCEV.PTAC** from the Communication Controller Error Vector register equals **SUCC1.PTA** - 1.
- “READY” state by writing **SUCC1.CMD** = 0010_B (READY command)

25.6.5.11 HALT State

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state

- By writing **SUCC1.CMD** = 0110_B (HALT command) while the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state
- By writing **SUCC1.CMD** = 0111_B (FREEZE command) from all states
- When exiting from “NORMAL_ACTIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from “NORMAL_PASSIVE” state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to “CONFIG” state

- By writing **SUCC1.CMD** = 0001_B (DEFAULT_CONFIG command)

When the Communication Controller enters “HALT” state, all configuration and status data is maintained for analyzing purposes.

When the Host writes **SUCC1.CMD** = 0110_B (HALT command) in the SUC Configuration Register 1 to 1, the Communication Controller sets bit **CCSV.HRQ** in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes **SUCC1.CMD** = 0111_B (FREEZE command) in the SUC Configuration Register to 1, the Communication Controller enters “HALT” state immediately and sets the **CCSV.FSI** bit in the Communication Controller Status Vector register.

FlexRay™ Protocol Controller (E-Ray)

The POC state from which the transition to HALT state took place can be read from **CCSV.PSL**.

25.6.6 Network Management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 (**NMV_x (x = 1-3)**). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set via **WRHS1.PPIT**. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

*Note: In case a Message Buffer is configured for transmission / reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by **NEMC.NML**.*

When the Communication Controller transits to “HALT” state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.

25.6.7 Filtering and Masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance / transmit filtering are allowed:

FlexRay™ Protocol Controller (E-Ray)

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

Note: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

25.6.7.1 Frame ID Filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive Buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit Buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

25.6.7.2 Channel ID Filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see [Table 25-13](#)).

Table 25-13 Channel Filtering Configuration

CHA	CHB	Transmit Buffer transmit Frame	Receive Buffer store valid receive Frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

FlexRay™ Protocol Controller (E-Ray)

Note: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted resp. received Frames are ignored (same function as CHA = CHB = 0)

Receive Buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective **NDn (n = 0-31)** to **NDn (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** register is set. In both cases, if bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

Transmit Buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled an service request is generated.

25.6.7.3 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits TXST, TXSY, and TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

*Note: Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in [Table 25-14](#).

Table 25-14 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values		
000000 _B	all Cycles		
000001 _B	every second Cycle	at (Cycle Count)mod2	= c
00001 _B	every fourth Cycle	at (Cycle Count)mod4	= cc
0001 _B	every eighth Cycle	at (Cycle Count)mod8	= ccc
001 _B	every sixteenth Cycle	at (Cycle Count)mod16	= cccc
01 _B	every thirty-second Cycle	at (Cycle Count)mod32	= ccccc
1 _B	every sixty-fourth Cycle	at (Cycle Count)mod64	= cccccc

Table 25-15 below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 25-15 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0000011 _B	1-3-5-7--63 ↓
0000100 _B	0-4-8-12--60 ↓
0001110 _B	6-14-22-30--62 ↓
0011000 _B	8-24-40-56 ↓
0100011 _B	3-35 ↓
1001001 _B	9 ↓

Receive Buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit Buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

25.6.7.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for **Channel** (2 bits), **Frame ID** (11 bits), and **Cycle Code** (7 bits). Rejection filter and rejection filter mask can be configured in

FlexRay™ Protocol Controller (E-Ray)

DEFAULT_CONGIF or “CONFIG” state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

25.6.8 Transmit Process

The transmit process is described in the following sections.

25.6.8.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

25.6.8.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID's which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID's on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by SLT in the MHD Configuration Register 1 defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

25.6.8.3 Transmit Buffers

A portion of the E-Ray Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done via the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment: channel A **or** channel B, channel A **and** channel B

FlexRay™ Protocol Controller (E-Ray)

- Dynamic segment: channel A **or** channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during runtime. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during runtime it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer (see [Section 25.6.6](#)).

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit **STXRH** in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID **and** cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

25.6.8.4 Frame Transmission

To prepare a transmit buffer for transmission the following steps are required:

FlexRay™ Protocol Controller (E-Ray)

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer.
- To transfer a transmit message from Input Buffer to the Message RAM proceed as described on **“Data Transfer from Input Buffer to Message RAM” on Page 25-224**.
- If configured in the Input Buffer Command Mask register the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed, and the Message Buffer is ready for transmission.
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1,2 registers (single-shot mode only).

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit **WRHS1.MBI** in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled an service request is generated.

25.6.8.5 NULL Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID's and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

25.6.9 Receive Process

The receive process is described in the following sections.

25.6.9.1 Frame Reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register.

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1) it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data **ND_n (n = 0-31)** to **ND_n (n = 96-127)** flag in the New Data **NDAT1** to **NDAT4** registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set. If bit **RDHS1.MBI** in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled an service request is generated.

To read a receive buffer from the Message RAM via the Output Buffer proceed as described on **“Data Transfer from Message RAM to Output Buffer” on Page 25-226**.

Note: The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

25.6.9.2 NULL Frame reception

The Payload Segment of a received NULL Frame is **not** copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1,2,3,4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

25.6.10 FIFO Function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by FFB and ending with the Message Buffer referenced by LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

25.6.10.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFF in the Status Service Request Register is set when the last available Message Buffer belonging to the FIFO is written, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message

FlexRay™ Protocol Controller (E-Ray)

overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

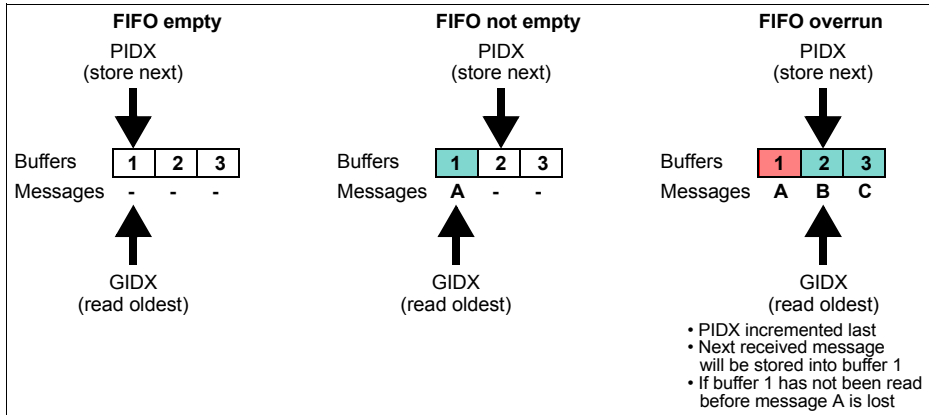

Figure 25-10 FIFO Status: Empty, Not Empty, Overrun

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in [Figure 25-10](#) for a three Message Buffer FIFO.

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “don’t care” for rejection filtering.

25.6.10.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured via the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

FlexRay™ Protocol Controller (E-Ray)

*Note: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 via **WRHS1.MBI** to avoid generation of RX interrupts.*

*If the payload length of a received Frame is longer than the value programmed by **WRHS2.PLC** in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.*

25.6.10.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

25.6.11 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM's are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

25.6.11.1 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input / Output Buffer Command Mask registers can be used to write / read Header and Data Section of the selected Message Buffer separately. If bit **STXRS** in the Input Buffer Command Mask register is set (**STXRS** = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

FlexRay™ Protocol Controller (E-Ray)

If bit **STXRS** in the Input Buffer Command Mask register is reset (**STXRS** = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

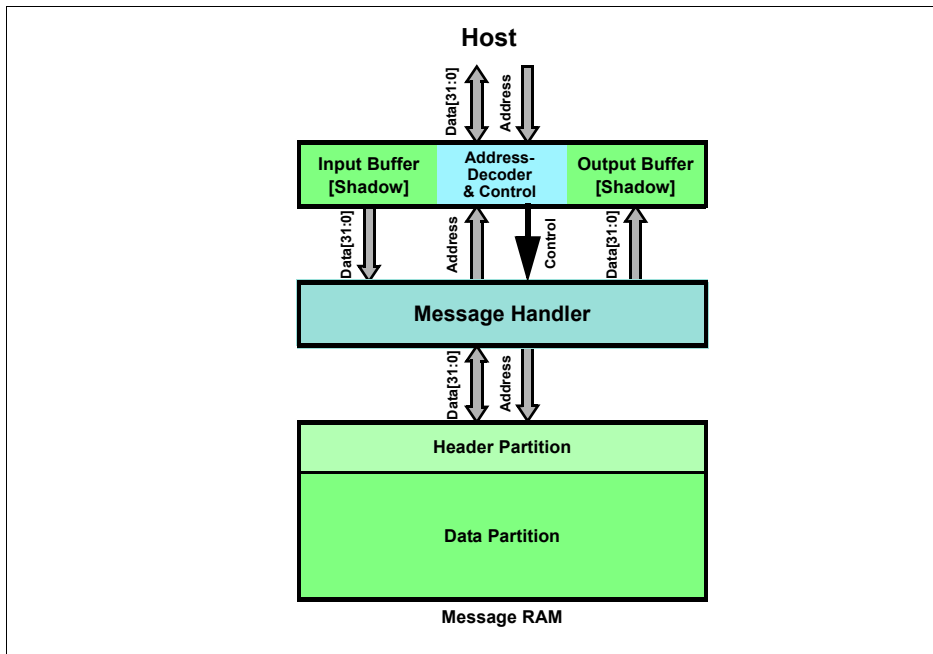

Figure 25-11 Host Access to Message RAM

Data Transfer from Input Buffer to Message RAM

To configure / update a Message Buffer in the Message RAM, the Host has to write the data to **WRDSnn** (**nn = 01-64**) and the Header to **WRHS1**, **WRHS2**, **WRHS3**. Two sets of **WRDSnn** (**nn = 01-64**) are available in parallel and selected by **CUST1.IBF1PAG** and **CUST1.IBF2PAG**. **CUST1.IBFS** shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. **WRHS1**, **WRHS2**, and **WRHS3** does only exist once. The specific action is selected by configuring the Input Buffer Command Mask **IBCM**.

FlexRay™ Protocol Controller (E-Ray)

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register **IBCR**, IBF Host and IBF Shadow are swapped (see **Figure 25-12**).

Figure 25-12 Double Buffer Structure Input Buffer

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see **Figure 25-13**).

Figure 25-13 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains set to 1, and the next transfer

FlexRay™ Protocol Controller (E-Ray)

to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 25-16 Assignment of Input Buffer Command Mask Bit

Pos.	Access	Bit	Function
18	rh	STXRS	Set Transmission Request Shadow
17	rh	LDSS	Load Data Section Shadow
16	rh	LHSS	Load Header Section Shadow
2	rw	STXRH	Set Transmission Request Host
1	rw	LDSH	Load Data Section Host
0	rw	LHSH	Load Header Section Host

Table 25-17 Assignment of Input Buffer Command Request Bit

Pos.	Access	Bit	Function
31	rh	IBSYS	IBF Busy Shadow , signals ongoing transfer from IBF Shadow to Message RAM
21–16	rh	IBRS	IBF Request Shadow , number of Message Buffer currently / last updated
15	rh	IBSYH	IBF Busy Host , transfer request pending for Message Buffer referenced by IBRH
5-0	rwh	IBRH	IBF Request Host , number of Message Buffer to be updated next

Data Transfer from Message RAM to Output Buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register **OBCR** to trigger the data transfer as configured in Output Buffer Command Mask **OBCM** register. After the transfer has completed, the Host can read the transferred data from **RDDSnn (nn = 01-64)**, **RDHS1**, **RDHS2**, **RDHS2**, and **MBS**.

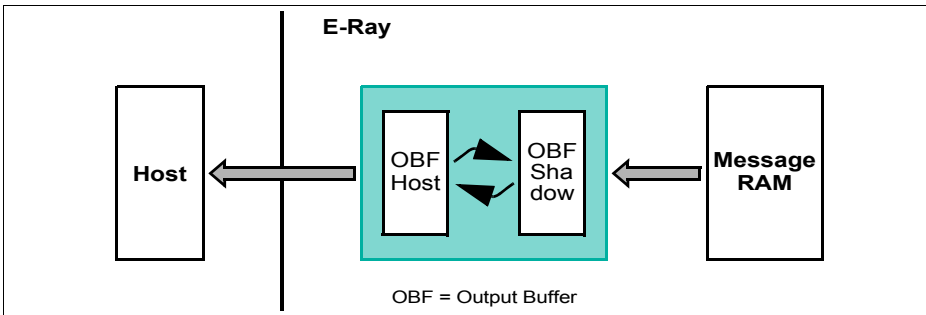

Figure 25-14 Double Buffer Structure Output Buffer

OBF Host and OBF Shadow as well as bits **OBCM.RHSS**, **OBCM.RDSS**, **OBCM.RHSH**, **OBCM.RDSH** and bits **OBCR.OBRS**, **OBCR.OBRH** are swapped under control of bits **OBCR.VIEW** and **OBCR.REQ**.

Writing bit **OBCR.REQ** to 1 copies bits **OBCM.RHSS**, **OBCM.RDSS** and bits **OBCR.OBRS** to an internal storage (see **Figure 25-15**).

After setting **OBCR.REQ** to 1, **OBCR.OBSYS** is set to 1, and the transfer of the Message Buffer selected by **OBCR.OBRS** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **OBCR.OBSYS** bit is set back to 0. Bits **OBCR.REQ** and **OBCR.VIEW** can only be set to 1 while **OBCR.OBSYS** is 0.

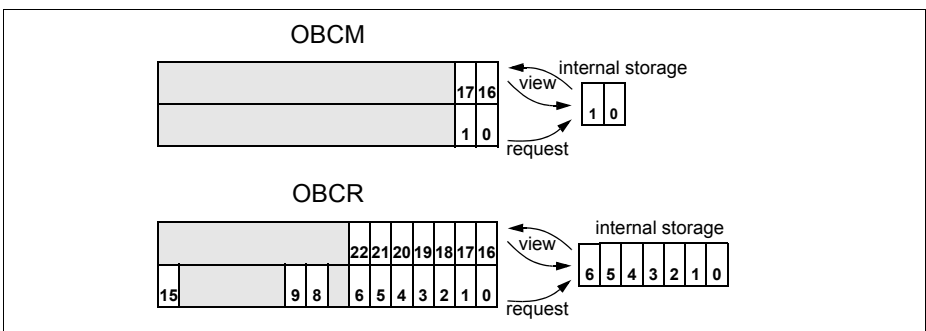

Figure 25-15 Swapping of OBCM and OBCR Bit

OBF Host and OBF Shadow are swapped by setting bit **OBCR.VIEW** to 1 while bit **OBCR.OBSYS** is 0 (see **Figure 25-14**).

In addition bits **OBCR.OBRH** and bits **OBCM.RHSH**, **OBCM.RDSH** are swapped with the registers internal storage thus assuring that the Message Buffer number stored in

FlexRay™ Protocol Controller (E-Ray)

OBCR.OBRH and the mask configuration stored in **OBCM.RHSH**, **OBCM.RDSH** matches the transferred data stored in OBF Host (see **Figure 25-15**).

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 25-18 Assignment of Output Buffer Command Mask Bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data Section available for Host access
16	rh	RHSH	Header Section available for Host access
1	rw	RDSS	Read Data Section Shadow
0	rw	RHSS	Read Header Section Shadow

Table 25-19 Assignment of Output Buffer Command Request Bit

Pos.	Access	Bit	Function
22–16	rh	OBRH	OBF Request Host , number of Message Buffer available for Host access
15	rh	OBSYS	OBF Busy Shadow , signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	Request Transfer from Message RAM to OBF Shadow
8	rwh	VIEW	View OBF Shadow, swap OBF Shadow, and OBF Host
6–0	rwh	OBRS	OBF Request Shadow , number of Message Buffer for next request

25.6.11.2 Data Transfers between IBF / OBF and Message RAM

This document uses the following terms and abbreviations:

Table 25-20 Terms and Abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)

FlexRay™ Protocol Controller (E-Ray)

Table 25-20 Terms and Abbreviations (cont'd)

IBF ⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF ⇒ TBF	Transfer from MBF to TBF
TBF ⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS ⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure 25-16.

Figure 25-16 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of 2-byte words the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is e.g. 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

FlexRay™ Protocol Controller (E-Ray)

Figure 25-17 Different Possible Buffer Transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

Figure 25-18 Update of Slot Status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY} periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IB F \Rightarrow MBF is started short after a TBF \Rightarrow MBF or SS \Rightarrow MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure 25-19)

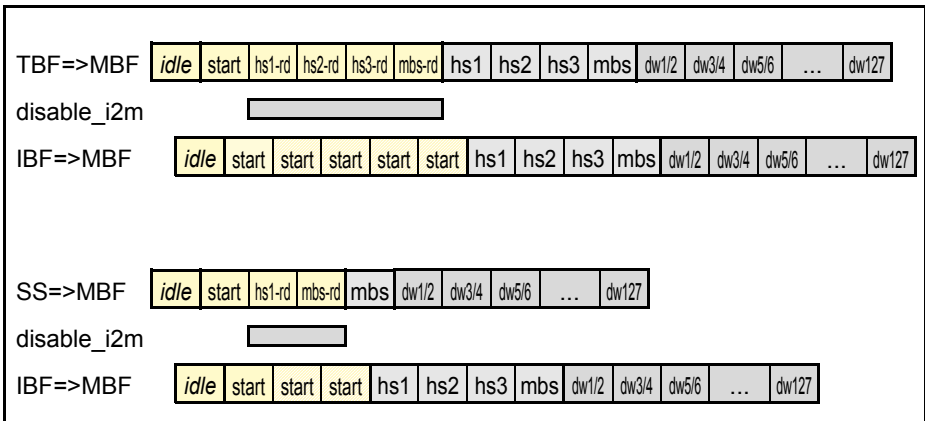

Figure 25-19 Delay start of IBF=>MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS ⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX / RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that e.g. a IBF ⇒ MBF has been started shortly before a

FlexRay™ Protocol Controller (E-Ray)

MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that e.g. a second IBF⇒MBF is requested, a MBF⇒OBF is requested and a IBF⇒MBF is ongoing, the MBF⇒OBF has to wait until the first IBF⇒IBF has completed. The second IBF=MBF has to wait until the MBF⇒OBF has completed (see figure 25-20) independent whether MBF⇒OBF or second IBF⇒MBF is requested first.

Figure 25-20 Multiple IBF/OBF Request

Worst case for single request

When a message with a large payload length is received the TBF⇒MBF is started at the begin of the next slot (n+1). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF⇒MBF has not finished until begin of the next but one slot (n+2). In this case the TBF⇒MBF will be service requested (break) to start a transmission in the next but one slot (MBF⇒TBF) and/or to update the slot status (SS⇒MBF) for the RX-buffer corresponding with next slot (n+1). After this interruption the TBF⇒MBF is continued.

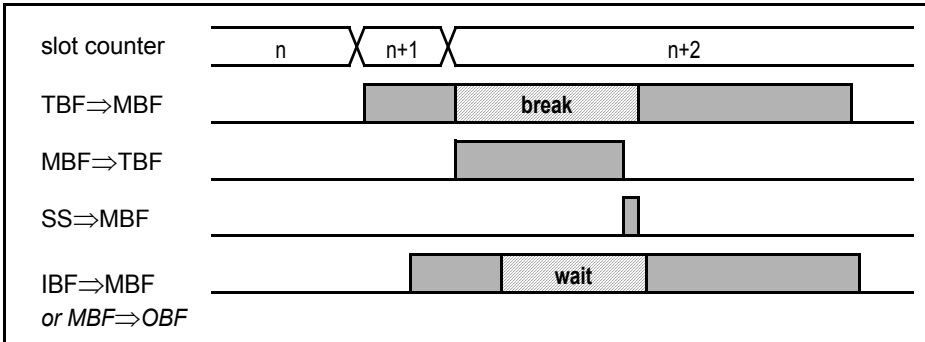

Figure 25-21 Address Counter Scheme of Message RAM (simplified)

For the transfers IBF⇒MBF / MBF⇒OBF, TBF⇒MBF and MBF⇒TBF separate address-counter are implemented (see Figure 25-21).

Figure 25-22 interruption of TBF=>MBF

If the address-counter for IBF=>MBF / MBF=>OBF (`acnt_mbf_io_reg`) reaches the address of the interrupted TBF=>MBF (`acnt_mbf_t2m_reg`) the IBF=>MBF / MBF=>OBF has to wait until the TBF=>MBF is continued (see Figure 25-22).

The relative time is measured in $f_{\text{CLC_ERAY}}$ cycles. Absolute time depends on the actual $f_{\text{CLC_ERAY}}$ cycle period.

$$\text{tbf_to_mbf_break time}_{\text{max}} = (\text{setup time} + \text{mbf_to_tbf time}_{\text{max}}) + (\text{setup time} + \text{ss_to_mbf})$$

$$\text{cycles}_{\text{req}} = (\text{number of concurrent tasks}) \times ((\text{setup time} + (\text{number of 4-byte words})_{\text{req}}) + \text{tbf_to_mbf_break time})$$

$$\text{setup time} = 2 \cdot f_{\text{CLC_ERAY}} \text{ cycles}$$

FlexRay™ Protocol Controller (E-Ray)

Worst case for one IBF⇒MBF or MBF⇒OBF:

$$\text{Max. break time: } t_{bf_to_mbf_break\ time}_{max} = (2+68) + (4+1) = 75$$

$$\text{Max. number of } f_{CLC_ERAY} \text{ cycles: } cycles_{req} = 3 \times (6 + 68 + 75) = 435$$

Worst case for multiple transfers

If a second IBF⇒MBF and a MBF⇒OBF (see Figure 25-20) is requested directly after the first IBF⇒MBF has started following worst case timing could appear:

$$cycles_{trans} = \begin{aligned} & \text{(remaining cycles of transfer running)} \\ & + \text{(cycles of second requested transfer)} \\ & + \text{(cycles of third requested transfer)} \end{aligned}$$

$$cycles_{trans} = cycles_{rem} + cycles_{req_2} + cycles_{req_3}$$

$$\text{Max. number of } f_{CLC_ERAY} \text{ cycles: } cycles_{trans} = 447 + 435 + 447 = 1329$$

25.6.11.3 Minimum f_{CLC_ERAY}

To calculate the minimum f_{CLC_ERAY} the worst case scenario has to be considered.

The worst case scenario depends on the following parameters

- maximum payload length
- minimum minislot length
- number of configured Message Buffers (excluding FIFO)
- used channels (single/dual channel)

Figure 25-23 worst case scenario

FlexRay™ Protocol Controller (E-Ray)

Worst case scenario:

- reception of message with a maximum payload length in Slot n (n is 7,15,23,31,39,...)
- slot n+1 to n+7 are empty dynamic slots (minislot) and configured as receive buffer
- the find-sequence (usually started in slot 8,16,24,32,40,...) has to scan the maximum number of configured buffers
- the number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8,16,24,32,40,...). It has to be finished until the next find-sequence is requested.

The length of a TBF⇒MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$$f_{\text{CLC_ERAY}} \text{ cycles}_{t2m} = \text{number of concurrent tasks} \times (\text{setup time}_{t2m} + (\text{number of 4-byte words})_{t2m})$$

A SS⇒MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

$$f_{\text{CLC_ERAY}} \text{ cycles}_{ss2m} = (\text{number of concurrent tasks}) \times 5$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$f_{\text{CLC_ERAY}} \text{ cycles}_{\text{find}} = (\text{number of concurrent tasks}) \times (\text{setup time}_{\text{find}} + (\text{number of configured buffers}))$$

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 μs. A sequence of 8 minislots has a length of

$$\text{time}_{8\text{minislots}} = 8 \times \text{gdMinislot} \times \text{cdMinMTNom}$$

FlexRay™ Protocol Controller (E-Ray)

The maximum period $T_{\text{CLC_ERAY}} = 1/f_{\text{CLC_ERAY}}$ can be calculated as followed:

$$\text{time}_{8\text{minislots}} \geq (f_{\text{CLC_ERAY}} \text{ period in } \mu\text{s}) \times (f_{\text{CLC_ERAY}} \text{ cycles}_{t2m}) + 7 \times (f_{\text{CLC_ERAY}} \text{ cycles}_{ss2m}) + (f_{\text{CLC_ERAY}} \text{ cycles}_{\text{find}})$$

$$f_{\text{CLC_ERAY}} \text{ period in ms} \leq \frac{\text{time}_{8\text{minislots}}}{(\text{cycles}_{t2m}) + 7 \times (\text{cycles}_{ss2m}) + (\text{cycles}_{\text{find}})}$$

$$\text{minimum time}_{8\text{minislots}} = 8 \times 2 \times 1 \mu\text{s} = 16 \mu\text{s}$$

$$\text{maximum } f_{\text{CLC_ERAY}} \text{ cycles}_{t2m} = 3 \times (6 + 68) = 222$$

$$\text{maximum } f_{\text{CLC_ERAY}} \text{ cycles}_{ss2m} = 3 * 5 = 15$$

$$\text{maximum } f_{\text{CLC_ERAY}} \text{ cycles}_{\text{find}} = 3 * (2 + 128) = 390$$

$$f_{\text{CLC_ERAY}} \text{ period in ms} \leq \frac{16\mu\text{s}}{222 + 7 \times 15 + 390} = 22.315\dots\text{ns}$$

The minimum $f_{\text{CLC_ERAY}}$ frequency for this worst case scenario is 44.8125 MHz.

A too low $f_{\text{CLC_ERAY}}$ frequency can cause a malfunction of the E-Ray.

The E-Ray can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (**MHDF**) register.

Minimum $f_{\text{CLC_ERAY}}$ for various maximum payload length

Table 25-21 summarizes the minimum required $f_{\text{CLC_ERAY}}$ frequency for various maximum payload length assuming:

- a minimum minislot length of 2μs.
- a maximum of 128 configured Message Buffers.
- dual channels in use.

Table 25-21 Minimum $f_{\text{CLC_ERAY}}$ for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum $f_{\text{CLC_ERAY}}$	32,82 MHz	33,57 MHz	35,07 MHz	38,07 MHz	44,1 MHz

Minimum $f_{\text{CLC_ERAY}}$ for various minimum minislot length

Table 25-22 summarizes the minimum required $f_{\text{CLC_ERAY}}$ frequency for various minimum minislot length assuming:

FlexRay™ Protocol Controller (E-Ray)

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a maximum 128 configured Message Buffers.
- dual channels in use.

Table 25-22 Minimum $f_{\text{CLC_ERAY}}$ for different minimum minislot length

gdMinislot at dMinMTNom = 1 μs	2 μs	3 μs	4 μs	7 μs	8 μs
minimum $f_{\text{CLC_ERAY}}$	44,82 MHz	29,88 MHz	22,412 MHz	12,8 MHz	9,96 MHz

Minimum $f_{\text{CLC_ERAY}}$ for various amount of configured Message Buffers

Table 25-23 summarizes the minimum required $f_{\text{CLC_ERAY}}$ frequency for various amount of configured Message Buffers assuming:

- a maximum payload length of 254 bytes / 64 four-byte-words.
- a minimum minislot length of 2 μs.
- dual channels in use.

Table 25-23 Minimum $f_{\text{CLC_ERAY}}$ for different amount of configured Message Buffers

Configured maximum amount of Message Buffers	128	64	32
minimum $f_{\text{CLC_ERAY}}$	44,82 MHz	32,82 MHz	26,82 MHz

Minimum $f_{\text{CLC_ERAY}}$ for a typical configuration

The minimum required $f_{\text{CLC_ERAY}}$ frequency for various assuming the following typical E-Ray configuration:

- a maximum payload length of 32 bytes / 8 four-byte-words.
- a minimum minislot length of 7 μs.
- a maximum 128 configured Message Buffers.
- dual channels in use

The minimum $f_{\text{CLC_ERAY}}$ frequency for this typical example would be 10 MHz.

FlexRay™ Protocol Controller (E-Ray)**25.6.11.4 FlexRay™ Protocol Controller access to Message RAM**

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

Figure 25-24 Access to Transient Buffer RAMs

25.6.12 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception / transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized 2048 x 32. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in [Figure 25-25](#).

The Data Partition is allowed to start at Message RAM word number: $(MRC.LCB + 1) \cdot 4$

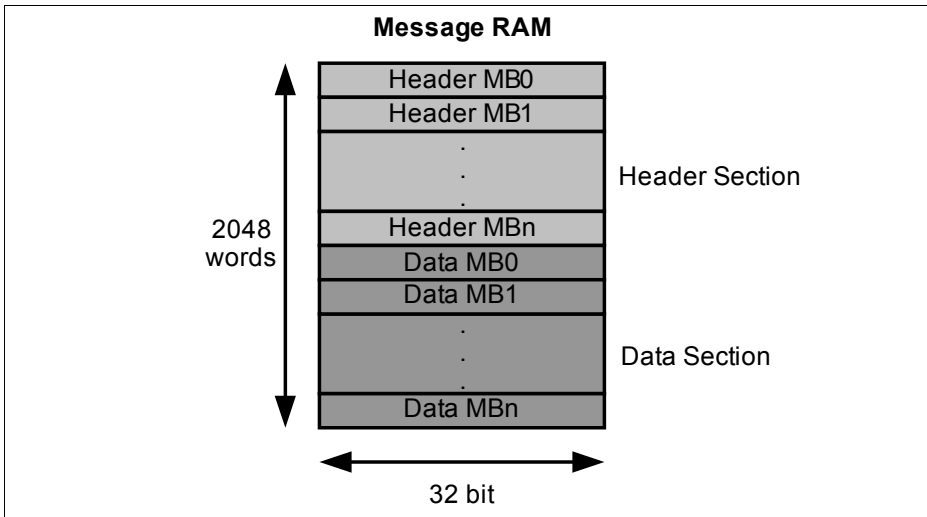

Figure 25-25 Structure of Message RAM

Header Partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 of each Message Buffer holds the 11 bit pointer to the respective Data Section in the Data Partition

Data Partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each
- Or 56 Message Buffers with 128 byte Data Section each
- Or 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

25.6.12.1 Header Partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR**, Receive Cycle Count **RCC**, Received on Channel Indication **RCI**, Startup Frame Indication bit **SFI**, Sync bit **SYN**, NULL Frame Indication bit **NFI**, Payload Preamble Indication bit **PPI**, and Reserved bit **RES** are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status **MBS** information.

Table 25-24 Header Section of a Message Buffer in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- Frame Configuration
- Filter Configuration
- Message Buffer Control
- Message RAM Configuration
- Updated from received Frame
- Message Buffer Status
- unused

Header 1 (word 0)

Write access via **WRHS1**, read access via **RDHS1**:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive / transmit
- PPIT: Payload Preamble Indicator Transmit
- XMI: Transmit mode configuration: single-shot / continuous
- MBI: Message Buffer receive / transmit service request enable

Header 2 (word 1)

Write access via **WRHS2**, read access via **RDHS2**:

- Header CRC
 - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
 - Receive Buffer: Updated from received Frame
- Payload Length Configured
 - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
 - Length of Payload Segment (2-byte words) stored from received Frame

Header 3

Write access via **WRHS3**, read access via **RDHS3**:

- Data Pointer
 - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access via **RDHS3**, valid for receive buffers only, updated from received Frames:

- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Startup Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message Buffer Status MBS (word 3)

Read access via MBS, updated by the Communication Controller at the end of the configured slot.

- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

25.6.12.2 Data Partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition. [Table 25-25](#) below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section,

FlexRay™ Protocol Controller (E-Ray)

respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see [Table 25-25](#) below)

Table 25-25 Example for Structure of the Data Section in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25.6.12.3 ECC Check

There is an ECC checking mechanism implemented in the E-Ray module to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator / checker attached as shown in [Figure 25-26](#). When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags [MHDS.EIBF](#), [MHDS.EOBF](#), [MHDS.EMR](#), [MHDS.ETBF1](#), [MHDS.ETBF2](#), and the faulty Message Buffer indicators [MHDS.FMBD](#), [MHDS.MFMB](#), [MHDS.FMB](#) are located in the Message Handler Status register. These error flags control the error interrupt flag [EIR.EERR](#).

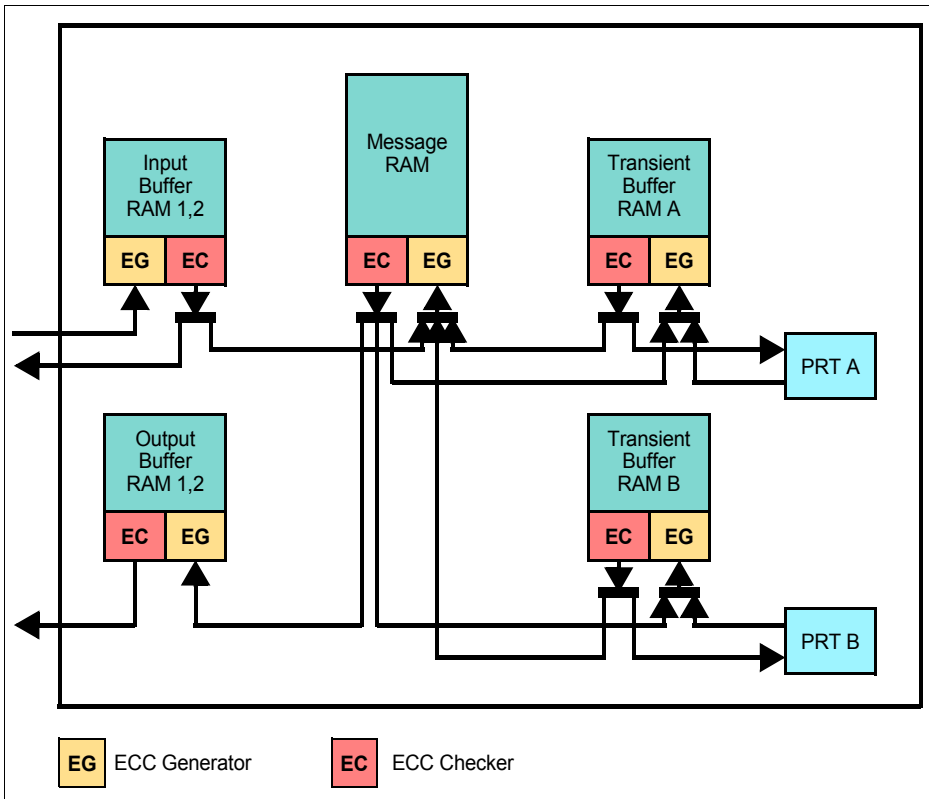

Figure 25-26 ECC Generation and Check

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status **MHDS** register is set
- The ECC error flag **EIR.EERR** in the Error Service Request Register is set, and if enabled, a module service request to the Host will be generated.

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Header and Data Section)
 - a) **MHDS.EIBF** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** has been updated
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
 - d) Transmit buffer: Transmission request for the respective Message Buffer is not set
2. ECC error in data transfer from Input Buffer RAM 1,2 ⇒ Message RAM (Transfer of Data Section only)
 - a) **MHDS.EMR** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
 - d) The Data Section of the respective Message Buffer is not updated
 - e) Transmit buffer: Transmission request for the respective Message Buffer is not set
3. ECC error during host reading Input Buffer RAM
 - a) • **MHDS.EIBF** bit is set
4. ECC error during scan of Header Sections in Message RAM
 - a) **MHDS.EMR** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
 - d) Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
 - a) **MHDS.EMR** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
 - d) Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
 - a) **MHDS.ETBF1**, **MHDS.ETBF2** bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Header Section of respective Message Buffer from Message RAM)
 - a) **MHDS.EMR** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
 - d) The Data Section of the respective Message Buffer is not updated

FlexRay™ Protocol Controller (E-Ray)

8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Transient Buffer RAM A, B)
 - a) **MHDS.ETBF1, MHDS.ETBF2** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
 - a) **MHDS.EMR** bit is set
 - b) **MHDS.FMBD** bit is set to indicate that **MHDS.FMB** points to a faulty Message Buffer
 - c) **MHDS.FMB** indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
 - a) • **MHDS.EOBF** bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

25.6.13 Host Handling of Errors

An ECC error caused by transient bit flips can be fixed by:

25.6.13.1 Self-Healing

ECC errors located in

- Input Buffer RAM 1,2
- Output Buffer RAM 1,2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

25.6.13.2 CLEAR_RAMs Command

When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMs initializes all module-internal RAMs to zero.

25.6.13.3 Temporary Unlocking of Header Section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-

FlexRay™ Protocol Controller (E-Ray)

access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **“Lock Register (LCK)” on Page 25-30**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

25.7 Module Service Request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable / enable controls for each individual service request source separately.

An service request may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register **EIR** and the Status Service Request **SIR** Register.

Table 25-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFF	Receive FIFO Full
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
MTSB	MTS Received on Channel B	
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	EERR	ECC Error
	RFO	Receive FIFO Overrun

FlexRay™ Protocol Controller (E-Ray)
Table 25-26 Module Service Request Flags and Service Request Line Enable

Register	Bit	Function
EIR	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTV A	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTV B	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host TINT0SR and TINT1SR are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/INT1SRC.SRE.

The interrupt lines to the Host NDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (**NDIC1** to **NDIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled new data interrupts (**MSIC1** to **MSIC4**). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured via the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered via input pin STPWn.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on signals IBUSY and OBUSY. When a transfer has completed bit **SIR.TIBC** or **SIR.TOBC** is set.

25.8 Restrictions

The following restrictions have to be considered when programming the E-Ray IP-module. A violation of these restrictions may lead to an erroneous behavior of the E-Ray IP-module.

25.8.1 Message Buffers with the same Frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay™ network is **not** allowed.

25.8.2 Data Transfers between IBF / OBF and Message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the setup time to start the first transfer, the number of 4-byte words to be transferred, and the number of concurrent tasks to be managed by the Message Handler. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX / RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX / RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that e.g. a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

$cyclestrans = (\text{remaining cycles of transfer running}) + (\text{cycles of requested transfer})$

$cyclesrem = cyclesrem + cyclesreq$

$cyclesrem = (\text{number of concurrent tasks}) * (\text{setup time} + (\text{number of 4-byte words})rem)$

$cyclesreq = (\text{number of concurrent tasks}) * (\text{setup time} + (\text{number of 4-byte words})req)$

$setup\ time = 2 \cdot f_{CLC_ERAY}\ \text{cycles}$

Under worst case conditions a transfer is requested directly after the previous transfer started:

FlexRay™ Protocol Controller (E-Ray)

Max. number of f_{CLC_ERAY} cycles: $cyclestrans = (3 * (2 + 68)) + (3 * (2 + 68)) = 420$
 Worst case timing: $timetrans(40MHz) = 420 * 25ns = 10.5 ms$

25.9 E-Ray Module Implementation

This section describes the E-Ray interfaces as implemented in TC26x B-Step with the clock control, port and DMA connections, interrupt control, and address decoding.

Figure 25-27 shows a detailed view of the E-Ray interface.

Figure 25-27 Detailed Block Diagram of the E-Ray Interface

25.9.1 Interconnections of the E-Ray Module

The E-Ray module has 2 FlexRay™ communication channels, channel A and channel B. Each channel provides a set of signals to drive a bus driver. The E-Ray module requires two different clocks, a sampling clock of the FlexRay™ bus f_{SCLK} . f_{SCLK} has to be 8 times the baud rate of the FlexRay™ communication. A second clock f_{CLC_ERAY} is

FlexRay™ Protocol Controller (E-Ray)

used for the main protocol controller state machine and the customer interface logic. To enable deactivation of the E-Ray Module, f_{CLC_ERAY} and f_{SCLK} may be disabled (clock gated) by the **CLC.DISR** Enable E-Ray (Clock Gating) bit. The following items are described in this section:

- E-Ray module (kernel) external registers
- Port control and connections
 - I/O port line assignment
 - I/O function selection
 - Pad driver characteristics selection
- On-chip connections
 - SCU Connections
 - DMA connections
- Module clock generation
- Interrupt registers
- E-Ray address map

25.9.2 Port Control and Connections

This section describes the I/O connections of the E-Ray module.

25.9.2.1 Input/Output Function Selection

Table 25-27 shows how bits and bit fields must be programmed for the required I/O functionality of the E-Ray I/O lines. This table also shows the values of the peripheral input select registers.

Table 25-27 E-Ray I/O Control Selection and Setup

Port Lines	Input Select Register	Input/Output Control Register Bits	I/O
FlexRay™ Channel A			
RXDA0/ P14.8	ERAY_CUST1.RISA = 00 _B	P14_IOC8.PC8 = 0XXXX _B	In
RXDA1/ P11.9	ERAY_CUST1.RISA = 01 _B	P11_IOC8.PC9 = 0XXXX _B	In

25.9.3 On-Chip Connections

This section describes all on-chip interconnections of the E-Ray modules except the connections to I/O ports (see).

25.9.3.1 E-Ray Connections with IR

The E-Ray module of the TC26x B-Step has several on-chip interconnections to the IR. [Table 25-28](#) shows these interconnections. These enable the IR to handle different service request of E-Ray module via the DMA or Interrupt Service Routine.

Table 25-28 Request Assignment for IR

Line #	ERAY Output Signal	IR Request Input Line
00	INT0	SRC_ERAYINT0
01	INT1	SRC_ERAYINT1
02	TINT0	SRC_ERAYTINT0
03	TINT1	SRC_ERAYTINT1
04	NDAT0	SRC_ERAYNDAT0
05	NDAT1	SRC_ERAYNDAT1
06	MBSC0	SRC_ERAYMBSC0
07	MBSC1	SRC_ERAYMBSC1
08	OBUSY	SRC_ERAYOBUSY
09	IBUSY	SRC_ERAYIBUSY

25.9.3.2 E-Ray Connections with SMU

The E-Ray module of the TC26x B-Step provides to the SMU the following alarms (ALMx): SRAM ECC single bit correction, SRAM ECC uncorrectable error, SRAM address error, SRAM buffer address error..

25.9.3.3 E-Ray Connections with the External Request Unit of SCU

The E-Ray module of the TC26x B-Step has several on-chip interconnections to the External Request Unit (ERU) in the SCU to externally trigger stop watch events and to provide a global time e.g. to the on chip timers. [Table 25-29](#) and [Table 25-30](#) show these interconnections.

Table 25-29 External Stop Watch Request Assignment

ERAY Input Signal	ERU Request Output Line	Selected by
STPWT0	ERU_PDOUT0	CUST1.STPWTS = 00 _B
STPWT1	ERU_PDOUT1	CUST1.STPWTS = 01 _B
STPWT2	ERU_PDOUT2	CUST1.STPWTS = 10 _B
STPWT3	ERU_PDOUT3	CUST1.STPWTS = 11 _B

Table 25-30 Global Macrotick Connection to ERU

ERAY Output Signal	ERU Request Input Line	Selected by
MT	ERU_IN23	ERU_EICR1.EXIS0 = 11 _B

25.9.3.4 E-Ray Connections to GTM

The E-Ray module of the TC26x B-Step has several on-chip interconnections to the Generic Timer Module (GTM). [Table 25-31](#) show these interconnections.

Table 25-31 Global Macrotick Connection to GTM

ERAY Output Signal	TIM Input Line
MT	TIM0_7
MT	TIM1_7
MT	TIM2_7
MT	TIM3_7

25.9.3.5 E-Ray Connections with the External Clock Output of SCU

The E-Ray module of the TC26x B-Step has one on-chip interconnections to the External Clock Output Unit in the SCU to distribute externally as also internally the Macro Tick as time base for distributed system control. [Table 25-32](#) shows this interconnection.

Table 25-32 Global Macrotick Connection to External Clock Output

ERAY Output Signal	External Clock Output	Selected by
MT0	f_{MT0}	SCU_EXTCON.SEL0 = 1111 _B

25.9.4 OCDS Trigger Bus (OTGB) Interface

The E-Ray module has two 16 bit and one 32 bit Trigger Sets ([Table 25-33](#)) which are selected with the **OTSS** register.

Table 25-33 E-Ray Trigger Sets

Trigger Set	Details
TS16_SEP Service Requests, Errors and POC State	Table 25-35
TS16_MC Macrotick Counter	Table 25-36
TS32_SCSC State, Cycle and Slot Counter	Table 25-37

Table 25-34 shows all possible Trigger Set mapping options. If OTGB0 and/or OTGB1 is not used for E-Ray, Trigger Sets of other sources can be added in the OTGM module.

Table 25-34 Trigger Set Mapping Options

Width	OTGB0	OTGB1	OTGB2
32 Bit	TS16_SEP/MC		
		TS16_SEP/MC	
	TS16_SEP/MC	TS16_SEP/MC	
64 Bit			TS32_SCSC
	TS16_SEP/MC		TS32_SCSC
		TS16_SEP/MC	TS32_SCSC
	TS16_SEP/MC	TS16_SEP/MC	TS32_SCSC

Table 25-35 TS16_SEP Service Requests, Errors and POC State

Bits	Description
0	Interrupt 0 Service Request (INT0SRC)
1	Interrupt 1 Service Request (INT1SRC)
2	Timer Interrupt 0 Service Request (TINT0SRC)
3	Timer Interrupt 1 Service Request (TINT1SRC)
4	New Data 0 Service Request (NDAT0SRC)
5	New Data 1 Service Request (NDAT1SRC)
6	Message Buffer Status Changed 0 Service Request (MBSC0SRC)
7	Message Buffer Status Changed 1 Service Request (MBSC1SRC)

FlexRay™ Protocol Controller (E-Ray)
Table 25-35 TS16_SEP Service Requests, Errors and POC State (cont'd)

Bits	Description
8	Output Buffer Busy Service Request (OBUSYSRC)
9	Input Buffer Busy Service Request (IBUSYSRC)
10	Reserved
11	Error on Channel A (EIR.EDA)
12	Error on Channel B (EIR.EDB)
[15:13]	POC State bits[2:0] (CCSV.POCS)

Table 25-36 TS16_MC Macrotick Counter

Bits	Description
[13:0]	Macrotick Value (MTCCV.MTV)
[15:14]	Reserved

Table 25-37 TS32_SCSC State, Cycle and Slot Counter

Bits	Description
[10:0]	Slot Counter Channel A (SCV.SCCA)
[22:12]	Slot Counter Channel B (SCV.SCCB)
[29:24]	Cycle Counter Value (MTCCV.CCV)
30	Transfer Input Buffer Completed (SIR.TIBC)
31	Transfer Output Buffer Completed (SIR.TOBC)
11,23	Reserved

TS32_SCSC becomes valid (posedge on otgb2_valid_o) on a change of any Slot Counter or Transfer Buffer state. This covers also the Cycle Counter which will always change with a slower rate.

25.9.5 OTGB E-Ray Registers

25.9.5.1 OCDS Trigger Bus (OTGB)

The OTGB control register is cleared by Debug Reset. Write access is 32 bit wide only and requires Supervisor Mode.

OTSS

OCDS Trigger Set Select (0870_H) **Reset Value: 0000 0000_H**

FlexRay™ Protocol Controller (E-Ray)

Field	Bits	Type	Description
RMC	[10:8]	rw	<p>Clock Divider in Run Mode</p> <p>000_B No clock signal f_{CLC_ERAY} generated (default after reset)</p> <p>001_B Clock $f_{CLC_ERAY} = f_{SPB}$ selected</p> <p>010_B Clock $f_{CLC_ERAY} = f_{SPB} / 2$ selected</p> <p>011_B Clock $f_{CLC_ERAY} = f_{SPB} / 3$ selected</p> <p>100_B Clock $f_{CLC_ERAY} = f_{SPB} / 4$ selected</p> <p>101_B Clock $f_{CLC_ERAY} = f_{SPB} / 5$ selected</p> <p>110_B Clock $f_{CLC_ERAY} = f_{SPB} / 6$ selected</p> <p>111_B Clock $f_{CLC_ERAY} = f_{SPB} / 7$ selected</p> <p><i>Note: This bit field is not affected by an application reset.</i></p> <p><i>Note: This bit field only controls the kernel clock f_{CLC_ERAY} and not the sampling clock f_{SCLK}.</i></p>
0	[31:16], [15:11], [7:4], 2	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency, which is selected via bit field RMC in the CLC register. Therefore, increasing CLC.RMC may result in a longer FPI Bus read cycle access time for kernel registers and can also slow down the write throughput to the kernel registers.

FlexRay™ Protocol Controller (E-Ray)
OCDS Control and Status Register (OCS)

The OCDS Control and Status (OCS) register is cleared by Debug Reset. The OCS register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

OCS

ENn (n = 0-31)	n	r/w	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Access Enable Register (ACCEN1)

The Access Enable Register 1 controls write access¹⁾ for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

1) The BPI_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

FlexRay™ Protocol Controller (E-Ray)

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 10000_B, EN1 -> TAG ID 100001_B, ... , EN31 -> TAG ID 111111_B.

ACCEN1
Access Enable Register 1
(08F8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Kernel Reset Register 0 (KRST0)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

Note: During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

FlexRay™ Protocol Controller (E-Ray)
KRST0
Kernel Reset Register 0
(08F4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
RSTSTAT	1	rw	Kernel Reset Status This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. 0 _B No kernel reset was executed 1 _B Kernel reset was executed This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)
Kernel Reset Register 1 (KRST1)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers (KRSTx1.RST and KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

KRST1
Kernel Reset Register 1
(08F0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	Kernel Reset This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. 0 _B No kernel reset was requested 1 _B A kernel reset was requested The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

FlexRay™ Protocol Controller (E-Ray)

Kernel Reset Status Clear Register (KRSTCLR)

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (KRST0.RSTSTAT).

KRSTCLR

Kernel Reset Status Clear Register (08EC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

25.9.7 Interrupt Registers

Two different type of Interrupt Registers are described within this chapter.

The Interrupt Control register enable the selection of the Service Request used to signal an event. The Interrupt Control registers **NDIC1** to **NDIC4** select the service request node used for New Data Events. The Interrupt Control registers **MSIC1** to **MSIC4** select the service request node used for Message Buffer Status Changed Events.

The Interrupt Service Request Control Registers control the eight service request nodes.

FlexRay™ Protocol Controller (E-Ray)
New Data Interrupt Control 1 (NDIC1)

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

NDIC1
New Data Interrupt Control 1

Version Number	Changes to Previous Version
Rev_1.4	<p>Updated the “Errata of E-Ray IP-Module”, revision 1.0 30.06.2006. Renamed from “Interrupt Flag Interface” to “Internal Signal and Flag Interface”</p> <p>With this revision it is possible to use Message Buffer 1 for SYNC Frame transmission in addition to Message Buffer 0 if SYNC Frames should have different payloads on channel A and B</p> <p>TEST1: Bit ELBE for control of internal / external loop back mode added, description of internal loop back added</p> <p>EIR: Handling of bits PERR and RFO same as for other bits, bit MHF added</p> <p>SIR: Bit RFF renamed to RFCL, handling of bits RFNE, RFCL same as for other bits</p> <p>EILS: Bit MHFL added, SILS: Bit RFFL renamed to RFCLL</p> <p>EIES, EIER: Bit MHFE added</p> <p>SIES, SIER: Bit RFFE renamed to RFCLE</p> <p>Register STPW renamed to STPW1</p> <p>STPW2: Register added</p> <p>CCSV: Bits PSL added</p> <p>SWNIT: Bits MTSA, MTSB added</p> <p>MRC: Bit SPLM added</p> <p>FCL: Register added</p> <p>FSR: Register added</p> <p>MHDF: Register added</p> <p>MBSC1/2/3/4: Naming of bits changed from MBS to MBC to distinguish between Message Buffer status flag (MBC) and Message Buffer status register (MBS)</p> <p>CREL: Register added</p> <p>ENDN: Register added</p> <p>Message Buffers in Message RAM: Header 2 and 3 updated from received Data Frames only</p> <p>MBS: Bits FTA, FTB, CCS, RCIS, SFIS, SYNS, NFIS, PPIS, RESS added</p> <p>Description Asynchronous Transmit Mode, added: ... This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence)...</p> <p>Description Loop Back Mode, added: ... This write operation has to be directly preceded by two consecutive write accesses to the Configuration LockKey (unlock sequence).</p>

Table 25-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	<p>Description LCK.CLK, corrected: To leave CONFIG state by writing SUCC1.CMD (commands READY, MONITOR_MODE, ATM_LOOP_BACK), ...Third write: SUCC1.CMD</p> <p>Description EIR.MHF, added: The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.WAHP changes from 0 to 1.</p> <p>Description SIR.CAS, added: This flag is set by the Communication Controller during STARTUP state when a CAS or a potential CAS was received. 1 = Bit pattern matching the CAS symbol received 0 = No bit pattern matching the CAS symbol received.</p> <p>Description SIR.MBSI, corrected: This flag is set by the Communication Controller when the Message Buffer status MBS has changed if bit MBI of that Message Buffer is set.</p> <p>Description T0C, added: Note: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0...</p> <p>Description SUCC1.CMD, modified: Note included into description of CHI command CLEAR_RAMs. ...Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMs...</p> <p>Description SUCC1.TSM, changed: ...The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case TSM = 1, Message Buffer 0 respectively Message Buffers 0,1 can be (re)configured in "DEFAULT_CONFIG" or "CONFIG" state only. In ALL slot mode the Communication Controller may transmit in all slots. TSM is a configuration bit which can only be set / reset by the Host. The bit can be written in "DEFAULT_CONFIG" or "CONFIG" state only. The Communication Controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing CMD = "0101" in POC states "NORMAL_ACTIVE" or "NORMAL_PASSIVE"...</p> <p>Description PRTC1.SPP, added: Note: The current revision 2.1 of the FlexRay™ protocol requires that SPP = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.</p> <p>Description CCSV.CSNI, corrected: ...Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state.</p>

Table 25-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.4 (cont'd)	<p>Description CCSV.CSAI, corrected: ...Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state.</p> <p>Description CCSV.WSV, corrected: ...Reset by CHI command RESET_STATUS_INDICATORS or by transition from "HALT" to "DEFAULT_CONFIG" state or from "READY" to "STARTUP" state.</p> <p>Description SFS.VSAE, modified: Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one...</p> <p>Description SFS.VSAO, modified: Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one...</p> <p>Description SFS.VSBE, modified: Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one...</p> <p>Description SFS.VSBO, modified: Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY the value is incremented by one...</p> <p>Description ACS, added: Note: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase...</p> <p>Description MRC.SEC1:0, changed: ...Exception: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) is always locked</p> <p>Description MRC.SPLM, changed: This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1)...</p> <p>Description MRC.SPLM, changed: Note: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.</p>

FlexRay™ Protocol Controller (E-Ray)
Table 25-38 Revision History (cont'd)

Rev_1.4 (cont'd)	<p>Description Parity Check, changed: ...When a parity error occurs when the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector register NMV1...3 is not updated from that Frame.</p> <p>Included TC1797 O Ports the Physical Layer Interface is connected to.</p> <p>Description MBS.MLST, added: The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame... ..The flag is reset by a Host write to the Message Buffer via IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer via OBF.</p> <p>Description MBS, corrected: Note: The FlexRay™ protocol specification requires that FTA, and FTB can only be reset by the Host...</p> <p>Description NULL Frame Transmission, changed: ...In this case, no Message Buffer status MBS is updated.</p>
Rev_1.5	<p>Included BPI Register (Service Request Nodes: INT0SRC, INT1SRC, TINT0SRC, TINT1SRC, NDAT0SRC, NDAT0SRC, MBSC0SRC, MBSC1SRC, CLC).</p> <p>Included for New Data and Message Buffer Status Changed Flags eight Interrupt Select Register (NDIC0, NDIC1, NDIC2, NDIC3, MSIC0, MSIC1, MSIC2, MSIC3)</p> <p>Included new address range for TC1797.</p> <p>Included into CUST1 Register Control (IBF1PAG, IBF1PAG) and Status Bits (IBS) for multiple buffer control.</p> <p>Included for TC1797 the IO Ports the Physical Layer Interface is connected to.</p> <p>Included into CUST1 1 out of 4 multiplexer Select Input Control for RXA (CUST1.RISA), RXB (CUST1.RISB) and STPWT (CUST1.STPWTS).</p> <p>Included DMA Trigger connections for TC1797.</p>
Rev_1.6	<p>Included a description of the Delayed Write Scheme to OBF and IBF.</p> <p>Corrected an erroneous description of IBF1PAG and IBF2PAG concerning the write access for specific values of IBFS. Included a verification scheme to verify correct polarity of IBFS and logic for IBF1PAG and IBF2PAG.</p>
Rev_1.7	<p>Changed P6.7 to P6.10 to use only p6.PDR1 only.</p> <p>Included table summarizing access wait states.</p>
Rev_1.8	<p>Included a description of registering the reset when E-Ray module is disabled and executing the reset when it is enabled hereafter.</p>

FlexRay™ Protocol Controller (E-Ray)

Table 25-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9	<p>Included IP Specification changes of Revision 1.2.3.</p> <p>Description TEST1, added: When the E-Ray IP is operated in one of its test modes that requires WRTEEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available. The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the E-Ray module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions. The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications.</p> <p>Description TEST1.ELBE, modified: ...Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non-multiplexing mode TMC = 00.</p> <p>Description TEST1.TMC, modified: TMC Test Multiplexer Control 00, 11= Normal signal path (default); 01 = RAM Test Mode - Internal busses are multiplexed to make all RAM blocks of the E-Ray module directly accessible by the Host...</p> <p>Description Loop Back Mode, corrected: ...Reading CCSV.POCS will return "00 1101" while the E-Ray module is in loop back mode...</p> <p>Description Loop Back mode, completed: ...When the CC is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to register IBCR...</p> <p>Description LCK.CLK, corrected: ...If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in CONFIG state and the sequence has to be repeated.</p> <p>Description LCK.TMK, corrected: ...If the write sequence below is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the TEST1 register, TEST1.WRTEEN is not set to '1' and the sequence has to be repeated.</p> <p>Description EIR.CCL, corrected: The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed...</p> <p>Description SIR.MTSA,B, modified: Media Access Test symbol received on channel A,B during the preceding symbol window...</p>

FlexRay™ Protocol Controller (E-Ray)

Table 25-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	<p>Description T1C, removed: ... In case the configured Macro tick count is not within the valid range, timer 1 will not start...</p> <p>Description SUCC1.CMD, corrected: ...In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the CC is already in the requested POC state will be ignored.</p> <p>Description SUCC1.CMD, added: ALLOW_COLDSTART; ...When called in states DEFAULT_CONFIG, CONFIG, HALT, or MONITOR_MODE, CMD will be reset to 0000 = command_not_accepted...</p> <p>Description SUCC1.CMD, completed: RESET_STATUS_INDICATORS; ...Flags internally evaluated in the actual POC state are not reset...</p> <p>Description SUCC1.CMD, corrected: MONITOR_MODE; ...In this mode the CC is able to receive FlexRay™ Frames and wakeup pattern...</p> <p>Description SUCC1.CMD, added: Table added which references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD.</p> <p>Description CCSV.RCA, completed: ...The READY command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.</p> <p>Description SWNIT.MTSA,B, modified: Media Access Test symbol received on channel A,B during the preceding symbol window...</p> <p>Description ESID[1...15].RXEA,B completed: ...sorted in ascending order,If the node transmits a SYNC Frame in an even communication cycle by itself, register ESID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXEA, RXEB are set... RXEA,B Received / Configured Even Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID (ESID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames; 0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames.</p>

FlexRay™ Protocol Controller (E-Ray)

Table 25-38 Revision History (cont'd)

Version Number	Changes to Previous Version
Rev_1.9 (cont'd)	<p>Description OSID[1...15].RXOA,B completed: ... sorted in ascending order,If the node transmits a SYNC Frame in an odd communication cycle by itself, register OSID1 holds the respective SYNC Frame ID as configured in Message Buffer 0 and flags RXOA, RXOB are set...RXOA,B Received / Configured Odd Sync ID on Channel A,B Signals that a SYNC Frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = OID(OSID1 only). 1 = SYNC Frame received on channel A / node configured to transmit SYNC Frames;0 = No SYNC Frame received on channel A / node not configured to transmit SYNC Frames</p> <p>Description FRF.FID, modified: Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected.</p> <p>Description MHDF.WAHP, added: Outside DEFAULT_CONFIG and CONFIG state this flag is set by the CC when the message handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer...</p> <p>Description MONITOR_MODE, completed: ...In this mode the CC is able to receive FlexRay™ Frames and to detect wakeup pattern...</p> <p>Modified the description of CUST1.POBFEN to: Parity Error Reporting of Output Buffer (OBF1/OBF1) RAMs Enable/Test Disable; 0_B: Parity error in Output Buffer (OBF1,OBF2) RAMs is not reported to SCU nor to OBF1, OBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to OBF1 and OBF2 RAM wrapper is enabled.</p> <p>Modified the description of CUST1.PMBFEN to: Parity Error Reporting of Message Buffer (MBF) RAMs Enable/Test Disable; 0_B: Parity error in Message Buffer (MBF) RAMs is not reported to SCU nor to MBF RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to MBF RAM wrapper is enabled.</p> <p>Modified the description of CUST1.PITBFEN to: Parity Error Reporting of Message Buffer (IBF1, IBF2, TBF1, TBF2) RAMs Enable/Test Disable; 0_B: Parity error in Input Buffer and Transient Buffer (IBF1, IBF2, TBF1, TBF2) RAMs is not reported to SCU nor to IBF1, IBF2, TBF1, and TBF2 RAM wrapper.1_B: The parity error reporting and thus the activation of error signals to SCU as also to IBF1, IBF2, TBF1, and TBF2 RAM wrapper is enabled</p>

26 Generic Timer Module (GTM)

26.1 Introduction

This document is based on the GTM_IP Specification version 1.5.5.1 (Released on 20.06.2013) of the Robert Bosch GmbH.

26.1.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The scalability and configurability is reached with an architecture philosophy where dedicated hardware submodules are located around a central routing unit (called Advanced Routing Unit (ARU)). The ARU can connect the submodules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM can run -once setup by an external CPU-independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.

The hardware submodules have dedicated functionalities, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several submodules through the ARU complex functions can be established. E.g. the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called infrastructural components further on. These components are present in all GTM variants.

Other submodules have a more general architecture and can fulfil typical timer functions, e.g. there are PWM generation units. The third class of submodules are those fulfilling a dedicated functionality for a certain application domain, e.g. the DPLL serves engine management applications. A fourth group of submodules is responsible for supporting the implementation of safety functions to fulfil a defined safety level. The module ICM is responsible for interrupt services and defines the fifth group.

Generic Timer Module (GTM)

Each GTM is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM.

26.1.2 Document Structure

The structure of this document is motivated out of the aforementioned submodule classes. [Section 26.2](#) describes the dedicated GTM implementation this specification is written for. It gives an overview about the implemented submodules.

[Section 26.3](#) up to [Section 26.9](#) deal with the so called infrastructural components for routing, clock management and common time base functions. [Section 26.10](#) to [Section 26.12](#) describe the signal input and output modules while the following [Section 26.13](#) explains the signal processing and generation submodule. [Section 26.14](#) outlines a memory configuration module for the described signal processing and generation submodule. The next sections provide a detailed description of application specific and safety related modules like the MAP, DPLL, SPE, CMP and MON submodules. [Section 26.18](#) describes a module that bundles several interrupts coming from the other submodules and connect them to the outside world.

These submodule groups are shown in the following table:

Table 26-1 Submodule groups

26.2 GTM Architecture

26.2.1 Overview

As already mentioned in [Section 26.1](#) the GTM forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different count of submodules (i.e. ATOM, BRC, MCS, PSM, SPE, TIM, TOM) are possible. In this section the GTM realization is outlined. The architecture of the GTM is depicted in.

26.2.1.1 GTM Architecture Block Diagram

Figure 26-1 GTM Architecture Block Diagram

Generic Timer Module (GTM)

The central component of the GTM is the Advanced Routing Unit (ARU) where most of the submodules are located around and connected to. This ARU forms together with the Broadcast (BRC) and the Parameter Storage Module (PSM) the infrastructural part of the GTM. The ARU is able to route data from a connected source submodule to a connected destination submodule. The routing is done in a deterministic manner with a round-robin scheduling scheme of connected channels which receive data from ARU and with a worst case round-trip time.

The routed data word size of the ARU is 53 bit. The data word can logically be split into three parts. These parts are shown in **Figure 26-2**. Bits 0 to 23 and bits 24 to 47 typically hold data for the operation registers of the GTM. This can be for example the duty cycle and period duration of a measured PWM input signal or the output characteristic of an output PWM to be generated. Another possible content of Data0 and Data1 can be two 24 bit values of the GTM time bases TBU_TS0, TBU_TS1 and TBU_TS2. Bits 48 to 52 can contain control bits to send control information from one submodule to another. These ARU Control Bits (ACB) can have a different meaning for different submodules.

It is also possible to route data from a source to a destination and the destination can act later on as source for another destination. These routes through the GTM are further on called data streams. For a detailed description of the ARU submodule please refer to **Section 26.3**.

26.2.1.2 ARU Data Word Description

Figure 26-2 ARU Data Word Description

The BRC is able to distribute data from one source module to more than one destination modules connected to the ARU. The PSM submodule consists of three subunits, the AEI-to-FIFO Data Interface (AFD), FIFO-to-ARU Interface (F2A) and the FIFO itself. The PSM can serve as a data storage for incoming data characteristics or as parameter storage for outgoing data. This data is stored in a RAM that is logically located inside the FIFO subunit. The AFD subunit is the interface between the FIFO and the GTM system bus interface AEI (please see **Section 26.2.2.1** for detailed discussion). The F2A subunit is the interface between the FIFO subunit and the ARU.

Signals are transferred into the GTM at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in

Generic Timer Module (GTM)

parallel and route the values to ARU for further processing. The internal operation registers of the TIM submodule are 24 bits wide.

The Clock Management Unit (CMU) serves up to 13 different clocks for the GTM and up to three external clock pins `GTM_ECLK0...2`. It acts as a clock divider for the system clock. The counters implemented inside other submodules are typically driven from this submodule. Please note, that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock `SYS_CLK`. This global clock typically corresponds to the microcontroller bus clock the GTM is connected to.

The TBU provides up to three independent common time bases for the GTM. Two of these time bases can also be clocked with the digital PLL (DPLL) `sub_inc1c` and `sub_inc2c` outputs. The DPLL generates the higher frequent clock signals `sub_inc1`, `sub_inc2`, `sub_inc1c` and `sub_inc2c` on behalf of the frequencies of up to two input signals. These two input signals can be selected out of six incoming signals from the TIM0 submodule. In this submodule the incoming signals are filtered and transferred to the MAP submodule where two of these six signals are selected for further processing inside the DPLL.

Signal outputs are generated with the Timer Output Modules (TOM) and the ARU-connected TOMs (ATOM). Each TOM channel is able to generate a PWM signal at its output. Because of the integrated shadow register even the generation of complex PWM outputs is possible with the TOM channels by serving the parameters with the CPU. It is possible to trigger TOM channels for a successor TOM submodule through a trigger line between `TOM(x)_CH(15)` and `TOM(x+1)_CH(0)`. But to avoid long trigger paths the trigger signal is registered at the TOM submodule output, resulting in one `SYS_CLK` cycle delay of the trigger signal.

In addition each TOM submodule can integrate functions to drive one BLDC engine. This BLDC support is established together with the TIM and Sensor Pattern Evaluation (SPE) submodule.

The ATOMs offer the additional functionality to generate complex output signals without CPU interaction by serving these complex waveform characteristics by other submodules that are connected to the ARU like the PSM or Multi Channel Sequencer (MCS). While the internal operation and shadow registers of the TOM channels are 16 bit wide, the operation and shadow registers of the ATOM channels are 24 bit wide to have a higher resolution and to have the opportunity to compare against time base values coming from the TBU.

It is possible to trigger ATOM channels for a successor ATOM submodule through a trigger line between `ATOM(x)_CH(7)` and `ATOM(x+1)_CH(0)`. But to avoid long trigger paths the trigger signal is registered at each second ATOM submodule in the trigger line, resulting in one `SYS_CLK` cycle delay of the trigger signal between each second ATOM submodule.

Together with the MCS the ATOM is able to generate an arbitrary predefined output sequence at the GTM output pins. The output sequence is defined by instructions

Generic Timer Module (GTM)

located in RAM connected to the MCS submodule. The instructions define the points where an output signal should change or to react on other signal inputs. The output points can be one or two time stamps (or even angle stamp in case of an engine management system) provided by the TBU. Since the MCS is able to read data from the ARU it is also able to operate on incoming data routed from the TIM. Additionally, the MCS can process data that is located in its connected RAMs. The MCS RAM is located logically inside the MCS while the silicon vendor has to implement its own RAM technology there.

The two modules Compare Module (CMP) and Monitor Module (MON) implement safety related features. The CMP compares two output channels of an ATOM or TOM and sends the result to the MON submodule where the error is signalled to the CPU. The MON module is also able to monitor the ARU and CMU activities.

In the described implementation the submodules of the GTM have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier management bunch of interrupts that are visible outside of the GTM.

On the GTM toplevel there are some configurable signal connections from the signal output of the TOM, ATOM modules to the input signals of the TIM modules.

26.2.1.3 GTM signal multiplex

Generic Timer Module (GTM)

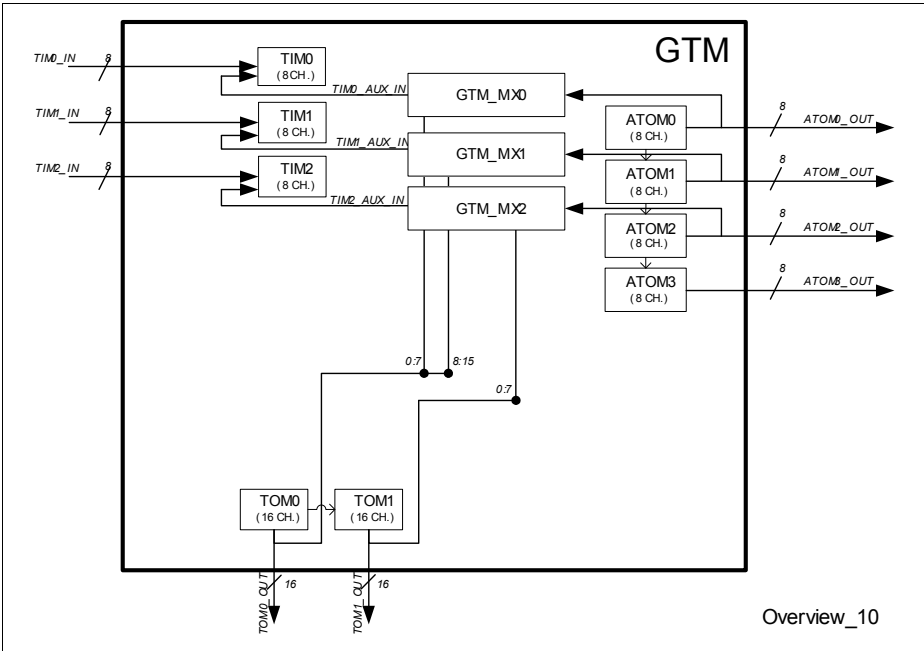

Figure 26-3 GTM Signal Multiplexer

The next diagram gives an overview of the connectivity. The source selection is defined with the bit SRXx in the register GTM_TIM[y]_AUX_IN_SRC.

Generic Timer Module (GTM)

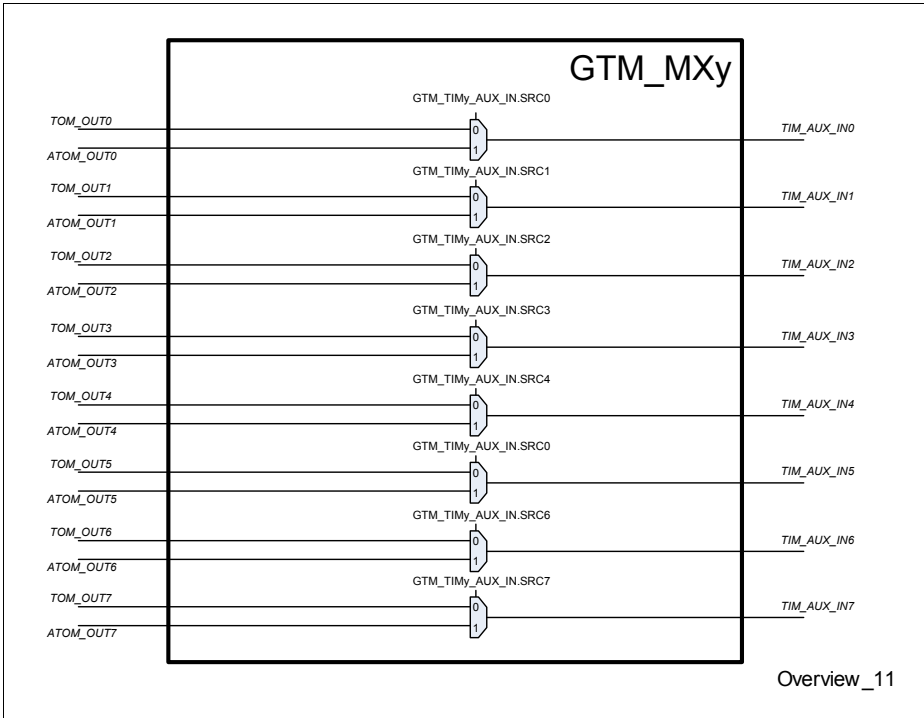

Figure 26-4 GTM TOM / ATOM to TIM Multiplexer

26.2.2 GTM Interfaces

In general the GTM can be divided into four interface groups. Two interface groups represent the ports of the GTM where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM input submodule TIM and to the GTM output submodules TOM and ATOM.

Another interface is the bus interface where the GTM can be connected to the SoC system bus. This generic bus interface is described in more detail in [Section 26.2.2.1](#). The last interface is the interrupt controller interface. The GTM provides several interrupt lines coming from the various submodules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated microcontroller environment where each interrupt handling can look different. The interrupt concept is described in more detail in [Section 26.2.5](#).

Generic Timer Module (GTM)
26.2.2.1 GTM Generic Bus Interface (AEI)

The GTM is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is done with a bridge module translating the AEI signals to the SPB bus signals. The AEI bus signals are depicted in the following table:

Table 26-2 AEI Bus Signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM select line	1
AEI_ADDR	I	GTM address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive on of the following values:

Table 26-3 AEI Status Options

AEI_STATUS	Description
00	No Error
01	Illegal Byte Addressing
10	Illegal Address Access
11	Unsupported Address

The signal value "00" is driven if no error occurred during AEI access.

The signal value "01" is driven if the bus address is not an integer multiple of 4 (byte addressing).

The signal value "11" is driven if the address is not handled in the GTM.

The signal value "10" is driven if an illegal write access to one of the following register is performed

a) register is protected (e.g. protected by bit RF_PROT).

In case of an illegal write access signaled by status "10" the register will not be modified.

Reading registers will never return status "10".

Generic Timer Module (GTM)

Write access to following addresses returns status "10" under special conditions:

ARU_IRQ_FORCINT
ATOMi_CHx_CM0
ATOMi_CHx_CM1
ATOMi_CHx_SR0

 MCS RAM during initialization
 DPLL RAM during initialization

26.2.2.2 GTM Multi-master and multi-tasking support

To support multi-master and multi-task access to the registers of the GTM a dedicated write-access scheme is used for critical control bits inside the GTM that need such a mechanism. This can be for example a shared register where more than one channel can be controlled globally by one register write access. Such register bits are implemented inside the GTM with a double bit mechanism, where the writing of '00' and '11' has no effect on the register bit and where '01' sets the bit and '10' resets the bit. If the CPU wants to read the status of the bit it always gets a '00' if the bit is reset and it gets a '11' if the bit is set.

Note: CPU accesses have to consider the configured SPB to SYS_CLK ratio if $SPB > SYSCLK$.

26.2.3 ARU Routing Concept

One central concept of the GTM is the routing mechanism of the ARU submodule for data streams. Each data word transferred between the ARU and its connected submodule is 53 bit wide. It is important to understand this concept in order to use the resources of the GTM effectively. Each module that is connected to the ARU may provide an arbitrary number of ARU write channels and an arbitrary number of ARU read channels. In the following, the ARU write channels are named data sources and the ARU read channels are named data destinations.

The concept of the ARU intends to provide a flexible and resource efficient way for connecting any data source to an arbitrary data destination. In order to save resource costs, the ARU does not implement a switch matrix, but it implements a data router with serialized connectivity providing the same interconnection flexibility. **Figure 26-5** shows the ARU data routing principle. Data sources are marked with a green rectangle and the data destinations are marked with yellow rectangles. The dashed lines in the ARU depict

Generic Timer Module (GTM)

the configurable connections between data sources and data destinations. A connection between a data source and a data destination is also called a data stream.

26.2.3.1 Principle of data routing using ARU

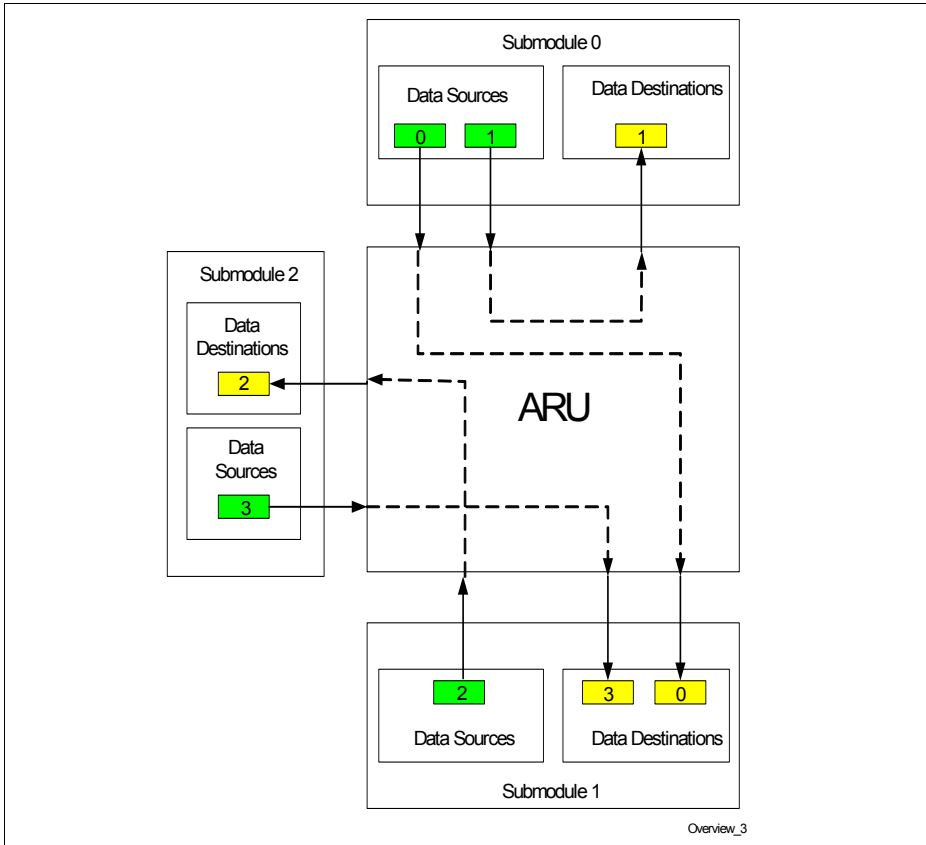

Figure 26-5 ARU Data Routing Principle

The configuration of the data streams is realized according to the following manner: Each data source has its fixed and unique source address: The fixed address of each data source is pointed out by the numbers in the green boxes of **Figure 26-5**. The address definitions of all available data sources in the GTM can be obtained from **Table 26.21.1**. The connection from a specific data source to a specific data destination is defined by configuring the corresponding address of a data source in the desired data destination. The configured address of each data destination is pointed out by the numbers in the yellow boxes of **Figure 26-5**.

Generic Timer Module (GTM)

Normally, the destination is idle and waits for data from the source. If the source offers new data, the destination does a destructive read, processes the data and goes idle again. The same data is never read twice.

There is one submodule for which this destructive read access does not hold. This is the BRC submodule configured in Maximal Throughput Mode. For a detailed description of this module please refer to [Section 26.4](#).

The functionality of the ARU is as follows: The ARU sequentially polls the data destinations of the connected modules in a round-robin order. If a data destination requests new data from its configured data source and the data source has data available, the ARU delivers the data to the destination and it informs both, the data source and destination that the data is transferred. The data source marks the delivered ARU data as invalid which means that the destination consumed the data.

It should be noted that each data source should only be connected to a single data destination. This is because the destinations consume the data. If two destinations would reference the same source one destination would consume the data before the other destination could consume it. Since the data transfers are blocking, the second destination would block until it receives new data from the source. If a data source should be connected to more than one data destination the submodule Broadcast (BRC) has to be used. On the other hand, the transfer from a data source to the ARU is also blocking, which means that the source channel can only provide new data to the ARU when an old data word is consumed by a destination. In order to speed up the process of data transfers, the ARU handles two different data destinations in parallel. Therefore, a transfer between source and destination takes two cycles, but since the transfers are pipelined these two cycles have only effect for one round trip of the ARU.

[Table 26-4](#) gives an overview about the number of channels for the GTM.

Table 26-4 ARU Channels

Submodule	Number of data sources	Number of data destinations
ARU	1	0
DPLL	24	24
TIM 0-2	24	0
MCS 0-2	72	24
BRC	22	12
TOM	0	0
ATOM 0-2	24	24
PSM 0	8	8
ICM	0	0
CMP	0	0

Table 26-4 ARU Channels (cont'd)

Submodule	Number of data sources	Number of data destinations
MON	0	0
Total	165	92

26.2.3.2 ARU Round Trip Time

The ARU uses a round-robin arbitration scheme with a fixed round trip time for all connected data destinations. This means that the time between two adjacent read requests resulting from a data destination channel always takes the round trip time, independently if the read request succeeds or fails.

The worst case round-trip time is defined as $65 * \text{SYS_CLC}$ of the GTM input system clock. Since the round-trip time depends on the number of destinations the ARU has to ensure that the round-trip time never exceeds the defined time.

26.2.3.3 ARU Blocking Mechanism

Another important concept of the ARU is its blocking mechanism that is implemented for transferring data from a data source to a data destination. This mechanism is used by ARU connected submodules to synchronize the submodules to the routed data streams. [Figure 26-6](#) explains the blocking mechanism.

Graphical representation of ARU blocking mechanism

Figure 26-6 Graphical representation of ARU blocking mechanism

If a data destination requests data from a data source over the ARU but the data source does not have any data yet, it has to wait until the data source provides new data. In this case the submodule that owns the data destination may perform other tasks. When a data source produces new data faster than a data destination can consume the data the source raises an error interrupt and signals that the data could not be delivered in time. The new data is marked as valid for further transfers and the old data is overwritten.

Generic Timer Module (GTM)

In any case the round trip time for the ARU is always fixed.

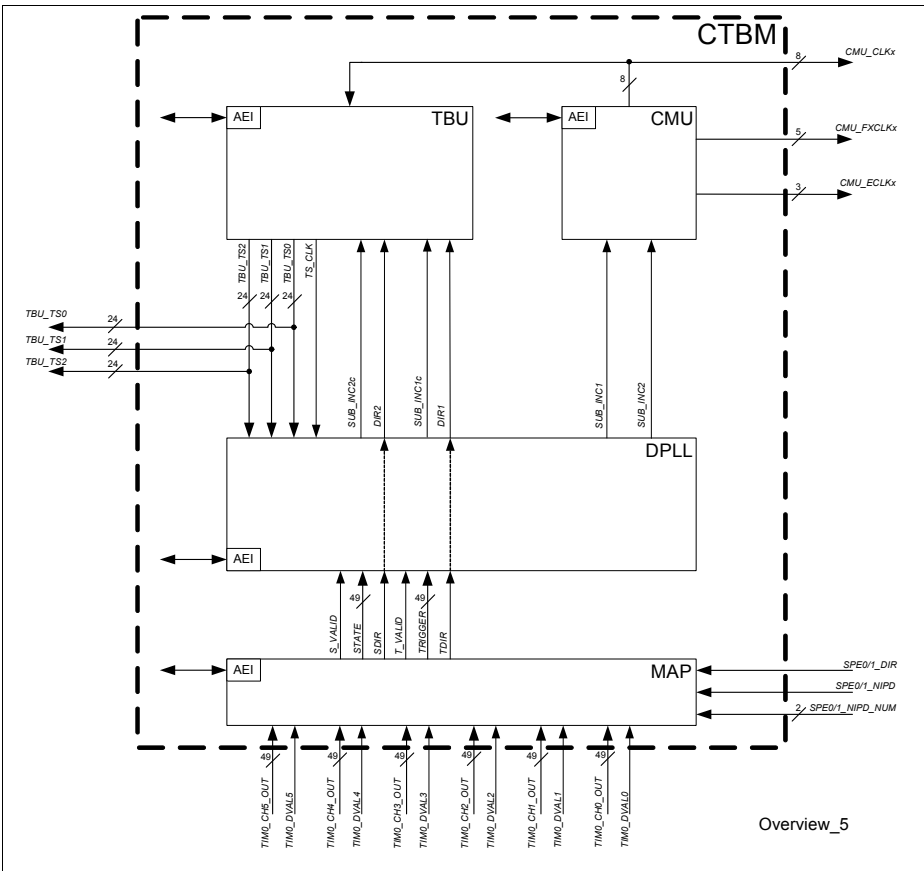

One exception is the BRC submodule when configured in Maximal Throughput Mode. Please refer to [Section 26.4](#) for a detailed description.

26.2.4 GTM Clock and Time Base Management (CTBM)

Inside the GTM several subunits are involved in the clock and time base management of the whole GTM. [Figure 26-7](#) shows the connections and subblocks involved in these tasks. The subblocks involved are called Clock and Time Base Management (CTBM) modules further on.

26.2.4.1 GTM Clock and time base management architecture

Generic Timer Module (GTM)

Overview_5

Figure 26-7 GTM Clock and time base management architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates up to 13 clocks for the submodules of the GTM and up to three GTM external clocks CMU_ECLK[z] (z: 0...2). For a detailed description of the CMU functionality and clocks please refer to [Section 26.8](#).

The five (5) CMU_FXCLK[y] (y: 0...4) clocks are used by the TOM submodule for PWM generation. A maximum of eight (8) CMU_CLK[x] (x: 0...7) clocks are used by other submodules of the GTM for signal generation.

Inside the Time Base Unit (TBU) one of these maximum eight clocks is used per channel to generate a common time base for the GTM. Besides the CMU_CLK[x] signals, the TBU can use the compensated SUB_INC[i]c (i: 1,2) signals coming from the DPLL

Generic Timer Module (GTM)

submodule for time base generation. This time base then typically represents an angle clock for an engine management system. For the meaning of compensated (SUB_INC[i]c) and uncompensated (SUB_INC[i]) DPLL signals please refer to the DPLL [Section 26.16](#). The SUB_INC[i]c signals in combination with the two direction signal lines DIR[i] the TBU time base can be controlled to run forwards or backwards. The TBU functionality is described in [Section 26.9](#).

The TBU submodule generates the three time base signals TBU_TS0, TBU_TS1 and TBU_TS2 which are widely used inside the GTM as common time bases for signal characterization and generation.

As stated before, the DPLL submodule provides the four clock signals SUB_INC[i] and SUB_INC[i]c which can be seen as a clock multiplier generated out of the two input signal vectors TRIGGER and STATE coming from the MAP submodule. For a detailed description of the DPLL functionality please refer to [Section 26.16](#).

The MAP submodule is used to select the TRIGGER and STATE signals for the DPLL out of six input signals coming from TIM0 submodule. Besides this, the MAP submodule is able to generate a TDIR (TRIGGER Direction) and SDIR (STATE Direction) signal for the DPLL and TBU coming from the SPE0 and SPE1 signal lines. The direction signals are generated out of a defined input pattern. For a detailed description of the MAP submodule please refer to [Section 26.15](#).

26.2.5 GTM Interrupt Concept

The submodules of the GTM can generate thousands of interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In this interrupt groups the GTM submodule interrupt signals are bundled to a smaller set of interrupts. Out of these interrupt sets a smaller amount of interrupt signals is created and signalled outside of the GTM as a signal GTM_<MOD>_IRQ, where as <MOD> identifies the name of the corresponding GTM submodule.

The controlling of the individual interrupts is done inside the submodules. If a submodule consists of several submodule channels that are most likely to work independent from each other (like TIM, PSM, MCS, TOM, and ATOM), each submodule channel has its own interrupt control and status register set, named as interrupt set in the following. Other submodules (SPE, ARU, DPLL, BRC, CMP and global GTM functionality) have a common interrupt set for the whole submodule.

The interrupt set consists of four registers: The IRQ_EN register, the IRQ_NOTIFY register, the IRQ_FORCINT register, and the IRQ_MODE register. While the registers IRQ_EN, IRQ_NOTIFY, and IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

Generic Timer Module (GTM)

In order to support a wide variety of microcontroller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

Level mode

Pulse mode

Pulse-Notify mode

Single-Pulse mode

It is recommended to use the Pulse-Notify mode as interrupt mode.

These interrupt modes are described in more details in the following subsections.

The register `IRQ_EN` allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal `GTM_<MOD>_IRQ`.

The register `IRQ_NOTIFY` collects the occurrence of interrupt events. The behaviour for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write access with value '1' to a bit in the register `IRQ_NOTIFY` always clears the corresponding `IRQ_NOTIFY` bit.

Moreover, the enabling of a disabled interrupt sources with a write access to the register `IRQ_EN` also clears the corresponding bit in the `IRQ_NOTIFY` register but only if the error interrupt source `EIRQ_EN` is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register `IRQ_NOTIFY` is not cleared.

Additionally, each write access to the register `IRQ_MODE`, clears all bits in the `IRQ_NOTIFY` register. It should be notified that the clearing of `IRQ_NOTIFY` is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register `IRQ_EN`, define the new interrupt mode by writing register `IRQ_MODE`, followed by enabling the desired interrupts with the register `IRQ_EN`.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register `EIRQ_EN`, define the new interrupt mode by writing register `IRQ_MODE`, followed by enabling the desired error interrupts with the register `EIRQ_EN`.

The register `IRQ_FORCINT` is used by software for triggering individual interrupts with a write access with value '1'. Since a write access to `IRQ_FORCINT` only generates a single pulse, `IRQ_FORCINT` is not implemented as a true register and thus any read access to `IRQ_FORCINT` always results with a value of '0'.

Generic Timer Module (GTM)

It should be noted, that the mechanism for triggering interrupts with `IRQ_FORCINT` is globally disabled after reset. It has to be explicitly enabled by clearing the bit `RF_PROT` in the register `GTM_CTRL` (see [Section 26.2.9.3](#))

For the modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE and CMP each interrupt may be configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register `EIRQ_EN`.

Note, it is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because of both interrupt clear signals could reset the notify bit this is expected to cause problems in a system and therefore it is strongly recommended to not enable both interrupt types at the same point in time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register `EIRQ_EN` also clears the corresponding bit in the `IRQ_NOTIFY` register only if the interrupt source is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register `IRQ_NOTIFY` is not cleared.

All enabled error interrupts are or-combined inside the ICM and assigned to the dedicated GTM port `gtm_err_irq`.

To be able to detect the module source of the error interrupt the ICM provides the register `ICM_IRQG_MEI`.

The error interrupt causing channel can be determined for the modules FIFO, TIM and MCS by evaluating the ICM register `ICM_IRQG_CEI0` to `ICM_IRQG_CEI4`.

26.2.5.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register `IRQ_NOTIFY`, independent of the corresponding enable bit of register `IRQ_EN` and `EIRQ_EN`.

An interrupt event, which is defined as a pulse on the signal `Int_out` of [Figure 26-8](#), may be triggered by the interrupt source of the submodule or by software performing a write access to the corresponding register `IRQ_FORCINT`, with a disabled bit `RF_PROT` in register `GTM_CTRL`.

Level interrupt mode scheme

Generic Timer Module (GTM)

Figure 26-8 Level interrupt mode scheme

A collected interrupt bit in register `IRQ_NOTIFY` may be cleared by a clear event, which is defined as a pulse on signal `Clear_out` of **Figure 26-8**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register `IRQ_NOTIFY` leading to a pulse on signals `SW_clear`. A clear event may also result from an externally connected signal `GTM_<MOD>_IRQ_CLR`, which is routed to the signal `HW_clear` of **Figure 26-8**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register `IRQ_EN`.

As the **Table 26-5** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 26-5 IRQ_NOTIFY behaviour

Int_in	Clear_in	Int_out	Clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

Priority of Interrupt Events and Clear Events

As it can be seen from the **Figure 26-8** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal `IRQ_bit`, if the corresponding interrupt is enabled in register `IRQ_EN`.

With exception of the submodules `ARU` and `DPLL`, the signal `IRQ_bit` is OR-combined with the neighboring `IRQ_bit` signals of the same interrupt set and they are routed as a single signal `IRQ_line` to the interrupt concentrator module (ICM). The interrupt signals `IRQ_bit` of the submodules `DPLL` and `ARU` are routed directly as a signal `IRQ_line` to the submodule `ICM`. In some cases (submodules `TOM` and `ATOM`) the `ICM` may further OR-

Generic Timer Module (GTM)

combine several IRQ_line signals to an outgoing interrupt signal GTM_<MOD>_IRQ. In the other cases the IRQ_line signals are directly connected to the outgoing signals GTM_<MOD>_IRQ. within the submodule ICM.

The signal IRQ_occurred is connected in a similar way as the signal IRQ_line, however this signal is used for monitoring the interrupt state of the register IRQ_NOTIFY in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown below.

Level interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

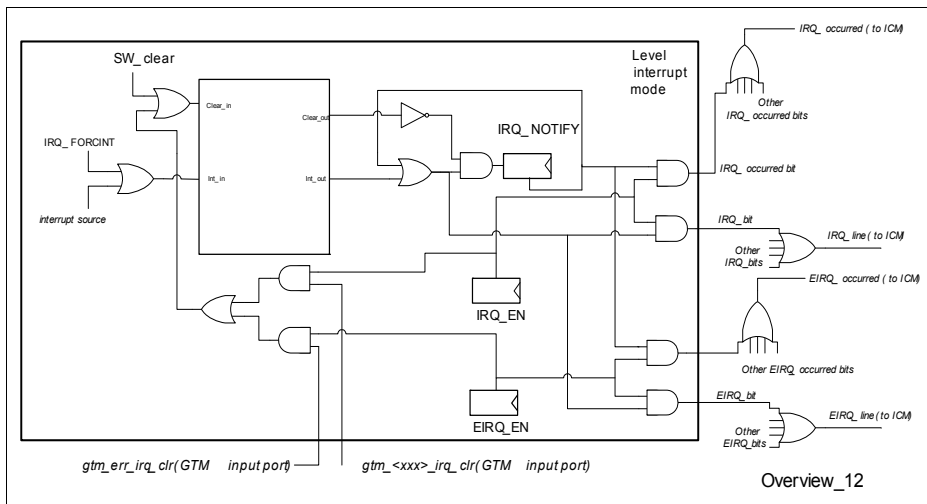

Figure 26-9 Level interrupt scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of [Figure 26-8](#). A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from externally connected signal gtm_<xxx>_irq_clr or gtm_err_irq_clr, which is routed as a HW_clear to Clear_in of [Figure 26-8](#). However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register IRQ_EN or EIRQ_EN.

As it can be seen from the [Figure 26-9](#) an occurred interrupt event is signalled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

26.2.5.2 Pulse interrupt mode

The Pulse interrupt mode behaviour can be observed from [Figure 26-10](#).

Pulse interrupt mode scheme

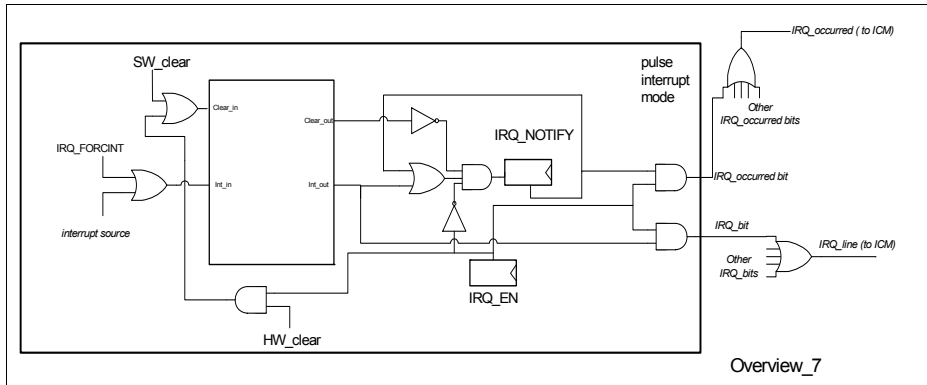

Figure 26-10 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_bit signal if IRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if IRQ_EN or IRQ_EN are enabled.

However, if an interrupt is disabled in the register IRQ_EN, an occurred interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

Pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

Generic Timer Module (GTM)

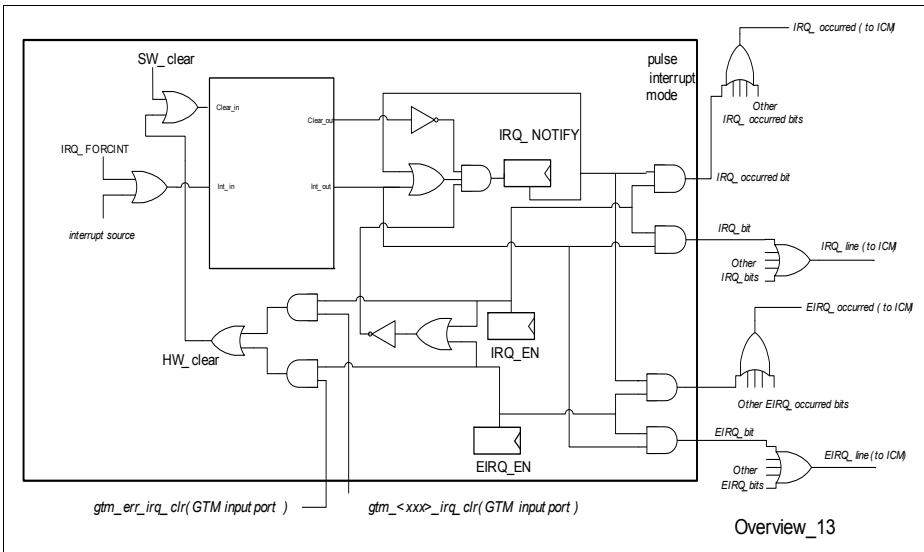

Figure 26-11 Pulse interrupt scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_bit signal if EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if EIRQ_EN is enabled.

However, if an error interrupt is disabled in the register EIRQ_EN, an occurred error interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

26.2.5.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register IRQ_NOTIFY. If an interrupt is enabled by the register IRQ_EN, each interrupt event will also generate a pulse on the IRQ_bit signal. The signal IRQ_occurred will be high if interrupt is enabled in register IRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in [Figure 26-12](#).

Pulse-notify interrupt mode scheme

Generic Timer Module (GTM)

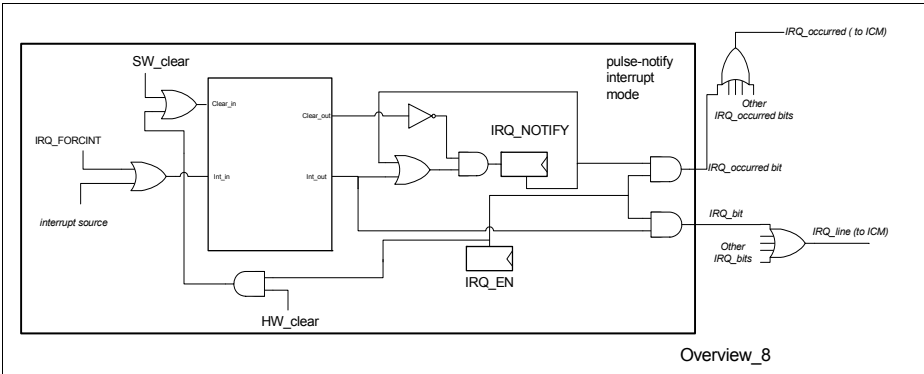

Figure 26-12 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

Pulse-notify interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

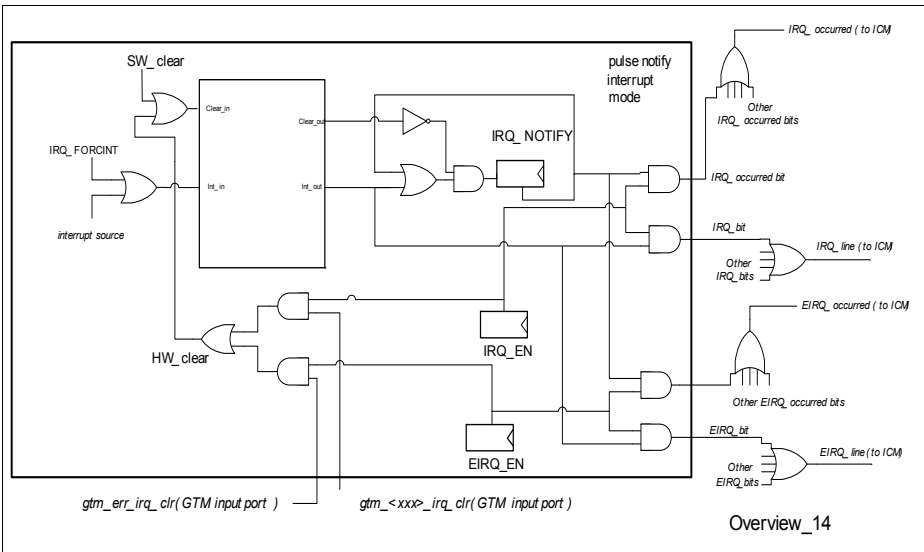

Figure 26-13 Pulse-notify interrupt scheme

Generic Timer Module (GTM)

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register IRQ_NOTIFY. If an error interrupt is enabled by the register EIRQ_EN, each error interrupt event will also generate a pulse on the EIRQ_bit signal. The signal EIRQ_occurred will be high if error interrupt is enabled in register EIRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in figure 2.5.3.2.

26.2.5.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of IRQ_EN. However, only the first interrupt event of an enabled interrupt within a common interrupt set is forwarded to signal IRQ_line. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled interrupts are cleared by a clear event. The IRQ_occurred signal line will be high, if the IRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode is shown in **Figure 26-14**.

The only exceptions are the modules ARU and DPLL. In these modules the IRQ_occurred bit of each interrupt is directly connected (without OR-conjunction of neighboring IRQ_occurred bits) to the inverter for suppressing further interrupt pulses.

Single-pulse interrupt mode scheme

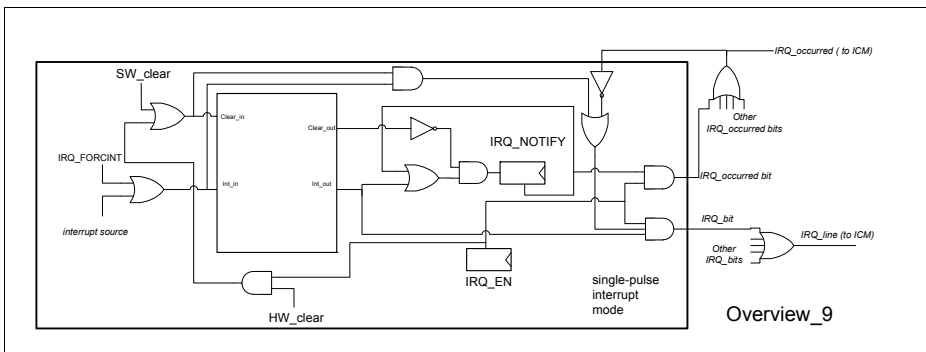

Figure 26-14 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behaviour in the single pulse mode, all desired interrupt sources should be enabled by a single write access to IRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

Generic Timer Module (GTM)

Single-pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

Figure 26-15 Single-pulse interrupt mode scheme

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_line. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_occurred signal line will be high, if the EIRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in figure 2.5.4.2.

To avoid unexpected EIRQ behaviour in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to EIRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The only exceptions are the modules ARU and DPLL. In these modules the EIRQ_occurred bit of each error interrupt is directly connected (without OR-conjunction of neighboring EIRQ_occurred bits) to the inverter for suppressing further error interrupt pulses.

Generic Timer Module (GTM)

26.2.5.5 GTM Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM submodule first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM submodule please refer to [Chapter 26.18](#).

26.2.6 GTM Software Debugger Support

For software debugger support the GTM comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behaviour to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The [Table 26-6](#) describes the behaviour of some GTM registers with special functionality on behalf of read accesses from the AEI bus interface.

26.2.6.1 Register behaviour in case of Software Debugger accesses

Table 26-6 Register behaviour in case of Software Debugger accesses

Module	Register	Description
AFD	AFDi_CHx_BUFFACC	The FIFO read access pointers are not altered on behalf of a debugger read access to this register.
TIM	TIMi_CHx_GPR0 / 1	The overflow bit is not altered in case of a debugger read access to this register.
ATOM	ATOMi_CHx_SR0 / 1	In SOMC mode a read access to this register by the debugger does not release the channel for a new compare / match event.

Further on, some important states inside the GTM submodule have to be signalled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signalling please refer to the GTM module integration guide.

The GTM provides an external signal gtm_halt, which disables clock signal SYS_CLK for debugging purposes. If SYS_CLK is disabled, a connected debugger can read any GTM related register and the GTM internal RAMs using AEI. Moreover, the debugger can also perform write accesses to the internal RAMs and to several GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

26.2.7 GTM Programming conventions

To serve different application domains the GTM is a highly configurable module with many configuration modes. In principle the submodules of the GTM are intended to be configured at system startup to fulfil certain functionality for the application domain the microcontroller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behaviour.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM submodules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behaviour of the GTM.

26.2.8 GTM TOP-Level Configuration Registers Overview

GTM TOP-level contains following configuration registers:

Table 26-7 GTM TOP-Level Configuration Registers Overview

Register name	Description	Details in Section
GTM_REV	GTM Version control register	Section 26.2.9.1
GTM_RST	GTM Global reset register	Section 26.2.9.2
GTM_CTRL	GTM Global control register	Section 26.2.9.3
GTM_AEI_ADDR_XPT	GTM AEI Timeout exception address register	Section 26.2.9.4
GTM_IRQ_NOTIFY	GTM Interrupt notification register	Section 26.2.9.5
GTM_IRQ_EN	GTM Interrupt enable register	Section 26.2.9.6
GTM_IRQ_EIRQ_EN	GTM Error interrupt generation register	Section 26.2.9.12
GTM_IRQ_FORCINT	GTM Software interrupt generation register	Section 26.2.9.7
GTM_IRQ_MODE	GTM top level interrupts mode selection. Please note that this mode selection is only valid for the three interrupts described in Section 26.2.9.5	Section 26.2.9.8
GTM_TIMi_AUX_IN_S RC (i= 0...n)	GTM-IP TIMi module AUX_IN source selection register	Section 26.2.9.13

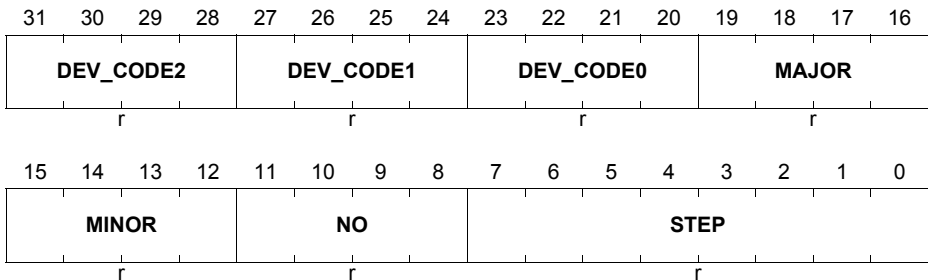

26.2.9 GTM TOP-Level Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.2.9.1 Register GTM_REV

GTM_REV

GTM Version Control Register (00000_H) **Reset Value: 122155A1_H**

Field	Bits	Type	Description
STEP	[7:0]	r	Release Step
NO	[11:8]	r	Define delivery number of GTM specification
MINOR	[15:12]	r	Define minor version number of GTM specification
MAJOR	[19:16]	r	Define major version number of GTM specification
DEV_COD E0	[23:20]	r	Device encoding digit 0
DEV_COD E1	[27:24]	r	Device encoding digit 1
DEV_COD E2	[31:28]	r	Device encoding digit 2 Note: The numbers are encoded in BCD. Values "A" - "F" are chapters.

Generic Timer Module (GTM)

26.2.9.2 Register GTM_RST

GTM_RST

GTM Global Reset Register

(00004_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RST	0	w	<p>GTM Reset</p> <p>0_B No reset action</p> <p>1_B Initiate reset action for all submodules</p> <p>Note: This bit is automatically cleared by hardware after it was written. Therefore, the register is always read as zero (0) by the software.</p> <p>Note: This bit is write protected by bit GTM_CTRL.RF_PROT.</p>
Reserved	[31:1]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

26.2.9.3 Register GTM_CTRL

GTM_CTRL

GTM Global Control Register (00008_H) Reset Value: 00000001_H

Field	Bits	Type	Description
RF_PROT	0	rw	<p>RST and FORCINT protection</p> <p>0_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled</p> <p>1_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled</p>
TO_MODE	1	rw	<p>AEI Timeout mode</p> <p>0_B Observe: If timeout_counter=0 the address and rw signal in addition with timeout flag will be stored to the GTM_AEI_ADDR_XPT register. Following timeout_counter=0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenale the storing of a next faulty access.</p> <p>1_B Abort: In addition to observe mode the pending access will be aborted by signalling an illegal module access on aei_status and sending ready. In case of a read deliver as data 0 by serving of next AEI accesses.</p>
Reserved	[3:2]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
TO_VAL	[8:4]	rw	AEI Timeout value Note: These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
Reserved	[31:9]	r	Reserved Read as zero, should be written as zero

26.2.9.4 Register GTM_AEI_ADDR_XPT
GTM_AEI_ADDR_XPT
**GTM AEI Timeout Exception Address Register
(0000C_H)**
Reset Value: 00000000_H

Field	Bits	Type	Description
TO_ADDR	[19:0]	r	AEI Timeout address Note: This bit field defines the AEI address for which the AEI timeout event occurred.
TO_W1R0	20	r	AEI Timeout Read/Write flag Note: This bit defines the AEI Read/Write flag for which the AEI timeout event occurred.
Reserved	[31:21]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.2.9.5 Register GTM_IRQ_NOTIFY

GTM_IRQ_NOTIFY

 GTM Interrupt Notification Register (00010_H)

 Reset Value: 00000000_H

Field	Bits	Type	Description
AEI_TO_XPT	0	rwh	<p>AEI Timeout exception occurred</p> <p>0_B No interrupt occurred</p> <p>1_B AEI_TO_XPT interrupt was raised by the AEI Timeout detection unit</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>
AEI_USP_ADDR	1	rwh	<p>AEI Unsupported address interrupt</p> <p>0_B No interrupt occurred</p> <p>1_B AEI_USP_ADDR interrupt was raised by the AEI interface</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>
AEI_IM_ADDR	2	rwh	<p>AEI Illegal Module address interrupt</p> <p>0_B No interrupt occurred</p> <p>1_B AEI_IM_ADDR interrupt was raised by the AEI interface</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
AEI_USP_BE	3	rwh	AEI Unsupported byte enable interrupt 0 _B No interrupt occurred 1 _B AEI_USP_BE interrupt was raised by the AEI interface Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.2.9.6 Register GTM_IRQ_EN

GTM_IRQ_EN

 GTM Interrupt Enable Register (00014_H) Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												AEI_USP_IRQ_EN	AEI_IM_DDR_IRQ_EN	AEI_USP_ADDR_DRQ_EN	AEI_TO_XPT_IRQ_EN
r												rw	rw	rw	rw

Field	Bits	Type	Description
AEI_TO_XPT_IRQ_EN	0	rw	AEI_TO_XPT_IRQ interrupt enable. 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
AEI_USP_ADDR_IRQ_EN	1	rw	AEI_USP_ADDR_IRQ interrupt enable. 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM

Generic Timer Module (GTM)

Field	Bits	Type	Description
AEI_IM_A DDR_IRQ_ EN	2	rw	AEI_IM_ADDR_IRQ interrupt enable. 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
AEI_USP_ BE_IRQ_E N	3	rw	AEI_USP_BE_IRQ interrupt enable. 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.2.9.7 Register GTM_IRQ_FORCINT
GTM_IRQ_FORCINT
**GTM Software Interrupt Generation Register
(00018_H)**
Reset Value: 00000000_H

Field	Bits	Type	Description
TRG_AEI_ TO_XPT	0	w	Trigger AEI_TO_XPT_IRQ interrupt by software. 0 _B No interrupt triggering 1 _B Assert AEI_TO_XPT_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRG_AEI_USP_ADDR	1	w	Trigger AEI_USP_ADDR_IRQ interrupt by software. 0 _B No interrupt triggering 1 _B Assert AEI_USP_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_IM_ADDR	2	w	Trigger AEI_IM_ADDR_IRQ interrupt by software. 0 _B No interrupt triggering 1 _B Assert AEI_IM_ADDR_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
TRG_AEI_USP_BE	3	w	Trigger AEI_USP_BE_IRQ interrupt by software. 0 _B No interrupt triggering 1 _B Assert AEI_USP_BE_IRQ interrupt for one clock cycle Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.2.9.8 Register GTM_IRQ_MODE

GTM_IRQ_MODE

GTM Top Level Interrupts Mode Selection

(0001C_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
IRQ_MOD E	[1:0]	rw	Interrupt strategy mode selection for the AEI timeout and address monitoring interrupts 00 _B Level mode 01 _B Pulse mode 10 _B Pulse-Notify mode 11 _B Single-Pulse mode Note: The interrupt modes are described in Section 26.2.5 .
Reserved	[31:2]	r	Reserved Read as zero, should be written as zero

26.2.9.9 Register GTM_BRIDGE_MODE

Note: The content of this register should never be changed.

GTM_BRIDGE_MODE

GTM to SPB BRIDGE MODE

(00030_H)

Reset Value: 04001001_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BUFF_DPT											Reserved				BRG _RS T

r			rw	r		rwh	r	r					rw	rw	

Field	Bits	Type	Description
BRG_MODE	0	rw	Defines the operation mode for the AEI bridge 0 _B AEI bridge operates in sync_bridge mode 1 _B AEI bridge operates in async_bridge mode
MSK_WR_RSP	1	rw	Mask write response 0 _B Do not mask the write response 1 _B Mask write response
Reserved	[7:2]	r	Reserved Read as zero, should be written as zero
MODE_UP_PGR	8	r	Mode update in progress 0 _B No update in progress. 1 _B Update in progress.
BUFF_OVERFLOW	9	rwh	Buffer overflow register 0 _B No buffer overflow occurred. 1 _B Buffer overflow occurred. Note: A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see GTM_BRIDGE_PTR1 register). This bit always read as zero.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[11:10]	r	Reserved Read as zero, should be written as zero.
SYNC_INP UT_REG	12	rw	Additional Pipeline Stage in Synchronous Bridge Mode 0 _B No additional pipeline stage implemented 1 _B Additional pipeline stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
Reserved	[15:13]	r	Reserved Read as zero, should be written as zero.
BRG_RST	16	w	Bridge software reset 0 _B No bridge reset request. 1 _B Bridge reset request. Note: This bit is cleared automatically after write. This bit always read as zero.
BUFF_DP T	[31:24]	r	Buffer depth of AEI bridge Signals the buffer depth of the GTM AEI bridge implementation.
Reserved	[23:17]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.2.9.10 Register GTM_BRIDGE_PTR1

GTM_BRIDGE_PTR1

GTM to SPB BRIDGE PTR1

 (00034_H)

 Reset Value: 00X00000_H

Field	Bits	Type	Description
NEW_TRAN_PTR	[4:0]	r	New transaction pointer Signals the actual value of the new transaction pointer.
FIRST_RSP_PTR	[9:5]	r	First response pointer Signals the actual value of first response pointer.
TRAN_IN_PGR	[14:10]	r	Transaction in progress pointer (acquire) Transaction in progress pointer.
ABT_TRAN_PGR	[19:15]	r	Aborted transaction in progress pointer Aborted transaction in progress pointer.
FBC	[25:20]	r	Free buffer count Number of free buffer entries.
RSP_TRAN_RDY	[31:26]	r	Response transactions ready Amount of ready response transactions. Note: This register operates on the AEI_CLK domain.

Generic Timer Module (GTM)

26.2.9.11 Register GTM_BRIDGE_PTR2

GTM_BRIDGE_PTR2

GTM to SPB BRIDGE PTR2

(00038_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TRAN_IN_PGR2	[4:0]	r	Transaction in progress pointer (acquire2) Transaction in progress pointer 2.
Reserved	[31:5]	r	Reserved Read as zero, should be written as zero <i>Note: This register operates on the GTM_CLK domain</i>

Generic Timer Module (GTM)

26.2.9.12 Register GTM_EIRQ_EN

GTM_EIRQ_EN

GTM Error Interrupt Enable Register(00020_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
AEI_TO_XPT_EIRQ_EN	0	rw	AEI_TO_XPT_EIRQ error interrupt enable 0 _B Disable error interrupt, interrupt is not visible outside GTM 1 _B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_ADDR_EIRQ_EN	1	rw	AEI_USP_ADDR_EIRQ error interrupt enable 0 _B Disable error interrupt, interrupt is not visible outside GTM 1 _B Enable error interrupt, interrupt is visible outside GTM
AEI_IM_A_DDR_EIRQ_EN	2	rw	AEI_IM_A_DDR_EIRQ error interrupt enable 0 _B Disable error interrupt, interrupt is not visible outside GTM 1 _B Enable error interrupt, interrupt is visible outside GTM
AEI_USP_BE_EIRQ_EN	3	rw	AEI_USP_BE_EIRQ error interrupt enable 0 _B Disable error interrupt, interrupt is not visible outside GTM 1 _B Enable error interrupt, interrupt is visible outside GTM

Generic Timer Module (GTM)

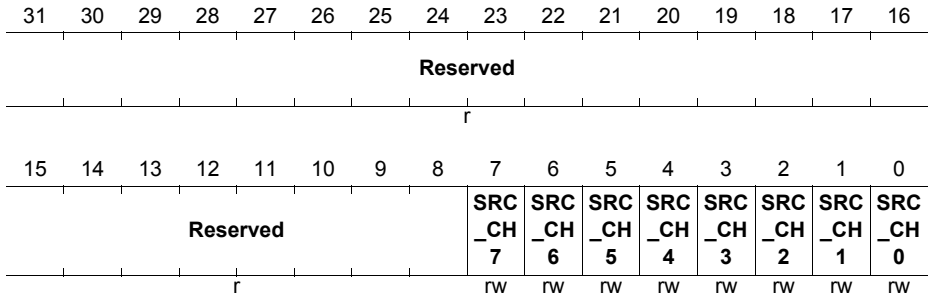

Field	Bits	Type	Description
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.2.9.13 Register GTM_TIMi_AUX_IN_SRC (i= 0...n)

GTM_TIMi_AUX_IN_SRC (i=0-2)

GTM TIMi AUX_IN_SRC (00040_H+i*04_H) Reset Value: 00000000_H

Field	Bits	Type	Description
SRC_CH0	0	rw	Defines AUX_IN source of TIMi channel 0 x=0 0 _B TOM Output selected TOM[a] channel [b] with a= (i* 8 +x) div 16; b=(i* 8 +x) mod 16; 1 _B ATOM Output selected ATOMi channel x
SRC_CH1	1	rw	Defines AUX_IN source of TIMi channel 1 x=1, see bit 0
SRC_CH2	2	rw	Defines AUX_IN source of TIMi channel 2 x=2, see bit 0
SRC_CH3	3	rw	Defines AUX_IN source of TIMi channel 3 x=3, see bit 0
SRC_CH4	4	rw	Defines AUX_IN source of TIMi channel 4 x=4, see bit 0
SRC_CH5	5	rw	Defines AUX_IN source of TIMi channel 5 x=5, see bit 0
SRC_CH6	6	rw	Defines AUX_IN source of TIMi channel 6 x=6, see bit 0
SRC_CH7	7	rw	Defines AUX_IN source of TIMi channel 7 x=7, see bit 0
Reserved	[31:8]	r	Reserved Read as zero, should be written as zero

26.3 Advanced Routing Unit (ARU)

26.3.1 Overview

The Advanced Routing Unit (ARU) is a flexible infrastructure component for transferring 53 bit wide data (five control bits and two 24 bit values) between several submodules of the GTM core in a configurable manner.

Since the concept of the ARU has already been described in [Section 26.2.3](#), this section only describes additional ARU features that can be used by the software for configuring and debugging ARU related data streams.

Also the definition of 'streams' and 'channels' in the ARU context is done in [Section 26.2.3](#).

26.3.2 Special Data Sources

Besides the addresses of the submodule related data sources as described in [Table 26.21.1](#), the ARU provides two special data sources that can be used for the configuration of data streams. These data sources are defined as follows:

Address 0x1FF: Data source that provides always a 53 bit data word with zeros. A read access to this memory location will never block a requesting data destination.

Address 0x1FE: Data source that never provides a data word. A read access to this memory location will always block a requesting data destination. This is the reset value of the read registers inside the data destinations.

Address 0x000: This address is reserved and can be used to bring data through the ARU registers ARU_DATA_H and ARU_DATA_L into the system by writing the write address 0x000 into the ARU_ACCESS register. This means that software test data can be brought into the GTM by the CPU.

26.3.3 ARU Access via AEI

Besides the data transfer between the connected submodules, there are two possibilities to access ARU data via the AEI.

26.3.3.1 Default ARU Access

The default ARU access incorporates the registers ARU_ACCESS, which is used for initiation of a read or write request and the registers ARU_DATA_H and ARU_DATA_L that provide the ARU data word to be transferred.

The status of a read or write transfer can be determined by polling specific bits in register ARU_ACCESS. Furthermore the acc_ack bit in the interrupt notify register is set after the read or write access is performed to avoid data loss e.g. on access cancellation.

Generic Timer Module (GTM)

A pending read or write request may also be cancelled by clearing the associated bit.

In the case of a read request, the AEI access behaves as a read request initiated by a data destination of a module. The read request is served by the ARU immediately when no other destination has a pending read request. This means, that an AEI read access does not take part in the scheduling of the destination channels and that the time between two consecutive read accesses is not limited by the round trip time.

On the other hand, the AEI access has the lowest priority behind the ARU scheduler that serves the destination channels. Thus, in worst case, the read request is served after one round trip of the ARU, when all destination channels would request data at the same point in time.

In the case of the write request, the ARU provides the write data at the address defined by the ADDR bit field inside the ARU_ACCESS register.

To avoid data loss, the reserved ARU address 0x0 has to be used to bring data into the system. Otherwise, in case the address specified inside the ADDR bit field is defined for another submodule that acts as a source at the ARU data loss may occur and no deterministic behaviour is guaranteed.

This is because the regular source submodule is not aware that its address is used by the ARU itself to provide data to a destination.

It is guaranteed that the ARU write data is send to the destination in case of both modules want to provide data at the same time.

Configuring both read and write request bits results in a read request, if the write request bit inside the register isn't already set. The following table describes the important cases of the bit 12 (RREQ) and bit 13 (WREQ) of the ARU_ACCESS register:

Table 26-8 ARU_ACCESS behaviour

AEI write access: aei_wdata(13:12)	actual value of ARU_ACCESS [13:12]	next value of ARU_ACCESS [13:12]	comment
00 _B	01 _B	00 _B	cancel read request
00 _B	10 _B	00 _B	cancel write request
01 _B	10 _B	10 _B	unchanged register
10 _B	01 _B	01 _B	unchanged register
11 _B	00 _B	01 _B	both read and write request results in a read request
11 _B	10 _B	10 _B	as before but WREQ bit is already set -> unchanged register

26.3.3.2 Debug Access

The debug access mode enables to inspect routed data of configured data streams during runtime.

The ARU provides two independent debug channels, whereas each is configured by a dedicated ARU read address in register ARU_DBG_ACCESS0 and ARU_DBG_ACCESS1 respectively.

The registers ARU_DBG_DATA0_H and ARU_DBG_DATA0_L (ARU_DBG_DATA1_H and ARU_DBG_DATA1_L) provide read access to the latest data word that the corresponding data source sent through the ARU.

Any time when data is transferred through the ARU from a data source to the destination requesting the data the interrupt signal ARU_NEW_DATA0_IRQ (ARU_NEW_DATA1_IRQ) is raised.

For advanced debugging purposes, the interrupt signal can also be triggered by software using the register ARU_IRQ_FORCINT.

Please note, that the debug mechanism should not be used by the application, when a HW-Debugger is used to trace the ARU communication. In that case, the debug registers are used by the HW-Debugger to specify the ARU streams that should be traced.

26.3.4 ARU Interrupt Signals

The following table describes ARU interrupt signals:

Table 26-9 ARU interrupt signals

Signal	Description
ARU_NEW_DATA0_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS0.
ARU_NEW_DATA1_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS1.
ACC_ACK_IRQ	ARU access acknowledge IRQ.

26.3.5 ARU Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 26-10 ARU Configuration Registers Overview

Register name	Description	Details in Section
ARU_ACCESS	ARU access register	Section 26.3.6.1
ARU_DATA_H	ARU access register upper data word	Section 26.3.6.2

Generic Timer Module (GTM)

Table 26-10 ARU Configuration Registers Overview (cont'd)

Register name	Description	Details in Section
ARU_DATA_L	ARU access register lower data word	Section 26.3.6.3
ARU_DBG_ACCESS0	Debug access channel 0	Section 26.3.6.4
ARU_DBG_DATA0_H	Debug access 0 transfer register upper data word	Section 26.3.6.5

26.3.6 ARU Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.3.6.1 Register ARU_ACCESS

GTM_ARU_ACCESS

ARU Access Register (00280_H) **Reset Value: 000001FE_H**

Generic Timer Module (GTM)

Field	Bits	Type	Description
ADDR	[8:0]	rw	ARU address Define the ARU address used for transferring data Note: For an ARU write request, the preferred address 0x0 have to be used. Note: A write request to the address 0x1FF (always full address) or 0x1FE (always empty address) are ignored and doesn't have any effect. Note: ARU address bits ADDR are only writable if RREQ and WREQ bits are zero
Reserved	[11:9]	r	Reserved Read as zero, should be written as zero
RREQ	12	rwh	Initiate read request 0 _B No read request is pending 1 _B Set read request to source channel addressed by ADDR Note: This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a read request. Note: RREQ bit is only writable if WREQ bit is zero, so to switch from RREQ to WREQ a cancel request has to be performed before. Note: Configuring both RREQ and WREQ bits results in a read request, so RREQ bit will be set if the WREQ bit of the register isn't already set. Note: The ARU read request on address ADDR is served immediately when no other destination has actually a read request when the RREQ bit is set by CPU. In a worst case scenario, the read request is served after one round trip of the ARU, but this is only the case when every destination channel issues a read request at consecutive points in time.

Generic Timer Module (GTM)

Field	Bits	Type	Description
WREQ	13	rwh	<p>Initiate write request</p> <p>0_B No write request is pending 1_B Mark data in registers ARU_DATA_H and ARU_DATA_L as valid</p> <p>Note: This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a write request.</p> <p>Note: WREQ bit is only writable if RREQ bit is zero, so to switch from WREQ to RREQ a cancel request has to be performed before.</p> <p>Note: Configuring both WREQ and RREQ bits result in a read request, so WREQ bit will not be set.</p> <p>Note: The data is provided at address ADDR. This address has to be programmed as the source address in the destination submodule channel. In worst case, the data is provided after one full ARU round trip.</p> <p>Note: It is strongly recommended that an address ADDR is used that is not reserved for another source submodule inside the GTM, for example the reserved address 0x000. Otherwise, data from another source submodule, that provides his data at the specified address ADDR may be lost. This can be avoided when the reserved ARU write address 0x0 is specified inside the ADDR bit field.</p>
Reserved	[31:14]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p> <p>Note: The register ARU_ACCESS can be used either for reading or for writing at the same point in time.</p>

26.3.6.2 Register ARU_DATA_H

GTM_ARU_DATA_H

ARU Access Register Upper Data Word

(00284_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	rw	Upper ARU data word Note: Transfer upper ARU data word addressed by ADDR. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero

26.3.6.3 Register ARU_DATA_L

GTM_ARU_DATA_L

ARU Access Register Lower Data Word

(00288_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	rw	<p>Lower ARU data word</p> <p>Note: Transfer lower ARU data word addressed by ADDR. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word are mapped to the data bits 24 to 28 of this register when data is read by the CPU.</p> <p>Note: For writing data into the ARU by the CPU the bits 24 to 28 are not transferred to bit 48 to 52 of the ARU word. Only bits 0 to 23 are written to bits 0 to 23 of the ARU word</p>
Reserved	[31:29]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

26.3.6.4 Register ARU_DBG_ACCESS0

GTM_ARU_DBG_ACCESS0

Debug Access Channel 0

 (0028C_H)

 Reset Value: 000001FE_H

Field	Bits	Type	Description
ADDR	[8:0]	rw	ARU debugging address Note: Define address of ARU debugging channel 0.
Reserved	[31:9]	r	Reserved Read as zero, should be written as zero

26.3.6.5 Register ARU_DBG_DATA0_H

GTM_ARU_DBG_DATA0_H

Debug Access 0 Transfer Register Upper Data Word

 (00290_H)

 Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	r	Upper debug data word Note: Transfer upper ARU data word addressed by register DBG_ACCESS0. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register Note: The interrupt ARU_NEW_DATA0_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.3.6.6 Register ARU_DBG_DATA0_L

GTM_ARU_DBG_DATA0_L

Debug Access 0 Transfer Register Lower Data Word
(00294_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	r	Lower debug data word Note: Transfer lower ARU data word addressed by register DBG_ACCESS0. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register. Note: The interrupt ARU_NEW_DATA0_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero

26.3.6.7 Register ARU_DBG_ACCESS1

GTM_ARU_DBG_ACCESS1

Debug Access Channel 0 (00298_H)

Reset Value: 000001FE_H

Field	Bits	Type	Description
ADDR	[8:0]	rw	ARU debugging address Note: Define address of ARU debugging channel 1.
Reserved	[31:9]	r	Reserved Read as zero, should be written as zero

26.3.6.8 Register ARU_DBG_DATA1_H

GTM_ARU_DBG_DATA1_H

Debug Access 1 Transfer Register Upper Data Word

(0029C_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	r	Upper debug data word Note: Transfer upper ARU data word addressed by register DBG_ACCESS1. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register Note: The interrupt ARU_NEW_DATA1_IRQ is raised if a new data word is available.
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero

26.3.6.9 Register ARU_DBG_DATA1_L

GTM_ARU_DBG_DATA1_L

Debug Access 1 Transfer Register Lower Data Word

(002A0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	r	<p>Lower debug data word</p> <p>Note: Transfer lower ARU data word addressed by register DBG_ACCESS1. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word is mapped to the data bits 24 to 28 of this register.</p> <p>Note: The interrupt ARU_NEW_DATA1_IRQ is raised if a new data word is available.</p>
Reserved	[31:29]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

26.3.6.10 Register ARU_IRQ_NOTIFY

GTM_ARU_IRQ_NOTIFY

ARU Interrupt Notification Register (002A4_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
NEW_DAT A0	0	rwh	<p>Data was transferred for addr ARU_DBG_ACCESS0</p> <p>0_B No interrupt occurred 1_B ARU_NEW_DATA0_IRQ interrupt was raised by the ARU</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>
NEW_DAT A1	1	rwh	<p>Data was transferred for addr ARU_DBG_ACCESS1</p> <p>0_B No interrupt occurred 1_B ARU_NEW_DATA1_IRQ interrupt was raised by the ARU</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>
ACC_ACK	2	rwh	<p>AEI to ARU access finished, on read access data are valid</p> <p>Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.</p>
Reserved	[31:3]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

26.3.6.11 Register ARU_IRQ_EN

GTM_ARU_IRQ_EN

ARU Interrupt Enable Register (002A8_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
NEW_DATA0_IRQ_EN	0	rw	ARU_NEW_DATA0_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
NEW_DATA1_IRQ_EN	1	rw	ARU_NEW_DATA1_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
ACC_ACK_IRQ_EN	2	rw	ACC_ACK_IRQ interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM 1 _B Enable interrupt, interrupt is visible outside GTM
Reserved	[31:3]	r	Reserved Read as zero, should be written as zero

26.3.6.12 Register ARU_IRQ_FORCINT

GTM_ARU_IRQ_FORCINT

ARU_NEW_DATA_IRQ Forcing Interrupt Register (002AC_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TRG_NEW_DATA0	0	w	<p>Trigger new data 0 interrupt</p> <p>0_B corresponding bit in status register will not be forced</p> <p>1_B Assert corresponding field in ARU_IRQ_NOTIFY register</p> <p>Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.</p>
TRG_NEW_DATA1	1	w	<p>1 Trigger new data 1 interrupt</p> <p>0_B corresponding bit in status register will not be forced</p> <p>1_B Assert corresponding field in ARU_IRQ_NOTIFY register</p> <p>Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.</p>

Generic Timer Module (GTM)

Field	Bits	Type	Description
TRG_ACC_ACK	2	w	<p>Trigger ACC_ACK interrupt</p> <p>0_B corresponding bit in status register will not be forced</p> <p>1_B Assert corresponding field in ARU_IRQ_NOTIFY register</p> <p>Note: This bit is cleared automatically after write. Note: This bit is write protected by bit GTM_CTRL.RF_PROT.</p>
Reserved	[31:3]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

26.3.6.13 Register ARU_IRQ_MODE

GTM_ARU_IRQ_MODE

IRQ Mode Configuration Register (002B0_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	IRQ mode selection 00 _B Level mode 01 _B Pulse mode 10 _B Pulse-Notify mode 11 _B Single-Pulse mode Note: The interrupt modes are described in Section 26.2.5 .
Reserved	[31:2]	r	Reserved Read as zero, should be written as zero

26.4 Broadcast Module (BRC)

26.4.1 Overview

Since each write address for the submodule channels of the GTM that are able to write to the ARU can only be read by a single module, it is impossible to provide a data stream to different modules in parallel (This statement holds not for sources, which do not invalidate their data after the data were read by any consumer, e.g. DPLL).

To overcome this issue for regular modules, the submodule Broadcast (BRC) enables to duplicate data streams multiple times.

The BRC submodule provides 12 input channels as well as 22 output channels.

In order to clone an incoming data stream, the corresponding input channel can be mapped to zero or more output channels.

When mapped to zero no channel is read.

To destroy an incoming data stream, the EN_TRASHBIN bit inside the BRC_SRCx_DEST register has to be set.

The total number of output channels that are assigned to a single input channel is variable. However, the total number of assigned output channels must be less than or equal to 22.

26.4.2 BRC Configuration

As it is the case with all other submodules connected to the ARU, the input channels can read arbitrary ARU address locations and the output channels provide the broadcast data to fixed ARU write address locations.

The associated write addresses for the BRC submodule are fixed and can be obtained from [Section 26.21](#).

The read address for each input channel is defined by the corresponding register BRC_SRCx_ADDR (x: 0...1).

The mapping of an input channel to several output channels is defined by setting the appropriate bits in the register BRC_SRCx_DEST (x: 0...11). Each output channel is represented by a single bit in the register BRC_SRCx_DEST. The address of the output channel is defined in [Section 26.21](#).

If no output channel bit is set within a register BRC_SRCx_DEST, no data is provided to the corresponding ARU write address location from the defined read input specified by BRC_SRCx_ADDR. This means that the channel does not broadcast any data and is disabled (reset state).

Besides the possibility of mapping an input channel to several output channels, the bit EN_TRASHBIN of register BRC_SRCx_DEST may be set, which results in dropping an

Generic Timer Module (GTM)

incoming data stream. In this case the data of an input channel defined by `BRC_SRCx_ADDR` is consumed by the BRC module and not routed to any succeeding submodule. In consequence, the output channels defined in the register `BRC_SRCx_DEST` are ignored. Therefore, the bits 0 to 21 are set to zero (0) when trash bin functionality is enabled.

In general, the BRC submodule can work in two independent operation modes. In the first operation mode the data consistency is guaranteed since a BRC channel requests only new data from a source when all destination channels for the BRC have consumed the old data value. This mode is called Data Consistency Mode (DCM).

In a second operation mode the BRC channel always requests data from a source and distributes this data to the destination regardless whether all destinations have already consumed the old data. This mode is called Maximum Throughput Mode (MTM).

MTM ensures, that always the newest available data is routed through the system, while it is not guaranteed data consistency since some of the destination channels can be provided with the old data while some other destination channels are provided with the new data. If this is the case, the Data Inconsistency Detected Interrupt `BRC_DID_IRQ[x]` is raised but the channel continues to work.

Furthermore in MTM mode it is guaranteed that it is not possible to read a data twice by a read channel. This is blocked.

The channel mode can be configured inside the `BRC_SRCx_ADDR` register.

To avoid invalid configurations of the registers `BRC_SRCx_DEST`, the BRC also implements a plausibility check for these configurations. If the software assigns an already used output channel to a second input channel, BRC performs an auto correction of the lastly configured register `BRC_SRCx_DEST` and it triggers the interrupt `BRC_DEST_ERR`.

Consider the following example for clarification of the auto correction mechanism. Assume that the following configuration of the 22 lower significant bits for the registers `BRC_SRCx_DEST`:

`BRC_SRC_0_DEST`: 00 0000 0000 1000 1000 0000 (binary)

`BRC_SRC_1_DEST`: 00 0000 0000 0100 0000 0100 (binary)

`BRC_SRC_2_DEST`: 00 0000 0000 0001 0100 0010 (binary)

`BRC_SRC_3_DEST`: 00 0000 0000 0010 0001 1001 (binary)

If the software overwrites the value for register `BRC_SRC_2_DEST` with

`BRC_SRC_2_DEST`: 00 0000 0000 1001 0010 0010 (binary)

(changed bits are underlined), then the BRC releases a `BRC_DEST_ERR` interrupt since bit 11 is already assigned in register `BRC_SRC_0_DEST`. The auto correction forces bit 11 to be cleared. The modifications of the bits 5 and 6 are accepted, since there is no violation with previous configurations. So the result of the write access mentioned above results in the following modified register configuration:

Generic Timer Module (GTM)

BRC_SRC_2_DEST: 00 0000 0000 0001 0010 0010 (binary)

For debug purposes, the interrupt BRC_DEST_ERR can also be released by writing to register BRC_IRQ_FORCINT. Nevertheless, the interrupt has to be enabled to be visible outside of the GTM.

26.4.3 BRC Interrupt Signals

Interrupt signals are defined in following table:

Table 26-11 BRC Interrupts

Signal	Description
BRC_DEST_ERR_IRQ	Indicating configuration errors for BRC module
BRC_DID_IRQ[x]	Data inconsistency occurred in MTM mode (x=0-11)

26.4.4 BRC Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 26-12 BRC Registers

Register Name	Description	Details in Section
BRC_SRCx_ADDR	Read address for input channel x (x=0-11)	Section 26.4.5.1
BRC_SRCx_DEST	Destination channels for input channel x (x=0-11)	Section 26.4.5.2
BRC_IRQ_NOTIFY	BRC Interrupt notification register	Section 26.4.5.3
BRC_IRQ_EN	BRC Interrupt enable register	Section 26.4.5.4
BRC_IRQ_EIRQ_EN	BRC Error interrupt enable register	Section 26.4.5.8
BRC_IRQ_FORCINT	Register for forcing the BRC_DEST_ERR interrupt	Section 26.4.5.5
BRC_RST	Software reset	Section 26.4.5.7
BRC_IRQ_MODE	IRQ mode configuration register	Section 26.4.5.6

26.4.5 BRC Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.4.5.1 Register BRC_SRCx_ADDR (x=0-11)

GTM_BRC_SRCx_ADDR (x=0-11)

Read Address For Input Channel x

(00400_H+x*08_H)

Reset Value: 000001FE_H

Field	Bits	Type	Description
ADDR	[8:0]	rw	Source ARU address Define an ARU read address used as data source for input channel x (x011)
Reserved	[11:9]	r	Reserved Read as zero, should be written as zero
BRC_MODE	12	rw	BRC Operation mode select 0 _B Consistency Mode (DCM) selected 1 _B Maximum Throughput Mode (MTM) selected Note: this bit field is only writable if channel is disabled.
Reserved	[31:13]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.4.5.2 Register BRC_SRCx_DEST (x:0...11)

GTM_BRC_SRCx_DEST (x=0-11)

Destination Channels For Input Channel x

 $(00404_H + x \cdot 08_H)$

 Reset Value: 00000000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

26.5 First In First Out Module (FIFO)

26.5.1 Overview

The FIFO unit is the storage part of the FIFO submodule. The F2A described in [Section 26.7](#) and the AFD described in [Section 26.6](#) implement the interface part of the FIFO submodule to the ARU and the AEI bus. Each FIFO unit embeds eight logical FIFOs. These logical FIFOs are configurable in the following manner:

- FIFO size (defines start and end address)
- FIFO operation modes (normal mode or ring buffer operation mode)
- Fill level control / memory region read protection

Each logical FIFO represents a data stream between the submodules of the GTM and the microcontroller connected to AFD submodule (see [Section 26.6](#)). The FIFO RAM counts 1K words, where the word size is 29 bit. This gives the freedom to program or receive 24 bit of data together with the five control bits inside an ARU data word.

The FIFO unit provides three ports for accessing its content. One port is connected to the F2A interface, one port is connected to the AFD interface and one port has its own AEI bus interface.

The AFD interface has always the highest priority. Accesses to the FIFO from AFD interface and direct AEI interface in parallel - which means at the same time - is not possible, because both interfaces are driven from the same AEI bus interface of the GTM.

The priority between F2A and direct AEI interface can be defined by software. This can be done by using the register FIFO0_CHx_CTRL for all FIFO channels of the submodule.

The FIFO is organized as a single RAM that is also accessible through the FIFO AEI interface connected to one of the FIFO ports. To provide the direct RAM access, the RAM is mapped into the address space of the microcontroller.

After reset, the FIFO RAM isn't initialized.

The FIFO channels can be flushed individually. Each of the eight FIFO channels can be used whether in normal FIFO operation mode or in ring buffer operation mode.

Beside the possibility of flushing each FIFO channel directly, a write access to FIFOi_CHx_END_ADDR or to FIFOi_CHx_START_ADDR will also flush the regarding channel which means that the read and write pointer and also the fill level of the regarding channel will be reset. In consequence of this existing data in the concerned FIFO channel are not longer valid- thereafter the channel is empty.

26.5.2 Operation Modes

26.5.2.1 Normal Operation Mode

In normal FIFO operation mode the content of the FIFO is written and read in first-in first-out order, where the data is destroyed after it is delivered to the system bus or the F2A submodule (see [Section 26.7](#)).

The upper and lower watermark registers (registers FIFO0_CHx_UPPER_WM and FIFO0_CHx_LOWER_WM) are used for controlling the FIFO's fill level. If the fill level declines the lower watermark or it exceeds the upper watermark, an interrupt signal is triggered by the FIFO submodule if enabled inside the FIFO0_IRQ_EN.

The interrupt signals are sending to the Interrupt Concentrator Module (ICM) (see [Section 26.18](#)). The ICM can also initiate specific DMA transfers.

26.5.2.2 Ring Buffer Operation Mode

The ring buffer mode is a powerful tool to provide a continuous data or configuration stream to the other GTM submodules without CPU interaction. In ring buffer mode the FIFO provides a continuous data stream to the F2A submodule. The first word of the FIFO is delivered first and after the last word is provided by the FIFO to the ARU, the first word can be obtained again.

If in ring buffer mode the read pointer reaches the write pointer it will be set again to the configured start address. So the read pointer always rotates cyclic between the configured start address of the regarding FIFO channel (first written data) and the write pointer which points to the last written data of the channel.

It is possible to add data via the AEI to FIFO interface (AFD) to the FIFO channel while running in ring buffer mode. The new written data will be added in the next ring buffer cycle.

It is recommended to fill the FIFO channel first before enabled the data stream in the FIFO to ARU interface (F2A).

There could be the requirement that the user must be able to change some data inside the continuous data stream to the GTM submodules or system bus. This is possible through direct memory access provided by the FIFO AEI interface.

26.5.3 FIFO Interrupt Signals

Interrupt signals are defined in following table:

Table 26-13 FIFO Interrupt Signals

Signal	Description
FIFOi_CH[x]_EMPTY	Indicating empty FIFOi x (x:0...7) was reached
FIFOi_CH[x]_FULL	Indicating full FIFOi x (x:0...7) was reached
FIFOi_CHx_LOWER_WM	Indicating FIFOi x (x:0...7) reached lower watermark.
FIFOi_CHx_UPPER_WM	Indicating FIFOi x (x:0...7) reached upper watermark.

26.5.4 FIFOi Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values:

Table 26-14 FIFOi Configuration Registers Overview

Register Name	Description	Details in Section
FIFOi_CHx_CTRL	FIFOi Channel x control register (x: 0...7)	Section 26.5.5.1
FIFOi_CHx_END_ADDR	FIFOi Channel x end address register (x: 0...7)	Section 26.5.5.2
FIFOi_CHx_START_ADDR	FIFOi Channel x start address register (x: 0...7)	Section 26.5.5.3
FIFOi_CHx_UPPER_WM	FIFOi Channel x upper watermark register (x: 0...7)	Section 26.5.5.4
FIFOi_CHx_LOWER_WM	FIFOi Channel x lower watermark register (x: 0...7)	Section 26.5.5.5
FIFOi_CHx_STATUS	FIFOi Channel x status register (x: 0...7)	Section 26.5.5.6
FIFOi_CHx_FILL_LEVEL	FIFOi Channel x fill level register (x: 0...7)	Section 26.5.5.7
FIFOi_CHx_WR_PTR	FIFOi Channel x write pointer register (x: 0...7)	Section 26.5.5.8
FIFOi_CHx_RD_PTR	FIFOi Channel x read pointer register (x: 0...7)	Section 26.5.5.9
FIFOi_CHx_IRQ_NOTIFY	FIFOi x interrupt notification register (x: 0...7)	Section 26.5.5.10

Generic Timer Module (GTM)

Table 26-14 FIFOi Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section
FIFOi_CHx_IRQ_EN	FIFOi x interrupt enable register (x: 0...7)	Section 26.5.5.11
FIFOi_CHx_EIRQ_EN	FIFO x Error interrupt enable register	Section 26.5.5.14
FIFOi_CHx_IRQ_FORCINT	FIFOi x register to force interrupt by software (x: 0...7)	Section 26.5.5.12
FIFOi_CHx_IRQ_MODE	FIFOi x IRQ mode control register (x: 0...7)	Section 26.5.5.13

26.5.5 FIFOi Configuration Registers Description

All of the following registers are 32-bit only accessible.

26.5.5.1 Register FIFOi_CHx_CTRL (x:0...7)

GTM_FIFO0_CHx_CTRL (x=0-7)

FIFO0 Channel x Control Register(18400_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
RBM	0	rw	Ring buffer mode enable 0 _B Normal FIFO operation mode 1 _B Ring buffer mode
RAP	1	rw	RAM access priority 0 _B FIFO ports have higher access priority than AEI-IF 1 _B AEI-IF has higher access priority than FIFO ports Note: RAP bit is only functional in register FIFOi_CHx_CTRL. The priority is defined for all FIFO channels there
FLUSH	2	w	FIFO Flush control 0 _B Normal operation 1 _B Execute FIFO flush (bit is automatically cleared after flush). Note: A FIFO Flush operation resets the FIFOi_CHx_FILL_LEVEL, FIFOi_CHx_WR_PTR and FIFOi_CHx_RD_PTR registers to their initial values.

Generic Timer Module (GTM)

Field	Bits	Type	Description
WULOCK	3	rw	RAM write unlock Enable/disable direct RAM write access to the memory mapped FIFO region 0_B Direct RAM write access disabled 1_B Direct RAM write access enabled Note: Only the bit WULOCK of register FIFOi_CH0_CTRL enables/disables the direct RAM write access for all FIFO channels (whole FIFO RAM). The WULOCK bits of the other channels are writable but have no effect.
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.5.5.2 Register FIFOi_CHx_END_ADDR (x:0...7)

GTM_FIFO0_CHx_END_ADDR (x=0-7)

FIFO0 Channel x End Address Register

$$(18404_H + x * 40_H)$$

Reset Value: 00000XXX_H

Field	Bits	Type	Description
ADDR	[9:0]	rw	End address for FIFOi channel x, (x:0...7) Note: Note: value for ADDR is calculated as $ADDR = 128 * (x + 1) - 1$. Note: A write access will flush the regarding channel.
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.5.5.3 Register FIFOi_CHx_START_ADDR (x:0...7)

GTM_FIFO0_CHx_START_ADDR (x=0-7)

FIFO0 Channel x Start Address Register

(18408_H+x*40_H)

Reset Value: 00000XXX_H

Field	Bits	Type	Description
ADDR	[9:0]	rw	Start address for FIFOi channel x, (x07) <i>Note: Note: Initial value for ADDR is calculated as ADDR = 128*x</i> <i>Note: A write access will flush the regarding channel.</i>
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

26.5.5.4 Register FIFOi_CHx_UPPER_WM (x:0...7)

GTM_FIFO0_CHx_UPPER_WM (x=0-7)

FIFO0 Channel x Upper Watermark Register

(1840C_H+x*40_H)

Reset Value: 00000060_H

Field	Bits	Type	Description
ADDR	[9:0]	rw	Upper watermark address Note: The upper watermark is configured as a relative fill level of the FIFOi. ADDR must be in range: 0 <= ADDR <= FIFOi_CHx_END_ADDR - FIFOi_CHx_START_ADDR. Initial value for ADDR is defined as ADDR = 0x60.

Generic Timer Module (GTM)

Field	Bits	Type	Description
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

26.5.5.5 Register FIFOi_CHx_LOWER_WM (x:0...7)

GTM_FIFO0_CHx_LOWER_WM (x=0-7)

FIFO0 Channel x Lower Watermark Register

(18410_H+x*40_H)

Reset Value: 00000020_H

Field	Bits	Type	Description
ADDR	[9:0]	rw	Lower watermark address Note: The lower watermark is configured as a relative fill level of the FIFOi. ADDR must be in range: 0 <= ADDR <= FIFOi_CHx_END_ADDR - FIFOi_CHx_START_ADDR. Initial value for ADDR is defined as ADDR = 0x20.
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)
26.5.5.6 Register FIFOi_CHx_STATUS (x:0...7)
GTM_FIFO0_CHx_STATUS (x=0-7)
FIFO0 Channel x Status Register (18414_H+x*40_H)
Reset Value: 00000005_H

Field	Bits	Type	Description
EMPTY	0	r	FIFO is empty 0 _B Fill level > 0 1 _B Fill level = 0 Note: Bit only applicable in normal mode
FULL	1	r	FIFO is full 0 _B Fill level < FIFOi_CHx_END_ADDR – FIFOi_CHx_START_ADDR + 1 1 _B Fill level = FIFOi_CHx_END_ADDR – FIFOi_CHx_START_ADDR + 1 Note: Bit only applicable in normal mode
LOW_WM	2	r	Lower watermark reached 0 _B Fill level > lower watermark 1 _B Fill level <= lower watermark Note: Bit only applicable in normal mode
UP_WM	3	r	Upper watermark reached 0 _B Fill level < upper watermark 1 _B Fill level >= upper watermark Note: Bit only applicable in normal mode
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.5.5.7 Register FIFOi_CHx_FILL_LEVEL (x:0...7)

GTM_FIFO0_CHx_FILL_LEVEL (x=0-7)

FIFO0 Channel x Fill Level Register

(18418_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
LEVEL	[10:0]	r	Fill level of the current FIFO Note: LEVEL is in range: $0 \leq \text{LEVEL} \leq \text{FIFOi_CHx_END_ADDR} - \text{FIFOi_CHx_START_ADDR} + 1$. Register content is compared to the upper and lower watermark values for this channel to detect watermark over- and underflow.
Reserved	[31:11]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.5.5.8 Register FIFOi_CHx_WR_PTR (x:0...7)

GTM_FIFO0_CHx_WR_PTR (x=0-7)

FIFO0 Channel x Write Pointer Register

(1841C_H+x*40_H)

Reset Value: 00000XXX_H

Field	Bits	Type	Description
ADDR	[9:0]	r	Position of the write pointer Note: ADDR must be in range $0 \leq \text{ADDR} \leq 1023$. Initial value for ADDR is defined as ADDR = FIFOi_CHx_START_ADDR
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

26.5.5.9 Register FIFOi_CHx_RD_PTR (x:0...7)

GTM_FIFO0_CHx_RD_PTR (x=0-7)

FIFO0 Channel x Read Pointer Register

(18420_H+x*40_H)

Reset Value: 00000XXX_H

Field	Bits	Type	Description
ADDR	[9:0]	r	Position of the read pointer Note: ADDR must be in range $0 \leq \text{ADDR} \leq 1023$. Initial value for ADDR is defined as ADDR = FIFOi_CHx_START_ADDR
Reserved	[31:10]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)
26.5.5.10 Register FIFO_i_CH_x_IRQ_NOTIFY (x:0...7)
GTM_FIFO0_CH_x_IRQ_NOTIFY (x=0-7)
FIFO0 Channel x Interrupt Notification Register
(18424_H+x*40_H)
Reset Value: 00000005_H

Field	Bits	Type	Description
FIFO_EMPTY	0	rwh	FIFO is empty 0 _B No interrupt occurred. 1 _B FIFO is empty interrupt occurred. Note: This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
FIFO_FULL	1	rwh	FIFO is full See bit 0
FIFO_LWM	2	rwh	FIFO Lower watermark was under-run See bit 0
FIFO_UWM	3	rwh	FIFO Upper watermark was over-run See bit 0
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.5.5.11 Register FIFO_i_CH_x_IRQ_EN (x:0...7)

GTM_FIFO0_CH_x_IRQ_EN (x=0-7)

FIFO0 Channel x Interrupt Enable Register

(18428_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
FIFO_EMPTY_IRQ_EN	0	rw	interrupt enable 0 _B Disable interrupt, interrupt is not visible outside GTM. 1 _B Enable interrupt, interrupt is visible outside GTM.
FIFO_FULL_IRQ_EN	1	rw	interrupt enable See bit 0
FIFO_LWM_IRQ_EN	2	rw	interrupt enable See bit 0
FIFO_UWM_IRQ_EN	3	rw	interrupt enable See bit 0
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.5.5.12 Register FIFOi_CHx_IRQ_FORCINT

GTM_FIFO0_CHx_IRQ_FORCINT (x=0-7)

FIFO0 Channel x Force Interrupt By Software Register

(1842C_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
TRG_FIFO_EMPTY	0	w	Force interrupt of FIFO empty status 0 _B corresponding bit in status register will not be forced 1 _B Assert corresponding field in FIFOi_CHi_IRQ_NOTIFY register Note: This bit is cleared automatically after write.
TRG_FIFO_FULL	1	w	Force interrupt of FIFO full status See bit 0
TRG_FIFO_LWM	2	w	Force interrupt of lower watermark See bit 0
TRG_FIFO_UWM	3	w	Force interrupt of upper watermark See bit 0
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.5.5.13 Register FIFO_i_CH_x_IRQ_MODE

GTM_FIFO0_CH_x_IRQ_MODE (x=0-7)

FIFO0 Channel x IRQ Mode Control Register

(18430_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
IRQ_MODE	[1:0]	rw	IRQ mode selection 00 _B Level mode 01 _B Pulse mode 10 _B Pulse-Notify mode 11 _B Single-Pulse mode Note: The interrupt modes are described in Section 26.2.5 .
DMA_HYSTERESIS	2	rw	Enable DMA hysteresis mode 0 _B Disable FIFO hysteresis for DMA access. 1 _B Enable FIFO hysteresis for DMA access.

Generic Timer Module (GTM)

Field	Bits	Type	Description
DMA_HYS T_DIR	3	rw	<p>DMA direction in hysteresis mode</p> <p>0_B DMA direction read in hysteresis mode. 1_B DMA direction write in hysteresis mode.</p> <p>Note: In the case of DMA writing data to a FIFO the DMA requests must be generated by the lower watermark. If the DMA hysteresis is enabled, the FIFO does not generate a new DMA request until the upper watermark is reached.</p> <p>Note: In the case of DMA reading data from FIFO the DMA requests must be generated by the upper watermark. If the DMA hysteresis is enabled, the FIFO does not generate a new DMA request until the lower watermark is reached.</p>
Reserved	[31:4]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

Generic Timer Module (GTM)

26.5.5.14 Register FIFOi_CHx_EIRQ_EN (x:0...7)

GTM_FIFO0_CHx_EIRQ_EN (x=0-7)

FIFO0 Channel x Error Interrupt Enable Register
(18434_H+x*40_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
FIFO_EMPTY_EIRQ_EN	0	rw	Error interrupt enable 0 _B Disable error interrupt, error interrupt is not visible outside GTM 1 _B Enable error interrupt, error interrupt is visible outside GTM
FIFO_FULL_EIRQ_EN	1	rw	Interrupt enable See bit 0
FIFO_LWM_EIRQ_EN	2	rw	Interrupt enable See bit 0
FIFO_UWM_EIRQ_EN	3	rw	Interrupt enable See bit 0
Reserved	[31:4]	r	reserved Note: read as zero, should be written as zero

26.6 AEI to FIFO Data Interface (AFD)

26.6.1 Overview

The AFD submodule implements a data interface between the AEI bus and the FIFO submodule, which consists of eight logical FIFO channels.

The AFD submodule provides one buffer registers that are dedicated to the logical channels of the FIFO. Access to the corresponding FIFO channel is given by reading or writing this buffer registers AFD0_CHx_BUF_ACC.

An AEI write access to the buffer register where the corresponding FIFO channel is full will be ignored. The data will be lost.

An AEI read access to the buffer register where the corresponding FIFO channel is empty will be served with zero data.

26.6.2 AFD Register overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 26-15 AFD Register overview

Register Name	Description	Details in Section
AFD0_CHx_BUF_ACC	AFD FIFO x buffer access register (x: 0...7)	Section 26.6.3.1

26.6.3 AFD Register description

All of the following registers are 32-bit only accessible.

26.6.3.1 Register AFD0_CHx_BUF_ACC (x:0...7)

GTM_AFD0_CHx_BUF_ACC (x=0-7)

AFD0 FIFO0 Channel x Buffer Access Register

(18080_H+x*10_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
DATA	[28:0]	rw	Read/write data from/to FIFO
Reserved	[31:29]	r	Reserved Read as zero, should be written as zero

26.7 FIFO to ARU Unit (F2A)

26.7.1 Overview

The F2A is the interface between the ARU and the FIFO submodule. Since the data width of the ARU (ARU word) is 53 bit (two 24 bit values and five control bits) and the data width of the FIFO is only 29 bit, the F2A has to distribute the data from and to the FIFO channels in a configurable manner.

The data transfer between FIFO and ARU is organized with eight different streams that are connected to the eight different channels of the corresponding FIFO module. A stream represents a data flow from/to ARU to/from the FIFO via the F2A.

The general definition of 'channels' and 'streams' in the ARU context is done in [Section 26.2.3](#).

Each FIFO channel can act as a write stream (data flow from FIFO to ARU) or as a read stream (data flow from ARU to FIFO).

Within these streams the F2A can transmit/receive the lower, the upper or both 24 bit values of the ARU together with the ARU control bits according to the configured transfer modes as described in [Section 26.7.2](#)

26.7.2 Transfer modes

The F2A unit provides several transfer modes to map 29 bit data of the FIFO from/to 53 bit data of the ARU. E.g. it is configurable that the 24 bit FIFO data is written to the lower ARU data entry (means bits 0 to 23) or to the higher 24 bit ARU data entry (means bits 24 to 47). Bits 24 to 28 of the FIFO data entry (the five control bits) are written/read in both cases to/from bits 48 to 52 of the ARU entry.

When both values of the ARU have to be stored in the FIFO the values are stored behind each other inside the FIFO if the FIFO is not full.

If there is only space for one 24 bit data word plus the five control bits, the F2A transfers one part of the 53 bits first and then waits for transferring the second part before new data is requested from the ARU.

When two values from the FIFO have to be written to one ARU location the words have to be located behind each other inside the FIFO.

The transfer to ARU is only established when both parts could be read out of the FIFO otherwise if only one 29 bit word was provided by the FIFO the F2A waits until the second part is available before the data is made available at the ARU.

[Figure 26-16](#) shows the data ordering of the FIFO when both ARU values must be transferred between ARU and FIFO.

When reading from the ARU the F2A first writes the lower word to the FIFO.

Generic Timer Module (GTM)

In case of writing to the ARU the F2A reads the lower word first from the FIFO, thus the lower word must be written first to the FIFO through the AFD interface.

Please note, that the five control bits (bits 48 to 52 of the ARU data word) are duplicated as bit 24 to 28 of both FIFO words in case of reading from ARU.

In the case of writing to the ARU, bits 24 to 28 of the last written FIFO word (the higher ARU word) are copied to bits 48 to 52 of the corresponding ARU location.

The transfer modes can be configured with the TMODE bits of registers F2A0_CHx_STR_CFG (x: 0...7).

26.7.2.1 Data transfer of both ARU words between ARU and FIFO

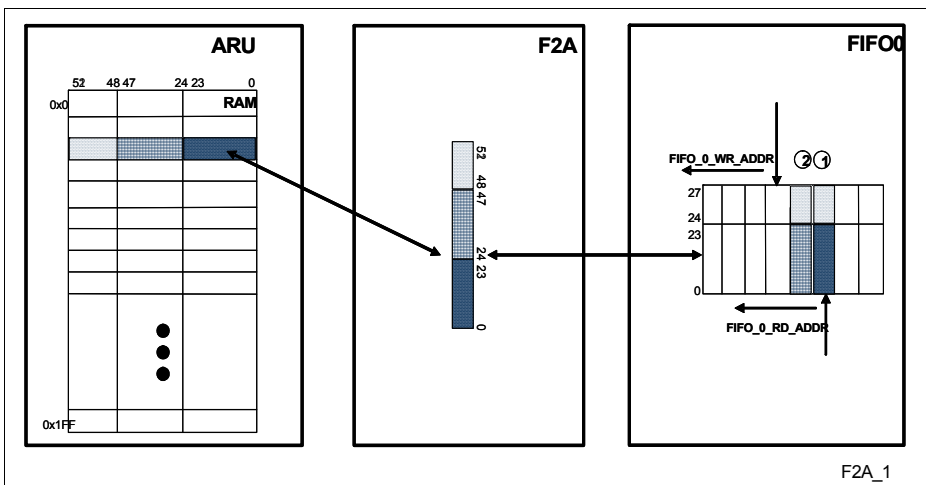

Figure 26-16 Data transfer of both ARU words between ARU and FIFO

26.7.3 F2A Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 26-16 F2A Configuration Registers Overview

Register name	Description	Details in Section
F2Ai_ENABLE	F2A stream activation register	Section 26.7.4.1
F2Ai_CHx_ARU_RD_FIFO	F2A read channel address register (x: 0...7)	Section 26.7.4.2
F2Ai_CHx_STR_CFG	F2A stream x configuration register (x: 0...7)	Section 26.7.4.3

26.7.4 F2A Configuration Registers description

All of the following registers are 32-bit only accessible.

26.7.4.1 Register F2Ai_ENABLE

GTM_F2A0_ENABLE

F2A0 Stream Activation Register (18040_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
STR0_EN	[1:0]	rw	<p>Enable/disable stream 0</p> <p>Write of following double bit values is possible:</p> <p>00_B Don't care, bits 1:0 will not be changed</p> <p>01_B Stream 0 is disabled and internal states are reset</p> <p>10_B Stream 0 is enabled</p> <p>11_B Don't care, bits 1:0 will not be changed</p> <p>Read of following double values means:</p> <p>00_B Stream disabled</p> <p>11_B Stream enabled</p>

Generic Timer Module (GTM)
26.7.4.3 Register F2Ai_CHx_STR_CFG (x: 0...7)
GTM_F2A0_CHx_STR_CFG (x=0-7)
F2A Stream x Configuration Register
 $(18020_H + x \cdot 04_H)$
Reset Value: 00000000_H

Field	Bits	Type	Description
Reserved	[15:0]	r	Reserved Read as zero, should be written as zero
TMODE	[17:16]	rw	Transfer mode for 53 bit ARU data from/to FIFO 00 _B Transfer low word (ARU bits 23:0) from/to FIFO 01 _B Transfer high word (ARU bits 47:24) from/to FIFO 10 _B Transfer both words from/to FIFO 11 _B Reserved Note: This bit is only writable if the corresponding enable bit STRx_EN of register F2A_ENABLE is cleared.
DIR	18	rw	Data transfer direction 0 _B Transport from ARU to FIFO 1 _B Transport from FIFO to ARU Note: This bit is only writable if the corresponding enable bit STRx_EN of register F2A_ENABLE is cleared.
Reserved	[31:19]	r	Reserved Read as zero, should be written as zero

26.8 Clock Management Unit (CMU)

26.8.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM. The CMU consists of three subunits that generate different clock sources for the whole GTM. [Figure 26-17](#) shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) subunit provides eight dedicated clock sources for the following GTM submodules: TIM, ATOM, TBU, and MON. Each instance of such a submodule can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The Fixed Clock Generation (FXU) subunit generates predefined non-configurable clocks `CMU_FXCLK[y]` ($y: 0 \dots 4$) for the TOM submodules and the MON submodule. The `CMU_FXCLK[y]` signals are derived from the `CMU_GCLK_EN` signal generated by the Global Clock Divider. The dividing factors are defined as 2^0 , 2^4 , 2^8 , 2^{12} , and 2^{16} .

The External Clock Generation (EGU) subunit is able to generate up to three GTM external clock signals visible at `CMU_ECLK[z]` ($z: 0 \dots 2$) with a duty cycle of about 50%.

The clock source signals `CMU_CLK[x]` ($x: 0 \dots 7$) and `CMU_FXCLK[y]` are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the `SYS_CLK` signal.

The four configurable clock signals `CMU_CLK0`, `CMU_CLK1`, `CMU_CLK6` and `CMU_CLK7` are connected to the TIM filter counters.

26.8.1.1 CMU Block Diagram

Figure 26-17 CMU Block Diagram

26.8.2 Global Clock Divider

The subblock Global Clock Divider can be used to divide the GTM global input clock signal SYS_CLK into a common subdivided clock signal.

The divided clock signal of the subblock Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the SYS_CLK signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

$$\text{TCMU_GCLK_EN} = (\text{Z}/\text{N}) * \text{TSYS_CLK}$$

is implemented according the following algorithm

(Z: CMU_GCLK_NUM(23:0); N: CMU_GCLK_DEN(23:0); Z,N >0):

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

$$r = Z, \text{OP1} = N, \text{OP2} = N - Z;$$

(2) After leaving init-phase (at least one CMU_CLK[x] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If $r > 0$ keep updating remainder and keep CMU_GCLK_EN='0':

$$r = r - \text{OP1};$$

(4) If $r < 0$ update remainder and set CMU_GCLK_EN='1':

$$r = r - \text{OP2};$$

After at most $(Z/N+1)$ subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock enable cycle phase. The new r value will be $r = r + (Z - N)$. In the worst case the remainder r will sum up to an additional cycle in the generated clock enable period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N no additional cycles will be included for the generated clock enable at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of $(Z - N)$.

26.8.3 Configurable Clock Generation Subunit (CFGU)

The CMU subunit CFGU provides up to eight configurable clock divider blocks that divide the common CMU_GCLK_EN signal into dedicated enable signals for the GTM subblocks.

The configuration of the eight different clock signals CMU_CLK[x] (x: 0...7) always depends on the configuration of the global clock enable signal CMU_GCLK_EN. Additionally, each clock source has its own configuration data, provided by the control register CMU_CLK_x_CTRL (x: 0...7).

Generic Timer Module (GTM)

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field CLK_CNT[x] of the register CMU_CLK_x_CTRL.

The frequency $f_x = 1/T_x$ of the corresponding clock enable signal CMU_CLK[x] can be determined by the unsigned representation of CLK_CNT[x] of the register CMU_CLK_x_CTRL in the following way:

$$TCMU_CLK[x] = (CLK_CNT[x] + 1) * TCMU_GCLK_EN$$

The corresponding wave form is shown in [Figure 26-18](#).

Each clock signal CMU_CLK[x] can be enabled individually by setting the appropriate bit field EN_CLK[x] in the register CMU_CLK_EN. Except for CMU_CLK6 and CMU_CLK7 individual enabling and disabling is active only if CLK6_SEL and CLK7_SEL is cleared.

Alternatively, clock source six and seven (CMU_CLK6 and CMU_CLK7) may provide the signal SUB_INC1 and SUB_INC2 coming from submodule DPPLL as clock enable signal depending on the bit field CLK6_SEL of the register CMU_CLK_6_CTRL and on the bit field CLK7_SEL of the register CMU_CLK_7_CTRL.

To avoid unexpected behaviour of the hardware, the configuration of a register CMU_CLK_x_CTRL can only be changed, when the corresponding clock signal CMU_CLK[x] is disabled.

Further, any changes to the registers CMU_GCLK_NUM and CMU_GCLK_DEN can only be performed, when all clock enable signals CMU_CLK[x] and the EN_FXCLK bit inside the CMU_CLK_EN register are disabled.

The clock source signals CMU_CLK[x] (x:0...7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The hardware guarantees that all clock signals CMU_CLK[x], which were enabled simultaneous, are synchronized to each other. Simultaneous enabling does mean that the bits EN_CLK[x] in the register CMU_CLK_EN are set by the same write access.

After EN_CLK[x] entries in CMU_CLK_EN have been disabled, internal states of these EN_CLK[x] paths will be reset to start with the same behaviour after enable.

26.8.4 Wave Form of Generated Clock Signal CMU_CLK[x]

Figure 26-18 Example clock signal

26.8.5 Fixed Clock Generation (FXU)

The FXU subunit generates fixed clock enables out of the CMU_GCLK_EN or one of the eight CMU_CLKx enable signal depending on the CMU_CLK_5.FXCLK_SEL bit field of the CMU_FXCLK_CTRL register. These clock enables are used for the PWM generation inside the TOM submodules.

All clock enables CMU_FXCLK[y] can be enabled or disabled simultaneously by setting the appropriate bit field EN_FXCLK in the register CMU_CLK_EN.

The dividing factors are defined as 2^0 , 2^4 , 2^8 , 2^{12} , and 2^{16} . The signals CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers (see also [Section 26.8.4](#))

After EN_FXCLK entry in CMU_CLK_EN have been disabled, internal states of EN_FXCLK paths will be reset to start with the same behaviour after enable.

26.8.6 External Generation Unit (EGU)

The EGU subunit generate up to three separate clock output signals CMU_ECLK[z] (z: 0...2).

Each of these clock signals is derived from the corresponding External Clock Divider z subblock, which generates a clock signal derived from the GTM input clock SYS_CLK.

In contrast to the signals CMU_CLK[x] and CMU_FXCLK[y], which are treated as simple enable signals for the registers, the signals CMU_ECLK[z] have a duty cycle of about 50% that is used as a true clock signal for external peripheral components.

Each of the external clocks are enabled and disabled by setting the appropriate bit field EN_ECLK[z] in the register CMU_CLK_EN.

After EN_ECLK[z] entries in CMU_CLK_EN have been disabled, internal states of these EN_ECLK[z] paths will be reset to start with the same behaviour after enable.

The clock frequencies $f_{\text{CMU_ECLK}[z]} = 1/T_{\text{CMU_ECLK}[z]}$ of the external clocks are controlled with the registers CMU_ECLK_z_NUM and CMU_ECLK_z_DEN as follows:

$$T_{\text{CMU_ECLK}[z]} = 2 * (\text{ECLK}[z]_{\text{NUM}} / \text{ECLK}[z]_{\text{DEN}}) * T_{\text{SYS_CLK}}$$

Generic Timer Module (GTM)

and is implemented according the following algorithm

(Z: CMU_ECLK_z_NUM(23:0); N: CMU_ECLK_z_DEN(23:0); $Z, N > 0$; $Z \geq N$; CMU_ECLK[z]='0');

(1) Set remainder (r), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):

$r=Z$, $OP1=N$, $OP2=N-Z$;

(2) After leaving init-phase (CMU_ECLK[z] has been enabled) the sign of remainder r for each SYS_CLK cycle will be checked:

(3) If $r > 0$ keep updating remainder and keep CMU_ECLK[z]:

$r=r-OP1$;

(4) If $r < 0$ update remainder and toggle CMU_ECLK[z]:

$r=r-OP2$;

After at most $(Z/N+1)$ subtractions (3) there will be a negative r and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder r is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock toggle phase. The new r value will be $r=r+(Z-N)$. In the worst case the remainder r will sum up to an additional cycle in the generated clock toggle period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock toggle. If Z is an integer multiple of N no additional cycles will be included for the generated clock toggle at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder r uses the complement of $(Z-N)$.

The default value of the CMU_ECLK[z] output is low.

26.8.7 CMU Configuration Registers Overview

Following configuration registers are considered in CMU submodule:

Table 26-17 CMU Configuration Registers Overview

Register Name	Description	Details in Section
CMU_CLK_EN	CMU Clock enable register	Section 26.8.8.1
CMU_GCLK_NUM	CMU Global clock control numerator register	Section 26.8.8.2
CMU_GCLK_DEN	CMU Global clock control denominator register	Section 26.8.8.3
CMU_CLK_x_CTRL	CMU Control for clock source x register (x:0...5)	Section 26.8.8.4
CMU_CLK_6_CTRL	CMU Control for clock source 6 register	Section 26.8.8.5

Generic Timer Module (GTM)

Table 26-17 CMU Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section

26.9 Time Base Unit (TBU)

26.9.1 Overview

The Time Base Unit TBU provides common time bases for the GTM. The TBU submodule is organized in channels, where the number of channels is device dependent. There are at most three channels implemented inside the TBU. The TBU channel 0 time base register TBU_CHO_BASE is 27 bits and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signal TBU_TS0. The two TBU channels 1 and 2 have a time base register TBU_CHy_BASE (y: 1, 2) of 24 bit length. The time base register value TBU_TS[y] and the time base register update event TBU_UP[y] are provided to subsequent submodules of the GTM.

The TBU_UP[z] (z:1...2) signals are set to high for a single SYS_CLK period, whenever the corresponding signal TBU_TS[z] (z:1...2) or TBU_TS0 is getting updated. The signal TBU_UP0_L is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS0 is getting updated and TBU_UP0_H is set to high for a single SYS_CLK period, whenever if the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register TBU_CHEN. [Section 26.9.1.1](#) shows a block diagram of the Time Base Unit.

26.9.1.1 TBU Block Diagram

Figure 26-19 TBU Block Diagram

Dependent on the device a third TBU channel exists which offers the same functionality as the time base channel 1.

The configuration of the independent time base channels TBU_BASE_[z] is done via the AEI interface. Each TBU channel may select one of the eight CMU_CLK[x] (x: 0...7) signals coming from the CMU submodule.

For TBU channels 1 and 2 an additional clock signal SUB_INC[y]c (y: 1, 2) coming from the DPLL can be selected as input clock for the TBU_BASE_[y]. This clock in combination with the DIR[y] signals determines the counter direction of the TBU_BASE_[y].

The selected time stamp clock signal for the TBU_BASE_0 subunit is served via the TS_CLK signal line to the DPLL submodule. The TS_CLK signal equals the signal TBU_UP0.

26.9.2 TBU Time Base Channels

The time base values are generated within the TBU time base channels in two independent operation modes.

26.9.2.1 TBU Channel Modes

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field `LOW_RES` of register `TBU_CH0_CTRL`, the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM submodules.

TBU channel 1 and channel 2 can run in two modes; the free running counter mode and forward/backward counter mode, where the time base can run backwards dependent on the `DIR[y]` input signal values.

In both modes, the time base register `TBU_CH[z]_BASE` can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register `TBU_CH[z]_BASE` can always be read in order to determine the actual value of the counter.

Free Running Counter Mode

In TBU Free running counter mode, the time base register `TBU_CHy_BASE` is updated on every specified incoming clock event by the selected signal `CMU_CLK[x]` (dependent on `TBU_CH[z]_CTRL` register). In general the time base register `TBU_CHy_BASE` is increment on every `CMU_CLK[x]` clock tick.

Forward/Backward Counter Mode

As mentioned above TBU channels 1 and 2 can also be configured to run in Forward/Backward Counter Mode. In this mode the `DIR[y]` signal provided by the DPLL is taken into account.

The value of the time base register `TBU_CHy_BASE` is increment in case when the `DIR[y]` signal equals '0' and decremented in case when the `DIR[y]` signal is '1'.

26.9.3 TBU Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 26-18 TBU Configuration Registers Overview

Register Name	Description	Details in Section
<code>TBU_CHEN</code>	TBU global channel enable register	Section 26.9.4.1
<code>TBU_CH0_CTRL</code>	TBU channel 0 control register	Section 26.9.4.2

Generic Timer Module (GTM)

Table 26-18 TBU Configuration Registers Overview (cont'd)

Register Name	Description	Details in Section
TBU_CH0_BASE	TBU channel 0 base register	Section 26.9.4.3
TBU_CHy_CTRL	TBU channel y control register (y:1,2)	Section 26.9.4.4
TBU_CHy_BASE	TBU channel y base register (y:1,2)	Section 26.9.4.5

Note: In a typical application the Time Base Unit (TBU) considers channels 0 and 1 only. In this case register addresses 0x20...0x2C are reserved and shall be read as zero. Channel 2 can be additionally implemented on special high-end application requirements.

26.9.4 TBU Registers description

All of the following registers are 32-bit only accessible.

26.9.4.1 Register TBU_CHEN

GTM_TBU_CHEN

TBU Global Channel Enable Register(00100_H)

Reset Value: 0000000_H

Field	Bits	Type	Description
ENDIS_CH 0	[1:0]	rw	TBU channel 0 enable/disable control Write of following double bit values is possible: 00 _B don't care, bits 1:0 will not be changed 01 _B channel disabled: is read as 00 (see below) 10 _B channel enabled: is read as 11 (see below) 11 _B don't care, bits 1:0 will not be changed Note: Read of following double values means: 00 _B channel disabled 11 _B channel enabled
ENDIS_CH 1	[3:2]	rw	TBU channel 1 enable/disable control See bits 1:0

Generic Timer Module (GTM)

Field	Bits	Type	Description
ENDIS_CH 2	[5:4]	rw	TBU channel 2 enable/disable control See bits 1:0 Note: These bits are only applicable if channel is implemented for this device, otherwise read and write as zero
Reserved	[31:6]	r	Reserved Read as zero, should be written as zero

26.9.4.2 Register TBU_CH0_CTRL
GTM_TBU_CH0_CTRL
TBU Channel 0 Control Register (00104_H) **Reset Value: 00000000_H**

Field	Bits	Type	Description
LOW_RES	0	rw	TBU_CH0_BASE register resolution 0 _B TBU channel uses lower counter bits (bit 0 to 23) 1 _B TBU channel uses upper counter bits (bit 3 to 26) Note: The two resolutions for the TBU channel 0 can be used in the TIM channel 0 and the DPLL submodules. Note: This value can only be modified if channel 0 is disabled.

Generic Timer Module (GTM)

Field	Bits	Type	Description
CH_CLK_SRC	[3:1]	rw	Clock source for channel x (x:0...2) time base counter 000 _B CMU_CLK0 selected 001 _B CMU_CLK1 selected 010 _B CMU_CLK2 selected 011 _B CMU_CLK3 selected 100 _B CMU_CLK4 selected 101 _B CMU_CLK5 selected 110 _B CMU_CLK6 selected 111 _B CMU_CLK7 selected Note: This value can only be modified (written) if channel 0 was disabled
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

26.9.4.3 Register TBU_CH0_BASE
GTM_TBU_CH0_BASE
TBU Channel 0 Base Register
(00108_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
BASE	[26:0]	rw	Time base value for channel 0 Note: The value of BASE can only be written if the TBU channel 0 is disabled Note: If channel 0 is enabled, a read access to this register provides the current value of the underlying 27 bit counter.
Reserved	[31:27]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)
26.9.4.4 Register TBU_CHy_CTRL (y:1, 2)
GTM_TBU_CHy_CTRL (y=1-2)
TBU Channel y Control Register (00104_H+y*08_H)
Reset Value: 00000000_H

Field	Bits	Type	Description
CH_MODE	0	rw	Channel mode 0 _B Free running counter mode 1 _B Forward/backward counter mode Note: This value can only be modified if channel y (y:1,2) was disabled. In Free running counter mode the CMU clock source specified by CH_CLK_SRC is used for the counter. In Forward/Backward counter mode the SUB_INC[y]c clock signal in combination with the DIR[y] input signal is used to determine the counter direction and clock frequency.
CH_CLK_SRC	[3:1]	rw	Clock source for channel x (x1...2) time base counter 000 _B CMU_CLK0 selected 001 _B CMU_CLK1 selected 010 _B CMU_CLK2 selected 011 _B CMU_CLK3 selected 100 _B CMU_CLK4 selected 101 _B CMU_CLK5 selected 110 _B CMU_CLK6 selected 111 _B CMU_CLK7 selected Note: This value can only be modified if channel y was disabled
Reserved	[31:4]	r	Reserved Read as zero, should be written as zero

Generic Timer Module (GTM)

26.9.4.5 Register TBU_CHy_BASE (y:1,2)

GTM_TBU_CHy_BASE (y=1-2)

TBU Channel y Base Register (00108_H+y*08_H)

Reset Value: 00000000_H

Field	Bits	Type	Description
BASE	[23:0]	rw	<p>Time base value for channel x (x 1, 2)</p> <p>Note: The value of BASE can only be written if the corresponding TBU channel y is disabled</p> <p>Note: If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.</p>
Reserved	[31:24]	r	<p>Reserved</p> <p>Read as zero, should be written as zero</p>

26.10 Timer Input Module (TIM)

26.10.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels. For advanced data processing the detected input characteristics of the TIM module can be routed through the ARU to subsequent processing units of the GTM.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal durations for a whole PWM period.

The architecture of TIM is shown in [Figure 26-20](#).

26.10.1.1 TIM Block Diagram

Figure 26-20 TIM Block Diagram

Generic Timer Module (GTM)

Each of the eight (8) dedicated input signals is filtered inside the FLTx subunit of the TIM Module. It should be noted that the incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The submodule TIM provides different filter mechanisms described in more detail in [Section 26.10.2](#). After filtering, the signal is routed to the corresponding TIM channel.

The measurement values can be read by the CPU directly via the AEI-Bus or they can be routed through the ARU to other submodules of the GTM.

For timeout detection of an incoming signal (no subsequent edge detected during a specified duration) each individual channel has a Timeout Detection Unit (TDU).

For the GTM TIM0 submodule only, the dashed signal outputs TIM[i]_CH[x](23:0), TIM[i]_CH[x](47:24) and TIM[i]_CH[x](48) come from the TIM0 submodule channels zero (0) to five (5) and are connected to MAP submodule. There, they are used for further processing and for routing to the DPLL.

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (TBU_TS0(23...0)) or the higher 24 bits (TBU_TS0(26...3)) are stored inside the GPR0 and GPR1 registers.

26.10.1.2 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT, TDU, TIM_CH units. It can be selected by the bit fields CICTRLx and MODE_x, VAL_x in the register TIMi_CHx_IN_SRC which source is in use.

Figure 26-21 TIM Source Selection

In a certain MODE_x, VAL_x combination the input signal F_IN(x) can be driven by VAL_x(1) with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register TIMi_CHx_IN_SRC a synchronous control of all 8 input channels is possible.

Generic Timer Module (GTM)

Two adjacent channels can be combined by setting the CICTRL bit field in the corresponding TIMi_CHx_CTRL register. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional input signal AUX_IN[x] can be selected as an input signal. The source of this signal is defined in the [Section 26.2.1.3](#).

26.10.1.3 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal EXT_CAPTURE. The source to use for this signal can be configured by the bit field EXT_CAP_SRCx in the register TIMi_CHx_ECTRL.

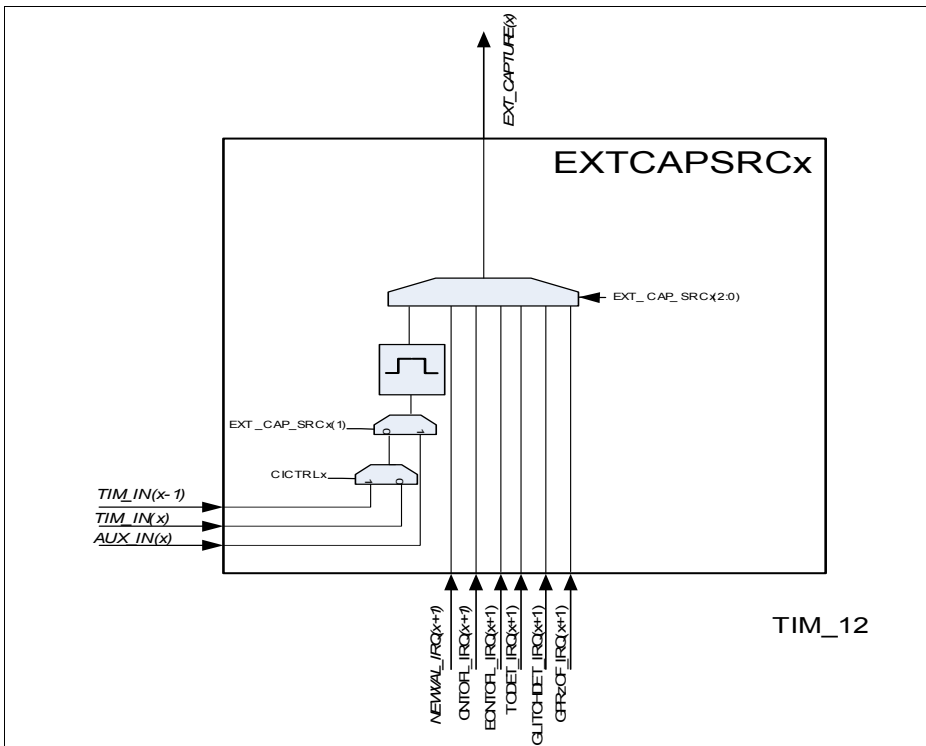

Figure 26-22 TIM external Capture Interrupt

The external capture functionality can be enabled for the TIM channel x with the bit EXT_CAP_EN in the register TIMi_CHx_CTRL, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal TIM_IN[x] and AUX_IN[x] is applied.

Generic Timer Module (GTM)

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register `TIMi_CHx+1_FORCINT`.

26.10.2 TIM Filter Functionality (FLT)

26.10.2.1 Overview

The TIM submodule provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT subunit.

FLT architecture is shown in [Figure 26-23](#)

The filter includes a clock synchronisation unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal `F_IN` to the selected filter clock frequency, which is controlled with the bit field `FLT_CNT_FRQ` of register `TIMi_CHx_CTRL`.

The synchronized input signal `F_IN_SYNC` is used for further processing within the filter. It should be noted that glitches with a duration less than the selected CMU clock period are lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- immediate edge propagation mode,
- individual de-glitch time mode (up/down counter), and
- individual de-glitch time mode (hold counter).

FLT Architecture

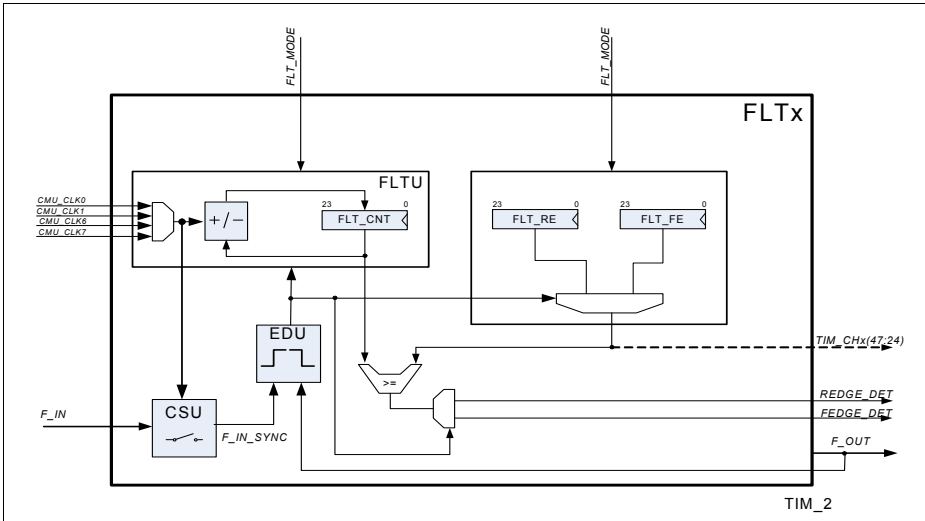

Figure 26-23 FLT Architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers FLT_RE (rising edge) and FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters FLT_xE can always be determined by:

$$T = (FLT_xE + 1) * TFLT_CLK,$$

whereas TFLT_CLK is the clock period of the selected CМУ clock signal in bit field FLT_CNT_FRQ of register TIMi_CHx_CTRL.

When a glitch is detected on an input signal a status flag GLITCHDET is set inside the TIMi_CHx_IRQ_NOTIFY register.

Table 26-19 gives an overview about the meanings for the registers FLT_RE and FLT_FE. In the individual deglitch time modes, the actual filter threshold for a detected regular edge is provided on the TIM[i]_CH[x](47:24) output line. In the case of immediate edge propagation mode, a value of zero is provided on the TIM[i]_CH[x](47:24) output line.
