Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Microcontrollers

TC26x B-Step User's Manual
Revision History: V1.3 2014-12
Significant changes since previous version: TC26x User's Manual V1.2

Chapter	Subjects (major changes since last revision)
Introduction	Removed redundant introduction sections.
FIRMWARE	<ul style="list-style-type: none"> Added description of the CRC calculation method below the table "Boot Mode Header (BMHD)"
SCU/CCU	<ul style="list-style-type: none"> Updated divider formula in registers CCUCON6,7,8. Updated table "CCU allowed Clock Ratios".
SCU/SCU	<ul style="list-style-type: none"> Corrected DTSCON.CAL width. Removed design related register reference from "OCDS Behavior of WDTs".
PORTS	<ul style="list-style-type: none"> Corrected description of LVDS pads in CMOS mode: removed sentence 'no open-drain mode available'
MTU	<ul style="list-style-type: none"> MCONTROL.Res4 field (bits 14:12) marked as "Must be written with 0x4" in to maintain redundancy. Sections "Reading a Single Memory Location" and "Writing a Single Memory Location" should always write MCONTROL with the MS nibble 0x4 instead of 0x0. Design related register reference "RDR" removed.

TC26x B-Step User's Manual

Revision History: V1.3 2014-12

SMU	<ul style="list-style-type: none"> • Corrected register long name of SMU_RTC to “Recovery Timer Configuration”. • DMA alarm ALM2[24] is now reserved. Alarm implemented by DMA SRI error detection alarms. • Improved description of alarm ALM3[27]. • SCU alarm ALM3[28] is now reserved. Feature not implemented. • Pre-alarms PreAlarm[129=DMA.(Safety FF Error Detection)] and PreAlarm[130=PMU.(Safety FF Error Detection)] removed because DMA and PMU do not implement Safety FF. • Added configuration hints to SMU_AG<n>CF<m> Registers: reserved alarms shall be configured as “No Action”. • Enhanced description of register SMU_RMEF and SMU_RMSTS. • Enhanced description of register SMU_PCTL with advice how to operate it in the application. • Changed section “SMU Integration Guidelines”. • Explained “Register Monitor” = “Safety Flip-Flop”. • Improved Figure “SMU State Machine”. • Improved section “FSP Fault State”.
-----	--

TC26x B-Step User's Manual

Revision History: V1.3 2014-12

PMU	<ul style="list-style-type: none"> Highlighted in the description of FCON and the wait cycle description that after System Resets and Power-On Resets the wait cycles are only sufficient for 100 MHz. Noted in the "Application Hints" that the recommended sequence for issuing "Verify Erased Logical Sector Range" is analog to "Erase". Changed recommendations in the "Application Hints" for ECC test patterns. Made the all-0/all-1 and address error patterns optional. Recommended to store 2 of the 4 pattern sets inverse to the other 2. Improved description of "Load Page" to make the offsets used for 32-bit transfers more explicit. Added to the description of "Write Page" the clear statement that each page shall be programmed only once. Noted that "Verify Erased Logical Sector Range" is not blocked on password containing UCBs when the protection is disabled. Removed confusing statement that unavailable DFlash ranges can be programmed to all-1. Noted explicitly that the UCBs 8 to 11 are read-only. Clarified that both "Write Page" and "Write Burst" can be used to program UCBs. Removed statement about restricted FAR capabilities. Removed note from "Erase Logical Sector Range" that warned from erasing more than 256 KByte because of increased suspend times. The suspend times are not increasing. Changed note for "Erase Logical Sector Range" that described that erase time can be much shorter than maximum times documented in the Data Sheet. The reason was removed as there are more dependencies. Documented "Test Pass Marker" in UCB_IFX. Removed term "Reset Class" and replaced by named resets. Stated explicitly that a failed HSM boot prevents device boot.
IR	<ul style="list-style-type: none"> Added clarification: a pending Service Request is cleared in the Service Request Node with the Acknowledge from the Service Provider. The Acknowledge does not mean that the Service Request is serviced at that time (e.g. disabled or not implemented DMA channel, Trap on CPU prevents execution of Service Request).
ASCLIN	<ul style="list-style-type: none"> Block "Auto Baud Rate Operation" added. Description of register field "BRD.MEASURED" improved.

TC26x B-Step User's Manual
Revision History: V1.3 2014-12

QSPI	<ul style="list-style-type: none"> Removed maximum baud rates from feature list as these depend on pad speeds and PCB implementation.
MSC	<ul style="list-style-type: none"> Description of "Clock Control when using the ABRA Block" improved. Equation of Ncycles for extended frames changed: added factor 32 to PPDE.
MultiCAN+	<ul style="list-style-type: none"> Fixed pad naming for all devices. CRC issue of CAN FD standard documented and recommended additional software CRC.
SENT	<ul style="list-style-type: none"> Updated Serial Message Frame Chapter.
GTM	<ul style="list-style-type: none"> Corrected error in BGA-416 TOUT numbering for P10.13 and P10.11. Connection shown in figures and register for SET5 and SET6 to MSC2 was corrected. Updated description of bit field OCS.SUS. Updated description of (A)TOM SOMP Mode. Clarified reset behavior of debug registers. Corrected error for P2.11; it is connected to TIM4_4 not to TIM4_7
VADC	<ul style="list-style-type: none"> Added hint how to use Pxx_PDISC for diagnostics in section "Signal Path Test Modes". Adjusted the position of accumulated results in section "Data Alignment".
DSADC	<ul style="list-style-type: none"> Changed in section "Recommended Settings" the documented full-scale values from $\pm 1900_D$ to $\pm 3800_D$ and their dependence on operating modes. Removed external modulator connections. Removed modulator combine mode. Separated rectifier and integrator, add data shift in figure DSADC structure overview.

1 TC26x B-Step Introduction

This User's Manual describes the Infineon TC26x B-Step, a 32-bit microcontroller DSP, based on the Infineon TriCore Architecture.

1.1 About this Document

This document is designed to be read primarily by design engineers and software engineers who need a detailed description of the interactions of the TC26x B-Step functional units, registers, instructions, and exceptions.

This TC26x B-Step User's Manual describes the features of the TC26x B-Step with respect to the TriCore Architecture. Where the TC26x B-Step directly implements TriCore architectural functions, this manual simply refers to those functions as features of the TC26x B-Step. In all cases where this manual describes a TC26x B-Step feature without referring to the TriCore Architecture, this means that the TC26x B-Step is a direct implementation of the TriCore Architecture.

Where the TC26x B-Step implements a subset of TriCore architectural features, this manual describes the TC26x B-Step implementation, and then describes how it differs from the TriCore Architecture. Such differences between the TC26x B-Step and the TriCore Architecture are documented in the section covering each such subject.

1.1.1 Related Documentations

A complete description of the TriCore architecture is found in the document entitled "TriCore Architecture Manual". The architecture of the TC26x B-Step is described separately this way because of the configurable nature of the TriCore specification: Different versions of the architecture may contain a different mix of systems components. The TriCore architecture, however, remains constant across all derivative designs in order to preserve compatibility.

This User's Manuals together with the "TriCore Architecture Manual" are required to understand the complete TC26x B-Step micro controller functionality.

1.1.2 Text Conventions

This document uses the following text conventions for named components of the TC26x B-Step:

- Functional units of the TC26x B-Step are given in plain UPPER CASE. For example: "The QSPI supports full-duplex and half-duplex synchronous communication".
- Pins using negative logic are indicated by an overline. For example: "The external reset pin, $\overline{\text{ESR0}}$, has a dual function."
- Bit fields and bits in registers are in general referenced as "Module_Register name.Bit field" or "Module_Register name.Bit". For example: "The Current CPU Priority Number bit field CPU_ICR.CCPN is cleared". Most of the

TC26x B-Step Introduction

register names contain a module name prefix, separated by an underscore character “_” from the actual register name (for example, “QSPI0_GLOBALCON”, where “QSPI0” is the module name prefix, and “GLOBALCON” is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.

- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name “MOFCRn” refers to multiple “MOFCR” registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, “n = 0-255”), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter “H”, as in 100_H. Binary constants are suffixed with a subscript letter “B”, as in: 111_B.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as “NAME[A:B]”, which defines a range for the named group from B to A. Individual bits, signals, or pins are given as “NAME[C]” where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
 - **MHz** = Megahertz
 - **μs** = Microseconds
 - **kBaud, kbit** = 1000 characters/bits per second
 - **MBaud, Mbit** = 1000000 characters/bits per second
 - **Kbyte, KB** = 1024 bytes of memory
 - **Mbyte, MB** = 1048576 bytes of memory

In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1,000,000 or 1048576, and μ scales by .000001. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is 1024 × 1024 bytes, 1 kBaud/kbit are 1000 characters/bits per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1000000 Hz.
- Data format quantities are defined as follows:
 - **Byte** = 8-bit quantity
 - **Half-word** = 16-bit quantity
 - **Word** = 32-bit quantity
 - **Double-word** = 64-bit quantity

1.1.3 Reserved, Undefined, and Unimplemented Terminology

In tables where register bit fields are defined, the following conventions are used to indicate undefined and unimplemented function. Furthermore, types of bits and bit fields are defined using the abbreviations as shown in [Table 1](#).

Table 1 Bit Function Terminology

Function of Bits	Description
Unimplemented, Reserved	Register bit fields named 0 indicate unimplemented functions with the following behavior. <ul style="list-style-type: none"> • Reading these bit fields returns 0. • These bit fields should be written with 0 if the bit field is defined as r or rh. • These bit fields have to be written with 0 if the bit field is defined as rw. These bit fields are reserved. The detailed description of these bit fields can be found in the register descriptions.
rw	The bit or bit field can be read and written.
rwh	As rw, but bit or bit field can be also set or reset by hardware.
r	The bit or bit field can only be read (read-only).
w	The bit or bit field can only be written (write-only). A read to this register will always give a default value back.
rh	This bit or bit field can be modified by hardware (read-hardware, typical example: status flags). A read of this bit or bit field give the actual status of this bit or bit field back. Writing to this bit or bit field has no effect to the setting of this bit or bit field.
s	Bits with this attribute are “sticky” in one direction. If their reset value is once overwritten by software, they can be switched again into their reset state only by a reset operation. Software cannot switch this type of bit into its reset state by writing the register. This attribute can be combined to “rws” or “rwhs”.
f	Bits with this attribute are readable only when they are accessed by an instruction fetch. Normal data read operations will return other values.

1.1.4 Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the terms as defined in [Table 2](#) are used.

TC26x B-Step Introduction

In general, if an access type is not permitted under these rules (e.g. attempted write to R, attempted user mode access to SV, attempted access to E without Endinit, etc.) then a Bus Error will result, unless the access is also marked as nBE (or otherwise stated in the specific module chapter).

Table 2 Access Terms

Symbol	Description
U	Access Mode: Access permitted in User Mode 0 or 1.
	Reset Value: Value or bit is not changed by a reset operation.
SV	Access permitted only in Supervisor Mode.
R	Read-only register.
32	Only 32-bit word accesses are permitted to this register/address range.
32/16	Only 32-bit or 16-bit accesses are permitted to this register/address range.
CEx	CPUx Endinit protected register/address.
SE	Safety Endinit protected register/address.
E	Any CPU Endinit-protected register/address.
P (or P0 / P1)	Access Enable Register protected register/address. (ACCEN0/1)
PW	Password-protected register/address.
NC	No change, indicated register is not changed.
BE	Indicates that an access to this address range generates a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
nE	Indicates that no Error is generated when accessing this address or address range, even though the access is to an undefined address or address range. True for CPU accesses (MTCR/MFCR) to undefined addresses in the CSFR range.

1.1.5 Abbreviations and Acronyms

The following acronyms and terms are used in this document:

ADC	Analog-to-Digital Converter
ALU	Arithmetic and Logic Unit

ASCLIN	Asynchronous/Synchronous Serial Controller with LIN
BCU	Bus Control Unit
BROM	Boot ROM & Test ROM
CAN	Controller Area Network
CAPCOM	Capture Compare Unit
CIF	Camera and ADC Interface
CPU	Central Processing Unit
CRC	Cyclic Redundancy Code
CSA	Context Save Area
CSFR	Core Special Function Register
CCU6	Capture Compare Unit 6
CCU	Clock Control Unit
DAP	Device Access Port
DAS	Device Access Server
DCACHE	Data Cache
DFLASH	Data Flash Memory
DMA	Direct Memory Access
DMBI	Data Memory Bus Interface
DMI	Data Memory Interface
DRLB	Data Read Line Buffer
DSPR	Data Scratch Pad RAM
DS-ADC	Delta-Sigma Analog to Digital Converter
EBU	External Bus Interface
ECC	Error Correction Code
EMI	Electro-Magnetic Interference
E-Ray	Flexray Controller
EtherMAC	Ethernet Media Access Controller
EVR	Embedded Voltage Regulator
FCE	Flexible CRC Engine
FPB	Flash Prefetch Buffer
FFT	Fast Fourier Transform Accelerator
FM-PLL	PLL with Frequency Modulation support

FPI	Flexible Peripheral Interconnect (Bus protocol)
FPU	Floating Point Unit
GPIO	General Purpose Input/Output
GPR	General Purpose Register
GPT12	General Purpose Timer 12
GTM	Generic Timer Module
HSSL	High Speed Serial Link
I2C	Inter-Integrated Circuit Controller
I/O	Input / Output
IOM	I/O Monitor Unit
JTAG	Joint Test Action Group = IEEE1149.1
LMU	Local Bus Memory Unit
MCHK	Memory Checker module
MBIST	Memory Build In Self Test
MMU	Memory Management Unit
MSB	Most Significant Bit
MSC	Micro Second Channel
MTU	Memory Test Unit
MultiCAN+	Enhanced Multiple CAN controller
NC	Not Connected
NMI	Non-Maskable Interrupt
NVM	Non Volatile Memory
OCDS	On-Chip Debug Support
OVRAM	Overlay Memory
PLL	Phase Locked Loop
PCACHE	Program Cache
PFLASH	Program Flash Memory
PMBI	Program Memory Bus Interface
PMI	Program Memory Interface
PMU	Program Memory Unit
PSI5	Peripheral Sensor Interface
PSI5-S	Peripheral Sensor Interface with Serial Interface to Phy

PSPR	Program Scratch Pad RAM
QSPI	Queued SPI Controller
RAM	Random Access Memory
RISC	Reduced Instruction Set Computing
SBCU	System Peripheral Bus Control Unit
SCU	System Control Unit
SCR	8-bit Standby Controller
SENT	Single Edge Nibble Transmission
SFR	Special Function Register
SMU	Safety Management Unit
SPB	System Peripheral Bus (based on FPI protocol)
SPD	Single Pin DAP
SPI	Synchronous Serial Controller
SRI	Shared Resource Interconnect
SRAM	Static Data Memory
SRN	Service Request Node
STM	System Timer
SWD	Supply Watchdog
TC1.6P	TriCore CPU 1.6 (High Performance variant)
TC1.6E	TriCore CPU 1.6 (High Efficiency variant)
VADC	Versatile Analog-to-Digital Converter
WDT	Watchdog Timer
XBar, XBar_SRI	Cross Bar Interconnect, based on the Shared Resource Interconnect protocol

TC26x B-Step Introduction**1.2 System Architecture of the TC26x B-Step**

The TC26x B-Step combines three powerful technologies within one silicon die, achieving new levels of power, speed, and economy for embedded applications:

- Reduced Instruction Set Computing (RISC) processor architecture
- Digital Signal Processing (DSP) operations and addressing modes
- On-chip memories and peripherals

DSP operations and addressing modes provide the computational power necessary to efficiently analyse complex real-world signals. The RISC load/store architecture provides high computational bandwidth with low system cost. On-chip memory and peripherals are designed to support even the most demanding high-bandwidth real-time embedded control-systems tasks.

Additional high-level features of the TC26x B-Step include:

- Efficient memory organization: instruction and data scratch memories, caches
- Serial communication interfaces – flexible synchronous and asynchronous modes
- Multiple channel DMA Controller – DMA operations and interrupt servicing
- Flexible interrupt system – configurable interrupt priorities and targets
- Flexible CRC Engine
- General-purpose timers
- High-performance on-chip buses
- On-chip debugging and emulation facilities
- Flexible interconnections to external components
- Flexible power-management

In addition, the following Advanced Driver Assistance System features are available in products derivatives marked as “ADAS” in the tables above.

- Camera Interface
- Extended Memory
- FFT accelerator

The TC26x B-Step is a high-performance microcontroller with two TriCore CPUs, program and data memories, buses, bus arbitration, interrupt system, DMA controller and a powerful set of on-chip peripherals. The TC26x B-Step is designed to meet the needs of the most demanding embedded control systems applications where the competing issues of price/performance, real-time responsiveness, computational power, data bandwidth, and power consumption are key design elements.

The TC26x B-Step offers several versatile on-chip peripheral units such as serial controllers, timer units, and analog-to-digital converters. Within the TC26x B-Step, all these peripheral units are connected to the TriCore CPUs / system via the System Peripheral Bus (SPB) and the Local Memory Bus (SRI). A number of I/O lines on the TC26x B-Step ports are reserved for these peripheral units to communicate with the external world.

TC26x B-Step Introduction

1.2.1 TC26x B-Step Block Diagram

Figure 1 shows the block diagram of the TC26x B-Step. Please note that not all features that are shown in the block diagram are available in all TC26x B-Step package variants.

Figure 1 TC26x Block Diagram

1.3 On-Chip Debug Support (OCDS)

AURIX devices contain powerful resources for debugging and performance optimization. They provide high visibility and controllability of software, hardware and system, especially also under hard real-time constraints. The resources are either embedded in specific modules (e.g. breakpoint logic of CPUs) or part of the central CERBERUS module.

Figure 1-1 shows the AURIX family concept of the OCDS with all potentially usable pins. The same OCDS function is always on the same port pin including full DAP/JTAG functionality but the number of TGI/TGO trigger pins depends on the device type.

Trace functionality is available for TC29x with miniMCDS, for all other AURIX devices only with the associated Emulation Device (ED) with MCDS.

Figure 1-1 OCDS Block Diagram (Family Concept)

When acting as bus master CERBERUS shares the master interfaces of the DMA (using a different master tag) to access memories and SFRs attached to the SPB or SRI via the shortest possible path.

1.3.1 Feature List

Please also refer to debug specific features in other modules, e.g.

- Eight hardware breakpoints for TriCore, based on instruction or data address.
- Unlimited number of software breakpoints (DEBUG instruction).
- Trigger generated by the access to a specific bus address by any bus master
- Peripheral trigger and trace with OCDS Trigger Bus (OTGB)
 - Peripherals provide vectors (Trigger Sets) of their most interesting signals
 - Signals can be routed to trigger pins
 - Flexible tracing of signal vectors from one or two peripherals in parallel (ED)
- Dedicated interrupt resources to handle debug events, both local inside the CPUs (breakpoint trap, software interrupt) and global (triggered by CERBERUS), e.g. for implementing monitor programs

Central functions implemented by CERBERUS

- Run/stop and single-step execution independently for each CPU.
- Run/stop and time-step execution of the complete device using the Trigger Switch.
- Automatic suspension of the SCU watchdogs when the device is halted by the tool.
- All kinds of reset can be requested using only the tool interface.
- Halt-after-Reset for repeatable debug sessions.
- Tool access to all SFRs and internal memories independent of the CPUs.
- Bus priority of CERBERUS can be chosen dynamically to minimize real-time impact.
- Up to 8 package pins can be used optional as with Trigger In/Out (TGI/TGO).
- Central OCDS Trigger Switch (OTGS) with 7 independent Trigger Lines to collect debug events from various sources (all CPUs, all interrupt requesters, bus controllers, several complex peripherals, MCDS, trigger input pins) and distribute them selectively to all CPUs and trigger output pins (extension of the former Break Switch concept).
- Central Suspend Switch using up to three Lines of the Trigger Switch infrastructure. This allows to selectively suspend all or only part of the CPUs and peripherals instead of halting them as reaction to any debug event.
- Access to all OCDS resources also for the CPUs themselves for debug tools integrated into the application code.
- Triggered Transfer of data for simple variable tracing.
- A dedicated trigger bank (TRIG) with 96/512 independent status bits is provided to post requests at a central location from application code to the tool.
- The tool is notified automatically when the trigger bank is updated by any processor. No polling via a system bus is required.

Tool Interfaces

Several options exist for the communication channel between tools and TC26x B-Step:

- DAP and JTAG are clocked by the tool.
- Two pin DAP (Device Access Port) protocol for long connections or noisy environments.
- Three unidirectional pin DAP mode for off-chip transceiver integration (e.g. LVDS).
- Three pin DAP Wide Mode for high bandwidth needs.
- DAP bit clock can have any frequency up to 160 MHz.
- 15 MByte/s for block read or write, 30 MByte/s in Wide Mode
- Optimized random memory accesses (read word within 0.5 μ s at 160 MHz).
- CAN (plus software linked into the application code) for embedded purposes with lower bandwidth requirements.
- Four pin JTAG (IEEE 1149.1) for standard manufacturing tests.
- Hot attach (i.e. physical disconnect/reconnect of the host connection without reset) for all interfaces.
- Infineon standard DAS (Device Access Server) implementation for seamless, transparent and parallel tool access over any supported interface.
- Lock mechanism to prevent unauthorized tool access to application code.
- DAP over CAN Messages (DXCM) u, TC23x/22x only)

FAR Support

To efficiently locate and identify faults after integration of an AURIX device into a system special functions are available:

- Boundary Scan (IEEE 1149.1) via JTAG or DAP.
- SSCM (Single Scan Chain Mode) for structural scan testing of the chip itself.
- DXCPL (DAP over CAN Physical Layer) via CAN pins (AP32264)

1.3.2 Family Overview

The OCDS architecture and features are very consistent over the whole AURIX family. This makes it easy for tool partners and users to switch between different devices. [Table 1-1](#) lists all OCDS and the main Emulation Device differences of the devices, and [Table 1-2](#) the JTAG IDs. The associated ED step has the same JTAG ID.

Table 1-1 OCDS Differences of AURIX Devices

Feature	TC29x	TC27x	TC26x	TC24x	TC23x	TC22x/1x
TRIG triggers	512	512	512	512	96	96
DAP Over CAN Msg. (DXCM)	-	-	-	-	yes	yes
miniMCDs	yes	-	-	-	-	-
Emulation Device (ED)	9xED	7xED	6xED	(6xED)	3xED	(3xED)

Table 1-1 OCDS Differences of AURIX Devices (cont'd)

Feature	TC29x	TC27x	TC26x	TC24x	TC23x	TC22x/1x
ED packages B=BGA, Q=QFP	B 292 B 416 B 516	B 292 Q 176	Q 176 Q 144	Q 144	Q 144	Q 144
ED's TDI pin replaced by VDDPSB	-	Q 176	Q 176 Q 144	Q 144	-	-

Table 1-2 JTAG IDs of AURIX Devices

	A-Step	B-Step	C-Step	D-Step
TC29x	101E9083 _H	201E9083 _H		
TC27x	201DA083 _H	301DA083 _H	401DA083 _H	501DA083 _H

TC24x	101EA083 _H			
TC23x	10200083 _H			
TC22x	10201083 _H			
TC21x	10202083 _H			

1.3.3 Tool Interface Recommendations

AURIX devices are well supported by many tool partners for different types of tools. Standard tool interface for debug, measurement and calibration is DAP due to its reduced pin-count, higher performance (3-6x) and higher robustness (CRC) than JTAG. Please note that the full "JTAG" boundary scan functionality is also available with DAP, it is supported however only by specific tool providers. Please refer to application note AP24003 for more information about the standard DAP connector and board design for high speed DAP. [Table 1-3](#) lists all pins and considerations for connecting tools.

Table 1-3 Tool Relevant Device Pins of AURIX Family

Pins	Remark
$\overline{\text{TRST}}$	DAP: Has to be high at $\overline{\text{PORST}}$ pin release. Can be statically connected to VDDP3 (e.g. in the development phase only) with these effects: <ul style="list-style-type: none"> • Causes a static current due to pull-down element on chip • VDDSB and VDDPSB supplies need to be ensured • DXCPL is disabled JTAG: Needs to be controlled by the tool via the tool connector.
DAP0/TCK	DAP: Please consider AP24003 for high speed DAP
DAP1/TMS	
$\overline{\text{DAP2/TDO}}$ $\overline{\text{TGI3/TGO3}}$	DAP: Needed for three pin modes like high bandwidth Wide Mode. The standard DAP connector (AP24003) allows to use this pin on demand either for Wide Mode e.g. for measurement or as trigger pin for system debugging.
$\overline{\text{TDI/VDDPSB}}$ $\overline{\text{TGI2/TGO2}}$	For certain EDs in QFP packages (Table 1-1) this pin is the VDDPSB supply pin and needs to be supplied with 3.3 V (e.g. VDDP3). Please note for the “TDI is VDDPSB” case: <ul style="list-style-type: none"> • JTAG is not available for such EDs • VDDP3 connection can be hardwired. This is compatible for PD and ED, however TGI2/TGO2 is then also unavailable for the PD.
VDDSB	1.3 V supply of the ED memory. This supply can be separate of VDD if standby functionality is needed. Please consider the additional VDDSB current for your supply.
VDDPSB	3.3 V supply for the DAP pins of EDs. Can be connected to VDDP3 or supplied by the tool.
$\overline{\text{TGIx/TGOx}}$	Optional trigger pins, overlaid to port pins. Availability depends on device and package type.
AGBT_xyz	AGBT high-speed serial pins in the center ball matrix of EDs in BGA packages. Please connect to VSS if no AGBT is needed.

Note: Please ensure that VDDSB and VDDPSB are always supplied in regular operation (VDD supplied, $\overline{\text{TRST/PORST}}$ inactive) to avoid internal cross currents which can damage the ED device. For instance connect VDDSB to VDD and VDDPSB to VDDP3.

For more information please contact your Infineon support.

1.3.4 Debug Access Server (DAS)

The DAS API provides an abstraction of the physical device interface for tool access. The key paradigm of DAS is to read or write data in one or several address spaces of the target device.

DAS Features

- Standard interface for all types of tools
- Efficient and robust methods for data transfer
- Standardized system security support (authorization)
- Several independent tools can share the same physical interface
- Product chip address space is represented with DAS address map 0, EEC with 1
- Infineon's miniWiggler supports DAP, JTAG, SWD and SPD

DAS is not device specific. It can be used for all Infineon 8-, 16- and 32-bit microcontrollers with DAP, JTAG, SWD, or SPD interface. For more information please refer to www.infineon.com/DAS.

1.4 Emulation Device (ED)

The TC26xED is the Emulation Device (ED) of the TC26x Production Device (PD) and its feature-reduced derivatives. The Emulation Device comprises the unchanged Product Chip Part (SoC) and the Emulation Extension Chip (EEC) part (Figure 1-2). Both are on the same silicon. The ED is available in similar package variants as TC26x for having a single PCB with minimal overhead for supporting PD and ED.

1.4.1 Block Diagram

Figure 1-2 shows the ED block diagram. The Product Chip Part is reduced to the directly connected modules only in the drawing. On the EEC part, the AGBT module is not shown in this block diagram.

Figure 1-2 Block Diagram TC26xED

Table 1-4 TC26xED Components (Figure 1-2)

Component	Definition
AGBT	Aurora GigaBit Trace module on EEC
BBB	Back Bone Bus (same FPI protocol as SPB)
BOB	Bus Observation Block. Trace and trigger logic within MCDS
Cerberus	Central debug and tool access control unit. Includes the OTGS.
DMC	Debug Memory Controller
EBCU	Emulation/BBB Bus Control Unit
ED	Emulation Device for calibration, measurement and debug
EEC	Emulation Extension Chip (product chip part + EEC = ED)
EMEM	Emulation Memory (calibration and trace memory). Provides also together with LMU the bus bridge functionality between SRI and BBB.
FPI	Flexible Peripheral Interconnect, the protocol of SPB and BBB buses
LMU	Local Memory Unit, SRI slave for all non-core RAM
MCDS	Multi Core Debug Solution
MCX	Multi Core Cross connect
OTGM	OCDS Trigger Multiplexer. Collects interrupt and peripheral trace and trigger signals.
OTGS	OCDS Trigger Switch. Routes triggers to pins, for halt/suspend, etc.
POB	Processor Observation Block
SBCU	SPB Bus Control Unit
SoC	System on Chip (used also for “product chip part”)
SPB	System Peripheral Bus
SRI	Shared Resource Interconnect cross bar
TCM	Trace and Calibration memory part of EMEM
XTM	Extended Trace Memory part of EMEM

The Emulation Memory on the EEC is used for two conceptually different purposes: Calibration and Tracing. The size allocation for both parts can be configured in the Emulation Memory (EMEM) module.

For calibration, RAM partitions are mapped into the address ranges of the CPUs, optionally replacing parts of the TC26x’s local Flash. The feature is described in detail in the Overlay section of the TC26x manual.

Tracing on the other hand is a non intrusive tool to aid the debugging process. Matching elements from the MCDS module are provided on the EEC to translate the signals - routed there from the TC26x's CPUs and other sources - into meaningful messages. The messages are buffered and can then be uploaded to the tool via a host interface, e.g. DAP/JTAG.

1.4.2 Feature List

This section lists the features of TC26xED.

TC26xED Applications

- Software development
 - Debugging
 - Performance analysis and optimization
- Calibration
- Measurement
- Rapid prototyping

TC26xED General Features

- ED and production device have identical behavior
- ED has a package with a footprint compatible to production device
- Minimum number of ED specific pins
- Full access to the EEC part via the regular DAP/JTAG package pins
- No external emulator hardware required other than DAP/JTAG interface
- Full access to the EEC for tool software (monitor), running on TriCore, for e.g. CAN based calibration, measurement or debug
- Protection against reverse engineering by competitors and against manipulation, both for production and emulation device (field trials)
- High-speed Aurora GigaBit Trace (AGBT) interface

Emulation Memory Features

- Emulation Memory (EMEM) size is 528 KB
- EMEM has eight 64 KB TCM tiles and two 8 KB XTM tiles
- Full Emulation Memory can be used for calibration, code, constants or data storage
- Up to 512 KB can be used for trace buffering
- Continuous trace via DAP requires just the two XTM tiles (only one for AGBT)
- Support of independently operating calibration and debug tools
- FIFO functionality for continuous trace (EMEM address triggers in MCDS)
- Emulation Memory is also mapped into the address range of TriCore
- Emulation Memory can be overlaid to Flash
- Code and data fetch from Emulation Memory
- Data retention of RAM during power down by isolated standby power supply

- ECC with SECCDED (Single Error Correction, Double Error Detection)

Measurement Features

- Highly efficient SW triggering via DAP interface (TRIG)
- Fine Grained Trace Qualification (FGTQ) for trace based measurement via DAP
- Aurora GigaBit Trace (AGBT) interface for high-end trace based measurement

Debug Features

- TriCore program trace (absolute, relative, functions only)
- Continuous Compact Function Trace (CFT) via DAP
- TriCore data trace (no register file trace)
- Parallel trace of two CPUs, two SRI slaves and the SPB bus
- Full visibility of internal peripheral bus (SPB)
- Full visibility of up to two arbitrary SRI slaves
- Time aligned trace of all sources
- Trace of internal states and signals of complex peripherals
- Trace of interrupt and DMA requests and processing
- Breakpoints and watch points based on common event generation logic
- Magnitude comparators working on instruction pointers and memory addresses:
A <= IP <= B
- Masked magnitude comparators working on the data busses: DATA = "xxxx55xx"
- Sequential event logic: Counters driven by events and equipped with limit comparators are used as event sources again for breakpoint or trace qualification
- Optimized compression of buffered trace data
- Highly sophisticated complex qualification- and trigger mechanism
- Pre- and post event trace buffering ("digital oscilloscope")
- Performance counters
- Concurrent trace logging and trace data acquisition up to the bandwidth of the used host interface
- Central time stamp unit to correlate traces from different CPUs and other sources
- Halt the system or parts of it when trace memory is full
- Regular and modular structure of the control blocks and registers
- Trace debug unit power reduction modes with clock gating
- Trace data in EMEM can be decoded after unsolicited PORST
- Output of continuous trace over Aurora GigaBit Trace interface

1.4.3 Comparison to TC27xED

The TC26xED is intentionally built as close to the predecessors of the AURIX family as feasible.

Changes

- Trace Multiplexer on Product Chip Part for two instead of three CPUs
- EMEM size reduced from 1024 KB to 528 KB
- EMEM has eight 64 KB TCM tiles and two 8 KB XTM tiles
- Changed address map due to EMEM size
- Changed current consumption

1.4.4 Trace Based Measurement

Traditional trace based measurement or Data Acquisition (DAQ) requires for the device a high speed trace interface. This interface is used to output the write data and address information of all CPUs. Already for single CPU devices, this approach is a challenge, since the CPU will create ca. 64 bit data per clock cycle in case of writes. Taking into account that the CPU writes on average just every 10 to 20 cycles, this results in roughly 1 Gbit/s per CPU (Figure 1-3). In the Tool HW, this trace data is then used to create mirrored RAM(s) of the device internal RAM(s). These mirrored RAM(s) are then the basis for collecting the DAQ data at given points of time. The resulting DAQ net data rate is then in the range of Mbyte/s.

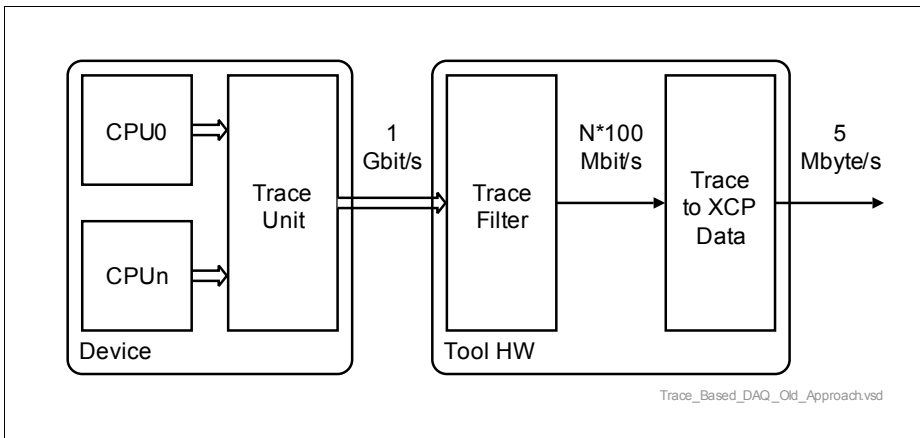

Figure 1-3 Trace Based Measurement - Traditional Approach

The basic idea for avoiding the high-bandwidth trace port is to trace only relevant CPU writes. TC26xED has for that purpose the Fine Grained Trace Qualification (FGTQ), which allows to select an arbitrary number of relevant data in RAM with 1, 2, 4, 8, 16 or 32 byte address granularity. In combination with the high DAP performance, the net XCP DAQ data rate will be up to 30 Mbyte/s. For even higher demands FGTQ can be combined with Aurora GigaBit Trace (AGBT).

Figure 1-4 Trace Based Measurement - New Approach

1.4.5 ED Design and Layout

The TC26x design is extended on top-level with the EEC part on the same silicon (**Figure 1-2**). A clear requirement and guideline from this implementation is the reuse without changes of the SoC Product Chip Part, which guarantees complete compatibility between emulation device and production device. The ED chip layout is as similar as possible to the product chip.

ED as Bare Die for Hybrid ECUs

TC26xED will be also available as bare die for mounting on ceramic hybrids. The hybrid layout needs to accommodate the enlarged die area and the shifted pads with a combi-layout.

1.4.6 Emulation System Components

1.4.6.1 Emulation Memory (EMEM)

The Emulation Memory contains RAM blocks (tiles) which can be alternatively used as Trace or Calibration Memory (TCM). The size of a tile is 64 Kbyte.

Features

- 528 Kbyte SRAM in total
- Standby power supply

- Calibration overlay block size configurable from 32 byte to 128 Kbyte
- Trace Memory size can be configured from 0 to 512 Kbyte in 64 Kbyte steps
- Two additional XTM tiles with just 8 Kbyte physical RAM each for supporting trace based measurement without reducing the Calibration Memory size
- ECC with SECDED (Single Error Correction, Double Error Detection)

1.4.6.2 Calibration Memory

The Calibration Memory uses two interfaces. One is to the Product Chip Part (LMU Interface), the other to the Backbone Bus (BBB) of the EEC.

LMU Interface

The Calibration Memory can be accessed from the Product Chip Part directly over the LMU Interface. The Calibration Memory is always accessible directly within a specific address range. Additionally read accesses to the Program Flash can be redirected to the Calibration Memory. In this overlay mode, read accesses to up to 32 different address ranges, defined by base and size, are forwarded to the Calibration Memory instead of the Flash. For further information please refer to “Data Access Overlay (OVC)”.

The overlay mechanism is limited to data accesses, code fetch is not supported. The overlay mechanism replaces the data of load/store accesses only. Note that immediate constants, embedded in the program code are not overlaid. If program code is to be executed from the Calibration Memory, it needs to be linked/located to the address range where the Calibration Memory is mapped directly.

EEC Backbone Bus Interface

- Random read and write of Calibration Memory in parallel to LMU accesses
- The accesses from the LMU interface have priority

1.4.6.3 Trace Memory

Trace Memory is operated at a much higher access rate than Calibration Memory. It is a frequent case, that trace data is recorded over a longer period with a sustained rate of more than 50% of the trace interface’s maximum bandwidth. Since power dissipation scales with the access rate and memory size, this behavior affects the maximum Trace Memory size and the ambient temperature and power supply for this mode.

Features

- Trace bandwidth max. 40 GBit/s (MCDS clock x memory bus width of 256 bits)
- Flexible trace operation modes:
 - Tracing from event
 - Tracing up to event
 - Tracing around event (buffer holds traces up to and after event)

- If more than one memory tile are allocated to tracing, the tiles currently not written can be uploaded to the emulation tool for continuous tracing. In this mode the trace buffer depth is only limited by the transfer speed of the used interface.

1.4.7 MCDS

The prime target for the EEC is to cater for the real-time tracing of the TC26x's CPUs. Nonetheless all event generating logic can be used for breakpoint generation via the central break switch as well. It should be noted that there is a certain latency using this route.

Processor Observation Block (POB) for TriCore

- 6 range comparators on the IP (fan type)
- 8 range comparators on the write or read address
- 4 masked range comparators on the data value written
- One fine grained address trigger
- Dedicated trigger inputs for TriCore's 8 OCDS L1 comparators
- Thread awareness: 2 comparators to restrict tracing to certain threads only
- Trace of data read and write address
- Trace of the data value written
- Full non-cached data access visibility with trace at SRI and SPB bus
- Watch point traces based on all before mentioned comparators
- Debug status message based on the execution mode of the CPU
- Complete program trace (absolute, relative, subroutine only)
- Dedicated programmable trace enable generator for each trace unit, using all local comparators as potential sources

Bus Observation Block (BOB) for System Peripheral Bus (SPB)

- 4 range comparators on the SPB address
- 4 masked range comparators on the SPB data bus
- 4 masked range comparators on the SPB operation code/mastership
- Watch point traces based on all before mentioned comparators
- Ownership trace (bus master) derived from bus arbiter
- Data trace with or without address information for Read and/or Write accesses
- Dedicated programmable trace enable generator for each trace unit, using all local comparators as potential sources

Bus Observation Block (BOB) for SRI Cross Connect

Two of the slaves can be observed concurrently.

- 2*4 range comparators on the SRI transaction address
- 2*4 masked range comparators on the SRI transaction data

- 2*4 masked range comparators on the SRI transaction originator (mastership)
- 2*1 fine grained address triggers
- Watch point traces based on all before mentioned comparators
- Ownership trace derived from transaction originator
- Data trace with or without address information for Read and/or Write access
- Dedicated programmable trace enable generator for each trace unit, using all local comparators as potential sources

Multi Core Cross-Connect (MCX)

- Gets 4 programmable pretrigger signals from each observation block
- One dedicated global trace enable for each trace unit
- 32 universal 16 bit counters, using programmable combinations of pretriggers as count and clear signals
- Performance counters can be configured for ca. 80 sources
- Limit comparators based on these counters, generating further pretriggers
- Global trace enables are sums of products (four multi-input ANDs ORed together)
- Global break generation based on all available pretriggers - including the counters'
- Bidirectional interface to the break switch on the Product Chip Part
- Global time stamp messages, based on emulation or reference clock.

1.4.8 DAP/JTAG based Tool Interface (IOC32)

- Uses the DAP/JTAG pins of the Product Chip Part (IO Client concept)
- Generic serial DAP/JTAG based link to access the complete address space
- Very robust, allows to debug also unfriendly systems (power down, reset etc.)
- External tool controls all transactions
- Bit clock up to 160 MHz for DAP and optional two DAP data pins in Wide Mode
- Block read and write support
- Hot attach to a running system
- Internal user software can lock the interface for security reasons

1.4.9 Aurora GigaBit Trace (AGBT)

The AGBT module outputs the MCDS trace data over a 2.5 Gbit/s differential link, which is compliant with the Aurora I/F of Xilinx FPGAs. [Figure 1-5](#) shows the block diagram of the ED with the AGBT module. The AGBT module uses an 8 Kbyte XTM tile of the EMEM as FIFO buffer, all other EMEM tiles can be used e.g. for Calibration.

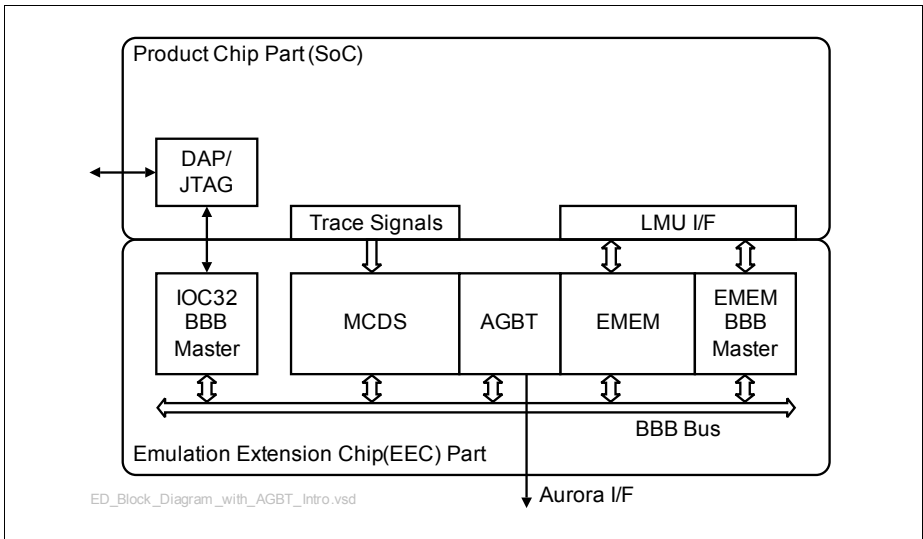

Figure 1-5 ED with AGBT Module

2 On-Chip System Buses and Bus Bridges

The TC26x B-Step has two independent on-chip buses:

- Shared Resource Interconnect (SRI)
- System Peripheral Bus (SPB)

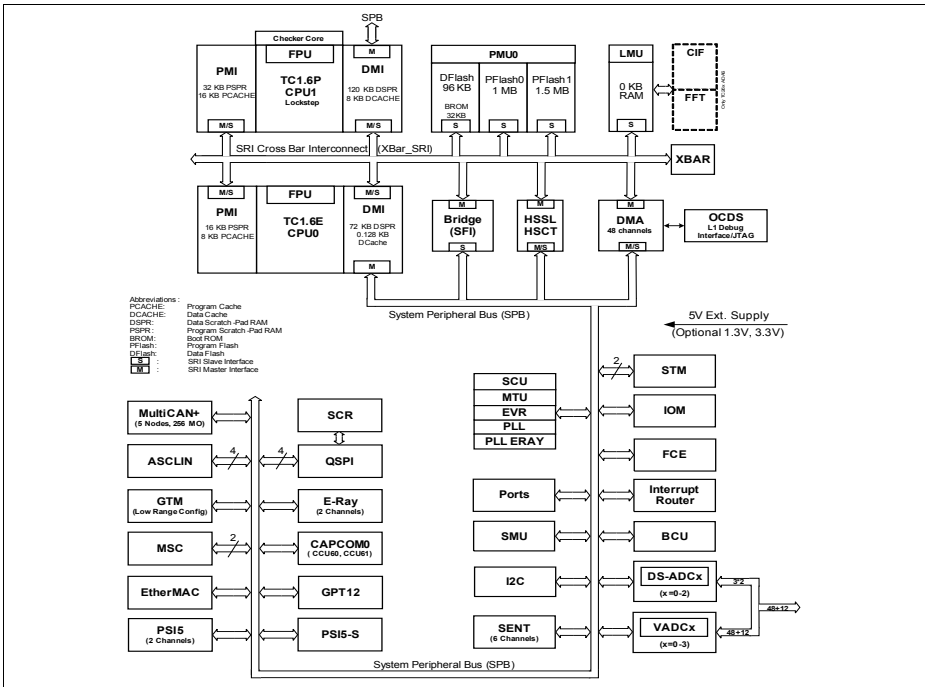

Figure 2-1 On Chip Buses in TC26x B-Step Processor Subsystem

The SRI connects the TC1.6 CPUs, the main high bandwidth peripherals and the general purpose DMA modules to its local resources for instruction fetches and data accesses.

The System Peripheral Bus connects the TC1.6 CPUs and the general purpose DMA modules to the medium and low bandwidth peripherals. The TC1.6P CPU has access to the SPB via the SRI to SPB bridge.

Note: The TC1.6 has one SRI slave interface that provides access to the TC1.6 SRAMs, SFRs and CSFRs.

On-Chip System Buses and Bus Bridges**2.1 What is new**

Major differences of the TC26x B-Step XBar Bus System architecture compared to previous TC1.6 based products:

- Empty list (this is the initial version of Aurix product)

2.2 SRI Crossbar (XBar_SRI)

2.2.1 Introduction

The Shared Resource Interconnection (SRI) is the high speed system bus for TriCore1.6.x CPU based devices. The central module of the interconnect is the XBar_SRI which connects all components in one SRI system. The XBar_SRI handles, arbitrates and forwards the communication between all connected SRI-Master and SRI-Slave peripherals.

The XBar_SRI supports parallel transaction between different SRI-Master and SRI-Slave peripherals. It supports also pipe lined requests from the SRI-Master interfaces and pipeline address phases to the connected SRI-Slave interfaces.

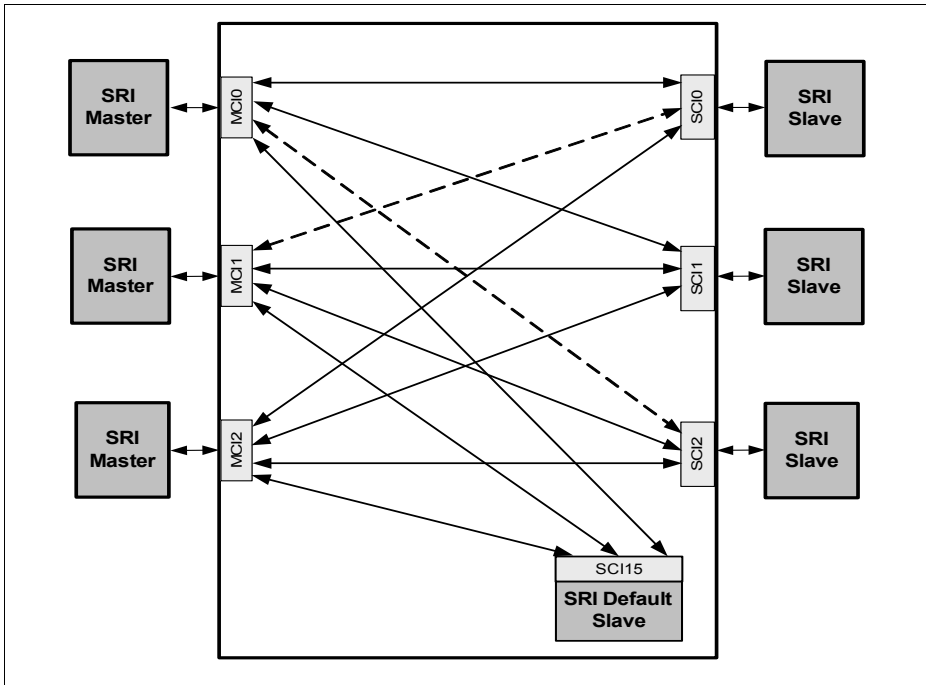

Figure 2-2 XBAR_SRI point to point connection scheme

The XBar_SRI provides SRI Slave Interfaces (SCIx) to connect SRI Slave modules and SRI Master Interfaces (MCix) to connect SRI Master models to the XBar_SRI. The XBar_SRI includes an Default SRI Slave that provides access to the XBar_SRI control

On-Chip System Buses and Bus Bridges

registers and that takes over all SRI transactions to address outside the connected SRI Slave address ranges. The XBar_SRI includes also one Arbiter module per connected SRI slave module and the infrastructure for the enabled read/write data paths. Each connected SRI slave module as well as the default slave have an related arbiter module within the XBar_SRI.

Please note that only these SRI-Master <-> SRI-Slave connections are implemented that are required for the system functionality (example: connection between PMI Master and PMI Slave is not implemented, see also [Table 2-7](#)).

For performance optimization the XBar_SRI includes arbitration schemes that allows to configure SRI master priorities for each SRI slave individually (arbiter functionality). For debug support on system level the XBar_SRI includes debug support for SRI-Error and SRI-Transaction ID errors (local SRI slave module support in the related arbiter, global control in the Default Slave) .

Table 2-1 SRI Bus Terms

Term	Description
Agent	An SRI agent is any master or slave device which is connected to the SRI Bus.
Master	An SRI master device is an SRI agent which is able to initiate transactions on the SRI.
Slave	An SRI slave device is an SRI agent which is not able to initiate transactions on the SRI. It is only able to handle operations that are dedicated to it by SRI CrossBar (XBar_SRI).
XBar_SRI	The SRI CrossBar (XBar_SRI) provides the interconnects between connected Master and Slaves. The XBar_SRI includes arbitration mechanisms and debug capabilities. The XBar_SRI has 16 Master Connection Interfaces (MCI0 - MCI15) to connect SRI master devices to it and 15 Slave Connection Interfaces (SCI0 - SCI14) to connect SRI slave devices to it.
MCI	Each Master is connected via one Master Connection Interface (MCI x, x = 0 ... 15). The XBar_SRI control registers include control and debug informations related to the Master Connection Interfaces MCI x (x = 0 ... 15).
SCI	Each Slave is connected via one Slave Connection Interface (SCI x, x = 0 ... 14). The XBar_SRI control registers include control and debug informations related to the Slave Connection Interfaces SCI x (x = 0 ... 14). The XBar_SRI default slave is connected to SCI 15.

2.2.1.1 XBar_SRI Features

XBar_SRI feature overview:

- Single/Block Data Read Transaction Support (8/16/32/64 Bit)
- Single/Block Data Write Transactions Support (8/16/32/64 Bit)
- Read Modify Write Support
- Supports pipelined requests from SRI master peripherals
- Supports pipelined address phases to SRI slave peripherals
- Single arbiter module for each connected Slave device
- Arbitration priority scheme can be configured for each Slave device individually
- Flexible arbitration schemes (priority, two round robin groups, starvation prevention)
- Breakpoint signal generation based on SRI transactions (OCDS Level 1)
- Configurable MCDS trace interface
- Information integrity support covering SRI address phase signals and the transmitted read/write data
- SRI Address Phase includes Supervisor Mode information (covered by SRI information integrity support)

2.2.2 SRI Transactions

Each SRI transaction consists of:

- one request phase
- one or multiple data phases if not finished with error acknowledge

An SRI master that is requesting for access to an SRI slave is providing all necessary informations about the transaction in parallel with the request. This means that there are no separate on chip bus request and on chip bus address phases. An SRI request/address phase consists of:

- request signal
- lock signal (indicating a read modify write transaction)
- 32-bit address
- 4-bit SRI Op-Code (kind of single data or burst transaction)
- read/write signal (read, write or read modify transaction)
- supervisor mode signal
- Transaction ID (consists of a unique 6-bit Master TAG ID and a 2 bit running number increased for each new transaction of this master)
- 8-bit address phase ECC¹⁾ (Error Correction Code covering all address phase signals with the exception of request and grant)
- one or multiple data phases if not finished with error acknowledge

1) In the current implementation the Error Correction Code is only used for error detection. Detected errors are reported to the SMU but not corrected.

On-Chip System Buses and Bus Bridges

After the request for a slave access was granted by the related XBar_SRI arbiter module, the transaction can be either finished with error acknowledge or with the read/write data phases as defined during the request/address phase.

Each data phase ends with the transmission of data phase informations including:

- Read or Write Transaction ID (must be equal to the related Transaction ID otherwise the address phase is invalid)
- 8-bit read/write data ECC¹⁾ (Error Correction Code covering the 64-bit read/write data and the bits [23:3] of the related address.
- 64 bit read or write data. In case of an 8-bit, 16-bit or 32-bit read/write transaction the unused bits are filled with 'don't care' data. The read/write data ECC¹⁾ covers the 64 data bits as transferred (including the possible don't care data).

2.2.3 SRI Op-Codes

The SRI Op-Code defines for a SRI transaction the number of data phases, the addressing mode in case of a multi beat transaction and valid bytes in case of a single data transaction.

Table 2-2 Operation Code Encoding

sri_opc[3:0]	Identifier	Description
0000	SDTB	Single Data Transfer Byte (8 bit)
0001	SDTH	Single Data Transfer Half-Word (16 bit)
0010	SDTW	Single Data Transfer Word (32 bit)
0011	SDTD	Single Data Transfer Double-Word (64 bit)
0100	-	Reserved
0101	-	Reserved
0110	-	Reserved
0111	-	Reserved
1000	BTR2	Block Transfer Request (2 transfers) Wrap Around Address Mode is used.
1001	BTR4	Block Transfer Request (4 transfers) Wrap Around Mode is used.
1010	BTRL2 ¹⁾	Block Transfer Request (2 transfers) Linear Address Mode is used.
1011	BTRL4 ¹⁾	Block Transfer Request (4 transfers) Linear Address Mode is used.
1100	-	Reserved

Table 2-2 Operation Code Encoding

sri_opc[3:0]	Identifier	Description
1101	-	Reserved
1110	-	Reserved
1111	-	Reserved

1) The SRI implementation in the TC26x B-Step does not support bursts with linear addressing modes.

2.2.4 SRI Error Conditions

The `sri_err_n` signal is used by the slave during a transaction to signal the corresponding master that an error has happened which results in an immediate termination of the current transaction. Errors during transaction are tracked by the `XBar_SRI` and are signalled to via an interrupt and directly to the SMU.

Only the following error conditions are supported and recognized by SRI slaves:

- access level is incorrect (user/supervisor)
- unmapped address access from an SRI master¹⁾
- unsupported op-code
- reserved op-code

An SRI error can be generated by the application SW e.g. with an access to a reserved address (see chapter Memory Map):

2.2.5 SRI Transaction ID Error Conditions

Transaction ID is an identifier connected to all phases of a transaction in order to make the transaction unique in the SRI system during the transactions live time.

The transaction ID is used by SRI masters and slaves to identify problems in the SRI system that results in data packets received by a master or slave that do not match the corresponding arbitration/address phase. If the read/write transaction identifier doesn't match with the previous send transaction identifier in the address phase, this is identified as a transaction ID error and tracked by the `XBar_SRI`.

In situations where at the data source side (master for write transactions, slave for read transactions) a data phase has to be invalidated (e.g. detection of an not correctable SRAM ECC error) and invalid transaction ID is send in order to invalidate the data phase.

An SRI Transaction ID error condition can be generated by injecting an non correctable error into one of the SRAMs (e.g. CPU Instruction Scratch Pad SRAM) and than reading the corrupted data by a CPU.

1) The accesses to unmapped slaves is checked by a default slave.

2.2.6 Operational Overview

This chapter describes the functionality of the XBar_SRI module in order to enable the user to configure the XBar_SRI control registers and to use the XBar_SRI debug resources.

Figure 2-3 XBAR_SRI connections between SRI Master and SRI Slaves

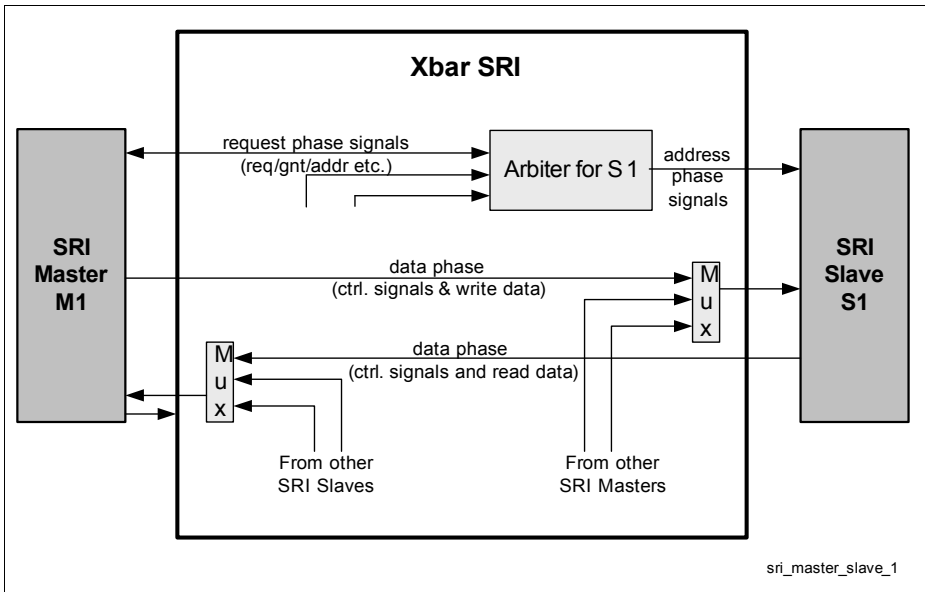

Figure 2-4 XBAR_SRI connections between SRI Slave and SRI Master modules

2.2.6.1 Functional Blocks

The XBar_SRI represents the highest level of the hierarchical SRI-Bus system. Since, it is closest to the TC1.6.xcore, peripherals critical to CPU performance can be attached to it.

The XBar_SRI module is partitioned into blocks for arbitration and data path control which are necessary for each XBar_SRI master- or slave interface and one block that covers the default slave - and debug functionality.

The XBar_SRI module can handle and process several transaction of different master in parallel if the masters requests different slaves.

XBar_SRI Master Connection Interface (MCI)

Each SRI master module in the system is mapped to one or more XBar_SRI Master Connection Interfaces (MCI). Each MCI is related within the XBAR_SRI module to a default arbitration priority and to register control bits and register control bit fields. So each SRI master in the system is mapped to an XBar_SRI internal default arbitration priority and to master related control register bits and bit fields via its MCI number (see also see also [Table 2-4](#) and [Table 2-6](#)).

On-Chip System Buses and Bus Bridges

XBar_SRI Slave Connection Interface (SCI)

Each SRI slave module in the system is mapped to one XBar_SRI Slave Connection Interfaces (SCIx). Each SCI is related within the XBAR_SRI module to one arbiter module with its arbiter module control register and to register control bits and register control bit fields related to this SCIx. So each SRI slave module in the system is mapped to an XBar_SRI internal arbiter module and to slave related control register bits and bit fields via its SCI number (see also see also [Table 2-7](#)).

XBar_SRI Arbiter

Each XBar_SRI slave connection interface is mapped to exactly one dedicated instantiation of the slave arbiter module in the XBar_SRI. This module includes all required functionality for the following tasks:

- Arbitration: the module includes all required functionality for the arbitration. This includes SRI address decoding, SRI request arbitration, SRI request starvation algorithm, SRI address phase generation and control registers for the priority of the connected master connection interfaces and an FSM to detect the end of the current SRI transaction.
- Debugging: the module tracks the SRI transactions to the dedicated slave connection interface for SRI errors. The transaction information of the first transaction where the SRI protocol error is captured in arbiter internal control registers. The module tracks the requests from all masters to detect starvation of masters in the arbitration rounds.
- Error signalling: The first SRI error or starvation error is signalled to the default slave module via two sideband signals.
- XBar_SRI control bus interface: the module has a slave interface to the XBar_SRI control bus. The slave arbiter decodes the address of each new control bus transaction and, if addressed, processes the read/write transaction to the module internal control registers.

Default Slave

The XBar_SRI default slave module is a XBar_SRI internal SRI slave module with its own, dedicated arbiter module inside the XBar_SRI. For accesses to the XBar_SRI control registers only SRI single data transactions of word size are supported. Other SRI op-codes are not supported by the default slave module and acknowledged with an error. The default slave module includes all required functionality for the following tasks:

- As a SRI default slave, it deals with all transactions that are directed to a nonexisting slave in the SRI system as it is described in the SRI protocol. The purpose of the SRI default slave in that situation is to guarantee a defined behavior by terminating these SRI transactions with an error.
- The XBar_SRI default slave module is the SRI interface to all XBar_SRI internal diagnostic- and control registers.

On-Chip System Buses and Bus Bridges

- The XBar_SRI default slave module samples the mci_id_err_n and sci_id_err_n signals from all XBar_SRI master and slave connection interface modules. If the default slave module detects mci_id_err_n and sci_id_err_n pulses it generates an interrupt to the system. The sampling of each mci_id_err_n and sci_id_err_n signal from an arbiter can be disabled via the default slave interrupt control register IDINTEN.
- The XBar_SRI default slave module includes the interrupt node control structure and the corresponding control register.

2.2.7 Functional Overview

2.2.7.1 Arbitration Block

The arbiter has access to all arbitration-/address phase signals from the master connector interfaces he is enabled for, therefore he sees requests from all master connector interfaces in parallel.

In order to check if a master request is addressed to 'its' slave connector interface for the next transaction the arbiter checks if the address transmitted together with the request from the master matches with the allocated address area of this slave via address decoding. Due to the fact that a master can access any slave for a transaction all arbiters of the XBar_SRI are checking the requested address from a requesting master in parallel.

Due to the fact that multiple masters can request for one slave in parallel, each slave has to decode the addresses from all the master connector interfaces it is enabled for in parallel.

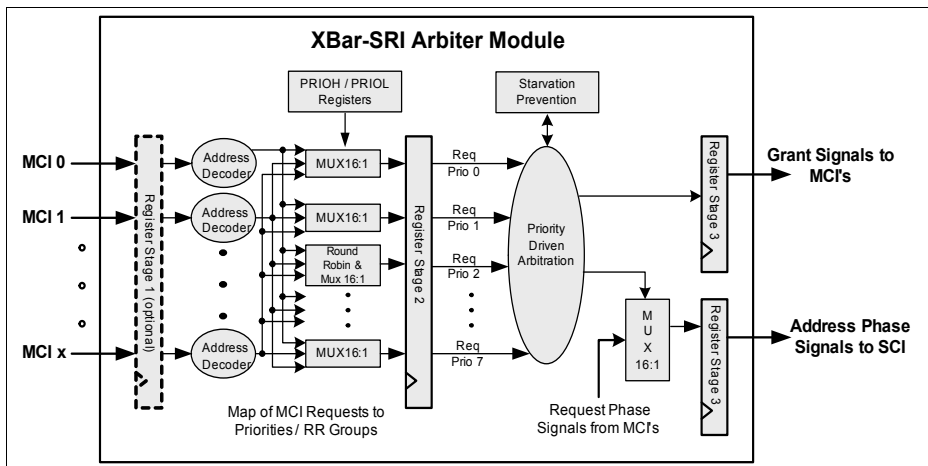

Figure 2-5 XBAR_SRI arbiter scheme

Address Map Checking

The arbiter performs the address comparison for all pending requests from the connected SRI master modules to its slave module in parallel.

On-Chip System Buses and Bus Bridges

Arbitration

A transaction request from a master that matches the address area of a slave connection interface takes part in the next arbitration cycle.

The arbitration is divided into two levels:

- priority driven arbitration
- arbitration within round robin groups (priority 2 and 5)

After reset all enabled master connector interface are mapped to the priorities 2 or 5 (also see also [Table 2-4](#)). The priorities and the priority algorithm of the master connection interfaces can be programmed for each arbiter individually. The programming of the master priorities can be done by SRI read/write transaction via the default slave module.

The highest priority for an arbiter is 0 and the lowest is 7.

According to the transaction rules described in the SRI protocol specification the arbiter asserts the `sri_gnt_x` signal to grant the slave to this winning master.

In parallel - or after granting the master, the arbiter sends the address phase for the next transaction to the slave by propagating all necessary informations via the slave connection interface to the slave. The arbiter sends the address phase in parallel with the grant or delayed depending on the address phase pipeline status of the corresponding SRI slave.

For debug purposes, the arbiter samples all necessary transaction informations and provides them to the `XBar_SRI` default slave module if an SRI error happened and the protocol error feature was enabled.

Arbitration Algorithms

The arbiter related to a slave connection interface (SCI) can be connected to all master connection interfaces (MCI), see also [Chapter 2.2.8.3](#). The priority of each MCI can be controlled via the arbiter priority registers (PRIOx). The priority of a master is defined by 3 bit field in the `PRIOL / PRIOH` register that is related to this master / its MCI number. This can be configured individually for each arbiter so the same master can be handled with different priorities for accesses to different slaves. After reset all enabled MCI are configured with the priority 2 or 5 (Round Robin group).

Please Note:

It must be ensured that two enabled masters don't have the same priority, with the exception of priority 2 and priority 5 (round robin group priorities).

For changing the priorities during runtime (switching the priorities), all master connection interfaces that should be remapped have to be mapped to the round robin group priorities (2 / 5) before mapping them to their new priorities can be done. This will prevent situations where two masters have the same priority but not a round robin one.

On-Chip System Buses and Bus Bridges
Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 7 the lowest one. If multiple masters are requesting for one slave, the master with the highest priority will win the next arbitration round (see also 'starvation prevention').

Round Robin Groups

The arbiter arbitrates in general priority driven, where Priority 2 and priority 5 contain a second 'arbitration' layer. Both priorities can be used as round robin priorities for a group of max. 8 MCI's each. If only one master is mapped to a round robin group priority, the master's request will be treated as normal master request with the priority of the round robin group. If more than one master is mapped to the priority of a round robin group, the requests of the mapped masters will be handled by the round robin algorithm, the winning request of the round robin group arbitration has the priority of the round robin group within the priority driven arbitration.

After the winner of a round robin group is granted, the round robin group starts with a new arbitration round which means the requesting MCI's of the round robin group with the next highest MCI ID number will win the next round robin arbitration round. If there is no requesting MCI with a higher ID number in the round robin group, the algorithm will start with the MCI with the lowest MCI ID number that is mapped to the group, going to the next higher MCI ID number and so on.

Request Latency

If no other request is pending, a request from an MCI has a latency of 1 clock cycle, starting with the detection of the SRI master request on the bus, ending with the SRI grant to the requesting MCI and the SRI address phase to the addressed SCI.

Table 2-3 XBar_SRI Request Latency

Clock Cycle Nr.:	Task(s)
0 (Default Slave)	sri_req_n is sampled at XBar_SRI MCI (Only valid for access to the XBar_SRI control registers)
1	address decoding, mapping of MCI's to priorities / round robin groups and starvation prevention. Round robin arbitrations, priority driven arbitration, mux request phase signals to the address phase registers masking sri_req_n from MCIX after granting the MCIX
2	sri_gnt_n to the requesting MCI, SRI address phase to SCI.

Grant -> New Request Latency (Request Dead Time)

After an MCI was granted, it takes 2 clock cycles before a new request from the same MCI will participate in a new arbitration round even when the SRI master has requested

On-Chip System Buses and Bus Bridges

permanently. This request dead time is a result of the synchronous sri_req_n de-assertion and the XBar_SRI request latency.

Default MCI x Priorities after Reset

After Reset all Master Connection interfaces are mapped to the round robin groups (priority 2 and 5, lower number means higher priority). [Table 2-4](#) shows the default priority of the MCI with the related coding in the XBAR_PRIOH and XBAR_PRIOL registers. After reset, the priority scheme of the MCIs can be re-configured via the XBAR_PRIOH and XBAR_PRIOL registers, for each SCI (accesses to the Slave connected to an SCI) individually. See also [Chapter 2.2.8.1](#),

Note: If multiple CPUs are connected to the Aurix_Bus it is proposed to give the CPU master interfaces (DMI and PMI) the same round robin priority, e.g. 5. This ensures a fair arbitration between CPU access conflicts to the same on chip resource, e.g. Flash.

Table 2-4 Default MCI Priority in the XBar_SRI Arbiters

Priority	Coding	Round Robin Group	Default Mapping:	Comments
0	000	-	-	
1	001	-	-	
2	010	Yes, max 8 master	MCI 0-7	Maximal 8 MCI can be mapped to the priority 2 e.g. can have the priority '010'.
3	011	-	-	
4	100	-	-	
5	101	Yes, max. 8 master	MCI 8-15	Maximal 8 MCI can be mapped to the priority 8 e.g. can have the priority '101'.
6	110	-	-	
7	111	-	-	

Starvation Prevention

Starvation can occur when masters with high priority continuously request a dedicated slave, preventing other masters with lower priority from getting access to this slave. To prevent such a situation, a starvation counter has been implemented in each arbiter. This mechanism allows the promotion of weak masters.

On-Chip System Buses and Bus Bridges

Each time the starvation counter in a slave module has an underflow, all pending requests to this arbiter will be entered in the arbiter's request list. This even applies to all masters mapped to a round robin group.

Next time when the starvation counter has an underflow, the masters of this request list will be entered in the arbiter's request promotion list if:

- The request was not granted during the last starvation period

The masters in that request promotion list will be the next to be granted independent of their priorities. The masters in the request promotion list will be granted one after the other, starting with the master which has the lowest MCI number in this list if there are more than one. The master promotion list has the highest priority within the arbiter's main arbitration algorithm, therefore all masters in the promotion list will be granted before the arbiter switches back to its 'normal' arbitration. A master is removed from both lists when it is granted.

If several masters are mapped to a round robin priority, all masters of that round robin arbitration round will be entered in the request list/request promotion list when not granted.

The value controlling the counter period is programmable. After reset the starvation counter has a value of zero. On a starvation counter underflow it is reloaded with the content of the arbiter control register ARBCON.SPC. An underflow occurs in the clock cycle when the counter tries to count down from zero.

The number of arbitration cycles a master must wait for the slave varies. But it's guaranteed to be no more than $2 \times \text{ARBCON.SPC}$ until the master is promoted to the request promotion list.

Each time there is an underflow it is checked if there are any masters in the request promotion list that were not granted since the last underflow. This can happen if there are too many/too long transactions to be promoted compared to ARBCON.SPC value. In this case an error is generated via the `xcb_sc_err_n` signal to the default slave if the feature was enabled (bit ARBCONx.SCERREN set).

If currently a RMW transaction is processed the starvation counter is stopped before the next overflow. The starvation counter is released again after the address phase of the write part is generated or an error for the RMW transaction was received.

If currently a Read-Modify-Write (RMW) transaction is processed by the slave the starvation protection counter is stopped until this RMW is finished.

2.2.7.2 Default Slave

The default slave serves three features in the XBar_SRI implementation:

On-Chip System Buses and Bus Bridges

Control and Configuration Registers Interface

The XBar_SRI default slave module handles all read and write transactions to the debug- and control registers of the XBar_SRI. For this purpose, the default slave module has its own address space which must be mapped into the system address space by an address decoder, provided by the customer.

For a detailed description of the registers see [Chapter 2.2.9](#).

Non Existing Addresses

The XBar_SRI internal default slave module has its own arbiter module.

If an SRI master sends a request with a non existing address¹⁾ to the XBar_SRI, the transaction will be directed to the default slave. The default slave finishes the transaction with error following the SRI protocol rules, which activates the error tracking mechanism of the arbiter. As a result of the error, the default slave module signals this incorrect behavior to the system by generating an interrupt.

A write from an SRI master to a non existing address on the System Peripheral Bus (SPB) will be handled by the Bus Control Unit on the SPB only. A read from an SRI master to a non existing address on the SPB will be handled by the by the Bus Control Unit on the SPB and also captured by the XBar_SRI arbiter as it will see the transaction as read transaction finished with Error Acknowledge.

Error Handling

If an arbiter detects an SRI protocol error during a transaction with a corresponding slave the involved arbiter samples all relevant information of the transaction in the arbiter internal diagnostic registers (ERRADDRx and ERRx) and signals this event via `xcb_sri_err_n` or `xcb_sri_err_d_n` sideband signal to the default slave module.

Note: The two error registers ERRx and ERRADDRx in each arbiter are updated with the content of the currently processed transaction in the data phase. The registers are only updated if they are not locked due to a pending protocol error and `sri_ready_n` was asserted in parallel with `sri_err_n` deasserted.

The error capture registers in the arbiter can't be changed until the interrupt was acknowledged to the slave arbiter module (set the ARBCON.INTACK) via the default slave.

The stored informations can be read from the default slave module with SRI single data read transactions, the acknowledge can be sent to the default slave via a write to a specific address.

1) non existing address = all Reserved address ranges described in the Memory Map chapter

On-Chip System Buses and Bus Bridges

This can result in a loss of interrupt data information of the same source beyond the first until the write was processed but as all SRI errors must be analyzed and fixed before the product will work, these kind of errors can be analyzed one after the other.

In case that a master or a slave signals an ID error to the XBar_SRI the default slave marks the source of the ID error by setting the according bit in register IDINTSAT if this feature was enabled for that specific master and/or slave interface.

As a result, the default slave generates an interrupt to the system.

Note: While a status bit for a error source is set in either the INTSAT or IDINTSAT register a new error from this particular source doesn't generate a new interrupt.

1. *Each participant in the SRI-Bus system has three interrupt sources; protocol errors, ID errors and time-out due to starvation. All error from the SRI-Bus components are combined in the single SRN of the XBar_SRI.*

Each arbiter has two 32 bit registers containing the error information. This registers are accessed as all other registers, via the default slave module.

The default slave module has one service request node (SRN) to start interrupts for detected SRI errors. Protocol errors, starvation errors as well as ID errors are handled together by this node.

2.2.7.3 Register Access Protection

The XBar_SRI registers are protected by a master TAG ID based access protection mechanism. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be use to identify the master of an on chip bus transaction.

Access Enable:

TAG ID based protection means that on chip bus write access to the XBar_SRI control registers can be disabled for each master TAG ID individually (with the exception of the Access Enable registers itself, which is Safety Endinit protected). For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed.

Access Enable Registers (XBAR_ACCEN1/0):

-> defines which master TAG ID is allowed to write to XBar_SRI control registers

-> are Safe Endinit write protected

The Access Enable registers (XBAR_ACCEN1/0) are Safe Endinit protected. The Safe Endinit system status is defined by a Watchdog Unit in the System Control Unit (SCU)

On-Chip System Buses and Bus Bridges

After reset, all XBAR_ACCEN1/0 access enable bits and access control bits are enabled, access protection mechanism has to be configured and checked to bring the system in a safe state.

Figure 2-6 XBar_SRI: Control Register Access Protection scheme

2.2.7.4 SRI ECC Error Handling

The SRI protocol provides information integrity support covering:

- The address phase of an SRI transaction
- The transmitted read and write data

The integrity support mechanism is using Error Correction Code (ECC).

Note: In the current implementation the Error Correction Code (ECC) is only used for error detection. Detected errors are reported to the SMU but not corrected.

Detected SRI address phase ECC errors:

- If an SRI slave detects an SRI address phase ECC error it finishes the transaction with SRI error acknowledge and does not further process it (see also [Chapter 2.2.7.5](#)). Error is signalled to the SMU.

Detected SRI read data ECC errors:

- PMI and DMI: a bus error trap will be generated but only if and when a received 64 bit read data is really used by the CPU. This as PMI / DMI can read complete cache lines (4x64 bit) where the critical 64 bit is used, the other 3 x 64 bit are speculative reads and might not be used by the CPU later.
- DMA: the DMA ignores read data ECC errors but signals the error to the SMU.
- SFI: the SFI SRI master ignores read data ECC errors but signals the error to the SMU

Detected SRI write data ECC errors:

- An detected write data ECC error is signalled to the SMU

On-Chip System Buses and Bus Bridges

- SFI: the SFI slave ignores the write data ECC errors but signals the error to the SMU
- SRI write data ECC errors to SRAMs will not be executed by the related slave modules.

It can happen that a data during a transaction shows an ECC error inside the data source peripheral (master during write, slave during read). Example: A burst read transaction from a memory slave peripheral where the second, third or fourth data taken from the SRAM shows inside the slave/master an ECC error. In this situation a slave can finish a read transaction with error acknowledge (if the error is detected before the first data phase) or a slave / master can invalidate the related data phase with an invalid read / write transaction ID error (see also [Chapter 2.2.7.5](#)).

ECC Code

The ECC codes used for the IR Error Detection mechanism is a Hsiao 22_5 code with DED (double error detection) capability:

- SRI Address Phase informations are protected by the 64_8 code
- SRI Read / Write data are protected by the 96_8 code

```

2.2.7.5 Error Tracking Capability

The XBar_SRI tracks all SRI transactions for SRI protocol errors. Additionally it tracks informations about starvation errors and SRI transaction ID errors. This is done by all arbiters and the default slave in parallel as the XBar_SRI supports the processing of multiple transactions from master and slaves in parallel which can result in parallel events at different slave connector interfaces.

For this purpose, each arbiter has two error/debug registers where it samples the transaction informations of the transaction where the first protocol error happened.

Note: Protocol errors and debug trigger events can lock the error/debug registers. Only the first event of both sources can lock the registers. All other events are not captured with this two error/debug registers unless the lock was released in the meantime.

Further protocol errors will be ignored by an arbiter that has detected an protocol error until the tracking mechanism is re-activated via the arbiter internal control register. A detected protocol error or starvation error is signalled by the arbiter to the default slave module via two separate sideband signals for SRI- and starvation error. The default slave samples the sideband signals pulses in an error status register INTSAT. As each slave has its own sideband signals, the default slave has the information which arbiter has detected an SRI protocol or starvation error. Each error signal can be masked individually by control registers in the arbiter modules. All debug registers are accessible via the SRI-Bus interface of the default slave.

For transaction ID errors of write transactions the SCI propagates the sci_id_err_n signal via the sri_wr_tr_id_err signal from the slave to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

For transaction ID error of read transactions the MCIs propagate the sri_id_err_n signal via the sri_rd_tr_id_err signal from the master to the default slave module. The default slave sets the assigned bit in register IDINTSAT.

On-Chip System Buses and Bus Bridges

Once an error was signalled from an arbiter or an MCI/SCI to the default slave, the default slave module sends an interrupt request to the system. The system can read out the error status registers in the default slave module to find out which arbiter(s) or master/slave have detected an error, then the system can start with more detailed diagnostics by reading out the error/debug registers in the arbiter for a protocol error. The error informations captured for an SRI protocol error allows the identification of the master via the sampled master tag ID and the final destination via the sampled target address. Additionally the arbiter samples the op-code and the sri_rd_n, sri_wr_n and sri_svm control signals of the transaction.

In addition to the SRI transaction information, the XBar_SRI captures sideband signal informations (**XBAR_ERRx (x = 0-1)**.MCI_SBS and **XBAR_ERRD**.MCI_SBS). In the TC26x B-Step these sideband signals are used by the DMA SRI master interface to provide informations about the requestor of a transaction, in parallel to the SRI request phase. **Table 2-5** shows the encoding of the MCI_SBS bit field for the encoding of the TC26x B-Step.

Table 2-5 Encoding of ERRx.MCI_SBS in the TC26x B-Step

MCI_SBS[7:0]	Bit field encoding
MCI_SBS[7:0]	<p>This bit field is only valid if the master TAG ID of the address phases is related to one of the DMA hardware resource groups.</p> <p>MCI_SBS[7:0] is showing the number of the DMA channel that initiated the transaction.</p>

After reading all relevant error informations, the error/debug tracking mechanism can be reactivated.

2.2.7.6 Debug Trigger Event Generation (OCDS Level 1)

This functionality can be used to generate breakpoints on selectable and configurable events in the SRI-Bus traffic.

The debug trigger event generation is controlled via the three debug registers DBCON, DBADD and DBMADD and the three status registers DBSAT, ERR and ERRADDR.

All DBXXX registers reset only with the debug reset (Class 1 reset).

The register DBSAT collects all debug trigger events from all arbiters in the XBar_SRI module. When an arbiter generates a debug trigger event the according bit in register DBSAT is set.

The DBCON register defines the debug trigger event conditions for each arbiter individually. Several individual break conditions can be combined by enabling them in parallel. Possible break conditions are:

- Write transactions

On-Chip System Buses and Bus Bridges

- If bit `DBCON.WREN` is set only transactions with an asserted `sri_wr_n` signal can generate a debug event.

Note: Only if `DBCON.WREN` and `DBCON.RDEN` are set together a RMW transaction generate a debug trigger event.

- Read transactions
 - If bit `DBCON.RDEN` is set only transactions with an asserted `sri_rd_n` signal can generate a debug event.

Note: Only if `DBCON.WREN` and `DBCON.RDEN` are set together a RMW transaction generate a debug trigger event.

- Supervisor mode transactions
 - If bit `DBCON.SVMEN` is set only transactions with an asserted `sri_svm` signal can generate a debug event.
- Transactions from a dedicated master
 - If bit `DBCON.MASEN` is set only transactions initiated by master `DBCON.MASTER` can generate a debug event.
- Transactions accessing a defined address area
 - If bit `DBCON.ADDEN` is set only transactions accessing an address in the selected address area can generate a debug event. The selected address area is defined by the registers `DBADD` and `DBMADD`. Register `DBADD` defines one global 32-bit address that is compared with `sri_addr[31:0]` for all bits where `DBMADDR` is set to '1'.

All enabled debug trigger conditions are combined by a logical AND.

Example: If `DBCON.WREN` and `DBCON.SVMEN` are set and all other enables are cleared a debug trigger event is only generated for a write transaction operating in the supervisor mode.

Additionally a debug trigger event is generated if `DBCON.ERREN` is set and an error occurs. Please note that an error occurs only when the generation for this source is enabled in the linked registers `ARBCON` or `IDINTEN`.

The result of the logical AND of the first five debug trigger event options is combined with the result of the error debug trigger event by a logical OR.

A debug event is signaled to the default slave. The default slave combines all `XBar_SRI` arbiter debug event signals with its own and generates the debug event signal that is sent to the OTGM module.

The debug event signal to the OTGM will be asserted for as long at least one condition inside an `XBar` module or the `XBar` default slave module is met.

Debug Trigger events inside the `XBar_SRI` are sampled in the register `DBSAT`. Additionally an interrupt can be generated for debug trigger events by the `XBar_SRI`.

When debug condition is reached in one of the `XBar_SRI` arbiter modules, informations of the transaction that matched to the debug condition is captured in the two error/debug

On-Chip System Buses and Bus Bridges

capture registers ERRx and ERRADDRx. If the two registers are already locked due to an earlier action the capturing is not performed.

Writing to DBCON.REARM will rearm the feature, this also sets DBCON.ARM.

2.2.7.7 Interrupt and Debug Events of the XBar_SRI Module

There are some interactions between interrupt them self and debug events. In general due to the nature of the crossbar concept several interrupts from the same or a different source (arbiter, MCI or SCI) can occur. One interrupt could occur several times before a service request routine is initiate. Additionally can all interrupts occur in parallel to one or more debug trigger events.

All following examples assume a time interval without any acknowledge either from a service routine or a debug routine and all consecutive interrupts/events come from the same source.

Two Consecutive Protocol Errors

The first protocol error is captured as normal together with a generation of an interrupt to the system. The second protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Two Consecutive Starvation Errors

The first starvation error generate an interrupt to the system. The second starvation error will not generate an interrupt to the system.

Two Consecutive Transaction ID Errors

The first transaction ID error generate an interrupt to the system. The second transaction ID error will not generate an interrupt to the system.

Two Consecutive Debug Trigger Events

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The second debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated.

Protocol Error followed by a Debug Trigger Event

The first protocol error is captured as normal together with a generation of an interrupt to the system. The later debug trigger event is not captured as the two registers ERR and ERRADD are already locked and a debug trigger event signal is generated to the system.

On-Chip System Buses and Bus Bridges

Debug Trigger Event followed by a Protocol Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later protocol error is not captured as the two registers ERR and ERRADD are already locked and no interrupt is generated.

Starvation/Transaction ID Error followed by a Debug Trigger Event

The first starvation/transaction ID error generate an interrupt to the system. The later debug trigger event is captured to the two registers ERR and ERRADD and a debug trigger event signal is generated to the system.

Debug Trigger Event followed by a Starvation/Transaction ID Error

The first debug trigger event is captured as normal together with a generation of debug trigger event signal to the system. The later starvation/transaction ID error generates an interrupt to the system.

Releasing the Lock from registers ERR and ERRADD

If the ERR and ERRADD registers are locked only from one even only (protocol error or debug trigger event) the lock can be releasing by:

- Writing a one to ARBCONx.INTACK when the registers are locked by a protocol error
- Writing a one to DBCONx.REARM when the registers are locked by a debug trigger event

If both, a protocol error and a debug trigger event occurred since the lock was released the last time both locks have to be released

- Writing a one to DBCONx.REARM AND Writing and to ARBCONx.INTACK when the registers are locked by a debug trigger event AND a protocol error

2.2.8 Implementation of the Cross Bar (XBar_SRI) in the TC26x B-Step

This chapter describes the SRI Interconnect implementation in the TC26x B-Step. The knowledge of the specific implementation (e.g. the connection of the SRI master / slave devices to the Interconnect) is necessary in order to:

- map error informations to the connected slave devices
- define the arbitration scheme for accesses to the connected slave devices
- map XBar_SRI (arbiter) control registers to connected slave devices

This chapter includes three tables that are describing: the relationship (mapping) of

- the relationship (mapping) of TC26x B-Step SRI master devices to the XBar_SRI Master Connection Interfaces MCI 0 - MCI 15 ([Table 2-6](#))
- the relationship (mapping) of TC26x B-Step SRI slave devices to the XBar_SRI Slave Connection Interfaces SCI 0 - SCI 15 ([Table 2-7](#))

On-Chip System Buses and Bus Bridges

- the point to point connections between TC26x B-Step SRI master and slave devices ([Table 2-7](#))

2.2.8.1 Mapping of SRI Master Modules to XBar_SRI Master Interfaces

[Table 2-6](#) shows the mapping of master devices to the XBar_SRI Master Interfaces (MCI 0 - MCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC26x B-Step SRI master device relates to which XBar_SRI Slave Interface.

Example 1:

The XBar_SRI includes error registers where each MCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI's an error situation occurred (e.g. [XBAR_IDINTSAT](#)).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes a four bit field where the priority requests from connected MCI can be defined. If the access priority of the DMI SRI master to one SRI slave device has to be changed, this can be done via the bit field related to MCI 4 in the arbiter control register related to this SRI slave (control registers: XBAR_PRIOHx, XBAR_PRIOLx, XBAR_PRIODx).

Table 2-6 Mapping of TC26x B-Step SRI master devices to MCI

XBar_SRI Master Connection Interface	MCI Number	Priority after Reset	Connected SRI master device
MCI 0	0	2	DMA
MCI 1	1	-	-
MCI 2	2	-	-
MCI 3	3	-	-
MCI 4	4	2	HSSL
MCI 5	5	2	SFI (ETH access to SRI)
MCI 6	6	2	-
MCI 7	7	-	-
MCI 8	8	5	CPU1.DMI
MCI 9	9	5	CPU1.PMI
MCI 10	10	-	-
MCI 11	11	-	-

On-Chip System Buses and Bus Bridges
Table 2-6 Mapping of TC26x B-Step SRI master devices to MCI

XBar_SRI Master Connection Interface	MCI Number	Priority after Reset	Connected SRI master device
MCI 12	12	5	CPU0.DMI
MCI 13	13	5	CPU0.PMI
MCI 14- MCI 15	14-15	-	-

Note: If multiple CPUs are connected to the Aurix_Bus it is proposed to give the CPU master interfaces (DMI and PMI) the same round robin priority, e.g. 5. This ensures a fair arbitration between CPU access conflicts to the same on chip resource, e.g. Flash.

2.2.8.2 Mapping of SRI Slave modules to XBar_SRI Slave Interfaces

Table 2-7 shows the mapping of slave modules to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15). Most of the XBar_SRI control registers are related to the XBar_SRI Slave Interfaces (SCI 0 - SCI 15) or the XBar_SRI Master Interfaces. Therefore it is important to know which TC26x B-Step SRI slave device relates to which XBar_SRI Slave Interface or arbiter module.

Example 1:

The XBar_SRI includes error registers where each SCI is represented with 1 bit, showing if during the transfers requested by the master devices connected to the MCI's an error situation occurred (e.g. **XBAR_DBSAT**, **XBAR_IDINTSAT**, **XBAR_IDINTEN**).

Example 2:

The XBar_SRI includes one arbiter module per connected SRI slave device. Each arbiter module includes error capturing resources and breakpoint capabilities. These can be used e.g. to analyze accesses to the connected slave device that were answered with error acknowledge by the slave device (e.g. **XBAR_ERRx (x = 0-1)**, **XBAR_ERRADDRD**).

Table 2-7 Mapping of TC26x B-Step SRI slave devices to SCI

XBar_SRI Slave Connection Interface (SCI)	Connected SRI master device

2.2.8.4 Connection Master-Slave in XBar_SRI

On-Chip System Buses and Bus Bridges

As the SRI-Bus protocol is a point to point based bus implementation multiplexer inside the data paths in front of the MCIs and arbiter/SCIs are required (see [Figure 2-3](#) and [Figure 2-4](#)).

The write data path multiplexer in front of the SCIs are controlled by the related arbiter modules. The read data path multiplexers in front of the MCIs are controlled by all arbiters.

Master - and Slave side MUX

During an SRI transaction, the corresponding arbiter has to establish the data path connection from his slave connection interface to the corresponding master connection interface in order to enable the master to receive the SCI control signals , if it is a read transaction the read data, send by the slave.

On-Chip System Buses and Bus Bridges

2.2.9 SRI Crossbar Registers

Figure 2-8 and Table 2-8 are showing the address maps with all registers of the SRI Crossbar (XBar_SRI) module.

1) The absolute register address is calculated as follows:
Module Base Address ([Table 2-9](#)) + Offset Address (shown in this column)

2) This register is located inside the default slave

On-Chip System Buses and Bus Bridges
2.2.9.1 TC26x B-Step Control Registers

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the LBCU module.

XBAR_ID

Module Identification Register (408_H) **Reset Value: 0004 D0XX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. The value for the LBCU module is 000F _H .

On-Chip System Buses and Bus Bridges

XBAR_DBSAT
Debug Trigger Event Status Register (40C_H)
Reset Value: 0000 0000_H

Arbiter Priority Register D (00C_H) Reset Value: 0022 0002_H
XBAR_PRIOLx (x = 0-1)
Arbiter Priority Register x (04C_H+x*40_H) Reset Value: 0022 0002_H
XBAR_PRIOL4
Arbiter Priority Register 4 (14C_H) Reset Value: 0022 0002_H
XBAR_PRIOLx (x = 6-8)
Arbiter Priority Register x (04C_H+x*40_H) Reset Value: 0022 0002_H

Field	Bits	Type	Description
MASTER0	[2:0]	rw	Master 0 Priority (Priority of DMA access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
MASTER4	[18:16]	rw	Master 4 Priority (Priority of HSSL access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
MASTER5	[22:20]	rw	Master 5 Priority (Priority of SFI access) This bit field contains the master priority for the arbitration used by the arbiter of slave x. For each master a unique number for this slave has to be used. A lower number has a higher priority in the arbitration round than a higher one.
0	[31:23], [15:3], 19	r	Reserved Read as 0; should be written with 0.

Note: Only the bits assigned to configured MCIs are implemented. Bits for non configured SCIs are treated as reserved bits.

Note: The 'D' at XBAR_PRIOLD stands for Default Slave.

Note: Reset values for bits/bit fields coupled to masters or slaves that are not configured or enabled are zero.

On-Chip System Buses and Bus Bridges

XBAR_ERRADDRD	Error/Debug Address Capture Register D(010 _H)	Reset Value: 7000 0000 _H
XBAR_ERRADDR0	Error/Debug Address Capture Register 0(050 _H)	Reset Value: 6000 0000 _H
XBAR_ERRADDR1	Error/Debug Address Capture Register 1(090 _H)	Reset Value: 5000 0000 _H
XBAR_ERRADDR4	Error/Debug Address Capture Register 4(150 _H)	Reset Value: 8000 0000 _H
XBAR_ERRADDR6	Error/Debug Address Capture Register 6(1D0 _H)	Reset Value: 8800 0000 _H
XBAR_ERRADDR7	Error/Debug Address Capture Register 7(210 _H)	Reset Value: 8020 0000 _H
XBAR_ERRADDR8	Error/Debug Address Capture Register 8(250 _H)	Reset Value: 8040 0000 _H

Field	Bits	Type	Description
ADDR	[31:0]	rh	Transaction Address This bifield contains the address of the erroneous transaction from the address phase

Note: The default value can differ from the one shown here because a constant can be used to reduce the number of compared bits in the arbitration if a slave occupies only a limited address area. For more details see the design specification of the XBar_SRI.

Note: The 'D' at XBAR_ERRADDRD stands for Default Slave.

On-Chip System Buses and Bus Bridges

XBAR_ERRx (x = 0-1)		
Error/Debug Capture Register x	(054_H+x*40_H)	Reset Value: 0000 0000_H
XBAR_ERR4		
Error/Debug Capture Register 4	(154_H)	Reset Value: 0000 0000_H
XBAR_ERRx (x = 6-8)		
Error/Debug Capture Register x	(054_H+x*40_H)	Reset Value: 0000 0000_H
XBAR_ERRD		
Error/Debug Capture Register D	(014_H)	Reset Value: 0000 0000_H

Field	Bits	Type	Description
RD	0	rh	Read Indication Status 0 _B The read indication SRI-Bus signal line was asserted (read or start of RMW transaction) 1 _B The read indication SRI-Bus signal line was deasserted (no read transaction)
WR	1	rh	Write Indication Status 0 _B The write indication SRI-Bus signal line was asserted (write or start of RMW transaction) 1 _B The write indication SRI-Bus signal line was deasserted (no write transaction)
SVM	2	rh	Supervisor Mode Indication Status 0 _B The supervisor mode indication SRI-Bus signal line was deasserted 1 _B The supervisor mode indication SRI-Bus signal line was asserted
OPC	[7:4]	rh	Operation Code This bit field contains the op-code of the erroneous transaction.

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
TR_ID	[15:8]	rh	Transaction ID This bit field contains the transaction ID of the erroneous transaction from the address phase. The Transaction ID is build out of an 6 bit unique TAG ID TR_ID[5:0] and a 2 bit running number TR_ID[7:6] (see also Chapter 2.6).
ADDR_ECC	[23:16]	rh	SRI Address Phase ECC This bit field contains the Address Phase Error ECC of the erroneous transaction <i>Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.</i>
MCI_SBS	[31:24]	rh	MCI Sideband Signals [7:0] This bit field contains the MCI Sideband Signals [7:0] that are related to the address phase informations captured by the ERRD/ERRADDR registers. In the TC26x B-Step the sideband signals are used by the DMA SRI master interface to provide information about the DMA requestor of a DMA transaction (for the encoding see Table 2-5).
0	3	r	Reserved Read as 0; should be written with 0

Note: The 'D' at XBAR_ERRD stands for Default Slave.

On-Chip System Buses and Bus Bridges

2.3 Shared Resource Interconnect to FPI Bus Interface (SFI Bridge)

This section describes the basic functionality of the SFI Bridge.

2.3.1 Functional Overview

The SFI Bridge is implemented as an uni-directional bus bridge that forwards transactions from the System Peripheral Bus (SPB) to the SRI Interconnect. The bridge supports all transactions types of both the SRI Bus and FPI Bus.

The bridge is transparent, this means that the address of a transaction and the master TAG of a bus master is forwarded to the other side of the bridge. Addresses are only changed by the bridge where it is required by the transaction conversion from the 64 bit SRI Interconnect to the 32 bit SPB.

Bus Errors at Writes via the SFI Bridge

Write transactions are handled as posted writes. The SFI is able to buffer multiple posted writes. This means that a write operation from the SPB through the SFI Bridge to the SRI Interconnect can be finished on SPB and then generated on the SRI autonomously by the SFI. If this write operation results in a bus error on the SRI the Error information is not passed back to the SPB bus. This is also valid for transactions from SRI to SPB via SFI bridge. The bus error is detected by the on chip bus control logic of the target on chip bus system (BCU_FPI on the SPB, XBar_SRI on the SRI) which can generate an interrupt.

Note that this behavior occurs only at write operations via the SFI Bridge. It can also be triggered by an erroneous write cycle of a read-modify-write bus transaction.

2.4 System Peripheral Bus

The TC26x B-Step has one on-chip FPI Bus:

- System Peripheral Bus (SPB)
 - System bus for on-chip peripherals

This section gives an overview of the on-chip FPI Bus. It describes its bus control units, the bus characteristics, bus arbitration, scheduling, prioritizing, error conditions, and debugging support.

2.4.1 Overview

The FPI Bus interconnects the on-chip peripheral functional units with the TC26x B-Step processor subsystem.

The FPI Bus is designed to be quick to be acquired by on-chip functional units, and quick to transfer data. The low setup overhead of the FPI Bus access protocol guarantees fast FPI Bus acquisition, which is required for time-critical applications.

The FPI Bus is designed to sustain high transfer rates. For example, a peak transfer rate of up to 320 Mbyte/s can be achieved with the 32-bit data bus at 80 MHz bus clock. Multiple data transfers per bus arbitration cycle allow the FPI Bus to operate close to its peak bandwidth.

Additional features of the FPI Bus include:

- Optimized for high speed and high performance
- Support of multiple bus masters and pipelined transactions
- 32-bit wide address and data buses
- 8-, 16-, and 32-bit data transfers
- 64-, 128-, and 256-bit block transfers
- Central simple per-cycle arbitration
- Slave-controlled wait state insertion
- Support of atomic operations LDMST, ST.T and SWAP.W
- Starvation prevention mechanism that can take care that even low priority requests will be granted after a configurable number of arbitration cycles, permanently enabled
- Default slave that takes over transactions no other slave responds
- Timeout detection and handling
- Capturing of transaction information in case of a bus error that can be released by again by SW incl. transaction address, control incl. op-code, data
- Address Phase includes Supervisor Mode information
- All SPB (FPI) slave modules implemented with a TAG ID based access protection that provides a generic write protection for the control registers

The functional units of the TC26x B-Step are connected to the FPI Bus via FPI Bus interfaces. An FPI Bus interfaces acts as bus agents, requesting bus transactions on behalf of their functional unit, or responding to bus transaction requests.

On-Chip System Buses and Bus Bridges

There are two types of bus agents:

- FPI Bus master agents can initiate FPI Bus transactions and can also act as slaves.
- Slave agents can only react and respond to FPI Bus transaction requests in order to read or write internal registers of slave modules as for example memories.

When an FPI Bus master attempts to initiate a transfer on the FPI Bus, it first signals a request for bus ownership to the bus control unit (SBCU). When bus ownership is granted by the SBCU, an FPI Bus read or write transaction is initiated. The unit targeted by the transaction becomes the FPI Bus slave, and responds with the requested action.

Some functional units operate only as slaves, while others can operate as either masters or slaves on the FPI Bus.

FPI Bus arbitration is performed by the Bus Control Unit (SBCU) of the FPI Bus. In case of bus errors, the SBCU generates an interrupt request to the CPU and provides debugging information about the actual bus error to the CPU.

2.4.2 Bus Transaction Types

This section describes the SPB transaction types.

Single Transfers

Single transfers are byte, half-word, and word transactions that target any slave connected to SPB. Note that the SFI Bridge operates as an SPB master.

Block Transfers

Block transfers operate in principle in the same way as single transfers do, but one address phase is followed by multiple data phases. Block transfers can be composed of 2 word, 4 word, or 8 word transfers.

Note: In general, block transfers (2 word, 4 word, or 8 word) cannot be executed in the TC26x B-Step with peripheral units that operate as FPI Bus slaves during an FPI Bus transaction.

Block transfers are initiated by the following CPU instructions: LD.D, LD.DA, MOV.D, ST.D and ST.DA. Additionally there are communication peripherals that are able to generate block transfers (e.g. Ethernet).

Atomic Transfers

Atomic transfers are generated by LDMST, ST.T and SWAP.W instructions that require two single transfers. The read and write transfer of an atomic transfer are always locked and cannot be interrupted by another bus masters. Atomic transfers are also referenced as read-modify-write transfers.

Note: See also [Table 2-11](#) for available FPI Bus transfer types.

2.4.3 Reaction of a Busy Slave

If an FPI Bus slave is busy at an incoming FPI Bus transaction request, it can delay the execution of the FPI Bus transaction. The requesting FPI Bus master releases the FPI Bus for one cycle after the FPI Bus transaction request, in order to allow the FPI Bus slave to indicate if it is ready to handle the requested FPI Bus transaction. This sequence is repeated as long as the slave indicates that it is busy.

Note: For the FPI Bus default master, the one cycle gap does not result in a performance loss because it is granted the FPI Bus in this cycle as default master if no other master requests the FPI Bus for some other reasons.

On-Chip System Buses and Bus Bridges

2.4.4 Address Alignment Rules

FPI Bus address generation is compliant with the following rules:

- Half-word transactions must have a half-word aligned address ($A_0 = 0$). Half-word accesses on byte lanes 1 and 2 addresses are illegal.
- Word transactions must always have word-aligned addresses ($A[1:0] = 00_B$).
- Block transactions must always have block-type aligned addresses.

2.4.5 FPI Bus Basic Operations

This section describes some basic transactions on the FPI Bus.

The example in **Figure 2-9** shows the three cycles of an FPI Bus operation:

1. **Request/Grant Cycle:** The FPI Bus master attempts to perform a read or write transfer and requests for the FPI Bus. If the FPI Bus is available, it is granted in the same cycle by the FPI Bus controller.
2. **Address Cycle:** After the request/grant cycle, the master puts the address on the FPI Bus, and all FPI Bus slave devices check whether they are addressed for the following data cycle.
3. **Data Cycle:** In the data cycle, either the master puts write data on the FPI Bus which is read by the FPI Bus slave (write cycle) or vice versa (read cycle).

Transfers 2 and 3 show the conflict when two master try to use the FPI Bus and how the conflict is resolved. In the example, the FPI Bus master of transfer 2 has a higher priority than the FPI Bus master of transfer 3.

Bus Cycle	1	2	3	4	5
Transfer 1	Request/Grant	Address Cycle	Data Cycle		
Transfer 2		Request/Grant	Address Cycle	Data Cycle	
Transfer 3		Request/Grant		Address Cycle	Data Cycle

MCA06109

Figure 2-9 Basic FPI Bus Transactions

At a block transfer, the address cycle of a second transfer is extended until the data cycles of the block transfer are finished. In the example of **Figure 2-10**, transfer 1 is a block transfer, while transfer 2 is a single transfer.

On-Chip System Buses and Bus Bridges

Bus Cycle	1	2	3	4	5	6	7
Transfer 1	Request/ Grant	Address Cycle	Data Cycle	Data Cycle	Data Cycle	Data Cycle	
Transfer 2		Request/ Grant	Address Cycle				Data Cycle

MCA06110

Figure 2-10 FPI Bus Block Transactions

2.5 FPI Bus Control Unit (SBCU)

The TC26x B-Step incorporates one FPI Bus control Unit (BCU) for the FPI based System Peripheral Bus (SPB), called System Bus Control Unit (SBCU).

2.5.1 FPI Bus Arbitration

The arbitration unit of the BCU determines whether it is necessary to arbitrate for FPI Bus ownership, and, if so, which available bus requestor gets the FPI Bus for the next data transfer. During arbitration, the bus is granted to the requesting agent with the highest priority. If no request is pending, the bus is granted to a default master. If no bus master takes the bus, the BCU itself will set the FPI Bus into an idle state.

2.5.1.1 Arbitration on the System Peripheral Bus

The TC26x B-Step SPB has multiple bus agents that can become SPB master:

- Each agent is assigned to 4-bit priority bit field in the PRIOH or in the PRIOL register
- The value in a priority bit field defines the related SPB master agent priority
- A lower priority number has a higher priority, '0' is the highest priority
- Each priority bit field in the PRIOH and PRIOL has a unique default value that can be changed during ramp up

Note: The DMA controller as an bus agent supports three priorities as this module covers two DMA Move Engines but also the Cerberus (JTAG/L1 Debug Interface) which might be used with the highest or lowest priority. Additionally the DMA Move Engine channels can be assigned to one of the three priorities.

2.5.1.2 Default Master

If no request is active, the FPI-Bus will be granted to a Default Master. The FPI master that was most recently granted will be granted to the Default Master. After reset, the master with the priority 0 will be the Default Master.

2.5.1.3 Arbitration Algorithms

The arbitration algorithm implemented in the BCU is based on:

- Priority driven arbitration of master agents with a pending request
- Starvation Prevention mechanism can increase master agent priorities during Starvation Prevention process

The default priority of each connected FPI master agent can be changed during runtime via the arbiter priority registers (PRIOH, PRIOL, see 'Changing Master Priorities'). There is a 4-bit priority bit field for each master agent in the PRIOH/PRIOL registers that defines the priority of this for this arbiter. After reset, each priority register has a default value, which means that each FPI master has unique default priority.

On-Chip System Buses and Bus Bridges

The default priority settings should be optimal for most applications. Where required, the arbitration setting can be adapted to the specific application needs (see 'Changing Master Priorities').

It must be ensured that two FPI master agents don't have the same priority.

Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 15 the lowest one. If multiple masters are requesting for one slave, the master with the highest priority will win the next arbitration round (see also 'starvation prevention').

Changing Master Priorities

Master priorities must be configured during ramp up as long only one FPI master agent is active (CPU0). Master priorities must not be changed while multiple FPI master agents are active / enabled.

2.5.1.4 Starvation Prevention

Starvation prevention is a feature of the SBCU that can take care that even requesting low priority master agents will be granted after a period, where the period length can be controlled by SBCU control registers. Because the priority assignment of the SPB agents is fixed, it is possible that a lower-priority bus requestor may never be granted the bus if a higher-priority bus requestor continuously asks for, and receives, bus ownership. To protect against bus starvation of lower-priority masters, the starvation prevention mechanism of the SBCU will detect such cases and momentarily raise the priority of the lower-priority requestor to the highest priority (above all other priorities), thereby guaranteeing it access.

Starvation protection employs a counter that is decremented each time an arbitration is performed on the connected FPI bus. The counter is re-loaded with the starvation period value in the SBCU_CON.SPC bit field as long it is enabled SBCU_CON.SPE. When this counter is counted down to zero, for each active bus request a request flag is stored in the BCU. This flag is cleared automatically when a master is granted the bus.

When the next period is finished, an active request of a master from which the request flag was set, a starvation event happened. This master will now be set to the highest priority and will be granted service. If there are several masters to which this starvation condition applies, they are served in the order of their configured priority ranking.

If a master that is processing its transaction under starvation condition is retried, its corresponding request flag is automatically again.

Starvation protection is permanently enabled. The sample period of the counter is programmed through bit field SBCU_CON.SPC. SPC should be set to a value at least greater than or equal to the number of masters. Its reset value is FF_H .

2.5.2 FPI Bus Error Handling

When an error occurs on an FPI Bus, its BCU captures and stores data about the erroneous condition and generates a service request if enabled to do so. The error conditions that force an error-capture are:

- Error Acknowledge: An FPI Bus slave responds with an error to a transaction.
- Un-implemented Address: No FPI Bus slave responds to a transaction request.
- Time-out: A slave does not respond to a transaction request within a certain time window. The number of bus clock cycles that can elapse until a bus time-out is generated is defined by bit field SBCU_CON.TOUT.

When a transaction causes an error, the address and data phase signals of the transaction causing the error are captured and stored in registers.

- The Error Address Capture Register (SBCU_EADD) stores the 32-bit FPI Bus address that has been captured during the erroneous FPI Bus transaction.
- The Error Data Capture Registers (SBCU_EDAT) stores the 32-bit FPI Bus data bus information that has been captured during the erroneous FPI Bus transaction.

On-Chip System Buses and Bus Bridges

- The Error Control Capture Register (SBCU_ECON) stores status information of the bus error event.

If more than one FPI Bus transaction generates a bus error, only the first bus error is captured. After a bus error has been captured, the capture mechanism must be released again by software. The lock is removed by reading the register SBCU_ECON which clears the SBCU_ECON.ERRCNT bit field.

Note: It is recommended to read in a debug session register ECON last as this removes the lock and a new error can already modify the content of the other two registers EDAT and EADD.

If a write transaction from TriCore causes an error on the SPB, the originating master is not informed about this error as it is not an SPB master agent. With each bus error-capture event, a service request is generated, and an interrupt can be generated if enabled and configured in the corresponding service request register.

Interpreting the BCU Control Register Error Information

Although the address and data values captured in registers SBCU_EADD and SBCU_EDAT, respectively, are self-explanatory, the captured FPI Bus control information needs some more explanation.

Register SBCU_ECON captures the state of the read (RDN), write (WRN), Supervisor Mode (SVM), acknowledge (ACK), ready (RDY), abort (ABT), time-out (TOUT), bus master identification lines (TAG) and transaction operation code (OPC) lines of the FPI Bus.

The SVM signal is set to 1 for an access in Supervisor Mode and set to 0 for an access in User Mode. The time-out signal indicates if there was no response on the bus to an access, and the programmed time (via SBCU_TOUT) has elapsed. TOUT is set to 1 in this case. An acknowledge code has to be driven by the selected slave during each data cycle of an access. These codes are listed in [Table 2-10](#).

Table 2-10 FPI Bus Acknowledge Codes

Code (ACK)	Description
00 _B	NSC: No Special Condition.
01 _B	SPT: Split Transaction (not used in the TC26x B-Step).
10 _B	RTY: Retry. Slave can currently not respond to the access. Master needs to repeat the access later.
11 _B	ERR: Bus Error, last data cycle is aborted.

Transactions on the FPI Bus are classified via a 4-bit operation code (see [Table 2-11](#)). Note that split transactions (OPC = 1000_B to 1110_B) are not used in the TC26x B-Step.

Table 2-11 FPI Bus Operation Codes (OPC)

OPC	Description
0000 _B	Single Byte Transfer (8-bit)
0001 _B	Single Half-Word Transfer (16-bit)
0010 _B	Single Word Transfer (32-bit)
0100 _B	2-Word Block Transfer
0101 _B	4-Word Block Transfer
0110 _B	8-Word Block Transfer
1111	No operation
0011 _B , 0111 _B , 1000 _B - 1110 _B	Reserved

2.5.3 System Registers

Figure 2-11 shows these system registers which include registers for:

The SBCU module includes the following TC26x B-Step standard system registers

- Register access protection

The following TC26x B-Step standard system registers are not included:

- Module Clock Control
- Module Kernel Reset
- OCDS Control and Status Register

Figure 2-11 TC26x OCB System System Registers

2.5.3.1 Register Access Protection (ACCEN1/0)

The TC26x OCB System module provides a master TAG ID based write access protection as part of the AURIX safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see [Chapter 2.5.3.1](#)). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

TAG ID based protection means that the support of write transactions to the TC26x OCB System control registers can be enabled / disabled for each master TAG ID individually. For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed (see also [Figure 2-11](#)).

The register access protection is controlled via the registers INT_ACCEN1 and INT_ACCEN0 where each bit is related to one encoding of the 6 bit On Chip Master TAG ID.

The INT_ACCEN1/0 registers are controlling the write access to all TC26x OCB System control and system registers with the exception of the INT_ACCEN1/0 registers themselves. INT_ACCEN1/0 are Safety Endinit protected.

After reset, all access enable bits and access control bits are enabled, access protection mechanism has to be configured and checked to bring the system in a safe state.

2.5.3.2 Kernel Reset Registers (KRST1/0, KRSTCLR)

The TC26x OCB System module does not include the kernel reset registers (KRST1, KRST0, KRSTCLR).

Note: The TC26x OCB System module does not support a module kernel reset.

2.5.3.3 Clock Control Register (CLC)

The TC26x OCB System module does not include the module clock control (CLC).

Note: The TC26x OCB System module does not support the Clock Control register functionality which means that the TC26x OCB System module clock can not be disabled by the CLC register.

2.5.3.4 OCDS Control and Status Register (OCS)

The TC26x OCB System module does not include OCDS Control and Status (OCS) register.

Note: The TC26x OCB System module does not support the OCS register functionality.

2.5.4 BCU Debug Support

For debugging purposes, the BCU has the capability for breakpoint generation support. This OCDS debug capability is controlled by the Cerberus module and must be enabled by it (indicated by bit SBCU_DBCNTL.EO).

When BCU debug support has been enabled (EO = 1), any breakpoint request generated by the BCU to the Cerberus disarms the BCU breakpoint logic for further breakpoint requests. In order to rearm the BCU breakpoint logic again for the next breakpoint request generation, bit SBCU_DBCNTL.RA must be set. The status of the BCU breakpoint logic (armed or disarmed) is indicated by bit SBCU_DBCNTL.OA.

There are three types of trigger events:

- Address triggers
- Signal triggers
- Grant triggers

2.5.4.1 Address Triggers

The address debug trigger event conditions are defined by the contents of the SBCU_DBADR1, SBCU_DBADR2, and SBCU_DBCNTL registers. A wide range of possibilities arise for the creation of debug trigger events based on addresses. The following debug trigger events can be selected:

- Match on one signal address
- Match on one of two signal addresses
- Match on one address area
- Mismatch on one address area

Each pair of DBADR_x registers and DBCNTL.ONA_x bits determine one possible debug trigger event. The combination of these two possible debug trigger events defined by DBCNTL.CONCOM1 determine the address debug trigger event condition.

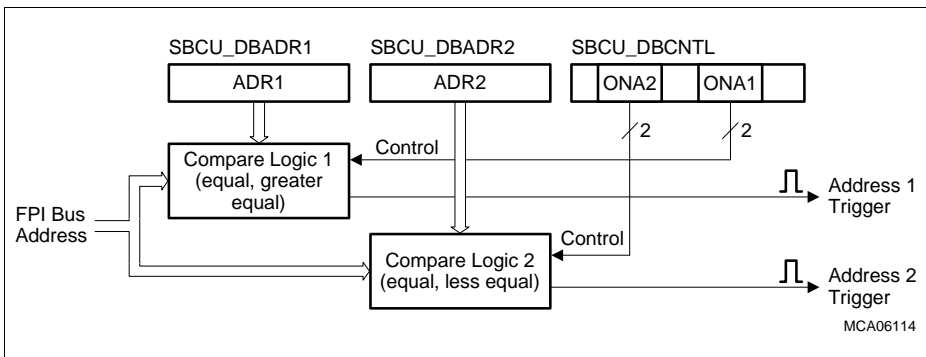

Figure 2-12 Address Trigger Generation

2.5.4.2 Signal Status Triggers

The signal status debug trigger event conditions are defined by the contents of the SBCU_DBBOS and SBCU_DBCNTL registers. Depending on the selected configuration a wide range of possibilities arise for the creation of a debug trigger event based on FPI Bus status signals. Possible combinations are:

- Match on a single signal status
- Match on a multiple signal status

With the multiple signal match conditions, all single signal match conditions are combined with a logical **AND** to the signal status debug trigger event signal. The selection whether or not a single match condition is selected can be enabled/disabled selectively for each condition via the SBCU_DBCNTL.ONBOSx bits.

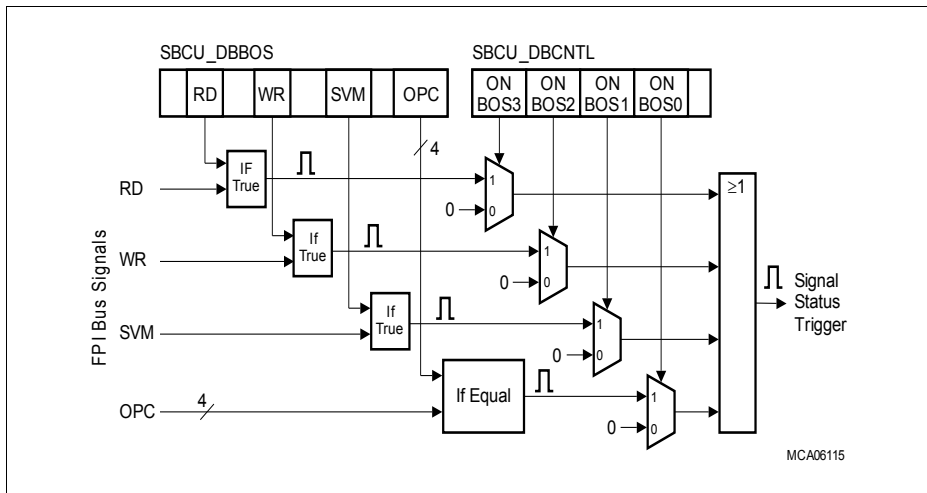

Figure 2-13 Signal Status Trigger Generation

2.5.4.3 Grant Triggers

The signal status debug trigger event conditions are defined via the registers SBCU_DBGRNT and SBCU_DBCNTL. Depending on the configuration of these registers, any combination of FPI Bus master trigger events can be configured. Only the enabled masters in the SBCU_DBGRNT register are of interest for the grant debug trigger event condition. The grant debug trigger event condition can be enabled/disabled via bit SBCU_DBCNTL.ONG (see [Figure 2-14](#)).

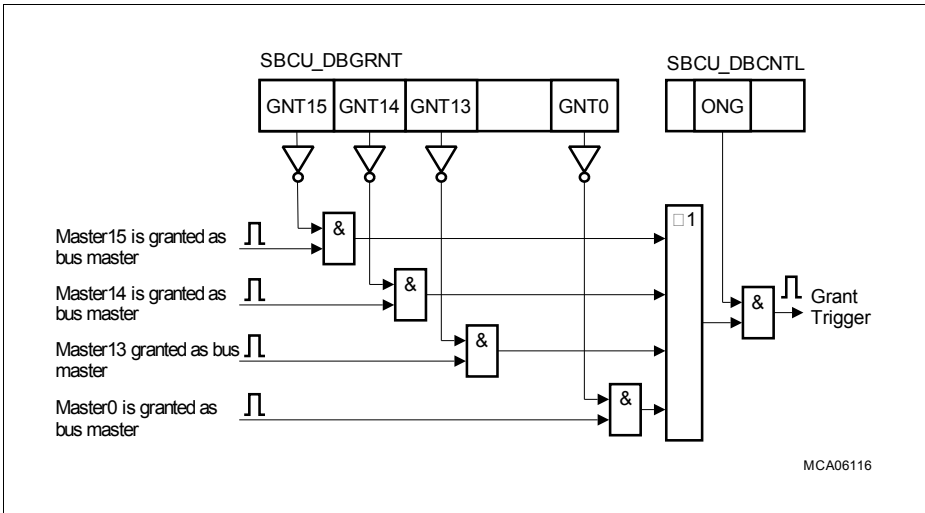

Figure 2-14 Grant Trigger Generation

2.5.4.4 Combination of Triggers

The combination of the four debug trigger signals to the single BCU breakpoint trigger event is defined via the bits CONCOM[2:0] of register SBCU_DBCNTL (see [Figure 2-15](#)). The two address triggers are combined to one address trigger that is further combined with signal status and grant trigger signals. A logical AND or OR combination can be selected for the BCU breakpoint trigger generation.

Figure 2-15 BCU Breakpoint Trigger Combination Logic

2.5.4.5 BCU Breakpoint Generation Examples

This section gives three examples of how BCU debug trigger events are programmed.

OCDS Debug Example 1

- Task: Generation of a BCU debug trigger event on any SPB write access to address 00002004_H or 000020A0_H by an SPB master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing SBCU_DBADR1 = 0000 2004_H
2. Writing SBCU_DBADR2 = 0000 20A0_H
3. Writing SBCU_DBCNTL = C1115010_H:
 - a) ONBOS[3:0] = 1100_B means that no signal status trigger is generated (disabled) for a read signal match AND write signal match condition according to the settings of bits RD and WR in register SBCU_DBBOS. Debug trigger event generation for Supervisor Mode signal match and op-code signal match condition is disabled.
 - b) ONA2 = 01_B means that the equal match condition for debug address 2 register is selected.

On-Chip System Buses and Bus Bridges

- c) $ONA1 = 01_B$ means that the equal match condition for debug address 1 register is selected.
 - d) $ONG = 1$ means that the grant debug trigger is enabled.
 - e) $CONCOM[2:0] = 101_B$ means that the address trigger is created by address trigger 1 OR address trigger 2 ($CONCOM1 = 0$), and that the grant trigger is ANDed with the address trigger ($CONCOM0 = 1$), and that the signal status trigger is ANDed with the address trigger ($CONCOM2 = 1$).
 - f) $RA = 1$ means that the BCU breakpoint logic is rearmed.
4. Writing $SBCU_DBGRNT = FFFFFFFD7_H$:
means that the grant trigger for the SPB master is enabled.
 5. Writing $SBCU_DBBOS = 00001000_H$:
means that the signal status trigger is generated on a write transfer and not on a read transfer.

OCDS Debug Example 2

- Task: generation of a BCU debug trigger event on any half-word access in User Mode to address area $01FFFFFF_H$ to $02FFFFFF_H$ by any master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

1. Writing $SBCU_DBADR1 = 01FFFFFF_H$
2. Writing $SBCU_DBADR2 = 02FFFFFF_H$
3. Writing $SBCU_DBCNTL = 32206010_H$:
 - a) $ONBOS[3:0] = 0011_B$ means that the signal status trigger is disabled for a read or for write signal status match but enabled for Supervisor Mode match AND op-code match conditions according to the settings of bit SVM and bit field OPC in register $SBCU_DBBOS$.
 - b) $ONA2 = 10_B$ means that the address 2 trigger is generated if the FPI Bus address is less or equal to $SBCU_DBADR2$.
 - c) $ONA1 = 10_B$ means that the address 1 trigger is generated if the FPI Bus address is greater or equal to $SBCU_DBADR1$.
 - d) $ONG = 0$ means that the grant debug trigger is disabled.
 - e) $CONCOM[2:0] = 110_B$ means that the address trigger is created by address trigger 1 AND address trigger 2 ($CONCOM1 = 1$), and that the grant trigger is OR-ed with the address trigger ($CONCOM0 = 0$), and that the signal status trigger is AND-ed with the address trigger ($CONCOM2 = 1$).
 - f) $RA = 1$ means that the BCU breakpoint logic is rearmed.
4. Writing $SBCU_DBGRNT = FFFFFFFF_H$:
means that no grant trigger for SPB masters is selected ("don't care" because also disabled by $ONG = 0$).
5. Writing $SBCU_DBBOS = 00000001_H$:
means that the signal status trigger is generated for read ($RD = 0$) and write ($WR = 0$) half-word transfers ($OPC = 0001_B$) in User Mode ($SVM = 0$).

On-Chip System Buses and Bus Bridges

2.5.5 System Bus Control Unit Registers

Figure 2-16 and Table 2-13 are showing the address maps with all registers of the System Bus Control Unit (SBCU) module.

Module Base Address ([Table 2-12](#)) + Offset Address (shown in this column)

2.5.5.1 SBCU System Registers

Module Identification Register (ID)

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the SBCU module.

SBCU_ID

Module Identification Register (008_H) **Reset Value: 0000 6AXX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_NUMBER	[15:8]	r	Module Number Value This bit field defines a module identification number. The value for the LBCU module is 006AH.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

Access Enable Register 0 (ACCEN0)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The registers ACCEN00 / ACCEN01 are providing one enable bit for each 6-bit On Chip Bus Master TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ..., EN31 -> TAG ID 011111_B.

On-Chip System Buses and Bus Bridges
SBCU_ACCEN0
Access Enable Register 0

Access Enable Register 1 (ACCEN1)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN11/01 are not implemented with register bits as the related On Chip Bus Master TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

On-Chip System Buses and Bus Bridges

SBCU_ACCEN1

Access Enable Register 1

(0F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

On-Chip System Buses and Bus Bridges
2.5.5.2 SBCU Control Registers Descriptions

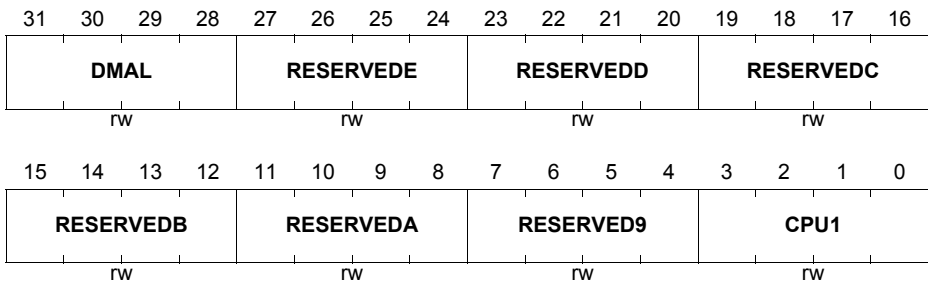

The SBCU Control Register controls the overall operation of the SBCU, including setting the starvation sample period, the bus time-out period, enabling starvation-protection mode, and error handling.

SBCU_CON
SBCU Control Register
(010_H)
Reset Value: FF09 FFFF_H

Field	Bits	Type	Description
TOUT	[15:0]	rw	SBCU Bus Time-Out Value The bit field determines the number of System Peripheral Bus time-out cycles. Default after reset is FFFF _H (= 65536 bus cycles). Please Note: TOUT value must be >= 5.
DBG	16	rw	SBCU Debug Trace Enable The bit enables/disables the error capture mechanism for the registers BCU_ECON, BCU_EADD, BCU_EDAT 0 _B SBCU debug trace disabled 1 _B SBCU debug trace enabled (default after reset) <i>Note: The bit does not affect the SMU alarm or the BCU interrupt that are send in case of an error condition.</i>
SPC	[31:24]	rw	Starvation Period Control Determines the sample period for the starvation counter. Must be larger than the number of masters. The reset value is FF _H .
ONE	19	r	Reserved Read as 1; should be written with 0.

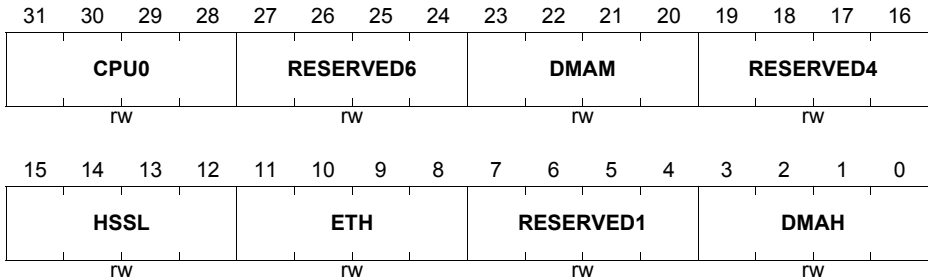

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
0	[23:20], [18:17]	r	Reserved Read as 0; should be written with 0.

SBCU_PRIOH
Arbiter Priority Register High
(014_H)
Reset Value: FCDE BA98_H

Field	Bits	Type	Description
CPU1	[3:0]	rw	Master 8 Priority This bit field contains the master priority for master connected to BCU request input 8 A lower number has a higher priority in the arbitration round than a higher one.
DMAL	[31:28]	rw	Master 15 Priority¹⁾ This bit field contains the master priority for master connected to BCU request input 15 A lower number has a higher priority in the arbitration round than a higher one.
RESERVEDE, RESERVEDD, RESERVEDC, RESERVEDB, RESERVEDA, RESERVED9	[27:24], [23:20], [19:16], [15:12], [11:8], [7:4]	rw	Reserved Read as reset value or last written value; should be written with 0.

1) Including DMA transactions from DMA channels with low priority. Including Cerberus transactions with IOCONF.FPI_PRI0=0'.

On-Chip System Buses and Bus Bridges
SBCU_PRIOL
Arbiter Priority Register Low
(018_H)
Reset Value: 7654 3210_H

Field	Bits	Type	Description
DMAH	[3:0]	rw	Master 0 Priority¹⁾ This bit field contains the master priority for master connected to BCU request input 0 A lower number has a higher priority in the arbitration round than a higher one.
ETH	[11:8]	rw	Master 2 Priority This bit field contains the master priority for master connected to BCU request input 2 A lower number has a higher priority in the arbitration round than a higher one.
HSSL	[15:12]	rw	Master 3 Priority This bit field contains the master priority for master connected to BCU request input 3 A lower number has a higher priority in the arbitration round than a higher one.
DMAM	[23:20]	rw	Master 5 Priority²⁾ This bit field contains the master priority for master connected to BCU request input 5 A lower number has a higher priority in the arbitration round than a higher one.

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
CPU0	[31:28]	rw	Master 7 Priority This bit field contains the master priority for master connected to BCU request input 8 A lower number has a higher priority in the arbitration round than a higher one.
RESERVED6, RESERVED4, RESERVED1	[27:24], [19:16], [7:4]	rw	Reserved Read as reset value or last written value; should be written with 0.

1) Including DMA transactions from DMA channels with high priority. Including Cerberus transactions with IOCONF.FPI_PRI0='1'.

2) Including DMA transactions from DMA channels with medium priority.

2.5.5.3 SBCU Error Registers Descriptions

The capture of bus error conditions is enabled by setting SBCU_CON.DBG to 1. In case of a bus error, information about the condition will then be stored in the SBCU error capture registers. The SBCU error capture registers can then be examined by software to determine the cause of the FPI Bus error.

If enabled and an FPI Bus error occurs, the SBCU_ECON register holds the captured FPI Bus control information and an error count of the number of bus errors. The SBCU_EADD register stores the captured FPI Bus address. The SBCU_EDAT register stores the captured FPI Bus data.

If the capture of FPI Bus error conditions is disabled (SBCU_CON.DBG = 0), the SBCU error capture registers remain untouched.

Note: The SBCU error capture registers store only the parameters of the first error. In case of multiple bus errors, an error counter SBCU_ECON.ERRCNT shows the number of bus errors since the first error occurred. An application reset clears this bit field to zero, but the counter can be set to any value through software. This counter is prevented from overflowing, so a value of $2^{16} - 1$ indicates that at least this many errors have occurred, but there may have been more. After SBCU_ECON has been read, the SBCU_ECON, SBCU_EADD and SBCU_EDAT registers are re-enabled to trace FPI Bus error conditions.

On-Chip System Buses and Bus Bridges

SBCU_ECON
SBCU Error Control Capture Register(020_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPC			TAG						RDN	WRN	SVM	ACK		ABT	
rwh			rwh						rwh	rwh	rwh	rwh		rwh	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDY	TOU T	ERRCNT													
rwh	rwh	rwh													

Field	Bits	Type	Description
ERRCNT	[13:0]	rwh	FPI Bus Error Counter ERRCNT is incremented on every occurrence of an FPI Bus error. ERRCNT is reset to 0 after the SBCU_ECON register is read. ¹⁾
TOU	14	rwh	State of FPI Bus Time-Out Signal This bit indicates the state of the time-out signal at an FPI Bus error. 0 _B No time-out occurred 1 _B Time-out has occurred
RDY	15	rwh	State of FPI Bus Ready Signal This bit indicates the state of the ready signal at an FPI Bus error. 0 _B Wait state(s) have been inserted. Ready signal was active 1 _B Ready signal was inactive
ABT	16	rwh	State of FPI Bus Abort Signal This bit indicates the state of the abort signal at an FPI Bus error. 0 _B Master has aborted an FPI Bus transfer. Abort signal was active 1 _B Abort signal was inactive
ACK	[18:17]	rwh	State of FPI Bus Acknowledge Signals This bit field indicates the acknowledge code that has been output by the selected slave at an FPI Bus error. Coding see Table 2-10 .

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
SVM	19	rwh	State of FPI Bus Supervisor Mode Signal This bit indicates whether the FPI Bus error occurred in Supervisor Mode or in User Mode. 0 _B Transfer was initiated in User Mode 1 _B Transfer was initiated in Supervisor Mode
WRN	20	rwh	State of FPI Bus Write Signal This bit indicates whether the FPI Bus error occurred at a write cycle (see Table 2-14).
RDN	21	rwh	State of FPI Bus Read Signal This bit indicates whether the FPI Bus error occurred at a read cycle (see Table 2-14).
TAG	[27:22]	rwh	FPI Bus Master Tag Number Signals This bit field indicates the FPI Bus master TAG number (definitions see Table 2-15).
OPC	[31:28]	rwh	FPI Bus Operation Code Signals The FPI Bus operation codes are defined in Table 2-11 .

1) In the TC26x B-Step, aborted accesses to a 0 wait state SPB slave may also increment ERRCNT when the slave generates an error acknowledge.

Table 2-14 FPI Bus Read/Write Error Indication

RD	WR	FPI Bus Cycle
0	0	FPI Bus error occurred at the read transfer of a read-modify-write transfer.
0	1	FPI Bus error occurred at a read cycle of a single transfer.
1	0	FPI Bus error occurred at a write cycle of a single transfer or at the write cycle of a read-modify-write transfer.
1	1	Does not occur.

On-Chip System Buses and Bus Bridges

SBCU_EADD

SBCU Error Address Capture Register (024_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
FPIADR	[31:0]	rwh	Captured FPI Bus Address This bit field holds the 32-bit FPI Bus address that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the address of the first bus error is captured.

SBCU_EDAT

SBCU Error Data Capture Register (028_H)

Reset Value: 0000 0000_H

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
FPIDAT	[31:0]	rwh	Captured FPI Bus Data This bit field holds the 32-bit FPI Bus data that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the data of the first bus error is captured.

On-Chip System Buses and Bus Bridges

2.5.5.4 SBCU OCDS Registers Descriptions

SBCU_DBCNTL

 SBCU Debug Control Register (030_H) Reset Value: 0000 7003_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ONB OS3	ONB OS2	ONB OS1	ONB OS0	0		ONA2		0		ONA1		0			ONG
r/w	r/w	r/w	r/w	r		r/w		r		r/w		r			r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CON COM 2	CON COM 1	CON COM 0				0				RA		0	OA	EO
r	r/w	r/w	r/w				r				w		r	r	r

Field	Bits	Type	Description
EO	0	r	Status of SBCU Debug Support Enable This bit is controlled by the Cerberus and enables the SBCU debug support. 0 _B SBCU debug support is disabled 1 _B SBCU debug support is enabled (default after reset)
OA	1	r	Status of SBCU Breakpoint Logic 0 _B The SBCU breakpoint logic is disarmed. Any further breakpoint activation is discarded 1 _B The SBCU breakpoint logic is armed The OA bit is set by writing a 1 to bit RA. When OA is set, registers SBCU_DBGNTT, SBCU_DBADRT, and SBCU_DBDAT are reset. Also SBCU_DBBOST is reset with the exception of the bit field FPIRST.
RA	4	w	Rearm SBCU Breakpoint Logic Writing a 1 to this bit rearms SBCU breakpoint logic and sets bit OA = 1. RA is always reads as 0.

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
CONCOM0	12	rw	<p>Grant and Address Trigger Relation</p> <p>0_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical OR for further control</p> <p>1_B The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical AND for further control (see Figure 2-15)</p>
CONCOM1	13	rw	<p>Address 1 and Address 2 Trigger Relation</p> <p>0_B Address 1 trigger condition and address 2 trigger condition are combined with a logical OR to the address trigger condition for further control</p> <p>1_B Address 1 trigger condition and address 2 trigger condition are combined with a logical AND to the address trigger condition for further control (see Figure 2-15)</p>
CONCOM2	14	rw	<p>Address and Signal Trigger Relation</p> <p>0_B Address trigger condition (see CONCOM1) and signal status trigger conditions are combined with a logical OR for further control</p> <p>1_B Address phase trigger condition (see CONCOM1) and the signal status trigger conditions are combined with a logical AND for further control (see Figure 2-15)</p>
ONG	16	rw	<p>Grant Trigger Enable</p> <p>0_B No grant debug event trigger is generated</p> <p>1_B The grant debug event trigger is enabled and generated according the settings of register SBCU_DBGRNT (see Figure 2-15)</p>
ONA1	[21:20]	rw	<p>Address 1 Trigger Control</p> <p>00_B No address 1 trigger is generated</p> <p>01_B An address 1 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR1</p> <p>10_B An address 1 trigger event is generated if FPI Bus address is greater or equal to SBCU_DBADR1</p> <p>11_B same as 00_B (See also Figure 2-12).</p>

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
ONA2	[25:24]	rw	Address 2 Trigger Control 00 _B No address 2 trigger is generated 01 _B An address 2 trigger event is generated if the FPI Bus address is equal to SBCU_DBADR2 10 _B An address 2 trigger event is generated if FPI Bus address is less or equal to SBCU_DBADR2 11 _B same as 00 _B See also Figure 2-12 .
ONBOS0	28	rw	Opcode Signal Status Trigger Condition 0 _B A signal status trigger is generated for all FPI Bus op-codes except a “no operation” op-code 1 _B A signal status trigger is generated if the FPI Bus op-code matches the op-code as defined in DBBOS.OPC (see Figure 2-13)
ONBOS1	29	rw	Supervisor Mode Signal Trigger Condition 0 _B The signal status trigger generation for the FPI Bus Supervisor Mode signal is disabled 1 _B A signal status trigger is generated if the FPI Bus Supervisor Mode signal state is equal to the value of DBBOS.SVM (see Figure 2-13)
ONBOS2	30	rw	Write Signal Trigger Condition 0 _B The signal status trigger generation for the FPI Bus write signal is disabled 1 _B A signal status trigger is generated if the FPI Bus write signal state is equal to the value of DBBOS.WR (see Figure 2-13)
ONBOS3	31	rw	Read Signal Trigger Condition 0 _B The signal status trigger generation for the FPI Bus read signal is disabled 1 _B A signal status trigger is generated if the FPI Bus read signal state is equal to the value of DBBOS.RD (see Figure 2-13)

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description

1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.

2) Including DMA transactions from DMA channels with medium priority.

3) Including DMA transactions from DMA channels with low priority and from Cerberus with low priority.

On-Chip System Buses and Bus Bridges

SBCU_DBADR1
SBCU Debug Address 1 Register
(038_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ADR1	[31:0]	rw	Debug Trigger Address 1 This register contains the address for the address 1 trigger event generation.

SBCU_DBADR2
SBCU Debug Address 2 Register
(03C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ADR2	[31:0]	rw	Debug Trigger Address 2 This register contains the address for the address 2 trigger event generation.

On-Chip System Buses and Bus Bridges
SBCU_DBBOS
SBCU Debug Bus Operation Signals Register
(040_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
OPC	[3:0]	rw	Opcode for Signal Status Debug Trigger This bit field determines the type (opcode) of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS0 = 1). 0000 _B Trigger on single byte transfer selected 0001 _B Trigger on single half-word transfer selected 0010 _B Trigger on single word transfer selected 0100 _B Trigger on 2-word block transfer selected 0101 _B Trigger on 4-word block transfer selected 0110 _B Trigger on 8-word block transfer selected 1111 _B Trigger on no operation selected Other bit combinations are reserved.
SVM	4	rw	SVM Signal for Status Debug Trigger This bit determines the mode of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS1 = 1). 0 _B Trigger on User Mode selected 1 _B Trigger on Supervisor Mode selected

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
WR	8	rw	Write Signal for Status Debug Trigger This bit determines the state of the WR signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS2 = 1). 0_B Trigger on a single write transfer or write cycle of an atomic transfer selected 1_B No operation or read transaction selected
RD	12	rw	Write Signal for Status Debug Trigger This bit determines the state of the RD signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS3 = 1). 0_B Trigger on a single read transfer or read cycle of an atomic transfer selected 1_B No operation or write transfer selected
0	[7:5], [11:9], [31:13]	r	Reserved Read as 0; should be written with 0.

SBCU_DBGNTT
SBCU Debug Trapped Master Register
(044_H)
Reset Value: 0000 FFFF_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw						rw	rw	rw	rw	rw	rw	rw	rw	rw

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
DMAH	0	rw	High-Priority DMA FPI Bus Master Status¹⁾ This bit indicates whether the DMA with a medium priority request was FPI Bus master when the break trigger event occurred. 0 _B The medium-priority DMA was the FPI bus master. 1 _B The medium-priority DMA was not the FPI Bus master.
ETH	2	rw	Ethernet FPI Bus Master Status This bit indicates whether the Ethernet was FPI Bus master when the break trigger event occurred. 0 _B The Ethernet was the FPI bus master. 1 _B The Ethernet was not the FPI Bus master.
HSSL	3	rw	HSSL FPI Bus Master Status This bit indicates whether the HSSL was FPI Bus master when the break trigger event occurred. 0 _B The Ethernet was the FPI bus master. 1 _B The Ethernet was not the FPI Bus master.
DMAM	5	rw	Medium-Priority DMA FPI Bus Master Status²⁾ This bit indicates whether the DMA with a medium priority request was FPI Bus master when the break trigger event occurred. 0 _B The medium-priority DMA was the FPI bus master. 1 _B The medium-priority DMA was not the FPI Bus master.
CPU0	7	rw	CPU0 FPI Bus Master Status This bit indicates whether the CPU0 was FPI Bus master when the break trigger event occurred. 0 _B The CPU0 was the FPI Bus master. 1 _B The CPU0 was not the FPI Bus master.
CPU1	8	rw	CPU1 FPI Bus Master Status This bit indicates whether the CPU1 was FPI Bus master when the break trigger event occurred. 0 _B The CPU1 was the FPI Bus master. 1 _B The CPU1 was not the FPI Bus master.

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
DMAL	15	rw	Low-Priority DMA FPI Bus Master Status³⁾ This bit indicates whether the DMA with a low-priority request was the FPI Bus master when the break trigger event occurred. 0 _B The low-priority DMA was the FPI Bus master. 1 _B The low-priority DMA was not the FPI Bus master.
DMACHNR	[23:16]	rw	DMA-FPI Channel Grant Status The encoding is directly dedicated to the dma channel number
ONE4, ONE3, ONE2, ONE1, ONE0	[31:24], [14:9], 6, 4, 1	rw	Reserved Read as 1; shall be written with 0.

- 1) Including DMA transactions from DMA channels with high priority and from Cerberus with high priority.
- 2) Including DMA transactions from DMA channels with medium priority.
- 3) Including DMA transactions from DMA channels with low priority, MLI and from Cerberus with low priority.

SBCU_DBADRT

SBCU Debug Trapped Address Register

(048_H)

Reset Value: 0000 0000_H

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
FPIADR	[31:0]	rh	FPI Bus Address Status This register contains the FPI Bus address that was captured when the OCDS break trigger event occurred.

SBCU_DBBOST
SBCU Debug Trapped Bus Operation Signals Register
(04C_H)
Reset Value: 0000 3180_H

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
FPI SVM	4	rh	FPI Bus Supervisor Mode Status This bit indicates the state of the Supervisor Mode signal captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B User mode 1 _B Supervisor mode
FPI ACK	[6:5]	rh	FPI Bus Acknowledge Status This bit field indicates the acknowledge signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00 _B No special case 01 _B Error 10 _B Reserved 11 _B Retry, slave did not respond
FPI RDY	7	rh	FPI Bus Ready Status This bit indicates the ready signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B Last cycle of transfer 1 _B Not last cycle of transfer
FPI WR	8	rh	FPI Bus Write Indication Status This bit indicates the write signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B Single write transfer or write cycle of an atomic transfer 1 _B No operation or read transfer
FPI RST	[10:9]	rh	FPI Bus Reset Status This bit field indicates the reset signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 00 _B Reset of all FPI Bus components 11 _B No reset Others Reserved

On-Chip System Buses and Bus Bridges

Field	Bits	Type	Description
FPIOPS	11	rh	FPI Bus OCDS Suspend Status This bit indicates the OCDS suspend signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B No OCDS suspend request is pending 1 _B An OCDS suspend request is pending
FPIRD	12	rh	FPI Bus Read Indication Status This bit indicates the read signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B Single read transfer or read cycle of an atomic transfer 1 _B No operation or write transfer
FPIABORT	13	rh	FPI Bus Abort Status This bit indicates the abort signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B A transfer that has already started was aborted 1 _B Normal operation
FPIOUT	14	rh	FPI Bus Time-out Status This bit indicates the time-out signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B Normal operation 1 _B A time-out event was generated
ENDINIT	15	rh	FPI Bus Endinit Status This bit indicates the ENDINIT signal status captured from the FPI Bus signal lines when the BCU break trigger event occurred. 0 _B Normal operation 1 _B System was in ENDINIT state
FPITAG	[21:16]	rh	FPI Bus Master TAG Status This bit field indicates the master TAG captured from the FPI Bus signal lines when the BCU break trigger event occurred (see Table 2-15). The master TAG identifies the master of the transfer which generated BCU break trigger event.
0	[31:22]	rh	Reserved Read as 0; should be written with 0.

On-Chip System Buses and Bus Bridges
SBCU_DBDAT
SBCU Debug Data Status Register
(050_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
FPIDATA	[31:0]	rh	FPI Bus Data Status This register contains the FPI Bus data that was captured when the OCDS break trigger event occurred.

2.6 On Chip Bus Master TAG Assignments

Each master interface on the System Peripheral Bus and on the SRI Bus is assigned to a 6-bit identification number, the master TAG number (see [Table 2-15](#)). This makes it possible for software debug and MCDS purposes to distinguish which master has performed the current transaction (see [“XBAR_ERRx \(x = 0-1\)” on Page 2-54^{1\)}](#) and [“SBCU_DBADRT” on Page 2-111](#)).

Table 2-15 On Chip Bus Master TAG Assignments

TAG-Number	Module	Location	Description
000000 _B	CPU0	SRI/SPB	DMI.NonSafe TAG ID
000001 _B	CPU0	SRI/SPB	DMI.Safe TAG ID
000010 _B	CPU1	SRI/SPB	DMI.NonSafe TAG ID
000011 _B	CPU1	SRI/SPB	DMI.Safe TAG ID
000100 _B	-	-	Reserved

1) Pls. note that the Transaction ID bit field in the register [“XBAR_ERRx \(x = 0-1\)” on Page 2-54](#) includes the TAG ID on the 6 LSB (TRID[5:0]).

On-Chip System Buses and Bus Bridges
Table 2-15 On Chip Bus Master TAG Assignments

TAG-Number	Module	Location	Description
000101 _B	-	-	Reserved
000110 _B	DMA	SRI/SPB	DMA Resource Partition 0
000111 _B	DMA	SRI/SPB	DMA Resource Partition 1

011101 _B	EMEM	BBB	EMEM Master on Back Bone Bus (ED)
011110 _B	CIF	BBB	CIF Master on Back Bone Bus (ED)
Others	-	-	Reserved

2.7 On Chip Bus Access Times

The table describes the CPU access times in CPU clock cycles for the TC26x B-Step. The access times are described as maximum CPU stall cycles where e.g. an data access to the local DSPR results in zero stall cycles. Pls. note that the CPU does not always immediately stall after the start of a data read from another SPR due to instruction pipelining effects. This means that the average number will be below the here shown numbers[RF00105].

Note: All values are preliminary

Table 2-16 CPU access latency in CPU clock cycles for TC26x B-Step

CPU Access Mode	CPU clock cycles
Data read access to own DSPR	0
Data write access to own DSPR	0
Data read access to own or other PSPR	5

On-Chip System Buses and Bus Bridges
Table 2-16 CPU access latency in CPU clock cycles for TC26x B-Step (cont'd)

CPU Access Mode	CPU clock cycles
Data write access to own or other PSPR	0
Data read access to other DSPR	5
Data write access to other DSPR	0
Instruction fetch from own PSPR	0
Instruction fetch from other PSPR (critical word)	5
Instruction fetch from other PSPR (any remaining words)	0
Instruction fetch from other DSPR (critical word)	5
Instruction fetch from other DSPR (any remaining words)	0
Initial Pflash Access (critical word)	5 + configured PFlash Wait States ¹⁾
Initial Pflash Access (remaining words)	0
PMU PFlash Buffer Hit (critical word)	4
PMU PFlash Buffer Hit (remaining words)	0
Initial Dflash Access	5 + configured DFlash Wait States ²⁾
TC1.6E Data read from System Peripheral Bus (SPB)	4 ($f_{\text{CPU}}=f_{\text{SPB}}$) 7 ($f_{\text{CPU}}=2*f_{\text{SPB}}$)
TC1.E Data write to System Peripheral Bus (SPB)	0

1) FCON.WSPFLASH + FCON.WSECPF (see PMU chapter for the detailed description of these parameters).

2) FCON.WSDFLASH + FCON.WSECDF (see PMU chapter for the detailed description of these parameters).

3 Memory Maps

This chapter gives an overview of the TC26x B-Step memory map, and describes the address locations and access possibilities for the units, memories, and reserved areas as “seen” from the two different on-chip buses’ point of view.

The TC26x B-Step has the following CPU related memories:

- Program Memory Unit (PMU0) with
 - 2.5 Mbyte of Program Flash Memory (PFLASH)
 - Data Flash Memory (DF_EEPROM)
 - User Configuration Blocks (DF_UCB)
 - 32 Kbyte of Boot ROM (BROM)
- CPU0:
 - 16 Kbyte of Program Scratch-Pad SRAM (PSPR)¹⁾
 - 72 Kbyte of Data Scratch-Pad SRAM (DSPR)¹⁾
 - 8 Kbyte of Program Cache (PCache)
- CPU1:
 - 32 Kbyte of Program Scratch-Pad SRAM (PSPR)¹⁾
 - 120 Kbyte of Data Scratch-Pad SRAM (DSPR)¹⁾
 - 16 Kbyte of Program Cache (PCache)
 - 8 Kbyte of Data Cache (DCACHE)
- LMU:
 - 0 Kbyte SRAM (LMURAM)¹⁾

Furthermore, the TC26x B-Step has two on-chip buses:

- System Peripheral Bus (SPB)
- Shared Resource Interconnect (SRI)

1) Before used by the application, the memory has to be initialized (see chapter ‘Memory Test Unit’, MTU)

3.1 How to Read the Address Maps

The bus-specific address maps describe how the different bus master devices react on accesses to on-chip memories and modules, and which address ranges are valid or invalid for the corresponding buses.

The detailed address mapping of e.g. control registers, sram blocks or flash banks/sectors within a module is described in the related module chapter.

The SPB Bus address map shows the system addresses from the point of view of the SPB master agents¹⁾.

The SRI address map shows the system addresses from the point of view of the SRI master agents¹⁾.

The SFI is an uni-directional bridge for access from SRI to SPB and therefore not mentioned here as SRI master in the Address Map. The SFI is fully transparent and does not include an address translation mechanism.

Note: In addition to the here described system address map, each TriCore has a TriCore IP internal access to its PSPR via C000_0000 and an internal access to its DSPR via D000_0000. This additional/private view to the local scratch pad srams is described in the CPU chapter.

1) Available SRI / SPB master agents are described in the On Chip Bus System chapter

Memory Maps

Table 3-1 defines the acronyms and other terms that are used in the address maps (**Table 3-2** and **Table 3-3**).

Table 3-1 Definition of Acronyms and Terms

Term	Description
...BE	Means "Bus error" generation.
SPBBE	A bus access is terminated with a bus error on the SPB.
SRIBE	A bus access is terminated with a bus error on the SRI.
access	A bus access is allowed and is executed.

3.2 Contents of the Segments

This section summarizes the contents of the segments.

The CPU attributes (cached / non-cached) of these segments can be configured for each CPU's data and program side individually (see CPU chapter: Physical Memory Attribute Registers, PMAx).

Segments 0-5

These memory segments are reserved in the TC26x B-Step.

Segments 6-7

These memory segments allow access to the CPU's Program and Data Scratch Pad SRAM (PSPR, DSPR), Program and Data Cache SRAMs (PCache, DCache) as well as TAG SRAMs related to Program and Data Cache (PTAG SRAM¹) and DTAG SRAM¹). Where DCache is supported, DCache and DTAG SRAM¹) can be only accessed if the Data Cache is disabled.

PCache and PTAG SRAMs¹) can be only accessed if the related Program Cache is disabled²).

CPUx default attributes for these segments: non-cached.

Segment 8

This memory segment allows access to PFlash and BROM.

CPUx default attributes for this segment: cached.

Segment 9

This memory segment allows access to LMU SRAM (if implemented) and to the EMEM (Emulation Device only).

CPUx default attributes for this segment: cached.

Segment 10

This memory segment allows access to PFlash, DFlash and BROM.

CPUx default attributes for this segment: non-cached.

1) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with single data access and only with 64 bit aligned address.

2) Mapping of Cache and TAG SRAMs is controlled via the MTU register MTU_MEMMAP.

Segment 11

This memory segment allows access to LMU SRAM (if implemented) and to the EMEM (Emulation Device only).

CPUx default attributes for this segment: non-cached.

Segment 12

This memory segment is reserved in the TC26x B-Step.

Segment 13

This memory segment is reserved in the TC26x B-Step.

Segment 14

This memory segment is reserved in the TC26x B-Step.

Segment 15

This memory segment allows accesses to all SFRs, CSFRs.

Access from DMA Move Engine, Cerberus to the lower 128 MB of this segment are processed by the DMA FPI master interface on the SPB Bus, to the upper 128 MB of this segment by the DMA SRI master interface on the SRI Bus.

Data access from TC1.6 CPUs to the lower 128 MB of this segment are processed by the CPU.DMI FPI master interface on the SPB Bus, to the upper 128 MB of this segment by the CPU.DMI SRI master interface on the SRI Bus.

3.3 Address Map of the On Chip Bus System

This chapter describes the system address map as it is seen from the SRI and SPB bus masters (bus master agents are described in the chapter On Chip Bus System).

All bus master agents can address identical peripherals and memories at identical address. The system address map is visible and valid for all CPUs which means that all peripherals and resources are accessible from all TriCore CPUs and other on chip bus master agents.

Parallel access by more than one bus master agents to one slave agent are executed sequentially. Additionally the SRI and SPB bus do support atomic Read Modify Write sequences from the CPUs. Hardware semaphores for temporary exclusive bus access from one master to a slave are not implemented

3.3.1 Segments 0 to 14

Table 3-2 shows the address map of segments 0 to 14.

Table 3-2 On Chip Bus Address Map of Segment 0 to 14

Segment	Address Range	Size	Description	Access Type	
				Read ¹⁾	Write ²⁾
0-5	0000 0000 _H - 0000 0007 _H	8 byte	Reserved (virtual address space)	SRIBE	SRIBE
	0000 0008 _H - 5FFF FFFF _H	-		SRIBE	SRIBE
6	6000 0000 _H - 6001 DFFF _H	120 Kbyte	CPU1 Data Scratch-Pad SRAM (CPU1.DSPR)	access	access
	6001 E000 _H - 6001 FFFF _H	8 Kbyte	CPU1.Data Cache SRAM (CPU1.DCACHE)	access ³⁾ / SRIBE	access ³⁾ / SRIBE

	BF08 0000 _H - BF0F FFFF _H	-	Reserved	SRIBE	SRIBE
	BF10 0000 _H - BF10 3FFF _H	16 Kbyte	Reserved for TC26x B-Step Emulation Device Memory (EMEM)	SRIBE	SRIBE ⁶⁾
	BF10 4000 _H - BFFF FFFF _H	-	Reserved	SRIBE	SRIBE
12	C000 0000 _H - CFFF FFFF _H	-	Reserved ⁸⁾	SRIBE	SRIBE
13	D000 0000 _H - DFFF FFFF _H	-	Reserved ⁸⁾	SRIBE	SRIBE
14	E000 0000 _H - EFFF FFFF _H	-	Reserved	SRIBE	SRIBE
15	F000 0000 _H - FFFF FFFF _H	256 Mbyte	see Table 3-3		

1) A read transaction through the SRI to FPI bridge that is terminated with Bus Error will result in Bus Errors on SRI and FPI (valid for transactions from FPI to SRI and SRI to FPI).

2) Write access to Flash resources are handled by the PMU module (Flash command sequence, see PMU chapter for details).

3) PCache/DCache SRAMs (and the corresponding TAG SRAMs) can be only accessed when mapped into the address space (PCache / DCache disabled. See MTU chapter, register MTU_MEMMAP for details).

Memory Maps

- 4) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with single data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing.
- 5) Online Data Acquisition address space can be disabled/enabled via LMU control register bit LMU_MEMCON.OLDAEN. TC1.6P access to OLDA address space via segment 8 (cached) results in SRIBE independent of the LMU_MEMCON.OLDAEN bit setting.
- 6) This address range is mapped to the LMU module. A read/write from/to this address range will result in an SRI Bus Error initiated by the LMU module,
- 7) DF0 is the address where all Data Flash blocks are mapped to. The details about the Data Flash block sizes, segmentation and exact mapping are described in the chapter PMU.
- 8) See also chapter 'CPU, 'Local and Global Addressing' for CPU local views to segment 'C' and segment 'D'.

3.3.2 Segment 15

Table 3-3 shows the address map of segment 'F' as seen from the SRI and SPB bus masters (bus master agents are described in the chapter On Chip Bus System).

Table 3-1 gives an overview about the address mapping of the module address ranges:

- which modules are mapped into the first 16 KB of segment 'F' and can be accessed by the TC1.6E/P with absolute addressing modes (left side)
- examples of covering modules with relative addressing mode (base address +/- 32 KB, in the middle)

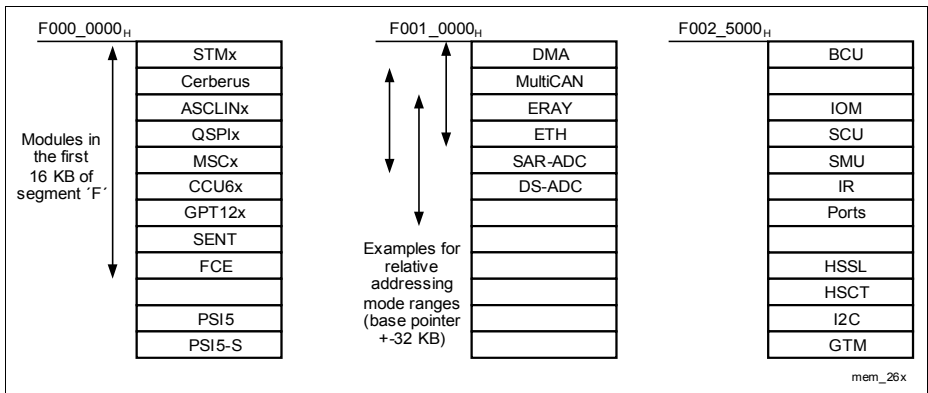

Figure 3-1 Segment F Structure

Please note that **Table 3-3** describes the mapping of modules to segment F. The details of the module address ranges can be found in the module chapters register overview.

3.4 Memory Module Access Restrictions

Table 3-4 describes which type of accesses are possible to the different memories in the TC26x B-Step.

Table 3-4 Possible Memory Accesses¹⁾

Memory		Bit	Byte		Half-word		Word		Double-word	
		rmw	r	w	r	w	r	w	r	w
PMI ²⁾	PSPR	y	y	y	y	y	y	y	y	y
	PTAG ³⁾	-	-	-	-	-	y	y	-	-
	PCACHE	y	y	y	y	y	y	y	y	y
DMI ²⁾	DSPR	y	y	y	y	y	y	y	y	y
	DTAG ³⁾	-	-	-	-	-	y	y	-	-
	DCACHE	y	y	y	y	y	y	y	y	y
LMU ²⁾	LMURAM	y	y	y	y	y	y	y	y	y
PMU	BROM	-	y	-	y	-	y	-	y	-
	PFLASH	-	y	-	y	-	y	y	y	y
	DFLASH	-	y	-	y	-	y	y	y	y

1) 'y' means: supported. '-' means: not supported

2) The module also supports SRI 2-Word and 4-Word Block read and write accesses.

3) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with 32-bit data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing. The TAG SRAM size is below 24 bit, so the 8 MSB of a 32 bit write or read are dont care.

3.5 Side Effects from Modules to CPU0 Data Scratch Pad SRAM (DSPR0)

Pls. note that a part of the CPU0 DSPR will be overwritten by the start-up (BootROM) procedure after cold power-on as well as the information in this area should be used and in case modified by the (user) SW procedure when preparing the device to enter Stand-By mode. The details are described in the Firmware chapter, sub-chapter 'RAMs Handling'.

4 TC26x B-Step BootROM Content

The BOOT_TC26X consists basically of three parts:

- Startup Software (short name SSW);
- Software modules implementing additional functions (Bootstrap Loaders);
- Test Firmware.

4.1 Startup Software

The Startup Software is the first software executed after a chip reset.

TC26x SSW is executed on CPU0 - all other CPUs are kept in Halt-state during boot, to be started by user software - and SSW has:

- one only entry point - SSW start address in BootROM is the reset value in Program Counter register of the CPU0. From this location an instruction is fetched and this is the first instruction executed after any device start-up.
 - immediately after this entry point the firmware checks for testmode, and in case testmode is selected - jump to test firmware is executed
- one only exit point - the last SSW instruction performs a jump to the first user code instruction. This first user instruction can be fetched from different locations depending on the start-up configuration as selected by the user.

The Startup Software contains procedures to initialize the device depending on one or more from the following:

- information previously stored into dedicated Flash locations
- the current state of special bits/fields in dedicated register/memory locations
- the type of event which has triggered the SSW-execution (the last reset event)
- values applied to external (configuration-) pins (optional)

The SSW also calls - in case - other firmware modules.

4.1.1 Events triggering SSW execution

SSW execution can be triggered by different events. SSW recognizes the triggering (reset) event and takes (partially) different execution flows.

4.1.1.1 Power-on

This is the initial powering-up of the device after the supply has been switched off, or in other words - the only way to generate this reset event is by applying power to a previously un-powered device.

The conditions at which the SSW execution starts upon this event include:

- all the registers are in their initial (reset) state
- Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation

- RAMs' content is undefined
- clock system is in its initial state

Due to the overall “fully initial” state of the device upon power-on, the SSW flow is respectively longer in this case and covers the biggest amount of activities compared to other reset events.

4.1.1.2 System reset

Attention: *From SSW point of view, the handling of system reset is the same as of “warm power-on”.*

Therefore further in this Chapter when system reset is referred - the same SSW handling applies upon warm power-on, exceptions will be in case specially notified.

This reset event can be requested by different sources:

- device internal hardware - from modules like watchdog timer and security/memory control logic
- external hardware - when active signal is applied to defined device pin(s)
- software - when defined control bit(s) are respectively installed during user code execution

For most of the sources, generating system reset is a feature configurable by software.

The exception is PORST pin, applying active low level to which generates system reset only if the supply voltage is above defined level permanently in the surrounding time window - e.g. the device is continuously powered before and during system reset activation. Otherwise - upon a supply drop below some level - power-on is immediately triggered. All this functionality is supported by the EVR module.

The conditions at which SSW execution starts upon system reset include:

- all the registers are in their initial (reset) state
- Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation
- RAMs' content is the same as just before the system reset has been triggered
- clock system is in its initial state

As seen from the above list, the only difference in the initial system status after power-on and system reset is in that the content of RAMs is not changed by the reset event.

4.1.1.3 Application reset

Similarly to system reset, an application reset can be requested by different sources: internal/external hardware as well as software. For all the sources, generating system reset is a feature configurable by software.

The conditions at which SSW execution starts upon application reset include:

- registers connected to this reset type are in their initial (reset) state

TC26x B-Step BootROM Content

- Flash is in read mode
- all the rest - RAMs and surround logic, clock system, registers under system reset - is not affected by this event.

Following the limited changes within the device status upon application reset, the SSW flow is shortest in this case.

4.1.2 Clock system during start-up

The state of clock system during device start-up depends on the reset event type:

- upon power-on and system reset - clock system is in its initial state, namely:
 - $f_{SRI} = f_{CPU0} = f_{FSI} = f_{BACK} = 100\text{MHz}$ nominal
 - $f_{SPB} = f_{STM} = f_{BACK}/2 = 50\text{MHz}$ nominal
 - in Emulation Device (ED) $f_{BBB} = f_{BACK}/2 = 50\text{MHz}$ nominal
 - PLL and VCO are in power-down mode
- upon application reset - clock system does not change its state, therefore the device runs at same frequency and clock source as before the reset event

With the same clock system state the first user code is started, with exception of the Bootstrap Loader mode upon power-on - refer to [Chapter 4.2](#).

4.1.3 RAM overwrite during start-up

Start-up procedure upon power-on and system reset can overwrite up to 8kByte at the beginning of CPU0 DSPR. Therefore this area should not be used by application software to save data, which must be preserved through warm power-on or system reset.

4.1.4 Boot Options Summary

This chapter summarizes the TC26x startup configurations in user mode.

Internal Start

In this basic startup mode, the first user instruction is fetched from address A000 0020_H in Internal Program Flash of the device.

Bootloader Modes

Different Bootstrap Loader routines are used in these modes to download code/data into the Instruction Scratchpad Memory SPRAM (PSPR), as follows:

- ASC bootloader
- CAN bootloader
- Generic bootloader mode - the bootloading procedure itself here is in fact one of the two above possibilities - ASC/CAN. The selection either to use ASC- or CAN-

TC26x B-Step BootROM Content

communication protocol is done by the SSW upon the first byte received at the couple of pins, which are then respectively configured to ASC or to MultiCAN module.

Alternate Boot Modes

In these modes, program code is started from user-defined address but only if all defined check-conditions are satisfied. Otherwise Generic Bootstrap Loader mode can be entered to download the code into device, this code is afterwards started by the SSW.

All the information needed for the SSW to handle ABM startup mode is collected into the so-called Headers. The checks are performed according to [Start-up mode selection](#) flow as defined in [Chapter 4.1.5](#).

4.1.5 Start-up mode selection

TC26x B-Step start-up flow in regard to mode selection is shown at [Figure 4-1](#).

There one way only to select start-up configuration in TC26x B-Step:

- [Configuration by Boot Mode Index \(BMI\)](#) - according to values taken from dedicated locations in Flash (new feature for Aurix products)

Additionally, as an option of the BMI-configuration flow the well known proceeding from previous devices is supported:

- [Hardware configuration](#) - according to the values at configuration pins

The flow to evaluate start-up configuration in TC26x B-Step is as follows:

1. if error happens during Flash ramp-up or Flash Config sector is corrupted (unrecoverable data error) - SSW terminates immediately
2. SSW evaluates sequentially up to four Boot Mode Headers BMHD0...BMHD3 - for header locations refer to [Table 4-2](#), evaluation procedure - see below and [Figure 4-2](#)
 - a) if a valid header is found - start-up mode is taken accordingly
 - b) if no valid header is found - continue with step 3.
3. check if the last BMI has enabled pin configuration and the pins have selected ABM but the code check failed:
 - a) if not - continue with step 4.
 - b) if yes - execute Generic or ASC Bootstrap Loader mode according to STSTAT.HWCFG[5:4] (refer to [Table 4-3](#))
4. check if the condition (OTP protected mode disabled) is true:
 - a) if yes - initialize all security-relevant RAMs, then check either debugger is connected and halt-after-reset is requested (OSTATE.HARR=1)
 - if yes - execute Internal start mode - CPU0 will be halted before the first user instruction
 - if no - execute Generic Bootstrap Loader mode - default mode if no valid BMI
 - b) if not - check and in case enable debug access using the general evaluation sequence, then enter endless loop - an external debugger (if access granted) are able to handle further the device start-up

TC26x B-Step BootROM Content

Note: The initialization of all security-relevant RAMs here is to prevent using BSL mode as back door for reading out user information previously stored into some RAM(s).

Table 4-1 Boot Mode Header (BMHD) structure

Offset Addr.	Size Byte	Field Name	Description
00 _H	4	STADABM	User Code Start Address
04 _H	2	BMI ¹⁾	Boot Mode Index (BMI)
06 _H	2	BMHDID ¹⁾	Boot Mode Header ID (Confirmation code) = B359 _H
08 _H	4	ChkStart	Memory Range to be checked - Start Address
0C _H	4	ChkEnd	Memory Range to be checked - End Address
10 _H	4	CRCRange	Check Result for the Memory Range
14 _H	4	<u>CRCRange</u>	Inverted Check Result for the Memory Range
18 _H	4	CRChead	Check Result for the ABM Header (offset 00 _H ..17 _H)
1C _H	4	<u>CRChead</u>	Inverted Check Result for the ABM Header

1) These fields are different from the ABM Headers in previous devices.

Table 4-2 Boot Mode Headers locations

Header	Start address	End address
BMHD0	A000 0000 _H	A000 001F _H
BMHD1	A002 0000 _H	A002 001F _H
BMHD2	A000 FFE0 _H	A000 FFFF _H
BMHD3	A001 FFE0 _H	A001 FFFF _H

Table 4-1 shows the Boot Mode Header (BMHD) structure, the procedure to evaluate one BMHD includes following steps (refer to **Figure 4-2**):

1. check either Boot Mode Header ID is correct
 - a) if BMHDID = B359_H - continue with 2.
 - b) if not - continue with 7.
2. calculate the CRC of the first 24 Bytes from the ABM Header (refer to **Table 4-1**) - process the fields STADABM...CRCRange at offsets 00_H..17_H
 - a) compare the result with the CRChead value (offset 18_H)
 - if OK - continue with 2.b)
 - if not - continue with 7.

TC26x B-Step BootROM Content

- b) inverse the result value and compare with $\overline{\text{CRChead}}$ (offset 1C_H)
 - if OK - continue with 3.
 - if not - continue with 7.
 - 3. check either BMI[15:10, 7:0] value is valid - refer to **Chapter 4.1.5.2**
 - a) if yes - continue with 4.
 - b) if not - continue with 7.
- Note: Bits BMI[9:8] are excluded from this check because they control Lockstep Logic and can have arbitrary values.*
- 4. check the conditions BMI[3]=0 (pin-configuration enabled) AND HWCFG[3] pin value=0 (pin-configuration selected) AND PROCONOTP[30:29]=00_B (boot flow with standard evaluation of headers):
 - a) if all the conditions are true - **Hardware configuration** is taken (refer to **Chapter 4.1.5.1**) meaning in the further handling STSTAT.HWCFG[6] will be ignored and the mode selection will be done according to **Table 4-3**, continue with 5.
 - b) if not - **Configuration by Boot Mode Index (BMI)** is taken (refer to **Chapter 4.1.5.2**) and respective value installed in STSTAT.HWCFG, then continue with 5.
 - 5. check either STSTAT.HWCFG value selects Alternate Boot Mode (ABM)
 - a) if yes - continue with 6.
 - b) if not - exit this procedure, BMI is OK, mode is selected in STSTAT.HWCFG
 - 6. calculate the CRC over the memory address range ChkStart...ChkEnd (start- and end- addresses taken from offsets 08_H and 0C_H respectively)
 - a) compare the result with the CRCrange value (offset 10_H)
 - if OK - continue with 6.b)
 - if not - continue with 7.
 - b) inverse the result value and compare with $\overline{\text{CRCrange}}$ (offset 14_H)
 - if OK - exit this procedure, BMI and code are OK, ABM is selected in STSTAT.HWCFG
 - if not - continue with 7.

Attention: If (some part of) the memory range selected by ChkStart...ChkEnd is into illegal address area (refer to Memory Map Chapter), attempting to read from there will cause a trap and SSW will terminate on error!

- 7. check again so called Magic number in Flash Config sector
 - a) if OK - exit this procedure, header and BMI check failed
 - b) if wrong - terminate SSW immediately on error

Note: The last step above is to reduce the probability that a hacker attack disturbs BMI/ABM checks targeting to cause unintentional (from the original user code) entry into Bootstrap Loader mode.

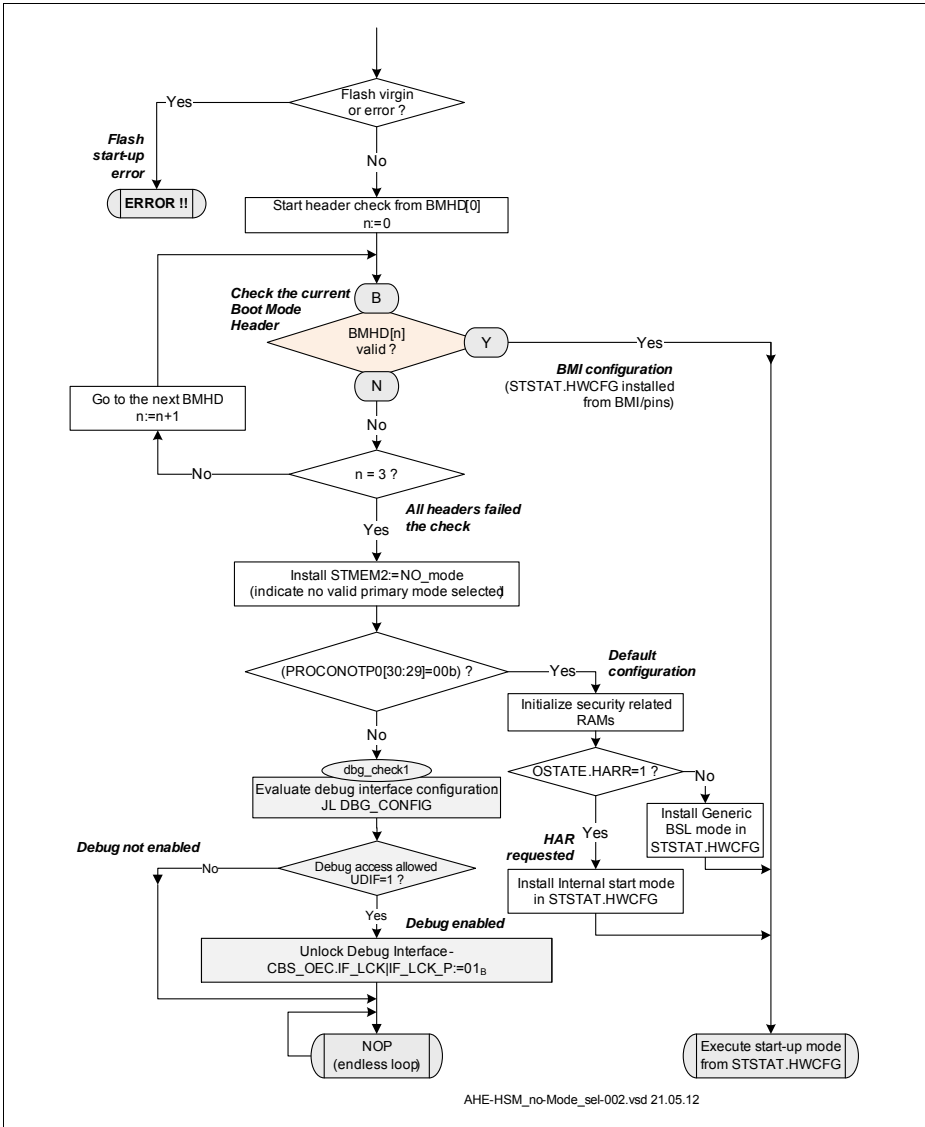

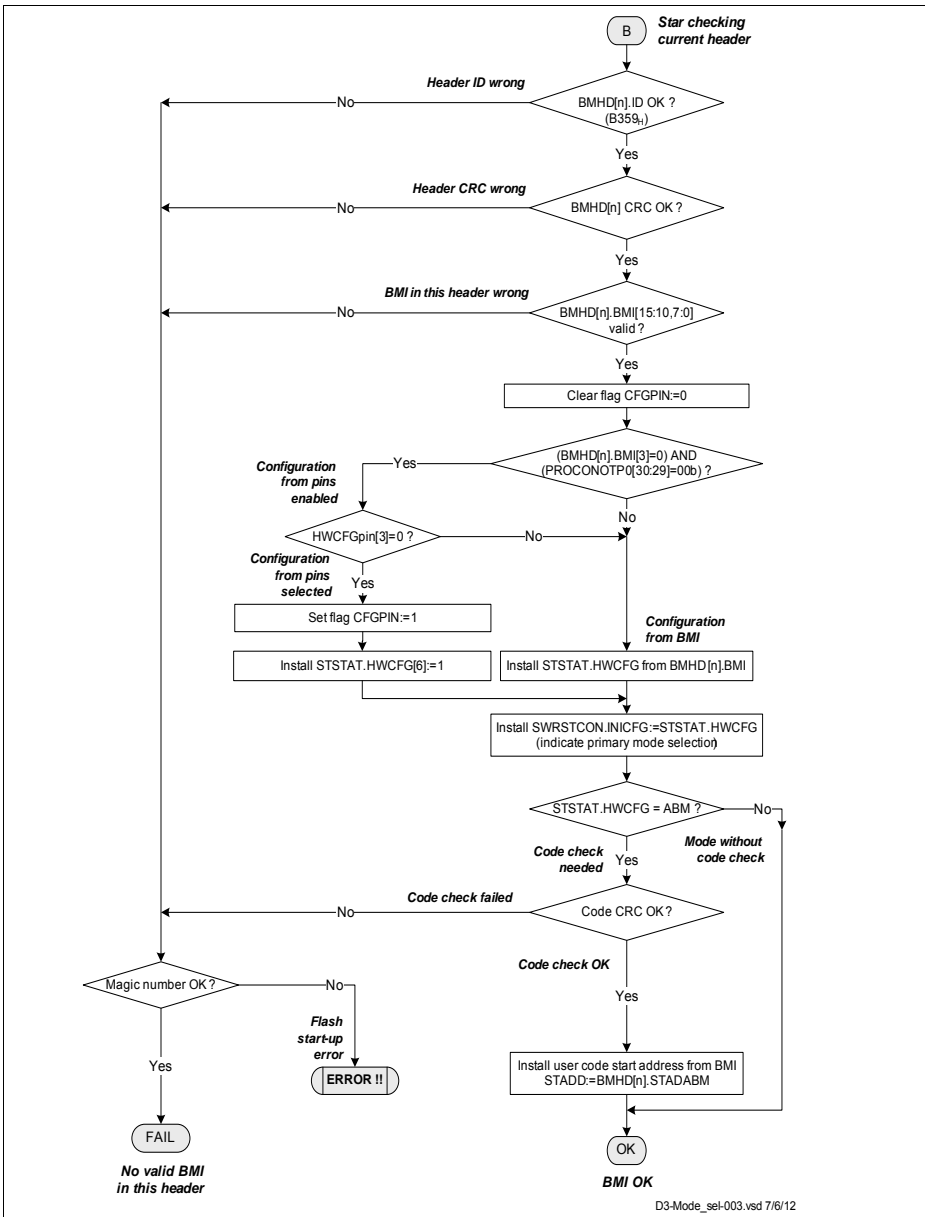

Figure 4-1 Start-up mode selection flow in TC26x B-Step

TC26x B-Step BootROM Content

D3-Mode_sel-003.vsd 7/6/12

Figure 4-2 Mode selection in TC26x B-Step: check of one Boot Mode Header

4.1.5.1 Hardware configuration

The start-up mode selection by configuration pins HWCFG[5:4] in TC26x B-Step is shown in [Table 4-3](#). The values at these pins are latched by hardware upon any reset (deactivation - rising edge) into register which is read and evaluated by SSW during start-up processing.

Note: HWCFG[2:0] pins are used for EVR control, HWCFG[6] - for pull-up/tristate pin configuration, HWCFG[7] is not available for TC26x B-Step.

Table 4-3 Start-up mode selection by pins in TC26x B-Step

HWCFG pins		Start-up Mode
[5]	[4]	
1	1	Internal start from Flash
1	0	ABM, Generic Bootstrap Loader on fail
0	1	ABM, ASC Bootstrap Loader on fail
0	0	Generic Bootstrap Loader

4.1.5.2 Configuration by Boot Mode Index (BMI)

The Boot Mode Index (BMI) is 2 Byte value holding information about start-up mode of the device and Lockstep mode enable/disable.

The data structure of BMI is described below, followed by the definition of FLASH0_PROCOND bits which control RAM initialization, oscillator circuit (OSC) configuration and ESR0 pin handling by SSW.

NOTE: The start-up mode selections defined as "Reserved" in BMI.HWCFG are treated as invalid by SSW

4.1.6 Startup Software Main Flow

Below the SSW functionality is outlined during different execution-steps (refer to [Figure 4-3](#)) and upon various configuration settings.

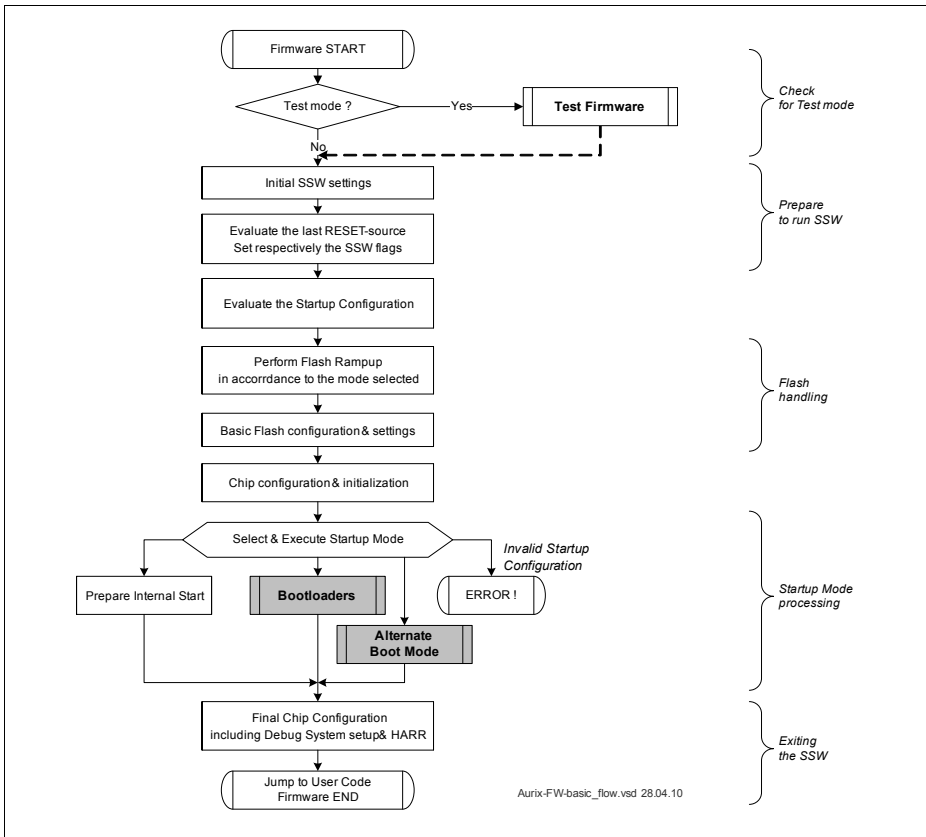

Figure 4-3 TC26x Firmware: Firmware main flow

4.1.6.1 Basic Device Settings

The target of this functional module is to initialize several TC26x-registers with the values, which will be first seen by the user - or generally available - after exiting the SSW.

4.1.6.2 Stand-by Controller preparation

Upon cold power-on, SSW checks either the Stand-by Controller (SCR) reset was activated by EVR, indicated by SCU_PMSWSTAT.SCRST=1. If this is the case - meaning no exit from stand-by mode took place and this is an initial power-on of the SCR itself - SSW performs the following:

- initialize SCR XRAM
- release SCR reset - the 8-bit microcontroller is activated to execute its start-up procedure
- check either SCR has booted successfully
 - if yes - do nothing, upon SSW exit SCR will be ready and waiting for further handling by user software
 - if not - activate SCR reset, then disable the module by setting SCU_PWSWCR0.SCREN=0

Therefore, SCR usage will be only possible if at the user software start SCU_PWSWCR0.SCREN=1. In such a case, code can be downloaded from user Flash into SCR XRAM via QSPI interface and its execution by SCR started. For more information - refer to SCR documentation.

4.1.6.3 RAMs Handling

By default SSW in TC26x initializes SCR XRAM upon cold power-on, if no exit from stand-by (see above).

For all the security-relevant RAMs initialization upon power-on/system reset can be requested by **FLASH0_PROCOND** register content (refer to [Chapter 4.1.5.2](#)).

4.1.6.4 Select and Prepare Startup Modes

TC26x B-Step User Startup Configurations and modes are summarized below.

Internal Start

This is the basic TC26x type of operation in which the user code is started out of the Internal Flash Memory.

The User Start Address is set to A000'0020_H.

Bootstrap Loader Modes

Two Bootstrap Loader modes are supported in TC26x B-Step:

- ASC Bootloader - ASC communication protocol via ASC pins
- Generic Bootloader via CAN pins - the communication protocol is automatically selected by the SSW between ASC and CAN

TC26x B-Step BootROM Content

After downloading (in case) the code, the User Start Address STADD is set to the beginning of Program Scratchpad RAM PSPR at C000 0000_H.

Alternate Boot Mode

The handling of this (ABM) start-up mode is according to the flow at [Figure 4-1](#) and [Figure 4-2](#).

If this mode is selected by a valid BMI Header (or by pins if pin configuration is enabled in a valid Header) - the handling depends on code check result:

- if code check pass - the User Start Address STADD is set to the respective value from the header (STADABM_x) and the code will be started from that address
- if code check fails - the current Boot Mode Header is considered as not valid and not used for configuration respectively ABM not effectively taken, then
 - if more Header(s) exist - the next one is taken for evaluation
 - if selected by pin-configuration enabled by BMHD3 (i.e. no more Headers available) - Generic or ASC Bootloader mode is taken in accordance to the pin-selection (refer to [Table 4-3](#))

4.1.6.5 Final Chip Settings

The last device configuration steps performed by the SSW include:

Flash access handling

SSW flow here includes:

- fetches (code/data, from Program/Data Flash) control
 - if user code will be started from internal flash - all fetches are enabled
 - otherwise - according to the protection (active/not) state
- Program and Erase operations are enabled

No handling of Unique Chip ID and Calibration data

This information (Unique Chip ID and Calibration data) is now stored in User Configuration Block which is readable for the user. As consequence it is no more installed into DSPR but can be read directly by the application software.

Debug System handling

As first point of this processing, the SSW internal flag Unlock Debug Interface is set if debug access to device will be enabled according to the following evaluation sequence:

1. SSW checks either an external tool has requested debug access by writing a defined content (32 bit value CMD_KEY_EXCHANGE=76D6E24A_H for TC26x B-Step) into COMDATA register
 - a) if yes - continue with the next step

TC26x B-Step BootROM Content

- b) if not - go to step 4.
- 2. still in Cerberus Communication mode, SSW confirms request reception and receives 8 further words through COMDATA register
- 3. the data received (256 bits) is sent by SSW to PMU to be checked as debug interface password and the result is evaluated by SSW:
 - a) if OK - set SSW internal flag, debug interface will be unlocked, exit the sequence
 - b) if fail - continue with the next step
- 4. install into COMDATA 32-bit value serving for an external tool to identify the device connected - UNIQUE_CHIP_ID_32BIT
- 5. check if Flash protection is activated:
 - a) if yes - debug interface will be left locked, no debug access to device, exit the sequence
 - b) if not - set SSW internal flag, debug interface will be unlocked, exit the sequence

The following steps are introduced to support so called “Debug Self-destructive Entry” feature. The target is, if this feature is activated and debugging is requested by correct debug password (see steps 1...3 above) - to destroy vital functions of the device (so that it is not usable in a real application anymore) before effectively granting debug access.

The steps performed are:

- 6. check either “Debug Self-destructive Entry” feature is activated for the device (PROCONHSMOTP.DESTDBG=11_B):
 - a) if yes - continue with the next step
 - b) if no - debug access granted, go to step 4.b)
- 7. using PMU command sequences, erase and re-program UCB_DBG with the previous password but setting “Entered Debug Mode” marker (EDM=11_B) in PROCONDBG; then go to step 4.b) - debug access granted

Next, Halt after Reset is prepared if requested. The SSW processing here is as follows:

- check either external (debug) access to the device will be generally granted
 - if Not -> exit this procedure
- check either Halt After Reset is requested
 - if Not -> exit this procedure
- configure a Break After Make breakpoint at the last SSW instruction
- enable On-Chip Debug Support system.

Note: The final debug-related operation - unlocking (in case) the debug interface - is performed later.

ESR0 pin handling

If both the conditions

- ESR0CNT<>FFF_H in **FLASH0_PROCOND** (refer to register description in **Chapter 4.1.5.2**) AND
- ESR0-pin configuration upon SSW entry is open-drain reset output (SCU_IOCR.PC0 in [1110_B, 1010_B])

are satisfied, SSW will:

- release ESR0 pin - by installing SCU_ESROCFG.ARC:=1 which clears Application Reset Indicator in SCU_ESROCFG.ARI - with some delay after device internal reset is released (i.e. CPU0 started), the delay is defined as follows
 - if **FLASH0_PROCOND**.ESR0CNT=000_H - about 500µsec upon cold power-on, not longer than 20µsec otherwise
 - if **FLASH0_PROCOND**.ESR0CNT=001_H...FFE_H - (ESR0CNT)*10µsec
- wait until ESR0 pin is effectively high - indicated by SCU_IN.P0=1 - at the very SSW end and before jumping to the first user instruction

To generate configurable ESR0 delay after device reset release, SSW uses System Timer 0 (STM0) and especially takes into account the following default settings after power-on/system reset:

- STM is reset and starts counting from zero
- STM is clocked with 50MHz i.e. $f_{STM} = F_{EVR_OSC} / 2$

Attention: Both the above conditions could not be true after application reset, if default settings are changed by user code executed after power-on/system reset. In such a case, ESR0 handling by SSW will not work correctly, meaning the real prolongation will not correspond to ESR0CNT value configured.

Lockstep configuration

Upon cold power-on only SSW performs Lockstep configuration as follows:

- if valid BMI has been found during start-up mode evaluation:
 - Lockstep control for CPU1 is installed in LCLCON1.LSEN from BMI[9]

4.1.6.6 Ending the SSW and Starting the User Code

The last steps executed by the SSW are:

- activate the Startup Protection
- unlock (in case) Debug Interface
- jump to the first User Instruction (for TriCore) at address STADD.

Additionally, if all the following conditions are satisfied:

- the device is an ED
- debug access to device is allowed
- halt after reset is not requested
- the last reset has been a power-on (cold or warm)

SSW performs at its very end additional checks and in case all these succeed - the last SSW instruction jumps not to the “standard” STADD but to an address inside EMEM (Emulation Memory). This SSW part implements the sequence defined in Emulation Device Target Specification, Chapter “Startup with prolog code in EMEM”.

4.2 Bootstrap Loaders

These routines provide mechanisms to load an user program via selected interface by moving code into PMI Scratchpad RAM (an Internal Program memory). The loaded code is started after exiting the BootROM.

The exact communication modules and pins used in different modes are summarized in [Table 4-4](#).

4.2.1 ASC Bootstrap loader

The ASC Bootloading routine implements the following steps:

- Rx/D/TxD pins configuration (refer to [Table 4-4](#)) is done in accordance to the TC26x definitions, as well as depending either the routine is invoked upon “ASC Bootloader”-startup mode (ASC-only pins are used) or following an ASC-protocol detection upon “Generic Bootloader”-mode (CAN/ASC-shared pins are used but configured to ASC module)
- baudrate calculation is done based on the zero Byte sent by the host
- ASCLIN channel n (refer to [Table 4-4](#)) is initialized (without enabling the receiver) to the baudrate as determined, 8 data and 1 stop bit
- acknowledge byte D5_H is sent to the host indicating the device is ready to accept a data transfer
- after the acknowledge byte is transmitted, the receiver is enabled
- the bootloader enters a loop waiting to receive exactly 128 bytes which are stored as 32 words in CPU0 Program Scratchpad RAM starting from address C000 0000_H

Once 128 bytes are received, the SSW continues further - refer to [Figure 4-3](#). After exiting the SSW, user code will be started from address C000 0000_H (CPU0_PSPR).

4.2.2 CAN Bootstrap Loader

The CAN bootstrap loader transfers program code/data via node n (refer to [Table 4-4](#)) of the MultiCAN module into CPU0 Program Scratchpad RAM.

Note: TC26x B-Step requires that an external clock source (oscillator) must be connected between XTAL1/XTAL2 pins if CAN Bootstrap Loader mode will be selected upon power-on/system reset.

Oscillator frequency should be greater or equal to 20 MHz for a baud rate of 1 Mbit/s.

The CAN Bootstrap Loader transfers data from an external host to the TC26x B-Step using eight-byte data frames. The number of data frames to be received is programmable and determined by the 16-bit data message count value DMSGC.

The communication between TC26x B-Step and external host is based on the following three CAN standard frames:

- Initialization frame - sent by the external host to the TC26x B-Step

TC26x B-Step BootROM Content

- Acknowledge frame - sent by the TC26x B-Step to the external host
- Data frame(s) - sent by the external host to the TC26x B-Step

The initialization frame is used in the TC26x B-Step for baud rate detection. After a successful baud rate detection is reported to the external host by sending the acknowledge frame, data is transmitted using data frames.

Initialization Phase

The first task is to determine the CAN baud rate at which the external host is communicating. This task requires the external host to send initialization frames continuously to the TC26x B-Step. The first two data bytes of the initialization frame include a 2-byte baud rate detection pattern (5555_H), an 11-bit (2-byte) identifier ACKID for the acknowledge frame, a 16-bit data message count value DMSGC, and an 11-bit (2-byte) identifier DMSGID to be used by the data frame(s).

The CAN baud rate is determined by analyzing the received baud rate detection pattern (5555_H) and the baud rate registers of the MultiCAN module are set accordingly. The TC26x B-Step is now ready to receive CAN frames with the baud rate of the external host.

Acknowledge Phase

In the acknowledge phase, the bootstrap loader waits until it receives the next correctly recognized initialization frame from the external host, and acknowledges this frame by generating a dominant bit in its ACK slot. Afterwards, the bootstrap loader transmits an acknowledge frame back to the external host, indicating that it is now ready to receive data frames. The acknowledge frame uses the message identifier ACKID that has been received with the initialization frame.

Data Transmission Phase

In the data transmission phase, data frames are sent by the external host and received by the TC26x B-Step. The data frames use the 11-bit data message identifier DMSGID that has been sent with the initialization frame. Eight data bytes are transmitted with each data frame. The first data byte is stored in Program Scratchpad RAM starting from address C000 0000_H. Consecutive data bytes are stored at incrementing addresses.

Both communication partners evaluate the data message count DMSGC until the requested number of CAN data frames has been transmitted.

After the reception of the last CAN data frame, the SSW continues further - refer to [Figure 4-1](#). After exiting the SSW, user code will be started from address C000 0000_H (CPU0_PSPR).

4.2.3 Summary of Bootstrap Loader Modes

This table summarizes the external hardware provisions for bootstrap loader modes in TC26x B-Step.

Table 4-4 Configuration Data for Bootstrap Loader Modes

Bootstrap Loader Mode	Channel/ node	RxD Line	TxD Line	Transferred Data	Supported baudrates
ASC Bootstrap Loader mode	ASCLIN0	P15.3	P15.2	128 Bytes	28k...2500k
Generic Bootstrap Loader mode - ASC protocol	ASCLIN0	P14.1	P14.0	128 Bytes	28k...2500k
Generic Bootstrap Loader mode - CAN protocol	CAN1	P14.1	P14.0	8×n Bytes ¹⁾	up to 1000k ²⁾

1) n = DMSGC, Data Message Count sent by the host with Initialization frame.

2) with 20MHz XTAL clock source

4.3 Shutdown request handler

All the active CPUs in TC26x B-Step jump unconditionally to the entry point of this handler upon any warm reset request - refer to Reset Control Unit Section in SCU ITS.

It is guaranteed by hardware, this handler can not be interrupted by any other (interrupt/trap) request, and upon its end all the CPUs are in stable passive state reached by a controlled ramp-down sequence, preventing big current jumps.

At its entry point - common for all the CPUs - the firmware causes any running CPU to jump further to its own handler. For this purpose CORE_ID register is read and because this register value is individual for any CPU - upon CORE_ID=0, 1 or 2 the firmware jumps to the routine for respective CPU.

The functionality of all handlers is similar, namely:

- prepare work data for execution of average-power loop
- execute average-power loop until SCU_RSTCON2.TOUT_{yy}=1
- execute WAIT instruction

Upon completion of the above sequence, CPU_x has reached passive state *yy* microseconds after shutdown request activation, whereas:

- *yy*=60 for CPU0
- *yy*=40 for CPU1

4.4 Power Supply Friendly Debug Monitor

TC26x B-Step BootROM contains a routine called Power Supply Friendly Debug Monitor (PSFDM). The purpose on this routine is to minimize the risk of getting EVR voltage over/undershoot due to a sudden current drop when more than one CPU is halted by OCDS, respectively current peak when the CPUs are released from halt.

PSFDM routine is an “independent/stand alone” module inside BootROM which is never executed during device start-up (SSW) or production test (TSW). It is intended to be used by CPUs as debug trap handler instead of halting. This means the debugger must configure properly the debug trap vector - it should point to address AFFF C020_H (inside BootROM).

Upon a debug event, trap will be triggered for all configured CPUs starting PSFDM execution, then they can be halted individually by the tool if needed.

PSFDM routine contains a “repeat **action** until **condition**” loop whereas:

- the **action** represents a sequence which execution consumes power close to the consumption of an average program code. For this purpose mixture between two TC1.6 instructions is implemented:
 - most power intensive (MADD.Q)
 - less power intensive (NOP)
- the **condition** to exit the loop is CBS_TLS.TL2=1 meaning OTGS Trigger Line 2 being activated

To continue user code execution, the debugger must:

- release from halt those CPUs which have being halted - so all the CPUs are running PSFDM as debug trap handler
- activate OTGS Trigger Line 2 - all the CPUs exit PSFDM (by RTE) and continue user code execution

At the end, after debug trap the CPUs are restarted in parallel, with a few cycles slack due to the individual CBS_TLS.TL2 polling.

4.4.1 PSFDM code with inverse exit condition

The same routine as above described is implemented in BootROM starting at AFFF FC80_H with one difference:

- the **condition** to exit the loop is CBS_TLS.TL2=0 meaning OTGS Trigger Line 2 being deactivated - i.e. the exit condition here is inverse to the above

5 CPU Subsystem

This chapter describes the implementation-specific options of the TriCore CPUs found in the Aurix series of devices. Details of both TriCore1.6P (TC1.6P) and TriCore1.6E (TC1.6E) CPUs are included. The CPU and local memory configurations of the various members of the Aurix family are detailed in the following table.

This chapter should be read in conjunction with the TriCore Architecture Manual. Topics covered by the architecture manual include:-

- Architectural Overview
- Programing Model
- CPU Registers
- Tasks and Functions
- Interrupt Handling
- Traps
- Memory Protection System
- Temporal Protection System
- Floating Point Operations
- Debug
- Instruction Set

5.1 Aurix Family CPU configurations

The different CPU and local memory configurations for the Aurix family of devices are detail in the following tables:-

Table 5-1 Processor and local memory configuration of the TC29x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	2	32 KB	32 KB	8 KB	240 KB	No	No
TC1.6P	1	32 KB	32 KB	8 KB	240 KB	No	Yes
TC1.6P	0	16 KB	32 KB	8 KB	120 KB	Yes	No

Table 5-2 Processor and local memory configuration of the TC27x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	2	16 KB	32 KB	8 KB	120 KB	No	No
TC1.6P	1	16 KB	32 KB	8 KB	120 KB	No	Yes
TC1.6E	0	8 KB	24 KB	0 ¹⁾	112 KB	Yes	Yes

1) TC1.6E has a 128Byte read buffer in place of a data cache

Table 5-3 Processor and local memory configuration of the TC26x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6P	1	16 KB	32 KB	8 KB	120 KB	No	Yes
TC1.6E	0	8 KB	16 KB	0 ¹⁾	72 KB	Yes	No

Table 5-4 Processor and local memory configuration of the TC24x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	16 KB	0 ¹⁾	80 KB	Yes	No

Table 5-5 Processor and local memory configuration of the TC23x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	8 KB	0 ¹⁾	184 KB	Yes	Yes

Table 5-6 Processor and local memory configuration of the TC22x

Processor	Core -ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	Standby SRAM	Lock-Step
TC1.6E	0	8 KB	8 KB	0 ¹⁾	88 KB	Yes	Yes

1) TC1.6E has a 128Byte read buffer in place of a data cache

5.2 Central Processing Unit Features

Key CPU Features include:-

Architecture

- 32-bit load store architecture
- 4 Gbyte address range (2^{32})
- 16-bit and 32-bit instructions for reduced code size
- Data types:
 - Boolean, integer with saturation, bit array, signed fraction, character, double-word integers, signed integer, unsigned integer, IEEE-754 single-precision floating point
- Data formats:
 - Bit, byte (8-bits), half-word (16-bits), word (32-bits), double-word (64-bits)
- Byte and bit addressing
- Little-endian byte ordering for data, memory and CPU registers
- Multiply and Accumulate (MAC) instructions: Dual 16×16 , 16×32 , 32×32
- Saturation integer arithmetic
- Packed data
- Addressing modes:
 - Absolute, circular, bit reverse, long + short, base + offset with pre- and post-update
- Instruction types:
 - Arithmetic, address arithmetic, comparison, address comparison, logical, MAC, shift, coprocessor, bit logical, branch, bit field, load/store, packed data, system
- General Purpose Register Set (GPRS):
 - Sixteen 32-bit data registers
 - Sixteen 32-bit address registers
 - Three 32-bit status and program counter registers (PSW, PC, PCXI)
- Debug support (OCDS):
 - Level 1, supported in conjunction with the CPS block
 - Level 3, supported in conjunction with the MCDS block (Emulation Device only).
- Flexible memory protection system providing multiple protection sets with multiple protection ranges per set.
- Temporal protection system allowing time bounded real time operation.

TC1.6P Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1, 2 or 3 cycles (using dynamic branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Four memory protection register sets
- Dual instruction issuing (in parallel into Integer Pipeline and Load/Store Pipeline)
- Third pipeline for loop instruction only (zero overhead loop)

- Single precision Floating Point Unit (IEEE-754 Compatible)
- Dedicated Integer divide unit
- Implementation optimised for performance.
- 16 data protection ranges, 8 code protection ranges

TC1.6E Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1 or 2 cycles (using static branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Four memory protection register sets
- Single instruction issue per cycle
- Single precision Floating Point Unit (IEEE-754 Compatible)
- Dedicated Integer divide unit
- Implementation optimised for power
- 16 data protection ranges, 8 code protection ranges

5.3 TC1.6P Implementation Overview

The following sections give an overview of the TC1.6P Implementation

5.3.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

Figure 5-1 CPU Block Diagram

5.3.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instructions from the 64-bit wide Program Memory Interface (PMI). Instructions are placed in predicted program order in the Issue fifo. The Issue fifo buffers up to six instructions and directs the instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The branch unit examines the fetched instructions for branch conditions and predicts the most likely execution path based on previous branch behavior. The Program Counter Unit (PC) is responsible for updating the program counters.

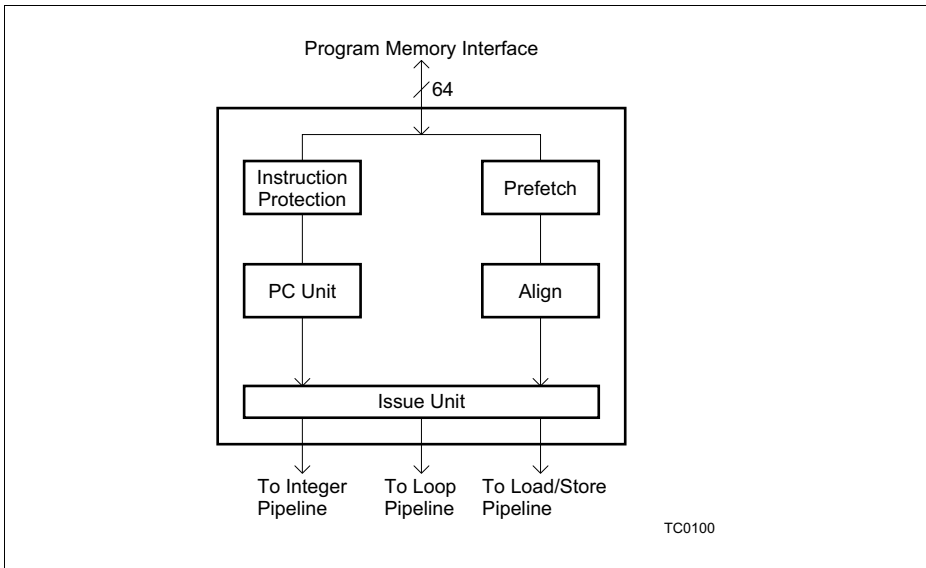

Figure 5-2 Instruction Fetch Unit

5.3.3 Execution Unit

The Execution Unit contains the Integer Pipeline, the Load/Store Pipeline and the Loop Pipeline. All three pipelines operate in parallel, permitting up to three instructions to be executed in one clock cycle. In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

Figure 5-3 Execution Unit

5.3.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

Figure 5-4 General Purpose Register File

5.4 TC1.6E Implementation Overview

The following sections give an overview of the TC1.6E Implementation

5.4.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

Figure 5-5 CPU Block Diagram

5.4.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instruction half-words from the 32-bit wide Program Memory Interface (PMI). The Issue Unit directs a single aligned instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The Program Counter Unit (PC) is responsible for updating the program counters.

Figure 5-6 Instruction Fetch Unit

5.4.3 Execution Unit

The Execution Unit contains the Integer Pipeline and the Load/Store Pipeline. In TC1.6E, loop instructions are always executed by the Load/Store pipeline.

The TC1.6E issues a single instruction per clock cycle, and as such no more than one instruction will be executed in one clock cycle.

In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

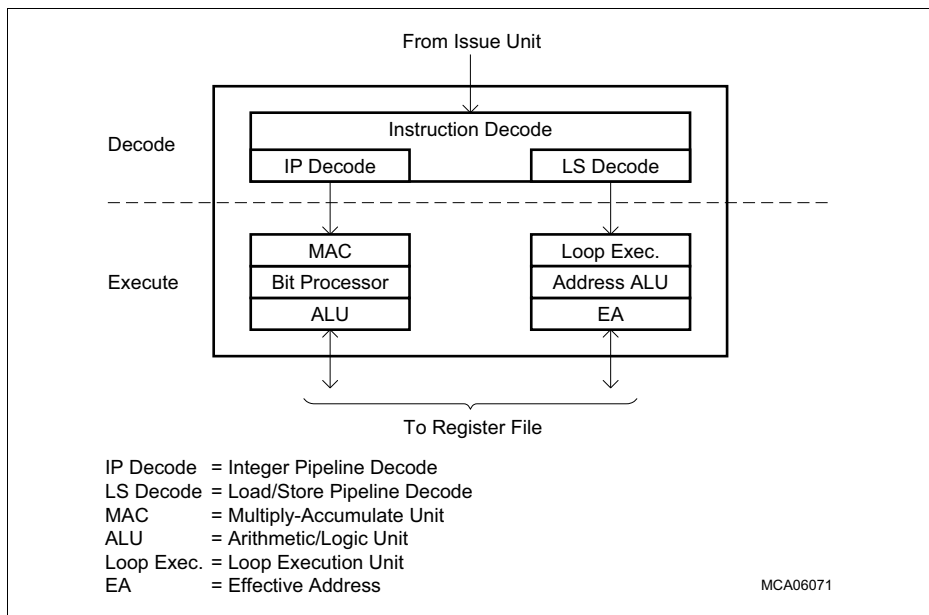

Figure 5-7 Execution Unit

5.4.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

Figure 5-8 General Purpose Register File

5.5 Summary of functional changes from TC1.3.1

The TC1.6P and TC1.6E CPUs utilise different pipeline organisations than that used in the TC1.3. One effect of the new pipeline organisation is to increase the load-use penalty to 1 from 0. This necessitates re-scheduling of code to achieve optimum performance.

Other significant adaptations to the existing TC1.3.1 CPU are as follows:

- Fully Pipelined Floating Point Unit (FPU)
 - Most floating point instructions now have a repeat rate of 1
- Improved debug system - now decoupled from protection system.
 - 8 comparators providing up to 4 ranges, selectable for PC or load-store address
- Expanded and enhanced memory protection unit (MPU)
 - 16 data ranges and 8 code ranges.
- New Temporal protection system.
 - Guards against task runtime overrun.
- New Safety protection system. Tasks identified as safe by new PSW bit (PSW.S)
- New instructions for improved Interrupt and Data Cache manipulation support.
 - DISABLE, RESTORE, CACHE.I
- New instructions for Fast Integer Divide
 - DIV, DIV.U
- New Instructions for fast call and return with minimal saving of state.
 - FCALL,FCALLA,FCALLI, FRET
- Long offset addressing mode introduced for byte, half word and address accesses.
 - LD.BU, LD.B, LD.HU, LD.H, ST.B, ST.H, ST.A
- Extended range of 16 bit jumps
 - JEQ, JNE
- New Synchronisation Instructions
 - CMPSWAP.W, SWAPMSK.W
- New CRC instruction
 - CRC32
- New wait for interrupt instruction
 - WAIT
- Increased flexibility in the system address map.
- Full SECDED ECC protection for all scratch, cache and tag memory structures.
- Cache and Scratchpad memory systems now entirely separated.
 - Cache memories may be mapped as additional scratchpad.
- Selectable interrupt vector table size (32bytes/entry, 8bytes/entry).

5.6 CPU Implementation-Specific Features

This section describes the implementation-specific features of the TC1.6P and TC1.6E CPUs. For a complete description of all registers, refer to the TriCore Architecture Manual.

5.6.1 Context Save Areas / Context Operations

The CPU uses a uniform context-switching method for function calls, interrupts and traps. In all cases the Upper Context of the task is automatically saved and restored by hardware. Saving and restoring of the Lower Context may be optionally performed by software.

In TC1.6P, Context Save Areas (CSA) and addresses targeted by explicit context load/store instructions (e.g. LDLCX) may be placed in DSPR or external memory (cached or uncached).

In TC1.6E, Context Save Areas (CSA) and addresses targeted by explicit context load/store instructions may be placed in DSPR only.

CSA Placement in DSPR

The actual timing of context operations is dependent upon the placement of the Context Save Areas. Maximum performance is achieved when the Context Save Area is placed in DSPR. In this case all context save and restores operations take four cycles.

CSA Placement in Cached External Memory (TC1.6P Only)

In this case, the timing is also dependent on the state of the Data Cache. The best case Data Cache operation occurs when context saves do not incur a cache line writeback, and context restores hit in the data cache. In this case all context saves and restores take eight cycles.

5.6.2 Program Counter (PC) Register

The Program Counter (PC) holds the address of the instruction that is currently fetched and forwarded to the CPU pipelines. The CPU handles updates of the PC automatically.

Software can use the current value of the PC for various tasks, such as performing code address calculations. Reading the PC through software executed by the CPU must only be done with an MFCR instruction. Such a read will return the PC of the MFCR instruction itself. Explicit writes to the PC through an MTCR instruction must not be done due to possible unexpected behavior of the CPU. The PC may be written only when the CPU is halted.

The CPU must not perform Load/Store instructions to the mapped address of the PC in Segment 15. A MEM trap will be generated in such a case. Bit 0 of the PC register is read-only and hard-wired to 0.

5.6.3 Store Buffers

To increase performance the TC1.6P/E CPUs implements store buffering to decouple memory write operations from CPU instruction execution. All stores from the CPU are placed in the store buffer prior to being written to local memory or transferred via the bus system. Write data is taken from the store buffers and written to memory when the target memory or bus interface becomes available. In normal operation the CPU will prioritise memory load operations over store operations in order to improve performance unless:-

- The store buffer is full.
- The load is to peripheral space and a store to peripheral space exists in the store buffer. (In order peripheral space access).
- The load or store is part of an atomic operation.

Typically the operation of the store buffer is invisible to the end user. If there is a requirement that data is written to memory prior to execution of a subsequent instruction then a DSYNC instruction may be used to flush the store buffers.

To further improve performance consecutive byte writes to the same half word location are merged in the store buffer.

The TC1.6P CPU store buffer can hold the data for up to 6 stores. The TC1.6E CPU store buffer can hold the data for up to 2 stores.

Store buffer operation may be disabled by setting the SMACON.IODT bit. This should not be done in normal execution as it will severely limit performance.

5.6.4 Interrupt System

An interrupt request can be generated by the on-chip peripheral units, or it can be generated by external events. Requests can be targeted to any CPU.

The interrupt system evaluates service requests for priority and to identify whether the CPU should receive the request. The highest-priority service request is then presented to the CPU by way of an interrupt.

On taking an interrupt the CPU will vector to a unique PC generated from the interrupt priority number and the Base Interrupt Vector (BIV). The spacing between the vector PCs in the interrupt vector table may be selected to be either 32 Bytes or 8 Bytes using BIV[0].

Both the TC1.6P and TC1.6E implement a fast interrupt system. This system avoids unnecessary context save and restore operations and hence speeds up interrupt routine entry. A fast interrupt is triggered when:-

- An Interrupt is pending
- A Return From Interrupt instruction is being executed (RFE)
- The priority of the pending interrupt is greater than the priority level that would be returned to should the RFE be executed ($ICR.PIPN > PCXI.PCPN$).
- Interrupts will be enabled should the RFE be executed. ($PCXI.PIE == 1$)
- Fast Interrupts are not otherwise disabled due to the presence of MTCR instructions or context operations in the pipeline.

Without the fast interrupt operation the RFE would cause a restore of the upper context immediately followed by a save of the same upper context back to exactly the same memory location (Minimum 8 cycles). The fast interrupt system replaces this redundant restore/save sequence with a load of PCXI/PSW/A10/A11 (Minimum 1 Cycle) from the saved context. System state at the end of the fast interrupt is the same as if the standard RFE/Interrupt sequence had been performed.

5.6.5 Trap System

The following traps have implementation-specific properties.

UOPC - Unimplemented Opcode (TIN 2)

The UOPC trap is raised on optional MMU instructions, coprocessor two and coprocessor three instructions.

OPD - Invalid Operand (TIN 3)

The CPU raised OPD traps for instructions that take even-odd register pairs as an operand where if the operand specifier is odd.

DSE - Data Access Synchronous Error (TIN 2)

The Data Access Synchronous Bus Error (DSE) trap is generated by the DMI module when a load access from the CPU encounters certain error conditions, such as a Bus error, or an out-of-range access to DSPR. When a DSE trap is generated, the exact cause of the error can be determined by reading the Data Synchronous Trap Register, DSTR. For details of possible error conditions and the corresponding flag bits in DSTR, see **“DMI Trap Generation” on Page 5-103**.

DAE - Data Access Asynchronous Error (TIN 3)

The Data Access Asynchronous Error Trap (DAE) is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as a Bus error. When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, DATR. For details of possible error conditions and the corresponding flag bits in DATR, see **“DMI Trap Generation” on Page 5-103**.

PIE Program Memory Integrity Error (TIN 5)

The PIE trap is raised whenever an uncorrectable memory integrity error is detected in an instruction fetch from a local memory or the SRI bus. The trap is synchronous to the erroneous instruction. The trap is of Class-4 and has a TIN of 5.

Program memories are protected from memory integrity errors on a 64 bit basis (TC1.6P) or 32 bit basis (TC1.6E). A PIE trap is raised when an attempt is made to execute an instruction from any fetch group containing a memory integrity error.

The PIEAR and PIETR registers may be interrogated to determine the source of any error more precisely.

DIE Data Memory Integrity Error (TIN 6)

The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory or the SRI bus. The trap is of Class-4 and has a TIN of 6.

DIE traps are always asynchronous independent of the operation which encountered the error.

A DIE trap is raised if any memory half word (local memory) or double word (SRI bus) accessed by a load/store operation contains an uncorrectable error. The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely.

MPX Memory Protection Execute (TIN 4)

The MPX trap is raised whenever a program attempts to execute an instruction from a memory area for which it does not have execute permission and memory protection is enabled. The trap is of Class-1 and has a TIN of 4.

The TC1.6E compares the PC of the instruction with the range(s) defined by the memory protection system to determine whether or not execution is permitted.

The TC1.6P compares the 64bit aligned fetch group address with the range(s) defined by the memory protection system to determine whether or not execution is permitted.

5.6.6 Memory Integrity Error Handling

The TriCore CPUs contain integrated support for the detection and handling of memory integrity errors. The handling of memory integrity errors for the various memory types in the CPU is as follows:

5.6.6.1 Program Side Memories

The program side memories of the CPU consist of two independent memory structures:- The Program Scratchpad RAM (PSPR) and Program Cache (PCACHE). Both memory structures are ECC protected from memory integrity errors on a 64bit basis (TC1.6P) or on a 32 bit basis (TC1.6E). Any sub-width write access to the PSPR from the Bus interface is converted to a Read-Modify-Write sequence by the PMI module.

Program Scratchpad RAM (PSPR)

The Scratchpad RAM of the CPU is protected from memory integrity errors on a 64bit basis (TC1.6P) or 32 bit basis (TC1.6E). ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PSPR, the ECC bits are read along with the data bits and are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable memory integrity error a synchronous PIE trap is raised. The trap handler is then responsible for correcting the memory entry and re-starting program execution.

For PSPR read operations from the Bus interface, either from the DMI module or another Bus master agent, an access that results in the detection of an uncorrectable memory integrity error in the requested data causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the CPU.

Writes to program scratchpad memory are only ever performed from the bus interface. For write operations less than the protection width of the PSPR the memory transaction is transformed into a read-modify-write sequence inside the PMI module. Such a write

operation may result in the detection of an uncorrectable memory integrity errors during the read phase which are handled as standard read operations.

Program Cache (PCACHE)

The Scratchpad RAM of the CPU is protected from memory integrity errors on a 64bit basis (TC1.6P) or 32 bits (TC1.6E). ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the ECC bits are read along with the data bits of all cache ways, and an uncorrectable error signal generated for each cache way. In the case of a tag hit, the uncorrectable error signals for the corresponding cache way are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable error a synchronous PIE trap is raised. The trap handler is then responsible for checking the source of the memory integrity error.

Program Tag (Ptag)

ECC protection of is enabled via the MBIST ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the program tag ECC bits are read along with the data bits and an error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the valid bit is set and no ECC error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either cache way then the cache line is filled/refilled as normal. In the case where an error is detected the cache controller replacement algorithm forces the way indicating an error to be replaced. In the case where one cache way flags a cache hit, and another cache way detects an uncorrectable ECC error, the error condition is masked and has no effect on the memory integrity error handling mechanisms.

5.6.6.2 Data Side Memories

The TC1.6P CPU implements both data scratch and data cache memories. The TC1.6E implements a data scratch memory but replaces the data cache with a data read buffer (DRB). All data memory structures are ECC protected from memory integrity errors on a per-half word basis. Any byte write access to either DSPR or DCache (TC1.6P) is converted to a halfword Read-Modify-Write sequence. In normal operation isolated byte write transactions to the data memories result in no additional stall cycles.

Data Scratchpad Ram (DSPR)

The DSPR memory of both TC1.6P and TC1.6E are protected from memory integrity errors on a per-halfword basis. ECC protection of is enabled via the MBIST ECCS register.

CPU Subsystem

For data load requests from the TriCore CPU to DSPR, the ECC bits are read along with the data bits and an uncorrectable error signal is generated for each half-word. If an error is detected associated with any of the data half-words passed to the CPU an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For DSPR read operations from the Bus interface, either from the PMI module or another Bus master agent, an access that results in the detection of an uncorrectable error in the requested data half-words causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SCU module to optionally generate an NMI trap back to the CPU.

For write operations to DSPR of half-word size or greater, the ECC bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors, which are handled as per standard read operations.

Data Cache (DCache) - TC1.6P Only

ECC protection of is enabled via the MBIST ECCS register.

For data load requests from the TriCore CPU to DCache, the ECC bits are read along with the data bits of both cache ways, and an uncorrectable error flag computed for each half-word of each cache way. In the case where an error is detected with any of the requested data half-words in a cache way which has a corresponding tag hit, an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For write operations of half-word size or greater, the check bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors as for read operations.

For cache line writeback, uncorrectable error detection is performed as dirty data is transferred to the store buffers. In all cases (normal cache line eviction, cachex.xx instruction) where an error condition is detected in a valid cache line a DIE trap is raised. The trap handler is then responsible for taking corrective action (such as system soft reset) since correction of the data is not possible.

Data Tag (DTag) - TC1.6P Only

ECC protection of is enabled via the MBIST ECCS register.

For data load or store requests from the TriCore CPU to DCache, the data tag ECC bits are read along with the data bits and an uncorrectable error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the tag location is valid and no uncorrectable error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either tag way then the cache line is filled/refilled as normal. In the case of a cache miss where an error is detected in one of the tag ways and the cache line does not contain dirty data the cache controller replacement algorithm forces the way indicating an error to be replaced when the refill operation returns. In the case where one cache way flags a cache hit, and the another way detects an uncorrectable error, the error condition is masked and has no effect on the memory integrity error handling mechanisms. If a cache miss occurs, with an uncorrectable error detected on the associated data tag way and dirty data detected, then an asynchronous DIE trap is signalled to the CPU and any writeback / refill sequence aborted. The trap handler is responsible for invalidating the cache line and processing any associated dirty data if possible, or taking other corrective action. Similar action is taken for forced cache writeback using the cache manipulation instructions.

5.6.6.3 Memory Initialisation

To avoid the generation of spurious ECC errors the DSPR, PSPR must be fully initialised prior to use. This may be done either by software or by automatically by hardware (see the PMU.PROCOND register for details). The entire physical memory as detailed in [Chapter 5.1](#) must be initialised irrespective of any memory size variants produced for derivative products.

5.6.7 WAIT Instruction

The WAIT instruction will suspend execution until the occurrence of one of the following events.

- Enabled Interrupt
- Non-Maskable Interrupt
- Asynchronous Trap
- Idle Request
- Suspend Request
- Asynchronous Debug Halt or Trap Request

5.6.8 Instruction Memory Range Limitations

To ensure the processor cores are provided with a constant stream of instructions the Instruction Fetch Units will speculatively fetch instructions from up to 64 bytes ahead of the current PC.

If the current PC is within 64 bytes of the top of an instruction memory the Instruction Fetch Unit may attempt to speculatively fetch instruction from beyond the physical

memory range. This may then lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that the upper 64 bytes of any memory are not used for instruction storage.

5.6.9 Atomicity of Data Accesses

The data alignment rules along with the number of bus transactions for each access type are detailed in the following tables: -

Alignment Rules

Table 5-7 Alignment rules for non-peripheral space

Access type	Access size	Alignment of address in memory	Min/Max number of SRI bus transactions
Load, Store Data Register	Byte	Byte (1 _H)	1/1
	Half-Word	2 bytes (2 _H)	1/1
	Word	2 bytes (2 _H)	1/2 *
	Double-Word	2 bytes (2 _H)	1/2 *
Load, Store Address Register	Word	4 bytes (4 _H)	1/1
	Double-Word	4 bytes (4 _H)	1/2 *
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4 _H)	1/1
ST.T	Byte	Byte (1 _H)	1/1
Context Operations	16 x 32-bit registers	64 bytes (40 _H)	2/2 *

Table 5-8 Alignment rules for peripheral space

Access type	Access size	Alignment of address in memory	Min/Max Number of SPB bus transactions	Min/Max Number of SRI bus transactions
Load, Store Data Register	Byte	Byte (1 _H)	1/1	1/1
	Half-Word	2 bytes (2 _H)	1/1	1/1
	Word	4 bytes (4 _H)	1/1	1/1
	Double-Word	8 bytes (8 _H)	1/1	1/1
Load, Store Address Register	Word	4 bytes (4 _H)	1/1	1/1
	Double-Word	8 bytes (8 _H)	1/1	1/1
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4 _H)	1/1	1/1
ST.T	Byte	Bytes (1 _H)	1/1	1/1
Context Operations	16 x 32-bit registers	Not Permitted	-	-

In the case where a single access results in a single bus transaction atomicity of the data is preserved when viewed from any bus master.

In the case where a single access leads to multiple bus transactions (marked as “*” in the above tables) then atomicity needs to be considered. In these accesses it is possible for another bus master to read or write the target memory location between the bus transactions required to complete the access.

In the case of word and double word access to the SRI bus the number of bus transactions will be 1 for naturally aligned data values and hence atomicity will be preserved.

5.6.10 A11 usage

In normal usage A11 will always contain the target of the next RET or RFE instruction. The processor uses this fact to speculatively load the return target ahead of the execution of the RET/RFE instruction. Code that modifies the A11 (e.g. test code) should be aware that any value stored in A11 may be used as the target of such speculation. If the value in A11 is not a valid address the speculation may lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that A11 should only ever contain a valid address value.

5.7 Memory Addressing

This chapter details the CPU specific addressing.

5.7.1 CSFR and SFR base Locations

Each CPU has a dedicated set of control and status registers accessed at the addresses detailed in the following table. These registers are divided into Special Function Registers (SFRs) and Core Special Function Registers (CSFRs).

A CPU must access its own CSFR registers using MTCR and MFCR instructions. CSFR registers of other CPUs may be accessed using load and store instructions via the XBAR_SRI.

SFR registers of any CPU may only be accessed using load and store instructions via XBAR_SRI. Currently the overlay control and the access protection registers of CPUx are mapped into CPUx SFR address range.

The base locations for the TC1.6P and TC1.6E SFR and CSFR registers are as follows:-

Table 5-9 CSFR and SFR Base Locations

Core-ID Value	CSFR Base Address	SFR Base Address
0	F881_0000 _H	F880_0000 _H
1	F883_0000 _H	F882_0000 _H
2	F885_0000 _H	F884_0000 _H

5.7.2 Local and Global Addressing

The TriCore architecture supports closely coupled program and data SRAM memories known as Program Scratch Pad RAM (PSPR) and Data Scratch Pad RAM (DSPR). The local PSPR memory is always located at C0000000_H. The local DSPR is always located at D0000000_H. In a multiprocessor system the local scratch pad memories appear in the global address map in the following locations:-

Table 5-10 Global Address Locations

Core-ID Value	PSPR_base	DSPR_base
0	70100000 _H	70000000 _H
1	60100000 _H	60000000 _H
2	50100000 _H	50000000 _H

The CPUs always use the global addresses for bus transactions. Thus a data load from C0000000_H (a CPU's local PSPR) will result in a bus transaction with an address in the range 50100000_H - 701FFFFF_H dependent on the Core-ID value of the processor.

CPU Subsystem

Similarly a code fetch from $D0000000_H$ (a CPU's local DSPR) will result in a bus transaction with an address in the range $50000000_H - 700FFFFFF_H$ dependent on the Core-ID value of the processor.

5.7.3 Cache Memory Access

The cache and tag memories may be mapped into the CPU's address space. When mapped the cache memories are contiguous with the DSPR/PSPR memories as detailed in the following table. When mapped the cache memories behave identically to the PSPR/DSPR memories and may be used as standard memory.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU_MEMMAP register. See the MTU chapter for details.

Table 5-11 Cache Memory Locations when mapped

Memory	Local Address	Global Address
Program Cache	$C000_0000_H +$ $PSPR_Memory_Size$	$PSPR_Base +$ $PSPR_Memory_Size$
Data Cache (TC1.6P)	$D000_0000_H +$ $DSPR_Memory_Size$	$DSPR_Base +$ $DSPR_Memory_Size$

When mapped the tag memories are available at the locations detailed in the following table. The mapping of the Tag memories is provided test purposes only. They may not be used as standard memory.

Table 5-12 Tag Memory Locations when mapped

Memory	Local Address	Global Address
Program Tag	$C00C_0000_H$	$PSPR_Base + 0x000C_0000_H$
Data Tag (TC1.6P)	$D00C_0000_H$	$DSPR_Base + 0x000C_0000_H$

The CACHEI.* instructions require a way and index value to be supplied in a valid address. The location of these bits in the 32bit address is as follows.

Table 5-13 Way and Index Location

Function	Address Bits
Way	[0]
Index	[11:5]

5.8 CPU Subsystem Registers

This section describes the implementation-specific features of the CPU Subsystem registers listed in [Table 5-14](#). For complete descriptions of all registers refer to the TriCore Architecture Manual.

Table 5-14 CPU Subsystem Registers

Registers	Purpose	Description
CPU Core Special Function Registers (CSFRs)	Program state information, context and stack management, interrupt and trap control, system control	see Page 5-28
CPU General Purpose Registers (GPRs)	General Purpose Address and Data Registers	see Page 5-40
CPU Memory Protection Registers (CSFRs)	Memory protection control and mode selection	see Page 5-40
FPU Registers (CSFRs)	Support for the standard floating point instructions.	see Page 5-41
Memory Integrity Registers (CSFRs)	Integrity and Protection Core Special Function Registers.	see Page 5-42
Core Debug Registers (CSFRs)	Debug control	see Page 5-53
Implementation Specific Reset Values	Reset values for CPU registers not defined in this chapter	see Page 5-56
Program Memory Interface Registers (PMI CSFRs)	PMI program cache control, status and trap information	see Page 5-93
Data Memory Interface Registers (DMI CSFRs)	DMI data cache control, status and trap information	see Page 5-105

Note: To increase performance all stores to CSFR or SFR register locations are posted writes and complete silently. Stores to non-existent CSFR or SFR locations are not errored.

5.8.1 CPU Core Special Function Registers (CSFR)

This section describes implementation specific features of the Core Special Function Registers.

5.8.1.1 Registers

The implementation-specific Program Status Word Register (PSW) is an extension of the PSW description in the TriCore Architecture Manual. The status flags used for FPU operations overlay the status flags used for Arithmetic Logic Unit (ALU) operations.

Program Status Word Register

Note: The non-shaded areas in the register description define the implementation-specific bits/bit fields. The shaded areas are defined in the TriCore Architecture Manual.

PSW

Program Status Word Register (CSFR_Base + FE04_H) Reset Value: 0000 0B80_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

C	31	rwh	Carry Flag
FS			FPU Some Exception Flag

Previous Context Information Register
PCXI
Previous Context Information Register
(CSFR_Base + FE00_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PCXO	[15:0]	rw	Previous Context Pointer Offset Field The PCXO and PCXS fields form the pointer PCX, which points to the CSA of the previous context.
PCXS	[19:16]	rw	Previous Context Pointer Segment Address Contains the segment address portion of the PCX. This field is used in conjunction with the PCXO field.
UL	20	rw	Upper or Lower Context Tag Identifies the type of context saved. If the type does not match the type expected when a context restore operation is performed, a trap is generated. 0 _B Lower Context 1 _B Upper Context
PIE	21	rw	Previous Interrupt Enable Indicates the state of the interrupt enable bit (ICR.IE) for the interrupted task.
PCPN	[31:22]	rw	Previous CPU Priority Number Contains the priority level number of the interrupted task.

Address Space Identifier Register (TASK_ASI)

The Task Address Space Identifier (ASI) register description.

TASK_ASI

Task Address Space Identifier Register

(CSFR_Base + 8004_H)

Reset Value: 0000 001F_H

Field	Bits	Type	Description
RES	[31:5]	r	Reserved
ASI	[4:0]	rw	Address Space Identifier The ASI register contains the Address Space Identifier of the current process.

CPU Identification Register (TC1.6P)

CPU_ID

CPU Identification Register

(CSFR_Base + FE18_H)

Reset Value: 00C0 C012_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Revision Number 12 _H Reset value
MOD_32B	[15:8]	r	32-Bit Module Enable C0 _H A value of C0 _H in this field indicates a 32-bit module with a 32-bit module ID register.
MOD	[31:16]	r	Module Identification Number 00C0 _H For module identification

Core Identification Register
CORE_ID
Core Identification Register
(CSFR_Base + FE1C_H)
Reset Value: 0000 000X_H

Field	Bits	Type	Description
RES	[31:3]	r	Reserved
CORE_ID	[2:0]	r	Core Identification Number The identification number of the core.

Customer ID Register

In circumstances where the Infineon defined Core identification numbering scheme is insufficient or incompatible with a customer numbering scheme a customer ID value may be supplied via the CUS_ID register.

CUS_ID
Customer ID register
(CSFR_Base + FE50_H)
Reset Value: 0000 000X

Field	Bits	Type	Description
RES	[31:3]	r	Reserved
CID	[2:0]	r	Customer ID

Physical Memory Attributes Registers

The Physical Memory Attributes registers (PMA0,PMA1,PMA2) define the physical memory attribute for each segment in the physical address space. The register is ENDINIT protected and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA0 defines the data access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for data accesses.

The register PMA1 defines the code access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for code accesses.

The register PMA2 defines the peripheral space identifier of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as a peripheral segment. PMA2 is a read-only register.

Registers PMA0 and PMA1 are freely programmable with the following restrictions:-

- In PMA0 Segment-C and Segment[7-CoreID] must have the same value.
- In PMA1 Segment-D and Segment[7-CoreID] must have the same value.

Irrespective of the setting of the PMA registers the following constraints are always enforced.

- Segments-F and segment-E are constrained to be Peripheral space and hence non-cacheable.
- Segment-A is constrained to be non-cacheable memory
- Segment-D and Segment[7-CoreID] are constrained to be non-cacheable for data accesses.
- Segment-C and Segment[7- CoreID] are constrained to be non-cacheable for code accesses.

Note: The PMA registers are ENDINIT protected.

PMA0

Data Access Cacheability Register

(CSFR_Base + 8100_H)

Reset Value: 0000 0300_H

Field	Bits	Type	Description

Field	Bits	Type	Description
RES	[31:16]	r	Reserved
PSI	[15:0]	r	Peripheral Attribute Segments F_H-0_H = C000 _H

Compatibility Control Register

The Compatibility Control Register (COMPAT) is an implementation-specific CSFR which allows certain elements of backwards compatibility with TriCore 1.3.x behavior to be forced. The reset value of the COMPAT register ensures that backwards compatibility with TriCore 1.3 is enabled by default. This register is safety_endinit protected.

COMPAT

Compatibility Control Register

(CSFR_Base + 9400_H) Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
RES	[2:0]	r	Reserved Read as 1; should be written with 1.
RM	3	rw	Rounding Mode Compatibility 0 _B PSW.RM not restored by RET. 1 _B PSW.RM restored by RET (TC1.3 behavior).
SP	4	rw	SYSCON Safety Protection Mode Compatibility 0 _B SYSCON[31:1] safety endinit protected. 1 _B SYSCON[31:1] not safety endinit protected (TC1.3 behavior).
RES	[31:5]	r	Reserved Read as 1; should be written with 1.

5.8.2 CPU General Purpose Registers

There are no implementation specific features of the General Purpose Registers. They are described in detail in the TriCore Architecture Manual.

5.8.3 CPU Memory Protection Registers

There are four Memory Protection Register Sets per CPU. The sets specify memory protection ranges and permissions for code and data. The PSW.PRS bit field determines which of these sets is currently in use by the CPU. The CPUs each implement 16 data and 8 code range comparators. These may be flexibly shared amongst the of protection sets to provide a maximum of 16 data ranges and 8 code ranges per set.

The protection registers protect the whole address space (In previous TriCore implementations the memory protection system did not cover peripheral space.) The granularity of the protection ranges is 8 bytes.

Code protection ranges define which memory areas the CPU may fetch instructions from. Instruction fetches from an area outside a valid code protection range will lead to a trap condition.

Data protection ranges define which memory areas the CPU may access for read and/or write operations. Each range may be separately enabled for read and/or write access. Data read accesses from an area outside a valid data protection range with read permissions will lead to a trap condition. Data write accesses to an area outside a valid data protection range with write permissions will lead to a trap condition

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore Architecture Manual.

5.8.4 Temporal Protection Registers

To Guard against task runtime overrun the CPU implements a temporal protection system. This system consists of three independent decrementing counters (TPS_TIMERn) arranged to generate a Temporal Asynchronous Error trap (TAE - Class-4, Tin-7) on decrement to zero. A control register (TPS_CON) contains status and control bits for temporal protection system. The temporal protection system is enabled by the SYSCON.TPROTEN register bit. The Temporal Protection Registers are Core Special Function Registers. They are described in detail in the TriCore Architecture Manual.

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore Architecture Manual.

5.8.5 FPU Registers

There are no implementation specific features of the FPU Registers. They are described in detail in the TriCore Architecture Manual.

5.8.6 Memory Integrity Registers

To monitor and debug the integrity of the memory subsystems the following registers are provided.

Table 5-15 Memory Integrity Registers

Short Name	Description	Offset Address	Access Mode		Reset Type, Value
			Read	Write	
PIEAR	Program Integrity Error Address Register	9210 _H	U, SV, 32	SV, 32, P	Application 0000 0000 _H
PIETR	Program Integrity Error Trap Register	9214 _H	U, SV, 32	SV, 32, P	Application 0000 0000 _H
DIEAR	Data Integrity Error Address Register	9020 _H	U, SV, 32	SV, 32, P	Application 0000 0000 _H
DIETR	Data Integrity Error Trap Register	9024 _H	U, SV, 32	SV, 32, P	Application 0000 0000 _H
SMACON	SIST Mode Access Control Register	900C _H	U, SV, 32	SV, SE, 32, P	Application 0000 0000 _H

5.8.6.1 Register Descriptions

Program Integrity Error Information Registers

Two architecturally visible registers (PIETR, PIEAR) allow software to localise the source of the last detected program memory integrity error.

These registers are updated when a program integrity error condition is detected and the PIETR.IED bit is zero. On update the PIETR.IED bit is set to one and remains set until cleared by software. Whilst PIETR.IED is set further hardware updates of PIETR and PIEAR are inhibited. The various error scenarios are defined below.

Program Integrity errors during instruction fetch from program memory

When an error is detected during a program fetch from a program memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable bit error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Since instruction fetches are speculative, the PIETR and PIEAR registers may be updated without a corresponding PIE trap

Program Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from program memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Note that a memory read can be generated by a sub word write operation. The IE_C bit can only ever be set if the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

Program Integrity errors due to safety protection

When a safety protection violation is detected during a program memory access or during access to the CPU registers the IE_SP, IE_BS bits are set and the E_INFO field updated. The PIEAR register is updated with the address of the access. The IED bit is set and all other PIETR register bits are set to zero.

Program Integrity errors due ECC errors at the bus interface

When an ECC error is detected at the program bus interface (either master or slave) the IE_BI bit is set. If the error is during an external access the IE_BS bit is set and the E_INFO fields updated. The PIEAR register is updated with the address of the access.

If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero.

Program Integrity Error Trap Register (PIETR)

PIETR

Program Integrity Error Trap Register

(CSFR_Base + 9214_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
IED	0	rwh	Integrity Error Detected Read Operation: 0 _B No program integrity error condition occurred. 1 _B Program integrity error condition detected. PIETR and PIEAR contents valid, further updates disabled. Write Operation: 0 _B Clear IED bit, re-enable updates. 1 _B No effect.
RES	1	r	Reserved
IE_C	2	rh	Integrity Error - Cache Memory
IE_S	3	rh	Integrity Error - Scratchpad Memory
IE_BI	4	rh	Integrity Error - Bus Interface
E_INFO	[10:5]	rh	Error Information If IE_BS= 1: Bus Master Tag ID of requesting master If IE_C = 1: Cache way.
IE_UNC	11	rh	Integrity Error - Uncorrectable Error Detected
IE_SP	12	rh	Safety Protection Error Detected
IE_BS	13	rh	Bus Slave Access Indicator
RES	[31:14]	r	Reserved Read as 0; should be written with 0.

Program Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable program memory integrity error. This register is only updated if PIETR.IED is zero.

PIEAR

Program Integrity Error Address Register

(CSFR_Base + 9210_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TA	[31:0]	rh	Transaction Address Physical address being accessed by operation that encountered program integrity error.

Data Integrity Error Information Registers

Two architecturally visible registers (DIETR, DIEAR) allow software to localise the source of the last detected uncorrectable data memory integrity error.

These registers are updated when an uncorrectable data integrity error condition is detected and the DIETR.IED bit is zero. On update the DIETR.IED bit is set to one and remains set until cleared by software. Whilst DIETR.IED is set further hardware updates of DIETR and DIEAR are inhibited. The various error scenarios are defined below.

Note that the TC1.6E has no data cache but will report Data Read Buffer errors as cache errors from way0.

Data Integrity errors during load from data memory

When an error is detected during a load from a data memory the IE_S, IE_C and IE_T bits are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction.

Data Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from data memory the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction. The IE_C bit can only ever be set if the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

Data Integrity errors due to safety protection

When a safety protection violation is detected during a data memory access the IE_SP, IE_BS bits are set and the E_INFO field updated. The DIEAR register is updated with the address of the access. The IED bit is set and all other DIETR register bits are set to zero.

Data Integrity errors due ECC errors at the bus interface

When an ECC error is detected at the data bus interface (either master or slave) the IE_BI bit is set. If the error is during an external access the IE_BS bit is set and the E_INFO fields updated. The DIEAR register is updated with the address of the access.

If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero.

Data Integrity Error Trap Register (DIETR)
DIETR
Data Integrity Error Trap Register
(CSFR_Base + 9024_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
IED	0	rwh	Integrity Error Detected Read Operation: 0 _B No data integrity error condition occurred. 1 _B Data integrity error condition detected. DIETR and DIEAR contents valid, further DIETR and DIEAR updates disabled. Write Operation: 0 _B Clear IED bit, re-enable DIETR and DIEAR update. 1 _B No effect.
IE_T	1	rh	Integrity Error - Tag Memory
IE_C	2	rh	Integrity Error - Cache Memory
IE_S	3	rh	Integrity Error - Scratchpad Memory
IE_BI	4	rh	Integrity Error - Bus Interface
E_INFO	[10:5]	rh	Error Information If IE_BS = 1: Bus Master Tag ID of requesting master If IE_C = 1: Cache way.
IE_UNC	11	rh	Dual Bit Error Detected
IE_SP	12	rh	Safety Protection Error Detected

Field	Bits	Type	Description
IE_BS	13	rh	Bus Slave Access Indicator
RES	[31:14]	r	Reserved Read as 0; should be written with 0.

Data Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable data memory integrity error. This register is only updated if DIETR.IED is zero.

DIEAR

Data Integrity Error Address Register

(CSFR_Base + 9020_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
TA	[31:0]	rh	Transaction Address Physical address being accessed by operation that encountered data integrity error.

SIST (Software In-System) Test Support

The CPU protects against memory integrity errors by ECC protection of the local CPU memories. This has the side-effect of requiring memory blocks wider than the normal data access path to the memory. The additional ECC storage bits are not easily accessible via the existing data paths, causing problems where software based testing of the memories is required. The CPU memories also include embedded memory arrays, such as the tag memories, which are not ordinarily accessible by the usual CPU datapaths. In order to address this problem, the CPUs include a modes allowing all local memory arrays to be accessed, both as a backup for MBIST based memory test and to allow the test and debug of the fault tolerant memory systems.

Each memory may be access either in normal operation, data array only or ECC check array only. This is controlled by the ECCS registers of the associated MBIST controller.

The IODT bit controls read/write operation ordering. In normal operation (IODT=0) non-dependent read operations may overtake write operations. When SMA.IODT is set all memory operations are performed in program order.

The SMACON register is protected by the safety_endinit signal.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU_MEMMAP register. See the MTU chapter for details.

SIST Mode Access Control Register

SMACON

SIST Mode Access Control Register

(CSFR_Base + 900C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	[31:25]	r	Reserved Read as 0; should be written with 0.
IODT	24	rw	In-Order Data Transactions 0 _B Normal operation, Non-dependent loads bypass stores. 1 _B In-order operation, Loads always flush preceding stores, processor store buffer disabled.
RES	[23:0]	r	Reserved Read as 0; should be written with 0.

5.8.7 CPU Core Debug and Performance Counter Registers

The CPU Core Debug and performance counter registers are available for debug purposes. For a complete description of all registers, refer to the TriCore Architecture Manual.

5.8.7.1 Counter Source Details

Details of the Performance counter sources is given below.

IP_DISPATCH_STALL

The counter is incremented on every cycle in which the Integer dispatch unit is stalled for whatever reason.

LS_DISPATCH_STALL

The counter is incremented on every cycle in which the Load-Store dispatch unit is stalled for whatever reason.

LP_DISPATCH_STALL

The counter is incremented on every cycle in which the Loop dispatch unit is stalled for whatever reason.

PCACHE_HIT

The counter is incremented whenever the target of a cached fetch request from the fetch unit is found in the program cache.

PCACHE_MISS

The counter is incremented whenever the target of a cached fetch request from the fetch unit is not found in the program cache and hence a bus fetch is initiated.

MULTI_ISSUE

The counter is incremented in any cycle where more than one instruction is issued.

DCACHE_HIT

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data cache.

DRB_HIT

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data read buffer.

DCACHE_MISS_CLEAN

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with no dirty cache line eviction.

DRB_MISS

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data read buffer and hence a bus fetch is initiated.

DCACHE_MISS_DIRTY

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with the writeback of a dirty cache line.

TOTAL_BRANCH

The counter is incremented in any cycle in which a branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC).

PMEM_STALL

The counter is incremented whenever the fetch unit is requesting an instruction and the Instruction memory is stalled for whatever reason.

DMEM_STALL

The counter is incremented whenever the Load-Store unit is requesting a data operation and the data memory is stalled for whatever reason.

Performance Counter Registers

RGNUA7	Safety Protection Upper Range Register 7	E074 _H	U, SV, 32	U,SV, 32,SE	Application 0000 0000 _H
RGNACCEN A7	Safety Protection Access Enable Register A Range 7	E078 _H	U, SV, 32	U,SV, 32,SE	Application 0000 0000 _H

Table 5-27 Safety Protection Registers (cont'd)

Short Name	Description	Offset Address	Access Mode		Reset Type, Value
			Read	Write	
RGNACCEN B7	Safety Protection Access Enable Register B Range 7	E07C _H	U, SV, 32	U, SV, 32, NC	Application 0000 0000 _H
ACCENA	Access Enable Register A	E100 _H	U, SV, 32	U, SV, 32, SE	Application 0000 0000 _H
ACCENB	Access Enable Register B	E104 _H	U, SV, 32	U, SV, 32, SE	Application 0000 0000 _H

Note: A disallowed access to any CPU register (e.g. attempted write to read only register, attempted user mode access to SV, attempted access to E without Endinit, etc.) will NOT result in a Bus Error.

5.9 CPU Instruction Timing

This section gives information on CPU instruction timing by execution unit. The Integer Pipeline and Load/Store Pipeline are always present, and the Floating Point Unit (FPU) is optional. The Load/Store unit implements the optional TLB instructions.

Definition of Terms:

- **Repeat Rate**

Assuming the same instruction is being issued sequentially, repeat is the minimum number of clock cycles between two consecutive issues. There may be additional delays described elsewhere due to internal pipeline effects when issuing a different subsequent instruction.

- **Result Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the result value is available to be used as an operand to a subsequent instruction or written into a GPR. Result latency is not meaningful for instructions that do not write a value into a GPR.

- **Address Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the addressing mode updated value is available as an operand to a subsequent instruction or written into an Address Register.

- **Flow Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the next instruction (located at the target location or the next sequential instruction if the control change is conditional) is issued.

5.9.1 Integer-Pipeline Instructions

These are the Integer-Pipeline instruction timings for each instruction.

5.9.1.1 Simple Arithmetic Instruction Timings

Each instruction is single issued.

Table 5-28 Simple Arithmetic Instruction Timing

MUL.H	3	2	1	1					

5.9.1.3 Multiply Accumulate (MAC) Instruction Timing

Each instruction is single issued.

Table 5-30 Multiply Accumulate Instruction Timing

Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E		Instruction	Result Latency TC16-TC16E		Repeat Rate TC16P-TC16E	
MADD	3	2	1	1	MSUB	3	2	1	1
MADD.U	3	2	1	1	MSUB.U	3	2	1	1
MADDS	3	2	1	1	MSUBS	3	2	1	1
MADDS.U	3	2	1	1	MSUBS.U	3	2	1	1
MADD.H	3	2	1	1	MSUB.H	3	2	1	1
MADD.Q	3	2	1	1	MSUB.Q	3	2	1	1
MADDM.H	3	2	1	1	MSUBM.H	3	2	1	1
MADDMS.H	3	2	1	1	MSUBMS.H	3	2	1	1
MADDR.H	3	2	1	1	MSUBR.H	3	2	1	1
MADDR.Q	3	2	1	1	MSUBR.Q	3	2	1	1
MADDRS.H	3	2	1	1	MSUBRS.H	3	2	1	1
MADDRS.Q	3	2	1	1	MSUBRS.Q	3	2	1	1
MADDS.H	3	2	1	1	MSUBS.H	3	2	1	1
MADDS.Q	3	2	1	1	MSUBS.Q	3	2	1	1
MADDSU.H	3	2	1	1	MSUBAD.H	3	2	1	1
MADDSUM.H	3	2	1	1	MSUBADM.H	3	2	1	1
MADDSUMS.H	3	2	1	1	MSUBADMS.H	3	2	1	1
MADDSUR.H	3	2	1	1	MSUBADR.H	3	2	1	1
MADDSURS.H	3	2	1	1	MSUBADRS.H	3	2	1	1
MADDSUS.H	3	2	1	1	MSUBADS.H	3	2	1	1

For All MADD, MSUB and MUL type instructions the result latency is reduced to 1 for accumulator forwarding between similar instructions.

For MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q Instructions:

MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q	Result Latency TC1.6P	Result Latency TC1.6E	Repeat Rate TC1.6P	Repeat Rate TC1.6E
16 × 16	3	2	1	1
16 × 32	3	2	1	1
32 × 32	3	2	1	1

5.9.1.4 Control Flow Instruction Timing TC1.6P

Control flow instruction timing for TC1.6P is complicated by the use of branch target buffers and fetch FIFOs.

- Incorrectly predicted LS instructions incur a three cycle branch recovery penalty.
- Incorrectly predicted IP instructions incur a four cycle branch recovery penalty.
- Correctly predicted not taken branches incur no penalty
- Correctly predicted taken branch incur a penalty of up to two cycles depending on the state of the fetch FIFOs and the branch target buffer.
- Loop instructions incur the same penalty as an LS conditional jump instruction.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

Table 5-31 Control flow timing(TC1.6P)

Prediction-Result	Flow Latency (LS, LP)	Repeat rate (LS,LP)	Flow Latency (IP)	Repeat Rate (IP)
Correct Not-Taken	1	1	1	1
Correct Taken	1-2	1-2	1-2	1-2
Incorrect Not-Taken	3	4	3	4
Incorrect Taken	3	4	3	4

5.9.1.5 Control Flow Instruction Timing TC1.6E

The TC1.6E implements a simple static branch prediction scheme. 16 bit instruction format (either direction) and 32 bit format backwards conditional branches are predicted taken. 32 bit format forwards conditional branches are predicted not taken.

- Correctly predicted not taken branches incur no penalty.
- Correctly predicted taken branches incur a single cycle penalty.
- Incorrectly predicted branches incur a two cycle branch recovery penalty.
- Loop instructions incur the same penalty as LS conditional jump instructions.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

Table 5-32 Control flow timing(TC1.6E)

Prediction-Result	Flow Latency	Repeat rate
Correctly predicted, not taken	1	1
Correctly predicted, taken	2	2
Incorrectly predicted	3	3

5.9.2 Load-Store Pipeline Instructions

This section summarizes the Load-Store Pipeline instructions.

5.9.2.1 Address Arithmetic Timing

Each instruction is single issued.

Table 5-33 Address Arithmetic Instruction Timing

Instruction	Result Latency		Repeat Rate		Instruction	Result Latency		Repeat Rate	
	TC16P-	TC16E	TC16P-	TC16E		TC16P-	TC16E	TC16P-	TC16E

MOVH.A	1	1	1	1	MOV.D	1	1	1	1

Sync Instructions

DSYNC	–	–	1	1	ISYNC³⁾	–	–	1	1
--------------	---	---	---	---	---------------------------	---	---	---	---

1) Execution cycles when no TRAP is taken. The execution timing in the case of raising these TRAPs is the same as other TRAPs such as SYSCALL.

2) The latency of the WAIT instruction is hidden by the context save of the interrupt. Effective latency is zero.

3) Repeat rate assumes that code refetch takes a single cycle.

5.9.2.2 CSA Control Flow Instruction Timing

This section summarizes the timing of CSA Control Flow instructions.

- All targets yield a full instruction in one access (not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle. Timing is best case; no cache misses for context operations, no pending stores.

Table 5-34 CSA Control Flow Instruction Timing

Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E		Instruction	Result Latency TC16P-TC16E		Repeat Rate TC16P-TC16E	
CALL	4-8	4	4-8	4	SYSCALL	4-8	4	4-8	4
CALLA	4-8	4	4-8	4	SVLCX	4-8	4	4-8	4
CALLI	4-8	4	4-8	4	RSLCX	4-8	4	4-8	4
RET	4-8	4	4-8	4	RFE	4-8	4	4-8	4
BISR	4-8	4	4-8	4	RFM	4-8	4	4-8	4
FCALL	1	1	1	1	FCALLA	1	1	1	1
FCALLI	1	1	1	1	FRET	1	1	1	1

Access to DSPR require 4 cycles, accesses to cached external memory require 8 cycles (TC1.6P only).

5.9.2.3 Load Instruction Timing

Load instructions can produce two results if they use the pre-increment, post-increment, circular or bit-reverse addressing modes. Hence, in those cases there are two latencies that must be specified, the result latency for the value loaded from memory and the address latency for using the updated address register result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to return a data item.
- Timing is best case; no cache misses, no pending stores.

Table 5-35 Load Instruction Timing TC1.6P

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
Load Instructions							
LD.A	1	3	1	LD.Q	1	2	1
LD.B	1	2	1	LD.W	1	2	1

Table 5-35 Load Instruction Timing TC1.6P (cont'd)

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
LD.BU	1	2	1	LDLCX	5-9	5-9	5
LD.D	1	2	1	LDUCX	5-9	5-9	5
LD.DA	1	3	1	SWAP.W	2	3	2
LD.H	1	2	1	LEA ¹⁾	–	1	1
LD.HU	1	2	1	CMPSWAP	2	3	1
SWAPMSK	2	3	1				

1) The addressing mode returning an updated address is not relevant for this instruction.

Table 5-36 Load Instruction Timing TC1.6E

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
Load Instructions							
LD.A	1	3	1	LD.Q	1	2	1
LD.B	1	2	1	LD.W	1	2	1
LD.BU	1	2	1	LDLCX	5	5	5
LD.D	1	2	1	LDUCX	5	5	5
LD.DA	1	3	1	SWAP.W	2	3	2
LD.H	1	2	1	LEA ¹⁾	–	1	1
LD.HU	1	2	1	CMPSWAP	2	3	1
SWAPMSK	2	3	1				

1) The addressing mode returning an updated address is not relevant for this instruction.

5.9.2.4 Store Instruction Timing

Cache and Store instructions similar to Load instructions will have a result for the pre-increment, post-increment, circular or bit-reverse addressing modes, but do not produce a 'memory' result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to accept a data item.
- Timing is best case; no cache misses, no pending stores.

Table 5-37 Cache and Store Instruction Timing

Instruction	Result Latency				Repeat Rate				
	TC16P		-TC16E		TC16P		-TC16E		
Cache Instructions									
CACHEA.I	1	1	1	1	CACHEA.WI¹⁾	1	1	1	1
CACHEA.W¹⁾	1	1	1	1	CACHEI.W	1	1	1	1
CACHEI.WI	1	1	1	1	CACHEI.I	1	1	1	1
Store Instructions									
ST.A	1	1	1	1	ST.T	1	1	2	2
ST.B	1	1	1	1	ST.W	1	1	1	1
ST.D	1	1	1	1	STLCX	1	1	9	5
ST.DA	1	1	1	1	STUCX	1	1	9	5
ST.H	1	1	1	1	LDMST	1	1	2	2
ST.Q	1	1	1	1					

1) Repeat rate assumes that no memory writeback operation occurs. Otherwise the repeat rate will depend upon the time for the castout buffers to clear.

5.9.3 Floating Point Pipeline Timing

These instructions are only valid if the optional Floating Point Unit is implemented. Each instruction is single issued.

Table 5-38 Floating Point Instruction Timing

Instruction	Result Latency				Repeat Rate				
	TC16P		TC16E		TC16P		TC16E

FTOUZ	2	1	1	1	UTOF	2	1	1	1

5.10 Program Memory Interface (PMI)

The program Memory Interface (PMI) provides the instruction stream to the CPU.

5.10.1 TC1.6P PMI Description

Figure 5-9 shows the block diagram of the Program Memory Interface (PMI) of the TC1.6P.

Figure 5-9 PMI Block Diagram

The Program Memory Interface (PMI) has the following features:

- Program Cache (PCACHE)
 - Two-way set associative cache
 - LRU (Least-Recently Used) replacement algorithm
 - Cache line size: 256 bits (4 double-words)
 - Validity granularity: One valid bit per cache line
 - Single cycle access for hit.

CPU Subsystem

- PCACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)
- PCACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
- PCACHE refill mechanism:
 - Critical word first, line wrap around, streaming to CPU
- Program Scratchpad memory (PSPR)
- CPU interface
 - Supporting 64bit aligned fetches. (TC1.6P)
- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Shared Resource Interconnect Bus (SRI) Slave Interface to scratchpad RAM and CPS.
- All PMI SRAMs (PSPR, PCACHE, and cache tag SRAM) are ECC protected
 - ECC is calculated on 64bit data for the PSPR and PCACHE

5.10.1.1 TC1.6P Scratchpad RAM

The TC1.6P of Program scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM.

The TC1.6P CPU fetch interface will generate aligned accesses (64-bit), which will result in 64-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The scratchpad RAM is ECC protected across 64bit data.

5.10.1.2 TC1.6P Program Cache

The program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction and associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states

CPU Subsystem

are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The program cache is ECC protected on 64bit data.

The program TAG Ram is ECC protected on 22bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

The PCON0 register is endinit protected.

Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a '1' to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU

stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

5.10.1.3 TC1.6P Program Line Buffer

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

5.10.1.4 TC1.6P CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the CPU CSFR and SFR registers.

5.10.2 TC1.6E PMI Description

Figure 5-10 shows the block diagram of the Program Memory Interface (PMI) of the TC1.6E.

Figure 5-10 PMI Block Diagram

The Program Memory Interface (PMI) has the following features:

- Program Cache (PCACHE)
 - Two-way set associative cache
 - LRU (Least-Recently Used) replacement algorithm
 - Cache line size: 256 bits (4 double-words)
 - Validity granularity: One valid bit per cache line

CPU Subsystem

- PCACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)
- PCACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
- PCACHE refill mechanism:
 - Critical word first, line wrap around, streaming to CPU
- Program Scratchpad memory (PSPR)
- CPU interface
 - Supporting 32-bit aligned fetches. (TC1.6E)
- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Shared Resource Interconnect Bus (SRI) Slave Interface to Program Scratchpad RAM and CPU Slave interface.
 - SRI Slave Interface is shared with DMI for Data Scratchpad RAM access.
- All PMI SRAMs (PSPR, PCACHE, and cache tag SRAM) are ECC protected.
 - ECC is calculated on 32bit data for the PSPR and PCACHE

5.10.2.1 TC1.6E Program Scratchpad RAM

The Program Scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM.

The TC1.6E CPU fetch interface will generate aligned accesses (32-bit), which will result in 32-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The scratchpad RAM is ECC protected across 32bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

5.10.2.2 TC1.6E Program Cache

The Program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction along with associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its

CPU Subsystem

associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The Program cache is ECC protected on 32bit data.

The Program TAG Ram is ECC protected on 22bit data.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

The PCON0 register is endinit protected.

Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a '1' to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries

marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

5.10.2.3 TC1.6E Program Line Buffer

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

5.10.2.4 TC1.6E CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the CPU CSFR and SFR registers.

5.10.3 PMI Registers

Three control registers are control the operation of the Program Memory Interface. These registers and their bits are described in this section.

5.10.3.1 PMI Register Descriptions

PMI Control Register 0

PCON0

Program Memory Control Register 0

(CSFR_Base + 920C_H)

Reset Value: 0000 0002_H

Field	Bits	Type	Description
RES	0	r	Reserved Read as 0; should be written with 0.
PCBYP	1	rw	Program Cache Bypass 0 _B Cache enabled 1 _B Cache bypassed (disabled)
RES	[31:2]	r	Reserved Read as 0; should be written with 0.

Note: This register is endinit protected.

PMI Control Register 1

PCON1

Program Memory Control Register 1

(CSFR_Base + 9204_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PCINV	0	rwh	<p>Program Cache Invalidate</p> <p>Write Operation:</p> <ul style="list-style-type: none"> 0_B No effect. Normal program cache operation. 1_B Initiate invalidation of entire program cache. <p>Read Operation:</p> <ul style="list-style-type: none"> 0_B Normal operation. Program cache available. 1_B Program cache invalidation in progress. Program cache unavailable.
PBINV	1	rw	<p>Program Buffer Invalidate</p> <p>Write Operation:</p> <ul style="list-style-type: none"> 0_B No effect. Normal program line buffer operation. 1_B Invalidate the program line buffer. <p>This field returns 0 when read.</p>
RES	[31:2]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

PMI Control Register 2

PCON2 contains size information for the Program memory system.

PCON2

Program Memory Control Register 2

(CSFR_Base + 9208_H) Reset Value: CPU Dependent

Field	Bits	Type	Description
PCACHE_SIZE	[15:0]	r	Program Cache (PCACHE) Size In KBytes
PSCRATCH_SIZE	[31:16]	r	Program Scratch Size In KBytes

Program Memory Interface Synchronous Trap Register (PSTR)

PSTR contains synchronous trap information for the program memory system. The register is updated with trap information for PSE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and the register has no bits already set. It is cleared by a CSFR write (independent of data value).

PSTR
Program Synchronous Trap Register
(CSFR_Base + 9200_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
FRE	0	rwh	Fetch Range Error Code fetch from local PSPR area outside of physically implemented memory
RES	1	r	Reserved
FBE	2	rwh	Fetch Bus Error Code fetch from bus address giving an error
RES	[11:3]	r	Reserved
FPE	12	rwh	Fetch Peripheral Error Code fetch from peripheral space
RES	13	r	Reserved
FME	14	rwh	Fetch MSIST Error Code fetch from memory mapped PTAG.
RES	[31:15]	r	Reserved

Fetch Range Error

A Fetch Range Error occurs whenever an access to the Program Scratch is outside the range of the SRAM.

Fetch Global Address Error

A Fetch Global Address Error occurs whenever there is access to an address that cannot be translated to a valid global address. This will occur for accesses in the range D1000000 to D7FFFFFFF.

Fetch Bus Error

A Fetch bus error will be set whenever the SRI flags an error due to a fetch from external memory. This will be set for both direct fetches from the bus and for cache refills.

Fetch Peripheral Error

A Fetch peripheral error will be flagged whenever a fetch is attempted to peripheral space.

Fetch MSIST Error

During SISTR mode, a fetch from the PTAG will cause a PSE trap to occur.

5.11 Data Memory Interface (DMI)

The Data Memory Interface (DMI) provides data values to the CPU and stores data values supplied by the CPU.

5.11.1 TC1.6P DMI Description

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1.6P.

Figure 5-11 DMI Block Diagram

The Data Memory Interface (DMI) has the following features:

- Data Scratchpad Ram (DSPR)
 - Supporting unaligned access (16-bit aligned) with no penalty.
- Data Memory (DCACHE):
 - Two-way set associative cache, Least recently used (LRU) replacement algorithm
 - Cache line size: 256 bits
 - Validity granularity: One valid bit per cache line

- Write-back Cache: Writeback granularity: 256 bits
- Refill mechanism: full cache line refill
- Single cycle access for hit.
- CPU interface
- Shared Resource Interconnect Bus (SRI) Master interface
- Shared Resource Interconnect (SRI) Slave interface to DSPR
- Flexible Peripheral Interconnect Bus (FPI) Master interface for fast access to peripherals
- All DMI SRAMs (DSPR, DCACHE, and cache tag SRAM) are ECC protected

5.11.1.1 TC1.6P Data Scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

All TC1.6P Data scratchpad RAMs are ECC protected.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

5.11.1.2 TC1.6P Data Cache (DCACHE)

The DCache is a Two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each line contains 256 bits of data along with ECC bits. A single valid bit and a single dirty bit are associated with each line.

CPU data accesses to a cacheable memory segment target the DCache. If the requested address and its associated data are found in the cache (Cache Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the DMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DCache line, no matter the alignment, and a cache hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DCache line, such that the requested data would span two DCache lines, a single wait cycle is incurred (if both cache lines are present in the cache, otherwise a refill sequence is required for the missing cache line(s)).

CPU Subsystem

The TC1.6P data cache is of the writeback type. When the CPU writes to a cacheable location the data is merged with the corresponding cache line and not written to main memory immediately. Associated with each cache line is a single 'dirty' bit, to denote that the data in the cache line has been modified. Whenever a CPU load-store access results in a cache miss, and each of the potential cache ways that could hold the requested cache line are valid, one of the cache lines is chosen for eviction based upon the LRU replacement algorithm. The line selected for eviction is then checked to determine if it has been modified using its dirty bit. If the line has not been modified the line is discarded and the refill sequence started immediately. If the line has been modified then the dirty data is first written back to main memory before the refill is initiated. Due to the single dirty bit per cache line, 256 bits of data will always be written back, resulting in a SRI Burst-4 Transfer (BTR4) transactions.

Data Cache refills always result in the full cache line being refilled, with the critical double-word of the DCache line being fetched first. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line. Due to the uniform size of DCache refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

All TC1.6P Cache SRAMs are ECC protected.

All TC1.6P TAG SRAMs are ECC protected

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

Data Cache Bypass

The Data Cache may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the data cache is bypassed after reset.

Whilst the data cache bypass is enabled, a data access request by the CPU to a cacheable address will result in a forced cache miss. Any valid cache lines within the data cache will remain valid and unchanged whilst the data cache is bypassed. As such data accesses to cacheable addresses with the data cache bypass enabled behave identically to data accesses to non-cacheable addresses.

The DCON0 register is endinit protected.

5.11.2 TC1.6E DMI Description

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1.6E.

Figure 5-12 DMI Block Diagram

The Data Memory Interface (DMI) has the following features:

- Data Scratchpad Ram (DSPR)
 - Supporting unaligned access (16-bit aligned) with no penalty.
- Data Read Buffer (DRB)
 - Four-entry fully associative Data Read Buffer
 - Least recently used (LRU) replacement algorithm
 - Buffer line size: 256 bits
 - Validity granularity: One valid bit per buffer line
 - Refill mechanism: full buffer line refill, critical double-word first
- CPU interface
- Shared Resource Interconnect Bus (SRI) Master interface

CPU Subsystem

- Flexible Peripheral Interconnect Bus (FPI) Master interface for fast access to peripherals
 - CPU accesses to lower half of segment F_H are directed to FPI master interface, other accesses directed to SRI master interface
- Shared Resource Interconnect (SRI) Slave interface to DSPR
 - SRI slave interface shared with PMI for access to PSPR / CPS
- All TC1.6E DMI SRAM (DSPR) ECC protected

5.11.2.1 TC1.6E Data Scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

Errors detected at the ECC decoders are signaled to the EMM via the MBIST logic of the associated SRAM

5.11.2.2 TC1.6E Data Read Buffer (DRB)

The TC1.6E implements a 128-byte Data Read Buffer (DRB). The DRB contains four fully associative buffer lines, with a Least-Recently-Used (LRU) replacement algorithm. Each buffer line contains 256-bits of data. A single valid bit is associated with each buffer line. The DRB will buffer CPU read data from cacheable memory segments.

CPU load data accesses, where the addressed memory segment is defined as cacheable, target the DRB. If the requested address and its associated data are found in the DRB (Buffer Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the DRB (Buffer Miss), the DMI controller issues a buffer refill sequence and wait states are incurred whilst the buffer line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DRB buffer line, no matter the alignment, and a buffer hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DRB line, such that the requested data would span two DRB lines, a single wait cycle is incurred (if both buffer lines are present in the DRB, otherwise a refill sequence is required for the missing buffer line(s)).

DRB refills always result in the full buffer line being refilled, with the critical double-word of the DRB line being fetched first. A refill sequence will always affect only one buffer

line. There is no prefetching of the next buffer line. Due to the uniform size of DRB refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

The TC1.6E DRB will buffer read data only. Any CPU store access which results in a hit in a DRB line will invalidate that DRB line and the store will continue as normal, bypassing the DRB. In addition, the execution of any CACHEA.xx or CACHEI.xx instruction by a TC1.6E CPU will invalidate all its DRB lines.

DRB Bypass

The DRB may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the DRB is bypassed after reset.

Whilst the DRB bypass is enabled, a data read request by the CPU to a cacheable address will result in a forced buffer miss. Any valid lines within the DRB will remain valid and unchanged whilst the DRB is bypassed. As such data reads to cacheable addresses with the DRB bypass enabled behave identically to data accesses to non-cacheable addresses.

The DCON0 register is endinit protected.

5.11.3 DMI Trap Generation

CPU data accesses to the DMI may encounter one of a number of potential error conditions, which result in one of the following trap conditions being reported by the DMI.

ALN Trap

An ALN trap is raised for the following conditions:

- An access whose effective address does not conform to the alignment rules
- An access where the length, size or index of a circular buffer is incorrect

Whenever an ALN trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

MEM Trap

A MEM trap is raised for the following conditions:

- An access whose effective address has a different segment to that of the base address (Segment Difference Error)
- An access whose effective address causes the data to span two segments (Segment Crossing Error)
- A memory address is used to access a CSFR area (CSFR Access Error)
- A context load or store instruction is executed where the effective address is not within the local DSPR range (Context Location Error)(TC1.6E only)

Whenever a MEM trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DSE Trap

A DSE trap is raised for the following conditions:

- An access outside the range of the DSPR (Scratch Range Error)
- An access to the lower half of segment C which cannot be translated into a global address, i.e. from C1000000 to C7FFFFFF (Global Address Error)
- An error on the bus for an external accesses due to a load (Load Bus Error)
- An error from the bus during a cache refill (Cache Refill Error)
- An error during a load whilst in SIST mode (Load MSIST Error)
- An error generated by the overlay system during a load.

Whenever a DSE trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

DAE Trap

A DAE trap is raised for the following conditions:

- An error on the bus for an external accesses due to a store (Store Bus Error)
- An error on the bus due to a cache writeback (Cache writeback Error)(TC1.6P only)
- An error from the bus due to a cache flush (Cache Flush Error)(TC1.6P only)
- An error due to a store whilst in SIST mode (Store MSIST Error)
- An error generated by the overlay system during a store.

Whenever a non-inhibited DAE trap occurs, the DATR (Data Asynchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated. DAE traps are inhibited if the DATR register is non-zero.

Data Memory Protection Traps

Data memory protection traps (MPW, MPR, MPP, MPN) are raised by the memory protection system when a protection violation occurs. Whenever a data memory protection trap occurs the DSTR (Data synchronous trap register) and the DEADD (Data Error Address Register) are updated.

5.11.4 DMI Registers

Two control registers and three trap flag registers control the operation of the DMI. These registers and their bits are described in this section.

5.11.4.1 DMI Register Descriptions

Note: There is no DCON1 register in this implementation.

Data Memory Control Register 0 (DCON0)

The DCON0 register allows the Data cache to be bypassed.

DCON0

Data Memory Control Register

(CSFR_Base + 9040_H)

Reset Value: 0000 0002_H

Field	Bits	Type	Description
RES	0	-	Reserved
DCBYP	1	rw	Data Cache/Data Read Buffer Bypass 0 _B DCache / DRB enabled 1 _B DCache / DRB Bypassed (disabled)
RES	[31:2]	-	Reserved

Note: This register is endinit protected

Data Control Register 2 (DCON2)

DCON2 contains size information for the Data memory system.

DCON2

Data Control Register 2 (CSFR_Base + 9000_H) Reset Value: CPU Dependent

Field	Bits	Type	Description
DCACHE_SIZE	[15:0]	r	Data Cache Size In KBytes
DSCRATCH_SIZE	[31:16]	r	Data Scratch Size In KBytes

DMI Synchronous Trap Flag Register

The DSTR contains synchronous trap information for the data memory system. The register is updated with trap source information to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

DSTR
Data Synchronous Trap Register
(CSFR_Base + 9010_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RES	[31:25]	r	Reserved

DMI Asynchronous Trap Flag Register

The DATR contains asynchronous trap information for the data memory system. The register is updated with trap information for DAE traps to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

DAE traps are inhibited if the DATR register is non-zero.

DATR
Data Asynchronous Trap Register
(CSFR_Base + 9018_H)

RES	[13:11]	r	Reserved
SOE	14	rwh	Store Overlay Error Store to invalid overlay address
RES	[31:15]	r	Reserved

Data Error Address Register

DEADD contains trap address information for the Data memory system. The register is updated with trap information for MEM, ALN, DSE or DAE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and either the DATR or DSTR registers have no bits already set.

The register contents are only valid when either the DATR or DSTR register is non-zero and hence should be read prior to clearing these registers.

5.12 Safety Features

The CPUs implements a number of safety concepts These are detailed in the following sections.

5.12.1 SRI Data Master Address Phase Error Injection

To allow the SRI address phase error detection system to be tested it is necessary to inject errors during the address phase of an SRI transaction. This is done by the TC1.6P or TC1.6E data master. The data master selectively inverts individual bits of the address phase of an SRI read or write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for an address phase error the address ECC bits indicated by the flip field are inverted for the next SRI data read or write bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI address ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

5.12.2 SRI Data Master Write Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI write transaction. This is done by the TC1.6P or TC1.6E data master. The data master selectively inverting individual bits of the SRI write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI write bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

5.12.3 SRI Data Slave Read Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI read transaction. This is done by the TC1.6P or TC1.6E slave. The data slave selectively inverts individual bits of the SRI read phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI read bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is ENDINIT protected.

5.12.4 SRI Error Capture

The SRI master and slave interfaces of the CPU implement the standard SRI ECC system. Error information detected during SRI transactions at the SRI master and slave interfaces is captured in the PIETR and PIEAR, or DIETR and DIEAR registers. On detection of an error the error information is captured and the relevant IED bit is set. No further error information is captured until this bit is cleared by software.

Error conditions at the SRI program interfaces are notified to the Safety Monitor Module via the `pbus_err_o` output from the CPU.

Error conditions at the SRI data interfaces are notified to the Safety Monitor Module via the `dbus_err_o` output from the CPU.

If an error is detected at an SRI slave interface during a write operation then the erroneous data will not be written.

5.12.5 SRI Safe Data Master tag

In order to differentiate between data accesses from safe and regular tasks a new safe task identification bit is introduced into the PSW register (PSW.S).

An SRI data access performed by a task when the PSW.S bit is set uses the safe data master tag. When this bit is not set the regular data master tag is used for the access. There is only one program master tag. This is used for SRI program fetches by both safe and regular tasks.

The initial value of the PSW.S bit for interrupt handlers is defined by the SYSCON.IS bit. The initial value of the PSW.S bit for trap handlers is defined by the SYSCON.IT bit.

On a trap the save of the current context is performed using the data master tag defined by SYSCON.TS

On an interrupt the save of the current context is performed using the data master tag defined by SYSCON.IS

5.12.6 Safety Memory Protection

The CPUs each allow for the definition of eight, protected regions of local SRAM memory.

The protection applies only to write or read-modify-write accesses to local SRAM included in the DMI or PMI from the bus.

Read accesses are not protected.

The protection scheme is based on the use of SRI tags to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters. 32 masters are supported in the current implementation.

Each region is defined using the registers, `SPROT_RGNLx (x=0-7)` to define the lower address of the region, `SPROT_RGNUx (x=0-7)` to define the upper address of the

CPU Subsystem

region and `SPROT_RGNACCENx` ($x=0-7$) to individually select the master tags permitted write access to the defined address range.

A write or read-modify-writes access is seen as valid if the master tag of the access is enabled in the `SPROT_RGNACCENx` register and the address of the access satisfies the following relationship:-

`SPROT_RGNLax <= address < SPROT_RGNUAx`

The `SPROT_RGNLax`, `SPROT_RGNUAx`, `SPROT_RGNACCENx` registers are protected by the `safety_endinit` signal.

After reset, the region address registers will be set to include the whole of the CPUs SRAM address space and write access by all masters will be enabled.

When altering protection settings, it should be noted that, due to access pipelining and resynchronization delays in the register block, a write to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

Whenever a Safety Memory Protection violation occurs the event is notified to the Safety Management Unit via the `tc16_safe_prot_err_o` output signal from the CPU. The `PIETR/DIETR` and `PIEAR/DIEAR` registers are updated to aid localisation of the error

5.12.7 Safety Register Protection

The CPUs implement the standard memory protection scheme for peripheral registers using the `SPROT_ACCEN` register. This allows all CPU CSFR and SFR registers to be protected from corruption by untrusted masters. The `SPROT_ACCEN` register defines which masters may modify the SFR and CSFR registers via bus access through the SRI slave interface.

The `SPROT_ACCEN` register is protected by the `safety_endinit` signal.

In all cases the master is identified using the SRI tag of the access. See On Chip Bus chapter for the product's TAG ID to master peripheral mapping.

Whenever a Safety Register Protection violation occurs the event is notified to the Safety Management Unit via the `safe_prot_err_o` output signal from the CPU. The `PIETR` and `PIEAR` registers are updated to aid localisation of the error.

5.12.8 Lock Step Implementation

The TC1.6E and TC1.6P CPUs may be implemented as standard CPU (as described in the chapter) or as a checker CPU for use in lockstep comparison system. The checker CPU implementation has the following features.

- No Memories

CPU Subsystem

- All signals that would normally be fed to the memories become additional outputs from the checker CPU.
- All signals that would normally be fed from the memories become additional inputs to the checker CPU.
- All outputs from the checker CPU are inverted.

The lockstep system compares the following CPU interfaces.

- Interface to the interrupt router.
- Interface to the SCU.
- Interface to the DMI Data Scratch pad memory.
- Interface to the PMI Program Scratch memory.
- Interface to the PMI Program Cache memory.
- Interface to the PMI Program Tag memory.
- Master interface to the Peripheral bus.
- Master interface to the SRI bus for PMI accesses.
- Master interface to the SRI bus for DMI accesses.
- Slave accesses from the SRI bus for PMI and DMI accesses.
- The CPUs run in lockstep mode at the full specified frequency. Enabling lockstep does not require operational frequency to be reduced.
- The Checker CPU is implemented using inverse state storage "AntiCore".

5.12.9 MBIST usage recommendations

The following usage of the CPU SRAM MBIST system is recommended.

- When any one of the CPU local data memories (DSPR/DCACHE or DTAG) is in MBIST test mode (MEMTEST enabled), then other CPU local data memories will be not be accessible. It is therefore recommended to enable DSPR/DCACHE MBIST mode and DTAG memory MBIST mode together.
- When any one of the CPU local program memories (PSPR/PCACHE or PTAG) is in MBIST test mode (MEMTEST enabled), then other CPU local program memories will be not be accessible. It is therefore recommended to enable PSPR/PCACHE MBIST mode and PTAG memory MBIST mode together.
- For configurations that use dual MBIST controllers for a single logical memory (e.g TC29x DSPR/DCACHE for CPU1,2), MBIST tests run on one CPU will report errors to both controllers. It is therefore recommended to enable MBIST mode on both controllers together and that the error notification bits of both controllers are cleared at the end of testing.

5.12.10 Registers Implementing Safety Features

SRI Error Generation Register

The SEGEN register controls the injection of SRI address phase errors from the DMI. This register is ENDINIT protected.

SEGEN

SRI Error Generation Register (CSFR_Base + 1030_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
ADFLIP	[7:0]	rw	Address ECC Bit Flip SRI address ECC Bits to be flipped on the next read or write transaction from the DMI when enabled by AE. 0 _B No Flip 1 _B Flip
ADTYPE	[9:8]	rw	Type of Error 00 _B Data Master Address Phase 01 _B Data Master Write Data 10 _B Data Slave Read Data 11 _B Reserved
RES	[30:10]	r	Reserved
AE	31	rwh	Activate Error Enable Enabled the selective inverting of SRI ECC packet bits defined by ADFLIP. This bit will be cleared by hardware after the next SRI read or write transaction from the DMI. 0 _B Not Enabled 1 _B Enabled

Safety Protection Region Lower Address Register

In conjunction with the associated SPROT_RGNUAx and SPROT_RGNACCENx registers, the SPROT_RGNLA register provides control of a memory protection region. SPROT_RGNLAx defines the lower address of a region of memory, SPROT_RGNUAx defines the upper address and the SPROT_RGNACCENx registers define the SRI tags allowed write access to the region. Address ranges can be set to be larger than the SRAM address space but only accesses to the SRAM are affected by these registers. The minimum resolution of the comparison logic is 32_D bytes so address bits 4_D down to 0_D are not used

SPROT_RGNLAx (x=0-7)

Safety Protection Region Lower Address Register

(SFR_Base + E000_H+x*10_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	[4:0]	r	Reserved
ADDR	[31:5]	rw	Region Lower Address Bits 32 to 5 of the address which is the lower bound of the defined memory region

Safety protection Region Upper Address Register

In conjunction with the associated SPROT_RGNLAx and SPROT_RGNACCENx registers, the SPROT_RGNUAx register provides control of a memory protection region. SPROT_RGNUAx defines the upper address of the memory region

SPROT_RGNUAx (x=0-7)

Safety protection Region Upper Address Register

(SFR_Base + E004_H+x*10_H) Reset Value: FFFF FFE0_H

Field	Bits	Type	Description
RES	4:0	r	Reserved Unused bits will always read as 0 _B . Written value will be ignored
ADDR	31:5	rw	Region Upper Address Bits 31 to 5 of the address which is the upper bound of the defined memory region

Safety Region Access Enable Register A

The Access Enable Register A controls write access for transactions to the protected memory region with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The Safety protection is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

SPROT_RGNACCENAx (x=0-7)

Safety Protection Region Access Enable Register A

(SFR_Base+ E008_H+x*10_H) Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
EN	[31:0]	rw	<p>Access Enable for Master TAG ID n (n=0-31)</p> <p>This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n</p> <p>0_B Write access will not be executed</p> <p>1_B Write access will be executed</p>

Safety Protection Region Access Enable Register B

The Access Enable Register B controls write access for transactions to the protected memory region with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The CPU is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to SPROT_ACCENB.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

SPROT_RGNACCENBx (x=0-7)

Safety Protection Region Access Enable Register B (SFR_Base + E00C_H+x*10_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RES	[31:0]	r	Reserved Read as 0; should be written with 0.

Safety Register Access Enable Register A

The Access Enable Register A controls write access for transactions to CSFR/SFR registers with the on chip bus master TAG ID 00000_B to 01111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The Safety protection is prepared for an 6 bit TAG ID. The registers SPROT_RACCEN0 / SPROT_RACCEN1 are provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 00000_B, EN1 -> TAG ID 00000_B, ... ,EN31 -> TAG ID 01111_B.

SPROT_ACCENA

Safety Protection Register Access Enable Register A

(SFR_Base + E100_H)

6 Lockstep Comparator Logic (LCL)

The Lockstep Comparator Logic module provides access to the control and self test functions of the processor lockstep comparators.

6.1 Feature List

An overview of the features implemented in the LCL follows:

- Monitoring the core comparators for the lockstep core and its shadow and flagging any detected differences
- Running background, continuous self test on the lockstep comparators to validate the correct operation of the logic.

6.2 Lockstep Control

The lockstep control function is enabled by the LSEN bitfield in a control register in the SCU. Each core capable of lockstep has its own instance of the control register. In this product, the CPU1 instance of the Tricore can be lockstepped so there is one register, LCLCON1 for CPU1.

These registers are only initialised by a cold power-on reset. In this initialisation state, all lockstepped processors in the system will have lockstep enabled. The lockstep function can only be disabled by the system initialisation software writing a 0_b to the LSEN bitfield. Application software cannot enable or disable the lockstep function.

The current mode of the lockstep logic can be monitored by reading the lockstep status bit, LS, in the associated LCLCON register.

Writes to the control registers will be subject to the protection mechanisms of the SCU.

6.3 Lockstep Monitoring

The lockstep monitoring function will compare the outputs from the master and checker cores and report that a failure has occurred to the Safety Management Unit (SMU) for appropriate action.

The monitoring function temporally separates the cores by inserting synchronisation delays to re-align the signals being compared. To achieve this, the checker core inputs and the master core outputs fed to the comparators are delayed by two clock cycles.

Lockstep Comparator Logic (LCL)

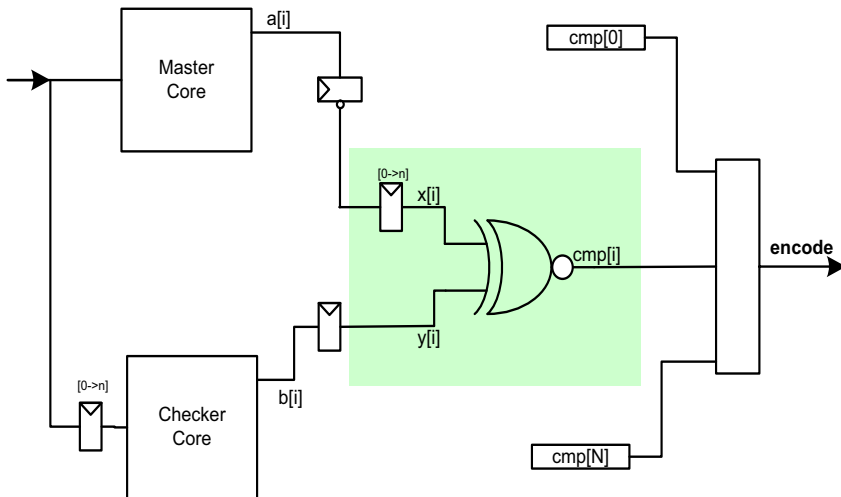

Figure 6-1 Node Comparator

Figure 6-1 above shows the equivalent circuit of an arbitrary node comparator, i , of 0 to N comparators. The comparator monitors two signals, a and b , which are connected to the same node in the master and checker cores. The signals can be synchronised in the relevant core using the core clock to minimise impact on the core timing.

After the optional synchronisation, the master core monitor point is inverted to reduce the risk of a common mode failure in the two monitored signals. Therefore, x is equivalent to a delayed by a n clock cycles, where $n=2$ in this implementation, to allow for the temporal shift between the master and checker cores and y is equivalent to b . If the nodes differ (i.e. x and y are the same), the CMP signal is set to 1_B . This will cause the **encode** signal to flag the failing node and the failure will be detected. In the event that multiple nodes fail, the encode output will be the minimum and maximum values of all the indices, i , of the failing nodes. This has no impact on normal functioning but allows the self test logic to detect a real failure occurring in the same clock cycle that a fault is injected for test purposes.

6.4 Lockstep Self Test

Each core capable of lockstep also has a continuously running background self test of the lockstep comparator.

The self test function will inject faults into both inputs of each of the monitored nodes and verify that the fault is correctly detected by the monitoring logic.

In the event of a self test failure being detected, the failure will be reported to the Safety Management Unit for an appropriate response.

Lockstep Comparator Logic (LCL)

An equivalent circuit of a node comparator showing the fault injection logic is shown in [Figure 6-2](#)

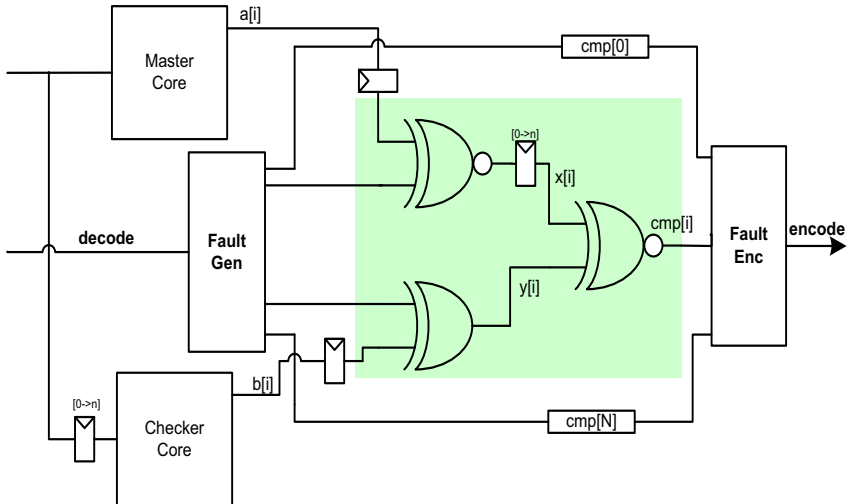

Figure 6-2 Node Comparator with Fault Injection

Faults are injected using the **Fault Gen** block. This will use a binary number, **decode**, to calculate which node is to be tested. **decode** will be generated from a free running, binary counter using gray code number representation (the **input counter**). The Self test circuit will test every node once every 8192 clock cycles. Alternate test cycles will inject faults into either the **a** or **b** side of the comparator node. The complete self test cycle will therefore repeat every 16384 clock cycles.

Injecting a fault into either side of the comparator node will cause that node to fail unless a real fault occurs in the same clock cycle in which case the two faults will cancel out.

The node failing is processed by the **Fault Enc** block to generate a binary representation of the failing node, **encode**. This contains two numbers, the node index of the first node found to be failing counting up from the lowest minimum node index and the node index of the first node found to be failing counting down from the maximum node index.

If the lockstep block is functioning correctly, both values in **encode**, will either be 0 if no failures have been detected or the number of the node which has had a fault induced by the self test logic.

The values in **encode** are checked against a second, independent binary counter (the **monitor counter**). The **monitor counter** is also compared against the value of the **input counter**. In the event that either of the values in **encode** or the **input counter** fails to match the value of the monitor counter, a failure condition will be flagged to the SMU.

Lockstep Comparator Logic (LCL)

With this implementation, any of the following conditions will cause a self test fail:

- an actual fault occurring on any of the **a** or **b** nodes
- a stuck at 0_B fault occurring on any of the **cmp** nodes
- a stuck at 1_B fault occurring on any of the **cmp** nodes
- a failure in the **Fault Gen** block causing an incorrect or no fault to be injected
- a failure in the **Fault Enc** block causing an incorrect detection or no fault to be detected
- a stuck at fault on **x** (assuming that an injected fault does not always coincide with a masking pulse on **b**)
- a stuck at fault on **y** (assuming that an injected does not always coincide with a masking pulse on **a**)
- an actual fault on any of the **a** or **b** nodes coinciding with an injected fault
- a soft error occurring on either the **input counter** or **monitor counter**.

6.5 Lockstep Failure Signalling Test

The lockstep comparator allows a failure to be injected into one of the comparator nodes to allow the signalling of failures to be verified. A failure can be injected by writing 1_B to the LCLT1 bitfield of the LCLTEST register. The failure will be injected for a single cycle of the SPB clock. It is not necessary to write a 0_B to clear the test.

6.6 Functional Redundancy

All registers in the lockstep block which are not capable of being directly monitored for correct operation by the self test function will be duplicated. In the event of the duplicated registers not storing the same state, an error will be flagged to the SMU.

6.7 Revision History

Deltas from Lockstep version 1.1 to version 1.2

- Bitfield names updated for LCLCON register. See [sections “Lockstep Monitoring” and “Lockstep Self Test”](#).
- Multiple failure detecton algorithm updates. See Lockstep Self Test section.

Deltas from Lockstep version 1.2 to 1.3

- Revision History Added

Deltas from Lockstep version 1.3 to 1.4

- Description of self test updated

Deltas from Lockstep version 1.4 to 1.5

- Control bits for self test and delay removed. Both functions will now be permanently enabled.
- Lockstep will now be on after reset and cannot be enabled once switched off

Deltas from Lockstep version 1.5 to 1.6

- Additional control bit added to allow injection of fault condition under software control.

Deltas from Lockstep version 1.6 to 1.7

- Specifying cold power-on reset / typo's.

Deltas from Lockstep version 1.7 to 1.8

- No functional change, updates to Requirements tags only.

Deltas from Lockstep version 1.8 to 1.9

- No functional change, correction of typos and support for TC23x configuration.

7 System Control Units

The System Control Cluster comprises various modules which each handle system control functions.

The System Control Cluster includes the following functional modules:

- Clock Control Unit (CCU)
- Reset Control Unit (RCU)
- Power Management Controller (PMC)
- System Control Unit (SCU), including ERU, LCL, WDT, EMS, NMI and OVC registers

7.1 Clocking and Clock Control Unit (CCU)

This section describes the TC26x B-Step clock system, its configuration and the principles upon which it is based.

The clock system itself is build up as chain composing out of different building blocks which allow different certain function parts for this complete chain.

Building blocks are:

- Basic clock generation (Clock Source)
- Clock speed upscaling
- Clock distribution
- Individual clock configuration

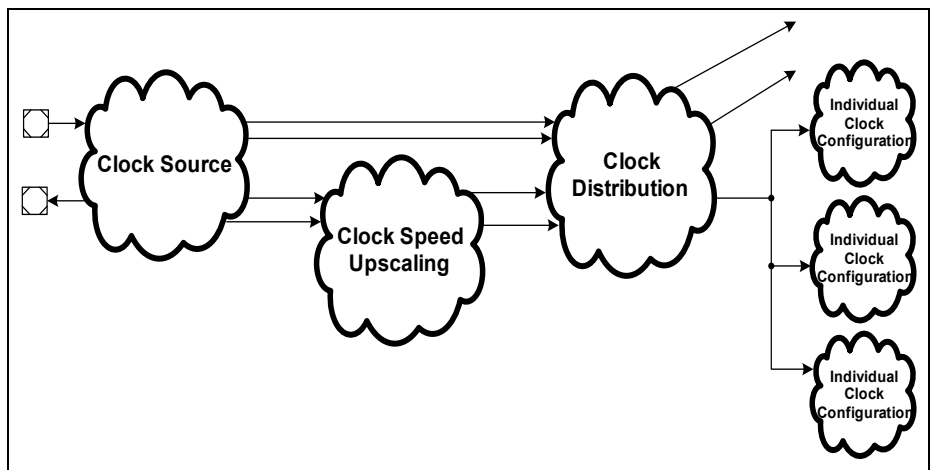

Figure 7-1 Clock Tree

Aside from the pure clock generation options there are several support functions which have been integrated in order to support easy and convenient controls.

In the following subsections the clock tree is explained from left to the right. Using this flow for the initial configuration is also recommended. Expert users can of course execute the configuration in a individual order.

Note: If a running system needs to be reconfigured not all parts of the clock tree need to be configured, only these parts that are required can be updated.

7.1.1 Clock Sources

There are several clock sources available which either source the complete device, a major or minor part, or only dedicated modules. This depends on the sources and the configuration.

Please note that several clock sources can be used in parallel inside the system but the main function of each peripheral is only related to one source at any time.

7.1.1.1 Oscillator Circuit (OSC)

The oscillator circuit, a Pierce oscillator, is designed to work with both an external crystal / ceramic resonator or an external stable clock source, consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output with an integrated feedback resistor.

External Input Clock Mode

When using an external clock signal it must be connected to XTAL1. XTAL2 is left open (unconnected).

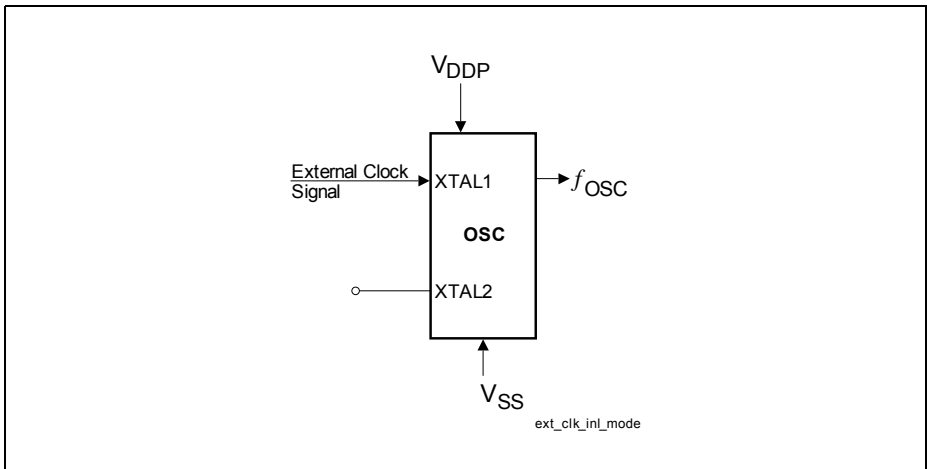

Figure 7-2 TC26x B-Step Direct Clock Input

When supplying the clock signal directly, not using an external crystal / ceramic resonator and bypassing the oscillator, the input frequency needs to be equal or greater than PLL VCO input frequency (the value is listed in the Data Sheet) if used in normal Mode.

External Crystal / Ceramic Resonator Mode

Figure 7-3 shows the recommended external circuitries for both operating modes, External Crystal / Ceramic Resonator Mode with and without external components.

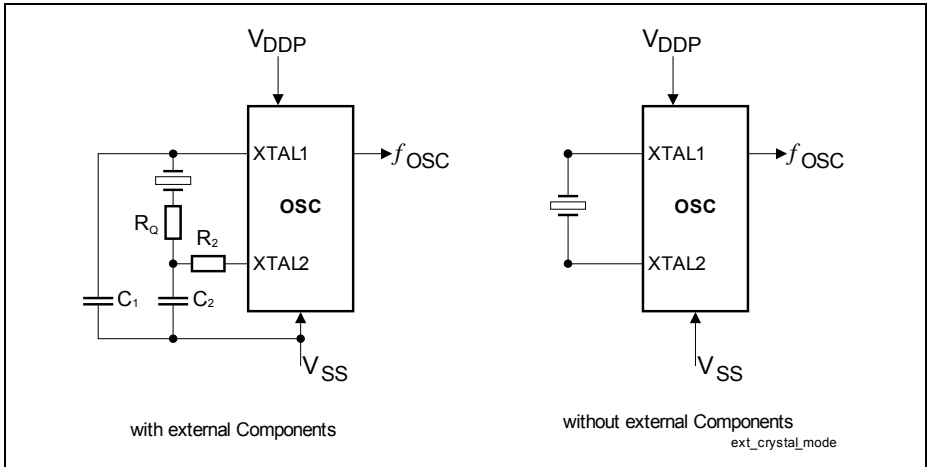

Figure 7-3 External Circuitry for Crystal / Ceramic Resonator operation

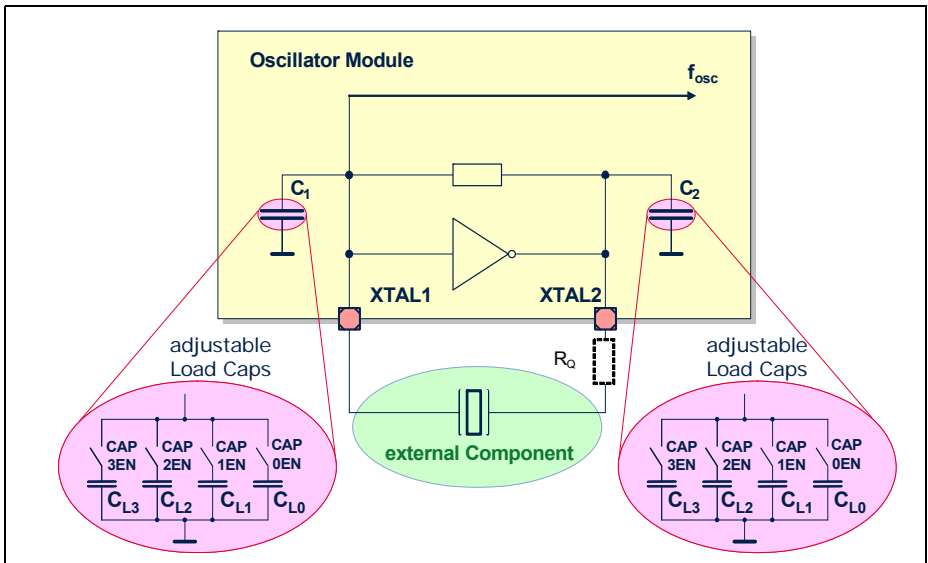

Figure 7-4 Circuitry for Crystal / Ceramic Resonator operation with internal CAPS

When using an external crystal / ceramic resonator, its frequency can be within the allowed range (the values are listed in the Data Sheet). An external oscillator load

circuitry can be used, connected to both pins, XTAL1 and XTAL2. Additionally are necessary, two load capacitances C_1 and C_2 (see [Figure 7-3](#)) or the internal loads can be used (see [Figure 7-4](#)), and depending on the crystal / ceramic resonator type, a series resistor R_2 to limit the current. A test resistor R_Q may be temporarily inserted to measure the oscillation allowance (negative resistance) of the oscillator circuitry. R_Q values are typically specified by the crystal / ceramic resonator vendor. The C_1 and C_2 values shown in the Data Sheet can be used as starting points for the negative resistance evaluation and for non-productive systems. The exact values and related operating range are dependent on the crystal / ceramic resonator frequency and have to be determined and optimized together with the crystal / ceramic resonator vendor using the negative resistance method. Oscillation measurement with the final target system is strongly recommended to verify the input amplitude at XTAL1 and to determine the actual oscillation allowance (margin negative resistance) for the oscillator-crystal / ceramic resonator system.

The oscillator can also be used in combination with a ceramic resonator. The final circuitry must be also verified by the resonator vendor.

Configuration of the Oscillator

A configuration of the oscillator is always required before an external crystal / ceramic resonator could be used as clock source. For this start-up configuration two options are supported:

- Configuration via the SSW
- Configuration after the execution of the SSW

Configuration via SSW

This option is enabled when bit FLASH0_PROCOND.OSCCFG is set. In this mode the control information for the register OSCCON is loaded from FLASH0_PROCOND by the SSW. Therefore the required information needs to be stored with the UCB_DFlash at offset 00_H.

In this mode OSCCON.MODE and OSCCON.CAPxEN together with bit OSCCON.APREN are controllable.

Note: A control for OSCCON.GAINSEL is not required as it is recommended always to keep the default configuration of 11_B.

If the oscillator was disabled it must be enabled by setting bit field OSCCON.MODE = 00_B.

If the integrated capacitors should be used this can be enabled via the bits OSCCON.CAPxEN. If OSCCON[27:24] ≠ 0000_B then bit OSCCON.APREN need to be set too. Please note that the Amplitude Regulation needs to be enabled always when integrated caps are used. Enabling the Amplitude Regulation does not require a change for OSCCON.GAINSEL, which should be left at 11_B.

Configuration after SSW

After the optional configuration in the SSW there is always an option to configure the oscillator in the application software.

This is done via register OSCCON. The register itself is Safety ENDINIT protected.

In general the same rules apply for configuration as described in the section before.

Miscellaneous Oscillator Features

Support for two additional features which are related to the oscillator are also located in the OSCCON register.

XTAL1 as General Purpose Input Pin

For the rare case that XTAL1 / 2 are not used for clocking purpose XTAL1 could be used as an input pad instead. Setting bit OSCCON.X1DEN enables this function and the input value can be read thereafter via bit OSCCON.XD1.

Please note that this defines only a basic input function and supports no output features for XTAL1 or XTAL2.

Note: For XTAL2 no input function is supported.

Note: If XTAL1 is used for clock functions bit OSCCON.X1DEN should be cleared, as otherwise bit OSCCON.X1D would toggle with the input clock frequency.

Oscillator Watchdog

In combination with the PLL, a monitoring function is implemented. This feature is defined to detect severe malfunctions of an external crystal / ceramic resonator. Detectable errors are loss of clock input or a much too high input frequency.

The oscillator watchdog monitors the incoming clock frequency f_{OSC} from OSC. A stable and defined input frequency is a mandatory requirement for operation in both Prescaler Mode and Normal Mode of the PLLs. For operation in Freerunning Mode no f_{OSC} input frequency is required. Therefore this mode is selected automatically after each System Reset. In addition for the Normal Mode it is required that the input frequency f_{OSC} is in a certain frequency range to obtain a stable master clock from the VCO part.

The expected input frequency is selected via the bit field OSCCON.OSCVAL. The OSC_WDT checks for frequencies which are too low or too high.

The frequency that is monitored is f_{OSCREF} which is derived from f_{OSC} .

(7.1)

$$f_{OSCREF} = \frac{f_{OSC}}{OSCVAL + 1}$$

The divider value OSCCON.OSCVAL has to be selected in a way that f_{OSCREf} is 2.5 MHz.

Note: f_{OSCREf} has to be within the range of 2 MHz to 3 MHz and should be as close as possible to 2.5 MHz.

Before configuring the OSC_WDT function all the SMU Oscillator Watchdog alarm response options should be disabled in order to avoid unintended traps. Thereafter the value of OSCCON.OSCVAL can be changed. Then the OSC_WDT should be reset by setting OSCCON.OSCRES. This requests the start of OSC_WDT monitoring with the new configuration. When the expected positive monitoring results of OSCCON.PLLLV and / or OSCCON.PLLHV are set the input frequency is within the expected range. As setting OSCCON.OSCRES clears both bits OSCCON.PLLLV and OSCCON.PLLHV all both status flags will be set. Therefore both flags should be cleared before the SMU alarm responses are enabled again. The trap disabling-clearing-enabling sequence should also be used if only bit OSCCON.OSCRES is set without any modification of OSCCON.OSCVAL.

The oscillator clock is selected as source for the watchdog by configuring CCUCON1.INSEL = 01_B.

7.1.1.2 Back-up Clock

A back-up clock source is available as alternate clock source. This clock source provides a stable but reliable clock source that can be used as clock for the system. It provides less accuracy than an external crystal or ceramic resonator. The back-up clock can not be enabled or disabled or anyhow else be controlled. Therefore no control bits beside the selection itself as source (CCUCON0.CLKSEL = 00_B as clock source for the clock distribution and CCUCON1.INSEL = 00_B as clock source for the PLL / PLL_ERAY) are available.

7.1.2 Clock Speed Upscaling

Typical CPU operating speeds are about 10 times higher than the speed of the used crystal as clock source. Therefore an upscaling of the clock frequency is required.

For the upscaling up to two Phase Lock Loop (PLLs) are provided.

7.1.2.1 Phase-Locked Loop (PLL) Module

The PLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

The PLL also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

Features

- VCO lock detection
- 4-bit input divider **P**: (divide by $PDIV+1$)
- 7-bit feedback divider **N**: (multiply by $NDIV+1$)
- 7-bit output divider **K1 or K2**: (divide by either by $K1DIV+1$ or $K2DIV+1$)
- 7-bit output divider **K3**: (divide by $K3DIV+1$)
- Oscillator Watchdog
 - Detecting too low input frequencies
 - Detecting too high input frequencies
- Different operating modes
 - Prescaler Mode
 - Freerunning Mode
 - Normal Mode
- VCO Power Down
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode
- Frequency Modulation
- Jitter reduction for modulation jitter

PLL Functional Description

The following figure shows the PLL block structure.

Figure 7-5 PLL Block Diagram

Mode Control

The PLL clock f_{PLL} and f_{PLL2} are generated from f_{OSC} in one of following software selectable modes:

- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 or K3.

The output frequency is given by

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_{OSC} \quad (7.2)$$

$$f_{PLL2} = \frac{N}{P \cdot K3} \cdot f_{OSC} \quad (7.3)$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1. The output frequency is given by

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (7.4)$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{PLLBASE}$ is only divided down by a factor K2 or K3.

The output frequency is given by

$$f_{PLL} = \frac{f_{PLLBASE}}{K2} \quad (7.5)$$

$$f_{PLL2} = \frac{f_{PLLBASE}}{K3} \quad (7.6)$$

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL is running at its VCO base frequency and f_{PLL} / f_{PLL2} is derived from f_{VCO} only by the K2 / K3-Divider.

The Freerunning Mode is entered after each System Reset.

Figure 7-6 PLL Free-Running Mode Diagram

The output frequency is given by

$$f_{PLL} = \frac{f_{PLLBASE}}{K2} \quad (7.7)$$

$$f_{PLL2} = \frac{f_{PLLBASE}}{K3} \quad (7.8)$$

The Freerunning Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLSTAT.FINDIS = 1
- AND
- PLLSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC} . The Freerunning Mode is automatically entered on a PLL VCO Loss-of-Lock event if bit PLLCON0.OSCDISDIS is cleared. This mechanism allows a fail-safe operation of the PLL as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{PLLBASE}$ is listed in the Data Sheet.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct effect on the power consumption of the device. Therefore this has to be changed carefully to avoid excessive current steps.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL is running at the external frequency f_{OSC} and f_{PLL} is derived from f_{OSC} only by the K1-Divider.

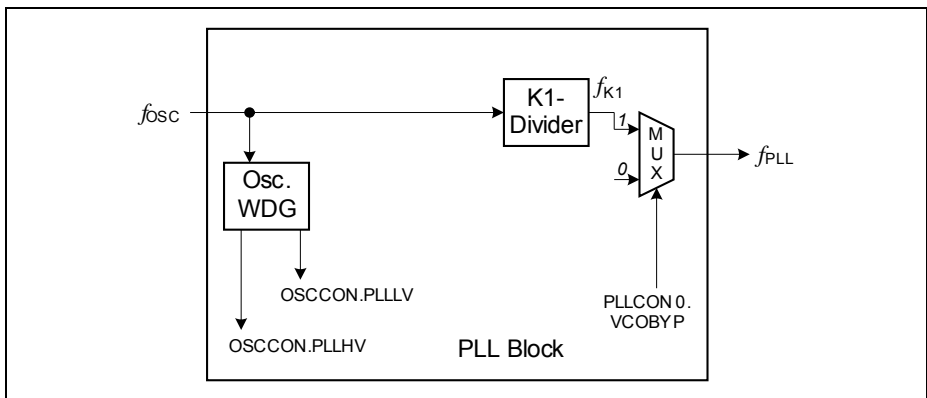

Figure 7-7 PLL Prescaler Mode Diagram

The output frequency is given by:

$$f_{PLL} = \frac{f_{OSC}}{K1} \quad (7.9)$$

The Prescaler Mode is selected by the following settings

- PLLCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirement is invalid:

- PLLSTAT.VCOBYST = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC} .

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLCON1.K1DIV was changed the next update of this value should not be done before bit PLLSTAT.K1RDY is set.

Note: Changing the system operation frequency by changing the value of the K1-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL output frequency f_{PLL} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLCON.VCOBYP. The Prescaler Mode is left when the status bit PLLSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the external frequency f_{OSC} divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3 resulting in $f_{\text{PLL}} / f_{\text{PLL}2}$.

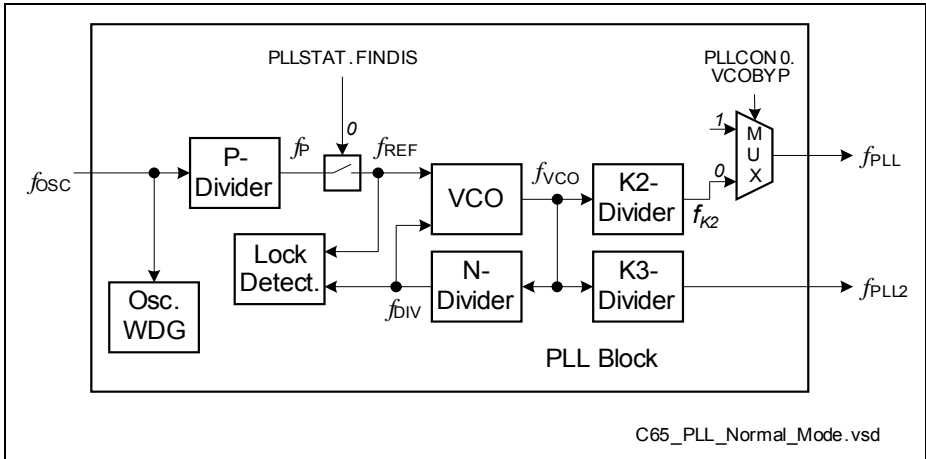

Figure 7-8 PLL Normal Mode Diagram

The output frequency is given by:

$$f_{\text{PLL}} = \frac{N}{P \cdot K_2} \cdot f_{\text{OSC}} \quad (7.10)$$

$$f_{\text{PLL2}} = \frac{N}{P \cdot K_3} \cdot f_{\text{OSC}} \quad (7.11)$$

The Normal Mode is selected by the following settings

- PLLCON0.VCOBYP = 0
- PLLCON0.CLRFINDIS = 1

The Normal Mode is entered when the following requirements are all together valid:

- PLLSTAT.FINDIS = 0
- PLLSTAT.VCOBYST = 0
- PLLSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the three dividers: P, N, and K2 / K3. A modification of the two dividers P and N has a direct influence to the VCO frequency and could lead to a loss of the VCO Lock status. A modification of the K2 / K3-divider has no impact on the VCO Lock status but still changes the PLL output frequency.

Note: Changing the system operation frequency by changing the value of the K2-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The SMU alarm generation for the VCO Loss of Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The P and N divider should be selected in the following way:

- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the P, N, and K2 / K3 dividers have been updated on the first configuration, the indication of the VCO Lock status should be checked (PLLSTAT.VCOLOCK = 1).

Note: When configuring the PLL for the first time after a system reset it is recommended to disconnect the input clock f_{OSC} before configuring P and / or N and to connect f_{OSC} before checking for the lock status.

Note: It is recommended to reset the VCO Lock detection (PLLCON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.

Note: Resetting the lock detection (PLLCON0.RESLD = 1) while PLLCON0.OSCDISCDIS = 0 when the PLL was already locked (PLLSTAT.VCOLOCK = 1) can lead to a disconnect of the input clock. In this case PLLCON0.OSCDISCDIS should be set before lock detection is reset. When the lock is thereafter is set again PLLCON0.OSCDISCDIS could be cleared again.

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLCON.VCOBYP. The Normal Mode is entered when the status bit PLLSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The SMU status flag for the system PLL VCO Loss-of-Lock event should be cleared and then enabled again. The intended PLL output target frequency can now be configured by changing only the K2 / K3-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

This can result in multiple changes of the K2-Divider to avoid too big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL} should be waited.

PLL VCO Lock Detection

The PLL has a lock detection that supervises the VCO part of the PLL in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL VCO Loss-of-Lock Event

The PLL may become unlocked, caused by a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

Additionally, the OSC clock input f_{OSC} is disconnected from the PLL VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC} , the PLL gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLCON0.OSCDISCDIS. If this bit is set the OSC clock remains connected to the VCO.

VCO Power Down Mode

The PLL offers a VCO Power Down Mode. This mode can be entered to save power within the PLL. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered the Prescaler Mode must be active.

PLL Power Down Mode

The PLL offers a Power Down Mode. This mode can be entered to save power if the PLL is not needed at all. The Power Down Mode is entered by setting bit PLLCON0.PLLPWD. While the PLL is in Power Down Mode no PLL output frequency is generated.

Frequency Modulation

If the PLL operates in Normal Mode the output frequency f_{PLL} can additionally be modified by a low-frequency modulation. f_{VCO} is randomly modulated.

The modulation is enabled via bit PLLCON0.MODEN. The modulation itself variate the VCO frequency randomly with the range of the configured modulation amplitude. The modulation amplitude is selected via PLLCON2.MODCFG[9:0].

(7.12)

$$\text{MA} = \frac{f_{\text{MV}}}{f_{\text{VCO}} \times 2} \times \text{MODCFG}[9, 0]$$

The modulation performed in a way that the resulting accumulated jitter added by the modulation stays below J_{MOD} . The modulation itself is monitored with f_{REF} and therefore the P-divider should be configured with the smallest possible value.

PLL Registers

PLL registers can be accessed by all CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU immediately after a reset, this is the logical choice.

These registers control the setting of the PLL.

PLLSTAT

PLL Status Register (014_H) **Reset Value: 0000 0038_H**

Field	Bits	Type	Description
VCOBYST	0	rh	VCO Bypass Status 0 _B Freerunning / Normal Mode is entered 1 _B Prescaler Mode is entered
VCLOCK	2	rh	PLL VCO Lock Status 0 _B The frequency difference of f_{REF} and f_{DIV} is greater than allowed. The VCO part of the PLL can not lock on a target frequency. 1 _B The frequency difference of f_{REF} and f_{DIV} is small enough to enable a stable VCO operation. <i>Note: In case of a loss of VCO lock the f_{VCO} is keep on the previous constant frequency.</i>

7.1.2.2 ERAY Phase-Locked Loop (PLL_ERAY) Module

The PLL_ERAY can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It can execute emergency actions if it loses its lock on the external clock.

This module is a phase locked loop for integer frequency synthesis. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

Features

- VCO lock detection
- 4-bit input divider **P**: (divide by PDIV+1)
- 5-bit feedback divider **N**: (multiply by NDIV+1)
- 7-bit output divider **K1 or K2**: (divide by either by K1DIV+1 or K2DIV+1)
- 7-bit output divider **K3**: (divide by K3DIV+1)
- Different operating modes
 - Prescaler Mode
 - Freerunning Mode
 - Normal Mode
- VCO Power Down (Sleep Mode)
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode

PLL_ERAY Functional Description

The following figure shows the PLL_ERAY block structure.

Figure 7-9 PLL_ERAY Block Diagram

Clock Source Control

The PLL_ERAY clocks f_{PLL_ERAY} / f_{PLL2_ERAY} are generated from f_{OSC} in one of three software selectable modes:

- Normal Mode
- Prescaler Mode
- Freerunning Mode

Normal Mode

In Normal Mode the input frequency f_{OSC} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3.

The output frequency is given by

(7.13)

$$f_{\text{PLL_ERAY}} = \frac{N}{P \times K2} \cdot f_{\text{OSC}}$$

(7.14)

$$f_{\text{PLL2_ERAY}} = \frac{N}{P \times K3} \cdot f_{\text{OSC}}$$

Prescaler Mode

In Prescaler Mode the reference frequency f_{OSC} is only divided down by a factor K1.

The output frequency is given by

(7.15)

$$f_{\text{PLL_ERAY}} = \frac{f_{\text{OSC}}}{K1}$$

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{\text{PLLBASEERAY}}$ is only divided down by a factor K2 / K3.

The output frequency is given by

(7.16)

$$f_{\text{PLL_ERAY}} = \frac{f_{\text{PLLBASEERAY}}}{K2}$$

(7.17)

$$f_{\text{PLL2_ERAY}} = \frac{f_{\text{PLLBASEERAY}}}{K3}$$

Configuration and Operation of the Freerunning Mode

In Freerunning Mode, the PLL_ERAY is running at its VCO base frequency and $f_{\text{PLL_ERAY}} / f_{\text{PLL2_ERAY}}$ are derived from f_{VCO} only by the K2 / K3-Divider.

The Freerunning Mode is entered after each System Reset.

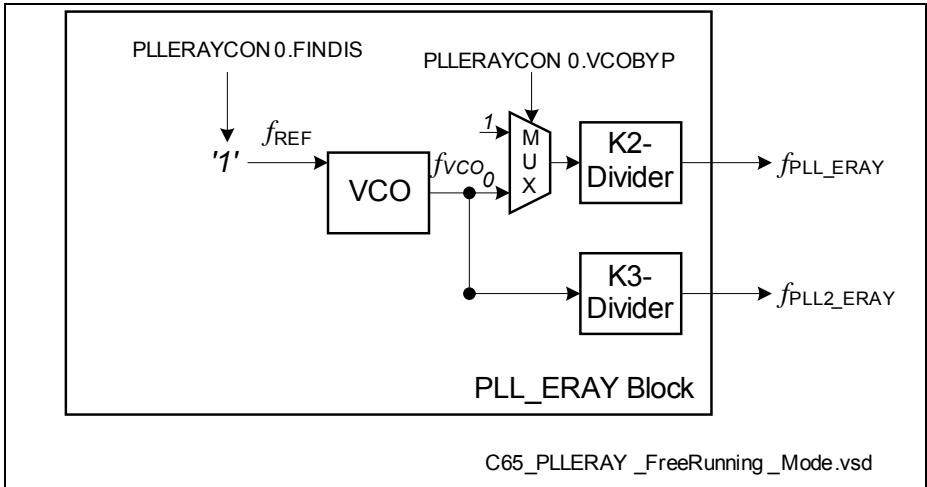

Figure 7-10 PLL_ERAY Free-Running Mode Diagram

The output frequency is given by

$$f_{\text{PLLERAY}} = \frac{f_{\text{PLLBASEERAY}}}{K2} \quad (7.18)$$

$$f_{\text{PLL2ERAY}} = \frac{f_{\text{PLLBASEERAY}}}{K3} \quad (7.19)$$

The Freerunning Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.SETFINDIS = 1

The Freerunning Mode is entered when

- PLLERAYSTAT.FINDIS = 1
- AND
- PLLERAYSTAT.VCOBYST = 0

Operation on the Freerunning Mode does not require an input clock frequency of f_{OSC} . The Freerunning Mode is automatically entered on a PLL_ERAY VCO Loss-of-Lock event if bit PLLERAYCON0.OSCDISDIS is cleared. This mechanism allows a fail-safe operation of the PLL_ERAY as in emergency cases still a clock is available.

The frequency of the Freerunning Mode $f_{\text{PLLBASEERAY}}$ is listed in the Data Sheet.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface.

Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL_ERAY is running at the external frequency f_{OSC} and f_{PLL_ERAY} is derived from f_{OSC} only by the K1-Divider.

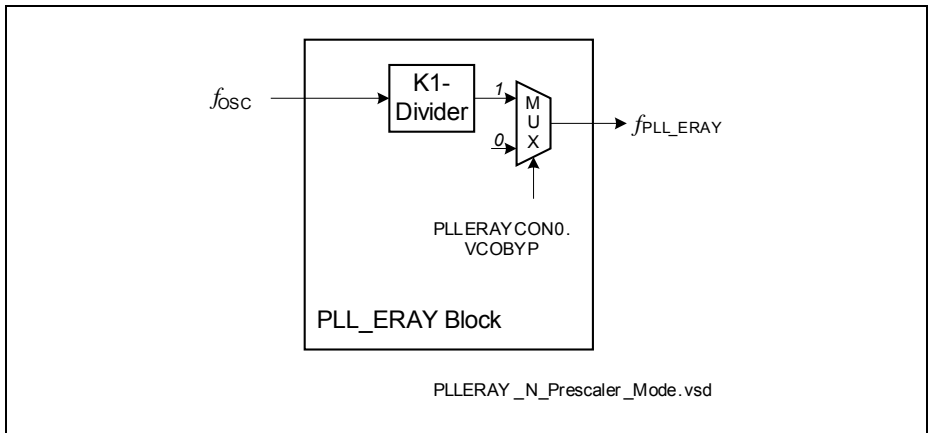

Figure 7-11 PLL_ERAY Prescaler Mode Diagram

The output frequency is given by:

$$f_{PLL_ERAY} = \frac{f_{OSC}}{K1} \tag{7.20}$$

The Prescaler Mode is selected by the following settings

- PLLERYCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirement is invalid:

- PLLERYSTAT.VCOBYST = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC} .

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLERAYCON1.K1DIV was changed the next update of this value should not be done before bit PLLERAYSTAT.K1RDY is set.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

The Prescaler Mode is requested from the Freerunning or Normal Mode by setting bit PLLERAYCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLERAYSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL_ERAY output frequency f_{PLL_ERAY} that matches the one generated by the Freerunning or Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLERAYCON.VCOBYP. The Prescaler Mode is left when the status bit PLLERAYSTAT.VCOBYST is cleared.

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the external frequency f_{OSC} divided down by a factor P, multiplied by a factor N and then divided down by a factor K2 / K3 resulting in $f_{PLL_ERAY} / f_{PLL2_ERAY}$.

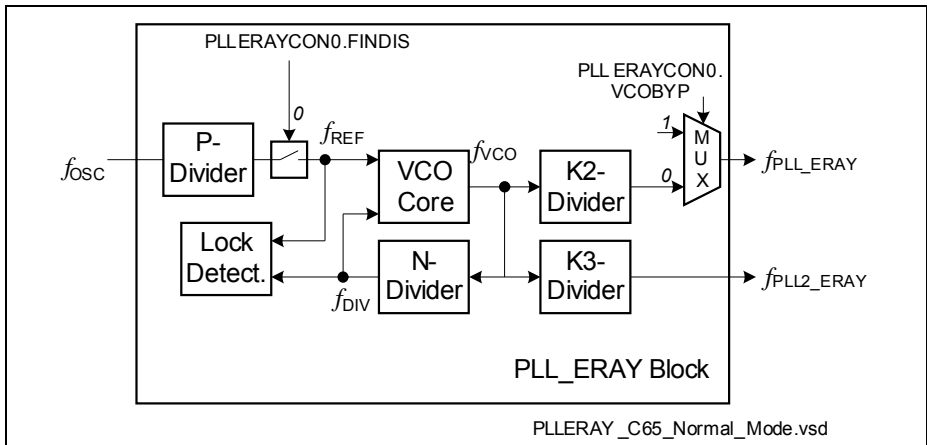

Figure 7-12 PLL_ERAY Normal Mode Diagram

The output frequency is given by:

(7.21)

$$f_{\text{PLL1ERAY}} = \frac{N}{P \times K2} \cdot f_{\text{OSC}}$$

(7.22)

$$f_{\text{PLL2ERAY}} = \frac{N}{P \times K3} \cdot f_{\text{OSC}}$$

The Normal Mode is selected by the following settings

- PLLERAYCON0.VCOBYP = 0
- PLLERAYCON0.CLRFINDIS = 1

The Normal Mode is entered when the following requirements are all together valid:

- PLLERAYSTAT.FINDIS = 0
- PLLERAYSTAT.VCOBYST = 0
- PLLERAYSTAT.VCOLOCK = 1
- OSCCON.PLLLV = 1
- OSCCON.PLLHV = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking OSCCON.PLLLV. For a better monitoring also the upper frequency can be monitored via OSCCON.PLLHV.

The system operation frequency is controlled in the Normal Mode by the values of the three dividers: P, N and K2 / K3. A modification of the two dividers P and N has a direct influence to the VCO frequency and could lead to a loss of the VCO Lock status. A modification of the K2 / K3-divider has no impact on the VCO Lock status but still changes the PLL_ERAY output frequency.

When the frequency of the Normal Mode should be modified or entered the following sequence should be followed:

First the Prescaler Mode should be configured and entered. For more details see the Prescaler Mode.

The SMU alarm generation for the VCO Loss of Lock should be disabled.

While the Prescaler Mode is used the Normal Mode can be configured and checked for a positive VCO Lock status. The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode. The N divider should be selected in the following way:

- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter

After the P, N and K2 / K3 dividers are updated for the first configuration the indication of the VCO Lock status should be await (PLLERYSTAT.VCOLOCK = 1).

Note: When configuring the PLL the input clock f_{OSC} should be disconnected before configuring P and / or N and connected before checking for the lock status.

Note: It is recommended to reset the VCO Lock detection (PLLERYCON0.RESLD = 1) after the new values of the dividers are configured to get a defined VCO lock check time.

Note: Resetting the lock detection (PLLERYCON0.RESLD = 1) while PLLERYCON0.OSCDISCDIS = 0 when the PLL_ERAY was already locked (PLLERYSTAT.VCOLOCK = 1) can lead to a disconnect of the input clock. In this case PLLERYCON0.OSCDISCDIS should be set before lock detection is reset. If the lock is subsequently set again PLLERYCON0.OSCDISCDIS could be cleared again.

When this happens the switch from Prescaler Mode to Normal Mode can be done. Normal Mode is requested by clearing PLLERYCON.VCOBYP. The Normal Mode is entered when the status bit PLLERYSTAT.VCOBYST is cleared.

Now the Normal Mode is entered. The SMU alarm flag for the PLL_ERAY VCO Loss-of-Lock event should be cleared and then enabled again. The intended PLL_ERAY output target frequency can not be configured by changing only the K2-Divider.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. This can result in multiple changes of the K2-Divider to avoid too big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL_ERAY} should be waited.

PLL_ERAY VCO Lock Detection

The PLL_ERAY has a lock detection that supervises the VCO part of the PLL_ERAY in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL_ERAY VCO Loss-of-Lock Event

The PLL_ERAY may become unlocked, caused by a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

Additionally, the OSC clock input f_{OSC} is disconnected from the PLL_ERAY VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC} , the PLL_ERAY gradually slows down to its VCO base frequency and remains there. This automatic feature can be disabled by setting bit PLLERAYCON0.OSCDISCDIS. If this bit is cleared the OSC clock remains connected to the VCO.

VCO Power Down Mode

The PLL_ERAY offers a VCO Power Down Mode. This mode can be entered to save power within the PLL_ERAY. The VCO Power Down Mode is entered by setting bit PLLCON0.VCOPWD. While the PLL_ERAY is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered, the Prescaler Mode must be active.

PLL_ERAY Registers

PLL_ERAY registers may be accessed by any CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset this is the logical choice.

These registers controls the setting of the PLL_ERAY.

7.1.3 Clock Distribution

Using the first two parts of the Clock System all clocks the system rely on for operation are defined. Now these different clocks need to be distributed to the single modules, CPUs, and blocks in a way that these IPs can operate in best way in terms performance and power consumption.

For the clock distribution the system is split into several sub-clock domains where the clock speed could be configured individually but there are also several limitation for each sub-clock domain derived out of the internal interfaces.

Each sub-clock domain defines a logical unit from clocking perspective point of view.

The clock distribution is done via the Clock Control Unit (CCU). The CCU receives the clocks that are created by the two PLLs ($f_{PLL/PLL2}$ and f_{PLL_ERAY/PLL_ERAY2}), the back-up clock f_{Back} , and f_{OSC0} . These clock are either forwarded directly or divided in order to supply the sub-clock domains.

The following figure shows the structure of the TC26x B-Step clock system that shows the different sub-clock domains together with their clock inputs.

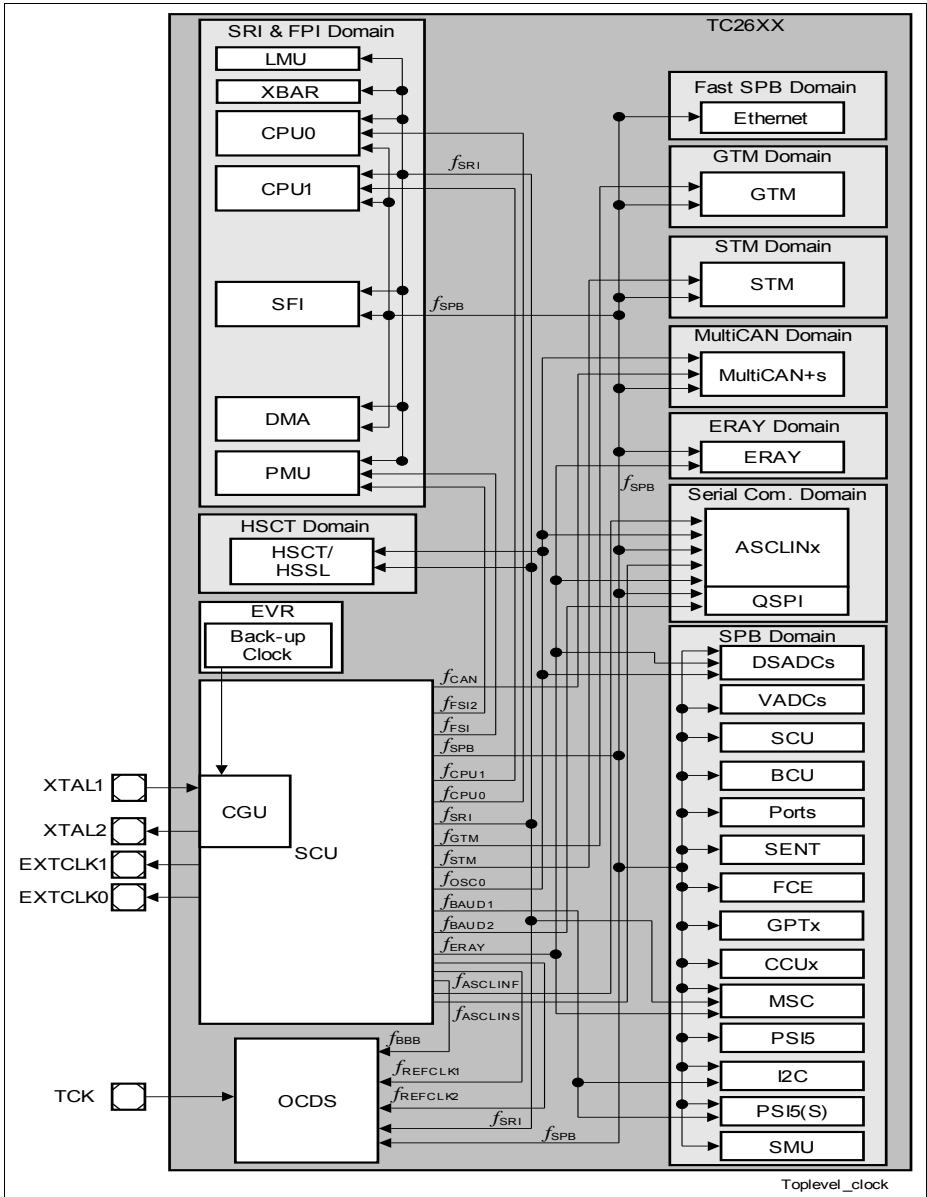

Figure 7-13 TC26x B-Step Clocking System

7.1.3.1 Clock Control Unit

The Clock Control Unit (CCU) receives the clocks that are created by the two PLLs ($f_{PLL/PLL2}$ and $f_{PLL_ERAY/PLL2_ERAY}$), the back-up clock f_{Back} , and f_{OSC0} .

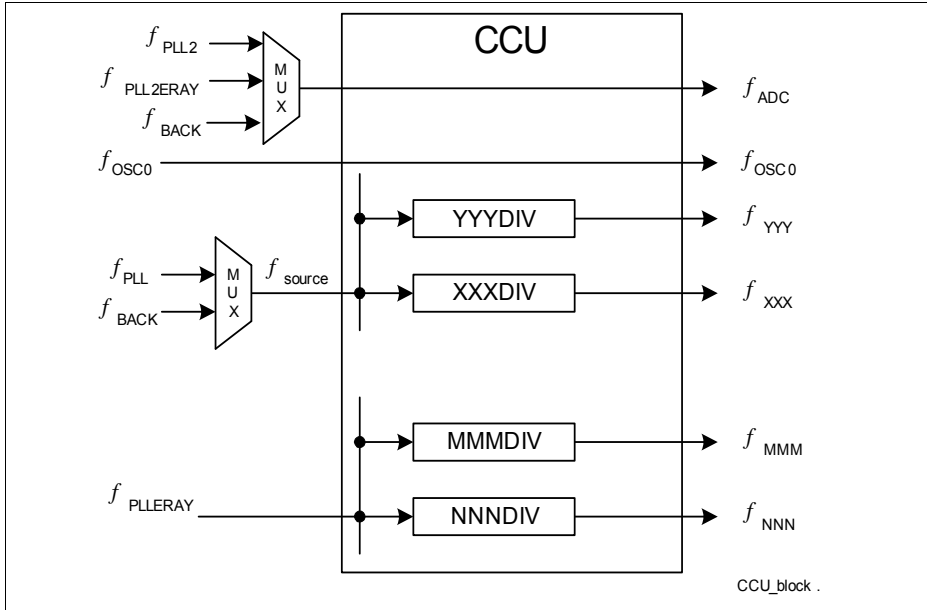

Figure 7-14 Clock Control Unit Overview

For most clocks a linear divider is provided to adapt the clock frequency to the application requirement. This divider is controlled by the bit field XXXDIV.

For the CPU clocks, more sophisticated dividers are implemented. This allows a better precision for the control in clock frequency changes of individual CPUs. This mechanism allows the adaptation of the frequency change to a specific current limit defined by the application.

There is also a fixed reference clock REFCLK1/2 for the debug block, which divides the master clock f_{PLL}/f_{PLL_ERAY} by 24. This allows the OCDS to generate timestamps independently of the selected SRI and SPB clock speeds.

Basic Clock System Mechanisms

The clocking system offers a lot of options and a high amount of flexibility. Behind this complex clocking system a set of basic ideas is implemented in order to allow a configuration as close as possible to the given application needs.

The heart of the system is a synchronous block including all modules except the ERAY. The heartbeat here is defined by f_{MAX} . f_{MAX} is defined as the highest frequency used inside the system for any clock derived out of f_{SOURCE} .

For different IPs (CPUs, modules or module clusters) options are included to influence the application execution / performance via the clock control.

Following is a brief overview of the different clocks:

- System buses
 - f_{SRI} defines the operating performance of the SRI-Bus and therefore the data exchange rate between all connected masters and slaves
 - f_{SPB} defines the operating performance of the SPB-Bus and therefore the data exchange rate between all connected masters and slaves and the interrupt system
- CPU controls
 - f_{CPU0} defines the execution speed of CPU0
 - f_{CPU1} defines the execution speed of CPU1
- PMU controls
 - f_{FSI2} defines the execution speed of the PFlash for reading operations
 - f_{FSI} defines the execution speed for all other flash operations
- Peripheral options
 - f_{STM} defines a basic frequency for the STMs independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the STMs to operate on a constant frequency.
 - f_{GTM} defines a basic frequency for the GTM independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the GTM to operate on a constant frequency.
 - f_{BAUD1} defines a basic frequency for ‘slow’ communication interfaces independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the IIC to operate on a constant baudrate (frequency).
 - f_{BAUD2} defines a basic frequency for ‘fast’ communication interfaces independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the QSPIs and PSI5S to operate on a constant baudrate (frequency).
 - f_{CAN} defines a basic frequency for the MultiCAN independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the MultiCAN to operate on a constant baudrate (frequency).
 - $f_{ASCLINF} / ASCLINS$ defines a basic frequency for the ASCLINs independent of the rest of the system (beside the limitations listed in [Table 7-2](#)). This allows the ASCLINs to operate on a constant baudrate (frequency).
- Debug system
 - As debugging should be non-intrusive to the application system, a separate clock f_{BBB} for dedicated debug resources is available. This allows debugging (trace generation) during changes of the other clock configurations. Please note that f_{BBB} needs to be faster than or equal to f_{SPB} for debug.

In addition several peripherals offer the option to operate on other clock sources. If frequency modulation is used, some peripherals should switch to a non-modulated clock. Due to its unique requirements the ERAY module is implemented as an asynchronous domain with its own independent clock source.

Table 7-1 CCU Clock Options

CCU Clock Output	Clock Source			
	PLL	PLL_ERAY	Back-up	OSC_XTAL
f_{MAX}	✓	–	Default	–
f_{SRI}	✓	–	Default	–
f_{CPU0}	f_{SRI}	–	–	–
f_{CPU1}	f_{SRI}	–	–	–
f_{SPB}	✓	–	Default	–
f_{FSI}	f_{SRI}	–	–	–
f_{FSI2}	f_{SRI}	–	–	–
$f_{REFCLK1/2}$	✓	✓	Default	–
f_{BBB}	✓	–	Default	–
f_{ERAY}	–	Default	–	–
f_{GTM}	✓	–	Default	–
f_{STM}	✓	–	Default	–
f_{BAUD1}	✓	–	Default	–
f_{BAUD2}	✓	–	Default	–
f_{CAN}	✓	–	Default	–
$f_{ASCLINF}$	✓	–	Default	–
$f_{ASCLINS}$	✓	–	Default	–

The complete system is based on a single clock (f_{SOURCE}) in order to achieve the performance advantage of a synchronous system. Therefore certain limitations have to be considered when configuring the clock control options.

Clock Divider Limitations

For the clock dividers which control the different sub-clock domains / modules the allowed values are limited and the following ratios have to be observed. The ratios are defined in the following way: clock A = f_{AAA} ; clock B = f_{BBB} the allowed ratio is 1 : n where n has a defined range of values. Clock A is always faster or equal to clock B in this definition with f_{AAA} [MHz] = n * f_{BBB} [MHz].

In addition the divider values are limited by the resulting maximum frequencies. These allowed max. frequencies are defined in the Target Data Sheet / ACDC Target Specification.

Table 7-2 CCU allowed Clock Ratios

Clock A	Clock B	Allowed Ratios ¹⁾	Recommended Default
f_{SRI}	f_{SPB}	1 : n; n = 1, 2, 3, 4, 5, 6	n = 2
f_{SRI}	f_{FSI}	1 : n; n = 1, 2	n = 2
f_{SRI}	f_{FSI2}	1 : n; n = 1, 2	n = 1
f_{FSI2}	f_{FSI}	1 : n; n = 1, 2	n = 2
f_{GTM}	f_{SPB}	1 : n ²⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{GTM}	1 : n ²⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{STM}	1 : n ³⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{STM}	f_{SPB}	1 : n ³⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SRI}	f_{BBB} ⁴⁾	1 : n; n = 1, 2	n = 2
f_{BAUD1}	f_{SPB}	1 : n ⁵⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{BAUD1}	1 : n ⁵⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{BAUD2}	f_{SPB}	1 : n ⁶⁾ ; n = 1, 2, 3, 4, 5,...	n = 2
f_{SPB}	f_{BAUD2}	1 : n ⁶⁾ ; n = 1, 2, 3, 4, 5,...	-
f_{CAN}	f_{SPB}	1 : n ⁷⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	f_{CAN}	1 : n ⁷⁾ ; n = 1, 2, 3, 4, 5,...	-
$f_{ASCLINF}$	f_{SPB}	1 : n ⁸⁾ ; n = 1, 2, 3, 4, 5,...	n = 2
f_{SPB}	$f_{ASCLINF}$	1 : n ⁸⁾ ; n = 1, 2, 3, 4, 5,...	-
$f_{ASCLINS}$	f_{SPB}	1 : n ⁹⁾ ; n = 1, 2, 3, 4, 5,...	n = 1
f_{SPB}	$f_{ASCLINS}$	1 : n ⁹⁾ ; n = 1, 2, 3, 4, 5,...	-

1) Configuring the registers CCUCON0, CCUCON1 and CCUCON2 to values that result in a violation of the allowed ratios are not allowed even if a single configuration entry for a bit field is with the allowed register bit field description.

2) f_{GTM} can be faster, slower, or equal to f_{SPB}

3) f_{STM} can be faster, slower, or equal to f_{SPB}

4) f_{BBB} has to be faster, or equal to f_{SPB}

5) f_{BAUD1} can be faster, slower, or equal to f_{SPB}

6) f_{BAUD2} can be faster, slower, or equal to f_{SPB}

7) f_{CAN} can be faster, slower, or equal to f_{SPB}

8) $f_{ASCLINF}$ can be faster, slower, or equal to f_{SPB}

9) $f_{ASCLINS}$ can be faster, slower, or equal to f_{SPB}

Note: Recommended values did not necessarily reflect the default configuration after a reset event. Instead they should give a hint how to configure the system for an optimal performance configuration.

CCU Registers

CCU registers may be accessed by any CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after a reset, this is the logical choice.

Note: The relation in between the described CCUCONx.yyyDIV bit fields is described in the table [CCU allowed Clock Ratios](#).

CCUCON0

7.1.4 Individual Clock Generation

Each module provides some individual clock control options. Most modules provide a Clock Control (CLC) Register for this purpose. Some modules provide in addition more options to control the clocks. For more details please see the dedicated module chapters.

Modules can have in addition other registers controlling sub-clock domains e.g. for baud rate generation. These registers are always defined in the module chapters.

7.1.4.1 Clock Control Register CLC

All CLC registers have basically the same bit and bit field layout. However, not all CLC register functions are implemented for each peripheral module. **Table 7-3** defines in detail which bits and bit fields of the CLC registers are implemented for each clock control register.

The following functions for the module are associated with the CLC register:

- Peripheral clock static on/off control
- Module clock behavior in Sleep Mode

Module Enable/Disable Control

If a module is not used at all by an application, it can be completely shut off by setting bit DISR in its CLC register. For peripheral modules with a run mode clock divider field RMC, a second option to completely switch off the module is to set bit field RMC to 00_H. This also disables the module's operation.

The status bit DISS always indicates whether a module is currently switched off (DISS = 1) or switched on (DISS = 0).

Write operations to the non CLC registers of disabled modules are not allowed. However, the CLC of a disabled module can be written. An attempt to write to any of the other writable registers of a disabled module except CLC will cause the corresponding Bus Control Unit (BCU) to generate a bus error.

A read operation of registers of a disabled module is allowed and does not generate a bus error.

When a disabled module is switched on by writing an appropriate value to its MOD_CLC register (DISR = 0 and RMC (if implemented) > 0), status bit DISS changes from 1 to 0. During the phase in which the module becomes active, any write access to corresponding module registers (while DISS is still set) will generate a bus error. When enabling a disabled module, application software should read back the CLC register once, to check that DISS is cleared, before writing to any module register (including the CLC register).

Sleep Mode Control

The EDIS bit in the CLC register controls whether or not a module is stopped during Sleep Mode. If EDIS is 0, a Sleep Mode request can be recognized by the module and, when received, its clock is shut off.

If EDIS is set to 1, a Sleep Mode request is disregarded by the module and the module continues its operation.

Entering Disabled Mode

Software can request that a peripheral unit be put into Disabled Mode by setting DISR. A module will also be put into Disabled Mode if the Sleep Mode is requested and the module is configured to allow Sleep Mode.

In Secure Shut-off Mode, a module first finishes any operation in progress, then proceeds with an orderly shut down. When all sub-components of the module are ready to be shut down, the module's clock control unit turns off the clock. The status bit DISS is updated by the peripheral unit accordingly.

Module Clock Divider Control

Peripheral modules of the TC26x B-Step can have a RMC control bit field in their CLC registers. This Run Mode Clock control bit field makes it possible to slow down the CLC clock via a programmable clock divider circuit.

A value of 00_H in RMC disables the clock signals to these modules (CLC clock is switched off). If RMC is not equal to 00_H, the clock for a module register (f_{CLC}) accesses is generated as

(7.23)

$$f_{CLC} = \frac{f_{SPB}}{RMC}$$

where RMC is the content of its CLC register RMC field with a range of 1 to 255. If RMC is not available in a CLC register, the CLC clock frequency f_{CLC} is always equal to the frequency of f_{SPB} .

Note: The number of module clock cycles (wait states) that are required for a "destructive read" access (means: flags/bits are set/cleared by a read access) to a module register of a peripheral unit depends on the selected CLC clock frequency.

Therefore, a slower CLC clock (selected via bit field RMC in the CLC register) may result in a longer read cycle access time on the SPB for peripheral units with "destructive read" access.

Module Clock Register Implementations

Table 7-3 shows which of the CLC register bits/bit fields are implemented for each peripheral module in the TC26x B-Step.

 (00_H)

Reset Value: Module-specific

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable is not requested 1 _B Module disable is requested
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module 0 _B Module is enabled 1 _B Module is disabled If the RMC field is implemented and if it is 0, DISS is set automatically.
EDIS	3	rw	Sleep Mode Enable Control Used for module Sleep Mode control. 0 _B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode. 1 _B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
RMC	[15:8]	rw	8-Bit Clock Divider Value in RUN Mode This is a maximum 8-bit divider value for clock f_{SPB} . If RMC is set to 0 the module is disabled.
0	2, [7:4], [31:16]	r	Reserved Read as 0; should be written with 0.

7.1.5 Clock Monitors

For safety reasons clock monitors are available. For the following safety relevant clocks in the system monitors are present:

 f_{PLL}
 f_{PLL_ERAY}
 f_{SRI}
 f_{SPB}
 f_{GTM}
 f_{STM}

Each of these clocks is monitored by its own counter.

As reference clock the back-up clock is used as diverse clock source.

The divider has to be set in a way that the monitored frequency is one of the possible frequencies of [Table 7-4](#).

Operating the Clock Monitors

The clock monitors are implemented in a way that safety system requirements are supported for a flexible system configuration of the clock system. So it is possible to adapt the monitor configuration to the application configuration of the clock system.

For each clock monitor two bit fields are available, either in register CCUCON3 or CCUCON4 depending on the monitor.

For each monitor a divider bit field and a select bit field are available for the configuration.

The CCUCONy.SELXXX bit field defines one target frequency out of four predefined options.

Bit field CCUCONy.DIVXXX is used to divide the real clock frequency down to the selected target frequency.

Example: if the SPB is configured to operate at 100 MHz and needs to be monitored, CCUCON3.SBPDIV should be written with 0x14 and CCUCON3.SBPSEL with 00_B. This selects a target monitoring frequency of 5 MHz and divides the SPB clock by 20 resulting also in 5 MHz. If the SPB is configured to operate at 20 MHz and needs to be monitored, CCUCON3.SBPDIV should be written with 0x04 and CCUCON3.SBPSEL with 00_B.

The four target frequencies are selected in a way that all normally used frequency in a system can be covered. This means that frequencies like 66 MHz, 120 MHz, 130 MHz, 133 MHz, ... can be monitored.

Goal of the clock monitoring is to detect and signal clock malfunctions before these errors lead to not longer working system. Therefore the back-up clock is trimmed automatically and operated on f_{BACKT} . This setup guarantees that error are detected before the system could not react anymore

Table 7-4 Target trimmed Check limits

Target Frequency	LOWER value	UPPER value	SELXXX	Error can be detected for min. deviation	Error is detected for min. deviation
7.5 MHz	0x24	0x27	11 _B	-1.23% +1.56%	-8.56% +9.44%
6.6 MHz	0x20	0x23	10 _B	-0.9% +2.38%	-8.59% +11.11%
6 MHz	0x1C	0x1F	01 _B	-3.23% +1.56%	-11.13% +10.11%
5 MHz	0x17	0x1A	00 _B	-3.9% +2.83%	-12.41% +12.11%

An error is detected if the reference counter has an overflow and the monitor counter of the dedicated clock is either below the lower limit (clock too slow) or greater as the upper limit (clock too fast). Errors are signaled to the SMU where the further reaction can be configured.

In addition there is a fast upper limit checking for the SPB frequency available. This limit checking checks only for high SPB compared to the maximum allowed value. A violation generates a trigger.

An error is detected when the reference counter generates an overflow AND:

- Counter_value - UPPER > 0 for the upper limit
- OR
- LOWER - Counter_value > 0 for the upper limit

Note: This feature is supported by the Infineon safety driver [saflib] and there is no additional customer software required.

7.1.5.1 Clock Monitor Registers

These registers can be accessed by all CPUs in the system. Anyway it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset this is the best choice.

0	[28:24]	r	Reserved Read as 0; should be written with 0.

7.1.6 Clock Emergency Behavior

In case of a clock error the CCU switches to the back-up clock f_{BACK} as clock source. The only exception here is the ERAY clock f_{ERAY} that stays operating on the PLL_ERAY. A clock error is defined by a loss of lock event of the PLL (not PLL_ERAY) while operating in Normal Mode or by an error of the PLL clock monitor.

Note: After a clock emergency bit field CCUCON0.CLKSEL has to be re-written following a reconfiguration of the clock system (see also [Page 7-88](#)) when the root cause for the clock error disappears.

Note: After a clock emergency bit field PLLCON0.SETFINDIS / PLLERAYCON0.SETFINDIS has to be set following by PLLCON0.CLRFINDIS / PLLERAYCON0.CLRFINDIS clear before a reconfiguration of the clock system (see also [Page 7-88](#)) when the root cause for the clock error disappears.

7.1.7 External Clock Output

Two external clock outputs are provided via pins EXTCLK0 and EXTCLK1. These external clocks can be enabled/disabled via bits EXTCON.EN0 for EXTCLK0 and EXTCON.EN1 for EXTCLK1. Each of the clocks that defines a clock domain can individually be selected to be seen at pins EXTCLK0 or EXTCLK1, this is configured via bit field EXTCON.SEL0/1. Changing the content of bit field EXTCON.SEL0/1 can lead to spikes at pins EXTCLK0/1.

7.1.7.1 Programmable Frequency Output for EXTCLK0

This section describes the external clock generation using the Fractional Divider.

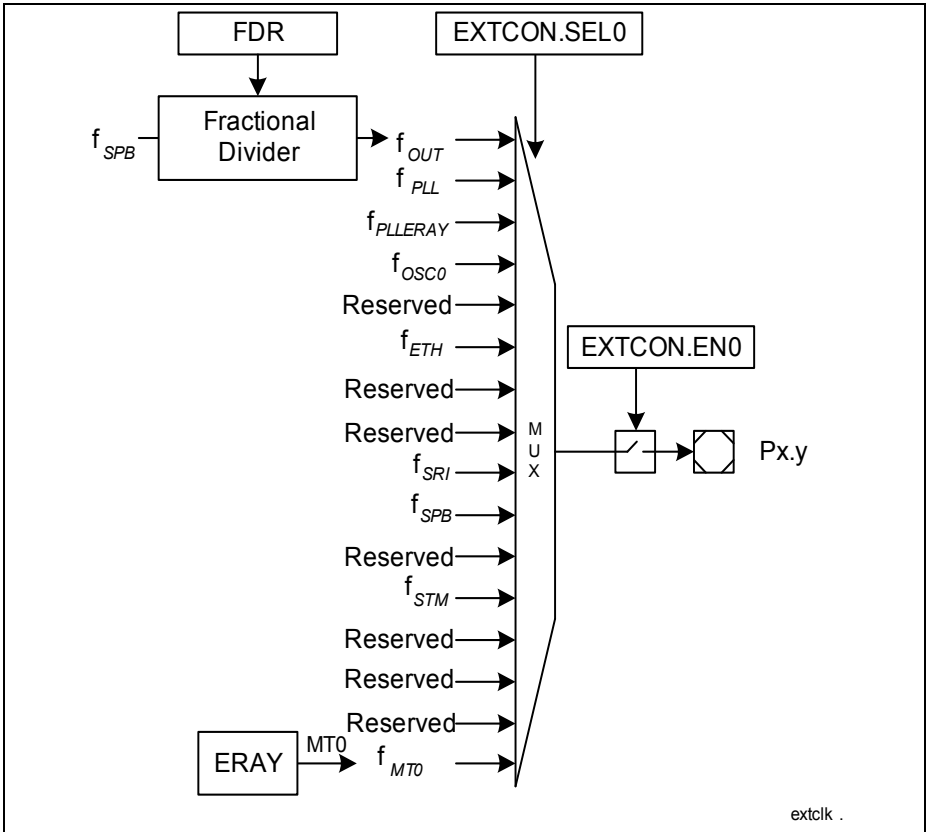

Figure 7-15 EXTCLK0 Generation

Overview

The fractional divider makes it possible to generate a external clock from the SPB clock using a programmable divider. The fractional divider divides the input clock f_{SPB} either by the factor $1/n$ or by a fraction of $n/1024$ for any value of n from 0 to 1023. This clock is thereafter divided additionally by a factor of two to guarantee a 50% duty cycle and outputs the clock, f_{OUT} . The fractional divider is controlled by the FDR register. [Figure 7-16](#) shows the fractional divider block diagram.

The adder logic of the fractional divider can be configured for two operating modes:

- Reload counter (addition of +1), generating an output clock pulse on counter overflow
- Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

Figure 7-16 Fractional Divider Block Diagram

The adder logic of the fractional divider can be configured for two operating modes:

- **Normal Mode:** Reload counter (RESULT = RESULT + 1), generating an output clock pulse on counter overflow.
- **Fractional Divider Mode:** Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow.

Fractional Divider Operating Modes

The fractional divider has two operating modes:

- Normal Divider Mode
- Fractional Divider Mode

Normal Divider Mode

In Normal Divider Mode (FDR.DM = 01_B), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse on the transition from 3FF_H to 000_H. FDR.RESULT represents the counter value and FDR.STEP determines the reload value.

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{\text{OUT}} = \frac{f_{\text{SPB}} \times \frac{1}{n}}{2}, \text{ with } n = 1024 - \text{STEP} \quad (7.24)$$

In order to get $f_{\text{OUT}} = f_{\text{SPB}}/2$ STEP must be programmed with $3FF_{\text{H}}$.

Fractional Divider Mode

When the Fractional Divider Mode is selected ($\text{FDR.DM} = 10_{\text{B}}$), the output is derived from the input clock f_{SPB} by division of a fraction of $n/1024$ for any value of n from 0 to 1023 followed by the division of two. In general, the Fractional Divider Mode makes it possible to program the average output clock frequency with a higher accuracy than in Normal Divider Mode.

In Fractional Divider Mode, a pulse is generated depending on the result of the addition $\text{FDR.RESULT} + \text{FDR.STEP}$. If the addition leads to an overflow over $3FF_{\text{H}}$, a pulse is generated for the divider by two. Note that in Fractional Divider Mode the clock f_{OUT} can have a maximum period jitter of one f_{SPB} clock period.

The output frequencies in Fractional Divider Mode are defined according to the following formulas:

$$f_{\text{OUT}} = \frac{f_{\text{SPB}} \times \frac{n}{1024}}{2}, \text{ with } n = \text{FDR.STEP} = 0-1023 \quad (7.25)$$

7.1.7.2 Programmable Frequency Output for EXTCLK1

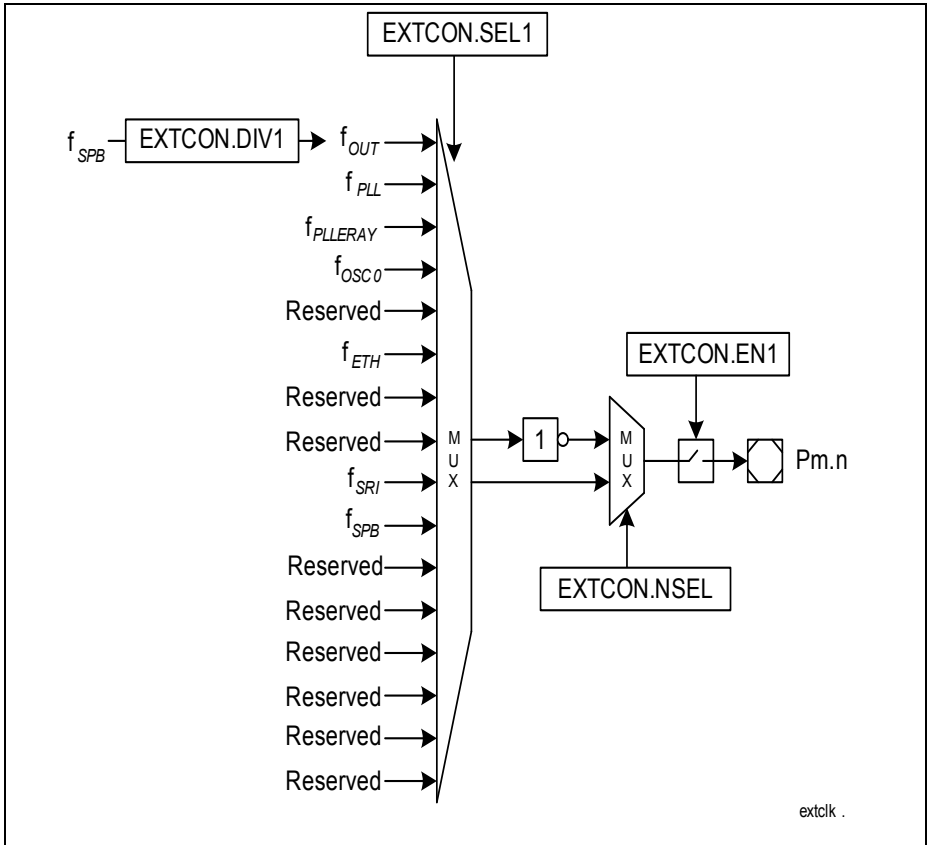

Figure 7-17 EXTCLK1 Generation

Clock f_{OUT} is generated via a counter, so the output frequency can be selected in small steps.

f_{OUT} always provides complete output periods.

Register EXTCON provides control over the output generation (frequency, activation).

7.1.7.3 Clock Output Control Register

These registers can be accessed by all CPUs in the system. Anyway it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset this is the best choice.

EXTCON

External Clock Control Register

7.1.8 Clock Generation Unit

The Clock Generation Unit (CGU) allows a very flexible clock generation for the TC26x B-Step. During user program execution the frequency can be programmed for an optimal ratio between performance and power consumption.

Figure 7-18 Clock Generation Unit Block Diagram

The CGU includes the clock source generation, the clock upscaling beside the clock distribution.

7.1.8.1 Example Sequence

The following sequence give an example for the clock ramp-up.

Goal for normal target setting is that system clock is based on PLL with external crystal.

- After power-on and system reset:
 - the system operates on the back-up clock
 - the oscillator (OSC) needs to be enabled via software or was enabled by firmware via BMI settings
- Fast clocks (SRI-Bus and CPUs) run with approximately 100 MHz

- Peripherals and SPB-Bus run with approximately 50 MHz
- Step 1: If f_{OSCO} is to be used but is not running, enable the oscillator to wait until it is providing a stable clock
- Step 2: Initialize the PLL to target f_{VCO} and f_{PLL} frequency
 - Select PLL input clock via CCUCON1.INSEL
 - Disconnect input clock from VCO; set PLLCON0.SETFINDIS
 - Select P, K2 / K3, and N divider for final target VCO and PLL frequency
 - 1) Select P as small as possible
 - 2) Select N (VCO) as high as possible
 - Connect input clock to VCO; set PLLCON0.CLRFINDIS
 - Configure resulting K2
- Step 3: Wait for PLL lock to be set
- Step 4: Configure CCUCON0, CCUCON1 and CCUCON5 to first target setting
 - Hint: both registers CCUCON0 and CCUCON1 can be reprogrammed without changing the clocking. Only setting the UP bit in one of the two registers transfers the values for both registers and lead to changes in the clock system.
 - Register CCUCON2 has its own UP bit
 - Bit fields CCUCON1.ERAY and CCUCON1.ETH are excluded from the update via UP in CCUCON0 or CCUCON1 and are always updated when a new value is programmed
- Step 5: Switch CCU input clock f_{SOURCE} to PLL via CCUCON0.CLKSEL
- Step 6: After setting CCU f_{SOURCE} to f_{PLL} , frequency has to be increased step by step to target frequency

Important hints for steps 4 and 5;

- Select CCUCON1 and CCUCON0 register settings in a way that the current consumption of the 1.3 V domain does not change more than the desired target value of the application, e.g. 50 mA.
- After every frequency programming step a wait time is recommended until supply ripple caused by supply current transient is faded away.

Note: The wait time between frequency steps depends on the supply and block concept.

- Continue these CCUCON1 and CCUCON0 update steps until the target system frequency is reached.

7.1.9 CCU Register Address

Table 7-5 Registers Address Spaces - CCU Registers

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

7.2 Reset Control Unit (RCU)

The Reset Control Unit (RCU) of the TC26x B-Step contains the following functional sub-blocks:

- Basic Reset Operation (see [Section 7.2.1](#))
- External Reset sources and indications (see [Section 7.2.2](#))
- Software Boot Support (see [Section 7.2.3](#))
- NMI Trap Generation (see [Section 7.2.4](#))
- RCU register overview table (see [Table 7-17](#))

7.2.1 Reset Operation

This section describes the conditions under which the TC26x B-Step will be reset and the reset operation configuration and control.

7.2.1.1 Overview

The following reset request triggers are available:

- Supply monitor (SWD) triggers a power-on reset (cold reset)
- 1.3V EVR monitor triggers a power-on reset (cold reset)
- 3.3V EVR monitor triggers a power-on reset (cold reset)
- Standby EVR (STBYR) monitor triggers a power-on reset (cold reset)
- External active low hardware “power-on” reset request trigger; $\overline{\text{PORST}}$ (can be either a warm reset or to extend a cold reset)
- External System Request reset trigger pins; $\overline{\text{ESR0}}$ and ESR1 (warm reset)
- Safety Management Unit (SMU) alarm reset request trigger, (warm reset)
- Software reset (SW), (warm reset)
- System Timer (STMx) trigger (warm reset)
- Resets via the JTAG interface
- JTAG resets (special reset)
- Software triggered module reset
-
-
-

Note: The JTAG resets are described in the OCDS chapter.

7.2.1.2 Reset Types

The following list describes the different reset types.

- Power-on Reset :
This reset results in initialization of the complete system into a defined state. A Power-on Reset also generates a Debug Reset and a System Reset (and therefore also an Application Reset).
- System Reset :
This reset leads to a initialization into a defined state of the complete system but without a reset of the power subsystem, debug subsystem or reset configuration registers.
A System Reset also generates an Application Reset.
- Debug Reset :
This reset leads to a initialization into a defined state of the complete debug system.
- Application Reset:
This reset leads to a initialization into a defined state of the complete application system with the following parts: all peripherals, the CPUs and parts of the SCU.

- **Module Resets:**
Module resets result in individual modules being initialized into a defined state without any impact on the rest of the system.

7.2.1.3 Reset Sources Overview

The connection of the reset sources and the activated reset signals/domains are shown in [Table 7-7](#).

Table 7-7 Effect of Reset Triggers

Reset Request Trigger	Application Reset	Debug Reset	System Reset
PORST	Activated	Activated	Activated
STBYR	Activated	Activated	Activated
SWD	Activated	Activated	Activated
EVR13	Activated	Activated	Activated

Cerberus RSTCL0¹⁾	Activated	Not Activated	Activated
Cerberus RSTCL1²⁾	Not Activated	Activated	Not Activated
Cerberus RSTCL3³⁾	Activated	Not Activated	Not Activated
Module Resets⁴⁾	Not Activated	Not Activated	Not Activated

1) Cerberus resets may be triggered by CBS_OCCTRL or CBS_OJCONF

2) Cerberus resets may be triggered by CBS_OCCTRL or CBS_OJCONF

3) Cerberus resets may be triggered by CBS_OCCTRL or CBS_OJCONF

4) Module Resets (via MOD_KRSTx.RST register bits in some modules) have no effect on chip-level reset system. The scope of a module reset is limited to the module itself.

7.2.1.4 Warm and Cold Resets

A cold “power-on” reset is a reset which is triggered for the first time during a system power-up or in response to a temporary power failure. During the power-up the EVR primary undervoltage monitors will trigger a complete reset of the system, placing the

system into a known state. The $\overline{\text{PORST}}$ pin can be used to extend this reset phase and control the timing of its release. The pins and internal states are placed immediately into their reset state when the trigger is asserted.

A warm reset is a reset which is triggered while the system is already operational and the supplies remain stable. It is used to return the system to the same known state. On a warm reset request, any reset of pin states will take place immediately, but the internal circuitry will only be reset after the system has been brought into a state where memory contents and debug trace data will not be corrupted and the current consumption has been ramped down. Note that $\overline{\text{PORST}}$ may be asserted as a warm reset.

7.2.1.5 EVR Resets and PORST

The $\overline{\text{PORST}}$ pin is a bidirectional reset in/output intended for external triggering of power-related resets. If this pin is left open then the default behavior shall be that the device remains in a reset state. If the $\overline{\text{PORST}}$ pin remains asserted after a power event then the reset will be extended until it is deasserted. This does not replace the ESR pins functional reset.

7.2.1.6 Module Reset Behavior

Table 7-8 lists how the various functions of the TC26x B-Step are affected by each reset type. An “X” means that this block has at least some register/bits that are affected by the corresponding reset.

Table 7-8 Effect of Reset on Device Functions

Module / Function	Application Reset	Debug Reset	System Reset	Warm “Power-on” Reset	Cold Power-on Reset

Other	Not affected, reliable	Not affected, reliable	Not affected, reliable	Not affected, reliable	Uninitialized

- 1) Lockstepped checker cores are initialized to the same reset state as the main core to avoid comparator fails during start-up
- 2) Reliable here means that also the redundancy is not affected by the reset.
- 3) DSPR is partially used as a scratchpad by the startup firmware. Previous data stored in the upper 32kB will be overwritten on start-up. Auto-initialization on reset can be optionally configured by PROCOND.RAMIN and PROCOND.RAMINSEL. Auto-initialization is disabled for CPU0 DSPR if the standby RAM is enabled.

- 4) Depending upon PROCOND.RAMIN and RAMINSEL setting, these memories may be automatically erased on cold or warm resets.
- 5) Tag memories are invalidated by hardware at reset. Depending upon PROCOND.RAMIN setting, cache content may also be automatically erased at reset (See MTU chapter for details).
- 6) Depending upon PROCOND.RAMIN and RAMINSEL setting, these memories may be automatically erased on cold or warm resets.

7.2.1.7 General Reset Operation

A reset is generated if an enabled reset request trigger is asserted. Most reset triggers can be configured to initiate different types of reset. No action (disabled) is a valid configuration which is selected by setting the corresponding bit field in the Reset Configuration Register to 00_B.

A Debug Reset can only be requested by dedicated reset request triggers and can not be selected via a Reset Configuration Register. For more information see also register RSTCON.

7.2.1.8 Reset Generation

The figure below shows the RCU controlling the reset generation for the complete device, with the exception of the JTAG reset domain.

Note: The JTAG reset domain is controlled by the \overline{TRST} pin.

The RCU detects the different reset requests, schedules a shutdown of the system, and then generates the appropriate internal reset pulse(s).

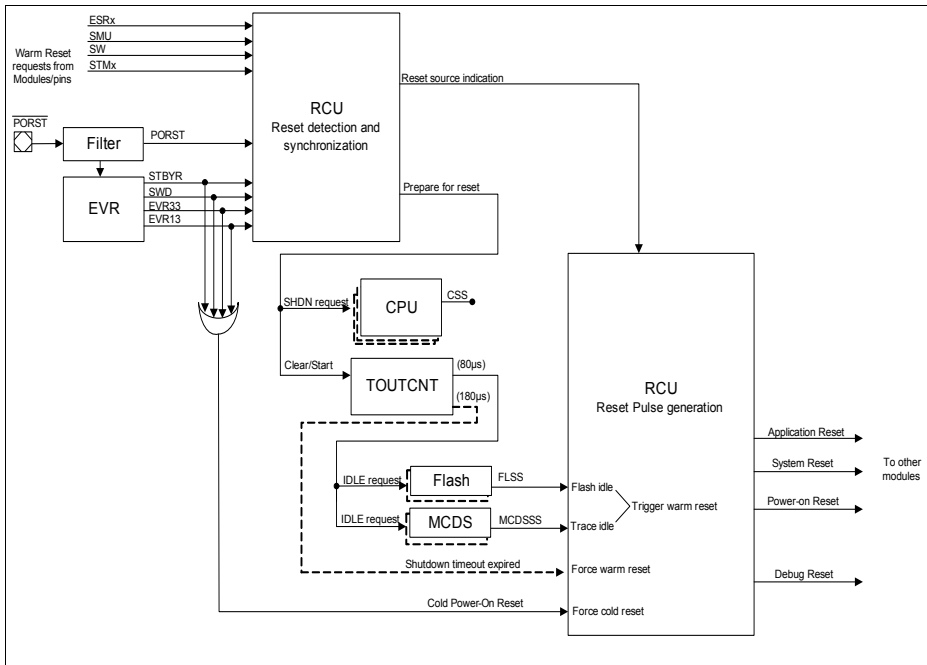

Figure 7-19 Reset Overview

7.2.1.9 Shutdown and Reset Delay Timeout Counter (TOUTCNT)

The system is automatically brought to a stable state before the internal reset(s) are applied so that the RAM content may be reliably reused after a warm reset

On detection of a warm Application Reset, System Reset or Power-On Reset trigger, a Shutdown Trap request is sent by the RCU to the CPU(s). This request causes the CPU(s) which are not already in a halt or idle state to unconditionally execute a ROM shutdown routine which executes a controlled rampdown of the device power consumption (to prevent current jumps which might trigger EVR reset). At the end of this routine each CPU executes a WAIT instruction and stalls, to ensure that all ongoing write transactions have been completed. Interrupts and NMI to the CPUs during the shutdown routine will not reawaken CPUs.

The internal reset starts when all relevant system modules are Idle. If timeout counter TOUTCNT exceeds a timeout period (180 microseconds) before the system become idle then the reset is started regardless. This timeout ensures that a reset would still occur in the case of an internal deadlock.

The RSTCON2.CSS bits indicate whether each CPU successfully flushed its write buffers and reached an idle state before the previous reset. These bits can therefore be used to determine whether RAM content integrity can be trusted after the previous reset cycle.

7.2.1.10 Reset Triggers

There are two types of reset triggers for the reset control logic:

- Triggers that lead to a specific reset
- Triggers that lead to a configurable reset

Specific Reset Triggers

Assertion of these triggers leads to a predefined reset type. These triggers can not be enabled / disabled. All specific reset triggers are listed in [Table 7-9](#).

Table 7-9 Specific Reset Triggers

Reset Trigger	Reset Type Request
Cerberus 0 (CB0)	SystemReset
Cerberus 1 (CB1)	DebugReset
Cerberus 3 (CB3)	ApplicationReset
STBYR	Power-on Reset
SWD	Power-on Reset
EVR13	Power-on Reset
EVR33	Power-on Reset

Configurable Reset Triggers

Assertion of these triggers leads to a configurable reset type. These triggers can be enabled / disabled. The result of the reset triggers is defined by the corresponding bit field in register RSTCON.

Prevention of Double SMU Resets

After boot firmware initialization, the default behaviour of the SMU/RCU is that a Watchdog timeout would result in an NMI followed by an Application Reset. If an SMU-induced Application Reset occurs twice, a severe system malfunction is assumed and the TC26x B-Step is held in permanent Application Reset until a Power-On or System Reset occurs. This prevents the device from being periodically reset if the application fails to service the watchdog correctly and the watchdog repeatedly times out.

An internal flag is set when the first SMU reset is requested. If a second reset is also requested by the SMU when the internal flag is already set, the double SMU reset event has occurred and a permanent reset request is automatically generated. This internal flag is only reset by a System Reset or when bit WDTSCON1.CLRIRF is set and bit WDTSCON0.ENDINIT has also been set. A correct service of the WDT does not automatically clear this flag.

If this behaviour is undesirable, then the CLRIRF bit should be written by the application during initialization (before the watchdog times out), to clear the flag and prevent any subsequent occurrence of a permanent reset.

Note: If for any reason random code is executed bit field RSTCON.SMU can be updated unintentionally. This can result in an SMU alarm not leading to a reset. To avoid this after the SSW is finished this bit field should be checked and the Safety WDT ENDINIT protection enabled.

7.2.1.11 Debug Reset Specific Behavior

For safety reasons it is required by the debugger that if the OCDS system is disabled a DebugReset is also asserted every time an Application Reset is asserted.

7.2.1.12 Module Resets

Many modules within TC26x B-Step can be reset individually. The module reset has no effect outside the module itself. A module reset can only be triggered by writing '1' into both of the module reset registers MOD_KRST1.RST and register MOD_KRST0.RST.

The Module Reset register bits may only be written by those masters which have been explicitly configured to have module access (See module ACCEN register). In addition, it is only possible to write to these reset bits during the short time window after a correct ENDINIT password unlock sequence (See Watchdog chapter for details). This prevents accidental module resets by rogue software.

The table below shows the modules which have Module Reset capability

Table 7-10 Module Resets

Module	Module Reset capability
CAN	Module reset implemented in CAN
ASCLIN	Module reset implemented in ASCLIN
GTM	Module reset implemented in GTM
Flexray	Module reset implemented in ERAY
QSPI	Module reset implemented in QSPI
HSSL	Module reset implemented in HSSL

Table 7-10 Module Resets

Module	Module Reset capability
ETHERMAC	Module reset implemented in ETHERMAC
MSC	Module reset implemented in MSC
SENT	Module reset implemented in SENT
VADC	Module reset implemented in VADC
SDADC	Module reset implemented in SDADC
SCR	Module reset implemented in PMC (PMSWCR1.SCRSTREQ)
CCU6	Module reset implemented in CCU6
GPT12	Module reset implemented in GPT12
CPUs	No individual CPU reset capability
SMU	Module reset implemented in SMU
STM	Module reset implemented in STM
PSI5	Module reset implemented in PSI5
PSI5-S	Module reset implemented in PSI5-S
DMA	Per channel reset implemented in DMA
SCU, RCU, PMC, CCU	No module reset capability
PMU, Flash	No module reset capability
LMU	No module reset capability
PORTS	No module reset capability
IR	No module reset capability
IOM	Module reset implemented in IOM
I2C	Module reset implemented in I2C

7.2.1.13 Reset Controller Registers

Status Registers

After a chip level reset has been executed, the Reset Status registers provide information on the trigger of the last reset(s). Warm reset status bits are updated upon each reset cycle. A reset cycle is finished when all resets are de-asserted. Within a reset cycle the status flags are used as sticky flags. Module level resets have no effect on the Reset Status register. Bits which may indicate a cold reset trigger (STBYR, SWD, EVR33, EVR13, PORST and EVR13) provide useful information to the application and are not cleared automatically. The application may clear these bits by writing to bit RSTCON2.CLRC.

RSTSTAT

Reset Status Register

(050_H)

Reset Value: 1381 0000_H

ARSTDIS

Application Reset Disable Register

(05C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
STM0DIS	0	rw	STM0 Disable Reset This bit field defines if an Application Reset leads to an reset for the STM0. 0 _B An Application Reset resets the STM0 1 _B An Application Reset has no effect for the STM0

Field	Bits	Type	Description
STM1DIS	1	rw	STM1 Disable Reset (If Product has STM1) This bit field defines if an Application Reset leads to an reset for the STM1. 0 _B An Application Reset resets the STM1 1 _B An Application Reset has no effect for the STM1
STM2DIS	2	rw	STM2 Disable Reset (If Product has STM2) This bit field defines if an Application Reset leads to an reset for the STM2. 0 _B An Application Reset resets the STM2 1 _B An Application Reset has no effect for the STM2
0	[31:8]	r	Reserved Read as 0; should be written with 0.
0	[7:3]	rw	Reserved Read as 0; should be written with 0.

SW Reset Configuration Register

This register controls the SW Reset operation.

As for other kernel registers, write access to the SWRSTCON register is configurable via SCU_ACCEN0 and additionally is temporally restricted by Safe ENDINIT. These restrictions can be used to provide protection against accidental reset by unauthorised CPUs or system bus masters.

SWRSTCON

Software Reset Configuration Register

(060_H)

Reset Value: 0000 XX00_H

Field	Bits	Type	Description
0	0	rw	Reserved Read as 0; should be written with 0.
SWRSTREQ	1	w	Software Reset Request 0 _B No SW Reset is requested 1 _B A SW Reset request trigger is generated This bit is automatically cleared and read always as zero.
RES	[15:8]	rw	Reserved Should be written with original content.
0	[7:2], [31:16]	r	Reserved Read as 0; should be written with 0.

Additional Reset Control Register

RSTCON2

Additional Reset Control Register

(064_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
USRINFO	[31:16]	rw	User Information User data register (Cleared only on Power-on reset).
Reserved	[11:2], 15	r	Reserved Internal use only. Bits may read as 0 or 1. Writes have no effect.
CSS2	14	r	Reserved in this product Bit reads as '1' after warm reset

Field	Bits	Type	Description
CSS1	13	rh	<p>CPU1 Safe State Reached</p> <p>The state of CPU1 before the last warm reset If any bit is zero after an Application Reset (or higher) then it is possible that SRAM content could have been corrupted by the reset</p> <p>0_B CPU1 safe state not achieved prior to last reset 1_B CPU1 in safe state at last reset</p>
CSS0	12	rh	<p>CPU0 Safe State Reached</p> <p>The state of CPU0 before the last warm reset If any bit is zero after an Application Reset (or higher) then it is possible that SRAM content could have been corrupted by the reset</p> <p>0_B CPU0 safe state not achieved prior to last reset 1_B CPU0 in safe state at last reset</p>
CLRC	1	w	<p>Clear Cold Reset Status</p> <p>This bit simultaneously clears the sticky status bits which may indicate any previous cold reset (i.e. RSTSTAT.STBYR, RSTSTAT.SWD, RSTSTAT.EVR33, RSTSTAT.EVR13 and RSTSTAT.PORST).</p> <p>0_B No effect 1_B Clear cold reset RSTSTAT status bits</p>
0	0	r	<p>Reserved</p> <p>Bits read as 0. Should only be written as 0.</p>

7.2.2 External Reset Sources and Indications

ESR interface pins are provided to give an external indication of internal resets, and to provide a mechanism for external sources to trigger internal resets:

ESR pin functions:

- Reset request trigger
- Wakeup trigger
- Reset indication output
- Trap request trigger

7.2.2.1 External Service Requests ($\overline{\text{ESRx}}$)

The ESR pins can be used in various ways:

- ESR inputs can trigger a reset
- ESR outputs can provide a reset indication
- ESR inputs can trigger a trap (NMI)
- ESR pins can be used as general data I/O pins
- ESR inputs can trigger a wake-up from standby mode

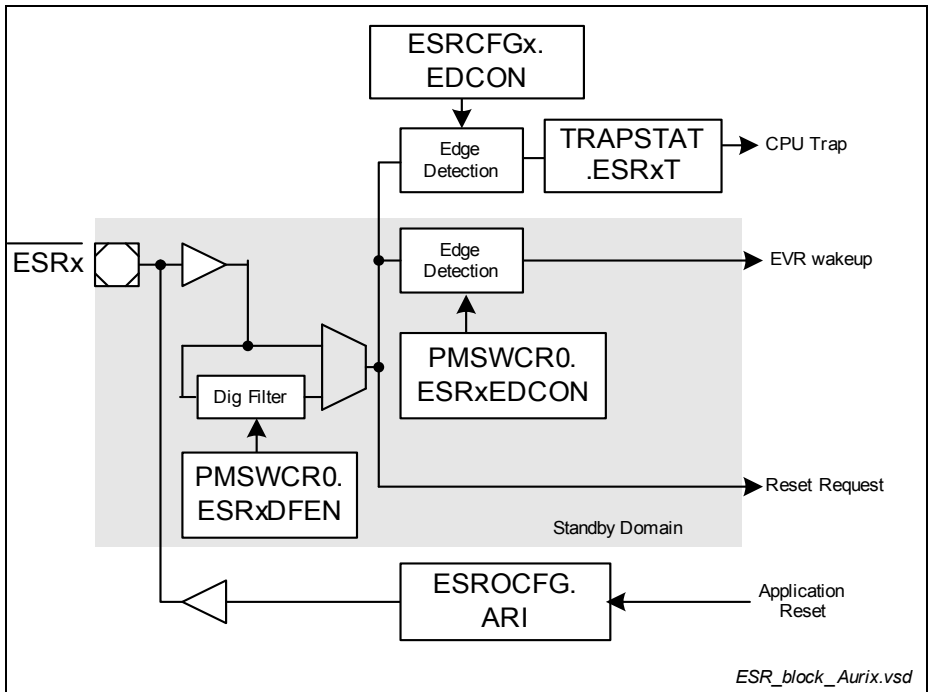

Figure 7-20 ESR Operation

ESRx as Reset Request Trigger

An $\overline{\text{ESR0}}/\overline{\text{ESR1}}$ pin reset request trigger can lead to a Systemor Application Reset. The type of the reset is configured via RSTCON.ESRx.

The input signals $\overline{\text{ESR0}}/\overline{\text{ESR1}}$ can be filtered. The filter can be disabled by register bit PMSWCR0.ESRxDFEN.

If the digital filter is enabled then pulses less than 20ns cannot trigger a reset and pulses longer than 100ns will always result in a trigger..

The behavior of $\overline{\text{ESR0}}/\overline{\text{ESR1}}$ pins can be configured by programming registers ESRCFG0/1. The pad control functionality can be configured independently for each pin. The configuration comprises:

- Selection of driver type (open-drain or push-pull)
- Enable of the output driver (input and/or output capability)
- Enable of internal pull-up or pull-down resistance

ESRx as Reset Output

The external pins $\overline{\text{ESR0}}/\overline{\text{ESR1}}$ can provide a reset output indication (open drain) for Application Resets .

Register ESROCFG.ARI determines the output of the ESR pin(s) when one or more are configured as functional reset outputs. ARI is set automatically when any Application Reset starts and cleared by Boot or Application software (Note that an Application Reset also occurs on a System Reset or Power-On Reset). While the ARI bit is set, the configured ESR pin(s) drive active low. A subsequent write to ESROCFG.ARC clears the ARI bit, which deasserts the ESR output(s). The exact duration of the ESR pulse is determined by the value of the Flash Config Sector setting “ESR0CNT” which is copied by Boot Code into FLASH0_PROCOND.ESR0CNT on a cold power-on reset. The effect of this value is shown in [Table 7-11](#). When the same ESR pin is configured as a PORT output, its state can instead be controlled directly by application software so that the application has the possibility to reset external devices.

Do not configure ESR pin to be used as both an output (reset indication or general purpose port) and a reset trigger input simultaneously.

Table 7-11 ESRx Reset Indication Options

ESR0CNT value	ESR Reset Indication Behaviour
0000 0000h	ESR0 deasserted as soon as possible after start of Boot Code execution
> 0000 0000h and < FFFh	ESR0 deasserted after programmed delay (by Boot Code). Boot Code may be extended and Application start may be delayed if programmed delay exceeds the normal Boot Code execution time. Programmed delay is ESR0CNT * 10 microseconds
FFFh	ESR0 not deasserted by Boot Code. Application code must deassert ESROCFG.ARI bit or PORT output to deassert ESRx pin(s).

An external device may extend an existing reset condition by holding the ESR pin active.

ESR Registers

ESRCFG0

ESR0 Input Configuration Register

 (070_H)

 Reset Value: 0000 0100_H

ESRCFG1

ESR1 Input Configuration Register

 (074_H)

 Reset Value: 0000 0100_H

Field	Bits	Type	Description
0	[6:0]	r	Reserved Read as 0; should be written with 0.
EDCON	[8:7]	rw	Edge Detection Control This bit field defines the edges that lead to an ESRx trigger of the synchronous path. 00 _B No trigger is generated 01 _B A trigger is generated upon a rising edge 10 _B A trigger is generated upon a falling edge 11 _B A trigger is generated upon a rising OR falling edge
0	[31:9]	r	Reserved Read as 0; should be written with 0.

ESROCFG
ESR Output Configuration Register

 (078_H)

 Reset Value: 0000 000X_H

Field	Bits	Type	Description
ARI	0	rh	<p>Application Reset Indicator</p> <p>This bit is set when an Application Reset request trigger occurs and cleared by writing to ARC.</p> <p>0_B No application reset trigger detected (since last clear)</p> <p>1_B Application reset trigger detected (since last clear)</p> <p>When the ARI bit is set and an ESR pin is configured as a reset output, the corresponding ESR input will not re-trigger a reset. This prevents feedback of the reset indication causing a new reset request. Extension of the reset by an external ESR source is handled by SSW.</p> <p><i>Note: Observed reset value after boot will depend upon ARI mode, see Table 7-11</i></p>
ARC	1	w	<p>Application Reset Indicator Clear</p> <p>0_B No effect</p> <p>1_B Clear Application Reset Indicator (ARI)</p> <p>Read as 0</p>
0	[31:2]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

The input/output control registers select the digital output and input driver functionality and characteristics of the pin. Direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-1).

IOCR
Input/Output Control Register (0A0_H) **Reset Value: 0000 20E0_H**

Field	Bits	Type	Description
PC0, PC1	[7:4], [15:12]	rw	Control for ESR Pin x This bit field defines the ESR x functionality according to the coding tables (see Table 7-12 and Table 7-13).
0	[3:0], [11:8], [31:16]	r	Reserved Read as 0; should be written with 0.

Pad Control Coding

Table 7-12 describes the coding of the PC0 bit field that determine the port line functionality.

Table 7-12 PC0 Coding

PC0[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
0X00 _B	Input is active and not inverted; Output is inactive		No input pull device connected
0X01 _B			Input pull-down device connected
0X10 _B			Input pull-up device connected
0X11 _B			No input pull device connected
1000 _B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001 _B			Output drives a 0 for System Resets until ESROCFG.ARI is cleared, a weak pull-up is active otherwise
1010 _B			Reserved, do not use this combination
1011 _B			Reserved, do not use this combination
1100 _B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101 _B			Output drives a 0 for System Resets until ESROCFG.ARI is cleared, a weak pull-up is active otherwise
1110 _B			Output drives a 0 for Application Resets until ESROCFG.ARI is cleared, a weak pull-up is active otherwise
1111 _B			Reserved, do not use this combination

Pad Control Coding

Table 7-13 describes the coding of the PC1 bit field that determine the port line functionality.

Table 7-13 PC1 Coding

PC1[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function
0X00 _B	Input is active and not inverted; Output is inactive		No input pull device connected
0X01 _B			Input pull-down device connected
0X10 _B			Input pull-up device connected
0X11 _B			No input pull device connected
1000 _B	Input is active and not inverted; Output is active	Push-pull	General-purpose Output
1001 _B			Reserved, do not use this combination
1010 _B			Reserved, do not use this combination
1011 _B			Reserved, do not use this combination
1100 _B	the input is active and not inverted; Output is active	Open-drain	General-purpose Output
1101 _B			Reserved, do not use this combination
1110 _B			Output drives a 0 for Application Resets until ESROCFG.ARI is cleared, a 'Z' otherwise
1111 _B			Reserved, do not use this combination

The output register determines the value of a GPIO pin when it is selected by IOCR as output. Writing a 0 to a OUT.Px (x = 0-1) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that each single bit or group of bits of OUT.Px can be set/cleared by writing appropriate values into the output modification register OMR.

OUT
ESR Output Register
(0A4_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
Px (x = 0-1)	x	rwh	Output Bit x This bit determines the level at the output pin $\overline{\text{ESRx}}$ if the output is selected as GPIO output. 0 _B The output level of $\overline{\text{ESRx}}$ is 0 1 _B The output level of $\overline{\text{ESRx}}$ is 1 Px can also be set/cleared by control bits of the OMR register.
0	[31:2]	r	Reserved Read as 0; should be written with 0.

The output modification register contains control bits that make it possible to individually set, clear, or toggle the logic state of a single pad by manipulating the output register.

OMR
ESR Output Modification Register
(0A8_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PSx (x = 0-1)	x	w	ESRx Pin Set Bit x Setting this bit will set or toggle the corresponding bit in the output register OUT. The function of this bit is shown in Table 7-14 . Reading this bit returns 0.
PCLx (x = 0-1)	x + 16	w	ESRx Pin Clear Bit x Setting this bit will clear or toggle the corresponding bit in the port output register OUT. The function of this bit is shown in Table 7-14 . Reading this bit returns 0.
0	[15:2], [31:18]	r	Reserved Read as 0; should be written with 0.

Table 7-14 Function of the Bits PCLx and PSx

PCLx	PSx	Function
0	0	Bit OUT.Px is not changed
0	1	Bit OUT.Px is set
1	0	Bit OUT.Px is cleared
1	1	Bit OUT.Px is toggled

The logic level of a GPIO pin can be read via the read-only port input register IN. Reading the IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

IN
ESR Input Register
(0AC_H)
Reset Value: 0000 000X_H

PDR
ESR Pad Driver Mode Register
(9C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PD0, PD1	[2:0], [6:4]	rw	Pad Driver Mode for ESR Pins 0 and 1 PD0 selects the driver mode for ESR0 output. PD1 selects the driver mode for ESR1 output. X00 _B Speed Grade 1 X01 _B Speed Grade 2 X10 _B Speed Grade 3 X11 _B Speed Grade 4
PL0, PL1	3, 7	rw	Pad Level Selection for ESR Pins 0 and 1 PL0 selects the pad level for ESR0. PL1 selects the pad level for ESR1. 0 _B Automotive Level 1 _B TTL Level
0	[31:8]	rw	Reserved

7.2.3 Boot Software Interface

In order to determine the correct starting point of operation for the software a minimum amount of hardware support is required. As much as possible is done via software. Some decisions have to be made in hardware because they must be known before any software is operational.

For a startup operation there are two general cases that have to be handled:

- Differentiation between Test Mode and Normal Mode for each Power-on Reset event (see [Section 7.2.3.1](#))
- Configuration of the boot option for each Application Reset event (see [Section 7.2.3.2](#))

7.2.3.1 Configuration done with Start-up

At device power-on some basic operating mode selection has to be done. The first decision that has to be made is whether the device should operate in Test Mode or in Normal (Customer) Mode. The Test Mode is only for Infineon internal device testing, it is not intended for any customer and is not related to debug.

If the Normal Mode was selected the next decision is which debug interface type issued for debugging for this session (until the next power-on event).

Table 7-15 Normal Mode / Test Mode Input Selection

Field	Description
TESTMODE	Latched TESTMODE Signal
	0 A Test Mode can be selected
	1 Normal Mode is selected
TRST	Latched TRST Signal
	0 The JTAG interface is active.
	1 The DAP interface is active.

After these two decisions were made the detailed decision has to be made to define the real startup configuration. Most is made via the software and can be supported by some hardware selections depending on the startup configuration that should be selected.

7.2.3.2 Start-up Configuration Options

The states of the HWCFG port pin inputs are latched on the rising edge of an Application Reset and stored in register STSTAT.HWCFG. The update of bit field STSTAT.HWCFG with the latched value is only done if bit STSTAT.LUDIS is cleared. If bit STSTAT.LUDIS is set then the value of STSTAT.HWCFG is not updated.

7.2.3.3 Status Registers

Startup Status Registers

Register STSTAT contains the information used by the boot firmware to identify the start-up settings.

7.2.4 NMI Trap Generation

The NMI trap structure is shown in [Figure 7-21](#). The trap request trigger or the corresponding trap set bit (in register TRAPSET) can trigger the NMI trap generation. An NMI trap is always issued simultaneously to all CPUs in the system. The trap flag can be cleared by software by writing to the corresponding bit in register TRAPCLR. A NMI request is only generated if the trap source was not disabled. Otherwise only the trap status flag is set but no NMI request is generated.

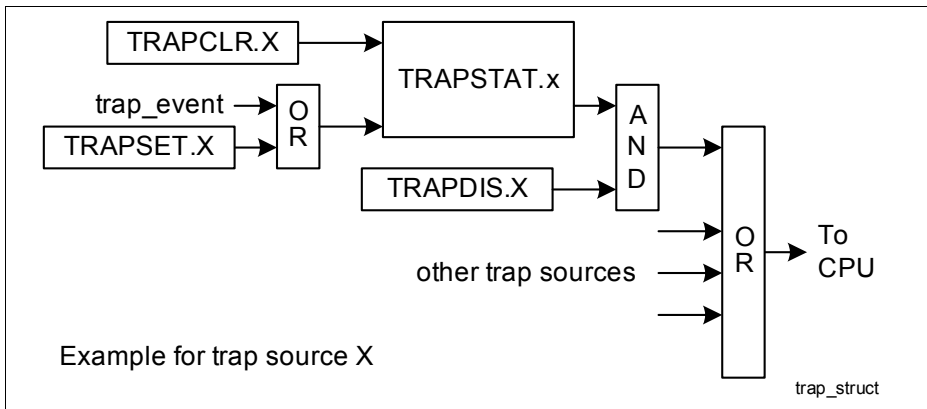

Figure 7-21 NMI Trap Generation

Handling NMI Traps

As an NMI trap is generated while the trap source is enabled AND the trap status flag is set, it is recommended to clear the trap status flag before the trap source is enabled. The trap status flag can be set before the trap source is enabled and simply enabling the trap source can result in unintended NMI traps. At the end of a NMI trap handling routine the trap status flag should be cleared.

7.2.4.1 Trap Control Registers

TRAPSTAT

7.3 Power Supply & Power Management Controller (PMC)

This chapter describes the Power Supply of the TC26x B-Step and the Power Management Controller (PMC).

This is described in the following sections:

- Power Supply and Control (see [Section 7.3.1](#))
- Power Management (see [Section 7.3.2](#))
- Power Supply and Power Management Registers (see [Table 7-23](#))

7.3.1 Power Supply and Control

7.3.1.1 Introduction

On-chip linear and switch mode voltage regulators are implemented in TC26x B-Step thereby enabling a single source power supply concept. The external nominal system supply may be either 5 V or 3.3 V. There are two separate parallel Embedded Voltage Regulators (EVR33 and EVR13) generating 3.3 V and 1.3 V supply voltages from the external supply. The nomenclature of these EVRs in the document are EVR33 and EVR13 respectively. Linear Drop Out (LDO) or Switch Mode Power Supply (SMPS) mode may be selected for the EVR13 regulator in case of 5 V or 3.3 V external supply. EVR33 regulator is implemented as a LDO regulator and is required only in case of 5 V external supply.

Depending on the chosen EVR mode, the actual power consumption, EMI requirements and thermal constraints of the system; additional external components like MOSFETs, inductors and capacitors may be required. It is also possible to supply 3.3 V and 1.3 V supply voltages externally thus ensuring compliance to the legacy supply concept.

All supply and generated voltages are monitored internally against overshoot and brownout conditions based on programmable thresholds. In case these thresholds are violated, either a cold power on reset is triggered or an alarm is provided to the SMU.

In case of single 5 V external supply, the ports would predominantly have 5 V logic level. However it is possible to run a part of the port domain, namely the Flexport (P11.x), on 3.3 V logic level even if the device is powered by 5 V. The Flexport could be supplied either directly from the 5 V external supply or from the internally generated 3.3 V EVR supply. The routing of the supply ($V_{\text{FLEX}} = 5 \text{ V}$ or 3.3 V) for the Flexport domain in both cases is done externally. In case of single 3.3 V external supply ($V_{\text{EXT}} = V_{\text{DDP3}} = V_{\text{FLEX}} = V_{\text{DDM}} = 3.3 \text{ V}$), the complete port and analog domain would have 3.3 V logic level.

All internal supplies except analog domain (V_{AREFX} & V_{DDM}) may be supplied by the EVRs. The analog supply domain is separated from the main EVR supply domain and can be supplied by separate external regulators or trackers. It is possible to have a mixed supply scheme with a 5 V ADC domain ($V_{\text{DDM}} / V_{\text{AREFX}} = 5 \text{ V}$) and the remaining system running on 3.3 V supply ($V_{\text{EXT}} = V_{\text{DDP3}} = 3.3 \text{ V}$).

7.3.1.2 Supply Mode and Topology Selection

The choice of the supply scheme at startup is based on the latched status of HWCFG[0:2] pins before PORST release and is indicated by **PMSWSTAT.HWCFG**EVR status flags. Following supply modes are supported and are further enumerated in **Table 7-18**.

- Single source 5 V supply level is supported in following topologies.

- EVR13 in SMPS mode with external switches and EVR33 in LDO mode with internal pass devices.
- EVR13 and EVR33 both in LDO mode with internal pass devices.
- EVR13 in LDO mode with external pass device and EVR33 in LDO mode with internal pass devices.
- Single source 3.3 V supply level is supported in following topologies.
 - EVR13 in SMPS mode with external switches and EVR33 is inactive.
 - EVR13 in LDO mode with internal pass devices and EVR33 is inactive.
 - EVR13 in LDO mode with external pass device and EVR33 is inactive.
- Supplies are provided externally and the respective EVRs are in disabled state.
 - 5 V and 1.3 V supplied externally. EVR33 in LDO mode with internal pass devices.
 - 5 V and 3.3 V supplied externally. 1.3 V is generated using the EVR13.
 - 5 V, 3.3 V and 1.3 V are supplied externally.

EVR13 is enabled or disabled at startup via the HWCFG[2] configuration pin. The selection between LDO or SMPS topology for EVR13 is decided via HWCFG[0] configuration pin. In case EVR13 SMPS mode is selected, V_{GATE1P} and V_{GATE1N} pins shall be connected to the gate of an external P-channel MOSFET and N-channel MOSFET respectively as shown in [Figure 7-27](#). In case EVR13 LDO mode with external pass device is selected, V_{GATE1P} pin shall be connected to the gate of an external P-channel MOSFET pass device as shown in [Figure 7-23](#). The pass device detector senses the presence of external pass device based on the current sinking capability of the V_{GATE1P} pin as indicated in [EVRSTAT.EXTPASS13](#) flag. In case EVR13 LDO with internal pass devices is selected, the gate control pad V_{GATE1P} shall be connected to ground as shown in [Figure 7-23](#).

EVR33 is enabled or disabled at startup via the HWCFG[1] configuration pin. In case of single source 3.3 V supply, EVR33 is disabled and V_{DDX3} & V_{EXT} pins are supplied externally by 3.3 V. In case EVR33 LDO mode is selected, internal pass devices may be used.

In case of smaller packages, HWCFG[0:2] configuration pins may be absent and both EVRs are active at startup in LDO mode. EVR33 may be disabled via [EVR33CON.EVR33OFF](#) bit and EVR13 via [EVR13CON.EVR13OFF](#) bit if required. The current state of EVRs are reflected in [EVRSTAT.EVRx3](#) flags. HWCFG[6] pin is latched during start-up to decide the default pin behaviour. Ports behave as inputs with pull-up if HWCFG[6] = 1 or are in tristate if HWCFG[6] = 0 as reflected in [PMSWSTAT.TRIST](#) bit. All supplies must be available and be stable with the release of the \overline{PORST} signal.

Table 7-18 Supply Mode and Topology selection

No.	HWCFG [0:2] ¹⁾	VGATE1P ²⁾ VGATE1N ³⁾	Supply Pin Voltage Level / Source	Selected Supply Scheme
a.)	011 _B	VGATE1P/ VGATE1N connected to gate of P- /N-ch. MOSFET.	$V_{EXT} = 5.0\text{ V}$ $V_{DDM}/V_{AREFX} = 5\text{ V} / 3.3\text{ V}$ $V_{FLEX} = 5\text{ V} / 3.3\text{ V}$ $V_{DDP3}/V_{DDFL3} = \text{EVR33}$ $V_{DD} = \text{EVR13}$ $V_{SS}/V_{SSM}/V_{AGND} = 0\text{ V}$	5 V single source supply, EVR13 in SMPS mode, EVR33 in LDO mode. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode supported.
b.)	111 _B	VGATE1P shall be connected to ground.	$V_{EXT} = 5.0\text{ V}$ $V_{DDM}/V_{AREFX} = 5\text{ V} / 3.3\text{ V}$ $V_{FLEX} = 5\text{ V} / 3.3\text{ V}$ $V_{DDP3}/V_{DDFL3} = \text{EVR33}$ $V_{DD} = \text{EVR13}$ $V_{SS}/V_{SSM}/V_{AGND} = 0\text{ V}$	5 V single source supply, EVR13 in LDO mode with internal pass devices, EVR33 in LDO mode. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode supported
c.)	111 _B	VGATE1P shall be connected to P-ch. MOSFET.	$V_{EXT} = 5.0\text{ V}$ $V_{DDM}/V_{AREFX} = 5\text{ V} / 3.3\text{ V}$ $V_{FLEX} = 5\text{ V} / 3.3\text{ V}$ $V_{DDP3}/V_{DDFL3} = \text{EVR33}$ $V_{DD} = \text{EVR13}$ $V_{SS}/V_{SSM}/V_{AGND} = 0\text{ V}$	5 V single source supply, EVR13 in LDO mode with external pass device, EVR33 in LDO mode. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode supported.
d.)	X10 _B	VGATE1P has int. pull- up active when left open.	$V_{EXT} = 5.0\text{ V}$ $V_{DDM}/V_{AREFX} = 5\text{ V} / 3.3\text{ V}$ $V_{FLEX} = 5\text{ V} / 3.3\text{ V}$ $V_{DDP3}/V_{DDFL3} = \text{EVR33}$ $V_{DD} = 1.3\text{ V external}$ $V_{SS}/V_{SSM}/V_{AGND} = 0\text{ V}$	5 V & 1.3 V external supply, EVR13 inactive, EVR33 in LDO mode. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 1.3V supply shall be switched off by external regulator after Standby state is entered.
e.)	001 _B ⁴⁾	VGATE1P/ VGATE1N connected to gate of P- /N-ch. MOSFET.	$V_{EXT}/V_{DDP3}/V_{DDFL3} = 3.3\text{ V}$ $V_{DDM}/V_{AREFX} = 5\text{ V} / 3.3\text{ V}$ $V_{FLEX} = 3.3\text{ V}$ $V_{DD} = \text{EVR13}$ $V_{SS}/V_{SSM}/V_{AGND} = 0\text{ V}$	3.3 V single source supply, EVR13 in SMPS mode, EVR33 inactive. 5 V or 3.3 V ADC domain. 3.3 V Flexport domain. Standby Mode supported.

Table 7-18 Supply Mode and Topology selection

No.	HWCFG [0:2] ¹⁾	VGATE1P ²⁾ VGATE1N ³⁾	Supply Pin Voltage Level / Source	Selected Supply Scheme
f.)	101 _B ⁴⁾	VGATE1P shall be connected to ground.	$V_{EXT}/V_{DDP3}/V_{DDFL3} = 3.3V$ $V_{DDM}/V_{AREFX} = 5V / 3.3V$ $V_{FLEX} = 3.3V$ $V_{DD} = EVR13$ $V_{SS}/V_{SSM}/V_{AGND} = 0V$	3.3 V single source supply, EVR13 in LDO mode with internal pass devices, EVR33 inactive. 5 V or 3.3 V ADC domain. 3.3 V Flexport domain. Standby Mode supported.
g.)	101 _B ⁴⁾	VGATE1P connected to P-ch. MOSFET.	$V_{EXT}/V_{DDP3}/V_{DDFL3} = 3.3V$ $V_{DDM}/V_{AREFX} = 5V / 3.3V$ $V_{FLEX} = 3.3V$ $V_{DD} = EVR13$ $V_{SS}/V_{SSM}/V_{AGND} = 0V$	3.3 V single source supply, EVR13 in LDO mode with external pass device, EVR33 inactive. 5 V or 3.3 V ADC domain. 3.3 V Flexport domain. Standby Mode supported
h.)	X00 _B	VGATE1P has int. pull-up active when left open.	$V_{EXT} = 5V \text{ or } 3.3V$ $V_{DDM}/V_{AREFX} = 5V / 3.3V$ $V_{FLEX} = 5V \text{ or } 3.3V$ $V_{DDP3}/V_{DDFL3} = 3.3V$ $V_{DD} = 1.3V$ $V_{SS}/V_{SSM}/V_{AGND} = 0V$	5 V, 3.3 V and 1.3 V are supplied externally, EVR13 and EVR33 inactive. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 3.3V and 1.3V supplies shall be switched off by external regulator after Standby state is entered.

- 1) if HWCFG[0,1,2,6] pins are left unconnected, it is ensured that EVR33 and EVR13 (LDO) are active by default.
- 2) VGATE1P pin is connected to a P- ch. MOSFET in case of EVR13 SMPS or LDO with external pass device. In case EVR13 LDO uses internal pass devices, VGATE1P pin is to be connected to ground. In case EVR13 is inactive, internal pull-up is active at VGATE1P pin as long as the pin is not externally connected to ground.
- 3) VGATE1N pin need to be connected to the gate of the N- channel MOSFET in case SMPS regulator mode is selected. In case EVR13 LDO mode is selected or EVR13 is inactive, VGATE1N pin behaves like a normal port pin (P32.0) and is default configured as input with weak internal pull-down after start-up/cold \overline{PORST} .
- 4) In this HWCFG combination, also VEXT may be supplied with 5V instead of 3.3V nominal voltage but with all other supply pin voltages remaining the same. This is to support the external supply case that 5 V and 3.3 V is supplied externally and 1.3 V is generated using the EVR13 regulator. It has to be ensured that the external regulator supplies the 5V at VEXT pins and 3.3V at VDDP3/VDDFL3 pins.

HWCFCG [0] P14.6	HWCFCG [1] P14.5	HWCFCG [2] P14.2	HWCFCG [3] P14.3	HWCFCG [4] P10.5	HWCFCG [5] P10.6	HWCFCG [6] P14.4
						
0 - SMPS 1 - LDO (default)	0 - EVR33OFF 1 - EVR33ON (default)	0 - EVR13OFF 1 - EVR13ON (default)	0 - Boot from pins HWCFCG [5:4] 1 - Flash BML boot (default)	HWCFCG [4:5] [0 0]- Generic Bootstrap (P14.0/1) [0 1]- ABM, Generic Bootstrap on fail (P14.0/1) [1 0]- ABM, ASC Bootstrap on fail (P15.2/3) [1 1]- Internal start from Flash (default)		Default Pad state 0 - Pins in tristate 1 - Pins with pull-up (default)

- 1.) HWCFCG [6] has weak internal pull-up active at start-up if the pin is left unconnected.
- 2.) If HWCFCG [6] is left unconnected or is externally pulled high, HWCFCG [0:5] pins have weak internal pull-ups active at start-up.
- 3.) If HWCFCG [6] is connected to ground, HWCFCG [0:5] pins are in tristate. External pull devices required for all HWCFCG pins.
- 4.) In packages smaller than QFP 144, HWCFCG [0:2] pins are absent & internally pulled high ensuring EVR13 (LDO) & EVR33 is active
- 5.) HWCFCG [0:2] and HWCFCG [6] pins are latched during supply ramp-up (VEXT < 2.97V) and stored in PMSWSTAT.HWCFCGEVR & TRIST register bits. The remaining HWCFCG pins are latched on internal reset release (between 100us – 180us after reset assertion) and stored in STSTAT register.

Figure 7-22 Hardware Configuration (HWCFCG) pins

7.3.1.3 Linear Regulator Mode

The LDO part of the EVR composes of the following sub-blocks.

- EVR33 regulator
- EVR13 regulator

The EVR13 regulator supplies mainly the core domain including RAMs. The EVR33 regulator supplies the flash modules, LVDS pads, oscillators and the JTAG interface. The EVR33 is additionally capable of driving a limited amount of non-inductive 3.3 V external load and may supply the Flexport in case configured as a 3.3 V Port. Each EVR constitutes a digital regulator, a pass device control unit and a voltage feedback loop. The pass device outputs are appropriately buffered by capacitors to handle load transients so as not to violate the operating voltage limits. Each EVR can be individually disabled via HWCFG pins as described in [Chapter 7.3.1.2](#). Each EVR can also be disabled via protected registers to enter power saving modes. The EVR13 can be disabled via [EVR13CON.EVR13OFF](#) and EVR33 via [EVR33CON.EVR33OFF](#) bits respectively.

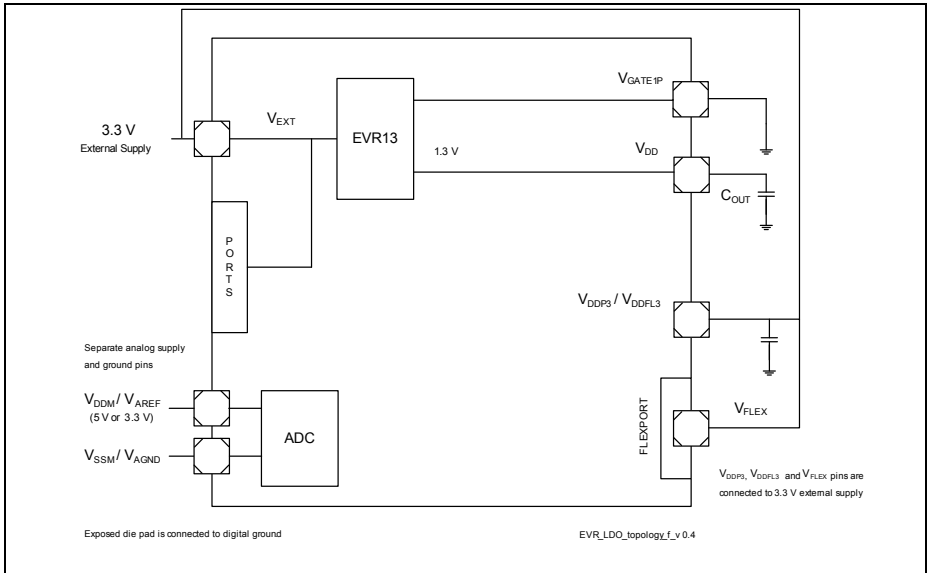

Figure 7-26 EVR LDO topology (f) - 3.3 V single supply with int. pass device

7.3.1.4 Step-down Regulator Mode

The Step-down regulator provides a higher efficiency of power conversion compared to the linear voltage regulator. However it requires additional external components and injects more switching noise into the system. The integrated DC/DC regulator modulates an external charge device to buffer the energy in a LC filter in order to generate a regulated core supply. The 5 V or 3.3 V external V_{EXT} supply shall be provided to the complementary MOSFET switches as shown in [Figure 7-27](#) and [Figure 7-28](#).

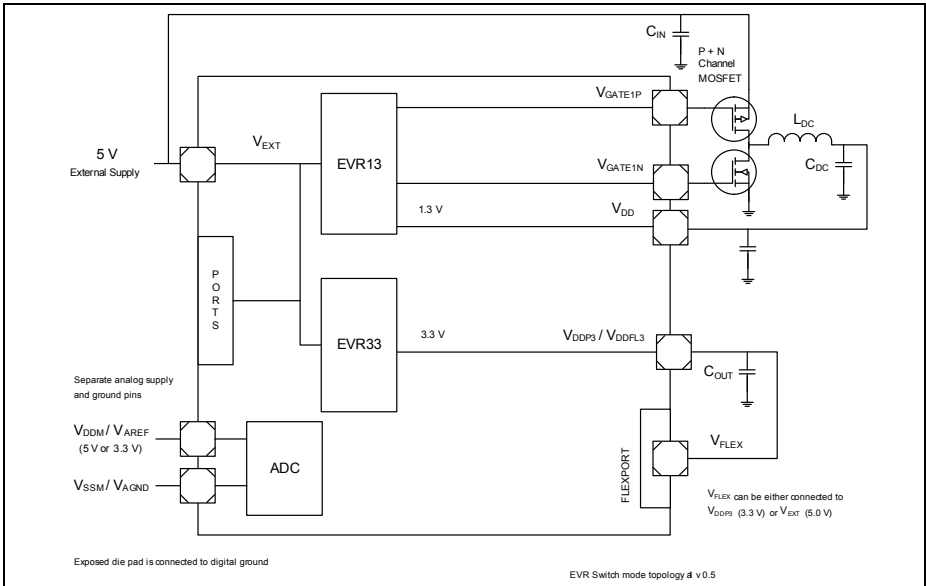

Figure 7-27 EVR Switch mode topology (a) - 5 V single supply

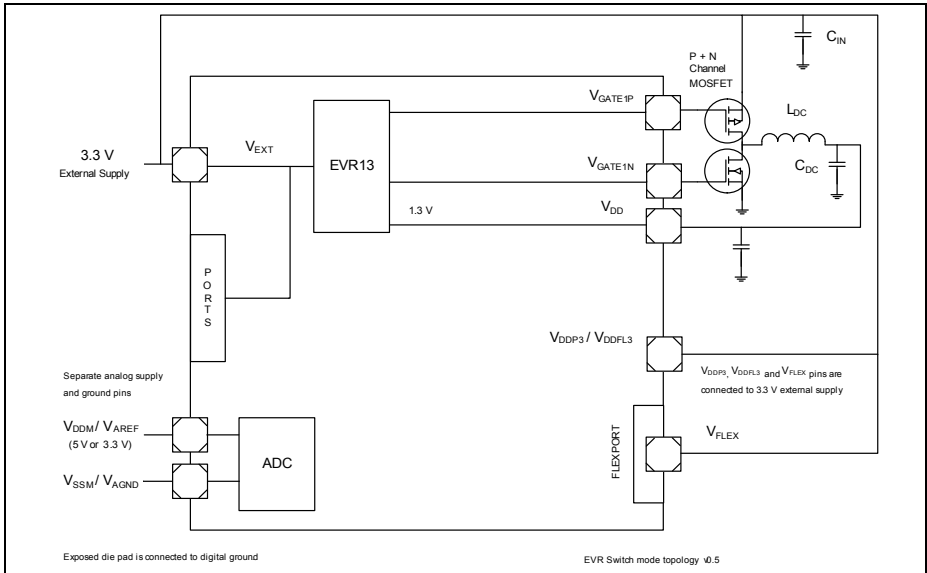

Figure 7-28 EVR Switch mode topology (e) - 3.3 V single supply

The control strategy involves synchronous switching of the charge device at a defined switching frequency using pulse width modulation. The switching frequency is selected between 0.4 MHz to 2.0 MHz based on application needs. The duty cycle has a resolution of the base clock frequency (100MHz internal clock source) and is controlled using a PID controller which reacts to the deviation of the output voltage against a reference voltage. The output voltage value is approximately equal to the input voltage multiplied by the duty cycle factor.

During the start-up phase, a different control strategy is used in order to avoid current overload in the coil and overshoot of the output voltage. In this phase, only the P-channel MOSFET is switched ON/OFF while the N-Channel MOSFET remains always OFF and behaves like a diode. This prevents the coil current from becoming negative in the start-up phase with a pre charged capacitor (especially immediately after a reset). The open loop operation ends when the ADC indicates that the output voltage has reached the target value. At this point the PID controller is configured and the normal closed loop operation begins. After a voltage transient (typically an overshoot), EVR13 is ready. The default switching frequency is 1.5 MHz during EVR start-up and is derived from the internal 100 MHz clock source. The step down regulator is consequently trimmed by the Firmware after reset release to achieve a more accurate EVR13 output voltage.

It is possible to synchronize an external step-down regulator which may run at much lower switching frequencies than the internal regulator. A scaled synchronisation clock output is provided and routed to an external pin (P33.13 pin - DCDCSYNC output).

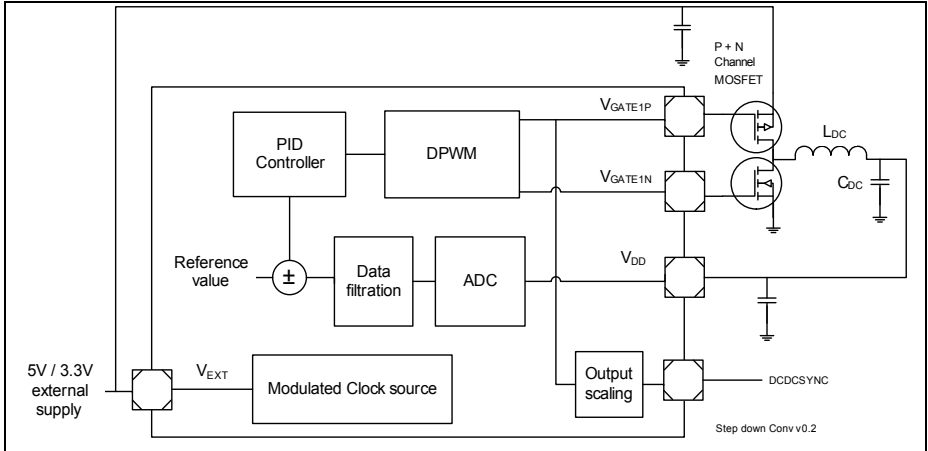

Figure 7-29 Step down regulator

Frequency spreading may be activated in case of SMPS mode to comply with EMI / EMC requirements. The spreading increases the switching period and 2% spreading as configured in [EVRSDCTRL1.SDFREQSPRD](#) field means that the average switching periods are 2% below the programmed switching frequency which is configured in [EVRSDCTRL1.SDFREQ](#) field.

7.3.1.5 External Supply Modes

The external supply modes involve deactivating any or both of the EVR13 and EVR33 regulators. In this mode, EVR33 is disabled via the HWCFG[1] configuration pin and the EVR13 is disabled via the HWCFG[2] configuration pin respectively.

Following external supply modes are supported.

- 5 V and 1.3 V supplied externally. 3.3 V is generated using the EVR33 regulator as shown in **Figure 7-30**.
- 5 V and 3.3 V supplied externally. 1.3 V is generated using the EVR13 regulator.
- 5 V, 3.3 V and 1.3 V are all supplied externally as shown in **Figure 7-31**.

Figure 7-30 External Supply mode (d) - 5 V and 1.3 V externally supplied

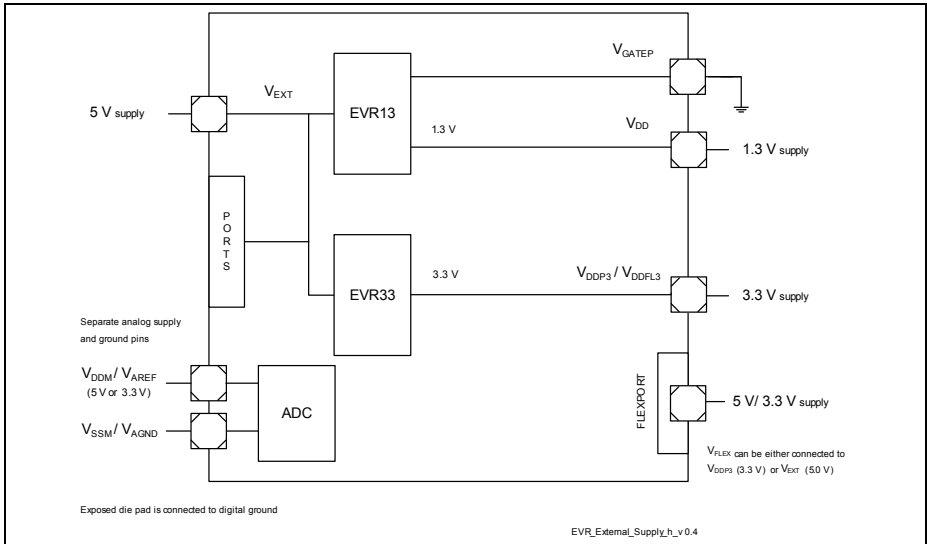

Figure 7-31 External Supply mode (h) - 5 V, 3.3 V & 1.3 V externally supplied

7.3.1.6 Components and Layout

The efficiency of the step-down regulator is influenced by the characteristics of the selected components and also the placement and routing of the components on the PCB. The additional external components constitute a coil, a capacitor and a complementary P-channel and N-channel MOSFET.

The coil need to have a low ESR and a relatively constant characteristic against temperature and current variations. Likewise the capacitor need to have a low ESR, a constant frequency characteristic and minimum DC voltage dependence. The capacitors may be a parallel combination of smaller and larger capacitors or capacitors of equal size for better efficiency. The P-channel MOSFET is preferred with lower R_{DS_ON} and gate capacitance values. The P-channel MOSFET gate need to be connected to VGATE1P pin which is a common gate pin used also to connect the pass device in EVR13 LDO mode. The N-channel MOSFET gate needs to be connected to VGATE1N pin for synchronous switching of the step-down regulator.

In case of usage of Emulation devices, it should be taken care that the component choice also considers the current additionally drawn by ED RAM and EEC part.

Component parameters and requirements would be documented in datasheet.

It should be taken care that each supply pin in QFP packages or a pair of supply pins in BGA packages has a decoupling capacitor close to the pins. Supply pins belonging to a common supply rail shall be connected together after the respective decoupling

capacitors and shall be buffered by an additional larger capacitor based on the constraints of the regulator which supplies the rail. It should be taken care to have a low trace resistance to the decoupling capacitors and buffer capacitors for better performance and EMI/EMC behaviour. The dimensioning of the buffer capacitors is based predominantly on the load jumps triggered during reset events and stability criteria of the regulator. During software triggered non reset events, it is recommended to limit the load jumps (di_{EXT}/dt , di_{DD}/dt) to a maximum of 100 mA/100 us. For example, during clock ramp-up phase it is recommended to limit the clock switching steps so as not to violate 100 mA/100 us limit. However in case of non deterministic events like loss of PLL lock or an NMI event to all CPUs, a higher current jump is expected.

7.3.1.7 Voltage Monitoring

The PMC module implements a staggered voltage monitoring build upon a primary and a secondary monitor. The primary monitor ensures that the microcontroller is put into a reset state when the lowest operational threshold is violated. The secondary monitor serves as an additional safety monitor providing over- and under-voltage alarms.

Primary under-voltage monitoring of the external V_{EXT} supply, V_{DD} / EVR13 supply and V_{DDP3} / EVR33 supply are inherently carried out to ensure proper functioning of the system. The EVR control loop as well as the under-voltage monitors are based on a primary bandgap reference. The thresholds for the basic monitoring are non-configurable and represents the lowest possible thresholds for the correct functioning of the system. In case of violation of these thresholds, cold \overline{PORST} is activated and \overline{PORST} pin is pulled low (strong current sink). Following the reset release and firmware boot, it can be inferred from STBYR, EVR13, EVR33 or SWD bits in RSTSTAT register as to whether the violation of these thresholds led to the previous reset. The primary under-voltage monitoring is kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in [Table 7-19](#).

In case of EVR33, primary under-voltage monitoring may be disabled for a definite duration via [EVR33CON.RST33OFF](#) bit. This allows handling a higher voltage drop of external supply up to 3.0 V without issuing a reset.

It needs to be ensured that none of the 3.3 V modules like Flash, system PLL and oscillator are active during the phase when VDDP3 voltage sinks below the primary reset threshold level. Once the VDDP3 supply regains the primary reset threshold level indicated by a secondary alarm event, the modules may be actively used again.

The primary Supply WatchDog (SWD monitor) monitors the ramp-up of external supply voltage and keeps the microcontroller in cold Power On Reset state as long as the supply has not reached the operational range. Likewise, it also detects ramp-down or brown out condition of external supply and sets the device into a cold Power On Reset state when the voltage has dropped below the lowest operational threshold. Nevertheless, It is recommended to monitor externally all supplies generated external to the microcontroller and to assert \overline{PORST} reset pin in case of violation of the lowest operational limits. In case of 5 V V_{EXT} nominal external supply and 3.3 V in turn being generated by the internal EVR33 LDO regulator, the external 5 V supply need to be kept above 4 V considering the pass device drop-out margin. A drop of V_{EXT} below this value may lead to a cold power-on reset as the generated 3.3 V supply may drop below the primary under-voltage threshold limit. The limits are documented in the datasheet.

The external V_{EXT} supply, V_{DD} / EVR13 and V_{DDP3} / EVR33 supplies are measured by 8 bit analog converters and the measured value is indicated in [EVRADCSTAT](#) register. This may be used to do a plausibility check of external regulator references.

Additional secondary over-voltage and under-voltage monitoring against programmable thresholds is provided for all supplied and generated voltages using a secondary bandgap reference. This includes the external supply voltage and the internally

generated EVR13 and EVR33 output voltages as shown in [Figure 7-32](#). The secondary voltage monitors are kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in [Table 7-19](#). In case of a threshold violation, an SMU alarm event is generated.

The secondary monitor violation is notified depending on the direction of voltage transition as programmed in [EVRMONCTRL](#) register. The appropriate thresholds for voltage monitoring can be programmed in the [EVROVMON](#) and [EVRUVMON](#) registers. In case of an active monitoring violation, respective status flags are set in the [EVRSTAT](#) register. It can be inferred from OV13, OV33 or OVSWD bits in [EVRSTAT](#) register as to whether over-voltage thresholds for the respective voltage domains were violated. Likewise, it can be inferred from UV13, UV33 or UVSWD bits in [EVRSTAT](#) register as to whether under-voltage thresholds were violated. It is also possible to deactivate the generation of SMU alarms from secondary monitors in [EVRMONCTRL](#) register.

The primary bandgap is compared with a secondary bandgap to detect bandgap drifts as reflected in [EVRSTAT.BGPROK](#) register bit. The bandgap BIST is only carried out during a supply ramp-up.

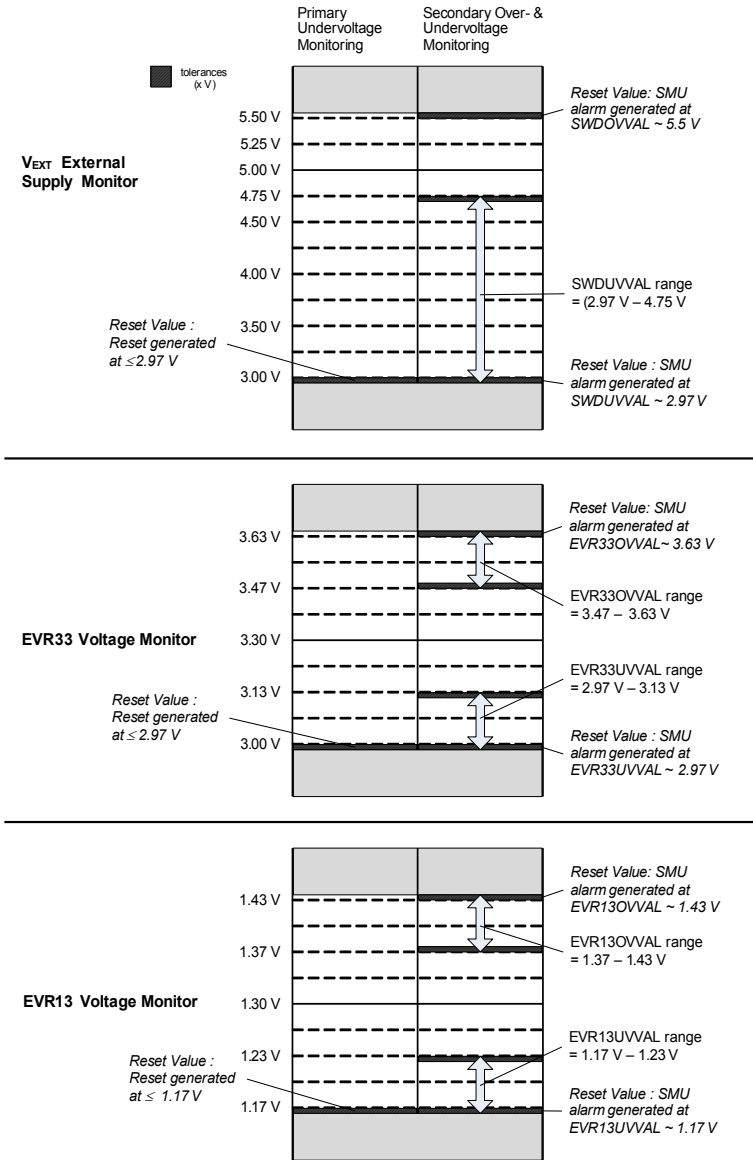

In case of primary monitor violation, respective status bits are set to indicate the event as shown in [Table 7-19](#). These bits maybe evaluated during consequent start-up after cold power-fail reset to recognize which among the supply rails had the power-fail. Likewise for secondary monitor violation, the respective status bits may be evaluated to discriminate between an overvoltage or an undervoltage event and to recognize which supply rail had triggered the alarm event to SMU.

Table 7-19 Voltage Monitoring

Supply Pin / Rail	Primary Under-voltage monitor State (ON/OFF)	Secondary Over & Under-voltage Monitor State (ON/OFF)	Supply Range V	Is the Pin supplied
RUN or SLEEP system mode during supply modes a-h.				
V _{EXT}	ON. RSTSTAT.SWD RSTSTAT.STBYR	ON EVRSTAT.OVSWD EVRSTAT.UVSWD	2.97– 5.50 V	External 5V or 3.3V Supply to be provided
V _{DDM}	-	-	2.97– 5.50 V	External Supply to be provided
V _{DDP3}	ON RSTSTAT.EVR33	ON EVRSTAT.OV33 EVRSTAT.UV33	2.97– 3.63 V	EVR33 active or external 3.3V supply to be provided
V _{DD}	ON RSTSTAT.EVR13	ON EVRSTAT.OV13 EVRSTAT.UV13	1.17– 1.43 V	EVR13 active or external 1.3V supply to be provided

Table 7-19 Voltage Monitoring

Supply Pin / Rail	Primary Under-voltage monitor State (ON/OFF)	Secondary Over & Under-voltage Monitor State (ON/OFF)	Supply Range V	Is the Pin supplied
STANDBY system mode during supply modes a-h.				
V_{EXT}	OFF RSTSTAT.STBYR	OFF	2.97– 5.50 V	ON
V_{DDM}	-	-	0– 5.50 V	ON or OFF
V_{DDP3}	OFF	OFF	0 V	OFF
V_{DD}	OFF	OFF	0 V	OFF

Monitoring tolerances and levels are specified in datasheet section EVR : Supply monitoring

Voltage_Monitoring_v0.3

Figure 7-32 Voltage Monitoring

Scaling EVR set point values and primary / secondary monitor thresholds

The adaptation of the EVR set point values, primary reset thresholds and secondary over and undervoltage thresholds shall be carried out in a sequential manner.

For example, in case of a change of VDD core supply range from the default 1.3V ± 10% (1.170 V to 1.430 V) to 1.3V - 5% + 10% (1.235 V to 1.430 V), following procedure may be carried out. Depending on external regulator constraints and application requirements, the setpoint may alternatively be raised by + 2.5% to 1.33 V nominal value to have an operational range of 1.33 V ± 7.5% symmetrical across the nominal value.

- Disable the Core supply secondary undervoltage alarm via **EVRRMONCTRL** register. Overvoltage monitoring is left active at the default 1.43 V (10%) limit as configured in **EVROVMON.EVR13OVVAL** register bits.
 - **EVRRMONCTRL**=0021 2101_H or **EVRRMONCTRL.EVR13UVMOD**=00_B.
 - **EVROVMON.EVR13OVVAL** = $FD_H - 253_D \sim 1.43V - 1.45V \sim 11\%$ (reset value)
- The EVR13 setpoint value maybe changed in maximum steps of 2.5 % to limit the current dynamics. The default EVR13 setpoint value is changed in **EVRTTRIM.EVR13TRIM** register in case LDO regulator is used. In case of SMPS regulator, **EVRTTRIM.SDVOUTSEL** value has to be changed. In case VDD core supply is provided externally, then the external regulator need to be configured so that it provides 1.33 V instead of 1.3 V.
- **EVRTTRIM.EVR13TRIM** = $[(1.33 / 5.7692 \text{ mV}) + 1] = E7_H = 231_D$.
- **EVRTTRIM.SDVOUTSEL** = $[(VIN - 725 \text{ mV}) / 5 \text{ mV}] = 79_H = 121_D$.
- VDD / EVR13 voltage value is measured and is indicated in **EVRRADCSTAT.ADC13V** register bits. This may allow a plausibility check whether the voltage change happened by comparing the value before and after the change. The voltage change would take less than 20 us in case of internal regulators to be visible at the VDD rail.
- The primary reset threshold limit is trimmed via **EVRRSTCON.RST13TRIM** register bits. The reset value is raised by 5% from 1.170 V at VDD pin to 1.235 V at VDD pin.
- **EVRRSTCON.RST13TRIM** = $[(1,235 \text{ V} / 5.7692 \text{ mV}) - 5] = D0_H = 208_D$
- In case not enough margin is available for the application, secondary undervoltage monitoring of core voltage maybe completely disabled. Otherwise the default limit of **EVRRVUMON.EVR13UVVAL** bits may be adapted by raising it by 5%.
 - **EVRRVUMON.EVR13UVVAL** = $[(1,235 \text{ V} / 5.7692 \text{ mV}) - 1] = D4_H = 212_D$.

7.3.1.8 100 MHz EVR Clock Source

The 100 MHz clock source is a precise back-up on-chip clock supplied by EVR Pre-regulator. The clock is used by the main EVRx3 regulators and monitors and serves as the system clock during the Startup phase. It is further used as an independent clock reference for clock monitoring and can be used as a back-up clock in case of loss of lock or crystal failures.

7.3.1.9 Sequence during Power-up and Power-down

Figure 7-33 Single Supply mode (a, b & c) - 5 V single supply

Single Supply mode (a, b & c)

5 V single supply mode. 1.3 V and 3.3 V are generated internally by the EVR13 and EVR33 internal regulators.

- The rate at which current is drawn from the external regulator (dI_{EXT}/dt) is limited during the basic infrastructure and EVRx3 regulator start-up phase (T_0 upto T_2) to a maximum of 100 mA/100 μ s. EVRx3 is also robust against a voltage ramp-up starting from a residual voltage between 0-1 V. Start-up slew rates for supply rails should comply to datasheet values.
- Furthermore it is also ensured that the current drawn from the external regulator (dI_{EXT}/dt) is limited during the Firmware start-up phase (T_2 upto T_3) to a maximum of 100 mA/100 μ s.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- $\overline{\text{PORST}}$ (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is required to keep the $\overline{\text{PORST}}$ (input) asserted for a minimum duration after the external supply is above the respective primary reset threshold as documented in datasheet.
- $\overline{\text{PORST}}$ (output) active means that μ C asserts the reset internally and drives the $\overline{\text{PORST}}$ pin low thus propagating the reset to external devices. The $\overline{\text{PORST}}$ (output) is asserted by the μ C when atleast one among the three supply domains (1.3 V, 3.3 V or 5 V) violate their primary under-voltage reset thresholds. The $\overline{\text{PORST}}$ (output) is deasserted by the μ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in **Figure 7-33** is enumerated below
 - T_1 refers to the point in time when basic supply and clock infrastructure is available as the external supply ramps up. The supply mode is evaluated based on the HWCFG[0:2,6] pins and consequently a soft start of EVR13 and EVR33 regulators are initiated.
 - T_2 refers to the point in time when all supplies are above their primary reset thresholds. EVR13 and EVR33 regulators have ramped up. $\overline{\text{PORST}}$ (output) is deasserted and HWCFG[3:5] pins are latched on $\overline{\text{PORST}}$ rising edge. Firmware execution is initiated.
 - T_3 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
 - T_4 refers to the point in time during the Ramp-down phase when atleast one of the externally provided or generated supplies (1.3 V, 3.3 V or 5 V) drop below their respective primary under-voltage reset thresholds.

Figure 7-34 External Supply mode (d) - 5 V and 1.3 V externally supplied

External Supply mode (d)

5 V and 1.3 V supplies are externally supplied. 3.3V is generated internally by the EVR33 regulator.

- External supplies V_{EXT} and V_{DD} may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). EVRx3 is also robust against a voltage ramp-up starting from a residual voltage between 0-1 V. Start-up slew rates for supply rails should comply to datasheet values.
- The rate at which current is drawn from the external regulator (di_{EXT}/dt or di_{DD}/dt) is limited in the Start-up phase to a maximum of 100 mA/100 us.
- \overline{PORST} is active/asserted when either \overline{PORST} (input) or \overline{PORST} (output) is active/asserted.
- \overline{PORST} (input) active means that the reset is held active by external agents by pulling the \overline{PORST} pin low. It is required to keep the \overline{PORST} (input) asserted for a minimum duration after the external supply is above the respective primary reset threshold as documented in datasheet.
- \overline{PORST} (output) active means that μC asserts the reset internally and drives the \overline{PORST} pin low thus propagating the reset to external devices. The \overline{PORST} (output) is asserted by the μC when atleast one among the three supply domains (1.3 V, 3.3 V or 5 V) violate their primary under-voltage reset thresholds. The \overline{PORST} (output) is deasserted by the μC when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in [Figure 7-34](#) is enumerated below
 - T1 refers to the point in time when basic supply and clock infrastructure is available as the external supplies ramp up. The supply mode is evaluated based on the HWCFG[0:2,6] pins and consequently a soft start of EVR33 regulator is initiated.
 - T2 refers to the point in time when all supplies are above their primary reset thresholds. EVR33 regulator has ramped up. \overline{PORST} (output) is deasserted and HWCFG[3:5] pins are latched on \overline{PORST} rising edge. Firmware execution is initiated.
 - T3 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
 - T4 refers to the point in time during the Ramp-down phase when atleast one of the externally provided or generated supplies (1.3 V, 3.3 V or 5 V) drop below their respective primary under-voltage reset thresholds.

Figure 7-35 Single Supply mode (e & f) - 3.3 V single supply

Single Supply mode (e & f)

3.3 V single supply mode. 1.3 V is generated internally by the EVR13 regulator.

- The rate at which current is drawn from the external regulator (di_{EXT}/dt) is limited in the Start-up phase to a maximum of 100 mA/100 μ s. EVR13 is also robust against a voltage ramp-up starting from a residual voltage between 0-1 V. Start-up slew rates for supply rails should comply to datasheet values.
- \overline{PORST} is active/asserted when either \overline{PORST} (input) or \overline{PORST} (output) is active/asserted.
- \overline{PORST} (input) active means that the reset is held active by external agents by pulling the \overline{PORST} pin low. It is required to keep the \overline{PORST} (input) asserted for a minimum duration after the external supply is above the respective primary reset threshold as documented in datasheet.
- \overline{PORST} (output) active means that μ C asserts the reset internally and drives the \overline{PORST} pin low thus propagating the reset to external devices. The \overline{PORST} (output) is asserted by the μ C when at least one among the three supply domains (1.3 V or 3.3 V) violate their primary under-voltage reset thresholds. The \overline{PORST} (output) is deasserted by the μ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in [Figure 7-35](#) is enumerated below
 - T1 refers to the point in time when basic supply and clock infrastructure is available as the external supply ramps up. The supply mode is evaluated based on the HWCFG[0:2,6] pins and consequently a soft start of EVR13 regulator is initiated.
 - T2 refers to the point in time when all supplies are above their primary reset thresholds. EVR13 regulator has ramped up. \overline{PORST} (output) is deasserted and HWCFG[3:5] pins are latched on \overline{PORST} rising edge. Firmware execution is initiated.
 - T3 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
 - T4 refers to the point in time during the Ramp-down phase when at least one of the externally provided or generated supplies (1.3 V or 3.3 V) drop below their respective primary under-voltage reset thresholds.

Figure 7-36 External Supply mode (h) - 5 V, 3.3 V & 1.3 V externally supplied

External Supply mode (h)

All supplies, namely 5 V, 3.3 V & 1.3 V, are externally supplied.

- External supplies V_{EXT} , V_{DDP3} & V_{DD} may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). The supply system is also robust against a voltage ramp-up starting from a residual voltage between 0 - 1 V. Start-up slew rates for supply rails should comply to datasheet values.
- The rate at which current is drawn from the external regulator (di_{EXT}/dt , di_{DD}/dt or di_{DDP3}/dt) is limited in the Start-up phase to a maximum of 100 mA/100 μ s.
- \overline{PORST} is active/asserted when either \overline{PORST} (input) or \overline{PORST} (output) is active/asserted.
- \overline{PORST} (input) active means that the reset is held active by external agents by pulling the \overline{PORST} pin low. It is required to keep the \overline{PORST} (input) asserted for a minimum duration after the external supply is above the respective primary reset threshold as documented in datasheet.
- \overline{PORST} (output) active means that μ C asserts the reset internally and drives the \overline{PORST} pin low thus propagating the reset to external devices. The \overline{PORST} (output) is asserted by the μ C when atleast one among the three supply domains (1.3 V, 3.3 V or 5 V) violate their primary under-voltage reset thresholds. The \overline{PORST} (output) is deasserted by the μ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available.
- The power sequence as shown in [Figure 7-36](#) is enumerated below
 - T1 refers to the point in time when all supplies are above their primary reset thresholds and basic clock infrastructure is available. The supply mode is evaluated based on the HWCFG[0:2,6] pins. \overline{PORST} (output) is deasserted and HWCFG[3:5] pins are latched on \overline{PORST} rising edge. Firmware execution is initiated.
 - T2 refers to the point in time when Firmware execution is completed. User code execution starts with a default frequency of 100 MHz.
 - T3 refers to the point in time during the Ramp-down phase when atleast one of the externally provided supplies (1.3 V, 3.3 V or 5 V) drop below their respective primary under-voltage reset thresholds.

7.3.1.10 EVR Control Registers

All EVR registers with LCK bits have corresponding shadow registers in the EVR Standby domain. When writing consecutive EVR registers with LCK bits, it need to be ensured that the consecutive register is written only when the respective LCK bit is in unlocked state. This is because all EVR shadow registers are addressed using a shared bus across multiple clock domains and power isolation. An ongoing write will block the complete bus inhibiting parallel or consecutive writes on other registers until LCK bit is released. In a multi- CPU system, it might be better to read back the value from the register to ensure that it is written before proceeding writing to the next register. After a cold $\overline{\text{PORST}}$, warm and system resets these registers may return a value 0 or the updated value by the Firmware. The reset value reflects the default isolation value in the shadow register. Otherwise, a read will provide the value of the most recent write operation. The status registers **EVRSTAT** and **EVRADCSTAT** are updated during Start-up and after every EVR measurement cycle and the reset value is dependent on the EVR topology. Therefore the value read from register may differ from the documented reset value.

EVRSTAT

EVR Status Register (0B0_H) **Reset Value: 0000 0400_H**

Field	Bits	Type	Description
EVR13	0	rh	EVR13 status This bit is set if the internal EVR13 LDO or SMPS regulator is active. EVR13 is activated if HWCFG[2] pin level is latched high during start-up phase. 0 _B EVR13 is inactive. 1 _B EVR13 is active.

Field	Bits	Type	Description
OV13	1	rh	<p>EVR13 Regulator Over-voltage event flag This bit is set if EVR13 secondary voltage monitor recognises a 1.3 V over-voltage event. An alarm is raised to the SMU.</p> <p>0_B No over-voltage condition happened. 1_B EVR13 Over-voltage event indication as configured in EVROVMON register.</p>
EVR33	2	rh	<p>EVR33 status This bit is set if the internal EVR33 LDO regulator is active. EVR33 is activated if HWCFG[1] pin level is latched high during start-up phase.</p> <p>0_B EVR33 is inactive. 1_B EVR33 is active.</p>
OV33	3	rh	<p>EVR33 Regulator Over-voltage event flag This bit is set if EVR33 secondary voltage monitor recognises a 3.3 V over-voltage event. An alarm is raised to the SMU.</p> <p>0_B No over-voltage condition happened. 1_B EVR33 Over-voltage event indication as configured in EVROVMON register.</p>
OVSWD	4	rh	<p>Supply Watchdog (SWD) Over-voltage event flag This bit is set if VEXT secondary voltage monitor recognises an over-voltage event. An alarm is raised to the SMU.</p> <p>0_B No over-voltage condition happened. 1_B SWD Over-voltage event indication as configured in EVROVMON register.</p>
UV13	5	rh	<p>EVR13 Regulator Under-voltage event flag This bit is set if EVR13 secondary voltage monitor recognises a 1.3 V under-voltage event. An alarm is raised to the SMU.</p> <p>0_B No under-voltage condition happened. 1_B EVR13 Under-voltage event indication as configured in EVRUVMON register.</p>

Field	Bits	Type	Description
UV33	6	rh	<p>EVR33 Regulator Under-voltage event flag</p> <p>This bit is set if EVR33 secondary voltage monitor recognises a 3.3 V under-voltage event. An alarm is raised to the SMU.</p> <p>0_B No under-voltage condition happened. 1_B EVR33 Under-voltage event indication as configured in EVRUVMON register.</p>
UVSWD	7	rh	<p>Supply Watchdog (SWD) Under-voltage event flag</p> <p>This bit is set if VEXT secondary voltage monitor recognises an under-voltage event. An alarm is raised to the SMU.</p> <p>0_B No under-voltage condition happened. 1_B SWD Under-voltage event indication as configured in EVRUVMON register.</p>
EXTPASS13	8	rh	<p>External Pass Device for EVR13</p> <p>This bit is set if an external device is detected at VGATE1P pin for EVR13 regulator in LDO or SMPS mode. If VGATE1P pin is externally connected to ground, then the bit is cleared. If the pin is left open or sinking of current is not possible via the pin, the bit is set.</p> <p>0_B No external pass device used 1_B External pass device is used for EVR13 LDO or external charge device is used for EVR13 DC-DC regulator</p>
EXTPASS33	9	rh	<p>External Pass Device for EVR33</p> <p>This bit is set if an external pass device is detected at VGATE3P pin for EVR33 regulator in LDO mode. In case VGATE3P pin is absent in the package, then this signal is internally connected to ground and the bit is cleared.</p> <p>0_B No external pass device used 1_B External pass device used for EVR33 LDO</p>

Field	Bits	Type	Description
BGPROK	10	rh	Primary Bandgap status This bit is set after any reset and indicates that the primary bandgap voltage is in operational range. In case primary bandgap is not ok, we remain in cold reset state. On a Cold PORST release, this bit would be set to 1. 0_B Primary bandgap not ok. 1_B Primary bandgap is ok.
0	[31:11]	r	Reserved Read as 0.

The over-voltage and under-voltage status signals are reported to SMU.EMM unit. An alarm for the upper and lower bound is supported in the SMU.EMM unit.

EVRADCSTAT
EVR ADC Status Register
(19C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
ADC13V	[7:0]	rh	ADC 1.3 V Conversion Result This bit field contains the last conversion result of the ADC measurement of the $V_{DD} / EVR13$ supply. $VIN = [LSB * (ADC13V-1)]$; $LSB = 5.7692 \text{ mV}$ Eg. $1.30 \text{ V} - E2_H - 226_D$ (refer datasheet)
ADC33V	[15:8]	rh	ADC 3.3 V Conversion Result This bit field contains the last conversion result of the ADC measurement of the $V_{DDP3} / EVR33$ supply. $VIN = [LSB * (ADC33V-1)]$; $LSB = 23.077 \text{ mV}$ Eg. $3.30 \text{ V} - 90_H - 144_D$ (refer datasheet)

Field	Bits	Type	Description

Field	Bits	Type	Description
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated
0	[29:24], 30	r	Reserved Read as 0; should be written with 0.

A configurable threshold with upper and lower voltage bounds can be defined in EVROVMON and EVRUVMON registers for monitoring EVR13 and EVR33 regulators. It need to be considered that after a system reset, Firmware overwrites the register values.

The EVROVMON and EVRUVMON registers can be configured to trigger SMU alarms via software. It is also possible to activate alarms via software in the SMU unit.

EVROVMON

EVR Under-voltage Configuration Register(1A0_H) **Reset Value: 00D0 84CD_H**

Field	Bits	Type	Description
EVR13UVVAL	[7:0]	rw	1.3 V Regulator Under-voltage threshold This field defines the under-voltage monitoring threshold level of the EVR13 regulator. $1.30\text{ V} - E_{2H} - 226_D$ (refer datasheet) Threshold = $[(VIN / LSB) + 1]$ LSB = 5.7692 mV

Field	Bits	Type	Description
EVR33UVVAL	[15:8]	rw	3.3 V Regulator Under-voltage threshold This field defines the under-voltage monitoring threshold level of the EVR33 regulator. $2.99\text{ V} - 83_{\text{H}} - 131_{\text{D}} \sim -10\%$ (refer datasheet) $\text{Threshold} = \lceil (\text{VIN} / \text{LSB}) + 1 \rceil$ $\text{LSB} = 23.077\text{ mV}$
SWDUVVAL	[23:16]	rw	Supply monitor (SWD) Under-voltage threshold value This field defines the under-voltage threshold level of the external VEXT supply monitor. 5 V external supply $5.01\text{ V} - \text{DB}_{\text{H}} - 219_{\text{D}}$ (refer datasheet) 3.3 V external supply $3.29\text{ V} - 90_{\text{H}} - 144_{\text{D}}$ (refer datasheet) $\text{Threshold} = \lceil (\text{VIN} / \text{LSB}) + 1 \rceil$ $\text{LSB} = 23.077\text{ mV}$
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_{B} The register is unlocked and can be updated 1_{B} The register is locked and cannot be updated
0	[29:24], 30	r	Reserved Read as 0; should be written with 0.

Field	Bits	Type	Description
0	2,3,6,7, 10,11, 14,15, 18,19, 23,22, 30,31	r	Reserved Read as 0; should be written with 0.
0	[29:24]	r	Reserved Read as 0; should be written with 0.

The default setting after reset is that over-voltage indication is notified via an SMU alarm when the overvoltage threshold is crossed in a lower to higher voltage transition.

The default setting after reset is that under-voltage indication is notified via an SMU alarm when the under-voltage threshold is crossed in a higher to lower voltage transition.

It can be configured in EVRMONCTRL register to generate an interrupt when the over-under-voltage thresholds are crossed in either direction. This may be used to notify when the violation condition disappears with respect to secondary voltage monitoring.

EVR13CON

EVR13 Control Register

(0B8_H)

Reset Value: 0380 0380_H

Field	Bits	Type	Description
EVR13OFF	28	rw	EVR13 Regulator Enable 0_B The EVR13 regulator module is enabled 1_B The EVR13 regulator module is disabled/switched off. The device may be operating in standby or with external 1.3V supply. This bit can only be changed if bit BPEVR13OFF is set in parallel.
BPEVR13OFF	29	w	Bit Protection EVR13OFF Setting this bit enables that bit EVR13OFF can be changed in this write operation. This bit is read as zero.
RES	30, [27:0]	r	Reserved These bits should not be written. Writes to other bitfields shall ensure that these bits are not changed.
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated

7.3.2 Power Management

7.3.2.1 Power Management Overview

The Power Management scheme allows activation of power down modes so that the system operates with the minimum required power for the corresponding application state. A progressive reduction in power consumption is achieved by invoking Idle, Sleep or Standby modes respectively. The Idle mode is specific to each individual CPU where as Sleep and Standby modes influence the complete system.

As shown in [Table 7-20](#), there are two power modes available for each CPU:

- CPU Run Mode
- CPU Idle Mode

Table 7-20 CPU Power Management

Mode	Description
Run Mode	The CPU clock is active and code is being executed.
Idle Mode	<p>CPU may enter Idle Mode on following events:</p> <ul style="list-style-type: none"> • On a SW Idle request issued by setting register bits PMCSRx.REQSLP = 01_B when CPU has no active tasks to perform. • On a SW Idle request (PMCSRy.REQSLP = 01_B) issued by another CPU. • On a SMU Idle request in case CPU faults are detected triggering safety alarms which are configured in SMU to set CPU into Idle state. <p>The CPU code execution is halted and CPU clock is disabled in Idle state. The peripherals continue to remain active. CPU RAM memories (PSPR / DSPR) are accessible to other bus masters and peripherals.</p> <p>CPU may exit Idle mode on following events:</p> <ul style="list-style-type: none"> • When an interrupt occurs on a CPU returning the CPU to Run Mode. • When a trap occurs like an NMI trap event. • When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm in turn leading to a CPU interrupt. • When a MSB bit wrap of the CPU Watchdog counter takes place. • When an Application reset, System reset or any higher reset occurs.

As shown in [Table 7-21](#), there are three main power modes available for the system:

- System Run Mode
- System Sleep Mode
- System Standby Mode

Table 7-21 System Power Management

Mode	Description
Run Mode	At least one master CPU has not requested Sleep Mode or Standby mode and is in Run mode. All peripheral modules are active.
Sleep Mode	<p>System may enter Sleep Mode on following events:</p> <ul style="list-style-type: none"> • On a SW Sleep request issued by setting $PMCSRx.REQSLP = 10_B$ by the master CPU. <p>CPU code execution is halted and CPU Idle state is entered. Peripherals are set into sleep state if so configured in the respective $CLCx.EDIS$ bit. Ports retain their earlier programmed state.</p> <p>System may exit Sleep mode on following events:</p> <ul style="list-style-type: none"> • When an interrupt or trap occurs on the master CPU. • When an NMI trap event takes place. • When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm leading in turn to a master CPU interrupt. • When a MSB bit wrap of master CPU Watchdog counter takes place. • When an Application reset, System reset or any higher reset occurs.
Standby Mode	<p>System may enter Standby Mode on following events if so configured:</p> <ul style="list-style-type: none"> • On a SW Standby request issued by setting $PMCSRx.REQSLP = 11_B$ by the master CPU. • On a secondary undervoltage event during V_{EXT} supply ramp-down. • On an $NMI / \overline{ESR1}$ assertion event. <p>The Standby domain constituting the Standby RAM, the 8 bit Standby Controller, shared ports and the wake-up unit remain actively supplied. The power to the rest of the chip is completely switched off.</p> <p>System may exit Standby mode on following events in case V_{EXT} remains supplied during Standby state:</p> <ul style="list-style-type: none"> • when a wake-up edge is detected on selected pins / $\overline{ESR1}$. • when a wake-up request is issued by the 8 bit standby controller. • when \overline{PORST} assertion is detected.

Furthermore, flexible reduction of power consumption is possible through following measures:

- Reduction of specific CPU power consumption by means of CPU clock scaling.
- Disabling the module clock by setting bit DISR in module CLC register.
- Reducing the system frequency without changing individual peripheral clocks.
- Reducing peripheral clock frequency without changing system clock frequency.

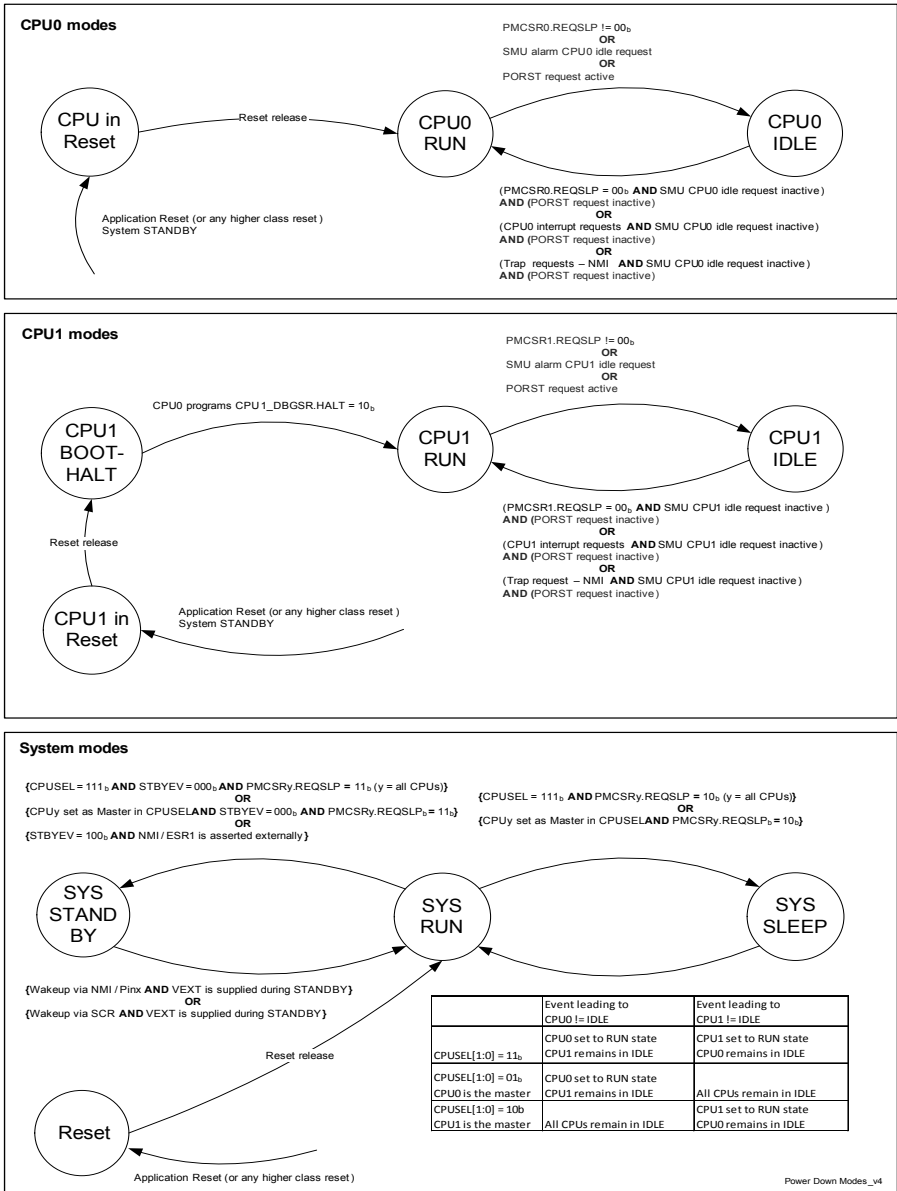

Figure 7-37 Power down modes and transitions

7.3.2.2 Idle Mode

In case there are no active tasks to perform, a CPU may be requested to enter Idle mode during runtime by writing to the respective PMCSR_x register and setting the bitfield REQSLP = 01_B.

Entering Idle Mode :

Following events can invoke a CPU_x Idle request

- CPU_x setting itself in Idle by writing its own PMCSR_x register: The respective PMCSR_x register shall be accessed by setting CPU_x ENDINIT = 0_B and consequently writing the bitfield REQSLP = 01_B. The Idle transition takes place only when CPU_x ENDINIT = 1_B is set back again. This ensures that a CPU_x does not enter Idle mode when it's WDT_x is in Time-Out mode and ENDINIT_x = 0_B to avoid wake-up on a consequent WDT time-out. Safety ENDINIT mechanism shall not be used by a CPU to set itself into Idle to avoid wake-up on a Safety WDT time-out. It is to be noted that CPU is set into Idle state during entry into SLEEP (REQSLP = 10_B) mode as well. In STANDBY mode (REQSLP = 11_B), CPU is set first into Idle state before power is switched off. Idle mode may also be simultaneously triggered for additional CPUs based on PMSWCR1.CPUIDLSEL configuration.
- CPU_y setting CPU_x into Idle: The PMCSR_x register shall be accessed by CPU_y by setting Safety ENDINIT = 0_B. The Idle request is issued immediately on setting PMCSR_x.REQSLP = 01_B. The device no longer waits for Safety ENDINIT = 1_B to be set back to trigger Idle transition. In case CPU_x is already in Idle owing to an SMU Idle request, REQSLP_x write accesses by CPU_y shall be ignored to keep CPU_x in permanent idle until the next application reset. SMU Software alarms maybe used alternatively to set a CPU_x in permanent Idle via CPU_y.
- CPU_x being set into Idle by SMU alarm: Idle mode may be requested by an SMU alarm in case of detected CPU faults thus setting the faulty CPU in Idle without initiating a full application reset.

The CPU watchdog may be disabled or slowed down by reprogramming the timers before triggering Idle request via Software. On an Idle request, the CPU finishes its current operations and sends an acknowledge back to the Power Management unit. It then enters an inactive state in which the CPU and the respective DMI and PMI memory units are shut off.

State during Idle mode

During Idle Mode, memory accesses to the DMI and PMI from other bus masters cause these units to wake-up automatically to handle these transactions. When memory transactions are complete, the DMI and PMI return to Idle state again. Once Idle Mode is entered, the state is reflected in PMCSR_x.PMST status bits. CPU Idle request from the SMU is reflected in PMCSR_x.SMUSLP bit.

Exiting Idle mode

In Idle mode, if there is no outstanding SMU Idle request to the CPU, the CPU will return to Run mode in response to the following events:

- An interrupt / trap received from an interrupt / trap source mapped to the CPU.
- An NMI trap request is received to wake-up all the CPUs.
- A MSB bit wrap of the corresponding CPU Watchdog counter occurs.
- Setting the register bits `PMCSRx.REQSLP = 00B` to set the CPUx into Run mode.

If there is an outstanding SMU Idle request to the CPU, then the CPU may only return to Run mode after an application reset or any higher reset. The system enters reset state on an Application, System reset or any higher reset. If it is woken by a watchdog timer overflow event routed via the SMU to the CPU or by an NMI or by an interrupt, the CPU will immediately vector to the appropriate interrupt / trap handler.

7.3.2.3 Sleep Mode

System may be requested to enter Sleep mode via software by master CPU by writing to the CPU's PMCSR_x register and setting the bitfield REQSLP = 10_B.

Sleep Mode is a system mode and may be entered as a unanimous decision of all the CPUs when ALL of the PMCSR_x registers in the system request it AND **PMSWCR1**.CPUSEL = 111_B. Sleep Mode may also be entered based on a singular decision of a master CPU based on the configuration of the CPUSEL register. The PMCSR_x register shall be accessed by setting CPU_x ENDINIT = 0_B. The Sleep request is issued only after CPU_x ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU_x to issue Sleep request.

Entering Sleep Mode

It should be ensured to select individual clocks from Clock Control Unit for peripherals which need to remain active during Sleep mode. This allows the reduction of system clock frequencies, namely SRI and SPB clocks, to the minimum possible values via the low power divider. Low power modes for Analog and Flash modules may also be requested. The CLC_x.EDIS register bit is cleared for all peripherals intended to be inactive in Sleep mode. The watchdogs may be disabled or slowed down before issuing a Sleep request.

State during Sleep Mode

Sleep Mode is disabled for a unit if CLC_x.EDIS bit is set. The sleep request is ignored in this case and the corresponding unit continues normal operation as intended. If CLC_x.EDIS is cleared, the clock of the module is gated. The exact sequence used for entering Sleep Mode is determined for each module by the setting of register field OCS_x.SUS. CPU Idle state is entered for all the CPUs as described in the previous section. All ports retain their earlier programmed state.

Exiting Sleep Mode

The system will exit Sleep mode on any wakeup event that causes any master CPU to exit Idle Mode depending on CPUSEL configuration. Only the master CPU associated with the interrupt wake-up event would be set into Run mode (REQSLP = RUN, PMST = RUN). Other CPUs will remain in Idle (REQSLP = SLEEP, PMST = IDLE). An NMI trap event will wake-up ALL the CPUs. A MSB bit wrap of the corresponding master CPU Watchdog counter would also wake-up the master CPU. The response of the CPU to being woken up from Sleep Mode is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation.

7.3.2.4 Standby Mode

The Standby domain constitutes the Standby RAM, the 8 bit Standby Controller, the power management unit, the wake-up unit, the V_{EXT} monitor and basic infrastructure components. The Standby domain is supplied by the EVR pre-regulator and is per default clocked by the 100 KHz internal low power clock source in Standby Mode.

Following events may trigger Standby mode entry based on PMSWCR1.STBYEV bits.

- Standby entry on SW request (PMCSRx.REQSLP = 11_B). The Standby request is issued only after CPUx ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPUx to issue Standby request.
- Standby entry on $\overline{ESR1}$ / \overline{NMI} edge event.

Following events may trigger wake-up from Standby mode.

- Wake-up via \overline{NMI} / Pinx: Wake-up on rising, falling or any edge of \overline{NMI} / $\overline{ESR1}$, Pin A or Pin B pins. Standby domain is supplied via V_{EXT} supply pins which in turn is supplied by an external regulator with Standby support.
- Wake-up via SCR: Wake-up is triggered by the Standby controller. V_{EXT} is supplied by an external regulator with Standby support. Wake-up on V_{EXT} supply ramp-up is unavailable in this configuration.

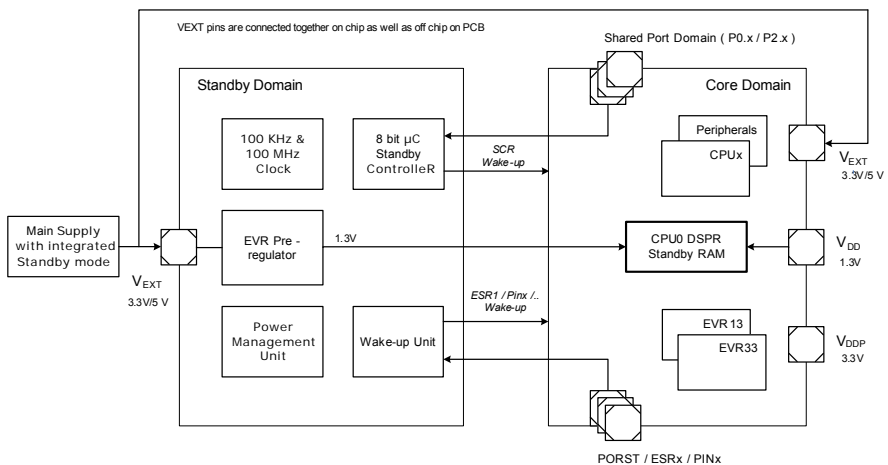

Figure 7-38 Standby domain

The Standby RAM constitutes a single block of ECC protected DSPR RAM of CPU0. The RAM remains supplied during Standby mode if configured in PMSWCR0.STBYRAMSEL bits. On wake-up, the status of the Standby RAM is reflected in PMSWSTAT.STBYRAM bits. During Standby state, the supply to the Standby RAM cell array is supplied by EVR Pre-regulator.

External events may be mapped to ESRx / PINx pins in turn acting as wake-up signals for the system. In Run Mode, NMI / ESR1 pin may be used as fault or functional interface for external devices. In Standby Mode, an edge event on the NMI / ESR1 pin may be configured to trigger wake-up of the main core domain via **PMSWCR0**.ESR1WKEN bit and is reflected in **PMSWSTAT**.ESR1WKEN status flag. It can be configured to trigger a wake-up on rising, falling or both edges via **PMSWCR0**.ESR1EDCON bit. Glitches on ESR1 input are filtered out by activating the filter via **PMSWCR0**.ESR1DFEN bit. Additional pins (PINA - P14.1 and PINB - P15.1) may likewise be configured to trigger wake-up via **PMSWCR0**.xEDCON, xDFEN & xWKEN bits. On wake-up, **PMSWSTAT**.ESR1WKP or PINxWKP event flags provide information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR** register. In case new wake-up events are captured while **PMSWSTAT**.xWKP flags are still set, then **PMSWSTAT**.xOVRRUN flags are set to indicate an overrun state owing to consecutive unserved wake-up events.

The 8 bit Standby controller (SCR) subsystem constitutes an XC800 core, 8KB XRAM memory, various timer and communication peripherals and 16 shared pins executing autonomous activity during Idle, Sleep and Standby modes. Various Standby functions and periodic monitoring tasks may be encapsulated in the SCR with minimal power consumption overhead. The SCR interacts with the main core domain via a dedicated SPI (QSPI2) interface and **PMSWCR2** register bits. The SCR is enabled via **PMSWCR0**.SCREN bit. The SCR enable bit needs to be set after every SCR reest triggered from the SCU side. After start-up, CPU0 programs the SCR via SPI interface and copies the code into the internal XRAM. A reset may be issued to the SCR via **PMSWCR1**.SCRSTREQ register bit. Consequently **PMSWSTAT**.SCRST register bit is flagged to indicate SCR reset and shall be cleared via **PMSWSTATCLR**.SCRSTCLR bit. After reset release, the firmware initializes the SCR subsystem based on the hardware configuration programmed in **PMSWCR1**.SCRCFG bits. The 100 KHz clock source is the default clock active in Standby Mode. The clock source may be switched to the internal 100 MHz clock source via **PMSWCR0**.SCRCLKSEL register bit thus enabling higher performance on the SCR subsystem. The SCR clock system in turn divides the 100 MHz clock to a value below 20 MHz maximum SCR clock frequency. SCR port module shares a part of the port domain with the main port system which may be kept active during Standby mode. The control to these pins need to be allocated explicitly to the SCR via port configuration registers. The SCR can make a direct interrupt request to the CPU in Run Mode and likewise CPU can also trigger a direct interrupt request to the SCR. It is possible to access the SCR XRAM via QSPI2 (SLSO15) interface. Simultaneous access to XRAM via QSPI2 and the XC800 is arbitrated by the SCR memory arbiter. Additionally, It is also possible to exchange data between SCR and main domain via **PMSWCR2** register. Unused wake-up pins may be configured as tristate in Standby Mode. SCR may wakeup the main core domain from Standby state if configured in **PMSWCR0**.SCRWKEN register bit. The enabling of SCR wake-up via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz. A

wake-up request is issued by the SCR SW via SCRWKP bit in STDBYWKP register as documented in the SCR SCU. On wake-up of the main core domain, **PMSWSTAT.SCRWKP** event flag is set which shall be cleared via **PMSWSTATCLR.SCRWKPCLR** register bit. Some of the system status and control registers are also available in the SCR subsystem. Critical SCR errors like XRAM ECC errors, SCR watchdog overflow event and reset are also communicated back to the main core domain via **PMSWCR2** register bits. The SCR is reset in case **PORST** is externally asserted. The SCR is not affected by an Application or System reset.

Entering Standby Mode (ESR1 / Pin or SCR Wake-up configuration)

The Standby Mode entry may be requested by writing to PMCSR_x register to set bitfield REQSLP = 1_B or via NMI / $\overline{\text{ESR1}}$ assertion as configured in **PMSWCR1**.STBYEV bits.

Standby mode via SW may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as a unanimous decision of all the CPUs when ALL of the PMCSR_x registers in the system request it and **PMSWCR1**.CPUSEL = 111_B. Each PMCSR_x register is written by the corresponding CPU_x.

Before entering standby mode, various modules should be sequentially shut off in a sequence mainly to avoid large current jump on standby entry.

- All peripherals and interrupts associated with CPUs except master CPU are switched off. This is to avoid wake-up of the CPUs once they are put into IDLE state.
- All CPUs except the master CPU are sequentially put into IDLE state. CPU watchdogs may be disabled or reconfigured for slower modes.
- Peripheral module clocks are switched off in respective CLC.DISR registers.
- Master CPU frequency reduction in steps compliant to load jump constraints.
- Master CPU code execution is switched from Flash to PSPR RAM. Flash modules are deactivated via FCON register.
- System Clock is switched to the internal 100 MHz clock source. System PLL & E-Ray PLL are switched off. Clock dividers are programmed to lower values.
- Set **PMSWCR1**.IRADIS bit to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. This ensures that standby request is not blocked by a pending reset request / sequence.
- Select the Standby RAM block via **PMSWCR0**.STBYRAMSEL bits. Copy Standby RAM redundancy data (16 words in size) to DSPR0 starting at 0xD000 2000h. The procedure is also described in Boot ROM chapter in section "Preparation before to enter Standby mode". Dcache write back to be executed before Standby entry.
- Select the clock source which need to be active on entry into Standby Mode via **PMSWCR0**.SCRCLKSEL bits. Wake-up trigger edge configuration and filter activation is configured via **PMSWCR0**.xxxEDCON and **PMSWCR0**.xxxDFEN bits.
- Configure pad state via **PMSWCR0**.TRISTREQ bit. All pads may either be in tristate or have pull-up devices active. Configure **PMSWCR0**.ESR0TRIST bit to configure ESR0 behavior as reset output or tristate during Standby and on wake-up. In case of HWCFG [2:5] pins it is recommended to tie them to external pull devices.
- Enable ESR1 or PIN_x pins for wake-up via **PMSWCR0**.xxxWKEN bits. The wake-up from 8 bit should be activated via **PMSWCR0**.SCRWKEN bit. The enabling of SCR wake-up via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz. The shared ports are configured either to be in tristate during standby or left to the control of SCR. SCR should be running before entering the Standby state in case used.
- Configure Standby Entry event in **PMSWCR1**.STBYEV register bits.

- Standby request issued. An orderly shut down of various sub-systems is triggered to enter Standby mode.

State during Standby Mode

The Standby RAM (DSPR RAM of CPU0), the 8 bit Standby controller, the shared ports and the wake-up logic are kept alive in this mode. PORST pin serves as a wakeup source when asserted and shall be held high externally for NMI and SCR Wake-up configuration to remain in Standby state.

All other ports are set in their default reset state. The default port behavior during standby and after wake-up may be configured as pull-up or tri-state accordingly by **PMSWCR0.TRISTREQ** register bit. The ESR0 pin may be configured as reset output or tristate during Standby mode by configuring **PMSWCR0.ESR0TRIST** bit.

The SCR continues to operate as a stand-alone 8 bit controller executing the intended operations. It should be ensured that the shared ports are configured in the corresponding port registers and the ownership of the pins are assigned either to the SCR or the main domain. In case the SCR needs to drive outputs during Standby mode, the default clock may need to be switched from 100 KHz to 20 MHz clock source. The SCR may request the EVR to activate or deactivate the 20 MHz clock. SCR may be programmed to issue wake-up based on inputs from internal modules or shared pins. When the wake-up of the main core domain is required, the SCR issues a wake-up request via SCRWKP bit in STDBYWKP register as documented in the SCR SCU

Exiting Standby Mode - Wake-up event

The wake-up event in case of NMI/Pin or SCR wake-up configuration may happen on

- ESR1 edge transition (NMI trap)
- Pin A or Pin B edge transition (P14.1 or P15.1)
- Wake-up from SCR via register STDBYWKP.SCRWKP in turn caused by following events
 - Edge transitions at the shared ports
 - RTC interrupt
 - SCR watchdog overflow
 - Selected interrupts from communication modules

The main EVRx3 regulators are ramped up on wake-up based on the latched configuration in **PMSWSTAT.HWCFGEVR** register bits. Firmware is executed thereafter including installation of RAM redundancy data. On wake-up, all pads are either in tristate or are connected to pull-ups as indicated in **PMSWSTAT.TRIST** register bit. ESR0 behaviour is indicated in **PMSWSTAT.ESR0TRIST** register bit. If Standby RAM was supplied during Standby state, it is indicated in **PMSWSTAT.STBYRAM** register bits. Additional RAM integrity checks may be carried out after wake-up. RSTSTAT.STBYR bit indicates that the supply was reliable during Standby. The wake-up and over-run status flags are set in **PMSWSTAT** register and shall be cleared by **PMSWSTATCLR**

register. The wake-up time is quite the same as the normal boot time as EVR need to be started and firmware need to be consequently executed. In case **PMSWSTAT**.STBYRAM bits are set after wake-up, it is ensured that the Standby RAM (CPU0 DSPR) is not initialised after wake-up by Firmware irrespective whether PROCOND.RAMIN / RAMINSEL bits are configured in Flash to initialise the Standby RAM region.

Exiting Standby Mode - Power Fail or $\overline{\text{PORST}}$ assertion

A power fail event of the Standby supply during Standby mode will inevitably result in the loss of Standby RAM contents. Consequently, a cold $\overline{\text{PORST}}$ event is issued and the Standby domain is set into reset. EVR Pre-regulator under-voltage violation is indicated in RSTSTAT.STBYR flag.

In case of NMI or SCR Wake-up configuration, the $\overline{\text{PORST}}$ pin triggers a wakeup from Standby if asserted low during Standby state. The SCR is also set into reset. The device boots up ramping up the regulators followed by firmware execution similar to a normal device start-up.

The Standby RAM contents are kept intact after $\overline{\text{PORST}}$ assertion. In case **PMSWSTAT**.STBYRAM bits are set after wake-up, it is ensured that the Standby RAM (CPU0 DSPR) is not initialised after a warm PORST wake-up by Firmware irrespective whether PROCOND.RAMIN / RAMINSEL bits are configured in Flash to initialise the Standby RAM region. Reset is propagated to external devices via the ESR0 pin on exit from Standby mode depending on **PMSWCRO**.ESR0TRIST configuration. Firmware may elongate ESR0 reset output depending on Flash configuration.

7.3.2.5 Power Management Registers

Power Management Control and Status Register

The set of registers used for Power Management control the issue of power modes, manage wake-up configuration and provide status information on mode transitions. The request for Idle, Sleep or Standby mode is issued via PMCSRx registers.

PMCSR0

Power Management Control and Status Register

(0D4_H)

Reset Value: 0000 0100_H

PMCSR1

Power Management Control and Status Register

(0D8_H)

Reset Value: 0000 0100_H

Field	Bits	Type	Function
REQSLP	[1:0]	rwh	<p>Idle Mode and Sleep Mode Request</p> <p>00_B Request CPU Run Mode 01_B Request CPU Idle Mode 10_B Request System Sleep Mode 11_B Request System Standby Mode</p> <p>In Idle Mode or Sleep Mode, these bits are cleared in response to an interrupt for the CPU, or when bit 15 of the corresponding CPU Watchdog Timer register (bit WDTCPUxSR.TIM[15]) changes from 0 to 1. In Standby Mode, these bits are cleared on wake-up. REQSLP maybe written only when either CPU or Safety ENDINIT bits are set to 0. CPU ENDINIT bit has to be set back after REQSLP is written for the mode transition to take place. In case of Safety ENDINIT, the mode transition will be issued immediately and does not wait till Safety ENDINIT is set back to 1 again.</p>
SMUSLP	2	rwh	<p>SMU CPU Idle Request</p> <p>0_B No SMU Alarm request for CPU Idle Mode 1_B SMU Alarm requested CPU Idle Mode</p> <p>This bit is set to '1' when an SMU Alarm requests that the CPU is put into Idle Mode.</p> <p>This bit is NOT cleared in response to an interrupt to the CPU, or when bit 15 of the CPU Watchdog Timer register (bit WDTCPUxSR.TIM[15]) change from 0 to 1. It is cleared only by reset or by a write of '0' to this register. An attempt to write '1' has no effect.</p>

SCREN	16	rw	Standby Controller Enable request 0 _B 8 bit Standby Controller is disabled 1 _B 8 bit Standby Controller is enabled <i>Note: The SCU cold PORST reset value is 0. Firmware initializes the value to 1 and carries out SCR-XRAM initialization after cold PORST event. In case of unsuccessful boot, Firmware resets value to 0.</i>
STBYRAMSEL	[18:17]	rw	Standby RAM supply in Standby Mode 00 _B Standby RAM is not supplied. 01 _B Standby RAM (CPU0 DSPR) is supplied. <i>Note: All other bit combinations are reserved. All other bit combinations are reserved. In case Standby RAM supply is activated, Standby RAM is not initialised after wakeup or PORST irrespective of configuration in PROCOND. RAMINSEL / RAMIN.</i>
SCRCLKSEL	19	rw	Default Clock selection on Standby Mode Entry 0 _B Only 100 KHz Clock Source is active in Standby Mode. 1 _B Both 100 KHz Clock Source and 100 MHz Clock to SCR are active in Standby Mode. SCR CCU divides the clock internally to run at lower frequency.
SCRWKEN	20	rw	Standby Controller Wake-up enable from Standby 0 _B System wake-up via 8 bit Standby Controller is disabled. 1 _B System wake-up is enabled via 8 bit Standby Controller.

Field	Bits	Type	Function
TRISTEN	21	w	Bit protection for Tristate request bit (TRISTREQ) Setting this bit enables that bit TRISTREQ can be changed by a write operation. 0 _B TRISTREQ keeps the previous state and cannot be changed. 1 _B TRISTREQ bit can be changed with a write operation.
TRISTREQ	22	rw	Tristate enable This bit decides whether pads behave as inputs with weak pull-up or tristate on reset assertion/deassertion or Standby- Wake-up transition. 0 _B No request to switch the input pad state of all the pads to tristate from pull-up (default reset state) 1 _B Pad domain in tristate.
PORSTDF	23	rw	PORST Digital Filter enable This bit field enables additional $\overline{\text{PORST}}$ digital filter to provide enhanced immunity against spurious spikes. 0 _B $\overline{\text{PORST}}$ recognition delay = Analog $\overline{\text{PORST}}$ pad filter delay (default reset state). 1 _B $\overline{\text{PORST}}$ recognition delay = Analog $\overline{\text{PORST}}$ pad filter delay + Digital filter delay.
0	24	r	Reserved Read as 0; should be written with 0.
DCDCSYNC	25	rw	DC-DC Synchronisation Enable This bitfield enables the synchronisation clock output to synchronize an external DC DC regulator with respect to the internal SMPS EVR13 regulator. 0 _B DC-DC Synchronisation signal not available. 1 _B DC-DC Synchronisation signal available.
0	[28:26]	r	Reserved Read as 0; should be written with 0.
ESR0TRIST	29	rw	ESR0 Tristate enable This bit configures ESR0 pin behavior either as reset output or tristate during Standby mode. 0 _B ESR0 configured as reset output and is held low during Standby state (default reset state) 1 _B ESR0 in tristate during Standby state.

Field	Bits	Type	Function
0	30	r	Reserved Read as 0; should be written with 0.
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0_B The register is unlocked and can be updated 1_B The register is locked and cannot be updated

Additional PORST digital filter activated via PMSWCR0.PORSTDF bit provides additional filtering of atleast 500 ns to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the PORST pad / pin as documented in the datasheet. After cold PORST this delay is by default inactive.

PMSWCR1
Standby and Wake-up Control Register 1 (0E8_H)
Reset Value: 0100 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0			SCR RST	SCR WDT	SCR ECC	BUS Y	SCRINT								
r			rh	rh	rh	rh	rh								

Field	Bits	Type	Description
SCRINT	[7:0]	r	Data exchange from Standby Controller to SCU. This bit field allows fast data exchange from SCR to SCU/CPUx. The data maybe read by CPUx consequent to an interrupt from the SCR to decode the interrupt. SCRINTEXCHG data from SCR is transferred to this register bitfield except incase of an SCR reset where the old value is retained.
BUSY	8	rh	SCR Arbiter Busy status flag 0 _B SCR RAM is accessible via QSPI interface. 1 _B SCR RAM is not accessible via QSPI as the arbiter is currently busy.

Field	Bits	Type	Description
SCRECC	9	rh	SCR RAM ECC error / reset flag 0 _B No ECC error / reset reported by SCR. 1 _B ECC error / reset was detected in SCR RAM. <i>Note: The flag is cleared when SCR is reset or when RSTST.ECCRST bit is cleared in SCR.</i>
SCRWDT	10	rh	SCR Watchdog Timer error / reset flag 0 _B No WDT error / reset reported by SCR. 1 _B WDT timer error / reset reported by SCR. <i>Note: The flag is cleared when SCR is reset or when RSTST.WDTRST bit is cleared in SCR.</i>
SCRRST	11	rh	SCR Software reset flag 0 _B No SW reset occurred in SCR. 1 _B A SW reset has occurred in SCR. <i>Note: The flag is cleared when SCR is reset or when RSTST.SOFRST bit is cleared in SCR.</i>
TCINT	[23:16]	rw	Data exchange from SCU to Standby Controller. This bitfield allows fast data exchange from SCU to SCR. The data may be read by SCR consequent to an interrupt request (TCINTREQ) from SCU/CPUx to SCR to decode the interrupt.
TCINTREQ	24	rw	SW Interrupt request from SCU to Standby Controller. Setting this bit triggers an interrupt to the 8 bit Standby controller.
SMURST	25	rh	SMU Reset indication flag 0 _B No reset was issued by SMU. 1 _B SMU issued an application or system reset.
RST	26	rh	Application or System Reset indication flag 0 _B No application or system reset occurred. 1 _B An application or system reset has occurred.
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0 _B The register is unlocked and can be updated 1 _B The register is locked and cannot be updated

Field	Bits	Type	Description
0	[30:27], [15:12]	r	Reserved Read as 0; should be written with 0.

0	[1:0]	r	Reserved Read as 0; should be written with 0.
ESR1WKP	2	rh	ESR1 Wake-up flag 0 _B No wake-up event detected on ESR1 input. 1 _B An event as defined by PMSWCR0. ESR1EDCON detected on ESR1 input.
ESR1OVRUN	3	rh	ESR1 Overrun status flag This flag indicates that an ESR1 wake-up event occurred while the last one was not yet serviced. 0 _B No overrun condition detected on ESR1 input. 1 _B An overrun condition detected on ESR1 input.
PINAWKP	4	rh	Pin A (P14.1) Wake-up flag 0 _B No wake-up event detected on Pin A input. 1 _B An event as defined by PMSWCR0. PINAEDCON detected on Pin A input.

Field	Bits	Type	Description
PINAOVRUN	5	rh	Pin A Overrun status flag This flag indicates that an PIN A wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected on Pin A input. 1_B An overrun condition detected on Pin A input.
PINBWKP	6	rh	Pin B (P15.1) Wake-up flag 0_B No wake-up event occurred on the Pin B input. 1_B An event as defined by PMSWCR0.PINBEDCON detected on Pin B input.
PINBOVRUN	7	rh	Pin B Overrun status flag This flag indicates that an PIN B wake-up event occurred while the last one was not yet serviced. 0_B No overrun condition detected on Pin B input. 1_B An overrun condition detected on Pin B input.
0	8	r	Reserved Read as 0; should be written with 0.
PORSTDF	9	rh	PORST Digital Filter status This bit field indicates whether additional $\overline{\text{PORST}}$ digital filter is activated. This bit is updated when PMSWCR0.PORSTDF is set. 0_B $\overline{\text{PORST}}$ recognition delay = Analog $\overline{\text{PORST}}$ pad filter delay (default reset state). 1_B $\overline{\text{PORST}}$ recognition delay = Analog $\overline{\text{PORST}}$ pad filter delay + Digital filter delay.
HWCFGGEVR	[12:10]	rh	EVR Hardware Configuration This bit field indicates the supply configuration latched by the EVR from HWCFG[2:0] during a cold startup. The latched configuration is used during STANDBY-RUN transition to reselect EVR mode. HWCFG[0] is tied to "1" in case of TC22x. .
STBYRAM	[14:13]	rh	Standby RAM Supply status This bit field indicates whether Standby RAM is supplied during Standby Mode and to infer status after a wake-up event. This bit is updated when PMSWCR0.STBYRAMSEL is set. 00_B Standby RAM is not supplied. 01_B Standby RAM (CPU0 DMI) is supplied. $1x_B$ Reserved, do not use this combination.

Field	Bits	Type	Description
TRIST	15	rh	<p>Pad Tristate / Pull-up status</p> <p>This bit indicates whether pads are configured as inputs with weak pull-up or as tristate during/after reset or after wake-up. At start-up, the value latched from HWCFG[6] pin decides the default state. This bit is updated when PMSWCR0.TRISTREQ is set.</p> <p>0_B Pads configured as inputs with weak pull-up. 1_B Pads are in tristate.</p>
SCRST	16	rh	<p>Standby Controller Reset Indication flag</p> <p>This bit is set after a power-on reset as SCR is in reset state.</p> <p>0_B No reset of Standby controller took place. 1_B Reset of Standby controller took place.</p>
SCRWKP	17	rh	<p>SCR Wake-up flag</p> <p>In case wake-up is triggered by SCR of the main controller, this flag is set.</p> <p>0_B No wake-up event has taken place. 1_B A wake-up event occurred.</p>
SCR	18	rh	<p>Standby Controller status</p> <p>This bit indicates whether SCR is enabled. This bit is updated when PMSWCR0.SCREN bit is set.</p> <p>0_B 8 bit Standby Controller is disabled 1_B 8 bit Standby Controller is enabled</p>
SCRWKEN	19	rh	<p>Standby Controller Wake-up Enable status</p> <p>This bit indicates that SCR is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.SCRWKEN bit is set.</p> <p>0_B Wake-up from Standby via SCR is disabled. 1_B Wake-up from Standby via SCR is enabled.</p>
ESR1WKEN	20	rh	<p>ESR1 Wake-up enable status</p> <p>This bit indicates that ESR1 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR1WKEN bit is set.</p> <p>0_B Wake-up from Standby via ESR1 is disabled. 1_B Wake-up from Standby via ESR1 is enabled.</p>

Field	Bits	Type	Description
PINAWKEN	21	rh	Pin A Wake-up enable status This bit indicates that PINA is enabled to trigger wake-up from Standby. This bit is updated when PMSWCRO.PINAWKEN bit is set. 0 _B Wake-up from Standby via PINA is disabled. 1 _B Wake-up from Standby via PINA is enabled.
PINBWKEN	22	rh	Pin B Wake-up enable status This bit indicates that PINB is enabled to trigger wake-up from Standby. This bit is updated when PMSWCRO.PINBWKEN bit is set. 0 _B Wake-up from Standby via PINB is disabled. 1 _B Wake-up from Standby via PINB is enabled.
0	[26:23]	r	Reserved Read as 0; should be written with 0.
ESR0TRIST	27	rh	ESR0 pin status during Standby This bit indicates if ESR0 pin is configured as reset output or tristate during Standby mode & transitions. This bit is updated when PMSWCRO.ESR0TRIST is set. 0 _B ESR0 configured as reset output and is held low during Standby state (default reset state) 1 _B ESR0 in tristate during Standby state.
0	28	r	Reserved Read as 0; should be written with 0.
0	[31:29]	r	Reserved Read as 0; should be written with 0.

- 1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)
- 2) All EVR registers excluding status registers have corresponding shadow registers in the EVR Standby domain. After a cold PORST, a read of these registers may return the reset value or the value updated by the Firmware. The reset value reflects the default isolation value in the shadow register. Otherwise, a read will provide the value of the most recent write operation.

7.4 System Control Unit (SCU)

The System Control Unit (SCU) of the TC26x B-Step contains miscellaneous control registers associated with other system functions.

This includes:

- External Request and Cross-triggering Unit (ERU) (see [Section 7.4.1](#))
- CPU Lockstep Comparator Logic (LCL) (see [Section 7.4.2](#))
- Die Temperature Sensor (DTS) (see [Section 7.4.3](#))
- Watchdog Timers (WDTx) (see [Section 7.4.4](#))
- Emergency Stop (EMS) (see [Section 7.4.5](#))
- Logic Built-in-Self-Test (LBIST) (see [Section 7.4.6](#))
- Overlay Control (OVC) (see [Section 7.4.7](#))
- Miscellaneous System Control Registers (see [Section 7.4.8](#))
- SCU register overview table (see [Table 7-28](#))

7.4.1 External Request Unit (ERU)

The External Request Unit (ERU) is a versatile event and pattern detection unit. Its major task is the **generation of interrupts based on selectable trigger events at different inputs**, e.g. to generate external interrupt requests if an edge occurs at an input pin. The detected events can also be used by other modules to trigger or to gate module-specific actions.

7.4.1.1 Introduction

The ERU of the TC26x B-Step can be split in three main functional parts:

- 8 independent **Input Channels x** for input selection and conditioning of trigger or gating functions
- Event distribution: A **Connecting Matrix** defines the events of the Input Channel x that lead to a reaction of an Output Channel y.
- 8 independent **Output Channels y** for combination of events, definition of their effects and distribution to the system (interrupt generation, ...)

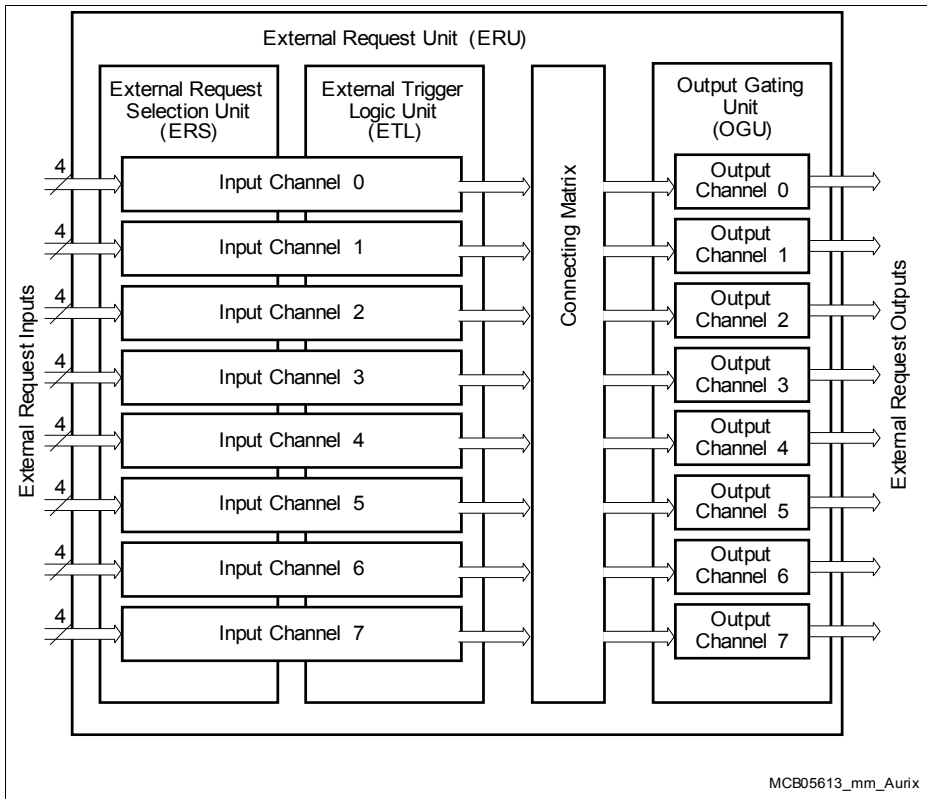

Figure 7-39 External Request Unit Overview

These tasks are handled by the following building blocks:

- An **External Request Select Unit (ERSx)** per Input Channel allows the selection of one input vector out of the 4 possible available inputs.
- An **Event Trigger Logic (ETLx)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events (event detected = event flag becomes set, independent of the polarity of the original input signals).
- The **Connecting Matrix** distributes the events and status flags generated by the Input Channels to the Output Channels.
- An **Output Gating Unit (OGUy)** per Output Channel that combines the available trigger events and status information from the Input Channels. An event of one Input Channel can lead to reactions of several Output Channels, or also events of several

Input Channels can be combined to a reaction of one Output Channel (pattern detection).

Different types of reactions are possible, e.g. interrupt generation (based on signals ERU_IOUTy).

7.4.1.2 ERU Input Pin Connections

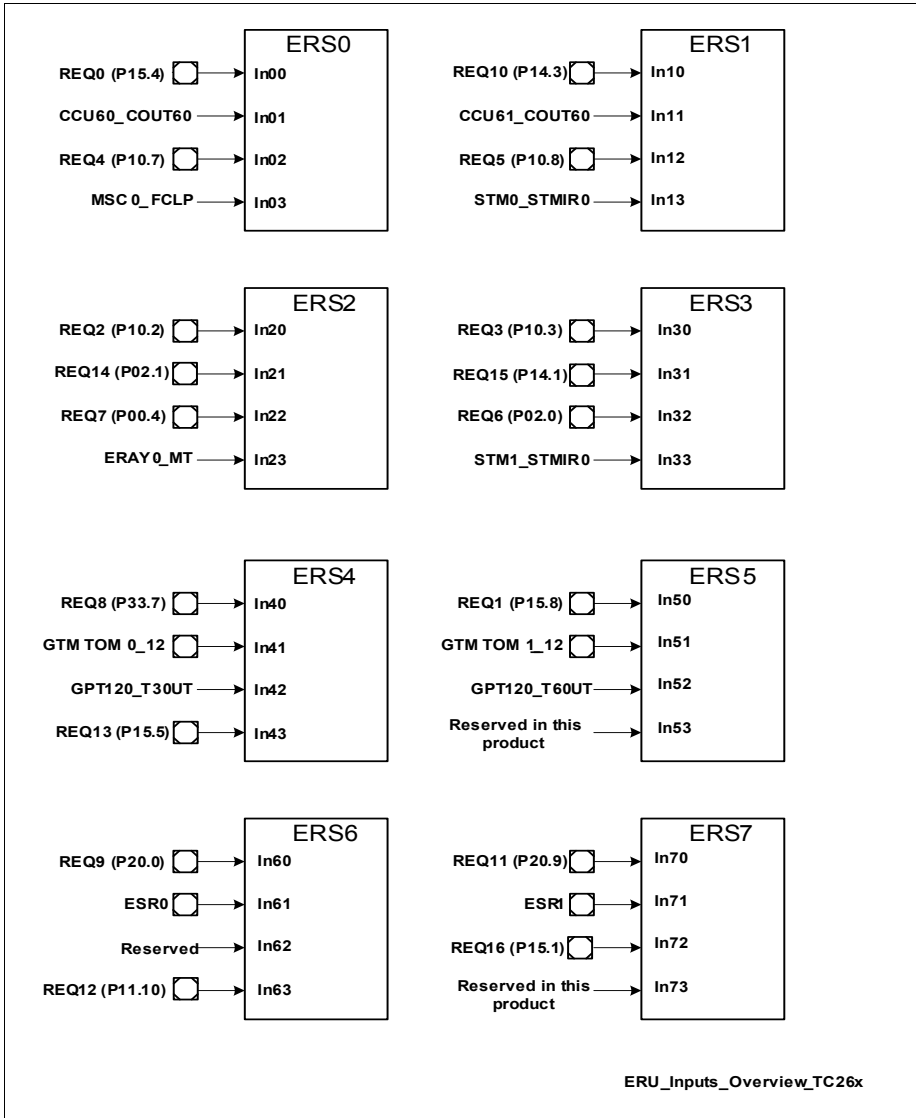

Figure 7-40 External Request Unit Input Connections for TC26x

The inputs to the ERU can be selected from a large number of input signals. 16 of these inputs come directly from input REQx ports, but other inputs come from various peripheral module status signals. Usually, such inputs would be selected for an ERU function when the module input function is not used by the application, or when the module is not used at all. However, it is also possible to select an input which is also used by the other module, to also be used in the ERU as a trigger or to be combined with other signals (e.g. to generate an interrupt trigger when a start-of-frame is detected on a selected communication interface input).

7.4.1.3 External Request Selector Unit (ERS)

Each ERS selects one of four inputs as the one input signal of the respective input channel. **Figure 7-41** shows the structure of this block.

Figure 7-41 External Request Select Unit Overview

The ERS unit for channel x is controlled via bit field EICRy.EXISx.

7.4.1.4 Event Trigger Logic (ETL)

For each Input Channel x, an event trigger logic ETLx derives a trigger event and a status from the input channel x delivered by the associated ERSx unit. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).

Each pair of the four ETL units has an associated EICRy register, that controls all options of an ETL (the register also holds control bits for the associated ERS unit pair, e.g. EICR0 to control ESR0 and ESR1 plus and ETL0 and ETL1).

Figure 7-42 Event Trigger Logic Overview

When the selected event (edge) is detected, the status flag EIFR.INTFx becomes set. The status flag is cleared automatically if the “opposite” event is detected, if so enabled via bit EICRy.LDENx = 1. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).

The output of the status flag is connected to all following Output Gating Units (OGUz) in parallel (see [Figure 7-43](#)) to provide **pattern detection capability of all OGUz** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxz of ETLx can be enabled (by bit EICRy.EIENx) and selected to **trigger actions in one of the OGUz** units. The target OGUz for the trigger is selected by bit field EICRy.INPx.

The trigger becomes active when the selected edge event is detected, independently from the status flag EIFR.INTFx.

7.4.1.5 Connecting Matrix

The connecting matrix distributes the trigger signals (TRxy) and status signals (EIFR.INPFx) from the different ETLx units between the OGUy units. [Figure 7-43](#) provides a complete overview of the connections between the ETLx and the OGUz units.

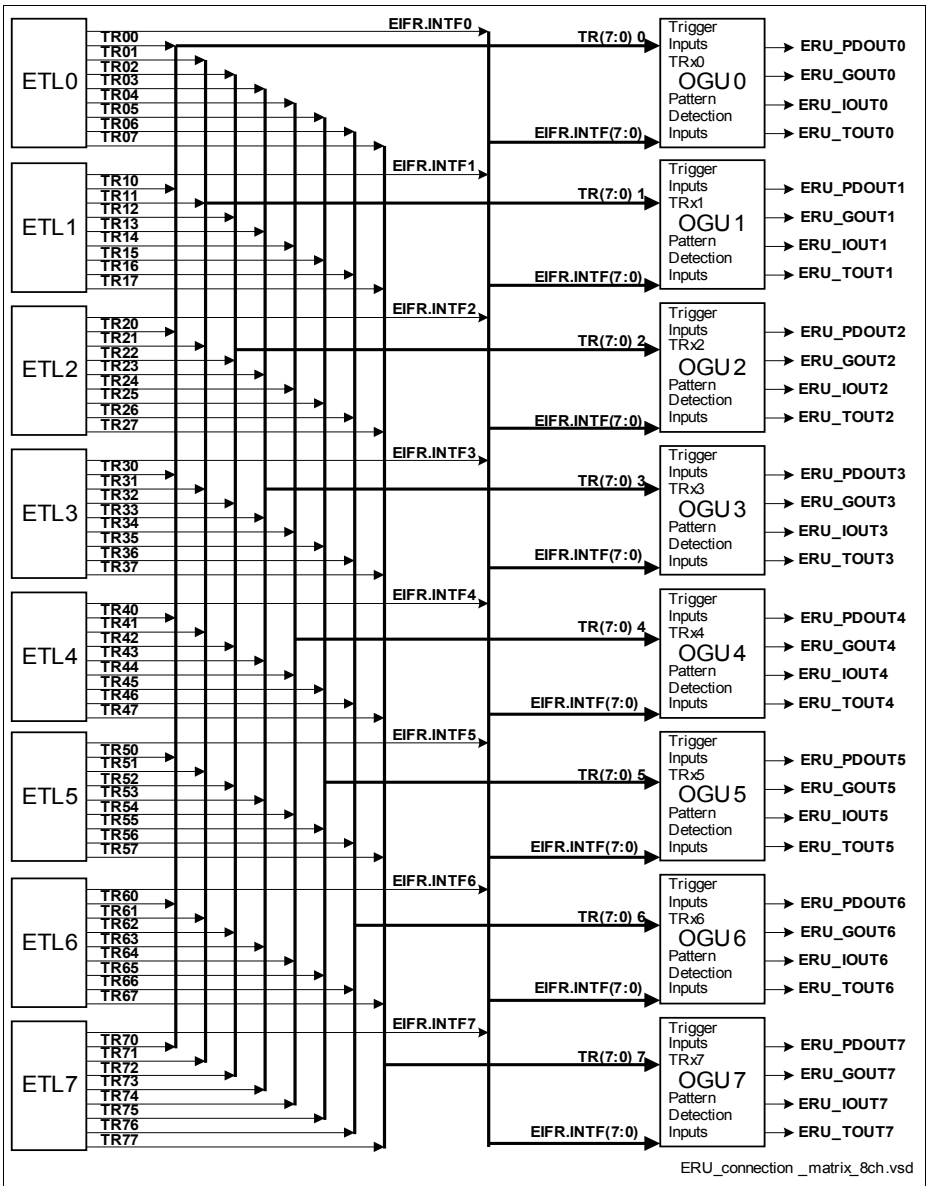

Figure 7-43 Connecting Matrix between ETLx and OGUy

7.4.1.6 Output Gating Unit (OGU)

Each OGUy unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. [Figure 7-44](#) illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by the associated IGCRm registers, one for each pair of output channels e.g. IGCR1 for OGU2 and OGU3. The function of an OGUy unit can be split into two parts:

- **Trigger combination:**
All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy and a pattern change event (if enabled) are logically OR-combined.
- **Pattern detection:**
The status flags EIFR.INTFx of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

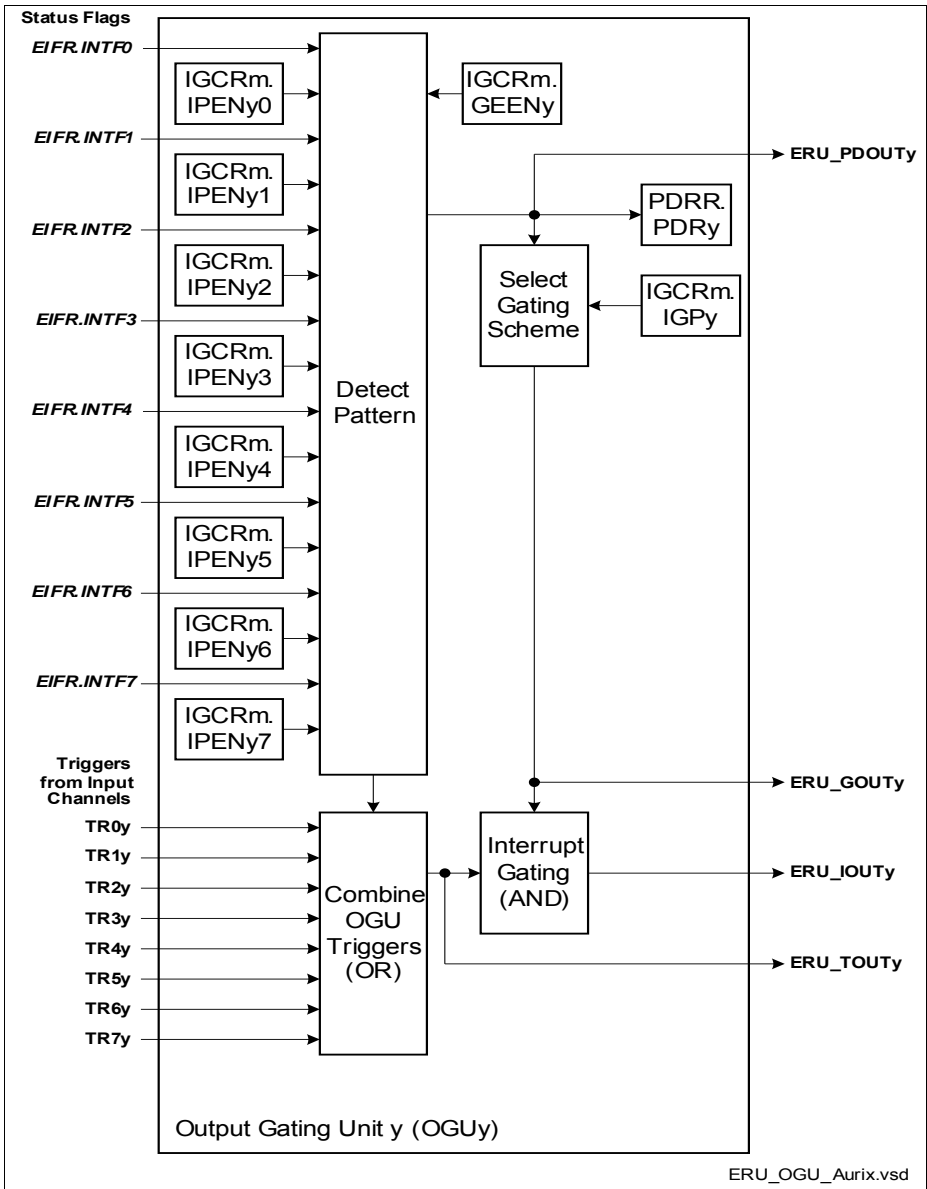

Figure 7-44 Output Gating Unit for Output Channel *y*

Each OGUy units generates 4 output signals that are distributed to the system.

- **ERU_PDOUTy** to directly output the pattern match information for gating purposes in other modules (pattern match = 1).
- **ERU_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU_IOUTy** as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger interrupts (e.g. the interrupt generation can be gated to allow interrupt activation during a certain time window).

Trigger Combination

The trigger combination logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units.
- In the case that at least one **pattern detection** input is enabled (IGCRm.IPENxy) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by IGCRm.GEENy).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an interrupt or to start an ADC conversion. This combination capability allows the generation of an interrupt per OGU that can be triggered by several inputs (multitude of request sources -> one reaction).

Pattern Detection

The pattern detection logic allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, via control bits IGCRm.IPENxy. The pattern detection block outputs the following pattern detection results:

- **Pattern match** (PDRR.PDRy = 1 and ERU_PDOUTy = 1):
A pattern match is indicated while all status flags that are included in the pattern detection are 1.
- **Pattern miss** (PDRR.PDRy = 0 and ERU_PDOUTy = 0):
A pattern miss is indicated while at least one of the status flags that are included in the pattern detection is 0.

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by IGCRm.GEENy = 1). The

pattern result change event is logically OR-combined with the other enabled trigger events to support interrupt generation or to trigger other module functions (e.g. in an ADC). The event is indicated when the pattern detection result changes and PDRR.PDRy becomes updated.

The interrupt generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of interrupts during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, interrupts can be issued on a regular time base while a combination of input signals occurs (pattern detection based on ETLx status bits).

Only four interrupt/service requests are generated by the ERU. The mapping of interrupt requests to OGUy blocks is shown in the ERU connection diagram.

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of interrupt requests ERU_IOUTy under different conditions:

- **Pattern match** (IGCRm.IGPy = 10_B):
An interrupt request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** (IGCRm.IGPy = 11_B):
An interrupt request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection (IGCRm.IGPy = 01_B):
In this mode, each occurring trigger event leads to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with interrupt requests on trigger events).
- **No interrupts** (IGCRm.IGPy = 00_B, default setting)
In this mode, an occurring trigger event does not lead to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without interrupt requests on trigger events).

7.4.1.7 ERU Output Pin Connections

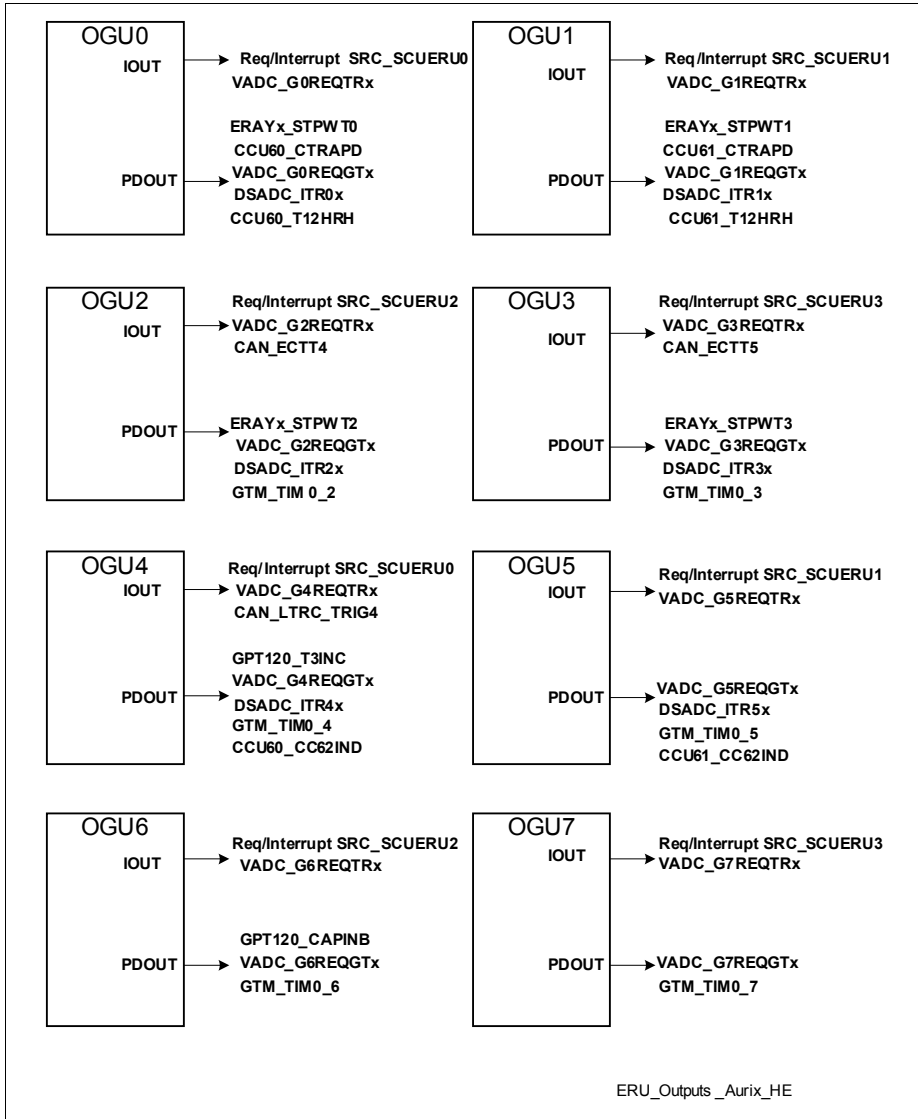

Figure 7-45 External Request Unit Output Connections for TC26x

7.4.1.8 External Request Unit Registers

The External Input Channel Registers EICR_i (i=0 to 3) for the 4 external input channels contain bits to configure the external request selection ERS and the event trigger logic ETL.

7.4.2 Lockstep CPU Configuration

This section contains the registers which are used to configure and enable CPU Lockstep Mode. These registers are only writeable by start-up firmware and are configured from the BMI . See the Firmware and Lockstep Control Logic chapters for further details.

7.4.2.1 Logic Monitor Control Registers

LCL CPU0 Control

Provides control for CPU0 lockstep compare logic block.

LCLCON0

LCL CPU0 Control Register

(134_H)

Reset Value: 8000 0000_H

Field	Bits	Type	Description
0	[15:0]	r	Reserved will be read as 0 _B , should be written as 0 _B
LS	16	r	Reserved in this product will be read as 0 _B , should be written as 0 _B
0	[30:17]	r	Reserved will be read as 0 _B , should be written as 0 _B
LSEN	31	rw	Reserved in this product will be read as 1 _B , should be written as 1 _B

LCL Test Register

Provides the capability for software to inject a fault condition into the comparators of each lockstep compare logic block. The implementation should generate a single cycle fault each time the bit is written with '1'.

LCLTEST

LCL Test Register

(13C_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:2]	r	Reserved
LCLT0	0	r	Reserved in this product
LCLT1	1	rwh	LCL1 Lockstep Test Fault injection for LCL1. Reads as zero. 0 _B No action 1 _B Inject single fault in LCL1

Critical Register Monitoring

Safety critical SCU registers are protected by the Safety Endinit signal against accidental software writes. In addition to this, a continuous monitoring mechanism is provided to check the content of these safety critical registers have not been affected by random single bit flip-flop failures. This mechanism is controlled by the SMU.

The System Control registers with write access mode "SE" listed in [Table 7-28](#) are covered by this mechanism. This includes:

- CCU registers OSCCON, PLLCONx, PLLERAYCONx, CCUCONx, FDR, EXTCON
- RCU registers RSTCON, ARSTDIS, SWRSTCON, RSTCONx, ESRCFGx, ESROCFG, PDISC
- EVR registers EVRRSTCON, EVRSDCOEFF*, EVRSDCTRL*, EVRTRIM, EVR13CON, EVR33CON
- PMC registers PMSWCRx, PMCSRx, PMSWSTATCLR
- Emergency Stop register EMSR
- Registers controlling safety monitors WDTSCONx1, WDTCPU*CON1, LBISTCTRLx, EVRUVMON, EVROVMON
- MTU registers MEMTEST, MEMMAP, MEMSTAT, ECCS and RAR

Any single bit flipflop failures will be reported via an SMU alarm.

7.4.3 Die Temperature Measurement

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The result of the measurement is displayed via bit field DTSSTAT.RESULT. In order to start one measurement bit DTSCON.START needs to be set.

The DTS has to be enabled before it can be used via bit DTSCON.PWD. When the DTS is powered after the start-up time of the DTS (defined in the Data Sheet) a temperature measurement can be started.

Note: If bit field DTSSTAT.RESULT is read before the first measurement was finished it will return 0x000.

When a measurement is started the result is available after the measurement time passed. If the DTS is ready to start a measurement can be checked via bit DTSSTAT.RDY. If a started measurement is finished or still in progress is indicated via the status bit DTSSTAT.BUSY. The measurement time is also defined in the Data Sheet.

In order to adjust production variations bit field DTSCON.CAL is available. DTSCON.CAL is automatically programmed with a predefined value.

Note: The first measurement after the DTS was powered delivers a result without calibration adjustment and should be ignored therefore.

The formula to calculate the die temperature is defined in the Data Sheet.

Note: The maximum resolution is only achieved for a measurement that is part of multiple continuous measurements (recommended to ignore are two here).

An interrupt service request (SRC_SCUDTS) is generated when DTS busy indication changes from 1 to 0.

7.4.3.1 Die Temperature Sensor Register

DTSCON

Die Temperature Sensor Control Register(0E4_H)

Reset Value: 0000 0001_H

Field	Bits	Type	Description
PWD	0	rw	Sensor Power Down This bit defines the DTS power state. 0 _B The DTS is powered 1 _B The DTS is not powered
START	1	w	Sensor Measurement Start This bit starts a measurement of the DTS. 0 _B No DTS measurement is started 1 _B A DTS measurement is started If set this bit is automatically cleared. This bit always reads as zero.
CAL	[25:4]	rw	Calibration Value This bit field interfaces the calibration values to the DTS.

Field	Bits	Type	Description
SLCK	31	rw	Security Lock 0_B No lock active 1_B Lock is active If this bit is set, no bits in this register (except START) are writeable. Attempted writes when LCK is set will cause an SMU SPB error alarm trigger. This bit can not be cleared by software. This bit can only be set by an access from the HSM master ($TAG = 001101_B$). A set operation performed by any other master is ignored and the bit is not modified.
0	[3:2], [30:24]	r	Reserved Read as 0; should be written with 0.

DTSSTAT
Die Temperature Sensor Status Register(0E0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
RESULT	[9:0]	rh	Result of the DTS Measurement This bit field shows the result of the DTS measurement. The value given is directly related to the die temperature. Only the bit [9:2] have to be evaluated.
RDY	14	rh	Sensor Ready Status This bit indicate the DTS is ready or not. 0_B The DTS is not ready 1_B The DTS is ready

Field	Bits	Type	Description
BUSY	15	rh	Sensor Busy Status This bit indicate the DTS is currently busy or not. If the sensor is busy currently a measurement is running and the result should not be used. 0_B The DTS is not busy 1_B The DTS is busy <i>Note: This bit is updated 2 cycles after bit DTSCON.START is set.</i>
0	[13:10] , [31:16]	r	Reserved Read as 0; should be written with 0.

DTSLIM
Die Temperature Sensor Limit Register(240_H)
Reset Value: 03FF 0000_H

Field	Bits	Type	Description
LOWER	[9:0]	rw	Lower Limit This bit field defines the lower limit of the DTS temperature check. The DTS measurement result is compared against this value and if the measurement result is smaller than LOWER bit LLU is set.

Field	Bits	Type	Description
LLU	15	rwh	<p>Lower Limit Underflow</p> <p>0_B No temperature underflow was detected 1_B A temperature underflow was detected When this bit is set an HSM temperature underflow trigger is generated. When this bit is set an temperature SMU DTS alarm trigger is generated. This bit is cleared by writing a zero. Writing a one has no effect. This bit is updated when either a DTS measurement is finished or if bit field LOWER is changed.</p>
UPPER	[25:16]	rw	<p>Upper Limit</p> <p>This bit field defines the upper limit of the DTS temperature check. The DTS measurement result is compared against this value and if the measurement result is greater than UPPER bit UOF is set</p>
SLCK	30	rw	<p>Security Lock</p> <p>0_B No lock active 1_B Lock is active If this bit is set both bit fields LOWER and UPPER can not longer be written. Write requests when LCK is set will cause a SMU SPB error alarm trigger. This bit can not be cleared by software. This bit can only be set by an access from the HSM master (TAG = 001101_B). A set operation performed by any other master is ignored and the bit is keep as cleared.</p>
UOF	31	rh	<p>Upper Limit Overflow</p> <p>0_B No temperature overflow was detected 1_B A temperature overflow was detected When this bit is set an HSM temperature overflow trigger is generated. When this bit is set an SMU DTS alarm trigger is generated. This bit is cleared by writing a zero. Writing a one has no effect. This bit is updated when either a DTS measurement is finished or if bit field UPPER is changed.</p>

0	[14:10] , [29:26]	r	Reserved Read as 0; should be written with 0.

7.4.4 Watchdog Timers

This section describes the TC26x B-Step Watchdog Timers (WDTs). Topics include an overview of the WDT functions and descriptions of the registers, the password-protection scheme, accessing registers, modes, and initialization.

The TC26x B-Step contains the following Watchdog Timers:

- Safety Watchdog
- CPU0 Watchdog
- CPU1 Watchdog

7.4.4.1 Watchdog Timers Overview

The WDTs provide a highly reliable and secure way to detect and recover from software or hardware failure. The WDTs help to abort an accidental malfunction of a CPU or TC26x B-Step system within a user-specified time period.

In addition to this standard “Watchdog” function, each of the WDTs incorporates an End-of-Initialization (ENDINIT) feature which can protect critical registers from accidental writes.

Servicing the Watchdogs and modifying the ENDINIT bits are critical functions that must not be allowed in case of a system malfunction. To protect these functions a sophisticated scheme is implemented that requires a password and guard bits during accesses to the WDT control registers. Any write access that does not deliver the correct password or the correct value for the guard bits is regarded as a malfunction of the system, and results in a watchdog alarm. In addition, even after a valid access has been performed and an ENDINIT bit has been cleared to provide access to the critical registers, the Watchdog imposes a time limit for this access window. If the ENDINIT bit has not been properly set again before this limit expires, the system is assumed to have malfunctioned, and a Watchdog alarm is reported to the Safety Management Unit (SMU). These stringent requirements, although not guaranteed, nonetheless provide a high degree of assurance of the robustness of system operation.

Configuration options are available which enable a Watchdog service to additionally check code execution sequence and intermediate code execution time. If these checks are enabled then any incorrect sequence or out-of-limit execution time will also result in an SMU alarm request.

Expiry of any of the TC26x B-Step WDTs leads to an SMU alarm request. It is possible to program the SMU to provide an interrupt or NMI to provide some time for recovery or status recording before further action is taken (eg reset of the device or stopping of the CPU via idle request).

Safety Watchdog

The Safety Watchdog Timer provides an overall system level watchdog which is independent from the CPU watchdogs and also provides temporal protection against

unintended writes to critical system registers which could have impact on safety-critical systems. When the Safety WDT is enabled, it can cause an SMU alarm request if it is not serviced within a user-programmable time period. A CPU must service the Safety WDT within this time interval to prevent this. The response to a Safety WDT timeout is configurable within the SMU. Hence, periodic servicing of the Safety WDT confirms that the system is functioning as expected.

Typically the SCU write protection (ACCEN) will be configured so that only restricted "Safety" CPU(s) can configure system-critical functionality. This includes the ability to service the Safety Watchdog. In addition, Safety Watchdog disable/enable/configuration function requires a Safety ENDINIT password.

The registers marked "SE" in [Table 7-28](#) and other module Register Tables are considered to be static properties of a safety-critical system and are all write-protected by the Safety ENDINIT feature so that they cannot be changed without unlocking the Safety Watchdog.

CPU Watchdogs

The individual CPU Watchdog Timers provide the ability to monitor separate CPU execution threads without the need for software to co-ordinate the shared use of a common watchdog. Each CPUx watchdog timer also incorporates a local CPUx_Endinit feature which provides temporal protection against unintended writes to critical local CPU registers and also some system registers which require protection but are not already covered by the Safety ENDINIT.

When a CPU WDT is enabled it can cause an SMU alarm request if it is not correctly serviced within a user-programmable time period. The CPU must service its CPU WDT within this time interval to prevent this. The response to each CPUx watchdog timeout is configurable within the SMU. Hence, periodic servicing of a CPU WDT confirms that the corresponding CPU is executing a software sequence as expected.

After a reset, CPU0 runs and CPU0 watchdog timer starts automatically. Other CPUs are initially in a HALT state and therefore their corresponding Watchdog Timers are disabled. The other CPU Watchdogs are not configured to generate a time-out reset by default, but this can be enabled (See SMU section). A CPU Watchdog may only be configured, enabled or disabled by its corresponding CPU.

7.4.4.2 Features of the Watchdog Timers

The main features of the WDTs are summarized here.

- 16-bit Watchdog counter
- Selectable input frequency: $f_{SPB}/64$, $f_{SPB}/256$ or $f_{SPB}/16384$
- 16-bit user-definable reload value for normal Watchdog operation, fixed reload value for Time-Out Mode
- Incorporation of the corresponding ENDINIT bit and monitoring of its modifications
- Sophisticated Password Access mechanism with user-definable password fields
- Access Error Detection: Invalid password (during first access) or invalid guard bits (during second access) trigger an alarm request to the SMU
- Temporal and logical monitoring capabilities:
 - Optional Code Sequence checking. An incorrect code sequence signature identification will trigger an alarm request to the SMU
 - Optional Code Execution Time checking. Code execution times out of expected limits will trigger an alarm request to the SMU.
- Overflow Error Detection: An overflow of the WDT counter triggers an alarm request to the SMU
- Watchdog function can be disabled; access protection and ENDINIT bit monitor function remain enabled
- Configurable mechanism to prevent Watchdog reloads after an unserviced safety warning alarm to ensure that unserviced warnings lead to an SMU hardware response
- External “Alive heartbeat” indication to show that WDT is running and SMU is not in alarm mode

7.4.4.3 The Endinit Functions

There are a number of registers in the TC26x B-Step that are usually programmed only once during the initialization sequence of the system or application. Modification of such registers during normal application run can have a severe impact on the overall operation of modules or the entire system.

While the Supervisor Mode and the Access Protection scheme provide a certain level of protection against unintentional modifications, they may not be sufficient to protect against all unintended accesses to system-critical registers.

The TC26x B-Step provides one more level of protection for such registers via the various Endinit features. This is a highly secure write-protection scheme that makes unintentional modifications of registers protected by this feature nearly impossible.

The Endinit feature consists of an ENDINIT bit incorporated in each WDT control register. Registers protected via an Endinit determine whether or not writes are enabled. Writes are only enabled if the corresponding ENDINIT = 0 AND Supervisor Mode is active. Write attempts if this condition is not true will be discarded and the register

contents will not be modified in this case. The BCU controls the further operation following a discarded write access.

To get the highest level of security, writes to the ENDINIT bits are protected by a highly secure access protection scheme implemented in the WDTs. This is a complex procedure, that makes it nearly impossible for ENDINIT bits to be modified unintentionally. In addition, each WDT monitors ENDINIT bit modifications by starting a time-out sequence each time software opens access to the critical registers through clearing the corresponding ENDINIT bit. If the time-out period ends before the corresponding ENDINIT bit is set again, a malfunction of the software is assumed and a Watchdog fault response is generated.

The access-protection scheme and the Endinit time-out operation of the WDTs is described in the following sections. In the register overview tables for each module (including the SCU itself) the registers which are protected via each Endinit type are identified in the column describing write accesses as follows:

- “CE0” - writeable only when CPU0 ENDINIT bit is zero
- “CE1” - writeable only when CPU1 ENDINIT bit is zero
- “E” - writeable when any (one or more) CPUx ENDINIT bit is zero
- “SE” - writeable only when Safety ENDINIT bit is zero
- None of the above - accessible at any time

Note: The clearing of an ENDINIT bit takes some time. Accesses to Endinit-protected registers after the clearing of an ENDINIT bit must only be done when the ENDINIT bit is really cleared. As a solution the ENDINIT bit should be read back once before Endinit-protected registers are accessed the first time after bit ENDINIT has been cleared.

Password Access to WDTxCON0

A correct password must be written to register WDTxCON0 (x=S,CPU0,CPU1) in order to unlock it for modifications. Software must either know the correct password in advance or compute it at runtime. The passwords for each of the Watchdogs (x=S,CPU0,CPU1) can be different in order to provide independent watchdog functionality program flows to have independent watchdog functions.

The Safety Watchdog password register WDTSCON0 is protected by the generic SCU protection scheme which allows only configured master(s) to have write access (See [ACCENO](#)).

CPU-specific Watchdog password registers WDTCPUyCON0 are individually protected such that they may only be written by the corresponding CPUy

A watchdog may be used within a safety application to provide a recovery time period during which software might attempt to recover from a safety alarm warning. To ensure that a CPU fault could not allow a fault to be ignored an option is provided to prevent watchdog unlocking if the Safety Management Unit (SMU) is not in the RUN state. This option may be enabled by bit WDTxCON0.UR.

If the password is valid and the SMU state meets the requirements of the WDTxCON0.US bit then WDTxCON0 will be unlocked as soon as the Password Access is completed. The unlocked condition will be indicated by WDTxCON0.LCK = 0. To ensure the correct servicing sequence, a password access is only permitted when the WDTxCON0.LCK bit was set prior to the access.

If an improper password value is written to WDTxCON0 during the Password Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

The 14-bit user-definable password, WDTxCON0.PW, provides additional options for adjusting the password requirements to the application's needs. It can be used, for instance, to detect unexpected software loops, or to monitor the execution sequence of routines.

[Table 7-24](#) summarizes the requirements for the password. Various options exist, which are described in more detail below

Table 7-24 Password Access Bit Pattern Requirements

Bit Position	Required Value
[1:0]	Fixed; must be written to 01 _B
[15:2]	<p>If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read from WDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8]</p> <p>If PAS=1: Must be written with Expected Next Sequence Password</p>
[31:16]	<p>If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL</p> <p>If TCS=1: Must be written with inverted estimate of the WDT count value, WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value</p>

Static Password

In the static password mode (WDTxSR.PAS=0) the password can only be changed by a valid Modify Access. The Password Access has been designed such that it is not possible simply to read the register and re-write it. Some of the password read bits must be inverted (toggled) before being re-written. This prevents a simple malfunction from accidentally unlocking the WDT through a simple read/write sequence.

Automatic Password Sequencing

If automatic password sequencing is enabled (WDTxSR.PAS=1) then the password changes automatically after each password check (i.e. Password Access or Check Access). The Expected Next Password follows a pseudo-random sequence based upon a 14-bit Fibonacci LFSR (Linear Feedback Shift Register) with characteristic polynomial $x^{14}+x^{13}+x^{12}+x^2+1$. An initial password (or subsequent manual password updates) can also be provided by Modify Accesses.

Figure 7-46 Password Sequencing LFSR

Time-Independent Password

If time checking is not enabled (WDTxSR.TCS=0) then the REL field of the WDTxCON0 register must be simply re-written with the existing reload value during the Password Access.

Time Check Password

If time checking is enabled (WDTxSR.TCS=1) the the REL field of the WDTxCON0 register must be written with an inverted (bitflipped) estimate of the current WDT count value. The acceptable margin of error of this estimate (in WDT clock periods) is specified by the value of WDTxSR.TCT. If the written estimate is outside the range WDTxSR.TIM +/- WDTxSR.TCT, then an SMU alarm condition is indicated. This mechanism can provide a check of the elapsed program execution time since the last WDT restart. Note that a Time Check comparison is still required for a Password or Check Access while the WDT is operating in Time-Out mode (e.g. After accessing ENDINIT-protected registers).

Check Access to WDTxCON0

A Check Access is identical to a Password Access except that the lock bit is not cleared and a subsequent Modify Access is therefore not allowed. A Check Access does not trigger an SMU Alarm Request provided that the write data requirements are satisfied. A Check Access may only be performed when the LCK bit is set.

This type of access is used for intermediate checkpoints between WDT services. This may be used (e.g. in conjunction with the timestamp count checking feature or sequence passwords) for task sequence or execution time monitoring.

Table 7-25 Check Access Bit Pattern Requirements

Bit Position	Required Value
[1:0]	Fixed; must be written to 11 _B
[15:2]	<p>If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read from WDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8]</p> <p>If PAS=1: Must be written with Expected Next Sequence Password</p>
[31:16]	<p>If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL</p> <p>If TCS=1: Must be written with inverted estimate of the WDT counter WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value</p>

If an improper value is written to WDTxCON0 during the Check Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

Modify Access to WDTxCON0

If a WDTxCON0 is successfully unlocked by a Password Access, the following write access to WDTxCON0 can modify it. However, this access must also meet certain requirements in order to be accepted and regarded as valid. [Table 7-26](#) lists the required bit patterns. If the access does not follow these rules, a Watchdog Access Error condition is detected, bit WDTxSR.AE is set, and an alarm request is sent to the Safety Management Unit (SMU).

Table 7-26 Modify Access Bit Pattern Requirements

Bit Position	Value
0	User-definable; desired value for bit WDTxCON0.ENDINIT.
1	Fixed; must be written with 1 _B .
[15:2]	User-definable; desired value of user-definable password field, WDTxCON0.PW.
[31:16]	User-definable; desired value of user-definable reload value, WDTxCON0.REL.

After the Modify Access has completed, WDTxCON0.LCK is set again, automatically re-locking WDTxCON0. Before the register can be modified again, a valid Password Access must be executed again.

External WDT “Alive Heartbeat” Indication

The current state of the SAFECON.HBT bit may optionally be routed to external pin(s). This register may only be written during a Safety WDT service (between a Modify Access with Safety ENDINIT=0 and the subsequent Modify Access with Safety ENDINIT=1). Periodic toggling of this bit by software can therefore be used to indicate to an external monitor that the CPU is operational and the Safety Watchdog Timer is still running. If the Unlock Restriction (UR bit) is also enabled then any other SMU safety alarm condition will prevent a WDT refresh and hence stop the heartbeat automatically.

Access to Endinit-Protected Registers

If write access to Endinit-protected registers is required during run time, write access can be re-enabled for a limited time period. To re-enable access, WDTxCON0 must first be unlocked with a valid Password Access. In the subsequent valid Modify Access, ENDINIT can be cleared. Access to Endinit-protected registers is now open again. However, when WDTxCON0 is unlocked, the WDT is automatically switched to Time-Out Mode. The access window is therefore time-limited. Time-Out Mode is only terminated after ENDINIT has been set again, requiring another Valid Password and Valid Modify Access to WDTxCON0.

If the WDT is not used in an application and is therefore disabled (WDTxSR.DS = 1), the above described case is the only occasion when WDTxCON0 must be accessed again after the system is initialized. If there are no further changes to critical system registers needed, no further accesses to WDTxCON0, WDTxCON1, or WDTxSR are necessary. However, it is recommended that the WDT be used in an application for safety reasons.

For debugging support the Cerberus module can override all the ENDINIT controls of all WDTs to ease the debug flow. If bit CBS_OSTATE.ENIDIS is set all ENDINIT protection is disabled independent of the current status configured by the WDTs. If CBS_OSTATE.ENIDIS is cleared the complete control is within the WDTs.

7.4.4.4 Timer Operation

The timers for Safety Watchdog and CPU0 are automatically active after an Application Reset. Each 16-bit counter implementing the timer functionality is either triggered with $f_{SPB} / 64$, $f_{SPB} / 256$ or $f_{SPB} / 16384$. The three possible counting rates are controlled via bit WDTxCON1.IRx.

Determining WDT Periods

All WDTs use the SPB clock f_{SPB} . A clock divider in front of each WDT provides three WDT counter frequencies, $f_{SPB} / 64$, $f_{SPB} / 256$ and $f_{SPB} / 16384$.

The general formula to calculate a Watchdog timeout period is:

(7.26)

$$\text{period} = \frac{(2^{16} - \text{startvalue}) \cdot \text{divider}}{f_{SPB}}$$

The parameter startvalue represents the fixed value $FFFC_H$ for the calculation of the Time-Out Period, and the user-programmable reload value WDTxCON0.REL for the calculation of the Normal Period.

The parameter divider represents the user-programmable source clock division selected by WDTxCON0.IRx, which can be 64, 256 or 16384.

Timer Modes

Each Watchdog Timer can operate in one of three different operating modes:

- Time-Out Mode
- Normal Mode
- Disable Mode

The following overview describes these modes and how the WDT changes from one mode to the other.

Time-Out Mode

The Time-Out Mode is entered after an Application Reset (Except CPU1 WDTs which are disabled after Application Reset) or when a valid Password Access to register WDTxCON0 is performed. The Time-Out Mode is indicated by bit WDTxSR.TO = 1. The timer is set to $FFFC_H$ and starts counting upwards. Time-Out Mode can only be exited properly by setting ENDINIT = 1 with a correct access sequence. If an improper access to the WDT is performed, or if the timer overflows before ENDINIT is set, and an alarm request is sent to the Safety Management Unit (SMU).

A proper exit from Time-Out Mode can either be to the Normal or the Disable Mode, depending on the state of the disable request bit WDTxCON1.DR.

Normal Mode

In Normal Mode (DR = 0), the WDT operates in a standard Watchdog fashion. The timer is set to WDTxCON0.REL, and begins counting up. It has to be serviced before the counter overflows. Servicing is performed through a proper access sequence to the control register WDTxCON0. This enters the Time-Out Mode.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed. Normal Mode is terminated and an alarm request is sent to the Safety Management Unit (SMU)

Disabled Mode

Disabled Mode is provided for applications which truly do not require the WDT function. It can be requested from Time-Out Mode when the disable request bit WDTxCON1.DR is set. The Disabled Mode is entered when was requested AND bit WDTxCON0.ENDINIT is set. The timer is stopped in this mode. However, disabling the WDT only stops it from performing the standard Watchdog function, eliminating the need for timely service of the WDT. It does not disable Time-Out mode. If an access to register WDTxCON0 is performed in Disabled Mode, Time-Out Mode is entered if the access was valid, and an alarm request is sent to the Safety Management Unit (SMU) if the access was invalid. Thus, the ENDINIT monitor function as well as (a part of) the system malfunction detection will still be active.

WDT Alarm Request

SMU alarm requests are generated for three cases:

- Invalid write data during access to register WDTxCON0
- Not executing a password access before a timer overflow occurs in the Time-Out Mode
- Not serving the WDT before a timer overflow occurs in the Normal Mode

The resulting alarm response(eg NMI, Reset etc) is programmable within the Safety Management Unit (SMU).

Note: The WDT itself is reset by any Application Reset .

Servicing the Watchdog Timer

If the WDT is used in an application and is enabled ($WDTxSR.DS = 0$), it must be regularly serviced to prevent it from overflowing.

Service is performed in two steps, a valid Password Access followed by a valid Modify Access. The valid Password Access to $WDTxCON0$ automatically switches the WDT to Time-Out Mode. Thus, the Modify Access must be performed before the time-out expires or an alarm request will be sent to the Safety Management Unit (SMU).

During the next Modify Access, the strict requirement is that $WDTxCON0.ENDINIT$ is written with 1.

Note: $ENDINIT$ must be written with 1 to perform a proper service, even if it is already set to 1.

Changes to the reload value $WDTxCON0.REL$, or the user-definable password $WDTxCON0.PW$, are not required.

When a WDT service is properly executed, Time-Out Mode is terminated, and the WDT switches back to its former mode of operation, and the WDT service is complete.

Check Accesses are optional and may be performed at any time when the WDT is locked.

WDT Operation During Power-Saving Modes

If one or more of the CPU are in Idle Mode, they cannot service a WDT because no software is running. Excluding the case where the system is running normally, a strategy for managing WDTs is needed while a CPU is in Idle Mode. There are two ways to manage a WDT in these cases. Firstly, the Watchdog can be disabled before idling the CPU. The disadvantage of this is that the system will no longer be monitored during the idle period.

A better approach to this problem relies upon the wake-up feature of the WDTs. Whenever $CPUx$ is put in Idle or Sleep Mode and the WDT is not disabled, the $CPUx$ is woken at regular intervals. When $WDTx$ changes its count value ($WDTxSR.TIM$) from $7FFF_H$ to 8000_H , $CPUx$ is woken and continues execution at the instruction following the instruction that was executed before entering the Idle or Sleep Mode.

Note: Before switching into a non-running power-management mode, software should perform a Watchdog service sequence. At the Modify Access, the Watchdog reload value, $WDTxCON0.REL$, should be programmed such that the wake-up occurs after a period which best meets application requirements. The maximum period between two CPU wake-ups is one-half of the maximum WDT period.

Suspend Mode Support

During a debug session the Watchdog functionality might lead to unintended alarms.

By default the WDTs are disabled when OCDS is enabled. However, it is possible to enable the WDTs also when debug is enabled. Please refer to the manual of your debugger tool for details.

7.4.4.5 Watchdog Timer Registers

Watchdog Timer Control Register 0

This register is written with check data in Check Accesses and Password Accesses. It also stores the timer reload value, password update and the corresponding End-of-Initialization (ENDINIT) control bit during a Modify Access.

There is a WDTxCON0 register for each Watchdog x.

WDTSCON0

Safety WDT Control Register 0 (0F0_H) **Reset Value: FFFC 000E_H**

WDTCPU0CON0

CPU0 WDT Control Register 0 (100_H) **Reset Value: FFFC 000E_H**

WDTCPU1CON0

CPU1 WDT Control Register 0 (10C_H) **Reset Value: FFFC 000F_H**

Field	Bits	Type	Description
ENDINIT	0	rwh	<p>End-of-Initialization Control Bit</p> <p>0_B Access to Endinit-protected registers is permitted.</p> <p>1_B Access to Endinit-protected registers is not permitted.</p> <p>This bit must be written with a '1' during a Password Access or Check Access (although this write is only used for the password-protection mechanism and is not stored). This bit must be written with the required ENDINIT update value during a Modify Access.</p>

Field	Bits	Type	Description
LCK	1	rwh	<p>Lock Bit to Control Access to WDTxCON0</p> <p>0_B Register WDTxCON0 is unlocked 1_B Register WDTxCON0 is locked (default after ApplicationReset)</p> <p>The current value of LCK is controlled by hardware. It is cleared after a valid Password Access to WDTxCON0 when WDTxSR.US is 0 (or when WDTxSR.US is 1 and the SMU is in RUN mode), and it is automatically set again after a valid Modify Access to WDTxCON0. During a write to WDTxCON0, the value written to this bit is only used for the password-protection mechanism and is not stored.</p> <p>This bit must be cleared during a Password Access to WDTxCON0, and set during a Modify Access to WDTxCON0.</p> <p>A Check Access does not clear LCK.</p>
PW	[15:2]	rwh	<p>User-Definable Password Field for Access to WDTxCON0</p> <p>This bit field is written with an initial password value during a Modify Access.</p> <p>A read from this bitfield returns this initial password, but bits [7:2] are inverted (toggled) to ensure that a simple read/write is not sufficient to service the WDT.</p> <p>If corresponding WDTxSR.PAS = 0 then this bit field must be written with its current contents during a Password Access or Check Access.</p> <p>If corresponding WDTxSR.PAS = 1 then this bit field must be written with the next password in the LFSR sequence during a Password Access or Check Access</p> <p>The default password after Application Reset is 00000000111100_B</p>

Field	Bits	Type	Description
REL	[31:16]	rw	<p>Reload Value for the WDT (also Time Check Value)</p> <p>The reload value can be changed during a Modify Access to WDTxCON0 (Default after ApplicationReset is FFFC_H). If the Watchdog Timer is enabled and in Normal Timer Mode, it will start counting from this value after a correct Watchdog service.</p> <p>A read from this bitfield always returns the current reload value.</p> <p>During a Password Access or a Check Access this bitfield may be used for additional checks. Writes during such checks have no effect upon the reload value.</p> <p>If corresponding WDTxSR.TCS=0 then this bit field must be written with its current contents during a Password Access or Check Access.</p> <p>If corresponding WDTxSR.TCS=1 then this bit field must be written with an inverted estimate of the current WDTxSR.TIM value during a Password Access or Check Access.</p>

The following register is implemented but is not functional in this product.

WDTCPU2CON0

Reserved Register

(118_H)

Reset Value: FFFC 000F_H

Field	Bits	Type	Description
FFFC	[31:16]	rw	Reserved Not functional in this device.
0	[15:8]	rw	Reserved Not functional in this device.
0	[7:4]	w	Reserved Not functional in this device.
1	[3:2]	w	Reserved Not functional in this device.
1	[1:0]	rw	Reserved Not functional in this device.

Watchdog Timer Control Register 1

The register WDTxCON1 for each Watchdog manages operation of the WDT. It includes the disable request, password configuration and frequency selection bits. Each WDTxCON1 register is protected by the corresponding ENDINIT which it controls.

WDTSCON1 has an additional bit CLRIRF which can be used to clear the internal reset status used to detect double SMU (eg WDT) resets.

WDTSCON1

Safety WDT Control Register 1 **(0F4_H)** **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLRIRF	0	rw	<p>Clear Internal Reset Flag</p> <p>This bit is used to request a clear of the internal flag which indicates whether a previous SMU reset has already been requested</p> <p>0_B No action 1_B Request to clear the internal previous-SMU-reset flag</p> <p>This bit can only be modified if WDTSCON0.ENDINIT is cleared. The internal flag is cleared when ENDINIT is set again. As long as ENDINIT is cleared, the internal flag is unchanged and continues to determine the response to a further SMU reset request. When ENDINIT is set again with a valid Modify Access, the internal flag is cleared together with this bit.</p>
IR1, IR0	5,2	rw	<p>Input Frequency Request Control</p> <p>00_B Request to set input frequency to $f_{SPB}/16384$. 01_B Request to set input frequency to $f_{SPB}/256$. 10_B Request to set input frequency to $f_{SPB}/64$. 11_B Reserved. Do not use.</p> <p>Bit IR0 and IR1 should be programmed together to determine the WDT timer frequency.</p> <p>These bits can only be modified if the corresponding WDTSCON0.ENDINIT is cleared. WDTSSR.ISx are updated by these bit only when ENDINIT is set again. As long as ENDINIT is cleared, WDTSSR.ISx controls the current input frequency of the Watchdog Timer. When ENDINIT is set again, WDTSSR.ISx is updated with the values of IRx.</p>
DR	3	rw	<p>Disable Request Control Bit</p> <p>0_B Request to enable the WDT 1_B Request to disable the WDT</p> <p>This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTSSR.DS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTSSR.DS controls the current enable/disable status of the WDT. When the ENDINIT is set again with a Valid Modify Access, WDTSSR.DS is updated with the state of DR.</p>

Field	Bits	Type	Description
UR	6	rw	<p>Unlock Restriction Request Control Bit</p> <p>0_B Request to disable SMU restriction of WDT unlock</p> <p>1_B Request to enable SMU restriction of WDT unlock</p> <p>This bit can only be modified if the corresponding WDTSCON0.ENDINIT is cleared. WDTxSR.US is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTSSR.US controls whether unlocking is possible at all times or only when the SMU is in the RUN state. When the ENDINIT is set again with a Valid Modify Access, WDTSSR.US is updated with the state of UR.</p>
PAR	7	rw	<p>Password Auto-sequence Request Bit</p> <p>0_B Request no automatic change of password after each Modify Access or Check Access</p> <p>1_B Request automatic sequence of password after each Modify Access or Check Access</p> <p>This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.PAS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.PAS controls password sequencing. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.PAS is updated with the state of PAR.</p>

Field	Bits	Type	Description
TCR	8	rw	<p>Counter Check Request Bit</p> <p>0_B Request to check only that REL field is written with existing REL value during Modify Access or Check Access</p> <p>1_B Request to check that REL field is written with correct TIM Count (within tolerance of WDTxSR.TCT) during Modify Access or Check Access</p> <p>This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCS is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCS controls whether counter check is enabled. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCS is updated with the state of TCR</p>
TCTR	[15:9]	rw	<p>Timer Check Tolerance Request</p> <p>This bit can only be modified if the corresponding WDTxCON0.ENDINIT is cleared. WDTxSR.TCT is updated when ENDINIT is set again. As long as the ENDINIT is cleared, bit WDTxSR.TCT controls the tolerance of timer checks. When the ENDINIT is set again with a Valid Modify Access, WDTxSR.TCT is updated with the state of TCTR</p>

SAFECON

Safety Heartbeat Register

(150_H)

Reset Value: XXXX XXXX_H

Field	Bits	Type	Description
HBT	0	rw	<p>Heartbeat</p> <p>This bit can be used by software to provide a “heartbeat” indication to an external safety monitoring device.</p> <p>It directly controls the output on the heartbeat ports. WDTxLCK P20.9, P20.8, P20.7 and/or P20.6 (Subject to port configuration).</p> <p>0_B Port drives low (reset value) 1_B Port drives high</p> <p>Writes are only possible when Safety ENDINIT=0</p>
Res	[31:1]	rw	<p>Reserved</p> <p>Content must not be changed. Write back only the original read value.</p>

7.4.5 Emergency Stop Output Control

The emergency stop feature of the TC26x B-Step provides a fast reaction to an emergency event without the intervention of software. In response to the emergency event, selected output ports can be immediately placed into a defined state (for more information see the port chapter).

An emergency stop may be triggered by either of the following emergency events:

- A transition on the port which is configured as the Emergency Stop input
- An SMU alarm event or SMU command which is enabled and configured to generate a port emergency stop (PES). See SMU Chapter for details.

Figure 7-47 shows a diagram of the emergency stop input logic. This logic is controlled by the SCU Emergency Stop Register EMSR.

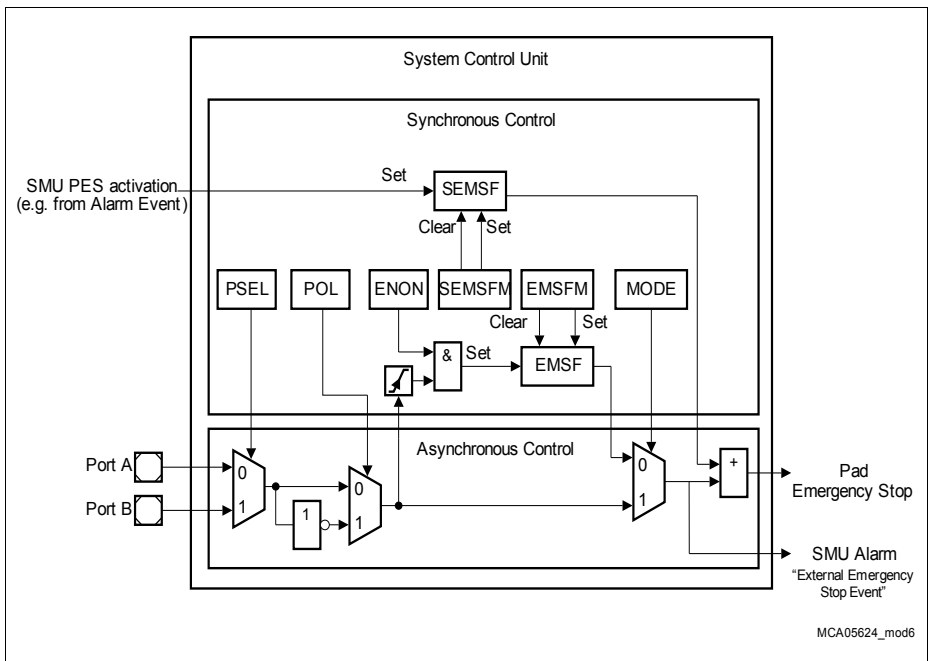

Figure 7-47 Emergency Stop Control

7.4.5.1 Port Triggered Emergency Stop

This can be configured to trigger on either transition edge of either one of two ports.

The two input port options for TC26x B-Step are (A) P 33.8 and (B) P21.2.

The emergency stop control logic for the ports can basically operate in two modes:

- Synchronous Mode (default after reset):
Emergency case is activated by hardware and released by software.
- Asynchronous Mode:
Emergency case is activated and released by hardware.

In Synchronous Mode (selected by `EMSR.MODE = 0`), the port signal is sampled for a inactive-to-active level transition, and an emergency stop flag `EMSR.EMSFS` is set if the transition is detected. The setting of `EMSR.EMSFS` activates the emergency stop. A port triggered emergency state can only be terminated by clearing `EMSR.EMSFS` via software (Write `EMSR.EMSFSM` with 10_{B}). The synchronous control logic is clocked by the system bus clock f_{SPB} . This results in a small delay between the port signal and emergency stop signal generation.

In Asynchronous Mode (selected by `EMSR.MODE = 1`), the occurrence of an active level at the port input immediately activates the emergency stop signal. Of course, a valid-to-invalid transition of the port input (emergency case is released) also immediately deactivates the emergency stop signal.

The `EMSR.POL` bit determines the active level of the input signal from the port. The `EMSR.MODE` bit selects Synchronous or Asynchronous Mode for emergency stop signal generation and the `EMSR.PSEL` bit selects which of the two ports is used as the emergency stop trigger.

7.4.5.2 SMU Event Triggered Emergency Stop

The Safety Alarm(s) which can trigger an Emergency Stop are configured and enabled within the Safety Management Unit (SMU). All SMU triggered Emergency Stop cases are in Synchronous Mode, regardless of the state of `EMSR.MODE`. The safety emergency stop flag `EMSR.SEMSF` is set when a configured and enabled SMU Safety Alarm occurs. The setting of `EMSR.SEMSF` activates the emergency stop. An SMU triggered emergency state can only be terminated by clearing the `EMSR.SEMSF` via software (Write `EMSR.SEMSFM` with 10_{B}). The synchronous control logic is clocked by the system bus clock f_{SPB} .

7.4.5.3 Emergency Stop Register

The Emergency Stop Register EMSR contains control and status bits/flags of the emergency stop input logic.

EMSR

Emergency Stop Register

 (0FC_H)

 Reset Value: 0000 0001_H

Field	Bits	Type	Description
POL	0	rw	Input Polarity This bit determines the polarity of the configured Emergency Stop input. 0 _B Input is active high 1 _B Input is active low
MODE	1	rw	Mode Selection This bit determines the operating mode of the emergency stop signal. 0 _B Synchronous Mode selected; emergency stop is derived from the state of flag EMSF 1 _B Asynchronous Mode selected; emergency stop is directly derived from the state of the input signal
ENON	2	rw	Enable ON This bit enables the setting of flag EMSF by an inactive-to-active level transition of input signal. 0 _B Setting of EMSF is disabled 1 _B Setting of EMSF is enabled

Field	Bits	Type	Description
PSEL	3	rw	PORT Select This bit selects which one of the two Emergency Stop port options is monitored. 0 _B Port A is used as Emergency Stop input 1 _B Port B is used as Emergency Stop input
0	[15:4]	r	Reserved Read as 0; should be written with 0.
EMSF	16	rh	Emergency Stop Flag This bit indicates that a synchronous mode port-triggered emergency stop condition has occurred. 0 _B An emergency stop has not occurred 1 _B An emergency stop has occurred and emergency stop state becomes active (if MODE = 0)
SEMSF	17	rh	SMU Emergency Stop Flag This bit indicates that an SMU Safety Alarm triggered emergency stop condition has occurred. 0 _B An emergency stop has not occurred 1 _B An emergency stop has occurred and emergency stop state becomes active
0	[23:18]	r	Reserved Read as 0; should be written with 0.
EMSMF	[25:24]	w	Emergency Stop Flag Modification This bit field sets or clears flag EMSF via software. 00 _B EMSF remains unchanged 01 _B EMSF becomes set 10 _B EMSF becomes cleared 11 _B EMSF remains unchanged EMSMF is always read as 00 _B .
SEMSFM	[27:26]	w	SMU Emergency Stop Flag Modification This bit field sets or clears flag SEMSF via software. 00 _B SEMSF remains unchanged 01 _B SEMSF becomes set 10 _B SEMSF becomes cleared 11 _B SEMSF remains unchanged SEMSFM is always read as 00 _B .
0	[31:28]	r	Reserved Read as 0; should be written with 0.

7.4.6 LBIST Support

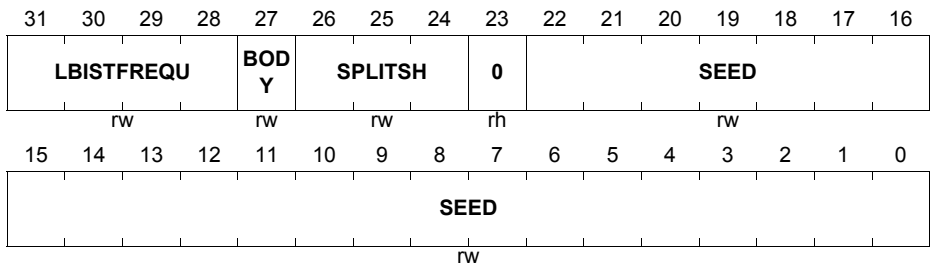

For TC26x B-Step an automatic executed scan-test mechanism is implemented, allowing the structural verification of the silicon in an application system. This process is controlled and monitored by the LBIST registers.

7.4.6.1 LBIST Control Register

The LBISTCTRL Control Register provides the link between software and the LBIST-controller.

LBISTCTRL0 - Logic BIST Control 0 Register
LBISTCTRL0
Logic BIST Control 0 Register
(164_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
LBISTREQ	0	w	LBIST Request If written high this bit requests the execution of an automatic scan-test procedure. Whether the request is successful or not depends on whether the LBIST procedure has already been executed since the last power-on-reset. If read this bit always returns a '0'. <i>Note: LBIST execution time depends on the number of scan-loads as defined in the PATTERNS field.</i>
LBISTREQP	1	w	LBIST Request Protection Bit Protect LBISTREQ against unintended changes. 0 _B LBISTREQ is not changed. 1 _B LBISTREQ is updated by this write access.
PATTERNS	[15:2]	rw	LBIST Pattern Number This field defines the number of scan-patterns (i.e. scan-loads), which will be executed during the LBIST-procedure. The two LSBs of scan pattern number are always assumed as '1' so LBIST patterns number can only be controlled with an accuracy of 4.
0	[31:16]]	r	Reserved Read as 0; should be written with 0.

LBISTCTRL1 - Logic BIST Control 1 Register
LBISTCTRL1
Logic BIST Control 1 Register
(168_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SEED	[22:0]	rw	LBIST Seed This field determines which pattern is applied during LBIST execution.
0	23	r	Reserved Read as 0; should be written with 0.
SPLITSH	[26:24]	rw	LBIST Split-Shift Selection The value of this bit will allow to run LBIST with partitioned scan-shift operation in order to reduce the power consumption. 0x _B , Concurrent scan-shift is selected. 1x0 _B , Partitioned scan-shift is selected (four scan partitions). 1x1 _B , Partitioned scan-shift is selected (two scan partitions).
BODY	27	rw	Body Application Indicator The value of this bit will determine the static reset behavior of all GPIOs during LBIST execution. If set to low GPIOs will show a weak pull-up behavior, if set to high GPIOs are constrained to tri-state. A high value must be written to this bit in case LBIST shall be executed for body applications.

Field	Bits	Type	Description
LBISTFREQ	[31:28]	rw	LBIST Frequency Selection Through this register-field a pre-scaler factor between 1..16 is selectable for LBIST operation clock (derived from EVR-oscillator). This will allow to determine the LBIST scan-shift frequency. Value of these bits will be mirrored inside of LBIST-controller and become effective if a new LBIST-procedure has been successfully initiated via LBISTCTRL0.LBISTREQ.

LBISTCTRL2 - Logic BIST Control 1 Register
LBISTCTRL2
Logic BIST Control 2 Register
(16C_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SIGNATURE	[23:0]	rh	LBIST Signature This field reflects the MISR signature from the last LBIST execution. It is mirrored from LBIST-controller and is only valid if LBISTCTRL0.LBISTDONE = 1.
0	[30:24]	r	Reserved Read as 0; should be written with 0.

Field	Bits	Type	Description
LBISTDONE	31	rh	LBIST Execution Indicator This bit indicates if since the last power-on-reset an automatic scan-test procedure has been executed: 0 _B No LBIST was executed since last power-on-reset. 1 _B LBIST was executed since last power-on-reset.

7.4.7 Global Overlay Controls

The following registers control the Global Overlay functionality.

7.4.7.1 Global Overlay Control

Two registers globally control the overlay operation for all CPUs:

- Overlay Enable Register OVCENABLE disables or enables data access overlay individually for each CPU.
- Overlay Control Register OVCCON can be used to perform the following actions on a selected set of CPUs:
 - concurrently enable / disable selected overlay blocks,
 - concurrently disable overlay blocks,
 - invalidate data cache.

All overlay control registers are reset to their default values with the Application Reset . A special debug reset is not considered.

The external overlay feature is not available in product variants offering ADAS functionality.

OVCENABLE
Overlay Enable Register
(1E0H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
OVEN0	0	rw	Overlay Enable 0 0 _B OVC is disabled on CPU0. All Overlay redirections are disabled regardless of the state of OVC0_RABRy.OVEN. 1 _B OVC is enabled on CPU0.
OVEN1	1	rw	Overlay Enable 1 0 _B OVC is disabled on CPU1. All Overlay redirections are disabled regardless of the state of OVC1_RABRy.OVEN. 1 _B OVC is enabled on CPU1.
OVEN2	2	rw	Reserved in this Product
0	[31:3]	r	Reserved Read/write 0.

OVCCON
Overlay Control Register
(1E4H)

Field	Bits	Type	Description
CSEL0	0	w	CPU Select 0 0 _B CPU0 not affected, 1 _B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU0. Return 0 if read.
CSEL1	1	w	CPU Select 1 0 _B CPU1 not affected, 1 _B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU1. Return 0 if read.
CSEL2	2	r	Reserved in this Product Return 0 if read.
0	[15:3]	r	Reserved Read/write 0.

Field	Bits	Type	Description
OVSTRT	16	w	Overlay Start 0 _B No action 1 _B For each CPU selected with CSEL, all the blocks selected with OVCx_OSEL will be activated. In the selected CPUs all the blocks deselected with OVCx_OSEL will be deactivated. CPUs which are not selected are not affected. No action is taken if OVSTP is also set. Return 0 if read.
OVSTP	17	w	Overlay Stop 0 _B No action 1 _B For CPUs selected with CSEL, all the overlay blocks are deactivated. OVCx_RABRy.OVEN bits are cleared. CPUs which are not selected are not affected No action is taken if OVSTRT is also set. Return 0 if read.
DCINVAL	18	w	Data Cache Invalidate No function in devices without data cache in CPU. 0 _B No action 1 _B Data Cache Lines in DMI are invalidated ¹⁾ Data Cache is affected only in the CPUs selected with CSEL. Return 0 if read.
0	[23:19]	r	Reserved Read/write 0.
OVCONF	24	rw	Overlay Configured Overlay configured status bit 0 _B Overlay is not configured or it has been already started 1 _B Overlay block control registers are configured and ready for overlay start This bit may be used as handshake bit between a debug device (via JTAG interface and Cerberus) and CPU(s).

Field	Bits	Type	Description
POVCONF	25	w	<p>Write Protection for OVCONF</p> <p>0_B OVCONF remains unchanged. 1_B OVCONF can be changed with write access to register OVCCON</p> <p>This bit enables OVCONF write during OVCCON write. Return 0 if read.</p>
0	[31:26]	r	<p>Reserved Read/write 0.</p>

- 1) Dirty (modified) cache lines are not effected by this operation. If data cache contains modified data, it is not invalidated, and has to be written-back and invalidated by the user. Therefore, it is highly recommended to either: access overlaid data in read-only mode, or use only non-cached access.

Field	Bits	Type	Description
0	[15:9],7,6,1	rw	Reserved Write only the read value
0	5	r	Reserved Read as 0
0	[31:16]	r	Reserved Read as 0

7.4.8.2 Identification Registers

The CHIPID register allows the user to determine the product, package option, FSI microcode version and chip revision (silicon step).

CHIPID

Chip Identification Register (140_H) **Reset Value: XXXX XXXX_H**

Field	Bits	Type	Description
CHREV	[5:0]	r	<p>Chip Revision Number</p> <p>This bit field indicates the revision number of the TC26x B-Step device. The value of this bit field is defined in the TC26x B-Step Data Sheet.</p> <p>Bits [3:0] are used to indicate the steps. These updates can be done with any metal-fix or FW ROM change.</p> <p>Bits [5:4] define the major silicon design steps (A, B, C, D). These bits can be changed only with a major redesign.</p> <p>Note that this specification refers to the latest available productive design step. Earlier silicon functionality may vary. Consult the appropriate delta documentation for details.</p> <p>00XXXX_B A-step silicon 01XXXX_B B-step silicon 10XXXX_B C-step silicon 11XXXX_B D-step silicon</p>

Field	Bits	Type	Description
CHTEC	[7:6]	r	Chip Family These bits indicate the product family and are changed only with a redesign. 00 _B Reserved 01 _B Aurix Gen1 Family 10 _B Reserved 11 _B Reserved
CHID	[15:8]	rw	Chip Identification Number This bit field defines the product by a unique number. This number may be used by SW to identify the system architecture (e.g. number of available CPUs). See Product Datasheet Addendum for more details.
EEA	16	rh	Emulation Extension Available Indicates if the emulation extension is available or not. 0 _B EEC is not available (TC2xxx_ or TC2xxxP) 1 _B EEC is available (TC2xxxE or TC2xxxF)

1) The absolute register address is calculated as follows:

Module Base Address + Offset Address (shown in this column)

2) Some registers marked (CPUx) are writeable only from the specified CPU. For these registers the setting of the ACCEN bits have no effect. For all other registers the ACCEN bits control access. Attempted writes by other masters or CPUs will not be successful, but no bus error will result.

8 Memory Test Unit (MTU)

All of the internal memories within the TC26x B-Step have a unified interface for the control of ECC (Error Correction), BIST (Built-in-Self-Test) and redundancy features. This interface can also be used to fill the memories with a predefined data value for initialization. The Memory Test Unit (MTU) controls and monitors these memory test, initialization and data integrity checking functions.

The MTU comprises two sections:

- MTU configuration registers.
- Memory Controller related registers.

The configuration registers are used to enable and disable memory test functionality. For some memories, a special sequence must be followed in order to execute memory tests without compromising data security. This sequence is ensured by simple state machines which automatically prevent test access to the memories at times when data content may be sensitive.

The Memory Controller registers are replicated for each memory bank in the device. These registers control the individual MBIST, redundancy and ECC settings for that specific memory block.

8.1 Memory Content Initialization

In security applications it is important that the MTU does not permit reading or modification of restricted memory content via the MBIST modules. In other applications (e.g. safety) it is important that modification of memory content is possible via MBIST (e.g. for ECC error injection or runtime self-test).

The TC26x B-Step can be configured for either of these application options via FLASH0.PROCOND.

Note that if RAMs embedded inside IP modules are not configured for initialization at boot then software initialization may be required before the IP module can be used. (E.g. GTM, ERAY modules)

8.1.1 Non-Security Applications

If FLASH0.PROCOND.RAMIN=11 then no automatic initialization of RAM content is performed on a reset and no automatic initialization of RAM content is performed when MBIST modules are enabled or disabled with MTU_MEMTEST.MEMxEN registers.

This permits the use of the MBIST controller by an application (E.g. for error injection, data modification or runtime memory testing) without unwanted corruption of memory content.

8.1.2 Security Applications

If FLASH0_PROCOND.RAMIN = 00, 01 or 10 then automatic memory content initialization is enabled. PROCOND.RAMIN configures whether the initialization is triggered by cold resets, warm resets or both. In these modes, an automatic initialization of security-sensitive memories is also triggered whenever the corresponding MTU_MEMTEST.MEMxEN is changed (i.e. The MBIST controller is enabled or disabled).

The following MBIST Controller enables are considered to be security-sensitive in this product:

- FSI0
- CPU0PTEN
- CPU0PSEN (Initializes only the cache part of the memory)
- CPU1PTEN
- CPU1PSEN (Initializes only the cache part of the memory)
- CPU1DTEN
- CPU1DSEN (Initializes only the cache part of the memory)

For security reasons, no MTU registers associated with HSM or FSI modules are accessible to the user after start-up.

8.2 Safety Notifications

SRAM ECC errors from all system SRAMs may be reported to the Safety Management Unit (SMU). The SMU may be programmed to initiate appropriate action.

8.3 Memory Test Unit (MTU) Kernel Registers

These are the MTU control registers

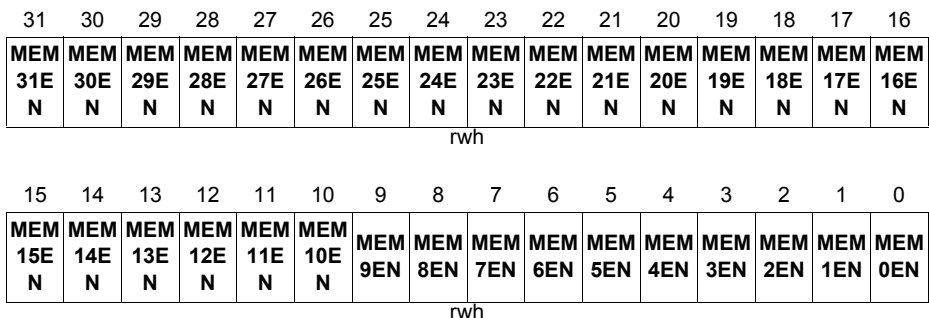

Memory Test Unit (MTU)
8.3.1 Descriptions
MTU_CLC
Identification Register
(F006 0000_H)
Reset Value: 0000 0003_H

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable is not requested 1 _B Module disable is requested
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module 0 _B Module is enabled 1 _B Module is disabled If the RMC field is implemented and if it is 0, DISS is set automatically.
Resvd	2	rw	Resvd Read as 0. Must be written with 0 _H
EDIS	3	rw	Sleep Mode Enable Control Used for module Sleep Mode control. 0 _B Sleep Mode request is regarded. Module is enabled to go into Sleep Mode on a request. 1 _B Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
Reserved	[15:8]	rw	Reserved Read as 0. Must be written with 0 _H
0	[31:16], [7:4]	r	0 Read as 0.

Memory Test Unit (MTU)
MTU_ID
Identification Register
(F006 0008_H)
Reset Value: 00B2 C0XX_H

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field indicates the revision number of the MTU module .
MODTYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines a 32-bit module
MODNUMBER	[31:16]	r	Module Number This bit field defines the module identification number. The identification number for the Aurix MTU is 00B2 _H

The memory test register MEMTEST holds CPU configurable select bits for the various MBIST controllers.

MTU_MEMTEST0
Memory MBISTEnable Register 0 (F006 0010_H)
Reset Value: 0000 0000_H

8.4 Memory Controllers

8.4.1 Control and Status Interfaces

8.4.1.1 Direct CPU Interface

There is a dedicated interface to the registers of each MBIST/ECC controller.

Memory Test Unit (MTU)

Register Mapping

Registers have an MTU system address and can be accessed through normal 16 bit SPB bus accesses. In the MTU the registers appear as if they were 16 bits wide.

Figure 8-1 MBIST/ECC Register Mapping Scheme

8.4.2 Registers

8.4.2.1 MBIST/ECC Registers

Some register field sizes or content depend upon the physical sizes of the memories. The default settings enable fill/test of the entire physical RAM and the register descriptions show the maximum bitfield sizes.

Configuration Registers

The bits in these registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion. If no legal

Memory Test Unit (MTU)

operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a $\{\uparrow(w0,r0)\}$ operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

CONFIG0
Configuration Register 0
(00_H)
Reset Value: 2002_H

Field	Bits	Type	Description
NUMACCS	15:12	rw	Number of accesses per address This field specifies the total number of accesses which are being performed to each single address in the current marching element. Range is from 0 to 15. With the sizes of ACCSPAT and ACCSTYPE given only 0 to 8 make sense. NUMACCS=0 will not access a memory.
Res	11:8	r	Reserved Reads return 0
ACCSTYPE	7:0	rw	Access type This field specifies the type of access which is being performed to each single address in the current marching element. ACCSTYPE[n] specifies n-th access of the marching element. 0 _B , write access 1 _B , read access

Memory Test Unit (MTU)

Field	Bits	Type	Description
SELFSTB	11:8	rw	<p>Select Fast Bit</p> <p>This field defines during a 2^i test the address bit position that has the Hamming distance of 1, i. e. changes fastest. Bit 0 of either column or row address is swapped with the indicated bit of either column or row according to MCONTROL.RCADR. MCONTROL.RCADR=0 -> column MCONTROL.RCADR=1 -> row 0000_B, normal addressing sequence, bit 0 in its normal position.</p> <p>others, bit 0 swapped with the indicated position.</p>
ACCSPAT	7:0	rw	<p>Access pattern</p> <p>This field specifies directly the bit pattern which is being used for an access to each single address in the current marching element. ACCSPAT[n] specifies the n-th access of the marching element. These patterns are toggled according to BITTOG and ROWTOG.</p>

Memory Test Unit (MTU)

MBIST Control Register

The bits in this register control the behavior of the MBIST, start and define tests to be performed. Any test will be performed and started when the startbit is set. The end will be signalled by MSTATUS.DONE . .

Required data (e.g. march elements, select fast bit) are taken from CONFIG0 and CONFIG1.

None of the tests are interruptable.

“Fast Row”, “Fast Column” (formerly called Fast Y and Fast X resp.) are defined as follows: “Fast Row” moves along the word-lines first and then in bit-line direction, “Fast Column” along the bit-lines first.

Note: Writes to this register are only permitted when no test is under way.

MCONTROL

MBIST Control Register

ROWTOG	6	rw	<p>Row toggling</p> <p>This field specifies whether to toggle the used bit pattern (non inverted/inverted) with each physical memory row. This is required when writing a checkerboard pattern or a row stripe pattern. Setting both BITTOG=1 and ROWTOG=1 would not make sense. The user must ensure that only one of these is set.</p> <p>0_B Do not toggle 1_B Do toggle with each row</p>

Memory Test Unit (MTU)

Field	Bits	Type	Description
RCADR	5	rw	Fast Row / Fast Column Addressing Scheme Select This bit selects between fast row and fast column addressing. It is compatible with the MBP 4.2 X/Y definitions. 0 _B Fast row 1 _B Fast column
DINIT	4	rw	Data Initialization Enable This bit enables a write of the RDBFL data to all locations defined by the range register. RDBFL can contain data that will produce an ECC error. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1 registers and the bits BITTOG, ROWTOG and DIR are ignored. 0 _B Disabled 1 _B Enabled
DIR	3	rw	Direction Select This field specifies the direction of a memory test operation. 0 _B Address direction is highest to lowest. 1 _B Address direction is lowest to highest.
ESTF	2	rw	Enable Sticky Fail Bit This bit enables the sticky fail bit MSTATUS.SFAIL. If set any fails will be collected in MSTATUS.SFAIL. Resetting this bit to 0 will also reset MSTATUS.SFAIL. 0 _B Do not collect fail events 1 _B Collect fail events
RESUME	1	rwh	Resume failed test This bit allows a test with fail that got suspended to be resumed after the dump of the fail bit map. A restart is possible only if MSTATUS.FDA was reset by hardware. It will be reset by hardware once the test is resumed. 0 _B Do not resume 1 _B Resume suspended MBIST run

Memory Test Unit (MTU)

Field	Bits	Type	Description
START	0	rw	<p>START</p> <p>If this bit is written to '1' by software the memory test will start. If it is reset by software, and the test has finished, MSTATUS.DONE will be set to 1.</p> <p>If MCONTROL.FAILDMP is set, a fail will stop the current execution. RESUME will continue a suspended test.</p> <p>1_B Start memory test 0_B No test started, finished or waiting for test end</p>

Fail Dump

Bit FAILDMP enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by RESUME. MSTATUS.FDA shows that a fail dump is available.

This bit has to be polled by the tester hardware as there is no signal that shows a stopped test.

Memory Test Unit (MTU)

MBIST Status Register

The bits in the status register show the status of the currently running and last test respectively.

MSTATUS

Status Register

(06_H)

Reset Value: 0001_H

Field	Bits	Type	Description
Res	15:4	r	Reserved Reads return 0
SFAIL	3	rh	Sticky Fail Bit This bit is set to 1 together with FAIL provided MCONTROL.ESTF is set. In contrast to FAIL it will not be reset when a new test is started. Therefore it will collect fail information over more than one MBIST run. It will be reset when MCONTROL.ESTF is reset or the 0 _B , No fail collected. 1 _B , A fail occurred during one of the test runs since MCONTROL.ESTF was set to 1.

Memory Test Unit (MTU)

Field	Bits	Type	Description
FDA	2	rh	<p>Fail Dump Available</p> <p>This bit shows that a fail has occurred if MCONTROL.FAILDMP is set. The test is suspended and fail dump information is available. The fail bit map is in RDBFL and the associated address is in ETRR(0). As long as no fail has occurred RDBFL contains the last read information and ETRR has no valid data . This bit will be set by hardware.</p> <p>It will be reset when MSTATUS was read with MSTATUS.FDA = 1 and the dump information was read from ETRR and RDBFL. Only the last read from the last word of RDBFL is checked by the hardware and taken as an indication for a complete read.</p> <p>A suspended test will be resumed by MCONTROL.RESUME if FDA was reset.</p> <p>This forms some sort of handshake to insure that a suspended test can only be resumed (by a broadcasted) MCONTROL.RESUME if the last fail information was actually collected.</p> <p>0_B , No fail dump data available. A suspended MBIST run can be resumed.</p> <p>1_B , Fail dump data is available and waiting for read.</p>
FAIL	1	rh	<p>FAIL</p> <p>This bit will be reset when a test is being started. It will be set to '1' by hardware under the following conditions: FAIL:='1' if the memory has at least one fault</p>
DONE	0	rh	<p>DONE</p> <p>Reset value is 1. This bit is reset at the start of a test and set when a test is completed and MCONTROL.START was reset by software. It is not set when a test is interrupted for fail dump.</p>

Memory Test Unit (MTU)

Range Register

The Range Register can be used to run a test only on a dedicated part of the RAM. This can be helpful to shorten the time which is needed to find a defect cell in a FAR where there's already some information available about a failing memory cell because it's not necessary to run the test using the full address range of the RAM under test.

The range can be set in 64 word increments.

The range register can also be used to write to one specific logical address or read from it. In this case the range is disabled and the remaining part of the register is used as the logical address field.

RANGE

Range Register, single address mode (08_H)

Reset Value: xxxx_H

Field	Bits	Type	Description
RAEN	15	rw	<p>Range Enable</p> <p>0 disabled, single address mode. In this case a single word can be addressed for read or write. Config registers have to be set as follows CONFIG.NUMACCS:= "0001" (single access) CONFIG.AG_MOD := "0000" (linear) MCONTROL.DIR :=1 (up) For read just the value in this location will be delivered. No check against expected values is made; i.e. MSTATUS.FAIL will not be set.</p>
ADDR	14:0	rw	<p>Address</p> <p>This field specifies the logical address (before descrambling) of a single memory location. Reads and writes to this location are possible.</p>

Setting Address Ranges

If the RAEN field is set to '1' then range mode is enabled. In this case, the ADDR field of the RANGE register is interpreted as two separate fields:

Memory Test Unit (MTU)

ADDR[14:7] is interpreted as the Upper Range Limit.

This field specifies the upper logical block address limit in 64 word increments.

Upper end of the address range is UPLIMIT & 111111B

ADDR[6:0] is interpreted as the Lower Range Limit

This field specifies the upper logical block address limit in 64 word increments.

Lower end of the address range is LOLIMIT & 000000B

Note that the default reset value of the ADDR field will be set to the maximum range of the physical memory. The default behaviour is therefore that an initialization or test will operate over the whole memory.

Revision ID Register

The revision ID register contains a hard coded read only constant which describes the current status of the MBIST/ECC IP.

REVID

Revision ID Register (0C_H) **Reset Value: 0510_H**

Field	Bits	Type	Description
REV_ID	15:0	r	<p>Revision Identifier</p> <p>This field defines the currently implemented release, version and functionality of the used MBIST/ECC controller to track the MBIST/ECC version for easier handling at the tester.</p>

ECC Safety Register

This register controls the various error detection and notification modes.

Writes to this register are only permitted when `safe_endinit= 0` and no test is under way.

The hardware features that implement fault tolerance mechanisms for the SRAMs (e.g. single bit correction) shall be enabled per default after any reset. This is ensured by the reset value of the ECC safety register where `ECCS.ECE = 1` after a reset.

ECCS

Memory Test Unit (MTU)

Field	Bits	Type	Description
AERR	3	rwh	Address Error Detected Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the hardware flag. ¹⁾ Read as: 0 _B No address error detected 1 _B Address error detected (AERR)
UERR	2	rwh	Uncorrectable Error Detected Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the associated hardware flag. Read as: 0 _B No uncorrectable error detected 1 _B Uncorrectable error detected (UERR)
CERR	1	rwh	Correctable Error Detected Write of '0' clears the sticky status. Write of '1' has no effect. A write does not clear the associated hardware flag. Read as: 0 _B No correctable error detected 1 _B Correctable error detected (CERR)
SERR	0	rwh	Error Detected Write of '0' clears the sticky status. Write of '1' has no effect. Read as: 0 _B No error detected 1 _B Error detected: any error detected :CERR, UERR or AERR

1) Note: A write to AERR, UERR and CERR does not clear the hardware flags.

Memory Test Unit (MTU)

Read Data and Bit Flip Register

This register is used for several purposes whenever a register with the size of the memory width is needed.

Normally this register contains the data which are directly read back from the RAM (without any data scrambling) during the last read access.

During logic test (LBIST) it contains the bit flip information. If ECCS.BFLE is set, this information is used to flip bits written to the SRAM.

After a failed test it contains the failed bit map if MCONTROL.FAILDMP is set. The address part is contained in the error tracking register.

When MCONTROL.DINIT is set, this information is written to all locations within range.

Writes to this register are not permitted while a test is underway.

RDBFLy (y=0-39)

Read Data and Bit Flip Register y (A0_H + y*02_H)

Reset Value: 0000_H

Field	Bits	Type	Description
WDATA	15:0	rwh	Word Data This field contains the data of the last memory read operation. The width of WDATA does always match the memory data width. $m = nb_mems_g * (n + k)$

8.4.3 Safety Features

Several Safety features are implemented in conjunction with ECC and Safety SRAMs.

There are three signals to provide an alarm to the SMU:

correctable error detected

uncorrectable error detected

address error detected. Address errors are detected by the Safety SRAM feature. This discovers all wordline failures including broken wordlines and decoder malfunctions.

The codes used for ECC are of the SECDED (single error correction double error detection) type..

Memory Test Unit (MTU)

All codes are able to detect all zeroes and all ones, despite the fact that all physical faults resulting in this condition are covered by the Safety SRAM feature.

Whenever a new error is detected, not only a signal is set as an alarm, also an associated bit is set in ECCD. Three bits available are ECCD.CERR, ECCD.UERR and ECCD.AERR. They are cleared by writing a 0 to their location.

Bit ECE switches error correction on and off.

All errors are being tracked in error tracking registers (1 to 4). Correctable and uncorrectable errors are treated the same way except for the alarms and notification bits.

If an error is tracked then the associated register contains a valid value and a valid bit is set ECCD.VAL

The valid bits can be cleared by writing to ECCD.TRC

A valid bit is associated with each error entry. Bit ECCD.EOV is set when the error tracking register has recorded the maximum number of errors already and another error gets detected before the error tracking register is read by software and the event cleared by ECCD.TRC. All errors are treated the same way.

Uncorrectable errors are treated the same way as correctable errors and stored in the same registers.

Also, valid bits are used the same way.

ECCS.ECCMAP allows to select separately either the data bits of the stored information or the ECC check bits or data bits with ECC bits operational. In normal mode (ECCS.ECCMAP = 00) only access to data with correctly enabled ECC is possible and the ECC bits as such are neither visible nor accessible.

This mode (ECCS.ECCMAP ≠ "00") cannot be left without prior changing safe_endinit.

Bit will switch on special test modes to inject errors into the ECC encoder to ECC decoder path. This way the redundancy of this path can be broken and the logic tested.

Also, the ECC can be tested by firmware by writing illegal codes into the ECC data fields.

Then any bit combination can be written to the ECC bits.

There is a Safety SRAM feature implemented to detect errors that involve more errors that can be detected by ECC. Also, there are signature bit flip enables provided to test the logic of address error detection.

The Safety SRAM feature will also detect the failure mode where a valid SRAM access request present at the SRAM input is not processed by the SRAM, as long as the attempted access does not have the same address as the last functioning valid access to the SRAM

The Safety SRAM feature detects addressing faults for both read and write accesses. Atomic read-modify-write sequences are also considered.

Memory Test Unit (MTU)

When such an error occurs or when a bit flip enable is set, an address error is flagged, provided ECCS.AENE is set.

Normally SRAM, MBIST and ECC are delivered as block. If the ECC decoder and/or decoder are embedded in a pipeline, then the blocks can be separated.

8.4.4 Operation Modes

8.4.4.1 Starting a Memory Test Sequence (example)

It's not possible any longer to start simple standard tests such as Checkerboard, Row Stripe, March C+ and March U without writing special values to the CONFIG registers. These tests now also require to write dedicated values into the CONFIG registers as described in the following example:

1. Enter memory test mode
2. Initialize registers
Write the desired march sequence into the CONFIG registers
CONFIG1.ACCSPAT is the pattern to be executed, CONFIG0.ACCSTYPE the read/write sequence and CONFIG0.NUMACCS the number of bits in CONFIG1.ACCSPAT and CONFIG0.ACCSTYPE to used
AG_MOD contains the address mode to be used
RANGE := <memory range to be tested>
3. Start memory test by writing a 1 to register bit MCONTROL.START
4. Reset MCONTROL.START
5. Wait for the end of the test
 - poll MSTATUS.DONE
 - or poll primary output DONE
6. Check the result of the test
 - verify MSTATUS.FAIL
 - or verify primary output FAIL

Complex algorithm may require several march starts to get a full test.

8.4.4.2 Getting Detailed Memory Test Results

The FAIL and DONE bits provide a general pass/fail information.

If MCONTROL.FAILDMP = '1', the test stops after a failed test and the fail information is immediately available for dump. MSTATUS.FDA (fail dump available) is set and signal faildumpreq asserted in this case. RDBFL contains the fail bit map and ETRR the failed address. Reading MSTATUS with MSTATUS.FDA = '1' and RDBFL(n-1) will reset MSTATUS.FDA and faildumpreq. A consequent setting of MCONTROL.RESUME will restart the interrupted test sequence.

The RANGE register can be used to run consecutive tests on constantly shifted memory ranges so that in the end the complete memory has been analyzed.

8.4.4.3 Dumping Fail Bitmap

Any dump information has to be polled from registers RDBFL and ETRR(0).

8.4.4.4 Filling a Memory with Defined Contents

The MBIST/ECC can be used to fill a memory range or a complete memory with a defined pattern very fast, i.e. one write access per cycle with the full memory data width. There are three methods implemented, one using bit MCONTROL.DINIT, one using input mtu_auto_data_init and another one using input mtu_partial_erase_i.

MCONTROL.DINIT will write a range with any pattern in RDBFL no matter whether this is a valid ECC code or not. This is useful if memories have additional ECC or parity bits and must be initialized before they can be used. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
RDBFL := <desired pattern>
RANGE := <memory range to be filled>
3. Start fill operation by setting MCONTROL.DINIT and MCONTROL.START of the MCONTROL register
4. Wait for MSTATUS.DONE to be reset and clear MCONTROL.START.
5. Wait for the end of fill operation by polling MSTATUS.DONE bit
6. Leave memory test mode.

Also, two hardware signals named mtu_auto_data_init_i and mtu_partial_erase_i are available to fill the whole memory with the data on d_i or erase parts of the memory. ECC codes are automatically correct. Range is ignored if mtu_auto_data_init_i is applied, in case mtu_partial_erase_i is used nb_partial_erase_size_g blocks of 1kB starting from the top of the memory are erased. Memory testmode does not need to be switched on but a clock must be available.

Both signals will have priority over MCONTROL.START and are not interruptable.

8.4.4.5 Reading a Single Memory Location

The MBIST/ECC can also be used to read the contents of a single word. The RDBFL register holds the contents of a complete memory word and thus it is possible to read all memory bits, including ECC or parity bits. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
RANGE := RAEN = 0 (range disabled = single address) & address to be read
CONFIG0 := 1001_H (NUMACCS = 1_H, ACCSTYPE = 01_H (read))
CONFIG1 := 0000_H (linear mode, non inverted pattern)
3. MCONTROL := 4009_H (FAILDMP = 0, direction up, start): Start read operation
4. MCONTROL := 4008_H (clear START)
5. Wait for MSTATUS.DONE to be reset
6. Read RDBFL register
7. Leave memory test mode

8.4.4.6 Writing to a Single Memory Location

The MBIST/ECC can also be used to write the contents of RDBFL register to a single memory location. RDBFL holds the contents of a complete memory word and thus it is possible to write to all memory bits, including ECC or parity bits. The necessary steps are:

1. Enter memory test mode
2. Initialize registers
 - RDBFL := write data
 - RANGE := RAEN= 0 (range disabled = single address) & address to be written to
 - CONFIG0 := 1000_H (NUMACCS = 1_H, ACCSTYPE = 00_H (write))
 - CONFIG1 := 0000_H (linear mode, non inverted pattern)
3. MCONTROL := 4009_H (FAILDMP = 0, direction up, start): Start write operation
4. MCONTROL := 4008_H (clear START)
5. Wait for MSTATUS.DONE to be reset
6. Leave memory test mode

8.4.5 Memory Controller Register Addresses

There is one set of Memory Controller Registers for each logical memory module in the TC26x B-Step.

The sets of registers are located at offsets from the following base addresses.

Table 8-2 Registers Address Space - Memory Controller Registers

Module	Base Address	End Address	Note
MC0	F006 1000 _H	F006 10FF _H	-

8.4.6 Memory Controller Register Overview

This section describes registers in each memory controller module. Register names described in this section will be referenced in other parts of the TC26x B-Step User's Manual by the prefix "MCx_" where x is the index or name of the specific memory controller. The registers are replicated for each memory controller.

MTU Memory Control Kernel Register Overview
Table 8-3 Register Overview of each MTU Memory Control register block

Short Name	Long Name	Offset Addr. ¹⁾	Access Mode		Re set	Description See
			Read	Write		
CONFIG0	Memory Config Register 0	00 _H	U, SV, 16	U, SV, 16	-	Page 8-18
CONFIG1	Memory Config Register 1	02 _H	U, SV, 16	U, SV, 16	-	Page 8-19

–	Reserved	$20_H - 9F_H$	BE	BE	–	–
RDBFLy	Memory Read Data Register y (y = 0-39)	$(y * 02_H) + A0_H$	U, SV, 16	U, SV, 16	–	Page 8-35
–	Reserved	$F0_H - FF_H$	BE	BE	–	–

1) The absolute register address is calculated as follows:
Memory Module Register Base Address + Offset Address (shown in this column)

8.5 ECC Implementation

8.5.1 ECC

8.5.1.1 ECC Codes

Most ECC codes except for the cache tag memories are of the SECDED (single error correction and double error detection) type. These are specially designed Hsiao codes optimized for triple error detection. They will detect all correctable errors and allow correction, detect all double errors and detect a relatively high percentage of triple errors. The cache tag memories will get DED codes (double error detection).

All codes will detect “all zeros” and “all ones”. However, with the safety SRAM concept of address error detection this feature is not required anymore as all physical faults that might produce an “all ones” or “all zeros” error are covered there.

SECDED Codes

Memory Test Unit (MTU)
14 bits total length, 8 bits data, 6 check bits

Matrix: [1, 2, 4, 8, 16, 32, 7, 11, 19, 35, 13, 22, 44, 52]

Check part of the matrix as bits:

00010011

00100101

01001010

10001111

11110100

11111000

No double columns, can be used as SEC code.

Type: Hsia-Code (all columns have odd weight)

Table 8-4 Code Characteristics 8/6

Number of codes with weight 3	0
Number of codes with weight 4	34
Can be used as SECDED code	
Undetectable double errors (correction on)	0
Undetectable triple errors (correction on)	136
Percentage of undetectable triple errors (correction on)	37.362637
Row weights	[6, 6, 6, 4, 4, 4]
Number of ones in the matrix	30

22 bits total length, 16 bits data, 6 check bits

Matrix: [1, 2, 4, 8, 16, 32, 7, 11, 19, 35, 13, 21, 37, 25, 41, 14, 22, 38, 26, 50, 44, 52]

Check part of the matrix as bits:

0001001010010111

0010010100101101

0100100111001010

1000111001110011

1111000001111100

1111111110000000

No double columns, can be used as SEC code.
 Type: Hsia-Code (all columns have odd weight)

Table 8-5 Code Characteristics 16/6

Number of codes with weight 3	0
Number of codes with weight 4	252
Undetectable double errors (correction on)	0

8.5.2 Address Error Detection

Address error detection has to capture several memory faults that cause multiple or all bits of a word to fail. Such faults could be address decoder stuck-at-faults, broken word-lines, bridged word-lines etc. Because of this origin an ECC detection would not cover these cases because the words read back from memory would have perfectly matched check bits despite corrupted word selects.

In this version of MBIST/ECC the SRAMs will detect any of the faulty cases.

8.6 Implementation Section

All Memory Controller register regions which are not allocated in the table below are not implemented. Attempted accesses to regions which are not implemented will return a bus error.

8.6.1 Memory Control Register Implementation

8.6.1.1 MEMTEST Implementation

The memory test register MEMTEST contains enable bits for the various Memory Controllers.

Memory control registers described in this chapter are accessible only when the Memory Controller is enabled (MTU_MEMTEST.MEMxEN = 1). The only exceptions to this are registers ECCD and ETRR (for each memory) which are available at all times to permit easy runtime access to ECC features.

Note:

2. *When a Memory Controller is enabled, functional access to the memory is temporarily unavailable. When a memory is being tested it is essential to prevent an attempted functional access to that memory (e.g. While testing a CPU's local memories, the CPU should be in an idle state, or executing from other memory). Attempted functional accesses to memories when MEMxEN=1 may result in unexpected behaviour.*
3. *Correct execution of a Memory Controller operation (e.g. MBIST or initialization sequence) requires that both the MTU and the module containing the memory-under-test are both operational for the duration of the sequence. A module reset of the MTU or the module containing the memory-under-test, during execution of such an MBIST sequence may result in unexpected behaviour.*

MTU_MEMTEST0

8.6.1.2 MEMMAP Implementation

The Memory Mapping Enable register MEMMAP has configurable control bits to select memory-mapped test mode for each CPU memory.

Cache and Scratchpad memories are physically implemented as a single RAM, but this register function assumes two separate logical RAM partitions. In this register additional bits CPUxDCMAP and CPUxPCMAP are defined. These control the Cache partitions of the RAMs for Data Side and Program side respectively. Since cache content and tags of a cache must be simultaneously switched from memory mapped to cache functional mode, the control bits are mirrored and only one bit is writeable for each cache. The bits corresponding to the tag memories of the same cache will always take the same value as that written to the main Cache Memory control bit. This linkage is product specific.

8.6.1.3 MEMSTAT Implementation

The Memory Status registers MEMSTATx have an implemented bit for each security-relevant RAM.

Cache and Scratchpad memories are physically implemented as a single RAM with a single MBIST, so bits CPUxDSAIU and CPUxPSAIU give the status of the partial initialization of the cache partitions for Data Side and Program side respectively. Since cache content and tags of a cache may take different lengths of time to erase, both are implemented as separate status bits.

9 Safety Management Unit (SMU)

9.1 Introduction

The SMU is a central and modular component of the safety architecture providing a generic interface to manage the behavior of the microcontroller under the presence of faults. The SMU centralizes all the alarm signals related to the different hardware and software-based safety mechanisms. Each alarm can be individually configured to trigger internal actions and/or notify externally the presence of faults via a fault signaling protocol. The default fault signaling protocol is a bi-stable Error Pin. The severity of each alarm shall be configured according to the needs of the safety application(s): per default every alarm is disabled with the exception of the watchdog timeout alarms. For debug and diagnosis purposes the alarm events are logged, the logged information is resilient to any system or application reset. The SMU also implements some housekeeping functions related to the management and test of dedicated safety mechanisms. A special test mode is available to test the SMU itself enabling to detect latent faults as required by the ISO 26262 safety standard. In addition to the generic register access protection, the SMU implements an independent configuration locking mechanism.

The SMU in combination with the embedded safety mechanisms enable to detect and report more than 99% of the critical failure modes of the microcontroller within the fault tolerance time interval. The timing characteristics of the fault tolerance time interval can be configured in the SMU.

Figure 9-1 “SMU Interfaces” on Page 9-2 gives an overview of the SMU interfaces.

Safety Management Unit (SMU)

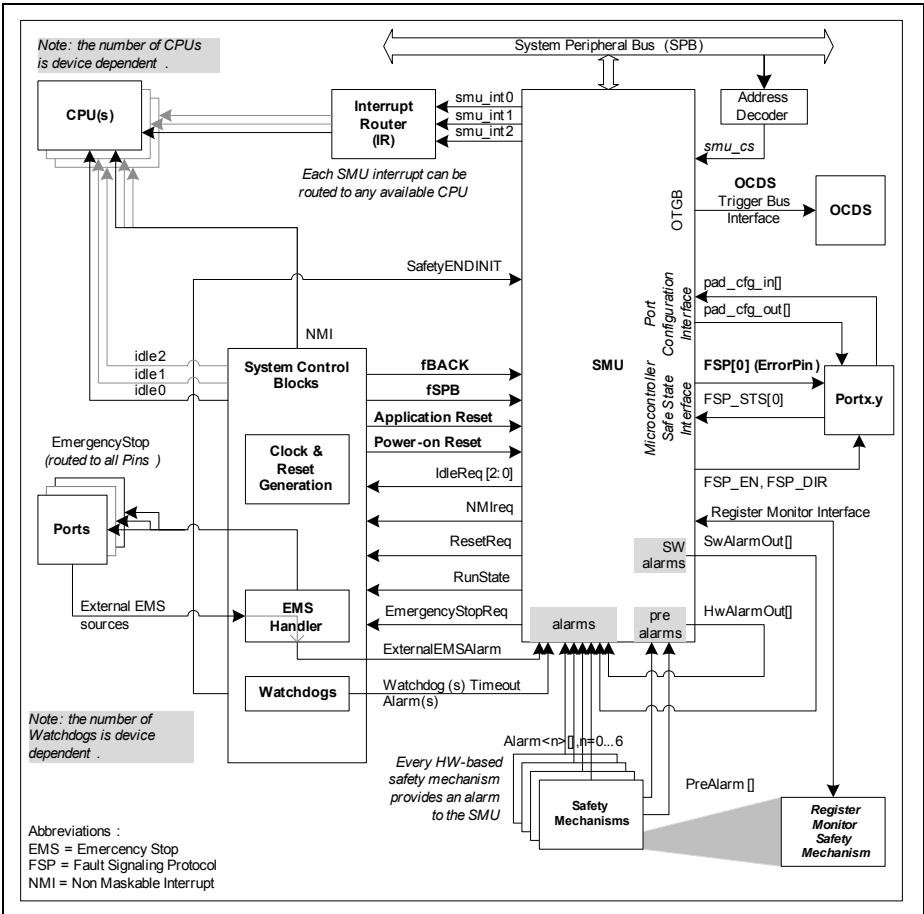

Figure 9-1 SMU Interfaces

9.2 Features

The SMU implements the following features:

- Collects every alarm (error notification) information from every safety mechanism:
 - CPU Lockstep
 - SRAM single bit error correction
 - SRAM uncorrectable error
 - SRAM Monitor: Address Buffer overflow
 - SRAM addressing fault
 - Program FLASH single bit error correction
 - Program FLASH double bit error correction
 - Program FLASH arbitrary multiple-bit uncorrectable error
 - Program FLASH Monitor: address buffer full
 - Program FLASH addressing fault
 - Processor interconnect (SRI) safety mechanisms
 - Safety Flip-Flop
 - Clock monitors
 - System PLL & Flexray-PLL loss of lock
 - Input/Output Monitoring Module
 - Interrupt Router and Interrupt Control Units hardware monitor
 - Voltage Monitor for internal voltage regulators
 - Error reporting from Shared Resource Interconnect and System Peripheral Bus
 - Die Temperature Sensor
- Alarm flags are stored in a debug register that is only reset by the Power-on reset, to enable fault diagnosis and possible recovery.
- An alarm emulation facility is provided to enable software-based diagnostics to post an alarm condition with the same properties as the hardware alarms.
- Implements the access protection and SafetyEndinit modes to protect configuration registers.
- Implements a Fault Signaling Protocol (FSP) reporting internal faults to the external environment. The FSP can be configured using the following modes:
 - Bi-stable single pin output (push-pull active low configuration using FSP[0]), also called ErrorPin.
 - Single-bit timed protocol using FSP[0]
- The FSP value driven by the microcontroller can be observed via an internal status flag
 - Additionally a monitor is available to check the timing and state properties of the FSP protocol when a fault is reported.
- After power-on reset the FSP is disabled, software needs to connect the FSP to the assigned port. The port is configured as GPIO.
- Each individual alarm can be configured to activate the fault signaling protocol and/or one of the following internal actions:

Safety Management Unit (SMU)

- generate an Interrupt request to any of the CPUs, concurrent interrupts to several CPUs can be configured
- generate a NMI request to the System Control Unit
- generate a reset request to the System Control Unit leading to a system or application reset
- activate the pad emergency stop signal controlling the safe state of output pads
- generate a CPU idle request
- After reset every alarm (except watchdog timeout) is disabled.
- A lock mechanism is available to protect the SMU configuration in addition to the standard access protection
- Implements internal watchdog(s) timeout pre-warning function.
- Implements an internal watchdog called recovery timer to monitor the execution of critical software error handlers. The watchdog is started automatically by hardware according to configurable alarm events.

9.3 Functional Overview

The SMU collects all the error flags (called alarms in this document) from all the hardware monitors (safety mechanisms) defined by the safety concept. The section **“Alarm Mapping” on Page 9-14** specifies the alarm interface and classifies them into alarm groups. The alarm groups do not define any hierarchy but only a logical mapping used to map input alarm signals to internal configuration registers. The section **“Alarm Handling” on Page 9-41** describes the configuration options that can be specified. The configuration options specify the behavior of the SMU when an alarm event is detected. The alarm event can trigger an internal action and/or the activation of the Error Pin that indicates the presence of a dangerous fault to the external environment. The section **“SMU Control Interface” on Page 9-48** specifies how the SMU can be controlled by software and the dependencies with the hardware operation. The section **“Fault Signaling Protocol (FSP)” on Page 9-52** describes the properties of the external fault signaling protocol defining the timing and logical properties of the Error Pin(s).

The SMU implements the technical safety requirements

9.4 Functional Description

9.4.1 Reset Types

The SMU requires multiple reset types for its operation. The reset types are fully specified in the System Control Units. The reset types that are required by the SMU are:

- Power-on Reset.
- Debug Reset.
- Application Reset.

Additionally the SMU supports the **module reset** feature. The module reset acts as an application reset, it is fully controlled by software using the [SMU_KRST0](#), [SMU_KRST1](#), [SMU_KRSTCLR](#) registers. The module reset only affects the SMU kernel and not the System Peripheral Bus (SPB) bus interface logic.

[Table 9-1 “Effect of Reset Types to SMU functionality” on Page 9-6](#) specifies the scope of each reset type to the SMU functions (a function includes the control and configuration registers and the related logic).

Table 9-1 Effect of Reset Types to SMU functionality

9.4.2 Interfaces Overview

This section describes the main interface signals between the SMU and the other modules.

9.4.2.1 Interfaces to SCU

Internal actions resulting from an alarm event that interface to the System Control Unit. The interface signals are:

- Emergency Stop Request
- Reset Request
- Idle Request
- NMI Request

9.4.2.2 Interfaces to the Interrupt Router

Internal actions resulting from an alarm event that interface to the Interrupt Router. The interface signals are:

- SMU Interrupt Request 0
- SMU Interrupt Request 1
- SMU Interrupt Request 2

The mapping of SMU Interrupt Requests to the Interrupt Router (IR) interrupt nodes can be found in the IR chapter.

The **SMU_AGC.IGCS<i>**, $i=\{0,1,2\}$ register fields provide the software interface to control how the SMU triggers interrupt requests to the interrupt router.

Each **SMU_AGC.IGCS<i>** is a 3-bits bit-field: **SMU_AGC.IGCS<i>[2:0]** that defines a direct relationship to the 3 SMU interrupt requests:

- **SMU_AGC.IGCS<i>[0]** shall be set to '1' to trigger SMU Interrupt Request 0
- **SMU_AGC.IGCS<i>[1]** shall be set to '1' to trigger SMU Interrupt Request 1
- **SMU_AGC.IGCS<i>[2]** shall be set to '1' to trigger SMU Interrupt Request 2

The usage of the three **SMU_AGC.IGCS<i>** bit-fields is defined in **“Alarm Configuration” on Page 9-41**; where each **SMU_AGC.IGCS<i>** can be selected as an internal action.

9.4.2.3 Interface to the Ports (Error Pin)

The generic port structure is presented in presented in **Figure 9-2 “Generic Port Structure” on Page 9-9**.

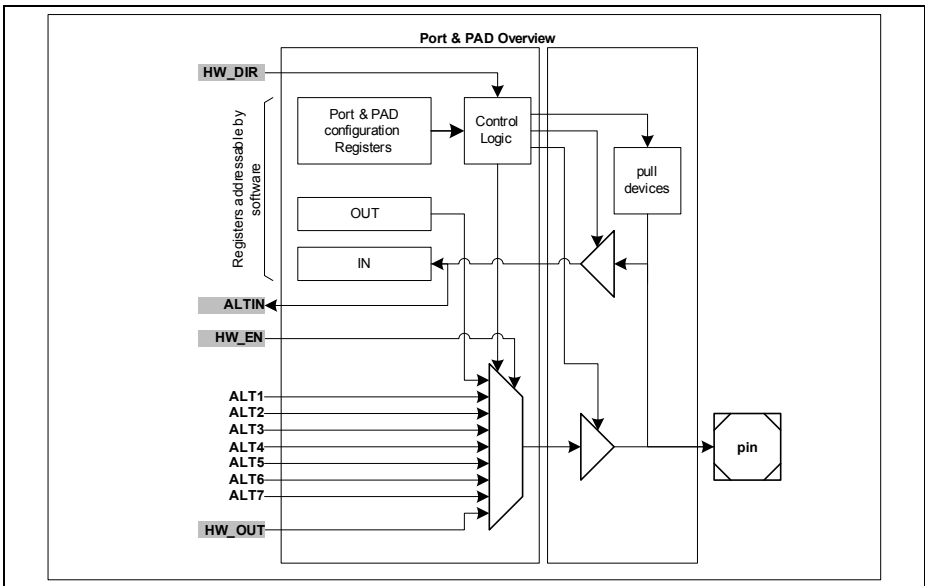

Figure 9-2 Generic Port Structure

The port can be connected to peripheral functions via the ALT_x inputs. This is the default state of the port after power-on reset. The SMU connects to the port using the HW_DIR, ALTIN, HW_EN, HW_OUT signals. When the HW_EN port input is driven active by the SMU, SMU gets full control over the port data path, bypassing any other software configuration related to the usage of the ALT_x inputs.

Figure 9-3 “SMU Data Path Interfaces with the Ports” on Page 9-10 fully specifies the data path connectivity of the SMU with the Ports. The mapping to the port for the product can be found in the port specification chapter of the TC26x B-Step microcontroller.

Safety Management Unit (SMU)

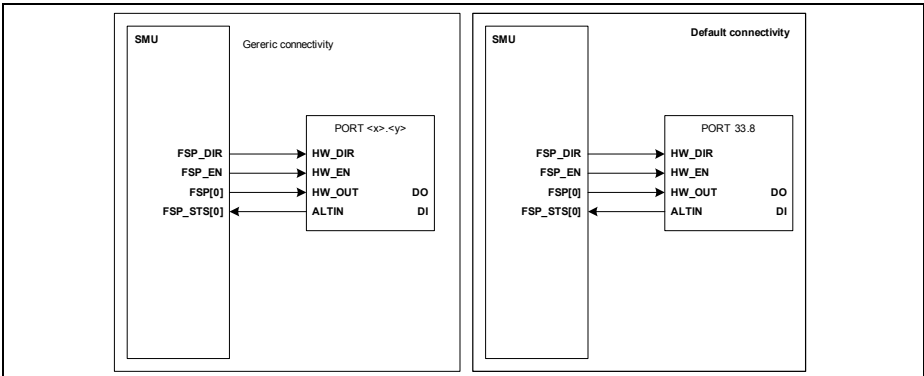

Figure 9-3 SMU Data Path Interfaces with the Ports

Figure 9-4 “SMU/PAD Control Interface to the PADs” on Page 9-10 provides a more detailed overview of the PORT structure and highlights the signals that play a role in the SMU connectivity.

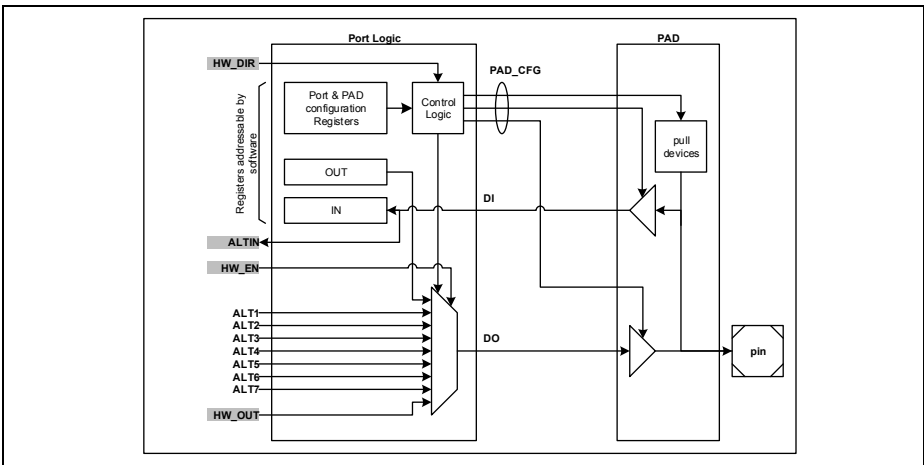

Figure 9-4 SMU/PAD Control Interface to the PADs

While FSP[0] is controlled by hardware, the FSP_DIR and FSP_EN are controlled by software as follows:

- FSP_DIR output is directly driven by the **SMU_PCTL** register HWDIR field
- FSP_EN output is directly driven by the **SMU_PCTL** register HWEN field

Safety Management Unit (SMU)

SMU_PCTL provides a field PCS that enables software to change the PAD control. With **SMU_PCTL** HWDIR, HWEN and PCS fields, software can control the PAD ownership transition from GPIO to full SMU hardware control following the guidelines provided by the **SMU_PCTL** register description.

To satisfy safety requirements it shall be ensured that the PAD operation is not affected by an application or system reset: the application can configure a system reset and the SMU Error Pin fault state activation upon detection of a critical alarm. This is achieved by safeguarding all the PAD configuration signals (see PAD_CFG signals [Figure 9-4](#)) into a special register. The contents of this register are exposed to software using the **SMU_PCTL**.PCFG field. They are only available for debug purposes.

The contents of the **SMU_PCTL** register are locked by the **SMU_KEYS** register and are only reset by a power-on reset, therefore the PAD configuration remains stable even in the presence of an application or system reset. Furthermore the **SMU_PCTL** register is implemented using dedicated Safety Flip-Flops safety mechanism that detects in run-time any bit change caused by a random hardware fault.

Refer to [“SMU Integration Guidelines” on Page 9-13](#) for the SMU and PORT configuration steps that are required to use the Error Pin.

9.4.2.4 Interface to the Safety Flip-Flop Safety Mechanism

The SMU provides a register interface that enables to test the Safety Flip-Flop safety mechanism. The register interface is realized by the **SMU_RMCTL**, **SMU_RMEF**, **SMU_RMSTS** registers.

9.4.3 SMU Integration Guidelines

This chapter extends the “[Interfaces Overview](#)” on [Page 9-8](#) section by providing additional information for the usage of the Error Pin (“[Fault Signaling Protocol \(FSP\)](#)” on [Page 9-52](#)) in combination with other input/output (GPIO) functions of the microcontroller.

Note: The PAD properties (push-pull, open-drain, drive strength,...) are configured in the registers of the PORT to which the SMU connects to. These registers are described in the PORT chapter of the microcontroller.

- During power-on-reset, the Error Pin is in high impedance: the pull devices are disabled under hardware control.
- After power-on-reset the default mode of the PORT to which the Error Pin is connected is GPIO. In that mode the pull devices can be used.
- Before changing the ownership of the PAD to SMU, software shall configure the PORT registers including the following:
 - Software shall disable the pull devices if GPIO is not used
 - Software shall program the GPIO registers of the error pin to strong driver output constant low
- To enable SMU to control the Error Pin PAD, software shall activate the PAD configuration safeguarding process (see “[Interface to the Ports \(Error Pin\)](#)” on [Page 9-8](#)).
 - The safeguarding process requires a software action that consists on writing a 1 into the `SMU_PCTL.PCS` field. **Only with the first transition from 0 to 1 leads to the safeguarding process. A new PORT configuration followed by a new transition from 0 to 1 of the `SMU_PCTL.PCS` has no effect to the hardware.**

9.4.4 Alarm Mapping

This section defines the mapping between the alarm signals at the input of the SMU and the alarm configuration registers. For that purpose alarm groups are defined. There is a one to one relationship between an alarm group index ALM<n>[index] signal and the alarm configuration and status registers (AG<n>[index]). A group is made of up to 32 input alarms; for convenience some entries may be reserved.

9.4.4.1 Pre-alarm Definition

There are situations where it is not necessary to implement configuration and status registers for every alarm; a typical case is a module with multiple SRAM instances. For that purpose a so-called PreAlarm[] bus is available to which the alarms that can be combined together are connected to. The result of the combination is sent to a HwAlarmOut[] output so that HwAlarmOut[] = Combine(PreAlarm[n], PreAlarm[m],...). The tables in **“Pre-alarm Signals” on Page 9-14** fully specify the arguments for the Combine() functions. The Combine() function implements a logical OR between all arguments.

Note: The unspecified (or unused) PreAlarm[] bits shall be tied to the logic level ‘0’ at the SMU input.

Note: The unspecified (or unused) HwAlarmOut[] bits shall be driven to the logic level ‘0’ by the SMU.

9.4.4.2 Pre-alarm Signals

In the next tables the PreAlarm[] bits are specified in the form index=MODULE.(type of error message), where MODULE.(type of error message) enables to identify the module instance and the nature of the error message. The error message is specified in a functional way and does not refer to a real signal name in the design. The modules connecting to the SMU shall use the same functional name to enable a cross-reference through the overall specification.

HwAlarmOut[50]= PreAlarm[210=PMU.PFLASH0.(Address buffer full)] or PreAlarm[211=PMU.PFLASH1.(Address buffer full)]

Table 9-14 HwAlarmOut[51]: Access Enable Alarms

Function
HwAlarmOut[51]= PreAlarm[218=IR.(Access Enable Error)] ¹⁾ or PreAlarm[219=SCU.DTS.(Access Enable Error)]
PreAlarm[229:220] bits are reserved for extensions of the Access Enable Alarms

- 1) This alarm is related to the event where a master not configured in the module ACCEN register tries to access a register protected by the ACCEN scheme. Depending on the module all or only a subset of the module registers are protected by the ACCEN. Most of the modules only generate a bus error condition and no dedicated ACCEN alarm when the aforementioned event happens.

9.4.4.3 Non-compliant Alarms

This section describes the alarms that are not compliant with the SMU alarm protocol and for which a special processing is required. They are first connected to a pre-alarm to be processed by the SMU in order to deliver a SMU compatible input alarm signal.

Table 9-15 HwAlarmOut[63] specification: SCR Alarm

Function
HwAlarmOut[63]= PreAlarm[255=SCR(Standby Controller Alarm)]
PreAlarm[255] is a signal clocked by the fBACK clock, it shall be synchronized to the fSPB clock. HwAlarmOut[63] shall be connected to ALM3[24].

Note: The Standby Controller is not available in all devices. When not available PreAlarm[255] shall be connected to '0' and ALM3[24] shall be reserved.

9.4.4.4 Internal SMU Alarms

The SMU has also the capability to generate its own alarm signals. They are specified in [Table 9-16 “Internal Alarms” on Page 9-23](#).

Table 9-16 Internal Alarms

HwAlarmOut	Function
HwAlarmOut[60]	Recovery Timer 0 Timeout
HwAlarmOut[61]	Recovery Timer 1 Timeout
HwAlarmOut[62]	FSP Fault State Activation
HwAlarmOut[63]	Reserved

9.4.4.5 Alarm Signals

The following tables fully specify the mapping between the alarms provided by the safety mechanisms implemented by the microcontroller and the alarm groups. Cells in **bold** refer to alarms coming from multiple instances of the same safety mechanism that are logically combined to a single alarm definition at the SMU level.

In the following tables the column “Safety Mechanism & Error Indication” indicates to which safety mechanism the alarm is related to. If multiple safety mechanisms are indicated, the alarm corresponds to the detection of an error by one of the listed safety mechanisms.

For some safety mechanisms different terms are used in the microcontroller documents; the following list provides a guideline between the term used in the alarm tables and the other definitions. In bold the definition used in the alarm tables.

- **Register Access Protection** or alternatively called Safety Register Protection
 - Purpose: Monitors the master identifier of a given bus-master during a write access to a configuration register. The master identifier is a hard-coded information that is provided during any bus access. If the master identifier is not enabled by the Register Access Protection configuration registers (ACCEN0) the write is aborted. Most of the modules do not provide a dedicated alarm for this event and instead will generate a bus error. Therefore the Register Access Protection is only documented where a dedicated alarm is available.
 - Note: for peripherals that implement memory-mapped SRAMs, the write accesses to the memories are monitored as well.
- **Bus-level Memory Protection Unit (MPU)** or alternatively called Safety Memory Protection
 - Purpose: Monitors the master identifier and the address of a given bus-master during a write access to a local SRAM. The master identifier is a hard-coded information that is provided during any bus access. If the master identifier is enabled by the Bus-level MPU configuration registers and the address is within the valid address range the write is accepted, otherwise the write is aborted and a Bus-level MPU alarm is issued.
 - The SRAMs monitored are the {PSPR, DSPR} SRAMs of each CPU and the LMU SRAMs when available in the product.

Safety Management Unit (SMU)

9.4.5 Alarm Handling

This section specifies the hardware and software alarm processes.

9.4.5.1 Alarm protocol

Each safety mechanism shall interface with the SMU using a pre-defined protocol. The protocol enables to cross clock domains in a reliable manner. The operation of the protocol has no influence to the software layers.

9.4.5.2 Alarm Configuration

Upon reception of an alarm event the SMU decodes the actions to be performed. The action can be classified into an internal behavior and an external behavior. Both the internal and external behavior can be configured for every alarm.

The external behavior is related to the Fault Signaling Protocol (see [“Fault Signaling Protocol \(FSP\)” on Page 9-52](#)). The external behavior is configured via the following registers:

- [SMU_AG0FSP](#)
- [SMU_AG1FSP](#)
- [SMU_AG2FSP](#)
- [SMU_AG3FSP](#)
- [SMU_AG4FSP](#)
- [SMU_AG5FSP](#)
- [SMU_AG6FSP](#)

Alarm Action Configuration Registers

The internal behavior of the SMU under the presence of an alarm is controlled via the following registers:

- [SMU_AG0CFx \(x=0-2\)](#)
- [SMU_AG1CFx \(x=0-2\)](#)
- [SMU_AG2CFx \(x=0-0\)](#), [SMU_AG2CFx \(x=1-1\)](#), [SMU_AG2CFx \(x=2-2\)](#)
- [SMU_AG3CFx \(x=0-0\)](#), [SMU_AG3CFx \(x=1-1\)](#), [SMU_AG3CFx \(x=2-2\)](#)
- [SMU_AG4CFx \(x=0-2\)](#)
- [SMU_AG5CFx \(x=0-2\)](#)
- [SMU_AG6CFx \(x=0-2\)](#)

Alarm Action Configuration Codes

The internal behavior is specified by a 3-bit code as follows:

- Code = SMU_AG<n>CF2. SMU_AG<n>CF1. SMU_AG<n>CF0, n=0...6

Table 9-24 SMU Alarm Configuration

Code	Name	Behavior
0x0	SMU_NA	No Action. Reset value. Alarm disabled.
0x1	SMU_RSVD	Reserved. No Action. Alarm disabled.
0x2	SMU_IGCS0	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 0 from the SMU_AGC register.
0x3	SMU_IGCS1	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 1 from the SMU_AGC register.
0x4	SMU_IGCS2	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 2 from the SMU_AGC register.
0x5	SMU_NMI	Sends an NMI request to the SCU
0x6	SMU_RESET	Sends a reset request to the SCU. The SCU shall be configured to generate an application or system reset.
0x7	SMU_IDLE	Triggers a CPU idle request using Idle Configuration Set from the SMU_AGC register

Unless otherwise specified the reset state of the alarms is “No Action”. Refer to reset values of registers listed in **“Alarm Action Configuration Registers” on Page 9-41** and special cases described in **“Watchdog Alarms” on Page 9-46**.

9.4.5.3 Alarm operation

Whenever an input alarm event is detected and the SMU state machine is in the RUN or FAULT state, the SMU checks for the corresponding actions to be done for the internal action and for the FSP in a concurrent way. If an input alarm event is detected and no action is specified for the alarm, the corresponding bit shall be set to 1 as well but no action takes place.

The processing of the incoming alarm events is performed as follows:

- The alarm groups are scanned in a linear order starting with alarm group 0. The switching from one alarm group to the next one, takes several clock cycles.
- During the switch operation to a new alarm group (AG_y) a snapshot of the pending alarms for AG_y is made by hardware.
- If there are no pending alarms for the active alarm group AG_y nothing happens during the processing time slot related to this alarm group.
- If there are pending alarms they are processed in a fixed order 0 up to 31.
 - If new alarms arrived for the active alarm group, they are only processed in the next time slot for the alarm group.
 - The processing of an alarm within an alarm group may take several fSPB cycles.
 - If the status flag related to a pending alarm event is already set to 1 the alarm event is ignored and the next available pending alarm within the active group is searched.
 - Whenever a pending alarm event is processed, the corresponding status bit is set to 1 by hardware in the AG<x> register. If an internal SMU action is configured the action counter (ACNT) in the **SMU_AFCNT** register is incremented.

9.4.5.4 Alarm Status Registers

Table 9-25 “Handling of Alarm Status” on Page 9-44 specifies the possible software actions on the AG<x> alarm group status registers depending on the SMU State machine state.

Table 9-25 Handling of Alarm Status

SMU State Machine	SW Action	Effect on AG<x>
START	SMU_ASCE(0) command Write Data at AG<x> Address	If (Data [i] == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
START	Write Data at AG<x> Address	If (Data [i] == 1) AG<x>[i] = 1 else AG<x>[i] unchanged
RUN	SMU_ASCE(0) command Write Data at AG<x> Address	If (Data [i] == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
RUN	Write Data at AG<x> Address	No Effect
FAULT	SMU_ASCE(0) command Write Data at AG<x> Address	If (Data [i] == 1) AG<x>[i] = 0 else AG<x>[i] unchanged
FAULT	Write Data at AG<x> Address	No Effect

In the START state software has the possibility to “emulate” the occurrence of input alarm events by writing at an AG<x> address. The resulting set of an AG<x> bit per software can take several hundreds of clock cycles depending on the hardware decoding state and the number of active alarms. Software shall read back the AG<x> register to ensure the completion of the operation if necessary.

9.4.5.5 Alarm Debug Registers

The Alarm debug registers enable the application to improve the diagnosis of the root cause that lead to a malfunction. In that context they may help to implement recovery strategies, if allowed by the application. The **SMU_ADx (x=0-6)** debug registers shall make a snapshot of the **SMU_AGx (x=0-6)** when:

- the action to be executed by the SMU is a reset when the SMU is in the RUN or in the FAULT state
- a SMU state machine (SSM) transition to the FAULT state takes place, either controlled by the SMU hardware or a software command

The **SMU_ADx (x=0-6)** shall only cleared by a power-on reset.

9.4.5.6 Port Emergency Stop

The port emergency stop feature enables forcing a pad into General Purpose Input Mode. The port emergency stop request to the SCU can be activated by any of the following situations:

- a `SMU_ActivatePES()` software command
- an alarm event with `SMU_AG<x>FSP` enabled and `SMU_FSP.PES` enabled
- an alarm event with an internal action configured in `SMU_AG<x>CFx` registers and `SMU_AGC.PES` enabled for that action.

9.4.5.7 Recovery Timer

A recovery timer (RT) is available to enable the monitoring of the duration or internal error handlers activated by an alarm NMI or Interrupt action. In the current SMU implementation two independent instances (RT0 and RT1) are available. The recovery timer duration (identical for all instances) is configured in the register `SMU_RTC`. It is possible to enable or disable each instance, however RT0 is enabled by default as it is required for the operation of the CPU watchdogs (see also “[Watchdog Alarms](#)” on [Page 9-46](#)). In addition to `SMU_RTC` an additional configuration register (`SMU_RTC<n>`) is available per instance to configure the alarm mapping.

The alarm mapping consists of a pair of parameters $\{GID<n>[2:0], ALID<n>[4:0]\}$, where $GID<n>[2:0]$ is a group identifier and $ALID<n>[4:0]$ is the alarm identifier belonging to the group. Four $\{GID[], ALID[]\}$ pairs can be configured per recovery timer instance. It is possible to configure multiple times the same group identifier. If less than four alarms need to be mapped to a recovery timer, the same $\{GID[], ALID[]\}$ shall be configured multiple times.

Note: The use of the recovery timer only makes sense if the internal action is an interrupt or NMI. However no hardware check is done, it is up to software to configure the SMU in the appropriate way.

If a recovery timer is enabled and for any of the $\{GID[], ALID[]\}$ pairs and an alarm event occurs and if an internal action is configured resulting to an internal action (the alarm status shall be cleared) the recovery timer is automatically started by hardware. Such situation is called a recovery timer event. An alarm without internal action shall not start a recovery timer.

Once an recovery timer event is occurs, the recovery timer starts and counts until software stops it with the `SMU_RTStop()`. If the timer expires an internal SMU alarm (Recovery Timer Timeout) is issued. During the time the recovery timer is running any other action that requests the recovery timer is ignored. If such event happens, the bit `RTME` (Recovery Timer Missed Event) is set to ‘1’ by hardware in the `SMU_STS` register. The bit `RTME` can only be cleared by software. The bit `RTS` (Recovery Timer Status) is set to ‘1’ by hardware in the `SMU_STS` register during the time the recovery

Safety Management Unit (SMU)

timer is running: from the timer activation until a SMU_RTStop() is received or the timer expires. The bit RTS is cleared by hardware upon reception of SMU_RTStop() or the timer expires.

If a SMU_RTStop() command is received when the recovery timer is not active, the command returns an error response.

9.4.5.8 Watchdog Alarms

The watchdogs (WDT) timeout alarms require a special processing in order to ensure a correct microcontroller behavior if the watchdogs are not serviced by software or firmware. It shall be ensured that the microcontroller is reset after a pre-warning phase, where software can still perform some critical actions.

- Every Timeout Alarm shall activate an NMI
- Recovery Timer 0 shall be configured to service WDT timeout alarms
- Recovery Timer 0 timeout alarm shall be configured to issue a reset request and activate the Fault Signalling Protocol.

The aforementioned properties are implemented as reset values for the watchdog(s) timeout alarm(s) and for the recovery timer 0.

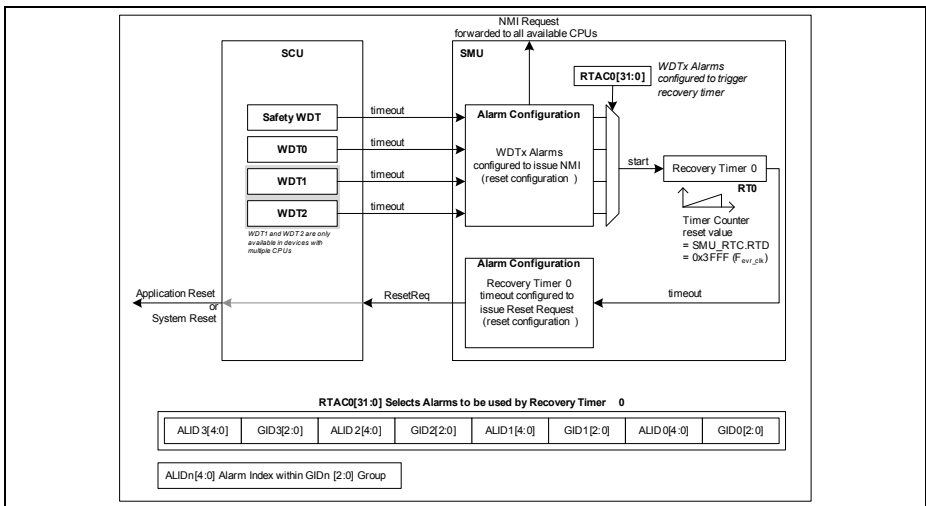

Figure 9-5 Watchdog timeout alarm configuration

The watchdog timeout detection is required from the very first instruction executed by a CPU: the SMU shall process any watchdog timeout alarm during the START state.

Note: If the same behavior is expected for all WDT alarms, it is recommended to use the global WDT timeout alarm that implements a logical OR among all WDT timeout

Safety Management Unit (SMU)

*alarms, thus freeing some {GID[], ALID[]} configuration pairs in **SMU_RTACO** for other purposes.*

9.4.6 SMU Control Interface

The core functionality of the SMU is introduced through its control interface. The control interface defines how the SMU can be controlled by software, as summarized in [Table 9-26 “SMU Commands” on Page 9-48](#). The control interface is directly linked to the SMU state machine (SSM) operation described in [“SMU state machine” on Page 9-50](#) and to the Fault Signaling Protocol (FSP) described in [“Fault Signaling Protocol \(FSP\)” on Page 9-52](#).

The control interface is implemented by the [SMU_CMD](#) register using the CMD and ARG fields. The command completion status is available via the [SMU_STS](#) register.

Table 9-26 SMU Commands

Command	Description	Code
SMU_Start(ARG)	Forces the SSM to go to the RUN state from the START state. Argument ARG shall be set to 0.	0x0
SMU_ActivateFSP(ARG)	Activates the Fault Signaling Protocol. This action is possible in any state of the SSM. Argument ARG shall be set to 0.	0x1
SMU_ReleaseFSP(ARG)	Turns the FSP into the fault free state. In the START state, SMU_ActivateFSP() and SMU_ReleaseFSP() can be called as many times as necessary to perform self tests of every alarm source. Argument ARG shall be set to 0.	0x2
SMU_ActivatePES(ARG)	Triggers the activation of the Port Emergency Stop (PES). The PES is also directly controlled by the SMU when entering the FAULT state. Argument ARG shall be set to 0.	0x3
SMU_RTStop()	Stop the recovery Timer. Argument ARG shall be set to the recovery timer instance available in the product.	0x4

Safety Management Unit (SMU)

Table 9-26 SMU Commands (cont'd)

Command	Description	Code
SMU_ASCE(ARG)	Alarm Status Clear Enable Command. Software shall execute this command prior to clear a AG<n> alarm status bit. This command sets the ASCE bit in the SMU_STS register. Argument ARG shall be set to 0.	0x5
SMU_Alarm(ARG)	Triggers a software based alarm. ARG specifies the alarm index according to the mapping defined in “Alarm Mapping” on Page 9-14 . A software alarm has the same properties as an hardware alarm.	0x6

Note: If the argument does not comply with the specification of the command the command is ignored and returns an error code.

The next table specifies the legal conditions that shall be followed for the execution of the commands. The conditions depend on the SMU state machine (SSM) states (see **“SMU state machine” on Page 9-50**). Any situation not specified leads to an error code.

Table 9-27 SMU commands and valid conditions

Command	SSM state	Other conditions
SMU_Start(ARG)	START	ARG == 0
SMU_ActivateFSP(ARG)	Any	ARG == 0
SMU_ReleaseFSP(ARG)	START	ARG == 0
SMU_ReleaseFSP(ARG)	FAULT	ARG == 0 & SMU_AGC.EFRST == 1 ¹⁾
SMU_ActivatePES(ARG)	Any	ARG == 0
SMU_RTStop(ARG)	Any	ARG >= 0 and ARG <= Number of Recovery Timer Instances and Recovery Timer Enabled
SMU_ASCE(ARG)	Any	ARG == 0
SMU_Alarm(ARG)	RUN, FAULT ²⁾	ARG >= 0

1) See also **“Fault Signaling Protocol (FSP)” on Page 9-52**.

2) In the START state of the SMU input alarms are not processed, therefore software triggered alarms will have no effect.

Safety Management Unit (SMU)

9.4.7 SMU state machine

Figure 9-6 “SMU state machine (SSM): transition conditions and actions” on Page 9-50 and Figure 9-6 “SMU state machine (SSM): transition conditions and actions” on Page 9-50 fully specifies the behavior of the SMU state machine (SSM).

Figure 9-6 SMU state machine (SSM): transition conditions and actions

Safety Management Unit (SMU)

Figure 9-7 SMU state machine: state actions

Fault Counter

The SMU implements a Fault Counter (**SMU_AFCNT**) that counts the number of transitions from the RUN state to the FAULT state. The Fault Counter register is only reset by a power-on-reset.

9.4.8 Fault Signaling Protocol (FSP)

The Fault Signaling Protocol enables the microcontroller to report a critical situation to an external safety controller device in order to control the safe state of the safety system.

9.4.8.1 Introduction

The fault signaling protocol is configured via the **SMU_FSP** command register. The FSP has three states:

- The power-on reset state. After power-on reset the SMU is disconnected from the ports (see **“SMU Integration Guidelines” on Page 9-13**). After power-on reset the SMU FSP output shall be the Fault State.
- The Fault-free State. Whenever the fault-free state is controlled by a timing, the timing will be called T_{FSP_FFS} and is controlled by the **SMU_FSP** register.
- The Fault State. The timing of the fault state is controlled by the **SMU_FSP** register. The minimum active fault state time is called T_{FSP_FS} .

The Fault-free and fault state behavior can be configured with the following protocols:

- Bi-stable protocol (default)
- Time-switching protocol

The FSP can be controlled by:

- Software using the **SMU_ActivateFSP()** and **SMU_ReleaseFSP()** commands using the **SMU_CMD** register
- Hardware based on the **SMU_AG0FSP**, **SMU_AG1FSP**, **SMU_AG2FSP**, **SMU_AG3FSP**, **SMU_AG4FSP**, **SMU_AG5FSP**, **SMU_AG6FSP** configuration registers.
- The logic state of the FSP PAD can be observed by reading the FSP field of the **SMU_STS** register.

Figure 9-8 “Reference clocks for FSP timings” on Page 9-53 specifies the intermediate clocks to generate the T_{FSP_FFS} and T_{FSP_FS} timings.

Safety Management Unit (SMU)

Figure 9-8 Reference clocks for FSP timings

9.4.8.2 Bi-stable fault signaling protocol

Figure 9-9 Bi-stable fault signaling protocol

Operation

FSP[0] is switched to a static logic level 0 or logic level 1 under software or hardware control.

- During power-on-reset FSP[0] = 0 (fault state)
- After power-on reset FSP[0] stays in the fault state
- FSP[0] must be set to the fault free state per software (`SMU_ReleaseFSP()`).
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes to the fault state and remains in this state until a `SMU_ReleaseFSP()` command is received and T_{FSP_FS} is satisfied or a Power-on Reset takes place.

9.4.8.3 Time switching protocol

Figure 9-10 Time switching protocol

Operation

FSP[0] is toggled between logic level 0 and logic level 1 with a defined frequency. This frequency modulation protocol is violated when the SMU enters the FAULT state.

- During power-on-reset FSP[0] = 0 (fault state).
- After power-on-reset FSP[0] stays in the fault state.
- FSP[0] must be set to the fault free state per software (**SMU_ReleaseFSP()**).
- In the fault free state, FSP[0] oscillates between logic level 0 and logic level 1 with the frequency configured via the **SMU_FSP** register (see **Figure 9-10**).
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes immediately to the fault state and remains in this state until a **SMU_ReleaseFSP()** command is received and T_{FSP_FS} is satisfied or a Power-on Reset takes place.

9.4.8.4 FSP Fault State

When an alarm configured to activate the FSP, the SMU automatically switches to the FAULT state. During this time it is also possible for the safety-related software to try to analyze the root cause (when the microcontroller is still operational) and decide about the severity of the error. As the FSP is active for at least T_{FSP_FS} (see **SMU_FSP** register), it is ensured that the safe state of the system is entered through external mechanisms independent from the microcontroller (besides FSP itself).

While in the Fault State, if a new alarm event configured to activate the FSP is received and the T_{FSP_FS} has not yet been reached, the T_{FSP_FS} timing shall be restarted.

During the time T_{FSP_FS} FSP is in the Fault State, software may have concluded that the fault is uncritical and decides to issue a `SMU_ReleaseFSP()` command, notifying the SMU it can return to the RUN state (the run-time of the software error handler is not directly correlated with the T_{FSP_FS} duration and in practice shall be much shorter). This feature shall be used with caution: a microcontroller reset is highly recommended to restart the operation of the safety function when a fault reported by the SMU is assessed to be uncritical. Therefore this feature is per default disabled and shall be configured with the `EFRST` (Enable Fault to Run State Transition) field in the **SMU_AGC** register.

Figure 9-11 FSP: Fault State to Fault Free State Transition

9.4.8.5 FSP and SMU START State

Figure 9-12 “Software Control of FSP during SMU START State” on Page 9-57 shows a typical use case where the FSP transitions between the Fault State and Fault Free State are controlled by software using the SMU_ReleaseFSP() and SMU_ActivateFSP() commands.

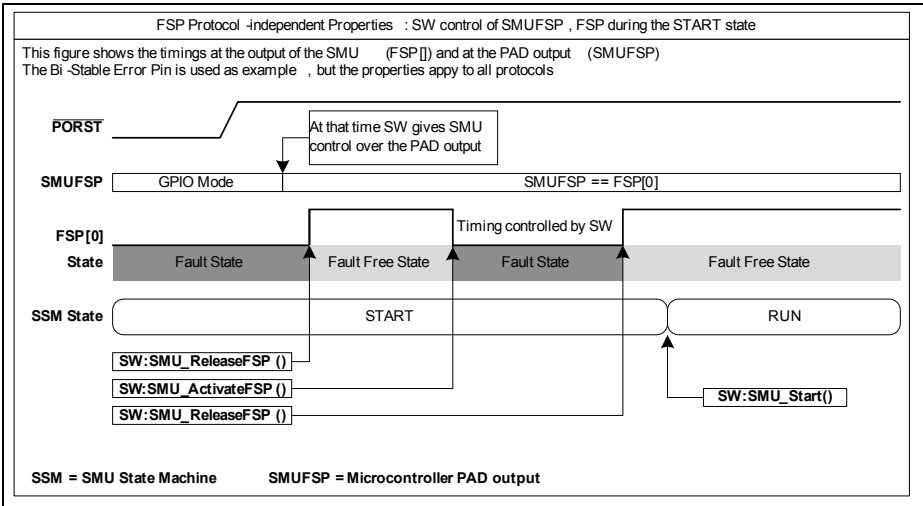

Figure 9-12 Software Control of FSP during SMU START State

Conditions of Use

- Software shall ensure that the FSP is in the Fault Free State before entering the RUN state with the SMU_Start() command.

9.4.9 OCDS Trigger Bus (OTGB) Interface

The SMU concentrates all failure indicator signals (alarms) of the device. By using them as MCDS trace information (failure type) and trace control (stop trace recording), the analysis of a failure's root cause is supported. This is even the case, when the alarm handling within the system includes a PORST, since the content of the trace memory will be still valid after the PORST.

The alarms handled in the SMU are very rare and sporadic. So it's acceptable that they are visible on the Trigger Bus with a small delay and not all in parallel with a cycle accurate timing resolution. The SMU Trigger Set is shown in [Table 9-28](#). It is output on OTGB0 or OTGB1 controlled by the [SMU_OCS](#) register.

Table 9-28 TS16_SMU Trigger Set SMU

Bits	Name	Description
0	AA	Any ALM bit active
1		Reserved
[3:2]	ABI	ALM Byte Index, selecting the byte within the ALM group
[6:4]	AGI	ALM Group Index
7		Reserved
[15:8]	ALM	Selected byte of the ALM group

If no alarm is active, TS16_SMU will be all zero. If alarms are only active within one ALM Byte, TS16_SMU will show statically this byte. If alarms are active in two or more ALM Bytes, TS16_SMU will change between these bytes.

Note that due to the implementation, that all the ALM Bytes are being scanned one per clock cycle, the TS16_SMU ALM Byte information on OTGB0/1 can be delayed by up to 27 clock cycles for the second alarm. TS16_SMU.AA will however become active (and inactive) immediately. The implementation will make sure, that the ALM Byte with the first causing alarm will be traced with MCDS before a reset as safety action clears this information.

9.4.10 Register Properties

9.4.10.1 Register Write Protection

The SMU registers are write protected against illegal master accesses by the master protection mechanism implemented in the System Peripheral Bus interface logic. The registers controlling the master access protection are described in the section “**System Registers description**” on Page 9-68. In addition the SMU registers can only be written if the SafeEinit is enabled. Read accesses have no restriction as there is no side effect specified when reading registers. The SafeEinit has the same properties as the system Einit but it is generated by the safety watchdog. In order to access a SMU register the software must first activate the safety watchdog via a signature protected sequence. The safety watchdog is configured to enable only safety-related software to activate the SafeEinit.

Configuration Lock

In addition to the aforementioned standard features, additional mechanisms are implemented to control and protect the SMU configuration. In order to configure and lock the SMU configuration the following steps shall be followed:

- The SMU configuration is only possible if the CFGLOCK field of the **SMU_KEYS** register is set to 0xBC.
- If the PERLOCK field of the **SMU_KEYS** register is set to 0xFF no further SMU configuration is possible, including the **SMU_KEYS** register itself. No SMU configuration is possible anymore until the PERLOCK field of the **SMU_KEYS** register is reset to 0x00 by an application reset.

The SMU configuration registers controlled by the **SMU_KEYS** register properties are:

- **SMU_FSP**
- **SMU_AGC**
- **SMU_RTC**
- **SMU_RTAC0**
- **SMU_RTAC1**
- **SMU_AG0CFx (x=0-2)**
- **SMU_AG1CFx (x=0-2)**
- **SMU_AG2CFx (x=0-0)**
- **SMU_AG3CFx (x=0-0)**
- **SMU_AG4CFx (x=0-2)**
- **SMU_AG5CFx (x=0-2)**
- **SMU_AG6CFx (x=0-2)**
- **SMU_AG0FSP**
- **SMU_AG1FSP**

Safety Management Unit (SMU)

- **SMU_AG2FSP**
- **SMU_AG3FSP**
- **SMU_AG4FSP**
- **SMU_AG5FSP**
- **SMU_AG6FSP**
- **SMU_PCTL**
- **SMU_RMCTL**

The **SMU_CMD** register is not locked as it is used for run-time hardware/software interaction, it is not a configuration register.

The **SMU_AGx (x=0-6)** registers are not locked as it is possible during run-time to clear the alarm flags by software.

The **SMU_OCS**, **SMU_KRSTCLR**, **SMU_KRST1**, **SMU_KRST0**, **SMU_ACCEN1**, **SMU_ACCEN0** do not belong to the SMU kernel but to the standard bus interface module, therefore they are not controlled by the **SMU_KEYS** register.

The read only registers are not protected by the lock mechanism.

9.4.10.2 Safety Flip-Flops

Safety Flip-Flops are special Flip-Flops that implement an hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The SMU configuration registers that shall be implemented with safety flip-flops are:

- **SMU_FSP**
- **SMU_AGC**
- **SMU_RTC**
- **SMU_KEYS**
- **SMU_PCTL**
- **SMU_RTAC0**
- **SMU_RTAC1**
- **SMU_AG0CFx (x=0-2)**
- **SMU_AG1CFx (x=0-2)**
- **SMU_AG2CFx (x=0-0)**
- **SMU_AG3CFx (x=0-0)**
- **SMU_AG4CFx (x=0-2)**
- **SMU_AG5CFx (x=0-2)**
- **SMU_AG6CFx (x=0-2)**
- **SMU_AG0FSP**
- **SMU_AG1FSP**
- **SMU_AG2FSP**
- **SMU_AG3FSP**
- **SMU_AG4FSP**
- **SMU_AG5FSP**
- **SMU_AG6FSP**

Safety Management Unit (SMU)

Additionally the following SMU functions shall also be implemented with safety flip-flops:

- SMU state machine registers
- Registers implementing the FSP function

Safety Management Unit (SMU)

9.5.1 System Registers description

SMU Clock Control Register (CLC)

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The SMU shall be enabled per default

SMU_CLC

Clock Control Register

(00_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

0												EDIS	FDIS	DISS	DISR
r												rw	rw	rh	rw

Field	Bits	Type	Description
DISR	0	rw	Module Disable Request Bit Used for enable/disable control of the module. 0 _B Module disable is not requested 1 _B Module disable is requested
DISS	1	rh	Module Disable Status Bit Bit indicates the current status of the module. 0 _B Module is enabled 1 _B Module is disabled
FDIS	2	rw	Force Disable The feature controlled by this field is not used. Read as 0; should be written with 0.
EDIS	3	rw	Sleep Mode Enable Control Used to control module's sleep mode. Sleep Mode is not supported safety applications. During the process of entering and resuming from sleep mode the intended processing of alarm events is not guaranteed.

Safety Management Unit (SMU)

Field	Bits	Type	Description
0	[31:4]	r	Reserved Read as 0; should be written with 0.

Note: The other features controlled by the CLC register are not supported by the SMU.

Safety Management Unit (SMU)

SMU Module Identification Register

SMU_ID

Module Identification Register (08_H) Reset Value: 0089 C001_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type The bit field is set to C0 _H which defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. The value for the SMU module is 0089 _H .

Safety Management Unit (SMU)

SMU OCDS Control Register. This register is implemented in the BPI.

The OCDS Control and Status (OCS) register is reset by Debug Reset.

The OCS register includes the module related control bits for the OCDS Trigger Bus (OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = '1'). While OCDS is not enabled, OCS reset values/modes are effective.

SMU_OCS
OCDS Control and Status
(7E8_H)
Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	SUS STA	SUS_P	SUS				0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												TG_P	TGB	TGS	
r												w	rw	rw	

Field	Bits	Type	Description
TGS	[1:0]	rw	Trigger Set for OTGB0/1 0 _H No Trigger Set output 1 _H TS16_SMU others , reserved
TGB	2	rw	OTGB0/1 Bus Select 0 _B Trigger Set is output on OTGB0 1 _B Trigger Set is output on OTGB1
TG_P	3	w	TGS, TGB Write Protection TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	[27:24]	rw	OCDS Suspend Control No effect. SMU will not suspend. Read as 0; must be written with 0.
SUS_P	28	w	SUS Write Protection SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

Safety Management Unit (SMU)

Field	Bits	Type	Description
SUSSTA	29	rh	Suspend State Read as 0; must be written with 0.
0	[23:4], [31:30]	r	Reserved Read as 0; must be written with 0.

Safety Management Unit (SMU)

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bit (<>_KRST0.RSTSTAT).

SMU_KRSTCLR

SMU Reset Status Clear Register

(7EC_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
CLR	0	w	Kernel Reset Status Clear 0 _B No action 1 _B Clear Kernel Reset Status KRST0.RSTSTAT Read always as 0.
0	[31:1]	r	Reserved Read as 0; should be written with 0.

Safety Management Unit (SMU)

The Kernel Reset Register 1 is used to reset the related module kernel. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers (<>_KRSTx1.RST and <>_KRSTx0.RST) related to the module kernel that should be reset (kernel 0 or kernel 1). The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

SMU_KRST1

SMU Reset Register 1

(7F0_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set.</p> <p>0_B No kernel reset was requested 1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.</p>
0	[31:1]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Safety Management Unit (SMU)

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers related to the module kernel that should be reset (kernel 0 or kernel 1). In order support modules with two kernel the BPI_FPI provides two set of kernel reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI_FPI in the same clock cycle the RST bit is re-set by the BPI_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the related KRSTCLR_x.CLR register bit.

SMU_KRST0

SMU Reset Register 0 (7F4_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
RST	0	rwh	<p>Kernel Reset</p> <p>This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set.</p> <p>0_B No kernel reset was requested</p> <p>1_B A kernel reset was requested</p> <p>The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.</p>

Safety Management Unit (SMU)

Field	Bits	Type	Description
RSTSTAT	1	rh	<p>Kernel Reset Status</p> <p>This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits.</p> <p>0_B No kernel reset was executed 1_B Kernel reset was executed</p> <p>This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register.</p>
0	[31:2]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

Safety Management Unit (SMU)

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

SMU_ACCEN1

SMU Access Enable Register 1

(7F8_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

Safety Management Unit (SMU)

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

SMU_ACCEN0
SMU Access Enable Register 0
(7FC_H)
Reset Value: FFFF FFFF_H

Field	Bits	Type	Description
ENn (n = 0-31)	n	rw	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

Note: The mapping with the on-chip master-capable modules is described in the bus chapters of the TC26x B-Step microcontroller.

9.5.2 SMU Configuration Registers

SMU Command Register.

SMU_CMD

Command Register (20_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
CMD	[3:0]	w	Implements the SMU Command Interface. See Table 9-26 “SMU Commands” on Page 9-48 for the command encoding. Read as 0.
ARG	[7:4]	w	Implements the SMU Command Interface. Argument to be used with the command. See Table 9-26 “SMU Commands” on Page 9-48 for the argument encoding. Read as 0.
0	[31:8]	r	Reserved Read as 0; should be written with 0

Safety Management Unit (SMU)

SMU Status Register.

SMU_STS
Status Register (24_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CMD	[3:0]	rwh	Last command received Same encoding as CMD field of SMU_CMD register
ARG	[7:4]	rwh	Last command argument received Same encoding as ARG field of SMU_CMD register
RES	8	rwh	Result of last received command 0 _B Command was successful 1 _B Command failed
ASCE	9	rwh	Alarm Status Clear Enable This bit controls if a status flag set in an AG<x> register upon detection of an alarm event can be cleared by software or not. When ASCE is enabled software shall write a 1 to the bit position in AG<x> to clear the bit (W1C). When a W1C action takes place the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again by using the SMU_ASCE() command. 0 _B Alarm status bits AG<x> can not be cleared 1 _B Alarm status bits AG<x> can be cleared.

Safety Management Unit (SMU)

Field	Bits	Type	Description
FSP	[11:10]	rh	Fault Signaling Protocol status FSP[0] = FSP_STS[0] input signal FSP[1] = FSP_STS[1] input signal This field is updated by hardware every clock cycle, therefore a software clear on write is not meaningful for this field.
FSTS	12	rwh	Fault State Timing Status This bit indicates if the minimum timing duration of the FSP fault state has been reached or not. The bit is cleared by hardware when the fault state is entered. 0 _B Minimum timing duration not reached 1 _B Minimum timing duration reached
RTS0	16	rwh	Recovery Timer 0 Status See “Recovery Timer” on Page 9-45 for the usage of this field. 0 _B Recovery Timer not running 1 _B Recovery Timer running
RTME0	17	rwh	Recovery Timer 0 Missed Event See “Recovery Timer” on Page 9-45 for the usage of this field. 0 _B Recovery Timer event not detected 1 _B Recovery Timer event detected
RTS1	18	rwh	Recovery Timer 1 Status See “Recovery Timer” on Page 9-45 for the usage of this field. 0 _B Recovery Timer not running 1 _B Recovery Timer running
RTME1	19	rwh	Recovery Timer 1 Missed Event See “Recovery Timer” on Page 9-45 for the usage of this field. 0 _B Recovery Timer event not detected 1 _B Recovery Timer event detected
0	[31:20], [15:13]	r	Reserved Read as 0; should be written with 0.

Safety Management Unit (SMU)

Note: A write to this register (regardless of the data written) clears all the fields with the wrh type. If on the same cycle a software write event and hardware event is detected the hardware action wins.

Safety Management Unit (SMU)

SMU Fault Signalling Timing Configuration.

This register controls the timing of the fault signaling protocol.

SMU_FSP

Fault Signaling Protocol

(28_H)

Reset Value: 003F FF00_H

Field	Bits	Type	Description
PRE1	[2:0]	rw	<p>Prescaler1</p> <p>Dividing factor to apply to the reference clock fBACK. It is assumed that the maximal value for fBACK is 100 Mhz with a precision of 5%. The divided clock is used as reference to generate the timing of the fault signaling protocol fault state. The frequency of the divided clock (called F_{SMU_FS}) is defined as follows:</p> <p>0_H reference clock frequency divided by 2 1_H reference clock frequency divided by 4 2_H reference clock frequency divided by 8 3_H reference clock frequency divided by 16 4_H reference clock frequency divided by 32 5_H reference clock frequency divided by 64 6_H reference clock frequency divided by 128 7_H reference clock frequency divided by 256</p>

Safety Management Unit (SMU)

Field	Bits	Type	Description
PRE2	[4:3]	rw	Prescaler2 Dividing factor to apply to the reference clock fBACK in order to generate the timing of the fault free state for the time switching modes of the fault signaling protocol. The frequency of the divided clock (called F_{SMU_FFS}) is defined as follows: 0_H reference clock frequency divided by 512 1_H reference clock frequency divided by 1024 2_H reference clock frequency divided by 2048 3_H reference clock frequency divided by 4096
MODE	[6:5]	rw	Fault Signaling Protocol configuration 0_H Bi-stable protocol 1_H Reserved 2_H Time switching protocol 3_H Reserved
PES	7	rw	Port Emergency Stop (PES) When this bit is set a Port Emergency Stop is automatically requested when an alarm event configured to start the Fault Signalling Protocol is detected. 0_B Port Emergency Stop disabled 1_B Port Emergency Stop enabled
TFSP_LOW	[21:8]	r	Specification of the FSP fault state duration $T_{FSP_FS} = TFSP_HIGH \& TPSP_LOW$. Note: symbol & designates a concatenation TFSP_LOW shall be specified as a number of FSMU_FS ticks. TFSP_LOW is defined so that the minimum duration is greater than 250 us. It can not be changed by software. Refer to Figure 9-8 “Reference clocks for FSP timings” on Page 9-53
TFSP_HIGH	[31:22]	rw	Specification the FSP fault state duration $T_{FSP_FS} = TFSP_HIGH \& TPSP_LOW$. Note: symbol & designates a concatenation TFSP_HIGH shall be specified as a number of FSMU_FS ticks. TFSP_HIGH and PRE1 shall enable to configure a fault state duration of 500 ms.

Safety Management Unit (SMU)

SMU Alarm Global Configuration.

This register controls some properties related to the behavior of the SMU to alarm.

SMU_AGC

Alarm Global Configuration

(2C_H)

Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		EFR ST	PES				0				ICS				
r		rw		rw				r				rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		IGCS2				0	IGCS1		0	IGCS0					
r		rw				r	rw		r	rw					

Field	Bits	Type	Description
IGCS0	[2:0]	rw	Interrupt Generation Configuration Set 0 Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 0. Enables to issue an interrupt request to several CPUs: see “Interfaces to the Interrupt Router” on Page 9-8.
IGCS1	[6:4]	rw	Interrupt Generation Configuration Set 1 Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 1. Enables to issue an interrupt request to several CPUs: see “Interfaces to the Interrupt Router” on Page 9-8.
IGCS2	[10:8]	rw	Interrupt Generation Configuration Set 2 Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 2. Enables to issue an interrupt request to several CPUs: see “Interfaces to the Interrupt Router” on Page 9-8.

Safety Management Unit (SMU)

Field	Bits	Type	Description
ICS	[18:16]	rw	Idle Configuration Set Defines the output value of the idle request vector when the alarm configuration flag selects the Idle Configuration Set. Enables to issue an idle request to several CPUs if required. More complex idle scenarios can be handled by using software interrupts.
PES	[28:24]	rw	Port Emergency Stop This field enables control of the Port Emergency Stop (PES) feature independently for each internal action. When an action is triggered and if the corresponding bit (as defined below) is set, the hardware triggers automatically a port emergency stop request. Each bit of PES is allocated to an action as follows: 1 _H SMU_IGCS0 activates PES 2 _H SMU_IGCS1 activates PES 4 _H SMU_iGCS2 activates PES 8 _H SMU_NMI activates PES 10 _H SMU_IDLE activates PES
EFRST	29	rw	Enable FAULT to RUN State Transition See “FSP Fault State” on Page 9-56 chapter for the usage of this field.
0	[31:30], [23:19], [15:11], 7, 3	r	Reserved Read as 0; should be written with 0

Safety Management Unit (SMU)

SMU Recovery Timer Duration Configuration.

This register controls the timing duration of the recovery timer.

SMU_RTC
Recovery Timer Configuration
(30_H)
Reset Value: 003F FF01_H

Field	Bits	Type	Description
RTD	[31:8]	rw	Recovery Timer Duration This field specifies the maximum duration of the recovery timer. When the timer counter reaches the programmed value, the internal alarm <code>rt_timeout</code> is issued. The timer is stopped by a <code>SMU_RTStop()</code> command before the recovery timer. RTD shall be specified as a number of the F_{SMU_FS} clock ticks.
RT1E	1	rw	RT1 Enable Bit 0 _B Recovery Timer 1 is disabled 1 _B Recovery Timer 1 is enabled
RT0E	0	rw	RT0 Enable Bit 0 _B Recovery Timer 0 is disabled 1 _B Recovery Timer 0 is enabled
0	[7:2]	r	Reserved Read as 0; should be written with 0

Safety Management Unit (SMU)

SMU Keys Register.

SMU_KEYS
Key Register

 (34_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
CFGLCK	[7:0]	rw	Configuration Lock The SMU configuration is only possible if this field is set to 0xBC. Refer to “Register Properties” on Page 9-59 for the list of registers controlled by this field.
PERLCK	[15:8]	rw	Permanent Lock If this field is set to 0xFF, no further configuration of the SMU is possible. Refer to “Register Properties” on Page 9-59 for the list of registers controlled by this field.
0	[31:16]	r	Reserved Read as 0; shall be written with 0

Safety Management Unit (SMU)

SMU Debug Register.

This register enables to observe some internal states of the SMU hardware. Definition will be completed based on design information.

SMU_DBG
Debug Register (38_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
SSM	[1:0]	rh	Running state of the SMU State Machine 0 _H START state 1 _H RUN state 2 _H FAULT state 3 _H unspecified state
0	[31:2]	r	Reserved Read as 0; should be written with 0

Safety Management Unit (SMU)

SMU register controlling the connectivity with the Ports.

1) The PCFG reset value depends on several conditions. The PFCG value is only relevant after user software configuration.

Field	Bits	Type	Description
HWDIR	0	rw	<p>Port Direction.</p> <p>This bit directly controls the value of the FSP_DIR SMU output signal. Also refer to the General Purpose I/O Ports chapter for the HW_DIR signal specification.</p> <p>0_B sets the PAD to input state 1_B sets the PAD to output state</p>
HWEN	1	rw	<p>Port Enable.</p> <p>This bit directly controls the value of the FSP_EN SMU output signal. When set to 1 the port output is directly driven by SMU FSP signal (Error Pin). Also refer to the General Purpose I/O Ports chapter for the HW_EN signal specification.</p>

Safety Management Unit (SMU)

Field	Bits	Type	Description
PCS	7	rw	<p>PAD Configuration Select</p> <p>This bit controls the latching of the SMU FSP (Error Pin) PAD configuration signals to ensure that upon an application reset or system reset the SMU FSP (Error Pin) PAD configuration is not affected. This field is only reset by power-on reset.</p> <p>0_B The PAD configuration is controlled by the PORT registers.</p> <p>1_B The PAD configuration is controlled by the SMU.</p> <ul style="list-style-type: none"> • Only with the first transition from 0 to 1 of this field the SMU FSP is operational. Any further configuration change in this bit field has no effect to the hardware. • The fields HWDIR, HWEN and PCS shall be configured with a single software write command. Configuring each bit-field separately may lead to configuration inconsistencies. Refer to “Interface to the Ports (Error Pin)” on Page 9-8 for the overview of the SMU FSP (Error Pin) connectivity.
PCFG	[31:16]	rh	<p>PAD Configuration</p> <p>This field contains the FSP PAD configuration input signals.</p> <p>The PAD configuration related to FSP[0] is provided by PCFG[7:0]</p> <p>The upper-bits PCFG[15:8] are not used.</p>
0	[15:8], [6:2]	r	<p>Reserved</p> <p>Read as 0; should be written with 0</p>

Safety Management Unit (SMU)

SMU Alarm and Fault Counter Register.

Field	Bits	Type	Description
FCNT	[3:0]	rh	Fault Counter. This field is incremented by hardware when the SMU state machine goes from the RUN state to the FAULT state (see Figure 9.4.7 “SMU state machine” on Page 9-50). The counter value holds if the maximum value is reached.
ACNT	[15:8]	rh	Alarm Counter. This field is incremented by hardware when the SMU processes an internal action related to an alarm event (see Figure 9.4.5.3 “Alarm operation” on Page 9-43). The counter value holds if the maximum value is reached.
FCO	30	rh	Fault Counter Overflow. This bit is set by hardware if the FCNT counter reached the maximum value and an increment condition is present.
ACO	31	rh	Alarm Counter Overflow. This bit is set by hardware if the ACNT counter reached the maximum value and an increment condition is present.
0	[29:16], [7:4]	r	Reserved Read as 0; should be written with 0.

Safety Management Unit (SMU)

SMU Recovery Timer 0 Alarm Configuration.

SMU_RTAC0

Recovery Timer Alarm Configuration (60_H)

Reset Value: A39B 938B_H

Field	Bits	Type	Description
GID0	[2:0]	rw	Group Index 0. This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID0	[7:3]	rw	Alarm Identifier 0. This field specifies the Alarm Index related to the Group Index specified in GID0.
GID1	[10:8]	rw	Group Index 1. This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID1	[15:11]	rw	Alarm Identifier 1. This field specifies the Alarm Index related to the Group Index specified in GID1.
GID2	[18:16]	rw	Group Index 2. This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in “Recovery Timer” on Page 9-45.

Safety Management Unit (SMU)

Field	Bits	Type	Description
ALID2	[23:19]	rw	Alarm Identifier 2. This field specifies the Alarm Index related to the Group Index specified in GID2.
GID3	[26:24]	rw	Group Index 3. This field enables to specify if an alarm from this alarm group can use the recovery timer 0. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID3	[31:27]	rw	Alarm Identifier 3. This field specifies the Alarm Index related to the Group Index specified in GID3.

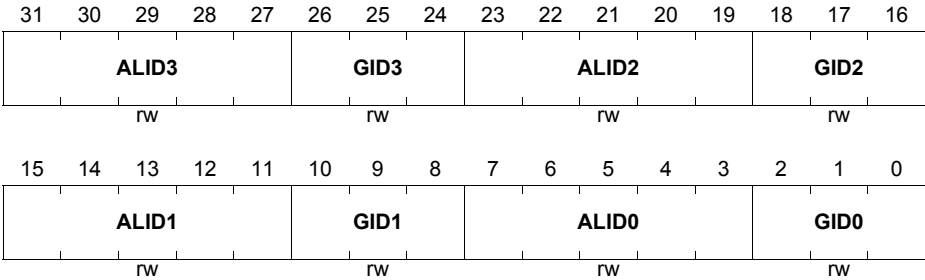

Note: It is possible to configure multiple times the same group identifier in GID0/1/2/3 fields. The reset value maps the watchdog timeout alarms to the recovery timer 0. The number of available watchdogs is product dependent.

Note: The reset values corresponds to Alarms 17, 18, 19, 20 from Alarm Group 3

Safety Management Unit (SMU)

SMU Recovery Timer 1 Alarm Configuration.

SMU_RTAC1
Recovery Timer Alarm Configuration (64_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
GID0	[2:0]	rw	Group Index 0. This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID0	[7:3]	rw	Alarm Identifier 0. This field specifies the Alarm Index related to the Group Index specified in GID0.
GID1	[10:8]	rw	Group Index 1. This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID1	[15:11]	rw	Alarm Identifier 1. This field specifies the Alarm Index related to the Group Index specified in GID1.
GID2	[18:16]	rw	Group Index 2. This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in “Recovery Timer” on Page 9-45.

Safety Management Unit (SMU)

Field	Bits	Type	Description
ALID2	[23:19]	rw	Alarm Identifier 2. This field specifies the Alarm Index related to the Group Index specified in GID2.
GID3	[26:24]	rw	Group Index 3. This field enables to specify if an alarm from this alarm group can use the recovery timer 1. The functionality of this field is described in “Recovery Timer” on Page 9-45.
ALID3	[31:27]	rw	Alarm Identifier 3. This field specifies the Alarm Index related to the Group Index specified in GID3.

Note: It is possible to configure multiple times the same group identifier in GID0/1/2/3 fields.

9.5.3 SMU Alarm Configuration Registers

SMU Alarm Configuration Registers related to Alarm Group 0.

SMU_AG0CFx (x=0-2)

Alarm Configuration Register (100_H + x*04_H) Reset Value: 0000 0000_H

10 Program Memory Unit (PMU)

The Program Memory Unit (PMU) controls the Flash memory and the BootROM and connects them to the SRI crossbar.

The devices of the AURIX family have at least one PMU. This is named “PMU0”. Depending on the amount of Flash memory more PMUs are added which are named “PMU1”, and so on. All PMUs are independent from each other.

TC26x B-Step has 1 PMU(s). Throughout this document a generic PMU is specified. The [Chapter 10.2](#) lists the configuration parameters of each PMU and their values in the TC26x B-Step. When PMU functionality depends on a parameter this is indicated in the text.

This chapter has the following structure:

- Generic feature list and block diagram ([Chapter 10.1](#)).
- PMU configuration of the TC26x B-Step ([Chapter 10.2](#)).
- Functionality of the BootROM ([Chapter 10.3](#)).
- Functionality of the tuning protection ([Chapter 10.4](#)).
- Functionality of the Flash memory ([Chapter 10.5](#)).
- Signaling to the Safety Management Unit “SMU” ([Chapter 10.6](#)).
- Register Set ([Chapter 10.7](#)).
- Application Hints ([Chapter 10.8](#)).

10.1 Generic Feature List

In general a PMU has the following features:

- Only in PMU0: BootROM.
- Program Flash “PFlash” with one or more banks “PFx”.
- Data Flash “DFlash” with one or more banks “DFx” containing:
 - Sectors for EEPROM emulation (only in PMU0).
 - UCB sectors for protection data.
- One Flash Standard Interface “FSI” that controls all Flash operations.
- Access control for safety and security for all assigned memories.
- Only in PMU0: Tuning protection (commonly called “Secure Watchdog”).
- Configuration and control registers.
- SRI interface(s) to all included resources. Separate SRI interfaces for DFlash and for each bank of PFlash.

[Figure 10-1](#) shows an abstracted block diagram of PMU, FSI, Flash and BootROM.

Program Memory Unit (PMU)

Figure 10-1 PMU/FSI/Flash Basic Block Diagram

10.2 PMU Configuration of TC26x B-Step

This chapter describes the superset of a range of devices with the following configuration:

- Number of PMUs: 1

Configuration of PMU0:

- PF0: 1 MByte.
- PF1: 1.5 MByte.
- DF0 consisting of:
 - DF_EEPROM: 96 KByte (12 logical sectors “EEPROM0 ... EEPROM11”).
 - DF_UCB: Flash area for protection data (16 logical sectors “UCB0 ... UCB15” with 1 KByte each).

Address Map

The following table(s) contains the address map.

Program Memory Unit (PMU)
Table 10-1 Address Map of PMU0

Start Address	Size	Range	Start Address Symbol
8000 0000 _H	1 MByte	PF0	AC_PF0
8010 0000 _H	1.5 MByte	PF1	AC_PF1
8FFF 8000 _H	32 KByte	BootROM	AC_BROM0
A000 0000 _H	1 MByte	PF0	AN_PF0
A010 0000 _H	1.5 MByte	PF1	AN_PF1
AF00 0000 _H	96 KByte	DF0 (DF_EEPROM) ¹⁾	AN_DFlash_B0
AF10 0000 _H	16 KByte	DF0 (DF_UCB)	
AF11 0000 _H	64 KByte	Not implemented (Reserved for DF1)	AN_DFlash_B1
AFFF 8000 _H	32 KByte	BootROM	AN_BROM0
F800 0500 _H	256 Byte	PMU Registers	
F800 1000 _H	5 KByte	Flash Registers	
FF11 0000 _H	64 KByte	Not implemented (Reserved for DF1, HSM private access)	AN_DFlash_B1F

1) In derivatives with reduced amount of DF0 (see data sheet) the available range is contiguous and starts also AN_DFlash_B0.

Derived Devices

This specification describes a superset of a range of devices. The concrete number and size of implemented Flash ranges is given in the respective Data Sheet.

In devices with PFlash banks of reduced size the sectors (see [Chapter 10.5.2.1](#)) with higher sector number are unavailable. The complete PFlash range is contiguous in all devices starting on AC_PF0/AN_PF0.

The “unavailable” PFlash sectors cannot exist or can be blocked during device manufacturing (the PMU handles these sectors then as not existing) or they stay accessible. In the latter case these sectors are delivered in the erased state. Full reliability is not ensured. These sectors shall not be read, programmed or erased. The write and OTP protection can be activated for these sectors to prevent later modification.

In devices with DFlash of reduced size the sectors EEPROM_x (see [Chapter 10.5.2.2](#)) with higher sector number *x* are unavailable (the whole DF_EEPROM range stays contiguous).

Program Memory Unit (PMU)

The “unavailable” DFlash sectors cannot exist or can be blocked during device manufacturing (the PMU handles these sectors then as not existing) or they stay accessible. In the latter case these sectors are delivered in the erased state.

The available DFlash sectors must be used round-robin to prevent accumulation of disturbs in unevenly cycled sectors (see [Chapter 10.5.2.2](#)).

10.2.1 Features of the BootROM

The BootROM contains the firmware:

- Startup software “SSW”: this software is executed at every reset.
- Test firmware: factory test routines for Infineon purposes.

Additionally the BootROM and its control logic implement the Tuning protection feature (“Secure Watchdog”).

10.2.2 Features of the Program and Data Flash

Depending on the PMU configuration the following Flash features are implemented. Timing and reliability figures are just indicative. Binding data can be found in the “Data Sheet”.

10.2.2.1 Program Flash Features:

Summary of Program Flash features:

- Consists of 2 bank(s). All banks are concurrently readable.
- Separate SRI ports, ECC decoders and pre-fetch logic for each bank.
- Commonly used for instructions and constant data.
- High throughput burst read based on a 256-bit Flash access (see parameter table t_{PF}).
- Application optimized sector structure with logical sectors ranging from 16 KBytes to 256 KBytes.
- Write protection separately configurable per logical sector (one-time programmable and 256-bit password protected).
- Password based read protection combined with write protection.
- Sectors (one 16 KB and two 64 KB) configurable as HSM code sectors by setting HSM_exclusive flag.
- Separate read, write and OTP protection for the HSM code sectors.
- Erase counter counts each sector erase (saturating).
- Fast programming of 32 byte pages (see Data Sheet t_{PRP}).
- High throughput burst programming of 256 byte units (see Data Sheet t_{PRPB}).
- Erase time per logical sector: see Data Sheet t_{ERP} .
- For development purposes sectors may incur more program/erase cycles than for productive purposes. Additionally further restrictions apply as an increased failure rate and lower retention.

Program Memory Unit (PMU)

- High throughput erase by multi-sector erase commands: see Data Sheet t_{MERP} .
- Erase and program performed by a Flash specific control logic independent of the CPU.
- Fast suspend erase to read and suspend burst programming to read command.
- Erase verify command.
- End of erase and program operations reported by interrupt.
- Configurable stall or bus error generation when reading busy PFlash banks.
- Dynamic correction of single-bit and double-bit errors and detection of triple-bit errors (“DEC-TED”).
- “Safe read path” ensuring detection of transient and permanent errors including addressing faults.
- ASIL-D optimized ECC for detection of >99% of faults in the white-noise model.
- Error reporting to the SMU, additionally local status flags and bus error generation.
- Margin reads for quality assurance.
- Delivery in the erased state.
- Configurable wait-state configuration.
- Endurance and retention figures are documented in the Data Sheet.
- Pad supply voltage used for program and erase. Separate programming modes for 5V and 3.3V supplied devices.

10.2.2.2 Data Flash Features

Summary of Data Flash features:

- Contains 12 EEPROMx sectors commonly used for EEPROM emulation (data storage at application run-time).
- UCBx sectors used for protection installation and the erase-cycle counter.
- Read-only UCB configured by Infineon with unique chip identifier and trimming data.
- Password based read protection combined with write protection.
- Flash read access based on 64-bit reads (see Data Sheet t_{DF}).
- Read path separated from PFlash (DFlash reads don't influence PFlash read accesses).
- Burst read is not supported.
- Requested read (data reading performed in background, read data supplied in registers).
- Fast programming of 8 byte pages (see Data Sheet t_{PRD}).
- High throughput burst programming of 32 byte units (see Data Sheet t_{PRDB}).
- Erase time per sector: see Data Sheet t_{ERD} .
- High throughput erase by multi-sector erase commands: see Data Sheet t_{MERD} .
- Erase and program performed by a Flash specific control logic independent of the CPU.
- Fast suspend erase to read command.
- End of erase and program operations reported by interrupt.

Program Memory Unit (PMU)

- Dynamic correction of single-bit, double-bit and triple-bit errors and detection of quad-bit errors ("TEC-QED").
- Error reporting to the SMU, additionally local status flags and bus error generation.
- Margin reads for quality assurance.
- Delivery in the erased state.
- Configurable wait-state configuration.
- The high endurance (see Data Sheet N_E) is granted under the condition of a robust EEPROM emulation algorithm (see corresponding section in the PMU chapter of the User's Manual).
- Endurance and retention figures are documented in the Data Sheet.
- Pad supply voltage used for program and erase.

10.3 BootROM

The content of the BROM is described in a separate chapter.

The BROM is readable and executable for user software but its functions shall only be executed when especially advised by Infineon.

All write accesses to the BootROM are refused with a bus error.

Its content is protected with ECC having SEC-DED capability and address error detection.

In the SRI address range it is mapped to the following start addresses:

- AC_BROM0 (cached address range).
- AN_BROM0 (non-cached address range).

10.4 Tuning Protection

The special tuning protection support represents a security function provided additionally to Flash read/write/OTP protection.

For details on the tuning protection please contact your Infineon representative.

10.5 Flash

This chapter introduces the Flash memory of the TC26x B-Step. It is split into the following sections:

- Definition of terms (**Chapter 10.5.1**): what means “program”, “erase”, “sector”, “pages”, ...
- Structure of a Flash module (**Chapter 10.5.2**): separation into “banks”, “sectors”, “word-lines”, “pages”, ...
- Reading Flash (**Chapter 10.5.3**).
- Command sequences for Flash (**Chapter 10.5.4**): programming, erasing, handling protection.
- Flash protection (**Chapter 10.5.5**): read and write protection.
- Data integrity and safety (**Chapter 10.5.6**): ECC and margin checks.
- Interrupt and traps (**Chapter 10.5.7**).
- Reset and startup (**Chapter 10.5.8**).
- Power reduction by sleep and idle (**Chapter 10.5.9**).

10.5.1 Definition of Terms

The description of Flash memories uses a specific terminology for operations and the hierarchical structure.

Flash Operation Terms

- **Erasing**: The erased state of a Flash cell is logical ‘0’. Forcing a cell to this state is called “erasing”. Depending on the Flash area always complete physical sectors, logical sectors or word-lines are erased. All Flash cells in this area incur one “cycle” that counts for the “endurance”.
- **Programming**: The programmed state of a cell is logical ‘1’. Changing an erased Flash cell to this state is called “programming”. The 1-bits of a page are programmed concurrently.
- **Retention**: This is the time during which the data of a flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (e.g. temperature profile) and is affected by operations on other Flash cells in the same word-line and physical sector. With an increasing number of program/erase cycles (see endurance) the retention is lowered.
- **Endurance**: As described above the data retention is reduced with an increasing number of program/erase cycles. The maximum number of program/erase cycles of each Flash cell is called “endurance”. As said for the retention it is a statistical figure that depends on operating conditions and the use of the flash cells and not to forget on the required quality level. The endurance is documented in the data sheet separately for PFlash logical sectors, UCBs and EEPROM sectors.

Flash Structure Terms

- **Flash Module:** A PMU contains one “Flash module” with its own operation control logic.
- **Bank:** A “Flash module” contains separate “banks”. In the PFlash there are one or more PFX banks and in the DFlash two DFX banks. “Banks” support concurrent operations with some limitations due to common logic.
- **Sub-Sector:** A Flash “bank” consists of sub-sectors. There are “physical sub-sectors” which are isolated from each other and “logical sub-sectors”. A PFlash bank is built from 512 KByte physical sub-sectors. A DFlash bank is separated into logical sub-sectors.
- **Logical Sector:** The sub-sectors are further separated into “logical sectors” which are groups of word-lines. They can be erased with a single operation.
- **Sector:** The plain term “sector” means “logical sector”.
- **User Configuration Block “UCB”:** A “UCB” is a specific logical sector. It is part of a DF_UCB sub-sector of bank DF0. It contains the protection settings and other data configured by the user.
- **Configuration Sector:** The “configuration sector” is a logical sector of the PFlash. It is not directly accessible to the user.
- **Page:** In the PFlash a page is an aligned group of 32 bytes and in DFlash of 8 bytes. It is the smallest unit that can be programmed (ECC width).
- **Program Burst:** A “burst” is the maximum amount of data that can be programmed with one command. The programming throughput is higher than for programming single pages. A burst in PFlash consists of 8 pages (256 bytes) and in DFlash 4 pages (32 bytes).
- **Word-Line:** In the PFlash and DFlash a word-line is an aligned group of 512 bytes.

10.5.2 Flash Structure

The PMU0 of TC26x B-Step contains the following Flash banks. The offset address of each sector is relative to the base address of its bank which is given in [Table 10-1](#). In devices of the same family the Flash banks keep the same base address.

10.5.2.1 PFlash

All banks PFX of the PFlash of all PMUs are based on the same sectorization (see [Table 10-2](#)). PFX banks with reduced capacity are built by cutting off sectors at the end. A 2 MByte bank implements logical sectors S0 to S26, a 1.5 MByte bank logical sectors S0 to S24 and a 1 MByte bank logical sectors S0 to S22. The implemented bank sizes are described in the Data Sheet.

Program Memory Unit (PMU)

S26		256 KB	1C'0000 _H

1) Offset with respect to AC_PFx and AN_PFx (see [Table 10-1](#)).

The sectors S0, S3, S7 and S8 of PF0 in PMU0 contain the BMI headers.

Program Memory Unit (PMU)

The sectors S6, S16 and S17 of PF0 in PMU0 are used as HSM code sectors in devices with HSM. Their access control (read, program, erase) is different from other PFlash sectors.

The sector S5 of PF0 in PMU0 has a specific purpose with an enabled Tuning Protection.

10.5.2.2 DFlash of PMU0

Bank DF0 of the DFlash of PMU0 (see [Table 10-3](#)).

Attention: *In the DF_EEPROM all sectors must be used round-robin in order to prevent the accumulation of erase disturbs in static sectors¹⁾. In derivatives with reduced amount of DFlash all sectors in this reduced DFlash range must be used round-robin.*

Attention: *In DF_EEPROM the overall number of erase commands over lifetime is limited by the parameter N_{ERD0} ²⁾, in DF_HSM by N_{ERD1} ³⁾.*

Attention: *In DF_EEPROM and DF_HSM at most 384 KByte shall be erased with one erase command.*

Table 10-3 Sector Structure of DFlash Bank 0

Logical Sector	Log. Sub-Sector	Size	Offset Address ¹⁾
EEPROM0	DF_EEPROM	8 KByte	00'0000 _H
EEPROM1		8 KByte	00'2000 _H
EEPROM2		8 KByte	00'4000 _H
EEPROM3		8 KByte	00'6000 _H
...	
EEPROM11		8 KByte	01'6000 _H

1) The parameter N_{DFD} (see Electrical Parameters or Data Sheet) documents the erase disturb limit. It is chosen higher than needed for pure round-robin usage to cover also error cases (e.g. repetition of erase commands on the same range due to power failures during operation).

2) This parameter is chosen to not reduce the endurance when always with one erase command at least 1/6th of the available DF_EEPROM is erased.

3) This parameter is chosen to not reduce the endurance when always with one erase command at least 1/4th of the available DF_HSM is erased

Program Memory Unit (PMU)
Table 10-3 Sector Structure of DFlash Bank 0 (cont'd)

Logical Sector	Log. Sub-Sector	Size	Offset Address ¹⁾
UCB0 = UCB_PFlash	DF_UCB	1 KByte	10'0000 _H
UCB1 = UCB_DFlash		1 KByte	10'0400 _H
UCB2 = UCB_HSMCOTP		1 KByte	10'0800 _H
UCB3 = UCB_OTP		1 KByte	10'0C00 _H
UCB4 = UCB_IFX		1 KByte	10'1000 _H
UCB5 = UCB_DBG		1 KByte	10'1400 _H
UCB6 = UCB_HSM		1 KByte	10'1800 _H
UCB7		1 KByte	10'1C00 _H
UCB8		1 KByte	10'2000 _H
UCB9		1 KByte	10'2400 _H
UCB10		1 KByte	10'2800 _H
UCB11		1 KByte	10'2C00 _H
UCB12		1 KByte	10'3000 _H
UCB13		1 KByte	10'3400 _H
UCB14		1 KByte	10'3800 _H
UCB15		1 KByte	10'3C00 _H

1) Offset with respect to AN_DFlash_B0 (see [Table 10-1](#)).

10.5.3 Flash Read Access

Flash banks that are active and in read mode can be directly (memory mapped) read as ROM.

The wait cycles for the Flash access must be configured as described in ([Chapter 10.5.3.3](#)).

The PFlash allows SRI bursts BTR4 and BTR2 and single transfers.

The Tricore uses BTR4 for code fetches from the cached address range in order to fill one cache line. Code fetches from the non-cached area are also performed with BTR4. Data reads from the cached range are performed with BTR4. Data reads from the non-cached address range are performed with single transfers.

The DFlash allows only single transfers. Therefore they are only accessible in the non-cached address range and Tricore can't fetch instructions from them.

Read accesses from Flash can be blocked by the read protection (see [Chapter 10.5.5](#)).

Program Memory Unit (PMU)

Read accesses from busy Flash banks are not possible (see [Chapter 10.5.4.1](#)).

ECC errors can be detected and corrected (see [Chapter 10.5.6](#)).

The DFlash sectors EEPROMx can be also read with requested reads (see [Chapter 10.5.3.4](#)).

10.5.3.1 Read Ports

For optimum performance the PFlash is read via dedicated SRI slave ports. Each PFp bank is assigned to one SRI port determined by its address (see [Table 10-4](#)). The DFlash, the BootROM and the registers share a separate SRI slave port.

Table 10-4 Memory Range to SRI Port Assignment

SRI Port	Address Range	Memory Ranges
p = 0 mapped to SCI 7	8000 0000 _H – 800F FFFF _H	PF0 (cached)
p = 8 mapped to SCI 9	8010 0000 _H – 8027 FFFF _H	PF1(cached)
p = 0 mapped to SCI 7	A000 0000 _H – A00F FFFF _H	PF0 (non-cached)
p = 1 mapped to SCI 8	A010 0000 _H – A027 FFFF _H	PF1(non-cached)
mapped to SCI 6	8FFF 8000 _H – 8FFF FFFF _H AF00 0000 _H – AF01 7FFF _H AF10 0000 _H – AF10 3FFF _H AF11 0000 _H – AF11 FFFF _H AFFF 8000 _H – AFFF FFFF _H F800 0500 _H – F800 05FF _H F800 1000 _H – F800 23FF _H FF11 0000 _H – FF11 FFFF _H	BootROM DF0 (DF_EEPROM) DF0 (DF_UCB) reserved for DF1 BootROM PMU Registers Flash Registers reserved for HSM private Flash command interface and DF1.

Each SRI port can be independently read. Each has its own path to its Flash range and its own ECC decoding logic.

As additional performance increasing measure each of the PFp ports has its own prefetching logic and a set of 3 read buffers.

Every read buffer is assigned by configuration (see [Chapter 10.7.2.7](#)) to one bus master. Additionally all read data passes through a pipeline stage in the FSI called “global read buffer”. The read buffers can be filled with a single PFlash read which delivers 256 data bits.

Upon finishing a pre-fetch and with no request from the bus the PMU reads the sequentially following 256 bits into the global read buffer. Buffer hits in this read buffer are also supported and don’t cause a Flash read. When this read buffer is also filled the PMU sends already the address for the following 256 bits to the Flash and keep this

Program Memory Unit (PMU)

address stable (this feature can be disabled with FCON.IDLE). A hit with this address is also detected and will reduce the Flash access time.

All read buffers are invalidated upon executing a command sequence that changed PFlash content. The read buffers are not invalidated by changes to the configuration registers (e.g. changing wait-states or changing the ECC correction).

10.5.3.2 DFlash, BootROM Read Port

The other resources (DFlash, BootROM, registers, etc) share a separate SRI slave port independent of the PFlash read ports.

Read accesses to the DFlash are always serviced by reading the Flash. Buffer hits are not supported.

10.5.3.3 Configuring Flash Wait Cycles

The Flash read path including the ECC decoders and read buffer accesses use the following clocks:

- PFX read ports: clocked with f_{FSI2} .
- DFlash, BootROM, register read port: clocked with f_{FSI} .

The wait cycles in register FCON are counted with this reference clock. The minimum number of wait cycles can be calculated based on the delays given in the Data Sheet or Electrical Specification as described in [Table 10-5](#).

Note: Please note that in case of using the FM-PLL the maximum frequency of these clocks has to enter the calculation.

Attention: After System Reset and Power-On Reset the wait cycles are configured for the clock configuration used during startup, i.e. f_{FSI} and f_{FSI2} running with maximum 100 MHz. Before changing to higher clock frequencies this default configuration must be changed.

The clock f_{FSI2} can be configured to be identical to f_{SRI} or f_{FSI} . Selecting the higher clock frequency increases the read performance.

Table 10-5 Wait Cycle Calculation

	Register Field	Minimum Value¹⁾
PFlash read access delay	FCON.WSPFLASH	$\text{Ceil}(t_{PF} * f_{FSI2}) - 1$
PFlash ECC decode delay	FCON.WSECPF	$\text{Ceil}(t_{PF ECC} * f_{FSI2}) - 1$
DFlash read access delay	FCON.WSDFLASH	$\text{Ceil}(t_{DF} * f_{FSI}) - 1$
DFlash ECC decode delay	FCON.WSECDF	$\text{Ceil}(t_{DF ECC} * f_{FSI}) - 1$

1) The Ceil(r) function rounds a real number up, i.e. the result is the smallest integer not less than the real argument. The mathematical function name is "Ceiling(r)".

Program Memory Unit (PMU)**Examples**

Example configuration for $t_{PF} = 30$ ns, $t_{PFECC} = 10$ ns, $t_{DF} = 100$ ns, $t_{DFECC} = 20$ ns with $f_{FSI2} = 200$ MHz and $f_{FSI} = 100$ MHz:

- FCON.WSPFLASH = 5
- FCON.WSECPF = 1
- FCON.WSDFLASH = 9
- FCON.WSECDF = 1

10.5.3.4 Requested DFlash Read

The direct memory mapped DFlash read stalls the requesting master for the duration of the read access. Applications that favor latency over throughput can use the “requested read” feature. This supports interrupt driven background reads from the DFlash.

The start address is written into RRAD.ADD. RRCT.CNT contains the number of 8 byte aligned transfers that will be performed.

The reading of each 8 byte block is started by setting RRCT.START. When the PMU starts the read process is clears RRCT.START and sets RRCT.BUSY.

When the data is available in RRD0-1 the flag RRCT.BUSY is cleared and RRCT.DONE is set. If RRCT.EOBM is set the requested read interrupt (SRC_PMU1) is triggered. The address in RRAD.ADD is incremented to the next address and the counter RRCT.CNT is decremented by 1.

The reading of the next 8 byte block has to be triggered again by setting RRCT.START. This clears RRCT.DONE.

The requested read can be aborted by setting RRCT.STP. This clears RRCT.START, RRCT.BUSY and RRCT.DONE. The requested read interrupt is not triggered.

An error is reported by RRCT.ERR when the read access addresses an illegal address (outside of the assigned DFlash ranges, insufficient access rights) or when started with CNT=0. This sets also RRCT.DONE.

The occurrence of an uncorrectable ECC error sets RRCT.ERR. The ECC error flags in the FSR are not influenced by requested reads.

Direct reads to the DFlash are not blocked by ongoing requested reads. They are executed with higher priority than requested reads.

10.5.4 Flash Operations

The Flash memory knows operations for reading, changing data (program/erase) and handling protection settings. This section and the following describe only the features as such. How to use them is described in the application notes ([Chapter 10.8](#)).

10.5.4.1 Modes of Operation

A Flash module can be in one of the following states:

- Active (normal) mode.
- Sleep mode (see [Chapter 10.5.8](#)).

In sleep mode write and read accesses to all Flash ranges of this PMU are refused with a bus error.

When the Flash module is in normal mode a Flash bank can be in one of these modes:

- Read mode.
- Command mode.

In read mode a Flash bank can be read and command sequences are interpreted. In read mode a Flash bank can additionally enter page mode which enables it to receive data for programming.

In command mode an operation is performed. During its execution the Flash bank reports BUSY in FSR. In this mode read accesses to this Flash bank are refused with a bus error or the ready is suppressed until BUSY clears. This can be configured (see [FCON.STALL](#)). At the end of an operation the Flash bank returns to read mode and BUSY is cleared. Only operations with a significant duration (shown in the command documentation) set BUSY.

Note: Using FCON.STALL = "STALL" is not recommended because the stalled CPU is inoperable and also the PMU SRI port is blocked as long the ready is suppressed. This feature should be only used under controlled conditions by a Flash loader.

Note: Using FCON.STALL = "STALL" together with Flash sleep ([Chapter 10.5.9](#)) is prohibited as it might lead to device hang-up.

In command mode further command sequences in this flash module are not allowed. They are refused with a bus error.

Flash modules of different PMUs are completely independent.

Register read and write accesses are not affected by these modes.

10.5.4.2 Command Sequences

All Flash operations except memory mapped reads are performed with command sequences. Every write access to the DF0 memory range is interpreted as command cycle belonging to a command sequence.

Write accesses to the PFlash memory range are refused with bus error.

Command sequences consist of 1 to 9 command cycles. The command interpreter checks that a command cycle is correct in the current state of command interpretation. Else a SQER is reported.

Program Memory Unit (PMU)

When the command sequence is accepted the last command cycle finishes read mode and the Flash bank transitions into command mode.

Command sequences can be blocked by the register access protection (see [Chapter 10.5.5.2](#)).

Generally when the command interpreter detects an error it reports a sequence error by setting FSR.SQER. Then the command interpreter is reset and a page mode is left. The next command cycle must be the 1st cycle of a command sequence. The only exception is “Enter Page Mode” when a Flash is already in page mode (see below).

10.5.4.3 Command Sequence Definitions

The command sequence descriptions use the following nomenclature (symbolic assembly language):

ST addr, data: Symbolic representation of a command cycle moving “data” to “addr”.

The parameter “addr” is defined as followed:

- **CCCC_H:** The “addr” must point into the DFlash. The last 16 address bits must match CCCC_H.

The parameter “data” can be one of the following:

- **PA:** Absolute start address of the Flash page. Must be aligned to burst size for “Write Burst” or to the page size for “Write Page”.
- **SA:** Absolute start address of a Flash sector. Allowed are the PFlash sectors Sx and the DFlash sectors EEPROMx, UCBx.
- **WD:** 64-bit or 32-bit write data to be loaded into the page assembly buffer.
- **xxYY:** 8-bit write data as part of a command cycle. Only the byte “YY” is used for command interpretation. The higher order bytes “xx” are ignored.
 - **xx5y:** Specific case for “YY”. The “y” can be “0_H” for selecting the PFlash or “D_H” to select the DFlash.
 - **xxnn:** Specific case for “YY”. The “nn” quantifies the number of logical sectors that are erased or verified. This number underlies certain restrictions (see [Erase Logical Sector Range](#) on [Page 10-20](#)).
- **UC:** Identification of the UCBx for which the password checking shall be performed: xx00_H for UCB0 = UCB_PFlash, xx01_H for UCB1 = UCB_DFlash, xx05_H for UCB5 = UCB_DBG.
- **PWx:** 32-bit word of a 256-bit password.

When using for command cycles 64-bit transfers the “data” is expected in the correct 32-bit word as indicated by the address “addr”.

Command Sequence Overview Table

The [Table 10-6](#) summarizes all commands sequences. The following sections describe each command sequence in detail.

Table 10-6 Command Sequences for Flash Control

Command Sequence		1. Cycle	2./6. Cycle	3./7. Cycle	4./8. Cycle	5./9. Cycle	6. Cycle
Reset to Read	Address	.5554					
	Data	..xxF0					
Enter Page Mode	Address	.5554					
	Data	..xx5y					
Load Page	Address	.55F0					
	Data	¹⁾ WD					
Write Page	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	PA	..xx00	..xxA0	..xxAA		
Write Page Once	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	PA	..xx00	..xxA0	..xx9A		
Write Burst	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	PA	..xx00	..xxA0	..xx7A		
Erase Logical Sector Range	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	SA	..xxnn	..xx80	..xx50		
Verify Erased Logical Sector Range	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	SA	..xxnn	..xx80	..xx5F		
Resume Prog/Erase	Address	.AA50	.AA58	.AAA8	.AAA8		
	Data	PA/SA	..xxnn	..xx70	..xxCC		
Disable Protection	Address	.553C	.553C	.553C	.553C	.553C	
	Data	UC	PW0/4	PW1/5	PW2/6	PW3/7	
Resume Protection	Address	.5554					
	Data	..xxF5					
Clear Status	Address	.5554					
	Data	..xxFA					

1) Address depends on data width of WD (see description of Load Page below).

Reset to Read

Calling:

- ST 5554_H, xxF0_H

Function:

This function resets the addressed command interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A page mode is aborted.

Program Memory Unit (PMU)

This command is the only that is accepted without SQER when the command interpreter has already received command cycles of a different sequence but is still not in command mode. Thus “Reset to Read” can cancel every command sequence before its last command cycle has been received.

The error flags of **FSR** (OPER, SQER, PROER, PFSBER, PFDBER, PFMBER, DFSBER, DFDBER, DFTBER, DFMBER, ORIER, PVER, EVER) are cleared. The flags can be also cleared in the status registers without command sequence.

Enter Page Mode

Calling:

- ST 5554_H, xx5y_H

Function:

The PFlash or the DFlash assembly buffer enter page mode selected by the parameter “y”.

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

The page mode is signaled by the flags PFPAGE/DFPAGE in the FSR separately for PFlash and DFlash.

If a new “Enter Page Mode” command sequence is received while any Flash is already in page mode SQER is set, the existing page mode is aborted, and the new “Enter Page Mode” sequence is correctly executed (i.e. in this case the command interpreter is not reset).

Load Page

Calling:

- ST 55F0_H/55F4_H, WD

Function:

Loads the data “WD” into the page assembly buffer and increments the write pointer to the next position.

All WD transfers for one page must have the same width (either all 32-bit or all 64-bit). Else the transfer is refused with SQER.

When using 64-bit transfers then all have to address the offset address 55F0_H.

When using 32-bit transfers then the lower order word has to be written first to offset 55F0_H and then the higher order word to offset 55F4_H. This alternating pattern is repeated for all WD.

If “Load Page” is called more often than allowed by the available buffer space of 256 bytes the overflow data is discarded, the page mode is not left. This overflow is reported by the following Write Page/Burst command with SQER.

Program Memory Unit (PMU)**Write Page**

Calling:

- ST AA50_H, PA
- ST AA58_H, xx00_H
- ST AAA8_H, xxA0_H
- ST AAA8_H, xxAA_H

Function:

This function starts the programming process for one page with the data transferred previously by “Load Page” commands. Upon entering command mode the page mode is finished (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

A page shall be programmed only once after erasing.

This command is refused with SQER when the addressed Flash is not in page mode.

SQER is also issued when PA addresses an unavailable Flash range or when PA does not point to a legal page start address.

If after “Enter Page Mode” too few data, no data or too much data was transferred to the assembly buffer with “Load Page” then “Write Page” programs the page but sets SQER. Missing data is programmed with the previous content of the assembly buffer.

When the page “PA” is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

When the programming process incurs an error the flag PVER is set.

Write Page Once

Calling:

- ST AA50_H, PA
- ST AA58_H, xx00_H
- ST AAA8_H, xxA0_H
- ST AAA8_H, xx9A_H

Function:

This function starts the programming process for one page as the normal “Write Page” does. But before programming it checks if the page is erased. If the page is not erased (allowing correctable errors) the command fails with PVER and EVER.

When the programming itself incurs an error the flag PVER is set.

On sectors with “write-once” protection only this write command can be applied.

This command is only supported for PFlash. When applied to DFlash the command fails with SQER.

Program Memory Unit (PMU)**Write Burst**

Calling:

- ST AA50_H, PA
- ST AA58_H, xx00_H
- ST AAA8_H, xxA0_H
- ST AAA8_H, xx7A_H

Function:

This function starts the programming process for an aligned group of pages. The programming process is more efficient than for a single page, achieving a significantly higher throughput (see data sheet).

In the PFlash 8 pages (256 bytes) are programmed and in DFlash 4 (32 bytes). The pages are programmed one after the other with increasing addresses.

Please note that with disabled ECC generation with ECCW.PECENCDIS or DECENCDIS this command sequence must not be used. It causes unpredictable results.

For further details see “Write Page”.

Erase Logical Sector Range

Calling:

- ST AA50_H, SA
- ST AA58_H, xxnn_H
- ST AAA8_H, xx80_H
- ST AAA8_H, xx50_H

Function:

This command erases “nn” sectors starting at the sector addressed by “SA”. Upon entering command mode the BUSY flag of the corresponding bank is set. When erasing PFlash sectors additionally D0BUSY is set (because the erase counters are programmed in DF0).

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

When SA or any of the following nn-1 sectors has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

The command fails with SQER if the range of logical sectors is not contained in one physical sector.

The error flag EVER is set to indicate an error during the erase process. The flags EVER and PVER are set when the erase counter programming incurs an error.

Note: The duration of an erase command applied to DFlash can be much shorter than documented as maximum duration (t_{ERD} , t_{MERD}).

Verify Erased Logical Sector Range

Calling:

- ST AA50_H, SA
- ST AA58_H, xxnn_H
- ST AAA8_H, xx80_H
- ST AAA8_H, xx5F_H

Function:

This command verifies if “nn” sectors starting at the sector addressed by “SA” are correctly erased, i.e. contain 0 data and ECC bits. Upon entering command mode the BUSY flag of the corresponding bank is set.

When the PFlash Safety ECC is enabled (see [Chapter 10.5.6.2](#)) the PFlash cannot be checked for “0” content by direct reads.

The error flag EVER is set to identify a found verification error.

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

The command fails with SQER if the range of logical sectors is not contained in one physical sector.

Especially security concerned customers can limit this function by configuring PROCONHSMCOTP.BLKFLAN to ‘1’:

- If PROCONHSMCOTP.BLKFLAN is 0 then “Verify Erase Logical Sector Range” is enabled for every address.
- If PROCONHSMCOTP.BLKFLAN is 1 then “Verify Erase Logical Sector Range” is blocked as follows:
 - If one of the PROCONCOTP.HSMsX = 1: blocked on the corresponding HSM code sector “s”.
 - If FPRO.PROINP = 1 and FPRO.PRODISP = 0: blocked on UCB_PFlash.
 - If FPRO.PROIND = 1 and FPRO.PRODISD = 0: blocked on UCB_DFlash.
 - If FPRO.PROINDBG = 1 and FPRO.PRODISDBG = 0: blocked on UCB_DBG.

If this function is blocked the command fails by setting PROER.

Note: The execution of this command has an effect on the Flash cells (they are slightly disturbed). Therefore the number of calls of this function is limited, see Data Sheet parameters N_{VERD} , N_{VERP} .

Resume Prog/Erase

Calling:

- ST AA50_H, PA/SA
- ST AA58_H, xxnn_H
- ST AAA8_H, xx70_H
- ST AAA8_H, xxCC_H

Program Memory Unit (PMU)

Function:

A suspended programming or erasing process is restarted as described in [Chapter 10.5.4.4](#).

Disable Protection

Calling:

- ST 553C_H, UC
- ST.W 553C_H, PW0
- ST.W 553C_H, PW1
- ST.W 553C_H, PW2
- ST.W 553C_H, PW3
- ST.W 553C_H, PW4
- ST.W 553C_H, PW5
- ST.W 553C_H, PW6
- ST.W 553C_H, PW7

Function:

The password protection of the selected UCB (if this UCB offers this feature) is temporarily disabled by setting FPRO.PRODIS_x (with “x” indicating the UCB) when all the passwords PW0–PW7 match their configured values in the corresponding UCB.

The command fails by setting PROER when any of the supplied PWs does not match. In this case until the next application reset all further calls of “Disable Protection” fail with PROER independent of the supplied password.

Resume Protection

Calling:

- ST 5554_H, xxF5_H

Function:

This command clears all FPRO.PRODIS_x effectively enabling again the Flash protection as it was configured.

Clear Status

Calling:

- ST 5554_H, xxFA_H

Function:

The flags FSR.PROG and FSR.ERASE and the error flags of **FSR** (OPER, SQER, PROER, PFSBER, PFDBER, PFMBER, DFSBER, DFDBER, DFTBER, DFMBER, ORIER, PVER, EVER) are cleared. These flags can be also cleared in the status registers without command sequence.

10.5.4.4 Operation Suspend and Resume

The operations “Erase Logical Sector Range”, “Verify Erased Logical Sector Range” and “Write Page”¹⁾ and “Write Burst”²⁾ can be suspended.

An operation is suspended by writing ‘1’ to **MARD.SPND**. The Flash operation stops when it reaches an interruptible state. After that the flag **FSR.SPND** is set and busy is cleared.

There can be at most one operation in the suspended state. Erroneous suspend and resume requests are detected and prevented by the PMU.

The target range of a suspend program or erase operation is in an undefined state. Reading this range delivers unpredictable results.

The suspended operation can be resumed with the command sequence “Resume Prog/Erase”. The flag **FSR.SPND** is cleared and the busy flag is set again.

The arguments “PA” or “SA” and “nn” of the resume command must be identical to the original argument of the suspended command³⁾. Using a different argument is detected by the PMU and lets the resume fail with **FSR.SQER** and **FSR.SPND** stays set.

When the operation had already finished when receiving the suspend request the request is ignored. The flag **FSR.SPND** is not set. Also **MARD.SPND** is immediately cleared again.

If a resume is requested without any suspended operation **SQER** is set.

Attention: Please ensure that between start or resume of an erase process and the suspend request normally at least ~1 ms erase time can pass. Shorter erase durations are allowed but the erase process will not advance.

In the suspended programming state:

- Reading Flash is allowed.
- New programming and erase commands are rejected with **SQER**.

In the suspended erase state:

- Reading Flash is allowed.
- New erase commands are rejected with **SQER**.
- Programming commands can be performed on any bank.
- However programming in the target range of the suspended erase fails with **SQER**.
- Suspending a programming command is not possible and fails by setting **MARD.SPNDERR**.

1) The “Write Page” operation is suspended between end of the programming and start of the verification. Therefore the programming process itself is not suspended.

2) The “Write Burst” operation in PFlash is suspended during the programming process. In DFlash it is only suspended after end of the programming before starting the verification.

3) For resuming a “Write Burst” the argument “nn” of “Resume Prog/Erase” has to be “00”.

Program Memory Unit (PMU)

In the suspended “Verify Erased Logical Sector Range” state:

- Reading Flash is allowed.
- New erase commands are rejected with SQER.
- Programming commands can be performed on any bank.
- Suspending a programming command is not possible and fails by setting **MARD.SPNDERR**.

10.5.4.5 Programming Voltage Selection

In devices which support 5 V supply via V_{EXT} this control bit allows to select the external supply as source of the programming voltage.

Attention:

When **FCON.PR5V** is “P5V” the programming voltage is directly taken from the external supply V_{EXT} . This shall be supplied with nominal 5V (for allowed tolerances see data sheet).

With **FCON.PR5V** set to “P3V” the programming voltage is internally generated from V_{DDP3} supplied with nominal 3.3 V. Consequently the allowed range of V_{EXT} is in this configuration much larger.

In the PFlash the P5V mode has a significantly shorter duration of the programming process (see data sheet). For the DFlash the P3V mode is recommended as this offers higher robustness against V_{EXT} fluctuations and has the same performance.

10.5.5 Protection

Protection has several aspects: security, safety, preventing maloperation.

The safety protection ensures that reading from PFlash can't be disturbed by software crashes or accesses by “unsafe” masters. Further on it ensures integrity of the read data. This is achieved by the following features:

- Safety ENDINIT protection of configuration registers.
- Master specific protection of PFlash relevant control and configuration registers.
- Protection of these registers against single-event effects “SEEs”.
- Master specific access control for command sequences.
- Integrity of read data is ensured by ECC (see [Chapter 10.5.6](#)).

The security protection prevents unauthorized Flash read and write from internal masters or from external:

- Flash read protection: protected Flash sections can only be read when booting from internal Flash.
- Flash write protection: protected Flash sections can only be changed after authentication.
- Flash OTP (One-Time Programmable) protection: these Flash sections can't be changed anymore.

Program Memory Unit (PMU)

- HSM specific protection: it ensures that the HSM can protect its private data from access by other software. Additionally selected data can only be read during HSM boot phase.
- Device debug protection (see [Chapter 10.5.5.6](#)): depending on the boot mode and the configuration of debug protection and the Flash read protection the debug access to the device is enabled.

The following features protect the Flash against maloperation including software crashes (even of “safe” masters):

- ENDINIT and SV mode protection of configuration registers.
- Command sequences that can change Flash content need more command cycles. SQER stops command interpretation.

Security features supplement safety because Flash data protected by the write protection is also safe against software crashes.

The following table gives an overview of all protection features and for which resources they are effective.

Table 10-7 Protection Layers

	PFlash	DFlash	Registers
Master Specific Access Control	–	–	Restricts Write Accesses
ENDINIT, SV, “Safety ENDINIT”	Restricts Commands (only SE)	–	Restrict Write Accesses
Flash Write Protection	Restricts Commands	Restricts Commands	–
Flash Read Protection	Restricts Read	Restricts Read	–

Any access to these resources has to pass all checks before the operation is performed.

Note: This means that an activation of a protection after start of the operation doesn't affect the operation anymore. Especially the “Safety ENDINIT” can become active as soon as a Flash command (e.g. program or erase) has started.

10.5.5.1 Master Specific Access Control

The master specific access control is configured and controlled by the registers ACCEN0 and ACCEN1 (see [Chapter 10.7.2.1](#)).

Program Memory Unit (PMU)

The registers ACCEN determine which master is allowed to perform writes to the protected resources. In the PMU the following resources are protected by this mechanism:

- Write access to all PMU and Flash registers with following exceptions (see also “Registers Overview” tables [Table 10-16](#) and [Table 10-18](#)):
 - Write access to ACCEN is controlled by the Safety ENDINIT.

Write accesses that are blocked by this mechanism create a bus error as response.

10.5.5.2 Register Access Control

The master unspecific register access control features “Safety ENDINIT”, “ENDINIT”, “Supervisor Mode” are described in the SCU chapter.

In the PMU the following resources are protected by Safety ENDINIT:

- When the Safety ENDINIT is active program and erase commands on the PFlash are rejected with PROER.
- Write access to ACCEN.

10.5.5.3 Effective Flash Read Protection

The Flash read protection depends on the master and the Flash address range.

The following Flash ranges have separate read protections:

- PFlash (with specific handling of the HSM code sectors in PF0).
- And in the DFlash:
 - EEPROMs.
 - UCBs.

PFlash Read Protection

A read access to PFlash (with the exception of sectors S6, S16 and S17 in PF0 of PMU0) fails with bus error under the following conditions:

- Tricore CPU0 PMI (code fetch): FPRO.DCFP.
- Tricore CPU0 DMI (data read): FPRO.DDFP.
- All other masters: FPRO.DDFPX.

The read access to the HSM code sectors S6, S16 and S17 depends on the setting of PROCONHSMCOTP.HSMsX which defines the “HSM_exclusive” attribute of these sectors.

If PROCONHSMCOTP.HSMsX is set for such a sector:

- HSM: full read access.
- All masters except HSM: a read fails with a bus error.
- Cerberus: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

Program Memory Unit (PMU)

If PROCONHSMCOTP.HSMsX is cleared for such a sector: the same rules as for the other PFlash0 sectors based on PROCONP0 as described above are valid.

DFlash Read Protection

A read access to the DFlash sectors EEPROMx fails with a bus error under the following conditions:

- All masters: FPRO.DDFD.

The read access to the UCBs is described in [Chapter 10.5.5.5](#).

Activating Read Protection

The bits FPRO.DCFP, FPRO.DDFP, FPRO.DDFPX and FPRO.DDFD are initialized by the startup software depending on the configured protection and the startup mode. They can also be directly modified by the user software under conditions noted in the description of [FPRO](#).

10.5.5.4 Effective Flash Write Protection

A range of Flash can be write protected by several means that are all configured in the UCBs.

PFlash Write Protection

Programming or erasing of a group of PFlash sectors (with the exception of sectors S6, S16 and S17 in PF0 of PMU0) fails with PROER if any of the following conditions is true:

- PROCONP0.RPRO and not FPRO.PRODISP (global write protection).
- PROCONPx.SxL and not FPRO.PRODISP (sector specific write protection).
- PROCONOTPx.SxROM (sector specific OTP protection).
- PROCONWOPx.SxWOP (sector specific write-once protection).
 - A set PROCONWOPx.SxWOP prohibits “Write Page”, “Write Burst” and erase commands. These fail with PROER.
 - Only “Write Page Once” is accepted by the PMU. The FSI checks if the addressed Flash range is erased. If this is not the case the FSI reports a PVER and doesn’t start programming.

Programming and erasing of the HSM reserved code sectors S6, S16 and S17 in PF0 of PMU0 depends on the setting of PROCONHSMCOTP.HSMsX which defines the “HSM_exclusive” attribute of these sectors and which master performs the access.

Programming or erase of such sectors fails if any of the following conditions is true:

- Not PROCONHSMCOTP.HSMsX and PROCONP0.RPRO and not FPRO.PRODISP (“global” write protection).

Program Memory Unit (PMU)

- Not PROCONHSMCOTP.HSMsX and PROCONP0.SxL and not FPRO.PRODISP (sector specific write protection).
- PROCONHSMCOTP.SxROM (HSM code sector specific OTP protection).
- For all masters except HSM: PROCONHSMCOTP.HSMsX.

For Cerberus the following rules apply: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

DFlash Write Protection

Programming and erasing of the DFlash sectors EEPROMx fails with PROER when any of the following conditions is true:

- PROCOND.RPRO and not FPRO.PRODISD.
- PROCOND.L and not FPRO.PRODISD.

Program and erase conditions for the UCBs are described in [Chapter 10.5.5.5](#).

10.5.5.5 Configuring Protection in the UCB

As indicated above the effective protection is determined by the content of the PROCONx registers. These are loaded during startup after each reset from the UCBs. Each UCB comprises 1 KByte of DFlash organized in 128 UC pages of 8 bytes.

An UCB is erased with the command “Erase Logical Sector Range”. It can be programmed with “Write Page” and “Write Burst”. Each UCB has its own access control.

When programming or erasing fail because of this access control PROER is set. When reading fails a bus error is returned.

The following UCBs are defined:

UCB_PFlash

Password protection of the PFlash.

Table 10-8 UCB_PFlash Content

Offset ¹⁾	Content	Description
00 _H	PROCONP0	Read protection for complete PFlash. Write protection for logical sectors of PF0.
04 _H	PROCONP1	Write protection for logical sectors of PF1.
08 _H		Reserved for PROCONP2.
0C _H		Reserved for PROCONP3.
10 _H	PROCONP0	Copy.
14 _H	PROCONP1	Copy.

Program Memory Unit (PMU)
Table 10-8 UCB_PFlash Content (cont'd)

Offset ¹⁾	Content	Description
18 _H		Reserved for copy of PROCONP2.
1C _H		Reserved for copy of PROCONP3.
20 _H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).
40 _H	PW0 – PW7	Copy of 256-bit password.
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See [PROCONPp \(p=0-1\)](#) on [Page 10-67](#).

The confirmed state of this UCB is indicated by FPRO.PROINP.

In the errored state of this UCB also FPRO.PROINP is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- FPRO.PROINP and not FPRO.PRODISP.

UCB_DFlash

Password protection of the DFlash.

This UCB is also used for configuring the PFlash ECC algorithm between the “Safety” and the “Legacy” version, configuring the memory initialization and contains an oscillator configuration.

Table 10-9 UCB_DFlash Content

Offset ¹⁾	Content	Description
00 _H	PROCOND	Read and write protection for the DFlash sectors EEPROMs, oscillator configuration, and enable of RAM initialization.
10 _H	PROCOND	Copy.
20 _H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).
40 _H	PW0 – PW7	Copy of 256-bit password.
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.

Program Memory Unit (PMU)

1) The offsets are given in number of bytes.

See **PROCOND** on **Page 10-68**.

The confirmed state of this UCB is indicated by FPRO.PROIND.

In the errored state of this UCB also FPRO.PROIND is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- FPRO.PROIND and not FPRO.PRODISD.

UCB_OTP

This UCB configures the one-time programmable “OTP” and the write-page once “WOP” protection. It offers the possibility to add this type of protection to Flash sections incrementally.

Table 10-10 UCB_OTP Content

Offset ¹⁾	Content	Description
00 _H	PROCONOTP0	OTP protection for the logical sectors of PF0, and enable of TP.
04 _H	PROCONOTP1	OTP protection for the logical sectors of PF1.
08 _H		Reserved for PROCONOTP2.
0C _H		Reserved for PROCONOTP3.
10 _H	PROCONOTP0	Copy.
14 _H	PROCONOTP1	Copy.
18 _H		Reserved for copy of PROCONOTP2.
1C _H		Reserved for copy of PROCONOTP3.
20 _H	PROCONWOP 0	WOP protection for the logical sectors of PF0.
24 _H	PROCONWOP 1	WOP protection for the logical sectors of PF1.
28 _H		Reserved for PROCONWOP2.
2C _H		Reserved for PROCONWOP3.
30 _H	PROCONWOP 0	Copy.
34 _H	PROCONWOP 1	Copy.

Program Memory Unit (PMU)

Table 10-10 UCB_OTP Content (cont'd)

Offset ¹⁾	Content	Description
38 _H		Reserved for copy of PROCONWOP2.
3C _H		Reserved for copy of PROCONWOP3.
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.
80 _H		Start of next set.
...		

1) The offsets are given in number of bytes.

See **PROCONOTPp (p=0-1)** on **Page 10-71** and **PROCONWOPp (p=0-1)** on **Page 10-73**.

This configuration set can be stored 8 times. Each set has its own confirmation code. A protection set can be programmed when it is in the “unlocked” state, else it is write-protected.

The content of the PROCONOTP and PROCONWOP registers is initialized by the first configuration set at offset 0 (if this is “unlocked” or “confirmed”). All following confirmed sets are or-ed to this initial value.

An errored set activates all protection bits and activates write protection for this complete UCB.

Attention: This means that always each of the 8 confirmation codes and their copies shall be either in the “confirmed” or “unlocked” state (see [UCB Confirmation on Page 10-36](#)).

The confirmed state of the complete UCB is indicated by FPRO.PROINOTP. It is set when there is at least one protection set in the confirmed state.

If any set is in the errored state FPRO.PROINOTP is also set.

This UCB is protected from erasing if:

- FPRO.PROINOTP.

This UCB is readable.

UCB_IFX

This UCB contains data supplied by Infineon during device production.

Table 10-11 UCB_IFX Content

Offset ¹⁾	Content	Description
00 _H	UID	128-bit Unique ID.
10 _H	Reserved	Reserved.
80 _H		Up to 128 bytes used for DSADC trimming (see DSADC chapter in devices with DSADC).
100 _H		Reserved for calibration data.
200 _H		Reserved for test information data.
380 _H		4 bytes "Test Pass Marker".

1) The offsets are given in number of bytes.

This UCB is read-only. It is readable by every master.

The unique ID is a device unique 128-bit number. Its least significant byte has the value 64_D which identifies an Infineon device.

Note: In order to ensure proper traceability in case of FARs, the unique ID shall be stored by the customer in an adequate database.

The unique ID is supplemented with identification data in the SCU registers CHIPID (device identification and revision, speed grade, Flash size and μ Code revision) and MANID (manufacturer identification). See SCU chapter.

These SCU registers are also sufficient to identify the needed Flash driver (replacement for the QRY record of the CFI standard).

The 4 bytes "Test Pass Marker" contains during test the value FFFFFFFF_H. When all tests have passed it signals this with the value 80658383_H. If customers receive a productive device with a different value in this address they can discard it.

UCB_DBG

This UCB configures the password protection for the debug interface.

Table 10-12 UCB_DBG Content

Offset ¹⁾	Content	Description
00 _H	PROCONDBG	Protection of the debug interface.
10 _H	PROCONDBG	Copy.
20 _H	PW0 – PW7	256-bit password, from least significant word to most significant word (8 words).
40 _H	PW0 – PW7	Copy of 256-bit password.

Program Memory Unit (PMU)
Table 10-12 UCB_DBG Content (cont'd)

Offset ¹⁾	Content	Description
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCONDBG** on [Page 10-74](#).

The confirmed state of this UCB is indicated by FPRO.PROINDBG.

In the errored state of this UCB also FPRO.PROINDBG is set. Disabling the protection is not possible in this state.

This UCB is write and read protected if:

- (FPRO.PROINDBG and not FPRO.PRODISDBG) or (PROCONHSMCOTP.DESTDBG = “destructive” and (FDEST = 0 or “not executing Startup Software”)) or PROCONDBG.EDM = “debug entered”.

UCB_HSMCOTP

This UCB configures the OTP and HSM_exclusive protection for the dedicated HSM code sectors S6, S16 and S17 of PF0 of PMU0. It offers the possibility to add this type of protection to Flash sections incrementally.

Table 10-13 UCB_HSMCOTP Content

Offset ¹⁾	Content	Description
00 _H	PROCONHSM COTP	OTP and HSM_exclusive protection for HSM code sectors and configuration of the HSM boot.
10 _H	PROCONHSM COTP	Copy.
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.
80 _H		Start of next set.
...		

1) The offsets are given in number of bytes.

See **PROCONHSMCOTP** on [Page 10-75](#).

This configuration set can be stored 2 times. Each set has its own confirmation code.

Program Memory Unit (PMU)

The content of the PROCONHSMCOTP register is initialized by the first configuration set at offset 0 (if this is “unlocked” or “confirmed”). All following confirmed sets are or-ed to this initial value.

The confirmed state of the complete UCB is indicated by FPRO.PROINHSMCOTP. It is set when there is at least one protection set in the confirmed state.

If any set is in the errored state FPRO.PROINHSMCOTP is also set. An errored set activates all protection bits.

Attention: This means that always each of the 2 confirmation codes and their copies shall be either in the “confirmed” or “unlocked” state (see UCB Confirmation on Page 10-36).

This UCB is protected from erasing when:

- FPRO.PROINHSMCOTP is set.

The set at offset 0 is protected from programming for all masters when it is in confirmed or errored state.

The set at offset 80_H is protected from programming for all masters except HSM when:

- FPRO.PROINHSMCOTP is set.

It is protected from programming by HSM when it is in the confirmed or errored state¹⁾.

This UCB is readable.

With enabled HSM debug Cerberus has the same access rights as HSM itself. With disabled HSM debug Cerberus is treated as any other master.

UCB_HSM

This UCB can be programmed and erased by all CPUs. However when its content is confirmed or errored only the HSM can modify this UCB.

Its content is only used in devices with activated HSM.

With enabled HSM debug Cerberus has the same access rights as HSM itself. With disabled HSM debug Cerberus is treated as any other master.

Table 10-14 UCB_HSM Content

Offset ¹⁾	Content	Description
00 _H	PROCONHSM	HSM Configuration.
10 _H	PROCONHSM	Copy.

1) Rationale: all masters can configure the protection in delivery state (both sets unlocked). When the first set is confirmed only HSM is allowed to program the second set. When this is also confirmed the complete UCB is OTP protected.

Program Memory Unit (PMU)
Table 10-14 UCB_HSM Content (cont'd)

Offset ¹⁾	Content	Description
70 _H	Confirmation	4 bytes.
78 _H	Confirmation	Copy.

1) The offsets are given in number of bytes.

See **PROCONHSM** on **Page 10-78**.

The confirmed state of this UCB is indicated by FPRO.PROINHSM.

In the errored state of this UCB also FPRO.PROINHSM is set.

This UCB is protected from programming and erasing by non-HSM masters if:

- FPRO.PROINHSM.

It can be read by every master.

Eraser Counter UCB12 – UCB15

These UCBs are used to implement erase counters. From user point of view their content is read-only. They are readable by every master.

For every call of an “Erase Logical Sector Range” the FSI increases automatically the corresponding erase counters until the maximum counting range is reached.

Each UCB12 – UCB15 contains the erase counters for one bank of PFlash PF0 – PF3.

Each logical sector S_x of one PFlash bank has an assigned UCB range of 32 bytes starting at offset address x * 32_D.

The counting is performed by programming the least significant unprogrammed nibble with 1111_B. For reliability reasons a nibble is considered as “unprogrammed” when it contains at most one 1-bit.

Each counter saturates when the last nibble is programmed. Therefore each counter saturates after 64_D erases.

For evaluating the counters the DFlash ECC correction must be disabled with ECCRD.ECCORDIS because this “thermometer code” is not ECC correct.

Remaining UCB8 – UCB11

Currently not used.

These UCBs are read-only.

 Program Memory Unit (PMU)

UCB Confirmation

As described above the UCBs (or sets of a UCB in case of UCB_OTP and UCB_HSMCOTP) can be in the states “confirmed”, “unlocked” and “errored”. This state is determined by the content of the confirmation code:

- 57B5 327F_H: the state is “confirmed”.
- 4321 1234_H: the state is “unlocked”. For over-programming this state (see below) the 4 bytes following the confirmation code need to be kept as 0.
- all other content including uncorrectable ECC errors: the state is “errored”.

An UCB is also in its errored state when at least one of its entries has an uncorrectable error in the original and its copy.

When during evaluation of the UCBs an errored state is detected the flag FSR.PROER is set. The derived values in the PROCONx registers are not set to the Flash content but as indicated in the register description the protection is fully activated. When during startup an errored UCB is detected by the SSW it recognizes this as failed Flash startup and consequently doesn't boot the device.

As also the erased state is considered as “errored” the transition from “unlocked” to “confirmed” state can be done without erasing the UCB. For this the “unlocked” code in the pages with the confirmation code and the copied confirmation code can be over-programmed with 57B5 327F_H. It has to be ensured that the 4 bytes following the confirmation code (e.g. at offset 74_H, 7C_H) are kept 0000 0000_H in the unlocked state and in the over-programmed data. Only then the result after over-programming is ECC clean.

Attention: In case of the multi-set UCBs “UCB_OTP” and “UCB_HSMCOTP” each of the n (8 or 2) confirmation codes and their copies have to be in the state “unlocked” or “confirmed” to prevent an errored state.

10.5.5.6 System Wide Effects of Flash Protection

An active Flash read protection needs to be respected in the complete system.

Additionally the customer can configure in UCB_DBG that OCDS or the debug interface are disabled.

This results in the following lock conditions:

- OCDS disabled: PROCONDBG.OCSDIS and not FPRO.PRODISDBG.
- Debug interface locked: OSTATE.IF_LCK¹⁾ or (PROCONDBG.DBGIFLCK and not FPRO.PRODISDBG).

The SSW performs the following operations:

- The SSW leaves the debug interface locked (OSTATE.IF_LCK stays 1) if any Flash read protection is configured (PROCONP0.RPRO or PROCOND.RPRO are 1).

1) Only for illustration, this bit and its or-combination with the following signals is part of the OCDS not the PMU. The distribution of OCDS documentation is restricted.

Program Memory Unit (PMU)

- If the selected boot mode executes from internal PFlash:
 - The SSW clears the FPRO bits DCFP, DDFP, DDFPX, DDFD.
- If the selected boot mode does not execute from internal PFlash:
 - The SSW sets the FPRO bits DCFP, DDFP, DDFPX, DDFD if their corresponding read protection is configured in PROCONP0.RPRO or PROCOND.RPRO.

Destructive Debug Entry

As described before the debug interface can be opened by supplying the correct password of UCB_DBG to the PMU.

A special destructive debug entry can be configured with **PROCONHSMCOTP.DESTDBG**. When this is configured as “destructive” only the SSW can accept the UCB_DBG password via debug interface (see BootROM chapter). Additionally the password is only accepted when the device pin “FDEST” is logic ‘1’ and the field **PROCONDBG.EDM** is “debug not entered”. When all these conditions match the field **PROCONDBG.EDM** is programmed by the SSW to “debug entered” before opening the debug interface. When EDM is “debug entered” automatically the clock system is manipulated to disallow communication via CAN or Flexray.

10.5.6 Data Integrity and Safety

The data in Flash is stored with error correcting codes “ECC” in order to protect against data corruption. Also data transfer over the SRI bus is protected with ECC. The healthiness of Flash data can be checked with margin checks.

The following measures ensure for reading from PFlash a single point failure metric of >99% and a latent fault metric of >90%.

10.5.6.1 SRI ECC (Safe Fetch Path)

The data transfer over the SRI bus is protected by ECC. This is described in the Safety Concept. The address phase signals are accompanied with an ECC code with Hamming distance 4. The write and read data phase signals are accompanied with an ECC code (also calculated over the address) with Hamming distance 4.

10.5.6.2 Flash ECC

The data in Flash is stored with ECC codes. These are automatically generated when the data is programmed. When data is read these codes are evaluated. Depending on the Flash bank different algorithms with different error correction capabilities are used:

- Data in PFlash uses an ECC code with DEC-TED (Double Error Correction, Triple Error Detection) capabilities. Each block of 256 data bits is accompanied with a set of ECC bits.
 - The ECC algorithm in the PFlash can be switched between a “Safety ECC” which is default and a “Legacy ECC”.

Program Memory Unit (PMU)

- The selection of this algorithm is done by the register field **FCON.NSAFECC**. This is set by the startup software depending on **PROCOND.NSAFECC** but can also be modified by software.
- Data in DFlash uses an ECC code with TEC-QED (Triple Error Correction, Quad Error Detection) capabilities. Each block of 64 data bits is accompanied with a set of ECC bits.

PFlash Safety ECC Details

The PFlash Safety ECC value is calculated over 256 data bits and the address bits 22:5 and the configuration area selection signal. This ECC has the following features:

- Correction of 1-bit and 2-bit errors.
- Detection of 3-bit errors.
- Detection of >99% of all error vectors in the white noise error model.
- Detection of >99% of all-0 and all-1 cases.
- Detection of addressing errors.

As side effect of the all-0 error detection an erased Flash range can't be read without ECC errors. Also over-programming of Flash ranges with all-1 would create entries with ECC errors.

The ECC is automatically generated when programming the PFlash when this is not disabled with **ECCW.PECENCDIS**.

The ECC is automatically evaluated when reading data. Errors are only reported for 256-bit data blocks for which at least one byte is read by a bus master. Errors found in internally pre-fetched data is stored and only reported when this data block is requested by a bus master.

The PMU does not know if the bus master uses the requested data or discards it (e.g. due to speculatively fetching code). Therefore this speculatively fetched data gets the same error response.

Error reporting and ECC disabling:

- Single-bit error:
 - Is noted in **FSR.PFSBER**.
 - Is reported to the SMU (which can trigger an interrupt).
 - Data and ECC value are corrected if this is not disabled with **ECCRp.ECCORDIS¹⁾**.
 - Depending on **CBABCFGp.DIS** and **CBABCFGp.SEL** the affected address is stored uniquely in the **CBAB**.
- Double-bit error:
 - Is noted in **FSR.PFDBER**.

1) Disabling the correction of errors with **ECCORDIS** is a test feature. During application run-time the correction must be enabled.

Program Memory Unit (PMU)

- Is reported to the SMU (which can trigger an interrupt).
- Data and ECC value are corrected if this is not disabled with ECCRPp.ECCORDIS¹⁾.
- Depending on CBABCFGp.DIS and CBABCFGp.SEL the affected address is stored uniquely in the CBAB.
- Triple-bit error (i.e. uncorrectable bit error):
 - Is noted in FSR.PFMBER.
 - Is reported to the SMU (which can trigger an interrupt).
 - Causes a bus error if not disabled by MARP.TRAPDIS.
 - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.
 - Can additionally report an address error.
- Address error:
 - Is noted in FSR.PFMBER.
 - Is reported to the SMU (which can trigger an interrupt).
 - Causes a bus error if not disabled by MARP.TRAPDIS.
 - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.
- All-0 and all-1 errors:
 - Are noted in FSR.PFMBER¹⁾.
 - Is reported to the SMU (which can trigger an interrupt).
 - Causes a bus error if not disabled by MARP.TRAPDIS.
 - Depending on UBABCFG.DIS and UBABCFG.SEL the affected address is stored in the UBAB.

PFlash Legacy ECC Details

The “Legacy” PFlash ECC is calculated only over 256 data bits, not over address bits or the configuration selection. Therefore addressing faults (correct data is read from an incorrect address) can not be detected by this algorithm.

This algorithm has the advantage that an erased PFlash range delivers ECC correct 0 data.

Consequently all-0 data and ECC is not reported as an error.

Note: Please note that this algorithm (in contrast to the Auto generation) does not have all-1 ECC bits for all-1 data, i.e. over-programming a page with all-1 will not create an ECC clean data block.

The error detection, reporting and correction capabilities for single-bit, double-bit and triple-bit errors is identical to the Safety ECC.

1) On some addresses additionally FSR.PFDBER is set.

DFlash ECC Details

The DFlash ECC value is calculated over 64 data bits. This ECC has the following features:

- Correction of 1-bit, 2-bit and 3-bit errors.
- Detection of 4-bit errors.
- All-0 (data and ECC) is a correct code vector.
- All-1 (data and ECC) is a valid code vector.
- Address errors are not detected.

An erased data block has an ECC value 0000_H. Therefore an erased sector is free of ECC errors. A data block with all bits '1' has an ECC value of FFFF_H. This is commonly used in EEPROM emulations to over-program data to mark it as "invalid".

Error reporting and ECC disabling:

- Single-bit, double-bit, triple-bit errors:
 - Are noted in FSR.DFSBER, FSR.DFDDBER, FSR.DFTBER respectively.
 - Data and ECC value are corrected if this is not disabled with ECCRD.ECCORDIS¹⁾.
- Quad-bit error:
 - Is noted in FSR.DFMBER.
 - Causes a bus error if not disabled by MARD.TRAPDIS.

10.5.6.3 Margin Checks

The Flash memory offers a "margin check feature": the limit which defines if a Flash cell is read as logic '0' or logic '1' can be shifted. This is controlled by the registers **MARP** and **MARD**.

After changing the read margin at least $t_{FL_MarginDel}$ have to be waited before reading the affected Flash module.

10.5.6.4 PMU and Flash Register Supervision

Safety relevant registers of PMU and Flash are automatically protected against SEUs by the extensive ECC coverage of the complete PFlash read path.

Only the following configuration registers should be supervised by the safety software against accidental modification:

- FCON.STALL: However modification of this affects safety only in case of errors in the application software, when this is reading busy Flash banks.
- MARP.TRAPDIS: Not really safety relevant because all data read errors are anyhow notified to the SMU.

10.5.7 Interrupts and Traps

Generally the PMU reports fatal errors by issuing a bus error which is translated by the CPU into a trap (PMI sets PSE trap and DMI the DSE trap).

This is a list of conditions for reporting a bus error:

- Uncorrectable ECC error (if not disabled by MARP or MARD).
- Write access to read-only register.
- Write access to BootROM.
- Write access to an access controlled register or PFlash address range by a master without allowance by the register access protection ([Chapter 10.5.5.1](#)).
- Not allowed write access to protected register (e.g. SV or ENDINIT).
- Not allowed Flash read access with active read protection.
- Read and write access to all Flash memories when the Flash is in sleep mode.
- Read access to not available Flash memory.
- Read-modify-write access to the Flash memory.
- Read accesses to a busy Flash bank (if not disabled with [FCON.STALL](#)).
- Write access to DF0 address range when normal command interpreter is busy with a command.
- Read or write access to unoccupied register address.

Furthermore selected events can trigger interrupts. The service request nodes SRC_PMUp0/1 are documented in the IR¹⁾.

The following events can trigger the SRC_PMUp0 service request node when enabled by [FCON](#):

- End of busy: any transition of any of the FSR flags P0BUSY, P1BUSY, D0BUSY or D1BUSY from '1' to '0' triggers the interrupt (program and erase sequences, wake-up).
- Operational error: see OPER flag.
- Verify error: see PVER, EVER flags.
- Protection error: see PROER flag.
- Sequence error: see SQER flag.

The event that triggered the interrupt can be determined from the [FSR](#) register.

An interrupt event it also triggered when the event appears again and the corresponding status flag is still set.

The requested read feature ([Chapter 10.5.3.4](#)) signals availability of data with a separate read interrupt via SRC_PMUp1. This can be used to trigger a DMA controller.

1) The parameter "p" in SRC_PMUp0/1 is "0" for PMU0 and "1" for PMU1.

10.5.8 Reset and Startup

The PMU is reset with the application reset with the exception of the following resources:

- Register bits: FSR.PROG, FSR.ERASE, FSR.OPER. These bits are reset with the power-on reset.
- The complete CBAB and UBAB (see [Chapter 10.7.2.11](#) and [Chapter 10.7.2.12](#)) including their status registers. These are also reset with the power-on reset.

The Flash module and the FSI are only reset with the system reset.

When during a Flash operation (program, erase) an application reset occurs the FSI is not reset but the operation is aborted to ensure that the Flash is readable during startup (see [Chapter 10.8.5](#)).

During startup after the application reset the protection setting is installed from the UCBs. If a protection field has an uncorrectable error its copy is used. This is indicated by setting FSR.ORIER. If a copy has also an uncorrectable error the startup software does not enter the user code.

10.5.9 Power Reduction

The Flash module can enter sleep mode to reduce its power consumption. The sleep request can have two sources:

- Global sleep mode requested by the SCU (see “Power Management”). Only executed by the Flash when FCON.ESLDIS = 0.
- Writing ‘1’ to the bit FCON.SLEEP.

After receiving a sleep request the Flash starts the ramp down when the Flash becomes idle, i.e. none of the banks is in command mode and no reads are executed anymore. An ongoing read burst is finished completely. During ramp down to sleep mode all FSR.BUSYx are set.

The sleep mode is indicated in FSR.SLM. The FSR.BUSYx stay set.

The Flash module can be woken up by releasing the sleep request. It enters read mode again after t_{WU} . During the wake-up phase the FSR.BUSYx are set.

Note: It is not recommended to use the SCU controlled sleep mode with FCON.ESLDIS = 0. Because software had to ensure that upon wake-up the Flash is only read after it has returned to read mode. Earlier reads cause bus errors! Therefore the reset value of FCON.ESLDIS is 1.

Note: Requesting sleep mode does not disable automatically an enabled end-of-busy interrupt. When requesting sleep mode during an ongoing Flash operation with enabled end-of-busy interrupt, the operation finishes, the interrupt is issued and then the Flash enters sleep mode. However this end-of-busy interrupt will wake-up the CPU again.

Program Memory Unit (PMU)

An additional power reduction feature is enabled by setting FCON.IDLE. In this case the PFlash read path is switched off when no read access is pending and the read buffers are filled. System performance is slightly reduced because a flash line hit can not be exploited.

10.6 Signaling to the Safety Management Unit (SMU)

The Safety Management Unit “SMU” is described in its own chapter. This section describes the signaling from the PMU to the SMU.

The following error conditions are internally detected and reported to the SMU:

- PMU registers are automatically supervised by the extensive ECC coverage of the PFlash read path (see [Chapter 10.5.6.4](#)). No dedicate alarm is reported to the SMU.
- PFlash detected ECC errors. There are separate signals for corrected single-bit errors, corrected double-bit errors, address errors and uncorrected bit errors.
- CBAB became full.
- SRI ECC errors from address phase, data write phase, data read phase.

The ECC correction logic of each PFlash read path is continuously supervised by the “ECC Monitor”. A detected error is notified to the SMU.

The detection of this error can be checked by disabling the error correction with ECCRPp.ECCORDIS and reading ECC errored data from PFlash. As the correction is disabled the checker reports an error in the correction logic.

The ECC error detection logic of each PFlash read path is also independently continuously supervised by a redundant error detection unit and a comparator “EDC Comparator”. A detected error is notified to the SMU.

The detection of this error can be checked separately for each PFlash “p” error detection logic by setting bit ECCERRPp.EDCERRINJ. An error is injected in the checked detection path.

10.7 Register Set

The register set consists of some general PMU registers which are partly only implemented for PMU0 because they control its specific functionality ([Chapter 10.7.1](#)). The other registers control Flash functionality ([Chapter 10.7.2](#)). Register fields related to DFlash and its sub-sectors are implemented also when these Flash banks or their functionality is not available but they are without function.

The register access conditions use the following abbreviations:

- “U”: Access permitted in User Mode 0 or 1 (applicable to write and read).
- “SV”: Access permitted in Supervisor Mode (applicable to write and read).
- “E”: ENDINIT protected write. “E” means a write access is only allowed before ENDINIT or after disabling this protection with a password as described in the SCU chapter.
- “SE”: Safety ENDINIT protected write.
- “P”: The access is controlled by the master specific register access protection ([Chapter 10.5.5.1](#)).
- “-” or “BE”: Access not permitted.

The PMU and Flash use the following combinations (see [Table 10-16](#) and [Table 10-18](#)):

- U, SV: access always allowed (i.e. in user mode or supervisor mode).
- P, U, SV: access always to masters allowed that are enabled by the register access protection ([Chapter 10.5.5.1](#)).
- P, SV: access only in supervisor mode for masters enabled by the register access protection.
- BE: access never allowed, causing a bus error.
- SV, E: access only in supervisor mode with disabled ENDINIT protection.
- P, SV, E: access only in supervisor mode with disabled ENDINIT protection for masters enabled by the register access protection.
- SV, SE: access only in supervisor mode with disabled Safety ENDINIT protection.

All accesses prevented due to these restrictions fail with a bus error.

Also accesses to unoccupied register addresses fail with a bus error.

Note: It is convention to use short register names (e.g. “FCON”) in the chapter that defines these registers. In all other chapters and in the development tools long register names are used that are a concatenation of the module instance (e.g. “PMU0” or “FLASH0”), an underscore and the short register name, i.e. “FLASH0_FCON”. This document uses for clarification also mostly the long names.

10.7.1 PMU Registers

Non-Flash related registers for the PMU. They have the prefix “PMUx_”.

Table 10-15 Registers Address Space

Module	Base Address	End Address	Note
PMU0	F800 0500 _H	F800 052B _H	

Table 10-16 Registers Overview

Short Name	Description	Offset Addr. ¹⁾	Access Mode		Reset	Page
			Read	Write		
ID	Module Identification	08 _H	U, SV	BE	Application Reset	10-45

1) The absolute register address is calculated as follows:
 Module Base Address (Table 10-15) + Offset Address (shown in this column)

10.7.1.1 PMU Identification

The PMU_ID register identifies the PMU and its version.

PMU0_ID

PMU0 Identification Register (F800 0508_H) **Reset Value: 00D8 C0XX_H**

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first rev.).

Program Memory Unit (PMU)

Field	Bits	Type	Description
MOD_TYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines the module identification number for PMU0.

Program Memory Unit (PMU)
10.7.2 Flash Registers

The absolute address of a Flash register is calculated by the base address from [Table 10-17](#) plus the offset address of this register from [Table 10-18](#).

Table 10-17 Registers Address Space

Module	Base Address	End Address	Note
FLASH0	F800 1000 _H	F800 23FF _H	Flash registers of PMU0

1) The absolute register address is calculated as follows:

Module Base Address ([Table 10-17](#)) + Offset Address (shown in this column)

2) Some bits are not reset with the application reset but only with the power-on reset.

10.7.2.1 Master Specific Access Control

The master specific access control is described in [Chapter 10.5.5.1](#).

Access Enable Register 0

The Access Enable Register 0 controls write access for transactions with the on-chip bus master TAG IDs 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID to master peripheral mapping). The PMU is prepared for a 6 bit TAG ID. The registers ACCEN0 and ACCEN1 provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ..., EN31 -> TAG ID 011111_B.

Program Memory Unit (PMU)

ACCEN0

Access Enable Register 0

Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID to master peripheral mapping). The PMU is prepared for a 6 bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

10.7.2.2 Flash Identification Register

The register identifies the Flash module which can have a different version from the PMU.

Flash Identification

ID

Flash Module Identification Register (1008_H)

Reset Value: 00D9 C0XX_H

Field	Bits	Type	Description
MOD_REV	[7:0]	r	Module Revision Number MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first revision).
MOD_TYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines the module as a 32-bit module.
MOD_NUMBER	[31:16]	r	Module Number Value This bit field defines a module identification number. For the TC26x B-Step Flash0 this number is 00D9 _H .

10.7.2.3 Flash Status

The Flash Status Register FSR reflects the overall status of the Flash module after Reset and after reception of the different commands.

Program Memory Unit (PMU)

The error flags and the two status flags (PROG, ERASE) are affected by the “Clear Status” command. The error flags are also cleared with the “Reset to Read” command. Some error flags are marked as writable. These flags can be cleared by writing a ‘1’ to this bit.

1) The startup process might report errors by setting some of the error flags.

Field	Bits	Type	Description
FABUSY	0	rh	Flash Array Busy¹⁾ Internal busy flag for testing purposes. Must be ignored by application software. This may only use PxBUSY and DxBUSY.
D0BUSY	1	rh	Data Flash Bank 0 Busy¹⁾ HW-controlled status flag. 0 _B DFlash0 ready, not busy; DFlash0 in read mode. 1 _B DFlash0 busy; DFlash0 not in read mode. Indication of busy state of DFlash bank 0 because of active execution of an operation; DFlash0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DFlash0 is not in read mode.
RES1	2	rh	Reserved for Data Flash Bank 1 Busy¹⁾

Program Memory Unit (PMU)

Field	Bits	Type	Description
P0BUSY	3	rh	Program Flash PF0 Busy¹⁾ HW-controlled status flag. 0 _B PF0 ready, not busy; PF0 in read mode. 1 _B PF0 busy; PF0 not in read mode. Indication of busy state of PF0 because of active execution of an operation; PF0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state, the PF0 is not in read mode.
P1BUSY	4	rh	Program Flash PF1 Busy¹⁾ HW-controlled status flag. 0 _B PF1 ready, not busy; PF1 in read mode. 1 _B PF1 busy; PF1 not in read mode. Indication of busy state of PF1 because of active execution of an operation; PF1 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state, the PF1 is not in read mode.
RES5	5	rh	Reserved for Program Flash PF2 Busy¹⁾
RES6	6	rh	Reserved for Program Flash PF3 Busy¹⁾
PROG	7	rwh	Programming State²⁾³⁾ HW-controlled status flag. 0 _B There is no program operation requested or in progress or just finished. 1 _B Programming operation requested or in action or finished. Set with last cycle of Write Page/Burst command sequence, cleared with Clear Status command (if not busy) or with power-on reset. If one BUSY flag is coincidentally set, PROG indicates the type of busy state. If OPER is coincidentally set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. Can be also cleared by writing '1' to it.

Program Memory Unit (PMU)

Field	Bits	Type	Description

Program Memory Unit (PMU)

Field	Bits	Type	Description
PFMBER	16	rwh	PFlash Uncorrectable Error¹⁾²⁾⁴⁾ 0 _B No uncorrectable error (3-bit error or more, address error, all-0/all-1) detected during read access to PFlash. 1 _B Uncorrectable error (3-bit error or more, address error, all-0/all-1) detected in PFlash. Registered status bit; must be cleared per command or by writing '1'.
RES17	17	rwh	Reserved¹⁾²⁾⁴⁾ Registered status bit; must be cleared per command or by writing '1'.
DFSBER	18	rwh	DFlash Single-Bit Error¹⁾²⁾⁴⁾ 0 _B No Single-Bit Error detected during read access to DFlash. 1 _B Single-Bit Error detected. Registered status bit; must be cleared per command or by writing '1'.
DFDBER	19	rwh	DFlash Double-Bit Error¹⁾²⁾⁴⁾ 0 _B No Double-Bit Error detected during read access to DFlash. 1 _B Double-Bit Error detected. Registered status bit; must be cleared per command or by writing '1'.
DFTBER	20	rwh	DFlash Triple-Bit Error¹⁾²⁾⁴⁾ 0 _B No Triple-Bit Error detected during read access to DFlash. 1 _B Triple-Bit Error detected. Registered status bit; must be cleared per command or by writing '1'.
DFMBER	21	rwh	DFlash Uncorrectable Error¹⁾²⁾⁴⁾ 0 _B No uncorrectable error detected during read access to DFlash 1 _B Uncorrectable error detected in DFlash. Registered status bit; must be cleared per command or by writing '1'.

Program Memory Unit (PMU)

Field	Bits	Type	Description
SRIADDERR	22	rwh	SRI Bus Address ECC Error¹⁾²⁾⁴⁾ This flag is set when the PMU detects an ECC error in the address phase bus transaction on the SRI bus. 0 _B No SRI address error detected. 1 _B SRI address error detected. Registered status bit; must be cleared by writing '1'.
RES	24	rwh	Reserved Write zero. Read value unpredictable.
PVER	25	rwh	Program Verify Error¹⁾²⁾⁴⁾ A verify error was reported during a Flash program operation. 0 _B The page is correctly programmed. All bits have full expected quality. 1 _B A program verify error has been detected. Full quality of all bits cannot be guaranteed. Registered status bit; must be cleared per command or writing '1'.
EVER	26	rwh	Erase Verify Error¹⁾²⁾⁴⁾ A verify error was reported during a Flash erase operation. 0 _B The sector is correctly erased. All erased bits have full expected quality. 1 _B An erase verify error has been detected. Full quality erased bits cannot be guaranteed. Registered status bit; must be cleared per command or writing '1'.
SPND	27	rwh	Operation Suspended³⁾ Requested by MARD.SPND a program or erase operation is suspended. 0 _B No Flash operation is suspended. 1 _B Suspended Flash operation. Can be also cleared by writing '1' to it to clean up after a reset that killed a suspended operation context.

Program Memory Unit (PMU)

Field	Bits	Type	Description
SLM	28	rh	Flash Sleep Mode¹⁾ HW-controlled status flag. Indication of Flash sleep mode taken because of global or individual sleep request; additionally indicates when the Flash is in shut down mode. 0 _B Flash not in sleep mode 1 _B Flash is in sleep or shut down mode
ORIER	30	rh	Original Error¹⁾²⁾⁴⁾ 0 _B No original error detected during startup. 1 _B Original data replaced by its copy.
0	31, 29, 23	r	Reserved Read zero, no write

- 1) Cleared with application reset
- 2) Cleared with command "Clear Status"
- 3) Cleared with power-on reset (PORST)
- 4) Cleared with command "Reset to Read"

Note: The xBUSY flags cannot be cleared with the "Clear Status" command or with the "Reset to Read" command. These flags are controlled by HW.

10.7.2.4 Flash Configuration Control

The Flash Configuration Register FCON reflects and controls the general Flash configuration functions.

FCON

Flash Configuration Register
(1014_H)
Reset value: 0091 XXXX_H¹⁾

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw		rw			rw				rw			rw			

Program Memory Unit (PMU)

- 1) The wait-cycles WSECDF, WSDFLASH, WSECPF and WSPFLASH are changed by the startup after system and power-on resets. **Attention: the configured value is only sufficient for the clock configuration used during startup.** The wait-cycles have to be configured after startup as described in [Chapter 10.5.3.3](#) before changing to higher clock frequencies.

Field	Bits	Type	Description
WSPFLASH	[3:0]	rw	<p>Wait States for read access to PFlash</p> <p>This bitfield defines the number of wait states in number of FSI2 clock cycles, which are used for an initial read access to the Program Flash memory area (see Chapter 10.5.3.3).</p> <p>0_D Read access takes 1 FSI2 clock cycle. 1_D Read access takes 2 FSI2 clock cycles. ..._D ...</p>
WSECPF	[5:4]	rw	<p>Wait States for Error Correction of PFlash</p> <p>This bitfield defines the number of wait-states for the ECC correction in FSI2 clock cycles (see Chapter 10.5.3.3).</p> <p>0_D Error correction takes 1 FSI2 clock cycle. 1_D Error correction takes 2 FSI2 clock cycles. ..._D ...</p>
WSDFLASH	[11:6]	rw	<p>Wait States for read access to DFlash</p> <p>This bitfield defines the number of wait states in number of FSI clock cycles, which are used for a read access to the Data Flash memory area (see Chapter 10.5.3.3).</p> <p>0_D Read access takes 1 FSI clock cycle. 1_D Read access takes 2 FSI clock cycles. ..._D ...</p>
WSECDF	[14:12]	rw	<p>Wait State for Error Correction of DFlash</p> <p>This bitfield defines the number of wait-states for the ECC correction in FSI clock cycles (see Chapter 10.5.3.3).</p> <p>0_D Error correction takes 1 FSI clock cycle. 1_D Error correction takes 2 FSI clock cycles. ..._D ...</p>

Program Memory Unit (PMU)

Field	Bits	Type	Description
IDLE	15	rw	Dynamic Flash Idle 0_B Normal/standard Flash read operation 1_B Dynamic idle of Program Flash enabled for power saving; static prefetching disabled <i>Note: In Data Flash, dynamic idle is always enabled (prefetching not supported).</i> Initial value after startup is 0_B .
ESLDIS	16	rw	External Sleep Request Disable 0_B External sleep request signal input is enabled 1_B Externally requested Flash sleep is disabled The 'external' signal input is connected with a global power-down/sleep request signal from SCU.
SLEEP	17	rw	Flash SLEEP 0_B Normal state or wake-up 1_B Flash sleep mode is requested, Wake-up from sleep is started with clearing of the SLEEP-bit.
NSAFECC	18	rw	Non-Safety PFlash ECC This bit selects if the data in PFlash is written and read with the "Safety" ECC code (calculated over address bits), or the "Legacy" ECC code (see Chapter 10.5.6). 0_B Safety ECC is used. 1_B Legacy ECC is used. Attention: this bit must not be changed while accessing Flash (reading, programming, erasing). Initial value after startup depends on PROCOND.NSAFECC.

Program Memory Unit (PMU)

Field	Bits	Type	Description
STALL	19	rw	<p>Stall SRI</p> <p>This field selects if reading from busy Flash banks causes a bus error or wait-states until busy is cleared again.</p> <p>1_B Stall, Reading busy Flash banks suppresses the SRI bus ready effectively causing wait-states until busy is cleared.</p> <p>0_B Error, Reading busy Flash banks causes a bus error.</p> <p><i>Note: This field must not be changed while any bank is busy. The results are unpredictable. Generally it's strongly recommended to configure this field once and avoid changing it during operation.</i></p> <p><i>Note: Reading Flash in sleep mode causes always a bus error independent of this field (although it reports "busy").</i></p>
RES21	[21:20]	rh	<p>Reserved</p> <p>Write 0; Read value unpredictable.</p>
RES23	[23:22]	rh	<p>Reserved</p> <p>Write 0; Read value unpredictable.</p>
VOPERM	24	rw	<p>Verify and Operation Error Interrupt Mask</p> <p>0_B Interrupt not enabled</p> <p>1_B Flash interrupt because of Verify Error or Operation Error in Flash array (FSI) is enabled</p>
SQERM	25	rw	<p>Command Sequence Error Interrupt Mask</p> <p>0_B Interrupt not enabled</p> <p>1_B Flash interrupt because of Sequence Error is enabled</p>
PROERM	26	rw	<p>Protection Error Interrupt Mask</p> <p>0_B Interrupt not enabled</p> <p>1_B Flash interrupt because of Protection Error is enabled</p>
EOBM	31	rw	<p>End of Busy Interrupt Mask</p> <p>0_B Interrupt disabled.</p> <p>1_B EOB interrupt is enabled.</p>

Program Memory Unit (PMU)

Field	Bits	Type	Description
PR5V	30	rw	Programming Supply 5V Selects the supply for programming. 0 _B P3V , The programming voltage is internally generated. 1 _B P5V , As programming voltage the external 5 V supply is used.
0	[29:27]	r	Reserved Write 0; Read 0.

Note: The default numbers of wait states represent the slow cases. This is a general proceeding and additionally opens the possibility to execute higher frequencies without changing the configuration.

10.7.2.5 Flash Protection

Flash Protection Control and Status Register

This register reports the state of the Flash protection (see [Chapter 10.5.5.5](#)) and contains protection relevant control fields.

FPRO

Flash Protection Control and Status Register (101C_H)

Reset Value: 00XX 00A0_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
PROINP	0	rh	PFlash Protection This bit reflects the confirmed state of UCB_PFlash.

Program Memory Unit (PMU)

Field	Bits	Type	Description
PRODISP	1	rh	PFlash Protection Disabled¹⁾ The protection configured by UCB_PFlash was successfully disabled by supplying the correct password to “Disable Protection”.
PROIND	2	rh	DFlash Protection This bit reflects the confirmed state of UCB_DFlash.
PRODISD	3	rh	DFlash Protection Disabled¹⁾ The protection configured by UCB_DFlash was successfully disabled by supplying the correct password to “Disable Protection”.
PROINHSMCOT P	4	rh	HSM OTP Protection This bit reflects the confirmed state of UCB_HSMCOTP.
RES5	5	rh	Reserved Read value don't care, updated during startup; should be written with 0.
PROINOTP	6	rh	OTP and Write-Once Protection This bit reflects the confirmed state of UCB_OTP.
RES7	7	rh	Reserved Read value don't care, updated during startup; should be written with 0.
PROINDBG	8	rh	Debug Interface Password Protection This bit reflects the confirmed state of UCB_DBG.
PRODISDBG	9	rh	Debug Interface Password Protection Disabled¹⁾ The password configured by UCB_DBG was correctly received with “Disable Protection”. When PROCONHSMCOTP.DESTDBG is “destructive” then only the SSW can disable this protection.
PROINHSM	10	rh	HSM Configuration This bit reflects the confirmed state of UCB_HSM.

Program Memory Unit (PMU)

Field	Bits	Type	Description
DCFP	16	rwh	<p>Disable Code Fetch from PFlash Memory for CPU0 PMI</p> <p>This bit enables/disables the code fetch from the internal PFlash memory area for CPU0 PMI (see Chapter 10.5.5.3). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO.</p> <p>This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash.</p> <p>0_B Code fetching by CPU0 from the PFlash memory area is allowed.</p> <p>1_B Code fetching by CPU0 from the PFlash memory area is not allowed.</p>
DDFP	17	rwh	<p>Disable Read from PFlash for CPU0 DMI</p> <p>This bit enables/disables the read access to the PFlash memory area by for CPU0 DMI (see Chapter 10.5.5.3). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO.</p> <p>This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash.</p> <p>0_B Read access to the PFlash memory area is allowed.</p> <p>1_B Read access to the PFlash memory area is not allowed.</p>
DDFPX	18	rwh	<p>Disable Read from PFlash for Other Masters</p> <p>This bit enables/disables the read access to PFlash for other masters (see Chapter 10.5.5.3). Once set, this bit can only be cleared when FPRO.PRODISP or not PROCONP0.RPRO.</p> <p>This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash.</p> <p>0_B The read access by other masters to the PFlash memory area is allowed.</p> <p>1_B The read access to the PFlash memory area is not allowed for other masters.</p>

Program Memory Unit (PMU)

Field	Bits	Type	Description
DDFD	20	rwh	<p>Disable Data Fetch from DFlash Memory</p> <p>This bit enables/disables the data fetch from the internal DFlash memory area (see Chapter 10.5.5.3). Once set, this bit can only be cleared when FPRO.PRODISD or not PROCOND.RPRO.</p> <p>This bit is automatically set with reset and is cleared during startup, if no RP installed, and during startup (BootROM SW) in case of internal start out of Flash.</p> <p>0_B Data fetching from the DFlash memory area is allowed.</p> <p>1_B Data fetching from the DFlash memory area is not allowed.</p>
ENPE	[23:22]	rw	<p>Enable Program/Erase</p> <p>The field prevents any Flash program or erase directly in the FSI. It is set to Enabled by the SSW upon finishing the startup.</p> <p>01_B Enabled, Program/Erase are enabled in the FSI.</p> <p>10_B Disabled, Program/Erase are disabled in the FSI.</p> <p>others: Illegal values, disabled also Program/Erase. Once in “Enabled” state this field can’t be changed anymore.</p>
0	[31:24], 21, 19, [15:11]	r	<p>Reserved</p> <p>Always read as 0; should be written with 0.</p>

1) Cleared with command “Resume Protection”.

Notes

After reset and execution of BootROM startup SW, the read protection control bits are set to the following values:

- Start not in internal Flash:
 - DCFP set to PROCONP0.RPRO.
 - DDFP set to PROCONP0.RPRO.
 - DDFPX set to PROCONP0.RPRO.
 - DDFD set to PROCOND.RPRO.

Program Memory Unit (PMU)

- Start in internal Flash:
 - DCFP, DDFP, DDFPX, DDFD set to 0.
- Independent of the start configuration: the PROIN fields are set depending on the content of their assigned UCB sectors.

Attention! Before disabling read access by setting any of the DCF* and DDF* flags all pending read accesses to the affected Flash ranges should have finished.

10.7.2.6 Protection Configuration

The configuration of read/write/OTP protection is indicated with registers PROCONP, PROCOND, PROCONHSMCOTP, PROCONOTP, PROCONWOP, PROCONHSM and PROCONDBG.

PFlash Protection Configuration

When UCB_PFlash is in errored state the initial value is “FFFF FFFF_H”, else the initial value after Flash startup reflects the UCB_PFlash content ([Table 10-8](#)).

PROCONPp (p=0-1)
PFlash Protection Configuration PFp
 $(1020_H + p \cdot 4_H)$

Program Memory Unit (PMU)

Field	Bits	Type	Description
L	0	rh	DF_EEPROM Locked for Write Protection This bit indicates whether the DFlash sectors EEPROMx are write protected. 0 _B No write protection is configured. 1 _B Write protection is configured.
NSAFECC	1	rh	Non-Safety PFlash ECC This bit indicates whether the SSW selects the “Safety” PFlash ECC algorithm or the “Legacy” ECC. 0 _B Safety ECC is configured. 1 _B Legacy ECC is configured.
RAMIN	[3:2]	rh	RAM Initialization by SSW Control These bits defined whether the RAMs selected by the field RAMINSEL are initialized. 00 _B Init_All , RAM initialization is performed after cold power-on resets and warm power-on resets. 01 _B Init_Warm , RAM initialization is performed after warm power-on resets but not after cold power-on resets (not recommended). 10 _B Init_Cold , RAM initialization is performed after cold power-on resets. 11 _B No_Init , No RAM initialization is performed. This field determines also if a RAM is initialized before MBIST access is granted. In all “Init_*” cases a RAM is initialized before MBIST access is enabled, in the “No_Init” case a RAM is not erased. This is independent of the memory selection with RAMINSEL for initialization during startup (see MTU chapter).

Program Memory Unit (PMU)

Field	Bits	Type	Description
RAMINSEL	[7:4]	rh	RAM Initialization Selection These bits select which memories are initialized when the RAM initialization is configured with RAMIN. Each bit with value '0' selects the corresponding memory for initialization. xxx0 _B RAMs (PSPR, DSPR, PCACHE and DCACHE) in CPU0 are selected for initialization. xx0x _B RAMs (PSPR, DSPR, PCACHE and DCACHE) in CPU1 are selected for initialization. x0xx _B Reserved for CPU2. 0xxx _B LMU RAMs are selected for initialization.
OSCCFG	8	rh	OSC Configuration by SSW This bit indicates whether the oscillator configuration (fields: CAPxEN, APREN, MODE) are installed by the SSW in SCU_OSCCON. 0 _B SSW copy this data into SCU_OSCCON (bits 17 to 23 of PROCOND are ignored). 1 _B SSW configures oscillator with this data.
MODE	[10:9]	rh	OSC Mode When enabled by OSCCFG this field is copied to SCU_OSCCON.MODE.
APREN	11	rh	OSC Amplitude Regulation Enable When enabled by OSCCFG this field is copied to SCU_OSCCON.APREN.
CAPxEN (x=0-3)	12+x	rh	OSC Capacitance x Enable When enabled by OSCCFG these fields are copied to SCU_OSCCON.CAPxEN.
ESR0CNT	[27:16]	rh	ESR0 Prolongation Counter Used to configure the ESR0 delay. Evaluation by SSW.
RES29	[29:28]	rh	Reserved Deliver the corresponding content of UCB_DFlash.
RES30	30	rh	Reserved Deliver the corresponding content of UCB_DFlash.

Program Memory Unit (PMU)

Field	Bits	Type	Description
RPRO	31	rh	Read Protection Configuration This bit indicates whether read protection is configured for DFlash sectors EEPROMx. 0_B No read protection configured 1_B Read protection and write protection is configured.

OTP Protection Configuration

After Flash startup this register represents the or-combination of all PROCONOTP entries of all confirmed configuration sets in UCB_OTP ([Table 10-10](#)).

When any OTP set is in the errored state the initial content is forced to “3FFF FFFF_H”.

PROCONOTPp (p=0-1)

Program Memory Unit (PMU)

Field	Bits	Type	Description
HSMBOOTEN	0	rh	HSM Boot Enable 0 _B HSM Boot is not enabled. 1 _B HSM Boot is enabled. HSMBOOTEN must not be set to 1 in devices without HSM.
SSWWAIT	1	rh	SSW Wait Defines if the SSW waits for the HSM to release the jump of CPU0 to user code. 0 _B The SSW does not wait for HSM. 1 _B SSW wait for acknowledge of HSM.
HSM DX	2	rh	HSM Data Sectors Exclusive This bit indicates whether the HSM data sectors HSMx are configured as "HSM_exclusive". 0 _B HSMx are not HSM_exclusive. 1 _B HSMx are HSM_exclusive.
HSM6X	3	rh	HSM Code Sector 6 Exclusive This bit indicates whether the HSM code sector S6 is configured as "HSM_exclusive". 0 _B S6 is not HSM_exclusive. 1 _B S6 is HSM_exclusive.
HSM16X	4	rh	HSM Code Sector 16 Exclusive This bit indicates whether the HSM code sector S16 is configured as "HSM_exclusive". 0 _B S16 is not HSM_exclusive. 1 _B S16 is HSM_exclusive.
HSM17X	5	rh	HSM Code Sector 17 Exclusive This bit indicates whether the HSM code sector S17 is configured as "HSM_exclusive". 0 _B S17 is not HSM_exclusive. 1 _B S17 is HSM_exclusive.
S6ROM	6	rh	HSM Code Sector 6 Locked Forever This bit indicates whether PFlash sector 6 is an OTP protected sector with read-only functionality. 0 _B No OTP protection is configured. 1 _B OTP protection is configured.

Program Memory Unit (PMU)

Field	Bits	Type	Description
HSMENPINS	[8:7]	rh	Enable HSM Forcing of Pins HSM1/2 This bit indicates whether HSM may force the value of the pins HSM1/2 (i.e. overrule the value driven by the application). 00 _B HSM can't force pins. 01 _B HSM can't force pins. 10 _B HSM can't force pins. 11 _B HSM can force pins.
HSMENRES	[10:9]	rh	Enable HSM Triggering Resets This bit indicates whether HSM may trigger application or system resets. 00 _B HSM can't trigger resets. 01 _B HSM can't trigger resets. 10 _B HSM can't trigger resets. 11 _B HSM can trigger resets.
DESTDBG	[12:11]	rh	Destructive Debug Entry This field configures the destructive debug entry (see Destructive Debug Entry on Page 10-37). 00 _B Debug entry is non-destructive. 01 _B Debug entry is non-destructive. 10 _B Debug entry is non-destructive. 11 _B Debug entry is destructive.
BLKFLAN	13	rh	Block Flash Analysis This bit allows to block the command “Verify Erased Logical Sector Range” on certain HSM related Flash ranges as described on Page 10-21 . 0 _B Functions allowed on all Flash ranges. 1 _B Functions blocked on HSM_exclusive Flash ranges.
RES	[15:14]	rh	Reserved Deliver the corresponding content of UCB_HSMCOTP.
S16ROM	16	rh	HSM Code Sector 16 Locked Forever This bit indicates whether PFlash sector 16 is an OTP protected sector with read-only functionality. 0 _B No OTP protection is configured. 1 _B OTP protection is configured.

Program Memory Unit (PMU)

Field	Bits	Type	Description
S17ROM	17	rh	HSM Code Sector 17 Locked Forever This bit indicates whether PFlash sector 17 is an OTP protected sector with read-only functionality. 0 _B No OTP protection is configured. 1 _B OTP protection is configured.
0	[31:18]	r	Reserved Always read as 0; should be written with 0.

HSM Interface Configuration

Only existing in PMU0. Content only evaluated in devices with activated HSM.

When UCB_HSM is in errored state the initial value is "0000 FFFF_H", else the initial value after Flash startup reflects the UCB_HSM content ([Table 10-14](#)).

PROCONHSM

HSM Interface Configuration (105C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
HSMDBGDIS	0	rh	HSM Debug Disable This bit indicates whether HSM debug is configured as "disabled". 0 _B HSM debug is enabled. 1 _B HSM debug is disabled.
DBGIFLCK	1	rh	Debug Interface Locked This bit indicates whether the chip debug interface is configured as "locked". 0 _B Debug is unlocked. 1 _B Debug is locked.

Program Memory Unit (PMU)

Field	Bits	Type	Description
TAG	[5:0]	rw	Master Tag This read buffer is assigned to the master with SRI tag = TAG.
0	[31:6]	r	Reserved Write 0, read 0.

10.7.2.8 Requested Read Interface

The following registers can be used by any CPU to control the requested read interface and perform data transfers (see [Chapter 10.5.3.4](#)) from the EEPROMx sectors.

Requested Read Control
RRCT
Requested Read Control Register
(1140_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
STRT	0	rwh	Start Request Writing '1' to this bit starts the next read process as configured by RRAD and RRCT.CNT. This bit is cleared by the PMU as soon the reading process starts executing.
STP	1	w	Stop Stops the read process.

Program Memory Unit (PMU)

Field	Bits	Type	Description
BUSY	2	rh	Flash Read Busy 0_B The RRD registers contain the data addressed by RRAD (data ready). 1_B The Flash is busy reading the data addressed by RRAD.
DONE	3	rh	Flash Read Done 0_B The Flash read has not finished. 1_B The Flash read has finished, data is available.
ERR	4	rh	Error Cleared when starting a sequence with STRT, set when an error is detected. 0_B No error occurred. 1_B Error occurred.
EOBM	8	rw	End of Busy Interrupt Mask Interrupt for RRCT.BUSY. 0_B Interrupt disabled. 1_B EOB interrupt is enabled.
CNT	[31:16]	rwh	Count Defines number of remaining data transfers.
0	[15:9], [7:5]	r	Reserved Always read as 0; should be written with 0.

Requested Read Data Registers
RRD_x (x=0-1)
Requested Read Data Register x

$$(1144_H + x \cdot 4_H)$$

Reset Value: 0000 0000_H

Program Memory Unit (PMU)

Field	Bits	Type	Description
DATA	[31:0]	rh	Read Data Read data.

Requested Read Address Register
RRAD
Requested Read Address Register

 (114C_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
ADD	[31:3]	rwh	Address Start address/current address Can be written by software to define the next read address. Is automatically incremented by the requested read hardware when finishing the last read access. In case both writes happen concurrently the hardware update is performed, the software write is ignored.
0	[2:0]	r	Reserved Always read as 0; should be written with 0.

10.7.2.9 Flash ECC Access
ECC Write Register

The Error Correction Code Write register ECCW contains bits for disabling the ECC encoding separately for PFlash and DFlash.

Program Memory Unit (PMU)

When disabling the ECC encoding for PFlash with PECENCDIS = '1' the ECC code for the next 256-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODE.

When disabling the ECC encoding for DF_EEPROM with DECENCDIS = '1' the ECC code for the next 64-bit data block transferred from PMU to the Flash assembly buffer is taken from ECCW.WCODE.

Because of internal dependencies only one of PECENCDIS or DECENCDIS may be set to '1'.

When any of PECENCDIS or DECENCDIS is set to '1' the "Write Burst" command sequence is not allowed. Its use would cause unpredictable results.

ECCW
ECC Write Register
(1090_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
WCODE	[21:0]	rw	Error Correction Write Code 22-bit ECC code for the current 64-bit (for DFlash) or 256-bit (for PFlash) write buffer to be written into the assembly buffer instead of a generated ECC.
DECENCDIS	30	rw	DF_EEPROM ECC Encoding Disable 0 _B The ECC code is automatically calculated. 1 _B The ECC code is taken from WCODE.
PECENCDIS	31	rw	PFlash ECC Encoding Disable 0 _B The ECC code is automatically calculated. 1 _B The ECC code is taken from WCODE.
0	[29:22]	r	Reserved Always read as 0.

Program Memory Unit (PMU)
ECC Read Registers

For each Flash read path there is a separate Error Correction Code Read register. These allow disabling the ECC correction. The ECC decoding (i.e. the error detection) is not influenced. After reset ECC correction is enabled. If necessary the trap generation has to be separately disabled by MARP.TRAPDIS and MARD.TRAPDIS. Further on these registers allows to read the ECC code.

The ECC code of the last read access is stored in the RCODE field.

Note: After reading data with disabled ECC correction data buffers throughout the system (e.g. pre-fetch buffers in PMU and CPUs) may contain uncorrected data values. Therefore it is recommended to perform a reset to resume normal operation with ECC correction.

ECCRpp (p=0-1)

ECC Read Register PFp (1094_H+p*4_H) **Reset value: 0000 0000_H**

ECCRD

ECC Read Register DF (10A4_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
RCODE	[21:0]	rh	Error Correction Read Code ECC code, read from the Flash read buffer with last data read operation.
RES	[23:22]	rh	Reserved Internal data.

Program Memory Unit (PMU)

Field	Bits	Type	Description
SELPi(i=0-1)	i	rw	PFLASH Bank PFi Selection Bank PFi is selected for reading with MARD.HMARGIN. 0 _B Bank PFi is read with the standard (default) margin independent of HMARGIN. 1 _B Bank PFi is read with the margin selected by HMARGIN.
RES2	2	rw	Reserved Reserved for PFLASH Bank Selection SELP2.
RES3	3	rw	Reserved Reserved for PFLASH Bank Selection SELP3.
TRAPDIS	15	rw	PFLASH Uncorrectable Bit Error Trap Disable 0 _B If an uncorrectable error occurs in PFLASH (setting FSR.PFMBER), a bus error trap is generated ¹⁾ . 1 _B The uncorrectable error trap is disabled.
0	[14:4], [31:16]	r	Reserved Always read as 0; should be written with 0.

1) After Boot ROM exit, uncorrectable bit error traps are enabled (TRAPDIS = 0_B).

Margin Check Control DFlash and Suspend
MARD
Margin Control Register DFlash (10AC_H) **Reset Value: 0000 8000_H**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRAPDIS						0					SPNDER	SPND	0	SELDO	HMARGIN
rw						r					rwh	rwh	r	rw	rw

Program Memory Unit (PMU)

Field	Bits	Type	Description
HMARGIN	0	rw	Hard Margin Selection Banks selected by MARD.SELi = 1 or MARP.SELi = 1 are read with: 0 _B Tight0 , Tight margin for 0 (low) level. Suboptimal 0-bits are read as 1s. 1 _B Tight1 , Tight margin for 1 (high) level. Suboptimal 1-bits are read as 0s. The concrete margin values are restored from the configuration sector and are determined by Infineon.
SELDO	1	rw	DFLASH Bank Selection Bank DF0 is selected for reading with HMARGIN. 0 _B Bank DF0 is read with the standard (default) margin independent of HMARGIN. 1 _B Bank DF0 is read with the margin selected by HMARGIN.
SPND	3	rwh	Suspend 0 _B No suspend requested or pending. 1 _B Suspension of the ongoing program/erase process is requested or pending.
SPNDERR	4	rwh	Suspend Error 0 _B No suspend error. 1 _B Last suspend request via MARD.SPND failed (see Chapter 10.5.4.4). Can be cleared by writing '1'.
TRAPDIS	15	rw	DFLASH Uncorrectable Bit Error Trap Disable 0 _B If an uncorrectable error occurs in DFLASH (setting FSR.DFMBER), a bus error trap is generated ¹⁾ . 1 _B The uncorrectable error trap is disabled.
0	2, [14:5], [31:16]	r	Reserved Always read as 0; should be written with 0.

1) After Boot ROM exit, uncorrectable bit error traps are enabled (TRAPDIS = 0_B).

Program Memory Unit (PMU)

10.7.2.11 Corrected Bits Address Buffer (CBAB)

When data is read from PFlash and the ECC decoder detects correctable bit errors those addresses are stored in the “corrected bits address buffer”. Each address is only entered once. Depending on its configuration 1-bit and 2-bit errors or only 2-bit errors are entered.

When CBAB becomes full the SMU is informed which can trigger an interrupt.

When the CBAB is full no further addresses are added. With CBABCFGp.CLR or CBABTOPp.CLR entries can be emptied.

There exists one CBAB per PFlash “p” SRI port.

Each CBAB instance implements ten entries.

The CBAB is called in safety documentation “PFLASH Monitor”.

CBAB Configuration

Reset: power-on reset.

CBABCFGp (p=0-1)

CBAB Configuration Port p (10B4_H+p*C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SEL	[5:0]	rw	<p>Select Bit-Errors</p> <p>This bit controls which type of errors are entered into the CBAB.</p> <p>000000_BNo errors enter the CBAB.</p> <p>000001_BCorrected single-bit errors enter the CBAB.</p> <p>000010_BCorrected double-bit errors enter the CBAB.</p> <p>000011_BCorrected single-bit and double-bit errors enter the CBAB.</p> <p>others: Reserved values.</p>

Program Memory Unit (PMU)

Field	Bits	Type	Description
CLR	8	w	Clear Clears the complete CBABp.
DIS	9	rw	Disable This bit allows to disable this CBAB. This reduces the power consumption. The content of the CBAB stays unchanged. <i>Note: Due to race conditions switching this bit concurrently to Flash read accesses can cause an erroneous address to become registered twice.</i>
0	[7:6], [31:10]	r	Reserved Always read as 0; should be written with 0.

CBAB Status

Reset: power-on reset.

CBABSTATp (p=0-1)
CBAB Status Port p

 (10B8_H+p*C_H)

 Reset Value: 0000 0000_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
VLDx (x=0-9)	x	rh	Filling Level Each VLDx indicates a valid entry. The complete set of VLD flags operates as thermometer code. Entry 0 is the top entry which is read in CBABTOP. The entry with the highest index number was entered last.
0	[31:10]	r	Reserved Always read as 0; should be written with 0.

Program Memory Unit (PMU)

CBAB FIFO Top Entry

This register displays the information of the top-most entry of the CBAB FIFO.

Reset: power-on reset (for the complete FIFO content).

CBABTOPp (p=0-1)

CBAB FIFO TOP Entry Port p ($10BC_H + p * C_H$) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLR	31	w	Clear Write-only trigger bit. Reading returns 0. 1 _B Clears valid flag "VLD" of this entry and removes it from the FIFO. 0 _B No operation.
VLD	30	rh	Valid Entry is valid.
ERR	[29:24]	rh	Error Type This field contains the error type found at ADDR. The bits correspond to CBABCFG.SEL. 000000 _B No error (reserved). 000001 _B Single-bit error. 000010 _B Double-bit error. others: Reserved.
ADDR	[23:5]	rh	Address Captured address (bits 23:5 of the SRI bus address) with detected error.
0	[4:0]	r	Reserved Always read as 0; should be written with 0.

Program Memory Unit (PMU)

10.7.2.12 Uncorrectable Bits Address Buffer (UBAB)

When data is read from PFlash and the ECC decoder detects uncorrectable bit errors those addresses are stored in the “uncorrected bits address buffer”. Each address is only entered once. Depending on its configuration selected failures can be entered.

When the UBAB is full no further addresses are added. With UBABCFGp.CLR or UBABTOPp.CLR entries can be emptied.

There exists one UBAB per PFlash “p” SRI port.

Each UBAB instance implements one entry.

UBAB Configuration

Reset: power-on reset.

UBABCFGp (p=0-1)

UBAB Configuration Port p (10E4_H+p*C_H) Reset Value: 0000 0000_H

Field	Bits	Type	Description
SEL	[5:0]	rw	Select Bit-Errors This bit controls which type of errors are entered into the UBAB. 000000 _b No errors enter the UBAB. 000100 _b Detected uncorrectable bit-errors (3-bit or more, address errors, all-0, all-1 enter the UBAB. others: Reserved values.
CLR	8	w	Clear Clears the complete UBABp.

Program Memory Unit (PMU)

Field	Bits	Type	Description
DIS	9	rw	Disable This bit allows to disable this UBAB. This reduces the power consumption. The content of the UBAB stays unchanged.
0	[31:10] , [7:6]	r	Reserved Always read as 0; should be written with 0.

UBAB Status

Reset: power-on reset.

UBABSTATp (p=0-1)
UBAB Status Port p (10E8_H+p*C_H) **Reset Value: 0000 0000_H**

r															rh

Field	Bits	Type	Description
VLD0	0	rh	Filling Level Each VLDi indicates a valid entry. The complete set of VLD flags operates as thermometer code. Entry 0 is the top entry which is read in UBABTOP. The entry with the highest index number was entered last.
0	[31:1]	r	Reserved Always read as 0; should be written with 0.

UBAB FIFO Top Entry

This register displays the information of the top-most entry of the UBAB FIFO.

Program Memory Unit (PMU)

Reset: power-on reset (for the complete FIFO content).

UBABTOPp (p=0-1)
UBAB FIFO TOP Entry Port p (10EC_H+p*C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
CLR	31	w	Clear Write-only trigger bit. Reading returns 0. 1 _B Clears valid flag "VLD" of this entry and removes it from the FIFO. 0 _B No operation.
VLD	30	rh	Valid Entry is valid.
ERR	[29:24]	rh	Error Type This field contains the error type found at ADDR. The bits correspond to UBABCFG.SEL. 000000 _B No error (reserved). XXX100 _B Uncorrectable error (3-bit or more, addressing error, all-0, all-1). others: Reserved.
ADDR	[23:5]	rh	Address Captured address (bits 23:5 of the SRI bus address) with detected error.
0	[4:0]	r	Reserved Always read as 0; should be written with 0.

10.7.2.13 Direct Flash Communication

 These registers enable direct communication of software (e.g. a Flash driver running on TriCore) with the FSI specifically with its μ Code.

Program Memory Unit (PMU)

Because of design particularities byte wide write accesses are not supported and cause unpredictable results. Only half-word (16-bit) wide writes shall be performed.

Read and write accesses during ongoing Flash operations (FSR shows BUSY flags) is forbidden. The PMU returns a bus error.

These registers shall be read or written in exceptional cases only when demanded by IFX for extended functions.

The behavior of these registers in specific Flash modes is special:

- During all FSI operations including Flash startup: the STATUS fields can deliver unpredictable data.
- When the Flash is in sleep mode: write and read accesses fail with a bus error.

Flash Communication Register 0
COMM0

FSI Communication Register 0 (0000_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
STATUS	[7:0]	rh	Status This field can be only written by the FSI.
0	[31:8]	r	Reserved Always read as 0.

Program Memory Unit (PMU)

Flash Communication Register

COMMx (x=1-2)

FSI Communication Register x (0000_H+4*x) Reset Value: 0000 0000_H

Field	Bits	Type	Description
STATUS	[7:0]	rh	Status This field can be only written by the FSI.
DATA	[15:8]	rwh	Data This field can be only written by software not by the FSI.
0	[31:16]	r	Reserved Always read as 0.

10.8 Application Hints

The following application hints should support the user in using the PMU and Flash optimally.

10.8.1 Changes with Respect to Audo Families Audo-NG/F/S/Max

The following changes of the PMU with respect to Audo-NG/F/S/Max products are highlighted. With “Audo-Max” are changes noted with respect to SRI based Audo-Max products. The tag “All” indicates changes with respect to all Audo product generations:

- All: Flash cell concept is changed enabling many significant improvements:
 - Performance of programming significantly enhanced.
 - Burst programming feature with even higher programming throughput.
 - No over-erased state anymore.
 - Sector structure of PFlash enhanced with more small Flash sectors.
 - EEPROM emulation in DFlash improved by smaller pages.
 - Enhanced retention and endurance figures.
 - All logical sectors of PFlash (see [Table 10-2](#)) have the same endurance. “Second class” logical sectors with only 100 cycle endurance are not existing anymore.
- All: Changed PMU and FSI architecture (enabled by the increased programming performance). Now one FSI and PMU can serve several PFlash banks in addition to the DFlash banks.
- All: Due to this one PMU and FSI has to support several independent read paths with independent bus interfaces to the assigned PFlash banks.
- All: Changed command sequences. In Audo the SA and PA arguments were transmitted in the address phase, thus these command cycles had to be written to the target Flash range. Now SA and PA are transmitted in the data phase. Only writes into the DFlash address range are interpreted as command sequences.
- Audo-NG/F/S: Enhanced Flash read buffer concept with master specific read buffers.
- Audo-NG/F/S: Changed bus interface from LMB to SRI.
- All: Changed supply concept supporting EVR. Dedicated programming modes for 3.3V only supply or 5V supply.
- Audo-NG/F/S: The wait-state settings in FCON don't relate by default to the bus clock as in Audo-NG/F/S (i.e. the LMB clock) but to the FSI and FSI2 clocks. These clocks have their own divider from the PLL clock which need to be configured in SCU_CCUCON0.FSIDIV and SCU_CCUCON0.FSI2DIV. They have to be configured to have a relation $f_{SRI}/f_{FSI(2)}$ of $n/1$.
- All: Explicit suspend to read feature replacing automatic “program while erase” of the Audo generation.
- Audo-NG/F/S: The OVRAM and the EMEM were moved to a different module “LMU”.
- All: The register field FCON.STALL configures the behavior when reading busy Flash banks. Either “ready” is suppressed or a bus error is generated.
- Audo-NG/F/S: TP: changed addresses RTPWT and RPSSW.

Program Memory Unit (PMU)

- Audo-NG/F/S: Programming and reading data with disabled ECC generation and correction allows customers to program data with invalid ECC.
- Audo-NG/F/S: Error flags in FSR can be selectively cleared to enable easier flag handling for concurrent operations.
- Audo-Max: Dropped extended status register XSFR.
- All: Protection fields assembled in new register FPRO.
- All: Changed protection concept:
 - Only one protection “user” in PFlash.
 - Separate protection with password for DFlash.
 - Password width increased from 64 bits to 256 bits.
 - More flexible OTP configuration that allows adding OTP.
 - New write-once protection enabling “automatic” OTP protection.
 - All UCBs realized as part of DFlash instead of PFlash.
 - Confirmation concept for UCB blocks changed. Now an erased confirmation code activates complete protection and locks the UCB.
 - New password protected debug lock.
- All: New erase counters.
- All: Changed base addresses of all Flash modules.
- All: Changed base address of BootROM.
- All: TEC-QED ECC algorithm in DFlash.
- All: DEC-TED ECC algorithm in PFlash with specific safety features for 99% white noise coverage, detection of all-0/all-1 inducing faults and addressing errors.
 - As in Audo-Max the ECC algorithm can be switched between safety and non-safety mode.
 - Attention: switching the algorithm with FCON.NSAFECC may only be done while no Flash accesses are performed. This feature may conflict with Audo-F Flash driver software.
- All: New “Erase Verify” functionality.
- All: New multiple sector erase command sequence “Erase Logical Sector Range”.
- All: Extended safety protection of registers with ACCEN and “Safety ENDINIT”.
- All: FIFOs that store uniquely addresses in PFlash read with corrected and uncorrectable bit errors.

10.8.2 Performing Flash Operations

This section offers advice for programming command sequences.

General Advice

- Please remember to disable the Safety ENDINIT protection before executing program and erase commands for the PFlash (see [Chapter 10.5.5.2](#)).
- Code that performs PFlash programming or erasing should not be executed from the same PFlash.

Program Memory Unit (PMU)

- The command cycles shall address the non-cached address range of the Flash (otherwise the data may stay in the cache or could be received by the PMU in an incorrect order).
- The non-cached Flash range is not regarded as peripheral address space by the TriCore. This means that a read (notably reading the FSR for checking the flags) placed behind the last command cycle write in program order might be executed before this last write.
The FSR flags xFPAGE, PROG, ERASE can be used to ensure that polling for a cleared BUSY starts only after the command was accepted by the PMU. Additionally it is recommended to place a “DSYNC” instruction between a command sequence and read accesses to depending data including affected registers.
- The caches (data cache in DMI “DCache” and program cache in PMI “PCACHE”) as well as the data line buffer in the DMI “DLB” are not automatically invalidated nor updated after changing Flash content by erasing or programming. It is therefore recommended to either invalidate them actively or read the Flash content via the non-cached address range. Otherwise old data might be delivered from these buffers. The DMI cache and line buffer can be invalidated by writing OVCCON.DCINVAL to ‘1’. The PCACHE can be invalidated by writing PCON1.PCINV to ‘1’. All buffers are invalidated by a reset.
- The PMU and Flash work with the SRI, FSI and FSI2 clocks. When changing the divider values of these clocks in SCU_CCUCON0 the following rules apply:
 - The only allowed PMU/Flash “operation” when switching is reading from Flash memory. Programming or erasing the Flash is forbidden.
 - It must be ensured that before, during and after the divider change the configured number of Flash wait-cycles is sufficient for the selected clock frequency. Remember that the wait-cycles are counted with f_{FSI2} for PFlash and f_{FSI} for DFlash.
 - After System Resets and Power-On Resets the wait cycle values are configured to a value only sufficient for the clock frequencies used during startup (i.e. 100 MHz). So basically always changes to the clock configuration must be preceded by changes to the wait cycles.

Sequence for Programming

The following sequence is the most defensive one for programming a page. It is however acceptable to skip some checks when the programmed data is later verified:

- “Clear Status” to clear flags.
- “Enter Page Mode”.
- DSYNC.
- Wait until FSR.xFPAGE = ‘1’ or fail if FSR.SQER = ‘1’ or FSR.PROER = ‘1’.
- Repeat “Load Page” until the page is filled.
- “Write Page”.
- DSYNC.

Program Memory Unit (PMU)

- Wait until FSR.PROG = '1' or fail if FSR.SQER = '1' or FSR.PROER = '1'.
- Wait until FSR.xBUSY = '0' or enable the interrupt.
 - While FSR.xBUSY is '1' the flags FSR.OPER can be checked for '1' as abort criterion to protect against hardware failures causing BUSY to stay '1'.
- Check for FSR.PVER flag.
- Fail if FSR.OPER = '1'.
- Recommended: check programmed content, evaluate FSR.xMBER and possibly count correctable errors.
- Clear error flags either with "Clear Status" or by directly writing to FSR.

Sequence for Erasing

The following sequence is the most defensive one for erasing a range of sectors. It is however acceptable to skip some checks when the programmed data is verified after programming (or the flag FSR.PVER is checked as described above):

- "Clear Status" to clear flags.
- "Erase Logical Sector Range".
- DSYNC.
- Wait until FSR.ERASE = '1' or fail if FSR.SQER = '1' or FSR.PROER = '1'.
- Wait until FSR.xBUSY = '0' or enable the interrupt.
 - While FSR.xBUSY is '1' the flags FSR.OPER can be checked for '1' as abort criterion to protect against hardware failures causing BUSY to stay '1'.
- Check for FSR.EVER/PVER flags.
- Fail if FSR.OPER = '1'.
- Clear error flags either with "Clear Status" or by directly writing to FSR.

An analog sequence can be used for "Verify Erased Logical Sector Range".

10.8.3 EEPROM Emulation With DFlash

The term "EEPROM emulation" designates an algorithm with the following features:

- It increases the effective endurance by spreading the EEPROM write accesses over a larger range of Flash memory.
- It ensures that all Flash cells incur a similar number of cycles independent of the update frequency of the EEPROM data ("wear levelling").
- It manages the allocation of EEPROM data to Flash ranges so that stale data can be erased.

A popular emulation algorithm is the "two sector" emulation, which splits the complete DFlash in two equally sized ranges:

- The EEPROM writes are performed in one range, the "active" one. The other range stays erased.
- The data is stored so that several writes of the same EEPROM address can be performed in one DFlash range. The position of the latest data version and the

Program Memory Unit (PMU)

original EEPROM address can be determined from the address in Flash and additional administrative data (e.g. all data is pushed to a stack and the pushed data contains the EEPROM address).

- At a certain range fill level a range switch is performed. This moves all active data to the erased range. After that the active range is erased and the other range becomes the active one.

With the 6 erasable DFlash ranges of the TC26x B-Step other more efficient algorithms are possible. However the algorithm must ensure that all sectors are used equally, e.g. it is not allowed to keep static data in certain sectors and often updated data in other sectors. The sectors with static data would incur too many disturbs.

One specific requirement for an EEPROM emulation algorithm is the resistance against aborts during its operation. In any case the algorithm must be able after device startup to recover without data loss, determine the active data and resume operation.

In many applications even resistance against aborted Flash processes (program, erase) is needed. See details in [Chapter 10.8.5.2](#).

10.8.3.1 Robust EEPROM Emulation

A key requirement for an EEPROM emulation algorithm is the reliability of the stored data. The DFlash with its TEC-QED ECC algorithm protects perfectly against bit or bit-line oriented failures.

However, ECC mechanisms do not protect against word-line oriented failures. Word-line failure modes may result in a complete word-line which can no longer be programmed or erased, and the data within the failed word-line may not be able to be read correctly. Word-line failures are most likely to occur during the high voltage conditions present during programming or erase operations. Therefore, a robust EEPROM emulation algorithm must tolerate word-line failures, and must protect against data loss in case the word-line fails during an erase or programming operation.

The following steps shall be followed to achieve the necessary robustness:

- Before programming a page save the content of all other pages on the same word-line that contain active data to SRAM.
- Program the new page and compare the content of this page and of the saved pages with their reference data. This can be done with normal read margins. Ignore correctable bit-errors.
- If the data comparison fails or the programming returned with PVER error program this page and the saved content of the other pages to a different word-line.
- This procedure can be repeated if the data comparison fails again. The number of repetitions should be limited (e.g. to 3) in case the programming fails because of out-of-spec operating conditions.
- Word-line oriented fails can also have the effect that the affected word-lines can not be erased anymore, yet the contents of the word-line data could still be read without

Program Memory Unit (PMU)

any error indication. Sequence counters for the data blocks or other means must be used to identify old data blocks in word-lines with this type of failure mode.

For the TC26x B-Step this robust EEPROM algorithm is required for the usage of the DFlash.

Due to the specificity of each application the appropriate usage and implementation of these measures must be chosen according to the context of the application.

10.8.4 Handling Errors

The earlier sections described shortly the functionality of “error indicating” bits in the flash status register **FSR**. This section elaborates on this with more in-depth explanation of the error conditions and recommendations how these should be handled by customer software.

10.8.4.1 Handling Errors During Operation

This first part handles error conditions occurring during operation (i.e. after issuing command sequences) and the second part ([Section 10.8.4.2](#)) error conditions detected during startup.

SQER “Sequence Error”

Fault conditions:

- Improper command cycle address or data, i.e. incorrect command sequence.
- New “Enter Page” in Page Mode.
- “Load Page” and not in Page Mode.
- “Load Page” results in buffer overflow.
- “Load Page” with mixed 32/64-bit transfers.
- First “Load Page” addresses 2. word.
- “Write Page” with buffer underflow.
- “Write Page” and not in Page Mode.
- “Write Page” to unavailable Flash range.
- Command sequence with address not pointing to a legal start address (e.g. page, UCB or sector).
- “Write Page Once” targeting DFlash.
- Byte transfer to password or data.
- “Erase Logical Sector Range” or “Verify Erased Logical Sector Range” with range leaving a physical sector.
- “Resume Prog/Erase” with arguments not matching the suspended command.
- “Resume Prog/Erase” when there is no suspended operation.
- Any programming or erase command when there is a suspended programming command.

Program Memory Unit (PMU)

- Any erase command when there is a suspended erase command, including “Verify Erased Logical Sector Range”.
- Programming to the target range of a suspended erase command.

New state:

Read mode is entered with following exceptions:

- “Enter Page” in Page Mode re-enters Page Mode.
- “Write Page” with buffer underflow is executed.
- After “Load Page” causing a buffer overflow the Page Mode is not left, a following “Write Page” is executed.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer should be notified. In production code this error will not occur. It is however possible to clear this flag with “Clear Status” or “Reset to Read” and simply issue the corrected command sequence again.

OPER “Operation Error”

Fault conditions:

ECC double-bit error detected in Flash microcode SRAM during an operation or the microcode has detected another significant failure. This can be a transient event due to alpha-particles or illegal operating conditions or it is a permanent error due to a hardware defect. This situation will practically not occur.

Attention: these bits can also be set during startup (see [Chapter 10.8.4.2](#)).

New state:

The Flash operation is aborted, the BUSY flag is cleared and read mode is entered.

Proposed handling by software:

The last operation can be determined from the PROG and ERASE flags. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page. Other sectors can still be read. New Flash commands (Write*, Erase*, Verify*, Resume*) must not be issued before the next system or power-on reset. “Clear Status” can be used to clear the OPER flag, however this doesn’t resolve the corrupted state of the FSI.

Attention: New FSI operations in this state can cause corruption of Flash content, which might even prevent the device from booting.

The next system or power-on reset performs a new Flash startup with initialization of the microcode SRAM. A power-on reset clears additionally the OPER flag. The application must determine from the context which operation failed and react accordingly. Mostly erasing the addressed sector and re-programming its data is most appropriate. If a “Program Page” command was affected and the sector can not be erased (e.g. in Flash

Program Memory Unit (PMU)

EEPROM emulation) the word-line could be invalidated if needed by marking it with all-one data and the data could be programmed to another empty word-line.

Only in case of a defective microcode SRAM the next program or erase operation will incur again this error.

PROER “Protection Error”

Fault conditions:

- Password failure.
- Erase/Write to protected sector.
- Erase/Write of protected UCB.
- “Verify Erased Logical Sector Range” to blocked addresses.
- Program or erase targeting PFlash with active Safety ENDINIT protection.

New state:

Read mode is entered. The protection violating command is not executed.

Proposed handling by software:

Usually this bit is only set during runtime due to a bug in the software. In case of a password failure a reset must be performed in the other cases the flag can be cleared with “Clear Status” or “Reset to Read”. After that the corrected sequence can be executed.

EVER “Erase Verify Error”

Fault conditions:

This flag is set by the erase commands when they don’t achieve an optimum result.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with “Clear Status” or “Reset to Read”.

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFlash an EVER can be regarded as device failure.

In the DFlash an EVER is a warning which doesn’t require immediate action. The robust EEPROM emulation will detect during programming the corresponding word-lines and “jump” over them.

Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see [Chapter 10.5.7](#), interrupt because of verify error).

Program Memory Unit (PMU)**PVER “Program Verify Error”**Fault conditions:

This flag is set by the program commands when they don't achieve an optimum result.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with “Clear Status” or “Reset to Read”.

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFlash a PVER can be regarded as device failure. However due to the high correction capability of the ECC customers may choose to check the amount of corrected and uncorrectable errors and decide on this basis if the device can stay in operation.

In the DFlash a PVER is a signal for the robust EEPROM emulation that programming on the current word-line failed. The algorithm has to “jump” over this word-line and programs its data to the next word-line.

Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see [Chapter 10.5.7](#), interrupt because of verify error).

PFSBER, PFDBER, DFSBER, DFDBER, DFTBER “Single/Double/Triple-Bit Error”Fault conditions:

When reading data or fetching code from PFlash or DFlash the ECC evaluation detected an error which was corrected.

This flag is a warning indication and not an error. A certain amount of correctable errors must be expected because of known physical effects.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This flag can be used to analyze the state of the Flash memory. During normal operation it should be ignored. High counts of correctable errors can indicate that the Flash is operated outside of the defined operating conditions (e.g. temperature, voltage, endured p/e cycles, configured wait-states).

When programming the PFlash (end-of-line programming or SW updates) customers can count the number of correctable errors using the CBAB or rely on the PVER indication.

Program Memory Unit (PMU)

In case of EEPROM emulation using DFlash the verification of programmed data should be done with the normal read level and correctable errors should be ignored. Further advice can be found in [Chapter 10.8.3](#).

10.8.4.2 Handling Errors During Startup

The FSR flags are not only used to inform about the success of Flash command sequences but they are also used to inform (1) the startup software and (2) the user software about special situations incurred during startup. In order to react on this information these flags must be evaluated after reset before performing any flag clearing sequence as “Clear Status” or “Reset to Read”.

The following two levels of situations are separated:

- Fatal level: the user software is not started. A WDT reset is performed.
- Warning level: the user software is started but a warning is issued.

Fatal Level (WDT Reset)

These error conditions are evaluated by the startup software which decides that the Flash is not operable and thus waits for a WDT reset. The application sees only a longer startup time followed by a WDT reset.

The reason for a failed Flash startup can be a hardware error or damaged configuration data.

Warning Level

These conditions inform the user software about an internally corrected or past error condition.

Leftover OPER:

FSR bits set: OPER.

The OPER flag are only cleared by the command sequence “Clear Status” or with a power-on reset. After any other reset a OPER flag can still be set when the user software is started.

Correctable error in UCB or configuration sector:

FSR bits set: PFSBER/PFDBER, DFSBER, DFDBER, DFTBER or ORIER.

An correctable ECC error was detected during installation of the protection or of the configuration sector content.

10.8.5 Resets During Flash Operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as violation of stable operating conditions. However the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied

Program Memory Unit (PMU)

as defined in the data sheet. The addressed Flash range is left in an undefined state. Additional means are implemented that help to prevent aborting programming processes in the DFlash.

10.8.5.1 General Advice

When an erase operation is aborted the previously programmed bits ('1') in the addressed Flash range can be in any state between '0' and '1'. When reading this range all-0 can be returned, the old data, or something in between. The result can be instable. Due to the ECC correction there may even appear '1' bits at positions which contained '0' bits before erase start.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is instable so that depending on the operating conditions different data is read.

For the detection of an aborted Flash process the flags FSR.PROG and FSR.ERASE could be used as indicator but only when the reset was an application reset. When Flash processes are aborted by power-on resets this is not indicated by any flags. It is not possible to detect an aborted operation simply by reading the Flash range (please note that the ECC is not a reliable means to detect an aborted Flash operation). Even the margin reads don't offer a reliable indication.

When erasing or programming the PFlash usually an external instance can notice the reset and restart the operation by erasing the Flash range and programming it again.

10.8.5.2 Advice for EEPROM Emulation

However for the case of EEPROM emulation in the DFlash this external instance is not existing. A common solution is detecting an abort by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation.

E.g. after erasing a DFlash sector a page is programmed. After reset the existence of correct data in this page proves that the erase process was performed completely.

The detection of aborted programming processes can be handled similarly. After programming a block of data an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption.

In very specific cases it is allowed to repair data left from an aborted programming operation: if the algorithm can detect that an abort occurred and the algorithm knows which data must be present in the page it is possible to simply redo the programming by programming the same data again.

Program Memory Unit (PMU)

In the AURIX family the probability of aborting a programming process can be minimized by the following means:

- In case of a reset with stable power supply (“warm resets”) the Flash gets automatically a request to enter safe state before the reset is applied. Due to their short duration single “Write Page” operations are finished correctly by this process. “Write Burst” operations however are interrupted after the current page programming has finished.
- The voltage monitoring (see SCU chapter) can be used to get an under voltage warning early enough that an ongoing programming process can be finished and no new one is started.
- By selecting an internally generated programming voltage (see [Chapter 10.5.4.5](#)) the needed voltage at V_{EXT} is reduced giving more headroom for an early warning by the voltage monitors.

10.8.6 ECC

For special applications the ECC features need to be considered.

Using the PFlash Safety ECC

The PFlash Safety ECC is a vital part of the safe fetch path needed for safety applications. The difference between Legacy ECC and Safety ECC is explained in [Chapter 10.5.6.2](#).

The calculation of the Safety ECC is done over 256 data bits, the address bits 22:5 and the configuration area selection signal. As side effect erased PFlash ranges or PFlash ranges programmed with the Legacy ECC will be read with ECC errors.

Thus the installation of an application using the Safety ECC should be done as follows:

- By default (delivery state) the device starts with the Safety ECC enabled.
- The Flash loader can execute from RAM. Erased PFlash ranges shall not be read.
- A sector should be programmed completely to ensure that it can be read without ECC errors.
- When changing the UCB_DFlash it is important to keep the ECC configuration flag `PROCOND.NSAFECC = 0`.

The installation of an application using the Legacy ECC should be done as follows:

- By default (delivery state) the device starts with the Safety ECC enabled.
- The Flash loader can execute from RAM.
- By writing `FCON.NSAFECC` to 1 the ECC algorithm is switched to Legacy ECC.
- Afterwards the PFlash programming is performed with the Legacy ECC.
- Erased PFlash ranges can be read without error.
- In UCB_DFlash the ECC configuration flag `PROCOND.NSAFECC` shall be programmed to 1 to ensure that the device starts after next reset with the Legacy ECC. It must be ensured that is kept when changing later the UCB_DFlash.

Program Memory Unit (PMU)

Attention: Changing `FCON.NSAFECC` while accessing the Flash (reading, programming, erasing) is forbidden.

Attention: Reading PFlash ranges with the incorrect ECC (e.g. Flash was programmed with Legacy ECC but reading with setting of `NSAFECC=0`) must not be done although it might seem to work when the uncorrectable error traps are disabled.

On certain address/data combinations mis-corrections will happen and single and double-bit errors in PFlash will not be corrected because for the wrong ECC algorithm nearly all addresses will have uncorrectable errors resulting in the delivery of the raw data.

Creating Incorrect ECC

In safety applications error detection features are usually checked at each startup. In order to check the detection logic for ECC errors addresses in PFlash need to be programmed with erroneous data.

The automatic ECC generation can be disabled with `ECCW.PECENCDIS`. With this feature any combination of data and ECC bits can be programmed.

The ECC code causing the required error type (e.g. triple-bit error) can be determined by first programming the data with automatic ECC generation on. When reading this data the corresponding ECC code can be found in `ECCRPp.RCODE`. After erasing this range of Flash a modified data/ECC combination can be programmed with automatic ECC generation switched off (`ECCW.PECENCDIS = 1`).

It is also possible to create ECC incorrect patterns by programming twice with enabled automatic ECC generation.

Ready-to-use programming routines for the creation of ECC errors are part of the Infineon safety software "SafeTlib".

10.8.7 Startup Tests of ECC Logic

As described in [Chapter 10.6](#) the ECC logic of the PFlash is protected by special hardware means, the "ECC Monitor" and the "EDC Comparator". Depending on the targeted ASIL level these units, their error signals and generally the ECC error signaling to the SMU has to be tested during each startup after reset.

The Infineon safety software "SafeTlib" contains routines to perform these tests.

10.8.7.1 Testing ECC Alarms and Error Flags

In order to test if each type of ECC error is correctly reported to the SMU and PMU status registers a pattern with this error needs to be stored in PFlash and read during startup after reset.

Such patterns can be created as described in [Chapter 10.8.6](#).

Test Pattern

As the patterns stored in PFlash might change their error signature over life-time (e.g. a single-bit error becomes a double-bit error due to a single bit toggling) each pattern needs to be stored redundantly (we propose 4 times).

As the ECC logic of each PFlash bank has separate paths the patterns have to be stored in each PFlash bank and tested in each PFlash bank.

Patterns for the following types of errors should be stored and read:

- No error (valid data). This data could be shared with the one for [Chapter 10.8.7.2](#).
- 1-bit error.
- 2-bit error.
- 3-bit error to trigger an uncorrectable error.
- Address error (can be created by generating an ECC for an address that is different by 1 or 2 address bits). This test pattern is optional. It is not needed for sufficient test coverage.
- All-0 in data and ECC. This test pattern is optional. It is not needed for sufficient test coverage.
- All-1 in data and ECC. This test pattern is optional. It is not needed for sufficient test coverage.

In sum these 7 pattern (each covering one 32-byte page) are stored 4 times per PFlash bank.

For best possible robustness 2 of the 4 pattern sets shall be inverse to the other 2.

Test Flow

For each error type its 4 patterns are read. The corresponding error flag and SMU alarm should occur at least once.

10.8.7.2 Testing the “ECC Monitor”

As the ECC Monitor is always in use its logic is usually tested sufficiently during startup of the application, simply by performing read accesses to the PFlash banks.

However in order to achieve a defined error coverage a dedicated test procedure recommended.

Test Pattern

In each PFlash bank a set of 32 valid pages (i.e. containing no intentional ECC error) is stored. These patterns are chosen by IFX to ensure >90% stuck-at coverage of the ECC Monitor logic.

Test Flow

The 32 pages of each PFlash bank are read by any master e.g. the CPU.

Program Memory Unit (PMU)

The ECC monitor logic is working correctly if during this test the alarm “PFLASH ECC monitor error” at the SMU is not activated.

10.8.7.3 Testing the SMU Alarm of the “ECC Monitor”

In order to test that the “PFLASH ECC monitor error” alarm to the SMU can be activated the ECC monitor has to receive a pattern with incorrect ECC for which the ECC correction logic states that a correction was performed.

Test Pattern

In each PFlash bank a pattern with a correctable error has to be read, e.g. the ones used in [Chapter 10.8.7.1](#).

Test Flow

The ECC correction has to be disabled for the tested PFlash bank “p” with ECCRPp.ECCORDIS. After that read 4 patterns from this bank with a correctable error. This shall trigger at least once the PFLASH ECC Error alarm in the SMU. Clear the alarm, clear ECCRPp.ECCORDIS for this bank and repeat the test for the other PFlash banks.

10.8.7.4 Testing the “EDC Comparator”

The EDC comparator compares the output of two error checking units. In case of a difference the SMU alarm “PFLASH EDC comparator error” is activated. This error can be enforced by setting for a PFlash bank “p” by setting ECCRPp.EDCERRINJ.

Test Pattern

The test patterns of [Chapter 10.8.7.1](#) can be used.

Test Flow

The test patterns are read with ECCRPp.EDCERRINJ = 0. This is already part of the test in [Chapter 10.8.7.1](#). The “PFLASH EDC comparator error” alarm must not be activated.

The test patterns are read with ECCRPp.EDCERRINJ = 1. This shall trigger the “PFLASH EDC comparator error” alarm in the SMU.

Repeat this test for all PFlash banks.

10.8.7.5 General Advice for Startup Tests

The previously described tests need to be executed under controlled conditions:

Program Memory Unit (PMU)

- Only a single master with blocked interrupts should execute these tests. This is mandatory for tests with disabled ECC correction (**Chapter 10.8.7.3**) because other masters might receive uncorrected Flash data during that time.
- For the same reason the Flash test code should execute from RAM. Especially it must not execute from a PFlash bank with disabled ECC correction (**Chapter 10.8.7.3**).
- It has to be taken into account that internal pre-fetching of the PMU can trigger the “PFLASH ECC monitor error” and the “PFLASH EDC comparator error” before the corresponding Flash read access is issued by the CPU. For the ECC alarms and error flags of **Chapter 10.8.7.1** this issue is not existing as the PMU activates these errors only when the respective data is read from the bus.
- The alarms activation in the SMU has a latency of several clock cycles.
- The software executing these tests has to cope with all consequent actions like activated error flags, entries in error buffers, bus-errors, SMU alarms. Before normal execution continues these mechanisms have to be cleared.
- The existence of Flash addresses with correctable and uncorrectable errors has to be respected by the application software. Interpretation as real error has to be prevented.

11 Local Memory Unit (LMU)

The Local Memory Unit is an SRI peripheral providing access to volatile memory resources. It's primary purpose is to provide access to the separate block of emulation and debug memory (EMEM) provided in the Emulation Devices.

The LMU also provides OnLine Data Acquisition (OLDA) region support. This provides an address space where writes complete without error but no memory is addressed. This allows production code to be written which writes data to memory which is only present in the Emulation Device. When running in the Emulation Device, the code maps EMEM to the OLDA region address space using the memory overlay feature and the writes are stored in the EMEM. when running in the Production Device, the LMU terminates writes to the OLDA address space without error, even though no memory exists at the target address, but the write data is discarded.

11.1 Feature List

An overview of the features implemented in the LMU follows:

- Interface to the EMEM of the Emulation Device.
- OLDA region support.

11.2 Local Memory (LMU SRAM)

This version of the LMU has no local memory.

11.3 Emulation Memory (EMEM)

In the Emulation Device, an area of Emulation Memory (EMEM) is provided, which can be used for either calibration via overlay of non-volatile memory or overlay of the OLDA address space (see [Chapter 1.8](#) below). The address range allocated for the memory is $9F000000_H$ to $9F3FFFFFF_H$ which allows the maximum EMEM size fitted in any of the derivative products to be addressed.

As well as the cached addresses (segment 9_H), noncached address (segment B_H) accesses can be used for EMEM accesses via the LMU.

The Emulation Memory interface controls the CPU-accesses to the Emulation Memory in the Emulation Device. All widths of write accesses are supported (byte, halfword, word, double-word).

CPU-controlled Load-Modify-Store accesses (with LDMST instruction) are supported as separate read and write instructions not as an atomic operation.

In the production device, the EMEM interface is always disabled. A CPU read access from the Emulation Memory region causes a DSE trap by returning an SRI bus error. If the Emulation Memory region read access is initiated by a SPB master (e.g. PCP), additionally a SPB error interrupt can be generated.

Local Memory Unit (LMU)

By default, write accesses to the Emulation Memory by any master will cause an SRI bus error trap in the production device.

In the Emulation Device, a SRI bus error is returned by the LMU if a read access can't be handled by the EMEM, for example, when the CPU accesses a trace memory tile in EMEM. In this case, the EMEM access is aborted by the LMU.

Write accesses which cannot be handled by the EMEM will fail silently as the write access is completed on the SRI bus before being passed to the EMEM. Therefore any error condition encountered by the EMEM will occur after the SRI access has completed. A status bit **LMU_MEMCON.EWERR** will be set if an error occurs on an EMEM write. This bit can be cleared by writing 0_B.

Wait states can be manually added to EMEM memory accesses using the **LMU_MEMCON.WSTATES** field. This can be programmed with a counter preload value. A counter is loaded with this value every time the LMU starts a read access to the EMEM. Data returned by the EMEM will be delayed until the counter reaches a count of zero. The counter is decremented by one every SRI clock cycle.

11.3.1 EMEM Memory Read Buffers

Accesses to the EMEM address space can be stored to read buffers. One read buffer will be instantiated for each CPU in the system. Each of these buffers will store 256 bits of data. Buffering of read data is controlled by the **LMU_BUFCONx (x=0-2).EREN** bit and will be enabled when **EREN** is 1_B. Speculative prefetch is available only if buffering of read data is enabled and is controlled by the **LMU_BUFCONx (x=0-2).EPEN** bit. Setting **EPEN** to 1_B will allow prefetch if **EREN** is also 1_B. Two Unique Master Tag IDs can be manually associated with each CPU using the **LMU_BUFCONx (x=0-2).TAG1** and **LMU_BUFCONx (x=0-2).TAG2**. Each tag field can be individually enabled using the **LMU_BUFCONx (x=0-2).EN1** and **LMU_BUFCONx (x=0-2).EN2** fields respectively.¹⁾

If read buffering is enabled, then all reads to the EMEM not using the BTR4 opcode will be mapped to BTR4 equivalent read accesses to the EMEM and the data returned stored in the related buffer while the requested data is returned to the SRI interface. Any further reads to the address range of the data stored in the buffer will be returned directly from the buffer.

If prefetch is enabled, then two conditions will trigger a prefetch:

- any SDTW read to the EMEM will cause a speculative read of the next BTR4 address range to be triggered if the address of the read corresponds to the highest 32 bit address of a BTR4²⁾ (even if the data for the read is already stored in the buffer).

1) Multiple buffers should not be configured to respond to the same Master Tag ID. LMU behaviour in this case is undefined.

2) A BTR4 access requires 256 bits of data or 8, 32 bit words. These words always have A_{SRI}[4:2] = 000_B, 001_B, 010_B, 011_B, 100_B, 101_B, 110_B, 111_B. An 32 bit access with A_{SRI}[4:2] = 111_B will trigger a prefetch

Local Memory Unit (LMU)

- Any BTR4 read to the cached segment address of the EMEM (9_H) will trigger a prefetch (even if the data for the read is already stored in the buffer).

The prefetched data will be stored in the related buffer and any reads to the address range of the prefetch will be returned directly from the buffer. A prefetch will not occur if another read to EMEM is already required. Write accesses will be scheduled after the prefetch has completed.

Prefetch takes priority over read buffering.

Any write access to EMEM which collides with the address range stored in a buffer will invalidate that buffer. Read accesses to the Emulation Device register space will not be buffered.

11.3.2 Access to Emulation Device Register Space

In addition to accessing EMEM, the EMEM interface in the LMU is also used to access configuration registers in the Emulation Device. To allow this accesses to the address range $F9000000_H$ to $F90FFFFF_H$ are directed to the ED register address space via the EMEM interface.

The interface to the ED register space only supports 32 bit accesses. Any other size of access will be errored.

11.4 Error Detection and Signalling

The LMU will detect several different classes of error which cannot be signalled on the SRI during the associated transaction. These will cause a flag to be set in the **LMU_MEMCON** register and a trigger will be sent to either the SMU or the Interrupt system for processing. In general ECC errors will be processed by the SMU and other errors will be passed to the Interrupt Router. The following list details the detected error conditions:

11.4.1 EMEM Read Error

An error signalled by the EMEM on the second data phase of a 256 bit access cannot be signalled on the SRI as this would violate the protocol or, in the case of a 32 bit read, occur after the SRI access has completed. In this event, the **LMU_MEMCON.ERERR** bit will set and a trigger will be sent to the Interrupt Router.

11.4.2 EMEM Write Error

All errors signalled by the EMEM during a write access will, by definition in the SRI protocol, occur after the access has been accepted from the SRI. These errors will set the **LMU_MEMCON.EWERR** bit and send a trigger to the Interrupt router

11.4.3 SRI write access data phase error

If an ECC error occurs on the data phase of an SRI write access then the LMU_MEMCON.DATAERR bit will be set and an error will be signalled to the SMU

11.4.4 SRI access address phase error

If an ECC error occurs on the address phase of an SRI access then the LMU_MEMCON.ADDERR bit will be set and an error will be signalled to the SMU. The SRI access will terminate with an error.

11.5 Online Data Acquisition (OLDA) and its Overlay

Calibration is additionally supported by an OLDA memory range of up to 32 Kbyte, which is a virtual memory and physically only available if it is redirected (by the overlay feature of the processor) to internal or external physical memory or to the EMEM in the Emulation Device.

If OLDA support is enabled in the LMU, direct write accesses (without redirection) to the OLDA range are not really executed, and they do not generate a bus error trap¹⁾. If OLDA support is not enabled, write accesses will generate a bus error trap. OLDA support is enabled by setting LMU_MEMCON.OLDAEN to 1_B.

Note that switching on or off the OLDA function takes a finite amount of time after the register write completes. It is therefore possible for an immediately following access pipelined into the LMU SRI interface to be acknowledged with either the "on" or "off" behaviour.

Read accesses to the OLDA range generate a bus error trap, if not redirected to a physically available overlay block. Successful accesses to the OLDA memory range will only take place when the accesses are redirected to real, physical memory.

The base address of the virtual OLDA memory range is A/8FE7 0000_H, the end address is A/8FE7 7FFF_H. Accesses to the OLDA range are also supported in cached address space.

Note: In OTARx registers, any target address can be selected for redirection, thus also addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled in the LMU.

11.6 Clock Control

The LMU contains a clock control register, **LMU_CLC**, which allows the LMU to be put into a power saving mode.

1) Write accesses to a cached memory address will trigger a read to fill the cache line before the data is written to the cache. This read will trigger a bus error.

Local Memory Unit (LMU)

If LMU_CLC.DISR is set then the LMU will be disabled and all accesses will be errored unless they are addressed to a register.

11.7 LMU Register Protection

The LMU implements the standard memory protection scheme for peripheral registers using the **LMU_ACCEN0** and **LMU_ACCEN1** registers. This allows the LMU control registers to be protected from corruption by untrusted masters. Masters are identified using the SRI tag of the access and, if the appropriate bit is not set in the access enable registers, write accesses will be disconnected with error acknowledge. See the On Chip Bus chapter for the product's master Tag ID to master peripheral mapping. This protection scheme does not apply to the **LMU_ACCEN0** and **LMU_ACCEN1** themselves.

LMU_ACCEN0 and **LMU_ACCEN1** are protected by Safe Endinit while all other registers are Endinit protected. The Endinit and Safe Endinit system status is defined by different Watchdog Units in the System Control Unit (SCU).

11.8 LMU Registers

The LMU registers are mapped into a 256 byte address space which allows for 64 registers. Accesses to unused register space will cause an SRI bus error.

Table 11-1 Registers Address Space

LMU Access Enable Register 0

The Access Enable Register 0 controls write access for transactions to registers with the on chip bus master TAG ID 000000_B to 011111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000_B, EN1 -> TAG ID 000001_B, ... ,EN31 -> TAG ID 011111_B.

12 Data Access Overlay (OVC)

The data overlay provides the capability to redirect selected data accesses to the Overlay memory. Data accesses made by the TriCore to Program Flash, Online Data Acquisition space, or EBU space can be redirected. Overlay memory may be located in the Local Memory (if present), in the Emulation Memory (Emulation Device only), or in the DPSR/PSPR memory. Overlay functionality makes it possible, for example, to modify the application's test and calibration parameters (which are typically stored in Flash memory) during run time of a program. Note that only read and write data accesses are redirected. The access redirection is executed without performance penalty.

Attention: As the address translation is implemented in the DMI it is only effective for data accesses by the TriCore. Instruction fetches by the TriCore or accesses by any other master (including the debug interface) are not effected!

Summary of Features and Functions

- Redirecting data accesses addressed to Program Flash, OLDA or External EBU Space.
- Support redirection to Overlay memory located in:
 - Local Memory (LMU) (if present)
 - Emulation Memory (Emulation Device only)
 - DPSR or PSPR memory
- Support of up to 4 MB overlay memory address range;
- Up to 32 overlay ranges ("blocks") available in each TriCore instance;
- Overlay block size from 32 byte to 128 Kbyte;
- Up to 4 MB of redirected space (32 ranges x 128 Kbyte);
- Overlay memory location and block size selected individually for every overlay block;
- Multiple overlay blocks can be enabled or disabled with one register write access;
- Programmable flush (invalidate) control for data cache in DMI.
- Overlay start/stop synchronised against data load.
- Individual Overlay system per processor core.

12.1 Data Access Redirection

The principle of redirecting data access from the original target memory (“Target Address”) to overlay memory (“Redirected Address”) is shown below.

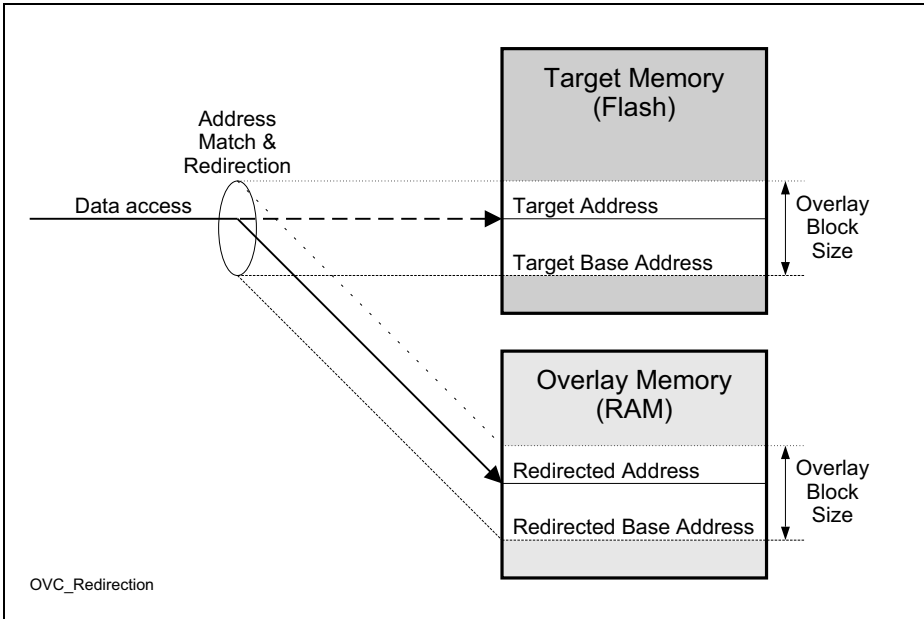

Figure 12-1 Data Access Redirection

Data access overlay is defined using overlay ranges (“overlay blocks”). Each overlay block defines one continuous range of address space for which the accesses are redirected. Each overlay block is configured with the following parameters:

- Overlay Block Target Base Address - the start address for the range of the target addresses to be redirected;
- Overlay Block Size - the size of the range of the addresses to be redirected;
- Overlay Block Redirection Base Address - the start address for redirection.

In TC26x B-Step up to 32 overlay ranges can be used in each TriCore instance.

Each overlay block has 3 associated registers for independent configuration of these parameters. The overlay parameters are configured as follows:

- Target Base Address is configured with OTARx register (“[OTARx \(x=0-31\)](#)” on [Page 12-13](#)),
- Overlay Block Size is configured with OMASKx register (“[OMASKx \(x=0-31\)](#)” on [Page 12-14](#)),

Data Access Overlay (OVC)

- Redirection Base Address is configured with RABRx register (“RABRx (x=0-31)” on Page 12-11).

The size of the overlay memory blocks can be $2^n \times 32$ bytes, with $n = 0$ to 12. This gives the block size range from 32 bytes to 128 Kbytes. The start address of the block can only be an integer multiple of the programmed block size (natural alignment boundary). If OTAR register value, or RABR register value is not aligned with the block size, the least significant bit values are ignored and treated as zero.

The Redirection Base Address is determined by two fields in RABRx register:

- RABRx.OMEM selecting the Overlay Memory, and
- RABRx.OBASE selecting the base address within this memory.

Each overlay block can be activated or deactivated with its RABRx.OVEN bit. Overlay blocks can be activated and deactivated independently, by directly accessing RABRx register, or in groups, where multiple configured blocks are activated or deactivated concurrently. For information on concurrent block activation see Chapter 12.4.1.

The address redirection process is shown in the following figure.

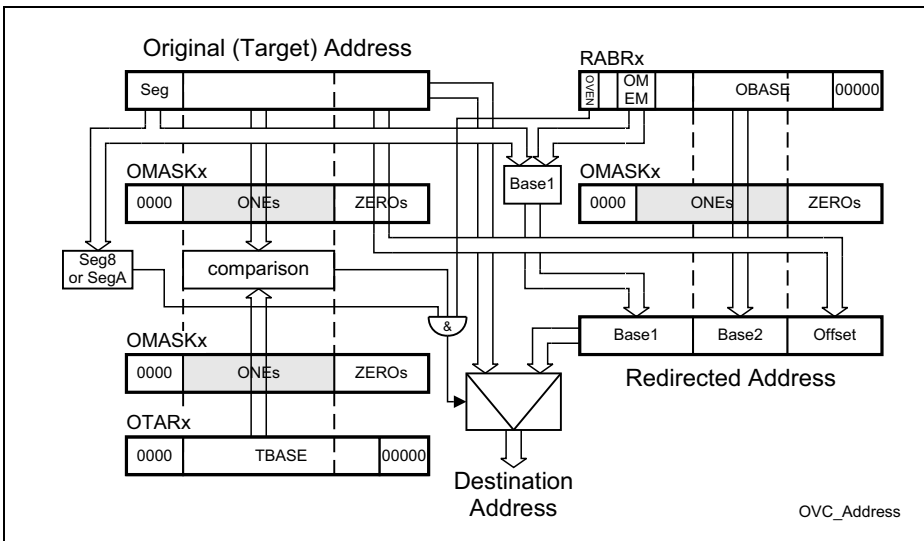

Figure 12-2 Address Redirection Process

Any data access to segment 8_H or segment A_H is checked against all the activated overlay blocks. For each activated overlay block, address bits 27..5 are compared with the target base address (OTARx), and this bit-wise comparison is qualified by the content of OMASKx register. Address bits participate in the comparison if the

Data Access Overlay (OVC)

corresponding OMASKx bits are set to one. The access is redirected, if all the address bits selected by OMASKx equal to the corresponding bits in OTARx register.

The address for redirection is constructed as follows:

- Address bits 31..22 are set according to the overlay memory selection (RABRx.OMEM) and the cache-ability of the original address.
- For address bits 21..5:
 - If the corresponding OMASKx bit is set, the address bit value is taken from RABRx.OBASE field;
 - If the corresponding OMASKx bit is cleared, the address bit value is taken from the original address.
- Address bits 4..0 are always taken directly from the original address.

If there is no redirection, the original address is used to perform the access.

Target address ranges for activated overlay blocks should not overlap or an exception may occur, see [Chapter 12.6](#).

12.2 Target Memories

Data access to any memory within the segment 8_H or segment A_H may be redirected to overlay memory. In particular, access to the following memories may be redirected:

- Program Flash;
- Data Flash;
- OLDA space;
- External EBU space.

12.2.1 Online Data Acquisition (OLDA) Space

Calibration is additionally supported by virtual OLDA memory range. The base address of the virtual OLDA memory range is $A/8FE7\ 0000_H$.

12.3 Overlay Memories

In the following, all the supported overlay memories are described. Note, that depending on the device type only a subset of the listed overlay memories is available. Overlay memory is selected independently for each block by RABRx.OMEM field value.

12.3.1 Local Memory

If present, the Local Memory (LMU) can be selected for overlay. The Local Memory is selected for overlay block x redirection, if RABRx.OMEM value is 6. The base address of the LMU is $B/9000\ 0000_H$. During address translation, the upper 10 address bits are set to $B0_H00_B$ (for target segment A_H) or to 90_H00_B (for target segment 8_H).

12.3.2 Emulation Memory

If present, the Emulation Memory (EMEM) can be selected for overlay. The Emulation Memory is selected for overlay block x redirection, if RABRx.OMEM value is 7. The base address of the Emulation Memory is B/9F00 0000_H. During address translation, the upper 10 address bits are set to BF_H00_B (for target segment A_H) or to 9F_H00_B (for target segment 8_H).

12.3.3 DSPR & PSPR Memory

Data Scratch Memory (DSPR) or Program Scratch Memory (PSPR) from Core 0, 1 or 2 can be selected for overlay. The DSPR or PSPR is selected for overlay block x redirection, if RABRx.OMEM value is 0, 1, or 2. The base address is 7000 0000_H, 6000 0000_H, or 5000 0000_H. During address translation, the upper 10 address bits are set to 70_H00_B, 60_H00_B, or 50_H00_B. Depending on the value set in RABRx.OBASE either DSPR memory (starting at offset 0_H) or PSPR memory (starting at offset 10 0000_H) can be used.

12.4 Global Overlay Control

Overlay can be disabled or enabled individually for each core with OVCENABLE register. If OVCENABLE.OVEN_x bit is cleared no address redirection is permitted on Core x regardless of the remaining register settings. A write to OVCENABLE register does not change any of the remaining register values.

While each overlay block can be activated and deactivated individually by writing its RABRx.OVEN bit, a dedicated functionality is provided for concurrently activating and deactivating multiple blocks. This can be useful in maintaining data consistency across several memory regions. For the purpose of concurrent activation and deactivation overlay blocks are selected in two stages:

- The individual blocks for activation and deactivation are selected with OVC_x_OSEL registers, for each core x independently;
- The set of cores is selected with OVCCON.CSEL field.

Multiple overlay blocks can be simultaneously activated or deactivated with OVCCON.OVSTRT bit. When OVCCON.OVSTRT bit is written with one:

- If OVCCON.CSEL_x bit is written with one, and OVC_x_OSEL.SHOVEN_y bit value is one, overlay block y in core x is activated, and OVC_x_RABR_y.OVEN bit is set;
- If OVCCON.CSEL_x bit is written with one, and OVC_x_OSEL.SHOVEN_y bit value is zero, overlay block y in core x is deactivated, and OVC_x_RABR_y.OVEN bit is cleared;
- If OVCCON.CSEL_x bit is written with zero, the overlay configuration in core x is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise. With this function it is possible to switch directly from one set of overlay blocks to another set of overlay blocks.

Data Access Overlay (OVC)

Multiple overlay blocks can be simultaneously deactivated with OVCCON.OVSTP bit. When OVCCON.OVSTP is written with one:

- If OVCCON.CSELx bit is written with one, all the overlay blocks in core x are deactivated, and all OVCx_RABRy.OVEN bits are cleared;
- If OVCCON.CSELx bit is written with zero, the overlay configuration in core x is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise.

Note: Overlay should not be enabled or disabled using global OVCENABLE register if any of the blocks are enabled with RABRx.OVEN. Instead, OVSTRT or OVSTP should be used if concurrent block enabling or disabling is required.

When OVCCON.DCINVAL is written with one, all the unmodified (clean) data cache lines in the selected cores are invalidated. The data cache lines containing modified (dirty) data are not effected. The cores not selected with OVCCON.CSEL field are not effected. Data Cache invalidation can be combined with OVSTRT or OVSTP action. This function helps to assure that the CPU can access the new data after the overlay blocks have been activated or deactivated.

Note: OVCCON.CSEL field is written together with OVSTRT, OVSTP and DCINVAL bits in the same register, and only impacts any action triggered by the same write. CSEL, OVSTRT, OVSTP and DCINVAL do not retain the written value and always read as zero.

The OVCCON.OVCONF user control flag is provided, together with its protection bit OVCCON.POVCONF. These bits do not impact the overlay functionality.

When OVCCON register is written with CSELx set and either OVSTRT or OVSTP set, and at the same time OVCx_RABRy register is written, the resulting value of OVCx_RABRy.OVEN bit is not defined. Possibility of such simultaneous access should be avoided.

OVSTRT, OVSTP and DCINVAL actions are not performed when TriCore is in IDLE state.

12.4.1 Global Overlay Control Synchronisation

When OVSTRT, OVSTP or DCINVAL action is requested its execution may be delayed to prevent changing Overlay configuration during an ongoing data load.

Sufficient time should be allowed after an action request, before another action is requested. If a new action is requested while previous action is still pending (due to synchronisation with CPU loads) some actions may be lost.

12.5 Overlay Configuration Change

Overlay block should be disabled, by clearing its RABRx.OVEN bit, before any changes are made to OTARx, OMASKx or RABRx registers. Otherwise, unintended access redirections may occur. Overlay block should only be enabled, if the target address, the overlay memory selection, the redirection address and the mask have all been configured with intended values.

Note: The Overlay Control does not prevent configuring the translation logic incorrectly. In particular, redirection to not implemented or forbidden address range is not prevented.

Special care needs to be taken to synchronise Overlay redirection change to the executed instruction stream if data consistency is required.

External accesses may be buffered in the CPU. External accesses that have not been completed may still be affected by overlay configuration changes. Therefore, it is advised to ensure completion of all pending accesses (for example, by executing DSYNC instruction) before any overlay range is activated or deactivated.

When overlay block is enabled and the same memory location is written through the target address space and read through the redirected address space, or vice-versa, the access synchronisation need to be enforced (with DSYNC and data cache writeback if applicable).

12.6 Access Protection, Attributes, Concurrent Matches

When data access is redirected by Overlay, access protection is applied as follows:

- Target address is subject to CPU Memory Protection (MPU) validation;
- Redirected address is subject to Safety Protection validation.

Physical Memory Attributes for the redirected access are determined basing on the Target Address segment (see CPU Physical Memory Attributes chapter).

Concurrent matches in more than one enabled overlay block are not supported. When an address matches two, or more, of the enabled overlay blocks, an exception is raised and the memory access is not performed. A load operation with multiple matches on overlay ranges, raises a Data Access Synchronous Error (DSE) trap, and a store operation raises Data Access Asynchronous Error (DAE) trap. In such case, relevant trap information registers: Data Synchronous Trap Register (DSTR), Data Asynchronous Trap Register (DATR), and Data Error Address Register (DEADD) are updated, see DMI Registers chapter for more information.

12.7 Overlay Control Registers

OVC block control registers are located in each module that supports data access overlay. OVC global control registers are located in SCU. OVC register access can be restricted by Safety Register Protection.

Figure 12-3 Overlay Register Overview

Registers OVCENABLE and OVCCON are described in SCU Chapter.

1) The OVC register short names are extended with the module name prefix "OVCI_", where i is core number.

- 2) Symbol P: Write access protected with Safety Protection
 Symbol SV: Access permitted in Supervisor Mode
 Symbol U: Access permitted in User Mode 0 or 1
 Symbol 32: Only 32-bit word access is permitted

12.7.1 Block control registers

For each of the 32 overlay memory blocks (indicated by index x), three registers control the overlay operation and the memory selection:

- Redirected Address Base Register RABRx, which selects the overlay memory, holds the block base address within this memory, and contains block enable bit.
- Overlay Target Address Register OTARx, which holds the base address of the memory block being overlaid.
- Overlay Mask Register OMASKx, which determines which bits (from RABRx) are used for the base address (of overlay memory and block) and which bits (of original data address) are directly used as offset within the block.

Additionally, Overlay Range Select Registers OSEL determines which blocks are to be enabled and which blocks are to be disabled when OVCCON.OVSTRT bit is set.

All overlay block control registers are reset to their default values with the application reset. A special debug reset is not considered.

Data Access Overlay (OVC)

OSEL

Overlay Range Select Register

(0000_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SHOVENx (x=0-31)	x	rw	<p>Shadow Overlay Enable x</p> <p>0_B Overlay block x is disabled when OVCCON.OVSTRT is set.</p> <p>1_B Overlay block x is enabled when OVCCON.OVSTRT is set.</p> <p>One enable bit is provided for each of the 32 overlay blocks (indicated by index x).</p>

Note: See [Chapter 12.4.1](#) for more information on using OSEL register.

RABRx (x=0-31)
Redirected Address Base Register x

$$(10_H + x \cdot C_H)$$

Reset Value: 0000 0000_H

Field	Bits	Type	Description
OVEN	31	rwh	Overlay Enabled This bit controls whether the overlay function of overlay block x is enabled. 0 _B Overlay function of block x is disabled. 1 _B Overlay function of block x is enabled. This bit can also be changed when OVCCON.OVSTP or OVCCON.OVSTRT is set. See OVCCON register description.
OMEM	[26:24]	rw	Overlay Memory Select Selects overlay memory used for redirection. 0 _H Redirection to Core 0 DSPR/PSPR memory 1 _H Redirection to Core 1 DSPR/PSPR memory 2..5 _H Reserved, do not use 6 _H Redirection to LMU 7 _H Redirection to EMEM
OBASE	[21:5]	rw	Overlay Block Base Address Bits 21..5 of the base address the overlay memory block in the overlay memory. If the corresponding bit in OMASK register is set to one, OBASE bit value is used in the redirection address. If the corresponding bit in OMASK register is set to zero, OBASE bit value is ignored.

Data Access Overlay (OVC)

Field	Bits	Type	Description
0	[30:27] [23:22] [4:0]	r	Fixed Value Read as 0; should be written with 0.

OTARx (x=0-31)

Overlay Target Address Register x

ONE	[27:17]	r	<p>Fixed “1” Values</p> <p>Corresponding address bits are participating in the address comparison. Corresponding final address bits are taken from RABRx.</p>

Data Access Overlay (OVC)

Field	Bits	Type	Description
0	[4:0] [31:28]	r	Fixed “0” Values Corresponding address bits are not used in the address comparison. Corresponding final address bits are taken from the original data address.

12.8 Global overlay control registers

Two registers globally control the overlay operation for all the cores:

- Overlay Enable Register OVCENABLE can be used to disable or enable data access overlay individually for each core;
- Overlay Control Register OVCCON can be used to perform the following action on selected set of cores:
 - concurrently enable / disable selected overlay blocks,
 - concurrently disable overlay blocks,
 - invalidate data cache.

8-Bit Standby Controller (TC2x_SCR)

13 8-Bit Standby Controller (TC2x_SCR)

TC2x_SCR is an 8-bit microcontroller that can continue to run during the standby mode. It is based on the XC800 Core that is compatible with the industry standard 8051 processor. There is an embedded 8 KB XRAM for program code and data.

Key features include a 16-bit general purpose timer with a capture/compare unit (T2CCU) for digital signal generation like pulse generation, pulse width modulation and pulse width measuring. It also includes a Real Time Clock (RTC) to support periodic wake-up in standby mode and an On-Chip Debug Support (OCDS) unit for software development and debugging of XC800-based systems. Local Interconnect Network (LIN) applications are also supported through extended UART features and the provision of LIN low level drivers for TC26x B-Step. For low power applications, various power saving techniques are available for selection by the user. Control of the numerous on-chip peripheral functionalities is achieved by extending the Special Function Register (SFR) address range with an intelligent paging mechanism optimized for interrupt handling.

Figure 13-1 TC2x_SCR Block Diagram

8-Bit Standby Controller (TC2x_SCR)
13.1 Features

The following list summarizes the main features of the TC2x_SCR.

- High performance XC800 Core
 - compatible to standard 8051 Core
 - two clocks per machine cycle architecture (for memory access without wait state)
 - two data pointers
 - maximum 20 MHz of core frequency
- On-chip Memory
 - 2-KByte Boot ROM for startup firmware
 - 256-byte RAM; plus 64-byte Monitor RAM
 - 8-Kbyte XRAM for program code and data; accessible by CPUx via SPI interface
- Power saving modes
 - idle mode
 - clock gating control to each peripheral
- Watchdog Timer (WDT) with programmable window feature for refresh operation and warning prior to overflow
- Two general purpose I/O ports
 - able to control the shared pins in P00 and P02
- Three 16-bit timers - Timer 0, Timer 1, Timer 2 of T2CCU
- Capture/compare unit of T2CCU for digital signal generation
- Real-time clock with on-chip oscillator to support periodic wake-up in standby mode
- Full duplex serial interface (UAR)
- Synchronous serial channel (SSC)
- Interrupt supported from TC2x_SCR to TriCore and vice versa.
- On-chip Debug Support via single pin DAP interface (SPD)
 - 1.5-KByte monitor ROM (part of the Boot ROM)
 - 64-byte monitor RAM

Feature Discontinued

13.2 XC800 Core

This chapter describes the XC800 Core.

13.2.1 SFRs of the CPU

The XC800 Core registers occupy direct Internal Data Memory space locations in the range 80_H to FF_H.

13.2.1.1 Stack Pointer (SP, 81_H)

The SP register contains the Stack Pointer. The Stack Pointer is used to load the program counter into internal data memory during LCALL and ACALL instructions and to retrieve the program counter from memory during RET and RETI instructions. Data may also be saved on or retrieved from the stack using PUSH and POP instructions. Instructions that use the stack automatically pre-increment or post-decrement the stack pointer so that the stack pointer always points to the last byte written to the stack, i.e. the top of the stack. On reset, the Stack Pointer is reset to 07_H. This causes the stack to begin at a location = 08_H above register bank zero. The SP can be read or written under software control. The programmer must ensure that the location and size of the stack in internal data memory do not overlap with other application data.

13.2.1.2 Data Pointer (DPTR, 80_H)

The Data Pointer (DPTR) is stored in registers DPL (Data Pointer Low byte) and DPH (Data Pointer High byte) to form 16-bit addresses for External Data Memory accesses (MOVX A,@DPTR and MOVX @DPTR,A), for program byte moves (MOVC A,@A+DPTR) and for indirect program jumps (JMP @A+DPTR).

Two true 16-bit operations are allowed on the Data Pointer: load immediate (MOV DPTR,#data) and increment (INC DPTR).

13.2.1.3 Accumulator (ACC, E0_H)

This register provides one of the operands for most ALU operations. ACC is the symbol for the accumulator register. The mnemonics for accumulator-specific instructions, however, refer to the accumulator simply as "A".

13.2.1.4 B Register (F0_H)

The B register is used during multiply and divide operations to provide the second operand. For other instructions, it can be treated as another scratch pad register.

13.2.1.5 Program Status Word (PSW, D0_H)

The PSW contains several status bits that reflect the current state of the core.

OV	2	rwh	Overflow Flag Used by arithmetic instructions.
RS	[4:3]	rw	Register Bank Select These bits are used to select one of the four register banks. 00 _B Bank 0 selected, data address 00 _H - 07 _H 01 _B Bank 1 selected, data address 08 _H - 0F _H 10 _B Bank 2 selected, data address 10 _H - 17 _H 11 _B Bank 3 selected, data address 18 _H - 1F _H
F0	5	rw	General Purpose Flag
AC	6	rwh	Auxiliary Carry Flag Used by instructions which execute BCD operations.
CY	7	rw	Carry Flag Used by arithmetic instructions.

Feature Discontinued

13.2.1.6 Extended Operation Register (EO, A2_H)

The instruction set includes an additional instruction `MOVC @(DPTR++),A`, which writes to program memory implemented as RAM. This instruction may be used both to download code into the program memory when the CPU is initialized and subsequently, to provide software updates. The instruction copies the contents of the accumulator to the code memory at the location pointed to by the current data pointer, then increments the data pointer.

The instruction uses the opcode A5_H, which is the same as the software break instruction TRAP (see [Table 13-1](#)). Bit TRAP_EN in the Extended Operation (EO) register is used to select the instruction executed by the opcode A5_H. When bit TRAP_EN is 0 (default), the A5_H opcode executes the `MOVC` instruction. When bit TRAP_EN is 1, the A5_H opcode executes the software break instruction TRAP, which switches the CPU to debug mode for breakpoint processing.

Register EO is also used to select the current data pointer.

0	[7:5]	r	Reserved Returns 0 if read; should be written with 0.

13.2.1.7 Power Control Register (PCON, 87_H)

The PCON register provides control for entering idle mode, baud rate control for UART in mode 2, as well as two general purpose flags.

The XC800 Core has two power-saving modes: idle mode and power-down mode. The idle mode can be entered via the PCON register. In idle mode, the clock to the core is disabled while the timers, serial port and interrupt controller continue to run. In power-down mode 1, the clock to the entire core is stopped.

Note: :Power down mode is not available in TC2x_SCF

PCON

0, 0	1, [6:4]	r	Reserved Returns 0 if read; should be written with 0.

13.2.1.8 Interrupt Registers

One non-maskable and fourteen maskable interrupt nodes are available.

Refer to Interrupt chapter for details of the interrupt registers.

13.2.2 SFRs of The Core Peripherals

13.2.2.1 Timer Registers

Two 16-bit timers are provided - Timer 0 (T0) and Timer 1 (T1).
Refer to Timer 0 and Timer 1 chapter for details of the timer registers.

13.2.2.2 UART Registers

The UART uses three SFRs - PCON, SCON and SBUF.
Refer to [Section 13.2.1.7](#) and UART chapter for details of the UART registers.

Feature Discontinued

13.2.3 Instruction Timing

A CPU machine cycle comprises two input clock periods, referred to as Phase 1 (P1) and Phase 2 (P2), that correspond to two different CPU states. Every CPU state within an instruction is referenced by the machine cycle and state number (e.g., C2P1 means the first clock period within machine cycle 2). Memory access takes place during one or both phases of the machine cycle. SFR writes occur only at the end of P2. Instructions are 1, 2, or 3 bytes long and can take 1, 2 or 4 machine cycles to execute. Registers are generally updated and the next opcode pre-fetched at the end of P2 of the last machine cycle for the current instruction.

The XC800 Core supports access to slow memory by using wait cycle(s). Each wait cycle lasts one machine cycle, i.e. two clock periods. For example, in case of a memory requiring one/two wait state(s), the access time is increased by one machine cycle for every byte of opcode/operand fetched.

Figure 13-2 shows the fetch/execute timing relative to the internal states and phases. Execution of an instruction occurs at C1P1. For a 2-byte instruction, the second reading starts at C1P1.

Figure 13-2 (a) shows two timing diagrams for a 1-byte, 1-cycle ($1 \times$ machine cycle) instruction. The first diagram shows the instruction being executed within one machine cycle since the opcode (C1P2) is fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over two machine cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the flash memory.

Figure 13-2 (b) shows two timing diagrams for a 2-byte, 1-cycle ($1 \times$ machine cycle) instruction. The first diagram shows the instruction being executed within one machine cycle since the second byte (C1P1) and the opcode (C1P2) are fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three machine cycles (instruction time extended), with one wait cycle inserted for each access to the flash memory. In this case, two wait cycles are inserted in total.

Figure 13-2 (c) shows two timing diagrams of a 1-byte, 2-cycle ($2 \times$ machine cycle) instruction. The first diagram shows the instruction being executed over two machine cycles with the opcode (C2P2) fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three machine cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the slow memory requiring one/two wait state(s).

Note: For instructions that are executed over two or more machine cycles, execution cycle may or may not be extended in case of access to slow memory with one/two wait states. The execution cycle is, nonetheless, guaranteed consistent for each instruction when accessed from slow memory with defined wait state(s).

Reference: [Table 13-1](#).

Figure 13-2 CPU Instruction Timing

The time taken for each instruction includes:

- decoding/executing the fetched opcode
- fetching the operands (for instructions > 1 byte)
- fetching the first byte (opcode) of the next instruction (due to CPU pipeline)

Note: The XC800 Core fetches the opcode of the next instruction while executing the current instruction.

Table 13-1 lists all the instructions supported by the XC800 Core. Instructions are 1, 2 or 3 bytes long as indicated in the 'Bytes' column. Each instruction takes 1, 2 or 4 machine cycles to execute (with no wait cycle). The table gives two values for the number of machine cycles required by each instruction. The first value applies to fetching operand/s and opcode from fast memory (e.g. Boot ROM and XRAM) without wait state. The second value applies to fetching operand/s and opcode (and in some cases accessing data) from slow memory (e.g. Flash) with wait cycles inserted due to memory requiring one/two wait state(s). One machine cycle comprises two ϕ CLK clock cycles.

1) In case of fetch from slow memory requiring only 1 wait state, no wait cycle may be required per the instruction fetched (normally for opcodes that do not require fetch in the next cycle).

2) Depending on whether the operation is accessing memory with zero or one/two wait state.

3) For branch instructions, the instruction time may vary depending on jump destination.

Feature Discontinued

13.3 Memory Organization

The TC2x_SCR CPU operates in the following four address spaces:

- 2 Kbytes of Boot ROM program memory
- 256 bytes of internal RAM data memory
- 8 Kbytes of XRAM memory
 - ECC protected
 - XRAM can be read/written as program memory or external data memory
- a 128-byte Special Function Register area

Figure 13-3 illustrates the memory address spaces of the TC2x_SCR.

Figure 13-3 Memory Map of the TC2x_SCR

13.3.1 Program Memory

The code space is theoretically 64 KBytes. However, only access to defined program memory (as shown in memory map figure) is supported. For TC2x_SCR, defined code space is occupied by on-chip memories.

13.3.2 Data Memory

The data space consists of an internal and external data space. Access to internal and external data space are distinguished by different sets of instruction opcodes. In TC2x_SCR, on-chip XRAM is located in external data space and accessed by MOVX instructions. TC2x_SCR does not support access to external (off-chip) memory. Internal data space is occupied by Internal RAM (IRAM) and Special Function Registers (SFRs), distinguished by direct or indirect addressing.

13.3.2.1 Internal Data Memory

The internal data memory is divided into two physically separate and distinct blocks: the 256-byte RAM and the 128-byte Special Function Register (SFR) area. While the upper 128 bytes of RAM and the SFR area share the same address locations, they are accessed through different addressing modes. The lower 128 bytes of RAM can be accessed through either direct or register indirect addressing, while the upper 128 bytes of RAM can be accessed through register indirect addressing only. The SFRs are accessible through direct addressing.

The 16 bytes of RAM that occupy addresses from 20_H to 2F_H are bitaddressable. RAM occupying direct addresses from 30_H to 7F_H can be used as scratch pad registers or used for the stack.

Feature Discontinued

13.3.2.2 External Data Memory

The 8-Kbyte XRAM is mapped to both the external data memory area and the program memory area. In TC2x_SCR, the XRAM can be accessed by both the TC2x_SCR core and CPU0. The arbiter module determines which CPU has control of the XRAM at any one time. CPU0 accesses the XRAM using the SPI processor. A SPI interface is established between the main TC2x system and the SPI slave interface (inside the Arbiter module) of the TC2x_SCR for this purpose.

TC2x_SCR core accesses the XRAM using either the 'MOVX' or 'MOVC' instructions. The 'MOVX' instructions for XRAM access use either 8-bit or 16-bit indirect addresses, as shown in [Table 13-2](#).

Table 13-2 Instructions for External Data Memory Access

Type of Access	8-bit Addressing Mode	16-bit Addressing Mode
Read	MOVX A, @DPTR, A	MOVX A, @Ri
Write	MOVX @DPTR, A	MOVX @Ri, A

While the DPTR register is used for 16-bit addressing, either register R0 or R1 is used to form the 8-bit address. The upper byte of the XRAM address during execution of the 8-bit accesses is defined by the value stored in register XADDRH. Hence, the write instruction for setting the higher order of XRAM address in register XADDRH must precede the 'MOVX' instruction.

A write access to a undefined external data memory address has no effect while a read access returns the last external data on the bus.

XADDRH

On-Chip XRAM Address Higher Order (F_{2H})

Reset Value: 00_H

RMAP: 0, PAGE: X

Field	Bits	Type	Description
ADDRH	[7:0]	rw	Higher Order of On-chip XRAM Address The value for TC2x_SCR is 00 _H .

13.3.3 Special Function Registers

The Special Function Registers (SFRs) occupy direct internal data memory space in the range 80_H to FF_H . All registers, except the program counter, reside in the SFR area. The SFRs include pointers and registers that provide an interface between the CPU and the on-chip peripherals. As the 128-SFR range is less than the total number of registers required, address extension mechanisms are required to increase the number of addressable SFRs. The address extension mechanisms include:

- Mapping
- Paging

13.3.3.1 Address Extension by Mapping

Address extension is performed at the system level by mapping. The SFR area is extended into two portions: the standard (non-mapped) SFR area and the mapped SFR area. Each portion supports the same address range 80_H to FF_H , bringing the number of addressable SFRs to 256. The extended address range is not directly controlled by the CPU instruction itself, but is derived from bit RMAP in the system control register SYSCON0 at address $8F_H$. To access SFRs in the mapped area, bit RMAP in SFR SYSCON0 must be set. However, the SFRs in the standard area can be accessed by clearing bit RMAP. **Figure 13-4** shows how the SFR area can be selected.

As long as bit RMAP is set, the mapped SFR area can be accessed. This bit is not cleared automatically by hardware. Thus, before standard/mapped registers are accessed, bit RMAP must be cleared/set, respectively, by software.

Feature Discontinued

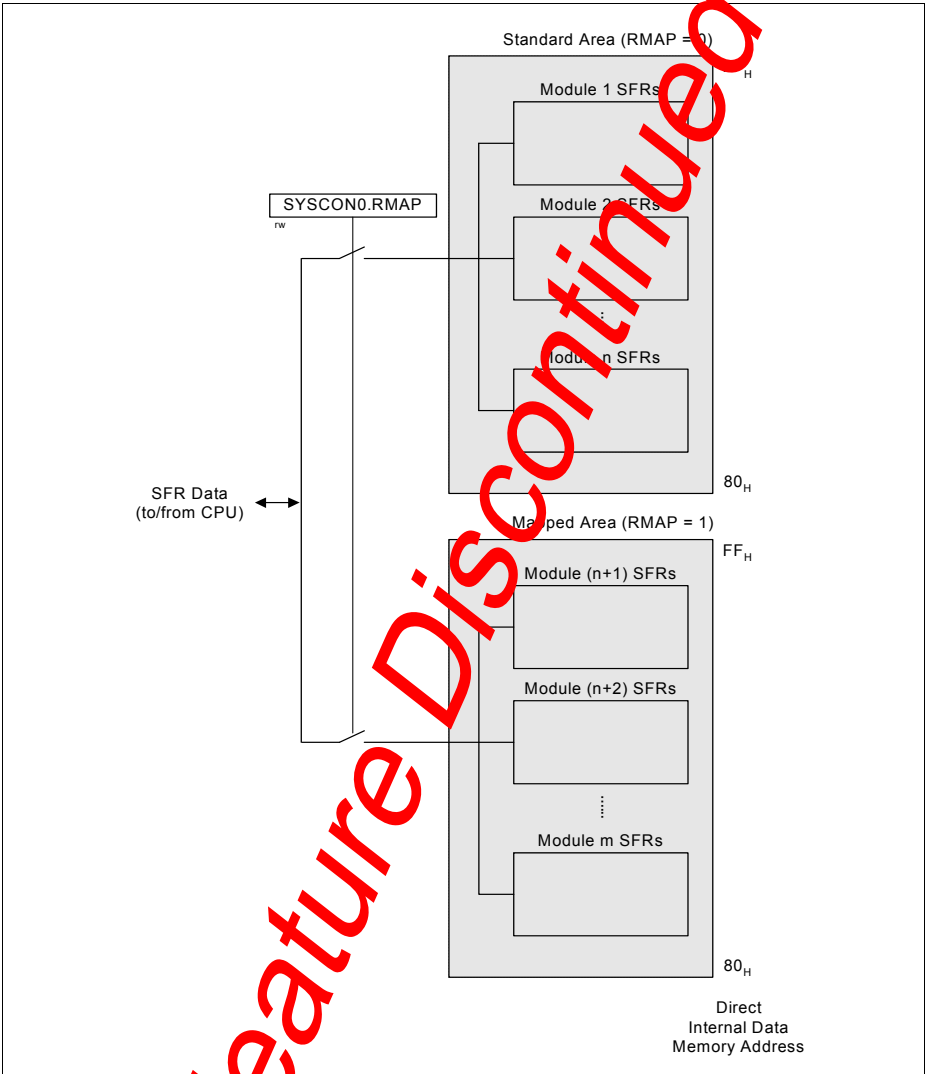

Figure 13-4 Address Extension by Mapping

13.3.3.2 System Control Register 0

The SYSCON0 register contains the bit to select the SFR mapping.

0	[7:3], 1	r	Reserved Returns 0 if read; should be written with 0.

Feature Discontinued

13.3.3.3 Address Extension by Paging

Address extension is further performed at the module level by paging. Certain peripherals have a built-in local address extension mechanism for increasing the number of addressable SFRs. The extended address range is not directly controlled by the CPU instruction itself, but is derived from bit field PAGE in the module page register MOD_PAGE. Hence, the bit field PAGE must be programmed before accessing the SFRs of the target module. Each module may contain a different number of pages and a different number of SFRs per page, depending on the specific requirement. Besides setting the correct RMAP bit value to select the SFR area, the user must also ensure that a valid PAGE is selected to target the desired SFRs.

Figure 13-5 shows how a page inside the extended address range can be selected.

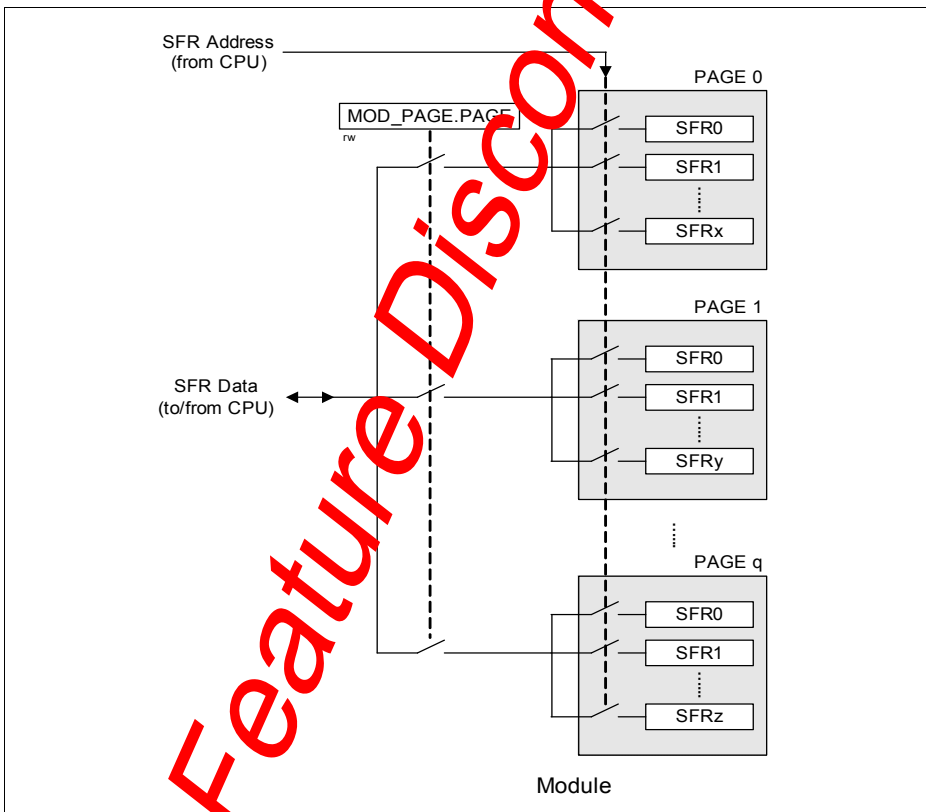

Figure 13-5 Address Extension by Paging

In order to access a register located in a page other than the current one, the current page must be exited. This is done by reprogramming the bit field PAGE in the page register. Only then can the desired access be performed.

If an interrupt routine is initiated between the page register access and the module register access, and the interrupt needs to access a register located in another page, the current page setting can be saved, the new one programmed, and the old page setting restored. This is possible with the storage fields MOD_STx (x = 0 - 3) for the save and restore action of the current page setting. By indicating which storage bit field should be used in parallel with the new page value, a single write operation can:

- Save the contents of PAGE in MOD_STx before overwriting with the new value (this is done at the beginning of the interrupt routine to save the current page setting and program the new page number); or
- Overwrite the contents of PAGE with the contents of MOD_STx, ignoring the value written to the bit positions of PAGE (this is done at the end of the interrupt routine to restore the previous page setting before the interrupt occurred)

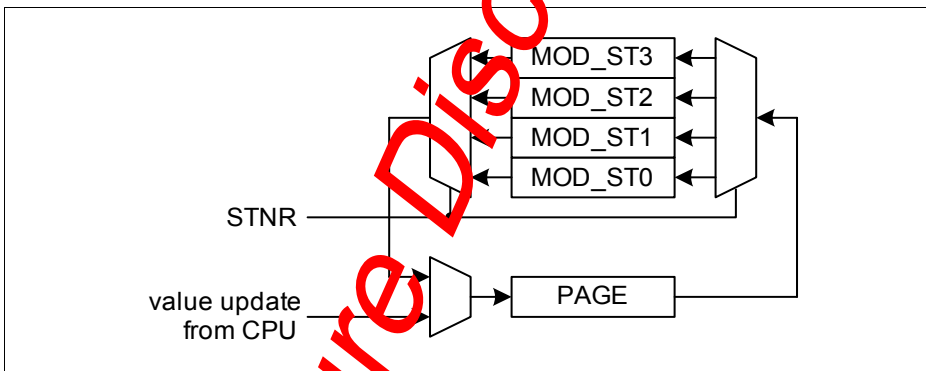

Figure 13-6 Storage Elements for Paging

With this mechanism, a certain number of interrupt routines (or other routines) can perform page changes without loading and storing the previously used page information. The use of only write operations makes the system simpler and faster. Consequently, this mechanism significantly improves the performance of short interrupt routines.

13.3.3.4 Page Register

The page register has the following definition:

MOD_PAGE

Page Register for module MOD

Reset Value: 00_H

Field	Bits	Type	Description
PAGE	[2:0]	rw	Page Bits When written, the value indicates the new page. When read, the value indicates the currently active page.
STNR	[5:4]	w	Storage Number This number indicates which storage bit field is the target of the operation defined by bit field OP. If OP = 10 _B , the contents of PAGE are saved in MOD_STx before being overwritten with the new value. If OP = 11 _B , the contents of PAGE are overwritten by the contents of MOD_STx. The value written to the bit positions of PAGE is ignored. 00 _B MOD_ST0 is selected. 01 _B MOD_ST1 is selected. 10 _B MOD_ST2 is selected. 11 _B MOD_ST3 is selected.

Feature Discontinued

Field	Bits	Type	Description
OP	[7:6]	w	Operation 0x _B Manual page mode. The value of STNR is ignored and PAGE is directly written. 10 _B New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the previous contents of PAGE are saved in the storage bit field STx indicated by STNR. 11 _B Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit field STx indicated by STNR.
0	3	r	Reserved Returns 0 if read, should be written with 0.

13.3.3.5 Bit-Addressing

SFRs that have addresses in the form of 1x...X000_B (e.g., 80_H, 88_H, 90_H, ..., F0_H, F8_H) are bit addressable.

Feature Discontinued

13.3.3.6 Bit Protection Scheme

The bit protection scheme prevents direct software writing of selected bits (i.e., protected bits) using the PASSWD register. When the bit field MODE is 11_B , writing 10011_B to the bit field PASS opens access to writing of all protected bits, and writing 10101_B to the bit field PASS closes access to writing of all protected bits. In both cases, the value of the bit field MODE is not changed even if PASSWD register is written with 98_H or $A8_H$. It can only be changed when bit field PASS is written with 11000_B ; for example, writing $C0_H$ to PASSWD register disables the bit protection scheme.

Note that access is opened for maximum 32 CCLKs if the "close access" password is not written. If "open access" password is written again before the end of 32 CCLK cycles, there will be a recount of 32 CCLK cycles.

Feature Discontinued

13.3.4 Memory Control Unit

The Memory Control Unit (MCU) is the interface between the CPU and the memories, providing three functions to the TC2x_SCR:

- Active memory map selection
- Allows one physical memory (i.e. XRAM) to be accessed as both program and data memory at the same time
- Memory protection

Feature Discontinued

13.3.4.1 Active Memory Map Select

After a reset, the CPU will always start by executing the Boot ROM code in active memory map 1. In active memory map 1, the Boot ROM occupies the program memory address space $0000_H - 01FF_H$ and $D600_H - D7FF_H$, with the remaining program memory address space disabled. The Boot ROM start-up procedure will first jump to $D60X_H$ before switching to active memory map 0 as shown in [Figure 13-7](#). As a result, the Boot ROM memory will be mapped to only $D000_H - D7FF_H$. Also, the remaining program memory blocks (XRAM) are enabled. After the active memory map switch, the remaining Boot ROM start-up procedure will be executed from $D600_H$. The memory organization of the TC26x B-Step shown in this document is after the active memory map switch, i.e. active memory map 0, where the different operating modes are executed.

Figure 13-7 Active Memory Map Select

13.3.4.2 Program and XRAM Data Bus Control

The MCU allows one physical memory or memories (non-overlapping) residing in the address range from $0000_H - 1FFF_H$, to be accessed as both program memory and external data memory at the same time.

The 'MOVC @(I,PTX++),A' instruction is used to download software into the program memory where this is implemented as RAM. This instruction can also be used subsequently to modify contents of the program memory. The 'MOVX' instructions are used to access the XRAM as external data memory.

13.3.4.3 Memory Protection Unit

The TC2x_SCR consists of the following memory blocks:

- Boot ROM
- XRAM

The target of the memory protection scheme is to prevent unauthorized read out of critical data from the Boot ROM.

The memory protection scheme is hardware-based and is used to protect the Boot ROM; MOVc read instructions executed out of the “unsafe” program memory address range (e.g. XRAM) that target the Boot ROM are blocked when protection is enabled.

13.3.4.4 Boot ROM Protection

The Boot ROM protection is enabled by default, and the following accesses are restricted:

- MOVc read instructions that are executed from the XRAM will be blocked if the Boot ROM addresses are targeted

Figure 13-8 shows the possible MOVc execution paths (fetch + execute) when the Boot ROM protection is enabled.

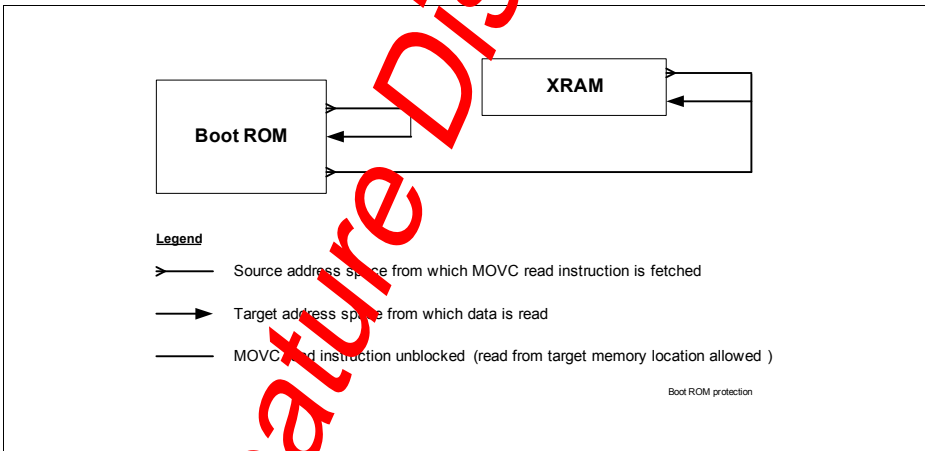

Figure 13-8 Boot ROM Protection Mode

If the Boot ROM protection is enabled:

- MOVc instructions that are executed from the the XRAM can target itself
- MOVc instructions that are executed from the Boot ROM can target itself or the XRAM

13.3.5 Arbiter

The arbiter serves the following purposes:

- Provides the SPI slave interface for communication with the main TC2x system
- Arbitrates the XRAM access between TC2x_SCR core and CPU0 in the main TC2x system (access via SPI slave interface)

13.3.5.1 SPI Slave Interface

The SPI slave interface supports full-duplex serial synchronous communication with the main TC2x system. It activates the Arbiter state machine upon reception of a complete 32-bit SPI data word from the SPI master in the main TC2x system.

Transfer Characteristics:

- Full-duplex operation
- 32-bit data width
- MSB first
- Idle low master shift clock
- Transmit data with clock rising edge; latches in receive data with falling edge
- Maximum baud rate of 50 Mbaud
- Minimum inter-word/frame idle time of 8 PCLK cycles for consecutive writes, 16 PCLK cycles for consecutive reads
- Minimum chip select hold time from last SCLK latching edge of 1 PCLK cycle

The SPI master at the main TC2x system first asserts the chip select signal (active low), which causes the transmit buffer (TBUF) of the SPI slave to reset to default 5555'5555_H. The 32-bit shift register in SPI slave is then loaded with the transmit buffer contents.

When the master shift clock is detected, the SPI slave shifts out data onto the master data-in line with the rising edge of the clock and shifts in data from the master data-out line with the falling edge.

Once the complete 32-bit data is received, the data will be loaded into the receive buffer (RBUF). The contents of TBUF is prepared by the Arbiter state machine.

The shift register is reset when the chip select signal is deasserted by the master SPI.

SPI Software Protocol

The communication between the main TC2x system and XRAM is based on a pre-fixed SPI software protocol. See [Table 13-3](#). The protocol frame can consist of a variable number of data words. Each data word must be of 32-bit width and contains an upper 16-bit command and a lower 16-bit data. Therefore, XRAM access is always a two-byte access, aligned to even address. Transmission is MSB first and master transmit on the rising edge, receives on the falling edge. A XRAM read or write access from main TC2x

system is determined by the MSB of the command word. 1 indicates a write access while a 0 indicates a read access.

Table 13-3 SPI Software Protocol Definition

Bits	Description
31	Read/Write indication: - 1 indicates a write access to XRAM. - 0 indicates a read access from XRAM.
[30:29]	Control bits: - Should be written with 0. - When the 32-bit SPI data word contains the value FFFF'FFFF _H , it indicates that the current word is the last of the frame, i.e. an End-of-Frame (EOF) condition. This word will then be ignored by the arbiter state machine.
[28:16]	13-bit XRAM address. <i>Note: For smaller XRAM where the address width is less than 13 bits, the unused uppermost bits should be written with 0.</i>
[15:0]	16-bit data.

For a XRAM read access, the SPI master in the main TC2x system first transmits the 32-bit data word containing the read command and data to the SPI slave. For a read command, the data from SPI master is not used. Since the SPI communication protocol is full-duplex, the SPI slave will at the same time return a 32-bit word containing an arbitrary value of 5555'5555_H. The SPI slave will only respond with the targeted read data in the next transmission period, which is triggered by the SPI master sending a second word. To read the last data from XRAM, the SPI master can send an EOF containing the value FFFF'FFFF_H.

Similarly for a XRAM write access, the SPI master in the main TC2x system first transmits the 32-bit word containing the write command and the data to be written to XRAM, to the SPI slave. The SPI slave always return a 32-bit word containing the arbitrary value of 5555'5555_H for write commands. The actual write to XRAM will be performed by the arbiter state machine some PCLK cycles after the SPI slave has received the corresponding write command.

Examples of data transfers using the SPI software protocol is shown in [Figure 13-9](#).

Figure 13-9 Data Transfers Examples using SPI Software Protocol

13.3.5.2 Arbiter State Machine

The Arbiter State Machine is clocked by PCLK. It is activated upon the reception of the complete 32-bit SPI data word from the main TC2x system.

If the word is an EOF, the state machine will do nothing and exit back to the default Idle state, else it will assert the mwait to CPU for 9 PCLK cycles. On the last of these 9 cycles, the state machine will generate the required signals and access the XRAM. The length of the mwait signal generation ensures that the current TC2x_SCR core instruction execution can be stalled temporarily to allow the XRAM access by the Arbiter State Machine.

Note: For each XRAM access, up to 5 wait states (i.e. 10 PCLK cycles) may be inserted into the execution cycle of a TC2x_SCR core instruction.

The access to XRAM is a single cycle access. However, to ensure that the XC800 core is in a safe state during the SPI XRAM access, a minimum of 8 PCLK cycles are required in between SPI words/frames sent from the master if the preceding word contains a write command. If the preceding word contains a read command, a minimum of 16 PCLK cycles are required. If the SPI idle time conditions are not met, the read/written data from/to the XRAM cannot be guaranteed.

In addition, a minimum of 1 PCLK is required for the chip select hold time from the last SCLK latching edge.

Figure 13-10 shows these inter-word/frame and chip select hold times.

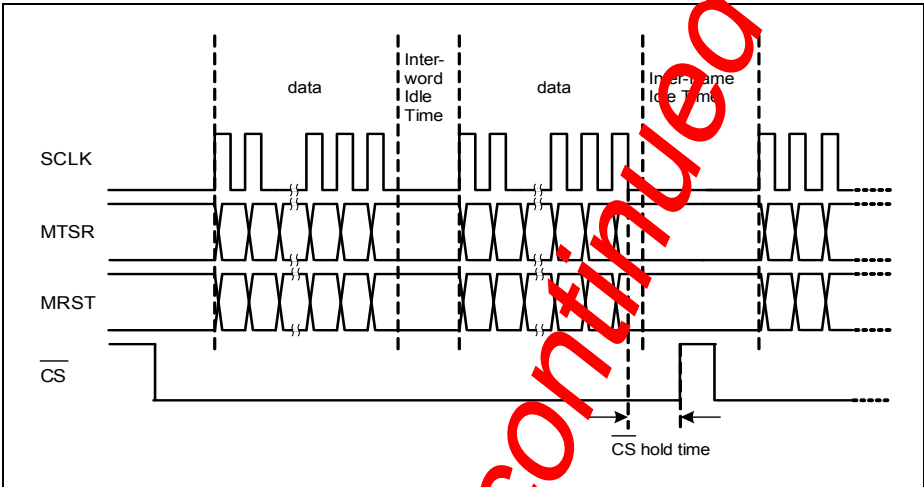

Figure 13-10 Inter-word/frame and chip select hold times

A signal, `spi_slave_busy`, is provided at the Arbitrator interface to indicate that the arbiter is busy with a current SPI XRAM data access. The signal is asserted four PCLK cycles after the detection of the last SPI clock of the current word and it will be deasserted after the SPI XRAM access is completed. The SPI master should transmit the next word/frame only after the deassertion of the `spi_slave_busy` signal.

Feature Discontinued

Feature Discontinued

13.4 TC2x_SCR Firmware

This chapter describes the BootROM firmware for TC26x B-Step. It contains the following sections.

- BootROM Overview
- Startup Procedure
- On-Chip Debug Support (OCDS)

13.4.1 Overview

TC26x B-Step BootROM firmware provides the following features:

- Startup procedure for stable operation of TC26x B-Step chip
- Basic debugging capability via OCDS mode

Startup procedure initializes the TC26x B-Step to a known state to ensure stable operation. The startup procedure consists of all the settings and initialization to be done after SCR reset, before branching to various boot modes. On-Chip Debug Support provides basic debugging capability to the user.

Please refer to the relevant sections for more details.

13.4.1.1 BootROM location

The size of the BootROM is 2KByte and it operates in two different memory maps:

- In Active Memory Map 1 (AMSEL=1), BootROM is mapped to two address spaces, 0000_H - 07FF_H and D000_H - D7FF_H.
- In Active Memory Map 0 (AMSEL=0), BootROM is mapped to address space D000_H - D7FF_H.

Upon reset, the active memory map is 1 and the BootROM code is executed from address 0000_H. At the beginning of the BootROM code, a jump instruction to address D60_{xH} is executed, followed by an instruction to clear the AMSEL bit. This is to switch the active memory map to 0. All other BootROM instructions will be executed in active memory map 0.

13.4.1.2 Boot Mode Option

Entry to various boot modes such as User Mode 0, User Mode 1 and debug mode (OCDS Mode) are done in the startup code of the BootROM. The startup code will depend on the SCR configuration value in the SFR SCR_HWCFG, to enter each mode.

Table 13-4 shows the Boot Modes configuration value.

Table 13-4 TC26x B-Step **Boot Mode**

Boot Mode¹⁾	SCR CFG Value
User Mode 0, XRAM is not programmed	0 _H
User Mode 1, XRAM is programmed and will be executed	01 _H
OCDS Mode, SCR DAP interface	02 _H - 03 _H
OCDS Mode, SCR SPD interface	04 _H - 07 _H
OCDS Mode, SOC DAP interface	0A _H - 0B _H
OCDS Mode, SOC SPD interface	0C _H - 0F _H

1) SPD : Single Pin DAP; DPD: Dual Pin DAP

Feature Discontinued

13.4.2 OCDS Mode

This section describes the On Chip Debug System (OCDS) module and the interaction with the Monitor ROM and external debugger. The OCDS provides basic functionality to support development without the need to purchase expensive on-chip emulator (ICE) device which is the traditional way of debugging the embedded systems. The interface that can be used to support this function is DAP.

The TRAP_EN bit in Extended Operation register (EOA) needs to be enabled for OCDS functionality to work properly.

13.4.2.1 Features

List of features supported:

- Set breakpoints on instruction address and within a specified range
- Set breakpoints on internal RAM address for read and write
- Support unlimited software breakpoint in RAM code region
- Processing External breaks
- Stepping through the program code

In summary, up to four hardware breakpoints can be set for the current implementation. It can be used for detection of specific Instruction Pointer (IP), a range of IP and specific range of read/write of internal RAM, unlimited software breakpoint (only possible in writable region) and external break. When any of the above is encountered, that corresponds to a debug event which will then trigger the execution of Monitor ROM.

13.4.2.2 OCDS Basic Understanding

For a complete understanding of the OCDS concept, it is found in the User's Manual, OCDS chapter.

Introduction of the XC800 Core Debug mode

The Program Counter will freeze when the core enters the debug mode and it will enter this mode when the TRAP instruction is executed and with the TRAP_EN = '1'. It will also enter upon DebugReq activation for IRAM and External Breaks. For hardware breakpoint, the TRAP instruction is actually supplied by the Monitor Mode Control (MMC) hardware block.

Minimum hardware and overhead are added

OCDS hardware consists of the MMC, additional internal RAM and JTAG and additional ROM memory.

The OCDS is built on top of debug mode together with minimum hardware overhead, Monitor ROM and additional 64 bytes of RAM to perform the breakpoint debugging functionality.

Monitor is resident in the BootROM region and it will make use of the additional 64 bytes of internal RAM termed Monitor RAM and together with the hardware to realize the OCDS functionality. The Monitor RAM which occupied the same memory location as the standard 8051 internal RAM, and it is selected through the MFAMS bit (MMCR).

Implementation of OCDS with the debug mode of XC800 Core

Some combination logic together with the support of the Monitor ROM to coordinate the processes. In this document, the tasks of the Monitor ROM will be explained in details in the next section.

13.4.2.3 OCDS Monitor Firmware

This section will describe the Monitor firmware interaction between the Monitor ROM with the OCDS hardware and the debugger software in host PC.

OCDS mode entry

OCDS mode is entered if:

- c) OCDS Boot option for SCR DAP interface, SFR SCR_HWCFG = 02_H - 03_H;
 - d) OCDS Boot option for SCR SPD interface, SFR SCR_HWCFG = 04_H - 07_H;
 - e) OCDS Boot option for SOC DAP interface, SFR SCR_HWCFG = 0A_H - 0B_H;
 - OCDS Boot option for SOC SPD interface, SFR SCR_HWCFG = 0C_H - 0F_H;
- IP hardware breakpoint at XRAM address 0x0000 is set before it exits OCDS mode.

Feature Discontinued

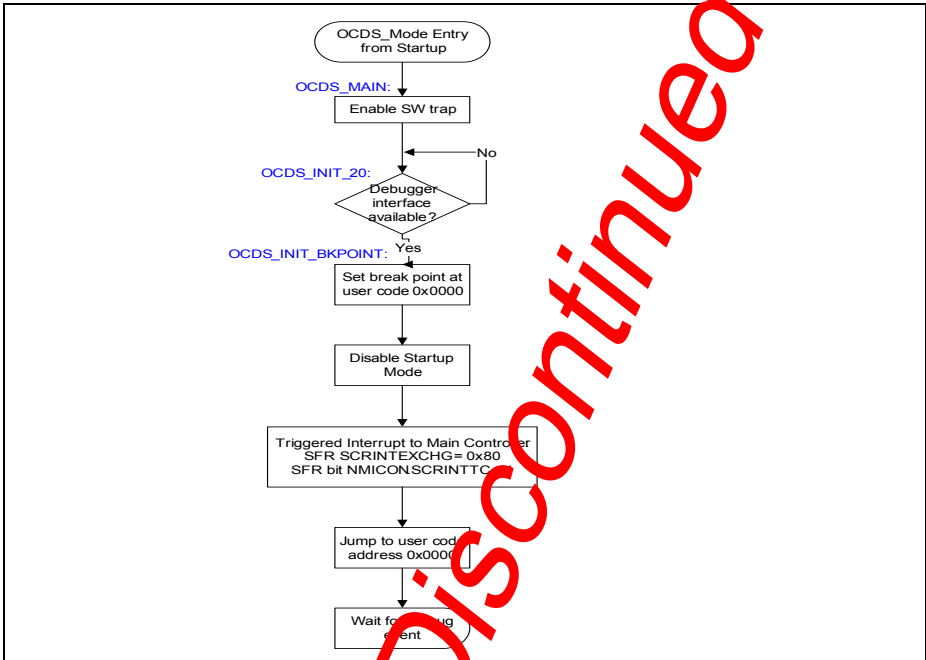

Figure 13-11 OCDS Initialisation

Communication between the debugger and Monitor

The debugger will be the master and it will control all the read and write transactions. A virtual memory map is defined as follows.

Virtual Address translation

To facilitate the debugger to get an insight of the memory map and all the registers in the system, a set of virtual addresses is defined to relate them to the physical address of the program memory, external memory and all of the other memories and registers within the system. In this way, the debugger will read or write to the virtual address and the actual reading and writing to the correct memory segment and register are controlled by the Monitor program.

Feature Discontinued

Table 13-5 Translation of virtual memory to physical memory

Description	Physical address	Valid Virtual Address for TC2x_SCR	Virtual Address (3.5 bytes)
Program memory	0000 _H - 1FFF _H	00000 _H - 01FFF _H (8K)	00000 _H - 0FFFF _H (64K)
External memory	0000 _H - 1FFF _H	10000 _H - 11FFF _H (8K)	10000 _H - 1FFFF _H (64K)
Internal memory	00 _H - FF _H	20000 _H - 200FF _H (256)	20000 _H - 2FFFF _H (64K)
Indirectly accessible OCDS register	HWBPxH/L 08 _H - 0F _H	22208 _H - 2220F _H (8)	22200 _H - 222FF _H (256)
Monitor Virtual Registers	22300 _H - 2233F _H	22300 _H - 2233F _H (up to 64 bytes but not all contain the valid data)	22300 _H - 223FF _H
Reserved			30000 _H - 3FFFF _H
SFR registers and page number. (Including standard, mapped and paged)	80 _H -FF _H As Bit7 is always set, thus only 7 bit is required to identify the desired SFR.	40000 _H - 7FFFF _H (always BIT18=1) BIT 17:15 Page number BIT 14:8 SFR page address BIT7: SFR standard (1), mapped (0) BIT6:0 SFR address	40000 _H - 7FFFF _H

For the XRAM program memory, the virtual translated address is the same as their address. For external memory and internal IRAM, the upper nibble of the virtual address is 1_H and 2_H respectively.

There are 8 indirect OCDS registers. They are the OCDS hardware breakpoint (HWBPxH/L). These registers are only accessible by setting HWBPSR first to select the relevant registers. To simplify the debugger task of setting breakpoint, the registers are mapped to the virtual address. The monitor program will base on the virtual address and write to these registers appropriately.

Feature Discontinued

Table 13-6 Indirectly accessible OCDS register

Register name	Virtual translated Address	Description
HWBP0L	22208 _H	Set the address for breakpoint 0
HWBP0H	22209 _H	
HWBP1L	2220A _H	Set the address for breakpoint 1
HWBP1H	2220B _H	
HWBP2L	2220C _H	Set the address for breakpoint 2
HWBP2H	2220D _H	
HWBP3L	2220E _H	Set the address for breakpoint 3
HWBP3H	2220F _H	

In order to optimise the amount of virtual address allocated to the SFR. A scheme has been devised to cope with all the SFR type i.e. standard, mapped, paged type. In order to access all the SFR, the following fields are required and defined below.

Table 13-7 Distribution of the bits definition

Field	Bit definition	Description
RMAP	BIT7	To indicate which region of SFR to access. '0' - standard and '1' - mapped
SFR_ADDRESS	BIT 6:0	SFR to be accessed. The value of the SFR is always 8 _H or above. Thus it is represented by 7bit omitting the most significant bit.
SFR_PAGE_ADDRESS	BIT14:8	For accessing paged SFR, there is a need to write the page number to the SFR PAGE address first. Once again, it is represented by 7 bit. For non-paged SFR, this field must be written with 00 _H .
PAGE_NUMBER	BIT17:15	For non-paged SFR, the page_number must be set to 0F _H . For paged SFR, this field can be used to specify page number from 0 to 07 _H .

The standard SFR refer to those SFR that required SYSCON0.RMAP=0 before they can be accessed and the mapped SFR refer to those SFR that can be accessed only when SYSCON0.RMAP=1. As for paged SFR, in addition to the standard or mapped properties, they also required the page number to be set, and it is written to the corresponding SFR page address. If the SFR does not paging, then SFR page address field must set to zero.

Bit17-Bit15 will represent the page number from 0x00-0x07, if the value equal to 0x07 and it is a non-paged SFR, then it is not necessary to set the SFR page address and BIT14-8 can be clear to zero. Otherwise, Bit14-8 will indicate the address (7bit only) for that SFR page. Bit7 = 0 will represent standard and 1 if mapped SFR. Bit6-0 will indicate the address (7bit only) for that desired SFR to be read out. The SFR is represented by 7 bit as its address is always above 80H and the MSB is not required and automatically handled by the firmware.

The list of registers that are used in the monitor program need to be preserved, thus to access these few SFR, the corresponding virtual address should be supplied instead of following the format given in [Table 13-7](#)

Table 13-8 Monitor virtual register

Monitor virtual register name	Virtual translated Address	Description
mons_SCU_PAGE	2231A _H	Current SCU_PAGE register
mons_IEN0	2231B _H	Current Interrupt Enabled register
mons_DPL	2231C _H	Current data pointer low byte
mons_DPH	2231D _H	Current data pointer high byte
mons_B	2231E _H	Current B register
mons_A	2231F _H	Current A register
mons_SYSCON0	22330 _H	Current SYSCON0 register
mons_PSW	22332 _H	Program Status Word
mons_RETH	22333 _H	Return address high byte
mons_RETL	22334 _H	Return address low byte
mons_SP	22335 _H	Current Stack Pointer

Protocol definition between the debugger and Monitor ROM

There are 5 Monitor processed commands that are defined and describe as followed.

Table 13-9 Monitor processed commands

Command	Value	Description
READ_BYTE	1X _H	Read a byte.
READ_BLOCK	2X _H	Read a block of data and return byte by byte to the host.
WRITE_BYTE	3X _H	Write a byte to memory location.

Table 13-9 Monitor processed commands

Command	Value	Description
WRITE_BLOCK	4X _H	Write a block of data starting from memory location.
WRITE_PROTECTED_SFR	5X _H	Write a byte to the password protected bit SFR

Note: In the command field, only the upper nibble will indicate the command type, the lower nibble is used to store the 4 MSB bit of the virtual address and is not part of the command.

Some assumptions made:

- Instead of 12 bit, it is round up to 16 bit for easy handling. Thus some are dummy bits that are not used but need to be there for data padding purpose to ensure the proper operation.
- Debugger send commands and data to Monitor, the Monitor ROM will acknowledge all bytes that are the command, parameters and data field that have been received. This is to ensure all the bytes from the debugger is received correctly.
- All commands (read or write) will be issued with a unique command_ID, since there are only five commands defined,.
- A new command 50_H is introduced to support the password protected bit SFR write operation.

Feature Discontinued

13.4.2.4 Monitor processed commands

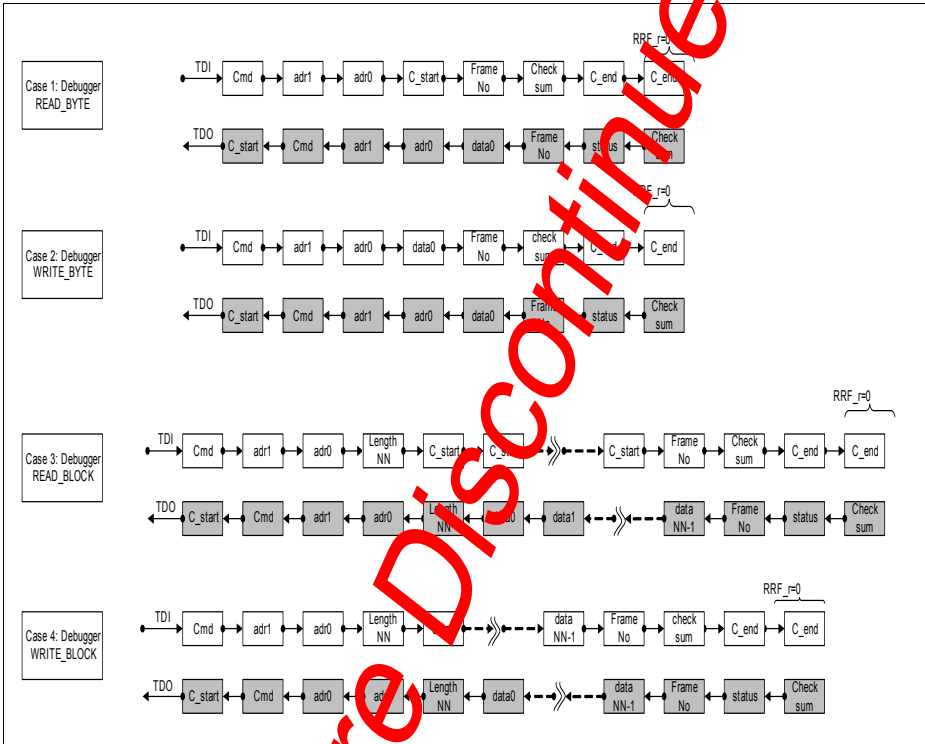

Figure 13-12 Monitor processed commands

The following is a list of the Monitor processed commands that are supported by the Monitor firmware.

Monitor processed command: READ_BYTE (1X_r)

The debugger will send 1 byte of command and 2 bytes of address. Next C_START, Frame No and Check sum are sent. Lastly followed by the C_end and C_end with RRF_r = 0. The corresponding data and the status byte are then checked by the debugger.

Monitor processed command: READ_BLOCK (2X_H)

The debugger will send 1 byte of command, 2 bytes of address and 1 byte of length. Next the C_START is send one after other until all the data are being transferred. Next the Frame No and Checksum are send followed by the C_end and C_end with RRF_r=0.

Monitor processed command: WRITE_BYTE (3X_H)

This command flow is very similar to the READ_BYTE command except that the C_START is not send out by debugger. Instead the data byte is written there.

Monitor processed command: WRITE_BLOCK (4X_H)

This command flow is similar to the READ_BLOCK except the C_START is not send out by the debugger. Instead all the data fields are send. Next the Frame No and checksum are also being sent out followed by the C_end and C_end with RRF_r=0.

Refer to the flow chart [Figure 13-12](#) that describe the commands flow.

Monitor processed command: WRITE_PROTECTED_SFR (5X_H)

This command is added to support writing to the password protected SFR and its functionality is similar to the WRITE_BYTE.

Note: For all the 5 commands being described, the upper 4 bit MSB of the address field is embedded inside the lower nibble of command byte. The Frame No is a 1 byte field wide, it just a sequence number that increment itself and warp around when it is overflows.

Description of the various fields use in the protocol

Various fields are define to establish the communication link between the debugger and Monitor ROM. They are outlined in [Table 13-10](#).

Table 13-10 Different fields that are defined

Description (byte)	Value	Description
C_START (1)	01 _H	To indicate start or ongoing event
C_END (1)	02 _H	To indicate ending event
FRAMENO (1)		The debugger will send a 00 _H first and sequentially increase it by 1 and wraps around if the value exceeds the single byte length. This value must reset and start from 00 _H when Monitor Mode is (re-)entered or when COMRST has been activated.
CHECKSUM (1)		The checksum for the debugger and Monitor side are calculated by XORING all the fields except its checksum.

Table 13-10 Different fields that are defined (cont'd)

Description (byte)	Value	Description
STATUS(1)		The following bit will set to indicate an error condition. BIT0 - Debugger CHECKSUM and the calculated value does not match. Read/Write operation to the memory is executed. BIT1 - Frame number out of sequence. Read/Write operation to the memory is executed. BIT2 - Control bytes, C_START not received correctly. Read/Write operation to the memory is executed. BIT3 - Invalid Range of the memory location. Read/Write operation to the memory is not executed.
ADR0 (1)		This represent the least significant 8 bit of the virtual address.
ADR1 (1)		This represent the next higher 8 bit of the virtual address.
CMD (1)		The upper nibble contains the command as specified in Figure 13-12 . The other nibble represent the most significant 4 bit of the virtual address. Thus together, they made up the 20 bits address.
Length (1)		This field is used in the read block command and write block command. It indicates the number of data bytes to be read or written into the memory. Valid range of this field is from 1 to 255.

JTAG communication and controlling the OCDS hardware control bits

[Table 13-11](#) list the monitor hardware related commands.

Table 13-11 Monitor hardware related command

Mode/Command	Data	Jena	RF	MMODE	MBCON	COMRST	Description
		_r	_r	_r	_r	_r	
HSTATE	XX _H	0	0	0	0	0	Get the status of the OCDS status bits.
HCONFIG	A5 _H	1	0	0	0	0	Debug interface enabled by MMCR2.JENA = 1
HDEBUG	DATA	0	1	0	0	0	Data read and write
HMONITOR	A5 _H	0	0	1	0	0	Enter the Monitor mode

Table 13-11 Monitor hardware related command (cont'd)

Mode/Command	Data	Jena_r	RRF_r	MMODE_r	MBCON_r	COMRST_r	Description
HMBCOUT	XX _H	1	0	0	X	0	Jena_r must be set together with the MBCON_r state to control the MBC output. To activate it, MBCON_r=1 and to disable it MBCON_r=0.
HCOMRST	A5 _H	0	0	0	0		Reset the transaction and start with a new command.

The prefix with H indicate that it is a OCDS hardware related commands.

The HDEBUG command/mode is use for any data read and write transaction and it is actually being used to support the five Monitor processed commands.

Activate the Monitor ROM

When a debug event occurred, the debug mode will be entered and instruction will be fetched from MM_START that represent the upper 8 bit of the program code address bus. MMCR.MMODE is set by the hardware to signal that the Monitor mode is entered.

The following need to be taken care (Extract from OCDS specification)

- Save user Interrupt Enable (IE₀) and disable the global interrupt.
- Save current (user) Stack Pointer (SP) into Monitor RAM.
- Initiate the stack to dedicate area in Monitor RAM
- Save the SYSCON0 into the Monitor RAM, to preserve the user value of RMAP control bit.
- Clear the RMAP and IMODE bit in SYSCON0.
- Set the SCU_PAGE to page 0 and save the current NMICON into the Monitor RAM and disable all sources of NMI by writing zeros to NMICON.
- Save the current (user) I-SW, A, B, DPH and DPL to Monitor IRAM.
- Set RMAP bit in the SYSCON0, to access MMICR.
- Clear the MMCR.DNTR
- Perform a LOCAL to MON_START_ST (or MON_NORMAL_ST), so the break address is saved and debug mode is exited and continue to run in Monitor ROM mode.
- NOP instruction is required here for proper functioning.

- Communication between the debugger and Monitor through the selected interface.

Figure 13-13 shows the flow diagram when the debug event occurred. Debugging a BootROM startup code will cause the device to enter endless loop. A reset of the device is needed to exit the endless loop.

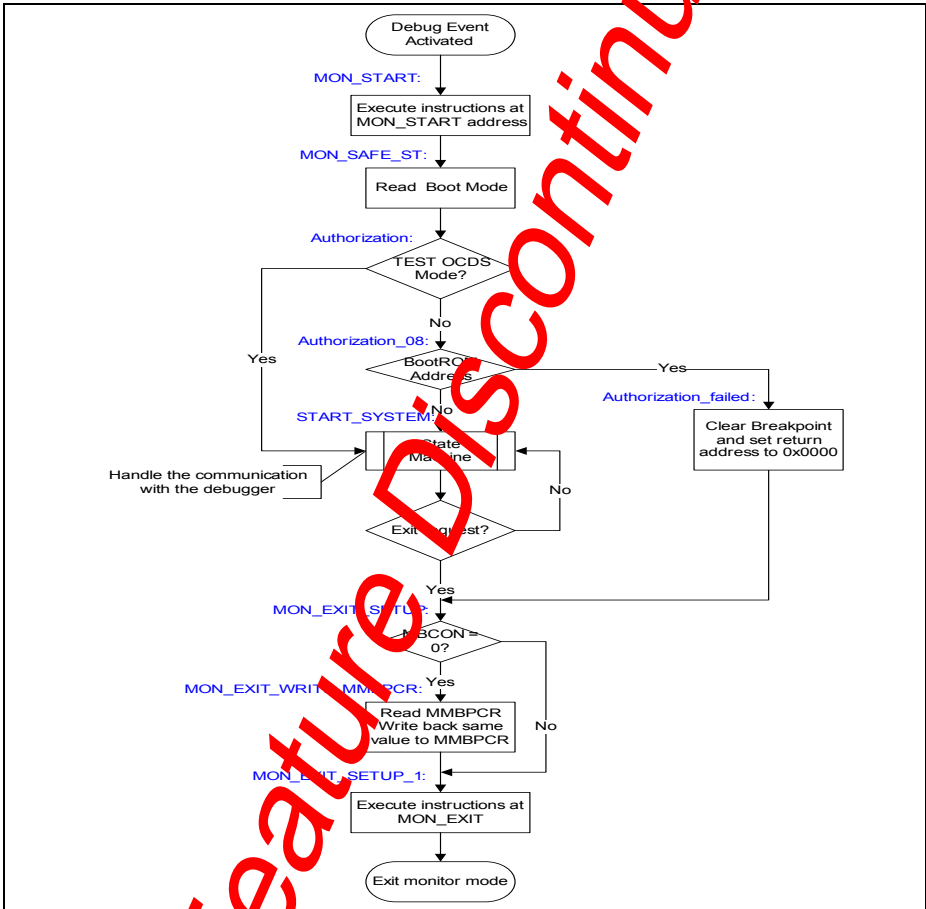

Figure 13-13 Debug mode Flow Diagram

Figure 13-14 shows the state-machine flow diagram in the monitor program. The detailed descriptions and flow diagrams of each state can be found in Chapter .

Figure 13-14 State Machine - To handle monitor processed commands from host

Exit the Monitor ROM to return to user mode

To exit monitor mode and return to the user code, the following steps are needed to restore the user status and return to the proper user address.

The steps needed to return to user mode.

- After writing to the MMCR.EXIT=1 followed by NOP, this will trigger the debug mode to be entered.
- Mons_SYSCON0 and mons_RETH are temporary stored into the 2 OCDS scratch registers.
- SYSCON.RMAP is cleared and set the SCU_PAGE=0 to restore back the saved mons_SCU_PAGE.
- IEN0,DPH,DPL,B,A,PSW and SP are restored back respectively from the Monitor IRAM.
- The return addresses which are contained in the mons_RETL and MMWR2 are pushed to the stack.
- The SYSCON0 is updated with the value stored in the MMWR1
- RET is performed, i.e jump to address that are stored in the stack which transfer the control back to the user program.
- NOP is followed to ensure proper operation.

Single step execution

Single step execution:

- Current instruction in the user mode is executed and a new debug event will automatically be triggered and the monitor mode is entered again.
- The return address is calculated by minus 1 of the break address.
- In the event when other break event happened due to single step or others, then step will always take the higher priority and consider first for the calculation of the return address.

Software breakpoint implementation

It is only possible if the original code can be replaced by the TRAP opcode. And this implies that the code memory must be writable. Thus for the XRAM, the XRAM content must be saved by the debugger and modified with the TRAP opcode A5_H. After the break has occurred, the debugger should program back the original user code, so that the normal flow of the program is not affected.

13.4.2.5 Important Information for Debugger

This section will describe the additional tasks that are required by the debugger to produce seamless integration and synchronization flow between the monitor firmware. The debugger is the master for all transaction and it must keep track of the flow and

always in sync with the current MCU resources changed. The OCDS capabilities will be disabled for BootROM region.

Specific Infineon DAP instruction to configure DUT

The debugger on the host side act as the master and is responsible for initiating and controlling all JTAG transactions.

From the BootROM perspective, it is only concern with the JTAG communication between the JTAG module and the OCDS module. The communication can begin once the JTAG Instruction Register (IR) is set with **JTAG_IO_INSTRUCTION1** ($C1_H$). This will effectively connect the external JTAG pins to the OCDS/JTAG Interface module thus enabling communication between the debugger and the OCDS module. Note `JTAG_IO_SELECT_PATH(C0_H)` command is not needed since OCDS is selected by default after reset (`IOPATH = 0`).

Initial entry to the monitor mode

There is only one possible initial entry into the monitor mode.

Upon a reset, with boot mode configured for OCDS by the SOC, it will enter OCDS mode. The IP break point is configured at address 0000_H and execution begin at that specific address and a break event is generated and monitor mode will be entered.

Implementation of the debugger

Upon the entry of the monitor, the PC value are saved into the `mons_RETH` and `mons_RETL`.

The 16 bytes from $1FE8_H$ to $1FF_H$ of the XRAM is been used by the Monitor ROM to perform reading and writing the SFR. Thus the contents at these location must be saved by the debugger when the Monitor mode is entered and restored them before exiting the Monitor mode.

IP and IRAM breakpoints can be support and are set by modified by writing to the OCDS registers. Likewise, the debugger can view and modified any SFR according based on the virtual address translation.

For every transaction, a status byte will be returned. A non-zero value will indicate that there is error, refer to the table for the STATUS byte field definition [Table 13-10](#).

Calculation of the return address upon a break event

The break address is stored in `mons_RETH` (32_H) and `mons_RETL` (33_H) upon a break and enter the monitor mode. Thus the debugger must check what type of break has occurred and calculate the return address accordingly.

For IP and IRAM breakpoint, the return address = **break address - 2**. For any other break, the return address = **break address -1**.

The debugger will need to update the return address into the `mons_RETH` and `mons_RETL` before exiting the monitor mode. To implement the "Go address" function, the debugger should modify the `mons_RETH` and `mons_RETL` directly before exiting.

Limitation of the monitor mode

Interrupt handling, if an external interrupt has occurred, the monitor will not be able to service it. For IRAM read and write break, only the return address can be calculated but the break address might not be known.

Exit sequence of the monitor mode

To exit the Monitor mode, the debugger will need to write to the `MMCR.MEXIT = 1` together with the `MMCR.MEXIT_P = 1`. Upon writing to these bits, the Monitor mode is automatically exited. Prior to this, the starting 16 bytes from (`1FE8H - 1FF7H`) of the XRAM must be restored.

An example of a Debugging session

Here is an example of a debugging session.

- Initial entry of the monitor mode through JTAG mode.
- The PC is saved to the stack by the monitor firmware. The debugger will buffer the 16bytes of XRAM at address `1FE8H - 1FF7H`, into its memories.
- Load a user hex file into the XRAM memory.
- Set the IP and IRAM breakpoints.
- Modify the `mons_RETH` and `mons_RETL` to the starting address for execution.
- Clear all the breakpoint flag.
- Follow the exit sequence.
- The break will occur and once again the monitor mode is entered and PC is saved.
- Debugger will once again buffer the 16 bytes of data into the its memories.
- All the memories and SFR can be read and modified.
- The return address is calculated based on the break address and the breakpoint flags.
- The return address is updated.
- Restore back the 16bytes of XRAM content back to its original location.
- Follow the exit sequence.
- This process will repeat as long as there is a break event.

Detailed description of Monitor Program State Machine

This session described the flow of the major states:

- Start state - start of the state machine

- Command state - Received OCDS command and the upper 4 bits of the virtual address.
- Parameter Address state - Received the lower 16-bits virtual address.
- Parameter Data Length state - Received the frame Length
- Data state - For read command, this state will perform the read commands and send out the data. For write command, this state will receive the data and perform the write operation to the respective memory.

Start and Command States

Figure 13-15 shows the flow of start state and command state. The lower nibble of the command byte contains the uppermost 4 bits of the virtual address.

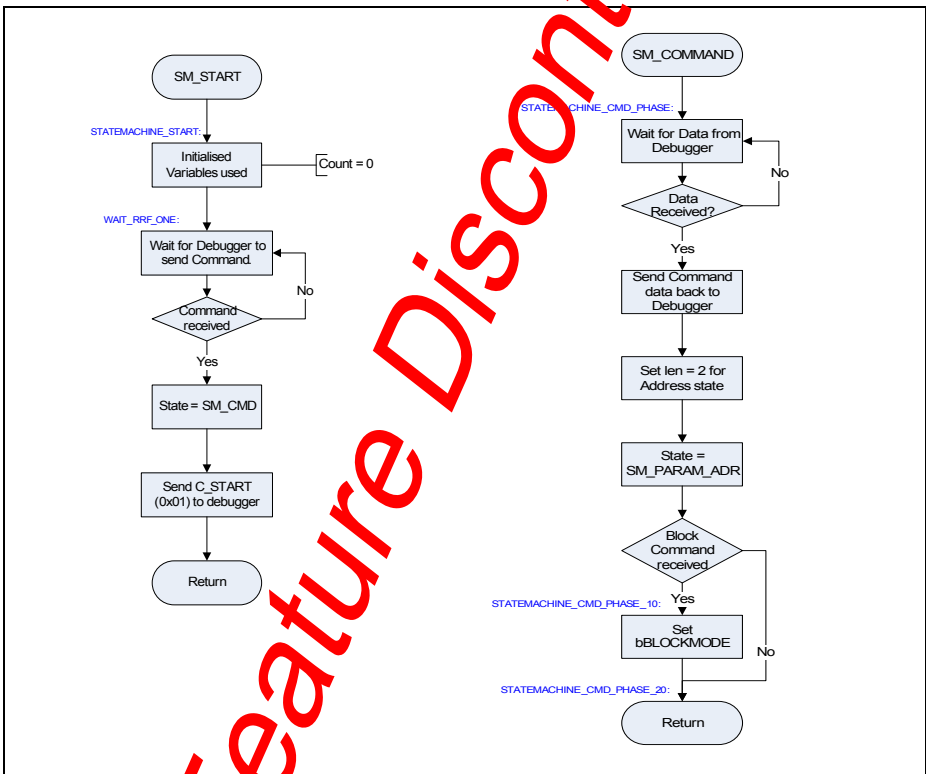

Figure 13-15 Start State and Command State

Parameter Address State

In this state, the next 16 bits of the virtual address are received. The 20-bits virtual address indicates which memory or SFR is to be accessed.

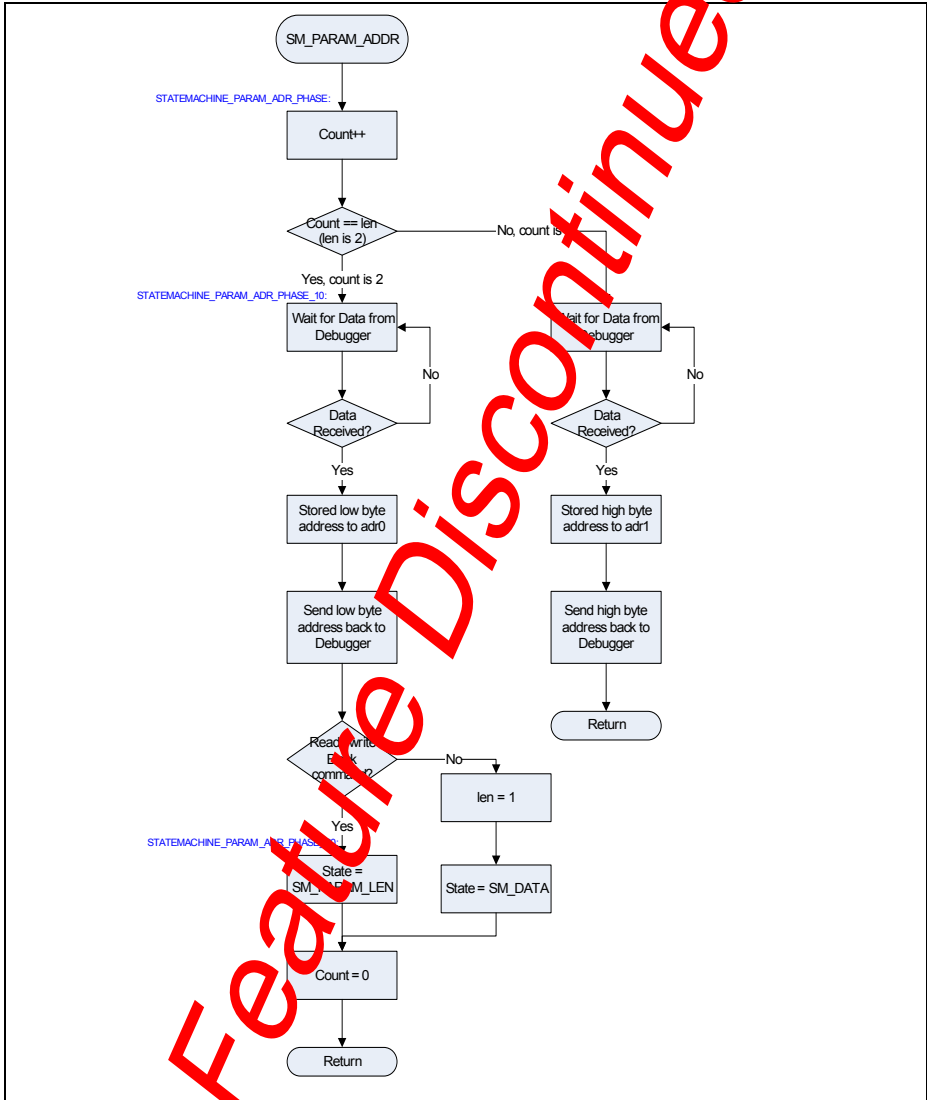

Figure 13-16 Parameter Address State

Parameter Length State

This state is entered if the command is read block command or write block command. The data received indicates the number of data bytes to be received or sent.

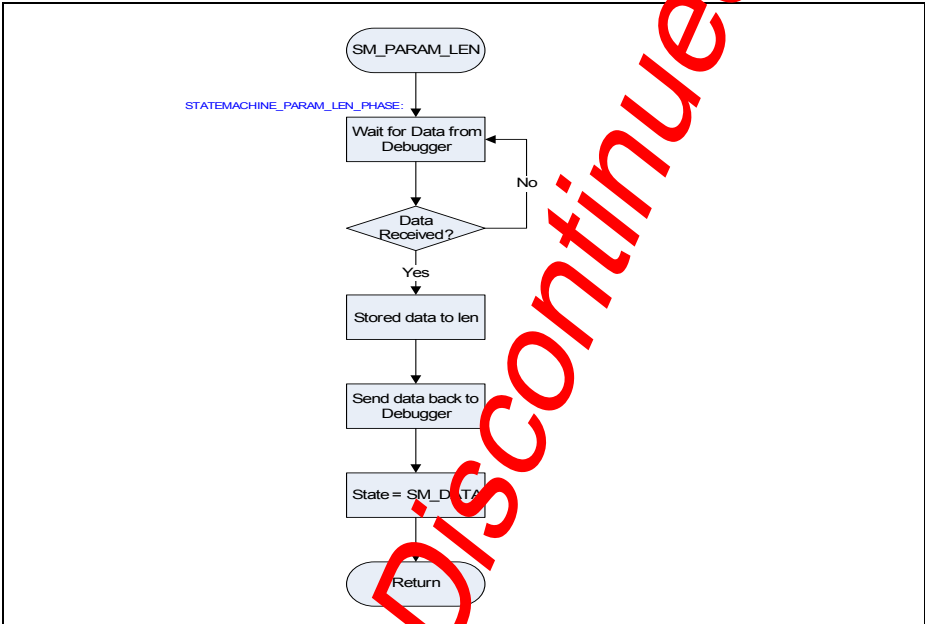

Figure 13-17 Parameter Length State

Data State

For Read_BYTE and READ_BLOCK commands, data is read from the respective memory or SFR and send to the debugger. For the other 3 commands, data is received from the debugger and written to the memory or SFR.

13.5 System Control Unit

The System Control Unit (SCU) supports all central control tasks in the TC2x_SCR. The SCU is made up of the following sub-modules:

- Clock System and Control (see [Section 13.5.1 on Page -54](#))
- Reset Control (see [Section 13.5.2 on Page -63](#))
- Interrupt Management (see [Section 13.5.3 on Page -70](#))
- Boot and Startup (see [Section 13.5.4 on Page -76](#))
- Power Management (see [Section 13.5.5 on Page -79](#))
- Flexible Peripheral Management (see [Section 13.5.6 on Page -84](#))
- XRAM Addressing Modes (see [Section 13.5.7 on Page -85](#))
- Module Suspend Control (see [Section 13.5.8 on Page -87](#))
- JTAD ID (see [Section 13.5.9 on Page -87](#))
- General Port Control (see [Section 13.5.10 on Page -88](#))
- Miscellaneous Control (see [Section 13.5.11 on Page -95](#))
- Register Mapping (see [Section 13.5.12 on Page 99](#))

13.5.1 Clock System and Control

Figure 13-22 shows the block diagram of the clock system in TC2x_SCR. It consists of two internal oscillators and a clock control unit (CCU). The two oscillators, a 100 MHz oscillator and a 100 kHz oscillator, are supplied by the internal EVR. These two clock sources to TC2x_SCR are gated with bit PMSWCR0.SCREEN in both normal and standby mode. If this bit is set to "0", TC2x_SCR is disabled and the clock inputs would be gated off. The system clock f_{SYS} is generated either by the 100 MHz or 100 kHz internal oscillator.

Upon any reset, 100 kHz oscillator is the default clock source. It is also the only clock source that is active in both normal and standby mode. In standby mode, the 100 MHz oscillator may be powered down as configured in PMSWCR0.SCRCLKSEL. When necessary, the 100 MHz oscillator can be powered up using bit CMCON.OSCPD. An oscillator watchdog circuit is needed to detect a stable 100 MHz oscillation before selecting the 100 MHz clock source. OSC2L bit in register CMCON is used to indicate the status of the 100 MHz clock.

When 100 MHz oscillator is selected as the clock source for the generation of the system frequency, the oscillator watchdog is also used to detect a 100 MHz clock failure and trigger an NMI interrupt if it is enabled by setting bit NMICON.NMIOSCCLK. When the 100 MHz oscillator falls below the threshold of 70 MHz, the clock source will be automatically switched to the 100 kHz oscillator.

Note: If 100 MHz (DI) clock is selected for WDT and/or RTC and 100 MHz oscillator fails, WDT and/or RTC clock will stop operation and NMI interrupt will be triggered. User can switch to the 100 kHz clock, and reinitialize WDT and RTC to run at 100 kHz.

The CCU generates all necessary clock signals within the microcontroller from the system clock. It consists of:

- Clock source selection in active mode
- Centralized enable/disable circuit for clock control

Figure 13-22 Clock System Block Diagram

In active mode, the main module frequencies (synchronous unless otherwise stated) are as follows:

- CPU clock (CCLK, SCLK) = 100 kHz (default) or 100 MHz / DIV
- Peripheral clock (PCLK) = CPU clock

When 100 MHz clock source is selected (CMCON.OSCSS = 1), the clock to the CPU and peripherals will be divided by the programmable factor DIV that is selectable by the bit field CMCON.DIV.

Peripherals that are running in PCLK frequency are UART, T0, T1, T2CCU.

Note: SPD Debug interface can only be supported when the 100 MHz oscillator is available.

Note: WDT and RTC clock running faster than PCLK frequency is not supported.

Feature Discontinued

13.5.2 Reset Control

The TC2x_SCR has four types of resets: main reset, watchdog timer reset, RAM double bit ECC reset and soft reset.

When the TC26x B-Step is first powered up, TC2x_SCR enters user mode 0 and start operation with the release of the system reset via the main reset. The CPU then starts to execute from the Boot ROM firmware. User mode 0 is used by CPUx to program the user code to the internal XRAM via the SPI interface. Once the XRAM is programmed, a new boot mode must be selected via PMSWCR1.SCRCFG. A reset must be issued by CPUx via bit PMSWCR1.SCRSTREQ to start running TC2x_SCR in the new boot mode.

In user mode 0, the 8-bit CPU starts to execute an infinite loop from the Boot ROM firmware and user code will not be executed in user mode 0 once the system reset is released. Please refer to “Boot mode” section for detailed information about the other boot modes.

The Watchdog Timer (WDT) module is capable of resetting the device if it detects a malfunction in the system.

A double bit ECC event in the SRAM can also trigger a reset.

As for soft reset, it can be triggered by application software where applicable.

13.5.2.1 Types of Reset

The following reset types are triggered by the TC2x_SCR.

- Main reset
 - Requested asynchronously when power failure (undervoltage) or synchronously by the main controller CPUx via bit PMSWCR1.SCRSTREQ. The PORST will also triggered this type of reset.
 - Reset all registers including the reset indication bits.
- SCU Watchdog Timer (WDT) reset
 - Requested by WDT overflow or out of boundary refresh event if it is enabled via RSTCON.WDTRSTEN.
 - Possible to reset all registers except the reset indication bits.
- RAM Double Bit ECC Reset
 - Requested by ECC event if it is enabled via RSTCON.ECCRSTEN.
 - Possible to reset all registers except the reset indication bits.
- Soft reset
 - Requested by soft reset event
 - Possible to reset all registers except the reset indication bits.

This section describes the definition and controls depending on the reset source.

Main Reset

When the TC26x B-Step is first powered up, TC2x_SCR enters user mode 0 and start operation with the release of the system reset via the main reset. User mode 0 is used by CPUx to program the user code to the internal XRAM via the SPI interface. Once the XRAM is programmed, a new boot mode must be selected via PMSWCR1.SCRCFG. A second main reset must then be issued as triggered by CPUx via bit PMSWCR1.SCRSTREQ to start running TC2x_SCR in the new boot mode.

In user mode 0, the 8-bit CPU starts to execute an infinite loop from the Boot ROM firmware and user code will not be executed. For more information on the other boot modes (user mode 1 and Debug mode), refer to “Boot mode” section.

Note: Resetting TC2x_SCR to enter a new boot mode is only possible via the reset that is triggered by bit PMSWCR1.SCRSTREQ from the main controller.

Watchdog Timer Reset

The watchdog timer reset is an internal reset and can be disabled by bit RSTCON.WDTRSTEN. The Watchdog Timer (WDT) maintains a counter that must be refreshed or cleared periodically. If the WDT is not serviced correctly and in time, it will generate an NMI request to the CPU and then reset the device after a predefined time-out period if this reset type is enabled. When the reset is disabled, no reset will be triggered when the overflow event or out of boundary refresh event happens.

Bit RSTST.WDTRST is used to indicate the watchdog timer reset status. The reset status can also be read via PMSWCR2.SCR.WDT bit in the main controller.

When a watchdog timer reset occurs, it is necessary to write to NMICON.SCRINTTC to indicate a valid watchdog timer reset. The main controller receives the valid signal and sends an acknowledge signal to TC2x_SCR. Once the acknowledge is received from the main controller, NMICON.SCRINTTC is cleared automatically and the watchdog timer reset indication bit (WDTRST) is allowed to be cleared via software.

Note: The watchdog timer event can be cleared by EVR reset.

Double Bit ECC Reset

The double bit ECC reset is an internal reset and can be disabled by bit RSTCON.ECCRSTEN. The 8-bit data from the CPU is encoded with an Error Correction Code (ECC) before being stored in the XRAM memory. During a read access, data is retrieved from the memory and decoded for dynamic error detection and correction. If a double bit error is detected, it will generate a reset if this reset type is enabled. When the reset is disabled, no reset will be triggered when the ECC event happens.

Bit RSTST.ECCRES is used to indicate the ECC reset status. The reset status can also be read via PMSWCR3.SCRECC bit in the main controller.

When an ECC reset occurs, it is necessary to write to NMICON.SCRINTTC to indicate a valid ECC reset. The main controller receives the valid signal and sends an

acknowledge signal to TC2x_SCR. Once the acknowledge is received from the main controller, NMICON.SCRINTTC is cleared automatically and the ECC reset indication bit (ECCRST) is allowed to be cleared via software.

Note: The ECC event can be cleared by EVR reset.

Soft Reset

Soft reset is an internal reset that is caused by a software set of the soft reset request bit, SWRQ, in RSTCON register. It can be triggered by application software where necessary.

Bit RSTST.SOFRST is used to indicate the soft reset status. The reset status can also be read via PMSWCR2.SCRRST bit in the main controller.

When a soft reset occurs, it is necessary to write to NMICON.SCRINTTC to indicate a valid soft reset. The main controller receives the valid signal and sends an acknowledge signal to TC2x_SCR. Once the acknowledge is received from the main controller, NMICON.SCRINTTC is cleared automatically and the soft reset indication bit (SOFRST) is allowed to be cleared via software.

Note: The soft reset event can be cleared by EVR reset.

Feature Discontinued

13.5.2.2 Module Reset Behavior

Table 13-12 gives an overview on how the various modules or functions of the TC2x_SCR are affected with respect to the reset type. A 'X' means that the module/function is reset to its default state.

Table 13-12 Effect of Reset on Modules/Functions

Module/ Function	Main Reset	Double Bit ECC Reset	Soft Reset	Watchdog Reset
CPU Core	X	X	X	X
SCU	X	X except reset indication bits	X except reset indication bits	X except reset indication bits

Feature Discontinued

13.5.3 Interrupt Management

This section describes the management of interrupts by the system control unit.

13.5.3.1 Overview

The Interrupt Management sub-module in the SCU controls the non-core-generated interrupt requests to the core. The core has one non-maskable interrupt (NMI) node and total 14 maskable interrupt nodes. [Figure 13.5.11](#) shows the block diagram of the Interrupt Management sub-module.

Figure 13-23 Interrupt Management Block Diagram

The non-maskable interrupt unit controls the NMI requests. Incoming NMI request is not maskable and in this sense, differs from the regular interrupts. In addition, NMI request always has the highest priority to be serviced. In the TC2x_SCR, five different sources can generate an NMI: watchdog timer prewarning, OCDS NMI, RAM ECC error, main controller interrupt, external NMI (via EXTNMI pin) and 100 MHz oscillator clock failure. Some NMI sources can be triggered by one of several events. These NMI sources are ORed to generate an NMI interrupt directly to the core. The triggering NMI sources/events are indicated in the NMI Status Register (NMISR), and in some cases the event flags are located in the peripheral register. The NMI node source control is via the NMI Control Register (NMICON).

There are generally 3 types of maskable inputs into the core: internal, external and extended interrupts. The maskable interrupt unit will generate the respective interrupt node request to the core and will maintain corresponding SCU flags and control. In

general, to support all types of peripheral interrupts, an interrupt node of the core may be shared among several interrupt sources.

Internal Interrupts

There are in total three internal interrupts, which separately come from Timer 0, Timer 1 and UART within the core. These interrupt request signals are controlled directly by the interrupt flag generated within the core. These interrupts do not go through Interrupt Management Unit in the SCU.

External Interrupts

The generation of interrupt request from an external source by edge detection in SCU is shown in **Figure 13-24**. External interrupts can be positive, negative or double edge triggered. Register EXICON0 specifies the active edge for the external interrupt. Among the external interrupts, external interrupt 0 and external interrupt 1 may be selected to bypass edge detection in SCU, as direct input to the core's NINT0 and NINT1.

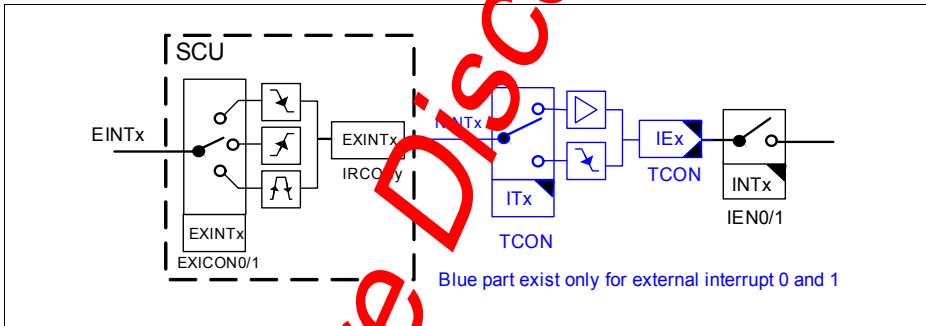

Figure 13-24 Interrupt Request Generation of External Interrupts

Extended Interrupts

Extended interrupts are not core on-chip peripherals for core-external trigger of interrupt requests to the core. There are nine such interrupt.

Interrupt signals from such on-chip peripherals are pulse triggered and active for two CPU clock cycles. These interrupt signals belonging to the same interrupt node will be latched as one direct interrupt request to the core. IRCONx (where x = 0-2) or peripheral registers hold the interrupt event flags for these extended and external interrupt events. Corresponding bits in the Interrupt Enable Registers (IEN) within the core may block or transfer these interrupt requests to the core interrupt controller. An enabled interrupt request is acknowledged when the core vectors to the interrupt routine. The software routine should clear the interrupt flags in the IRCONx registers.

As there are more peripheral interrupts than interrupt nodes supported by the core, some interrupts are multiplexed to the same interrupt node. Where possible and necessary, critical peripheral interrupts (e.g. SSC) have their own dedicated interrupt node. Refer to [Chapter 7, Interrupt System](#).

13.5.3.2 Interrupt Node Assignment

[Table 13-14](#) shows the interrupt node assignment for TC2x SCU.

Table 13-14 Interrupt Node Assignment within TC2x_SCR

Interrupt Node	Vector Address	Assignment for TC2x_SCR
NMI	0073 _H	Watchdog Timer, RAM ECC, OCDS, Main controller, External NMI (via EXT_NMI pin), 100 MHz oscillator clock failure
XINTR0	0003 _H	External Interrupt 0
XINTR1	000B _H	Timer 0
XINTR2	0013 _H	External Interrupt 1
XINTR3	001B _H	Timer 1
XINTR4	0023 _H	UART
XINTR5	002B _H	T2/TCU, LIN
XINTR6	0033 _H	WCAN
XINTR7	003B _H	SSC
XINTR8	0043 _H	External Interrupt 2
XINTR9	004B _H	External Interrupt [6:3]
XINTR10	0053 _H	External Interrupt [9:7]
XINTR11	005B _H	External Interrupt [12:10]
XINTR12	0063 _H	External Interrupt [15:13]
XINTR13	006B _H	RTC

Events/Interrupts to CPU

During run mode, there are several events (see [Table 13-15](#)) that could trigger an interrupt to the CPU.

Table 13-15 Events/Interrupts to CPUx

Modules	Events
WDT	Watchdog Timer overflow, Watchdog Timer out of boundary refresh
Memory	RAM ECC double bit error
Reset	Soft reset via bit RSTCON.SWRQ

13.5.3.3 NMI Event Flags Handling

Each NMI event and status flag is reset to default value with all types of reset. It include all the flags of NMISR register: FNMIWDT, FNMIWCLS and FNMIWEC. In the case of watchdog reset and ECC reset, the requestor can be identified via the reset indicator bits WDRTRST and ECCRST of RSTCON register.

13.5.3.4 Interrupt from/to CPUx

There is an interrupt signal from CPUx to trigger an 8-bit NMI event. It is triggered by setting a bit in register (PMSWCR2.TCINTREQ) that is located in the main SCU. The interrupt data exchange register, TCINTEXCHG, is used to indicate the type of SOC events that causes this interrupt.

In SCR, there is also an interface to trigger an interrupt to CPUx. This is done via bit NMICON.SCRINTTC. The type of SCR events that causes this interrupt to CPUx can be stored in register SCRINTEXCHG.

Feature Discontinued

13.5.3.5 Interrupt Related Registers

Several interrupt related registers are located in the SCU.

Interrupt Event Enable Control

The three interrupt events of SSC module are of interrupt structure 2. As there is no enable/disable bit(s) for these interrupt events within the module, bits are defined in the SCU register MODIEN to provide for this purpose.

MODIEN

Peripheral Interrupt Enable Register (FD_H)

7	6	5	4	3	2	1	0
TCINT							

r

Field	Bits	Type	Description
TCINT	[7:0]	r	Data exchange from main controller to SCR Fast data exchange between main controller and SCR. The data can only be read in SCR.

Other Interrupt Related Registers

The following registers are related to the interrupt system:

- NMICON
- NMISR
- IRCON0
- EXICON0, EXICON1

 All interrupt related registers, except MODIEN, SCRINTEXCHG and TCINTEXCHG registers, are described in the Interrupt System [Chapter 7](#).

13.5.4 Boot and Startup

This section describes the boot mode for TC2x_SCR. After the first power-up, TC2x_SCR will enter User mode 0. Subsequently, bit PMSWCR1.SCRCFG is used to change the boot mode that TC2x_SCR will enter after a reset is asserted. A reset to the TC2x_SCR can be triggered by a PMSWCR1.SCRSTREQ reset request to start it off in the chosen mode. However, if an internal TC2x_SCR reset happens during standby mode (eg, WDT reset), the previous SCRCFG value will be used. **Table 13-16** shows the various boot modes available in TC2x_SCR.

Table 13-16 Boot Modes

SCRCFG Value	Boot Mode	Descriptions
00 _H	User Mode 0	Default mode after cold reset with no user code in XRAM and CPUx can download code using this mode. User code in XRAM will not be executed
01 _H	User Mode 1	User Code in XRAM at address 0000 _H will be executed
02 _H	OCDS Mode	Debug mode using SCR DAP0_0 pin and DAP1_0 pin
03 _H		Debug mode using SCR DAP0_1 pin and DAP1_1 pin
04 _H - 05 _H		Debug mode using SCR SPD_0 pin
06 _H - 07 _H		Debug mode using SCR SPD_1 pin
0A _H - 0B _H		Debug mode using SOC DAP interface
0C _H - 0F _H		Debug mode using SOC SPD interface

At end of the startup routine, an interrupt is triggered to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 80_H in SCRINTEXCHG register depending on the boot mode. This is used to indicate that TC2x_SCR has finished executing the startup code and is ready for CPUx to download code to XRAM in User mode 0 or jump to user code in User mode 1 or jump to debug monitor code in OCDS mode.

Note: To change the boot mode, TC2x_SCR has to be enabled first. Changing of boot mode when TC2x_SCR is disabled will have no effect.

13.5.4.1 Boot ROM Operating Mode

After a reset, the CPU will always start by executing the Boot ROM code which occupies the program memory address space 0000H – 07FFH. The Boot ROM start-up procedure

will first switch the address space for the Boot ROM to D000H – D7FFH. The remaining Boot ROM start-up procedure will be executed from D60XH. The memory organization of the TC2x_SCR shown in this document is after the Boot ROM address switch where the different operating modes are executed.

User Mode 0

User Mode 0 is the default boot mode after a cold reset where XRAM memory is not programmed. This mode allows the downloading of code to XRAM memory via CPUx. In this mode, the CPU will only execute start-up code in Boot ROM. At the end of start-up code, an interrupt would be triggered to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 80_H in SCRINTEXCHG register. This is used to indicate that TC2x_SCR is ready for CPUx to download code to XRAM.

User Mode 1

If the User mode 1 is selected, the Boot ROM will jump to program memory address 0000_H to execute the user code in the XRAM memory. To use this mode, the XRAM must be pre-loaded with user code. This is the normal operating mode of the TC2x_SCR.

For the last 8 bytes of XRAM starting at address 1FF8_H, user need to program 4 sets of pre-fixed bytes with each set containing 55_H followed by AA_H. User code will not be executed and SCR will enter an endless loop if the memory content does not match these data sequence. It is used to avoid an unintentional entry to User Mode 1. Before entering the endless loop, the start-up code will trigger an interrupt to the main controller by setting bit NMICON.SCRINTTC to 1 with a value of 81_H in SCRINTEXCHG register. If there is a match, the same interrupt is triggered to the main controller with a value of 80_H in SCRINTEXCHG register to indicate the execution of user code.

OCDS Mode with SCR DAP/SPD pin

If the OCDS mode with SCR DAP/SPD pin is selected, the debug mode will be entered for debugging program code. The OCDS hardware is initialized and a jump to program memory address 0000_H is performed next. The user code in the XRAM memory is executed and the debugging process may be started.

Note: The DAP/SPD pin must be directly accessible by TC2x_SCR. The control of these pins must be given to TC2x_SCR using bit Pn_PCSR.SELx before enabling this boot mode.

OCDS Mode with SOC DAP/SPD pin

If the OCDS mode with SOC DAP/SPD pin is selected, the debug mode will be entered for debugging program code using the SOC DAP/SPD pins that are also used by the main debug system. The OCDS hardware is initialized and a jump to program memory

address 0000_H is performed next. The user code in the XRAM memory is executed and the debugging process may be started.

Feature Discontinued

13.5.5 Power Management

This section describes the features and functionality provided for power management of the TC2x_SCR. In addition, the exiting of standby mode via TC2x_SCR will be described in this section. Standby mode is one of the power saving modes in TC26x B-Step.

13.5.5.1 Overview

The TC2x_SCR power-management system allows software to configure the various processing units so that they automatically adjust to draw the minimum necessary power for the application.

There are generally two power modes: Active Mode and Idle Mode. The operation of the system components in each of these states can be configured by software. The power modes provide flexible reduction of power consumption through a combination of techniques, including:

- Stopping the CPU clock
- Stopping the clocks of other system components individually
- Clock-speed reduction of some peripheral components

In Active mode, the CPU and peripherals is running in system frequency.

In Idle mode, the Core is stopped with its clock disabled. Peripherals, with respective input clocks not disabled, are still functional. The watchdog timer, however, must be disabled by user before the system enters into an idle mode; otherwise, it may generate an internal reset when an overflow occurs and this will disrupt the idle mode. The idle mode is terminated automatically when any enabled interrupt signal is detected.

13.5.5.2 Functional Description

This section describes the power save modes, their operations, and entry and exit. It also describes the respective behavior of TC2x_SCR system components.

Idle Mode

Software requests Idle Mode by setting the bit PCON.IDLE to 1.

The power management state machine (PMSM) posts an idle request signal to the CPU. The CPU finishes its current operation, sends an acknowledge signal back to the PMSM, and then enters into an inactive state in which the CPU clock (CCLK) is disabled.

The system returns to either active mode when there is an incoming interrupt request to an enabled interrupt mode.

Interrupt to the CPU causes the CCLK to recover. Upon RETI instruction, the CPU will return to execute the next instruction following the instruction which sets the IDLE bit to 1.

Note: The user is advised to disable watchdog timer prior to entering the Idle Mode.

13.5.5.3 Exit Standby Mode via TC2x_SCR

In standby mode, one of the power saving modes in TC26x B-Step, TC2x_SCR could be operating in either active mode or idle mode. Hence, TC2x_SCR could be one of the wake-up source to exit standby mode. Before entering standby mode, the followings steps related to TC2x_SCR need to be setup before issuing the standby request :

- Configure the wake-up signals related to TC2x_SCR that would trigger the exit from standby mode via PMSWCR0 register
- Configure the clock selection for TC2x_SCR in standby mode via SCRCLKSEL bit.

To exit from standby mode, one of the following wake-up sources from TC2x_SCR could be used :

- WDT event
- SRAM ECC double bit error
- Software request
- WCAN WUF event
- RTC compare match event

Besides the specified events such as WDT overflow event, SRAM ECC error, WCAN event or RTC compare match event, other types of events from SSC, T0, T1, T2CCU and UART could issue a wake-up request via the bit SCRWKP in STDBYWKP register.

Feature Discontinued

13.5.6 Flexible Peripheral Management

The Flexible Peripheral Management sub-module provides the system designer greater control on the operational status of each individual peripheral. Peripherals which are not required for a particular functionality can be disabled by programming the assigned register bits which would gate off the clock inputs. This would further reduce overall power consumption of the microcontroller.

Each register bit controls one peripheral. When this bit is set, the request signal to gate the peripheral clock is activated. The peripheral will then synchronize the gating off of the clock to the peripheral. In TC2x_SCR, the clock inputs of all peripherals as specified in the PMCON1 register are gated off upon power on reset.

Feature Discontinued

13.5.7 XRAM Addressing Modes

External Data Memory (XRAM) is accessed using MOVX instructions only. These use either 8-bit or 16-bit indirect address. The DPTR register is used for 16-bit addressing and either register R0 or R7 is used to form the 8-bit address.

13.5.7.1 Access to XRAM Using the DPTR (16-bit addressing Mode)

The external memory can be accessed by two read/write instructions, which use the 16-bit DPTR for indirect addressing. These instructions are:

- MOVX A, @DPTR (Read)
- MOVX @DPTR, A (Write)

13.5.7.2 Access to XRAM Using the Register R0/R1 (8-bit addressing Mode)

The TC2x_SCR provides also instructions for accesses to XRAM using the 8-bit address (indirect addressing with registers R0 or R1). These instructions are:

- MOVX A, @Ri (Read)
- MOVX @Ri, A (Write)

To access the XRAM properly, higher order address must be put in SFR XADDRH. And this write instruction must be preceding the MOVX instructions.

XADDRH

On-Chip XRAM Address Higher Order (F3_H)

13.5.11 Miscellaneous Control

This module consists of the Bit-Protection Scheme and general system control SFRs.

13.5.11.1 Bit Protection Register

The Bit-Protection Scheme disallows direct software writing of selected bits (i.e. Protected bits) by the SFR PASSWD. When the bit field MODE is 11_B, writing 10011_B to the bit field PASS opens access to writing of all protected bits and writing 10101_B to the bit field PASS closes access to writing of all protected bits. Note that access is opened for maximum 32 CCLKs if the “close access” password is not written. If “open access” password is written again before the end of 32 CCLK cycles, there will be a recount of 32 CCLK cycles.

13.6 Watchdog Timer

13.6.1 Overview

The Watchdog Timer (WDT) provides a highly reliable and secure way to detect and recover from software or hardware failures. The WDT is reset at a regular interval that is predefined by the user. The CPU must service the WDT within this interval to prevent the WDT from causing an TC2x_SCR system reset. Hence, routine service of the WDT confirms that the system is functioning properly. This ensures that an accidental malfunction of the TC2x_SCR will be aborted in a user-specified time period. The WDT reset is default enabled. It can also be disabled via PSTCON register.

The WDT is by default disabled.

In debug mode, the WDT is default suspended and stops counting (its debug suspend bit is default set i.e., MODSUSP.WDTSUSP = 1). Therefore during debugging, there is no need to refresh the WDT.

Features

- 16-bit Watchdog Timer
- Programmable reload value for upper 8 bits of timer
- Programmable window boundary
- Clock source from either the 100 kHz clock or the 100 MHz/DIV clock
- Selectable input frequency of fWDTCLK/2 or fWDTCLK/128

Feature Discontinued

13.6.2 System Information

This section consist of the system information required to use the WDT.

13.6.2.1 Reset effects

The Watchdog Timer maintains a counter which must be refreshed or cleared periodically. Otherwise, the counter will overflow and the watchdog reset will be asserted. The assertion of the reset could be disabled by setting bit RSTCON.WDTRSTEN. The occurrence of a WDT reset is indicated by the bit WDTRST in RSTST register.

13.6.2.2 Clocking Configuration

The WDT runs on either the 100 kHz clock or the 100 MHz/DIV clock. Bit WDTCON.WDTCLK is used to select the WDT clock source, fWDTCLK.

13.6.2.3 Interrupt Events and Assignment

Table 13-19 shows the non-maskable interrupt node assignment of the WDT interrupt source.

Table 13-19 WDT Events' Non-maskable Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
WDT Overflow	NMICON.NMIWDT	NMISR.FNMIWDT	73H

13.6.2.4 Module Suspend Control

The timer in WDT is by default suspended on entering debug mode. The WDT can be allowed to run in debug mode by clearing the bit WDTSUSP in SFR MODSUSP to 0. Refer to the definition of register MODSUSP.

Feature Discontinued

13.6.3 Functional Description

The Watchdog Timer (WDT) is a 16-bit timer, which is incremented by a count rate of $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$. The f_{WDTCLK} clock input is selectable between the 100 kHz clock or the 100 MHz/DIV clock using the WDTCLK bit. This 16-bit timer is realized as two concatenated 8-bit timers. The upper 8 bits of the WDT can be preset to a user-programmable value via a watchdog service access in order to vary the watchdog expire time. The lower 8 bits are reset on each service access. Figure 13-25 shows the block diagram of the WDT unit.

Figure 13-25 WDT Block Diagram

If the WDT is enabled by setting $WDTEN$ to 1, the timer is set to a user-defined start value and begins counting up. It must be serviced before the counter overflows. Servicing is performed through a refresh operation (setting bit $WDTRS$ to 1). This reloads the timer with the start value, and normal operation continues.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed and normal mode is terminated. A WDT NMI request ($FNMIWDT$) is then asserted and prewarning is entered. The prewarning lasts for 30_H count. During the prewarning period, refreshing of the WDT is ignored and the WDT cannot be disabled. A reset ($WDTRST$) of the TC2x_SCR is imminent (if it is enabled by bit $RSTCON.WDTRSTEN$) and can no longer be avoided. The occurrence of a WDT reset is indicated by the bit $WDTRST$ in $RSTST$ register. If refresh happens at the same time an overflow occurs, WDT will not go into prewarning period.

Note: In TC26x B-Step, it is possible to wake-up the main controller from standby mode when the WDT overflow event happened by setting bit $STDBYWKP.WDTWKSEL$ to 1.

The WDT must be serviced periodically so that its count value will not overflow. Servicing the WDT clears the low byte and reloads the high byte with the present value in bit field WDTREL. Servicing the WDT also clears the bit WDTRS.

The WDT has a “programmable window boundary”, which disallows any refresh during the WDT’s count-up. A refresh during this window-boundary constitutes an invalid access to the WDT and causes the WDT to activate WDTRST, although no NMI request is generated in this instance. The window boundary is from 0000_H to the value obtained from the concatenation of WDTWINB and 00_H. This feature can be enabled by WINBEN.

After being serviced, the WDT continues counting up from the value ($\langle \text{WDTREL} \rangle * 2^8$). The time period for an overflow of the WDT is programmable in two ways:

- The input frequency to the WDT can be selected via bit WDTIN in register WDTCON to be either $f_{\text{WDTCLK}}/2$ or $f_{\text{WDTCLK}}/128$.
- The reload value WDTREL for the high byte of WDT can be programmed in register WDTREL.

The period P_{WDT} between servicing the WDT and the next overflow can be determined by the following formula:

$$P_{\text{WDT}} = \frac{2^{(1+\langle \text{WDTIN} \rangle * 6)} * (2^{16} - \text{WDTREL} * 2^8)}{f_{\text{WDTCLK}}} \quad (13.1)$$

If the Window-Boundary Refresh feature of the WDT is enabled, the period P_{WDT} between servicing the WDT and the next overflow is shortened if WDTWINB is greater than WDTREL. See also [Figure 13-26](#). This period can be calculated by the same formula by replacing WDTREL with WDTWINB. In order for this feature to be useful, WDTWINB cannot be smaller than WDTREL.

Figure 13-26 WDT Timing Diagram

Table 13-20 lists the possible ranges for the watchdog time which can be achieved using a certain module clock. Some numbers are rounded to 3 significant digits.

Table 13-20 Watchdog Time Range

Reload value in WDTREL	Prescaler for fWDT					
	2 (WDTIN = 0)			128 (WDTIN = 1)		
	20 MHz	16 MHz	12 MHz	20 MHz	16 MHz	12 MHz
FF _H	25.5 μs	32.0 μs	42.67 μs	1.63 ms	2.05 ms	2.73 ms
7F _H	3.3 ms	4.13 ms	5.5 ms	211 ms	264 ms	352 ms
00 _H	6.55 ms	8.19 ms	10.92 ms	419 ms	524 ms	699 ms

Note: For safety reasons, the user is advised to rewrite WDTCON each time before the WDT is serviced.

Note: The Watchdog Timer can be suspended when OCDS enters Monitor Mode and has the Debug-suspend signal activated, provided the respective suspend bit, WDTXSUSP in SFR MODSUSP, are set. See Module Suspend Control section.

13.6.4 Registers Description

Five SFRs control the operations of the WDT. They can be accessed from the SCU page 2 of the mapped SFR area.

Table 13-21 lists the addresses of these SFRs.

Table 13-21 Register Map

Address	Register
F6 _H	WDTCON
F7 _H	WDTREL
FA _H	WDTWINB
FB _H	WDTL
FC _H	WDTH

13.6.4.1 Watchdog Timer Registers

The Watchdog Timer Current Count Value is contained in the Watchdog Timer Register WDTH and WDTL, which are non-bitaddressable read-only register. The operation of the WDT is controlled by its bitaddressable Watchdog Control Register WDTCON. This register also selects the input clock prescaling factor. The register WDTREL specifies the reload value for the high byte of the timer. WDTWINB specifies Watchdog Window-Boundary count value.

13.7 Interrupt System

The XC800 Core supports one non-maskable interrupt (NMI) and 14 maskable interrupt requests. In addition to the standard interrupt functions supported by the core, e.g., configurable interrupt priority and interrupt masking, the TC2x_SCR interrupt system provides extended interrupt support capabilities such as the mapping of each interrupt vector to several interrupt sources to increase the number of interrupt sources supported, and additional status registers for detecting and identifying the interrupt source.

13.7.1 Interrupt Sources

The TC2x_SCR supports 14 interrupt vectors with four priority levels. These interrupt vectors are assigned to the on-chip peripherals: Timer 0, Timer 1, UART, RTC, WCAN, and SSC are each assigned one dedicated interrupt vector. T2CCU and LIN interrupts has to share an interrupt vector. External interrupt 0, 1 and 2 are each assigned one dedicated interrupt vector. The remaining 13 external interrupts are shared among 4 interrupt vectors.

A non-maskable interrupt (NMI) with the highest priority is shared by the following:

- Watchdog Timer, warning before overflow
- OCDS, on user IRAM event
- RAM ECC error
- External NMI (via EXTNMI pin)
- Main controller
- 100 MHz oscillator clock failure

Figure 13-27, **Figure 13-28**, **Figure 13-29** and **Figure 13-30** give a general overview of the interrupt sources and nodes and their corresponding control and status flags. **Figure 13-32** gives the corresponding overview for the NMI sources.

13.7.1.1 Interrupt Source and Vector

Each interrupt event source has an associated interrupt vector address for the interrupt node it belongs to. This vector is accessed to service the corresponding interrupt node request. The interrupt service of each interrupt node can be individually enabled or disabled via an enable bit. The assignment of the TC2x_SCP interrupt sources to the interrupt vector address and the corresponding interrupt node enable bits are summarized in [Table 13-22](#).

13.7.1.2 Interrupt Source and Priority

An interrupt that is currently being serviced can only be interrupted by a higher-priority interrupt, but not by another interrupt of the same or lower priority. Hence, an interrupt of the highest priority cannot be interrupted by any other interrupt request.

If two or more requests of different priority levels are received simultaneously, the request with the highest priority is serviced first. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced first. Thus, within each priority level, there is a second priority structure determined by the polling sequence as shown in [Table 13-23](#).

13.7.2 Interrupt Structure

An interrupt event source may be generated from the on-chip peripherals or from external. Detection of interrupt events is controlled by the respective on-chip peripherals. Interrupt status flags are available for determining which interrupt event has occurred, especially useful for an interrupt node which is shared by several event sources. Each interrupt node (except NMI) has a global enable/disable bit. In most cases, additional enable bits are provided for enabling/disabling particular interrupt events (provided for NMI events). No interrupt will be requested for any occurred event that has its interrupt enable bit disabled.

The TC2x_SCR has, in general, two interrupt structures distinguished mainly by the manner in which the pending interrupt request (one per interrupt vector/node going directly to the core) is generated (due to the events) and cleared.

Common among these two interrupt structures is the interrupt masking bit, EA, which is used to globally enable or disable all interrupt requests (except NMI) to the core. Resetting bit EA to 0 only masks the pending interrupt requests from the core, but does not block the capture of incoming interrupt requests.

Note: The NMI node is similar to the other interrupt nodes, except for the exclusion of EA bit. Effectively, NMI node is non-maskable.

13.7.2.1 Interrupt Structure 1

For interrupt structure 1 (see [Figure 13-33](#)), the interrupt event will set the interrupt status flag which doubles as a pending interrupt request to the core. An active pending interrupt request will interrupt the core only if its corresponding interrupt node is enabled. Once an interrupt node is serviced (interrupt acknowledged), its pending interrupt request (represented by the interrupt status flag) may be automatically cleared by hardware (the core).

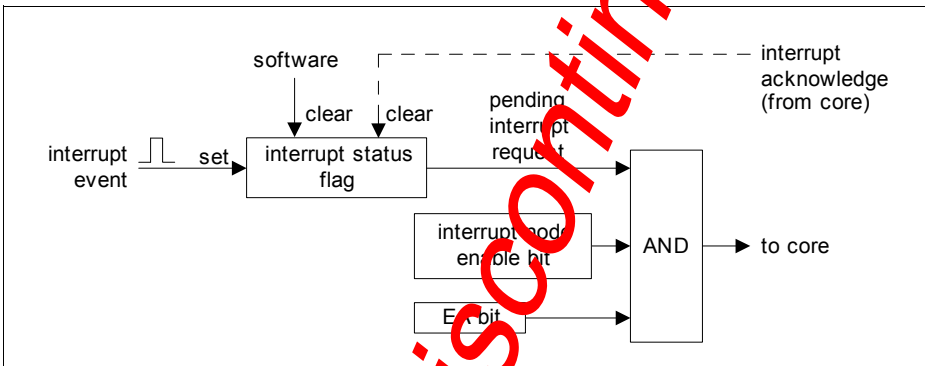

Figure 13-33 Interrupt Structure 1

For the TC2x_SCR, interrupt sources Timer 0, Timer 1, external interrupt 0 and external interrupt 1 (each have a dedicated interrupt node) will have their respective interrupt status flags TF0, TF1, IE0 and IE1 in register TCON cleared by the core once their corresponding pending interrupt request is serviced. In the case that an interrupt node is disabled (e.g. software polling is used), its interrupt status flag must be cleared by software since the core will not be interrupted (and therefore the interrupt acknowledge is not generated). For the UART, which has its dedicated interrupt node, interrupt status flags RI and TI in register SC01 will not be cleared by the core even when its pending interrupt request is serviced. The UART interrupt status flags (and hence the pending interrupt request) can only be cleared by software.

13.7.2.2 Interrupt Structure 2

This structure applies to the Timer 2, LIN, external interrupts 2 to 15, WCAN, SSC and RTC interrupt sources. For interrupt structure 2 (see [Figure 13-34](#)), the interrupt status flag does not directly drive the pending interrupt request.

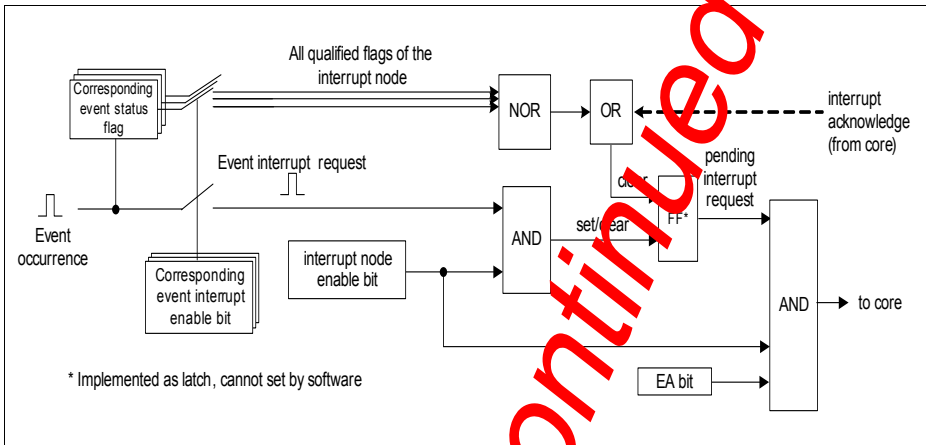

Figure 13-34 Interrupt Structure 2

An event generated by its corresponding interrupt source will set the status flag, and in parallel, if the event is enabled for interrupt, activate the pending interrupt request. Consider the case where interrupt event occurred while its interrupt node was disabled (assume global interrupt enable EA is set). When the interrupt node is enabled later, previously activated pending interrupt request will now cause an active interrupt request to the core. Note for the special case of NMI node, that it is essentially non-maskable.

An active pending interrupt request interrupts the core and is automatically cleared by hardware (the core) once the interrupt node is serviced (interrupt acknowledged); the status flag remains set and must be cleared by software. A pending interrupt request can also be cleared by software: only on clearing all interrupt-enabled status flags of the node will indirectly clear its pending interrupt request. Note that this is not exactly like interrupt structure 1 where the pending interrupt request is cleared directly by resetting the node's interrupt status flags.

In summary, the following lists in descending order the priority handling of pending interrupt request for interrupt nodes of structure 2: 1) CPU acknowledge of interrupt on vectoring to the service routine will clear the pending interrupt request, 2) Any event occurring and enabled for interrupt will set the pending interrupt request, 3) on clearing of all interrupt-enabled status flags will clear the pending interrupt request.

13.7.3 Interrupt Handling

The interrupt request signals are sampled at phase 2 in each machine cycle. The sampled requests are then polled during the following machine cycle. If one interrupt node request was active at phase 2 of the preceding cycle, the polling cycle will find it

and the interrupt system will generate a LCALL to the node's service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of equal or higher priority is already in progress.
2. The current (polling) cycle is not in the final cycle of the instruction in progress.
3. The instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP/IPH or IP1/IPH1.

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress is completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP/IPH or IP1/IPH1, then at least one more instruction will be executed before any interrupt is vectored to; this delay guarantees that changes of the interrupt status can be observed by the CPU.

The polling cycle is repeated with each machine cycle, and the values polled are the values that were present at phase 2 of the previous machine cycle. Note that if any interrupt flag is active but its node interrupt request was not responded to for one of the conditions already mentioned, and if the flag is no longer active at a later time when servicing the interrupt node, the corresponding interrupt source will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle interrogates only the pending interrupt requests.

The processor acknowledges an interrupt request by executing a hardware generated LCALL to the corresponding service routine. In some cases, hardware also clears the flag that generated the interrupt, while in other cases, the flag must be cleared by the user's software. The hardware-generated LCALL pushes the contents of the Program Counter (PC) onto the stack (but it does not save the PSW) and reloads the PC with an address that depends on the interrupt node being vectored to, as shown in the [Table 13-22](#).

Program execution returns to the next instruction after calling the interrupt when the RETI instruction is encountered. The RETI instruction informs the processor that the interrupt routine is no longer in progress, then pops the two top bytes from the stack and reloads the PC. Execution of the interrupted program continues from the point where it was stopped. Note that the RETI instruction is important because it informs the processor that the program has left the current interrupt priority level. A simple RET instruction would also have returned execution to the interrupted program, but it would have left the interrupt control system on the assumption that an interrupt was still in progress. In this case, no interrupt of the same or lower priority level would be acknowledged.

13.7.4 Interrupt Response Time

Due to an interrupt event of (the various sources of) an interrupt node, its corresponding request signal will be sampled active at phase 2 in every machine cycle. The value is not polled by the circuitry until the next machine cycle. If the request is active and conditions

are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two machine cycles. Thus, a minimum of three complete machine cycles will elapse from activation of the interrupt request to the beginning of execution of the first instruction of the service routine as shown in **Figure 13-35**.

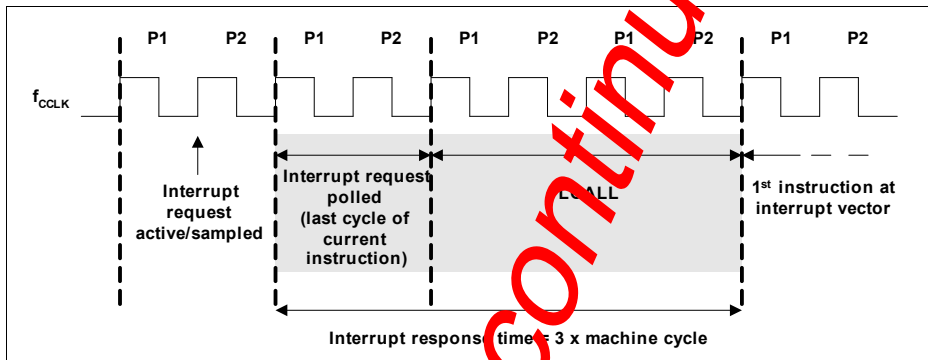

Figure 13-35 Minimum Interrupt Response Time

A longer response time would be obtained if the request is blocked by one of the three previously listed conditions:

1. If an interrupt of equal or higher priority is already in progress, the additional wait time will depend on the nature of the other interrupt's service routine.
2. If the instruction in progress is not in final cycle, the additional wait time cannot be more than three machine cycles since the longest instructions (MUL and DIV) are only four machine cycles long. See **Figure 13-36**.
3. If the instruction in progress is RETI or a write access to registers IEN0, IEN1 or IP(H), IP1(H), the additional wait time cannot be more than five cycles (a maximum of one more machine cycle to complete the instruction in progress, plus four machine cycles to complete the next instruction, if the instruction is MUL or DIV). See **Figure 13-37**.

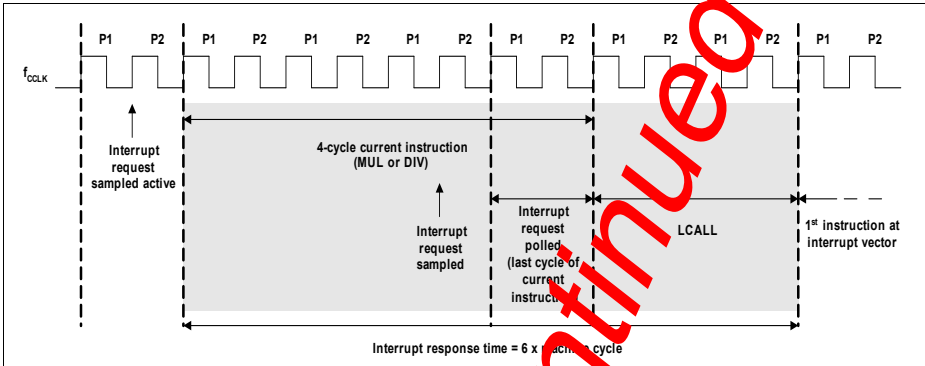

Figure 13-36 Interrupt Response Time for Condition 2

Figure 13-37 Interrupt Response Time for Condition 3

Thus in a single interrupt system, the response time is always more than three machine cycles and less than nine machine cycles (wait states are not considered). When considering wait states, the interrupt response time will be extended depending on the user instructions (also the hardware generated LCALL) being executed during the interrupt response time (shaded region in [Figure 13-36](#) and [Figure 13-37](#)).

13.7.5.1 Interrupt Node Enable Registers

Each interrupt node can be individually enabled or disabled by setting or clearing the corresponding bit in the interrupt enable registers IEN0 and IEN1. Register IEN0 also contains the global interrupt masking bit (EA), which can be cleared to block all pending interrupt requests at once.

The NMI interrupt vector is shared by a number of sources, each of which can be enabled or disabled individually via register NMICON.

After reset, the enable bits in IEN0, IEN1 and NMICON are cleared to 0. This implies that all interrupt nodes are disabled by default.

13.7.5.2 External Interrupt Control Registers

The 16 external interrupts, EXT_INT[15:0], are driven into the TC2x_SCR from the ports. The external interrupt pin assignment for TC2x_SCR is shown in [Table 13-25](#). External interrupts can be positive, negative or double edge triggered. Registers EXICON0 and EXICON1 specify the active edge for the external interrupt. Among the external interrupts, external interrupt 0 and external interrupt 1 can be selected to bypass edge detection in the SCU, for direct feed through to the core. This signal to the core can be further programmed to either low-level or negative transition activated, by the bits IT0 and IT1 in the TCON register. However, for edge detection in SCU, TCON.IT0/1 must be set to falling edge triggered. An active edge event detected in SCU will generate internally two CCLK cycle low pulse for detection by core.

If the external interrupt is positive (negative) edge triggered, the external source must hold the request pin low (high) for at least one CCLK cycle, and then hold it high (low) for at least one CCLK cycle to ensure that the transition is recognized. If edge detection is bypassed for external interrupt 0 and external interrupt 1, the external source must hold the request pin "high" or "low" for at least two CCLK cycles.

External interrupts 3 to 15 share between 4 interrupt nodes. Therefore in addition to the corresponding interrupt logic enable, each external interrupt 3 to 15 may be disabled individually, and are disabled by default after reset.

Note: NMISR register can only be cleared by software or reset to the default value after the Main Reset. Its value is retained on any other resets. This allows the cause of the previous NMI to be checked.

Feature Discontinued

13.7.5.4 Interrupt Priority Registers

Each interrupt node can be individually programmed to one of the four priority levels available. Two pairs of Interrupt Priority Registers are available to program the priority level of the each interrupt vector. The first pair of Interrupt Priority Registers are SFRs IP and IPH. The second pair of Interrupt Priority Registers are SFRs IP1 and IPH1.

The corresponding bits in each pair of Interrupt Priority Registers select one of the four priority levels as shown in [Table 13-26](#).

Table 13-26 Interrupt Priority Level Selection

IPH.x / IPH1.x	IP.x / IP1.x	Priority Level
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

Note: NMI always has the highest priority (above Level 3); it does not use the priority level selection shown in [Table 13-26](#).

13.8 Debug System

This chapter describes the XC800 debug system, in particular focus on the OCDS unit which provides the hardware to support debug functionality.

13.8.1 Overview

The debug system comprises of the On-Chip Debug Support (OCDS) unit and Debug-Monitor in ROM which provides basic debug functionality for XC800-based systems, controlled directly by an external tool via debug interface pin(s).

13.8.1.1 Features

The main debug functionality supported are:

- Set breakpoints on instruction address and on address range within the Program Memory
- Set breakpoints on Internal RAM address range
- Support unlimited software breakpoints in Flash/RAM code region
- Process external breaks via debug interface
- Step through the program code
- User handling of OCDS NMI in case of ROM read/write breakpoint

13.8.1.2 Components of the Debug System

The components of the debug system are briefly described here.

Debug Interface

The debug interface allows to access the device, such as for data read or write. The debug interface supported:

- 2-pin Device Access Port (DAP)
- Single-pin DAP (SPD)

The DAP interface refers to the dual-pin Device Access Port standardized for the Infineon microcontrollers. It offers high noise immunity and robustness, and utilizes only two pins DAP0 (clock), DAP1 (serial data in/out).

The SPD interface refers to the single-pin Device Access Port standardized for the Infineon microcontrollers. It utilizes only one pin DAP1 for serial data in/out.

Monitor Program

Part of the Boot ROM is occupied by the OCDS Monitor program (or OCDS firmware). On the command from the debugger, the Monitor program executes the actual instructions for accessing the addressable locations such as memories, sfrs of the device.

On-Chip Debug System Unit (OCDS)

The OCDS hardware is the core of the debug system, controlling the debugging with interfaces to the XC800 CPU.

13.8.2 Product Specific Information

This section provides product specific information relevant to the OCDS.

13.8.2.1 Pinning

[Table 13-28](#) describes the OCDS pin function.

Table 13-28 OCDS Pin Functions

Pin	Function	Description
P02.2	DAP0_1	Dual-pin debug access port: clock
P02.6	DAP0_0	
P02.3	DAP1/SPD_1	Single-pin debug access port: data
P02.7	DAP1/SPD_0	

The pin will be set up via hardware once the OCDS mode is selected.

13.8.2.2 Clocking Configuration

The OCDS runs at the peripheral frequency, PCLK.

13.8.2.3 Interrupt Events and Assignment

Instead of entering Monitor Mode on a break event, it can be configured such that OCDS NMI is vectored to. In this configuration, the action on OCDS NMI is fully under user software control. Details of this usage is described in later sections.

[Table 13-29](#) lists the interrupt event sources from the OCDS, and the corresponding event interrupt enable bit and flag bit.

Table 13-29 OCDS Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit
IRAM read event	MMICR.NMIRRE	MMICR.FNMIRR
IRAM write event	MMICR.NMIRWE	MMICR.FNMIRW

shows the interrupt node assignment for each OCDS interrupt source.

13.8.2.4 Debug Suspend Control

It is enabled for selected modules to suspend operation when Monitor Mode becomes active. The module functions that can be enabled for debug suspend are:

- Watchdog timer
- Timer 2
- CCT timer
- RTC timer

By debug suspend, these module functions are frozen during the duration of the device in Monitor Mode, e.g. timers stop counting. Register MODSUSP is used to control the debug suspend function.

MODSUSP

Module Suspend Control Register (FB_H)

Reset Value: 01_H

CCTSUSP	3	rw	Compare/Capture Timer Debug Suspend Bit 0 _B CCT will not be suspended. 1 _B CCT will be suspended.
0	[7:4]	r	Reserved Returns 0 if read; should be written with 0.

13.8.2.5 JTAG ID

This is a read-only register located inside the SCR JTAG module, and it is used by the tool to identify the target connected via the SCR DAP/SPD interface. Its content is shifted out when **INSTRUCTION** register contains the **IDCODE** command (opcode 04_H). After power on and any JTAG reset, the **BYPASS** instruction (opcode FF_H) will be latched onto the **INSTRUCTION** register.

The JTAG ID for the TC2x_SCR devices is 101EC083_H.

13.8.3 Functional Overview of the Debug System

XC800 debug-operation is based on close interaction between the OCDS-hardware and the Monitor program in ROM.

These operations are elaborated in the following.

13.8.3.1 Recognizing Debug-events

The OCDS hardware takes care to startup properly the Monitor, in case some **Debug-event** happens.

The debug events (breakpoints) supported are described in following.

Hardware Breakpoints

Up to 4 hardware breakpoints can be set, causing a break in case of

- code is fetched from a defined Program Memory (IP) address - the break is set just at one instruction from the user software
- code is fetched from a defined Program Memory (IP) address-range - the break is set over a number of consecutive instructions from the user software
- Read or Write (selectable) is performed at a defined Internal RAM address - the break is caused by moving data from/to a memory location

For setting of breakpoint on instruction address,HWBPx defines the 16-bit address. For setting of breakpoint on IRAM address, HWBP2/3L and HWBP2/3H define the 8-bit IRAM address range.

The configurations supported are:

- Breakpoint 0
- Breakpoint 1
 - Two equal breakpoints on Instruction Address = HWBP0 and Instruction Address = HWBP1 or
 - One range breakpoint on HWBP0 <= Instruction Address <= HWBP1
- Breakpoint 2
 - One equal breakpoint on Instruction Address = HWBP2, or

- One range breakpoint on HWBP2L <= IRAM Read Address <= HWBP2H
- Breakpoint 3
 - One equal breakpoint on Instruction Address = HWBP3, or
 - One range breakpoint on HWBP3L <= IRAM Write Address <= HWBP3H

Setting both values for a range breakpoint to the same address leads to generation of an equal breakpoint.

Software Breakpoints

These are implemented by storing into the code XC800-specific TRAP instruction (not 8051-standard), while at the same time TRAP_EN bit within the Extended Operation (EO) register is also set to 1.

Upon fetching a TRAP instruction, a breakpoint is generated and the relevant Break Action is taken.

The software breakpoints are in fact similar in behavior to the equal breakpoints on Instruction address, except that they are raised by a program code instead of specialized (compare) logic.

An unlimited number of software breakpoints can be set by replacing the original instruction codes into the user program. Of course this is possible only at addresses, where RAM/Flash is implemented.

External Breaks

External breaks could be:

- Requested via the debug interface by OCDS command: An external Debugger can activate the Monitor and interrupt a user program, running on the target XC800.

13.8.3.2 Activating the Monitor Program

Once a Debug-event is identified and the OCDS-registers are properly programmed, the Monitor program (in ROM) is started as a primary reaction.

The OCDS hardware ensures that the Monitor is always safely started, and fully independent of the current system status at the moment when the debug action is taken. Also, interrupt requests externally raised during Monitor-entry will not disturb the Monitor firmware functioning.

Once started, the Monitor runs with its own stack- and data- memory, which guarantees that all of the core and memory resources will be found untouched when returning control back to the user program. Therefore the OCDS-debugging is fully non-destructive.

The functions of the Monitor include:

- Communication with an external Debugger via the debug interface
- Read/write access to arbitrary memory locations and Special Function Registers (SFRs), including the Instruction Pointer and password-protected bits

- Configuring OCDS and setting/removing breakpoints
- Executing a single instruction (step-mode)

Note: Details of the Monitor program functionality is not covered in this documentation.

13.8.3.3 Debug Suspend Control

Next to the basic debug functionality - setting breakpoints and halting the execution of user software - OCDS supports also for module suspending during debugging.

As long as the device is in monitor mode (i.e. while the user software is not running but in break) and if debug suspend functionality is generally enabled by on-chip software, modules or functions can be suspended in this duration.

This feature could be quite useful, especially regarding the Watchdog Timer: it prevents unintentional WDT-resets during the debug session. Usually debug suspend is provided for other timer-modules. Stopping counters provide for a complete “freeze” of the device-status during a break.

Generally, the debug suspend control bits (global enable in OCDS and individual selections in SCU) are disabled after reset, i.e. by default no module will be suspended upon a break. Normally for debugging the device will be started in OCDS mode and then the monitor will be invoked before to start any user code. The debugger should provide for user configuration of suspend-controls.

13.8.3.4 Running the Monitor

The Monitor runs with its own stack- and data- work space, therefore the complete status of the core is saved and later - restored before returning to the user code.

Once the Monitor is running, it can access for read and write all of the system resources, and data can be communicated with the Debugger.

13.8.3.5 Returning to the User Program

When a return to User-Program is requested, the Monitor sets core-registers including the Instruction Pointer (IP) as required. This can be either the same status as at the Breakpoint, or including some changes done during the Break by a host debugger. Then a jump to the location pointed by IP is performed and the target system returns to User Mode.

13.8.3.6 Single Step Execution

For this functionality OCDS operates at first as when Returning to the User Program, but also a dedicated flag is set into a control-register (MMCR.MSTEP). This way, just one user-instruction is executed before re-entering the Monitor again.

13.8.4 JTAG Module

In XC800 implementation for JTAG:

- **IO client 0** is assigned to the XC800 OCDS.

Note: Following from the last assignment, the Debugger does not need to write into IOPATH-upon reset this register is cleared and Client 0 is selected by default.

Feature Discontinued

13.8.4.1 JTAG ID Register

This is a read-only register, used to recognize the device(s) connected to the JTAG/DAP/SPD interface. Its content is shifted out when the **INSTRUCTION** register contains the **IDCODE** command (opcode 04_H). After power on and any JTAG reset, the **BYPASS** instruction (opcode FF_H) will be latched onto the **INSTRUCTION** register.

ID JTAG ID Register

Field	Bits	Typ	Description
1	0	r	Always 1
MANUFACTURER_ID	[11:1]	r	Infineon's Manufacturer ID
PART_NUMBER	[27:12]	r	Part number of the chip
VERSION	[31:28]	r	Version of the chip

The **MANUFACTURER_ID** for Infineon is 041_H, therefore the three LS nibbles of the JTAG ID Register are 083_H.

The rest - **PART_NUMBER** and **VERSION**-fields are chip-specific.

13.8.5 Interface Block

The Debug-communication channel - JTAG/DAP/SPD interface - goes through OCDS as a 16-bit shift register **MMSHR** (refer to [Figure 13-38](#)) and it is controlled by a few signals coming from the JTAG Module:

- **jm_sel_io_i**
 a select signal; any operation around the JTAG-interface within the OCDS is only possible while it is activated
- **jm_capture_ioreg_i**
 while having high level at this input, on the rising edge of tck_i:
 - four status bits from the OCDS control registers are stored into the lowest part of **MMSHR** (**MBCON**, **MMODE**, **RRF** and **TRF**) and one (**COMRST**) - as bit 12 into **MMSHR**
 - the current status of **RRF** flag which is stored into **MMSHR** is also saved into the shadow-bit **RRF_s**
 - data transmit register **MMTR** is stored into the middle of the shift-register **MMSHR**

- **jm_shift_dr_i**

as long as this signal is active, the input data from JTAG Module (tdo_i) is shifted into the MMSHR on any rising edge of tck_i (LSB first), while the data out of MMSHR goes back to JTAG Module through $jm_tdo_io0_o$

Four status bits: MBCON, MMODE, RRF and TRF are the first to be sent out via JTAG during any communication session with a Debugger, followed by the 8 bits of data from MMTR and the last status bit (within the current version of OCDS) - COMRST.

MMSHR is reset by the OCDS-reset signal.

- **jm_update_dr_i**

with this signal activated after a shift-sequence, the 16 bits last shifted into MMSHR are stored into respective OCDS-registers.

For potential update of control signals/data, there are rules defined to assure correct and reliable functionality, as follows:

1. any update is only possible, if at least one out of the five control signal requests - JENA_r, RRF_r, MMODE_r, MBCON_r and COMRST_r is active.
Therefore, sending only '0's the Debugger can check the current OCDS-status, without any further influence.
2. some of the control signals requests are meaningful only when send together with $RRF_r=0$ AND $Data=A5_H$.
The reason for this is that some functions within the OCDS are requested as dedicated commands through the Debug-interface, not combined with other (data-) transfers. This refers to:
 - a) setting the OCDS-flag for active JTAG
JENA_r - request to update JENA within MMCR2
 - b) requesting a Monitor Mode Entry
MMODE_r - request to enter Monitor Mode
Note, that MMODE_r does not set directly the MMODE flag!
 - c) requesting a Communication Restart
COMRST_r - request to set COMRST within MMICR, which causes the Monitor to restart the communication protocol.
3. The middle 8 bits from the MMSHR are stored into the data receive register MMRR, only when $RRF_r=1$ AND $RRF_s=0$.
In case the data is stored, RRF is also updated to 1.
This avoids overwriting the data within MMRR, till the Monitor reads it which will also automatically clear MMCR.RRF. Note, that RRF can not be reset via the JTAG but only by OCDS hardware.
4. TRF flag is checked by the Debugger to determine when a new data has been transmitted by the Target (XC800). This bit is fully controlled by OCDS-hardware:
 - a) set when the Monitor writes a new Byte for transfer into the transmit register MMTR
 - b) reset when MMTR is stored into MMSHR.

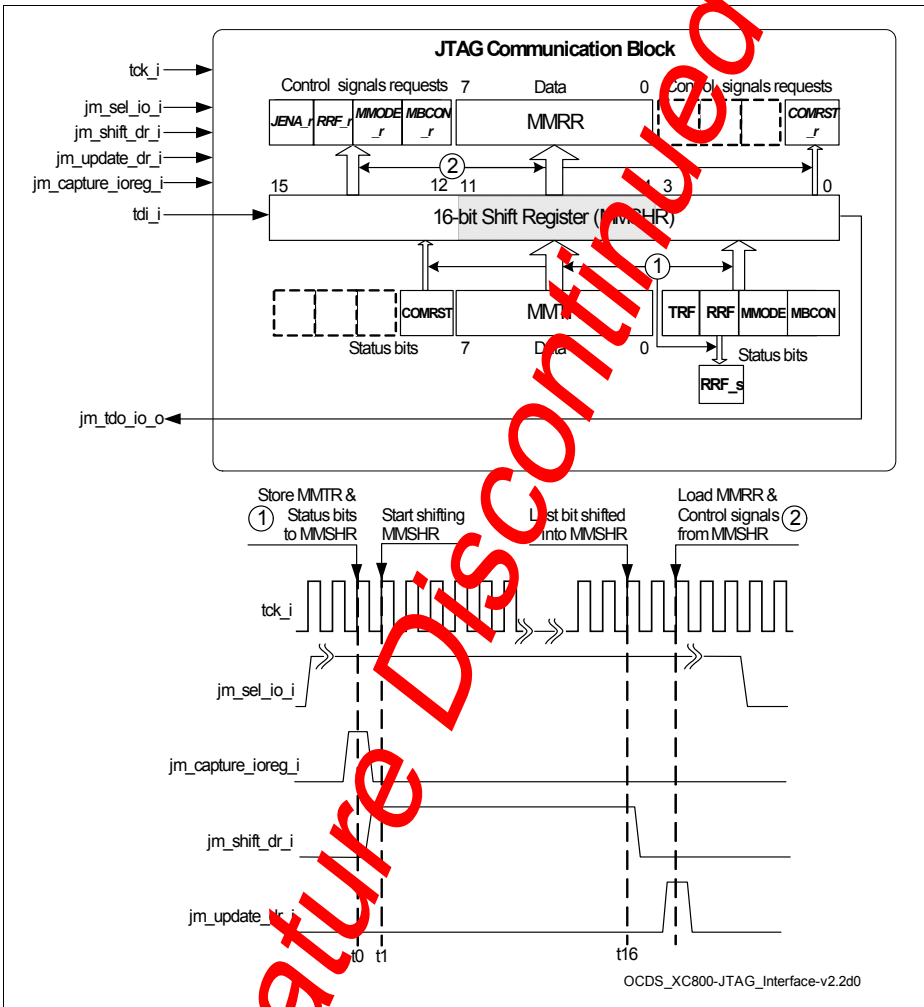

Figure 13-38 JTAG Communication: Structure and Signals

Attention: To keep backwards compatibility, the Debugger must always send only zero to the unused control bits - currently to MMSHR[3:1].

13.8.6 Program Execution Control

The basic feature of the OCDS module is to switch the code executed between user software and the Monitor program.

13.8.6.1 Entering Monitor Mode

The OCDS can enter Monitor Mode **only** when MMODE=0 and MBCON=0 within the MMCR2 register.

Main steps performed upon Monitor Entry:

1. some Debug-event happens, recognized by OCDS
2. OCDS activates a request to the XC800 core
At the same time:
 - a) MMCR.MRAMS is set to 1, to select Monitor RAM
 - b) MMCR2.MMODE is set to 1, to mark entering the Monitor Mode
3. the core starts fetching
4. MMCR2.MMEP is set to '1', signaling the Monitor is entered.

Functions supported by the first Monitor-instructions:

- save current (user) PSW and Accumulator into Monitor RAM, which is already selected by MMODE & MRAMS
- save current SYSCON0 into Monitor RAM, to prevent the user value of RMAP control bit
- set SYSCON0.RMAP to '0' allowing access to standard SFRs

Note: The core registers like SP, IE, PSW and MEX1 are accessed in both SFR spaces.

- save the Page of SCU-SFRs currently in use
- save user IE register into Monitor RAM and disable all maskable interrupts
- save current (user) Stack Pointer into Monitor RAM
- initiate the Stack to a dedicated area into Monitor RAM
- select (in Manual Page Mode) Page 0 from SCU-SFRs

Note: In case and where applicable furthermore inside the Monitor relevant PAGE-bitfields are properly controlled to access all Pages of SFRs.

- store the Break-address into dedicated Monitor RAM locations.

The Break-address will be used furthermore to determine the Return-address to User Program - if not explicitly set by the Debugger.

Note:

Feature Discontinued

13.8.6.2 Exiting Monitor Mode

For exiting Monitor Mode and returning to the User Program:

1. the Monitor sets MMCR.MEXIT to 1, while at the same time MMCR2.MMODE=1
OCDS activates a request to the XC800 core
2. the core enters Debug Mode executing the last Monitor instructions
3. MMCR2.MMODE and MMCR.MRAMS are reset by OCDS
4. MMCR.MEXIT is reset by OCDS
5. the core runs in normal mode, the system is back in User Mode.

The last Monitor instructions are doing the following.

- restore the basic core-status as saved when Entering Monitor Mode
 - interrupt enable register within the core
 - user Page of SCU-SFRs
 - SYSCON0 register (RMAP is here)
 - user Accumulator, PSW and Stack Pointer
- prepare the user MEX1 register at the top of Memory Extension Stack (has effect only in devices with Memory Extension)
- prepare the return-address on the top of stack

Note: Have in mind, the stack is still in Monitor RAM, with A7 and A6 ignored for addressing.

Feature Discontinued

13.8.6.3 Single Step Execution

In case Single Step Execution is requested, the Monitor sets MMCR.MSTEP=1 before to proceed with Exiting Monitor Mode. After executing the steps above described, the further OCDS functionality is as follows:

- the core ends current instruction - the first from user-program
- the core signals Entering Debug Mode
this is recognized as a new Debug Event - see step 1 from the sequence when Entering Monitor Mode ([Section 13.8.6.1](#)).

When the monitor mode is exited for a single step execution (with MMCR.MSTEP=1), the recognition of all breakpoints is temporary blocked by OCDS hardware to assure a correct stepping.

After (re-)entering Monitor mode, MMCR.MSTEP must be checked by the firmware to identify the single-stepping performed, and in case the return-address must be calculated accordingly (refer to [Section 13.8.9.1](#)).

Note: Single Stepping is not possible inside a MMI-servicing routine. For more information refer to [Section 13.8.11](#).

13.8.7 Breakpoint Generation Module

Breakpoint generation is only possible in Monitor Mode when MMODE=0 within the MMCR2 register.

Attention: To be able to debug via Monitor Mode, the application software should not change the TRAP_EN bit within Extended Operation (EO) register.

Attention: Upon MBCON=1 the Monitor Mode is not entered as well as no Break Flags are set into MMSR register.

Breakpoints can be classified into three types:

- Break Before Make
The break happens just before the break instruction (i.e. the instruction causing the break) is executed. Therefore, the break instruction itself will be the next instruction from the user program flow but executed only after the relevant debug action has been taken.
- Break After Make
The break happens immediately after the instruction causing it has been executed. Therefore, the break instruction itself has already been executed when the relevant debug action is taken.
- Break Now
The events of this type are asynchronous to the code execution inside the TC2x_SCR and there is no "instruction causing the debug event" in this case. The debug action is performed by OCDS "as soon as possible" once the debug event is raised.

13.8.7.1 Generating Hardware Breakpoints

This block is built around a set of comparators, dedicated to recognize two types of hardware breakpoints:

Breakpoints on Instruction Address

These IP breakpoints are generated, only when the BP-address is matched for the first byte of an instruction - i.e. just for the opcode. In case of 2- and 3- byte instructions, the break will not be generated at all for addresses of the second and third instruction-bytes.

The IP breakpoints are of Break Before Make type, therefore the instruction at the breakpoint is executed only after the proper debug action is taken.

The processing goes as follows:

1. break conditions are met
2. forces a TRAP-code $A5_H$ to be supplied to the Core, instead of a Byte currently addressed within the Program Memory

Address Comparators, Control bits and Flags

Below the comparators used for IP Breakpoints are described, together with control bits HWBxC and respective flags HWBxF:

- **CMPO**

A 16-bit comparator between the two **HWBP0** registers (A-side) and the 16-bit Program Memory Address Bus (B-side).

Two output signals are generated:

- A=B - sets HWB0F if HWB0C=01 (break on IP= **HWBP0**)
- A<B - see below.

- **CMP1**

A 16-bit comparator between the two **HWBP1** registers (A-side) and the 16-bit Program Memory Address Bus (B-side).

Two output signals are generated:

- A=B - sets HWB1F if HWB1C=1 (break on IP= **HWBP1**)
- A>=B when activated together with A<=B from CMP0 - sets HWB0F if HWB0C=11 (break on **HWBP0** =<IP=> **HWBP1**)

- **CMPIP2**

A 16-bit comparator between the two **HWBP2** registers (A-side) and the 16-bit Program Memory Address Bus (B-side).

One output signal is generated:

- A=B - sets HWB2F if HWB2C=10 (break on IP = **HWBP2**)

- **CMPIP3**

A 16-bit comparator between the two **HWBP3** registers (A-side) and the 16-bit Program Memory Address Bus (B-side).

One output signal is generated:

- A=B - sets HWB3F if HWB3C=10 (break on IP = **HWBP3**)

Table 13-30 MMBPCR [2:0]: Configuring Hardware Breakpoints 0 and 1

HWB1C	HWB0C	Break Event	Flag to set
0	00	no	---
x	01	Program Memory Address = HWBP0	HWB0F
1	xx	Program Memory Address = HWBP1	HWB1F
0	11	HWBP0 =< Program Memory Address =< HWBP1	HWB0F

Breakpoints on Internal RAM Address

These Internal RAM (IRAM) Breakpoints are recognized primary by observing the Internal Data Memory Address Buses `SOURCE_A[7:0]` and `DESTIN_A[7:0]`, respectively for Breakpoints on Read and Write addresses respectively.

The IRAM breakpoints are of Break After Make type, therefore the proper debug action is taken immediately after the operation to the breakpoint address is performed.

The OCDS supports only range breakpoints on IRAM address.

The OCDS differentiates between a breakpoint on read and a breakpoint on write operation to the IRAM.

The conditions to have a Memory Access (IRAM) Breakpoint are:

- `SOURCE_A / DESTIN_A` matches some Compare Address `HWBPxx`, **and**
- the relevant control signals are active showing a valid Read/Write operation, **and**
- the respective control field `HWBxC` is properly programmed.

The exact processing is different in case of Read and Write Breakpoints.

Break on IRAM read

The functionality is as follows:

1. the read address `SOURCE_A` matches a configured Compare Address `HWBPxx` and the respective control field `HWBxC` is set to 1
2. the Preliminary Condition - having an address-match AND `NSOURCE_RE_SGNF=0` (active low) - is registered
3. the very last clock cycle (CLP2) of the instruction reading from IRAM is executed
 - a) the respective `HWBxF` flag is set within MMSR status-register
4. Follow on:
 - a) a TRAP-code `A5H` is supplied to the Core via `PROGDI[7:0]` instead of a Byte currently addressed within the Program Memory
 - b) the registration of the Preliminary Condition is cleared.
5. This is recognized by OCDS as a Break-event (**B**), and the processing continues as described in [Section 13.8.6.1](#).

Break on IRAM write

The functionality is as follows:

1. the write address DESTIN_A matches a configured Compare address HWBPxx and the respective control field HWBxC is set to 1
2. the Preliminary Condition - having an address-match AND !DESTIN_WE=0 (active low) - is registered
3. the very last clock cycle (CLP2) of the instruction accessing the IRAM is executed
 - a) the respective HWBxF flag is set within MMSR status-register
4. Follow on:
 - a) a TRAP-code A5_H is supplied to the Core via PROGDI[7:0] instead of a Byte currently addressed within the Program Memory
 - b) the registration of the Preliminary Condition is cleared.
5. This is recognized by OCDS as a Break-event (BR), and the processing continues as described in [Section 13.8.6.1](#).

Address Comparators, Control bits and Flags

Below the comparators used for Memory Access Breakpoints are described, together with control bits HWBxC and respective flags HWBxF:

- **CMPRL2, CMPRH2**

Two 8-bit comparators:

- CMPRL2 - between HWBP2L register (A-side) and the 8-bit IRAM Source Address Bus (B-side), generating $A < B$.
- CMPRH2 - between HWBP2H register (A-side) and the 8-bit IRAM Source Address Bus (B-side), generating $A = B$.

Then:

HWB2F is set if $HWB2C = 01$,
i.e. break on $HWBP2L = \text{IRAM Read Address} \leq HWBP2H$.

- **CMPWL3, CMPWH3**

Two 8-bit comparators:

- CMPWL3 - between HWBP3L register (A-side) and the 8-bit IRAM Destination Address Bus (B-side), generating $A < B$;
- CMPWH3 - between HWBP3H register (A-side) and the 8-bit IRAM Destination Address Bus (B-side), generating $A \geq B$. Then:

HWB3F is set if $HWB3C = 01$,
i.e. break on $HWBP3L \leq \text{IRAM Write Address} \leq HWBP3H$.

Tracing changes in Break Address

The mechanism to generate Hardware Breakpoints assures, that "immediately" upon a break-condition match, the XC800 core is forced to Debug Mode. The Program Counter freezes then at a value, related to the address of instruction that would have been fetched, had the core not been in Debug Mode. This PC-value upon Monitor Mode Entry

is saved as "Break Address" and used later for [Calculating the Return Address](#) (refer to [Section 13.8.9.1](#)).

In fact, a TRAP-opcode is provided to the core instead of the next instruction from the user software-flow. In case of an IP breakpoint, this TRAP replaces just the instruction at the breakpoint and therefore the address saved is clearly connected to the address of the Break itself.

The functionality of MMICR.DVECT is as follows:

1. a shadow register is reset at the end of every instruction
 Upon an IRAM breakpoint, the TRAP comes **next** after the instruction causing the Break (break-instruction). The break-instruction itself can be an branch-instruction, performing also an IRAM-access (like CJNE, DJNZ). If so, before entering Monitor Mode the PC will be already in case updated with the branch-address. Further, the Break Address will be saved and its value will reflect properly where from the user program must continue later on (Return Address). But from the address saved in such a situation, the address where the Break Event (IRAM access) has happened **can not** be determined.
 MMICR.DVECT bit supports recognition of such situations. The core activates this signal upon any discontinuity in the program flow - when a branch instruction is executed.
2. any activation of DebugVector immediately sets the shadow register
3. an IRAM Breakpoint is recognized - the Preliminary Condition is registered, a TRAP is forced to the core; then the MMICR.DVECT bit is set to 1.

When entered, the Monitor will determine the source of the Break (flags in MMICR), and in case of Breakpoints 2 and 3 (marked by HWB2F and HWB3F respectively) - check either the respective BP has been configured as IRAM (control bits HWB2C and HWB3C in MMBPCR). If yes - the Monitor will check DVECT next and relevant information is to be forwarded to the Debugger, concerning the Break Event source (IRAM read/write):

- when DVECT=0 - the Break Event has been caused by the instruction preceding the Return Address (calculated in accordance to [Section 13.8.9.1](#))
- when DVECT=1 - the instruction causing the Break Event can not be determined.

Note: After evaluating DVECT, the Monitor must take care to reset it before returning to User Mode.

Feature Discontinued

13.8.7.2 Processing External Breaks

Possible external break-requests are generated and processed as follows:

1. a request comes from one of the possible source(s)
 - a) Debugger-request via DAP SPD - a dedicated command has been sent, with **MMODE_r=1**, **RRF_r=0** and data-Byte=A5_H, while at the same time: **MMCR2.MMODE=0** and **MMCR2.ALTDI=0**
2. a Break request is activated high to the core
 - a) OCDS sets **MMSR.EXBF** flag upon any accepted external break request
3. during the next few SCLK cycles the core ends executing current instruction, the core enters Debug Mode and activates Debug Ack. This is recognized by OCDS as a Break-event, and the processing continues as described in [Section 13.8.6.1](#).

Note: External Breaks are not possible inside a NM₀ servicing routine.

For more information refer to [Section 13.8.1](#).

Feature Discontinued

13.8.7.3 Processing Software Breakpoints

Software breakpoints are of Break Before Make type, therefore the instruction at the breakpoint is executed only after the proper debug action is taken.

Upon fetching a TRAP instruction, Software Breakpoint is effected. Due to this, it goes to Debug Mode.

Attention: The user software must not clear the TRAP_EN bit in EO register.

The OCDS reacts in two ways:

- a Break event is recognized for Entering Monitor Mode
This happens when:
(MMCR2.MMODE=0) and (MMBPCR.SWBC=1 or MMCR.MSTEP=1)
i.e. when Software Breakpoints are enabled or a Single Step has been executed.
The further processing is as described in [Section 13.8.6.1](#).
- the Software Break is ignored
This happens when the above condition is not satisfied, i.e. basically when the Software Breakpoints are disabled with MMBPCR.SWBC=0.

Upon matching a not enabled Software Breakpoint, the user software execution is suppressed for 4 clock cycles after the TRAP instruction.

Note: In order to continue user program execution after the debug event, an external Debugger must restore the original PC value at the address of the current software breakpoint.

13.8.8 Reactions on Breakpoints without Monitor Entry

In case a Break-event happens while Monitor Mode is disabled:

(MMCR2.MBCON=1) AND (MMCR2.MMODE=0)

, the Monitor program is not started (MM_no_entry) but another action is triggered by OCDS system.

13.8.8.1 Triggering a NMI request

Instead of starting the Monitor program, OCDS NMI is requested, refer [Section 13.8.10.1](#).

The flags FNMIRR/FNMIRW here set can be cleared only per software - this must be done by the user NMI-responding routine.

13.8.9 Important Notes about Break Event Processing

A few specifics must be taken into account - especially by tool vendors - when using XC800 OCDS.

13.8.9.1 Calculating the Return Address

Here two values are considered:

- the **Break Address** - the address saved while **Entering Monitor Mode**, refer to [Section 13.8.6.1](#);
- the **Return Address** - the address where from the user program will continue upon Monitor Exit, i.e. the address of the first instruction executed when back in User Mode.

The relationship between the both addresses depends on the type of event which has caused the Break. This type is to be determined by:

- Breakpoint Configuration - as programmed within MMBPCR register,
- Breakpoint Flags - as set by OCDS-hardware within the MMSR register.

The behavior required in different scenarios is described below:

1. in case of **Hardware Breakpoints** (refer to [Section 13.8.7.1](#)):
Return Address = Break Address - 2
2. in case of **External Breaks** and **Single Step Execution** (refer to [Section 13.8.7.2](#) and [Section 13.8.6.3](#)):
Return Address = Break Address - 1

3. in case of **Software Breakpoints** (refer to [Section 13.8.7.3](#))
both the above equations are applicable in the following sense:

- a) if take Return Address = Break Address - 2
this will cause upon Monitor exit an instruction to be fetched again from the same address where the Software BP has been raised - i.e. where the TRAP has been fetched from.

Therefore, if the TRAP has not been replaced by another opcode during the Monitor Mode, this will lead immediately to a new Software Break and again to Monitor entry, with no user instruction executed in between.

- b) if take Return Address = Break Address - 1
this will cause upon Monitor exit the next instruction to be fetched from the location immediately following the address where the Software BP has been matched - i.e. the next instruction after the TRAP.

Therefore, such an address-calculation is applicable when the Software BPs - i.e. the TRAPs - stay continuously within the code debugged but not dynamically swapped with user instructions.

The Return Address is also related in general to the point where a Debug Event has happened:

- upon **Breakpoints on Instruction Address** and Software Breakpoints, the events are of type "Break Before Make".

In this case the Return Address targets just the instruction which has caused the Break, and this instruction will be only executed after returning to User Mode.

- upon **Breakpoints on Internal RAM Address** the events are of type "Break After Make", i.e. the user program execution is broken only after the IRAM access configured as a breakpoint has been performed.
In this case the Return Address again targets the next instruction to be executed after returning to user mode, but the instruction which has caused the Break can be only determined, if MMICR.DVECT=0 upon monitor entry (refer to **Section**).
- the External Breaks are anyway asynchronous events - not caused by execution of an instruction.
Therefore, the only needed in this case is to have a correct continuity of the program-flow - this is assured by the Return Address properly calculated as shown above.

Feature Discontinued

13.8.9.2 Specific Behavior while XC800 is in Debug Mode

Upon a recognized and enabled Break-event, the core is immediately put into Debug Mode. There are two possibilities about the further processing:

- Monitor is to be entered
- No Monitor-Mode

The scenarios considered:

- If available, MBC pin only must be activated (MMCP2.MBCON=1),
- a TRAP-instruction is fetched from the user-code but Software Breakpoints are disabled (MMBPCR.SWBC=0).

In both these cases, the core is put into Debug Mode for 4 SCLK cycles, then released to continue user-code execution.

During these 4 SCLK cycles, **any other Break-request will be ignored** by OCDS.

In fact, only an **External Break** is possible meanwhile, as far as XC800 is in Debug Mode and all its activity is suppressed now.

Feature Discontinued

13.8.10 NMI Request and Control by OCDS

The OCDS module provides hardware allowing to generate a NMI, request itself as well as to control the general NMI-processing within the XC800 system.

13.8.10.1 NMI request from OCDS

The OCDS generates one interrupt request at the output `ocds_nmi_o`. This signal goes to the Interrupt-Management Module into XC800 SCU (System Control Unit), where it sets a flag within NMI Status Register NMISR. In case OCDS is an enabled source in NMI Control Register NMICON, a non-maskable interrupt request will be activated to the core.

The NMI-request can be activated by OCDS upon memory access performed to defined address areas (separately configurable for read/write operations) in XC800 Internal RAM. This is an advanced and fully controllable by application code feature, allowing to utilize parts of OCDS not for debugging but to support a general, user-accessible functionality.

The basics for implementation of this feature are:

- the Breakpoint Generation module is able to recognize read/write accesses to IRAM address-ranges (refer to [Section](#))
- upon a breakpoint match but while MMCR2.MBCON=1, the Monitor firmware is not started and therefore in fact no debug-session takes place.

Note: It is required to set the EO.TRAP_EN bit to enable the breakpoint generation.

To configure, trigger and handle an OCDS NMI request upon IRAM access (refer also to [Section 13.8.8.1](#)):

1. at all is possible only as long as MMCR2.MBCON=1
2. user software must execute the following sequence:
 - a) set the NMI-enable bit(s) NMIRRE/NMIRWE in MMICR, respectively for request upon IRAM read/write
 - b) write the low address(es) of the observed area into HWBP2L/HWBWP3L, respectively for NMI-request upon IRAM read/write
 - c) write the high address(es) of the observed area into HWBP2H/HWBWP3H, respectively for NMI-request upon IRAM read/write
3. after the settings according to point 2) are done and as long as MBCON=1, a NMI-request will be triggered by the OCDS upon an access to the respectively configured (for read/write) IRAM area(s).
4. in case a NMI-request has been raised by the OCDS, respective flag FNMIRR/FNMIRW is set in MMICR - refer to the register-description in [Section 13.8.8.1](#) and functional definition in [Section 13.8.8.1](#).

If the request is sent to the core - in case enabled by NMICON.NMIOCD=1 (in SCU) - then a NMI-servicing routine will be invoked by a jump to its standard location in XC800 Program Memory, and this routine:

- a) can identify OCDS as NMI-requesting source and the type of IRAM-access causing the request by evaluating NMISSR.FNMIOOCS (in SCU) and MMICR.FNMIRR/FNMIRW (in OCDS)
 - b) must clear FNMIRR/FNMIRW flags before its end, to allow a proper reaction on next NMIs.
5. any attempt to configure/activate a Breakpoint for debugging by writing into MMBPCR will reset the internal nmi_*e/nmi_*e_l flags and therefore - disable the generation of NMI-request upon IRAM access.

Attention: all the software-handling of OCDS NMI (servicing routine) is to be supported by user code!

13.8.10.2 OCDS NMI Service Routine Handling

For the correct HW behavior when the OCDS NMI is triggered due to IRAM read/write access, special handling is necessary in OCDS nmi service routine to set up a correct RETI address.

The recommended code handling is:

```

NMI_OCDS_MAIN: ;OCDS NMI service routine
    POP RETADD_H ;get the return address stored in SP
    POP RETADD_L
    ;/--user code to handle the OCDS NMI---//
    ;// USER CODE BEGIN
    ...
    ;// USER CODE END
    MOV A,RETADD_L
    CJNE A,#00H,DEC_LOW_BYTE ;low address byte under-flow?
    DEC RETADD_H
DEC_LOW_BYTE:
    DEC RETADD_L ;decrement return address by one location
    PUSH RETADD_L ;store the correct return address back to SP
    PUSH RETADD_H
    RETI
    
```

13.8.10.3 General NMI Control by OCDS

The controls are aimed to support a correct NMI-related behavior:

- all the pending NMI requests raised before Monitor Mode entry and as long as the system is in Monitor Mode will be not affected, i.e. these requests are safely kept and sent to the core when the system returns to User Mode

13.8.11 NMI-mode priority over Debug-mode

While the core is in NMI-mode (after an NMI-request has been accepted and before the RETI instruction is executed, i.e. the time during a NMI-servicing routine), certain debug functions are blocked/restricted:

1. No external break (refer to [Section 13.8.7.2](#)) is possible while the core is servicing a NMI.
External break requested inside a NMI-servicing routine will be taken only after RETI is executed.
2. A breakpoint into NMI-servicing routine is taken, but single stepping (refer to [Section 13.8.6.3](#)) is not possible afterwards.
If a step is requested, the servicing routine will run continuously and monitor mode will be invoked again only after a RETI is executed.

Hardware breakpoints and software breakpoints proceed as normal while CPU is in NMI-mode.

Feature Discontinued

13.8.12 Registers Description

The OCDS Special Function Registers are accessed from the mapped SFR area. [Table 13-31](#) lists the (direct addressable) SFRs and corresponding address.

Table 13-31 Register Map (Direct Addressable)

Address	Register
F1 _H	MMCR
F2 _H	MMSR
F3 _H	MMBPCR ⁽¹⁾
F4 _H	MMICR
E9 _H	MMCR ⁽¹⁾
F5 _H	MMDR
F6 _H	HWBPSR
F7 _H	HWBPDR ⁽¹⁾
EB _H	MMWR ⁽¹⁾
EC _H	MMVR2

1) The whole register or some of the bits are writable by software only in Monitor and Startup Mode, i.e. upon MMCR2.MMODE=1 OR MMCR2.STMODE=1 (marked also within the register description).

Additionally, there are Hardware Breakpoint Registers, which are indirect accessible via HWBPSR (register select) and HWBPDR (data) - refer to [Table 13-32](#) and [Table 13-33](#) (for more information look at [Section 13.8.12](#)).

Table 13-32 Hardware Breakpoint Registers (Indirect Accessed)

Register	Description
HWBP0L	Hardware Breakpoint 0 Low Register
HWBP0H	Hardware Breakpoint 0 High Register
HWBP1L	Hardware Breakpoint 1 Low Register
HWBP1H	Hardware Breakpoint 1 High Register
HWBP2L	Hardware Breakpoint 2 Low Register
HWBP2H	Hardware Breakpoint 2 High Register
HWBP3L	Hardware Breakpoint 3 Low Register
HWBP3H	Hardware Breakpoint 3 High Register

Table 13-33 HWBPSR [3:0]: Selecting Hardware Breakpoint Registers

BPSEL	Register Selected	BPSEL	Register Selected
0xxx	reserved - no selection		
1000	HWBP0L	1001	HWBP0H
1010	HWBP1L	1011	HWBP1H
1100	HWBP2L	1101	HWBP2H
1110	HWBP3L	1111	HWBP3H

The OCDS registers are exclusively dedicated to the on-chip Monitor program and the user should not write into them. Most of the OCDS registers or separate bits/fields are protected and can not be written by user software but only by the firmware in two modes of XC800:

- Startup mode (STMODE) - while the Bootcode is executed after reset, the user code is still not started
- Monitor mode (MMODE) - while the Monitor program is running, the user code is in break.

Therefore an unintentional access to OCDS registers by the user software cannot disturb the normal debug functionality.

Note about the bits modified both by HW and SW

- Here considered are the bits marked as (r)wh within the register descriptions below:
 - **the rule** is: if both the OCDS hardware and the software are accessing to set the same bit, the hardware has priority
 - **one exception** is the MMCF2MICON bit, where the software-access has priority

Note: Apart from the above, the implementation takes care: if a bit is modified by hardware during the execution of a read-modify-write instruction, the new value set by HW is not affected by the SW write-back operation.

Feature Discontinued

13.8.12.1 Control and Status Registers

MMCR

Monitor Mode Control Register (F1_H)

1) Writable by software only in Monitor and Startup Mode, i.e. upon MMCR2.MMODE=1 OR MMCR2.STMODE=1.

RRF bit:

-set via the debug interface (refer to [Section 13.8.5](#))

-reset upon reading MMRR by XC800

TRF bit:

-set upon writing MMTR by XC800

-reset upon writing MMTR to MMSHR (refer to [Section 13.8.6.1](#))

MRAMS bit:

-set upon Monitor-entry (refer to [Section 13.8.6.1](#))

-changeable by software (Monitor, Boot code)

MEXIT bit:

-set by software (the Monitor) only

-reset by OCDS-hardware upon returning to the user-code (refer to [Section 13.8.6.2](#))

Field	Bits	Type	Description
DSUSP¹⁾	5	rw	Debug-Suspend signal activation in Monitor Mode 0 _B Disabled 1 _B Enabled
STMODE	7	r	Startup Mode 0 _B Disabled 1 _B Enabled

1) Writable by software only in Monitor and Startup Mode, i.e. upon MMCR2.MMODE=1 OR MMCR2.STMODE=1.

JENA bit:

- reset by OCDS-reset
- can be set via the JTAG/DAP/SPD interface (refer to [Section 13.8.5](#))

MMODE bit:

- changeable by OCDS-hardware only
- main control bit reflecting the overall debug functionality
- controls directly the wdt_susp_o signal to the System Control Unit, which signal disables the Watchdog Timer while in Monitor Mode (refer to [Section 13.8.11](#))

MMEP bit:

- reset by CPU-reset
- set upon Monitor-entry (refer to [Section 13.8.6.1](#))
- software can only reset it

MBCON bit:

- changeable by software
- can be set/reset via the JTAG/DAP/SPD interface (refer to [Section 13.8.5](#))

DSUSP bit:

- set to 1 after device reset - supported modules are suspended by default during a debug-break.

For additional information on this functionality, refer to the System Control Unit Chapter of product documentation.

STMODE bit:

- set by any system Reset
- software can only reset it

This bit is reset by the startup software of the device.

COMRST	5	rwh	Communication-protocol Restart requested
DVECT	7	rwh	DebugVector signal latched

FNMIRR / FNMIRW bits:

-set by hardware in case of NMI request from OCDS activated upon read/write access to the Internal RAM (refer to [Section 13.8.8.1](#) and [Section 13.8.10.1](#))

-the software can only reset these bits

MSTSEL bit:

-set and reset by hardware only, directly following the current value of `mm_start_sel_i` input

-the software can only read it

This bit is used to determine the running Memory Scheme, in particular - by the Monitor program upon [Entering Monitor Mode](#) (refer to instruction sequences in [Section 13.8.6.1](#)).

COMRST bit:

-set by hardware

-reset by software only; the software can only reset it but not set

The bit is used to synchronize the communication protocol between the on-chip Monitor and the host Debugger. This will be needed, if some error happens and/or the data-flow can not be correctly recognized. In such a case:

-the Debugger sends a dedicated command to set COMRST=1

-the Monitor polls COMRST before starting any JTAG/DAP/SPD-transaction, i.e. together with checking RRF. Upon COMRST=1 the Monitor resets it and "resets itself" - i.e. jumps to the beginning of JTAG/DAP/SPD communication protocol (waiting for the first transaction).

DVECT bit:

-can be set by hardware only (refer to [Section](#))

-reset by software only; the software can only reset it but not set

Feature Discontinued

13.8.12.2 Data Transfer Registers

What considers the addressing, only one data-register (MMDR) is to be accessed. The real operations are performed as follows:

- Read: from the JTAG/DAP/SPD Receive Data register MMRR,
- Write: to the JTAG/DAP/SPD Transmit Data register MMTR.

MMDR

Monitor Mode Data Register - Receive (F5_H)

13.9 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The TC2x_SCR has a maximum of 16 general purpose I/O ports with 8-bit peripheral I/O lines that are shared with the 32-bit peripherals I/O lines. It is organized into two parallel ports, Port 00 (SCR_P00) and Port 02 (SCR_P02). The pin assignment of these functions are shown in [Table 13-34](#).

Upon reset, the 32-bit Ports module has the full control of all the pads. During run mode, the control of these 16 pins can be switched to TC2x_SCR if necessary via the 32-bit Ports register Pn_PCSR. For P00.2 and P00.3, SPARE[NOB]0.PULL_CTRL needs to be configured in addition to Pn_PCSR, to enable pull-up and pull-down control by the 8-bit controller. During standby mode, the control of these ports will be based on the setting of register Pn_PCSR.SELx before the device enter standby mode. If the control is from the 32-bit controller during standby mode, the pad will stay in its default reset state based on the setting of PMSWCR0.TRISTREQ.

A separate set of pad control registers as shown in [Table 13-37](#) are available in TC2x_SCR to control these ports.

Table 13-34 Pin assignment for Ports in TC2x_SCR

TC2x_SCR Ports	TC2x Ports
SCR_P00.0 - SCR_P00.7	P00.0 - P00.7
SCR_P02.0 - SCR_P02.7	P02.0 - P02.7

13.9.1 Basic Port Operation

[Figure 13-39](#) is a general block diagram of a TC2x_SCR GPIO port slice.

Feature Discontinued

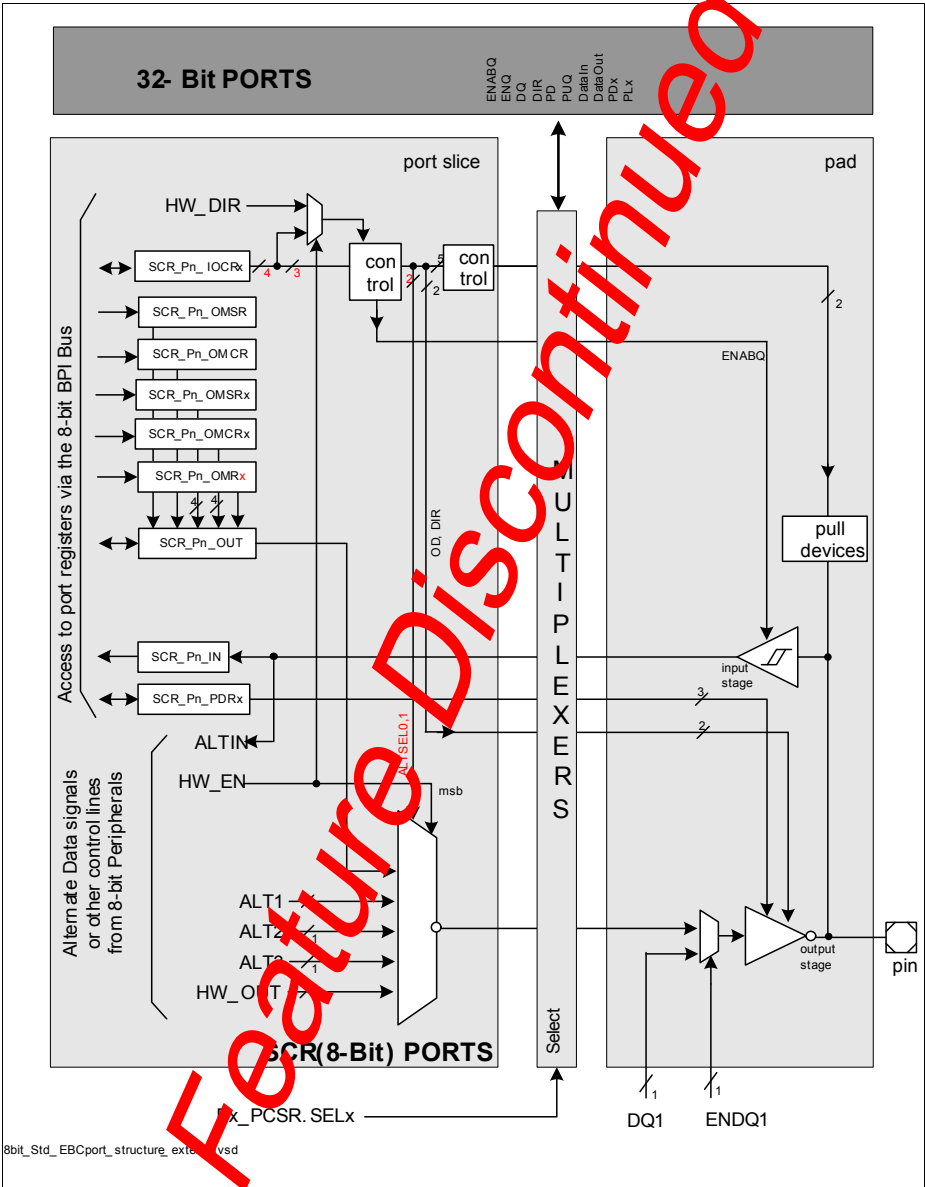

Figure 13-39 General Structure of a Port Pin

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register SCR_Pn_IN (n=00, 02). Input signals are connected directly to the various inputs of the peripheral units (AltDataIn). The function of the input line from the pin to the input register SCR_Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output.

This means that when the port is in output mode, the level of the pin can be read by software via SCR_Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the SCR_Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register SCR_Pn_IOCR has to be written for input or output selection. The SCR_Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as a general-purpose output, the multiplexer is switched by software (SCR_Pn_IOCR register) to the Output Data Register SCR_Pn_OUT. Software can set or clear the bit in SCR_Pn_OUT through separate SCR_Pn_OMSR or SCR_Pn_OMCR registers. The set or clear operations for the bits in SCR_Pn_OUT can also be done for up to four bits per register in SCR_Pn_OMSRx and SCR_Pn_OMCRx (x=0,4). Alternatively, the set, clear or toggle function can be achieved through SCR_Pn_OMR0 and SCR_Pn_OMR1, where adjacent pins within the same port can be set, cleared or toggled within one write operation. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register SCR_Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register SCR_Pn_OMSR, Output Modification Set Register x SCR_Pn_OMSRx (x=0,4), Output Modification Clear Register SCR_Pn_OMCR, Output Modification Clear Register x SCR_Pn_OMCRx (x=0,4) or Output Modification Register, OMR0/OMR_1. The bits in SCR_Pn_OMSR/SCR_Pn_OMSRx and SCR_Pn_OMCR/SCR_Pn_OMCRx make it possible to set and clear the bits in the SCR_Pn_OUT register. While the bits in SCR_Pn_OMR0/SCR_Pn_OMR1 allows the bits in SCR_Pn_OUT to be set, cleared, toggled or remain unchanged.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied through software via the output register SCR_Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register SCR_Pn_IN.

Feature Discontinued

13.9.2 Description Scheme for the Port IO Functions

The following two general building blocks can be used to describe each GPIO pin:

Table 13-35 Port x Input/Output Functions

Port Pin	I/O	Select	Connected Signal(s)	From / to Module
Px.y	Input		Signal(s)	module(s)
	Output	GPIO	Signal	module

	O	GPIO		Px_OUT.Py		1X000 _B
						1X001 _B
						1X010 _B
						1X011 _B
						1X100 _B
					1X101 _B	
					1X110 _B	
					1X111 _B	
HW_DIR		module; group En	Signal		HW_DIR	

- **HW_DIR:**
The type Alternate Direction signal which is needed if HW_En is active:
 - Out -always output
DIRx - the pins in one port having the same DIRx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_DIR signal.
SDIR- Single DIR- the pin is controlled by its own, dedicated, single HW_DIR signal.
- grouping indicates if the respective pin is controlled by hardware:
 - ENx - the pins in one port having the same ENx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_EN signal.
 - SEN - Single EN - the pin is controlled by its own, dedicated, single HW_EN signal
- Digital port slices with HW_DIR defined are the ports described in [Figure 13-39](#).

HW_DIR signal, output case, switches the pad to push-pull output state.

HW_DIR signal, input case, switches the pad to the input state with pull-up/down setting as defined by the PCR register.

13.9.3 Port Register Overview

The individual control and data bits of each parallel port are implemented in a number of 8-bit registers. Bits with the same meaning and function are assembled together in the same register. The registers configure and use the port as general purpose I/O or alternate function input/output. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described separately. The definition of these registers are similar to the 32-bit format.

Feature Discontinued

13.9.3.1 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-7).

For P00.2 and P00.3, pull-up and pull-down can be controlled by the 8-bit controller by setting SPAREINOUT0.PULL_CTRL (see [SPAREINOUT0](#) register).

Each 8-bit wide port input/output control register controls two GPIO port lines:

- Register SCR_Pn_IOCR0 controls the Pn.0 port lines
- Register SCR_Pn_IOCR1 controls the Pn.1 port lines
- Register SCR_Pn_IOCR2 controls the Pn.2 port lines
- Register SCR_Pn_IOCR3 controls the Pn.3 port lines
- Register SCR_Pn_IOCR4 controls the Pn.4 port lines
- Register SCR_Pn_IOCR5 controls the Pn.5 port lines
- Register SCR_Pn_IOCR6 controls the Pn.6 port lines
- Register SCR_Pn_IOCR7 controls the Pn.7 port lines

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

Note: The reset values of 10_H and 00_H for SCR_Pn_IOCRx registers represents input pull-up and no input pull device (tri-state mode) being activated, respectively. The switching of the intended mode of the device is controlled by HWCFG6. When a cold reset is activated and HWCFG6=1, the pins are set to input pull-up mode as long as PORST is activated. If HWCFG6=0, the pins have the default state of tri-state mode. The pad state can also be configured by software through PMSWCR0.TRISTREQ bit. In the event of a warm reset or wake-up from standby mode, PMSWCR0.TRISTREQ is not affected by reset, hence SCR_Pn_IOCRx registers have the reset values configured as per the last state of the TRISTREQ bit.

13.9.3.2 Pad Driver Mode Register

Overview

The pad structure of the TC26x_SCR GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the PDx bit fields in the pad driver mode registers SCR_Pn_PDRy (y=0, 2, 4, 6), independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. SCR_Pn_PDRy registers are assigned to each port.

The assignment of each port pin to one of these pad classes is shown in the port configuration figures. Further details about pad driver classes that are available in the TC26x B-Step are summarized in the Target Data Sheet/Data Sheet.

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDx in the pad driver mode registers SCR_Pn_PDRy make it possible to select the port line functionality as shown in [Table 13-40](#).

Table 13-40 Pad Driver Mode Selection

PDx.2	PDx.1	PDx.0	Functionality
X	0	0	Speed grade 1
X	0	1	Speed grade 2
X	1	0	Speed grade 3
X	1	1	Speed grade 4

Note: TC26x B-Step Data Sheet describes the DC characteristics of all pad classes.

Depending on whether it is 3.3V- or 5V-pad, the pad level is CMOS or automotive level, respectively. The TTL level can be enabled for both for 3.3V and 5V pads through the PLx bit in the SCR_Pn_PDRy. The coding is shown in [Table 13-41](#).

Table 13-41 Pad Level Selection

PLx	3.3V-Pad	5V-Pad
0	CMOS level	Automotive level
1	TTL level	TTL level

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDRy (y = 0, 2, 4, 6) registers, respectively. Each PDx field controls 1 pin. For coding of PDx, see [Table 13-40](#). Similarly, each PLx bit controls 1 pin. For coding of PLx, see [Table 13-41](#).

13.9.3.3 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by SCR_Pn_IOCRx as output. Writing a 0 to a SCR_Pn_OUT_Px (x = 0-7) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of SCR_Pn_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register SCR_Pn_OMSR or port output modification clear register SCR_Pn_OMCR, respectively. The SCR_Pn_OUT.Px bits can also be set, cleared or toggled with register SCR_Pn_OMR within the same write operation.

13.9.4 T2X_SCR functions in Port 00

This section describes the TC2X_SCR functions in Port 00.

13.9.4.1 T2X_SCR Port 00 Configuration

TC2X_SCR has functions in Port 00.0 - P00.7. It can be alternatively used for UART, WCAN, SSC, T0/T1, T2CCU and External Interrupt input and output functions.

13.9.4.2 Port 00 Function Table

Table 13-43 summarizes the TC2X_SCR I/O control selection functions of the 8 Port 00 lines.

Table 13-43 Port 00 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

13.10 Timer 0 and Timer 1

13.10.1 Overview

Timer 0 and Timer 1 can function as both timers or counters. When functioning as a timer, Timer 0 and Timer 1 are incremented every machine cycle, i.e. every 2 input clocks (or 2 PCLKs). When functioning as a counter, Timer 0 and Timer 1 are incremented in response to a 1-to-0 transition (falling edge) at their respective external input pins, T0 or T1.

They are useful in many timing applications such as measuring the time interval between events, counting events and generating signals at regular intervals. In particular, Timer 1 can be used as the baud-rate generator for the on-chip serial port.

Features:

- Four operational modes :
 - Mode 0: 13-bit timer/counter
 - Mode 1: 16-bit timer/counter
 - Mode 2: 8-bit timer/counter with auto-reload
 - Mode 3: Two 8-bit timers/counters

13.10.2 System Information

This section provides system information relevant to the Timer 0 and 1.

13.10.2.1 Pinning

Table 13-47 Timer 0 and Timer 1 Pin Functions

Pin	Function	Description	Selected By
P02.0	T1A	Timer 1 Input A	MODPISEL5.T1IS = 00 _B SCR_P02_IOCRO.PC0 = 0XX10 _B

P02.5	T0B	Timer 0 Input B	MODPISEL5.T0IS = 01 _B SCR_P02_IOC5R.PC5 = 0XX10 _B

Table 13-47 Timer 0 and Timer 1 Pin Functions (cont'd)

Pin	Function	Description	Selected By
P00.4	T1C	Timer 1 Input C	MODPISEL5.T1IS = 10 _B SCR_P00_00CR4.PC4 = 0XX10 _B
P00.5	T0C	Timer 0 Input C	MODPISEL5.T0IS = 10 _B SCR_P00_10CR5.PC5 = 0XX10 _B

The bit field PAGE of SCU_PAGE register must be programmed before accessing the MODPISEL5 register.

MODPISEL5
Peripheral Input Select Register 5 (F7_H)
Reset Value: 00_H
RMAP: 0, PAGE: 3

7	6	5	4	3	2	1	0
0			T0IS		T1IS		
r			rw		rw		

Field	Bits	Type	Description
T1IS	[1:0]	rw	Timer 1 Input Select 00 _B Timer 1 Input T1A is selected. 01 _B Timer 1 Input T1B is selected. 10 _B Timer 1 Input T1C is selected. 11 _B Reserved
T0IS	[3:2]	rw	Timer 0 Input Select 00 _B Timer 0 Input T0A is selected. 01 _B Timer 0 Input T0B is selected. 10 _B Timer 0 Input T0C is selected. 11 _B Reserved
0	[7:4]		Reserved Returns 0 if read; should be written with 0.

13.10.2.2 Clocking Configuration

The Timer 0 and 1 runs on the PCLK.

13.10.2.3 Interrupt Events and Assignment

Table 13-48 lists the interrupt event sources from the Timer 0 and 1, and the interrupt node assignment for each Timer 0 and 1 interrupt source.

Table 13-48 Timer 0 and 1 Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
Timer 0 Overflow	IEN0.ET0	TCON.TF0	0BH
Timer 1 Overflow	IEN0.ET1	TCON.TF1	1BH

13.10.3 Basic Timer Operations

The operations of the two timers are controlled using the Special Function Registers (SFRs) TCON and TMOD. To enable a timer, i.e., allow the timer to run, its control bit TCON.TRx is set. To select the timer input to be either from internal system clock or external pin, the input selector bit TMOD is used.

Note: The "x" (e.g., TCON.TRx) in this chapter denotes either 0 or 1.

Each timer consists of two 8-bit registers, TLx (low byte) and THx (high byte) which defaults to 00_H on reset. Setting or clearing TCON.TRx does not affect the timer registers.

Timer Overflow

When a timer overflow occurs, the timer overflow flag, TCON.TFx, is set, and an interrupt may be raised if the interrupt enable control bit, IEN0.ETx, is set. The overflow flag is automatically cleared when the interrupt service routine is entered.

When Timer 0 operates in mode 3, the Timer 1 control bits, TR1, TF1 and ET1 are reserved for TH0, see [Section 13.10.4.4](#).

External Control

In addition to pure software control, the timers can also be enabled or disabled through external port control. When external port control is used, SFR EXICON0 must first be configured to bypass the edge detection circuitry for EXINTx to allow direct feed-through. When the timer is enabled (TCON.TRx = 1) and TMOD.GATEx is set, the respective timer will only run if the corresponding external interrupt EXINTx = 1. This facilitates pulse width measurements. However, this is not applicable for Timer 1 in mode 3.

If TMOD.GATEx is cleared, the timer reverts to pure software control.

13.10.4 Timer Modes

Timers 0 and 1 are fully compatible and can be configured in four different operating modes, as shown in [Table 13-49](#). The bit field TxM in register TMOD selects the operating mode to be used for each timer.

In modes 0, 1 and 2, the two timers operate independently, but in mode 3, their functions are specialized.

Table 13-49 Timer 0 and Timer 1 Modes

Mode	Operation
0	13-bit timer/counter The timer is essentially an 8-bit counter with a divide-by-32 prescaler. This mode is included solely for compatibility with Intel 8048 devices.
1	16-bit timer/counter The timer registers, TLx and THx, are concatenated to form a 16-bit timer/counter.
2	8-bit timer/counter with auto-reload The timer register TLx is reloaded with a user-defined 8-bit value in THx upon overflow.
3	Timer 0 operates as two 8-bit timers/counters The timer registers, TL0 and TH0, operate as two separate 8-bit counters. Timer 1 is halted and retains its count even if enabled.

Feature Discontinued

13.10.4.1 Mode 0

Putting either Timer 0 or Timer 1 into mode 0 configures it as an 8-bit timer/counter with a divide-by-32 prescaler. **Figure 13-40** shows the mode 0 operation.

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1s to all 0s, it sets the timer overflow flag TFX. The overflow flag TFX can then be used to request an interrupt. The counted input is enabled for the timer when TRx = 1 and either GATEx = 0 or EXINTx = 1 (setting GATEx = 1 allows the timer to be controlled by external input EXINTx to facilitate pulse width measurements). TRx is a control bit in the register TCON; bit GATEx is in register TMOD.

The 13-bit register consists of all the 8 bits of THx and the lower 5 bits of TLx. The upper 3 bits of TLx are indeterminate and should be ignored. Setting the run flag (TRx) does not clear the registers..

Mode 0 operation is the same for Timer 0 and Timer 1.

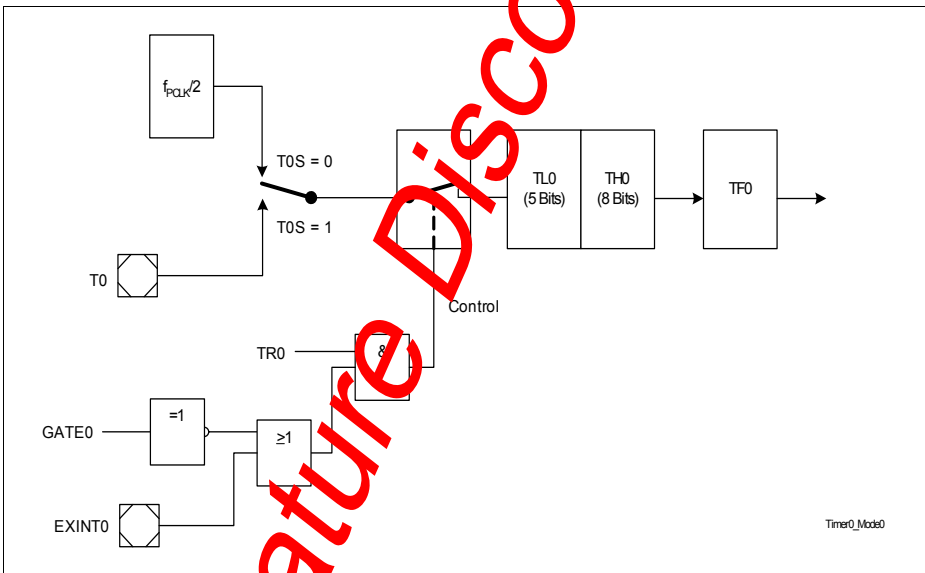

Figure 13-40 Timer 0, Mode 0: 13-Bit Timer/Counter

13.10.4.2 Mode 1

Mode 1 operation is similar to that of mode 0, except that the timer register runs with all 16 bits. Mode 1 operation for Timer 0 is shown in [Figure 13-41](#).

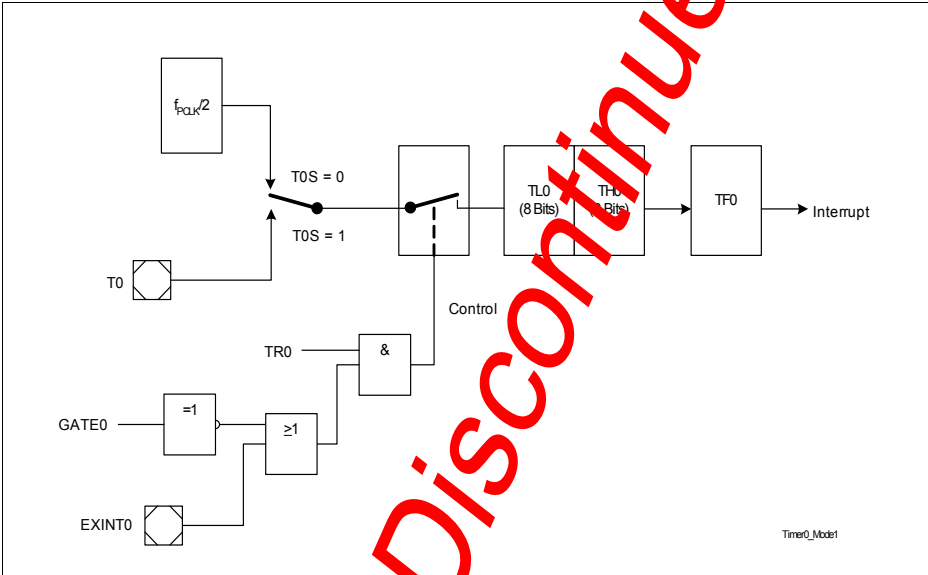

Figure 13-41 Timer 0, Mode 1: 16-Bit Timer/Counter

13.10.4.3 Mode 2

In Mode 2 operation, the timer is configured as an 8-bit counter (TLx) with automatic reload, as shown in **Figure 13-42** for Timer 0.

An overflow from TLx not only sets TFx, but also reloads TLx with the contents of THx that has been preset by software. The reload leaves THx unchanged.

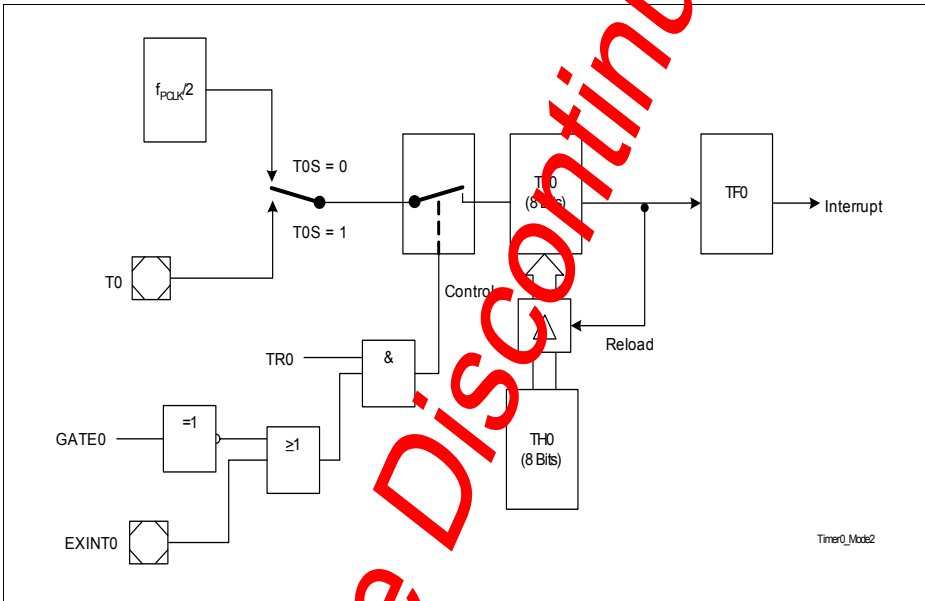

Figure 13-42 Timer 0, Mode 2: 8-bit Timer/Counter with Auto-Reload

Feature Discontinued

13.10.4.4 Mode 3

In mode 3, Timer 0 and Timer 1 behave differently. Timer 0 in mode 3 establishes TL0 and TH0 as two separate counters. Timer 1 in mode 3 simply holds its count. The effect is the same as setting $TR1 = 0$

The logic for mode 3 operation for Timer 0 is shown in [Figure 13-43](#). TL0 uses the Timer 0 control bits GATE0, TR0 and TF0, while TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now sets TF1 upon overflow and generates an interrupt if ET1 is set.

Mode 3 is provided for applications requiring an extra 8-bit timer. When Timer 0 is in mode 3 and TR1 is set, Timer 1 can be turned on by switching it to any of the other modes and turned off by switching it into mode 3.

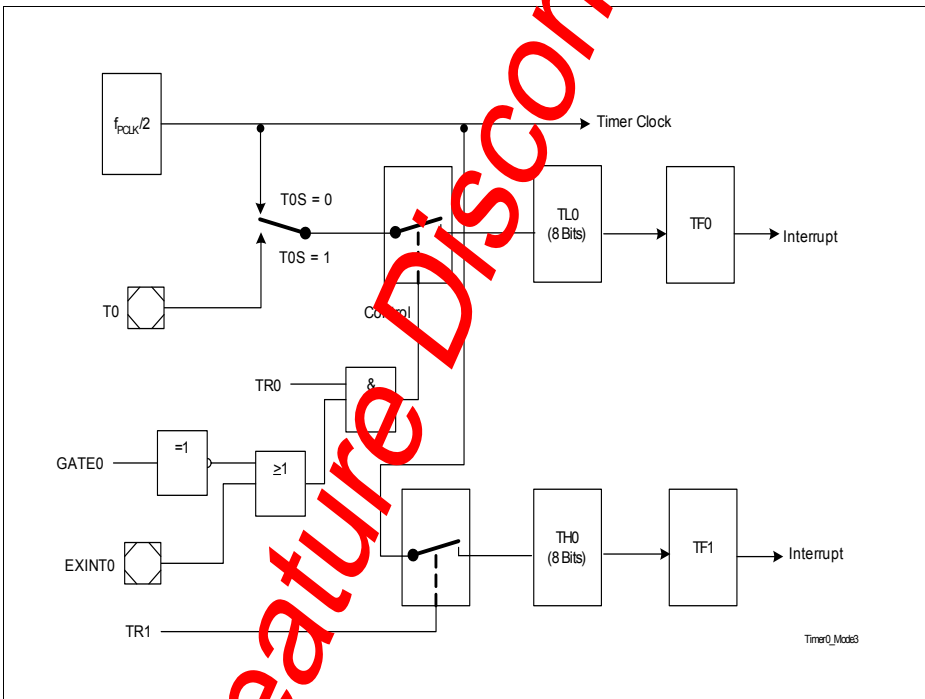

Figure 13-43 Timer 0, Mode 3: Two 8-Bit Timers/Counters

13.10.5 Register Map

Seven SFRs control the operations of Timer 0 and Timer 1. They can be accessed from both the standard (non-mapped) and mapped SFR area.

Table 13-50 lists the addresses of these SFRs.

Table 13-50 Register Map

13.10.6 Register Description

The low bytes (TL0, TL1) and high bytes (TH0, TH1) of both Timer 0 and Timer 1 can be combined to a one-timer configuration depending on the mode used. Register TCON controls the operations of Timer 0 and Timer 1. The operating modes of both timers are selected using register TMOD. Register IEN0 contains bits that enable interrupt operations in Timer 0 and Timer 1.

13.11 Timer 2

13.11.1 Overview

Timer 2 is a 16-bit general purpose timer which is functionally compatible with the Timer 2 in the C501 product family. Timer 2 can function as a timer or counter in each of its modes. As a timer, it counts with an input clock of PCLK/42 (if prescaler is disabled). As a counter, Timer 2 counts 1-to-0 transitions on pin T2. In the counter mode, the maximum resolution for the count is PCLK/24 (if prescaler is disabled).

Features

- 16-bit auto-reload mode
- selectable up or down counting
- One channel, 16-bit capture mode

13.11.2 System Information

This section provides system information relevant to the Timer 2.

13.11.2.1 Pinning

Timer 2 can be used as an event counter which count 1-to-0 transitions at the external input pin, T2. These pins are selected from three different sources, T2A, T2B and T2C. This selection is performed by the SFR bits MODPISEL3.T2IS. In addition, there are eight sources of T2EX pin for Timer 2. They can be selected by MODPISEL3.T2EXIS.

The Timer 2 pin assignment for T2EX, SCR is shown in [Table 13-51](#).

Table 13-51 Timer 2 Pin Functions

Pins	Function	Description	Selected By
P02.3	T2A	Timer 2 Input	MODPISEL3.T2IS = 00 _B
P02.7	T2B		MODPISEL3.T2IS = 01 _B
P00.2	T2C		MODPISEL3.T2IS = 10 _B

Table 13-51 Timer 2 Pin Functions (cont'd)

13.11.2.2 Clocking Configuration

The Timer 2 runs on the PCLK.

If the Timer 2 functionality is not required at all, it can be completely disabled by gating off its clock input for maximal power reduction. This is done by setting bit T2CCU_DIS in register PMCON1 as described below.

PMCON1

13.11.2.3 Interrupt Events and Assignment

Table 13-52 lists the interrupt event sources from the Timer 2, and the corresponding event interrupt enable bit and flag bit.

Table 13-52 Timer 2 Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit
Timer 2 Overflow	T2_T2CON1.TF2EN	T2_T2CON.TF2
Timer 2 External	T2_T2CON1.EXF2EN	T2_T2CON.EXF2

Table 13-53 shows the interrupt node assignment for each Timer 2 interrupt source.

Table 13-53 Timer 2 Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
Timer 2 Overflow	IEN0.ET2	–	2BH
Timer 2 External			

13.11.2.4 Module Suspend Control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (MMCR2.MMODE = 1) and the Debug-Suspend signal is active (MMCR2.DSUSP = 1), the timer/counter in Timer 2 module in TC2x_SCR can be suspended based on the settings of their corresponding module suspend bits in register MODSUSP. When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

13.11.3 Basic Timer Operations

Timer 2 can be started by using TR2 bit by hardware or software. Timer 2 can be started by setting TR2 bit by software. If bit T2RHEN is set, Timer 2 can be started by hardware. Bit T2REGS defines the event on pin T2EX, falling edge or rising edge, that can set the run bit TR2 by hardware. Timer 2 can only be stopped by resetting TR2 bit by software.

13.11.4 Auto-Reload mode

The auto-reload mode is selected when the bit $\overline{CP/RL2}$ in register T2CON is zero. In this mode, Timer 2 counts to an overflow value and then reloads its register contents with a 16-bit start value for a fresh counting sequence. The overflow condition is indicated by setting bit TF2 in the T2CON register. At the same time, an interrupt request to the core will be generated (if interrupt is enabled). The overflow flag TF2 must be cleared by software.

The auto-reload mode is further classified into two categories depending upon the DCEN control bit in register T2MOD.

13.11.4.1 Up/Down Count Disabled

If DCEN = 0, the up-down count selection is disabled. The timer, therefore, functions as a pure up counting timer only. The operational block diagram is shown in [Figure 13-44](#).

If the T2CON register bit EXEN2 = 0, the timer starts to count up to a maximum of $FFFF_H$ once the timer is started by setting the bit TR2 in register T2CON to 1. Upon overflow, bit TF2 is set and the timer register is reloaded with the 16-bit reload value of the RC2 register. This reload value is chosen by software, prior to the occurrence of an overflow condition. A fresh count sequence is started and the timer counts up from this reload value as in the previous count sequence.

If EXEN2 = 1, the timer counts up to a maximum of $FFFF_H$ once TR2 is set. A 16-bit reload of the timer registers from register RC2 is triggered either by an overflow condition or by a negative/positive edge (chosen by the bit EDGESEL in register T2MOD) at input pin T2EX. If an overflow caused the reload, the overflow flag TF2 is set. If a negative/positive transition at pin T2EX caused the reload, bit EXF2 in register T2CON is set. In either case, an interrupt is generated to the core if the related interrupt enable bit EXF2EN/TF2EN in register T2CON1 is enabled and the timer proceeds to its next count sequence. The EXF2 flag, similar to the TF2, must be cleared by software.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The reload will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

Note: In counter mode, if the reload via T2EX and the count clock T2 are detected simultaneously, the reload takes precedence over the count. The counter increments its value with the following T2 count clock.

Feature Discontinued

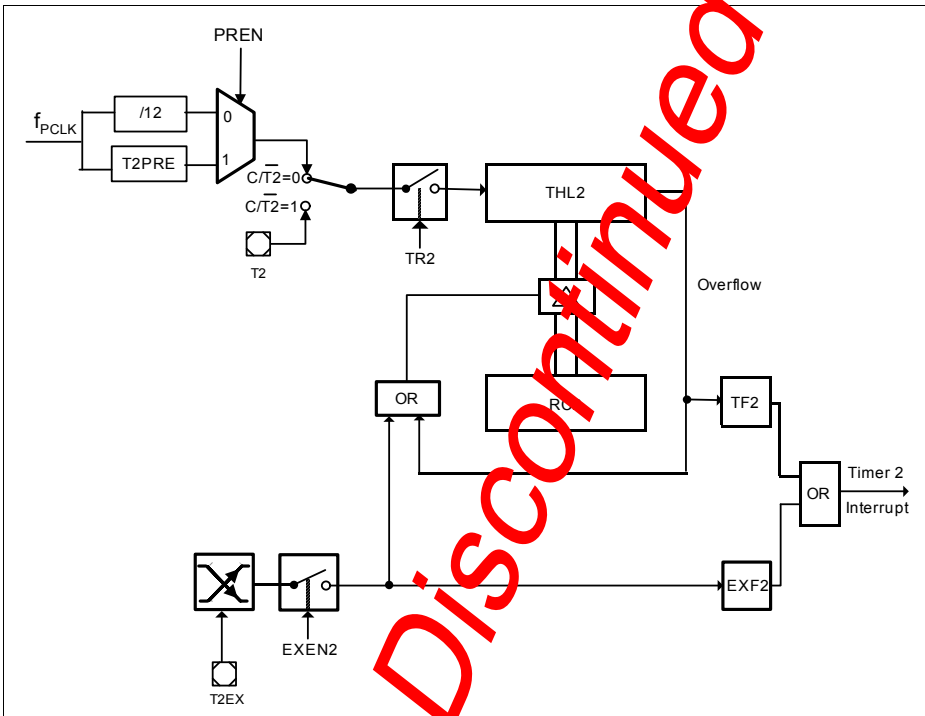

Figure 13-44 Auto-Reload Mode (DCEN = 0)

13.11.4.2 Up/Down Count Enable

If DCEN = 1, the up-down count selection is enabled. The direction of count is determined by the level at input pin T2EX. The operational block diagram is shown in [Figure 13-45](#).

A logic 1 at pin T2EX sets the Timer 2 to up counting mode. The timer, therefore, counts up to a maximum of $FFFF_H$. Upon overflow, bit TF2 is set and the timer register is reloaded with a 16-bit reload value of the RC2 register. A fresh count sequence is started and the timer counts up from this reload value as in the previous count sequence. This reload value is chosen by software, prior to the occurrence of an overflow condition.

A logic 0 at pin T2EX sets the Timer 2 to down counting mode. The timer counts down and underflows when the THL2 value reaches the value stored at register RC2. The underflow condition sets the TF2 flag and causes $FFFF_H$ to be reloaded into the THL2 register. A fresh down counting sequence is started and the timer counts down as in the previous counting sequence.

If bit T2RHEN is set, Timer 2 can only be started either by rising edge (T2REGS = 1) at pin T2EX and then proceed with the up counting, or be started by falling edge (T2REGS = 0) at pin T2EX and then proceed with the down counting.

In this mode, bit EXF2 toggles whenever an overflow or a underflow condition is detected. This flag, however, does not generate an interrupt request.

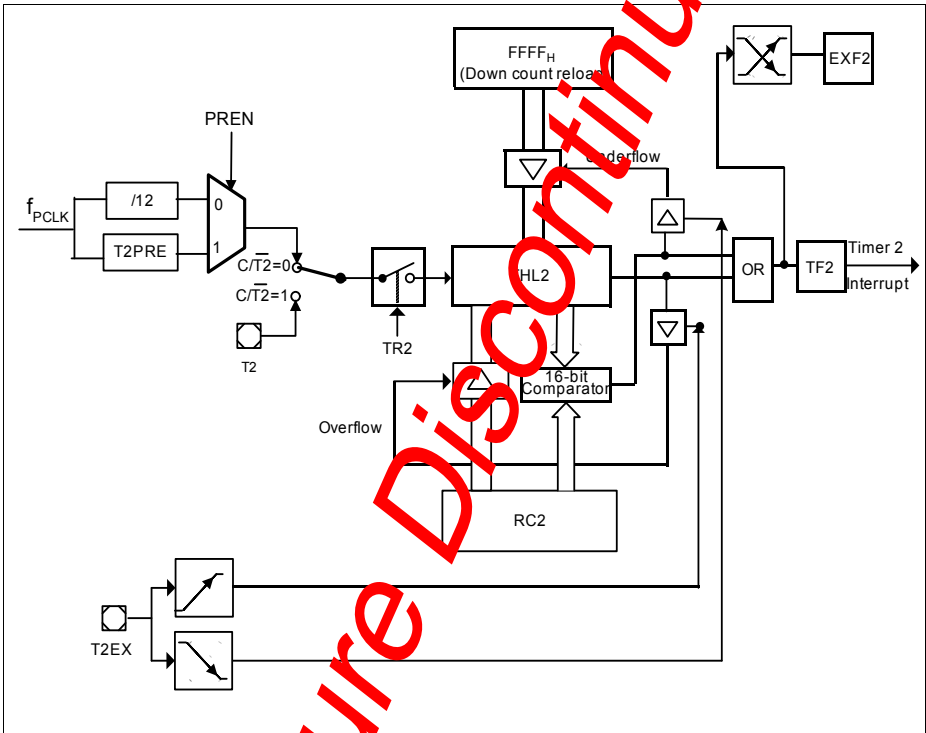

Figure 13-45 Auto-Reload Mode (DCEN = 1)

Feature Discontinued

13.11.5 Capture Mode

In order to enter the 16-bit capture mode, bits CP/RL2 and EXEN2 in register T2CON must be set. In this mode, the down count function must remain disabled. The timer functions as a 16-bit timer and always counts up to $FFFF_H$, after which, an overflow condition occurs. Upon overflow, bit TF2 is set and the timer reloads its registers with 0000_H . The setting of TF2 generates an interrupt request to the core.

Additionally, with a falling/rising edge (chosen by T2MOD_EDGE_SEL) on pin T2EX, the contents of the timer register (THL2) are captured into the RC2 register. The external input is sampled in every PCLK clock cycle. When a sampled input shows a low (high) level in one PCLK clock cycle and a high (low) in the next PCLK clock cycle, a transition is recognized. If the capture signal is detected while the counter is being incremented, the counter is first incremented before the capture operation is performed. This ensures that the latest value of the timer register is always captured.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The capture will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

When the capture operation is completed, bit EXF2 is set and can be used to generate an interrupt request. [Figure 13-46](#) describes the capture function of Timer 2.

Feature Discontinued

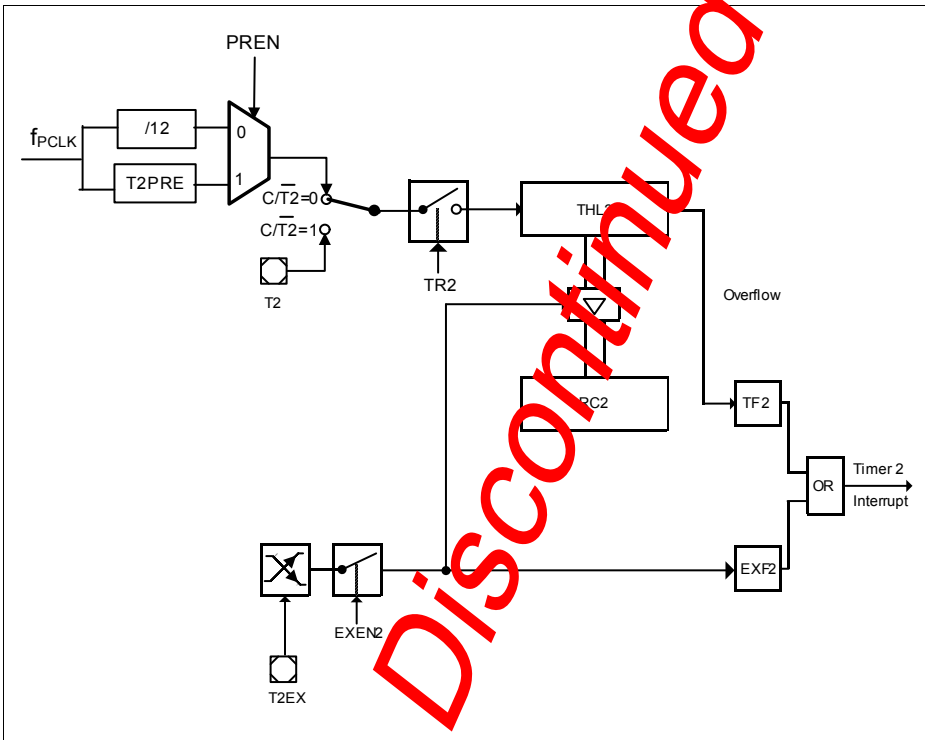

Figure 13-46 Capture Mode

13.11.6 Count Clock

The count clock for the auto-reload mode is chosen by the bit $\overline{C/T2}$ in register T2CON. If $\overline{C/T2} = 0$, a count clock of $f_{PCLK}/12$ (if prescaler is disabled) is used for the count operation.

If $\overline{C/T2} = 1$, Timer 2 behaves as a counter that counts 1-to-0 transitions of input pin T2. The counter samples pin T2 over 2 PCLK clock cycles. If a 1 was detected during the first clock and a 0 was detected in the following clock, then the counter increments by one. Therefore, the input levels should be stable for at least 1 clock.

If bit T2RHEN is set, Timer 2 can be started by the falling edge/rising edge on pin T2EX, which is defined by bit T2REGS.

Note: The C501 compatible feature requires a count resolution of at least 24 clocks.

13.11.7 External Interrupt Function

While the timer/counter function is disabled ($TR2 = 0$), it is still possible to generate a Timer 2 interrupt to the core via an external event at T2EX, as long as Timer 2 remains enabled ($PMCON1.T2CCU_DIS = 0$). To achieve this, bit EXF2 in register T2CON must be set. As a result, any transition on T2EX will cause either a dummy reload or a dummy capture, depending on the CP/ RL2 bit selection.

By disabling the timer/counter function, T2EX can be alternatively used to provide an edge-triggered (rising or falling) external interrupt function, with bit EXF2 serving as the external interrupt flag.

Feature Discontinued

13.11.8 Register Map

All Timer 2 register names described in the following sections are referenced in other chapters of this document with the module name prefix "T2_", e.g. T2_T2CON.

The Timer 2 SFRs are located in the standard (non-mapped) SFR area. [Table 13-54](#) lists these addresses.

Table 13-54 SFR Address List

Feature Discontinued

13.12 T2CCU

The block diagram of the Timer 2 Capture/Compare Unit module is shown in [Figure 13-47](#). It consists of the standard Timer 2 and a Capture/compare unit (CCU). The Capture/Compare Timer (CCT) is part of the CCU. Control is available in the CCU to select individually for each of its 16-bit capture/compare channel, either the Timer 2 or its own Capture/Compare Timer (CCT) as the time base. Both timers have a resolution of 16 bits. The clock frequency of T2CCU, f_{T2CCU} , is set at PCLK frequency.

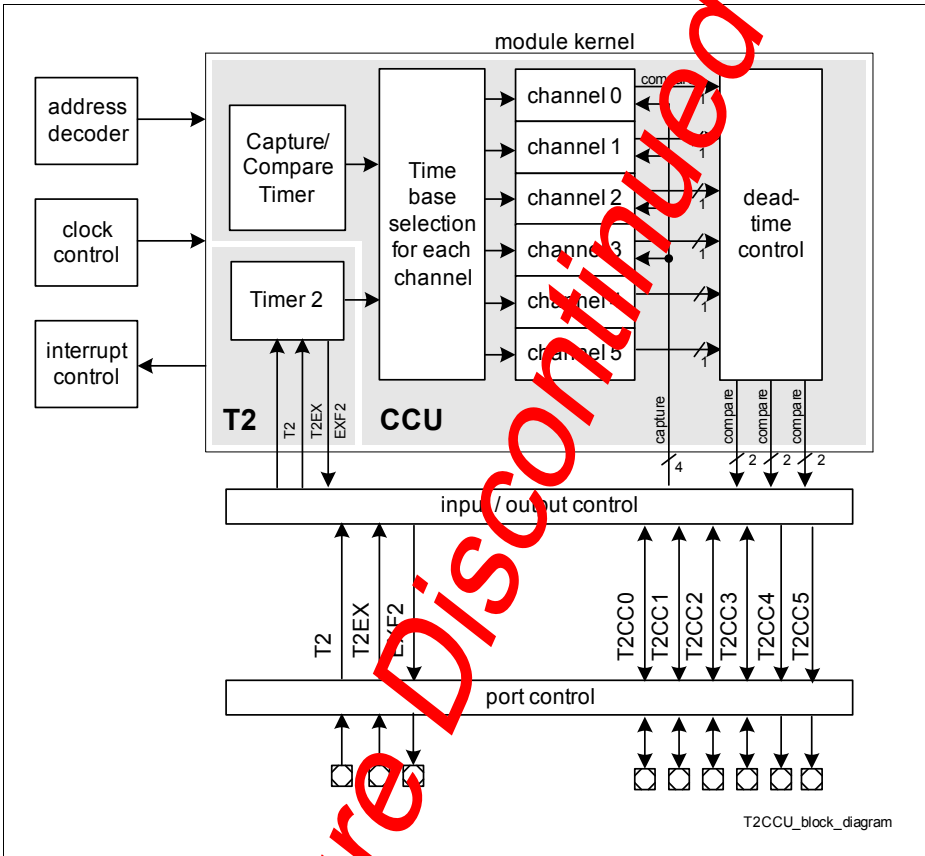

The T2CCU can be used for various digital signal generation and event capturing like pulse generation, pulse width modulation, pulse width measuring etc. Target applications include various automotive control as well as industrial (frequency generation, digital-to-analog conversion, process control etc.).

13.12.1 Features

Timer 2 Capture/Compare Unit has the following features:

- Option to select individually for each channel, either Timer 2 or Capture/Compare Timer as time base
- Extremely flexible Capture/Compare Timer count rate by cascading with Timer 2
- Capture/Compare Timer may be 'reset' immediately by triggering overflow event
- 16-bit resolution
- Six compare channels in total
- Four capture channels multiplexed with the compare channels, in total
- Shadow register for each compare register
 - Transfer via software control or on timer overflow.
- Compare Mode 0: Compare output signal changes from the inactive level to active level on compare match. Returns to inactive level on timer overflow.
 - Active level can be defined by register bit for channel groups A and B.
 - Support of 0% to 100% duty cycle in compare mode 0.
- Compare Mode 1: Full control of the software on the compare output signal level, for the next compare match.
- Concurrent Compare Mode with channel 0
- Capture Mode 0: Capture on any external event (rising/falling/both edge) at the 4 pins T2CC0 to T2CC3.
- Capture Mode 1: Capture upon writing to the low byte of the corresponding channel capture register.
- Capture mode 0 or 1 can be established independently on the 4 capture channels.

Figure 13-47 Timer 2 Capture/Compare Unit Block Diagram

13.12.2 Requirements of Timer 2

By default, all T2CCU channels select the 16-bit Timer 2 as the time base. Timer 2 can be started in timer function (C/T2), by setting bit TR2 or by external start via T2EX. Prior to this, the Timer 2 reload value on overflow should be initialized in the registers RC2H/L. The Up/Down Counter function of Timer 2 must be disabled (DCEN = 0), so that Timer 2 functions as a pure up timer only. T2PRE should be set to select the timer operating frequency, this setting depends on the application requirement.

Timer 2 supports operational frequencies of f_{PCLK} , $f_{PCLK}/2$, $f_{PCLK}/4$, $f_{PCLK}/8$, $f_{PCLK}/16$, $f_{PCLK}/32$, $f_{PCLK}/64$, or $f_{PCLK}/128$. Thus, the 16-bit timer is incremented in the fastest case, twice in every machine cycle and in the slowest case, once in every sixty-four machine cycles.

The timer overflow flag TF2 is set when there is an overflow of the timer contents, and can generate an interrupt if enabled.

Timer 2 may be stopped any time by clearing bit TR2.

Note: Only T2CCU related functions of Timer 2 are discussed in this section. For more details on Timer 2, refer to the corresponding chapter/section.

13.12.3 Capture/Compare Timer of T2CCU

The Capture/Compare Timer (CCT) is part of the T2CCU and is a dedicated time base for the T2CCU capture/compare operations.

CCT is basically a free-running counter that is started by setting bit T2CCU_CCTCON.CCTST. When this bit is set, CCT will start counting from the value in the CCTH/L timer register. The timer counts up to $FFFF_H$ and on overflow, the timer will be reloaded with the value initialized in the registers CCTRELH/L, and count up from this value. CCT can be clocked at frequencies of f_{PCLK} , $f_{PCLK}/2$, $f_{PCLK}/4$, $f_{PCLK}/8$, $f_{PCLK}/16$, $f_{PCLK}/32$, $f_{PCLK}/64$, $f_{PCLK}/128$, $f_{PCLK}/256$, $f_{PCLK}/512$, $f_{PCLK}/1024$, or $f_{PCLK}/2048$. Thus, CCT is incremented in the fastest case, twice in every machine cycle and in the slowest case, once in every 1024 machine cycles.

The timer overflow flag CCTOVF is set on overflow of the timer contents, and can generate an interrupt if enabled by bit CCTOVEN.

The CCT timer registers CCTH/L may be written any time to (re-)initialize the timer value, even when it is running. When CCT is not running, write to CCTL/H updates the corresponding byte of timer. However, when CCT is running, CCTH has to be written first. On write to CCTL, the values in CCTH and CCTL will be updated to the timer which starts counting from this value.

CCT may be stopped any time by clearing bit CCTST. The timer registers will hold the last timer count.

Triggered CCT Timer Overflow

A special feature of the CCT timer is the possibility to 'reset' the timer immediately by a Triggered Timer Overflow event. By 'reset', CCT timer is reloaded and start counting from the value of the reload registers, while all actions associated with the operation mode of the timer changes on base timer overflow will be executed. On setting bit T2CCU_CCTBSEL.CCTFOW the CCT timer overflow event is triggered asynchronously to accomplish all the above. An example usage for a channel operating in compare mode 0 is illustrated in [Figure 13-48](#). For more details on compare mode 0, refer to [Section 13.12.6](#).

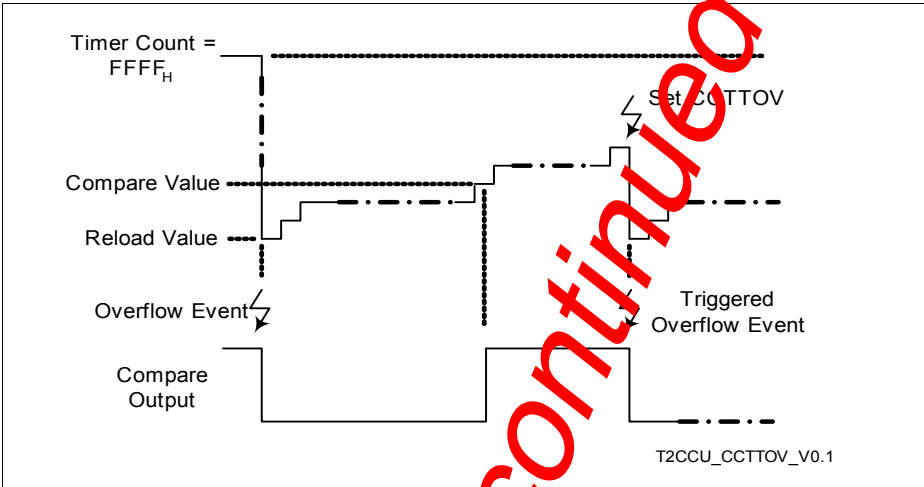

Figure 13-48 Example of Channel in Compare Mode 0 on 'Triggered Timer Overflow' Event

13.12.3.1 Synchronized Timer Start

As described in above sections, it is possible to individually start/stop the timers: Timer 2 by TR2 bit; Capture/Compare Timer by CCTST bit. If the user wants to synchronize the timer starts, then the procedure required is:

1. Ensure CCT timer is not already running,
2. Clear bit TR2 (stop Timer 2) and ensure timers are properly initialized,
3. Set bit TIMSYN to enable synchronized timer starts,
4. Set bit CCTST.

Step 3 and 4 can be combined in a single write operation to the sfr T2CCU_CCTCON.

Synchronized timer start is defined for the case where CCT timer is not already running. When T2CCU_CCTCON bit TIMSYN = 1 and CCTST = 0, setting CCTST sets also the Timer 2 T2CON.TR2 bit. Therefore, both timers are started simultaneously. In the case Timer 2 is already running when CCTST is set, Timer 2 is not affected and continues normal counting operation.

To stop the timers, the respective timer bits can be cleared independently.

13.12.3.2 Cascading Timers For Flexible Count Rate

Especially for applications requiring the base timer to run at flexible count rate, it is allowed to cascade the Timer 2 with the CCT timer. If the bit T2CCU_CCTBSEL.CASC

is set, CCT timer will count at the overflow rate of Timer 2. Refer to [Figure 13-49](#) where Timer 2 is configured as a timer.

An example usage could modify the reload value of Timer 2 for the next overflow, whenever required by the application. If it fits the application, Timer 2 may still be used by the channels as the time base for capture or compare operations.

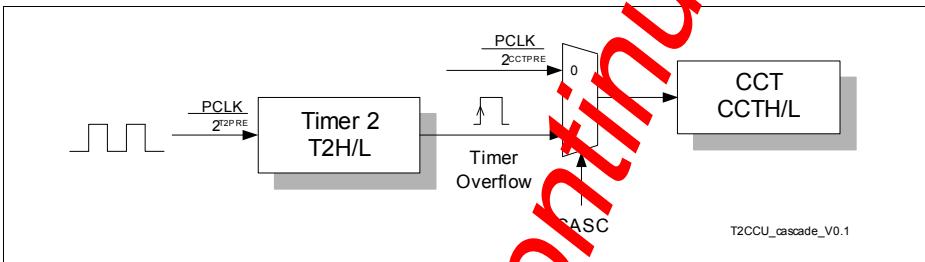

Figure 13-49 Cascading Timer 2 to CCT Timer

Note: Timer 2 may be configured in timer mode or as an external event counter via pin T2.

13.12.3.3 Dead-time with CCT Timer

The generation of (complementary) signals with dead-time for the highside and the lowside switches of one power inverter phase is based on twin grouping of the consecutive compare channels – one from group A and the other from group B. The three compare channel pairs therefore comprise of channel 0 with 1, channel 2 with 3, and channel 4 with 5. All channels must be enabled to run in compare mode 0 with CCT timer as the time base. The compare value must be set the same for the channels of a channel pair. It is also required that all the highside and lowside switches have the same active polarity. If the highside switch should be active while the CCT timer value is above the compare value, then the lowside switch should be active while the CCT timer value is below the compare value. The polarity on compare match is controlled via the bits T2CCU_COCON.POLA and PCPLB for compare group A and B respectively – settings of which must be inverted.

Feature Discontinued

Figure 13-50 PWM-signals with Dead-time Generation (Illustrated for One Channel Pair)

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the times needed to switch on and to switch off. A general problem arises if the time taken to switch on is less than the time to switch off the power device. This leads to a short-circuit in the inverter bridge leg, which may damage the complete system. In order to solve this problem by hardware, T2CCU contains a programmable dead-time counter, which delays the passive to active edge of the switching signals (the active to passive edge is not delayed); see [Figure 13-50](#).

The dead-time generation logic (see [Figure 13-51](#)) is built in a similar way for all three channel pairs. Each instance of the CCT timer overflow or compare match event (of channel from group A) triggers the corresponding dead-time counter (8-bit down counter, clocked at CCT_count_freq) and toggles DTCx to the active level. The trigger pulse (DTCx_rl) leads to a reload of the dead-time counter with the value programmed in bit field T2CCU_CCTDTCL.DTM. This reload can only take place if the dead-time feature is enabled by bit T2CCU_CCTDTCH.DTEx and while the counter is zero.

While counting down (zero is not yet reached), the control signal DTCx stays at active level. On reaching the counter value zero, the dead-time counter stops counting and the signal DTCx toggles again to the inactive level. The DTCx signal is logically manipulated with the CCT modulation signals CCA and CCB, leading to a delay of the passive to active edge of the resulting compare output signal, which is shown in **Figure 13-50**. The active level of the DTCx and the manipulation of the modulation signals is defined and handled differently depending on setting of T2CCU_CCTDTCx.DTLEV (defines the passive level of the switches).

Note: Signal DTCx toggles only if dead-time is enabled by T2CCU_CCTDTCH.DTEX. While DTEX is enabled, DTCx toggles only when dead-time counter is reloaded or when the counter value changed to zero (counter was actively down-counting). When DTEX is set from the clear state, DTCx is held at inactive level according to setting of DTLEV until the next dead-time event.

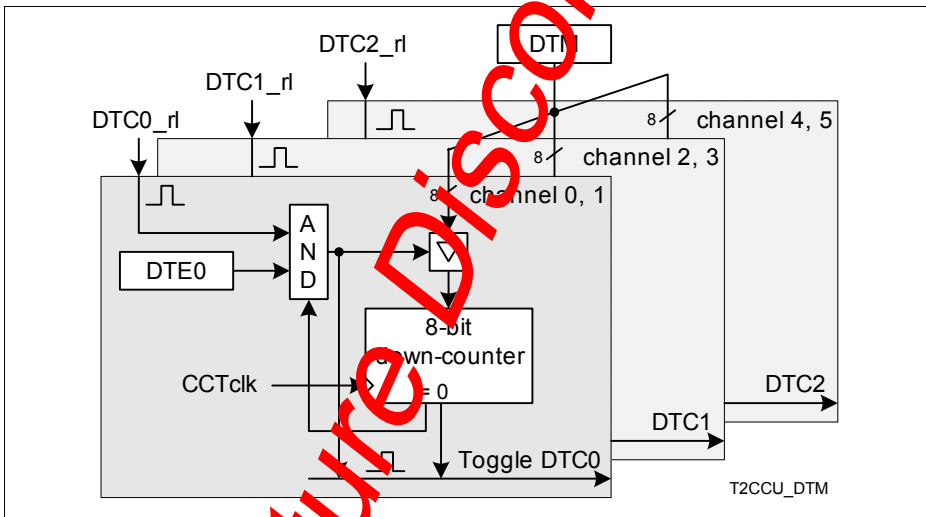

Figure 13-51 Dead-time Counter

Each of the three channel pairs works independently with its own dead-time counter, the trigger and enable signals. The value of bit field DTM is valid for all three channel pairs.

13.12.4 T2CCU Capture/Compare Channels

The T2CCU allows the following operating modes:

- Compare: Up to 4 PWM output signals with 65536 steps at maximum
- Capture: Up to 4 high speed capture inputs

The capture/compare resolution for each channel is per the timer base operating frequency.

Figure 13-52 shows a block diagram of Timer 2 with the T2CCU Capture/Compare Timer (CCT) and capture/compare function for a channel. The I/O pins are generally assigned as alternate function to general purpose I/O port. As shown in **Table 3**, the I/Os T2CC0, 1, 2, 3, 4 always share the same pin as the external interrupts EXT_INT3, 4, 5, 6 respectively. The corresponding external interrupt request flags are set for the capture/compare function. The respective timer overflow flags are also set on timer overflow.

Table 3 I/Os of T2CCU

Pins	Function
T2CC0 / EXINT3	Compare output/Capture input for channel 0
T2CC1 / EXINT4	Compare output/Capture input for channel 1
T2CC2 / EXINT5	Compare output/Capture input for channel 2
T2CC3 / EXINT6	Compare output/Capture input for channel 3
T2CC4	Compare output for channel 4
T2CC5	Compare output for channel 5

Note: The pins T2CCU4, 5 are not available on devices which support up to 4 compare channels.

Feature Discontinued

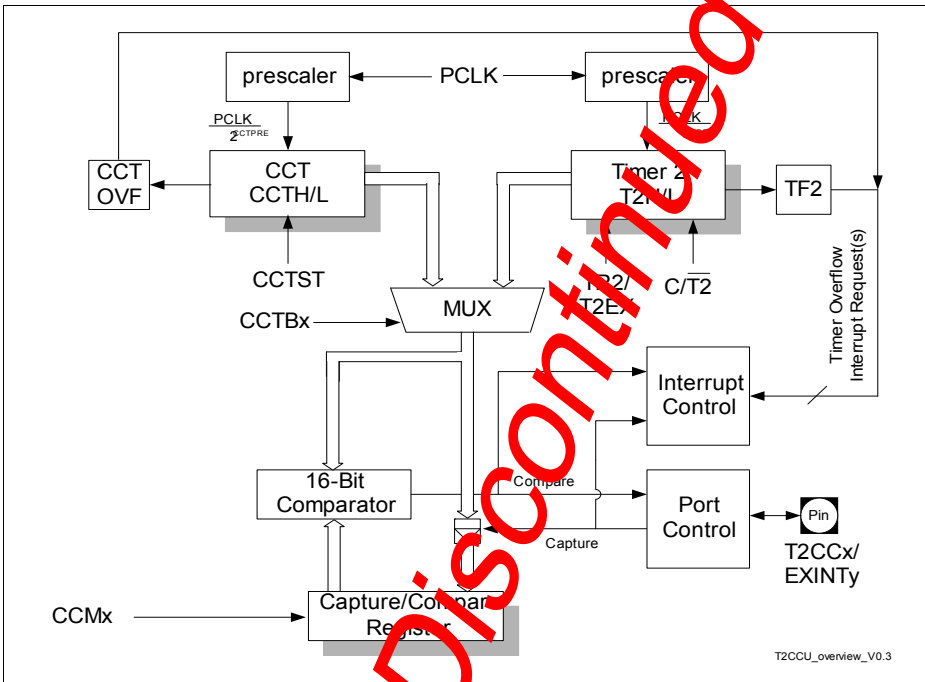

Figure 13-52 Timer 2 with T2CCU CC and Capture/Compare Function for Channel x

13.12.5 Capture/Compare Operation

There are altogether six compare channels and altogether four capture channels, which can be individually enabled. The capture channels can be independently selected for capture mode 0 or 1. A general selection of the capture/compare function for each channel is done in register T2CCU_CCEN.

In case of compare mode selected, the register T2CCU_COCON allows to configure the compare mode for all compare channels. The compare channels are further divided into two groups - A and B. If the channels are configured for compare mode respectively, group A consists of the channels CC0, CC2 and CC4 while group B consists of the channels CC1, CC3 and CC5. In this way, the level of the output signal on compare match till timer overflow (active level) can be configured separately for the channels of the two groups.

In case of capture mode selected, the external event for the capture can be configured by the external interrupt SFR bits. The active trigger could be selected individually for each channel for rising, falling or both edge triggered.

Note: For defined behavior, it is required of the user to initialize properly all the T2CCU related SFRs before enabling any T2CCU capture or compare mode.

13.12.6 Compare Function

The T2CCU compare output is only actively driven on enabling the compare function. When the compare function is enabled by writing to a channel's CCMx bits, the respective compare output is latched (as initial value) based on the settings to the channel SFR bits.

In compare mode, the 16-bit value stored in a compare register is compared with the contents of the timer. When the timer count matches the compare register value, the corresponding channel's output signal is toggled at the pin and an interrupt is requested if enabled.

The contents of a compare register can be regarded as a "time stamp" at which the corresponding output reacts in a predefined way (with either a positive or negative transition). Variation of this "time stamp" changes the waveform of a rectangular output signal at the pin. As a variation of the duty cycle of a periodic signal, this may be used for pulse width modulation as well as for a continually controlled generation of any kind of square waveforms. Two compare modes plus one concurrent compare mode are available to cover a wide range of possible applications.

The active compare mode is selected by bit T2CCU_COCON.COMOD, and applies to all enabled compare channels. In all compare modes, the new output value arrives at the port pin within the same PCLK cycle in which the internal compare signal is activated.

The compare match signal stays high for as long as the comparator inputs are equal (at least one PCLK). The rising edge of the compare match signal is the active edge for all compare match operations.

Shadow Registers for Compare Registers

The compare registers of the T2CCU cannot be accessed directly by user code. Update of channel compare value is by shadow transfer from the corresponding SFR T2CCU_CCx. The user may choose to select one out of two events to start a shadow transfer to the internal compare registers.

1. By setting the SFR bit T2CCU_COSHDW.TXOV = 1, shadow transfer is started for the compare channels on the overflow of their corresponding timer base. In this case, the update of the compare registers is controlled by hardware and is therefore independent from any service delay.
2. By setting the SFR bit T2CCU_COSHDW.ENSHDW = 1, shadow transfer is started for each channel when the corresponding SFR bit COOUTx is set under user control. COOUTx will be cleared automatically by hardware at the next PCLK, after being set.

In both cases, the rising edge of the event pulse signal is the active edge for the shadow transfer of the compare register(s). The advantage of the shadow transfer mechanism is

that it allows glitch-free pulse width modulation, which can occur due to the two instructions needed to update the 16-bit compare registers.

Note that it is not allowed to set both bits TXOV and ENSHDW at the same time. If bit TXOV is set to enable shadow transfer on timer overflow, bit ENSHDW will be cleared by internal hardware to disable shadow transfer by software.

Figure 13-53 illustrates the shadow transfer mechanism.

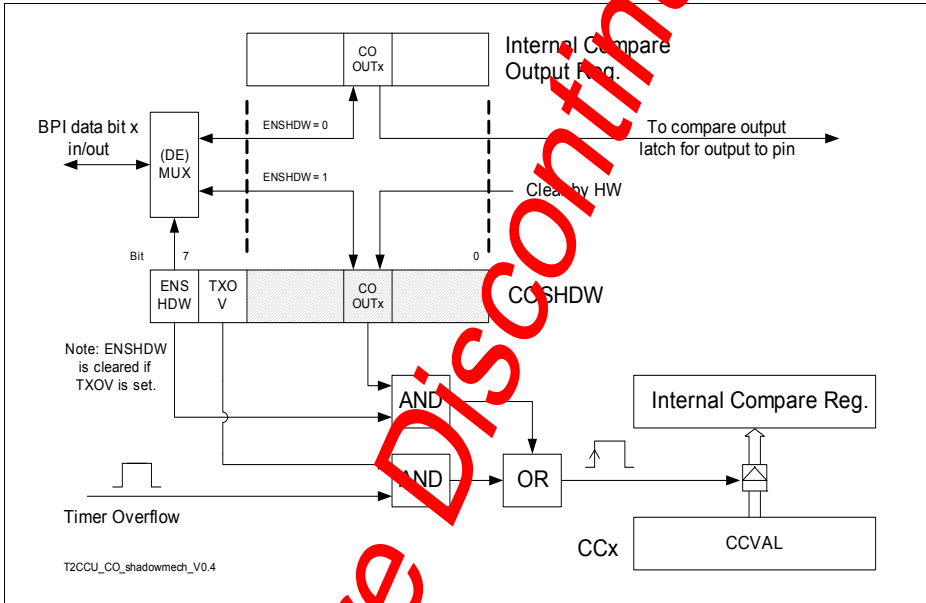

Figure 13-53 Compare Value Shadow Transfer Mechanism and The Dual Function of Bits COOUTx

Mapped Compare Output Bits

To enable dual function on the COOUTx bits of SFR T2CCU_COSHDW, bit ENSHDW is used for the control of access to these bits. When ENSHDW = 1, the SFR bits COOUTx can be directly accessed for control of shadow transfer of compare value. When ENSHDW = 0, writing or reading to COOUTx bits actually access an internal compare output register instead of the COSHDW bits. The corresponding bits of this internal compare output register control the output polarity of the compare channels in compare mode and concurrent compare mode.

Figure 13-53 illustrates the dual function of the bits COOUTx.

13.12.6.1 Compare Mode 0

When compare mode 0 is selected, on setting CCMx to enable compare function, the compare output is latched,

- To the active level if the base timer content are equal or bigger than the compare register content, or,
- To the inactive level if the base timer content is less than the compare register content.

The active level is defined for each channel by its compare group A or B, via the SFR bit T2CCU_COCON.POLA or POLB.

In compare mode 0, when the timer and compare register contents match, the output signal changes from the inactive level to active level. The compare output signal goes back to inactive level on timer overflow.

Compare mode 0 is ideal for generating pulse width modulated output signals, which in turn can be used for digital-to-analog conversion via a filter network or by the controlled device (e.g. the inductance of a DC or AC motor). Mode 0 may also be used for providing output clocks with initially defined period and duty cycle. This usage needs the least CPU time. Once set up, the output goes on oscillating without any CPU intervention.

Figure 13-54 illustrates the function of compare mode 0. In this function, the compare output signal is directly controlled by the setting of SFR bit T2CCU_COCON.POLA/B and the events: timer overflow and compare match.

Figure 13-54 Functional Diagram of Compare Mode 0

Figure 13-55 illustrates the channel output when POLA/B is set to 0. Interrupts may be generated on timer overflow or compare match, and update the next compare value etc., in the interrupt service routine.

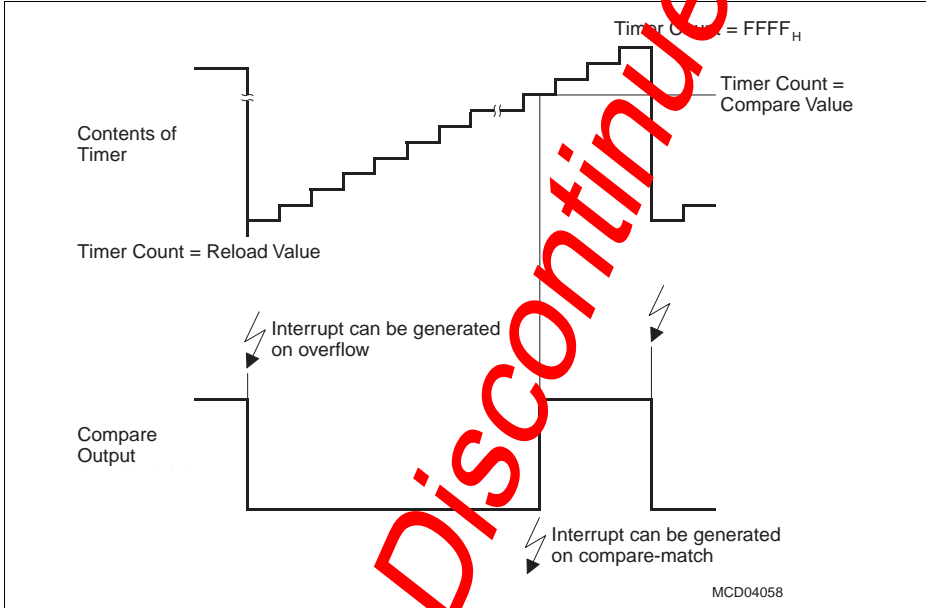

Figure 13-55 Channel Output in Compare Mode 0 (POLA/B = 0)

PWM Signal from 0% to 100% Duty Cycle in Compare Mode 0

The active level of a PWM signal refers to the compare output signal level from the time of compare match till the next timer overflow.

To support a 100% duty cycle for a compare channel with T2CCU_COCON.POLA/B = 0 (active level = high), the 16-bit channel x compare value must be set equal to the timer overflow reload value. In this case, the internal hardware will not cause the compare output signal to the inactive level on timer overflow, and the output stays at the active level until the next timer overflow when the compare value is no more equal to the timer reload value.

To support a 0% duty cycle for a compare channel with T2CCU_COCON.POLA/B = 0, the channel x compare value must be smaller than the timer overflow reload value. In this case, the timer reload value must not be zero. The compare match event will not happen and the compare output stays at the inactive level (low).

The above mechanism applies for compare channel with T2CCU_COCON.POLA/B = 1 correspondingly.

13.12.6.2 Compare Mode 1

When compare mode 1 is selected, on setting CCMx to enable compare function, the compare output is latched with the value initialized to bit COOUTx of the internal compare output register.

In compare mode 1, the software adaptively determines the transition of the output signal. It is commonly used when output signals are not related to a constant signal period (as in a standard PWM Generation) but must be controlled very precisely with high resolution and without jitter. In compare mode 1, the compare output signal level is under the full control of the software, for the next compare match.

If compare mode 1 is enabled and the software writes to COOUTx bit(s) of the internal compare output register (in this case, bit T2CCU_C0SHDW.ENSHDW must be cleared), the new value will not appear at the output pin until the next compare match occurs. Thus, one can choose independently for each compare channel, whether the output signal is to toggle (1-to-0 or 0-to-1) or to remain at the same level, when the channel timer count matches the contents of the channel internal compare register.

Figure 13-56 illustrates the function of compare mode 1. In this function, the bit COOUTx of the internal compare output register will only be transferred to the compare output latch as alternate data out, on the next compare match event.

Figure 13-56 Functional Diagram of Compare Mode 1

13.12.6.3 Concurrent Compare Mode

When concurrent compare mode is selected, on setting CCMx to enable compare function, the compare outputs are latched with the corresponding values initialized to the COOUTx bits of the internal compare output register.

Concurrent Compare is similar to compare mode 1, with the additional capability to manipulate the output at more than one compare channel. Like in compare mode 1, the software updates the COOUTx bits of the internal compare output register (bit T2CCU_COSHDW.ENSHPDW must be cleared), so that up to six compare channel outputs are updated concurrently when channel 0 compare match occurs. When this happens, all enabled compare channel outputs will be updated with the corresponding value in the internal compare output register.

Concurrent compare is an ideal and effective mode for applications where more than one synchronous output signal is to be generated. Such applications could include for e.g., a multiple-phase stepper motor control, or control of ignition coils of a car engine. These applications generally require predefined bit-patterns to be put to an output port at precisely predefined moment.

Figure 13-57 illustrates the function of concurrent compare mode. Compare channel 0 must be enabled and initialized for proper operation.

Figure 13-57 Functional Diagram of Concurrent Compare Mode

Figure 13-58 illustrates two examples of how four rectangular waveforms can be generated at the port using a pattern table. The patterns are written to the internal compare output register (with T2CCU_COSHDW.ENSHDW = 0) before the corresponding timer count is reached. The (future) timer count at which the pattern shall be available at the port must be loaded to the compare shadow registers T2CCU_CC0H and T2CCU_CC0L, and transferred to the internal compare registers. To manage the waveform generation, one example uses a time schedule table with list of compare values, the other example makes use of a fixed compare value (such as FFF0_H) with shorter timer period. In these ways, each channel can be controlled at predefined time(s) by the user on whether to toggle or not.

Figure 13-58 Two Examples of Waveform Generation in Concurrent Compare Mode (by Schedule Table of Compare Values or Fixed Compare Value)

13.12.6.4 Using Interrupts in Combination with the Compare Function

Reserved External Interrupts

Each of the compare channels T2CCU_CC0-3 share the same port pin with an external interrupt as alternate functions at port pins. When compare mode is enabled and the corresponding port pin is set to output mode for use as compare output, the input driver of the port pin is disabled. Therefore the corresponding external interrupt inputs cannot be used for any purpose.

However, the interrupt function of the external interrupts can still be enabled for the compare match interrupts. In this case, the corresponding external interrupt lines are connected directly to the internal compare match signal.

Compare Match Interrupt

The compare match interrupt (including that for channels 4 and 5) is enabled together with the capture interrupt by the IEN1.EXM bit for all channels. A channel compare match occurs when timer count matches the channel register contents. Besides manipulating the corresponding channel compare output, the corresponding compare match flag IRCON0.EXINTx or T2CCU_CCW00.CMxF is set for the interrupt request. For this, the interrupt edge trigger for compare match must be set to rising edge in the corresponding EXICON register. The compare match interrupt service routine can be used to set up the parameters for the next channel compare event, such as change the contents of the compare registers or to determine the level of the compare port outputs for the next “compare match”.

The main advantage in using compare match interrupts is to avoid unintentional overwriting of compare/compare output registers before a match has been reached. This could happen when the CPU writes to the compare registers without knowing about the actual timer count.

Note: As an alternative, the timer overflow interrupt may be used in place of the compare match interrupt.

13.12.7 Capture Function

This mode allows the measurement of external signal pulse widths through the Capture/Compare registers CC0-3. Each of the 16-bit registers can be used to latch the current 16-bit count of the timer base of the corresponding channel. Two capture modes are provided for this function.

In mode 0, any external event (rising/falling/both edge) at pins T2CC0 to T2CC3 latches the channel timer contents to the corresponding channel capture register. The capture edge is defined by the corresponding external interrupt set up (each capture input share the same pin with an external interrupt). The external input(s) is sampled in every CCLK

cycle. When a sampled input shows a low (high) level in one CCLK cycle and a high (low) in the next CCLK cycle, a transition is recognized. The corresponding external interrupt request flag(s) (EXINT3 to EXINT6) is set. If the interrupt(s) is enabled, the CPU will vector to the appropriate interrupt service routine. The timer contents are latched to the corresponding capture register in the PCLK cycle following the one in which the transition was identified.

In mode 1, a capture will occur upon writing to the low byte of the corresponding channel capture register. The software is able to read the contents of the channel timer “on-the-fly”. The value written to the capture register is irrelevant for this function. The timer contents will be latched into the channel capture register following the write instruction. In this mode no interrupt request will be generated.

Figure 13-59 shows the capture operation of the Capture/Compare channels.

The two capture modes can be established individually for each capture channel by bits in SFR T2CCU_CCEN (Capture/Compare enable register). That means, in contrast to the compare modes, it is possible to simultaneously select mode 0 for one capture channel and mode 1 for another channel.

Figure 13-59 Functional Diagram of Capture Mode

13.12.8 T2CCU Registers

This section describes all T2CCU special function registers. The Timer 2 and interrupt related SFRs are also listed, as shown in [Table 4](#).

Note: All T2CCU register names shall be referenced fully with the module name prefix "T2CCU_".

Table 4 Registers Overview

Name	Description
T2CCU Special Function Registers	
CCTBSEL	Capture/Compare Timer Base Select Register
CCTRELL	Capture/Compare Timer Reload Register Low
CCTRELH	Capture/Compare Timer Reload Register High
CCTL	Capture/Compare Timer Register Low
CCTH	Capture/Compare Timer Register High
CCTCON	Capture/Compare Timer Control Register
CCTDTCL	Capture/Compare Timer Dead-Time Control Register Low
CCTDTCH	Capture/Compare Timer Dead-Time Control Register High
CCEN	Capture/Compare Enable Register
COSHDW	Compare Shadow Register
COCON	Compare Control Register
CC0L	Capture/Compare Register 0 Low
CC0H	Capture/Compare Register 0 High
CC1L	Capture/Compare Register 1 Low
CC1H	Capture/Compare Register 1 High

13.12.8.1 Register Mapping

The BPI of the Timer 2 with T2CCU supports local address extension mechanism. The SFRs of the Timer 2 are accessed from Page 0, while SFRs of the T2CCU are accessed from Page 1 to Page 4.

The addresses (non-mapped) of the SFRs are listed in [Table 5](#).

Table 5 SFR Address List for Pages 0-4

Address	Page 0	Page 1	Page 2	Page 3	Page 4
C0 _H	T2CON	CCEN	COSHDW	COCON	
C1 _H	T2MOD	CCTBSEL	CC0L	CC3L	
C2 _H	RC2L	CCTRELL	CC0H	CC3H	CCTDTCL
C3 _H	RC2H	CCTRELH	CC1L	CC4L	CCTDTCH
C4 _H	T2L	CCTL	CC1H	CC4H	
C5 _H	T2H	CCTH	CC2L	CC5L	
C6 _H	T2CON1	CCTCON	CC2H	CC5H	

Note: For Timer 2 with T2CCU, the Timer 2 SFRs must be accessed via the paging mechanism at Page 0.

SFR T2_PAGE, at address C7H, contains the page value and the page control information.

13.12.9 Implementation Details of T2CCU

This section describes the implementation details of the T2CCU module.

13.12.9.1 Interfaces of the T2CCU

Figure 13-60 gives an overview of the interconnections of the T2CCU. Timer 2 and T2CCU have direct interfaces to support the capture/compare operations.

The T2CCU shares the Timer 2 Bus Peripheral Interface (BPI). The BPI enables the T2CCU kernel to be attached to the 8-bit PD8 Bus. The BPI consists of a clock control logic which gates the clock input to both kernels, and an address decoder for SFRs in the Timer 2 and T2CCU kernels.

The interrupt lines of the T2CCU are connected similarly with that of Timer 2, to the CPU interrupt controller via the SCU.

The General Purpose I/O (GPIO) Ports provide the interface from the T2CCU to the external world.

The T2CCU timers can be suspended when OCDS enters Monitor Mode and has the Debug-Suspend signal activated, provided the respective timer suspend bits, T2SUSP and CCTSUSP (normally in SCU SFR MODSUSP), are set. Refer to SCU and OCDS chapters.

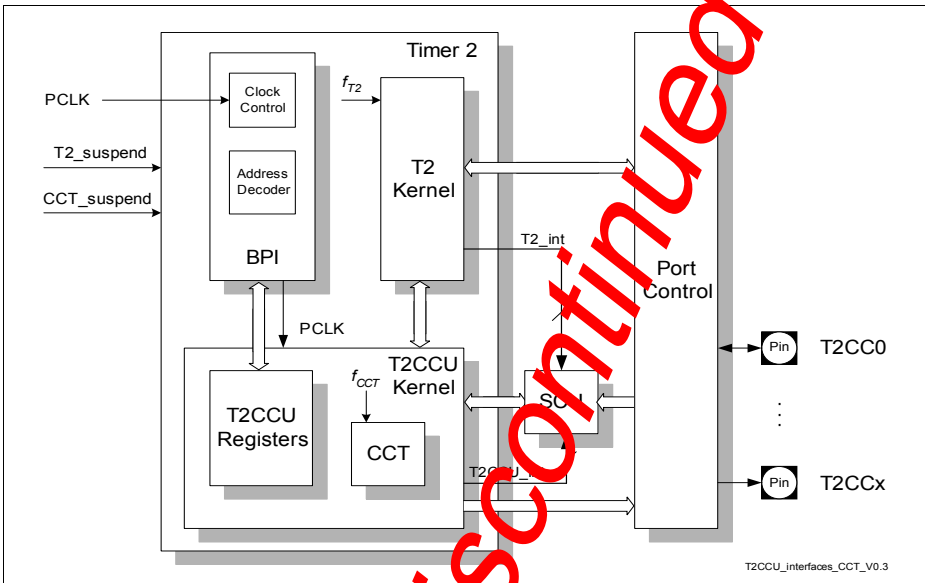

Figure 13-60 Interconnections of T2CCU

13.12.9.2 Design Options

Within the T2CCU kernel, following configurations should be provided:

1. Option for 4 or 6 compare channels depending on product.
2. Option for Concurrent Compare mode.
3. Option for removal of CCT timer and SFRs (and optionally other related components).

Feature Discontinued

13.13 Real-Time Clock

13.13.1 Overview

One of the TC2x_SCR's peripherals is the Real-Time Clock (RTC) that, once started, can work independently of the state of the rest of the microcontroller.

Features

- Periodic Wake-up Mode using either the 100 kHz clock or the 100 MHz/DIV clock
- Wake-up source during standby mode

13.13.2 System Information

This section provides system information relevant to the Real-Time Clock.

13.13.2.1 Interrupt Events and Assignment

Table 13-55 lists the interrupt event sources from the RTC, and the corresponding event interrupt enable bit and flag bit.

Table 13-55 RTC Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit
RTC compare/wake-up	RTC_RTCON.E_RTC	RTC_RTCON.CFRTC

Table 13-56 shows the interrupt node assignment for each RTC interrupt source.

Table 13-56 RTC Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
RTC compare/wake-up	EN1.ECCIP3	–	6BH

13.13.2.2 Module Suspend Control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (MMCR2.MMODE = 1) and the Debug-Suspend signal is active (MMCR2.DSUSP = 1), the timer/counter in RTC module in TC2x_SCR can be suspended based on the settings of their corresponding module suspend bits in register MODSUSP.

When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

13.13.3 Clock Source

RTC clock, f_{RTC} , is selectable between the 100 kHz clock or the 100 MHz/DIV clock via bit RTCLKSEL in RTCON register.

Once power-up, these clocks can operate irrespective of the state of the microcontroller. That is, it keeps running even when the TC2x_SCR has entered idle or the device has entered standby mode.

13.13.4 Real Time Clock Operation

The real-time clock consists of a 41-bit timer (including 8-bit prescaler) which count up. It contains a set of 4 count registers, collectively known as CNT register, that shows the current count value or the current time of the real-time clock. Before starting the real-time clock, CNT register can be written with any value. The value written is used as an initial value for the real-time clock when it is started. Another set of registers, RTCCR register, that consists of 4 registers can be used for interrupt generation. It can also be used to wake-up device from standby mode. The RTCCR register is also used to store the capture value when a capture event is triggered. The real-time clock is started by setting bit RTCC in the RTCON register to 1. This enables the input clock into the real-time clock timer.

13.13.4.1 Periodic Wake-up Mode

Figure 13-61 shows the real-time clock. It consists of a 41-bit general purposes timer. The PCLK is the input clock to the timer.

Before the real-time clock starts to run, CNT register of the real-time clock can be written with any values. The value written is used as an initial value for the real-time clock timer, when it is started by setting bit RTCC in the RTCON register to 1. This bit also enables the input clock into the real-time clock timer. CNT register is protected by the bit protection scheme as described in the SCU chapter. The initial count value can only be updated when the protection scheme is being disabled in the stop mode (RTCC = 0). The real-time clock's lower 9 bits, which serve as a prescaler into the 32-bit counters, CNT, are set to an initial value of 00000000_b when the RTC starts to run. The prescaler can be bypassed by setting bit RTPBYP in the RTCON register to 1.

Feature Discontinued

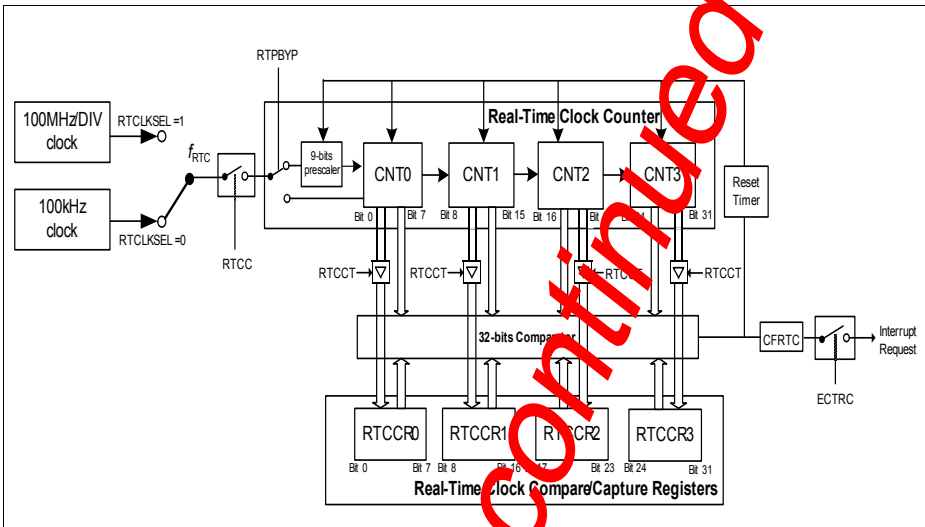

Figure 13-61 Real-time Clock Periodic Wake-up Mode with 9-bit prescaler

While the real-time clock is in operation, the contents of RTCCR register will be compared to the real-time clock counter (CNT). An interrupt will be generated when the contents are equal if ECRTC is set to 1; bit CFRTC in register RTON will be set. The CFRTC flag can be monitored for the real-time clock wake-up request, but the flag has to be cleared to 0 by user software. In such situation, the real-time clock is reset and count from zero again.

With RTC still running in standby mode, it is able to wake-up at a fixed time by programming the number of count value that is equivalent to the length of time to wake-up in the RTCCR register. The real-time clock can generate a wake-up request to the main controller if bit STDBYWRP_RTCWKSEL is set to 1.

A capture event could be triggered by setting RTCCT bit in RTON register to 1. The previous content in the RTCCR register will be overwritten with the captured CNT values after 2 CPU clock cycles. An update of the actual compared value is necessary once a captured event is triggered. In TC2x_SCR, it is recommended to trigger a capture event to read the value of the RTC counter (CNT). There is a potential of reading a wrong 32 bits real-time value while the RTC is in running mode as only 8 bit of data could be fetch at one time.

The real-time clock stops counting and CNT register holds the last value when the RTCC bit is set to 0. Setting this bit subsequently will start a new counting sequence which begin with the stop count.

Note: A compare match event could happen concurrently with the capture event when both events happen within the same clock cycle.

13.13.5 Power Saving Mode Option

Once started, the real-time clock continues counting until the bit FTCON.RTCC is cleared. The real-time clock is not affected by the idle mode of the TC2x_SCR, and continues counting in standby mode provided the PCLK clock is available. In addition, the real-time clock will not automatically disable the operation when there is a clock failure.

Feature Discontinued

13.13.6 Real-Time Clock Register

13.13.6.1 Register Mapping

9 SFRs are used to control the operation of real-time clock. They can be accessed from the standard (non-mapped) SFR area. The registers are described as follows.

Table 13-57 lists the addresses of these SFRs.

Table 13-57 Register Map

Address	Register
95 _H	RTCON

13.14 Universal Asynchronous Receiver/Transmitter

13.15 Overview

The UART provides a full-duplex asynchronous receiver/transmitter, i.e., it can transmit and receive simultaneously. It is also receive-buffered, i.e., it can commence reception of a second byte before a previously received byte has been read from the receive register. However, if the first byte still has not been read by the time reception of the second byte is complete, one of the bytes will be lost.

UART Feature:

- Full-duplex asynchronous modes
 - 8-bit or 9-bit data frames, LSB first
 - fixed or variable baud rate
- Receive buffered
- Multiprocessor communication
- Interrupt generation on the completion of a data transmission or reception

13.15.1 System Information

This section provides system information relevant to the UART.

13.15.1.1 Pinning

In mode 0 (the serial port behaves as shift register), data is shifted in through RXD and out through RXDO, while the TXD pin is used to provide a shift clock which can be used by external devices to clock data in and out. In modes 1, 2 and 3, the port behaves as an UART. Data is transmitted on TXD and received on RXD.

The UART I/O pins are generally assigned as alternate functions to general purpose I/O ports. Bit URRIS in register MODPISEL0 is used to select one of the RXD input function. The UART pin assignment is shown in [Table 13-58](#).

Table 13-58 UART Pin Functions

Pin	Function	Description	Selected By
P02.1	RXDA	UART Receive Data Input A	MODPISEL0.URRIS = 0000 _B SCR_P02_IOC1.PC1 = 0XX10 _B
P02.3	RXDB	UART Receive Data Input B	MODPISEL0.URRIS = 0001 _B SCR_P02_IOC3.PC3 = 0XX10 _B
P02.4	RXDC	UART Receive Data Input C	MODPISEL0.URRIS = 0010 _B SCR_P02_IOC4.PC4 = 0XX10 _B

Table 13-58 UART Pin Functions (cont'd)

Pin	Function	Description	Selected By

13.15.1.2 Clocking Configuration

The UART runs on the PCLK at a frequency of up to 20 MHz.

13.15.1.3 Interrupt Events and Assignment

Table 13-59 lists the interrupt event sources from the UART, and the corresponding event interrupt enable bit and flag bit.

Table 13-59 UART Interrupt Events

Event	Event Interrupt Enable Bit	Event Flag Bit
Data Received	URRIS	SCON.RI
Data Transmitted	URRIS	SCON.TI

Table 13-60 shows the interrupt node assignment for each UART interrupt source.

Table 13-60 UART Events' Interrupt Node Control

Event	Interrupt Node Enable Bit	Interrupt Node Flag Bit	Vector Address
Data Received	IEN0.ES	–	23H
Data Transmitted			

13.15.2 UART Modes

The UART can be used in four different modes. In mode 0, it operates as an 8-bit shift register. In mode 1, it operates as an 8-bit serial port. In modes 2 and 3, it operates as a 9-bit serial port. The only difference between mode 2 and mode 3 is the baud rate, which is fixed in mode 2 but variable in mode 3. The variable baud rate is set by the underflow rate on the dedicated baud-rate generator.

The different modes are selected by setting bits SM0 and SM1 to their corresponding values, as shown in [Table 13-61](#).

Table 13-61 UART Modes

SM0	SM1	Operating Mode	Baud Rate
0	0	Mode 0: 8-bit shift register	$f_{PCLK}/2$
0	1	Mode 1: 8-bit shift UART	Variable
1	0	Mode 2: 9-bit shift UART	$f_{PCLK}/64$ or $f_{PCLK}/32$
1	1	Mode 3: 9-bit shift UART	Variable

13.15.2.1 Mode 0, 8-Bit Shift Register, Fixed Baud Rate

In mode 0, the serial port behaves as an 8-bit shift register. Data is shifted in through RXD, and out through RXDO, while the TXD line is used to provide a shift clock which can be used by external devices to clock data in and out.

The transmission cycle is activated by a write to SBUF. One machine cycle later, the data has been written to the transmit shift register with a 1 at the 9th bit position. For the next seven machine cycles, the contents of the transmit shift register are shifted right one position and a zero shifted in from the left so that when the MSB of the data byte is at the output position, it has a 1 and a sequence of zeros to its left. The control block then executes one last shift before setting the TI bit.

Reception is started by the condition REN = 1 and RI = 0. At the start of the reception cycle, 11111110_b is written to the receive shift register. In each machine cycle that follows, the contents of the shift register are shifted left one position and the value sampled on the RXD line in the same machine cycle is shifted in from the right. When

the 0 of the initial byte reaches the leftmost position, the control block executes one last shift, loads SBUF and sets the RI bit.

The baud rate for the transfer is fixed at $f_{PCLK}/2$ where f_{PCLK} is the input clock frequency, i.e. one bit per machine cycle.

13.15.2.2 Mode 1, 8-Bit UART, Variable Baud Rate

In mode 1, the UART behaves as an 8-bit serial port. A start bit (0), 8 data bits, and a stop bit (1) are transmitted on TXD or received on RXD at a variable baud rate.

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and a 1 is loaded to the 9th bit position (as in mode 0). At phase 1 of the machine cycle after the next rollover in the divide-by-16 counter, the start bit is copied to TXD, and data is activated one bit time later. One bit time after the data is activated, the data starts getting shifted right with zeros shifted in from the left. When the MSB gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baud rate). The divide-by-16 counter is then reset and $1111\ 1111_B$ is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads R8 (SCON.2) with the stop bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see [Section 13.15.3](#)) or the received stop bit = 1. If none of these conditions is met, the received byte is lost.

The associated timings for transmit/receive in mode 1 are illustrated in [Figure 13-62](#).

Feature Discontinued

Figure 13-62 Serial Interface, Mode 1, Timing Diagram

13.15.2.3 Mode 2, 9-Bit UART, Fixed Baud Rate

In mode 2, the UART behaves as a 9-bit serial port. A start bit (0), 8 data bits plus a programmable 9th bit and a stop bit (1) are transmitted on TXD or received on RXD. The 9th bit for transmission is taken from TB8 (SCON.3) while for reception, the 9th bit received is placed in RB8 (SCON.2).

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and TB8 is copied into the 9th bit position. At phase 1 of the machine cycle following the next rollover in the divide-by-16 counter, the start bit is copied to TXD and data is activated one bit time later. One bit time after the data is activated, the data starts shifting right. For the first shift, a stop bit (1) is shifted in from the left and for subsequent shifts, zeros are shifted in. When the TB8 bit gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baud rate). The divide-by-16 counter is then reset and 11111111_B is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the 9th data bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see [Section 13.15.3](#)) or the 9th bit = 1. If none of these conditions is met, the received byte is lost.

The baud rate for the transfer is either $f_{PCLK}/64$ or $f_{PCLK}/32$, depending on the setting of the top bit (SMOD) of the PCON (Power Control) register, which acts as a Double Baud Rate selector.

13.15.2.4 Mode 3, 9-Bit UART, Variable Baud Rate

Mode 3 is the same as mode 2 in all respects except that the baud rate is variable.

In all modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in the modes by the incoming start bit if REN = 1.

The serial interface also provides interrupt requests when transmission or reception of the frames has been completed. The corresponding interrupt request flags are TI or RI, respectively. If the serial interrupt is not used (i.e., serial interrupt not enabled), TI and RI can also be used for polling the serial interface.

The associated timing for transmit/receive in modes 2 and 3 are illustrated in [Figure 13-63](#).

Figure 13-63 Serial Interface, Modes 2 and 3, Timing Diagram

13.15.3 Multiprocessor Communication

Modes 2 and 3 have a special provision for multiprocessor communication using a system of address bytes with bit 9 = 1 and data bytes with bit 9 = 0. In these modes, 9 data bits are received. The 9th data bit goes into RB8. The communication always ends with one stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1.

This feature is enabled by setting bit SM2 in SCON. One of the ways to use this feature in multiprocessor systems is described in the following paragraph.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte that identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that were not being addressed retain their SM2s as set and ignore the incoming data bytes.

Bit SM2 has no effect in mode 0. SM2 can be used in mode 1 to check the validity of the stop bit. In a mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

Feature Discontinued

13.15.4 Baud Rate Generation

There are several ways to generate the baud rate clock for the serial ports, depending on the mode in which they are operating.

The baud rates in modes 0 and 2 are fixed, so they use the fixed clock, (see [Section 13.15.4.1](#)). In modes 1 and 3, the variable baud rate is generated using the UART baud-rate generator (see [Section 13.15.4.2](#)).

“Baud rate clock” and “baud rate” must be distinguished from each other. The serial interface requires a clock rate that is 16 times the baud rate for internal synchronization. Therefore, the UART baud-rate generator must provide a “baud rate clock” to the serial interface where it is divided by 16 to obtain the actual “baud rate”. The abbreviation f_{PCLK} refers to the input clock frequency.

13.15.4.1 Fixed Clock

The baud rates in modes 0 and 2 are fixed. However, while the baud rate in mode 0 can only be $f_{PCLK}/2$, the baud rate in mode 2 can be selected as either $f_{PCLK}/64$ or $f_{PCLK}/32$ depending on bit SMOD in the PCON register.

Bit SMOD acts as a double baud rate selector, as shown in [Equation \(13.2\)](#). If SMOD = 0 (value after reset), the baud rate is 1/64 of the input clock frequency f_{PCLK} . If SMOD = 1, the baud rate is 1/32 of f_{PCLK} .

(13.2)

$$\text{Mode 2 baud rate} = \frac{2^{\text{SMOD}}}{64} \times f_{PCLK}$$

13.15.4.2 UART Baud-rate Generator

The UART baud-rate generator is used to generate the variable baud rate for the UART in modes 1 and 3. It has a programmable 11-bit reload value, 3-bit prescaler and 5-bit fractional divider.

The baud-rate generator is clocked derived via a prescaler (f_{DIV}) from the input clock f_{PCLK} . The baud rate timer counts downwards and can be started or stopped through the baud rate control run bit PCON.R. Each underflow of the timer provides one clock pulse to the serial channel. The timer is reloaded with the 11-bit BR_VALUE stored in its reload register BG each time it underflows. The duration between underflows depends on the ‘n’ value in the fractional divider, which can be selected by the bits BGL.FD_SEL. ‘n’ times out of 32, the timer counts one cycle more than specified by BR_VALUE. The prescaler is selected by the bits BCON.BRPRE.

Register BG is the dual-function Baud-rate Generator/Reload register. Reading BG returns the contents of the timer, while writing to BG (low byte) always updates the reload register.

The BG should be written only when BCON.R is 0. An auto-reload of the timer with the contents of the reload register is performed one instruction cycle after the next time BCON.R is set. Any write to BG, while BCON.R is set, will be ignored.

The baud rate of the baud-rate generator depends on the following bits and register values:

- Input clock f_{PCLK}
- Value of bit field BCON.BRPRE.
- Value of bit field BG.FD_SEL
- Value of the 11-bit reload value BG.BR_VALUE

Figure 13-64 shows a simplified block diagram of the baud rate generator.

Figure 13-64 Simplified Baud Rate Generator Block Diagram

The following formula calculate the final baud rate.

(13.3)

$$\text{Baud rate} = \frac{f_{PCLK}}{16 \times \text{PRE} \times \left(\text{BR_VALUE} + \frac{n}{32} \right)}$$

The value of PRE (prescaler) is chosen by the bit field BCON.BRPRE. BR_VALUE represents the contents of the reload value, taken as unsigned 11-bit integer from the bit field BG.BR_VALUE. $\frac{n}{32}$ is defined by the fractional divider selection in bit field BG.FDSEL.

The maximum baud rate that can be generated is limited to $f_{PCLK}/32$. Hence, for a module clock of 20 MHz, the maximum achievable baud rate is 0.625 MBaud.

Table 13-62 lists various commonly used baud rates together with their corresponding parameter settings and the deviation errors compared to the intended baud rate.

Table 13-62 Typical Baud Rates of UART ($f_{PCLK} = 20 \text{ MHz}$)

Baud rate ($f_{PCLK} =$ 20 MHz)	PRE	Reload Value (BR_VALUE)	Numerator of Fractional Value (FD_NUM)	BG Register	Deviation Error
115.2 kBaud	1 (BRPRE = 000)	10 (0A _H)	27 (1B _H)	015B _H	+0.06%
20 kBaud	1 (BRPRE = 000)	62 (3E _H)	16 (10 _H)	07D0 _H	+0.00%
19.2 kBaud	1 (BRPRE = 000)	65 (41 _H)	3 (03 _H)	0823 _H	+0.02%
9600 Baud	2 (BRPRE = 001)	65 (41 _H)	3 (03 _H)	0823 _H	+0.02%
4800 Baud	4 (BRPRE = 010)	65 (41 _H)	3 (03 _H)	0823 _H	+0.02%
2400 Baud	8 (BRPRE = 011)	65 (41 _H)	3 (03 _H)	0823 _H	+0.02%

1) The value of the 16-bit BG register is obtained by concatenating the 11-bit BRVALUE and 5-bit FD_NUM into a 16-bit value.

Feature Discontinued

13.15.5 LIN Support in UART

The UART module can be used to support the Local Interconnect Network (LIN) protocol for both master and slave operations. The LIN baud rate detection feature, which consists of the hardware logic for Break and Synch Field detection, provides the capability to detect the baud rate within LIN protocol using Timer 2. This allows the UART module to be synchronized to the LIN baud rate for data transmission and reception.

13.15.5.1 LIN Protocol

LIN is a holistic communication concept for local interconnected networks in vehicles. The communication is based on the SCI (UART) data format, a single-master/multiple-slave concept, a clock synchronization for nodes without stabilized time base. An attractive feature of LIN is self-synchronization of the slave nodes without a crystal or ceramic resonator, which significantly reduces the cost of hardware platform. Hence, the baud rate must be calculated and returned with every message frame.

The structure of a LIN frame is shown in [Figure 13-65](#). The frame consists of the:

- header, which comprises a Break (13-bit time low), Synch Byte (55_H), and ID field
- response time
- data bytes (according to UART protocol)
- checksum

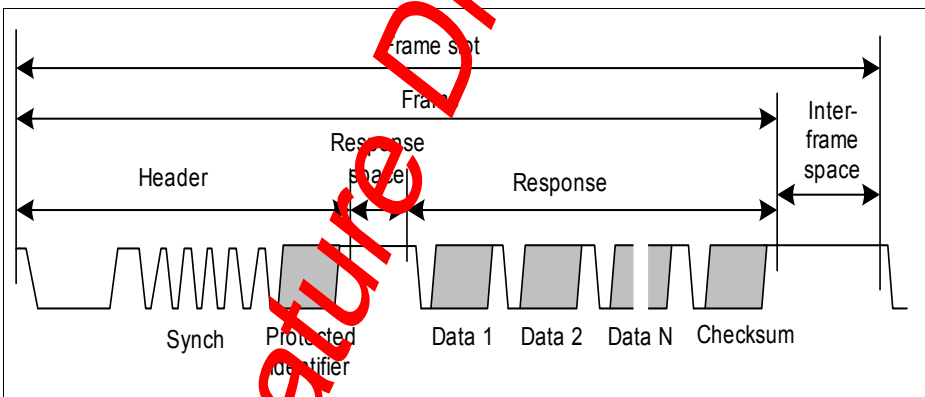

Figure 13-65 The Structure of LIN Frame

Each byte field is transmitted as a serial byte, as shown in [Figure 13-66](#). The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and the stop bit is encoded as a bit with value one (recessive).

Figure 13-66 The Structure of Byte Field

The break is used to signal the beginning of a new frame. It is the only field that does not comply with [Figure 13-66](#). A break is always generated by the master task (in the master mode) and it must be at least 13 bits of dominant value, including the start bit, followed by a break delimiter, as shown in [Figure 13-67](#). The break delimiter will be at least one nominal bit time long.

A slave node will use a break detection threshold of 11 nominal bit times.

Figure 13-67 The Break Field

Synch Byte is a specific pattern for determination of time base. The byte field is with the data value 55_{Hex}, as shown in [Figure 13-68](#).

A slave task is always able to detect the Break/Synch sequence, even if it expects a byte field (assuming the byte fields are separated from each other). If this happens, detection of the Break/Synch sequence will abort the transfer in progress and processing of the new frame will commence.

Figure 13-68 The Synch Byte Field

The slave task will receive and transmit data when an appropriate ID is sent by the master:

1. Slave waits for Synch Break
2. Slave synchronizes on Synch Byte
3. Slave snoops for ID
4. According to ID, slave determines whether to receive or transmit data, or do nothing
5. When transmitting, the slave sends 2, 4 or 8 data bytes, followed by check byte

13.15.5.2 LIN Header Transmission

LIN header transmission is only applicable in master mode. In the LIN communication, a master task decides when and which frame is to be transferred on the bus. It also identifies a slave task to provide the data transported by each frame. The information needed for the handshaking between the master and slave tasks is provided by the master task through the header portion of the frame.

The header consists of a break and synch pattern followed by an identifier. Among these three fields, only the break pattern cannot be transmitted as a normal 8-bit UART data. The break must contain a dominant value of 13 bits or more to ensure proper synchronization of slave nodes.

In the LIN communication, a slave task is required to be synchronized at the beginning of the protected identifier field of frame. For this purpose, every frame starts with a sequence consisting of a break field followed by a synch byte field. This sequence is unique and provides enough information for any slave task to detect the beginning of a new frame and be synchronized at the start of the identifier field.

13.15.5.3 Automatic Synchronization to the Host

Upon entering LIN communication, a connection is established and the transfer speed (baud rate) of the serial communication partner (host) is automatically synchronized in the following steps that are to be included in user software:

STEP 1: Initialize interface for reception and timer for baud rate measurement

STEP 2: Wait for an incoming LIN frame from host

STEP 3: Synchronize the baud rate to the host

STEP 4: Enter for Master Request Frame or for Slave Response Frame

The next section, [Section 13.15.5.4](#), provides some hints on setting up the microcontroller for baud rate detection of LIN.

*Note: Re-synchronization and setup of baud rate are always done for **every** Master Request Header or Slave Response Header LIN frame.*

13.15.5.4 Initialization of Break/Synch Field Detection Logic

The LIN baud rate detection feature provides the capability to detect the baud rate within the LIN protocol using Timer 2. Initialization consists of:

- Serial port of the microcontroller set to Mode 1 (8-bit UART, variable baud rate) for communication.
- Provide the baud rate range via bit field BCON.BGSEL.
- Toggle BCON.BRDIS bit (set the bit to 1 before clearing it back to 0) to initialize the Break/Synch detection logic.
- Clear all status flags LINST.BRK, LINST.EOFSYN and LINST.ERRSYN to 0.
- Timer 2 is set to capture mode with falling edge trigger at pin T2EX. Bit T2MOD.EDGESEL is set to 0 by default and bit T2CON.CP/RL2 is set to 1.
- Timer 2 external events are enabled. T2CON.EXEN2 is set to 1. (EXF2 flag is set when a negative transition occurs at pin T2EX)
- f_{T2} can be configured by bit field T2MOD.T2PREF.

Note: It is also recommended to toggle the BCON.BRDIS bit after the reception of each complete LIN frame to avoid a wrong Break field detection in noisy environments (i.e. spikes on the LIN bus).

13.15.5.5 Baud Rate Range Selection

The Break/Synch Field detection logic supports a maximum number of bits in the Break field as defined by [Equation \(13.4\)](#).

$$\text{Maximum number of bits} = \text{Baud Rate} \times \frac{4095}{\text{Sample Frequency}} \quad (13.4)$$

The sample frequency is given by [Equation \(13.5\)](#).

$$\text{Sample Frequency} = \frac{\text{PCLK}}{8 \times 2^{\text{BGSEL}}} \quad (13.5)$$

If the maximum number of bits in the Break field is exceeded, the internal counter will overflow, which results in a baudrate detection error. Therefore, an appropriate BGSEL value has to be selected for the required baudrate detection range.

The baud rate range defined by different BGSEL settings is shown in [Table 13-63](#).

Table 13-63 BGSEL Bit Field Definition for Different Input Frequencies

f_{PCLK}	BGSEL	Baud Rate Select for Detection $f_{pclk}/(2184 \cdot 2^{BGSEL})$ to $f_{pclk}/(72 \cdot 2^{BGSEL})$
20 MHz	00 _B	9.2 kHz to 277.8 kHz
	01 _B	4.6 kHz to 138.9 kHz
	10 _B	2.3 kHz to 69.4 kHz
	11 _B	1.1 kHz to 34.7 kHz

Each BGSEL setting supports a range of baud rate for detection. If the baud rate used is outside the defined range, the baud rate may not be detected correctly.

When $f_{pclk} = 20$ MHz, the baud rate range between 1.1 kHz to 277.8 kHz can be detected. The following examples serve as a guide to select BGSEL value:

- If the baud rate falls in the range of 1.1 kHz to 2.3 kHz, selected BGSEL value is “11_B”.
- If the baud rate falls in the range of 2.3 kHz to 4.6 kHz, selected BGSEL value is “10_B”.
- If the baud rate falls in the range of 4.6 kHz to 9.2 kHz, selected BGSEL value is “01_B”.
- If the baud rate falls in the range of 9.2 kHz to 277.8 kHz, selected BGSEL value is “00_B”. If the baud rate is 20 kHz, the possible values of BGSEL that can be selected are “00_B”, “01_B”, “10_B”, and “11_B”. However, it is advisable to select “00_B” for better detection accuracy.

Feature Discontinued

13.15.5.6 LIN Baud Rate Detection

The baud rate detection for LIN is shown in **Figure 13-69**, the Header LIN frame consists of the:

- SYN Break (13 bit times low)
- SYN byte (55_{H})
- Protected ID field

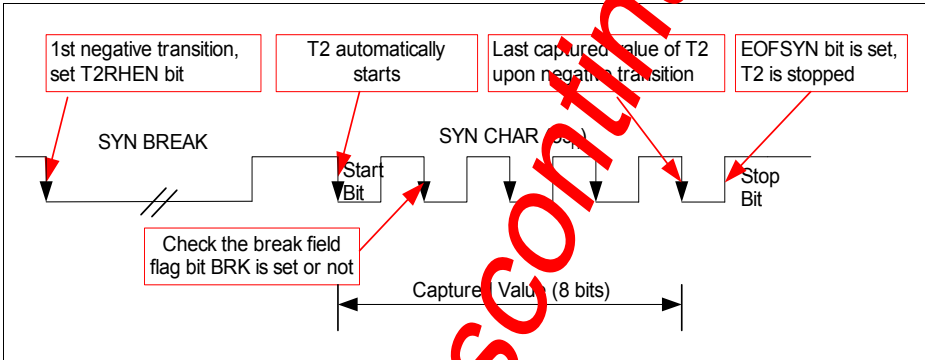

Figure 13-69 LIN Auto Baud Rate Detection

With the first falling edge:

- The Timer 2 External Start Enable bit (T2MOD.T2RHEN) is set. The falling edge at pin T2EX is selected by default for Timer 2 External Start (bit T2MOD.T2REGS is 0).

With the second falling edge:

- Start Timer 2 by the hardware.

With the third falling edge:

- Timer 2 captures the timing of 2 bits of SYN byte.
- Check the Break Field Flag bit LINST.BRK.

If the Break Field Flag LINST.BRK is set, software may continue to capture 4/6/8 bits of SYN byte. Finally, the End of SYN Byte Flag (LINST.EOFSYN) is set, Timer 2 is stopped. T2 Reload/Capture register (RC2H/L) is the time taken for 2/4/6/8 bits according to the implementation. Then the LIN routine calculates the actual baud rate, sets the PRE and BG values if the UART module uses the baud-rate generator for baud rate generation.

After the third falling edge, the software may discard the current operation and continue to detect the next header LIN frame if the following conditions were detected:

- The Break Field Flag LINST.BRK is not set, or
- The SYN Byte Error Flag LINST.ERRSYN is set, or
- The Break Field Flag LINST.BRK is set, but the End of SYN Byte Flag LINST.EOFSYN and the SYN Byte Error Flag LINST.ERRSYN are not set.

13.15.6 Register Description

Besides the SCON and SBUF registers, which can be accessed from both the standard (non-mapped) and mapped SFR area, the rest of the UART's SFRs are located in SCU page 2 of the standard area.

Table 13-64 lists the addresses of these SFRs.

Table 13-64 Register Map

Address	Register
98 _H	SCON
99 _H	SBUF
F2 _H	BCON

F4 _H	BGM
F5 _H	LNSI

Feature Discontinued

13.15.6.1 UART Registers

UART contains the two Special Function Registers (SFRs), SCON and SBUF. SCON is the control register and SBUF is the data register. On reset, both SCON and SBUF return 00_H. The serial port control and status register is the SFR SCON. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8) and the serial port interrupt bits (TI and RI).

SBUF is the receive and transmit buffer of the serial interface. Writing to SBUF loads the transmit register and initiates transmission. This register is used for both transmit and receive data. Transmit data is written to this location and receive data is read from this location, but the two paths are independent.

Reading out SBUF accesses a physically separate receive register.

13.15.6.3 Baud-rate Generator Time/Reload Registers

The low and high bytes of the baud rate timer/reload register BG contains the 11-bit reload value for the baud rate timer and the 5-bit fractional divider selection.

Reading the low byte of register BG returns the content of the lower three bits of the baud rate timer and the FD_SEL setting, while reading the high byte returns the content of the upper 8 bits of the baud rate timer.

Writing to register BG loads the baud rate timer with the reload and fractional divider values from the BG register, the first instruction cycle after BCON.R is set.

BG should only be written if R = 0.

Feature Discontinued

13.16 High-Speed Synchronous Serial Interface

13.16.1 Overview

The High-Speed Synchronous Serial Interface (SSC) supports both full-duplex and half-duplex serial synchronous communication. The serial clock signal can be generated by the SSC itself (Master Mode) through its own 16-bit baud rate generator, or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices using other synchronous serial interfaces. Transmission and reception of data is double-buffered.

Features

- Master and Slave Mode operation
 - Full-duplex or half-duplex operation
- Transmit and receive buffered
- Flexible data format
 - Programmable number of data bits: 7 to 8 bits
 - Programmable shift direction: Least Significant Bit (LSB) or Most Significant Bit (MSB) shift first
 - Programmable clock polarity: true low or high state for the shift clock
 - Programmable clock/data phase: data shift with leading or trailing edge of the shift clock
- Variable baud rate
- Compatible with Serial Peripheral Interface (SPI)
- Interrupt generation
 - On a transmitter empty condition
 - On a receiver full condition
 - On an error condition (receive, phase, baud rate, transmit error)

Figure 13-70 shows the block diagram of the SSC.

Feature Discontinued

Figure 13-70 SSC Block Diagram

13.16.2 General Operation

The SSC supports full-duplex and half-duplex synchronous communication up to 10 MBaud (@ 20 MHz module clock). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit baud-rate generator provides the SSC with a separate serial clock signal.

The SSC can be configured in a very flexible way, so it can be used with other synchronous serial interfaces, can serve for master/slave or multimaster interconnections or can operate compatible with the popular SPI interface. Thus, the SSC can be used to communicate with shift registers (I/O expansion), peripherals (e.g. EEPROMs, etc.) or other controllers (networking). The SSC supports half-duplex and full-duplex communication. Data is transmitted or received on lines TXD and RXD,

normally connected with pins MTSR (Master Transmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output via line MS_CLK (Master Serial Shift Clock) or input via line SS_CLK (Slave Serial Shift Clock). Both lines are normally connected to pin SCLK.

13.16.2.1 Operating Mode Selection

The operating mode of the serial channel SSC is controlled by its control register CON. This register serves two purposes:

- During programming (SSC disabled by CON.EN = 0), it provides access to a set of control bits
- During operation (SSC enabled by CON.EN = 1), it provides access to a set of status flags.

The shift register of the SSC is connected to both the transmit lines and the receive lines via the pin control logic. Transmission and reception of serial data are synchronized and take place at the same time, i.e. the same number of transmitted bits is also received. Transmit data is written into the Transmit Buffer (TB) and is moved to the shift register as soon as this is empty. An SSC master (CON.MS = 1) immediately begins transmitting, while an SSC slave (CON.MS = 0) will wait for an active shift clock. When the transfer starts, the busy flag CON.BSY is set and the Transmit Interrupt Request line TIR will be activated to indicate that register TB may be reloaded again. When the programmed number of bits (2 ... 8) has been transferred, the contents of the shift register are moved to the Receive Buffer RB and the Receive Interrupt Request line RIR will be activated. If no further transfers take place (TB is empty), CON.BSY will be cleared at the same time. Software should not modify CON.BSY, as this flag is hardware controlled. The level of the transmit line after the completion of the data transfer is dependent on the value of the first bit shifted in on the receive line.

Note: The SSC starts transmission and sets CON.BSY minimum two clock cycles after transmit data is written into TB. Therefore, it is not recommended to poll CON.BSY to indicate the start and end of a single transmission. Instead, interrupt service routine should be used if interrupts are enabled, or the interrupt flags IRCON1.TIR and IRCON1.RIR should be polled if interrupts are disabled.

Note: Only one SSC (etc) can be master at a given time.

The transfer of serial data (bits) can be programmed in many respects:

- The data width can be specified from 2 bits to 8 bits
- A transfer may start with either the LSB or the MSB
- The shift clock may be idle low or idle high
- The data bits may be shifted with the leading edge or the trailing edge of the shift clock signal
- The baud rate may be set from 152.59 Baud up to 10 MBaud (@ 20 MHz module clock)

- The shift clock can be generated (MS_CLK) or can be received (SS_CLK)

These features allow the adaptation of the SSC to a wide range of applications requiring serial data transfer.

The Data Width Selection supports the transfer of frames of any data length, from 2-bit “characters” up to 8-bit “characters”. Starting with the LSB (CON.HB = 0) allows communication with SSC devices in Synchronous Mode or with 8051 like serial interfaces for example. Starting with the MSB (CON.HB = 1) allows operation compatible with the SPI interface.

Regardless of the data width selected and whether the MSB or the LSB is transmitted first, the transfer data is always right-aligned in registers TR and RB, with the LSB of the transfer data in bit 0 of these registers. The data bits are rearranged for transfer by the internal shift register logic. The unselected bits of TR are ignored; the unselected bits of RB will not be valid and should be ignored by the receiver service routine.

The Clock Control allows the adaptation of transmit and receive behavior of the SSC to a variety of serial interfaces. A specific shift clock edge (rising or falling) is used to shift out transmit data, while the other shift clock edge is used to latch in receive data. Bit CON.PH selects the leading edge or the trailing edge for each function. Bit CON.PO selects the level of the shift clock line in the idle state. Thus, for an idle-high clock, the leading edge is a falling one, a 1-to-0 transition (see [Figure 13-71](#)).

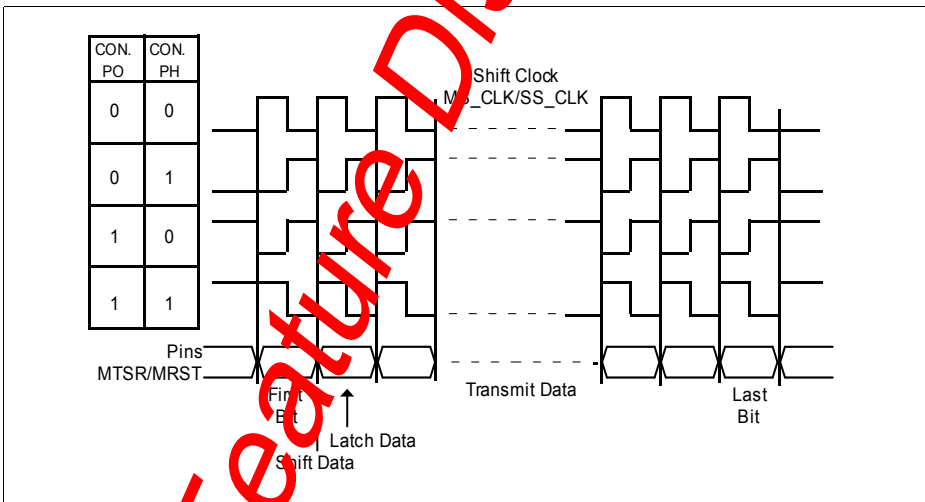

Figure 13-71 Serial Clock Phase and Polarity Options

13.16.2.2 Full-Duplex Operation

The various devices are connected through three lines. The definition of these lines is always determined by the master: the line connected to the master's data output line TXD is the transmit line; the receive line is connected to its data input line RXD; the shift clock line is either MS_CLK or SS_CLK. Only the device selected for master operation generates and outputs the shift clock on line MS_CLK. Since all slaves receive this clock, their pin SCLK must be switched to input mode. The output of the master's shift register is connected to the external transmit line, which in turn is connected to the slaves' shift register input. The output of the slaves' shift register is connected to the external receive line in order to enable the master to receive the data shifted out of the slave. The external connections are hard-wired, the function and direction of these pins is determined by the master or slave operation of the individual device.

Note: The shift direction shown in the figure applies for MSB-first operation as well as for LSB-first operation.

When initializing the devices in this configuration, one device must be selected for master operation while all other devices must be programmed for slave operation. Initialization includes the operating mode of the device's SSC and also the function of the respective port lines.

Feature Discontinued

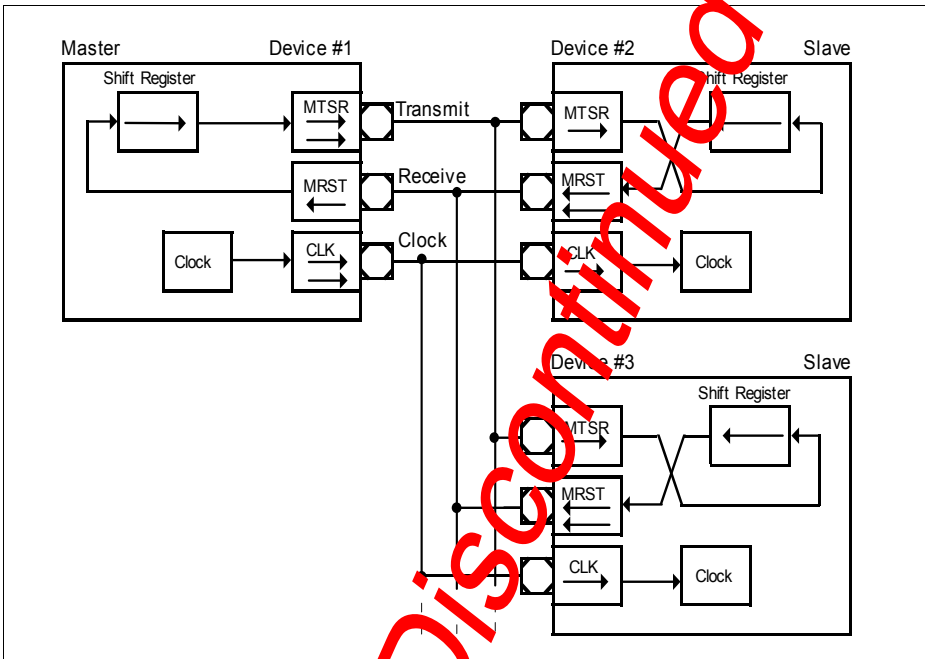

Figure 13-72 SSC Full-Duplex Configuration

The data output pins MRST of all slave devices are connected together onto the one receive line in the configuration shown in [Figure 13-72](#). During a transfer, each slave shifts out data from its shift register. There are two ways to avoid collisions on the receive line due to different slave data:

- Only one slave drives the line, i.e. enables the driver of its MRST pin. All the other slaves must have their MRST pins programmed as input so only one slave can put its data onto the master receive line. Only receiving data from the master is possible. The master selects the slave device from which it expects data either by separate select lines or by sending a special command to this slave. The selected slave then switches its MRST line to output until it gets a de-selection signal or command. This option is applicable only if pin has output driver disabling capability.
- The slaves use open-drain output on MRST. This forms a wired-AND connection. The receive line needs an external pull-up in this case. Corruption of the data on the receive line sent by the selected slave is avoided when all slaves not selected for transmission to the master only send ones (1s). Because this high level is not actively driven onto the line, but only held through the pull-up device, the selected slave can pull this line actively to a low-level when transmitting a zero bit. The master selects

the slave device from which it expects data either by separate select lines or by sending a special command to this slave.

After performing the necessary initialization of the SSC, the serial interfaces can be enabled. For a master device, the alternate clock line will now go to its programmed polarity. The alternate data line will go to either 0 or 1 until the first transfer starts. After a transfer, the alternate data line will always remain at the logic level of the last transmitted data bit.

When the serial interfaces are enabled, the master device can initiate the first data transfer by writing the transmit data into register TB. This value is copied into the shift register (assumed to be empty at this time), and the selected first bit of the transmit data will be placed onto the TXD line on the next clock from the baud-rate generator (transmission starts only if CON.EN = 1). Depending on the selected clock phase, a clock pulse will also be generated on the MS_CLK line. At the same time, with the opposite clock edge, the master latches and shifts in the data detected at its input line RXD. This “exchanges” the transmit data with the receive data. Because the clock line is connected to all slaves, their shift registers will be shifted synchronously with the master’s shift register — shifting out the data contained in the registers, and shifting in the data detected at the input line. After the preprogrammed number of clock pulses (via the data width selection), the data transmitted by the master is contained in all the slaves’ shift registers, while the master’s shift register holds the data of the selected slave. In the master and all slaves, the contents of the shift register are copied into the receive buffer RB and the receive interrupt line RIF is activated.

A slave device will immediately output the selected first bit (MSB or LSB of the transfer data) at line RXD when the contents of the transmit buffer are copied into the slave’s shift register. Bit CON.BSY is not set until the first clock edge at SS_CLK appears. The slave device will not wait for the next clock from the baud-rate generator, as the master does. The reason for this is that, depending on the selected clock phase, the first clock edge generated by the master may already be used to clock in the first data bit. Thus, the slave’s first data bit must already be valid at this time.

*Note: On the SSC, a transmission **and** a reception takes place at the same time, regardless of whether valid data has been transmitted or received.*

Note: The initialization of the CLK pin on the master requires some attention in order to avoid undesired clock transitions, which may disturb the other devices. Before the clock pin is switched to output mode, the clock output level will be selected in the control register CON and the alternate output be prepared via the related ALTSEL register, or the output latch must be loaded with the clock idle level.

13.16.2.3 Half-Duplex Operation

In a Half-Duplex Mode, only one data line is necessary for both receiving **and** transmitting of data. There are two port configuration options for Half-Duplex Mode. The first option uses all the three pins but with the data exchange line connected to both the MTSR and MRST pins of each device; the shift clock line is connected to the SCLK pin. The second option uses two pins and requires the MTSR and MRST lines to be selected for the same GPIO pin, thus establishing also only a single data exchange line. The shift clock line is connected to the SCLK pin as before.

The master device controls the data transfer by generating the shift clock, while the slave devices receive it. Due to the fact that all transmit and receive pins are connected to the one data exchange line, serial data may be moved between arbitrary stations.

Similar to Full-Duplex Mode, there are two ways to avoid collisions on the data exchange line:

- Only the transmitting device may enable its transmit pin driver. This option is applicable only if pin has output driver disabling capability.
- The non-transmitting devices use open drain output and send only ones.

Because the data inputs and outputs are connected together, a transmitting device will clock in its own data at the input pin (MRST for a master device, MTSR for a slave). By this method, any corruptions on the common data exchange line are detected if the received data is not equal to the transmitted data.

Feature Discontinued

The Half-Duplex Mode port configuration using three pins is shown in [Figure 13-73](#).

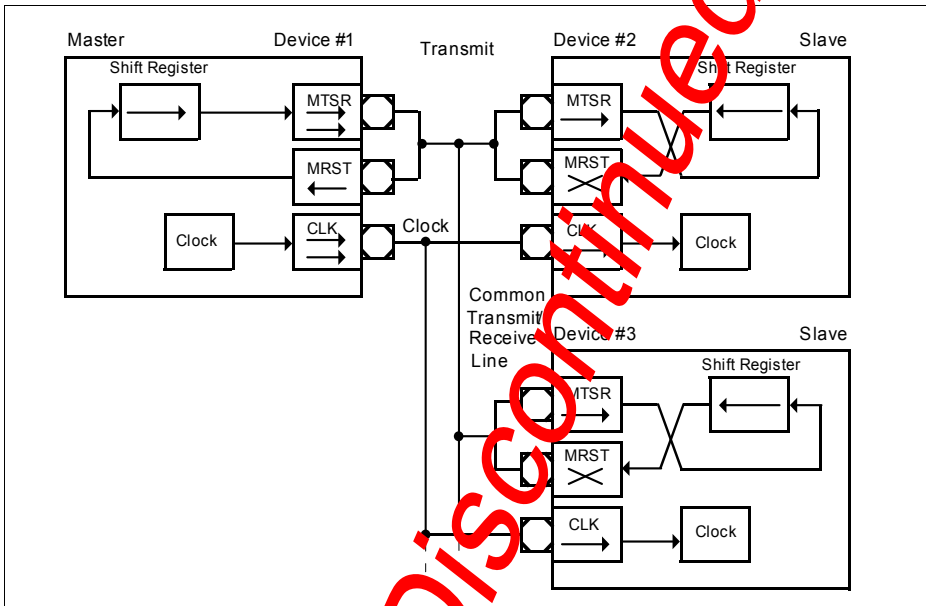

Figure 13-73 SSC Half-Duplex Configuration

13.16.2.4 Continuous Transfers

When the transmit interrupt request flag is set, it indicates that the transmit buffer TB is empty and ready to be loaded with the next transmit data. If TB has been reloaded by the time the current transmission is finished, the data is immediately transferred to the shift register and the next transmission will start without any additional delay. On the data line, there is no gap between the two successive frames. For example, two byte transfers would look the same as one word transfer. This feature can be used to interface with devices that can operate with or require more than 8 data bits per transfer. It is just a matter of software, how long a total data frame length can be. This option can also be used to interface to byte-wide and word-wide devices on the same serial bus, for instance.

Note: Of course, this can happen only in multiples of the selected basic data width, because it would require disabling/enabling of the SSC to reprogram the basic data width on-the-fly.

13.16.2.5 Baud Rate Generation

The serial channel SSC has its own dedicated 16-bit baud-rate generator with 16-bit reload capability, allowing baud rate generation independent of the timers. **Figure 13-74** shows the baud-rate generator.

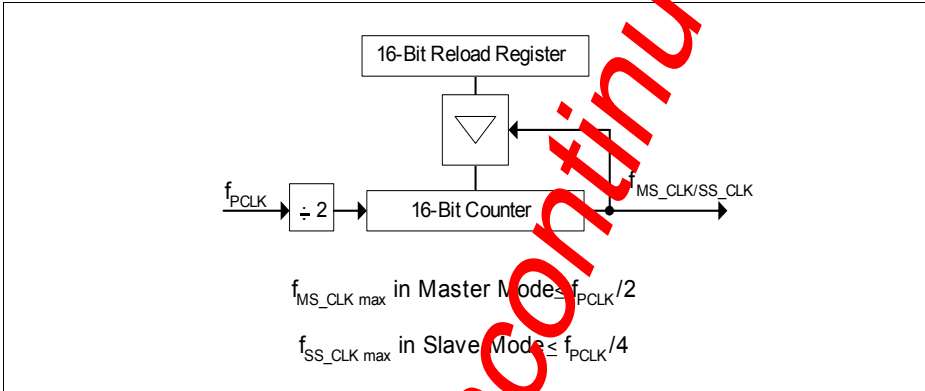

Figure 13-74 SSC Baud-rate Generator

The baud-rate generator is clocked with the module clock f_{hw_clk} . The timer counts downwards. Register BR is the dual-function Baud-rate Generator/Reload register. Reading BR, while the SSC is enabled, returns the contents of the timer. Reading BR, while the SSC is disabled, returns the programmed reload value. In this mode, the desired reload value can be written to BR.

Note: Never write to BR while the SSC is enabled.

The formulas below calculate either the resulting baud rate for a given reload value, or the required reload value for a given baud rate:

$$\text{Baud rate} = \frac{f_{hw_clk}}{2 \cdot (\langle BR \rangle + 1)} \qquad BR = \frac{f_{hw_clk}}{2 \cdot \text{Baud rate}} - 1 \qquad (13.6)$$

$\langle BR \rangle$ represents the contents of the reload register, taken as an unsigned 16-bit integer, while baud rate is equal to f_{MS_CLK/SS_CLK} as shown in **Figure 13-74**.

The maximum baud rate that can be achieved when using a module clock of 20 MHz is 10 MBaud in Master Mode (with $\langle BR \rangle = 0000_H$) or 5 MBaud in Slave Mode (with $\langle BR \rangle = 0001_H$).

Table 13-65 lists some possible baud rates together with the required reload values and the resulting bit time, assuming a module clock of 20 MHz.

Table 13-65 Typical Baud Rates of the SSC ($f_{hw_clk} = 20\text{ MHz}$)

Reload Value	Baud Rate ($= f_{MS_CLK/SS_CLK}$)	Deviation
0000 _H	10 MBaud (only in Master Mode)	0.0%
0001 _H	5 MBaud	0.0%
0004 _H	2 MBaud	0.0%
000A _H	1 MBaud	0.0%
0013 _H	500 kBaud	0.0%
0063 _H	100 kBaud	0.0%
FFFF _H	152.59 Baud	0.0%

13.16.2.6 Error Detection Mechanisms

The SSC is able to detect four different error conditions. Receive Error and Phase Error are detected in all modes; Transmit Error and Baud Rate Error apply only to Slave Mode. When an error is detected, the respective error flag is/can be set and an error interrupt request will be generated by activating the FIR line (see [Figure 13-75](#)) if enabled. The error interrupt handler may then check the error flags to determine the cause of the error interrupt. The error flags are not reset automatically but rather must be cleared by software after servicing. This allows servicing of some error conditions via interrupt, while the others may be polled by software.

Note: The error interrupt handler must clear the associated (enabled) error flag(s) to prevent repeated interrupt requests.

Feature Discontinued

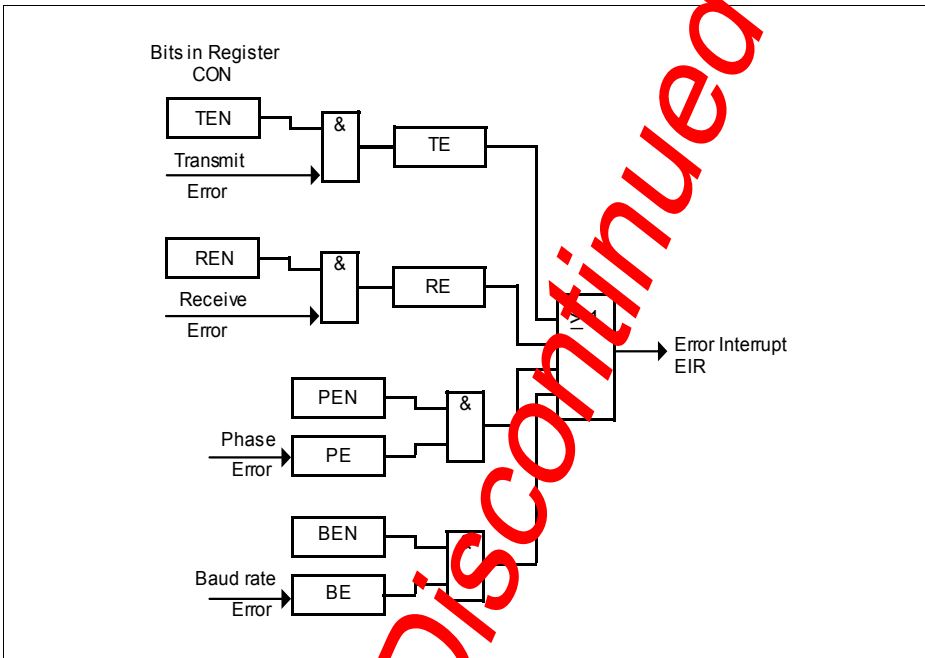

Figure 13-75 SSC Error Interrupt Control

A **Receive Error** (Master or Slave Mode) is detected when a new data frame is completely received but the previous data was not read out of the receive buffer register RB. This condition sets the error flag CON.RE and the error interrupt request line EIR, when enabled via CON.REN. The old data in the receive buffer RB will be overwritten with the new value and is irretrievably lost.

A **Phase Error** (Master or Slave Mode) is detected when the incoming data at pin MRST (Master Mode) or MTSR (Slave Mode), sampled with the same frequency as the module clock, changes between one cycle before and two cycles after the latching edge of the shift clock signal SCLK. This condition sets the error flag CON.PE and, when enabled via CON.PEN, the error interrupt request line EIR.

Note: When receiving and transmitting data in parallel, phase errors occur if the baud rate is configured to $\frac{f_{hw_clk}}{2}$.

A **Baud Rate Error** (Slave Mode) is detected when the incoming clock signal deviates from the programmed baud rate by more than 100%, i.e. it is either more than double or less than half the expected baud rate. This condition sets the error flag CON.BE and, when enabled via CON.BEN, the error interrupt request line EIR. Using this error detection capability requires that the slave's baud-rate generator is programmed to the

same baud rate as the master device. This feature detects false, additional, or missing pulses on the clock line (within a certain frame).

Note: If this error condition occurs and bit CON.AREN = 1, an automatic reset of the SSC will be performed in case of this error. This is done to reinitialize the SSC if too few or too many clock pulses have been detected.

Note: This error can occur after any transfer if the communication is stopped. This is the case due to the fact that the SSC module supports back-to-back transfers for multiple transfers. In order to handle this, the baud rate detector expects after a finished transfer immediately a next clock cycle for a new transfer.

A **Transmit Error** (Slave Mode) is detected when a transfer was initiated by the master (SS_CLK gets active) but the transmit buffer TB of the slave was not updated since the last transfer. This condition sets the error flag CON.TE and the error interrupt request line EIR, when enabled via CON.TEN. If a transfer starts while the transmit buffer is not updated, the slave will shift out the 'old' content of the shift register, which normally is the data received during the last transfer. This may lead to corruption of the data on the transmit/receive line in half-duplex mode (open drain configuration) if this slave is not selected for transmission. This mode requires that slaves not selected for transmission only shift out ones; that is, their transmit buffers must be loaded with 'FFFF_H' prior to any transfer.

Note: In order to avoid possible conflicts or misinterpretations, it is recommended to always load the slave's transmit buffer prior to any transfer.

The cause of an error interrupt request (receive, phase, baud rate, transmit error) can be identified by the error status flags in control register CON.

Note: In contrast to the error interrupt request line EIR, the error status flags CON.TE, CON.RE, CON.PE, and CON.BE, are not reset automatically upon entry into the error interrupt service routine, but must be cleared by software.

Feature Discontinued

13.16.3 Interrupts

The three SSC interrupts can be separately enabled or disabled by setting or clearing their corresponding enable bits in SFR SCU_MODIEN.

For a detailed description of the various interrupts see [Section 13.16.2](#). An overview is given in [Table 13-66](#).

Table 13-66 SSC Interrupt Sources

Interrupt	Signal	Description
Transmission starts	TIR	Indicates that the transmit buffer can be reloaded with new data.
Transmission ends	RIR	The configured number of bits have been transmitted and shifted to the receive buffer.
Receive Error	EIR	This interrupt occurs if a new data frame is completely received and the last data in the receive buffer was not read.
Phase Error	EIR	This interrupt is generated if the incoming data changes between one cycle before and two cycles after the latching edge of the shift clock signal SCLK.
Baud Rate Error (Slave Mode only)	EIR	This interrupt is generated when the incoming clock signal deviates from the programmed baud rate by more than 100%.
Transmit Error (Slave Mode only)	EIR	This interrupt is generated when TB was not updated since the last transfer if a transfer is initiated by a master.

Feature Discontinued

13.16.4 Register Description

The SSC Special Function Registers are accessed from the standard (non-mapped) SFR area. The addresses of the SFRs are listed in [Table 13-67](#).

Table 13-67 Register Map

13.17 Wake-up CAN (WCAN) Filter

This chapter describes the WCAN controller of the SCR module. It contains the following sections:

- Overview on the Wake-up Capabilities (see [Page 13-364](#))
- Functional description of the WCAN Kernel (see [Page 13-366](#))
- WCAN Kernel register description (see [Page 13-367](#))
- Functional description on the CAN based Kernel (see [Page 13-390](#))
- SCR implementation specific details and registers of the WCAN (port connections and control, interrupt control, address decoding, clock control (see [Page 13-405](#)))

Note: The WCAN kernel register names described in this chapter will be referenced in the Standby Domain Internal Target Specification by the module name prefix "WCAN_".

Feature Discontinued

13.17.1 Wake-up CAN Filter Implementation

13.17.1.1 Overview

This section describes the 11898-6 datalink layer controller based on the well known MultiCAN. The Wakable CAN module contains of 1 CAN node, representing the receive part of the communication interface. Furthermore, the the Wake-up CAN filter functionality and interfaces in TC26x B-Step module.

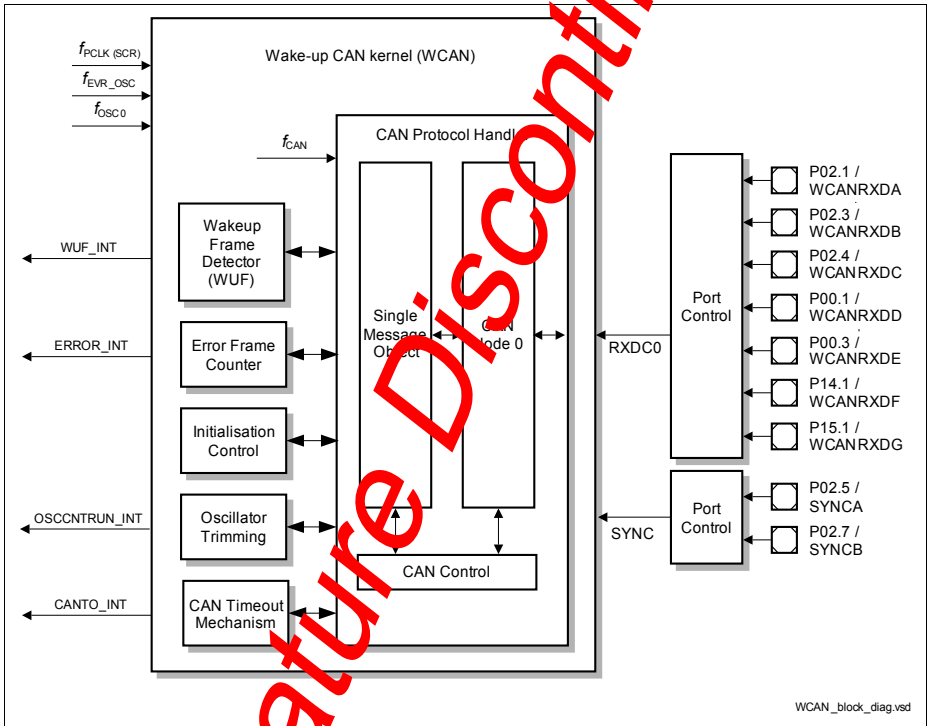

Figure 13-76 Wake-up CAN Filter Interfaces

13.17.1.2 WCAN Filter Features

There are three types of CAN frames:

- Wake-up CAN functionality in conformance to ISO 11898-
- 1 Wake-up CAN node mapped to CAN 0
- Guaranteed data transfer rate up to 500kBaud, baudrates higher are dependent on customer settings. Default settings for 125k, 250k and 500k are according to the given propagation delays of German OEMs.
- 1 Wake-up message object mapped to the wake-up node
 - Set up to handle frames with 11-bit and/or 29-bit identifiers
 - Programmable acceptance mask register for filtering
 - Programmable wake-up message ID, DLC and Data
- High Precision Oscillator trimming possible either via external pin or external crystal
- Wake-up CAN message Time-out feature
- Error counter to debounce CAN protocol and wake-up function errors
- Interrupt generation on
 - Successful Wake-up message frame reception
 - Completion of an Oscillator trim period.
 - Error recognition
 - Wake-up CAN timeout

Feature Discontinued

13.17.1.3 Introduction

Feature Overview

Reception and evaluation of CAN frames is handled in accordance to CAN specification ISO 11898-6 data link layer. The received messages will be compared against the programmed wake-up pattern and in case of pattern match a wake-up will be issued. In case of an erroneous understanding or errors on the bus, the receive error counter can also reach a wake-up threshold. The node will be purely listening to the bus and will not communicate to the outside.

The CAN node is having a single message object. In this message object, the identifier including a bitwise mask, the corresponding DLC, as well as a data mask is included. Only (outside the erroneous case), if all criteria match, a wake-up will be initiated.

The bit timings for the CAN nodes are derived from the peripheral clock (f_{CAN}) and are programmable up to a data rate of 1 MBaud, nonetheless guaranteed wake-up is only given for special configurations according to the propagation delay defined by the German OEMs. The ports are overlapping to the normal CAN nodes.

Features

- Compliant to ISO 11898-6.
- Receive operation according to ISO 11898-6.
- Dedicated control registers for the CAN node.
- Data transfer rates are guaranteed until 500kBaud, in case of higher baudrates more wake-up frames might be needed.
- Transmitter tolerances up to 0.4% are calculated and guaranteed. Higher transmitter tolerances are not pretested.
 - The message object can be configured to accept only standard or only extended frames or to accept both standard and extended frames.
 - Four interrupt sources do exist, oscillator trimming, wake-up frame found, $t_{SILENCE}$ expired and error overview.

Feature Discontinued

13.17.1.5 Wake-up Frame Configuration and Detection

The received frame is compared to the configured wake-up frame and in case a match is detected a wake-up request is issued. The wake-up request sets the flag and issues an interrupt.

*Note: In addition to the message object configuration registers (i.e. **DLC_CTRL**, **IDn_CTRL**(n=0-3), **MASK_IDn_CTRL**(n=0-3), **DATAN_CTRL** (n = 0-7)) the node bit timing configuration is configured in the **BTLn_CTRL**(n=1-2) register.*

Configuration of wake-up frame filter

The message object configuration of the wake-up frame are done in the following registers

- Register **IDn_CTRL** (n=0-3) contains the CAN identifier filter bits.
- Register **MASK_IDn_CTRL** (n=0-3) contains the ID mask bits.
- Register **DLC_CTRL** are the data length code filter bits.
- Register **DATAN_CTRL** (n = 0-7) are the data filter bits.

Detection of wake-up frame filter

The compare mechanisms are different according to the information field inside the CAN frame.

- The identifier programmed inside **IDn_CTRL** (n=0-3) and **MASK_IDn_CTRL** (n=0-3) have to match the data in the received frame and the logic seen in **Figure 13-77**, a wake-up condition is detected.
- The DLC programmed in **DLC_CTRL** together with the data filter bits in **DATAN_CTRL** (n = 0-7) will be compared to the DLC and data inside the received frame, in case a single '1' match in **DATAN_CTRL** (n = 0-7), a wake-up condition within the data is detected. DLC values greater than 8 will be treated as 8. See **Figure 13-77**.

If and only if, identifier and masking, the **DLC_CTRL** and the **DATAN_CTRL** (n = 0-7) will lead to a match, a valid wake-up Frame (WUF) is detected and a wake-up interrupt will be issued if **CFG.SELWUF_EN** is enabled.

Feature Discontinued

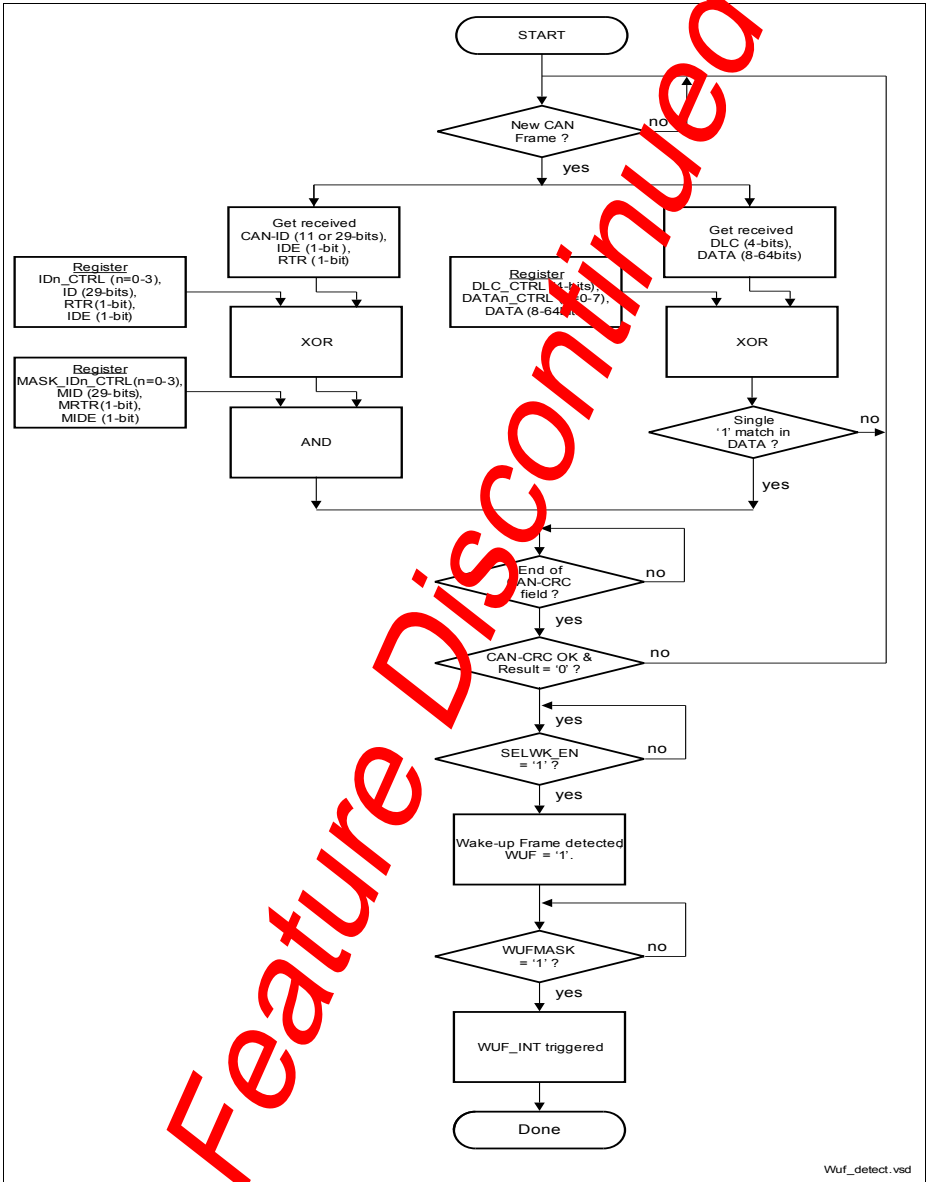

Figure 13-77 Wake-up Frame Detection

13.17.1.6 Oscillator Trimming

An internal oscillator trimming mechanism is available which is able to trim the internal 100MHz RC-OSC, F_{EVR_OSC} present at the EVR. Trimming of the internal high precision oscillator is implemented to cover process and supply / frequency variation over temperature.

The internal oscillator trimming process is achieved by calibrating the internal 100MHz RC-OSC (F_{EVR_OSC}) with a more accurate reference clock F_{OSCO} (XTAL) or F_{SYNC} via the SYNC pin selected by programming **INTMRSLT.GATESEL**.

Next the length of time for F_{OSCO} (XTAL) and F_{EVR_OSC} (100MHz) comparison has to be selected by programming the 16-bit **REFCLK0/1** register. The XTALPERIOD0/1 allows a value from 0 to 65535, say when a value of 8 is chosen, 8 periods of F_{OSCO} (XTAL) time is used to compare with F_{EVR_OSC} and vice versa.

The difference between F_{OSCO} (XTAL) and F_{EVR_OSC} (100MHz) comparison for the length of time defined by **REFCLK0/1** register is accumulated over the 16bit counter (**CLKCMP0/1.OSCNT**). See [Figure 13-78](#)

To start the process of F_{EVR_OSC} with reference clock (F_{OSCO}/F_{SYNC}) comparison, **CFG.OSCCAL** and **CFG.TRIMEN** have to be first programmed accordingly. When comparison of F_{EVR_OSC} with the reference clock signal is completed, an interrupt (**OSCCNTRUN_INT**) is generated and **INTLSTAT0.OSCCNTRUN** flag stopped.

The difference accumulated over **CLKCMP0/1.OSCNT** is communicated by the SCR (safe CPU) to the EVR module and the difference value is used in the trimming register, thereby completing the trimming process.

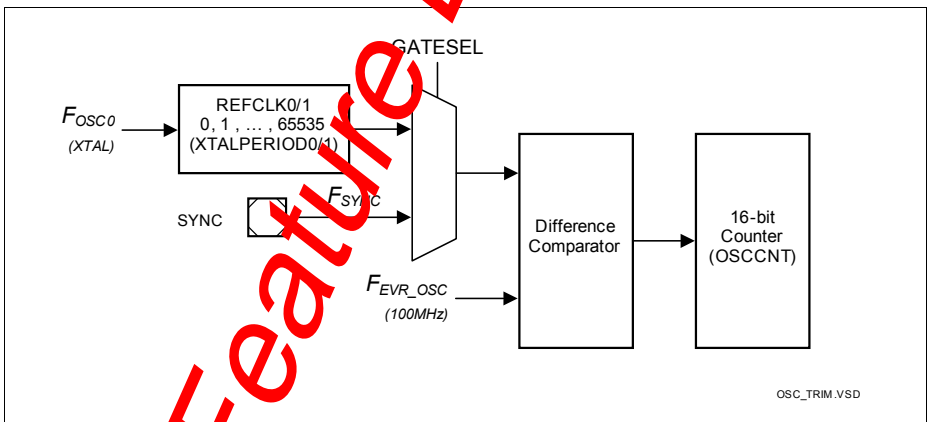

Figure 13-78 Oscillator trimming

Clock Compare Result Register

Clock Compare Result Register 0

The Clock Compare Result Register contains the difference in terms of counts of the reference clock (F_{OSCO} or F_{SYNC}) and the internal 100MHz RC Oscillator (F_{EVR_OSC}).

CLKCMP0

Clock Compare Result Register 0 (B4_H) **Reset Value: 00_H**
RMAP: 0, PAGE: 0

Field	Bits	Type	Description
OSCCNT0	[7:0]	rh	Oscillator Counter This bit field specifies the lower LSB in the 16-bit Oscillator counter.

Clock Compare Result Register 1

CLKCMP1

Clock Compare Result Register 1 (B5_H) **Reset Value: 00_H**
RMAP: 0, PAGE: 0

Field	Bits	Type	Description
OSCCNT1	[7:0]	rh	Oscillator Counter This bit field specifies the upper MSB in the 16-bit Oscillator counter.

Feature Discontinued

13.17.1.7 CAN Message Timeout

A timeout mechanism to monitor CAN bus activity is available on the WCAN. The timeout mechanism monitors the RXDC0 pin. When the RXDC0 pin is inactive for a $t_{SILENCE}$ time of 750ms, both CAN bus silent bit (**INTESTAT1.CANSIL**) and CAN timeout bit (**INTESTAT0.CANTO**) will be set with a CAN time out interrupt (**CANTO_INT**).

The CAN bus silent bit is reset when there is activity on the CAN bus where else the CAN timeout bit can be reset by setting CAN time out clear bit (**INTESTCLR0.CANTOCLR**).

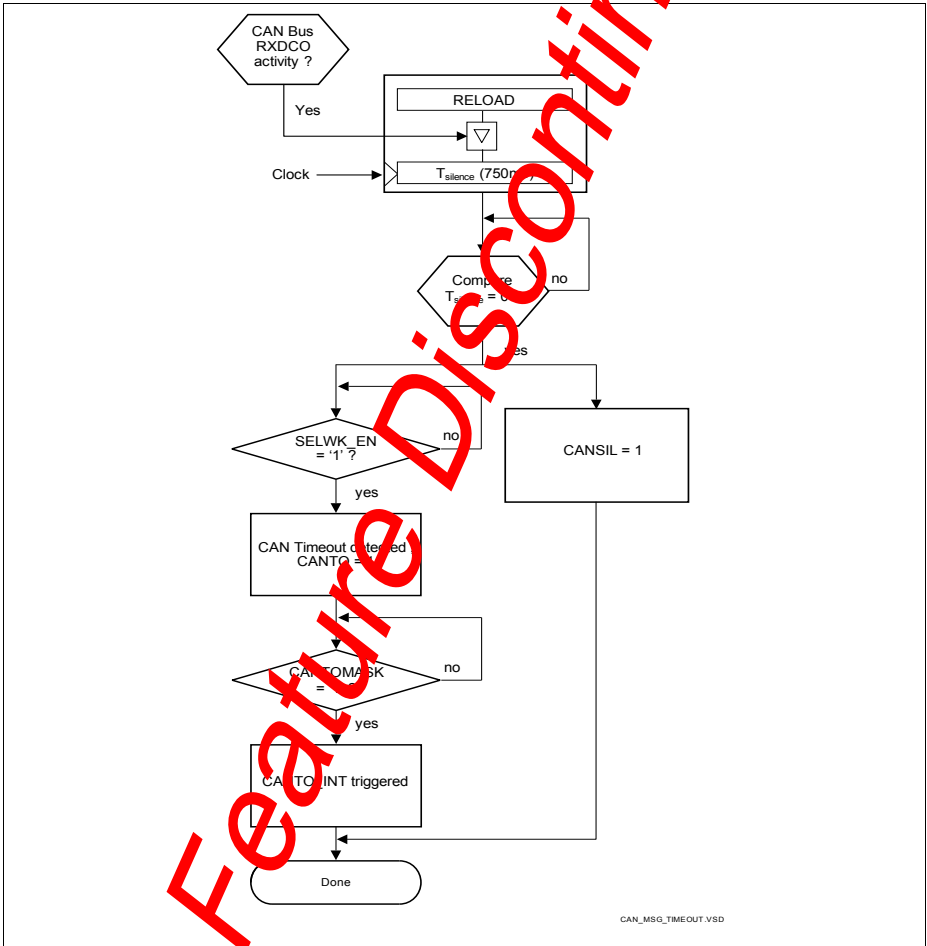

Figure 13-79 CAN Timeout

13.17.1.8 Error Counter

The error counting mechanism in ISO 11898-6 is different to ISO 11898-1. As the device is only receiving messages and never transmitting it could never get into a bus-off situation. Therefore an ISO11898-6 implementation is incrementing its error counter on a Form, Stuff and a CRC error will lead to an increment of the error counter. In case of a correct message, the error will be decremented, if it is greater than 0. In case the error counter is greater than 31 an overflow occurs and a wake-up will be initiated. This shall enable the software to correct the situation. In case of overflow the SYSERR flag is set. See [Figure 13-80](#)

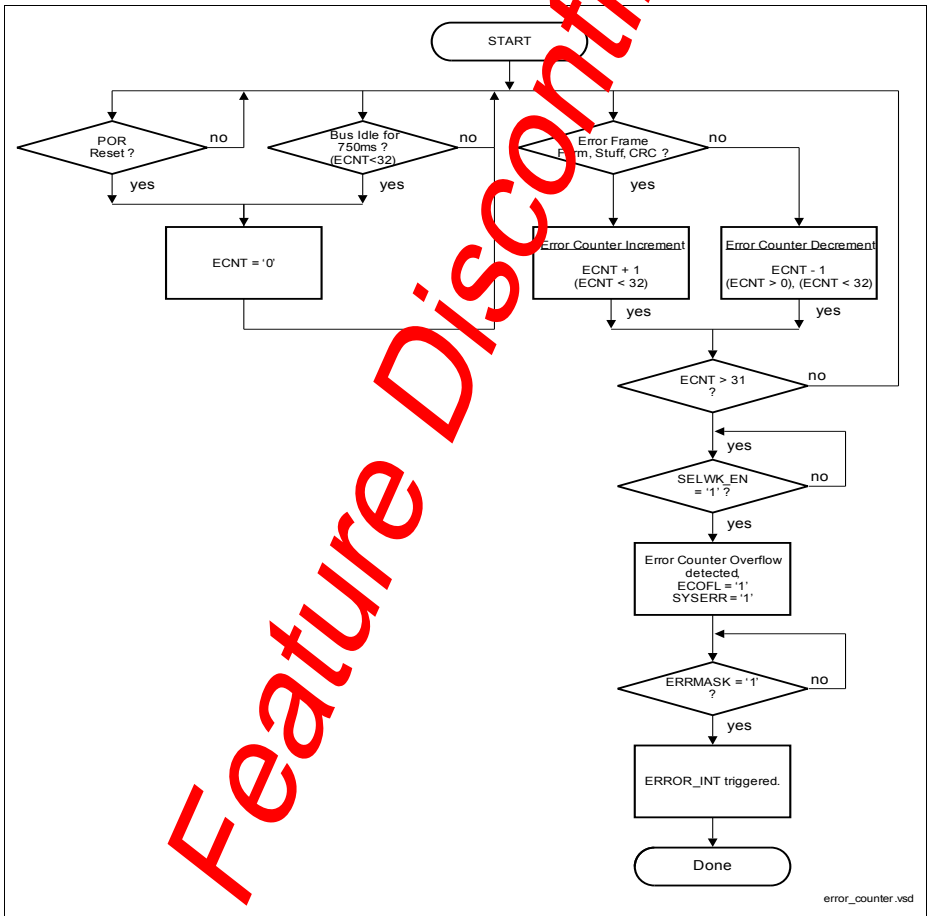

Figure 13-80 Error counter

13.17.2 CAN Functional Description

13.17.2.1 CAN Node Control

The CAN node is equipped with an individual set of SFR registers to control and to monitor the CAN node.

Bit Timing

According to ISO 11898 standard, a CAN bit time is subdivided into different segments (). Each segment consists of multiples of a time quantum t_q . The magnitude of t_q is adjusted by the bit field BRP, both controlling the baud rate prescaler (see bit timing register BTLn_CTRL(n=1-2)). The baud rate prescaler is driven by the MultiCAN module clock f_{CAN} . For ISO 11898-6 some settings are guaranteed to be working according to the given propagation delay times (see [Section](#)). Working settings for 125k, 250k and 500k will be provided. The information below is given to enable settings for different networks.

Figure 13-81 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows a phase synchronization between transmitter and receiver time bases. The Synchronization Segment length is always $1 t_q$. The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver, on the CAN bus line and in the transceiver circuit. For a working collision detect mechanism, T_{Prop} has to be two times the sum of all propagation delay quantities rounded up to a multiple of t_q . The Phase Buffer Segments 1 and 2 (T_{b1} , T_{b2}) before and after the signal sample point are used to compensate a mismatch between transmitter and receiver clock phase detected in the synchronization segment.

The maximum number of time quanta allowed for resynchronization is defined by bit field SJW in the CAN Node Bit Timing register BTLn_CTRL(n=1-2). The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter TSeg1, which is

defined by the value TSEG1 in the respective CAN Node Bit Timing register BTLn_CTRL(n=1-2). A minimum of 3 time quanta is requested by the ISO standard. Parameter TSeg2, which is defined by the value of TSEG2 in the CAN Node Bit Timing Register BTLn_CTRL(n=1-2), covers the Phase Buffer Segment (t_q) minimum of 2 time quanta is requested by the ISO standard. According ISO standard, a CAN bit time, calculated as the sum of T_{Sync}, T_{Seg1} and T_{Seg2}, must not fall below 8 time quanta.

Calculation of the bit time:

$$\begin{aligned}
 t_q &= (\text{BRP} + 1) / f_{\text{CAN}} \\
 T_{\text{Sync}} &= 1 \times t_q \\
 T_{\text{Seg1}} &= (\text{TSEG1} + 1) \times t_q \quad (\text{min. } 3 t_q) \\
 T_{\text{Seg2}} &= (\text{TSEG2} + 1) \times t_q \quad (\text{min. } 2 t_q) \\
 \text{bit time} &= T_{\text{Sync}} + T_{\text{Seg1}} + T_{\text{Seg2}} \quad (\text{min. } 8 t_q)
 \end{aligned}$$

To compensate phase shifts between clocks of different CAN controllers, the CAN controller has to synchronize on any edge from the recessive to the dominant bus level. If the hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the resynchronization jump width T_{SJW} defines the maximum number of time quanta a bit time may be shortened or lengthened by one resynchronization. The value of SJW is programmed in the CAN Node Bit Timing Register.

$$\begin{aligned}
 T_{\text{SJW}} &= (\text{SJW} + 1) \times t_q \\
 T_{\text{Seg1}} &\geq T_{\text{SJW}} + T_{\text{prop}} \\
 T_{\text{Seg2}} &\geq T_{\text{SJW}}
 \end{aligned}$$

The maximum relative tolerance for f_{CAN} depends on the Phase Buffer Segments and the resynchronization jump width:

$$\begin{aligned}
 df_{\text{CAN}} &\leq \min(T_{b1}, T_{b2}) \times (1.3 \times \text{bit time} - T_{b2}) \quad \text{AND} \\
 df_{\text{CAN}} &\leq T_{\text{SJW}} / 20 \times \text{bit time}
 \end{aligned}$$

The configuration change enable, **CFG.CCE** bit has to be enabled before a valid CAN bit timing can be written to the CAN Node Bit Timing Register, BTLn_CTRL(n=1-2). This is then followed by resetting the INIT bit in **CFG.INITREQ**, i.e. before enabling the operation of the CAN node.

Note: The proposed sample point is at 80% of the bit time. For optimum oscillator tolerance, $BTLn(CTRL(n=1-2))$ setting should be done such that the number of time quantas, t_q and SJW is maximum.

Network Propagation Delays

The “worst case” network propagation delay is the network propagation delay after the 5th bit for the dominant to recessive edge on the bus. (See [Figure 13-82](#))

Figure 13-82 Network propagation delay after 5th bit

The WCAN module will sample the 5th bit after 5 consecutive dominant bits as recessive bit to ensure a safe wake-up, even if the dominant to recessive edge is delayed for the value of the network propagation delay shown in [Table 13-69](#). The network propagation delay describes the maximal occurrence propagation delay which can be seen on the bus. This maximum network propagation delay does not include any EMC jitter. (i.e no HF injection)

Table 13-69 Network propagation delay

Baud Rate (Baud)	Network Propagation Delay (ns)	Maximum Dominant time (ns) (sender oscillator tolerance included)
1MBaud	550	5550
500KBaud	1350	11350
250KBaud	2675	22675
125KBaud	5400	45450

For HF injection the WCAN module is able to handle EMC network propagation delay as shown in [Table 13-70](#).

Table 13-70 EMC Network propagation delay

Baud Rate (Baud)	Network Propagation Delay (ns)	Maximum Dominant time (ns) (sender oscillator tolerance included)
1MBaud	450	5450
500KBaud	1250	11250
250KBaud	2575	22575
125KBaud	5350	45350

Also the WCAN module is able to decode frames that contain sequences of 5 consecutive dominant bits followed by 5 consecutive recessive bits as shown in **Figure 13-82**.

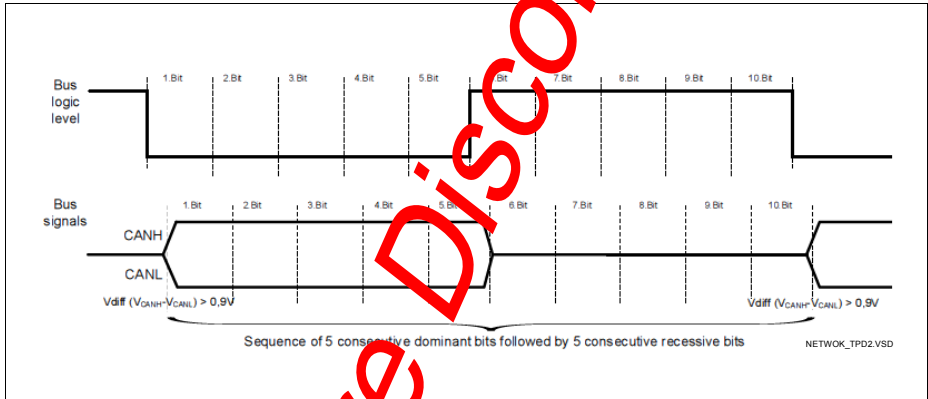

Figure 13-83 Network propagation delay after 10th bit

The transmitting CAN node on the bus has to guarantee a maximum baud rate tolerance of +/- 0.4% for correct detection of the CAN frames (See **Table 13-71**)

Table 13-71 Worst Case length of 10 bits

Baud Rate (Baud)	Worst Case time for length of 10 bits by sender oscillator tolerance (-0.4%)	Worst Case time for length of 10 bits by sender oscillator tolerance (+0.4%)
1MBaud	9970ns	10040ns
500KBaud	19970ns	20080ns

Table 13-71 Worst Case length of 10 bits

Baud Rate (Baud)	Worst Case time for length of 10 bits by sender oscillator tolerance (-0.4%)	Worst Case time for length of 10 bits by sender oscillator tolerance (+0.4%)
250KBaud	39840ns	40160ns
125KBaud	79680ns	80320ns

Feature Discontinued

13.17.2.2 WCAN Kernel Registers

Register Address Map

The register set of the WCAN module consists of the below distinct subsets:

1. The **Configuration, Miscellaneous Registers** exists in one instance and applies for the entire WCAN module.
2. The **Wake-up CAN Registers** consists of the following:
 - a) **CAN Node Registers** (BTLx_CTRL), which applies to a single CAN node and exist once for each CAN node
 - b) **Message Object Registers** (DLC_CTRL, IDx_CTRL, MASK_IDx_CTRL, DATAx_CTRL) is define for a single message object and thus exists once for each message object.

Configuration Registers

The configuration registers of a WCAN node are located according to [Table 13-72](#) which shows the absolute address as seen on the Standby Controller (SCR).

Table 13-72 CAN Nodes Register Address Map (Relative to MultiCAN Base Address)

Register	Addr.	Page	Total Range
CFG	B0 _H	0	Configuration Register
INTMRSLT	B1 _H	0	Interrupt Mask and Reference Select Register
REFCLK0	B2 _H	0	Clock Divider 0 Register
REFCLK1	B3 _H	0	Clock Divider 1 Register
CLKCMP0	B4 _H	0	Clock Compare Result 0 Register
CLKCMP1	B5 _H	0	Clock Compare Result 1 Register
INTESTAT0	B0 _H	1	Interrupt and Event Status 0 Register
INTESTAT1	B1 _H	1	Interrupt and Event Status 1 Register
FRMERRCNT	B3 _H	1	Frame Error Counter Register
INTESCLR0	B3 _H	1	Interrupt and Event Status Clear Register
INTESCLR1	B4 _H	1	Interrupt and Event Status Clear Register

CAN Node Registers

The registers of a CAN node are located according to [Table 13-73](#) which shows the absolute address of the CAN Node Registers as seen on the Standby Controller (SCR).

Table 13-73 CAN Nodes Register Address Map (Relative to MultiCAN Base Address)

Register	Addr.	Page	Total Range
BTL1_CTRL	B5 _H	1	Bit Timing Logic Control Register
BTL2_CTRL	B6 _H	1	Bit Timing Logic Control Register

Message Object Registers

The registers of a message object are located according to [Table 13-74](#) which shows the absolute address of the CAN Message Object Registers as seen on the Standby Controller (SCR).

Table 13-74 CAN Message Object Registers Address Map (Relative to MultiCAN Base Address)

Register	Addr.	Page	Full Name of Register
DLC_CTRL	B7 _H	1	Message Data Length Code Control Register
ID0_CTRL	B0 _H	2	Message Identifier Control Register 0
ID1_CTRL	B1 _H	2	Message Identifier Control Register 1
ID2_CTRL	B2 _H	2	Message Identifier Control Register 2
ID3_CTRL	B3 _H	2	Message Identifier Control Register 3
MASK_ID0_CTRL	B4 _H	2	Message Identifier Acceptance Mask Register 0
MASK_ID1_CTRL	B5 _H	2	Message Identifier Acceptance Mask Register 1
MASK_ID2_CTRL	B6 _H	2	Message Identifier Acceptance Mask Register 2
MASK_ID3_CTRL	B7 _H	2	Message Identifier Acceptance Mask Register 3
DATA0_CTRL	B0 _H	3	Message Data Control Register 0
DATA1_CTRL	B1 _H	3	Message Data Control Register 1
DATA2_CTRL	B2 _H	3	Message Data Control Register 2
DATA3_CTRL	B3 _H	3	Message Data Control Register 3
DATA4_CTRL	B4 _H	3	Message Data Control Register 4
DATA5_CTRL	B5 _H	3	Message Data Control Register 5
DATA6_CTRL	B6 _H	3	Message Data Control Register 6
DATA7_CTRL	B7 _H	3	Message Data Control Register 7

CAN Node Registers

The CAN node specific registers exist once for each CAN node of the MultiCAN module. They contain information that is directly related to the operation of the CAN nodes and which may not be shared among the nodes.

The Node Control Register contains basic settings that define the operation of the CAN node and the interaction of the CAN node with the message objects.

Bit Timing Logic Control Register

The Bit Timing Logic Control Registers contains all parameters to setup the bit timing for the CAN transfer.

Note: The startup-software (SSW) overwrites the BTL1_CTRL register with 14_H and BTL2_CTRL register with 58_H after reset to obtain a 500Kbits/s baud rate. Please use the following values for 1Mbits/s (BTL1_CTRL1, BTL2_CTRL), 250Kbits/s (BTL1_CTRL1, BTL2_CTRL) and 125Kbits/s (BTL1_CTRL1, BTL2_CTRL) baud rate.

The Configuration Change Enable, CFG.CCE has to be enabled before the BTLx_CTRL register can be written.

BTL1_CTRL

Bit Timing Logic 1 Control Register (15_H)

Reset Value: 7D_H

RMAP: 0, PAGE: 1

7	6	5	4	3	2	1	0
0	TSEG2			TSEG1			
r	rw			rw			

Field	Bits	Type	Description
TSEG1	[3:0]	rw	Time Segment Before Sample Point (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15.

Field	Bits	Type	Description
TSEG2	[6:4]	rw	Time Segment After Sample Point (TSEG2 + 1) time quanta is the user defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to resynchronization. Valid values for TSEG2 are 4 to 7.
0	7	r	Reserved Read as 0 after reset, value last written is read back; should be written with 0.

Feature Discontinued

Bit Timing Logic Control Register

BTL2_CTRL

Bit Timing Logic 2 Control Register (B6_H)

Reset Value: C7_H

RMAP: 0, PAGE: 1

Field	Bits	Type	Description
BRP	[5:0]	rw	Baud Rate Prescaler The duration of one time quantum is given by (BRP + 1) clock cycles.
SJW	[7:6]	rw	(Re)Synchronization Jump Width (SJW + 1) time quanta are allowed for resynchronization.

Feature Discontinued

Message Object Registers

Message Data Length Code Control Register

Register DLC_CTRL are the data length code filter bits. There are no additional mask bits. See [Figure 13-77](#) for flow of acceptance filtering which would determine if a wake-up frame has been detected.

DLC_CTRL

Message Data Length Code Control Register(B7_H) **Reset Value: 00_H**
RMAP: 0, PAGE: 1

Field	Bits	Type	Description
DLC	[3:0]	rwh	Data Length Code Valid values for the data length are 0 to 8. DLC = 8 leads to 8 data bytes, but the DLC code is not truncated upon reception or transmission of CAN frames.
0	[7:4]	r	Reserved Read as 0 after reset; value last written is read back; should be written with 0.

Feature Discontinued

Message Identifier Control Register 0

Register IDn_CTRL (n=0-3) contains the CAN identifier filter bits. See [Figure 13-77](#) for flow of acceptance filtering which would determines if a Wake-up Frame have been detected.

ID0_CTRL

13.17.3.2 Port and I/O Line Control

The interconnections between the Wake-up CAN module and the port I/O lines are controlled in the port control logic for Port 0, 2 and in the EVR for Port 14, 15. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (SCR_IOCR registers (SCR module) and IOCR registers (GPIO module))

Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selection. The I/O lines for the WCAN module are controlled by the port input/output control registers shown below. (See MODPISEL0 register at SCU chapter)

Table 13-77 shows how bits and bit fields must be programmed for the required I/O functionality of the CAN I/O lines.

Table 13-77 WCAN I/O Control Selection and Setup

Module	Port Lines	Input Output Control Register Bits	I/O
CAN	CAN0		
	P02.1 / WCANRXDA	SCR_P02_IOCR1.PC1 = 0XXXX _B	Input
	P02.3 / WCANRXDB	SCR_P2_IOCR3.PC3 = 0XXXX _B	Input
	P02.4 / WCANRXDC	SCR_P2_IOCR4.PC4 = 0XXXX _B	Input
	P00.1 / WCANRXDD	SCR_P0_IOCR1.PC1 = 0XXXX _B	Input
	P00.3 / WCANRXDE	SCR_P0_IOCR3.PC3 = 0XXXX _B	Input
	P14.1 / RXDCAN	P14_IOCR12.PC1 = 0XXXX _B	Input
	P15.1 / RXDCAN	P15_IOCR12.PC1 = 0XXXX _B	Input
	P02.5 / SYNCA	SCR_P2_IOCR5.PC5 = 0XXXX _B	Input
P02.7 / SYNCF	SCR_P2_IOCR7.PC7 = 0XXXX _B	Input	

Interrupt Control

The interrupt control logic in the Wake-up CAN module consists of the following interrupts shown in **Table 13-78** and **Figure 13-85**.

Table 13-78 WCAN Interrupt Outputs

Interrupt inputs	Connected to WCAN Interrupt Output
SCR	WUF_INT (Wake-up Frame Interrupt)
	ERROR_INT (Error Counter Overflow Interrupt)
	OSCCNTRUN_INT (Oscillator Counter Run Interrupt)
	CANTO_INT (CAN Timeout Interrupt)

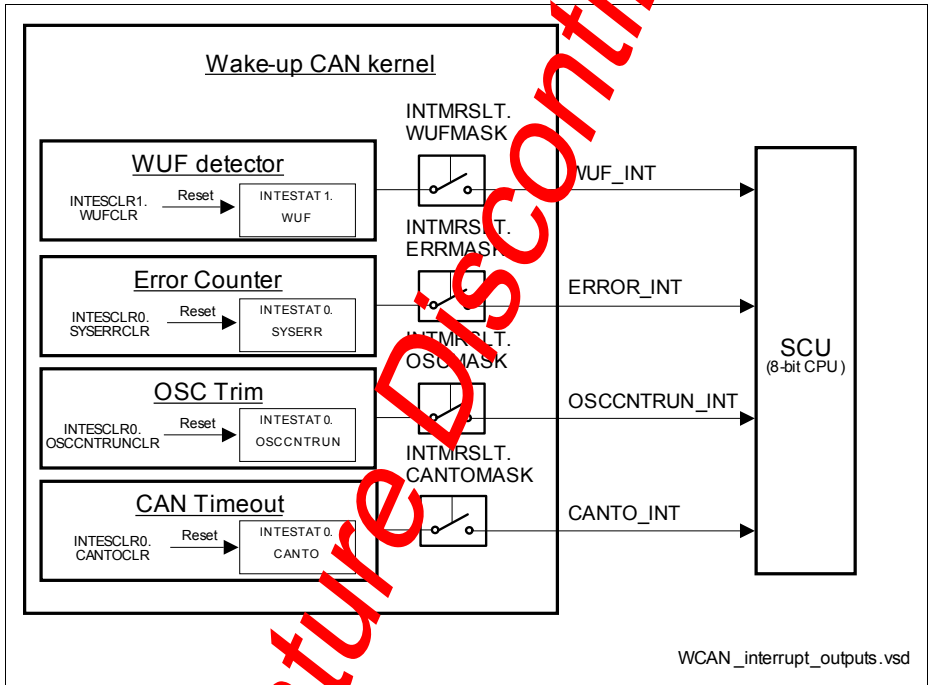

Figure 13-85 Wake-up CAN Interrupt Outputs

13.17.4 Revision history

Revision History

Revision History (from WCAN v0.1 to WCAN v0.2)

- Picture 1-42 Interrupt Compressor picture 64 message objects exchanged by picture 256 message objects
- Correction to match register generation tool
- Mark Oscillator measurement registers as internal (can be external as soon as patent situation is clear)

Revision History (from WCAN v0.2 to WCAN v0.3)

- Unhide all text and Registers set visible internal
 - Section 1.2.2.2 CAN Error Handling
 - Section 1.2.3 CAN Node Interrupts
 - Section 1.2.4 CAN Node Analysis Features
 - Section 1.2.6 Message Postprocessing Feature
 - Section 1.2.7 Message Object Data Handling
 - Section 1.2.8 Message Object Functionality
 - NCR, NSR, NIPR, NBTR, NECNT, NFCR, MOFGPR, MOIPR, MOCTR, ID, PANCTR, MCR, MITR, LIST, MSPND, MSIDK, MSIMASK, NCR, NSR, NIPR, VECNT, NFCR

Revision History (from WCAN v0.3 to WCAN v0.4)

- structured document and added various registers

Revision History (from WCAN v0.4 to WCAN v0.5)

- Corrected external conditional text settings for ITS as it is not correct

Revision History (from WCAN v0.5 to WCAN v0.6)

- Modified **INTESCLR0** and **INTESCLR1** bit settings to “w” for bit clear register
- Corrected **CFG.CFGVAL** to wh
- As per meeting on 6. April CAN Wake-up Filter Function Alignment
 - For node registers, only NBTR, NECNT, NFCR are available in CAN protocol handler, however only NBTR are only made available for CAN timing control. Keeping the same naming structure of (DoorSBC+Selective wake-up), this is the CTRL_DAT0 register. Thus removed NBTR0_DAT0, NBTR0_DAT1 and NPCR0_DAT0 register.
 - For Message Object registers, MOAR0_DATn (n=0-3), MOAMR0_DATn (n=0-3), MOFCR0_DATn (n=0-3), MODATAL0_DATn (n=0-3), MODATAH0_DATn (n=0-3), MOCTRn, MOIPRn, MOFGPRn are not delivered on the CAN protocol handler

and thus these registers are removed. Message Object Registers available for Acceptance Filter Operation to determine Wake-up are added keeping the same naming structure of (Door SBC + selective wake-up) DLC_CTRL, MASK_IDn_CTRL (n=0-3), IDn_CTRL (n=0-3), DATAn_CTRL (n=0-3).

- All other CAN registers such as global module registers ID, PANCTR, MCR, MITR, LISTn, MSPNDk, MSIDk, MSIMASK, NCRx, NSRx, NIPRx, NPCRx are not available on the CAN protocol handler and not implemented on the IP (Door SBC + selective wake-up) are also deleted.
- Removed Section CAN Module Related External Registers as these are not available on IP (Door SBC + selective wake-up) and will not be implemented as there are no further registers to access. WCAN_ADCON0, WCAN_ADL, WCAN_ADH, WCAN_DAT0, WCAN_DAT1, WCAN_DAT2, WCAN_DAT3 are removed.
- Removed Section Message Object Registers and corresponding MOFGPRn, MOIPRn, MOCTRn registers as these are not available on IP (Door SBC + selective wake-up).
- Removed Section CAN Node Registers and corresponding NFCRx, NECNTx, NPCR, NIPRx, NSRx, NCRx as these are not available on IP (Door SBC + selective wake-up).
- Removed Section Global Module Registers and corresponding MSIMASK, MSIDK, MSPNDK, LISTn, MITR, MCR, PANCTR, ID as these are not available on IP (Door SBC + selective wake-up).
- Removed Section on CAN Module Constants, Message Object List Structure, List of Unallocated Elements, List Command Panel, Analyze Mode, CAN Node Analysis Feature, CAN Bit Timing Analysis, Message Postprocessing Interface, Message Object Functionality, Message Object Data Handling, Message Acceptance Filtering, Message Object List Structure as these are not available on IP (Door SBC + selective wake-up).

Revision History (from WCAN v0.6 to WCAN v0.8)

- Replaced [Figure 13-76](#)
- Replaced Fig1-3 WUF detection with [Figure 13-77](#) Wake-up Frame Detection
- Replaced Fig1-4 with [Figure 13-78](#) Oscillator Trimming and modified description of [Section 13.17.1.6](#) Oscillator Trimming.
- Replaced Fig1-5 with [Figure 13-79](#) CAN Timeout and modified description of [Section 13.17.1.7](#) CAN MessageTimeout.
- Replaced Fig 1-6 with [Figure 13-80](#) Error Counter
- Added Section 1.2.2 CAN Protocol Handler Clock
- Rename of registers below and on [Figure 13-84](#)
 - CTRL_DATn (n = 0-3) to CTRLn (n = 0-3)
 - OSCTRIMSTAT_DATn (n = 0-1) to OSCTRIMSTATn (n = 0-1)
 - STAT_DATn (n = 0-2) to STATn (n = 0-2)

- STATCLR_DATn (n = 0-1) to STATCLRn (n = 0-1)
- Added additional register bits below
 - Selective Wake Enable Bit on CTRL0.SELWK_EN.
 - Oscillator Run Interrupt Masking Bit on CTRL1.OSCMAK.
 - Wake-up Frame Interrupt Masking on CTRL1.WUFMASK.
- Added on CTRL2 on XTALOSCCNT0 divider factor is XTALOSCCNT0+1.
- Removed on DIV8=1 information on BTL2_CTRL.BRP and [Section](#)

Revision History (from WCAN v0.8 to WCAN v0.9)

- Added CTRL0.SELWK_EN, selective wake-up enabled bit functions with added text on functions. Modified [Figure 13-77](#), [Figure 13-79](#), [Figure 13-80](#) to include SELWK_EN.
- Added text on CTRL0.SYSERR to indicate configuration error and overcounter overflow condition.
- Added text on STAT0.CANTO to indicate CAN bus inactivity in $t_{SILENCE}$ of 750ms.

Revision History (from WCAN v0.9 to WCAN v1.0)

- Modified BTL1_CTRL reset value to 12_H, $T_{seg1} = 3t_q$, $T_{seg2} = 2t_q$. Thus Bit time = $T_{sync} + T_{seg1} + T_{seg2} = 8t_q$.
- Modified BTL2_CTRL reset value to 18_H, BRP = 24 (decimal). Assume $F_{CAN} = 100\text{MHz}$, default Baud Rate is set to 500 kbits/s after reset.
- Added note on CTRL0.OSCCAL, Oscillator calibration is disabled for the standby domain.
- Removed text SWKSET= CFGVAL of SYSERR under STAT1.SWKSET.
- Added Section 1.2.1.2 Network Propagation Delays
- [Table 13-73](#).

Revision History (from WCAN v1.0 to WCAN v1.1)

- [Table 13-73](#).
- Removed of NIPR2.TEINP as Timer Event Interrupt Node Pointer is not available for CAN.
- Modified BTL1_CTRL reset value to 14_H, $T_{seg1} = 5t_q$, $T_{seg2} = 2t_q$. Thus Bit time = $T_{sync} + T_{seg1} + T_{seg2} = 8t_q$.
- Modified BTL2_CTRL reset value to 58_H. Assume $F_{CAN} = 100\text{MHz}$, default Baud Rate is set to 500Kbits/s after reset.
- Modified STAT0 register reset value to 08_H. At reset STAT0.CANTO value is '1' CAN time out detected.
- Modified STAT1 register reset value to 08_H. At reset STAT1.CANSIL value is '1' $t_{SILENCE}$ is exceeded.

Revision History (from WCAN v1.1 to WCAN v1.2)

- Updated Fig1-2, 1-4, 1-5 addition of “done” complete flowchart
- Corrected text on CTRL0.SELWK_EN. On item 3. Triggers ERROR_INT and wake-up if there are any changes to the message object register.
- Added STAT0.ECOFL, MORC, ERSEL to indicate if SYSERR occurs what is the trigger source. Error Counter Overflow, Message Object Register Changed after SELWK_EN is set, SYSERR is set while SELWK_EN is set. Updated Fig1-5 to include ECOFL='1'
- Added corresponding clear registers STATCLR0.ECOFLCLR, MORCCLR, ERSELCLR.

Revision History (from WCAN v1.2 to WCAN v1.3)

- Updated text on CTRL0.SELWK_EN to indicate source of ERROR_INT.
- Modified on CTRL0.INITREQ register bit 'rwh' to 'rw'

Revision History (from WCAN v1.3 to WCAN v1.4)

- Removed NCR0/1, NSR0/1, NIPR0/1, NIPR0, NECNT0/1/2/3, NFCR0/1/2 register and remove corresponding Table on SFR address listings for Pages 4-7 which housed these registers.
- Added Last Error Code (LEC), 3bits to **INTESTAT1** bit7-5 and moved SYNC bit 6 to bit 1. Also moved SYNCCLR of STAT1 bit 6 to bit 1 correspond to move on **INTESTAT1** register.
- Added hint on [Section Input/Output Function Selection in Ports](#) reference to (See MODPISEL0 register at SCU chapter) for port control selection.
- Rename of registers
 - STAT0/1 to **INTESTAT0/1**, Interrupt and Event Status Register 0/1
 - STAT2 to **FRMERRCNT**, Frame Error Counter Register
 - STATCLR0/1 to **INTESCLR0/1**, Interrupt and Event Status Clear Register 0/1
 - CTRL0 to **CFG**, Configuration Register
 - CTRL1 to **INTMRSLT**, Interrupt Mask and Reference Select Register
 - CTRL2/3 to **REFCLK0/1**, Clock Divider Register 0/1
 - OSCTRIMSTAT0/1 to **CLKCMP0/1**, Clock Compare Result Register 0/1

Revision History (from WCAN v1.4 to WCAN v1.5)

- CEC bit added to **CFG** bit 3. **INTESTAT1**.LEC bit 7-5 changed to 'rh' and bit 111_B option removed.
- Added back NECNT0/1/2/3, NFCR0/1/2 registers and added corresponding Table on “SFR address listings for Pages 4-7” which housed these registers.

Revision History (from WCAN v1.5 to WCAN v1.6)

- Modified on below

- Definition on **CFG.INITREQ**, **INTESTAT0.INITACK**, .
- Added on **FRMERRCNT.ECNTCLR** bit 7, error counter clear bit.
- Added note on **BTL1_CTRL**, **BTL2_CTRL** register that startup software will overwrite the reset values to 14_H, 58_H after reset.
- Corrected typo error on **INTESCLR1.SYNCLR** bit 6 to bit 7.
- Corrected typo error on **CFG** to page 0.
- Modified naming, definition on **REFCLK0/REFCLK1.PERIOD** and on **Section 13.17.1.6 Oscillator Trimming**.

Revision History (from WCAN v1.6 to WCAN v1.7)

- Modified on **NECNT2.EWRNLVL** reset value to 60_H.
- Modified on **INTESCLR1.SWKSETCLR**, bit 2 is removed.
- Corrected on **INTMRSLT** bit 7 to 4 to 'r' reserved bits.
- Modified on **INTESTAT0.CANTO** reset from 08_H to 00_H and on **INTESTAT1.CANSIL** reset from 08_H to 00_H.

Revision History (from WCAN v1.7 to WCAN v1.8)

- Added on **Section** note “ The proposed sample point is at 80% of the bit time. For optimum oscillator tolerance, BTLn(CTRLn[1-2]) setting should be done such that the number of time quantas, tq and SW is maximum.”
- Removed Section 1.2.2 CAN Protocol Handler Clock with Table on Minimum Operating Frequencies.

Revision History (from WCAN v1.8 to WCAN v1.9)

- Added text on **Section**, **Section** “CFG.CCE has to be enabled, before writing to the bit timing registers BTLx_CTR.”

Revision History (from WCAN v1.9 to WCAN v1.10)

- Updated Fig1-3, Fig1-5 to include the 'No' Path.
- Per AI 237961, defined the **INTESTAT0.INITACK** bit, and added section on “Initialisation Request and Initialisation Acknowledge”.

13.18 TC2x_SCR Implementation

This chapter describes the product specific implementation of TC2x_SCR.

13.18.1 TC2x_SCR and QSPI Interface

This section describes the implementation details for TC2x_SCR and QSPI interface. The main TC2x system can access TC2x_SCR XRAM via the QSPI2 interface. **Table 13-79** summarizes the interface signals for SPI communication.

Table 13-79 QSPI interface signals for SPI communication with SCR XRAM

Signal name	Signal Description
SLSO215	SPI chip select output
MRST2H	SPI MRST input
MTRSR2	SPI MTRSR output
SCLK2	SPI clock output

Feature Discontinued

14 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The TC26x B-Step has digital General Purpose Input/Output (GPIO) port lines which are connected to the on-chip peripheral units.

14.1 Basic Port Operation

Figure 14-1 is a general block diagram of a TC26x B-Step GPIO port slice.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

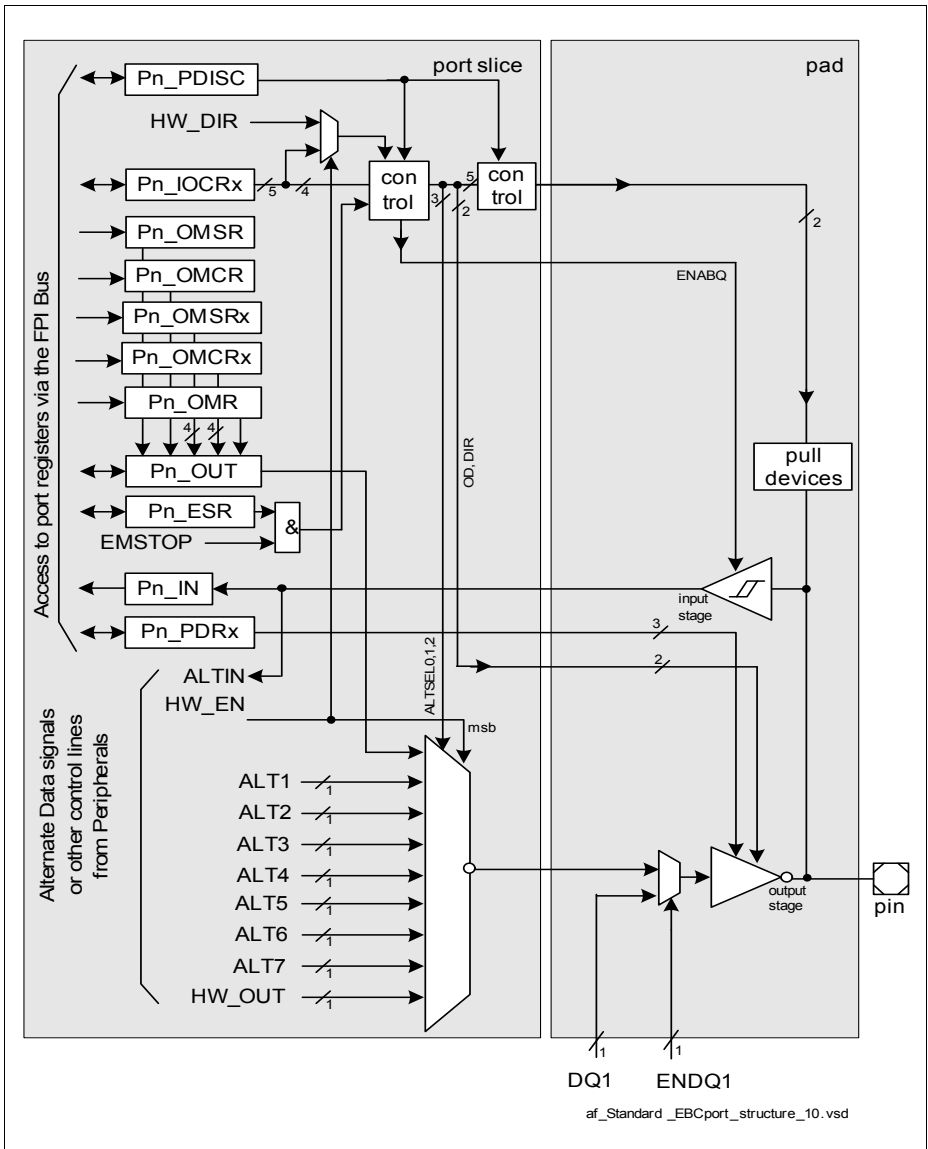

Figure 14-1 General Structure of a Port Pin

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin can be configured for input or output operation. In input mode, the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register Pn_IN. Input signals are connected directly to the various inputs of the peripheral units (AltDataIn). The function of the input line from the pin to the input register Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output. This means that when the port is in output mode, the level of the pin can be read by software via Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register Pn_IOCR has to be written for input or output selection. The Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (Pn_IOCR register) to the Output Data Register Pn_OUT. Software can set or clear the bit in Pn_OUT through separate Pn_OMSR or Pn_OMCR registers. The set or clear operations for the bits in Pn_OUT can also be done for up to four bits per register in Pn_OMSRx and Pn_OMCRx (x=0,4,8,12). Alternatively, the set, clear or toggle function can be achieved through Pn_OMR, where adjacent pins within the same port can be set, cleared or toggled within one write operation. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register Pn_OMSR, Output Modification Set Register x Pn_OMSRx (x=0,4,8,12), Output Modification Clear Register Pn_OMCR, Output Modification Clear Register x Pn_OMCRx (x=0,4,8,12) or Output Modification Register, OMR. The bits in Pn_OMSR/Pn_OMSRx and Pn_OMCR/Pn_OMCRx make it possible to set and clear the bits in the Pn_OUT register. While the bits in Pn_OMR allows the bits in Pn_OUT to be set, cleared, toggled or remain unchanged.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied through software via the output register Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register Pn_IN.

Most of the GPIO lines of the TC26x B-Step have an emergency stop logic¹⁾. This logic makes it possible to individually disconnect outputs and put them onto a well defined logic state in an emergency case. In an emergency case, the pin is switched to input function with internal pull-up device connected or tri-state. The Emergency Stop Register Pn_ESR determines whether an output is enabled or disabled in an emergency case.

1) This feature is not available for all port lines, for detail please see the dedicated Target Data Sheet / Data Sheet.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.2 Description Scheme for the Port IO Functions

The following two general building block can be used to describe each GPIO pin:

Table 14-1 Port x Input/Output Functions

Port Pin	I/O	Select	Connected Signal(s)	From / to Module
Px.y	Input		Signal(s)	module(s)
	Output	GPIO	Signal	module
		ALT1	Signal	module
		ALT2	Signal	module
		ALT3	Signal	module
		ALT4	Signal	module
		ALT5	Signal	module
		ALT6	Signal	module
	ALT7	Signal	module

or:

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
Table 14-2 Port x Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.		
				Reg./Bit Field	Value	
Px.y	I	GPIO	Px_IN.Py	Px_IOCz. PC0	0XXX0 _B	
	O	GPIO		Px_OUT.Py		1X000 _B
						1X001 _B
						1X010 _B
						1X011 _B
						1X100 _B
						1X101 _B
						1X110 _B
				1X111 _B		
HW_DIR	module; group En	Signal		HW_DIR		

- **HW_DIR:**
The type Alternate Direction signal which is needed if HW_En is active:
 - Out -always output
DIRx - the pins in one port having the same DIRx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_DIR signal.
SDIR- Single DIR- the pin is controlled by its own, dedicated, single HW_DIR signal.
- grouping indicates if the respective pin is controlled by hardware:
 - ENx - the pins in one port having the same ENx (x=0, 1, 2, ...), are controlled as a group by a dedicated HW_EN signal.
 - SEN - Single EN - the pin is controlled by its own, dedicated, single HW_EN signal
- Digital port slices with HW_DIR defined are the ports described in [Figure 14-1](#).

Note: Emergency Stop has higher priority than the HW_EN signal. Emergency Stop is functional when the pins are set in the GPIO mode.

*Note: HW_DIR signal, output case, switches the pad to push-pull output state.
HW_DIR signal, input case, switches the pad to the input state with pull-up/down setting as defined by the IOCR register.*

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.3 Port Register Description

The individual control and data bits of each GPIO port are implemented in a number of registers. The registers are used to configure and use the port as general-purpose I/O or alternate function input/output. Destructive read is not implemented in any of the registers. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described separately.

Note: Parallel requests from on chip bus masters to the ports module are executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the ports module in between the operations.

14.3.1 Module Identification Register

The module Identification Register ID contains read-only information about the module version.

ID

Identification Register (08_H) Reset Value: 00C8 C0XX_H

Field	Bits	Type	Description
MODREV	[7:0]	r	Module Revision Number This bit field indicates the revision number of the TC26x B-Step module (01 _H = first revision).
MODTYPE	[15:8]	r	Module Type This bit field is C0 _H . It defines a 32-bit module
MODNUMBER	[31:16]	r	Module Number This bit field defines the module identification number. The value for the Ports module is 00C8 _H

14.3.2 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn_IOCR0 controls the Pn.[3:0] port lines

Register Pn_IOCR4 controls the Pn.[7:4] port lines

Register Pn_IOCR8 controls the Pn.[11:8] port lines

Register Pn_IOCR12 controls the Pn.[15:12] port lines

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

The reset values of 1010 1010_H and 0000 0000_H for Pn_IOCRx registers represents input pull-up and no input pull device (tri-state mode) being activated, respectively. The switching of the intended mode of the device is controlled by HWCFG6. When a cold reset is activated and HWCFG6=1, the port pins except P33.8 and P40 are set to input pull-up mode, P33.8 and P40 are in tri-state mode as long as PORST is activated. If HWCFG6=0, the pins has the default state of tri-state mode. The pad state can also be configured by software through PMSWCR0.TRISTREQ bit. In the event of a warm reset or wake-up from standby mode, PMSWCR0.TRISTREQ is not affected by reset, hence Pn_IOCRx registers have the reset values configured as per the last state of the TRISTREQ bit.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

The structure with one control bit field for each port pin located in different register bytes offers the possibility to configure the port pin functionality of a single pin with byte-oriented accesses without accessing the other PCx bit fields.

Port Control Coding

Table 14-5 describes the coding of the PCx bit fields that determine the port line functionality.

When a port line is configured as input (PCx), its hysteresis function can be activated/inactivated via its related PDx bit field (see **Table 14-6** and **Table 14-7**).

When a port line is configured as output (PCx), its speed grade can be configured via its related PDx bit field (see **Table 14-6** and **Table 14-7**).

Table 14-5 PCx Coding

PCx[4:0]	I/O	Characteristics	Selected Pull-up / Pull-down / Selected Output Function
0XX00 _B	Input	–	No input pull device connected, tri-state mode
0XX01 _B			Input pull-down device connected
0XX10 _B			Input pull-up device connected ¹⁾
0XX11 _B			No input pull device connected, tri-state mode

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Table 14-5 PCx Coding

PCx[4:0]	I/O	Characteristics	Selected Pull-up / Pull-down / Selected Output Function
10000 _B	Output	Push-pull	General-purpose output

11111 _B			Alternate output function 7

1) This is the default pull device setting after reset for powertrain applications.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.3.3 Pad Driver Mode Register
Overview

For port lines that are configured as output (PCx), the speed grade can be configured via the related PDx bit fields (registers Pn_PDR0/1). The speed grade defines the output driver strength and the slew rate of the faster output slopes (slope control only available for speed grades 1 and 2). For port lines configured as input (PCx), the PDx fields determines if hysteresis is active or inactive for the input function (hysteresis function is only available for MP, MP+, MPR and LP pads).

Further details about pad driver classes that are available in the TC26x B-Step are summarized in the Target Data Sheet/Data Sheet.

Table 14-6 Pad Driver Mode and Hysteresis Selection for Pads of type MP, MP+ MPR

PDx.2	PDx.1	PDx.0	Output Functionality	Input Functionality
X	0	0	Speed grade 1	Hysteresis is inactive
X	0	1	Speed grade 2	Hysteresis is active
X	1	0	Speed grade 3	Hysteresis is active
X	1	1	Speed grade 4	Hysteresis is active

Table 14-7 Pad Driver Mode and Hysteresis Selection for Pads of type LP

PDx.2	PDx.1	PDx.0	Output Functionality	Input Functionality
X	X	0	Speed grade 1	Hysteresis is inactive ¹⁾
X	X	1	Speed grade 2	Hysteresis is active

1) This feature is not available for all LP pads, for detail please see the dedicated Target Data Sheet / Data Sheet.

Note: TC26x B-Step Data Sheet describes the DC characteristics of all pad classes.

The default CMOS mode can be switched to LVDS mode in LVDS pads. For LVDSM pads, the LVDS mode can be enabled through port control by setting PDx.2 of the lower pin, CMOS mode is selected if PDx.2 of the lower pin of the pin-pair is cleared. For LVDSH pads, the LVDS mode can be enabled through LPCRx register.

Depending on whether it is 3.3V- or 5V-pad, the pad level is Automotive Level (AL). The TTL level can be enabled for both for 3.3V and 5V pads through the PLx bit in the Pn_PDRx. The coding is shown in [Table 14-8](#).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
Table 14-8 Pad Level Selection

PLx	3.3V-Pad	5V-Pad
0	Automotive Level (AL)	Automotive Level (AL)
1	TTL Level	TTL Level

Note: 3.3V-Pad corresponds to A2, F pads and 5V-Pad corresponds to LP, MP and MP+ pads in the Data Sheet, respectively.

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDR0 and PDR1 registers, respectively. Each PDx field controls 1 pin. For coding of PDx, see [Table 14-6](#). Similarly, each PLx bit controls 1 pin. For coding of PLx, see [Table 14-8](#).

The reset value of Pn_PDR0/1 registers is 3333 3333_H.

14.3.4 LVDS Pad Control Register

The LVDS Pad Control Register controls the RX or TX functions of the LVDSH pads. For usage of RX pad, bit field [9:0] are applicable. If used for TX pad, bit field [15:12] apply. Register P21_LPCR_x (x=0-7) controls the LVDSH functions of P21._[(x*2+1):x*2] port lines.

Alternatively, the LVDS Pad Control Register also selects if the LVDSM pads are supplied by 5V or 3.3V at V_{EXT} .

Register P_x_LPCR0.1,(x=13, 22) selects the pad supply for P_x._[1:0] port lines.

Register P_x_LPCR1.1,(x=13, 22) selects the pad supply for P_x._[3:2] port lines.

P21_LPCR_x (x = 0-7)
Port 21 LVDS Pad Control Register x(00A0_H+x*0004_H) Reset Value: 0000 6046_H

Field	Bits	Type	Description
RDIS_CTRL	0	rw	LVDS RX_DIS controller The LVDS RX_DIS control function can be selected from the Port (default) or HSCT module. 0 _B Port controlled 1 _B HSCT controlled
RX_DIS	1	rw	Disable Receive LVDS Disable the receive LVDS / enable CMOS path. If this bit is set to 1 - no transfer from the LVDS sender can be received and the receiver LVDS is in low power state. 0 _B enable LVDS / disable CMOS mode 1 _B disable LVDS / enable CMOS mode

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
TERM	2	rw	Select Receiver Termination Mode Selects a suitable internal load capacitance. 0 _B external termination - on the PCB 1 _B 100 Ω Receiver internal termination
LRXTERM	[7:3]	rw	LVDS RX Poly-resistor configuration value Programming bits for the on die poly resistor termination. The value is configured during production test. Each chip configuration on this bit field is unique and configured during production testing. <i>Note: The configuration value shall not be changed by user after start-up for a guaranteed behavior.</i>
LVDSR	8	rw	Special reduced LVDS electrical signaling mode LVDSR = 1 and LVDSRL = 0 activates LVDSR electrical. LVDSR = 1 and LVDSRL = 1 Not allowed - Software must prevent this situation! <i>Note: LVDSR = 1 and LVDSRL = 1 the special reduced electrical LVDS signaling is enabled.</i>
LVDSRL	9	rw	LVDS IEEE electrical signaling mode LVDSR = 0 and LVDSRL = 1 activates the IEEE reduced LVDS link electrical signaling specification LVDSR = 0 and LVDSRL = 0 activates the IEEE general purpose link.
TDIS_CTRL	12	rw	LVDS TX_DIS controller The LVDS TX_DIS control function can be selected from the Port (default) or HSCT module. 0 _B Port controlled 1 _B HSCT controlled
TX_DIS	13	rw	Disable Transmit LVDS Disable the transmit LVDS / enable CMOS path. If this bit is set to 1 - no transfer on LVDS data path can be initiated and the LVDS driver is disabled. 0 _B enable LVDS / disable CMOS mode 1 _B disable LVDS / enable CMOS mode

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
TX_PD	14	rw	LVDS Power Down 0 _B LVDS power on 1 _B LVDS power down (default)
TX_PWDPD	15	rw	Disable TX Power down pull down. This function disables or enables the LVDS pull down resistor. The application code must disable TX power down pull down resistor with a power up. With a LVDS Power Down configuration the pull down function must be enabled, if required. 0 _B disabled TX Power down pull down resistor. 1 _B enabled TX Power down pull down resistor.
0	[31:16], [11:10]	r	Reserved Read as 0; should be written with 0.

For P13_LPCR_x (x=0,1) and P22_LPCR_x (x=0,1) , the PS_x needs to be configured to the intended pad supply level before the LVDSM function is enabled.

14.3.5 Pin Function Decision Control Register

Pin Function Decision Control Register

The pad structure of the TC26x B-Step GPIO lines offers the possibility to select digital input or analog ADC input functionalities. For the selection of digital input, the parameters defined for Class S pads must be met. This feature can be controlled by individual bits in the Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCRR register. One Pn_PDISC register is assigned to each port.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.3.6 Pin Controller Select Register

The pin controller select register is capable to decide the controller for all data and control functions of each shared port pin separately during run, sleep and standby modes. The 8-bit controller can handle the functions for the shared port pins in standby mode, if the controller is selected before entering the standby mode. Upon a wake-up from standby mode, the reset value does not reflect the actual latched value stored in the 8-bit controller. The value written into the PCSR before entering standby mode is kept by the 8-bit controller when standby mode is exited. The value is not available as status information.

PCSR register is also used to enable or disable the VADC Multiplexer Diagnostics (MD) feature. For pins selected for 8-bit controller, SPAREINOUT0 bit 0 decides if pull-up and pull-down function is controlled by 8-bit controller or VADC Multiplexer Diagnostics (MD) feature is enabled.

Alternatively, this register can also select Ethernet output signals through ports alternate output or fast RMII mode.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.3.7 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_IOC Rx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register Pn_OMSR or port output modification clear register Pn_OMCR, respectively. The Pn_OUT.Px bits can also be set, cleared or toggled with register Pn_OMR within the same write operation.

Pn_OMCR8 (n=14-15)

 Port n Output Modification Clear Register 8(F003 A688_H + n*100_H) Reset Value: 0000 0000_H
P20_OMCR8

 Port 20 Output Modification Clear Register 8(88_H) Reset Value: 0000 0000_H
P33_OMCR8

 Port 33 Output Modification Clear Register 8(88_H) Reset Value: 0000 0000_H

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
PCLx (x = 11-8)	x + 16	w	Port n Clear Bit x Setting this bit will clear the corresponding bit in the port output register Pn_OUT. Read as 0. 0 _B No operation 1 _B Clears Pn_OUT.Px
0	[31:28], [23:0]	r	Reserved Read as 0; should be written with 0.

P00_OMCR12
Port 00 Output Modification Clear Register 12(8C_H) **Reset Value: 0000 0000_H**
P11_OMCR12
Port 11 Output Modification Clear Register 12(8C_H) **Reset Value: 0000 0000_H**
P20_OMCR12
Port 20 Output Modification Clear Register 12(8C_H) **Reset Value: 0000 0000_H**
P33_OMCR12
Port 33 Output Modification Clear Register 12(8C_H) **Reset Value: 0000 0000_H**

Field	Bits	Type	Description
PCLx (x = 15-12)	x + 16	w	Port n Clear Bit x Setting this bit will clear the corresponding bit in the port output register Pn_OUT. Read as 0. 0 _B No operation 1 _B Clears Pn_OUT.Px
0	[27:0]	r	Reserved Read as 0; should be written with 0.

14.3.13 Emergency Stop Register

All digital GPIO lines have an emergency stop logic implemented (see [Figure 14-1](#)).

Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop register Pn_ESR of Port n. If the emergency stop signal becomes active, one of two states can be selected:

- Emergency stop function disabled (ENx = 0):
The output line remains connected (alternate function).
- Emergency stop function enabled (ENx = 1):
The mapped output function is disconnected and the safe state is entered by switching to input function with internal pull-up connected or tri-state, depending on the configured reset value of the corresponding Pn_IOCR register through PMSWCR0.TRISTREQ or setting of HWCFG[6]. (the content of the corresponding PCx bit fields in register Pn_IOCR will not be considered).

P00_ESR

Port 00 Emergency Stop Register (50_H) Reset Value: 0000 0000_H

P02_ESR

Port 02 Emergency Stop Register (50_H) Reset Value: 0000 0000_H

Pn_ESR (n=10-11)

Port n Emergency Stop Register (F003 A650_H + n*100_H) Reset Value: 0000 0000_H

Pn_ESR (n=13-15)

Port n Emergency Stop Register (F003 A650_H + n*100_H) Reset Value: 0000 0000_H

Pn_ESR (n=20-23)

Port n Emergency Stop Register (F003 AC50_H + n*100_H) Reset Value: 0000 0000_H

Pn_ESR (n=32-33)

Port n Emergency Stop Register (F003 B250_H + n*100_H) Reset Value: 0000 0000_H

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
ENx (x = 0-15)	x	rw	Emergency Stop Enable for Port n Pin x This bit enables the emergency stop function for all GPIO lines. If the emergency stop condition is met and enabled, the output selection is automatically switched from alternate output function to GPIO input function with internal pull-up device connected or tri-state. See Page 14-50 . 0 _B Emergency stop function for Pn.x is disabled. 1 _B Emergency stop function for Pn.x is enabled.
0	[31:16]	r	Reserved Read as 0; should be written with 0.

14.3.14 Port Input Register

The logic level of a GPIO pin can be read via the read-only port input register Pn_IN. Reading the Pn_IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P00_IN		
Port 00 Input Register	(24 _H)	Reset Value: 0000 XXXX _H
P02_IN		
Port 02 Input Register	(24 _H)	Reset Value: 0000 XXXX _H
Pn_IN (n=10-11)		
Port n Input Register	(F003 A624 _H + n*100 _H)	Reset Value: 0000 XXXX _H
Pn_IN (n=13-15)		
Port n Input Register	(F003 A624 _H + n*100 _H)	Reset Value: 0000 XXXX _H
Pn_IN (n=20-23)		
Port n Input Register	(F003 AC24 _H + n*100 _H)	Reset Value: 0000 XXXX _H
Pn_IN (n=32-33)		
Port n Input Register	(F003 B224 _H + n*100 _H)	Reset Value: 0000 XXXX _H
P40_IN		
Port 40 Input Register	(24 _H)	Reset Value: 0000 XXXX _H

Field	Bits	Type	Description
Px (x = 0-15)	x	rh	Port n Input Bit x This bit indicates the level at the input pin Pn.x. 0 _B The input level of Pn.x is 0. 1 _B The input level of Pn.x is 1.
0	[31:16]	r	Reserved Read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
ENx (x = 0-31)	x	rw	Access Enable for Master TAG ID n This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n 0 _B Write access will not be executed 1 _B Write access will be executed

The Access Enable Register 1 controls write¹⁾ access for transactions with the on chip bus master TAG ID 100000_B to 111111_B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000_B, EN1 -> TAG ID 100001_B, ... ,EN31 -> TAG ID 111111_B.

P00_ACCEN1

Port 00 Access Enable Register 1 (F8_H) Reset Value: 0000 0000_H

P02_ACCEN1

Port 02 Access Enable Register 1 (F8_H) Reset Value: 0000 0000_H

Px_ACCEN1 (x=10-11)

Port x Access Enable Register 1(F003 A6F8_H + x*100_H) Reset Value: 0000 0000_H

Px_ACCEN1 (x=13-15)

Port x Access Enable Register 1(F003 A6F8_H + x*100_H) Reset Value: 0000 0000_H

Px_ACCEN1 (x=20-23)

Port x Access Enable Register 1(F003 ACF8_H + x*100_H) Reset Value: 0000 0000_H

Px_ACCEN1 (x=32-33)

Port x Access Enable Register 1(F003 B2F8_H + x*100_H) Reset Value: 0000 0000_H

P40_ACCEN1

Port 40 Access Enable Register 1 (F8_H) Reset Value: 0000 0000_H

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
0	[31:0]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.4 Port 00

This section describes the Port 00 functionality.

14.4.1 Port 00 Configuration

Port 00 is a 13-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, CCU6, Ethernet, MSC, QSPI, MultiCAN+, PSI5, PSI5-S, SENT, DSADC, VADC, SCU, CIF, ASCLIN and GPT12 input and output functions.

14.4.2 Port 00 Function Table

Table 14-10 summarizes the I/O control selection functions of each Port 00 line.

Table 14-10 Port 00 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 00 section because they differ from the general port register description given in [Section 14.3](#).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.4.3.1 Port 00 Output Register

The basic P00_OUT register functionality is described on [Page 14-36](#). Port lines P00.[15:13] are not connected. Reading the P00_OUT bits P[15:13] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P00_OMR, P00_OMSR, P00_OMCR, P00_OMSRx (x=0,4,8,12), P00_OMCRx (x=0,4,8,12).

14.4.3.2 Port 00 Output Modification Register

The basic P00_OMR register functionality is described on [Page 14-38](#). However, port lines P00.[15:13] are not connected. The P00_OMR bits PS[15:13] and PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.3.3 Port 00 Output Modification Set Register

The basic P00_OMSR register functionality is described on [Page 14-40](#). However, port lines P00.[15:13] are not connected. The P00_OMSR bits PS[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.3.4 Port 00 Output Modification Set Register 12

The basic P00_OMSR12 register functionality is described on [Page 14-44](#). However, port lines P00.[15:13] are not connected. The P00_OMSR12 bits PS[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.3.5 Port 00 Output Modification Clear Register

The basic P00_OMCR register functionality is described on [Page 14-45](#). However, port lines P00.[15:13] are not connected. The P00_OMCR bits PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

14.4.3.6 Port 00 Output Modification Clear Register 12

The basic P00_OMCR12 register functionality is described on [Page 14-49](#). However, port lines P00.[15:13] are not connected. The P00_OMCR12 bits PCL[15:13] have no direct effect on port lines but only on register bits P00_OUT.P[15:13].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.4.3.7 Port 00 Input/Output Control Register 12

The PC13, PC14 and PC15 bit fields in register P00_IOC12 are not connected.

P00_IOC12

Port 00 Input/Output Control Register 12

(1C_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC13	[15:11]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC14	[23:19]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC15	[31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC12	[7:3]	rw	Port Control for Port 00.12 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P00_IOCR12
Port 00 Input/Output Control Register 12

 (1C_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC13	[15:11]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC14	[23:19]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC15	[31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC12	[7:3]	rw	Port Control for Port 00.12 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.4.3.8 Port 00 Input Register

The basic P00_IN register functionality is described on [Page 14-52](#). However, port lines P00.[15:13] are not connected. Therefore, bits P[15:13] in register P00_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.4.3.9 Port 00 Pad Driver Mode 1 Register

P00_PDR1
Port 00 Pad Driver Mode 1 Register (44_H)

PL13, PL14, PL15	23, 27, 31	rw	Reserved Read as 0 _B after reset; returns value that was written.

14.4.3.10 Port 00 Emergency Stop Register

The basic P00_ESR register functionality is described on [Page 14-50](#). Port lines P00.[15:13] are not connected. Reading the P00_ESR bits EN[15:13] returns the value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.4.3.11 Port 00 Pin Controller Select Register

P00_PCSR selects the 32-bit or 8-bit controller for all data and control functions of each shared port pin separately during run, sleep and standby modes.

For pins used for 8-bit controller and VADC Multiplexer Diagnostics (MD) feature, SPAREINOUT0 bit 0 decides if input pull-up and pull-down is controlled by 8-bit controller or VADC Multiplexer Diagnostics (MD) feature is enabled.

P00_PCSR

Port 00 Pin Controller Select Register (64_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
SELx (x = 1-0)	0 + x	rw	<p>Pin Controller Select for Pin x</p> <p>This bit selects the controller in all data and control functions of the port pin.</p> <p>0_B 32-bit controller is selected for data and control of pin x.</p> <p>1_B 8-bit controller is selected for data and control functions of pin x.</p>
SELx (x = 7-4)	0 + x	rw	<p>Pin Controller Select for Pin x</p> <p>This bit selects the controller in all data and control functions of the port pin.</p> <p>0_B 32-bit controller is selected for data and control of pin x.</p> <p>1_B 8-bit controller is selected for data and control functions of pin x.</p>

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
SELx (x = 3-2)	0 + x	rw	<p>Pin Controller Select for Pin x</p> <p>This bit selects the controller in all data and control functions of the port pin. This bit along with SPAREINOUT0 bit 0 decides if pull-up and pull-down is selected through 8-bit controller or VADC Multiplexer Diagnostics (MD) is enabled feature for pin x .</p> <p>For the respective analog signal connection, see analog connections table in VADC chapter.</p> <p>0_B 32-bit controller is selected for data and control of pin x. Disables VADC MD feature.</p> <p>1_B 8-bit controller is selected for data and control of pin x. If SPAREINOUT0 bit 0=0, VADC MD feature is enabled and pull-up and pull-down is not controlled by 8-bit controller.</p> <p>If SPAREINOUT0.bit 0=1, pull-up and pull-down is controlled by 8-bit controller, and VADC MD feature is disabled.</p>
SELx (x = 11-10)	0 + x	rw	<p>Pin Controller Select for Pin x</p> <p>This bit enables or disables the VADC Multiplexer Diagnostics (MD) feature.</p> <p>For the respective analog signal connection, see analog connections table in VADC chapter.</p> <p>0_B Disables VADC MD feature.</p> <p>1_B Enables VADC MD feature.</p>
LCK	31	rh	<p>Lock Status</p> <p>This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect.</p> <p>0_B The register is unlocked and can be updated.</p> <p>1_B The register is locked and can not be updated.</p>
0	[9:8], [15:12]	rw	<p>Reserved</p> <p>Read as 0; returns value last written, must be written with 0.</p>
0	[30:16]	r	<p>Reserved</p> <p>Read as 0; should be written with 0.</p>

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.5 Port 02

This section describes the Port 02 functionality.

14.5.1 Port 02 Configuration

Port 02 is a 9-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, SCU, CCU6, ASCLIN, QSPI, DSADC, MultiCAN+, ERAY, PSI5, MSC, I2C, SENT, GPT12, VADC, CIF, PSI5-S and Ethernet functions.

14.5.2 Port 02 Function Table

Table 14-12 summarizes the I/O control selection functions of each Port 02 line.

Table 14-12 Port 02 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Table 14-13 Port 02 Registers (cont'd)

Register Short Name	Register Long Name	Offset ¹⁾ Address	Description see
P02_ACCEN1	Port 02 Access Enable Register 1	00F8 _H	Page 14-53
P02_ACCEN0	Port 02 Access Enable Register 0	00FC _H	Page 14-54

- 1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))
- 2) These registers are listed and noted here in the Port 02 section because they differ from the general port register description given in [Section 14.3](#).

14.5.3.1 Port 02 Output Register

The basic P02_OUT register functionality is described on [Page 14-36](#). Port lines P02.[15:9] are not connected. Reading the P02_OUT bits P[15:12] always return 0. Reading P[11:9] returns the value that was last written. These connected bits can be also set/reset by the corresponding bits in P02_OMR, P02_OMSR, P02_OMCR, P02_OMSRx (x=0,4,8), P02_OMCRx (x=0,4,8).

14.5.3.2 Port 02 Output Modification Register

The basic P02_OMR register functionality is described on [Page 14-38](#). However, port lines P02.[15:9] are not connected. The P02_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.3.3 Port 02 Output Modification Set Register

The basic P02_OMSR register functionality is described on [Page 14-40](#). However, port lines P02.[15:9] are not connected. The P02_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.3.4 Port 02 Output Modification Set Register 8

The basic P02_OMSR8 register functionality is described on [Page 14-43](#). However, port lines P02.[11:9] are not connected. The P02_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.3.5 Port 02 Output Modification Clear Register

The basic P02_OMCR register functionality is described on [Page 14-45](#). However, port lines P02.[15:9] are not connected. The P02_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

14.5.3.6 Port 02 Output Modification Clear Register 8

The basic P02_OMCR8 register functionality is described on [Page 14-48](#). However, port lines P02.[11:9] are not connected. The P02_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P02_OUT.P[11:9].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.5.3.7 Port 02 Input/Output Control Register 8

The PC[11:9] bit fields in register P02_IOC8 are not connected.

P02_IOC8

Port 02 Input/Output Control Register 8

(18_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC8	[7:3]	rw	Port Control for Port 02 Pin 8 Coding see Table 14-5 .
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Port 02 Input/Output Control Register 8

 (18_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC8	[7:3]	rw	Port Control for Port 02 Pin 8 Coding see Table 14-5 .
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.5.3.8 Port 02 Input Register

The basic P02_IN register functionality is described on [Page 14-52](#). However, port lines P02.[15:9] are not connected. Therefore, bits P[15:9] in register P02_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.5.3.9 P02 Pad Driver Mode 1 Register

P02_PDR1

 Port 02 Pad Driver Mode 1 Register (44_H)

Field	Bits	Type	Description
PD8	[2:0]	rw	Pad Driver Mode for Port n Pin 8
PL8	3	rw	Pad Level Selection for Port n Pin 8
PD9, PD10, PD11	[6:4], [10:8], [14:12]	rw	Reserved Read as 000 _B after reset; returns value that was written, have to be written with 0.
PD12, PD13, PD14, PD15	[18:16], [22:20], [26:24], [30:28]	r	Reserved Read as 000 _B after reset; should be written as 0.
PL9, PL10, PL11	7, 11, 15	rw	Reserved Read as 0 _B after reset; returns value that was written, have to be written with 0.
PL12, PL13, PL14, PL15	19, 23, 27, 31	r	Reserved Read as 0 _B after reset; should be written as 0.

14.5.3.10 Port 02 Emergency Stop Register

The basic P02_ESR register functionality is described on [Page 14-50](#). Port lines P02.[15:9] are not connected. Reading the P02_ESR bits EN[15:12] always returns 0. Reading the P02_ESR bits EN[11:9] returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.5.3.11 Port 02 Pin Controller Select Register

P02_PCSR selects the 32-bit or 8-bit controller for all data and control functions of each shared port pin separately during run, sleep and standby modes.

P02_PCSR
Port 02 Pin Controller Select Register (64_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SELx (x = 7-0)	0 + x	rw	Pin Controller Select for Pin x This bit selects the controller in all data and control functions of the port pin. 0 _B 32-bit controller is selected for data and control of pin x. 1 _B 8-bit controller is selected for data and control functions.
LCK	31	rh	Lock Status This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus has no effect. 0 _B The register is unlocked and can be updated. 1 _B The register is locked and can not be updated.
0	[30:8]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.6 Port 10

This section describes the Port 10 functionality.

14.6.1 Port 10 Configuration

Port 10 is a 9-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, QSPI, CCU6, ASCLIN, MSC, SCU, VADC, MultiCAN+ and GPT12 functions.

After the required state is latched in based on HWCFGx during reset, the corresponding pins can be used as GPIO. For the different start-up configuration, please refer to the firmware and SCU chapters.

14.6.2 Port 10 Function Table

Table 14-14 summarizes the I/O control selection functions of each Port 10 line.

Table 14-14 Port 10 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value

P10_ACCEN1	Port 10 Access Enable Register 1	00F8 _H	Page 14-53
P10_ACCEN0	Port 10 Access Enable Register 0	00FC _H	Page 14-54

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 10 section because they differ from the general port register description given in [Section 14.3](#).

14.6.3.1 Port 10 Output Register

The basic P10_OUT register functionality is described on [Page 14-36](#). Port lines P10.[15:9] are not connected. Reading the P10_OUT bits P[15:12] always return 0. Reading P[11:9] returns the value that was last written. These connected bits can be also

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

set/reset by the corresponding bits in P10_OMR, P10_OMSR, P10_OMCR, P10_OMSRx (x=0,4,8), P10_OMCRx (x=0,4,8).

14.6.3.2 Port 10 Output Modification Register

The basic P10_OMR register functionality is described on [Page 14-38](#). However, port lines P10.[15:9] are not connected. The P10_OMR bits PS[11:9] and PCL[11:9] have no direct effect on port lines but only on register bits P10_OUT.P[11:9].

14.6.3.3 Port 10 Output Modification Set Register

The basic P10_OMSR register functionality is described on [Page 14-40](#). However, port lines P10.[15:9] are not connected. The P10_OMSR bits PS[11:9] have no direct effect on port lines but only on register bits P10_OUT.P[11:9].

14.6.3.4 Port 10 Output Modification Set Register 8

The basic P10_OMSR8 register functionality is described on [Page 14-43](#). However, port lines P10.[11:9] are not connected. The P10_OMSR8 bits PS[11:9] have no direct effect on port lines but only on register bits P10_OUT.P[11:9].

14.6.3.5 Port 10 Output Modification Clear Register

The basic P10_OMCR register functionality is described on [Page 14-45](#). However, port lines P10.[15:9] are not connected. The P10_OMCR bits PCL[11:9] have no direct effect on port lines but only on register bits P10_OUT.P[11:9].

14.6.3.6 Port 10 Output Modification Clear Register 8

The basic P10_OMCR8 register functionality is described on [Page 14-48](#). However, port lines P10.[11:9] are not connected. The P10_OMCR8 bits PCL[11:9] have no direct effect on port lines but only on register bits P10_OUT.P[11:9].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.6.3.7 Port 10 Input/Output Control Register 8

The PC[11:9] bit fields in register P10_IOC8 are not connected.

P10_IOC8
Port 10 Input/Output Control Register 8

 (18_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC9, PC10, PC11	[15:11], [23:19], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC8	[7:3]	rw	Port Control for Port 10 Pin 8 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 11 section because they differ from the general port register description given in [Section 14.3](#).

14.7.3.1 Port 11 Output Register

The basic P10_OUT register functionality is described on [Page 14-36](#). Port lines P11.[15:13], P11.[8:7], P11.[5:4], P11.[1:0] are not connected. Reading the P11_OUT P[15:13], [8:7], [5:4], [1:0] bits return the value that was last written. These connected bits can be also set/reset by the corresponding bits in P10_OMR, P11_OMSR, P11_OMCR, P11_OMSRx (x=0,4,8,12), P11_OMCRx (x=0,4,8,12).

14.7.3.2 Port 11 Output Modification Register

The basic P11_OMR register functionality is described on [Page 14-38](#). However, port lines P11.[15:13], P11.[8:7], P11.[5:4], P11.[1:0] are not connected. The P11_OMR bits PS[15:13], PS[8:7], PS[5:4], PS[1:0] and PCL[15:13], PCL[8:7], PCL[5:4], PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P[8:7], P[5:4], P[1:0].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.3 Port 11 Output Modification Set Register

The basic P11_OMSR register functionality is described on [Page 14-40](#). However, port lines P11.[15:13], P11.[8:7], P11.[5:4], P11.[1:0] are not connected. The P11_OMSR bits PS[15:13], PS[8:7], PS[5:4], PS[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P[8:7],P[5:4],P[1:0].

14.7.3.4 Port 11 Output Modification Set Register 0

The basic P11_OMSR0 register functionality is described on [Page 14-41](#). However, port lines P11.[1:0] are not connected. The P11_OMSR0 bits PS[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[1:0].

14.7.3.5 Port 11 Output Modification Set Register 4

The basic P11_OMSR4 register functionality is described on [Page 14-42](#). However, port lines P11.[5:4], P11.7 are not connected. The P11_OMSR4 bits PS[5:4], PS7 have no direct effect on port lines but only on register bits P11_OUT.P[5:4], P11_OUT.P7.

14.7.3.6 Port 11 Output Modification Set Register 8

The basic P11_OMSR8 register functionality is described on [Page 14-43](#). However, port lines P11.8 is not connected. The P11_OMSR8 bits PS8 has no direct effect on port lines but only on register bits P11_OUT.P8.

14.7.3.7 Port 11 Output Modification Set Register 12

The basic P11_OMSR12 register functionality is described on [Page 14-44](#). However, port lines P11.[15:13] are not connected. The P11_OMSR12 bits PS[15:13] have no direct effect on port lines but only on register bits P11_OUT.P[15:13].

14.7.3.8 Port 11 Output Modification Clear Register

The basic P11_OMCR register functionality is described on [Page 14-45](#). However, port lines P11.[15:13], P11.[8:7], P11.[5:4], P11.[1:0] are not connected. The P11_OMCR bits PCL[15:13], PCL[8:7], PCL[5:4], PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[15:13], P[8:7],P[5:4],P[1:0].

14.7.3.9 Port 11 Output Modification Clear Register 0

The basic P11_OMCR0 register functionality is described on [Page 14-46](#). However, port lines P11.[1:0] are not connected. The P11_OMCR0 bits PCL[1:0] have no direct effect on port lines but only on register bits P11_OUT.P[1:0].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)**14.7.3.10 Port 11 Output Modification Clear Register 4**

The basic P11_OMCR4 register functionality is described on [Page 14-47](#). However, port lines P11.[5:4], P11.7 are not connected. The P11_OMCR4 bits PCL[5:4], PCL7 have no direct effect on port lines but only on register bits P11_OUT.P[5:4], P11_OUT.P7.

14.7.3.11 Port 11 Output Modification Clear Register 8

The basic P11_OMCR8 register functionality is described on [Page 14-48](#). However, port lines P11.8 is not connected. The P11_OMCR8 bits PCL8 has no direct effect on port lines but only on register bits P11_OUT.P8.

14.7.3.12 Port 11 Output Modification Clear Register 12

The basic P11_OMCR12 register functionality is described on [Page 14-49](#). However, port lines P11.[15:13] are not connected. The P11_OMCR12 bits PCL[15:13] have no direct effect on port lines but only on register bits P11_OUT.P[15:13].

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.13 Port 11 Input/Output Control Register 0

The PC[1:0] bit fields in register P11_IOCRO are not connected.

P11_IOCRO

Port 11 Input/Output Control Register 0

(10_H)

Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC2	[23:19]	rw	Port Control for Port 11 Pin 2
PC3	[31:27]	rw	Port Control for Port 11 Pin 3
PC0, PC1	[7:3], [15:11]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P11_IOCRO
Port 11 Input/Output Control Register 0

 (10_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC2	[23:19]	rw	Port Control for Port 11 Pin 2
PC3	[31:27]	rw	Port Control for Port 11 Pin 3
PC0, PC1	[7:3], [15:11]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.14 Port 11 Input/Output Control Register 4

The PC[5:4] and PC7 bit fields in register P11_IOCR4 are not connected.

P11_IOCR4
Port 11 Input/Output Control Register 4

 (14_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC4, PC5, PC7	[7:3], [15:11], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC6	[23:19]	rw	Port Control for Port 11 Pin 6 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P11_IOCRA4
Port 11 Input/Output Control Register 4

 (14_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC4, PC5, PC7	[7:3], [15:11], [31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC6	[23:19]	rw	Port Control for Port 11 Pin 6 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.15 Port 11 Input/Output Control Register 8

The PC8 bit field in register P11_IOC8 is not connected.

P11_IOC8
Port 11 Input/Output Control Register 8

 (18_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC8	[7:3]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC9	[15:11]	rw	Port Control for Port 11 Pin 9 (coding see Table 14-5)
PC10	[23:19]	rw	Port Control for Port 11 Pin10 (coding see Table 14-5)
PC11	[31:27]	rw	Port Control for Port 11 Pin 11 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P11_IOC8
Port 11 Input/Output Control Register 8

 (18_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC8	[7:3]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC9	[15:11]	rw	Port Control for Port 11 Pin 9 (coding see Table 14-5)
PC10	[23:19]	rw	Port Control for Port 11 Pin10 (coding see Table 14-5)
PC11	[31:27]	rw	Port Control for Port 11 Pin 11 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.16 Port 11 Input/Output Control Register 12

The PC13, PC14 and PC15 bit fields in register P00_IOCR12 are not connected.

P11_IOCR12
Port 11 Input/Output Control Register 12

 (1C_H)

 Reset Value: 1010 1010_H

Field	Bits	Type	Description
PC13, PC14, PC15	[15:11], [23:19], [31:27]	rw	Reserved Read as 00010 _B after reset; returns value that was written.
PC12	[7:3]	rw	Port Control for Port 11.12 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P11_IOC12
Port 11 Input/Output Control Register 12

 (1C_H)

 Reset Value: 0000 0000_H

Field	Bits	Type	Description
PC13, PC14, PC15	[15:11], [23:19], [31:27]	rw	Reserved Read as 00000 _B after reset; returns value that was written.
PC12	[7:3]	rw	Port Control for Port 11.12 (coding see Table 14-5)
0	[2:0], [10:8], [18:16], [26:24]	r	Reserved Read as 0; should be written with 0.

14.7.3.17 Port 11 Input Register

The basic P11_IN register functionality is described on [Page 14-52](#). However, port lines P11.[15:13] are not connected. Therefore, bits P[15:9] in register P10_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.7.3.18 Port 11 Pad Driver Mode 0 Register

The basic P11_PDR0 register functionality is described on [Page 14-25](#).

P11_PDR0
Port 11 Pad Driver Mode 0 Register (40_H)
Reset Value: 3333 3333_H

PL8, PL13, PL14, PL15	3, 23, 27, 31	rw	Reserved Read as 0 _B after reset; returns value that was written.

14.7.3.20 Port 11 Emergency Stop Register

The basic P11_ESR register functionality is described on [Page 14-50](#). Port lines P11.[15:13], P11.[8:7], P11.[5:4], P11.[1:0] are not connected. Reading the P11_ESR bits EN[15:13], EN[8:7], EN[5:4], EN[1:0] returns value that was last written.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.7.3.21 Port 11 Pin Controller Select Register

P11_PCSR selects Ethernet output signals through ports alternate output or fast RMII mode.

P11_PCSR
Port 11 Pin Controller Select Register (64_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
SEL2	2	rw	Pin Controller Select for Pin 2 This bit selects the Ethernet output signal through ports alternate output or fast RMII mode. 0 _B ETHTXD1 output via ports alternate output of pin 2. 1 _B ETHTXD1 output via fast RMII mode of pin 2.
SEL3	3	rw	Pin Controller Select for Pin 3 This bit selects the Ethernet output signal through ports IOCR or fast RMII mode. 0 _B ETHTXD0 output via ports alternate output of pin 3. 1 _B ETHTXD0 output via fast RMII mode of pin 3.
SEL6	6	rw	Pin Controller Select for Pin 6 This bit selects the Ethernet output signal through ports IOCR or fast RMII mode. 0 _B ETHTXEN output via ports alternate output of pin 6. 1 _B ETHTXEN output via fast RMII mode of pin 6.
0	[1:0], [5:4]	rw	Reserved Read as 0; returns value last written, must be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
0	[31:16], [15:7]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.8 Port 13

This section describes the Port 13 functionality.

Port 13 is an 4-bit GPIO port. Pins associated to it be used in two ways:

- as a CMOS Port where each pin outputs one signal, as any other port (only exception - no open drain mode available), and
- as an output LVDS port where a pin pair (two pins) outputs one differential MSC signal.

The switching between the CMOS/LVDS modes is done via the P13_PDR0 register.

The switching between Input/Ouput and Pull-Up/Pull-Down control is done via the IOCR register.

Attention: In the LVDS mode the IOCR.PCx bit field of each pin of the LVDS pair must be programed as output, that is 1xxxx_B.

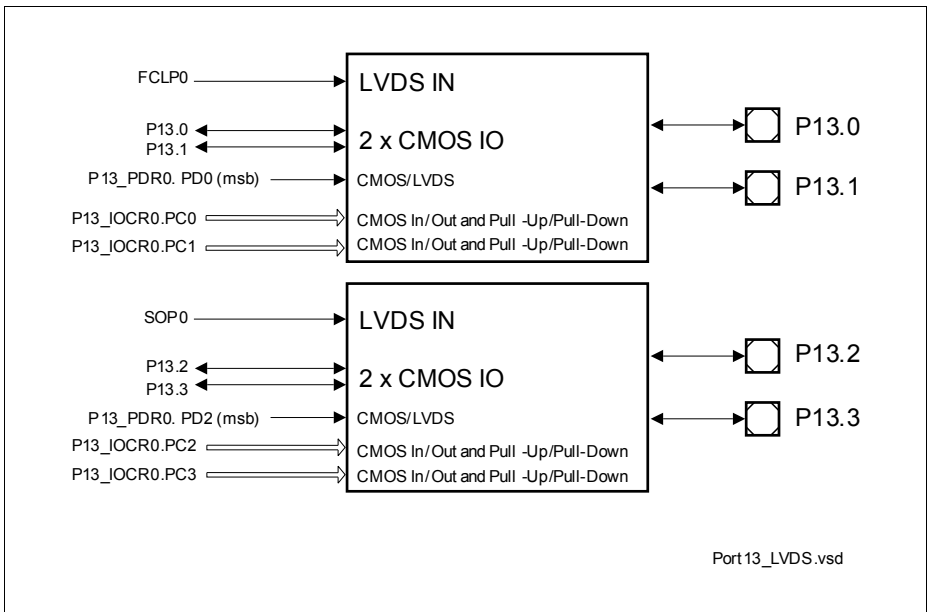

Figure 14-3 Port 13 Pad Connections

14.8.1 Port 13 Configuration

Port 13 is a 4-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, GPT12, QSPI, MSC, I2C and CCU6 functions.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.8.2 Port 13 Function Table

Table 14-18 summarizes the I/O control selection functions of each Port 13 line.

Table 14-18 Port 13 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P13.0	I	General-purpose input	P13_IN.P0	P13_IOCRO. PC0	0XXXX _B

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.8.3 Port 13 Registers

The following registers are available on Port 13:

Table 14-19 Port 13 Registers

Register Short Name	Register Long Name	Offset¹⁾ Address	Description see
P13_OUT	Port 13 Output Register	0000 _H	Page 14-124 ²⁾
P13_OMR	Port 13 Output Modification Register	0004 _H	Page 14-124 ²⁾
P13_IOCRO	Port 13 Input/Output Control Register 0	0010 _H	Page 14-14
P13_IN	Port 13 Input Register	0024 _H	Page 14-124 ²⁾
P13_PDR0	Port 13 Pad Driver Mode 0 Register	0040 _H	Page 14-125 ²⁾
P13_ESR	Port 13 Emergency Stop Register	0050 _H	Page 14-128 ²⁾
P13_OMSR0	Port 13 Output Modification Set Register 0	0070 _H	Page 14-41
P13_OMCR0	Port 13 Output Modification Clear Register 0	0080 _H	Page 14-46
P13_OMSR	Port 13 Output Modification Set Register	0090 _H	Page 14-124 ²⁾
P13_OMCR	Port 13 Output Modification Clear Register	0094 _H	Page 14-124 ²⁾
P13_LPCR0	Port 13 LVDS Pad Control Register 0	00A0 _H	Page 14-127 ²⁾
P13_LPCR1	Port 13 LVDS Pad Control Register 1	00A4 _H	Page 14-127 ²⁾
P13_ACCEN1	Port 13 Access Enable Register 1	00F8 _H	Page 14-54
P13_ACCEN0	Port 13 Access Enable Register 0	00FC _H	Page 14-53

1) The absolute addresses are calculated by adding the offset address to the module base address (see [Table 14-3](#))

2) These registers are listed and noted here in the Port 13 section because they differ from the general port register description given in [Section 14.3](#).

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.8.3.1 Port 13 Output Register

The basic P13_OUT register functionality is described on [Page 14-36](#). Port line P13.[15:4] are not connected. Reading the P13_OUT bit P[15:4] always return 0. These connected bits can be also set/reset by the corresponding bits in P13_OMR, P13_OMSR, P13_OMCR, P13_OMSR0, P13_OMCR0.

14.8.3.2 Port 13 Output Modification Register

The basic P13_OMR register functionality is described on [Page 14-38](#). However, port lines P13.[15:4] are not connected.

14.8.3.3 Port 13 Output Modification Set Register

The basic P13_OMSR register functionality is described on [Page 14-40](#). However, port lines P13.[15:4] are not connected.

14.8.3.4 Port 13 Output Modification Clear Register

The basic P13_OMCR register functionality is described on [Page 14-45](#). However, port lines P13.[15:4] are not connected.

14.8.3.5 Port 13 Input Register

The basic P13_IN register functionality is described on [Page 14-52](#). However, port lines P13.[15:4] are not connected. Therefore, bits P[15:4] in register P13_IN are always read as 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

14.8.3.6 Port 13 Pad Driver Mode 0 Register

 The basic P13_PDR0 register functionality is described on [Page 14-25](#).

P13_PDR0
Port 13 Pad Driver Mode 0 Register (40_H)
Reset Value: 0000 3333_H

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PL7		PD7		PL6		PD6		PL5		PD5		PL4		PD4	
r		r		r		r		r		r		r		r	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PL3		PD3		PL2		PD2		PL1		PD1		PL0		PD0	
rw		rw		rw		rw		rw		rw		rw		rw	

Field	Bits	Type	Description
PD0	[2:0]	rw	Pad Driver Mode for Port 13 Pin [1:0] The MSB of PDx switches between CMOS (default) and LVDS modes. 0XX _B CMOS input or output (depending on IOCRx setting). 1XX _B LVDS output (pull-up or pull-down must be switched off via IOCRx)
PD2	[10:8]	rw	Pad Driver Mode for Port 13 Pin [3:2] The MSB of PDx switches between CMOS (default) and LVDS modes. 0XX _B CMOS input or output (depending on IOCRx setting). 1XX _B LVDS output (pull-up or pull-down must be switched off via IOCRx)
PD1, PD3	[6:4], [14:12]	rw	Pad Driver Mode for Port 13 Pin 1 and 3
PL0, PL1, PL2, PL3	3, 7, 11, 15	rw	Pad Level Selection for Port 13 Pin 0 to 3
PD4, PD5, PD6, PD7	[18:16], [22:20], [26:24], [30:28]	r	Reserved Read as 000 _B after reset; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Field	Bits	Type	Description
PL4, PL5, PL6, PL7	19, 23, 27, 31	r	Reserved Read as 0 _B after reset; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.8.3.7 Port 13 LVDS Pad Control Register

For P13_LPCR_x($x=0-1$), PS1 needs to be configured to the intended pad supply level before the LVDSM function is enabled.

P13_LPCR0
Port 13 LVDS Pad Control Register 0 (A0_H)
Reset Value: 0000 0000_H

Field	Bits	Type	Description
PS1	1	rw	Pad Supply for pins [1:0] Selects between 5V or 3.3V supply on V_{EXT} for the LVDSM pad-pair. 0_B 5V supply 1_B 3.3V supply
0	[3:2], 0	rw	Reserved Read as 0; must be written with 0.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)

P13_LPCR1

Port 13 LVDS Pad Control Register 1 (A4_H)

Reset Value: 0000 0000_H

Field	Bits	Type	Description
PS1	1	rw	Pad Supply for pins [3:2] Selects between 5V or 3.3V supply on V_{EXT} for the LVDSM pad-pair. 0 _B 5V supply 1 _B 3.3V supply
0	[3:2], 0	rw	Reserved Read as 0; must be written with 0.
0	[31:4]	r	Reserved Read as 0; should be written with 0.

14.8.3.8 Port 13 Emergency Stop Register

The basic P13_ESR register functionality is described on [Page 14-50](#). Port lines P13.[15:4] are not connected. Reading the P13_ESR bits EN[15:4] always returns 0.

General Purpose I/O Ports and Peripheral I/O Lines (Ports)
14.9 Port 14

This section describes the Port 14 functionality.

14.9.1 Port 14 Configuration

Port 14 is a 11-bit bi-directional general-purpose I/O port that can be alternatively used for GTM, ASCLIN, ERAY, MultiCAN+, CCU6, SCU, QSPI and MSC functions.

After the required state is latched in based on HWCFGx during reset, the corresponding pins can be used as GPIO. For the different start-up configuration, please refer to the firmware and SCU chapters.

14.9.2 Port 14 Function Table

Table 14-20 summarizes the I/O control selection functions of each Port 14 line.

Table 14-20 Port 14 Functions

Port Pin	I/O	Pin Functionality	Associated Reg./ I/O Line	Port I/O Control Select.	
				Reg./Bit Field	Value
P14.0	I	General-purpose input	P14_IN.P0	P14_IOCRO. PC0	0XXXX _B
		GTM input	TIN80		
	O	General-purpose output	P14_OUT.P0		1X000 _B
